a) Energy units in cm^{-1}. Diff=Exptl−Calcd. When the location of the center of a term is not known experimentally, the position which yields the best agreement with the calculation is taken as the center assumed in column 2. Values in parentheses are less reliable. b) The values from the Zeeman effect (Ref. 17). Here, $s_1=2|g|$. c) The values are increased by 9% according to the footnote in Table 3 of Ref. 17.

a) Energy units in cm^{-1}. Diff=Exptl−Calcd. b) The values from the Zeeman effect (Ref. 24).

experimental ones is possible only for a few levels as can be seen in the last two columns of Table 3. The agreement is fairly good except the $^4G_{5/2}$ ($\eta=\pm 1/2$) level, in which the experimental value is over twice as large as the calculated one. The resolution of this point must await further studies. Eisenstein[16] compared the g values of Nd^{3+} in $LaCl_3$ calculated by complete J-mixing with the experimental ones, and found the calculated values in good agreement with the experimental ones for all but 3 of 33 levels. Thus the g values in the present calculation should be fairly reliable and can be taken as a reference when the experimental values are not available.[22,23]

Er(ES). The spectrum of Er(ES) has been reported by several authors.[24-27] Wheeler and Hill[27] observed directly in the far infra-red the crystal field splitting of the $^4I_{15/2}$ ground multiplet and determined the crystal field parameters. Erath[25] calculated the crystal field parameters by a first-order perturbation on the ground multiplet in Er(ES) using the electrostatic and spin-orbit interaction parameters obtained by Wong.[28] He computed the splitting of excited levels due to the crystal field using these crystal parameters. Rajnak[2] made a CI calculation for the ion levels of Er^{3+} in Er(ES) by use of both the linear parameters, α, β, and γ, and the nonlinear parameter $Y(kk': l')$. The latter parameter results from the interactions of a configuration with the configurations differing from f^N in the quantum numbers of only one electron.[9]

As seen in Table 2, the inclusion of CI parameters reduces the rms deviation for the ion levels to less than one third of that without CI. Furthermore an improvement of about 30 cm^{-1} is achieved by including only one nonlinear parameter $Y(22: 1)$. This fact shows that CI effects are highly important for the ion levels. There are several differences between the present assignment of some electronic terms and those by previous authors, especially for the levels with $J=9/2$, of which the eigenvectors are given in Table 5. The present assignment of terms for higher levels over 30000 cm^{-1} is markedly different from that by Erath[25] in some cases; for example, the present $^2P_{3/2}$, $^4G_{5/2}$, and $^2P_{1/2}$ terms are assigned to the $^3D_{3/2}$, $^2P_{1/2}$, and $^4G_{5/2}$ terms by Erath, respectively. For the crystal field splitting, the present result including complete J-mixing does not show any improvement over Erath's result in contrast with Nd(ES). On the other hand, the centers of gravity of multiplets with complete J-mixing shift within 10 cm^{-1} from the ion levels without J-mixing among all the terms except the higher two terms, $^2L_{15/2}$ and $^2H_{9/2}$,

a) The calculated values. b) (A), the present results; (B), Dieke (Ref. 20); (C), Rajnak (Ref. 2); (D) Erath (Ref. 25).

with a shift of about 50 cm^{-1}. This means that J-mixing for Er(ES) is not so significant as for Nd(ES). Since the magnitude of the spin-orbit coupling of Er^{3+} ($\approx$2350 cm^{-1}) is considerably larger than that of Nd^{3+} ($\approx$870 cm^{-1}) and then the ion levels of Er^{3+} are more separated than those of Nd^{3+}, the mixing among the ion levels with different J due to a crystal field becomes smaller for Er(ES) than for Nd(ES). Thus it will generally be the case that the effect of J-mixing for crystal levels is not so important for electron holes with large spin-orbit interaction. In Table 4, good agreement between the calculated g values and those by the Zeeman experiment is found except for a few cases as in the case of Nd(ES).

In conclusion, it will be stated that: (1) CI for the ion levels of both Nd(ES) and Er(ES) makes a remarkable improvement. (2) Inclusion of complete J-mixing for the crystal field levels yields some improvement for Nd(ES) but not so for Er(ES). This originates exclusively from the fact that the ion levels of Er(ES) with large spin-orbit coupling are substantially well separated, and mixing among different J levels is small due to weak perturbation by a crystal field. (3) The g values obtained by the present procedure may be fairly reliable and of practical usage in some cases.

The Theory of the Adsorption Monolayer with Lateral Intermolecular Interaction and Its Application to Aqueous Alcohol Solutions

Masayuki NAKAGAKI and Mihoko YAMAMOTO

Faculty of Pharmaceutical Sciences, Kyoto University, Sakyo-ku, Kyoto 606

(Received September 3, 1976)

A theoretical relation between the fractional adsorption amount, θ, and the concentration, C, taking account of the lateral interaction between the adsorbed molecules is used to integrate the Gibbs equation, and the relation between the surface pressure, F, and the molecular area, A, is derived. Since the equation does not contain the parameter, k_0, related to the strength of adsorption, it is concluded that there is no substantial difference between the adsorption monolayers and the insoluble monolayers. The relation between F and C is also derived and compared with the experimental data for normal alcohols. The standard affinity of adsorption, $-\Delta\mu^0$, and the energy of lateral interaction, ε, increased linearly with the number of carbon atoms of the alcohols, n. Finally, it has been shown that the experimental data can be explained well with the theoretical equation presented here, but not with Szyszkowski's, the latter being derived for negligible lateral interaction.

The energy or free energy of adsorption from a solution to its surface has been discussed for many years in connection with the surface activity of various substances, but not much attention has been paid to the lateral interaction between solute molecules in the adsorption monolayers. This interaction, however, seems to be important because the adsorption monolayers seem to fairly compact in ordinary concentration ranges.

The behavior of the adsorption monolayer could not be discussed hitherto in enough detail so that the effect of the lateral interaction could be detected. This is because some ambiguity is introduced when the experimental relation between the surface tension of a solution and the concentration of the surface-active solute is differentiated, graphically or numerically, in order to use the Gibbs differential equation in the determination of the adsorption amount or the molecular area in the adsorption monolayer.

In the present paper, theoretical equations will be derived for the adsorption monolayer with lateral intermolecular interaction. A method will be proposed to determine the values of the parameters which are used in the equations. Finally, the method will be applied to aqueous normal alcohol solutions and the parameter values thus obtained will be discussed.

Theoretical

Adsorption Equation of Interacting Molecules. Adsorption isotherms of surface active substances at the surfaces of their own solutions are often expressed by the Langmuir equation. This is in accord with the well-known fact that the surface tension of such a solution as a function of the concentration is expressed by the empirical Szyszkowski equation, because the latter equation can be derived theoretically when the Gibbs adsorption equation is integrated with the Langmuir equation if the solute is a nonelectrolyte at a dilute concentration, so the activity coefficient is assumed to be independent of the concentration.[1)]

The Langmuir equation takes the size of the adsorbed molecules, or the repulsion by steric hindrance, into account, but it does not take the lateral cohension between adsorbed molecules into account, since the equation was originally derived from the idea of site adsorption. If the lateral interaction is taken into consideration, the chemical potential of the solute in such an adsorption monolayer, μ, is taken to be different from that of the Langmuir monolayer, μ_L, by $\Delta\mu_{int}$:

$$\mu = \mu_L + \Delta\mu_{int}. \tag{1}$$

Since the probability of a molecule existing next to a given molecule may be assumed to be equal to the fractional adsorption amount, θ, the interaction energy in the monolayer is proportional to θn; therefore,

$$\Delta\mu_{int} = \frac{\partial}{\partial n}\left(-\frac{\varepsilon}{2}\theta n\right) = -\varepsilon\theta, \tag{2}$$

where ε is the energy of lateral interaction and

$$\theta = n/n_0 = \Gamma/\Gamma_0 = A_0/A. \tag{3}$$

Here, n is the moles of the adsorbed solute, Γ is the adsorption amount per unit area, A is the area occupied by one molecule, and the values with the 0 subscript are for the saturated adsorption.

At the adsorption equilibrium, μ is equal to the chemical potential of the solute in the solution, μ_S, which is given by the following equation if the activity coefficient is assumed to be independent of the concentration, C:

$$\mu_S = \mu_S^0 + RT\ln C, \tag{4}$$

where μ_S^0 is the standard chemical potential, R is the gas constant, and T is the absolute temperature. Together with the following equation for μ_L

$$\mu_L = \mu_L^0 + RT\ln[\theta/(1-\theta)], \tag{5}$$

the final result is obtained as

$$\theta/(1-\theta) = (k_0 e^{2K\theta})\cdot C, \tag{6}$$

which is the same equation as that used by Levine *et al.*[2)] for the adsorption of methanol from an aqueous solution by a plain solid surface. Here,

$$k_0 = \exp[-(\mu_L^0 - \mu_S^0)/RT], \tag{7}$$

and

$$K = \varepsilon/2RT. \tag{8}$$

The k_0 parameter is related to the strength of the adsorption from the solution to the adsorption monolayer, while K is related to the lateral interaction in the monolayer. The latter is so defined that $K<0$ for intermolecular repulsion, $K=0$ for the Langmuir

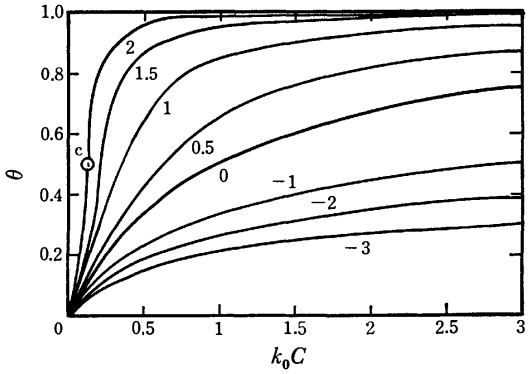

Fig. 1. Theoretical adsorption isotherms shown as the dependence of the fractional adsorption amount θ on k_0C, the parameter being K. The point C is the critical point where the phase separation in the adsorption monolayer starts.

case, and $K>0$ for intermolecular attraction. If $K>2$, phase separation occurs in the adsorption monolayer.[3] According to Eq. 6, the theoretical relations between θ and k_0C for various values of K are shown in Fig. 1. The C point, located at $\theta=0.5$, $k_0C=0.13534$ for $K=2$ in Fig. 1, shows the critical point at which the phase separation starts.

Equation of State of the Adsorption Monolayer. In the studies of the adsorption at the interface of a solution, the quantity measured experimentally is the surface tension, γ, of the solution, while the surface pressure, F, of the adsorption monolayer is defined by

$$F = \gamma_0 - \gamma, \tag{9}$$

where γ_0 is the surface tension of the solvent.

Theoretical equations for F can be derived by integrating the Gibbs equation:

$$F = \Gamma_0 RT\int_0^{\theta}\theta\left(\frac{\mathrm{d}\ln C}{\mathrm{d}\theta}\right)\mathrm{d}\theta. \tag{10}$$

By introducing Eq. 6 into Eq. 10,

$$(A_0/k_BT)F = -\ln(1-\theta) - K\theta^2 \tag{11}$$

is obtained, because $\Gamma_0 RT=k_BT/A_0$, where k_B is the Boltzmann constant. In the case of $K=0$, Eq. 11 is reduced, by using Eq. 6, to the Szyszkowski equation:

$$(A_0/k_BT)F = \ln(1+k_0C). \tag{12}$$

The equation of the state of the adsorption monolayer is derived from Eq. 11 by using Eq. 3:

$$(A_0/k_BT)F = \ln\left(\frac{A}{A-A_0}\right) - K\left(\frac{A_0}{A}\right)^2. \tag{13}$$

According to this equation, theoretical curves for various values of K are drawn in Fig. 2, where the relation between two dimensionless quatities, $(A_0/k_BT)F$ and (A/A_0) is shown instead of the F-A relation which is usually studied experimentally. It may be seen from Fig. 2 how a monolayer is expanded by the intermolecular repulsion ($K<0$) and is contracted by the intermolecular attraction ($K>0$).

The contraction of a monolayer by two-dimensional condensation is often examined by drawing the FA-A relation. Figure 3 shows the corresponding relation between the dimensionless quantities, FA/k_BT and $(A_0/k_BT)F$. Each theoretical curve has a minimum

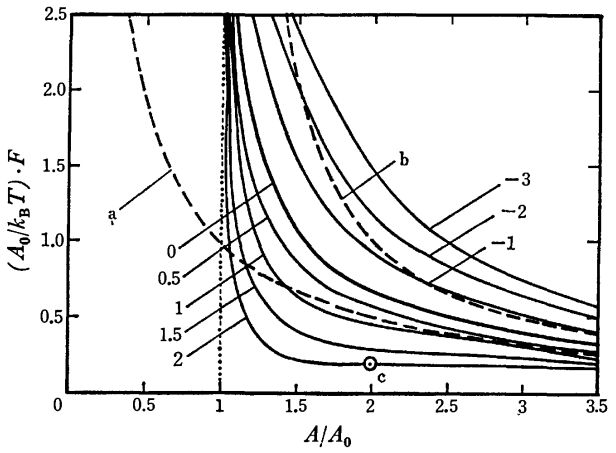

Fig. 2. Theoretical pressure-area curves of adsorption monolayers with various K values as indicated. The broken curve a is for $FA=k_BT$ and b for $F(A-A_0)=k_BT$.

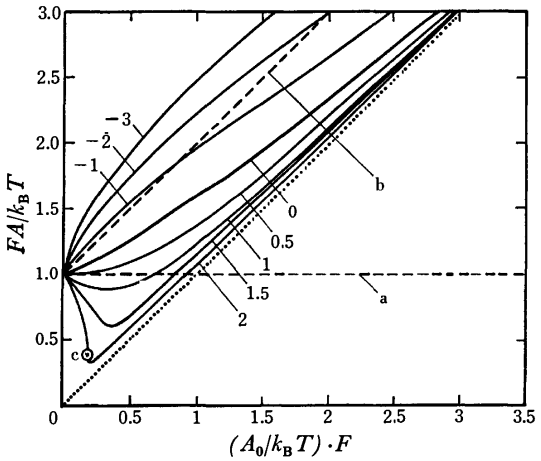

Fig. 3. Theoretical FA-A curves for various K values as indicated. The dotted line is for $A=A_0$. The broken straight line a is for $FA=k_BT$ and b for $F(A-A_0)=k_BT$.

point if $K>0.5$ and approaches to the asymptote, $A=A_0$, when F increases. If $K>2$, the entire curve is very close to the asymptote in the region where F is higher than that for the critical point, c, of the phase separation.

It may be emphasized here that the F-A relation, and also, therefore, the FA-A relation, of the adsorption monolayer are independent of the strength of the adsorption, because the equation of state, Eq. 13, does not contain the k_0 parameter. This conclusion is important both theoretically and experimentally. This means theoretically that there is no substantial difference between the adsorption monolayer and the insoluble monolayer. Experimentally, it is expected that the F-A relation or FA-A relation must be adequate for examining the intermolecular interaction in an adsorption monolayer, because the value of the K parameter may be determined on the basis of Fig. 2 or Fig. 3 without bothering to estimate the k_0 value. This expectation, however, was not realized because of the ambiguity brought in when the experimental γ-ln$C$ curve was differentiated graphically in order to obtain the value of Γ or A according to the Gibbs adsorption equation.

Therefore, a direct comparison between the experimental and theoretical γ-C relations is desirable in order to estimate the value of the K parameter.

Relation between the Surface Pressure and Concentration. The surface tension, γ, or the surface pressure, F, is given explicitly as a function of the concentration, C, if $K=0$, as has been shown in Eq. 12. If, however, $K\neq 0$, an explicit expression cannot be obtained; instead, the numerical relations between F and C for various values of K must be calculated by using Eqs. 6 and 11 simultaneously. This means that the following simultaneous equations must be solved numerically, taking θ as the parameter:

$$\left.\begin{aligned}(A_0/k_BT)F &= -2.303\log(1-\theta) - K\theta^2\\ \log(k_0C) &= \log\theta - \log(1-\theta) - 0.8686K\theta\end{aligned}\right\}. \quad (14)$$

The results are shown in Fig. 4, where dimensionless quantities, $(A_0/k_BT)F$ and k_0C, are used in place of F and C respectively.

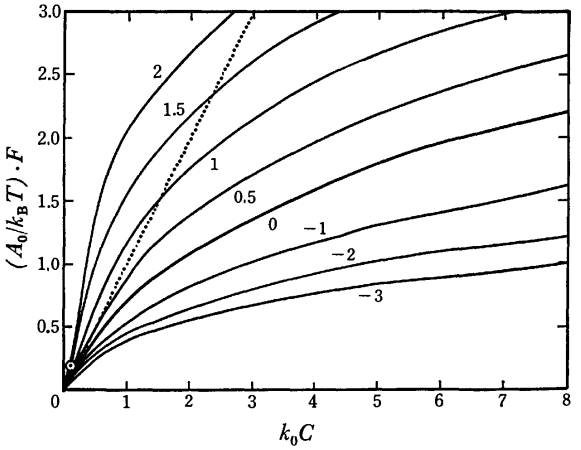

Fig. 4. Theoretical relations between the surface pressure F and concentration C, for various K values as indicated. The dotted line is the initial slope.

It might seem strange at first glance that the value of F, or the decrease of γ, is larger when the lateral intermolecular attraction is larger and when the value of K is larger for any given k_0 and (A_0/k_BT). This, however, does not mean that the adsorption monolayer of the larger lateral attraction shows a larger surface pressure at a given amount of adsorption; it does mean that the amount of adsorption is larger when the lateral attraction in the monolayer is larger, as has already been shown in Fig. 1.

To estimate the parameter values experimentally, two methods are commonly used, one in low-concentration, and the other in high-concentration, regions.

In the low concentration region ($\theta\rightarrow 0$), the expansion of $(A_0/k_BT)F$ in a power series of k_0C is performed by using the simultaneous equations 14; the following result is thus obtained:

$$(A_0/k_BT)F = k_0C + \left(K-\frac{1}{2}\right)(k_0C)^2 + \cdots. \quad (15)$$

According to this equation, it may be said that F is proportional to C if $k_0C\ll 1$ and that the proportionality coefficient is equal to $(k_0/A_0)k_BT$. This proportionality is considered to be helpful for the experimental determination of the parameter values. However, the theoretical curves in the low-concentration range, as shown in Fig. 5, start curving at an unexpectedly low concentration, except in the particular case of $K=0.5$, where the F-C relation is linear up to fairly large values of C because the coefficient of the C^2 term in Eq. 15 is zero. It may be seen from Fig. 5 that the concentration range where the F-C relation is not affected by the value of K and where the proportionality between F and C holds is as low as $(A_0/k_3T)F<0.03$. This means that the proportionality coefficient must be determined in the region where $F<0.4\times 10^{-3}$ N m^{-1} if $A_0=30\times 10^{-2}$ nm^2·molecule^{-1} at 25 °C. Experimentally, this is not always easy.

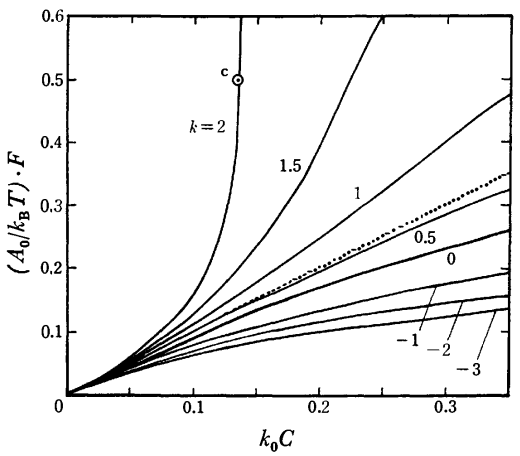

Fig. 5. Theoretical relations between F and C at a low concentration range. The dotted line is the initial slope, which is common to all curves and corresponds to the equation $F=(k_0/A_0)\,k_BTC$.

In the high-concentration region ($\theta\rightarrow 1$), the F-log C curve approaches an asymptotic straight line. The equation of this asymptote is obtained from Eq. 14:

$$(A_0/k_BT)F_{asymp} = K + \ln(k_0C) \quad (\theta\rightarrow 1). \quad (16)$$

Some of the theoretical curves obtained from Eq. 14 are shown in Fig. 6, together with the asymptotes of Eq. 16. It can be understood from Eq. 16 that the inclination of the asymptote of an F-log$C$ curve is equal to $(2.303\,k_BT/A_0)$, but it is clear from Fig. 6 that A_0 values thus estimated are acceptable only when K has a large positive value. If, for example, $K=0$, it may be seen from Fig. 6 that a correct value of the inclination may be obtained by using only the experimental data for $(A_0/k_BT)F>3.0$; this means that $F>41\times 10^{-3}$ N m^{-1} if $A_0=30\times 10^{-2}$ nm^2 molecule^{-1} at 25 °C. This condition is, however, not easy to realize experimentally, and it is impossible to fulfill when the monolayer collapses at this high surface pressure or when the concentration of the solution cannot be high enough because the solubility of the solute is not high enough. The method is, therefore, not applicable except for long-chain derivatives such as surfactants in which the K value may be supposed to be large.

As the conclusion of these considerations, it may be said that a method is needed which makes the estimation of the A_0, k_0, and K parameters possible by using the experimental data obtained in the intermediate

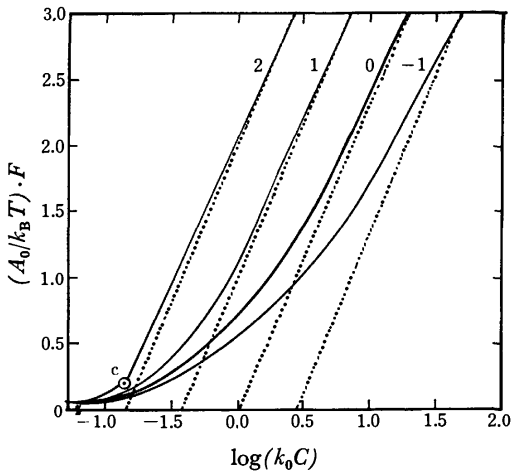

Fig. 6. Theoretical relations between F and log C for various K values as indicated. The dotted lines are the asymptotes.

concentration range.

Proposed Method to Determine Parameter Values. It has been found, after several trials, that the use of the relation between log (F/k_BTC) and log C is the most convenient for determining the values of A_0, k_0, and K. The theoretical curves of log $(F/k_BTC)+\log(A_0/k_0)$ against log $C+\log k_0$ are calculated by using Eq. 14 and are shown in Fig. 7 for the K values from 0 to 2 at regular intervals of 0.2. For $K>0.5$, each curve has a maximum point which corresponds to the θ_{max} given by the following equation:

$$\theta_{max} + \ln(1-\theta_{max}) + K\theta_{max}^2 = 0. \quad (17)$$

On the other hand, the experimental data are plotted, taking log (F/k_BTC) and log C on the ordinate and abscissa respectively, on the same scales as those of the theoretical plot in Fig. 7 and are superimposed on the latter so that the experimental data fit one of the theoretical curves. The shape of the theoretical curve for the best fit will give the K-value. Then, the k_0-value is obtained from the value of log C for log $C+\log k_0=0$, and the A_0-value, from the value of log (F/k_BTC) for log $(F/k_BTC)+\log(A_0/k_0)=0$.

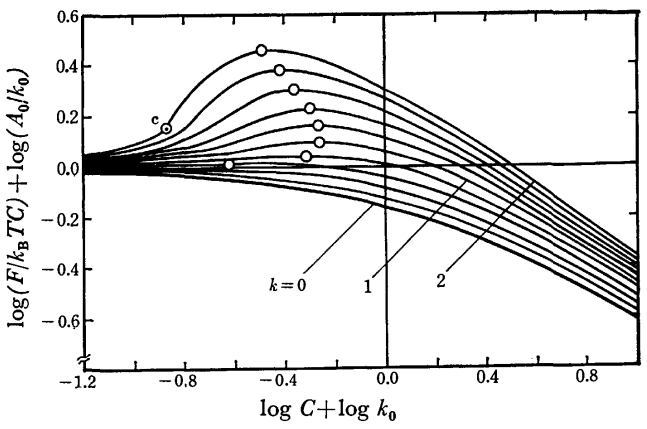

Fig. 7. Theoretical log (F/k_BTC)-log C curves for $K=$ 0(0.2)2. Open circles show the maximum points. The point c is the critical point of phase separation.

Comparison with Experimental Data

Parameter Values of Normal Alcohols. The experimental values of Posner *et al.*[4] were used to test the method proposed above. For example, the case of 25 °C is shown in Fig. 8, where the circles are experimental and the curves are theoretical. The parameter values thus obtained are given in Table 1, together with those obtained for other temperature values.

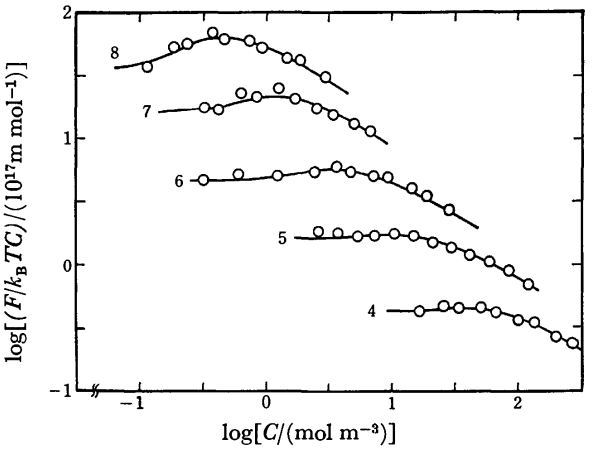

Fig. 8. Comparison between experimental values[4] (open circles) and theoretical curves for normal alcohols, which have the carbon numbers n as indicated, at 25 °C.

TABLE 1. PARAMETER VALUES OF NORMAL ALCOHOLS

Alcohol	Temp (°C)	K	$k_0\times10^3$ ($m^3\,mol^{-1}$)	$A_0\times10^2$ ($nm^2\cdot molecule^{-1}$)
Butyl	12	0.75	20.9	35.5
	25	0.75	14.8	34.7
	39	0.75	12.6	30.2

	39	1.4	708	26.9

The k_0 parameter is essentially the equilibrium constant between solute molecules adsorbed on the surface and dissolved in the solution, and it is related to the change in the standard chemical potential due to the adsorption according to Eq. 7. Before the standard affinity of adsorption $(-\Delta\mu^0)$ is calculated, however, the experimental parameter value, k_0, in $m^3\,mol^{-1}$ based on the molar concentration, C, must be recalculated to the dimensionless "unitary" quantity,[5] k_x, based on the mole fraction, x,

$$k_x = (C/x)k_0 \simeq (d_1/M_1)k_0$$
$$= 55.34(k_0\times10^3)/(m^3\,mol^{-1}), \quad (18)$$

for aqueous solutions at 25 °C, where d_1 and M_1 are

( ): Averages.

the density and the molecular weight of water respectively.

The values of the standard affinity of adsorption obtained by the following equation from the k_0-values of Table 1 are shown in Table 2 (1 cal=4.184 J):

$$-\Delta\mu^0 = RT\ln k_x. \tag{19}$$

From these tables it may be seen that $(-\Delta\mu^0)$ does not depend much on the temperature, although k_0 and, therefore, k_x decrease with increase in the temperature. The energy of lateral interaction, ε, calculated by Eq. 8 from the K values given in Table 1 is shown in Table 2 as well. Since the temperature dependences of $-\Delta\mu^0$ and ε are not large, the average values (shown in parentheses in Table 2) are plotted against the number of carbon atoms of alcohols, n, in Fig. 9. It may be seen that the value of ε is about 1/4 of $-\Delta\mu^0$ for each alcohol in this region of n.

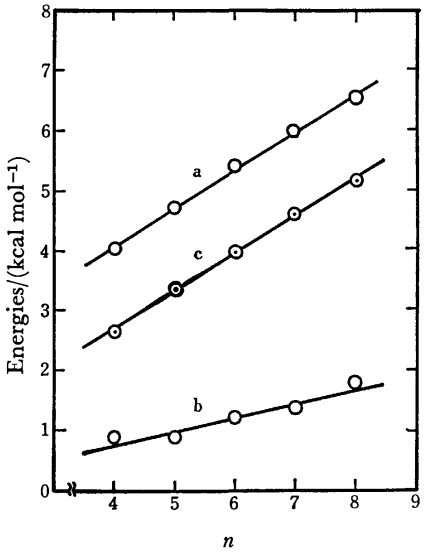

Fig. 9. Dependence, on the carbon number n, of (a) the standard affinity $-\Delta\mu^0$ of Eq. 19, (b) the energy of lateral interaction ε of Eq. 8 and (c) the standard free energy of adsorption $-\Delta G^0$ of Eq. 25.

The relations of $-\Delta\mu^0$ and of ε against n in Fig. 9 are linear and give the following empirical equations:

$$-\Delta\mu^0/(\text{kcal mol}^{-1}) = 1.60 + 0.62n \tag{20}$$

and

$$\varepsilon/(\text{kcal mol}^{-1}) = -0.16 + 0.23n. \tag{21}$$

Equation 20 means that the affinity of adsorption is 620 cal mol^{-1} per methylene group and 1600 cal mol^{-1} per hydroxyl group. The latter value, however, depends on the selection of the standard states. The former value, 620 cal mol^{-1}, is not much different from Traube's value,[6] 650 cal mol^{-1}. The former value obtained for n=4—8 is, however, a little smaller than the value, 682 cal mol^{-1}, for n=12—16 obtained for disodium monoalkyl phosphates,[7] probably because of the difference in the range of n. Equation 21 means that the energy of lateral attraction per methylene group is 230 cal mol^{-1}, while the energy of lateral repulsion per hydroxyl group is 160 cal mol^{-1}.

On the other hand, Ward and Tordai[8] and also Posner *et al.*[4] calculated the standard free energy of adsorption by means of

$$\Delta G^0 = -RT\ln(\alpha/k_BT\delta), \tag{22}$$

where δ is the thickness of the adsorption monolayer and α is the Traube constant defined at an infinite dilution by:

$$\alpha = \lim_{C\to 0}(F/CN_A), \tag{23}$$

where N_A is the Avogadro number.

According to our Eq. 15,

$$\alpha = k_BT(k_0/A_0N_A), \tag{24}$$

therefore, we have

$$-\Delta G^0 = RT\ln(k_0/A_0\delta N_A). \tag{25}$$

As for the parameter values to be used in this equation, the values of k_0 and A_0 have been shown in Table 1; the values of δ given by Posner *et al.*[4] are cited in Table 3. The values of $-\Delta G^0$ thus calculated are given in the same table, together with the values reported by Posner *et al.*,[4] the latter being indicated by $-\Delta G_p{}^0$. It may be seen that these values are in good agreement with each other. This is because, at an infinite dilution,

Table 3. Standard free energy of adsorption as calculated by means of Eq. 25

Alcohol	$\delta\times 10$ (nm)[4]	Temp (°C)	$-\Delta G^\circ$ (kcal mol^{-1})		$-\Delta G_p{}^\circ$ (kcal mol^{-1})[4]

		25	5.10		
		39	5.18		

( ): Averages.

the lateral interaction between the adsorbed molecules becomes negligible and the $k_0\exp(2K\theta)$ term in Eq. 6 approaches k_0.

Since the temperature dependence of $-\Delta G^0$ is negligible, the average values are plotted in Fig. 9. The linear relation in the figure gives the empirical relation

$$-\Delta G^0 = 0.17 + 0.63n. \quad (26)$$

The free energy of adsorption per methylene group is, therefore, 630 cal mol^{-1}, which is almost the same as the value of Eq. 20. This can be understood directly from Fig. 9 in view of the fact that the straight lines for $-\Delta\mu^0$ and $-\Delta G^0$ are parallel with each other.

By comparing Eqs. 19 and 25, it can be understood that the parallel relation means that the molar volume of the adsorption monolyer, $V_m = A_0\delta N_A$, obtainable from our value of the molecular area, A_0, is independent of the number of carbon atoms, n, of the alcohols. The value of V_m at 25 °C is actually almost constant and is 181.7×10^{-6} m^3 mol^{-1} on the average from butyl to octyl alcohols, while the molar volume of the liquid, V_l, increases from 91.6×10^{-6} m^3 mol^{-1} in butyl alcohol to 157.8×10^{-6} m^3 mol^{-1} in octyl alcohol, according to the increase in the molecular weight, because the density does not increase so much. This seems to be an interesting point.

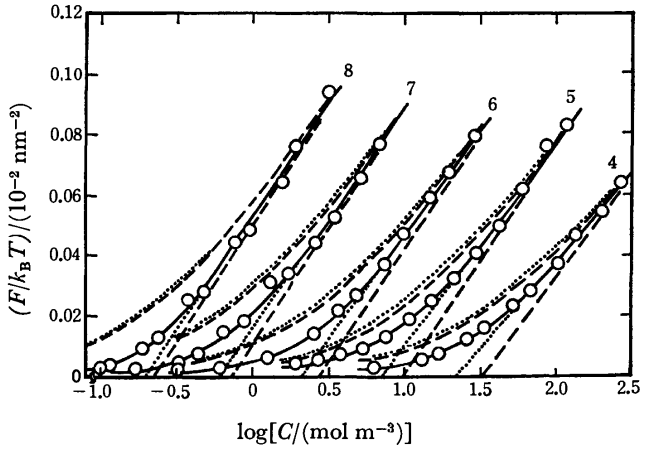

Fig. 10. Comparison between experimental values (open circles)[4] and theoretical solid curves drawn by Eq. 14 at 25 °C for normal alcohols whose carbon numbers are as indicated. Broken straight lines are calculated by Eq. 16, and broken curves are the Szyszkowski curves corresponding to them. Dotted straight lines are empirical and dotted curves are the corresponding Szyszkowski's.

Relation between F *and log* C. It is shown in Fig. 10 that the agreement is good between the experimental data by Posner *et al.*[4] at 25 °C (open circles) and the theoretical curves (solid lines) drawn according to Eq. 14 by using the parameter values given in Table 1. In Fig. 10 the asymptotes, too, are shown by broken straight lines according to Eq. 16, using the same parameter values.

Table 4. Comparison of parameter values of Eq. 27 at 25 °C

Alcohol	$A_0'\times10^2$ (nm^2 · molecule^{-1})	$k_0'\times10^3$ (m^3 mol^{-1})	A_0'/A_0	$k_0'/(k_0e^K)$
Butyl	39.6	44.7	1.14	1.43
Pentyl	34.6	142	1.12	1.37
Hexyl	34.1	490	1.10	1.31
Heptyl	32.2	1700	1.07	1.21
Octyl	31.1	5130	1.05	1.14

Experimentally, however, one might draw asymptotes like those shown by dotted straight lines in Fig. 10. For these asymptotes, if one used the following equation,

$$A_0'F_{asymp}/k_BT = \ln k_0' + \ln C \quad (27)$$

which can be derived from Szyszkowski's Eq. 12, the parameter values, A_0' and k_0', given in Table 4 may be obtained. By using these values for A_0 and k_0 of Eq. 12, Szyszkowski's theoretical curves are drawn in Fig. 10 by dotted curves; those curves are not, however, in agreement with the experimental values.

This discrepancy is partly due to the overestimation of the parameter values shown in Table 4 in that A_0'/A_0 and $k_0'/(k_0e^K)$ are larger than 1.0. Here, k_0' is compared to k_0e^K, because the latter is the value obtained from the broken straight lines, as can be understood by comparing Eq. 27 with Eq. 16. Even if the values of A_0 and k_0e^K are inserted into A_0 and k_0 of Eq. 12, however, the Szyszkowski curves shown by broken curves in Fig. 10 are still distant from the experimental values. The discrepancy is, therefore, mainly the result of the use of the Szyszkowski equation. It can be concluded that the use of Eq. 14, which takes the lateral interaction between the adsorbed molecules into account, is indispensable in explaining the experimental results over the entire concentration range.

Intersystem Crossing Processes of Acridine

Koichi KIKUCHI, Koji UJI-IE, Yoshikatsu MIYASHITA, and Hiroshi KOKUBUN

Department of Chemistry, Faculty of Science, Tohoku University, Aoba, Aramaki, Sendai 980

(Received June 11, 1976)

The $T_1(\pi, \pi^*) \rightarrow T_3(\pi, \pi^*)$ absorption of acridine has first been observed at about 985 nm in ethanol. Temperature dependences of the fluorescence lifetime and the triplet yield of acridine were investigated in poly(vinyl alcohol) film, and it was found that the intersystem crossing from the first excited singlet state $S_1(\pi, \pi^*)$ to $T_1(\pi, \pi^*)$ occurs through both temperature dependent and independent processes. The activation energy of the temperature dependent process corresponds substantially to the energy difference between $T_3(\pi, \pi^*)$ and $S_1(\pi, \pi^*)$. The intersystem crossing from $S_1(\pi, \pi^*)$ to $T_2(n, \pi^*)$ followed by the internal conversion to $T_1(\pi, \pi^*)$ was assigned to the temperature independent process.

Photoreduction of acridine has been studied in various solvents,[1-5] particularly in alcohols in which acridine is fluorescent,[6] and it was suggested that there are two reactive states in alcohols; the first excited singlet state, S_1, and the second excited triplet state, $T_2(n, \pi^*)$.[7-9] However, it is still uncertain whether the reactive singlet state is of π, π^* character or of n, π^*,[10-12] because the energy levels of the $^1(\pi, \pi^*)$ and $^1(n, \pi^*)$ states are close together.[11-13]

The mechanism of the intersystem crossing of acridine from the first excited singlet state to $T_1(\pi, \pi^*)$ has been unknown because of the uncertainty of the energy levels responsible for the intersystem crossing. Recently, Hirata and Tanaka investigated the rise-up of the transient absorption of acridine in ethanol by a picosecond laser technique, and suggested that the intersystem crossing is essentially $S_1(\pi, \pi^*) \rightarrow T_2(n, \pi^*)$ transition followed by $T_2(n, \pi^*) \rightarrow T_1(\pi, \pi^*)$ transition.[14] It was suggested that all of $T_1(\pi,\pi^*)$ is produced through $T_2(n, \pi^*)$ in alcohols.[15]

The energy level of $T_1(\pi,\pi^*)$ was determined experimentally by Evans as 15840 cm^{-1} [16] and that of $T_2(n,\pi^*)$ was calculated by Goodman and Harrell as 21400 or 23500 cm^{-1},[17] while those of the $^1(\pi, \pi^*)$ and $^1(n, \pi^*)$ states are about 26600 cm^{-1} in hydrocarbon solvent.[17] Since the energy difference between the lowest excited singlet state and $T_1(\pi, \pi^*)$ is considerably large, it seems that the intersystem crossing occurs to $T_2(n, \pi^*)$ more easily than to $T_1(\pi, \pi^*)$, particularly if the S_1 state is of π, π^* character.[18]

Bowen *et al.* found that the fluorescence yield decreases with increasing temperature in the ethanol-water mixture.[6] The triplet yield of 9-methylacridine increases with increasing temperature in ethanol.[11] These earlier observations suggest that acridine is subject to temperature dependent intersystem crossing similar to the 9,10-disubstituted anthracenes.[19-22]

In order to clarify the mechanism of the intersystem crossing of acridine, we have measured the T-T absorption spectrum in the near infrared region and studied the temperature dependences of the fluorescence lifetime and the yield of $T_1(\pi, \pi^*)$ in poly(vinyl alcohol) film (PVA), where the photoreduction is negligible and the S_1 state seems to be a $^1(\pi, \pi^*)$ state.

Experimental

Materials. Acridine (C. P. grade, Tokyo Kasei) was recrystallized from the ethanol-water mixture after pretreatment with activated charcoal in ethanol. Ethanol (G. R. grade, Wako Jun-Yaku) and poly(vinyl alcohol) (the degree of polymerization 1400, Koso Kagaku) were used without further purification.

Apparatus and Procedure. The absorption spectrum was measured with a Hitachi EPS-3T spectrophotometer, and the fluorescence spectrum with a modified Hitachi EPU spectrophotometer. Lifetime measurement was made with a phase-fluorometer modulated at 10.7 MHz. Relative yields of the triplet acridine and the T-T absorption spectra in the visible region were measured with an ordinary flash apparatus. The T-T absorption spectrum in the near infrared region was measured by the use of the combination of a HTV R-406 photomultiplier and an Ushio JC-12-130 L halogen lamp as a monitoring light source. Absolute yield of the triplet acridine was determined by the use of a flash irradiation apparatus as shown in Fig. 1.

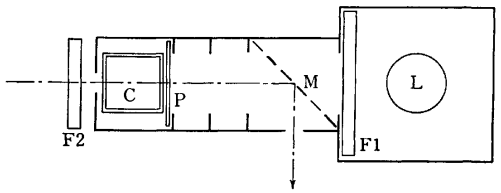

Fig. 1. The flash irradiation apparatus used to determine the intersystem crossing probability of acridine in PVA.

Results and Discussion

The absorption and fluorescence spectra of acridine in PVA are shown in Fig. 2, from which the energy level of $S_1(\pi, \pi^*)$ is estimated to be 25450 cm^{-1} as an average of the absorption maximum in the ^1L_a band at 25900 cm^{-1} and the fluorescence maximum at 25000 cm^{-1}.[23] Figure 3 shows the T-T absorption spectra of acridine in PVA and ethanol. The absorption maxima in the near infrared region lie at 10150, 11500, and 12850 cm^{-1} in ethanol. Since no transient absorption was observed below 9800 cm^{-1}, the absorption at 10150 cm^{-1} was assigned to the 0-0 band of the $T_1(\pi,\pi^*) \rightarrow T_3(\pi, \pi^*)$ transition. Hence the energy level of $T_3(\pi, \pi^*)$ is estimated to be 25990 cm^{-1}.

The fluorescence lifetime in PVA is 8.2$_6$ ns at 13 °C. Since the rate constant of the fluorescence emission, k_f, is estimated to be 3.6×10^7 s^{-1} from the known values of

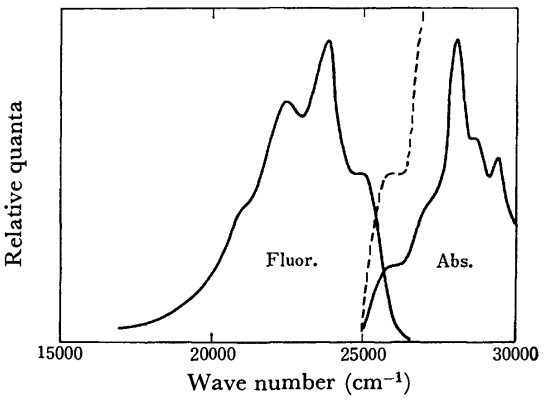

Fig. 2. The absorption and fluorescene spectra of acridine in PVA.

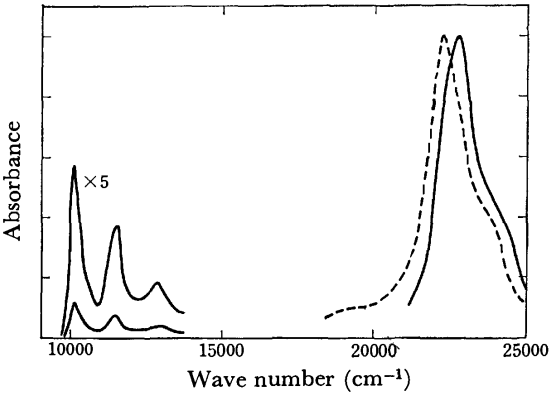

Fig. 3. The T-T absorption spectra of acridine in PVA (----) and in ethanol (——).

the fluorescence yield ($\phi_f=0.37$)[6] and the lifetime (10.3 ns)[24] in water, the fluorescence yield in PVA is evaluated as 0.30 at 13 °C. The large yield and the long lifetime imply that the S_1 state is a $^1(\pi, \pi^*)$ state in PVA.

According to a method similar to that in a previous paper,[15] the intersystem crossing probability of acridine from $S_1(\pi, \pi^*)$ to $T_1(\pi, \pi^*)$ was determined to be 0.56 in PVA at 23 °C by the use of the molar extinction coefficient of the T-T absorption maximum in ethanol, $\varepsilon_T=18500\ M^{-1}\ cm^{-1}$ at 440 nm.[25]

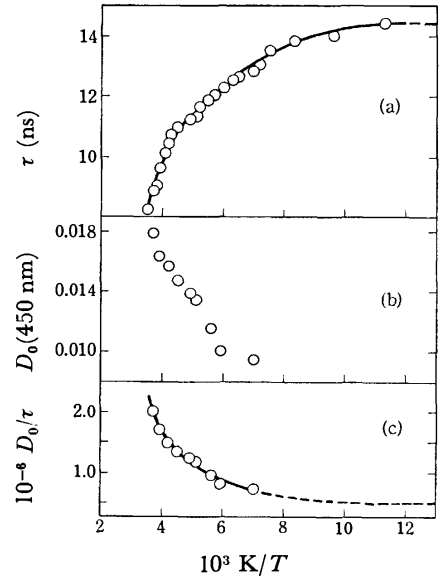

Fig. 4. The temperature dependencies of the fluorescence lifetime (a), the absorbance of the T-T absorption immediately after flashing (b), and their ratio (c).

Figure 4 shows the temperature dependences of the fluorescence lifetime (τ), the absorbance (D_0) of the T-T absorption immediately after flashing, and the ratio (D_0/τ). The lifetime increases with decreasing temperature and approaches to about 14 ns at low temperature. On the other hand, D_0/τ which is associated with the rate of intersystem crossing, decreases with decreasing temperature. It is obvious that both the decay of the singlet excited state and the intersystem crossing occur through temperature dependent and independent processes. When the extrapolated values of $1/\tau$ and D_0/τ at lower temperature are subtracted from their original values, the resulting Arrhenius plots are linear as shown in Fig. 5, and their slopes are nearly the same; the apparent activation energy is estimated to be 420 cm^{-1}. Therefore, we can safely conclude that both the deactivation of $S_1(\pi, \pi^*)$ and the production of $T_1(\pi, \pi^*)$ occur through two kinds of processes; one is temperature dependent and the other is temperature independent.

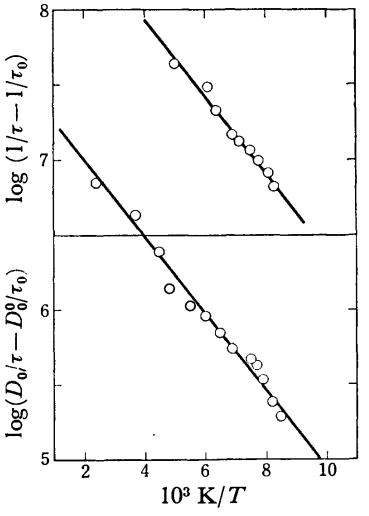

Fig. 5. The Arrhenius plots of $(1/\tau-1/\tau_0)$ and $(D_0/\tau-D_0^0/\tau_0)$ *vs.* temperature.

The energy difference between $S_1(\pi, \pi^*)$ and $T_3(\pi, \pi^*)$ is nearly equal to the activation energy, so that the temperature dependent process seems to be the intersystem crossing from $S_1(\pi, \pi^*)$ to $T_3(\pi, \pi^*)$. In the case of acridine, there are two low-lying triplet states, $T_1(\pi, \pi^*)$ and $T_2(n, \pi^*)$. According to the spin-orbit coupling selection rule of El-Sayed[18] and the energy gap law,[26] the $S_1(\pi, \pi^*)\rightarrow T_2(n, \pi^*)$ transition would be much easier than the $S_1(\pi, \pi^*)\rightarrow T_1(\pi, \pi^*)$ transition. This view coincides with the suggestions that $T_1(\pi, \pi^*)$ is mainly produced through $T_2(n, \pi^*)$ in alcohols,[15] and that the first step of the intersystem crossing is $S_1(\pi, \pi^*)\rightarrow T_2(n, \pi^*)$ transition in ethanol.[14]

On the basis of the above informations, we propose a Jablonski diagram as shown in Fig. 6, where k_d is the rate constant of non-radiative transitions other than intersystem crossing. According to the diagram, the

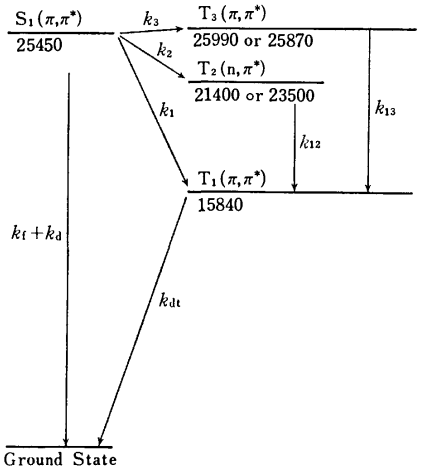

Fig. 6. The Jablonski diagram of acridine in PVA.

fluorescence lifetime and the yield of $T_1(\pi, \pi^*)$ are expressed as follows;

$$\tau = 1/(k_f+k_d+k_1+k_2+k_3), \quad (1)$$

$$\phi_{ST} = (k_1+k_2+k_3)\tau. \quad (2)$$

D_0 is related to the light absorbed during flashing, I_{ab}, as follows;

$$D_0 = \varepsilon_T[T]_0 d = \varepsilon_T d \cdot \phi_{ST} I_{ab}, \quad (3)$$

where $[T]_0$ is the triplet concentration immediately after flashing and d is the thickness of PVA. At sufficiently low temperature, following relations hold;

$$\tau_0 = 1/(k_f+k_d+k_1+k_2), \quad (4)$$

$$\phi^0_{ST} = (k_1+k_2)\tau_0, \quad (5)$$

$$D^0_0 = \varepsilon_T d \cdot \phi^0_{ST} I_{ab}. \quad (6)$$

Putting $k_3=k\exp(-\Delta E/RT)$, we obtain the following equations from Eqs. 1—6;

$$\frac{D_0}{\tau} - \frac{D^0_0}{\tau_0} = \varepsilon_T d I_{ab} k \exp\left(-\frac{\Delta E}{RT}\right), \quad (7)$$

$$\frac{1}{\tau} - \frac{1}{\tau_0} = k \exp\left(-\frac{\Delta E}{RT}\right). \quad (8)$$

These equations can analyze the results shown in Fig. 5, and the following values are obtained;

$$\frac{1}{\tau_0} = 7\times10^7\ s^{-1},$$

$$k = 3.7\times10^8\ s^{-1},$$

$$\Delta E = 420\ cm^{-1},$$

$$\varepsilon_T(450) d I_{ab} k = 1.3\times10^7\ s^{-1},$$

$$\frac{D^0_0}{\tau_0} = \varepsilon_T(450) d I_{ab} \cdot (k_1+k_2) = 5\times10^5\ s^{-1}.$$

From the last two relations, the rate constant of the intersystem crossing to the two lower triplet states, k_1+k_2, was calculated to be $1.4\times10^7\ s^{-1}$.

All of the rate constants involved in the Jablonski diagram were summarized in Table 1. The yield of $T_1(\pi, \pi^*)$ in PVA at any temperature can be calculated by the following relation derived from the above results;

$$\phi_{ST} = (k_1+k_2+k_3)\tau = \frac{0.20+5.3\times\exp(-604/T)}{1.0+5.3\times\exp(-604/T)}. \quad (9)$$

Table 1. Rate constants of the deactivation of excited acridine

$k_f=3.6\times10^7\ s^{-1}$	
$k_d=2.0\times10^7\ s^{-1}$	
$k_3=3.7\times10^8\times\exp\left(-\frac{\Delta E}{RT}\right)$	$\Delta E=420\ cm^{-1}$
$k_1+k_2=1.4\times10^7\ s^{-1}$	$k_1 \ll k_2$
$k_{dt}=4.2\times10\ s^{-1}$	

From Eq. 9, we get $\phi_{ST}=0.53$ at 23 °C, which agrees satisfactorily with the experimental value 0.56. Such agreement between the calculated and observed values supports strongly the validity of both the deactivation pathways shown in Fig. 6 and their rate constants cited in Table 1. The fluorescence and intersystem crossing yields at sufficiently low temperature are calculated to be 0.51 and 0.20, respectively.

In the above discussion, the contribution of the $^1(n, \pi^*)$ state to the deactivation of $S_1(\pi, \pi^*)$ has been ignored. The value of k obtained is the same order of magnitude for the frequency factor of a intersystem crossing process in aromatic hydrocarbons;[27] there seems to be no enhancement of the intersystem crossing due to the spin-orbit coupling between the $^1(n, \pi^*)$ state and $T_3(\pi, \pi^*)$. Therefore, it is probable that the energy level of the $^1(n, \pi^*)$ state is too high to play an important role in the intersystem crossing.

In this study, it has first been confirmed that there are two kinds of processes in the intersystem crossing of acridine from $S_1(\pi, \pi^*)$ to $T_1(\pi, \pi^*)$ in PVA; the temperature dependent process through $T_3(\pi, \pi^*)$ whose energy level is about 420 cm^{-1} higher than that of $S_1(\pi, \pi^*)$ and the temperature independent processes in which the path through $T_2(n, \pi^*)$ seems to be most important.

As regards k_d, the internal conversion is unreasonable because of the large energy gap between $S_1(\pi, \pi^*)$ and the ground state. Although the quantum yield of photoreduction of acridine by steady light illumination is very small in PVA, the weak transient absorption other than the T-T absorption was observed at about 560 nm where acridine radicals have the absorption.[28] Therefore, the non-radiative process may be due to the transient reaction in $S_1(\pi, \pi^*)$.

Derivatographic Studies on Transition Metal Complexes. XVIII.[1] Thermal Isomerization of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ in Solid Phase[2]

Tadatsugu YOSHIKUNI, Ryokichi TSUCHIYA, Akira UEHARA, and Eishin KYUNO*

Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa 920

**Department of Pharmaceutical Science, School of Pharmacy, Hokuriku University, Kanazawa 920*

(Received July 14, 1976)

The thermal *cis*-to-*trans* isomerization of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ in a solid phase was studied by means of derivatographic and isothermal measurements. It was found that *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ in which trimethylenediamine(tn) forms six-membered chelate ring with chromium undergoes isomerization to the *trans*-complex in contrast with the isomerization of *trans*-$[MX_2(diam)_2]X \cdot HX \cdot nH_2O$ (M=Co or Cr, X=halogen) to the *cis*-one in which the diamine (diam) forms five-membered chelate ring with metal M. The isomerization proceeded in anhydrous state. The activation energy of the isomerization of the complex was found to be 163 kJ mol^{-1} from the isothermal measurements, which is fairly greater than that of the *trans*-$[CoCl_2pn_2](H_5O_2)Cl_2$ and *cis*-$[CoCl_2tn_2]Cl \cdot H_2O$. The difference was explained by whether or not water molecule involved as a lattice water contributes to the isomerization.

The thermal *trans*-to-*cis* isomerization of the transition metal complexes in a solid phase was reported for the dihalogenobis(diamine) series, *trans*-$[CoCl_2pn_2](H_5O_2)Cl_2$,[3,4] *trans*-$[CoBr_2pn_2](H_5O_2)Br_2$,[5] *trans*-$[CrCl_2en_2]Cl$[6], and *trans*-$[CrBr_2pn_2]Br \cdot H_2O$.[7] In these complexes of the type $[MX_2(diam)_2]X \cdot HX \cdot nH_2O$, the modes of isomerization are influenced more or less by the kind of metal ion, M, halide ion, X, and diamine (diam). In the complex, *trans*-$[CoCl_2pn_2](H_5O_2)Cl_2$, most part of the isomerization was reported to proceed simultaneously with dehydration and dehalogenation, the process being considered to follow an "aquation-anation" mechanism.[4] However, in the complex where the chloride ion is replaced by the bromide ion, *trans*-$[CoBr_2pn_2](H_5O_2)Br_2$, the ratio of isomerization was 55% at the most, no isomerization proceeding after the dehydration was complete.[5]

On the other hand, in the case of the corresponding chromium(III) complex, *trans*-$[CrBr_2pn_2]Br \cdot H_2O$, dehydration was complete rapidly, isomerization successively proceeding even after complete dehydration.[7]

So far as the three complexes are concerned, isomerization occurred in the presence of water molecules involved in the cobalt(III) complexes, whereas it took place mainly in anhydrous state in the chromium(III) complexes. Although the cobalt(III) and chromium(III) complexes containing propylenediamine which forms a five-membered chelate ring with metal undergoes the *trans*-to-*cis* isomerization, it might be of interest to study type of isomerization appearing in the complexes containing trimethylenediamine which forms a six-membered chelate ring.

The present work was undertaken to investigate the kinetics of the isomerization of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$, with the purpose of comparing its mode of isomerization with the modes of the corresponding cobalt(III) and propylenediamine complexes.

Experimental

Preparation of Complexes. Dichlorobis(trimethylenediamine)chromium(III) chlorides, *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$, and *trans*$[CrCl_2tn_2]Cl$, were prepared by a modification of the methods reported.[8] The chemical formulas of these compounds were confirmed by elemental analysis and spectrophotometric measurement.

Found: C, 22.82; H, 6.81; N, 17.76%. Calcd for *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$: C, 22.84; H, 6.71; N, 17.76%. Found: C, 23.73; H, 6.68; N, 18.28%. Calcd for *trans*-$[CrCl_2tn_2]Cl$: C, 23.51; H, 6.58; N, 18.28%.

Derivatography. The derivatogram for the complex *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ was obtained with a MOM Typ-OD-102 Derivatograph. 0.5 g of the sample was used in each run under a constant flow of nitrogen with a heating rate of 1 °C min^{-1}. The activation energy was estimated by analysis of the DTA peak in a manner similar to that reported.[9]

Isothermal Measurements. The rate of dehydration of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ was measured at 129, 136, 144, and 155 °C with a CHO 100L thermobalance. 0.3 g of the sample in each run was heated at the desired temperature. The rate of dehydration was determined from the loss in mass of each sample in a constant time interval at each temperature, and the activation energy was calculated by means of the Arrhenius plots.

The rates of isomerization at 160, 170, 181, 190, 199, and 209 °C were followed by measuring the changes in absorbancy on the basis of the following equations similar to those report-

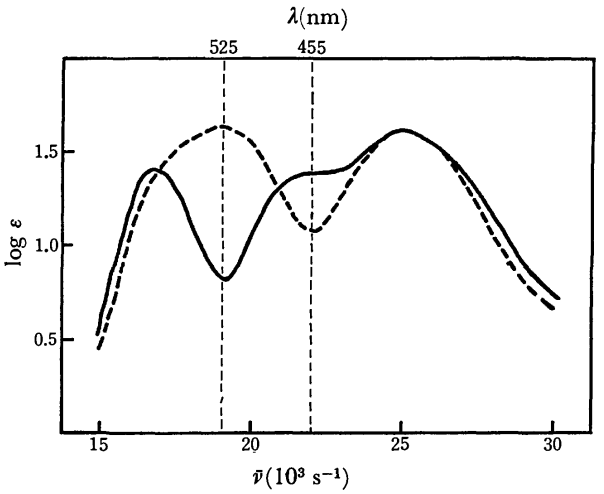

Fig. 1. Electronic spectra of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ (——) and the corresponding *trans*-form complex (----).

ed.[7]

$$5.87X + 46.10Y = D_{525}$$
$$23.98X + 12.00Y = D_{455},$$

where 5.87 and 23.98 are the molar extinction coefficients of the *cis*-complex, and 46.10 and 12.00 are those of the corresponding *trans* complex at 525 and 455 nm, respectively. The electronic spectra of the *cis* and *trans* complexes are shown in Fig. 1.

Results and Discussion

Derivatography. The derivatogram of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ is given in Fig. 2. The TG curve shows that the mass loss corresponding to the liberation of a half mole of water appears at 160 °C, followed by the presence of a plateau from 160 to 220 °C, the decomposition of complex then taking place rapidly.

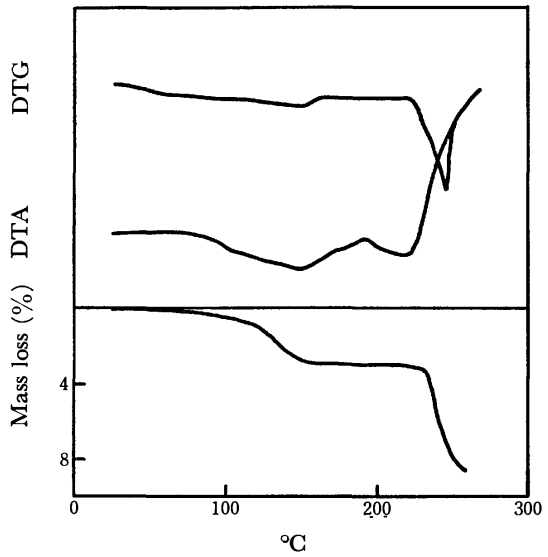

Fig. 2. Derivatogram of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$.

The DTA curve shows that an endothermic peak corresponding to the dehydration appears in the range 70—190 °C, one more endothermic peak due to the isomerization appearing at 200—225 °C before an exothermic decomposition reaction begins. The isomerization from *cis*- to *trans*-form could be detected to occur at the second endothermic peak by the color change of the sample from violet to green.

The results indicate that the isomerization of the complex proceeds after the dehydration is complete. Such a tendency was also observed in *trans*-$[CrBr_2pn_2]Br \cdot H_2O$. In contrast to those chromium(III) complexes, the isomerization of the cobalt(III) complexes such as *trans*-$[CoCl_2pn_2](H_5O_2)Cl_2$ and *trans*-$[CoBr_2pn_2](H_5O_2)Br_2$ is always accompanied by dehydration.[4,5] This conspicuous difference in the thermal reaction might

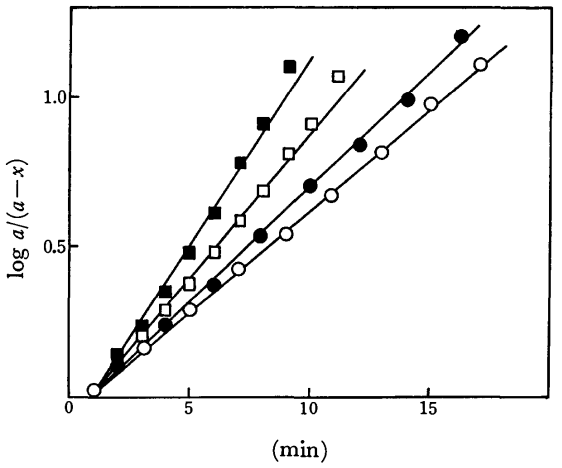

Fig. 3. Relation of log $a/(a-x)$ *vs.* time for the dehydration.
○129°C, ●136°C, □144°C, ■155°C.

arise from the difference in mechanism of the isomerization.

The enthalpy change, ΔH, of the dehydration was obtained by analysis of the endothermic curve in the derivatogram to be 25 kJ mol^{-1}. The value is twice to that for *trans*-$[CrBr_2pn_2]Br \cdot H_2O$, 12.6 kJ mol^{-1}.

Rate of Dehydration. If the rate of dehydration at each temperature follows the first order law, the following equation holds:

$$2.303 \log \frac{a}{(a-x)} = k_d t,$$

where a and x are the initial amount of the starting complex and the amount of an anhydrous complex formed during time t, respectively, and k_d is the rate constant of dehydration. Approximately linear relationships were obtained (Fig. 3) when the values of $\log a/(a-x)$ were plotted *versus* t for each temperature. The rate constants at each temperature were obtained from the slopes of the respective lines. Their values are given in Table 1, together with those of isomerization (*vide post*). From the Arrhenius plots the activation energy of dehydration, E_d, was found to be 42 kJ mol^{-1}. This value is almost equal to the heat of evaporation of water. It is presumed, therefore, that the lattice water molecule in *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ is bound loosely like liquid water.

Rate of Isomerization. If the rate of isomerization obeys the first order law, it could be expressed by the equation,

$$2.303 \log b/(b-y) = k_i t,$$

where b is the initial amount of the starting complex, *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$, y is the amount of *trans* complex produced during time t and k_i is the rate constant of isomerization.

Table 1. Rate constants of dehydration and isomerization

t °C	129	136	144	155	160	170	181	190	199	209
$k_d \times 10^{-3}$ s^{-1}	2.46	2.79	3.69	4.98						
$k_i \times 10^{-5}$ s^{-1}					1.40	3.56	10.44	22.52	59.11	126.0

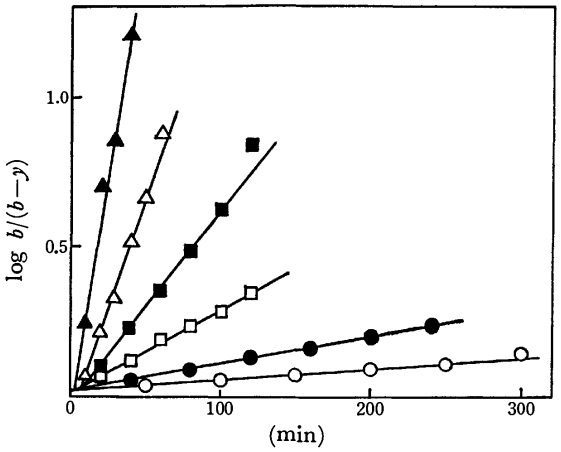

Fig. 4. Relation of log $b/(b-y)$ *vs.* time for the isomerization.
○ 160°C, ● 170°C, □ 181°C, ■ 190°C, △ 199°C, ▲ 209°C.

When the values of log $b/(b-y)$ were plotted *versus* t at each temperature, approximately linear relationships were also obtained (Fig. 4). The rate constants obtained from the slope of the respective lines are given in Table 1, together with those for dehydration. We see that the dehydration occurs at a relatively lower temperature, while most part of the isomerization proceeds in the higher temperature region.

From the Arrhenius plots of the rate constants, the activation energy, E_i, for the isomerization was calculated to be 163 kJ mol^{-1}. This value is slightly lower than 179.7 kJ mol^{-1} for the isomerization of *trans*-$[CrBr_2pn_2]Br \cdot H_2O$, but fairly greater than 96.1 kJ mol^{-1} for that of *trans*-$[CoCl_2pn_2](H_5O_2)Cl_2$ and 117.0 kJ mol^{-1} for that of *trans*-$[CoBr_2pn_2](H_5O_2)Br_2$.

As far as these complexes are concerned, the chromium(III) complexes give higher values of activation energy than the corresponding cobalt(III) complexes. This seems to be due to the fact that cobalt(III) complexes easily undergo isomerization with the aid of the lattice water through aqration-anation mechanism, whereas the chromium(III) complexes require excess energy for the structural change owing to the intramolecular rearrangement such as twisting or bond rupture in order to isomerize in anhydrous state. It should be noted that the coexistence of the lattice water noticeably causes the difference in the modes of isomerization between cobalt(III) and chromium(III) complexes.

It was found that the *trans*-to-*cis* isomerization occurs in the complexes $[MX_2pn_2]X \cdot HX \cdot nH_2O$ (M=Co or Cr; X=Cl or Br), where diamine forms a five-membered chelate ring, whereas the *cis*-to-*trans* isomerization takes place in the complex $[CrCl_2tn_2]Cl \cdot 0.5H_2O$, in which the diamine forms a six-membered chelate ring, as also observed in the complexes $[CoCl_2tn_2]X \cdot H_2O$ (X=Cl, ClO_4) and $[CoBr_2tn_2]X \cdot H_2O$ (X=Br, ClO_4).

Thermochemical Reaction Scheme. The thermochemical reaction scheme for the path-way of the *cis*-to-*trans* isomerization of $[CrCl_2tn_2]Cl \cdot 0.5H_2O$ can be expressed as follows.

cis-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$

$-\frac{1}{2}H_2O$

$\Delta H = 9.2$ kJ mol^{-1}
(from analysis of the derivatogram)
129—155 °C
$E_d = 42$ kJ mol^{-1}

cis-$[CrCl_2tn_2]Cl \longrightarrow$ *trans*-$[CrCl_2tn_2]Cl$
160—209 °C
$E_i = 163$ kJ mol^{-1}

The scheme for the dehydration and isomerization of *cis*-$[CrCl_2tn_2]Cl \cdot 0.5H_2O$ is similar, except for the direction of isomerization, to that for *trans*-$[CrBr_2pn_2]Br \cdot H_2O$ in that isomerization occurs in an anhydrous state, but is quite different from that of the cobalt(III) complexes, *trans*-$[CoCl_2pn_2](H_5O_2)Cl_2$ and *trans*-$[CoBr_2pn_2](H_5O_2)Br_2$, in which isomerization takes place simultaneously with dehydration.

Quantitative Analysis of Hydrogen in Titanium with an Ion Microanalyzer

Yoshiaki OKAJIMA, Yukiyoshi AIZAWA, Katsumi SUZUKI, and Yasushi SUGAWARA

Hitachi Research Laboratory, Hitachi Ltd., Kuzi-machi, Hitachi-shi, Ibaraki 319-12

(Received July 31, 1976)

Quantitative analysis of hydrogen in titanium was investigated with an ion microanalyzer. Argon ions as primaries were accelerated at a voltage of 10 kV. The diameter and the current of the beam were 1 mm and 2 μA, respectively. A mass spectrum was measured at 2×10^{-7} Torr. It was found that the intensity ratio of $m/e=49(^{48}TiH^+)$ and $46(^{46}Ti^+)$ can be used for the determination of hydrogen in titanium. A linear relation was obtained between the intensity ratio and hydrogen concentration determined by the standard vacuum fusion method. The present method was applied to determine the hydrogen concentration in the surface layer of a sample treated by cathodic polarization. It was observed that hydrogen concentrations in the surface layer were much higher than those in the bulk of the sample.

It is well known that titanium is embrittled by the presence of small amounts of hydrogen. Phillips *et al.* investigated the kinetics of embrittlement by observing a sample cross section with an optical microscope, determining the hydrogen concentration by the vaccum fusion method.[1] In order to investigate the mechanism of embrittlement, it is necessary to determine hydrogen concentrations on a microscopic scale. The vacuum fusion method, however, cannot be applied to determination of hydrogen concentration in a microscopically thin layer.

An ion microanalyser (IMA) enables us to carry out analyses of the impurities contained in a small selected volume and in very thin layers. Gray[2] and Someno *et al.*[3] reported on the application of IMA to the determination of hydrogen in titanium. Gray used the intensity ratio of titanium ($m/e=48$) to hydrogen ($m/e=1$). However, Gray's method cannot be applied with sufficient reproducibility, due to a trace amount of contaminants containing hydrogen compounds in the sample chamber. Someno *et al.* used deuterium instead of hydrogen.

The present paper describes an IMA method which can be applied to the determination of hydrogen in titanium with good reproducibility.

Experimental

Materials. The titanium specimens used were 1 mm thick and 5×5 mm in size. Table 1 gives the composition obtained by chemical analysis. In order to obtain specimens with high concentrations of hydrogen, hydrogen was diffused in the specimen by cathodic polarization. Specimens were ultrasonically cleaned in acetone and methyl alcohol. The hydrogen concentration was analyzed by the standard vacuum fusion method.

Argon gas, used as a source of primary ions, was purified by passing through CuO particles heated to 500 °C, $Mg(ClO_4)_2$ particles and a liquid oxygen trap.

TABLE 1. CHEMICAL ANALYSIS OF TITANIUM SPECIMEN

Specimen	Concentration (%)				
	N	O	H	Fe	C
1	0.003	0.059	0.0012	—	—
2	0.008	0.057	0.0020	0.002	0.005
3	0.009	0.070	0.0020	0.030	0.007

Experimental Procedure. A Hitachi type IMA-2 ion microanalyzer was used. Argon ionized by a duoplasmatron was accelerated from 6 to 15 kV and struck the sample mounted with silver paste on a holder. The beam diameter was focused to about 1 mm. The primary ion current at the sample was 0.5 to 5 μA. The pressure in the sample chamber was 4×10^{-6}—8×10^{-8} Torr. Secondary ions sputtering from the sample surface were accelerated at a voltage of 3 kV and analyzed with a mass spectrometer.

Results

Principle of Quantitative Analysis. The secondary ion current I_x of an element X with one isotope only is given by

$$I_X = I_p S_X^+ C_X \eta_X, \quad (1)$$

where I_p is primary ion current, S_x^+ the yield of ions of element X, C_x the concentration of element X, and η_x the transmission of the instrument between sample and collector. Thus the ratio of the secondary ion current of an element X to a reference element (matrix) R is given by[4]

$$I_X/I_R = S(\mathrm{rel})^+ C_X/C_R, \quad (2)$$

where I_R is the secondary ion current of a reference element R, C_R the concentration of a reference element R, and $S(\mathrm{rel})^+$ the ratio of the yield of ions of an element X to a reference element R. When the analysis is carried out by means of Eq. 2, it is necessary to select the peak of the element to be analyzed and that of a reference element.

Selection of Peak. Figure 1 shows the mass spectra of samples of different hydrogen concentrations. The hydrogen concentrations of samples A and B analyzed by the vacuum fusion method are 12 and 3800 ppm, respectively. The heights of the peaks of hydrogen ($m/e=1$) do not show any appreciable difference. On the other hand, the peak height difference of $m/e=49$ between A and B is very large. The peak at $m/e=49$ contains both $^{49}Ti^+$ and $^{48}TiH^+$ ions. Hydrogen sources of the ion TiH^+ seem to be the hydrogen in the titanium sample and impurities such as water and hydrocarbons in the sample chamber. In order to determine the hydrogen in titanium using the peak at $m/e=49$, the impurities in the system should be minimized.

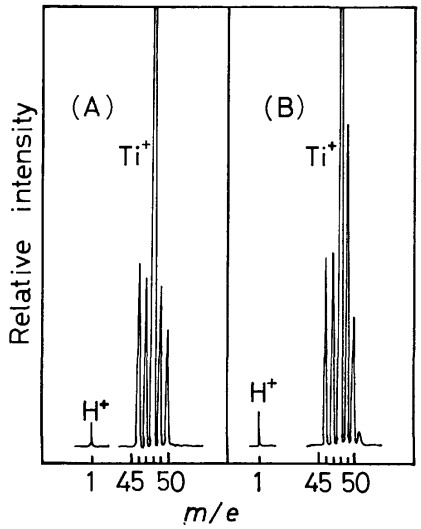

Fig. 1. Mass spectra of titanium before and after hydrogen absorption.
(A): Before absorption(12 ppm H), (B): after absorption (3800 ppm H).

In the present work, argon gas was purified by passing through CuO particles heated to 500 °C, $Mg(ClO_4)_2$ particles and a liquid oxygen trap. The impurities in the sample chamber were minimized by cooling with liquid nitrogen. Since the impurities adsorbed on the sample surface also give a TiH^+, they should be separated from other secondary ions using a high accelerating voltage.

Table 2. Peak height ratio for titanium

m/e	Peak height ratios (%)				
	46	47	48	49	50
Sample A	8.06	7.20	73.94	5.83	4.97
Sample B	6.94	7.82	66.67	13.47	5.10

Isotopic ratio of m/e=46, 47, 48, 49, and 50 is 7.93, 7.20, 73.94, 5.51, and 5.34, respectively.

Table 2 gives the peak height ratios for samples A and B, as compared to the isotopic ratio of titanium. The values at m/e=49 are greater than the isotopic ratio. The high value at m/e=49 for sample B indicates a high concentration of hydrogen. Thus the peak at m/e=49 can be used for the determination of the concentration of hydrogen.

It is preferable to select the peak at m/e=46 as a reference, since titanium of m/e=45 is not detected and the TiH^+ gives no signal at m/e=46. Since the intensities at m/e=46 and 49 are comparable, errors can be minimized.

Effect of Primary Ion Current on I_{49}/I_{46}. The temperature of the sample surface and the sputtering rate[5] are influenced by the primary ion corrent. When the sample is heated by primary ions, the absorbed hydrogen in titanium might be released. Figure 2 shows the relation between the intensity ratio of m/e=49 to 46(I_{49}/I_{46}) and to the primary ion current. I_{49}/I_{46} is constant in the range 0.5—5 μA. The results show that no thermal release of hydrogen occurs by the present method.

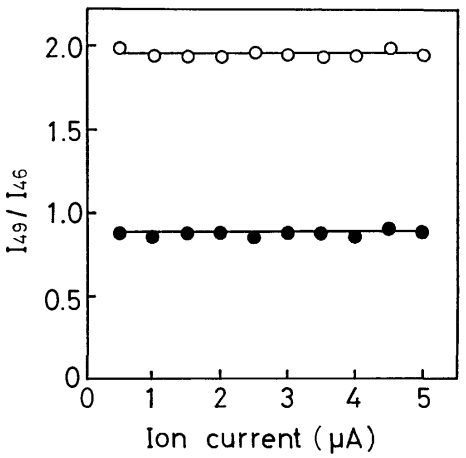

Fig. 2. Relation between I_{49}/I_{46} and primary ion current.
●: Before absorption (12 ppm H), ○: after absorption (3800 ppm H). Primary ion accelerating voltage :10kV.

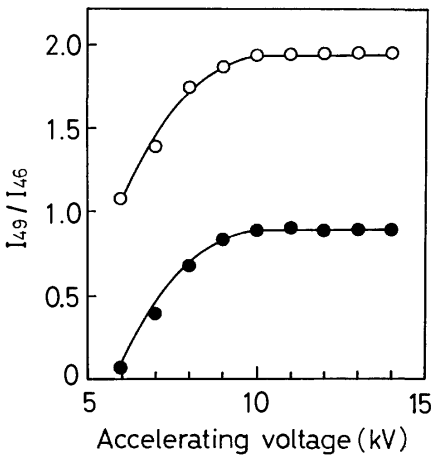

Fig. 3. Relation between I_{49}/I_{46} and primary ion accelerating voltage.
●: Before absorption(12 ppm H), ○: after absorption (3800 ppm H). Primary ion current: 2 μA.

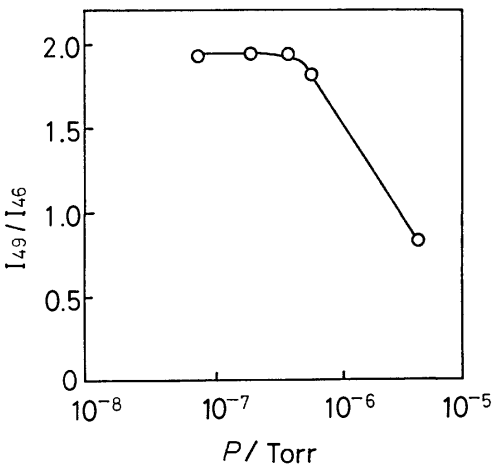

Fig. 4. Relation between I_{49}/I_{46} and pressure in sample chamber at primary ion current of 2 μA and primary ion accelerating voltage of 10 kV.

Effect of Primary Ion Accelerating Voltage on I_{49}/I_{46}. The measurements were carried out at a primary ion current of 2 μA. Figure 3 shows the relation between I_{49}/I_{46} and the primary ion accelerating voltage. I_{49}/I_{46} increases with the accelerating voltage and becomes constant at voltages above 10 kV.

Effect of Pressure in Sample Chamber on I_{49}/I_{46}. Figure 4 shows the relation between I_{49}/I_{46} and pressure. I_{49}/I_{46} decreases at pressure above 4×10^{-7} Torr. Decrease in I_{49}/I_{46} with pressure seems to be due to the increase of oxygen present in the sample chamber.[6]

Effect of Surface Layer on I_{49}/I_{46}. The sample surface is contaminated with impurities such as oxygen, water and hydrocarbons which generate secondary ions, making the quantitative analysis of hydrogen difficult. Surface sputtering is effective in removing the impurities on the surface. In the early stages of bombardment, the peak intensity changes widely. However, a stable signal can be obtained after bombardment for *ca.* 10 min. It was confirmed by surface roughness measurement that 2 μm or less had been sputtered by 10 min bombardment.

TABLE 3. WORKING CONDITIONS FOR QUANTITATIVE ANALYSIS

Ionic species	Argon(Ar^+)
Primary ion accelerating voltage	10 kV
Primary ion current	2 μA
Primary ion beam diameter	1 mm
Pressure in sample chamber	2×10^{-7} Torr
Preliminary sputtering time	10 min
Secondary ion accelerating voltage	3 kV

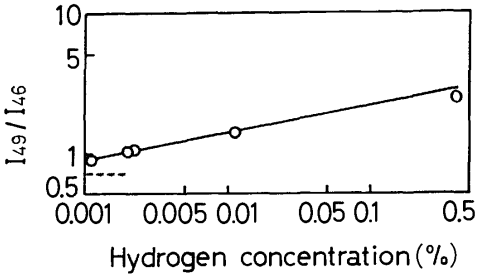

Fig. 5. Calibration curve.
----: Isotopic ratio($^{49}Ti/^{46}Ti$).

Calibration Curve. The working conditions for the IMA method are summarized in Table 3. Under these conditions, I_{49}/I_{46} was plotted as a function of hydrogen concentrations, which were determined by the vacuum fusion method. A linear relation was obtained between I_{49}/I_{46} and hydrogen concentration as shown in Fig. 5.

Hydrogen Concentration in Surface Layer. The present method has been applied to determine hydrogen concentration in the surface layer of a sample treated by cathodic polarization. The hydrogen concentration decreases with increase in depth (Fig. 6).

Phase Equilibria in Sm_2O_3-V_2O_3-V_2O_5 System at 1200 °C

Kenzo KITAYAMA and Takashi KATSURA

Department of Chemistry, Faculty of Science, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

(Received September 1, 1976)

The phase equilibria in the Sm_2O_3-V_2O_3-V_2O_5 system was established at 1200 °C. In this system, Sm_2O_3, $Sm_{10}V_2O_{20}$, $SmVO_3$, $SmVO_4$, V_2O_3, V_3O_5, V_4O_7, V_5O_9, V_6O_{11}, and VO_2 were stable and $Sm_{10}V_2O_{20}$, $SmVO_4$, V_2O_3, and VO_2 had the non-stoichiometry. On the basis of the phase equilibria, the Gibbs free energy for the reactions, $SmVO_3+1/2O_2=SmVO_4$ and $4\,Sm_2O_3+2\,SmVO_3+O_2=Sm_{10}V_2O_{20}$, were determined to be -30.4 ± 0.1 and -76.8 ± 0.1 kcal, respectively. Also, standard Gibbs free energies of oxidation of various vanadium oxides were calculated.

$LnVO_4$ has been prepared and its crystallographic,[1,2] fluorescent,[3] and magnetic[4] properties have been investigated. $LnVO_4$ has a tetragonal structure, except for $LaVO_4$. On the other hand, $LnVO_3$ has the crystallographic form of orthorhombic, except for $LaVO_3$ and $CeVO_3$.[5]

Although $LnVO_4$ and $LnVO_3$ had been prepared and their various physical properties studied, as described above, the phase equilibria in the system Ln-V-O had not been determined at high temperature in low oxygen partial pressures.

Many studies have been carried out on the system V-O. Among early studies, Andersson[6] investigated the system VO-V_2O_5 at temperatures between 650—1000 °C, and found a series of vanadium oxides which could be represented with the general formula, V_nO_{2n-1}, changing the n's from 2 to 8.

Kosuge *et al.*[7] also investigated the system V_2O_3-V_2O_5 at 800 °C, and recognized the phases V_nO_{2n-1} of $n=2$—7.

Recently, thermochemical studies and phase equilibria in the system V_2O_3-VO_2 at 1600 K,[8] in the system V_2O_3-V_4O_7 at temperatures from 1400 to 1700 K,[9] in the system V_2O_3-VO_2 at 1307 K,[10] in the system V_nO_{2n-1} at temperatures from 1000 to 1200 °C,[11] and in the system V_2O_3-VO_2 at temperatures from 1173 to 1423 K[12] were investigated by means of the quenching and thermogravimetric methods under a controlled oxygen partial pressure by equilibration with CO_2 and H_2 or CO and CO_2. They reported the phases of vanadium oxide and standard free energies of oxidation,[8-12] standard enthalpy,[9,10,12] and entropy change.[9,10,12]

The precise phase equilibria in the system Sm_2O_3-V_2O_3 have not been reported. But the existence of stable phase of $SmVO_3$ is well known, as described above. Recently the phase equilibria in the system Sm_2O_3-V_2O_5 was studied by Brusset *et al.*[13] and Remizov *et al.*[14]

In the report, Brusset *et al.* showed the existence of compounds of $4Sm_2O_3\cdot V_2O_5$ and $5Sm_2O_3\cdot V_2O_5$. On the other hand Remizov *et al.* showed the existence of compounds of $Sm_2O_3\cdot 2V_2O_5$ and $3Sm_2O_3\cdot V_2O_5$. There are sharp differences in the results regarding to the composition.

The objectives of the present study are to establish the detailed phase equilibria in the system Sm_2O_3-V_2O_3-V_2O_5 at 1200 °C by changing the oxygen partial pressures, to calculate the thermochemical values based upon the phase equilibria, and to ascertain, upon completion of the studies of the Ln-V-O system, whether the trend of the linearity of the Gibbs free energy of reaction with rare-earth ionic radii in the system Ln-Fe-O[15] will be observed or not when the iron is changed to vanadium.

Experimental

Analytical grade of Sm_2O_3 (99.9%) and V_2O_5 which was made from the guaranteed grade of NH_4VO_3 by heating at 500 °C in air for 24 h have been employed as starting materials. The desired ratios of Sm_2O_3/V_2O_5 were obtained by mixing throughly in an agate mortar with ethyl alcohol. The mixed samples were heated at 600 °C for 24 h at an oxygen partial pressure of $10^{-10.0}$ atm to reduce V_2O_5 to V_2O_3. The temperature of the furnace was increased to 1200 °C in the same P_{O_2} to solidify the samples. After 6 h, the samples were quenched. Samples thus prepared were crushed to obtain small size pieces (about $2\times3\times3$ mm^3), as described previously.[16]

Mixed gases of CO_2 and H_2 were used to obtain low oxygen partial pressures in the present experiment. The actual oxygen partial pressure of the gas phases was measured by means of a solid electrolytic cell composed of $(ZrO_2)_{0.85}(CaO)_{0.15}$.[8] Phases in quenched samples were identified by the powder X-ray diffraction method with (Ni-filtered) Cu$K\alpha$ radiation.

Details of the apparatus, procedures for maintaing constant temperature, methods of thermogravimetry and quenching, and the criterion for equilibrium establishment were the same as those described in previous papers.[8,16,17]

Lattice constants were determined by the powder X-ray diffraction method with Ni-filtered Cu$K\alpha$ radiation and with a slow scanning speed of 0.5° per minute. Instrumental errors were calibrated by measuring the diffraction angles of a standard specimen of silicon.

It was found that the V_2O_3 phase was stable: that is, its composition remains constant over a wide range of oxygen partial pressures.[8] During the preliminary work in the present experiments on the V-O system and mixed samples, this fact was ascertained (Fig. 1). On the basis of these preliminary results, an oxygen partial pressure of $10^{-12.00}$ atm was chosen as the reference weight standard. Vanadium contents in the starting materials and quenched samples are determined volumetrically by adopting the zinc-amalgam method[18] in order to check the thermogravimetric results. Samarium contents in the samples are determined by precipitating as samarium oxalate and igniting of the precipitate to samarium sesquioxide.

The results of duplicated wet chemical analysis and the

results of the thermogravimetric determination are shown in Table 1. Molecular formulas in the first column in Table 1 imply the compositions obtained from the thermogravimetry at each oxygen partial pressure in the second column. V_t and Sm_t are the weight % of the vanadium and samarium calculated from the compositions in the first coumn, whereas V_a and Sm_a are the weight % of the vanadium and samarium of the quenched samples obtained by wet chemical analysis.

Results and Discussion

Phase Equilibrium. Eight samples with Sm_2O_3/V_2O_5 compositions of 0.1111, 0.2500, 0.4286, 1.000, 1.500, 2.333, 5.000, and 5.667 were prepared. In Fig. 1, the relationship between oxygen partial pressures and compositions, VO_x or $W_{O_2}/W_T \times 100$, are shown, where W_{O_2} is the weight gain from the standard state and W_T the total weight gain of the mixed sample as if the reaction, $V_2O_3+O_2=V_2O_5$, were to be completed. Based upon the experimental results of the thermogravimetry and identifications of the sample phases (Table 2), a phase diagram can be depicted. The results of the phase equilibria are illustrated in Fig. 2. The following phases were stable under the present experimental conditions: Sm_2O_3(R), $Sm_{10}V_2O_{20}$(A), $SmVO_4$(B), $SmVO_3$(C), V_2O_3(D), V_3O_5(E), V_4O_7(F), V_5O_9(G), V_6O_{11}(H), V_7O_{13}(I), and VO_2(J). Letters in parentheses are the abbreviations of the compounds. Other Magnèli phases of V-O system could not definitely be detected as a single phase under the experimental

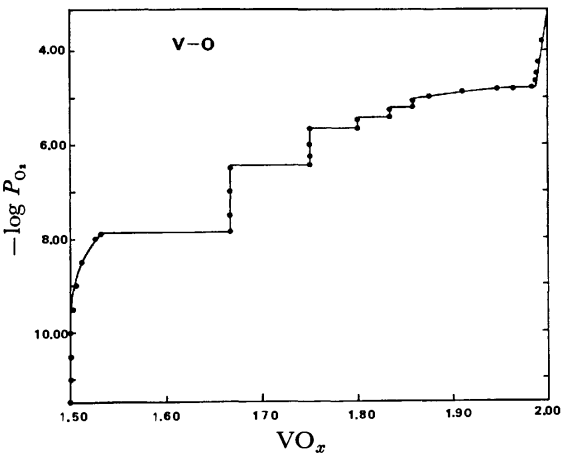

Fig. 1-1. The relationship between $-\log P_{O_2}$ and VO_x at 1200 °C.

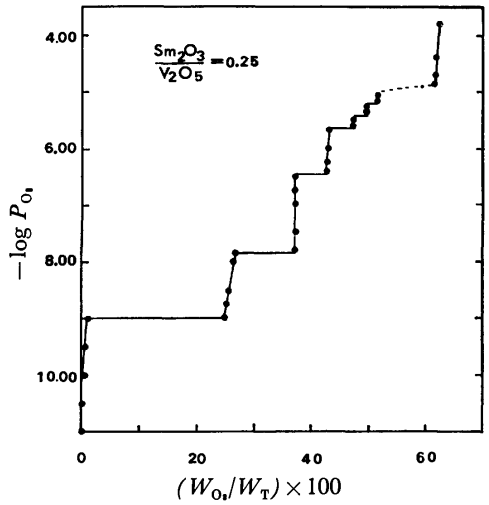

Fig. 1-2. The relationship between $-\log P_{O_2}$ and weight gains of the sample, $Sm_2O_3/V_2O_5=0.25$, at 1200 °C.

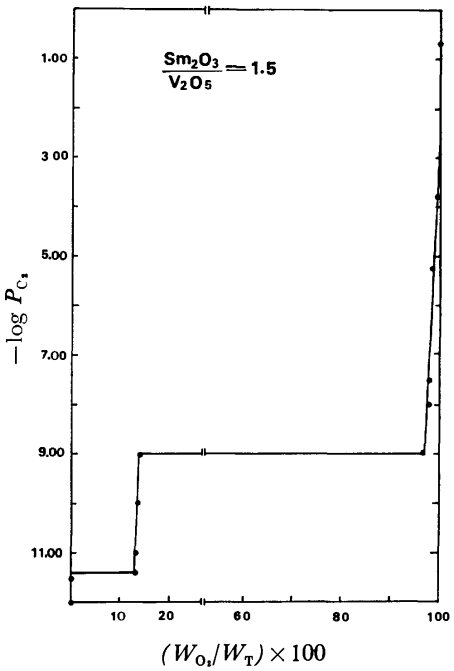

Fig. 1-3. The relationship between $-\log P_{O_2}$ and weight gains of the sample, $Sm_2O_3/V_2O_5=1.5$ at 1200 °C.

conditions.

Also the compounds of $3Sm_2O_3 \cdot V_2O_5$ and $4Sm_2O_3 \cdot V_2O_5$ did not appear under the experimental conditions.

Sm_2O_3 was stable in this experimental condition as already described.[19] $Sm_{10}V_2O_{20}$, $SmVO_4$, V_2O_3, and VO_2 have apparent deviations from the stoichiometric composition, judging by the results of thermogravimetry. As for V_2O_3, many investigators have already pointed out the same phenomena.[6-8] Deviations from the stoichiometry of VO_2 were recognized by Hoschek and Klemm.[20] They stated that the VO_2 phase was homogeneous between $VO_{1.8}$ and $VO_{2.0}$. But Andersson pointed out that the homogeneity range of this phase might be very low, arguing from his experimental

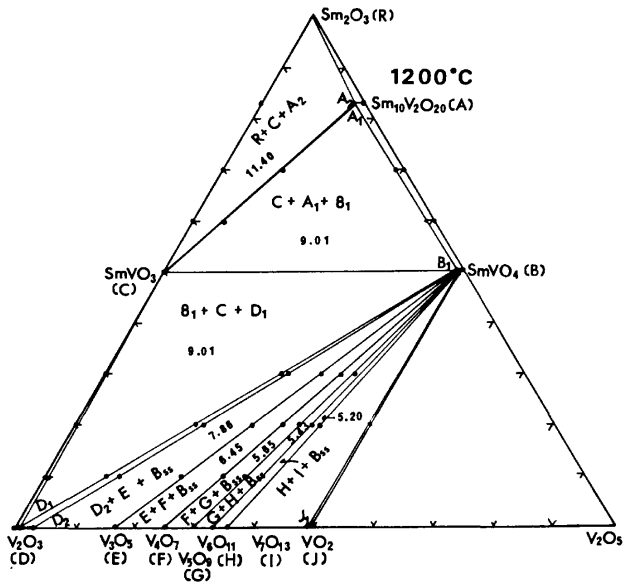

Fig. 2. Phase equilibria in the system Sm_2O_3–V_2O_3–V_2O_5 at 1200 °C. Numerical values in the three solid phases regions are the oxygen partial pressures in $-\log P_{O_2}$ in equilibrium. Abbreviations are the same as those in Table 4.

results of no displacement of the powder lines. The present results showed that the solid solution range is from $VO_{1.988}$ at $\log P_{O_2}=-4.71$ to $VO_{1.995}$ at $\log P_{O_2}=-3.79$ (in CO_2 at 1200 °C).

The deviation from the stoichiometric composition of $Sm_{10}V_2O_{20}$ extended up to $Sm_{10}V_2O_{19.78}$ at $\log P_{O_2}=-11.40$ atm, that of $SmVO_4$ up to $SmVO_{3.980}$ at $\log P_{O_2}=-9.01$, and that of V_2O_3 up to $V_2O_{3.065}$ at $\log P_{O_2}=-7.86$.

The lattice constants of the phases which appear in this system are given in Table 3, together with the data of other authors.[8,21,22,24] The crystal system of $Sm_{10}V_2O_{20}$ could not be determined. Although the relative intensities and *d*-values of $Er_{10}V_2O_{20}$,[26] $Gd_{10}V_2O_{20}$,[26] and $Y_{10}V_2O_{20}$[27] had been reported, their crystal systems have also not yet been determined. *d*-Values and relative intensities of $Sm_{10}V_2O_{20}$ obtained by the powder X-ray method are shown in Table 4. As shown in Table 3, the crystal data of the present samples are in very good agreement with those of the previous authors. Lattice constants of V_2O_3 were determined on the basis of the hexagonal type, and rhombohedral values recalculated from the hexagonal values are shown in parentheses. The lattice constants of $SmVO_4$ and VO_2 solid solutions are constant irrespective of the compositional variations, but those of V_2O_3 decrease with the increasing of the oxygen partial pressures. These phenomena seem to be reflected in the narrow solid solution range of $SmVO_4$ and VO_2, and in the more wide solid solution range of V_2O_3 and in the increasing of the smaller quadrivalent vanadium content.

Calculations of Standard Gibbs Free Energies of Ternary Compounds. On the basis of the phase equilibria, the standard Gibbs free energies of reaction of the $Sm_{10}V_2O_{20}$ and $SmVO_4$ compounds can be calculated

by referring to the following equations:

$$SmVO_3 + 1/2O_2 = SmVO_4 \quad (1)$$

$$4Sm_2O_3 + 2SmVO_3 + O_2 = Sm_{10}V_2O_{20} \quad (2)$$

The standard Gibbs free energies of both reactions may be calculated directly by adopting the equilibrium oxygen partial pressures corresponding to the Eqs. 1 and 2. Here, the activity of each component, $SmVO_4$ and $Sm_{10}V_2O_{20}$, in each solid solution was set equal to one, the composition $SmVO_{3.980}$ (B_1 in Fig. 2) was in equilibrium with $SmVO_3$, and $Sm_{10}V_2O_{19.78}$ (A_2 in Fig. 2) was in equilibrium with $SmVO_3$ and Sm_2O_3. The standard Gibbs free energies of the reactions (1) and (2) may be determined from the equation: $\Delta G^\circ=-RT\ln K$, where R is the gas constant, T the absolute temperature, and K the equilibrium constant. The values, -30.4 ± 0.1 and -76.8 ± 0.1 kcal, are obtained by referring to reactions

(1) and (2) respectively.

The activities of the $Sm_{10}V_2O_{20}$ and $SmVO_4$ components in stoichiometric composition, that is, A and B in Fig. 2, were readily calculated by means of the Gibbs-Duhem equation on the basis of the experimental results. The relationships, $\log P_{O_2}$ - N_O/N_{SmVO_4} and $\log P_{O_2}$ - $N_{O_2}/N_{Sm_{10}V_2O_{20}}$, are determined to be $N_O/N_{SmVO_4}= 3.77\times10^{-3} \log P_{O_2}+0.01377$ and $N_O/N_{Sm_{10}V_2O_{20}}=0.0227 \log P_{O_2}+0.0388$ from the thermogravimetric results. Here N_{O_2}/N_{SmVO_4} and $N_O/N_{Sm_{10}V_2O_{20}}$ are the fraction rations of oxygen to $SmVO_4$, and to $Sm_{10}V_2O_{20}$, indicating the deviation from the stoichiometry. A detailed calculation method has been described in the paper of Kimizuka and Katsura.[28] The calculated activity values and stability ranges of the oxygen partial pressures of the compounds which appeared are summarized in Table 5.

TABLE 5. COMPOSITIONS, STABILITY RANGES IN OXYGEN PARTIAL PRESSURES, AND ACTIVITIES IN SOLID SOLUTIONS

Component	Composition	Symbol	$-\log P_{O_2}$ (atm)	$\log a_i$
$Sm_{10}V_2O_{20}$	$Sm_{10}V_2O_{20.00}$	A	0.68[a] — 1.59[b]	0.533
	$Sm_{10}V_2O_{19.81}$	A_1	9.01	0.231
	$Sm_{10}V_2O_{19.78}$	A_2	11.40	0.0
$SmVO_4$	$SmVO_{4.000}$	B	0.68[a] — 3.70[b]	0.0264
	$SmVO_{3.980}$	B_1	9.01	0.0
$SmVO_3$	$SmVO_{3.000}$	C	9.01 —12.00[c]	0.0
V_2O_3	$V_2O_{3.000}$	D	9.98 —12.00[c]	
	$V_2O_{3.012}$	D_1	9.01	
	$V_2O_{3.065}$	D_2	7.86	
V_3O_5	$V_3O_{5.000}$	E	6.45 — 7.86	
V_4O_7	$V_4O_{7.000}$	F	5.65 — 6.45	
V_5O_9	$V_5O_{9.000}$	G	5.43 — 5.65	
V_6O_{11}	$V_6O_{11.00}$	H	5.20 — 5.43	
V_7O_{13}	$V_7O_{13.00}$	I	5.05 — 5.20	
VO_2	$VO_{2.000}$	J	3.07[b]	0.0046
	$VO_{1.988}$	J_1	4.71	0.0

a) Stability range in log P_{O_2} may be higher than −0.68. b) These values were obtained by extrapolations by using the experimental values. c) Stability range in log P_{O_2} may be lower than −12.00.

The Standard Gibbs Free Energies of Oxidation of Vanadium Oxides. On the basis of the phase equilibria of the V–O system, the standard Gibbs free energies of oxidation of vanadium oxides which appeared in the present experimental conditions can be calculated. Although the details of the method were already described by Katsura and Hasegawa[8] at 1600 K and by Smiltens,[29] we will briefly describe them below.

In the cases of the following reactions:

$$VO_{5/3} + 1/24O_2 = VO_{7/4}, \quad (3)$$

$$VO_{7/4} + 1/40O_2 = VO_{9/5}, \quad (4)$$

$$VO_{9/5} + 1/16O_2 = VO_{11/6}, \quad (5)$$

$$VO_{11/6} + 1/84O_2 = VO_{13/7}, \quad (6)$$

which are concerned with the stoichiometric compounds in equilibrium states at fixed oxygen partial pressures, the standard Gibbs free energies of the oxidations can be readily calculated. For example, in the case of reaction (3), $\Delta G^\circ = -RT \ln K = 1/24\ RT \ln P_{O_2}(eq)$ is applicable, where $P_{O_2}(eq)$ is the equilibrium oxygen partial pressure at which two solid phases are in equilibrium.

In the case of the following reactions, which involve solid solutions:

$$VO_{3/2} + 1/12O_2 = VO_{5/3}, \quad (7)$$

$$VO_{13/7} + 1/14O_2 = VO_2, \quad (8)$$

the method of the calculation of the standard Gibbs free energy of oxidation is more complicated. We assume from the results of the phase diagram that $VO_{13/7}$ has a solid solution, although the phase diagram between $VO_{13/7}$ and VO_2 is not so exactly determined because of the slow reaction rate.

On the basis of Smiltens's method, the standard free energies referring to reactions (7) and (8) may be given as follows:

$$\Delta G^\circ_{1473}(7) = RT/12 \ln P_{O_2}(eq) + RT/2\int_{0.000}^{0.0320} \ln [P_{O_2}/P_{O_2}(eq)]dx_1,$$

$$\Delta G^\circ_{1473}(8) = RT/14 \ln P_{O_2}(eq) + RT/2\int_{0.000}^{0.1301} \ln [P_{O_2}/P_{O_2}(eq)]dx_2,$$

where x_1 and x_2 are defined as $VO_{3/2}+x_1/2O_2=VO_{3/2+x1}$ and $VO_{13/7}+x_2/2O_2=VO_{13/7+x2}$, respectively.

The second term of the right side of the above equations is named by Smiltens as the correction term. We obtained the values by adopting the graphical integration method. The relationships, $\log [P_{O_2}/P_{O_2}(eq)]$ - x_1 and $\log [P_{O_2}/P_{O_2}(eq)]$ - x_2, are shown in Fig. 3-1 and 3-2. The results of the standard Gibbs free energies of the oxidation of vanadium oxides are summarized in Table 6 together with the values calculated from equations presented by Okinaka *et al.*[11] The present values are in good agreement with those of Okinaka *et al.*

The standard Gibbs free energy of the reaction,

$$VO_{3/2} + 1/4O_2 = VO_2 \quad (9)$$

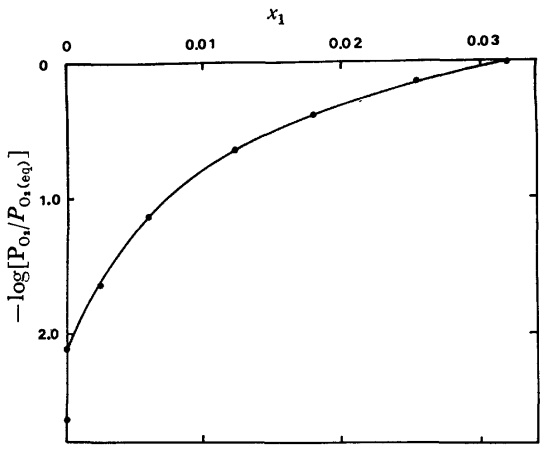

Fig. 3-1. The log $[P_{O_2}/P_{O_2}(eq)]$ *versus* x_1 curve for V_2O_3 solid solution at 1200 °C.

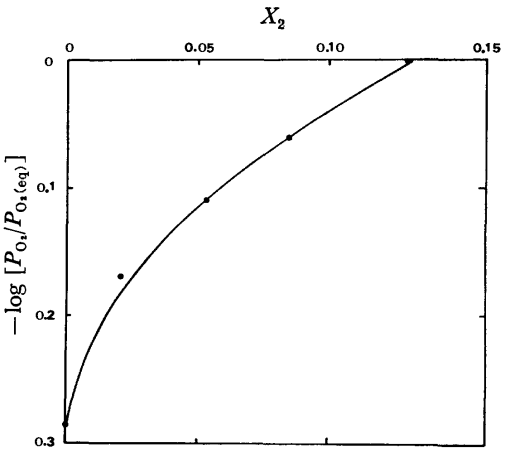

Fig. 3-2. The log $[P_{O_2}/P_{O_2}(eq)]$ *versus* x_2 curve for V_7O_{13} solid solution at 1200 °C.

can be calculated as the summation of the values of the respective reactions, and is also shown in Table 6.

Allen *et al.*[30] obtained the free energy equation, $\Delta G^\circ = 102800 - 33.5\ T$ (calcd, 1020—1180 K, ±5 kcal), for the reaction $4VO_2=2V_2O_3+O_2$ and Anderson *et al.*[12] −26.9 at 1173, −24.77 at 1273, and −21.24 kcal at 1473 K for the reaction $V_2O_3+1/2O_2=2\ VO_2$. Althoguh this equation and values are not adequate for 1200 °C, we obtained the values −13360 and −10070 cal for reaction (9) at 1200 °C by extrapolation.

According to Coughlin,[31] Mah and Kelly,[32] and Okinaka *et al.*,[11] the standard free energy of the reaction $V_2O_3+1/2O_2=2VO_2$ was given as $\Delta G^\circ = -43650+$

Table 6. Standrad free energies of oxidation at 1200 °C

Oxidation Reaction	$-\log P_{O_2}(eq)$ (atm)	Correction term (cal)	$-\Delta G^\circ$ (calcd)	
			Present	Okinaka *et al.*
$VO_{3/2}+1/12\ O_2=VO_{5/3}$	7.86	−70	4490±100	4370
$VO_{5/3}+1/24\ O_2=VO_{7/4}$	6.45	0	1810± 50	1710
$VO_{7/4}+1/40\ O_2=VO_{9/5}$	5.65	0	950± 50	910
$VO_{9/5}+1/60\ O_2=VO_{11/6}$	5.43	0	610± 50	550
$VO_{11/6}+1/84\ O_2=VO_{13/7}$	5.20	0	420± 50	390
$VO_{13/7}+1/14\ O_2=VO_2$	4.71	−40	2310±100	2400
$VO_{3/2}+1/4\ O_2=VO_2$			10590±400	10330

16.75 T (calcd, 500—1800 K, ±2000 cal), $\Delta G^\circ = -42200 + 13.0\ T$ (calcd, 800—1600 K, ±400 cal), and $\Delta G^\circ = -48860 + 19.14\ T$ (calcd, above 1120 K, ±200 cal), respectively. Values calculated by using these equations at 1200 °C are −9490, −11530, and −10330 cal, respectively. The present value (−10590 cal) is in good agreement with the value of Okinaka *et al.*

The relationship between N_O/N_{VO_2} and log P_{O_2} in the VO_2 solid solution is obtained to be $N_O/N_{VO_2} = 6.85 \times 10^{-3} \log P_{O_2} + 0.0210$. The activity of the stoichiometric VO_2 was also determined and is shown in Table 6.

Nickel(II) Complexes of *N,N'*-Polymethylenebis(*o*-mercaptobenzylamine)

Hiroyuki KOYAMA and Ichiro MURASE

Laboratory of Chemistry, College of General Education, Kyushu University, Ropponmatsu, Chuo-ku, Fukuoka 810

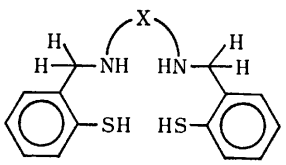
(Received October 15, 1976)

N,N'-Polymethylenebis(*o*-mercaptobenzylamine) ligands (polymethylene=ethylene, 1,2-cyclohexylene, trimethylene, and tetramethylene) have been synthesized by the reduction of the corresponding amides, which were prepared by the condensation of 2,2'-dithiodibenzoyl chloride and polymethylenediamines, and then their nickel(II) complexes have been prepared and characterized. The elemental analyses and the magnetic and spectroscopic data indicate that all of the complexes are monomeric with metal-ligand ratio of 1 : 1, and their geometries are essentially square-planar. When the bridging carbon chain was replaced from ethylene up to tetramethylene, the electronic spectra of the complexes exhibited pronounced change in the d-d bands.

As a typical N_2O_2 type quadridentate ligand, *N,N'*-ethylenebis(salicylideneimine)(salen) is well known to form square-planar complexes with nickel(II) ions as well as other transition metal ions.[1] A sulfur analogue of salen, *i.e.*, *N,N'*-ethylenebis(*o*-mercaptobenzylideneimine)(tib-en), has been synthesized and it acts as a N_2S_2 type quadridentate ligand and also forms a square-planar nickel(II) complex.[2] Both nickel(II) complexes are monomeric in solution, and no significant difference has been observed in their electronic spectra showing only one absorption band due to d-d transition at 18300 cm^{-1} for salen[3] and near 15000 cm^{-1} for tib-en.[2]

O'Connor and West[4] investigated a nickel(II) complex with the hydrogenated ligand of salen, *i.e.*, *N,N'*-ethylenebis(*o*-hydroxybenzylamine), and suggested a polymeric structure in which the donor atoms displayed a distorted octahedral arrangement around the nickel ion.

This was evidenced by the paramagnetic property and the spectroscopic observation. In this connection it is worthwhile to investigate the hydrogenated ligand of tib-en, *i.e.*, *N,N'*-ethylenebis(*o*-mercaptobenzylamine) (H_2enmba), for complex formation with nickel(II) ions.



H_2Xmba

X=$-(CH_2)_2-$ (en)
= (ch)
$=-(CH_2)_3-$ (tri)
$=-(CH_2)_4-$ (tet)

This paper deals with the synthesis of H_2enmba as well as its polymethylene analogues such as *N,N'*-1,2-cyclohexylenebis(*o*-mercaptobenzylamine)(H_2chmba), *N,N'*-trimethylenebis(*o*-mercaptobenzylamine) (H_2-trimba), and *N,N'*-tetramethylenebis(*o*-mercaptobenzylamine)(H_2tetmba).

Their nickel(II) complexes have also been investigated in terms of the electronic spectra and the magnetic properties.

Experimental

Synthesis of the Ligands. To a solution of 2,2'-dithiodibenzoyl chloride (0.01 mol) in 60 ml of dry dioxane was added dropwise a mixture of polymethylenediamine (0.01 mol) and triethylamine (0.02 mol) in dry dioxane (10 ml). The mixture was stirred in an ice-cold water bath for one hour and the resulting precipitate was filtered and quickly washed with cold water. The product was crushed with a glass rod in a large amount of 1% acetic acid until it became nonsticky powder, and filtered, washed with water repeatedly, and dried at 60 °C.

Under a nitrogen stream the powdered polyamide (3 g) was added little by little to a stirred suspension of lithium aluminium hydride (3 g) in 120 ml of dry tetrahydrofuran at room temperature.

After the addition, the stirring was continued for 7 h and 10 ml of cold water carefully added to the mixture with cooling in an ice-bath and then 150 ml of 3 M hydrochloric acid was added. After stirring overnight, the tetrahydrofuran was removed under reduced pressure. The residual solution was allowed to stand in a refrigerator to separate the desired compound as a hydrochloride; it was filtered and washed with a small amount of cold water and acetone. These compounds were pure enough without recrystallization, and the analyses are listed in Table 1 together with the yields and the melting points.

Synthesis of the Nickel(II) Complexes. All of the nickel(II) complexes were prepared in a similar manner. The synthesis of Ni(tetmba) is given as an example: In a warm solution of 15 ml of 65% aqueous ethanol containing sodium hydroxide (0.004 mol), *N,N'*-tetramethylenebis(*o*-mercaptobenzylamine) dihydrochloride (0.001 mol) was dissolved. To this was added nickel(II) acetate tetrahydrate (0.001 mol) in 10 ml of water. Formation of a reddish-violet precipitate completed in a few minutes; it was collected by filtration and washed with water. The crude complex was dissolved in DMSO and recrystallized by adding water to give reddish-violet crystals.

Other complexes were purified in the following manner: Ni(enmba) was dissolved in a mixture of chloroform-DMSO (5: 8 V/V) and the solution was permitted to stand at room temperature until chloroform had evaporated spontaneously and dark reddish-violet prisms separated. Ni(chmba) and Ni(trimba) were recrystallized from DMF and from a mixture of chloroform-ethanol (2: 1 V/V) to give dark reddish-violet needles and blue-violet crystals respectively.

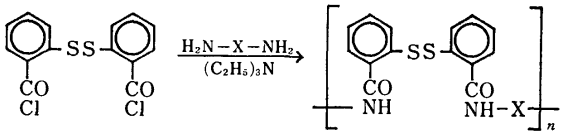
The elemental analyses are listed in Table 2.

Measurements. The molecular weights were determined on a Hitachi Osmometer Type-115 using DMF as a solvent. Electronic spectra were recorded in DMF with a Hitachi EPS-3T spectrophotometer.

A reflectance attachment was used for the measurement of the solid samples. Magnetic susceptibilities were measured by the Gouy method at room temperature and the susceptibilities of the ligand molecules were calculated using Pascal's constants.

Results and Discussion

The ligands may be prepared by the catalytic hydrogenation of corresponding Schiff bases of *o*-mercaptobenzaldehyde with polymethylenediamine, but sulfur poisoning of the catalyst may cause a poor yield of the products. In this case, reduction of a corresponding amide will be more preferable and we found that the following synthetic route gave a fairly good yield to obtain a series of *o*-mercaptobenzylamine bridged by a polymethylene chain.



$H_2Xmba \cdot 2HCl$

The condensation of 2,2′-dithiodibenzoyl chloride with polymethylenediamine afforded polymeric amides. The elemental analyses of the amides were in agreement with the unit molecular formulas within an error of 1.9 for carbon, 0.3 for hydrogen, and 0.9 for nitrogen percentages. The amide carbonyl and the disulfide bond underwent reduction simultaneously with lithium aluminium hydride and the desired mercaptobenzylamine derivatives were finally isolated as hydrochlorides.

The infrared spectra of these compounds may exhibit absorptions due to a SH stretching vibration in the vicinity of 2550 cm^{-1}. However, these bands were not detected probably due to overlapping with the strong ammonium absorption which appeared in the same region. The nickel(II) complexes are insoluble in water, slightly soluble in most organic solvents, and moderately soluble in *N*,*N*′-dimethylformamide (DMF). Data for the elemental analyses and the molecular weight determination in DMF are listed in Table 2. They indicate that all complexes are monomeric and the ligands act as N_2S_2 type quadridentate dianions.

The electronic spectra of the complexes in DMF exhibit three bands in visible and near-ultraviolet regions as seen in Fig. 1.

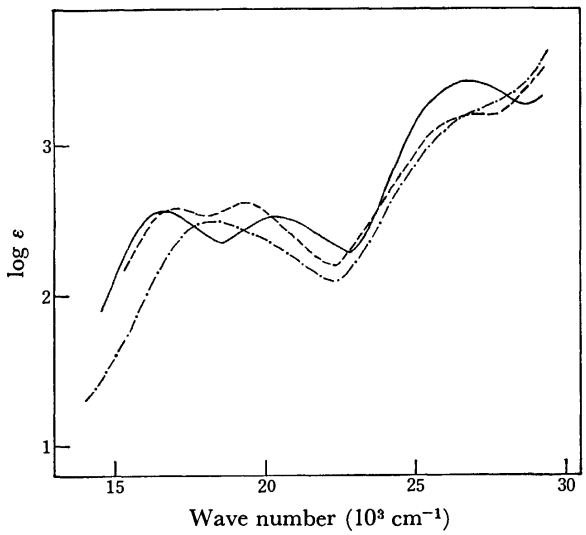


Fig. 1. Absorption spectra of Ni(enmba), ——; Ni(trimba), ——; Ni(tetmba), – · –.

The absorption maxima in 10^3 cm^{-1} are: Ni(enmba), 16.7(ε 362), 20.2(ε 319), 26.8(ε 2380); Ni(chmba), 16.8(ε 248), 20.6(ε 301), 27.0(ε 1654); Ni(trimba), 17.0(ε 374), 19.2(ε 405), 27.0(ε 1542); Ni(tetmba), 18.1(ε 309), 19.6sh(ε 258), 27.8sh(ε 1974).

The first and the second low energy bands having a moderate molar extinctions are attributed to d–d transitions, and the third bands in the near-ultraviolet region will be due to charge transfer considering from their high molar extinctions. These spectral patterns are different from that of the nickel(II) complex of tib-en[2] which exhibits only one band near 15000 cm^{-1} in the visible region, but similar to those of square-planar nickel(II) complexes of bis(*N*-substituted 2-aminoethanethiol) which consist of three bands around 16000 cm^{-1} and 20000 cm^{-1} in the visible and 27000—30000 cm^{-1} in the near-ultraviolet regions.[5]

The magnetic susceptibilities of the complexes are very low with magnetic moments of 0.18 B.M. for

Table 1. Analyses, yields, and melting points of the ligands

Ni(tetmba)	55.38	5.80	6.92	55.54	5.70	7.20	358(389)

Ni(enmba), 0.47 B.M. for Ni(chmba), 0.64 B.M. for Ni(trimba), and 0.41 B.M. for Ni(tetmba) at room temperature. These values are often observed for spin-paired ions,[6] and for the d^8 electron configuration of nickel(II), diamagnetism commonly means that the metal ion is coordinated with four strong donor atoms in a square-planar structure or with five donor atoms of phosphorus, arsenic, or sulfur in a trigonal bipyramidal or square-pyramidal structure.

Judging from the spectral similarity with known square-planar nickel(II) complexes with similar N_2S_2 type ligands which consist of a thiol sulfur and a secondary amine nitrogen, five-coordinate structure can be ruled out, and it is concluded that these nickel(II) complexes are essentially square-planar.

It should be noted as pointed out by Gerlach and Holm[7] that substitution of two or more oxygen atoms by sulfur without any other stereochemically significant alternations in ligand composition causes depolymerization of metal complexes. The present case is a typical example which is in conformity with this criterion, namely the nickel(II) complex of *N,N'*-ethylenebis(*o*-hydroxybenzylamine) is polymeric, whereas its mercapto analogues are monomeric.

As for the effect of increasing length of the bridging carbon chain in the diamine moiety, a significant change of the d-d transition bands has been observed in their electronic spectra. When the bridging ethylene was replaced by the trimethylene, the first band moved to a higher frequency, whereas the second one shifted to a lower frequency. In the case of the tetramethylene analogue, two bands almost overlapped at 18000 cm^{-1}.

From the steric consideration, increasing length of the bridging carbon chain will cause the weakening of the ligand field strength and distortion from planarity. Thus in the nickel(II) complexes of *N,N'*-polymethylenebis(salicylideneimine), red shift of the d-d bands with increasing chain length of the polymethylene bridge has been observed.[8] In the present case, the lowest energy bands undergo blue shift with increasing the number of bridged carbon atoms. The source of this phenomenon is not clear at present.

The reflectance spectrum of each complex is essentially similar to the corresponding spectrum in solution, except that a very weak band can be observed around 8000—11000 cm^{-1} in every complex in the solid state. Similar weak absorptions have been observed in the electronic spectra of dithiocarbazatonickel(II) and dithiocarbamatonickel(II) in the solid state and in concentrated solutions, and tentatively assigned to the spin-forbidden $^1A_{1g} \rightarrow {}^3B_{2g}(D_{4h})$ transition.[9] Nevertheless, the possibility of the presence of a small amount of high-spin species together with the predominant low-spin species could not be ruled out.

For the definite assignment, further investigations should be awaited.

The authors wish to thank Prof. K. Hirakawa and Dr. Y. Nishida, Kyushu University, for the magnetic measurements.

(Received November 6, 1976)

The circular dichroism spectra of a series of complexes of the type $[Co(NH_3)_{2n}(RR\text{-ptn})_{3-n}]^{3+}$($n$=0, 1, 2), where the *RR*-ptn is (*RR*)-2,4-pentanediamine, were recorded in aqueous solutions with and without the addition of electrolytes such as chloride or sulfate, and in DMSO solutions. The circular dichroism spectra in the region of the first absorption band of Δ-$[Co(RR\text{-ptn})_3]^{3+}$ and *cis*-Δ-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ were extremely sensitive to the environment of the complexes and showed a remarkable variation, while those of the corresponding diastereomers, Λ-$[Co(RR\text{-ptn})_3]^{3+}$ and *cis*-Λ-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ were little affected by the given environment. The other complexes, *trans*-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ and $[Co(NH_3)_4(RR\text{-ptn})]^{3+}$ exhibited small variations in the circular dichroism spectra. These variations seem to be accounted for by the conformational change of the flexible six-membered chelate ring brought about by ion-pair formation between the complex cations and anions.

In a previous paper,[1] we have reported that the solution CD spectra of $\Delta(lel_3)$-$[Co(RR\text{-ptn})_3]^{3+}$(*RR*-ptn=(*RR*)-2,4-pentanediamine) in the region of the first absorption band are seriously affected by its counter ions which comprise the complex salts; the chloride salt in water (2.7 mM) gives two CD bands, a strong negative and a weak positive band, while the perchlorate salt a single negative band in the same solvent. Such influences of counter ions have generally been reckoned to be negligibly small for the corresponding tris-chelated complexes formed with 1,2-diamines.

The *RR*-ptn chelate rings in the crystals of $\Delta(lel_3)$-[2] and $\Lambda(ob_3)$-$[Co(RR\text{-ptn})_3]Cl_3\cdot nH_2O$[3] have been shown by X-ray analyses to have the λ-*skew*(*twist*) conformation with two equatorially orientated methyl groups. However, PMR studies suggest that the *RR*(or *SS*)-ptn chelate ring is conformationally labile in solution at room temperature; in planar complexes such as $[Pt(RR\text{-(or }SS\text{)-ptn})_2]^{2+}$ [4,5] where no appreciable interaction is expected between the ligands, the chelate rings prefer to take the *chair* form with one axial methyl group rather than the *skew* form, while in octahedral complexes such as $[PtCl_2(NH_3)_2(RR\text{(or }SS\text{)-ptn})]^{2+}$ [5] and $[Ni(H_2O)_4(RR\text{(or }SS\text{)-ptn})]^{2+}$ [6] the stability of the *skew* form increases to reduce interactions between an apical ligand and the axial methyl group of the *RR*(or *SS*)-ptn in the *chair* form. Thus the stable conformation of *RR*(or *SS*)-ptn chelate ring in a complex seems to depend primarily on the magnitude of intramolecular interactions with other ligands. The conformation in solution may also be affected by various other factors such as the kind of solvent, the presence of excessive electrolyte, and temperature. That the CD spectrum of Δ-$[Co(RR\text{-ptn})_3]^{3+}$ in water is very sensitive to the kind of counter ion seems to be correlated with such a conformational behavior of the chiral six-membered *RR*-ptn chelate ring. In order to investigate this correlation, we have prepared a series of complexes of the type $[Co(NH_3)_{2n}(RR\text{-ptn})_{3-n}]^{3+}$ and measured their CD spectra in various matrices.

Very recently Boucher and Bosnich[7] reported the CD spectra of a number of complexes of the type, $[CoX_2(RR\text{-ptn})_2]^{n+}$, involving three isomers of the diammine complex, and found some unusual features in the CD spectra of the diammine complexes.

Experimental

Ligand. (*RR*)-2,4-pentanediamine was prepared by the method of Bosnich *et al.*,[8] and its hydrochloride (*RR*-ptn·2HCl) was used to prepare the complexes.

(−)$_{546}$-Δ-tris[(RR)-2,4-pentanediamine]cobalt(III) Complex. Mizukami *et al.*[9] prepared this complex from *trans*-$[CoCl_2(RR\text{-ptn})_2]ClO_4$ and *RR*-ptn. However, the following method gives pure Δ-isomer stereoselectively in a high yield.

RR-ptn·2HCl (2.7 g, 15.4 mmol) was dissolved in water (3 cm^3), and the pH of the solution was adjusted to 9 with NaOH. To this solution were added $[CoBr(NH_3)_5]Br_2$ (1.8 g, 4.6 mmol) and active charcoal (0.5 g). The mixture was stirred for 10 h at 50 °C, filtered off in hot to remove the charcoal, and the residue was washed with hot water. The resulting orange filtrate was then diluted with 1 dm^3 of water and poured on SP-Sephadex. The complex adsorbed on SP-Sephadex was found to be pure Δ-$[Co(RR\text{-ptn})_3]^{3+}$ by an SP-Sephadex column chromatography using a 0.2 M aqueous Na_2SO_4 solution as the eluent. The complex was isolated as various salts by the following methods.

(−)$_{546}$-Δ-[Co(RR-ptn)$_3$](ClO$_4$)$_3\cdot 3H_2O$. The complex adsorbed on SP-Sephadex was eluted with a 1.0 M $NaClO_4$ solution. The effluent was concentrated at 40 °C under reduced pressure to give orange needle crystals. They were filtered off, and recrystallized from water.

(−)$_{546}$-Δ-[Co(RR-ptn)$_3$]Cl$_3\cdot 2.5H_2O$. The complex was eluted similarly with 0.5 M HCl. Orange needle crystals were obtained by evaporating the effluent to almost dryness in a vacuum desiccator over NaOH and P_2O_5. They were recrystallized from a small amount of water by the addition of concd HCl.

(−)$_{546}$-Δ-[Co(RR-ptn)$_3$]Br$_3\cdot 2H_2O$. This complex was obtained by converting the perchlorate into bromide with the anion exchanger, Dowex 1×8, in the bromide form and recrystallized from water.

(−)$_{546}$-Δ-[Co(RR-ptn)$_3$]I$_3$. This complex was obtained by adding a NaI solution to an aqueous solution of the perchlorate. Orange crystals were filtered off, washed with cold water and recrystallized from ethanol.

(+)$_{546}$-Λ-tris[(RR)-2,4-pentanediamine)]cobalt(III) Complex. The preparative method reported by Mizukami *et al.*[9] was modified as follows. A suspension of *RR*-ptn·2HCl (0.256 g, 1.46 mmol) and sodium methoxide (0.158 g, 2.92 mmol) in methanol (5 cm^3) was added to a solution of *trans*-$[CoCl_2(RR\text{-ptn})_2]Cl$[9] (0.54 g, 1.46 mmol) in DMSO (20 cm^3). The reaction took place immediately to give a brown solution.

It was then diluted with about 1 dm^3 of water and passed through an SP-Sephadex column (ϕ 2.7×5 cm). A small portion of the Sephadex saturated with the product was poured on the top of an SP-Sephadex column (ϕ 2.7×120 cm), and the adsorbed complexes were eluted with a 0.2 M aqueous solution of Na_2SO_4. Two separate bands were obtained. The first and the second were *Δ*- and *Λ*-[Co(*RR*-ptn)$_3$]$^{3+}$, respectively. The formation ratio of the former to the latter was 10: 1. The effluent containing the *Λ*-isomer was poured again on an SP-Sephadex column (ϕ 1.5×3 cm) after dilution with water and the adsorbed complex was eluted by the following method.

*(+)$_{546}$-Λ-[Co(*RR*-ptn)$_3$](ClO$_4$)$_3$.* This complex was obtained from the SP-Sephadex adsorbed the *Λ*-isomer in a similar way to that for *Δ*-[Co(*RR*-ptn)$_3$](ClO$_4$)$_3$·3H$_2$O.

*(+)$_{546}$-Λ-[Co(*RR*-ptn)$_3$]Cl$_3$·3H$_2$O.* An aqueous solution of the complex perchlorate was passed through a column containing the anion exchanger, Dowex 1×8, in the chloride form to convert into the chloride. Needle crystals were obtained by evaporating the effluent to almost dryness in a vacuum desiccator over P_2O_5.

trans, *(+)$_{470}$*-cis-*Δ*-, *and (−)$_{470}$*-cis-*Λ*-*diamminebis[(RR)-2,4-pentanediamine]cobalt(III) Complexes.* To a solution of sodium methoxide (0.227 g, 4.2 mmol) in methanol (3 cm^3) was added *RR*-ptn·2HCl (0.45 g, 2.6 mmol) with stirring, and the mixture was filtered to remove NaCl. The filtrate was added to a solution of [Co(H$_2$O)(NH$_3$)$_5$](ClO$_4$)$_3$ (1 g, 2.2 mmol) in DMSO (20 cm^3). The solution was stirred for 25 min at 85 °C, diluted with 1 dm^3 of water and acidified (pH≈3) with HCl. This was poured on SP-Sephadex, and the adsorbed complexes were chromatographed by a method similar to that for [Co(*RR*-ptn)$_3$]$^{3+}$ with a 0.2 M aqueous Na_2SO_4 solution. The column gave three separate bands, I, II, and III in the order of elution, which were [Co(NH$_3$)$_6$]$^{3+}$, [Co(NH$_3$)$_4$(*RR*-ptn)]$^{3+}$, and a mixture of three isomers of [Co(NH$_3$)$_2$ (*RR*-ptn)$_2$]$^{3+}$, respectively. The effluent of the band III was reloaded on an SP-Sephadex column after dilution with water, and the adsorbed band was eluted with a 0.18 M sodium (+)$_{589}$-tartratoantimonate(III) solution. Two separate bands, III$_A$ and III$_B$ were eluted in this order. The band III$_B$ was (+)$_{470}$-*cis*-*Δ*-[Co(NH$_3$)$_2$(*RR*-ptn)$_2$]$^{3+}$, but the band III$_A$ was still a mixture of *trans*- and (−)$_{470}$-*cis*-*Λ*-[Co(NH$_3$)$_2$(*RR*-ptn)$_2$]$^{3+}$. However, these two isomers were successfully separated by a repeated SP-Sephadex column chromatography using a 0.2 M Na_2SO_4 solution as the eluent. The *trans*-isomer(III$_A$-1) moved faster than did the (−)$_{470}$-*cis*-*Λ*-isomer(III$_A$-2). The formation ratio, *trans*: *cis*-*Λ*: *cis*-*Δ* was about 1: 1: 20.

trans-[*Co(NH$_3$)$_2$(RR-ptn)$_2$](ClO$_4$)$_3$·H$_2$O*, *(+)$_{470}$*-cis-*Δ*- *and (−)$_{470}$*-cis-*Λ*-[*Co(NH$_3$)$_2$(RR-ptn)$_2$](ClO$_4$)$_3$*. These complexes were obtained from each separated eluate described above by a method similar to that for *Δ*-[Co(*RR*-ptn)$_3$](ClO$_4$)$_3$·3H$_2$O using 1.0 M HClO$_4$ as the eluent. The effluent was concentrated to a small volume with a rotary evaporator under a reduced pressure. Orange crystals which formed were filtered off and washed with ethanol.

(+)$_{470}$-cis-*Δ*-[*Co(NH$_3$)$_2$(RR-ptn)$_2$]Cl$_3$·1.5H$_2$O.* This complex was obtained by a method similar to that for *Δ*-[Co(*RR*-ptn)$_3$]Cl$_3$·2.5H$_2$O.

[*Co(NH$_3$)$_4$(RR-ptn)]Cl$_3$ and [Co(NH$_3$)$_4$(RR-ptn)](ClO$_4$)$_3$·H$_2$O.* These complexes were isolated from the reaction product of [Co(H$_2$O)(NH$_3$)$_5$](ClO$_4$)$_3$ and *RR*-ptn in DMSO described before and crystallized by methods similar to those for the chloride and the perchlorate salts of *Λ*-[Co(*RR*-ptn)$_3$]$^{3+}$.

(−)$_{589}$-Λ-Tris(trimethylenediamine)cobalt(III) Perchlorate The racemic complex was prepared by the method of Bailar and Works[10] and resolved by the method of Fujita *et al.*[11] The *Λ*-isomer was isolated as the perchlorate salt by a method similar to that for *Δ*-[Co(*RR*-ptn)$_3$] (ClO$_4$)$_3$·3H$_2$O.

Table 1 shows the results of chemical analyses of all the complexes obtained.

Measurements. Absorption spectra were obtained on a Hitachi 323 and a Carl Zeiss PMQ-II spectrophotometer, and CD spectra on a JASCO model J-20 spectropolarimeter. CD spectra in Nujol mulls were measured by a method simliar to that used for IR measurement with two quartz plates. PMR spectra were recorded in D_2O at 60 MHz on a JEOL PMX-60 spectrometer taking HOD signal as the internal reference. FT ^{13}C NMR spectra were obtained in D_2O at 15.04 MHz on a JEOL FX-60 spectrometer using dioxane as the internal reference, the chemical shift of which is at 67.69 ppm downfield from TMS sealed in an external capillary.

Results and Discussion

Preparation and Characterization of the Complexes. Mizukami *et al.*[9] prepared first a pair of diastereomers, (+)$_{546}$- and (−)$_{546}$-[Co(*RR*-ptn)$_3$]$^{3+}$ by the reactions of *trans*-[CoCl$_2$(*RR*-ptn)$_2$]$^+$ with *RR*-ptn in 50% aqueous methanol in the absence of active charcoal, and in water in the presence of active charcoal, respectively. In the

present study, these two isomers are formed by the same reaction in DMSO without the addition of active charcoal at room temperature, and separated by SP-Sephadex column-chromatography with a 0.2 M Na_2SO_4 solution as the eluent. On the other hand, the reaction of $[CoBr(NH_3)_5]Br_2$ with *RR*-ptn in water in the presence of active charcoal gives only the $(-)_{546}$-isomer. It is known that the $(+)_{546}$- and the $(-)_{546}$-isomers have $\Lambda(ob_3)$[3] and $\Delta(lel_3)$[2] configurations, respectively, all the *RR*-ptn chelate rings taking *λ-skew-(twist)* conformation. Niketic and Woldbye[12] showed by the conformational analysis that the $(+)_{546}$-$\Lambda(ob_3)$ isomer is about 18.8 kJ·mol^{-1} less stable than the $(-)_{546}$-$\Delta(lel_3)$ isomer. This value implies that the complexes formed under an equilibrium condition are almost all (>99.9%) the $\Delta(lel_3)$ isomer. The fact that only the $\Delta(lel_3)$ isomer is formed stereoselectively in the presence of active charcoal agrees well with this implication. The formation of the $(+)_{546}$-$\Lambda(ob_3)$ isomer in the absence of active charcoal may be related with a kinetic route to form $[Co(RR\text{-ptn})_3]^{3+}$ in the reaction between *trans*-$[CoCl_2(RR\text{-ptn})_2]^+$ and *RR*-ptn.

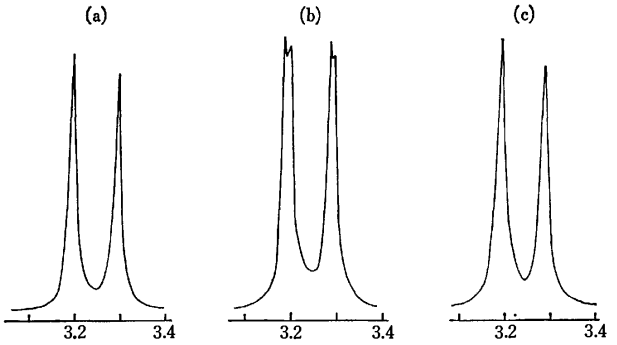

Fig. 1. PMR spectra of methyl signals of the isomers (a) III_A-1(*trans*), (b) III_A-2(*cis*)-Λ, and (c) III_B(*cis*-Λ) in D_2O.
Chemical shifts in ppm from HOD signal.

The complex, $[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ exists in three isomers, *trans*, *cis*-Δ, and *cis*-Λ configurations, all of which have been obtained. Figure 1 shows the PMR spectra of these three isomers in D_2O at 60 MHz. The *trans*(D_2 symmetry) and the *cis*(C_2 symmetry) isomers are expected to show one and two kinds of doublet signal due to the methyl protons, respectively. The III_A-2 isomer exhibits two kinds of doublet in the methyl signal region and is assigned safely to the *cis* configuration. However, each isomer of the other two(III_A-1 and III_B) gives only one doublet methyl signal. To distinguish them ^{13}C-NMR spectroscopy has been utilized. As Fig. 2 shows, the III_A-1 isomer gives only one kind of signal for each resonance of the methyl, the methylene, and the methine carbons, while the III_B isomer two, one, and two signals for the corresponding carbons, respectively. The III_A-2 isomer exhibits the same spectral pattern as that of the isomer III_B. Thus, all of the NMR data lead to the conclusion that the III_A-1, the III_A-2, and the III_B isomers are *trans*, *cis*, and *cis* configurations, respectively. For the two *cis* III_A-2 and III_B isomers, the $\Lambda(ob_2)$ and $\Delta(lel_2)$ configurations are assigned, respectively on the basis of their CD patterns in the region of the first absorption band, as shown in Figs. 3 and 4. These assignments will be supported by the fact that the formation ratio of the $\Lambda(ob_2)$ to the $\Delta(lel_2)$ isomer is 1: 20 as described in the Experimental part, since the yield of one diastereomer

involving more steric interactions is expected to be lower than that of the other.[13] Molecular models indicate that the *Λ*(*ob*$_2$) structure involves such interactions to a greater extent than the *Δ*(*lel*$_2$) structure. The assignments for these three isomers of the diammine complex agree with those made by Boucher and Bosnich.[7]

The *cis*-*Λ*(*ob*$_2$) isomer gives the first absorption band at a longer wavelength (482 nm) than does the *cis*-*Δ*(*lel*$_2$) isomer (480 nm). These results agree with the observations reported by Mizukami *et al.*[9] that in a pair of diastereomers, the d-d absorption bands of the one involving more steric interactions lie at a longer wavelength than those of the other. For [Co(*RR*-ptn)$_3$]$^{3+}$, the first absorption band of the *Λ*(*ob*$_3$) isomer is at a longer wavelength side by 6 nm than that of the *Δ*(*lel*$_3$) isomer, as shown in Table 2.

Circular Dichroism Spectra. As stated previously, the solution CD spectra of *Λ*-[Co(*RR*-ptn)$_3$]$^{3+}$ in the region of the first absorption band are seriously affected by its counter ion. Figure 5 and Table 2 show the CD data of various salts of this complex ion in water. The positive CD component at a shorter wavelength side of the first absorption band, which has been assigned to the $^1A_2\leftarrow{}^1A_1$ transition (D_3 symmetry) based on the analysis of the solid state CD spectrum of the chloride,[14] increases the magnitude in the order of perchlorate< iodide<bromide<chloride. The absorption spectra are all nearly identical with one another in this region. Since all the anions have uni-negative charge and the sizes of ions decrease in this order, such CD changes are suggested to be correlated with ion-pair formation between the complex cation and anions. Figure 6 shows dependence of the CD spectra of *Λ*-[Co(*RR*-

ptn)$_3$]$^{3+}$ on the concentration of chloride ion. The measurements were carried out at 25 °C, and at the ionic strength of 0.091 adjusted with $NaClO_4$, and using a 2.8 mM aqueous solution of the complex perchlorate. The CD spectrum of this perchlorate was little affected by the addition of $NaClO_4$ up to its 0.5 M concentration. From the change of CD strengths at 475 nm, association constant, K=13.8 was obtained by the method of Tanaka *et al.*[15] for the following equilibrium; Δ-[Co(*RR*-ptn)$_3$]$^{3+}$ + Cl$^-$ $\rightleftarrows$ Δ-[Co(*RR*-ptn)$_3$]$^{3+}$·Cl$^-$. On the other

hand, the constant K determined from the absorbancies[15] at 290 nm was 12.6 for the same equilibrium system. That the two K values obtained by both the CD and the UV methods are nearly the same strongly suggests that the CD variation of Δ-[Co(*RR*-ptn)$_3$]$^{3+}$ in the region of the first absorption band is brought about by ion-pair formation between the complex ion and counter ions. A further evidence to support this suggestion is that the CD spectra of the complex chloride in aqueous solutions depend clearly on its concentration as shown in Fig. 7. Figure 6 includes the calculated CD curve of the ion-paired species, Δ-[Co(*RR*-ptn)$_3$]$^{3+}\cdot$Cl$^-$ (K=13.8). The A_2 component is considerably enhanced and the sign of the so-called main CD band is reversed.

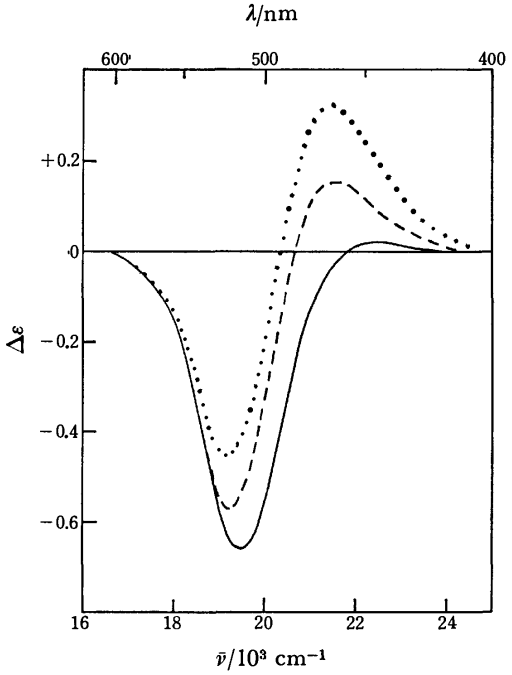

Fig. 7. Dependence of CD of Δ-[Co(*RR*-ptn)$_3$]Cl$_3\cdot$2.5 H$_2$O on its concentration in water; 1.76×10^{-4}M (——), 3.90×10^{-3} M(——), and 1.71×10^{-2} (·····).

The effect of sulfate ion on the CD spectrum of Δ-[Co(*RR*-ptn)$_3$]$^{3+}$ is very similar to that of chloride ion and the CD curve of the ion-paired species, Δ-[Co(*RR*-ptn)$_3$]$^{3+}\cdot$SO$_4^{2-}$ closely resembles that of the Δ-[Co(*RR*-ptn)$_3$]$^{3+}\cdot$Cl$^-$ (Fig. 8). The association constant K of the complex ion with a sulfate ion was determined to be 61.7 by the CD method under the same condition as that measured for chloride ion. This value and 13.8 (or 12.6) in the case of chloride ion may be reasonable for the constants of ion-pair formation in the systems of ions of a tripositive-dinegative and a tripositive-uninegative, respectively.[15,16] Thus, the CD pattern of Δ-[Co(*RR*-ptn)$_3$]$^{3+}$ in the region of the first absorption band seems to be affected in a similar manner by ion-pair formation with counter anions irrespective of their kinds.

The ion-pair formation should be facilitated in an organic solvent to a greater extent than in an aqueous solution. Figure 9 shows the CD spectra of Δ-[Co(*RR*-ptn)$_3$]Br$_3\cdot$2H$_2$O in DMSO at various concentrations. The spectra give strong A_2 components without the addition of excessive bromide ion and depend clearly

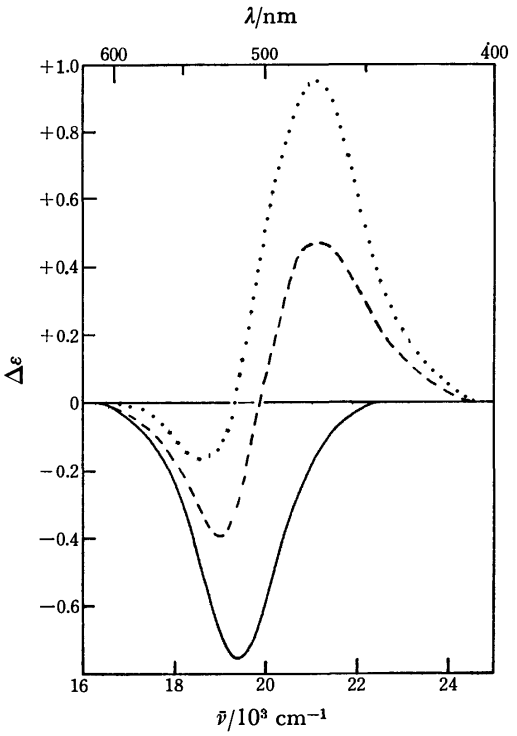

Fig. 8. CD spectra of Δ-[Co(*RR*-ptn)$_3$](ClO$_4$)$_3\cdot$3H$_2$O(3.45 $\times10^{-3}$ M) in water(——) and in 0.1 M Na$_2$SO$_4$(——). Calculated CD curve of the ion-paired species, Δ-[Co(*RR*-ptn)$_3$]$^{3+}\cdot$SO$_4^{2-}$(·····).

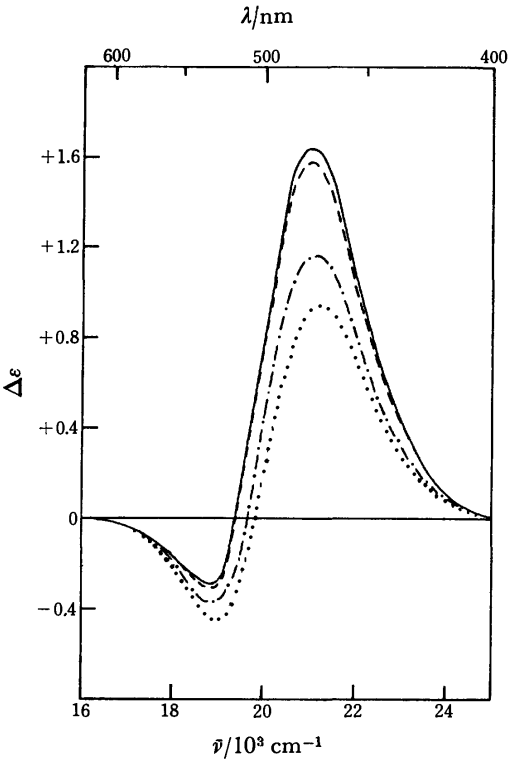

Fig. 9. CD spectra of Δ-[Co(*RR*-ptn)$_3$]Br$_3\cdot$2H$_2$O in DMSO; 4.52×10^{-5} M (·····), 2.09×10^{-4} M(-·-·-), 1.93×10^{-3} M(----), and 9.33×10^{-3} M(——).

on the concentration of the complex. The complex chloride in DMSO gives a CD pattern very similar to that of the ion-paired species shown in Fig. 6 even at a very dilute solution (6.13×10^{-5} M). With increase in the concentration of the complex chloride, both CD components, the A_2 and the E, increase their strengths. Since the association constant between the complex cation and a chloride ion is expected to be larger than that between the complex ion and a bromide ion, this might be attributed to the formation of higher ion-paired species, 1 : 2 or 1 : 3 than 1 : 1. The complex perchlorate in DMSO exhibits a marked A_2 component which is never observed in an aqueous solution, but shows no dependence on the concentration of the complex in the range between 9.75×10^{-3} and 7.05×10^{-5} M. The reason for this is not clear at present, but it is clear that a perchlorate ion is weak in ability to form an ion-pair with the complex ion in DMSO.

In marked contrast to the large variety of solution CD spectra of $\Delta(lel_3)$-[Co(*RR*-ptn)$_3$]$^{3+}$, the CD spectra of $\Lambda(ob_3)$-[Co(*RR*-ptn)$_3$]$^{3+}$ show little solvent dependence in the region of the first absorption band. As Fig. 10 shows, the CD patterns of the latter isomer are nearly the same in water, 0.2 M Na_2SO_4, and DMSO solutions, although the spectrum in the last solution gives a small negative CD band at a longer wavelength side.

It is known that the polarizable oxoanions such as phosphate and selenite have a marked effect on the CD spectra of some tris(diamine)cobalt(III) complexes. The CD spectrum of Δ(or Λ)-[Co(tn)$_3$]$^{3+}$(tn: trimethylenediamine) is particularly sensitive to the excessive presence of these oxoanions.[17,18] Figure 11 shows that a chloride ion affects also the CD of Λ-[Co(tn)$_3$]$^{3+}$ in a similar way, giving rise to the increase in the major negative CD band(A_2) at the expense of the minor positive CD band(E). Beddoe and Mason[17,19] found that the CD spectra of Δ-[Co(tn)$_3$]$^{3+}$ in the presence of phosphate or selenite resemble that of the solid Δ-[Co(tn)$_3$]$Br_3\cdot H_2O$ in a KBr disk. Since all the tn chelates in the crystals adopt the chair conformation,[20] they suggested that on the addition of oxoanions, [Co(tn)$_3$]$^{3+}$ in an aqueous solution is stabilized to have the tris-*chair* conformation by ion-pair formation (Fig. 12). However, CD spectra in KBr disks should be viewed with some caution for such conformationally labile complexes as [Co(tn)$_3$]$^{3+}$, because these spectra depend often on the condition such as pressure and its duration time employed for the preparation of KBr disk. In fact, Λ-[Co(tn)$_3$]$Br_3\cdot H_2O$ in Nujol mull exhibits no detectable CD in the region of the first absorption band, indicating that the tris-*chair* form has substantially very small CD. Furthermore, molecular models indicate that either the tris-*chair* or the ob_3 conformation ($\Delta(\delta\delta\delta)$ and $\Lambda(\lambda\lambda\lambda)$) of [Co(tn)$_3$]$^{3+}$ has no set of N-H bonds parallel to the C_3 axis of the complex ion to form an ion-pair most effectively with the oxoanion through

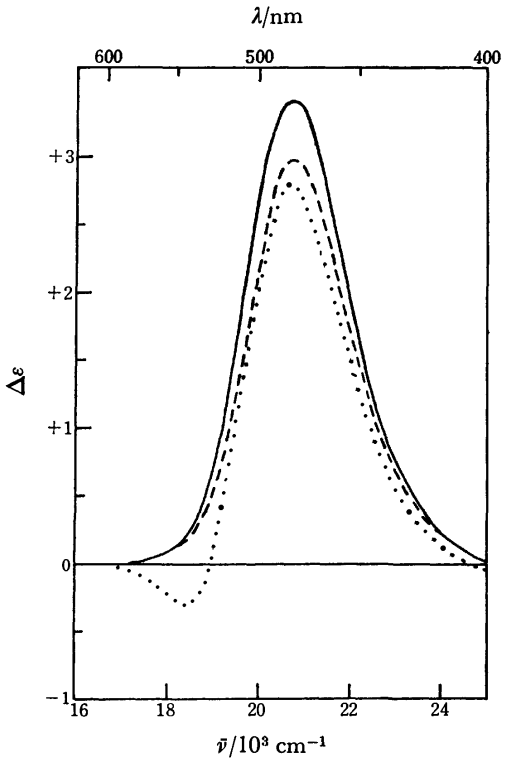

Fig. 10. CD spectra of Λ-[Co(*RR*-ptn)$_3$](ClO$_4$)$_3$; 2.88×10^{-3} M in water (——), 2.88×10^{-3} M in 0.2 M Na_2SO_4 (——), and 1.81×10^{-3} M in DMSO(·····).

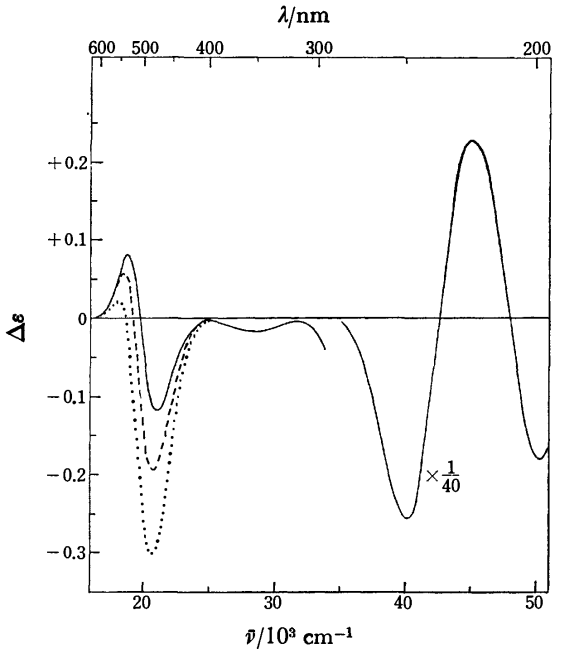

Fig. 11. CD spectra of Λ-[Co(tn)$_3$](ClO$_4$)$_3$(5.68×10^{-3} M in visible region and 2.27×10^{-4} M in UV region) in water(——), in 1 M NaCl(——), and in 0.2 M Na_2SO_4 (·····).

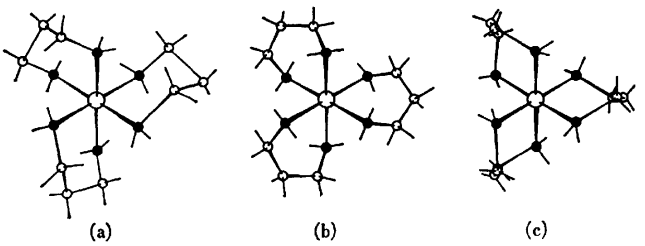

Fig. 12. Schematic structures of tris(trimethylenediamine)cobalt(III) complexes; (a) $\Lambda(chair_3)$, (b) $\Lambda(ob_3, \lambda\lambda\lambda)$, and (c) $\Lambda(lel_3,\delta\delta\delta)$.

hydrogen bonding, while that only the lel_3 conformation ($\Delta(\lambda\lambda\lambda)$ and $\Lambda(\delta\delta\delta)$) has a set of three N–H bonds suitable for forming such hydrogen bonds with the oxoanion.[21] This suggests that the conformer stabilized by ion-pair formation is not the tris-*chair* proposed by Beddoe *et al.*,[19] but the lel_3 conformation. Then, the increase in the magnitude of the negative CD band of Λ-$[Co(tn)_3]^{3+}$ in the presence of excessive anions can be attributed to the contribution of the vicinal effect of the *δ-skew* chelate rings in the lel_3-$\Lambda(\delta\delta\delta)$ conformer stabilized by ion-pair formation (Fig. 11). It is known that the vicinal effect due to a chiral chelate ring in *δ* form gives negative CD in the region of the first absorption band and that the vicinal and the configurational effect contribute additively to the CD in this region.[22] The addition of other anions such as a chloride ion than the oxoanions may result in a similar stabilization of the lel_3 form, since the effect of chloride ion on the CD spectrum of $[Co(tn)_3]^{3+}$ quite resembles that of sulfate ion. Thus the CD variation of $[Co(tn)_3]^{3+}$ on the addition of anions can resonably be explained by the stabilization of the lel_3 conformer due to ion-pair formation and by the contribution of the vicinal effect due to the chiral, skew tn chelate rings in this conformer. The interconversion between the tris-*chair* and the lel_3 conformation seems to occur easily in solution, since the energy difference between them has been calculated to be very small.[23] The ob_3 conformation has been shown to have a substantially higher energy.[23]

A similar discussion can be made on the CD variation of $[Co(RR\text{-ptn})_3]^{3+}$ in solution. As stated previously, the *RR*-ptn chelate ring has been shown to prefer to take the *chair* conformation with one axial methyl group rather than the *skew* conformation in solution, although those in the crystals of $\Delta(lel_3)$-[2] and $\Lambda(ob_3)$-$[Co(RR\text{-ptn})_3]Cl_3\cdot nH_2O$[3] are all in the *λ-skew* conformation with two equatorial methyl groups. As molecular models (Fig. 12) show, $\Delta(lel_3)[Co(RR\text{-ptn})_3]^{3+}$ has much less crowded structure than $\Lambda(ob_3)[Co(RR\text{-ptn})_3]^{3+}$ and the chelate rings in the former seem to be able to convert their conformations without difficulty into others, the *chair* or some intermediate conformations between the *λ-skew* and the *chair*. On the other hand, the more crowded $\Lambda(ob_3)$-isomer seems to have too rigid a structure to change the conformation.

If it is assumed that the conformations of Δ-$[Co(RR\text{-ptn})_3]^{3+}$ in an aqueous solution are in an equilibrium among the tris-*skew* and some others involving the *chair* conformation, the CD variation on the addition of anions can be explained by the same ion-pair effect as that described for $[Co(tn)_3]^{3+}$; on the addition of anions the $\Delta(lel_3, \lambda\lambda\lambda)$ conformer is stabilized by ion-pair formation and the positive CD component in the region of the first absorption band is strengthened by the contribution of the vicinal effect due to the increasing amount of the *λ-skew* chelate ring (Figs. 6 and 8). This explanation will be supported by the fact that the CD spectrum of $\Delta(lel_3, \lambda\lambda\lambda)$-$[Co(RR\text{-ptn})_3]Cl_3\cdot 2.5H_2O$ in Nujol mull shows a pattern very similar to that of the ion-paired species.

The small CD variation of $\Lambda(ob_3)$-$[Co(RR\text{-ptn})_3]^{3+}$ on the addition of anions may be due to the conformational rigidity resulted from the crowded and strained structure. Although this isomer will be thermodynamically much unstable than the $\Delta(lel_3)$-isomer[12] as stated previously, the $\Lambda(ob_3)$-isomer seems to be stable from the viewpoint of conformational lability.

The same difference in the CD variation on the addition of anions is seen between *cis*-$\Delta(lel_2)$- and *cis*-$\Lambda(ob_2)$-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$. As Figs. 3 and 4 show, the positive CD band of the *cis*-$\Delta(lel_2)$ isomer in the region of the first absorption band gives rise to a pronounced increase in the presence of sulfate ion, while the CD change of the *cis*-$\Lambda(ob_2)$ isomer is negligible under the same condition. The CD spectrum of the chloride of *cis*-$\Delta(lel_2)$ isomer in the region of the first absorption band also differs from that of the perchlorate in an aqueous solution, as shown in Table 2. The structures of *cis*-$\Delta(lel_2)$- and $\Lambda(ob_2)$-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ may be compared to those of $\Delta(lel_3)$- and $\Lambda(ob_3)$-$[Co(RR\text{-ptn})_3]^{3+}$, respectively, and the *RR*-ptn chelate rings in the *cis*-$\Delta(lel_2)$ isomer are expected to be more conformationally flexible than those in the more crowded *cis*-$\Lambda(ob_2)$ isomer. Thus, on the addition of sulfate ion the $\Delta(lel_2)$ isomer is stabilized by forming an ion-pair in a mechanism similar to that described for $\Delta(lel_3)$-$[Co(RR\text{-ptn})_3]^{3+}$. A set of three N–H bonds suitable for hydrogen bonding may be provided by two *RR*-ptn and one ammonia ligands in the complex. The $\Lambda(ob_2)$ isomer which is insensitive to the ion-pair effect seems to have a rigid structure similar to that of $\Lambda(ob_3)$-$[Co(RR\text{-ptn})_3]^{3+}$, although the crowded structure of $\Lambda(ob_2)$ isomer might be reduced to some extent by coordinating two ammonia molecules in place of a bulky bidentate *RR*-ptn.

The CD spectra of *trans*-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ in water, 0.2 M Na_2SO_4, and DMSO solutions show small variations in the region of the first absorption band, giving rise to an increase and a decrease in the magnitudes of the positive and the negative CD bands, respectively in the latter two solutions (Fig. 13). The $[Co(NH_3)_4(RR\text{-ptn})]^{3+}$ ion exhibits similar small variations, as shown in Fig. 14. Thus, the observed CD variations are rather small, although the tendency to increase the magnitude of the positive CD band in 0.2 M Na_2SO_4 and DMSO solutions is consistent with that observed for Δ-$[Co(RR\text{-ptn})_3]^{3+}$ and *cis*-Δ-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$. The *RR*-ptn chelate rings in *trans*-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ and $[Co(NH_3)_4(RR\text{-ptn})]^{3+}$ seem to be more flexible than those in the more crowded *tris*- and *cis*-bis(*RR*-ptn) complexes. Furthermore, the ability to form ion-pairs between the present series of complexes, $[Co(NH_3)_{2n}(RR\text{-ptn})_{3-n}]^{3+}$ and sulfate ions will not differ greatly from one another.[15] However, molecular models seem to indicate that *trans*-$[Co(NH_3)_2(RR\text{-ptn})_2]^{3+}$ can not provide a set of three N–H bonds to form effective hydrogen bonds with a sulfate ion without distorting the *λ-skew* conformation of the *RR*-ptn chelate ring. On the other hand, $[Co(NH_3)_4(RR\text{-ptn})]^{3+}$ can have such a set of N–H bonds provided by two ammonia molecules and one *RR*-ptn chelate in the *λ-skew* conformation, but similar two sets of three N–H bonds can also be formed by the three ammonia ligands in the facial positions without the participation of the *RR*-ptn. An ion-pair may also be formed by hydrogen

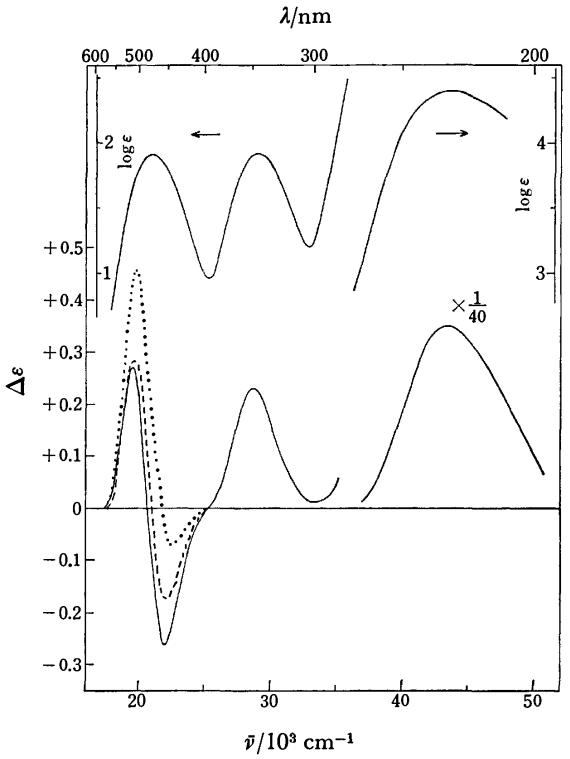

Fig. 13. Absorption and CD spectra of *trans*-$[Co(NH_3)_2(RR\text{-ptn})_2](ClO_4)_3 \cdot H_2O$; 3.12×10^{-3}M in visible region and 1.25×10^{-4} M in UV region in water (——), 3.12×10^{-3} M in 0.2 M Na_2SO_4(----), and 2.59×10^{-3} M in DMSO(·····).

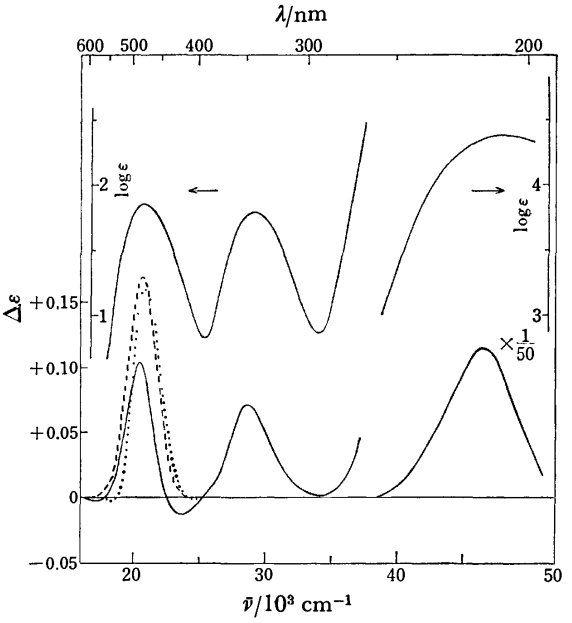

Fig. 14. Absorption and CD spectra of $[Co(NH_3)_4(RR\text{-ptn})](ClO_4)_3 \cdot H_2O$; 7.77×10^{-3} M in 0.1 M in visible region and 7.06×10^{-4} M in UV region in water(——), 7.77×10^{-3} M in 0.1 M Na_2SO_4(----), and 4.59×10^{-3} M in DMSO(·····).

bonding between such N–H bonds provided by three ammonia ligands and a sulfate ion. In this case, the *λ-skew* conformation of the *RR*-ptn chelate ring will not be stabilized by the ion-pair formation.

Other proposals[24,25] have been put forth in an attempt to rationalize the effect of electrolyte on the CD spectra in the region of the first absorption band of tris(diamine)-cobalt(III) complexes. However, so far as complexes containing puckerd six-membered chelate rings are concerned, a conformational change of the chelate ring seems to play the most important role in determining a pattern of CD bands in the region of the first absorption band. Such a conformational change may also account for the lack of the additivity of the vicinal (conformational) and the configurational contributions to the CD of these six-membered chelate complexes.[7,9]

The authors wish to thank Dr. Yuzo Yoshikawa of Nagoya University for measuring ^{13}C-NMR spectra.

Palladium(II) Complexes of 2,2,6,6-Tetramethylpiperidine *N*-Oxyl Radical

Masaaki OKUNAKA, Gen-etsu MATSUBAYASHI, and Toshio TANAKA

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-kami, Suita, Osaka 565

(Received November 9, 1976)

2,2,6,6-Tetramethylpiperidine *N*-oxyl radical $(CH_3)_4C_5H_6NO\cdot$ (TMPNO·) reacts with palladium dichloride to give complexes of both anionic and cationic TMPNO; $[PdCl(TMPNO)]_2$ (I) and $[TMPNO^+]_2[Pd_2Cl_6]^{2-}$ (II). I further reacts with dimethylsulfonium phenacylide or triphenylphosphine (L) to afford a mononuclear complex of the PdCl(TMPNO)(L) type. II undergoes a facile reaction with acetone to yield bis(*N*-acetonyl-*N*-hydroxy-2,2,6,6-tetramethylpiperidinium)hexachlorodipalladate, $[(CH_3)_4C_5H_6\overset{+}{N}(OH)CH_2COCH_3]_2[Pd_2Cl_6]^{2-}$. Configurations of these complexes are described.

Di-*t*-butyl nitroxide radical (DTBNO·) reacts with palladium dichloride to give a diamagnetic dipalladium complex, $[PdCl(DTBNO)]_2$, involving the $DTBNO^-$ anion.[1] This is in contrast with other metal complexes of DTBNO·, in which the nitroxide coordinates to the metal as a neutral radical through the oxygen atom.[2-7] 2,2,6,6-Tetramethylpiperidine *N*-oxyl radical (TMPNO·) is also known to coordinate to several metal ions through the oxygen atom.[4-7] In addition, this radical reacts with tin(IV) halides to afford stable hexahalogenostannate(IV) complexes containing the $TMPNO^+$ cation.[8] Marked stabilities of the TMPNO· radical and its cation have been demonstrated by the electrochemical study.[9] Thus, no metal complex containing the $TMPNO^-$ anion has been isolated so far. This paper reports the isolation and configuration of some palladium(II) complexes of the $TMPNO^-$ anion as well as the $TMPNO^+$ cation; $[PdCl(TMPNO)]_2$, PdCl(TMPNO)(L) (L=dimethylsulfonium phenacylide, triphenylphosphine), and $[TMPNO^+]_2[Pd_2Cl_6]^{2-}$. It is also described that the latter compound easily reacts with acetone, giving bis(*N*-acetonyl-*N*-hydroxy-2,2,6,6-tetramethylpiperidinium) hexachlorodipalladate, $[(CH_3)_4C_5H_6\overset{+}{N}(OH)CH_2COCH_3]_2[Pd_2Cl_6]^{2-}$.

Experimental

Materials. The TMPNO·radical,[8] $(CH_3)_4C_5H_6NO\cdot$, and dimethylsulfonium phenacylide,[10] $Me_2\overset{+}{S}\overset{-}{C}HCOPh$, were prepared as described in the literatures.

Isolation of $[PdCl(TMPNO)]_2$ (I), $[TMPNO^+]_2[Pd_2Cl_6]^{2-}\cdot 2CH_3CN$ (II), and $[(CH_3)_4C_5H_6\overset{+}{N}(OH)CH_2COCH_3]_2[Pd_2Cl_6]^{2-}$ (III). A suspension of $PdCl_2$ (1.77 g, 10.0 mmol) in a dichloromethane solution (2 ml) of TMPNO· (2.34 g, 15.0 mmol) was stirred for 72 h at room temperature, followed by evaporation to dryness under reduced pressure. The resulting product was washed with diethyl ether several times to remove the unreacted radical. The solid (3.01 g) thus obtained was dissolved in dichloromethane (100 ml) in order to separate a soluble product from an insoluble one (1.44 g). To the dichloromethane solution was added ethanol (20 ml). The mixture was evaporated to about one-fifth volume under reduced pressure to give reddish brown crystals (0.31 g), mp 160—162 °C, whose elemental analysis agreed well with the composition of PdCl (TMPNO)·0.1$PdCl_2$, although this compound has not been further studied. Further evaporation of the residual solution to about a half volume yielded dark red crystals of I (0.14 g, 0.23 mmol, 9% yield), mp 151—154 °C. Found: C, 36.28; H, 6.25; N, 4.77%; mol wt, 622. Calcd for $C_9H_{18}NOClPd$: C, 36.26; H, 6.09; N, 4.70%; mol wt, 298.

The insoluble product in dichloromethane was recrystallized from a mixture of acetonitrile and diethyl ether to give brown crystals of II (1.12 g, 1.36 mmol, 55% yield), mp 94—96 °C. Found: C, 32.06; H, 5.25; N, 6.71%. Calcd for $C_9H_{18}NOCl_3Pd\cdot CH_3CN$: C, 32.21; H, 5.16; N, 6.83%. II (1.00 g, 1.22 mmol) was dissolved in acetone (20 ml), followed by the addition of diethyl ether (10 ml) to develop dark red crystals of III (0.58 g, 0.68 mmol, 56% yield), mp 164—166 °C. Found: C, 33.56; H, 5.90; N, 3.31%. Calcd for $C_{12}H_{24}NO_2Cl_3Pd$: C, 33.74; H, 5.66; N, 3.28%.

Isolation of PdCl(TMPNO)(L) (L=$Me_2\overset{+}{S}\overset{-}{C}HCOPh$ (IV) and PPh_3 (V)). To a dichloromethane (5 ml) solution of I (0.15 g, 0.5 mmol) was added dimethylsulfonium phenacylide (0.09 g, 0.5 mmol) in dichloromethane (5 ml). The mixture was stirred for 10 min at room temperature, and evaporated to dryness under reduced pressure. The resulting product was recrystallized from benzene–petroleum ether to give orange crystals of IV (0.14 g, 0.29 mmol, 59% yield), mp>145 °C (dec). Found: C, 46.99; H, 6.14; N, 2.60%; mol wt, 466. Calcd for $C_{19}H_{30}NO_2SClPd$: C, 47.70; H, 6.32; N, 2.93%; mol wt, 478. Orange crystals of V were similarly prepared by the reaction of I with triphenylphosphine, and recrystallized from benzene–petroleum ether (65% yield), mp >150 °C (dec). Found: C, 58.18; H, 5.97; N, 2.36%; mol wt, 553. Calcd for $C_{27}H_{33}NOPClPd$: C, 57.87; H, 5.93; N, 2.50%; mol wt, 560.

Physical measurements. Infrared and ^1H NMR spectra were recorded as described previously.[8,11] Molecular weight determinations were carried out in dichlomethane using a vapor pressure osmometer. Electric conductivities were measured at 25 °C as described elsewhere.[12]

Results and Discussion

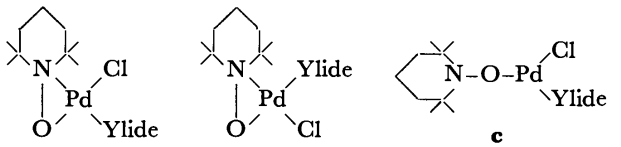
Molecular weight determinations indicate that both IV and V are essentially monomeric in dichloromethane. The infrared spectrum of I shows the ν(Pd–Cl) band at 270 cm^{-1}, which is close to the ν(Pd–Cl) frequency of the corresponding DTBNO complex (303 cm^{-1}),[11] while this band of IV is obscured by ylide vibrations. The ^1H NMR spectrum of IV shows only one methine signal (Table). In addition, no exchange is observed between the coordinating ylide and free ylide added into the solution of the complex. These results suggest the presence of only one species of IV in solution. In the infrared spectrum, the ν(C=O) band of the ylide shifts to high frequency upon complexation (complexed ylide: 1605 cm^{-1}, free ylide: 1508 cm^{-1}), indicating, as

Table. Chemical shifts of the TMPNO complexes in chloroform-d_1 at 24 °C[a)]

Complex	CH_3	$-CH_2-$	Other protons
$[PdCl(TMPNO)]_2$	1.45(s), 2.33(s)	1.60(m)	—
$PdCl(TMPNO)(PPh_3)$	1.38(s), 1.97(s)	1.62(m), 1.77(m)	7.41(m), 7.57(m)(PPh_3)
$PdCl(TMPNO)(Me_2\overset{+}{S}\overset{-}{C}HCOPh)$	1.12(s), 1.25(s) 1.54(s), 1.93(s)	1.61(m)	2.87(s), 3.15(s)(SMe); 2.54(s) (CH); 7.42(m), 8.21(m) (Ph)

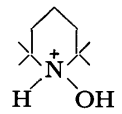
a) s: singlet, m: multiplet.

discussed previously,[13)] the coordination through the ylide-carbon atom. Thus, the coordinating ylide-carbon is an asymmetric center. This is also supported from the occurrence of two *S*-methyl proton signals with an identical intensity (Table), while free ylide exhibits only one *S*-methyl signal.



a **b** **c**

There are three possible configurations for IV, **a**—**c**, of which **a** and **b** are geometrical isomers. In spite of the presence of the chiral ylide-carbon, four methyl groups of TMPNO in the configuration **c** may be magnetically equivalent, because the inversion at the nitrogen atom would be very fast.[14)] On the other hand, both **a** and **b** involve a quadrivalent nitrogen atom, which predicts no inversion at the nitrogen. In fact, this kind of inversion is restricted in the *N*-hydroxyl-2,2,6,6-tetramethylpiperidinium cation (**d**), as confirmed by the ^1H NMR spectrum in dichloromethane at room temperature, which shows two separated methyl signals at δ 1.39 and 1.65 ppm.[15)] Thus, both configurations

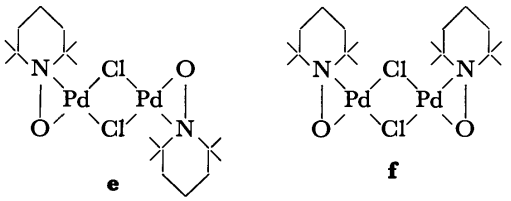


d

a and **b** predict the occurrence of the axial and equatorial methyl proton signals with an equal intensity. Furthermore, each signal should be split into two owing to the presence of the chiral ylide-carbon. This is compatible with the occurrence of two doublet signals due to the methyl protons (Table). Stereochemical considerations support the preference of **a** to **b**, since in **b** the piperidine ring is placed near to the bulky ylide.

The complex V involving no chiral atom exhibits two methyl proton signals with an equal intensity. This does not contradict with the assumption that the complex exists as only one species in solution and the inversion at the nitrogen atom of TMPNO is restricted. The bulkiness of triphenylphosphine suggests the configuration similar to **a**.

The conductivity measurement and molecular weight determination indicate that I is a non-electrolyte (0.02 $ohm^{-1}\,cm^2\,mol^{-1}$ at 1.51×10^{-3} M) and dimeric in dichloromethane. By analogy with $[PdCl(DTBNO)]_2$,[1)] I is considered to adopt chloride-bridged configurations (**e**) and/or (**f**). This is compatible with the occurrence



e **f**

of the ν(Pd-Cl) band at 270 cm^{-1}. The ^1H NMR spectrum shows two methyl signals with an identical intensity, suggesting the presence of either **e** or **f** with the restriction of inversion at the nitrogen atom.

Ionic structures of II and III are confirmed by conductivity measurements; Λ_M=256 and 121 $ohm^{-1}\,cm^2\,mol^{-1}$ (1.35×10^{-3} M in acetonitrile), respectively. Infrared spectra of both compounds show the ν(Pd-Cl) bands at 343 (very strong) and 303 (medium) cm^{-1}, which are characteristic of the hexachlorodipalladate anion.[16)] In addition, II exhibits a strong band at 1605 cm^{-1}, which is assigned to $\nu(\overset{+}{N}=O)$.[8)] The ^1H NMR spectrum of II in liquid sulfur dioxide shows somewhat broad methyl and methylene signals at δ 1.88 and 2.72 ppm, respectively; there is no separation of the methyl signal. These observations are consistent with the ionic formulation having the piperidineoxoammonium cation (**g**). On the other hand, III exhibits the ν(C=O) band at 1730 cm^{-1}, but no $\nu(\overset{+}{N}=O)$. The ^1H NMR spectrum shows again two methyl signals with an equal intensity, suggesting the presence of a quadrivalent nitrogen atom. These results and the following proton signals observed can well explain the formulation of **h**; δ 1.60 [singlet, 6 (relative intensity)] and 1.78 [s, 6] for the ring methyl; 1.96 [multiplet, 6] for the ring methylene; 2.36 [s, 3] for CH_3-C(O)-; 5.37 [s, 2] for $-CH_2$-C(O); 9.03 [broad, 1] for OH.

The Reaction of Aromatic Nitrile *N*-Oxides with Tetrahalo-*p*-benzoquinones

Shinsaku SHIRAISHI, Satoru IKEUCHI, Manabu SENŌ, and Teruzo ASAHARA
Institute of Industrial Science, University of Tokyo, Roppongi, Minato-ku, Tokyo 104
(Received May 21, 1976)

Cycloaddition reaction of aromatic nitrile *N*-oxides, such as benzonitrile *N*-oxide, 2,4,6-trimethylbenzonitrile *N*-oxide, and 2,3,5,6-tetramethylbenzonitrile *N*-oxide, with tetrahalo-*p*-benzoquinones was studied. The reaction gave 1: 1- and/or 2: 1-adducts of a nitrile *N*-oxide and a tetrahalobenzoquinone according to the conditions, especially the mole ratios of each reactant. The 2: 1-adducts are formed *via* 1: 1-adducts, each having two stereoisomers. The structures of these adducts were determined to be dioxazole derivatives formed by the addition of nitrile *N*-oxides to the carbonyl bonds of the tetrahalobenzoquinones.

Nitrile *N*-oxide is known to be a typical 1,3-dipole and to react with many unsaturated bonds to form heterocycles.[1] In general, nitrile *N*-oxides, like other 1,3-dipoles, react with C=C double bond much faster than with C=O bond. Benzonitrile *N*-oxide reacts with styrene by 180 times faster than with its isoelectronic compound, benzaldehyde.[2] *p*-Benzoquinone and alkenyl ketones each have two different dipolarophilic functions, C=C and C=O bonds in the molecules. They give C=C addition products in the reactions with various nitrile oxides.[3] In very rare cases, however, preference for C=O addition has been reported. Some *o*-quinones gave C=O addition products. As an example, benzonitrile *N*-oxide reacts with *o*-naphthoquinone to give two isomeric 1: 1-C=O adducts, followed by the addition of nitrile *N*-oxide to the C=C and/or C=O bonds according to the first addition site.[4] Cyclobutene diones have been found to react with mesitonitrile *N*-oxide at the C=O bonds.[5] α-Azidovinyl ketones react with nitrile *N*-oxides at both C=C and C=O bonds.[6]

We have studied the reaction of aromatic nitrile *N*-oxides with tetrahalo-*p*-benzoquinones (*p*-haloanils) and found that the reaction gives dioxazole derivatives unlike the reaction with unsubstituted *p*-benzoquinone, which gives isoxazoline derivatives.[3]

Results and Discussion

Aromatic nitrile *N*-oxides, such as benzonitrile N-oxide (BNO), 2,4,6-trimethylbenzonitrile *N*-oxide (MNO), and 2,3,5,6-tetramethylbenzonitrile *N*-oxide (DNO), were allowed to react with tetrahalo-*p*-benzoquinones, such as fluoranil (FA), chloranil (CA), bromanil (BA), and iodanil (IA), in chloroform at room temperature or at elevated temperatures. Completion of the reaction was confirmed by complete comsumption of the nitrile *N*-oxide in the reaction mixture by thin layer chromatography (TLC). An equimolar reaction of MNO with CA gave a 1: 1-adduct in 93% yield and a small amount of a 2: 1-adduct in 7% yield based on MNO, the reaction in 2: 1 mole ratio giving a 2: 1-adduct. When the reaction was interrupted at an earlier stage, the 1: 1-adduct was obtained as the sole isolable product with unreacted reactants. Irrespective of solvent and temperature, 1: 1- and/or 2: 1-adducts were obtained according to the mole ratio of the reactants in more than 90% yield on the completion of the reaction. The dependence of the product composition on the reaction conditions is shown in Table 1 for the reaction of MNO with CA. When haloanil was added very slowly to a refluxing solution of a nitrile *N*-oxide, the corresponding 2: 1-adduct was obtained quantitatively without contamination of 1: 1-adduct. The condition was fulfilled by using a Soxhlet extraction apparatus. The solubility of haloanils in chloroform is sufficiently small for this procedure. The result shows that the addition reaction proceeds stepwise and irreversibly, the second addition step being much slower than the first.

The 2: 1-adduct from MNO and CA has two isomers, which differ in solubility and thermal behavior. Their elementary analyses gave the same results, the IR spectra differing slightly in finger print region. One isomer (**6a**) is almost insoluble in hexane and the other (**6b**) fairly soluble. The product mixture could be separated into **6a** and **6b** by the difference in solubility. Their ratio was always 50: 50 as shown in Table 1. This indicates that the orientation of the second addition reaction is not influenced by the mode of the first, the addition reaction occurring such a mode that only two isomers are possible for the 2: 1-adduct.

TABLE 1. DEPENDENCE OF THE PRODUCTS COMPOSITION ON THE REACTION CONDITIONS FOR THE REACTION OF MNO WITH CA

Reactants (mole ratio)	Solvent	Temp °C	Time h	Products (yield, %)	2:1-Adduct isomer ratio **6b**:**6a**
MNO/CA (1/1)	$CHCl_3$	r.t.	15	1:1-adduct(93)[a] 2:1-adduct(7)[a]	
(1.5/1)	$CHCl_3$	r.t.	18	1:1-adduct(49) 2:1-adduct(46)	
(2/1)	$CHCl_3$	r.t.	18	2:1-adduct(98)	46:54
	$CHCl_3$	reflux	11	2:1-adduct(94)	53:47
	C_6H_6	r.t.	30	2:1-adduct(93)	52:48
(2.5/1)	$CHCl_3$	r.t.	18	2:1-adduct(96)	
MNO/1:1-adduct(1/1)	$CHCl_3$	r.t.	18	2:1-adduct(86)	54:46

a) The values are calculated based on the nitrile *N*-oxide.

The IR spectra of **6a** and **6b** have very strong absorption bands in the ν_{C-O-C} region 1100—1300 cm^{-1}, but no absorption in the $\nu_{C=O}$ region 1650—1750 cm^{-1}. The mass spectra of the 1: 1-adduct (**5**) and the 2: 1-adducts (**6a** and **6b**) have molecular ion peak (M^+)

Table 2. The reaction products from nitrile *N*-oxides and haloanils

a) All the compounds were recrystallized from hexane unless otherwise stated. b) Recrystallized from chloroform. c) Recrystallized from a mixture of hexane and chloroform. d) Compound **14** was also obtained in 32% yield based on MNO. e) No apparent change was observed except for very gradual discoloration at above 160 °C, but a small endotherm was observed at 154 °C in its differential thermogram as shown in Fig. 1-(c).

at the *m/e* corresponding to their molecular weights with the peaks at $M^+ + 2$ and $M^+ + 4$ with the intensities characteristic to tetra-chlorinated compounds. They are also the composite of the fragmentation patterns of mesityl isocyanate and chloranil, except for their molecular ion peaks and the fragment ion peaks corresponding to the 1: 1-adduct for the spectra of **6a** and **6b**, which gave the same fragmentation patterns. All the other addition products obtained from the reactions of the nitrile *N*-oxides and haloanils show similar spectroscopic results. Characterization data of these reaction products are summarized in Table 2. Separation of the isomers of the 2: 1-adducts other than those from MNO and CA was not successful. The melting points might be those of isomer mixtures, showing fluctuation.

The results indicate that the structure of the addition products is not isoxazoline but dioxazole formed by the addition of nitrile *N*-oxides to the carbonyl bonds of haloanils as shown in the scheme.

The addition products, **5**, **6a**, and **6b**, decomposed into mesityl isocyanate and CA on heating. The isocyanate might be derived by the thermal rearrangement of MNO generated by thermal retro-addition reaction or by pyrolytic rearrangement of the dioxazoles. The precise mechanism of the decomposition should be

Scheme.

determined by isotope labeling experiment. The

decomposition temperature differed among the products (Fig. 1). The differential thermal analysis (DTA) of **6b** gives a complicated thermogram with a small endothermic peak at 154 °C and exothermic ones at 163 and 173 °C, while **6a** shows no endotherm but only an exotherm at 192 °C. Thermogravimetric analysis (TGA) of the compounds shows rapid weight decrease at the temperature at which an exotherm was observed in DTA, followed by subsequent slow decrease. The first weight loss corresponds to the weight of nitrile oxide moiety, which volatiled as isocyanate rapidly with nitrogen stream. The second slow decrease might be due to the sublimation of chloranil.

The reaction of a nitrile *N*-oxide with a C=C double bond of a haloanil would give 2-isoxazoline derivative, pyrolysis of which might result in aromatization to afford isoxazole derivative rather than degradation to a quinone and an isocyanate. The angular C–Cl bond is thought to be cleaved more easily. Thus, the result of the pyrolysis of **5** also supports the dioxazole structure of the adducts.

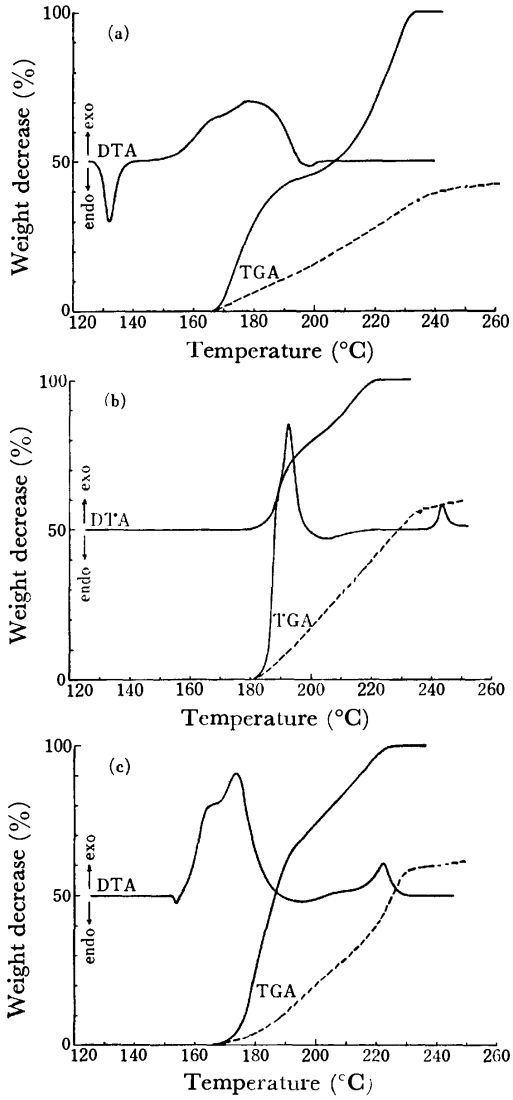

Fig. 1. Thermal analyses of the addition products of MNO with CA, (a): **5**, (b): **6a**, and (c): **6b**, under nitrogen stream (——) and under air (– – –). Heating rate: 5°C/min.

The fact that **6a** has higher melting point and is more thermally stable and less soluble in solvents than **6b** indicates that **6a** has a more symmetrical *trans* structure of the two stereoisomers.

FA, BA, and JA also reacted with MNO to give similar results, but the rate difference between the first addition and the second one differs among them. The rate difference for the reaction of MNO with IA was rather small, and thus the equimolar reaction of them gave 1: 1-(**13**) and 2: 1-adducts (**14**) in 48 and 32% yields based on MNO, respectively.

BNO and DNO also underwent similar cycloaddition with haloanils at the carbonyl sites (Table 2). In the reaction of BNO with haloanils, however, the usual *in situ* reaction process using triethylamine as an acid acceptor was not applicable because of faster reaction of the amine with haloanils. The cycloaddition was performed effectively with a solution of free BNO prepared prior to the reaction, or by heating a solution of benzhydroxamoyl chloride and a haloanil in toluene to reflux.

The PMR spectral data for the 1: 1-adducts from MNO are summarized in Table 3. The signals due to 2- and 6-methyl substituents on the mesityl radical move to down field with the change of the quinone substituents in the order of the atomic radii of halogen atoms, FA<CA<BA<JA, while the other signals due to 4-methyl and 3- and 5-hydrogens have almost the same chemical shifts. Considering the thru-space interaction of 2- and 6-methyl groups with halogens, this may also support the spiro-dioxazole structure of the adducts.

TABLE 3. PMR SPECTRAL DATA of 1:1-ADDUCTS OF MNO AND HALOANILS, 6,7,9,10-TETRAHALO-3-MESITYL-2-AZA-1,4-DIOXASPIRO[4,5]DECA-2,6,9-TRIEN-8-ONES, δ (ppm) IN $CDCl_3$

Addition of nitrile *N*-oxides to the carbonyl of the compounds having two potential dipolarophilic functions, C=C and C=O in the molecules is very rare. Preferential carbonyl addition in the reaction of nitrile *N*-oxides with haloanils is considered to be due to the halogen substituents on the quinones, which deactivate the reactivity of the C=C by steric hindrance and activate that of the C=O by inductive effect. This type of C=O addition is known in the reaction of diazomethane which also has a 1,3-dipole.[7] Diazomethane adds to a carbonyl group in quinones with all of the hydrogens replaced by electronegative groups. Many similarities in the modes of reaction feature were observed in 1,3-dipolar cycloaddition and Diels-Alder reactions. How-

ever, we see a distinct difference in the reactions with substituted quinones, where Diels-Alder reaction gave C=C addition products even with chloranil.[8] The reaction of diazomethane with tetramethyl-*p*-benzoquinone, however, occurs at the C=C bonds,[9] and 1,4-diphenyl-2,6-piperazinedione adds also to the C=C bond of chloranil *via* an azomethine ylide intermediacy.[10] The reactions with quinones might give clues for the elucidation of reaction mechanisms.

Experimental

All the melting points cited are uncorrected. Characterization data for the addition products from nitrile *N*-oxides and haloanils are given in Table 2.

Materials. 2,4,6-Trimethylbenzonitrile *N*-oxide and 2,3,5,6-tetramethylbenzonitrile *N*-oxide were prepared by Grundmann's procedure.[11] Commercial chloranil was purified by recrystallization from gracial acetic acid. Bromanil was prepared by the method of Jackson and Bolton[12] and recrystallized from gracial acetic acid. Iodanil was prepared from bromanil according to the procedure of Torrey and Hunder.[13]

Reaction of MNO with CA. 6,7,9,10-Tetrachloro-3-mesityl-2-aza-1,4-dioxaspiro[4, 5]deca-2,6,9-trien-8-one (5): A solution of 1.23 g (5.0 mmol) of CA and 0.18 g (5.0 mmol) of MNO in 300 ml of chloroform was stirred for 15 h at room temperature. After confirming the completion of the reaction by TLC on silica gel plate with benzene, the solvent was evaporated under vacuum. The residual solid was extracted with hot hexane to give 1.90 g (93%) of the title product as the extract, which was recrystallized from hexane.

*6, 7, 13, 14-Tetrachloro-3, 11-dimesityl-2, 10-diaza-1, 4, 9, 12-tetraoxadispiro[4,2,4,2]tetradeca-2,6,10,13-tetraene (**6a** and **6b**)*: A solution of 0.61 g (2.5 mmol) of CA and 0.81 g (5.0 mmol) of MNO in 200 ml of chloroform was heated to reflux for 11 h. The solvent was removed by evaporation under vacuum and the residue was extracted with hexane for 4 h using a Soxhlet extractor and then with chloroform for 6 h. The hexane extract (**6b**, 0.70 g, 50%) was recrystallized from hexane and 0.62 g (44%) of the chloroform extract (**6a**) from chloroform.

The same compounds were obtained by the reaction of **5** with MNO. A solution of 1.0 g (2.5 mmol) of **5** and 0.40 g (2.5 mmol) of MNO in 200 ml of chloroform was stirred for 18 h at room temperature. The reaction mixture was treated in the same manner as mentioned above to give 0.65 g (46%) of **6b** and 0.55 g (40%) of **6a**.

Reaction of BNO with CA. 6,7,9,10-Tetrachloro-3-phenyl-2-aza-1,4-dioxaspiro[4, 5]deca-2,6,9-trien-8-one (3): A solution of 0.55 g (5.0 mmol) of triethylamine in 100 ml of tetrahydrofuran (THF) was added dropwise into a solution of 0.85 g (5.0 mmol) of benzhydroxamoyl chloride in 300 ml of THF with vigorous stirring at room temperature. The mixture was stirred for 5 min, and then filtered into a solution of 1.23 g (5.0 mmol) of CA in 200 ml of THF. The solution was stirred for 10 h at room temperature. The solvent was evaporated to give tan yellow residue, which was worked up with column chromatography on silica gel (Wakogel C-100) with benzene as an eluent. The mixture was eluted in the order of diphenylfuroxan, the title compound, and chloranil. The title compound (0.88 g, 48%) was recrystallized from hexane.

The compound was also prepared by the following procedure. A solution of 1.23 g (5.0 mmol) of CA and 0.86 g (5.5 mmol) of benzhydroxamoyl chloride in 300 ml of toluene was heated to reflux for 12 h. Evolution of hydrogen chloride was observed during the course of reaction. The solvent was removed by evaporation under vacuum to give viscous tan yellow oil, which was treated in the same manner as described above to give 0.85 g (47%) of **3**.

6, 7, 13, 14-Tetrachloro-3, 11-diphenyl-2, 10-diaza-1,4,9, 12-tetraoxadispiro[4,2,4,2]tetradeca-2,6,10,13-tetraene (4): A solution of BNO prepared from 1.14 g (7.3 mmol) of benzhydroxamoyl chloride by treating with triethylamine was added into a solution of 0.82 g (3.3 mmol) of CA in THF and the mixture was stirred for 10 h. The mixture was treated in the same manner as mentioned above. Diphenylfuroxan, **3**, **4**, and CA were eluted in this order. The reaction gave 0.40 g (33%) of **3** and 0.22 g (14%) of the title compound **4**, which was recrystallized from hexane.

The compound was also prepared by the reaction of 0.82 g (3.3 mmol) of CA with 1.14 g (7.3 mmol) of benzhydroxamoyl chloride in 300 ml of toluene at refluxing temperature. The work-up of the product with column chromatography on silica gel with benzene gave 0.42 g (34%) of **3** and 0.30 g (19%) of **4**.

The Reaction of Other Haloanils with Nitrile N-*Oxides.* The reaction of other haloanils with MNO or DNO were ciarred out almost in the same manner as described in the preceding section. The results are given in Table 2.

Thermolysis of 5. Compound **5**, 2.0 g (4.9 mmol), was placed in a sublimer and heated up to 190 °C under reduced pressure (*ca.* 1 Torr). Colorless crystals and yellow ones deposited on the condenser. The colorless part weighed 0.38 g (38%) and melted at 44—46 °C. It was shown to be mesityl isocyanate from its IR spectrum and elementary analysis (Found: C, 74.27; H, 6.77; N, 8.43%. Calcd for $C_{10}H_{11}NO$: C, 74.51; H, 6.88; N, 8.69%). The yellow one weighed 0.56 g (46%) and was shown to be chloranil from its melting point and IR spectrum.

Cyanamide Derivatives. Part 106.* The Preparation of ^{15}N-Labeled Cyanoguanidines

Akira OMURA,** Tsutomu NONAKA, Toshio FUCHIGAMI, Eiichi ICHIKAWA, and Keijiro ODO

Department of Electronic Chemistry, The Graduate School, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

(Received July 12, 1976)

Methods for labeling the chemically non-equivalent nitrogen atoms of cyanoguanidine with ^{15}N were established. 1-Cyanoguanidine-1-^{15}N and 1-cyano-^{15}N-guanidine were prepared, and their labeled positions were also confirmed by mass spectroscopic analysis. ^{15}N FT-NMR spectra of cyanoguanidine enriched with ^{15}N were measured.

Cyanoguanidine (**1**), also called dicyandiamide, is one of the useful starting compounds for the synthesis of C–N alternating compounds. However, no reliable mechanisms of many reactions of **1** and its related compounds have been established because of the ambiguity in the correlation between the arrangement of nitrogen atoms in a product molecule and that in a reactant. Such a problem would be solved by using a ^{15}N tracer. The authors had already prepared a labeled **1**, 1-cyanoguanidine-2,3-$^{15}N_2$, and put it to use for clarification of the mechanism of cathodic crossed hydrocoupling of acetone with **1**.[1]

$$\underset{\displaystyle N^{2(a)}H_2}{\overset{\displaystyle H_2N^{3(a)}-C=N^{1(b)}-C\equiv N^{(c)}}{|}}$$

1

In this work, methods for labeling the non-equivalent nitrogen atoms (N^b and N^c) other than N^a and for enriching all nitrogen atoms with ^{15}N were developed. It is required in preparation of a labeled compound that its formation mechanism has been established, at least reliably. And also, the labeled position should be reconfirmed in some way. Such requirements were satisfied in this work.

Results and Discussion

A procedure for labeling the N^b was newly designed because there was no earlier literature which could be used for the preparation of 1-cyanoguanidine-1-^{15}N. At the first stage, 2-imino-1,3-dithiolane-^{15}N (**2**) was synthesized in a 98% yield from 1,2-ethanedithiol and cyanogen bromide-^{15}N.[2] Cyanogen bromide-^{15}N was prepared by the bromination of potassium cyanide-^{15}N (^{15}N abundance, 2.7 atom %).[3]

$$KC\equiv{}^{15}N + Br_2 \longrightarrow Br-C\equiv{}^{15}N + KBr$$

$$\begin{matrix}CH_2-SH\\|\\CH_2-SH\end{matrix} + Br-C\equiv{}^{15}N \longrightarrow \begin{matrix}CH_2-S\\|\quad\quad C={}^{15}NH\\CH_2-S\end{matrix} + HBr$$

2

And then the free base of **2** was also treated with ordinary cyanogen bromide in acetone so as to be converted into 2-[(cyano)imino-^{15}N]-1,3-dithiolane (**3**) in an 80% yield. The compound, **3**, was identified with an independently synthesized authentic sample by an IR spectrum and a mixed melting test.[4] The hydrobromide, which was inevitably produced, of **2** could be repeatedly used.

$$2\,\mathbf{2} + Br-C\equiv N \longrightarrow \begin{matrix}CH_2-S\\|\quad\quad C={}^{15}N-C\equiv N\\CH_2-S\end{matrix} + \mathbf{2}\cdot HBr$$

3

An attempt to obtain directly 1-cyanoguanidine-1-^{15}N by the ammonolysis of **3** was unsuccessful. The ammonolysis in the presence of silver nitrate afforded the ammonium salt of dicyanoamine-^{15}N (**4**) in a 47% yield. The compound, **4**, was converted into the potassium salt[5] and identified with an authentic sample by an IR spectrum. The by-product seemed to be mainly a compound, **5**. But **5** could not be purely isolated from the coprecipitated silver salt of 1,2-ethanedithiol.

$$\mathbf{3} + 4NH_3 + 2AgNO_3 \longrightarrow$$

$$N\equiv C-{}^{15}NH-C\equiv N\cdot NH_3 + \begin{matrix}CH_2-SAg\\|\\CH_2-SAg\end{matrix} + 2NH_4NO_3$$

4

$$AgS-CH_2-CH_2-S-\underset{\displaystyle NH_2}{\overset{\displaystyle C={}^{15}N-C\equiv N}{|}}$$

5

The compound, **4**, was converted into 1-cyanoguanidine-1-^{15}N in a 49% yield by reflux in 1-butanol.[6]

$$\mathbf{4} \longrightarrow H_2N-\underset{\displaystyle NH_2}{\overset{\displaystyle C={}^{15}N-C\equiv N}{|}}$$

1-Cyano-^{15}N-guanidine labeled at the N^c was prepared in an 84% yield from guanidine and cyanogen bromide-^{15}N (^{15}N abundance, 5.0 atom %) in DMF.

$$2H_2N-\underset{\displaystyle NH_2}{\overset{\displaystyle C=NH}{|}} + Br-C\equiv{}^{15}N \longrightarrow$$

$$H_2N-\underset{\displaystyle NH_2}{\overset{\displaystyle C=N-C\equiv{}^{15}N}{|}} + H_2N-\underset{\displaystyle NH_2}{\overset{\displaystyle C=NH\cdot HBr}{|}}$$

Also, **1** enriched at all the nitrogen atoms with ^{15}N was prepared in order to supply a sample to ^{15}N FT-NMR spectroscopy. After cyanamide-^{15}N prepared from cyanogen bromide and ammonia-^{15}N (^{15}N abundance, 10.3 atom %) was dissolved in dilute hydrochloric acid to disperse completely ^{15}N to the two nitrogen atoms by the formation of a carbodiimido form,[7] it was dimerized in an alkaline solution.[8] Yields of cyanamide and cyanoguanidine were 100 and 85%, respectively.

* Part 105: T. Fuchigami and K. Odo, *Bull. Chem. Soc, Jpn.*, **49**, 3607 (1976).

** Present address: Nippon (Japan) Carbide Industries Inc., Uozu, Toyama.

$$Br\text{-}C{\equiv}N + 2{}^{15}NH_3 \longrightarrow H_2{}^{15}N\text{-}C{\equiv}N + {}^{15}NH_4Br$$

$$H_2{}^{15}N\text{-}C{\equiv}N \xrightarrow{H^+} [H_2{}^{15}N^+{=}C{=}NH \longleftrightarrow H^{15}N{=}C{=}\overset{+}{N}H_2] \xrightarrow{-H^+} H_2{}^{15}N\text{-}C{\equiv}{}^{15}N$$

$$2H_2{}^{15}N\text{-}C{\equiv}{}^{15}N \longrightarrow H_2{}^{15}N\text{-}C(=\,{}^{15}NH_2){=}{}^{15}N\text{-}C{\equiv}{}^{15}N$$

The labeled position was confirmed by the measurement of ^{15}N abundance of ammonia generated in the hydrolytic decomposition of 2,4-diimino-5,5-dimethyl-1,3-oxazolidine (**6**), which was formed by the electrolytic reduction of a mixture of labeled cyanoguanidine and acetone.[1,9]

$$H_2N^a\text{-}C(=N^b\text{-}C{\equiv}N^c)(N^aH_2) + (CH_3)_2C{=}O + 2e + 2H^+ \longrightarrow \mathbf{6} + N^aH_3$$

$$\mathbf{6} \xrightarrow[-N^cH_3]{H_2O} \xrightarrow[-N^aH_3]{H_2O} \xrightarrow{H_2O} N^bH_3$$

The labeled position in 1-cyano-^{15}N-guanidine was further confirmed by the following procedure. Cyanoguanidine was converted into carbamoylguanidine (**7**) by reflux in dilute hydrochloric acid and then **7** was hydrolyzed to give guanidine and ammonia (yield, 93%) in a hot aqueous sodium hydroxide solution.[10] The guanidine was also decomposed quantitatively to ammonia by the Kjeldahl method.

$$H_2N\text{-}C(=N\text{-}C{\equiv}{}^{15}N)(NH_2) + H_2O \longrightarrow H_2N\text{-}C(=N\text{-}C(=O)\text{-}{}^{15}NH_2)(NH_2)$$

7

$$\mathbf{7} + H_2O \longrightarrow H_2N\text{-}C(=NH)(NH_2) + {}^{15}NH_3 + CO_2$$

As shown in Table 1, ^{15}N abundances in the samples of ammonia agreed with the calculated values.

^{15}N FT-NMR spectra of the enriched cyanoguanidine were measured in DMF to obtain some preliminary data. These exhibited three resonance peaks under the condition of proton decoupling at a long pulse interval (180 s). The peak at a lower magnetic field split into a triplet set in non-decoupling, while the peaks at a higher magnetic field did not split. In the measurement using a shorter pulse interval (1 s), no signal was observed at such a higher magnetic field even when accumulated ten thousand times. The peak at the lower magnetic field was also assigned to N^a by a spectrum of 1-cyanoguanidine-2,3-$^{15}N_2$.[1] These facts suggest that the two N^a nitrogen atoms are also magnetically equivalent to each other. The singlet peaks at the higher magnetic field would be assigned to N^b and N^c with no hydrogen atom. Some ambiguities in the assignment might be taken away by measuring spectra of labeled cyanoguanidines other than 1-cyanoguanidine-2,3-$^{15}N_2$, but those were not measured in this work because an extremely long time would be required for measurement. Some spectra are schematically shown in Fig. 1.

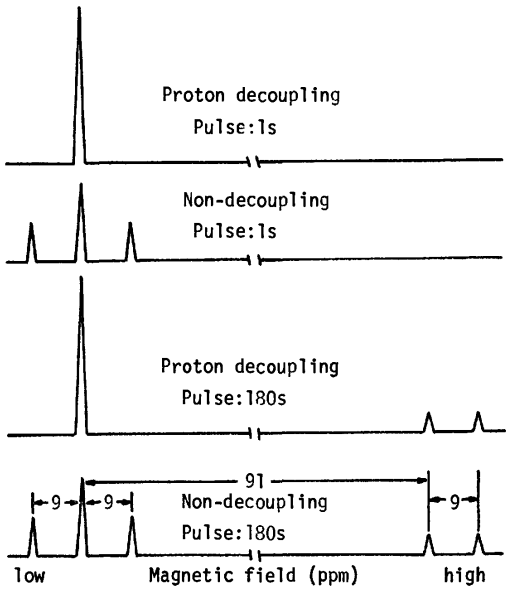

Fig. 1. Schematic ^{15}N FT-NMR spectra of enriched cyanoguanidine.

Experimental

Heavy Nitrogen Reagents. Ammonium chloride-^{15}N(^{15}N abundance, 10.3 atom %) and potassium cyanide-^{15}N(^{15}N abundance, 98.0 atom %) were supplied from the Japan Iso-

tope Association.

Preparation of Labeled Cyanoguanidines. *1-Cyanoguanidine-1-^{15}N*: A solution of potassium cyanide-^{15}N (^{15}N abundance, 2.7 atom %, 11 g, 0.17 mol) in water (24 ml) was slowly added to an ice-cooled mixture of 27 g (0.17 mol) of bromine and 27 ml of water. Wet cyanogen bromide-^{15}N was first distilled from the reaction mixture, then redistilled after being dried with anhydrous calcium chloride: bp 60—62 °C; yield, 72%.

Into 21 ml of toluene containing small amounts of ethanol and hydrogen chloride as catalysts was dissolved 10.4 g (0.11 mol) of 1,2-ethanedithiol, and 10.9 g (0.10 mol) of cyanogen bromide-^{15}N in 50 ml of toluene was added dropwise into the solution. After three hours, 20.5 g of the hydrobromide of 2-imino-1,3-dithiolane-^{15}N (**2**) were crystallized out of the reaction mixture: mp 183—187 °C, dec.; yield, 98%. The hydrobromide was converted into the free base by sodium hydrogencarbonate in a mixture of ether and water as a suspension: yield, 86%; mp 64—65 °C (lit[2] 63.8—64.8 °C); and *m/e* 119 (M^+).

To an acetone solution containing 5.0 g (0.047 mol) of ordinary cyanogen bromide was added a solution of **2** (10.3 g, 0.087 mol) in acetone, dropwise. The hydrobromide of **2** was filtered off, then the solvent was evaporated to leave 4.5 g (yield, 80%) of 2-[(cyano)imino-^{15}N]-1,3-dithiolane (**3**) as a residue: mp 79—81 °C (an authentic sample,[4] 79—81 °C).

Concentrated ammonia water containing 3.5 g (0.024 mol) of **3** and 8.2 g (0.048 mol) of silver nitrate was heated in a sealed tube at 100 °C for 3 h. After cooling, the resultant precipitate was filtered off and the mother liquor was concentrated to dryness. Extraction of the solids with acetone gave 0.95 g of the ammonium salt of dicyanoamine-^{15}N (**4**): yield, 47%.

The ammonium salt was then heated in 1-butanol under reflux for 20 h. The solvent was evaporated to dryness and the residue was extracted with warm ethanol. Concentration of the extract afforded 0.49 g (yield, 49%) of 1-cyanoguanidine-1-^{15}N.

1-Cyano-^{15}N-guanidine: A mixture of 12.5 g (0.21 mol) of guanidine and 11.2 g (0.11 mol) of cyanogen bromide-^{15}N (^{15}N abundance, 5.0 atom %) in 50 ml of DMF was stirred at 5 °C for 2 h. After evaporation of the solvent under reduced pressure and treatment of the residue with a small amount of water, 3.5 g of the titled compound were left as an insoluble part: yield, 84%.

Enriched Cyanoguanidine: Ammonia generated from 13.9 g (0.26 mol) of ammonium chloride-^{15}N (^{15}N abundance, 10.3 atom %) was introduced into an ethereal solution of 14.2 g (0.13 mol) of cyanogen bromide with a nitrogen stream. Ammonium bromide was filtered off and ether was evaporated to dryness. Cyanamide-^{15}N (4.1 g) was left as a residue in 76% yield.

The above cyanamide was dissolved in 30 ml of water containing several drops of concentrated hydrochloric acid, and then the pH of the solution was adjusted to 8.5 with sodium hydroxide. After a few days, the solution was concentrated to 10 ml and 3.5 g (yield, 85%) of the titled compound was collected on a filter paper.

Confirmation of Labeled Position. Procedures for the preparation of **6**, its hydrolysis, and the determination of ^{15}N abundance were similar to those reported in the previous works.[1,9]

Decomposition of 1-Cyano-^{15}N-guanidine: A mixture of 0.42 g (0.005 mol) of cyanoguanidine in 6.7 ml of 1.5 M hydrochloric acid was heated at 100 °C for 2 h, then 6.7 ml of 1.5 M sodium hydroxide was added to the solution. The ammonia thus generated was introduced into dilute hydrochloric acid with a nitrogen stream, giving 0.25 g of ammonium chloride in 93% yield. On the other hand, the above solution was acidified with hydrochloric acid again, then the solvent was evaporated to dryness. Extraction of the residue with ethanol gave 0.47 g of guanidine hydrochloride (yield, 98%). The guanidine was strongly heated with sulfuric acid and potassium and copper(II) sulfates in a Kjeldahl flask to decompose completely to ammonia.

The authors wish to thank Dr. M. Itagaki, JEOL Ltd., for the measurement of the ^{15}N FT-NMR spectra and also for his many helpful discussions on the spectra.

Studies on Hydroxy Amino Acids. VI. Formation of the Oxazoline Derivatives from *N*-Acyl-β-hydroxy Amino Acid Peptides[1]

Kiichiro NAKAJIMA, Haruki KAWAI, Michihiro TAKAI, and Kenji OKAWA
Department of Chemistry, Faculty of Science, Kwansei Gakuin University, Nishinomiya 662
(Received July 22, 1976)

Oxazoline derivatives were mainly obtained from the *O*-tosyl-*N*-acyl-β-hydroxy amino acid peptides by β-elimination reaction. Dehydroalanine or hydantoin derivatives were isolated when the urethane type acyl groups were used.

It was found in a study on the β-elimination reaction of the β-hydroxy amino acid derivatives that only oxazoline derivative (**3**) was obtained from *N*-(benzyloxycarbonyl)-glycyl-(or phenylalanyl-)-L-threonylglycine benzyl ester, *via* the corresponding *O*-tosylated intermediate.[2]

We have carried out further application of the β-elimination reaction to the *N*-acylseryl- or *N*-acylthreonyl peptide (Scheme 1).

Several acyl groups, benzoyl, phenylacetyl, benzyloxycarbonyl, *t*-butoxycarbonyl, *N*-(benzyloxycarbonyl)-glycyl, and *N*-(benzyloxycarbonyl)-D-phenylglycyl, were used as the *N*-acyl group of the β-hydroxy amino acid or peptide derivatives.

O-tosyl derivatives (**2**) were prepared by treatment of the *N*-acyl-β-hydroxy amino acid derivatives (**1**) and tosyl chloride in a pyridine solution at 0 °C. The yield and analytical data of *N*-acyl-β-hydroxy amino acid peptides (**1**) and *O*-tosylated peptides (**2**) are summarized in Tables 1 and 2, respectively.

The detosylation reaction was carried out in a solution of tetrahydrofuran with triethylamine at 70 °C. The results are summarized in Tables 3 and 4. The structure of the products was confirmed by NMR spectra.

From the results of β-elimination reaction *O*-tosyl-*N*-acyl-β-hydroxy amino acid derivatives (**2**), we see that the resulting main products are oxazoline derivatives (**3**) but not dehydroalanine (**4**) or aziridine derivatives.

Z-Gly-Ser-Gly-OEt is an exceptional example to produce the dehydroalanine derivative (**4**) as the main product.[2]

In the case of urethane type acyl derivatives, however, both dehydroalanine (**4**) and hydantoin derivatives (**5**) were isolated from the *N*-benzyloxycarbonyl peptide derivatives, only the former being obtained from the *t*-butoxycarbonyl peptide derivatives (Scheme 2).

R_1: $C_6H_5CH_2O$- or $(CH_3)_3C$-O-, R_2: CH_3- or H-

Scheme 2.

Concerning the hydantoin formation, Dekker *et al.* reported[3] that compound (**5**) is produced when the *N*-[α-(benzyloxycarbonylamino)acyl]glycine ester is treated with methanolic ammonia at room temperature. However, we detected no aziridine derivatives.

Experimental

All the melting points are uncorrected. The NMR spectra were obtained with a Hitachi R-20 B High Resolution NMR Spectrometer, the chemical shifts being given from TMS as the internal reference. The purity of the compounds was confirmed by thin layer chromatography on silica gel. Hydroxy amino acid peptides were prepared by use of *N*,*N*′-dicyclohexylcarbodiimide (DCC). *N*-hydroxybenzotriazole (HOBt) or *N*-hydroxysuccinimide was employed in order to avoid the racemization of *N*-acyl-β-hydroxy amino acid during the course of coupling.

Synthesis of N-*Acyl-β-hydroxy Amino Acid Peptide Derivatives* (**1**). *Phenylacetyl*-L-*Thr*-*Gly*-*OEt* (**1b**): All the dipeptide derivatives were synthesized as follows. Phenylacetyl-L-Thr-OH (23.7 g, 0.1 mol) was treated with DCC (22.7 g, 0.11 mol), H-Gly-OEt (from the hydrochloride 15.3 g, 0.11 mol), HOBt (16.2 g, 0.12 mol) in DMF (100 ml) and dichloromethane (100 ml) at −10 °C. After the reaction mixture had been allowed to stand overnight in a refrigerator, acetic acid (2 ml) was added and the mixture was stirred for 15 min. The *N*,*N*′-dicyclohexylurea produced was filtered off, and the filtrate was washed successively with 1 M sodium hydrogencarbonate, 1 M hydrochloric acid and water, dried over anhydrous sodium sulfate, and concentrated under reduced pressure. **1b** was obtained from ethyl acetate–ether–hexane as crystals. The results are summarized in Table 1.

Z-D-*Phg*-L-*Thr*-*NHCH*$_3$ (**1f**): Methylamidation was carried out as follows. A solution of 30% methylamine (45 ml) in methanol was added to a solution of **1d** (4.5 g, 11.5 mmol) in methanol with stirring at 0 °C. After the reaction mixture had been allowed to stand at room temperature, the crystals (**1f**) produced were filtered off. Recrystallization was carried out from methanol–ether. The results are summarized in Table 1.

Z-D-*Phg*-L-*Ser*-*NH*$_2$ (**1i**): Amidation was carried out as follows. Dry ammonia gas was bubbled into a solution of **1h** (5 g, 12.9 mmol) in methanol at 0 °C until saturation. After the mixture had been allowed to stand at room temperature, the crystals (**1i**) produced were filtered off. Recrystallization was carried out from methanol–ether. The results are summarized in Table 1.

Z-D-*Phg*-L-*Thr*-*Gly*-*OBzl* (**1g**): Dry hydrogen chloride gas was bubbled for 30 min at 0 °C into a solution of Boc-Thr-Gly-OBzl[1] (2.02 g, 6 mmol) in ethyl acetate (20 ml) containing anisole (1 ml). The reaction mixture was allowed to stand at room temperature for 30 min. After the reaction mixture had been concentrated under reduced pressure, anhydrous ether was added to the residual products. Crystals were obtained in theoretical yield. The hydrochloride, Z-D-Phg-OH(1.71 g, 6 mmol), Et_3N (0.83 ml, 6 mmol) was treated with DCC (1.24 g, 6 mmol) in THF at −10 °C for 4 h. After the reaction mixture had been allowed to stand overnight in a refrigerator, acetic acid (1 ml) was added. The *N*,*N*′-dicyclohexylurea produced was filtered off, and the filtrate was concentrated under reduced pressure. The residual oil was dissolved in ethyl acetate and the solution was washed successively with 1 M sodium hydrogencarbonate, 1 M hydrochloric acid, and water, dried over anhydrous sodium sulfate, and concentrated under reduced pressure. The

oily products were crystallized from ethyl acetate–ether–hexane. **1g** was obtained 70.5% yield from Boc-Thr-Gly-OBzl.

Synthesis of O-Tosyl-N-acyl-β-hydroxy Amino Acid Peptide Derivatives (2). *Phenylacetyl-L-Thr(Tos)-Gly-OBzl(2c)*: *O*-tosylation was carried out as follows. A solution of tosyl chloride (3.73 g, 30 mmol) in dry pyridine (10 ml) was added drop by drop with stirring at −10 °C to a solution of **1c** (3.84 g, 10 mmol) in dry pyridine (30 ml). When the addition was over, the reaction mixture was allowed to stand at −10 °C for 3 days. It was then concentrated under reduced pressure, and the residual products were dissolved in ethyl acetate. The solution was washed with water and dried over anhydrous sodium sulfate, and concentrated under reduced pressure. The crystals (**2c**) produced were recrystallized from ethyl acetate–ether–hexane. The results are recrystallized from ethyl acetate–ether–hexane. The results are summarized in Table 2.

Detosylation of O-Tosyl Peptide Derivatives (2). *2-[α-(Benzyloxycarbonylamino)benzyl]-4-methylcarbamoyl-2-oxazoline (3-9)*: Detosylation was carried out as follows. A solution of **2j** (3.5 g, 6.5 mmol) and Et_3N (1.86 ml, 13 mmol) was refluxed at 70 °C for 3 days. After the solvent had been evaporated under reduced pressure, the oily product was dissolved in ethyl acetate. The solution was washed with water, dried over anhydrous sodium sulfate, and concentrated under reduced pressure. The residual product (**3**-9) was crystallized from ethyl acetate–ether. The results are summarized in Tables 3 and 4. NMR ($CDCl_3$): δ; 2.62 ppm (3H d, 4.9 Hz, -NHC$\underline{H}_3$); 4.35, 4.39, 4.53 ppm (3H 3q, 6.0, 12 Hz, 4.5, 12 Hz, 4.5, 6.0 Hz, -C$\underline{H}_2$-C$\underline{H}$-); 5.06 ppm (2H s, C_6H_5-C$\underline{H}_2$-); 5.43 ppm (1H d, 8.5 Hz, C_6H_5C$\underline{H}$=).

2-Benzyl-4-[(ethoxycarbonyl)methylcarbamoyl]-5-methyl-2-oxazoline (3-2): **2b** (8.19 g, 17.6 mmol) and Et_3N (4.9 ml, 35.2 mmol) were treated in THF as in the synthesis of **3**-9. The crude product was crystallized from ethyl acetate–ether. A small amount of crystals appeared were collected by filtration. The crystals were identified as Phenylacetyl-D-Thr-Gly-OEt [mp 147—148 °C, $[\alpha]_D^{23}$ −6.5° (*c* 1.0, DMF)]. **3**-2 was isolated from the mother liquor by the addition of hexane (Table 3). **3**-2 NMR ($CDCl_3$): δ; 1.11 ppm (3H d, 5.5 Hz, C$\underline{H}_3$-CH=); 1.15 ppm (3H t, 7.0 Hz, C$\underline{H}_3$-C$\underline{H}_2$-); 3.60 ppm (2H s, C_6H_5C$\underline{H}_2$-); 3.84 ppm (2H d, 6.2 Hz, -NH-C$\underline{H}_2$-CO-); 4.07 ppm (2H q, 7.0 Hz, CH_3-C$\underline{H}_2$-); 4.80 ppm (2H m, CH_3-C$\underline{H}$-C$\underline{H}$-); 7.28 ppm (5H s, $C_6\underline{H}_5$-CH_2-).

2c also gave a trace amounts of Phenylacetyl-D-Thr-Gly-OBzl [mp 165—166 °C, $[\alpha]_D^{23}$ −10.6° (*c* 1.0, DMF)].

N-[α-(Benzyloxycarbonylamino)crotonylglycine Ethyl Ester (4-11) and Ethyl 5-Ethylidenehydantoin-3-acetate (5-11): **2m** (2.1 g, 4.26 mmol) and Et_3N (1.78 ml, 12.8 mmol) was treated in THF by the above detosylation procedure. The crude product having two components was subjected to silica gel chromatography developed by the mixed solvent, $CHCl_3$–ethyl acetate (2:1 v/v). The product of R_f 0.85[5] was **4**-11 and R_f 0.65[5] was **5**-11: **4**-11 NMR (DMSO-d_6): δ; 1.17 ppm (3H t, 7.0 Hz, C$\underline{H}_3$-C$\underline{H}_2$-); 1.63 ppm (3H d, 7.0 Hz, C$\underline{H}_3$-CH=); 3.81 ppm (2H d, 6.0 Hz, -NH-C$\underline{H}_2$-); 4.08 ppm (2H q, 7.0 Hz, CH_3-C$\underline{H}_2$-); 5.04 ppm (2H s, C_6H_5C$\underline{H}_2$-); 6.30 ppm (1H q, 7.0 Hz, CH_3-C$\underline{H}$=); 7.35 ppm (5H s, $C_6\underline{H}_5CH_2$-); 8.18 ppm (1H t, 6.0 Hz, -N$\underline{H}$-CH_2-); 8.52 ppm (1H s, -N$\underline{H}$-C(=O)-), **5**-11 NMR ($CDCl_3$): δ; 1.26 ppm (3H t, 7.0 Hz, C$\underline{H}_3$-C$\underline{H}_2$-); 1.83 ppm (3H d, 7.8 Hz, C$\underline{H}_3$-CH=); 4.23 ppm (2H q, 7.0 Hz, CH_3-C$\underline{H}_2$-); 4.29 ppm (2H s, =N-C$\underline{H}_2$-); 5.99 ppm (1H q, 7.8 Hz, CH_3-C$\underline{H}$=); 9.01 ppm (1H s, -N$\underline{H}$-CO-).

N-[α-(t-Butoxycarbonylamino)crotonyl]glycine Ethyl Ester (4-12) and 5-11: **2n** (2.1 g, 4.26 mmol) and Et_3N (1.78 ml, 12.8 mmol) was subjected to the above detosylation procedure. The crude product having two components was subjected to silica gel chromatography with use of the mixed solvent, $CHCl_3$–ethyl acetate (2:1 v/v). The product of R_f 0.85[5] was **4**-12 and that of R_f 0.64[5] was **5**-11: **4**-12 NMR (DMSO-d_6): δ; 1.18 ppm (3H t, 7.0 Hz, C$\underline{H}_3$-C$\underline{H}_2$-); 1.39 ppm (9H s, (C$\underline{H}_3$)$_3$-C); 1.62 ppm (3H d, 7.0 Hz, C$\underline{H}_3$-CH=); 3.82 ppm (2H d, 6.0 Hz, -NH-C$\underline{H}_2$-CO-); 4.08 ppm (2H q, 7.0 Hz, CH_3-C$\underline{H}_2$-); 6.20 ppm (1H q, 7.0 Hz, CH_3-C$\underline{H}$=). Formation of a small amounts of **5**-11 was detected by thin layer chromatography, no isolation being carried out.

N-(Benzyloxycarbonyldehydroalanyl)glycine Ethyl Ester (4-13) and Ethyl 5-Methylenehydantoin-3-acetate (5-13): **2o** (1.9 g, 4 mmol) and Et_3N (1.1 ml, 8 mmol) were subjected to the above detosylation procedure in THF. The crude product having two components was subjected to silica gel chromatography with use of the mixed solvent, $CHCl_3$–ethyl acetate (1:1 v/v). The product of R_f 0.78[6] was **4**-13 and R_f 0.60[6] was **5**-13: **4**-13 NMR ($CDCl_3$): δ; 1.24 ppm (3H t, 7.1 Hz, C$\underline{H}_3$-C$\underline{H}_2$-); 4.02 ppm (2H d, 5.5 Hz, -NH-C$\underline{H}_2$-CO-); 4.19 ppm (2H q, 7.1 Hz, CH_3-C$\underline{H}_2$-); 5.12 ppm (2H s, C_6H_5C$\underline{H}_2$-); 5.21, 6.08 ppm (1H m, 1H d, 2.0 Hz, C$\underline{H}_2$=C<); 7.33 ppm (5H s, $C_6\underline{H}_5CH_2$-), **5**-13 NMR ($CDCl_3$): δ; 1.25 ppm (3H t, 6.5 Hz, C$\underline{H}_3$-C$\underline{H}_2$-); 4.22 ppm (2H q, 6.5 Hz, CH_3-C$\underline{H}_2$-); 4.28 ppm (1H s, =N-C$\underline{H}_2$-); 4.90 ppm (2H m, C$\underline{H}_2$=C<); 8.42 ppm (1H s, -N$\underline{H}$-CO-).

N-(t-Butoxycarbonyldehydroalanyl)glycine Benzyl Ester (4-14): **2p** (1.45 g, 3 mmol) and Et_3N (0.83 ml, 6 mmol) were subjected to the above detosylation procedure in THF. The crude product was purified by means of silica gel chromatography with use of the mixed solvent, $CHCl_3$–ethyl acetate (1:1 v/v). **4**-14 NMR ($CDCl_3$): δ; 1.45 ppm (9H s, (C$\underline{H}_3$)$_3$-C); 4.12 ppm (2H d, 5.0 Hz, -NH-C$\underline{H}_2$-CO-); 5.10 ppm, 6.02 ppm (1H m, 1H d, 2 Hz, C$\underline{H}_2$=C<); 5.19 ppm (2H s, C_6H_5C$\underline{H}_2$-); 7.34 ppm (5H s, $C_6\underline{H}_5CH_2$-).

(Received July 24, 1976)

Photo-irradiation of friedelin (**1**) in diethyl ether gave a keto ether (**2**), a hydroxy ether (**3**), and an alcohol (**4**). A hydroxy ketone (**5**) was formed by the photo-irradiation reaction of **1** in diethyl ether containing acetone. In the latter case, labeled experiments showed that the photo-produced ketene (**12**) reacted with 1-hydroxy-1-methylethyl radical derived from acetone to give **5**. The formation of **2** could be explained by an attack of an α-radical derived from diethyl ether to **12**. Both **3** and **4** were shown to be derived from a norseco-aldehyde (**11**) which was produced from the ketene (**12**).

The photochemical reaction of friedelin (**1**) in various organic solvents has been reported.[2)] In the present communication, the formation of a keto ether (**2**), a hydroxy ether (**3**), and an alcohol (**4**) by photo-irradiation of **1** in diethyl ether is described. The isolation of a hydroxy ketone (**5**) from the photolysate of **1** in diethyl ether containing acetone is also reported.

Friedelin (**1**) was irradiated in anhydrous diethyl ether under nitrogen* with a high pressure mercury lamp (100 W) for 7 h at room temperature. After the usual work-up, the reaction product proved to be a complex mixture which showed on a thin layer chromatogram (silica gel) three major spots (A, B, and C) and three minor spots in addition to those attributable to known hydrocarbons,[2a,d)] aldehydes,[2f,g,i)] friedelin, and 4-epifriedelin.[2c)] The fraction A gave a keto ether component (**2**). Three diastereomers of hydroxy ether (**3a**—**c**) were obtained from the fractions A, B, and C. From the fraction C, an alcohol (**4**) was obtained.

The keto ether component (**2**) had a molecular formula $C_{31}H_{60}O_2$, which corresponds to a 1 : 1 addition product of friedelin (**1**) and diethyl ether. The IR spectrum showed a carbonyl absorption. In the PMR spectrum, the presence of an α′-methylene group and an α-methine group to an ether oxygen atom was detected. The presence of the ether-moiety was further substantiated by a peak at *m/e* 427 due to a fragmentation $(M-CH_3CH_2OCHCH_3)^+$.

Although the keto ether component (**2**) is considered to consist of a mixture of diastereomers, no information on this point was obtained from its spectral data and a separation of diastereomers by thin layer chromatography using various developing solvents was unsuccessful.

The proposed structure was supported by the following chemical transformations. The reduction of the keto ether (**2**) with lithium aluminium hydride afforded a mixture of hydroxy ethers (**6**). The ether linkage of **6** was cleaved by treatment with boron trichloride[3)] to give a mixture of diols (**7**), which on oxidation with lead tetraacetate afforded an aldehyde (**8**). This aldehyde was found to be identical with the seco-aldehyde (**8**) prepared by oxidation of the known seco-alcohol (**9**)[2d)] (Scheme 1). From these observations, the keto ether (**2**) was formulated as 10β-(4-ethoxy-3-oxopentyl)-5α-ethyl-des-A-friedelane.

Three stereoisomeric hydroxy ethers (**3a**—**c**) from the fractions A, B, and C gave similar spectral data. The IR spectrum and mass spectrum (a peak at *m/e* 414 due to a fragment ion $(M-CH_3CH_2OCH_2CH_3)^+$) of each hydroxy ether (**3a**—**c**) showed the presence of a hydroxyl group and an ether-moiety. The high resolution mass spectrum showed a formula $C_{33}H_{60}O_2$ for **3**. In the PMR spectrum of **3b**, an α′-methylene and α-methine to the ether oxygen atom resonated as quartet, respectively. These results suggest that these hydroxy ethers (**3**) should be formulated as 10β-(3-ethoxy-2-hydroxybutyl)-5α-ethyl-des-A-friedelane.

These hydroxy ethers (**3a**—**c**) were combined and were treated with boron trichloride[3)] to afford a mixture of diols (**10**), which was then oxidized with lead tetraacetate to give a known norseco-aldehyde (**11**)[2f,g,j)] (Scheme 1). The structure of **3** thus determined has two additional asymmetric carbon atoms in addition to those present in 3,4-seco-friedelane skeleton. Although four diastereomers should be obtained theoretically, only three isomers could be isolated from the photolysate. A question, however, whether one of them consists of a mixture of two diastereomers remains to be proved. Configurations have not been assigned to these diastereomers.

The alcohol (**4**) was identical with 5α-ethyl-10β-(2-hydroxyethyl)-des-A-friedelane[2j)] obtained by reduction of the known norseco-aldehyde (**11**).[2f,g,j)]

The oxidation state of the isolated norseco-products, corresponding to an overall reduction, was rather unexpected and requires an explanation. Since the norseco-alcohol (**4**) obtained from irradiation of friedelin-^{18}O (**1**-^{18}O; isotopic abundance, *ca.* 17%)[2g,j)] was shown to contain no ^{18}O atom, the oxygen atom in **4** is not derived from the oxygen atom of the friedelin carbonyl group. The experimental data is shown in Table 1.

We have previously shown[2g,j)] that the ketene (**12**), formed by irradiation of friedelin (**1**) *via* an acyl-alkyl biradical (**13**), is autoxidized with oxygen during the product isolation to afford the norseco-aldehyde (**11**). Two mechanisms have now been considered for the formation of **4**: (i) a mechanism involving a carbene (**14**)[4)] and (ii) a mechanism *via* the norseco-aldehyde (**11**).

In terms of mechanism (i), the ketene (**12**) might

* The commercial nitrogen was used without purification.

undergo decarbonylation on irradiation affording a carbene (**14**), which could react with water to give the norseco-alcohol (**4**) (Scheme 2).

To test this hypothesis, friedelin (**1**) was irradiated in water-free ether saturated with deuterium oxide (99.75% D_2O) and the norseco-alcohol (**4**) was isolated. If the reaction had proceeded through the carbene (**14**), the product would have been the dideuterio alcohol (**4**-d_2), which would give a monodeuterio alcohol (**4**-d_1) by usual aqueous work-up. Therefore, the reaction product should contain *one* deuterium atom at C-2 as shown in **4**-d_1.

The mass spectrometric examination of the product showed, however, that the incorporation of a deuterium atom had not occurred (Table 2) and that the mechanism (i) can consequently be excluded.

Directing attention to the second mechanism, the photo-produced ketene (**12**) could be autoxidized by oxygen[2g,j,5,6] which may be present in the reaction system to afford the norseco-aldehyde (**11**). The aldehyde (**11**) would then undergo photochemical reduction[7] in ether to give the norseco-alcohol (**4**).

4 (photoproduct obtained by irradiation with D_2O)	100	32.1	5.7

a) Relative intensities in %.

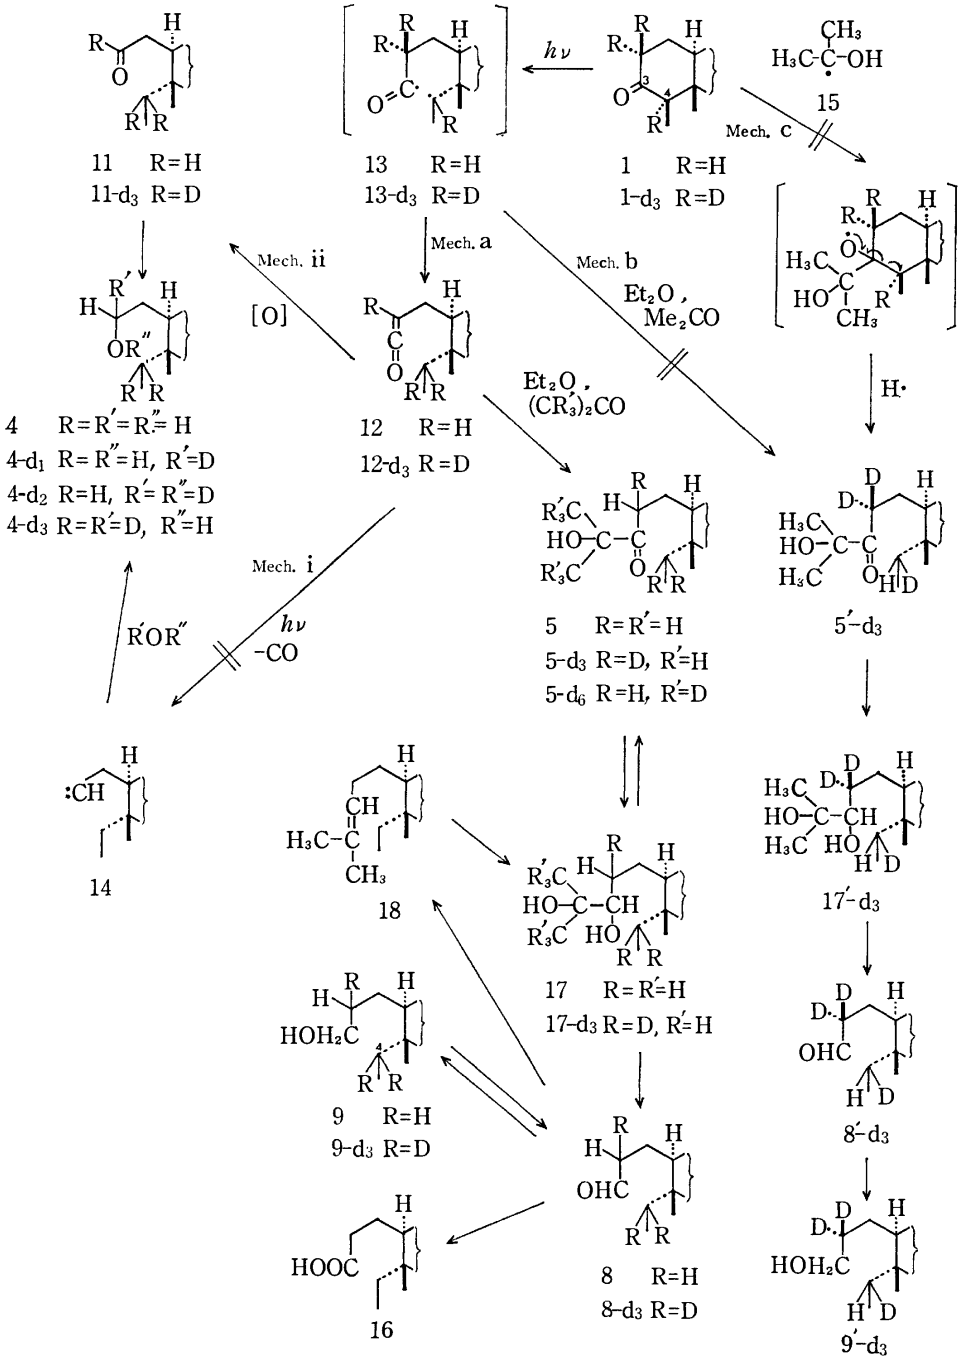
The involvement of oxygen in the formation of **4** was demonstrated as follows. Friedelin (**1**) was irradiated in anhydrous diethyl ether under oxygen-free argon purified by passing over copper at 500 °C. The hydrocarbons, aldehydes, friedelin, 4-epifriedelin, and the keto ether (**2**) were obtained, while neither the hydroxy ether (**3**) nor the norseco-alcohol (**4**) was detected by thin layer chromatography. Since the irradiation of friedelin (**1**) under commercial nitrogen gave **3** and **4**, oxygen present in the commercial nitrogen is implicated in the formation of these products. Following this conclusion, the intermediacy of the ketene (**12**) and norseco-aldehyde (**11**) in the photo-reaction was examined.

Irradiation of 2α,2β,4α-trideuteriofriedelin (**1**-d_3)[2g,i] in ether afforded a deuteriated alcohol (**4**-d_3), which gave a molecular ion peak at *m/e* 419. The methylene group at C-2 in **4** resonated as a triplet with an integrated intensity due to two protons, while the integrated intensity of a triplet in **4**-d_3 corresponded to one proton. On addition of $Eu(dpm)_3$ as a shift reagent, the C-4 methyl protons were readily assignable with the triplet signal for nonlabeled alcohol (**4**) appearing as a singlet in **4**-d_3. These observations indicate that the methylene group at C-4 of **4**-d_3 was labeled with two deuterium atoms and the methylene group at C-2 with one deuterium atom, in accordance with formation of **4**-d_3 *via* the ketene (**12**-d_3).

The norseco-aldehyde (**11**)[2f,j] was irradiated in ether, and from the reaction products, the norseco-alcohol (**4**) and the hydroxy ether (**3**) were isolated.

These experimental results show that the ketene (**12**) formed by irradiation is autoxidized with oxygen in the reaction system to give the norseco-aldehyde (**11**), which is subsequently reduced photochemically to yield **3** and **4**. The final photoreduction step[7] is outlined in Scheme 3.

The formation of the keto ether (**2**) is likely to suggest a novel reaction between a photochemically produced ketene and an α-radical derived from diethyl ether.



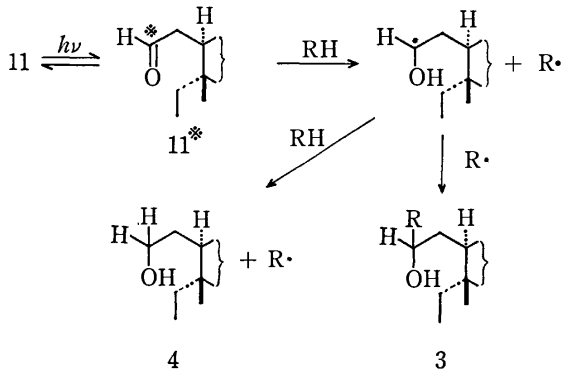
Scheme 2.

Friedelin (**1**) in ether containing acetone was irradiated in a quartz vessel under the usual conditions. The irradiation products were separated by column and thin layer chromatography to give a hydroxy ketone (**5**), whose PMR spectrum showed the presence of $(CH_3)_2C$-(OH)- group and whose molecular formula $C_{33}H_{58}O_2$ showed an increment of C_3H_8O in comparison with that of friedelin. On acetylation, the hydroxy ketone (**5**) gave an acetoxy ketone.

The structure of the hydroxy ketone (**5**) was confirmed by conversion to the known 10β-(2-carboxyethyl)-5α-ethyl-des-A-friedelane (**16**).[2b] It was subjected to consecutive reduction with lithium aluminium hydride, oxidation with lead tetraacetate and with silver oxide to afford a seco-acid (**16**) (Scheme 2).

A partial synthesis of **5** confirmed the proposed structure. The aldehyde (**8**) was treated with isopropyltriphenylphosphonium bromide.[8,9] The resulting isopropylidene derivative (**18**)[10] was oxidized with osmium tetraoxide[11] to give a mixture of diols (**17**), which on oxidation with chromium trioxide[12] yielded the hydroxy ketone (**5**), identical with the photo-irradiation product (Scheme 2).

A solution of **1** in ether and acetone-d_6 was irradiated for 5 h, and the resulting hydroxy ketone (**5**-d_6) was isolated and examined. The molecular ion peak was observed at *m/e* 492, *i.e.* 6 mass units higher than that of the non-labeled **5**. In the PMR spectrum, a singlet



$$R = -\underset{\underset{CH_3}{|}}{CH}OC_2H_5$$

(An asterisk refers to an activated state.)

Scheme 3.

signal (δ 1.37) due to two tertiary methyl group in **5** was not observed in **5**-d_6. The presence of pinacol in the photolysate was demonstrated by gas chromatographic examination further supporting the involvement of 1-hydroxy-1-methylethyl radical (**15**) in the photolysis of friedelin (**1**) in ether containing acetone.

Three mechanisms (outlined in Scheme 2 as "a", "b", and "c") were considered for the formation of the hydroxy ketone (**5**). a) The attack of the radical (**15**) at the carbonyl carbon atom of the ketene (**12**), followed by addition of a hydrogen atom to C-2. b) The addition of the radical (**15**) to the acyl radical (C-3) of the biradical (**13**), followed by addition of a hydrogen atom to the alkyl radical (original C-4 of friedelin). c) The attack of the radical (**15**) to the carbonyl carbon atom (C-3) of friedelin (**1**), followed by β-scission between C-3 and C-4, and then by addition of a hydrogen atom to the carbon atom at C-4.

In order to distinguish among these hypotheses, 2α,2β,4α-trideuteriofriedelin (**1**-d_3) was irradiated in ether containing acetone. A trideuteriated hydroxy ketone (**5**-d_3) was obtained showing the molecular ion peak at *m/e* 489. The trideuteriated hydroxy ketone (**5**-d_3) was degradated to give **8**-d_3 and **9**-d_3 by the previously described procedures. In the PMR of the trideuteriated seco-aldehyde (**8**-d_3), the aldehydic proton was observed as a doublet. Furthermore, a triplet signal due to the methyl group (proton on C-23) attached to the C-4 atom of non-labeled alcohol (**9**) appeared as a singlet in the case of the trideuteriated seco-alcohol (**9**-d_3).

These observations lead to the conclusion that 1-hydroxy-1-methylethyl radical (**15**) attacked the carbonyl carbon atom of the ketene (**12**) to form a C-2 radical, which abstracts a hydrogen atom from the solvent (mechanism "a"). The alternative mechanisms "b" and "c" are excluded by the same experiment, since the degradation of the photo-product (**5'**-d_3) would lead to the aldehyde (**8'**-d_3) and then to the alcohol (**9'**-d_3). The aldehydic proton of **8'**-d_3 and the methyl protons at C-4 of **9'**-d_3 should resonate as a singlet and a doublet, respectively, in the PMR spectra. The formation of the keto ether (**2**), obtained by the photo-irradiation of friedelin (**1**) in ether, may also best be interpreted by a pathway analogous to the mechanism "a".

Experimental

Instruments and general procedures are described in previous papers.[1,2k] Gas-liquid phase chromatographic (GLC) analyses were determined on a Shimadzu gas chromatograph model GC-6A. Analytical and preparative thin layer chromatographies (TLC) were carried out on Kieselgel G nach Stahl (E. Merck) and Silica gel PF_{254} (E. Merck), respectively. Column chromatography was carried out on Wakogel C-200 (Wako). Diethyl ether (Wako) was washed with dilute sulfuric acid and water and dried over calcium chloride. The ether was distilled from lithium aluminium hydride. Acetone (Wako) was dried over potassium carbonate and distilled.

Photochemical Reaction of Friedelin (1) in Diethyl Ether. Nitrogen (Suzuki-shokan Co.) was bubbled through a refluxing solution of friedelin (**1**: 455 mg) in diethyl ether (300 ml) for 30 min, then the solution cooled to room temperature was irradiated with a high pressure mercury lamp for 7 h under nitrogen. The solvent was evaporated under reduced pressure, the residue dissolved in benzene and passed through a column of silica gel (50 g), and eluted with benzene (each fraction 50 ml). In fractions 1—3, hydrocarbons and aldehydes were eluted and from fractions 4—13 a residue (131 mg) was obtained. Subjection of the residue to preparative TLC using benzene–chloroform (1: 1) afforded fractions A, B, and C. Each fraction was further separated by preparative TLC developed with benzene–ether (10: 1).

The keto ether (**2**; 24 mg) was isolated from the fraction A but could not be separated into each diastereomer by TLC using various eluents. A few milli grams of a stereoisomer of the hydroxy ether (**3a**; IR (Nujol) 3580, 3470, and 1100 cm^{-1}; MS *m/e* 488) was also obtained from the fraction A.

The fraction B gave a diastereomer of the hydroxy ether (**3b**; about 40 mg) by the second preparative TLC, IR (Nujol) 3580, 3470, and 1100 cm^{-1}; MS *m/e* 488; the PMR and high resolution mass spectra (*vide infra*).

From the fraction C, the third isomer of the hydroxy ether (**3c**; a few mg; IR (Nujol) 3580, 3470, and 1100 cm^{-1}; MS *m/e* 488) and the norseco-alcohol (**4**; 9 mg) were isolated.

10β-(4-Ethoxy-3-oxopentyl)-5α-ethyl-des-A-friedelane (2). The keto ether (**2**) was obtained as an oil, IR (Nujol) 1705, 1110, 1000, 910, 850, and 800 cm^{-1}; PMR δ ≈0.80 (6H, s and t overlapped, 2×CH_3), 0.89, 0.97, 1.20, 1.25 (each 3H, s, *t*-CH_3), 1.00—1.05 (12H, br. s, 4×CH_3), 2.58 (2H, t, J=8 Hz, $C_{(2)}$-H), 3.49 (2H, q, J=7 Hz, $CH_3C\underline{H}_2O$), and 3.79 (1H, q, J=7 Hz, $CH_3\underline{C}H$–O); MS *m/e* 500 (M^+, 18%), 485, 471, 455, 427, 371, 333, 312, 301, 273 (100%), 259, 245, 231, 218, and 205; Found: C, 81.24; H, 11.93%. Calcd for $C_{34}H_{60}O_2$: C, 81.53; H, 12.08%.

10β-(3-Ethoxy-2-hydroxybutyl)-5α-ethyl-des-A-friedelane (3). Three diastereomers (**3a**—**c**) were obtained as oil and gave similar spectral data (*vide supra*). The hydroxy ether (**3b**), obtained from fraction B, provided the following data; IR (Nujol) 3580, 3470, 1100, 1000, 850, and 800 cm^{-1}; PMR δ ≈0.80 (6H, s and t overlapped, 2×CH_3), 0.90, 0.96 (each 3H, s, *t*-CH_3), 1.01 (12H, br. s, 4×CH_3), 1.19 (6H, s, 2×CH_3), 3.48 (2H, q, J=7 Hz, $CH_3C\underline{H}_2O$), 3.52 (1H, q, J=7 Hz, $CH_3\underline{C}H$–O), and 3.3—3.8 (1H, br. s, $C_{(2)}$–H); MS *m/e* 488 (M^+, 22%), 473, 459, 432, 411, 402, 387, 385, 301, 273 (100%), 218, and 205; MW 488.4636 (by high resolution mass spectrometry). Calcd for $C_{33}H_{60}O_2$: 488.4591.

5α-Ethyl-10β-(2-hydroxyethyl)-des-A-friedelane (4). Crystallization from ether gave colorless crystals, mp 155—156 °C; IR (Nujol) 3300, 1050, and 800 cm^{-1}; PMR δ ≈0.80

(6H, s, and t overlapped, $2\times CH_3$), 0.89, 0.97, 1.19 (each 3H, s, t-CH_3), 1.01 (9H, s, $3\times t$-CH_3), and 3.53 (2H, t, J=8 Hz, $C_{(2)}$-H); MS *m/e* 416 (M^+, 33%), 401, 387, 381, 360, 301, 273 (100%), 249, 218, and 205. This was identical with an authentic 5α-ethyl-10β-(2-hydroxyethyl)-des-A-friedelane (**4**).

Degradation of 10β-(4-Ethoxy-3-oxopentyl)-5α-ethyl-des-A-friedelane (2). The keto ether (**2**; 38 mg) in ether (30 ml) and lithium aluminium hydride (150 mg) were heated under reflux for 3 h. The usual work-up and separation on preparative TLC using benzene–ether (10: 1) gave 10β-(4-ethoxy-3-hydroxypentyl)-5α-ethyl-des-A-friedelane (**6**; 32 mg) as a mixture of diastereomers; an amorphous solid, IR (Nujol) 3550, 3450, 1100, 1000, 840, and 800 cm^{-1}; PMR $\delta \approx 0.79$ (6H, s and t overlapped, $2\times CH_3$), 0.89, 0.95 (each 3H, s, t-CH_3), 1.00 (12H, br. s, $4\times CH_3$), and 3.15—3.85 (4H, m, CH–O–); MS *m/e* 502 (M^+, 10%), 487, 473, 446, 430, 415, 401, 335, 323, 301, 273 (100%), 218, and 205.

A solution of **6** (26 mg) in dry methylene dichloride (1 ml) was kept at −78 °C, and a solution of boron trichloride (3 ml) in methylene dichloride (2 ml) was added. The resulting solution was stirred at −78 °C for 2 h and then allowed to stand overnight at room temperature. The solvent was removed under reduced pressure and aqueous methanol was added. Methanol was removed under reduced pressure and the residue was extracted with ether (100 ml). Usual work-up and purification by preparative TLC developed with benzene–ether (10: 1) afforded diastereomers of 10β-(3,4-dihydroxypentyl)-5α-ethyl-des-A-friedelane (**7**; 9 mg) as an oil; IR (Nujol) 3400 and 1080 cm^{-1}; PMR $\delta \approx 0.80$ (6H, s and t overlapped, $2\times CH_3$), 0.89, 0.95, 1.19 (each 3H, s, t-CH_3), 1.00 (12H, br. s, $4\times CH_3$), and 3.25—3.95 (2H, m); MS *m/e* 474 (M^+, 12%), 459, 457, 445, 441, 425, 418, 413, 380, 307, 301, 273 (100%), 218, and 205.

To a solution of the diastereomeric diols (**7**; 8.4 mg) in benzene (5 ml), a saturated solution of lead tetraacetate in acetic acid (10 ml) was added and the mixture was stirred at room temperature for 2 h. A saturated aqueous sodium hydrogencarbonate solution was added and the mixture was extracted with ether. The reaction products were separated by preparative TLC using benzene to afford 5α-ethyl-10β-(2-formylethyl)-des-A-friedelane (**8**; 5.4 mg). This was identical with an authentic seco-aldehyde (**8**).

Degradation of 10β-(3-Ethoxy-2-hydroxybutyl)-5α-ethyl-des-A-friedelane (3). Due to a paucity of the hydroxy ethers (**3a**—**c**), these compounds were combined and subjected to the following degradation.

A solution of the hydroxy ethers (**3a**—**c**; 41 mg) in methylene dichloride (1 ml) was kept at −78 °C and a solution of boron trichloride (3 ml) in methylene dichloride (2 ml) was added. The resulting solution was stirred at 0 °C for 1.5 h and then at room temperature for 5 h. The solvent was removed under reduced pressure and aqueous methanol (1 ml) was added. Methanol was removed under reduced pressure and the residue was extracted with ether (100 ml). After usual work-up, the reaction mixture was separated by preparative TLC using benzene–ether (10: 1) to give diastereomers of 10β-(2,3-dihydroxybutyl)-5α-ethyl-des-A-friedelane (**10**; 18 mg) as an oil; IR (Nujol) 3400, 1050, 980, 860, and 800 cm^{-1}; PMR $\delta \approx 0.83$ (6H, s and t overlapped, $2\times CH_3$), 0.90, 0.95, 1.19 (each 3H, s, t-CH_3), 1.10 (12H, br. s, $4\times CH_3$), and 3.20—3.38 (2H, m); MS *m/e* 460 (M^+, 31%), 445, 431, 427, 404, 380, 301, 293, 273 (100%), 218, and 205.

To a solution of the diols (**10**; 18 mg) in benzene (5 ml), a saturated solution of lead tetraacetate in acetic acid (10 ml) was added. The solution was treated according to the same procedure as in the case of the diols (**7**). 5α-Ethyl-10β-formylmethyl-des-A-friedelane (**11**; 10 mg) was obtained, mp 182 °C (crystallized from ether); IR (Nujol) 2710 and 1705 cm^{-1}; PMR $\delta \approx 0.80$ (6H, s and t overlapped, $2\times CH_3$), 0.90, 0.96, 1.20 (each 3H, s, t-CH_3), 1.01 (9H, s, $3\times CH_3$), and 9.78 (1H, t, J=2.5 Hz, -CHO); MS *m/e* 414 (M^+, 27%), 399, 301, 290, 273, 218, and 205 (100%). This was identical with an authentic norseco-aldehyde (**11**).[2f,g,j]

Photochemical Reaction of Friedelin-^{18}O (1-^{18}O) in Ether. Irradiation of friedelin-^{18}O (**1**-^{18}O; 180.7 mg) in ether (200 ml) in a quartz vessel under a nitrogen atmosphere for 10 h, followed by solvent removal under reduced pressure yielded a residue, which was chromatographed on silica gel (20 g). A norseco-alcohol fraction was further subjected to preparative TLC to give 5.2 mg of **4**. The ^{18}O-isotopic abundance in the starting material (**1**-^{18}O) and the product (**4**) was examined by the mass spectrometry (Table 1).

Photochemical Reaction of Friedelin (1) in Ether Containing Deuterium Oxide. Friedelin (**1**; 322 mg) was dissolved in ether (200 ml) which was freshly distilled from lithium aluminium hydride and was saturated with deuterium oxide (D_2O 99.75%, Showa-denko Co.). The solution was irradiated for 8 h as before. The same work-up and separation procedure gave the norseco-alcohol (**4**; 9.1 mg). The deuterium isotopic abundance of the product (**4**) was examined by mass spectrometry (*Cf.* Table 2).

Photochemical Reaction of 2α,2β,4α-Trideuteriofriedelin (1-d_3) in Ether. Trideuteriofriedelin** (**1**-d_3; 292 mg) in ether (200 ml) was irradiated under the same conditions for 10 h and worked up as before to afford a trideuterio norseco-alcohol (**4**-d_3; 7.3 mg), PMR $\delta \approx 0.80$ (6H, s, $2\times CH_3$), 0.89, 0.95, 1.19 (each 3H, s, t-CH_3), 1.00 (9H, s, $3\times t$-CH_3), and 3.53 (1H, t, J=8 Hz, $C_{(2)}$-H); MS *m/e* 419 (M^+, 19%), 404, 388, 301, 273, 218, and 205 (100%). When $Eu(dpm)_3$ was added to a 1% (w/v) solution of **4**-d_3 in $CDCl_3$ [$Eu(dpm)_3$/**4**-d_3=1.1 (in molar ratio)], $C_{(4)}$-CH_3 signal appeared at δ 2.35 as a singlet. Under the same conditions, $C_{(4)}$-CH_3 of non-labeled alcohol (**4**) resonated at δ 2.35 as a triplet (J=7 Hz).

Photochemical Reaction of Friedelin (1) in Ether Under Oxygen-free Argon. Friedelin (**1**; 1.07 g) in ether (700 ml) was heated under reflux for 30 min with bubbling of oxygen-free argon*** in a quartz irradiation vessel. The solution, after cooling, was irradiated for 24 h under the oxygen-free argon at room temperature. The solvent was removed under reduced pressure to give a residue, which was examined by TLC and shown to contain neither **3** nor **4**. The residue was dissolved in benzene, passed through a column of silica gel (100 g), and eluted with benzene (each fraction 100 ml). Fractions 5 and 6 were combined and further subjected to preparative TLC developed with benzene–petroleum ether–methylene dichloride (4: 3: 2) to give keto ether component (**2**; 78 mg).

Photochemical Reaction of 5α-Ethyl-10β-formylmethyl-des-A-friedelane (11). A solution of the norseco-aldehyde (**11**; 178 mg, prepared from norfriedelin[2j]) in ether (700 ml) was irradiated in a Pyrex vessel for 62 h under a nitrogen atmosphere at room temperature. After usual treatment, preparative TLC using benzene–chloroform (1: 1) gave the three diastereomers of hydroxy ether (**3a**—**c**; total weight 49 mg) and the norseco-alcohol (**4**; 11 mg).

Photochemical Reaction of Friedelin (1) in Ether Under an Oxygen Atmosphere. Friedelin (**1**; 1.01 g) in ether (800 ml)

** Mass spectrometry showed that the deuteriated friedelin (**1**-d_3) consisted of -d_3 (80%), -d_2 (20%), -d_1 (0%), and -d_0 (0%).

*** Argon was purified by passing over copper (pretreated with a flow of hydrogen at 200 °C) placed in a quartz tube and heated at 500 °C.

was irradiated in a Pyrex vessel with a high pressure mercury lamp for 48 h under an oxygen atmosphere at room temperature.[2h] The solvent was removed to afford a residue. The TLC examination showed the presence of friedelin (recovered unchanged, a major spot), the seco-carboxylic acid (**16**), a norseco-carboxylic acid[2e,j] and putranjivic acid,[2h,13] while the presence of the hydroxy ether (**3**) and the norseco-alcohol (**4**) could not be demonstrated.

Photochemical Reaction of Friedelin (1) in Ether Containing Acetone. Friedelin (**1**; 86 mg) was dissolved in ether (30 ml) containing acetone (0.5 ml) in a quartz vessel and heated under reflux for 30 h with bubbling of nitrogen. The solution was cooled and irradiated with a high pressure mercury lamp for 2 h at room temperature. A small quantity of the solution was taken out and subjected to GLC examination, which showed the formation of pinacol (R_t 7.7 min (Carbowax C-20 M, 100 °C) and 11.7 min (DGS, 100 °C)). The reaction mixture, after evaporation of the solvent under reduced pressure, was separated by preparative TLC with benzene as eluent. 5α-Ethyl-10β-(4-hydroxy-4-methyl-3-oxopentyl)-des-A-friedelane (**5**; 12 mg) was obtained after recrystallization from light petroleum, mp 180.5—181.5 °C; IR (Nujol) 3500, 1705, and 1140 cm^{-1}; PMR δ ≈0.80 (6H, s and t overlapped), 0.89, 0.95, 1.03, 1.18 (each 3H, s, *t*-CH_3), 1.00 (6H, s, 2×*t*-CH_3), 1.37 (6H, s, $(C\underline{H}_3)_2C(OH)$-), 2.40—2.75 (2H, m, -$C\underline{H}_2$-C=O), and 3.77 (1H, s, -C̈-OH; disappeared on addition of D_2O); (CD_3COCD_3) δ≈4.18 (1H, s, -C̈-OH; disappeared on addition of D_2O); MS *m/e* 486 (M^+, 10%), 471, 457, 453, 443, 430, 428, 413, 319, 307, 275, 274, 273, and 205 (100%); Found: C, 81.57; H, 12.07%. Calcd for $C_{33}H_{58}O_2$: C, 81.42; H, 12.01%.

Acetate of 5α-Ethyl-10β-(4-hydroxy-4-methyl-3-oxopentyl)-des-A-friedelane (5). A mixture of the hydroxy ketone (**5**; 32 mg), pyridine, and acetic anhydride was heated on stream bath for 10.5 h. The reaction mixture was treated as usual and the product crystallized from methanol twice to afford the acetate (21 mg), mp 159—160 °C; IR (Nujol) 1724 and 1247 cm^{-1}; PMR δ≈0.79 (6H, s and t overlapped, 2×CH_3), 0.86, 0.94, 1.01, 1.17 (each 3H, s, *t*-CH_3), 0.99 (6H, s, 2×*t*-CH_3), 1.44 (6H, s, $(C\underline{H}_3)_2C(OAc)$-), and 2.25—2.60 (2H, m, -CH_2C=O); MS *m/e* 528 (M^+).

Degradation of 5α-Ethyl-10β-(4-hydroxy-4-methyl-3-oxopentyl)-des-A-friedelane (5). To the hydroxy ketone (**5**; 12 mg) in ether (5 ml), lithium aluminium hydride (17 mg) in ether (5 ml) was added and the mixture was heated under reflux for 2 h. After decomposition of the excess reagent by addition of wet ether, the mixture was treated as usual. Column chromatography of the residue on silica gel (50 g) afforded a mixture of the diastereomeric diols (**17**; 9 mg), mp 188—189 °C; IR (Nujol) 3400, 1170, 1080, and 960 cm^{-1}; PMR δ ≈0.80 (6H, s and t overlapped, 2×CH_3), 0.90, 0.96, 1.03, 1.16, 1.19, 1.21 (each 3H, s, *t*-CH_3), 1.01 (6H, s, 2×*t*-CH_3), and 4.62 (1H, s, -C̈-OH; disappeared on addition of D_2O); MS *m/e* 488 (M^+, 15%), 473, 470, 459, 455, 441, 432, 430, 415, 321, 309, 301, 273 (100%), 218, and 205; Found: C, 79.80; H, 12.51%. Calcd for $C_{33}H_{60}O_2 \cdot 1/2\,H_2O$: C, 79.62; H, 12.35%.

A saturated solution of lead tetraacetate in acetic acid (10 ml) was added to the diols (**17**; 2.8 mg) in benzene (5 ml) and the mixture was stirred for 1 h. The excess lead tetraacetate was decomposed by addition of saturated sodium hydrogencarbonate solution until the solution became alkaline and the solution was extracted with ether (500 ml). After usual work-up, the residue was chromatographed on silica gel using benzene to give an aldehyde (**8**; 2.5 mg). This was identical with an authentic seco-aldehyde (**8**).

A mixture of silver nitrate (41 mg) in water (1 ml) and 0.05 M sodium hydroxide solution (5 ml) was added to the seco-aldehyde (**8**; 1.8 mg) in ethanol (5 ml) with stirring, which was continued for 2 h. The solvents were evaporated under reduced pressure to give a residue, to which ether (100 ml) was added. The resulting solution was acidified with 1 M hydrochloric acid and extracted with ether. After usual work-up, purification of the residue by preparative TLC afforded 10β-(2-carboxyethyl)-5α-ethyl-des-A-friedelane (**16**; 1.1 mg); IR (Nujol) 1705, 1290, and 1220 cm^{-1}; MS *m/e* 444 (M^+, 16%), 429, 405, 401, 388, 369, 368, 320, 301, 291, 273, 218 (100%), and 205. This was identical with an authentic seco-carboxylic acid (**16**).[2b]

Synthesis of 5α-Ethyl-10β-(4-hydroxy-4-methyl-3-oxopentyl)-des-A-friedelane (5) from 5α-Ethyl-10β-(3-hydroxypropyl)-des-A-friedelane (9). 5α-Ethyl-10β-(3-hydroxypropyl)-des-A-friedelane (**9**; 694 mg) was dissolved in a minimum volume of methylene dichloride and a mixture of chromium trioxide (1.34 g), pyridine (840 mg), and methylene dichloride (23 ml) was added to the solution. After stirring for 15 min, the methylene dichloride solution was separated by decantation and the precipitate was washed with methylene dichloride (150 ml). The supernatant and the washings were combined and washed with 5% sodium hydrogencarbonate solution (100 ml), 5% hydrochloric acid (100 ml), and then with 5% sodium hydrogencarbonate solution (100 ml). Usual work-up gave a residue, which was recrystallized from ether to afforded the seco-aldehyde (**8**; 657 mg); mp 147—148 °C; IR (Nujol) 2720, 1720, and 1005 cm^{-1}; PMR δ ≈0.81 (6H, s and t overlapped, 2×CH_3), 0.90, 0.96, 1.19 (each 3H, s, *t*-CH_3), 1.01 (9H, s, 3×*t*-CH_3), 2.20—2.60 (2H, m, -$C\underline{H}_2$-CHO), and 9.73 (1H, t, *J*=2 Hz, -CHO); MS *m/e* 428 (M^+, 9%), 413, 400, 399, 385, 372, 362, 319, 304, 279, 273, 265 (100%), 218, and 205; Found: C, 84.26; H, 12.44%. Calcd for $C_{30}H_{52}O$: C, 84.04; H, 12.23%.

To a suspension of isopropyltriphenylphosphonium bromide (960 mg) in ether, 15% butyllithium solution in hexane (2.1 ml) was added with stirring under nitrogen. A deep red solution was obtained, to which a solution of the seco-aldehyde (**8**; 206 mg) in ether (10 ml) was added. The reaction mixture was stirred for 3 h and then tetrahydrofuran (50 ml) was added. The ether was removed and the remaining solution was heated under reflux for 2 h. After cooling, water (100 ml) was added to the solution and the mixture was extracted with ether (200 ml). The ethereal extract was washed with saturated aqueous sodium chloride solution, 1 M hydrochloric acid (100 ml) and then with aqueous sodium chloride solution. Usual work-up gave a residue, which was purified by column chromatography on silica gel (30 g) using petroleum ether. Recrystallization from petroleum ether gave the isopropylidene derivative (**18**; 130 mg), mp 147.5—148 °C; IR (Nujol) 1050, 1000, and 990 cm^{-1}; PMR δ≈1.50 (3H, br., C=C-CH_3), 1.68 (3H, br., C=C-CH_3), and 5.10 (1H, t, *J*=7 Hz, C=C$\underline{H}$-CH_2-); MS *m/e* 454 (M^+, 17%) and 205 (100%); Found: C, 87.38; H, 12.90%. Calcd for $C_{33}H_{58}$: C, 87.14; H, 12.86%.

To a solution of the isopropylidene derivative (**18**; 68 mg) in ether (5 ml), osmium tetraoxide (55 mg) in pyridine (1 ml) was added and the reaction mixture was stirred for 6 h. The solvents were evaporated and ethanol (3 ml), sodium sulfite (406 mg), and water (1 ml) were added to the residue. The reaction mixture was heated under reflux for 2 h and, after cooling, filtered. The precipitate was washed with ethanol. The filtrate and the washings were combined and evaporated under reduced pressure, and the residue purified by column chromatography on silica gel (20 g). Elution with benzene–ether (5: 3) afforded a mixture of the diastereomeric diols (**17**; 27 mg), mp 188—189 °C (crystallized from ether); IR (Nujol) 3400, 1170, 1090, and 960 cm^{-1}; PMR δ ≈0.80 (6H,

s and t overlapped, $2\times CH_3$), 0.90, 0.96, 1.03, 1.16, 1.19, 1.21 (each 3H, s, *t*-CH_3), 1.01 (6H, s, $2\times$*t*-CH_3), and 4.62 (1H, s, -C̲-OH; disappeared on addition of D_2O); MS *m/e* 488 (M^+, 31%) and 273 (100%).

To a solution of chromium trioxide (60 mg) in pyridine (52 mg) and methylene dichloride (50 ml), the diols (**17**; 22 mg) in methylene dichloride (5 ml) was added and the reaction mixture was stirred for 15 min. The methylene dichloride solution was separated by decantation and the precipitate was washed with methylene dichloride (100 ml). The supernatant and washings were combined and washed with 5% sodium hydrogencarbonate solution. After usual work-up, the residue was subjected to column chromatographic separation to afford the seco-aldehyde (**8**; 12 mg) and the hydroxy ketone (**5**; 3 mg). The former was identical with the seco-aldehyde (**8**). The latter was completely identical with the photoproduced hydroxy ketone (**5**).

Photochemical Reaction of Friedelin (1) in Ether Containing Acetone-d_6. Friedelin (**1**; 317 mg) was dissolved in ether (150 ml) containing acetone-d_6 (1 ml; 99.8%, Showa-denko Co.) in a quartz vessel, The solution was irradiated for 5 h under the same conditions and then treated as before. The residue was chromatographed on silica gel (50 g), eluted with benzene and fractions containing the keto ether were collected and purified by preparative TLC to give 5α-ethyl-10β-(5,5,5-trideuterio-4-hydroxy-4-trideuteriomethyl-3-oxopentyl)-des-A-friedelane (**5**-d_6; 45 mg); IR (Nujol) 3500, 2220, 1705, and 1130 cm^{-1}; PMR δ ≈0.80 (6H, s and t overlapped), 0.89, 0.95, 1.03, 1.18 (each 3H, s, *t*-CH_3), 1.00 (6H, s, $2\times$*t*-CH_3), 2.40—2.75 (2H, m, -C̲H_2-C̲=O), and 3.75 (1H, s, -OH); MS *m/e* 492 (M^+, 15%), 477, 463, 446, 443, 428, 413, 325, 313, 301, 273, 218, and 205 (100%).

Photochemical Reaction of 2α,2β,4α-Trideuteriofriedelin (1-d_3*) in Ether Containing Acetone.* 2α,2β,4α-Trideuteriofriedelin (**1**-d_3; 514 mg) was dissolved in ether (450 ml) containing acetone (2 ml) and the solution was irradiated for 5 h. The reaction mixture was treated as usual and separated by column chromatography on silica gel (50 g) and subsequently preparative TLC to afford 5α-(1,1-dideuterioethyl)-10β-(2-deuterio-4-hydroxy-4-methyl-3-oxopentyl)-des-A-friedelane (**5**-d_3; 55 mg); IR (Nujol) 3500, 2160, 2100, 1705, 1130, and 980 cm^{-1}; PMR δ ≈0.80 (6H, s and t overlapped, $2\times CH_3$), 0.89, 0.95, 1.02, 1.08 (each 3H, s, *t*-CH_3), 1.00 (6H, s, $2\times$*t*-CH_3), 1.37 (6H, s, $(C\underline{H}_3)_2C(OH)$-), 2.30 (1H, m, -CHD-C=O), and 3.76 (1H, br., -OH); MS *m/e* 489 (M^+, 9%) and 205 (100%).

Degradation of Trideuterio-5α-ethyl-10β-(4-hydroxy-4-methyl-3-oxopentyl)-des-A-friedelane (5-d_3*).* The hydroxy ketone-d_3 (**5**-d_3; 48 mg) in ether (10 ml) was heated under reflux with lithium aluminium hydride (47 mg) and usual treatment and separation gave the diols-d_3 (**17**-d_3; 20 mg); MS *m/e* 419 (M^+, 24%), 476, 458, 324, 301, 273 (100%), 218, and 205.

To the diols-d_3 (**17**-d_3; 18 mg) in benzene (10 ml), was added lead tetraacetate (45 mg) in acetic acid (15 ml) and the reaction mixture was stirred for 3 h. Usual treatment and purification afforded the aldehyde-d_3 (**8**-d_3; 16 mg); PMR δ ≈0.80 (6H, s and t overlapped, $2\times CH_3$), 0.90, 0.97, 1.19 (each 3H, s, *t*-CH_3), 1.00 (9H, s, $3\times$*t*-CH_3), 2.20—2.60 (1H, m, -C̲HD-CHO), and 9.73 (1H, d, J=2 Hz, -CHD-C̲HO); MS *m/e* 431 (M^+, 19%), 416, 301, 273, 218 (100%), and 205.

A mixture of the trideuterio-seco-aldehyde (**8**-d_3; 15 mg) in ether (10 ml) and lithium aluminium hydride (70 mg) was heated under reflux for 3 h. After usual work-up, separation afforded 2,4,4-trideuterio-5α-ethyl-10β-(3-hydroxypropyl)-des-A-friedelane (**9**-d_3; 12 mg); IR (Nujol) 3600, 3450, 2160, 1280, and 1050 cm^{-1}; PMR δ ≈0.79 (6H, s and t overlapped, $2\times CH_3$), 0.88, 0.96, 1.19 (each 3H, s, *t*-CH_3), 1.00 (9H, s, $3\times$*t*-CH_3), 3.95 (2H, d, J=6 Hz, -CHD-C̲H_2OH); MS *m/e* 433 (M^+, 31%), 428, 402, 301, 279, 273 (100%), 265, 218, and 205. When $Eu(dpm)_3$ was added to a 1.6% (w/v) solution of **9**-d_3 in $CDCl_3$ [$Eu(dpm)_3$/**9**-d_3=1.1 (in molar ratio)], $C_{(4)}$-CH_3 signal appeared at δ 2.12 as a singlet. Under the same conditions, $C_{(4)}$-CH_3 of non-labeled alcohol (**9**) resonated at δ 2.12 as a triplet (J=7 Hz).

Photochemical Reaction of Friedelin (1) in Acetone. Friedelin (**1**; 705 mg) in acetone (88 ml) in a Pyrex vessel was photolyzed. The rate of the photolysis was very slow and the photolysate after 27 h-irradiation was found to consist of recovered friedelin (**1**; 545 mg), the hydroxy ketone (**5**; 12 mg), and an unknown hydroxy dicarbonyl compound (32 mg).

The authors wish to thank Dr. Hidehiro Ishizuka for PMR (100 MHz) measurements, and Dr. Kazuyuki Aizawa for the measurements of the high resolution mass spectrum.

A Facile Synthesis of Anomeric Methyl DL-Tolyposaminides, Methyl DL-Forosaminides, and Related Substances[1)]

Eisuke KAJI, Haruo KOHNO, and Shonosuke ZEN

School of Pharmaceutical Sciences, Kitasato University, Shirokane, Minato-ku, Tokyo 108

(Received August 7, 1976)

The reaction of β-nitro alcohols (2-nitroethanol, 1-nitro-2-propanol, and 1-nitro-2-butanol) with acrylaldehyde in the presence of diethylamine–formic acid gave anomeric mixture of 4-nitro-DL-pento-, hexo-, and heptopyranoses (**5**) in reasonable yields. **5** were converted to the corresponding methyl 4-amino-DL-pento-, hexo-, and heptopyranosides (**8**) by *O*-methylation followed by reduction. Anomeric methyl DL-tolyposaminides and DL-forosaminides were synthesized in a good yield from anomeric methyl 4-nitro-2,3,4,6-tetradeoxy-DL-*erythro*-hexopyranosides (**6b**$_1$ and **6b**$_2$). The configuration of methyl 4-nitro-DL-hexo-, and heptopyranosides (**6b** and **6c**) and methyl 4-acetamido-DL-hexo- and heptopyranosides (**8b** and **8c**) was established on the basis of PMR data.

As a part of the investigation on the exploration of newer synthetic reactions for aliphatic nitro compounds, we had been interested in a facile route to some nitropyranose derivatives, which are potentially useful as substrates for versatile syntheses of amino sugars, especially in the syntheses of amino-polydeoxy sugars contained in several antibiotics, *e.g.*, tolyposamine[2)] and forosamine.[3)] Recently several synthetic routes to these amino-polydeoxy sugars starting from carbohydrate[4)] or non-carbohydrate[5)] precursors have been reported. In this paper we describe a facile synthesis of 4-amino-polydeoxy sugars (**7**) *via* the respective 4-nitro derivatives (**5**) which were obtained by one-step cyclization reaction of β-nitro alcohols with acrylaldehyde using diethylamine–formic acid.[6)]

The reaction of excess nitro alcohols: 2-nitroethanol (**1a**), 1-nitro-2-propanol (**1b**), or 1-nitro-2-butanol (**1c**) with acrylaldehyde in the presence of a catalytic amount of diethylamine–formic acid (1 : 1.75 mol) at 60±5 °C for about 20 h gave anomeric mixtures of 4-nitro-DL-pento-, hexo-, and heptopyranoses (**5a**—**5c**) in a reasonable yield (Table 1). In the case of **5b**, optimum reaction conditions were examined and **5b** was obtained in a 52% yield by equimolar reaction of **1b** with acrylaldehyde at reflux temperature in benzene for 20 h. **5c** was separated into two diastereomers (**5c**$_1$ and **5c**$_2$)

through column chromatography on silica gel.

We attempted an alternative route (path A) for cyclization, where 2-substituted 4-hydroxy-3-nitrotetrahydropyran (**3**) is formed *via* initial ether formation[7] followed by intramolecular condensation[8] as shown in Fig. 1. However, the formation of **3** could not be detected on TLC analysis and column chromatographic purification.

The main structure of **5** was deduced from the following experimental data: (i) The formation of 2,4-dinitrophenylhydrazone (**9**) of δ-hydroxy-γ-nitroaldehyde (**4**), as well as its acetate (**10a**). (ii) Treatment of **5b** with hydrochloric acid in methanol gave α- and β-anomers of methyl hexopyranosides (**6b**$_1$ and **6b**$_2$) which were separated by silica gel column chromatography with benzene as eluant. Analogous methylation of **5c**$_1$ gave anomeric methyl heptopyranosides (**6c**$_1$ and **6c**$_2$). **5c**$_2$ was also methylated to give **6c**$_3$ and **6c**$_4$. Ordinary methylation[9] of **5** using methyl iodide and silver oxide also gave the same **6**. On the other hand, methylation of **5a** under above conditions gave only α-anomer of **6a**. These results are shown in Table 3.

The assignment of configuration of **6** was based on its PMR spectral data. The chemical shifts and coupling constants were assigned as shown in Table 4 with the aid of double resonance method. The anomeric configuration of **6** was readily deduced from the first-order analysis of its spectrum. In the spectrum of **6a**, **6b**$_1$, **6c**$_1$, and **6c**$_3$ a relatively low-field signal (δ 4.65—4.87) of a methine proton exhibits a singlet with fine splitting ($J_{1,2}<5$ Hz), which is assigned to the equatorial hydrogen of C-1. Hence the anomeric configuration is α. On the other hand, in **6b**$_2$ and **6c**$_2$, the anomeric proton exhibits a pair of doublet ($J_{1,2a}=9$ Hz, and $J_{1,2e}<3$ Hz), which is deduced to be the axial hydrogen of the β-anomers. The methoxyl group of α-anomers appeared at higher field (δ 3.40—3.43) in comparison with that of β-anomers (δ 3.52—3.53) as shown in Table 4.

The orientation of C-3 and C-4 positions was established by spin decoupling studies. In the PMR spectrum of **6b**$_1$, irradiation of C-6 methyl protons (δ 1.25) collapsed C-5 methin proton (δ 4.28, multiplet) to a doublet ($J_{4,5}=9$ Hz). Reasonably assuming that **6** has chair conformation, a relatively large H-4, H-5 coupling

constant (9 Hz) could be taken as an indication of 4,5-diaxial arrangement of protons.[2] From the above data, **6b$_1$** was concluded to be a methyl 4-nitro-2,3,4,6-tetradeoxy-α-DL-*erythro*-hexopyranoside, and **6c$_1$** was analogously assigned to α-*erythro* configuration. Accordingly **6b$_2$** and **6c$_2$** (anomer of **6b$_1$** and **6c$_1$**) were deduced to have a β-*erythro* configuration. In the spectrum of **6c$_3$**, irradiation of H-6 (δ 1.53) changed the H-5 signal (δ 3.90) into a doublet which has a relatively small coupling constant ($J_{4,5}$=2.8 Hz). Moreover, irradiation of H-5 collapsed the H-4 signal (δ 4.57) to a singlet with fine splitting ($J_{3a,4}$ and $J_{3e,4}$<3 Hz), indicating the equatorial orientation of C-4 hydrogen. Hence, we ascribed it to α-*threo* configuration. Alternatively, β-*threo* configuration was assigned to the minor product (**6c$_4$**), corroborated by $J_{4,5}$ (2.5 Hz) and the chemical shift of the methoxyl group (δ 3.53). This deduction is supported by the fact that **6c$_1$** and **6c$_3$** gave the same PMR spectrum in the presence of NaOD in D_2O in which they would be converted to the same aci-nitro type compound. It should be noted that stereoselectivity of this cyclization reaction depends on the kind of nitro alcohols. The reaction of acrylaldehyde with 1-nitro-2-propanol gave only the anomeric *erythro* isomers, whereas that with 1-nitro-2-butanol gave all the possible isomers.

The reduction of **6a**, **6b$_1$**, **6b$_2$**, **6c$_1$**, and **6c$_2$** over Raney nickel catalyst afforded the corresponding methyl 4-aminopyranosides, which were subsequently acetylated in the usual manner giving methyl 4-acetamido-DL-pento-, hexo-, and heptopyranosides (**8a**, **8b$_1$**, **8b$_2$**, **8c$_1$**, and **8c$_2$**) in reasonable yields (Table 5). However the yield of **8a** remained rather low under the same reaction condition. The structure of **8** was established by its PMR spectra (Table 6) as described above for compound **6**. The large coupling constants between H-4 and H-5 ($J_{4,5}$=9.5—10.0 Hz) strongly suggest that **8b$_1$**, **8b$_2$**, **8c$_1$**, and **8c$_2$** have *erythro* configuration as well as their corresponding nitropyranosides (**6**). Another evidence was provided by a correlation of reference compounds **11** and **12**. The configuration of **8a** was not deduced except anomeric configuration (see Table 6) because the spectrum was rather complicated.

The anomeric methyl *N*-benzoyl-DL-tolyposaminides (methyl 4-benzamido-2,3,4,6-tetradeoxy-α- and β-DL-*erythro*-hexopyranoside (**11** and **12**) were synthesized respectively from the corresponding methyl 4-nitro-DL-*erythro*-hexopyranosides (**6b$_1$** and **6b$_2$**) by hydrogenation followed by benzoylation in a good yield. **11** and **12** were identical with the authentic samples[10] by the

a) Could not be obtained because of covering by OMe protons signal.

mixed melting point determination, and IR and PMR spectra.

The reductive dimethylation of **6b**$_1$ and **6b**$_2$ over Raney nickel in the presence of formaldehyde led to methyl 2,3,4,6-tetradeoxy-4-dimethylamino-α-DL-*erythro*-hexopyranoside (methyl α-DL-forosaminide, **13**) and its β-anomer (**14**), respectively. The IR and PMR spectra of these compounds were in good agreement with those of the reported data.[4b]

Experimental

All boiling and melting points are uncorrected. TLC was carried out on Kiesel gel G (Merck), and spots were detected with iodine vapor or 10% sulfuric acid on hot plate. Kanto Kagaku silica gel (up to 100 mesh) was used for column chromatography. PMR spectra were recorded with a 60 MHz Varian T-60 spectrometer and a 100 MHz JEOL PS-100 spectrometer with a spin decoupler. Chemical shifts are given in δ value. IR spectra were measured for either liquid films or potassium bromide disks with a JASCO Model IRA-1 spectrometer.

*Typical Procedure for the Cyclization: 4-Nitro-2,3,4,6-tetradeoxy-*DL-*hexopyranose (5b).* A mixture of 3 g (53.6 mmol) of acrylaldehyde and 5.61 g (53.6 mmol) of 1-nitro-2-propanol[11] was refluxed in 30 ml of benzene for about 20 h in the presence of diethylamine and formic acid (1: 1.75 mol; employed 0.5 wt % of total reagent). After removal of the solvent *in vacuo*, the oily product was chromatographed on silica gel using di-isopropyl ether–hexane (2: 1) as eluant. 4.5 g of anomeric mixture (α: β=4: 3 by PMR signal intensity) of **5b** was thus obtained in 52% yield. In the case of **5a** and **5c**, excess nitro alcohols (4 equivalent to acrylaldehyde) were employed. **5c** was separated into two diastereomers (**5c**$_1$ and **5c**$_2$) through the column on silica gel with ethyl acetate–chloroform (1: 2) as eluant. Yields, physical constants and elemental analyses of **5a**—**5c** were summarized in Table 1.

Typical Procedure of Hydrazone Formation: 5-Hydroxy-4-nitropentanal 2,4-Dinitrophenylhydrazone (9a). To a solution of 0.6 g (4.1 mmol) of **5a** in 6 ml of methanol, 0.81 g (4.1 mmol) of 2,4-dinitrophenylhydrazine–hydrochloric acid (0.5 ml) in methanol (40 ml) was added and the solution was heated to boiling for 2 min. The reaction mixture was allowed to stand overnight at room temperature. The precipitated yellow crystals were collected and recrystallized from ethanol to give 1.05 g of **9a** in 79% yield; mp 126.5—127.5 °C, IR (KBr): 3480 (OH), 3280 (NH), 1610 (C=N), 1550, 1515, and 1330 cm^{-1} (C–NO$_2$). In the case of **9b** and **9c**, 2,4-dinitrophenylhydrazine–phosphoric acid reagent[12] was employed. The results are summarized in Table 2.

5-Acetoxy-4-nitropentanal 2,4-dinitrophenylhydrazone (10a). Trifluoroacetic anhydride (1.9 ml) was added to a solution of 190 mg (0.58 mmol) of **9a** in 0.8 ml of acetic acid. The mixture was heated at 55—60 °C for 15 min. After cooling to room temperature aqueous sodium hydrogencarbonate was added to the solution and it was extracted with chloroform. The extracts were dried over anhydrous sodium sulfate and the solvent was evaporated. The red-brownish residue was crystallized with ethyl acetate–hexane (1: 1) mixture and recrystallized from methanol to give 17 mg (3%) of **10a**, mp. 129—130 °C, IR (KBr): 3280 (NH), 1740 (acetyl C=O), 1620 (C=N), 1550, 1515, and 1330 cm^{-1} (C–NO$_2$). Found: C, 42.41; H, 4.22; N, 18.98%. Calcd for $C_{13}H_{15}N_5O_8$: C, 42.28; H, 4.09; N, 18.97%.

*Typical Procedure of O-Methylation of 5: Methyl 4-Nitro-2,3,4,6-tetradeoxy-α- and β-*DL-erythro-*Hexopyranosides (6b$_1$ and 6b$_2$).* i) Hydrochloric acid (0.03 ml) in 3 ml of methanol was added to 300 mg (1.86 mmol) of **5b** and the solution was heated at 50 °C for 0.5 h to give two products, α and β anomer of methyl hexopyranoside (**6b**$_1$ and **6b**$_2$), which were separated by silica gel column chromatography with benzene as developer. The first moving isomer was collected and distilled to give 180 mg of α-anomer (**6b**$_1$) in 55% yield; bp 33—35 °C/0.02 Torr, IR (liq. film): 1550 and 1375 cm^{-1} (C–NO$_2$). The second moving isomer was also collected and recrystallized from ethanol–water to give 65 mg of β-anomer (**6b**$_2$), 20% yield, mp 31.5—32 °C, IR (KBr): 1550 and 1345 cm^{-1} (C–NO$_2$). ii) A mixture of **5b**, excess methyl iodide, and silver oxide was stirred for 2.5 h at room temperature. Insoluble salts were filtered off and the filtrate was evaporated to give also an anomeric mixture of methyl hexopyranosides (**6b**) in analogous yield as above i). **6a**, **6c**$_1$, **6c**$_2$, **6c**$_3$, and **6c**$_4$ were also obtained from corresponding **5a** and diastereomeric **5c** in analogous way.

*Typical Procedure of Reduction and Acetylation of 6: 4-Acetamido-2,3,4,6-tetradeoxy-α-*DL-erythro-*hexopyranoside (8b$_1$).* To a suspension of Raney nickel T1 catalyst[13] (5 ml) in 50 ml of methanol was added 500 mg (2.86 mmol) of **6b**$_1$. The mixture was hydrogenated under 3.5 kg/cm^2 of hydrogen (initial) for 2 h at room temperature. The catalyst was filtered off and the solvent was evaporated to yield 250 mg of **7b**$_1$ as light yellow oil in 61% yield. Without further purification **7b**$_1$ was acetylated with 2.5 ml of pyridine and 4 ml of acetic anhydride under stirring for 1 h at room temperature. After removal of the solvent the residue was chromatographed on silica gel to give 277 mg of **8b**$_1$ as colorless crystals in 86% yield based on **7b**$_1$; mp 87.5—90 °C (from petroleum ether). **8a**, **8b**$_2$, **8c**$_1$, and **8c**$_2$ were also obtained in a similar procedure. The results are shown in Table 5.

Methyl N-*Benzoyl-α-*DL-*tolyposaminide (11).* **7b**$_1$ obtained by the reduction of 450 mg (2.57 mmol) of **6b**$_1$ described as above, was subsequently benzoylated with 580 mg of benzoic anhydride in methanol for 0.5 h at room temperature. The reaction mixture was poured into 20 ml of aqueous sodium hydrogencarbonate and extracted with chloroform (3×40 ml). The combined extracts were dried over anhydrous sodium sulfate and evaporated to give 505 mg (79% based on **6b**$_1$) of **11** as colorless crystals. Recrystallization from ethyl acetate–petroleum ether gave analytically pure sample; mp 148—149 °C (Reported[10] mp 148—149 °C), mixed mp 148—149 °C, IR and PMR spectra were identical with those of the authentic sample.[10] IR (KBr): 3220 (NH), 1625 (amide I), 1560 (amide II), 1275 cm^{-1} (amide III), PMR (CDCl$_3$ at 100 MHz): δ 1.25 (3H, d, H-6 $J_{5,6}$=6 Hz), 1.7—2.0 (4H, m, H-2,3), 3.35 (3H, s, OCH$_3$), 3.70 (1H, d-d, H-5, $J_{4,5}$=9 Hz, $J_{5,6}$=6 Hz), 3.6—4.1 (1H, m, H-4), 4.68 (1H, s with fine splitting, H-1, $J_{1,2a}$ and $J_{1,2e}$<3 Hz), 6.05 (1H, d, NH), 7.4 and 7.75 (5H, m, C$_6$H$_5$). Found: C, 67.52; H, 7.74; N, 5.51%. Calcd for $C_{14}H_{19}NO_3$: C, 67.44; H, 7.68; N, 5.62%.

Methyl N-*Benzoyl-β-*DL-*tolyposaminide (12).* Reduction and benzoylation of **6b**$_2$, carried out according to the procedure described above, gave **12** in 84% yield; mp 171.5—172.5 °C (from ethyl acetate–petroleum ether) (Reported[10] mp 169—171 °C). No depression was observed on mixed melting point. IR and PMR spectra were identical with those of the authentic sample.[10] IR (KBr): 3210 (NH), 1630 (amide I), 1570 (amide II), 1275 cm^{-1} (amide III). PMR (CDCl$_3$ at 100 MHz): δ 1.31 (3H, d, H-6, $J_{5,6}$=6 Hz), 1.5—2.3 (4H, m, H-2,3), 3.48 (3H, s, OCH$_3$), 3.47 (1H, d-d, H-5, $J_{4,5}$=9 Hz, $J_{5,6}$=6 Hz), 3.7—4.0 (1H, m, H-4), 4.37 (1H, d-d, H-1, $J_{1,2a}$=8 Hz, $J_{1,2e}$=3 Hz), 6.20 (1H, d, NH), 7.4 and 7.75 (5H, m, C$_6$H$_5$). Found: C, 67.78; H, 7.66; N, 5.91%.

Calcd for $C_{14}H_{19}NO_3$: C, 67.44; H, 7.68; N, 5.62%.

Methyl α-DL-Forosaminide (13). To a solution of 520 mg (2.97 mmol) of **6b**$_1$ in 80 ml of ethanol, was added 1 ml of aqueous formaldehyde (*ca.* 40%), 70 mg of sodium acetate, and Raney nickel T1 catalyst (3 ml of ethanolic slurry). The mixture was hydrogenated under 3.5 kg/cm^2 of hydrogen (initial) for 4 h at room temperature. After removal of the catalyst, the solvent was evaporated and the residue was dissolved with 50 ml of 2.5% aqueous ammonia. The solution was extracted with chloroform (3×15 ml), dried over anhydrous sodium sulfate and evaporated. The residual oil was distilled to give 255 mg of **13** as colorless oil in 49% yield; bp 57—59 °C/2.5 Torr (Reported[4b] bp 30—35 °C (bath)/0.5 Torr for D-isomer) n_D^{20} 1.4458. The PMR spectrum was identical with that reported data[4b] for D-isomer. IR (liq. film): 2820 and 2780 cm^{-1} (NMe_2), PMR ($CDCl_3$ at 100 MHz): δ 1.22 (3H, d, H-6, $J_{5,6}$=6.5 Hz), 1.5—2.0 (4H, m, H-2,3), 2.23 (6H, s, NMe_2), *ca.* 2.3 (1H, m, H-4), 3.33 (3H, s, OMe), 3.77 (1H, q, H-5, $J_{4,5}$=10 Hz, $J_{5,6}$=6.5 Hz), 4.59 (1H, s with fine splitting, H-1, $J_{1,2a}$ and $J_{1,2e}$<3 Hz).

Methyl β-DL-forosaminide (14). Reductive dimethylation of **6b**$_2$ as described above for **13**, gave **14** in 57% yield; bp 60—65 °C (bath)/2.5 Torr, n_D^{20} 1.4477. IR (liq. film): 2820 and 2770 cm^{-1} (NMe_2), PMR ($CDCl_3$ at 100 MHz): δ 1.33 (3H, d, H-6, $J_{5,6}$=6 Hz), 1.5—2.1 (4H, m, H-2,3), 2.28 (6H, s, NMe_2), *ca.* 2.3 (1H, m, H-4), 3.50 (3H, s, OMe), 3.35—3.6 (1H, m, H-5), 4.30 (1H, m, H-1).

Deep thanks are due to Dr. Y. Suhara (Institute of Microbial Chemistry) for providing the authentic samples of methyl *N*-benzoyltolyposaminides.

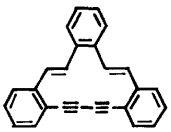
The Synthesis of Benzannelated Annulenes. Tribenzo[*a,g,m*]-15,17-bisdehydro[18]annulene, and Bis[dibenzo[1,2:9,10]-11,13-bisdehydro[14]annuleno][5,6-*a*:5′,6′-*d*]benzene[1]

Jūro Ojima,* Michiko Enkaku, and Chikako Uwai
Faculty of Literature and Science, Toyama University, Gofuku, Toyama 930
(Received August 10, 1976)

The Wittig reaction between *o*-ethynylcinnamaldehyde (II) and α,α′-bis(triphenylphosphonio)-*o*-xylene dibromide (III) gave the corresponding acyclic compound (IV and V) in a good yield, while that between *o*-ethynylbenzaldehyde (VII) and α,α′,α″,α‴-tetrakis(triphenylphosphonio)durene tetrabromide (VIII) similarly afforded an acyclic compound (IX) in a moderate yield. The title compounds, VI and X, were obtained by the oxidative coupling of V (or, IV and V) and IX, respectively. The examination of the NMR spectra indicated that VI and tribenzo-fused, fourteen-membered periphery on the sides of the benzene nucleus of X are atropic.

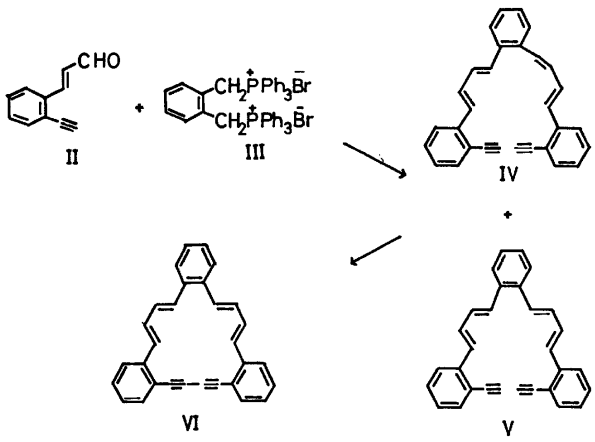
The Wittig reaction has been used to synthesize many unsaturated cyclic compounds.[2]



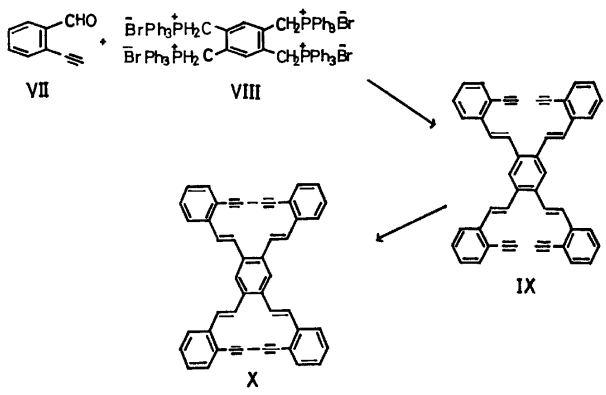
I

In the previous work, we reported the preparation of the tribenzo[*a,e,i*]-11,13-bisdehydro[14]annulene (I) from the *o*-ethynylbenzaldehyde (VII) by the Wittig reaction with α,α′-bis(triphenylphosphonio)-*o*-xylene dibromide (III) followed by the oxidative coupling.[3] In connection with our works on benzo-fused annulenes,[4] the present paper deals with syntheses of a higher vinylogue of I, *i.e.*, tribenzo[*a,g,m*]-15,17-bisdehydro[18]annulene (VI), and bis[dibenzo[1,2:9,10]-11,13-bisdehydro[14]annuleno][5,6-*a*:5′,6′-*d*]benzene (X), formally derived from I by the fusion of the second benzannelated fourteen-membered ring system on the opposite side of one benzene nucleus.

The preparation of VI and X was carried out according to the same procedure as used in that of I.



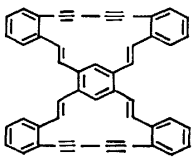
The double Wittig reaction of 2 molar equivalents of *o*-ethynylcinnamaldehyde (II)[5] and 1 molar equivalent of α,α′-bis(triphenylphosphonio)-*o*-xylene dibromide (III)[6] in *N,N*-dimethylformamide with ethanolic lithium ethoxide at 80 °C afforded an acyclic stereoisomeric mixture in a 53% yield, which, upon chromatography on alumina, yielded the *cis-trans* isomer (IV) and the *trans-trans* isomer (V) in a ratio of *ca.* 1 : 1. The structure of IV was assigned to the compound based on the following evidence. The two signals due to acetylenic protons were observed in the NMR spectrum of IV, whereas only one signal was observed in that of V (Table 1). In addition, the longest wavelength maximum of IV in the electronic spectrum appeared at a lower wave length than that of V (Experimental). Furthermore, the IR spectrum of IV exhibited a band at 660 cm^{-1} which is characteristic of *cis*-ethylene linkage. The oxidation with copper(II) acetate in pyridine[7] gave the desired VI in a 34% yield. The Dreiding molecular model of VI suggested that VI should be an almost strainless molecule.



The Wittig reaction of α,α′,α″,α‴-tetrakis(triphenylphosphonio)durene tetrabromide (VIII)[8] and four equivalents of *o*-ethynylbenzaldehyde (VII),[2] under the same conditions as indicated for the reaction of II and III, yielded the acyclic compound (IX) in a moderate yield. The configuration of ethylenic bonds of IX was confirmed to be *trans*, since the IR spectrum exhibits a band at 960 cm^{-1} which is characteristic of *trans*-ethylenic linkage. Oxidation of IX with copper(II) acetate in pyridine[7] gave X in a 16% yield, together with an unidentified substance. Under the oxidation conditions employed, it seems likely that the IX also provides the alternative product, XI, arising from the coupling of 2-(*o*-ethynylphenyl)vinyl moieties at 1

* Author to whom correspondence should be addressed.

and 3 positions of the central benzene nucleus of IX. However, inspection by the use of the molecular model revealed that this possibility is presumably precluded, since the molecular model corresponding to the structure of X can be constructed more readily, as compared with that for XI, which can be done only with difficulty. Thus, the structure of X rather than XI was assigned to the oxidation product from IX, although the available spectral properties, such as NMR, UV, and IR, did not give a sufficient reason for such an assignment.



XI

Table 1. ^{1}H-NMR data of IV—VI and IX—X in $CDCl_3$ at 100 MHz
(τ-values, TMS as an internal standard)

	IV	V	VI[a)]	IX	X
Olefinic and Phenyl H	2.25—3.42	2.20—3.05	2.31—3.29	2.10—2.84	2.14—3.76
-C≡CH	6.65 6.67	6.64		6.73	

a) The NMR spectra of VI were found to be essentially temperature independent over the range from −60 to 25 °C.

The chemical shifts on the protons of the obtained compounds IV—VI and IX—X are given in Table 1. The signals due to olefinic protons could not be located precisely, because the signals due to phenyl protons were also observed in almost the same region as those of olefinic protons. Consequently, it is difficult to compare the chemical shifts between each proton of the acyclic compound (IV and V) and the corresponding proton of the cyclic one (VI). The same is true for the comparison of the NMR spectra between IX and X. However, the chemical shifts of all protons of VI and X are in the normal region. Therefore, it appears from this result that VI and tribenzo-fused, fourteen-membered periphery on both sides of the central benzene nucleus of X are atropic.

Experimental

All the melting points are uncorrected. Brockmann alumina (Act. II—III) was used for column chromatography. The IR and UV spectra were taken on a Hitachi EPI-S2 and a Hitachi 124 spectrophotometer respectively. Shoulders in the UV spectra are indicated by sh. The NMR spectra were recorded on a Varian XL-100 spectrometer. The mass spectra were measured using a JEOL-JMS-OI-SG-2 spectrometer operating at 75 eV.

The Isomeric o-*Bis[4-(*o-*ethynylphenyl)-1,3-butadienyl] benzene (IV) and (V).* Lithium ethoxide prepared from lithium (224 mg, 0.032 gatm) in ethanol (84 ml) was added drop by drop with stirring under a nitrogen atmosphere at 80—85°C over a period of 1 h to *o*-ethynylcinnamaldehyde (II, 5.0 g, 0.032 mol)[5] and α,α′-bis(triphenylphosphonio)-*o*-xylene dibromide (III, 12.9 g, 0.0165 mol)[6] in dry *N,N*-dimethylformamide (320 ml). After completion of the addition, the reaction mixture was stirred under a nitrogen atmosphere at the same temperature for 2 more hours; then it was poured into water (1000 ml) and extracted with ether (300 ml×3). The ethereal extracts were washed successively with dilute hydrochloric acid, sodium hydrogencarbonate, and saturated sodium chloride solutions, and dried over sodium sulfate. After the solvent had been evaporated, the residual dark red liquid obtained was chromatographed on alumina (100 g) with light petroleum-ether (92: 8—96: 4) to give a mixture of acyclic isomers as a partly crystallized liquid (3.2 g, 53%). The mixture was dissolved in ether and absorbed on alumina (75 g). Careful elution with solvents with increasing polarity resulted in the separation of stereoisomers. Fractions eluted with light petroleum-ether (97: 3) yielded *cis-trans* isomer, IV. Recrystallization from hexane-benzene gave pure IV as pale yellow cubes: mp 149.5—150.5 °C; IR (KBr disk): 3250 (-C≡CH), 2100 (-C≡C-), 990, 970, 950 (*trans* C=C), 660 cm^{-1} (*cis* C=C); UV: λ_{max}^{THF} 250 (28000), 260 sh (27200), 268 (23200), 287 sh (26100), 310 sh (38600), 325 (44000), 354 nm (53600); Mass: *m/e* 382 (M^+, 10), 253 (100); mol wt, 382.5; NMR: see Table 1.

Found: C, 93.93; H, 5.77%. Calcd for $C_{30}H_{22}$: C, 94.20; H, 5.80%.

The following fractions eluted with light petroleum-ether (96: 4—95: 5) gave *trans-trans* isomer, V. Recrystallization from hexane-benzene afforded pure V as yellow cubes: mp 185 °C (dec); IR (KBr disk): 3280 (-C≡CH), 2100 (-C≡C-), 975 cm^{-1} (*trans* C=C); UV; λ_{max}^{THF} 260 (28700), 269 sh (25300), 314 sh (51500), 325 (56000), 364 nm (54100); Mass: *m/e* (M^+, 25), 253 (100); mol wt, 382.5; NMR: see Table 1.

Found: C, 94.03; H, 6.06%. Calcd for $C_{30}H_{20}$: C, 94.20; H, 5.80%.

Tribenzo[a,g,m]-*15,17-bisdehydro*[*18*]*annulene (VI).* A solution of V (0.6 g, 0.0016 mol) dissolved in pyridine (13 ml) was added dropwise to a vigorously stirred solution of copper-(II) acetate monohydrate (4.9 g) in pyridine (16 ml) for 45 min at 50 °C, and the reaction mixture was stirred for an additional 2 h at 60—65 °C. The mixture, after had been chilled to room temperature and diluted with benzene (300 ml), was filtered through Hyflo Super-Cel,[9] and the resulting precipitate was further washed with benzene (100 ml×2). Then the filtrate was washed with 5% hydrochloric acid until it was acid to litmus, and then with a saturated sodium chloride solution, and dried over sodium sulfate. The dark red liquid obtained after evaporation of the solvent was chromatographed on alumina (130 g) with light petroleum-ether (8: 2) to give VI (0.2 g, 34%). Recrystallization from hexane-benzene afforded pure VI as yellow needles: mp 248 °C (dec); IR (KBr disk): 980 cm^{-1} (*trans* C=C); UV: λ_{max}^{THF} 275 sh (29700), 292 (42600), 328 (64100), 378 sh nm (14100); Mass *m/e* 380 (M^+, 100); mol wt, 380.5; NMR: see Table 1.

The elemental analyses of VI always afforded low values of carbon, but the spectral properties clearly support the structure of VI.

In a run performed under similar conditions using a mixture of IV and V, VI was obtained in a 23% yield.

1,2,4,5-Tetra[trans-*2-(*o-*ethynylphenyl)vinyl*]*benzene (IX).* Lithium ethoxide prepared from lithium (441 mg, 0.063 gatm) in ethanol (160 ml) was added dropwise, with stirring under a nitrogen atmosphere at 82—85 °C for 2 h, to *o*-ethynylbenzaldehyde (VII, 8.0 g, 0.062 mol) and α,α′,α″,α‴-tetrakis(triphenylphosphonio)durene tetrabromide (VIII, 19.4 g, 0.013 mol) in dry *N,N*-dimethylformamide (634 ml).

After completion of the addition, the reaction mixture was stirred maintaining the same temperature under a nitrogen atmosphere for an additional 2 h; then it was poured into water (1000 ml) and extracted with ether (500 ml×3). The ethereal extracts were worked up in the usual manner to give a dark red liquid. The liquid was chromatographed on alumina (150 g) with light petroleum–ether (8: 2) to give IX (1.3 g, 17%) as a partly crystallized liquid. Recrystallization from hexane–benzene afforded pure IX as yellow needles: mp 186 °C (dec); Mass: m/e 583 (M^+, 5), 149 (100); mol wt, 582.7; IR (KBr disk): 3300 (–C≡CH), 2100 (–C≡C–), 1600 (C=C), 960 cm^{-1} (*trans* C=C); UV: λ_{max}^{THF} 221 (56800), 240 sh (45000), 254 sh (41000), 344 (60400), 376 sh nm (48700); NMR: see Table 1.

Found: C, 94.29; H, 5.07%. Calcd for $C_{46}H_{30}$: C, 94.81; H, 5.19%.

*Bis[dibenzo[1,2:9,10]-11,13-bisdehydro[14]annuleno][5,6-a:5′,6′-*d*]benzene (X).* A solution of IX (1.82 g, 0.0031 mol) in pyridine (52 ml) was added dropwise to a stirred solution of copper(II) acetate monohydrate (18.0 g) in pyridine (37 ml) for 25 min at 55 °C, and the reaction mixture was stirred for an additional 3 h at 60—65 °C. Then the mixture was chilled, diluted with benzene (200 ml), and filtered through a Hyflo Super-Cel. The precipitate formed was washed with benzene (100 ml×3). Then the filtrate was washed with 5% hydrochloric acid until it was acid to litmus, and with saturated sodium chloride solution, and dried over sodium sulfate. The dark red liquid obtained after evaporation of the solvent was chromatographed on alumina (200 g). The fractions eluted with light petroleum–ether (7: 3—6: 4) gave X (0.29 g, 16%) as a partly crystallized liquid. Recrystallization from benzene afforded pure X as yellow cubes: mp 216 °C (dec). Although a satisfactory elemental analysis is not obtained, the Mass (*m/e* 579 (M^+, 57), 576 (100); mol. wt., 578.7), the IR (KBr disk) (2200 (–C≡C–), 965, 950 cm^{-1} (*trans* C=C)), the UV (λ_{max}^{THF} 224 (60200), 260 sh (32000), 307 (48400), 324 sh (38300), 352 sh (17200), 393 sh (6150)), and the NMR (see Table 1) were found to be consistent with the assigned structure.

The following fractions with the same solvents afforded crystals (0.15 g) which, on recrystallization from benzene, yielded yellow cubes, mp 206 °C (dec). The structure of the material is not established. Its spectral properties are as follows: Mass: *m/e* 280 (70), 254 (100); IR (KBr disk): 2200, 1635, 1620, 975 cm^{-1}; UV (THF): λ_{max} 228, 281, 296, 354, 376, sh nm; NMR ($CDCl_3$): 1.54[a] (d, J=16), 2.44—2.82[b] (m), 3.21[c] (d, J=16); The integral ratio of each signal (a, b, and c) is 1: 5: 1.

The authors wish to thank Dr. S. Akiyama and Prof. M. Nakagawa, Osaka University, for measuring the NMR spectra at 100 MHz. This work was financially supported by a Grant-in-Aid (054103, 1975) for Scientific Research from the Ministry of Education, which is gratefully acknowledged.

A New Method for the Synthesis of 1-Cycloalkenyl Alkyl Sulfides

Fuminori AKIYAMA

Chemical Research Institute of Non-Aqueous Solutions, Tohoku University, Sendai 980

(Received August 23, 1976)

2-Isopropyl-5-methyl-1-cyclohexenyl alkyl sulfides were obtained in about a 60% yield by the reaction of 2-isopropyl-5-methylcyclohexanone with thioacetals or thiols in the presence of aluminum chloride. 1-Cycloalkenyl ethyl sulfides, $\overline{\text{-(CH}_2)_n\text{-C(R)=C-SEt}}$ (n=4, 5, or 6, R=H or alkyl) were obtained in good yields by the reaction of cycloalkanones with ethanethiol in the presence of diphosphorus pentaoxide. However, an attempt to apply this method to acyclic vinyl sulfides was unsuccessful.

Vinyl sulfides have been synthesized by the nucleophilic addition of thiols to acetylenic hydrocarbons[1-3] and by the reaction of α-halogenoalkenes with sodium ethanethiolate,[4] of cyclohexanethione with alkyl halides,[5] and of chloroalkyl sulfides with a base.[6,7]

Although the reaction of ketones with thiols in the presence of acids or metal salts have been reported to give bis(alkylthio)alkanes,[8-11] Mukaiyama *et al.* reported the synthesis of vinyl sulfides by the reaction of carbonyl compounds with thiols in the presence of titanium tetrachloride and triethylamine.[12] In our previous paper[13] the synthesis of substituted 1-cyclohexenyl alkyl sulfides by the reaction of substituted cyclohexanones with thiols or thioacetals in the presence of aluminum chloride was reported. In the present report a more convenient method for the synthesis of 1-cycloalkenyl ethyl sulfides by the reaction of cycloalkanones with ethanethiol in the presence of diphosphrus pentaoxide will be reported.

Results and Discussion

Reactions of Substituted Cyclohexanones with Thioacetals or Thiols in the Presence of Aluminum Chloride. The heating of a mixture of a thioacetal (0.02 mol), a substituted cyclohexanone (0.02 mol), and benzene (20 ml) under reflux for 15 min in the presence of a 1 mol equiv. $AlCl_3$ gave substituted 1-cyclohexenyl alkyl sulfide, as is shown in Table 1. The reaction using thiol instead of the thioacetal for 1 min gave the same product, but heating for 15 min caused the sulfide to disappear giving a resinous material. The different behaviors between the reaction using a thiol and that using a thioacetal are illustrated in Fig. 1.

a) Reaction time: 1 min. b) Reaction time: 15 min.

In a similar reaction of cyclohexanone with thioacetals or thiols, a quick disappearance of 1-cyclohexenyl alkyl sulfide and the formation of a resinous material were observed. Thus, reactions using aluminum chloride are useful only for the synthesis of such sterically hindered vinyl sulfides as 2-isopropyl-5-methyl-1-cyclohexenyl alkyl sulfides. This limitation appears to be attributable to the stability of the product in the presence of aluminum chloride. The reaction of acyclic ketones with thiol or thioacetal in the presence of aluminum chloride gave a resinous material and unidentified oily products.

Reactions of Cycloalkanones with Ethanethiol in the Presence of Diphosphorus Pentaoxide. The heating of a mixture of ethanethiol (0.02 mol), a cycloalkanone (0.02 ml), and benzene (20 ml) under reflux for one hour in the presence of a 1 mol equiv. of diphosphorus pentaoxide gave 1-cycloalkenyl ethyl sulfide, as is shown in Table 2. Although the reaction of thiols carried out in the presence of aluminum chloride showed a rapid disappearance of the products (see Fig. 1), the reactions

Table 2. Yield of 1-cycloalkenyl ethyl sulfides[a)]

Starting ketone	Product	Remaining ketone (%)	Yield (%) of product
		5	43
		8	75
		36	42
		18	60
		12	81

a) Reaction time: one hour.

carried out in the presence of diphosphorus pentaoxide showed only a slight decrease in 1-cycloalkenyl ethyl sulfide on prolonged heating.

1-Cyclopentenyl ethyl sulfide was obtained in a low yield (less than 20%) by the reaction of cyclopentanone with ethanethiol in the presence of diphosphorus pentaoxide. Similar reactions of acyclic ketones gave bis(alkylthio)alkanes.

As is shown in Table 2, the yields of 1-cycloalkenyl ethyl sulfides are in the order: 1-cyclooctenyl>1-cycloheptenyl>1-cyclohexenyl. This reaction appears to be useful for the synthesis of large-membered 1-cycloalkenyl alkyl sulfides, $\overline{\text{-(CH}_2)_n\text{-C(R')=C-SR}}$ ($n \geqq 4$, R'=H or alkyl). Although the application of the method using diphosphorus pentaoxide has thus far been restricted to the synthesis of 1-cycloalkenyl alkyl sulfides, it appears to be more convenient than that using $TiCl_4$ and triethylamine.[12)]

Experimental

Materials. Commercially available cycloalkanones and thiols were used. 1,1-bis(ethylthio)ethane or 1,1-bis(propylthio)ethane was obtained by the reaction of acetaldehyde with ethanethiol or 1-propanethiol respectively in the presence of calcium chloride.

General Procedure. A mixture of thiol (or thioacetal) (0.02 mol), cycloalkanone (0.02 mol), an internal standard (hexamethylbenzene), and benzene (20 ml) was heated under reflux in the presence of aluminum chloride or diphosphorus pentaoxide (0.02 mol). At an appropriate time a small portion of the solution was sampled and washed with water, and then this solution was analyzed by GLC using an ethylene glycol adipate polyester, 20% on a chromosorb W column at 150 °C. The reaction times shown in Table 1 or 2 are nearly optimum ones.

For the purpose of the isolation of 1-cycloalkenyl sulfides, a mixture of 0.06 mol of each material in benzene (30 ml) was heated under reflux. At an appropriate time, which is shown in Table 1 or 2, the benzene solution was cooled and washed several times and then distilled under reduced pressure. Redistillation and separation by GLC each gave pure 1-cycloalkenyl alkyl sulfide.

Identification of 1-Cycloalkenyl Alkyl Sulfides. The structures of the 1-cycloalkenyl sulfides were established on the basis of the following data.

2-Methyl-1-cyclohexenyl Ethyl Sulfide. NMR (in CCl_4): δ 2.56 (2H, q, J=7 Hz; -SC$\underline{H}_2$CH$_3$), 1.85 (3H, s, CH$_3$-C=C), 1.96—2.4 and 1.5—1.76 (8H, m, ring protons), 1.2 (3H, t, J=7 Hz, -SCH$_2$C$\underline{H}_3$). IR (neat): 1620 cm^{-1} (very weak, C=C). Elementary analyses: Found: C, 68.89; H, 10.01; S, 20.61%. Calcd for $C_9H_{16}S$: C, 69.17; H, 10.32; S, 20.50%.

2-Methyl-1-cyclohexenyl Propyl Sulfide. NMR (in CCl_4): δ 2.51 (2H, t, J=7 Hz, -SC$\underline{H}_2$CH$_2$CH$_3$), 1.84 (3H, s, CH$_3$-C=C), 1.90—2.30 and 1.3—1.74 (10H, m, ring protons and -SCH$_2$C$\underline{H}_2$CH$_3$), 1.0 (3H, t, J=7 Hz, -SCH$_2$CH$_2$C$\underline{H}_3$). IR (neat): 1600 cm^{-1} (weak, C=C). Elementary analyses: Found: C, 70.38; H, 10.57; S, 18.61%. Calcd for $C_{10}H_{18}S$: C, 70.52; H, 10.65; S, 18.82%.

2-Isopropyl-5-methyl-1-cyclohexenyl Ethyl Sulfide. NMR (in CCl_4): δ 3.45 (1H, seven, J=7 Hz, (CH$_3$)$_2$C$\underline{H}$-C=C), 2.57 (2H, q, J=7 Hz, -SC$\underline{H}_2$CH$_3$), 1.55—2.40 (7H, m, ring protons), 1.2 (3H, t, J=7 Hz, -SCH$_2$C$\underline{H}_3$), 0.88—1.04 (9H, m; CH$_3$ attached to ring and (C$\underline{H}_3$)$_2$CH). IR (neat): 1618 cm^{-1} (very weak, C=C). Elementary analyses: Found: C, 72.45; H, 11.06; S, 16.34%. Calcd for $C_{12}H_{22}S$: C, 72.65; H, 11.17; S, 16.16%.

2-Isopropyl-5-methyl-1-cyclohexenyl Propyl Sulfide. NMR (in CCl_4): δ 3.48 (1H, seven, J=7 Hz, (CH$_3$)$_2$C$\underline{H}$-C=C), 2.50 (2H, q, J=7 Hz, -SC$\underline{H}_2$CH$_3$), 1.40—2.3 (9H, m, ring protons and -SCH$_2$C$\underline{H}_2$CH$_3$), 0.88—1.08 (12H, m, CH$_3$ attached to ring (C$\underline{H}_3$)$_2$CH, and -SCH$_2$CH$_2$C$\underline{H}_3$). IR (neat): 1600 cm^{-1} (weak, C=C). Elementary analyses: Found: C, 73.63; H, 11.69; S, 15.43%. Calcd for $C_{13}H_{24}S$: C, 73.51; H, 11.39; S, 15.10%.

1-Cyclohexenyl Ethyl Sulfide. NMR (in CCl_4): δ 5.5 (1H, m, >C=C$\underline{H}$-), 2.62 (2H, q, J=7 Hz, -SC$\underline{H}_2$CH$_3$), 1.90—2.30 and 1.47—1.85 (8H, m, ring protons), 1.23 (3H, t, J=7 Hz, -SCH$_2$C$\underline{H}_3$). IR (neat): 1630 cm^{-1}. Elementary analyses: C, 67.40; H, 9.85; S, 22.26%. Calcd for $C_8H_{14}S$: C, 67.54; H, 9.92; S, 22.54%.

1-Cycloheptenyl Ethyl Sulfide. NMR (in CCl_4): δ 5.5 (1H, t, J=7 Hz, olefinic), 2.58 (2H, q, J=7 Hz, -SC$\underline{H}_2$CH$_3$), 2.04—2.30 and 1.36—1.90 (10H, m, ring protons), 1.28 (3H, t, J=7 Hz, -SCH$_2$C$\underline{H}_3$). IR (neat): 1632 cm^{-1}. Elementary analyses: Found: C, 69.10; H, 10.44; S, 20.84%. Calcd for $C_9H_{16}S$: C, 69.17; H, 10.32; S, 20.52%.

1-Cyclooctenyl Ethyl Sulfide. NMR (in CCl_4): δ 5.38 (1H, t, J=8 Hz, olefinic), 2.64 (2H, q, J=7 Hz; -SC$\underline{H}_2$CH$_3$), 2.04—2.40 and 1.40—1.90 (12H, m, ring protons), 1.28 (3H, t, J=7 Hz, -SCH$_2$C$\underline{H}_3$). IR (neat): 1619 cm^{-1}. Elementary analyses: Found: C, 70.36; H, 10.80; S, 19.08%. Cacld for $C_{10}H_{18}S$: C, 70.52; H, 10.65; S, 18.82%.

Synthesis and Spectral Characteristics of 4*H*-1-Benzothiopyran-4-ones

Hiroyuki NAKAZUMI and Teijiro KITAO

Department of Applied Chemistry, College of Engineering, University of Osaka Prefecture, Sakai-shi 591

(Received August 26, 1976)

The physical properties of 4*H*-1-benzothiopyran-4-ones (thiochromones) and related compounds were characterized by means of mass, NMR, and UV spectra in order to distinguish thiochromones from 2*H*-1-benzothiopyran-2-ones (thiocoumarins). In the mass spectra, the fragmentation due to the retro-Diels-Alder reaction directly from the molecular ion is the most useful for differentiation. In the NMR spectra, thiochromones show the characteristic deshielding effect of benzenoid proton in 5-position and in the UV spectra a very strong absorption band in the region 250—270 nm. It was found that in the reaction of *S*-phenyl 3-oxobutanethioates with PPA, most of these compounds afford thiochromones through rearrangement giving an intermediate (IVa). The effect of the substituent of the *S*-phenyl 3-oxobutanethioate on the formation of the thiocoumarin was also discussed.

4*H*-1-Benzothiopyran-4-ones (thiochromones) and 2*H*-1-benzothiopyran-2-ones (thiocoumarins) are well known as a structural isomer. The thermal conversion of the thiochromone into the thiocoumarin is also known.[1] A new synthesis of thiocoumarin derivatives was reported by Konishi *et al.*,[2] but some structural formulas of these compounds are doubtful. We therefore carried out an extensive study of the chemical structure of the related compounds by means of mass and NMR spectra. We found that some thiocoumarins are in line with the structural formulas of thiochromone derivatives. In this paper, we wish to report on a) the characteristic physical properties of thiochromone derivatives in order to distinguish them from thiocoumarins by means of their mass, NMR, IR, and UV spectra, and b) the effect of the substituent of the *S*-phenyl 3-oxobutanethioate on the formation of the thiocoumarin by the reaction with polyphosphoric acid (PPA).

Results and Discussion

Most of the thiochromones and thiocoumarins were prepared from *S*-phenyl 3-oxobutanethioate derivatives obtained by the reaction of substituted thiophenols with diketene. The IR, NMR, UV, and mass spectra of these compounds are summarized in Tables 1 and 2.

Identification of Thiochromone and Thiocoumarin Derivatives. It is very difficult to distinguish thiochromones from thiocoumarins. Lozac'h and Pfister-Guillouzo[3] reported a comparative method to distinguish them by means of their IR spectra. However, sufficient and systematic data necessary for identification are still lacking. In the case of compound **2**, the mass spectra showed the fragmentation of retro-Diels-Alder reaction characteristic of chromone derivatives[4] and we deduced the compound to be 2-methyl(thiochromone). This is also supported by the following experimental results: When compound **2** was hydrolyzed with NaOH, isolated products were bis(*o*-acetylphenyl) disulfide and bis(*o*-carboxyphenyl) disulfide. Compound **2** was also obtained by the authentic method.[5]

Thus, 4-methyl(thiocoumarin) reported[2] should be 2-methyl(thiochromone). 2-Methyl-7-methoxy(thiochromone) (**3**), the isomer of thiocoumarin **12**, was prepared by the well known method[6] for thiochromone derivatives. Compounds **4**—**9** were also identified as thiochromone derivatives by means of their mass and NMR spectra. The structure of compound **11** was determined to be thiochromone derivative by the following preparative method and chemical reactivity. The same product was obtained by the reaction of 2,5-dimethoxybenzenethiol with ethyl acetoacetate in PPA. A bluish thianaphthalenium salt (λ_{max} 590 nm (in acetone)) was obtained by the *O*-alkylation of compound **11** with dimethyl sulfate and 60% $HClO_4$. A similar alkylation afforded a yellow thianaphthalenium salt[7] (λ_{max} 386 nm) in the case of compound **12** and a bluish thianaphthalenium salt (λ_{max} 590 and 596 nm) in the case of compounds **2** and **3**, respectively.

Spectral Characteristics. *1) NMR Spectra*: Methyl(thiochromone) derivatives showed the characteristic deshielding effect of benzenoid proton in 5-position by contribution of the carbonyl group in peri-position as indicated in the case of some thiochromones.[8,9] The proton showed the chemical shift in the range 8.30—8.50 ppm. The values are unusually greater than those of the aromatic protons (*ca.* 1 ppm). The abnormally strong deshielding effect might be due to the even closer proximity of the proton on the annelated benzene in compound **8**, which was observed at 10.10 ppm. In the case of thiocoumarin derivatives, no such unusual deshielding effect was observed because of the lack of carbonyl group affecting the benzenoid proton. This difference may be utilized to distinguish them.

2) Mass Spectra: Thiochromone derivatives were characterized by an abundant molecular ion as the base peak. The major fragmentation pathway for these compounds was the elimination of $CH{\equiv}C{-}CH_3$ by the retro-Diels-Alder reaction, followed by the loss of

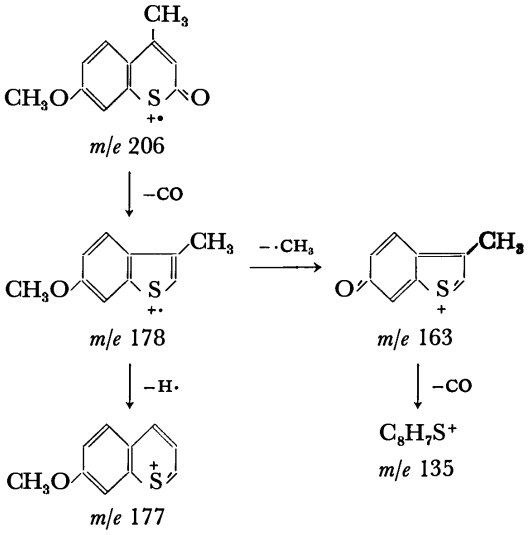
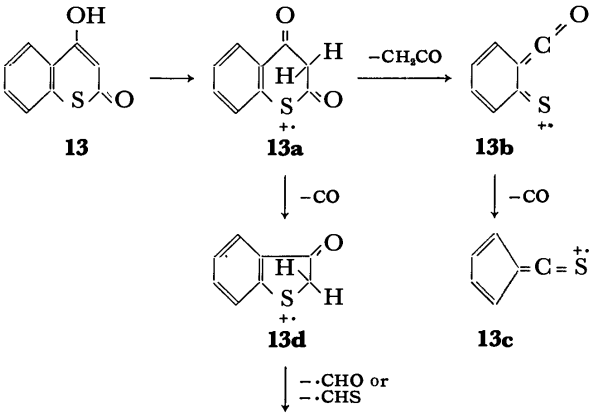
carbon monoxide (M→[M−40]→[M−68]). The other important fragmentation was initial loss of carbon monoxide from the molecular ion, followed by the loss of a hydrogen atom leading to the formation of the ring-expanded thianaphthalenium ion (M→[M−28]→[M−29]) (Scheme 1). The results are given together with relative abundance in Table 2. In the case of compounds **3** and **4**, the subsequent fragmentation of M-28 is modified by the methoxy substituent, *viz.*, the loss of methyl radical from M−28 giving an intensive fragment ion peak at *m/e* 163. However, in the case of 5,8-dimethoxy derivative **11**, fragmentation due to the retro-Diels-Alder reaction was not observed as in the case of some methoxyfuranochromones.[10]



Scheme 2.

On the other hand, the base peak of thiocoumarin derivatives was due to M−28. The main fragmentation of thiocoumarin **12** involved the ejection of carbon monoxide followed by the loss of methyl radical and carbon monoxide. The sequence may be rationalized as in Scheme 2.



Scheme 3.

The mass spectra of 4-hydroxy(thiocoumarin) **13** showed the fragmentation of the retro-Diels-Alder reaction in spite of thiocoumarin derivatives. If the molecular ion exists in the tautomeric form **13a**, the spectra can be easily rationalized. There are two fragmentation pathways. One which differs a great deal from that of other thiocoumarins is the loss of a neutral ketene by the retro-Diels-Alder reaction, followed by the loss of carbon monoxide (**13a**→**13b**→**13c**). The other is the loss of carbon monoxide from the molecular ion, which gives **13d** as the base peak of the spectrum (**13a**→**13d**→*m/e* 121 and 105).

The fragmentations were formulated by analogy of coumarin derivatives[4] and by following the fragmention containing a chlorine atom in the fragmentation of compound **7**. The retro-Diels-Alder reaction of the molecular ion of thiochromones might be the most useful for mass spectrometric differentiation between isomeric thiocoumarin and thiochromone, except for hydroxy(thiocoumarin) and dimethoxy(thiochromone) derivatives.

3) UV Spectra: Monosubstituted methyl(thiochromone) derivatives showed three complicated strong absorption bands due to the substituent in the benzene ring. On the other hand, the spectra of thiocoumarins showed two strong absorption bands, very weak in the region 250—270 nm.

4) IR Spectra: The carbonyl bands of methyl(thiochromone) derivatives were found in the region 1605—1630 cm^{-1}, which is considerably lower than that of a general ketone. Legrand and Lozac'h[1] reported that carbonyl bands of thiochromone are lower by 10—20 cm^{-1} than those of thiocoumarins. However, the difference can not be used reliably to distinguish them, since the region of thiocoumarins overlapped considera-

Table 3. The NMR and IR spectra of *S*-phenyl 3-oxobutanethioate derivatives

Compound No.	X	IR in KBr ν_{CO} (cm^{-1})	NMR in $CDCl_3$ δ (ppm)

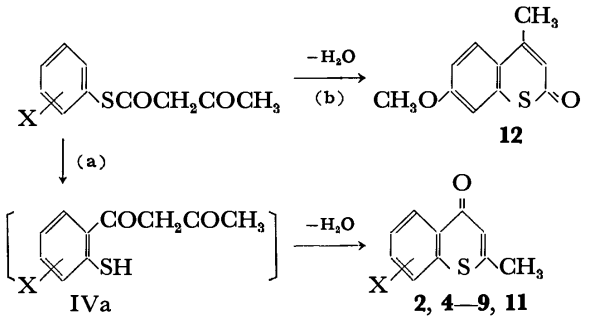
1g	2,3-Benzo	1670	2.40 (3H)s	4.85 (1H)s	7.60—8.20 (7H)m[b]	
1h	3,4-Benzo	1670	2.40 (3H)s	5.15 (1H)s	7.55—8.20 (7H)m[b]	
1i	2,5-Dimethoxy	1675	1.90 (3H)s 6.90—7.10 (3H)m[a]	3.78 (3H)s	3.83 (3H)s	5.90 (1H)s

a) No enol proton was observed. b) The NMR spectra were measured in DMSO-d_6, no enol proton being observed.

bly with that of thiochromones as shown in compound **13** and 3-methyl(thiocoumarin) (1620 cm^{-1}).

Synthesis of Thiochromone Derivatives from S-*Phenyl 3-Oxobutanethioates.* It was shown by spectral data that all *S*-phenyl 3-oxobutanethioates retain the enol form; ν_{OH} was observed at 2500—3000 cm^{-1} in IR and a vinyl proton was observed at 5.15—5.90 ppm as shown in Table 3. When these *S*-phenyl 3-oxobutanethioates were cyclodehydrated with PPA, only *m*-methoxy derivative (compound **1b**) gave a thiocoumarin **12**. However, the other *S*-phenyl 3-oxobutanethioates with substituents such as chlorine and methyl group in the meta-position gave thiochromones (compounds **5** and **7**) as the isomeric product of thiocoumarins. Two annelated derivatives **1g** and **1h** gave the corresponding thiochromones.

Thus, the meta-position of methoxyl group on *S*-phenyl 3-oxobutanethioate seems to be important for the preparation of thiocoumarin derivatives. In the case of compounds **1c** and **1i** where one or two methoxyl group(s) are introduced in the other position, thiochromone derivatives **4** and **11**, respectively, were obtained as isomeric products.



Scheme 4.

Cyclodehydration of *S*-phenyl 3-oxobutanethioate with 100% H_2SO_4 instead of PPA also afforded 2-methyl(thiochromone). The reaction with 100% H_2SO_4 in ether solution or concd H_2SO_4 gave diphenyl disulfide in a high yield (81%). The rearrangement of *S*-phenyl 3-oxobutanethioates giving an intermediate [IVa] (path a) predominantly occurs rather than the direct dehydration (path b) as shown in Scheme 4. The synthesis of thiocoumarins by the Pechmann reaction[11] is very difficult even from *S*-phenyl 3-oxobutanethioate.

Experimental

All the melting points are uncorrected. Infrared spectra were recorded on a Hitachi ESI-S2 spectrophotometer using KBr pellets. Ultraviolet spectra were recorded on a Hitachi EPS-3T spectrophotometer. H-NMR spectra were taken on a Hitachi Perkin-Elmer Model R-20 spectrometer, unless otherwise stated in $CDCl_3$ solution with tetramethylsilane as an internal standard. Mass spectra were recorded on a Hitachi RMU-6E mass spectrometer operating at 80 eV. Elemental analyses were recorded on a Yanaco CHN corder MT-2.

S-*Phenyl 3-Oxobutanethioate (**1a**).* Compound **1a** was obtained by the reaction of thiophenol with diketene.[2]

S-(m-*Methoxyphenyl) 3-Oxobutanethioate (**1b**).* Compound **1b** was prepared by the method reported[2] and isolated from the isomer mixture by repeated recrystallization from EtOH. The mixture contained an unidentified compound with the following data. NMR: δ 2.40 (3H) s, 3.80 (3H) s, 5.25 (1H) s, 6.90—7.30 (4H) m, 8.35 (1H) b; Found, C, 59.29; H, 5.52%. From the results, the compound was assigned as the structural isomer of compound **1b**.

S-(p-*Methoxyphenyl) 3-Oxobutanethioate (**1c**).* Concd H_2SO_4 (9.2 g) was added dropwise at 30 °C to a stirred Et_2O (50 ml) solution of *p*-methoxybenzenethiol (6.3 g, 0.045 mol).[12] Diketene (4.5 g, 0.054 mol) was then added to this reaction mixture at 25 °C. After 2.5 h, the ether was removed by rotary evaporation *in vacuo* at 20 °C and the residue was poured into an ice-water solution. White solid separated from the solution was collected by filtration and was recrystallized from EtOH to give 0.5 g of **1c**. Compounds **1d**, **1e**, **1g**, and **1h** were prepared by a similar method.

Recrystallization of compound **1g** from EtOH was repeated until the melting point became constant (mp 161—163 °C[2]).

S-(m-*Chlorophenyl) 3-Oxobutanethioate (**1f**).* *m*-Chlorobenzenethiol was obtained as a pale yellow oily material from *m*-chloroaniline by the Leukart reaction[12] in 60% yield; bp 76—78 °C (7 Torr), NMR (CCl_4); δ 2.30 (1H) s, 7.05 (3H) m, 7.20 (1H) m. Compound **1f** was prepared by the same method as for **1c** from *m*-chlorobenzenethiol.

S-(2,5-*Dimethoxyphenyl) 3-Oxobutanethioate (**1i**).* 2,5-Dimethoxybenzenethiol was obtained from 2,5-dimethoxyaniline by the Leukart reaction[12] in 64% yield; bp 104—106 °C (4 Torr), NMR (CCl_4); δ 3.70 (3H) s, 3.80 (3H) s, 3.75

Table 4. Physical properties of *S*-phenyl 3-oxobutanethioate derivatives

Compd	Mp (°C)	Yield (%)	Formula (MW)	Analysis (%) Calcd (Found) C	H

1i	169—171	22	$C_{12}H_{14}O_4S$ (254)	56.69 (57.07	5.51 5.66)

a) Yield (%) of the crude product.

(1H) b, 6.55—6.70 (3H) m. Concd H_2SO_4 (6.1 g, 0.060 mol) was added dropwise to a stirred solution of 2,5-dimethoxybenzenethiol (5 g, 0.029 mol) in ether (30 ml) at 5 °C. Diketene (3 g, 0.036 mol) was then added to this reaction mixture at the same temperature. After 5 h at 5—10 °C, a white solid was separated from the solution by filtration. Recrystallization from EtOH afforded 1.4 g (22%) of **1i**.

The results of elemental analysis, yield and mp are given in Table 4.

2-Methyl-4H-1-benzothiopyran-4-one (2). Method A). Compound **2** was obtained from condensation of thiophenol (10 ml, 0.1 mol) and ethyl acetoacetate (11 ml, 0.1 mol) in polyphosphoric acid (PPA).[5] Method B). *S*-Phenyl 3-oxobutanethioate **1a** (3 g, 0.015 mol) was added to 60 g of PPA at 60 °C. The solution was heated for 1 h at the same temperature. After cooling, the reaction mixture was poured into an ice-water solution and neutralized with NaOH. Crude product (2.3 g) was collected by filtration and washed with water. Recrystallization from a methanol-water mixture (3: 1) afforded 1.8 g (66%) of **2**.

7-Methoxy-2-methyl-4H-1-benzothiopyran-4-one (3). A solution of 14 g (0.1 mol) of *m*-methoxybenzenethiol and 28 g (0.2 mol) of ethyl acetoacetate was added to 300 g of PPA at 80 °C. The reaction mixture was heated at 90 °C for 2 h. After cooling, it was poured into an ice-water solution and collected by filtration and washed with water. Recrystallization from EtOH–water afforded 4 g (20%) of compound **3** as a pale yellow material; mp 118—119.5 °C, Found: C, 63.76; H, 4.85%; Calcd for $C_{11}H_{10}O_2S$: C, 64.08; H, 4.85%; mol wt 206.

Compounds **4**—**9** were prepared by a method silimar to method B for compound **2**. Reaction time in the case of compounds **8** and **9** was 2 h and 3 h, respectively. The yield, mp and elemental analysis are given in Table 5.

3-Methyl-4H-1-benzothiopyran-4-one (10). Compound **10** was prepared by the method of Martin *et al.*,[8] mp 103—104.5 °C (lit, 105 °C), Found: C, 67.42; H, 4.54%; Calcd for $C_{10}H_8OS$: C, 68.18; H, 4.54%; mol wt 176.

5,8-Dimethoxy-2-methyl-4H-1-benzothiopyran-4-one (11). Compound **11** was prepared by method B for compound **2** (36% yield) or by the method for compound **3** (31%).

7-Methoxy-4-methyl-2H-1-benzothiopyran-2-one (12) and 4-Hydroxy-2H-1-benzothiopyran-2-one (13). Compounds **12** and **13** were prepared by method B for compound **2** (reaction time 2 h) and by the method of Ruwet *et al.*[13] (mp 212—213.5; lit, 215 °C), repsectively.

Table 5. reaction of *S*-phenyl 3-oxobutanethioate derivatives with PPA

Compd	Yield (%)	Mp (°C)	Formula (MW)	Analysis (%) Calcd (Found) C	H
2	66[85][a]	103—104	$C_{10}H_8OS$ (176)	68.18 (68.20	4.54 4.78)
12	27	158—160	$C_{11}H_{10}O_2S$ (206)	64.08 (64.28	4.85 5.08)
4	87[90][a]	102—103	$C_{11}H_{10}O_2S$ (206)	64.08 (64.24	4.85 4.93)

11	36[59][a]	146—148	$C_{12}H_{12}O_3S$ (236)	61.02 (61.58	5.08 5.23)

a) Yield (%) of the crude product. b) (**1e**) recovered (18% Yield). c) (**1g**) recovered (24% yield).

Hydrolysis of Compound 2. Compound **2** (5 g) was added to a solution of MeOH (100 ml) and NaOH (40 g). The reaction mixture was heated under reflux for 4.5 h. After cooling, the solution was neutralized to pH 5—6 with HCl and filtered. The residue was washed with water and extracted with ether. The extract was evaporated and the residue recrystallized from EtOH to give 0.6 g (7% yield) of bis(*o*-acetylphenyl) disulfide; mp 162—164 °C (lit,[14] 167 °C), γ_{CO} 1650 cm^{-1}, NMR; δ 2.65 (6H) s, 7.20—7.80 (8H) m. The first filtrate was, after concentration by evaporation, was extracted with MeOH. The extract was recrystallized from MeOH to give 0.5 g (6% yield) of bis(*o*-carboxyphenyl) disulfide; mp 287—288 °C (lit,[15] 288.5); γ_{CO} 1680 cm^{-1}, γ_{OH} 2500—3000 cm^{-1}.

(Received September 6, 1976)

The racemic and meso bis(1-mesitylethyl) ethers were synthesized. The optical resolution of the dicarboxylic acid derivative showed that the high-melting compounds were racemic in form and the low-melting isomers meso in form.

In a previous paper,[1] we reported that 1-(4-substituted 2,6-dimethylphenyl)-1-ethanol gave meso and racemic bis[1-(4-substituted 2,6-dimethylphenyl)ethyl] ethers in the presence of a Lewis acid such as *p*-toluenesulfonic acid.

This paper will describe a synthesis of optically active and meso bis(1-mesitylethyl) ethers from mesitylene. This experiment clarified unambiguously that the high-melting isomer, **1B** (mp 119—120 °C), was racemic and the low-melting one, **1A** (mp 98.5—99.5 °C), was meso in form.

Results

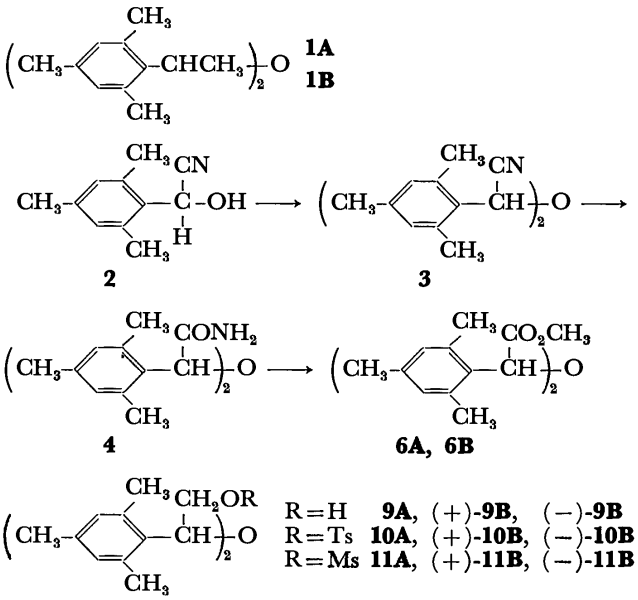
Optically active bis(1-mesitylethyl) ethers (+)-**1B** and (−)-**1B** were synthesized from 2,4,6-trimethylbenzaldehyde by the following method. 2,4,6-Trimethylbenzaldehyde was treated with hydrogen cyanide in the presence of calcium oxide to give a cyanohydrin, **2**, in a 90% yield. When **2** was heated under reflux in absolute benzene in the presence of a catalytic amount of *p*-toluenesulfonic acid, a dibenzyl ether, **3**, was obtained in a 60% yield. Though, in the IR spectrum of **3**, the absorption for nitrile groups was not observed, an elemental analysis and the NMR spectrum supported the structure. The separation of meso and racemic isomers was unsuccessful (on TLC showed only a single spot), and in the NMR spectrum the presence of a hindered rotation was not observed. The treatment of **3** with hydrogen chloride in absolute ethanol gave a carboxamide, **4**. Again, the separation of isomers was unsuccessful (by either recrystallization or column chromatography). The hydrolysis of **4**, followed by methylation, gave a dimethyl ester. Careful chromatography over silica gel of the crude products and elution with acetone–$CHCl_3$ (3: 97) gave the dimethyl ester samples with a mp of 114—116 °C, **6A**, and a mp of 167—168 °C, **6B**, in a ratio of 1: 2. In the NMR spectra of these esters, the aromatic methyls at C_2 and C_6 appeared as singlets at 2.10 and 2.20 ppm respectively. Upon hydrolysis, dicarboxylic acids (**5A**, mp 199—199.5 °C (dec) and **5B**, mp 230—231 °C (dec) respectively) were obtained. On the other hand, the treatment of the carboxamide, **7**, which was obtained directly from the cyanohydrin, **2**, and of the methyl ester, **8**, with *p*-toluenesulfonic acid in benzene did not give the corresponding esters, **4** and **6**.

The treatment of the dicarboxylic acid **5B** with cinchonine and cinchonidine in methanol and the recrystallization of each salt gave optical active salts **I**; $[\alpha]_D^{20}+1°$ ($c=1$, MeOH) and **II**; $[\alpha]_D^{20}-29°$ ($c=1$, MeOH). The subsequent acid hydrolysis of these salts gave a (+)-dicarboxylic acid, (+)-**5B**, $[\alpha]_D^{20}+223.5°$ ($c=1$, MeOH) and a (−)-dicarboxylic acid, (−)-**5B**, $[\alpha]_D^{20}-235°$ ($c=1$, MeOH), respectively. The carboxylic acids gave the (+)-**6B** and (−)-**6B** esters. The reduction of the **6A**, (+)-**6B**, and (−)-**6B** esters with lithium aluminum hydride gave **9A**, (+)-**9B**, and (−)-**9B** respectively. The NMR spectra of these alcohols indicated the presence of a hindered rotation of the benzene rings. The meso isomer **9A** showed a broad singlet ($W_{1/2}=12$ Hz) at 2.15 ppm for two aromatic methyl resonances at C_2 and C_6 at room temperature; this singlet changed to two signals at a lower temperature, whereas the racemic **9B** showed two broad lines at 1.50 and 2.50 ppm at room temperature, while at a higher temperature, they changed to one sharp signal.

The treatment of the **9A**, (+)-**9B**, and (−)-**9B** alcohols with tosyl chloride in pyridine at room temperature gave only monotosylates, but at 80 °C it gave the **10A**, (+)-**10B**, and (−)-**10B** ditosylates respectively. The reduction of these ditosylates with lithium aluminum hydride failed to give the desired methyl derivatives, but it did give the starting alcohols. Then **10A** was converted into an iodide with sodium iodide in acetone in a sealed tube at 100 °C.[2] The iodide was treated with activated zinc in acetic acid to give 1-ethyl-2,4,6-trimethylbenzene, presumably formed by the cleavage of the ether linkage with hydrogen iodide formed *in situ*.

The conversion of the carboxyl group into the methyl one was finally achieved by the following routes. The **9A** alcohol was converted into a meso mesylate, **11A**, which was reduced by lithium aluminum hydride to give the **1A** ether (a low-melting isomer) in a 4% yield. The **1A** ether was identical with the specimen obtained by a different route[1] (IR and mixed mp). However, the corresponding optically active mesylates (+)-**11B** and (−)-**11B** gave only the starting alcohols on reduction with lithium aluminum hydride. Optically active **1B**'s were obtained from the ditosylates (+)-**10B** and (−)-**10B** by treatment with phenylmethanethiol, followed by desulfurization with Raney Ni, according to the method of Hussey *et al.*[3] (+)-**1B**; $[\alpha]_D^{20}+214°$ ($c=0.11$, MeOH), (−)-**1B**; $[\alpha]_D^{20}-212°$ ($c=0.175$, MeOH). A similar treatment of **10A** gave **1A** in an 8% yield. These isomers also indicated the presence of a hindered rotation of the benzene rings in their NMR spectra. The aromatic methyl resonances at C_2 and C_6 of **1A** and **1B** showed a singlet ($W_{1/2}=4.4$ Hz) at 2.20 ppm and a broad signal at 1.5—2.5 ppm at room temperature respectively; each

of them changed to two signals at lower temperatures and to one sharp signal at higher temperatures.



Experimental

All the melting points are uncorrected. The IR spectra were recorded with a Shimadzu IR-27C spectrophotometer. The NMR spectra were measured with a JEOL JNM 60 apparatus at room temperature and at different temperatures with a JEOL JNM 100 apparatus (with TMS as the internal standard). The optical rotations were measured with a Shimadzu photoelectropolarometer, TA-20.

Cyanohydrin 2 of 2,4,6-Trimethylbenzaldehyde. A mixture of 2,4,6-trimethylbenzaldehyde (2 g) and anhydrous HCN (2 ml) was kept with CaO (400 mg) in a sealed tube at 50 °C for 3 h. After the removal of the unchanged HCN and CaO, the crude product gave 2.1 g (90%) of a cyanohydrin, **2**, as plates from petroleum ether; mp 112 °C. Found: C, 75.64; H, 7.50; N, 7.96%. Calcd for $C_{11}H_{13}NO$: C, 75.40; H, 7.48; N, 7.99%. NMR ($CDCl_3$): δ 2.33 (3H, s, Ar-C$\underline{H}_3$), 2.41 (6H, s, Ar-C$\underline{H}_3$), 3.12 (1H, d, J=4 Hz, -O$\underline{H}$), 5.80 (1H, d, J=4 Hz, -C$\underline{H}$-OH), 6.84 (2H, s, Ar-$\underline{H}$) ppm.

Bis(α-cyano-2,4,6-trimethylbenzyl) Ether, 3. The cyanohydrin, **2**, (3 g) was refluxed with a catalytic amount of TsOH in dry benzene for 6 h. The crude product gave 1.7 g (61%) of **3** as prisms from EtOH; mp 150—151 °C. Found: C, 79.64; H, 7.32; N, 8.33%. Calcd for $C_{22}H_{24}N_2O$: C, 79.48; H, 7.28; N, 8.43%. NMR ($CDCl_3$): δ 2.28 (6H, s, Ar-C$\underline{H}_3$), 2.48 (12H, s, Ar-C$\underline{H}_3$), 5.82 (2H, s, Ar-C$\underline{H}$-O), 6.94 (4H, s, Ar-$\underline{H}$) ppm.

Bis(α-carbamoyl-2,4,6-trimethylbenzyl) Ether, 4. Into a solution of the ether **3** (250 mg) in abs EtOH, dry HCl gas was passed for 5 h at 45—50 °C. The subsequent crystallization of the crude product from acetone gave 237 mg (85%) of **4**; mp 261—295 °C. Found: C, 71.85; H, 7.77; N, 7.48%. Calcd for $C_{22}H_{28}N_2O_3$: C, 71.71; H, 7.60; N, 7.60%.

Bis(α-carboxy-2,4,6-trimethylbenzyl) Ether, 5. The **4** ether (300 mg) was hydrolyzed with 30% aq KOH in ethylene glycol to give 227 mg(75%) of **5** as prisms from ether-petroleum ether. Found: C, 70.84; H, 7.14%. Calcd for $C_{22}H_{26}O_5$: C, 71.33; H, 7.08%.

Bis(α-methoxycarbonyl-2,4,6-trimethylbenzyl) Ethers, 6A and 6B. The **5** acid was methylated with diazomethane, and the crude product was chromatographed over silica gel. Elution with $CHCl_3$ containing acetone (3% v/v) gave **6A** (32%) as needles from EtOH; mp 114—116 °C. Found: C, 72.44; H, 7.69%. Calcd for $C_{24}H_{30}O_5$: C, 72.33; H, 7.59%. IR (CCl_4): 1760, 1740, 1200, 1185 (sh), 1150, 1105 cm^{-1}. NMR (CCl_4): δ 2.10 (12H, s, Ar-C$\underline{H}_3$), 2.23 (6H, s, Ar-C$\underline{H}_3$), 3.65 (6H, s, $CO_2C\underline{H}_3$), 5.35 (2H, s, Ar-C$\underline{H}$-O), 6.73 (4H, s, Ar-$\underline{H}$) ppm. Further elution with the same solvent gave the second isomer, **6B** (61%), as prisms from EtOH; mp 167—168 °C. Found: C, 72.25; H, 7.83%. IR (CCl_4): 1740, 1210, 1195, 1180 (sh), 1145, 1100 cm^{-1}. NMR (CCl_4): δ 2.20 (12H, s, Ar-C$\underline{H}_3$), 2.23 (6H, s, Ar-C$\underline{H}_3$), 3.64 (6H, s, $CO_2C\underline{H}_3$), 5.35 (2H, s, Ar-C$\underline{H}$-O), 6.77 (4H, s, Ar-$\underline{H}$) ppm.

Mesitylglycolamide, 7. In a manner similar to that described for **3**, the **2** cyanohydrin gave **7** (78%) as plates from benzene; mp 145.5—146 °C. Found: C, 68.49; H, 7.91; N, 7.29%. Calcd for $C_{11}H_{15}NO_2$: C, 68.37; H, 7.82; N, 7.25%.

Methyl Mesitylglycolate, 8. The **7** amide was hydrolyzed with 30% aq KOH and methylated with diazomethane to give **8** (66%) as prisms from hexane-acetone; mp 149—150 °C. Found: C, 68.02; H, 7.27%. Calcd for $C_{12}H_{16}O_3$: C, 67.64; H, 7.38%.

Bis(α-carboxy-2,4,6-trimethylbenzyl) Ethers, 5A and 5B. The **6A** and **6B** esters were hydrolyzed to give **5A** (mp 199—199.5 °C (dec)) and **5B** (mp 230—231 °C (dec)) respectively.

Optical Resolution of Bis(α-carboxy-2,4,6-trimethylbenzyl) Ether, 5B. (1) The high-melting carboxylic acid **5B** (170 mg) was dissolved with cinchonidine (307 mg) in MeOH, after which the solution was allowed to stand overnight at room temperature. The residue, after removal of the MeOH, was crystallized from MeOH–AcOEt six times to give one optically active salt, **I** (110 mg) as prisms; $[\alpha]_D^{20}$ +1° (MeOH); mp 189—190 °C. Found: C, 73.41; H, 7.63; N, 5.62%. Calcd for $C_{60}H_{70}N_4O_7$+AcOEt: C, 73.39; H, 7.51; N, 5.35%. Into a solution of **I** in MeOH we stirred concd HCl to give (+)-**5B**; $[\alpha]_D^{20}$ +223.5° (MeOH); mp 219°C (dec). (2) **5B** (470 mg) was treated with cinchonine (250 mg) in MeOH, and the product was recrystallized from acetone–AcOEt five times to give another optically active salt, **II** (136 mg); $[\alpha]_D^{20}$ −29° (MeOH); mp 151—152 °C. Found: C, 70.07; H, 7.49; N, 3.71%. Calcd for $C_{41}H_{48}N_2O_6$ +2AcOEt: C, 69.97; H, 7.67; N, 3.33%. (−)-**5B** was afforded from **II**; $[\alpha]_D^{18}$ −235° (MeOH).

Optically Active Bis(α-methoxycarbonyl-2,4,6-trimethylbenzyl) Ethers, (+)-6B and (−)-6B. (+)-**5B** and (−)-**5B** were methylated with diazomethane to give (+)-**6B** ($[\alpha]_D^{20}$ +148° (MeOH); mp 157—157.5 °C) and (−)-**6B** ($[\alpha]_D^{20}$ −147° (MeOH)) respectively.

Bis[α-(hydroxymethyl)-2,4,6-trimethylbenzyl] Ethers, meso-9A, (+)-9B, and (−)-9B. The **6A**, (+)-**6B**, and (−)-**6B** esters were reduced with $LiAlH_4$ in ether to give **9A**, (+)-**9B**, and (−)-**9B** respectively as needles from acetone. **9A**; mp 147—147.5 °C. Found: C, 77.26; H, 8.83%. Calcd for $C_{22}H_{30}O_3$: C, 77.15; H, 8.83%. NMR ($CDCl_3$): δ 2.20 (18H, s, Ar-C$\underline{H}_3$), 3.15 (2H, dd, J=4.3 and 11.7 Hz, Ar-$\underline{\text{C}}\underline{\text{H}}$-$\underline{\text{C}}$(H)-OH), 4.20 (2H, dd, J=9.0 and 11.7 Hz, Ar-$\underline{\text{C}}\underline{\text{H}}$-$\underline{\text{C}}$(H)-OH), 5.15 (2H,dd,$J$=4.3 and 9.0 Hz, Ar-C$\underline{H}$-$CH_2$-), 6.75 (4H, s, Ar-H) ppm. (+)-**9B**; $[\alpha]_D^{23}$ +153° (MeOH); mp 172—173 °C. Found: C, 77.13; H, 8.87%. NMR ($CDCl_3$): δ 1.50 (6H, broad s, Ar-C$\underline{H}_3$), 2.20 (6H, s, Ar-C$\underline{H}_3$), 2.52 (6H, broad s, Ar-CH_3), 3.55 (2H, dd, J=4.5 and 10.5 Hz, Ar-$\underline{\text{C}}\underline{\text{H}}$-$\underline{\text{C}}$(H)-OH), 4.10 (2H, dd, J=8.5 and 10.5 Hz, Ar-

H
CH–C–OH), 4.80 (2H, dd, J=4.5 and 8.5 Hz, Ar–CH–CH_2–),
H
6.8 (4H, s, Ar–H) ppm. (−)-**9B**; $[\alpha]_D^{22}$ −154° (MeOH).

*Bis[α-(tosyloxymethyl)-2,4,6-trimethylbenzyl] Ethers, meso-**10A**, (+)-**10B**, and (−)-**10B**.* The **9A**, (+)-**9B**, and (−)-**9B** alcohols were tosylated with tosyl chloride in pyridine at 80 °C to give **10A** (78%), (+)-**10B** (73%), and (−)-**10B** (74%) respectively. **10A**; mp 163 °C. Found: C, 66.65; H, 6.62%. Calcd for $C_{36}H_{42}O_7S_2$: C, 66.45; H, 6.51%. (+)-**10B**; $[\alpha]_D^{22}$ +125° ($CHCl_3$); mp 140—141 °C. Found: C, 66.48; H, 6.63%. (−)-**10B**; $[\alpha]_D^{22}$ −125° ($CHCl_3$). Found: C, 66.52; H, 6.56%.

*Reaction of the **10A** Tosylate with Sodium Iodide.* The **10A** tosylate (250 mg) was reacted with sodium iodide (300 mg) in acetone in a sealed tube at 100 °C for 24 h. The reaction product (128 mg) was then treated with activated zinc (300 mg) in acetic acid under reflux for 3 h to give 63 mg of 1-ethyl-2,4,6-trimethylbenzene; bp 209—211 °C.

*Reactions of the **10A**, (+)-**10B**, and (−)-**10B** Tosylates with LAH.* The treatments of **10A**, (+)-**10B**, and (−)-**10B** with $LiAlH_4$ gave the **9A**, (+)-**9B**, and (−)-**9B** alcohols respectively in high yields.

*Bis[α-(mesyloxymethyl)-2,4,6-trimethylbenzyl] Ethers, meso-**11A**, (+)-**11B**, and (−)-**11B**.* The mesylations of the **9A**, (+)-**9B**, and (−)-**9B** alcohols with mesyl chloride in pyridine at 80 °C for 2 h gave **11A** (63%), (+)-**11B** (72%), and (−)-**11B** (68%) respectively. **11A**; mp 127—127.5 °C. Found: C, 58.02, H, 6.95%. Calcd for $C_{24}H_{34}O_7S_2$: C, 57.81; H, 6.87%. (+)-**11B**; $[\alpha]_D^{20}$ +41° (MeOH); mp 134 °C. Found: C, 58.01; H, 6.94%. (−)-**11B**; $[\alpha]_D^{20}$ −42° (MeOH). Found: C, 57.95; H, 6.92%.

meso-*Bis(1-mesitylethyl) Ether, **1A**.* (1) The treatment of the **11A** mesylate (200 mg) with $LiAlH_4$ (531 mg) in ether under reflux for 2 h gave 6 mg (4%) of **1A** (mp 98—99 °C) as plates from EtOH. IR (CCl_4): 1615, 1160, 1095, 1075, 945, 855 cm^{-1}. (2) The **10A** tosylate (440 mg) was reacted with phenylmethanethiol (330 mg) and Na (80 mg) in diethylene glycol monoethyl ether (8 ml) under reflux for 4 h. The reaction mixture was then poured into ice water, and the unreacted thiol was removed by steam distillation after acidification with dil HCl. An ether extract of the reaction product was treated with Raney Ni(w-2) in EtOH under reflux for 8 h to give 23 mg (11%) of **1A**.

*Reaction of the (+)-**11B** Mesylate with LAH.* The treatment of (+)-**11B** with $LiAlH_4$ in ether under reflux gave the (+)-**9B** alcohol (83%).

*Optically Active Bis(1-mesitylethyl) Ethers, (+)-**1B** and (−)-**1B**.* The optically active tosylates, (+)-**10B** and (−)-**10B**, were transformed into dibenzyl sulfides in a manner similar to that described for **10A**. These crude sulfides were then treated with Raney Ni(w-2) to give (+)-**1B** (8%) and (−)-**1B** (12%) respectively. (+)-**1B**; $[\alpha]_D^{20}$ +214° (MeOH); mp 132.5—133 °C. (−)-**1B**; $[\alpha]_D^{20}$ −212° (MeOH). IR (CCl_4): 1615, 1160, 1095, 1075, 945, 885 cm^{-1}. These compounds were identical in IR spectrum with, but differ in mp from, the high-melting isomer, **1B**, obtained by another route.[1]

We wish to express our sincere gratitude to Professor T. Tokoroyama of Osaka City University for his many helpful discussions.

Reactions of Aromatic Compounds in Molten Salts. I. Dimerization of Aromatic Amines in a Molten Mixture of $AlCl_3$-NaCl-KCl

Hiroshi IMAIZUMI, Shizen SEKIGUCHI, and Kohji MATSUI

Faculty of Engineering, Gunma University, Kiryu, Gunma 376

(Received September 6, 1976)

Aromatic amines underwent dimerization in a molten salt consisting of a mixture of $AlCl_3$-NaCl-KCl. The reaction is an oxidative cationic polymerization but, in contrast with the reactions of the ordinary aromatic compounds which gave the corresponding polyaryls, in the cases of aromatic amines the reaction was regiospecific and stopped at the stage of biaryl to yield benzidine derivatives.

The coupling of aromatic nuclei using Lewis or protonic acids as a catalyst is called a Scholl reaction,[1] and is applicable to the preparation of derivatives of polyaryl;[2-4] however, this reaction is not useful for the synthesis of ordinary biaryl derivatives because of their low yields.

When aromatic amines were heated in a molten salt consisting of a mixture of $AlCl_3$-NaCl-KCl, derivatives of *p,p'*-diaminobiaryl were found to be obtained as a major product. This paper reports the reactions of aromatic amines in molten salts to give benzidine derivatives.

Experimental

All the melting points are uncorrected. NMR spectra were recorded on a Varian A-60D spectrometer. Mass spectra were recorded on a JEOL-JMS-07 mass spectrometer. Elemental analyses were performed in the Micro-analytical Center of Gunma University. The structural assignments of the reaction products were done by means of their NMR, MS spectra, and elemental analyses and by a mixed-melting-point test with an authentic sample.

Materials. $AlCl_3$, NaCl, KCl, and other inorganic materials used were of reagent grade. The aromatic amines employed were purified by distillation or recrystallization and their purities were checked by TLC before use.

Table 1. Benzidine derivatives

No.	Compound	Mp (°C) (Lit,)	Solvent for recrystalization	Anal. (%), Found (Calcd) C	H	N	Cl

A typical example of the reaction is shown below: 5 ml of aniline (0.0549 mol) was added into a molten mixture of $AlCl_3$–NaCl–KCl (0.60: 0.20: 0.20 mol) under stirring and then the reaction mixture was stirred under blowing of O_2 (or N_2) (20—30 ml/min). The mixture was then poured into a mixture of 500 ml of 0.1M HCl and 100 g of ice. After a small amount of the insoluble matter had been filtered off, the filtrate was made alkaline and the unreacted aniline was removed by steam distillation. The reaction products which remained in the residue were extracted with benzene, separated by column chromatography [silica gel, benzene–acetone (10: 1 v/v)], and recrystallized (Table 1).

Results and Discussion

Formation of Benzidines. When aniline and some *N*-alkylanilines were heated at 150 °C in a mixture of $AlCl_3$–NaCl–KCl (0.6: 0.2: 0.2 mol), the corresponding benzidine derivatives were obtained as the major products. Table 1 lists the benzidine derivatives thus obtained in this work. The yields increased very much in the presence of O_2, but above 250 °C dealkylation of *N*-alkylanilines occurred. Table 2 lists the yields of benzidine derivatives in the presence of O_2. When a mixture of two kinds of amines (in a molar ratio 1: 1) was heated in the molten salt, the unsymmetric derivative of *p,p'*-diaminobiaryl was obtained along with the symmetric ones.

Effects of Lewis Acid. The dimerization of aromatic amines was affected very much by the Lewis acids used: in the reaction of aniline, $AlBr_3$ was found to be as effective as $AlCl_3$, but in the case of $ZnCl_2$, no benzidine derivative was found in the reaction mixture. On the other hand, $SnCl_4$ was ineffective at 100 °C; most of the starting material was recovered even after heating for a long time.

Table 2. Yields of benzidine derivatives in the reaction of anilines in molten salts ($AlCl_3$:NaCl:KCl=3:1:1)[a] at 150 °C in the presence of O_2

a) Substrate: aniline, 0.0549 mol. b) This system is not a molten salt, but cited here for comparison. In this case, anilinium salt was insoluble in $SnCl_4$ at 100 °C.

These Lewis acids are known to form complexes with aromatic amines. In our experiment, the complexation was much more exothermic in the mixture of $AlBr_3$–NaCl–KCl (0.6: 0.2: 0.2 mol) or of $AlCl_3$–NaCl–KCl (0.6: 0.2: 0.2 mol) than in the mixture of $ZnCl_2$–NaCl–KCl (0.6: 0.2: 0.2 mol).[5] Table 4 clearly shows that the above-described heat of complexation is parallel to the yields for the dimerization, and also comparable to the relative acid-strengths of $AlBr_3$, $AlCl_3$, and $ZnCl_2$ toward 2-methyl-4-nitroaniline in diethyl ether *ca.* 2: 1: *ca.* 0.01.[6] These results suggest that the complexation ability of the Lewis acids with amines plays an important role in the dimerization.

Formation of Chlorinated Benzidines. When aromatic amines were heated in the molten salts in the presence

of O_2, a small amount of chlorinated benzidines was obtained; their amounts increased with the reaction time. However, the formation of chlorinated benzidines was not observed in the absence of O_2; in the presence of O_2, the gas mixture evolved in the reaction vessel turned KI-starch test paper into blue, indicating the presence of Cl_2 which would react with amines to yield the chlorinated benzidines. Thus, when benzidine hydrochloride was heated in the molten salt, various chlorinated benzidines were obtained (Table 5). In the presence of aniline hydrochloride, chlorinated products were formed more rapidly and in high yields; thus, the formation of chlorinated products is assumed to proceed by the sequence shown in Scheme 1.

Effects of Composition of Molten Salt. Although $AlCl_3$ is known to form the 1:1 complex with NaCl or KCl in a molten salt and only the remaining $AlCl_3$ has any catalytic activity,[7] benzidine was also formed even in the molten salt of a molar ratio [$AlCl_3$/(NaCl+KCl)] less than unity, suggesting that aniline took $AlCl_3$ away from the complex. When the molar ratio of aniline to free $AlCl_3$ was 1:4 or 1:2 in the molten salt of $AlCl_3$: NaCl: KCl (0.6: 0.2: 0.2 mol) at 200 °C in a stream of N_2, the reaction mixture remained completely clear. On the other hand, as the molar ratio became 1:1 or larger, the

mixture increasingly became more turbid. These facts indicate that the $AlCl_3$-aniline, $AlCl_3$-NaCl, and $AlCl_3$-KCl complexes are practically soluble in a molten salt and that the free NaCl and KCl, formed when aniline takes $AlCl_3$ from the $AlCl_3$-NaCl or $AlCl_3$-KCl complex, are insoluble in a molten salt,[8-10] supporting the above-

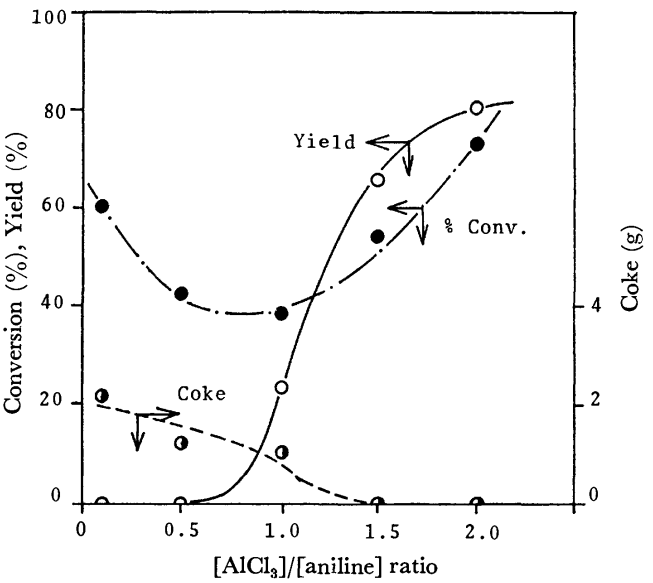

Fig. 2. Effect of [$AlCl_3$]/[aniline] ratio on the product yields (reaction temp 150 °C, reaction time 20 h, substrate; aniline 0.0549 mol).

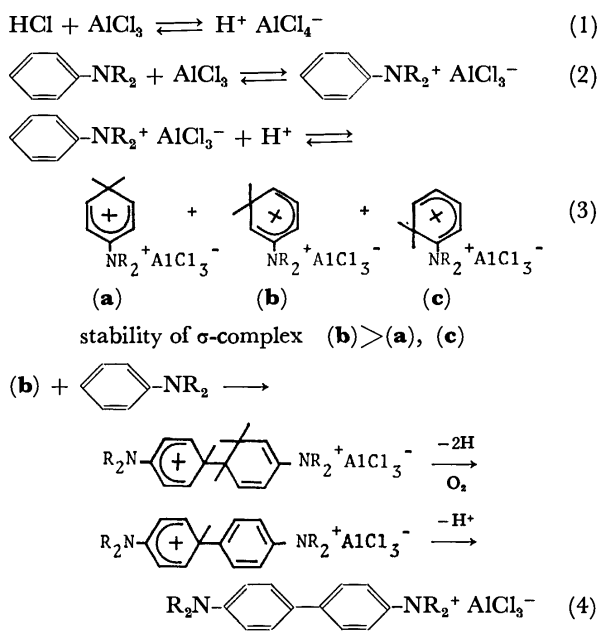
described suggestion. Of course, the yield of benzidine increased with an increase in the ratio of $AlCl_3/(NaCl+KCl)$; in the region of ratio between 1—2 the increase in yield was most remarkable.

Reactions of Aniline with $AlCl_3$ in the Absence of NaCl and KCl. In the reaction of aniline with $AlCl_3$ in the absence of KCl and NaCl, a large amount of black tarry matter was obtained, and the yield of benzidine increased with an increase in the amount of $AlCl_3$. These results suggest that $AlCl_3$ complexed aniline at the site of amino group preferentially, arguing from a consideration of the similar spectral change on addition of $AlCl_3$ or HCl to aniline, and that more than one equivalent amount of $AlCl_3$ is necessary for the dimerization of aniline.

When aniline was heated with aniline hydrochloride in the absence of $AlCl_3$, no benzidine was formed, and no corresponding derivative of benzidine was similarly observed when dimethylaniline was heated with *N,N*-dimethyl-*N*-ethylanilinium iodide. Therefore, it may be obvious that the activation by quaternization of an amino group is not sufficient to dimerize an aromatic amine, in spite of the strong electron-withdrawing power of the $-\overset{+}{N}R_3$ group.[11]

From these results, a probable process for the formation of benzidine from aniline in the molten salt is shown in Scheme 2:



Scheme 2. A probable process for the formation of benzidine in molten salts.

1) Formation of $H^+AlCl_4^-$ from $AlCl_3$ and HCl, which would be formed from $AlCl_3$ and trace amounts of water in the molten salt.

2) Formation of a complex from aniline and $AlCl_3$. Although an equilibrium of the complex formation should lie far to the right, a slight amount of free aniline would be present in the reaction mixture, judging from the fact that all the chlorinated benzidine derivatives obtained in the reactions should be derived from free amines; all of them have halogen atoms at *ortho* or/and *para* positions to the amino group.

3) Formation of a σ-complex by the reaction of the aniline–$AlCl_3$ complex with $H^+AlCl_4^-$. In this reaction, the formation of three kinds of σ-complexes may be possible and from the adjacent charge rule the complex (**b**) should be the most stable and probable one among them; a similar σ-complex was observed by Olah *et al.*[11] However, the σ-complex formation would take place only with difficulty because of the positive character of the aniline–$AlCl_3$ complex. Thus, even though the concentration of the complex (**b**) is very low, **b** would be very electrophilic and a true reactive species in this reaction.

4) Formation of protonated dihydrobenzidine by a combination of the complex (**b**) with aniline, which would be present in a slight amount in the reaction mixture; this combination of two aromatic nuclei would be the key step in the benzidine formation from aniline in the molten salt.

5) Formation of a complex consisting of benzidine and $AlCl_3$ from protonated dihydrobenzidine by dehydrogenation and deprotonation. Monosubstituted benzenes such as halo-[3] and alkyl-benzenes[4] reacted with Lewis acids to give the derivatives of polyphenylene. However, the reaction of aromatic amines was very regiospecific and stopped at the stage of dimerization to yield *p,p'*-diaminobiaryls. The difference in the reaction between amine and other aromatic compounds would be attributed to the amino group which complexes $AlCl_3$ preferentially. Then the coordinated amine would react with $H^+AlCl_4^-$ to give the σ-complex of *meta* type (**b**), which would attack a free amine at the *ortho* or *para* position to the amino group, with the *para* attack predominating because of the steric hindrance in the *ortho* attack.

As to the reaction site of the free amine component, it may be reasonable to consider as follows: in the ordinary electrophilic substitution of aromatic compounds having an *o*- and *p*-directive group, the *para* attack proceeds more readily than the *ortho* attack even in the absence of steric hindrance. The positive charge of the reagent (**b**) spreads over three *o*- and *p*-positions to the sp^3 carbon in the ring, and consequently the electrophilic reactivities of *para* and *ortho* carbon atoms would be very low. Therefore, this reaction should be very selective, as in the cases of azo-coupling reactions of diazonium salts with aromatic amines; thus, in the present cases, the reactions took place almost exclusively at the *o*-position to the sp^3 carbon.

It may also be possible to form a similar benzidine–$AlCl_3$ complex (of the molar ratio of 1 : 1 or 1 : 2) to that from aniline. However, protonation of the 1 : 2 complex to yield a reactive species (**d**), corresponding to **b** in structure, would be much harder by two $-\overset{+}{N}\lessgtr$ groups than in the case of an aniline complex.[11] The concentration of a 1 : 1 complex should be very low in the presence of an excess of $AlCl_3$. Moreover, protonation would occur at the free amino group to give a complex similar to the 1 : 2 complex. After all, protonation is considered to be very difficult in the case of the benzidine–$AlCl_3$ complex (1 : 1 or 1 : 2), and, therefore, there is little possibility that a corresponding reactive

species to **b** reacts with aniline to produce a trimer.

On the other hand, the concentration of free benzidine would be very low in the presence of an excess of $AlCl_3$ compared with the case of aniline, and, moreover, the attack of **b** on the *ortho* position to the amino group of benzidine is considered to be very difficult because of the steric hindrance. Thus, **b** should react with aniline preferentially even in the presence of benzidine. Therefore, the possibilities of giving a trimer [reaction product of **b** with benzidine or reaction product of **d** with aniline] or tetramer [reaction product of **d** with benzidine] should be very low. This interpretation is consistent with the fact that the reaction of aromatic amines stopped at the stage of dimerization.

These speculations may be supported by the fact that *m*-phenylenediamine did not undergo dimerization and most of it was recovered in the molten salt; in the presence of an excess of $AlCl_3$, *m*-phenylenediamine would complex 2 mol of $AlCl_3$ to form a 1 : 2 complex, whose protonation to yield a σ-complex would occur with great difficulty. Even if a σ-complex is formed, little biphenyl would be formed, because *m*-phenylenediamine would not be present as a free base in the presence of an excess of $AlCl_3$.

Amidrazones and Related Compounds. IV.[1] The Cyclization of Hydrazidines to 2,3,4,5-Tetrahydro-1,2,4,5-tetrazine and 4-Amino-1,2,4-triazole Derivatives

Masahiko TAKAHASHI, Hideya TAN, Kunio FUKUSHIMA, and Hiroaki YAMAZAKI

Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Hitachi, Ibaraki 316

(Received September 16, 1976)

Three methods of cyclization of hydrazidines are described. The reaction of N^4-arylhydrazidines (**2**) with dimethyl acetylenedicarboxylate in refluxing tetrahydrofuran afforded 6-alkyl and aryl-2-aryl-3-methoxycarbonyl-3-methoxycarbonylmethyl-2,3,4,5-tetrahydro-1,2,4,5-tetrazines (**3**). Oxidation of N^4-aryl-N^2-arylmethylenehydrazidines (**6**) with mercuric oxide in refluxing ethanol gave 3-alkyl and aryl-5-aryl-4-arylamino-1,2,4-triazoles (**7**). 3-Alkyl and aryl-4-arylamino-1,2,4-triazoles (**7f, g**) were obtained upon the heating of (**2a, e**) in formic acid.

In contrast to amidrazones[2] the use of hydrazidines, nitrogen analogues of amidrazone, as starting materials for the preparation of nitrogen heterocycles has not been extensively studied.

The reaction of N^4-arylhydrazidines with nitrous acid has been reported to give 2,6-diarylpentazines,[3] which were later corrected to be 1-arylamino-5-aryltetrazoles.[4] Methylthiohydrazonium salts have been noted[5] to cyclize in the presence of hydrazines to give 2,5-diphenyltetrazoles through intermediary hydrazidines. The synthesis of 3,5-disubstituted 4-arylamino-1,2,4-triazoles from acylhydrazidines has been investigated by Buzykin and coworkers.[6a,b] Recently, Neunhoeffer *et al.* have prepared some *N*-unsubstituted hydrazidines,[7] and pyrrolo[1,2-*b*][1,2,4,5]tetrazines.[8]

In this paper, the methods of cyclization of hydrazidines to some heterocycles by use of dimethyl acetylenedicarboxylate, mercuric oxide, and formic acid are reported.

Results and Discussion

Hydrazidines (**2**) are available by the reaction of hydrazonyl bromide (**1**) and hydrazine hydrate in alcohol.[9] Although the presence of the tautomerism **2A**⇌**2B** of hydrazidine appears possible, no study of it has been reported. However, the formation of 4-amino-1,2,4-triazoles[6,7] and 1-aminotetrazoles[4] supports the tautomerism. All the reported cyclization occured at the N^2 and N^3 positions. However, when **2** were treated with dimethyl acetylenedicarboxylate, compounds cyclized at the N^2 and N^4 positions were formed.

Thus, when N^4-(2-bromo-4-nitrophenyl)benzohydrazide hydrazone (**2a**) was allowed to react with dimethyl acetylenedicarboxylate in refluxing tetrahydrofuran, an orange product was obtained. This compound was proved to be a 1:1 adduct on the basis of elemental analysis and its mass spectrum (*m/e* 491, M^+). The IR spectrum showed NH, C=N, and ester absorptions at 3260, 1625, and 1705 cm^{-1}, respectively. The presence of two methyl and one methylene groups was ascertained by resonance at δ 3.65 (s, 3H), 3.75 (s, 3H), and 3.90 (s, 2H) in the NMR spectrum. However, these data do not distinguish between the tetrahydrotetrazine (**3a**) and dihydrotriazole (**5a**). Therefore, to determine the structure, some reactions were attempted and an oxidized product was obtained upon treatment of the adduct with nitric acid, which was previously used for the oxidation of dihydrotetrazine to tetrazine.[10] The oxidized product showed no NH absorption, but two ester absorptions at 1736 and 1725 cm^{-1}. In the NMR spectrum, the absorptions at δ 3.64, 3.74, and 3.31 were assigned to two methyl and one methylene groups, respectively. The mass spectrum (*m/e* 489, M^+) and elemental analysis suggest one molar dehydrogenation from the 1:1 adduct. From these data, it is concluded that the structure of the adduct is **3a**, 2,3,4,5-tetrahydro-1,2,4,5-tetrazine and the oxidized product is 2,3-dihydro-1,2,4,5-tetrazine (**4**).The physical properties and the spectral data of other tetrazine derivatives are listed in Table 1.

Scheme 1.

The synthesis of nitrogen heterocycles from hydrazidines has also been attempted. Spasov *et al.*[11] have described the oxidation of arylmethylene derivatives of amidrazones with mercuric oxide to yield 3,4,5-triaryl-substituted 1,2,4-triazoles. Then this method was applied to hydrazidines. A mixture of N^2-benzylidene-N^4-(2-bromo-4-nitrophenyl)benzohydrazide hydrazone (**6a**) and mercuric oxide in ethanol was refluxed for 24 h. The elemental analysis, mass spectrum (*m/e*

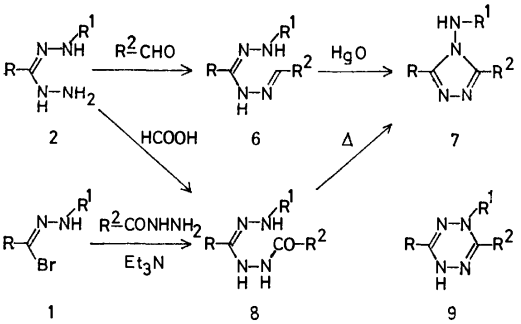
435, M^+), and IR spectrum (NH absorption at 3140 cm^{-1}) of the product indicate it to be 4-amino-1,2,4-triazole (**7a**) or 2,5-dihydro-1,2,4,5-tetrazine (**9a**). The NMR measurement of a product, whose substituents R and R^2 are the same, would reveal the structure to be symmetric (**7**) or asymmetric (**9**). In the NMR spectrum of products **7e** and **9e** obtained from **6e**, four methyl and two methylidyne groups of the two isopropyl groups on R and R^2 were observed at δ 1.15 (12H, d, J=7.0 Hz) and 2.80 (2H, m, J=7.0 Hz), respectively, and the aromatic protons on R and R^2 were observed at δ 7.01 (4H, d, J=8.2 Hz) and 7.55 (4H, d, J=8.2 Hz). These results show that the product apparently is not asymmetric **9e**, but is symmetric **7e**. The confirmation of the structure of **7** has been further conducted according to reported method,[7] that is, the dehydration of N^2-acyl-N^4-substituted hydrazidines (**8**) to **7**. **8a** prepared from **1a** was heated in acetic acid and the product was identical with **7a**. The physical and spectral data for product **7** from **6a—e** are listed in Table 2.

When **2a** was heated in formic acid, a product was obtained. The analytical and mass spectral results suggest **7f** or **9f** to be possible structures. But **7f** is prefered on the basis of the NMR spectrum, which is as follows: six aromatic protons and one NH proton at δ 7.4—7.95 (m) and 9.04 (s), respectively, besides protons due to the 2-bromo-4-nitrophenyl group, which were clearly assigned (see Experimental). The reaction presumably proceeded *via* formylated hydrazidine (**8f**) to **7f**. However, this cyclization method was sometimes



6, 7, 8, 9,	R	R^1	R^2

Scheme 2.

accompanied by by-products and only **7f** and **7g** were obtained in pure forms.

Experimental

All the melting points are uncorrected. The IR, UV, and NMR spectra were measured using a JASCO Model IRA-2 spectrometer, a Shimadzu Model MPS-501 spectrometer, and a Hitachi Model R-20 spectrometer, respectively. A Shimadzu Model UM-3B apparatus was used for the elemental analysis.

Materials. Compounds **1a**,[12] **1b**[12] **1c**,[12] **1d**,[13] **1e**,[13] and **1f**[12] were prepared using reported methods. The hydrazines (**2a—f**) were prepared by the method of Hegarty *et al.*[9] The arylmethylene hydrazidines **6a**,[9] **6c**,[9] and **6d**[13] were prepared by known methods. **6b** was prepared by refluxing the EtOH solution of **2a** and *p*-dimethylaminobenzaldehyde for 30 min. Recrystallization from benzene afforded red plates; mp 184—186 °C. Found: C, 55.02; H, 4.11%. Calcd for $C_{22}H_{21}O_2N_6Br$: C, 54.89; H, 4.40%. **6e** was prepared as follows: a mixture of **2f** (1.24 g, 3.2 mmol), *p*-isopropylbenzaldehyde (950 mg, 6.4 mmol), and triethylamine (320 mg, 3.2 mmol) in EtOH (64 ml) was refluxed for 2 h. After cooling, the precipitates were filtered to give **6e** (658 mg, 39% yield). Recrystallization from THF–MeOH gave brown needles; mp 193—195 °C. Found: C, 59.49; H, 5.25%. Calcd for $C_{26}H_{28}O_2N_5Br$: C, 59.77; H, 5.40%.

2-(2-Bromo-4-nitrophenyl)-3-methoxycarbonyl-3-methoxycarbonylmethyl-6-phenyl-2,3,4,5-tetrahydro-1,2,4,5-tetrazine (3a). A mixture of **2a** (1.0 g, 2.9 mmol) and dimethyl acetylenedicarboxylate (490 mg, 3.4 mmol) in THF (40 ml) was refluxed for 4 h. After evaporation of the solvent under reduced pressure, the residue was washed with a small amount of MeOH and filtered to give **3a** (1.1 g, 77% yield). Recrystallization from benzene afforded orange crystals; mp 184—187 °C. NMR (DMSO-d_6): δ 3.65 (3H, s, $-CH_3$), 3.75 (3H, s, $-CH_3$), 3.90 (2H, s, $-CH_2-$), 7.4—8.3 (8H, m, aromatic H), 10.85 (1H, s, NH), 11.30 (1H, s, NH). MS *m/e* (%): 493 (M^++2, 51), 491 (M^+, 53), 434 (54), 432 (54), 334 (13), 332 (15), 245 (33), 216 (38), 214 (40), 104 (82), 103 (100).

The tetrazines (**3b—3e**) were prepared in a manner similar to that described above by refluxing the reaction mixture for 2.5—4 h.

2-(2-Bromo-4-nitrophenyl)-3-methoxycarbonyl-3-methoxycarbonylmethyl-6-phenyl-2,3-dihydro-1,2,4,5-tetrazine (4). To a suspension of **3a** (500 mg, 1.0 mmol) in AcOH (20 ml) was added nitric acid (0.43 ml) dropwise with cooling and stirring. After the color of the reaction mixture became red, crushed ice was added and the solution was made alkaline with aq sodium carbonate. The resulting precipitates were filtered to give **4** (390 mg, 79% yield). Quick recrystallization from MeOH afforded orange plates; mp 133—136 °C. Found: C, 46.35; H, 3.30%. Calcd for $C_{19}H_{16}O_6N_5Br$: C, 46.54; H, 3.29%. IR (KBr): 3090, 2950, 1736, 1725, 1584 cm^{-1}. UV (MeOH) nm (log ε): 218 (4.46), 231 sh (4.32), 256 sh (4.00), 278 (3.87), 360 (4.32). NMR ($CDCl_3$): δ 3.31 (2H, s, $-CH_2-$), 3.64 (3H, s, $-CH_3$), 3.74 (3H, s, $-CH_3$), 7.3—8.6 (8H, m, aromatic H). MS *m/e* (%): 491 (M^++2, 0.4), 489 (M^+, 0.4), 463 (7.8), 461 (8.0), 404 (5.8), 402 (5.8), 360 (11), 358 (12), 332 (13), 330 (14), 301 (43), 299 (45), 279 (39), 269 (39), 267 (21), 258 (19), 256 (19), 233 (24), 116 (23), 103 (100).

4-(2-Bromo-4-nitroanilino)-3,6-diphenyl-1,2,4-triazole (7a). A mixture of **6a** (200 mg, 0.41 mmol) and yellow mercuric oxide (260 mg, 1.2 mmol) in EtOH (120 ml) was refluxed for 24 h. After the inorganic materials were filtered off, the filtrate was concentrated under reduced pressure and the resulting precipitates were filtered to give **7a** (138 mg, 48% yield). Recrystallization from benzene–petroleum ether afforded a pale yellow powder; mp 265—267 °C. MS *m/e* (%): 437 (M^++2, 41), 435 (M^+, 43), 221 (43), 192 (51), 118 (36), 103 (58), 89 (100). The triazoles (**7b—e**) were prepared in a manner similar to that described above by refluxing the reaction mixture for 15—28 h. The NMR spectrum of **7e** ($CDCl_3$): δ 1.15 (12H, d, J=7.0 Hz, $-CH_3$ on isopropyl), 2.80 (2H, m, J=7.0 Hz, CH on isopropyl), 5.98 (1H, d, J=9.0 Hz, 6-H on R^1), 7.01 (4H, d, J=8.2 Hz, *o*- or *m*-H on R and R_2), 7.55 (4H, d, J=8.2 Hz, *o*- or *m*-H on R and R^2), 7.73 (1H, dd, J=9.0 and 2.2 Hz, 5-H on R^1), 8.21 (1H, d, J=2.2 Hz, 3-H on R^1), 8.80 (1H, s, NH).

N^4-(2-Bromo-4-nitrophenyl)-N^2-benzoylbenzohydrazide hydrazone (8a). To a solution of **1a** (600 mg, 1.5 mmol) and benzoylhydrazine (245 mg, 1.8 mmol) in THF (10 ml) was added a solution of triethylamine (300 mg, 3.0 mmol) in THF (3 ml) dropwise with stirring at room temperature. After stirring for an additional 2 h, the resulting precipitates were removed by filtration and the filtrate was evaporated under reduced pressure giving an oily residue. To the residue was added a small amount of MeOH to lead to solidification. The solids were collected by filtration and recrystallized once from MeOH–THF to give **8a** (303 mg, 44% yield). An additional recrystallization afforded orange needles; mp 196—198 °C. Found: C, 53.16; H, 3.39%. Calcd for $C_{20}H_{16}O_3N_5Br$: C, 52.87; H, 3.55%. IR (KBr): 3440, 3280, 1653, 1588, 1508, 1488 cm^{-1}.

Cyclization of 8a to 7a. A solution of **8a** (100 mg, 0.22 mmol) in AcOH (3.0 ml) was refluxed for 30 min. After removal of the solvent under reduced pressure, the residual solid was washed with a small amount of MeOH and collected by filtration. One recrystallization from MeOH afforded white needles; mp 265—267 °C (60 mg, 62% yield). The mp and IR spectrum were identical to those of **7a**.

4-(2-Bromo-4-nitroanilino)-3-phenyl-1,2,4-triazole (7f). A solution of **2a** (200 mg, 0.57 mmol) in formic acid (1.0 ml) was refluxed for 2 h. After cooling, a small amount of MeOH was added to the reaction mixture to give crystalline precipitates, which were collected by filtration and recrystallized once from MeOH to give **7f** (116 mg, 56% yield). MS *m/e* (%): 361 (M^++2, 84), 359 (M^+, 86), 145 (36), 104 (100). NMR (DMSO-d_6): δ 6.28 (1H, d, J=9.0 Hz, 6-H on R^1), 7.4—7.95 (6H, m, aromatic H on R and the triazole ring), 8.08 (1H, dd, J=9.0 and 2.2 Hz, 5-H on R^1), 8.45 (1H, d, J=2.2 Hz, 3-H on R^1), 9.04 (1H, s, NH).

4-(2,4-Dinitroanilino)-3-methyl-1,2,4-triazole (7g). A solution of **2e** (300 mg, 1.2 mmol) in formic acid (3.0 ml) was refluxed for 1 h. Water was added to the reaction mixture and the solution was allowed to stand overnight. The resulting precipitates were collected by filtration to give **7a** (216 mg, 69% yield).

The authors wish to express their thanks to Dr. Masatoshi Hirayama and Mr. Mamoru Sekine for the NMR measurements and to the Sankyo Co., Ltd., for the mass spectral measurements.

Amidrazones and Related Compounds. V.[1] The Formation of Pyrazole, 1*H*-1,2,4-Triazepine, and 4*H*,11*H*-[1,5]Diazocino-[2,3-*e*: 6,7-*e'*]di[1*H*-1,2,4]triazepine Derivatives

Masahiko TAKAHASHI, Noriyuki SUGAWARA, and Kaoru YOSHIMURA

Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Hitachi, Ibaraki 316

(Received September 30, 1976)

Amidrazones $RC(NH_2)=NNH_2$ (**1a**, **b**) (R=2-pyridyl, phenyl) reacted with $EtOCH=CR^1R^2$ (**2a—d**) (R^1,R^2=CN, $CO_2C_2H_5$, $COCO_2C_2H_5$) to give $RC(NH_2)=NNHCH=CR^1R^2$ (**3a—g**). 3,4-Disubstituted pyrazoles (**4a**, **b**) were obtained on the heating of **3a**, **b**, **e**, and **f** (R=2-pyridyl, phenyl, R^1=CN, R^2=CN, $CO_2C_2H_5$) in toluene. However, the heating of **3c** (R=2-pyridyl, $R^1=R^2=CO_2C_2H_5$) gave a dimer, the 2,3,7,9,10-pentaazadodeca-1,4,8,11-tetraene derivative (**9**), instead of **4**. 5-Amino-6-ethoxycarbonyl-3-(2-pyridyl)-1*H*-1,2,4-triazepine (**10**) was obtained by the reaction of **3a** (R=2-pyridyl, R^1=CN, $R^2=CO_2C_2H_5$) with ethanolic hydrogen chloride. The treatment of **10** with alkaline gave 2,9-di-2-pyridyl-6,7,13,14-tetrahydro-4*H*,11*H*-[1,5]diazocino-[2,3-*e*: 6,7-*e'*]di[1*H*-1,2,4]triazepine-6,13-dione (**11**). Triazepine (**10**) reacted with hydrazines to give 5-hydrazino-1*H*-1,2,4-triazepine derivatives (**13a**, **b**).

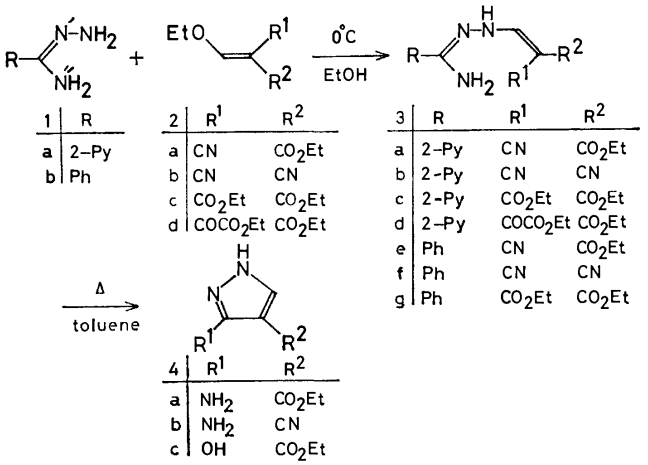
Amidrazones[2] show a strong nucleophilicity similar to hydrazine and are known as versatile reagents in the synthesis of some nitrogen heterocycles. However, the synthesis of monocyclic 1,2,4-triazepine derivatives by the use of amidrazone has not been reported. The fully or partially saturated monocyclic 1,2,4-triazepine derivatives have been synthesized by the reactions of thiosemicarbazides with malonyl dichloride,[3a,b] β-keto esters,[4,5] β-diketo compounds,[4] and 1,1,3,3-tetraethoxypropane.[6] On the other hand, the synthesis of fully unsaturated monocyclic 1,2,4-triazepine derivatives has been reported recently; 2*H*-1,2,4-triazepines were prepared by the cycloaddition reaction of 1,2,4,5-tetrazines with 1-azirines,[7a-d] and 4*H*-1,2,4-triazepines were formed photochemically from 3,4,7-triaza-2,4-norcaradienes.[8]

In the present paper we wish to report the results of the attempted synthesis of the 1*H*-1,2,4-triazepine derivative from amidrazones and ethoxymethylenic compounds.

Results and Discussion

When picolinamidrazone (**1a**) was treated with ethoxymethylenic compounds (**2a—d**) in EtOH at 0 °C, the products isolated were *N*-(2,2-disubstituted vinyl)-picolinamidrazones (**3a—d**). Similarly, the treatment of benzamidrazone (**1b**), which was generated *in situ* by the reaction of ethyl benzimidate with hydrazine hydrate, with **2a—c** gave **3e—g**. The physical properties and spectral data, shown in Table 1, are consistent with the assigned structure.

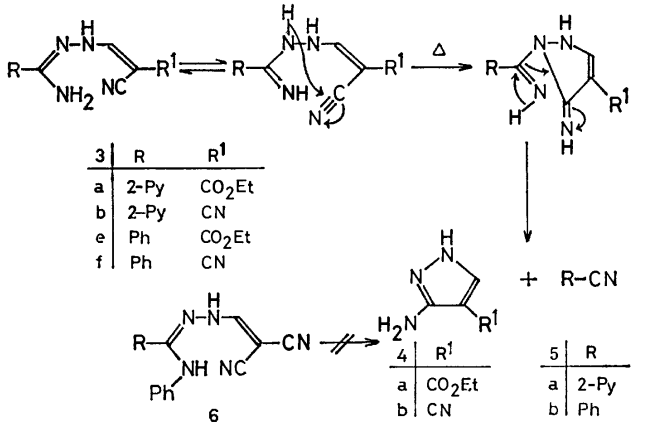
Next, the thermal and acid- or base-catalyzed cyclizations of **3** to 1,2,4-triazepine derivatives were attempted. When a toluene solution of **3a** was heated for 4 h, a product was obtained in an 87% yield as white needles. Its mp and IR spectrum were consistent with those of ethyl 3-amino-4-pyrazolecarboxylate (**4a**).[9] Similarly, the heating of a toluene solution of **3b** gave a white crystalline product (91% yield) which was identical with 3-amino-4-cyanopyrazole (**4b**).[10] In a similar manner, **4a** and **4b** were obtained from **3e** and **3f** respectively. It can be assumed that the formation of **4a** and **4b** has occurred by mean of the intramolecular nucleophilic attack of the N′ atom on the cyano group,



Scheme 1.

followed by the elimination of arylnitrile, as is shown in Scheme 2. In fact, when a toluene solution of *N*-(2,2-dicyanovinyl)-*N*″-phenylbenzamidrazone (**6**) was heated for 24 h, the pyrazole derivative was not obtained as expected, and the starting material was recovered.

However, on the treatment of **3c** in a similar manner, the pyrazole derivative was not obtained, rather yellow needles were obtained in a 45% yield. The IR spectrum showed the absorption band of the amide NH at 3440



Scheme 2.

Table 1. The physical properties and the spectral data of **3**

Compd	Yield (%)	Mp (°C) (Solvent)	Molecular formula	Found (Calcd) C%	Found (Calcd) H%	IR (KBr) cm^{-1}	NMR δ, ppm

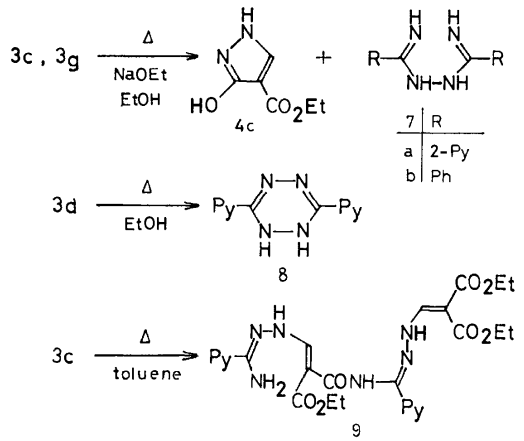
a) The NMR spectrum was measured in DMSO-d_6. b) The NMR spectrum was measured in $CDCl_3$.

cm^{-1} and those of the carbonyl groups at 1645—1695 cm^{-1}. The mass spectrum showed the parent peak at *m/e* 566. From the above data and the results of the elemental analysis, the product was confirmed to be a dimer, triethyl 1-amino-6-oxo-1,8-di-2-pyridyl-2,3,7,9,10-pentaazadodeca-1,4,8,11-tetraene-5,12,12-tricarboxylate (**9**). The treatment of **3c** in EtOH in the presence of sodium ethoxide gave **4c**[11] and 1,2-bis(2-pyridylcarbonimidoyl)hydrazine (**7a**).[12a,b] Similarly, **4c** was obtained from **3g** in the same manner, but the method failed to isolate the corresponding product (**7b**). On the heating of an ethanol solution of **3d**, an orange product was obtained and revealed to be 1,2-dihydro-3,6-di-2-pyridyl-1,2,4,5-tetrazine (**8**).[13a,b]

When **3a** was treated with an ethanolic hydrogen chloride, followed by neutrallization with sodium hydrogen carbonate, a product was obtained in a 57% yield as white needles. The IR spectrum indicated the presence of ester (1700 cm^{-1}) and amino (3320—3110 cm^{-1}) groups, but it did not show the absorption band of the cyano group at *ca.* 2200 cm^{-1}. The ester group was confirmed by the signals at δ 3.96 and δ 1.15 ppm due to the ethyl group. Considering the above data and the parent peak at *m/e* 259, the structure of the product can clearly be assigned to the desired compound, 5-amino-6-ethoxycarbonyl-3-(2-pyridyl)-1*H*-1,2,-4-triazepine (**10**). However, all attempts at the cyclization of **3b**—**g** to 1*H*-1,2,4-triazepine derivatives were unsuccessful. Then the reactivity of **10** was studied. When an aqueous sodium hydroxide solution of **10** was

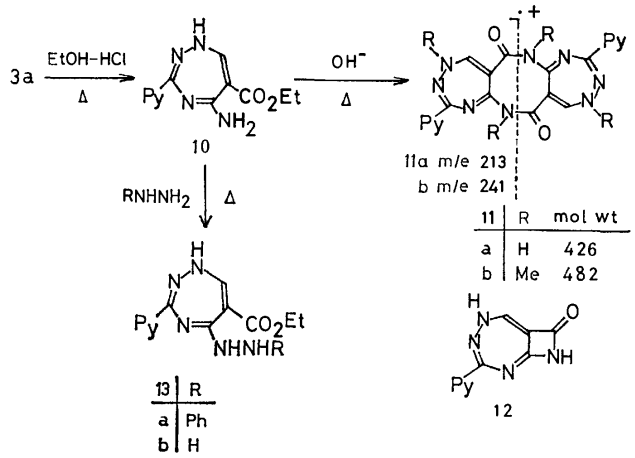


Scheme 3.

heated, a product was obtained in a 74% yield as white powder. According to the emperical formula, $C_{10}H_7N_5O$, and the mass spectral parent peak at *m/e* 213, the product seems to be [2,3-*e*][1*H*-1,2,4]triazepine (**12**). However, the carbonyl absorption observed at the comparably low frequency (1680 cm^{-1}) is in conflict with the strained β-lactam structure, **12**. Consequently, the only possible structure which satisfies both the analytical and mass spectral results is the dimeric and symmetric one, 2,9-di-2-pyridyl-6,7,13,14-tetrahydro-4*H*,11*H*-[1,5]diazocino[2,3-*e*: 6,7-*e'*]di[1*H*-1,2,4]triazepine-6,13-dione (**11a**), which belongs to a new ring system. A similar condensation, followed by a dimeriza-

tion reaction, that is the conversion of 4-amino-5-ethoxycarbonyl-pyrimidine to 5,6,11,12-tetrahydro[1,5]-diazocino[2,3-*d*: 6,7-*d'*]dipyrimidine-5,11-dione, has been reported by Bredreck *et al.*[14] Additional support for the structure of **11a** was provided by its methylation with methyl iodide. The IR spectrum of the product showed the absorption band of the carbonyl at 1705 cm^{-1} and none of the imino group in the NH region. The NMR spectrum showed the two singlet signals at δ 4.20 and δ 3.82 ppm due to two pairs of four methyl groups, although the mass spectrum showed the parent peak at *m/e* 241 corresponding to half the molecular weight. These data show the structure to be a tetramethyl derivative (**11a**).

The treatment of **10** with phenylhydrazine gave a substituted product, 6-ethoxycarbonyl-5-(2-phenylhydrazino)-3-(2-pyridyl)-1*H*-1,2,4-triazepine (**13a**), whose structure was clarified on the basis of the spectral and analytical measurements. Similarly, the treatment of **10** with hydrazine hydrate gave corresponding product (**13b**).



Scheme 4.

Experimental

All the melting points are uncorrected. The IR, UV, and NMR spectra were measured with a JASCO Model IRA-2 spectrometer, a Shimadzu Model MPS-501 spectrometer, and a Hitachi Model R-20 spectrometer respectively. A Shimadzu Model UM-3B apparatus was used for the elemental analysis.

Materials. The compounds **1a**,[15] **2a**,[16] **2b**,[16] and **2d**[17] were prepared by the reported methods. The **2c** was commercially available.

N-(2-Cyano-2-ethoxycarbonylvinyl)picolinamidrazone (3a). To a stirred solution of **2a** (1.01 g, 6.0 mmol) in EtOH (15 ml), was added **1a** (0.82 g, 6.0 mmol) at 0 °C. After the stirring had continued for 30 min, the resulting precipitates were filtered and dried to give **3a** (1.43 g, 92%). Recrystallization from MeOH afforded yellow plates; mp 126—129 °C. **3b—d** were prepared by the same procedure.

N-(2-Cyano-2-ethoxycarbonylvinyl)benzamidrazone (3e). Ethyl benzimidate hydrochloride[18] (1.91 g, 10.2 mmol) was added to an aq solution (10 ml) containing potassium hydroxide (10.2 mmol). The resulting oil was extracted twice with ethyl acetate (10 ml), and the organic phase was concentrated *in vacuo*. The oily residue was dissolved into EtOH (10 ml), and hydrazine hydrate (532 mg, 10.5 mmol) was stirred into this solution in portions at 0 °C. After the stirring had continued for 2 h, at 0 °C, **2a** (1.74 g, 10.3 mmol) was added to the EtOH solution with stirring at 0 °C. After the stirring had continued for 30 min, the precipitates were filtered and dried to give **3e** (1.63 g, 61% based on the hydrochloride). Recrystallization from EtOH afforded yellow needles; mp 129—131 °C. **3e** and **g** were prepared by the same procedure.

Ethyl 3-Amino-4-pyrazolecarboxylate (4a). A toluene solution (20 ml) of **3a** (520 mg, 2.0 mmol) was refluxed for 4 h. After cooling at 0 °C, the precipitates were filtered and dried to give **4a** (270 mg, 87%). Recrystallization from benzene afforded white needles; mp 100—101 °C. Its mp, TLC, and IR spectrum were identical with those of the authentic sample.[9] **4a** was also obtained from **3e** by the same procedure (84%).

3-Amino-4-cyanopyrazole (4b). A toluene solution (10 ml) of **3b** (420 mg, 2.0 mmol) was refluxed for 8 h. After cooling, the precipitates were filtered and dried to give **4b** (200 mg, 91%). Recrystallization from benzene–THF afforded white needles; mp 171—174 °C. Its mp TLC, and IR spectrum were identical with those of the authentic sample.[10] **4b** was also obtained from **3f** by the same procedure (71%).

N-(2,2-Dicyanovinyl)-N''-phenylbenzamidrazone (6). To a stirred solution of **2b** (122 mg, 1.0 mmol) in EtOH (5 ml) was added *N''*-phenylbenzamidrazone[19] (211 mg, 1.0 mmol) at room temperature. After 30 min, the resulting precipitates were filtered and dried to give **6** (159 mg, 55%). Recrystallization from EtOH afforded white needles; mp 223—226 °C. Found: C, 71.26; H, 4.47%. Calcd for $C_{17}H_{13}N_5$: C, 71.06; H, 4.56%. IR (KBr): 3360, 3250, 2200, 1640, 1618, 1550 cm^{-1}.

Ethyl 3-Hydroxy-4-pyrazolecarboxylate (4c) and 1,2-Bis(2-pyridylcarbonimidoyl)hydrazine (7a). To a solution of sodium ethoxide (3.0 mmol) in EtOH (10 ml) was added **3c** (569 mg, 1.9 mmol), after which the solution was refluxed for 2 h. The resulting sodium salts were filtered, dissolved in water (10 ml), and neutralized with dil hydrochloric acid. After cooling, white crystals were filtered out and dried to give **4c** (86 mg, 30%). Recrystallization from MeOH–H_2O afforded white needles; mp 182—183 °C. Its mp, TLC, and IR spectrum were identical with those of the authentic sample.[11] Then the filtrate was concentrated *in vacuo*, and a small amount of water was added to the residue. The resulting yellow crystals were filtered and dried to give **7a** (15 mg, 8%). Recrystallization from MeOH afforded yellow needles; mp 208—210 °C. Its mp, TLC, and IR spectrum were identical with those of the authentic sample.[12a,b] **4c** was also obtained from **3g** by the same procedure (30%).

1,2-Dihydro-3,6-di-2-pyridyl-1,2,4,5-tetrazine (8). An EtOH solution (10 ml) of **3d** (337 mg, 1.0 mmol) was refluxed for 24 h. After cooling, the precipitates were filtered and dried to give **8** (23 mg, 29%). Recrystallization from EtOH afforded orange needles; mp 198—202 °C. Its mp, TLC, and IR spectrum were identical with those of the authentic sample.[13a,b]

Triethyl 1-Amino-6-oxo-1,8-di-2-pyridyl-2,3,7,9,10-pentaaza-1,4,8,11-tetraene-5,12,12-tricarboxylate (9). A toluene solution (15 ml) of **3c** (461 mg, 1.5 mmol) was refluxed for 9 h. After cooling, the toluene was evaporated *in vacuo*, and a small amount of MeOH was added to the residue. Crystallization was induced by scratching the flask, and the resulting precipitates were filtered and dried to give **9** (194 mg, 45%). Recrystallization from MeOH–benzene afforded yellow needles; mp 196—198 °C. Found: C, 55.50; H, 5.35%. Calcd for $C_{26}H_{30}N_8O_7$: C, 55.12; H, 5.30%. IR (KBr):

3440, 3140, 2960, 1695, 1670, 1645, 1615, 1500 cm^{-1}. MS *m/e* (%): 566 (M^+, 0.4), 359 (3), 332 (5), 260 (7), 162 (10), 147 (40), 110 (20), 105 (100), 79 (26), 78 (30). UV (MeOH, nm (log ε)): 223 (4.50), 328 (sh, 4.70), 341 (4.80), 370 (sh, 4.40).

5-Amino-6-ethoxycarbonyl-3-(2-pyridyl)-1H-1,2,4-triazepine (10). A solution of **3a** (1.58 g, 6.1 mmol) in ethanolic hydrogen chloride (0.2 M, 46 ml) was refluxed for 1 h. The solvent was then evaporated *in vacuo*, and the water (10 ml) was added to the residue. The acidic solution was neutrallized with sodium hydrogen carbonate. After cooling, the resulting precipitates were filtered and dried to give **10** (901 mg, 57%). Recrystallization from MeOH–DMF afforded white needles; mp 200 °C (dec). Found: C, 55.63; H, 5.12%. Calcd for $C_{12}H_{13}N_5O_2$: C, 55.59; H, 5.05%. IR (KBr): 3320, 3250, 3110, 1700 cm^{-1}. NMR of **10**·HCl (D_2O): δ 7.97 (s, 1H, =CH–), 7.45—8.38 (m, 4H, aromatic H), 3.96 (q, J= 6.8 Hz, 2H, $-CH_2-$), 1.15 (t, J=6.8 Hz, 3H, $-CH_3$). MS *m/e* (%): 259 (M^+, 69), 214 (14), 186 (100), 155 (95), 109 (86), 105 (53), 78 (44). UV (MeOH, nm, (log ε)): 221 (4.29), 278 (3.96), 300 (3.98).

2,9-Di-2-pyridyl-6,7,13,14-tetrahydro-4H,11H-[1,5]diazocino[2,3-e:6,7-e']di[1H-1,2,4]triazepine-6,13-dione (11a). A solution of **10** (266 mg, 1.0 mmol) in aq NaOH (0.2 M, 10 ml) was refluxed for 1 h. After cooling, the solution was neutrallized with dil hydrochloric acid, and the resulting precipitates were filtered and dried to give **11a** (162 mg, 74%). Recrystallization from DMF–MeOH afforded white powder; mp>300 °C. Found: C, 56.17; H, 3.43%. Calcd for $C_{20}H_{14}N_{10}O_2$: C, 56.33; H, 3.31%. IR (KBr): 3200, 1680, 1550 cm^{-1}. NMR (CF_3COOH): δ 8.20—9.20 (m, 10H, aromatic H and =CH–). MS *m/e* (%): 213 (93), 157 (3), 135 (9), 109 (100), 105 (20), 89 (14), 88 (24), 78 (5). UV (MeOH, nm (log ε)): 228 (4.61), 301 (4.43).

2,9-Di-2-pyridyl-4,7,11,14-tetramethyl-6,7,13,14-tetrahydro-4H,11H-[1,5]diazocino[2,3-e:6,7-e']di[1H-1,2,4]triazepine-6,13-dione (11b). To a suspension of NaH (41 mg, about 50% in oil, 0.85 mmol) in *N,N*-dimethylacetamide (5 ml) added **11a** (113 mg, 0.27 mmol) in portions. After the evolution of hydrogen had ceased, methyl iodide (0.5 ml) was added, and the mixture was stirred at room temperature for 1 day. The reaction mixture was poured into water (20 ml), the resulting precipitates were filtered off, and then the filtrate was extracted three times with ethyl acetate (20 ml). The organic phase was evaporated *in vacuo*, and a small amount of ether was added to the residue. The resulting precipitates were filtered and dried to give **11b** (60 mg, 46%). Recrystallization from MeOH afforded white needles; mp 266—227 °C. Found: C, 59.71; H, 4.62%. Calcd for $C_{24}H_{22}N_{10}O_2$: C, 59.74; H, 4.60%. IR (KBr): 3100, 2960, 1705, 1560, 1550 cm^{-1}. NMR (CF_3COOH): δ 8.25—9.30 (m, 10H, aromatic H and =CH–), 4.20 (s, 6H, $-CH_3$), 3.82 (s, 6H, $-CH_3$). MS *m/e* (%): 241 (100), 240 (72), 213 (6), 212 (13), 171 (7), 105 (4), 82 (16), 79 (24). UV (MeOH, nm (log ε)): 213 (4.66), 261 (sh, 4.18), 282 (4.23).

6-Ethoxycarbonyl-5-(2-phenylhydrazino)-3-(2-pyridyl)-1H-1,2,4-triazepine (13a). A mixture of **10** (132 mg, 0.5 mmol) and phenylhydrazine (117 mg, 1.1 mmol) in EtOH (10 ml) was refluxed. After 3 h, additional phenylhydrazine (113 mg, 1.0 mmol) was added to the reactoin mixture and it was refluxed for 4 h again. After cooling, the precipitates were filtered off and the filtrate was concentated *in vacuo*. A small amount of ether was added to the residue, and crystallization was induced by scratching the flask. The resulting precipitates were filtered and dried to give **13a** (77 mg, 44%). Recrystallization from MeOH–H_2O afforded yellow plates; mp 181—183° °C. Found: C, 61.69; H, 5.11%. Calcd for $C_{18}H_{18}N_6O_2$: C, 61.70; H, 5.18%. IR (KBr): 3320, 3240, 3020, 2980, 1670, 1570, 1550 cm^{-1}. NMR (DMSO-d_6): δ 9.72 (br, 1H, =NH), 8.12 (s, 1H, =CH–), 7.60—8.58 (m, 4H, aromatic H), 7.03—7.55 (m, 5H, aromatic H), 6.75 (br, 1H, =NH), 4.34 (q, J=7.0 Hz, 2H, $-CH_2-$), 1.40 (t, J= 7.0 Hz, 3H, $-CH_3$).

6-Ethoxycarbonyl-5-hydrazino-3-(2-pyridyl)-1H-1,2,4-triazepine (13b). A mixture of **10** (529 mg, 2.0 mmol) and 100% hydrazine hydrate (213 mg, 4.0 mmol) was refluxed, with stirring, for 1 h, After cooling, the resulting precipitates were filtered and dried to give **13b** (161 mg, 29%). Recrystallization from benzene–THF afforded pale yellow particles; mp 163—166 °C. Found: C, 52.50; H, 5.18%. Calcd for $C_{12}H_{14}N_6O_2$: C, 52.54; H, 5.15%. IR (KBr): 3380, 3120, 1700, 1580, 1535 cm^{-1}.

The authors wish to express their thanks to Professor Masaki Ohta for his encouragement, to Dr. Masatoshi Hirayama and Mr. Mamoru Sekine for the NMR measurements, and to Sankyo Co., Ltd., for the mass measurements.

Synthetic Proof for the Structures of Maturinone and Cacalol

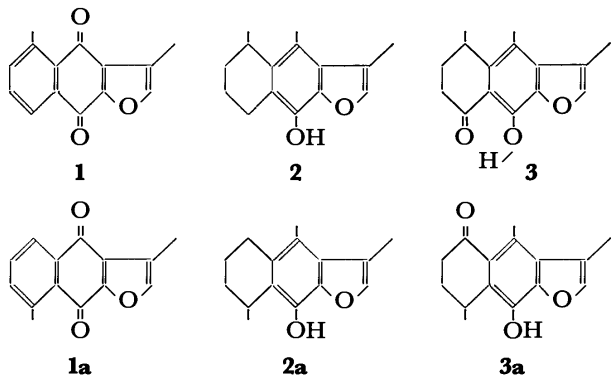
Yoshinobu INOUYE, Yuji UCHIDA, and Hiroshi KAKISAWA
Department of Chemistry, Tokyo Kyoiku University, Bunkyo-ku, Tokyo 112
(Received September 17, 1976)

By unambiguous syntheses, the structures of maturinone and cacalol were shown to be 3,5-dimethylnaphtho-[2,3-*b*]furan-4,9-dione (**1**) and 5,6,7,8-tetrahydro-3,4,5-trimethylnaphtho[2,3-*b*]furan-9-ol (**2**), respectively. 3,8-Dimethylnaphtho[2,3-*b*]furan-4,9-dione (**1a**), an isomer of maturione, was also synthesized.

In 1964, Romo and Joseph-Nathan[1] isolated several components, now known as a rearranged eremophilanoid sesquiterpene, from the root of *Cacalia decomposita* A. Gray, a compositae widely distributed in the northern part of Mexico. Maturinone (**1**), cacalol (**2**), and cacalone are the major components. They were initially erroneously assigned as **1a**, **2a**, and **3a**, respectively, using their chemical and spectroscopic data.[2,3] The relations among these three compounds were shown as follows:

maturinone $\xleftarrow[\text{ii) } CrO_3]{\text{i) DDQ}}$ cacalol $\xleftarrow{LiAlH_4}$ cacalone

The alternative possibility of **1**, **2**, and **3** was abandoned chiefly because the characteristic absorption for the 8-hydroxy-1-tetralone moiety (see **3**) in the IR and NMR spectra of cacalone[1] was not recognized.



1 **2** **3**

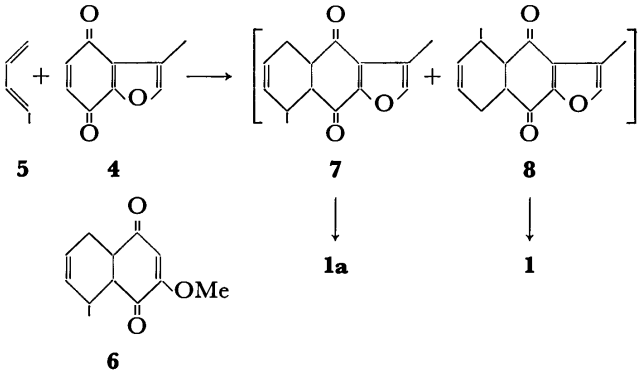
1a **2a** **3a**

In 1969, however, we synthesized both quinones, **1** and **1a**, and established the identity of **1** with maturinone.[4] At the same time, two other groups[5,6] reached the same conclusion by independent syntheses of the quinone **1**. These results required the structures of cacalol and cacalone to be revised as **2** and **3**, respectively, although the latter was pointed out[5] to be inconsistent with the reported spectroscopic data for cacalone. Joseph-Nathan referred to the structure of cacalone and explained the anomalous data by considering the presence of an inherently dissymmetric chromophore (ORD study).[7]

Since then, several Japanese workers[8-10] have reported the isolation of new compounds which belong to this class of sesquiterpene, from various *Cacalia* species. Although we, in collaboration with Romo, reported[4] the relation of cacalol with the known 6-epidecompostin derivative,[11] a recent synthesis of **2**[12] has finally established the structure of cacalol.

The present paper deals with the details of our synthetic works on maturinone (**1**) and cacalol (**2**).

Synthesis of 3,8-Dimethylnaphtho[2,3-b]furan-4,9-dione (1a). In the course of our study on the Diels-Alder reaction of unsymmetrically substituted benzoquinones and dienes, both methoxybenzoquinone and 3-methylbenzofuran-4,7-dione (**4**) were found to exhibit high specificity to 6,6-dimethyl-1-vinylcyclohexene;[13] the orientation phenomena of both quinones were the same, with respect to the oxygen moiety, and were rationalized by considering the radical stabilities of the formal "biradical intermediates."[4,13] Based on the evidence that 1,3-pentadiene (**5**) reacted with methoxybenzoquinone to give mainly **6**,[14] we anticipated that the chief product in the Diels-Alder reaction of **4** and **5** would be **7**; the skeleton initially assumed was for maturinone.



5 **4** **7** **8** **1a** **1** **6**

The reaction between **4** and **5** proceeded smoothly at room temperature and the *mixture* was oxidized by air in the presence of potassium hydroxide[15] to give the quinones **1a** and **1** (**1a**/**1**=7: 1) in 77% yield. Repeated recrystallization afforded the pure **1a**, mp 189—190 °C; its spectroscopic properties were very similar to those of maturinone, but distinct differences in the IR spectra were observed in the region of 1200—900 cm^{-1}.

Synthesis of 3,5-Dimethylnaphtho[2,3-b]furan-4,9-dione (1, Maturinone). Treatment[16] of 2-acetoxy-5-methyl-1,4-naphthoquinone (**10**), prepared from **9**[17] by acetylation with acetic anhydride and zinc chloride, with 1-morpholino-1-propene (**11**)[18] in the presence of a small amount of ethanol gave a quinone **1**, mp 164—166 °C, in 12% yield in a one-step reaction. The quinone **1** and maturinone were identical in every aspect.

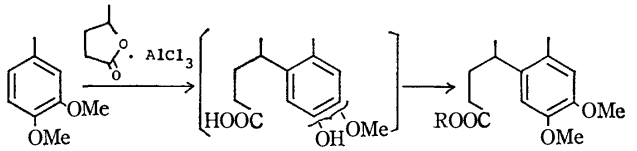
10 R=Ac
11

Synthesis of 5,6,7,8-Tetrahydro-3,4,5-trimethylnaphtho[2,3-b]furan-9-ol (2, Cacalol). The Friedel-Crafts reaction of 3,4-dimethoxytoluene (**12**) with γ-valerolactone in the presence of aluminium chloride gave a mixture **13** of two carboxylic acids, which without separation into each component was successively treated with diazomethane and dimethyl sulfate to afford a single ester **14** in 84% yield.



12 **13** **14** R=Me
15 R=H

The position of the new alkyl group was decided from the following facts. The two singlets which appear at 6.50 and 6.57 ppm in the NMR spectrum of **14** require the two hydrogens on the aromatic nucleus to be positioned para to each other and the pseudocontact shift with Eu-(fod)$_3$ clearly showed that the H_B proton present in **12** disappeared in **14** (Fig. 1). Furthermore, the corresponding acid **15** was converted into the 8-hydroxy-1-tetralone derivative **16**, as shown below.

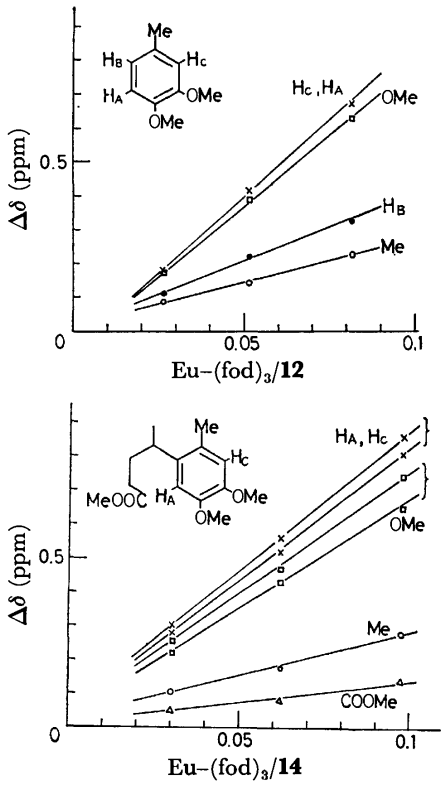


Fig. 1. Pseudocontact shifts of **12** (upper) and **14** (bottom) with Eu-(fod)$_3$ in CCl_4.

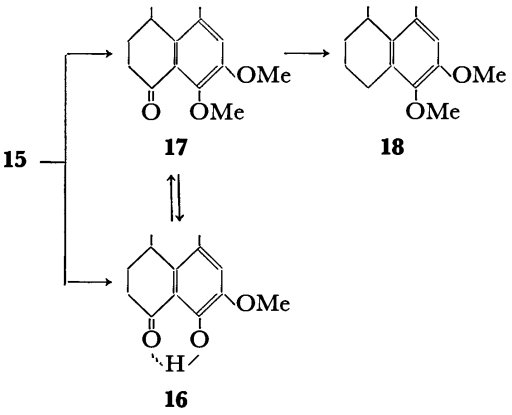
The acid **15** was cyclized with polyphosphoric acid at 160 °C to give 4,5-dimethyl-8-hydroxy-7-methoxy-1-tetralone (**16**); the carbonyl absorption at 1630 cm^{-1} in the IR spectrum and a singlet at 12.94 ppm in the NMR spectrum showed that the structure **16** has an 8-hydroxy-1-tetralone moiety. When diphosphorus pentoxide-methanesulfonic acid[19] was used, 7,8-dimethoxy-4,5-dimethyl-1-tetralone (**17**), $\nu_{C=O}$ at 1673 cm^{-1}, was obtained in 87% yield. Both tetralone **16** and **17** were convertible with each other. Catalytic hydrogenolysis of **17** over Pd-C in the presence of perchloric acid resulted in the removal of the carbonyl functional group to give 7,8-dimethoxy-4,5-dimethyltetraline (**18**).



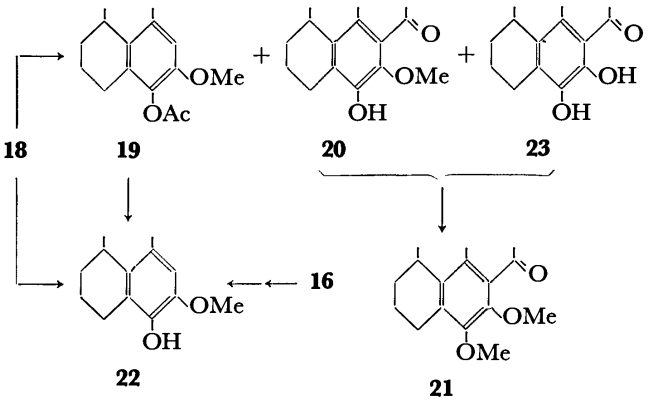
The next step is the introduction of the acetyl group at the remaining position on the aromatic nucleus. Friedel-Crafts acylations using two catalysts were investigated and the results are shown in Table 1.

Table 1. Friedel-Crafts acylation of **18**

Molar ratio **18**: Catalyst: AcCl			Temp (°C)	Time (h)	Yield (isolated %)		
					18	**19**	**21**
	$AlCl_3$						
1	2	6	70—75	4		58	22
	$ZnCl_2$						
1	5	10	0—2	41	20	16[b]	55[a]
1	5	10	30	4	15	22[b]	51
1	5	10	70	1/4	11	43[b]	30

a) After methylation with dimethyl sulfate. b) After hydrolysis to **22**.

In the case of aluminium chloride, a complex mixture resulted, and by chromatographic separation the acetate **19** was obtained as the main product, in 58% yield. The residue contained a mixture of acetophenone derivatives **20** and **23**, and after methylation with dimethyl sulfate, the dimethoxyacetophenone **21** was isolated in 22% yield. No aromatic proton was observed in the NMR spectrum of **21**, but the new acetyl protons appeared at 2.07 ppm.



When the reaction was carried out without acetyl

chloride, only a monodemethylated compound **22** was obtained easily. **22** was also derived from the acetate **19** by lithium aluminium hydride reduction.

The position of the hydroxyl group in **22** was proved by deriving it from **16** with sodium borohydride reduction, followed by hydrogenolysis over Pd-C. The facile hydrolysis of the 8-methoxyl group in **18** would be explainable as due to a steric factor.[20]

On the other hand, the yield of **21** increased up to 55% when the reaction was done with zinc chloride, a fairly mild catalyst, at 0—2 °C. From Table 1, two points are worthy of notice in the case of zinc chloride. At low temperatures, introduction of the acetyl group on the aromatic nucleus was preferential but, at elevated temperatures, the hydrolysis increased drastically. Secondly, the reaction with zinc chloride differed from that with aluminium chloride in recovering some of the starting material in every case. These indicate that a complex reaction, including an equilibrium[21] between **18** and **21**, is involved in these conditions, but no further studies on these points were made in the present work.

The final step is the conversion of **21** into a furan derivative. As the ajacent methoxyl to the acetyl group was less reactive than the other to aluminium chloride or boron tribromide (see experimental), both methoxyl groups were cleaved with boron tribromide at room temperature to afford a dihydroxy compound **23**, which was subsequently converted into bis(methoxycarbonylmethyl) ether **24**, $\nu_{C=O}$ at 1760, 1740, and 1695 cm^{-1}. The corresponding carboxylic acid **25** was converted under the known process[22] into 5,6,7,8-tetrahydro-3,4,5-trimethylnaphtho[2,3-*b*]furan-9-yl carboxymethyl ether **26** in good yield. The structure assignment was based on the presence of two signals coupled to each other at 2.38 (br. s, 3H) and 7.27 ppm (m, 1H) in the NMR spectrum, which correspond to the adjacent β-methyl and α-proton groups on a furan nucleus.

30 R=Ac

After reduction of **26** with lithium aluminium hydride, removal of the hydroxyethyl group in **27** was achieved[23] by successive treatment with tosyl chloride in pyridine, sodium bromide in dimethyl sulfoxide, and butyllithium in ether to get 5,6,7,8-tetrahydro-3,4,5-trimethylnaphtho[2,3-*b*]furan-9-ol (**2**). The alcohol **2**, however, decomposed[24] gradually on storage and failed to crystallize even after purification by chromatography.

When the crude **2** was acetylated, the acetate **30** was obtained as a crystal, mp 119—120 °C, in 71% yield from **27**. The IR and NMR spectra of both **30** and cacalol acetate in carbon tetrachloride were identical in all respects.

On the Structure of Cacalone. Confirmation of the structures of maturinone (**1**) and cacalol (**2**) by unambiguous syntheses requires a reexamination of the structure of cacalone. The structure **3**[4] was only based on the report that cacalone was converted into cacalol (**2**) by lithium aluminium hydride.[1] Its spectroscopic properties, however, are inconsistent with the structure **3**, although Joseph-Nathan explained these anomalies by means of the presence of an inherently dissymmetric chromophore.[7]

The tetralone **16** prepared in the present work is one of the model compounds for the structure **3**; the lack of the furan ring would cause little effect on the stereochemistry of cacalone. As shown before, the compound **16** showed normal spectroscopic properties for an 8-hydroxy-1-tetralone moiety: a strong chelation between the carbonyl and hydroxyl groups was observed in both IR and NMR spectra. Moreover, when **16** was subjected to react under the Romo's condition (lithium aluminium hydride reduction and subsequent acetylation),[1] no detectable amount of **19** was recognized, but two diacetates **31** and **32** were isolated in 88% yield (the ratio of **31**/**32** was *ca.* 2: 1; see experimental).

From these results, we can safely concluded that cacalone is neither **3** nor **3a** and abandon the former

Table 2. Pseudocontact shift on the mixture of **31** and **32**

		δ (ppm) in CCl_4		
		31+**32**	Adn of 0.1 mol eq of Eu-(fod)$_3$	$\Delta\delta$

proposal[4] for its structure. Recently, the *p*-quinol structure **33** was presented for the structure of cacalone.

Experimental

All melting points were uncorrected. IR and UV spectra were recorded on a Hitachi 215 grating spectrophotometer and a Hitachi EPS-3T spectrophotometer, respectively, and NMR spectra were obtained on a Hitachi H-60 spectrophotometer using TMS as an internal standard. Microanalyses were carried out at the Institute for Physical and Chemical Research.

*Diels-Alder Reaction of 3-Methylbenzofuran-4,7-dione (**4**) and 1,3-Pentadiene (**5**).* A mixture of 260 mg of 3-methylbenzofuran-4,7-dione (**4**)[13] and 350 mg of 1,3-pentadiene (**5**) in 4 ml of ethanol was left overnight. After evaporating the ethanol, the residue was oxidized in ethanol containing potassium hydroxide by bubbling air through the solution.[15] The ether extract, when evaporated, gave yellow solids (314 mg), form which 207 mg of 3,8-dimethylnaphtho[2,3-*b*]-furan-4,9-dione (**1a**) was obtained by recrystallization from chloroform–ethanol.

1a: mp 189—190 °C; IR (KBr): 1670, 1190, 1170, 1100, 1040, 995, and 950 cm^{-1}; UV (EtOH): 251 (log ε=4.34), 267 sh (3.91), 294 (3.56), and 357 nm (3.55); NMR ($CDCl_3$): 2.33 (d, 3H, J=1.5 Hz), 2.79 (s, 3H), 7.4—7.7 (m, 3H), 8.03 ppm (dd, 1H, J=3.5 and 6 Hz); NMR (C_6H_6): 2.03 (br. s, 3H) and 2.68 (s, 3H). Found: C, 74.61; H, 4.40%. Calcd for $C_{14}H_{10}O_3$: C, 74.33; H, 4.46%.

From the mother liquor, 73 mg more (total yield: 77%) of dimethylnaphtho[2,3-*b*]furan-4,9-diones, **1a** and **1**, were obtained; IR (KBr): 1670, 1190, 1170, 1150, 1100, 1040, 1030, 995, 965, and 950 cm^{-1}; NMR (C_6H_6): 2.03 (br. s, 3H), 2.63 (s, 1.5 H, **1**), and 2.68 ppm (s, 1.5 H, **1a**).

*2-Acetoxy-5-methyl-1,4-naphthoquinone (**10**).* A solution of 770 mg of 2-hydroxy-5-methyl-1,4-naphthoquinone (**9**),[17] mp 152—154 °C (dec), and a small amount of zinc chloride in 5 ml of acetic anhydride was left for 30 min at room temperature. The cloudy mixture was heated for several min until the solution became clear and then cooled to room temperature. After pouring the solution into ice–water, the precipitates which formed were collected on a filter paper to give 899 mg (96%) of 2-acetoxy-5-methyl-1,4-naphthoquinone (**10**). Recrystallization from ethanol afforded a pure **10**: mp 119—120 °C. Found: C, 68.09; H, 4.40%. Calcd for $C_{13}H_{10}O_4$: C, 67.82; H, 4.38%.

*3,5-Dimethylnaphtho[2,3-b]furan-4,9-dione (**1**).* A mixture of 100 mg of **10**, 72 mg of 1-morpholino-1-propene (**11**),[18] and 0.05 ml of ethanol was left overnight at room temperature.[16] The whole was chromatographed directly on silicic acid (10 g) and 12 mg (12%) of 3,5-dimethylnaphtho[2,3-*b*]-furan-4,9-dione (**1**) was obtained from the chloroform eluates. Recrystallization from ethanol gave a pure **1**: mp 164—166 °C; IR (KBr): 1670, 1170, 1150, 1110, 1090, 1030, 995, and 965 cm^{-1}; UV (EtOH): 251 (log ε=4.40), 267 sh (4.00), 294 (3.67), and 352 nm (3.67); NMR ($CDCl_3$): 2.35 (d, 3H, J=1.5 Hz), 2.77 (s, 3H), 7.4—7.7 (m, 3H), and 8.10 ppm (dd, 1H, J=3 and 5.5 Hz); NMR (C_6H_6): 2.01 (d, 3H, J=1.5 Hz) and 2.63 ppm (s, 3H). Found: C, 74.22; H, 4.35%. Calcd for $C_{14}H_{10}O_3$: C, 74.33; H, 4.46%.

The quinone **1** was identical with maturinone in every aspect and melted at 163—165 °C when mixed with maturinone.

From later fractions, 45 mg of orange crystals, mp 178—180 °C (ethanol), were obtained but no characterization was tried.

*Friedel-Crafts Reaction of 3,4-Dimethoxytoluene (**12**) with γ-Valerolactone.* To a cold solution of 15 g of 3,4-dimethoxytoluene (**12**) and 4.92 g of γ-valerolactone in 15 ml of tetrachloroethane (TCE), there was added in portions 26.4 g of freshly powdered aluminium chloride. After the addition was complete, the mixture was stirred mechanically at 70 °C for 4 h; 5 ml more of TCE was added and stirring was continued for another 4 h. After standing overnight, the whole was poured into 75 ml of concd hydrochloric acid and 200 g of ice, and was extracted with ether (140 ml×3). A mixture **13** of acidic materials was treated with an excess of ethereal diazomethane followed by dimethyl sulfate to obtain a red oil. Fractional distillation gave 11.03 g (84%) of the ester **14**: bp 157—159 °C/2 Torr; IR (CCl_4): 1730, 1250, 1200, and 1155 cm^{-1}; NMR (CCl_4): 1.17 (d, 3H, J=7 Hz), 2.19 (s, 3H), 3.53 (s, 3H), 3.74 (s with a shoulder at 3.72, 6H), 6.50 (s, 1H), and 6.57 ppm (s, 1H). Found: C, 67.73; H, 8.39%. Calcd for $C_{15}H_{22}O_4$: C, 67.64; H, 8.33%.

*Cyclization of the Acid **15** with Polyphosphoric Acid.* The ester **14** was hydrolyzed under refluxing in 1 M sodium hydroxide–methanol to give an acid, **15**.

The acid **15** (824 mg) was heated with polyphosphoric acid (prepared from 4 g of diphosphorus pentaoxide and 3.3 ml of phosphoric acid) at 160 °C for 20 min and the mixture was poured into ice–water. Products were taken in ether and the ether layer was washed with water and dried over Na_2SO_4. After removal of the ether, the residual oil was purified through a silica gel column and distilled to give 203 mg (28%) of a yellow 4,5-dimethyl-8-hydroxy-7-methoxy-1-tetralone (**16**): bp 134—136 °C/0.15 Torr. When left in a refrigerator, **16** crystallized and melted at 62—63 °C (pentane); IR ($CHCl_3$): 3540 w, 3320—2600 br, 1630, 1345, and 1265 cm^{-1}; NMR ($CDCl_3$): 1.26 (d, 3H, J=7 Hz), 2.29 (s, 3H), 3.86 (s, 3H), 6.87 (s, 1H), and 12.94 ppm (s, 1H). Found: C, 70.90; H, 7.33%. Calcd for $C_{13}H_{16}O_3$: C, 70.89; H, 7.32%.

*Cyclization of the Acid **15** with Diphosphorus Pentaoxide–Methanesulfonic Acid.* The acid **15** (1.5 g) was heated at 50—55 °C for 6 h with 25 g of diphosphorus pentaoxide–methanesulfonic acid (1 : 10).[19] After cooling, the mixture was poured into ice–water and extracted with ether. The ether layer was washed with water, dil alkaline solution, water, and saline, and dried over Na_2SO_4. Evaporating the solvent gave 2.0 g (87%) of 7,8-dimethoxy-4,5-dimethyl-1-tetralone (**17**): mp 100—103 °C (methanol); IR (KBr): 1673 and 1585 cm^{-1}; NMR ($CDCl_3$): 1.21 (d, 3H, J=7 Hz), 2.33 (s, 3H), 3.85 (s, 3H), and 6.89 ppm (s, 1H). Found: C, 71.62; H, 7.81%. Calcd for $C_{14}H_{18}O_3$: C, 71.77; H, 7.74%.

*Methylation of **16**.* A solution of 60 mg of **16** in 2 ml of acetone was refluxed for 5 h with 480 mg of anhydrous potassium carbonate and 240 mg of dimethyl sulfate. The mixture was poured into water and was extracted with ether. The ether layer was washed with dil sodium hydroxide solution, water, and saline, and was dried over Na_2SO_4. Evaporating off the ether and purifying through a silica gel column gave 47 mg (74%) of **17**.

*Action of Aluminium Chloride on **17**.* To a solution of 500 mg of **17** in 5 ml of dry benzene, 570 mg of aluminium chloride was added at 0 °C and the mixture was stirred for for 3 h at room temperature. The whole was poured into ice–water, 4 ml of 6 M hydrochloric acid was added, and products were taken in ether. The ethereal extract was concentrated, purified through a silica gel column, and recrystallized from pentane to give 355 mg (76%) of **16**.

*7,8-Dimethoxy-4,5-dimethyltetralin (**18**).* The tetralone **17** (2.00 g) in 40 ml of acetic acid was hydrogenated over 280 mg of 10% Pd–C in the presence of 0.3 ml of 60% perchloric acid. After 8 h (468 ml of hydrogen consumed), 1 g of anhydrous potassium acetate was added and the catalyst

was removed by filtration. The filtrate was concentrated *in vacuo*, and the residue was dissolved in ether, which was washed with water, dil sodium hydroxide, water, and saline, and dried over Na_2SO_4. Evaporating off the solvent and fractional distillation gave 1.65 g (87%) of **18**; bp 145—146 °C/6 Torr; IR ($CHCl_3$): 1590, 1310, and 1120 cm^{-1}; NMR ($CDCl_3$): 1.11 (d, 3H, J=7 Hz), 2.20 (s, 3H), 3.66 (s, 3H), 3.73 (s, 3H), and 6.42 ppm (s, 1H). Found: C, 76.40; H, 9.14%. Calcd for $C_{14}H_{20}O_2$: C, 76.32; H, 9.15%.

Friedel-Crafts Acylation of ***18****.* *A) With Aluminium Chloride*: To a cooled (below −5 °C) solution of 962 mg of **18** and 2.06 g (6 eq) of acetyl chloride in 7 ml of TCE, there was added 1.16 g (2 eq) of aluminium chloride in portions, the mixture was stirred for one hour at room temperature, followed by heating at 70—75 °C for 4 h. The cooled mixture was poured into 200 ml of 6 M hydrochloric acid and 100 g of ice, and products were taken in ether. The ether layer was extracted with 1M sodium hydroxide to obtain acidic materials (mainly of **20** and **23**) and the neutral residue was chromatographed on silica acid. From the benzene eluates, 631 mg (58%) of **19** was obtained. Recrystallization from methanol gave a pure **19**: mp 68—69 °C; IR ($CHCl_3$): 1750, 1600, 1305, and 1115 cm^{-1}; NMR (CCl_4): 1.15 (d, 3H, J=7 Hz), 2.22 (s, 3H), 2.28 (s, 3H), 3.73 (s, 3H), and 6.53 ppm (s, 1H). Found: C, 72.56; H, 8.08%. Calcd for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12%.

The acidic materials were refluxed in 30 ml of acetone with 0.5 ml of dimethyl sulfate in the presence of anhydrous potassium carbonate for 3 h. The mixture was poured into dil ammonia and a product was extracted with ether to give an oil. The oil was chromatographed on alumina (10 g) and 237 mg (22%) of **21** was collected from pentane to 10% benzene–pentane fractions: bp 100—115 °C (bath temp)/2 Torr; IR (CCl_4): 1700, 1320, and 1055 cm^{-1}; NMR (CCl_4): 1.15 (d, 3H, J=7 Hz), 2.07 (s, 3H), 2.38 (s, 3H), 3.75 (s, 3H), and 3.78 ppm (s, 3H). Found: C, 73.00; H, 8.13%. Calcd for $C_{16}H_{22}O_3$: C, 73.25; H, 8.45%.

When the acidic materials were directly subjected to chromatography (silicic acid, benzene–ethyl acetate (5: 1)), a monohydroxy compound **20** was obtained in 12% yield: mp 153—154 °C (ether–pentane); IR ($CHCl_3$): 3520, 1690, and 1620 cm^{-1}; NMR (CCl_4): 1.13 (d, 3H, J=7 Hz), 2.24 (s, 3H), 2.50 (s, 3H), 3.74 (s, 3H), and 8.24 ppm (s, 1H, exchangeable with D_2O). Found: C, 72.10; H, 8.08%. Calcd for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12%.

B) With Zinc Chloride. To a cold solution of 220 mg (1 mmol) of **18** and 0.7 ml (10 mmol) of acetyl chloride in 2 ml of TCE, there was added 680 mg (5 mmol) of zinc chloride and the mixture was stirred at 0—2 °C for 41 h. The whole was treated with 4 ml of 6 M hydrochloric acid and was extracted with ether. The ether layer was washed with water, 1 M sodium hydroxide, water, and saline, and was dried over Na_2SO_4. Evaporating the solvent gave an oil, which was chromatographed on silicic acid (5 g). From 20% benzene–hexane eluates, 44 mg (20%) of **18** was recovered; from benzene to chloroform eluates, 193 mg of a mixture of **19** and **21** was obtained. The mixture was refluxed in 2 ml of methanol and 2 ml of 1 M sodium hydroxide for 30 min; 32 mg (16%) of **22** and 141 mg (54%) of **21** were separated from each other by a column chromatography on silicic acid (20% benzene–hexane).

By the same procedure, except for the temperature and time, several reaction were carried out; the results are shown in Table 1. In all cases, the optimal condition was not pursued.

*4,5-Dimethyl-8-hydroxy-7-methoxytetralin (****22****).* A) *From the Tetralone* ***16****.* To a solution of 86 mg of **16** in 2 ml of methanol, sodium borohydride was added until the yellow color disappeared. Dil hydrochloric acid was added, the solvent was evaporated, and the ether extract gave a colorless oil. The oil was hydrogenated under the same condition as **17** (9.5 ml of hydrogen consumed). By a chromatographic separation (silicic acid, benzene), 27 mg (33%) of **22** was obtained as a crystalline form. Recrystallization from pentane afforded a pure **22**: mp 46—48 °C; IR (CCl_4): 3540, 1610, 1480, 1295, and 1120 cm^{-1}; NMR (CCl_4): 1.14 (d, 3H, J=7 Hz), 2.22 (s, 3H), 3.80 (s, 3H), 5.32 (s, 1H, exchangeable with D_2O), and 6.42 ppm (s, 1H). Found: C, 75.58; H, 8.72%. Calcd for $C_{13}H_{18}O_2$: C, 75.69; H, 8.80%.

B) From the Acetate ***19****:* The acetate **19** was reduced with lithium aluminium hydride under refluxing in dry ether to give **22** quantitatively.

C) From the Tetralin ***18****:* A mixture of 104 mg of **18** and 136 mg (2 eq) of aluminium chloride in 1 ml of TCE was heated at 66 °C for 2 h. About half of **18** was found to have been converted into **22** by VPC analysis (1.5% SE-30, 2.9 m, 170 °C).

Demethylation of ***21*** *and Preparation of the Bis(methoxycarbonylmethyl) Ether* ***24****.* To a solution of 230 mg of **21** in 10 ml of dichloromethane, *ca.* 800 mg of boron tribromide in 2 ml of dichloromethane was dropwise added at −70 °C and the mixture was stirred at room temperature for 2 h. The whole was poured into ether then the ether solution was washed with water and dried over Na_2SO_4. Evaporating the solvent afforded 197 mg of an oil, from which 157 mg (77%) of **23** was obtained by chromatography on silicic acid (15 g) with benzene. **23**; IR (CCl_4): 3540, 1625, and 1295 cm^{-1}; NMR ($CDCl_3$): 1.17 (d, 3H, J=7 Hz), 2.44 (s, 3H), 2.65 (s, 3H), 5.80 (s, 1H, exchangeable with D_2O), and 11.50 ppm (s, 1H, exchangeable with D_2O). This material was used directly in the subsequent reaction without further purification.

When the reaction was carried out with one equivalent of boron tribromide at room temperature for 50 min or with one equivalent of aluminium chloride at room temperature for several hours, the main product was recognized as the monodemethylated compound **20** by IR spectra.

A mixture of 125 mg of **23**, 400 mg of anhydrous-potassium carbonate, and 1 ml of methyl bromoacetate in 6 ml of acetone was refluxed for 2.5 h. Potassium carbonate was removed by filtration, and the filtrate was evaporated. The residue was chromatographed on silicic acid (5 g). From 20% chroform–benzene fractions, 130 mg (65%) of **24** was obtained; mp 89—90 °C (methanol); IR (CCl_4): 1760, 1740, 1695, 1200, and 1075 cm^{-1}; NMR ($CDCl_3$): 1.16 (d, 3H, J=7 Hz), 2.16 (s, 3H), 2.55 (s, 3H), 3.77 (s, 3H), 3.80 (s, 3H), 4.55 (s, 2H), and 4.63 ppm (s, 2H). Found: C, 63.38; H, 6.97%. Calcd for $C_{20}H_{26}O_7$: C, 63.48; H, 6.93%.

*5,6,7,8-Tetrahydro-3, 4, 5-trimethylnaphtho[2,3-b]furan-9-yl Carboxymethyl Ether (****26****).* A solution of 132 mg of **24** in 3 ml of methanol and 3 ml of 1 M sodium hydroxide was refluxed under nitrogen for one hour. The whole was acidified with dil hydrochlocic acid and was extracted with ether. After evaporating the ether, crystals (**25**: IR (CCl_4): 3300—2500 br, 1740, 1725, and 1700 cm^{-1}) were dried in a dessicator over diphosphorus pentaoxide and were heated under reflux with 300 mg of sodium acetate and 3 ml of acetic anhydride for 2 h.[22] The mixture was poured into ice–water and products were taken in ether. Evaporating the solvent gave a solid **26** (100 mg); the compound was difficult to recrystallize. **26**: mp 168—169 °C (acetone–hexane); NMR ($CDCl_3$): 1.18 (d, 3H, J=7 Hz), 2.38 (br. s, 3H), 2.54 (s, 3H), 4.96 (br. s, 2H), 7.27 (m, 1H), and 9.45 (br. s, 1H). Found: C, 70.28; H, 7.04%. Calcd for $C_{17}H_{20}O_4$: C, 70.81; H, 6.99%.

5, 6, 7, 8-Tetrahydro-3, 4, 5-trimethylnaphtho[2, 3-b]furan-9-yl 2-Hydroxyethyl Ether (27). A solution of 110 mg of the acid **26** in 15 ml of dry ether was refluxed with lithium aluminium hydride for one hour. The excess lithium aluminium hydride was decomposed with the addition of ethyl acetate and the mixture was poured into dil hydrochloric acid. The ether extract was evaporated to give 105 mg of a crude alcohol, **27**. Recrystallization from pentane afforded a pure **27**: mp 78—79 °C; IR (CCl_4): 3580, 1335, and 1110 cm^{-1}; NMR (CCl_4): 1.16 (d, 3H, J=7 Hz), 2.18 (s, 1H, -OH), 2.38 (d, 3H, J=1.5 Hz), 2.52 (s, 3H), 3.80 (m, 2H), 4.30 (m, 2H), and 7.20 ppm (m, 1H). Found: C, 74.35; H, 8.17%. Calcd for $C_{17}H_{22}O_3$: C, 74.42; H, 8.08%.

5, 6, 7, 8-Tetrahydro-3, 4, 5-trimethylnaphtho[2, 3-b]furan-9-yl Acetate (30). To a solution of 50 mg of **27** in 0.3 ml of pyridine, there was added 50 mg of tosyl chloride in 0.3 ml of pyridine at 0 °C; the mixture was left at −6 °C for 17 h. According to Johnson's procedure,[23b] a crude tosylate **28** was isolated as an oil (72 mg). Without purification, **28** was stirred for 94 h with 300 mg of sodium bromide in 2 ml of dimethyl sulfoxide. The product was taken in ether and 45 mg of a bromide **29** was obtained as an oil by chromatography on silicic acid (3 g). **29**: IR (CCl_4): 1605, 1333, and 1110 cm^{-1}; NMR (CCl_4): 1.16 (d, 3H, J=7 Hz), 2.38 (d, 3H, J=1.5 Hz), 2.51 (s, 3H), 3.58 (t, 2H, J=7 Hz), 4.56 (t, 2H, J=7 Hz), and 7.20 ppm (m, 1H).

To a cooled solution of 45 mg of **29** in 2 ml of dry ether, 0.6 ml of 15% butyllithium–hexane solution was added dropwise and the mixture was stirred at room temperature for 10 min.[23a] Aqueous ammonium chloride was added and the ether extract, when evaporated, gave an oily **2** (39 mg) which showed one spot on TLC.

The oily **2** was left overnight with 0.6 ml of acetic anhydride and 1 ml of pyridine. Working up as usual afforded crystals (36 mg, 71% from **27**). Recrystallization from acetone–hexane gave the acetate **30**: mp 119—120 °C; IR (CCl_4): 1760, 1200, 1190, and 1110 cm^{-1}; NMR (CCl_4): 1.18 (d, 3H, J=7 Hz), 2.30 (s, 3H), 2.35 (d, 3H, J=1.5 Hz), 2.53 (s, 3H), and 7.15 ppm (m, 1H). Found: C, 74.79; H, 7.40%. Calcd for $C_{17}H_{20}O_3$: C, 74.97; H, 7.40%.

Lithium Aluminium Hydride Reduction of the Tetralone 16. According to the Romo's condition,[1] a solution of 53 mg of **16** in 5 ml of dry ether was treated with excess lithium aluminium hydride under reflux for one hour. Working up as usual gave an oil, which was acetylated with acetic anhydride in pyridine to give an oily mixture. The NMR spectrum of the mixture showed no detectable amount of **19** being formed. By a chromatographic separation on silicic acid (3 g), 65 mg (88%) of a mixture of *cis*-1,8-diacetoxy-4,5-dimethyl-7-methoxytetralin (**31**) and *trans*-1,8-diacetoxy-4,5-dimethyl-7-methoxytetralin (**32**) was obtained. The stereochemistry of both acetates was based on the pseudocontact shift with Eu-$(fod)_3$ (see Table 2). The ratio of **31**/**32** was *ca.* 2: 1.

We are deeply indebted to Dr. J. Romo for a gift of samples of maturinone and cacalol acetate.

Thermal Analysis and NMR Observation of 66-Nylon

Masayoshi Ito, Tetsuo Kanamoto, and Koji Tanaka

Department of Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received October 1, 1976)

The effects of morphology on γ-relaxation in 66-Nylon is investigated. The morphology of the samples was characterized mainly by thermal analysis. Information about the molecular motion of 66-Nylon is obtained from the temperature dependence of the spin-lattice relaxation times (T_1). In order to compare the relaxation behavior of 66-Nylon with that of other semicrystalline polymers, the T_1 of polyoxymethylene (POM) was also measured as a function of temperature. It was found that in 66-Nylon, both solution-grown crystals and bulk samples are composed of folded chain lamellae with fairly large amounts of less perfect crystalline regions. Both the magnitude and the temperature of the T_1 minimum at about 30 °C (γ-region) for 66-Nylon are not sensitive to the sample history, in contrast to those for POM. In addition, the T_1-temperature curve in the γ-region for 66-Nylon is much broader than that for POM. These NMR results for 66-Nylon are interpreted in terms of a rather wide variety of structural heterogeneities from the usual amorphous regions to fairly restricted regions, such as the less-perfect crystalline regions at the lamellar surface.

It is well known that 66-Nylon has three principal relaxations α, β, and γ, in the decreasing order of the temperatures at which they occur.[1] The α-relaxation corresponds to the glass transition[1] and the β-relaxation is related to the motions of polar groups.[2] For the γ-relaxation, different results and explanations have been presented,[3-5] and a complete understanding of this relaxation is still lacking. Bell and Murayama[3] have reported that for 66-Nylon, melt-quenched sample exhibits mechanical γ-dispersion, while slowly-cooled and cold-drawn samples do not show this dispersion. These samples can be characterized from their melting behavior: the former has folded chain crystals and the latter two have less-perfect bundle crystals.[6] Olf and Peterlin[4] have proposed, on the basis of NMR data of drawn fibers of 66-Nylon, that the origin of the γ-relaxation is related to the motions of strained tie molecules. These suggest that 66-Nylon exhibits complex γ-relaxation related to various morphological origins. Hence, the morphological characterization of the sample is very important for understanding the γ-relaxation of 66-Nylon. In this study, thermal analysis, infrared spectroscopy, and density measurements were employed to make a detailed characterization of the morphology of the samples.

Information about the molecular motion of 66-Nylon for a variety of morphologies is obtained from the temperature dependence of the spin-lattice relaxation times (T_1). The relaxation behavior of 66-Nylon is compared with that of polyoxymethylene for which the relaxation mechanisms are well defined.[7,8] Marked differences between them are observed for γ-relaxation and are discussed in light of a morphological interpretation of 66-Nylon.

Experimental

Samples. Commercial 66-Nylon (Toray Co., Ltd.) was dissolved in formic acid and precipitated in an excess of methanol in order to remove impurities. After repeated washing with methanol, the polymer was dried *in vacuo* at 100 °C for one week. Morphological varieties of the samples were prepared by the following procedures.

Solution-crystallized 66-Nylon: *(1) Rapidly-cooled solution grown (SGQ) sample*: One gram of 66-Nylon was dissolved in one liter of glycerin at 220 °C for 40 min, and then the solution was cooled to room temperature at a rate of 30 °C/h. The precipitated crystals were washed with methanol several times and then dried *in vacuo* at 80 °C for one week. *(2) Isothermal solution grown (SGI) sample*: 0.5 g of 66-Nylon was dissolved in one liter of 1,4-butanediol at 180 °C for 15 min, and then the crystals were precipitated at 114 °C for 42 h. The washing and drying procedures for the crystals were identical with those for the SGQ sample.

Observation by electron microscopy indicated that these crystals consist of multilayer single crystals and two dimensional open spherulites.

Bulk-crystallized 66-Nylon: Various bulk-crystallized 66-Nylon specimens were prepared by the treatment similar to those described by Bell and Dumbleton.[6] The polymer samples, sealed in glass tube *in vacuo*, were heat-treated, melt-quenched (MQ) sample, annealed after melt quenching (MQA) sample, slowly-cooled (SC) sample, and annealed after slow cooling (SCA) sample. The thermal history of the bulk crystallized samples is summarized in Fig. 1.

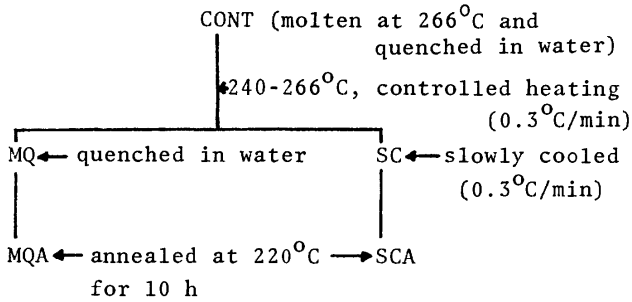

Fig. 1. Shematic representation of the procedures for heat treatment.

Solvent-cast films held in polytetrafluoroethylene sheets and powdered 66-Nylon were heat treated. The melting behavior and densities of the solvent-cast films were substantially identical to those powder samples in regard to the effects of thermal history.

Drawn 66-Nylon Fibers: Drawn fibers were prepared by stretching melt-spun fibers having no orientation to an elongation of about 400% at room temperature.

Polyoxymethylene: Delrin 500 (Du. Pont Co.) was crystallized at several crystallization temperatures. Another sample consisted of extended chain crystals obtained by solid-state

polymerization of trioxane, which was kindly supplied by the Japan Atomic Energy Research Institute, at Takasaki.

Measurements. The melting behavior was observed using a Perkin-Elmer differential scanning calorimeter (DSC-1B), in a nitrogen atmosphere. Sample weights of the order of 1—7 mg were required. The temperature and heat of fusion were calibrated against lead. The melting peak temperature was reproducible for the same sample to within ±0.5 °C.

Pulsed NMR experiments were carried out with a JEOL pulsed NMR (JSE-5) spectrometer, operating at a frequency of 60 MHz. The dead time was 10—12 μs following a 2-μs pulse. 90-τ-90° pulse sequences were used to obtain the proton spin-lattice relaxation times (T_1) to within a precision of ±6% or better. Samples were packed in a sample tube *in vacuo*. Fibers were placed randomly in the sample tube. The sample temperature was regulated to ±0.5 °C by a gas-flow thermostat.

IR spectra were recorded on a JASCO infrared photometer (DS-403G) at room temperature. Spectra of the bulk samples were obtained on films and those of the solution-grown crystals were obtained using samples of about 2 mg in KBr disks.

Densities were determined using a density gradient column at 30 °C in carbon tetrachloride and toluene for 66-Nylon, and in xylene and tetrachloroethylene for polyoxymethlene. The amorphous fraction was calculated using a two-phase model with a crystal density.[9] $\rho_c = 1.24$ g/cm³, and an amorphous density,[9] $\rho_a = 1.09$ g/cm³, for 66-Nylon, and ρ_c[10] = 1.492 g/cm³, ρ_a[11] = 1.25 g/cm³ for polyoxymethylene.

Results and Discussion

Regular Fold Content. Koenig *et al.*[12] have reported that infrared spectroscopy (IR) is a useful method for estimating the regular fold content of 66-Nylon. The regular fold content indexes (the ratio of the absorbances at 1329 and at 936 cm^{-1}) calculated using their method are given in Table 1. All the samples, except the drawn fibers clearly show the regular fold band at 1329 cm^{-1}. It should be noted that the regular fold content indexes for SC and SCA samples, which were previously assumed to be due to a bundle-like crystal structure,[6] have values similar to that for solution-grown crystals (SGI).

Table 1. Characterization data of the samples

Sample	Fold content 1329/936 (IR)	Density g/cm³	Amorphous fraction from density
MQ	0.053	1.162	0.491
MQA	0.059	1.164	0.474
SC	0.074	1.167	0.452
SCA	0.077	1.169	0.440
SGI	0.079	1.190	0.305
SGQ	0.088	1.198	0.250

Thermal Analysis. DSC thermograms for the solution-grown crystals and the heat-treated samples obtained for a heating rate 16 °C/min, are shown in Fig. 2. The MQ and SC samples exhibited a single endothermic peak. On annealing the MQ and SC samples at 220 °C, the former (MQA) produced a new additional peak at a low-temperature side of the original peak, while the latter (SCA) showed no such peak. In solution-grown crystals, the isothermally crystallized SGI sample had double melting peaks, while, the rapidly-cooled SGQ sample gave a single peak.

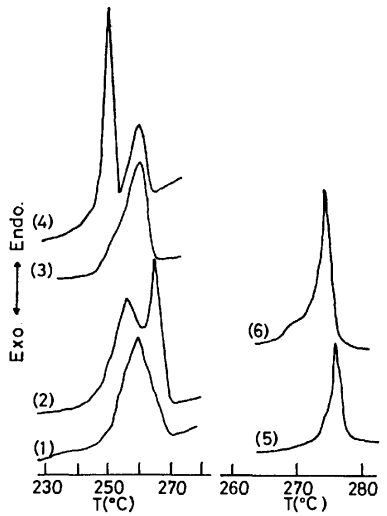

Fig. 2. DSC thermograms of the samples; (1) SGQ, (2) SGI, (3) MQ, (4) MQA, (5) SC, (6) SCA; heating rate was 16 °C/min.

The effect of the heating rate on the melting peaks for the samples are shown in Table 2. When the heating rate was increased, the melting temperature of the SC, SCA, and SGQ samples increased, while that of the MQ and the high-temperature side of the MQA and SGI samples tended to decrease. Such melting behavior of the heat-treated samples agrees well with that of samples used in the dynamic mechanical study by Bell and Murayama.[3]

Table 2. Effect of heating rate on the apparent melting temperature

Heating rate °C/min	Melting temperature, °C							
	MQ	MQA		SC	SCA	SGI		SGQ
2				274	272			
4	263	250	262			255	266	262
8	260	250	261	274	274	256	266	261
16	260	251	260	276	275	257	265	262
32	260			278				266

It has been suggested that extended chain crystals tend to superheat, whereas folded chain crystals do not.[13]

In addition to reorganization during the DSC scan, the thermal diffusivity or temperature gradient in the sample may sometimes affect the melting-peak temperature observed for rapid heating. Indeed, it was found in the present study that even the melting temperature of thin solution-grown crystals (SGQ) (*ca.* 60 Å thick) with typical chain foldings increased with increased heating rate. Furthermore, the samples (SC, SCA) which exhibited apparent superheating showed regular fold bands in their IR spectra. Hence, it was not possible to distinguish between folded chain crystals and extended chain crystals only on the basis of heating-rate dependence of the apparent melting temperature determined by DSC.

In order to reveal the melting behavior inherent in the morphology of the samples, the solution-grown crystals and heat-treated samples were methoxymethylated following the method proposed by Cairns *et al.*[14] This chemical treatment has been found by Arakawa *et al.*[15] to suppress the reorganization of Nylon-6 during thermal analysis, although this has not been applied to 66-Nylon of various morphologies.

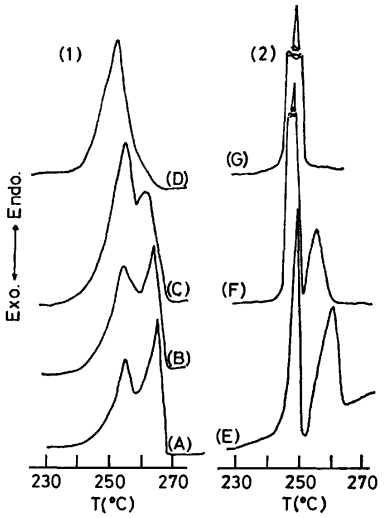

Fig. 3. Changes of melting behavior with methoxymethylation time for (1) MQA, (2) SGI; reaction time was (A) 0 h, (B) 0.7 h, (C) 2 h, (D) 3 h, (E) 0 h, (F) 4 h, (G) 6 h, heating rate was 8 °C/min.

Figure 3 shows the effects of the methoxymethylation time on the thermograms of the MQA and SGI samples obtained for a heating rate of 8 °C/min. The area under the higher melting peak decreased in both samples with increasing reaction time. In the SGI sample, a single melting peak was obtained after a reaction period of 3 h, while the MQA sample exhibited a sharp single peak after 6 h of treatment.

These facts clearly show that the double melting of untreated samples is not associated with the two different lamellar structures, as has been previously deduced from the heating-rate dependence of the melting temperature,[6] but is related to reorganization during the DSC scan

The reaction-time dependence of the melting temperature and the heat of fusion for the solution-grown crystals (SGI) and bulk samples (MQ and SC) are shown in Fig. 4. In all the samples, both the melting temperature and the heat of fusion decreased with increasing reaction time and approached nearly constant values for prolonged reaction times. Such changes were most prominent in the MQ sample. The reduction of the heat of fusion for the MQ, SC, and SGI samples was about 27, 13, and 6%, respectively. The fact that, with the chemical treatment, the heat of fusion decreased initially and reached a nearly constant value for prolonged reaction times indicates that some of the less-perfect crystalline regions or small crystallites were destroyed as a consequence of this treatment. Hence, the observed reduction in the heat of fusion is directly related to the amount of less-perfect crystalline regions

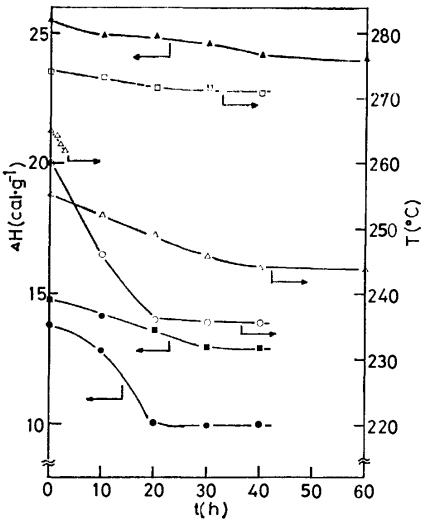

Fig. 4. Changes in the melting temperature with methoxymethylation time for △ SGI, □ SC, ○ MQ; heating rate was 8 °C/min, and changes in the heat of fusion with methoxymethylation time for ▲ SGI, ■ SC, ● MQ.

accessible to the chemical reaction. Although the lowering of the melting points in these samples might be caused primarily by the suppression of the reorganization during the DSC scan, the large decrease in the heat of fusion for the MQ sample suggests that the melting point was also affected by the partial breakdown of the less-perfect regions in the crystallites. In summary, for 66-Nylon, the heat-treated and solution-grown samples were composed of folded chain crystals with different amounts of fold content and of less-perfect crystalline regions depending on the sample history.

NMR Data. The temperature dependence of the spin-lattice relaxation times (T_1) of protons for samples with various morphologies are shown in Figs. 5 and 6. A broad T_1 minimum is present around 30 °C in all the samples studied. In addition to this minimum, the MQ, SC, and SGQ samples showed a small T_1 minimum at 70—80 °C. According to the relaxation map of 66-Nylon,[1,16] the T_1 minima observed here at about 30 and 80 °C at 60 MHz, correspond to the γ- and β-relaxations, respectively, which are usually observed at

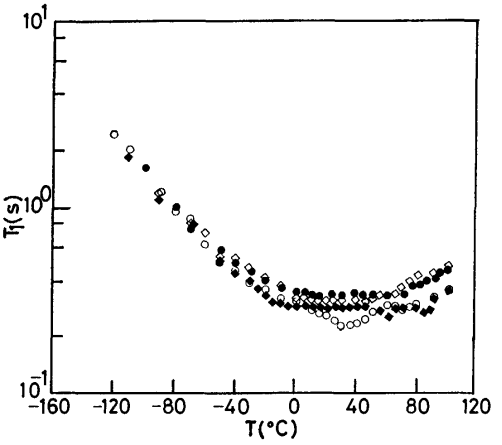

Fig. 5. Temperature dependence of T_1 for ○MQ, ●MQA, ◆SC, ◇SCA.

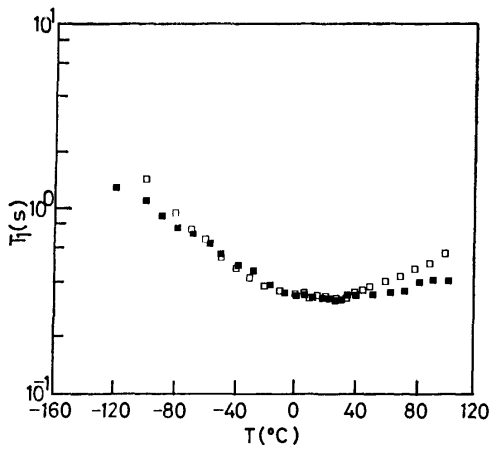

Fig. 6. Temperature dependence of T_1 for ■SGQ, □Drawn Fibers.

around −120 and −40 °C for low-frequency measurement. β-relaxation was found in the MQ, SC, and SGQ samples, but this is not discussed in detail in the present paper.

It should be noted that γ-relaxation in 66-Nylon was found for the SC, SCA, and drawn fibers samples for which other authors[3] failed to detect any mechanical γ-dispersion.

Although the SC, SCA, and drawn fibers samples have been previously considered to be composed of less-perfect bundle crystals,[6] it was confirmed in these measurements using IR and thermal analysis that the SC and SCA samples are composed of the usual folded chain crystals having different amounts of fold content. Furthermore, a large difference in morphology such as in the fold content, might be expected between drawn fibers and solution-grown crystals, these samples have similar spectra for molecular motion in the γ-region. Hence, it is not possible to explain the γ-relaxation in 66-Nylon in terms of only the molecular motions of folded chains at the lamellar surface, as proposed by Bell and Murayama.[3]

In the limit of rapid spin diffusion to the reorienting segments, if the simple two-phase (crystalline-amorphous) model is applicable, the observed maximum relaxation rate $(1/T_1)_{max}$ at the minimum is given by[17]

$$(1/T_1)_{max} = (1-X)/T_1^a, \quad (1)$$

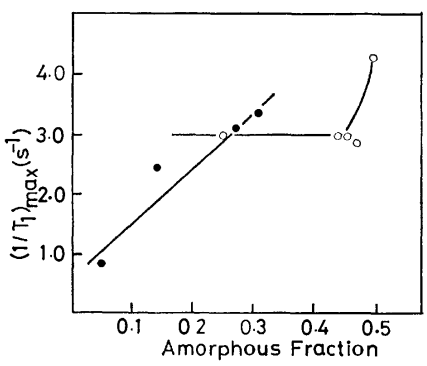

Fig. 7. Maximum relaxation rate at γ-relaxation as a function of the amorphous fraction for ○66-Nylon, ●POM.

where $(1-X)$ is the amorphous fraction and T_1^a is the relaxation time appropriate for the amorphous regions. In Fig. 7, the maximum relaxation rates for the γ-relaxation of 66-Nylon and polyoxymethylene (POM) are plotted against the amorphous fraction calculated from the density. The maximum relaxation rates for POM increased linearly with increasing amorphous fraction. A similar observation for polyethylene and POM has also been reported by Crist and Peterlin.[7,17] For 66-Nylon, on the other hand, all the samples except the MQ sample, exhibited similar relaxation rates despite the fairly large differences in the amorphous fraction.

It is well known that spin diffusion is sufficiently rapid in these γ-regions compared to the dipole-dipole relaxation rate. Therefore, the effects of the amorphous fraction on the maximum relaxation rates for 66-Nylon cannot be explained on the basis of Eq. 1. This means that the simple two-phase model cannot explain the γ-relaxation in 66-Nylon. This is unique to 66-Nylon in comparison with other well-known semicrystalline polymers such as POM[7] and PE,[17] and appears to be important to the understanding of the γ-relaxation in 66-Nylon.

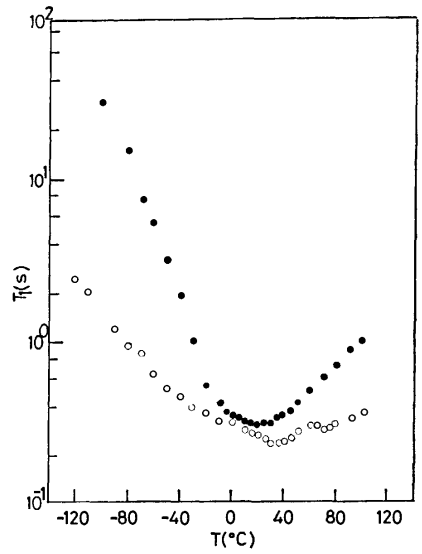

Fig. 8. Temperature dependence of T_1 for ○66-Nylon melt-quenched sample, ●POM melt-quenched sample.

In order to elucidate the characteristic relaxation behavior of 66-Nylon, the temperature dependence of T_1 for 66-Nylon was compared with that for POM for which the γ-relaxation has been explained on the basis of the simple two-phase model[7] in Fig. 8. It is clearly seen that the T_1-temperature curve in the γ-region for 66-Nylon is much broader than that for POM. The broadening of this curve in the higher temperature region could be caused by a coupling of the γ- and β-relaxations. However, this phenomenon in the lower temperature region cannot be caused by coupling with any other relaxation mechanism, because 66-Nylon is known to exhibit no noticeable relaxation below the γ-relaxation.[18] Thus, the broadening indicates that the local mode motions in 66-Nylon have a much wider distribution of correlation times.

Although no fundamental difference (chain folded or extended chain crystals) in the crystalline morphology was found in these bulk samples, they contained, depending on the sample history, different amounts of disordered crystalline regions which were accessible to the chemical reaction.

Atkins *et al.*[19] have carried out an X-ray diffraction analysis of the lamellar structure of 66-Nylon single crystals and found that sharp chain foldings occur at the lamellar surface but that half the lamellar thickness is composed of a less-perfect crystalline core; the chain packing becomes gradually looser in going from the lamellar interior to the fold surface. This type of crystalline disorder in 66-Nylon, which is not found in polyethylene and POM, is considered to occur as the result of a fairly long chemical repetition unit and the small number of such units contained within the lamellar thickness. The observed density defficiency of the SGI sample may be consistent with the lamellar structure revealed by the X-ray diffraction analysis. Hence, the small reduction in the heat of fusion of the solution-grown crystals (SGI) found as a consequence of the chemical treatment indicates that the fraction of the disordered crystalline regions accessible to the chemical reaction was very small. As the bulk samples are thought to be complex aggregates of amorphous materials and crystalline lamellae, it is postulated that both bulk samples and solution-grown crystals contain disordered crystalline regions varying in the degree of perfection from those accessible to the chemical reaction to those revealed by X-ray diffraction.

On considering the above discussions concerning morphology, the structure of the disordered regions of 66-Nylon appears to be very complex compared with those of POM which has a rather short chemical repetition unit and these disordered regions in 66-Nylon appear to consist of a rather wide variety of structural heterogeneity varying from the usual amorphous regions between lamellae or spherulites to fairly restricted regions including those of less-perfect crystalline regions at the lamellar surface. Therefore, it is postulated that the molecular motions in these disordered regions exhibit a wider distribution of correlation times corresponding to the degree of restriction.

Thus, the T_1-temperature curve in the γ-region for 66-Nylon becomes much broader than that for POM.

In summary, γ-relaxation in 66-Nylon cannot be explained by only the motions of the folds or in terms of the simple two-phase model. This relaxation appears to be associated with the motions of segments in the disordered region, which are much more complex than those of POM.

The difference between the dynamic mechanical results previously reported[3] and the present NMR results might be due to the different type and degree of perturbation imposed upon the samples during the measurements. In the NMR experiment, perturbation of the sample system is negligible, but in the dynamic mechanical test, the sample is subjected to a stress and the overall strain on the sample in a complex composition of deformation of the crystalline core and the disordered regions. Indeed, the magnitude of mechanical dispersion has been interpreted in relation to the fine structure of the crystalline polymers using series and parallel models of crystalline and amorphous regions.[20]

The authors wish to express their thanks to Professor Masatami Takeda for continuing interest and encouragement during this investigation.

Improved Syntheses of 3′-Deoxybutirosin A and B

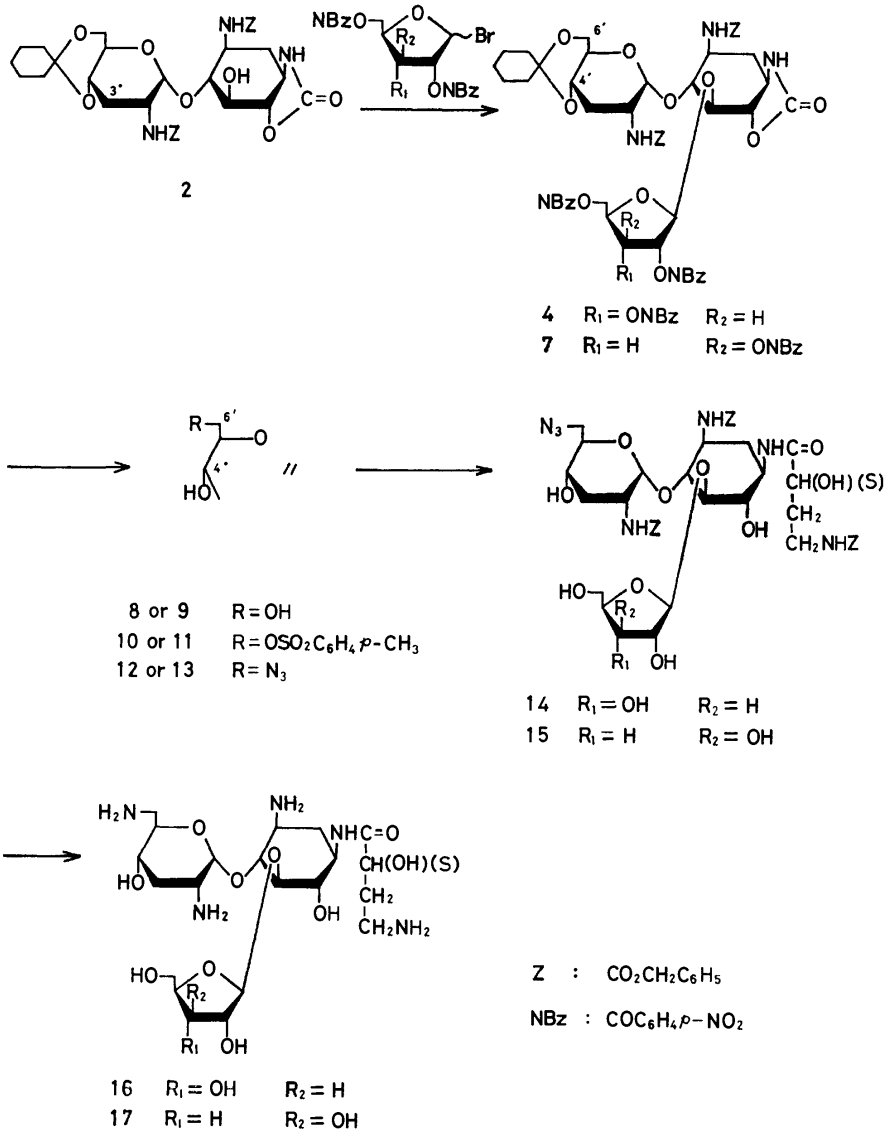
Isamu WATANABE, Tsutomu TSUCHIYA, and Sumio UMEZAWA
Institute of Bioorganic Chemistry, 1614, Ida, Nakahara-ku, Kawasaki 211

(Received September 9, 1976)

3′-Deoxybutirosin B and A (**16**, **17**) were synthesized *via* condensation of 3,2′-bis-*N*-benzyloxycarbonyl-4′,6′-*O*-cyclohexylidene-3′-deoxyparomamine 1,6-carbamate (**2**) with tris-*O*-(*p*-nitrobenzoyl)-D-ribofuranosyl and -D-xylofuranosyl bromide, respectively, followed by 6′-*O*-tosylation of the decyclohexylidene derivative (**8** and **9**), cyclic 1,6-carbamate opening and amidation with (*S*)-4-benzyloxycarbonylamino-2-hydroxybutyric acid at the free C-1 amino group.

In a previous paper,[1] we described a synthesis of 3′-deoxybutirosin B starting from 3′-deoxyparomamine. Here we describe another synthesis of 3′-deoxybutirosin B as well as A by an alternative route. In the previous synthesis[1] there have been found the following disadvantages: 1) regioselective 6′-*O*-tosylation and 4′-*O*-α-naphthoylation gave unsatisfactory yields owing to the presence of other similarly reactive hydroxyl groups, 2) low solubilities of the 6′-*O*-tosyl and other related derivatives (compound **2**, **3**, **4**, and **5** in the previous paper[1]) in organic solvents render the column-chromatographical purification difficult, 3) the 4′-*O*-naphthoyl group unexpectedly resisted to the basic hydrolysis, and the removal of this group was forced to be incomplete in order to prevent the removal of the *N*-benzyloxycarbonyl groups. One device to overcome this disadvantage was the use of sodium *p*-methoxybenzylate, a stronger base.[1]

The condensing partner adopted in this paper is 4′,6′-*O*-cyclohexylidene-1,6-carbamate (**2**), prepared



from tris-*N*-benzyloxycarbonyl-3′-deoxyparomamine[1] (**1**). The compound **2** has a free hydroxyl group only at C-5 and suitable solubilities in organic solvents. The condensation of **2** with tris-*O*-(*p*-nitrobenzoyl)-α,β-D-ribofuranosyl bromide[1] (**3**) or α,β-D-xylofuranosyl bromide[2] was successfully carried out to give **4** or **7**. The latter bromide was prepared from 1,2-*O*-isopropylidene-3,5-bis-*O*-(*p*-nitrobenzoyl)-α-D-xylofuranose (**5**) *via* methyl 2,3,5-tris-*O*-(*p*-nitrobenzoyl)-α,β-D-xylofuranoside[2] (**6**). The cyclohexylidene group of the condensation product (**4** or **7**) was then selectively hydrolyzed and the 6′-hydroxyl group of the resulting diol derivative (**8** or **9**) was tosylated to give **10** or **11**.

Treatment of **10** or **11** with sodium azide gave a 6′-azido derivative (**12** or **13**). Treatment with aqueous barium hydroxide cleaved their ester groups as well as cyclic carbamate smoothly in comparison to the *O*-α-naphthoyl group described in the previous paper.[1] Introduction of (*S*)-4-benzyloxycarbonylamino-2-hydroxybutyryl group to the amino group at C-1 gave **14** or **15** and catalytic hydrogenolysis of the *N*-benzyloxycarbonyl and azido groups gave 3′-deoxybutirosin B (**16**) or A (**17**). By taking this synthetic route, the aforementioned disadvantages were substantially avoided and the overall yields based on **1** were 10—15%.

Experimental

General procedures were the same as described in a previous paper.[1]

*3,2′-Bis-*N*-benzyloxycarbonyl-4′,6′-*O*-cyclohexylidene-3′-deoxyparomamine 1,6-Carbamate (2).* To an ice-cold solution of tris-*N*-benzyloxycarbonyl-3′-deoxyparomamine[1] (**1**) (9.60 g) in DMF (190 ml), 50% oily sodium hydride (1.92 g) was added and the mixture was vigorously stirred for 2 h in the cold. Acetic acid (5 ml) was added and the mixture was poured into ice–water (3 l). Precipitates were collected by filtration and dried. To a solution of the solid (7.53 g) in dry DMF (150 ml), 1,1-dimethoxycyclohexane (15 ml) and anhydrous *p*-toluenesulfonic acid (430 mg) were added and the solution was stirred for 2.5 h at 30 °C under reduced pressure (≈15 Torr). The solution was poured into aqueous acetic acid–sodium acetate buffer (0.2 M, pH 4.5, 2 l) and the precipitates were collected by filtration and thoroughly washed with hexane and then with water to give a solid, 8.1 g (89%). It was reprecipitated from dioxane–acetone–hexane, mp 264—265 °C, $[\alpha]_D^{20}$ +52° (*c* 1, C_5H_5N); IR (KBr): 2930, 1775, 1700 cm^{-1}.

Found: C, 61.47; H, 6.38; N, 5.97%. Calcd for $C_{35}H_{43}N_3O_{11}$: C, 61.66; H, 6.36; N, 6.16%.

*3,2′-Bis-*N*-benzyloxycarbonyl-4′,6′-*O*-cyclohexylidene-3′-deoxy-5-*O*-[2,3,5-tris-*O*-(p-nitrobenzoyl)-β-D-ribofuranosyl]paromamine 1,6-Carbamate (4).* A mixture of **2** (5.0 g), **3**[1] (20.5 g), mercuric cyanide (9 g), and calcium sulfate (Drierite, 18 g) in dichloromethane (115 ml) was vigorously stirred at room temperature overnight. After addition of methanol (20 ml) and pyridine (10 ml) followed by agitation for a while, the mixture was filtered and the solid was washed with dichloromethane (≈50 ml). The filtrate and the washings combined were washed with aqueous sodium hydrogencarbonate and water, dried (Na_2SO_4), and concentrated. The resulting solid was chromatographed over silica gel with chloroform–ethanol–triethylamine (30: 1: 0.1) to give a solid of **4**, 5.8 g, $[\alpha]_D^{23}$ +10° (*c* 1, $CHCl_3$); Though the solid still contained 1—2% ash, it was used without purification to the next step.

*1,2-*O*-Isopropylidene-3,5-bis-*O*-(p-nitrobenzoyl)-α-D-xylofuranose (5).* 1,2-*O*-Isopropylidene-α-D-xylofuranose[4] was treated with *p*-nitrobenzoyl chloride in pyridine in a usual manner to give a solid of **5**, which was recrystallized from ethyl acetate–hexane to give needles in a yield of 76%, mp 149—150 °C, $[\alpha]_D^{23}$ −70° (*c* 1, $CHCl_3$).

Found: C, 53.84; H, 4.11; N, 5.53%. Calcd for $C_{22}H_{20}N_2O_{11}$: C, 54.10; H, 4.13; N, 5.74%.

*Methyl 2,3,5-Tris-*O*-(p-nitrobenzoyl)-α,β-D-xylofuranoside (6).* To a solution of **5** (2.5 g) in dichloromethane (40 ml), 0.5 M methanolic hydrogen chloride (45 ml) was added and the solution was kept at room temperature for 60 h. Pyridine (10 ml) and toluene (20 ml) were added and the solution was concentrated. The residue was dissolved in pyridine (50 ml) and the solution was treated with *p*-nitrobenzoyl chloride in a usual manner to give a syrup of **6**, 3.1 g; PMR ($CDCl_3$) δ: 5.20 (≈0.6H s, β-H-1); the peaks corresponding to α-H-1 could not be discerned by overlapping with other signals. The syrup was used without purification to bromination followed by glycosylation (The crystalline β-anomer of **6** was described by El Khadem *et al.*[2]).

*3,2′-Bis-*N*-benzyloxycarbonyl-4′,6′-*O*-cyclohexylidene-3′-deoxy-5-*O*-[2,3,5-tris-O-(p-nitrobenzoyl)-β-D-xylofuranosyl]paromamine 1,6-Carbamate (7).* To a cold (≈10 °C) solution of **6** (2.02 g) in dry dichloromethane (40 ml), hydrogen bromide was introduced until saturation and the solution was kept at 0 °C overnight. Removal of the solvent and the excess hydrogen bromide by coevaporation with toluene gave a syrup, which was dissolved in dichloromethane (21 ml). To the solution, **2** (750 mg), mercuric cyanide (1.0 g), and calcium sulfate (Drierite, 2.0 g) were added and the mixture was vigorously stirred at room temperature overnight. The reaction mixture was then treated similarly as described for **4** to give a solid of **7**, 583 mg (42%), $[\alpha]_D^{23}$ +53° (*c* 1, $CHCl_3$).

Found: C, 57.66; H, 4.82; N, 6.51%. Calcd for $C_{61}H_{60}N_6O_{24}$: C, 58.09; H, 4.80; N, 6.66%.

*3,2′-Bis-*N*-benzyloxycarbonyl-3′-deoxy-5-*O*-[2,3,5-tris-O-(p-nitrobenzoyl)-β-D-ribo- and -β-D-xylofuranosyl]paromamine 1,6-Carbamates (8 and 9).* To a solution of crude **4** (350 mg) in acetone (3.5 ml), acetic acid (7 ml) and water (3.5 ml) were added and the mixture was heated at 60 °C for 6 h. The solution was concentrated and the residue was dissolved in chloroform. The solution was washed with aqueous hydrogencarbonate and water, dried (Na_2SO_4), and concentrated to give a solid of **8**, 230 mg (≈70%). Since the solid contained slight impurities, it was further purified by chroma tography over silica gel with chloroform–ethanol (20: 1) (30: 1, in the case of **9**), $[\alpha]_D^{22}$ +10° (*c* 1, $CHCl_3$); IR (KBr): 1775, 1720, 1525 cm^{-1}.

Found: C, 55.68; H, 4.51; N, 6.85%. Calcd for $C_{55}H_{52}N_6O_{24}$: C, 55.93; H, 4.44; N, 7.12%.

Compound **9**: Compound **7** (440 mg) was treated similarly as described for **8** to give a solid of **9**, 237 mg (57.5%); $[\alpha]_D^{23}$ +57° (*c* 1, $CHCl_3$); IR (KBr); 1780, 1725, 1530 cm^{-1};

Found: C, 55.71; H, 4.44; N, 6.92%.

*3,2′-Bis-*N*-benzyloxycarbonyl-3′-deoxy-5-*O*-[2,3,5-tris-O-(p-nitrobenzoyl)-β-D-ribo- and -β-D-xylofuranosyl]-6′-O-tosylparomamine 1,6-Carbamates (10 and 11).* To a solution of **8** (360 mg) in pyridine (10 ml), *p*-toluenesulfonyl chloride (230 mg) was added and the solution was kept at −10 °C for 40 h. Water (0.1 ml) was added and the solution was concentrated. A solution of the residue in chloroform was washed with aqueous potassium hydrogensulfate. aqueous sodium hydrogencarbonate and water, dried (Na_2SO_4), and concentrated to give a solid, which was chromatographed over silica gel with chloroform–ethanol (40: 1), giving a solid of **10**, 320 mg (79%), $[\alpha]_D^{22}$ +4° (*c* 0.4, $CHCl_3$); IR (KBr):

1770, 1725, 1525, 1175 cm^{-1} (Ts); PMR ($CDCl_3$) δ: 2.37 (3H, s, CH_3 (Ts)).

Found: C, 55.85; H, 4.54; N, 6.28; S, 2.35%. Calcd for $C_{62}H_{58}N_6O_{26}S$: C, 55.77; H, 4.38; N, 6.29; S, 2.40%.

Compound ***11***: Compound **9** (335 mg) was treated similarly as described for **10** to give a solid of **11**, 298 mg (79%); $[\alpha]_D^{23}$ +70° (*c* 0.6, $CHCl_3$); IR (KBr): 1775, 1725, 1530, 1180 cm^{-1} (Ts); PMR ($CDCl_3$ δ: 2.35 (3H, s, CH_3 (Ts)).

Found: C, 55.48; H, 4.48; N, 5.99; S, 2.36%.

*6'-Azido-3,2'-bis-*N*-benzyloxycarbonyl-3',6'-dideoxy-5-*O*-[2,3,5-tris-*O*-(*p*-nitrobenzoyl)-β-*D*-ribo- and -β-*D*-xylofuranosyl]paromamine 1,6-Carbamates (**12** and **13**).* To a solution of **10** (160 mg) in DMF (3.2 ml), sodium azide (80 mg) was added and the mixture was stirred at 60 °C for 4 h. Chloroform (30 ml) was added and the reaction mixture was washed with saturated sodium chloride solution (30 ml × 3) and then with water (30 ml). The solution was concentrated and the residue was washed with water to remove trace of DMF accompanied, and dried to give a solid of **12**, 142 mg (96%), $[\alpha]_D^{22}$ +6.5° (*c* 0.8, $CHCl_3$); IR (KBr): 2100 (N_3), 1775, 1720, 1525 cm^{-1}.

Found: C, 54.57; H, 4.34; N, 10.52%. Calcd for $C_{55}H_{51}N_9O_{23}$: C, 54.77; H, 4.26; N, 10.45%.

Compound ***13***: Compound **11** (130 mg) was treated similarly as described for **12** to give a solid of **13**, 115 mg (98%); $[\alpha]_D^{23}$ +54° (*c* 1, $CHCl_3$); IR (KBr): 2100 (N_3), 1775, 1720, 1525 cm^{-1}.

Found: C, 54.44; H, 4.36; N, 10.30%.

*6'-Azido-3,2'-bis-*N*-benzyloxycarbonyl-1-*N*-[(*S*)-4-benzyloxycarbonylamino-2-hydroxybutyryl]-3',6'-dideoxy-5-*O*-(β-*D*-ribo- and -β-*D*-xylofuranosyl)paromamines (**14** and **15**).* To a solution of **13** (260 mg) in dioxane (13 ml), 0.05 M aqueous barium hydroxide (5.8 ml) was added and the mixture was stirred at 60 °C for 30 min. To the resulting neutral solution, additional aliquots of the barium hydroxide solution (5.0 and 2.1 ml) were added at intervals and the mixture was treated as stated above. Carbon dioxide was introduced, and, after filtration, the solution was concentrated to give a residue, which was again dissolved in dioxane. After filtration, the solution was concentrated to give a solid.

To a solution of the solid in THF (2.7 ml), *N*-hydroxysuccinimide ester[3] (115 mg) of (*S*)-4-benzyloxycarbonylamino-2-hydroxybutyric acid and triethylamine (0.1 ml) were added and the solution was stirred at 0 °C for 1 h and then kept at room temperature overnight. The solution was concentrated and the residue was chromatographed over silica gel with chloroform–ethanol (7: 1) to give a solid of **15**, 142 mg (68%), mp 86—90 °C, $[\alpha]_D^{23}$ +23° (*c* 1, CH_3OH); IR (KBr): 2100, 1700, 1530 cm^{-1}.

Found: C, 55.47; H, 5.83; N, 9.77%. Calcd for $C_{45}H_{57}N_7O_{17}$: C, 55.84; H, 5.94; N, 10.13%.

Compound ***14***: Compound **12** (95 mg) was treated similarly as described for **15** to give a solid of **14**, 50 mg (66%); mp 94—96 °C, $[\alpha]_D^{22}$ +20° (*c*, 1 $CHCl_3$) (lit,[1] +19°); IR (KBr): 2100 (N_3), 1695, 1525 cm^{-1}.

Found: C, 55.67; H, 6.07; N, 9.87%.

*3'-Deoxybutirosin B (**16**).* Compound **14** (115 mg) was catalytically hydrogenated as described in the foregoing paper[1] to give a solid of **16**, 55 mg (77%), $[\alpha]_D^{22}$ +32° (*c* 1, H_2O) (lit,[1] +29°).

Found: C, 44.08; H, 7.37; N, 11.57%. Calcd for $C_{21}H_{41}N_5O_{11}\cdot H_2CO_3$: C, 43.92; H, 7.20; N, 11.64%.

*3'-Deoxybutirosin A (**17**).* Compound **15** (126 mg) was catalytically hydrogenated as described for the preparation of 3'-deoxybutirosin B in the foregoing paper[1] to give a solid of **17**, 55 mg (74%), $[\alpha]_D^{23}$ +23° (*c* 1, H_2O).

Found: C, 45.33; H, 7.49; N, 12.29%. Calcd for $C_{21}H_{41}N_5O_{11}\cdot 1/2H_2CO_3$: C, 45.26; H, 7.42; N, 12.27%.

The authors are grateful to Professor Hamao Umezawa, Director of Institute of Microbial Chemistry, for his support and encouragement.

(Received October 8, 1976)

2′-*N*-Acetyl-4′,6′-di-*O*-acetyl-3,3a-*O*-carbonyl-3′-deoxydihydrostreptobiosamine (**15**), a precursor in the synthesis of 3″-deoxydihydrostreptomycin, was prepared from benzyl α-dihydrostreptobiosaminide. The synthesis involves formation of L-allo compound (**5**) with inversion of the 3′-hydroxyl group of L-gluco derivative (**2**) in order to facilitate 3′-chlorination, dechlorination, of the 3′-chloro-L-gluco derivative (**7** or **11**) with tributyltin hydride, and utilization of cyclic 3,3a-*O*-carbonyl group instead of 3,3a-*O*-isopropylidene group which was unstable in the later reactions.

Recent studies have clarified that streptomycin is inactivated by resistant bacteria carrying R factor and resistant *Pseudomonas* producing enzymes which adenylylate[1] or phosphorylate[2] the 3″-hydroxyl group of the antibiotic. Removal of the 3″-hydroxyl group from dihydrostreptomycin is expected, therefore, to afford a dihydrostreptomycin derivative active against the resistant organisms. In this paper the synthesis of a key intermediate for the synthesis of 3″-deoxydihydrostreptomycin, namely, 4′,6′-di-*O*-acetyl-3′-deoxy-3,3a-*O*-carbonyldihydrostreptobiosamine** (**15**) starting from benzyl α-dihydrostreptobiosaminide is reported. The glycosyl chloride of **15** was successfully condensed with di-*N*-acetyl-di-*N*-benzyloxycarbonyl-4,5(5,6)-*O*-cyclohexylidenestreptidine[3] to give a condensation product which was led to 3″-deoxydihydrostreptomycin.[4]

Benzyl α-dihydrostreptobiosaminide[10] was treated with benzyl chloroformate to give the *N*-benzyloxycarbonyl derivative (**1**), which was converted to the di-*O*-isopropylidene derivative (**2**) by treatment with 2,2-dimethoxypropane in the presence of acidic catalyst. Thereafter, the free hydroxyl group at C-3′ of **2** was mesylated. Treatment of the 3′-*O*-mesyl derivative (**3**) with sodium iodide in *N*,*N*-dimethylformamide (DMF) afforded the *N*,*O*-carbonyl-L-allo derivative (**4**). It should be noted that, in the synthesis[5] of tobramycin, similar treatment of a structurally related compound having a 2,6-bis(ethoxycarbonylamino)-2,6-dideoxy-3-*O*-tosyl-α-D-glucopyranosyl moiety with sodium iodide in DMF gave a 3′-iodo derivative as a major product possibly with participation of the neighbouring ethoxycarbonyl group. It was further found that the derivative (**4**) was more easily obtained by alkaline treatment of **3** (86% yield). The L-allo structure of **4** was confirmed by the PMR spectra of **4** and **5** in which the $J_{2',3'}$ and $J_{3',4'}$ had suitable values (3—6 Hz) for *1C* L-allopyranoside.

Hydrolysis of the carbamate (**4**) with barium hydroxide gave **5**, which was acetylated to give **6**. It should also be noted that treatment of the 3′-*O*-mesyl derivative of **5** with sodium iodide in DMF gave no definite product. This result is unusual because, in a separate experiment,[6] we found that a 3-*O*-mesyl-D-allo compound, namely benzyl 4,6-*O*-benzylidene-2-benzyloxycarbonylamino-2-deoxy-3-*O*-mesyl-2-*N*-methyl-α-D-allopyranoside gave the corresponding 3-iodo derivative on treatment with 50% sodium iodide in DMF (100 °C, 48 h) in good yield.

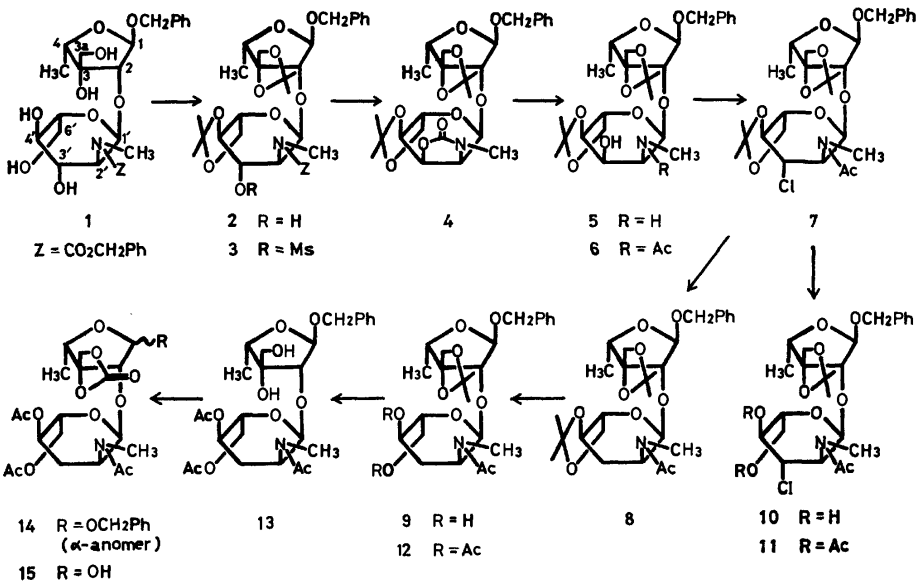
Treatment of **6** with sulfuryl chloride successfully gave 3′-chloro-L-gluco derivative (**7**) with inversion of the configuration at C-3′. The L-gluco configuration of **7** was confirmed by its PMR spectrum, in which the $J_{2',3'}$, gave 11.5 Hz, an indication that the 3′-chlorine is equatorial. At this stage, we have to mention that treatment of **2** with sulfuryl chloride gave no 3′-chloro derivative.

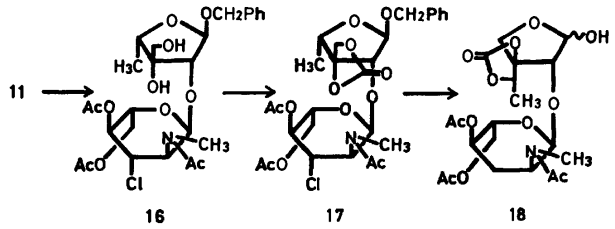
Catalytic hydrogenolysis of **7** with platinum oxide only recovered the starting material. Hydrogenolysis of **7** with palladium black gave a debenzylated product, while treatment with Raney nickel with addition of potassium hydroxide or triethylamine gave a dechlorodebenzylated product, both products being useless for the present synthesis. Reduction with tributyltin hydride[7] in the presence of α,α′-azobisisobutyronitrile successfully gave the 3′-deoxy compound (**8**) quantitatively. Its structure was confirmed by its PMR spectrum.

The deoxy derivative was modified to a derivative suitable for glycosylation. In the first place the 4′,6′-*O*-isopropylidene group of **8** was selectively removed to give **9**, which was then acetylated to give 4′,6′-di-*O*-acetyl derivative (**12**). This requirement originated from our experience in the synthesis of dihydrostreptomycin,[3,8,9] in which similar replacement of an isopropylidene group by two acyl groups gave a successful result. Alternatively, compound **12** was prepared from **7** by acid hydrolysis of **7** (which selectively removed the isopropylidene group at C-4′ and 6′ to give **10**) followed by acetylation to give **11** and dechlorination with tributyltin hydride.

The 3,3a-*O*-isopropylidene group of **12** was unstable for later treatment with thionyl chloride to prepare a glycosyl chloride; transketalization[8] was expected to occur in the dihydrostreptose moiety. The 3,3a-*O*-isopropylidene group of **12** was therefore removed by treatment with 75% acetic acid and the resulting diol

** In this paper, the dihydrostreptose moiety is taken as a parent monosaccharide and numbers of the carbon atoms of the 2-deoxy-2-methylamino-L-glucose moiety, the second monosaccharide, are primed and the hydroxymethyl carbon of dihydrostreptose moiety is numbered 3a.





(**13**) was treated with *p*-nitrophenyl chloroformate by a procedure previously described[8] to give the 3,3a-carbonate derivative (**14**). The presence of the cyclic carbonate group was confirmed by the absorption peak at 1810 cm^{-1} in the IR spectrum. Catalytic hydrogenolysis of the benzyl group with palladium black gave a masked derivative (**15**) of 3'-deoxydihydrostreptobiosamine. As separately reported,[4] the C-1 chloride of **15** was prepared and coupled[4] with a protected derivative[3] of streptidine and the condensation product was successfully led to 3"-deoxydihydrostreptomycin.[4]

In an alternative approach to **15** from **11**, deisopropylidenation of **11** gave the corresponding diol (**16**), which was converted into a 3,3a-carbonate (**17**). An attempt to prepare **15** from **17** by simultaneous removal of the 3'-chloro and 1-*O*-benzyl groups by catalytic hydrogenolysis, however, gave an unusual result. Treatment of **17** with Raney nickel and hydrogen gave **18**, an isomer of **15**. Its structure was confirmed by PMR spectroscopy. The methine proton signal at C-4 appeared as a quartet at a low field (δ 5.16), indicating that 4-hydroxyl group is acylated. This observation is another example which shows that the dihydrostreptose moiety is labile and tends to undergo ring-isomerization.

Experimental

General. Infrared spectra were recorded for potassium bromide pellets with a Hitachi Model 285 grating infrared spectrophotometer. PMR spectra were recorded at 60 and 100 MHz with Hitachi R-24A and Varian XL-100 spectrometers. Thin layer chromatography (TLC) was performed on Wakogel B-5 with sulfuric acid spray for detection. For column chromatography, silica gel (Wakogel C-200) was used.

Benzyl 2'-N-Benzyloxycarbonyl-α-dihydrostreptobiosaminide (1). To a mixture of benzyl α-dihydrostreptobiosaminide hydrochloride[10] (6.81 g) and sodium carbonate (3.23 g) in aqueous acetone (1: 1, 180 ml), benzyl chloroformate (4.6 ml) was added and the mixture was stirred at 0 °C for 5 h. The mixture was filtered and the filtrate was concentrated. The residue, after washing with ether, was dissolved in chloroform. Filtration followed by concentration gave a residue. Recrystallization from chloroform–ether gave needles, 5.56 g (67%), mp 152—152.5 °C, $[\alpha]_D^{24}$ −140° (*c* 1, $CHCl_3$).

Found: C, 59.57; H, 6.57; N, 2.54%. Calcd for $C_{28}H_{37}NO_{11}$: C, 59.67; H, 6.62; N, 2.49%.

Benzyl 2'-N-Benzyloxycarbonyl-3,3a: 4',6'-di-O-isopropylidene-α-dihydrostreptobiosaminide (2). To a solution of **1** (6.72 g) in DMF (120 ml), anhydrous *p*-toluenesulfonic acid (960 mg) and 2,2-dimethoxypropane (19.2 ml) were added and the solution was heated at 50 °C for 3 h. The solution was poured into a mixture of aqueous 5% sodium hydrogencarbonate solution (850 ml) and chloroform (850 ml) with vigorous stirring and the organic layer separated was concentrated to a syrup. The chloroform solution of the syrup was washed with water, dried (Na_2SO_4), and concentrated to give a syrup, which was chromatographed over silica gel (benzene–methyl ethyl ketone 9: 1) to give a thick syrup of **2**, 7.28 g (94%), $[\alpha]_D^{24}$ −117° (*c* 1, $CHCl_3$); PMR ($CDCl_3$) δ: 1.25 (3H d, CCH_3); 1.23, 1.3, 1.42, and 1.48 (each 3H s, $2C(CH_3)_2$); 3.06 (3H s, NCH_3), 4.56 (2H q, OCH_2Ph) 4.9—5.15 (4H, H-1,1' and CO_2CH_2Ph).

Found: C, 63.14; H, 6.94; N, 1.94%. Calcd for $C_{34}H_{45}NO_{11}$: C, 63.34; H, 7.19; N, 2.17%.

Benzyl 2'-N-Benzyloxycarbonyl-3,3a: 4',6'-di-O-isopropylidene-3'-O-mesyl-α-dihydrostreptobiosaminide (3). Compound **2** was treated with methanesulfonyl chloride in pyridine in a usual manner to give a thick syrup of **3**, 99%, $[\alpha]_D^{24}$ −95° (*c* 1, $CHCl_3$); PMR ($CDCl_3$) δ: 3.07 and 3.10 (each 3H s, NCH_3 and SO_2CH_3).

Found: C, 58.03; H, 6.50; N, 1.99; S, 4.66%. Calcd for $C_{35}H_{47}NO_{13}S$: C, 58.24; H, 6.56; N, 1.94; S, 4.44%.

Benzyl 2-O-(2,3-N,O-Carbonyl-2-deoxy-4,6-O-isopropylidene-2-methylamino-α-L-allopyranosyl)-3,3a-O-isopropylidene-α-dihydrostreptoside (4). A solution of **3** (8.14 g) and sodium

acetate trihydrate (8.14 g) in 2-methoxyethanol (160 ml) was refluxed for 65 h. Evaporation of the solvent gave a solid, which was dissolved in chloroform. The solution was washed with water, dried (Na_2SO_4), and concentrated to give a solid. Recrystallization from ethanol gave prisms, 5.17 g (86%), mp 170.5—172 °C, $[\alpha]_D^{24}$ −171° (*c* 1, $CHCl_3$); IR: 1760 cm^{-1} (cyclic carbamate); PMR ($CDCl_3$) δ: 1.29 (3H, d J=6.5 Hz, CCH_3; collapsed to a singlet on irradiation at 4.05); 1.40 (6H), 1.45 (3H) and 1.50 (3H) (each s, $2C(CH_3)_2$); 3.00 (3H s, NCH_3), 3.5—3.9 (6H), 4.05 (1H q, J=6.5 Hz, H-4; collapsed to a singlet on irradiation at δ 1.29); 2H AB q centered at δ 4.07 (J=9 Hz, H-3a); 4.54 (1H q, J=3 and 6 Hz, H-3′; collapsed to a singlet on irradiation at δ ≈3.84 (H-2′,4′)); 2H AB q centered at δ 4.54 (OCH_2Ph); 5.04 (1H d, J≈1 Hz, H-1), 5.12 (1H d, J=5 Hz, H-1′), 7.27 (5H s, Ph). The doublets of H-1 and H-1′ were collapsed to singlets, respectively, on irradiation at δ ≈3.84, therefore, the signals at δ ≈3.84 were assigned to H-2, 2′,4′.

Found: C, 60.37; H, 6.87; N, 2.45%. Calcd for $C_{27}H_{37}NO_{10}$: C, 60.55; H, 6.96; N, 2.62%.

Benzyl 2-O-(2-Deoxy-4,6-O-isopropylidene-2-methylamino-α-L-allopyranosyl)-3,3a-O-isopropylidene-α-dihydrostreptoside (5). To a solution of **4** (4.74 g) in methanol (120 ml), 5.5% aqueous barium hydroxide (120 ml) was added and the mixture was stirred at 50 °C for 110 h. Filtration followed by evaporation of the filtrate gave a residue, which was extracted with chloroform. The solution was washed with water, dried (Na_2SO_4), and concentrated to give a thick syrup, which was crystallized from ether to give needles, 3.39 g (75%), mp 110—111 °C, $[\alpha]_D^{24}$ −131° (*c* 1, $CHCl_3$); PMR ($CDCl_3$) δ: 1.28 (3H d, CCH_3); 1.42 (3H) and 1.47 (9H) (each s, $2C(CH_3)_2$); 2.46 (3H s, NCH_3), 5.03 (1H d, J=4 Hz, H-1′), 5.05 (1H s, H-1). When measured in $CDCl_3$–D_2O, an 1H triplet ($J_{1',2'}=J_{2',3'}$ ≈3.5 Hz, H-2′) appeared at δ 2.65 and it was collapsed to a doublet on irradiation at δ 5.03.

Found: C, 61.31; H, 7.73; N, 2.66%. Calcd for $C_{26}H_{39}NO_9$: C, 61.28; H, 7.71; N, 2.75%.

Benzyl 2-O-(2-Acetamido-2-deoxy-4,6-O-isopropylidene-2-N-methyl-α-L-allopyranosyl)-3,3a-O-isopropylidene-α-dihydrostreptoside (6). To a solution of **5** (652 mg) in methanol (17.5 ml), acetic anhydride (0.28 ml) was added and the solution was kept at room temperature overnight. Concentration of the solution gave a syrup, which was dissolved in chloroform. The solution was washed with water, dried (Na_2SO_4), and evaporated to give a thick syrup, 659 mg (93%), $[\alpha]_D^{23}$ −132° (*c* 1.3, $CHCl_3$); IR: 1650 cm^{-1}; PMR ($CDCl_3$) δ: 2.12 (3H s, Ac), 3.38 (3H s, NCH_3).

Found: C, 60.75; H, 7.32; N, 2.35%. Calcd for $C_{28}H_{41}NO_{10}$: C, 60.96; H, 7.49; N, 2.54%.

Benzyl 2′-N-Acetyl-3′-chloro-3′-deoxy-3,3a: 4′,6′-di-O-isopropylidene-α-dihydrostereptobiosaminide (7). To a cold solution (−5 °C) of **6** (487 mg) in dichloromethane (5.3 ml), pyridine (0.9 ml) and sulfuryl chloride (0.35 ml) were added and the solution was kept in the cold for 18 h and then at 5 °C for 25 h. The solution was poured into a mixture of chloroform (90 ml) and saturated sodium hydrogencarbonate solution (90 ml) with vigorous stirring and the organic layer separated was dried (Na_2SO_4). Concentration gave a reddish-brown syrup, which was chromatographed over silica gel (benzene–methyl ethyl ketone 9: 1) and the fractions containing **7** were concentrated to give a reddish syrup (334 mg). Recrystallization from ether gave colorless prisms, 284 mg (56%), mp 170—171.5 °C, $[\alpha]_D^{24}$ −129° (*c* 1, $CHCl_3$). PMR ($CDCl_3$) δ: 1.26 (3H d, J=6.5 Hz, CCH_3); 1.36, 1.38, 1.47, and 1.51 (each 3H s, $2C(CH_3)_2$); 2.13 (3H s, Ac), 3.06 (3H s, NCH_3), 3.80 (1H d, J≈1 Hz, H-2; collapsed to a singlet on irradiation at δ 4.98 (H-1)); 3.83, 3.93, 4.14, and 4.23 (2H, AB q, H-3a); 4.38, 4.50, 4.65, and 4.77 (2H AB q, OCH_2Ph); 4.90 (1H q, J=3.5 and 11.5 Hz, H-2′; collapsed to a doublet (J=3.5 Hz) on irradiation at δ 4.15 (H-3′)), 4.98 (1H s, H-1; on irradiation at δ 3.80 (H-2), the signal sharpened), 5.08 (1H d, J=3.5 Hz, H-1′), 7.30 (5H s, Ph).

Found: C, 58.87; H, 7.00; N, 2.33; Cl, 6.38%. Calcd for $C_{28}H_{40}NO_9Cl$: C, 58.99; H, 7.07; N, 2.46; Cl, 6.22%.

Benzyl 2′-N-Acetyl-3′-deoxy-3,3a: 4′,6′-di-O-isopropylidene-α-dihydrostreptobisaminide (8). To a solution of **7** (1.01 g) in dry toluene (21 ml), tributyltin hydride (1.0 ml) and α,α′-azobisisobutyronitrile (10 mg) were added under the atmosphere of nitrogen and the solution was heated at 80 °C for 2 h. Concentration of the solution gave a syrup, which was chromatographed over silica gel (benzene–methyl ethyl ketone 4: 1). The fraction containing **8** were concentrated to give a thick syrup, 935 mg (99%), $[\alpha]_D^{25}$ −100° (*c* 1, $CHCl_3$); PMR ($CDCl_3$) δ: 1.27 (3H d, J=6.5 Hz, CCH_3); 1.36, 1.38, 1.42, and 1.50 (each 3H s, $2C(CH_3)_2$; 1.80 (1H double t, J≈4, ≈4, and 11 Hz, H-3′$_{eq}$; on irradiation at δ 3.8, the sextet collapsed to a quartet (J≈4 and 11 Hz (J_{gem})), 2.09 (3H s, Ac), 3.01 (3H s, NCH_3).

Found: C, 62.47; H, 7.46; N, 2.46%. Calcd for $C_{28}H_{41}NO_9$: C, 62.79; H, 7.72; N, 2.62%.

Benzyl 2′-N-Acetyl-3′-deoxy-3,3a-O-isopropylidene-α-dihydrostreptobiosaminide (9). A solution of **8** (932 mg) in 25% acetic acid in methanol (34 ml) was refluxed for 50 min. Concentration of the solution gave a syrup, which was chromatographed over silica gel (benzene–ethanol 9: 1) to give a thick syrup of **9**, 821 mg (95%), $[\alpha]_D^{25}$ −161° (*c* 1, $CHCl_3$).

Found: C, 60.36; H, 7.31; N, 2.75%. Calcd for $C_{25}H_{37}NO_9$: C, 60.59; H, 7.53; N, 2.83%.

Benzyl 2′-N-Acetyl-3′-chloro-3′-deoxy-3,3a-O-isopropylidene-α-dihydrostreptobiosaminide (10). A solution of **7** (284 mg) in 25% acetic acid in methanol (10 ml) was refluxed for 3 h. Concentration of the solution *in vacuo* gave a syrup. It showed, on TLC (benzene–ethanol 9: 1), spots of R_f 0.15 (very slight), 0.3 (**10**), and 0.45 (very slight, **7**). The syrup was chromatographed over silica gel (benzene–ethanol 12: 1) to give a colorless thick syrup, 253 mg (96%), $[\alpha]_D^{24}$ −148° (*c* 1, $CHCl_3$).

Found: C, 56.36; H, 6.92; N, 2.34; Cl, 6.92%. Calcd for $C_{25}H_{36}NO_9Cl$: C, 56.65; H, 6.85; N, 2.64; Cl, 6.69%.

Benzyl 2′-N-Acetyl-4′,6′-di-O-acetyl-3′-chloro-3′-deoxy-3,3a-O-isopropylidene-α-dihydrostreptobiosaminide (11). To a solution of **10** (215 mg) in pyridine (6 ml), acetic anhydride (0.13 ml) was added and the solution was kept at room temperature overnight. Water (0.1 ml) was added and the solution was concentrated. The chloroform solution of the residual syrup was successively washed with aqueous sodium hydrogencarbonate solution, aqueous potassium hydrogensulfate solution, and water, dried (Na_2SO_4), and concentrated to give a syrup of **11**, 236 mg (94%), $[\alpha]_D^{25}$ −84° (*c* 2, $CHCl_3$); PMR ($CDCl_3$) δ: 1.36 (6H s, $C(CH_3)_2$), 2.03 (3H s, Ac), 2.11 (6H s, Ac), 3.00 (3H s, NCH_3).

Found: C, 56.46; H, 6.49; N, 2.16; Cl, 5.86%. Calcd for $C_{29}H_{40}NO_{11}Cl$: C, 56.72; H, 6.57; N, 2.28; Cl, 5.77%.

Benzyl 2′-N-Acetyl-4′,6′-di-O-acetyl-3′-deoxy-3,3a-O-isopropylidene-α-dihydrostreptobisaminide (12). *From 11*: To a solution of **11** (2.04 g) in dry toluene (39 ml), tributyltin hydride (1.9 ml) and α,α′-azobisisobutyronitrile (19 mg) were added and the solution was treated similarly as described for **8**. Column chromatography over silica gel (benzene–methyl ethyl ketone 6: 1) gave an amorphous solid of **12**, 1.81 g (94%), $[\alpha]_D^{25}$ −140° (*c* 1, $CHCl_3$); PMR ($CDCl_3$) δ: 1.29 (3H d, CCH_3), 1.40 (6H s, $C(CH_3)_2$), 2.09 (6H s, Ac), 2.11 (3H s, Ac), 3.00 (3H s, NCH_3).

Found: C, 60.27; H, 7.16; N, 2.38%. Calcd for $C_{29}H_{41}$-

NO_{11}: C, 60.09; H, 7.13; N, 2.42%.

From ***9***: Compound **9** was treated with acetic anhydride in pyridine to give **12** in a 98% yield.

*Benzyl 2'-*N*-Acetyl-4',6'-di-*O*-acetyl-3'-deoxy-α-dihydrostreptobiosaminide (**13**).* A solution of **12** (1.73 g) in 75% acetic acid (43 ml) was heated at 80 °C for 3 h. Concentration of the solution gave a syrup, which was chromatographed over silica gel (benzene–ethanol 9: 1) to give **12** (470 mg, 27%) and **13**. The latter was recrystallized from ether to give needles, 811 mg (51%), mp 157—159 °C, $[\alpha]_D^{25}$ −169° (*c* 1, $CHCl_3$); PMR ($CDCl_3$) δ: 2.00, 2.06, and 2.09 (each 3H s, Ac).

Found: C, 57.82; H, 6.87; N, 2.51%. Calcd for $C_{26}H_{37}NO_{11}$: C, 57.87; H, 6.91; N, 2.60%.

*Benzyl 2'-*N*-Acetyl-4',6'-di-*O*-acetyl-3,3a-*O*-carbonyl-3'-deoxy-α-dihydrostreptobiosaminide (**14**).* To a solution of **13** (251 mg) in pyridine (7.5 ml), *p*-nitrophenyl chloroformate (115 mg) was added and the mixture was stirred at room temperature. Triethylamine (0.16 ml × 3) and the chloride (230 mg × 3) were added alternately in every 5 h. After 35 h, chloroform (80 ml) was added and the solution was washed with aqueous sodium hydrogencarbonate solution and water throughly, dried (Na_2SO_4), and concentrated to give a yellow syrup. Column chromatography over silica gel (benzene–methyl ethyl ketone 3: 1) gave a thick syrup of **14**, 225 mg (85%), R_f 0.35 (TLC, benzene–ethanol 9: 1), $[\alpha]_D^{25}$ −144° (*c* 1, $CHCl_3$). IR: 1810 (carbonate), 1740 (ester), 1640 (amide) cm^{-1}. PMR ($CDCl_3$) δ: 1.34 (3H d, CCH_3); 2.02, 2.07, 2.12 (each 3H s, Ac), 2.94 (3H s, NCH_3), 4.96 (1H d, J=3 Hz, H-1 or 1'), 5.19 (1H d, J=3 Hz, H-1' or 1; on irradiation at δ 4.24, the doublet collapsed to a singlet).

Found: C, 57.47; H, 6.21; N, 2.29%. Calcd for $C_{27}H_{35}NO_{12}$: C, 57.34; H, 6.24; N, 2.48%.

*2'-*N*-Acetyl-4',6'-di-*O*-acetyl-3,3a-*O*-carbonyl-3'-deoxydihydrostreptobiosamine (**15**).* Compound **14** was hydrogenated with palladium black in a usual manner to give **14** as a syrup in a yield of 96%, $[\alpha]_D^{25}$ −141°→−127° (*c* 1, $CHCl_3$). IR: 1820, 1740, 1640 cm^{-1}. PMR ($CDCl_3$) δ: 1.30 and 1.40 (totally 3H d in the ratio of ≈3: 1, J=6 Hz, CCH_3), 2.06 (6H s, OAc), 2.13 (3H s, NAc (?)), 2.95 (3H s, NCH_3), 5.39 (≈1H d, J=4 Hz, H-1 (?)).

Found: C, 49.67; H, 6.27; N, 2.51%. Calcd for $C_{20}H_{29}NO_{12}\cdot 0.5H_2O$: C, 49.58; H, 6.24; N, 2.89%.

*Benzyl 2'-*N*-Acetyl-4',6'-di-*O*-acetyl-3'-chloro-3'-deoxy-α-dihydrostreptobiosaminide (**16**).* Prepared from **11** in a similarn manner as described for **13** to give a thick syrup of **16** in a 77% yield, $[\alpha]_D^{23}$ −144° (*c* 2, $CHCl_3$).

Found: C, 54.34; H, 6.14; N, 2.24; Cl, 6.32%. Calcd for $C_{26}H_{36}NO_{11}Cl$: C, 54.40; H, 6.32; N, 2.44; Cl, 6.18%.

*Benzyl 2'-*N*-Acetyl-4',6'-di-*O*-acetyl-3,3a-*O*-carbonyl-3'-chloro-3'-deoxy-α-dihydrostreptobiosaminide (**17**).* Prepared from **16** in a similar manner as described for **14** to give a thick syrup of **17** in a 87% yield, $[\alpha]_D^{24}$ −126° (*c* 1, $CHCl_3$).

Found: C, 54.21; H, 5.72; N, 2.16; Cl, 6.00%. Calcd for $C_{27}H_{34}NO_{12}Cl$: C, 54.05; H, 5.71; N, 2.33; Cl, 5.91%.

*Hydrogenolysis of **17** with Raney Nickel to **18**.* A solution of **17** (28 mg) in aqueous dioxane (1: 10, 1 ml) was hydrogenated under pressure (50 lb/in²) with Raney nickel at room temperature for 26 h. Filtration followed by concentration of the filtrate gave colorless needles, which was filtered with aid of benzene to give **18**, 17 mg (66%), mp 188—190 °C, $[\alpha]_D^{25}$ −78° (final value, *c* 0.5, $CHCl_3$); IR: 1810, 1770 (sh), 1740, 1620 cm^{-1}. PMR ($CDCl_3$+CD_3OD) δ: 1.52 (3H d, J=7 Hz, $CHCH_3$); 2.09, 2.10, and 2.13 (each 3H s, Ac); 2.98 (3H s, NCH_3), 5.01 (1H d, J=3.5 Hz, H-1'; it collapsed to a singlet on irradiation at δ 4.61), 5.16 (1H q, J=7 Hz, $CHCH_3$; it collapsed to a singlet on irradiation at δ 1.52).

Found: C, 49.52; H, 6.52; N, 2.89%. Calcd for $C_{20}H_{29}NO_{12}\cdot 0.5H_2O$: C, 49.58; H, 6.24; N, 2.89%.

A Semi-empirical Calculation of the Substituent Effects on the ^1H Chemical Shifts of 1-Substituted Naphthalenes[1,2]

Jun NIWA

College of General Education, Nagoya University, Chikusa, Nagoya 464

(Received October 13, 1976)

A semi-empirical equation for predicting the ^1H chemical shift induced by substituents in an aromatic system (J. Niwa, *Bull. Chem. Soc. Jpn.*, **48**, 118, 1637 (1975)) has been applied to the ring protons of 1-substituted naphthalenes. The predictions of the equation are tested against the available experimental data for six representative substituents and are also compared with those of the electric-field model.

The ^1H chemical shifts of a number of 1-substituted naphthalenes have been examined by Emsley, Lindon, Salman, and Clark[3] in the light of some simple theories of the origins of substituent-induced chemical shifts (SCS). They have separately assessed the following models as the main factors governing the SCS values: (i) the local diamagnetic term of the relevant hydrogen atom; (ii) the magnetic anisotropy of the substituent group, calculated by using the expression developed by Pople for the paramagnetic part of the magnetic anisotropic tensor;[4] (iii) the empirically established correlation between the SCS values and changes in the π or total electron density on the attached carbon atom;[5] (iv) the modified equation of the correlation between the SCS values and changes in the π electron density, where the π electron densities on the attached and the next neighbor carbon atoms are considered,[6] and (v) the electric-field model derived by Buckingham.[7] It has been indicated by them that, although no one simple model can predict the SCS values of all the protons of 1-substituted naphthalenes, it is possible to predict some of the larger effects and to relate them to the structure, and that the electric-field model gives the best overall agreement with the observed SCS values.

In our preceding papers,[1,2] we derived a semi-empirical equation (Eq. 2) for obtaining the SCS values of protons in substituted aromatic side-chains[1] and monosubstituted benzenes[2] by considering the ring-current effect ($\sigma^{A,ring}$) in addition to the diamagnetic term of the hydrogen atom, A (σ^{AA}_{dia}), in the C–H bond in question and that from its bonded carbon atom, B (σ^{AB}_{dia}):

$$\delta_{calcd}(\equiv\Delta\sigma^A) = \Delta\sigma^{AA}_{dia} + \Delta\sigma^{AB}_{dia} + \Delta\sigma^{A,ring} \quad (1)$$

$$= a\Delta q^A + b\Delta q^B - 0.4f(\rho, z)|\sigma_\pi| \quad (2)$$

where the Δq's are the increments in electron densities on specified atoms, where a and b are, respectively, the constants particular to the hydrogen atom and the C–H bond, and where the third term is the modified Johnson and Bovey ring-current shift.[8] We showed that Eq. 2 could reasonably reproduce the observed SCS values of protons in the aromatic side-chains and the benzenes.

The aim of the present paper is to demonstrate the validity of the predictions by Eq. 2 for a variety of substituents in the series of 1-substituted naphthalenes, to examine the range of applicability of this approach, and to determine its limitations. The advantage of the naphthalenes in examining the success of Eq. 2 is that they have seven protons situated in different magnetic environments. Second, we will discuss which approach, Eq. 2 or the electric-field model, is more appropriate for understanding and predicting the SCS values in 1-substituted naphthalenes.

Results and Discussion

The local diamagnetic term, σ^{AA}_{dia}, of the hydrogen atom of naphthalene has been calculated by using the expression given by Kajimoto and Fueno.[9] The calculated values of σ^{AA}_{dia}, relative to the unsubstituted compound, are linearly correlated with the increments in electron densities on the hydrogen atoms:

$$\Delta\sigma^{AA}_{dia} = 16.1\Delta q^A. \quad (3)$$

The diamagnetic contribution from the bonded carbon (σ^{AB}_{dia}) in the case of naphthalene can be calculated in the same way as in the cases of olefinic compounds[1] and benzenes,[2] because the C–H bond length is taken to be 1.08 Å and the ring proton also bonds to the sp^2-hybridized carbon atom. Thus, the σ^{AB}_{dia} term, relative to the unsubstituted compound, becomes:

$$\Delta\sigma^{AB}_{dia} = 8.70\Delta q^B. \quad (4)$$

The paramagnetic term, σ^{AB}_{para}, of the B atom has been calculated according to Pople's expression.[4] It remains almost constant for the series of 1-substituted naphthalenes so long as we assume the same average excitation energy and the same value of the integral $\langle r_{AB}^{-3}\rangle$. Accordingly, we can ignore the contribution of the paramagnetic term to the SCS.

In order to estimate the contribution of the ring-current effect ($\sigma^{A,ring}$) to the ring proton of naphthalenes, we have used the ring-current model presented by Pople,[10] as Fig. 1 illustrates. The contribution of the "quinonoid" structure due to the introduction of a substituent into the A ring causes the decrease in the

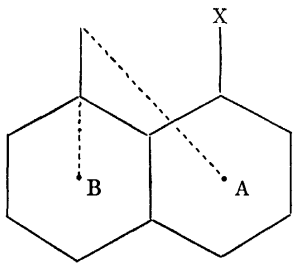

Fig. 1. The ring-current model for 1-substituted naphthalenes.

ring-current on the A ring. This contribution can be expressed by Eq. 5, which was derived for the ^1H chemical shifts in aromatic side-chains:[1,11]

$$\Delta\sigma^{A\text{-}ring} = -0.4f(\rho, z)|\sigma_\pi| \quad (5)$$

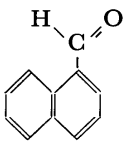
where $f(\rho, z)$ is the Johnson and Bovey ring-current shift in ppm, which is expressed as a function of the geometric factors for the proton located at the cylindrical co-ordinates, ρ and z, and where σ_π is the Yukawa-Tsuno parameter for measuring the resonance ability of the substituent. The "quinonoid" structure of the A ring may secondarily induce the localization of the π-electron system of the B ring. We may assume that the change in the ring-current induced on the B ring can be ignored, because the secondary effect may be considered to be very small compared with the contribution of the "quinonoid" structure of the A ring to the SCS value. Then, the ring-current effect due to the B ring cancels out the other in the calculation of the relative contribution of the ring-current effects in 1-substituted naphthalenes. Therefore, Eq. 5 can be applied, just as it is, to all the protons of the naphthalenes.

By combining Eqs. 3, 4 and 5, we obtain the following equation for the SCS of 1-substituted naphthalenes:

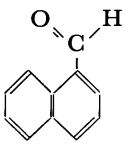
$$\delta_{calcd} = 16.1\Delta q^A + 8.70\Delta q^B - 0.4f(\rho, z)|\sigma_\pi|. \quad (6)$$

The value of $f(\rho, z)$ for each proton of the naphthalenes has been graphically estimated by utilizing the table of the Johnson and Bovey ring-current shift.[8] The values of $f(\rho, z)$ obtained are -1.50 ppm for the 2-, 3- and 4-protons, -0.60 ppm for the 5- and 8-protons, and -0.23 ppm for the 6- and 7-protons.

The geometry of naphthalene used in the calculation and that of the substituent group are taken from the standard compilations.[12] The molecules of 1-nitronaphthalene, 1-naphthylamine, 1-naphthol, and 1-naphthaldehyde are assumed to be planar. The stable conformation of 1-naphthaldehyde may be I or II, or some equilibrium between the two. The calculation of the chemical shifts has been performed for both the I and II forms.

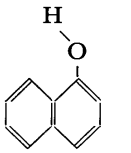


I

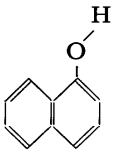


II

The 1-naphthol molecule may exist as an equilibrium between the two conformers, III and IV. These two conformers, however, give virtually identical predicted chemical shifts.



III



IV

In evaluating the first and second terms of Eq. 1, we have used the CNDO/2 formalism. In Table 1, the SCS values calculated by Eq. 6 are compared with the observed values. In Fig. 2, plots of the observed SCS

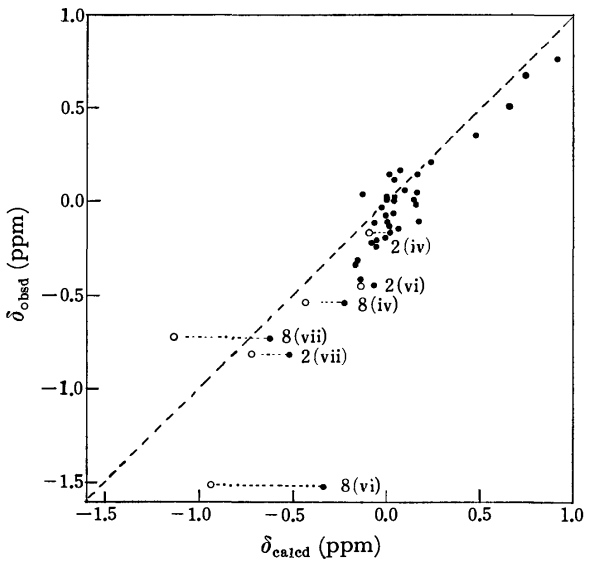


Fig. 2. Plots of δ_{obsd} against δ_{calcd} for ring protons of 1-substituted naphthalenes.
Numbered points correspond to entries in Table 1. Open circles are plotted against the chemical shifts corrected for the anisotropy effects of the substituent groups.

values are shown against the calculated shifts. As may clearly be seen from Fig. 2, the calculated chemical shifts can reasonably reproduce the overall aspect of the SCS. However, Fig. 2 shows that Eq. 6 can not sufficiently reproduce such major features of the SCS as the large negative values for the 8-proton of 1-naphthaldehyde. In deriving Eq. 6, the long-range shielding effect of the substituent group has not been taken into consideration. Therefore, the magnetic anisotropy effect should also be considered for the 2- and 8-protons in the neighborhood of a substituent group which has a large magnetic anisotropy, as in the cases of 1-chloronaphthalene, 1-naphthaldehyde, and 1-nitronaphthalene.*

Unfortunately, no theoretical and empirical estimations of the magnetic anisotropy effects of these substituent groups are yet completely settled. The point magnetic dipole approximation[13] is quantitatively not always reliable for the proton in the nearest neighborhood of the substituent group. Nevertheless, it may provide a qualitative basis for the discussion of the long-range shielding.

In the cases of 1-chloronaphthalene and 1-naphthaldehyde, we have attempted to estimate the magnetic

* On the whole, Eq. 6 correctly reproduces the SCS value of the 4-proton for the electron-donating substituent better than that for the electron-withdrawing substituent. A similar trend has also been obtained in the case of benzene.[2] The insufficiency of Eq. 6 for the 3-proton may be mainly attributed to ignoring the magnetic contributions from carbon atoms neighboring the B atom, but that for the electron-withdrawing substituent may not be attributed to ignoring the magnetic anisotropy of the substituent group, because the anisotropy effect on the 3- and 4-protons is too small to correct the calculated SCS to the observed SCS. Accordingly, this shortcoming of Eq. 6 may show an inherent limitation of the present calculation.

a) All the values are relative to the unsubstituted compound. b) All the electron densities are calculated by the CNDO/2 method. The electron densies of naphthalene are: q^{A} (the 1-proton)=1.0056, q^{A} (the 2-proton)=1.0108; q^{B} (the 1-carbon)=4.0070, q^{B} (the 2-carbon)=3.9908 c) Cited from Ref. 3. The chemical shifts were measured in 5 mol% in CCl_4.

TABLE 2. THE MAGNETIC ANISOTROPY EFFECTS OF FORMYL, NITRO, AND CHLORO GROUPS ON THE 2- AND 8-PROTONS

Substituent	χ_x ($\times 10^{-30}$ cm^3 esu)	χ_y	χ_z	2-proton (ppm)	8-proton (ppm)
CHO(form I)[14]	28.8	34.6	18.0	−0.45	−0.08
CHO(form II)[14]	28.8	34.6	18.0	−0.04	−0.59
NO_2[16]	−18	−3.3	−23	−0.16	−0.54
		$\Delta\chi$			
Cl[12]		−7.5		−0.09	−0.16

a) x is in the direction of the C=O bond for the formyl group and in that of the C–N bond for the nitro group, and y and z are in- and out-of-plane respectively.

anisotropy effect on the 2- and 8-protons by using the values of the magnetic susceptibilities given by McConnell for the chlorine atom[12] and those given by Pople for the carbonyl group.[14] The respective values of the anisotropy effects obtained on the 2- and 8-protons are listed in Table 2. When these anisotropy effects are taken into account, the predicted SCS values in 1-naphthaldehyde become, respectively, −0.8 and −0.1 ppm for the 2- and 8-protons of Form I, while those of Form II become, respectively, −0.1 and −0.9 ppm. This result predicts that Form I may cause the considerable low-field shift in the 2-proton, whereas Form II causes that in the 8-proton. The present approach favors Form II over Form I for the aldehyde on the basis of the predicted SCS values for the 2- and 8-protons. Recently Hatano has indicated, on the basis of NMR measurements with the paramagnetic reagent technique, that Form II may be the stable conformer.[15] The present result corresponds with his indication.

With respect to the magnetic anisotropy of the nitro group, no theoretical estimation has been presented. Therefore, we have attempted to estimate the anisotropy effect by utilizing the values of the magnetic susceptibilities empirically obtained by Yamaguchi, who investigated the magnetic anisotropy effect of the nitro group on ortho methyl groups in nitrobenzene derivatives.[16] The values obtained for the 2- and 8-protons are shown in Table 2.

Emsley *et al.* have indicated that, among the simple models which they have assessed, the electric-field model (Eq. 7) gives the best overall agreement with the observed SCS values.[3] The electric-field model given by Buckingham[7] is:

$$\sigma_E = -AE_z, \tag{7}$$

where A is calculated to be about 2×10^{-12} esu. E_z arises from point charges located on atoms; then E_z is given classically by Eq. 8, where q_B is the atomic charge:

$$E_z = \sum_{A\neq B} q_B \cos\theta_{AB}/r_{AB}^2. \tag{8}$$

The θ_{AB} angle is that between the C–H and r_{AB}. In deriving Eq. 7, the rough approximation is originally used. Moreover, Emsley *et al.* introduced some assumption in applying Eq. 8 to the naphthalenes; they rather arbitrarily restricted the summation in Eq. 8 to charges which neighbor the proton, because of the difficulty of knowing how electric fields are transmitted within

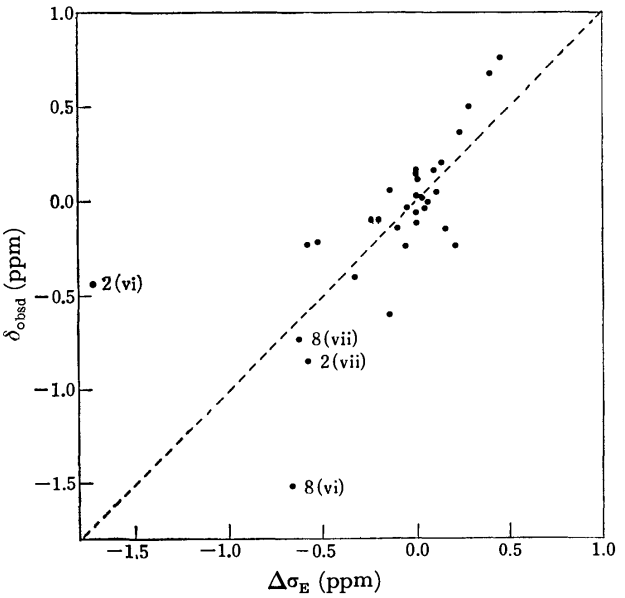

Fig. 3. Plots of δ_{obsd} against $\Delta\sigma_E$ calculated by Emsley *et al.*[3]
Numbered points correspond to entries in Table 1.

molecules.[3] The SCS values, $\Delta\sigma_E$, calculated by them are cited in Table 1. The correlation between the observed and the calculated SCS values is shown in Fig. 3. A comparison of Fig. 2 with Fig. 3 clearly shows that Eq. 6 can more correctly reproduce the observed SCS values than the electric-field model, even though Eq. 6 can not sufficiently reproduce the chemical shift of the 8-proton of 1-naphthaldehyde.

When the anisotropy effects are taken into consideration for the substituent groups, Cl, CHO, and NO_2, the shortcoming of Eq. 6 for the 2-protons of 1-chloronaphthalene, 1-naphthaldehyde, and 1-nitronaphthalene seems to be reasonably improved. However, the corrected chemical shift of the 8-proton of 1-nitronaphthalene seems to be overestimated, while that of 1-naphthaldehyde can not still sufficiently reproduce the observed SCS value. The improvement of Eq. 6 for the 8-protons of the two compounds remains a subject of future research, along with the exact estimation of the magnetic anisotropy effects of the substituent groups.

The CNDO/2 calculations were carried out on a FACOM-230 60 computer at the Nagoya University Computation Center.

Reaction of Carbon Dioxide with Tetraphenylporphinatoaluminium Ethyl in Visible Light

Shohei INOUE and Norikazu TAKEDA

Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received October 12, 1976)

Tetraphenylporphinatoaluminium ethyl reacts with carbon dioxide in the presence of 1-methylimidazole to produce tetraphenylporphinatoaluminium propionate in the presence of visible light but not in the dark.

In the photosynthesis of green plants, carbon dioxide is fixed and reduced by species activated by the energy of light in visible region of the spectrum which is absorbed by and transferred from chlorophylls——a dihydroporphyrin system. In this connection, the reaction of carbon dioxide with species activated by visible light is very interesting.

In the course of the present study on the reaction of carbon dioxide with organometallic compounds and related systems,[1-3] it was found that the reaction of $\alpha,\beta,\gamma,\delta$-tetraphenylporphinatoaluminium ethyl with carbon dioxide was induced by visible light in the presence of 1-methylimidazole.

Experimental

Materials. $\alpha,\beta,\gamma,\delta$-Tetraphenylporphine ($TPPH_2$) was synthesized from pyrrole and benzaldehyde in propionic acid.[4] Contaminated $\alpha,\beta,\gamma,\delta$-tetraphenylchlorin was transformed into $TPPH_2$ using 2,3-dichloro-5,6-dicyanobenzoquinone in boiling methylene chloride.[5]

1-Methylimidazole was prepared by the alkylation of imidazole with methyl iodide in liquid ammonia.[6]

Carbon dioxide was purified upon passage through a series of columns packed with cupric sulfate, potassium bicarbonate, reduced copper, phosphorous pentoxide and activated cupric oxide.

Methylene chloride was washed with sulfuric acid followed by water, dried over calcium chloride and then calcium hydride, and distilled over calcium hydride in a nitrogen atmosphere. Benzene was washed with sulfuric acid and then with water, dried over calcium chloride, and distilled in the presence of sodium wire in a nitrogen atmosphere.

Triethylaluminium was purified by distillation under reduced pressure (111 °C/24 Torr).

Procedure. Formation of Tetraphenylporphinatoaluminium Ethyl (TPPAlEt) by the Reaction of Tetraphenylporphine ($TPPH_2$) with Triethylaluminium: The reaction of $TPPH_2$ and triethylaluminium was carried out in a quartz cell having four flat faces (2.5×2.5×4.0 cm) fitted with a three-way cock. The cell containing $TPPH_2$ (0.92 g, 1.5 mmol) was purged with nitrogen and a solvent (20 ml) was added to dissolve the $TPPH_2$. Triethylaluminium (0.21 ml, 1.5 mmol) was added slowly to the solution using a syringe from the three-way cock in a nitrogen stream at room temperature. The reaction of $TPPH_2$ with triethylaluminium was completed within a few minutes under the evolution of two equivalent amounts of ethane (Fig. 1) which was identified by gas chromatography and measured volumetrically by a mercury-sealed gas burette. By adding an excess of hydrochloric acid to this reaction mixture, a stoichiometric amount of ethane to aluminium was evolved, indicating the existence of one ethyl-aluminium bond.

In the ^1H NMR spectra of the reaction mixture, the ratio of phenyl protons (δ=8.22 ppm (ortho) and δ=7.85 ppm (meta and para)) to β-protons on the pyrrole ring (δ=9.05 ppm) of the porphine was found to be 5:2, excluding the possibility of the reaction of triethylaluminium with the C–H protons of the porphine ring. Methylene (-aluminium) and methyl signals are found at δ=−6.35 ppm (quartet) and δ=−3.40 ppm (triplet), respectively, which occur for a much higher magnetic field compared with the methylene (δ=0.46 ppm) and methyl (δ=1.26 ppm) signals of triethylaluminium. This fact clearly indicates that the ethyl group is attached to the aluminium atom as an axial ligand and is affected by the ring current of the porphine ring.

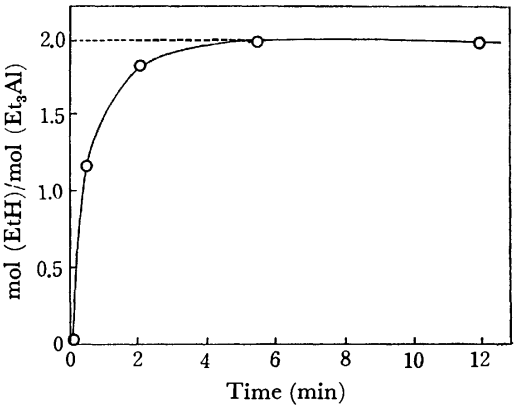

Fig. 1. Reaction of tetraphenylporphine($TPPH_2$) and triethylaluminium(Et_3Al), $TPPH_2$; 1.8 mmol, Et_3Al; 1.8 mmol, CH_2Cl_2; 30 ml, temp; 30 °C.

From these results, $TPPH_2$ and triethylaluminium are considered to react to form tetraphenylporphinatoaluminium ethyl (TPPAlEt):

$$TPPH_2 + Et_3Al \longrightarrow TPPAlEt + 2EtH$$

A similar reaction for triethylaluminium with octaethylporphyrin has been reported,[7] though a detailed examination of the reaction was not presented.

Reaction of Carbon Dioxide with TPPAlEt: Reactions of tetraphenylporphinatoaluminium ethyl (TPPAlEt) with carbon dioxide were carried out in the quartz cell which was placed in a glass water bath at 25 °C. Several hours after the formation of TPPAlEt, 1-methylimidazole (0.13 ml, 1.5 mmol) was added, followed by carbon dioxide bubbling for 5 min, and the mixture was irradiated for a given period of time by visible light (450—750 nm) obtained from a 500-W xenon lamp placed at a distance of 10 cm outside the water bath. Light of higher and lower wavelength was eliminated using appropriate filters.

Separation of the Reaction Product: In order to obtain the reaction product in an amount sufficient to conduct further examinations, carbon dioxide was bubbled for 10 min at room temperature in a 300 ml two-necked Pyrex flask which

contained $TPPH_2$ (6.14 g, 10 mmol), Et_3Al (1.37 ml, 10 mmol) and 1-methylimidazole (1.00 ml, 10 mmol). After an appropriate period of time, hydrogen chloride gas was bubbled through the above reaction mixture, and the solvent and excess hydrogen chloride were removed under reduced pressure at room temperature giving a solid residue, which was further treated in accordance with the following two procedures: 1) 1-Butanol (5 ml), concd sulfuric acid (1 ml) and sodium sulfate (5 g) were added to the residue, and the mixture was heated at 130 °C for 20 min. The reaction mixture was concentrated and extracted with hexane, then fractionated into several parts employing column chromatography on silica gel using hexane as the eluent. Some fractions which were found to contain butyl propionate by gas chromatography were collected and purified by passage through a column of silica gel using a mixture of hexane and methylene chloride as the eluent, then through another silica gel column using methylene chloride as the eluent. After removing the solvent from the fractions, a liquid was obtained, and its IR spectrum agreed with that of authentic butyl propionate.
2) An ether solution of diazomethane (in great excess with respect to TPPAlEt) was added to the residue at room temperature, and after one day the reaction mixture was concentrated to remove the solvent by evaporation and subjected to gas chromatography.

Measurement. Infrared spectra were measured in a fixed cell (0.1 mm) using a Hitachi EPI-G3 spectrophotometer. Ultraviolet and visible spectra were obtained with the sample in a quartz cell (of length 0.1 cm) using a Shimadzu RSP-7B spectrophotometer. ^1H NMR spectra were measured using a JEOL 4H-A type spectrometer. Gas chromatographic analysis was carried out using a Yanagimoto Model G80 gas chromatograph with the column (of 1—1.5 m) packed with dioctyl phthalate, silica gel, polyethylene glycol, and with hydrogen as the carrier gas.

Results

Reaction of Tetraphenylporphinatoaluminium Ethyl with Carbon Dioxide. When carbon dioxide was bubbled in a solution of TPPAlEt in methylene chloride in the presence of from one to three equivalent amounts of 1-methylimidazole and irradiated by visible light, a new carbonyl absorption band appeared at 1642 cm^{-1} in the infrared spectrum (Figs. 2 and 3). The figures show that the absorption increased with time fairly rapidly but substantially ceased after about 40 h. On the other hand, absorption due to carbon dioxide at 2340 cm^{-1} decreased as the band at 1642 cm^{-1} increased. In the dark, however, absorption at this frequency was very slight even after 48 h. The temperature in the irradiated case was the same as that for the measurements in the dark. The same effect was also observed when benzene was used as the solvent.

In the absence of 1-methylimidazole, no absorption at 1642 cm^{-1} was present even when the system was irradiated by visible light. Thus, TPPAlEt reacts with carbon dioxide only when irradiated by visible light in the presence of 1-methylimidazole.

Reaction Products. In the reaction of carbon dioxide and TPPAlEt in methylene chloride for 20 h, treatment of the reaction mixture with hydrogen chloride gas followed by 1-butanol gave butyl propionate in a 4% yield based on the amount of porphinatoaluminium ethyl.

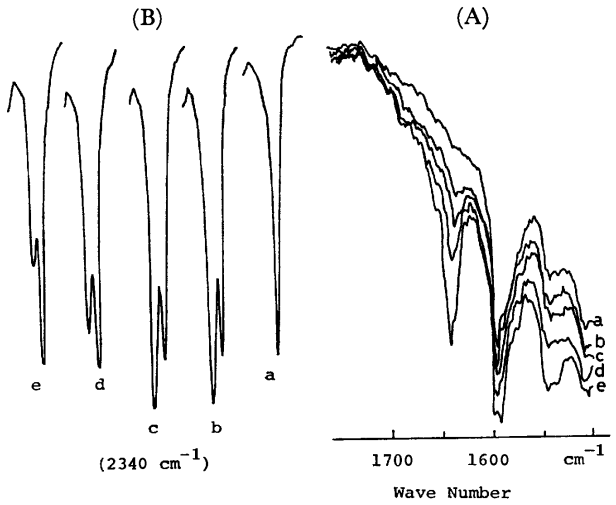

Fig. 2. Infrared spectra of the reaction mixture of tetraphenylporphinatoaluminium ethyl(TPPAlEt) with carbon dioxide(CO_2, bubbling for 5 min) in the presence of 1-methylimidazole.
TPPAlEt; 3mmol, 1-methylimidazole; 3mmol, CH_2Cl_2; 50ml, temp; 25 °C; (A) a; before bubbling of CO_2, b; 20 min, c; 40 min, d, 60 min, e; 14 h; (B) Absorption due to CO_2.

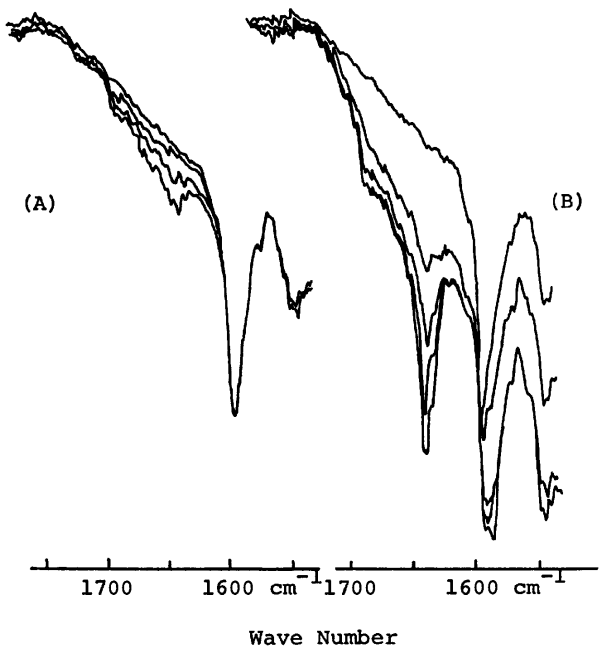

Fig. 3. Infrared spectra of the reaction mixture of tetraphenylporphinatoaluminium ethyl(TPPAlEt) with carbon dioxide(CO_2) in dark(A) and under radiation of visible light(B); TPPAlEt; 1.5mmol, 1-methylimidazole; 1.5mmol, CO_2 bubbling for 5 min.

In another reaction, treatment with diazomethane gave methyl propionate in a 12% yield based on the amount of porphinatoaluminium ethyl. Thus, carbon dioxide was inserted into aluminium-ethyl bond of TPPAlEt to form aluminium propionate.

$$\text{TPPAlEt} \xrightarrow{CO_2} \text{TPPAl-O-C(=O)-Et} \xrightarrow{HCl} \begin{cases} \xrightarrow{BuOH} \text{EtCOOBu} \\ \xrightarrow{CH_2N_2} \text{EtCOOMe} \end{cases} \text{EtCOOH}$$

Other expected products, such as 3-ethyl-3-pentanol, 3-pentanol and ethyl formate were not detected in the reaction mixture after treatment with hydrogen chloride.

Attempted direct esterification of the reaction mixture with methyl iodide and ethyl iodide at 130 °C were unsuccessful.

Discussion

As described above, irradiation by visible light in the presence of 1-methylimidazole is necessary for the reaction of TPPAlEt and carbon dioxide. Figure 4 shows the visible spectra of the TPPAlEt and TPPAlEt–1-methylimidazole (1 : 1) system in methylene chloride at room temperature. The absorption maximum of the TPPAlEt spectrum shifted from 548 to 568 nm in the presence of 1-methylimidazole. By changing the ratio of the amount of 1-methylimidazole to that of TPPAlEt, an isosbestic point was observed at 557 nm, and the strength of the absorption maximum at 568 nm remained almost the same when a more than equimolar amount of 1-methylimidazole was added. Therefore, 1-methylimidazole is considered to form an equimolar coordination compound with TPPAlEt in methylene chloride. Such coordination of 1-methylimidazole possibly to the aluminium is considered to increase the nucleophilicity of the ethyl group.

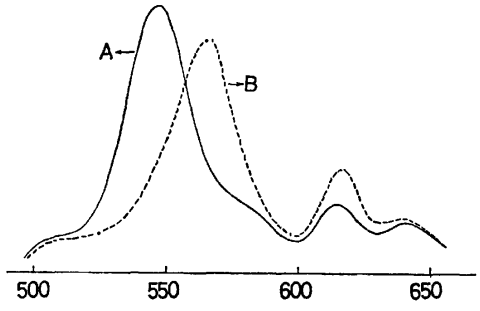

Fig. 4. Visible spectra of tetraphenylporphinatoaluminium ethyl(A) and tetraphenylporphinatoaluminium ethyl–1-methylimidazole(1:1) system(B) in methylene chloride, TPPAlEt; 7.0×10^{-3} mmol, CH_2Cl_2; 20ml, 1-methylimidazole; 7.0×10^{-3} mmol.

However, irradiation by visible light is essential for the reaction. Since neither 1-methylimidazole nor the aluminium-ethyl bond have absorptions in the visible region, it is reasonable to consider that the aluminium-ethyl bond of the TPPAlEt–1-methylimidazole complex was indirectly activated by visible light excitation of the porphine ring.

Such an activation effect by visible light on the reaction of carbon dioxide is very interesting in relation to the electron transfer in photosynthesis.

Notes on the Formations of Oxaziridines by the Irradiation and Benzoylation of (22*S*, 25*S*)-*N*-Acetyl-11a-aza-c-homo-5*α*-veratra-11a,13(17)-diene-3*β*,11*β*,23*β*-triol 11a-Oxide, a Fused 6-Membered-ring Nitrone[1]

(Received October 15, 1976)

The irradiation of the title nitrone (**5**) with monochromatic light afforded a single isomeric oxaziridine (**6**), which reverted to the original nitrone (**5**) thermally at room temperature. The title nitrone was also converted into another oxaziridine (**8**) by treatment with benzoic anhydride.

In our previous paper,[1] we proposed a pathway for the formation of the title nitrone (**5**) *via* the photorearrangement of a (22*S*, 25*S*)-veratr-13(17)-enine-11*β*-yl nitrite (**2**) on the basis of several pieces of experimental evidence.

We wish to report here on the transformations of the nitrone (**5**) into a single isomeric oxaziridine (**6**) by irradiation with monochromatic light (285 nm) and on a reaction toward acylating reagents which led to a product (**8**) with an oxaziridine ring.

Results

Photochemical Oxaziridine Formation.[2] The photochemical behavior of the nitrone (**5**) in ethanol toward Pyrex-filtered light was parallel to the nitrone we previously reported.[3] Thus, thenitrone (**5**) in ethanol was transformed into a single, less polar substance on 3 h irradiation with the Pyrex-filtered light generated by 100-W high-pressure Hg arc lamp. The less polar substance should be an oxaziridine (**6**), since it reverted to the starting nitrone when refluxed in acetone for *ca.* 1 h and it oxidized the iodide ion to iodine. The configuration of the oxaziridine ring could not be assigned since it was thermally unstable, even at room temperature. However, the α-configuration is more probable on the basis of the concideration of the relative stalility.

The quantitative transformation of the nitrone (**5**) into the corresponding oxaziridine (**6**) with monochromatic light and the quantitative thermal regeneration of the nitrone (**5**) from the oxaziridine (**6**) at room temperature were confirmed spectroscopically. Thus, a methanolic solution of the nitrone (**5**) (5.8×10^{-5} M) was irradiated with monochromatic light (285 nm) at room temperature. The nitrone (**5**) was completely transformed into the oxaziridine (**6**) by irradiation for 2 min, as was indicated by the vanishing of the absorption maximum at 285 nm of the nitrone (**5**) (Fig. 1). When the irradiated solution was set aside at room temperature in the dark, the oxaziridine gradually reverted to the nitrone, and after 18 h the oxaziridine (**6**) was quantitatively transformed into the nitrone (**5**)[2] as was indicated by the gradual appearance of the absorption maximum at 285 nm in the solution (Fig. 2).

The quantum yields of the oxaziridine formation in methanol and in isopropyl alcohol with monochromatic light (285 nm) were found to be 0.17 and 0.10 respectively. The formation of the oxaziridine was also observed in ethanol, *t*-butyl alcohol, dioxane, tetrahydrofuran, and cyclohexane. The nitrone (**5**) was equally transformed into the oxaziridine in methanol containing triplet quenchers, piperylene, or oxygen. The quantum yields of the oxaziridine formation were found to be 0.16 and 0.19 respectively. These facts indicated that the oxaziridine was formed from the singlet-excited nitrone.[4]

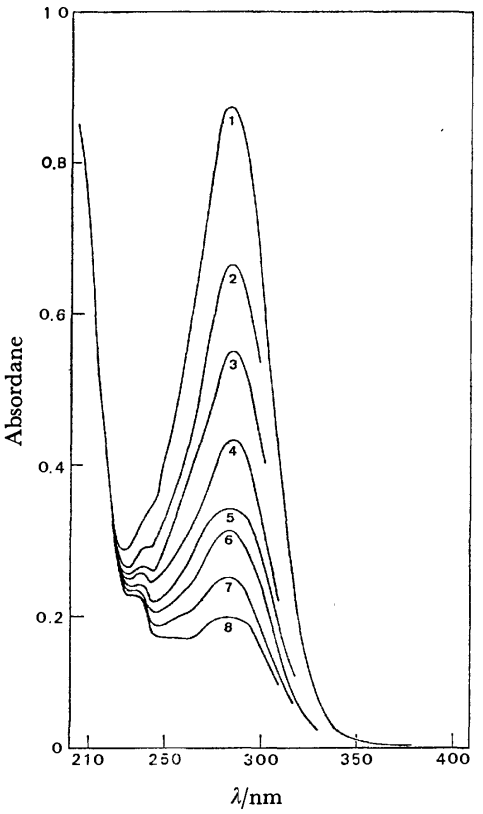

Fig. 1. Decline in the UV spectrum of **5** on irradiation with 285 nm light in 5.8×10^{-5} M methanol.
1: before irradiation, 2: 5 s irradiation, 3: 10 s, 4: 15 s, 5: 20 s, 6: 25 s, 7: 30 s, 8: 35 s.

The Reaction of the Nitrone (5) with Acylating Reagent. The treatment of this nitrone (**5**) with benzoic anhydride and pyridine at room temperature afforded a mixture of products from which only the major product, **8** (mp 194—195 °C) was obtained in a pure form. The results of the elemental analysis and the mass spectrum were consistent with a molecular formula of $C_{40}H_{54}O_8$-

N_2. The oxaziridine structure was assigned to this compound on the basis of the IR and NMR spectra in a manner entirely analogous to the product in the benzoylation of the nitrone we previously reported.[3] The assignments of the NMR signals are described in the table. As in the previous case,[2] the N-Ac protons were considerably shielded and appeared near the signal due to the 19-H. The signal due to the N-Ac was further confirmed by a comparison of ^{1}H NMR spectra between the product **8** and the deuterium-labeled compound **9**.

The partial $[^2H]_3$ acetylation of (22*S*,25*S*)-5α-veratr-13(17)-enine-3β,11β,23β-triol (**1**) afforded a deuterium-labeled derivative (**3**). Its subsequent nitrosation afforded (22*S*,25*S*)-*N*-$[^2H]_3$acetyl-5α-veratr-13(17)-enne-3β,11β,23β-triol 3,23-di-$[^2H]_3$ acetate 11-nitrite (**4**). The nitrite (**4**) in carbon tetrachloride was photolyzed by a procedure analogous to that used in the case of the **2** nitrite to afford the nitrone(**7**)in a 28% yield. The treatment of it with benzoic anhydride and pyridine under the same conditions as were used for the **5** nitrone afforded a mixture of products. Its recrystallization from ether afforded an oxaziridine (**9**). The ^{1}H NMR spectrum of compound **9** indicated the presence of all the signals found in the spectrum of compound **8** with the exceptions of two sharp signals at τ 8.02 and at τ 8.86 due to the OAc and NAc of the product (**8**).

Therefore, the singlet at τ 8.86 in the spectrum of the product (**8**) was assigned to that of NAc. This considerable shielding of NAc protons, found in the spectrum of the product (**8**), was attributable to an anisotropy by the newly introduced phenyl ring. The assignments of the rest of the signals of the product (**8**) are shown in the table. There was a clear doublet at τ 3.32 (J= 9.6) ascribable to the 11β-H on the newly formed oxaziridine ring. An inspection of the Dreiding model of compound **8** in conjunction with the considerable shielding of the *N*-acetyl protons by the benzene ring in the ^{1}H NMR spectrum suggested that the configura-

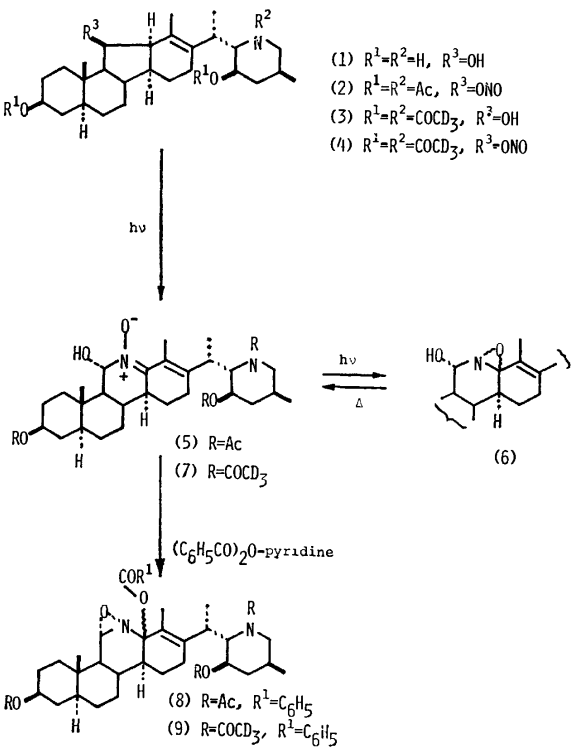

Scheme 1.

tion of compound **8** at the C-13 position was β. However, this assignment is not conclusive.

Although we obtained the oxaziridine(**8**)as the major product, we were unsuccessful in isolating a compound with a pyridine nucleus corresponding to the compound which was isolated previously.[2] This probably shows that the compound with the pyridine nucleus was formed only in a poor yield in this benzoylation. This difference from the previous case demonstrate that a balance of two competitive processes leading to oxaziridine and to a compound with a pyridine nucleus depends upon a rather slight modification of the substrate structure.

Experimental

For the instruments used and the general procedures, see Part 30.[5]

The Formation of the Oxaziridine (6) on the Irradiation of the Nitrone (5) in Ethanol and the Thermal Treatment of the Oxaziridine (6). The nitrone (**5**) (53 mg) in ethanol (73 ml) was irradiated through Pyrex with a 100-W high-pressure Hg arc lamp under nitrogen. The progress of the reaction was monitored by TLC (Solvent: acetone/chloroform 1/3). After 3.5 h, the nitrone disappeared and was transformed into a less polar substance which appeared as a single spot on the TLC. After the removal of the solvent at 22 °C, the residue developed a yellow color on the addition of a KI–acetic acid solution. This residue was dissolved in 10 ml of acetone and they refluxed for 1 h 10 min. An examination by TLC of this solution showed that nearly all the oxaziridine had reverted to the starting nitrone. The acetone was then evaporated and the residue was recrystallized from isopropyl ether to yield crystals (29 mg) which were identical with the starting nitrone.

The Transformation of the Nitrone (5) into the Oxaziridine (6) in Methanol on Irradiation with 285 nm Light. Quantum-yield Measurements: Solutions of the nitrone (**5**) containing 1,3-pentadiene or oxygen were prepared by dissolving 0.16 mg of the nitrone in 5 ml of methanol containing *ca.* 0.2 g of 1,3-pentadiene and 0.21 mg of the nitrone in 5 ml of methanol saturated with oxygen.

The solutions for the quantum-yield measurements were prepared by dissolving 0.17 mg of the nitrone (**5**) in 5 ml of methanol and 0.19 mg of **5** in 5 ml of isopropyl alcohol. Each 4 ml portion of the solutions in silica cells ($10\times10\times45$ mm) was placed in a chamber of the Jasco CRM-FA grating spectro-irradiator. The solutions were then irradiated with a 285 nm light. Figure 1 shows the decline in the intensity of the absorption maximum of compound **5** at 285 nm in methanol.

The quantum yields of the transformation of the nitrone (**5**) into the oxaziridine (**6**) were measured as in the case of the disappearance of the nitrite.[1] The decreases in the absorbance at 285 nm of the UV spectrum of the solutions upon the irradiation for 5 s in the case of methanol and for 20 s in the case of isopropyl alcohol were found to be 0.2 and 0.47.

Since the molar absorptivity at 285 nm in the UV spectrum of the **5** nitrone was known to be 15800, and since the output of the Xe arc lamp at 285 nm was 0.6×10^5 erg/cm², s, the quantum yield of the decomposition of the nitrone in methanol was calculated to be 0.18.

In the same manner, the quantum yield of the decomposition of the nitrone in isopropyl alcohol was calculated to be 0.10.

(22S,25S)-N-[H^2]$_3$Acetyl-veratr-13(17)-enine-3β,11β,23β-triol 3,23-di-[^2H]$_3$-acetate (3). The triol (**1**) (620 ml) and acetic anhydride-d_6 (2.5 ml) in pyridine (6.2 ml) were stirred for 22 h at room temperature. After the addition of methanol (10 ml), the solvent was removed with added benzene under reduced pressure. The residue was dissolved in chloroform and the chloroform solution was washed with 2M-hydrochloric acid, a 5% aqueous sodium hydrogencarbonate solution, and water successively. After the removal of the chloroform, the amorphous residue (955 mg) was submitted to column chromatography (Mallinckrodt silicic acid; 100 mesh: eluent, benzene) to yield 462 mg of colorless crystals of the tri-[^{2}H]$_3$ acetyl derivative (**3**). The analytical specimen was obtained by recrystallization from ether. Mp 196—197°C. Found: C, 69.84, H and D, 10.80, N, 2.36%. Calcd for $C_{33}H_{42}D_9O_6N$: C, 69.92; H and D, 10.67; N, 2.47%. ν_{max} 1736 cm^{-1} ($OCOCD_3$), 1632 cm^{-1} ($NCOCD_3$), 3468 (OH), 1244, 1079 cm^{-1}. NMR; see Table. MS, *m/e* 568 (M+2, 0.2%), *m/e* 361 (0.5%), *m/e* 204 (54%), *m/e* 160 (100%), *m/e* 116 (16%).

Nitrosation of the 11β-ol (3). To a solution of the 11β-ol (**3**) (430 mg) in acetic acid (6 ml) at 60°C, there was added sodium nitrate (200 mg) within a period of 30 s. To the reaction mixture there was then added water (40 ml). The resultant precipitates of the nitrite were collected by filtration, washed with a 10% aqueous sodium hydrogencarbonate solution, washed with water, and dried *in vacuo*. Yield, 435 mg. NMR; see Table.

Photolysis of the Nitrite (4). The above nitrite (435 mg) in carbon tetrachloride (20 ml) was irradiated through Pyrex with a 100-W high-pressure Hg arc for 8.5 h under argon. A small amount of a solid which appeared on the wall of the vessel was dissolved in chloroform. The photolyzed solution and the chloroform solution were combined, and the solvent was removed. The residue was submitted to preparative TLC (solvent: acetone/benzene 1/5). The amorphous crude nitrone was recrystallized from ether to afford 120 mg of the nitrone (**7**). Mp 126—127 °C. Found: C, 66.30; H and D, 10.20; N, 4.52%. Calcd for $C_{33}H_{41}D_9O_7N_2$: C, 66.50; H and

D, 9.98; N, 4.73%. NMR; see Table.

Benzoylation of the Nitrone (5). The nitrone (**5**) (79 mg) and benzoic anhydride (100 mg) in pyridine (3.5 ml) were stirred for 24 h at room temperature. The reaction mixture was then poured into a mixture of ice and water (80 ml). The mixture was extracted with chloroform (20 ml×2). The chloroform solution was washed successively with 2M-hydrochloric acid (20 ml), a 5% aqueous sodium hydrogencarbonate solution (20 ml), and water, and then dried (Na_2SO_4). The removal of the solvent afforded a residue (310 mg). This was submitted to preparative TLC (acetone/chloroform 1: 3). Four fractions-A (142 mg), B (44 mg), C (17 mg), and D (17 mg) were obtained in the order of increasing polarity. The least polar fraction, A, was recovered benzoic anhydride. The B fraction was recrystallized from ether to yield 11 mg of the oxaziridine (**8**). Mp 194—195 °C. Found: C, 69.40, H, 7.55; H, 4.30%. Calcd for $C_{40}H_{54}O_8N_2$: C, 69.54; H, 7.88; N, 4.06%. UV λ_{max}^{EtOH} 231 nm (ε; 11000). ν_{max} ($CHCl_3$) 1720 cm^{-1} (OAc and $OCOC_6H_5$), 1629 cm^{-1} (NAc). NMR; see text.

Benzoylation of the Nitrone (7). The above nitrone (**7**) (90 mg) and benzoic anhydride (110 mg) in pyridine (3.5 ml) were stirred for 3 h. After the addition of 2 M hydrochloric acid (500 ml), the reaction mixture was extracted with chloroform (50 ml+40 ml+20 ml). The chloroform solution was washed successively with a 5% aqueous sodium hydrogencarbonate solution and water and then dried (Na_2SO_4). After the removal of the solvent, the residue was recrystallized from ether to yield 28 mg of the pure oxaziridine (**9**). Mp 243—244 °C (from acetone). Found: C, 68.40; H and D, 8.90; N, 3.80%. Calcd for $C_{40}H_{45}D_9O_8N$: C, 68.64; H and D, 9.07; N, 4.00%. NMR see Table.

The authors wish to thank the Application Laboratory, Japan Spectroscopic Co., Ltd., where the experiments with monochromatic light were undertaken. We also wish to thank Mrs. Satoko Araki and Mrs. Tomoko Okayama for their measurements of the 100 MHz NMR spectra.

Chemical Synthesis of Antigenic Determinants in Hen Egg-White Lysozyme. I. Heneicosapeptide Corresponding to Positions 34—54 in the Primary Structure

Takayuki MITAKI and Yasutsugu SHIMONISHI

Institute for Protein Research, Osaka University, Yamada-kami, Suita, Osaka 565

(Received October 18, 1976)

For elucidating one of the antigenic determinants of hen egg-white lysozyme close to its catalytic site, heneicosapeptide was synthesized by a conventional method. This peptide, phenylalanylglutamylserylasparaginylphenylalanylasparaginylthreonylglutaminylalanylthreonylasparaginylarginylasparaginylthreonylaspartylglycylserylthreonylaspartyltyrosylglycine, corresponds to positions 34—54 of the amino acid sequence of hen egg-white lysozyme.

Two methods have been used in studies on the antigenic structures of hen egg-white lysozyme (HEL). One is screening of proteolytic digests of HEL for immunologically active peptides;[1-7] characterization of these peptides then provides various informations about the structures of the antigenic determinants. This method has the disadvantages that fractions of digests may be contaminated with small quantities of immunologically active materials and that it cannot be used to study the minimal structures of antigenic determinants for activity and the functions of the individual amino acid residue. The second method is chemical synthesis of antigenic structures of HEL.[8-10] This method does not have the disadvantages of the other method, because it can give pure substance with natural structure and also various artificial analogs, whereas it cannot be used alone for determining the antigenic determinants.

Sakato *et al.*[4] found that certain peptides isolated from thermolytic digests of HEL, *i.e.*, P_{Ib} [sequence[11,12] Val^{29} to Gly^{54} and Val^{109} to Trp^{123} linked by a single disulfide (Cys^{30} and Cys^{115}) bond], P_{Ba-1} (sequence Phe^{34} to Gly^{54}) and P_{Ba-2} (sequence Phe^{38} to Gln^{57}), are immunologically active, and described that the antigenic determinant of HEL included in these peptides is in the sequence Phe^{38} to $Gly.^{54}$ It seemed interesting to characterize this determinant, because these immunoreactive peptides are close to a catalytic site of HEL and because antibody populations directed to them also neutralize the enzymatic activity of HEL.[4] The second method described above seemed most suitable for examining this antigenic determinant of HEL, because various peptides related to this determinant could not be isolated from enzymatic digests of HEL. Studies on this have been carried out in collaboration[13] with Prof. T. Amano and his group of the Research Institute for Microbial Diseases, Osaka University. This paper reports the synthesis of a heneicosapeptide, phenylalanylglutamylserylasparaginylphenylalanylasparaginylthreonylglutaminylalanylthreonylasparaginylarginylasparaginylthreonylaspartylglycylserylthreonylaspartyltyrosylglycine corresponding to P_{Ba-1}, which includes two residues of the catalytic sites of HEL (Glu^{35} and Asp^{52}).[14]

This peptide was synthesized from appropriately protected smaller fragments by the azide coupling reaction. In planning the synthesis, easy ways of purifying peptide intermediates and the ultimate removal of protecting groups with liquid hydrogen fluoride[15] were considered. For the synthesis, heneicosapeptide (sequence Phe^{34} to Gly^{54}) was divided into four subfragments (P_1—P_4), as shown in Figs. 1—4. For synthesis of subfragment P_1, N^{α}-benzyloxycarbonyl-γ-*t*-butylglutamic acid *N*-hydroxysuccinimide ester[16] was condensed with serine methyl ester. Then N^{α}-benzyloxycarbonyl-γ-*t*-butylglutamylserine methyl ester (I) was hydrogenated catalytically and the resulting peptide ester was not isolated but coupled directly with benzyloxycarbonylphenylalanine[17] by dicyclohexylcarbodiimide to give benzyloxycarbonylphenylalanyl-γ-*t*-butylglutamylserine methyl ester (II). The protected tripeptide methyl ester was converted to the corresponding hydrazide (III). Benzyloxycarbonylphenylalanyl-γ-*t*-butylglutamylserine azide obtained from compound III

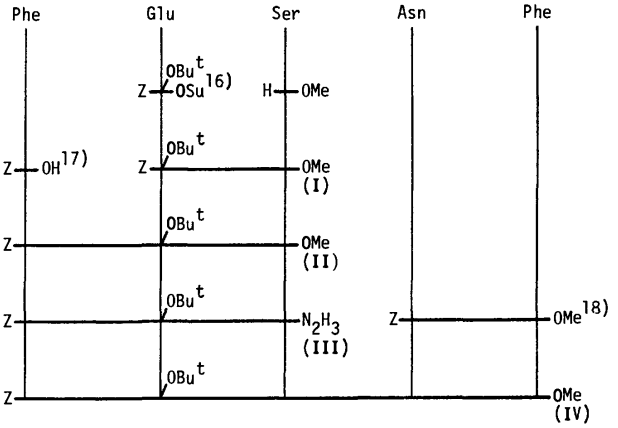

Fig. 1. Scheme for synthesis of subfragment P_1 (sequence 34—38)[28]

was not isolated but allowed to react directly with asparaginylphenylalanine methyl ester, which was obtained by removal of the benzyloxycarbonyl group from the protected peptide[18] by catalytic hydrogenation. In this way benzyloxycarbonylphenylalanyl-γ-*t*-butylglutamylserylasparaginylphenylalanine methyl ester (IV) was obtained without difficulty.

Subfragment P_2 was synthesized using benzyloxycarbonylalanylthreonine methyl ester[19] as starting material by a stepwise elongation procedure. The benzyloxycarbonyl group was removed by catalytic hydrogenation and the resulting peptide ester was not isolated but coupled directly with benzyloxycarbonylglutamine *p*-nitrophenyl ester[20] to yield benzyloxycarbonylglutaminylalanylthreonine methyl ester (V). The protecting group was cleaved by catalytic hydrogenation and the tripeptide methyl ester was condensed with benzyloxycarbonylthreonine azide prepared from its corresponding hydrazide[21] to give benzyloxycarbonylthreonylglutaminylalanylthreonine methyl ester (VI). The benzyloxycarbonyl group was removed by catalytic hydrogenation and the tetrapeptide methyl ester thus obtained was coupled with benzyloxycarbonylasparagine *p*-nitrophenyl ester[20] to give benzyloxycarbonylasparaginylthreonylglutaminylalanylthreonine methyl ester (VII).

Subfragment P_3 was constructed using benzyloxycarbonyl-β-*t*-butylaspartylglycine *t*-butoxycarbonylhydrazide (VIII), which was prepared by coupling benzyloxycarbonyl-β-*t*-butylaspartic acid *N*-hydroxysuccinimide ester[22] with glycine *t*-butoxycarbonylhydrazide.[23] The benzyloxycarbonyl group of compound VIII was removed by catalytic hydrogenation and the resulting peptide *t*-butoxycarbonylhydrazide was coupled with benzyloxycarbonylthreonine azide to yield benzyloxycarbonylthreonyl-β-*t*-butylaspartylglycine *t*-butoxycarbonylhydrazide (IX). The protecting group for amino terminus was removed by catalytic hydrogenation and the chain elongated by further three single steps using benzyloxycarbonylasparagine *p*-nitrophenyl ester,[20] N^{α}-benzyloxycarbonyl-N^{ω}-tosylarginine[24] and dicyclohexylcarbodiimide in the presence of *N*-hydroxysuccinimide, and benzyloxycarbonylasparagine *p*-nitrophenyl ester[20] for acylation. Thus, benzyloxycarbonylasparaginyl-N^{ω}-tosylarginylasparaginylthreonyl-β-*t*-butylaspartylglycine *t*-butoxycarbonylhydrazide (XII) was obtained.

Subfragment P_4 (XV) was synthesized by coupling benzyloxycarbonylserylthreonine azide with β-*t*-butylaspartyltyrosylglycine *t*-butyl ester, which was obtained by removal of the benzyloxycarbonyl group from the protected tripeptide ester (XIV) by catalytic hydrogenation, without isolation. The tripeptide derivative (XIV) was prepared by condensation of benzyloxycarbonyl-β-*t*-butylaspartic acid *N*-hydroxysuccinimide ester[22] with tyrosylglycine *t*-butyl ester, which was prepared by removal of the protecting groups from benzyloxycarbonyl-*O*-benzyltyrosylglycine *t*-butyl ester (XIII) by catalytic hydrogenation. The dipeptide derivative (XIII) was obtained by condensation of benzyloxycarbonyl-*O*-benzyltyrosine *p*-nitrophenyl ester[26] with glycine *t*-butyl ester.[27]

The couplings of subfragment P_1 with P_2 and of subfragment P_3 with P_4 were carried out separately, as shown in Fig. 5. The hydrazide (XVI) of subfragment P_1 was converted to the corresponding azide and coupled with pentapeptide methyl ester, which was prepared by removal of the benzyloxycarbonyl group of subfragment P_2 by catalytic hydrogenation. The decapeptide

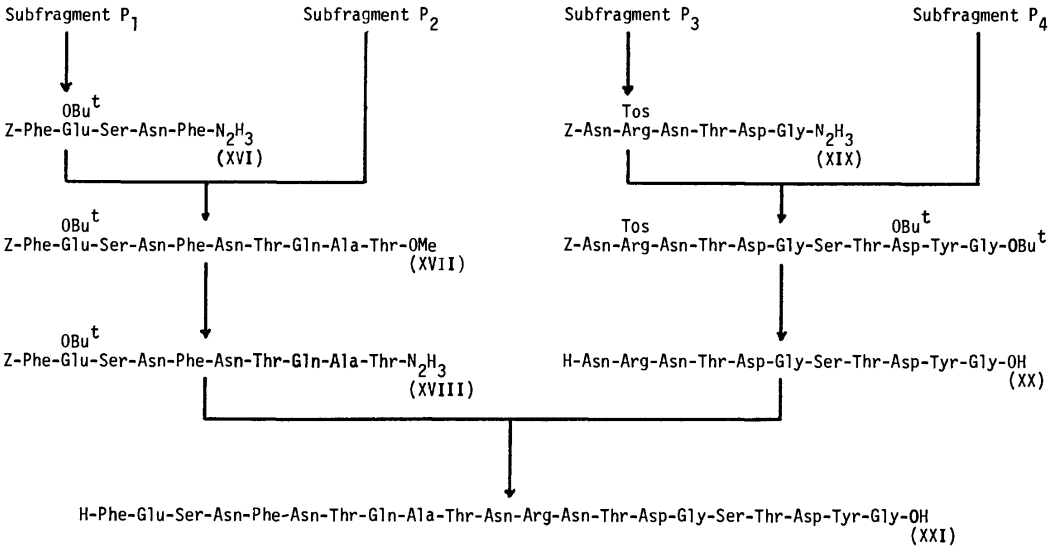

Fig. 5. Scheme for synthesis of the heneicosapeptide (sequence 34—54).

derivative (XVII) obtained was converted to its corresponding hydrazide (XVIII). On the other hand, subfragment P_3 was treated with trifluoracetic acid and the corresponding hydrazide (XIX) obtained was coupled with serylthreonyl-β-*t*-butylaspartyltyrosylglycine *t*-butyl ester prepared from subfragment P_4 by Rudinger's azide method[29] to give a protected undecapeptide. Without further purification the peptide was treated with liquid hydrogen fluoride in an HF-apparatus[15] to remove its protecting groups. The free undecapeptide (XX), asparaginylarginylasparaginylthreonylaspartylglycylserylthreonylaspartyltyrosylglycine, was purified on a column of diethylaminoethyl-cellulose. The azide, prepared from the hydrazide (XVIII) by Rudinger's method,[29] was further coupled *in situ* with free undecapeptide (XX) to give protected heneicosapeptide. The crude heneicosapeptide was not purified due to its low solubility but was directly treated with hydrogen fluoride[15] to remove its protecting groups. The resulting free peptide was fractionated on a column of Sephadex G-25, as shown in Fig. 6, and the main fraction collected was purified further on a column of carboxymethyl-cellulose, as shown in Fig. 7.

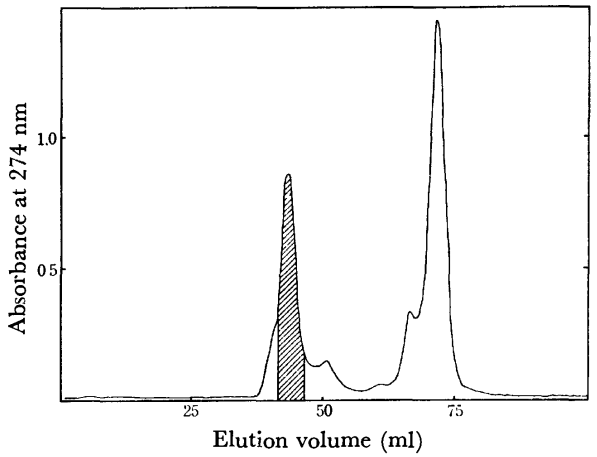

Fig. 6. Gel-filtration of crude heneicosapeptide (XXI) on Sephadex G-25 in 50% acetic acid.

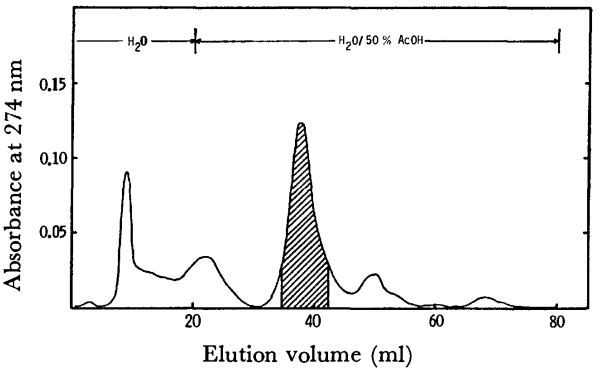

Fig. 7. Chromatogram of the main fraction shown in Fig. 6 on carboxymethyl-cellulose (H^+ cycle) using a linear gradient from water to 50% acetic acid.

The heneicosapeptide thus synthesized showed the same order of inhibitory activity in a precipitin reaction between ^{125}I-HEL and the purified *anti*-P_{Ib} antibody, as that reported elsewhere.[13] This confirms that one of the antigenic determinants of HEL is in the region from Phe^{34} to Gly^{54} of HEL. Chemical synthesis of the minimal structure necessary for inhibitory activity is now in progress.

Experimental

All chemicals were of reagent grade and they were used without further purification. The amino acids except glycine were of the L-configuration. Sephadex G-25 fine was purchased from Pharmacia Co. (Uppsala). Thin layer chromatography was performed on silica gel G (Merck) using the following solvent systems (volume ratios); chloroform: methanol: acetic acid (95: 5: 3), ethyl acetate: benzene (1: 1), 1-butanol: acetic acid: water (4: 1: 1), 1-butanol: acetic acid: pyridine: water (15: 3: 10: 12), phenol: water (3: 1) and chloroform: methanol: acetic acid: water (10: 10: 1: 10, lower phase). Paper electrophoresis was performed at pH 4.8 in 0.2 M pyridinium acetate buffer. Peptide derivatives were hydrolyzed in 6 M hydrochloric acid with phenol in sealed tubes for 24 h at 105 °C, and amino acids in the hydrolysates were examined in a Hitachi KLA-5

analyzer by the method of Moore *et al.*[30] Optical rotations were determined with a Perkin-Elmer Model 241 polarimeter. The purities of the peptide derivatives synthesized were confirmed by thin layer chromatography and paper electrophoresis and by the ratio of their constituent amino acids measured in acid hydrolysates by amino acid analysis. Melting points were measured by the capillary method and are given as uncorrected values.

N$^{\alpha}$-Benzyloxycarbonyl-γ-t-butylglutamylserine Methyl Ester (I). A solution of serine methyl ester hydrochloride (6.80 g, 44.0 mmol) in *N,N*-dimethylformamide (50 ml) was cooled to 0—5 °C. The chilled solution was mixed with triethylamine (6.2 ml) and then a solution of *N$^{\alpha}$*-benzyloxycarbonyl-γ-*t*-butylglutamic acid *N*-hydroxysuccinimide ester[16] (17.4 g, 40.1 mmol) in *N,N*-dimethylformamide (40 ml) and stirred for 2 h at room temperature. Then the mixture was concentrated *in vacuo*, and diluted with ethyl acetate. The diluted solution was washed successively with 0.1 M hydrochloric acid, 5% aqueous sodium hydrogencarbonate, and water, and dried over anhydrous sodium sulfate. The dried solution was concentrated *in vacuo* to a syrup, and the material was crystallized in a mixture of ethyl acetate and hexane; wt 15.7 g (89.2%). The crude product was recrystallized from ethyl acetate and hexane; wt 12.7 g (72.2%); mp 70—72 °C; $[\alpha]_D^{19}$ −5.3° (*c* 0.9, ethanol).

Found: C, 57.64; H, 6.91; N, 6.40%. Calcd for $C_{21}H_{30}O_8N_2$: C, 57.52; H, 6.90; N, 6.39%.

Benzyloxycarbonylphenylalanyl-γ-t-butylglutamylserine Methyl Ester (II). Compound I (12.7 g, 29.0 mmol) was dissolved in methanol (500 ml), and hydrogenated over a 5% palladium-charcoal catalyst for 1.5 h at atmospheric pressure. The catalyst was filtered off and washed with a small volume of methanol. The filtrate and washings were combined and concentrated to a syrupy residue *in vacuo*. The residue was dissolved with benzyloxycarbonylphenylalanine[17] (8.70 g, 29.1 mmol) in *N,N*-dimethylformamide (70 ml), and the solution was cooled to −10 °C. Then a solution of dicyclohexylcarbodiimide (6.00 g, 29.1 mmol) in *N,N*-dimethylformamide (20 ml) was added and the mixture was stirred for one hour at the same temperature and then overnight at room temperature. The precipitate formed was filtered off and washed with *N,N*-dimethylformamide. The filtrate and washings were combined, concentrated to a small volume *in vacuo*, and diluted with ethyl acetate. The diluted solution was washed successively with 0.1 M hydrochloric acid, 5% aqueous sodium hydrogencarbonate, and water, and dried over anhydrous sodium sulfate. The dried solution was concentrated to a syrup under reduced pressure, and crude material was crystallized from ethyl acetate and hexane; wt 12.6 g (74.1%). It was recrystallized from ethyl acetate and hexane; wt 11.7 g (68.8%); mp 87.5—89 °C; $[\alpha]_D^{19}$ −14.9° (*c* 1.1, ethanol).

Found: C, 61.67; H, 6.87; N, 7.30%. Calcd for $C_{33}H_{39}O_9N_3$: C, 61.52; H, 6.71; N, 7.18%.

Benzyloxycarbonylphenylalanyl-γ-t-butylglutamylserine Hydrazide (III). A solution of compound II (11.7 g, 20.0 mmol) in methanol (200 ml) was cooled to 0—5 °C, and then 90% hydrazine hydrate (7 g) was added. The mixture was kept for 24 h at room temperature, and the precipitate formed was filtered off and washed with methanol; wt 10.9 g (91.6%); mp 171—173 °C.

Found: C, 58.85; H, 6.70; N, 11.65%. Calcd for $C_{29}H_{39}O_8N_5 \cdot 0.5H_2O$: C, 58.57; H, 6.78; N, 11.78%.

Benzyloxycarbonylphenylalanyl-γ-t-butylglutamylserylasparaginylphenylalanine Methyl Ester (IV). Benzyloxycarbonylasparaginylphenylalanine methyl ester[18] (6.41 g, 15.0 mmol) was dissolved in methanol (1 liter) and hydrogenated over a 5% palladium-charcoal catalyst for 3.5 h at atmospheric pressure. The catalyst was filtered off and washed with methanol. The filtrate and washings were combined and concentrated to a solid residue *in vacuo*. The residue was dissolved in *N,N*-dimethylformamide (50 ml), and cooled to −10 °C. Compound III (8.78 g, 14.8 mmol) was suspended in *N,N*-dimethylformamide (40 ml), cooled to −20 °C and mixed with 3.90 M HCl in dioxane (11.5 ml). The clear solution was mixed with isopentyl nitrite (2.10 ml) at the same temperature. After 10 min a solution of *N*-methylmorpholine (4.55 g) in *N,N*-dimethylformamide (10 ml) and then a cooled solution of the amino component were added. The mixture was stirred for 40 h in a refrigerator (0 °C). Then a solution of *N*-methylmorpholine (0.98 g) in *N,N*-dimethylformamide (2.1 ml) was added and the mixture was stirred for 48 h at the same temperature. Then, the solution was poured into large volume of water. The precipitate formed was collected by filtration; wt 10.2 g (79.7%). The crude product was reprecipitated from *N,N*-dimethylformamide and ethyl acetate; wt 8.70 g (68.0%); mp 214—215 °C; $[\alpha]_D^{27}$ −3.8° (*c* 1.1, *N,N*-dimethylformamide). Amino acid ratio: Asp, 1.00 (1); Ser, 0.93 (1); Glu, 1.05 (1); Phe, 2.00 (2).

Found: C, 60.51; H, 6.45; N, 9.92%. Calcd for $C_{43}H_{54}O_{12}N_6 \cdot 0.5H_2O$: C, 60.33; H, 6.47; N, 9.82%.

Benzyloxycarbonylglutaminylalanylthreonine Methyl Ester (V). Benzyloxycarbonylalanylthreonine methyl ester[19] (3.38 g, 10.0 mmol) was dissolved in ethanol (120 ml) and hydrogenated over a 5% palladium-charcoal catalyst. The catalyst was filtered off and the filtrate was concentrated to a syrup *in vacuo*. The syrup was dissolved with benzyloxycarbonylglutamine *p*-nitrophenyl ester[20] (3.34 g, 8.33 mmol) in *N,N*-dimethylformamide (25 ml). The solution was stirred for an hour at room temperature, and then concentrated to a syrup *in vacuo*. The syrup was triturated in ethyl acetate. The solid thus formed was collected by filtration, and recrystallized from methanol; wt 2.64 g (68.0%); mp 190.5—191 °C; $[\alpha]_D^{10}$ −7.6° (*c* 0.94, *N,N*-dimethylformamide).

Found: C, 53.80; H, 6.47; N, 12.09%. Calcd for $C_{21}H_{30}O_8N_4$: C, 54.07; H, 6.48; N, 12.01%.

Benzyloxycarbonylthreonylglutaminylalanylthreonine Methyl Ester (VI). Compound V (11.7 g, 25.1 mmol) was suspended in methanol (900 ml) and hydrogenated over a 5% palladium-charcoal catalyst at atmospheric pressure for 1.5 h. The catalyst was filtered off and washed with methanol. The filtrate and washings were combined and evaporated to dryness under reduced pressure. The residue was dissolved in a mixture of *N,N*-dimethylformamide (100 ml) and dimethyl sulfoxide (40 ml), and then cooled in ice-water. Benzyloxycarbonylthreonine hydrazide[21] (6.70 g, 25.1 mmol) was suspended in *N,N*-dimethylformamide (50 ml) and cooled to −25 °C. The chilled suspension became clear on adding 3.55 M HCl in dioxane (21.1 ml). The solution was mixed with isopentyl nitrite (3.50 ml) and stirred for 15 min at the same temperature. Then it was carefully mixed with a solution of triethylamine (10.5 ml) in *N,N*-dimethylformamide (10 ml). The mixture was combined with the above cooled solution of the hydrogenated product of compound V, and stirred for 48 h at 0 °C. The mixture was concentrated to a solid residue *in vacuo*, and collected with water; wt 10.4 g (72.7%). The crude material was reprecipitated from *N,N*-dimethylformamide and water; wt 9.30 g (65.0%); mp 241—243 °C; $[\alpha]_D^{20}$ −7.6° (*c* 1.1, *N,N*-dimethylformamide).

Found: C, 52.82; H, 6.62; N, 12.34%. Calcd for $C_{25}H_{37}O_{10}N_5$: C, 52.90; H, 6.57; N, 12.34%.

Benzyloxycarbonylasparaginylthreonylglutaminylalanylthreonine Methyl Ester (VII). Compound VI (8.00 g, 14.1 mmol) was suspended in methanol (750 ml) and hydrogenated over a

5% palladium-charcoal catalyst at atmospheric pressure for 3 h. The catalyst was filtered off and the filtrate was evaporated to dryness *in vacuo*. The residue was dissolved in a mixture of *N,N*-dimethylformamide (40 ml) and dimethyl sulfoxide (20 ml), and mixed with benzyloxycarbonylasparagine *p*-nitrophenyl ester[20] (5.40 g, 14.0 mmol). The solution was stirred overnight at room temperature, and then poured into a large volume of ethyl acetate. The precipitate formed was collected by filtration; wt 9.20 g (94.0%). The crude material was dissolved in a boiling mixture of *N,N*-dimethylformamide (200 ml) and water (100 ml), and insoluble material was filtered off. The filtrate was mixed with ethyl acetate (250 ml), and allowed to stand overnight in a refrigerator. The precipitate formed was collected by filtration; wt 6.70 g (68.4%); mp 245—246 °C (decomp); $[\alpha]_D^{27}$ −21.0° (*c* 1.0, *N,N*-dimethylformamide). Amino acid ratio: Asp, 1.00 (1); Thr, 2.00 (2); Glu, 1.07 (1); Ala, 1.00 (1).

Found: C, 50.38; H, 6.39; N, 13.96%. Calcd for $C_{29}H_{43}O_{12}N_7 \cdot 0.5H_2O$: C, 50.43; H, 6.42; N, 14.20%.

N$^{\alpha}$-Benzyloxycarbonyl-β-t-butylaspartylglycine t-Butoxycarbonylhydrazide (VIII). A solution of glycine *t*-butoxycarbonylhydrazide[23] (14.5 g, 76.7 mmol) in *N,N*-dimethylformamide (150 ml) was mixed with benzyloxycarbonyl-β-*t*-butylaspartic acid *N*-hydroxysuccinimide ester[22] (32.2 g, 76.7 mmol). The solution was stirred for 50 min at room temperature and concentrated to a syrup *in vacuo*, and this was dissolved in ethyl acetate. The solution was washed successively with 0.1 M hydrochloric acid, 5% aqueous sodium hydrogencarbonate, and water, and then dried over anhydrous sodium sulfate. The dried solution was concentrated to an oily residue *in vacuo*, and this was treated with hexane to give an amorphous powder; wt 35.8 g (94.2%); mp 60—65 °C.

Benzyloxycarbonylthreonyl-β-t-butylaspartylglycine t-Butoxycarbonylhydrazide (IX). Compound VIII (35.3 g, 71.3 mmol) was dissolved in methanol (1 liter) and hydrogenated over a 5% palladium-charcoal catalyst at atmospheric pressure. The catalyst was filtered off and the filtrate was concentrated to a syrup *in vacuo*. This was dissolved in *N,N*-dimethylformamide (170 ml). On the other hand, benzyloxycarbonylthreonine hydrazide[21] (19.1 g, 71.5 mmol) was suspended in *N,N*-dimethylformamide (200 ml) and cooled to −30 °C. To the cooled suspension were added 3.90 M HCl in dioxane (55.0 ml) and then isopentyl nitrite (10.1 ml). After 15 min a solution of *N*-methylmorpholine (21.7 g) in *N,N*-dimethylformamide (20 ml) and then the solution obtained above were added. The mixture was stirred for 48 h at 0 °C, and then diluted with ethyl acetate. The diluted mixture was washed successively with 0.1 M hydrochloric acid, 5% aqueous sodium hydrogencarbonate, and water, and dried over anhydrous sodium sulfate. The dried solution was concentrated to a syrup *in vacuo*. The syrup was triturated in ethyl acetate and ether; wt 25.7 g (60.5%); mp 107—109 °C; $[\alpha]_D^{10}$ −19.3° (*c* 1.0, ethyl acetate).

Found: C, 54.53; H, 7.03; N, 11.69%. Calcd for $C_{27}H_{41}O_{10}N_5$: C, 54.44; H, 6.94; N, 11.76%.

Benzyloxycarbonylasparaginylthreonyl-β-t-butylaspartylglycine t-Butoxycarbonylhydrazide (X). Compound IX (10.7 g, 18.0 mmol) was dissolved in methanol (700 ml) and hydrogenated over a 5% palladium-charcoal catalyst at atmospheric pressure. The catalyst was filtered off and washed with methanol. The filtrate and washings were combined and concentrated to a syrup under reduced pressure, and the syrup was dissolved with benzyloxycarbonylasparagine *p*-nitrophenyl ester[20] (8.40 g, 21.7 mmol) in *N,N*-dimethylformamide (40 ml). The solution was stirred overnight at room temperature, and then concentrated to a residue under reduced pressure. The residue was triturated in ethyl acetate and ether; wt 11.3 g (85.0%). The powder obtained was reprecipitated from ethanol and water; wt 7.70 g (57.9%); mp 121—125 °C; $[\alpha]_D^{27}$ −22.1° (*c* 1.0, *N,N*-dimethylformamide).

Found: C, 50.33; H, 6.74; N, 13.02%. Calcd for $C_{31}H_{47}O_{12}N_7 \cdot 1.5H_2O$: C, 50.53; H, 6.84; N, 13.31%.

N$^{\alpha}$-Benzyloxycarbonyl-N$^{\omega}$-tosylarginylasparaginylthreonyl-β-t-butylaspartylglycine t-Butoxycarbonylhydrazide (XI). N$^{\alpha}$-Benzyloxycarbonyl-N$^{\omega}$-tosylarginine[24] (3.70 g, 7.99 mmol) and *N*-hydroxysuccinimide (0.92 g, 8.0 mmol) were dissolved in tetrahydrofuran (6 ml). The solution was cooled to −10 °C and then mixed with dicyclohexylcarbodiimide (1.70 g, 8.25 mmol). The solution was stirred for one hour at −10 °C and then for one hour at room temperature. The precipitate formed was filtered off and the filtrate was concentrated to a solid residue *in vacuo*. The residue was dissolved in *N,N*-dimethylformamide (10 ml) with the material which was obtained by hydrogenation of compound X (3.60 g, 4.89 mmol) over a 5% palladium-charcoal catalyst at atmospheric pressure. The solution was stirred for 4 h at room temperature and then concentrated to a small volume *in vacuo*. The residue was diluted with ethyl acetate and washed with 0.1 M hydrochloric acid, and water, and then dried over anhydrous sodium sulfate. The dried solution was concentrated to a gelatinous solid *in vacuo*, and this was collected by filtration; wt 4.50 g (89.3%). The crude material was reprecipitated from ethanol and water; wt 3.30 g (65.5%); mp 148—151 °C; $[\alpha]_D^{10}$ −19.2° (*c* 1.1, *N,N*-dimethylformamide). Amino acid ratio: Asp, 1.94 (2); Thr, 0.92 (1); Gly, 1.00 (1); Arg, 1.02 (1).

Found: C, 51.38; H, 6.59; N, 15.00; S, 3.09%. Calcd for $C_{44}H_{65}O_{15}N_{11}S \cdot 0.5H_2O$: C, 51.35; H, 6.46; N, 14.97; S, 3.12%.

Benzyloxycarbonylasparaginyl-N$^{\omega}$-tosylarginylasparaginylthreonyl-β-t-butylaspartylglycine t-Butoxycarbonylhydrazide (XII). Compound XI (3.25 g, 3.16 mmol) was dissolved in methanol (300 ml) and hydrogenated over a 5% palladium-charcoal catalyst at atmospheric pressure. The catalyst was filtered off and the filtrate was concentrated to a syrup under reduced pressure. The syrup was dissolved with benzyloxycarbonylasparagine *p*-nitrophenyl ester[20] (1.41 g, 3.64 mmol) in *N,N*-dimethylformamide (7 ml). The solution was stirred for 24 h at room temperature, and then concentrated to a residue *in vacuo*. The residue was collected with ethanol; wt 1.80 g (50.0%). The crude product was reprecipitated from *N,N*-dimethylformamide and ethanol; wt 1.60 g (44.4%); mp 190—191 °C; $[\alpha]_D^{23}$ −24.4° (*c* 1.0, *N,N*-dimethylformamide). Amino acid ratio: Asp, 3.09 (3); Thr, 1.02 (1); Gly, 1.00 (1); Arg, 0.96 (1).

Found: C, 50.35; H, 6.48; N, 16.03; S, 2.80%. Calcd for $C_{48}H_{71}O_{17}N_{13}S \cdot 0.5H_2O$: C, 50.45; H, 6.34; N, 15.93; S, 2.80%.

Benzyloxycarbonyl-O-benzyltyrosylglycine t-Butyl Ester (XIII). Glycine *t*-butyl ester, prepared by the hydrogenation of benzyloxycarbonylglycine *t*-butyl ester[27] (11.8 g, 44.5 mmol) over a 5% palladium-charcoal catalyst at atmospheric pressure, was dissolved with benzyloxycarbonyl-*O*-benzyltyrosine *p*-nitrophenyl ester[26] (19.0 g, 36.0 mmol) in *N,N*-dimethylformamide (60 ml). The solution was stirred overnight at room temperature, and then concentrated to a syrup *in vacuo*. The syrupy residue was dissolved in ethyl acetate, and washed successively with 0.1 M hydrochloric acid, 5% aqueous sodium hydrogencarbonate, and water, and then dried over anhydrous sodium sulfate. The dried solution was concentrated to a crystalline residue *in vacuo*; wt 15.8 g (84.5%); mp 120—121 °C; $[\alpha]_D^{13}$ −13.4° (*c* 1.0, ethanol).

Found: C, 69.33; H, 6.60; N, 5.35%. Calcd for $C_{30}H_{34}$-

O_6N_2: C, 69.48; H, 6.61; N, 5.40%.

N^{α}-Benzyloxycarbonyl-β-t-butylaspartyltyrosylglycine t-Butyl Ester (XIV). Compound XIII (14.3 g, 27.6 mmol) was dissolved in methanol (500 ml) and hydrogenated over a 5% palladium-charcoal catalyst at atmospheric pressure. The catalyst was filtered off and washed with methanol. The filtrate and washings were combined and concentrated to a syrup *in vacuo*. The syrup was dissolved with benzyloxycarbonyl-β-*t*-butylaspartic acid *N*-hydroxysuccinimide ester[22] (12.8 g, 30.5 mmol) in *N,N*-dimethylformamide (50 ml). The solution was stirred for 24 h at room temperature, and then diluted with ethyl acetate. The diluted solution was washed successively with 0.1 M hydrochloric acid, 5% aqueous sodium hydrogencarbonate, and water, and then dried over anhydrous sodium sulfate. The dried solution was concentrated to a syrup *in vacuo*. The syrup was washed with a mixture of ethyl acetate and hexane, and triturated in hexane. The crude material obtained was reprecipitated from ether and hexane; wt 11.2 g (67.5%); mp 97—99 °C; $[\alpha]_D^{14}$ −35.4° (*c* 1.0, ethanol).

Found: C, 62.19; H, 7.02; N, 6.86%. Calcd for $C_{31}H_{41}O_9N_3$: C, 62.09; H, 6.89; N, 7.01%.

Benzyloxycarbonylserylthreonyl-β-t-butylaspartyltyrosylglycine t-Butyl Ester (XV). Benzyloxycarbonylserylthreonine hydrazide[25] (4.61 g, 13.0 mmol) was suspended in *N,N*-dimethylformamide (40 ml) and cooled to −20 °C. Then 3.90 M HCl in dioxane (10 ml) was added. The resulting clear solution was mixed with isopentyl nitrite (1.82 ml) and stirred for 20 min at the same temperature. Then a solution of *N*-methylmorpholine (1.37 g) in *N,N*-dimethylformamide (5 ml) was added. The solution was mixed with a solution in *N,N*-dimethylformamide (30 ml) of the material obtained by hydrogenation of compound XIV (8.40 g, 14.0 mmol) over a 5% palladium-charcoal catalyst. The solution was stirred for 48 h at 0 °C, and then poured into cold water. The precipitate formed was collected by filtration; wt 6.70 g (64.4%). The crude product was reprecipitated from *N,N*-dimethylformamide and water; wt 6.00 g (57.5%); mp 174—176 °C; $[\alpha]_D^{24}$ −13.5° (*c* 1.0, *N,N*-dimethylformamide). Amino acid ratio: Asp, 1.11 (1); Thr, 1.05 (1); Ser, 1.02 (1); Gly, 1.00 (1); Tyr, 0.97 (1).

Found: C, 57.33; H, 6.85; N, 8.93%. Calcd for $C_{38}H_{53}O_{13}N_5 \cdot 0.5H_2O$: C, 57.27; H, 6.83; N, 8.79%.

Benzyloxycarbonylphenylalanyl-γ-t-butylglutamylserylasparaginyl-phenylalanine Hydrazide (XVI). A solution of compound IV (4.23 g, 4.90 mmol) in *N,N*-dimethylformamide (50 ml) was cooled to 0—5 °C in an ice-bath, and then 80% hydrazine hydrate (2 g) was added. The solution was stirred for 24 h at room temperature, and then the precipitate formed was collected by filtration and washed with ethanol. The product was boiled in hot ethanol, and then cooled and filtered; wt 4.15 g (100%); mp 238—240 °C (decomp).

Found: C, 59.61; H, 6.49; N, 13.29%. Calcd for $C_{42}H_{54}O_{11}N_8$: C, 59.56; H, 6.43; N, 13.23%.

Benzyloxycarbonylphenylalanyl-γ-t-butylglutamylserylasparaginyl-phenylalanylasparaginylthreonylglutaminylalanylthreonine Methyl Ester (XVII). Compound XVI (1.27 g, 1.50 mmol) was suspended in *N,N*-dimethylformamide (4 ml) and cooled to −20 °C. Then 3.90 M HCl in dioxane (1.15 ml) and isopentyl nitrite (0.212 ml) were added. The mixture was stirred for 80 min at the same temperature and insoluble material was filtered off. The filtrate was mixed with *N*-methylmorpholine (0.46 g) and then with a solution in a mixture of *N,N*-dimethylformamide (5 ml) and dimethyl sulfoxide (1 ml) of the material obtained by hydrogenation of compound VII (1.36 g, 1.97 mmol) over a 5% palladium-charcoal catalyst at atmospheric pressure. The mixture was stirred for 48 h at 0 °C, and then poured into cold water. The precipitate formed was filtered off and washed with 0.1 M hydrochloric acid and water; wt 1.60 g (77.3%). The crude material was reprecipitated repeatedly from *N,N*-dimethylformamide and water; wt 1.04 g (50.2%); mp 233 °C (sintered) and 248 °C (decomp); $[\alpha]_D^{18}$ −10.7° (*c* 0.42, dimethyl sulfoxide). Amino acid ratio: Asp, 1.98 (2); Thr, 1.93 (2); Ser, 0.89 (1); Glu, 2.02 (2); Ala, 0.97 (1); Phe, 2.00 (2).

Found: C, 54.65; H, 6.44; N, 13.08%. Calcd for $C_{63}H_{87}O_{21}N_{13} \cdot H_2O$: C, 54.81; H, 6.50; N, 13.19%.

Benzyloxycarbonylphenylalanyl-γ-t-butylglutamylserylasparaginyl-phenylalanylasparaginylthreonylglutaminylalanylthreonine Hydrazide (XVIII). Compound XVII (0.92 g, 0.67 mmol) was dissolved in a mixture of dimethyl sulfoxide (60 ml) and *N,N*-dimethylformamide (10 ml) and mixed with 80% hydrazine hydrate (5 g). The solution was stirred for 48 h at room temperature, concentrated to a small volume *in vacuo*, and mixed with ethanol. The precipitate formed was boiled in ethanol and collected by filtration; wt 0.87 g (94%); mp 240 °C (sintered) and 246—247 °C (decomp).

Found: C, 53.22; H, 6.55; N, 14.74%. Calcd for $C_{62}H_{87}O_{20}N_{15} \cdot 2H_2O$: C, 53.25; H, 6.56; N, 15.02%.

Benzyloxycarbonylasparaginyl-N^{ω}-tosylarginylasparaginylthreonyl-aspartylglycine Hydrazide Trifluoracetate (XIX). Compound XII (0.60 g, 0.53 mmol) was dissolved in cold trifluoracetic acid (8 ml). The solution was stirred for 40 min at room temperature, and then concentrated to a syrup *in vacuo*. The syrup was triturated in ether; wt 0.57 g (95.0%).

Asparaginylarginylasparaginylthreonylaspartylglycylserylthreonyl-aspartyltyrosylglycine (XX). Compound XIX (0.57 g, 0.52 mmol) was suspended in *N,N*-dimethylformamide (2 ml), cooled to −20 °C and mixed with 3.90 M HCl in dioxane (0.40 ml). The clear solution was mixed with isopentyl nitrite (0.074 ml) and stirred for 20 min at the same temperature. Then, the solution was mixed with *N*-methylmorpholine (0.32 g) and with a solution in *N,N*-dimethylformamide (1 ml) of the material (0.41 g, 0.63 mmol) prepared by hydrogenation of compound XV over a 5% palladium-charcoal catalyst. The solution was stirred for 48 h at 0 °C and poured into cold 0.1 M hydrochloric acid. The precipitate formed was collected by filtration; wt 0.64 g (77%). The crude product was reprecipitated from *N,N*-dimethylformamide and ethanol; wt 0.53 g (64%). Amino acid ratio: Asp, 4.35 (4); Thr, 2.05 (2); Ser, 0.99 (1); Gly, 2.00 (2); Tyr, 0.92 (1); Arg+Orn, 0.76 (1). The protected peptide (161.1 mg) was steeped in anisole (0.46 ml) and dissolved in cold trifluoracetic acid (10 ml). The solution was stirred for 60 min at room temperature, and then concentrated to a syrup *in vacuo*. The syrup was triturated in ether; 140.3 mg. The powder and anisole (0.5 ml) were put into the Daiflon cylinder of an HF-reaction apparatus.[15] Anhydrous hydrogen fluoride (5 ml) was distilled into the cylinder cooled to −78 °C in a Dry Ice and methanol bath. The contents of the cylinder were stirred for 60 min at −15 °C, and then the hydrogen fluoride was evaporated off *in vacuo*. The residue was dissolved in 1 M acetic acid and washed with ether. Then, the solution was applied to a column of Amberlite IR-45 (acetate cycle) and eluted with 1 M acetic acid. The eluate was lyophilized; wt 111.8 mg. The lyophilized material (35.0 mg) was dissolved in water (1 ml) and charged on a column of diethylaminoethylcellulose (OH^- cycle, 0.7×10 cm). The column was eluted with a linear gradient from water (150 ml) to 0.2 M ammonium acetate (150 ml). The fractions (from 33 ml to 58 ml) of the eluate with absorption at 274 nm were collected and lyophilized; wt 29.3 mg. Thin layer chromatography: R_f 0.18 in 1-butanol: acetic acid: pyridine: water (15: 3: 10: 12, by volume) and 0.08 in phenol: water (3: 1, by volume);

paper electrophoresis: $R_{f,ala}$ 1.7 (0.2 M acetic acid, 14 V/cm); $[\alpha]_D^{18}$ −33.5° (*c* 0.55, water). Amino acid ratio: Asp, 4.06 (4); Thr, 1.94 (2); Ser, 0.93 (1); Gly, 2.00 (2); Tyr, 0.89 (1); Arg, 1.03 (1).

Found: C, 43.35; H, 6.18; N, 17.63%. Calcd for $C_{46}H_{70}O_{22}N_{16}\cdot 4H_2O$: C, 43.39; H, 6.14; N, 17.43%.

Phenylalanylglutamylserylasparaginylphenylalanylasparaginylthreonylglutaminylalanylthreonylasparaginylarginylasparaginylthreonylaspartylglycylserylthreonylaspartyltyrosylglycine (XXI). Compound XVIII (0.82 g, 0.59 mmol) was suspended in a mixture of dimethyl sulfoxide (3.3 ml) and *N,N*-dimethylformamide (1 ml), cooled to −10 °C and mixed with 4.74 M HCl in dioxane (0.45 ml) and isopentyl nitrite (0.09 ml). The mixture was stirred for 60 min at −20 °C and then mixed with a solution of compound XX (0.53 g, 0.42 mmol) in dimethyl sulfoxide (2.1 ml) and *N,N*-dimethylformamide (0.5 ml), and then with a solution of *N*-methylmorpholine (0.26 g) in dimethyl sulfoxide (0.5 ml). The mixture was stirred for 3 days at 0 °C, and then poured into cold 0.1 M hydrochloric acid. The precipitate formed was collected by filtration and dried over P_2O_5; wt 0.84 g. The crude product (403.1 mg) and anisole (0.62 ml) were treated with hydrogen fluoride (5 ml) at −10 °C for 60 min in an HF-reaction apparatus.[15] Hydrogen fluoride was distilled off, and the residue was dissolved in aqueous formic acid and lyophilized; wt 411.8 mg. The freeze-dried powder was dissolved in 50% acetic acid, charged on a column of Sephadex G-25 (2×130 cm) and eluted using the same solvent. The fractions shaded in Fig. 6, with an absorption at 274 nm, were collected and lyophilized; wt 93.5 mg. The lyophilized powder (46.4 mg) was dissolved in water and charged on a column of carboxymethyl-cellulose (H^+ cycle, 15×170 mm). The column was eluted with a linear gradient from water (150 ml) to 50% acetic acid (150 ml). The portions shaded in Fig. 7 with an absorption at 274 nm were collected and lyophilized; wt 22.4 mg; R_f (TLC) 0.18 in 1-butanol: acetic acid: pyridine: water (15: 3: 10: 12, by volume); $R_{f,ala}$ (paper electrophoresis) 1.1 (0.2 M acetic acid, 14 V/cm). Amino acid ratio: Asp, 5.84 (6); Thr, 3.85 (4); Ser, 1.81 (2); Glu 2.08 (2); Ala, 1.00 (1); Gly, 1.92 (2); Tyr, 0.87 (1); Phe, 1.92 (2); Arg, 1.00 (1).

Effects of Pressure on the Disproportionation of Olefins over MoO_3-Al_2O_3 and Re_2O_7-Al_2O_3 Catalysts

Toshiaki SODESAWA, Eisuke OGATA, and Yoshio KAMIYA

Department of Reaction Chemistry, Faculty of Engineering, University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received October 28, 1976)

The disproportionation of propylene and 1-butene over MoO_3-Al_2O_3 and Re_2O_7-Al_2O_3 catalysts was carried out in order to investigate the effects of reaction pressure in the range from 1.0 to 130 kg/cm^2. The effects of the pressure on the reaction can be identified as two independent of the reaction phase; the catalytic activity increased with the reaction pressure, and the time needed to reach the maximum conversion (T_{max}) as well as the time when the conversion falls to half the maximum value ($\tau_{1/2}$) decreased with the increase in the reaction pressure. It can be concluded that the catalytic activity by the polymers formed over the catalyst falls off rapidly with the increase in the pressure. In both phases, the disproportionation of olefins over the Re_2O_7-Al_2O_3 catalyst exhibits the following features as compared with that over the MoO_3-Al_2O_3 catalyst: (1) a much higher activity at temperatures of 0—140 °C; (2) a much higher selectivity for disproportionation, and (3) a lower apparent activation energy.

The disproportionation of propylene over the MoO_3-Al_2O_3 catalyst shows a high selectivity, but the catalytic activity decreases markedly with the lapse of time.[1] Several methods to improve these defects have been studied— *e.g.*, the addition of third materials and solvents.[2-4] We reported in the previous papers[3,4] that the polymers produced under pressure on MoO_3-Al_2O_3 have high molecular weights.

Hardly studies of the disproportionation of olefins over the Re_2O_7-Al_2O_3 catalyst have been reported. Echigoya and his co-workers observed, however, that the metathesis of isobutene with 2-butene or propylene produces isoamylene in high yields, even at low temperatures.[5,6] In the case of disproportionation over the Re_2O_7-Al_2O_3 catalyst, it was found that the longest catalyst life is attained under the lowest pressure for liquefying the olefins.[7]

In this paper, the disproportionation of propylene or 1-butene was carried out in order to compare the effect of the reaction pressure on the catalytic activity of MoO_3-Al_2O_3 with that of Re_2O_7-Al_2O_3 in the pressure range from 1.0 to 130 kg/cm^2.

Experimental

The MoO_3-Al_2O_3 catalyst was prepared in the way reported in the previous papers.[2-4] The Re_2O_7-Al_2O_3 catalyst was obtained by impregnating the 20% Re content of $HReO_4$ with γ-Al_2O_3 and by then calcining it at 550 °C for 5 h. The atomic ratio of Re to Al was 1 : 25, the same as that of Mo to Al in the case of the MoO_3-Al_2O_3 catalyst. The pretreatment of catalysts before starting the reaction was carried out in a flow of oxygen or air for a few hours, and then in a flow of nitrogen for several hours at 600 °C.

A conventional flow system with a fixed catalyst bed was used as the experimental apparatus. The upper and lower sections of the catalyst bed were filled with γ-Al_2O_3. The reaction products were analyzed by gas chromatography, as has been reported in the previous papers.[2-4]

Results and Discussion

Effects of Pressure. The disproportionation of propylene over the MoO_3-Al_2O_3 catalyst in the pressure range from 1.0 to 130 kg/cm^2 is shown as Figs. 1 and 1′. The relationship of the maximum conversion (Max_{conv}), the time when the conversion attains to its maximum value(T_{max}), and the time when the conversion falls to half its maximum value ($\tau_{1/2}$) is shown in Fig. 2. In both the gas-phase reactions at various GHSV values and the liquid-phase reaction as the same LHSV, the maximum conversion increased with the increase in the pressure, while T_{max} and $\tau_{1/2}$ decreased. In the reaction at 1.05 kg/cm^2, the catalytic activity was markedly more elongated than that at higher pressures. This phenomenon is in good agreement with the following equation suggested by Milanovic and his co-workers:[9]

$$r = \text{Conversion} \times D/22400 \times 273/T \times P/760 \times 1/m$$

D: Total flow rate (ml/h)
T: Reactant temperature (K)
P: Reactant pressure (Torr)
m: Catalyst weight (g).

The molar ratio of butenes to ethylene was 1.03 at 1.05

kg/cm², but 1.24 at 130 kg/cm². On the other hand, the selectivity to ethylene and butenes under 130 kg/cm² was 94.5%, showing that the selectivity to ethylene and butenes decreases with an increase in the reaction pressure, as is shown in Fig. 3. The amount of the polymers formed over the MoO_3–Al_2O_3 catalyst increased with the reaction pressure. This suggests that the degradation of the catalytic activity results from the polymers formed over the catalyst.[3,4]

We reported in the previous papers[3,4] that the catalyst life of MoO_3–Al_2O_3 was elongated in the presence of solvents and that heptane was the most effective. This indicates that the surface of the MoO_3–Al_2O_3 catalyst is kept clean in the presence of solvents. In the presence of heptane, the effect of the pressure on the conversion of propylene is shown in Fig. 4. At every pressure, the catalyst life of MoO_3–Al_2O_3 was remarkably elongated by the addition of heptane.

The time when the conversion attains to its maximum values under 15 kg/cm² was about twice that under

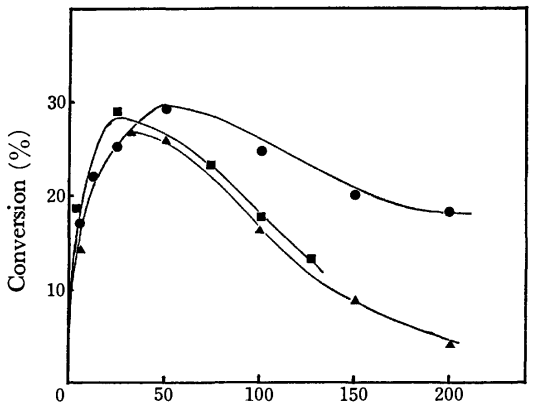

Fig. 4. Effect of pressure on the activity of MoO_3–Al_2O_3 catalyst in the disproportionation of propylene in the presence of heptane at 80 °C.

50 kg/cm². However, it was not observed that the maximum conversion was greatly affected by the reaction pressure. The time when the conversion falls to half its maximum value under 15 kg/cm² was approximately 400 h, five times longer than that under 50 kg/cm².

Gas-phase Reaction of Propylene. In the disproportionation of propylene over the Re_2O_7–Al_2O_3 catalyst, the catalytic activity changed with the reaction time as is shown in Fig. 5. In the reaction at 80 °C the conversion showed approximately the equilibrium value of 44.0%. At the same GHSV of 350, the catalytic activity of the Re_2O_7–Al_2O_3 catalyst was twice the value of the MoO_3–Al_2O_3 catalyst and decreased rather slowly with the reaction time. Even at 0 °C, the Re_2O_7–Al_2O_3 was a considerably active catalyst.

The ratio of *trans*-2-butene to *cis*-2-butene showed a lower value than the equilibrium value at every temperature, indicating that the amount of *trans*-2-butene formed increases with the reaction temperature. The selectivity to ethylene and butenes was 99.5% at a steady state, and the molar ratio of butenes to ethylene was approximately 1.0. These facts show that the disproportionation over the Re_2O_7–Al_2O_3 catalyst is highly selective. The apparent activation energy of the Re_2O_7–Al_2O_3 catalyst obtained from the Arrhenius plots was 2.51 kcal/mol, lower than the 4.09 kcal/mol of the MoO_3–Al_2O_3 catalyst. The selectivity to ethylene and butenes or the ratio of butenes to ethylene was not much affected by the reaction temperature. The ratio of 1-butene in the butenes produced over Re_2O_7–Al_2O_3 was lower than that over MoO_3–Al_2O_3. This seems to show that the Re_2O_7–Al_2O_3 catalyst has fewer active sites for isomerization.

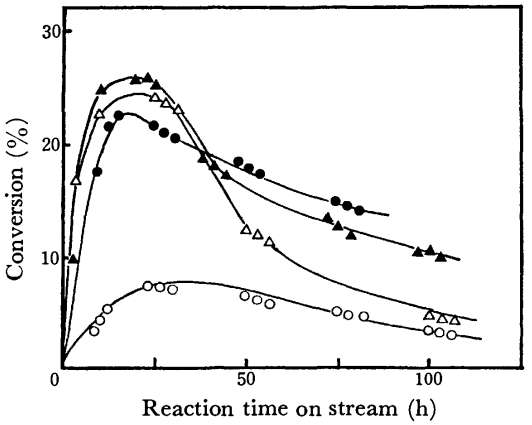

Fig. 6. Comparison of the activity of MoO_3–Al_2O_3 catalyst with that of Re_2O_7–Al_2O_3 catalyst.
△: MoO_3–Al_2O_3, 80 °C, ○: MoO_3–Al_2O_3, 40 °C,
▲: Re_2O_7–Al_2O_3, 80 °C, ●: Re_2O_7–Al_2O_3, 40 °C.

Liquid-phase Reaction of Propylene. In the reaction over Re_2O_7–Al_2O_3 and MoO_3–Al_2O_3 under 50 kg/cm², the catalytic activity changed as is shown in Fig. 6. The difference in catalytic activity between Re_2O_7–Al_2O_3 and MoO_3–Al_2O_3 at 80 °C seems not to be significant. However, in the reaction at 40 °C, the difference becomes larger, suggesting that the difference in apparent activation energy between Re_2O_7–Al_2O_3 and MoO_3–Al_2O_3 is larger than in the case of the gas-phase disproportionation. It can be assumed that Re_2O_7–Al_2O_3 offers a lower activation energy than MoO_3–Al_2O_3. The selectivity to ethylene and butenes in the disproportionation over Re_2O_7–Al_2O_3 at 40 °C was entirely 100%, with the ratio of butenes to ethylene nearly 1.0.

In the liquid-phase reaction, the selectivity to ethylene and butenes was lower than in the gas-phase reaction. This shows that polymerization of propylene or ethylene increases with the reaction pressure, the ratio of butenes to ethylene having a larger value than that in the gas phase. The ratio of *trans*-2-butene to *cis*-2-butene showed a little higher value. It seems that, in the liquid-phase disproportionation, the desorption from the surface of the catalyst does not proceed easily and that the steric hindrance in the reaction is larger than in the gas phase.[10]

As has been mentioned above, it was concluded that the pressure increase in the liquid-phase disproportionation enhances the reaction rate.*

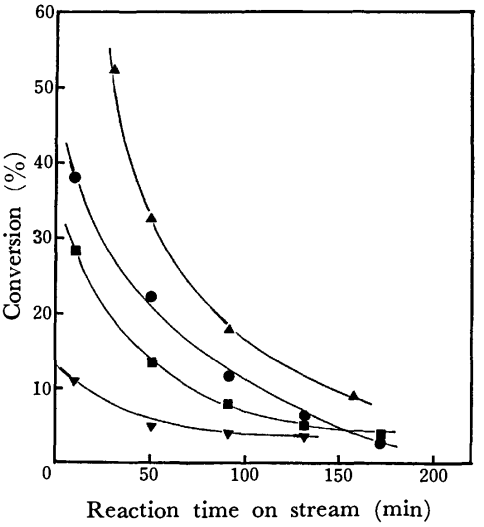

Fig. 7. Dispropornation of 1-butene in the gas phase over Re_2O_7–Al_2O_3 catalyst at GHSV=2000.
▲: 140 °C, ●: 80 °C, ■: 40 °C, ▼: 0 °C.

Gas-phase Reaction of 1-Butene. In the range from 0 to 140 °C, the catalytic activity of Re_2O_7–Al_2O_3 was the highest at 140 °C (Fig. 7); it decreased markedly with a decrease in the reaction temperature. At any temperature the catalytic activity of Re_2O_7–Al_2O_3 was higher than that of MoO_3–Al_2O_3. In the disproportionation of 1-butene, the reaction scheme can be written as follows:

* The relationship between the equilibrium constant K and the pressure P (molar concentration) can be written as follows:[8]

$$\frac{\partial RT\ln K}{\partial P} = -\Delta V.$$

ΔV will have a large negative value in a polymerization where the difference in molecular volume between the original system and the production system is quite high.

The disproportionation of 1-butene over MoO_3–Al_2O_3 and Re_2O_7–Al_2O_3 is shown in Fig. 8. The relative reactivities in the various reactions may be shown as follows:

Disproportionation ($C_2'+C_6'$)	MoO_3–$Al_2O_3 < Re_2O_7$–Al_2O_3
Isomerization (2-C_4')	$\gg$
Hydrogenation (C_4H_{10})	≈ 0

At a conversion of 13.0%, Re_2O_7–Al_2O_3 showed a higher selectivity to ethylene and hexenes than MoO_3–Al_2O_3, as is shown in Fig. 9. Moreover, the relationship between the yield of the disproportionation products and the yield of the isomerization products is shown in Fig. 10. These figures indicate that a more selective disproportionation occures over the Re_2O_7–Al_2O_3 catalyst than over MoO_3–Al_2O_3.

Liquid-phase Reaction of 1-Butene. The liquid-phase disproportionation of 1-butene over MoO_3–Al_2O_3 was very different from the reaction of propylene. That is to say, in the former case saturated hydrocarbons, such as butane, propane, and isobutane, were produced.[4] The hydrogen produced by dehydrogenation (Deh.) will result in the formation of saturated

hydrocarbons.[11] From the product distribution, it is estimated that the reaction of 1-butene proceeds not only by means of the D_1 reaction but also by means of the D_3 reaction.

On the other hand, the total conversion over Re_2O_7–Al_2O_3 has shown a maximum at 20 h, then it gradually decreased. Most of the reaction products over Re_2O_7–Al_2O_3 derived from the disproportionation. The difference between the two catalysts for isomerization (I) was not observed clearly, but the catalytic activity of Re_2O_7–Al_2O_3 for hydrogenation was markedly smaller.

From these facts, it seems that the Re_2O_7–Al_2O_3 catalyst is preferable to MoO_3–Al_2O_3 for the disproportionation of 1-butene.

Reaction of Di-*t*-butyl Thioketone with Aryllithium. Effect of Temperature and Solvent

Atsuyoshi OHNO, Kaoru NAKAMURA, Yasumasa SHIZUME, and Sinzaburo OKA
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611
(Received November 4, 1976)

Di-*t*-butyl thioketone reacts with phenyllithium affording both *C*-phenylated and *S*-phenylated products. The product distribution largely depends on the reaction temperature and solvent: the lower the temperature and the more solvated the counter cation, the larger the yield of the *S*-phenylated product. Steric effect is also important: 2,6-dimethylphenyllithium affords only *S*-arylated product. The result has been interpreted in terms of the charge-transfer-intermediate—radical-combination mechanism.

In contrast to carbonyl compounds, thiocarbonyl compounds have abnormal reactivity in the sense that thiocarbonyl-sulfur, in general, reacts with a nucleophile.[1-6]

$$\text{C=S} + \text{Nu}^- \xrightarrow{\text{H}^+} \text{CHSNu}$$

Although several prausible explanations have been proposed for the thiophilic attack of nucleophiles to thiocarbonyl compounds, none of them are satisfactory to explain the reactivity universally. In a previous paper we reported that the charge-transfer (CT)-intermediate —radical-combination mechanism is most prausible for the reaction of thiocarbonyl compounds with nucleophiles.[6] We now wish to report that the preference of the thiophilic attack over the carbophilic attack in the reaction of phenyllithium with di-*t*-butyl thioketone changes largely with the change of reaction temperature or the solvent and the result is consistent with the previously proposed CT-intermediate—radical-combination mechanism.

Results

The reaction of di-*t*-butyl thioketone with phenyllithium in ether afforded two products, 2,2,4,4-tetramethyl-3-phenylpentane-3-thiol (**1**) and di-*t*-butylmethyl phenyl sulfide (**2**).

$$\text{Bu}^t_2\text{C=S} + \text{PhLi} \xrightarrow{\text{ether}} \underset{\textbf{1}}{\text{Bu}^t_2\text{C}(\text{SH})(\text{Ph})} + \underset{\textbf{2}}{\text{Bu}^t_2\text{CHSPh}}$$

The yields depended largely on the reaction temperature: for example, **1** was isolated in 80% yield together with trace amount of **2** from the reaction mixture kept at 30 °C, whereas the reaction at −30 °C resulted in the formation of **2** in 80% yield with trace amount of **1**. It was reported that the reaction at 0 °C aforded **1** and **2** in 25 and 35% yields, respectively.[6,7] It has been confirmed that **2** does not rearrange into **1** under the reaction condition. That is, the reaction mixture at −30 °C was warmed to 30 °C before the addition of water and no difference in the yield was observed from that obtained by quenching the reaction mixture at −30 °C.

$$\text{Bu}^t_2\text{CSPh} \not\longrightarrow \text{Bu}^t_2\text{C}(\text{S}^-)(\text{Ph})$$

Table 1. Reaction of di-*t*-butyl thioketone with phenyllithium in various solvents at 20 °C

Solvent	Yield, %	
	Bu^t_2CH–SPh	Bu^t_2CPh–SH
Ether	trace	75
Tetrahydrofuran	80	trace
Ether–Hexane (1:1)	trace	70
Ether–THF (1:1)	94	
Ether–THF (9:1)	98	
Ether–THF[a]	43	31

a) Mole-equivalent to phenyllithium.

When the reaction at 20 °C was run in tetrahydrofuran (THF), the sole product isolated was **2**. As shown in Table 1, the effect of THF is striking and the presence of an equivalent-to-phenyllithium amount of THF results in the formation of **2** in 43% yield. On the other hand, the presence of nonpolar hexane in a reaction mixture did not affect the product distribution.

The reaction of di-*t*-butyl thioketone with 2,6-dimethylphenyllithium at 20 °C afforded 1,1-dimethyl-2-*t*-butylcyclopropane and 2,6-dimethylphenyl thiol in 40 and 70% yields, respectively. No product expected from the carbophilic attack of a 2,6-dimethylphenyl anion was detected.

Discussion

Since **1** and **2** are kinetically controlled products of the reaction of di-*t*-butyl thioketone with phenyllithium, the ratio of yields (Y_s/Y_c) may reflect the ratio of rate constants (k_s/k_c) for the formations of products, where

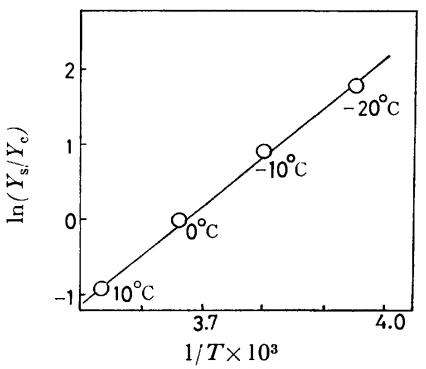

Fig. 1. Temperature-dependency of the ratio of yields of *S*-phenylated and *C*-phehnylated products.

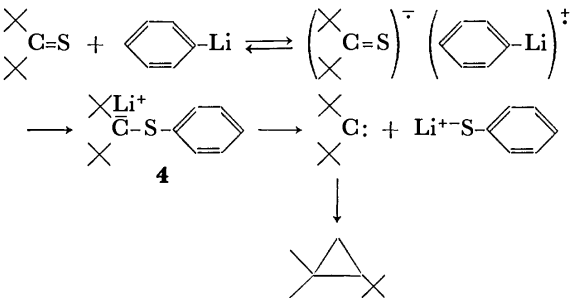
subscripts s and c denote thiophilic and carbophilic attacks, respectively. A plot of $\ln(Y_s/Y_c)$, which is equivalent to $\ln(k_s/k_c)$, against $1/T$ shows a good linear relationship as illustrated in Fig. 1. From the slope and intercept of the line, the differences in apparent parameters of activation were calculated to be -11.2 kcal/mol and -48 e.u. for $\Delta H_s^{\ddagger}-\Delta H_c^{\ddagger}$ and $\Delta S_s^{\ddagger}-\Delta S_c^{\ddagger}$, respectively. Although the absolute values may not represent the real physical meaning, the values indicate, at least qualitatively, that the thiophilic attack is more favored in enthalpy but much less favored in entropy than the carbophilic attack. Since it is not the sulfur atom but the thiocarbonyl-carbon which has bulky substituents, the result may suggest that the transition state for the carbophilic attack resembles the reactant much more than that for the thiophilic attack. In other words, the electronic structure of the reactant may contribute more for the carbophilic attack than for the thiophilic attack. Together with the fact that a nucleophile which has an β-hydrogen reduces di-*t*-butyl thioketone into the corresponding thiol, the above result leads to the conclusion that **3a** is more important canonical form than **3b** for the anion radical of di-*t*-butyl thioketone as previously proposed.[6] That is, a phenyl radical is sterically prevented from the carbophilic attack by two *t*-butyl groups and radical combination takes place with the sulfur atom, although the spin density on this atom is smaller than that on the carbon atom.

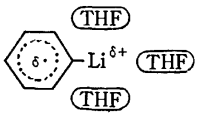
$$\mathrm{Bu}^t_2\dot{\mathrm{C}}\text{-}\bar{\mathrm{S}} \longleftrightarrow \mathrm{Bu}^t_2\bar{\mathrm{C}}\text{-}\dot{\mathrm{S}}$$

3a **3b**

The steric inhibition for the carbophilic attack is also recognized in the reaction with 2,6-dimethylphenyllithium: products from the reaction with this reagent indicate that the reaction proceeds only with the thiophilic attack under the condition where phenyllithium attacks on the thiocarbonyl-carbon. Here, two methyl groups on a phenyl ring interfere further the carbophilic attack. However, since these methyl groups still cause steric crowd in the intermediate carbanion **4**,[8] it decomposes either to products or to starting materials.



The effect of THF is also understandable with the idea of steric bulk of a nucleophile at the transition state for the carbophilic attack. The cation radical of phenyllithium, which is formed from phenyllithium after the transfer of an electron onto di-*t*-butyl thioketone, still remaines covalent bond character between the lithium and carbon atoms. Since THF has larger ability of solvation than ether, the net bulk of the nucleophile becomes larger in the presence of THF, **5**, than in its



absence and the carbophilic attack is sterically more reduced under the former condition than the latter. The phenomenon is the reverse of that normally observed in nucleophilic attack of anions, where dipolar aprotic solvents make an anion free and reactive by the solvation onto a cation.[9] We believe that this is another support for the presence of a CT-intermediate in the reaction of di-*t*-butyl thioketone with a nucleophile.

Experimental

Reaction of Di-t-butyl Thioketone with Phenyllithium. The reaction was carried out in a thermostat kept at an appropriate temperature. The general procedure was described in a previous paper.[6] Products were analyzed on a VPC (Yanagimoto G-1800; Dexil, 1 m; 150 °C; N_2, 0.4 kg/cm^2).

Reaction of Di-t-butyl Thioketone with 2,6-Dimethylphenyllithium. Into 20 ml of ether solution containing 168 mg (1.5 mmol) of 2,6-dimethylphenyllithium, was added 148 mg (1.0 mmol) of di-*t*-butyl thioketone in 20 ml of ether over a period of 24 h under an atmosphere of nitrogen. After the color of the thioketone had disappeared, 30 ml of water was added to the mixture and organic materials were extracted with ether. The extract was subjected to preparative VPC(Varian 920; Dexil, 1 m; 80 °C) and 50 mg (40% yield) of 1,1-dimethyl-2-*t*-butylcyclopropane. NMR $\delta^{\mathrm{TMS}}_{\mathrm{CCl_4}}$ 0.07—0.9 (3H, m), 0.93 (9H, s), 1.00 (3H, s), and 1.44 (3H, s). Mass spectrum M$^+$: *m/e* 126. Found: C, 85.04; H, 14.43%. Calcd for C_9H_{18}: C, 85.63; H, 14.34%.

The aqueous layer was acidified with dil sulfuric acid and organic materials were extracted with ether. The extract was chromatographed on silica gel with hexane eluent to give 96 mg (70% yield) of 2,6-dimethylphenylthiol. NMR $\delta^{\mathrm{TMS}}_{\mathrm{CCl_4}}$ 2.30 (6H, s), 3.00 (1H, s), and 6.80—6.90 (3H, m).

Support of a part of this research by the Ministry of Education, Japanese Government, with a Scientific Research Grant is acknowledged.

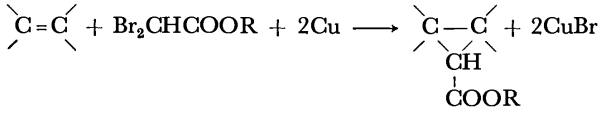
Generation of Ketocarbenoid by α-Elimination of ω,ω-Dibromoacetophenone with Copper, and Trapping by Cycloaddition to Olefins

Nariyoshi KAWABATA,* Tetsuya FUJII, Michiharu NAKA, and Shinzo YAMASHITA
Department of Chemistry, Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto 606
(Received December 17, 1976)

Ketocarbenoid was generated by the reaction of ω,ω-dibromoacetophenone with copper in aromatic hydrocarbon, and was trapped by cycloaddition to olefins. This is the first example of cyclopropanation of olefins by formally divalent carbon intermediate without use of diazoketones.

Thermal, photochemical, and catalytic decomposition of diazoketones have been the source of ketocarbenes and carbenoids.[1] The most useful reaction of carbene and carbenoid in synthesis is the cycloaddition to olefins to give the corresponding cyclopropane derivatives. However, in the reaction of the above ketocarbenes and carbenoids with olefins, the yields of acylcyclopropane derivatives are low due to Wolff rearrangement[2] and other side reactions.

On the other hand, α-elimination reaction provides a good route to most classes of carbenes and carbenoids.[1] The metal α-haloenolates of α-haloketones have served as intermediates in a number of synthetically useful reactions such as Darzens condensation and related reactions, but these enolates usually do not decompose to ketocarbenes.[3] Even the addition of copper(I) compounds does not promote their decomposition to ketocarbenes.[3] Charpentier-Morize and Sansoulet[4] reported the formation of 1,2,3-tripivaloylcyclopropane and 1,2,3,4,5,6-hexapivaloylcyclohexane by the reaction of dichloromethyl *t*-butyl ketone with zinc-copper couple in ether. Furukawa and coworkers[5] reported that the reaction of ω,ω-dibromoacetophenone with zerovalent transition metal complexes gave *trans*-1,2,3-tribenzoylcyclopropane, or *trans*-1,2-dibenzoylethylene. Ketocarbene or carbenoid seems to be included as an intermediate of these reactions, but it was not trapped by cycloaddition to olefins. Scott and Cotton[6] reported the formation of ketocarbenoid by α-elimination of α,α-dibromoketone with zinc dust or diethylzinc. The ketocarbenoid was trapped by an intramolecular carbon-hydrogen insertion reaction, but not by the cycloaddition to olefins. The reaction of the ketocarbenoid with olefin was reported to give a substituted dihydrofuran, which represents the product of formal 1,3-dipolar addition of the ketocarbenoid to olefin.[7]



Recently, we found that the reaction of dibromoacetic esters with copper powder in the presence of olefins gave the corresponding alkoxycarbonylcyclopropane derivatives.[8] As an extension of this work, we have investigated the α-elimination of α,α-dihaloketones with copper powder, and found that ketocarbenoid was generated by the reaction and was trapped by cycloaddition to olefins. This is the first example of acylcyclopropanation of olefins by formally divalent carbon intermediate without use of diazoketones.

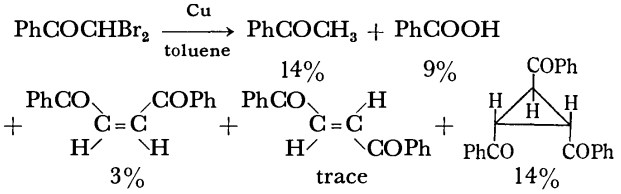
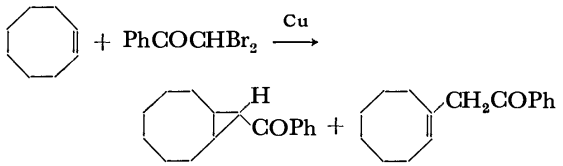
Results and Discussion

The reaction of ω,ω-dibromoacetophenone with copper powder in toluene at 100 °C for 93 h was found to give acetophenone, benzoic acid, *cis*- and *trans*-1,2-dibenzoylethylene, and *trans*-1,2,3-tribenzoylcyclopropane. In addition, a large amount of unidentified tar was obtained. Most of ω,ω-dibromoacetophenone was consumed under the conditions. This result suggests that the reaction involves ketocarbene or carbenoid intermediate. In order to ascertain the nature of the intermediate, we attempted to trap it by the cycloaddition to olefins.



Treatment of *cis*-cyclooctene, ω,ω-dibromoacetophenone, and copper powder in toluene at 100 °C for 93 h gave *exo*-9-benzoyl-*cis*-bicyclo[6.1.0]nonane (**1**) together with ω-1-cycloocten-1-ylacetophenone (**2**) in 12 and 3% yields, respectively, based on the olefin.



1 **2**

Assignment of the exo stereochemistry of **1** rests on NMR coupling constant arguments. That is, with the aid of a shift reagent, the absorption of the cyclopropane ring proton in the geminal position to the benzoyl group was shown to exhibit a triplet (J=3.5 Hz). The coupling constant is consistent with the exo structure. The *cis* and *trans* coupling constants of the cyclopropane ring protons were reported to be 4—9 and 3—5 Hz, respectively.[9] The coupling constant 3.5 Hz of **1** agrees well with the corresponding coupling constants in the structurely similar cyclopropane derivatives. The absorption of the ring proton in the geminal position to the methoxycarbonyl group of *exo*-9-methoxycarbonyl-*cis*-bicyclo-[6.1.0]nonane, *exo*-8-methoxycarbonylbicyclo[5.1.0]-octane, and *exo*-7-methoxycarbonylbicyclo[4.1.0]-heptane appeared as triplets with the coupling constants of 4.2, 3.9, and 4.2 Hz, respectively.[8] The coupling constants of the corresponding endo isomers were 8.6,

8.3, and 9.4 Hz, respectively.[8]

The endo isomer of **1** was not detected in the reaction mixture. Presumably the steric repulsion between the benzoyl group and the cyclooctane ring is significant.

Treatment of styrene, ω,ω-dibromoacetophenone, and copper powder in ethylbenzene at 100 °C for 120 h gave a 1: 1.6 mixture of *cis*- and *trans*-1-phenyl-2-benzoylcyclopropane in 2% yield based on the olefin. In this case, most of styrene polymerized during the course of the reaction.

Since organocopper intermediates rather than free carbenes are probable intermediates in the reaction of copper powder with diiodomethane, chlorodiiodomethane, and dibromoacetic esters,[8] reaction of ω,ω-dibromoacetophenone with copper powder would also proceed *via* organocopper intermediate (ketocarbenoid of copper) rather than free ketocarbene.

Experimental

Elementary analyses were performed at the Elementary Analysis Center of Kyoto University. IR spectra were recorded on a Hitachi Model 215 grating spectrometer or Japan Spectroscopic Co. Model 402G grating spectrometer. NMR spectra were obtained with a Varian T-60-A spectrometer using tetramethylsilane as an internal standard. Mass spectra were obtained on a Hitachi Model RMU-6 mass spectrometer. Gas chromatographic analysis was carried out on a Shimadzu GC-4A or GC-4B gas chromatograph.

Materials. ω,ω-Dibromoacetophenone was prepared according to the procedure of Taylor.[10] The ordinary commercial grade of copper powder provided by Nakarai Chemicals Ltd., Kyoto, was used without further purification. Olefins and solvents were purified by distillation.

Reaction of ω,ω-Dibromoacetophenone with Copper Powder. Copper powder (11.4 g, 180 mmol) was treated with 0.5 g (2 mmol) of iodine in 50 ml of toluene at room temperature with stirring. After the brown color of iodine disappeared, ω,ω-dibromoacetophenone (22.2 g, 80 mmol) was added, and the mixture was heated at 100 °C for 93 h. After the reaction, the inorganic materials were separated by filtration. Weight of the inorganic materials was 23.7 g after drying, suggesting that most of copper powder was converted to copper(I) bromide under the reaction condition. Solvent and other volatile materials were removed from the organic layer by heating under a reduced pressure, and the residue was dissolved in benzene. Addition of light petroleum ether to this benzene solution gave 1.29 g (14%) of *trans*-1,2,3-tribenzoylcyclopropane as a crystalline solid, which was purified by washing with carbon tetrachloride followed by recrystallization from benzene. It was identified by comparing its IR and NMR spectra with those of an authentic sample.[11] When solvents were removed from the filtrate, 7.26 g of unidentified tar was obtained.

In another run of experiment which was carried out under the same reaction condition, the organic layer was analyzed by gas chromatography. The analysis showed the formation of acetophenone and benzoic acid in 14 and 9% yields, respectively, which were identified by comparing spectral data with those of authentic samples, and the presence of only 1.3% of unchanged ω,ω-dibromoacetophenone in the reaction mixture. The analysis also showed the presence of two minor reaction products in 3% and trace yields, respectively. Spectral data of these products were identical with *cis*- and *trans*-1,2-dibenzoylethylene, respectively.

Reaction of ω,ω-Dibromoacetophenone with Copper Powder in the Presence of cis-*Cyclooctene.* Copper powder (1.14 g, 18.0 mmol), iodine (0.05 g, 0.2 mmol), ω,ω-dibromoacetophenone (2.22 g, 8.0 mmol), and *cis*-cyclooctene (0.44 g, 4.0 mmol) were treated in a similar manner in 3.0 ml of toluene at 100 °C for 93 h, and **1** and **2** were obtained in 12 and 3% yields, respectively, based on the olefin. The yields were determined by gas chromatographic analysis of the reaction mixture. A sample of **1** collected by gas chromatography was analyzed. $n_D^{30}=1.5546$; IR (neat) 1660 cm^{-1} ($\nu_{C=O}$); NMR (CCl_4) τ 2.1 (2H, m), 2.6 (3H, m), 8.0 (3H, m), 8.42 (12 H, m). With aid of a shift reagent, tris(dipivaloylmethanato)europium ($Eu(dpm)_3$), the absorption of the cyclopropane ring proton in the geminal position to the benzoyl group was shown to exhibit a triplet ($J=3.5$ Hz). Found: C, 84.31; H, 9.01%. Calcd for $C_{16}H_{20}O$: C, 84.16; H, 8.83%. A sample of **2** collected similarly from the reaction mixture was also analyzed. NMR (CCl_4) τ 2.1 (2H, m) 2.6 (3H, m), 4.5 (1H, m), 7.04 (2H, s), 7.9 (2H, m), 8.40 (10H, m); IR (neat) 1681 cm^{-1} ($\nu_{C=O}$); MS *m/e* (rel intensity) 228 (7, M^+), 120 (28), 108 (15), 105 (100), 77 (39), 67 (13), 44 (47), 40 (22).

Reaction of ω,ω-Dibromoacetophenone with Copper Powder in the Presence of Styrene. Copper powder (11.4 g, 180 mmol), iodine (0.5 g, 2 mmol), ω,ω-dibromoacetophenone (22.2 g, 80 mmol) and styrene (4.2 g, 40 mmol) were treated in a similar manner in 30 ml of ethylbenzene at 100 °C for 120 h. Gas chromatographic analysis of the reaction mixture showed the presence of two reaction products in a ratio of 1: 1.6 in 2% yield based on the olefin. Spectral data of these two products were consistent with *cis*- and *trans*-1-phenyl-2-benzoylcyclopropane, respectively. A sample of the cis isomer collected from the reaction mixture by gas chromatography was analyzed. NMR (CCl_4) τ 2.1 (2H, m), 2.6 (2H, m), 2.8 (1H, m), 2.91 (5H, narrow m), 7.2 (2H, m), 7.9 (1H, m), 8.7 (1H, m); IR (CCl_4) 1675 cm^{-1} ($\nu_{C=O}$). A sample of the trans isomer collected similarly was also analyzed. NMR (CCl_4) τ 2.1 (2H, m), 2.6 (2H, m), 2.8 (1H, m), 2.83 (5H, narrow m), 7.3 (2H, m), 7.8—9.2 (2H, m); IR (CCl_4) 1670 cm^{-1} ($\nu_{C=O}$).

Principal Axes of the EFG Tensors and Torsional Oscillations in Boron Triiodide

Tsutomu OKUDA, Hideta ISHIHARA, Koji YAMADA, and Hisao NEGITA
Department of Chemistry, Faculty of Science, Hiroshima University, Hiroshima 730
(Received October 14, 1976)

Synopsis. The Zeeman effect of ^{127}I NQR and the quadrupole effect of ^{11}B NMR on a single crystal of BI_3 were observed in order to investigate the principal axes of the EFG tensors. The frequencies of the torsional oscillations were determined from the temperature dependence of e^2Qq_{ii}/h.

From X-ray analysis, it is well known that the BI_3 molecule has a planar trigonal structure with D_{3h} symmetry.[1] From the molecular symmetry, it can be expected that the z principal axis of the ^{11}B EFG tensor is consistent with the 3-fold rotation axis of the molecule. Using a single crystal, the direction of the principal axes of the ^{127}I and ^{11}B atoms can be determined experimentally from the Zeeman effect of ^{127}I NQR and the quadrupole effect of ^{11}B NMR, respectively.

The infrared and Raman spectra of BI_3 have been observed and the frequencies of the lattice vibrations were estimated.[2] With regard to these results it appears worthwhile to examine the effect of torsional oscillations from the temperature dependence of e^2Qq_{ii}/h.

Experimental

The NQR spectrometer was a self-quenching, super-regenerative oscillator with frequency modulations; the absorption lines were displayed on an oscilloscope. The temperature dependence of the NQR frequencies was found for a sample which was immersed in petroleum ether cooled to a given temperature using liquid nitrogen. The Zeeman effect was examined by the zero-splitting cone method. A magnetic field of *ca.* 250 G was applied by means of a Helmholtz coil.

Using a broad line NMR spectrometer of Japan Electron Optics Lab. Co., Ltd., the measurement of the ^{11}B NMR was made at 13.00 MHz and the magnetic field was varied to observe the resonance.

Results and Discussion

^{127}I NQR. Two resonance lines for ^{127}I NQR were observed and were attributed to the ν_1 and ν_2 lines, corresponding to the $\pm1/2\leftrightarrow\pm3/2$ and $\pm3/2\leftrightarrow\pm5/2$ transitions, respectively.[3] Each of the resonance lines consisted of a doublet with an intensity ratio of *ca.* 2 to 5 and a frequency difference of *ca.* 25 to 30 kHz at room temperature. They were observed at temperatures ranging from −186 to 23 °C. The cause of the doublet has been attributed to the existence of ^{10}B and ^{11}B in BCl_3 and BBr_3.[4] This is true for BI_3 as well.

Figure 1 shows the zero-splitting pattern of the ν_1 line which was observed at room temperature. Since the derived asymmetry parameter η is 0.460 which is greater than the critical value of 0.412, the direction of the axis

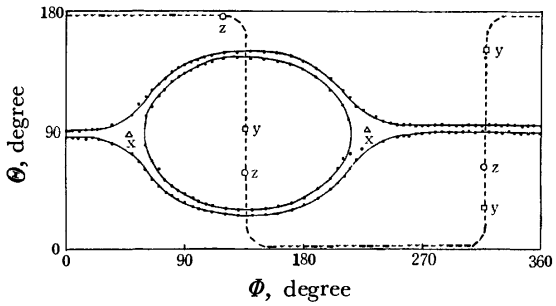

Fig. 1. Zero-splitting pattern of the Zeeman effect on the resonance line, ν_1. The molecular plane is indicated by the broken line.

of the zero-splitting cone is parallel to the y principal axis of the ^{127}I EFG tensor.[5] On the other hand, the direction of the x principal axis of the ^{127}I EFG tensor lies along the 3-fold rotation axis of the molecule. The direction of the z principal axis of the ^{127}I EFG tensor is considered to be parallel to the B–I bond, so that the angle <I–B–I can be obtained from the Zeeman effect, which gives a value of $120\pm0.6°$.

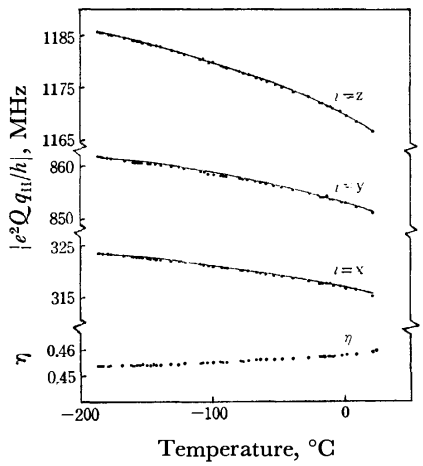

Fig. 2. Temperature dependences of the quadrupole coupling constants and the asymmetry parameter.

The temperature dependence of the quadrupole coupling constants, e^2Qq_{ii}/h (i=x, y, and z) and the asymmetry parameter, η, were derived from the temperature dependence of the ν_1 and ν_2 lines, as shown in Fig. 2. It was found that the absolute temperature coefficients of the quadrupole coupling constants are in the sequence $e^2Qq_{zz}/h>e^2Qq_{yy}/h>e^2Qq_{xx}/h$, and that η increases gradually with temperature. If the

amplitudes of the torsional oscillation about the x, y, and z principal axes of the ^{127}I EFG tensor are denoted by ϑ_x, ϑ_y, and ϑ_z, respectively, the averaged principal values of the EFG tensor can be expressed by the following equations,[6]

$$V_{xx} = eq_0[-(1-\eta_0)/2-\langle\vartheta_z^2\rangle\eta_0+\langle\vartheta_y^2\rangle(3-\eta_0)/2],$$
$$V_{yy} = eq_0[-(1+\eta_0)/2+\langle\vartheta_z^2\rangle\eta_0+\langle\vartheta_x^2\rangle(3+\eta_0)/2], \quad (1)$$
$$\text{and } V_{zz} = eq_0[1-\langle\vartheta_y^2\rangle(3-\eta_0)/2-\langle\vartheta_x^2\rangle(3+\eta_0)/2],$$

where q_0 and η_0 are the values in the static lattice, and the $\langle\vartheta_i^2\rangle$ (i=x, y, and z) indicate the mean square amplitudes of the oscillation about each i principal axis of the EFG tensor. If the torsional oscillations are approximated by harmonic oscillations, $\langle\vartheta_i^2\rangle$ is given by[7]

$$\langle\vartheta_i^2\rangle = h\coth(h\nu_i/2kT)/8\pi^2I_i\nu_i, \quad (2)$$

where the I_i are the moments of inertia about each i principal axis of the inertia tensor and the ν_i are the torsional frequencies. In order to reflect the effect of thermal expansion of the lattice, the ν_i are expressed empirically by

$$\nu_i = \nu_{i0}(1-\alpha_i T), \quad (3)$$

where the α_i are coefficients of expansion. In the case of BI_3, the principal axes of the ^{127}I EFG tensor coincide with the principal axes of the inertia tensor. Considering the molecular symmetry it can be assumed that $\langle\vartheta_y^2\rangle = \langle\vartheta_z^2\rangle$. Thus a best fit using the least-squares method was tried.[8] The following results were obtained: $e^2Qq_0/h = 1190.6\pm1.1$ MHz, $\eta_0 = 0.4518\pm0.0003$, $\nu_{x0} = 46.1\pm2.6$ cm^{-1}, $\nu_{y0}=\nu_{z0}=34.9\pm1.2$ cm^{-1}, $\alpha_x = 0.0012\pm0.0002$ deg^{-1}, and $\alpha_y=\alpha_z=0.0003\pm0.0004$ deg^{-1}. The curves reproduced using these values are shown as full lines in Fig. 2. The standard deviation is between 0.11 and 0.22 MHz. The frequencies of the torsional oscillations obtained above are comparable to those of the R_z and R_{xy} modes of the lattice vibrations.[2] Consequently, it is believed that the effective vibrations for the temperature dependence of the quadrupole coupling constants are in the lattice region.

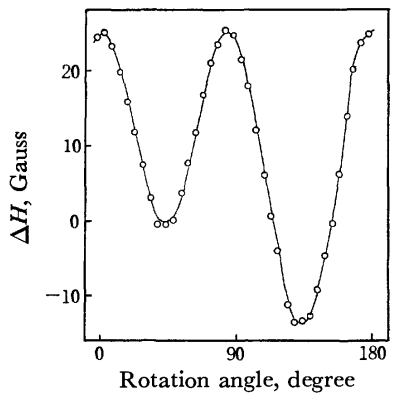

Fig. 3. The rotation pattern of ^{11}B central line.

^{11}B NMR. In ^{11}B NMR, only one central resonance line corresponding to the $m=+1/2\leftrightarrow m=-1/2$ transition was observed and was seen to be affected by the second-order quadrupole interaction. The rotation pattern of the central line was obtained by measuring its shift from the magnetic field corresponding to the Larmor frequency as a function of the rotation angle of the crystal, the results of which are shown in Fig. 3. A second-order frequency shift, $\Delta\nu$, can be represented in terms of the magnetic field by[9]

$$\Delta\nu = -\nu_L(\Delta H/H_L^2)(\Delta H+H_L), \quad (4)$$

where ν_L and H_L are the Larmor frequency of 13.00 MHz and the corresponding magnetic field, respectively. $\Delta H=H_R-H_L$, where H_R is the resonance magnetic field of ^{11}B shifted by the second-order quadrupole interaction. From the molecular symmetry it can be assumed that the asymmetry parameter for ^{11}B is zero. Accordingly, the frequency shifts of the central transition are given by the following equation for $\eta=0$[10]

$$\Delta\nu = -(\nu_Q^2/16\nu_L)(a-3/4)(1-\mu^2)(9\mu^2-1), \quad (5)$$

where $\nu_Q=3e^2Qq/2I(2I-1)h$, $a=I(I+1)$, $\mu=\cos\vartheta$, and ϑ is the angle between the direction of the z principal axis of the EFG tensor and that of the applied magnetic field. From this analysis it is found that the direction of the 3-fold rotation axis of the molecule which was determined by the Zeeman effect of the ^{127}I NQR is consistent with the direction of the z principal axis of the ^{11}B EFG tensor within an experimental error of $\pm0.6°$. The quadrupole coupling constant of the ^{11}B atom obtained was 2.32 ± 0.05 MHz at room temperature. This value differs slightly from 2.40 ± 0.04 MHz at -196 °C.[11] The ratio of e^2Qq_{zz} at -196 °C to that at room temperature is 1.03. This ratio can be explained by the torsional oscillations of the ^{11}B atom about the principal axes of the EFG tensor as follows: assuming $\eta_0=0$, the z component of the quadrupole coupling constant, which is averaged over the torsional oscillation, is given by

$$e^2Qq_{zz} = e^2Qq_0(1-\langle\vartheta_x^2\rangle3/2-\langle\vartheta_y^2\rangle3/2). \quad (6)$$

The x and y principal axes of the ^{11}B EFG tensor lie in the plane of the molecule and it can be assumed that $\langle\vartheta_x^2\rangle=\langle\vartheta_y^2\rangle$. The evaluation of $\langle\vartheta_x^2\rangle$ and $\langle\vartheta_y^2\rangle$ can be derived from the results of the temperature dependence of the ^{127}I NQR. The ratio e^2Qq_{zz} (-196 °C)/e^2Qq_{zz} (23 °C) is found to be 1.02 from Eq. 6.

Mesomorphic Properties of 2-(4-*n*-Alkoxybenzylideneamino)anthracenes

Sakumitsu SAKAGAMI and Minoru NAKAMIZO

National Industrial Research Institute of Kyushu, Tosu, Saga 841

(Received October 26, 1976)

Synopsis. 2-(4-*n*-Alkoxybenzylideneamino)anthracenes were synthesized, and the phase transitions were determined using a differential scanning calorimeter and a polarizing microscope. Methoxy through propoxy derivatives exhibit the monotropic nematic state, whereas the higher members show the enantiotropic nematic state.

It is well recognized that the molecules which can form liquid crystalline phases generally possess common structural features. The four structural features that appear essential are; (1) the molecules will be rod-like in shape; (2) they must be rigid; (3) the simultaneous presence of permanent dipoles and easily polarizable groups within a molecule plays an important role, and (4) weak dipoles at the end groups of the molecule are of importance.[1-4] Indeed, the molecules of an unelongated and plate-like shape exhibit no mesomorphic properties. It has, however, been found that naphthalene,[5] fluorene,[6] and phenanthrene,[7] the molecular structures of which are not rod-like, can exhibit liquid crystalline states if one introduces appropriate substituents to them. In order to elucidate the relationship between the molecular structure and the mesomorphic properties, it is of much interest that a liquid crystalline compound can be obtained by introducing the end substituent to the compounds which exhibit potentially non-mesomorphic behavior. In this paper we wish to report first that anthracene, whose molecule is plate-like and is much wider than that of naphthalene or phenanthrene, can indeed exhibit a liquid crystal state if a 4-*n*-alkoxybenzylidene group is introduced at the 2-position.

Experimental

Materials. The 2-(4-*n*-alkoxybenzylideneamino)anthracenes studied here were synthesized from 4-*n*-alkoxybenzaldehyde and 2-aminoanthracene which were themselves commercially obtained by refluxing several hours in a mixed solution of benzene and methanol. The crude products were successively recrystallized from methanol, benzene, and hexane. They were thoroughly dried under a vacuum in order to remove the solvent and any moisture.

Measurements. The transition heat was determined by means of a Rigaku differential scanning calorimeter which was calibrated in terms of the temperature and the energy using potassium nitrate, indium, benzoic acid, and tin. All the samples were packed in closed aluminium sample pans. Each sample was heated and cooled under a flow of nitrogen gas to prevent the decomposition of the sample. The phase transition and the liquid crystal texture were observed by using a polarizing microscope and a Mettler FP 52 microfurnance for sample temperature control.

Results and Discussion

All the compounds studied exhibit the nematic liquid crystal state, except for 2-(benzylideneamino)-

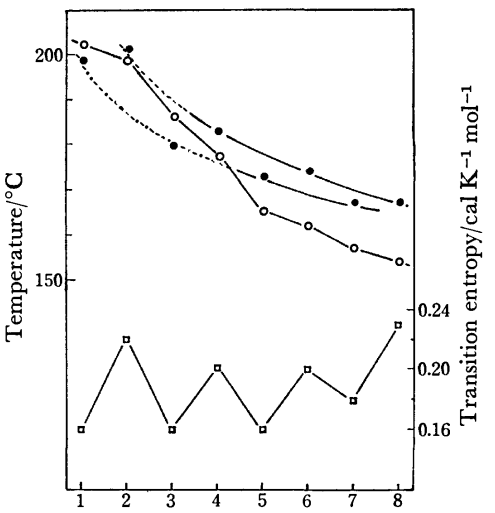

Fig. 1. Phase transition diagram and the transition entropy for 2-(4-*n*-alkoxybenzylideneamino)anthracene series.
○: Solid-nematic or isotropic; ●: nematic-isotropic; □: transition entropy for the nematic-isotropic transition. The dotted lines indicate the monotropic transitions.

anthracene, which gives no mesomorphic state. The phase-transition temperatures are summarized in Table 1, together with the calorimetric data. The first three members in this series show the monotropic nematic state, while the higher members, starting with 2-(4-*n*-butoxybenzylideneamino)anthracene, exhibit the enantiotropic nematic phase. Furthermore, the solid-solid transition is observed for the homologous series with longer alkoxy chains than pentyloxy. This is not surprising since the presence of two or more solid phases is very common with materials forming mesomorphic states.

Figure 1 shows the variation in the transition temperature with the increase in the length of the alkoxy chain. Both the solid-nematic and the nematic-isotropic liquid transition temperatures become lower as the alkoxyl group grows. In addition, an even-odd alternation of the nematic-isotropic liquid transition temperature is apparent. Such an even-odd effect for the nematic-isotropic liquid transition has frequently been found in most homologous series of liquid crystals.[1-4] In particular, for a homologous alkoxy series[1-4,8] each of the clearing points for both even and odd carbon-chain members falls on a smooth curve. In the homologous series of 2-(4-*n*-alkoxybenzylideneamino)-anthracenes studied here, two smooth curves can be drawn, as shown in Fig. 1, one connecting the even carbons and the other connecting the odd carbons. The curve for the even carbons lies above that for the odd carbons, as in other homologous alkoxy series. The even-odd alternation can be understood as a consequence of the even-odd effect in the chain-order parameter with respect to the molecular axis.[9] The entropies of transition for the nematic-isotropic liquid transition are also shown in Fig. 1. As is expected in view of the results mentioned above, the transition entropy shows the even-odd alternation more striking than the transition temperature.

The Analytical Application of Oleophilic Quaternary Ammonium Salts. X.[1-9] The Extraction of the Niobium-Pyrocatechol Violet-Tridodecylethylammonium Ternary Complex

Yoshio SHIJO

Department of Industrial Chemistry, Faculty of Engineering, University of Utsunomiya, Ishii-machi, Utsunomiya 321-31

(Received August 20, 1976)

Synopsis. The formation and extraction of the niobium–Pyrocatechol Violet–tridodecylethylammonium ternary complex have been examined. The optimal pH for the extraction is 4—5. The molar absorptivity of the complex is 4.4×10^4 $cm^{-1}\cdot mol^{-1}\cdot l$ at 553 nm. Its composition is estimated to be $Nb(PV)_2(R-\overset{R}{\underset{R}{N}}-R')_3$.

Pyrocatechol Violet (PV) reacts with niobium[10] to form a violet chelate which is suitable for photometric determination. The sensitivity of the color reaction increases upon the addition of a long-chain quaternary ammonium salt.[11] Many papers[12-15] have been published on the extraction of Pyrocatechol Violet chelate anions with large organic cations. The lack of information on the extraction of ionic associates in the case of the niobium–Pyrocatechol Violet chelate anion with large organic cations, however, led us to carry out the present investigation. Furthermore, the investigation of the extraction of the metal chelate anions with an oleophilic quaternary ammonium salt such as tridodecylethylammonium bromide (TDEA), its superior extraction efficiency with relation to many chelate anions has been demonstrated. On the extraction of the Pyrocatechol Violet chelate anion with TDEA, we have already reported the spectrophotometric study of copper,[2] tin,[4] aluminum,[5] and zirconium.[8] In this paper, the fundamental conditions for the extraction of niobium as a niobium–PV–TDEA ternary complex with carbon tetrachloride and the composition of the ternary complex will be discussed.

Experimental

Reagent. A 2.5×10^{-3} M niobium solution was prepared by the following procedure. A definite amount of diniobium pentoxide and a small amount of potassium disulfate were placed in a platinum crucible and melted. After cooling, a 104-ml portion of sulfuric acid was added and the solution was diluted to 250 ml with de-ionized water. A working standard solution was prepared as needed by the dilution of the 2.5×10^{-3} M solution with 7.5 M sulfuric acid to each desired concentration. A 5.0×10^{-4} M PV solution was prepared by dissolving the Dotite PV in de-ionized water without further purification. TDEA was prepared, by refluxing for 4 h, to an ethanolic solution of tridodecylamine and ethyl bromide. After the evaporation of the solvent, the salt was recrystallized two times from butyl acetate. The 10^{-3} M TDEA solution was prepared by dissolving the above TDEA in carbon tetrachloride. All the other chemicals used were of a guaranteed-reagent quality.

Apparatus. All the measurements of the absorbance were made with a Hitachi manual spectrophotometer, model Epu-2A. Matched 10-mm absorption cells were used. The pH measurements were made with a Hitachi-Horiba model M-5 glass electrode pH meter.

Standard Procedure. Up to 7 μg of niobium were placed in a 50-ml polyethylene beaker; 0.5 ml of 0.03% hydrogen peroxide, a definite amount of 1 M sulfuric acid, and 3 ml of a 5×10^{-4} M PV solution were then added. The pH of the solution was adjusted to 4.5 by the addition of 2 ml of a 2 M sodium acetate solution and a definite amount of ammonia buffer solution (pH 9). Then the solution was diluted to 25 ml with de-ionized water. The solution was transferred into a 35-ml test tube, and a 5-ml portion of 10^{-3}M TDEA in carbon tetrachloride was added. The extraction was carried out for 5 min by turing the test tube upside down two times per 5 s. After a complete phase separation, the organic layer was taken out and centrifuged for 3 min at 3000 rpm. The extract was transferred into an absorption cell, and the absorbance at 553 nm was measured against the reagent blank.

Results and Discussion

Absorption Spectra. The absorption spectra of the ternary complex extracted into carbon tetrachloride and of the niobium–PV chelate anion in an aqueous solution are given in Fig. 1, along with that of the reagent blank. The ternary complex and the niobium–PV chelate anion have absorption maximum at 553 nm and 562 nm respectively. The absorbance of the ternary complex increases about two times more than that of the niobium–PV chelate anion.

Effect of pH. The effect of the pH on the extraction of the ternary complex with 2×10^{-6} M niobium, 6×10^{-5} M PV in the aqueous phase, and 10^{-3} M TDEA

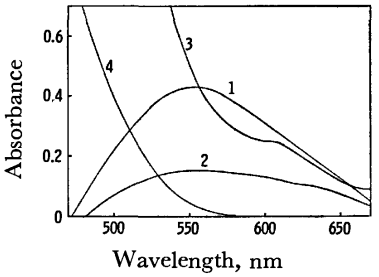

Fig. 1. Absorption spectra of the Nb–PV–TDEA in carbon tetrachloride and the Nb–PV in aqueous solution.
pH=4.5
(1): Nb–PV–TDEA in carbon tetrachloride $[Nb]_w=2\times10^{-6}$ M, (2): Nb–PV in aq soln $[Nb]_w=10^{-5}$ M, (3): PV–TDEA in carbon tetrachloride $[PV]_w=6\times10^{-5}$ M, (4): PV in aq soln $[PV]_w=6\times10^{-5}$ M.

in carbon tetrachloride was examined. The optimum pH range for the extraction is found to be 4—5. The pH dependence of the extraction may change with the change in the reagent concentration. The carbon tetrachloride extract is stable for at least 30 min. The absorbance of the reagent blank in the organic layer increases remarkably with an increase in the pH value.

Organic Solvents. The niobium–PV–TDEA ternary complex can be extracted into such substances as carbon tetrachloride, butyl acetate, carbon disulfide, benzene, and nitrobenzene, but not into 1-butanol, methyl isobutyl ketone, and chloroform.

The Effect of the PV Concentration. The effect of the PV concentration in the aqueous phase on the extraction of the ternary complex was also examined. The absorbance of the extract is constant when the initial aqueous phase is in the concentration range 4×10^{-5}—1×10^{-4} M. The absorbance of the extract gradually decreases, however, upon the further addition of PV.

The Effect of the TDEA Concentration. The effect of the concentration of TDEA in carbon tetrachloride on the extraction of the ternary complex was also examined. The constant and maximum absorbance of the extract is obtained when the organic phase is in the concentration range 5×10^{-4}—2×10^{-3} M.

The Effect of the Mixing Time. The extractability of the ternary complex with 10^{-3} M TDEA in carbon tetrachloride at pH 4.5 is given as a function of the mixing time. The absorbance of the extract is constant for the mixing times from 3 to 10 min.

Extractability and Molar Absorptivity. The extractability of the ternary complex under optimum conditions was examined by the spectrophotometric determination of niobium in the extract with Xylenol Orange after evaporating the organic layer. When a 250-ml portion of an aqueous layer containing 46.5 μg of niobium is mixed with 50 ml of a carbon tetrachloride solution of TDEA, 98.1% of the niobium is extracted by one extraction. The distribution ratio and the molar absorptivity are 2.58×10^{2} and 4.3×10^{4} $cm^{-1}\cdot mol^{-1}\cdot l$ respectively.

Calibration Curve. A calibration curve was made by extracting different amounts of niobium under optimum conditions. A good linear relationship is obtained over the concentration range from 0.58 to 7 μg of niobium per 5-ml portion of carbon tetrachloride. The variation coefficient of the absorbance is 1.3% for the 7 measurements. The effect of foreign ions was also examined. Copper, bismuth, and tin were masked with 2-mercaptoethanol, but uranium, thorium, molybdenum, tungsten, aluminum, iron, and vanadium interfered seriously. Of the anions tested, nitrate, iodide, thiocyanate, and perchlorate interfered considerably, giving a negative error.

The Composition of the Ternary Complex. The molar ratio of the components in the ternary complex was established by the continuous variation method. The results indicate that the molar ratios of niobium to PV to TDEA are 1 : 2 : 3, as is shown in Figs. 2 and 3. The same results were also obtained by the mole-ratio method. The application of the equilibrium-shift method to this system had not been successfully carried out because the complete formation of the ternary complex occurred in a small excess of reagents. Consequently, it may be assumed that the ternary complex is an ion-association system for $\{[Nb(PV)_2]^{3-}\}\cdot\left\{(R-\overset{R}{\overset{|}{N}}{}^{\pm}-R')_3\right\}$.

The Analytical Application of Oleophilic Quaternary Ammonium Salts. XI.[1] The Extraction of the Iron(III)-Pyrocatechol Violet-Tridodecylethylammonium Ternary Complex

Yoshio SHIJO

Department of Industrial Chemistry, Faculty of Engineering, University of Utsunomiya, Ishii-machi, Utsunomiya 321-31

(Received August 30, 1976)

Synopsis. The ionic associate of the iron(III)–Pyrocatechol Violet chelate anion with tridodecylethylammonium bromide is extracted into methyl isobutyl ketone. The ternary complex has an absorption maximum at 623 nm. The optimum pH for the extraction is 5.7—6.4 The molar absorptivity of the complex is 7.76×10^4 $cm^{-1}\cdot mol^{-1}\cdot l$. Its composition is estimated to be $Fe(PV)_2(R\text{–}\overset{\overset{R}{|}}{N}\text{–}R')_2$.

Pyrocatechol Violet (PV) reacts with many metal ions to form water-soluble chelates. The utility of its extraction-photometric variant in ionic-association systems has been reported by many workers.[2–5] Ishito and Ichinohe[6] studied the formation of the iron(III)–PV chelate in an aqueous solution. The extraction of the iron(III)–PV chelate anion in the presence of diphenylguanidine was studied by Jurevicius and Valiukevicius.[7] The author has found that the iron(III)–PV chelate anion is extracted with tridodecylethylammonium bromide (TDEA) in methyl isobutyl ketone to form an ionic associate and that the molar absorptivity is greater than that of the iron(III)–PV–diphenylguanidine system. The sensitivity of the present method is higher than those of the bathophenanthroline, 4-(2-pyridylazo)-resorcinol, and chromazurol S methods. In this paper, the fundamental conditions for the extraction of iron(III) as the iron(III)–PV–TDEA ternary complex in methyl isobutyl ketone and the composition of the ternary complex will be discussed.

Experimental

Reagent. A 2.5×10^{-3} M iron(III) solution was prepared by dissolving a definite ammount of ferric ammonium sulfate in 0.5 M sulfuric acid. The iron(III) concentration in the solution was determined by EDTA titration. A working standard solution was prepared as needed by the dilution of the 2.5×10^{-3} M solution to the desired concentration with de-ionized water. A 5×10^{-4} M PV solution was prepared by dissolving the Dotite PV in de-ionized water without further purification. The TDEA was prepared by the refluxing of an ethanolic solution of tridodecylamine and ethyl bromide for 4 h. After the evaporation of the solvent, the salt was recrystallized two times from butyl acetate. A 10^{-3} M TDEA solution was prepared by dissolving the above TDEA in methyl isobutyl ketone. All the other chemicals used were of a guaranteed reagent quality.

Apparatus. All the measurements of the absorbance were made with a Hitachi mannual spectrophotometer, model Epu-2A. Matched 10-mm absorption cells were used. The pH measurements were made with a Hitachi-Horiba model M-5 glass electrode pH meter.

Standard Procedure. To 2 ml of the 2.5×10^{-5} M iron(III) solution in a 50-ml polyethylene beaker, a definite amount of 0.1 M sulfuric acid and 2 ml of the 5×10^{-4} M PV solution were added. The pH of the solution was then adjusted to 5.8 by the addition of 2 ml of the 2 M sodium acetate solution and diluted to 25 ml with de-ionized water. The solution was transferred into a 35-ml test tube, and a 5-ml portion of 10^{-3} M TDEA in methyl isobutyl ketone was added. The extraction was carried out for 5 min by turning the test tube upside down two times per 5 s. After the complete phase separation, the organic layer was taken out and centrifuged for 3 min at 3000 rpm. The extract was then transferred into an absorption cell, and the absorbance was measured at 623 nm against the reagent blank.

Results and Discussion

Absorption Spectra. The absorption spectra of an aqueous solution of the iron(III)–PV chelate and of a solution of the iron(III)–PV–TDEA ternary complex in methyl isobutyl ketone, and also the absorption spectra of the respective blanks, are shown in Fig. 1. The ternary complex and the iron(III)–PV chelate anion have their absorption maxima at 623 and 604 nm respectively. The absorption maxima of the ternary complex shifted toward wavelengths longer by 20 nm compared with that of the iron(III)–PV chelate.

Effect of pH. The effect of the pH of the aqueous phase on the extraction was also examined. The maximum extraction was obtained at pH values from 5.7 to 6.4. PV itself is readily extracted with TDEA in methyl isobutyl ketone.

Organic Solvents. Of the solvents examined,

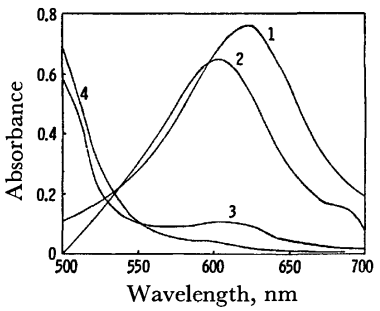

Fig. 1. Absorption spectra of the Fe–PV–TDEA in methyl isobutyl ketone and the Fe–PV in aqueous solution.
pH=5.8.
(1): Fe–PV–TDEA in MIBK, $[Fe]_w=2\times10^{-6}$ M, (2): Fe–PV in aq soln $[Fe]_w=10^{-5}$ M, (3): PV–TDEA in MIBK, $[PV]_w=4\times10^{-5}$ M, (4): PV in aq soln $[PV]_w=1\times10^{-4}$ M.

methyl isobutyl ketone, butyl acetate, carbon tetrachloride, carbon disulfide, and benzene were suitable for the quantitative extraction of the ternary complex. The organic layers separated out rapidly, and the molar absorptivity was maximal, when the methyl isobutyl ketone was used.

The Effect of the PV Concentration. With other factors kept constant, the PV concentration in the aqueous phase was varied from 2×10^{-6} to 10^{-4} M. The optimum concentration range of PV is from 2×10^{-5} to 6×10^{-5} M. The absorbance of the extract gradually decreases upon the further addition of PV.

The Effect of the TDEA Concentration. The concentration of TDEA in the organic phase was varied from 1×10^{-4} to 3×10^{-3} M. The optimum concentration range of TDEA is from 4×10^{-4} to 2×10^{-3} M.

The Effect of the Mixing Time. The mixing time was varied from 10 s to 15 min. The absorbance of the extract is constant for mixing times over 3 min.

The Extractability and Molar Absorptivity. 25 ml of an aqueous solution containing 2.8 μg of iron(III) and the reagents of an optimum concentration were mixed with 5 ml of 10^{-3} M TDEA in methyl isobutyl ketone. Extraction was repeated with 5 ml of an organic layer for the remaining aqueous phase, to which 0.2 ml of the 5×10^{-3} M PV solution was added afresh after the separation of the extract. It was found that 97.9% of the iron(III) was extracted by one extraction. The distribution ratio and the molar absorptivity were 2.33×10^{2} and 7.76×10^{4} $cm^{-1}\cdot mol^{-1}\cdot l$ respectively.

Calibration Curve. The plot of the absorbance of the extract *versus* the concentration of iron(III) in the aqueous phase gave a straight line from 2×10^{-7} to 3×10^{-6} M. The variation coefficient of the absorbance was 1.1% for the 8 measurements. The effects of foreign ions were also examined. Copper, bismuth, and tin were masked with 2-mercaptoethanol. Thorium, aluminum, and uranium, also, were masked with hydrogen peroxide and potassium fluoride. However, vanadium, molybdenum, tungsten, chromium, and zirconium interfered seriously. Of the anions tested, nitrate, iodide, thiocyanate, and perchlorate interfered considerably, giving a negative error.

The Composition of the Ternary Complex. The ratio of iron(III) to PV was found to be 1:2 by the continuous-variation method. To find the iron(III) to TDEA ratio, we attempted to apply the continuous-variation, molar-ratio, and equilibrium-shift methods. However, all these experiments were unsuccessful because the complexes precipitated on the aqueous-organic interface in a lower concentration of TDEA when the methyl isobutyl ketone was used as the solvent. When carbon tetrachloride was used as a solvent, no precipitates of the complex appeared on the interface, and the application of the continuous-variation method was successful. The results indicate that the

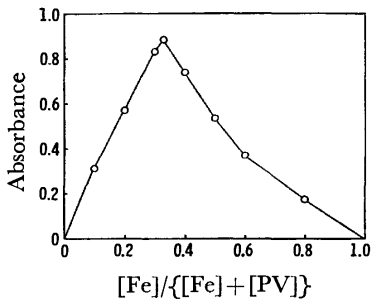

Fig. 2. Continuous variation method applied to the Fe–PV–TDEA system in carbon tetrachloride. $[Fe]_w+[PV]_w=1\times10^{-5}$ M, pH=5.8.

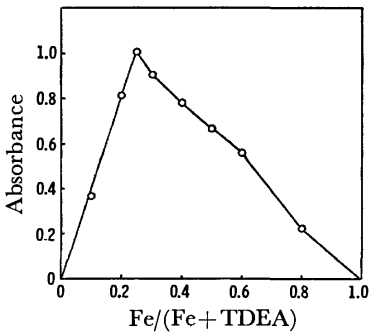

Fig. 3. Continuous variation method applied to the Fe–PV–TDEA system in carbon tetrachloride. Fe+TDEA=5×10^{-7} mol, pH=5.8.

ratio of iron(III) to PV to TDEA is 1:2:2, as is shown in Figs. 2 and 3. Consequently, it may be assumed that the ternary complex in carbon tetrachloride is an ion-association system for $\{[Fe(PV)_2]^{2-}\}\cdot\left\{\begin{matrix}R\\|\\(R-\overset{+}{N}-R')_2\\|\\R\end{matrix}\right\}$. The same composition may hold in the methyl isobutyl ketone.

Solvent Extraction Equilibria of Acids. V. The Extraction of Hydrobromic, Hydroiodic, and Thiocyanic Acids with Trioctylphosphine Oxide in Hexane

Masaru NIITSU and Tatsuya SEKINE*

Faculty of Pharmaceutical Sciences, Josai University, Sakado, Saitama 350-02
**Department of Chemistry, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162*

(Received November 4, 1976)

Synopsis. The solvent extraction of hydrohalogenic acids and thiocyanic acid (HX) in 1 mol dm^{-3} electrolyte solutions with trioctylphosphine oxide (E) has been studied at 25 °C. The extraction constant, $K_{ex_1}=[HXE]_{org}[H^+]^{-1}[X^-]^{-1}[E]_{org}^{-1}$, for thiocyanic acid was found to be $10^{2.5}$, while $K_{ex_2}=[HXE_2]_{org}[H^+]^{-1}[X^-]^{-1}[E]_{org}^{-2}$ for hydrobromic and hydroiodic acids were found to be $10^{0.34}$ and $10^{1.78}$ respectively.

The solvent extraction of such metal ions as halides and thiocyanates has been employed for various purposes. In these systems, an extraction of the hydrohalogenic acids or thiocyanic acid in the aqueous phase should occur when the acidity of the aqueous phase is high. In the present study, the solvent extraction of hydrobromic, hydroiodic, and thiocyanic acids in 1 mol dm^{-3} aqueous electrolyte solutions with trioctylphosphine oxide (TOPO) in hexane has been studied at 25 °C. The extraction constants of these acids were compared with those for other strong inorganic acids under the same conditions.

Experimental and Statistical

All the experiments were carried out in a thermostatted room at 25 °C. A portion of an aqueous solution and the same volume of an organic solution were placed in a stoppered glass tube, the tube was vigorously agitated for one minute and then centrifuged. The acid in the two phases was titrated with a standard barium hydroxide solution, and the thiocyanate ions, with a standard silver nitrate solution.

In the present study, the acid and TOPO are denoted by HX and E respectively. The subscript "org" denotes a chemical species in the organic phase, while the lack of a subscript denotes one in the aqueous phase. It was assumed that only one species containing X^- was extracted and that the extracted species could be written as HXE_n where n was unity or two. After several trials, these assumptions were confirmed to be reasonable, as will be shown later; thus, the following equations were derived.

The equilibrium under the above assumptions can be written as:[1)]

$$H^+ + X^- + nE(org) \rightleftharpoons HXE_n(org)$$

$$K_{ex_n} = [HXE_n]_{org}[H^+]^{-1}[X^-]^{-1}[E]_{org}^{-n} \quad (1)$$

where n is unity or two.

Since the amount of TOPO in the aqueous phase is probably very small, the following equations can also be written under the above assumptions for the extraction of HX in the presence of Na^+, H^+, and ClO_4^-:[1)]

$$[E]_{org,initial} = [E]_{org} + 2[HClO_4E_2]_{org} + n[HXE_n]_{org} \quad (2)$$

$$[H^+]_{org} = [HClO_4E_2]_{org} + [HXE_n]_{org} \quad (3)$$

The concentration of these species containing HX can be determined by titration with silver nitrate and that of the hydrogen-ion by titration with barium hydroxide.

When the aqueous phase contains only the HX acid, the terms of perchloric acid in Eqs. 2 and 3 can be eliminated and the distribution ratio of HX may be defined as:

$$D(HX) = [HXE_n]_{org}[H^+]^{-1} \quad (4)$$

Results and Discussion

It was found that the oxidation of iodide to iodine occurred during the two-phase agitation if it was continued for a long time, and the two phases turned pale yellow. This caused an extraction of the HI_3E_n species and introduced positive errors. However, when the agitation continued for only one minute, no color appeared in the two phases and still the equilibrium was reached. No trouble of this kind was encountered in the extraction of other acids.

The distribution ratio of thiocyanic acid with 3.0×10^{-2} mol dm^{-3} TOPO in hexane from aqueous solutions containing 1.0×10^{-1} mol dm^{-3} thiocyanate ions, 9.0×10^{-1} mol dm^{-3} perchlorate ions, and hydrogen and sodium ions at various molar ratios was determined as a function of the hydrogen-ion concentration. Under these conditions, the extraction of thiocyanic acid was much better than that of perchloric acid. After several trials, only the solvation number of unity was found to give a reasonable extraction constant; the error of the constant obtained by assuming an extraction of other species such as $(HX)_2E_2$ was always larger than that of the constant obtained by assuming the extraction of the

H_2SO_4[a)]	—	−0.30

a) Data taken from Ref. 1.

HXE species. Table 1 shows the extraction data and the calculated extraction constants.

The extraction equilibria of hydrobromic and hydroiodic acids were studied when the initial aqueous phase contained 1 mol dm^{-3} of the acid and when the hexane phase contained TOPO at various concentrations. Figure 1 gives the results, together with those of hydrochloric acid, in Ref. 1. From the slope of the plot, the solvation number of these acids was concluded to be two and their extraction constants were determined to be as is listed in Table 2. The solid lines in the figure were drawn on the basis of Eqs. 1 and 4 and the constants in Table 2.

Khopkar and Narayanankutty[2)] reported the value of Kex_1 of thiocyanic acid extracted from 1 mol dm^{-3} ammonium thiocyanate solutions at pH 1.6 to 3 with TOPO in xylene to be $10^{2.43}$, which agrees well with the present value. There have also been some reports on the solvent extraction of thiocyanic acid with TOPO.[3,4)]

As may be seen from Table 2, the values of the extraction constant, Kex_2, increase in the order of: HCl<HBr<HI<$HClO_4$. This order agrees with the order of the molar volumes of the anion. The extraction constant of Kex_1 of thiocyanic acid is much greater than that of nitric acid. Thus, when a metal ion in an acid solution containing thiocyanate ions is extracted with a neutral extractant such as TOPO, the extraction of thiocyanic acid should be taken into account in the analysis of the data, because this thiocyanic acid extraction probably decreases the concentration of thiocyanate ions in the aqueous phase and also that of the free extractant in the organic phase.

Condensation Products of Benzanthrone Obtained Using Copper Powder and Fused Zinc Chloride

Junji AOKI, Minoru TAKEKAWA, Shoji FUJISAWA, and Satoshi IWASHIMA*

Department of Chemistry, Faculty of Science, Toho University, Miyama-cho, Funabashi-shi, Chiba 274

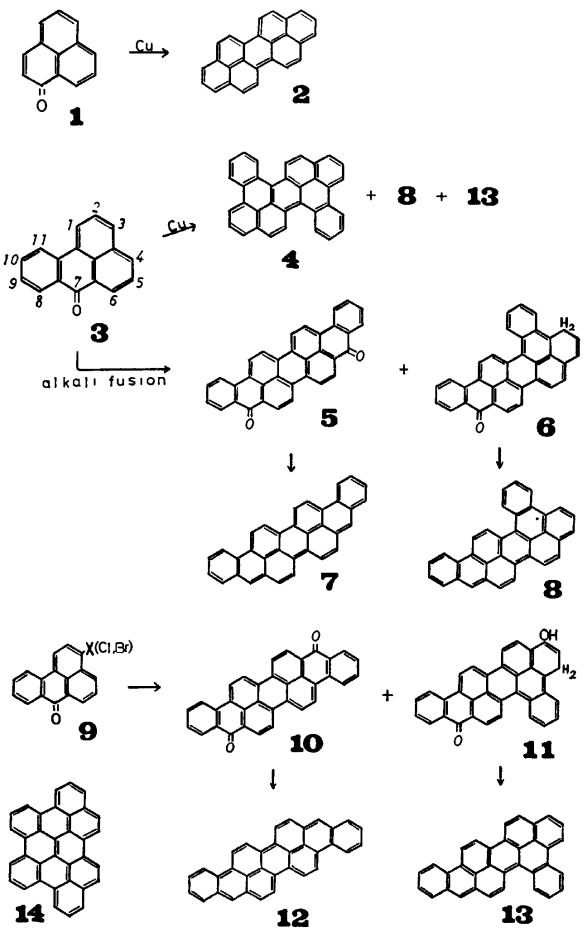
**Department of Chemistry, Faculty of Science and Technology, Meisei University, Hino-shi, Tokyo 191*

(Received June 28, 1976)

Synopsis. By heating benzanthrone (**3**) with copper powder, zinc chloride, and sodium chloride, violanthrene B (**8**) and isoviolanthrene B (**13**) were obtained in addition to the tetrabenzo[*a, cd, j, lm*]perylene (**4**) reported previously. This method may be considered to be a convenient method of synthesizing not only **4**, but also **13**.

Previously, Aoki reported[1] that 1-phenalenone (**1**) and benzanthrone (**3**) gave dibenzo[*cd, lm*]perylene (**2**) and tetrabenzo[*a,cd,j,lm*]perylene (**4**), respectively, upon heating with copper powder in a mixed flux of zinc chloride and sodium chloride. However, in the case of **3**, other compounds are possibly produced by coupling at positions other than the carbonyl carbon atom. In this paper, the results of a reinvestigation of work reported in Ref. 1 are reported.

By elution chromatography of the reaction products, a small amount of violanthrene B (**8**)[2,4] and a considerable amount of isoviolanthrene B (**13**)[3–5] were isolated along with **4**, and small amounts of unidentified materials.



On the other hand, however, alkali fusion, the typial condensation method for ketones such as **3**, gives violanthrones[6] (**5**, **6**;[6b] **10**, **11**[6c]). Since the carbonyl group remains, the Clar reduction method[7] must be applied in order to obtain the hydrocarbons (**7**, **8**; **12**, **13**).[2,3] Futhermore, no reports have been published concerning the formation of products having a 4-type skeleton.

In the present work, the above unidentified materials were not obtained in a pure state, but they were considered to be present in a mixture with a few hydrocarbons.[8] Consequently, the present method produces hydrocarbons in a single step from **3**, but affords no A-type substances (**5**, **7**, **10**, **12**).[9] This method may be considered to be a convenient method for preparing not only **4**, but also **13**, since it more readily gives pure **13** in a higher yield than the method of reducing **11**.

Experimental

The UV spectra were recorded with a Shimadzu Model D 40 RW Multiconvertible Spectrophotometer.

Dibenzo[*a,cd*]naphtho[3,2,1-*lm*]perylene (**8**) (violanthrene B). The synthesis from **6** has already been reported.[2] Mp 344 °C (corr.), $\lambda_{max}^{benzene}$ nm (log ε): 482 (5.00), 451 (4.57), 424 (4.21), 400 (sh., 3.70), 363 (4.69), 345.5 (4.46), 318 (4.63), 305 (4.48).[10]

Dibenzo[*a,cd*]naphtho[1,2,3-*lm*]perylene (**13**) (isoviolanthrene B).[5] Using the Clar method,[3,7] 1.00 g of isoviolanthrone B (**11**) was reduced. The crude product (0.95 g) was sublimated at high vacuum (10^{-3}—10^{-4} Torr), and the yellowish-brown sublimates (0.35 g) were purified by means of recrystallization from benzene and then column chromatography on alumina with benzene, to give 0.05 g of brown-yellow, fine needles. Mp 307 °C (uncorr.), 319 °C (corr.), $\lambda_{max}^{benzene}$ nm (log ε): 471 (4.87), 441 (4.55), 415 (4.22), 390 (sh., 3.70), 357 (4.81), 340.5 (4.50), 325 (4.24), 308 (4.76), 294 (4.55).

Found: C, 95.61; H, 4.31%. Calcd for $C_{34}H_{18}$: C, 95.75; H, 4.25%.

Condensation. A mixture of 5.00 g of benzanthrone (**3**), 5.0 g of copper powder, 25 g of zinc chloride and 5 g of sodium chloride was maintained at 230 °C for 30 min, and treated, by a method similar to that reported previously.[1] The crude product (9.85 g) was refluxed with 600 g of xylene for 2 h, and the insoluble part was filtered off after cooling. The filtrate was chromatographed on alumina into several fractions (using xylene as the eluent). The product, obtained by evaporation of successive fractions, were purified by recrystallization and high vacuum sublimation, to give 616 mg of **4**, 56 mg of **8**, 308 mg of recovered **3**, 623 mg of **13**, and 85 mg of reddish-brown crystals. This last material has absorption peaks at about 420, 495, and 530 nm in benzene and appeared to be a mixture of unidentified hydrocarbons[8] not of the A-type (**7**, **12**),[9] however, further purification was

very difficult.

That part insoluble in xylene (7.0 g) was refluxed with 200 g of *o*-dichlorobenzene for 2 h, and the insoluble material (5.25 g) was removed by hot filtration. This filtrate was evaporated to dryness, and the residue was chromatographed on alumina with chlorobenzene, and worked up in a manner similar to that used for the xylene filtrate, giving various amounts of the same products described above.

The total amounts and yields of the products were:

tetrabenzo[*a*,*cd*,*j*,*lm*]perylene (**4**)	754 mg	18.1%,
violanthrene B (**8**)	90 mg	2.2%,
isoviolanthrene B (**13**)	833 mg	20.0%,
unidentified material	195 mg	4.7%,
recovered benzanthrone (**3**)	505 mg	10.1%.

The Electrochemical Behavior of Mononitrophenyltrimethylsilanes and 2,4-Dinitrophenyltrimethylsilane

Hamao WATANABE, Masafumi AOKI, Hideyuki MATSUMOTO, Yoichiro NAGAI, and Takeo SATO*

Department of Applied Chemistry, Faculty of Engineering Gunma University, Kiryu, Gunma 376
**Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Setagaya, Tokyo 158*

(Received October 1, 1976)

Synopsis. The CV data for *o*-, *m*-, and *p*-nitrophenyltrimethylsilanes and 2,4-dinitrophenyltrimethylsilane revealed that the former three show E_{pc} slightly more anodic than the corresponding nitrotoluenes; the latter shows a third peak (O_3) together with two successive reversible couples, while the methyl analogue exhibits no peak corresponding to O_3, but shows extremely weak O_1. The behavior of these silyl compounds are interpreted in terms of less electron-donating nature of trimethylsilyl group and (p-d)π bonding between the siliicon and benzene ring.

To date only a few reports have appeared on the study of the electrochemical behavior of organosilicon compounds by polarography,[1,2] and controlled potential electrolysis in non-aqueous solutions.[3,4] Recently, Allred and co-worker have reported on the electrochemical reduction of chloropermethylpolysilanes by means of cyclic voltammetry (CV) and discussed the effect of chain length of the polysilanes on the reduction potentials.[5] It is interesting to investigate by the CV technique the electrochemical behaviors for other types of silicon compounds which contain at least one of electroactive groups. The present study was undertaken to examine the substituent effect on reduction-oxidation potentials and electron transfer processes for *o*-, *m*-, and *p*-nitrophenyltrimethylsilanes and 2,4-dinitrophenyltrimethylsilane.

Results and Discussion

o-, m-, *and* p-*Nitrophenyltrimethylsilanes.* In Table 1, the CV data are listed to compare mononitrophenyltrimethylsilanes with nitrotoluenes. The peak potentials E_{pc}, E_{pa}, and $E_{p1/2}$, for the silyl compounds are both slightly more anodic than those of the corresponding toluene derivatives. This may be attributable to the polar effect of substituent attached to the nitrophenyl group, less electron-donating trimethylsilyl substituent compared with methyl group requires lower reduction potentials as shown by Hammett σ constants.[6]

TABLE 1. THE CV DATA OF NITROPHENYLTRIMETHYLSILANES AND NITROTOLUENES[a]

Compound	E_{pc} (V)	E_{pa} (V)	$E_{p1/2}$ (V)	i_{pa}/i_{pc}
o-$MeC_6H_4NO_2$	−1.66	−0.80	−1.23	1.0
o-$Me_3SiC_6H_4NO_2$	−1.62	−0.68	−1.14	0.9
m-$MeC_6H_4NO_2$	−1.52	−0.76	−1.13	1.0
m-$Me_3SiC_6H_4NO_2$	−1.50	−0.76	−1.11	1.0
p-$MeC_6H_4NO_2$	−1.29	−0.92	−1.11	0.9
p-$Me_3SiC_6H_4NO_2$	−1.26	−0.84	−1.05	1.0

a) Scan rate: 80 mV/s.

It is seen that from the values of the ratio of i_{pa} to i_{pc} all the compounds are chemically stable during the electron transfer over a wide range of scan rates. However, the features of the potentials for *para* silyl and tolyl compounds are distinctly different from those of *ortho* and *meta* compounds. Thus, the value of $|E_{pc}|-|E_{pa}|$ of the former is about one-half relative to the latter two. It could be interpreted in terms of the poor reversible electron-transfer process in the *ortho* and *meta* compounds, the peak separation of which increased at a higher scan rate. The E_{pc} values for the compounds became more cathodic by 400 mV on 10-fold increase in the scan rate (40 mV/s→400 mV/s). At 3 V/s scan the peak separation reached 1.6 V.

2,4-Dinitrophenyltrimethylsilane. Cyclic voltammograms of 2,4-dinitrophenyltrimethylsilane, 2,4-dinitrotoluene and *m*-dinitrobenzene are shown in Figs. 1a—c. Of the compounds tested in the range of 0——2.0 V, two cathodic peaks (R_1 and R_2) and the corresponding two anodic peaks (O_1 and O_2) appeared. When scanning was clipped at −1.20 V, the CV charts show that all the anion radicals, formed by one electron transfer (R_1), are chemically stable. However, in the scan range of 0——2.0 V, the CV behavior among these compounds

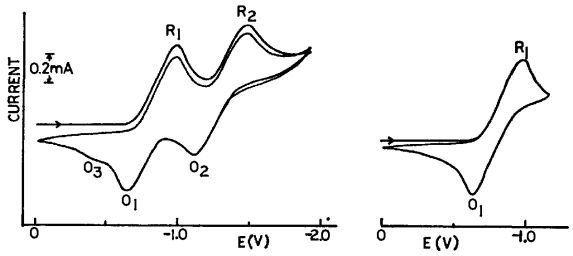

Fig. 1a. Cyclic voltammogram of 2,4-dinitrophenyltrimethylsilane. (First and second cyclic scan; scan rate: 80 mV/s.)

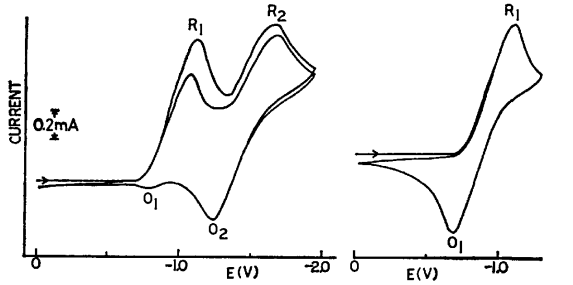

Fig. 1b. Cyclic voltammogram of 2,4-dinitrotoluene. (First and second cyclic scan; scan rate: 80 mV/s.)

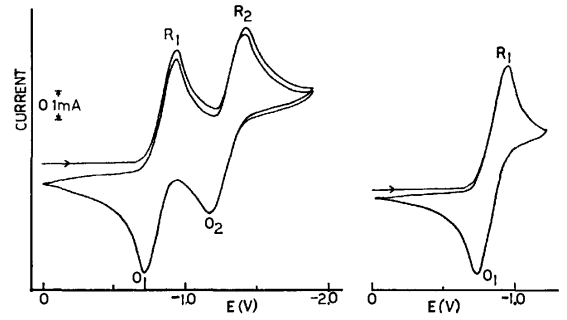

Fig. 1c. Cyclic voltammogram of *m*-dinitrobenzene. (First and second cyclic scan; scan rate: 80 mV/s.)

differed significantly. Thus, on potential reversal, 2,4-dinitrophenyltrimethylsilane exhibited a weak third anodic peak (O_3) at a low potential (Fig. 1a), which was absent when the potential was clipped at −1.20 V. This is presumably due to the reduction product which was derived from dianion. The explanation was supported by the fact that the addition of a proton donor such as methanol to the system causes an increase in peak O_3 and a decrease in peak O_1 and O_2, although the structure of the reduction product was not determined. On the other hand, the CV chart of 2,4-dinitrotoluene is very different from those of 2,4-dinitrophenyltrimethylsilane and *m*-dinitrobenzene. As Fig. 1b shows, the anodic peak of O_1 is extremely weak relative to the corresponding cathodic peak of R_1 when the scan was extended to −2.0 V. This fact indicates that the resulting anion radical is chemically unstable when it was allowed to stand until the second peak is swept and one electron removal from the anion radical to the starting compound is slow compared with chemical process.

The above observation might be expressed as following equations (1 and 2):

2,4-Dinitrophenyltrimethylsilane (DNS)

$$[\mathrm{DNS}] \underset{-e(O_1)}{\overset{+e(R_1)}{\rightleftharpoons}} [\mathrm{DNS}]^{-} \underset{-e(O_2)}{\overset{+e(R_2)}{\rightleftharpoons}} [\mathrm{DNS}]^{=} \quad (1)$$

2,4-Dinitrotoluene (DNT)

$$[\mathrm{DNT}] \underset{-e(O_1)}{\overset{+e(R_1)}{\rightleftharpoons}} [\mathrm{DNT}]^{-} \underset{-e(O_2)}{\overset{+e(R_2)}{\rightleftharpoons}} [\mathrm{DNT}]^{=} \quad (2)$$

From the values of peak separation of $|R|-|O|$ in Figs. 1a and 1b, that the silane compound has better reversibilities (Eq. 1) than the toluene in the electron transfer processes could be interpreted in terms of the substituent effect, in which the trimethylsilyl group contributes to stabilize the system *via* (p-d)π bonding between silicon and benzene ring, although the both dianions are considered to be highly reactive species. With respect to $[DNS]^{-}$ and $[DNS]^{=}$, many resonance structures are possible and the evidence for such a structure has been shown by ESR spectrum in the electrochemical reduction of *p*-nitrophenyltrimethylsilane.[7]

Experimental

Cyclic Voltammetry. All measurements were performed in purified anhydrous *N,N*-dimethylformamide (DMF) containing 0.1 M tetrabutylammonium perchlorate (TBAP) as supporting electrolyte using a divided cell. The working electrode is a platinum inlay electrode (Beckman 32273) and the counter electrode is a platinum wire. A saturated calomel electrode was used as a reference which was connected to the cell using two salt bridges, saturated KCl solution and DMF-TBAP solution. A Hokuto Denko Model HB-107A function generator and Hokuto Denko Model HA-101 potentiostat were used. Cyclic voltammetry performed at the scan rate of 40—400 mV/s was recorded using a Rikadenki X-Y recorder Model BW 133. For higher speed recording, two channel wave memory, NF Model WM-812A, was employed. All runs were made after a 15 min purge with purified nitrogen and within 30 min of preparing the solutions.

Materials. Nitrophenyltrimethylsilanes and 2,4-dinitrophenyltrimethylsilanes were obtained by the method reported elsewhere.[8] Mono- and di-nitrotoluenes and *m*-dinitrobenzene were commercially available (extra pure grade).

This work was supported by a Scientific Research Grant from the Ministry of Education (No. 080422).

Palladium-catalyzed Reaction of Olefins and Acetylenes with Iodoferrocenes

Akira KASAHARA, Taeko IZUMI, and Mitsugi MAEMURA

Department of Applied Chemistry, Faculty of Engineering, Yamagata University, Yonezawa 992

(Received November 11, 1976)

Synopsis. Iodoferrocene (**1**) reacts readily with olefinic compounds in the presence of a catalytic amount of palladium(II) acetate to produce alkenylferrocene derivatives. In the presence of a copper(I) iodide and palladium complex, **1** also reacts with acetylene to afford diferrocenylacetylene.

Recently, the palladium-catalyzed reaction of olefin[1-5] with aryl and vinylic halides has received wide attention. Meanwhile, Sonogashira *et al.*[6] have reported the palladium-catalyzed substitution of acetylenic hydrogen with aryl iodide. We are, therefore, intrigued by the palladium-catalyzed reaction of olefins and acetylenes with iodoferrocene (FcI) (**1**) and 1,1′-diiodoferrocene (**2**) and wish to report herein the results of a study of these reactions.

In the presence of triethylamine and catalytic amounts of palladium(II) acetate and triphenylphosphine, **1** and **2** were allowed to react separately with various olefins at 100 °C; the substitution reaction on the double bond has been observed to lead to the formation of 1-alkenylferrocenes and 1,1′-dialkenylferrocenes. The reactions carried out are summarized in Table 1.

The reaction of **1** with simple olefins, such as styrene and ethyl acrylate, resulted in the formation of strylferrocene (**3**) and ethyl 3-ferrocenylacrylate (**4**) respectively in moderate yields. The mechanism of the

Table 1. A palladium-catalyzed ferrocenylation of olefins and acetylenes

Halide	Olefin or acetylene	Product, mp °C	Yield %[a]
1	Styrene	Styrylferrocene (**3**), 120—121[b]	59
1	Ethyl acrylate	Ethyl 3-ferrocenylacrylate (**4**), 74—75[c]	54
1	Methyl methacrylate	Methyl 3-ferrocenylmethacrylate (**5**), 62—63[d]	64

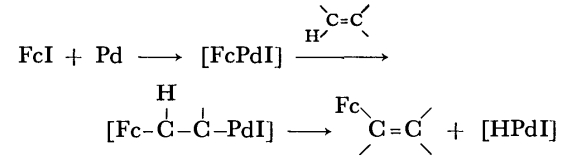
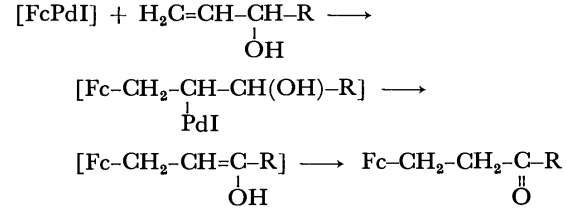
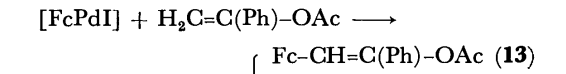
reaction involves the formation of ferrocenylpalladium iodide by oxidative addition, followed by addition to the olefin and the elimination of [HPdI], as in the palladium-catalyzed reaction of olefins with aryl halide.[3a)]



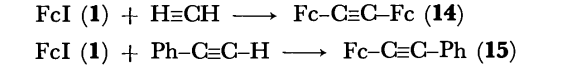
The ferrocenylation of allylic alcohols with **1** or **2** led to the formation of the 3-ferrocenyl-aldehyde or -ketone (**9**, **10**, or **17**) in a good yield; neither 2-ferrocenyl-isomer nor 3-ferrocenylated allyl alcohol was observed. The allylic alcohol ferrocenylation can account for the reaction mechanism, which is similar to the one proposed for the allylic alcohol arylation:[4)]



Vinyl acetate and isopropenyl acetate reacted with **1** to yield differrocenylethylene (**11**) and 1,2-diferrocenyl-1-propene (**12**) respectively. In addition, the reaction of acetophenone enol acetate with **1** afforded a mixture of **3** and 1-acetoxy-1-phenyl-2-ferrocenylethylene (**13**). The formation of **3** suggested that the addition of the ferrocenyl group occurs on the terminal carbon atom, followed by the elimination and a re-addition of palladium hydride in the reverse direction and another elimination of Pd(OAc)I.



In the presence of copper(I) iodide and dichlorobis-(triphenylphosphine)palladium(II), **1** reacted with acetylene and phenylacetylene to yield diferrocenylacetylene (**14**) and ferrocenylphenylacetylene (**15**) respectively in good yields.



Experimental

Materials. All the melting points are uncorrected. Iodoferrocene (**1**) and 1,1′-diiodoferrocene (**2**) were prepared according to the method described by Fish and Rosenblum.[7)] All the olefinic compounds were commercial products and were purified by distillation before use.

General Procedure for the Ferrocenylation of Olefins. A mixture of 1.56 g (5 mmol) of **1**, 0.7 g (7 mmol) of triethylamine, 7 mmol of olefin, 0.026 g (0.1 mmol) of triphenylphosphine, 0.011 g (0.05 mmol) of palladium(II) acetate, and 10 ml of acetonitrile was heated under nitrogen in a sealed tube at 100 °C for 8 h. In the reaction with **2**, 1.08 g (2.5 mmol) of **2** was used. The cooled reaction mixture was diluted with ether and water. The ether phase was separated, washed with water, dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was then purified by column chromatography (Al_2O_3–benzene or chloroform), followed by recrystallization from ethanol or benzene. The structure of the products was confirmed by a mixed-melting-point determination with an authentic sample and by the observation of the IR and NMR spectra. The results are summarized in Table 1.

General Procedure for the Ferrocenylation of Acetylenes. A mixture of 1.56 g (5 mmol) of **1** (or 2.5 mmol of **2**), 0.61 g (6 mmol) of phenylacetylene, 0.095 g (0.05 mmol) of copper(I) iodide, 0.033 g (0.1 mmol) of dichlorobis(triphenylphosphine)-palladium(II), and 40 ml of diethylamine was heated under nitrogen in a sealed tube at 80 °C for 6 h. In the case of the reaction with acetylene, a slow current of acetylene was passed through the reaction mixture for 6 h at room temperature. After the removal of diethylamine under reduced pressure, ether and water were added to the residue. The ether phase was separated, washed with water, dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by column chromatography (Al_2O_3–benzene or chloroform), followed by recrystallization from ethanol or benzene. The structure of the products was confirmed by a mixed-melting-point determination with an authentic sample and by the observation of the IR and NMR spectra. The results are summarized in Table 1.

Synthesis and Electrical Conductivity of Phosphorus-Nitrogen Compounds. V. Synthesis and Electrical Resistivity of Poly[bis(amino)phosphazenes]

Takashi HAYASHI and Hajime SAITO

Department of Applied Chemistry, Faculty of Engineering, Nagoya University, Chikusa-ku, Nagoya 464

(Received August 26, 1976)

Three new poly[bis(amino)phosphazenes] of formulas $[NP(NHC_6H_{13})_2]_n$, $[NP(NHCH_2CHCH_2)_2]_n$, and $[NP(NHCH_2C_6H_5)_2]_n$ have been synthesized by direct aminolysis of $(NPCl_2)_n$. The electrical resistivity and thermal stability of a series of poly[bis(amino)phoshazenes], (NPR_2) (R: amino group), have been examined. Most polymers showed an increase in resistance with time to an equilibrium value, possibly due to space charge effects, allowance for this conductivity being ohmic up to 500(V/cm). The aliphatic amino derivatives have a lower resistivity and a lower ΔE value than the aromatic amino derivatives. The resistivity of the poly [bis(amino)-phosphazenes] was found to decrease in the order, R : $NHC_2H_5 > NHC_3H_7 > NHC_4H_9 > NHC_6H_{13} \gg N(CH_3)_2$. This seems to be predominantly due to the nature of an inductive electron supply of amino side groups. In some polymers the change of energy gap, ΔE, was observed in the range 70—90 °C. The ΔE value was usually lower in the low temperature region than in the high temperature region. All the polymers were found to decompose at about 200 °C, losing the amino side group.

Although the synthesis and chemistry of phosphazene compounds have been extensively investigated, very little[1,2] has been done to measure the electrical resistivity of these compounds. In previous papers[3,4] we reported on the electrical resistivity of the phosphonitrilic chloride, $(NPCl_2)_3$, and its derivatives.[3,4]

It was found that the resistivity of phosphazene compounds obeys an equation of the form : $\rho = \rho_0 \exp(E/kT)$, where ρ is the resistivity, E the activation energy, k Boltzmann constant, and T the absolute temperature. It has been suggested that the resistivity of $(NPR_2)_3$ was remarkably dependent upon side group R. It was found that the highest conductivities were obtained with side groups containing amino groups.

The purpose of this work is to synthesize poly[bis-(amino)phosphazenes] and to measure the resistivity of the polymers. The difference in side group R of (NPR_2) is expected to affect the electrical resistivity of the polymers.

Experimental

Preparation of Poly(dichlorophosphazene). Sublimed hexachlorocyclotriphosphazene (5.000 g) and benzoic acid (0.200 g) were weighed directly into a carefully cleaned Pyrex ampoule. The ampoule was evacuated to 10^{-1} Torr for 1 h and then sealed. The sealed ampoule was placed in a furnace and heated at 210±2 °C for 4 h. After polymerization, the ampoule was opened and the conetnts were extracted with dry benzene. The solvent was removed and the unreacted materials were separated from the residue by vacuum sublimation. Linear $(NPCl_2)_n$ was obtained.

Preparation of Poly[bis(amino)phosphazenes]. Aliphatic primary amines (ethylamine, propylamine, butylamine, hexylamine, allylamine, benzylamine), secondary amine (dimethylamines), and aromatic amine (aniline) were used. The amino-substituted polymers of the structure $[NP(NHR)_2]_n$ (NHR: NHEt, $NHPr^n$, $NHBu^n$, NHPh) and $[NP(NMe_2)_2]_n$ were synthesized and purified according to the procedure given by Allcock and Kugel.[5,6] The amino-substituted polymers of the structure $[NP(NHR)_2]_n$ (NHR: $NHhexyl^n$, $NHCH_2CHCH_2$, $NHCH_2Ph_5$) were prepared as follows.

Poly[bis(mono-hexylamino)phosphazene]; $[NP(NHC_6H_{13})_2]_n$: A solution of polydichlorophosphazene (3.68 g, 0.032 mol) in tetrahydrofuran (150 ml) was added slowly to a stirred solution of mono-hexylamine (25.0 g, 0.25 mol) and triethylamine (25.3 g, 0.25 mol) in tetrahydrofuran (100 ml). The reaction was allowed to proceed at 25 °C for 5 days and then allowed to proceed at 40 °C for 7 h.

The mixture of polymer and amine salts was filtered off, and the solvent was removed from the filtrate by distillation.

The residue obtained was dissolved in trifluoroethanol and the polymer was precipitated from the solution by addition of acetone. The procedure was repeated, and the polymer was dried in a vacuum over P_2O_5.

Poly[bis(allylamino)phosphazene]; $[NP(NHCH_2CH{=}CH_2)_2]_n$: This polymer was prepared by a modification of the method of Allcock *et al.*[7] A solution of polydichlorophosphazene (7.20 g, 0.062 mol) in benzene (80 ml) was added dropwise to a stirred solution of allylamine (56.50 g, 0.990 mol) and triethylamine (12.5 g, 0.124 mol) in benzene (60 ml).

The mixture was then boiled under reflux for 55 h and then allowed to stand at 25 °C for 2 days. The upper benzene layer was decanted from the amine salts and the oily bottom layer. The benzene solution was washed with water and dried over anhydrous magnesium sulfate. Filtration and evaporation of the filtrate at reduced pressure gave a white solid.

Poly[bis(benzylamino)phosphazene]; $[NP(NHCH_2C_6H_5)_2]_n$: A solution of polydichlorophosphazene (8.450 g, 0.073 mol) in benzene (70 ml) was added slowly to a stirred solution of benzylamine (46.8 g, 0.437 mol) and triethylamine (44.2 g, 0.437 mol) in tetrahydrofuran (70 ml). The reaction mixture was stirred at 25 °C for 50 h and then at 45 °C for 7 h. The mixture of polymer and amine salts was filtered off, solvent being removed from the filtrate by distillation. The residue was redissolved in acetone, and the polymer was then precipitated from the solution by addition of ehtanol and dried in a vacuum over P_2O_5.

Resistivity Measurement. All the polymers were powdered and molded pellets were used for resitivity measurements. Pellets (12 mm diameter and 1—2 mm thick) were molded at pressures up to 500 kg/cm^2). The pellets were provided with vacuumevaporated platinum–palladium alloy contacts. Among the contact materials platinum–palladium alloy seemed to give the best ohmic contacts.

The electrical resistivity was studied as a function of temperature in the range 20—180 °C. In order to get exact resistivity values, the current was measured as a function of the voltage in the range 0—90 V, with use of a guard electrode.

Physical Measurements. Molecular weights were measured by vapor pressure osmometry with a Hitachi Model-117 type osmometer using benzene as a solvent.

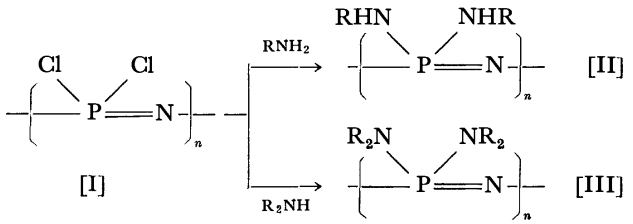
a) A small amount.

IR spectra were recorded on a Shimadzu Model-450 type spectrometer by means of the KBr disk technique.

Thermogravimetric analysis and differential thermal analysis were carried out with a Shimadzu Model DT 20-B under dry nitrogen (50 ml/min) at a heating rate of 15 °C/min.

Results and Discussion

Syntheses. In general, poly[bis(amino)phosphazenes] are synthesized by the reaction of poly(dichlorophosphazene) with a primary or secondary amine according to the following scheme.



We have synthesized three new compounds: poly(mono-hexylaminophosphazene), poly(allylamino phosphazene), and poly(benzylaminophosphazene).

Excess amines and triethylamine were used as hydrohalide acceptors for the steric property of these bulky amines. The results of chemical analysis and molecular weights of the products are given in Table 1.

We see that the elemental compositions of the polymers correspond satisfactorily to the expected structures.

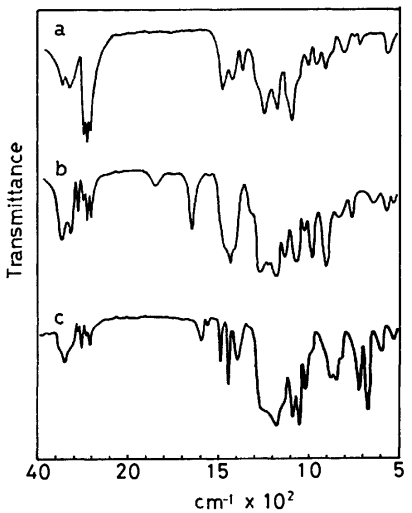


Fig. 1. IR spectrum of the products.
a: $[NP(NH\text{-}mono\text{-}C_6H_{13})_2]_n$,
b: $[NP(NHCH_2CH{=}CH_2)_2]_n$,
c: $[NP(NHCH_2C_6H_5)_2]_n$.

The IR spectra of the products obtained from the reaction of poly(dichlorophosphazene) with monohexylamine, allylamine, benzylamine are shown in Fig. 1. All the polymers exhibit a characteristic P=N stretching absorption in the region 1200—1260 cm^{-1}.

The assignments for the main peaks are as follows (frequncies in cm^{-1}): for $[NP(NHR_2]_n$ where R is mono-C_6H_{13}, 1260 (P–N), 1180, 1100 (C–N), 905 (P–N, C–N), 1467, 1370(–CH_3), 3360, 3250, (N–H), CH_2-CH=CH_2, 1260, 1230(P–N), 1190, 1080(C–N), 915, 995, 1420, 1640, 3080, (allyl), 3220(N–H), CH_2–C_6H_5, 1220, 1250(P–N), 1180(P–N, C–N), 1070, 1090(C–N), 1450, 1500, 1580, 1600(–C_6H_5), 2900, 2850(–CH_2), 3345(N–H). The results indicate that the monohexylamino, allylamino, and benzylamino derivatives are of open chain structure similar to that of the $(NPCl_2)_n$.

The complete replacement of chlorine atoms of poly(dichlorophosphazene) by monohexylamine or benzylamine required severer conditions than those reported for ethylamine, methylamine, propylamine, *etc.* This seems to be associated with steric hindrance of side group.

All the polymers are soluble in mineral acid, trifluoroethanol or benzene, but not in common organic solvents or water. The solubility of the polymers indicates that the meterials are not cross-linked. The polymers seem to have a linear structure. It was found from IR spectra, chemical analysis, and UV spectra that the five polymers prepared by the method of Allcock are consistent with the expected structure, $[NP(NHR)_2]_n$ (NHR: NHEt, $NHPr^n$, $NHBu^n$, NHPh) and $[NP(NMe_2)_2]_n$.

Thermal Stability. The thermal stability of the eight poly[bis(amino)phosphazenes] were examined by TGA and DTA. The results are given in Figs. 2 and 3. The polymers begin to decompose at about 200 °C, a remarkable weight loss being observed between 250 and 400 °C. On the other hand, in the ethylamino, propylamino, butylamino, mono- hexylamino, allylamino, and diethylamino derivatives, the broad endothermic peaks appear between 200 and 400 °C. In the phenylamino and benzylamino derivatives the endothermic peaks appear between 400 and 470 °C.

In the decomposition of all the polymers at 400 °C, the corresponding amines to side groups were detected by gas chromatography. Decomposition took place with elimination of appropriate amines. The endothermic peaks appearing above *ca.* 500 °C might be due to breakdown of phosphorus nitrogen bonds. In the ethylamino, propylamino, butylamino, and monohexylamino derivatives, exothermic peaks which seem

to be oxidation of the alkyl groups appear between 150 and 175 °C. In the allylamino derivative, the sharp exothermic peak appears at 125 °C. This is probably due to the addition polymerization of the allylamino side group similar to that reported for $[NP(NHCH_2CH{=}CH_2)_2]_3$ and $[NP(NHCH_2CH{=}CH_2)_2]_4$ by Allcock *et al.*[7]

D. c. Resistivity. The results of initial measurements of all the samples were not reproducible.

Several thermal cycles for each sample were carried out in order to obtain reproducible results. A typical example is shown for dimethylamino derivative in Fig. 4.

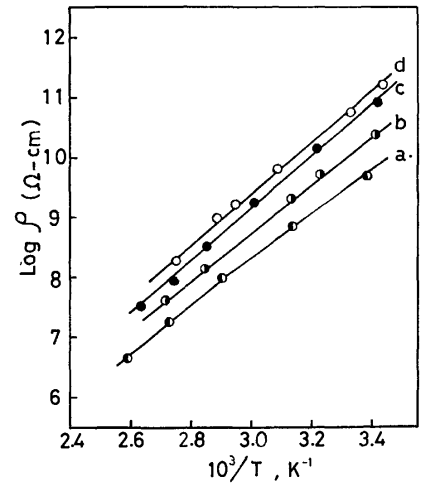

Fig. 4. Temperature dependence of resistivity of $[NP(N(CH_3)_2)_2]_n$.
a: Ascend first time, b: ascend second time, c: ascend third time, d: desend third time.

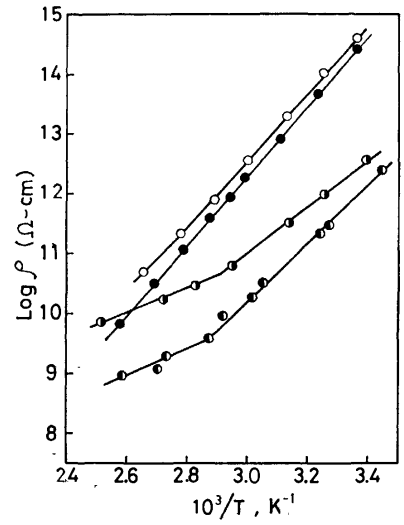

Fig. 5. Temperature dependence of resistivity of poly-[bis(amino)phosphazenes], $[NPR_2]_n$.
○: R=NHC_2H_5, ●: R=$NHC_3H_7{}^n$, ◑: R=$NHC_4H_9{}^n$, ◐: R=NH-mono-C_6H_{13}.

Lower resistivity was always observed in the initial runs.

Initial heating curves are usually of anomalous low ΔE and frequently curved, due to the evaporation of moisture or solvents. Reproducible results were obtained after several thermal cycles had been carried out.

The results are given in terms of log ρ *vs.* $1/T$ (Figs. 5 and 6).

The results can be expressed by the relationship $\rho=\rho_0 \exp(\Delta E/2RT)$. The calculated energy gaps ΔE and values of log ρ_0 are given in Table 2. Some curves show a break point in the range 70—90 °C. A break point was found by measurements on other polymers.[8] The break point is usually associated with thermal decomposition of the sample.

However, our investigations of thermal stability show-

ed no decomposition of the polymers in the range 70—90 °C. It was found that the resistivity of poly(aminophosphazenes), $[NP(NHR)_2]_n$, decreases in the order, NHR: $NHCH_2C_6H_5$, $NHC_6H_5 \gg NHC_2H_5 > NHC_3H_7 > NHC_4H_9 > NHC_6H_{13} \gg N(Me_3)_2$. Thus, the resistivity of polymers decreases with an increase in the number of C in side groups of aliphatic primary amino derivatives, and the resistivity of the secondary amino derivative, $[NP(NMe_2)_2]_n$, showed lower values than those of the primary amino derivatives. This is probably attributed to the nature of an inductive electron supply. Both the inductive electron supply from amino to phosphorus, and π effects involving donation of the nitrogen lone pair electrons into phosphorus d_{z^2} orbitals would raise the electron density at phosphorus,[9] raising electrical conductivity. However, it appears that P_π–d_π bonding cannot bring about enough π-orbital overlap to cause high electrical conduction. If the π bonds in the phosphazene chain were delocalized, as suggested for cyclic oligomers,[10] then the conductivity would be expected to be comparable to that of the carbon polyene polymers.

On the other hand, the values of resistivity of phenylamino and benzylamino derivatives are greater than 10^{-15} Ω cm at room temperature. The bulky side groups such as aromatic amino would be expected to reduce the interaction between molecules, as compared with aliphatic amines which possess a possible degree of rotation about the C–C single bonds. A similar behavior was reported for polyacethylenes.[11] In phenylamino derivatives, the break point was observed at 90 °C corresponding to the glass transition temperature reported by Allcock and Kugel.[5] The amino derivatives have low resistivity when compared to alkoxy or aryloxy derivatives.[12] Thus, it appears that the high side-group polarity of amine and increased opportunities for hydrogen bonding (when NHR groups are present) decrease the resistivity of the polymers. The conductivity observed for the poly(aminophosphazenes) is assumed to be associated primarily with the electrons of its conjugated double bond.

When an external field was applied, polarization, *i.e.*, an increase in resistance with time to a steady value, occurred for most samples, the resistivity reaching equilibrium values after 30 min—1h. Although similar results have been described,[13,14] it is assumed that

●: Previous data.

the effect arises from either space-charge build-up in the sample or barrier between electrode and sample.

The correlation of energy gap ΔE and preexponential factor $\log \sigma_0 (=1/\rho_0)$ is shown in Fig. 7. A straight line with a large amount of scatter is obtained, suggesting the relationship $\log \sigma_0 \approx \Delta E(\text{eV}) - 6$. The compensation law is valid for poly[bis(amino)phosphazenes]. However, it is difficult to give a physical meaning. An interpretation is given in terms of molecular motion as a condution mechanism such as presented by Gutmann and Lyons[13] and Cardew and Eley.[15] However, exprimental results are so few that a quantitative discussion of this type of conduction mechanism cannot be realized.

Most polymers showed ohm's law behavior up to *ca.* 500 (V/cm) or above.

The authors wish to express their appreciation to Mr. T. Yamamoto for his cooperation in the experiments.

The Hindered Internal Rotation of Amide Groups of Polyacrylamide of Low Molecular Weights

Yoshiyuki HIRAI, Mitsuyoshi YUKAWA, and Yoshio IMAMURA

Department of Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received August 31, 1976)

Polyacrylamides of low molecular weights (average degrees of polymerization($\overline{DP}$): 7.2, 18.3, 21.3, and 45.4) were prepared by radical polymerization, and their PMR spectra were observed over the temperature range of 30—90 °C. From the temperature dependence of the PMR spectra, the values of the energy barrier to the internal rotation about C–N bonds were determined by means of a total line-shape analysis. The energy barriers for the polymers above $\overline{DP}$: 18.3 were 10.6 kcal/mol, while those for the polymer of $\overline{DP}$: 7.2 were 9.2 kcal/mol. These results were interpreted in terms of the local environment around the amide groups. The intramolecular hydrogen bonding was also investigated.

In a previous investigation,[1] we observed an anomalous broadening for the absorption of *ortho* protons of poly(*p*-chlorostyrene) of very low molecular weights (average degrees of polymerization($\overline{DP}$)$<$15). This phenomenon was elucidated by assuming the "permissible conformation" which is permitted only in very short chains, and was termed the "polymeric effect on molecular structure" of polymers in solutions. The present investigation will be concerned with the "polymeric effect on intramolecular motion" of polymers in solutions.

Recent studies by various authors[2-6] have shown that the NMR spin-lattice relaxation times (T_1) of polymers in solutions change appreciably with the chain length in the region of short chains, and that T_1 becomes less sensitive to the chain length as the chains become longer ($\overline{DP}$: 10—30). Similar phenomena were also observed in ESR studies of spin-labeled polymers.[7,8] These observations have been interpreted in terms of the "polymeric effect on relaxation process"[4] (in other words, the "polymeric effect on molecular motion" of polymer chains). However, the rigorous analysis of NMR T_1 or ESR line widths is not always easy; that is, the precise separation of motional modes is impossible at the present stage. Therefore, the observations were understood rather qualitatively in either case, and a discussion focused on a local motion in the molecular motions of polymer chains was desired.

If the rate constants or the energy barriers on the specific local motion of polymer chains are estimated precisely as functions of the molecular weights, the polymeric effect on molecular motion could be understood in more detail.

Polyacrylamide is one of the most favorable samples for such a purpose. The amide protons of polyacrylamide represent the characteristic patterns of PMR signals reflecting the internal rotation about C–N bonds in amide groups. They make it possible to evaluate precisely the rate constants or the energy barriers on the specific local motion by analyzing the spectra of amide protons.

The PMR spectra of amide protons of polyacrylamide of a high molecular weight were analyzed by Bovey and Tiers[9] by means of peak separation method.* In the present investigation, the PMR spectra for the polymers of low molecular weights($\overline{DP}$: 7.2—45.4) were analyzed by means of more exact procedures (the total line-shape analysis). The local environment around the amide groups was discussed on the basis of the obtained rotational barriers.

The intramolecular hydrogen bonding was also investigated in a conventional manner.

Experimental

The samples of polyacrylamide were prepared by the procedure of Bovey and Tiers.[9] In order to control the molecular weights, the amount of the chain-transfer agent (sodium mercaptoacetate) was changed over the range from 0.5 g to 3 g per 10 g of the monomer. The polymers were precipitated in a large amount of ethanol in order to free them from any residual monomer, and were then dried *in vacuo*. The number-average molecular weights of these polymers were determined by using "KUNAUAR's vapor-pressure osmometer" in aqueous solutions at 37 °C. The number-average degrees of polymerization ($\overline{DP}$) of the polymer samples were 7.2, 18.3, 21.3, and 45.4 (they will be denoted as 7-, 18-, 21-, and 45-polymer).

The infrared spectra of these polymer samples were nearly identical. They consist of the absorption bands which were assigned by Savitskaya and Kholodova.[11]

The polymer solutions for PMR spectral measurements were prepared by dissolving 0.08 g of the polymer in 1.0 ml of water, previously adjusted to the proper pH, in small vials. One per cent of 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) was added to each solution to serve as the internal reference. The pH of the solutions was adjusted according to the directions of Bovey and Tiers.[9]

The polymer solutions were then transferred to 5 mm o.d. NMR tubes, which were sealed after the atmosphere had been replaced with nitrogen gas. The PMR spectra were observed by using a Japan Electric Laboratory "JNM PS-100 spectrometer" operated at 100 MHz. In the spectra, the peak-position values of each absorption were termed δ values to the methyl peak of DSS as the reference.

Results and Discussion

Hindered Internal Rotation of Amide Groups and Molecular Weight. Figure 1a shows the absorption of the amide protons (NH_2) of the 21-polymer in the aqueous solution of pH 4.5 at 40 °C. The absorption

* However, Allerhand *et al.*[10] estimated the errors introduced in various approximate methods; the errors involved in the peak-separation method reach 100% in some cases, and so approximations are undesirable.

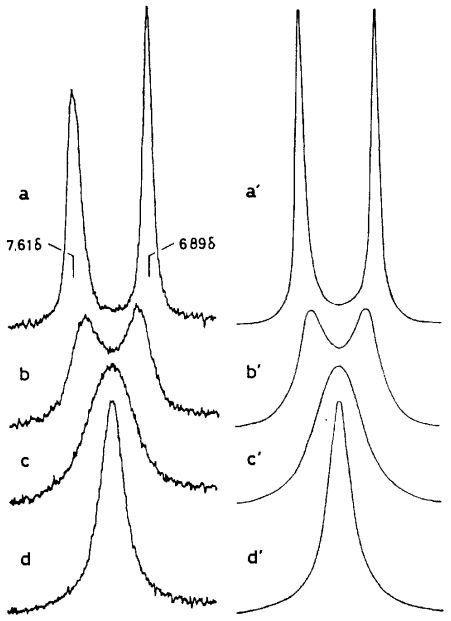

Fig. 1. Experimental PMR spectra (left) of amide protons of polyacrylamide ($\overline{DP}$: 21.3) in aqueous solutions of pH 4.5 (8 w/v%): (a) 40 °C; (b) 70 °C; (c) 80 °C; (d) 90 °C. The best-fit calculated spectra (right): the mean life time $\tau_{AB}(\tau_{BA})$ (a') 0.032 s; (b') 0.0090 s; (c') 0.0050 s; (d') 0.0030 s.

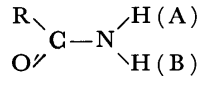
in the lower field is broader than that in the higher field; such spectra were also observed by Bovey and Tiers.[9] The broadening of the absorption may be attributed to the spin coupling with protons of the main chain.[12] In the line-shape analysis to be described below, the line-widths of the calculated spectra are arranged for the absorptions in the higher field. The absorption of water protons appeared to the right (4.62δ) of these amide peaks. Figures 1b, c, and d show the NH_2 absorptions at 70, 80, and 90 °C respectively.

The structure of amides is generally regarded as being approximately planar, and the two sites marked A and B are chemically nonequivalent. The C–N bond



R: $-CH_2CH-$ in the present study

has a partial double-bond character, and the rotation about the bond can be described as a rate process which interchanges the two protons between two environments. The rate process is characterized by rate constants in the range of 10^{-1} to 10^5 s^{-1}; such a rate process causes profound changes in the shapes of the PMR signals. On the other hand, when water is used as the solvent, the amide protons undergo a hydrogen-exchange reaction with the hydrogen of water. This rate process is also characterized by similar rate constants. Therefore, the spectra shown in Fig. 1 should be analyzed by assuming the three-site exchange system represented in Fig. 2.[13a] A total line-shape analysis[13b] can be used for the exact analysis of the spectra reflecting such an exchange system.

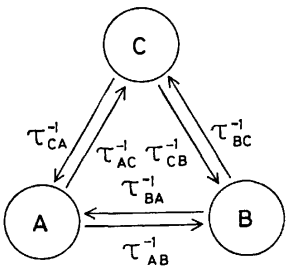


Fig. 2. Diagram for three-site exchange process. A: position A in amide group; B: position B in amide group; C: solvent(water). The arrows indicate the six possible transitions. τ_{ij}^{-1}(i, j=A, B, and C): the rate constants for jumps from site i to j.

80	0.0050	0.0050
90	0.0030	

$\tau_{AC}(\tau_{BC})$: 1.0×10^2 s, $\tau_{CA}(\tau_{CB})$: 9.8×10^3 s. Spin-spin relation times(T_2): 0.6 s for the proton at each site.

The analysis is accomplished by fitting a calculated curve to an experimental curve. Figures 1a'—d' show the best-fit calculated curves for the NH_2 spectra of the 21-polymer. The parameters which yield the best-fit curves are listed in Table 1. The values of T_2 were determined in the following way: we calculated the theoretical spectra for various T_2 values and chose 0.6 s as the most reasonable value of T_2; the line-width of the calculated spectra for 0.6 s does not exceed that of the observed spectra. The parameters, $\tau_{AC}(\tau_{BC})$ and $\tau_{CA}(\tau_{CB})$, did not depend on the temperature; the values of these parameters remained constant. The spectra of other polymer samples ($\overline{DP}$: 7.2, 18.3, and 45.4) were also analyzed in the same way. For example, the parameters for the NH_2 spectra of the 7-polymer are also given in Table 1. In these parameters, the parameters which characterize the rotation about C–N bonds are the mean life-times $\tau_{AB}(\tau_{BA})$. The rotational barriers about the C–N bonds can be calculated by means of the Arrhenius plots of those mean life-times.[13b] The energy barriers for each polymer sample were determined, and they are collected in Table 2. The energy bar-

Table 2. Degrees of polymerization and energy barriers for internal rotation about the C–N bond in polyacrylamide

$\overline{DP}$	7.2	18.3	21.3	45.4
E_a(kcal/mol)	9.2	10.6	10.6	10.6

riers for the 18-, 21-, and 45-polymer were 10.6 kcal/mol, while those for the 7-polymer were smaller by 1.4 kcal/mol.

In NMR or ESR studies of polymers, the molecular motion of polymer chains has mainly been discussed on the basis of NMR T_1 or ESR line-width measurements. The effective correlation times, reduced from the T_1 or line-widths, can be divided into two terms: (a) an overall rotation with rate (τ_o^{-1}), and (b) a segmental motion with rate (τ_s^{-1}). The polymeric effect on molecular motion cited in the beginning section has been understood in terms of τ_o and τ_s.[3,5-8] However, such an analysis provides only limited insight into the details of molecular motion because such a motional model is undoubtedly oversimplified for realistic models of the molecular motion of polymer chains. In these investigations, a detailed discussion of the motion of the local mode was not presented. Analyses of the detailed motion of polymer chains (the rigorous analyses of correlation times) have been devised by various investigators;[14-17] however, they are not yet useful.

On the other hand, the reciprocals of the mean life-times (τ_{AB}, τ_{BA}) obtained in this experiment are the rate constants for the rotation about C–N bonds of amide groups. The energy barriers(E_a) reflect the amount of hindrance to this internal rotation. Therefore, $\tau_{AB}(\tau_{BA})$ or E_a is well suited for a detailed discussion of the local motion. Tables 1 and 2 obviously show that the internal rotation in the 7-polymer is less hindered than that in the polymers above $\overline{DP}$:18. This observation may be termed the polymeric effect on local motion.

In the previous work,[1] we assumed the "permissible conformation" in order to elucidate the PMR spectra of poly(*p*-chlorostyrene) of low molecular weights. This conformation is permitted only in short chains: in short chains side groups are able to escape from each other, whereas in long chains such a conformation is limited by steric restrictions. The phenomenon called the "polymeric effect on molecular structure" was understood as the limitation of the permissible conformation.

Meanwhile, the limitation of the permissible conformation would result in a decrease in the distance between side groups in a polymer chain. This intramolecular packing of side groups causes an increse in the interaction between side groups, and may interfere with the local motion of polymer chains.

The permissible conformation can be assumed not only for poly(*p*-chlorostyrene), but also for polyacrylamide chains. Therefore, on the basis of the experimental fact and the consideration described above, we can draw a reasonable interpretation for the molecular-weight dependence of the energy barriers to the internal rotation about C–N bonds.

Although the 7-polymer could occupy the permissible conformations, in the polymers above $\overline{DP}$: 18 such conformations are forbidden. The intramolecular packing of side groups resulting from the limitation of the conformation increases the intraction between side groups in a polymer chain. The increase in this interaction inhibits the internal rotation about the C–N bonds of amide groups. As a result, the energy barriers (E_a) increase from 9.2 to 10.6 kcal/mol as the degrees of polymerization increase from 7.2 to 18.3.

This change in the local environment arising from the limitation of the conformation corresponds to the phenomenon called the "polymeric effect on molecular motion" cited in the beginning section.

Recently, Nomura and Miyahara[18] observed the molecular-weight dependence of the local motion (the tumbling motion of phenyl groups of polystyrene). Their observation may also be termed the polymeric effect on local motion.

Hydrogen Exchange and Intramolecular Hydrogen Bond. Polyacrylamide has NH groups and CO groups, which can form hydrogen bonds. For some polymer amides, intramolecular hydrogen bonds (NH···O=C) were observed.[19] If such intramolecular hydrogen bonds exist in polyacrylamide chains, a modification of the conclusion presented in the preceding section may be required. Therefore, in this section, the possibility of the existence of the intramolecular hydrogen bond in polyacrylamide will be discussed in a conventional manner(the investigation of the pH dependence of hydrogen exchange between amide groups and water).[20]

Figure 3 shows the NH_2 absorptions of the 45-polymer in solutions of various pH at 30 °C, and the best-fit calculated curves for these absorptions. The exchange rates, τ_{AC}^{-1}, which characterize the hydrogen-exchange reaction between amide groups and water are shown in Fig. 4 as a function of the pH. Figure 4 indicates that the hydrogen exchange is catalyzed by both H^+ and OH^- and that the rates of the reaction are minimum at near pH 4.5 and the rates (k_{min}) are 9×10^{-3} s^{-1}. The discussion of the intramolecular hydrogen bonds is carried out on the basis of this k_{min}.

Snyder and Klotz[19] investigated the k_{min} of poly(*N*-isopropylacrylamide) in the range of molecular

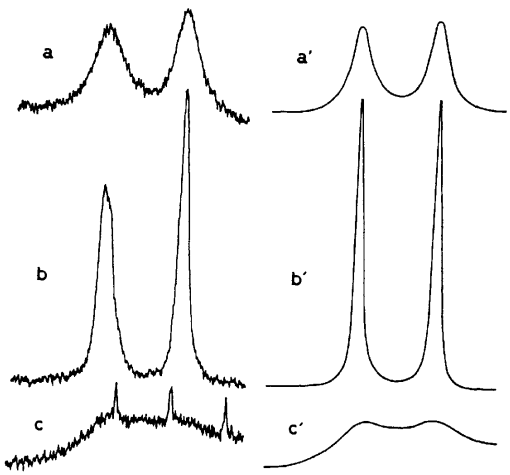

Fig. 3. Experimental PMR spectra (left) of amide protons of polyacrylamide ($\overline{DP}$: 45.4) in aqueous solutions of various pH (8 w/v%) at 30 °C: (a) pH 8.6; (b) pH 7.0; (c) pH 0.0. The spike peaks in (c) are side bands of absorptions of solvent. The best-fit calculated spectra (right): the mean life times τ_{AC} (τ_{BC}) (a') 0.020 s; (b') 0.90 s; (c') 0.0050 s.

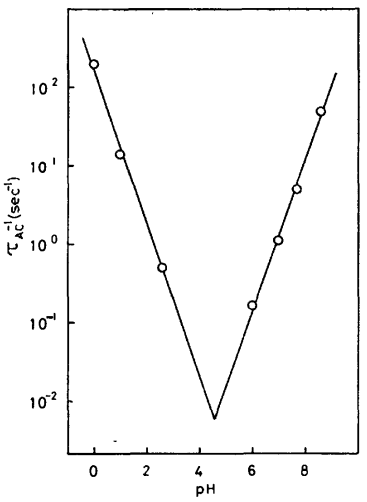

Fig. 4. Hydrogen exchange rates between amide groups and solvent (water) as a function of pH.

weights from 100 (monomer) to 2×10^5. They found that the k_{min} decreased abruptly from 1×10^{-2} to 8×10^{-5} s^{-1} when the amide was transferred from the monomer to the polymer of molecular weights 10^3 ($\overline{DP}\approx10$). The abrupt decrease in k_{min} was concluded to be due to the formation of intramolecular hydrogen bonds.

If the intramolecular hydrogen bonds are formed by NH and CO groups in polyacrylamide chains, the k_{min} must be of the order of 10^{-5}. However, the k_{min} values of the 45-polymer were quite large, and were of the same magnitude as the k_{min} values of small amides (poly(*N*-isopropylacrylamide)-monomer (k_{min}: 1×10^{-2} s^{-1})[19] or *N*-methylacetamide (k_{min}: 2×10^{-3} s^{-1}),[21] *etc.*). The k_{min} for the 21-polymer gave the same value as that for the 45-polymer.

These results mean that no intramolecular hydrogen bond exists in polyacrylamide chains, and indicate that the modification of the conclusion presented in the preceding section is not required.

Statistical Mechanical Calculation of the Radial Distribution Function for a Water-like Fluid

Fumio HIRATA

Research Institute of Applied Electricity, Hokkaido University, Sapporo 060

(Received October 15, 1976)

The radial distribution function (RDF) for a *water-like system*, which has the fundamental characteristics of water, is calculated using the graph-theoretical technique developed by Andersen and Chandler. An interaction potential devised to simulate the hydrogen bond is regarded as a perturbation of the pair interaction between the two molecules of a reference system which consists of hard spheres each having a point dipole at each center. The effect of the hydrogen bond-like potential on the distribution of the molecules is shown explicitly. The results show a tetrahedral coordination similar to that in water. The resulting RDF has qualitatively reproduced the features observed in the experimental RDF curve for water.

Water possesses various anomalous physicochemical properties. It is believed that such properties are caused by an "ice-like" structure tetrahedrally-linked *via* hydrogen bonds.[1] The strongest evidence for the tetrahedral coordination is radial distribution function (RDF) obtained from X-ray diffraction and neutron scattering data.[2] The first peak in the RDF is narrow in comparison with that of simple fluids, and corresponds to the low local-density caused by the tetrahedral coordination of the molecules. Another feature in the RDF of water concerns the location of the second peak. The location is characteristic not of simple fluids but of ice. Molecular dynamics and Monte Carlo studies have reproduced the features of the RDF of water.[3]

If we confine ourselves to simple fluids, there are theoretical methods which satisfactorily reproduce the observed values without the aid of any assumptions concerning the arrangement of the molecules.[4] In the case of water, however, if we do not wish to use such assumptions, we are immediately faced with the trouble problem of how to treat strong orientational correlations between water molecules.

Ben-Naim has numerically solved the Percus-Yevick (PY) equation,[5] which has been generalized to involve angular coordinates, in order to obtain the RDF of water.[6a] They used a model potential that effectively accounts for some geometrical features of the hydrogen bond, favoring the tetrahedral orientation. This model potential has a Lennard-Jones (12,6) part and an angle-dependent part based on Bjerrum's four point-charge model of a water molecule. Ben-Naim has proposed another model for the effective pair potential of water. This is expressed by the superposition of the following three terms: a Lennard-Jones (12,6) potential, a dipole-dipole interaction, and a potential devised to act only along the four directions pointing to the vertices of a regular tetrahedron. The hydrogen bond is simulated by the third term. However, actual calculations were carried out only for the case of a two-dimensional system with no dipole-dipole interaction.[6b,7]

New graph-theoretical methods, which are based on the technique of topological reduction, have recently been developed,[4] and have been successfully applied to electrolyte solutions, and dipolar and molecular fluids.[8–14] On the basis of their previous work,[12] Chandler and Andersen have proposed computationally simple techniques for calculating the thermodynamic properties and pair distribution functions of molecular fluids in which the intermolecular interactions are highly angular dependent.[13] The technique is based on the idea that a molecule has several interaction sites, and that the total interaction between two molecules is the sum of the site-site interactions that depend only on the distances between the sites of the two molecules.

Here, an application of this technique to a model system, which we refer to as a "water-like system," is reported. The water-like system is the simplest model which maintains the fundamental features of water, and is distinguished from water by the simplifications described in the following section.

In section I, the model which was used throughout this study is described in detail. In section II, a brief summary is given of the theoretical methods employed and then the methods are extended to the model system. In section III, the procedure for applying the method described in section II to the model is given and the results of the calculation are shown. In the final section, some consideration is given to the results obtained.

I. Effective Pair Potential for a Water-like System

It is expected that the interaction energy between two real water molecules consists of several parts: (1)

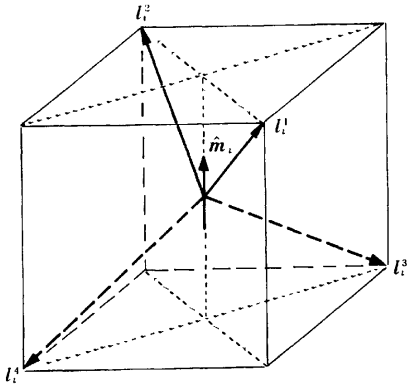

Fig. 1. Schematic representation of the water-like molecule. The molecule is a hard sphere which has a point dipole at its center and four interaction sites seated on the vertices of a regular tetrahedron. The positions of the four sites in a molecule are denoted by vectors starting from the center, $\boldsymbol{l}_i^1$, $\boldsymbol{l}_i^2$, $\boldsymbol{l}_i^3$, and $\boldsymbol{l}_i^4$. The sites at $\boldsymbol{l}_i^1$ and $\boldsymbol{l}_i^2$ correspond to hydrogen atoms of a water molecule and $\boldsymbol{l}_i^3$ and $\boldsymbol{l}_i^4$ to the lone pairs.

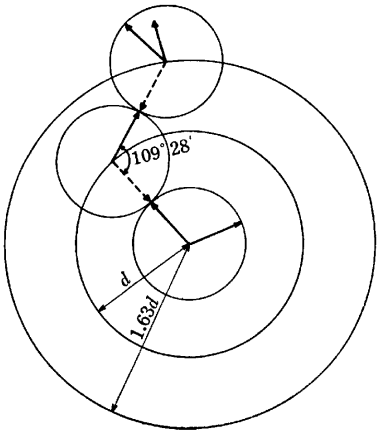

Fig. 2. A typical arrangement of a triplet of molecules in the crystal which consists of water-like molecules.

a steep repulsive part which plays a dominant role in the liquid state and a weak attraction at a short distance, (2) the dipole-dipole interaction at large distances, and (3) hydrogen bonding which is presumably of very short range and highly dependent on the orientation of the molecules. In place of a more realistic system, we consider a simplified model which maintains the fundamental characteristics of the real system. Imagine a hard sphere which has a point dipole at its center and four interaction sites situated on the surfaces of the sphere in the four tetrahedral directions from the center. Let unit vectors pointing to the four sites from the center of the i-th molecule be $\hat{\boldsymbol{l}}_i^\alpha$ (α; 1, 2, 3, 4). The vector giving a dipole orientation is denoted by $\hat{\boldsymbol{m}}_i$. The angles between $\hat{\boldsymbol{l}}_i$ and $\hat{\boldsymbol{m}}_i$ are denoted by χ_α, thus

$$\cos\chi_\alpha = (\hat{\boldsymbol{m}}_i\cdot\hat{\boldsymbol{l}}_i^\alpha), \qquad (\alpha = 1,\cdots,4) \tag{1-1}$$

It is assumed that

$$\begin{aligned}&\cos\chi_1 = \cos\chi_2 = \cos\chi,\\ \text{and}\quad&\\ &\cos\chi_3 = \cos\chi_4 = -\cos\chi.\end{aligned} \tag{1-2}$$

Figure 1 shows a schematic picture of such a model particle. The interaction energy between two such molecules may be expressed as the superposition ot three terms:

$$u(i,j) = u_{\rm d}(R) + u_{\rm DD}(i,j) + u_{\rm HB}(i,j), \tag{1-3}$$

where i and j denote the positions and the orientations of molecules i and j, respectively, and R is the distance between the centers of the two molecules. In particular, let i represent $\boldsymbol{R}_i$ (the position of the center of the i-th molecule) and $\boldsymbol{\Omega}_i$ (the Euler angle required to specify the orientation of the i-th molecule). The position of the α-site on the i-th molecule is denoted by $\boldsymbol{r}_i^\alpha = \boldsymbol{R}_i + \boldsymbol{l}_i^\alpha$. The molecules are assumed to be rigid. Thus, $\boldsymbol{l}_i^\alpha$ depends only on $\boldsymbol{\Omega}_i$. The magnitudes of all $\boldsymbol{l}_i^\alpha$ (α=1, 2,3,4) are identical and are represented by l. $u_{\rm d}(R)$ and $u_{\rm DD}(i,j)$ are defined as

$$\begin{aligned}u_{\rm d}(R) &= \infty, \qquad R<d,\\ &= 0, \qquad R>d,\end{aligned} \tag{1-4}$$

and

$$u_{\rm DD}(i,j) = (-m^2/R^3)D(i,j), \tag{1-5}$$

where

$$D(i,j) = 3(\hat{\boldsymbol{m}}_i\cdot\hat{\boldsymbol{R}})(\hat{\boldsymbol{m}}_j\cdot\hat{\boldsymbol{R}}) - (\hat{\boldsymbol{m}}_i\cdot\hat{\boldsymbol{m}}_j),$$

d is the hard-sphere diameter and $\hat{\boldsymbol{R}}$ the unit vector along the relative position $\boldsymbol{R}=\boldsymbol{R}_i-\boldsymbol{R}_j$. The $u_{\rm HB}(i,j)$ is a sum of site-site interactions of the two molecules, and thus the hydrogen bonding is simulated by

$$u_{\rm HB}(i,j) = \sum_\alpha^4\sum_\gamma^4 u_{\alpha\gamma}(|\boldsymbol{r}_i^\alpha-\boldsymbol{r}_j^\gamma|). \tag{1-6}$$

It is assumed that the site located at $\boldsymbol{l}_i^1$ is identical with that at $\boldsymbol{l}_i^2$ in kind and is different from those at $\boldsymbol{l}_i^3$ and $\boldsymbol{l}_i^4$, which are of the same kind. The sites at $\boldsymbol{l}_i^1$ and $\boldsymbol{l}_i^2$ correspond to the hydrogen atoms of a water molecule and those at $\boldsymbol{l}_i^3$ and $\boldsymbol{l}_i^4$ to lone pairs. A site on one molecule is assumed to interact with a site on another molecule only if the two sites differ in kind. A square-well potential is chosen as the interaction potential, such that

$$\begin{aligned}u_{\alpha\gamma}(|\boldsymbol{r}_i^\alpha-\boldsymbol{r}_j^\gamma|) &= -\varepsilon_{\rm H}, \qquad 0<|\boldsymbol{r}_i^\alpha-\boldsymbol{r}_j^\gamma|<b,\\ &= 0, \qquad b<|\boldsymbol{r}_i^\alpha-\boldsymbol{r}_j^\gamma|,\end{aligned} \tag{1-7}$$

where $\varepsilon_{\rm H}$ and b are parameters which represent the depth and the width of the hydrogen-bond potential. These circumstances correspond to the fact that the hydrogen bond in water occurs only if a hydrogen atom of one molecule encounters a lone pair of another molecule.

The model potential just described is similar to that of Ben-Naim but is apparently distinguishable from the latter in the details of the short-range and the hydrogen bond parts.[7]

II. Application of Graph-Theoretical Techniques to the Water-like System

Outline of the Andersen-Chandler Theory. In this section, the graph-theoretical technique of Andersen and Chandler is applied to the model described in the preceding section. The technique is outlined here.[12]

An interaction potential between two molecules is expressed as a superposition of two parts, a reference part $u_0(1,2)$ and a perturbation $u_1(1,2)$:

$$u(1,2) = u_0(1,2) + u_1(1,2). \tag{2-1}$$

Let $h_0(1,2)$ be the total correlation function[4] of the reference system which depends only upon $u_0(1,2)$. Functions $F_0(1,2)$ and $\Phi(1,2)$, which are referred to as the "*reference system hypervertex*"[8b,12] and the "*perturbation bond*,"[12] respectively, are defined as:

$$F_0(1,2) = \rho\delta(1,2) + \rho^2 h_0(1,2), \tag{2-2}$$

$$\Phi(1,2) = -\beta u_1(1,2), \tag{2-3}$$

where $\beta=1/kT$, k is the Boltzmann constant and $\delta(1,2)$ the Dirac delta function. The sum of an infinite series is defined by convolution integrals of functions F_0 and Φ, whose first few terms are represented with the aid of diagrams:

$$\begin{aligned}C(1,2) &= \sum_{n=1}^\infty C^{(n)}(1,2),\\ C^{(1)}(1,2) &= \int F_0(1,3)\Phi(3,4)F_0(4,2)\mathrm{d}(3)\mathrm{d}(4)\end{aligned} \tag{2-4}$$

$$= \quad ,$$

and

$$C^{(2)}(1,2) = \int F_0(1,3)\Phi(3,4)F_0(4,5)\Phi(5,6) \times F_0(6,2)\mathrm{d}(3)\mathrm{d}(4)\mathrm{d}(5)\mathrm{d}(6)$$

where the large circles with two small circles tangent to their circumferences represent F_0 and the lines with small circles at both ends denote Φ. $C^{(n)}(1,2)$ and $C(1,2)$ are called a "*generalized chain*" with n perturbation bonds and a "*renormalized potential*," respectively. Andersen and Chandler have shown that the pair distribution function is approximately expressed by the equation:[12]

$$\rho^2 g(1,2) = \rho^2 g_0(1,2)\exp C(1,2), \tag{2-5}$$

where $\rho^2 g_0(1,2)$ is the pair distribution function of the reference system and

$$g_0(1,2) = h_0(1,2) + 1. \tag{2-6}$$

Thus, our problem is reduced to the evaluation of the renormalized potential $C(1,2)$, if we know $h_0(1,2)$ in advance.

Application of Graph-Theoretical Techniques to the Water-like System. Here a representation for the pair distribution function of the water-like system is presented using the graph-theoretical technique above outlined. The procedure follows the method presented by Chandler and Andersen.[13]

The first two terms of Eq. 1-3 are regarded as the reference potential and the last term as the perturbation. Thus,

$$u_0(1,2) = u_{\mathrm{d}}(R) + u_{\mathrm{DD}}(1,2), \tag{2-7}$$

$$u_1(1,2) = u_{\mathrm{HB}}(1,2). \tag{2-8}$$

Many studies have been devoted to applying the graph-theoretical and integral equation techniques of the theory of classical fluids to the problem of the dielectric constant or the pair distribution function of a system possessing the pair interaction described by Eq. 2-7. Recent progress in such studies involves an analytical solution of the MSM equation[15] and treatments based on the γ-ordering technique.[8,10,11] These studies can be employed to postulate the form of the total correlation function of our reference system. It has been proven that the renormalized potential (Eq. 2-4) for such a system reduces to only the sum of convolution integrals of the perturbation bonds, $-\beta u_{\mathrm{DD}}(1,2)$.[16] The convolution intergrals can be evaluated to explicitly represent the renormalized potential:[10]

$$C_{\mathrm{DD}}(1,2) = \frac{\beta m^2}{(1+2y)(1-y)} \times \left\{\frac{1}{R^3}D(1,2) + \frac{8\pi y}{3}\delta(R)\boldsymbol{\Delta}(1,2)\right\} \tag{2-9}$$

where $y=4\pi\beta m^2\rho/9$ and $\boldsymbol{\Delta}(1,2)=(\hat{\boldsymbol{m}}_1\cdot\hat{\boldsymbol{m}}_2)$.

It is assumed that the total correlation function of the present reference system can be represented by the superposition of two terms,

$$h_0(1,2) = h_{\mathrm{d}}(R) + C_{\mathrm{DD}}(1,2), \tag{2-10}$$

where $h_{\mathrm{d}}(R)$ is the total correlation function of the hard-sphere fluid. The right-hand side of Eq. 2-10 coincides with the MSM approximation if the PY approximation is used for $h_{\mathrm{d}}(R)$[5,17] and $C_{\mathrm{DD}}(1,2)$ equals zero for $R<d$.[12,16] Using Eqs. 1-6, 2-3, 2-8, and 2-10 the perturbation bond and the reference system hypervertex for the water-like system are, respectively, defined as:

$$\Phi_{\alpha\gamma}(1,2) = -\beta u_{\alpha\gamma}(|\boldsymbol{r}_1^\alpha - \boldsymbol{r}_2^\gamma|), \tag{2-11}$$

and

$$F_0(1,2) = (\rho/\Omega)\delta(\boldsymbol{R}_1-\boldsymbol{R}_2)\delta(\boldsymbol{\Omega}_1-\boldsymbol{\Omega}_2) + (\rho/\Omega)^2 h_0(1,2). \tag{2-12}$$

The generalized chain with n perturbation bonds is given by

$$C_{\mathrm{WL}}^{(n)}(1,2) = (\rho/\Omega)^{-2}\int \mathrm{d}(3)\mathrm{d}(4)\cdots\mathrm{d}(2n+2) \times \sum_{\alpha,\gamma}\cdots\sum_{\eta,\nu} F_0(1,3)\Phi_{\alpha\gamma}(3,4)F_0(4,5)\cdots \times \Phi_{\eta\nu}(2n+1,2n+2)F_0(2n+2,2). \tag{2-13}$$

The simple case of $n=2$ is investigated in some detail.

$$C_{\mathrm{WL}}^{(2)}(1,2) = (\rho/\Omega)^{-2}\int \mathrm{d}(3)\cdots\mathrm{d}(6) \times \sum_{\alpha,\gamma}\sum_{\eta,\nu} F_0(1,3)\Phi_{\alpha\gamma}(3,4)F_0(4,5) \times \Phi_{\eta\nu}(5,6)F_0(6,2). \tag{2-14}$$

We assume that the Fourier transform of $\Phi_{\alpha\gamma}(1,2)$ is $\Phi_{\alpha\gamma}(k)$ and hence,

$$\Phi_{\alpha\gamma}(1,2) = (2\pi)^{-3}\int \mathrm{d}\boldsymbol{k}\tilde{\Phi}_{\alpha\gamma}(k)\exp[i\boldsymbol{k}\cdot(\boldsymbol{r}_1^\alpha - \boldsymbol{r}_2^\gamma)]. \tag{2-15}$$

By inserting Eq. 2-15 into Eq. 2-14, we obtain

$$C_{\mathrm{WL}}^{(2)}(1,2) = (\rho/\Omega)^{-2}(2\pi)^{-6}\int \mathrm{d}(3)\cdots\mathrm{d}(6)\int \mathrm{d}\boldsymbol{k}_1\mathrm{d}\boldsymbol{k}_2 \times \sum_{\alpha,\gamma}\sum_{\eta,\nu}\tilde{\Phi}_{\alpha\gamma}(k_1)\tilde{\Phi}_{\eta\nu}(k_2) \times F_0(1,3)F_0(4,5)F_0(6,2) \times \exp[i\boldsymbol{k}_1\cdot(\boldsymbol{r}_3^\alpha - \boldsymbol{r}_4^\gamma) + i\boldsymbol{k}_2\cdot(\boldsymbol{r}_5^\eta - \boldsymbol{r}_6^\nu)]. \tag{2-16}$$

Integrals over the configurations of molecules 4 and 5 are carried out, giving

$$(2\pi)^{-3}\int \mathrm{d}(4)\mathrm{d}(5)F_0(4,5)\exp[-i(\boldsymbol{k}\cdot\boldsymbol{r}_4^\alpha + \boldsymbol{k}'\cdot\boldsymbol{r}_5^\gamma)] = \delta(\boldsymbol{k}+\boldsymbol{k}')\Gamma_{\alpha\gamma}(k) \tag{2-17}$$

$\Gamma_{\alpha\gamma}(k)$ is the sum of two terms, $\Gamma^{\mathrm{h}}_{\alpha\gamma}(k)$ and $\Gamma^{\mathrm{c}}_{\alpha\gamma}(k)$ as follows,

$$\Gamma_{\alpha\gamma}(k) = \Gamma^{\mathrm{h}}_{\alpha\gamma}(k) + \Gamma^{\mathrm{c}}_{\alpha\gamma}(k). \tag{2-18}$$

$\Gamma^{\mathrm{h}}_{\alpha\gamma}(k)$ and $\Gamma^{\mathrm{c}}_{\alpha\gamma}(k)$ are given by

$$\Gamma^{\mathrm{h}}_{\alpha\gamma}(k) = \rho\omega_{\alpha\gamma}(k) + \rho^2 z_\alpha(k)z_\gamma(-k)\tilde{h}_{\mathrm{d}}(k) \tag{2-19}$$

and

$$\Gamma^{\mathrm{c}}_{\alpha\gamma}(k) = \frac{\beta m^2}{(1+2y)(1-y)}\left(\frac{\rho}{\Omega}\right)^2 \times \int \mathrm{d}\boldsymbol{\Omega}_i\mathrm{d}\boldsymbol{\Omega}_j\tilde{C}'_{\mathrm{DD}}(i,j)\exp[-i\boldsymbol{k}\cdot(\boldsymbol{l}_i^\alpha - \boldsymbol{l}_j^\gamma)], \tag{2-20}$$

where

$$\omega_{\alpha\gamma}(k) = \frac{\sin(k|\boldsymbol{l}_i^\alpha - \boldsymbol{l}_i^\gamma|)}{k|\boldsymbol{l}_i^\alpha - \boldsymbol{l}_i^\gamma|}, \tag{2-21}$$

$$z_\alpha(k) = \frac{\sin(kl^\alpha)}{kl^\alpha}, \tag{2-22}$$

$$\tilde{C}'_{DD}(i,j) = -\frac{4\pi}{3}\tilde{D}(i,j) + \frac{8}{3}\pi y\tilde{\Delta}(i,j), \quad (2\text{-}23)$$

$$\tilde{D}(i,j) = 3(\hat{m}_i\cdot\hat{k})(\hat{m}_j\cdot\hat{k}) - (\hat{m}_i\cdot\hat{m}_j), \quad (2\text{-}24)$$

$$\tilde{\Delta}(i,j) = (\hat{m}_i\cdot\hat{m}_j), \quad (2\text{-}25)$$

and $\hat{k}$ is the unit vector pointing in the direction of k. Substituting Eq. 2-17 into Eq. 2-16 and integrating over k', we have

$$C^{(2)}_{WL}(1,2) = (\rho/\Omega)^{-2}(2\pi)^{-3}\int d(3)d(6)\int dk \sum_{\alpha,\gamma}\sum_{\eta,\nu}\tilde{\Phi}_{\alpha\gamma}(k)\Gamma_{\gamma\eta}(k)\tilde{\Phi}_{\eta\nu}(k)F_0(1,3)F_0(6,2)\exp[ik\cdot(r_3^\alpha + r_6^\nu)]. \quad (2\text{-}26)$$

The integrals of Eq. 2-26 over the configurations of molecules 3 and 6 lead to

$$\begin{aligned} C^{(2)}_{WL}(1,2) = {} & (2\pi)^{-3}\int dk \sum_{\alpha,\gamma}\sum_{\eta,\nu}\tilde{\Phi}_{\alpha\gamma}(k)\Gamma_{\gamma\eta}(k)\tilde{\Phi}_{\eta\nu}(k)\exp[ik\cdot(r_1^\alpha - r_2^\nu)][1+\rho\{z_\alpha(k)\tilde{h}_d(k) \\ & + \Omega^{-1}\int d\Omega_3\tilde{C}_{DD}(1,3)\exp(ik\cdot l_3^\alpha)\}\exp(-ik\cdot l_1^\alpha)] \\ & \times [1+\rho\{z_\nu(-k)\tilde{h}_d(k) + \Omega^{-1}\int d\Omega_6 C_{DD}(6,2)\exp(-ik\cdot l_6^\nu)\}\exp(ik\cdot l_2^\nu)] \end{aligned} \quad (2\text{-}27)$$

The generalized chain with n perturbation bonds is analyzed in the same way. The result is

$$\begin{aligned} C^{(n)}_{WL}(1,2) = {} & (2\pi)^{-3}\int dk \sum_{\alpha,\nu}\{\tilde{\Phi}(k)[\Gamma(k)\tilde{\Phi}(k)]^{n-1}\}_{\alpha,\nu}\exp[ik\cdot(r_1^\alpha - r_2^\nu)] \\ & \times [1+\rho\{z_\alpha(k)\tilde{h}_d(k) + \Omega^{-1}\int d\Omega_3\tilde{C}_{DD}(1,3)\exp(ik\cdot l_3^\alpha)\}\exp(-ik\cdot l_1^\alpha)] \\ & \times [1+\rho\{z_\nu(-k)\tilde{h}_d(k) + \Omega^{-1}\int d\Omega_6\tilde{C}_{DD}(6,2)\exp(-ik\cdot l_6^\nu)\}\exp(ik\cdot l_2)], \end{aligned} \quad (2\text{-}28)$$

where $\Phi(k)$ and $\Gamma(k)$ are 4×4 matrices with elements $\tilde{\Phi}_{\alpha\gamma}(k)$ and $\Gamma_{\alpha\gamma}(k)$, respectively. The renormalized potential is given by the sum over the entire generalized chain ($n\geq1$):

$$\begin{aligned} C_{WL}(1,2) = \sum_{n=1}^{\infty} C^{(n)}_{WL}(1,2) = {} & \sum_{\alpha,\nu}(2\pi)^{-3}\int dk\{\tilde{\Phi}(k)[\mathbf{1}-\Gamma(k)\tilde{\Phi}(k)]^{-1}\}_{\alpha,\nu}\exp[ik\cdot(r_1^\alpha - r_2^\nu)] \\ & \times [1+\rho\{z_\alpha(k)\tilde{h}_d(k) + \Omega^{-1}\int d\Omega_3\tilde{C}_{DD}(1,3)\exp(ik\cdot l_3^\alpha)\}\exp(-ik\cdot l_1^\alpha)] \\ & \times [1+\rho\{z_\nu(-k)\tilde{h}_d(k) + \Omega^{-1}\int d\Omega_6\tilde{C}_{DD}(6,2)\exp(-ik\cdot l_6^\nu)\}\exp(ik\cdot l_2^\nu)], \end{aligned} \quad (2\text{-}29)$$

where $\mathbf{1}$ is the 4×4 identity matrix. Remembering Eq. 2-5, we have the representation for the pair distribution function of the water-like fluid, thus

$$g_{WL}(1,2) = g_0(1,2)\exp C_{WL}(1,2), \quad (2\text{-}30)$$

or in its linearized version,

$$g_{WL}(1,2) = g_0(1,2)\{1+C_{WL}(1,2)\}. \quad (2\text{-}31)$$

The radial distribution function is obtained by integrating Eq. 2-31 over the orientations of molecules 1 and 2. Remembering Eq. 2-10 and taking account of the fact that

$$\Omega^{-2}\int C_{DD}(1,2)d\Omega_1 d\Omega_2 = 0,$$

we get

$$\begin{aligned} g_{WL}(R) &= \Omega^{-2}\int g_{WL}(1,2)d\Omega_1 d\Omega_2 \\ &= \{1+C_{WL}(R)\}g_d(R) + C_{WL}{*}C_{DD}, \end{aligned} \quad (2\text{-}32)$$

where $g_d(R)$ is the RDF for the hard-sphere fluid and $C_{WL}(R)$ and $C_{WL}{*}C_{DD}$ are defined by

$$C_{WL}(R) = \Omega^{-2}\int C_{WL}(1,2)d\Omega_1 d\Omega_2 \quad (2\text{-}33)$$

and

$$C_{WL}{*}C_{DD} = \Omega^{-2}\int C_{WL}(1,2)C_{DD}(1,2)d\Omega_1 d\Omega_2. \quad (2\text{-}34)$$

III. Computational Procedures and Results

After some manipulation, we obtain a more tractable quation for $C_{WL}(R)$ from Eqs. 2-29 and 2-33:

$$\begin{aligned} C_{WL}(R) = {} & (2\pi)^{-2}\int_0^\infty dk\frac{2k\sin(kR)}{R}[z(k)(1+\rho\tilde{h}_d(k))]^2 \\ & \times \sum_{\alpha,\nu}\{\tilde{\Phi}(k)[\mathbf{1}-\Gamma(k)\tilde{\Phi}(k)]^{-1}\}_{\alpha,\nu}, \end{aligned} \quad (3\text{-}1)$$

where $z(k)=\sin(kl)/kl$. The integral in Eq. 2-20 must be carried out to obtain the elements of $\Gamma(k)$. It can be performed by a suitable choice of Euler angles to give

$$\Gamma^s_{\alpha\gamma}(R) = \frac{-6y\rho}{(1+2y)}\cos\chi_\alpha\cos\chi_\gamma\left\{\frac{\cos(kl)}{kl} - \frac{\sin(kl)}{(kl)^2}\right\}^2. \quad (3\text{-}2)$$

The details of calculations leading to Eq. 3-2 are given in the appendix. The equation for $C_{WL}{*}C_{DD}$ is obtained from Eqs. 2-9, 2-29, and 2-34 after some tedious calculations and the result is

$$\begin{aligned} C_{WL}{*}C_{DD} = {} & \frac{(2\pi)^{-2}\beta m^2}{(1+2y)^3(1-y)}\left\{\frac{2}{R^2} + \frac{8\pi y}{3}\delta(R)\right\} \\ & \times \int_0^\infty dk k^2\left\{\frac{\cos(kl)}{(kl)} - \frac{\cos(kl)}{(kl)^2}\right\}^2 \\ & \times \left\{\frac{2\sin(kR)}{kR} + \frac{4\cos(kR)}{(kR)^2} + \frac{4\sin(kR)}{(kR)^3}\right\} \\ & \times \sum_{\alpha,\nu}\cos\chi_\alpha\cos\chi_\nu\{\tilde{\Phi}(k)[\mathbf{1}-\Gamma(k)\tilde{\Phi}(k)]^{-1}\}_{\alpha,\nu}. \end{aligned} \quad (3\text{-}3)$$

It is necessary to obtain explicit forms of the summations in Eqs. 3-1 and 3-3. Combining Eqs. 2-18, 1-2, and 3-2, we obtain the explicit form of $\Gamma(k)$:

$$\Gamma(k) = \begin{pmatrix} \Gamma'_- & \Gamma_- & \Gamma_+ & \Gamma_+ \\ \Gamma_- & \Gamma'_- & \Gamma_+ & \Gamma_+ \\ \Gamma_+ & \Gamma_+ & \Gamma'_- & \Gamma_- \\ \Gamma_+ & \Gamma_+ & \Gamma_- & \Gamma'_- \end{pmatrix}, \tag{3-4}$$

where Γ_-, Γ'_- and Γ_+ are

$$\Gamma_- = \Gamma_h - \Gamma_c, \tag{3-5}$$

$$\Gamma'_- = \Gamma'_h - \Gamma_c, \tag{3-6}$$

and

$$\Gamma_+ = \Gamma_h + \Gamma_c, \tag{3-7}$$

and

$$\Gamma_h = \rho\omega(k) + \rho^2 z(k)^2 \tilde{h}_d(k), \tag{3-8}$$

$$\Gamma'_h = \rho + \rho^2 z(k)^2 \tilde{h}_d(k), \tag{3-9}$$

and

$$\Gamma_c = -\frac{6y\rho}{(1+2y)}\cos^2\chi\left\{\frac{\cos(kl)}{kl} - \frac{\sin(kl)}{(kl)^2}\right\}^2. \tag{3-10}$$

Taking into account the characteristics of the site-site interactions described in the section I, we have

$$\tilde{\Phi}(k) = \tilde{\Phi}(k)\begin{pmatrix} 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \end{pmatrix}, \tag{3-11}$$

where $\tilde{\Phi}(k)$ is given by

$$\tilde{\Phi}(k) = -4\pi\beta\varepsilon_H\left\{\frac{b\cos(kb)}{k^2} - \frac{\sin(kb)}{k^3}\right\}. \tag{3-12}$$

The inverse matrix which appears in Eqs. 3-1 and 3-3 can easily be calculated thanks to the high symmetry of matrices $\Gamma(k)$ and $\tilde{\Phi}(k)$, and as a result we obtain

$$\sum_{\alpha,\nu}\{\tilde{\Phi}(k)[\mathbf{1}-\Gamma(k)\tilde{\Phi}(k)]^{-1}\}_{\alpha,\nu} = \frac{8\tilde{\Phi}(k)}{1-2\tilde{\Phi}(k)\{3\Gamma_h(k)+\Gamma'_h(k)\}}, \tag{3-13}$$

and

$$\sum_{\alpha,\nu}\cos\chi_\alpha\cos\chi_\nu\{\tilde{\Phi}(k)[\mathbf{1}-\Gamma(k)\tilde{\Phi}(k)]^{-1}\}_{\alpha,\nu} = \frac{-8\tilde{\Phi}(k)\cos^2\chi}{1-2\tilde{\Phi}(k)\{\Gamma_h(k)-\Gamma'_h(k)+4\Gamma_c(k)\}}. \tag{3-14}$$

The correlation function obtained on the basis of the PY approximation is used as the total correlation function of the hard-sphere system, h_d, and its Fourier transform is expressed as

$$\tilde{h}_d(k) = \frac{\tilde{C}_{PY}(k)}{1-\tilde{C}_{PY}(k)}, \tag{3-15}$$

where $\tilde{C}_{PY}(k)$ is the Fourier transform of the direct correlation function of the hard-sphere fluid, which is the Wertheim solution to the PY equation.[5,17] Although $h_d(R)$, and hence $g_d(R)$, are obtained from the Fourier transform of $\tilde{h}_d(k)$, the numerical calculation is performed in practice with the aid of a function,

$$\tilde{\gamma}(k) = \tilde{h}_d(k) - \tilde{C}_{PY}(k), \tag{3-16}$$

because $h_d(R)$ and its derivatives are discontinuous at $R=d$.[18] All the integrals over k are performed numerically on the basis of the Simpson rule. The accuracy

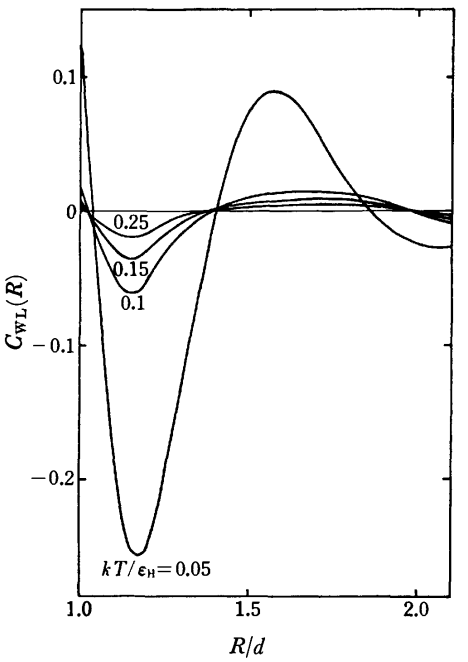

Fig. 3. The functions $C_{WL}(R)$ for $b=0.2d$, $\rho d^3=0.6$, $kT/\varepsilon_H=0.05$, 0.1, 0.15, and 0.25. It represents the effect of the hydrogen bonds.

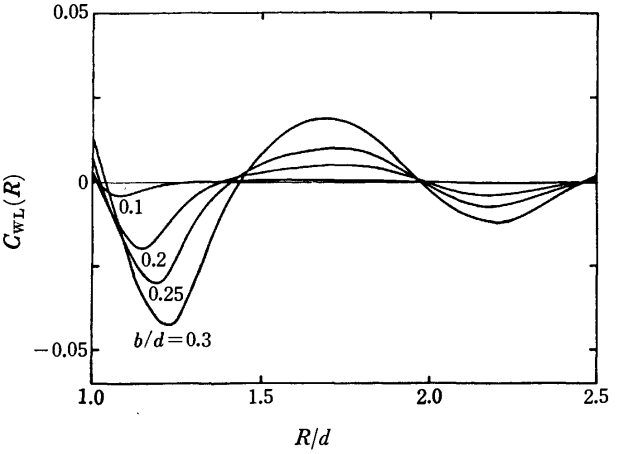

Fig. 4. The functions $C_{WL}(R)$ for $\rho d^3=0.6$, $kT/\varepsilon_H=0.25$, $b=0.3d$, $0.25d$, $0.2d$, and $0.1d$.

of the calculations has been checked against the exact values of $g_d(R)$ given by Throop and Bearman.[19] The results for $C_{WL}(R)$ are shown in Figs. 3—5 and those for $g_{WL}(R)$ in Figs. 6 and 7. $C_{WL}{}^*C_{DD}$ is not shown explicitly, since its contribution is very small compared with that of $C_{WL}(R)$. It should be noted that $C_{WL}(R)$ represents the effect of the hydrogen bonds on the molecular distribution.

IV. Discussion

We imagine a crystal consisting of water-like molecules, which has a tetrahedral structure similar to ice. A typical arrangement for a triplet of molecules in the crystal is depicted in Fig. 2. If the model potential described in section I favors such an arrangement, it is expected that the following two effects on the molec-

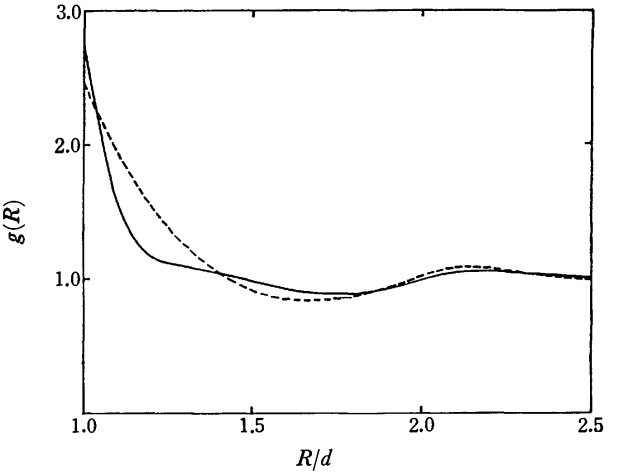

Fig. 7. The calculated RDF for the water-like fluid (solid line) at $\rho d^3=0.6$, $kT/\varepsilon_H=0.05$, and $b=0.2d$, compared with one for the hard-sphere fluid (dashed line).

ular distribution of the reference system are produced: a decrease in the density of the first coordination shell and an increase in the density in the neighborhood of a position $1.63d$ distant from the central molecule. The behavior of $C_{WL}(R)$ in Fig. 3 is consistent with this expectation. The negative value of $C_{WL}(R)$ at short distances is due to the former effect and the positive values in the neighborhood of $R=1.6d$ to the latter. It should be noted that there is a peak in the neighborhood of $R=1.6d$. It is also reasonable that the features become more prominent as the depth of the square-well potential, ε_H, increases. All the curves with various values of kT/ε_H given in Fig. 3 are observed to have a nearly common point of intersection with the abscissa. This is supposed to be primarily due to the maintenance of the magnitude of b as a constant through all the calculations. This is determined easily from Fig. 4, where several $C_{WL}(R)$ curves with different values of b are depicted. An evident shift in the location of the intersection is observed. The manner in which the $C_{WL}(R)$ curves change with density is shown in Fig. 5. Appreciable differences are observed between the curves for high and low densities. It appears that the trend of forming a tetrahedral geometry is dominant at low densities and that it weakens with increasing density. On the basis of rapid increase of the first peak, the behavior of $C_{WL}(R)$ at higher densities appears to indicate that the square-well potential serves as a central attractive force rather than as a non-central force leading to the tetrahedral geometry. The increase in density would have two results: an enhancement of the role of repulsive force in the determination of the molecular distribution and an increase in the probability of sites on one molecule encountering those on another molecule. The former effect prevents the hydrogen bonds from forming a tetrahedral geometry, and the latter produces a strong attraction between the two molecules.

The results for the RDF are shown in Figs. 6 and 7. A narrowing of the first peak similar to that observed for the RDF of water[2,7] is found, and this feature increases as the magnitude of ε_H increases. Although characteristics of the second peak for the RDF of water do not appear in the present calculation, this peak does appear to grow. This is noticeable in spite of the use of overestimated values of ε_H.

The coordination number is to be obtained from the first peak of the RDF curve using the equation,

$$n_{CN}=\rho\int_0^{R_m} g(R)4\pi R^2 dR. \qquad (4\text{-}1)$$

It should be noted that the values of n_{CN} depend on the choice of R_m. The most reasonable choice of R_m would be the location of the first minimum in the RDF. However, this choice cannot be adopted in the present case since no minimum corresponding to the first minimum in the RDF of water is found. Therefore, it is only possible to give the coordination number obtained for a rather arbitrary value of R_m. The coordination number is about 6.2 when R_m equals $1.4d$ which corresponds to the point of intersection of the $C_{WL}(R)$ curve with the abscissa.[20] It should be noted that a similar arbitrariness in the choice of R_m is also found

in the report of Ben-Naim.[6a]

It is hoped that the application of the method proposed here to water and ionic solutions will be reported in future publications. There are several possibilities for improving the model and the mathematical formalism. It is not too difficult to replace the hard-sphere potential with the Lennard-Jones (12,6) potential. Systematic ways of performing such a replacement have been given.[21] Moreover, the present rough representation of $h_0(1,2)$, Eq. 2-10, could be replaced by a more elaborate representation. More fundamental improvements concern the graph-theoretical treatment. A possible improvement could be achieved by taking account of the graphs ignored in this study. However, it would be rather promising to employ the optimization procedure proposed by Andersen and Chandler.[12]

It is interesting to apply this method to the problems of ion-water interactions. The orientational effect due to ion-dipole interactions is different in charater from that due to the hydrogen bonds. It is possible that the ion-dipole interaction exerts a torque on the molecule, which prevents the molecule from hydrogen-bonding. If this is true, the contribution of ion-dipole interactions to the molecular distribution should be opposite to the effect of the hydrogen bonds. It is expected, therefore, that the RDF for a water-like system under the influence of an electrostatic field due to ions approaches that for a simple fluid. This would provide an explanation of the so-called "*structure-breaking effect*" of ions.[22-24]

The author wishes to thank Assistant Professor Kiyoshi Arakawa for his kind supervision and continuous encouragement.

Appendix: the Derivation of Eq. 3-2

Let $\boldsymbol{k}$ be the z-axis, then Eq. 2-23 becomes:

$$\tilde{C}'_{DD}(i,j) = -\frac{4\pi}{3}\tilde{D}(i,j) + \frac{8\pi}{3}y\tilde{\Delta}(i,j)$$
$$= \frac{8}{3}\pi(y-1)\cos\theta_{ik}\cos\theta_{jk} + \frac{4}{3}\pi(1+2y)\cos(\phi_i-\phi_j), \quad \text{(A-1)}$$

where θ_{ik} and ϕ_i are the polar and the azimuthal angles of the unit vector $\hat{\boldsymbol{m}}_i$ of the i-th molecule, respectively, and θ_{jk} and ϕ_j are those of the j-th molecule. Eq. 2-20 can, therefore, be rewritten as

$$\Gamma^c_{\alpha\gamma}(k) = -\frac{8\pi\beta m^2\rho^2}{3(1+2y)}\frac{1}{\Omega^2}\int d\boldsymbol{\Omega}_i\cdot d\boldsymbol{\Omega}_j \times \exp[-i\boldsymbol{k}\cdot(\boldsymbol{l}^\alpha_i-\boldsymbol{l}^\gamma_j)]\cos\theta_{ik}\cos\theta_{jk} + \frac{4\pi\beta m^2\rho^2}{3(1-y)}\frac{1}{\Omega^2}\int d\boldsymbol{\Omega}_i\cdot d\boldsymbol{\Omega}_j \times \exp[-i\boldsymbol{k}\cdot(\boldsymbol{l}^\alpha_i-\boldsymbol{l}^\gamma_j)]\cos(\phi_i-\phi_j). \quad \text{(A-2)}$$

The integrals can be broken up into factors each of which is an integral over $\boldsymbol{\Omega}_i$ or $\boldsymbol{\Omega}_j$. As an example, we investigate in some detail the integral, involving the i-th molecule and the α site.

Let us first take the Cartesian-coordinate system, x'y'z', fixed to the i-th molecule, whose origin coincides with the center of the molecule and the z'-axis points in the direction of the α site of the molecule. The Cartesian coordinates of the unit vector of the dipole, $\hat{\boldsymbol{m}}_i$, in the coordinate system are denoted by $m_{x'}$, $m_{y'}$ and $m_{z'}$. Then, this coordinate system is rotated to a new coordinate system, xyz, whose z axis coincides with $\boldsymbol{k}$. The orientation of the xyz system relative to the x'y'z' system can be specified by the Euler angles θ, ϕ and ψ. Thus, the components of $\hat{\boldsymbol{m}}_i$ in the new xyz system are given by the linear transformation:[25]

$$\begin{bmatrix} m_x \\ m_y \\ m_z \end{bmatrix} = \begin{bmatrix} \cos\psi\cos\phi - \cos\theta\sin\phi\sin\psi & \cos\psi\sin\phi + \sin\theta\cos\phi\sin\psi & \sin\psi\sin\theta \\ -\sin\psi\cos\phi - \cos\theta\sin\phi\cos\psi & -\sin\psi\sin\phi + \cos\theta\cos\phi\sin\psi & \cos\psi\sin\theta \\ \sin\theta\sin\phi & -\sin\theta\cos\phi & \cos\theta \end{bmatrix} \begin{bmatrix} m_{x'} \\ m_{y'} \\ m_{z'} \end{bmatrix} \quad \text{(A-3)}$$

The components of $\hat{\boldsymbol{m}}_i$ are also represented by the polar coordinate system whose polar axis coincides with $\boldsymbol{k}$:

$$m_x = \sin\theta_{ik}\cos\phi_i, \quad m_y = \sin\theta_{ik}\sin\phi_i, \quad m_z = \cos\theta_{ik}. \quad \text{(A-4)}$$

From Eqs. A-3 and A-4, we obtain

$$\left.\begin{aligned} \cos\theta_{ik} &= m_{x'}\sin\theta\sin\phi - m_{y'}\sin\theta\cos\phi + m_{z'}\cos\theta, \\ \cos\phi_i &= \{m_{x'}(\cos\psi\cos\phi-\cos\theta\sin\phi\sin\psi) + m_{y'}(\cos\psi\sin\phi+\sin\theta\cos\phi\sin\psi) + m_{z'}\sin\psi\sin\theta\}/\sin\theta_{ik} \\ \sin\phi_i &= \{m_{x'}(-\sin\psi\cos\phi-\cos\theta\sin\phi\cos\psi) + m_{y'}(-\sin\psi\sin\phi+\cos\theta\cos\phi\cos\psi) + m_{z'}\cos\psi\sin\theta\}/\sin\theta_{ik}. \end{aligned}\right\} \quad \text{(A-5)}$$

Thus, the integral over $\boldsymbol{\Omega}_i$ can be performed using Eq. A-5.

$$\frac{1}{\Omega}\int d\boldsymbol{\Omega}_i\exp(-i\boldsymbol{k}\cdot\boldsymbol{l}^\alpha_i)\cos\theta_{ik} = \frac{1}{8\pi^2}\int_0^\pi d\theta\sin\theta\int_0^{2\pi}d\phi\int_0^{2\pi}d\psi\exp(-ikl\cos\theta)\{m_{x'}\sin\theta\sin\phi - m_{y'}\sin\theta\cos\phi + m_{z'}\cos\theta\}$$
$$= \frac{m_{z'}}{2}\int_0^\pi d\theta\sin\theta\cos\theta\exp(-ikl\cos\theta) = im_{z'}\left\{\frac{\cos(kl)}{kl} - \frac{\sin(kl)}{(kl)^2}\right\} = i\cos\chi_\alpha\left\{\frac{\cos(kl)}{kl} - \frac{\sin(kl)}{(kl)^2}\right\}. \quad \text{(A-6)}$$

The last equation results since the angle between vectors $\boldsymbol{l}^\alpha_i$ and $\hat{\boldsymbol{m}}_i$ is χ_α. By similar manipulations, we obtain

$$\frac{1}{\Omega}\int d\boldsymbol{\Omega}\exp(i\boldsymbol{k}\cdot\boldsymbol{l}^\gamma_j)\cos\theta_{jk} = \frac{\cos\chi_\gamma}{i}\left\{\frac{\cos(kl)}{kl} - \frac{\sin(kl)}{(kl)^2}\right\}. \quad \text{(A-7)}$$

Therefore, the first intergal in Eq. A-2 is

$$\frac{1}{\Omega^2}\int d\boldsymbol{\Omega}_i\cdot d\boldsymbol{\Omega}_j\exp[-i\boldsymbol{k}\cdot(\boldsymbol{l}^\alpha_i-\boldsymbol{l}^\gamma_j)]\cos\theta_{ik}\cos\theta_{jk} = \cos\chi_\alpha\cos\chi_\gamma\left\{\frac{\cos(kl)}{kl} - \frac{\sin(kl)}{(kl)^2}\right\}^2. \quad \text{(A-8)}$$

It may be proved in the same way that the second integral vanishes. Using the relation, $y=4\pi\beta m^2\rho/9$, one obtains

$$\Gamma^{c}_{\alpha\gamma}(k) = \frac{-6y\rho}{1+2y}\cos\chi_\alpha\cos\chi_\gamma\left\{\frac{\cos(kl)}{kl}-\frac{\sin(kl)}{(kl)^2}\right\}^2. \quad \text{(A-9)}$$

Isomerization of Butenes over Thorium Dioxide

Yuzo IMIZU, Tsutomu YAMAGUCHI, Hideshi HATTORI, and Kozo TANABE
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received November 1, 1976)

The isomerization of butenes has been studied over four kinds of ThO_2 catalysts which differ in starting materials or preparative procedures. The selective ThO_2 catalysts for the formation of 1-olefin in the dehydration of 2-alkanol, which were prepared from nitrate and oxalate, were active and gave high *cis*/*trans* ratios in the isomerization of 1-butene, whereas the non-selective ThO_2 catalyst, which was prepared from chloride, was completely inactive. The isomerization reaction was poisoned by both CO_2 and NH_3. The activity was enhanced by the treatment with hydrogen, but was reduced by the treatment with oxygen, the selectivity being unchanged with both treatments. The coisomerization of *cis*-2-butene and *cis*-2-butene-d_8 showed that the isomerization involved an intramolecular hydrogen transfer, and a large isotope effect, 6.0, for the formation of 1-butene and a small isotope effect, 1.5, for the formation of *trans*-2-butene were observed. With these results, the nature of active sites on thorium oxide, and the reaction mechanism were discussed.

Thorium dioxide has been used as a catalyst for dehydration of alcohols.[1,2] In recent years, it has been recognized to be a selective catalyst for the dehydration of 2-alkanol to form 1-alkene when it is properly prepared.[3,4]

Davis and Brey reported that the selectivity of thorium dioxide in dehydration and dehydrogenation of alcohols strongly depended upon the preparative procedures of the catalyst.[5] The thorium dioxide prepared from nitrate shows a high selectivity for the formation of 1-octene in the dehydration of 2-octanol, whereas the thorium dioxide prepared from thorium chloride gives a considerable amount of 2-octenes. Besides the preparative procedure, the pretreatment condition is another major factor for determining selectivity. Thorium dioxide pretreated with hydrogen is a dehydration catalyst, while thorium dioxide pretreated with oxygen is a dehydrogenation catalyst.[5]

The nature of active sites on thorium dioxide which determines the selectivity, however, has not yet extensively been investigated. Yamaguchi *et al.* reported in the dehydration of alcohol over alumina[6] and zirconium dioxide[7,8] that the selectivity of the catalysts can be determined by surface acidic and basic properties. The isomerization of butenes is known to be a reaction suitable for testing the correlation of acidic and basic properties of catalysts with the activity and selectivity.[9—13] In the present work, the isomerization of butenes was carried out over several thorium dioxides to investigate the nature of active sites.

Experimental

Catalysts and Reactants. Four kinds of thorium dioxide were prepared, which differ in starting materials or in preparative procedures. ThO_2(I) and ThO_2(II) were obtained from oxalate and nitrate, respectively, by thermal decomposition in air at 500 °C for 6—8 h. ThO_2(III) was prepared from nitrate by the precipitation method as shown by Brey *et al.*[14] To 5000 ml aqueous solution of thorium nitrate (0.145 M), 500 ml aqueous ammonia (28%) was added. Precipitate was filtered, followed by washing with 1500 ml distilled water. The resulting thorium hydroxide was dried for 2 days and finally calcined at 500 °C in air for 6 h. ThO_2(IV) was prepared from thorium chloride by precipitation as follows. Aqueous ammonia (28%, 50 ml) was added to 500 ml aqueous solution of 50 g thorium chloride. Precipitate was washed, dried, and calcined as in the case of ThO_2(III). Those thorium salts were supplied from Wako Pure Chemical Co. All catalysts were evacuated at 500 °C for 3 h before use for the reaction.

Butenes (Takachiho pure grade) were purified by passage through a column of molecular sieves 3A or 4A maintained at the temperature of dry ice–acetone. 2-Butanol was obtained from Wako Pure Chemical Co. and purified by passage through molecular sieves 3A at room temperature.

Apparatus and Procedure. Dehydration of *s*-butyl alcohol and isomerization of butenes were carried out in two recirculation reactors whose volumes were 3000 ml for dehydration and 410 ml for isomerization. For dehydration, the initial pressure of *s*-butyl alcohol was 6 Torr and about 300 mg of a catalyst was used. Reaction temperature was 300 °C. Products were analyzed by gas chromatography. A 1 m column packed with TCP 30% on Celite 545 was operated at 100 °C. For isomerization of butenes, 88 Torr of butene and 50—150 mg of catalyst were used. Reaction temperature was 80 °C. Products were analyzed by gas chromatography with a 5 m column containing VZ-7, operating at room temperature.

For poisoning experiment with carbon dioxide or ammonia, the catalyst that had been evacuated at 500 °C was cooled to 100 °C and was exposed to 88 Torr of carbon dioxide or ammonia for 1 h. After evacuation at certain temperatures (200—500 °C) for 1 h, the catalyst was served for a reaction.

For hydrogen or oxygen treatment, the catalyst that had been evacuated at 500 °C was exposed to hydrogen or oxygen (60 Torr) at 500 °C or 300 °C for 2 h, followed by evacuation at various temperatures for 1 h.

For the coisomerization of non-deuterated and perdeuterated *cis*-2-butenes,[10,15] a mixture containing about equal amount of *cis*-2-butene-d_0 and *cis*-2-butene-d_8 was reacted at 80 °C.

Results

Specific surface areas, the activities, and the selectivities for the dehydration of 2-butanol and the isomerization of butenes are listed in Table 1. The catalysts showed a high selectivity for the formation of 1-alkene in the dehydration except for ThO_2(IV), over which considerable amounts of 2-alkenes were produced.[5] For the isomerization of butenes, the ThO_2(IV) was completely inactive. This was true even for the catalyst evacuated at 900 °C. The other thorium dioxides were active and gave high *cis*/*trans* and 1-/*trans* ratios in the isomerization of 1-butene and

Table 1. Catalytic activity and selectivity of ThO_2 for isomerization of butenes and dehydration of *s*-butyl alcohol

Catalyst	Surface area (m^2/g)	1-Butene		2-Butanol			
		Activity[a]	Ratio of *cis* to *trans*	Activity[a]	composition of butenes[b]		
					1-butene	*trans*-2-butene	*cis*-butene

cis-2-butene, respectively.

Poisoning effects of carbon dioxide and ammonia are given in Table 2. Both carbon dioxide and ammonia poisoned the active sits for isomerization. The catalyst regained the original activity by evacuation at 400 °C for ammonia poisoned catalyst and by evacuation at 500 °C for carbon dioxide poisoned catalyst. Poisoning with ammonia and carbon dioxide did not result in appreciable change in selectivity.

In Table 3 are listed the effects of oxygen or hydrogen treatment on the activity and selectivity in the isomerization. While hydrogen treatment resulted in an increase in the activity, oxygen treatment reduced the activity. The selectivity was almost unchanged with these treatments.

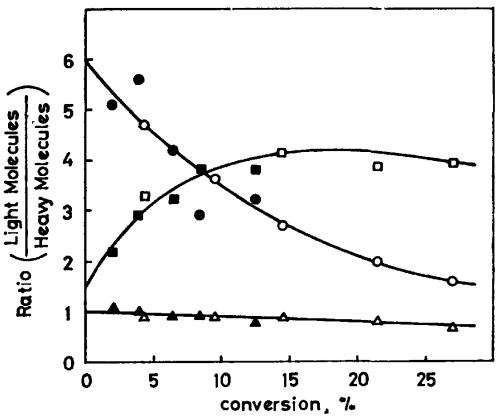

Fig. 1. The variations of the ratios of "*light molecules*" to "*heavy molecules*" with the conversion in the coisomerization of *cis*-2-butene d_0/d_8 over both untreated ThO_2 and hydrogen treated ThO_2. Reaction temperature; 80 °C, untreated ThO_2; (●) 1-butene, (■) *trans*-2-butene, (▲) *cis*-2-butene, treated ThO_2; (○) 1-butene, (□) *trans*-2-butene, (△) *cis*-2-butene.

Isotopic distribution of butene isomers in the coisomerization of *cis*-2-butene d_0/d_8 are listed in Table 4. Since the numbers of hydrogen (or deuterium) atoms exchanged per molecule (AEM value) are much smaller than 0.5, the value of which is expected if the reaction involves an intermolecular hydrogen transfer, the reaction is suggested to involve an intramolecular hydrogen transfer. The ratios of "*light molecule*" to "*heavy molecule*" are plotted against isomerization conversion in Fig. 1 for both untreated and hydrogen treated catalysts. The plots are on the same lines for both untreated and hydrogen treated catalysts. The intercepts of the plots show the isotope effect. A large isotope effect, 6.0, for the formation of 1-butene and a small isotope effect, 1.5, for the formation of *trans*-2-butene were observed.

Discussion

As suggested by Davis and Brey, catalytic properties of thorium dioxide vary with both preparative procedure and pretreatment.[5] There seem to be different types of active sites on the surface of thorium dioxide.

In the isomerization of butenes, the selectivities did

not substantially change with either pretreatment or poisoning. It appears that only one type of active sites is operative for the isomerization of butenes. One type of active sites on ThO_2(IV) which is non-selective for dehydration, is not active for isomerization of butenes. Oxygen treatment of ThO_2(III) resulted in the elimination of the active sites for the isomerization. By referring to the report that oxygen treatment enhances the active sites for dehydrogenation,[5] the active sites for dehydrogenation are not considered to be active for the isomerization. On the other hand, hydrogen treatment was reported to produce the active sites for selective dehydration to 1-alkene. Since it actually increased the activity for the isomerization, it is suggested that the active sites for the isomerization are of a type of active sites which catalyze the selective dehydration.

The active sites for the isomerization were poisoned by both an acidic molecule, carbon dioxide, and a basic molecule, ammonia. It is plausible that the active site is an acid-base pair site. If either part of a pair site is blocked by a poison, the rest of the pair site may not show any activity. This interprets the observed selectivity which was unchanged by poisoning with both molecules.

Breysse has shown that the treatment of thorium dioxide with hydrogen or oxygen at 500 °C caused a slight deviation from stoichiometry.[16] It is suggested that hydrogen treatment removes surface oxygen ion and provides a surface with excess thorium ions. The coordinatively unsaturated thorium ion is expected to be more strongly acidic than saturated thorium ion.[17] There should be oxygen ions adjacent to the unsaturated thorium ion. These oxygen ions are expected to be more strongly basic than oxygen ion adjacent to saturated thorium ion.

Since the isomerization involves an intramolecular hydrogen transfer, the reaction may be initiated by the abstraction of a hydrogen atom (or ion) from a butene molecule. In the isomerization of 1-butene where a π-allyl carbanion is an intermediate, a preferential formation of *cis*-2-butene is generally observed[9,12,18,19] which is attributed to a greater stability of a π-allyl carbanion in *cis*-form than in *trans*-form. A rotation of a C^2–C^3 bond within a π-allyl carbanion may not easily occur because of a double bond character of the bond. Therefore, if the reaction proceeds *via* a π-allyl carbanion intermediate, high raios of *cis*-2-butene to *trans*-2-butene and 1-butene to *trans*-2-butene are expected. This is the case observed. The reaction is considered to be initiated by the abstraction of a proton from butene to form a π-allyl carbanion. Oxygen ion may abstract a proton. A π-allyl carbanion may be adsorbed on the coordinatively unsaturated thorium ion.

In the isomerization of *cis*-2-butene, the abstraction of a proton may be common for both the formation of 1-butene and the formation of *trans*-2-butene. If the slow step were the abstraction of a proton, a large isotope effect would be observed for formation of both compounds. A small isotope effect for the formation of *trans*-2-butene indicates that the abstraction of a proton is not a slow step. A rotation of the C^2–C^3 bond within a π-allyl carbanion may be the slow step for the formation of *trans*-2-butene. A large isotope effect observed only for the formation of 1-butene

suggests that a slow step is involved in a transfer of the adsorbed proton which had been abstracted from one of the terminal carbon atoms to the carbon atom 3 of a π-allyl carbanion.

Pyrolysis of Acetylene behind Shock Waves

Hiroo OGURA

Institute of Space and Aeronautical Science, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153

(Received November 12, 1976)

The pyrolysis of acetylene was investigated behind the reflected shock waves in a single-pulse shock tube over the temperature range from 1000 to 1670 K. The major products were 1-buten-3-yne, 1,3-butadiyne, and hydrogen. The main primary C_4 product, however, changes from 1-buten-3-yne to 1,3-butadiyne with the increase of temperature. At the lower temperatures the formation of 1-buten-3-yne dominates the pyrolysis of acetylene. The rate of 1-buten-3-yne formation is second order with respect to acetylene concentration, and its second-order rate constant is expressed as follows:

$$k(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{14.39\pm0.26}\exp((-46400\pm1400)/RT)$$

The isotopic distribution of 1-buten-3-yne in the pyrolysis of the equimolar C_2H_2 and C_2D_2 mixture, proved that the pyrolysis proceeds *via* a free-radical mechanism. A free-radical chain mechanism initiated by the bimolecular reaction of acetylene, $2C_2H_2 \rightarrow C_4H_3+H$, was proposed.

The thermal decomposition of acetylene has been studied over a wide temperature range by various methods. At low and intermediate temperatures, static[1–6] and flow[7–16] systems were employed and the reaction rate of acetylene consumption, reaction order, products distribution, wall effects, and the effects of a variety of additives, for example, reaction products and radical scavengers such as nitrogen oxide, were extensively investigated.

There is substantial agreement on some aspects of the pyrolysis at low and intermediate temperatures. At the initial stage of the reaction, an induction period is observed and succeeded by a homogeneous reaction. The latter is second order with respect to acetylene with a low activation energy of 40—50 kcal*/mol. The reaction leads to the formation of high molecular weight compounds and is inhibited markedly by nitric oxide. The polymer produced at the early stage is solely 1-buten-3-yne(vinylacetylene), and benzene is an important secondary product. Palmer and Dormish[15] have shown that there is a transition as regards the primary C_4 product at about 1500 K, where 1,3-butadiyne (diacetylene) becomes predominant.

In high temperature region shock tube technique was used exclusively, because it is excellent to realize high temperature without worry about wall effects. The experimetal results obtained from the shock tube studies,[17–28] however, are somewhat confusing with regard to the reaction order and the main C_4 product, butenyne or butadiyne. These discrepancies may be ascribed to the difficulties to analyze the reaction products and to determine the reaction order by shock tube technique. It seems desirable to study the pyrolysis over a fairly wide temperature range, the lower of which overlaps the flow tube investigations.

The mechanism of the pyrolysis has not been well established. Many investigators favored a bimolecular reaction of acetylene to give an excited molecule of acetylene or butenyne in the triplet state or biradical. Recently several attempts have been made to interpret the pyrolysis of unsaturated hydrocarbons in terms of free-radical chain mechanisms initiated by the bimolecular reactions of unsaturated hydrocarbons,[29,30] and have attracted the attention of many investigators. In the shock tube experiments above 1700 K, Gay and coworkers,[25] and Bopp and Kern[28] detected C_4H_3 radical by use of a time of flight mass spectrometer.

In the present experiment, a wide temperature range from 1000 to 1670 K was covered. Complete analysis of the reaction products was performed as far as possible. Particular attention has been paid to determine the order of the reaction and the major products as a function of temperature. In the temperature range studied, it is difficult to find radicals in a direct manner,[12] but the deuterium content of the main primary product in the pyrolysis of the equimolar C_2H_2 and C_2D_2 mixture, may be expected to provide information for testing the mechanisms.

Experimental

Apparatus and Procedure. The pyrolysis was studied in a 4-cm i.d. single-pulse shock tube. The driven section was 277 cm long, the main portion of which was made of terex glass tubing. The driver section was steel tubing and its length was variable, but it was fixed at 157 cm in the present runs. A 80-l dump tank was connected to the driven section near the diaphragm. The driver section was seperated from the driven section by a "Lumirror" (polyethylene terephthalate) film of 0.05 mm thickness. The details of the shock tube was described by Tsuda and Kuratani,[31] but a slight modification was made.

Before each test run, the shock tube was evacuated to below 1×10^{-4} Torr by an oil diffusion pump. The ultimate vacuum was 8×10^{-5} Torr, and the leak plus outgassing rate was approximately 6×10^{-5} Torr/min.

In order to measure the incident shock velocity, the outputs of the three pressure gauges(barium titanate-lead zirconate) spaced at 23.1 cm intervals were fed into a home-built electronic counter(Hop Step Jump Counter),[32] having the accuracy of 0.1 μs. Reflected shock parameters were calculated from the incident shock velocity extrapolated to the end-plate, considering the attenuation of the shock wave. Ideal shock wave theory was used. The thermodynamical data were taken from the JANAF tables.[33] The pressure profiles at the downstream end were recorded on an oscilloscope, from which the reaction times were determined with the accuracy of ±5%. Helium was used as the driver gas throughout the experiment. The shocks were fired within five minutes after the two section were filled with the desired gases.

* 1 $\mathrm{cal_{th}}$=4.184 J.

Materials. The three kinds of mixtures, with the ratios of C_2H_2/Ar equal to 5/95 and 10/90; and with the ratio of C_2H_2/C_2D_2/Ar equal to 5/5/90, were prepared in a glass vessel of 5-l volume, and were allowed to stand at least one day before use.

Acetylene, from Matheson Company, was bubbled through concentrated sulfuric acid, passed through a sodalime tower and then collected in a liquid nitrogen trap. The condensate was purified by bulb-to-bulb vacuum distillation. Acetylene-d_2(99% D atom guaranteed) was obtained from Merck Sharp and Dohme of Canada. For the purification, it was condensed in a liquid nitrogen trap, and subjected to a brief pumping period. Argon(nominal purity of 99.9995%), from Nippon Sanso Co., was used without further purification and served as the diluent.

Butenyne and butadiyne were prepared from 1,3-dichloro-2-butene and 1,4-dichloro-2-butyne, respectively.[34,35] They were purified by distillation through a low temperature column. The purified gases were quickly diluted with a large amount of argon as the stabilizer, and stored. Gas chromatographic analysis showed that the butenyne and butadiyne contained allene, propyne, and butadiene as the impurities. The purity of the butenyne and butadiyne was found 82.0 and 91.4%, respectively.

Research Grade CH_4, C_2H_4, C_2H_6, allene, propyne, and 1,3-butadiene were obtained from Takachiho Shoji Co., and used as received. The reference gases for the gas chromatographic calibration were prepared barometrically with mercury and oil manometers. Argon was used as the diluent gas.

Analytical. As soon as the shock was fired, the test gas around the end-plate was quickly extracted into an evacuated bulb of 60-ml volume with the aid of a solenoid valve operated by compressed air. The hydrocarbons in the products were analyzed on Yanaco G-80 and Shimadzu GC-3AF gas chromatographs using flame ionization detectors. CH_4, C_2H_4, C_2H_6 were analyzed at 50 °C on a 3 mm× 2 m column packed with 80—100 mesh Porapak N. The higher molecular weight hydrocarbons were analyzed at 130 °C. The hydrogen was detected at a room temperature by a thermal conductivity cell, on a 4-m column packed with 40—50 mesh molecular sieve 5A with argon as the carrier gas. The concentration of each product was determined from the peak area relative to that of the reference gas.

The shock heated samples of the equimolar mixture of C_2H_2 and C_2D_2 in argon were analyzed by a Hitachi model RM-50 mass spectrometer to determine the isotopic distributions of acetylene and butenyne. The ionization potential was kept at 50 eV. The pattern coefficient of acetylene-d_1 was taken equal to the arithmetical mean of those acetylene-d_0 and acetylene-d_2. The fragmentation patterns of butenyne isomers were calculated statistically from that of butenyne-d_0 assuming the same fragmentation.

Results

The two mixtures with the ratios of C_2H_2/Ar equal to 5/95 and 10/90 were pyrolyzed over the temperature range from 1000 to 1670 K. The shock heated samples were analyzed by gas chromatography. Complete analysis was carried out for the hydrocarbons having carbon number from 1 to 4.

Major Products. Under the experimental conditions employed, the major products of the pyrolysis were butenyne, butadiyne, and hydrogen. Butenyne and butadiyne were identified by both gas chromatography and mass spectrometry. The analytical results are shown in Fig. 1. As shown in Fig. 1, at the lower temperatures the yield of butenyne increases with temperature. And it attains to its maximum at about 1500 K, and then with the increase of temperature, it becomes to decrease.

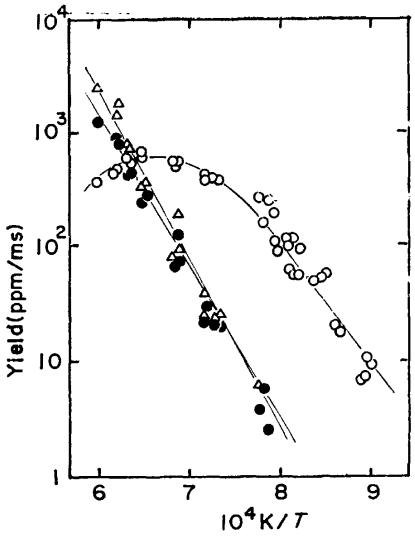

Fig. 1. Major products distribution as a function of temperature. (C_2H_2/Ar=5/95).
○: Butenyne, ●; butadiyne, △; hydrogen.

The yields of butadiyne and hydrogen increase linearly with increasing temperature in the temperature range studied. At the lower temperatures approximately equal amounts of butadiyne and hydrogen are produced, while at the higher temperatures above 1500 K the yield of hydrogen evidently goes beyond that of batadiyne. It is thus confirmed that at the lower temperatures butenyne is the main primary product, on the other hand, butadiyne and hydrogen become predominant at the higher temperatures.

Minor Products. CH_4, C_2H_4, allene, and propyne were found as the minor products. They are shown in Fig. 2 in the case of the mixture of C_2H_2/Ar=10/90. On the gas chromatograph a low and broad peak with a very long retention time (about 3 h) was observed, and identified as benzene. But the quantitative analysis was not carried out. In addition, trace amounts(less than 1 ppm) of C_2H_6 and 1,3-butadiene were detected. It is noteworthy that the hydrocarbons containing odd number of carbon atoms such as CH_4 and C_3H_4 were observed.

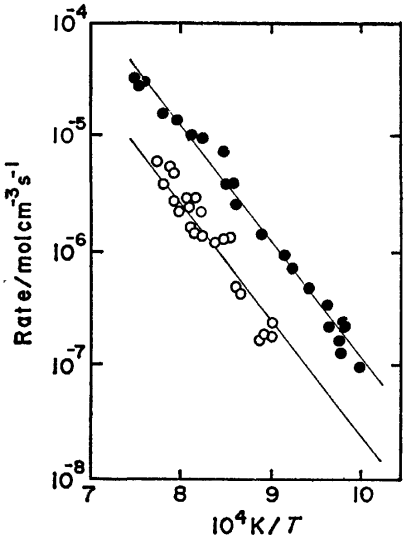

Fig. 3. Dependence of the rate of butenyne formation on acetylene concentration.
○; C_2H_2/Ar=5/95, ●; C_2H_2/Ar=10/90.

Formation Rate of Butenyne. The two kinds of mixtures stated above also served to determine an empirical reaction rate formula of butenyne formation. The total densities behind the reflected shock waves were $(2.35\pm0.11)\times10^{-5}$ mol/cm^3 throughout all runs. And the reaction times were limited within 1 ms to maintain the low conversions of acetylene. Since we are concerned with the early stage of the pyrolysis, where the yields of butadiyne and hydrogen are negligible compared with that of butenyne, only the data obtained below 1350 K are collected. The dependence of the rate of butenyne production on the acetylene concentration is shown in Fig. 3. The empirical power rate equation such as, $d[C_4H_4]/dt=A\exp(-E/RT)[C_2H_2]^n$, was assumed. Applying the method of least squares to A, E, and n;

$$d[C_4H_4]/dt = k_1[C_2H_2]^{2.35\pm0.15} \quad (1)$$

where

$$k_1 = 10^{16.74\pm1.05}\exp((-48000\pm1500)/RT) \quad (2)$$

was obtained in cm^3 mol^{-1} s^{-1} units. The errors denote the standard deviation of the least squares method.

In the literatures of the shock tube studies, first[19,24,26] or second[20-23,25] order rate with respect to acetylene was reported. And in the context of the first or second order reaction, the second-order reaction is supported from the present analysis. Therefore, when we take the view of the second-order reaction, the experimental data will be fitted by the following rate constant:

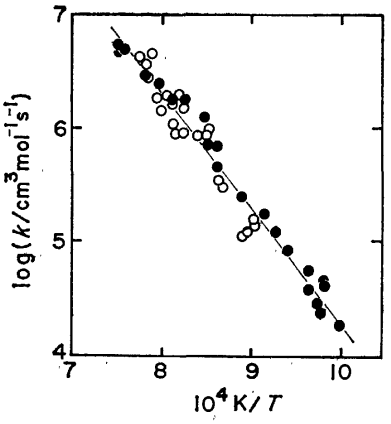

Fig. 4. Arrhenius plot of the second-order rate constants.
○; C_2H_2/Ar=5/95, ●; C_2H_2/Ar=10/90.

$$k_3(\text{cm}^3\,\text{mol}^{-1}\,\text{s}^{-1}) = 10^{14.39\pm0.26}\exp((-46400\pm1400)/RT) \quad (3)$$

The Arrhenius plot of the second-order rate constant is shown in Fig. 4.

Isotopic Distribution. The equimolar mixture of C_2H_2 and C_2D_2 in argon was shock heated below 1350 K, and the isotopic distributions of butenyne and acetylene were determined by mass spectrometry. In the temperature range up to 1350 K, the interference due to butadiyne on the mass spectra of butenyne isomers could be neglected, for the amount of butadiyne formed was negligibly small compared with that of butenyne. The results of the mass spectral analyses are given in Table 1. Evidently, considerable amounts of butenyne isomers containing odd number of hydrogen and deuterium atoms, C_4H_3D and C_4HD_3, are produced. This finding may be useful for testing the proposed mechanisms, which will be discussed in the following section.

Discussion

Comparison of the Second-order Rate. An exact analysis showed that at the early stage of the pyrolysis, butenyne is the main primary product, and the second-order rate with respect to acetylene is preferred for the formation of butenyne. It is noticed that the second-order rate constants for the consumption of acetylene

a) T_5 is the temperature behind the reflected shock wave. b) The total amounts of butenyne and acetylene are taken equal to 1.000, respectively. c) τ is the dwell time.

obtained by many investigators, covering the temperature range 620—2450 K, apparently lie on a single Arrhenius expression:[25]

$$k_4(\mathrm{cm^3\,mol^{-1}\,s^{-1}}) = 10^{13.8}\exp(-41600/RT) \quad (4)$$

At the early stage of the pyrolysis, the relationship of $2\mathrm{d}[C_4H_4]/\mathrm{d}t = -\mathrm{d}[C_2H_2]/\mathrm{d}t$ holds well, since butenyne is the only reaction product and the other minor products may be neglected. In the temperature range 1000—1350 K the absolute values of $2k_3$ agree well with those of k_4.

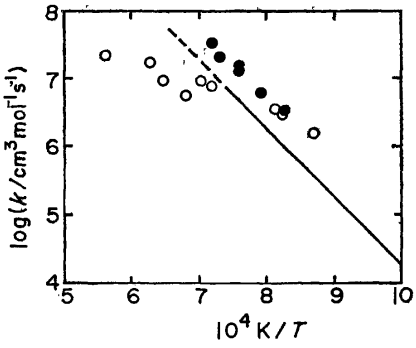

Fig. 5. Comparison of the second-order rate constant of butenyne formation with the literatures.
○; Skinner and Sokoloski, ●; Towell and Martin, ——; this work.

The second-order rate constants for butenyne formation were obtained by only two groups; by Towell and Martin in a flow tube study[14] and by Skinner and Sokoloski in a shock tube experiment.[20] A comparison with the literatures is made in Fig. 5. The absolute values of the present rate constant are about a factor of 0.5 lower than those obtained by them in the temperature range 1000—1350 K. But when the activation energy is compared, the present rate constant is in good agreement with that of Towell and Martin's rather than with that of Skinner and Sokoloski's. The rate constant derived by Towell and Martin is expressed as:

$$k_5(\mathrm{cm^3\,mol^{-1}\,s^{-1}}) = 10^{14.5}\exp(-45000/RT) \quad (5)$$

As shown in Fig. 1, the concentration of butenyne has a maximum value. Consequenly, in the neighborhood of the temperature where the yield of butenyne shows its maximum, the increase of butenyne concentration slows down with increasing temperature. It seems probable that under the conditions employed by Skinner and Sokoloski, the apparent lower activation energy may be obtained by the reason mentioned above.

As far as the second-order rate is concerned, the absolute values are fairly well consistent among many investigators, although there are significant dissents as to the main primary product of the pyrolysis.

The reaction products observed in the present analysis, are in good accordance with those detected in static and flow systems, for example, Cullis and Franklin[16] reported butenyne, butadiyne, CH_4, C_2H_4, C_2H_6, H_2, propyne, and benzene as the reaction products. Further, the nature and sequence of the formation of their products as a function of time have strong resemblance to those in the present shock tube experiment as a function of temperature. This may suggest that the same or similar mechanism is operative in the temperature range up to 1350 K, where the formation of butenyne is predominant.

Mechanism of Butenyne Formation. The strong inhibition by nitric oxide observed especially at low temperatures[2,3,5] cannot be accounted for by a simple bimolecular reaction of acetylene. The excited-state molecule mechanisms were proposed to be compatible with the low activation energy and the inhibition by radical scavengers. The following molecular chain mechanism involving excited-state molecules was presented as the most probable one to explain the fairly high frequency factor;[2,15]

$$C_2H_2 + C_2H_2 \rightarrow C_2H_2^* + C_2H_2 \quad \text{initiation}$$

$$C_2H_2^* + C_2H_2 \rightarrow C_4H_4^*$$
$$C_4H_4^* + C_2H_2 \rightarrow C_4H_4 + C_2H_2^* \quad \text{chain propagation}$$

where, $C_2H_2^*$ and $C_4H_4^*$ were supposed to be the excited molecules in the triplet state or biradicals.

In the pyrolysis of the equimolar mixture of C_2H_2 and C_2D_2, C_4H_3D and C_4HD_3 would be formed by the reaction of C_2HD molecule with C_2H_2 and C_2D_2 molecules, respectively. C_2HD molecule may result from the H–D exchange reaction between C_2H_2 and C_2D_2 molecules.

As can be seen from Table 1, the yields of C_4H_3D and C_4HD_3 are too large to be accounted for by the above mechanism, because the yield of C_2HD in the present experiment is less than 10% of the initial acetylene concentration.

The appearance of C_4H_3D and C_4HD_3 in significant quantities in the C_2H_2–C_2D_2 system may suggest that the pyrolysis of acetylene proceeds *via* a free-radical mechanism. The acitivation energy of 46.4 kcal/mol is too low to allow the initiation process of unimolecular scission of bonds, C≡C and C–H, in acetylene molecule. We have tried to interpret our data in terms of a free-radical chain mechanism initiated by a bimolecular reaction of acetylene. This attempt is basically an extention of that proposed by Back.[36] And in this study each reaction participated in the pyrolysis was examined in detail from the thermochemical point of view.

The heats of formation for the relevant C_4 molecules and radicals used in the following calculation are the same as those evaluated by Cowperwaite and Bauer,[37] and the heat of formation of 59.6 kcal/mol, the smallest value in the literatures, is adopted for C_2H_3 radical.[38] The other values are taken from the JANAF tables. The standard heats of the reactions, $\Delta H°$(kcal/mol), are given at 298 K.

The most probable free-radical chain mechanism is represented as follows:

$$2C_2H_2 \rightarrow C_4H_3 + H \qquad \Delta H° = 46.2 \quad (6)$$
$$H + C_2H_2 \rightarrow C_2H_3 \qquad \Delta H° = -46.7 \quad (7)$$
$$C_2H_3 + C_2H_2 \rightarrow C_4H_4 + H \qquad \Delta H° = 13.6 \quad (8)$$
$$C_4H_3 + C_2H_2 \rightarrow C_6H_5^{39)} \qquad \Delta H° \simeq -22.0 \quad (9)$$
$$C_6H_5 + C_2H_2 \rightarrow C_4H_4 + C_4H_3 \qquad \Delta H° \simeq -11.0 \quad (10)$$

Ethynylvinyl(C_4H_3) radical has two isomers, 1-ethynyl-

vinyl and 2-ethynylvinyl radicals. The heat of formation of the former radical is about 20 kcal/mol lower than that of the latter.[40] In our mechanism C_4H_3 is supposed to be 1-ethynylvinyl radical, since it is more advantageous than 2-ethynylvinyl radical in the view of the enthalpy change of Reaction 6.

In the above mechanism Reactions 8 and 10 are regarded as elementary reactions. In reality, however, the formation of C_4H_4 proceeds *via* relevant hot radical, for example, C_4H_5* in the case of Reaction 8. And when the energy present in the hot radical C_4H_5* is low enough, the hot radical may be stabilized by the collision with the third body to the C_4H_5 radical. Thus Reaction 8 should be divided into the following two reactios;

$$C_2H_3 + C_2H_2 \rightarrow C_4H_5 \qquad \Delta H^\circ = -33.4 \quad (11)$$

$$C_4H_5 \rightarrow C_4H_4 + H \qquad \Delta H^\circ = 47.0 \quad (12)$$

Reactions 11 and 12 show that C_4H_4 is formed by addition and subsequent decomposition reactions of the radicals. For simplicity the reactions of both types will be referred to addition-decomposition reactions hereafter.

The chain propagation processes to form butenyne are composed of addition reaction to acetylene and subsequent addition-decomposition reaction. Both radicals, C_4H_3 and H, generated by the initiation step can lead to the production of butenyne .

When the equimolar mixture of C_2H_2 and C_2D_2 in argon is pyrolyzed, appreciable amounts of C_4H_3D and C_4HD_3 among the butenyne isomers will be produced by the above mechanism. This prediction is consistent with the observed isotopic distribution of butenyne summarized in Table 1.

The isotopic distribution for the above mechanism was calculated in the case where H atom and C_2H_3 radical are predominant. If equal collision probability for C_2H_2 and C_2D_2 is assumed and the kinetic isotope effect is neglected, H and D atoms are produced by Reaction 6 in equal amounts, and the amounts of vinyl radical isomers, C_2H_3, C_2H_2D, C_2HD_2, and C_2D_3 formed by Reaction 7 are also equal. And then C_2H_2D radical, for instance, will react with C_2D_2 in the following process:

$$\begin{aligned} HDC{=}\dot{C}H + DC{\equiv}CD &\rightarrow HDC{=}CHCD{=}\dot{C}D \\ &\rightarrow HDC{=}CHC{\equiv}CD(C_4H_2D_2) + D \end{aligned} \quad (13)$$

By the similar reactions to Reaction 13, the equal amounts of H and D atoms will be generated again. The above estimation produces the ratios among the butenyne isomers, $C_4H_4/C_4H_3D/C_4H_2D_2/C_4HD_3/C_4D_4 = 1/2/2/2/1$. The agreement between the calculated and the observed values seems considerably good. The similar isotopic distribution of butenyne may be obatined when the chain propagation step of Reactions 9 and 10 is dominant.

In order to estimate the rate constant of the initiation step of Reaction 6, the enthalpy and entropy of C_4H_3 radical were calculated from the spectroscopic data of butenyne[41] following the evaluation method presented by O'Neal and Benson.[42] At 1300 K the enthalpy and entropy changes of Reaction 6 are 47.4 kcal/mol and 1.16 cal K^{-1} mol,$^{-1}$ respectively. The reverse rate constant of Reaction 6 is uncertain, but may be assumed to be the same as that of recombination reaction of atom with radical estimated by Benson and O'Neal:[43]

$$k_{-6}(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{13.3} \quad (14)$$

Then combining Eq. 14 with the equilibrium constant at 1300 K, the approximate forward reaction rate constant is given by:

$$k_6(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{13.55} \exp(-47400/RT) \quad (15)$$

An alternative initiation step was proposed by Back:[36]

$$2C_2H_2 \rightarrow C_2H + C_2H_3 \qquad \Delta H^\circ = 65.2 \quad (16)$$

And the estimated rate constant was given by:

$$k_{16}(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{15.7} \exp(-70000/RT) \quad (17)$$

The frequency factor of k_{16} seems abnormally high,[44] and k_6 is above ten times faster than k_{16} in the temperature range 1000—1350 K. Therefore, it may be concluded that Reaction 16 is not likely to occur as the initiation step for the formation of butenyne. Reaction 16, however, may be more important at higher temperatures than Reaction 6 in the view of the entropy change.[28]

In the above mechanism the termination occurs *via* the recombination or disproportionation reaction of the radicals involved. For the rate constants of the termination, the recombination rate constant of alkyl radical with radical[43] may be used as an alternative one;

$$k_t(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{12.3} \quad (18)$$

where, k_t is rate constant of the termination reaction.

Under the present shock tube experiment the reaction times are extremely short. This provides a serious problem in applying the steady-state assumption to the system stated above. As to the formation of butenyne, however, Silcocks,[2] and Cullis and Franklin[16] observed no appreciable induction period at lower temperatures. Accordingly the assumption of steady-state of the radicals may apply to some extent. Imposing the steady-state of the radicals on the above mechanism, the second-order rate of butenyne formation is expressed as;

$$\mathrm{d[C_4H_4]/dt(mol\ cm^{-3}\ s^{-1})} = k_{ad}(k_6/2k_t)^{1/2}[C_2H_2]^2 \quad (19)$$

where, k_{ad} is the rate constant of Reaction 8 or 10. By the comparison with the observed second-order rate constant k_3, k_{ad} in Eq. 19 is derived as follows:

$$k_{ad}(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{13.9} \exp(-22600/RT) \quad (20)$$

When compared with the rate constant $k_4/2$:

$$k_{ad}(\mathrm{cm^3\ mol^{-1}\ s^{-1}}) = 10^{13.0} \exp(-17900/RT) \quad (21)$$

The addition and addition-decomposition reactions may compete with each other. And the addition of the radicals to acetylene may proceed successively at the lower temperatures, since the addition reaction to acetylene has, in general, lower activation energy than that of the addition-decomposition reaction. Consequently butenyne may be produced by the subsequent addition-decomposition reaction. In the case of the competition between Reactions 8 and 11, butenyne

may be formed by the reaction of C_4H_5 radical with acetylene:

$$C_4H_5 + C_2H_2 \rightarrow C_4H_4 + C_2H_3 \quad \Delta H^\circ = 13.3 \quad (22)$$

Generally the bond dissociation energy of C–C is lower than that of C–H bond in the larger radicals, and low molecular weight molecules may be formed by the C–C bond scission rather than the C–H bond fission at the lower temperatures. In some experiments at the lower temperatures benzene is reported as the main primary product.[11,13] This might be interpreted in the similar way:

$$C_6H_5 + C_2H_2 \rightarrow C_8H_7 \quad (23)$$

$$C_8H_7 + C_2H_2 \rightarrow C_6H_6(\text{benzene}) + C_4H_3 \quad (24)$$

As mentioned above, the chain propagation steps consist of addition and addition-decomposition reactions, and both of which may be expected to show similar kinetic behavior regardless of different radicals involved. An Arrhenius plot linear within the error limits involved in the measurement of acetylene pyrolysis[25] is therefore consistent with our mechanism. Palmer and Dormish[15] pointed out that the Arrhenius plot of the data in the literatures shows a discontinuity in the neighborhood of 1000 K, and suggested a change of the mechanism of the pyrolysis. But on the basis of the similarities that exist between frequency factors and activation energies of homologous reactions, it seems more likely that from the kinetic data obtained at low temperatures where the formation of butenyne dominates, we can predict no change of the chain propagation step in the mechanism.

Furthermore, the chain propagation steps initiated by H atom and C_4H_3 radical, respectively, will show quite similar kinetic behavior. Thus in the present stage we could not determine the relative importance of H atom and C_4H_3 radical in the above mechanism. Further study as regards the relative importance of the two radicals, C_4H_3 and H, is in progress.

Formation of Butadiyne and Hydrogen. At the higher temperatures the formation of butadiyne and hydrogen becomes important, which may be interpreted in terms of a free-radical chain mechanism in the same way. The abstraction reaction of H atom from acetylene becomes faster than the addition of H atom to acetylene with increasing temperature. The following chain propagation may dominate:[28,34]

$$H + C_2H_2 \rightarrow H_2 + C_2H \quad \Delta H^\circ = 7.7 \quad (25)$$

$$C_2H + C_2H_2 \rightarrow C_4H_2 + H \quad \Delta H^\circ = -4.8 \quad (26)$$

The alternative scheme of Reaction 26 is as follows:

$$HC{\equiv}C\cdot + HC{\equiv}CH \rightarrow HC{\equiv}CCH{=}\dot{C}H \quad \Delta H^\circ = -44.8 \quad (27)$$

$$HC{\equiv}CCH{=}\dot{C}H \rightarrow HC{\equiv}C\text{-}C{\equiv}CH + H \quad \Delta H^\circ = 40.0 \quad (28)$$

As shown in Reaction 27, the stabilized C_4H_3 radical is 2-ethynylvinyl radical, which is different from that produced by Reaction 6.

At the higher temperatures covered in the present experiment the amount of hydrogen is greater than that of butadiyne. This implies that another path to yield hydrogen is operative, since by the above chain propagation nearly equal amounts of hydrogen and butadiyne may be formed. One of the possible paths is the decomposition of butenyne by the following reactions:

$$H + C_4H_4 \rightarrow H_2 + C_4H_3 \quad \Delta H^\circ = -24.9 \quad (29)$$

$$C_2H + C_4H_4 \rightarrow C_2H_2 + C_4H_3 \quad \Delta H^\circ = -32.6 \quad (30)$$

In the present experiment the sum of carbon atom over the whole products was less than that of hydrogen atom. There must have been some undetected hydrocarbons present, containing on the average less than one atom of hydrogen per atom of carbon. Thus C_6H_2 and C_8H_2[25,26] appear possible hydrocarbons undetected in the present analysis. As the pyrolysis continues the following reactions may be expected to occur;

$$H + C_4H_2 \rightarrow C_4H + H_2 \quad (31)$$

$$C_4H + C_2H_2 \rightarrow C_6H_2 + H \quad (32)$$

and succeeded by:

$$H + C_6H_2 \rightarrow C_6H + H_2 \quad (33)$$

$$C_6H + C_2H_2 \rightarrow C_8H_2 + H \quad (34)$$

The formation of carbon soot becomes very important with increasing temperature at high temperatures. But this problem is beyond our discussion. Under the experimental conditions studied, however, the formation of soot was insignificant.

As shown in Fig. 1, the activation energies of butadiyne and hydrogen formation are higher than that of butenyne. Assuming the second-order rates for butadiyne and hydrogen production, the activation energies of 69.5 and 77.6 kcal/mol were obtained, respectively. If the formation of butadiyne and hydrogen were the predominant reaction consuming acetylene, the low activation energy of 41.6 kcal/mol of k_4 would be difficult to be accounted for. Therefore, the secondary reactions which consume acetylene, with lower activation energies than those of the main reactions, or which reproduce acetylene might contribute to lowering the apparent activation energy of the over-all acetylene consumption reaction.

Secondary Products. As the minor products the hydrocarbons containing odd number of carbon atoms, CH_4 and C_3H_4, were produced. The formation of these products may be easily accounted for by the reaction of the radical involved in the mechanism stated above. For example, CH_3 radical may be formed by the isomerization and decomposition of C_6H_7 radical as follows;[36]

$$C_4H_5 + C_2H_2 \rightarrow H_2C{=}CH\text{-}CH{=}CH\text{-}CH{=}\dot{C}H \quad (35)$$

and then 1,5 hydrogen shift may occur:

$$\rightarrow H_3C\text{-}\dot{C}H\text{-}CH{=}CH\text{-}C{\equiv}CH \quad (36)$$

The terminal methyl group may split off to CH_3 radical. CH_3 radical will abstract a hydrogen atom from acetylene to form CH_4 molecule. C_3H_3 radical may be generated in the similar way, which will ultimately lead to the formation of allene and propyne. Benzene may also be produced from C_6H_7 radical:[45]

$$C_6H_7 \rightarrow C_6H_6(\text{benzene}) + H \quad (37)$$

The formation of benzene provides an evidence that the

chain of carbon atoms has extended to six within the reaction times in the present experiment. And the participation of C_6 radicals may be justified. Considerable amount of ethylene was obtained in the persent analysis. There are two possible paths to yield ethylene:

$$C_2H_3 + C_2H_2 \rightarrow C_2H_4 + C_2H \quad \Delta H^\circ = 12.7 \quad (38)$$

$$2C_2H_3 \rightarrow C_2H_4 + C_2H_2 \quad \Delta H^\circ = -52.5 \quad (39)$$

The trace amounts of ethane and 1,3-butadiene may result from the recombination reactions of two CH_3 and C_2H_3 radicals, respectively. The ratio of disproportionation reaction rate constant to that of recombination is uncertain, but it is more likely that ethylene is formed mainly by the reaction of C_2H_3 radical with acetylene.

The author would like to thank Professor Kenji Kuratani, The University of Tokyo, for his valuable discussions and suggestions throughout this investigation.

The Crystal and Molecular Structures of *trans*-Dichlorobis(dimethylneomenthylphosphine)nickel(II), an Asymmetric Hydrosilylation Catalyst of Olefin*

Kojiro KAN, Yasushi KAI, Noritake YASUOKA, and Nobutami KASAI**
Department of Applied Chemistry, Faculty of Engineering, Osaka University
Yamadakami, Suita, Osaka 565
(Received November 18, 1976)

The molecular structure of $[NiCl_2\{Me_2neoMen)P\}_2]$, an asymmetric hydrosilylation catalyst of olefin was determined by means of X-ray diffraction. This complex forms dark red monoclinic crystals; $a=9.527(1)$, $b=8.048(2)$, $c=19.461(3)$ Å, $\beta=99.12(1)°$, space group $P2_1$ with $Z=2$. The structure, determined by the heavy-atom method, has been refined anisotropically by a least-squares procedure to $R=0.099$ for 3023 non-zero reflections. The geometry around the nickel atom is *trans*-square planar [Ni–Cl 2.151(5) and 2.175(6) Å, Ni–P 2.239(5) and 2.230(5) Å]. Two neomenthyl groups are located above and below the co-ordination plane.

A variety of dihalodiphosphinenickel(II) complexes have been found to be effective catalysts for hydrosilylation of olefins and acetylene by Kumada and co-workers.[1–3] Dichlorobis(dimethylneomenthylphosphine)nickel(II) is a complex in which each phosphine has a chiral substituent, and is also a catalyst for the hydrosilylation of olefins.[4]

This paper describes the X-ray molecular structure of dichlorobis(dimethylneomenthylphosphine)nickel(II) $[NiCl_2\{Me_2neoMen)P\}_2]$.*** Interest in the correlation between molecular structure and the catalytic activity for asymmetric hydrosilylation of olefins promoted this study.

Experimental

The crystals of $[NiCl_2\{Me_2neoMen)P\}_2]$ used in this study were provided by Professor Kumada and co-workers of Kyoto University. They are dark red, long and prismatic and sublime gradually at room temperature. Preliminary oscillation and Weissenberg photographs taken with Cu$K\alpha$ radiation showed that the crystal belongs to the monoclinic system. The systematic absence of reflections ($0k0$ for $k=2n+1$) indicated the space group to be $P2_1$ or $P2_1/m$. The correct space group was determined to be $P2_1$ on the basis of the optical activity of this complex since the molecule contains asymmetric carbon atoms.

The unit-cell dimensions were determined by a least-squares fit from 2θ values of 20 high-angle reflections measured on a G. E. single-crystal orienter mounted on a Rigaku SG-2 goniometer.

Crystal Data: $C_{24}H_{50}Cl_2NiP_2$, FW 530.2, monoclinic, space group $P2_1$, $a=9.527(1)$, $b=8.048(2)$, $c=19.461(3)$Å, $\beta=99.12(1)°$, $U=1473.3(4)$Å^3, $Z=2$, $D_c=1.20$ g cm^{-3}, μ(Mo)$=9.5$ cm^{-1}.

The intensity data were collected using a Rigaku automated, four-circle diffractometer using zirconium-filtered Mo$K\alpha$ radiation. The $\theta-2\theta$ scan technique was employed. The integrated intensity of each reflection was determined by scanning over a peak at a rate of 4° min^{-1}, and subtracting the background obtained by averaging the two values measured for 5 s at both ends of the scan. The 2θ scan width was from $-1.0°$ for the $K\alpha_1$ peak to 1.0° for the $K\alpha_2$ peak. A total of 1508 reflections ($F(hkl)$'s, $\sin\theta/\lambda\leq0.482$) was measured at room temperature. At the same time an other set of data ($F(\bar{h}k\bar{l})$'s) was also collected in order to determine the absolute configuration of the molecule. The crystal used had the dimensions of $0.20\times0.18\times0.10$ mm and was coated with collodion. This crystal was too small, however, to give sufficient intensity for high-angle reflection measurements. Therefore, a second crystal of dimensions of $0.25\times0.20\times0.18$ mm was chosen, and the remaining 1802 reflections ($0.48\leq\sin\theta/\lambda\leq0.63$) were measured. The intensities of three standard reflections, 020, 003, and 400 were measured after every 50 reflections. The intensities of these reflections decreased almost uniformly with time due to the gradual decomposition of the crystal. A linear correction was applied to each set of data, and then the relative scaling between two sets of data was carried out by comparing the intensities of standard reflections in the two sets. A total of 3310 independent intensity values within a 2θ sphere of 53°($\sin\theta/\lambda\leq0.63$) was obtained. Lorentz and polarization corrections were made in the usual manner, while neither absorption nor extinction corrections were applied to the intensity data.

Solution and Refinement of the Structure

The structure was determined by the heavy-atom method. Approximate co-ordinates of the nickel, the two chlorine and the two phosphorus atoms were obtained from a three-dimentional Patterson function. The subsequent Fourier synthesis revealed positions of all the remaining non-hydrogen atoms.

The structure was refined by the block-diagonal least-squares procedure using the HBLS-V program.[5] The quantity minimized was $\Sigma(|F_o|-k|F_c|)^2$, where k is a scaling factor. The atomic scattering factors used were taken from those given by Hanson and co-workers.[6] Since the space group is $P2_1$, the y parameter of the nickel atom was fixed at 0.25 in order to define the origin of the unit-cell. The difference Fourier map did not clearly reveal any hydrogen atom positions. An attempt to find the positions of the hydrogen atoms by the technique of LaPlaca and Ibers[7] was also unsuccessful. Hydrogen atoms except for methyl hydrogen (20 out of the 50 hydrogen atoms) were then located assuming a C–H bond length of 1.08 Å and a tetrahedral angle for each carbon atom. In subsequent refinements, the contributions were included in the structure factor calculations, their parameters being fixed. The final R is 0.099 for 3023 non-zero reflections.

** To whom correspondence should be addressed.

*** *neo*Men: neomenthyl group.

In order to determine the absolute configuration of the molecule, a refinement was also carried out of the structure obtained and its enantiomorph. The R factors converged to 0.0689 and 0.0702, respectively, for the sets of $F(hkl)$ and $F(\bar{h}\bar{k}\bar{l})$ data ($\sin\theta/\lambda=0.48$), whereas for the enantiomorphic structure it converged to the slightly higher R values, 0.0697 and 0.0710, respectively. The former structure was, therefore, chosen as the final result (Fig. 1). This result confirmed the absolute configurations of both neomenthyl groups.

Results and Discussion

The molecular structure is illustrated in Fig. 1. A stereoscopic drawing of the molecule is given in Fig. 2. Bond lengths and bond angles are listed in Table 2.

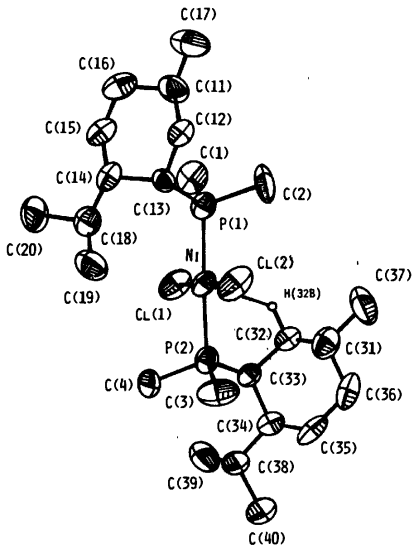

Fig. 1. An ORTEP drawing[19] of the molecule with the numbering of atoms.

The co-ordination geometry around the nickel atom is *trans*-square planar, the deviations of Ni, Cl(1), Cl(2), P(1), and P(2) atoms from the co-ordination plane being 0.018, 0.009, 0.009, −0.018, and −0.018 Å, respectively.

The Ni–Cl bond lengths, 2.151(5) and 2.175(6) (av 2.163) Å are in agreement with the value 2.166(1) Å reported for $[NiCl_2(C_8H_{14}PPh)_2]$,[8] and are comparable to those of 2.175(2) and 2.167(2) Å found in $[NiCl_2\{(MeO)_2C_5H_8PPh\}_2]$.[9] The Ni–P length are 2.239(5) and 2.230(5) (av 2.235) Å, which are equal to the values 2.227(1) and 2.232(3) Å reported for $[NiCl_2(C_8H_{14}PPh)_2]$ and $[NiBr_2\{(t\text{-}Bu)_2PF\}_2]$,[10] respectively. They are equal to or slightly shorter than the values 2.245(2) and 2.254(2) Å in $[NiCl_2\{(MeO)_2C_5H_8PPh_2\}]$. They are significantly shorter than those of 2.251(3) and 2.263(7) Å found in diamagnetic *trans*-square planar $[NiBr_2(Me_2PhP)_2]$[11] and $[NiBr_2(PhCH_2PPh_2)_2]$,[12] respectively, and are also shorter than those of 2.263(3) and 2.273(3) Å in distorted tetrahedral $[Ni(N_3)(NO)(PPh_3)_2]$.[13] However, they are slightly longer than the values 2.175(4) or 2.220(3) Å in *trans*-square planar $[Ni(PhC{\equiv}C)_2(Et_3P)_2]$[14,15] and 2.221(1) Å in distorted tetrahedral $[Ni(CO)_2(Ph_3P)_2]$.[16]

The conformation about P(1)–Ni–P(2) shown in Fig. 3 is approximately staggered. Two neomenthyl groups bonded to the P(1) and P(2) atoms are located above and below the co-ordination plane. The conformations about the P(1)–C(13) and P(2)–C(33) bonds

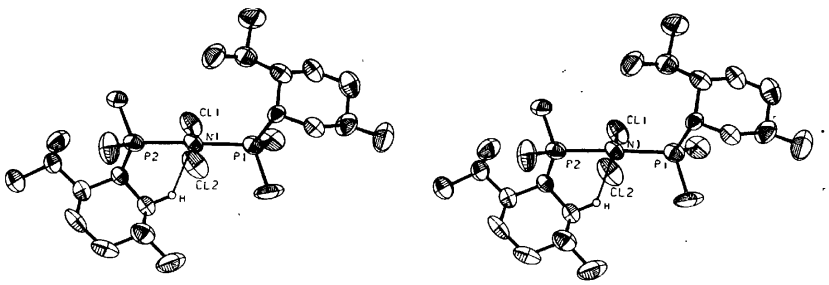

Fig. 2. A stereoscopic drawing[19] of the molecule.

† The table of observed and calculated structure factors is kept as Document No. 7705 at the Chemical Society of Japan.

(c) Short atomic contacts [l/Å] and angle [φ/°]

Ni···C(19)	3.431(21)	Ni···H(32B)[a]	2.54	P(2)-Ni-H(32B)[a]	71.1

a) Positional parameters of the H(32B) atom were calculated under the assumption that the C(sp^3)-H bond length is 1.08Å.

are intermediate between staggered and eclipsed conformations (Fig. 4). However, there is a significant difference in both conformations. The neomentyl group about the P(1)–C(13) bond is rotated by *ca.* 120° with respect to that about the P(2)–C(33) bond.

The steric hindrance between the neomenthyl and methyl groups on the phosphorus causes distortions of the P–C–C angles. The P(1)–C(13)–C(12), P(1)–C(13)–C(14), and P(2)–C(33)–C(34) angles, 116.7(8), 114.8(9), and 121.5(9)°, are considerably different from the normal value of 109.5°.

The C(19) and C(32) atoms are located in the vacant positions respectively above and below the nickel atom. An equatorial hydrogen atom, H(32B) attached to the C(32) atom has a short intramolecular atomic distance of 2.54 Å with the nickel atom. Although the position of this hydrogen atom is the calculated value, this short distance suggests the existence of a metal-hydrogen interaction in the present complex. Such short distances between metal and hydrogen atoms are also found in $[PdI_2\{(Me_2Ph)P\}_2]$ (Pd···H 2.84 and 2.85 Å (red isomer) and 3.28 Å (yellow isomer))[17] and $[PdI_2(Ph_3P)_2]$(Pd···H 3.18 Å).[18]

The bond lengths and bond angles of both the neomenthyl groups appear to be normal for the sp^3 carbon (C–C(av)=1.543 Å and C–C–C(av)=111.9°), except for the bond angles given above.

Figure 5 shows a stereoscopic drawing of the molecular packing along the b axis. No abnormally short intermolecular atomic distance is present.

The calculations were carried out on the NEAC 2200-500 computer at Osaka University.

This work was supported in part by a Grant-in-Aid for Scientific Research from the Ministry of Education (No. 843005), for which the authors express their grati-

Violet Emission Bands of the CN Radical Produced by Photodissociation of BrCN

Setsuko TATEMATSU, Tamotsu KONDOW, Toru NAKAGAWA, and Kozo KUCHITSU
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received January 10, 1977)

The violet emission spectra of $CN(B^2\Sigma-X^2\Sigma)$, $\Delta v=0$, were observed by the photodissociation of BrCN by Lyman-α radiation (121.6 nm). The peak intensities for the vibrational levels $v'\geqq 1$ relative to $v'=0$ decreased with the BrCN pressure (up to 2 Torr), whereas at 0.1 Torr or lower the spectrum was essentially independent of the pressure. The relative vibrational populations ($v'=0$—10) and the effective rotational temperatures were estimated by a band-envelope analysis. The effective rotational temperature, estimated to be 2000±200 K for $v'=0$—4, was practically independent of the pressure. Within the low-pressure limit the distributions of the excess energy to vibration and rotation were estimated to be 0.50±0.08 and 0.17±0.02 eV, respectively.

The kinetic and internal energies contained in the fragments produced by dissociation of polyatomic molecules have been investigated by various methods. Wilson *et al.*[1,2] measured the translational energies of fragments by the time-of-flight technique applied to laser photodissociation of molecular beams. The internal excitation of fragments can be studied by emission spectroscopy. For instance, the rotational distribution of the $OH(A^2\Sigma)$ formed in the photodissociation of H_2O was measured by Carrington.[3]

The emission spectra of the $CN(B^2\Sigma)$ produced in the vacuum-ultraviolet photodissociation of cyanides were measured by Mele and Okabe,[4] by whom the vibrational and rotational distributions were reported. Their estimations could be only qualitative,[5] since their spectral resolution was only about 0.5 nm and since their light sources, mostly rare-gas resonance lines, were not monochromatic. Despite these limitations, they showed that the distributions of internal energies contained in $CN(B^2\Sigma)$ had a characteristic dependence on the cyanides from which they were formed. Their estimates of the energy distributions were often referred to as a basis for theoretical considerations on the dynamics of dissociative excitation.[6–8] Furthermore, the distributions appeared to be remarkably different from those of the $CN(B^2\Sigma)$ radicals formed from the same cyanides by impact of electrons[9] or metastable argon atoms[10,11] instead of photons. In order to supply more quantitative information in this regard, we have undertaken systematic measurements of the CN violet bands produced from various cyanides by Lyman-α radiation using higher resolution. The present report is concerned with the BrCN case measured at different sample pressures.

Experimental

The apparatus consists of a vacuum-ultraviolet source, a sample cell and a detection system (Fig. 1). The Lyman-α radiation was obtained by 2450 MHz microwave discharge in a 1:3 mixture of hydrogen and helium gases. This mixture, purified by a liquid-nitrogen trap filled with molecular sieve 13X, was introduced into a quartz discharge tubing (15 mm o.d.), and the light was admitted into the sample cell through a MgF_2 window of 1.0 mm thickness. The pyrex cell, o.d. about 40 mm and length 60 mm, was coated inside with graphite to reduce stray light. The sample gas was introduced through needle valves, the pressure being monitored during the observation with a Pirani gauge calibrated against a McLeod gauge.

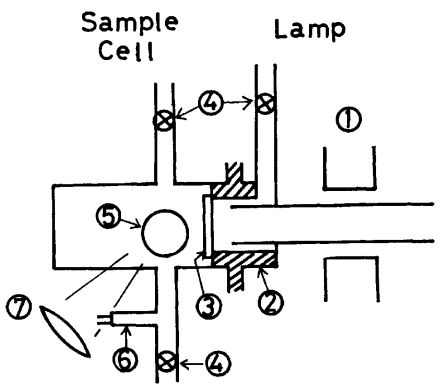

Fig. 1. A schematic design of the apparatus.
1) Microwave discharge, 2) water-jacket, 3) MgF_2 window, 4) needle valves, 5) quartz window, 6) Pirani gauge, 7) quartz lens.

Fluorescence from the emission region was detected in a direction perpendicular to the incoming photons. The emission was focussed through a Suprasil window (20 mm diameter) and a collimating lens into the entrance slit of Nikon P-250 grating monochromator (1200 Gr/mm). The slit width was adjusted in the range between 10—60 μm. The slit width of 50 μm corresponds to an energy resolution of 0.2 nm. The signal from a photomultiplier (HTV R585) was measured by a photon counting system. The relative intensity response of the spectrometer and the detection system was calibrated by a halogen standard lamp (JC 12V-50W of Ushio Electric Co.), the color temperature of which was determined at the Electrotechnical Laboratory.

A commercial sample of BrCN (Nakarai Chemical, Co.) was purified by vacuum distillation. The IR spectrum showed no evidence of impurities. The emission spectra were observed at BrCN pressures ranging from about 0.01 to 2 Torr.

The reproducibility of the observed spectra depends mainly on the stability of the light source and the sample pressure, which was kept constant by needle valves during the observation. Though the intensity of the lamp was not monitored during the spectral measurement, its stability was tested by recording the emission intensity at a fixed wavelength over the time interval needed for scanning the whole spectral region. Moreover, a check of reproducibility of the intensity signal was made immediately before and after each measurement. From these tests, the total error in the observed spectrum, including the random errors caused by the instability of the light source, the sample pressure and the detection system, was estimated to be less than 10% of the

highest peak.

Results and Analysis

Observed Spectra. The $\Delta v=0$ series of the CN violet band ($B^2\Sigma-X^2\Sigma$) observed around 388 nm (Fig. 2) was assigned according to the table prepared by Pearce and Gaydon.[12] Though the sequences of $\Delta v=0$ and $\Delta v=-1$ of the violet system were observed, the former was used in the analysis, because the intensity of the latter was not strong enough. The $v'=0$ peak is the strongest and the intensities of the $1\leqq v'\leqq 4$ peaks decrease with v'. Bands of the $5\leqq v'\leqq 10$ levels are overlapped by those of the lower levels, and the $v'\geqq 11$ bands, which should appear above 391 nm, are not detectable.

The observed dependence of the spectrum on the BrCN pressure is shown in Fig. 3. Below about 0.1 Torr the spectrum is nearly independent of the sample pressure, but at a higher pressure the peak intensities for $v'\geqq 1$ relative to $v'=0$ decrease with the pressure, until at about 2 Torr they are almost completely obscured by the R-branch tail of the (0,0) band. On the other hand, there is no observable effect of pressure on the band shapes, particularly as regards the peak (the P-branch head) of the (0,0) band.

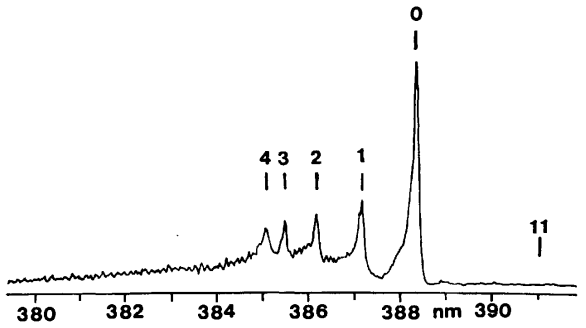

Fig. 2. Emission spectra of the CN($B^2\Sigma-X^2\Sigma$), $\Delta v=0$ band from BrCN taken with a slit width of 10 μm. The numbers indicate positions of the P-branch heads for the $v'=0$—4 and 11 bands.

The broken line represents the background contribution from the R-branch contour of the (0, 0) band calculated at $T_r=2000$ K.

Band-Envelope Analysis. The relative vibrational populations were estimated by a band-envelope simulation using a MELCOM 7000 computer in the Educational Computer Center of the University of Tokyo.

The relative intensity (the number of photons) of a transition from the (v',N') level to the (v'',N'') level can be expressed[13] by

$$I(v',N'-v'',N'')\propto\frac{P_{v'}}{Q_{r,v'}}\cdot\nu^3\cdot q_{v',v''}\cdot S_{N',N''}\cdot R_{v'}(N') \quad (1)$$

where v and N are the vibrational and rotational quantum numbers, respectively, ν is the transition frequency, $P_{v'}$ is the population, $q_{v',v''}$ is the Franck-Condon factor, $S_{N',N''}$ is the rotational line strength, and $R_{v'}(N')$ is the rotational distribution function. The rotational state sum, $Q_{r,v'}$, is given by

$$Q_{r,v'}=\sum_{N'} g_{N'}R_{v'}(N') \quad (2)$$

where $g_{N'}$ represents degeneracy. If the rotational distribution is described by a Boltzmann function, then $R_{v'}(N')$ is given by

$$R_{v'}(N')=\exp\{-hcB_{v'}N'(N'+1)/kT_r(v')\} \quad (3)$$

where $T_r(v')$ is an effective rotational temperature for the vibrational state v'.

The band envelope was obtained from $I(v',N'-v'',N'')$ by use of the experimental parameters of the band origin ν_0,[14,15] $B_{v'}$,[14,15] and $q_{v',v''}$.[16] A Gaussian slit function, which was estimated from the observed shape of the Hg 404.7 nm line measured under similar experimental conditions, was taken into account. The

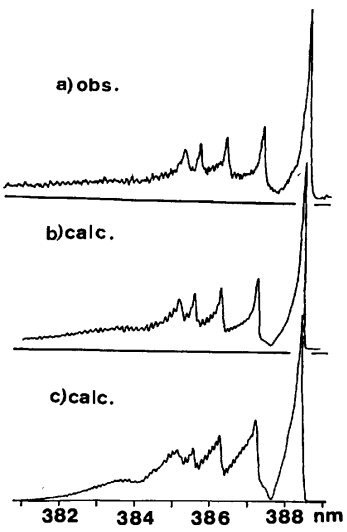

Fig. 4. Comparison of the calculated band envelopes of the CN violet $\Delta v=0$ bands with the observed spectrum produced by the photodissocation of BrCN.
a) Observed at 0.03 Torr, b) calculated with $T_r(v'=0$—$10)=2000$ K; best-fit, c) calculated with $T_r(v'=0$—$10)=1000$ K.

parameters, $N_{v'}$ and $T_r(v')$, were adjusted in such a way that the calculated band envelope fits the observed spectrum. A typical comparison of the observed and calculated band envelopes is shown in Fig. 4.

It was possible to estimate the effective rotational temperatures for $v'=0$—4 independently from their individual band shapes. The values turned out to be essentially equal, 2000±200 K. On the other hand, the band shapes were insensitive to the assumed values of $T_r(v')$ for $v'=5$—10. The effective temperatures were therefore assumed to be all equal, 2000 K.

The relative vibrational populations of CN($B^2\Sigma$) thus estimated are plotted in Fig. 5 for the different sample pressures. The population for $v'=11$ level, which has a negligible intensity, is assumed to be zero, and those for the levels $v'=5-10$ are estimated by a smooth interpolation. Since the vibrational populations estimated for pressures lower than 0.1 Torr are essentially unchanged, they are assumed to be the initial populations unaffected by collisional relaxation

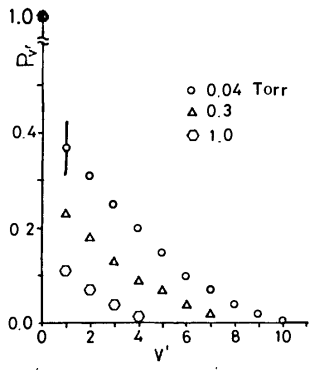

Fig. 5. Pressure dependence of the relative vibrational populations, $P_{v'}/P_0$, of CN($B^2\Sigma$) produced by the photodissociation of BrCN. Estimated from the analysis of the spectra at different sample pressures. A bar indicates estimated limit of uncertainties.

a) Vibrational energies taken from Ref. 17 (above zero-point energy). b) Uncertainties represent estimated limits of error in the last significant digits. c) The $P_{v'}/P_0$ and $T_r(v')$ values for $v'=5$—10 are only rough estimates. d) The effective rotational temperatures for $v'=5$—10 are assumed to be equal.

(see Discussion), as listed in Table 1.

The uncertainties in $P_{v'}$ and $T_r(v')$ estimated in Table 1 originate mainly from the limitation in recording the spectrum, the overlapping of bands, and the approximations made in the analysis. Since the $5\leqq v'\leqq 10$ bands are buried within those of the lower vibrational levels, the estimated values of $P_{v'}$ and $T_r(v')$ for $v'=5$—10 are less reliable than those for $v'=0$—4. In addition, a strong correlation is found between the vibrational population and the rotational temperature for each of the $v'\geqq 5$ bands. For these reasons, the above estimates of $P_{v'}$ and $T_r(v')$ for the $v'\geqq 5$ simply represent one of the most probable sets of the parameters for which calculated envelope agrees well with the observed spectrum. However, the values of $P_{v'}$ and $T_r(v')$ for the $v'=0$—4 bands can be estimated independently, since each of the $v'=0$—4 bands forms a distinct head peak.

Discussion

Internal Energy Distribution. The average energy distributed to the vibration of CN($B^2\Sigma$) is estimated as a sum of the vibrational energies[17] multiplied by the estimated populations to be 0.50±0.08 eV above the zero-point energy. Since the effective rotational temperature is estimated to be 2000±200 K, the average rotational energy is 0.17±0.02 eV. Therefore, the rotational excitation, about one third of the vibrational excitation, is much lower than that of OH($A^2\Sigma$) formed by the photodissociation of H_2O.[3]

Energetically possible processes producing CN($B^2\Sigma$) from BrCN by Lyman-α radiation (10.20 eV) are the following:

$$BrCN + h\nu \rightarrow Br(^2P_{3/2}) + CN(B^2\Sigma) \quad (v'\leqq 14) \quad (1)$$

$$\rightarrow Br(^2P_{1/2}) + CN(B^2\Sigma) \quad (v'\leqq 12) \quad (2)$$

The threshold of process (1) was estimated by Davis and Okabe[18] to be 6.97 eV. They reported that process (2) was insignificant, because they observed no apparent inflection in the excitation curve of CN($B^2\Sigma$) near the threshold of process (2), 7.43 eV. If the $Br(^2P_{3/2})$ atom is produced, then the available excess energy distributed to the fragments is 3.23 eV. Thus the average kinetic energy is estimeted to be *ca.* 2.56 eV. From the conservation of momenta, the CN radical has an average kinetic energy of *ca.* 1.9 eV.

Comparison with Other Experiments. The CN($B^2\Sigma$) states formed from cyanides exited by photons (10.2 eV), electrons (≈300 eV) and metastable argon atoms (11.5 and 11.7 eV) have distinctly different vibrational populations, as illustrated in Fig. 6. The intensity enhancements in higher vibrational levels ($v'\geqq 11$) observed in the case of metastable-atom impact[9] are interpreted as a result of the rotational perturbation between the A and B states. In the electron-impact case,[10,11] lower vibrational levels have larger relative populations than in the metastable-atom impact case. In contrast with either case, photodissociation gives a monotonically decreasing curve. Photodissociation by Lyman-α radiation can excite the CN($B^2\Sigma$) radical up to $v'=14$. However, only a small fraction of the available energy goes into vibrational excitation so that

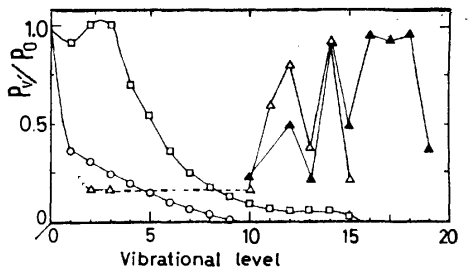

Fig. 6. Relative vibrational populations, $P_{v'}/P_0$, of the CN($B^2\Sigma$) radicals produced from BrCN by photodissociation (○), electron impact (□ for Ref. 9) and impact of metastable argon ($^3P_{0,2}$) atoms (▲ for Ref. 10 and △ for Ref. 11).

no detectable populations in the $v' \geqq 11$ levels are observed, and overall vibrational excitation is very much weaker than in the electron-impact case.

Effect of Collisions. From the following argument, the present estimates can be regarded as "initial" energy distributions since the values relate to a pressure region where any energy transfer processes induced by collision may be disregarded.

The spontaneous radiative lifetime of CN($B^2\Sigma$) is reported to be 60—85 ns by measurements of a decay curve[19,20] or phase shifts.[21,22] The cross section for electronic quenching was estimated by Luk and Bersohn[20] to be 19.4 Å^2 as a lower limit calculated from a measurement of the electronic quenching rate of BrCN. If one assumes that excited CN radicals have average translational energy of 1.9 eV, the mean time between collisions of CN($B^2\Sigma$) with BrCN is estimated to be about 60 ns when the sample pressure is about 0.7 Torr, which is comparable with the radiative lifetime of CN($B^2\Sigma$). This pressure is much higher than that used in the present study from which the energy distribution was determined. In other words, in the pressure region of the present measurements electronic quenching is probably negligible. Furthermore, the vibrational and rotational distributions have been estimated at a low-pressure limit, where no pressure-dependence was observed. Therefore, the distribution seems to be free from the effect of collisions.

Pressure Dependence. The relative vibrational populations depend strongly on the BrCN pressure when it is higher than 0.1 Torr. In particular, the emission spectrum is essentially that of the (0,0) band (Fig. 3) when the BrCN pressure is higher than about 0.8 Torr. Possible processes causing the vibrational relaxation are the following: 1) The vibrational energy of CN($B^2\Sigma$) is transmitted to the translational and/or vibrational energy (possibly the ν_3 mode) of BrCN. In the latter case, the deficiency of the energy ranging from 75 cm^{-1} (from $v'=1$ to $v'=0$) to 250 cm^{-1} (from $v'=5$ to $v'=4$) has to be supplied by the translational energy of the CN radical. 2) The rates of collision-induced transitions (B-X) for higher vibrational levels may be much larger than those for lower levels. However, no further experimental evidence for any of these processes has yet been provided.

On the other hand, the effective rotational temperature of the (0,0) band, *ca.* 2000 K, seems to be essentially independent of the sample pressure up to 2 Torr. Therefore, the pressure effect seems to appear only in the vibration and not in the rotation in the pressure region of the present study (from 0.01 to 2 Torr). However, such a trend has not been observed for any other cyanides studied so far,[23] namely, HCN, DCN, ICN and $(CN)_2$.

The authors are grateful to Professor Ikuzo Tanaka and the members of his laboratory of Tokyo Institute of Technology and to Dr. Hideo Okabe of U.S. National Bureau of Standards for their helpful advice.

2-Mercaptobenzothiazole Supported on Silica Gel for the Chromatographic Concentration of Cadmium, Copper, Lead, and Zinc in Natural Water Samples

Kikuo TERADA, Akihiko INOUE, Junko INAMURA, and Toshiyasu KIBA

Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa, Ishikawa 920

(Received August 2, 1976)

The preparation and characteristics of 2-mercaptobenzothiazole supported on silica gel (MBT–SG), and its application to the preconcentration and determination of cadmium, copper, lead, and zinc in natural water samples are described. The MBT–SG was prepared by impregnating silica gel with MBT in a dioxane–methyl acetate solvent mixture, drying, washing with deionized water, and finally drying. The chelating capacity of the material was 0.01 meq. Cu/g. Cadmium, copper, lead, and zinc were quantitatively retained on the MBT–SG at pH values of 4.8, 2.5, 4.8, and 6.5 for an aqueous solution, and at pH values of 4.8, 2.8, 4.8, and 6.5 for sea water. A column made of the material provided quantitative recovery of these metals from natural water samples at higher flow rates (2—5 l/h) than other chelating resins, *e. g.*, chelex 100. Cadmium was eluted with hydrochloric acid (1 : 99), copper and lead with acetone–hydrochloric acid mixture (9 : 1), and zinc with an acetate–hydrochloric acid buffer solution (pH 4.0). Then, the quantities of the four metals in their effluents were determined by atomic absorption spectrometry.

Because of their low concentration in natural water, including sea water, heavy metals often require preliminary concentration prior to the determination of their quantities. Recently, chelating resins have been conveniently used for this purpose by many investigators[1–3] in a manner originally described by Riley and Taylor.[1] Dingman *et al.*[4] prepared some new polyamine–polyurea resins and used them to concentrate several heavy metals from dilute solutions. They found that, among these resins, TEPA (tetraethylenepentamine polymerized with methylphenylene diisocyanate) is the most effective for this purpose when the resin is used in the column mode of operation with concentration factors as high as 1000. On the other hand, Mussarelli *et al.*[5–9] have used chitosan, a natural chelating polymer, to collect traces of transition metals from salt solutions and sea water using column chromatography. Since this natural polymer does not appreciably react with sodium and magnesium, it is useful for the separation of small amounts of transition metals from sodium and magnesium matrices. These methods are thought to be simpler and less time-consuming than solvent extraction[10] or the precipitation method. However, if a large volume of natural water must be treated, these resins cannot withstand the rapid flow of the sample water through the column.

Previously, Terada *et al.*[11] revealed the excellent ion-exchange properties of some inorganic exchangers supported on silica gel, *e.g.* KCFC–, NCFC–, and AMP–SiO_2, and applied them to the concentration of Cs-137 in natural water. Most inorganic exchangers appear to have been used preferentially for the concentration of alkali metals and some univalent metals such as silver and thallium *etc.*, but rarely for that of the transition metals.[12,13]

2-Mercaptobenzothiazole has been used as a precipitant for several metals, especially copper, gold, and lead to form sparingly soluble chelates in neutral solutions, and also as an extractant for solvent extraction of these metals. This reagent itself is insoluble in water, but soluble in ethanol, benzene, dioxane, and other organic solvents. This reagent will be used for the selective preconcentration of copper and some other transition metals in a large volume of natural water as previously described.[11]

The present paper describes a simple method for preparing such material, called 2-mercaptobenzothiazole–silica gel (MBT–SG), and its successful application to natural water concentration, especially for sea water, in the monitoring of the environmental pollution resulting from some heavy metals.

Experimental

Reagents. The 2-mercaptobenzothiazole, dioxane, methyl acetate, acetone, ethanol used were of analytical reagent grade.

A standard solution of metals was prepared as follows: copper metal was dissolved in nitric acid plus sulfuric acid, recrystallized lead nitrate was dissolved in nitric acid (1:100), zinc metal was dissolved in concd hydrochloric acid, nickel sulfate and cobalt sulfate were dissolved in deionized water, and chromium metal was dissolved in concd hydrochloric acid. Each stock solution was made up to contain the metal of interest at a concentration of 1000 ppm.

Silica gel of chromatographic grade (WAKOGEL C-100) was sieved in the range of 60—80 mesh and digested with a double volume of hydrochloric acid (1 : 1) for one day and then washed with deionized water until no chloride appeared in the washings. The cleaned silica gel was dried at 110 °C for one day.

Apparatus. A Perkin-Elmer 303-type atomic absorption spectrophotometer, Hitachi-Horiba M-5 type glass-electrode pH meter.

An Iwaki Model VS electric shaker.

A Toyo Type E-E SF200A fraction collector.

The chromatographic column was a glass tube of 9.8 and 20 mm inside diameters 140 mm in length with a coarse sintered-glass disc and a stop-cock at the bottom.

Preparation of 2-Mercaptobenzothiazole–Silica Gel (MBT–SG). About 70 g of silica gel (60—80 mesh) were put into a solution of 2-mercaptobenzothiazole in 100 ml of a dioxane–methyl acetate mixture (4 : 1 v/v) and stirred occasionally. After standing for about 20 h the supernatant was sucked out and the remaining silica gel impregnated with the reagent was then heated at about 80 °C at reduced pressure for about 20 h. The dried materials were washed repeatedly with deionized water to remove any nonadsorbed reagent until the washings appeared clear. Finally, the product was dried

at about 80 °C under reduced pressure for about 20 h. The product was sieved (60—80 mesh) using a nylon sieve and stored in a darkened bottle.

Procedure for Batch Experiments. Into a 50-ml centrifuge tube, 10 ml of a metal solution (5 ppm), 5 ml of a buffer solution and 0.5 g of MBT-SG were mixed together. The contents were then agitated with an electric shaker for 30 min at room temperature. The supernatant was filtered through a millipore filter into a 20-ml measuring flask and adjusted to the desired volume. The metal concentration was measured with an atomic absorption spectrophotometer and then the percent retention was calculated.

Chelating Column Preparation. The chromatographic tube (20 mm in diameter) was filled with 10 g of dried MBT-SG, and a piece of glass wool was placed on the top of the column so that the bed was not disturbed during sample passage. In this case, the bed length became about 7 cm.

Procedure for Column Method. A given volume of an aqueous sample containing individual metal ions was adjusted to a suitable pH, then percolated through the column at a flow rate of 2—5 l/h under the suction of an aspirator. The lower level of the sample solution was maintained about 1 cm above the surface of the column bed during sample passage. After washing the column with about 20 ml of deionized water, an eluting solution of definite composition was passed through at a flow rate of about 1 ml/min. The effluent was collected in a measuring flask, diluted to the desired volume, and the metal concentration was determined with an atomic absorption spectrophotometer.

Results and Discussion

Characteristics of the Chelating Material. The amount of 2-mercaptobenzothiazole on the silica gel was determined as follows. One gram of the dried material was put onto the column tube. Then about 20 ml of ethanol was passed through to completely remove the reagent from the column. The effluent was collected in a 50-ml measuring flask and diluted to the desired volume with ethanol. Two milliliters of the solution were pipetted out and put into another 50-ml measuring flask and diluted to the desired volume with ethanol. The absorbance of the solution was measured at a wavelength of 327 nm using ethanol as a reference. The absorption spectra of the effluent and the ethanol solution of the reagent are shown in Fig. 1. Both absorption curves have identical absorption peaks at 239 and 327 nm. This fact suggests that the reagent was retained without any loss. The amount of reagent supported on the silica gel was found using the conventional working curve method to be about 11±1 mg per g of the material.

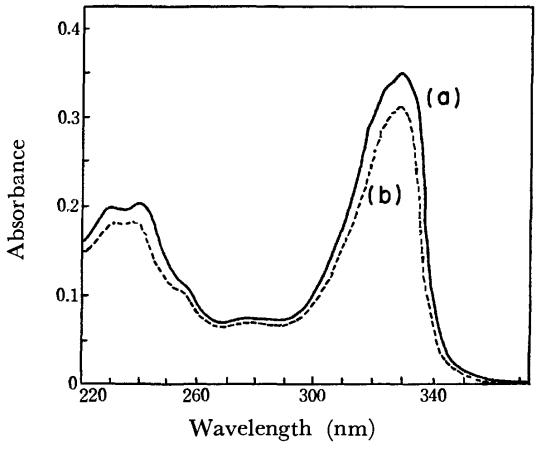

Fig. 1. Absorption spectra of 2-mercaptobenzothiazole.
(a) MBT dissolved in ethyl alcohol, (b) MBT in the effluent.

The chelating capacity for copper was measured by the batch method. Ten milliliters of the copper solution (50 ppm), 5 ml of a buffer solution (pH 4.0), and 0.5 g of MBT-SG were mixed together in a 50-ml centrifuge tube. The contents were then agitated for 30 min at room temperature. The copper concentration in the supernatant was measured with an atomic absorption spectrophotometer. The capacity was calculated to be about 0.01 meq. Cu(II)/g of MBT-SG. The chelating capacity of the material appeared to be large enough to collect copper from a large volume (*e. g.* 10 l) of sea water which is believed to contain as low as 1—20 μg copper per liter,[14] 10 g of the material has an operating capacity at least 32 times greater than the total amount of copper in 10 l of sea water (200 μg).

This solid chelating material also showed no change in its adsorbability after a storage period of about one month and was then dipped in a solution over the range from pH 1 to 10.

Recovery of Cadmium, Copper, Lead, and Zinc at Various pH Values. The recovery of each individual metal ion was examined by the batch method, using a 10 ml sample solution with a 5 ppm concentration of each metal and 0.5 g of MBT-SG, for a pure aqueous solution and for sea water of various pH values. The pH of the solution was adjusted using the following buffer solutions: sodium acetate plus hydrochloric acid for pH 1—5, potassium dihydrogen phosphate plus sodium hydroxide for pH 6—7, and boric acid plus potassium chloride and sodium hydroxide for pH 8—10. The results are illustrated in Fig. 2 along with those obtained using only silica gel. The pH value mentioned is that measured after equilibration. Copper was found to be retained quantitatively on the material at pH 2.5 for aqueous solutions and at pH 2.8 for sea water, but when untreated pure silica gel was put into an aqueous solution copper began to be adsorbed when the pH increased above 6. However, in the case of sea water only a recovery rate of 25% (the maximum value) was obtained at pH values of 7 or above. Cadmium and lead showed similar behavior on MBT-SG, and their quantitative retention values were obtained for pH 4.8—5.2 in both aqueous solutions and sea water. A remarkable difference in adsorbability was observed between MBT-SG and untreated silica gel. On the other hand, zinc ions showed similar adsorption rates for both MBT-SG and untreated silica gel and quantitative retention was obtained at pH 6.5 for both aqueous solutions and sea water. However, in column experiments, a reduction of about ten percent in the adsorption for zinc was observed when 5 l of an aqueous solution containing 2 ppb of zinc was passed through the untreated silica gel column at a flow rate of 4 l/h, although it was quantitative for the MBT-SG column.

From these results, the separation of copper from

—○— MBT-SG, --●-- untreated silica gel.

lead and cadmium, and lead and cadmium from zinc will be possible with eluting solutions of different pH values with column operation.

Retention of Individual Ions on the Column. To examine quantitatively the retention of each metal ion on a column, several kinds of test solutions (an aqueous solution, a sodium chloride solution of ionic strength 0.63, and sea water) containing metals in various concentrations were passed through the column at different flow rates. In the experiment, copper(II) at pH 4.0, lead(II) at pH 5.0, and cadmium(II) and zinc(II) at pH 7.0 were individually fed onto a column (20 mm in dia. ×70 mm) of MBT-SG. After washing the column with about 20 ml of deionized water, cadmium was eluted with hydrochloric acid (1 : 99) and zinc with a buffer solution at pH 4.0 (sodium acetate–hydrochloric acid). Copper and lead adhered tightly to the column, and therefore, the following treatment was necessary to remove them quantitatively. Water held on the column had to be removed as much as possible by sucking under aspiration, then 20 ml of ethanol was run through to remove any untreated reagent, then copper and lead were eluted with 20 ml of a solvent mixture of acetone and hydrochloric acid (9 : 1 v/v). Each effluent was adjusted to be exactly 25 ml in a measuring flask and subjected to atomic absorption spectrometry for the determination of the quantities of the various metals.

Table 1. Recovery of metal ions using the column method

Ion	Vol. of sample (l)	Flow rate (l/h)	Concn of metal (ppb)	Recovery (%)
Cd(II)	1.0	2.3	100	100±2
	1.0	4.0	10	100±2
	5.0	4.2	1	100±2
	1.0	2.7	0.1	100±2
Cu(II)	1.0	3.7	100	100±2
	5.0	5.0	1	100±2
	5.0[a]	5.0	1	100±2
Cb(II)	1.0	3.0	100	100±2
	5.0	2.5	1	100±2
	5.0[a]	2.5	1	100±2
Zn(II)	1.0	3.0	100	100±2
	5.0	5.0	1	100±2
	5.0[b]	4.1	5	100±2

Pure aqueous solution at adjusted pH 4.0 (Cu), 5.0 (Pb) and 7.0 (Cd and Zn).
a) NaCl solution, μ=0.63. b) Sea water. MBT-SG: 10 g, column: 20 mm in dia.×70 mm.

The separation data in Table 1 show that quantitative retention was obtained for cadmium in the 0.1—100 ppb range, and for copper, lead, and zinc below in the range from 1—100 ppb at flow rates from 2.3 to 5.0 l/h. Thus, preconcentration of each metal from 5 l of sample water was attainable within 1 h.

Elution of Each Metal. Zinc(II) was found to be eluted from the column with 20—25 ml of a buffer solution which contained 20 ml of 1 M sodium acetate and 16 ml of 1 M hydrochloric acid per liter (pH 4.0), while lead and copper were not released from the column at all; consequently, separation of lead and copper from zinc was achieved. However, part of the cadmium was released by passing this buffer solution through the column. Both cadmium and zinc were completely eluted with nitric acid (1 : 99) or hydrochloric acid (1 : 99), with the latter eluting solution being more favorable for the subsequent atomic absorption spectrometric determination of the cadmium content. However, in this case, 30—38% of the retained amount of lead was also released using 25 ml of either of the above acids while no copper appeared in the eluate.

Effect of Various Ions and Substances on the Adsorption of Cadmium, Copper, Lead, and Zinc. The various metal ions thought to react with MBT, cobalt(II), iron(III), and nickel(II) were examined for their effects on this separating procedure. One liter of a test solution containing cadmium, copper, lead, and zinc in concentrations of 5 ppm, as well as one of other ions in the concentration range of 0.1—10 ppm was prepared. This solution was passed through a column containing 7 g of MBT-SG at flow rate of 2—5 l/h. At the same time, the mutual separation of the four ions of interest was also

Metal: 0.05 ppm, MBT-SG: 7 g, column: 20 mm in dia. × 50 mm.

examined in varying concentrations. The results are given in Tables 2 and 3. At the 1 ppm level, iron(III) significantly reduced the recovery of the other four metal ions. Since iron(III) itself was found to be retained quantitatively on the both MBT-SG and on untreated silica gel at pH 7, it is not expected that iron competed with copper, cadmium, and lead on MBT. In fact, in the first solutions passed, which originally contained microgram amounts of each metal and 1 ppm of iron(III), no copper, cadmium, lead, and zinc at all were found. Therefore, iron appears to be adsorbed on the column as a hydroxide, retaining some of these metals with it and not liberating them on elution. Nickel(II) at the 1 ppm level produced a slight reduction in the recovery of copper and lead, and also zinc and cobalt at the same concentration produced the same effect for copper and lead, respectively. In general, 1 l of sea water contains about 0.3×10^{-3} meq. of heavy metal ions in all which is compatible with 0.03 g of MBT-SG. Therefore, the interference of heavy metal ions on the adsorption of these four metal ions from sea water may be practically neglected. On the other hand, some organic compounds, such as EDTA, citric acid, and tartaric acid, substantially hindered the adsorption of the metal ions. Particularly, EDTA considerably lowered adsorbability on MBT-SG of cadmium, lead, and zinc at a concentration of 10^{-6} mol EDTA/l. However, since in natural water, especially in sea water, these organic substances are never found in the concentrations shown in Table 3, the interference produced by these substances may be neglected.

Atomic Absorption Measurements for Copper and Lead. To determine the optimum conditions for atomic absorption measurements of copper and lead in an acetone–hydrochloric acid solvent mixture, the effects of acid and reagent concentrations and the mixing ratio of air and fuel were examined.

The effect of the hydrochloric acid concentration in acetone on the absorption of copper is shown in Fig. 3, from which it is seen that the smaller the absorbance, the higher the acid concentration. The solvent mixture used in the present experiments is considered to have no effect on the absorbance of copper. For lead, similar results were obtained. As shown in Fig. 4, the concentration of the MBT reagent in acetone had no significant effect on the absorption measurements under these conditions. Since the effluent became turbid when free MBT remained in it, excessive reagent was removed from the column by passing ethanol prior to the elution of the metal–MBT complexes with an acetone–hydrochloric acid solvent mixture. After several

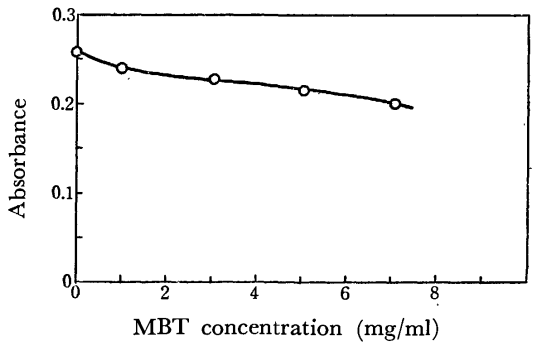

Fig. 4. Effect of concentration of 2-mercaptobenzothiazole in acetone on atomic absorption spectrometry for copper.

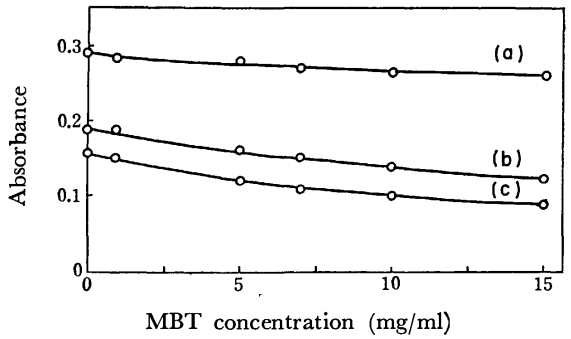

Fig. 5. Effect of mixing ratio of air and acetylene on atomic absorption spectrometry for copper in the presence of various concentration of MBT.
(a) Air : acetylene 4.7 : 2.7—5.0 : 3.0, (b) air : acetylene 9.0 : 7.0, (c) air : acetylene 9.0 : 9.0.

tests, it was found that the mixing ratio and the fuel flow rate had serious effects on the absorbance of copper and lead, and that maximum absorption was obtained at mixing ratios of air and acetylene of 4.7 : 2.7 to 5.0 : 3.0 for copper (Fig. 5) and 6.0 : 4.0 for lead.

Analytical Procedure Recommended. In general, the cadmium content of natural water is lower than the contents of the other three metals by a factor 10 to 100. Consequently, from these results, the copper, lead, and zinc contents should be determined in one sample after preconcentration using this method and the cadmium content should be measured in another smaller portion of the sample using flameless atomic absorption spectrometry.

Thus, the recommended procedure is as follows: two to five liters of the water sample adjusted to about pH 7, is passed through the MBT-SG column (20 mm in dia. ×70 mm) at a flow rate of 2—5 l/h. Even at a higher flow rate, if the sample solution is poured onto the column by aspiration, numerous minute air bubbles appear on all parts of the column which are of course, not filled with sample solution and rather quantitative retention of the metal ions can be maintained. This may result from closer contact between the sample solution film and the MBT-SG particles. Subsequently, the column is washed with about 20 ml of deionized water, and then 20 ml of an acetate–hydrochloric acid buffer solution (pH 4.0) is passed through at a flow rate of 1 ml/min. The effluent is diluted to the desired volume with deionized water in a 25-ml measuring flask and subjected to atomic absorption measurement for the zinc content. The absorbance is measured at a wavelength of 213.8 nm in a flame of air and acetylene (9 : 9). The column is washed again with 20 ml of deionized water and then with about 20 ml of ethanol, and finally 20 ml of a solvent mixture of acetone–hydrochloric acid in a volume ratio of 9 : 1 is passed through. The effluent is diluted to 25 ml with acetone and subjected to the atomic absorption measurement for copper and lead. The absorption is measured at wavelengths of 324.8 and 283.3 nm for copper and lead, respectively, in a flame of air and acetylene (5 : 3 for copper and 6 : 4 for lead).

Cadmium and zinc are detemined in another manner, as follows: two liters of the water sample adjusted to pH 7.0 is passed through the column. Then the column is washed with about 20 ml of deionized water, and 20 ml of hydrochloric acid (1 : 99) is passed at a flow rate of 1 ml/min. The effluent is diluted to 25 ml with deionized water and submitted to the atomic absorption measurement for cadmium and zinc. Cadmium is measured with flameless atomic absorption using a carbonrod atomizer at a wavelength of 228.8 nm and the absorption of zinc is measured as described above. From the remaining column material, copper can be eluted with an acetone–hydrochloric acid solvent mixture as indicated above.

Analysis of Tap, River and Sea Water. Using the recommended method, laboratory tap water, river water, and sea water were analyzed for cadmium, copper, lead, and zinc. The results are summerized in Table 4.

TABLE 4. CADMIUM, COPPER, LEAD AND ZINC CONTENTS OF VARIOUS WATER SAMPLES

Sample water	Cd(II) ppb	Cu(II) ppb	Pb(II) ppb	Zn(II) ppb
Pacific Ocean (10 m)	0.1_4[a)]	0.2_2	3.1	3.0[a)]
Pacific Ocean (7 m)	0.07[a)]	20.9	3.4	$13._1$[a)]
Tsukumo Bay (0 m)	—	0.2_7	—	2.9
Watarase River	—	55	6.7	74
Tap water (Marunouti)	0.03[a)]	0.5[a)]	—	8.3[a)]

MBT-SG: 10 g, column: 20 mm in dia. × 70 mm, flow rate: 5 l/h. a) MBT-SG: 7 g, column: 20 mm in dia. × 50 mm, flow rate: 2.3 l/h.

Two samples of Pacific Ocean water and a sample of Watarase River water were distributed to a number of laboratories in Japan for comparison of the analytical results and the results using the recommended method are in good agreement with those obtained by the other laboratories. The 7-m sample of Pacific Ocean water with remarkably high values for copper and zinc was collected with a pump equipped on a research vessel, the Hakuho Maru belonging to the University of Tokyo. This contamination may originated from the metal in the gun-metal parts of the pump used for the sampling.

Conclusion

2-Mercaptobenzothiazole–silica gel (MBT–SG) provides an easy means of preconcentrating cadmium, copper, lead, and zinc and of separating copper from cadmium, lead, and zinc, and lead and cadmium from zinc for subsequent atomic absorption measurements of the contents of each metal. The attractive features of this chelating material are the easiness of preparation, reproducibility, and fast adsorbability for several metal ions from water samples in spite of its relatively low chelating capacity. Because dissolution of the reagent from the column is too small to be measured, a large volume of sample water (5—10 l) can be treated with a relatively small column, and the preconcentrated metal ions can be eluted from the column with a small volume of eluant resulting in a high concentration factor.

Photoemission and Solvation Free Energies of Electrons in Polar Solvents

Kazuo YAMASHITA and Hideo IMAI

Faculty of Integrated Arts and Sciences, Hiroshima University, Hiroshima 730

(Received September 24, 1976)

The red limit potential of electron photoemission was measured in various polar solvents, and the apparent solvation free energies of the electrons were estimated. The energy state and transformation of photoemitted electrons in solution were discussed as regards the role of dry or damp electrons as an intermediate species. A proportionality between the intermediate solvation free energy and the energy quantum of the optical absorption band maximum of solvated electron in various polar solvents is pointed out.

In polar solvents the electrons produced by high energy radiation are localized or trapped by the surrounding solvent molecules in a delicate balance of short- and long-range interactions.[1] Such a solvated electron can also arise in photo-electrochemical processes, where the photoemission from a cathode under suitable conditions of illumination is measured as the cell current flowing due to the homogeneous electron capture process.[2] The dependence of the photocurrent on the square root of the scavenger concentration and rate constant of a scavenging reaction has been proved by the theory based on the semi-infinite diffusion equation.[3] The red limit potential or threshold potential, which can be estimated from the photoelectrochemical process, is related to the estimate of the work function of the electron from a metal into solution. The interaction of photoemitted electron with solvent molecules can be expressed in terms of the difference between the work function of the electron from a metal into vacuum and that from the metal into solution, when the Volta potential difference is taken into account. The values estimated for water from this relationship, however, show a fairly remarkable discrepancy from the hydration free energy of the electron obtained by radiation chemical studies.[4,5] Schiffrin[6] extensively discussed the difference, attributing it to the contribution of the solvent reorganization energy. On the other hand, Pleskov and his co-workers[7,8] interpreted the difference by assuming free or delocalized electrons.

In this paper precise data of the red limit potential in various polar solvents are presented. The physical meaning of the energy value estimated as an interaction energy of emitted electrons with solvent molecules prior to the electron capture reaction is discussed.

Experimental

The apparatus is shown in Fig. 1. A lock-in amplifier (Model LI-572B, NF Circuit Design Block Co.) with a light chopper, Model CH-352, was used at a *ca.* 20 Hz frequency. A three-electrode cell, equipped with a water jacket to control the temperature, was used. The potential of the working electrode (a mercury pool electrode renewed by spilling mercury in each run; illuminated area *ca.* 0.3 cm^2) was controlled with a potentiostat (Shimadzu Model PS-2). A 500 watt super high pressure mercury lamp (Ushio Type USH 500D) was used for illumination through a monochrometer or color filters. The wavelength of the incident light was 365 nm. When gas bubbles are evolved by a scavenging reaction, *e. g.* N_2 from N_2O or H_2 from H_3O^+, it is preferable to measure under a small current density. Since the current signal is very small, an electrode with wide illumination area gives more accurate measurements.

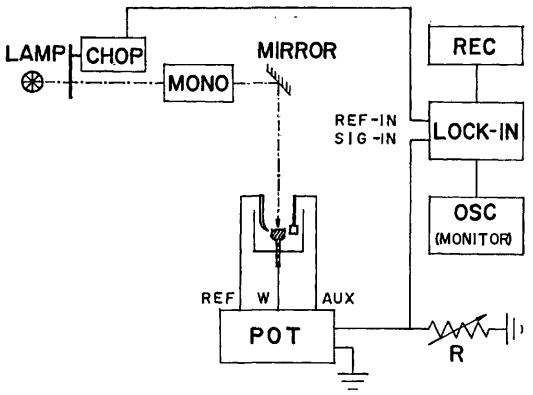

Fig. 1. Apparatus used for experimental measurements of photocurrents.

All the solvents were purified by the usual methods.[9] Measurements were carried out at 25 °C.

Results and Discussion

Estimation of Intermediate Solvation Free Energy of Electron from Red Limit Potential. The dependence of photoemission current, I_e, on the quantum energy of incident light, $h\nu$, and the field strength or electrode potential, ϕ, under sufficiently high electrolyte concentration is given by[10]

$$I_e = A(h\nu - h\nu_0 - e\phi)^{5/2}, \quad (1)$$

where A is a constant depending upon the properties of the metal, h the Planck constant, and ν_0 the threshold frequency at the potential of zero charge, ϕ_{pzc}. All the potential values are referred to ϕ_{pzc}. The relationship known as the law of five halves, was derived as an approximate solution of a theoretical equation postulating the transmission of electrons through the energy barrier at the electrode-solution interface. The equation was verified experimentally to hold not only in aqueous solutions,[7,10] but also in non-aqueous solutions.[11] Figure 2 shows the linear relationship between $i_p^{0.4}$ and ϕ in hexamethylphosphoramide (HMPA) solution saturated with nitrous oxide, where i_p is the photocurrent measured in experiments. The extrapolation of $i_p^{0.4}$-ϕ straight line to $i_p=0$ gives the red limit potential of -0.42 V *vs.* Ag/0.01 M $AgClO_4$

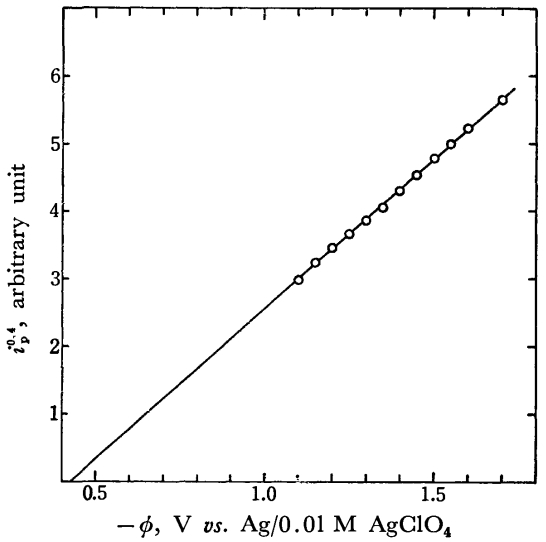

Fig. 2. Dependence of $i_p^{0.4}$ on ϕ for 0.2 M $NaClO_4$ HMPA solution saturated with N_2O.

electrode. According to the definition of the red limit potential, ϕ_0, Eq. 1 leads to

$$h\nu_0 = h\nu - e\phi_0 \tag{2}$$

The energy quantum, $h\nu_0$, can be replaced by the work function, W_{m-s}, of the electron emission from a metal into solution as given by

$$W_{m-s} = h\nu - e\phi_0. \tag{3}$$

A tentative energy cycle was proposed from a comparison of the electron photoemission in solution with that *in vacuo* (the work function; W_{m-v}).[12] However, there is a discrepancy between the data obtained by this method and those by radiation chemical studies. A modification of the energy cycle can be deduced by taking the discrepancy into consideration. The

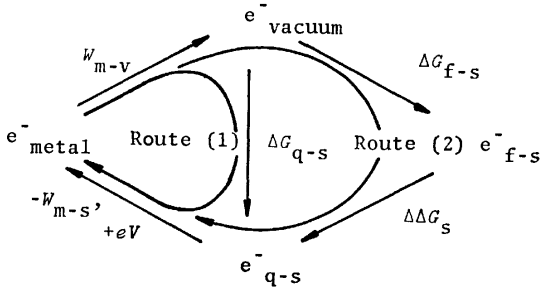

Fig. 3. Modified energy cycle of the electron.

modified energy cycle involves two stages of the electron-solvent interaction, namely an intermediate state[6] of solvation (a quasi-solvated state) and fully solvated state as shown in Fig. 3. The symbols, e^-_{q-s} and e^-_{f-s}, represent the quasi-solvated and fully solvated electrons, respectively, ΔG the free energy change for respective solvation process, and $\Delta\Delta G_s$ the difference between ΔG_{f-s} and ΔG_{q-s}. The energy balance in routes (1) and (2) lead to the following expressions.

$$-\Delta G_{q-s} = W_{m-v} - W_{m-s} + eV_{m-s}$$
$$= W_{m-v} - h\nu + e(\phi_0 + V_{m-s}) \tag{4}$$
$$-\Delta G_{f-s} = -\Delta G_{q-s} + \Delta\Delta G_s, \tag{5}$$

where V_{m-s} is the Volta potential difference between a metal and solution.

Taking $W_{Hg-vacuum}$=4.52 eV, $h\nu$=3.40 eV corresponding to λ=365 nm, $e\phi_0$=0.26 eV for saturated-N_2O aqueous solution containing 0.2 M KCl, and eV_{Hg-aq}=−0.26 eV, which is evaluated from the data obtained by Randles[13] and Grahame *et al.*,[14] we obtain $-\Delta G_{q-s}$=1.14 eV from Eq. 4. This value coincides with previous estimates,[3,6,7] the value of $-\Delta G_{f-s}$ estimated in radiation chemical studies being

1.67[4] or 1.71[5] eV. Thus the value of $\Delta\Delta G_s$ is estimated to be 0.53—0.57 eV, *viz.*, the energy of the quasi-hydrated state is higher by 0.53—0.57 eV than that of the fully hydrated state.

The data of ΔG_{q-s} estimated similarly in various polar solvents and related values are summarized in Table 1.

Transformation of Emitted Electrons and the Succeeding Reaction. In the reaction sequence of the photo-emitted electrons in solution containing a scavenger, it seems that the emitted electrons are thermalized and solvated, and then the solvated electrons are captured by scavengers, resulting in the photocurrent. At low concentrations of electron acceptor the mechanism was supported by the coincidence with a theory[2,3] based on the semi-infinite diffusion coupled with the scavenging reaction. The solvent effect on the rate of scavenging process was also confirmed experimentally.[3] At low scavenger concentrations the participation of the fully solvated electron in the reaction pathway seems to be predominant. In the present case, however, the experiment was carried out at relatively high scavenger concentrations, so that the emitted electrons may have been captured by the scavenger prior to full solvation. Hunt and his co-workers[15–17] developed a picosecond stroboscopic pulse radiolysis technique. They found that there are precursors called dry or damp electrons, around which solvent molecules relax to form the fully solvated electrons. This intermediate species might be quasi-solvated and reacts with a scavenger prior to full solvation. The life of the intermediate species is shown to be within the order of picoseconds in aqueous solutions and much longer in alcoholic media.[18]

Taking these findings into consideration, the transformation of photoemitted electrons and the reaction sequence in solution can be expressed as shown in Fig. 4.

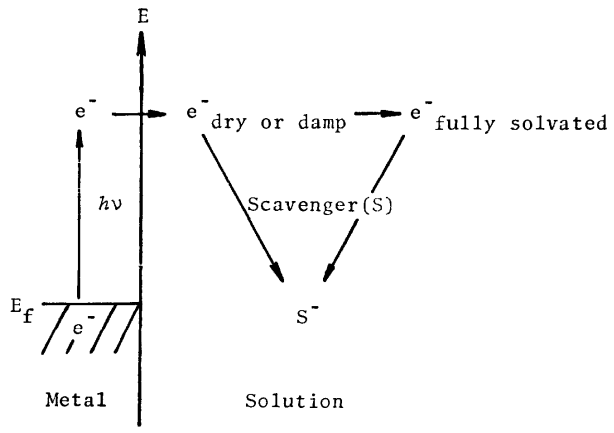

Fig. 4. Transformation of photoemitted electrons and the sequence of reactions.

Relationship between ΔG_{q-s} and $h\nu_{max}$ of Optical Absorption Band Maximum of Solvated Electron. A plot of ΔG_{q-s} *vs.* $h\nu_{max}$, the energy quantum of the optical absorption band maximum of solvated electrons, is shown in Fig. 5.

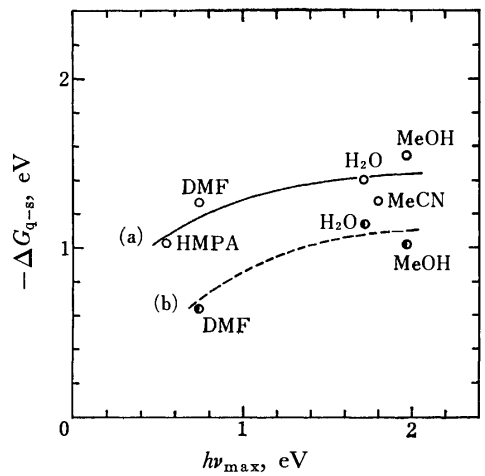

Fig. 5. Empirical correlation between quasi-solvation free energy of the electron and energy of optical absorption band maximum of the solvated electron.
(a) Values uncorrected for the Volta p. d.
(b) Values corrected for the Volta p. d.

The value of $-\Delta G_{q-s}$ increases with increase in $h\nu_{max}$. The solvents used have static dielectric constants ranging from 17 to 84 at room temperature. The optical absorption spectra[1] of the solvated electrons in hydroxy compounds including water are mostly in the visible or near-infrared region. The amides or amines are in the intermediate region 1400—2050 nm, and the ethers are in the infrared region 1800—2300 nm. Corresponding to this trend, it is expected that the free energy of fully solvated electrons decreases in the solvents in the order

hydroxy compounds>amides and amines>ethers,

since the transition energy, $h\nu_{max}$, for optical absorption maximum corresponds to the depth of the potential well of the solvated electron. It is noteworthy that the energy of quasi-solvated electrons also shows the same trend as shown in Fig. 5.

This investigation was supported by the Science Research Grant 054194 of the Ministry of Education.

Preparations and Properties of Some Cationic Palladium(II) Complexes of the Di-*t*-butylnitroxide Radical

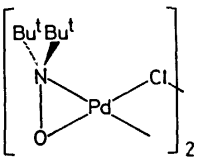
Masaaki Okunaka, Gen-etsu Matsubayashi, and Toshio Tanaka

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-kami, Suita, Osaka 565

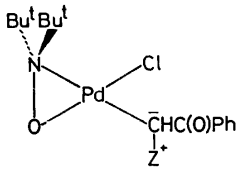
(Received October 27, 1976)

Cationic palladium(II) complexes of the di-*t*-butylnitroxide radical, $[Pd(Bu^t_2NO)(L\text{-}L)]X$ (L-L=2,2'-bipyridine, 1,10-phenanthroline, *N*-substituted 2-pyridylmethyleneamine and bis(triphenylphosphine); $X^-=ClO_4^-$ and/or BPh_4^-), were prepared. ^1H NMR spectra of the complexes indicate that the nitroxide forms a three-membered ring with the palladium atom. The *N*-methyl- and *N*-ethyl-2-pyridylmethyleneamine complexes exist as two geometrical isomers in solution, whose ratios are 1 : 1 and 1 : 0.2, respectively. In the *N*-butyl and *N*-*p*-tolyl analogs, however, only one of the isomers exists in solution. These results are interpreted in terms of steric repulsion between the *t*-butyl groups and *N*-substituents. The bipyridine complex reacts with dialkyl disulfides in the presence of catalytic amounts of bipyridine to give a sulfur-bridged dimeric complex, $[Pd(bipyridine)(SR)]_2(ClO_4)_2$(R=Me and Pr), and a free nitroxide radical.

Nitroxide radicals ($R_2NO\cdot$) usually coodinate to metal ions through the oxygen atom as a neutral ligand.[1-7] However, di-*t*-butylnitroxide has been reported to react with palladium dichloride to form a chloride-bridged diamagnetic complex **A**, in which the nitroxide was assumed to coordinate to the palladium atom as an

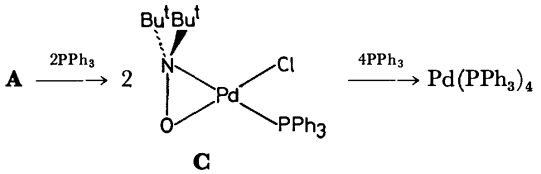


A



B

anionic ligand.[8] A recent ^1H NMR study by the present authors on the nitroxide-palladium(II) complexes **B** which involve prochiral phenacylides, $Z\overset{+}{C}H\overset{-}{C}(O)Ph$ (Z=PPh_2Me, PPh_3, $AsPh_3$, and SMe_2), has demonstrated that a three-membered ring exists in the complexes.[9] It was also found that **A** reacts with triphenylphosphine to give a mononuclear complex **C**, which undergoes a novel redox reaction of the nitroxide-palladium moiety by nucleophilic attack of excess triphenylphosphine yielding tetrakis(triphenylphosphine)palladium(0).[10]



C

$$+\ PdCl_2(PPh_3)_2 + 2Bu^t_2NO\cdot$$

This reaction indicates a characteristic coordination property of the nitroxide toward palladium. However, few palladium complexes with nitroxides have so far been isolated. It is, therefore, of interest to extend the study of the nitroxide-palladium(II) complexes.

This paper reports the preparations and properties of cationic palladium(II) complexes having the chemical formula $[Pd(Bu^t_2NO)(L\text{-}L)]X$ (L-L=2,2'-bipyridine (bipy), 1,10-phenanthroline(phen), *N*-substituted 2-pyridylmethyleneamine(pyma-R) and bis(triphenylphosphine); $X^-=ClO_4^-$ and/or BPh_4^-), and the redox reactions using dialkyl disulfides as oxidizing reagents.

Experimental

Materials. The chloride-bridged dipalladium complex, $[PdCl(Bu^t_2NO)]_2$, and *N*-substituted 2-pyridylmethyleneamines, 2-C_5H_4N-CH=N-R (R=Me, Et, Bu, and *p*-tolyl), were prepared as described elsewhere.[8,11]

Preparation of $[Pd(Bu^t_2NO)(L\text{-}L)]X$ (L-L=bipy, phen, pyma-R and bis(triphenylphosphine); $X^-=ClO_4^-$ and/or BPh_4^-). Into a dichloromethane solution (10 ml) of $[PdCl(Bu^t_2NO)]_2$ (286 mg, 0.5 mmol) was poured an acetone solution (15 ml) containing bipy (156 mg, 1.0 mmol) and sodium perchlorate monohydrate (140 mg, 1.0 mmol) with vigorous stirring at room temperature. The original brown solution changed immediately to a yellow suspension, which was filtered to remove the sodium chloride produced. The filtrate was evaporated to dryness under reduced pressure. The resulting product was recrystallized from acetone/petroleum ether to afford yellow crystals of $[Pd(Bu^t_2NO)(bipy)]ClO_4\cdot 1/2Me_2CO$ (427 mg, 80% yield). Other yellow perchlorate complexes were prepared by the same method (50—80% yields), and yellow tetraphenylborate complexes were similarly obtained using sodium tetraphenylborate in place of sodium perchlorate monohydrate (70—85% yields). The results of elemental analysis, the melting points and the molar electric conductances of the complexes are summarized in Table 1.

Reaction of $[Pd(Bu^t_2NO)(bipy)]ClO_4$ with Dialkyl Disulfides in the Presence of bipy. Dimethyl disulfide (470 mg, 5.0 mmol) was mixed with an acetone solution (15 ml) of $[Pd(Bu^t_2NO)(bipy)]ClO_4$ (268 mg, 0.5 mmol) in an atmosphere of dry nitrogen, followed by the addition of bipy (15.6 mg, 0.1 mmol) in acetone (5 ml) with stirring at room temperature. The solution was further stirred for 40 h to give a precipitate, which was collected by filtration. Recrystallization from acetonitrile gave yellow crystals of $[Pd(bipy)(SMe)]_2(ClO_4)_2$-MeCN (160 mg, 82% yield). Found: C, 33.46; H, 2.89; N, 8.21%. Calcd for $C_{24}H_{25}N_5O_8S_2Cl_2Pd_2$: C, 33.54; H, 2.94; N, 8.20%. Λ_M=309 ohm^{-1} cm^2 mol^{-1} (1.0×10^{-3} M in acetonitrile). The propyl analog, $[Pd(bipy)(SPr)]_2(ClO_4)_2$, was prepared by the same method (75% yield). Found: C, 35.59; H, 3.42; N, 6.57%. Calcd for $C_{26}H_{30}N_4O_8S_2Cl_2Pd_2$: C, 35.71; H, 3.46; N, 6.41%. Λ_M=328 ohm^{-1} cm^2 mol^{-1} (1.0×10^{-3} M in acetonitrile).

Physical Measurements. ^1H NMR and ESR spectra were measured as described previously,[10] and the electric con-

ductance was determined at 25 °C using a universal bridge, as has also been described elsewhere.[12]

Results and Discussion

The complexes are stable in air in the solid state, however, they gradually decompose in solution. Electric conductance measurements appear to indicate that the complexes are 1 : 1 electrolytes in acetonitrile (Table 1). The assignment of the ^1H NMR spectra is easily carried out by refering to those of other metal complexes of bipy,[13] phen,[13] and 2-pyridylmethyleneamines,[11,14] as summarized in Table 2.

Configuration of the $[Pd(Bu^t_2NO)(L\text{-}L)]^+$. Figure 1 shows a comparison of the ^1H NMR spectra of the bipy complex and free bipy in the bipy proton region in acetonitrile. The H_4 and H_5 signals of bipy move down-field upon complex formation with the former being observed near the H_3 signal. It is to be noted that two distinct H_6 signals appear separately with equal intensities; one of the H_6 signals undergoes a little down-field shift, while the other H_6 signal occurs at a higher field than does bipy itself. This result

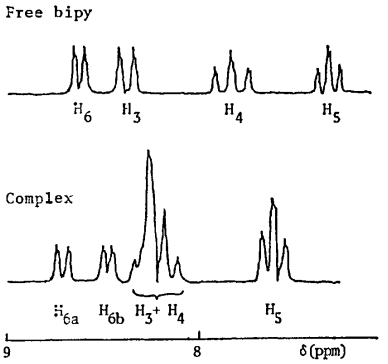

Fig. 1. ^1H NMR spectra of bipy and $[Pd(Bu^t_2NO)(bipy)]ClO_4$ in the bipy proton region, in acetonitrile at 24 °C.

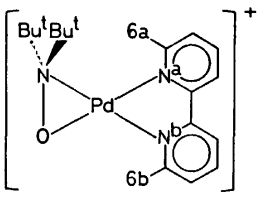
indicates a three-membered ring formed by the nitroxide and the palladium atom in a square planar configuration, as shown in I. The small shifts of the H_6 signals are ascribed to the counteraction of two opposite effects: a down-field shift due to a decrease in the electron density on the pyridine ring and an



I

up-field shift due to a decrease in the original paramagnetic anisotropy of lone pair electrons of the bipy nitrogen upon coordination, as was suggested for the pyridine complexes of triethylaluminum.[12] Steric repulsion between the *t*-butyl groups and the pyridine ring can possibly weaken the Pd–N^a bond compared with the Pd–N^b bond. Therefore, the larger paramagnetic anisotropy effect of the lone pair electrons may dominate more in N^a than in N^b. As a result, the H_{6a} signal is considered to occur at a lower field than the H_{6b} signal. The phen complex also exhibits two separated H_2 and H_9 signals, which suggests that the configuration is similar to I.

The ^1H NMR spectrum of the *N*-methyl-2-pyridylmethyleneamine complex shows two sets of H_6, *N*-methyl and *t*-butyl signals, as shown in Fig. 2; the intensity ratio of each pair is 1 : 1. This is due to the presence of two equimolar geometrical isomers, IIa and IIb, in solution. In the *N*-ethyl-2-pyridylmethyleneamine complex, the intensity ratio of each pair of H_6 and *N*-ethyl signals is 1 : 0.2, whereas the *N*-butyl and *N*-*p*-tolyl analogs exhibit only one set of signals. In view of the steric repulsion between the *t*-butyl and *N*-alkyl or *N*-aryl groups, configuration IIa would be more probable than IIb. This is consistent with the X-ray crystallographic analysis of $PdCl(Bu^t_2NO)(Me_2\overset{+}{S}\overset{-}{C}HC(O)Ph)$, in which the bulky phenacylide is located in the position *trans* to the di-*t*-butyl nitrogen.[15] The preference of IIa over IIb is also supported by failure to isolate the nitroxide–palladium(II) complex of *N*,*N*′-di-*p*-tolyl-2,3-butanediimine, in which the *p*-tolyl group should be located in the position *cis* to the di-*t*-butyl nitrogen.

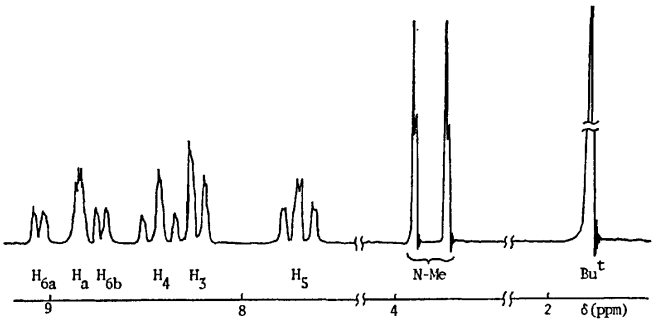


Fig. 2. The ^1H NMR spectrum of $[Pd(Bu^t_2NO)$-(pyma-Me)$]ClO_4$ in acetone at 24 °C; the solvent signals are omitted.

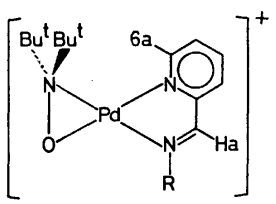
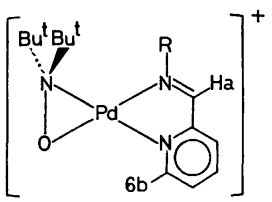


IIa



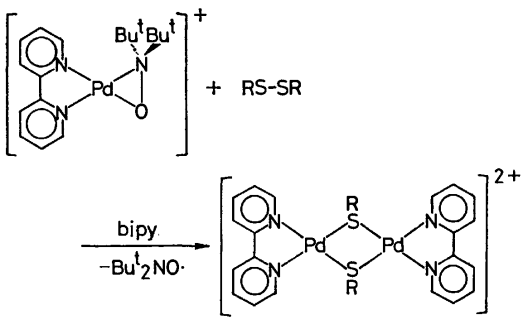
IIb

The bis(triphenylphosphine) complex is obtained in a high yield. On the other hand, the isolation of the corresponding 1,2-bis(diphenylphosphino)ethane complex was not successful possibly because the inflexibility of the bidentate ligand results in an unfavorable steric repulsion upon chelation.

Stability of the Complex to Nucleophiles. The ESR spectrum of $[Pd(Bu^t_2NO)(bipy)]ClO_4$ in degassed acetone shows a weak triplet signal due to a free di-*t*-butylnitroxide radical which may be produced by slight dissociation from the palladium atom. No appreciable enhancement of the ESR signal is observed upon the addition of bipy to a degassed acetone solution of the complex. These observations confirm that no reaction occurs between the complex and bipy. $[Pd(Bu^t_2NO)(PPh_3)_2]ClO_4$ does not react with excess PPh_3. This is in contrast to the facile reaction of $PdCl(Bu^t_2NO)(PPh_3)$ with PPh_3, generating a free nitroxide radical.[10]

Reaction of $[Pd(Bu^t_2NO)(bipy)]ClO_4$ *with Some Oxidizing Reagents.* When bipy is added to an acetone (not degassed) solution of $[Pd(Bu^t_2NO)(bipy)]ClO_4$ in air, an orange crystalline complex is obtained and a free nitroxide radical is generated as confirmed by the ESR spectrum of the reaction mixture. The ^1H NMR spectrum of the orange complex in DMSO-d_6 shows only the signals due to the coordinated bipy, but no signal for the di-*t*-butyl protons. The results of elemental analysis confirm the chemical formula, $[Pd(bipy)_2]$-$(ClO_4)_2 \cdot O_2$. Although details of the configuration are ambiguous, a redox reaction appears to occur between the $Bu^t_2NO^-$ moiety and dioxygen.

The redox reaction of $[Pd(Bu^t_2NO)(bipy)]ClO_4$ with dialkyl disulfides was further examined in the presence of catalytic amounts of bipy in an atmosphere of dry nitrogen. This reaction yields $[Pd(bipy)(SR)]_2$-$(ClO_4)_2$ (R=Me and Pr) (Reaction 1),



(1)

III
(R=Me and Pr)

where the anionic nitroxide is oxidized to a neutral radical and dialkyl disulfides are reduced. Analogous complexes $[Pd(ethylenediamine)(SPh)]_2X_2$ (X=Cl and Br) were prepared by Boschi *et al.*,[16] who proposed a configuration similar to III.

Studies on 5-8 Fused Ring Compounds. I. Halogenation of 4,4-Dimethylbicyclo[6.3.0]undecane-2,6-dione

Misao UMEHARA, Shinzaburo HISHIDA,* Kunimi FUJIEDA,* and Hirooki SASAKI

Department of Chemistry, Keio University, Hiyoshi-cho, Kohoku-ku, Yokohama 223

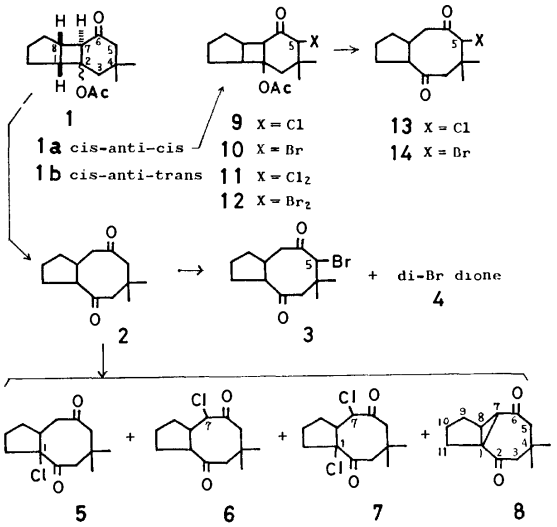
**Naka Works, Hitachi Ltd., Ichige, Katsuta, Ibaraki 312*

(Received July 12, 1976)

Bromination and chlorination of 4,4-dimethylbicyclo[6.3.0]undecane-2,6-dione (**2**) with pyridinium bromide perbromide and sulfuryl chloride gave several α-halo-diones. The substituted positions and the stereochemistry of the halogen atoms have been assigned on the basis of their dehydrohalogenation and spectral data. The chlorination of **2** also gave a tricyclic dione (**8**) containing a cyclopropane ring. The structure of **8** was determined by means of ^{13}C-NMR, as well as other types of spectroscopy. Dehydrochlorination of **7** gave a 5*H*-benzocycloheptene derivative (**18**).

Umehara *et al.* recently reported results concerning the photochemical cycloaddition of the enol acetate of dimedone to cyclopentene, and indicated that the photoadducts, 2-acetoxy-4,4-dimethyltricyclo[6.3.0.$0^{2,7}$]-undecan-6-one (**1a** and **1b**), undergo retro-aldol cleavage under acidic conditions to give 4,4-dimethylbicyclo-[6.3.0]undecane-2,6-dione (**2**).[1] Halogenation of the dione (**2**) was attempted to prepare intermediates for the synthesis of terpenes containing a medium-size ring, and several α-halo-diones were obtained. In the present paper, the dehydrohalogenation of the α-halo-diones and the substituted positions of the halogen atoms are reported.

It is interesting to study the chemical properties of compounds containing a 5-8 fused ring, since few investigations have been reported concerning them. Furthermore, such compounds constitute the partial skeleton of sesterterpenes (5-8-5 fused ring) and are of interest in this respect.



Scheme 1.

Results and Discussion

Bromination of the dione (**2**) with pyridinium bromide perbromide in ethanol yielded only a monobromo-dione (**3**), but, in acetic acid, **3** and a dibromo-dione (**4**) were obtained.

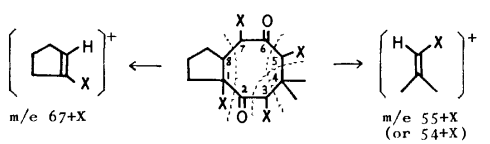
Chlorination of **2** with sulfuryl chloride in carbon tetrachloride yielded a mixture of two monochloro-dione (**5** and **6**), a dichloro-dione (**7**) and a compound (**8**) presumably formed as the result of the dehydrochlorination.

Other halogenated diones were also synthesized through the halogenation of the photoadduct **1a** (*cis-anti-cis*), followed by retro-aldol cleavage. The halogenation of **1a** with sulfuryl chloride and pyridinium bromide perbromide gave chloro derivatives (**9** and **11**), and bromo derivatives (**10** and **12**), respectively. Then retro-aldol cleavage of **9** and **10** under similar conditions,[1] used for the synthesis of **2** from **1a** and **1b**, gave monohalo-diones (**13** and **14**), respectively.

The monohalo-diones (**3**, **5**, **6**, **13**, and **14**) were subjected both to mass spectrometric analysis and to dehydrohalogenation with γ-collidine in order to determine the positions of halogen. The halogen atom can be substituted on the dione (**2**) at positions 1, 3, 5, or 7.

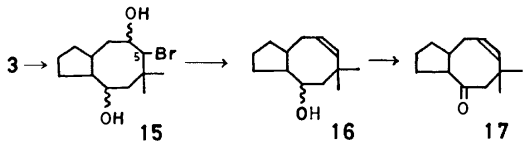
Compounds **3**, **13**, and **14** were found to remain unreacted upon treatment with γ-collidine, suggesting that the halogen atom is present at position 3 or 5 in any of these compounds because of the absence of a hydrogen atom at a neighboring position. The mass spectral data also support this. Scheme 2 shows the possible fragmentation patterns giving the fragment ions, $m/e=55+X$ (or $54+X$) (containing a *gem*-dimethyl group) and $m/e=67+X$ (containing a halogenated five-membered ring). Compounds **3**, **13**, and **14** showed a fragment peak corresponding to $m/e=55+X$ (or $54+X$) [where m/e is 133 for **3** (X=Br), 134 for **14** (X=Br), and 90 for **13** (X=Cl)], but none corresponding to $m/e=67+X$ indicating that the halogen atom is present at the 3 or the 5 positions of these compounds. The resemblance of the IR spectra of **13** and **14** indicates that a chlorine or bromine atom is substituted at the same position. Since **13** and **14** arose from **9** and **10**, respectively, the halogenation occurred at position 5 in **13** and **14**.

To identify the position of the bromine atom in **3**, compound **3** was reduced with $NaBH_4$ to a mixture of stereoisomers of diol (**15**), which was refluxed with zinc



Scheme 2. (X=Cl or Br)

in acetic acid,[2] converted to **16** and then oxidized to enone **17** with chromic acid. The enone **17** was subjected to ^{13}C-NMR spectroscopy by proton noise decoupling and off-resonance decoupling and the multiplicity of the α-carbon atom in the carbonyl group was carefully observed. The ^{13}C-NMR spectroscopy of the enone revealed that the one α-carbon atom of the carbonyl group resonated at 62.6 ppm as a doublet while the other occured at 52.4 ppm as a triplet. This finding suggests that the enone has the same structure as **17** (4,4-dimethylbicyclo[6.3.0]undec-5-en-2-one) and it can be concluded that the bromine atom in **3** is not at position 3 but is at position 5. Therefore, **3** and **14** are epimers.



Scheme 3.

In α-halo ketones, the relationship between the IR[3] or UV[4] spectra and the orientations of the halogen atoms is known. The IR spectra of the dione (**2**) and the α-halo-diones (**3**, **5**, **6**, **13**, and **14**) were measured in carbon tetrachloride and the UV spectra in ethanol (Table 1). From these results, the C–X links in **6**, **13**, and **14** are nearly coplanar with the carbonyl group while the bromine atom in **3** is twisted away from the carbonyl oxygen atom. These results agree with the above-mentioned finding that **3** and **14** are epimers with respect to the bromine atom at position 5.

Table 1. The spectral data of monohalo-diones

Compound	UV (EtOH)			IR (CCl_4)	
	λ_{max}(nm)	ε	Δλ	ν(cm^{-1})	Δλ
2 (dione)	300	53	0	1700	0
3 (5-Br)	317	120	+17	1703	+3
14 (5-Br)	308	76	+8	1700 1720	+20
13 (5-Cl)	305	58	+5	1700 1723	+23
5 (1-Cl)	313	77	+13	1700 1710	+10
6 (7-Cl)	313	74	+13	1700 1720	+20

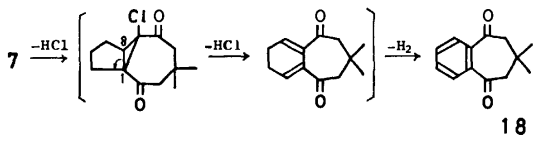
Both **5** and **6**, which were obtained by chlorination of **2**, undergo dehydrochlorination upon treatment with γ-collidine yielding **8**. The mass spectra of **5** and **6** show no fragment peak of m/e=55+Cl (or 54+Cl). On the other hand, **5** has a fragment peak at m/e=102 (67+Cl), which was not detected in **6**. Hence, it is inferred that the chlorine atom of **5** is at position 1 and the chlorine atom of **6** is at position 7.

In the mass spectrum of **8**, the parent peak is 206 (M^+). The IR spectrum of **8** shows a weak C–H stretching peak at 3040 cm^{-1}, and carbonyl absorption peaks appear at 1660 and 1675 cm^{-1} in Nujol, which are at frequencies lower than the 1695-cm^{-1} peak observed for **2**. In the UV spectrum of **8**, the end absorption at 210 nm has a higher intensity (ε=7100 in EtOH) compared with the value for **2** (ε=131, EtOH). Furthermore, the ^{1}H-NMR spectrum of **8** has no signal for any magnetic field lower than 3δ, and no signals appear in the ^{13}C-NMR spectrum over the range from 100—160 ppm. These experimental results can be explained more satisfactorily by the presence of a three-membered ring than by the presence of a double bond.

The structure of **8** was determined to be 4,4-dimethyltricyclo[6.3.0.$0^{1,7}$]undecane-2,6-dione with the aid of the multiplicity results of the ^{13}C-NMR spectra due to proton noise decoupling and off-resonance decoupling. In addition to the signals of two carbonyl carbon atoms (both at 206 ppm), two singlet peaks are present at 49.2 and 34.2 ppm. The peak at 34.2 ppm is assigned to C-4 carrying a *gem*-dimethyl group, and that at 49.2 ppm to C-1, since only C-1 can be converted into a quarternary carbon by dehydrohalogenation. Moreover, two doublet peaks at 40.9 and 37.6 ppm indicate the presence of two tertiary carbon atoms which are assigned to C-7 and C-8, respectively.

The cyclopropane ring of **8** is probably formed by intramolecular nucleophilic substitution involving an intermediate carbanion.[5] Compound **8** appears to be rather strained judging from a molecular model, but conjugation of the cyclopropane ring and two carbonyl groups is likely to stabilize the compound to such an extent as to readily permit its formation.

The dichloro compound (**7**) obtained by the chlorination of **2** yielded 7,7-dimethyl-6,7,8,9-tetrahydro-5*H*-benzocycloheptene-5,9-dione (**18**) containing a benzene ring when treated with γ-collidine. The structure of **18** was determined by ^{1}H-NMR spectroscopy. The signals centered at 7.71 δ, attributable to benzene ring protons, appear as a symmetrical multiplet. The signal for the *gem*-dimethyl protons appears as a singlet (6H) at 1.25 δ and that for the equivalent two methylene protons as a singlet (4H) at 2.75 δ.



Scheme 4.

Experimental

The ^{13}C-NMR and the ^{1}H-NMR spectra were obtained on Hitachi R-26 and R-22 spectrometers in $CDCl_3$ with TMS as the internal standard. The mass spectra were measured with Hitachi RMU-6L and RMU-7M spectrometers. The IR and UV spectra were recorded using JASCO IR-G and Hitachi EPS-3 spectrophotometers, respectively. The VPC analysis was carried out on a 063 Hitachi gas chromatograph.

Bromination of Dione (2). A mixture of **2** (0.2 g) and pyridinium bromide perbromide (0.3 g) in ethanol (10 ml) was stirred at 40—50 °C. The reaction mixture was poured into water (150 ml) and the precipitated bromodione (**3**) (0.21 g) was collected. The product showed one spot on a TLC (silica gel). Recrystallization from ethanol gave pure **3** (0.15 g); mp 111—113 °C. IR and UV (see Table 1). Found: C, 54.67; H, 6.58%. Calcd for $C_{13}H_{19}O_2Br$: C,

54.37; H, 6.62%. MS: *m/e* 288 (M+2, 4%), 286 (M^+, 5), 273 (5), 271 (6), 232 (7), 230 (7), 220 (5), 218 (5), 207 (72), 191 (5), 189 (6), 179 (47), 163 (5), 161 (6), 151 (35), 135 (5), 133 (5), 123 (30), 109 (48), 95 (27), 83 (base, 100), 81 (62), 67 (27), 55 (62), and 41(62).

A similar reaction of **2** in acetic acid (10 ml) yielded a crude product (0.25 g) which was subjected to column chromatography on silica gel. Elution with ether–hexane (1 : 1) gave **4**. Crystallization (EtOH) gave pure **4**; mp 164—165 °C. IR (CCl_4) 1710 cm^{-1}. UV (EtOH) λ_{max} 324 nm (ε, 180). Found: C, 42.53; H, 4.86%. Calcd for $C_{13}H_{18}O_2Br_2$: C, 42.65; H, 4.92%. Further elution with ether–hexane (1 : 1) gave **3**. Mp 110—112 °C (EtOH), which was identified by IR spectroscopy.

Chlorination of Dione (2). Into a solution of **2** (0.4 g) in CCl_4 (15 ml), a solution of sulfuryl chloride (0.26 g) in CCl_4 (10 ml) was added dropwise with stirring. The mixture was allowed to stand at room temperature overnight. The resulting solution was washed successively with water and aqueous sodium hydrogencarbonate. After the organic solution had been dried over sodium sulfate, it was concentrated under reduced pressure. The residual oil was chromatographed on a silica gel column with ether–hexane (1 : 2). The amounts of the products isolated in the order of their elution were: 51 mg of dichloro-dione (**7**), 42 mg of monochloro-dione (**6**), 20 mg of monochloro-dione (**5**), 58 mg of dione (**2**), and 167 mg of 4,4-dimethyltricyclo[6.3.0.$0^{1,7}$]-undecane-2,6-dione (**8**). Recrystallization of chlorodiones **5**, **6**, and **7** from ethanol and of **8** from hexane–ether (5 : 1) gave pure products.

5: mp 108—110 °C. IR and UV (see Table 1). Found: C, 64.47; H, 7.68%. Calcd for $C_{13}H_{19}O_2Cl$: C, 64.33; H, 7.84%. MS: *m/e* 242 (M^+, 3%), 207 (3), 151 (3), 141 (80), 123 (5), 112 (36), 109 (2), 104 (2), 102 (6), 95 (7), 83 (base, 100), 81 (10), 67 (17), 55 (13), and 41 (18).

6: mp 126—127 °C. IR and UV (see Table 1). Found: C, 64.39; H, 7.52%. MS: *m/e* 242 (M^+, 2%), 207 (37), 179 (7), 151 (2), 123 (3), 122 (3), 111 (12), 109 (6), 95 (13), 83 (base, 100), 81 (17), 67 (12), 55 (16), and 41 (14).

7: mp 168—170 °C. IR and UV (see Table 1). Found: C, 56.47; H, 6.24%. Calcd for $C_{13}H_{18}O_2Cl_2$: C, 56.32; H, 6.50%. MS: *m/e* 276 (M^+, 0.5%), 261 (1.5), 243 (5), 242 (14), 227 (2), 213 (3), 207 (3), 205 (3), 178 (2), 176 (8), 174 (25), 163 (2), 161 (7), 159 (3), 157 (4), 153 (2), 150 (2), 149 (2), 143 (4), 141 (5), 123 (4), 115 (6), 111 (17), 108 (3), 107 (3), 102 (3), 95 (3), 83 (base, 100), 79 (13), 77 (12), 67 (12), 55 (19), and 41 (19). The mass spectrum of **7** shows a fragment peak at *m/e*=102 (67+Cl) and it is likely that one chlorine atom is present at the ring junction and the other at position 7.

8: mp 106—107 °C. IR: (CCl_4) 3040, 2950, and 2805 cm^{-1} (C–H), 1685 cm^{-1} (C=O); (Nujol) 1660 and 1675 cm^{-1} (C=O). UV (EtOH) λ_{max} 288 nm (ε, 69), ε at 210 nm (7100). ^{1}H-NMR ($CDCl_3$) 0.91 δ (s, 3H, CH_3) and 1.10 δ (s, 3H, CH_3). ^{13}C-NMR ($CDCl_3$) 206 ppm (s, C-2, C-6), 56.2 and 54.6 ppm (t, C-3, C-5), 49.2 ppm (s, C-1), 40.9 ppm (d, C-7), 37.6 ppm (d, C-8), 34.2 (s, C-4), 32.9 and 24.7 ppm (q, diCH_3), 29.0 and 27.7 ppm (t, C-9, C-11), and 19.5 ppm (t, C-10). Found: C, 75.45; H, 9.06%. Calcd for $C_{13}H_{18}O_2$: C, 75.73, H, 8.74%. MS: *m/e* 206 (M^+, $C_{13}H_{18}O_2$, 63%), 191 ($C_{12}H_{15}O_2$, 8), 188 ($C_{13}H_{16}O$, 5), 178 ($C_{12}H_{18}O$, 9), 163 ($C_{11}H_{15}O$, 11), 150 ($C_9H_{10}O_2$, 41), 135 ($C_8H_7O_2$, 11), 122 ($C_8H_{10}O$, 48), 108 (C_7H_8O, 80), 94 (C_6H_6O, C_7H_{10}, 14), 83 (C_5H_7O, 100), 79 (C_6H_7, 36), and 67 (C_5H_7, 8).

Chlorination of 1a. To a solution of **1a** (0.3 g) in CCl_4 (10 ml), sulfuryl chloride (0.1 ml) in CCl_4 (5 ml) was added dropwise with stirring at 60 °C. The resulting solution was stirred for 1 h and then washed with water, aqueous sodium hydrogencarbonate and aqueous sodium chloride. After the organic solution had been dried over (sodium sulfate) and concentrated under reduced pressure, a crude crystalline compound (0.35 g) was obtained. Recrystallization (EtOH) afforded pure **9** (0.22 g); mp 130—132 °C. IR (Nujol) 1703 cm^{-1} (C=O) and 1730 cm^{-1} ($OCOCH_3$). Found: C, 63.41; H, 7.10%. Calcd for $C_{15}H_{21}O_3Cl$: C, 63.27; H, 7.38%.

From the parent solution, **11** (25 mg) was obtained; mp 163—165 °C. IR (Nujol) 1708 cm^{-1} (C=O) and 1733 cm^{-1} ($OCOCH_3$). Found: C, 56.32; H, 6.03%. Calcd for $C_{15}H_{20}O_3Cl_2$: C, 56.43; H, 6.27%.

Bromination of 1a. A mixture of **1a** (0.3 g) and pyridinium bromide perbromide (0.5 g) in acetic acid (10 ml) was stirred at room temperature until the reagent was dissolved and the mixture had reacted. The reaction mixture was poured into ice water (150 ml) and the precipitate (0.42 g) was collected. Recrystallization (EtOH) gave **10** (0.25 g); mp 142—144 °C. IR (Nujol) 1690 cm^{-1} (C=O) and 1740 cm^{-1} ($OCOCH_3$). Found: C, 54.88; H, 6.61%. Calcd for $C_{15}H_{21}O_3Br$: C, 54.73; H, 6.38%.

From the parent solution, **12** (48 mg) was obtained; mp 164—166 °C. IR (Nujol) 1705 cm^{-1} (C=O) and 1730 cm^{-1} ($OCOCH_3$). Found: C, 43.96; H, 5.14%. Calcd for $C_{15}H_{20}O_3Br_2$: C, 44.14; H, 4.90%.

Chloro-dione (13) and Bromo-dione (14). A solution of 0.35 g of **9** (or **10**) in methanol (40 ml) containing sulfuric acid (2 ml) was left to stand at room temperature for two weeks. The reaction mixture was concentrated at reduced pressure and extracted with ether. The ethereal extract was neutralized with aqueous sodium hydrogencarbonate, washed with water, and then dried over sodium sulfate. After the removal of the ether, a crystalline residue was obtained. Recrystallization from methanol gave **13** (0.10 g) (or **14** (0.12 g)).

13: mp 90—92 °C. IR and UV (see Table 1). Found: C, 64.17; H, 7.96%. Calcd for $C_{13}H_{19}O_2Cl$: C, 64.33; H, 7.84%. MS: *m/e* 242 (M^+, 1%), 207 (1.5), 188 (2), 186 (4), 175 (11), 173 (18), 152 (17), 124 (56), 109 (10), 95 (73), 92 (5), 90 (12), 83 (base, 100), 81 (25), 67 (73), 55 (38), and 41 (58).

14: mp 115—116 °C. IR and UV (see Table 1). Found: C, 54.52; H, 6.40%. Calcd for $C_{13}H_{19}O_2Br$: C, 54.37; H, 6.62%. MS: *m/e* 288 (M+2, 2%), 286 (M^+, 2), 232 (4), 230 (4), 221 (11), 219 (14), 207 (64), 179 (4), 152 (42), 136 (7), 134 (7), 124 (72), 111 (10), 109 (10), 97 (23), 95 (70), 83 (base, 100), 81 (28), 67 (56), 55 (37), and 41 (50).

Dehydrochlorination of 5, 6, and 7. A mixture of **5** (20 mg) and γ-collidine (0.5 ml) was refluxed for 10 min in a nitrogen atmosphere. Rapidly, a precipitate of γ-collidine hydrochloride was produced. The resulting mixture was diluted with petroleum ether, filtered to separate of γ-collidine hydrochloride and then washed successively with 4% aqueous hydrochloric acid, aqueous sodium hydrogencarbonate, and water. The solvent was removed and the residue was crystallized from hexane, mp 100—103 °C (92% yield). The product was identical to **8** on the basis of a comparison of their IR spectra.

A similar reaction of **6** (20 mg) with refluxing for 2 h also gave **8** (85% yield).

Similarly, **7** (0.2 g) was refluxed with γ-collidine (1.5 ml) for 2 h and treated in the manner described above. The product was crystallized from hexane, mp 90—92 °C (58 mg). Recrystallization (hexane) afforded pure **18**; mp 97—99 °C. IR (Nujol) 1690 cm^{-1} (C=O) and 1590 cm^{-1} (C=C). UV

(EtOH) λ_{max} 221.5 nm (ε, 22700), 258 (7080), and 296 (2070). ^{1}H-NMR ($CDCl_3$) 1.25 δ (s, 6H, diCH_3), 2.75 δ (s, 4H, 2CH_2), and 7.56—7.87 δ (m, 4H, ArH). Found: C, 77.18; H, 7.06 %. Calcd for $C_{13}H_{14}O_2$: C, 77.23; H, 6.93%. MS: *m/e* 202 (M^+, 14%), 174 (3), 159 (3), 146 (base, 100), 129 (4), 104 (26), 90 (9), 76 (22), 50 (9), and 41 (9), The formation of **18** from **7** probably proceeds *via* an intermediate containing a cyclopropane ring similar to **8**, followed by the opening of the cyclopropane ring at C_1–C_8 and further dehydrogenation (Scheme 4).

*Reactions of **3**, **13**, and **14** with γ-Collidine.* In the manner described above, **3**, **13**, and **14** (20 mg) were refluxed with γ-collidine for 2 h. In each case, no precipitation of γ-collidine hydrochloride occured and the starting material was recovered in a 80—87% yield, and identified by IR spectroscopy.

*4,4-Dimethylbicyclo[6.3.0]undec-5-en-2-one (**17**).* In a solution of **3** (0.3 g) in ethanol (20 ml), $NaBH_4$ (0.15 g) in ethanol (20 ml) was added at 20 °C. The solution was left to stand at room temperature for 48 h, diluted with water and extracted with ether. The ethereal solution was dried and evaporated *in vacuo*. The glassy residue (**15**) was dissolved in acetic acid (30 ml) and refluxed with zinc dust (2 g) for 1.5 h. The reaction mixture was filtered and extracted with ether. The extract was processed by the usual method and gave an oily residue (**16**); Tetranitromethane test positive. To a solution of crude **16** in acetic acid (10 ml), chromic trioxide (0.3 g) in acetic acid (12 ml) was added dropwise with stirring at 25 °C and the solution was allowed to stand at room temperature overnight, diluted with water and extracted with ether. After the usual procedure, the extract gave an oily residue. Column chromatography (on silica gel) of the product using hexane elution gave **17** (62 mg) and a by-product (54 mg) which is probably acetate of **16** (ν 1730 cm^{-1}). Product **17** was further purified by column chromatography and preparative TLC (Silica Gel G) and obtained as a colorless oil which solidified in a refrigerator and showed one peak on a VPC; Beilsteine test negative and tetranitromethane test positive. Mp 26 °C. IR (neat) 3000, 2940, and 2850 cm^{-1} (C–H), 1695 cm^{-1} (C=O), 1640 cm^{-1} sh (C=C). ^{1}H-NMR ($CDCl_3$) 0.93 δ (s, 3H, CH_3), 1.12 δ (s, 3H, CH_3) and 5.56—5.80 δ (m, 2H, olefinic). ^{13}C-NMR ($CDCl_3$) 211.6 ppm (s, C-2), 134.8 and 128.8 ppm (d, C-5, C-6), 62.6 ppm (d, C-1), 52.4 ppm (t, C-3), 43.2 ppm (d, C-8), 39.6 and 34.2 ppm (t, C-7, C-11), 33.0 ppm (s, C-4), 29.0 and 29.4 ppm (q, diCH_3), 25.8 and 23.0 ppm (t, C-9, C-10). Found: C, 81.07; H, 10.51%. Calcd for $C_{13}H_{20}O$: C, 81.25; H, 10.42%. MS: *m/e* 192 (M^+, 6%), 177 (16), 159 (2), 149 (5), 136 (28), 121 (11), 108 (base, 100), 93 (47), 81 (17), 80 (18), 79 (15), 68 (15), and 67 (14). 2,4-DNP: mp 148—149 °C.

The Transannular Cyclization and Hydrogen Shift in the Chlorination of 1,5-Cyclooctadiene and *cis*-Cyclooctene with Antimony(V) Chloride

Sakae UEMURA,* Akira ONOE, and Masaya OKANO
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611

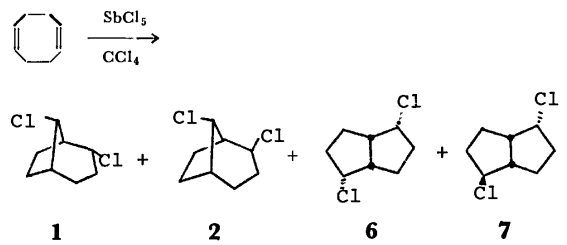
(Received September 18, 1976)

The slow addition of $SbCl_5$ to a CCl_4 solution of 1,5-cyclooctadiene or *cis*-cyclooctene gives an isomeric mixture of *endo*- and *exo*-2, *anti*-8-dichlorobicyclo[3.2.1]octanes (**1** and **2**) or an isomeric mixture of *trans*- and *cis*-1,4-dichlorocyclooctanes (**12** and **13**) respectively in a good yield. The former reaction involves the transannular cyclization, while the latter is accompanied by the transannular hydrogen shift. The addition of 1,5-cyclooctadiene to a CCl_4 solution of $SbCl_5$ (reverse addition) affords *endo*-2,6- and *endo*, *exo*-2,6-dichlorobicyclo[3.3.0]octanes (**6** and **7**) as additional products, besides **1** and **2**. In the case of *cis*-cyclooctene, however, a reverse addition produces only chlorocyclooctane. It has been revealed that a mixture of **6** and **7** is readily isomerized to a mixture of **1** and **2** by the interaction with $SbCl_5$. The 1,4-chlorination of *cis*-cyclooctene which gives **12** and **13** also occurs with VCl_4, $SeCl_4$, $PhICl_2$, and PCl_5, although the selectivity and the yield are low compared to the case of $SbCl_5$.

It has been reported that $SbCl_5$ is a good reagent for the *cis*-chlorination of simple olefins[1,2] and for the formation of *cis*-1,4-dichloro-2-butene from 1,3-butadiene.[2,3] Other features of $SbCl_5$ have recently been recognized in the favorable *cis*-chlorination of alkylphenylacetylenes[4] and in the facile isomerization of some dichloronorbornenes to other isomers.[5] As a part of the study of chlorination with $SbCl_5$, we now wish to report the unusual chlorinations of 1,5-cyclooctadiene (1,5-COD) and of *cis*-cyclooctene, both involving a transannular interaction.[6]

Results and Discussion

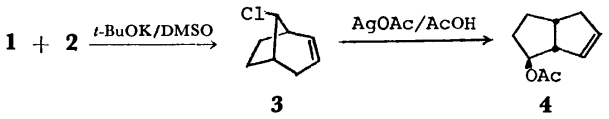
Chlorination of 1,5-COD (Table 1). When two equivalents of $SbCl_5$ in CCl_4 were slowly added to a CCl_4 solution of one equivalent of 1,5-COD at −20 °C, an isomeric mixture of *endo*- and *exo*-2, *anti*-8-dichlorobicyclo[3.2.1]octanes (**1** and **2**, respectively) was obtained in a 59% yield (**1** : **2**=67 : 33 by GLC). When equimolar amounts of $SbCl_5$ and 1,5-COD were used, the yields of **1** and **2** were increased, and the additional formation of small amounts of stereoisomeric dichlorobicyclo[3.3.0]octanes (**6** and **7**) was observed (Scheme 1). Almost identical results were obtained by the use of CH_2Cl_2 or $CHCl_3$ as the solvent. Some typical results are recorded in Table 1 (Runs 1—3).



1 **2** **6** **7**

Scheme 1.

A mixture of **1** and **2** was analyzed as $C_8H_{12}Cl_2$, did not have any absorption due to olefinic protons in its IR and NMR spectra, did not decolorize bromine in CCl_4, and was monodehydrochlorinated to *anti*-8-chlorobicyclo[3.2.1]oct-2-ene (**3**) by treatment with *t*-BuOK in DMSO (Scheme 2).



3 **4**

Scheme 2.

Here, it was observed that **2** was more readily dehydrochlorinated than **1**, as was expected from the E2 elimination.[7] In **2**, the chlorine, two carbons (C_2 and C_3), and the hydrogen on C_3 lie in a common plane. By this procedure **1** was separated from **2**. A sharp singlet at δ 3.85 in **1** and δ 4.23 in **3** could be assigned to a *syn*-hydrogen at C_8, the absorption being very similar to that of *anti*-8-chloro-*endo*-2-(methoxymethyl)bicyclo[3.2.1]octane[8] [δ 3.94, singlet] (See Experimental). Although the isolation of pure **2** was not achieved, a sharp singlet at δ 4.60 in the NMR spectrum of a mixture of **1** and **2** could be assigned to a *syn*-hydrogen at C_8 in **2**. This greater deshielding of the C_8-hydrogen in **2** than that in **1** may be due to the anisotropy of *exo*-chlorine at C_2. Additional proof for the structure of **3** was obtained by its reaction with silver acetate in acetic acid, which gave *exo-cis*-bicyclo[3.3.0]oct-7-en-2-yl acetate (**4**).[9] LeBel and Spurlock[10] have reported that **4** was formed by the acetolysis of the *p*-toluenesulfonate analogue of **3**.

It has been known that the transannular cyclization of 1,5-COD usually gives bicyclo[3.3.0]octane derivatives.[8] The formation of bicyclo[3.2.1]octane derivatives has been reported only in the case of the reaction with $MeOCH_2Y$ (Y=OAc, Cl, and OMe), and even in this case the main products were bicyclo[3.3.0]octane derivatives.[8] Considering that $SbCl_5$ is a very effective catalyst for isomerization between the isomeric dichloronorbornanes,[5] the most probable pathway for the formation of **1** and **2** seems to be that a mixture of *endo*-2,6- and *endo*, *exo*-2,6-dichlorobicyclo[3.3.0]octanes (**6** and **7**) is first formed through the **5** cation (*endo*-Cl) and then isomerized to a mixture of **1** and **2** by the $SbCl_5$ catalyst through the **8** cation (*exo*- and *endo*-Cl) (Scheme 3). In fact, when 1,5-COD was added all at once to a CCl_4 solution of equimolar $SbCl_5$ at −20 °C, instead of slow addition of $SbCl_5$ to a CCl_4 solution of 1,5-COD, the

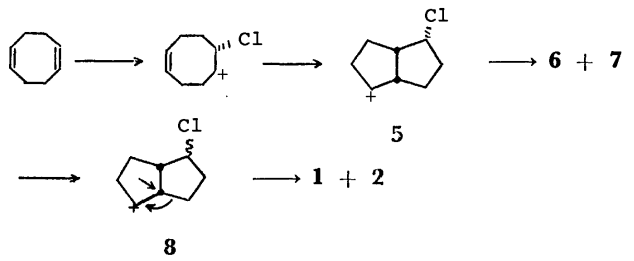
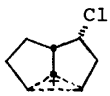


Scheme 3.

formation of considerable amounts of **6** and **7** besides **1** and **2** was observed (Table 1, Runs 4 and 5). Since **6** and **7** could not be isolated in a pure state, and since, also, several attempts at the preparation by different methods were unsuccessful, these structures were tentatively assigned by means of NMR spectra and the analytical data of the mixture (See Experimental). In separate experiments we observed that a mixture containing **1**, **2**, **6**, and **7** was readily converted to a mixture of **1** and **2** by treatment with $SbCl_5$. These results appear to show that the $SbCl_5$-catalyzed isomerization of a mixture of **6** and **7** to that of **1** and **2** considerably rapid and that their rates are sufficient to compete with that of the first step (producing **6** and **7**) of the chlorination. That is, in the case of the rapid addition of excess 1,5-COD, enough $SbCl_5$ did not remain to make the isomerization of **6** and **7** complete, because $SbCl_5$ turned to $SbCl_3$ as soon as chlorination took place. This finding parallels that in the chlorination of norbornene with $SbCl_5$.[5] Although we have not yet been successful in finding out the reaction conditions under which only **6** and **7** were formed, it may be worthwhile to refer to the facts that the isomerization is slower in the CS_2 solvent than in CCl_4 and that more **6** and **7** are obtained in this solvent (Table 1, Runs 6 and 7).

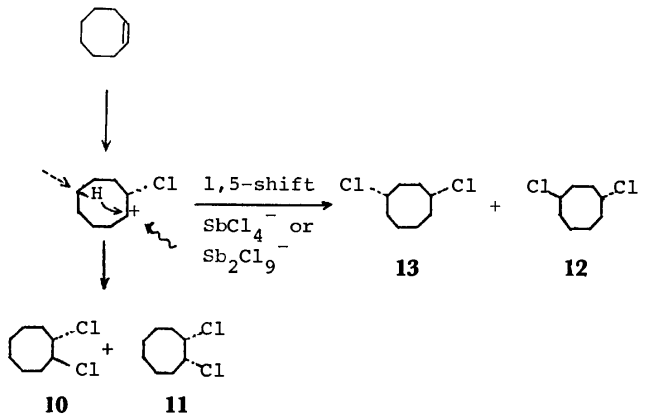
As has been described above, we proposed and partly confirmed that **1** and **2** could be formed through **6** and **7**. Apparently, another route for all the products may be considered when the attack of $SbCl_6^-$ on the nonclassical cation **9**, which is a stabilized form of **5**, is involved. However, the lesser stereospecificity in the bicyclo[3.2.1]octane ring formation and the complete absence of isomers of dichlorobicyclooctanes other than **1**, **2**, **6**, and **7** appear to imply that such a route is improbable.



9

The chlorination of 1,5-COD with other chlorinatingi agents, such as Cl_2, $PhICl_2$, $CuCl_2$, $SeCl_4$, $MoCl_5$, and $PbCl_4$, gave a mixture of *cis*- and *trans*-5,6-dichlorocyclooctenes and no **1** or **2**.[11]

Chlorination of cis-*Cyclooctene (Table 2).* The application of the chlorination with $SbCl_5$ to *cis*-cyclooctene at −30 °C (the addition of $SbCl_5$ to olefin) resulted in the preferable formation of *cis*-1,4-dichlorocyclooctane (**13**, 71% yield), together with small amounts of the *trans*-1,4-isomer (**12**, 6%) and the *cis*-1,2-isomer (**11**, 4%). It was confirmed that no interconversion occurred between the 1,2- and 1,4-isomers or also between the *cis*- and *trans*-1,4-isomers under the present conditions. The reaction apparently involves a transannular 1,5-hydride shift, and the strikingly high selectivity for the formation of the *cis*-1,4-isomer **13** may be explained by assuming a hydrogen-bridged chlorocyclooctyl cation intermediate (Scheme 4), almost the same as that



Scheme 4.

proposed in the formolysis of *cis*-cyclooctene oxide.[12] Both the total yields of the products (**10**—**13**) and the selectivities affording **13** were decreased when the reaction was carried out at 0 °C or at room temperature. A reverse addition, namely, the addition of *cis*-cyclooctene to $SbCl_5$, afforded only chlorocyclooctane at −20, 20, or 76 °C, irrespective of the speed of the addition. This may be explained by the rapid hydride abstraction by $SbCl_5$ from olefin, followed by the addition of the produced hydrogen chloride to olefin, because excess $SbCl_5$ is present in the solution when olefin has been added. Such hydride abstraction by $SbCl_5$ from alkane and alkene to form hydrogen chloride has previously been reported.[2] Although the 1,4-chlorination with $PbCl_4$ has been known,[14] $SbCl_5$ is superior to $PbCl_4$ in its yield and in its selectivity for the formation of the *cis*-1,4-isomer. This seems to be another feature of the chlorination of olefin with $SbCl_5$. As a part of our study of the chlorination of olefins with various chlorinating agents,[5,11,14] we have examined their behavior toward *cis*-cyclooctene and found that 1,4-chlorination also occurred with $PhICl_2$ (ionic condition), VCl_4, $SeCl_4$, and PCl_5, although the selectivities and the yields were low compared to those in the cases of $SbCl_5$ and $PbCl_4$. The chlorinations with $CuCl_2$, SO_2Cl_2 (radical condition), and $PhICl_2$ (radical condition) gave almost only the 1,2-somers, **10** and **11**.

Experimental

All the organic and inorganic materials were commercial products. The IR and NMR spectra were recorded with a Hitachi EPI-S2 and a Varian A-60 (CCl_4 as solvent) apparatus respectively. The GLC analyses were carried out on Shimadzu 4BMPF apparatus, using EGSS-X(15%)-Chromosorb-W (3 m), PEG 6000(25%)-Chromosorb-W (3 m), and Apiezon-L(30%)-Celite (1 m) columns (N_2 as carrier gas).

Chlorination of 1,5-COD with $SbCl_5$. To a CCl_4 (200 ml) solution of 1,5-COD (16.2 g), we slowly added a solution of $SbCl_5$ (45 g, 150 mmol) in CCl_4 (100 ml) at −20 °C under N_2 for 30 min. Aqueous NaOH was then added, and the organic layer was separated after the usual work-up. Distillation gave 13.2 g of a mixture of **1** and **2** (**1** : **2**=*ca.* 70 : 30), contaminated by a trace amount of **6**; bp 117—119 °C/22 Torr. Found: C, 53.30; H, 7.06; Cl, 39.75%. Calcd for $C_8H_{12}Cl_2$: C, 53.64; H, 6.76; Cl, 39.60%.

When 1,5-COD (5.4 g, 50 mmol) was added, all at once, to a CS_2 (100 ml) solution of $SbCl_5$ (7.5 g, 25 mmol) at a refluxing temperature, an isomeric mixture of four dichloroalkanes which contained **6** and **7** besides **1** and **2** was obtained (18 mmol, **1** : **2** : **6** : **7**=29 : 11 : 40 : 20 by GLC). Although it was not possible to isolate both **6** and **7** in a pure state by fractional distillation, two fractions (**A** and **B**) which contain mainly **6** and **7** respectively were obtained by the distillation of the combined reaction products of several runs. The NMR spectrum of Fraction **A** (bp 110—114 °C/21 Torr, **1** : **2** : **6** : **7**=7 : 4 : 14 : 75 by GLC) showed two multiplet peaks at δ 4.7—4.3 and δ 4.3—3.8 which could be assigned to *exo*- and *endo*-hydrogen in **7** respectively. Found: C, 53.37; H, 7.07%. Calcd for $C_8H_{12}Cl_2$: C, 53.64; H, 6.76%. The NMR spectrum of Fraction B (bp 118—122 °C/21 Torr, **1** : **2** : **6** : **7**=30 : 12 : 55 : 3 by GLC) showed a broad multiplet peak at δ 4.65—4.0 which could be assigned to two *exo*-hydrogen in **6**. Found: C, 52.93; H, 7.22%. Calcd for $C_8H_{12}Cl_2$: C, 53.64; H, 6.76%.

*Dehydrochlorination of **1** and **2**.* A mixture of **1** and **2** (25 g, 140 mmol) was added, drop by drop, to a DMSO (200 ml) solution of *t*-BuOK (50 g, 446 mmol) at room temperature, and then the mixture was heated to 60 °C for 10 h. The reaction mixtures were worked up by the following successive treatments: dilution with water, extraction with ether, and then the evaporation of the ether. After the fractional distillation of the residue, the monochloride (**3**; 2.8 g, 20 mmol, bp 78—81 °C/22 Torr) and the dichloride (**1**; 8.7 g, 49 mmol, bp 123—124 °C/25 Torr) were both purely isolated. **3**, NMR: δ 6.0—5.2 (m, 2H), 4.23 (s, 1H), 2.8—1.2 (m, 8H); mass: *m/e* 142 (M^+), 144 (M^++2). **1**, NMR: δ 4.1—3.85 (m, 1H), 3.85 (s, 1H), 2.7—1.2 (m, 10H); mass: *m/e* 178 (M^+), 180 (M^++2), 182 (M^++4). Found: C, 53.51; H, 7.01%. Calcd for $C_8H_{12}Cl_2$: C, 53.64; H, 6.76%. **2**, NMR: δ 4.60 (s, 1H); the other absorptions overlap those of **1** and have not been clarified.

*Acetolysis of **3**.* The reaction of **3** (2.9 g, 20.3 mmol) with AgOAc (4.0 g, 24.0 mmol) in acetic acid (40 ml) at a refluxing temperature for 10 h gave 2.1 g of **4**; bp 101—102 °C/18 Torr (lit,[9] 69—73 °C/5 Torr), *m/e* 166 (M^+). The NMR spectrum (in $CDCl_3$) of **4** was identical with that of *exo-cis*-bicyclo[3.3.0]oct-7-en-2-yl acetate reported by Fujita *et al.*;[9] δ 5.6 (s, 2H), 4.9—4.7 (m, 1H), 1.94 (s, 3H), 3.1—1.2 (m, 8H).

*Isomerization of a Mixture of **6** and **7** to a Mixture of **1** and **2** with $SbCl_5$.* A CCl_4 (10 ml) solution containing a

mixture of the dichlorides (0.14 g, 0.76 mmol; **1** : **2** : **6** : **7**= 29 : 11 : 40 : 20) and $SbCl_5$ (0.65 g, 2.2 mmol) was kept at 0 °C for 30 min. A GLC analysis of the CCl_4 layer after a usual work-up revealed the presence of a mixture of **1** (63%) and **2** (37%); yield of the mixture, 65%.

Chlorination of cis-*Cyclooctene with* $SbCl_5$. To a solution of *cis*-cyclooctene (5.5 g, 50 mmol) in CCl_4 (40 ml), we added $SbCl_5$ (7.5 g, 25 mmol) in CCl_4 (10 ml) at −30 °C under N_2 for 30 min; aqueous NaOH was then added to stop the reaction. After the usual work-up, the distillation of the organic layer afforded 2.3 g of **13** in an almost pure state; bp 115—118 °C/8 Torr (lit,[13] 116—119 °C/10 Torr). NMR: δ 4.5—3.9 (m, 2H), 2.4—1.8 (m, 12H). The NMR spectrum was identical with that of *cis*-1,4-dichlorocyclooctane reported by Havinga *et al.*[13]

When the reverse addition was carried out at 20—30 °C under N_2——namely, the addition of *cis*-cyclooctene (5.5 g, 50 mmol) to a solution of $SbCl_5$ (7.5 g, 25 mmol) in CCl_4 (100 ml), chlorocyclooctane (1.2 g, bp 98—104 °C/30 Torr, lit,[15] 82—90 °C/21 Torr) was the sole product; none of dichlorocyclooctane was formed.

The chlorinations with other metal salts were carried out by almost the same method as those previously reported.[5,11,14]

We wish to thank Dr. Kahee Fujita of Department of Pharmaceutical Sciences of Kyushu University for showing us the NMR spectrum of **4**.

Photochemical Valence Bond Isomerization of Some Benzo-C_9H_{10} Hydrocarbons*

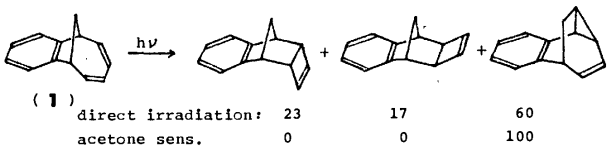
Masahiko KATO, Takeji CHIKAMOTO, and Toshio MIWA

Faculty of Science, Osaka City University, Sugimoto-cho, Sumiyoshi-ku, Osaka 558

(Received September 18, 1976)

Studies have been carried out on the photochemical valence bond isomerization of some benzobicyclo-C_9H_{10} hydrocarbons, *i. e.*, benzo[8,9]bicyclo[5.2.0]nona-2,4,8-triene (**2**), benzo[2,3]bicyclo[6.1.0]nona-2,4,6-triene (**3**), *cis*-3*a*,9*b*-dihydro-1*H*-benz[*e*]indene (**6**), and benzo[6,7]bicyclo[3.2.2]nona-2,6,8-triene (**10**), with use of a low pressure mercury lamp. From a comparison of photolysis at low temperatures with that at room temperature, the stereochemical courses are discussed in terms of conformations of these compounds.

Interest has been taken in the thermal isomerization of benzo-C_9H_{10} hydrocarbons in connection with the valence bond isomerization of parent C_9H_{10}-hydrocarbons,[1] several studies[2] having been carried out. In the photochemical reaction of benzo[7,8]bicyclo-[4.2.1]nona-2,4,7-triene (**1**), Hahn and Johnson reported a difference in the product distribution between the direct and sensitized irradiation.[3] Their recent

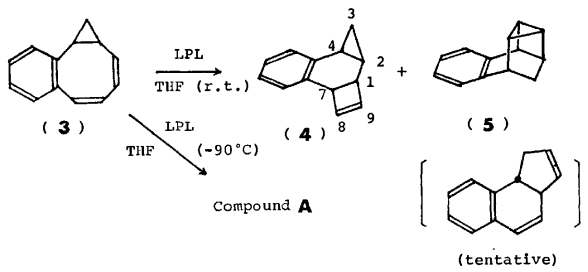


Scheme 1.

paper on photochemical rearrangements of benzo[2,3]-bicyclo[6.1.0]nona-2,4,6-triene (**3**) with use of a medium pressure mercury lamp (MPL)[4] has prompted us to report our independent study* on these reactions and those of other benzo-C_9H_{10} hydrocarbons photoinduced by a low pressure mercury lamp (LPL). Compound **3** was formed by thermal isomerization of **2**,[2a] both **2** and **3** being related to (*Z*,*Z*,*Z*,*Z*)-benzo[2,3]cyclonona-1,3,5,7-tetraene. Photochemical interconversion of these compounds is allowed in view of the orbital symmetry rule.

Results and Discussion

Photolysis of Benzo[2,3]bicyclo[6.1.0]nona-2,4,6-triene (3). Photolysis of **3** in tetrahydrofuran using an LPL at room temperature gave, along with some Skellysolve B insoluble polymeric material, a Skellysolve B soluble hydrocarbon mixture consisting of more than 70% *anti*-benzo[5,6]bicyclo[5.2.0.$0^{2,4}$]nona-5,8-diene (**4**) and less than 30% benzotetracyclononene (**5**).[5] The structure of **4** was deduced from its spectral data. The small coupling between H_1 and H_2 in the NMR spectrum is consistent only with the *anti*-structure. Compound **5** was also obtained by UV irradiation of *cis*-3*a*,9*b*-dihydro-1*H*-benz[*e*]indene (**6**) (*vide infra*). The latter compound is very likely to be an intermediate product in the formation of **5** from **3**. The production of **4** and **5** by photolysis of **3** with an MPL was reported by Hahn and Johnson, but their product ratio of **5** to **4** is larger than that we obtained using an LPL. Since it is reasonable to assume that the efficiency of a four pi-electrocyclic reaction is much grater with an LPL than that with an MPL, **4** was considered to be the main product in our experiment.



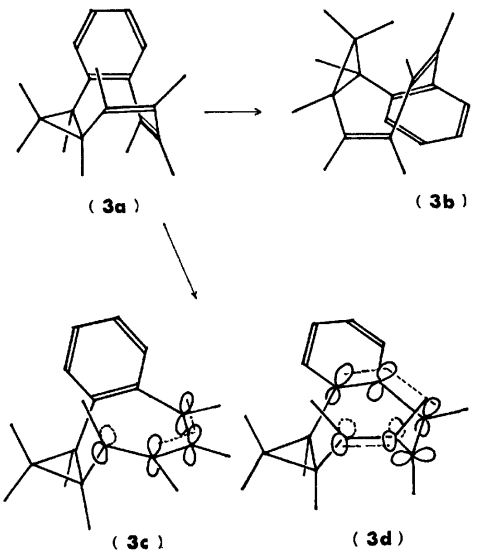
Scheme 2.

On the other hand, when **3** dissolved in THF-d_8 in a quartz NMR tube was irradiated at −90 °C using the same lamp, an unknown isomer **A**[6] (mass *m/e* 168 (M^+)) was obtained along with some polymeric material at the expense of **3**. Compound **4** was not detected.

The rigid extended conformation (**3a**) for **3** in its ground state very likely predominates at ambient temperature from the fact that thermal rearrangement occurs moderately only at elevated temperature, 150 °C, probably *via* inversion to the envelope conformer (**3b**), and that the NMR spectrum of **3** shows no temperature dependence in the range from room temperature to −90 °C. The following surmise on the photochemical behavior of **3** is possible from an examination of the molecular model. If the excitation occurs with 2537 Å light, one of the double bonds slightly conjugated to phenyl or another ethylenic group would change the conformation by turning its p-orbitals to nearly right angles to each other,[7] and the p-orbitals would enter into conjugation with either an aromatic or some other olefinic double bond as depicted in **3c** and **3d** with no additional strain. Since **3c** and **3d** are more flexible than **3a** or **3b** at room temperature, fast bonding between the nearest lobes of p-orbitals at C_4 and C_7 occurs in disrotatory motion to give **4**.[8]

On the other hand, **3** would be more firmly fixed in the extended conformation, **3a**, at −90 °C, rearrangement to **4** thus being suppressed and some other slow reaction becoming dominant. In sensitized irradiation at room temperature, **3** gives **6**[4] probably through inversion to **3b** from its triplet state followed by allowed

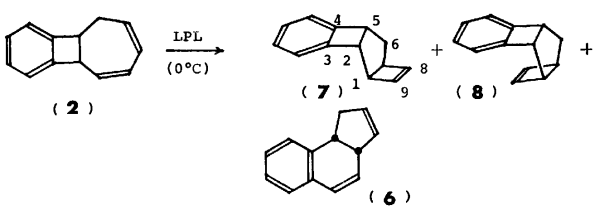
* Parts of this work (on the photolysis of Compounds **3** and **6**) were presented at the 30th Spring Meeting of the Japan Chemical Society, April 1—4, 1974 (Osaka). See the abstracts (1974), p. 1528.



Scheme 3.

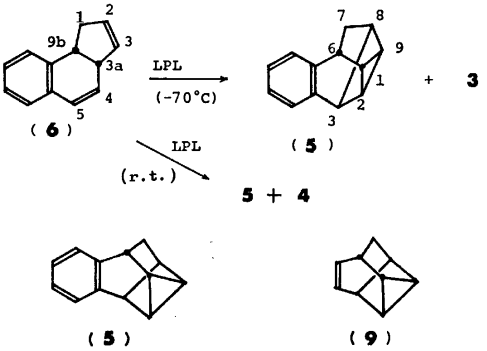
1,3-sigmatropic shift of 1-8 bond to 1-6.

Photolysis of Benzo[8,9]bicyclo[5.2.0]nona-2,4,8-triene (2). Irradiation of **2** in methanol with an LPL for 35 min gave three compounds; **6** (yield 9%), **7** (15%), and **8** (15%). They were separated by GLC, **7** and **8** being identified respectively as *anti*- and *syn*-benzo[3,4]-tricyclo[5.2.0.$0^{2,5}$]nona-3,8-diene in the following way. The UV spectra of the two compounds [**7** λ_{max}^{EtOH}: 262 (log ε, 3.16), 268 (3.34), 274 (3.31); **8** λ_{max}^{EtOH}; 265 sh (3.13), 270 (3.27), 276 (3.22)] showed a strong benzenoid band, suggesting the presence of benzocyclobutene moiety.[9] Their NMR spectra showed AB type proton signals characteristic of cyclobutene olefinic: δ 6.04 and 5.96 ppm (J=2.6 Hz) in **7** and δ 5.90 and 5.55 ppm (J=2.5 Hz) in **8**. Comparing the spectra with those of bicyclo[3.2.0]hept-6-ene derivatives,[10] and considering the splitting pattern of C_2 protons [**7** δ 3.76, d, $J_{2,5}$=4.0 Hz; $J_{1,2}$=quite small; **8** δ 3.94, d,d $J_{1,2}$= 9.0 Hz, $J_{2,5}$=5.0 Hz], we conclude that the structures of **7** and **8** are respectively of *anti* and *syn* conformation. Hahn and Johnson reported the formation of **3**, **6**, and **5** in addition to the main product (**7**) by photolysis of **2** with an MPL.[4] It is worth while to note that a new electrocyclic reaction product **8** was produced in an amount almost equal to that of **7** in the photolysis with an LPL. Neither **3** nor **4** was detected in the UV irradiation mixture of **2**. Even if compound **3** is formed, showing a high intensity absorption at 258 nm in UV spectrum, it would absorb light of the LPL to undergo change to **4** and others. The presence of **6** and the absence of **4** suggest a possible direct route from **2** to **6** under the present conditions.



Scheme 4.

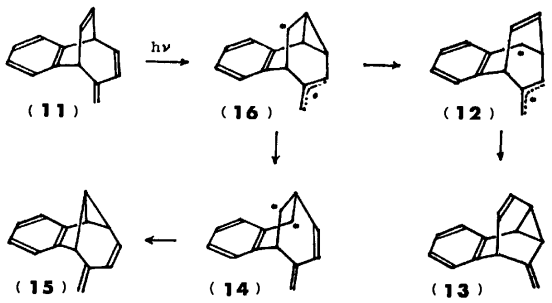
Photolysis of cis-*3a,9b-Dihydro-1H-benz*[e]*indene (6).* In the photochemical isomerization of the parent C_9H_{10}-hydrocarbons, it was reported that *cis*-8,9-dihydroindene and *cis*-bicyclo[6.1.0]nona-2,4,6-triene afford a similar photostationary mixture *via cis-trans* interconversion between (*E,Z,Z,Z*)- and (*Z,Z,Z,Z*)-cyclonona-1,3,5,7-tetraene.[1a] Taking this into consideration, we studied the photochemical behavior of **6**. Benzo[4,5]tetracyclo[4.3.0.$0^{2,9}$.$0^{3,8}$]non-4-ene(**5**) was formed readily, along with **4**, by irradiation of **6** with an LPL at room temperature. Compound **5** was separated by means of GLC and characterized by UV and NMR spectra. The unusually high field resonance of one of the methylene protons in the NMR spectrum was observed in the case of a similar compound (**9**).[1b] The formation of **3** from **6** has been proved by photolysis at low temperature, a condition which suppresses the conversion of **3** into **4**.



Scheme 5.

Thus compound **6** dissolved in THF in a quartz NMR tube was irradiated with an LPL at −65——70 °C and was partly transformed into **5** along with a small quantity of **3**. The acetophenone sensitized irradiation of **6** proceeded more distinctly, compound **5** being the only product detected.

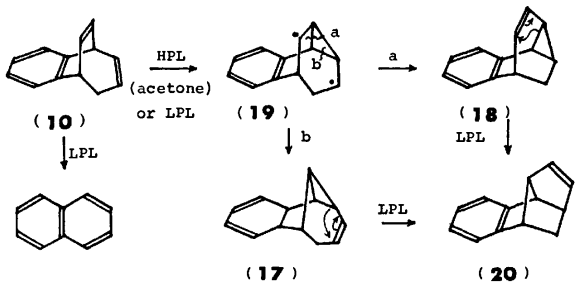
Photolysis of Benzo[6,7]bicyclo[3.2.2]nona-2,6,8-triene (10). Photochemical isomerization of **10** has been studied, since 4-oxo derivative of **10** is photochemically related to 1-oxo derivative of **6**.[11] Sensitized photochemical isomerization of this sort of compound has been extensively studied and found to proceed in two directions through di-pi-methane mechanism.[12] In the case of the 9-*exo*-methylene analogue (**11**) of **10**, two products are formed, of which **13** is formed through stabilized biradical **12**



Scheme 6.

preferably to **15** produced through less stabilized biradical **14**.

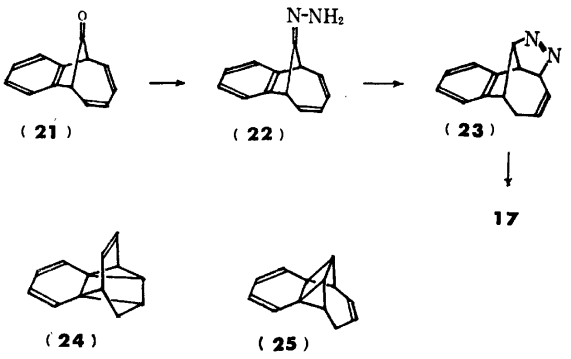
In contrast, photolysis of **10** in acetone[13] using a high pressure mercury lamp (HPL) through a Pyrex filter gave rise to the formation of **17** and **18** in 52 and 9% yields, respectively, accompained by recovery of **10** (15%). If we assume that the initial bonding occurs between olefinic carbons as observed in the case of benzobicyclo[2.2.2]octatriene,[14] the reaction is governed by the comparative easiness of bond fission at *b* rather than *a* in the biradical intermediate (**19**). From an examination of the molecular model, the bond C_1–C_2 is seen to be more parallel to benzenoid pi-orbitals than the bond C_1–C_8. Thus the fission at *b* predominates over *a* to give **17** as the main product.



Scheme 7.

The difference in behavior of benzobicyclo[2.2.2]-octatriene in direct and sensitized irradiation[14] led us to study direct photolysis of **10**. When irradiation was carried out by use of an LPL at room temperature, **10** in ether was transformed into **17** (18%) and **18** (12%) accompanied by naphthalene (8%)[15] and a new compound (**20**)(11%). Both **17** and **18** isolated in pure form were independently transformed entirely into **20** by photolysis (LPL) in quartz NMR tubes in ether solution; *i.e.*, **17** gave **20** in 52% yield after 12 h irradiation, and **18**, **20** in 4% yield after 15 h irradiation. In acetone using a HPL, both **17** and **18** remained unchanged. Examination of Newman's projection formula of **17** and **18** revealed that in **17**, pi-electron at C_3 position is nearly parallel to the sigma bond at C_2 extended to C_9, while in **18**, the C_6–C_7 olefinic plane bisects the interior angle at C_8 of the three membered ring. It is reasonable to assume that the fission of C_2–C_9 in **17** is easier than that of C_2–C_8 in **18**, if we assume that the difference in ring strains between **17** and **18** is small. From the experiments, it is evident that, in contrast to benzobicyclo[2.2.2]-octatriene, **10** does not undergo the rearrangement involving aromatic-olefinic [$\pi 2+\pi 2$] intermediates such as **24** and **25**, **20** being a secondary product originating mainly from **17** and partly from **18** on irradiation of **10** using an LPL.

Characterization of ***17***, ***18***, *and* ***20***. Compound **17** was synthesized starting from benzo[7,8]bicyclo-[4.2.1]nona-2,4,7-trien-9-one (**21**)[16] as follows. Its hydrazone (**22**) was treated with potassium *t*-butoxide in DMSO giving its isomeric azo-compound (**23**), which was either pyrolyzed at 180 °C or photolyzed with a HPL (Pyrex filter) to give **17**, each in 70% yields. The compound was identical with a product obtained by photolysis of **10**.



Scheme 8.

Benzobarbaralane (**18**) is one of the products obtained by the thermal rearrangement of **10**,[2b] the physical data being identical with those reported.

The structure of **20** was deduced mainly on the basis of its NMR spectrum and decoupling experiments. The UV spectrum [λ_{max}^{EtOH}: 262 (log ε, 3.14), 268 (3.16), 275 (3.13)] showed the presence of benzocycloalkene moiety of ring size less than 5.[17] Introduction of a methylene group and an ethylenic linkage without conjugation to aromatic ring, and its structural relationship to **17** and **18** make up the structure of **20**.

As expected, the proton coupling constants (Table 1) of **20** were similar to those of norbornane and norbornene,[18] strongly supporting the structure.

TABLE 1. THE PMR CHEMICAL SHIFTS AND THE COUPLING CONSTANTS OF COMPOUND **20** BY MEANS OF THE FIRST-ORDER ANALYSIS OF THE 100 MHz SPECTRA AND ITS DECOUPLING EXPERIMENTS

Chemical shifts (δ):

7.3—6.74 ppm	m	Ar-H	2.74—2.56	m	H_3
6.38	d, d	H_9	2.50—2.32	m	H_1
5.72	d, d, d	H_8	1.38	d, d	H_{2exo}
3.3—3.02	m	H_6, H_7	1.19	d, d	H_{2endo}

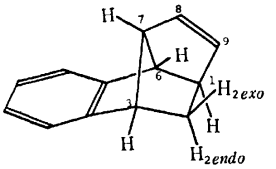
Coupling constants (J):

$J_{2exo,3}$=5.0 Hz — $J_{1,9}$=3.4 Hz

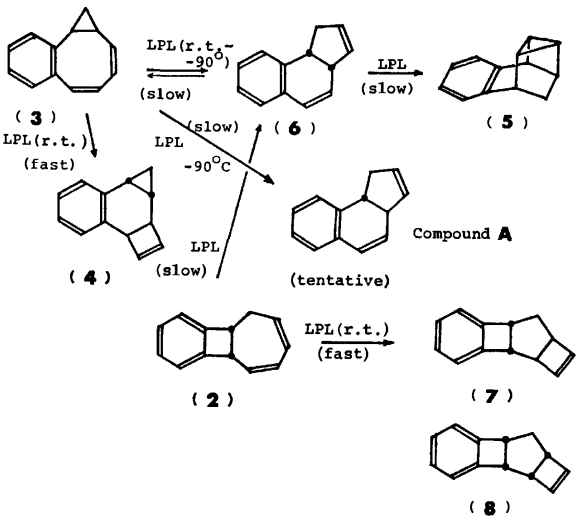
$J_{1,2endo}$=4.5 Hz — $J_{7,8}$=2.8 Hz

$J_{8,9}$=5.8 Hz — $J_{2exo,2endo}$=11.0 Hz

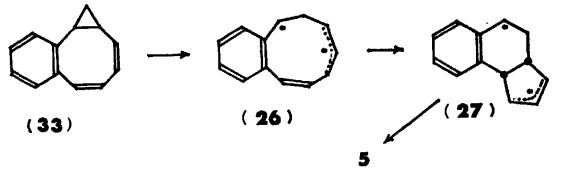
$J_{2endo,3}$, $J_{1,2exo}$, $J_{3,7}$; quite small



The photochemical relationship between compounds **2**—**8** is summarized in Scheme 9. We could not obtain evidence for the transient formation of **26** when **2**, **3** and **6** were photolysed. We consider that the formation of **5** on photolysis of **2** and **3** takes place *via* an intermediate **6** and not *via* a route involving **26** and **27**.



Scheme 9.



Scheme 10.

Experimental

The NMR spectra were obtained on a JEOL Model PS-100 spectrometer, with tetramethylsilane as the internal standard. The chemical shifts are expressed in ppm from TMS. The Mass spectra were measured on a Hitachi RMU-6 mass spectrometer by the indirect injection method at 180 °C. The IR were recorded on a JASCO Model IRE spectrometer, and the UV on a Hitachi Recording Spectrometer, Model EPS-2 or Model 323. VPC analysis was carried out on a Varian Aerograph Model-90P gas chromatograph under the quoted conditions. The NMR measurements at low temperatures were carried out at the University of Alberta by courtesy of Professor Satoru Masamune.

Photolysis of Benzo[2,3]bicyclo[6.1.0]nona-2,4,6-triene (3). Irradiation at Room Temperature: The triene **3** (14 mg), dissolved in anhydrous THF (1 ml) in a sealed quartz test tube, was externally irradiated with an LPL (200 Watts) for 30 min. The subsequent evaporation of the solvents gave a semi-solid, which was extracted with Skellysolve B. The Skellysolve B soluble oily material (10.5 mg) showed an NMR spectrum mainly composed of **4**, along with some **5**. The GLC separation of **4** was carried out using GLC [10% Apiezone L on Chromosorb WAW 1/4″×6 ft; He flow rate, 40 ml/min; column temperature, 150 °C; retention time, 20 min]. **4** UV, λ_{max}^{EtOH}; 258 (infl.), 270.5, 280. NMR (CCl_4) δ: 6.7—7.2 (4H, m), 6.20, 6.10 (H_8, H_9, AB-type, J=2.7 Hz), 3.70, 3.50 (H_1, H_7, AB-type, J=4.5 Hz), 1.86 (H_4, d, J=2.1, t, J=4.3 Hz), 1.43 (H_{3exo}, d, J=2.9, t, J=4.3 Hz), 1.06 (H_2, d, J=4.3, t, J=2.1 Hz), 0.22 (H_{3endo}, d, J=2.9, t, J=2.1 Hz). MS (80 eV), *m/e* (rel. intensity), 168(M^+,63), 167(100), 165(46), 153(73), 152(52), 141(39), 115(55), 83(27). Found: C, 92.88; H, 7.12%. Calcd for $C_{13}H_{12}$: C, 92.81; H, 7.19%.

Irradiation at −90 °C: Compound **3** (17 mg), dissolved in THF-d_8 (0.3 ml) containing 15% of TMS, was degassed and sealed in a quartz NMR tube. This was then irradiated at −90 °C for 6 h while the reaction was monitored by NMR measurements at −90 °C. The gradual appearance of a sharp singlet at 6.48 ppm in compensation for those of the starting material was noticed. After six hours' irradiation, the peak height at 6.48 ppm became almost the same intensity as the 2H signal at 5.74 ppm of the starting **3**. The NMR spectra of the mixture remained unaltered when taken at several elevated temperatures, *i.e.*, −60, −30, 0 °C, and room temperature. After the evaporation of the solvent, a Skellysolve B insoluble material (4 mg) was filtered out and the soluble part (13 mg) was separated by GLC [10% Apiezone L on Chromosorb WAW, 1/4″×5 ft; He, 38 ml/min; 138 °C]. The materials corresponding to Peak 1 [retention time, 17.9 min; 7.5 mg] and Peak 2 [r.t., 21.1min; 2.6 mg] were collected. The physical data of the former were consistent with those of **3**.[17] The latter was separated again using GLC[10% Carbowax 20M on Chromosorb WAW 1/8″×6ft; He, 40 ml/min; 160 °C] and gave two peaks in almost equal intensities [r.t., (*i*) 11.8 min; (*ii*) 12.9 min]. From the physical data, it was revealed that the compound corresponding to *i* was an unknown substance, A[6], while the one corresponding to *ii* was **6**.[17,18] The physical data of **3** and **6**: **3**; IR $\nu_{max}^{liq.\ film}$: 3050, 3000, 2910, 2840, 1497, 1455, 1448 sh, 1125, 1115, 1030, 985, 945, 895, 850, 830, 790, 782, 760, 724, 700 cm^{-1}. UV λ_{max}^{EtOH}: 259 (log ε; 3.69), 269(3.61). NMR (CCl_4) δ: 7.40—6.80 (4H, m), 6.53 (H_4, d, J=12 Hz), 5.99 (H_5, broad d, J=12 Hz), 5.71 (H_6, H_7 ,broad s), 2.01 (H_1, broad t, d, $J_{1,8}=J_{1,9exo}$=8.8 Hz, $J_{1,9endo}$=6.0 Hz), 1.57 (H_8, broad t, d, $J_{1,8}=J_{8,9exo}$=8.8 Hz, $J_{8,9endo}$=6.0 Hz), 1.06 (H_{9exo}, t, d, $J_{1,9exo}=J_{8,9exo}$= 8.8 Hz, $J_{9exo,9endo}$=4.0 Hz), 0.53 (H_{9endo}, t, d, $J_{1,9endo}=J_{8,9endo}$=6.0 Hz, $J_{9exo,9endo}$=4.0 Hz). MS (80 eV), *m/e* (rel. intensity), 168 (M^+, 84), 167(100), 166(22), 165(47), 153 (55), 152(41). Found: C, 92.52; H, 7.27%. Calcd for $C_{13}H_{12}$: C, 92.81; H, 7.19%. **6**; UV λ_{max}^{EtOH}: 225 sh (log ε; 4.32), 261(3.89), 269.5(3.90), 280 sh (3.66). NMR(CCl_4) δ: 7.08—6.81 (4H, m), 6.21 (H_5, d, d, $J_{4,5}$=9.6 Hz, $J_{5,3a}$=2.6 Hz), 5.93—5.70 (H_2, H_3, m), 5.46 (H_4, $J_{4.5}$= 9.6 Hz, $J_{4,3a}$=2.6 Hz), 3.71—3.29 (2H, m), 2.86—2.11 (2H, m). MS (80 eV), *m/e* (rel intensity), 168 (M^+, 100), 167(97), 166(26), 165(46), 153(53), 152(32). Found: C, 92.65; H, 7.17%. Calcd for $C_{13}H_{12}$: C, 92.81; H, 7.19%.

Photolysis of Benzo[8,9]bicyclo[5.2.0]nona-2,4,8-triene (2). Compound **2** (170 mg), dissolved in methanol (150 ml), was irradiated using an LPL (10 watts) for 35 min under nitrogen with external cooling. After the rough separation of the products by column chromatography on alumina, the hydrocarbon mixture was separated by GLC [10% Apiezone L on Chromosorb WAW 1/4″×5 ft; He 40 ml/min; 150 °C], yielding **7** (15%), **8** (15%), and **6** (9%). Physical data of **7** and **8**: **7**; NMR (CCl_4) δ: 7.25—6.76 (4H, m), 6.04 (1H, d, J=2.6 Hz), 5.96 (1H, d, J=2.6 Hz), 4.32 (H_5, m), 3.76 (H_2, d, J=4.0 Hz), 3.72—3.56 (H_7, m), 3.38 (H_1, d, J=3.5 Hz), 2.08—1.60 (H_6, m). **8**; NMR (CCl_4) δ: 7.15—6.60 (4H, m), 5.90 (1H, d, J=2.5 Hz), 5.55 (1H, d, J=2.5 Hz), 4.32—4.1 (H_5, m), 3.94 (H_2, d, d, J=9.0, 5.0 Hz), 3.72—3.48 (H_1, H_7, m), 1.80—1.52 (H_6, m).

Photolysis of Benzo[2,3]bicyclo[4.3.0]nona-2,4,7-triene (6). Compound **6** (50 mg), dissolved in THF (0.6 ml) in a quartz NMR tube, was degassed and sealed. The tube was then irradiated externally with an LPL (200 watts) while being cooled externally with dry ice–methanol in a quartz Dewar bottle with a quartz window. In the course of 7 hours' irradiation, a characteristic broad doublet at δ 0.61 ppm appeared, and gradually increased in the NMR spectrum. The separation of the products by column chromatography on silicic acid gave a colorless liquid (21 mg), which contained

6, **5**, and **3** in a ratio of *ca.* 6 : 3 : 1, as estimated by means of the NMR spectrum. The GLC separation of the liquid was carried out as follows: 10% Apiezone L on Chromosorb WAW 1/4″×6 ft; He, 40 ml/min; 147 °C: Retention times; **5**, 22 min; **3**, 24 min; **6**, 28 min. **5**; NMR (CCl_4) δ: 7.2—6.8 (4H, m), 3.44 (2H, m), 2.56 (1H, m), 2.88 (1H, m), 2.05—1.6 (3H, m), 0.62 (1H, d, J=10 Hz).

Similarly, **6** (20—70 mg), dissolved in THF (80 ml), was irradiated using an LPL (10 watts) at room temperature for 1 h under nitrogen; this resulted in **5** and **4**, instead of **5** and **3**. The NMR analysis of the products revealed that it contained **5** and **4** in a ratio of *ca.* 3 : 1.

*Photolysis of Benzo[6,7]bicyclo[3.2.2]nona-2,6,8-triene (**10**).*

Irradiation Using a HPL (Ushio High Pressure Mercury Lamp, UM-425, 450 Watts) in Acetone: Compound **10** (300 mg), dissolved in acetone (350 ml), was irradiated using a HPL through a Pyrex filter under nitrogen for 70 min. After a usual work up, the product was roughly chromatographed on silicic acid (hexane), giving a colorless liquid (228 mg). The GLC separation of the liquid, performed on 10% Apiezone L on Chromosorb WAW at 141 °C, gave three peaks, which led us to estimate the yields as follows; **10** (15%), **17** (52%), and **18** (9%). The tetracyclic compound, **17**, was identical with the sample synthetically obtained below. **18**; IR $\nu_{max}^{liq.\ film}$: 3020, 2916, 2840, 1629, 1495, 1462, 1040, 1025, 1000, 962, 945, 868, 835, 810, 781, 767, 740, 707 cm^{-1}. NMR (CCl_4) δ: 7.3—6.8 (4H, m), 5.88—5.4 (2H, finely-splitted m), 3.20 (1H, b), 2.52 (1H, t, J=8Hz), 2.3—1.9 (2H, m), 1.44 (1H, t, J=2Hz). MS (80 eV) *m/e* (rel intensity), 168(M^+, 100), 167(90), 165(29), 153(48), 152(27).

Irradiation Using an LPL at 0 °C: Compound **10** (188 mg), dissolved in ether (230 ml), was irradiated using an LPL (10 watts, immersion type) for 4.5 h under nitrogen while the reaction was monitored with TLC. After the evaporation of the solvent, the residue was chromatographed on silicic acid (hexane), and the hydrocarbon fractions were collected. The GLC analysis [5% Apiezone L, 1/4″×6 ft; He, 50 ml/min; 141 °C] revealed that it contained five species, estimated to be as follows: Retention times (yield); (a) 3.2 min (naphthalene, 8%), (b) 5.7 min (**20**, 11%), (c) 8.1 min (**10**, 18%), (d) 9.4 min (**17**, 18%), (e) 12 min (**18**, 12%). They were separated in pure forms and characterized. **20**; IR $\nu_{max}^{liq.\ film}$: 3060, 2970, 2865 1572, 1328, 1265, 958, 915, 866, 726, 729 cm^{-1}. NMR: Table 1. MS (80 eV), *m/e* (rel intensity); 168 (M^+, 88), 167 (100), 165 (28), 153 (38), 152 (23).

*The Direct Irradiation of **17** and **18** Using an LPL*: Compound **17**, (20 mg), dissolved in anhydrous ether (0.5 ml) in a quartz NMR tube, was irradiated using an LPL (10 Watts) for 12 h at 0—5 °C. The NMR and GLC analysis of the products showed that they were composed of **20** and **17** in a ratio of 48 : 52. The same experiment using **18** (20 mg) instead of **17** was also carried out (15 hs' irradiation). The products were **20** and **18** in a ratio of 4 : 96.

*Synthesis of **17**. Preparation of the Hydrazone (**22**)*: The **21** ketone (180 mg) and 100% hydrazine hydrate (0.4 ml), dissolved in absolute ether (7 ml), were stirred under reflux for 20 h. The solvent was then evaporated *in vacuo*, and the residual liquid, dissolved in benzene, was dried with anhydrous sodium sulfate. The subsequent evaporation of the solvent gave a crude hydrazone (220 mg). **22**; IR $\nu_{max}^{liq.\ film}$: 3360, 3200, 3020, 2940 cm^{-1}, (no νC=O). NMR ($CDCl_3$) δ: 7.22, 7.19 (4H, Ar-H), 6.4—5.5 (4H, m), 4.56 (1H, d, J=8 Hz), 4.08 (1H, d, J=8 Hz), 6.0—4.0 (very broad, N-H).

*9,10 - Diazabenzo [2,3] tricyclo [6.3.0.0^{4,11}] undeca - 2,6,9 - triene (**23**)*: To the hydrazone (**22**), dissolved in anhydrous DMSO (1.5 ml), was added, drop by drop, a solution of potassium *t*-butoxide (1.5 g) in DMSO (3.8 ml) over a period of 95 min. After the mixture had then been stirred further for 19 h at room temperature, it was poured into water and extracted with dichloromethane. The combined organic extracts were washed with water, dried (anhydrous Na_2SO_4), and concentrated to dryness. The residue was chromatographed on silicic acid, using hexane–ether (10 : 1 v/v) as the solvent. The crude crystalline product (138 mg) was purified by sublimation. **23**; 100 mg (52%), mp 80—81 °C. UV λ_{max}^{EtOH}: 261.5 (log ε, 2.90), 268.5 (3.08), 275.5 (3.09), 335(2.53). IR $\nu_{max}^{CCl_4}$: 3040, 2960, 1537, 1485, 1465 cm^{-1}. NMR (CCl_4) δ: 7.2—6.84 (4H, m), 5.58 (H_{11}, t, J=8Hz), 5.68—5.16 (H_6,H_7,H_8, m), 3.77—3.56 (H_4, m), 3.31 (H_1, bt, J=8Hz), 2.38—1.80 (H_5, 2H, m). Found: C, 79.71; H, 6.25; N, 13.81%. Calcd for $C_{13}H_{12}N_2$: C, 79.56; H, 6.16; N, 14.28%.

*Preparation of **17**: Photolysis of the Azo Compound (**23**).* The azo compound, **23** (12 mg), dissolved in anhydrous ether (1.5 ml), was irradiated for one hour with a HPL through a Pyrex filter at room temperature. Silicic acid chromatography of the products gave pure **17** (7 mg; 69%).

*Thermal Decomposition of **23**.* Compound **23** (30 mg), dissolved in diethylene glycol (1 ml), was heated at 180 °C for 4 h. The reaction mixture was then poured into water and extracted with ether. After being washed and dried, the combined organic layer was concentrated and chromatographed on silicic acid (hexane–ether 1: 1 v/v) to give **17** (18 mg; 70%), along with recovered **23** (7 mg). **17**; IR $\nu_{max}^{liq.\ film}$: 3025, 2910, 2840, 1483, 1462, 1182, 1142, 1027, 998, 943, 912, 880, 843, 808, 772, 745, 718 cm^{-1}. UV λ_{max}^{EtOH}: 266.5 sh (log ε, 2.95), 272(3.07), 279.5(3.03). NMR (CCl_4) δ: 7.2—6.7 (4H, m), 5.7—5.3 (H_3, H_4, m), 3.50 (H_6, d, t, $J_{1,6}$=6.0 Hz, $J_{6,5exo}$=$J_{6,5endo}$=3.2 Hz), 2.74—2.32 (H_{5exo}, m), 2.50 (H_9, d, d, $J_{1,9}$=6.0, $J_{2,9}$=7.5 Hz), 2.12 (H_1, q, $J_{1,9}$=$J_{1,6}$=6.0, $J_{1,2}$=7.5 Hz), 1.87 (H_{5endo}, d,d,d, $J_{5endo,5exo}$=16.5 Hz, $J_{4,5endo}$=5.5 Hz, $J_{6,5endo}$=2.7 Hz), 1.52 (H_2, broad t, $J_{2,9}$=$J_{1,2}$=7.5 Hz). MS (80 eV), *m/e* (rel. intensity), 168 (M^+, 91), 167(100), 165(49), 153(77), 152(66), 141(21), 115(47). Found: C, 92.81; H, 7.29%. Calcd for $C_{13}H_{12}$: C, 92.81; H, 7.19%.

The authors thank Professor Satoru Masamune, who kindly allowed one of them (M.K.) the use of his low temperature photochemical apparatus at the University of Alberta, for his helpful discussions. The authors are grateful to Mr. Jun-ichi Goda for the analytical data and to Dr. Yoshiko Hirose of the Institute of Food Chemistry for the mass spectral measurements.

5) It has been reported that Compounds **4** and **5** were formed in a ratio of 1.0 : 1.2 when Compound **3** was irradiated using an MPL.[4]

6) Owing to its limiting amount, the structure of the unknown substance, **A**, has not yet been limited. This compound was thermally stable and showed a fragmentation pattern in its mass spectrum very similar to that of **6**. The UV spectrum of this compound exhibited strong absorptions at 247 and 255 nm. Its NMR spectrum showed a sharp aromatic proton peak at 7.01, olefinic at 6.38 and 5.96 ppm and aliphatic at 3.6—2.1 ppm in a ratio near 4 : 2 : 2 : 4. The catalytic hydrogenation of **A** gave 2,3-dihydro-1*H*-benz[*e*]indene and a substance whose UV spectrum was similar to that of *cis*- or *trans*-2,3,3*a*,4,5,9*b*-hexahydro-1*H*-benz[*e*]indene. Therefore we tentatively identified this compound, **A**, as *trans*-3*a*,9*b*-dihydro-1*H*-benz[*e*]indene.

7) When Compound **3** was irradiated with an LPL at room temperature in the presence of O_2, a mixture of dialdehydes was formed by the cleavage of one of the double bonds. The spectral data of the product: IR $\nu_{max}^{liq.\ film}$: 2840, 2750, 1700(vs), 1680(vs), 1620, 1600 cm^{-1}. UV λ_{max}^{EtOH}: 288. NMR (CCl_4) δ: 8.64 (d,d, J=2.5 Hz, 6 Hz), 9.72 (d, J=8 Hz).

Another explanation is possible involving the isomerization of one of the *cis* double bond to *trans*, followed by thermal conrotatory ring closure to a cyclobutene, as is often observed in medium-sized cyclic polyenes. However we consider this as an unlikely possibility because we could not detect in the NMR spectra either a *trans* compound isomeric to **3**, taken at −90 °C just after the irradiation of **3** at the same temperature, or **4**, taken at room temperature after the solution had been allowed to warm up.

(Received September 20, 1976)

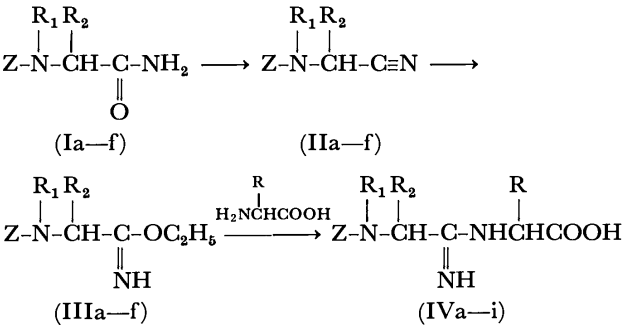
As a basic study for synthesis of bottromycin, the syntheses and the reactions of iminodipeptides were investigated. Nine *N*-benzyloxycarbonyl(Z) iminodipeptides were prepared by the condensation of ethyl Z-amino carboximidates with amino acids according to the method of Ried *et al.* All the imidates were prepared from the corresponding nitriles, and ethyl *N*-Z-2-pyrrolidinecarboximidate (IIIf) was also successfully obtained from Z-proline thioamide by the method of Suydam *et al.* Though Z-(iminoprolyl)glycine was easily deprotected or esterified, its *C*-terminal could not be elongated because it was likely to cyclize into an imidazolone ring. This side reaction could be avoided by locating a carboxyl group further apart from an imino group in a molecule; *i. e.*, the imidate (IIIf) could be coupled with methyl glycylphenylalaninate, thus affording the desired iminotripeptide, Z-ImPro-Gly-Phe-OMe, in a good yield.

Bottromycin, a family of peptide antibiotics produced by *Streptomyces bottropensis*[2] and analogous strains,[3] is an iminopeptide, *i.e.*, a peptide in which an oxo group in the peptide bond is replaced by an imino group. The structure shown in Fig. 1 was given by Umezawa and his co-workers.[4]

An iminopeptide bond is very rare in peptides, though an amidino group itself can be found in amidinomycin,[5] netropsin,[6] and so on.[7] This structural feature of bottromycin has been asserted to contribute to its biological activity to some extent.[8] The present paper will deal with a study of such iminopeptides.

Syntheses of amidines have been widely investigated, but there have been few studies of the syntheses of iminopeptides: Ried and his co-workers[9] synthesized some *N*-benzyloxycarbonyl(Z) iminodipeptides containing optically-active amino acids, and Vargha and Balàzs[10] synthesized *N*-phthalyl(iminoglycyl)-D-valine, along with some analogues. In both cases, however, nothing was reported about their optical properties.

As a basic study of the synthesis of bottromycin, we undertook to investigate the syntheses and the reactions of optically-active iminopeptides, especially those of (iminoprolyl)glycine,[11] which would be an important unit if bottromycin could be conveniently built up by the fragment condensation of three dipeptides (pivaloyl-*t*-leucylvaline,[12] (iminoprolyl)glycine, *β*-methylphenylalanyl-*β*-(2-thiazolyl)-*β*-alanine methyl ester[13]). In principle, we adopted the method of Ried *et al.* for the syntheses of iminopeptides. As an *N*-protecting group, the Z group was chosen because it can easily be removed by hydrogen bromide in anhydrous acetic acid, under which conditions an amidino group seems to be stable. A scheme of the synthesis is shown in Scheme 1.



Scheme 1.

Z-Amino nitriles (II) were prepared by dehydrating the corresponding amides (I) with *p*-toluenesulfonyl chloride in pyridine according to the method of Hirotsu *et al.*[14] The reaction temperature was, however, kept at 50 °C instead of refluxing, and three equivalents of *p*-toluenesulfonyl chloride were used to cover the lowered reaction rate. The excess sulfonyl chloride could easily be removed by stirring the reaction mixture for a few hours with 10% aqueous pyridine at room temperature. Thus, the nitriles were obtained quantitatively in a purer state, hardly any by-products being observed. It is noteworthy that 2-(Z-amino)-3-methylvaleronitrile (IId), which has been reported to solidify only after distillation,[14] could be obtained in crystalline forms without further purification. The results are shown in Table 1.

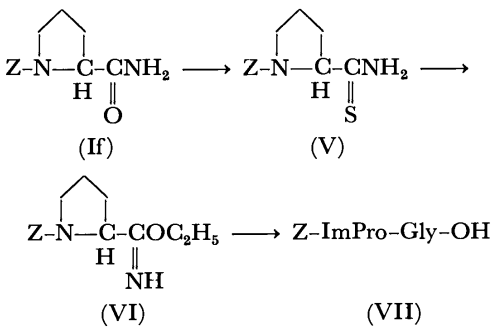
a) *c* 1 in acetic acid at 23 °C. b) *c* 1 in methanol at 20 °C. c) *c* 1 in methanol at 25 °C. d) *c* 1 in ethanol at 28 °C.

Ethyl Z-amino carboximidates (III) were prepared from the nitriles (II) by the method of Pinner.[14,15] Except from glycine and alanine, every free imidate was obtained as an oil and was used in the next reaction without any purification.

Two types of optically-active iminodipeptides (IV) (Z-ImGly-AA-OH and Z-ImAA-Gly-OH)[11] were successfully prepared by the reactions of the imidates (III) with free amino acids in anhydrous methanol under reflux. The results are summarized in Table 2.

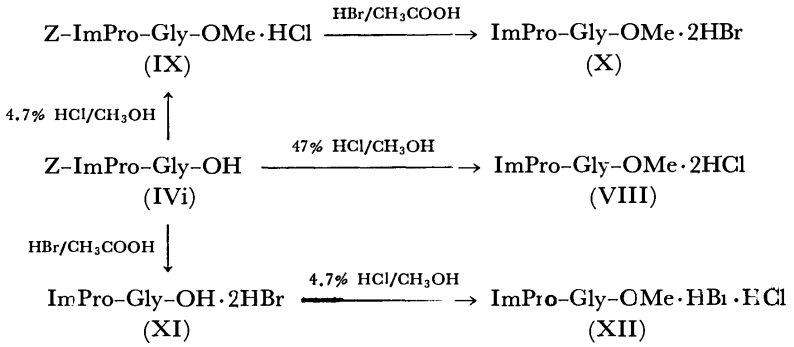
Suydam and his co-workers[16] have reported another convenient method for preparing imidate directly from amide. They obtained a number of aliphatic imidates in fairly good yields by the reaction of the corresponding amides with ethyl chloroformate. Though their method could not be applied to Z-proline amide (If) itself, the corresponding thioamide (V) reacted smoothly with ethyl chloroformate at room temperature, giving an optically-active imidate (VI), which then, by reaction with glycine, afforded Z-(iminoprolyl)-glycine (VII). The optical rotation of this product



Scheme 2.

(VII) agreed well with that of the same compound (IVi) obtained through Pinner's method. (Scheme 2)

Some reactions of iminodipeptides were investigated by using Z-(iminoprolyl)glycine (IVi). When IVi was treated with saturated hydrogen chloride in methanol at room temperature in order to esterify it, the removal of the Z group rapidly occurred, followed by slow esterification, and (iminoprolyl)glycine methyl ester was



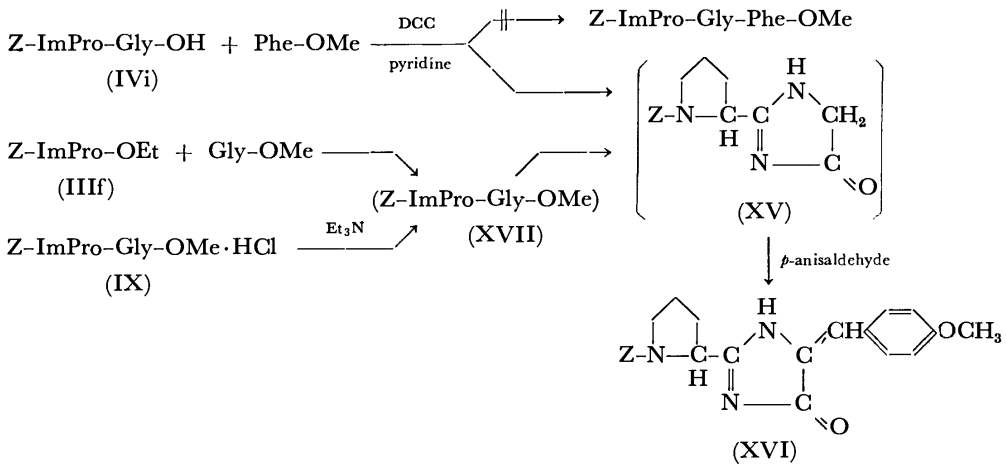
Scheme 3.

obtained as dihydrochloride (VIII). On the other hand, when IVi was treated with 4.7% hydrogen chloride in methanol, it could be quantitatively esterified without the removal of the protecting group and the resulting ester was isolated as monohydrochloride (IX), which was then further treated with hydrogen bromide in acetic acid to give (iminoprolyl)glycine methyl ester dihydrobromide (X). The same ester was also obtained by the esterification of (iminoprolyl)-glycine dihydrobromide (XI) with 4.7% hydrogen chloride in methanol, though the ester was isolated as a hydrochloride-hydrobromide salt (XII). The iminodipeptide (XI) was obtained as expected in the form of dihydrobromide on the treatment of IVi with hydrogen bromide in acetic acid. The correlation between these compounds is shown in Scheme 3.

In order to elongate the *C*-terminal of Z-iminodipeptides (IV), many attempts were made under various conditions, but the expected results were not obtained. One of the troubles is the low solubilities of these compounds in solvents; *e. g.*, Z-(iminoglycyl)glycine (IVa) dissolved neither in acetonitrile, tetrahydrofuran, *N,N*-dimethylformamide, nor dimethyl sulfoxide, though it is fairly soluble in such protic solvents as methanol and acetic acid, and in such basic solvents as pyridine it is soluble to some extent. On the other hand, even a more soluble compound, Z-(iminoprolyl)-glycine (IVi), was hardly soluble in polar aprotic solvents. The use of *N*-isobornyloxycarbonyl(IBOC) derivatives[17] was attempted with hopes founded on their high solubilities:[18] IBOC-proline amide (XIII) and the corresponding nitrile (XIV) were prepared successfully, but the conversion of the nitrile to IBOC-(iminoprolyl)glycine *via* an imidate did not occur smoothly.

We attempted to couple the iminopeptide (IVi) with methyl phenylalaninate in the presence of dicyclohexylcarbodiimide (DCC) in pyridine. The isolated main product, however, was not the desired iminotripeptide derivative, but probably an imidazolone derivative (XV),[19] which might have been produced by the intramolecular cyclization of the starting iminodipeptide, since the same compound was also obtained in a good yield instead of the free iminodipeptide ester (XVII) when the iminodipeptide ester hydrochloride (IX) was treated with triethylamine in methanol. Furthermore, when the imidate (IIIf) was coupled with methyl glycinate, the same compound (XV) was again produced as the main product. Compound XV was too unstable to purify; it was identified by its conversion to a more stable derivative, (*p*-methoxyphenylmethylene)imidazolone (XVI).[20] These facts provide evidence for the smooth cyclization reaction of the iminodipeptide ester (Scheme 4).

From the facts mentioned above, we could not but conclude that it is impossible to elongate the *C*-terminal of an iminodipeptide directly. If an imino group and a carboxyl group were situated further apart in a molecule, such an intramolecular cyclization might be avoided. In order to confirm this possibility, the imidate (IIIf) was coupled with glycylphenylalanine methyl ester hydrobromide in the presence



Scheme 4.

of triethylamine in methanol at room temperature for 2 days. The desired iminotripeptide derivative, *i.e.*, Z-(iminoprolyl)glycylphenylalanine methyl ester (XVIII), was thus successfully obtained in a 61.4% yield after purification by column chromatography. It is interesting that the iminotripeptide ester (XVIII) was isolated as a hydrobromide, though an equimolecular amount of triethylamine was added in order to remove hydrogen bromide.

Consequently, it was concluded that, for the syntheses of bottromycin and its analogues, the route through the fragment condensation of three dipeptides described above is not adequate, while the route through the condensation by the formation of an iminopeptide bond between two tripeptides may be better.

Experimental

All the melting points are uncorrected. The optical rotations were measured by means of a Yanagimoto polarimeter, OR-10. The ORD-curves were recorded on a JASCO ORD/UV-5 spectropolarimeter. The NMR spectra were recorded on a Varian A-60 spectrometer or a Hitachi R-20A spectrometer, using TMS or DSS as the internal standard. Thin-layer chromatographies (TLC) were carried out on Merck's Kieselgel GF_{254} (Type 60). The amino acids and their derivatives mentioned in this report are all of the L-configuration unless otherwise mentioned.

Benzyloxycarbonylamino Acid Amides (I). All the amides were prepared by the mixed anhydride method using ethyl chloroformate.[21] The ammonolysis of the mixed anhydride intermediates was successfully carried out with 28% aqueous ammonia instead of liquid ammonia.

α-Benzyloxycarbonylamino α-Substituted Acetonitriles (II). The nitriles were prepared by the dehydration of the corresponding amides with *p*-toluenesulfonyl chloride in pyridine in the usual way,[14,22] but with some modifications. A typical example was as follows: into a solution of Z-proline amide (12.4 g, 0.15 mol) in dry pyridine, *p*-toluenesulfonyl chloride (28.5 g, 0.15 mol) was stirred at room temperature, and thus the mixture was heated at 50 °C for 4 h. After pyridine had been removed under reduced pressure, the residue was treated with 10% aqueous pyridine (200 ml) with stirring for 2 h. The mixture was extracted with ethyl acetate. The organic layer was washed with 1M-HCl, 1M-$NaHCO_3$, and then water, and dried over $MgSO_4$. The solution was concentrated to afford a pale yellow oil; yield, 11.4 g (99%). The other nitriles, prepared in the same manner, are summarized in Table 1.

α-Benzyloxycarbonylamino Carboximidates (III). The imidates were prepared according to the method of Pinner.[14,15] A typical example was as follows: to a cold solution of *N*-Z-2-cyanopyrrolidine (IIf) (1.15 g, 5 mmol) in a mixture of absolute ethanol (0.3 g, 6.5 mmol) and dry ether (15 ml), dry hydrogen chloride was passed with stirring below −5 °C until the gas was saturated, and then at room temperature for 1 h. The reaction mixture was evaporated under reduced pressure to leave ethyl *N*-Z-2-pyrrolidinecarboximidate hydrochloride as a foamy solid. The imidate hydrochloride was immediately converted to a free imidate in the manner described by Hirotsu *et al.*;[14] a colorless oil of IIIf was thus obtained; yield, 1.375 g (99%); $[\alpha]_D^{21}$ −59° (*c* 1, methanol). All the imidates obtained were used for the next reaction without any purification.

N-Benzyloxycarbonyl Iminodipeptides (IV). General Procedure. A mixture of imidate (0.01 mol) and amino acid (0.012 mol) in dry methanol (50 ml) was refluxed for 3 h. After cooling, the unreacted amino acid was filtered off, and the filtrate was evaporated to dryness. The residual crude iminodipeptide was purified by recrystallization from methanol–ethyl acetate or by column chromatography (silica gel, methanol or methanol–ethyl acetate). The results are summarized in Table 2.

N-Benzyloxycarbonylproline Thioamide (V). This compound was prepared from the corresponding amide (2.48 g, 10 mmol) according to our previously described procedure.[23] The reaction was completed in 2.5 h at room temperature. The recrystallization of the crude product from benzene–petroleum ether gave colorless crystals; yield, 1.78 g (67%); mp 93—94 °C, $[\alpha]_D^{26}$ −49.4° (*c* 1, methanol). Found: C, 59.06; H, 6.24; N, 10.46%. Calcd for $C_{13}H_{16}N_2O_2S$: C, 59.07; H, 6.10; N, 10.60%.

N-Benzyloxycarbonyl(iminoprolyl)glycine (VII), via Imidate from N-Benzyloxycarbonylproline Thioamide (V). A mixture of thioamide (V) (529 mg, 2 mmol), ethyl chloroformate (260 mg, 2.4 mmol), and absolute ethanol (0.5 ml) was stirred at room temperature. The reaction proceeded with a smooth evolution of gas and was completed in 2 h. The reaction mixture was then diluted with dry ether to separate a yellow oil. The oil, imidate hydrochloride, was immediately converted to a free imidate, a slightly yellow oil, as described above; yield, 399 mg (65%); $[\alpha]_D^{28}$ −48.9° (*c* 4, methanol).

The imidate, without any purification, was coupled with glycine (150 mg, 2 mmol) in dry methanol under reflux for 3.5 h, giving Z-(iminoprolyl)glycine (222 mg, 56%). $[\alpha]_D^{28}$ −66.9° (*c* 1, ethanol).

(Iminoprolyl)glycine Methyl Ester Dihydrochloride (VIII). To saturated hydrogen chloride in methanol (47%) (1 ml) was added in portions Z-(iminoprolyl)glycine (IVi) (100 mg, 0.33 mmol), which immediately dissolved with the evolution of gas. The solution was allowed to stand at room temperature for 3 days, and then evaporated under reduced pressure to leave white crystals; yield, 80 mg (94.5%); mp 167—168 °C (dec) (methanol–ether), $[\alpha]_D^{20}$ −0.5° (*c* 3, methanol). ORD: $[\phi]_{260}$ +372°, $[\phi]_{300}$ +111°, $[\phi]_{400}$ +23° (*c* 3, methanol). NMR(D_2O): δ 1.9—2.8 (m, 4H, C_3–H and C_4–H in proline), 3.57 (t, J=7 Hz, 2H, C_5–H in proline), 3.81 (s, 3H, CH_3-OCO–), 4.36 (s, 2H, glycine-CH_2). Found: C, 37.05; H, 6.79; N, 16.28%. Calcd for $C_8H_{15}N_3O_2 \cdot 2HCl$: C, 37.22; H, 6.64; N, 16.28%.

N-Benzyloxycarbonyl(iminoprolyl)glycine Methyl Ester Hydrochloride (IX). A solution of IVi (100 mg, 0.33 mmol) in 4.7% hydrogen chloride in methanol (3 ml) was allowed to stand overnight at room temperature. After the solvent had then been removed under reduced pressure, the residue was dissolved in methanol–ethyl acetate and the solution was again evaporated to afford a colorless foamy solid; yield, 115 mg (98.5%); mp 83—87 °C, $[\alpha]_D^{20}$ −55.0° (*c* 0.5, methanol). TLC: R_f 0.18 (methanol–ethyl acetate (1 : 4)). UV: λ_{max}^{MeOH} (ε); 257 nm (197). NMR(D_2O): δ 1.6—2.5 (m, 4H, C_3–H and C_4–H in proline), 3.58 (t, J=7 Hz, 2H, C_5–H in proline), 3.76 (s, 3H, CH_3OCO–), 4.06 (s, 2H, glycine-CH_2), 5.18 (s, 2H, benzyl-CH_2), 7.43 (s, 5H, phenyl). Found: C, 51.34; H, 6.45; N, 11.21%. Calcd for $C_{16}H_{21}N_3O_4 \cdot HCl \cdot H_2O$: C, 51.41; H, 6.47; N, 11.24%.

(Iminoprolyl)glycine Methyl Ester Dihydrobromide (X). The treatment of IX (50 mg) with 25% hydrogen bromide in acetic acid (0.15 g) at room temperature for 45 min gave (iminoprolyl)glycine methyl ester dihydrobromide; yield, 41 mg (84%); mp 165—166 °C (dec) (methanol–ether), $[\alpha]_D^{17}$ −2.0° (*c* 1, methanol). ORD: $[\phi]_{250}$ +510°, $[\phi]_{300}$ +101°, $[\phi]_{400}$ +14° (*c* 1, methanol). Found: C, 27.44; H, 5.12;

N, 11.94%. Calcd for $C_8H_{15}N_3O_2 \cdot 2HBr$: C, 27.69; H, 4.94; N, 12.11%.

(Iminoprolyl)glycine Dihydrobromide (XI). This compound was obtained by the removal of the Z group from IVi (100 mg, 0.33 mmol) with 25% hydrogen bromide in acetic acid (340 mg) as usual; yield, 100 mg (92%); mp 161—162 °C (methanol-ether), $[\alpha]_D^{20}$ −9.2° (*c* 0.4, methanol). Found: C, 25.65; H, 4.67; N, 12.28%. Calcd for $C_7H_{13}N_3O_2 \cdot 2HBr$: C, 25.25; H, 4.54; N, 12.62%.

(Iminoprolyl)glycine Methyl Ester Hydrochloride-hydrobromide (XII). The treatment of XI (60 mg) with 4.7% hydrogen chloride in methanol (3 ml) at room temperature for 4 days gave white crystals; yield, 39 mg (84%); mp 164—165 °C (dec) (methanol-ether). Found: C, 31.41; H, 5.35; N, 14.65%. Calcd for $C_8H_{15}N_3O_2 \cdot HBr \cdot HCl$: C, 31.75; H, 5.66; N, 13.89%.

N-*Isobornyloxycarbonylproline.* This compound was prepared in the manner described by Fujino and his co-workers;[17] yield, 57%; mp 134—135 °C (lit,[17] mp 135.5—136 °C).

N-*Isobornyloxycarbonylproline Amide (XIII).* The mixed anhydride method described above for Z-amino acid amides gave the desired amide (65.4%), along with the recovered starting material (30.6%). The recrystallization of the amide from aqueous ethanol afforded white crystals; mp 175.5—176 °C, $[\alpha]_D^{28}$ −83.7° (*c* 1, ethanol). Found: C, 65.14; H, 9.26; N, 9.41%. Calcd for $C_{16}H_{26}N_2O_3$: C, 65.28; H, 8.90; N, 9.52%.

N-*Isobornyloxycarbonyl-2-cyanopyrrolidine (XIV).* IBOC-proline amide (XIII) (3.94 g, 0.01 mol) was dehydrated with *p*-toluenesulfonyl chloride (5.7 g, 0.03 mol) in pyridine (20 ml) in the manner described above for the Z series, giving colorless crystals; yield, 3.70 g (98.7%); mp 73—76 °C.

The analytical sample was obtained by recrystallization from petroleum ether; mp 78—79 °C, $[\alpha]_D^{28}$ −127.1° (*c* 1, ethanol). Found: C, 69.39; H, 9.00; N, 10.20%. Calcd for $C_{16}H_{24}N_2O_2$: C, 69.53; H, 8.75; N, 10.14%.

Formation of the Imidazolone Derivative (XV). a) By the Reaction of N-*Benzyloxycarbonyl(iminoprolyl)glycine (IVi) with Methyl Phenylalaninate in the Presence of Dicyclohexylcarbodiimide:* Into a solution of IVi (153 mg, 0.5 mmol), methyl phenylalaninate hydrochloride (113 mg, 0.5 mmol), and triethylamine (51 mg, 0.5 mmol) in pyridine (5 ml), DCC (103 mg, 0.5 mmol) was stirred at room temperature. After 1 day, the resulting white crystals were filtered off and the filtrate was concentrated under reduced pressure. The residue was chromatographed on a preparative thin layer with methanol–ethyl acetate (1 : 9) to afford an oil; yield, 18 mg (19%); TLC: R_f 0.37 (methanol–ethyl acetate (1 : 9)).

b) By the Treatment of N-*Benzyloxycarbonyl(iminoprolyl)glycine Methyl Ester Hydrochloride (IX) with Triethylamine:* A solution of the hydrochloride (IX) (100 mg) and triethylamine (60 mg) in methanol (3 ml) was allowed to stand at room temperature for 3 h. The solution was then evaporated under reduced pressure to give a brown-yellow oil, which was chromatographed on a preparative thin layer; yield, 62 mg (77%); TLC: R_f 0.37 (methanol–ethyl acetate (1 : 9)).

c) By the Reaction of Ethyl N-*Benzyloxycarbonyl-2-pyrrolidinecarboximidate (IIIf) with Methyl Glycinate:* A mixture of the imidate (IIIf) (2.36 g, 8.5 mmol), methyl glycinate hydrochloride (0.76 g, 8.5 mmol), and triethylamine (0.86 g, 8.5 mmol) in dry tetrahydrofuran (50 ml) was stirred at room temperature for 2 days. After a white precipitate had been filtered off, the filtrate was concentrated to give a reddish brown oil. The oil was chromatographed on a silica gel column with methanol–ethyl acetate (1 : 4), thus affording as the main product a yellow oil, which soon turned a reddish brown; yield, 0.82 g (29%); TLC: R_f 0.37 (methanol–ethyl acetate (1 : 9)).

*2-(*N-*Benzyloxycarbonyl-2-pyrrolidinyl)-5(or 4)-(*p-*methoxyphenylmethylene)-2-imidazolin-4(or 5)-one (XVI).* a) A solution of the crude compound (XV) (100 mg) and *p*-anisaldehyde (360 mg) in methanol (1 ml) was allowed to stand at room temperature for 2 days. The reaction mixture was then chromatographed on a preparative thin layer with benzene–ethyl acetate (3 : 2) to give two sorts of yellow crystals; major product; yield, 43 mg; TLC: R_f 0.62 (benzene–ethyl acetate (2 : 3)); minor product: yield, 11 mg; TLC: R_f 0.44. The analytical sample of the major product was obtained by recrystallization from ethyl acetate; mp 194—195 °C, $[\alpha]_D^{20}$ −53.1° (*c* 1, $CHCl_3$). UV: $\lambda_{max}^{CHCl_3}$ (ε); 368 nm (3.70×10^4). NMR ($CDCl_3$): δ 1.8—2.5 (m, 4H, C_3–H and C_4–H in pyrrolidine ring), 3.58 (t, J=6 Hz, 2H, C_5–H in pyrrolidine ring), 3.86 (s, 3H, OCH_3), 4.7—5.0 (m, 1H, C_2–H in pyrrolidine ring), 5.19 (s, 2H, benzyl-CH_2), 6.95 (d, J=9 Hz, 2H, *meta*-H of *p*-methoxyphenyl), 7.09 (s, 1H, C=C<u>H</u>), 7.35 (s, 5H, C_6H_5–), 8.13 (d, J=9 Hz, 2H, *ortho*-H of *p*-methoxyphenyl), 9.36 (s, 1H, NH). Found: C, 68.06; H, 5.72; N, 10.05%. Calcd for $C_{23}H_{23}N_3O_4$: C, 68.13; H, 5.72; N, 10.36%.

The minor product seemed to be an isomer since it gradually changed into the major product in methanol, but it was not investigated further.

b) A more convenient method to prepare XVI was as follows: a mixture of IX (608 mg), *p*-anisaldehyde (2.23 g), and triethylamine (331 mg) in methanol (2 ml) was allowed to stand at room temperature for 2 days. After the solvent had been removed under reduced pressure, the residue was taken up in ethyl acetate in order to remove triethylamine hydrochloride. The solution was then concentrated to give a yellow oil, which was chromatographed on a silica gel column with benzene–ethyl acetate (4 : 1—3 : 2), affording yellow crystals; yield, 507 mg (77%); mp 193—194 °C, TLC: R_f 0.62 (benzene–ethyl acetate (2 : 3)).

Glycylphenylalanine Methyl Ester Hydrobromide. This compound was prepared by the coupling of Z-glycine with methyl phenylalaninate using DCC, followed by the removal of the Z group with 25% hydrogen bromide in acetic acid, according to the method of Mazur and Schlatter;[24] yield, 94%; mp 166—168 °C (dec) (lit,[24] mp 167—170 °C). It was used for the next reaction without further purification.

N-*Benzyloxycarbonyl(iminoprolyl)glycylphenylalanine Methyl Ester (XVIII).* A solution of the imidate (IIIf) (665 mg, 2.4 mmol), glycylphenylalanine methyl ester hydrobromide (634 mg, 2.0 mmol), and triethylamine (220 mg, 2.0 mmol) in dry methanol (10 ml) was stirred at room temperature for 1 day. The solution was then evaporated under reduced pressure to leave a syrup with some crystals. The syrup was taken up in ethyl acetate, and any insoluble materials were filtered off. The filtrate was evaporated under reduced pressure, and the residue was chromatographed on a silica gel column with methanol–ethyl acetate (1 : 9), giving a foamy solid; yield, 683 mg (61.4%); mp 90—94 °C, $[\alpha]_D^{23}$ −23.6° (*c* 0.75, methanol). Found: C, 53.94; H, 5.84; N, 10.03%. Calcd for $C_{25}H_{30}N_4O_5 \cdot HBr \cdot 1/2H_2O$: C, 53.96; H, 5.80; N, 10.07%.

A Three-Component Reaction of Isocyanides with Halogens and Cyclic Ethers

Takeshi YAMAZAKI,* Yasuo WADA,* Shigeo TANIMOTO, and Masaya OKANO**

Institute for Chemical Research, Kyoto University, Uji, Kyoto 661

(Received October 8, 1976)

In the presence of a Lewis-acid catalyst, such as $HgCl_2$ or $ZnCl_2$, cyclohexyl isocyanide reacted with chlorine and tetrahydrofuran to give, after hydrolysis, 4-chlorobutyl cyclohexylcarbamate in a fair yield. When one of the reactants was replaced by another isocyanide, bromine, or another cyclic ether, the reactions proceeded similarly, but the corresponding carbamate yields were rather poor.

Isocyanides are known to undergo multi-component reactions[1] in which more than two reactants selectively combine to form a single product, as represented by the Passerini reaction. In an attempt to find a new example of triple addition reactions, reactions of isocyanides with halogens and 3- to 5-membered cyclic ethers were examined in the presence of Lewis-acid catalysts. The ω-haloalkyl carbamates, $RNHCOO(CH_2)_nX$ (n=2—4), which correspond to the hydrolysis products of the 1 : 1 : 1 adducts, were successfully obtained in various yields, by treatment of the reaction mixtures with water. The present paper deals with the new reaction:

$$R\text{-}N{\equiv}C + X_2 + (CH_2)_nO \xrightarrow{MX_n} R\text{-}N{=}C(X)O(CH_2)_nX \xrightarrow{H_2O} RNHCOO(CH_2)_nX \quad (1)$$

In connection with this, phenylcabonimidoyl dichloride has been known to undergo an insertion reaction of ethylene oxide into the C–Cl bond of the dichloride in the presence of triethylamine, the isolated product being not 2-chloroethyl *N*-phenylchloroformimidate, but the isomeric carbamoyl chloride resulting from a Chappmann rearrangement of the expected product (Eq. 2).[2]

$$Ph\text{-}N{=}CCl_2 + \underset{O}{CH_2\text{-}CH_2} \xrightarrow{Et_3N} [Ph\text{-}N{=}C(Cl)O(CH_2)_2Cl] \longrightarrow Ph\text{-}N(COCl)CH_2CH_2Cl \quad (2)$$

On the other hand, it has also been reported that the $ZnCl_2$- or $SnCl_4$-catalyzed cycloaddition of arylcarbonimidoyl dichlorides to aliphatic epoxides, followed by hydrolysis, gives 3-aryl-5-alkyl-2-oxazolidinones, although the yields are very low (Eq. 3).[3]

$$Ar\text{-}N{=}CCl_2 + \underset{O}{R\text{-}CH\text{-}CH_2} \xrightarrow{\text{Lewis acid}} \left[Ar\text{-}N\text{—}C(Cl_2)\text{—}O\text{—}R\right] \xrightarrow{H_2O} Ar\text{-}N(C{=}O)\text{—}O\text{—}R \quad (3)$$

Results and Discussion

When cyclohexyl isocyanide was treated with chlorine in tetrahydrofuran (hereinafter abbreviated as THF) at room temperature in the presence of $HgCl_2$ or $ZnCl_2$ and the reaction mixture was hydrolyzed before isolation, 4-chlorobutyl cyclohexylcarbamate was obtained in a good yield, along with small amounts of various by-products which will be described below. Some results are shown in Table 1.

Table 1. Reaction of cyclohexyl isocyanide with halogens and THF

Isocyanide 24 mmol: Halogens 72 mmol; THF 360 mmol. Reaction conditions: 5—10 °C, 1.5 h and 20—25 °C, 50 h.

X_2	Catalyst (mmol)	Yield (%) of cyclo-$C_6H_{11}NHCOO(CH_2)_4X$[c]
Cl_2	None	0[d]
Cl_2	$HgCl_2$, 3	2[e]
Cl_2	$HgCl_2$, 8[a]	0[f]
Cl_2	$HgCl_2$, 8	70
Cl_2	$HgCl_2$, 8[b]	80
Cl_2	$HgCl_2$, 24	67
Br_2	$HgBr_2$, 8	32
Cl_2	$ZnCl_2$, 8	59
Cl_2	$ZnCl_2$, 24	68

a) Reaction conditions: −15 °C, 1 h and −10—0 °C, 5 h. b) Reaction conditions: 55—60 °C, 6.5 h. c) Based on isocyanide (determined by GLC). d) cyclo-$C_6H_{11}N{=}CCl_2$, 90%. e) cyclo-$C_6H_{11}N{=}CCl_2$, 69%. f) cyclo-$C_6H_{11}N{=}CCl_2$, 87%.

When $AlCl_3$ or $FeCl_3$ was used as the catalyst, the reaction was considerably exothermic and afforded mainly a polymeric substance which consists mostly of oligomers of THF rather than the desired carbamate. Moreover, the reaction without the catalyst yielded only cyclohexylcarbonimidoyl dichloride and no amount of the carbamate could be found in the reaction mixture. In the case of a $HgCl_2$ catalyst, *ca.* 4 mol% (based on chlorine) was found to be insufficient to yield the carbamate predominantly, and the optimum amount was estimated to be *ca.* 10 mol%, although no accurate determination was made.

An increase in the yield of the carbamate was observed for a rise in the reaction temperature. However, the reaction below 0 °C, even in the presence of 11.5 mol% of $HgCl_2$, afforded only the carbonimidoyl dichloride as the reaction product.

When bromine and $HgBr_2$ were used in place of chlorine and $HgCl_2$, respectively, the reaction with cyclohexyl isocyanide proceeded similarly affording 4-bromobutyl cyclohexylcarbamate, but the yield was rather poor compared with the preparation of the corresponding chlorine compound. An analogous reaction with iodine and HgI_2, however, did not give the desired compound and yielded only a tarry product.

Data on the reaction of some aliphatic and aromatic isocyanides with chlorine in THF are shown in Table 2a. In the case of *t*-butyl isocyanide, the yield of carbamate was rather low. This is probably due to the decreased stability of the intermediate *t*-butylchloroimidoyl cation, which tends to decompose to *t*-butyl cation and ClCN rather easily.[4] Phenyl isocyanide afforded carbamate in a low yield, although the recorded yield was only the isolated yield in this case.

Table 2. Reaction of isocyanides with chlorine and cyclic ethers

(a) Variation of the isocyanide component.
Isocyanides 24 mmol; Cl_2 72 mmol; THF 360 mmol; $HgCl_2$ 8 mmol. Reaction conditions: 55—60 °C, 6.5 h.

Isocyanide	Yield (%) of $RNHCOO(CH_2)_4Cl$[a]	
n-BuNC	R=*n*-Bu,	67
cyclo-$C_6H_{11}NC$	R=cyclo-C_6H_{11},	80
t-BuNC	R=*t*-Bu,	49
PhNC	R=Ph,	44[b]

a) Based on isocyanide (determined by GLC).
b) Isolated yield.

(b) Variation of the cyclic ether component.
Cyclohexyl isocyanide 24 mmol; Cl_2 72 mmol; Cyclic ethers 360 mmol; $HgCl_2$ 8 mmol. Reaction conditions: 5—10 °C, 1.5 h and 20—25 °C, 50 h.

Cyclic ether	Yield (%) of cyclo-$C_6H_{11}NHCOOR$[a]	
	R=$CH_2CH(CH_3)Cl$,	12
	R=$(CH_2)_3Cl$,	37
	R=$(CH_2)_4Cl$,	68

a) Based on isocyanide (determined by GLC).

The $HgCl_2$-catalyzed reaction of cyclohexyl isocyanide with chlorine was also carried out in trimethylene oxide and propylene oxide, for comparison with that in THF. The results are shown in Table 2b. The yields of the corresponding carbamates decreased as the ring size changed from 5 to 3 *via* 4. This order is the same as that obtained for the case of Lewis acid-catalyzed ring-opening polymerization of cyclic ethers.[5]

In this reaction, the chloroimidoyl cation (**1**), formed by the electrophilic addition of Cl^+ to isocyanide, appears to act as a key intermediate. This reacts with THF, and with a complex halide anion successively to afford a chloroformimidate (**2**), which then forms 4-chlorobutyl carbamate (**3**) when hydrolyzed.

$$Cl_2 + HgCl_2 \rightleftharpoons Cl^+ + HgCl_3^- \quad (4)$$

$$R\text{-}N{\equiv}C \xrightarrow{Cl^+} R\text{-}N{=}C^+\text{-}Cl \xrightarrow{THF} \left[R\text{-}N{=}C\begin{matrix}Cl\\ O^+\end{matrix}\right]$$

1

$$\xrightarrow{HgCl_3^-} R\text{-}N{=}C\begin{matrix}Cl\\ O(CH_2)_4Cl\end{matrix} \quad (5)$$

2

$$\mathbf{2} \xrightarrow{H_2O} RNHCOO(CH_2)_4Cl \quad (6)$$

3

Here, the intermediate **1** may be formed by another route *via* carbonimidoyl dichloride. However, when cyclohexylcarbonimidoyl dichloride was treated with THF in the presence of $HgCl_2$ under the same reaction conditions (20—25 °C, 50 h), the expected carbamate was obtained in only a 6% yield and most of the unreacted dichloride was recovered. Therefore, such a possibility can be ruled out as the main course of the reaction.

Finally, a short comment on the by-products of the reaction must be added. From the reaction mixture of cyclohexyl isocyanide, chlorine, and THF, small amounts of 1,4-dichlorobutane, 4-chloro-1-butanol, bis(4-chlorobutyl) ether, and 2-(4-chlorobutoxy)-3-chlorotetrahydrofuran (**4**) were isolated, along with the carbamate and occasionally with the carbonimidoyl dichloride. It is obvious that all the minor products come from the reaction between THF and chlorine. It has been reported that the chlorination of THF at room temperature results only in 2,3-dichlorotetrahydrofuran (**5**) (Reaction 7).[6] In the presence of a $ZnCl_2$ catalyst, cleavage of THF by **5** is known to afford **4** (Reaction 8).[7] 4-Chloro-1-butanol is probably formed by the action of HCl on THF during the chlorination of THF. This compound would be a precursor of 1,4-dichlorobutane and bis(4-chlorobutyl) ether.

Experimental

GLC analysis was carried out on a Shimadzu 5APTF apparatus using an EGSS-X(30%)-Chromosorb-W (1 m) column (with N_2 as the carrier gas). The IR spectrum was recorded with a Hitachi EPI-S2 apparatus.

Isocyanides (RNC) were prepared using the method of Ugi *et al.*:[8] R=C_6H_{11}, bp 67—69 °C/20 Torr (lit,[8] bp 67—72 °C/13 Torr); R=*n*-Bu, bp 48 °C/20 Torr (lit,[8] bp 40—42 °C/11 Torr); R=*t*-Bu, bp 48 °C/60 Torr (lit,[8] bp 92—93 °C/750 Torr); R=Ph, bp 61—62 °C/18 Torr (lit,[8] bp 50—51 °C/11 Torr). Trimethylene oxide was prepared from 3-chloropropyl acetate[9] (bp 47—49 °C, lit,[9] bp 47—48 °C). Commercial THF and propylene oxide were used after distillation, while the inorganic substances were used without further purification.

$HgCl_2$-Catalyzed Reaction of Isocyanides with Chlorine and THF. A typical example is given below. Into a stirred solution of $HgCl_2$ (2.2 g, 8 mmol) in THF (29 ml, 360 mmol) containing cyclohexyl isocyanide (2.6 g, 24 mmol), chlorine gas (5.1 g, 72 mmol) was bubbled over a period of 1.5 h, the temperature being maintained at 5—10 °C by cooling with ice water. After stirring for an additional 50 h at 20—25 °C, the reaction mixture was added to a suspension of $CaCO_3$ (5 g) in water (20 ml). The resulting heterogeneous mixture was stirred at 20—25 °C for 3 h. Then ether was added and inorganic precipitates were filtered off. The ether extract was separated from the aqueous layer. This was combined with a dichloromethane extract in the aqueous phase. The combined organic layer was washed with aqueous K_2CO_3 and aqueous NaCl, successively, dried over anhydrous $MgSO_4$, and most of the solvents were evaporated. GLC analysis of the residue using isopropylbenzene, *p*-methoxyacetophenone, and triphenylmethane as internal standards showed the presence of 1,4-dichlorobutane (**6**) (1.4 g, 10.9 mmol), 4-chloro-1-butanol (**7**) (3.5 g, 32.3 mmol), bis(4-chlorobutyl) ether (**8**) (0.6 g, 2.8 mmol), 2-(4-chlorobutoxy)-3-chlorotetrahydrofuran (**4**) (2.9 g, 13.6 mmol), and 4-chloro butyl cyclohexylcarbamate (**3**, R=cyclo-C_6H_{11}) (4.0 g, 17.3 mmol, 72% yield). Distillation afforded the following fractions: fraction A, bp 55—90 °C/25 Torr (3.4 g), fraction B, bp 90—100 °C/3 Torr (3.1 g), fraction C, bp 131—133 °C/3 Torr (4.5 g), and a black semi-solid residue D (1.7 g). The fractions A and B were shown by GLC to be a mixture of **6** and **7**, and of **7**, **8**, and **4**, respectively. The fraction C was revealed to contain **3** (89%) and **8** (11%), and redistillation gave the pure carbamate, bp 132 °C/3 Torr, mp 55—56 °C (from hexane) (lit,[10] mp 57—58 °C). The IR spectrum of residue D showed the characteristic absorptions due to carbamate [1710 cm^{-1} (CO), 1530, 3380 cm^{-1} (NH) and 1055 cm^{-1} (C–O–C)] and ether [1120 cm^{-1} (C–O–C)] groups, indicating the existence of oligomers of **3**, cyclo-$C_6H_{11}NHCO[O(CH_2)_4]_nCl$($n>1$), and of THF.

Reaction of Cyclohexyl Isocyanide with Chlorine in THF without the Catalyst. Chlorine gas (5.1 g, 72 mmol) was slowly bubbled into a stirred solution of cyclohexyl isocyanide (2.6 g, 24 mmol) in THF (29 ml, 360 mmol) at 5—10 °C, as described above. After being maintained for an additional 50 h at 20—25 °C with stirring, the mixture was poured into water. The resulting mixture was extracted with ether, and the extract was dried over anhydrous $MgSO_4$. Distillation gave cyclohexylcarbonimidoyl dichloride (3.9 g, 90% yield), bp 91—92 °C/20 Torr (lit,[11] 79—82 °C/13 Torr).

Authentic Samples for GLC Analysis. All ω-haloalkyl carbamates were prepared by the reaction of ω-halo-1-alkanols with isocyanates.[10,12] cyclo-$C_6H_{11}NHCOOR$: R=$(CH_2)_4Cl$, bp 132 °C/3 Torr; R=$(CH_2)_3Cl$, bp 126 °C/3 Torr (Found: C, 54.42; H, 8.52; N, 6.27%. Calcd for $C_{10}H_{18}NO_2Cl$: C, 54.67; H, 8.26; N, 6.38%); R=$CH_2CH(CH_3)Cl$, bp 107 °C/5 Torr (Found: C, 54.54; H, 8.22; N, 6.28%. Calcd for $C_{10}H_{18}NO_2Cl$: C, 54.67; H, 8.26; N, 6.38%); R=$(CH_2)_4Br$, bp 148 °C/2.8 Torr (Found: C, 47.73; H, 7.21; N, 5.17%. Calcd for $C_{11}H_{20}NO_2Br$: C, 47.49; H, 7.25; N, 5.04%). RNHCOO$(CH_2)_4Cl$: R=*n*-Bu, bp 115—118 °C/4 Torr (Found: C, 51.89; H, 9.03; N, 6.95%. Calcd for $C_9H_{18}NO_2Cl$: C, 52.05, H, 8.74; N, 6.74%); R=*t*-Bu, bp 92 °C/3 Torr (Found: C, 51.97; H, 9.03; N, 6.54%. Calcd for $C_9H_{18}NO_2Cl$: C, 52.05, H, 8.74; N, 6.74%); R=Ph, mp 54—55 °C (from hexane) (lit,[12] mp 54 °C).

Reactivities of Stable Rotamers. II. Lithiation of 9-(2-Methyl-1-naphthyl)-fluorene and Related Compounds[1]

Mikio NAKAMURA, Nobuo NAKAMURA, and Michinori ŌKI

Department of Chemistry, Faculty of Science, The University of Tokyo, Tokyo 113

(Received October 26, 1976)

Studies were carried out on the rates of lithiation of 9-arylfluorenes, in which the aryls are hydrocarbons. The reactivities of these compounds are explained in terms of the effective blocking of the reaction site by the substituent. The steric effect of the substituent which is attached to the aryl group but is over the fluorene ring is found to play a role in the reactivities.

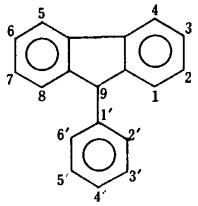
Abundant data on the reactivity of organic compounds have been obtained but they are usually weighted means of rotational isomers, except when the compound in question reacts at a site where no rotamer is possible. In the former case, the observed reaction rates may be expressed by the following equation if there are two possible rotamers:[2]

$$k_{obsd} = k_a N_a + k_b N_b, \quad (1)$$

where k and N denote the intrinsic reaction rates and molar fractions of each rotamer, respectively. When the reactivities of both rotamers are comparable, the reactivity of a less populated isomer can be neglected if the molar fraction is one-sided. However, it becomes significant if the reaction rate of a trace-populated rotamer is exceedingly high. Our recent finding on the difference in reactivities of rotamers[1] singles out the importance of this view.

In discussing the solvent effect on reactions, the consideration of rotamers becomes important because the solvation can stabilize the ground states of rotamers to a different degree, thus controlling the populations. The transition states derived from the different rotamers can also be affected by solvation in a different manner. Study of behavior of rotamer in various solvents thus is necessary for understanding the reactions which are affected by solvents.

We thought it would be worthwhile to launch a project on the reactivities of rotamers, since we could isolate various types of stable rotamers.[3] This is the first full paper of such a series giving a discussion on the lithiation of 9-arylfluorenes together with the origin of the difference in reactivities. The series of hydrocarbons was studied first, since it would not contain complexities such as ligation by oxygen atom in the case of 9-(2-methoxy-1-naphthyl)fluorene.[1] The numbering of arylfluorenes used throughout this text is given below.



Experimental

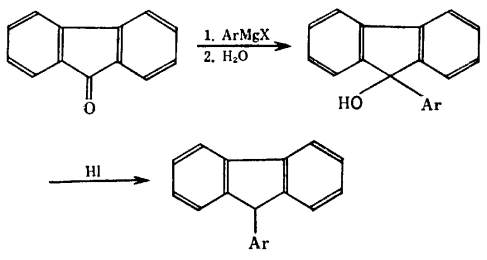
NMR Measurement. ^1H NMR spectra were determined on a Hitachi R-20B spectrometer obtained at 60 MHz. The temperature was calibrated by the peak separation of ethylene glycol. The error in temperature reading was estimated to be ±1.0 °C. ^{13}C NMR spectra were measured on a JNM-FX 60 spectrometer operating at 15.04 MHz, ^{13}C–^1H coupling constants being obtained from all proton undecoupled spectra. The estimated error in the coupling constants was ±0.5 Hz.

Kinetic Measurement. A solution of 0.098 mmol of a 9-arylfluorene in 0.08 ml of benzene was mixed with 0.2 ml of butyllithium in hexane. The quantity of butyllithium was calculated to be *ca.* 1.0 mmol from the integration of methylene signals α to lithium. The rates of reaction were followed by integrating the proton signals due to 4-H and 5-H of the fluorene ring. The protons give signals at δ *ca.* 7.8 in the mother compounds whereas the lithio dervatives give signals at δ 8.0 or below.

9-(*p*-Tolyl)fluorene gave signals at δ *ca.* 8.0 due to 4 protons, two of which are unknown, on lithiation. Integration and calculation were carried out with this fact being taken into consideration. In the case of 9-(2-methyl-1-naphthyl)fluorene, the lithio derivative was hardly soluble in the solvent system and the integrated area of a signal due to 9-H of the mother compound had to be compared with that of a signal due to 9-H of 9-(2,6-xylyl)fluorene which did not react to a measurable extent.

In each case, plot of $\log(1-x/a)$ *vs.* time gave a straight line and the pseudo-first order rate constants were obtained in the usual way. The errors are given in Table 3. The rates of reaction of 9-(2,6-xylyl)- and 9-(2-*t*-butylphenyl)-fluorene were too small to measure in hexane–benzene solution whereas those of other compounds were too large to measure in ether.

Syntheses. Syntheses were carried out by the Grignard reaction of fluorenone with the corresponding arylmagnesium halide followed by reduction with hydriodic acid.[4]



Some 9-aryl-9-fluorenols were not isolated but reduced directly. The overall yields were 50—70%.

9-Aryl-9-fluorenol. To a vigorously stirred solution of arylmagnesium halide prepared from 0.02 mol of aryl halide, 0.02 mol of magnesium and 40 ml of tetrahydrofuran, 0.02 mol of fluorenone was added at 0 °C. The mixture was stirred for 3 h at room temperature and then heated under reflux for 1 h. The cooled mixture was decomposed with dilute hydrochloric acid. The organic layer was separated and the aqueous layer was extracted with ether. The

combined organic layer was washed with aqueous sodium bicarbonate and dried over sodium sulfate. The following compounds were isolated by chromatography on silica gel.

9-(2-Isopropylphenyl)-9-fluorenol. Mp 147—148 °C. Yield 65%. ^{1}H NMR ($CDCl_3$, δ): 0.48 [$(CH_3)_2CH$], 2.18 [$(CH_3)_2CH$], 2.3(OH), 8.3(6'-H). Found: C, 88.11; H, 6.77%. Calcd for $C_{22}H_{20}O$: C, 87.96; H, 6.71%.

The compound exists in an ap form solely. The high chemical shift of the $(CH_3)_2CH$ signals and appearance of a signal due to 6'-H at a low field support the assignment.

9-(2-t-Butylphenyl)-9-fluorenol. Mp 156.5—158.0 °C. Yield 66%. ^{1}H NMR ($CDCl_3$, δ): 1.79 (*t*-Bu), 2.3 (OH), 6.42 (6'-H). Found: C, 88.16; H, 7.08%. Calcd for $C_{23}H_{22}O$: C, 87.86; H, 7.05%.

The compound is judged to exist in an sp form from the low field *t*-butyl signal and a high field 6'-H signal.

9-Arylfluorene. 9-Aryl-9-fluorenol (*ca.* 0.01 mol) was dissolved in 30—60 ml of acetic acid and heated with 10 ml of 57% hydriodic acid for 1 h at 80 °C. The mixture was washed with aqueous sodium bisulfite and then with sodium bicarbonate, and dried over sodium sulfate. After evaporation of the solvent the product was purified by either chromatography on alumina or thin layer chromatography on silica gel. The yield was 75—80%. Pertinent data are given in Tables 1 and 2.

b) Reported melting point was 129—130.5 °C.[13]

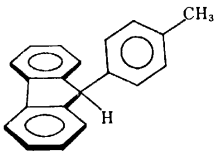
Results and Discussion

Assignment of the Conformation of 9-Arylfluorenes. Features of the conformation of the ap and sp forms of 9-arylfluorenes are characterized by the fact that the alkyl group is located over the fluorene ring in ap (sp in the case of 2-methyl-1-naphthyl derivative (**8**)) form, whereas it is almost within the plane of the fluorene ring in sp (ap in the case of **8**) form. The opposite situation exists for 6'-protons of the aryl group.

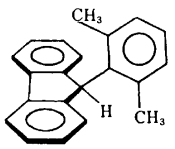
The spacial arrangement of the alkyl group is reflected in the chemical shift of the alkyl protons. 9-(2,6-Xylyl)fluorene (**2**) gives signals due to methyls at δ 1.12 and δ 2.70. The former should be due to a methyl over the ring and the latter to a methyl within the plane of the ring. Thus, if we can observe two forms in ^{1}H NMR spectra, the assignment is straightforward by comparison of the chemical shift.

The conformation of the *t*-butyl compound can also be assigned by taking advantage of the above facts, although it exists as a single form. The *t*-butyl signal is located in a lower field than that of *t*-butylbenzene (δ 1.32),[5] the chemical shift of the 6'-H signal being located at a high field close to the other known sp forms. Thus the conformation of 9-(2-*t*-butylphenyl)fluorene (**3**) should be sp, this being in line with the consideration of the steric effect.

Rates of Lithiation. The pseudo-first order rate constants of lithiation of 9-arylfluorenes are given in Table 3. For the sake of convenience we will start the discussion from the symmetric compounds.



(**1**)



(**2**)

The internal rotation about the C_9–C_{ar} bond in 9-(*p*-tolyl)fluorene (**1**) should be fast at room temperature since analogous 9-(*m*-tolyl)fluorene is known to rotate fast even at −85 °C, whereas that in **2** is frozen.[6] The very low reactivity of **2** can be attributed to the steric blocking of the approach of the deprotonating reagent by the methyl group. Room for the approach of the reagent is made by rotation about the C_9–C_{ar} bond, the rotation itself requiring a fair amount of energy in com-

TABLE 2. NMR SPECTRAL DATA OF ROTAMERIC 9-ARYLFLUORENES IN $CDCl_3$ AT ROOM TEMPERATURE (δ from TMS)

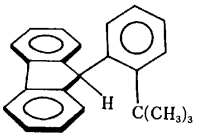
a) The ^{1}H NMR data were obtained at 0 °C.
b) These signals are due to 8'-H's of the naphthalene ring.

Table 3. Rates of lithiation of 9-arylfluorenes in hexane–benzene-d_6 at 42 °C

Aryl	Conformation	Pseudo-first order rate constant (k s^{-1})	k_{rel}
p-$CH_3C_6H_4$		$(1.2\pm0.1)\times10^{-4}$	23
2,6-$(CH_3)_2C_6H_3$[a]		0	0
o-$CH_3C_6H_4$	ap	$(4.1\pm0.2)\times10^{-5}$	8
o-$(CH_3)_2CHC_6H_4$	ap	$(1.9\pm0.4)\times10^{-5}$	4
o-$(CH_3)_3CC_6H_4$[a]	sp	0	0
2-Methyl-1-naphthyl	sp	$(3.6\pm0.6)\times10^{-5}$	7
	ap	$(5.2\pm0.6)\times10^{-6}$	1

a) These compounds were successfully lithiated in diethylether. The rate constants at 34 °C were $(5.4\pm0.4)\times10^{-4}$ s^{-1} and $(4.3\pm0.3)\times10^{-6}$ s^{-1} for the dimethyl and the t-butyl compounds, respectively.

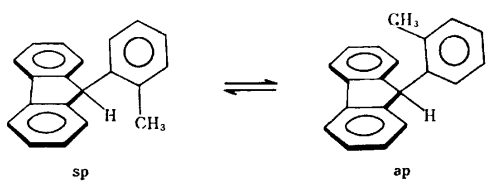
pound **2**. The steric hindrance toward the reaction seems to be of major importance in this case.



(**3**)

The importance of the steric hindrance is also demonstrated in **3**. Although the barrier to internal rotation about the C_9–C_{ar} bond is unknown, the compound exists as one form exclusively even at 180 °C, probably because the steric interference between the t-butyl group and the fluorene ring in an ap form is very severe. Compound $\mathbf{3}_{sp}$ failed to react with butyllithium in hexane–benzene-d_6 as did compound **2**. This should be attributed to the steric effect of the t-butyl group. Importance of the steric effect on lithiation of thiophene derivatives has been pointed out by Wiersema and Gronovitz.[7]

Both compounds **2** and **3** can be lithiated in ether, though they cannot be lithiated in hexane–C_6D_6. Ether would stabilize the transition state of proton abstraction where the polar nature of the C–H bond is developed to some extent. The pseudo-first order rate constants of **2** and **3** at 34 °C were 5.4×10^{-4} s^{-1} and 4.3×10^{-6} s^{-1}, respectively. The rates reflect the steric effect, compound **3** reacting much more slowly than compound **2**. The occurrence of the reaction of compound **3** in spite of the presence of the bulky substituent might be ascribed to rotation about the C_9–C_{ar} bond to some degree to open a path for the reagent approach.



(**4**)

Rates of rotation about the C_9–C_{ar} bond of 9-(o-tolyl)-fluorene (**4**) are estimated to be 10^1-10^2 s^{-1} at ambient temperature from the reported barrier.[6] Thus the rates of rotation are much greater than those of lithiation by butyllithium, the factor being 10^5-10^6. Equilibration between the sp and ap forms is quick. The observed reaction rates can be expressed by the following equation, where the suffixes sp and ap stand for the respective rates and moleculr fractions of the rotamers:

$$k_{obsd} = k_{sp}N_{sp} + k_{ap}N_{ap}. \quad (2)$$

The circumstances of the reaction site of the sp and ap forms can be taken to be similar to those of compounds **2** and **1**, respectively, since o-tolyl, p-tolyl, and 2,6-xylyl groups should not differ much in giving the electronic effect. It is reasonable to assume that $\mathbf{4}_{sp}$ does not react with butyllithium, when the k_{sp} value is practically zero. Equation 2 can be rewritten as follows and k_{ap} can be obtained from the observed rates and the equilibrium constant K:

$$k_{ap} = \left(1+\frac{1}{K}\right)k_{obsd}. \quad (3)$$

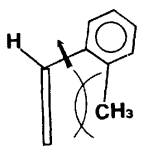
The equilibrium constant was obtained in toluene-d_8 as 1/1.3* by integrating the two methyl signals. It was found to be independent of temperature. Putting the equilibrium constant and the observed rate constant, $k_{obsd}=(1.8\pm0.2)\times10^{-5}$ s^{-1}, into Eq. 3, we find k_{ap} at 42 °C to be $(4.1\pm0.2)\times10^{-5}$ s^{-1}.

So far discussion has been given on the rates of lithiation from the viewpoint of steric effect given by the group located closely to the hydrogen to be abstracted. Close examination of the data reveals, however, that the above treatment is only a first approximation; the rate of lithiation of $\mathbf{4}_{ap}$ is about 1/3 of that of **1**. We wish to attribute the fact to the steric effect of the methyl group anti to the 9-hydrogen for the following reasons.

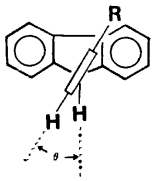
Two possibilities can be considered. One is the bond-angle enlargement due to the substituent-fluorene interaction (see **5**). This will necessarily give additional steric hindrance to the approach of the reagent toward the 9-H and simultaneously cause the change in hybridization. From an examination of the NMR C–H coupling constants (Table 2), the larger substituent in 2′-position of the aryl group in the ap form causes a decrease in magnitude of the coupling constant: $^1J_{CH}$'s decrease from 128.8 to 125.1 Hz by going from **1** to $\mathbf{4}_{sp}$ and from 125.1 to 122.7 Hz by going from $\mathbf{4}_{ap}$ to $\mathbf{7}_{ap}$. The s-character and C–H coupling constants are correlated,[8] although the correlation is questionable in highly strained molecules.[9] The difference in the chemical shifts of 9-C's in ^{13}C NMR spectra increases as the size of the alkyl group increases, the results supporting the bond-angle deformation at 9-C. Thus the decrease in $^1J_{CH}$ and the change in chemical shifts are interpreted as an increase in p-character of the C–H bond orbital. However, this should result in easier deprotonation of $\mathbf{4}_{ap}$ relative to **1** from a kinetic viewpoint and is contrary to the observed trend. Thus the change in hybridization is of minor importance. The steric effect resulting from deformation may also be a minor one since the equilibrium constant is 1/1.3 for $\mathbf{4}_{sp}\rightleftharpoons\mathbf{4}_{ap}$. If it were a major effect, the population ratio should have been affected to a greater extent.

The other possibility is the steric effect caused by the substituent on rotation about the C_9–C_{ar} bond. The access of the deprotonating reagent to the 9-H would

* The equilibrium constant in $CDCl_3$ at 0 °C was reported to be 1/1.6.[6]



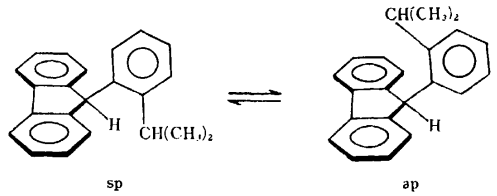
(5)



(6)

be facilitated by the rotation (see **6**) which forms room for the access at the expense of increasing steric interaction between the substituent and the fluorene ring. Thus higher energy is required for rotation about the bond to a same degree (θ) in compound $\mathbf{4}_{ap}$ than in compound **1**.

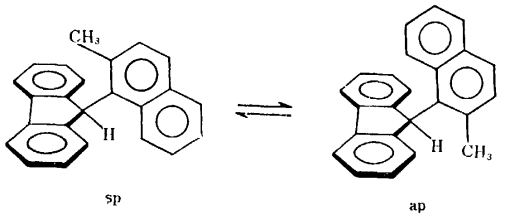
Although the second possibility can be tested in the case of 9-(2-*t*-butylphenyl)fluorene (**2**), the ap form is not detected because of its relative instability to the sp form. Thus 9-(2-isopropylphenyl)fluorene (**7**) was prepared and its reactivity was examined. The compound shows a barrier to rotation (ΔG_c^*) of 19 kcal/mol at 92 °C as determined from the coalescence temperature of the 9-H signals. The rate of rotation at 42 °C is of the order of 10^{-1} s^{-1}. The equilibrium constants for rotamers at 42 °C were 1/2.4 in $CDCl_3$, and 1/1.8 in hexane–C_6D_6.



(7)

The results expected from the steric effect are as follows. The population of the sp form is greater than that of **4**, but the ap form is still detectable. The deformation of the bond angle for the ap form is detected by a decrease in C–H coupling constant from the sp form. If the angle deformation is a main factor which retards the reaction, the isopropyl compound ($\mathbf{7}_{ap}$) should react still more sluggishly than the methyl compound ($\mathbf{4}_{ap}$). On the other hand, if the steric effect on rotation to open room for access of the reagent is the main factor, $\mathbf{7}_{ap}$ is expected to show a little less reactivity than $\mathbf{4}_{ap}$, since the isopropyl group is known to be a little bulkier than the methyl group.[10]

The observed pseudo-first order rate constant was 6.9×10^{-6} s^{-1} for compound **7** at 42 °C. The value was treated in the same way as in the case of compound **4**, the value obtained for k_{ap} being 1.9×10^{-5} s^{-1}. The result is in line with the expectation, as in the change in $^1J_{CH}$ values. We conclude that the steric effect on the rotation is a main factor controlling the reactivities of these compounds of similar steric environment at the reaction site.



(8)

We thought it would be worthwhile to compare the reactivities of stable rotamers of 9-(2-methyl-1-naphthyl)-fluorene (**8**) as an extension of the above discussion. The compound was prepared by Siddall and Stewart, although the rotamers were concentrated but not completely isolated.[6] The equilibrium constant of the two forms was 1.0 and was not affected by temperature. The barrier (ΔG^*) to rotation about the C_9–C_{ar} bond was reported to be 29.2 kcal/mol at 116 °C. The rate of isomerization was 6.2×10^{-7} s^{-1} at 67 °C.

We were able to isolate these stable rotamers by repeated thin layer chromatography: sp, mp 121—122 °C; ap, mp 125—126 °C. The pseudo-first order rate constants for deprotonation obtained were 5.2×10^{-6} s^{-1} and 3.6×10^{-5} s^{-1} for $\mathbf{8}_{ap}$ and $\mathbf{8}_{sp}$, respectively, at 42 °C. Since the rotation about the C_9–C_{ar} bond is negligible at 42 °C, we observed the net reaction rates for the respective isomers. There is a difference in reactivities by a factor of **7**.

The results indicate that a methyl group is more effective than a benzo group in blocking the reaction. This is an unusual indication since the benzo is usually a larger group than the methyl in stereochemistry and 9-(1-naphthyl)fluorene is known to give a higher barrier to rotation than 9-(*o*-tolyl)fluorene by *ca.* 1 kcal/mol.[6] The apparent discrepancy can be understood by considering the geometry of the transition state for the proton abstraction. The main factor which rules the reaction rate is the easiness of rotation to open up room for access for the reagent. The methyl group is considered to be a rotating top and its van der Waals radius is 2.0 Å, whereas the benzo ring extends within a plane but has van der Waals thickness of only 1.85 Å. Thus room for the reagent would be made by a smaller displacement for the sp form than for the ap form. The higher reactivity of $\mathbf{8}_{ap}$ than **2** might be attributed to a similar cause. The methyl group over the fluorene ring would give larger steric hindrance than the benzo group when the same degree of rotation is required. It is also interesting to note that $\mathbf{8}_{sp}$ shows about the same reactivity as $\mathbf{4}_{ap}$. The same degree of rotation would be sufficient for the reaction to occur in these compounds.

Although both $\mathbf{8}_{ap}$ and $\mathbf{8}_{sp}$ give identical ^{1}H NMR spectra on lithiation, stereochemistry of the lithio derivatives is hard to study because of its poor solubility and the difficulty in detecting the difference in spectral characteristics. It might be a mixture of two forms which give resembling NMR peaks, or a single form, or a mixture which shows no signals of a minor constituent. Quenching an extremely dilute solution of the lithio derivative of **8** in hexane–benzene with water afforded the sp and the ap forms in an 8 : 1 ratio. If we can assume that quenching of the lithio derivative with a highly covalent C–Li bond proceeds with the retention of configuration, as is observed in other cases,[11] the stability of the lithio derivatives could be discussed.

Preparation and Properties of Stable Alkylcopper(I) Complexes Containing Tertiary Phosphine Ligands

Akira MIYASHITA and Akio YAMAMOTO

Tokyo Institute of Technology, Research Laboratory of Resources Utilization
O-okayama, Meguro-ku, Tokyo 152

(Received November 12, 1976)

A variety of stable alkylcopper(I) complexes of composition $RCuL_n$ ($n=1-3$) containing various monodentate tertiary phosphine ligands (L), such as triphenylphosphine, diphenylmethylphosphine, dimethylphenylphosphine, tributylphosphine, triethylphosphine, and tricyclohexylphosphine have been prepared by the reactions of copper(II) acetylacetonate, dialkylaluminium monoethoxide, and the tertiary phosphines. Similar reactions employing 1,2-bis(diphenylphosphino)ethane(dpe) give $(RCu)_2(dpe)_3$. The complexes have been isolated and characterized by elemental analysis, determination of molecular weight, chemical reactions, IR and NMR spectroscopy. All the isolated complexes show considerable thermal stability compared with alkylcopper compounds without phosphine ligand indicating the marked contribution of these phosphine ligands to the stabilization of the copper-carbon bond. The dpe-coordinated alkylcopper complexes are thermally stable in the solid state but readily decompose in solution with hydrogen abstraction accompanied by scission of the C–P bond of dpe to give $Ph_2PCu(dpe)$, $Ph_2PCH{=}CH_2$, and alkane. These alkylcopper complexes initiate the polymerization of vinyl monomers such as acrylonitrile, methacrylonitrile, methyl acrylate, and methyl methacrylate. Alkyl halides and acyl halides react with the alkylcopper complexes to give cross-coupling products of alkyl groups and alkyl-acyl groups.

The chemistry of organocopper compounds is worthy of study in its own right as a branch of rapidly developing organotransition metal chemistry and also because of its relevance to various copper-catalyzed organic reactions in which organocopper compounds play an important role as reactive intermediates.[1] Many attempts have been made to prepare alkylcopper compounds since the first report by Buckton in 1859.[2] The preparation of methyl- and ethylcopper by the reaction of copper salts with methyllithium,[3a,b] methylmagnesium chloride,[3a] dimethylzinc[4] and tetramethyl- and tetraethyllead[5] has been reported, but most compounds have been prepared *in situ* and attempts to isolate them in the pure state, free from the alkylating agents and reaction by-products, have encountered great difficulties because of their extreme instability which often leads to violent explosions and of their insolubility in common organic solvents.[3-6] The instability of the simple alkylcopper compounds is in contrast to the stability of alkylcopper compounds having electronegative substituents such as fluoroalkylcopper[7] and cyanomethylcopper.[8] Some considerably stable arylcopper complexes are also known.[9]

Employment of ligands such as tertiary phosphines and 2,2′-bipyridine often contributes to the stabilization of alkyltransition metal compounds.[10] Concerning the unsubstituted alkylcopper compounds, however, failure to stabilize the copper-alkyl bond using triphenylphosphine,[11] 2,2′-bipyridine,[4] and *N,N*-dimethylformamide[4] has been claimed. Some alkylcopper complexes coordinated with trimethylphosphite and tributylphosphine have been prepared *in situ* at low temperatures but the complexes have not been isolated in analytically pure state.[3b,12]

We have been able to isolate alkylcopper(I) complexes containing triphenylphosphine[13] and tricyclohexylphosphine[6] by the reactions of bis(acetylacetonato)copper, dialkylaluminium monoethoxide, and the phosphine ligands. Extension of the study to the preparation of other phosphine-containing ligands has revealed the marked stabilizing effect of tertiary phosphine ligands in contrast to statements of some of previous papers and led to the isolation not only of the methylcopper complex but also of series of alkylcopper complexes containing longer alkyl chains which are usually regarded unstable because of their tendency to undergo β-elimination. We now describe the preparation and some properties of these alkylcopper complexes containing various tertiary phosphine ligands. The thermal stability of these complexes will be discussed subsequently.

Results and Discussion

Preparation of the Alkylcopper(I) Complexes Containing Various Monodentate Tertiary Phosphines. The methylcopper(I) complexes having various monodentate tertiary phosphine ligands such as triphenylphosphine (PPh_3), diphenylmethylphosphine(PPh_2Me), dimethylphenylphosphine($PPhMe_2$), tributylphosphine(PBu_3), triethylphosphine(PEt_3), and tricyclohexylphosphine (PCy_3), were prepared from copper bis(acetylacetonate), dimethylaluminium monoethoxide, and the appropriate tertiary phosphine (in a 1 : 4 : 3—4 mole ratio) in diethyl ether or toluene under nitrogen. They were isolated as yellow or light yellow crystals, free from aluminum compounds, after recrystallization from appropriate solvents such as tetrahydrofuran(THF), diethyl ether, toluene or mixture thereof.

$Cu(acac)_2$, $Al(CH_3)_2OEt$, Tertiary phosphine →

$CH_3Cu(PPh_3)_2(ether)_{0.5}$	**1a**
$CH_3Cu(PPh_3)_3(toluene)$	**1b**
$CH_3Cu(PPh_2Me)_3$	**3**
$CH_3CuPPhMe_2$	**4**
CH_3CuPEt_3	**5**
CH_3CuPBu_3	**6**

Methylcopper(I) complexes of triphenylphosphine contained toluene or ether as solvent of crystallization. White yellow prisms of $PPhMe_2$, PBu_3, and PEt_3 complexes contained 1—2 molar equivalent of ether or THF as solvent of crystallization which was eliminated by drying *in vacuo*.

a), b) See Table 1. c) Micro analyses were not feasible because of extreme air sensitivity.

The ethyl-, propyl-, isobutylbis(triphenylphosphine)-copper(I) complexes and isobutyl(tricyclohexylphosphine)copper(I) complex were prepared from diethylaluminum ethoxide, dipropylaluminum ethoxide and isobutylaluminum ethoxide, respectively, by a procedure similar to that used for the methyl analogs and were recrystallized from diethyl ether or THF–diethyl ether.

All the isolated complexes are diamagnetic, fairly stable at room temperature in an inert gas atmosphere or *in vacuo* but decomposed rapidly in air. Triphenylphosphine complexes are somewhat light-sensitive and decompose slowly, even at low temperature in sunlight or upon UV irradiation, releasing alkane. Micro analyses of the $PPhMe_2$, PBu_3, and PEt_3 complexes were not feasible because of their extreme instabilities to air. Tables 1 and 2 summarize the analytical data for the isolated alkyl copper complexes having various monodentate tertiary phosphines. Acidolysis or alcoholysis of each alkyl-copper complex released 1 mol equivalent of the corresponding alkane; deuteriolysis with D_2SO_4 liberated alkane-d_1, further supporting the presence of the alkyl-copper bond. These reactions are considered to proceed through stepwise exchange of the acetylacetonato ligands with the alkyl group of AlR_2OEt. Although the nickel[14] and iron[15] complexes with alkyl, acetylacetonato, and triphenylphosphine ligands were isolated respectively as intermediates in the alkylation of their acetylacetonates in the presence of triphenylphosphine to give unstable dialkyl complexes, our attempts to isolate alkylcupric complex containing the acetylacetonato ligand were unsuccessful. However, judging from the gas evolved during the reaction, we believe that the intermediate, unstable alkylCu(II) complex is reduced by splitting of the R–Cu bond yielding the alkylCu(I) complexes.

The alkylcopper(I) complexes having various tertiary phosphine ligands have been also prepared by ligand exchanges of triphenylphosphine complexes with more electron-releasing phosphines such as PPh_2Me, $PPhMe_2$, PBu_3, PEt_3, and PCy_3.

$$RCu(PPh_3)_2 + L \xrightarrow[\text{ether}]{} RCuL + 2PPh_3 \qquad (2)$$

$L = PPh_2Me$, $PPhMe$, PBu_3, PEt_3, PCy_3

In none of these reactions could alkylcopper complexes containing mixed ligands be obtained. Examination of the composition of the alkylcopper complexes in Tables 1 and 2 reveals that the 18 electron rule is fulfilled only for the methylcopper complexes with triphenylphosphine and diphenylmethylphosphine, the least basic ligands among the phosphines used. There seems to be a delicate balance in the number of ligands capable of coordination to copper. Replacement of the methyl group bonded to copper by the ethyl, propyl or isobutyl groups, which are more electron-releasing than methyl, led to alkylcopper complexes containing

two triphenylphosphine ligands even when three molar equivalents of phosphine were used. Furthermore, for ethylcopper, when *ca.* 1 mol equivalent of triphenylphosphine was used, a pale grey complex of approximate composition, $EtCu(PPh_3)$, was obtained, which on further addition of 1 mol equivalent of triphenylphosphine was converted into $EtCu(PPh_3)_2$. Replacement of PPh_2Me with the more basic ligand, $PPhMe_2$, caused a decrease in the number of coordinated phosphine ligands from 3 to 1, and coordination of more basic ligands such as PBu_3, PEt_3, and PCy_3 gave only the alkylcopper complex containing one phosphine ligand.

Since some organocopper compounds are known to be aggregated[16] and some of our complexes are coordinatively unsaturated, it was suspected that some might have polymeric structures. Cryoscopic determination of these complexes, however, revealed the complexes to be all monomeric in benzene as shown in Table 3. The molecular weight determination of $CH_3Cu(PPh_3)_2$-$(ether)_{0.5}$ and $CH_3Cu(PPh_3)_3(toluene)$ gave about the half of the calculated values for the compositions indicated, presumably owing to the dissociative removal of the solvents of crystallization and also, in part, of the three triphenylphosphine ligands in benzene solution.

The IR spectra of the alkylcopper complexes showed ν(C–H) bands assigned to the alkyl group bonded to copper at 2980—2750 cm^{-1} and the characteristic absorption bands of coordinated phosphine ligands. The IR spectra of the ν(C–H) bands in the methylcopper complexes appeared at rather low frequencies, (summarized in Table 4) compared with those of the saturated alkanes. A similar trend has been noted also in other methyl-transition metal complexes.[15,17] The medium intensity IR band observed in the methylcopper complexes in the region from 570 to 610 cm^{-1} which decreases on contact with air or upon pyrolysis was tentatively assigned to the ν(Cu–C) band.

The ^{1}H-NMR spectra of the methylcopper complexes showed a singlet due to the methyl group bonded to copper (Table 4). This band was observed as a somewhat broadened singlet but no splitting due to coupling with ^{31}P and ^{65}Cu or ^{63}Cu was observed at the temperature above −30 °C.

The NMR spectrum of the ethyl complex, **1c,** in toluene-d_8 at −20 °C showed a broad unresolved methyl peak at τ 8.90 and a methylene peak at 8.60. The propyl complex **1e** showed broad peaks due to the methyl and the copper-bonded methylene groups at τ 8.95 (5H) and a peak due to the central methylene at 8.60 (2H). In toluene-d_8 at 25 °C the spectrum of i-$C_4H_9Cu(PPh_3)_2$, **1f**, showed a doublet at τ 9.13 (2H, $C\underline{H}_2$–Cu, $^3J_{H-H}$ 7 Hz), a doublet at 8.68 (6H, $2C\underline{H}_3$, $^3J_{H-H}$ 6 Hz) and an unresolved multiplet at 8.00 (1H, C<u>H</u>). It is note-worthy that the protons attached to carbon bonded to copper appear at considerably higher field because of the shielding effect of copper in the complexes. It appears that peaks of methyl protons in copper complexes coordinated to rather basic ligands is slightly shifted to higher field, but the effect is not particulary conspicuous.

The ^{1}H-decoupled ^{31}P NMR spectrum of **3** in toluene at −80 °C showed a sharp singlet resonance at 6.1 ppm (up-field from the external PPh_3 reference in toluene) and a small signal of free PPh_2Me at 19.3 ppm whereas at −40 °C the singlet at 6.1 ppm broadened and shifted to higher field 8.4 ppm accompanied by disappearance of the free PPh_2Me signal. The spectrum of a toluene solution of **3** containing three mol equivalents of added PPh_2Me at −80 °C exhibited a somewhat broadened singlet at 9.2 ppm and a sharp singlet due to free PPh_2Me at 19.7 ppm. At −20 °C the two peaks collapsed to a broadened singlet centered at 16.8 ppm. These results indicate that at −80 °C the methylcopper complex with three PPh_2Me ligands is not extensively

dissociated but that upon raising the temperature the complex liberates part of the coordinated PPh_2Me ligands. In the presence of added PPh_2Me at −20 °C the exchange between the coordinated and added PPh_2Me ligands is considered to be taking place rapidly.

Preparation of the Alkylcopper(I) Complexes Containing a Bidentate Tertiary Phosphine. The alkylcopper complexes containing a coordinated bidentate ligand, dpe, present unique features quite different from those of the alkylcopper complexes containing monodentate ligands. Ethyl, propyl, and isobutylcopper complexes of composition $(RCu)_2(dpe)_3$ have been obtained by the reaction of bis(acetylacetonato)copper, dpe and dialkylalminium monoethoxides in diethyl ether or in toluene under nitrogen. Analytical data are given in Table 5.

$$\left.\begin{array}{l}Cu(acac)_2\\ Ph_2PCH_2CH_2PPh_2(dpe)\\ AlR_2(OEt)\end{array}\right\} \longrightarrow (RCu)_2(dpe)_3 \qquad (3)$$

2c, R=C_2H_5; **2d**, R=C_3H_7; **2e**, R=i-C_4H_9

The number of alkyl groups and dpe ligands attached to copper has been determined by elemental analysis, volumetry after acidolysis or alcoholysis, and spectroscopic determination of the released dpe ligands upon acidolysis. Copper complexes having dpe ligands in a Cu/P ratio of 2/3 are known for the arylcopper(I)[18] and copper(I) halide complexes[19] and the molecular structure,[20] in which dpe ligands are bonded with copper, one forming a chelate and the other bridging between copper atoms has been established. The present alkyl complexes with dpe ligands may well have a similar structure, but the instability of the complexes in solution (*vide infra*) has precluded further characterization.

The use of dimethylaluminium monoethoxide in the reaction with $Cu(acac)_2$ and dpe gave a binary complex which is thermally very stable and moderately insensitive to air. The complex contains both copper and aluminum in a ratio of 1 : 2 and four methyl groups per copper, one of which is probably bonded to copper since one mol equivalent of methane was liberated from the complex on thermolysis at 180 °C. On treatment with HCl in diethyl ether, a quantitative yield of ethyl alcohol was obtained. The overall complex composition is $CuAl_2(CH_3)_4(dpe)_2(OEt)_2$ **2a**. Similar binary addition products containing alkylaluminium components are known for manganese[21] and titanium.[22]

Recrystallization of this complex **2a** from relatively basic solvents such as tetrahydrofuran led to dissociation of the aluminium and copper components and gave a cream yellow complex $(CH_3Cu)_2(dpe)_3$, **2b**. Use of more basic solvents such as pyridine and *N,N*-dimethylformamide led to decomposition of the methylcopper complex liberating CH_4.

Intramolecular Reaction of Alkylcopper Complexes with dpe Ligands Involving the P–C Bond Cleavage of the dpe Ligand. Despite the fact that the dpe-coordinated complexes show substantially enhanced thermal stability in the solid state, dissolution of $(RCu)_2(dpe)_3$ type complexes **2b**—**2e** in THF, benzene, toluene, and pyridine, leads to a quite facile decomposition with the evolution of an almost quantitative amount of alkane as expressed by the following equation.

$$\underset{\textbf{(2b—2d)}}{(RCu)_2(dpe)_3} \xrightarrow[\text{solvent}]{} \underset{\textbf{(2f)}}{Ph_2PCu(dpe)} + Ph_2PCH{=}CH_2 + RH + [RCu(dpe)] \qquad (4)$$

R=CH_3, C_2H_5, n-C_3H_7, i-C_4H_9

The greenish yellow complex **2f** isolated from the reaction solution analyzed as $Ph_2PCu(dpe)$ (Table 5) and gas chromatographic analysis of the reaction products confirmed the formation of diphenylvinylphosphine and of alkanes. Complex **2f** was characterized by its reaction with dry hydrogen chloride yielding diphenylphosphine, PPh_2H, and with methyl iodide or ethyl iodide affording PPh_2Me or PPh_2Et.

The reaction may proceed as shown in the following Scheme 1.

Dissolution of the coordinatively saturated binuclear complex $(RCu)_2(dpe)_3$ may cause dissociation to RCu(dpe) and complex (A) containing one chelated dpe ligand and the other dpe ligand bonded to copper as a monodentate ligand having the other phosphine end free in solution. This situation may lead to the approach of one of the methylene groups in the partially dissociated dpe into the proximity of the alkyl group which then attacks the methylene and abstracts hydro-

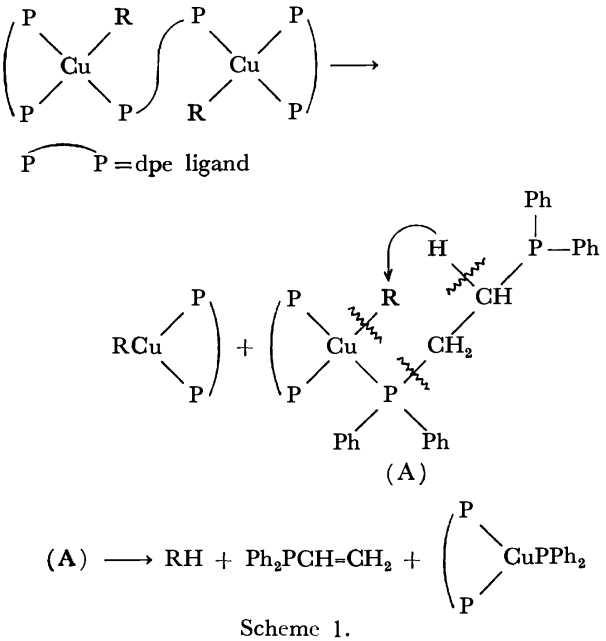
a), b) See Table 1.



Scheme 1.

gen, at the same time causing scission of the P–C bond in dpe, thus yielding alkane, diphenylvinylphosphine, and $Ph_2PCu(dpe)$. Addition of one or more equivalent of dpe to the system promoted the reaction: all the alkyl groups were liberated as alkane more rapidly than in the absence of added dpe, and $(RCu)_2(dpe)_3$ was quantitatively converted into $Ph_2PCu(dpe)$, $Ph_2PCH=CH_2$, and the alkane. Presumably the addition of the extra dpe ligand enhances the formation of intermediate species (A) thus promoting decomposition. Addition of Lewis acids such as trimethylaluminium, aluminium trichloride, and boron trifluoride markedly promoted the decomposition even at low temperature. Similar promotion of decomposition of a stable arylcopper complex in the presence of dpe has been reported by van Koten and Noltes.[23]

Attempts to isolate RCu(dpe) using the dpe ligand and $Cu(acac)_2$ (1 : 1 ratio) led to the isolation of an extremely air-sensitive white powder, which could not be identified.

Properties of Alkylcopper Complexes. Polymerization: The isolated alkylcopper complexes exhibited polymerization activity toward vinyl monomers containing electron-withdrawing substituents. Acrylonitrile, methacrylonitrile, acrylaldehyde, methyl acrylate, methyl methacrylate, and 2-vinylpyridine were rapidly polymerized in the presence of alkylcopper complexes. As with other alkyltransition metal complexes polymerization mayproceed by a coordination mechanism.[24] Polymerization of vinyl compounds by organocopper complexes has also been reported.[25]

Among the alkylcopper complexes, the binary complex **2a** showed the highest polymerization activity. The polymerization of acrylonitrile, methacrylonitrile, and acrylaldehyde took place explosively, and methyl acrylate and methyl methacrylate also polymerized very rapidly with **2a**. Other dpe-coordinated complexes **2b** and **2c** were also very active, quantitatively converting acrylonitrile, methacrylonitrile, and methyl methacrylate, into their polymers below −10 °C within several minutes.

Reactions with Alkyl and Acyl Halides: Methylcopper complexes **1a**, **1b**, **2b**, and **3** reacted with methyl iodide to yield one mol equivalent of C_2H_6. Reactions with ethyl bromide gave mainly C_3H_8 and small amounts of CH_4, C_2H_4, and C_2H_6. The reactions of the ethylcopper complexes **1c**, **1d**, and **2c** with methyl iodide released only C_3H_8 and propylcopper complexes **1e** and **2d** with methyl iodide liberated only C_4H_{10}. The formation of the cross-coupling products as the main gaseous products and of small amounts of CH_4, C_2H_4, and C_2H_6 in the reaction of the methylcopper complexes with ethyl bromide suggests that an unstable Cu(III) intermediate might be formed by oxidative addition of the alkyl halide to the alkylcopper complexes. Cu(III) complexes have not been isolated, but the comparison of the behavior of the alkylcopper complexes with that of alkylgold complexes, the Au(III) state of which is well known,[26] makes the assumption of the intermediacy of Cu(III) complexes not too unreasonable.

$CH_3Cu(PPh_3)_2(ether)_{0.5}$ **1a** reacted also readily with acetyl chloride to give acetone and with benzoyl chloride to yield acetophenone.

Experimental

Materials and General Procedures. All preparations and recrystallizations were carried out under deoxgenated nitrogen, argon, or *in vacuo*. Solvents were dried by usual procedures, distilled, and stored under argon or nitrogen.

Copper bis(acetylacetonate) was prepared as described in the literature.[27] Found; C, 45.3; H, 5.49; Cu, 24.4%(Calcd for; C, 45.8; H, 5.39; Cu, 24.3%). Dialkylaluminium monoethoxide was prepared by the reaction of trialkylalminium with ethyl alcohol in hexane followed by vaccum distillation.

Triphenylphosphine was used as purchased, mp 80—81 °C. dpe,[28] tricyclohexylphosphine,[29] diphenylmethylphosphine,[30] dimethylphenylphosphine,[28] triethylphosphine,[30] and tributylphosphine[31] were prepared as described in the literature.

Analytical Methods. IR spectra were recorded on a Hitachi Model EPI-G3 using KBr discs prepared under nitrogen and proton NMR spectra were recorded on a Japan Electron Optics Lab. JNM-PS-100 spectrometer. Evolved gases were analyzed using a Hitachi RMU-5B mass-spectrometer and a Shimadzu GC-5B gas chromatograph. Microanalyses for carbon, hydrogen and nitrogen were performed by Mr. T. Saito of our laboratory with a Yanagimoto CHN Autocorder Type MT-2. Triphenylphosphine and dpe contents were determined spectroscopically after hydrolysis with dilute sulfuric acid or by weighing triphenylphosphine oxide. The tricyclohexylphosphine-content was also determined by weighing its oxide, as described above. The other phosphine contents were determined by NMR proton concentration measurements as compared with internal references in their NMR spectra. Molecular weights were determined in benzene solution by a cryoscopic method.

The copper-content was determined by iodometry after digesting the sample with concentrated sulfuric acid. The aluminium content was determined, after the removal of cupric hydroxide and phosphine, gravimetrically as the alminium oxime complex, $Al(C_9H_6ON)_3$.

Preparation of a Series of Alkylcopper Complexes with Triphenylphosphine. *$CH_3Cu(PPh_3)_2(ether)_{0.5}$, **1a***: To an ethereal suspension of copper bis(acetylacetonate) 2.6 g (10 mmol)

and 3 molar eqivalents of triphenylphosphine(7.8 g), 4 molar equivalents of dimethylalminium ethoxide(6.5 ml) was added slowly at −40 °C. The mixture was allowed to react initially at −40 °C and the temperature was subsequently raised gradually to −10 to 0 °C until yellow crystals precipitated from the yellow orange solution. The complex wihch was separated by filtration was dissolced in ether–THF below 0 °C. From the yellow orange solution, the yellow cristals which were obtained upon cooling, were filtered, repeatedly washed with dry ether, dried *in vacuo* at room temperature in the dark and characterized as $CH_3Cu(PPh_3)_2\cdot(ether)_{0.5}$; yield, 5.5 g (86%). Upon pyrolysis at 85 °C, **1a** gave one half molar equivalent of diethyl ether which was identified by mass spectrometry. The NMR spectrum of **1a** in THF had a singlet at τ 10.3 (3H, C$\underline{H}_3$–Cu), a quartet at 7.5 (2H, –C$\underline{H}_2$– in ether), a triplet at 8.8 (3H, C$\underline{H}_3$– in ether) and a multiplet at 2.5 (30H, C$_6\underline{H}_5$).

$CH_3Cu(PPh_3)_3$(toluene), ***1b***: Dimethylalminium ethoxide (5 ml, 30 mmol) was added slowly to an ethereal suspension of copper bis(acetylacetonate) (2.0 g, 7.6 mmol) and PPh_3 (7.3 g, 27 mmol) at −40 °C. The mixture was subsequently raised gradually to room temperature (6 h) to give a deep yellow solution. On cooling, the light yellow needles which precipitated were filtered off and recrystallized from toluene, washed with hexane, dried *in vacuo* and characterized as $CH_3Cu(PPh_3)_3$(toluene); yield, 3.6 g (50%). On pyrolysis at 160 °C, **1b** gave one molar equivalent of toluene. The NMR spectrum of **1b** in THF showed singlets at τ 10.4 (3H, C$\underline{H}_3$–Cu), 7.7 (3H, C$\underline{H}_3$–C$_6$H$_5$) and a multiplet at 2.7 (50H, C$_6\underline{H}_5$).

$C_2H_5Cu(PPh_3)_2$, ***1c***: $Cu(acac)_2$ (2.6 g, 10 mmol), PPh_3 (7.8 g, 30 mmol) and diethylalminium ethoxide 7 ml were mixed at −30 °C. The temperature was gradually raised to 0 °C, and a bright yellow complex slowly precipitated with dissolution of $Cu(acac)_2$ in ether. After 7 h stirring the reaction products were removed by filtration, recrystallized from ether–THF, dried *in vacuo* and characterized as C_2H_5-$Cu(PPh_3)_2$; yield, 4.4 g (71%).

$C_2H_5CuPPh_3$, ***1d***: Diethylaluminium monoethoxide (7.0 ml, 45.6 mmol) was added to the ethereal suspension containing $Cu(acac)_2$ (4.0 g, 15.2 mmol) and triphenylphosphine (4.5 g, 17.2 mmol) at −40 °C. From the dark yellow solution, obtained after the $Cu(acac)_2$ had completely dissolved in ether, a white gray complex gradually precipitated as the temperature was raised to 0 °C. After stirring for 3 h below 0 °C, the complex was filtered, washed repeatedly with ether and dried *in vacuo* at room temperature (yield, 60%).

n-*$C_3H_7Cu(PPh_3)_2$*, ***1e***: $Cu(acac)_2$ (2.6 g, 10 mmol), PPh_3 (7.8 g, 30 mmol) and dipropylalminium ethoxide(8 ml) were mixed at −30 °C. The temperature was gradually raised to 0 °C, and an orange yellow solution was obtained with dissolution of $Cu(acac)_2$ in ether. On cooling the solution after addition of a small amount of hexane, greenish yellow prisms precipitated, which were filtered, repeatedly washed with ether–hexane, and dried *in vacuo* at room temperature in the dark. The complex was characterized as n-$C_3H_7Cu(PPh_3)_2$; 3.0 g (48%).

i-*$C_4H_9Cu(PPh_3)_2$*, ***1f***: This compound was prepared by the procedure described above. The complex, obtained as primrose-yellow crystals, was characterized as i-C_4H_9Cu-$(PPh_3)_2$, (yield, 54%).

Preparation of Alkylcopper Complexes with 1,2-Bis(diphenyl phosphino)ethane. Methylcopper Complex Containing Alkylalminium Components, $CuAl_2(CH_3)_4(dpe)_2(OEt)_2$, ***2a***: Dimethylalminium ethoxide, 10 ml, was added slowly to an ethereal suspension containing copper bis(acetylacetonate) (4.5 g) and dpe (17.1 g) at −40 °C. When the mixture was subsequently raised gradually to room temperature, a cream yellow complex slowly precipitated with dissolution of copper bis(acetylacetonate) in ether. After about 10 h of stirring a light yellow precipitate formed was filtered, repeatedly washed with ether, dried *in vacuo*, and characterized as $CuAl_2(CH_3)_4(dpe)_2(OEt)_2$. The complex was diamagnetic and had the correct elemental analyses, (yield, 80—90%). Acidolysis with dry HCl in ether resulted in a quantitative yield of CH_4 together with ethyl alcohol.

$(CH_3Cu)_2(dpe)_3$, ***2b***: The alminium-containing complex **2a** was dissolved in THF and addition of ether to the resultant light orange solution gave white yellow prisms on cooling overnight. The crystals were filtered, washed repeatedly with ether, dried *in vacuo* and characterized as $(CH_3Cu)_2$-$(dpe)_3$, (yield, 20%).

$(C_2H_5Cu)_2(dpe)_3$, ***2c***: Copper bis(acetylacetonate) (2.6 g) and dpe (8.8 g) were suspended in 100 ml of ether and 6.5 ml of diethylalminium ethoxide was added at −40 °C. The mixture was allowed to react initially at this temperature which was then raised gradually to room temperature until the reagents completely dissolved in ether, and then a lemon yellow complex was gradually precipitated from the resulted yellow orange solution. After about 5 h of stirring at room temperature, the reaction product was filtered, repeatedly washed with ether, dried in vacuum, and characterized as $(C_2H_5Cu)_2(dpe)_3$, (yield, 85%). Attempts of recrystallization resulted in decomposition.

(n-$C_3H_7Cu)_2(dpe)_3$, ***2d*** *and (i-$C_4H_9Cu)_2(dpe)_3$*, ***2e***: These were prepared by the procedure described above but attempts of recrystallization resulted in decomposition, (yield, 80—90%).

$Ph_2PCu(dpe)$, ***2f***: The alkylcopper complexes of dpe, $(CuR)_2(dpe)_3$, were suspended in THF or toluene and then allowed to warm from room temperature until the complexes were completely dissolved in THF or toluene. After cooling the solution, greenish yellow prisms were obtained, which were recrystallized from THF or toluene, (yield, 45%).

Preparation of Alkylcopper(I) Complexes with Other Tertiary Phosphines. $CH_3Cu(PPh_2Me)_3$, ***3***: To an ethereal suspension of $Cu(acac)_2$, 4 molar equivalents of PPh_2Me was added at −45 °C and then 4 molar equiv of Me_2AlOEt was slowly added at the same temperature. Blue crystals of $Cu(acac)_2$ gradually dissolved in ether with evolution of CH_4 and C_2H_6 with temperature being raised gradually to room temperature. A white yellow complex precipitated from the orange yellow solution on stirring for 6 h. The complex which was separated by filtration was dissolved in ether–THF at the temperature below 0 °C. From the yellow solution, white yellow crystals were obtained on cooling, washed repeatedly with ether, dried *in vacuo* at room temperature in the dark and characterized as $CH_3Cu(PPh_2Me)_3$, (yield, 63%). The NMR spectrum of **3**, in toluene-d_8 at −20 °C, had a singlet at τ 10.50 (3H, C$\underline{H}_3$–Cu), a singlet at 8.60 (9H, C$\underline{H}_3$–P), a multiplet at 3.16—2.50 (30H, (C$_6\underline{H}_5$)$_2$–P).

$CH_3Cu(PPhMe_2)$, ***4***: At −45 °C, 3 molar equivalents of $PPhMe_2$ was added to an ethereal suspension of $Cu(acac)_2$ and then 4 molar equiv of Me_2AlOEt was slowly added. After the temperature was gradually raised to 0 °C with stirring, a light yellow solution was obtained. The solution was allowed to condense by evaporation under a reduced pressure and then a small amount of hexane was added to it. After cooling the solution at −78 °C, white yellow crystals slowly precipitated and were recrystallized from ether–hexane solvent mixture. The white yellow complex thus obtained was characterized as $CH_3CuPPhMe_2$, (yield, 35%).

CH_3CuPBu_3, ***6***: To an ethereal suspension of $Cu(acac)_2$, 3—4 molar equiv of PBu_3 was added at −40 °C and then 4 molar equiv of dimethylalminium ethoxide was slowly added at the same temperature. With a gradual raise of the temperature, $Cu(acac)_2$ dissolved in ether and CH_4 and C_2H_6 were released to give a yellow solution at room temperature. After condensation of the ether solution, the residue was extracted with hexane. White yellow prisms, isolated from the hexane solution upon cooling, were washed repeatedly with small amounts of hexane below 0 °C, dried *in vacuo* and characterized as CH_3CuPBu_3, **6**, (yield 65%).

CH_3CuPEt_3, ***5***: This was prepared by the procedure described above, and recrystallized from an ether–THF–hexane solvent mixture, (yield, 45%). Light yellow crystals.

Preparation of Butyl(tricyclohexylphosphine)copper, ***7***:

$Cu(acac)_2$ 4 g (15 mmol) and tricyclohexylphosphine 9 g (31.9 mmol) were suspended in 100 ml of ether, and 13 ml of diisobutylaluminium ethoxide was added to the suspension at −30 °C. After the temperature was raised gradually to room temperature with stirring, a pale yellow solution was obtained. After cooling the solution, cream yellow prisms deposited, which were filtered, washed repeatedly with ether and hexane, dried *in vacuo*, and characterized as *i*-$BuCuPCy_3$. The complex was recrystallized from ether, (yield, 60%).

Polymerization. Most of the polymerizations were carried out in a sealed ampoule or in a Schlenk type flask in which the alkylcopper complex (50—100 mg) and olefin (5—10 ml) were transferred in an atmosphere of nitrogen or by a trap-to-trap distillation *in vacuo*. After the polymerization was complete, the content in the flask was poured into acidic methanol. The precipitate was filtered, washed with methanol and dried. The polymers of acrylonitrile obtained with **Ia** and **Ic** had molecular weights of *ca.* 1.2×10^4, and poly(methyl methacrylate) 1.3—7.1×10^5 determined by a viscosity method.

Thermal Stability of Alkylcopper(I) Complexes Coordinated with Tertiary Phosphines

Akira MIYASHITA, Takakazu YAMAMOTO, and Akio YAMAMOTO
Research Laboratory of Resourecs Utilization, Tokyo Institute of Technology, O-okayama, Meguro-ku, Tokyo 152
(Received November 12, 1976)

Thermolysis of isolated alkylcopper(I) complexes having tertiary phosphine ligand(s) $RCuL_n$ ($R=CH_3$, C_2H_5, n-C_3H_7, i-C_4H_9) in the solid state and in toluene has been studied in order to clarify the role of the tertiary phosphine ligand in stabilizing the alkylcopper(I) complexes. The distribution of the thermolysis products shows that the thermolysis of the alkylcopper complexes having ethyl or longer alkyl chain proceeds through a β-elimination mechanism. The rate of the thermolysis obeys the first order rate law, $-d[RCuL_n]/dt=k[RCuL_n]$. The activation parameters of the thermolysis were obtained from the temperature dependence of k and a compensation effect between ΔH^* and ΔS^* was demonstrated. The activation energy E_a of the thermolysis of $RCu(PPh_3)_2$ increases in the order of $R=C_2H_5<n$-$C_3H_7<i$-C_4H_9. Coordination of electron-donating tertiary phosphine decreases E_a and a linear relationship between $\nu(Cu-CH_3)$ frequencies and E_a for thermolysis of the methylcopper complexes was observed. Addition of PPh_3 into the toluene solutions of $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$ and C_2H_5-$Cu(PPh_3)_2$ causes some retardation of the thermolysis. The major role of the tertiary phosphine ligand in stabilizing the alkylcopper complexes is proposed to strengthen the Cu–C bond by changing the electronic state of copper atom. An energetic consideration based on Chatt and Shaw's theory is given in order to account for the results concerning the stabilities of the alkylcopper complexes. Photolysis of the alkylcopper complexes takes a quite different decomposition pathway producing mainly RH from $RCuL_n$.

The problem of the stability of transition metal to carbon bond is of fundamental importance in organotransition metal chemistry. Information regarding the stability of trasition metal-carbon σ bond and how to stabilize or activate the σ bond is quite desirable for theoretical discussion of the nature of the metal-carbon σ bond as well as in accounting for the mechanisms of organic syntheses promoted by transition metal compounds.[1] However, because of the scarcity of the isolated alkyltransition metal compounds possessing considerable thermal stabilities, the discussions have remained empirical and often have been based on the relative ease for the preparation of an alkyltransition metal compound. Two lines of theories have been proposed concerning the factors determining the stability of a transition metal-carbon bond. The first one, originally proposed by Chatt and Shaw,[2] relates the stability with the energy gap required to promote an electron from predominantly non-bonding d-orbitals to antibonding metal-carbon orbitals (σ^*_{M-C}) or from bonding metal-carbon orbitals (σ_{M-C}) to vacant or half-filled d-orbitals, and the role of the stabilizing ligand was accounted for in terms of the increase in the energy gap. A partially modified scheme of this model was proposed by us to account for the stability of dialkyl(2,2′-bipyridine)nickel and activation of the Ni–C bonds in the presence of electronegative olefins.[3] The other theory stresses the importance of low energy decomposition pathway, particularly a β-elimination process[4,5] and accounts for the role of the "stabilizing ligand" mainly as blocking the site required for the β-elimination process to proceed. On the basis of the latter theory some "elimination stabilized alkyls" such as trimethylsilylmethyl have been successfully prepared.[4,5c,5d]

Although the number of isolated alkyltransition metal complexes is rapidly increasing in recent years, works reporting the kinetics of the decomposition process and dealing with the analysis of the decomposition products are relatively limited.[3,5,6,12,15] Thermolysis of alkylcopper complexes have been studied by Whitesides[5a,5e] and Kochi.[7] Unfortunately, however, the studies have been made on the complexes prepared *in situ* from copper salts and alkylating agents and the systems studied may well contain some impurities, albeit in small quantities. Since the presence of a Lewis acid is known to affect the stability and decomposition course of an alkyl- or hydridotransition metal complex,[8,9] results obtained in somewhat impure systems are not quite unequivocal.

We have isolated series of alkylcopper complexes containing various tertiary phosphines and observed the pronounced effect of the tertary phosphine ligands on stabilization of the alkylcopper compounds.[10] In contrast to the extremely unstable ligand-free methylcopper which decomposes violently at room temperature, the phosphine-stabilized alkylcopper complexes are considerably stable and provide a suitable probe for testing the validity of the existing theories. We report here the kinetic study of thermolysis of the alkylcopper complexes and analysis of the gaseous products generated in the thermolysis with a hope to provide pertinent data relevant to the discussion of the thermal stability of alkylcopper complexes.

Results and Discussion

Thermolysis of Alkylcopper Complexes in Solid State. Decomposition Temperature and Thermolysis Products: The isolated alkylcopper complexes containing tertiary phosphine ligands were thermolyzed in solid state in vacuum and the composition of the evolved gases was analyzed. Table 1 summarizes the decomposition points of various alkylcopper complexes with teriary phosphine ligands and the compositions of the evolved gases. Table 1 also includes the sum of the amounts of gaseous products generated per copper atom (ΣR).

The results in Table 1 indicate almost quantitative

Table 1. Decomposition points (dp) of alkylcopper complexes and their pyrolysis products

liberation of the alkyl groups as gaseous products on the thermolysis. Decomposition points in Table 1 refer to the temperature at which smooth evolution of gas started on heating the complexes in vacuum. Most complexes decompose with melting but some complexes evolve gas at much higher temperature than their melting points. The dpe-coordinated complexes (dpe=1,2-bis(diphenylphosphino)ethane) showed the highest decomposition points and particularly the methylcopper complex containing an aluminum component was so stable as it was not decomposed up to 230 °C. A similar enhancement of the thermal stability was observed in a manganese hydride complex containing an alkylaluminum component.[9] The decomposition points of the tricyclohexylphosphine (PCy_3) -coordinated complexes ranked next to the dpe-containing complexes to be followed by PPh_3-coordinated (PPh_3=triphenylphosphine) complexes. The dpe- and PCy_3-coordinated complexes showed some variation in decomposition points depending on the alkyl group bonded to copper, whereas the difference in decomposition points of the PPh_3-coordinated complexes was not so marked.

In the thermolysis of solid methylcopper complexes coordinated with $P(C_6H_5)(CH_3)_2$, $P(C_2H_5)_3$, and $P(C_4H_9)_3$ ligands, considerable amounts of methane were evolved in addition to ethane. Since the value of ΣR is about 100%, the source of hydrogen for methane formation should be the phosphine ligands and this fact together with the absence of ethylene in the thermolysis products excludes the possibility of α-elimination which was observed for thermolysis of $(CH_3)_2Fe(dpe)_2$[11] and $CH_3CrCl_2L_n$.[12] On the other hand, evolution of ethylene was observed in thermolysis of $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$ and $(CH_3Cu)_2(dpe)_3$ which may partly decompose by the α-elimination.

In the thermolysis of the alkylcopper complex with ethyl or longer alkyl chain, both alkane and alkene are formed, the latter being more predominant, accompanied by evolution of molecular hydrogen. Examination of the distributions of alkanes, alkenes and H_2 evolved from PPh_3- and PCy_3-coordinated complexes revealed that the amounts of H_2 evolved correspond to about half of the difference between the amounts of alkanes and alkenes.

These observations suggest that the thermolysis of the alkylcopper complexes having ethyl or longer alkyl chain proceeds by the following scheme comprising β-elimination (Eq. 1), coupling of the alkyl and hydrido ligands (Eq. 2), and evolution of H_2 from the copper hydride (Eq. 3). The participation of all molecules of the copper hydride in either the reaction (2) or (3) was confirmed by the absence of hydrogen evolution on treatment of the thermolysis residue with H_2SO_4.

$$RCuL_n \rightarrow CuHL_n + R(-H) \quad (1)$$

$$HCuL_n + RCuL_n \rightarrow RH + 2CuL_n \quad (2)$$

$$HCuL_n \rightarrow 1/2H_2 + CuL_n \quad (3)$$

Whitesides and coworkers have proposed a similar mechanism for the thermolysis of butyl-1,1-d_2-(tributylphosphine)copper(I) prepared *in situ* by analyzing the composition of the gases evolved.[5a]

in solid state was followed by measuring the gas evolved at fixed temperatures.

Figure 1 shows the results of typical thermolysis experiments. The volume of gas evolved on heating a solid sample at certain temperature was measured and plotted *versus* time. Since the composition of the gas evolved during the course of thermolysis did not vary significantly, the value of $(V_\infty - V_t)$, where V_∞ and V_t refer to the gas volumes evolved at infinite time and time t, corresponds to the amount of the alkylcopper complex remaining undecomposed. Plots of $\log(V_\infty - V_t)$ *versus* time t give straight lines with some curvatures in the initial stages as shown in Fig. 2. In most cases the portion of the straight line covers a

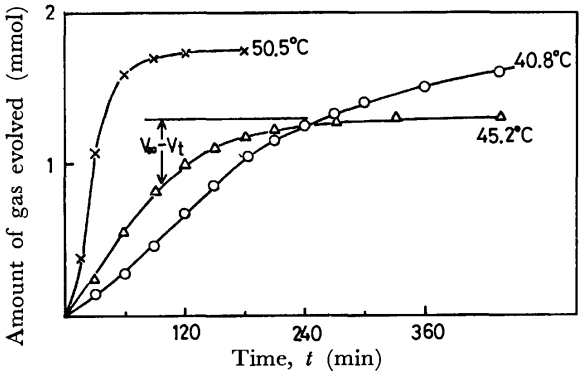

Fig 1. Time curves of the amount of gas evolved in the thermolyses of $C_2H_5Cu(PPh_3)_2$ at fixed temperatures. Amount of $C_2H_5Cu(PPh_3)_2$: 50.5 °C, 920 mg; 45.2 °C, 690 mg; 40.8 °C, 950 mg.

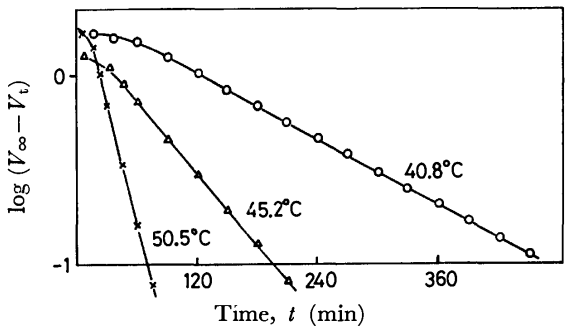

Fig. 2. The first-order plots of the data in Fig. 1.

range corresponding to decomposition of about 80% of the alkylcopper complex. In this paper we are concerned with the region where the linear relationship holds between $\log(V_\infty - V_t)$ and time. The rate constants in the first-order expression

$$-d[RCuL_n]/dt = k[RCuL_n]$$

are given in Table 2. From Arrhenius plots of the rate constants in Table 2 activation energies and kinetic parameters were computed and are summarized in Table 3.

That the first-order rate law holds in the thermolysis of the alkylcopper complexes having ethyl or longer alkyl chain indicates that the formation of the copper hydride by the β-elimination (Eq. 1) is rapidly followed by the process (2) or (3). This is consistent with Whitesides and coworker's observation[13] that the copper hydride prepared *in situ* decomposed even at −20 °C to evolve H_2 and in the presence of an alkylcopper(I) complex it underwent a facile coupling reaction to produce RH at −20 °C to −30 °C.

Furthermore, the first-order rate law for the thermolysis of the methylcopper complexes suggests that the methyl group ("CH_3") liberated from the methylcopper complex by a spontaneous unimolecular process

(Eq. 4) will rapidly abstract hydrogen from the phosphine ligand (Eq. 5) or couple with the CH_3 group in another molecule of the methylcopper complex (Eq. 6) to evolve CH_4 and C_2H_6, respectively. Abstraction of hydrogen of CH_3 group in the methylcopper complex by "CH_3" to produce CH_4 and a carbenoid species (Eq. 7) may also take place,

$$CH_3CuL_n \rightarrow \text{"}CuL_n\text{"} + \text{"}CH_3\text{"} \quad (4)$$

$$\text{"}CuL_n\text{"} + \text{"}CH_3\text{"} \rightarrow CH_4 + CuL_{n-1}(L(-H)) \quad (5)$$

$$\text{"}CH_3\text{"} + CH_3CuL_n \rightarrow C_2H_6 + CuL_n \quad (6)$$

$$\text{"}CH_3\text{"} + CH_3CuL_n \rightarrow CH_4 + CH_2{=}CuL_n \quad (7)$$

$$CH_2{=}CuL_n \rightarrow 1/2C_2H_4 \quad (8)$$

where L(−H) represents a ligand from which a hydrogen atom was taken away by the methyl group.

The course of the thermolysis of $CH_3Cu(PPh_3)_2$ (diethyl ether)$_{0.5}$ consists of two stages. The gas evolved at the earlier stage was composed mainly of diethyl ether and scission of the Cu–CH_3 bond started after the quantitative evolution of diethyl ether. The rate constants in Table 2 and the activation energy in Table 3 are referred to the latter stage.

A Compensation Effect between the Enthalpy of Activation and the Entropy of Activation: Examination of the results in Tables 1, 2 and 3 reveals several interesting features of the thermolysis. Although it may be expected that a complex having higher activation energy for the thermolysis has a higher decomposition temperature, it is seen from the tables that there exists no correlation between the decomposition point of an alkylcopper complex and its activation energy for thermolysis. We consider that the activation energy for thermolysis more directly reflects the intrinsic strength of the Cu–C bond than the decomposition temperature. The present observation suggests that it is not always justified to discuss the strength of the alkyl-transition metal bond referring only to the decomposition points of the complexes, although they may be often used as practical criteria of the strength of the alkyl-transition metal bond.

A plot of the enthalpy of activation ΔH^* against the entropy of activation ΔS^* for the thermolysis of the alkylcopper complexes gave a straight line with a slope $\Delta H^*/\Delta S^* = 270$ deg (Fig. 3) which corresponds to a value of about one for $\Delta H^*/T\Delta S^*$ under the experimental conditions indicating that the increase in ΔH^* does not cause a direct increase in ΔF^* but is almost completely cancelled by the decrease in $-T\Delta S^*$.

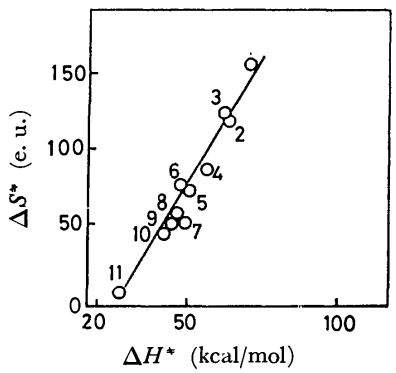

Fig. 3. The compensation effect between ΔH^* and ΔS^*. 1: i-$C_4H_9Cu(PPh_3)_2$, 2: n-$C_3H_7Cu(PPh_3)_2$, 3: $C_2H_5CuPPh_3$, 4: $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$, 5: $CH_3Cu(PPh_3)_3$(toluene), 6: $C_2H_5Cu(PPh_3)_2$, 7: $(CH_3Cu)_2(dpe)_3$, 8: i-$C_4H_9CuPCy_3$, 9: $CH_3Cu(P(C_6H_5)_2CH_3)_3$, 10: $(i\text{-}C_4H_9Cu)_2(dpe)_3$, 11: $CH_3Cu(PCy_3)$.

These results explain the lack of correlation between the decomposition points of alkylcopper complexes and their activation energies for thermolysis. The compensation effect is particularly well demonstrated in a series of $RCu(PPh_3)_2$ complexes. In contrast to the steady and significant increase of the activation energy for thermolysis from the ethyl (47 kcal/mol) through the propyl (63) to the isobutyl (70) the decomposition points vary only slightly (Table 1).

We have observed a compensation effect between ΔH^* and ΔS^* for the splitting of nickel-alkyl bonds induced by olefin coordination.[14]

Thermolysis of Alkylcopper Complexes in Solution.

The alkylcopper complexes have lower stability in solution than in the solid state. The decomposition of the complexes in solution set in at the lower temperature by 40—50 °C than that in the solid state. One mol of $C_2H_5Cu(PPh_3)_2$ evolved 0.59 mol of ethylene, 0.33 mol of ethane and 0.15 mol of H_2 on the thermolysis in toluene at 10 °C. The distribution of the gases evolved in toluene is essentially the same as that of gases evolved in solid state. The results indicate that the thermolysis of the ethylcopper complex in toluene proceeds through the same processes as those proposed for the thermolysis in the solid state (Eqs. 1, 2 and 3). The thermolysis in toluene obeyed

Table 4. The first-order rate constants of the thermolysis of $C_2H_5Cu(PPh_3)_2$ and $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$ in toluene

Compound[a]	[PPh_3 added]/[Cu complex]	Rate constant[b] (s^{-1})
$C_2H_5Cu(PPh_3)_2$	0	4.8(−2.1), 7.1(0.3), 18(4.7), 34(7.8)
$C_2H_5Cu(PPh_3)_2$	1.0	13(4.7)
$C_2H_5Cu(PPh_3)_2$	2.0	9.4(4.7)
$C_2H_5Cu(PPh_3)_2$	4.1	1.3(−3.3), 3.0(0.2), 8.9(4.7)
$CH_3Cu(PPh_3)_2(Et_2O)_{0.5}$	0	1.3(22.6), 3.4(27.1), 7.7(30.0)
$CH_3Cu(PPh_3)_2(Et_2O)_{0.5}$	1.9	3.0(27.0)
$CH_3Cu(PPh_3)_2(Et_2O)_{0.5}$	4.0	0.52(17.0), 1.2(21.6), 2.7(27.0), 7.1(30.3)

a) Et_2O=diethyl ether. b) 10^4 k. The numbers in the parentheses show the thermolysis temperatures in °C.

the first-order rate law and the first-order rate constants are listed in Table 4.

The activation energy for the thermolysis of $C_2H_5Cu(PPh_3)_2$ in toluene calculated from an Arrhenius polt of the rate constants was 32 kcal/mol, being considerably smaller than that in the solid state (48 kcal/mol) The heat of fusion of the ethylcopper complex required in the thermolysis in the solid phase accounts for a part of the difference between the two activation energies. However, in order to account for whole of such a great difference, it will be necessary to consider other unrevealed factors such as ease of intramolecular rearrangement of the copper complex in forming the so-called activated complex and the coordination of solvent.

On addition of PPh_3 into the toluene solution of $C_2H_5Cu(PPh_3)_2$ the first-order rate constant decreased approaching a limiting value. The effect of the addition of PPh_3 on the rate constant can be accounted for by assuming the formation of a stabler ethylcopper complex having three PPh_3 ligands $C_2H_5Cu(PPh_3)_3$. In fact the methyl analog of $C_2H_5Cu(PPh_3)_3$ is isolable from toluene containing sufficient amount of PPh_3.[10c] An alternative explanation that there exists a dissociation equilibrium in the solution to form a less stable complex $C_2H_5Cu(PPh_3)$ by an equilibrium, $C_2H_5Cu(PPh_3)_2 \rightleftharpoons C_2H_5Cu(PPh_3)+PPh_3$, and addition of PPh_3 suppresses the dissociation seems less probable, since the molecular weight determination of $C_2H_5Cu(PPh_3)_2$ in benzene showed a negligible dissociation of PPh_3 from the complex.[10c]

Thermolysis of $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$ in toluene also obeyed the first-order rate law and the rate constants are included in Table 4. Addition of PPh_3 into the solution influences the rate of the thermolysis. However, this is not so marked as that observed in the thermolysis of $C_2H_5Cu(PPh_3)_2$ and the result suggests that the methylcopper complex having three PPh_3 ligands which is formed in solution on addition of PPh_3 is thermolyzed at almost the same rate as the methylcopper complex having two PPh_3 ligands.

Thermolysis of $CH_3Cu(P(n\text{-}C_4H_9)_3)_3$ in toluene did not obey the first-order rate law. $(RCu)_2(dpe)_3$ in solutions underwent a quite different reaction, a selective hydrogen abstraction reaction from the methylene group of the dpe ligand by the alkyl group.[10c]

Consideration of the Effect of the Tertiary Phosphine Ligands on the Thermal Stability of the Cu–R Bond.

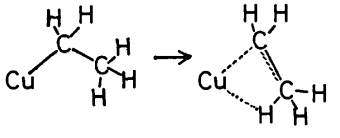
The Role of the Tertiary Phosphine Ligands in Stabilizing the Alkylcopper Complexes: If addition of ligand L to the solution of an alkyltransition metal complex R_mML_n causes complete inhibition of the thermolysis of the alkyltransition metal complex as observed in the thermolysis of alkylplatinum,[5b] -iron[6d,15a] and -cobalt[15b] complexes in solutions, the major role of the ligand in stabilizing the alkyltransition metal complex may be the blocking the site to hinder the β-elimination to proceed.[4,5] However, this is not the case for the thermolysis of the present alkylcopper complexes, since addition of PPh_3 into a toluene solution of $C_2H_5Cu(PPh_3)_2$ did not cause complete inhibition of the thermolysis of the ethylcopper complex though it caused a change in the rate of the thermolysis which may be accounted for by assuming a change in the strength of the Cu–C bond by the coordination of the third PPh_3(see above). Furthermore, ^{31}P-NMR spectra of mixtures of the alkylcopper complex ($C_2H_5Cu(PPh_3)_2$ or $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$) and PPh_3 in toluene showed that a rapid exchange between the coordinated PPh_3 and free PPh_3 occurs even at -60 °C. This observation is not compatible with the assumption that the dissociation of a ligand from copper constitutes the rate determining step in the thermolysis.

The following three observations also are not consistent with the assumption that the predominant role of the tertiary phosphines in stabilizing the Cu–R bond is the blocking of the site for β-elimination.

(1) Comparison of the activation energies of $C_2H_5Cu(PPh_3)$ and $C_2H_5Cu(PPh_3)_2$ (Table 3) reveals that the ethylcopper complex containing one triphenylphosphine ligand has a *higher* activation energy than the ethylcopper complex with two PPh_3 ligands. As far as one compares the stability of an alkylcopper complex in terms of the activation energy for the thermolysis, this is not compatible with the theory to explain the role of the stabilizing ligand as blocking the site to hinder the β-elimination.

(2) The alkylcopper complexes generally have a monomeric structure in benzene as revealed by the cryoscopic molecular weight measurements of the complexes in benzene.[10c] This indicates that the copper complexes, especially those having one or two tertiary phosphines are not fully coordinated and have vacant site(s) at least in benzene. Thereupon the dissociation of the tertiary phosphine ligand seems not to be required for the β-elimination to proceed.

(3) The presence of the compensation effect between ΔH^* and ΔS^* (Fig. 3) for both the methylcopper complexes and the other copper complexes having ethyl or longer alkyl chain implies that the same factor which control the thermal stability of the methylcopper complexes dominates the thermal stability of the copper complexes having ethyl or longer alkyl chains. Since the thermal stability of the methylcopper complexes seems to be controlled only by the strength of the Cu–C bond, the observation concerning the compensation effect implies that even the thermolysis of the copper complexes having ethyl or longer alkyl chain is controlled by the intrinsic strength of the Cu–C bond. We assume that the loosening of the Cu–C bond as shown below is necessary to allow the copper atom to approach the β-hydrogen and thus to allow the β-elimination to proceed. If the β-elimination does not require the loosening of the Cu–C bond, we may anticipate that the activation energy for the thermolysis of copper complexes having ethyl or longer chain is much smaller than that for the



thermolysis of the methylcopper complexes. However, this is not the case in the thermolysis of the alkylcopper complexes.

From the above described reasons we conclude that the prime role of the tertiary phosphine ligand in stabilizing the present alkylcopper complexes is not simply to block the site but rather to strengthen the Cu–C bond by changing the electronic state of the complexes.

Effect of the Tertiary Phosphine Ligands on the Strength of the Cu–C Bond: Figure 4 shows a correlation between the activation energies for thermolysis and ν(Cu–CH_3) frequencies of the methylcopper complexes. The correlation supports our assumption that the activation energy for thermolysis corresponds to the energy required for loosening the Cu–C bond. Figure 5 shows the relationship between ν(Cu–CH_3) frequencies and pK_a of the conjugate acid of the tertiary phosphine ligand $[HPR'_3]^+$, and Fig. 6 shows the correlation between the activation energy and the pK_a value. It is seen that the complex with less basic ligands exibits the ν(Cu–CH_3) band at higher frequency and has a higher activation energy.

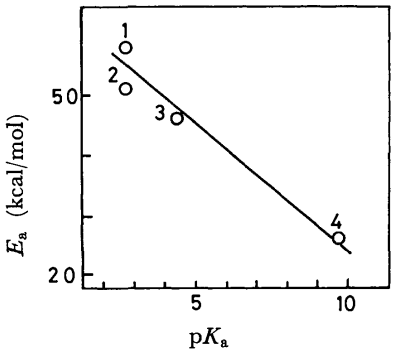

Fig. 6. Relationship between activation energy for thermolysis of methylcopper complexes and pK_a value of the conjugated acid of the tertiary phosphine ligand. 1: $CH_3Cu(PPh_3)_2$(diethyl ether)$_{0.5}$, 2: $CH_3Cu(PPh_3)_3$(toluene), 3: $CH_3Cu(P(C_6H_5)_2CH_3)_3$, 4: $CH_3Cu(PCy_3)$.

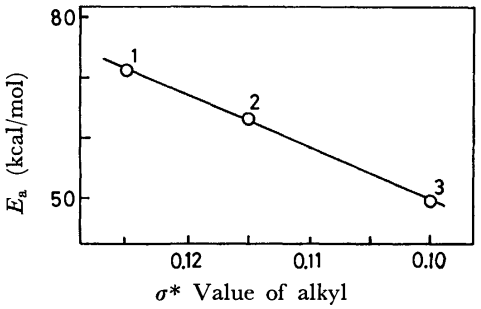

Fig. 7. Relationship between Taft's σ^* value of alkyl and activation energy for thermolysis of $RCu(PPh_3)_2$. 1: R=i-C_4H_9, 2: n-C_3H_7, 3: C_2H_5.

In order to see the effect of the alkyl group bonded to copper on the activation energy for thermolysis, the activation energies were plotted *versus* Taft's σ^* values[16] of the alkyl groups in Fig. 7.

The theory originally proposed by Chatt and Shaw,[2] upon some modification by Yamamoto and coworkers,[3] is consistent in accounting for the strength of the alkyl-copper bond which may be evaluated from the activation energy.

Since alkylcopper(I) complex has completely filled d-orbitals it is not necessary in terms of Chatt-shaw's theory[2] to consider the electronic promotion from bonding Cu–R orbital to vacant d-orbitals ($\sigma_{M-R}\rightarrow$d) and consideration of only the promotion from the filled d-orbital to anti-bonding Cu–R orbital (d$\rightarrow\sigma^*_{Cu-R}$) is required. If we assume that the order of energy of anti-bonding Cu–R orbitals (σ^*_{Cu-R}) is related to the order of electron affinities (E.A.) of alkyl radicals (E. A. in kcal/mol: CH_3, 32.2; C_2H_5, 21.6; C_3H_7, 15.9; C_4H_9, 15.0),[17] the anti-bonding Cu-methyl orbital ($\sigma^*_{Cu-CH_3}$) is expected to have the lowest energy and the energy level of σ^*_{Cu-R} is expected to increase in the order of R=CH_3<C_2H_5<n-C_3H_7<i-C_4H_9. The energy gap required for an electronic promotion from the metal d-orbitals to the σ^*_{Cu-R} orbital may be related to the activation energy for thermolysis of the alkyl-copper complex (Fig. 8). The agreement between the order of the increasing activation energy of the thermolysis of $RCu(PPh_3)_2$ by changing

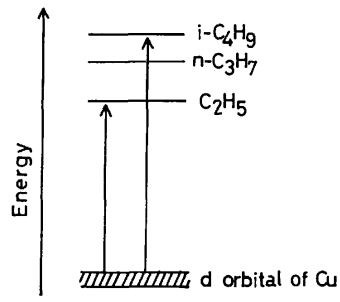

Fig. 8. Tentative energy level relation diagram in activation of Cu–R bond.

R,R=C_2H_5<*n*-C_3H_7<*i*-C_4H_9, and the order of the increasing energy gap in Fig. 8, R=C_2H_5<*n*-C_3H_7<*i*-C_4H_9, can be seen. The effect of the tertiary phosphine on the stability of the alkylcopper complexes can also be accounted for by assuming the scheme represented in Fig. 8. The fact that the methylcopper complex having phosphines with the larger Lewis basicity shows the smaller thermolysis activation energy may arise from raise in the energy of the d-orbital by coordination of phosphines with the larger Lewis basicity thus causing the decrease in the energy required for promotion. If this interpretation is valid the pronounced stabilizing effect of the tertiary phosphine ligand may be related with its ability of accepting d-electron by back-donation from the metal to phosphorus orbital, the consequence being the lowering of the energy of d-orbitals and higher stability for alkylcopper complexes with phosphine ligands having greater π-accepting ability.

One serious argument against this type of energetic consideration is that the concept of such a direct electronic exitation as depicted in Fig. 8 may not be related to thermolysis. We agree that in the thermolysis the simple electronic exitation may not be involved, but the energy gap for the excitation may still provide a measure for the stability to a first approximation. In lack of the knowledge about the potential energy curves for the bonding and anti-bonding orbitals a discussion based on energetic consideration admittedly remain speculative. However, the scheme depicted in Fig. 9 seems to be fairly consistent with the experimental facts obtained in this work. When an electron is directly promoted to the anti-bonding orbital shown as the upper curve in Fig. 9a, the splitting of Cu–C bond will take place. In the thermal reaction, if the potential curve of the anti-bonding orbital is crossed with that of d-orbital (Fig. 9a), on loosening of the Cu–C bonding to a certain extent a crossing over to the anti-bonding potential curve may take place, thus splitting of the Cu–C bond will result. The effects of the alkyl group and of the basicity of the tertiary phosphine ligands are explained similarly in this model as in Fig. 8. The crossing over to the anti-bonding orbital curve would take place at lower energy when the energy of the σ^*_{Cu-R} orbital lies lower (Fig. 9b), and the raise in the d-orbital by coordination of more electron-donating phosphines would lead to the crossing-over at smaller ΔE (Fig. 9c).

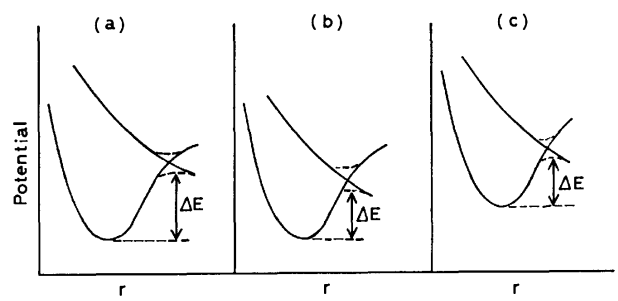

Fig. 9. Tentative potential energy curves for the splitting of Cu–R bond. Upper curve, σ^*_{Cu-R}; lower curve, d-orbital. For (a), (b), and (c) see the text. *r*=distance between Cu and C.

Previously Yamamoto *et al.* discussed the stability of alkylnickel[3] and alkylchromium[12b] complexes by taking into account similar energetic consideration. In contrast to the alkylcopper(I) complexes, these alkyltransition metal complexes have vacant d-orbital(s) and the stability of the transition metal-alkyl (M–R) bond in the series of the alkyltrasition metal complexes increased in a reverse order compared with the stability of the Cu–R bond, R=*n*-C_3H_7<C_2H_5<CH_3. Furthermore, the effect of the basicity of ligand in stabilizing the M–R bond in these alkyltransition metal complexes is reversed to that observed in the alkylcopper complexes; coordination of electron-donating ligand enhanced the stability of the M–R bond, whereas that acidic ligand destabilized the M–R bond. The stability of these alkyltransition metal complexses with vacant d-orbitals was explained by considering the electronic promotion from the low-lying bonding M–R orbital to the vacant d-orbital(s) ($\sigma_{M-R}\rightarrow$d) instead of that from the d-orbital to σ^*_{M-R} bond(d$\rightarrow\sigma^*_{M-R}$). Therefore, the postulate considered here is consistent with previously proposed scheme to explain the order of the stability in the series of the alkylnickel and alkylchromium complexes, although the order of the stability of these alkyltransition metal complexes is reversed to that of alkylcopper complexes.

We are concerned here with the loosening of the copper-alkyl bond in the thermolysis, but it should be stressed that we do not imply the formation of a free radical of any significant life time. The experimental results concerning the thermolysis do not indicate the formation of the free radicals. As described above the alkyl group will be subject to the further reaction, such as β-elimination reaction (Eq.1) at the instant when the copper-carbon bond in the alkylcopper complex become loose.

Photolysis of the Alkylcopper(I) Complexes. In order to get further information concerning the stability of the alkylcopper complexes we studied the photolysis of the alkylcopper complexes. The alkylcopper complexes are quite light-sensitive[10] and decompose even below −20 °C upon illumination by light. Comparison of the gaseous products in the thermolysis (Table 1) with those in the photolysis (Table 5) indicates a considerable difference in the decomposition pathways. In contrast to the thermolysis of $CH_3Cu(PPh_3)_3$(toluene) which gave ethane as the main product, the photolysis of the complex gave methane exclusively. Since the use of dueterated PPh_3 ligand and solvent did not

TABLE 5. PRODUCTS IN THE PHOTOLYSIS OF THE ALKYLCOPPER(I) COMPLEXES

cause the deuterium incorporation into methane, abstraction of a hydrogen of CH_3 group by another CH_3 group may consitute an important decomposition pathway in the photolysis of the methylcopper complex. Evolution of considerable amount of ethylene on irradiation of the methyl copper complex at 80 °C also suggest the hydrogen abstraction from the methyl group which will yield a carbenoid species. Formation of carbenoid species during thermolysis[11,12,18] and photolysis[19] of methyltrasition metal complexes has been proposed, and isolation of an alkylcarbene complex of tantalum has been reported.[20]

Photolysis of $C_2H_5Cu(PPh_3)_2$ produced ethane as the main gaseous product and ethylene as the minor product. This result is in contrast with thermolysis which generated ethylene as the major decomposition product.

Experimental

General Procedures and Preparation of Alkylcopper(I) Complexes. All experiments were carried out under deoxygenated argon or nitrogen atmosphere, or in vacuum. IR spectra were recorded on a Hitachi Model EPI-G3 spectrometer, and ^{31}P-NMR and ^1H-NMR spectra were recorded with a Japan Electron Optics Lab. JNM-PS-100 spectrometer. Evolved gas was analyzed with a Hitachi RMU-5B mass spectrometer and with a Shimadzu GC-5B gas chromatograph, using an active carbon column for C_1 and C_2 hydrocarbons, a VZ-7 column for C_1–C_4 hydrocarbons and a column with 20% TCP on 40/60 Uniport B for diethyl ether. A series of alkylcopper(I) complexes having various tertiary phosphines were prepared as previously reported.[10]

Preparation of $CH_3Cu(PPh_3\text{-}d_6)_3$(toluene-$d_8$). Triphenylphosphine-2,6,2′,6′,2″,6″-d_6 (PPh_3-d_6) was prepared by exchange reaction of PPh_3 with excess deuterium gas catalyzed by $RuH_2(PPh_3)_4$[21] and had 98.0% isotopic purity as determined by ^1H-NMR spectroscopy. To an etheral suspension of copper(II) acetylacetonate (2.0 g.) and PPh_3-d_6 (4.0 g.), 4 ml of dimethylaluminum monoethoxide was added slowly at −40 °C. The light yellow complex $CH_3Cu(PPh_3\text{-}d_6)_2$-(diethyl ether)$_{0.5}$ precipitated after sufficient reaction time at −10 °C was separated by filtation, washed with dry ether and then dried *in vacuo*. From toluene-d_8 (isotopic purity, 98.8%) solution containing $CH_3Cu(PPh_3\text{-}d_6)_2$(diethyl ether)$_{0.5}$ (3.0 g) and PPh_3-d_6 (1.0 g), yellow crystals of $CH_3Cu(PPh_3\text{-}d_6)_3$-(toluene-$d_8$) was isolated.

Kinetic Studies for the Thermal Decomposition of Alkylcopper(I) Complexes. A 20 ml Schlenk tube containing 0.10—0.20 g of the solid alkylcopper(I) complex or a toluene solution (3 ml) of the alkylcopper(I) complex (0.13—0.35 g) and PPh_3 (0—400 mg) was connected to a vacuum line equipped with a mercury manometer and the system was evacuated. The Schlenk tube was placed in a thermostatted bath controlled to ±0.5 °C. The rate constant for the thermal decomposition of the complex was obtained by measuring the volume of the gas evolved with time.

Photolysis of Alkylcopper(I) Complexes. A 10 ml quartz Schlenk tube containing 0.3 g of the alkylcopper(I) complex in the solid state or its solution in 2 ml of toluene-d_8 was irradiated by a 100-Watt Toshiba super high-pressure mercury lamp in a thermostatted aqueous ethylalcohol bath controlled to −30±0.5 °C. The sample tubes were positioned in the region of maximum luminosity. Evolved gas was collected with a Toepler pump and analyzed by mass spectrometry.

The sample in toluene-d_8 solution was immediately decomposed on irradiation turning to dark brown.

Oxidative Addition of α-Bromo Esters to Tetrakis(isocyanide) Rhodium(I) Complexes. Evidence for a Chain Mechanism

Sei Otsuka and Kikuo Ataka

Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560

(Received November 15, 1976)

The oxidative additions of chiral alkyl halides, (*S*)-(−)-ethyl α-bromopropionate $[\alpha]_D$ −18.9° (*c* 3.3, $CHCl_3$) and (*S*)-(+)-ethyl α-phenylbromoacetate $[\alpha]_D$ +56.4° (*c* 1.6, C_2H_5OH) to $[Rh(R'NC)_4]^+$ (R′=*t*-Bu, *p*-$CH_3C_6H_4$) produced the corresponding adducts, *trans*-$[RhBr(R)(R'NC)_4]^+$ (R=CH_3CHCO_2Et, $PhCHCO_2Et$), which were well characterized by elemental analysis, IR and ^1H NMR spectra. These adducts were found optically inactive, a fact which precludes a concerted mechanism. The reaction of $C_6H_5CHBrCO_2C_2H_5$ with $[Rh(t\text{-}BuNC)_4]^+$ commenced immediately in the absence of light. Taking this system as a typical example, the rate was studied by the stopped-flow method to find a rate equation, $R=k[Rh(I)]^2[RX]$. The relative rate of addition of *p*-$XC_6H_4CHBrCO_2C_2H_5$ to $[Rh(t\text{-}BuNC)_4]^+$ decreases in an order of Cl>H>CH_3 for X. The addition of $C_6H_5CHBrCO_2C_2H_5$ to $[Rh(p\text{-}CH_3C_6H_4NC)_4]^+$ in the dark proceeds only slowly, but rapidly under a low energy photo-irradiation (440 nm) with a large quantum yield (Φ 4.8). The addition of $CH_3CHBrCO_2C_2H_5$ requires photo-initiation. The optical activity of (*S*)-(−)-$CH_3CHBrCO_2C_2H_5$ was completely lost before the oxidative addition commenced. The rate of decrease in optical activity of the system (*S*)-(−)-$C_6H_5CHBrCO_2C_2H_5$ /$[Rh(t\text{-}BuNC)_4]^+$ exhibited approximate second order kinetic behavior, and quantitative racemization took place prior to the completion of the oxidative addition. A chain mechanism appears to be consistent with all these results. Alternate mechanisms are also discussed in the light of the present results.

So called oxidative additions have received widespread interest in recent years from the stand point of their novelty as a new class of transition metal reactions and of their significance in homogeneous catalytic reactions.[1] A number of papers have reported mechanistic studies on the alkyl halide addition reaction yielding divergent conclusions. Halpern's group[2] and others[3,4] proposed a linear dipolar transition state $M^+\cdots R\cdots X^-$ similar to that involved in the Menschutkin reaction. Ugo[5] *et al.* have invented a somewhat sophisticated version of a multi-center mechanism, *i.e.* a non-concerted polar three center S_N2 attack. In contrast to these views is the radical mechanism proposed by Osborn.[6–9] Lappert's[10] group has detected a radical in the system, MeI/*t*-BuNO/Pt(O). Recently Stille[11,12] *et al.* reported the stereospecific oxidative addition of chiral C_6H_5CHDCl to Pd(O) complexes. Kinetic studies on the addition of alkyl halides to Ir(I)[5,13,14] or Rh(I)[15–17] complexes gave a general impression in favor of the polar mechanism. Doubtless the mechanisms will depend on the electronic and steric characteristics of reactants involved and also on the nature of solvent.

The stereochemical course of addition should be related to the structure of the transition state and to the timing of bond-forming and bond-breaking processes. Our previous study[18] on the addition of an optically active *s*-alkyl bromide, $CH_3CHBrCO_2C_2H_5$ or $C_6H_5CHBrCO_2C_2H_5$, to a strong nucleophile, "$Pd(t\text{-}BuNC)_2$", indicates loss of the stereochemical integrity at the chiral carbon. Pearson *et al.*[19] reported that addition of $CH_3CHBrCO_2C_2H_5$ to Ir(I) was stereospecific, but Osborn[7] *et al.* reexamined this reaction to show that the adduct has no optical activity. We were able to isolate the oxidative adducts from the reaction of two chiral *s*-alkyl halides, (*S*)-(−)-$CH_3CHBrCO_2C_2H_5$ and (*S*)-(+)-$C_6H_5CHBrCO_2C_2H_5$ with $[Rh(R'NC)_4]^+$ (R′=*t*-Bu, *p*-$CH_3C_6H_4$). The adducts, however, showed no optical activity. Various other experimental facts were then collected to elucidate the reaction mechanism. The study has led to a discovery of a dramatic effect of low-energy photo-irradiation in the alkyl halide addition, a fact intelligible in terms of a chain reaction. In this paper we also describe a few other interesting observations consistent with the chain mechanism.

Experimental

IR spectra were measured with a Hitachi-Perkin Elmer 225, UV spectra with a Hitachi EPS-3T, ^1H NMR spectra with a Jeol JNM-4H-100 or JNM-C60-HL, ESR spectra with a JES-ME-2X and optical rotation with a JASCO DIP-SL equipped with an automatic recorder using a 0.5 dm, 5φ mm cell incorporating a three way stop cock allowing measurements to be carried out in an inert atmosphere. Solvents were dried and distilled under nitrogen. All reactions and manipulations were carried out under a pure nitrogen atmosphere.

Preparation of Starting Materials. "$Pd(t\text{-}BuNC)_2$",[20] $[Rh(t\text{-}BuNC)_4]BPh_4$[21] and $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$[21] were prepared by known methods. (*S*)-(−)-Ethyl α-bromopropionate, $[\alpha]_D$ −18.9° (*c* 3.3; $CHCl_3$), was prepared from L-alanin according to the conventional method.[22] The optical purity was estimated to be about 38%. (*S*)-(+)-Ethyl phenylbromoacetate, $[\alpha]$ +56.4° (*c* 1.75; C_2H_5OH), was prepared from (−)-ethyl mandelate by bromination with PBr_3.[23] The rotation was about 70% of the highest literature value.[23] Methyl 1-bromo-2,2-diphenylcyclopropanecarboxylate was prepared by the reaction of methyl α-bromoacrylate with diazodiphenylmethane.[24] *d*-3-*endo*-Bromocamphor was a commercial product of which stereochemical purity was found by ^1H NMR to be 95%. *d*-3-*endo*-Iodocamphor was prepared by known method from *d*-3-*endo*-bromocamphor.[25]

Kinetic Experiments. The initial rates were measured in CH_2Cl_2 with a stopped-flow spectrophotometer (Union RA-1100) by following the intensity of the 440 nm absorption band (ε=358) of $[Rh(t\text{-}BuNC)_4]^+$ at 25±0.5 °C.

The initial concentration of $C_6H_5CHBrCO_2C_2H_5$ being kept at 0.16 M, the concentration of $[Rh(t\text{-}BuNC)_4]^+$ was varied over a range of $3.2—11\times10^{-3}$ M. Similarly, with an initial concentration of 0.16×10^{-2} M for $[Rh(t\text{-}BuNC)_4]^+$,

the concentration of $C_6H_5CHBrCO_2C_2H_5$ was varied from 7.8×10^{-2} M to 2.7×10^{-1} M. Generally a short induction period (3—20 s) was observed. It was found in case of the addition of $CH_3CHBrCO_2C_2H_5$ to $[Rh(t\text{-BuNC})_4]^+$ that the light (440 nm) used to monitor the reaction initiates the addition with some induction periods. After the commencement of the reaction, the spectrum showed a diffusion controlled process preventing determination of the kinetic orders (see Text).

The rates of decrease in optical rotation during slow addition of α-bromoesters were followed by the polarimetric measurement of the $[\alpha]_D$ values. A dichloromethane solution of a mixture of $[Rh(t\text{-BuNC})_4]^+$ and the α-bromoesters was prepared and an aliquot was immediately transferred to the cell. The rotation was measure at 20 °C using the following two solutions; one containing 1.9×10^{-2} M of $[Rh(t\text{-BuNC})_4]^+$ plus 2.0×10^{-2} M of $C_6H_5CHBrCO_2C_2H_5$ and other containing 0.10 M of $[Rh(t\text{-BuNC})_4]^+$ plus 0.98 M of $CH_3CHBrCO_2C_2H_5$. The initial rates could not be measured accurately because a few minutes were required to secure a stable response on the polarimeters.

Addition of (S)-(−)-*Ethyl α-Bromopropionate to* $[Rh(t\text{-}BuNC)_4]BPh_4$. (*S*)-(−)-Ethyl α-bromopropionate (44 mg, 0.22 mmol) was added to a solution of $[Rh(t\text{-BuNC})_4]BPh_4$ (150 mg, 0.2 mmol) in 2 ml of CH_2Cl_2 at room temperature. When the reaction mixture was stirred under diffused sun light, the yellow color rapidly (within a few min) faded yielding a colorless solution. After stirring was continued for 2 h, the mixture was concentrated. Treatment of the concentrate with a few ml of hexane allowed isolation of *trans*-$[RhBr(CH_3CHCO_2C_2H_5)(t\text{-BuNC})_4]BPh_4$ (**1**), as colorless powder (130 mg, 70%), which showed no optical activity in $CHCl_3$ at 24°. Recrystallization from methanol gave an analytically pure sample, mp 110—111° dec. The mother liquor from the above concentrate contains approximately equimolar amounts of ethyl acrylate and ethyl propionate as detected by GLC.

Addition of (S)-(+)-*Ethyl Bromophenylacetate to* $[Rh(t\text{-}BuNC)_4]BPh_4$. To a suspension of $[Rh(t\text{-BuNC})_4]BPh_4$ (160 mg, 0.21 mmol) in ethanol (5 ml) was added (*S*)-(+)-ethyl phenylbromoacetate (60 mg, 0.25 mmol) at room temperature. The reaction appears to occur immediately even in dark. After stirring for a few hours, the reaction mixture yielded the adduct, *trans*-$[RhBr(PhCHCO_2C_2H_5)(t\text{-BuNC})_4]BPh_4$ (**2**) as a pale yellow precipitate (190 mg, 90%) which was separated, washed with hexane, and dried *in vacuo*. The optical activity was totally lost. Recrystallization from methanol gave an analytically pure sample, mp 118—119° dec.

Addition of (S)-(−)-*Ethyl α-Bromopropionate to* $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$. Similar to the above, reaction of $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$ (251 mg, 0.28 mmol) with an excess of ethyl α-bromopropionate (0.21 ml, 1.6 mmol) was carried out under irradiation of tungsten lamp (500 W) in CH_2Cl_2 solution at room temperature for 2 h. The product obtained was optically inactive *trans*-$[RhBr(CH_3CHCO_2C_2H_5)(p\text{-}CH_3C_6H_4NC)_4]BPh_4$ (**3**), colorless crystals, recrystallized from a methanol-ethanol system, mp 140—145° dec (115 mg, 36% yield). The reaction does not take place in the absence of light.

Addition of (S)-(−)-*Ethyl Phenylbromoacetate to* $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$. The reaction of $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$ (144 mg, 0.16 mmol) with ethyl phenylbromoacetate (150 mg, 0.6 mmol) in CH_2Cl_2 occurs rapidly under irradiation with decoloration producing the adduct, *trans*-$[RhBr(C_6H_5CHCO_2C_2H_5)(p\text{-}CH_3C_6H_4NC)_4]BPh_4$. (**4**), as pale yellow crystals, recrystallized from ethanol (80 mg, 45% yield).

Reaction of d-*3*-endo-*Bromocamphor with "Pd*(t-*BuNC)*$_2$*"*. To a suspension of "$Pd(t\text{-BuNC})_2$" (530 mg, 1.9 mmol) in ether (40 ml) was added at −70 °C *d*-*3*-*endo*-bromocamphor (460 mg, 2 mmol). The temperature was allowed to rise to 0 °C and stirring was continued for 4 h at 0 °C to give a slurry. The slurry was filtered and the solid was washed with cold ether (50 ml). The combined ether solution was concentrated to give ,on cooling to −20°, an adduct as almost colorless crystals (520 mg, 53%), mp. 114° (dec). ^1H NMH ($CDCl_3$): a double doublet peak at τ 6.5 (M–CH).

Found: C, 46.6; H, 6.50; N, 5.64%. Calcd for $C_{20}H_{25}N_2OBrPd$: C, 47.7; H, 6.60; N, 5.56%.

Rection of d-*3*-endo-*Iodocamphor with* $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$. A mixture of the Rh(I) compound (670 mg, 0.75 mmol) and iodocamphor (230 mg, 0.75 mmol) in ethanol–dichloromethane (2 : 1, 10 ml) was stirred overnight to give a yellow brown slurry. Filtration gave the adduct as pale yellow crystals (430 mg, 49%) mp 140—143° (dec).

Found: C, 67.7; H, 5.38; N, 4.71%. Calcd for $C_{66}H_{63}N_4BIORh$: C, 67.8; H, 5.43; N, 4.79%.

Quantum yield for the Reaction of $[Rh(p\text{-}CH_3C_6H_5NC)_4]BPh_4$ *with* $C_6H_5CHBrCO_2C_2H_5$. Noyes's method was essentially followed.[26] The photo-reaction was carried out using the following optical system; a 150 W Xenon lamp, a slit, a lens for paralleling the beam, a filter cutting off ultraviolet light shorter than 350 nm, and a square window of *ca.* 2 cm^2. Two 1 cm quartz cells, one for the reaction mixture and another for the actiometer, were placed so as to successively receive the incident light. A mixture of 40 ml of $K_3[Fe(C_2O_4)_3]$ (5.2×10^{-2} M) in 1/2 M sulfuric acid and 10 ml of a buffer solution containing acetic acid (1 M) and sodium acetate (1 M) was used as the actinometer solution.[27] The quantity of Fe^{2+} ion formed by irradiation was measured colorimetrically as the 1,10-phenanthroline complex (λ_{max} 510 nm). Irradiating the solution containing $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$ (1.8×10^{-3} M) and $C_6H_5CHBrCO_2C_2H_5$ (1.1×10^{-2} M) in dichloromethane for 180 s, the concentration of the unreacted Rh(I) complex was determined by measuring the absorption at 462 nm. Correction was made by measuring the difference in concentration of the Rh(I) complex between the irradiated sample and the unirradiated one as the blank. The quantum yield (Φ) was calculated by the equation, $\Phi=A/I\cdot F$, where A is the number of the Rh(III) molecules formed by the photo-reaction, I the number of photons entering the reaction cell, and F the fraction of photons absorbed by the reaction mixture.[26]

Spin Trap Experiment. ESR samples, *e.g.*, a mixture of $[Rh(t\text{-BuNC})_4]BPh_4$, RBr (R=$C_6H_5CHCO_2C_2H_5$, $CH_3CHCO_2C_2H_5$) and *t*-BuNO in CH_2Cl_2, was prepared in a 50 ml flask in the dark under pure nitrogen. The solutions ($1.3—1.5\times10^{-3}$ M for each component) were transferred to the 2 mm ESR tubes by syringe, and the measurement was carried out for a temperature range 77—300 K.

ESR Measurement. A sample solution was prepared by mixing two dichloromethane solutions of $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$ (1.1×10^{-2} M) and $C_6H_5CHBrCO_2C_2H_5$ (4.4×10^{-2} M) of equal volume at room temperature. After standing for a few minutes under diffuse sunlight, the mixture was chilled to 195 K. ESR measurements (X band) were carried out at 77, 200, 240 K, and room temperature. Signals were difficult to detect at 77 K. Broad signals of weak intensities centered at $g=2.14$ were observed above 200 K, the hyperfine structure being unresolved.

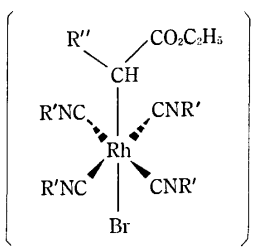
a) Measured in Nujol mull. b) Measured in $CDCl_3$. TMS as internal reference. Multiplicity is indicated in parentheses. c) Not fully resolved. d) This CH_3 peak appears as doublet-doublet pattern presumably due to $^3J_{Rh-H} \approx 1.5$ Hz.

t-Bu, *p*-$CH_3C_6H_4$) with $CH_3CHBrCO_2C_2H_5$ or C_6H_5-$CHBrCO_2C_2H_5$ in CH_2Cl_2 produces the corresponding thermally unstable adducts, *trans*-$[RhBr(CHR''CO_2C_2H_5)(R'NC)_4]^+$($R''=CH_3$, C_6H_5) as characterized by the elemental analysis, and IR and ^1H NMR spectra (Tables 1, 2). The *trans* geometry is deduced from the IR spectra which contain only one N≡C stretching absorption. Consistently the ^1H NMR spectra show one singlet signal for the *t*-butyl or *p*-methyl protons of the four isocyanide ligands. The NC stretching



1 $R'=t$-Bu, $R''=CH_3$
2 $R'=t$-Bu, $R''=C_6H_5$
3 $R'=p$-$CH_3C_6H_4$, $R''=CH_3$
4 $R'=p$-$CH_3C_6H_4$, $R''=C_6H_5$

frequencies of the adducts **1**—**4** are higher than those of the corresponding starting complex $[Rh(t\text{-BuNC})_4]^+$ (2170 cm^{-1}) or $[Rh(p\text{-}CH_3C_6H_4NC)_4]^+$ (2190 cm^{-1}) reflecting the oxidation state, Rh(III). The CO stretching vibration of the carboxylate group in the adducts shifts to the lower frequency region compared to that of free ester (1740 cm^{-1} for $CH_3CHBrCO_2C_2H_5$ or 1750 cm^{-1} for $C_6H_5CHBrCO_2C_2H_5$). Thermal decomposition of **1** or **3** takes place at 80 °C during a few hours yielding ethyl propionate and ethyl acryate indicating *β*-hydrogen elimination. The optical rotation of adducts **1**—**4**, measured immediately after the solution make-up below 20 °C, was still zero.

Methyl 1-bromo-2, 2-diphenylcyclopropanecarboxylate does not react with $[Rh(t\text{-BuNC})_4]^+$ or with a stronger nucleophile, "$Pd(t\text{-BuNC})_2$". Other halocycloalkanes, *e. g.* 3-*endo*-halocamphor, react with the low valent metal complexes. Thus, *d*-3-*endo*-bromocamphor reacts with "$Pd(t\text{-BuNC})_2$" to give an adduct [PdBr-(η^1-3-camphor)(t-BuNC)$_2$] which retains the *endo* form. The conformation can be readily established by the ^1H NMR of the methine signal at the 3-position which shows a double doublet pattern ($^3J_{HH}=4$ Hz, $^4J_{HH}=1.3$ Hz). It has been established[28] that the *exo* proton at the 3-position couples with the methine proton at the 4-position and the *exo* proton at the 5-position, but the *endo* proton does not couple with the proton at the 4-position, because of the bond angle of nearly 90 °C. $[Rh(t\text{-BuNC})_4]^+$ reacts with 3-*endo*-iodocamphor at ambient temperature to give an adduct whose conformation could not be determined from the key ^1H NMR signal due to the complexity induced by the coupling with ^{103}Rh. Interestingly, it fails to react with 3-*endo*-bromocampher under diffused light. *erythro*-1-Bromo-3,3-dimethyl-1,2-didueteriobutane does not react with $[Rh(t\text{-BuNC})_4]^+$ or "$Pd(t\text{-BuNC})_2$".

Photochemical Effects. Unexpectedly, the addition reaction of $CH_3CHBrCO_2C_2H_5$ to $[Rh(RNC)_4]^+$ ($R'=$ *t*-Bu, *p*-$CH_3C_6H_4$) does not take place in the absence of light, as indicated by the IR NC stretching absorption which shows no change over a day or two at room temperature, reflecting the retention of the oxidation state Rh(I). There is, however, some indication in the ^1H NMR spectrum for complexation of the bromo ester as will be described later. On exposure to light the addition occurred with an induction period ranging from a few minutes to half an hour, depending on the intensity of light. Remarkably, this irradiation effect was observed even with a low-energy light beam

(440 nm) used for monitoring the concentration of the species $[Rh(t\text{-BuNC})_4]^+$. Generally, the induction period is followed by a very rapid addition reaction which prevents an accurate kinetic measurement and intelligible analysis. A photo-initiation was required for the reaction of $[Rh(p\text{-}CH_3C_6H_4NC)_4]BPh_4$ with both of the α-bromo esters; under irradiation with a 500 W tungsten lamp the reaction of $C_6H_5CHBrCO_2C_2H_5$ is complete within a few minutes and that of $CH_3CHBrCO_2C_2H_5$ within one hour. The quantum yield of the photo-reaction of the former system was estimated to be 4.8, implying a chain mechanism. Since the addition of $CH_3CHBrCO_2C_2H_5$ to $[Rh(R'\text{-}NC)_4]BPh_4$ ($R'=t$-Bu, p-$CH_3C_6H_4$) exhibits an induction period even under photo-irradiation, it was impossible to obtain the quantum yield.

Mechanistic Features. The reaction of $C_6H_5CHBrCO_2C_2H_5$ with $[Rh(t\text{-BuNC})_4]^+$ does not require photo-initiation. However, the oxidative addition shows an induction period ranging from a few seconds to half a minute depending on the concentration of substrates. The intensity of the absorption at 440 nm of the reaction mixture increased slightly during the induction period. After the induction period, the rate was found, by differential analysis, to be first order with respect to the alkyl halide, while it approximated an order of 1.5 with respect to Rh(I). Integral analyses of a few typical runs using a large excess of the alkyl halide (*e. g.* $[Rh(I)]=1.6\times10^{-2}$ M, $[RBr]=0.22$ M) revealed pseudo second-order dependence on [Rh(I)]. Thus the overall rate roughly follows the following rate equation:

$$R = k[Rh(I)]^2[RX].$$

Perhaps the accuracy of the differential analysis suffers from the occurrence of the induction period. Addition of 1—3 mol of free *t*-BuNC to system RX/$[Rh(t\text{-BuNC})_4]^+$ does not affect the rate appreciably.

The relative rate of addition of p-$XC_6H_4CHBrCO_2C_2H_5$ to $[Rh(t\text{-BuNC})_4]^+$ was measured at 20 °C. The rate decrease in a sequence of Cl>H>CH_3 for X, *i.e.*, t 1/2 (min) at 20 °C: Cl, 2.8; H, 6.0; CH_3, 9.6, a trend suggestive of nucleophilic character of the metal species. The relative rate, however, deviates from the Hammett plots. In contrast to $C_6H_5CHBrCO_2C_2H_5$ the oxidative addition of the corresponding chloride does not occur.

Attempting to study solvent effect, we found that the addition of $C_6H_5CHBrCO_2C_2H_5$ to $[Rh(t\text{-BuNC})_4]^+$ in acetone and CH_3CN also exhibits a complex kinetic feature thus preventing a reasonable analysis. Qualitatively the reaction rate does not vary appreciably among the solvents, acetone, CH_3CN, and CH_2Cl_2. A peculiar phenomenon was observed for the reaction in acetone; the time-conversion curve obtained by recording the intensity of the absorption at 440 nm on an ordinary spectrometer exhibited oscillations of small amplitudes suggesting a diffusion-controlled process. In addition to the 440 nm absorption the acetone solution shows two absorption maxima at 524 ($\varepsilon=692$) and 670 nm ($\varepsilon=365$) and the acetonitrile solution one maximum at 566 nm ($\varepsilon=1420$), indicating strong solvation in both solvents.

The rates of decrease in optical activity of the alkyl halide upon interaction with metal nucleophiles deserve investigation. The decrease in optical rotation of the system $C_6H_5CHBrCO_2C_2H_5/[Rh(t\text{-BuNC})_4]^+$ was fairly fast at 20 °C in CH_2Cl_2. Apart from the initial peroid (2—3 min), we were able to follow the polarimetric rate for a certain limited initial concentration (1.0×10^{-2}M), and found approximate second order kinetics with a rate constant, k_2, of 0.6 $M^{-1}s^{-1}$. As the addition of $CH_3CHBrCO_2C_2H_5$ to $[Rh(t\text{-BuNC})_4]^+$ takes place neither in the dark nor under irradiation of Na-D light beam (589 nm), the rate of optical loss can be followed by the polarimeter in the absence of concurrent oxidative addition. Surprisingly, the optical activity of a mixture of $CH_3CHBrCO_2C_2H_5$ (4.4×10^{-2} M) and $[Rh(t\text{-BuNC})_4]^+$ (0.92×10^{-2} M) decreases rapidly even in the dark. The initial rate could not be measured accurately because of the experimental difficulty due to the low $[\alpha]_D$ value of the bromo ester and to the strong color of $[Rh(t\text{-BuNC})_4]^+$, which prevents use of high concentrations. The rotation of a mixture containing 4.4×10^{-2} M of $CH_3CHBrCO_2C_2H_5$ and 0.92×10^{-2} M of $[Rh(t\text{-BuNC})_4]^+$ in CH_2Cl_2 kept at 20 °C decreased after 2 hr from a calculated value of 0.167 to 0.116° which corresponds to a value of a solution containing 3.4×10^{-2} M of the chiral propinate. Hence the amount (1.0×10^{-2} M) of the propionate which has lost the chirality is quite close to that (0.93×10^{-2} M) of $[Rh(t\text{-BuNC})_4]^+$ initially present in the system. Beyond this stoichiometric point, the rate of decrease in optical rotation became extremely slow. The starting complex, $[Rh(t\text{-BuNC})_4]^+$ was recovered almost completely from the sample solution upon precipitation by adding ethanol. The racemization of chiral $CH_3CHBrCO_2C_2H_5$ in the presence of $[Rh(t\text{-BuNC})_4]^+$ in methanol, which is faster than in CH_2Cl_2, was completed within a few hours at 80 °C. In the absence of the metal complex no racemization took place under the comparable conditions. The rate of decrease in optical rotation of the system $C_6H_5CHBrCO_2C_2H_5/[Rh(t\text{-BuNC})_4]^+$ was faster than the system $CH_3CHBrCO_2C_2H_5/[Rh(t\text{-BuNC})_4]^+$, and the rapid rate prevented accurate measurements.

Since the racemization suggests a possibility of complexation of the bromo esters to the metal, the IR and ^1H NMR spectra were examined. Electronic absorption spectroscopy cannot be employed here, as light of wavelength shorter than 440 nm initiates the addition reactions. An equimolar mixture of $CH_3CHBrCO_2C_2H_5$ and $[Rh(t\text{-BuNC})_4]^+$ in CH_2Cl_2 shows a slight bathochromic shift (10 cm^{-1}) in the IR CO stretching band as compared to the free bromoester. The sharp single absorption of NC stretching remains unchanged. The free bromo ester exhibits six peaks (1 : 2 : 4 : 5 : 4 : 2) for the methine and methylene protons derived from overlap of two quartet signals ($^3J_{HH}=6.2$ Hz). The equimolar mixture of the bromo ester and $[Rh(t\text{-BuNC})_4]^+$ in $CDCl_3$ gives a complex pattern for the protons, in which at least fourteen peaks are discernible. Although the complete assignment was impossible, these spectral data point to the presence of the complexed bromo ester. This is consistent with the slight intensity increase at 440 nm observed during

the induction period.

An ESR measurement was carried out during the oxidative addition of the bromo ester to $[Rh(t\text{-BuNC})_4]^+$, using *t*-BuNO as a spin trap as applied to a system of $CH_3I/Pt(PPh_3)_3$.[10] The ESR signals of a radical, *t*-Bu(R)NO·(R=$CH_3CHCO_2C_2H_5$, $C_6H_5CHCO_2C_2H_5$) were observed as three doublets with hyperfine coupling constants (Gauss): $A_0(N)=14.5$, $A_0(H)=3.0$ for R=$CH_3CHCO_2C_2H_5$; $A_0(N)=15.5$, $A_0(H)=4.5$ for R=$C_6H_5CHCO_2C_2H_5$. The ESR signals were more intense in the case of bromo phenylacetate than that of the bromo propionate. An irradiation of a few minutes duration of both systems with a low pressure mercury lamp does not cause any essential change in the ESR signals. The ESR signals was observed for system $[RhBr(C_6H_5CHCO_2C_2H_5)(t\text{-BuNC})_4]^+/t$-BuNO, but not for the alkyl halides/*t*-BuNO or $[Rh(t\text{-BuNC})_4]^+/t$-BuNO system.

A radical scavenger, duroquinone, was not effective in inhibiting the reaction. Because of the facile reaction of reactive radical scavengers like galvinoxyl with Rh(I) species itself, the use as a diagnostic probe was not attempted.

Discussion

Here we focus our discussion on the mechanism of the oxidative addition of *s*-alkyl halides, α-bromo esters, to $[Rh(R'NC)_4]^+$(R'=*t*-Bu, *p*-$CH_3C_6H_4$). Other alkyl halides were also studied as the substrate and "$Pd(t\text{-BuNC})_2$" was used as the acceptor to argue the above results. The oxidative addition of RX to $[Rh(t\text{-BuNC})_4]^+$, producing *trans*-octahedral Rh(III) complexes **1**—**4**, may be viewed as a substitution reaction at the saturated carbon atom. Any proposal on the mechanism must accommodate various experimental observation: (i) the *trans* geometry of the Rh(III) complexes formed, (ii) the absence of the dihalide complex, alkene, and alkane in the products, (iii) the effect of leaving group X, (iv) the electronic effect and structural effect of the alkyl moiety, (v) the racemization of the chiral bromoesters prior to the oxidative addition, (vi) the observed kinetic behaviors involving an induction period, (vii) the low-energy photoinitiation and the large quantum yield, and (viii) the results of spin-trap experiments. These results, *inter alia* vi and vii strongly suggest a chain mechanism. While non-radical chain mechanisms cannot be excluded conclusively we favor a radical chain as will be discussed later.

The following simple scheme is sufficient to describe the radical chain reaction ($[Rh(RNC)_4]^+$=M).

Scheme 1.

initiation:

$$M + RX \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} M\cdots X\cdots R \quad (1)$$

$$M\cdots X\cdots R \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} M\text{—}X + R\cdot \quad (2)$$

chain:

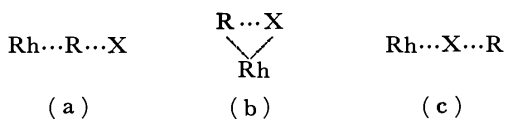
$$M^*\cdots X\cdots R + M\text{-}X \xrightarrow{k_3} M^*\text{-}X + RMX \quad (3)$$

termination:

$$M\text{-}X + R\cdot \xrightarrow{k_t} RMX \quad (4)$$

Note: Star was added to distinguish the metal identity in the product R-M-X from that involved the reagent M-X.

Step (1) is a reversible formation of an intermediate from RX and $[Rh(R'NC)_4]^+$. Although the instability prevents isolation and characterization, the existence in system $CH_3CHBrCO_2C_2H_5/[Rh(t\text{-BuNC})_4]^+$ is supported by the IR, ^1H NMR, and electronic spectra. Three possible modes may be distinguished for the interaction between the alkyl halide and the metal species; a) an essentially linear complex with a metal-carbon interaction, $(R'NC)_4Rh\cdots R\cdots X$, similar to a Menshutkin-type intermediate, b) a three-centered cyclic structure, and c) an essentially linear complex with a metal-halogen interaction, $(R'NC)_4Rh\cdots X\cdots R$.



The former, (a), corresponds to a transition state of an S_N2 type attack of the metal species at the alkyl carbon. The *para*-substituent effect on the rate of oxidative addition of *p*-$XC_6H_4CHBrCO_2C_2H_5$ shows the feeble nucleophilic character of $[Rh(R'NC_4]^+$. If the interaction of type (a) leads to the final adduct, then the stereochemical course should be inversion. Although Stille[11,12,29] has observed the inversion of configuration the oxidative addition of PhCHDCl to $Pd(PPh_3)_4$, the racemization observed for the present system renders the transition state structure untenable. The addition of 3-*endo*-iodocamphor, to which an *exo*-attack by a bulky nucleophile is prohibited, would not occur through the S_N2 type complex.

A cyclic intermdieate (b) is evidently incompatible with the observed loss of stereochemical integrity at the carbon atom. Ugo *et al.*[5] proposed a polar asymmetric three center transition state in which the iridium-carbon interaction takes place prior to the carbon-halogen bond breaking. The mechanism alleged would still imply retention of the carbon atom configuration since the incipient metal-alkyl bond formation prohibits configurational change at the carbon atom. Both claims of retention[19] and inversion[30] for an oxidative addition of a chiral *s*-alkyl halide to Ir(I) complexes were found erroneous. The cyclic transition state would lead to stereospecific *cis*-addition of alkyl halides to the metal. The possibility of *cis*-addition in a kinetically-controlled process followed by a rapid isomerization to the *trans*-adduct is unlikely in the present case where even trace of the *cis*-product was not detected. This was confirmed by monitoring the IR NC stretching band region (2200 cm^{-1}) which showed no indication for appearance of absorptions other than the bands due to the starting materials and the *trans*-adduct.

The third intermediate (c) appears to be the most likely species whose incipient formation must be assumed in order to account for the racemization preceding

the addition. Complexation of the corresponding chloride is not detected spectroscopically for the system $C_6H_5CHClCO_2C_2H_5/[Rh(t\text{-}BuNC)_4]^+$, and the system shows neither racemization nor oxidative addition. Thus, the racemization of the chiral α-bromoesters may be associated with step (1) and/or (2). The racemization of (*S*)-(+)-$CH_3CHBrCO_2C_2H_5$ in CH_2Cl_2 became extremely slow after the amount of the racemate reached a stoichiometric amount, equivalent to that of the complex present, while it proceeds catalytically in methanol. Practically, no oxidative addition takes place during the racemization in both solvents. The result in CH_2Cl_2 can then be accounted for by the large formation constant, $K_1=(k_1/k_{-1})$, coupled with a small value of k_2. Thus, the reversible step (1) appears to be responsible for the racemization. This constitutes, in turn, strong evidence for complexation of the *s*-alkyl halides forming (c). The observation of an increase in absorption intensity around 440 nm delineates the formation of an intermediate complex. This intermediate complex, albeit not isolable, must be fairly substitution stable since the catalytic racemization occurs slowly.

A radical or an ionic character could emerge in the alkyl moiety in intermediate, $L_4Rh\cdots X\cdots R$. If the alkyl group is held in the vicinity of the metal through, *e. g.*, a weak interaction of the carbonyl group with metal, the intermediate resembles a radical pair or an ion pair. Some cage reactions of chiral radical pairs have been shown to lead to racemization before diffusing apart with a rate depending on solvents.[31] Thus the observed solvent effect for the racemization does not necessarily imply an ionic intermediate.

The step (2) is the formation of the chain carrier. The failure of $CH_3CHBrCO_2C_2H_5$ to initiate the reaction in the dark and the contrasting smooth initiation of $C_6H_5CHBrCO_2C_2H_5$ reflect the relative ease of the halide abstraction. The primary importance of the C–Br bond cleavage for the initiation is evident. The facile addition of $CH_3CHBrCO_2C_2H_5$ to "Pd-(*t*-Bu)$_2$" in the dark suggests that the nucleophilicity of the metal species affects the initiation. There is no indication for disproportionation or coupling of the radicals. The acrylate and propionate detected in small amounts during isolation of adduct $[Rh(CH_3CHCO_2C_2H_5)(R'NC)_4]^+$ are presumably produced due to the thermal decomposition of the adduct once formed. CIDNP was not observed. The system RX/PtL_3 ($L=P(C_2H_5)_3$) showed CIDNP due to the alkane or alkene derived from diffused encounter of the alkyl radical only when PtX_2L_2 was formed.[9] Consistently the present system does not produce $[RhX_2(RNC)_4]$.$^+$ Spin-trap experiments using *t*-BuNO showed formation of a radical *t*-BuN(R)O. This again does not prove the presence of a free alkyl radical in the reaction mixture, since *t*-BuNO could react with both the alkyl halide complex $(R'NC)_4Rh\cdots X\cdots R$ and the final product, $[(R'NC)_4RhX(R)]$.$^+$

$$(R'NC)_4Rh^+\cdots X\cdots R \text{ or } [(R'NC)_4RhX(R)]^+ + t\text{-BuNO} \longrightarrow [(R'NC)_4Rh^{II}X(R)]^+ + t\text{-BuN(R)O}\cdot \quad (5)$$

The ineffectiveness of radical scavengers, *e.g.* 1,2,4,5-tetramethyl-*p*-benzoquinone, was observed. These results, however, fail to exclude conclusively the formation of organic radicals (in fact, the formation in a small amount is implied in Eq. 2). A mechanism involving short lived radicals or caged radical pairs is perfectly consistent with the available data.

Both possibilities, radical and ionic chains, must then be examined for step (3) which is rate-determining. The relative rates of $[Rh(p\text{-}CH_3C_6H_4NC)_4]^+$ and $[Rh(t\text{-}BuNC)_4]^+$ suggest that the nucleophilicity of the metal species affects the rate-determining step too. Although this trend is in accord with the observed electronic effect for the addition of $p\text{-}XC_6H_4CHBrCO_2C_2H_5$, the chain cannot be described in terms of a simple S_N2 type scheme as is evident from the molecularity of the step and the deviation from the Hammett rule. Since a low-energy photo-exitation of a similar Ir(I) compound is known,[32] let us examine an ionic chain mechanism such as Scheme II, which assumes a dissociative process (Eq. 6) to be photochemically induceable.

Scheme 2.

$$RhL_3^+ \rightleftharpoons RhL_3^+ + L \quad (6)$$

$$RhL_3^+ + RX \longrightarrow \{RhL_3X + R^+\} \rightarrow RhL_3X(R)^+ \quad (7)$$

$$RhL_3X(R)^+ + RhL_4^+ \longrightarrow RhL_4S(R)^+ + RhL_3^+ \quad (8)$$

$$RhL_3X(R)^+ + L \longrightarrow RhL_4X(R)^+ \quad (9)$$

Irradiation effect for the addition or substitution reaction of $[Rh(t\text{-}BuNC)_4]^+$ with neutral ligand such as CO, PR_3 or RNC was examined to find no effect. Further, an addition of free *t*-BuNC (1—3 mol) caused practically no effect on the rate of oxidative addition of the bromo ester to $[Rh(t\text{-}BuNC)_4]^+$.
Thus the dissociative process (Eq. 6) appears not to be important.

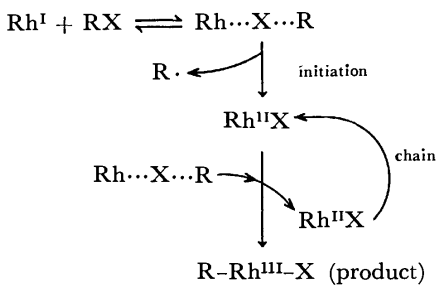
Alternative mechanisms involving carbonium ions may be possible. However, participation of carbonium ions in the rate-determining step is incompatible with the observed relative rate, *i. e.*, $C_6H_5CHBrCO_2C_2H_5 > CH_3CHBrCO_2C_2H_5$. Therefore we favor Scheme 1. Experimental tools are not available to kinetically discern the photochemical effect for the addition of $C_6H_5CHBrCO_2C_2H_5$, which occurs rapidly without irradiation. The information, even if available, would not affect our conclusion.

The low-energy of light (440 nm) used for initiating the reaction of $CH_3CHBrCO_2C_2H_5$ is insufficient to cause fission of the RX bond. The photochemical effect can only be expected for the complexed RX, but not for the free RX. The possibility of an alkyl radical as the chain carrier is excluded on the basis of the quantum yield ($\Phi=4.8$ for $C_6H_5CHBrCO_2C_2H_5$). It is most unlikely for a reactive alkyl radical (or carbonium ion) in solution to achieve such a high quantum yield.[33] Tentatively RhL_4X^+ species is assigned as the carrier.

It is rather surprising to find the inability of 1-bromo-2,2-diphenyl-cyclopropanecarboxylate to undergo the oxidative addition to $[Rh(R'NC)_4]$.$^+$ At first sight, this seems to support an ionic, solvolysis mechanism, because the formation of an S_N2-type transition state would be hindered sterically. The steric hindrance,

however, could also be influential for the bimolecular reaction step (3). The observed addition of 3-*endo*-iodo campher to $[Rh(R'NC)_4]^+$ is apparently incompatible with an S_N2-type transition state. The failure of the bromocyclopropane toward the addition may then be accounted for by the high activation energy required for a substituted cyclopropane to form the cyclopropyl radical.[35] The inertness of a primary alkyl bromide, *erythro*-1-bromo-3,3-dimethyl-1,2-dideuteriobutane, to $[Rh(t\text{-}BuNC)_4]^+$ can be accounted for by the steric effect primarily operating in step (3). The steric congestion around the carbon atom carrying the bromine atom is apparently more enhanced in step (3) than in the preceding steps (1)—(2).

The reverse reaction of the initiation constitutes the terimination (4). A similar situation has been found for halogen radical chain reactions.[34] Another termination could be dimerization of the Rh(II) species[36] forming $[RhX(t\text{-}BuNC)_4]_2^{2+}$. The formation, however, could not be detected, a result expected from the high yield of the oxidative addition. The whole sequence may be depicted as shown.



Although the addition of α-bromopropionate showed complicated kinetic features, it seems reasonable to assume a similar radical chain mechanism involving a rate-determining initiation. Once the initiation has started photochemically, the reaction apparently proceeds through the same sequence as for $C_6H_5CHBrCO_2C_2H_5$.

In summary, various facts described above appear to be mostly consistent with a radical chain mechanism. Osborn[9] has suggested such a mechanism for a similar addition reaction to a stronger metal nucleophile PtL_3 without direct experimental evidence. The present results clearly exclude an intermediacy of an alkylrhodium species[37] such as $[Rh^{III}(R)L_4]^{2+}$. We do not claim that this radical chain mechanism is valid for the addition of different types of alkyl halides to the metal system. However, a similar radical mechanism should be valid for the addition of these α-bromo esters to Pd(0) systems which also show complete loss of stereochemical integrity at the carbon atom.[18]

Enzyme-like Reaction Catalyzed by NAD$^+$–Reduced Keratin Systems

Morio HIRANO and Fujio TAKAHASHI*

Research Laboratory of Resources Utilization, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

**Faculty of Engineering, Utsunomiya University, Ishii-cho, Utsunomiya 321-31*

(Received November 24, 1976)

Reduced keratin, which was obtained by reductive cleavage of human hair, was found to form a 1 : 1 complex with nicotinamide adenine dinucleotide (NAD$^+$). The complex exhibited catalytic activity for the oxidation of glyceraldehyde to form glyceric acid. It was found from the results of pH titration, polarograms and NMR measurements that the NAD$^+$-reduced keratin complex binds to glyceraldehyde to form an intermediate, which is susceptible to oxidation by oxygen. It was concluded from kinetic studies that this catalytic reaction showed a homotropic effect.

In a previous paper, it was reported that reduced keratin (RK) was found to form a 1 : 1 complex with flavin adenine dinucleotide (FAD) and that the complex exhibits catalytic activity for dehydrogenation of succinic acid to form fumaric acid.[1] It was suggested that the FAD–RK complex is formed by the interaction between arginine residues of RK and an adenine moiety and the pyrophosphate linkage of FAD. From this conclusion, it is expected that NAD$^+$, which has a nicotinamide moiety in place of an isoalloxazine moiety of FAD, might form a complex with the RK and act as an enzyme-like catalyst.

It is well known that there are many dehydrogenases in which NAD$^+$ and mercapto group are located in the active center of an enzyme, such as alcohol dehydrogenase, aldehyde dehydrogenase, *etc.*

Since it is expected that the NAD$^+$–RK system possesses catalytic activity like that of an enzyme, various substrates such as ethanol, monosaccharide (glucose, mannose, xylose), methyl mandelate, glyceraldehyde 3-phosphate and glyceraldehyde were examined. The formation of NADH (the reduced form of NAD$^+$) was observed spectrophotometrically when glyceraldehyde was added as a substrate into a solution containing NAD$^+$ and RK. The results of kinetic studies of the catalytic reaction between glyceraldehyde and the NAD$^+$–RK complex will be presented in this paper.

Experimental

Materials. The RK used was prepared by the procedure described in a previous paper.[2] The molecular weight of the RK was 4500 (measured by viscometry). Mercapto group: 0.2 mgeq/g of protein. S content: 2.7%. The glyceraldehyde, NAD$^+$, dichlorophenolindophenol (DCIP), and other chemicals used were of reagent grade or the best commercially available.

Equipment and Measurements. The equilibrium constant and the maximum number of bonds in the NAD$^+$–RK system were determined by the dialysis-equilibrium method[3] as follows: Into a 50-ml Ehrenmyer flask containing 20 ml of 0.2—5.0$\times$10^{-3}M NAD$^+$ in a 0.1 M phosphate buffer (pH 8.0) (or 20 ml of a buffer solutoin as a reference solution without NAD$^+$), a cellulose tube containing 10 ml of 1.0$\times$10^{-4} M RK in a 0.1 M phosphate buffer (pH 8.0) was inserted. The cellulose tube used was made by the Visking Company. The flasks were allowed to stand at 35 °C for 24 h. The NAD$^+$ concentration in the flasks were determined spectrophotometrically after 24 h.

The UV absorption spectra were determined with a Shimadzu spectrophotometer UV-200. The anode polarograms were obtained using a Yanaco platinum rotating-electrode polarograph equipped with a Hokuto Denko LS-1D linear scanning unit, and PS-500B potentiostat and a Toa Electronics SXR-1A X-Y recorder. The NMR spectra were measured with a JEOL JNM-FX60.

Glyceric acid was identified using paper chromatography with a mixture of 1-propanol and concentrated aqueous ammonia (6 : 4) as the developer, and using NMR.

Results

The Formation of the NAD$^+$–RK Complex. The binding number, n, and the concentration of free NAD$^+$, [NAD$^+$], were determined using the method of Klotz *et al.* Plots of $1/n$ *vs.* $1/[\mathrm{NAD}^+]$ are shown in Fig. 1. A straight line was obtained. The values of the equilibrium constant, K, and the maximum number of bonds were calculated from the intercept and the slope of this line to be 1.2×10^3 M^{-1} and 1.3 (35 °C), respectively.

The Reaction Product. RK, NAD$^+$, and glyceraldehyde were dissolved into 100 ml of a 0.02 M phoshpate buffer (pH 8.0) to produce 1.0×10^{-4}, 1.0×10^{-3}, and 1.0×10^{-3} M solutions and the mixtures were allowed to stand at 35 °C. The absorption spectra of the mixtures were measured in the 230—400 nm region 0, 24, 48, and 68 h after perparation. The reference solution contained the same concentrations of RK and glyceraldehyde as the sample solution, except that no NAD$^+$ was present. The results are shown in Fig. 2. The absorption maximum at 340 nm, which was assigned to NADH, was found to increase with the lapse of time.

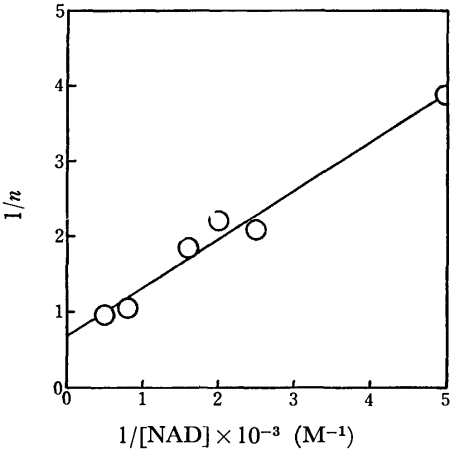

Fig. 1. The $1/n$ - $1/[\mathrm{NAD}]$ plots for the dialysis equilibrium.

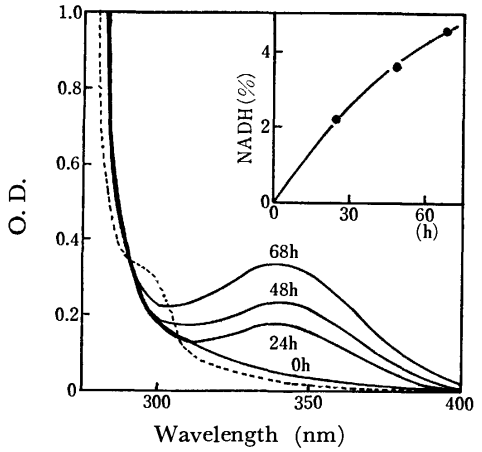

Fig. 2. Absorption spectra.
——: pH 8.0, ----: pH 7.0.

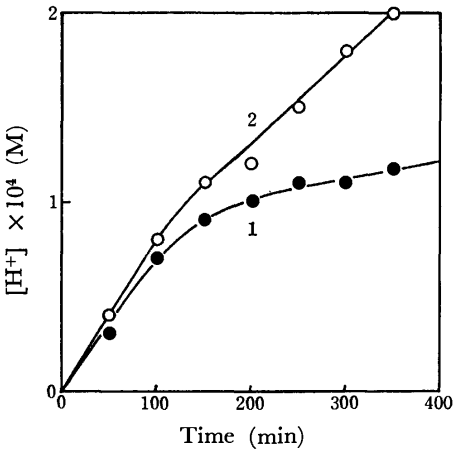

Fig. 3. The alkaline titration curves.
—○—: Oxygen bubbling,
—●—: nitrogen bubbling.

In the case of a pH 7.0 mixture, an absorption shoulder appeared at 290 nm and no absorption maximum was observed at 340 nm. On the paper chromatogram of the mixture 68 h after preparation, only one spot was observed at R_f=0.25, which is agreement with an authentic sample of glyceric acid (R_f=0.26).

Into 100 ml of distilled water, 1.0×10^{-4} M of RK, 1.0×10^{-4} M of NAD$^+$ and 1.0×10^{-3} M of glyceraldehyde were dissolved and adjusted to pH 8.0 by adding a sodium hydroxide solution. The mixture was bubbled with oxygen at 35 °C for 40 h, and the pH of the mixture was maintained at 8.0 by adding a sodium hydroxide solution. It was estimated from alkaline titration that 70% of the glyceraldehyde was converted to produce acid for a period of 40 h. The reaction mixture was dialyzed against distilled water, concentrated by evaporation, and then treated with an ion exchange resin (SE-sephadex-C50 H type) to remove any sodium ions. The solution was decolored by active charcoal and then evaporated resulting in a sticky syrup. The NMR spectrum of the syrup in deuterium oxide was found to be in agreement with that of glyceric acid (a multiplet at 3.68 (CH_2) and another at 4.32 (CH) ppm using the signal from tetramethylsilane as the external reference).

It is concluded from these results that glyceraldehyde was oxidized to form glyceric acid and NAD$^+$ was reduced to form NADH in the solution containing glyceraldehyde, NAD$^+$, and RK. The catalytic reaction could not proceed in either case because one component of the glyceraldehyde, NAD$^+$, and RK system had been omitted. Glyceraldehyde 3-phosphate, which is a compound similar to glyceraldehyde, was not oxidized by the NAD$^+$–RK system.

Reaction Rate. The rate of acid formation was determined by the alkaline titration method. A sample solution was prepared by dissolving glyceraldehyde, NAD$^+$ and RK into distilled water to produce 0.4—6.0×10^{-3}, 2.0×10^{-4}, and 1.0×10^{-4} M solutions and by adding a 0.1 M sodium hydroxide solution to adjust the mixture to pH 8.0. The reaction commenced immediately upon preparation of the sample solution at 35 °C. The alkaline titration was carried out manually to maintain the pH at 8.0. Typical results are shown in Fig. 3. Curves 1 and 2 in Fig. 3 show the results obtained by bubbling nitrogen and oxygen into the sample solution, respectively. The initial rate of acid formation did not appear to be influenced by the presence of oxygen. In the case of nitrogen bubbling, however, the rate of acid formation was found to decrease after the amount of acid produced in the reaction had reached the equivalent amount of RK.

The relation between the initial rate and the concentration of glyceraldehyde is shown by Lineweaver-Burk plots in Fig. 4. The plots are lines which gave two slopes about a turning point at 1.4×10^{-3} M of glyceraldehyde. It is speculated from this fact that same glyceraldehyde was tightly bound to the NAD$^+$–RK complex to be inactivated. The Lineweaver-Burk plot is a straight line in the case that 2.0×10^{-3} M glyceraldehyde 3-phosphate, which was not oxidized, was contained in the NAD$^+$–RK solution before adding glyceraldehyde. The values of the Michaelis constant and the maximum rate of the oxidation of glyceraldehyde were obtained from the intercept and the slope of the line to be 1.1×10^{-3} M and 3.6×10^{-6} M/min, respectively.

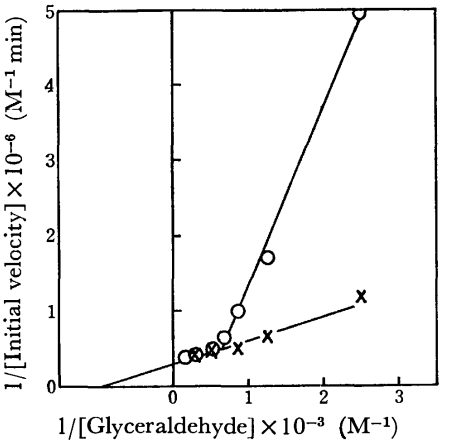

Fig. 4. Lineweaver-Burk plots.
—○—: Glyceraldehyde, —×—: glyceraldehyde with 2.0×10^{-3} M glyceraldehyde-3-phosphate.

Intermediates. This reaction should obey Michaelis-Menten kinetics. The glyceraldehyde–NAD+–RK complex appears to be an intermediate which was susceptible to oxidation by oxygen. In order to verify the existence of the intermediate, a polarographic study and DCIP oxidation were carried out.

The sample solution contained 2.0×10^{-4} M of glyceraldehyde, 2.0×10^{-4} M of NAD+, and 2.0×10^{-4} M of RK in a 0.1 M phosphate buffer (pH 8.0). Polarograms were measured (1) as fast as possible after preparation of the sample solution and (2) after 24 h at 35 °C. The sample solution was bubbled with nitrogen. The polarogam of NADH in the phosphate buffer was obtained and compared with that of the sample solution. The results are shown in Fig. 5. The oxidation wave of NADH was found to appear around +0.66 V *vs.* SCE. In the case of measurement immediately after preparation of the sample solution, no oxidation wave was observed in this region. Polarograms of the sample solutions after 24 h of preservation showed an oxidation wave at +0.19 V *vs.* SCE. It is plausible that this new oxidation wave can be assigned to the intermediates. No oxidation wave for NADH was observed.

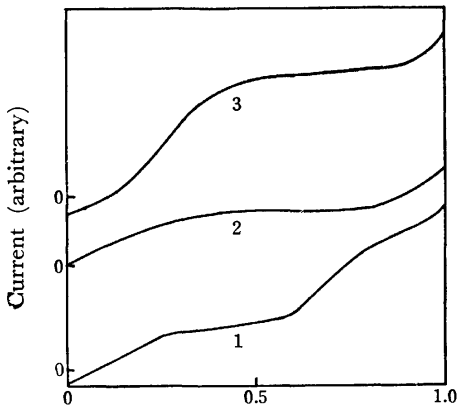

Fig. 5. Anode polarography.
1: NADH solution, 2: the NAD+–RK–glyceraldehyde system immediately after preparation, 3: the same system after 24 h.

DCIP oxidation was carried out by inserting the constituents as given in Table 1 into the Tunberg tube in which oxygen was removed by the passage of nitrogen gas. The conversion ratios of DCIP to reduced DCIP were determined spectrophotometrically at 600 nm after 30 min. DCIP was found to oxidize glyceraldehyde directly (Table 1). The conversion ratio decreased for a solution containing both NAD+ and RK. The DCIP oxidation was thought to be disturbed by the complexation of glyceraldehyde with the NAD+–RK complex.

It is assumed that the absorption shoulder at 290 nm in the pH 7.0 solution can be assigned to the intermediate, which is more stable in a pH 7.0 solution than in a pH 8.0 solution, because the absorption change at 290 nm is smaller than that at 340 nm. The NMR spectra at pH 7.0 were measured in order to better understand the struture of the intermediate. Proton signals (H4–6) of the nicotinamide moiety of NAD+ in the NAD+–RK solution were found to shift by 0.15—0.25 ppm to higher fields compared to that in NAD+ itself, as is indicated in Table 2. The RK signal may be located on the H4—6 side of the nicotinamide moiety, and that due to glyceraldehyde may be on the H2 side.

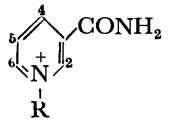
Table 1. DCIP oxidation of various systems

	Formation of $DCIPH_2$
NAD+–RK GCHO (1 : 1 : 10)	24.8 (%)
NAD+–RK (1 : 1)	0.0 (%)
NAD+–GCHO (1 : 10)	43.0 (%)
RK–GCHO (1 : 10)	18.2 (%)
NAD+	0.0 (%)
RK	0.0 (%)
GCHO	45.4 (%)

1.0×10^{-4} M NAD+, 1.0×10^{-4} M RK, 10×10^{-4} M GCHO, 1.0×10^{-4} M DCIP.
pH 8.0, 35 °C, 30 min, GCHO: glyceraldehyde.

Table 2. NMR of NAD+ in an NAD+–RK–GCHO solution

	NAD+	NAD+–RK	NAD+–RK–GCHO
H2	10.55	10.50	10.41
H4	9.67	9.52	9.50
H5	9.50	9.25(s)	9.23(d)
H6	10.05	9.87	9.85



1.0×10^{-3} M NAD+, 1.0×10^{-3} M RK, 1.0×10^{-3} M GCHO in D_2O (pH 7.0), GCHO: glyceraldehyde.

Discussion

It can be speculated from the fact that in Fig. 4 the catalytic reaction of NAD+–RK complex is seen to proceed *via* a similar reaction mechanism, which is called a homotropic effect, as that for tryptophane pyrolase.[4] It is possible for an aldehyde group of glyceraldehyde to form a Schiff base linkage with an amino group of RK. Glyceraldehyde forming the Schiff base linkage may be only slightly oxidized because the active center of the NAD+–RK complex may be located in a position different from that of the Schiff base linkage. Therefore, the actual concentration of glyceraldehyde is reduced. It is surely possible that glyceraldehyde 3-phosphate can bind more easily to RK than to glyceraldehyde, because ionic bond formation of that phosphate group may facilitate the formation of the Schiff base linkage. In the mixture of glyceraldehyde 3-phosphate and glyceraldehyde, the former may preferentially form a Schiff base linkage, so that oxidation may be carried out by a Michaelis-Menten type reaction as follows:

$$\text{NAD+RK} + \text{GCHO} \rightleftharpoons \text{NAD+RK GCHO} \longrightarrow \text{X} + \text{H+}, \quad (1)$$

where X and GCHO indicate an intermediate and glyceraldehyde, respectively.

The rate of NADH formation shown in Fig. 2 was

very slow as compared with that of acid formation. Therefore, the conversion of the intermediate in the following reaction is thought to be the rate-determining step:

$$X + H_2O \xrightarrow{A} NADH + RK + GCOOH, \quad (2)$$

where GCOOH denotes glyceric acid.

The intermediate is susceptible to oxidation by oxygen and to an anodic reaction (Figs. 3, 5). Oxygen may participate in the second step in a subsequent reaction. The reaction can be expressed as follows:

$$X + 1/2O_2 \longrightarrow NAD^+RK + GCOO^-. \quad (3)$$

The DCIP oxidation suggests the existence of the ES complex in Fig. 1. Tagaki *et al.* have isolated *N*-benzyl-5-[hydroxy(1-pyridyl)methyl]nicotinamide, which exhibits an absorption maximum at 290 nm, by a reaction between aldehyde and a reduced nicotinamide derivative.[5] They explained that the product obtained may be one of the intermediates in the reaction. The absorption shoulder at 290 nm in Fig. 2 can thus be assigned to a similar intermediate.

Many authors have recently proposed that, at the active center of glyceraldehyde 3-phosphate dehydrogenase, a nicotinamide moiety in NAD^+ combines with an apoenzyme located near Cys-149 and that this center is activated by a mercapto group.[6-9] If the NAD^+–RK complex is assumed to catalyze the oxidation of glyceraldehyde in the same way as glyceraldehyde 3-phosphate dehydrogenase, a mercapto group on RK may play a similar role in the catalytic reaction. However, this assumption is still open to further investigation.

The authors express their sincere thanks to Professor Shuichi Suzuki of the Tokyo Institute of Technology for his encouragement.

Effect of Hydrogen Bonding on the Rotational Barriers of Partial Double Bonds. III. 2,6-Dihydroxyaryl Carbonyl Compounds

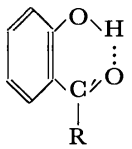
Minoru HIROTA, Toshio SUZUKI, and Kazuhisa ABE

Department of Applied Chemistry, Faculty of Engineering, Yokohama National University, Minami-ku, Yokohama 233

(Received December 20, 1976)

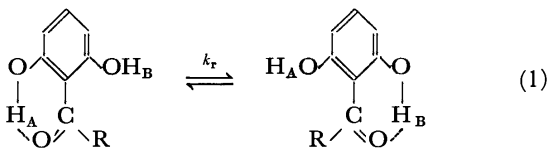
Activation parameters of internal rotation around C_{ar}–$C_{carbonyl}$ bonds are determined by means of DNMR spectroscopy for 2,6-dihydroxybezaldehyde and some 2,6-dihydroxybenzoates. The ΔG^* and ΔH^* of these compounds are *ca.* 10 kJ mol^{-1} higher than those for the reference compounds void of *ortho*-hydroxyl groups, and the excess stabilization is attributed to the contribution of the intramolecular hydrogen bonding. The intramolecular hydrogen bonding in these compounds were discussed on the basis of their infrared spectra in the ν_{OH} region.

The intramolecular hydrogen bond is formed when the hydrogen donating and the hydrogen accepting groups are located close enough to interact each other, and the whole molecule is stabilized at the sacrifice of the freedom of the intramolecular motion. Thus, the intramolecular hydrogen bonding in salicylaldehyde and salicylate esters fixes their molecules to the conformation I, and the rotational barrier around the C_{ar}–$C_{carbonyl}$ single bonds becomes considerably higher.



I : R=H or OCH_3

In other words, the coplanar conformation I of ortho-hydroxy derivatives are stabilized by the intramolecular hydrogen bonding in addition to the π-stabilization energy of conjugation common with the aryl carbonyl compounds void of the hydrogen bond, and the difference in the barrier heights between the aryl carbonyl compounds with and without *o*-hydroxyl group will reflect the energy of the intramolecular hydrogen bonding. In the previous report of the present authors, the hydrogen bond energy of *o*-hydroxybenzaldehyde was estimated in this way from the rotational barriers of 2,6-diformylphenols.[1,2] Rotational barriers of partial double bonds (C_{sp^2}–C_{sp^2} single bonds) can be best estimated by the techniques of dynamic nuclear magnetic resonance (DNMR) from the separations or from the widths of the NMR signals at various temperatures.[3-6]



IIa $\qquad$ II_b $\qquad$ (1)

For this purpose, such protons should be chosen as the probe of the intramolecular rotation that they are equivalent in the condition of fast exchange but nonequivalent when the exchange is slow. Since two hydroxyl protons (H_A and H_B in II) of 2,6-dihydroxyaryl carbonyl compound are suitable for this purpose, the DNMR measurements were carried out on these compounds and their intramolecular hydrogen bonding was discussed in this paper.

Experimental

Preparation of Materials. 2,6-Dihydroxybenzaldehyde and 2,6-dihydroxyacetophenone were prepared from resorcinol by the methods in literatures.[7,8] 2,6-Dihydroxybenzoate esters were obtained by reacting the corresponding alkyl halides with silver 2,6-dihydroxybenzoates.[9] All materials and solvents employed in this investigation were purified either by distillation or by recrystalization.

Measurement of the Spectra. Infrared spectra were recorded on a Hitachi Model 225 infrared spectrometer. Nuclear magnetic resonance spectra were obtained on a JEOL JNM C-60H spectrometer. Chemical shifts are given as parts per million (ppm) downfield from TMS.

Evaluation of the Rotational Barriers from the Line Shapes Above Coalescence. Because of the relatively low coalescence temperature (T_c), the exchange rate of the two equivalent protons without the splitting caused by spin-spin coupling (H_A and H_B in II) was obtained from the half-widths W^* (in Hz) of the signal above T_c by the following equation.[3]

$$(\pi\delta\nu\tau)^{-1} = [(\delta\nu/W^*)^2 - (W^*/\delta\nu)^2 + 2]^{1/2}$$

where $\delta\nu$ refers to the chemical shift difference (in Hz) of the two protons H_A and H_B. As the measurements were carried out within the temperature range where the signals were considerably broader than usual, it is assumed that the exchange contribution W^* to the observed line width W is by far greater than that from the natural width (hence, $W=W^*$).

Results and Discussion

Kinetic studies of some alkyl 2,6-dihydroxybenzoates in chloroform-*d* and of 2,6-dihydroxybenzaldehyde in diethyl ether were carried out employing the techniques of DNMR spectroscpy. From Eq. 1, the rate constants (k_r in s^{-1}) of the intramolecular exchange process between H_A and H_B due to the rotational interconversion between II_a and II_b were calculated from the half widths (in Hz) observed at various temperatures, and given, together with the half widths, in Table 1.

In 2,6-dihydroxy-benzaldehyde and -acetophenone, H_A and H_B are the free and the intramolecularly hydrogen bonded hydroxyl protons, while, in alkyl 2,6-dihydroxybenzoates, they are the hydroxyl protons intramolecularly hydrogen bonded to the alkoxyl and to the carbonyl groups of the ester.

The Arrhenius plot (k_r *vs.* $1/T$ plot in Fig. 1) gives the enthalpy and the entropy of activation of the interconversion between the degenerate geometrical isomers II_a and II_b, and thus obtained activation parameters

a) The $\Delta\nu$ values given in Table 2 were used for the calculations of k_r values, and $W=W^*$ is assumed. (See text.)

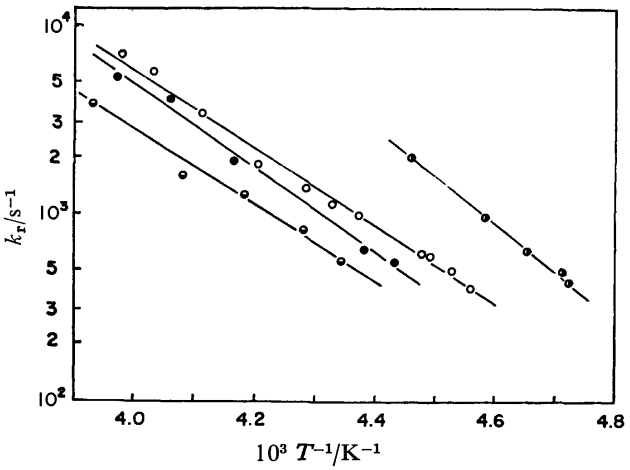

Fig. 1. Arrhenius plots for 2,6-dihydroxybenzaldehyde (—○—), methyl 2,6-dihydroxybenzoate (—◑—), ethyl 2,6-dihydroxybenzoate (—●—), and propyl 2,6-dihydroxybenzoate (—◒—).

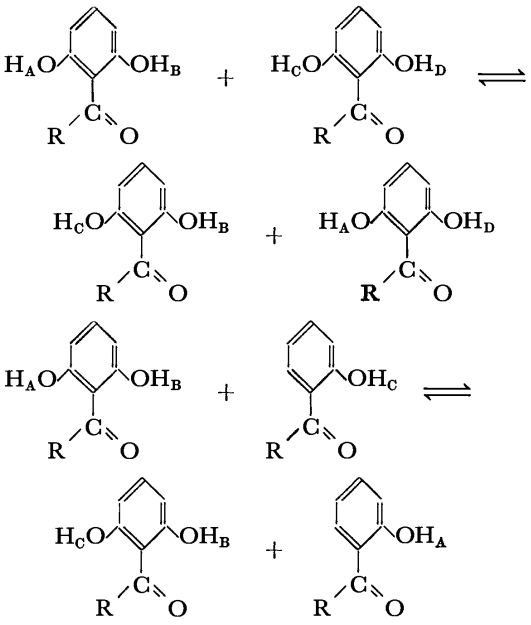

The OH proton signals of the two species appear separately and quite sharply in the spectra of the above ternary systems even at room temperature and when their chemical shift difference is only 5 Hz or so.[10)]

are shown in Table 2. The activation parameters of 2,6-dihydroxyacetophenone could not be determined owing to its very low coalescence temperature (≈195 K) which made difficult the determination of the exact resonance frequencies of the free and the hydrogen bonded hydroxyl protons.

Since the activation parameters are obtained only for the fastest process, any other process faster than the internal rotation will prevent the determination of the rotational barrier height. Thus, the effect of intermolecular exchange processes (rate constant k_e), such as Eq. 2, is checked by the measurement of the spectra on salicylaldehyde–methyl salicylate–chloroform-*d* and methyl 2,6-dihydroxybenzoate–salicylaldehyde–chloroform-*d* ternary systems.

TABLE 2. ACTIVATION PARAMETERS FOR THE INTERNAL ROTATION IN SOME 2,6-DIHYDROXYARYL CARBONYL COMPOUNDS AND RELATED SUBSTANCES

Compound	T_c/K	$\Delta\nu$/Hz	ΔG^*/kJ mol^{-1}	ΔH^*/kJ mol^{-1}	ΔS^*/J mol^{-1} K^{-1}
1	215.6	143.0	41.8	37.4	−21
2	≈195		≈33		
Benzaldehyde	150		33.1		
3	207.5	147.6	40.2	41.8	+8
4	222.1	150.0	43.1	41.1	−9
5	227.1	148.0	44.1	38.4	−25
6[a)]	<163		<34.7[b)]		

a) 3,4,5-Trimethoxybenzoic acid as the reference substance without intramolecular hydrogen bond. b) To calculate the upper limit of the ΔG^* value, $\Delta\nu$ is assmed to be 10 Hz, which corresponds to the chemical shift difference between H_3 and H_5 of 2,6-diformylphenol in the frozen state.

Thus, the intermolecular exchange processes are proven to be slower than the intramolecular process, *i.e.* $k_r \gg k_e$.

The ΔG^* and ΔH^* for 2,6-dihydroxybenzaldehyde (**1**) are 41.8 and 37.4 kJ mol^{-1}, respectively, and a little smaller than those of 2,6-diformylphenols (46.4 and 43.9 kJ mol^{-1}, respectively, for the *p*-methyl derivative in chloroform-*d*).[1] The measurement on **1** was carried out in diethyl ether instead of chloroform-*d*, and the lower energy barrier in **1** is at least partly due to the effect of the more polar solvent. While, the steric interaction between formyl hydrogen atom and the free hydroxyl group should be slightly repulsive, which may contribute additionally to the instabilization of the planar hydrogen bonded conformation. However, the stabilization due to the intramolecular hydrogen bond is remarkably more predominant, and the planar conformations of **1** are about 9 kJ mol^{-1} more stable than those of benzaldehyde. The activation parameters for 2,6-dihydroxyacetophenone (**2**) could not be determined exactly because of its lower T_c and of its poor solubilities in available solvents (chloroform, diethyl ether, vinyl chloride, *etc.*) under the experimental conditions. The remarkably lower rotational barrier of **2** must be caused by the increase in steric hindrance, since the C–H···OH interaction in **1** is replaced by much serious repulsive interaction between the methyl and the hydroxyl groups in this molecule. Judging from the Stuart molecular models, the most stable conformation of **2** is expected to become nonplanar, and its rotational barrier might be illustrated schematically by the broken line in Fig. 2. The nonplanar conformation is supported by the fact that the ν_{OH} absorption due to the chelated hydroxyl group is very weak in the infrared spectrum of **2** in dilute carbon tetrachloride solution.

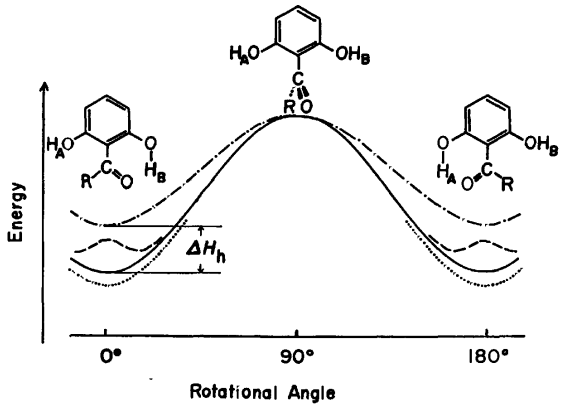

Fig. 2. Schematic diagrams for the potential energy barriers of 2,6-dihydroxybenzaldehyde (——), 2,6-dihydroxyacetophenone (----), and 2,6-dihydroxybenzoate esters (·····).
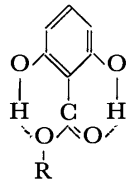
The potential barriers of benzaldehyde (—·—·) is also illustrated as reference.

Table 3. Infrared spectra of 2,6-dihydroxyaryl carbonyl compounds in the ν_{OH} region (3600—3000 cm^{-1})

Compound	c/mol l^{-1}	ν_{OH}/cm^{-1}	ε_{max}/l mol^{-1} cm^{-1}	Assignment[a]
1	0.013	3596.9 3140	137 27	f. h. c.
2	0.020	3593.2[b]	190	f.
3	0.010	3473.2 3202	149 70	h. a. h. c.
4	0.010	3461.0 3202	129 40	h. a. h. c.

a) f=free, h. c.=hydrogen-bonded to carbonyl oxygen atom, h. a.=hydrogen-bonded to alkoxyl oxygen atom. b) A broad absorption band centered at about 3150 cm^{-1} is observed, but its intensity is by far lower than that of **1**.



(III)

The infrared spectra of 2,6-dihydroxybenzoate esters (**3**,**4**) in Table 3 show the presence of two kinds of hydrogen bonded species. However, the absorption of the free species is not detected in any of their spectra. The fact is reasonably explained by assuming a planar conformation in which one hydroxyl group is chelated to the carbonyl oxygen atom and the other to the alkoxyl oxygen atom by forming intramolecular hydrogen bonds, as illustrated by III. Since the OH···O=C hydrogen bond is stronger than the OH···OR hydrogen bond,[11] the OH stretching absorption at the lower frequency is assigned to the hydroxyl group hydrogen bonded to the carbonyl, and the absorption at the higher ferquency to the hydroxyl group hydrogen bonded to the alkoxyl oxygen atom (as shown in Table 3).

The ΔG^* and ΔH^* values of the 2,6-hydroxybenzoates **3**, **4**, **5** are similar to those of **1** and a considerable stabilization due to the intramolecular hydrogen bond formation is suggested. In order to estimate the contribution of the hydrogen bonding to the stability of the planar conformation, DNMR measurement of methyl 3,4,5-trimethoxybenzoate **6**, as a reference, was also carried out. However, the aromatic proton signal of **6** was rather a sharp singlet even at 173 K, and no indication of splitting into an AB quartet was observed. The π-bond order of the C_{ar}–$C_{carbonyl}$ bond from MO calculation serves as a criterion for the potential barrier height.[12] The π-bond orders for benzoate ester and benzaldehyde are calculated to be 0.247 and 0.271, respectively, by PPP approximation, and the rotational barrier of **6** is expected to be lower than that of benzaldehyde. Anyhow, the rotational barrier is at least 10 kJ mol^{-1} higher than that of the reference compound, and the excess stabilization energy is again attributed to the contribution of the intramolecular hydrogen bonding. The OH···OR hydrogen bonding in the esters **3**—**5** must increase the stability of the planar conformation III, but its contribution cannot be determined quantitatively because of the uncertain activation parameters of the reference substance **6**.

The rotational barriers of the aryl carbonyl compunds are illustrated schematically in Fig. 2. In the transition state of the internal rotation het

aromatic nucleus is perpendicular to the plane of the carbonyl group, and both the hydrogen bonding and the steric hindrance do not affect its potential energy remarkably. Thence, the hydrogen bond energy can be estimated as the difference in ΔH^* (ΔH_h in Fig. 2) of the chelated and the reference substances. Hydrogen bond energies thus obtained are *ca.* 9 kJ mol^{-1} for 2,6-dihydroxybenzaldehyde and 8 kJ mol^{-1} for 2,6-dihydroxybenzoates. These values are considerably smaller than the hydrogen bond energies of the similar substances obtained by other methods.[13] The lower ΔH_h may be justified by the polar nature of the solvents used and the negative contribution of the steric hindrance in the planar conformation.

The authors are grateful to Mrs. Shigeko Yoshida and to Miss Hiroko Endo for their technical assistance in the measurement of NMR spectra.

A New Synthesis of Pyrocin and Related Compounds*

Akira TAKEDA, Takashi SAKAI, Shohei SHINOHARA, and Sadao TSUBOI

Department of Synthetics Chemistry, School of Engineering, Okayama University, Tsushima, Okayama 700

(Received January 5, 1977)

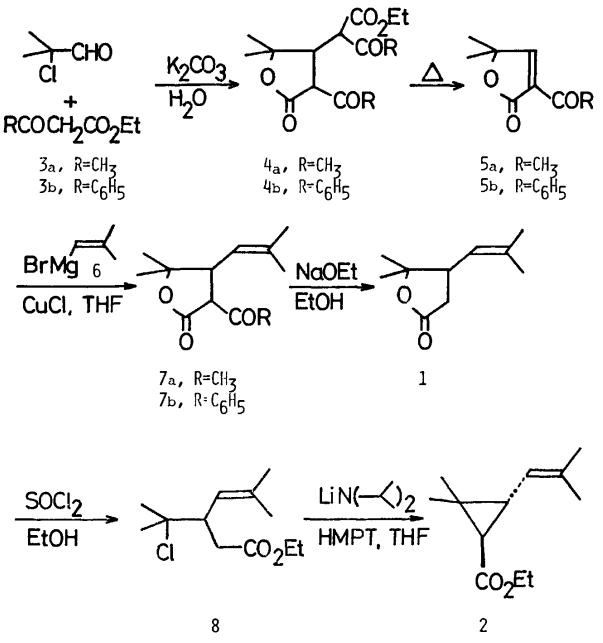
A new synthesis of pyrocin (**1**) and related compounds is described. The reaction of 2-benzoyl-4,4-dimethyl-2-buten-4-olide (**5b**) with 2-methyl-1-propenylmagnesium bromide (**6**) in the presence of CuCl gave α-benzoylpyrocin (**7b**) in 90% yield. The product of **7b** with a specific rotation of +2.43° was obtained when the reaction was carried out in the presence of (−)-sparteine. α-Acetylpyrocin (**7a**) was prepared in the similar manner in 63% yield. The treatment of **7a** and that of **7b** with ethanolic sodium ethoxide gave **1** in 65% and 81% yields, respectively. The reaction of **1** with large excess of $SOCl_2$ in absolute ethanol gave ethyl 3-(1-chloro-1-methylethyl)-5-methyl-4-hexenoate (**8**) in 82% yield. Similar treatment of **7** with $SOCl_2$ gave ethyl 2-substituted-4-(2-methyl-1-propenyl)-5,5-dimethyl-4,5-dihydrofuran-3-carboxylate (**12**). Compound **8** was transformed to ethyl *trans*-(±)-chrysanthemate (**2**) in 75% yield.

Several syntheses of pyrocin (**1**), found in the pyrolysate of pyrethrine and known to possess insecticidal activity,[1a–1d] have been reported.[2a–2k] Recently, we[3] have reported an efficient preparation of 2-acyl-4,4-dimethyl-2-buten-4-olide (**5**) by the thermal decomposition of 2-acyl-3-[benzoyl(ethoxycarbonyl)methyl]-4,4-dimethyl-4-butanolide (**4**), which is readily obtained by the reaction of 2-chloro-2-methylpropanal and ethyl acylacetate (**3**) in aqueous K_2CO_3. In this paper, we wish to report a new synthesis of **1** and ethyl (±)-*trans*-chrysanthemate (**2**) using **5** as a starting material. An attempted synthesis of optically active pyrocin using (−)-sparteine as a chirality-creating reagent also has been described.

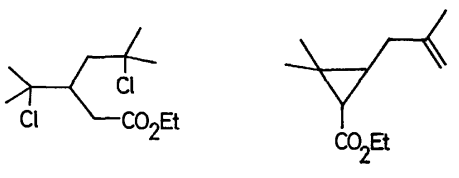
The Michael addition of 2-methyl-1-propenylmagnesium bromide (**6**) to the butenolide **5b** in the presence of CuCl in THF medium afforded α-benzoylpyrocin (**7b**) in 90 % yield. The IR spectrum of **7b** showed strong bands at 1765 and 1685 cm^{-1} due to lactone carbonyl and benzoyl carbonyl, respectively. The NMR spectrum exhibited a multiple splitting doublet at δ 5.03 due to one olefinic proton. α-Acetylpyrocin (**7a**) was obtained similarly from **5a** and **6** in 63% yield.

Deacylation of **7a** and **7b** with ethanolic EtONa at reflux temperature afforded **1** in 65% and 81% yields, respectively. The NMR spectrum of this product was identical with that[5] of the authentic sample. Hirai, *et al.*,[6] have reported a synthesis of optically active pyrocin *via* the asymmetric, catalytic hydrogenation of optically active alcohol esters of 2,2,5,5-tetramethyltetrahydrofurylidene-3-acetic and 2,2,5,5-tetramethyldihydrofuryl-3-acetic acids. We now describe the preparation of optically active **1** by an asymmetric Michael addition of the Grignard reagent **6** to the butenolide **5b**.[7a,7b] The reaction, carried out in the presence of twice molar amount of (−)-sparteine as well as a catalytic amount of CuCl, gave a product of **7b** with $[\alpha]_D^{25}$ +2.43° (ethanol) in 47% synthetic yield. Debenzoylation of this product gave **1** with $[\alpha]_D^{25}$ +1.36° (ethanol), 2.0% optical yield.

Several procedures to transform **1** to the ester **2** have been reported.[1d,2k,8a,8b] They involve the base-catalyzed cyclization of the dichloro ester **9**, which is obtained from **1** by the treatment with $SOCl_2$ in benzene and the subsequent addition of ethanolic HCl. While the isomer **10** is usually produced as an undesirable by-product in these procedures, we are successful to prevent the formation of **10** by using ethyl 3-(1-chloro-1-methylethyl)-5-methyl-4-hexenoate (**8**)[8c] in place of **9** as a starting material. Successive treatments of **1** with large excess of $SOCl_2$ in ethanol, at room temperature for 1 h and then at 60 °C for additional 4 h, yielded the desired ester **8** in 82% yield. The NMR spectrum showed a multiple splitting doublet at δ 4.95 due to one olefinic proton. The treatment of **8** with lithium diisopropylamide in the presence of



Scheme 1.



9 **10**

* Presented in part at the 32nd Annual Meeting of the Chemical Society of Japan, Tokyo, April 1975 and in part at the 5th International Congress of Heterocyclic Chemistry, Ljubljana, Yugoslavia, July 1975.

a catalytic amount of hexamethylphosphoric triamide (HMPT) in THF afforded **2** in 75% yield. Its spectral data (IR, NMR, and MS) were identical with those described in the literatures.[9a,9b] The reaction conducted in ethanolic EtONa gave rise to the cyclization of **8** to pyrocin.

Because of the facile formation of dihydrofuran ring, we failed to obtain the α-acyl derivatives of the chloro ester **8**. The reaction of **7** with $SOCl_2$, carried out in the same manner as **1**, gave only ethyl-2-substituted-4-(2-methyl-1-propenyl)-5,5-dimethyl-4,5-dihydrofuran-3-carboxylate (**12**) in good yields (>82%). Ethylene acetal of α-acetylpyrocin (**13**) also underwent the re-cyclization to produce **12**.

The present work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education (Grant No. 647079).

Experimental

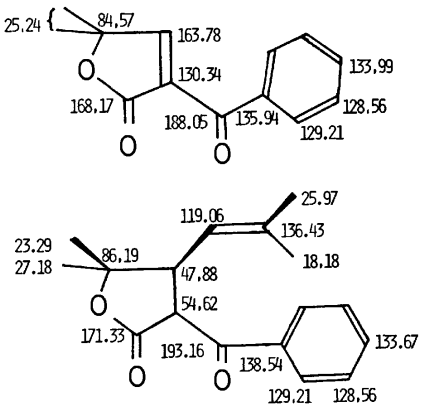
Melting points and boiling points are uncorrected. Elemental analyses were carried out by Mr. Eiichiro Amano of our laboratory. Distillations were evaporative bulb-to-bulb distillations using a Büchi Kugelrohrofen at the pressure and oven temperature indicated. Analytical determination and preparative isolation by GLPC were performed on a Hitachi K-53 model gas chromatograph and a Yanagimoto G-80 model gas chromatograph respectively. IR spectra were determined on a Hitachi EPI-S2 model spectrometer. ^1H NMR spectra were taken at 60 MHz on a Hitachi R-24 model spectrometer using TMS as an internal standard. ^{13}C NMR spectra were taken at 25 MHz on a JEOL FX-100 model spectrometer equipped with FT facilities using TMS as an internal standard and $CDCl_3$ as solvent. The pulse width was 6 μs (45° tip) and the FIDs were compiled by using 8 K data points over a spectral width of 6000 Hz. MS spectra were obtained at 70 eV with a Hitachi RMS-4 model mass spectrometer. Optical rotation was measured with a Yanagimoto OR-50 model polarimeter and the cell path length was 0.1 dm. Analytical and preparative TLC were done on a silica gel PF_{254} (E. Merck AG., Darmst.) with layers of 0.25 mm and 1.0 mm thickness respectively. Column chromatography was done on a silica gel, Wakogel C-200 and C-300 (Wako Junyaku Kogyo Co., Ltd.).

Starting materials such as **5a**, **5b**[3] and 1-bromo-2-methyl-propene[10] were prepared by the procedure described in the literatures.

(±)-α-Benzoylpyrocin (7b). To a refluxing mixture of magnesium turnings (0.98 g, 0.04 g-atom), a few drops of ethyl bromide and trace of iodine in 20 ml of THF, was added isobutenyl bromide (5.40 g, 0.04 mol) dropwise. The mixture was refluxed until magnesium turnings were completely dissolved. After cooling to 0 °C and addition of copper(I) chloride (0.2 g, 0.02 mol), the mixture was stirred for 20 min. To the mixture was added the butenolide **5b** (4.32 g, 0.02 mol) in 20 ml of THF dropwise at 0 °C. After being stirred for 2 h at 0 °C, the mixture was allowed to warm to room temperature. To the resulting mixture was added 10 ml of saturated aqueous NH_4Cl and then it was acidified with 10% HCl. An organic layer was extracted with ether and dried over $MgSO_4$. After removal of the solvent, the residual brown oil was obtained and separated by column chromatograph on a silica gel (30 g of Wakogel C-200, hexane : acetone=10 : 1) to give 4.90 g (90% yield) of **7b**. The analytical sample was obtained by one recrystallization from the mixed solvent of benzene and petroleum ether (1 : 1 in v/v): mp 94—95 °C; IR (KBr) 1767 (lactone C=O), 1683 (benzoyl C=O), 1598, 1579 cm^{-1} (benzene C=C); NMR ($CDCl_3$) δ 1.37 (s, 3H, γ-CH_3), 1.49 (s, 3H, γ-CH_3), 1.70 (t, 6H, J=0.1 Hz, $=\langle^{CH_3}_{CH_3}$), 3.37 (dd, 1H, J=11 Hz and 10 Hz, β-H), 4.55 (d, 1H, J=11 Hz, α-H), 5.03 (md, 1H, J=10 Hz, >-H), 7.23—8.18 (m, 5H, C_6H_5); MS *m/e* (rel. intensity) 272 (M^+), 227 (8.0), 214 (4.0), 186 (6.3), 171 (100), 105 ($C_6H_5CO^+$, 97), 77 (C_6H_5, 62).

Found: C, 75.12; H, 7.41%. Calcd for $C_{17}H_{20}O_3$: C, 74.97, H, 7.40%.

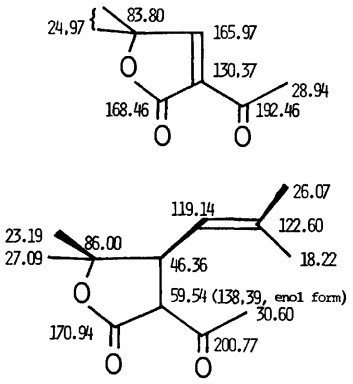
The natural abundance ^{13}C NMR spectra of **5b** and **7b** are summarized in the following structure.



(±)-α-Acetylpyrocin (7a). The mixture of butenolide **5a** (3.08 g, 0.02 mol), 2-methyl-1-propenylmagnesium bromide (0.04 mol), and 0.02 g of copper(I) chloride in 40 ml of THF was reacted and worked up in the same manner as the foregoing experiment to give 2.62 g (63% yield) of **7a**: IR (neat) 1760 (lactone C=O), 1717 (acetyl C=O), 1645 cm^{-1} (C=C); NMR (CCl_4) δ 1.22 (s, 3H, γ-CH_3), 1.38 (s, 3H, γ-CH_3), 1.73 (sharp m, 6H, $=\langle^{CH_3}_{CH_3}$), 2.32 (s, 3H, $COCH_3$), 3.29 (d, 1H, J=16 Hz, α-H), 3.50 (dd, 1H, J=16 Hz and 11 Hz, β-H), 4.83 (m, 1H, >-H); MS *m/e* (rel. intensity) 210 (M^+), 195 ($M-CH_3$, 0.3), 177 (0.4), 167 ($M-COCH_3$), 152 (5), 137 (4), 124 (11), 108 (100).

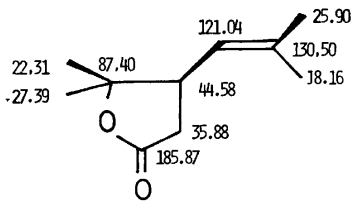
Found: C, 68.66; H, 8.42%. Calcd for $C_{12}H_{18}O_3$: C, 68.55; H, 8.63%.

The natural abundance ^{13}C NMR spectra of **5a** and **7a** are summarized in the following structure. Off-resonance decoupling was used to support the assignments in each case.



(±)-Pyrocin (1) (Debenzoylation of 7b). To a stirried mixture of EtONa (4.76 g, 0.07 mol) in 100 ml of ethanol was added **7b** (3.82 g, 0.014 mol) dissolved in 50 ml of ethanol. The resulting mixture was refluxed for 42 h. After evaporation of ethanol under reduced pressure, the residue was acidified with 10% HCl, and then extracted with ether. The ether extract was washed with aqueous $NaHCO_3$ to remove benzoic acid and dried over $MgSO_4$. After removal of the solvent 2.0 g of crude pyrocin was obtained. The purification by column chromatograph on a silica gel (15 g of Wakogel C-200, hexane : acetone=10 : 1) gave 1.90 g of pyrocin, 81% yield: mp 58—58.5 °C (lit,[4] 59—60 °C); IR (KBr) 1761 cm^{-1} (lactone C=O); NMR (CCl_4) δ 1.20 (s, 3H, γ-CH_3), 1.36 (s, 3H, γ-CH_3), 1.68 (d, 3H, J=0.2 Hz, $\gtrless$-CH_3), 1.75 (d, 3H, J=0.2 Hz, $\gtrless$-CH_3), 1.95—2.45 (m, 2H, α-H_2, ABX), 2.60—3.35 (m, 1H, β-H, ABX), 5.01 (md, 1H, J=10 Hz, $\gtrless$-H).[5]

The natural abundance ^{13}C NMR spectrum of **1** is summarized in the following structure. Off-resonance decoupling was used to support the assignment.



Deacetylation of **7a** (343 mg, 1.63 mmol) with EtONa gave 177 mg of **1**, 65% yield.

Optically Active α-Benzoylpyrocin and Pyrocin. To a stirred solution of 2-methyl-1-propenylmagnesium bromide (10.4 mmol) in 15 ml of THF prepared by the same procedure as **7b**, were added copper(I) chloride (100 mg, 1.0 mmol) and (−)-sparteine (5.0 g, 20.8 mmol) at 0 °C. The mixture was stirred for 1 h at 0 °C. To the mixture, a solution of **5b** (2.25 g, 10.4 mmol) in 15 ml of THF was added slowly. The stirring was continued for 7 h at 0 °C and for additional 12 h at room temperature. The resulting mixture was poured into a saturated aqueous solution of NH_4Cl. It was then acidified with 10% HCl. An organic layer was extracted with ether and dried over $MgSO_4$. After removal of the solvent, 2.77 g of brown oil was obtained. After separation by column chromatograph on a silica gel (40 g of Wakogel C-200, hexane : acetone=10 : 1), 0.98 g of **5b** and 1.36 g of (+)-α-benzoylpyrocin were obtained, 47% synthetic yield. An analytical sample was obtained after one recrystallization from the mixed solvent of benzene and petroleum ether (1 : 1 in v/v): mp 94—95 °C; $[\alpha]_D^{25}$ +2.43° (*c* 4.12 g, ethanol). Its NMR and IR spectra were completely identical with those of **7b**.

(+)-Pyrocin was obtained from this product of (+)-α-benzoylpyrocin in the same manner as described in the foregoing section: $[\alpha]_D^{25}$ +1.36° (*c* 1.21 g, ethanol), optical yield 2%. Its IR and NMR spectra were identical with those of authentic sample of **1**.

Ethyl 3-(1-chloro-1-methylethyl)-5-methyl-4-hexenoate (8). To a stirred solution of **1** (750 mg, 4.46 mmol) in 40 ml of ethanol was added thionyl chloride (3.8 ml, 44.6 mmol) with caution at room temperature. The stirring was continued for 1 h at room temperature and then for additional 4 h at 60 °C. After removal of the solvent and low boiling materials, 1.41 g of dark brown oil was obtained. It was separated by column chromatograph on a silica gel (30 g of Wakogel C-300, hexane) to afford 852 mg of **8**, 82% yield. The analytical sample was obtained by bulb-to-bulb distillation: bp 90 °C (0.06 Torr); IR (neat) 1734 cm^{-1} (C=O); NMR (CCl_4) δ 1.19 (t, 3H, J=7 Hz, ester CH_3), 1.44 (s, 3H, CH_3), 1.53 (s, 3H, CH_3), 1.65 (d, 3H, J=2 Hz, $\gtrless$-CH_3), 1.70 (d, 3H, J=2 Hz, $\gtrless$-CH_3), 1.8—3.2 (m, 3H, α-H_2 and β-H), 3.99 (q, 2H, J=7 Hz, ester CH_2), 4.95 (md, 1H, J=10 Hz, $\gtrless$-H); MS *m/e* (rel. intensity) 196 (M^+−HCl, 20), 181 (6), 155 (42), 109 (100), 123 (32), 77 (75).

Found. C, 62.10; H, 8.88%. Calcd for $C_{12}H_{21}O_2Cl$: C, 61.92; H, 9.10%.

Ethyl (±)-trans-Chrysanthemate (2). To a solution of diisopropylamine (0.39 ml, 3.0 mmol) in 3 ml of THF was added dropwise the solution of butyllithium (3.6 mmol) in 3 ml of ether at 0 °C. After the mixture was stirred for 30 min at 0 °C, 0.25 ml of HMPT was added dropwise. After being stirred for additional 30 min at 0 °C, was added the solution of the chloroester **8** (225 mg, 0.97 mmol) in 2 ml of THF. The mixture was stirred for 40 min at 0 °C and then allowed to react for overnight at room temperature. The resulting mixture was poured into a large exess of 10% HCl and extracted with ether, dried over $MgSO_4$. After removal of the solvent, an yellow oil was obtained. It was separated by column chromatograph on a silica gel (7 g of Wakogel C-200, hexane : acetone=10 : 1) to afford 114 mg of **2**, 75% yield. The analytical sample was obtained by preparative GLPC[11] and identified by comparison of its IR and NMR spectra with those of authentic sample.[9]

Ethyl 2-Methyl-4-(2-methyl-1-propenyl)-5,5-dimethyl-4,5-dihydrofuran-3-carboxylate (12a). To a stirred solution of lactone **7a** (331 mg, 1.58 mmol) in 15 ml of ethanol was added thionyl chloride (1.16 ml, 15.8 mmol) dropwise at room temperature. During the addition a vigorous exothermic reaction occurred. The resulting solution was stirred for 6 h at 70 °C. After removal of the solvent and low boiling materials under reduced pressure, there was obtained a residual dark brown oil. It was separated by column chromatograph on a silica gel (Wakogel C-200, hexane : acetone=10 : 1) to give 308 mg of crude **12a**, 82% yield. The analytical sample was obtained by preparative TLC on a silica gel (hexane : acetone=4 : 1) followed by bulb-to-bulb distillation: bp 110 °C (5 Torr); IR (neat) 1695 (conjugated ester C=O), 1648 cm^{-1} (C=C); NMR (CCl_4) δ 1.17 (t, 3H, J=7 Hz, ester CH_3), 1.17 (s, 3H, 5-CH_3), 1.28 (s, 3H, 5-CH_3), 1.64 (d, 3H, J=1 Hz, $\gtrless$-CH_3), 1.69 (d, 3H, J=1 Hz, $\gtrless$-CH_3), 2.08 (d, 3H, J=0.2 Hz, 2-CH_3), 3.45 (d, 1H, J=10 Hz, 4-H), 4.01 (q, 2H, J=7 Hz, ester CH_2), 4.91 (md, 1H, J=10 Hz, $\gtrless$-H); MS *m/e* (rel. intensity) 238 (M^+), 223 (M−CH_3), 183 (32), 177 (12), 149 (14), 119 (14), 1.0

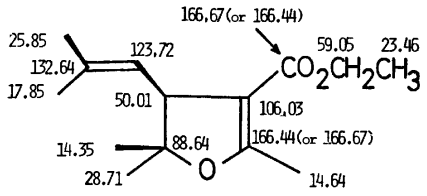
(14), 107 (27), 91 (32), 79 (17), 67 (20), 43 (100).

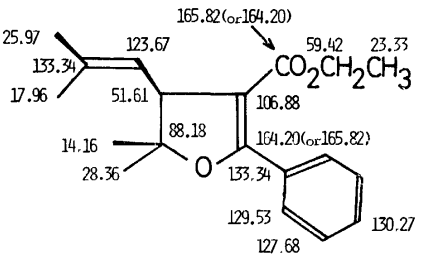
Found: C, 70.77; H, 9.35%. Calcd for $C_{14}H_{20}O_3$: C, 70.56; H, 9.30%.

Ethyl 2-Phenyl-4-(2-methyl-1-propenyl)-5,5-dimethyl-4,5-dihydrofuran-3-carboxylate (**12b**). The reaction of α-benzoylpyrocin (971 mg, 3.57 mmol) with thionyl chloride (3.04 ml, 35.7 mmol) in 20 ml of ethanol was carried out in the same manner as the foregoing experiment to give 940 mg of **12b**, 87% yield. The analytical sample was obtained by preparative TLC on a silica gel (hexane : acetone=4 : 1): IR (neat) 1685—1690 (conjugated ester C=O), 1622 (C=C), 1597—1580 cm^{-1} (phenyl C=C); NMR (CCl_4) δ 1.17 (t, 3H, J=8 Hz, ester CH_3), 1.25 (s, 3H, 5-CH_3), 1.35 (s, 3H, 5-CH_3), 1.68 (d, 3H, J=1 Hz, $\gtrless$-CH_3), 1.70 (d, 3H, J=1 Hz, $\gtrless$-CH_3), 3.66 (d, 1H, J=10 Hz, 4-H), 3.97 (q, 2H, J=8 Hz, ester CH_2), 5.05 (md, 1H, J=10 Hz, $\gtrless$-H), 7.2—7.8 (m, 5H, C_6H_5); MS *m/e* 300 (M^+), 285 ($M-CH_3$), 227 ($M-CO_2Et$).

Found: C, 76.11; H, 8.16%. Calcd for $C_{19}H_{23}O_3$: C, 75.97; H, 8.05%.

The natural abundance ^{13}C NMR spectra of **12a** and **12b** are summarized in the following structures. Off-resonance decoupling was used to support the assignment of **12a**.





2-(1,1-Ethylenedioxyethyl)-3-(2-methyl-1-propenyl)-4,4-dimethyl-4-butanolide (**13**). A mixture of α-acetylpyrocin **7a** (840 mg, 4 mmol), ethylene glycol (248 mg, 4 mmol), and *p*-toluenesulfonic acid (3 mg, 0.02 mmol) in 5 ml of benzene was refluxed for 6.5 h with continuous removing of water as a benzene azeotrope. After cooling, the reaction mixture was washed with saturated aqueous $NaHCO_3$ and brine. An organic layer was separated and dried over $MgSO_4$. The removal of the solvent left 840 mg of the crude acetal **13**, 82% yield. The analytical sample was obtained as a clean oil by column chromatograph on a silica gel (7 g of Wakogel C-200, hexane : acetone=10 : 1): IR (neat) 1766 cm^{-1} (lactone C=O); NMR (CCl_4) δ 1.16 (s, 3H, γ-CH_3), 1.32 (s, 6H, γ-CH_3 and CH_3- ), 1.68 (d, 3H, J=0.1 Hz, $\gtrless$-CH_3), 1.74 (d, 3H, J=0.1 Hz, $\gtrless$-CH_3), 2.68 (d, 1H, J=11 Hz, α-H), 3.04 (dd, 1H, J=11 Hz and 9 Hz, β-H), 3.83 (m, 4H, O-CH_2CH_2-O), 5.06 (md, 1H, J=9 Hz, $\gtrless$-H).

Reaction of 2-(1,1-Ethylenedioxyethyl)-3-(2-methyl-1-propenyl)-4,4-dimethyl-4-butanolide with Thionyl Chloride in Ethanol. To a stirred solution of acetal **13** (372 mg, 1.47 mmol) in 15 ml of ethanol was added thionyl chloride (1.17 ml, 14.7 mmol) slowly at room temperature and allowed to react for additional 3 h at 60 °C. The removal of the solvent and low boiling materials left a dark brown oil. Filtration through a silica gel column (3 g of Wakogel C-200, hexane : acetone=10 : 1) helped to remove dark brown impurities. Evaporation of the solvent yielded 240 mg of an yellow oil. The GLPC analysis of the oil[12] showed two peaks at the retention times of 1.5 and 3.4 min in the ratio of 54 : 46. Each fraction was collected by preparative GLPC. The component with the retention time of 1.5 min was identified as dihydrofuran **12a** (20% yield estimated by GLPC) and the other as **7a**.

These authors have found that (−)-sparteine causes asymmetric Michael addition of organometallic reagents to $\Delta^{\alpha,\beta}$-unsaturated carbonyl compounds. It has been suggested in these literatures that this chiral diamine acts as a bindetate ligand which creates a chiral environment around the metal atom, and this chirality is reflected in the stereochemistry of the addition product. It also has been suggested that the synthetic yield is reduced, due to the formation of bulky and hindered metal complex of **6** and (−)-sparteine.

Substituent Effects on the Photo-ethoxycarbonylation of Monosubstituted Ferrocenes

Takeo AKIYAMA, Taro KITAMURA, Takao KATO, Haruo WATANABE, Toshio SERIZAWA, and Akira SUGIMORI

Department of Chemistry, Faculty of Science and Technology, Sophia University, Kioi-cho 7, Chiyoda-ku, Tokyo 102

(Received March 17, 1976)

The effect of the substituent in the ferrocene nucleus on the photo-ethoxycarbonylation of monosubstituted ferrocene in carbon tetrachloride–ethanol solution is described. The electron withdrawing substituents, such as chloro, bromo, iodo, cyano, and acetyl, retarded the photo-ethyoxycarbonylation, whereas the electron releasing substituents, such as ethyl accelerated the reaction. The electronic effects which affect the formation of the charge transfer complex and those which affect the reactivity of the cyclopentadienyl ring toward the attack of a trichloromethyl radical can be considered for the photo-ethoxycarbonylation.

In the previous paper,[1a] we reported the photochemical introduction of ethoxycarbonyl, formyl, and ethoxymethyl into the ferrocene nucleus in carbon tetrachloride–, chloroform–, and dichloromethane–ethanol solutions. In the photo-ethoxycarbonylation of ferrocene in the carbon tetrachloride–ethanol system, the excitation of the charge transfer complex of ferrocene with carbon tetrachloride plays an important role in the initial stage of the photo-substitution.[1b] This paper deals with the effect of the substituent in the ferrocene nucleus upon the photo-ethoxycarbonylation of monosubstituted ferrocene in carbon tetrachloride–ethanol solutions.

Experimental

Materials. Ethylferrocene[2] [bp 92 °C/1 Torr, (lit,[3] 93—94 °C/1 Torr)], acetylferrocene[4] [mp 85—86.5 °C(lit,[4] 85—86 °C)], iodoferrocene[5] [mp 48—49 °C (lit,[5] 43—45 °C)], chloroferrocene[6] [mp 59 °C(lit,[7] 59—60 °C)], bromoferrocene[6] [mp 36.1—36.2 °C(lit,[6] 30—31 °C)], cyanoferrocene[6] [mp 103.5 °C(lit,[8] 107—108 °C)], methoxyferrocene[7] [mp 41.5—41.8 °C(lit,[7] 38.5—40 °C)], and phenylferrocene[9] [mp 114 °C(lit,[9] 114—5 °C)] were prepared from ferrocene(Wako Junyaku Co., G. R. grade reagent) by the method given in the literatures. Carbon tetrachloride and ethanol were purified by the method described in the previous paper.[1a]

Irradiation Procedure. General procedure is similar to that described previously.[1a]

Separation of the Photoproducts (General Procedure). After irradiation, the reaction mixture was washed successively with water, aqueous sodium hydrogencarbonate solution and aqueous sodium thiosulfate solution, and then extracted with dichloromethane or ether. The extract was dried over anhydrous sodium sulfate, then the solvent was removed by a rotary evaporator below 30 °C. The residue was subjected to thin layer(Merck, GF-254) or column(Wako Junyaku Co., Wakogel C-200) chromatography in order to separate the photoproducts and the starting material, and then the ethoxycarbonylated compounds were isolated by the second thin layer chromatography(TLC).

Identification of the Photoproducts. The assignments of the chemical shifts of 2-, 3-, 4-, and 5-position were done based on the calculated chemical shifts of those positions. The calculated chemical shifts were obtained by summing the deshielding or the shielding effect of the substituent and the deshielding effect of ethoxycarbonyl to α- and β-positions.[10] The experimentally obtained chemical shifts agreed generally with the calculated ones.

Ethyl 2-Ethylferrocenecarboxylate: A dark red liquid substance. NMR(CCl_4), δ(ppm from TMS) 4.60(t), 1H(H_5); 4.26—4.09, 2H(H_3 and H_4); 4.20(q), 2H(–CH_2– of ester); 4.0(s), 5H(C_5H_5); 2.45—2.93(m), 2H(–CH_2– of ethyl[11,12]); 1.34(t), 3H(–CH_3 of ester); 1.13(t), 3H(–CH_3 of ethyl). IR (direct), 3100, 2960, 2920, 1100, 1000, 920 cm^{-1} (2-substituted ethylferrocene), 1705, 1290 cm^{-1} (ester). MS(70 eV), *m/e*, 286(M^+). Found: C, 62.13; H, 6.35%. Calcd for $C_{15}H_{18}O_2Fe$: C, 62.94; H, 6.29%, Mol wt, 286.

Ethyl 3-Ethylferrocenecarboxylate: A dark red oily substance. NMR(CCl_4), δ(ppm from TMS) 4.62(t), 2H(H_2 and H_5); 4.26—4.2(q and t), 3H(–CH_2– of ester and H_4); 4.05(s), 5H(C_5H_5); 2.35(q), 2H(–CH_2– of ethyl); 1.32(t), 3H(–CH_3 of ester); 1.19(t), 3H(–CH_3 of ethyl). IR(direct), 3100, 2960, 2920, 1100, 1000, 930, 910 cm^{-1} (3-substituted ethylferrocene), 1705, 1285 cm^{-1}(ester). MS(70 eV), *m/e*, 286(M^+). Found: C, 62.29; H, 6.45%. Calcd for $C_{15}H_{18}O_2Fe$: C, 62.94; H, 6.29%, Mol wt, 286.

Ethyl 1'-Ethylferrocenecarboxylate: A red oily substance. NMR(CCl_4), δ(ppm from TMS) 4.61(t), 2H(H_2 and H_5); 4.24—4.15, 4H(H_3 and H_4, and –CH_2– of ester); 3.98(s), 4H($H_{2'}$, $H_{3'}$, $H_{4'}$, $H_{5'}$); 2.30(q), 2H(–CH_2– of ethyl); 1.32(t), 3H(–CH_3 of ester); 1.12(t), 3H(–CH_3 of ethyl). IR(direct), 3080, 2960, 2920, 900, 890 cm^{-1} (the absence of absorption at 9 and 10 μ indicates 1,1'-disubstituted ferrocene), 1710, 1270 cm^{-1} (ester). MS(70 eV), *m/e*, 286(M^+). Found: C, 62.67; H, 6.60%. Calcd for $C_{15}H_{18}O_2Fe$: C, 62.94; H, 6.60%, Mol wt, 286.

Ethyl 3-Phenylferrocenecarboxylate: A yellow orange solid. NMR(CCl_4), δ(ppm from TMS) 7.50—7.05(m), 5H(–C_6H_5); 5.18(t), 1H(H_2); 4.83(t), 1H(H_5); 4.74(t), 1H(H_4); 4.24(q), 2H(–CH_2– of ester); 4.01(s,) 5H(C_5H_5); 1.36(t), 3H(–CH_3 of ester). IR(KBr), 3100, 3050, 1600, 1100, 1000, 925, 890 cm^{-1} (3-substituted phenylferrocene), 1705, 1240 cm^{-1} (ester). MS (70 eV), *m/e*, 334(M^+). Found: C, 68.27; H, 5.36%. Calcd for $C_{19}H_{18}O_2Fe$: C, 68.26; H, 5.39%, Mol wt, 334.

Ethyl 2-Phenylferrocenecarboxylate: A yellow oily substance. IR(KBr), 3100, 3050, 1600, 1105, 997, 950 cm^{-1} (2-substituted phenylferrocene), 1705, 1240 cm^{-1} (ester). MS(70 eV), *m/e*, 334(M^+). Found: C, 68.77; H, 5.44%. Calcd for $C_{19}H_{18}O_2Fe$: C, 68.26; H, 5.39%, Mol wt, 334.

Ethyl 1'-Phenylferrocenecarboxylate: A yellow orange solid. NMR(CCl_4), δ(ppm from TMS) 7.5—7.1(m), 5H(–C_6H_5); 4.55(t), 4H($H_{2'}$, $H_{5'}$ and H_2, H_5); 4.25(t), 2H(H_3 and H_4); 4.14(t), 2H($H_{3'}$ and $H_{4'}$); 4.01(q), 2H(–CH_2– of ester); 1.26 (t), 3H(–CH_3 of ester). IR(KBr), 3090, 3050, 1600, 920, 880 cm^{-1} (1'-substituted phenylferrocene), 1685, 1280 cm^{-1} (ester). MS(70 eV), *m/e*, 334(M^+). Found: C, 68.14; H, 5.38%. Calcd for $C_{19}H_{18}O_2Fe$: C, 68.26; H, 5.39%, Mol wt, 334.

Ethyl p-*Ferrocenylbenzoate*: A yellow orange solid substance. NMR(CCl_4), δ(ppm from TMS) 7.95—7.35(q), 4H (1,4-disubstituted benzene); 4.16(t), 2H(H_2 and H_5); 4.28(t), 2H(H_3 and H_4); 4.35(q), 2H(-CH_2- of ester); 3.96(s), 5H(C_5H_5); 1.38(t), 3H(-CH_3 of ester). IR(KBr), 3070, 3040, 1610, 1100, 1000 cm^{-1} (phenylferrocene), 1705, 1235 cm^{-1}(ester). Found: C, 68.00; H, 5.39%. Calcd for $C_{19}H_{18}O_2Fe$: C, 68.26; H, 5.39%.

Ethyl 3-Methoxyferrocenecarboxylate: A yellow liquid substance. NMR(CCl_4), δ(ppm from TMS) 4.58(t), 1H(H_2); 4.45(q), 1H(H_5); 4.23(q), 1H(H_4); 4.19(q), 2H(-CH_2- of ester); 4.10(s), 5H(C_5H_5); 3.60(s), 3H(-OCH_3); 1.32(t), 3H (-CH_3 of ester). IR(KBr), 3100, 2960, 2920, 2860, 1100, 1000(sh), 940, 920 cm^{-1} (3-substituted methoxyferrocene), 1700, 1300 cm^{-1} (ester). MS(70 eV), *m/e*, 288(M^+). Found: C, 57.71; H, 5.51%. Calcd for $C_{14}H_{16}O_3Fe$: C, 58.38; H, 5.55%, Mol wt, 288.

Ethyl 1'-Methoxyferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.71(t), 2H(H_2 and H_5); 4.26(t), 2H(H_3 and H_4); 4.19(q), 2H(-CH_2- of ester); 3.97 (t), 2H(H_2' and H_5'); 3,74(t), 2H(H_3' and H_4'); 3.55 (s), 3H(-OCH_3), 1.33(t), 3H(-CH_3 of ester). IR(KBr), 3100, 2960, 2920, 2860, 1100, 920, 865 cm^{-1} (1'-substituted methoxyferrocene), 1710, 1280 cm^{-1} (ester). MS (70 eV), *m/e*, 288(M^+).

Ethyl 2-Chloroferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.68(t), 1H(H_5); 4.32—4.16, 4H(H_3 and H_4, and -CH_2- of ester); 4.10(s), 5H(C_5H_5); 1.33(t), 3H(-CH_3 of ester). IR(KBr), 3100, 3020, 1100, 1000, 915 cm^{-1} (2-substituted chloroferrocene), 1710, 1280 cm^{-1} (ester). MS(70 eV), *m/e*, 292(M^+).

Ethyl 3-Chloroferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.97(t), 1H(H_2); 4.65(t), 1H(H_5); 4.54(*t*), 1H(H_4); 4.21(q), 2H(-CH_2- of ester); 4.23(s), 5H(C_5H_5); 1.31(t), 3H(-CH_3 of ester). IR(KBr), 3100, 1100, 1000, 905, 900 cm^{-1} (3-substituted chloroferrocence), 1710, 1280 cm^{-1} (ester). MS(70 eV), *m/e*, 292(M^+).

Ethyl 1'-Chloroferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.77(t), 2H(H_2 and H_5); 4.35(t), 4H(H_2', H_5', and H_3, H_4); 4.24(q), 2H(-CH_2- of ester); 4.03(t), 2H(H_3' and H_4'); 1.35(t), 3H(-CH_3 of ester). IR(KBr), 3120, 1090, 915, 880 cm^{-1} (1'-substituted chloroferrocene), 1710, 1280 cm^{-1}(ester). MS(70 eV), *m/e*, 292(M^+).

Ethyl 2-Bromoferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.63(t), 1H(H_5); 4.30—4.15, 4H(H_3, H_4, and -CH_2- of ester); 4.11(s), 5H(C_5H_5); 1.32(t), 3H(-CH_3 of ester). IR(KBr), 3100, 1095, 1000, 905 cm^{-1} (2-substituted bromoferrocene), 1700, 1265 cm^{-1} (ester). MS(70 eV), *m/e*, 337(M^+).

Ethyl 3-Bromoferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.97(t), 1H(H_2); 4.67(t), 1H(H_5); 4.53(t), 1H(H_4); 4.20(s), 5H(C_5H_5); 4.30—4.15(q), 2H(-CH_2- of ester); 1.31(t), 3H(-CH_3 of ester). IR(KBr), 3110, 1100, 1000, 875 cm^{-1} (3-substituted bromoferrocene), 1700, 1275 cm^{-1} (ester). MS(70 eV), *m/e*, 337(M^+).

Ethyl 1'-Bromoferrocenecarboxylate: A yellow oily substance. NMR(CCl_4), δ(ppm from TMS) 4.73(t), 2H(H_2 and H_5); 4.35(t), 4H(H_2', H_5', and H_3, H_4); 4.23(q), 2H(-CH_2- of ester); 4.07(t), 2H(H_3' and H_4'); 1.38(t), 3H(-CH_3 of ester). IR(KBr), 3100, 910, 865 cm^{-1} (1'-substituted bromoferrocene), 1705, 1270 cm^{-1} (ester). MS(70 eV), *m/e*, 337(M^+).

Ethyl 2-Iodoferrocenecarboxylate: An orange red oily substance. NMR(CCl_4), δ(ppm from TMS) 4.68(t), 2H(H_3 and H_5); 4.24(t), 1H(H_4); 4.23(q), 2H(-CH_2- of ester); 1.33(t), 3H(-CH_3 of ester). IR(KBr), 3060, 1100, 1000(sh), 960, 930(sh) cm^{-1} (2-substituted iodoferrocene), 1700, 1270 cm^{-1} (ester). MS(70 eV), *m/e*, 384(M^+).

Ethyl 3-Iodoferrocenecarboxylate: An orange red oily substance. NMR(CCl_4), δ(ppm from TMS) 4.98(t), 1H(H_2); 4.68 (t), 1H(H_5); 4.52(t), 1H(H_4); 4.19(q), 2H(-CH_2- of ester); 4.12(s), 5H(C_5H_5); 1.24(t), 3H(-CH_3 of ester). IR(KBr), 3080, 1100, 990, 915, 860 cm^{-1} (3-substituted iodoferrocene), 1710, 1265 cm^{-1} (ester). MS(70 eV), *m/e*, 384(M^+).

Ethyl 1'-Iodoferrocenecarboxylate: An orange red oliy substance. NMR(CCl_4), δ(ppm from TMS) 4.70(t), 2H(H_2 and H_5); 4.34(t), 2H(H_3 and H_4); 4.27(t), 2H(H_2' and H_5'); 4.22(q), 2H(-CH_2- of ester); 4.12(t), 2H(H_3' and H_4'); 1.31 (t), 3H(-CH_3 of ester). IR(KBr), 3100, 905, 860 cm^{-1} (1'-substituted iodoferrocene), 1700, 1270 cm^{-1} (ester). MS(70 eV), *m/e*, 384(M^+).

Quantitative Analysis: For the photoreaction of phenyl- and haloferrocenes, quantitative analyses were carried out with GLPC(carbowax 20 M, 2 m glass column, column temperature: 170 °C for phenylferrocene and 202—230 °C for haloferrocenes. Ethyl ferrocenecarboxylate was used as an internal standard). For other monosubstituted ferrocenes, quantitative analyses were carried out by gravimetry, after the isolation of the photoproducts by column or thin layer chromatography.

Measurements: UV-spectra were recorded on a Hitachi 124 UV-VS spectrophotometer. IR-spectra were recorded on a Hitachi 215 grating infrared spectrophotometer. NMR spectra were taken with a Hitachi R-22(90 MHz) spectrometer. Mass spectra were recorded on a Hitachi RMU-6 spectrometer. Gas chromatography were performed on a Yanagimoto 550F gas chromatograph equipped with glass column.

Results and Discussion

On the irradiation with 365 nm light, ethyl-, methoxy-, phenyl-, and bromoferrocene in carbon tetrachloride–ethanol (1 : 1, v/v) solutions afforded the corresponding ethoxycarbonylated products, whereas chloro- and iodoferrocene gave only a small amount of ethoxycarbonylated products. No ethoxycarbonylation occurred in the case of cyano- and acetylferrocene. The yields of ethoxycarbonylated products and the yields of isomers are listed in Tables 1 and 2.

Ethylferrocene was effectively ethoxycarbonylated on the irradiation with 365 nm light. Ethyl 2-ethylfer-

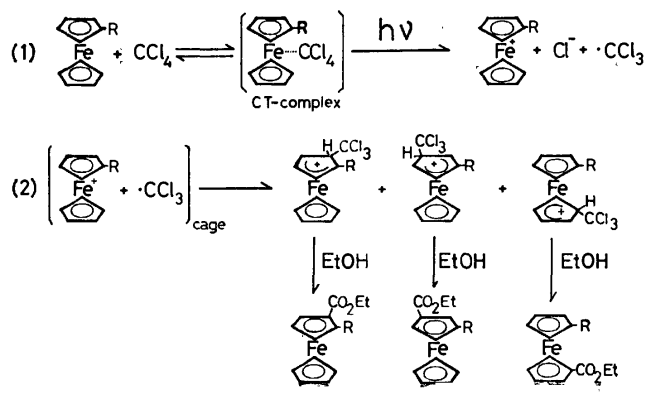
rocenecarboxylate, ethyl 3-ethylferrocenecarboxylate, and ethyl 1'-ethylferrocenecarboxylate were obtained. In phenylferrocene, ethoxycarbonylation occurred not only on the ferrocene ring but also on the *para*-position of the benzene ring. In spite of the high conversion of methoxyferrocene, the yield of ethoxycarbonylated product is low. Among the haloferrocenes, bromoferrocene was most effectively ethoxycarbonylated on the irradiation with 365 nm light, and 1,2- and 1,3-isomer were obtained in addition to 1,1'-isomer. Although the yields were lower, both 1,2- and 1,3-isomer were obtained in the case of iodoferrocene. The 2-position of chloroferrocene was less effectively ethoxycarbonylated than the same position of other haloferrocenes. No ethoxycarbonylation occurred in acetyl- and cyanoferrocene on the irradiation with 365 nm light, and only decomposition of the starting materials was observed. The results listed in Table 1 indicate that the reactivities of the monosubstituted ferrocenes toward photo-ethoxycarbonylation seem to be determined primarily by the electronic character of the substituent. Based on the proposed mechanism of photo-ethoxycarbonylation of ferrocene,[1b)] the effects of the substituent on the photo-ethoxycarbonylation can be considered in the following two separate cases:

(1) The effect of the substituent on the formation of the charge transfer complex of monosubstituted ferrocene with carbon tetrachloride.

(2) The effect of the substituent on the reactivity



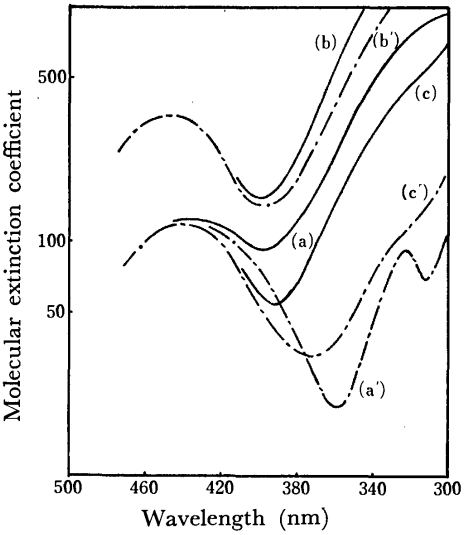


Fig. 1. UV-Spectra of ethylferrocene(2×10^{-3} mol l^{-1}), phenylferrocene(2×10^{-3} mol l^{-1}), and methoxyferrocene (2×10^{-3} mol l^{-1}) in ethanol and in carbon tetrachloride–ethanol(1 : 1, v/v) solutions. of the cyclopentadienyl ring of ferrocene toward the attack of a trichloromethyl radical.

The contribution of the charge transfer complex to this photo-substitution was examined by the analyses of UV-spectra. The UV-spectra of monosubstituted ferrocenes in ethanol solutions and in carbon tetrachloride–ethanol(1 : 1, v/v) solutions are shown in Figs. 1, 2, and 3. The UV-spectra of methoxy-, ethyl-, phenyl-, chloro-, bromo-, and iodoferrocene in carbon tetrachloride–ethanol solutions show an increment of absorption compared with those in ethanol solutions in 300—360 nm region, whereas only slight enhancements of absorption were observed in the cases of acetyl- and cyanoferrocene. The increment of absorption in this region can be ascribed to the formation of a charge

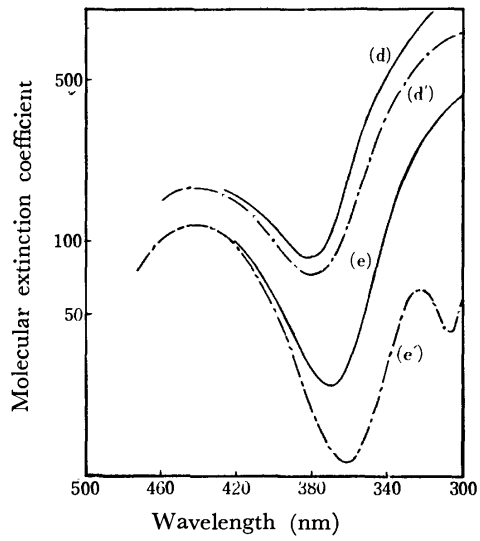

Fig. 2. UV-Spectra of iodoferrocene(2×10^{-3} mol l^{-1}), and chloroferrocene(2×10^{-3} mol l^{-1}) in ethanol and in carbon tetrachloride-ethanol(1 : 1, v/v) solutions. transfer complex between monosubstituted ferrocene and carbon tetrachloride. The increment of absorption, $\Delta\varepsilon$ (expressed in terms of the increase in apparent molar extinction coefficient, therefore, $\Delta\varepsilon=\varepsilon_{app.}-\varepsilon$) at 300 nm for monosubstituted ferrocenes, was used as a measure of the ability of charge transfer complex formation of monosubstituted ferrocene. Ferrocenes with an electron releasing substituent, such as ethyl and methoxyl, gave higher $\Delta\varepsilon_{300}$ values, whereas those with an electron withdrawing substituent gave lower values

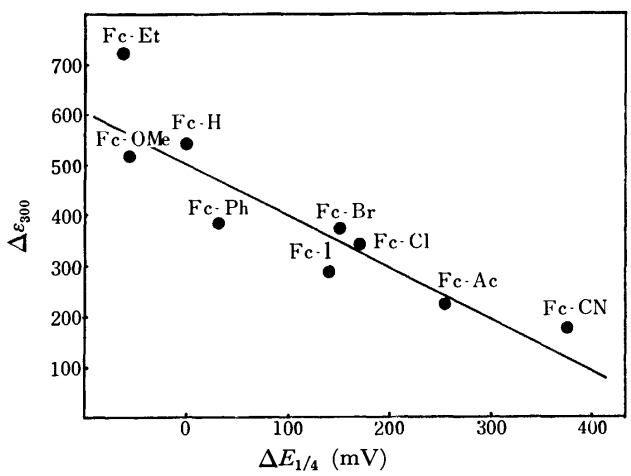

Fig. 4. Plot of the increment of UV-absorption at 300 nm against the oxidation potential, $\Delta E_{1/4}$.

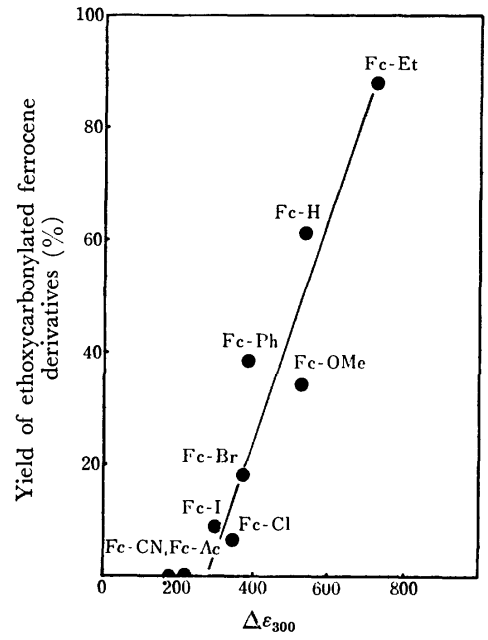

Fig. 5. Plot of the yield of ethoxycarbonylated ferrocene derivative against the increment of UV-absorption at 300 nm.

than ferrocene. These values and the oxidation potentials $\Delta E_{1/4}$(the difference of the chronopotentiometric quarter wave oxidation potentials of substituted ferrocene from that of ferrocene)[13] show a good correlation(Fig. 4). The yields of ethoxycarbonylated products of monosubstituted ferrocenes can also be correlated to $\Delta\varepsilon_{300}$(Fig. 5). These results indicate that the excitation of the charge transfer complex of monosubstituted ferrocene and carbon tetrachloride contribute greatly to the photo-ethoxycarbonylation, as in the case of ferrocene.[1b]

Because of the electrophillic nature of the trichloromethyl radical, the site reactivities of monosubstituted ferrocenes for photo-ethoxycarbonylation can be compared with those for Friedel Crafts' acetylation, which have been extensively investigated by many workers.[14] The site reactivities of monosubstituted ferrocenes for

a) The values in parentheses are the site reactivities for Friedel Crafts' acetylation taken from references.[14)] The reactivity of unsubstituted ring (1′-position) is taken as 1.00. b) Fc- denotes $(C_5H_5)Fe(C_5H_4-)$.

photo-ethoxycarbonylation and those for acetylation are shown in Table 3.

In the case of ethylferrocene, the reactivities of 2- and 3-position for photo-ethoxycarbonylation are lower than those for acetylation, but the relative reactivities of 2-position to 3-position are similar to that of acetylation. The lower reactivity of 2-position than those of 3- and 1′-position indicates that the steric effect is also important in the substitution. In the case of methoxyferrocene, an extremely low reactivity of 2-position can not be explained only by a steric effect, since this position is one and a half times more reactive than 3-position for the electrophillic substitution.[14a)] In the case of phenylferrocene, the reactivities of 2- and 3-position seem to be quite different from those for acetylation; although the higher reactivity of 3-position than 2-position for ethoxycarbonylation can be explained by a steric repulsion of a large phenyl group and a bulky trichloromethyl radical, the value 1.44 for 3-position is very high compared to 0.4 for 3-position in acetylation. In the cases of haloferrocenes, this tendency is more obvious; although the homoannular substitution is completely inhibited in acetylation even under drastic conditions,[15)] homoannular substitution occurred with nearly the same efficiency as heteroannular substitution in the photo-ethoxycarbonylation. These results indicate that the electrophilicity of the trichloromethyl radical is not so high as to be affected by the electronic nature of the substituents. Therefore, the low yields of ethoxycarbonylated products for haloferrocenes may be due mainly to the efficiency of the formation of the charge transfer complex between monosubstituted ferrocene and carbon tetrachloride.

The authors wish to express their thanks to Mr. Tatsuzo Ishigami of Aoyama Gakuin University for the measurement of mass spectra. The present work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education.

ESR Studies of Nitrogen-centered Free Radicals, *N*-Aryl-*N*-phenylthioaminyls[1)]

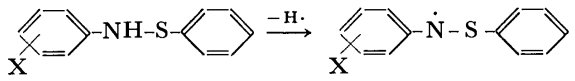
Yozo MIURA and Masayoshi KINOSHITA

Department of Applied Chemistry, Faculty of Engineering, Osaka City University, Sumiyoshi-ku, Osaka 558

(Received September 21, 1976)

A variety of substituted *N*-phenyl-*N*-phenylthioaminyls (**2**), Ar–N̈–S–Ar′, were generated by the photolysis of benzenesulfenanilides (**1**) in benzene in the presence of di-*t*-butyl peroxide or by the oxidation of **1** in benzene with lead dioxide. The ESR spectra of the radicals were completely analyzed by labeling some radicals with deuterium and with the aid of a computer simulation technique. The unpaired electron is distributed mainly on the nitrogen atom and the *N*-phenyl ring. The values of a_N were plotted against the σ or σ^- in the Hammett equation, and it was found that **2**, in terms of Walter's criteria, belong to class S.

A number of nitrogen-centered free radicals have been prepared, and extensive ESR spectroscopic studies have been undertaken.[2)] In the course of our studies of nitrogen-centered free radicals bearing sulfur atoms adjacent to the radical centers, *N*-aryl-*N*-phenylthioaminyls (**2**) have been found to be easily generated by hydrogen-abstraction from benzenesulfenanilides (**1**). The radicals possess a divalent sulfur atom adjacent to the radical center and have never been reported to be detected unambiguously.[3)] A few radicals relating to **2** have thus far been reported, but no systematic ESR spectroscopic investigation of the radicals has yet been undertaken.[4–7)] More recently, however, Ingold *et al.* have reported a detailed ESR spectroscopic investigation of radicals which are generated by radical additions to di-*t*-butyl sulfur diimide.[8)]



1 **2**

The present authors have now generated a variety of substituted *N*-aryl-*N*-phenylthioaminyls (**2**) and investigated them in detail by means of ESR spectroscopy. In the present report, the results will be described and discussed.

Results and Discussion

The generation of **2** was performed by two procedures: a) the photolysis of **1** in degassed benzene in the presence of di-*t*-butyl peroxide, and b) the oxidation of **1** in degassed benzene with lead dioxide and potassium carbonate. In the present studies, procedure a has been mainly employed, because that the procedure is more convenient and, although a low-power mercury lamp (100 W) was used as the source, the procedure generated **2** at a sufficient concentration for us to record well-resolved ESR spectra (10^{-5} mol/l except for **2a** and **2c**, the concentrations of which were lower). The radicals **2a** and **2c**, after irradiation for 10 min, immediately decayed on the turning out of the lamp. On the other hand, the radicals **2f** and **2m** could be detected over a period of more than 1 h, and the radicals **2d** and **2g** over a period of at least 2 h.

The radical **2a** presented a very complex ESR spectrum (Fig. 1). In order to facilitate the analysis of the spectrum and to avoid erroneous assignments, the

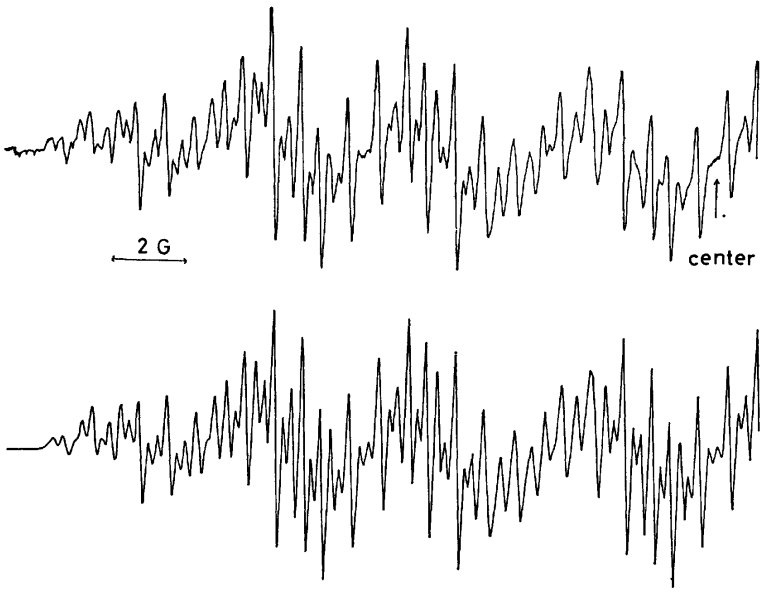


Fig. 1. Experimental ESR spectrum (low-field half) of *N*-phenyl-*N*-phenylthioaminyl (**2a**) in benzene (upper), and computer simulated, using Lorentzian line shapes and a line width of 0.20 G (lower).

radical was labeled with deuterium. The labeled radical, **2b**, gave a simple 1 : 1 : 1 triplet spectrum, which was obviously split by the interaction with the nitrogen nucleus. On the other hand, the spectrum of the other labeled radical, **2c**, was split into a 1 : 1 : 1 triplet due to the nitrogen nucleus, and each component of the triplet was split into 1 : 2 : 1 triplets of a 1 : 3 : 3 : 1 quartet due to the three equivalent *ortho*- and *para*-protons and the two *meta*-protons respectively. On the basis of these results, the spectrum of **2a** was analyzed.

Next, substituted *N*-phenyl-*N*-phenylthioaminyls were generated and the spectra were analyzed. The radicals **2f**—**h** each gave a relatively simple ESR spectrum (Fig. 2). On the other hand, the spectra of the other radicals were very complex (Figs. 3 and 4). Thus, some radicals were also labeled with deuterium, and the complex spectra were analyzed on the basis of the data from the labeled radicals. The ESR parameters for **2** are summarized in Table.

In general, it is well known that nitrogen-centered free radicals tend to convert into the corresonding ni-

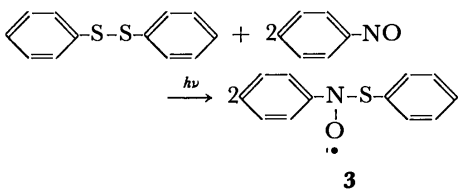
troxide radicals by reactions with oxidizing agents (*e. g.* atmospheric oxygen, *etc.*). In order to exclude this possibility, the corresponding nitroxide radical, **3**, was generated by the photolysis of diphenyl disulfide in benzene in the presence of nitrosobenzene (Fig. 5). The ESR parameters for **3** are 11.52 (a_N), 2.56 ($a_{o\text{-}H}$ and $a_{p\text{-}H}$), and 0.86 G ($a_{m\text{-}H}$).[9] From the results, it is clear that the radicals **2** are not nitroxide radicals.



3

The radicals **2** can also be generated by the treatment of **1** with lead dioxide and potassium carbonate. For example, the sulfenamide **1d** in benzene, on contact

a) In benzene at room temperature. b) The coupling constants were determined by means of the computer simulation technique.

with the oxidizing agents under degassed conditions, instantly turned dark blue. The color remained for *ca.* 10 s, after which, it slowly turned brown. The blue color seems to be responsible for **2d**,[10] while the brown color is probably attributable to decomposition products of **2d**. Similar blue solutions were also obtained in the cases of **1e**, **1f**, and **1m**. On the other hand, in **1j**, a greenish blue solution, and in **1g** and **1m**, green solutions were obtained. These colors immediately turned brown (except for **1g**, and in this case, the green color remained for *ca.* 20 min). From the brown solutions, however, only **2** was detected as a paramagnetic species by ESR spectroscopic measurements.

From the values of the coupling constants shown in the table, it may be concluded that, in **2**, the unpaired electron is distributed mainly on the nitrogen ($2p_z$ orbital) and the *N*-phenyl ring. On the other hand, it is of interest that couplings due to the *S*-phenyl ring protons are observed, indicating that the unpaired electron is also delocalized onto the *S*-phenyl ring across the divalent sulfur atom, though the degree of delocalization is small.

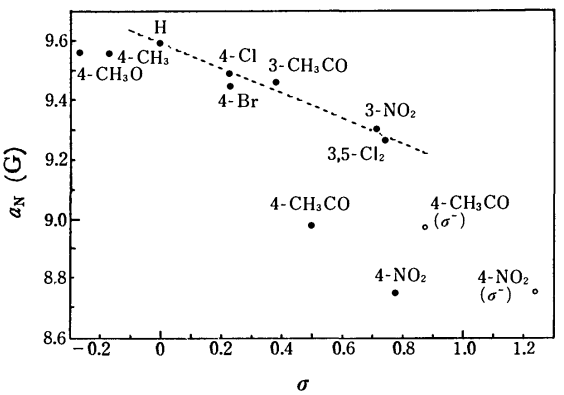

Fig. 6. Plot of nitrogen coupling constants (a_N) of *N*-aryl-*N*-phenylthioaminyls (**2**) *vs.* σ (and σ^-).

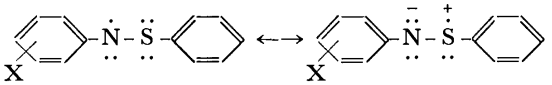
The values of a_N were plotted against the Hammett σ and σ^- parameters (Fig. 6).[11] In terms of Walter's criteria,[12] substituted aryl nitroxide radicals and nitrobenzene anion radicals[11] belong to class O, while *N*-alkyl-*N*-arylamino radicals have been reported to belong to class S.[13] As may be found in the figure, the values of a_N are correlated by neither σ nor σ^-,[14,15] indicating that **2** belong to class S. In the present radicals, the values of a_N seem to be decreased by two effects:[16] the delocalization of spin onto the substituents and the polar effect to be described below (Form B), as has been pointed out by Danen *at al.* in the case of *N*-alkoxy-*N*-arylamino radicals.[13]



Form A Form B

About the polar effect, as more powerful electron-withdrawing substituents are introduced into the *N*-phenyl ring, the polar form B becomes more important. Therefore, the effect results in a decrease in the spin density on the nitrogen atom, while, on the contrary, that on the sulfur atom is increased. The degree of the effect may reflect the magnitude of coupling due to the *S*-phenyl ring protons. As can be seen in the table, the introduction of electron-withdrawing groups brings about an increase in the magnitude of the proton coupling constants. Although the difference in the magnitude of the coupling constants of the *para* protons in the *S*-phenyl ring is small, we attempted to plot the values against σ (and σ^-), the values being correlated by σ (and σ^-).

In the cases of non- and *meta*-substituted radicals (**2a**, **2g**, **2k**, and **2n**), only the polar effect is important because, as the spin density at the *meta* position is

considerably smaller than those at the *ortho* and *para* positions, the delocalization of the spin onto the substituents is negligibly small. About the four free radicals, the values of a_N are well correlated by σ, as may be found in the figure. In the cases of the other free radicals, on the other hand, the two effects are operative and the values of a_N are significantly decreased. Therefore, the values of a_N are correlated by neither σ nor σ^-.

Experimental

All the melting points are uncorrected. The IR spectra were run on a Jasco Model IR-G Spectrometer. The NMR spectra were recorded on a Hitachi-Perkin Elmer R-20 Spectrometer, using TMS as the internal standard. The elemental analyses were carried out with a Yanaco MT-2 CHN Corder.

Meterials. The benzene used for the ESR measurement was purified by the usual method.[1] Commercially available di-*t*-butyl peroxide was used without further purification, while nitrosobenzene was recrystallized once from ethanol just before use.

Benzenethiol-2,3,4,5,6-d_5. Aniline-2,3,4,5,6-d_5 (*D*-content; 99%, E. Merck, Darmstadt, Germany) was diazotized and treated with potassium xanthate.[17] The resulting xanthate ester was hydrolyzed with potassium hydroxide in ethanol, and then neutralized with sulfuric acid and water-distilled. The resulting oily product was extracted with ether and dried over anhydrous sodium sulfate. After filtration, ether was evaporated and the product was distilled (82—83 °C/55 Torr) to give the desired benzenethiol in a 53% yield. The *D*-content was determined to be 98% from the proton ratio in the NMR spectrum.

*General Procedure for the Preparation of Benzenesulfenanilides (**1**).* Benzenethiol was allowed to react with chlorine gas in dry chloroform at −5—0 °C. After the subsequent removal of chloroform, the resulting oily residue was distilled (56—57 °C/3 Torr) to give pure benzenesulfenyl chloride.[1] However, benzenesulfenyl chloride-d_5 was used for the following step without distillation.

Benzenesulfenyl chloride (0.025 mol) in dry ether (25 ml) was added, drop by drop, to aniline (0.055 mol) in dry ether (100—1000 ml) at −20——30 °C under stirring. After the completion of the addition, the reaction mixture was stirred for an additional 30 min and the reaction temperature was raised to room temperature. After the formed aniline hydrochloride had been filtered off, ether was evaporated to give crude **1**, which was treated with decoloring carbon and repeatedly recrystallized from the appropriate solvents.

Benzenesulfenanilide (**1a**): 54—56 °C (petroleum ether, lit,[18] 53—55 °C). 4'-Methylbenzenesulfenanilide (**1d**): 51—52 °C (petroleum ether, lit,[19] 52 °C). 4'-Methoxybenzenesulfenanilide (**1e**): 69—70 °C (hexane, lit,[19] 67 °C). 4'-Nitrobenzenesulfenanilide (**1l**): 109—110 °C (methanol-water, lit,[18] 108 °C).

Generation of N-*Aryl*-N-*phenylthioaminyls (**2**).* a) Benzenesulfenanilide (**1**, 5 mg), di-*t*-butyl peroxide (0.02 ml), and benzene (0.2 ml) were placed in an ESR tube. After the solution had been degassed by three freeze-and-thaw cycles, the tube was sealed off. An ESR spectrum of the solution was recorded while the solution was being UV-irradiated from a distance of 40 cm using a high-pressure mercury lamp (JES-UV-1, 100 W) at room temperature; b) in one arm of a two-armed glass tube which was attached to an ESR tube, **1** (0.1 g) and benzene (2 ml) were placed, while lead dioxide (0.5 g) and potassium carbonate (0.5 g) were placed in the second arm. After the contents had been degassed as has been described above and the tube had been sealed off, the benzene solution of **1** was poured into the second arm containing the oxidizing agents and the resulting mixture was shaken well. A part of the supernatant of the mixture was poured into the ESR tube, and the tube was sealed off.

*Generation of the Nitroxide Radical **3**.* Nitrosobenzene (4 mg), diphenyl disulfide (5 mg), and benzene (0.2 ml) were placed in an ESR tube and the solution was degassed as has been described above, the tube was then sealed off. An ESR spectrum of the solution was recorded under UV-irradiation as has been described above.

The ESR spectra were recorded on a JES-ME 3X Spectrometer equipped with 100 kHz field modulation. Computer simulations of the ESR spectra were carried out using a FACOM 270-30 Computer with a FACOM 6201B Plotter; they were fitted by means of a trial-and-error method.

The Formation of Amino Acids and Related Oligomers from Formaldehyde and Hydroxylamine in Modified Sea Mediums Related to Prebiotic Conditions*

Hiroshi HATANAKA and Fujio EGAMI

Mitsubishi-Kasei Institute of Life Sciences, 11 Minamiooya, Machida-shi, Tokyo 194

(Received September 22, 1976)

Amino acids and related oligomers were produced from formaldehyde and hydroxylamine in modified sea mediums at pH 5.5 and 105 °C. The modified sea mediums are characterized by a lower concentration of sodium chloride and a higher concentration of essential transition metal** ions (Zn^{2+}, Mo^{6+} as MoO_4^{2-}, Fe^{3+}, Cu^{2+}, Co^{2+}, and Mn^{2+}) than in sea water; generally small amounts of clays (kaolin and montmorillonite) were added. About 40 species of amino acids were detected in the automatic amino acid analyzer, and 20 of them were tentatively assigned. Glycine, alanine, and serine among the protein amino acids and β-alanine were further confirmed by thin-layer chromatography. Oligomers with molecular weights of about 200—1000 were produced which gave rise to an amino acid mixture by acid hydrolysis. From the ratio (maximum, about 5) of the content of the amino groups after to before hydrolysis and the molecular size, the oligomers were tentatively regarded as oligopeptides of an unknown nature, resistant to pronase digestion. The large-molecular fraction (M. W. about 700) had a phosphatase-like activity able to hydrolyze *p*-nitrophenyl phosphate.

Since the first experimental demonstration of the synthesis of amino acids under possible primeval conditions published by Miller,[1] a substantial number of investigations have been carried out in this field of research, most of which have been collected in two volumes.[2,3] For the further chemical evolution, that is, for the formation of primary organisms, the existence of an aqueous medium is absolutely required.[4] The dissolved substances in earth's primeval hydrosphere are regarded as the initial materials for the development of life.

Egami, one of the present authors,[5] has reported that a good correlation was found between the biological behaviour of minor elements, such as molybdenum and iron, and their concentrations in the present sea water. A hypothesis has been presented that the composition of the present sea water reflects that of the primeval sea water at the time of early evolution. In accordance with the above hypothesis, iron, molybdenum, and zinc, which are the most abundant transition elements in sea water, are found to be essential components of the enzymes in microorganisms, including *Clostridium*, which is regarded as the most primitive existing organism.[6] These transition elements presumably complexed with compounds accumulated in the primeval sea in the course of chemical evolution, thus forming compounds which subsequently evolved to form protoenzymes with a low activity and a broad specificity.

Taking into consideration the fact that essential transition metal ions had to contribute to chemical evolution in primeval sea water, and anticipating the concerted catalytic action of clays and metal ions, we have been investigating the formation of biomolecules in modified sea mediums, in which the concentration of sodium chloride is lower, and that of transition metal ions in higher, than in sea water. We suppose that the modified sea mediums are essentially similar to primeval sea conditions and are more effective for the formation of organic substances from simple materials.

The present paper will deal with the formation of amino acids and related oligomers from formaldehyde (as the C_1 compound) and hydroxylamine (as the N_1-compound) in the modified sea mediums, with special reference to the effects on their formation of essential transition elements, *i.e.*, iron, molybdenum, zinc, copper, cobalt and manganese, and of such clays as kaolin and montmorillonite. The starting materials, formaldehyde and hydroxylamine, were selected on the basis of the experiments of Oró *et al.*[7] Preliminary experiments under similar conditions by Ventilla and Egami[8] were reported elsewhere.

Materials and Methods

Materials. The formaldehyde was obtained from Wako Chemicals, and the hydroxylamine hydrochloride, from Nakarai Chemicals. They were of a reagent grade. All of the six transition elements, 0.1 M solutions in the chemical forms of $Fe(NO_3)_3$, Na_2MoO_4, $ZnCl_2$, $Cu(NO_3)_2$, $CoCl_2$, and $MnCl_2$, were kind gifts of Miss Kayoko Nakamura (Laboratory of Social Life Science, in our Institute). The kaolin was purchased from Kukita Chemicals and the montmorillonite, from Hohjun Yoko Co. All the other compounds used as the components in the modified sea mediums were of a reagent grade.

The Nuclepore (pore size of 0.4 μ, 47 mm disc) was obtained from the Nomura Micro Science Co. The Dowex 1 (2X, 100—200 mesh, OH form) and Dowex 50 (8X, 100—200 mesh, H^+ form)were purchased from the Muromachi Kagaku Co. The biogel P-2 (100—200 mesh) and P-10 (100—200 mesh) were obtained from Bio-Rad Chemicals. The fluorescamine (Fluram<Roche>) and disodium *p*-nitrophenyl phosphate were purchased from the Japan Roche Co. and Sigma Chemicals respectively. Six M HCl for acid hydrolysis was purified by distillation at a constant boiling temperature. The dioxane was used after distillation over solid NaOH. The other chemicals were reagent-grade.

Preparation of the Modified Sea Mediums for Large-scale Experiments. The original solution (250 ml), with a concentration of 0.6 M of formaldehyde and 0.1 M of hydroxylamine hydrochloride and of containing 0.02 M of magne-

* A part of this report was presented at the 67 th Annual Meeting of the American Society of Biological Chemists, San Francisco, June 7, 1976: *Fed. Proc., Fed. Am. Soc. Exp. Biol.*, 35, 1458 (1976)

** The term "transition element" is used here in its broader sense to include zinc and similar elements.

TABLE 1. COMPOSITIONS OF A MODIFIED SEA MEDIUM (500 ml)

Compositions	Concentration
HCHO	0.3 M
NH_2OH	0.05 M
HPO_4^{2-}, SO_4^{2-}, Mg^{2+}, Ca^{2+}	0.01 M each
Na^+	0.015 M
K^+	0.045 M
Cl^-	0.07 M
NO_3^-	0.0005 M
Zn^{2+}, Mo^{6+} as MoO_4^{2-}, Fe^{3+}, Cu^{2+}, Co^{2+}, Mn^{2+}	0.0001 M each
Kaolin, Montmorillonite	2% (wt/vol) each

sium sulfate, 0.02 M of calcium chloride, 0.02 M potassium phosphate (dibasic), and 0.0002 M each of the six transition elements, was adjusted to pH 5.5 by titration with an alkaline solution containing 0.7 M KOH and 0.3 M NaOH. The volume of the solution was diluted to 500 ml, and then 10 g each of kaolin and montmorillonite were added to the solution. The original pH value, 5.5, of the solution was not changed by the addition of clays. The final composition of the reaction mixture, in a total volume of 500 ml, is listed in Table 1. This reaction mixture (namely the modified sea medium) was glass-sealed *in vacuo* under a nitrogen atmospher and kept at 105 °C±5 °C for 35 days in a Dry-Block DB-3H (M ε S Instruments Co.). As the reaction proceeded, the reaction mixture turned yellow after about 2 weeks and reddish brown after about 3 weeks.

Extraction Procedure of the Products from Modified Sea Mediums after the Reaction. After a 35-day reaction at 105 °C, the sealed ampoule was cut off in an ice bath. After centrifugation at 10000 rpm for 30 min, the sediment was at once washed by 100 ml of distilled water. The resulting supernatants (590 ml) were combined and filtered off on a 0.4 μ pore size Nuclepore membrane. The washed sediment was then resuspended in 400 ml of 2 M aqueous ammonia, and the suspension was vigorously shaken at 37 °C for 1 day. After the centrifugation of the suspension, the supernatant (390 ml) was filtered off. Further extraction from the resulting sediment with 200 ml of 2 M aqueous ammonia was repeated twice. After the final extraction at 37 °C for 2 days, the resulting sediment was washed twice with 150 ml of distilled water.

All of the extracts (total volume of 1670 ml) were lyophilized by means of a Virtis-model 10—145 MR-BA freeze-mobile. The lyophilized dark brown powder was redissolved in distilled water and filtered off on a Nuclepore membrane. The color of the resulting extract (19 ml) was a deep reddish brown. It was designated "Golden Primordial Broth" from the color tone and the richness of the products.

Biogel P-2-column Chromatographic Separation of Products. Biogel P-2 column chromatography was used for the initial separation of oligomeric products with different molecular weights. An aliquot (15 ml) of concentrated "Golden Primordial Broth" was placed in the column beds under an overlying buffer layer. Biogel P-2 (100—200 mesh) was equilibrated with 0.1 M ammonium hydrogencarbonate (approximate pH value of 9.0) and then packed in a large column (2.65×130 cm=700 ml). The fraction (5.0 ml each) was eluted at 13 ml/h with a constant pressure head of 15 cm by means of 0.1 M ammonium hydrogencarbonate.

For the purpose of the further characterization of each fraction, for example, the determination of the primary amino groups before and after acid hydrolysis, and the measurement of the alkaline phosphatase activity, each fraction was lyophilized in order to remove the ammonium hydrogencarbonate and then, with distilled water, brought back to the original volume.

The molecular weight of each fraction was calibrated on the basis of the interpolation of semi-logarithmic plots (elution volume *versus* molecular weight) obtained from separate experiments with the following standard compounds; horse heart cytochrome *c*, oxidized and reduced glutathione, adenosine triphosphate, and sodium chloride.

Small-scale Experiments. In order to examine the reaction requirements of catalysts such as transition elements and clays, small-scale (total volume of 10 ml) experiments were carried out under essentially the same reaction conditions and using the same extraction procedures as those of the above large-scale experiments except for their experimental scale. After the reaction an aliquot of each extract was placed in a small Biogel P-2 column (1.25×49 cm=60 ml) equilibrated with 0.1 M ammonium hydrogencarbonate. Each fraction (5 ml) was lyophilized and then brought back to the original volume with distilled water.

The same small-scale experiments used to discover the time course of the formation of amino acids and related oligomers were carried out in the same way.

Determination of the Content of Primary Amino Groups. The fluorescamine reagent has been employed for the fluorometric determination of the content of primary amino groups. The advantages of the use of this reagent instead of ninhydrin are the high sensitivity of amino acid, the non-sensitivity of hydroxylamine, and the low sensitivity of ammonia. The manual determination procedure was undertaken according to Böhlen *et al.*[9] An aliquot of the sample (10—250 μl, 1—25 nmol of primary amino groups) was transferred into a 18×105 mm test tube, and then the volume was brought to 2.5 ml with a 0.05 M sodium phosphate buffer (pH 8.0). While the test tube was being vigorously shaken on a vortex-type mixer [a Thermomixer (Termonics Co.)], 0.5 ml of a fluorescamine solution in dioxane (30 mg/100 ml) was rapidly added to the buffer solution by means of a Finnpipette (Kemistien Oy). A reagent blank and a standard leucine solution in two different concentrations (5 and 10 nmol) were run routinely. The fluorescence was measured on a Shimadzu model RF-502 recording spectrofluorometer with the excitation wavelength at 390 nm and the emission at 470 nm with a slit width of 5 μm in each. Measurement was made with a regular quartz cuvette (1 cm light path).

As a more sensitive method, we also employed a one-fifth-scal-down procedure. Its sensitivity range for leucine was 0.1—10 nmol. The final volume was 0.6 ml. The quartz cuvette used had a 0.25 cm light path.

Acid Hydrolysis. An aliquot of the sample was transferred to a 15×105 mm test tube (made of Pyrex glass) and lyophilized to a powder; the volume was then brought up to about 1 ml of 6M HCl. This solution was glass-sealed *in vacuo* and kept at 110 °C for 20 h in a hydrolysis furnace (Mitamura Riken Co.). After hydrolysis, the HCl was removed *in vacuo* at 40 °C.

Amino Acid Analysis. Amino acid analyses were conducted using a JEOL model JLC-6AH automatic amino acid analyzer. Before the amino acid analysis, the sample was placed in a small Dowex 1 (OH^- form) anion-exchange column (1.2×5 cm=5.7 ml). The pass-through fraction (neutral) was discarded. After washing with distilled water, the amino acid fraction (acidic) was eluted with about 10 ml of 4 M acetic acid. The acetic acid solution was evaporated to dryness *in vacuo* at 40 °C. Then the sample was dissolved

in a 0.2 M sodium citrate–citric acid buffer (pH 2.2) and eluted from a long column (0.8×50 cm) with a pH gradient of 3.30 to 4.25 by a step-by-step procedure. The sample solution was eluted from a short column (0.8×15 cm) with a pH of 5.29. JEOL custom spherical resin LCR-2 (strong-acidic cation exchange resin) was used to pack the column.

Manual Handling of Amino Acid Analyzer for the Preparation of Individual Amino Acids. The acid hydrolysates of an aliquot of the concentrated "Golden Primordial Broth" were subjected to Dowex 1 (OH^- form)-column treatment. The resulting acidic fraction was evaporated and dissolved with a 0.2 M sodium citrate-citric acid buffer (pH 2.2). An aliquot (0.8 ml; 12.9 μmol of primary amino groups) was placed in a moderately long column (0.8×50 cm) of the amino acid analyzer. The elution was carried out by the step-by-step pH gradients of 3.30 and 4.25 at a constant elution speed of 0.84 ml/min. At the end of the buffer (pH 4.25) elution, the residual amino acids retained on the resin were eluted off with 0.2 M NaOH. The fractionation (0.5 ml for each fraction volume) was done by means of a LKB model 7000 Ultrolac fraction collector. An aliquot (10 μl) of each fraction was estimated for the primary amino groups with fluorescamine. The fractions—peak No. 9 shown in Fig. 1 (possibly containing serine), Peak No. 15 (possibly containing glycine), Peak No. 16 (possibly containing alanine), Peak No. 30 (possibly containing β-alanine) and the 0.2 M NaOH eluate (the basic amino acid fractions)—were pooled. The pooled fractions except for the 0.2 M NaOH eluates were then adjusted to pH 1.0 with HCl and placed in a Dowex 50 (H^+ form) resin column (1.2×5 cm=5.7 ml). After the drying of the 2 M aqueous ammonia eluate, they were subsequently placed in a Dowex 1 (OH^- form) resin column (1.2×2 cm=2.3 ml). The 4 M acetic acid eluate was evaporated to dryness and then dissolved with a small volume of distilled water. An aliquot of each desalted sample was placed on a thin-layer chromatogram coated with cellulose on a plastic roll (DC-Plastikrolle Cellulose; 20 cm height; Merick). The solvent system used was butyric acid : acetic acid : water (4 : 1 : 5, by volume).[10] After developing for 8 h, each spot was visualized by means of a spray of 0.2% ninhydrin butyric acid saturated in a water solution and heating at 95 °C for 10 min.

Spectrophotometric Analysis of the Oligomers. The oligomers used for analysis were concentrated pooled fractions (Fractions Number 51—58 in the Biogel P-2 column shown in Fig. 2) which contained 4.25 μmol of primary amino groups per ml. The ultraviolet spectrum was measured in a diluted aqueous solution (17.9 nmol of primary amino groups per ml) of the oligomer, using a Hitachi model 323 spectrophotometer. The infrared spectrum was recorded as potassium bromide disc on a JASCO model IRA-1 spectrophotometer.

Attempted Pronase-catalyzed Hydrolysis of the Oligomers. In order to remove the small-molecular weight peptides contaminating the commercially available pronase preparation (Pronase E from the Kaken Kagaku Co.), a 30-mg portion of Pronase E was placed in a small column (1.25×47 cm =58 ml) packed with Biogel P-10 equilibrated with a 0.02 M potassium phosphate buffer (pH 7.5). The main peak just behind the void peak of Biogel P-10 chromatography was collected and then used immediately for the following hydrolysis experiment. The oligomers used were the same preparation as the one above used for the spectrophotometric analysis. The reaction mixture for pronase-catalyzed hydrolysis, in a total volume of 0.5 ml, contained 0.904 μmol of the oligomers, as calculated from the content of the primary amino groups, 0.63 mg of Biogel P-10-treated pronase, and 20 μmol of a potassium phosphate buffer (pH 7.5). After incubation at 37 °C for 17 h, the mixture was placed in a Biogel P-10 column (1.25×47 cm=58 ml) equilibrated with a 0.02 M potassium phosphate buffer (pH 7.5). The fractions (1 ml each) were then collected by eluting at 2.5 ml/h with a pressure head of 15 cm. The effluents were monitored in terms of their absorbance at 280 nm, using a LKB Uvicord II absorption spectrophotometer, and by then measuring their content of primary amino groups by the use of fluorescamine.

Measurement of Alkaline Phosphatase Activity. The reaction rate of alkaline phosphatase activity in the oligomer fractions formed was determined by measuring the *p*-nitrophenol released from *p*-nitrophenyl phosphate according to the method of Oshima,[11] with slight modifications. The assay mixture, in a total volume of 0.9 ml, contained 90 μmol of the Tris-acetic acid buffer (pH 7.5), 9 μmol of $MgCl_2$, 0.9 μmol of $ZnCl_2$, 9 μmol of disodium *p*-nitrophenyl phosphate, 80 μl of the oligomer fraction, and 5 μl of toluene. The reaction was carried out at 37 °C in a 13×100 mm test tube (Corning Co.) with a tight cap, and the reaction rate was directly measured at 400 nm, using a Zeiss PMQ II spectrophotometer, at suitable time intervals (1—5 days).

Results and Discussion

Extraction of "Golden Primordial Broth" after the Reaction in Modified Sea Mediums Containing Formaldehyde and Hydroxylamine. After 35 days at 105±5 °C, the following four-step extractions from a sealed ampoule containing 500 ml of modified sea mediums were done:

Table 2. Extraction of the products from a modified sea medium (500 ml)

Steps of extraction	Volume	Content of primary amino groups		Ratio of (B) to (A)
		Before acid hydrolysis (A)	After acid hydrolysis (B)	
	ml	μmol		
H_2O extract	590	154	1214	7.88
1st 2 M NH_4OH extract	390	178	423	2.38
2nd 2 M NH_4OH extract	190	33.3	100	3.00
3rd 2 M NH_4OH extract	500	34.6	107	3.09
Summation	1670	400	1844	4.61
Concentrated "Golden Primordial Broth"	19	404	1519	3.76

The extraction procedures are described in the text.

extraction with distilled water, and 1st, 2nd, and 3rd extractions with 2 M aqueous ammonia. The extraction volumes and their contents of primary amino groups before and after the acid hydrolysis are listed in Table 2. As is shown in Table 2, the compounds with a high ratio of the content of the primary amino groups after acid hydrolysis to that before the procedure were extracted with distilled water. The extraction percent reached 65% of the total extraction. However, it appeared that even the third extraction with 2 M aqueous ammonia did not accomplish the complete extraction of the products. Although tightly bound compounds seem to be present in the clays, most of the products with primary amino groups might be recovered in the concentrated "Golden Primordial Broth." In order to eliminate the clays finely pulverized in 2 M aqueous ammonia, the concentrated solution was filtered through a Nuclepore membrane (pore size 0.4 μ). As can be seen in Table 2, though, this operation did not reduce the recovery of primary amino groups.

The yield of primary amino groups in the concentrated "Golden Primordial Broth" was calculated to be 6.06% from the amount of hydroxylamine used as the starting N_1 compound. The fraction eluted from a Dowex 1 (OH^- form) anion-exchange resin column by 4 M acetic acid contained 1311 μmol of primary amino groups (5.24% yield calculated from the hydroxylamine). That is, most (86.3%) of the compounds with primary amino groups in the hydrolyzate of the "Golden Primordial Broth" were acidic ones (probably with a carboxyl or sulfonate group). This amphoteric character strongly suggested that most of the hydrolyzates were amino acids.

Amino Acid Analysis of the Hydrolyzate Formed from "Golden Primordial Broth". After the treatment of the Dowex 1 (OH^- form), an aliquot of the hydrolyzate formed from the "Golden Primordial Broth" was examined by means of the automatic amino acid analyzer using cation-exchange resin. The resulting chart is shown in Fig. 1. As is shown in Fig. 1, the peaks of the ninhydrin-positive materials consisted of 40 species. The retention times of natural protein amino acids are presented in the same chart (shown in Fig. 1). In the separate experiments, the retention times of 16 non-protein amino acids (β-alanine, α-aminobutyric, α-aminoisobutyric, β-aminobutyric, β-aminoisobutyric, γ-aminobutyric and α,γ-diaminobutyric acids, homoserine, phosphoserine, taurine, norvaline, norleucine, alloisoleucine, sarcosine, citrulline, and ornithine) were also measured. The substances with the same retention times as these authentic amino acids are listed in Table 3. The identities with respect to the retention times on the amino acid analyzer were further confirmed by a mixed experiment using the samples and authentic amino acids. The individual peak area calculated on the basis of the response factor to the peak area of a known amount of glycine gave the content of the products as is shown in Table 3. The recovery (46.9%) introduced by the summation of the peak area was rather wrong. This might be due to the difference in sensitivity between the fluorescamine and ninhydrin detections. Another possibility was that the sample might contain high-basic compounds yet retained on the resin. To confirm the former possibility, the determination of the amino groups in the hydrolyzate by the ninhydrin method is required, but this is difficult because of the unavoidable contamination of the ammonia used in a large amount in the extraction procedure. However, the lesser sensitivity of β-amino groups compared with that of α-amino groups is well-known. It seems to explain the incomplete recovery in the amino acid analyzer with ninhydrin detection.

In a separate experiment, several individual peaks were obtained by means of the manual handling of the amino acid analyzer. The total recovery was about 70% by the use of fluorescamine. Especially, the amount of Peak No. 30 was 5.22 mol%. The difference between the yields determined by ninhydrin (2.40 mol%) and by fluorescamine seems to show, together with the fact of the same retention time, that this peak (Peak No. 30) was β-alanine. Furthermore, the fractions corresponding to Peaks No. 9, 15, 16, and 30, shown in Fig. 1, were analyzed by thin-layer chromatography coated with cellulose powder. The R_f values

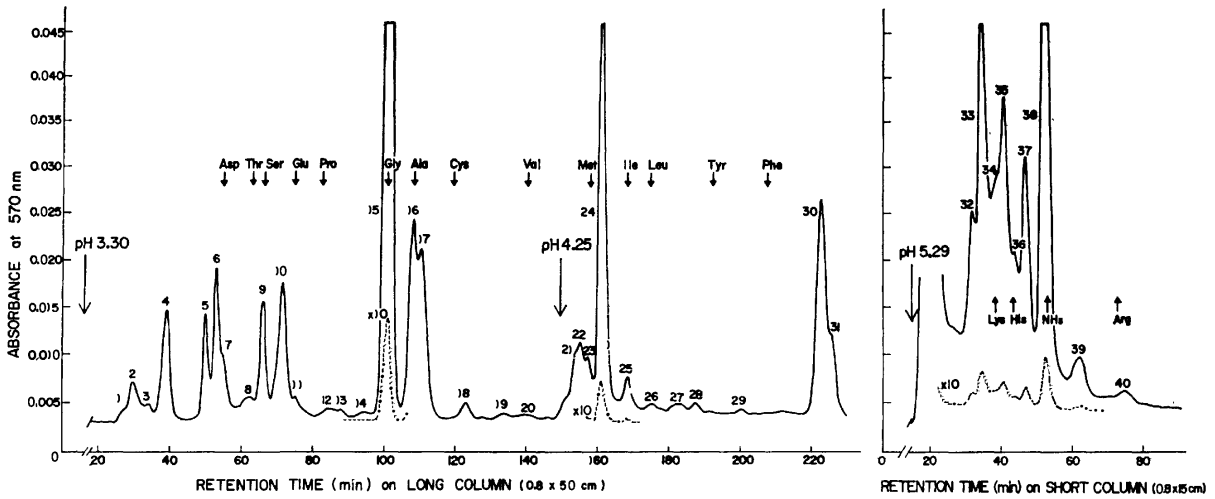

Fig. 1. Amino acid analysis of the acid hydrolyzate from the concentrated "Golden Primordial Broth." The experimental conditions were given in the text.

The amounts of amino acid residues corresponding to the respective peaks shown in Fig. 1 were calculated on the basis of the response factor to the peak area of the known amount of glycine obtained from a separate experiment under the same operation conditions of the automatic amino acid analyzer.

in the butyric acid : acetic acid : water (4 : 1 : 5, by volume) solvent system were 0.13, 0.15, 0.22, and 0.23 respectively. These values agreed with those obtained with the authentic amino acids, serine, glycine, alanine, and β-alanine respectively. The purple colorations after the spray of ninhydrin except in the case of β-alanine were practically the same (the coloration for β-alanine was blue-violet). Since these compounds had the same retention times on the automatic amino acid analyzer as those of the respective authentic amino acids, these results indicate that the compounds eluted at the positions of Peaks No. 9, 15, 16, and 30, shown in Fig. 1, correspond to serine, glycine, alanine, and β-alanine respectively. The other compounds eluted on the automatic amino acid analyzer could not be analyzed by means of the thin-layer chromatography because of their small amounts.

Gel-filtration of Concentrated "Golden Primordial Broth" using Biogel P-2. Most (15 ml) of the concentrated "Golden Primordial Broth" was placed in a column packed with Biogel P-2 (fractionation range; MW 100—1800) equilibrated with 0.1 M ammonium hydrogencarbonate. The chromatographic patterns of the products containing, as expected, the high-molecular-weight

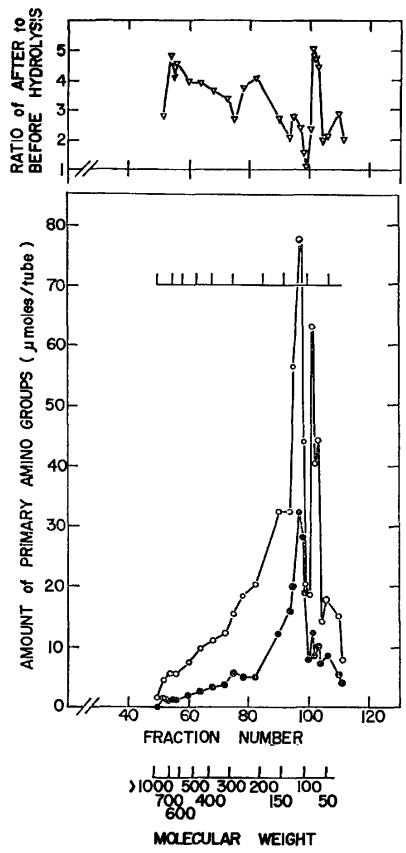

Fig. 2. Elution profiles of Biogel P-2 column chromatography of the concentrated "Golden Primordial Broth." The procedure of the column chromatography was given in the text. Closed and open circles represent the amount of primary amino groups determined by the usage of fluorescamine before and after acid hydrolysis, respectively. Reversed open triangles in the upper figure represent the ratio of the amount of primary amino groups after to before acid hydrolysis. The given scale of molecular weight was obtained from the separate experiment using the several authentic compounds listed in the text.

compounds are shown in Fig. 2. After the lyophilization of each fraction in order to remove the excess of ammonium hydrogencarbonate, the resulting powder was brought back to the original volume with distilled water. The amount of primary amino groups in each fraction before and after acid hydrolysis was measured by using fluorescamine, with leucine as the standard. As can be seen in Fig. 2, a considerable amount of the compounds with primary amino groups was found in the high-molecular-weight fractions. In addition, the ratio of the amount of primary amino groups after to before acid hydrolysis in the column effluents increased by about 5-fold, together with the molecular size. These results mean that the compounds present in the high-molecular-weight fractions possessed latent primary amino groups which appeared as primary amino groups upon 6 M HCl hydrolysis, and suggest that they were oligomers consisting of several amino acid residues.

The sharp peak having a rather high ratio of the amount of primary amino groups after to before acid hydrolysis but eluted in the small-molecular-weight region (corresponding to a molecular weight of about 100) might contain a cyclic dipeptide of glycine, 2,5-piperadinedione.

Three column effluents — *i. e.*, Fraction Number 55 (at the position with 700 daltons as the average molecular weight), Fraction Number 75 (at 300 daltons), and Fraction Number 95 (at 130 daltons) — were analyzed for amino acid composition using the automatic amino acid analyzer. The amount of 40 species of ninhydrin positive materials is shown in Table 4 in mol%. The difference between the composition in the high- and low-molecular-weight fractions was tended to be small under the present experimental conditions.

Some Characteristics of the Oligomer Fractions Eluted from the Biogel P-2 Column. The collected fractions from Fraction Numbers 51 to 58 (oligomer fractions) were subjected to the following spectrophotometric measurements. Figure 3 shows the ultraviolet and infrared absorption spectra of the oligomer fraction. A shoulder peak in the neighborhood at 280 nm was observed in the ultraviolet spectrum. A rather broad, low-resolution band in the region at 1500—1600 cm^{-1} was also detected in the infrared spectrum. These results were not in contradiction with the existence of oligopeptides in the oligomer fraction. However, this fraction certainly contains various compounds other than oligopeptides. In fact, a considerble amount of sugar derivatives was detected in a separate experiment. Thus, the above findings can not be regarded as evidence for the presence of oligopeptides or peptide bonds.

In a separate experiment, an enzymatic degradation of the oligomers was attempted using pronase, a bac-

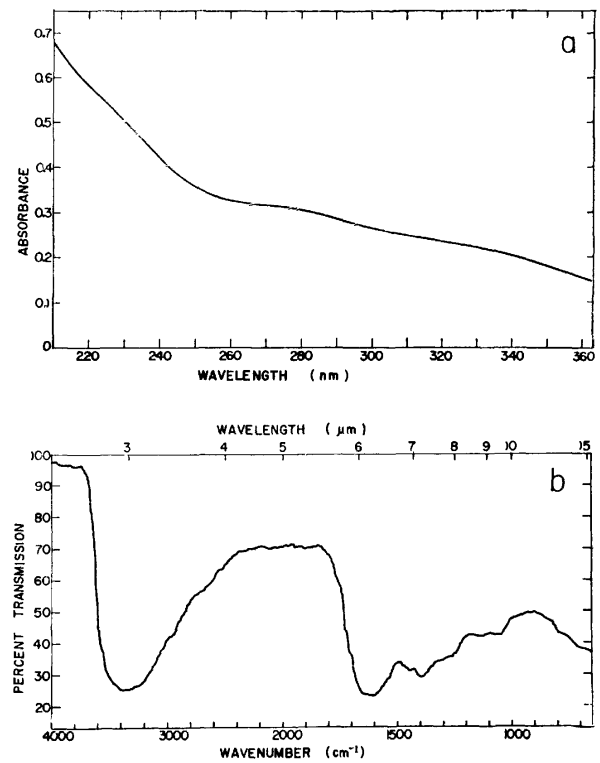

Fig. 3. Ultraviolet (a) and infrared (b) spectra of the oligomers. Experimental conditions were given in the text.

terial non-specific protease. Contray to expectations, no amino acids and no newly-formed primary amino groups were detected — only the autolysis of pronase itself. A similar observation was reported by Ferris *et al.*,[12] who used the oligomers derived from HCN. They reported that no amino acids were released from the oligomers by pronase. Based on their results, they concluded that the oligomers did not contain peptide bonds.

In our case, however, taking into consideration the abundant formation of amino acids in the monomer fractions and the reasonable ratio of the primary amino group content after acid hydrolysis to before the procedure for the molecular size, the apparent non-susceptibility to pronase may be attributed, not to the absence of peptide bonds, but to the complex nature of the products with the predominant amount of unnatural peptide bonds due to D-amino acids, other nonprotein amino acids such as β-alanine, and those due to diamino or dicarboxylic amino acids.

Phosphate Ester Hydrolysis by the Oligomer Fractions Formed from Formaldehyde and Hydroxylamine. The oligomers formed in the modified sea mediums containing several transition elements were tested for the hydrolysis of the phosphate ester bond of *p*-nitrophenyl phosphate, as is shown in Fig. 4. Four column effluents, *i.e.*,

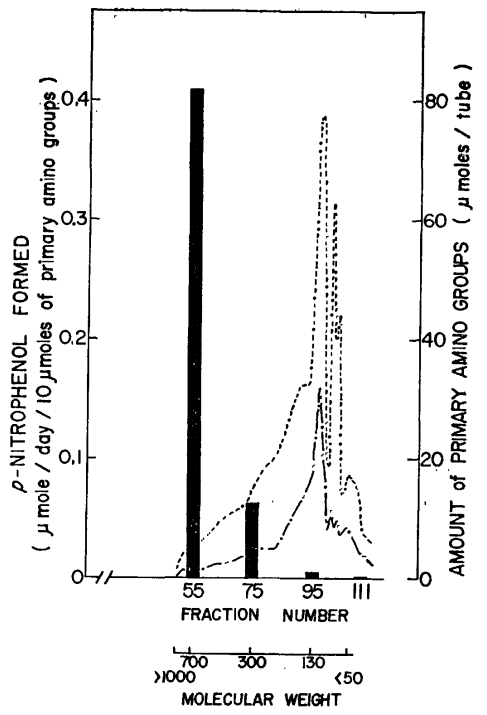

Fig. 4. Phosphate ester hydrolysis by the oligomer fractions. Closed bar represent the specific activity of alkaline phosphatase in the fractions obtained from the Biogel P-2 column chromatography shown in Fig. 2. Dotted and broken lines were the trace lines of the amount of primary amino groups before and after acid hydrolysis, respectively, obtained from the experiment shown in Fig. 2.

Fraction Numbers 55, 75, 95, and 111, were tested; only the high-molecular-weight fractions were found to show any hydrolytic activity for *p*-nitrophenyl phosphate. This catalytic activity was presented as μmol of *p*-nitrophenol formed per day per 10 μmol of primary amino groups in its hydrolyzate. This representation was regarded as μmol/day/mg oligopeptide, by assuming that each amino acid residue has 100 daltons as its molecular weight. Oshima[11] reported that proteinoid (molecular weight, 2500—4000), termally prepared polyamino acids containing 18 common amino acids, promotes the hydrolysis of the ester bond of *p*-nitrophenyl phosphate; its specific activity, 3 μmol/day/mg proteinoid at 30 °C. As can be seen in Fig. 4, the oligomers in Fraction Number 55 (average molecular weight, 700) had 0.409 μmol/day/mg oligopeptide at 37 °C. Its specific activity seems reasonable considering the different molecular weight. The possibility that the activity found was due to contamination by microorganisms or by phosphatases from them can be rejected on the basis of the following observations: toluene was added to hinder the growth of microorganisms; the time course of the reaction was linear, unlike the logarithmic growth curve occurring in the case of bacterial growth; only the high-molecular-weight fractions showed catalytic activities. Of course, another possibility — that this catalytic hydrolysis of *p*-nitrophenyl phosphate might be due to a high-molecular-weight metal complex of different constituents — cannot be excluded. At any rate, it is remarkable that a phosphatase-like activity appeared.

Dependency of the Production of Amino Acids and the Related Oligomers from Formaldehyde and Hydroxylamine on Transition Elements and Clays. The requirements for the production of amino acids and related oligomers from formaldehyde and hydroxylamine were investigated in small-scale (10 ml) experiments, as is shown in Table 5. The production of primary amino groups after acid hydrolysis in the complete system (Exp. a) was calculated as a 5.52% yield from hydroxylamine; this value is almost the same as that in the former large-scale experiment. However, the production of primary amino groups in the hydrolyzates in the minus experiments, such as minus transition elements (Exp. b) and minus clays (Exp. c), was considerably decreased, by 81.5% and 75.7% respectively. The composition of the amino acid residues was examined by using the automatic amino acid analyzer in separate experiments. The composition was almost the same as that in the former large-scale experiments. The no-reaction control (stocked at −20 °C instead of reacted at 105 °C) experiment (Exp. d) gave a small amount of the primary amino groups (0.67% yield). It was found to consist practically exclusively of glycine (41.3 mol%) by a separate experiment using the automatic amino acid

TABLE 5. REQUIREMENTS OF THE PRODUCTION OF AMINO ACIDS AND THE RELATED OLIGOMERS FROM FORMALDEHYDE AND HYDROXYLAMINE IN MODIFIED SEA MEDIUMS

Experiments	Amounts of primary amino groups		Ratio of (B) to (A)
	Before acid hydrolysis (A)	After acid hydrolysis (B)	
	μmol		
a. Complete	9.51	27.6	2.90
b. Minus transition elements (Mo^{6+}, Zn^{2+}, Cu^{2+}, Fe^{3+}, Co^{2+}, Mn^{2+})	7.18	22.5	3.13
c. Minus clays (kaolin, montmorillonite)	7.69	20.9	2.71
d. No-reaction control	1.95	3.34	1.71

The reaction in the complete system (Exp. a) with the reaction mixture listed in Table 1 was carried out in a glass-sealed ampoule at 105±5 °C for 35 days on a small scale (10 ml of total volume). The reaction in the minus system (Exp. b and c) was carried out in the same way except for the omission of transition elements and clays respectively. The no-reaction control (Exp. d) with the same reaction mixture as the complete system was stocked in a glass-sealed ampoul at −20 °C for 35 days. The extraction procedures and the determination of primary amino groups are described in the text.

analyzer. This result shows that most of the compounds with primary amino groups formed in the no-reaction control were not due to the contamination of the impurities in the starting materials such as clays or to the contamination during the experimental handling, and that the formation of glycine in modified sea mediums was so easy that such a detectable amount of glycine could be formed during storage at −20 °C and operation at room temperature. It should be pointed out that clays were not absolutely required for either the formation of amino acids or that of oligomers, as had been observed in preliminary experiments by Ventilla and Egami.[8] It remains unsolved, however, whether the formation of amino acids and oligomers in the case of minus transition elements was realized by the clays themselves or by transition elements contained in the clays.

An aliquot of each product formed from Exps. a, b, c, and d was placed in a small column packed with Biogel P-2 and equilibrated with 0.1 M ammonium hydrogencarbonate. The elution profile obtained by measuring the amount of primary amino groups before and after acid hydrolysis is shown in Fig. 5. All these elution patterns except for that of Exp. d (no-reaction control) were observed to be almost the same. However, the formation of primary amino groups in the high-molecular-weight fraction in Exp. b (minus transition elements) was considerably decreased compared with that in Exp. a (complete). The relatively low production suggests that these transition elements were required for the formation of oligomers in the modified sea mediums. In fact, a separate experiment using a higher concentration (0.001 M) of molybdenum was found to give about twice as much of the primary amino groups.

Effect of the Reaction Time on the Formation of Amino Acids and the Related Oligomers from Formaldehyde and Hydroxylamine in Modified Sea Mediums. The time-dependent formation of primary amino groups before and after acid hydrolysis was measured as is shown in Fig. 6. The formation of primary amino groups before acid hydrolysis was observed to reach its maximum in about 30 days. However, the formation of primary amino groups after acid hydrolysis seemed to progress over a reaction time of about 40 days. As a consequence, the ratio of the content of primary amino groups after to before acid hydrolysis was found to increase linearly for 30 days. This means that the formation of oligomers required rather a long reaction time at 105 °C. The products obtained in different reaction times were measured for their amino acid composition using the automatic amino acid analyzer in separate experiments. No amino acids required a specially long reaction time for the formation, but the formation of alanine, β-alanine, and especially glycine was found to reach the maximum at rather an early stage.

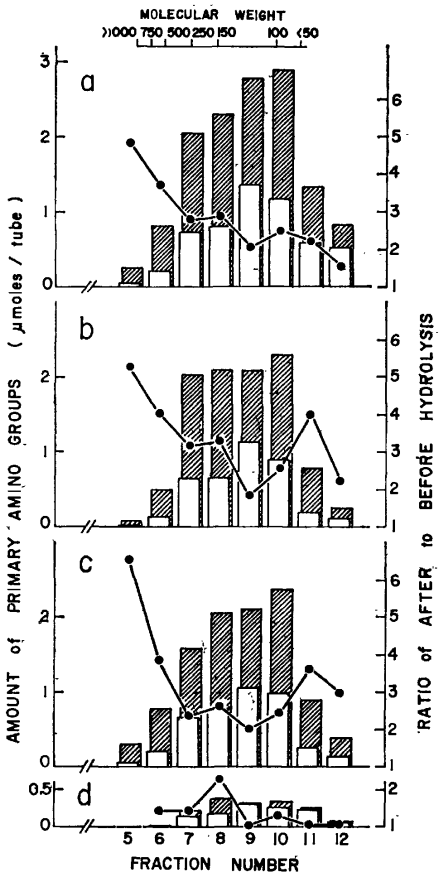

Fig. 5. Elution profiles of small-scale Biogel P-2 column chromatographies of the products obtained from the requirement experiments. Four column profiles; a, b, c, and d, represent that obtained from the Exp. a, b, c, and d, respectively, shown in Table 5. Open and shadowed bars represent the amount of primary amino groups before and after acid hydrolysis, respectively. Closed circles represent the ratio of the amount of primary amino groups after to before acid hydrolysis.

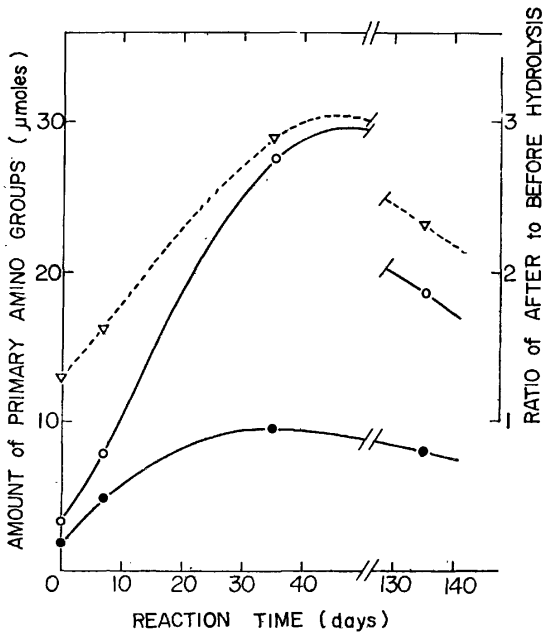

Fig. 6. Time course of the formation of amino acids and related oligomers from formaldehyde and hydroxylamine. Closed and open circles represent the amount of primary amino groups before and after acid hydrolysis, respectively. Reversed open triangles represent the ratio of the amount of primary amino groups after to before acid hydrolysis.

General Discussion. Amino acids were the first organic compounds of biological interest produced under simulated primitive earth conditions.[1] Reactions in one-step processes from simple compounds of carbon with simple nitrogen compounds have been accomplished by several investigators using highly activating forms of energy, such as electric discharges, ultraviolet light, and ionizing radiation [shown in the literature listed in the monograph[13]]. A common feature of all these experiments is the employment of highly activating forms of energy. In these experiments, part of the energy was found to be used to oxidize methane to formaldehyde, and in the reduction of nitrate. Thus, certain C_1 and N_1 compounds, such as formaldehyde and hydroxylamine respectively, of intermediate degrees of oxidation could be expected to produce amino acids even in the absence of electric discharges, ultraviolet, and ionization radiation. Based on the above consideration, Oró *et al.*[7] first reported that it is possible to synthesize appreciable amounts of glycine and certain amino acids by heating aqueous solutions of paraformaldehyde and hydroxylamine hydrochloride at a moderate temperature [Compare 14].

Egami's hypothesis that the composition of the present sea water reflects that of the primeval sea water at the time of early evolution suggests the possibility that the abundant transition elements in sea media, such as iron, molybdenum, and zinc, might play an important role in the prebiotic amino acid synthesis.[5] In addition, these transition elements would be expected to evolve to form protoenzymes.[6] In fact, as is reported in the present paper, the possible direct formation of amino acids and the related oligomers from formaldehyde and hydroxylamine, with six species of essential transition elements and clays, was realized in modified sea mediums. It was of especial interest to ascertain the phosphatase activity in the oligomeric products. The hydrolytic activity of the oligomers (with 700 daltons as the average molecular weight) was found to be 0.409 μmol/day/mg oligopeptide by regarding the oligomers as oligopeptides. This protoenzyme-like activity is in good correlation with the consideration by Egami[6] that the zinc complex in the early stage of evolution may be regarded as a precursor of hydrolytic and transferring enzymes, including enzymes participating in the metabolism of macromolecules and information transfer.

However, attempts to find positive evidence for the existence of peptide bonds in the oligomers formed from formaldehyde and hydroxylamine were unsuccessful. It must be considerably difficult to find the peptide linkage in the crude oligomers mixture, for the oligomers would consist of various compounds of different natures, but all highly microheterogeneous. We hope that it will be elucidated by future experiments.

In the former paper of Oró *et al.*,[7] they reported that the formation of amino acids from paraformaldehyde and hydroxylamine occurred under acidic as well as basic conditions, but no measurable formation of amino acids took place between pH 3 and 6.

Contrary to their finding, in our experiments with modified sea mediums amino acid formation took place at pH 5.5. We chose the pH expecting the accumulation of oligopeptides. As can be seen in Fig. 6, although a rather long time (approximately 40 days) was required for the maximum yield of primary amino groups in the acid hydrolysate, oligomers accumulated as expected. The total yield of primary amino groups was comparable with that reported by Oró *et al.*[7]

In course of the reaction the reaction mixture gradually colored and finally gave rise to the "Golden Primordial Broth." The nature of the colored substance has not been studied, but in view of the nature of the starting materials and intermediates, it might be regarded as a melanoidin-like polymer, the important role of which in chemical evolution has recently been suggested by Nissenbaum *et al.*[15]

It is generally accepted that the origin of life took place in the primeval sea of the earth and that most of the organic substances of general biological interest accumulated in the primeval sea. Our research may be regarded as an attempt to search for the synthesis of organic compounds in modified or improved primeval sea mediums. We hope that it will not only contribute to the elucidation of chemical evolution, but will also open a new way to organic synthesis in general.

The authors are indebted to the following persons (all in the Mitsubishi-Kasei Institute of Life Sciences) for their helpful discussions: Drs. Tairo Oshima, Tsuneko Uchida, Martha Ventilla, Hiroshi Yanagawa, and Nobuyuki Wakayama. The authors also wish to express their gratitude to Miss Yoko Ogawa for her technical assistance and to Mrs. Michiko Tanaka for her amino acid analysis.

Synthesis of Ferrocene–Phenol Resins and Liberation of Iron Particles by Pyrolysis

Mamoru OMORI, Kazuo NAGASHIMA, and Seishi YAJIMA
The Oarai Branch, The Research Institute for Iron, Steel and Other Metals, Tohoku University, Oarai, Ibaraki 311-13
(Received October 15, 1976)

Ferrocene–phenol resin was synthesized from 1-ferrocenylethanol, phenol, and formaldehyde in the presence of an ammonia catalyst. The resin structure was elucidated by chemical and infrared analyses and then confirmed by micro Vickers hardness measurements. To liberate iron atoms from ferrocene skeletons, the resin was pyrolyzed *in vacuo* at 400 °C. The properties of the iron dispersed in a glasslike carbon matrix were investigated by magnetic susceptibility measurements, ESR, and Mössbauer spectroscopy. The iron atoms coagulated into ferromagnetic iron particles in the glasslike carbon matrix. This coagulation is discussed in connection with the resin structure.

In recent years considerable efforts have been made to prepare ultra-fine particles of metals and metal compounds. These ultra-fine particles have proven to be a powerful tool in the clarification of physical properties. Furthermore, various kinds of ultra-fine particles, from atoms to submicroscopic particles, provide important information about the mechanism of crystal growth. Several workers have reported methods for preparing the ultra-fine particles.[1–4] In previous papers[5,6] we reported an approach to the size control of ultra-fine iron particles dispersed in a glasslike carbon matrix prepared from acetylferrocene–furfural resins by heat treatment. However, it still remains obscure whether the formation of ultra-fine particles depends on the molecular structure of acetylferrocene–furfural resin or the dispersion of glasslike carbon.

This investigation has been undertaken to determine the relationship between the preparation of ultra-fine iron particles and the molecular structure of a resin. The acetylferrocene-furfural resin is synthesized from furfural and acetylferrocene. The ferrocene skeleton forms the main chain of this resin and is fixed in the resin structure.[7] On the other hand, the ferrocene skeleton of the side chain is not fixed in the resin structure. Such a resin (ferrocene–phenol resin) was synthesized from 1-ferrocenylethanol, phenol, and formaldehyde in the presence of an ammonia catalyst. The structure of ferrocene–phenol resin was elucidated by chemical analyses, infrared spectroscopic analyses, and micro Vickers hardness measurements. The ferrocene–phenol resin was pyrolyzed up to 400 °C *in vacuo* to liberate iron. The properties of iron particles dispersed in the glasslike carbon matrix were investigated by magnetic susceptibility measurements, ESR, and Mössbauer spectroscopy.

Experimental

Materials. Ferrocene was synthesized according to the method proposed by Hata *et al.*[8] Acetylferrocene[9] derived from ferrocene and acetic anhydride was reduced to 1-ferrocenylethanol using $LiAlH_4$.[10] The product was purified by recrystallization from hexane and sublimation *in vacuo*: mp 72—74 °C (Ref. 11, 73—75 °C). The other chemicals used were reagent grade.

Preparation of Resins. Ferrocene–phenol resin was synthesized in the presence of an alkali catalyst according to the method for the preparation of resole-type phenolic resin.[11] 30% aqueous ammonia was used as the alkali catalyst to avoid contamination with metal elements in the resin. 1-Ferrocenylethanol (0—1.0 mol), 1 mol of phenol, and 1.5 mol of formaldehyde (37% solution) were mixed in a three-necked separable flask. To this mixture was added aqueous ammonia amounting to 0.7 mol% of 1-ferrocenylethanol, phenol, and formaldehyde. The reaction mixture was vigorously stirred at 70 °C for 3 h, cooled to room temperature, and then neutralized with dilute hydrochloric acid. The water in the reaction product was removed to form oligomers under reduced pressure at 70 °C. Further, the oligomer was dried *in vacuo* at 70 °C for 24 h in order to remove the volatile materials. The yield of the oligomer was 70—80% The oligomer containing ferrocene was mixed with 10 wt % of hexamethylenetetramine and then heated in argon at 150 °C for 24 h. The yield of the ferrocene–phenol resin was 85—93%.

Pyrolysis. The ferrocene–phenol resin was pyrolyzed up to 400 °C *in vacuo*: 20—350 °C, 3h; 350—400 °C, 2.5 h. The heat-treated samples in the vacuum container were placed in a glovebox filled with argon gas. The following operations were carried out in the glovebox. The heat-treated resins were ground to a powder using an agate mortar and a pestle. The powdered sample for magnetic susceptibility measurements was put in the glass tube filled with anhydrous hexane, and then sealed with a rubber cap. For ESR spectral measurements, the powdered samples were put into a silica tube ($5\phi \times 200$ mm) and sealed with an epoxy resin. The powdered sample mixed with silicone grease was used for Mössbauer spectral measurements.

Elemental Analysis and Measurement of Properties. Iron determination was carried out with a Hitachi-207 atomic absorption spectrophotometer. IR spectra were measured with a Jasco IR-S grating spectrometer using potassium bromide disks. Micro Vickers hardness was measured with an Akashi model MVK type D instrument with a load of 200 g. The magnetic susceptibility was recorded on a Shimadzu MB-10A magnetic balance at temperatures of 77 to 293 K. Number-average molecular weights were determined by a Hitachi model-117 vapor pressure osmometer using dimethyl sulfoxide as a solvent. ESR spectra were taken on a Hitachi model 771-0061 spectrometer at 77 K. Mössbauer spectra were measured with an automechanical acceleration spectrometer at 4.2 K using a ^{57}Co-in-Cu source. All of the isomer shifts were obtained with respect to the centroid of iron metal at 293 K.

Results and Discussion

Polycondensation Reaction and Resin Structure. 1-Ferrocenylalkanols are polycondensed in the pre-

a) Phenol: 1 mol; formaldehyde: 1.5 mol. b) O=100−C−H−Fe−N.

sence of an acid and a Lewis acid. However, a base does not catalyze the polycondensation. The polycondensation reaction of aldehydes and cyclopentadienyl rings of ferrocene is catalyzed by a Lewis acid, but not by a base.[12] A resole-type oligomer is synthesized from 1 mol of phenol and 1.5 mol of formaldehyde in the presence of an alkali catalyst. Cured resole-type phenolic resins are obtained by the thermosetting of a resole-type oligomer.[11]

1-Ferrocenylethanol, phenol, and formaldehyde were polycondensed to make ferrocene–phenol oligomers, using aqueous ammonia as a catalyst. The curing of the ferrocene–phenol oligomer was not achieved in the absence of hexamethylenetetramine. The larger the amount of ferrocene skeletons in the oligomer was, the less the thermosetting reaction took place. The elemental analyses of the cured resins are shown in Table 1, together with the molar ratios of the starting materials. The nitrogen in the resin arose from hexamethylenetetramine, since no nitrogen is contained in any oligomer. The reactivities of 1-ferrocenylethanol and formaldehyde with phenol have not been investigated. Nevertheless, it is possible to estimate the reactivity and the structure of ferrocene–phenol resin from the data of elemental analyses. As shown in Table 1, the iron contents in the starting materials were less than those in resins 1 to 9. This relation was not valid for resin 10. The result of elemental analysis of resin 9 was identical with that of resin 10. Thus, the rate of reaction of 1-ferrocenylethanol and phenol was much faster than that of formaldehyde and phenol. The maximum quantity of 1-ferrocenylethanol allowed to react with phenol seemed to be restricted by a stoichiometric reaction. The stoichiometric reaction of 1-ferrocenylethanol, phenol, and formaldehyde should be an intermediate reaction between resins 8 and 9. From the elemental analysis of resins 9 and 10, the structural unit of the resin was calculated to be $C_{46}H_{47}O_3Fe_2N$. The number-average molecular weight of the oligomer of resin 9 was 650, which was close to the molecular weight of the structural unit of the resin. It was obvious that two ferrocene units ($C_{12}H_{13}Fe$) were contained in the structural unit. If three phenols (C_6H_6O) were bonded in it, four carbons and a nitrogen constituted the structure of the resins as the crosslinking unit. The above results suggest the resin structure shown in Fig. 1. The structure of the oligomer of resin 9 would be similar to this structure. On the initial step in the polycondensation reaction of the resin, 2 mol of phenol react with 2 mol of 1-ferrocenylethanol and the hydroxymethylation of phenol (1 mol) takes place. The ferrocenyl phenol (2 mol) reacts with 1 mol of the hydroxymethylated phenol to form the oligomer. The structure of the oligomer is classed as a novolac-type oligomer, because the cure reaction does not proceed sufficiently in the absence of hexamethylenetetramine.

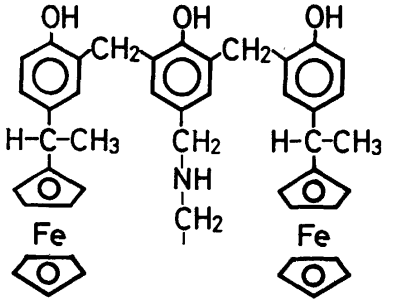

Fig. 1. The structure of ferrocene–phenol resin 9.

The amount of crosslinkage in a resin is related to its rigidity.[13] The micro Vickers hardness of resins, which is an indication of the rigidity, decreased rapidly with the increase in iron content, as shown in Fig. 2. The amount of crosslinkages in the resins decreased with an increase in the amount of ferrocene skeletons. This result indicated that the unsubstituted cyclopentadienyl ring does not take part in the formation of the main chain.

The IR spectra of ferrocene–phenol and resole-type phenolic resins are shown in Fig. 3. The absorption bands at 480, 818, 998, 1103, and 3080 cm^{-1} were assigned to ferrocene. The 480 cm^{-1} band was due to the ring metal stretching of ferrocene.[14] The

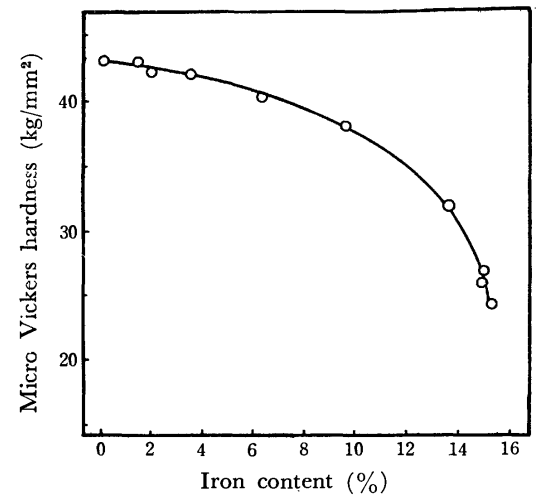

Fig. 2. Relation between micro Vickers hardness and iron contents of ferrocene-phenol resins.

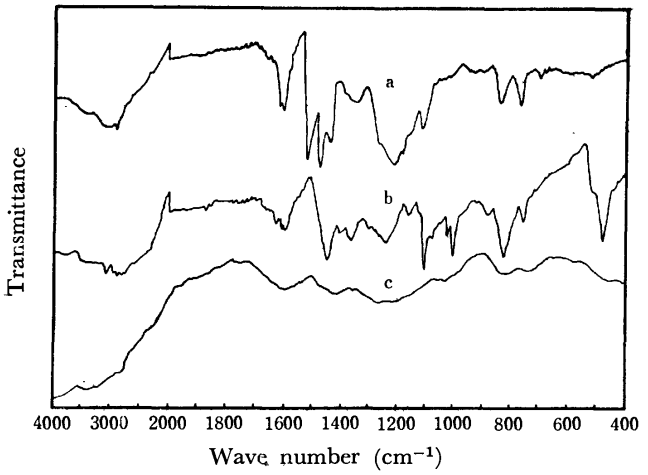

Fig. 3. IR spectra of phenolic resin and ferrocene-phenol resin, the heat-treated at 400 °C; (a) phenolic resin 11, (b) ferrocene-phenol resin 9, (c) ferrocene-phenol resin 9 heat-treated at 400 °C.

out-of-plane bending of ferrocene CH was manifested by the band at 818 cm^{-1}.[15] The presence of unsubstituted cyclopentadienyl rings was revealed by two bands at 998 and 1103 cm^{-1}.[16] The absorption band which appeared at 3080 cm^{-1} could be assigned to the stretching of ferrocenyl C–H.[14] In the IR spectrum of resole resin, the three bands at 1500—1650 cm^{-1} were assigned to the skeletal stretching mode of semi-unsaturated carbon-carbon bond. The band at 1220 cm,$^{-1}$ which was observed in both ferrocene–phenol and resole resins, corresponded to the absorption band of phenolic OH. In the IR spectrum of resole resin, two bands at 855 and 753 cm^{-1} were assigned to a 1,2,4,6-tetrasubstituted aromatic ring and a 1,2,4-trisubstituted aromatic ring, respectively. However, two bands at 753 and 874 cm^{-1} due to the 1,2,4-trisubstituted aromatic ring were strongly observed in the IR spectrum of ferrocene–phenol resin.[17] Results of IR spectral studies are in accord with the structure of ferrocene–phenol resin shown in Fig. 1.

Pyrolysis. The pyrolysis of resins was carried out by heat treatment up to 400 °C *in vacuo*. The IR spectrum of heat-treated ferrocene–phenol resin is shown in Fig. 3. All absorption bands due to ferrocene disappeared in the spectrum. This shows that the ferrocene skeleton in the ferrocene–phenol resin was destroyed, and iron was liberated by the heat treatment at 400 °C. Elemental analyses of heat-treated resins are shown in Table 2. The heat-treated resins contained carbon, hydrogen, iron, nitrogen, and oxygen. The nitrogen contents were less than those of the resins. The iron contents were 0.55—14.7%, which were close to that of acetylferrocene–furfural resin (1.00—13.2%).[5] It is well known that phenol and furan resins are converted into the hard and impervious carbon which does not contain open pores.[18] Especially, the impervious carbon prepared at 400 °C is in a completely glassy state.

a) O=100−Fe−C−H−N.

Properties of Liberated Iron Particles. The measurement of magnetization is useful in determining whether the iron particles dispersed in the glasslike carbon matrix are superparamagnetic or not. Magnetic susceptibilities of heat-treated resins 1 to 10 indicated that the iron particles were ferromagnetic. The measurement of ESR spectra was carried out for all heat-treated resins. The ESR spectra of heat-treated resins

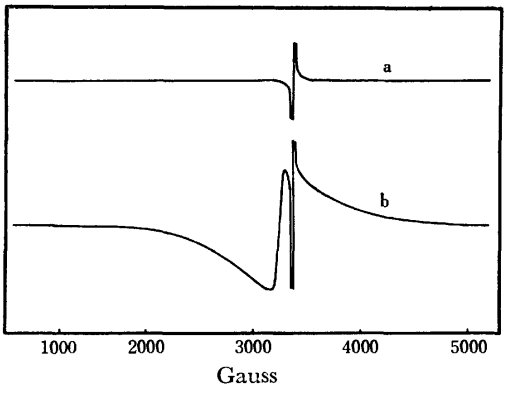

Fig. 4. ESR spectra of phenolic and ferrocene-phenol resins heat-treated at 400 °C; (a) phenolic resin 11, (b) ferrocene-phenol resin 1.

1 and 11 are shown in Fig. 4. The broad line near $g=2.09$ in resin 1 was due to the ferromagnetic resonance absorption of iron.[19] The ferromagnetic resonance absorption was common to the other heat-treated resins, 2 to 10. However, the peak intensity in the spectra increased with increase in iron contents. The sharp line at $g=2.002$, which was observed in the resins 1 and 11, corresponded to the resonance of free electrons on the carbon atom.[20] Further, the presence of ferromagnetic irons was confirmed in detail by their magnetic hyperfine splitting in the Mössbauer spectrum of the heat-treated resin 3, as shown in Fig. 5.[21] Because additional lines were not observed in the spectrum, only ferromagnetic iron was formed in the glasslike carbon matrix.

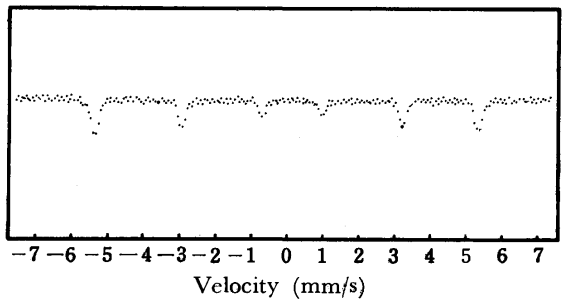

Fig. 5. Mössbauer spectrum of ferrocene–phenol resin 3 heat-treated at 400 °C.

The results of the present work lead to the following conclusions. Iron particles are formed in the glasslike carbon matrix by the heat treatment of ferrocene–phenol resins, in which the ferrocene skeleton is contained as a side chain. These iron particles are ferromagnetic and are different from the iron particles prepared from acetylferrocene–furfural resins in which the ferrocene skeleton forms the main chain of the resin. In the case of the side chain structure, the iron liberated from ferrocene skeletons is considered to coagulate to form the ferromagnetic iron because the spaces around the ferrocene skeleton are loosely surrounded by the resin structure. In this respect, it is necessary to take into account the differences between the properties of glasslike carbons prepared from ferrocene–phenol resin and acetylferrocene–furfural resin. However, these differences are considered to be small compared with the structural differences between these two resins; the details of these differences are now under investigation.

The authors would like to thank Dr. T. Shinjo, the Institute for Chemical Research, for performing the Mössbauer spectral measurements. Thanks are also due to Mr. T. Shoji and Mrs. H. Arai, Tohoku University, for their cooperation in the iron and CH analyses.

A New Method for the Preparation of δ-Alkoxy-α,β-unsaturated Aldehydes and Polyenals

Akihiko ISHIDA* and Teruaki MUKAIYAMA

Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

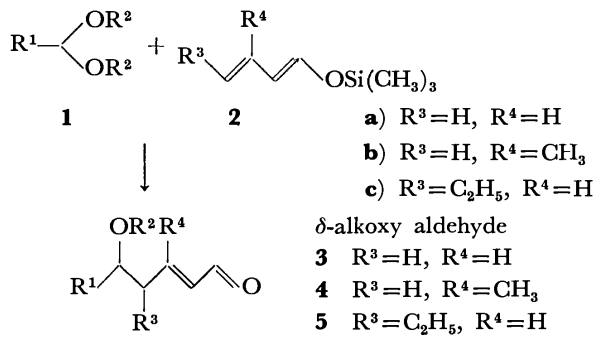
(Received October 16, 1976)

Dienoxysilanes (**2**) react with acetals in the presence of $TiCl_4$ and also in the coexistence of $TiCl_4$ and $Ti(O^iPr)_4$ to give δ-alkoxy-α,β-unsaturated aldehydes (**3**—**5**) in good yields. In the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene or 1,5-diazabicyclo[4.3.0]non-5-ene and molecular sieves 3A or 4A, the elimination reaction of δ-alkoxyl group of α,β-unsaturated aldehydes (**3**—**5**) proceeds smoothly to afford the corresponding polyenals in good yields.

In previous papers,[1,2] it was reported that the reaction of 1-trimethylsiloxy-1,3-butadiene (**2a**)[3] with various acetals (**1**) in the coexistence of $TiCl_4$ and $Ti(O^iPr)_4$ gives δ-alkoxy-α,β-unsaturated aldehydes (**3**), and that the aldehydes (**3**) are converted into polyenals by the elimination of δ-alkoxyl group with tertiary amines as 1,8-diazabicyclo[5.4.0]undec-7-ene (DUB) and 1,5-diazabicyclo[4.3.0]non-5-ene (DBN) in the presence of molecular sieves 3A and 4A. In the present paper, the preparation of δ-alkoxy-α,β-unsaturated aldehydes and polyenals is described in detail.

Results and Discussion

Preparation of δ-Alkoxy-α,β-unsaturated Aldehydes. Dienoxysilanes (**2**) reacted exclusively at their terminal sp^2 carbon atoms with acetals (**1**) activated by $TiCl_4$ to give the corresponding δ-alkoxy-α,β-unsaturated aldehydes (**3**—**5**) without the accompanying competitive products, β-alkoxy aldehydes[4] as shown in the following scheme 1.



Scheme 1.

Dienoxysilanes (**2**) are very sensitive toward $TiCl_4$ readily undergoing polymerization. When the reaction was carried out in solvents inert to $TiCl_4$, such as dichloromethane and toluene, dienoxysilanes (**2**) instantaneously afforded polymeric substance instead of the desired δ-alkoxy-α,β-unsaturated aldehydes (**3**—**5**). The difficulty was overcome by diminishing the effect of $TiCl_4$ on dienoxysilanes (**2**) by a proper choice of solvents or addition of $Ti(O^iPr)_4$. Aldehydes (**3**—**5**) were prepared according to methods A, B, and C as follows.

Method A). $TiCl_4$-THF + **1** $\xrightarrow[-78\,°C\ THF]{2}$ **3**—**5**

Method B). **1** + $TiCl_4$ + $Ti(O^iPr)_4$ $\xrightarrow[-40\,°C\ CH_2Cl_2]{2}$ **3**—**5**

Method C). $TiCl_4$ + $Ti(O^iPr)_4$ $\xrightarrow[-40\,°C\ CH_2Cl_2]{1+2}$ **3**—**5**

Method A. $TiCl_4$ formed a yellow complex with tetrahydrofuran (THF). The complex still possessed sufficient ability to activate unsaturated acetals (**1d**—**f**), the reaction proceeding smoothly at −78 °C to give the desired aldehydes (**3**—**5**) in good yields. The saturated acetals (**1a** and **1c**), however, gave unsatifactory results. The results are summarized in Table 1.

Method B. In order to moderate the activity of $TiCl_4$, $Ti(O^iPr)_4$ was added to a mixture of $TiCl_4$ and acetals (**1**) in dichloromethane at −40 °C followed by the addition of dienoxysilane (**2**). Combined use of $TiCl_4$ and

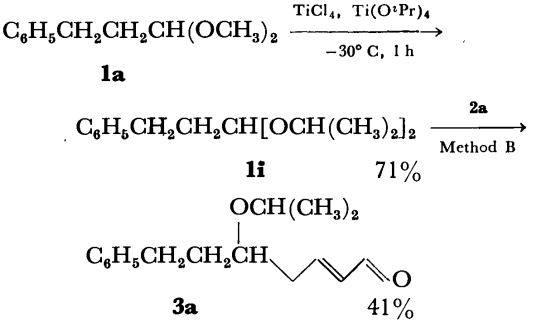
$Ti(O^iPr)_4$ enabled us to use dichloromethane as a solvent. The saturated acetals (**1a**, **c**) also gave the corresponding δ-alkoxy-α,β-unsaturated aldehydes (**3**—**5**) in good yields (Table 2). However, the δ-alkoxyl group of most products prepared according to Method B was replaced by the isopropoxyl group originated from $Ti(O^iPr)_4$. In the case of sterically blocked α- and β-cyclocitral dimethyl acetal (**1g** and **1h**), no replacement of a methoxyl group of the parent acetal by an isopropoxyl group took place, and the normal δ-methoxy aldehydes could be obtained.



3-Phenylpropionaldehyde dimethyl acetal (**1a**) was readily converted into the diisopropyl acetal (**1i**)[5] in 71% yield by treatment with a mixture of $TiCl_4$ and $Ti(O^iPr)_4$ at −30 °C for 1 h under an argon atmosphere. When the diisopropyl acetal (**1i**) was treated with dienoxysilane (**2a**) under the conditions of Method B, 5-isopropoxy-7-phenyl-2-heptenal (**3a**) was isolated only in 41% yield. The lower yield of **3a** from **1i** might indicate that the reaction according to Method B proceeded through an intermediate, monoisopropyl acetal (**6**) rather than diisopropyl acetal (**1i**).

Method C. By changing the order of addition of the reagents, the replacement of the alkoxyl groups of starting acetals (**1**) with the isopropoxyl group of $Ti(O^iPr)_4$ could be easily prevented. A mixture of dienoxysilanes (**2**) and acetals (**1**) was added to a solution of $TiCl_4$ and $Ti(O^iPr)_4$ in dichloromethane at −40 °C. Various kinds of δ-alkoxy-α,β-unsaturated aldehydes (**3**—**5**) could be obtained in satisfactory yields without exchanging the alkoxyl groups of the parent acetals during the course of reaction (Table 3).

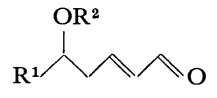
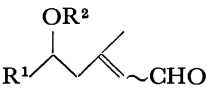
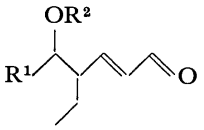
The δ-alkoxy-α,β-unsaturated aldehydes (Tables 1, 2, and 3) can be classified into three groups: i) α,β-Unsaturated aldehydes, **3**(**a**—**f**, **h**); ii) 3-Methyl-α,β-unsaturated aldehydes, **4**(**a**, **c**, **d**, **f**, **g**); iii) 4-Ethyl-α, β-unsaturated aldehydes, **5**(**c**, **d**). The configuration of each aldehyde was determined mainly on the basis of NMR spectroscopy.



3 $J_{1,2}=8$Hz
$J_{2,3}=16$Hz



4 C_3-CH_3 group
2*E* δ 2.15—2.25
2*Z* δ 1.95—2.05



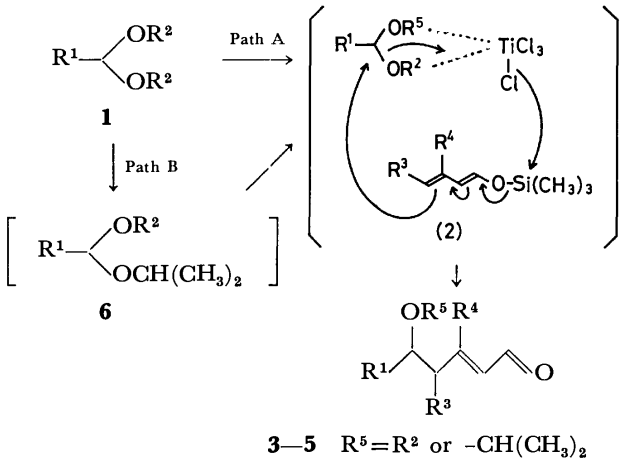
5 $J_{1,2}$=8Hz
$J_{2,3}$=16Hz

The aldehydes (**3**) of the first group were obtained as the sole product by this reaction, exhibiting peaks due to α,β-olefinic protons in the region of δ 5.00—6.10(C_2–H) and δ 6.75—6.80(C_3–H) with large coupling constants($J_{2,3}$=16 Hz), which supported the *trans* configuration of the double bonds in aldehydes (**3**).

On the other hand, the aldehydes (**4**) of the second group were mixtures of 2*E* and 2*Z* isomer(2*E* : 2*Z*=*ca.* 3—5 : 1). 3-Methyl group of 2*Z* isomers showed the signal in the region of δ 1.95—2.05 as a singlet or a doublet. In 2*E* isomers, the corresponding signal shifted to δ 2.15—2.25 as expected.[6]

The aldehydes (**5**) of the final group were found to be mixtures of *threo* and *erythro* isomers from their NMR spectra. No double bond isomer was detected. Without separation, these diasteromeric mixtures were subjected to the subsequent elimination reaction discussed later.

From the results, the reaction is assumed to proceed through a similar pathway proposed in the reaction of acetals with various nucleophiles,[7] *viz.*, the acetals (**1**) activated by $TiCl_4$ react with dienoxysilanes (**2**) to afford aldehydes (**3**—**5**) (path A of Scheme 2). The formation of δ-isopropoxy aldehydes by Method B could be explained by assuming an initial formation of monoisopropyl acetals (**6**) (path B).

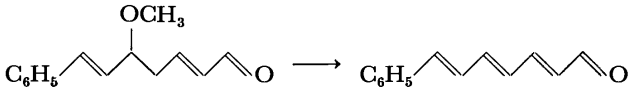


3—5 R^5=R^2 or $-CH(CH_3)_2$

Scheme 2.

Preparation of Polyenals: The conversion of δ-alkoxy-α,β-unsaturated aldehydes into polyenals was examined under acidic[8-11] and basic conditions.[12] The results obtained by use of 5-methoxy-7-phenyl-2,6-heptadienal (**3d**) as a substrate are summarized in Table 4. Besides low yields, disadvantage of the use of acids might be expected when the reaction is undertaken with 5-methoxy-5-(2,6,6-trimethyl-1-cyclohexen-1-yl)-2-pentenals (**3h**, **4h**), since a double bond of 2,6,6-trimethyl-1-cyclohexenyl group of these compounds is very labile to acids and the double bond migration takes place readily.[13]

Table 4. Yield of 7-phenyl-2,4,6-heptatrienal (**7c**)



3d **7c**

	Acid or Base	Conditions	Yield (%)
1)	*p*-TsOH–C_6H_6	refl. 5 h	46
2)	CH_3CO_2Na-CH_3CO_2H	refl. 2 h	13
3)	$BF_3 \cdot O(C_2H_5)_2$-$(CH_3CO)_2O$	−10 °C 0.5 h	26(63)[a]
4)	$BF_3 \cdot O(C_2H_5)_2$-CH_2Cl_2	−10 °C 1 h	63
5)	*t*-BuOH–THF	−10 °C 1 h	59

a) 7-Phenyl-1,1,5-triacetoxy-2,6-heptadiene is obtained as a major product and converted into **7c** in 37% yield based on **3d**.

After several experiments on the elimination under basic conditions,[2] we found that 5-methoxy-7-phenyl-2,6-hetadienal (**3d**) gives the desired trienal (**7c**) in 92% yield by treatment with 2 molar amounts of DBU or DBN in the presence of molecular sieves 3A or 4A. There is no singificant difference either between the yields of DBU and DBN, or those of molecular sieves 3A and 4A. The longer reaction time was required when the reaction was carried out in the absence of molecular sieves.

In a similar manner, various δ-alkoxy-α,β-unsaturated aldehydes can be easily converted into corresponding polyenals (**7a**—**f**). **3h** also gave 5-(2,6,6-trimethyl-1-cyclohexen-1-yl)-2,4-pentadienal (**7f**) in 78% yield without the migration of double bond. The reactions usually proceed at room temperature in a short reaction time. The results are summarized in Table 5.

Although the method is applicable to the preparation of various polyenals from δ-alkoxy-α,β-unsaturated aldehydes, the results with 3-methyl-5-alkoxy-α,β-unsaturated aldehydes (**4**) (Table 6) were unsatisfactory even after prolonged refluxing. For conversion of **4** into polyenals (**8**, **9**), 4 molar amounts of DBU and addition of CH_3CN were required.

By this procedure, 5-methoxy-3-methyl-7-phenyl-2,6-heptadienal (**4d**) gave a mixture of (2*E*,4*E*,6*E*)-3-methyl-7-phenyl-2,4,6-heptatrienal (**8b**) and its (2*Z*,4*E*,6*E*)-isomer (**9b**). **8b** and **9b** were isolated by preparative TLC in 78% and 15% yields, respectively. Their configurations were easily determined by a comparison of the chemical shift of the 3-methyl group; 2*E* isomer (**8b**) has a signal due to 3-methyl protons at δ 2.30 and 2*Z* isomer (**9b**) has the corresponding signal at δ 2.10. The NMR data are consistent with the assigned configurations.

9b can be converted into thermodynamically stable **8b** in 67% yield by treating with a catalytic amount of iodine[12] in benzene–ether (1 : 1) at room temperature for 7 h. Oxidation of **8b** with silver oxide[14] afforded (2*E*,4*E*,6*E*)-3-methyl-7-phenyl-2,4,6-heptatrienoic acid (**10a**). The melting point of the acid (**10a**) and the NMR spectrum of its methyl ester (**10b**) coincide with those reported.[15,16]

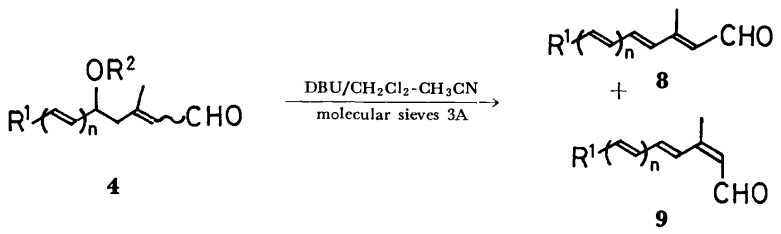
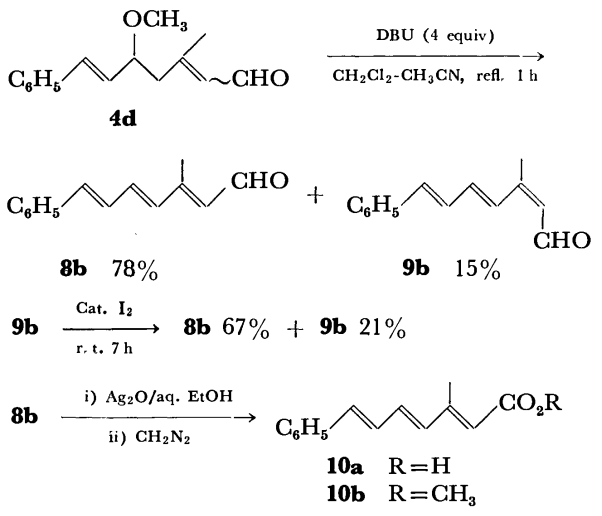
Table 6. Yield of 3-methyl polyenal



4

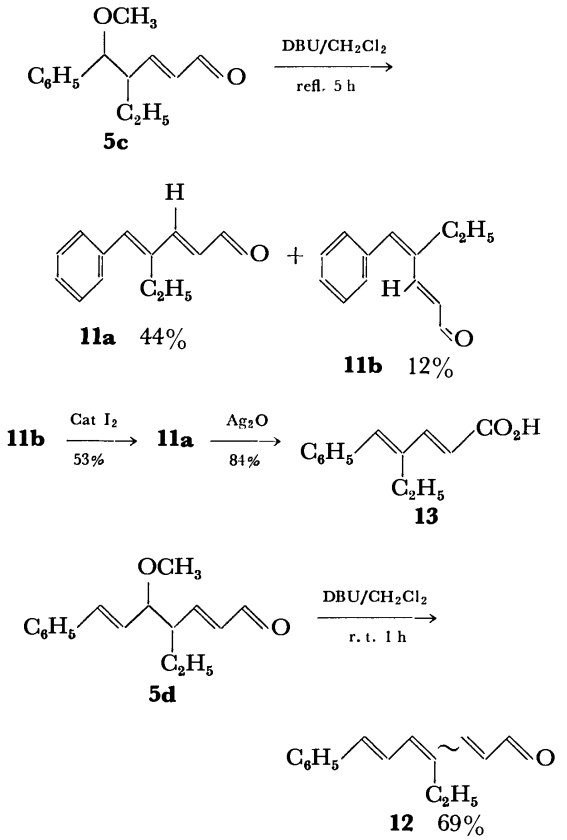
δ-Alkoxy aldehyde (4)		Conditions		Yield (%) of 8 and 9			
R^1	n	Temp	Time (h)	Product 2E		Product 2Z	
C_6H_5	0	refl.	4.0	**8a**	54	**9a**	10
C_6H_5	1	refl.	1.5	**8b**	78	**9b**	15
	0	refl.	5.0	**8c**	56	**9c**	19



Similarly, 5-methoxy-3-methyl-5-phenyl-2-pentenal (**4c**) and 5-methoxy-3-methyl-5-(2,6,6-trimethyl-1-cyclohexen-1-yl)-2-pentenal (**4h**) were converted into the corresponding polyenals **8a** and **8c** (Table 6). The product **8c** is a useful intermediate for the syntheses of vitamin A and β-carotene.[17,18]

Elimination of a methoxyl group of 4-ethyl-5-methoxy-α,β-unsaturated aldehydes (**5**) proceeded smoothly under the conditions described for compounds **3a**—**f** in Table 5, as shown in the following Scheme 3.

4-Ethyl-5-methoxy-5-phenyl-2-pentenal (**5c**) gave (2E, 4E)-dienal (**11a**) and its (2E,4Z)-isomer (**11b**) in 44% and 12% yields, respectively. The configuration of **11a** and **11b** were deduced from their NMR data. The NMR spectrum of **11a** showed a doublet centered at δ7.25 (J=16 Hz) due to the C_3-vinyl proton and a quartet centered at δ 2.57 due to methylene protons of



Scheme 3.

a 4-ethyl group, whereas the corresponding signals of **11b** appeared at δ 7.63(J=16 Hz) and δ 2.47. The differences in the chemical shifts of the corresponding signals could be produced from the anisotropic effect of the benzene ring at C-5. The data obtained are in line with the assigned stuctures.

Isomerization of **11b** by iodine also indicates that **11a** has a stable (2*E*,4*E*)-configuration. Further proof of the structure was provided by a comparision of the NMR spectrum of the dienoic acid (**13**) derived from **11a** with that of (2*E*,4*E*)-4-methyl-5-phenyl-2,4-pentadienoic acid.[19] Both spectra are almost the same except for the peaks due to 4-substituents.

Similarly, 4-ethyl-5-methoxy-7-phenyl-2,6-heptadienal (**5d**) was easily converted into the polyenal (**12**) in 69% yield at room temperature.

By a proper choice of conditions (Method A, B, or C) various δ-alkoxy-α,β-unsaturated aldehydes (**3**—**5**) can be easily synthesized in good yields by the reaction of dienoxysilanes (**2**) and acetals (**1**) activated by $TiCl_4$. Elimination of the resulting δ-alkoxy-α,β-unsaturated aldehydes was found to proceed in satiafsctory yields by the use of tertiary amines in the presence of molecular sieves 3A or 4A. The present work would provide a simple and useful route for the synthesis of polyenals.

Experimental[20]

Materials. Commercial $TiCl_4$ and $Ti(O^iPr)_4$ were distilled under an argon atmosphere before use.

*Perparation of 1-Trimethylsiloxy-1,3-butadiene (**2a**).*[3] To a solution of crotonaldehyde(8.4 g, 120 mmol) and triethylamine (12.6 g, 125 mmol) in anhydrous C_6H_6(15 ml) were added quickly anhydrous $ZnCl_2$ (120 mg), hydroquinone (200 mg), and trimethylchlorosilane(12.7 g, 125 mmol). The mixture was heated at 70 °C for 8 h in a sealed tube and quenched with aqueous $NaHCO_3$ solution at 0 °C. After filtration of undissolved substance filtrate was washed with 10% $KHSO_4$ solution and water, and dried over anhydrous Na_2SO_4. The solvent was removed and the residual oil was distilled. 1-Trimethylsiloxy-1,3-butadiene (**2a**) was obtained in 65% yield (10.4 g, bp 57—60 °C/50 Torr).

In a similar way, dienoxysilanes (**2b** and **2c**) were obtained in 70% and 65% yields, respectively. **2b**: bp 68—70 °C/40 Torr; **2c**: bp 80—83 °C/28 Torr.

*Reaction of Dienoxysilane (**2a**) with Cinnamaldehyde Dimethyl Acetal (**1d**) by Method A.* To a mixture of $TiCl_4$(3.0 mmol) and cinnamaldehyde dimethyl acetal(455 mg, 2.5 mmol) in 10 ml of dry THF was added a solution of dienoxysilane (**2a**) (426 mg, 3.0 mmol) in 4 ml of dry THF at −78 °C under an argon atmosphere. The mixture was stirred for 4 h at the same temperature and quenched with K_2CO_3 (3.0 g, in 10 ml of water). The resulting precipitate was filtered off and the filtrate was extracted with ether. The extract was washed with water, dried over anhydrous Na_2SO_4 and concentrated under reduced pressure. 5-Methoxy-7-phenyl-2,6-heptadienal (475 mg) was isolated in 88% yield by preparative TLC on silica gel developing with hexane–ethyl acetate (4 : 1). IR(neat): 1695, 1640, 1600 cm^{-1}; NMR(CCl_4): δ 9.45(1H, d, J=8 Hz, aldehyde H), 7.25(5H, s, aryl CH), 5.7—7.2(4H, m, olefinic H), 3.6—3.9(1H, br. q, C_5–H), 3.25 (3H, s, $-OCH_3$), 2.4—2.7(2H, br. t, $-CH_2-$); Found: C, 77.89; H, 7.41%. Calcd for $C_{14}H_{16}O_2$: C, 77.75; H, 7.46%.

The IR and NMR spectra of the other δ-alkoxy-α,β-unsaturated aldehydes (**3c—e**, **4d—f**, and **5d**) prepared by Method A are consistent with the assigned structures. **3c**(R^2=CH_3): bp 80 °C/0.05 Torr (bath temperature); IR(neat): 1690, 1640 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 7.30(5H, s, aryl CH), 6.80(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.05(1H, dd, J=8,16 Hz, C_2–H), 4.1—4.4(1H, br. t, C_5–H), 3.20(3H, s, $-OCH_3$), 2.45—2.80(2H, m, $-CH_2-$); Found: C, 75.91; H, 7.55%. Calcd for $C_{12}H_{14}O_2$: C, 75.76; H, 7.42%. **3d**(R^2=C_2H_5): IR(neat): 1690, 1640 cm^{-1}; NMR(CCl_4): δ 9.45(1H, d, J=8 Hz, aldehyde H), 7.30(5H, s, aryl CH), 5.8—7.5(4H, m, olefinic H), 3.7—4.1 (1H, q, C_5–H), 3.2—3.7(2H, br. q, $-OCH_2-$), 2.4—2.7(2H, br. t, $-CH_2-$), 1.20(3H, t, CH_3). **3d**(R^2=CH_2CH_2OH): IR (neat): 3430, 1690, 1640 cm^{-1}; NMR(CCl_4): δ 9.45(1H, d, J=8 Hz, aldehyde H), 7.30(5H, s, aryl CH), 5.6—7.1(4H, m, olefinic H), 3.8—4.1(1H, m, C_5–H), 3.0—3.8(5H, m, $-OCH_2CH_2OH$), 2.5—2.8(2H, $-CH_2-$). **3e**(R^2=CH_3): bp 70 °C/0.5 Torr(bath temperature); IR(neat): 1690, 1630 cm^{-1}; NMR(CCl_4): δ 9.55(1H, d, J=8 Hz, aldehyde H), 6.85(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.10(1H, dd, J=16,8 Hz, C_2–H), 5.2—5.8(2H, m, olefinic H), 3.4—3.8(1H, br. q, C_5–H), 3.20(3H, s, $-OCH_3$), 2.4—2.7(2H, t, $-CH_2-$), 1.75(3H, d, J=6 Hz, CH_3). **4d**(R^2=CH_3, a mixture of 2*E* and 2*Z* isomers): IR(neat): 1670, 1630 cm^{-1}; NMR(CCl_4): δ 10.00(1H, d, J=8 Hz, aldehyde H), 7.35(5H, s, aryl CH), 6.63(1H, d, C_7–H), 5.8—6.3(2H, br, C_6–H, C_2–H), 3.7—4.2 (1H, br. Calcd for $C_{16}H_{20}O_2$: C, 78.65; H, 8.25%.

*Reaction of Dienoxysilane (**2a**) with Cinnamaldehyde Dimethyl Acetal (**1d**) by Method B.* To a mixture of $Ti(O^iPr)_4$ (2.0 mmol) and 356 mg(2.0 mmol) of cinnamaldehyde dimetl yl acetal (**1d**) in 25 ml of CH_2Cl_2 was added $TiCl_4$ (2.3 mmol) in 1 ml of CH_2Cl_2 at -40 °C under an argon atmosphere. After stirring for a minute, dienoxysilane (**2a**, 355 mg, 2.5 mmol in 4 ml of CH_2Cl_2) was added to the mixture. The mixture was kept at -40 °C for 30 min, quenched with K_2CO_3 (2 g in 10 ml of H_2O) and worked up in the usual way. 5-Isopropoxy-7-phenyl-2,6-heptadienal(441 mg) was isolated in 90 % yield by preparative TLC on silica gel developing with hexane–ethyl acetate(4 : 1). IR(neat): 1690, 1640, 1600 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 7.30(5H, s, aryl CH), 5.8—7.2(4H, m, olefinic H), 3.4—4.3 (2H, m, $-OCH<$, C_5–H), 2.4—2.8(2H, m, $-CH_2-$), 1.15(6H, d, $2\times CH_3$).

The IR and NMR spectra of other δ-alkoxy-α,β-unsaturated aldehydes (**3a**—**h** and **4a**—**h**) prepared by Method B are consistent with the assigned structures. **3a** (R^2=*i*-pr): IR (neat): 1690, 1630, 1600 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 7.20(5H, s, aryl CH), 6.80(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.05(1H, dd, J=16, 8 Hz, C_2–H), 3.2 —3.8(2H, m, $2\times$–O–CH<), 2.2—2.8(4H, m, $-CH_2-$), 1.5—1.9(2H, m, $-CH_2-$), 1.10(6H, d, $2\times CH_3$). **3b**(R^2=*i*-pr): bp 140 °C/0.2 Torr (bath temperature); IR(neat); 1680, 1625 cm^{-1}; NMR(CCl_4); δ 9.55(1H, d, J=8 Hz, aldehyde H), 6.80 (1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.05(1H, dd, J=16, 8 Hz, C_2–H), 3.2—3.8(2H, m, $2\times$–O–CH<), 2.3—2.7(2H, m, $-CH_2-$), 0.7—1.6(17H); Found: C, 73.23; H, 11.35%. Calcd for $C_{13}H_{24}O_2$: C, 73.53; H, 11.39%. **3c**(R^2=*i*-pr): IR(neat): 1695, 1640 cm^{-1}; NMR(CCl_4): δ 9.45(1H, d, J=8 Hz, aldehyde H), 7.30(5H, s, aryl CH), 6.80(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.00(1H, dd, J=16, 8 Hz, C_2–H), 4.2 —4.65 (1H, m, C_5–H), 3.3—3.7 (1H, m, $-OCH<$), 2.5—2.8 (2H, $-CH_2-$), 1.00—1.30(6H, $2\times CH_3$). **3h**(R^2=CH_3): IR (neat); 1690, 1635 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 6.85(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.05 (1H, dd, J=16, 8 Hz, C_5–H), 3.15(3H, s, $-OCH_3$), 1.75(3H, s, C=C–CH_3), 0.95—1.00(6H, 2s, $2\times CH_3$), 1.20—2.90(7H, aliphatic H), **4a**(R^2=*i*-pr, a mixture of 2*E* and 2*Z* isomers): IR(neat): 1680, 1630, 1600 cm^{-1}; NMR(CCl_4): δ 9.90(1H, d, J=8 Hz, aldehyde H), 7.15(5H, s, aryl CH), 5.7—6.0(1H, br. d, C_2–H), 3.25—3.8(2H, m, $2\times$–O–CH<), 1.5—3.0(5H, m, aliphatic H), 1.10(6H, d, $2\times CH_3$), 2.15(s, 2*E*, C_3–CH_3), 1.95(s, 2*Z*, C_3–CH_3). **4g**(R^2=CH_3): 2*E* isomer: IR(neat): 1680, 1625 cm^{-1}; NMR(CCl_4); δ 9.95(1H, d, J=8 Hz, aldehyde H), 5.6—5.9(1H, br. d, C_2–H), 5.2—5.9(1H, br, olefinic H), 3.0—3.3(1H, br, C_5–H), 3.25(3H, s, $-OCH_3$), 1.75 (3H, s, C=C–CH_3), 1.00, 0.85(6H, 2s, $2\times CH_3$), 0.5—2.5(7H, aliphatic H), 2.20(3H, s, C_3–CH_3). 2*Z* isomer: IR(neat): 1680, 1625 cm^{-1}; NMR(CCl_4): δ 9.90(1H, d, J=8 Hz, aldehyde H), 5.65—5.95(1H, br. d, C_2–H), 5.3—5.6(1H, br, olefinic H), 3.25(3H, s, $-OCH_3$), 2.00(3H, s, C_3–CH_3), 1.75 (3H, s, C=C–CH_3), 1.05, 0.90(6H, 2s, $2\times CH_3$).

*Reaction of Dienoxysilane(**1a**) with 3-Phenylpropionaldehyde Dimethyl Acetal (**1a**) by Method C.* To a stirred solution of $TiCl_4$(1.5 mmol) and $Ti(O^iPr)_4$ (1.5 mmol) in 10 ml of CH_2Cl_2 was added a solution of 3-phenylpropionaldehyde dimethyl acetal(180 mg, 1.0 mmol) and dienoxysilane (**2a** 170 mg, 1.2 mmol) in 5 ml of CH_2Cl_2 at -40 °C under an argon atmosphere. After being stirred for 30 min at the same temperature, the mixture was quenched with K_2CO_3 (1.5 g in 10 ml of H_2O), and the resulting precipitate was filtered off. The filtrate was extracted with ether and the resulting solution was dried over anhydrous Na_2SO_4. After removal of the solvent, the residual oil was chromatographed on silica gel developing with hexane–ethyl acetate(4 : 1) to give 5-methoxy-7-phenyl-2-heptenal (112 mg) in 51% yield. IR(neat): 1690, 1640, 1600 cm^{-1}; NMR(CCl_4): δ 9.55(1H, d, J=8 Hz, aldehyde H), 7.20(5H, s, aryl CH), 6.80(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.05(1H, dd, J=16, 8 Hz, C_2–H), 3.35(3H, s, $-OCH_3$), 3.0—3.4(1H, br, C_5–H), 2.3—2.9(4H, m, $-CH_2-$), 1.5—2.0(2H, m, $-CH_2-$).

2,4-Dinitrophenylhydrazone: mp 123—124 °C; Found: C, 60.29; H, 5.57; N, 14.06%. Calcd for $C_{20}H_{22}O_5N_4$: C, 60.06; H, 5.76; N, 13.96%.

The IR and NMR spectra of other δ-alkoxy-α,β-unsaturated aldehydes (**3a**—**h**, **4c**—**h** and **5c**—**d**), prepared by Method C are consistent with the assigned structures. **3a**(R^2=C_2H_5): IR (neat): 1685, 1630, 1600 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 7.20(5H, s, aryl CH), 6.75(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.00(1H, dd, J=16, 8 Hz, C_2–H), 3.2 —3.7(3H, m, $-OCH_2-$, C_5–H), 2.3—2.9(4H, m, $-CH_2-$), 1.5 —2.0(2H, m, $-CH_2-$), 1.20(3H, t, $-CH_3$). **3b**(R^2=CH_3): bp 125 °C/0.1 Torr(bath temperature); IR(neat): 1695, 1640 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 6.80(1H, ddd, J=16, 8, 8 Hz, C_3–H), 6.05(1H, dd, J=16, 8 Hz, C_2–H), 3.30(3H, s, $-OCH_3$), 3.1—3.5(1H, br, C_5–H), 2.4 —2.7(2H, m, $-CH_2-$), 0.7—1.6(11H); Found: C, 71.84; H, 11.18%. *Conversion of 3-Phenylpropionaldehyde Dimethyl Acetal (**1a**) into Diisopropyl Acetal (**1i**) in the Presence of $TiCl_4$ and $Ti(O^iPr)_4$*[4]. To a mixture of 3-phenylpropionaldehyde dimethyl acetal (360 mg, 2.0 mmol) and $Ti(O^iPr)_4$ (2.0 mmol) in 25 ml of CH_2Cl_2 was added a solution of $TiCl_4$(2.4 mmol) in 5 ml of CH_2Cl_2 at −30 °C under an argon atmosphere. The mixture was stirred for 1 h and quenched with K_2CO_3(2 g in 10 ml of water). The precipitate was filtered off and the filtrate was extracted with ether. The extract was washed with water and dried over anhydrous Na_2SO_4. After removal of the solvent, the resulting oil was distilled. 3-Phenyl propionaldehyde diisopropyl acetal(335 mg) was obtained in 71% yield. bp 135 °C/11 Torr; NMR(CCl_4): δ 7.25(5H, s, aryl CH), 4.6(1H, t, $-CH\langle^{O-}_{O-}\rangle$), 3.7—4.1(1H, m, 2×$-OCH\langle$), 2.6—2.9, 1.7—2.2(4H, m, $-CH_2-$), 1.12, 1.22(12H, 2d, 4×CH_3). The IR and NMR spectra of this diisopropyl acetal (**1i**) are identical with those of the sample prepared from 3-phenylpropionaldehyde and isopropyl alcohol according to the method of Roelofsen and Bekkum.[5]

*Conversion of 5-Methoxy-7-phenyl-2,6-heptadienal (**3d**) into 7-Phenyl-2,4,6-heptatrienal (**7c**) under Acidic and Basic Conditions.* p-*TsOH–C_6H_6*: A solution of **3d** (108 mg, 0.5 mmol) and *p*-toluensulfonic acid(5 mg) in 10 ml of abs. C_6H_6 was refluxed for 3 h under an agron atmosphere. The C_6H_6 solution was washed with 10% $NaHCO_3$ solution and water, dried over anhydrous Na_2SO_4 and concentrated under reduced pressure. The resulting solid was chromatographed on silica gel and eluted with hexane–ethyl acetate(4 : 1) to afford **7c**(42 mg) in 46% yield. IR(KBr): 1670, 1605, 1595 cm^{-1}; NMR (CCl_4): δ 9.55(1H, d, J=8 Hz, aldehyde H), 7.35(5H, s, aryl CH), 6.4—7.5(5H, m, olefinic H), 6.15(1H, dd, J=8,16 Hz, C_2–H).

AcONa–AcOH: A solution of **3d**(108 mg, 0.5 mmol) and sodium acetate(30 mg) in 1 ml of acetic acid was refluxed for 2 h under an argon atmosphere. The reaction mixture was poured into 10% $NaHCO_3$ solution at 0 °C and extracted with ether. After being worked up in the usual way, **7c**(12 mg) was obtained in 13% yield.

$BF_3\cdot O(C_2H_5)_2$–Ac_2O: To a solution of **3d**(216 mg, 1 mmol) in 1 ml of acetic anhydride was added one drop of $BF_3\cdot O(C_2H_5)_2$ at −10 °C under an argon atmosphere. The mixture was stirred for 0.5 h at −10 °C, poured into ice cold water and extracted with ether. The extract was washed with 10% $NaHCO_3$ solution and water, dried and worked up in the usual way. **7c**(48 mg) and 7-phenyl-1,1,5-triacetoxy-2,6-heptadiene(150 mg) were obtained in 26% and 43% yields, respectively. 7-Phenyl-1,1,5-triacetoxy-2,6-heptadiene: IR (neat), 1760, 1740, 1600, 1240, 1200 cm^{-1}; NMR(CCl_4): δ 7.20(5H, s, aryl CH), 5.2—7.5(6H), 2.3—2.6(2H, $-CH_2-$), 2.00(9H, s, 3×$-COCH_3$). A mixture of the above triacetate (150 mg) in 3 ml of CH_3OH and 20% KOH solution(0.5 ml) was stirred for 15 h at room temperature under an argon atmosphere. After removal of CH_3OH, the residual aqueous solution was neutralized with dil. HCl and extracted with ether. The ether layer was washed with water, dried over anhydrous Na_2SO_4 and concentrated under reduced pressure. Another crop of crystals, **7c**(68 mg), was obtained in 37% yield based on **3d**, the total yield of **7c** being 63%.

$BF_3\cdot O(C_2H_5)_2$–CH_2Cl_2: To a solution of **3d** (108 mg, 0.5 mmol) in 3 ml of CH_2Cl_2 was added a solution of $BF_3\cdot O(C_2H_5)_2$ (1 mmol) in 2 ml of CH_2Cl_2 at −10 °C under an argon atmosphere. The mixture was stirred for 1 h and quenched with 10% K_2CO_3 solution. After the usual work up, **7c** (58 mg) was isolated in 63% yield.

t-*BuOK–THF*: To a solution of *t*-BuOK (125 mg, 1.1 mmol) in 5 ml of dry THF was added a solution of **3d** (108 mg, 0.5 mmol) in 3 ml of dry THF at −10 °C under an argon atmosphere. The mixture was stirred for 1 h at −10 °C and poured into ice cold water containing hydrochloric acid. After being worked up in the usual way, **7c** (54 mg) was obtained in 59% yield.

*Conversion of 5-Methoxy-7-phenyl-2,6-heptadienal(**3d**) to 7-Phenyl-2,4,6-heptatrienal (**7c**) with DBU.* To a solution of 5-methoxy-7-phenyl-2,6-heptadienal(350 mg, 1.6 mmol) in 10 ml of CH_2Cl_2 were added a solution of DBU(492 mg, 3.2 mmol) in 5 ml of CH_2Cl_2 and molecular sieves 3A(500 mg) at room temperature under an argon atmosphere. The mixture was stirred for 1 h and poured into ice cold brine containing acetic acid. The organic layer was separated, washed with brine and dried over anhydrous Na_2SO_4. After removal of the solvent, the residual solid was chromatographed on silica gel and eluted with hexane–ethyl acetate(4 : 1) to afford 274 mg of 7-phenyl-2,4,6-heptatrienal(**7c**) in 92% yield. mp 114—115 °C, (lit,[21] mp 116 °C).

The IR, UV, and NMR spectra of polyenals(**7a**—**f**) are consistent with the assigned structures: **7a**: bp 70 °C/0.5 Torr(bath temperature), (lit,[22] bp 70 °C/0.7 Torr); IR(neat): 1680, 1610 cm^{-1}; NMR(CCl_4): δ 9.50(1H, d, J=8 Hz, aldehyde H), 5.8—7.3(6H, m, olefinic H), 2.0—2.5(2H, m, $-CH_2-$), 1.2—1.7(2H, m, $-CH_2-$), 0.8—1.2(3H). **7b**: mp 39—41 °C(lit,[23] mp 37—39 °C); IR(KBr): 1670, 1615 cm^{-1}; NMR(CCl_4): δ 9.60(1H, d, J=8 Hz, aldehyde H), 7.35(5H, s, aryl CH), 5.9—7.4(4H, m, olefinic H). **7d**: mp 141—142 °C(lit,[24] mp 139—141 °C); IR(Nujol): 1680, 1595, 1560 cm^{-1}; NMR(d_6-DMSO): δ 9.55(1H, d, J=8 Hz, aldehyde H), 7.35(5H, s, aryl CH), 6.4—7.4(7H, m, olefinic H), 6.10 (1H, dd, J=8,16 Hz, C_2–H); UV λ_{max}^{EtOH} 382 nm(ε 5.6×10⁴), 275 nm(ε 1.1×10⁴); Mass: *m/e* 210(M^+). **7e**: mp 185—186 °C(lit,[25] mp 183 °C); IR(KBr): 1660, 1600, 1560 cm^{-1}; UV λ_{max}^{EtOH} 406 nm(ε 7.49×10⁴), 295 nm(ε 1.49×10⁴); Mass: *m/e* 236 (M^+). **7f**: IR(neat): 1680, 1610 cm^{-1}; NMR (CCl_4): δ 9.55(1H, d, J=8 Hz, aldehyde H), 5.85—7.30 (4H, m, olefinic H), 1.75(3H, s, C=C–CH_3), 1.05(6H, s, 2×CH_3), 0.9—2.4(6H, aliphatic H).

*Conversion of 5-Methoxy-3-methyl-7-phenyl-2,6-heptadienal (**4d**) to 3-Methyl-7-phenyl-2,4,6-heptatrienal with DBU.* To a solution of 5-methoxy-3-methyl-7-phenyl-2,6-heptatrienal (450 mg, 1.96 mmol) in 8 ml of CH_2Cl_2 were added a solution of DBU(1.0 g) in 8 ml of CH_3CN and molecular sieves 3A (1.0 g) under an argon atmosphere. The mixture was refluxed for 1.5 h and poured into ice cold brine containing acetic acid, and worked up in the usual way. After separation by preparative TLC on silica gel [hexane–ethyl acetate(4 : 1)], (2*E*, 4*E*,6*E*)-3-methyl-7-phenyl-2,4,6-heptatrienal (**8b**) (303 mg) and (2*Z*,4*E*,6*E*)-isomer (**9b**) (58 mg) were obtained in 78% and 15% yields, respectively. **8b**: mp 76—77 °C; IR (Nujol) 1650, 1600, 1580 cm^{-1}; NMR($CDCl_3$): δ 10.15(1H, d, J= 8 Hz, aldehyde H), 6.4—7.7(9H, aryl CH, olefinic H), 6.00 (1H, d, C_2–H), 2.30(3H, s, CH_3); Found: C, 85.06; H, 7.19%. Calcd for $C_{14}H_{14}O$: C, 84.81; H, 7.12%. **9b**: IR(neat): 1650, 1600, 1580 cm^{-1}; NMR($CDCl_3$): δ 10.20 (1H, d, J=8 Hz, aldehyde H), 6.4—7.6(9H, aryl CH, olefinic H), 5.90(1H, d, C_2–H), 2.15(3H, s, CH_3).

The IR and NMR spectra of other 3-methyl polyenals (**8a**—**c** and **9a**—**c**) are consistent with the assigned structures. **8a**: IR(neat): 1660, 1615, 1590 cm^{-1}; NMR($CDCl_3$): δ 10.23(1H, d, J=8 Hz, aldehyde H), 6.99—7.80(7H, m, aryl CH, olefinic H), 6.11(1H, d, J=8 Hz, C_2–H), 2.37(3H, s, C_3–CH_3). **9a**: NMR($CDCl_3$): δ 10.33(1H, d, J=8 Hz, aldehyde H), 7.1—7.8(7H, m,) 5.98(1H, d, J=8 Hz, C_2–H), 2.21 (3H, s, C_3–CH_3). **8c**: IR(neat): 1660, 1600 cm^{-1}; NMR (CCl_4); δ 10.20(1H, d, J=8 Hz, aldehyde H), 6.10, 6.65 (2H, 2d, J=16 Hz, C_4–H, C_5–H), 5.85(1H, d, J=8 Hz, C_2–

H), 2.30(3H, s, C_3-CH_3), 1.70(3H, s, C=C-CH_3), 1.50—2.20 (6H, aliphatic CH_2), 1.05(6H, s, 2×CH_3). **9c**: IR(neat): 1670, 1610 cm^{-1}; NMR(CCl_4): δ 10.15(1H, d, J=8 Hz, aldehyde H), 6.50, 7.10(2H, 2d, J=16 Hz, C_4-H, C_5-H), 5.75(1H, d, J=8 Hz, C_2-H), 2.10(3H, s, C_3-CH_3), 1.75(3H, s, C=C-CH_3), 1.50—2.20(6H, aliphatic H), 1.05(6H, s, 2×CH_3).

*Conversion of 4-Ethyl-5-methoxy-5-phenyl-2-pentenal (**5c**) to 4-Ethyl-5-phenyl-2,4-pentadienal (**11**) with DBU.* To a solution of 4-ethyl-5-methoxy-5-phenyl-2-pentenal(218 mg, 1 mmol) in CH_2Cl_2 (5 ml) were added a solution of DBU (304 mg, 2 mmol) in CH_2Cl_2 (5 ml) and molecular sieves 3A (500 mg) under an argon atmosphere. The mixture was refluxed for 5 h and the solvent was removed at 20 °C under reduced pressure. The residual oil was chromatographed on silica gel using hexane–ethyl acetate(8 : 1) as an eluent. (2*E*,4*E*)-4-Ethyl-5-phenyl-2,4-pentadienal (**11a**) (82 mg) and (2*E*, 4*Z*) isomer (**11b**) (23 mg) were obtained in 44% and 12% yields, respectively. **11a**: IR(neat): 1680, 1600 cm^{-1}; NMR($CDCl_3$): δ 9.75(1H, d, J=8 Hz, aldehyde H), 7.24(5H, s, aryl CH), 7.25(1H, d, J=16 Hz, C_3-H), 6.93(1H, s, C_5-H), 6.38 (1H, dd, J=16, 8 Hz, C_2-H), 2.57(2H, q, -CH_2-), 1.21(3H, t, CH_3). **11b**: IR(neat): 1680, 1610 cm^{-1}; NMR($CDCl_3$): δ 9.76(1H, d, J=8 Hz, aldehyde H), 7.38(5H, s, aryl CH), 7.63(1H, d, J=16 Hz, C_3-H), 6.93(1H, s, C_5-H), 6.35(1H, dd, J=16,8 Hz, C_2-H), 2.47(2H, q, -CH_2-), 1.20(3H, t, CH_3).

4-Ethyl-5-methoxy-7-phenyl-2,6-heptadienal (**5d**) was convered into 4-ethyl-7-phenyl-2,4,6-heptatrienal (**12**) in 69% yield by treating with DBU(4 equiv) at room temperature for 1 h. **12**: mp 93—94 °C: IR(Nujol): 1660, 1600, 1580 cm^{-1}; NMR($CDCl_3$): δ 9.75(1H, d, J=8 Hz, aldehyde H), 5.5—7.7(9H, aryl CH, olefinic H), 6.25(1H, dd, J=8, 16 Hz, C_2-H), 2.52(2H, q, -CH_2-), 1.12(3H, t, CH_3). Found: C, 84.97; H, 7.65%. Calcd for $C_{15}H_{16}O$: C, 84.87; H, 7.60%.

*Isomerization of (2Z,4E,6E)-3-Methyl-7-phenyl-2,4,6-heptatrienal(**9b**) to (2E,4E,6E)-3-Methyl-7-pehnyl-2,4,6-heptatrienal (**8b**) with Iodine.* A solution of (2*E*,4*Z*,6*E*)-3-methyl-7-phenyl-2,4,6-heptatrienal (106 mg) in 10 ml of abs. C_6H_6–ether(1 : 1) was treated with a catalytic amount of iodine at room temperature under an argon atmosphere. After stirring for 7 h, the reaction mixture was washed with aqueous $Na_2S_2O_3$ solution and dried over anhydrous Na_2SO_4. The solvent was removed and the crystalline residue was chromatographed on silica gel and eluted with hexane–ethyl acetate (4 : 1) to afford 71 mg of **8b** and 21 mg of **9b** in 67% and 21% yields, respectively.

(2*E*,4*Z*)-4-Ethyl-5-phenyl-2,4-pentadienal (**11a**) and the recovered (2*E*,4*Z*)-isomer(**11b**) were obtained in 53% and 14% yields, respectively, by treating (2*E*,4*Z*)-isomer(**11b**) with iodine under similar conditions.

*Oxidation of (2E,4E,6E)-3-Methyl-7-phenyl-2,4,6-heptatrienal (**8b**) to (2E,4E,6E)-3-Methyl-7-phenyl-2,4,6-heptatrienoic Acid (**10a**).* To a solution of silver nitrate(123 mg, 0.72 mmol) in 1.5 ml of water were added a solution of (2*E*,4*E*,6*E*)-3-methyl-7-phenyl-2,4,6-heptatrienal(120 mg, *ca.* 0.6 mmol) in ethanol(2.5 ml) and NaOH(112 mg in 1.5 ml of water). The mixture was stirred for 15 h at room temperature in the dark and the precipitate was filtered off. Ethanol was removed under reduced pressure. The residual aqueous solution was acidified with dil. HCl and extracted with ethyl acetate. (2*E*,4*E*,6*E*)-3-Methyl-7-phenyl-2,4,6-heptatrienoic acid (**10a**) (116 mg) was obtained in 89% yield. mp 201—203 °C, (lit,[15] mp 203 °C); IR(Nujol): 1660, 1590 cm^{-1}; NMR($CDCl_3$): δ 6.27—7.6(10H), 5.88(1H, br. s, C_2-H), 2.35(3H, s, C_3-CH_3); UV λ_{max}^{EtOH} 329 nm(ε 6.0×10^4), 242 nm(ε 1.0×10^4).

Acid (**10a**) was converted into the corresponding methyl ester (**10b**) in 90% yield according to the method of Wiley *et al.*,[16] **10b**: mp 56—57 °C; IR(Nujol): 1700, 1600 cm^{-1}; NMR(CCl_4): δ 7.26(5H, br. s, aryl CH), 6.3—6.9(4H, olefinic H), 5.72(1H, br. s, C_2-H), 3.60(3H, s, -OCH_3), 2.29 (3H, s, C_3-CH_3); UV λ_{max}^{MeOH} 336 nm(ε 5.06×10^4), 245 nm(ε 9.66×10^3).

Similarly, (2*E*,4*E*)-4-ethyl-5-phenyl-2,4-pentadienoic acid (**13**) was obtained in 84% yield by treating with silver oxide in the dark. **13**: mp 98—99 °C; IR(KBr): 1670, 1600 cm^{-1}; UV λ_{max}^{hexane} 302 nm(ε 2.76×10^4), 225 nm(ε 6.65×10^3); NMR($CDCl_3$): δ 10.56(1H, br. -CO_2H), 7.56(1H, d, J= 16 Hz, C_3-H), 7.41(5H, s, aryl CH), 6.87(1H, s, C_5-H), 6.06 (1H, d, J=16 Hz, C_2-H), 2.55(2H, q, -CH_2-), 1.21(3H, t, CH_3); Found: C, 71.75; H, 6.37%. Calcd for $C_{13}H_{14}O_2$: C, 71.54; H, 6.47%.

Photochemical Reactions of 4-Flavanols in the Presence of Ketone Sensitizers

Morio SUZUKI, Jiro AMANO, Motonobu MORIOKA, Hideo MIZUNO, and Ryoka MATSUSHIMA*

Department of Industrial Chemistry, Faculty of Engineering, Shizuoka University, Hamamatsu 432

(Received October 18, 1976)

Irradiation of an oxygen-free benzene solution of *cis*-4-flavanol **1a** by a mercury lamp in the presence of benzophenone gave 4-flavanone (32%), benzopinacol (85%), *cis*- and *trans*-2-(diphenylhydroxymethyl)-4-flavanols (7.6%), and 2-(diphenylhydroxymethyl)-4-flavanone (7.7%), whereas photolysis of *cis*-4-acetoxyflavane under similar conditions gave *cis*-2-(diphenylhydroxymethyl)-4-acetoxyflavane(24%), 2,2′-bi-4-acetoxyflavane (6%), and benzopinacol. Photolysis of **1a** in acetone gave 4-flavanone (3.6%), *trans*-4-(1-hydroxy-1-methylethyl)-4-flavanols (9.9%). The *cis* isomers of the parent and substituted 4-flavanols showed higher reactivities than the corresponding *trans* isomers.

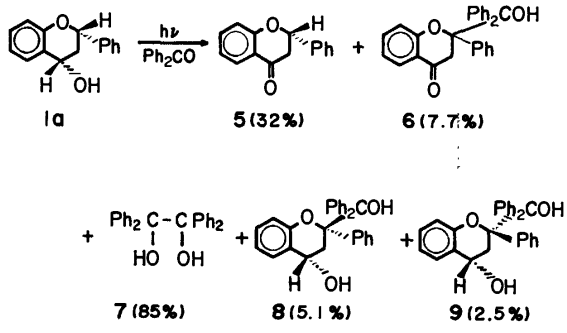
For epimeric cycloalkanols, significant structural effects on oxidation rates are known.[1,2] Significant rate ratios, *cis*/*trans*=3.3—12, have been reported for the oxidation of a series of *cis* and *trans* substituted 4-chromanols with chromic acid,[3] and the observed ratio has been attributed to the stereoelectronic effect[1] and the strain relaxation of the chromate esters of the substrates.

The present work was undertaken to determine the structural effects on the photoreactions of 4-flavanols with ketones. It has been assumed that the hydrogen atom at the 4-position on the dihydropyrane ring is quasi-axial for the *cis* isomer **1a** and quasi-equatorial for the *trans* isomer **1b**, while the hydrogen atom at the 2-position is axial for both isomers.[4,5] The rates of the photoreactions of these isomeric substrates with ketones are expected to depend on the respective structures. It was observed, however, that not only the rate, but also the course of the photoreaction, changed remarkably with changes in the structures of the 4-flavanols and ketones.

Results and Discussion

*Photoreactions of **1a** and **1b** with Benzophenone.*

A deaerated benzene solution of *cis*-4-flavanol **1a** (0.02 M) containing benzophenone (0.02 M) gave 4-flavanone **5**, 2-(diphenylhydroxymethyl)-flavanone **6**, benzopinacol **7**, and *cis*- and *trans*-2-(diphenylhydroxymethyl)-4-flavanols **8** and **9**, upon irradiation



Scheme 1. Photolysis of **1a** with benzophenone.

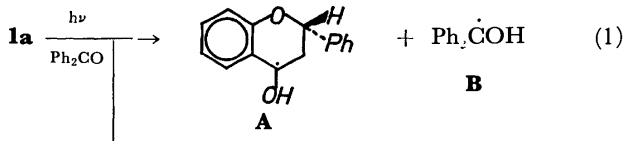
TABLE 1. MAIN PRODUCTS AND THEIR YIELDS IN THE PHOTOREACTIONS OF **1a** AND **1b** WITH BENZOPHENONE

Substrate	Product, %		Recovery, %	
	5	**7**	Substrate	Benzophenone
1a	32	85	40[a]	trace
1b	15	60	53[a]	20

a) No epimerization product (*via* inversion at the 4-position) was detected.

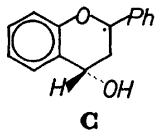
with a 100 W high-pressure mercury lamp for 100 min (Scheme 1). The NMR signal of the proton at the 3-position of **6** showed a singlet at δ=3.49 ppm. This suggests rapid inversion of the carbon at the 2-position of the dihydropyrane ring of **6**. Photolysis of *trans*-4-flavanol **1b** under similar conditions gave **5** and **7** as the main products, but the rate or the yields were significantly lower than those for **1a** (Table 1).

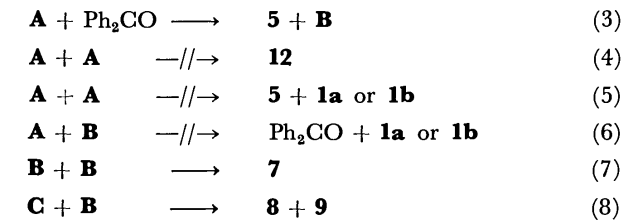
In the recovered 4-flavanol resulting from the irradiation of **1a** and benzophenone, no epimerized product, **1b**, was detected, nor was any pinacol-type dimer, 4,4′-bi-4-flavanol, **12**. The lack of the formation of **12** is not necessarily due to the steric hinderance of the coupling of the 4-(4-hydroxyflavanyl) radical, **A**, since **12** can be formed as the main product in the photoreaction of **1a** with acetone, as is shown below (Scheme 4). The lack of formation of **12** (4) and **1b** (5, 6), may imply that radical **A** rapidly reacts with ground state benzophenone to give benzophenone ketyl radical **B** (3), before coupling and disproportionation or reaction with **B** (4—6). The benzophenone ketyl radical, which is stabilized by two phenyl groups, is assumed to be more stable than radical **A**, which is stabilized by only one phenyl group. Hence, radical **A** could transfer a hydrogen atom from its oxygen atom to a ground-state benzophenone molecule, thus producing a benzophenone ketyl radical and a molecule of flavanone (3), as is proposed for the photochemical reduction of aliphatic alcohols with benzophenone. On the other hand, the formation of a small amount of the cross coupling products, **8** and **9**, may imply the intermediacy of the 2-(4-hydroxyflavanyl) radical, **C** (2). This radical would combine with **B** giving an epimeric mixture, **8** and **9** (8).



(1)

(2)

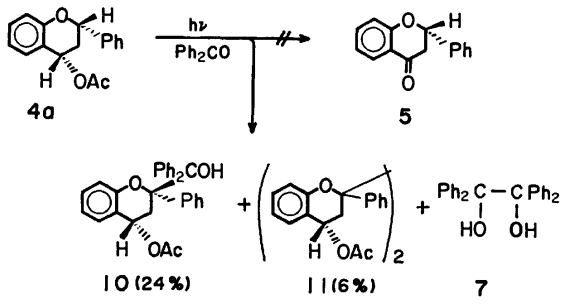




Scheme 2. Photolysis of **1a** and benzophenone.

Product **6** may be formed by further photoreaction of **5**, **8**, or **9**. However, it seems likely that the main source of **6** is **5**, since the yields of **8** and **9** are low and photolysis of **5** and benzophenone actually gave **6** under similar conditions.

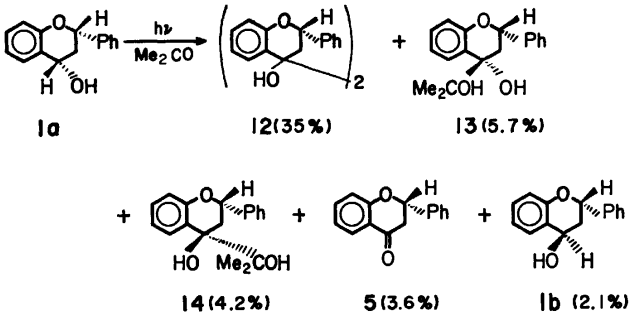
*Photoreaction of **4a** with Benzophenone.* Photolysis of *cis*-4-acetoxyflavane **4a** and benzophenone under conditions similar to those for **1a** gave no **5**, but 2,2′-bi-4-acetoxyflavanes **11** and a cross coupling product, *cis*-2-(diphenylhydroxymethyl)-4-acetoxyflavane **10**, besides benzopinacol **7**, as shown in Scheme 3. Because of the insolubility of **11**, its NMR spectrum was not obtained. The NMR signal due to the proton of the 4-position of **10** showed a quartet at $\delta=5.42$ (1H, $J=11$ Hz), which implies that the diphenylhydroxymethyl group at the 2-position and the hydrogen atom at the 4-position are of *cis* conformation.[4]



Scheme 3. Photolysis of **4a** with benzophenone.

In contrast to the results of **1a** (Scheme 1), high yields of products derived from the *cis*-2-(4-acetoxyflavanyl) radical and the lack of products derived from the *cis*-4-(4-acetoxyflavanyl) radical may be noted. The inefficiency of the abstraction of the hydrogen atom at the 4-position of **4a** may be due to the electron-withdrawing effect of the acetyl group[6] as well as steric hinderance.

Photolysis of a mixture of **4a** and the *trans* isomer **4b** in the presence of benzophenone gave the following ratio of the consumption rates, *cis*/*trans*=3.6.



Scheme 4. Photolysis of **1a** with acetone.

*Photoreaction of **1a** with Acetone.* Photolysis of **1a** in acetone gave 4,4′-bi-4-flavanols, **12** (mixture of isomers), *cis*- and *trans*-4-(1-hydroxy-1-methylethyl)-4-flavanols, **13** and **14**, 4-flavanone, **5**, and **1b**, besides the recovered **1a** (40%), as shown in Scheme 4. The photochemical behavior of **1a** and acetone (acetone acts as a photosensitizer as well as the solvent) differs markedly from that with benzophenone in the following respects: a) neither 4-flavanone, **5**, nor acetone pinacol, **15**, was obtained, while **5** and **7** were the main products in the **1a**–benzophenone system, b) dimeric products, **12** were obtained in a significant yield, while they none were detected in the photolysis of **1a** and benzophenone, c) cross-coupling products, **13** and **14**, derived from radical **A** were obtained instead of the cross-coupling products analogous to **8** and **9** in Scheme 1, d) the formation of **1b**, *i.e.*, epimerization at the 4-position, was observed.

Radical **A**, which is stabilized due to its benzylic structure, is assumed to be more stable than ketyl radical **D**. Hence the latter should transfer a hydrogen atom from an oxygen atom to **1a**, to produce acetone and radical **A** (13), before collisional coupling with another **D** resulting in **15** (14). For similar reasons, the reaction of **A** with acetone giving **D** and **5** (12) is assumed to be unfavorable (an endothermic process) and hence racical **A** should either couple to give **12** (10) or disproportionate resulting in **5** and **1a** or **1b** (11). In the case of the **1a**–benzophenone system, however, radical **A** should rapidly undergo process (3) because of the higher stability of **B**, before the coupling and disproportionation processes (4)—(6) can occur.

Scheme 5. Photolysis of **1a** with acetone.

Table 2. Relative reactivities of the *cis* and *trans* isomers of the substituted 4-flavanols with benzophenone

Substrate	Form	Rel. reactivity[a]
4-Chromanol		1.00
1a	*cis*	1.8
1b	*trans*	0.17
2a	*cis*	2.2
2b	*trans*	0.91
3a	*cis*	1.3
3b	*trans*	0.18

a) The relative reactivity is based on that of 4-chromanol.

In Scheme 5 process (9) represents the cross-coupling reaction within the solvent cage.

No suitable explanation is available as yet, as to why no cross-coupling products analogous to **8** and **9**, shown in Scheme 1, were formed in the photolysis of the **1a**–acetone system.

Relative Photoreactivities of cis- *and* trans-*4-Flavanols with Benzophenone.* Table 2 shows the relative consumption rates, as compared with the consumption rate of 4-chromanol, for the photolysis of **1a**, **1b**, *cis*-7-methoxy-4-flavanol **2a**, *trans*-7-methoxy-4-flavanol **2b**, *cis*-7-chloro-4-flavanol **3a**, and *trans*-7-chloro-4-flavanol **3b**.

It may be noted that a) the reactivities of the *cis* isomers (**1a**, **2a**, **3a**) are higher than the corresponding *trans* isomers (**1b**, **2b**, **3b**), and b) that the order of the reactivities is **2a**>**1a**>**3a**, **2b**>**1b**≒**3b**. Yamaguchi *et al.*[3] have explained the relative reactivities of the *cis*- and *trans*-substituted chroman-4-ols with chromic acid in terms of the stereoelectronic effect[1] and the strain relaxation of the chromate esters of the substrates. Also, in the present photoreaction system, the stereoelectronic effect may be assumed to be one of the factors controlling the relative reactivities of the isomers. In addition to these effects, abstraction of the hydrogen atoms from these substrates by triplet benzophenone is assumed to be significantly sterically hindered for effective encounter collisions. A reactivity ratio *cis*/*trans* of 3.6 was found for the photoreaction of isomeric 4-acetoxyflavanes **4a** and **4b**. The products resulting from the photolysis of **4a** or **4b** and benzophenone (Scheme 3) imply that the intermediate radical is not the radical at the 4-position but is that at the 2-position. The latter is not conjugated with the 5,6-fused benzene ring and is free from the stereoelectronic effect. Thus, the reactivity ratio of 3.6 for isomeric 4-acetoxyflavanols is assumed to be due to the steric hinderance for encounter collisions. The abstraction of hydrogen atoms would be sterically less favorable for the *trans* isomers than for the *cis* isomers, since for the *trans* isomers the phenyl group at the 2-position would interfer with the attack of the triplet benzophenone.

The order of the reactivities indicates that electron releasing substituents stabilize the intermediate radical, such as **A**, and accelerate the reaction rate.

Experimental

The light souce was a 100-W high pressure mercury lamp (Riko Kagaku) immersed in a 200-ml reaction vessel. Each solution was bubbled using a purified nitrogen stream before and during photolysis. The temperature was maintained at 20—25 °C. The melting points are uncorrected. NMR and IR spectra were obtained by using Hitachi IRA-1 and R-24 spectrometers, respectively.

Materials. *cis*-4-Flavanol **1a**,[7] *cis*-7-methoxy-4-flavanol **2a**, and *cis*-7-chloro-4-flavanol **3a** were prepared from 4-flavanone,[8] 7-methoxy-4-flavanone,[9] and 7-chloro-4-flavanone,[10] respectively, by reduction with sodium borohydride. *trans*-4-Flavanol **1b**,[11] *trans*-7-methoxy-4-flavanol **2b**, and *trans*-7-chloro-4-flavanol **3b** were prepared from **1a**, **2a**, and **3a**, respectively, by treatment with phosphorus tribromide in ether followed by hydrolysis in a *t*-butyl alcohol–water solution of potassium hydroxide. *cis*-4-Acetoxyflavane **4a** and *trans*-4-acetoxyflavane **4b**, were prepared from **1a** and **1b**, respectively, by acetylation in acetic anhydride–pyridine.

Table 3. Yields and physical constants of a series of 4-flavanols

Substrate	Yield, %	Mp (solvent)[a]	NMR ($CDCl_3$) δ, ppm	IR, cm^{-1}
1a	87	147—148 (M)	1.9—2.1 (M, 2H), 4.5 (d, 1H), 5.0 (q, 1H) 5.2 (q, 1H), 6.7—7.6 (m, 9H)	3410, 1580 1210

4b		97—98 (E)	2.0 (s, 3H), 2.0—2.3 (m, 2H), 5.2 (q, 1H) 6.0 (t, 1H), 6.7—7.6 (m, 9H)	1700

a) Solvents for crystallization; M: methanol, E: ethanol, B: benzene, EW: ethanol–water, BH: benzene–hexane.

4-Chromanol was prepared by reduction of chromanone[12] with sodium borohydride. The yields and the phydical constants of these substrates are summarized in Table 3.

*Photolyses of **1a** and **1b** with Benzophenone.* A 200-ml benzene solution containing 0.025 M **1a** and 0.07 M benzophenone was irradiated for 100 min. Isolation by column chromatography on silica gel gave **7** (0.62 g), **5** (0.29 g), **6** (0.19 g), **8** (0.05 g), **9** (0.10 g), in addition to the recovered **1a** (0.13 g). The photolysis of **1b** and the analysis of the products were carried out under conditions similar to those for **1a**, but only the main products **5** and **7** were isolated. The acetylation of **8** and **9** in pyridine-acetic anhydride gave *cis*-2-(diphenylhydroxymethyl)-4-acetoxyflavane **8'** and *trans*-2-(diphenylhydroxymethyl)-4-acetoxyflavane **9**. Products **5** and **7** were identified by comparing their mp and IR and NMR spectra with authentic samples. **6**: colorless needles from ethanol; mp 182—183 °C; IR (KBr): 3440, 1680 cm^{-1}; NMR ($CDCl_3$): δ 2.95 (s,1H), 3.49 (s, 2H), 6.7—7.9 (m, 19H). Found: C, 82.32; H, 5.49%. Calcd for $C_{28}H_{22}O_3$: C, 82.73; H, 5.45%. **8**: colorless needles from ethanol; mp 222—223 °C; IR: 3570, 3335, 1590 cm^{-1}. **8'**: colorless prisms from ethanol; mp 207—212 °C; IR: 3445, 1700 cm^{-1}; NMR ($CDCl_3$): δ 1.98 (s, 3H), 2.30 (q, 1H), 2.90 (s, 1H), 3.31 (q, 1H), 5.42 (q, 1H), 6.8—7.9 (m, 19H). J_{3a-4}=11 Hz, J_{3a-3e}=13.4 Hz, J_{3e-4}=6.5 Hz. **9'**: colorless prisms from ethanol; mp 212—213 °C; IR: 3445, 1700 cm^{-1}; NMR ($CDCl_3$) : δ 1.50 (s,3H), 2.67 (q, 1H), 2.98 (s, 1H), 3.20 (q, 1H), 5.71 (q, 1H), 6.8—7.8 (m, 14H). J_{3a-3e}=16.0 Hz, J_{3a-4}=2.0 Hz. Found: C, 79.34; H, 5.81%. Calcd for $C_{30}H_{26}O_4$: C, 79.98; H, 5.82%.

*Photolysis of **4a** and Benzophenone.* A 200-ml benzene solution containing **4a** (0.025 M) and benzophenone (0.06 M) was irradiated for 10 h. Isolation of the products by column chromatography on silica gel gave **7** in an undetermined significant amount, **11** (0.08 g), and **10** (0.36 g), in addition to the recovered **4a** and benzophenone. **11**: colorless crystal from benzene-ethyl acetate; mp 275—280 °C; IR: 1720, 1220 cm.$^{-1}$ Found: C, 74.35; H, 5.68%. Calcd for $C_{34}H_{30}O_6$: C, 76.39; H, 5.66%. The NMR spectra of **11** was not obtained because of the low solubility in any suitable solvent.

*Photolysis of **1a** and Acetone.* A 150-ml acetone solution of **1a** (0.067 M) was irradiated for 60 h. Isolation by CC on silica gel, after acetylation with pyridine-acetic anhydride, gave **4a** (0.76 g), **4b** (0.05 g), **5** (0.08 g), bi-4-(acetoxyflavane) **12'** (0.79 g), and *cis*- and *trans*-4-(1-hydroxy-2-methylethyl)-4-flavanols **13** (0.16 g) and **14** (0.12 g). The TLC of **12** on silica gel with benzene gave four spots which were identified as isomeric mixtures by comparing their NMR spectra with those of authentic samples.[13] **13**: white crystals from CCl_4; mp 130—132 °C; IR: 3520, 3450 cm^{-1}; NMR ($CDCl_3$): δ 1.26 (s, 3H), 1.34 (s, 1H), 2.0—3.0 (m, 4H), 5.63 (q, 1H), 6.7—7.7 (m, 9H). **14**: colorless crystals from petroleum benzine; mp 125—130 °C; IR: 3400, 2900, 1600 cm^{-1}; NMR: δ 1.00 (s, 3H), 1.30 (s, 3H), 2.0—2.2 (m, 2H), 2.70 (s, 2H), 5.05 (q, 1H), 6.8—7.0 (m, 9H).

Relative Photoreactivities. A 100-ml benzene solution of each substrate (0.005 M) in the presence of 4-chromanol (0.005 M) and benzophenone (0.03 M) was irradiated for 20 min. After separation by PLC on silica gel with benzene, the NMR signal intensities for 4-chromanone at δ=4.39 and 4-flavanones at δ=5.34 ppm were measured. In the case of **4a** and **4b**, for which the photoreaction rates are slow compared to those of 4-chromanol, a 50-ml benzene solution containing **4a** (0.01 M), **4b** (0.01 M), and benzophenone (0.016 M) was irradiated for 3 h.

The authors wish to thank Miss S. Yamazaki for her help during this work.

Sequential Polypeptides. The Steric Hindrance of L-Valine Residues in the Polycondensation of Peptide Active Esters

Ryoichi KATAKAI

Department of Industrial Chemistry, College of Technology, University of Gunma, Tenjin-cho, Kiryu-shi 376

(Received October 23, 1976)

Five tripeptide *N*-hydroxysuccinimide esters with *N*-terminal L-valine, L-phenylalanine, and L-alanine were polymerized in *N,N*-dimethylformamide with a variety of concentration of the monomers. The yields and molecular weights of the resulting sequential polypeptides were then compared in order to demonstrate the presence of the steric hindrance of the L-valine residue in polycondensation. The results of the polycondensation and the conformational study of the resulting polypeptides suggest that the side chain of the L-valine residue at the *N*-terminal position of the monomers hinders the polycondensation of the monomers.

L-Valine is a very interesting amino acid in polypeptide chemistry from synthetic as well as conformational aspects. Poly(L-valine) takes predominantly the β-structure and does not form the α-helix, although the L-valine residues can be incorporated in the stable α-helical conformation in naturally occurring proteins[1] and synthetic sequential polypeptides.[2,3] These facts can be explained by the steric hindrance of the side chain of the amino acid.

In a previous study,[4] we reported on the synthesis and conformation of two sequential polypeptides, $(\text{L-Ala–L-Val–Gly})_n$ and $(\text{L-Val–L-Ala–Gly})_n$. In that study, we found that the HBr·H–L-Ala–L-Val–Gly–ONSu monomer polymerized to give a sequential polypeptide, $(\text{L-Ala–L-Val–Gly})_n$, with high molecular weights and in higher yields than the HBr·H–L-Val–L-Ala–Gly–ONSu monomer.[5] This fact was tentatively explained by the presence of the steric hindrance of the side chain of L-valine at the *N*-terminal position of the latter monomer. However, a question if the lowering of the yield and the molecular weight of $(\text{L-Val–L-Ala–Gly})_n$ results only from the steric hindrance of the L-valine residue remains unresolved, because there are many factors responsible for the yield and the molecular weight of the sequential polypeptides. Among them, the conformations of the growing polypeptide chains may greatly influence the results of polycondensation. The previous study compared the results of the polycondensation of different polypeptides which may take different conformations in the polymerization system.

We chose in this study monomers with the same composition, but with different sequences of amino acids, which give the same sequential polypeptide—for example, HCl·H–L-Val–L-Phe–L-Phe–ONSu and HCl·H–L-Phe–L-Val–L-Phe–ONSu, which give the same polymer $(\text{L-Val–L-Phe–L-Phe})_n$. In the polycondensation of these monomers, the conformational effect is removed and the sterical effect of the L-valine residue may be clearly demonstrated. We polymerized five monomers: the above two monomers, HCl·H–L-Val–L-Ala–L-Ala–ONSu, HCl·H–L-Ala–L-Val–L-Ala–ONSu, and HCl·H–L-Val–L-Val–Gly–ONSu. The results are discussed, together with a conformational study in the solid state.

Results and Discussion

Synthesis of Monomers. For such a study as this, in which the mechanism of the polycondensation of peptide active esters is deduced from the yields and the molecular weights of the resulting polypeptides, exact and reproducible values of the yield must be obtained in polycondensation. Thus, a large amount of the peptide active esters as a monomer for polycondensation must be prepared for repeated polycondensations. The peptide active esters are comparatively difficult to synthesize because many treatments are needed for their synthesis. An easy synthetic method giving a high yield must be adopted to prepare a large amount of the monomers.[6] In this study, the monomers were prepared by means of the *o*-nitrophenylthio *N*-carboxy α-amino acid anhydride (Nps-NCA) method,[7] which can rapidly produce in a high yicld a peptide derivative protected by the Nps group.[8] This method is especially useful for the synthsis of a large amount of peptides. The Nps-NCA method gives no by-products such as the *N,N'*-dicyclohexylurea in the dicyclohexylcarbodiimide method, and the resulting product is easily purified by simple recrystallization.

An amino acid ethyl ester was treated with an Nps-NCA to give the Nps-dipeptide ethyl ester in a yield above 85%. The subsequent removal of the Nps group of the dipeptide derivative by treatment with hydrochloric acid in dioxane gave, almost quantitatively, the dipeptide ethyl ester hydrochloride, which was then treated with another Nps-NCA to give the Nps-tripeptide ethyl ester in a yield above 82%. The Nps-tripeptide ester was saponified to lead to Nps-tripeptide free acid, which was active-esterified by treating it with *N*-hydroxysuccinimide and dicyclohexylcarbodiimide.[9] The resulting Nps-tripeptide ONSu ester was purified by recrystallization from tetrahydrofuran.

A series of treatments for the synthesis leading to Nps-tripeptide ONSu esters was started from the 0.2 mol scale of the amino acid ester. Though many reactants were used, every condensation with Nps-NCA produced in a yield above 82%, and all the products were easily purified by recrystallization. The results of the syntheses are shown in Table 1.

Polycondensation of the Monomers. All the polymerizations of the tripeptide ONSu esters were done in *N,N*-dimethylformamide for one day at room temperature.[4,6] Every polymerization system was treated with different procedures for the isolation of the resulting polypeptide. We supposed that the yield of polycondensation may vary with each isolation pro-

cedure, because we have found that the solubility of peptides in solvents such as *N*,*N*-dimethylformamide differs greatly with the sequences of amino acids.[10] The results of the polycondensation of HCl·H-L-Val-L-Phe-L-Phe-ONSu and HCl·H-L-Phe-L-Val-L-Phe-ONSu are shown in Table 2. For the first isolation procedure, the polymerization system was diluted with diethyl ether. This treatment precipitates from the polymerization system the polymer, an oligomer with a very low molecular weight, and also triethylammonium chloride. The precipitate was collected by filtration and washed with methanol to remove the salt. The yields by the first procedure are shown by the values with the superscript a. The polymer isolated by the first procedure was suspended in *N*,*N*-dimethylformamide and reprecipitated by the addition of methanol. By this treatment, the oligomer with very low molecular weights and cyclic oligomers were removed from the polymer.[11] The yields by the second procedure are shown with the superscript b. In the third procedure the polymer was precipitated from the polymerization system by the addition of methanol. The yields by the third procedure are shown with the superscript c.

A comparison of the yields of the two polymers suggests an interesting feature of polycondensation. The HCl·H-L-Val-L-Phe-L-Phe-ONSu monomer with the *N*-terminal L-valine residue, gave, by the first isolation procedure, the (L-Val-L-Phe-L-Phe)$_n$ polymer in higher yields than did another HCl·H-L-Phe-L-Val-L-Phe-ONSu monomer with *N*-terminal L-phenylalanine. However, the yields of the (L-Val-L-Phe-L-Phe)$_n$ polymer decreased after the second treatment to become similar to the values of the yields of (L-Phe-L-Val-L-Phe)$_n$. These results suggest that the first procedure of isolation precipitated not only the polymer but also oligomers with very low molecular weights, which were then removed by the second isolation procedure. This is demonstrated by the fact that the second procedure gave the yields similar to those of the third isolation procedure, which does not precipitated the lower oligomers.

We should also discuss the results of the polycondensation in connection with the values of the yields obtained by the second and third procedures for the isolation of the polymer. Two polymers with the same sequence, (L-Val-L-Phe-L-Phe)$_n$ and (L-Phe-L-Val-L-Phe)$_n$, were isolated in similar yields. This is also true for other sequential polypeptides. The results of the polycondensation of another pair of monomers, HCl·H-L-Val-L-Ala-L-Ala-ONSu and HCl·H-L-Ala-L-Val-L-Ala-ONSu, are shown in Table 3. Table 3 also contains the yields of the polymers isolated by the third procedure. These sequential polypeptides, (L-Val-L-Ala-L-Ala)$_n$ and (L-Ala-L-Val-L-Ala)$_n$, were obtained in the same yields by three different isolation

0.13	98	0.152	8	94	0.178	15

procedures, in contrast to the results for the sequential polypeptides containing L-phenylalanine residues. The polymer containing L-alanine residues, therefore, may contain lower oligomers. This is consistent with the fact that the yields of the polypeptides containing L-alanine residues are higher than those containing L-phenylalanine residues. Another fact which is analogous for the polymers containing L-phenylalanine is that the polymers containing L-alanine residues were isolated in the same yields and no effect of the *N*-terminal amino acid residue appeared. It may be conclusively stated from the above results that the effect of the *N*-terminal amino acid of the monomer in polycondensation, if it is present, cannot detected by comparing the yields of the resulting sequential polypeptides.

Contrary to the above results for the yields, the viscosity of the resulting sequential polypeptides clearly shows the influence of the *N*-terminal amino acid of the monomers on the polycondensation. The sequential polypeptide, (L-Val-L-Phe-L-Phe)$_n$ obtained from a monomer with the *N*-terminal L-valine has lower viscosities than the polypeptide, (L-Phe-L-Val-L-Phe)$_n$, obtained from a monomer with *N*-terminal L-phenylalanine (Table 2). An analogous result was obtained by the polycondensation of another pair of monomers containing L-alanines (Table 3). The polymer with *N*-terminal L-valine (L-Val-L-Ala-L-Ala)$_n$ has lower viscosities than those of the polymer with *N*-terminal L-alanine (L-Ala-L-Val-L-Ala)$_n$. We determined the number-average degree of polymerization ($\overline{DP}$) of these polymers by measuring the NMR peak area of the *N*-terminal amino protons and the internal amide protons. These results are also shown in Table 3. The polymer with *N*-terminal L-alanine has $\overline{DP}$s from 15 to 27, about ten repeating units longer than those of the polymer with *N*-terminal L-valine, which has $\overline{DP}$s from 6 to 14. This finding is consistent with the results of the viscosity measurement.

As the pairs of the monomers studied in this study give the same polypeptides, the growing polymer chains may have similar conformations in the polycondensation system. Therefore, the most important factors responsible for the molecular weight of the resulting polymers is the *N*-terminal amino acid of the monomers. The above results can best be explained by the presence of the steric hindrance of the side chain of L-valine at the *N*-terminal position of the monomers. Though the detailed mechanism of polycondensation of peptide active esters has not yet been demonstrated because there are many complicated factors resulting from the use of the very concentrated polymerization system containing the salt, the monomer-active ester may polymerize in a manner similar to that of the monomers of conventional polycondensation; *i.e.*, the monomers are condensed to give dimers, which are then again condensed to give tetramers. The resulting oligomers with the *C*-terminal active ester is condensed with the amino group of another oligomer-active ester to give a higher oligomer. The reactivity of the terminal functional groups may not vary with the chain lengths, but the rate of polycondensation decreases greatly as the peptide chains become longer, because the molecular motion is prevented, especially in a solid state or in gelatinous systems. As the sterical effect of the L-valine residue may not be very large, the presence of L-valine at the *N*-terminal position does not influence the condensation of short peptide chains, but does hinder the condensation of larger peptides. Thus, the polycondensation of monomers with *N*-terminal L-valine was terminated at a lower peptide stage; the polymer thus obtained had lower molecular weight than those with *N*-terminal L-phenylalanine and L-alanine. This explanation points out the importance of stirring the polycondensation system containing the monomer with *N*-terminal L-valine. In fact, the sequential polypeptide, (L-Val-L-Phe-L-Phe)$_n$ with the highest viscosity was obtained in a polycondensation system with the lowest concentration of the monomer-active ester, which was a gelatinous liquid state which could be well stirred (Table 2). In a more gelatinous polycondensation system containing a higher concentration of the monomer, where effective stirring becomes difficult, the molecular motion and the reaction of the growing peptide chains may be prevented to form a lower-molecular-weight polymer. This is demonstrated by the conformational study in the solid state (see below).

In order to demonstrate further the presence of the steric hindrance of L-valine in polycondensation, we polymerized another monomer with L-valines, HCl·H-L-Val-L-Val-Gly-ONSu. The results are shown in Table 4. The (L-Val-L-Val-Gly)$_n$ polymer has $\overline{DP}$s of about 10 over the range of concentration of the monomer used in this study. These $\overline{DP}$s are

Table 4. Results of polycondensation of HCl·H-L-Val-L-Val-Gly-ONSu

Monomer concn mol/l	Yield %	$\eta_{sp/c}$	$\overline{DP}_n$
0.50	95	0.185	10
0.33	92	0.167	8
0.25	91	0.180	10
0.17	90	0.185	10
0.13	89	0.172	8

similar to those of (L-Val–L-Ala–L-Ala)$_n$ with the *N*-terminal L-valine and are lower than those of (L-Ala–L-Val–L-Ala)$_n$ with *N*-terminal L-alanine. This comparison may not be reasonable because these polymers are different compounds, and so many effects other than the steric hindrance of the *N*-terminal amino acid must be taken into consideration in discussing the results. However, the fact that the *N*-terminal L-valine decreases the molecular weight of the resulting polypeptides suggests the presence of the steric hindrance of the amino acid.

Conformations of the Polypeptides in the Solid State.

The conformations of the sequential polypeptides were studied by means of far-infrared spectroscopy. Itoh *et al.*[12] found some characteristic bands of amino acid residues with the α-helical and β-form structures, and showed that the far-infrared spectroscopy is very useful for elucidating the conformations of polypeptides in the solid state. We analyzed the far-infrared spectra of the sequential polypeptides according to the assignments established by Itoh *et al.* Figure 1 shows the far-infrared spectra of the sequential polypeptide (L-Ala–L-Val–L-Ala)$_n$. This polypeptide showed a strong band at 441 cm^{-1} characteristic of the L-alanine residue with the β-structure and weak bands at 540, 520, 409, and 375 cm^{-1} characteristic of the L-alanine and L-valine residues with the α-helix. The spectra suggest that the polypeptide takes predominantly the β-structure and contains a portion of the α-helix. Some polypeptides are known to transform their conformation from the β-structure to the α-helix upon treatment with dichloroacetic acid. The polypeptide (L-Ala–L-Val–L-Ala)$_n$ with $\overline{DP}$ 16, when treated with dichloroacetic acid, showed the infrared bands at 540, 524, 409, and 374 cm^{-1}, while the band at 441 cm^{-1} almost disappeared. This suggests that the polypeptide transformed the conformation to the α-helix upon treatment. Figure 2 shows the spectra of (L-Val–L-Ala–L-Ala)$_n$. The polypeptide isolated showed the band at 441 cm^{-1} characteristic

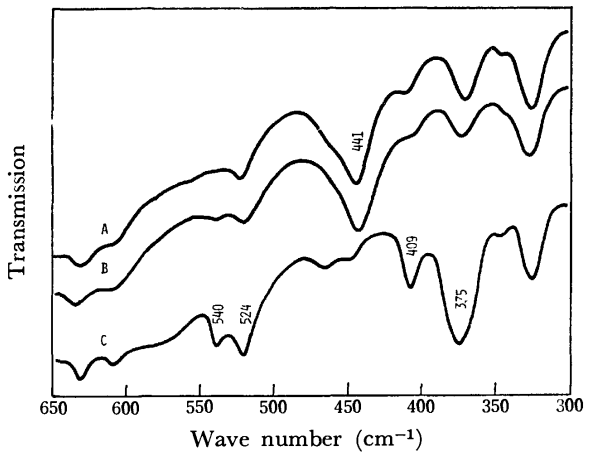

Fig. 1. Far-infrared spectra of the sequential polypeptide (L-Ala–L-Val–L-Ala)$_n$. A: The polypeptide with $\overline{DP}$ 27, B: The polypeptide with $\overline{DP}$ 16, C: The polypeptide with $\overline{DP}$ 16 after treatnemt with dichloroacetic acid.

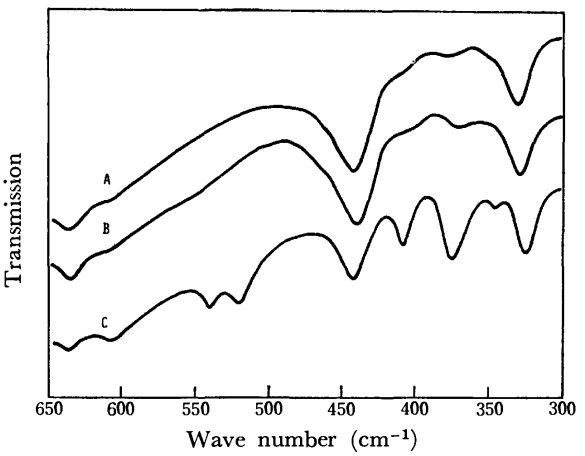

Fig. 2. Far-infrared spectra of the sequential polypeptide (L-Val–L-Ala–L-Ala)$_n$. A: The polypeptide with $\overline{DP}$ 8, B: The polypeptide with $\overline{DP}$ 14, C: The polypeptide with $\overline{DP}$ 14 after treatment with dichloroacetic acid.

of the β-structure, while the sample with $\overline{DP}$ 14 treated with dichloroacetic acid showed the bands at 540, 524, 409, and 375 cm^{-1} characteristic of the α-helix, and also that at 441 cm^{-1} characteristic of the β-structure. These results suggest that the polypeptide with *N*-terminal L-valine takes not only the α-helix but also the β-structure after the treatment. We suppose that the β-structure of the latter polypeptide may result from the presence of the oligomers with low molecular weights, perhaps five or lower repeating tripeptide units, because we have shown in another series of studies that some sequential tripeptide oligomers begin to take the α-helix at pentadecapeptides in the solid state.[13] Thus, the above results demonstrate that the sequential polypeptide with *N*-terminal L-valine (L-Val–L-Ala–L-Ala)$_n$ contains a fair portion of the lower oligomers, which cannot form the α-helical conformation. This is consistent with the results of polycondensation described above.

Some interesting results were obtained by the conformational study of the polypeptides, (L-Phe–L-Val–L-Phe)$_n$, (L-Val–L-Phe–L-Phe)$_n$, and (L-Val–L-Val–Gly)$_n$, though no evidence for elucidating the sterical

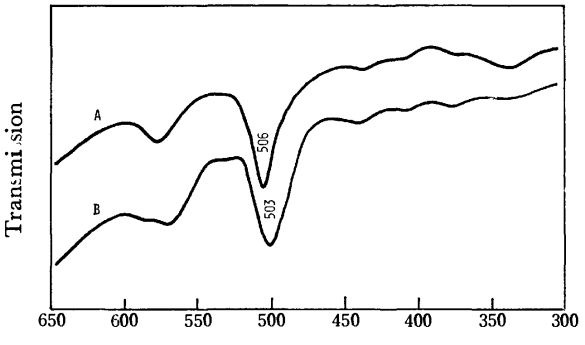

Fig. 3. Far-infrared spectra of the sequential polypeptide (L-Phe–L-Val–L-Phe)$_n$ with η_{sp}/c 0.161. A: Before treatment with dichloroacetic acid, B: After the treatment.

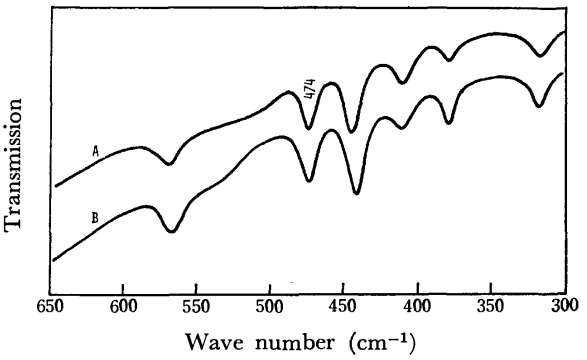

Fig. 4. Far-infrared spectra of the sequential polypeptide (L-Val-L-Val-Gly)$_n$. A: Before treatment with dichloroacetic acid, B: After the treatment.

effect of the *N*-terminal L-valine in polycondensation was obtained. Fig. 3 shows the far-infrared spectra of the polypeptide (L-Phe-L-Val-L-Phe)$_n$ before and after treatment with dichloroacetic acid. The spectrum of (L-Val-L-Phe-L-Phe)$_n$ was similar to those shown in Fig. 3. The spectra have the band near 505 cm^{-1} which has been assigned as characteristic of the L-phenylalanine residue with the β-structure. It is known that poly(L-phenylalanine) can take the α-helical conformation, but the stability of the α-helix is not so large as that for poly(L-alanine) and poly(L-leucine).[14] The β-structure of the sequential polypeptide in this study shows that it may not have an adequate molecular weight to form the α-helical conformation. Figure 4 shows the spectra of (L-Val-L-Val-Gly)$_n$ before and after the treatment. The polypeptide has already been studied by Itoh *et al.*[15] They found the band at 470 cm^{-1} characteristic of the poly(L-valine) structure, which differs from the β-structure.[3] Though the spectra of our sample have some new bands at 568, 412, and 380 cm^{-1} which were not found in the spectrum reported by Itoh, they have the characteristic band at 474 cm.$^{-1}$ This shows that the polypeptide takes the structure characteristic of poly(L-valine) before and after the treatment with dichloroacetic acid.

Experimental

Synthesis of Monomers. Nps-tripeptide ONSu esters were prepared by the stepwise synthesis of the Nps-tripeptide ethyl ester, the saponification of the tripeptide esters, and the active esterification of the tripeptide free acid. A typical synthesis of the monomers is illustrated by the following preparation of Nps-L-Phe-L-Val-L-Phe-ONSu.

Nps-L-Val-L-Phe-OEt. L-Phenylalanine ethyl ester hydrochloride (46.0 g (0.2 mol)) was suspended in 400 ml of tetrahydrofuran, and then 28 ml of triethylamine was added. The resulting crystals of the salt were removed by filtration. To the filtrate were added 59.2 g (0.2 mol) of Nps-L-valine NCA, after which the solution was stirred for 3 h at room temperature. The solvent was evaporated under reduced pressure. The residue was dissolved in 600 ml of ethyl acetate. The solution was washed with 5% citric acid, 5% sodium hydrogencarbonate, and water, and dried over sodium sulfate. The solution was concentrated under reduced pressure. To the residue hexane was added to crystallize the product, which was then recrystallized from warm ethyl acetate to give 81.1 g (91%) of a pure dipeptide; mp 149—150 °C, $[\alpha]_D$ −11.4 (*c* 1.0, *N,N*-dimethylformamide). Found: C, 59.25; H, 6.19; N, 9.40. Calcd for $C_{22}H_{27}N_3O_5S$: C, 59.31; H, 6.11; N, 9.43%.

Nps-L-Phe-L-Val-L-Phe-OEt. The above Nps-dipeptide ester (80.2 g (0.18 mol)) was dissolved in 180 ml of 2 M hydrochloric acid in ethanol. To the solution were added 500 ml of diethyl ether and 300 ml of hexane to precipitate the dipeptide ester hydrochloride. The precipitate was collected by filtration, washed with diethyl ether, and reprecipitated from methanol. The product was dissolved in 600 ml of tetrahydrofuran, and then 26 ml of triethylamine was added. The resulting crystals were removed. To the solution were added 63.7 g (0.18 mol) of Nps-L-phenylalanine NCA, after which the solution was stirred for 2 h at room temperature. The solution was treated analogously to the case of the dipeptide synthesis. The obtained Nps-tripeptide ester was recrystallized from tetrahydrofuran; 99.2 g (93%); mp 165—166 °C, $[\alpha]_D$ +41.9 (*c* 1.0, *N,N*-dimethylformamide). Found: C, 62.76; H, 6.21; N, 9.48. Calcd for $C_{31}H_{36}N_4O_6S$: C, 62.82; H, 6.12; N, 9.45%.

Nps-L-Phe-L-Val-L-Phe-OH. The Nps-triprptide ethyl ester (59.3 g (0.1 mol)) was dissolved in 200 ml of acetone, and then 100 ml of 1 M sodium hydroxide was added. The system was stirred for 1 h to give a clear solution, which was then concentrated under reduced pressure at 30 °C: the residual aqueous solution was diluted with 200 ml of water. The solution was extracted with 300 ml of diethyl ether and acidified with 15% citric acid. The system was extracted with ethyl acetate. The extract was washed with water and dried over sodium sulfate. The solution was concentrated under reduced pressure. Hexane was added to crystallize the product. The crude product was purified by recrystallization from tetrahydrofuran; 48.5 g (86%); mp 111—113 °C, $[\alpha]_D$ +50.5 (*c* 1.0, *N,N*-dimethylformamine). Found: C, 61.60; H, 5.82; N, 9.98%. Calcd for $C_{29}H_{32}N_4O_6S$: C, 61.68; H, 5.71; N, 9.93%.

Nps-L-Phe-L-Val-L-Phe-ONSu. The Nps-tripeptide free acid (56.5 g (0.1 mol)) was dissolved in 500 ml of tetrahydrofuran. To the solution were added 12.7 g (0.11 mol) of *N*-hydroxysuccinimide, after which the system was stirred for 10 min to give a clear solution. The solution was cooled at −10 °C, and 20.9 g (0.11 mol) of dicyclohexylcarbodiimide was added. The solution was then stirred for 5 h at −10 °C and allowed to stand for 20 h at 0 °C. The crystals of the urea were removed by filtration. A few drops of glacial acetic acid were added, and the solution was concentrated under reduced pressure at 10 °C. Hexane was added to the residue. The crystals were isolated and redissolved in tetrahydrofuran. The undissolved materials were removed, and the solution was concentrated. To the residue hexane was added to crystallize the product; 58.9 g (89%); mp 185—190 °C (dec). $[\alpha]_D$ +22.0 (*c* 1.0, *N,N*-dimethylformamide). Found: C, 59.97; H, 5.45; N, 10.46%. Calcd for $C_{33}H_{35}N_5O_8S$: C, 59.89; H, 5.33; N, 10.59%.

Polycondensation of Tripeptide ONSu Esters. Nps-tripeptide ONSu ester (0.03 mol) was dissolved in 30 ml of 2 M hydrochloric acid in dioxane, and 300 ml of diethyl ether were added. The resulting precipitate was isolated by filtration, washed with diethyl ether until the yellow color disappeared, and dried. The product was dissolved in a small amount of methanol. To the solution was added diethyl ether to precipitate the tripeptide ONSu ester hydrochloride. The hydrochloride (0.005 mol) was dissolved in *N,N*-dimethyl formamide at the concentrations listed in Table 2 to 4. To the solution was then added, with vigorous stirring, 0.84 ml of triethylamine. The system was stirred or allowed to

stand for 1 day at room temperature. After the polycondensation, the system was treated by the following three different procedures for the isolation of the polypeptide. First procedure: the polymerization system was diluted with 100 ml of diethyl ether. The precipitate was collected by filtration, washed with 200 ml of methanol and 50 ml of diethyl ether, and dried over P_2O_5. Second procedure: the product isolated by the first procedure was suspended with vigorous stirring in 30 ml of *N,N*-dimethylformamide for 6 h. The system was then diluted with 100 ml of methanol, and the resulting precipitate was isolated by filtration, washed with 50 ml of methanol and 50 ml of diethyl ether, and dried. Third procedure: the polymerization system was diluted with 100 ml of methanol. The resulting precipitate was treated in the same way as in the second procedure.

Measurements. The viscosity of the sequential polypeptides was measured at 25±0.1 °C with an Ostwald viscometer. The concentration of the polypeptide was adjusted to 0.5 g/100 ml of dichloroacetic acid. The NMR spectrum of the polypeptides was obtained with a JEOL JNM-PMX 60 NMR spectrometer at room temperature. The concentration of the polymer was adjusted to 10% in trifluoroacetic acid. The far-infrared spectrum was measured with a JASCO IR-F spectrophotometer. Nujol mulls were used.

The Reactions of Aryldiazomethanes with Sulfur Dioxide in the Presence of Enamines

Toyoshige TANABE and Toshikazu NAGAI

Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560

(Received October 28, 1976)

The reactions of several arydiazomethanes with sulfur dioxide in the presence of 2-methyl-1-morpholinopropene gave cyclic sulfones, thietane 1,1-dioxides, indicating the existence of sulfene as a reaction intermediate. The stereoselectivity of the sulfene–enamine cycloaddition showed that the less thermodynamically stable *cis* orientation was generally preferred. On the other hand, the reactions in the presence of 1-morpholinocyclohexene, which has a labile proton β to the morpholino moiety, afforded acyclic or cyclic sulfones, depending on the substituents of diazomethanes. The mechanism of these reactions is discussed.

Recently sulfenes, generated by the action of amines on alkanesulfonyl chlorides, have received considerable attention.[1] Though the reactivities of sulfene towards enamines have been extensively investigated, the research on the stereochemistry of the products is meager and the mechanism for sulfene–enamine addition is still not determined.[2] Another useful method for generating sulfene is the reaction of diazoalkanes and sulfur dioxide,[3] but there are only a few publications[4] about this reaction, where episulfones and olefins are formed. In the present paper,[5] we deal with the stereoselecitve formations of thietane 1,1-dioxide in the reactions of aryldiazomethanes with sulfur dioxide in the presence of enamines and with the preference of non-cyclo to cycloaddition.

The mechanism of sulfene–enamine addition has already been discussed in the base-induced β-elimination reaction of alkanesulfonyl chlorides in the presence of enamines.[2] But in this system, the triethylamine used as the elimination reagent is liable to cause a slow post-isomerization[2b] of the cycloadduct, 3-aminothietane 1,1-dioxide. The present system, as compared with the amine–chloride system, could be more favorable for the mechanistic study of sulfene–enamine addition from the stereochemical point of view.

Results and Discussion

Reactions in the Presence of 2-Methyl-1-morpholinopropene (MMP). The reactions of mono- and di-arylsubstituted diazomethanes (**1**) with sulfur dioxide in the presence of MMP, which has no hydrogen atom β to the morpholino moiety, led to the cycloadducts, thietane 1,1-dioxide derivatives (**2**) (Scheme 1).

In the reactions of mono-arylsubstituted diazomethanes (**1c, 1d,** and **1e**) with sulfur dioxide in the presence of MMP, mixtures of *cis* and *trans* isomers were obtained. The less thermodynamically stable *cis* orientation of the morpholino and the aryl groups was preferred in the cycloadducts **2c** and **2d**; on the contrary, the *trans* orientation was preferred in the case of **2e** which has an electron-withdrawing group. The results are summarized in Table 1.

Table 1. The reaction of **1** with SO_2 in the presence of MMP

Diazomethane	R^1	R^2	Solvent	Yield of **2** mol%[a]	*cis* %[b]

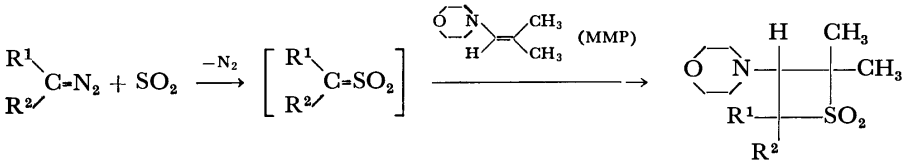
			THF	82	22

a) Isolated yield calculated on the basis of **1** used.
b) The value shows the ratio of the *cis* isomer in the yield of **2**.

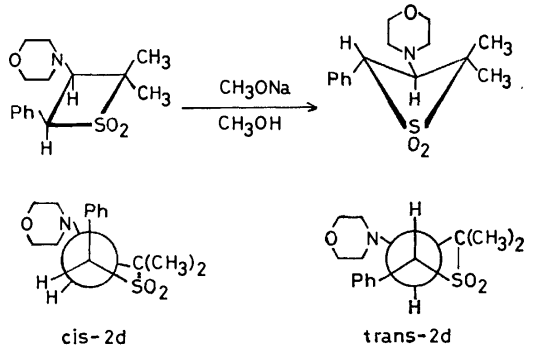
The product, **2d**, obtained from the reaction of **1d** was separated into its *cis* and *trans* isomers (*cis*-**2d** and *trans*-**2d**) by repeated fractional recrystallizations; the isolation of only the *trans* isomer had been made by Truce and Rach.[2b] The isolated isomers were identified on the basis of the NMR spectra. The signals of the phenyl protons appeared as a separate peak in *cis*-**2d** and as a single peak in *trans*-**2d**. The difference between the chemical shifts of the two methyl proton signals was 6 Hz in *cis*-**2d** and 1.8 Hz in *trans*-**2d**, showing an interaction between the phenyl ring and one methyl group in *cis*-**2d**. In the NMR spectra of *cis*-**2d** and *trans*-**2d**, both coupling constants for the two methylidyne protons in the thietane rings were the same and equal to 10 Hz. The large conpling coustant (10 Hz) suggests a dihedral angle between the two protons



1 (**a**) R^1, R^2=fluorenylidene; (**b**) R^1=R^2=phenyl; (**c**) R^1=*p*-tolyl, R^2=H; (**d**) R^1=phenyl, R^2=H; (**e**) R^1=*p*-nitrophenyl, R^2=H. **2a, b, c, d, e**

Scheme 1.

of 0 or 180°.[6] The former angle can be attained only in a planar thietane ring by a *cis* orientation of the morpholino and aryl groups, while the 180° alignment can be achieved only by *trans* substituents in a puckered conformation, as shown in Scheme 2. The assigned stereochemistry was further supported by a study of epimerization: the *cis* isomer or the *cis–trans* mixutre of **2d** was isomerized to the pure *trans* isomer by stirring its methanol solution under the influence of a catalytic amount of sodium methoxide over a period of several days (Scheme 2).



Scheme 2.

The assignment of each of the isomers of **2c** and **2e** was established with their respective NMR spectra, with reference to those of **2d**. And the findings in **2d**, described above, were also applicable to **2c** and **2e**. The *cis* percentages in the yields of **2** were determined by the intensity measurement of the methylidyne proton signals in the NMR spectra of the crude reaction products.

In order to examine the effect of solvent on the stereoselectivity, reactions of **1d** were carried out in various solvents. These results are presented in Table 2. An increasing tendency of the *trans* isomer, though not so drastic, was observed in the polar solvents. Such an effect was also observed in the case of the *para*-substituted phenylsulfene, as seen in Table 1: the reaction of **1c** or **1e** gave the increasing *trans* adduct in THF instead of benzene.

Reactions in the Presence of 1-Morpholinocyclohexene (MCH). A series of reactions of aryldiazomethanes (**1**) and MCH, which has a hydrogen atom β to the morpholino moiety,

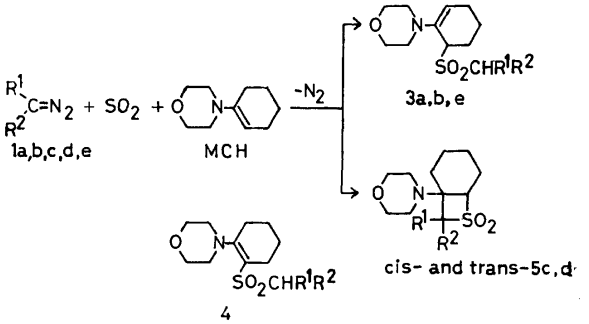
was carried out in the same way. The reactions of 9-diazofluorene (**1a**), diphenyldiazomethane (**1b**), and *p*-nitrophenyldiazomethane (**1e**) were carried out and the spectra of IR and NMR for these reaction products could be explained satisfactorily by the structures of the acyclic sulfones (**3**) instead of the other acyclic sulfones (**4**)[7] or the expected cyclic sulfones (**5**). On the contrary, the reactions of *p*-tolyldiazomethane (**1c**) and phenyldiazomethane (**1d**) gave a *cis–trans* mixture of cyclic sulfone (**5**) (Scheme 3). Table 3 shows the results.



Scheme 3.

Three cyclic products (*cis*-**5c**, *cis*-**5d**, and *trans*-**5d**) were isolated respectively by careful recrystallizations from suitable solvents and their configurations were determined by NMR analysis using a shift reagent, Eu(dpm)$_3$.[8] The results of the complexation studies for *cis*-**5d** and *trans*-**5d** are shown in Fig. 1. The primary site of complexation with Eu(dpm)$_3$ is the oxygen of the morpholine ring, since the largest shifts were induced in the protons vicinal to oxygen. In Fig. 1a, the difference in chemical shifts of the two methylidyne protons H_6 and H_8 decreased whereas, in Fig. 1b, the difference remained essentially constant. Thus in *cis*-**5d**, H_8 is deshielded less than H_6, whereas in *trans*-**5d** both protons are deshielded to approximately the same extent. The observed difference in induced shifts must lie in the distance from the chelation site to the protons, establishing the fact that H_6 and H_8 are *trans* to each other in *cis*-**5d** and *cis* to each other in *trans*-**5d**. The induced shift spectra for *cis*-**5c** were similar to those of *cis*-**5d**.

The ratio of the two geometric isomers was deter-

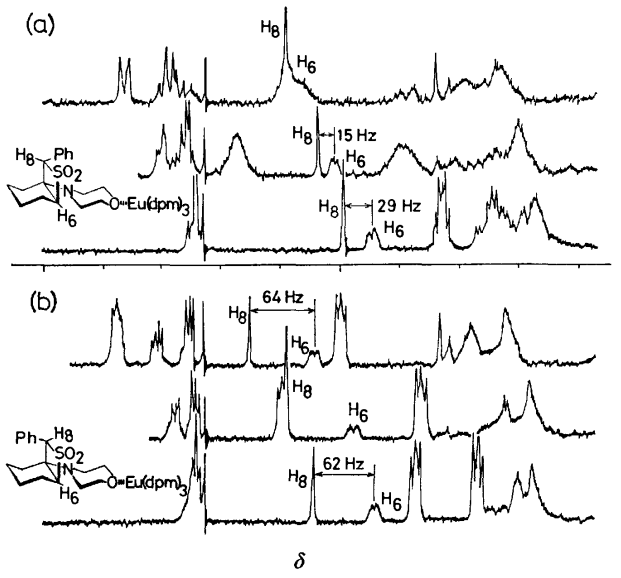


Fig. 1. Succesive scans displaying the effect of the addition of incremental amounts of $Eu(dpm)_3$ on the 60 MHz NMR spectra in $CDCl_3$; (a): for *cis*-**5d**, (b): for *trans*-**5d**.

mined by means of the intensity measurement of the H_8 proton signal in the NMR spectrum of the crude product. In the isomeric mixture of **5d**, the *cis* percentage was as high as 81% in benzene and was lowered to 70% in THF. In the case of **5c**, the predominant yield of the *cis* isomer was evident in the spectrum, though the *cis* percentage could not be determined because the peaks assigned to the *trans* isomer were weak and ambiguous. Interesting to say, the results suggest that the alternative of acyclic (**3**) or cyclic (**5**) is caused by the electronic character of the α-carbon atom in the sulfene.

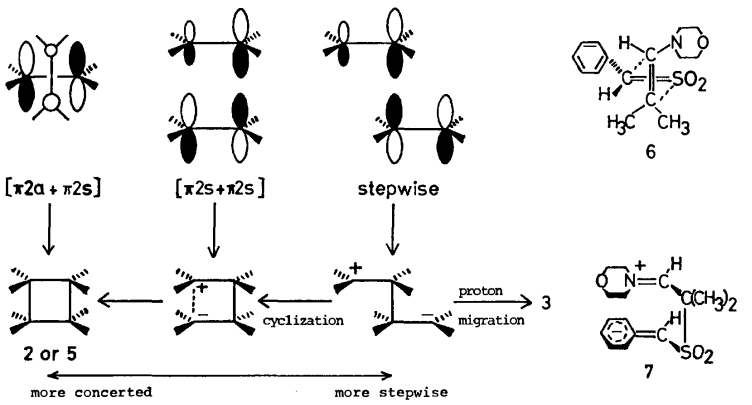
Reaction Mechanism. On the basis of the frontier orbitals' interaction in the [2+2] cycloaddition,[2b,9] different mechanistic processes are possible (Scheme 4). A concerted $[{}_{\pi}2_a+{}_{\pi}2_s]$ process could conceivably account for the *cis* preference in the cyclic sulfones (**2** and **5**). In this concerted process, one unsaturated system must approach the other with an orthogonal orientation.[12] The most probable transition state is shown for the formation of *cis*-**2**, such as **6**. If the reaction indeed proceeds *via* this concerted process, it should be required that the acyclic sulfones (**3a**, **3b**, and **3e**) were formed through the cyclic sulfones. And so, from the consideration of a steric interaction between the morpholino and the aryl groups, the cyclic isomers of **3a**, **3b**, and **3e** like **5c** and **5d** should also be isolated even in the MCH system, as well as in the MMP system. Actually, however, in the current observation, only acyclic sulfones **3a**, **3b**, and **3e** were afforded without the cyclic isomers in the MCH system. And in the case of the formation of cyclic sulfone, the *cis* preference was lowered when polar solvents were employed.

As an alternative, a concerted $[{}_{\pi}2_s+{}_{\pi}2_s]$ process can be significantly preferred, as pointed out by Epiotis *et al.*,[13] if one addend is very electron rich and the other is very electron defficient. However, from the evidence of the preference of noncycloaddition when a zwitterionic intermediate (**7**) is stabilized, a stepwise process, which is a third alternative, is rather likely.

The formation of the less stable *cis* isomer of cyclic sulfone (**2** and **5**) can be well explained on the basis of an electrostatic interaction of cisoid 1,4-dipolar intermediate (**7**). In the addition of sulfene to MMP, which has no proton β to the morpholino moiety, the *cis* isomer of **2** was predominantly afforded. If the carbanion is stabilized and given a long lifetime by its substituting group(like *p*-NO_2–Ph) or by a solvation in the polar solvents, the amount of the more thermodynamically stable *trans* isomer of **2** may increase. The addition of sulfene to MCH, which has a labile proton β to the morpholino moiety, resulted in the formation of **5c** and **5d**, where the *cis* isomer was predominant. However, if the carbanion was stabilized or if the negative charge is dispersed and the effective electrostatic attraction is reduced to a great extent by its substituting group, *e. g.* fluorenylidene, diphenyl, or *para*-nitrophenyl group, the proton migration to the carbanion to afford **3** would be more favored than the cyclization of the zwitterion to give **5**.

Experimental

The NMR spectra were recorded on a Varian EM-360 (60 MHz) instrument in $CDCl_3$ with tetramethylsilane as the internal standard. The IR spectra were measured in KBr disks with Hitachi EP-S and 215 spectrophotometers.



Scheme 4. Indicates acceptor(sulfene) LUMO[10]-donor(enamine) HOMO[11] interaction.

Materials. All the diazomethanes were prepared according to the procedures given in the literature: 9-diazofluorene (**1a**),[14] diphenyldiazomethane (**1b**),[15] *p*-tolyldiazomethane (**1c**),[16] phenyldiazomethane (**1d**),[17] and *p*-nitrophenyldiazomethane (**1e**).[18] The enamines were also prepared by the methods in the literature: 2-methyl-1-morpholinopropene(MMP)[19] and 1-morpholinocyclohexene (MCH).[20] Sulfur dioxide, obtained from a commercial source, was dried by passing it through $CaCl_2$ and P_2O_5 tubes. The solvents were purified according to the published directions,[21] stored over sodium wire or calcium hydride, and redistilled just before use.

General Procedure. In a 100 ml three-necked flask equipped with a magnetic stirrer, a dropping funnel, a thermometer, and a calcium chloride drying tube were placed 70 ml of a dry solvent containing 50 mmol of sulfur dioxide and 10 mmol of an enamine, and the flask was kept at 20 °C. To this solution, 30 ml of dry solvent containing 5 mmol of diazomethane was added dropwise over a period of 15 minutes with stirring. After the addition was complete, the mixed solution was stirred for an additional 45 minutes. Then the solvent and the excess sulfur dioxide were removed as quickly as possible *in vacuo* at room temperature. After an aliquot of the oily residue was dissolved in $CDCl_3$ and analyzed by NMR, the NMR solvent was removed at reduced pressure and the combined residue was crystallized from a suitable solvent. The NMR data for *cis* isomers were obtained from the mixtures except where noted. An analytically pure sample was obtained by recrystallization.

*2-Fluorenylidene-3-morpholino-4,4-dimethylthietane 1,1-Dioxide (**2a**).* The white powder was obtained in 99% yield by adding a small amount of cold petroleum ether to the oily residue. The recrystallization from methanol gave the colorless leaflets, mp 156—157 °C. IR(KBr): 1106 and 1315 cm^{-1} (SO_2). NMR($CDCl_3$): δ 1.55—2.33[4H, broad m, $(CH_2)_2N$], 1.84(3H, s, CH_3), 2.01(3H, s, CH_3), 3.43[5H, m, $(CH_2)_2O$ and methylidyne], and 7.3—8.1(8H, m, aromatic). Found: C, 68.12; H, 6.42; N, 3.89%. Calcd for $C_{21}H_{23}NO_3S$: C, 68.28; 6.28; N, 3.79%.

*2,2-Diphenyl-3-morpholino-4,4-dimethylthietane 1,1-Dioxide (**2b**).* The white powder was obtained in 95% yield in the same manner as described above. The recrystallization from benzene-ethanol(1 : 1) gave the colorless plates, mp 136—137 °C. IR(KBr): 1112 and 1305 cm^{-1} (SO_2). NMR($CDCl_3$): δ 1.64(3H, s, CH_3), 1.70(3H, s, CH_3), 2.37[4H, m, $(CH_2)_2N$], 3.64[4H, m, $(CH_2)_2O$], 3.77(1H, s, methylidyne), 7.15—7.65 (8H, m, C_6H_5 *trans* to morpholine ring and 3H of C_6H_5 *cis* to morpholine ring), and 7.8—8.2(2H, m, 2H of C_6H_5 *cis* to morpholine ring). Found: C, 68.01; H, 6.82; N, 3.85%. Calcd for $C_{21}H_{25}NO_3S$: C, 67.90; H, 6.78, N, 3.77%.

*3-Morpholino-2-*p*-tolyl-4,4-dimethylthietane 1,1-Dioxide (**2c**).* The *cis-trans* mixture was obtained in the yield of 51% in benzene and 57% in THF by adding a small amount of cold methanol to the oily residue. NMR($CDCl_3$) (*cis* isomer): δ 1.62 and 1.73(each 3H, s, *gem*-dimethyl), 2.28[4H, m, $(CH_2)_2N$], 2.32(3H, s, CH_3-Ph), 3.30(1H, d, J=10 Hz, CHN), 3.60[4H, m, $(CH_2)_2O$], 5.27(1H, d, J=10 Hz, $CHSO_2$), and 7.17 and 7.53(each 2H, d, J=7.8 Hz, phenyl). Repeated recrystallization of the crude product from methanol gave analytically pure *trans* isomer, colorless plates, mp 167—168 °C. IR(KBr): 1098, 1118, 1292, and 1304 cm^{-1} (SO_2). NMR ($CDCl_3$): δ 1.63 and 1.67(each 3H, s, *gem*-dimethyl), 2.29 [4H, m, $(CH_2)_2N$], 2.35(3H, s, CH_3-Ph), 3.08(1H, d, J= 10 Hz, CHN), 3.65[4H, m, $(CH_2)_2O$], 5.08(1H, d, J=10 Hz, $CHSO_2$), and 7.25(4H, broad s, phenyl). Found: C, 61.72; H, 7.37; N, 4.52%. Calcd for $C_{16}H_{23}NO_3S$: C, 62.12; H, 7,49; N, 4.53%.

*3-Morpholino-2-phenyl-4,4-dimethylthietane 1,1-Dioxide (**2d**).* The crude isomeric mixtures of the *cis* and *trans* cycloadducts were obtained in the yields of 43—80% according to the solvent used. The mixture was separated into the *cis* and *trans* isomers by repeated fractional recrystallization from a mixed solvent of petroleum ether and benzene. The *cis* isomer: colorless prisms, mp 128—129 °C. IR(KBr): 1089 and 1301 cm^{-1} (SO_2). NMR($CDCl_3$): δ 1.67 and 1.77(each 3H, s, *gem*-dimethyl), 2.33[4H, m, $(CH_2)_2N$], 3.35 (1H, d, J=10 Hz, CHN), 3.63[4H, m, $(CH_2)_2O$], 5.30(1H, d, J=10 Hz, $CHSO_2$), and 7.2—7.8(5H, m, phenyl). Found: C, 61.10; H, 7.23; N, 4.75%. Calcd for $C_{15}H_{21}NO_3S$: C, 61.00; H, 7.17; N, 4.74%. The *trans* isomer was also obtained by treating the *cis* isomer or the isomeric mixture in methanol containing a 0.02 part of sodium methoxide for about a week. The *trans* isomer: colorless plates, mp 179—180 °C(lit, 181—182 °C).[2b] IR(KBr): 1105 and 1298 cm^{-1} (SO_2). NMR ($CDCl_3$): δ 1.65 and 1.68(each 3H, s, *gem*-dimethyl), 2.26 [4H, m, $(CH_2)_2N$], 3.10(1H, d, J=10 Hz, CHN), 3.64[4H, m, $(CH_2)_2O$], 5.13(1H, d, J=10 Hz, $CHSO_2$), and 7.40(5H, s, phenyl). Found: C, 60.89; H, 7.25; N, 4.75%. Calcd for $C_{15}H_{21}NO_3S$: C, 61.00; H, 7.17; N, 4.74%.

*3-Morpholino-2-*p*-nitrophenyl-4,4-dimethylthietane 1,1-Dioxide (**2e**).* The NMR spectrum of the crude product showed the peaks derived from both *cis* and *trans* isomers. The yield of the product was 82% both in benzene and in THF. The *cis* isomer: NMR($CDCl_3$): δ 1.67 and 1.77(each 3H, s, *gem*-dimethyl), 2.25[4H, m, $(CH_2)_2N$], 3.41(1H, d, J=10 Hz, CHN), 3.63[4H, m, $(CH_2)_2O$], 5.40(1H, d, J=10 Hz, CH-SO_2), and 7.79 and 8.32(each 2H, d, J=9 Hz, phenyl). The pure *trans* isomer was obtained by recrystallization of the crude product from methanol: colorless plates, mp 193—194 °C. IR(KBr): 1115 and 1305 cm^{-1} (SO_2). NMR(CD-Cl_3): δ 1.67 and 1.69(each 3H, s, *gem*-dimethyl), 2.23[4H, m, $(CH_2)_2N$], 3.10(1H, d, J=10 Hz, CHN), 3.61[4H, m, $(CH_2)_2O$], 5.17(1H, d, J=10 Hz, $CHSO_2$), and 7.58 and 8.25(each 2H, d, J=9 Hz, phenyl). Found: C, 52.87; H, 5.97; N, 8.46%. Calcd for $C_{15}H_{20}N_2O_5S$: C, 52.93; H, 5.92; N, 8.46%.

*3-(9-Fluorenylsulfonyl)-2-morpholinocyclohexene (**3a**).* A white powder was afforded in 84% yield by adding a small amount of cold petroleum ether to the oily residue. An analytiacally pure sample was obtained by recrystallization from methanol: colorless plates, mp 142—143 °C. IR(KBr): 1120 and 1315 cm^{-1}(SO_2), 1653 cm^{-1}(C=C). NMR($CDCl_3$): δ 1.25—2.75(6H, broad m, cyclohexane ring), 2.58[4H, m, $(CH_2)_2N$], 3.48[5H, m, $(CH_2)_2O$ and $CHSO_2$], 5.28(1H, t, J=3 Hz, vinyl), 5.58(1H, s, SO_2CH-Ar), and 7.2—8.1(8H, m, aromatic). Found: C, 70.48; H, 6.40; N, 3.31%. Calcd for $C_{23}H_{25}NO_3S$: C, 69.85; H, 6.37; N, 3.54%.

*3-Diphenylmethylsufonyl-2-morpholinocyclohexene (**3b**).* A white powder was obtained in 87% yield by adding a small amount of cold petroleum ether to the oily residue and was recrystallized from ethanol, giving the colorless plates, mp 150.5—151.5 °C. IR(KBr): 1112 and 1305 cm^{-1} (SO_2), 1645 cm^{-1} (C=C). NMR($CDCl_3$): δ 1.3—3.2(6H, broad m, cyclohexane ring), 2.76[4H, m, $(CH_2)_2N$], 3.83[5H, m, $(CH_2)_2O$ and $CHSO_2$], 5.43(1H, t, J=4 Hz, vinyl), 6.02(1H, s, SO_2CH-Ar), and 7.3—8.0(10H, m, aromatic). Found: C, 69.41; H, 6.96; N, 3.65%. Calcd for $C_{23}H_{27}NO_3S$: C, 69.50; H, 6.85; N, 3.52%.

*3-*p*-Nitrobenzylsulfonyl-2-morpholinocyclohexene (**3e**).* The NMR spectrum of the residue showed that the reaction products consisted exclusively of acyclic isomer. The crude product was collected as white powder by adding cold methanol to the residue in the yield of 88.5% in benzene and 93% in THF. Recrystallization from methanol afforded analytically

pure **3e**: colorless needles, mp 181—182 °C. IR(KBr): 1128 and 1304 cm^{-1} (SO_2), 1639 cm^{-1} (C=C). NMR($CDCl_3$): δ 1.5—2.7(6H, broad m, cyclohexane ring), 2.48—3.35[4H, broad m, $(CH_2)_2N$], 3.83[4H, m, $(CH_2)_2O$], 3.87 (1H, m, methylidyne), 4.40 and 4.73 (each 1H, ABq, J= 12.5 Hz, SO_2CH_2-Ph), 5.40(1H, t, J=3.5 Hz, vinyl), and 7.53 and 8.22 (each 2H, d, J=8.5 Hz, phenyl). Found: C, 55.55; H, 6.02; N, 7.69%. Calcd for $C_{17}H_{22}N_2O_5S$: C, 55.72; H, 6.05; N, 7.65%.

*1-Morpholino-8-*p*-tolyl-7-thiabicyclo[4.2.0]octane 7,7-Dioxide (5c).* The crude product consisted exclusively of cyclic adduct; the peaks in the NMR spectrum which are derived from *trans*-**5c** were weak and ambiguous. After careful recrystallization from cold methanol, analytically pure *cis* isomer was isolated in the yield of 49% in benzene and 54% in THF; its structure was established by means of NMR, using $Eu(dpm)_3$. The *cis* isomer: colorless plates, mp 123—124 °C. IR(KBr): 1120 and 1320 cm^{-1} (SO_2). NMR($CDCl_3$): δ 1.3—2.8(8H, broad m, cyclohexane ring), 2.32(3H, s, CH_3), 2.47[4H, m, $(CH_2)_2N$], 3.30[4H, m, $(CH_2)_2O$], 4.42 (1H, m, H_6), 4.86(1H, s, H_8), and 7.24 and 7.36(each 2H, d, J=8.5 Hz, phenyl). Found: C, 65.06; H, 7.49; N, 4.16 %. Calcd for $C_{18}H_{25}NO_3S$: C, 64.46; H, 7.51; N, 4.18%.

1-Morpholino-8-phenyl-7-thiabicyclo[4.2.0]octane 7,7-Dioxide (5d).[22] The mixture of *cis* and *trans* cyclic adducts was obtained when **1d** was used. The NMR spectrum of the residue showed that the reaction product consisted exclusively of cyclic adduct. The yields were 87% both in benzene and THF. The *cis* and *trans* isomers were isolated by careful fractional recrystallization from methanol. The ratios of the *cis* isomer were 81% in benzene and 70% in THF. Each of the structures was confirmed by means of NMR using $Eu(dpm)_3$, as described before. The *cis* isomer: white crystalline, mp 103—104.5 °C. IR(KBr): 1150 and 1314 cm^{-1} (SO_2). NMR($CDCl_3$): δ 1.2—2.8(8H, broad m, cyclohexane ring), 2.50[4H, m, $(CH_2)_2N$], 3.30[4H, m, $(CH_2)_2O$], 4.44(1H, m, H_6), 4.92(1H, s, H_8), 7.37(5H, m, phenyl). Found: C, 64.04; H, 7.09; N, 4.87%. Calcd for $C_{17}H_{23}NO_3S$: C, 63.53; H, 7.21; N, 4.36%. The *trans* isomer; colorless prisms, mp 115—116 °C. IR(KBr):1140 and 1298 cm^{-1} (SO_2). NMR($CDCl_3$): δ 1.2—2.6(8H, broad m, cyclohexane ring), 2.63[4H, m, $(CH_2)_2N$], 3.80[4H, m, $(CH_2)_2O$], 4.37(1H, m, H_6), 5.40(1H, s, H_8), and 7.2—7.7(5H, m, phenyl). Found: C, 63.48; H, 7.22; N, 4.23%. Calcd for $C_{17}H_{23}NO_3S$: C, 63.53; H, 7.21; N, 4.36%.

(Received November 5, 1976)

The reaction of 3-phenylpyrrolo[2,3-*b*]tropone (**7**) with phosphoryl chloride gave 8-chloro-3-phenyl-1-azaazulene (**5**). When **5** and **7** were treated with *N*-chlorosuccinimide, 2,8-dichloro-3-phenyl-1-azaazulene (**6**) and 2-chloro-3-phenylpyrrolo[2,3-*b*]tropone (**8**) were obtained respectively. **6** was also obtained from **8** by treatment with phosphoryl chloride. The reactions of **5** and **6** with nucleophilic reagents gave the corresponding substituted products (**14a—m** and **15a—m**). 8-Hydrazino-3-phenyl-1-azaazulene (**14m**) and 2-chloro-8-hydrazino-3-phenyl-1-azaazulene (**10**), which had been obtained by the reaction of **5** and **6** with hydrazine hydrate, were decomposed by treatment with copper(II) sulfate in acetic acid to give 3-phenyl-1-azaazulene (**2**) and 2-chloro-3-phenyl-1-azaazulene (**11**) respectively.

1-Azaazulene (**1**),[2] a seven-membered analog of indole, and its 3-phenyl derivative (**2**),[3] were synthesized a little more than twenty years ago by one of the present authors (T. N.) and his co-workers; the molecular diagram of this interesting compound (**1**) was calculated by Kon[4] (*cf.* Fig. 1). As the reactivity of the same

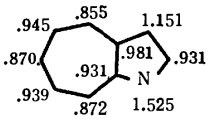

Fig. 1. Charge density of 1-azaazulene calculated by H. Kon.[4]

functional group should be different according to its position in such a nonbenzenoid nucleus, we first studied the nucleophilic substitution reaction of 2-chloro- (**3**)[2] and 2,6-dichloro-1-azaazulene (**4**).[5] Brief mention was

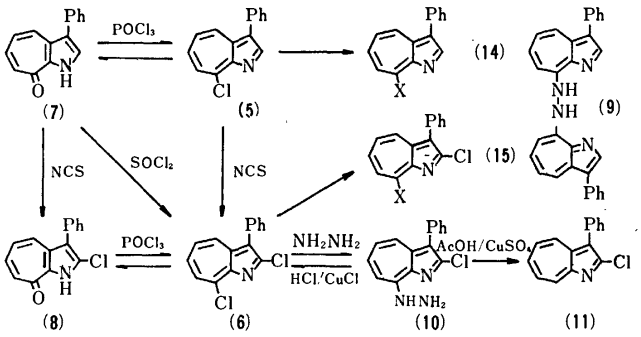
(**1**): R=H
(**2**): R=Ph

(**3**): X_1=Cl, X_2=H
(**4**): X_1=X_2=Cl

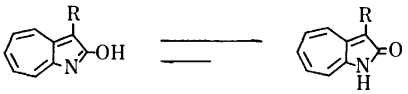
also made of the nucleophilic displacement reaction of 8-chloro-(**5**)[1,3] and 2,8-dichloro-3-phenyl-1-azaazulene (**6**),[1] the results of which have remained unpublished. We now wish to report on the nucleophilic substitution reaction of these two compounds (**5** and **6**).

Results and Discussion

The reaction of 3-phenylpyrrolo[2,3-*b*]tropone (3-phenylcyclohept[2,3-*b*]pyrrol-8-one) (**7**)[3] with phosphoryl chloride gives 8-chloro-3-phenyl-1-azaazulene (**5**) as reddish purple needles. When **5** and **7** are treated with *N*-chlorosuccinimide, dichloro- (**6**) and monochloro compound (**8**) are obtained respectively in good yields. The same compound (**6**) is also obtained by the treatment of **5** or **7** with thionyl chloride or sulfuryl chloride, but in poor yields. Compound **6** is also obtained from **8** by treatment with phosphoryl chloride. Compounds (**5** and **6**) afford **7** and **8** respectively on treatment with ethanolic alkali. Similarly, one of the two chlorine atoms in **6** is easily replaced by a hydrazino group on treatment with hydrazine hydrate to give **10**; the latter compound (**10**) reverts back to **6** upon treatment with concentrated hydrochloric acid and copper(I) chloride, while the monochloro compound (**11**) is obtained when **10** is decomposed by treatment with copper(II) sulfate in acetic acid.



When **11** is treated with ethanolic alkali, 1,2-dihydro-3-phenyl-1-azaazulen-2-one (**12**) is formed as a saponification product. The structure of **12** was confirmed by a direct comparison with the sample obtained by the reaction of aminotropone with methyl phenylacetate.



(**12**) : R=Ph
(**13**) : R=H

From the above-mentioned experimental evidence and the results of elemental analyses, **6** is identified as 2,8-dichloro-3-phenyl-1-azaazulene. The UV and NMR spectra of **5** and **6** also support the structure described above (Tables 4 and 5).

8-Hydroxy, 8-amino, and related derivatives of 1-azaazulene have two tautomeric forms, such as A and B. It seems that those substances exist mainly in their

** Present address: Faculty of Science, Korean University, 1-700, Ogawacho, Kodaira-shi, Tokyo 187.

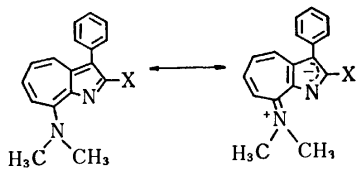
14k	$N(CH_3)_2$	H	252(4.41), 264(4.38) 329(4.56), 408(3.32) (cyclohexane)	1612, 1513	3.63(6H, s, $N(CH_3)_2$) 6.81(1H, ddd, J=10.0, 8.6, 1.0 Hz, H-5) 7.12(1H, dm, J=12.0 Hz, H-7) 7.30—7.62(7H, m, H-6 and phenyl) 8.28(1H, dm, J=10.0 Hz, H-4)
15l	$N(CH_3)_2$	Cl	253(4.38), 265(4.40) 331(4.54), 390(3.72) 412(3.70) (sh), 447 (3.52) (sh) (cyclohexane)	1613, 1518	3.60(6H, s, $N(CH_3)_2$) 6.83(1H, ddd, J=10.0, 8.4, 1.0 Hz, H-5) 7.09(1H, dm, J=11.6 Hz, H-7) 7.25—7.53 (7H, m, H-6 and phenyl) 7.94(1H, dm, J=10.0 Hz, H-4)

ketonic form (B) rather than in the enolic form (A), as in the case of 2-hydroxy derivatives of 1-azaazulene (**13**)[6] or its 3-substituted products (**12** or other compounds),[5] as is shown by their spectroscopic data, presented in Table 3.

(A) (B)

As for the 8-dimethylamino derivatives (**14k** and **15l**), the visible and PMR spectra indicate that there is a contribution of the zwitterion structure (D),[5] as will be described below. In the absorption spectra of **14k** and **15l**, the absorption maxima in the visible region were shifted to shorter wavelengths than those of **5** and **6** (Tables 3 and 4). The PMR spectra of **14k** and **15l** exhibited the signals for H-5 at *ca.* 6.8 PMR, and they were observed upfield from those of **5** and **6**, as in the case of the 8-hydroxy derivatives of 1-azaazulene (**7** and **8**) (Tables 3 and 5).



(C) (D)

The C_8-positions of Compounds **5** and **6** are easily replaced by the treatment of various nucleophilic reagents; the results are summarized in Tables 1 and 2. Only the chlorine atom at C_8 in the dichloro compound (**6**) is displaced by the nucleophilic reagent. However, a strong nucleophile such as *p*-thiocresol afforded a disubstituted product (**16**). This is quite understandable in view of Fig. 1 and the electron-releasing effect

TABLE 4. ULTRAVIOLET AND VISIBLE ABSORPTION MAXIMA OF SUBSTITUTED 1-AZAAZULENES

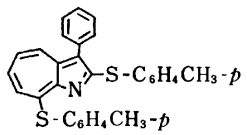
6	Cl	Cl	7.42—7.86(7H, m, H-5, 6 and phenyl) 8.02(1H, dd, J=9.9, 2.0 Hz, H-7) 8.39(1H, dd, J=9.0, 2.4 Hz, H-4)

of the reaction products (**15**).



(**16**)

The reaction of **5** with hydrazine hydrate in methanol gave **9** besides **14m**.[3]

Experimental†

All the melting points are uncorrected.

Phenylacetaldehyde Troponylhydrazone. To a solution of 2-hydrazinotropone (16.7 g) in ethanol (200 ml), phenylacetaldehyde (16.1 g) was added, and the mixture was refluxed for 30 min. After cooling, the separated precipitates were collected and recrystallized from ethanol to give yellow needles (27.5 g, 94%); mp 127—128 °C. UV: λ_{max}^{MeOH} 252 (log ε=4.32), 350 (4.24), and 410 (4.29) nm. Found: C, 75.33; H, 6.20; N, 11.70%. Calcd for $C_{15}H_{14}ON_2$: C, 75.60; H, 5.92; N, 11.76%.

3-Phenylpyrrolo[2,3-b]tropone (7). A mixture of phenylacetaldehyde troponylhydrazone (23.5 g), water (650 ml), and concd sulfuric acid (32 ml) was refluxed at 110—120 °C for 3 h. After cooling, the reaction mixture was made slightly acid with 2 M sodium hydroxide and, then extracted with chloroform. The extract was dried over anhydrous sodium sulfate, and the solvent was removed. The residue was recrystallized from benzene to give pale yellow needles (15.2 g, 70%); mp 188—189 °C. Found: C, 81.21; H, 5.09; N, 6.24%. Calcd for $C_{15}H_{11}ON$: C, 81.43; H, 5.01; N, 6.33%.

8-Chloro-3-phenyl-1-azaazulene (5). A mixture of **7** (7.0 g) and phosphoryl chloride (28.0 g) was heated at 105 °C for 1 h. After cooling, the reaction mixture was poured onto ice water and the solution was made alkaline with a sodium hydrogencarbonate solution, followed by extraction with benzene. The extract was dried, the solvent was removed, and the residue was recrystallized from cyclohexane to give reddish purple needles (6.5 g, 85%); mp 106—107 °C. Found: C, 75.57; H, 4.29; N, 6.01%. Calcd for $C_{15}H_{10}NCl$: C, 75.17; H, 4.18; N, 5.84%.

Picrate: Orange micro needles (from ethanol); mp 189 °C (decomp). Found: C, 53.75; H, 2.84; N, 11.34%. Calcd for $C_{21}H_{13}O_7N_4Cl$: C, 53.79; H, 2.78; N, 11.95%.

Hydrolysis of 5. A solution of **5** (0.3 g) in ethanol (8 ml) containing 2 M sodium hydroxide (4 ml) was refluxed for 30 min. The solvent was then removed, the residue was made acid with dil hydrochloric acid, and the solution was extracted with chloroform. The dried extract was concentrated, and the residue was recrystallized from ethanol to give colorless needles (0.11 g, 60%); mp 187—188 °C. The IR spectrum was identical with that of **7**, and the mixed melting point with the sample was not depressed.

2,8-Dichloro-3-phenyl-1-azaazulene (6). *(a)* A mixture of **5** (0.3 g) in carbon tetrachloride (210 ml), *N*-chlorosuccinimide (2.6 g), and benzoyl peroxide (0.06 g) was refluxed for 3 h. The solvent was then removed, and the residue was washed with hot water several times and extracted with benzene. The dried extract was concentrated to about 30 ml and chromatographed on silica gel. From the bright red effluent, **6** was obtained as bright red plates (2.5 g, 73%); mp 160—161 °C. Found: C, 65.76; H, 3.48; N, 5.58%.

† The authors are grateful to the Sankyo Co., Ltd., for the elemental analyses.

Calcd for $C_{15}H_9NCl_2$: C, 65.69; H, 3.28; N, 5.11%.

(b) A mixture of **7** (6.0 g) in dry benzene (300 ml) and thionyl chloride (20.0 g) was refluxed for 15 h with stirring at 80—90 °C. The solvent was then removed, and the residue was treated with a saturated solution of sodium hydrogencarbonate and extracted with benzene. The extract was dried, concentrated, and chromatographed on alumina. The red effluent gave bright red needles (1.5 g, 20%), which were subsequently recrystallized from cyclohexane. The mixed melting point with the sample obtained by Method (a) was not depressed.

(c) A mixture of **5** (6.0 g) in carbon tetrachloride (150 ml) and sulfuryl chloride (3.4 g) was refluxed for 1 h. The solvent was then removed, and the residue was treated with a saturated of sodium hydrogencarbonate and extracted with benzene. The extract was concentrated and chromatographed on alumina. From the red effluent, **6** was obtained as bright red plates (1.2 g, 35%).

From the purple effluent, a purple powder was obtained; its structure can not be clarified yet. Mp 193—195 °C. UV: $\lambda_{max}^{CHCl_3}$ 256, 302, and 514 nm. Found: C, 58.50; H, 2.64; N, 4.73; Cl, 34.39%. Calcd for $C_{15}H_8NCl_3$: C, 58.38; H, 2.61; N, 4.54; Cl, 34.37%.

(d) A mixture of **8** (0.5 g) and phosphoryl chloride (2.6 g) was heated at 105 °C for 1 h. After cooling, the reaction mixture was poured into ice water, and the solution was treated with a saturated solution of sodium carbonate and extracted with benzene. The dried extract was concentrated, and the residue was recrystallized from cyclohexane to give red plates (0.37 g, 63%). The mixed melting point with the sample obtained by Method (a) was not depressed.

(e) A mixture of **7** (0.6 g) in dry benzene (30 ml) and thionyl chloride (3.0 g) was heated under reflux for 16 h at 90—100 °C. The reaction mixture was then worked up as above (Method b). A small amount of **6** was obtained, and most of the starting material (**7**) was recovered.

(f) A mixture of **10** (0.1 g), concd hydrochloric acid (2.5 ml), and 1 M copper(II) sulfate (3 ml) was heated for a few min on a water hath. After cooling, the reaction mixture was neutralized with a 5% sodium hydrogencarbonate solution and extracted with benzene. The dried extract was concentrated and passed through a silica gel column. From the red effluent, **6** was obtained as red plates (0.06 g, 54%); mp 160—161 °C.

2-Chloro-3-phenylcyclohept[2,3-b]pyrrol-8(1H)-one (8). A mixture of **7** (1.0 g) in carbon tetrachloride (60 ml), *N*-chlorosuccinimide (0.97 g), and benzoyl peroxide (0.06 g) was refluxed for 3 h. The solvent was then removed, and the residue was treated with hot water and extracted with chloroform. The extract was washed with water, dried, and concentrated, and the residue was recrystallized from benzene to give pale yellow needles (0.52 g, 47%); mp 223—224 °C. Found: C, 70.44; H, 4.11; N, 5.58%. Calcd for $C_{15}H_{10}ONCl$: C, 70.45; H, 3.91; N, 5.48%. The spectral data are shown in Table 3.

Hydrolysis of 6. A solution of **6** (0.2 g) in ethanol (8 ml) containing 2 M sodium hydroxide (5 ml) was refluxed for 1 h on a water bath. The solvent was then removed, and the residue was made acid with dil sulfuric acid and extracted with chloroform. The dried extract was evaporated, and the residue was recrystallized from benzene to give pale yellow needles (0.18 g, 94%); mp 224—225 °C. The IR spectrum was identical with that of **8**, and the mixed melting point was not depressed.

The Reaction of 8-Chloro- and 2,8-Dichloro-3-phenyl-1-azaazulenes (5 and 6) with Nucleophilic Reagents. The mixtures obtained by the reaction of chloroazaazulenes (**5** and **6**) with nucleophilic reagents were worked up in the usual manner, and the products were purified by chromatography and recrystallization. The conditions and results are given in Tables 1 and 2.

The Reaction of 8-Chloro-3-phenyl-1-azaazulene (5) with Hydrazine Hydrate.[3] A solution of 80% hydrazine hydrate (4.0 g) in methanol (100 ml) was added, drop by drop, to a solution of **5** (1.0 g) in methanol (100 ml), after which the solution was stirred at room temperature for 2 h. The reddish purple crystals which precipitated out were collected and recrystallized from cyclohexane–benzene to give *N,N'*-bis(3-phenyl-1-azaazulen-8-yl)hydrazine as reddish purple micro prisms (0.55 g); mp 277—278 °C.

On the other hand, the solvent was removed from the filtrate of the reaction mixture, water was added, and the solution was extracted with benzene. The extract was dried, the solvent was removed, and the residue was recrystallized from cyclohexane to afford 8-hydrazino-3-phenyl-1-azaazulene (**11**) (0.40 g).

3-Phenyl-1-azaazulene (2). A mixture of 8-hydrazino-3-phenyl-1-azaazulene (0.2 g), acetic acid (5 ml), water (5 ml), and a 10% copper(II) sulfate solution was heated for a few min on a water bath. After cooling, the reaction mixture was made slightly alkaline with 2 M sodium hydroxide and the solution was extracted with ether. The dried extract was concentrated to leave a reddish purple oil. The residual oil was purified by distillation under reduced pressure (bp 90 °C/0.01 Torr). *Picrate*: Orange needles, mp 236 °C (decomp.). The results are given in Table 1.

2-Chloro-3-phenyl-1-azaazulene (11). A mixture of **10** (0.7 g), acetic acid (28 ml), 1 M copper(II) sulfate (56 ml), and water (28 ml) was heated for 15 min on a water bath. After cooling, the reaction mixture was made slightly alkaline with 2 M sodium hydroxide and extracted with chloroform. The dried extract was concentrated and chromatographed on silica gel. From the red effluent, a red oil was obtained and subsequently distilled under reduced pressure (bp 100 °C/1 Torr) (0.37 g). The results are given in Table 2.

2-Chloro-8-bromo-3-phenyl-1-azaazulene (15n). A mixture of **10** (0.12 g), 48% hydrobromic acid (8 ml), and 1 M copper(II) sulfate (9.6 ml) was heated for a few min on a water bath. After cooling, the reaction mixture was treated with a 5% sodium hydrogencarbonate solution and extracted with chloroform. The dried extract was concentrated and chromatographed on silica gel. The product obtained from the red effluent was recrystallized from cyclohexane to give red plates (0.04 g). The results are given in Table 2.

1,2-Dihydro-3-phenyl-1-azaazulen-2-one (12). *(a)* A mixture of **11** (0.37 g) in ethanol (15 ml) and 2 M sodium hydroxide (30 ml) was refluxed for 5 h on a water bath. After cooling, the reaction mixture was made slightly acid with a dil sulfuric acid solution and extracted with benzene. The dried extract was then concentrated, and the residue was recrystallized from benzene to give micro prisms (0.04 g, 12%); mp 264—265 °C. IR(KBr): 1638 cm^{-1} (C=O). UV λ_{max}^{MeOH} 235(log ε=4.34), 283(4.41), 420(4.00)nm. Found: C, 81.33; H, 5.00; N, 6.13%. Calcd for $C_{15}H_{11}ON$: C, 81.43; H, 5.01; N, 6.33%.

(b) To a sodium ethoxide solution prepared from sodium metal (1.25 g) and absolute ethanol (30 ml), aminotropone (3.0 g) and methyl phenylacetate (7.4 g) were added, after which the mixture was heated in a sealed tube at 130 °C for 5 h. The reaction mixture was concentrated, made acid with 2 M hydrochloric acid, and then extracted with benzene. The benzene layer was dried over anhydrous sodium sulfate and the benzene was removed. From the residual oily product, a small amount of **12** (0.14 g, 3%) was obtained,

with the recovery of the starting material. The mixed melting point with the sample obtained by Method (a) was not depressed.

*2,8-Di(p-tolylthio)-3-phenyl-1-azaazulene (**16**).* *(a)* To a sodium methoxide solution prepared from sodium metal (0.37 g) and absolute methanol (7 ml), *p*-thiocresol (0.2 g) and **6** (0.2 g) were added, and then the mixture was heated under reflux for 15 min. The reaction mixture was concentrated under reduced pressure and extracted with benzene, and the benzene extracts were washed with water, dried over anhydrous sodium sulfate, and chromatographed on alumina. The product obtained from the benzene effluent was recrystallized from cyclohexane to give red prisms (0.12 g, 39%); mp 209—210 °C. Found: C, 77.46; H, 5.16; N, 3.12; S, 14.26%. Calcd for $C_{29}H_{23}NS_2$: C, 77.10; H, 5.19; N, 3.04; S, 13.97%.

(b) A mixture of **6** (0.2 g) and *p*-thiocresol (0.18 g) in dimethyl sulfoxide (10 ml) was stirred for 15 h at room temperature. The reaction mixture was diluted with water, made alkaline with aqueous sodium carbonate, and extracted with benzene. The benzene extracts were dried over anhydrous sodium sulfate and chromatographed on alumina. The product obtained from the benzene effluent was recrystallized from cyclohexane to give red prisms (0.13 g, 42%); mp 209—210 °C. The IR spectrum was identical with that of the sample obtained by Method (a), and the mixed melting point was not depressed.

This work was financially supported by grants from the Ministry of Education of Japan, to which the authors' thanks are due. One of the authors (Je-Kyun Sin) especially wishes to acknowledge the kind guidance of the late Professor Yoshio Kitahara of Tohoku University. We also wish to thank Dr. Masafumi Yasunami of Tohoku University for his helpful suggestions regarding the NMR spectra.

Branched-chain Sugars. IX. Reaction of 3,6-Anhydro-1,2-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose with Nitromethane or Hydrogen Cyanide[1]

Ken-ichi SATO, Juji YOSHIMURA, and Chung-gi SHIN*

(Received December 1, 1976)

3,6-Anhydro-1,2-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose (**2**) was converted into 5,6-di-*O*-acetyl-1,2-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose (**5**) by the protection of the carbonyl function with hydroxylamine, followed by acetylation and removal of the protecting group with chromium(II) acetate. Nitromethane condensation of **2** and **5** at room temperature gave the corresponding 3-nitromethyl derivatives having D-gluco- and D-*allo*-configuration, respectively. The difference in the stereoselectivity was explained by the easiness of isomerization of the initial product to thermodynamically stable epimer, because the reaction temperature was essential to control the selectivity in the same reaction of 1,2 : 5,6-di-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose. Reaction of **2** with hydrogen cyanide in dry pyridine followed by acetylation gave the corresponding 3,5,6-tri-*O*-acetyl-3-cyano derivative of D-*allo*-type, whereas, the reaction in water gave instantly 3-(hydroxycarbonimidoyl)-1,2-*O*-isopropylidene-α-D-allofuranose 3',5-lactone, by the participation of the C_5-hydroxyl group.

Up to date, many works have been reported on the nucleophilic reaction of easily available 1,2 : 5,6-di-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose (**1**),[2-4] and we also reported on the stereoselectivities of some reactions.[5] This compound decomposes often to 3,6-anhydro-1,2-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose (**2**)[6] during the storage, unless kept at lower temperature in pure state. Although **2** is easily obtained by the partial hydrolysis of **1**,[7] it is unfavorably formed during the preparation of **1** by the dimethyl sulfoxide oxidation of 1,2 : 5,6-di-*O*-isopropylidene-α-D-glucofuranose, and easily separated from the chloroform solution of the products by extraction with water, sometimes in *ca.* 30% yield. Intramolecular hemiacetal structure of **2**[8] indicates a diminished reactivity of the carbonyl function, but the hydrogenation[6] and *p*-nitrophenylhydrazone formation[7] of **2** were described in literatures.

In order to find useful utilizations of **2** as a starting material for the branched-chain sugar synthesis, **2** was converted into 5,6-di-*O*-acetyl-1,2-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose, and the addition of nitromethane and hydrogen cyanide to both compounds were carried out in this paper. A new evidence on the stereoselectivity of the former reaction and a participation of a neighboring hydroxyl group in the latter reaction are described.

Results and Discussion

Attempted acetonation of **2** into **1** and the Grignard reaction of **2** gave unsuccessful results, indicating that the intramolecular hemiacetal ring of **2** is fairly stable like that of 2-ketoses. Although much stronger nucleophiles such as nitromethanide anion and cyanide ion are deduced to be reactable with **2**, conversion of **2** into a more reactive 3-ulose derivative having the naked carbonyl group was tried at first. Condensation of **2** with hydroxylamine in aqueous ethanol gave the cor-

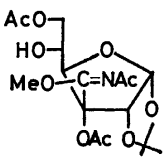
(**14**)



(**15**)

responding oxime derivative (**3**) in 74% yield, and then base-catalyzed acetylation of **3** gave the tri-*O*-acetate (**4**) quantitatively. The NMR spectrum of **4** indicated the presence of both *syn*- and *anti*-forms, but they were not assigned. Treatment of **4** with excess chromium-(II) acetate[9] in tetrahydrofuran–water (9 : 1) at room temperature for 12 h gave successfully the corresponding 3-ulose (**5**) in 85% yield. Tronchet *et al.* synthesized **5** from 3-*O*-benzyl-1,2;5,6-di-*O*-isopropylidene-α-D-glucose *via* four step conversions, and reported that **5** is unstable on TLC.[7]

Reaction of **2** with *aci*-nitro salt of nitromethane in ethanol does not proceeded at −70 °C; however, at room temperature for 30 min a condensation product (**6**) was obtained in 83% yield. The configuration of **6** was determined to be D-*gluco*-type by acetonation of **6** into well known 1,2 : 5,6-di-*O*-isopropylidene-3-(nitromethyl)-α-D-glucofuranose.[10] Base-catalyzed acetylation of **6** gave the corresponding 5,6-di-*O*-acetate (**7**) quantitatively. Hydrogenation of **6** in the presence of palladium–charcoal afforded the 3-*C*-aminomethyl derivative (**8**), which was then converted into the corresponding *N*,*O*-triacetate (**9**) in a good yield. Besides, the nitromethane condensation of **5** under the same conditions as used for **2** gave unexpectedly a different 3-*C*-nitromethyl derivative (**10**) from **7** in 71% yield. These compounds are considered to be 3-epimer to each other, however, there is also the possibility of the inversion at C-4 position[11] under the reaction conditions. Consequently, 1,2 : 5,6-di-*O*-isopropylidene-3-(nitromethyl)-α-D-allofuranose[5,10] was partially hydrolyzed to the corresponding 1,2-*O*-isopropylidene derivative (**11**) quantitatively, and then acetylated. The identity of the di-*O*-acetate obtained and **10** clearly established the 3-epimeric interrelation between **10** and **7**.

Table 1. The predominant epimer produced in the nitromethane condensation of **1** under various conditions[a]

Reaction conditions				Epimer ratio

a) The reaction mixture was extracted with chloroform, after neutralization with 60% acetic acid. The configuration and ratio of epimers were estimated from the intensity of H_1-proton signals in the NMR spectrum. b) THF=tetrahydrofuran, DMF=*N*,*N*-dimethylformamide, HMPA=hexamethylphosphoramide, DMSO =dimethyl sulfoxide, Glyme=1,2-dimethoxyethane. c) The amount of bases used are a slightly excess than the equivalent. d) Cited from the literature, A. Rosenthal, K.-S. Ong, and D. Baker, *Carbohyd. Res.*, **13**, 113 (1970).

In general, the nitromethane condensation of uloses give one epimer or mixture of epimers depending on the reaction conditions.[12] As is seen in Table 1, the reaction temperature is the most essential to control the stereoselectivity of the nitromethane condensation of **1**. This fact implies that the composition of the product is determined by the rate of isomerization of the initial product: kinetically controlled product, to the thermodynamically stable isomer. Thus, the difference of the configuration of the products in the reaction of **2** and **5** should be explained from the free energy difference between the epimers in each case. The kinetic studies will be reported elsewhere.

On the other hand, reaction of **2** with hydrogen cyanide in pyridine at 0 °C for 6 h and successive acetylation of the reaction mixture with acetic anhydride gave the corresponding 3-cyano-tri-*O*-acetate (**12**) in 54% yield. The configuration of **12** was confirmed to be D-*allo*-type by comparison of the NMR spectrum with that of the authentic sample, prepared from the corresponding 5,6-*O*-isopropylidene derivative.[13] Besides, the reaction of **2** with potassium cyanide in water in the presence of sodium hydrogencarbonate at 0 °C gave instantly a crystalline product (**13**) in 66% yield, which shows charateristic IR absorptions at 3300 (C=NH) and 1705 (–O–C=NH) cm^{-1}. From the elemental analysis and the following reactivities, **13** was deduced to be 3-(hydroxycarbonimidoyl)-1,2-*O*-isopropylidene-α-D-allofuranose 3′,5-lactone. On standing in water, **13** changed gradually into the corresponding lactone ($\nu_{C=O}$ 1785 cm^{-1}).[13] When **13** was acetylated with acetic anhydride in pyridine and then the reaction mixture poured into water, known 3,6-di-*O*-acetyl-3-carboxy-1,2-*O*-isopropylidene-α-D-allofuranose 3′,5-lactone (**14**)[13,14] was obtained in 61% yield, whereas treatment of the acetylated product with methanol gave 3,6-di-*O*-acetyl-1,2-*O*-isopropylidene-3-[(acetylimino)methoxymethyl]-α-D-allofuranose (**15**) in 65% yield. The structure of **15** was determined from the analytical values and the absence of the deshielding effect of acetyl group on H_5 proton in the NMR spectrum. Moreover, treatment of **13** with sodium hydrogencarbonate in methanol overnight at reflux temperature gave quantitatively the corresponding carboxylate (**16**) which can be converted into **14** by acetylation with acetic anhydride in a good yield.

Bourgeois reported on the isomerization of the initially formed 3-cyano-1,2 : 5,6-di-*O*-isopropylidene-α-D-allofuranose to the corresponding D-gluco-epimer in the reaction of **1** with hydrogen cyanide.[15] From the fact, it is considered that the kinetically controlled product **12** was simply formed in the same reaction of **2** in pyridine at 0 °C. However, the reaction in water gave **13**, whose formation is attributed to the further participation of a sterically favorable hydroxyl group in the same molecule. The reason for this difference is

ambiguous at present, but the similar participations are known in carbohydrate chemistry.[16,17]

Experimental

All the melting points are uncorrected. The solution were evaporated under diminished pressure at a bath temperature not exceeding 45 °C. Specific rotations were measured in a 0.5 dm tube, with a Carl Zeiss LEP-Al polarimeter. The IR spectra were recorded with a Hitachi Model EPI-G2 spectrometer. The NMR spectra were taken with a JEOL-4H-100 MHz spectrometer, using tetramethylsilane as an internal standard, in deuteriochloroform unless otherwise stated. Chemical shifts and coupling constants were recorded in δ and Hz units, and frequencies in cm^{-1}.

1,2-O-Isopropylidene-α-D-ribo-hexofuranos-3-ulose Oxime (3). To an aqueous ethanol solution (1 : 1, 100 ml) of hydroxylamine prepared from hydroxylamine hydrochloride (1.8 g, 25.9 mmol) and sodium hydroxide (1.10 g, 27.5 mmol) was added the hemiketal **2** (5 g, 22.9 mmol). After standing the reaction mixture at room temperature for 18 h, the solution was concentrated to a half volume, and then extracted with 1-butanol. Evaporation of the butanol solution gave crystals which were recrystallized from ethanol–hexane. Yield, 3.95 g (74%); mp 161—164 °C; $[\alpha]_D^{23}$ +97.2° (*c* 1.3, MeOH); IR: 3400, 3210, and 3125(OH).

Found: C, 46.30; H, 6.38; N, 5.83%. Calcd for $C_9H_{15}NO_6$: C, 46.35; H, 6.48; N, 6.01%.

3-Acetoxyimino-5,6-di-O-acetyl-1,2-O-isopropylidene-α-D-ribo-hexofuranose (4). Base-catalyzed acetylation of **3** with acetic anhydride in the usual manner gave a sirupy product quantitatively. NMR spectrum of the sirup showed the presence of two kind of isomers (*syn-* and *anti-*form) in the ratio of 1 : 1 (H_1 : 6.05 and 5.98). This sirup was used for the next conversion without further identification. IR; 1740 (OAc).

5,6-Di-O-acetyl-1,2-O-isopropylidene-α-D-ribo-hexofuranos-3-ulose (5). A suspension of the above sirup (200 mg, 0.56 mmol) and excess chromium(II) acetate (340 mg, 2 mmol) in tetrahydrofuran–water (9 : 1, 10 ml) was stirred at room temperature for 24 h until the starting material had disappeared on TLC. The reaction mixture was bubbled with air to oxidize excess chromous ion and most of tetrahydrofuran was evaporated. The remaining solution was diluted with water, and then extracted with ether. The ether extract was washed with water, and then evaporated to give a nearly pure sirupy ulose in 85% yield. The NMR spectrum was identical with that of authentic sample: 6.10 (H_1: d, $J_{1,2}$=4.4), 5.26 (H_5: m), 4.53 (H_4: dd, $J_{2,4}$= 1.2, $J_{4,5}$=3.4), 4.45—4.16 (H_2, H_6, $H_{6'}$: m), 2.08 and 2.01 (2×OAc), 1.47 and 1.42 (2×C-CH_3).

1,2-O-Isopropylidene-3-(nitromethyl)-α-D-glucofuranose (6). A solution of **2** (5.0 g, 22.9 mmol) in ethanol (15 ml) was added to a solution of nitromethane (20 ml) and sodium ethoxide (sodium 0.53 g, 23.0 mmol) in ethanol (50 ml) with stirring. The reaction mixture was kept at room temperature for 30 min, neutralized with 60% acetic acid, and then evaporated. A 1-butanol solution (100 ml) of the residue was washed with a small amount of water and then evaporated to give crystals which were recrystallized from ether. Yield, 5.2 g (81.4%), mp 104—105 °C, $[\alpha]_D^{23}$ +57.1° (*c* 0.99, MeOH). IR: 3430 and 3250 (OH), 1540 (NO_2).

Found: C, 43.11; H, 6.14; N, 4.90%. Calcd for $C_{10}H_{17}NO_8$: C, 43.01; H, 6.14; N, 5.02%.

The configuration of this compound was determined by conversion into 1,2 : 5,6-di-*O*-isopropylidene-3-(nitromethyl)-α-D-glucofuranose as follows: a suspension of **6** (1.0 g, 3.6 mmol) and anhydrous copper(II) sulfate (3.0 g) in dry acetone (50 ml) was stirred at 50 °C for 24 h, filtered through active carbon, and the filtrate was evaporated. A chloroform solution of the residue was washed with water and evaporated to give crystals which were recrystallized from ethanol. Yield, 0.82 g (71.4%), mp 139—140 °C, $[\alpha]_D^{23}$ +22.3° (*c* 1.0, $CHCl_3$) [lit,[10] mp 140—141 °C, $[\alpha]_D^{23}$ +22.8° ($CHCl_3$)]. This specimen showed no depression of mp by admixture with an authentic sample.

5,6-Di-O-acetyl-1,2-O-isopropylidene-3-(nitromethyl)-α-D-glucofuranose (7). Base-catalyzed acetylation of **6** with acetic anhydride in the usual manner gave the corresponding di-*O*-acetate quantitatively. Mp 163.5—164.5 °C, $[\alpha]_D^{23}$ +52.6° (*c* 0.5, $CHCl_3$). IR: 3430 (OH), 1745 (OAc), 1560 (NO_2); NMR: 5.97 (H_1: d, $J_{1,2}$=3.8), 5.25 (H_5; oct), 4.62 (H_2: d), 4.62 (H_6: q, $J_{5,6}$=2.5), 4.18 ($H_{6'}$: q, $J_{5,6'}$=5.3, $J_{6,6'}$=12.8), 4.87 and 4.60 (CH_2: ABq $J_{A,B}$=14.8), 4.05 (H_4: d, $J_{4,5}$=8.5), 3.76 (OH, s), 2.10 and 2.06 (2×OAc), 1.52 and 1.34 (2×C-CH_3).

Found: C, 46.28; H, 5.82; N, 3.87%. Calcd for $C_{14}H_{21}NO_{10}$: C, 46.28; H, 5.82; N, 3.86%.

3-(Aminomethyl)-1,2-O-isopropylidene-α-D-glucofuranose (8). A suspension of **6** (300 mg, 1.07 mmol) and palladium-charcoal (5%, 0.2 g) in water (20 ml) was hydrogenated under hydrogen atmosphere, filtered, and then the filtrate was evaporated. The ninhydrin-positive residue was crystallized from ethanol–ether. Yield, 168 mg (68.2%), mp 122—123 °C, $[\alpha]_D^{23}$ +41.5° (*c* 0.68, EtOH).

Found: C, 47.78; H, 7.68; N, 5.34%. Calcd for $C_{10}H_{19}NO_6$: C, 48.18; H, 7.68; N, 5.62%.

3-(Acetaminomethyl)-5,6-di-O-acetyl-1,2-O-isopropylidene-α-D-glucofuranose (9). To a solution of **8** (100 mg, 0.36 mmol) in pyridine (2 ml) was added acetic anhydride (1 ml), and the mixture was kept at room temperature for 5 h. The solution was treated in the usual procedure to give a sirup which was crystallized from ethanol. Yield, 128 mg (95%), mp 130.5–131 °C; $[\alpha]_D^{23}$ +82.9° (*c* 0.23, $CHCl_3$). IR: 3320 (OH and NH), 1740 (OAc); NMR: 6.40 (NH : t), 5.86 (H_1: d, $J_{1,2}$=3.4), 5.26 (H_5: sex), 4.59 (H_6: q, $J_{5,6}$=2.4), 4.34 (H_2: d), 4.24 ($H_{6'}$: q, $J_{5,6'}$=6.1, $J_{6,6'}$=13.0), 4.06 (H_4: d, $J_{4,5}$=6.4), 3.74 and 3.47 (CH_2: dABq, $J_{A,B}$= 13.0, $J_{NH,3'}$=6.4), 2.12, 2.08, and 2.06 (2×OAc, NAc), 1.51 and 1.32 (2×C-CH_3).

Found: C, 51.16; H, 6.72; N, 3.60%. Calcd for $C_{16}H_{25}NO_9$: C, 51.19; H, 6.71; N, 3.73%.

5,6-Di-O-acetyl-1,2-O-isopropylidene-3-(nitromethyl)-α-D-allofuranose (10). i) From **5**. A solution of **5** (200 mg, 0.6 mmol) in ethanol (5 ml) was added with stirring to a solution of nitromethane (1 ml) and sodium (100 mg, 4.3 mmol) in ethanol (5 ml) at room temperature. After standing the reaction mixture for 30 min, it was neutralized with 60% acetic acid, and then evaporated to give crystals which were recrystallized from ethanol–hexane. Yield, 154 mg (71%), mp 130—132 °C $[\alpha]_D^{23}$ +42.4° (*c* 0.9, $CHCl_3$). IR: 3420 (OH), 1740 (OAc), 1550 (NO_2); NMR: 5.79 (H_1: d, $J_{1,2}$=4.0), 5.22 (H_5: septet), 4.93 and 4.43 (CH_2: ABq, $J_{A,B}$=12.4), 4.77 (H_2: d), 4.40 (H_6: q, $J_{5,6}$=3.5), 4.17 ($H_{6'}$: q, $J_{5,6'}$=6.1, $J_{6,6'}$=12.5), 4.03 (H_4: d, $J_{4,5}$=8.2), 3.30 (OH), 2.10 and 2.06 (2×OAc), 1.58 and 1.37 (2×C-Me).

Found: C, 46.28; H, 5.85; N, 3.80%. Calcd for $C_{14}H_{21}NO_{10}$: C, 46.28; H, 5.83; N, 3.86%.

ii) From 1,2 : 5,6-di-*O*-isopropylidene-3-(nitromethyl)-α-D-allofuranose. A solution of the starting material (500 mg) in acetic acid (70%, 20 ml) was kept at room temperature for 24 h, and then evaporated to give a glassy solid [1,2-*O*-isopropylidene-3-(nitromethyl)-α-D-allofuranose (**11**)] quantitatively, which could not be crystallized. $[\alpha]_D^{23}$ +18.5° (*c*

0.7, MeOH), IR: 1560 (NO_2).

Found: C, 42.55; H, 6.12; N, 4.60%. Calcd for $C_{10}H_{17}NO_8$: C, 43.01; H, 6.14; N, 5.02%.

Acetylation of **11** (200 mg) with acetic anhydride (3 ml) in pyridine (3 ml) in the usual manner gave **10** quantitatively which was identical with the above mentioned sample.

3,5,6-Tri-O-acetyl-3-cyano-1,2-O-isopropylidene-α-D-allofuranose (12). To a solution of **2** (1 g, 4.6 mmol) and hydrogen cyanide (0.3 ml) in pyridine (10 ml) which was stirred at 0 °C for 6 h was added acetic anhydride (3 ml), the mixture was kept at room temperature for 15 h, and the excess hydrogen cyanide was evacuated under reduced pressure. The reaction mixture was poured into ice-water, and the resulting solution was extracted with methylene dichloride. The extracted solution was washed with water and evaporated to give a sirup which was crystallized and recrystallized from ethanol-hexane. Yield, 0.92 g, (54%), mp 140—142 °C, $[\alpha]_D^{23}$ +70.4° (*c* 0.47, $CHCl_3$) [lit,[13] mp 129.5—130.5 °C, $[\alpha]_D^{21}$ +72.8° (*c* 0.3, $CHCl_3$)]. IR and NMR spectra were also identical with those of theauthentic sample.

3-(Hydroxycarbonimidoyl)-1,2-O-isopropylidene-α-D-allofuranose 3',5-Lactone (13). An aqueous solution (2 ml) of potassium cyanide (325 mg, 5 mmol) was added to an aqueous solution (15 ml) of **2** (1.0 g, 4.6 mmol) and sodium hydrogencarbonate (630 mg, 5.1 mmol) with stirring at 0 °C. The crystals deposited immediately were filtered and recrystallized from methanol. Yield, 744 mg (66%), mp 166—168 °C, $[\alpha]_D^{23}$ +60.4° (*c* 0.4, H_2O). IR: 3450 (OH), 3300 (NH), 1705 (-O-C=NH).

Found: C, 48.81; H, 6.07; N, 5.23%. Calcd for $C_{10}H_{15}NO_6$: C, 48.97; H, 6.17; N, 5.71%.

3,6-Di-O-acetyl-3-carboxy-1,2-O-isopropylidene-α-D-allofuranose 3',5-Lactone (14). i) From **13**. To a suspension of **13** (245 mg, 1.0 mmol) in acetic anhydride (1.5 ml) was added pyridine (0.1 ml), and kept at room temperature for 12 h until the mixture became homogenous. The reaction mixture was poured into ice-water to give crystals which were recrystallized from ethanol-hexane. Yield, 201 mg (61%), mp 114—115 °C, $[\alpha]_D^{23}$ +5.2°, $[\alpha]_{365}^{23}$ −28.7° (*c* 0.9, $CHCl_3$), [lit,[14] mp 113—113.5 °C: $[\alpha]_D^{22}$ +6.2°, $[\alpha]_{365}^{22}$ −33.0° (*c* 1.7, $CHCl_3$)].

Found: C, 51.00; H, 5.52%. Calcd for $C_{14}H_{18}O_9$: C, 50.91; H, 5.49%.

IR and NMR spectra were also identical with those of authentic sample.[14]

ii) From **16**. Base-catalyzed acetylation of **16** with acetic anhydride in the usual manner gave **14** quantitatively.

3-[(Acetylimino)methoxymethyl]-3,6-di-O-acetyl-1,2-O-isopropylidene-α-D-allofuranose (15). To a homogeneous reaction mixture of the above experiment was added absolute methanol (4 ml) instead of pouring into ice-water, and then evaporated to give a sirup. The main component of the sirup composed of three components was isolated by TLC (benzene : methanol =8 : 1, and recrystallized form ethanol-hexane. Yield, 273 mg (65%), mp 145—147 °C, $[\alpha]_D^{23}$ +53.5° (*c* 0.6, $CHCl_3$). IR: 3450 (OH), 1765 (OAc), 1660 (C=NAc). NMR: 5.98 (OH : s), 5.85 (H_1 : d, $J_{1,2}$=3.6), 5.34 (H_2 : d), 4.73 (H_4 : d, $J_{4,5}$=1.8), 4.45—4.05 (H_5, H_6, $H_{6'}$: m), 3.30 (OMe), 2.07 and 1.98 (2×OAc, NAc), 1.49 and 1.34 (2×C-CH_3).

Found: C, 50.10; H, 6.19; N, 3.42%. Calcd for $C_{17}H_{25}NO_{10}$: C, 50.61; H, 6.25; N, 3.42%.

3-Carboxy-1,2-O-isopropylidene-α-D-allofuranose Sodium Salt (16). A solution of **13** (245 mg, 1.0 mmol) and sodium hydrogen carbonate (84 mg, 1.0 mmol) in methanol (5 ml) was refluxed for 12 h, evaporated, and the residue was crystallized from ethanol-hexane to give needles quantitatively. Mp 269—271 °C (decomp), $[\alpha]_D^{23}$ +46.6° (*c* 0.9, H_2O). IR: 3350 and 3250 (OH), 1610 (C=O).

Found: C, 41.91; H, 5.42%. Calcd for $C_{10}H_{15}O_8Na$: C, 41.96; H, 5.28%.

(Received December, 22, 1976)

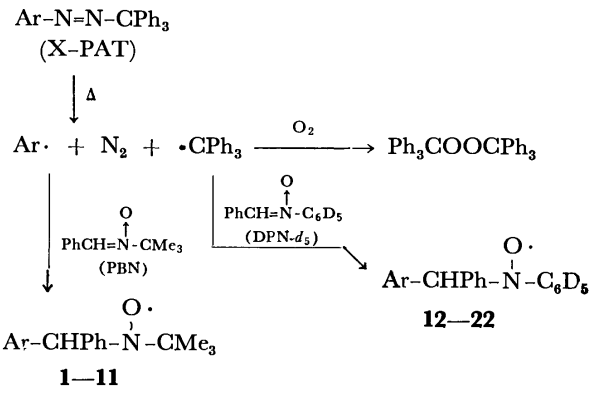
Monosubstituted phenyl radicals produce only aryl spin adducts in the reaction with nitrones described in the title, while polyhalo-substituted phenyl radicals add to solvent benzene, in competition with the formation of aryl spin adducts, to give arylcyclohexadienyl radicals, which in turn are trapped by the nitrones giving nitroxides incorporating the solvent benzene (Scheme 3).

The relative merits and applications of spin traps have been well discussed. Of various spin traps, comparison of the scavenging ability to some limited radicals was made.[2] For example, nitrones are shown to offer considerable advantages over nitroso compounds as a probe for alkoxyl radicals.[3] However, little is known about the relative reactivity of different radicals to a given spin trap. Previously we reported the decomposition of arylazotriphenylmethanes in benzene in the presence of nitrosodurene (2,3,5,6-tetramethylnitrosobenzene)[1] and showed that the aryl radicals carrying electron donating groups add to nitrosodurene to give arylduryl-nitroxides (*N*-aryl-2,3,5,6-tetramethylanilinyloxyls),[1] the aryl spin adducts, while those with electron withdrawing groups produce no such aryl spin adducts, but afford spin adducts incorporating the solvent benzene.[4] The relative reactivity of different aryl radicals to nitrosodurene and benzene changes according to the nature of substituents attached to the aryl radicals. We have undertaken a study on decomposition of arylazotriphenylmethanes in benzene in the presence of *N*-*t*-butyl-α-phenylnitrone (PBN) and *N*-pentadeuteriophenyl-α-phenylnitrone (DPN-d_5) in order to see whether aryl radicals behave in a similar manner to the nitrones or not, and the results are described in this paper.

Results and Discussion

Reaction of Monosubstituted Phenyl Radicals with Nitrones. The thermal decomposition of phenylazotriphenylmethane (PAT) at 80 °C in benzene or in carbon tetrachloride containing *N*-*t*-butyl-α-phenylnitrone (PBN) under an atmosphere of argon gave an ESR spectrum of a triphenylmethyl radical and a nitroxide (**1**; a_N=14.1 and $a_{\beta\text{-H}}$=2.1 G) with the same hyperfine splitting constants as obtained for the phenyl spin adduct.[5] However, the signals of the triphenylmethyl radicals disappeared on standing or on exposure to air, presumably due to the reaction with oxygen. Similarly, 2- or 4-substituted phenylazotriphenylmethanes (2- or 4-X-PAT) produced the corresponding aryl spin adducts of PBN in both benzene and carbon tetrachloride (Scheme 1). The structural assignment of the spin adducts is based on the consistency of the hfsc's within the series, which are recorded in Table 1.

When α,*N*-diphenylnitrone was used as a spin trap in the decomposition of PAT, an ESR spectrum consisting of complex sets identified as the phenyl spin adduct was observed.[6] By the use of *N*-pentadeuteriophenyl-α-phenylnitrone (DPN-d_5) as a spin trap the spectrum of the phenyl spin adduct was simplified to a signal composed of broad three doublets (**12**; a_N=10.4 and $a_{\beta\text{-H}}$=3.4 G) (Fig. 1). Similar spectra were obtained in the decomposition of 2- and 4-X-PAT's in



Scheme 1.

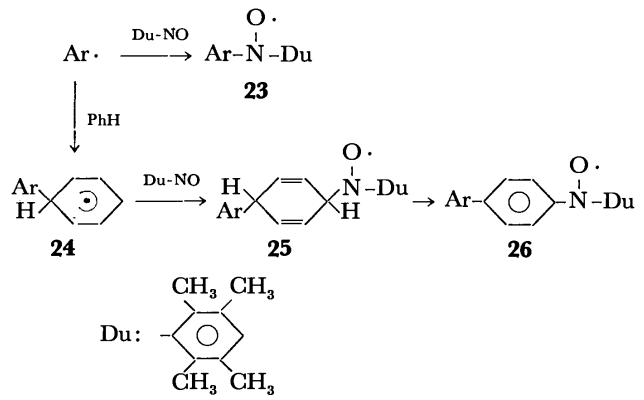
22	2-Br-C_6H_4	10.2	4.1

a) In G in benzene and carbon tetrachloride at room temperature.

both benzene and carbon tetrachloride and the ESR parameters are shown in Table 2.

We showed previously[4)] that the aryl radicals having an electron donating substituent, such as methyl and methoxy at the 4 position, are trapped directly by nitrosodurene (Du–NO) in benzene to produce the aryl spin adducts (**23**). On the contrary, the aryl radicals with an electron withdrawing group, like chloro, bromo, or nitro group, add exclusively to benzene to give arylcyclohexadienyl radicals (**24**), which are subsequently trapped by Du–NO to yield the nitroxides (**25** and **26**) incorporating the solvent benzene (Scheme 2). However, this is not the case for the nitrones, PBN and DPN-d_5. The aryl radicals carrying a substituent at the *ortho* or the *para* position produced only the aryl spin adducts of PBN (**1**—**11**) and DPN-d_5 (**12**—**22**).

Substituent effects on the ESR spectra of various nitroxides have been reported and the nitrogen hfsc's in nitroxides are known to be correlated with the Hammett σ constants.[7)] To illustrate this relationship further-



Scheme 2.

more, the N hfsc's of the 4-substituted phenyldurylnitroxides[4)] (**23**) are plotted against σ. The correlation is only approximate, but the ρ value ($\rho=-1.2$, correlation coefficient=0.93) is consistent with the value reported for 4-substituted anilinyloxyl (Ar–NHO·; $\rho=-1.2$).[8)]

In the aryl spin adducts of PBN (**1**—**11**) and DPN-d_5 (**12**—**22**), the substituents attached to the β-phenyl group might exert influence on the N hfsc's. The data listed in Tables 1 and 2, however, show that the N hfsc's are essentially the same irrespective of the substituents within each series (**1**—**11** and **12**—**22**). The β-aryl group is two bonds apart from the nitrogen atom in both species of the nitroxides (**1**—**22**) and thus, the effect of substituents does not extend as far as the nitrogen atom through the bonds.

Other features emerged from the data are that the β-H hfsc does not depend on the nature of the substituents, but on the position of the substituents in the respective nitroxides. The nitroxides having the *ortho*-substituents (**7**—**11** and **18**—**22**) and those with the *para*-ones (**2**—**6** and **13**—**17**) are distinguished definitely to different groups. Thus, operation of other factors such as steric effect is suspected and this problem will be further discussed in the latter part.

Reaction of Polysubstituted Phenyl Radicals with Nitrones. The decomposition of 2,4,6-tribromophenylazotriphenylmethane (Br_3–PAT) in carbon tetrachloride containing PBN (30 mM) at 80 °C gave a spectrum ascribable to a 2,4,6-tribromophenyl spin adduct (**28**; $a_N=14.0$ and $a_{\beta\text{-H}}=7.5$ G) (Fig. 2-A), while in benzene Br_3–PAT produced another nitroxide (**33**; $a_N=14.1$ and $a_{\beta\text{-H}}=2.1$ G) along with **28** and triphenylmethyl radicals (Fig. 2-B). Since **33** is only produced in benzene, the incorporation of the solvent benzene in **33** is inferred. The relative intensity of **28** to **33** in the ESR spectra was raised with increasing amounts of PBN (see Figs. 2-C and 2-D). These facts indicate that **28** is formed directly by the reaction of 2,4,6-tribromophenyl radicals with PBN, while **33** is not. From the analogy of the reaction of aryl radicals with Du–NO, it is suggested that 2,4,6-tribromophenyl radicals add benzene to form arylcyclohexadienyl radicals (**24**; Ar=2,4,6-$Br_3C_6H_2$) in competition to the reaction with PBN. The intermediate radicals (**24**) are further scavenged by PBN to give the spin adduct (**33**). Since triphenylmethyl radicals are observed in the spectra, the further

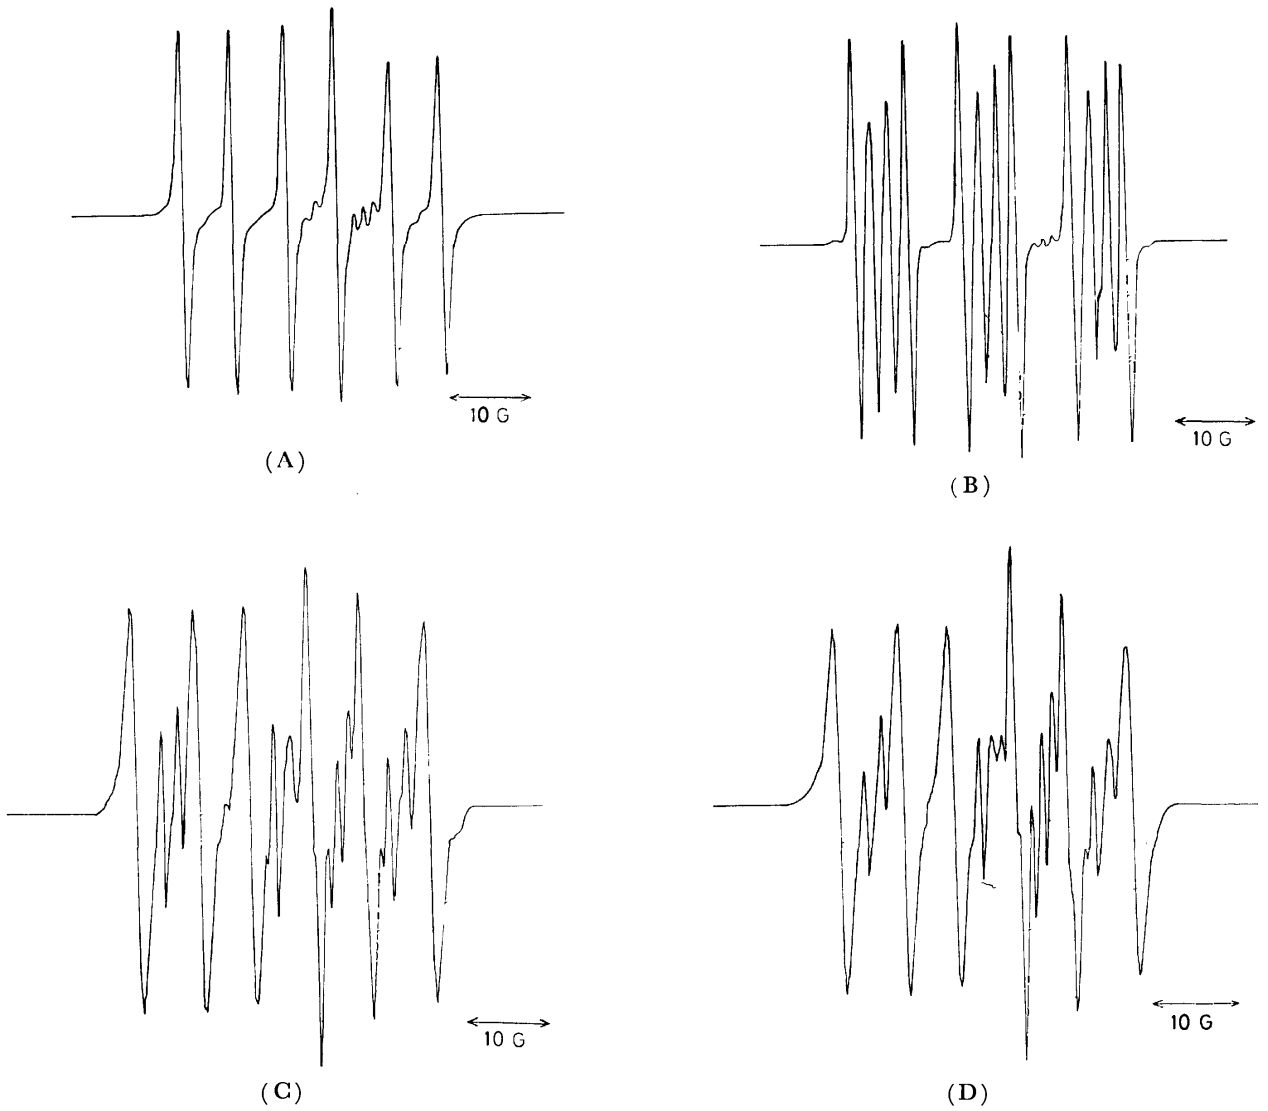


Fig. 2. (A) The ESR spectrum of **28** obtained from the decomposition of Br_3-PAT in carbon tetrachloride at 80 °C in the presence of PBN (30 mM). (B) The ESR spectrum obtained from the decomposition of Br_3-PAT in benzene at 80 °C in the presence of PBN (30 mM). The spectrum is due to both **28** and **33**. (C) The ESR spectrum of **28** and **33** obtained from the decomposition of Br_3-PAT in benzene at 80 °C in the presence of PBN (68 mM). (D) The ESR spectrum of **28** and **33** obtained from the decomposition of Br_3-PAT in benzene at 80 °C in the presence of PBN (135 mM). A small concentration of triphenylmethyl radicals is always present in all the cases.

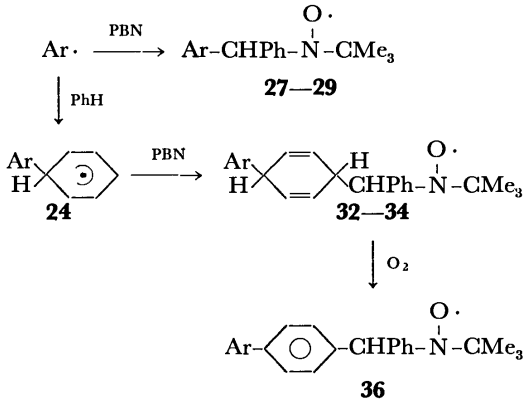
Table 3. Hyperfine splitting constants of nitroxides obtained in the decomposition of polysubstituted phenylazotriphenylmethanes (X_n-PAT) in benzene containing PBN

X_n-PAT	Aryl radicals generated (Ar·)	Nitroxides[a]					
		Ar-CHPh-N(O·)-CMe_3[b]					
			a_N	$a_{,\text{-H}}$		a_N	$a_{\beta\text{-H}}$
Cl_3-PAT	2,4,6-$Cl_3C_6H_2$·	**27**	13.9	6.6	**32**	14.0	2.1
Br_3-PAT	2,4,6-$Br_3C_6H_2$·	**28**	14.0	7.5	**33**	14.1	2.1
F_5-PAT	C_6F_5·	**29**	14.0	4.4	**34**	13.8	2.1
Me_3-PAT	2,4,6-$Me_3C_6H_2$·	**30**[c]	14.5	8.8	**35**[d]	14.0	2.2

a) In G in benzene at room temperature. b) Unless otherwise noted, the same spectrum was obtained in CCl_4. c) A trichloromethyl spin adduct (**31**; a_N=13.6, $a_{\beta\text{-H}}$=1.6 G) was obtained concurrently in CCl_4. d) The structure was tentatively assigned to a 3,5-dimethylbenzyl spin adduct (**35a**).



Ar: 2,4,6-$Cl_3C_6H_2$ (**27** and **32**), 2,4,6-$Br_3C_6H_2$ (**28** and **33**), and C_6F_5 (**29** and **34**).

Scheme 3.

oxidation of **33** to a nitroxide (**36**; Ar=2,4,6-$Br_3C_6H_2$) by molecular oxygen is highly improbable (Scheme 3).

Similar results were obtained with 2,4,6-trichloro- (Cl_3–PAT) and 2,3,4,5,6-pentafluoro-phenylazotriphenylmethane (F_5–PAT) in carbon tetrachloride and benzene. The hfsc's of the nitroxides obtained are recorded in Table 3.

Migita and his co-workers[9] reported recently that the relative rate of addition of 4-nitrophenyl radicals and phenyl radicals to benzene is 5.6 at 60 °C. Accordingly, electron withdrawing halogen substituents increase the rate of addition of the aryl radicals to benzene, but the effect is small. Thus, the formation of the benzene incorporated nitroxides (**32**—**34**) may be accounted for in view that the rate of addition of aryl radicals to PBN is much suppressed in the polyhalogenated phenyl radicals than in phenyl ones due to steric or electronic effects.

When 2,4,6-trimethylphenylazotriphenylmethane (Me_3–PAT) was decomposed in carbon tetrachloride in the presence of PBN, ESR spectra due to two nitroxides were observed (Fig. 3-A). One spectrum was attributed to a 2,4,6-trimethylphenyl spin adduct (**30**; a_N=14.5 and $a_{\beta\text{-H}}$=8.8 G) by analogy with the values obtained for the polyhalophenyl spin adducts (**27**—**29**). Further verification for the structural assignment of **30** was obtained in the decomposition of PAT with *N*-*t*-butyl-α-2,4,6-trimethylphenylnitrone [*N*-(2,4,6-trimethylbenzylidene)-*t*-butylamine oxide; Me_3–PBN] in benzene. The ESR spectrum obtained is completely the same as that observed above. The other spectrum was assigned as a trichloromethyl spin adduct (**31**; a_N= 13.6 and $a_{\beta\text{-H}}$=1.6 G), because the same spectrum was independently produced from the photolysis of di-*t*-butyl peroxide in chloroform in the presence of PBN (Scheme 4). Chlorine abstraction from carbon tetrachloride by 2,4,6-trimethylphenyl radicals may be facilitated by the electron donating substituents on the phenyl radicals[10] to afford trichloromethyl radicals, which were subsequently trapped by PBN.

In benzene, Me_3–PAT produced another nitroxide as well as **30** with PBN (Fig. 3-B). The newly formed nitroxide (**35**; a_N=14.0 and $a_{\beta\text{-H}}$=2.2 G) has almost the same N and β-H hfsc's as those of **33**. Thus, incorporation of the solvent benzene in the nitroxide (**35**)

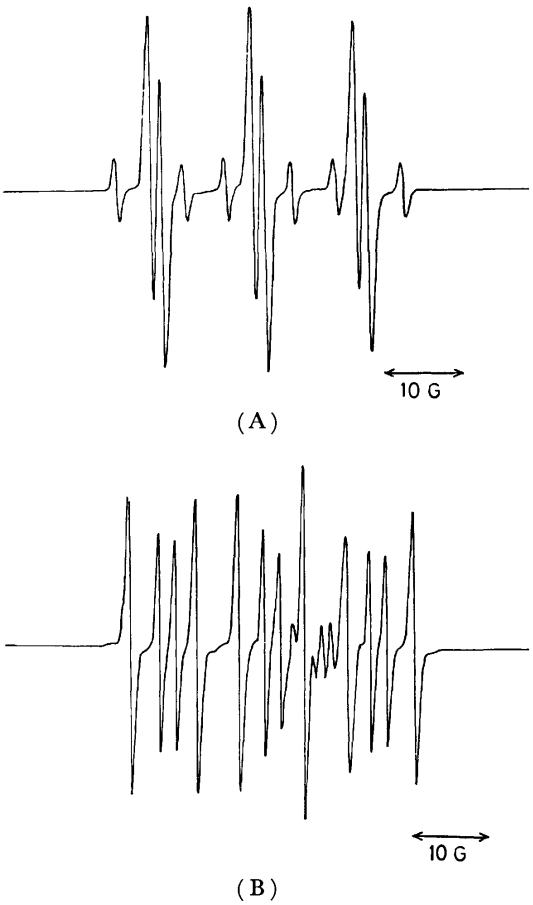


Fig. 3. (A) The ESR spectrum of **30** and **31** obtained from the decomposition of Me_3–PAT in carbon tetrachloride at 80 °C in the presence of PBN. (B) The ESR spectrum of **30** and **35a** obtained from the decomposition of Me_3–PAT in benzene at 80 °C in the presence of PBN. A small concentration of triphenylmethyl radicals is also present.

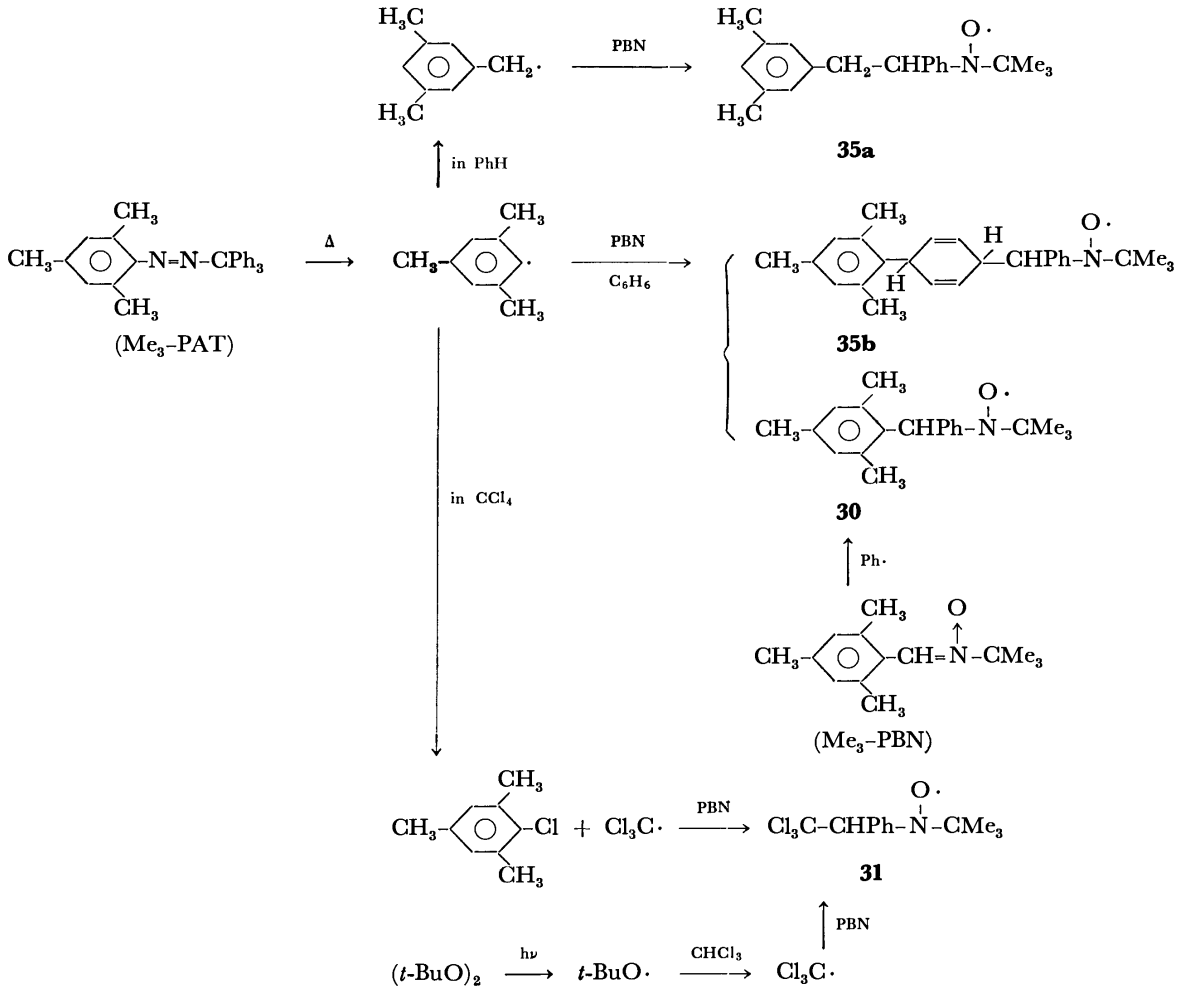
was suspected. Recently, it was found by the use of CIDNP technique that the rearrangement of 2-methylphenyl radicals to benzyl radicals occurs during the thermolysis of bis(2-methylbenzoyl) peroxide.[11] If such a rearrangement would take place for the 2,4,6-trimethylphenyl radicals, the resulting 3,5-dimethylbenzyl radicals would produce a spin adduct (**35a**) consistent with the observed spectrum. Since a benzyl spin adduct is known to have similar hfsc's (a_N=13.9 and $a_{\beta\text{-H}}$=2.4 G)[5] to those of **35**, assignment of **35a** is also consistent with the observation. Thus, the structure of the nitroxide (**35**) could be assigned as either the 3,5-dimethylbenzyl spin adduct (**35a**) or 2,4,6-trimethylphenylcyclohexadienyl spin adduct (**35b**). Judging from the known behavior of aryl radicals to benzene,[9] the reactivity of 2,4,6-trimethylphenyl radicals is supposed to be lowered, and the formation of the benzene incorporated nitroxide **35b** is implausible. Accordingly, the nitroxide is believed to be **35a** rather than **35b**.

With Me_3–PBN, Cl_3–PAT produced a trichlorophenyl spin adduct (**37**; a_N=14.1 and $a_{\beta\text{-H}}$=8.8 G) in carbon tetrachloride. The same spectrum was obtained in benzene, but none of signals due to a benzene in-



Scheme 4.

corporated nitroxide were observed. These findings show that Me_3–PBN is much more efficient than PBN in trapping of 2,4,6-trichlorophenyl radicals. In other words, the 2,4,6-trichlorophenyl radical is electrophilic and the transition state has some polar character with electron donation from Me_3–PBN. The view is borne out, because the rate of addition of the electrophilic benzoxyl radical to PBN is known to increase with electronegative substituents on PBN (Hammett ρ against $\sigma^+ = -0.47$).[12]

The decomposition of Cl_3–PAT, Br_3–PAT, and F_5–PAT in CCl_4 in the presence of DPN-d_5 gave the corresponding aryl spin adducts (**38**—**40**) (Table 4).

Table 4. Hyperfine splitting constants of aryl spin adducts of DPN-d_5[a]

Nitroxide	Ar in nitroxide	a_N	$a_{\beta\text{-H}}$
38[b]	2,4,6-$Cl_3C_6H_2$	9.8	6.5
39[b]	2,4,6-$Br_3C_6H_2$	9.8	6.5
40	C_6F_5	10.2	5.6

a) In G in carbon tetrachloride at room temperature. b) The same spectra were obtained in benzene.

In benzene containing DPN-d_5, Cl_3–PAT produced **38** and another nitroxide (**41**), but the spectra observed are not well resolved. Br_3–PAT produced definitely a similar mixture of **39** and **42**, while F_5–PAT gave only a benzene incorporated nitroxide (**43**; $a_N = 10.3$ and $a_{\beta\text{-H}} = 3.5$ G). The structure of **41** and **42** was believed to be the benzene incorporated nitroxides by the analogy with the behavior of polyhalogenated phenyl radicals to PBN.

Finally, it is of interest to discuss conformations of the nitroxides obtained. Since the $a_{\beta\text{-H}}$ value depends on the dihedral angle between the C–H bond and the p orbital on the nitrogen atom, the generally low $a_{\beta\text{-H}}$ values of the nitroxides listed in Tables 1 (**1**—**6**) and 2 (**12**—**17**) certainly indicate that the C–H bond lies close to the plane perpendicular to the p orbital on the nitrogen atom. The nitroxides should then be assigned as the *trans* conformer (**44**), in which the C–H bond is approximately *trans* with respect to the N–O bond, between two preferred conformers. The *cis* conformer should be disregarded because of large steric hindrance between the two aryl and *t*-butyl groups. Thus, we infer that, for the species with *ortho* substituents, the steric repulsion between the *ortho* group and the oxygen atom in the *trans* conformer (**44**) causes the twisting around the C–H bond, resulting in a decrease of the dihedral angle and in concomitant higher $a_{\beta\text{-H}}$ values (**45**).

TABLE 5. SUBSTITUTED PHENYLAZOTRIPHENYLMETHANES (X_n-PAT's)

Compd X_n in X_n-PAT	Mp (dec), °C	Elemental analysis, % Found C	Found H	Found N	Molecular formula	Calcd C	Calcd H	Calcd N
2,4,6-Me_3	101—102	86.29	6.71	6.89	$C_{28}H_{26}N_2$	86.29	6.71	7.17

45

Experimental

Materials. *N-t*-Butyl-α-phenylnitrone[13] (PBN) and substituted phenylazotriphenylmethanes[14,15,16] (X_n-PAT's) were prepared according to published procedures. Newly prepared X_n-PAT's were listed in Table 5.

N-Pentadeuteriophenyl-α-phenylnitrone (DPN-d_5). DPN-d_5 was obtained in a method similar to the preparation of α,*N*-diphenylnitrone:[17] mp 106—107 °C (from ethanol); NMR ($CDCl_3$) δ 2.0(s, 1H, vinyl proton) and 7.5—8.5(m, 5H, phenyl protons). Found: C, 77.07; H, 8.80; N, 6.92%. Calcd for $C_{13}H_6D_5NO$: C, 77.19; H, 7.97; N, 6.92%.

N-t-Butyl-α-2,4,6-trimethylphenylnitrone (Me_3-PBN). To a mixture of 2,4,6-trimethylbenzaldehyde (3.5 g) and *t*-butylamine (8.0 g) in 10 ml of benzene was added dropwise a solution of $TiCl_4$ (2.3 g) in 20 ml of benzene at 0 °C with stirring. After the addition was completed, the mixture was allowed to warm at room temperature and left for 3 days. The precipitate was filtered off and the filtrate was concentrated on evaporation of the solvent under reduced pressure. Residual oil (1.9 g) was oxidized and isomerized in similar ways described in the literature:[13] mp 112—114 °C (from hexane); NMR($CDCl_3$) δ 2.2(s, 1H, vinyl proton), 1.6(s, 9H, *t*-butyl protons), 2.2(s, 9H, methyl protons), and 6.9—7.7(m, 2H, aromatic protons). Found: C, 76.67; H, 9.81; N, 6.22%. Calcd for $C_{14}H_{21}NO$: C, 76.66; H, 9.65; N, 6.39%.

Thermal Decomposition of Arylazotriphenylmethanes. A solution of arylazotriphenylmethanes (10 mM) in benzene or carbon tetrachloride containing *N-t*-butyl-α-phenylnitrone or *N*-pentadeutetriophenyl-α-phenylnitrone (30 mM) was purged with argon for 2 min in an ESR tube in order to remove dissolved oxygen, and was heated at 80 °C for 3 min. ESR signals were observed by use of a JEOL JES-ME-1X spectrometer.

Rishitin I. The Isolation and Structure Elucidation[1)]

Tadashi MASAMUNE, Akio MURAI, Mitsuo TAKASUGI, Akira MATSUNAGA, Nobukatsu KATSUI, Norio SATO*, and Kohei TOMIYAMA*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

**Hokkaido National Agricultural Experiment Station, Sapporo 060-01*

(Received November 1, 1976)

A modification of the isolation procedure and the details of the structure elucidation of rishitin (**1**) are described.

One decade ago we reported in preliminary communications[2)] on the isolation and structure of rishitin, an antifungal norsesquiterpene qualified as "phytoalexin",[3)] from tuber tissues of white potatoes (*Solanum tuberlosum*×*S. demissum*) infected by an incompatible race of *Phytophthora infestans*. Since the isolation of rishitin, a number of sesquiterpenes have been isolated and characterized as antifungal stress metabolites from various plants of the Solanaceae in our and other laboratories.[4)] In this paper we describe our recently modified isolation procedure of rishitin from diseased potatoes, leading to separation of thermally unstable compounds, and the details of its structure determination.

Tuber slices of R_1 cultivar "Rishiri" (338 kg) were inoculated with a zoospore suspension of an incompatible race of *Phytophthora infestans* (Mont.) de Bary, race 0, and incubated at 18—20 °C for 2 days. The inoculated slices were stored in an ice-box (−30 °C) for a week, and then immersed in methanol at room temperature for a week. The methanol extracts were concentrated below 30 °C and extracted with chloroform. The chloroform extracts were treated with acetone and then with hexane to remove the respective solvent-insoluble meterials, and the resulting hexane-soluble fraction was evaporated to leave an oily residue (160 g), which was dissolved in ether. The ether solution, after removal of acidic and basic components, gave a neutral syrup (107 g), which contained many compounds as shown in Fig. 1. The neutral syrup was separated over silicic acid and celite, hexane, benzene, ether, acetone, and methanol being used successively as eluents. Fractions eluted with a 1 : 1 mixture of benzene and ether gave crude rishitin (**1**, *ca.* 8.0 g), which was further purified by rechromatography over silica gel to yield rishitin (**1**, 3.9 g), mp 65—67 °C and $[\alpha]_D$ −35.1°,[5)] in pure state.

1b R=$COC_6H_3(NO_2)_2$

Rishitin (**1**) was analyzed for $C_{14}H_{22}O_2$ [*m/e* 222 (M^+)] and gave the diacetate (**1a**), mp 70—71 °C and $[\alpha]_D$ −14.1°,[5)] and also the bis(3,5-dinitrobenzoate) (**1b**), mp 172—173 °C and $[\alpha]_D$ −45°, which were reconverted into the starting alcohol (**1**) by saponification. When hydrogenated over platinum in ethyl acetate, compound **1** formed the dihydro derivative (**2**), $C_{14}H_{24}O_2$ [*m/e* 224 (M^+)], mp 64—66 °C and $[\alpha]_D$ −8.7°, which consumed *ca.* 1.2 mol of peroxybenzoic acid and showed an intense yellow color with tetranitromethane, and also gave the diacetate (**2a**), mp 79—81 °C and $[\alpha]_D$ +4.3°. Further hydrogenation of **2** over rhodium-platinum[6)] in ethanol produced tetrahydrorishitin (**3**), $C_{14}H_{26}O_2$ [*m/e* 226 (M^+)], mp 112—114 °C, which was negative to the tetranitromethane test. On the other hand, rishitin consumed 0.96 mol of periodic acid at room temperature for 20 h, and also was converted readily into the acetonide (**4**), mp 32—35 °C, when treated with acetone over silica gel (Wakogel Q-23). These chemical reactions and the UV, IR, and NMR spectral data of each compound indicated that rishitin contains the following structural units: a secondary methyl group [**1**, δ 1.12 (3H, d, J=6 Hz); **1a**, δ 1.06 (3H, d, J=6.5 Hz)]: an isopropenyl group [**1**, ν_{max} 3060, 1640 and 890 cm^{-1}, δ 1.70 (3H, s) and 4.64 (2H, br); **2**, ν_{max} 1386 and 1370 cm^{-1}, and no absorption near 1640 and 890 cm^{-1}; **2a**, δ 0.91 (6H, d, J= 6 Hz)]: a tetrasubstituted double bond [**1**, **2**, and **3**, only end absorptions (log ε 3.89, 3.74, and less than 2.8 at 205 nm, respectively, *cf.*, cholesterol and 5α-cholestanol, log ε 3.58 and 2.82 at 205 nm); **2**, no absorption below δ 5.0]: two vicinal secondary hydroxyl groups [**1**, ν_{max} 3320 cm^{-1}, δ 3.12 (1H, t, J=9 Hz), 3.55 (1H, br do d, J=9 and 7 Hz), and 4.18 (2H, br s, 2OH); **1a**, ν_{max} 1745 and 1250 cm,$^{-1}$

δ 2.00 and 2.04 (each 3H, s), 4.80 (2H, br), and no absorption near δ 3.5; **4**, ν_{max} 1378 and 1370 cm^{-1}; δ 3.18 (1H, t, J=9 Hz) and 3.59 (1H, do t, J=9, 9, and 7 Hz)].

Dehydrogenation of dihydrorishitin (**2**) with selenium proceeded smoothly to give eudalene (**5**) in a high (60%) yield, which formed the picrate, mp 92—93 °C, and the trinitrobenzene adduct, mp 113—114 °C.[7] This result, combined with the presence of the functional groups described above, led to proposal of the (planar) formula (**1**) for rishitin. The structure was supported by the ^{13}C NMR spectra of **1**, obtained with proton noise decoupling and also under off-resonance decoupled conditions; manely, the spectra indicated, together with chemical shift considerations,[8] that the skeleton of rishitin consisted of the following carbon units; three C(C=C)–C (δ 148.9, 129.0, and 124.9 for C_{11}, C_5, and C_{10}), one CH_2(=C)–C (109.0 for C_{12}), two C–CH(OH)–C (79.2 and 71.5 for C_3 and C_2), two C–CH(C)–C (41.6 and 40.4 for C_7 and C_4), four C–CH_2–C (38.3, 31.1, 29.7, and 26.5 for C_8, C_6, C_9, and C_1), and two CH_3–C (21.0 and 16.4 for C_{13} and C_{14}).[9]

Oxidation of dihydrorishitin (**2**) with the Jones reagent in a heterogeneous mixture of ether and water[10] followed by acid treatment produced a mixture of phenols, from which a 3,5-dinitrobenzoate (**6a**), $C_{21}H_{22}O_6N_2$ [*m/e* 398 (M^+)], mp 159—160 °C and $[\alpha]_D$ +56°, was isolated in a low (3%) yield after treatment with 3,5-dinitrobenzoyl chloride and subsequent purification by preparative TLC. On the other hand, "6-epi-1-desmethyldesmotroposantonin 3-acetate" (**7b**), prepared from (−)-α-santonin (**8**) *via* a known two-step process,[11] was submitted to hydrogenolysis over palladium–charcoal in acetic acid to yield a phenol acetate acid (**9**), oil, which was converted with diazomethane into the methyl ester (**9a**), oil, and then reduced with lithium aluminium hydride to give a phenol alcohol (**10**), mp 126—127 °C and $[\alpha]_D$ +76.7 °C, in an 86% yield from **7b**. The bis(*p*-toluenesulfonate) (**10a**), oil, obtained from **10**, gave on the hydride reduction a phenol (**6**), oil and $[\alpha]_D$ +85.7°, in a 65% yield from **10**. This phenol (**6**) was converted into its 3,5-dinitrobenzoate, mp 159.5—160 °C and $[\alpha]_D$ +60.1°, which was identical with the dinitrobenzoate (**6a**), derived from **2**, in all respects. This correlation confirms the structure **1** for rishitin and also elucidates the absolute configuration at C_7.

The configurations of a methyl at C_4 and two hydroxyl groups at C_2 and C_3 in rishitin (**1**) were deduced from the spectra of **1** and its dihydro-dibromo derivative (**11**), mp 129—130 °C, prepared in good yields by treatment of dihydrorishitin (**2**) with bromine or pyridinium bromide perbromide[12] in chloroform; δ 3.78 (1H, t, J=9 Hz, H at C_3) and 4.32 (1H, do t, J=9, 9, and 7 Hz, H at C_2) for **11**. Both the compounds (**1** and **11**) exhibited almost the same absorption patterns due to the protons at C_3 and C_2, indicating that the ring of **1** in question adopts a half-chair conformation and the three substituents are oriented equatorial, equatorial, and quasi-equatorial at C_2, C_3, and C_4, respectively. Rishitin is, therefore, represented either by the formula **1** or **1'**. Of these formulas, the former structure (**1**) seems to be more favorable on the basis of the following considerations. If rishitin is formulated as structure **1'** the bromination would possibly result in formation of two dibromides (**11'** and **11"**) with comparable instability due to severe 1,3-diaxial interaction(s), assuming the reaction in question proceeded in a kinetically controlled and *trans*-addition manner as observed usually. The situation becomes completely different with formula **1**, and the bromination is expected to produce only one dibromo compound (**11**) of two possible dibromides derivable from **2**. The observed fact that the relevant dibromodihydrorishitin was obtained stereoselectively in a high yield and was recovered unchanged on standing in a refrigerator for 6 months or after repeated recrystallizations, is in line with this expectation. Confirmatory evidence for structure **1** was later presented independently on the basis of the CD spectrum of a chelate complex of rishitin in a cuprammonium solution by Bukhari and Guthrie[13] as well as the CD spectrum of rishitin dibenzoate (the dibenzoate chirality rule) by Harada and Nakanishi.[14] Hence, rishitin is represented correctly by the formula **1**, which has completely been demonstrated by the synthesis (the succeeding paper).[15]

11" 5α-Br, 10β-Br

Experimental

All the melting points were uncorrected. The homogenity of each compound was always checked by TLC on silica gel (Wakogel B-5) with various solvent systems, and the spots were developed with ceric sulfate in dil sulfuric acid and/or iodine. The optical rotations, UV and IR spectra were measured in ethanol, ethanol and Nujol, respectively, unless otherwise stated. The NMR and ^{13}C NMR spectra were obtained in chloroform-*d* at 60 and/or 100 MHz, and the chemical shifts were given in δ-values, TMS being used as an internal reference. The abbreviations "s, d, t, m, br, and do" in the NMR spectra denote "singlet, doublet, triplet, multiplet, broad, and double", respectively.

*Isolation of Rishitin (**1**).* *(i) Materials.* Tubers of potato variety, Rishiri *(Solanum tuberosum×S. demissum)*, having the R_1 gene, were used for the experiments. Zoosporangia of an incompatible race of *Phytophthora infestans* (Mont.) de Bary, race 0, were obtained from mycerial mats growing on the cut surfaces of fresh potato tuber slices, Irish Cobbler, having no resistance gene. Zoospores were liberated by holding the sporangial suspensions at 11—12 °C for 2—3 h. Both sides of the tuber slices (338 kg) of 1.5—2.0 mm thickness were inoculated with the zoospore suspension (250000—500000 zoospores/ml), and the inoculated slices were incubated at 18—20 °C for 2 d. Tubers showing abundant brown spots were then stored at −30 °C for a week.

(ii) Extraction and Isolation. The frozen tuber slices were immersed in methanol (250 l) for a week, and the supernatant was separated by decantation. The tubers were re-extracted twice with methanol (2×150 l), and the methanol extracts were combined and concentrated to *ca.* 200 l by a film evaporator under reduced pressure (30—60 Torr) below 30 °C. The concentrate was extracted with an equal volume of chloroform under shaking, and the emulsion forming unavoidably was centrifuged to be separated into chloform and aqueous layers. The chloroform layer was evaporated to leave an oily residue. When the residue was treated with acetone (1.2 l), precipitates separated out and were removed by filtration. The filtrate was concentrated again to give an oily residue, which was treated with hexane (1.2 l). After removal of hexane-insoluble materials by decantation and filtration, the hexane solution was evaporated to give oily substances, which were dissolved in ether (5 l) and washed with 10% aq sodium carbonate and then with 0.1 M hydrochloric acid to remove acidic and basic components. The ether solution was washed with water, dried and evaporated to yield a neutral syrup (107 g), which was subjected to chromatographic purification over silicic acid (Mallinckrodt AR-100, 900 g) and celite (300 g), hexane, benzene, ether, acetone and methanol being used as eluents. Eluates with hexane, hexane–benzene (1 : 1) and benzene, on evaporation of the solvents, left oily (Fraction A, 2.1 g), semi-solid (B, 6.2 g), and solid residues(C, 42 g), respectively, the last fraction consisting mainly of higher fatty acids. Fractions D and E (2.5 g and 4.8 g) eluted with benzene–ether (3 : 1) and benzene–ether (3 : 2) contained rishitinol[16] and lubimin,[17] respectively. The following fraction (F), eluted with benzene–ether (1 : 1 and 1 : 2), afforded crude rishitin (8.0 g). Further eluates with benzene–ether (3 : 7) and ether gave an oil (G, 1.7 g) and those with ether–acetone (9 : 1) an oil (H, 2.4 g), the latter containing oxylubimin[17] and lubiminol.[17b] Subsequent fractions eluted with ether–acetone (1 : 1), acetone, acetone–methanol (1 : 1), and methanol were combined to give a resinous oil (I, 3.9 g). The crude rishitin, showing an almost single spot on TLC, was again purified by chromatography over silica gel (Merck 400 g) with ether, each fraction (60 ml) being checked by the NMR spectrum. Fractions (No. 11—40) were combined, crystallized on standing and amounted to 3.9 g.

*Rishitin (**1**), and Its Diacetate, Bis(3,5-dinitrobenzoate), and Acetonide (**1a**, **1b**, and **4**).* *(i)* Rishitin (**1**) had mp 65—67 °C and $[\alpha]_D$ −34.1°,[5] and showed the Mass, UV, IR, NMR, (CCl_4), and ^{13}C NMR spectra, in the text. Found: C, 75.58; H, 9.75%. Calcd for $C_{14}H_{22}O_2$: C, 75.63; H, 9.97%.

A soln of **1** (100 mg) was treated with acetic anhydride (Ac_2O, 0.5 ml) and pyridine (Py, 1 ml) at room temp for 19 h. The reaction mixture was poured into ice-water and extracted with ether. The ether soln was washed with 2 M hydrochloric acid, 5% aq sodium carbonate and water, dried, and evaporated to give **1a** (115 mg), mp 68—70 °C. This was recrystallized from hexane to yield an analytical sample (70 mg), mp 70—71 °C and $[\alpha]_D$ −14.1°;[5] MS, in the text; IR, ν_{max} 1745, 1250, 1645, and 885 cm^{-1}; NMR (CCl_4), δ 1.06 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.75, 2.00, and 2.04 (each s, 3H, 13-C$\underline{H}_3$ and 2OCOC$\underline{H}_3$), 4.70 (2H, br s, 12-C$\underline{H}_2$), and 4.80 (2H, br m, 2$\underline{H}$ at C_2 and C_3). Found: C, 70.74; H, 8.51%. Calcd for $C_{18}H_{26}O_4$: C, 70.56; H, 8.55%.

A soln of crude rishitin (*cf.*, the isolation of rishitin) (279 mg) in benzene (10 ml) and Py (3 ml) was stirred with 3,5-dinitrobenzoyl chloride (760 mg) in benzene (10 ml) at room temp for 15 h, and diluted with ether (30 ml). The soln was washed with 0.5 M hydrochloric acid, water, 1 M aq sodium hydroxide (30 ml) and water, dried and evaporated to leave a crystalline residue (580 mg), which on recrystallization from ethyl acetate gave **1b** (230 mg), mp 172—173 °C and $[\alpha]_D$ −45° ($CHCl_3$). Found: C, 55.14; H, 4.42; N, 9.40%. Calcd for $C_{28}H_{26}O_{12}N_4$: C, 55.08; H, 4.29; N, 9.18%.

(ii) A suspended mixture of **1b** (240 mg) in methanol (20 ml) containing potassium hydroxide (1 M) was refluxed for 1 h under nitrogen. After being cooled, the mixture was mixed with 3 M hydrochloric acid, when the pH value became *ca.* 9.0, and was concentrated and then shaken with water and ether. The ether soln, after being worked up as usual, gave oily rishitin (**1**, 100 mg), showing a single spot on TLC, which was distilled at 90—100 °C (bath temp) under less than 1 mmHg pressure and allowed to stand to give crystalline rishitin (**1**, 83 mg). Compound **1a** was also converted under the same conditions as **1b** to give crystalline rishitin (**1**).

(iii) A suspended mixture of silica gel (Wakogel Q-23, 5 g) in chlorcform was packed in a column, and washed with acetone and then hexane. Compound **1** (10 mg) was passed through the column, using 8% acetone in hexane to yield **4** (10 mg), oil, which was distilled at 100 °C (bath temp) (1 mmHg) to give its crystalline acetonide (**4**, 8.5 mg), mp 32—35 °C; MS, *m/e* 262 (M^+) and 131 (base); IR (liquid), ν_{max} 3080, 1643, 1378, 1370, 1229, 1100, 1083, 1042, and 888 cm^{-1}; NMR (CCl_4), δ 1.13 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.39 [6H, s, $(C\underline{H}_3)_2CO$], 1.74 (3H, s, 13-C$\underline{H}_3$), 3.18 (1$\underline{H}$, t, J=9 Hz, $\underline{H}$ at C_3), 3.59 (1H, do t, J=9,9, and 7 Hz, $\underline{H}$ at C_2), 4.59 and 4.68 (each 1H, s, 2$\underline{H}$ at C_{12}). Found: C, 77.70; H, 9.82%. Calcd for $C_{17}H_{26}O_2$: C, 77.82; H, 9.99%.

Attempted formation of **4** from **1** (14 mg) with *p*-toluenesulfonic acid (7 mg) in dry acetone (5 ml) under reflux or from **1** (10 mg) in acetone (4 ml) containing one drop of 60% aq perchloric acid led to recovery of the starting glycol (**1**). When treated with acetone over anhydrous copper sulfate at room temp for 90 h, compound **1** was converted into **4** only in 20—30% yields.

*11,12-Dihydrorishitin (**2**) and Its Diacetate (**2a**).* A soln of **1** (110 mg) in ethyl acetate (30 ml) was hydrogenated over

Adams platinum (100 mg as $PtO_2 \cdot H_2O$) at room temp for 30 min, when one equiv of hydrogen had been consumed. The reaction mixture was worked up as usual to leave a crystalline substance (118 mg), which was recrystallized from hexane to give **2** (95 mg), mp 64—66 °C and $[\alpha]_D$ −8.7°; MS and UV, in the text; IR (CCl_4), ν_{max} 3360, 1386, and 1370 cm^{-1}. Found: C, 74.52; H, 10.62%. Calcd for $C_{14}H_{24}O_2$: C, 74.95; H, 10.78%.

Compound **2** (44 mg) was treated with Ac_2O (0.4 ml) and Py (0.8 ml) at room temp for 15 h. The mixture was worked up as usual to give a crystalline substance (60 mg), which was recrystallized from hexane to yield **2a** (38 mg), mp 79—81 °C and $[\alpha]_D$ +4.3°; IR (CCl_4), ν_{max} 1751, 1385, 1369, 1245, 1228, and 1029 cm^{-1}; NMR, δ 0.91 (6H, d, J=6 Hz, 12- and 13-C$\underline{H}_3$), 1.05 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 2.04 and 2.08 (each 3H, s, 2OCOC$\underline{H}_3$), and 4.95 (2H, br m, 2$\underline{H}$ at C_2 and C_3). Found: C, 69.93; H, 8.95%. Calcd for $C_{18}H_{28}O_4$: C, 70.10; H, 9.15%.

*5,10,11,12-Tetrahydrorishitin (**3**).* A soln of **1** (100 mg) in a 1 : 9 mixture (40 ml) of acetic acid and ethanol was hydrogenated over rhodium-platinum catalyst[6] (60 mg as $Rh_2O_3 \cdot PtO_2 \cdot H_2O$) at room temp for 20 h with shaking. The mixture was worked up as usual to leave an oily residue (100 mg), showing two spots on TLC, which was separated into two fractions by preparative TLC over silica gel. A major, more polar fraction gave a crystalline substance, which on recrystallization from ether afforded **3** (50 mg), mp 112—114 °C; MS and UV, in the text; IR, ν_{max} 3380, 1385, and 1370 cm^{-1}; NMR, δ 0.86 and 0.97 (total 9H, each d, J=6 and 7 Hz, 12-, 13- and 14-C$\underline{H}_3$), and 3.42 (2H, br m, 2$\underline{H}$ at C_2 and C_3).

*5,10-Dibromo-11,12-dihydrorishitin (**11**).* To a soln of **2** (60 mg) in chloroform (1 ml) was added dropwise bromine in chloroform (1.6 ml) (278 mg of Br_2 in 10 ml of $CHCl_3$) with stirring, when crystalline substances precipitated and were collected by filtration and recrystallized from carbon tetrachloride to give **11** (85 mg), mp 129—130 °C. This compound (**11**, 13 mg) was also obtained from **2** (11.2 mg) with pyridinium bromide perbromide[12] (16 mg); $[\alpha]_D$ +30.9°; MS, *m/e* 222 (M^+−2HBr), 204 (M^+−2HBr−H_2O), 186 (M^+−2HBr−2H_2O), 161 (204−C_3H_7), and 143 (186−C_3H_7); IR, ν_{max} 3475, 3340 and 1040 cm^{-1}; NMR ($CDCl_3$), δ 0.92 (6H, d, J=6.5 Hz, 12- and 13-C$\underline{H}_3$), 1.22 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 2.44 (2H?, s, 2O$\underline{H}$), 3.78 (1H, t J=9 Hz, $\underline{H}$ at C_3), and 4.32 (1H, do t, J=9, 9, and 7 Hz, $\underline{H}$ at C_2); NMR (C_5D_5N), δ 0.87 (6H, d, J=7 Hz, 12- and 13-C$\underline{H}_3$), 1.54 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 4.31 (1H, t, J=9.5 Hz, $\underline{H}$ at C_3), 4.90 (1H, do t, J=9.5, 9.5, and 6 Hz, $\underline{H}$ at C_2) and 5.93 (2H, s, 2O$\underline{H}$).

*Dehydrogenation of **2** with Selenium.* A mixture of **2** (100 mg) and selenium (170 mg) was heated at 240 °C for 22 h and then at 300 °C for 6 h in a sealed tube, and cooled. The reaction mixture was extracted with ether, and the ether soln was washed with 1 M aq sodium hydroxide and water, dried and evaporated to leave a neutral oil (68 mg), which was distilled at 60—70 °C (bath temp) under reduced pressure (1 Torr) to give an oil (45 mg), showing a single spot on TLC. This was further purified by preparative TLC over silica gel to yield eudalene (**5**, 20 mg) in pure state, which formed the picrate, mp 92—93 °C, and the trinitrobenzene adduct, mp 113—114 °C; (lit,[7] 92.8 °C and 113 °C, respectively).

*Conversion of **2** into (2R)-2-Isopropyl-8-methyl-1,2,3,4-tetrahydronaphthalen-7-ol 3,5-Dinitrobenzoate (**6a**).* To a stirred mixture of **2** (90 mg) in ether (10 ml) and water (5 ml) was added dropwise the Jones reagent[9] (0.5 ml) at room temp,[10] and the whole mixture was further stirred for 1 h. The ether soln was worked up as usual to leave an oily residue (46 mg), which without further purification was refluxed with concd hydrochloric acid (2.5 ml) in methanol (5 ml) for 1 h under nitrogen. The resulting soln was mixed with water (10 ml) and extracted with ether repeatedly. The ether soln, after usual work-up, left an oily residue, showing two mian spots on TLC, which was purified by preparative TLC over silica gel with chloroform. One (less polar) of the two main fractions gave a colorless oil (6 mg), which was treated with 3,5-dinitrobenzoyl chloride (8 mg) in Py (0.5 ml) at room temp overnight and heated on a water bath for 1 h. The soln, after being worked up as usual, gave a crystalline substance, which on recrystallization from ethanol-acetone gave **6a** (3 mg), mp 159—160 °C and $[\alpha]_D$ +56° ($CHCl_3$). Compound **6a** was identical with an authentic sample obtained from (−)-α-santonin in all respects.

*6-Epi-1-desmethyldesmotroposantonin 3-Acetate (**7b**).* This compound (**7b**) was prepared by the procedure of Sharif and coworkers.[11] (−)-α-Santonin (20 g), mp 170—172 °C and $[\alpha]_D$ −172.4°, was stirred with activated zinc powder (200 g) under reflux in *N,N*-dimethylformamide (200 ml) and water (15 ml) for 30 min, and gave 1-desmethyldesmotroposantonin (**7a**, 4.1 g), mp 231—232 °C (acetone) (lit.,[11] 228—229 °C) and $[\alpha]_D$ +105.1° ($CHCl_3$) (lit,[11] +115°); MS, *m/e* 232 (M^+), 217, 204, 189, and 159; IR, ν_{max} 3400, 1764, 1605, 1588, and 812 cm^{-1}; NMR, δ 1.28 (3H, d, J=6.5 Hz, 13-C$\underline{H}_3$), 1.60 (1H, s, O$\underline{H}$), 2.35 (3H, s, 14-C$\underline{H}_3$), 2.93 (2H, br m, W_H=14Hz, 2$\underline{H}$ at C_9), 5.02 (1H, d, J=9 Hz, $\underline{H}$ at C_6), 6.66 and 6.83 (each 1H, ABq, J=8 Hz, 2$\underline{H}$ at C_2 and C_1).

A soln of **7a** (1.76 g) in Ac_2O (28 ml) containing 7 drops of concd sulfuric acid was heated on a water bath for 20 min, and gave **7b** (1.78 g), mp 157.5—158 °C (methanol) (lit,[11] 159.5—160.5 °C) and $[\alpha]_D$ −170.8° ($CHCl_3$) (lit,[11] −155.7°); Mass, *m/e* 274 (M^+), 232 (base, M^+−CH_2CO), 217, 188, 173, and 159; IR, ν_{max} 1769 and 1747 cm^{-1}; NMR, δ 1.40 (3H, d, J=7 Hz, 13-C$\underline{H}_3$), 2.25 and 2.34 (each 3H, s, 14-C$\underline{H}_3$ and OCOC$\underline{H}_3$ or *vice versa*), 5.59 (1H, d, J=5.5 Hz, $\underline{H}$ at C_6), and 6.98 (2H, s, 2$\underline{H}$ at C_1 and C_2). The overall yield amounted to 18.7% (lit,[11] 12.2%).

*2-(7-Acetoxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)propanoic Acid (**9**) and Its Methyl Ester (**9a**).* A solnof **7b** (3.00 g) in acetic acid (50 ml) was hydrogenated over 5% palladium charcoal (Wako, 1.5 g) at room temp for 20 h, when 327 ml (1.24 equiv) of hydrogen had been consumed. The mixture was filtered to remove the catalyst, which was washed with chloroform. The filtrate and washings were combined and evaporated to leave a foamy residue (**9**, 3.33 g), showing a single spot on TLC, after azeotropization; IR ($CHCl_3$), ν_{max} 1750, 1702, 1601, and 1063 cm^{-1}; NMR, δ 1.30 (3H, d, J=6 Hz), 2.01 and 2.32 (each 3H, s), 6.76 and 6.95 (each 1H, ABq, J=8 Hz).

The residue (**9**), without further purification, was dissolved in ether (50 ml) and treated with diazomethane, prepared from nitrosomethylurea (10.5 g), in ether (80 ml) at room temp for 4 h. The soln was concentrated to dryness, leaving oily residue (3.66 g), which was purified by column chromatography over silica gel (60 g). Eluates with benzene-ether (5 : 1, 150 ml) gave **9a** (3.17 g), after being dried *in vacuo* for 2 d, oil and $[\alpha]_D$ +77.2° ($CHCl_3$); MS, *m/e* 290 (M^+), 248 (M^+−CH_2CO), 216, 203, 201, 189, 160 (base), and 145; IR ($CHCl_3$), ν_{max} 1762, 1736, and 1603 cm^{-1}; NMR, δ 1.23 (3H, d, J=7 Hz), 2.00 and 2.30 (each 3H, s), 3.69 (3H, s, COOC$\underline{H}_3$), 6.74 and 6.92 (each 1H, ABq, J=8 Hz). Found: C, 70.31; H, 7.44%. Calcd for $C_{17}H_{22}O_4$: C,

70.32; H, 7.64%.

*2-(7-Hydroxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)-1-propanol (**10**) and Its Bis(*p*-toluenesulfonate) (**10a**).* To a suspended mixture of lithium aluminium hydride (LAH, 1.3 g) in tetrahydrofuran (THF, 100 ml) was added dropwise a soln of **9a** (2.67 g) in dry THF (35 ml) under cooling with ice. The mixture was stirred under reflux for 24 h, and cooled to 0 °C. After addition of ethyl acetate, methanol and water to decompose an excess of the reagent, the mixture was submitted to filtration to remove insoluble materials, which were washed with ethanol. The filtrate and washings were combined and evaporated to dryness, leaving an oily residue, which was shaken with ethyl acetate and 2 M hydrochloric acid. The acidic layer was washed twice with ethyl acetate. The ethyl acetate solns were combined, washed with 2 M hydrochloric acid, 5% aq sodium hydrogen carbonate and saturated brine, dried and evaporated to leave a crystalline residue (2.02 g), which on recrystallization from ethyl acetate–hexane yielded **10** (1.76 g), mp 126—127 °C and $[\alpha]_D$ +76.7°; MS, *m/e* 220 (M^+), 187, 173, 161, and 159 (base); IR, ν_{max} 3565, 3280, 1605, 1591, 1200, 1070, and 816 cm^{-1}; NMR, δ 1.00 (3H, d, J=7 Hz), 2.10 (3H, s), 3.67 (2H, m, W_H=11 Hz, $C\underline{H}_2OH$), 4.96 (1H, s, O$\underline{H}$), 6.53 and 6.76 (each 1H, ABq, J=8 Hz). Found: C, 76.33; H, 9.07%. Calcd for $C_{14}H_{20}O_2$: C, 76.32; H, 9.15%.

Compound **10** (223 mg) was treated with *p*-toluenesulfonyl chloride (446 mg) in Py (3 ml) at room temp for 40 h, and then poured into ether (100 ml). The whole soln was washed with 2 M hydrochloric acid (3×10 ml), 5% aq sodium hydrogencarbonate and saturated brine, dried and evaporated to leave an oily residue (523 mg), which was purified by column chromatography over silica gel (30 g). Eluates with benzene gave **10a** (438 mg) in pure state, oil and $[\alpha]_D$ +39.5° ($CHCl_3$); MS, *m/e* 528 (M^+), 356, 314, 313, 238, 201, 159 (base), and 157; IR ($CHCl_3$), ν_{max} 3030, 1600, 1175 (strong), 850, 832, and 815 cm^{-1}; NMR, δ 0.95 (3H, d, J=7 Hz), 1.90 (3H, s), 2.44 and 2.46 (each 3H, s, $2C\underline{H}_3C_6H_4SO_3$), 4.00 (2H, s, $C\underline{H}_2OSO_2C_6H_4CH_3$), 6.62 and 6.77 (each 1H, ABq, J=8 Hz), 7.20 and 7.72 (each 4H, m, $2CH_3C_6\underline{H}_4SO_3$).

*Conversion of **10a** into (2R)-2-Isopropyl-8-methyl-1,2,3,4-tetrahydronaphthalen-7-ol (**6**) and Its 3,5-Dinitrobenzoate (**6a**).* Compund **10a** (315 mg) in dry THF (20 ml) was treated with LAH (364 mg) under reflux for 24 h. The reaction mixture, after being cooled, was worked up as described above to leave an oily residue (131 mg), showing a single spot, which was purified by column chromatography over silica gel (6 g). Eluates with benzene yielded **6** (98 mg) in pure state, oil and $[\alpha]_D$ +85.7° ($CHCl_3$); MS, *m/e* 204 (base, M^+), 189, 161, 147, 146, 134, 122, and 121; IR (liquid), ν_{max} 3420, 1598, 1386, 1367, and 817 cm^{-1}; NMR, δ 0.98 [6H, d, J=6 Hz, $CH(C\underline{H}_3)_2$], 2.11 (3H, s, $C\underline{H}_3$ at C_8), 4.76 (1H, s, O$\underline{H}$), 6.51 and 6.75 (each 1H, ABq, J=8 Hz, 2$\underline{H}$ at C_6 and C_5).

Compound **6** (73.5 mg) was stirred with 3,5-dinitrobenzoyl chloride (112.5 mg) in dry Py (1 ml) at room temp for 16 h. The mixture was poured into ice-water (50 ml), when precipitates separated out and were collected by filtration, washed with water, 5% aq sodium carbonate and water, and dried to give a crystalline material (140 mg). This was recrystallized from acetone to give **6a** (106.5 mg), mp 159.5—160 °C and $[\alpha]_D$ +60.1° ($CHCl_3$); MS, *m/e* 398 (M^+), 368, 355, 204, 195, 186, 165 (base), 149, and 135; IR, ν_{max} 3095, 1740, 1629, 1599, 1545, 1343, 1163, 1073, 921, and 717 cm^{-1}; NMR, δ 1.01 [6H, d, J=6 Hz, $CH(C\underline{H}_3)_2$], 2.08 (3H, s, $C\underline{H}_3$ at C_8), 6.82 and 6.96 (each 1H, ABq, J=8 Hz, 2$\underline{H}$, at C_5 and C_6), and 9.24 [3H, m, $(NO_2)_2C_6\underline{H}_3COO$]. Found: C, 63.37; H, 5.55; N, 6.82%. Calcd for $C_{21}H_{22}O_6N_2$: C, 63.31; H, 5.57; N, 7.03%.

Rishitin. II. Synthesis[1]

Akio MURAI, Kouichi NISHIZAKURA, Nobukatsu KATSUI, and Tadashi MASAMUNE
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received November 1, 1976)

The regio- and stereo-selective synthesis of rishitin (**1**) from (−)-α-santonin (**2**) is described. The transformation involves twelve steps including two known processes, the overall yield amounting to 2.9% from the santonin (**2**).

In the preceding paper[2] a report was given on the details of isolation and structure elucidation of rishitin (**1**), a representative member of a group of sesquiterpenes qualified as "phytoalexin" from diseased potatoes. As a result of continuing studies on the phytoalexins, we reported[3] the regio- and stereo-selective synthesis of rishitin (**1**) from (−)-α-santonin[4] (**2**). Details of the transformation are given in this paper.

The structure and configuration of rishitin (**1**) are characterized by an eudesmane skeleton with a double bond intervening between the two rings as well as three asymmetric centers in the flexible A ring. After many attempts starting with (2*R*)-2-isopropenyl-7-methoxy-8-methyl-1,2,3,4-tetrahydronaphthalene (**3**), bp 89—91 °C (0.07 Torr), obtained from "desmethyl-6-epidesmotroposantonin"[5] (**4**) *via* several steps (see Experimental), we functionalized the rigid A ring of a compound with a *trans*-decalin system, derivable from santonin **2**, as stereoselectively as possible and then introduce a double bond between both the A and B rings.

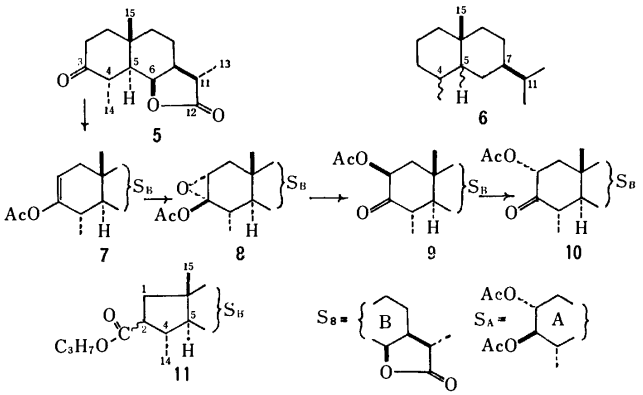
(−)-α-Santonin (**2**) was converted into (11*S*)-3-oxo-4β,5α-eudesman-6β,12-olide[6] (**5**) by the two-step procedure,[7] which on treatment with isopropenyl acetate in the presence of acid under reflux for 3 h[8] gave the corresponding Δ^2-3-ol acetate (**7**), mp 140—141 °C, in a 99% yield. The spectral data [*m/e* 292 (M^+) and 250 (M^+-CH_2CO);[9] ν_{max} 1773, 1755, and 1682 cm^{-1}; δ 2.17 (3H, s, $OCOC\underline{H}_3$) and 5.28 (1H, do t, *J*=5.5, 2.5, and 2.5 Hz)] were in good accord with the structure. Oxidation of enol acetate (**7**) with perbenzoic acid in chloroform at 0 °C for 24 h afforded 2α,3α-epoxy 3β-acetate (**8**), mp 156—156.5 °C, in a 91% yield, which was rearranged by heating at 170 °C for 10 min to 3-oxo 2β-acetate (**9**), mp 128—129 °C, and then epimerized with hydrobromic acid in acetic acid at room temperature[10] to give 3-oxo 2α-acetate (**10**), mp 204—205 °C, in a 72% yield from **8**. The oxo acetate (**10**) could be obtained in a 74% overall yield from **5**, when the afore-mentioned four-step reactions (**5**→**10**) were carried out without isolation of the intermediates (**7**, **8**, and **9**). The mass [*m/e* 308 (M^+) and 266] and IR (ν_{max} *ca.* 1780 and 1740 cm^{-1}) spectra of the oxo acetates (**9** and **10**) were consistent with the assigned structures. The spectral patterns due to the C_2-proton in the respective NMR spectra clearly determined the configurations of the 2-acetoxyl groups [H at C_2, δ 5.35 (1H, do d, *J*=9 and 6 Hz) for **9**, and δ 5.45 (1H, do d, *J*=13 and 7 Hz) for **10**], as compared with those of the corresponding protons of 2-acetoxycholestan-3-ones[11] [H at C_2, δ 5.12 (1H, do d, *J*=9.5 and 7.4 Hz) for 2β-acetate, and δ 5.07 (1H, do d, *J*=13.1 and 6.6 Hz) for 2α-acetate]. On the other hand, the 2α,3α-epoxy configuration of epoxide **8** was assigned on mechanistic considerations on transformation of **8** into unstable 3-oxo 2β-acetate (**9**).[10,11]



One-step oxidation of 3-ketone (**5**) to 3-oxo 2α-acetate (**10**) was carried out under various conditions. Treatment of **5** with lead tetraacetate in benzene containing boron trifluoride and 2-propanol at room temperature[12] produced a mixture, from which 3-oxo 2α-acetate(**10**), 3-oxo 2β-acetate (**9**), and a new compound (**11**), mp 112.5—113 °C, were isolated after chromatography in 41, 9, and 14% yields, respectively. Compound **11**, $C_{18}H_{28}O_4$, gave the following spectra: MS, *m/e* 308 (M^+), 249 ($M^+-C_3H_7O$) and 221 ($M^+-C_3H_7OCO$); IR, ν_{max} 1772, 1728, 1213, 1200, 1184, 1163, and 1111 cm^{-1}; NMR, δ 0.91 (3H, s, 15-$C\underline{H}_3$), 1.04 and 1.32 (each 3H, d, *J*=7 and 7.5 Hz, 14- and 13-$C\underline{H}_3$), 1.26 [6H, d, *J*=6 Hz, $(C\underline{H}_3)_2CHOCO$], 1.68 (2H, br d, *J*=8.5 Hz, 2H at C_1), 2.39 (1H, q, *J*=7.5 Hz, H at C_{11}), 2.51 (1H, m, H at C_4), 3.05 (1H, do t, *J*=10.5, 8.5, and 8.5 Hz, H at C_2), 4.68 (1H, t, *J*=4 Hz, H at C_6), and 5.01 [1H, sep, *J*=6 Hz, $(CH_3)_2C\underline{H}OCO$]. These spectra indicated that (i) the B ring, including

the γ-lactonic group, and one secondary methyl group in the original A ring remained unchanged, and (ii) an isopropoxycarbonyl group was newly formed. Assignment of formula **11** was made from these data together with those of spin decoupling studies. It is interesting that the ring contraction occurred in the presence of 2-propanol, in contrast to the corresponding reaction of 5α-cholestan-3-one.[12c]

Reduction of 3-oxo 2α-acetate (**10**) with sodium borohydride in methanol at 0 °C afforded a mixture of diastereoisomeric 3-alcohols, which was separated by preparative TLC to give 3β-alcohol (**12**), mp 251—252 °C, and 3α-alcohol (**13**), mp 191—192 °C, in 41 and 48% yields, respectively. Each of these alcohols, when oxidized with the Jones reagent, was reconverted into the original 3-ketone (**10**) in 85—90% yields, indicating the configurational retention during the course of reduction. The C_3 configuration in question in these alcohols is evident from the NMR spectra. The former (**12**) showed two one-proton signals (1H, t, J=9 Hz and 1H, do do d, J=11.5, 9, and 5 Hz) due to the protons at C_3 and C_2 at δ 3.13 and 4.93, respectively, and the latter (**13**) the corresponding signals (1H, br s, W_H=6.5 Hz, and 1H, do do d, J=11, 5.5, and 3 Hz) at δ 3.91 and 5.01. These hydroxy acetates (**12** and **13**) were converted into the diacetates (**12a** and **13a**), mp 189.5—190.5 °C and 150—151 °C, and were hydrolyzed quantitatively to the glycols (**12b** and **13b**), mp 184—185 °C and 94.5—95 °C, respectively. In line with the assigned configurations, *cis*-glycol (**13b**) readily formed the acetonide (**14**), mp 131—132 °C, on treatment with acetone over silica gel (Wakogel Q-23), whereas *trans*-glycol (**12b**) was recovered unchanged under the same conditions.

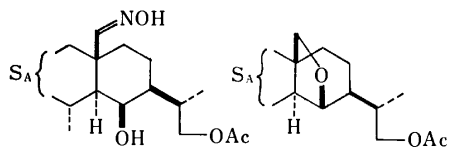
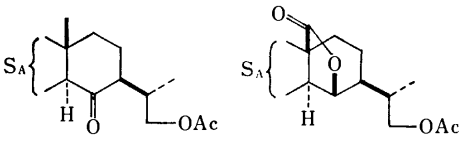
Further reduction of 2α-acetoxy 3β-hydroxy γ-lactone (**12**) with lithium aluminium hydride under reflux gave tetraol (**15**), amorphous, which was isolated as the triacetate (**15a**), mp 96.5—98 °C, almost quantitatively after acetylation at room temperature. The triacetate (**15a**) showed a broad singlet (W_H=6.5 Hz) due to the C_6-proton at δ 4.08, and the steric interaction between 1,3-diaxial methyl and hydroxyl groups at C_{10} and C_6 evidently hindered acetylation of the hydroxyl group. By the same treatment the 3α-hydroxy epimer (**13**) gave the 3-epimeric tetraol (**16**), mp 174—174.5 °C, which was also converted into the triacetate (**16a**), mp 80—81 °C, showing a broad singlet (W_H=7 Hz) due to the C_6-proton at δ 4.00, in an 80% yield, along with the 2,12-diacetate (**16b**), oil (15%). The same hydride reduction of 3-oxo 2α-acetate (**10**) followed by acetylation produced a mixture of **15a** and **16a**, from which the desired 2α, 3β,12-triacetate (**15a**) could be isolated in an 80% yield with the epimer (**16a**) (9%). The triacetate (**15a**) was then transformed quantitatively into the 6-nitrite (**17**), mp 103.5—105.5 °C, by treatment with nitrosyl chloride in pyridine, whose NMR spectrum was in line with the structure; δ 4.72 (1H, t, J=10 Hz, H at C_3), 5.05 (1H, do do d, J=11.5, 10, and 5 Hz, H at C_2), and 5.94 (1H, br s, W_H=5 Hz, H at C_6).

Irradiation of the 6-nitrite (**17**) by a 200 watt high pressure Hanovia lamp in benzene at room temperature for 2 h followed by reflux in a 1 : 1 mixture of tetrahydrofuran and 2-propanol[13] resulted in functionalization at C_{15}, giving a three-component mixture, which was separated by chromatography over Florisil to yield 15-oxime (**18**), amorphous, as a major product (78%) with 6,15-oxolane and 6-ketone (**19** and **20**), mp 100—101 °C and 109.5—111 °C (5 and 7%). The 6-ketone (**20**) could readily be identified by oxidation of **15a** with the Jones reagent. The structure of oxime **18** was deduced from the following spectra. The mass spectrum indicated fragmentation peaks at *m/e* 410 (M^+—OH), 367 ($M^+-C_2H_4O_2$), and 350. The NMR spectrum revealed, instead of a singlet peak due to the 15-methyl protons, a doublet (J= 9 Hz) and two singlet peaks at δ 6.56, 7.18, and 10.45, which were ascribed to 6-hydroxy, hydroxyimino methylidene and oxime-hydroxy protons, respectively. The structure was further supported by oxidation of **18** with the Jones reagent to γ-lactone (**21**), mp 126—127 °C, in a 56% yield. The γ-lactone (**21**) was characterized by fragmentation peaks at *m/e* 382 (M^+—CO), 350 ($M^+-C_2H_4O_2$), and 322 (350—CO) as well as absorption maxima at 1780 and 1745 cm^{-1} and at δ 4.49 (1H, br s, W_H=2.5 Hz, H at C_6) in the mass, IR, and NMR spectra. Similarly, the structure of oxolane (**19**) was assigned as shown in the formula on the basis of the following spectral data: *m/e* 396 (M^+) and 336 ($M^+-C_2H_4O_2$); ν_{max} 1743, 1478, and 862 cm^{-1};[14]



18 **19**



20 **21**

δ 3.62 and 3.86 (each 1H, ABq, J=8 Hz, 2H at C_{15}),[14] and 4.18 (1H, s, H at C_6). The oxolane (**19**) was also obtained by direct hypoiodite reaction[15] of **15a** in a 73% yield, confirming the structure for oxolane **19**. However, the oxolane resisted further oxidation to **21** and/or its analogues under various conditions, giving only multi-component intractable materials.

Treatment of 15-oxime (**18**) with acetic anhydride in pyridine at room temperature led to only dehydration of the hydroxyimino group to give 6β-hydroxy 10-nitrite (**22**), mp 175—176 °C in an 89% yield, whose functional groups were characterized by absorption maxima at 3530, 2230, 1739, and 1728 cm^{-1} in the IR spectrum. Compound **22**, when treated with methanesulfonyl chloride in pyridine at room temperature and then with collidine under reflux, underwent further dehydration to yield an oily mixture of olefins, from which Δ^5- and Δ^6-10-nitriles (**23** and **24**), mp 106—107 °C and 81—82 °C, were isolated after chromatography in 78 and 9% yields, respectively. Alternately, the hydroxy nitrile (**22**) was obtained by prolonged treatment of **18** with phosphoryl chloride at room temperature in 60—70% yields with a small amount of **23** (4%). However, attempted double dehydration of 15-oxime (**18**) with methanesulfonyl chloride under the afore-mentioned conditions resulted in formation of an intractable material, from which the desired nitrile (**23**) could be isolated only in a 15% yield.

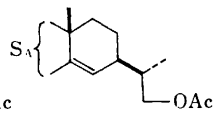
25



26

Both the olefins (**23** and **24**) exhibited almost the same mass [m/e 331 ($M^+-C_2H_4O_2$) and 211], IR (ν_{max} *ca.* 2230 and 1745 cm^{-1}), and NMR spectra [δ *ca.* 5.55 (1H, br s, W_H=5 Hz, olefinic H)], indicating that the olefins are isomers differing only in the double bond position (Δ^5 or Δ^6). The position was assigned on the basis of the following considerations. i) In the NMR spectra of normal[16] and modified steroids,[17] the shielding effects of various substituents on the chemical shift of 19-methyl protons are additive. The additivity is expected to hold for the present 4β,5α-eudesmanes, in which the A and B rings are regared as the A and B rings in normal steroids, and the 15-methyl protons as the 19-methyl protons. The chemical shifts of 15-methyl protons were then estimated, by assuming the relevant shift of 4β,5α-eudesman-12-ol acetate[6] (**25**), a hypothetical compound, to be δ 0.18 (reference chemical shift) and by using well-established contributions of functional groups in the A and B rings of normal steroids.[16] The calculated values were in good accord with the observed: δ_{calcd} (δ_{obsd}) 1.18 (1.18), 1.15 (1.15), 1.14 (1.13), and 0.90 (0.88) for **15a**, **16a**, **16b**, and **20**, respectively. Compound **15a**, a 10-methyl analogue of **22**, when treated with methanesulfonyl chloride under the above conditions, underwent dehydration to give an olefin (**26**), oil, in a 97% yield, as the only isolatable product, whose 15-methyl protons appeared as a singlet at δ 1.18 in the NMR spectrum. The chemical shift coincided with the calculated value, δ 1.18, only when the compound (**26**) was assigned Δ^5-triacetate formula (*cf.*, δ_{calcd} 0.92 for Δ^6-triacetate). The result indicates that dehydration of the 6β-hydroxyeudesmanes would proceed regioselectively to form the corresponding Δ^5-eudesmanes, and hence the major dehydration product (**23**) would be represented by Δ^5-10-nitrile structure rather than Δ^6-10-nitrile. (ii) Tori and co-workers[16b] discussed the chemical shifts of the A ring protons in normal steroids in terms of the effects of functional groups in the A and B rings. The discussion apparently applies to eudesmanes; *e.g.*, the axial 3α-proton (δ 4.60) of Δ^5-triacetate (**26**) was observed at a field 0.10 ppm higher than that (δ 4.70) of 6β-hydroxy triacetate (**15a**), as expected by their presumption. The 3α-proton of the relevant major olefin (**23**) appeared as a double doublet (J= 11 and 9.5 Hz) at 0.13 ppm higher field, δ 4.56, as compared with the corresponding proton of 6β-hydroxy-10-nitrile (**22**), δ 4.69, and that of the minor olefin (**24**) as a triplet (J=9.5 Hz) at 0.09 ppm lower field, δ 4.78.

Δ^5-10-Cyano triacetate (**23**) was saponified to the triol (**23a**), oil, which was converted into Δ^5-10-cyano tris(methoxymethyl ether) (**23b**), oil, in a 56% yield from **23**, showing absorption maxima at 2255 cm^{-1} and at δ 3.38, 3.41, 3.46 (each 3H, s, $3OCH_3$), and 5.57 (1H, br s, W_H=4 Hz, H at C_6) in the IR and NMR spectra. Hydrolysis of the cyano group of **23** followed by decarboxylation with concomitant migration of the 5,6-double bond was unsuccessful, giving a tarry material. However, treatment of Δ^5-10-nitrile (**23**) with sodium in toluene containing ethanol under reflux[18] effected reductive decyanation with concurrent migration of the double bond to give $\Delta^{5(10)}$-triol (**27**), oil, which was converted into the triacetate (**27a**), oil, showing no olefinic proton in the NMR spectrum, in a 71% yield from **23**. The structure of olefin **27a** was identified by comparison with an authentic sample obtained from natural rishitin (**1**) *via* a four-step process (formation of the acetonide, hydroboration, acid hydrolysis, and acetylation). On the other hand, $\Delta^{5(10)}$ 2,3,10-triol (**27**), when treated with acetone over silica gel (Wakogel Q-23), formed the 2,3-acetonide (**28**), oil, ν_{max} 3390, 1380, and 1371 cm^{-1} and δ 1.46 [6H, s, $(CH_3)_2CO$], in a 75% yield from **23**. The 2,3-acetonide (**28**) was treated successively with tosyl chloride in pyridine at room temperature and then

with sodium iodide in acetone under reflux to give the 12-iodide (**29**), semi-soild, *m/e* 390 (M^+) and ν_{max} 1380 and 1371 cm^{-1}, in a 92% yield. Further treatment of the 12-iodide (**29**) with potassium hydroxide in refluxing methanol led to formation of a mixture of two compounds, which were separated by chromatography to give the 12-methoxy derivative (**30**), oil, *m/e* 294 (M^+), ν_{max} 1105 and 1088 cm^{-1}, and δ 3.32 (3H, s, $OC\underline{H}_3$), and $\Delta^{5(10),11}$-2,3-diol acetonide (**31**), oil, in 14 and 70% yields, respectively. The latter (**31**) exhibited parent and fragmentation peaks at *m/e* 262 (M^+) and 131 (base) in the mass spectrum and absorption maxima at 3080, 1643, and 888 cm^{-1} and δ 1.72 (3H, s, 13-$C\underline{H}_3$), 4.63 and 4.74 (each 1H, br s, W_H=4 Hz, 2H at C_{12}) in the IR and NMR spectra, and was identical with an authentic specimen[2] derived from natural rishitin (**1**). Hydrolysis of the acetonide (**31**) with 0.5% phosphoric acid in ethanol under reflux afforded $\Delta^{5(10),11}$-2,3-diol, mp 58—60 °C and $[\alpha]_D$ −30.4°, in a 78% yield, which was converted into the diacetate, mp 66—68 °C and $[\alpha]_D$ −14.1°. The glycol and diacetate were identical with natural rishitin[2] (**1**) and the diacetate[2] (**1a**), respectively. The present transformation from (−)-α-santonin (**2**) into rishitin (**1**) completes the first and total[4] synthesis of rishitin. The overall yield of rishitin amounted to 12.0% from compound **5** and 2.9% from (−)-α-santonin.

Experimental

All the melting points were uncorrected. The homogenity of each compound was checked by TLC on silica gel (Wakogel B-5) with various solvent systems, and the spots were developed with cerium(IV) sulfate in dil sulfuric acid. The optical rotations, ORD curves, IR, and NMR (100 MHz) spectra were measured in chloroform, methanol, Nujol, and chloroform-*d*, respectively, unless otherwise stated. Abbreviations "s, d, t, q, m, br, and do" in the NMR spectra denote "singlet, doublet, triplet, quartet, multiplet, broad, and double," respectively.

(2R)-2-Isopropenyl-7-methoxy-8-methyl-1,2,3,4-tetrahydronaphthalene (3). *(i)* A soln of 2-(7-acetoxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)propanoic acid[2] (12.63 g) in dry tetrahydrofuran (THF, 200 ml) was stirred with lithium aluminium hydride (LAH, 3.15 g) under reflux for 17 h. After addition of water to decompose an excess of the reagent, the suspended mixture was mixed with chloroform and stirred vigorously. The insoluble substance was removed by filtration and washed with chloroform and water. The filtrate and all the chloroform and water washings were combined and evaporated to dryness to leave an oily residue, which was again dissloved in chloroform. The chloroform soln was washed with water, dried, and evaporated to leave a crystalline residue (1.50 g), which was collected and recrystallized from ethyl acetate–hexane to give 2-(7-hydroxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)-1-propanol[2] (1.26 g), mp 125—126 °C. The water washings were acidified (pH<4.0) with 6 M hydrochloric acid and extracted with chloroform repeatedly. The extracts were washed with water, dried, and evaporated to leave an amorphous substance (7.35 g), showing a single spot, which was identified as the corresponding saponified product, 2-(7-hydroxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)-propanoic acid on the basis of the spectral data: IR ($CHCl_3$), ν_{max} 3585, 1704, 1598, 1486, 1271, and 1063 cm^{-1}; NMR, δ 1.27 (3H, d, J=6.5 Hz), 2.09 (3H, s), 5.85 (2H, br, 2O$\underline{H}$), 6.59 and 6.81 (each 1H, d, J=8 Hz). The hydroxy acid was dissolved in ether (150 ml), without further purification, and treated with diazomethane, prepared from nitrosomethylurea (20.6 g), in ether (230 ml) at room temp for 22 h. The soln was concentrated to give the corresponding methyl ester (6.72 g), oil, showing a single spot on TLC, which was purified by distillation at 168—172 °C (bath temp) under reduced pressure (1 Torr) and crystallized on standing: mp 43—45 °C and $[\alpha]_D$ +92.5°; MS, *m/e* 248 (M^+); IR ($CHCl_3$), ν_{max} 3410, 1722, 1597, 1483, 1267, 1162, and 1060 cm^{-1}; NMR, δ 1.27 (3H, d, J=7 Hz), 2.11 (3H, s), 3.74 (3H, s), 6.57 and 6.80 (each 1H, d, J=8 Hz). Found: C, 72.26; H, 8.11%. Calcd for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12%.

(ii) A soln of methyl 2-(7-hydroxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)propanoate (6.61 g) in methanol (250 ml) was treated with diazomethane, prepared from nitrosomethylurea (20.6 g), in ether (220 ml) at room temp for 13 h. After addition of the same amount of diazomethane in ether (220 ml), the soln was allowed to stand at room temp for 66 h and then evaporated below 36 °C to leave an oily residue (7.34 g), which was purified by column chromatography over silica gel (70 g) and celite (30 g) followed by distillation to give methyl 2-(7-methoxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)propanoate in pure state: bp 143—148 °C (bath temp) (1 Torr) and $[\alpha]_D$ +89.3°; MS, *m/e* 262 (M^+); IR ($CHCl_3$), ν_{max} 1727, 1599, 1483, 1262, 1163, and 1088 cm^{-1}; NMR, δ 1.26 (3H, d, J=7 Hz), 2.13 (3H, s), 3.75 and 3.83 (each 3H, s), 6.67 and 6.93 (each 1H, d, J=8.5 Hz). Found: C, 73.10; H, 8.35%. Calcd for $C_{16}H_{22}O_3$: C, 73.25; H, 8.45%.

(iii) A soln of the methoxy methyl ester (6.14 g) in THF (160 ml) was mixed with LAH (3 g) in THF (250 ml), and the whole mixture was stirred at room temp for 18 h. After careful addition of water (40 ml), the resulting suspension was submitted to filtration to remove insoluble materials, and the filtrate was evaporated to dryness to leave an oily residue, which was extracted in ether. The ether soln was washed with saturated brine, dried, and evaporated to give an oil (5.69 g), showing a single spot, which was identical with an authentic sample of 2-(7-methoxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)-1-propanol prepared from the corresponding 7-hydroxy analogue as described in the following.

A soln of 2-(7-hydroxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)propanol[2] (896 mg), mp 125—126 °C, in acetone (40 ml) was stirred with dimethyl sulfate (1.6 ml) and potassium carbonate (4.8 g) under reflux for 9 h, cooled and then filtered. The ppts were washed with chloroform, and the filtrate and washings were combined and evaporated to leave an oily

residue, which was again dissolved in chloroform. The chloroform soln was washed with water, dried, and evaporated to leave an oily substance (1.82 g), which was purified by chromatography over silica gel (Merck 30 g). Eluates with benzene–ether (3 : 1) (100 ml) afforded the methyl ether (800 mg), which was distilled for analysis: bp 97—102 °C (bath temp) (1 Torr) and $[\alpha]_D$ +70.9°; MS, *m/e* 234 (M^+), 216, 201, 186, 175, and 173 (base); IR (film), ν_{max} 3360, 1601, 1485, 1463, 1441, 1260, 1103, 1031, 812, and 794 cm^{-1}; NMR δ 1.00 (3H, d, J=7 Hz), 1.83 (1H, s, OH), 2.13 (3H, s), 3.69 (2H, m), 3.81 (3H, s), 6.69 and 6.93 (each 1H, d, J=8 Hz). Found: C, 76.69; H, 9.43%. Calcd for $C_{15}H_{22}O_2$: C, 76.88; H, 9.46%.

(iv) The methoxy-propanol (730 mg), described in *(iii)*, was treated with *p*-toluenesulfonyl chloroide (660 mg) in pyridine (Py, 8 ml) at room temp for 20 h, and then poured into ice-water (300 ml). The resulting ppts were collected by filtration, washed with water, dried in a desiccator, and triturated with isopropyl ether to yield a crystalline substance (980 mg). Recrystallization from isopropyl ether afforded 2-(7-methoxy-8-methyl-1,2,3,4-tetrahydro-2-naphthyl)-1-propanol tosylate, mp 86.5—87 °C and $[\alpha]_D$ +56.3°; MS, *m/e* 388 (M^+), 216, 201, and 174 (base); IR, ν_{max} 1598, 1485, 1355, 1261, 1188, 1180, 1171, 1106, 1096, 957, 929, 850, and 792 cm^{-1}; NMR, δ 0.97 (3H, d, J=6.5 Hz), 2.04, 2.45, and 3.78 (each 3H, s), 4.05 (2H, d, J=5 Hz), 6.65 and 6.87 (each 1H, d, J=8.5 Hz), 7.31 and 7.78 (each 2H, ABq, J=8 Hz). Found: C, 68.01; H, 7.23; S, 8.30%. Calcd for $C_{22}H_{28}O_4S$: C, 68.01; H, 7.26; S, 8.25%.

(v) The tosylate (650 mg) was stirred with sodium iodide (3 g) in acetone (30 ml) under reflux for 20 h. After removal of the insoluble substance by filtration, the mixture was evaporated to dryness and extracted with ether (50 ml). The extracts were washed with 5% aq sodium thiosulfate and saturated brine, dried, and evaporated to leave a crystalline substance (617 mg), which was recrystallized from hexane to give the corresponding iodide (570 mg), mp 73.5—75.5 °C. This was recrystallized from hexane for analysis: mp 75.5—77.5 °C and $[\alpha]_D$ +95°; MS, *m/e* 344 (M^+), 217, 175, and 161 (base); IR, ν_{max} 1599, 1587, 1479, 1258, 1105, and 801 cm^{-1}; NMR, δ 1.09 (3H, d, J=6.5 Hz), 2.14 (3H, s), 3.37 (2H, d, J=5 Hz, CH_2I), 3.82 (3H, s), 6.70 and 6.94 (each 1H, d, J=8 Hz). Found: C, 52.32; H, 6.20; I, 37.21%. Calcd for $C_{15}H_{21}OI$: C, 52.33; H, 6.15; I, 36.87%.

(vi) The iodide (4.97 g) was refluxed in methanol (300 ml) containing potassium hydroxide (17.6 g) under nitrogen for 2.5 h. The reaction mixture was concentrated below 40 °C under reduced pressure (90 Torr), and then shaken with water (150 ml), ether (100 ml), and sodium chloride (40 g). The aqueous layer was separated and washed with ether (4×50 ml). The ether layer and washings were combined, washed with saturated brine (2×50 ml), dried, and evaporated to leave an oily residue (3.19 g), which was purified by column chromatography over silica gel (Mallinckrodt, 21 g) and celite (9 g). Eluates with hexane (1.6 l), after distillation, afforded (2*R*)-2-isopropenyl-7-methoxy-8-methyl-1,2,3,4-tetrahydronaphthalene (**3**, 2.68 g), bp 89—91 °C (bath temp) (0.07 Torr) and $[\alpha]_D$ +76.6°; MS, *m/e* 216 (M^+), 201, and 173 (base); IR (CCl_4), ν_{max} 3080, 1645, 1601, 1484, 1260, 1114, 1090, and 890 cm^{-1}; NMR, δ 1.83, 2.13, and 3.79 (each 3H, s), 4.80 (2H, s, $=CH_2$), 6.69 and 6.94 (each 1H, d, J=8.5 Hz). Found: C, 83.52; H, 9.25%. Calcd for $C_{15}H_{20}O$: C, 83.28; H, 9.32%.

(11S)-3-Oxo-4β,5α-eudesman-6β,12-olide[6,7] *(**5**).* Compound **5** was prepared by a modification of the procedure of Cocker *et al.*[7b] A soln of "6-epi-(−)-α-santonin"[7,19] (3 g), mp 102—103 °C, in acetic acid (AcOH, 400 ml) was hydrogenated over 10% palladium charcoal (200 mg) at room temp for 2 h, when 590 ml of hydrogen had been absorbed. The reaction mixture was worked up as usual to leave neutral crystalline substances (1.64 g), showing two 1 : 1 overlapped spots on TLC. The mixture, dissolved in AcOH (150 ml) at 50 °C, was stirred with *p*-toluenesulfonic acid (PTS, 1.5 g) at room temp for 18 h, evaporated to dryness, and diluted with water (500 ml). The resulting ppts were separated, collected by filtration and washed with water. Recrystallization from aq ethanol gave **5** (1.16 g), mp 164—165 °C. This was recrystallized from ethanol for analysis: mp 164—165 °C and $[\alpha]_D$ −106.0° (lit,[7] mp 177—178° and $[\alpha]_D$ −91°); ORD, $[\Phi]_{304}^{peak}$ +800°, $[\Phi]_{265}^{trough}$ −4790°, a=+55.9°; IR, ν_{max} 1762, 1703, 1420, 1210, 1178, 1153, 975, and 937 cm^{-1}; NMR, δ 1.14 (3H, d, J=7 Hz, 14-CH_3), 1.22 (3H, s, 15-CH_3), 1.33 (3H, d, J=8 Hz, 13-CH_3), and 4.66 (1H, t, J=4 Hz, H at C_6). Found: C, 72.10; H, 9.07%. Calcd for $C_{15}H_{22}O_3$: C, 71.97; H, 8.86%.

*(11S)-3-Acetoxy-4β,5α-eudesm-2-en-6β,12-olide (**7**).* A soln of **5** (67.2 g) in isopropenyl acetate (250 ml) containing concd sulfuric acid (0.7 ml) was refluxed for 3 h with stirring in a stream of argon gas. The mixture was cooled, concentrated, mixed with water, and extracted with dichloromethane. The extracts were worked up as usual to leave a crystalline residue, which on trituration with a 2 : 1 mixture of acetone and water followed by filtration afforded **7** (63.4 g), mp 139—140 °C. The filtrate (15.2 g), still containing the unreacted ketone (**5**) (TLC), was again treated with isopropenyl acetate (62 ml) and concd sulfuric acid (10 drops) for 3 h under reflux. The resulting crystalline residue, subjected to the same treatment as above, yielded **7** (14.3 g), mp 139—140 °C. The samples (**7**) were recrystallized from aq acetone for analysis: mp 140—141 °C and $[\alpha]_D$ −74.3 °C; MS, *m/e* 292 (M^+), 250 (base), and 177; IR, ν_{max} 1773, 1755, 1682, 1214, 1207, 1063, and 1021 cm^{-1}; NMR, δ 1.07 (3H, s, 15-CH_3), 1.10 and 1.32 (each 3H, d, J=7 and 8 Hz, 14- and 13-CH_3), 2.17 (3H, s, $OCOCH_3$), 2.41 (1H, q, J=8 Hz, H at C_{11}), 2.74 (1H, br, W_H=24 Hz, H at C_4), 4.76 (1H, t, J=4 Hz, H at C_6), and 5.28 (1H, do t, J=5.5, 2.5, and 2.5 Hz, H at C_2). Found: C, 69.97; H, 8.47%. Calcd for $C_{17}H_{24}O_4$: C, 69.83; H, 8.27%.

*(11S)-3β-Acetoxy-2α,3α-epoxy-4β,5α-eudesman-6β,12-olide (**8**).* A soln of **7** (2.45 g) in chloroform (40 ml) was treated with peroxybenzoic acid (purity 99.3%, 2 g) at 0 °C for 24 h. The mixture was washed with 5% aq sodium thiosulfate, 5% aq sodium hydrogencarbonate and water, dried, and evaporated to leave a crystalline substance, which was collected with acetone to give **8** (2.34 g), mp 153—154 °C. This was recrystallized from acetone for analysis: mp 156—156.5 °C and $[\alpha]_D$ −58.7°; MS, *m/e* 308 (M^+), 266 (base), 248, and 193; IR, ν_{max} 1771, 1750, 1223, 1158, 1050, and 976 cm^{-1}; NMR, δ 1.20 (3H, s, 15-CH_3), 1.24 and 1.30 (each 3H, d, J=6.5 and 7.5 Hz, 14- and 13-CH_3), 2.10 (3H, s, $OCOCH_3$), 2.37 (1H, q, J=7.5 Hz, H at C_{11}), 2.67 (1H, do q, J=10.5, 6.5, 6.5, and 6.5 Hz, H at C_4), 3.45 (1H, d, J=5 Hz, H at C_2), and 4.67 (1H, t, J=4 Hz, H at C_6). Found: C, 66.15; H, 7.79%. Calcd for $C_{17}H_{24}O_5$: C, 66.21; H, 7.85%.

*(11S)-2β-Acetoxy-3-oxo-4β,5α-eudesman-6β,12-olide (**9**).* Compound **8** (1.27 g) was heated in an oil-bath maintained at 170 °C for 10 min. The mixture, when cooled, crystallized spontaneously and showed a single spot on TLC. This was recrystallized from acetone–isopropyl ether to give **9** (1.187 g), mp 127—129 °C. Further recrystallization from the same solvent mixture afforded an analytical sample: mp 128—129 °C and $[\alpha]_D$ −7.7°; ORD, $[\Phi]_{304}^{peak}$ +3040°, $[\Phi]_{270}^{trough}$ −3790°, a=+68.3°; MS, *m/e* 308 (M^+), 266 (base), 248, and

193; IR, ν_{max} 1782, 1737, and 1229 cm^{-1}; NMR, δ 1.06 (3H, s, 15-C$\underline{H}_3$), 1.26 and 1.33 (each 3H, d, J=7 and 8 Hz, 14- and 13-C$\underline{H}_3$), 2.14 (3H, s, OCOC$\underline{H}_3$), 2.43 (1H, q, J=8 Hz, $\underline{H}$ at C_{11}), 2.92 (1H, do q, J=12, 7, 7, and 7 Hz, $\underline{H}$ at C_4), 4.69 (1H, t, J=4 Hz, $\underline{H}$ at C_6), and 5.35 (1H, do d, J=9 and 6 Hz, $\underline{H}$ at C_2). Found: C, 65.91; H, 7.82%. Calcd for $C_{17}H_{24}O_5$: C, 66.21; H, 7.85%.

*(11S)-2α-Acetoxy-3-oxo-4β,5α-eudesman-6β,12-olide (**10**).* *(i)* A soln of **9** (1.76 g) in glacial AcOH (35 ml) containing 47% hydrobromic acid (0.25 ml) was allowed to stand at room temp for 41 h. The soln was concentrated, diluted with water, and extracted with chloroform. The chloroform soln was worked up as usual to leave an oily residue, which on trituration with acetone-isopropyl ether followed by filtration afforded slightly crude **10** (1.24 g), mp 191—193 °C. The filtrate (0.35 g) was purified by chromatography over silica gel (25 g) to give an another sample of **10** (0.1 g), mp 193—195 °C, from ether-benzene (1 : 4) eluates. Recrystallization of both samples repeated twice yielded an analytical sample of **10**: mp 204—205 °C and $[\alpha]_D$ −32.8°; ORD, $[\Phi]_{305}^{peak}$ +2570°, $[\Phi]_{269}^{trough}$ −5010°, a=+75.8°; MS, *m/e* 308 (M^+), 266 (base), 248, and 193; IR, ν_{max} 1779, 1747, 1718, and 1244 cm^{-1}; NMR, δ 1.19 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.32 (3H, s, 15-C$\underline{H}_3$), 1.34 (3H, d, J=8 Hz, 13-C$\underline{H}_3$), 2.17 (3H, s, OCOC$\underline{H}_3$), 2.45 (1H, q, J=8 Hz, $\underline{H}$ at C_{11}), 2.89 (1H, do q, J=12, 7, 7, and 7 Hz, $\underline{H}$ at C_4), 4.63 (1H, t, J=4 Hz, $\underline{H}$ at C_6), and 5.45 (1H, do d, J=13 and 7 Hz, $\underline{H}$ at C_2). Found: C, 65.98; H, 7.83%. Calcd for $C_{17}H_{24}O_5$: C, 66.21; H, 7.85%.

*Oxidation of Compound **5** with Lead Tetraacetate.* A soln of **5** (1.44 g, 5.8 mmol) and lead tetraacetate (3.2 g, *ca.* 6.4 mmol) in a mixture of benzene (154 ml, 1.73 mol) and 2-propanol (4 ml, 57 mmol) containing boron trifluoride etherate (BF_3 5 ml, 39.6 mmol) was stirred at 25 °C under argon gas for 3.5 h, when the starch-iodide test for lead tetraacetate showed negative, an appreciable amount of **5** remaining unreacted (TLC). After addition of fresh lead tetraacetate (1.6 g, *ca.* 3.2 mmol), the soln was further stirred for 20 h under the same conditions. The reaction mixture was washed with 1 M hydrochloric acid, 5% aq sodium hydrogencabonate and water, dried, and evaporated to leave a crystalline residue (1.79 g), which was separated into three fractions by chromatography over silica gel (60 g) with ether-benzene (1 : 5) as eluents. The most mobile fraction gave A-nor-ester (**11**, 0.25 g), mp 111—112 °C, on trituration with hexane-isopropyl ether. Recrystallization from the same solvent mixture yielded an analytical sample of **11**: mp 112.5—113 °C and $[\alpha]_D$ −116.8°; MS, *m/e* 308 (M^+), 293, 249, 221, and 193 (base); IR and NMR, in the text. Found: C, 69.77; H, 9.05%. Calcd for $C_{18}H_{28}O_4$: C, 70.10; H, 9.15%.

The middle and least mobile fractions were triturated with acetone-isopropyl ether to give **10** (0.73 g), mp 202—203 °C, and **9** (0.16 g), mp 127.5—128.5 °C, respectively, which were identical with the corresponding authentic specimens.

*(11S)-2α,3β- and (11S)-2α,3α-Dihydroxy-4β,5α-eudesman-6β,12-olides (**12b** and **13b**), their 2-acetates (**12** and **13**), and their 2,3-diacetates (**12a** and **13a**).* *(i)* A soln of **10** (200 mg) in methanol (6 ml) was stirred with sodium borohydride (14 mg) at 0 °C for 14 min. After addition of AcOH (0.2 ml), the mixture was worked up as usual to leave a crystalline residue, showing two spots on TLC, which was separated into two fractions by preparative TLC over silica gel (Wakogel B-5) with a 2 : 3 mixture of ether and benzene. The more mobile fraction (117 mg), when triturated with acetone-isopropyl ether, gave **13** (96 mg), mp 190—191 °C. This was recrystallized from the same solvent mixture for analysis: mp 191—192 °C and $[\alpha]_D$ −77.6°; MS, *m/e* 250 (base, $M^+-C_2H_4O_2$), 235, 232, 217, and 204; IR, ν_{max} 3440, 1755, 1741, 1243, 1214, 1025, and 1018 cm^{-1}; NMR, δ 1.03 (3H, s, 15-C$\underline{H}_3$), 1.13 and 1.29 (each 3H, d, J=6 and 7.5 Hz, 14- and 13-C$\underline{H}_3$), 1.93 (1H, br s, O$\underline{H}$), 2.07 (3H, s, OCOC$\underline{H}_3$), 2.35 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 3.91 (1H, br s, W_H=6.5 Hz, $\underline{H}$ at C_3), 4.59 (1H, t, J=4 Hz, $\underline{H}$ at C_6), and 5.01 (1H, do do d, J=11, 5.5, and 3 Hz, $\underline{H}$ at C_2). Found: C, 65.59; H, 8.53%. Calcd for $C_{17}H_{26}O_5$: C, 65.87; H, 8.44%.

The less mobile fraction (94 mg) on trituration with acetone-isopropyl ether afforded **12** (82 mg), mp 249—249.5 °C. This was recrystallized from the same solvent mixture for analysis: mp 251—252 °C and $[\alpha]_D$ −88.2°; MS, *m/e* 250 (base, $M^+-C_2H_4O_2$), 235, 232, 217, and 204; IR, ν_{max} 3435, 1742, 1732, 1243, and 1055 cm^{-1}; NMR, δ 1.06 (3H, s, 15-C$\underline{H}_3$), 1.16 and 1.31 (each 3H, d, J=6 and 7.5 Hz, 14- and 13-C$\underline{H}_3$), 2.07 (3H, s, OCOC$\underline{H}_3$), 2.36 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 2.45 (1H, br s, O$\underline{H}$), 3.13 [(1H, do t, J=9, 9, and 5 Hz, $\underline{H}$ at C_3) (1H, t, J=9 Hz, on addition of D_2O)], 4.65 (1H, t, J=4 Hz, $\underline{H}$ at C_6), and 4.93 (1H, do do d, J=11.5, 9, and 5 Hz, $\underline{H}$ at C_2). Found: C, 65.58; H, 8.46%. Calcd for $C_{17}H_{26}O_5$: C, 65.78; H, 8.44%.

(ii) A soln of **12** (40 mg) in methanol (1 ml) containing 5% potassium hydroxide was stirred at room temp for 1 h. The reaction mixture was worked up as usual to leave a crystalline substance (32 mg), which was recrystallized from acetone-isopropyl ether to yield **12b** (29 mg), mp 182—183 °C. This was recrystallized from the same solvent mixture for analysis: mp 184—185 °C and $[\alpha]_D$ −93 °C; MS, *m/e* 268 (M^+), 250, 235, 232, 224 (base), 217, 209, and 206; IR, ν_{max} 3380, 3220, 1764, 1204, 1164, 1047, and 968 cm^{-1}; NMR, δ 0.99 (3H, s, 15-C$\underline{H}_3$), 1.14 and 1.30 (each 3H, d, J=6 and 7.5 Hz, 14- and 13-C$\underline{H}_3$), 2.37 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 2.93 (1H, do d, J=9.5 and 8.5 Hz, $\underline{H}$ at C_3), 3.03 (2H, br s, 2O$\underline{H}$), 3.73 (1H, do do d, J=11, 8.5, and 5 Hz, $\underline{H}$ at C_2), and 4.66 (1H, t, J=4 Hz, $\underline{H}$ at C_6). Found: C, 66.97; H, 8.95%. Calcd for $C_{15}H_{24}O_4$: C, 67.13; H, 9.02%.

Compound **13** (139 mg) was hydrolyzed in methanol (4 ml) in the same manner as described above, giving a crystalline glycol (141 mg), which on recrystallization from ethyl acetate-isopropyl ether afforded **13b** (101 mg), mp 90—92 °C. This was recrystallized from the solvent mixture for analysis: mp 94.5—95 °C and $[\alpha]_D$ −90.1°; MS, *m/e* 268 (M^+), 250, 235, 232, 224, 217, and 206; IR, ν_{max} 3480, 3440, 1763, 1213, 1177, 1063, 1036, 1013, 999, and 971 cm^{-1}; NMR, δ 0.96 (3H, s, 15-C$\underline{H}_3$), 1.13 and 1.29 (each 3H, d, J=6.5 and 7.5 Hz, 14- and 13-C$\underline{H}_3$), 2.35 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 2.65 (2H, br s, 2O$\underline{H}$), 3.84 (1H, br s, W_H=7 Hz, $\underline{H}$ at C_3), 3.91 (1H, br, W_H=20 Hz, $\underline{H}$ at C_2), and 4.62 (1H, t, J=4 Hz, $\underline{H}$ at C_6). Found: C, 65.00; H, 9.09%. Calcd for $C_{15}H_{24}O_4 \cdot 1/2CH_3COOC_2H_5$: C, 65.36; H, 9.03%.

(iii) Compound **12** (41 mg) was treated with acetic anhydride (Ac_2O, 1 ml) and Py (1 ml) at room temp for 12 h. The mixture was worked up as usual to leave a crystalline substance (47 mg), which on recrystallization from acetone-isopropyl ether gave **12a** (33.5 mg), mp 189.5—190.5 °C and $[\alpha]_D$ −82.0°; MS, 292 ($M^+-C_2H_4O_2$), 250 (base), 235, 232, and 217; IR, ν_{max} 1769, 1750, 1245, 1219, 1043, and 1030 cm^{-1}; NMR, δ 0.99 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.07 (3H, s, 15-C$\underline{H}_3$), 1.31 (3H, d, J=7.5 Hz, 13-C$\underline{H}_3$), 1.99 and 2.08 (each 3H, s, 2OCOC$\underline{H}_3$), 2.39 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 4.66 (1H, t, J=4 Hz, $\underline{H}$ at C_6), 4.70 (1H, t, J=10 Hz, $\underline{H}$ at C_3), and 5.12 (1H, do do d, J=11, 9.5, and 5 Hz, $\underline{H}$ at C_2). Found: C, 64.70; H, 8.00%. Calcd for $C_{19}H_{28}O_6$: C, 64.75; H, 8.01%. Compound **12b** (14.5 mg) was acetylated in the same manner as **12** to give **12a** (crude 18.7 mg, pure 13.5 mg), mp 189—189.5 °C.

Compound **13** (84 mg) was treated with Ac_2O (1 ml) and Py (1 ml) at room temp for 24 h. The mixture was worked up as usual to leave a crystalline substance (97 mg), which was recrystallized from acetone–isopropyl ether to give **13a** (87 mg), mp 149.5—150.5 °C. Recrystallization from the same solvent mixture afforded an analytical sample: mp 150—151 °C and $[\alpha]_D$ −59.9 °; MS, *m/e* 292 ($M^+-C_2H_4O_2$), 250 (base), 235, 232, and 217; IR, ν_{max} 1772, 1741, 1260, 1248, 1233, and 1030 cm^{-1}; NMR, δ 1.01 (3H, d, J=8 Hz, 14-C$\underline{H_3}$), 1.05 (3H, s, 15-C$\underline{H_3}$), 1.30 (3H, d, J=7.5 Hz, 13-C$\underline{H_3}$), 1.97 and 2.11 (each 3H, s, 2OCOC$\underline{H_3}$), 2.39 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 4.60 (1H, t, J=4 Hz, $\underline{H}$ at C_6), 5.11 (1H, do do d, J=11, 6, and 3 Hz, $\underline{H}$ at C_2), and 5.33 (1H, br, W_H=6.5 Hz, $\underline{H}$ at C_3).

Found: C, 64.52; H, 7.97%. Calcd for $C_{19}H_{28}O_6$: C, 64.75; H, 8.01%. Compound **13b** (37.5 mg) was acetylated in the same manner as **13** to give **13a** (crude 48.5 mg, pure 31.8 mg), mp 150—151 °C.

(11S)-2α,3α-Dihydroxy-4β,5α-eudesman-6β,12-olide 2,3-acetonide (14). (*i*) Silica gel (Wakogel Q-23, 25 g) packed in a column was washed twice with methanol, thrice with acetone, and once with hexane. Compound **13b** (100 mg) dissolved in hexane–acetone (1 : 1) was adsorbed onto the column and eluted with hexane–acetone (92 : 8) to give a crystalline material (112 mg), which was collected with hexane–isopropyl ether to yield **14** (57 mg), mp 115—117 °C. Recrystallization from the same solvent mixture afforded an analytical sample: mp 131—132 °C and $[\alpha]_D$ −53.9°; MS, *m/e* 293 (M^+-CH_3), 251, 233, 187, and 159 (base); IR (CCl_4), ν_{max} 1782, 1380, 1368, 1240, 1213, 1171, 1151, 1051, 1030, 1010, and 977 cm^{-1}; NMR, δ 0.90 (3H, s, 15-C$\underline{H_3}$), 1.19 and 1.30 (each 3H, d, J=7 and 7.5 Hz, 14- and 13-C$\underline{H_3}$), 1.35 and 1.48 [each 3H, s, $(C\underline{H_3})_2CO$], 2.37 (1H, q, J=7.5 Hz, $\underline{H}$ at C_{11}), 4.23 (2H, br m, 2$\underline{H}$ at C_2 and C_3), and 4.70 (1H, t, J=4 Hz, $\underline{H}$ at C_6). Found: C, 70.09; H, 9.06%. Calcd for $C_{18}H_{28}O_4$: C, 70.10; H, 9.15%.

(*ii*) Compound **12b** (22.6 mg) was treated with silica gel (Wakogel Q-23, 25 g) and acetone in the same manner as **13b**. The crystalline eluate (22.8 mg) was triturated with acetone–isopropyl ether to give a crystalline material (13.7 mg), mp 170.5—172 °C, which was identical with the unreacted starting glycol (**12b**).

*Oxidation of Compounds **12** and **13** to **10**.* (*i*) A soln of **12** (25 mg) in acetone (3 ml) was stirred with the Jones reagent (0.3 ml) at 0 °C for 1 h. After addition of ethanol, the mixture was evaporated *in vacuo* below 40 °C, diluted with water, and extracted with chloroform. The chloroform soln was worked up as usual to leave a crystalline residue (27.4 mg), showing a single spot, which on recrystallization from acetone–isopropyl ether yielded **10** (22 mg), mp 203.5—204 °C, identical with an authentic sample.

(*ii*) Compound **13** (25 mg) was oxidized with the Jones reagent (0.3 ml) in the same manner as **12** to yield **10** (21 mg), mp 203—204 °C, on recrystallization from acetone–isopropyl ether.

(11S)-4β,5α-Eudesmane-2α,3β,6β,12-tetraol (15) and Its 2,3,12-Triacetate (15a). A soln of **12** (403 mg) in dry THF (40 ml) was stirred with LAH (400 mg) under reflux for 24 h and cooled. After successive addition of ethyl acetate, methanol and water, the mixture was filtered to remove insoluble materials, which were washed with hot ethanol. The filtrate and ethanol washings were combined, evaporated below 40 °C, diluted with water, and extracted with chloroform with a Soxhlet apparatus for 5 d. The chloroform soln was concentrated to dryness to leave an oily substance (**15**, 410 mg), showing a single spot, which was treated with Ac_2O (2.7 ml) in Py (4 ml) at room temp for 19 h. The reaction mixture was worked up as usual to leave an oily residue (654 mg), which on trituration with isopropyl ether gave **15a** (427 mg), mp 96.5—98 °C. This was recrystallized from isopropyl ether for analysis: mp 96.5—98 °C and $[\alpha]_D$ −7.6 °C; MS, *m/e* 338 ($M^+-C_2H_4O_2$), 279, 278, 236, 219 (base), and 218; IR, ν_{max} 3535, 1733, 1241, 1050, 1033, and 1027 cm^{-1}; NMR, δ 0.92 and 1.02 (each 3H, d, J= 6.5 and 7 Hz, 14- and 13-C$\underline{H_3}$), 1.18 (3H, s, 15-C$\underline{H_3}$), 1.99 and 2.08 (3H and 6H, each s, 3OCOC$\underline{H_3}$), 3.89 and 4.21 (each 1H, do d, J=11, 6 and 11, 5 Hz, 2$\underline{H}$ at C_{12}), 4.08 (1H, br s, W_H=6.5 Hz, $\underline{H}$ at C_6), 4.70 (1H, t, J=10 Hz, $\underline{H}$ at C_3), and 5.11 (1H, do do d, J=11.5, 10, and 5 Hz, $\underline{H}$ at C_2). Found: C, 63.21; H, 8.74%. Calcd for $C_{21}H_{34}O_7$: C, 63.29; H, 8.60%.

Compound **15a** (132 mg) was refluxed in methanol (5 ml) containing 5% potassium hydroxide under nitrogen for 1 h. The soln was worked up as usual to give **15** (84 mg), amorphous; $[\alpha]_D$ −3.2° (EtOH). Found: C, 64.00; H, 10.17%. Calcd for $C_{15}H_{28}O_4 \cdot 1/2H_2O$: C, 64.02; H, 10.39%.

(11S)-4β,5α-Eudesmane-2α,3α,6β,12-tetraol (16) and Its 2,3,12-Triacetate and 2,12-Diacetate (16a and 16b). A soln of **13** (211 mg) in dry THF (21 ml) was stirred with LAH (300 mg) under reflux for 24 h. The reaction mixture was worked up in almost the same manner as that for **12** to leave a crystalline substance (118 mg), showing a single spot, which was recrystallized from acetone–isopropyl ether to give **16** (76 mg), mp 170—171 °C. Recrystallization twice from the same solvent mixture afforded an analytical sample: mp 174—174.5 °C and $[\alpha]_D$ −14.6° (EtOH); IR, ν_{max} 3410, 3290, 1077, 1053, 1038, 1022, and 1000 cm^{-1}. Found: C, 66.16; H, 10.32%. Calcd for $C_{15}H_{28}O_4$: C, 66.14; H, 10.36%.

The tetraol (**16**, 133 mg) was treated with Ac_2O (1.3 ml) and Py (1.5 ml) at room temp for 17 h. The mixture was worked up as usual to leave an oily residue (231 mg), showing two spots, which was separated into two fractions by column chromatography over silica gel (20 g) with a 3 : 1 mixture of benzene and ether. The more mobile fraction (175 mg) was crystallized and recrystallized from hexane–isopropyl ether to give **16a** (127 mg), mp 78.5—80 °C. This was recrystallized from the same solvent mixture for analysis: mp 80—81 °C and $[\alpha]_D$ +7.2°; MS, *m/e* 338 ($M^+-C_2H_4O_2$), 296, 279, 278, 263, 260, 236, 219, 218, 203, 200, 176, 161, and 107 (base); IR, ν_{max} 3590, 1743, 1253, 1226, and 1024 cm^{-1}; NMR, δ 0.97 and 1.02 (each 3H, d, J= 7 Hz, 14- and 13-C$\underline{H_3}$), 1.15 (3H, s, 15-C$\underline{H_3}$), 1.97, 2.08, and 2.11 (each 3H, s, 3OCOC$\underline{H_3}$), 3.87 and 4.22 (each 1H, do d, J=11, 6 and 11, 5 Hz, 2$\underline{H}$ at C_{12}), 4.00 (1H, br s, W_H= 7 Hz, $\underline{H}$ at C_6), 5.10 (1H, do do d, J=11.5, 5.5, and 3 Hz $\underline{H}$ at C_2), and 5.33 (1H, t, J=3 Hz, $\underline{H}$ at C_3). Found: C, 63.42; H, 8.65%. Calcd for $C_{21}H_{34}O_7$: C, 63.29; H, 8.60%. The less mobile fraction afforded **16b** (29 mg), oil and $[\alpha]_D$ −1.2°; MS, *m/e* 338 (M^+-H_2O), 296 ($M^+-C_2H_4O_2$), 278, 254, 236, 221, 218, and 203; IR ($CHCl_3$), ν_{max} 3610, 3500, 1733, 1246, and 1023 cm^{-1}; NMR, δ 1.00 and 1.07 (each 3H, d, J=7 Hz, 14- and 13-C$\underline{H_3}$ or *vice versa*), 1.13 (3H, s, 15-C$\underline{H_3}$), 2.08 (6H, s, 2OCOC$\underline{H_3}$), 3.88 and 4.21 (each 1H, do d, J=11, 6 and 11, 5 Hz, 2$\underline{H}$ at C_{12}), 3.97 (2H, m, 2$\underline{H}$ at C_3 and C_6), and 5.06 (1H, do do d, J=11.5, 5, and 3 Hz, $\underline{H}$ at C_2).

*Reduction of **10** with LAH and Subsequent Acetylation to **15a**.* To a cold suspension of LAH (15 g) in dry THF (1000 ml) was added dropwise a soln of **10** (30 g) in THF (200 ml) at 0 °C during a period of 15 min with stirring. The mixture, after further addition of THF (200 ml), was stirred under reflux for 24 h and cooled. After successive addition of ethyl

acetate (100 ml), ethanol (200 ml), and water (100 ml), the resulting suspension was stirred overnight at room temp and then filtered to remove an insoluble substance, which was washed with ethanol. The filtrate and ethanol washings were combined and evaporated to dryness to leave an oily residue (40.9 g), which was treated with Ac_2O (170 ml) and Py (260 ml) at room temp for 13 h. After being worked up as usual, the mixture left oily substances (40 g), which on trituration with isopropyl ether gave **15a** (25.2 g), mp 95.5—96.5 °C, identical with the authentic sample described in the previous section. The mother liquors, obtained by removal of the pure sample of **15a**, were dissolved in methanol (150 ml), refluxed with 10% potassium hydroxide in methanol (150 ml) for 1 h under nitrogen and then allowed to stand overnight at room temp. The reaction mixture was concentrated at 50 °C, diluted with water (50 ml), neutralized with 6 M hydrochloric acid at 0 °C, and extracted with chloroform with a Soxhlet apparatus for 5 d. The chloroform extracts afforded a foamy residue (9.4 g), showing two spots, which was separated into two fractions by chromatography over silica gel (500 g) with ethyl acetate. The more mobile fraction (3.1 g) crystallized on trituration with acetone-isopropyl ether to yield **16** (2.6 g), mp 174—174.5 °C, identical with an authentic sample. The less mobile fraction (5.1 g), amorphous, was again treated with Ac_2O (36 ml) and Py (50.5 ml) at room temp for 17 h to give **15a** (5.8 g) on trituration with isopropyl ether.

*(11S)-2α,3β,12-Triacetoxy-4β,5α-eudesman-6-one (**20**).* A soln of **15a** (103 mg) in acetone (11 ml) was stirred with the Jones reagent (0.6 ml) at 0 °C for 1 h. After addition of ethanol, the mixture was concentrated, diluted with water, and extracted with chloroform. The chloroform extracts, after being worked up as usual, left a crystalline residue, which was recrystallized from isopropyl ether to give **20** (87.5 mg), mp 109—109.5 °C. Recrystallization from isopropyl ether afforded an analytical sample: mp 109.5—111 °C and $[\alpha]_D$ −44.7°; MS, *m/e* 396 (M^+), 336, 276, and 216 (base); IR, ν_{max} 1751, 1738, 1703, 1253, 1235, 1222, 1080, 1038, and 1025 cm^{-1}; NMR, δ 0.88 (3H, s, 15-C$\underline{H}_3$), 0.89 and 0.93 (each 3H, d, J=7 and 6.5 Hz, 14- and 13-C$\underline{H}_3$ or *vice versa*), 2.00, 2.05, and 2.06 (each 3H, s, 3OCOC$\underline{H}_3$), 3.96 (2H, d, J=5 Hz, 2$\underline{H}$ at C_{12}), 4.72 (1H, t, J=10 Hz, $\underline{H}$ at C_3), and 5.03 (1H, do do d, J=11, 10, and 4.5 Hz, $\underline{H}$ at C_2). Found: C, 63.72; H, 8.28%. Calcd for $C_{21}H_{32}O_7$: C, 63.61; H, 8.14%.

*Photolysis of (11S)-2α,3β,12-Triacetoxy-4β,5α-eudesman-6β-ol 6-Nitrite (**17**).* To a soln of **15a** (2.94 g) in Py (30 ml) cooled at −20——30 °C was added dropwise excess nitrosyl chloride in Py during a period of 20 min, the yellow color of nitrosyl chloride remaining unchanged and the starting alcohol (**15a**) disappearing on TLC. The mixture was poured into ice-water (800 ml), and the resulting crystalline ppt was collected by filtration, washed with water, and dried over phosphorus pentaoxide for 18 h in a vacuum desiccator to yield **17** (3.13 g), mp 103.5—105.5 °C; IR, ν_{max} 1748, 1653, 1643, 1253, 1050, and 768 cm^{-1}; NMR, δ 0.89 and 0.91 (each 3H, d, J=6.5 Hz, 14- and 13-C$\underline{H}_3$ or *vice versa*), 1.01 (3H, s, 15-C$\underline{H}_3$), 1.98, 2.04, and 2.06 (each 3H, s, 3OCOC$\underline{H}_3$), 3.99 (2H, d, J=5 Hz, 2$\underline{H}$ at C_{12}), 4.72 (1H, t, J=10 Hz, $\underline{H}$ at C_3), 5.05 (1H, do do d, J=11.5, 10, and 5 Hz, $\underline{H}$ at C_2), and 5.94 (1H, br s, W_H=5 Hz, $\underline{H}$ at C_6).

The 6β-nitrite (**17**, 3.00 g) in dry benzene (thiophene-free, 200 ml) in a Pyrex vessel, without further purification, was irradiated with a 200 watt Hanovia high pressure mercury arc lamp at room temp for 2 h under a stream of argon. The reaction mixture was evaporated to dryness to leave a foamy residue, which was dissolved in THF (50 ml) and 2-propanol (50 ml) and refluxed for 1 h to decompose the nitroso dimer. The soln was evaporated below 50 °C to leave an oily residue, which was purified by chromatography over Florisil (100 g). Elution with benzene (180 ml), benzene–dichloromethane (5 : 1, 300 ml), and dichloromethane (570 ml) afforded oily materials (884 mg), which were purified as described later. Further elution with dichloromethane (280 ml) and dichloromethane–methanol (4 : 1, 240 ml) gave 15-oxime (**18**, 2.22 g), amorphous, resisting crystallization: $[\alpha]_D$ +12.1°; MS, *m/e* 410 (M^+−OH), 395, 382, 367, 350 (base), 335, 322, and 308; IR ($CHCl_3$), ν_{max} 3235, 3135, 1739, 1250, 1048, and 1032 cm^{-1}; NMR, δ 0.98 and 0.99 (total 6H, each d, J=7 and 6 Hz, 14- and 13-C$\underline{H}_3$ or *vice versa*), 2.00 and 2.07 (3H and 6H, each s, 3OCOC$\underline{H}_3$), 4.04 (3H, m, 3$\underline{H}$ at C_6 and C_{12}), 4.77 (1H, do d, J=8.5 and 7.5 Hz, $\underline{H}$ at C_3), 4.85 (1H, br m, W_H=10 Hz, $\underline{H}$ at C_2), 6.56 (1$\underline{H}$, d, J=9 Hz, O$\underline{H}$), 7.18 (1H, s, C$\underline{H}$=N), and 10.45 (1H, s, N-O$\underline{H}$).

The oily material (884 mg) described above was separated by rechromatography over silica gel (30 g). Elution with ether–benzene (1 : 5, 50 ml) afforded a crystalline substance (186 mg), which was recrystallized from isopropyl ether to give **20** (70 mg), mp 109—109.5 °C, identical with an authentic sample. Further elution with ether–benzene (1 : 2, 75 ml) afforded an oily substance (131 mg), which crystallized on standing, giving 6,15-oxolane (**19**, 80 mg), mp 72.5—74 °C, on trituration with hexane–isopropyl ether. Recrystallization twice from the same solvent mixture yielded an analytical sample: mp 100—101 °C and $[\alpha]_D$ −8.9°; MS, *m/e* 396 (M^+), 336, 294 (base), 277, 276, 251, 234, and 216; IR, ν_{max} 1741, 1244, 1230, and 1032 cm^{-1}; IR (liquid), ν_{max} 1743, 1478, 1240, 1229, 1035, and 862 cm^{-1}; NMR, δ 0.96 (6H, d, J=6.5 Hz, 14- and 13-C$\underline{H}_3$), 2.00, 2.05, and 2.07 (each 3H, s, 3OCOC$\underline{H}_3$), 3.62 and 3.86 (each 1H, ABq, J=8 Hz, 2$\underline{H}$ at C_{15}), 4.04 (2H, d, J=5.5 Hz, 2$\underline{H}$ at C_{12}), 4.18 (1H, s, $\underline{H}$ at C_6), 4.76 (1H, t, J=10 Hz, $\underline{H}$ at C_3), and 5.01 (1H, do t, J=5, 10, and 10 Hz, $\underline{H}$ at C_2). Found: C, 63.65; H, 8.24%. Calcd for $C_{21}H_{32}O_7$: C, 63.61; H, 8.14%. Further elution with ether–benzene 1 : 2, 175 ml) gave 15-oxime (**18**, 125 mg), amorphous, identical with the afore-mentioned sample.

*Hypoiodite Reaction of **15a** to **19**.* A suspection of lead tetraacetate (7.1 g) and calcium carbonate (4 g), precipitated and dried, in benzene (100 ml) was stirred under reflux for 40 min. To the mixture were added iodine (1.95 g), freshly sublimed, and **15a** (1.22 g) in benzene (50 ml), and the whole mixture was refluxed for 1.3 h and then stirred at room temp for 1.5 h under nitrogen. This was filtered through celite to remove an insoluble substance and the filtrate was washed with 30% aq sodium thiosulfate (200 ml) and water, dried, and evaporated to leave an oily residue (1.43 g), showing a single spot on TLC, which was purified by chromatography over silica gel (30 g). Eluates with benzene–ether (5 : 1) afforded an oily substance (893 mg), which crystallized on standing. This was recrystallized from hexane–isopropyl ether to give 6,15-oxolane (**19**), mp 99—100 °C, identical with an authentic sample.

*(11S)-2α,3β,12-Triacetoxy-4β,5α-eudesman-6β,15-olide (**21**).* Compound **18** (100 mg) was stirred with the Jones reagent (0.25 ml) in acetone (2 ml) at 0 °C for 30 min. The reaction mixture was worked up as usual to leave an oily residue (112 mg), showing an almost single spot on TLC, which was purified by preparative TLC over silica gel (Wakogel B-5) with ether–benzene (1 : 2). Elution with methanol gave a crystalline substance (54 mg), which was recrystallized from acetone–isopropyl ether to yield **21** (36 mg), mp 125—126 °C. This was recrystallized from the same solvent

mixture for analysis: mp 126—127 °C and $[\alpha]_D$ −1.5°; MS, *m/e* 382 (M^+−CO), 350, 322, 308, 290, 280, 262, 248, 230, 202, and 186; IR, ν_{max} 1780, 1745, 1242, 1229, 1116, 1047, and 1028 cm^{-1}; NMR, δ 0.96 and 1.00 (each 3H, d, J=6.5 and 5.5 Hz, 14- and 13-$C\underline{H}_3$ or *vice versa*), 1.97, 2.03, and 2.04 (each 3H, s, 3OCO$C\underline{H}_3$), 2.42 (1H, do d, J=13 and 5 Hz, $\underline{H}$ at C_1), 3.92 and 4.10 (each 1H, do ABq, J=5 and 11 Hz, 2$\underline{H}$ at C_{12}), 4.49 (1H, br s, W_H= 2.5 Hz, $\underline{H}$ at C_6), 4.68 (1H, t, J=10 Hz, $\underline{H}$ at C_3), and 4.74 (1H, do t, J=5, 10, and 10 Hz, $\underline{H}$ at C_2). Found: C, 60.89; H, 7.38%. Calcd for $C_{21}H_{30}O_8$: C, 61.45; H, 7.37%.

*(11S)-4β,5α-Eudesm-5-ene-2α,3β,12-triol Triacetate (**26**).* Compound **15a** (855 mg) was treated with methanesulfonyl chloride (MsCl, 1.5 ml) in Py (4 ml) at room temp for 44 h. The mixture was poured into ice-water and extracted with chloroform. The chloroform soln, after being worked up as usual, left an oily residue (928 mg), showing a single spot on TLC. This was purified by column chromatography over silica gel (50 g) with benzene–ether (5 : 1) to yield **26** (801 mg), bp 121—123 °C (bath temp) (5 Torr) and $[\alpha]_D$ −35.1°; MS, *m/e* 380 (M^+), 320, 260, and 200; IR (liquid), ν_{max} 1743, 1651, 1240, and 1041 cm^{-1}; NMR, δ 0.86 and 1.02 (each 3H, d, J=7 and 6.5 Hz, 13- and 14-$C\underline{H}_3$), 1.18 (3H, s, 15-$C\underline{H}_3$), 2.00 and 2.06 (3H and 6H, each s, 3OCO$C\underline{H}_3$), 3.98 (2H, br d, J=7 Hz, 2$\underline{H}$ at C_{12}), 4.60 (1H, do d, J=11 and 9.5 Hz, $\underline{H}$ at C_3), 5.16 (1H, do do d, J=12, 9.5, and 5 Hz, $\underline{H}$ at C_2), and 5.27 (1H, br s, W_H= 5 Hz, $\underline{H}$ at C_6). Found: C, 65.75; H, 8.50%. Calcd for $C_{21}H_{32}O_6$: C, 66.30; H, 8.48%.

*Dehydration of (11S)-15-Hydroxyimino-4β,5α-eudesmane-2α,3β, 6β,12-tetraol 2,3,12-Triacetate (**18**).* (*i*) A soln of **18** (1.24 g) in Py (20 ml) was stirred with phosphoryl chloride (8.5 ml) at room temp for 70 h, cooled, poured into ice-water (1 l) and extracted with chloroform. The chloroform soln, after being worked up as usual, left a foamy residue (1.13 g), which was separated by chromatography over silica gel (36 g). Eluates with benzene–ether (2 : 1) afforded an oily substance, which was crystallized on trituration with isopropyl ether and collected to give Δ^5-10-nitrile (**23**, 44 mg), mp 101—103 °C. Recrystallization from the same solvent afforded an analytical sample: mp 106—107 °C and $[\alpha]_D$ −90.3°; MS, *m/e* 331 ($M^+-C_2H_4O_2$), 289, 271, 262, 244, 229, 211 (base), 202, and 184; IR, ν_{max} 2225, 1745, 1252, 1227, 1052, and 1038 cm^{-1}; NMR, δ 0.87 and 1.09 (each 3H, d, J=7 and 6.5 Hz, 14- and 13-$C\underline{H}_3$ or *vice versa*), 2.01, 2.06, and 2.08 (each 3H, s, 3OCO$C\underline{H}_3$), 3.98 (2H, br d, J=6.5 Hz, 2$\underline{H}$ at C_{12}), 4.56 (1H, do d, J=11 and 9.5 Hz, $\underline{H}$ at C_3), 5.21 (1H, do do d, J=11.5, 9.5, and 4.5 Hz, $\underline{H}$ at C_2), and 5.58 (1H, br s, W_H=5 Hz, $\underline{H}$ at C_6). Found: C, 64.30; H, 7.51; N, 3.53%. Calcd for $C_{21}H_{29}O_6N$: C, 64.43; H, 7.47; N, 3.58%.

Eluates with benzene–ether (1 : 1) afforded a crystalline substance (751 mg), which on recrystallization from acetone–isopropyl ether gave 6β-hydroxy-10-nitrile (**22**, 606 mg), mp 174.4—175.5 °C. This was recrystallized from the same solvent mixture for analysis: mp 175—176 °C and $[\alpha]_D$ +21.5°; MS, *m/e* 409 (M^+), 366, 350 (base), 308, and 248; IR, ν_{max} 3530, 2230, 1739, 1728 (shoulder), 1240, 1050, and 1030 cm^{-1}; NMR, δ 0.98 and 1.02 (each 3H, d, J= 6.5 Hz, 14- and 13-$C\underline{H}_3$ or *vice versa*), 1.79 (1H, s, O$\underline{H}$), 1.98, 2.04, and 2.06 (each 3H, s, 3OCO$C\underline{H}_3$), 4.00 (3H, br m, 3$\underline{H}$ at C_6 and C_{12}), 4.69 (1H, do d, J=10.5 and 9.5 Hz, $\underline{H}$ at C_3), and 5.11 (1H, do do d, J=11.5, 9.5, and 5 Hz, $\underline{H}$ at C_2). Found: C, 61.62; H, 7.65; N, 3.46%. Calcd for $C_{21}H_{31}O_7N$: C, 61.59; H, 7.63; N, 3.42%.

(*ii*) Compound **18** (566 mg) was treated with Ac_2O (6 ml) and Py (10 ml) at room temp for 26 h. The mixture was worked up as usual to leave a foamy residue, showing a single spot on TLC, which was purified by chromatography over silica gel (25 g). Elution with ether–benzene (1 : 2) afforded a crystalline substance (484 mg), which on recrystallization from acetone–isopropyl ether yielded 6β-hydroxy-10-nitrile (**22**, 331 mg), mp 171.5—173.5 °C, identical with an authentic sample.

(*iii*) A soln of **18** (308 mg) in Py (2 ml) was treated with MsCl (0.5 ml) at room temp for 47 h. The mixture was worked up as usual to leave an amorphous residue (321 mg), which was dissolved in collidine (6 ml) and refluxed in a silicon-bath kept at 190 °C for 3 h. The mixture was cooled and diluted with chloroform. The whole soln gave an amorphous substance after the usual work-up, showing at least seven spots on TLC, which were purified by chromatography on silica gel (15 g). Elution with benzene–ether (2 : 1, 50 ml) afforded Δ^5-10-nitrile (**23**, 42 mg), mp 104—105 °C, on recrystallization from isopropyl ether. The other fractions were not examined further.

*Dehydration of (11S)-2α,3β,12-Triacetoxy-6β-hyrdoxy-15-nor-4β,5α-eudesmane-10β-carbonitrile (**22**).* A soln of **22** (4.24 g) in Py (20 ml) was stirred with MsCl (6.5 ml) at room temp for 47 h. The mixture was worked up as usual to leave an amorphous residue (5.00 g), which was refluxed in collidine (60 ml) for 3 h. The mixture was worked up in the same manner as that for **18** to give an oily residue (4.90 g), which was separated by chromatography over silica gel (100 g). Eluates with benzene–ether (2 : 1, 240 ml) afforded an oily substance (4.18 g), which was crystallized and recrystallized from isopropyl ether to give Δ^5-10-nitrile (**23**, 2.19 g), mp 106—107 °C, identical with an authentic sample. The mother liquors, obtained on crystallization and recrystallization, were concentrated to dryness and rechromatographed over silica gel (80 g). Eluates with benzene–ether (5 : 1, 180 ml) gave a crystalline substance (0.97 g), which on recrystallization from isopropyl ether yielded **23** (0.84 g), mp 106—106.5 °C. Further elution with benzene–ether (5 : 1, 240 ml) afforded an oily substance (0.38 g), which was crystallized and recrystallized from isopropyl ether to give Δ^6-10-nitrile (**24**), mp 80.5—82 °C. Recrystallization from the solvent gave an analytical sample: mp 81—82 °C and $[\alpha]_D$ −18°; MS, *m/e* 391 (M^+), 349, 331, 289, 271, 262, 244, 229, 211 (base), 202, 196, and 184; IR, ν_{max} 2230, 1742, 1242, 1224, 1051, and 1033 cm^{-1}; NMR, δ 1.04 and 1.09 (each 3H, d, J=5.5 and 7 Hz, 14- and 13-$C\underline{H}_3$), 2.02, 2.05, and 2.10 (each 3H, s, 3OCO$C\underline{H}_3$), 3.92 and 4.16 (each 1H, do d, J=11, 6.5 and 11, 7.5 Hz, 2$\underline{H}$ at C_{12}), 4.78 (1H, t, J=9.5 Hz, $\underline{H}$ at C_3), 5.24 (1H, do do d, J=11.5, 9.5, and 5 Hz, $\underline{H}$ at C_2), and 5.51 (1H, br s, W_H= 5 Hz, $\underline{H}$ at C_6). Found: C, 64.31; H, 7.49; N, 3.47%. Calcd for $C_{21}H_{29}O_6N$: C, 64.43; H, 7.47; N, 3.58%.

*(11S)-2α,3β,12-Trihydroxy-15-nor-4β-eudesm-5-ene-10β-carbonitrile (**23a**) and Its 2,3,12-Trimethoxymethyl Ether (**23b**).* A soln of **23** (2.53 g) in methanol (60 ml) was stirred with 10% potassium hydroxide in methanol (60 ml) at room temp overnight. The mixture was concentrated below 40 °C, diluted with water (100 ml), salted out, and extracted with ethyl acetate (4×250 ml). The ethyl acetate soln was washed with saturated brine (4×50 ml), dried, and evaporated to leave an amorphous substance (**23a**, 1.79 g), showing a single spot on TLC; NMR, δ 0.87 and 1.23 (each 3H, d, J=7 Hz, 14- and 13-$C\underline{H}_3$), 2.94 (1H, do d, J=10 and 8 Hz, $\underline{H}$ at C_3), 3.58 (2H, br d, J=6.5 Hz, 2$\underline{H}$ at C_{12}), 3.72 (1H, br m, $\underline{H}$ at C_2), and 5.58 (1H, br s, W_H=4 Hz, $\underline{H}$ at C_6). Compound **23a** (32 mg) was treated with Ac_2O (0.5 ml) in Py (0.5 ml) at room temp overnight to give **23** (38 mg), mp 102—104 °C, identical with the starting triacetate.

To a stirred soln of **23a** (269 mg) in dry chloroform (10 ml) and dimethoxymethane (10 ml), cooled at 0 °C, was added in portions phosphorus pentaoxide (5.7 g) during a period of 20 min.[20] The mixture was poured into cold 10 % aq sodium carbonate (400 ml) and extracted with chloroform. The chloroform extracts were washed with water, dried, and evaporated to leave an oily residue (362 mg), showing two spots on TLC, which was separated into two fractions by chromatography over alumina (Merck, standard, activity II-III, 40 g). Elution with benzene (460 ml) afforded an oily substance (55 mg), which would be the 2,3-methylenedioxy-12-methoxymethyl ether but was not further examined: IR ($CHCl_3$), ν_{max} 2255, 1141, 1114, 1093 (shoulder), 1040, and 917 cm^{-1}; NMR, δ 0.87 and 1.20 (each 3H, d, J=7 and 6.5 Hz, 14- and 13-C$\underline{H}_3$), 2.94 (1H, do d, J=10 and 8 Hz, $\underline{H}$ at C_3), 3.37 (3H, s, OC$\underline{H}_3$), 3.45 (2H, br d, J=6.5 Hz, $\underline{2H}$ at C_{12}), 3.82 (1H, do do d, J=12, 8, and 4 Hz, $\underline{H}$ at C_2), and 5.59 (1H, br s, W_H=6 Hz, $\underline{H}$ at C_6).

Eluates with benzene–ether (2 : 1, 400 ml) gave **23b** (235 mg), oil; MS, *m/e* 304 (M^+-3OCH_3); IR ($CHCl_3$), ν_{max} 2255, 1150, 1105, 1039, 1030, and 915 cm^{-1}; NMR, δ 0.87 and 1.23 (each 3H, d, J=7 and 6 Hz, 14- and 13-C$\underline{H}_3$), 3.02 (1H, do d, J=11 and 9 Hz, $\underline{H}$ at C_3), 3.38, 3.41, and 3.46 (each 3H, s, 3OC$\underline{H}_3$), 3.42 ($\underline{2H}$, br d, J=6 Hz, $\underline{2H}$ at C_{12}), 3.89 (1H, do do d, J=12, 9, and 4 Hz, $\underline{H}$ at C_2), 4.81 (6H, br m, 3OC$\underline{H}_2$O), and 5.57 (1H, br s, W_H=4 Hz, $\underline{H}$ at C_6).

(11S)-15-Nor-4β-eudesm-5(10)-ene-2α,3β,12-triol (27), Its Triacetate (27a), and 2,3-Acetonide (28). (*i*) To a suspension of sodium metal (1 g) in refluxing dry toluene (15 ml) was added dropwise a soln of **23** (125 mg) in dry ethanol (1.5 ml) and dry toluene (1.5 ml) during a period of 2 min. After 2 min, dry ethanol (4 ml) was again added, and the mixture was refluxed for 10 min and cooled. After addition of ethanol to decompose an excess of the sodium, the mixture was concentrated below 50 °C, diluted with water, salted out, and extracted with ethyl acetate. The acetate extracts were worked up as usual to leave **27** (79 mg), showing a single spot on TLC: NMR ($CDCl_3$ at 50 °C), δ 0.94 and 1.14 (each 3H, d, J=7 Hz, 13- and 14-C$\underline{H}_3$), 3.21 (1H, do d, J=9.5 and 8 Hz, $\underline{H}$ at C_3), and 3.60 (4H, br m, $\underline{3H}$ at C_2 and C_{12}, and O$\underline{H}$). Compound **27** (79 mg), without further purification, was treated with Ac_2O (2 ml) in Py (2 ml) at room temp overnight. The mixture was worked up as usual to give an oily residue (106 mg), which was purified by chromatography over silica gel (5 g). Elution with benzene–ether (5 : 2) yielded **27a** (83 mg) in pure state, oil and $[\alpha]_D$ +1.7°; MS, *m/e* 306 ($M^+-C_2H_4O_2$), 264, 246, 204, 203, 186, 171, 157, 144 (base), and 143; IR (CCl_4), ν_{max} 1748, 1242, 1228, and 1031 cm^{-1}; NMR, δ 0.95 and 1.05 (each 3H, d, J=6.5 and 7 Hz, 13- and 14-C$\underline{H}_3$), 2.03 and 2.08 (3H and 6H, each s, 3OCOC$\underline{H}_3$), 3.91 and 4.11 (each 1H, do d, J=11, 6 and 11, 5.5 Hz, $\underline{2H}$ at C_{12}), and 4.98 (2H, br m, $\underline{2H}$ at C_2 and C_3). Found: C, 65.27; H, 8.41%. Calcd for $C_{20}H_{30}O_6$: C, 65.55; H, 8.25%.

(*ii*) To a suspension of sodium metal (16.1 g) in refluxing dry toluene (240 ml) was added dropwise a soln of **23** (1.99 g) in dry ethanol (24 ml) and dry toluene (24 ml) during a period of 7 min. After 5 min, dry ethanol (64 ml) was again added over a period of 8 min, and the whole mixture was stirred under reflux for 10 min. The reaction mixture was worked up in the same manner as described above to yield triol (**27**, 1.20 g), showing a single spot on TLC. A soln of the triol was immediately dissolved in a 1 : 1 mixture of acetone and hexane and passed through silica gel (Wakogel Q-23, 240 g), which had been packed in a column with chloroform and washed successively with methanol, acetone and hexane. Elution with acetone–hexane (1 : 3) afforded crude acetonide (**28**, 1.15 g), which was purified twice by chromatography over alumina (60 g). Eluates with ether–benzene (1 : 2) gave **28** (1.07 g) in pure state, oil and $[\alpha]_D$ −54.7°; MS, *m/e* 280 (M^+), 265, 222, 145, and 131 (base); IR (CCl_4), ν_{max} 3390, 1380, 1371, 1229, 1152, 1089, and 1034 cm^{-1}; NMR, δ 0.94 and 1.14 (each 3H, d, J=6.5 Hz, 13- and 14-C$\underline{H}_3$), 1.46 [6H, s, $(C\underline{H}_3)_2CO$], 3.20 (1H, t, J=9.5 Hz, $\underline{H}$ at C_3), and 3.57 (3H, br m, $\underline{3H}$ at C_2 and C_{12}).

(*iii*) To a soln of rishitin acetonide[2] (**31**, 388 mg), obtained from natural rishitin (**1**), in dry ether (40 ml) was bubbled at room temp excess diborane, generated by dropwise addition of boron trifluoride etherate (1.2 ml) in dry diglyme (10 ml) to a soln of sodium borohydride (450 mg) in dry diglyme (15 ml), with stirring over a period of 25 min. The soln was stirred at room temp for 2 h, while the generator flask of diborane was allowed to stand at room temp for 1 h and then heated at 70—80 °C for 1 h. After removal of the generator and subsequent careful addition of water to decompose an excess of the diborane, the whole mixture was treated with 30% aq hydrogen peroxide (2 ml) and 3 M aq sodium hydroxide (2 ml) at 30—50 °C for 1 h with stirring. The mixture was cooled and extracted with ether repeatedly. The ether extracts were worked up as usual to leave an oily residue (500 mg), which was, without further purification, refluxed with 10% aq phosphoric acid (5 ml) in ethanol (30 ml) for 1 h. The reaction mixture was concentrated and extracted with ethyl acetate. The acetate extracts were worked up as usual to leave an oily residue (320 mg), showing two spots on TLC. A part (230 mg) of the residue was treated with Ac_2O (3 ml) in Py (6 ml) at room temp for 8 h to give oily materials, showing two spots on TLC, which were separated into two fractions by chromatography over silica gel (15 g) with benzene–ether (5 : 1). The less polar fraction (140 mg) was found to be identical with the diacetylrishitin[2] by comparison with an authentic sample. The more polar fraction (83 mg), oil, was identical with the triacetate (**27a**), derived from **23**, described above (TLC, Mass, IR, and NMR).

(11S)-15-Nor-4β-eudesm-5(10)-ene-2α,3β,12-triol 2,3-Acetonide 12-Methyl Ether (30) and Rishitin Acetonide (31). (*i*) Compound **28** (1.00 g) was treated with *p*-toluenesulfonyl chloride (1.03 g) in Py (10 ml) at room temp for 20 h. The soln was poured into ice-water (400 ml), salted out, and extracted with ether (4×200 ml). The ether extracts were worked up as usual to leave 12-tosylate (**28a**, 1.52 g), oil and $[\alpha]_D$ −5.8°; IR (CCl_4), ν_{max} 1600, 1377, 1371, 1229, 1189, 1180, 1100, 1087, 1044, 1032, 970, 842, and 815 cm^{-1}; NMR, δ 0.91 and 1.06 (each 3H, d, J=6 and 6.5 Hz, 13- and 14-C$\underline{H}_3$), 1.45 [6H, s, $(C\underline{H}_3)_2CO$], 2.44 (3H, s, $C\underline{H}_3C_6H_4SO_2$), 3.18 (1H, t, J=9 Hz, $\underline{H}$ at C_3), 3.51 (1H, m, $\underline{H}$ at C_2), 3.89 and 3.97 (each 1H, do ABq, J=5 and 9.5 Hz, $\underline{2H}$ at C_{12}), 7.30 and 7.75 (each 2H, d, J=8 Hz, $CH_3C_6\underline{H}_4SO_2$).

(*ii*) A soln of 12-tosylate (**28a**, 1.49 g) in acetone (80 ml) was stirred with sodium iodide (8 g) under reflux for 22 h. The mixture was evaporated and extracted with ether (100 ml). The ether extracts were washed with 5% aq sodium thiosulfate (yellow color disappeared) and saturated brine, dried, and evaporated to leave 12-iodide (**29**, 1.26 g), showing a single spot, oil, which crystallized on cooling at −15 °C, and had mp 58—61 °C and $[\alpha]_D$ −28.5°; MS, *m/e* 390 (M^+), 375, 332, 315, 263, 262, 247, 205, 187, 163, 145, and 131; IR (CCl_4), ν_{max} 1380, 1371, 1230, and 1098 cm^{-1}; NMR, δ 0.99 and 1.15 (each 3H, d, J=6 and 6.5 Hz, 13- and 14-C$\underline{H}_3$), 1.45 [6H, s, $(C\underline{H}_3)_2CO$], 3.25 (3H, br m, $\underline{3H}$ at C_3 and C_{12}), and 3.59 (1H, do t, J=7, 9, and 9 Hz, $\underline{H}$ at C_2).

(*iii*) 12-Iodide (**29**, 1.21 g) was refluxed with 5% potassium hydroxide in methanol (100 ml) for 2.5 h under nitrogen.

The mixture was worked up as usual to leave an oily residue (0.82 g), showing two spots on TLC, which was separated into two fractions by chromatography over alumina (60 g). Elution with hexane–benzene (1 : 1, 50 ml) afforded **31** (0.57 g), oil and $[\alpha]_D$ −71.7° (EtOH); MS, *m/e* 262 (M^+), 247, 205, 204, 203, 187, and 131 (base); IR (liquid), ν_{max} 3080, 1643, 1378, 1370, 1229, 1100, 1083, 1042, and 888 cm^{-1}; NMR, δ 1.14 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.44 [6H, s, ($C\underline{H}_3$)$_2$CO], 1.72 (3H, s, 13-C$\underline{H}_3$), 3.20 (1H, t, J=9 Hz, $\underline{H}$ at C_3), 3.58 (1H, do t, J=7, 9, and 9 Hz, $\underline{H}$ at C_2), 4.63 and 4.74 (each 1H, br s, W_H=4 Hz, 2$\underline{H}$ at C_{12}). This was identical with an authentic sample derived from natural rishitin. Further elution with hexane–benzene (1 : 1, 100 ml) gave **30** (0.13 g), oil and $[\alpha]_D$ −43.1°; MS, *m/e* 294 (M^+), 279, 236, and 131 (base); IR (liquid), ν_{max} 1378, 1371, 1105, and 1088 cm^{-1}; NMR, δ 0.92 and 1.14 (each 3H, d, J=6 and 6.5 Hz, 13- and 14-C$\underline{H}_3$), 1.45 [6H, s, ($C\underline{H}_3$)$_2$CO], 3.32 (3H, s, OC$\underline{H}_3$), and 3.41 (4H, br m, 4$\underline{H}$ at C_2, C_3 and C_{12}).

*Rishitin (**1**) and Its Diacetate (**1a**).* A soln of **31** (96 mg) in ethanol (24 ml) was stirred with 10% aq phosphoric acid (1.2 ml) under reflux for 1 h. After being worked up as usual, the soln gave an oily residue (84 mg), which was purified by chromatography over silica gel (9 g). Eluates with ether afforded an oily substance (**1**, 63 mg), which was further purified by distillation at 100—115 °C (bath temp) under reduced pressure (1 Torr) to yield crystalline rishitin (**1**), mp 58—60 °C and $[\alpha]_D$ −30.4° (EtOH) (lit,[2] mp 65—67 °C and $[\alpha]_D$ −35.1°); MS, *m/e* 222 (M^+), 204, and 189; IR (CCl_4), ν_{max} 3370, 3080, 1642, 1075, 1039, 1017, and 890 cm^{-1}; NMR, δ 1.14 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.75 (3H, s, 13-C$\underline{H}_3$), 3.18 (1H, t, J=9 Hz, $\underline{H}$ at C_3), 3.63 (1H, br do d, J=9 and 7 Hz, $\underline{H}$ at C_2), 4.64 and 4.74 (each 1H, br s, W_H=4 Hz, 2$\underline{H}$ at C_{12}). The synthetic rishitin (33 mg) was treated with Ac_2O (1 ml) and Py (1 ml) at room temp overnight. The mixture, after being worked up as usual, gave an oily substance, which was crystallized and recrystallized from hexane to give the diacetate (**1a**, 15 mg), mp 66—68 °C and $[\alpha]_D$ −14.1° (EtOH) (lit,[2] mp 70—71 °C and $[\alpha]_D$ −14.1°); Mass, *m/e* 246 ($M^+-C_2H_4O_2$), 204, 186, and 171; IR (CCl_4), ν_{max} 3070, 1749, 1642, 1242, 1225, 1030, and 890 cm^{-1}; NMR, δ 1.06 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.75 (3H, s, 13-C$\underline{H}_3$), 2.03 and 2.08 (each 3H, 2OCOC$\underline{H}_3$), 4.64 and 4.74 (each 1H, br s, W_H=4 Hz, 2$\underline{H}$ at C_{12}), and 4.98 (2H, br m, 2$\underline{H}$ at C_2 and C_3). These synthetic rishitin and diacetylrishitin were identical with the corresponding authentic specimens of natural rishitin (**1**) and its diacetate (**1a**) in all respects, respectively.

(Received November 1, 1976)

The isolation and structure elucidation of lubimin (**3**) and oxylubimin (**4**), stress metabolites from diseased white potato tubers, are described.

In continuing studies on phytoalexins produced by diseased potato tubers, we have isolated several new sesquiterpenes besides rishitin[2] (**1**) and rishitinol[3] (**2**) from white potato tubers (*Solanum tuberlosum* × *S. demissum*, "Rishiri") infected by an incompatible race of *Phytophthora infestans*. On the other hand, in 1971 Metlitskii and coworkers[4] reported the isolation of an antifungal metabolite, qualified as phytoalexin and designated as lubimin[4a] (**3**), along with rishitin (**1**) from white potato tubers (*S. tuberlosum*, "Lubimets") stressed with various pathogens. They presumed the metabolite to be sesquiterpene aldehyde and proposed formula **3'** on the basis of the spectral data.[4b] One of our new sesquiterpenes could immediately be identified as the Metlitskii lubimin, and one of the other sesquiterpenes was designated as oxylubimin (**4**). We recently reported in preliminary communications[5] that lubimin is represented more favorably by formula **3** rather than the proposed formula (**3'**),[4b] and oxylubimin correctly by formula **4**. The same structures and configurations for these stress metabolites have recently been reported independently by Stoessl and coworkers.[6]

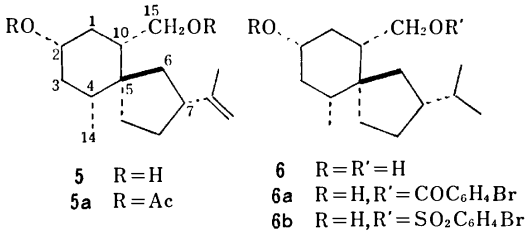
Lubimin. Planar Structure. Lubimin (**3**), colorless oil and $[\alpha]_D$ +36°, had the molecular formula $C_{15}H_{24}O_2$ and gave the monoacetate (**3a**), oil and $[\alpha]_D$ +35°. These compounds exhibited the following spectra: **3**, MS, *m/e* 236 (M^+); IR, ν_{max} 3410, 3085, 2740, 1715, 1640, and 890 cm^{-1}; NMR, δ 0.94 (3H, d, J=7 Hz), 1.68 (3H, s), 3.65 (1H, m, W_H=25 Hz), 4.65 (2H, s), and 9.74 (1H, d, J=3 Hz): **3a**, MS, *m/e* 278 (M^+); IR, ν_{max} 2715, 1735, 1720, 1640, 1238, and 888 cm^{-1}; NMR, δ 1.69 (3H, s) and 4.70 (1H, m, W_H=25 Hz). These spectral data were indistinguishable from the corresponding data reported by Metlitskii and coworkers[4b] and indicated that the following structural units are involved in the molecule, as had been pointed out by them;[4b] –(CH$_3$)CH–, –C(CH$_3$)=CH$_2$, –CH(OH)–, and –CHO.

Reduction of lubimin (**3**) with sodium borohydride in ethanol afforded unsaturated glycol, dihydrolubimin[7] (**5**), mp 129—130 °C; *m/e* 238 (M^+); δ 3.28 (1H, t, J= 10 Hz) and 3.90 (1H, do d, J=10 and 2.5 Hz), which formed the diacetate (**5a**), oil; ν_{max} 1743 and 1238 cm^{-1}; δ 2.04 and 2.07 (each 3H, s) 3.83 and 4.36 (each 1H, do ABq, J=11, 8 and 11, 4 Hz), and 4.69 (1H, br m, W_H=25 Hz). Compound **5**, when hydrogenated over Adams platinum in ethanol, gave saturated glycol, tetrahydrolubimin (**6**), mp 145—147 °C; *m/e* 240; ν_{max} 1387 and 1372 cm^{-1}; δ 0.86 (9H, d, J=7 Hz). All these spectra confirmed the presence of the four groupings in bicyclic lubimin.



5 R=H

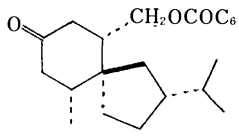
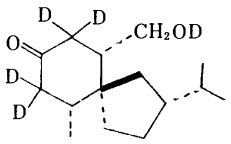
6 R=R'=H
6a R=H,R'=COC$_6$H$_4$Br
6b R=H,R'=SO$_2$C$_6$H$_4$Br

Treatment of tetrahydrolubimin (**6**) with *p*-bromobenzoyl chloride (one mole) and pyridine resulted in monobenzoylation, giving the mono-*p*-bromobenzoate (**6a**), mp 106—108 °C; IR, ν_{max} 3400, 1718, 1594, and 847 cm^{-1}; NMR, δ 3.64 (1H, br m, W_H=25 Hz), 3.99 and 4.46 (each 1H, do ABq, J=11, 10 and 11, 2 Hz). Likewise, compound **6**, when treated with *p*-bromobenzenesulfonyl chloride (2 mole) and pyridine, underwent monobrosylation to give the monobrosylate (**6b**), oil; IR, ν_{max} 3400, 1372, and 1183 cm^{-1}; NMR, δ 3.64 (1H, br m, W_H=25 Hz), 3.70 and 4.15 (each 1H, do ABq, J=11, 8 and 11, 4 Hz). The NMR spectra revealed that the primary hydroxyl group, formed by reduction of the formyl group, was acylated but the secondary hydroxyl remained unchanged in each of the compounds (**6a** and **6b**). Oxidation of the benzoate (**6a**) with chromium(VI) oxide produced oxo-benzoate (**7**), mp 71—73 °C; MS, *m/e* 220 (M^+–BrC$_6$H$_4$CO$_2$H) and 177; IR, ν_{max} 1720 and 1705 cm^{-1} (sh). Treatment of the ketone (**7**) with sodium deuteroxide in a mixture of dioxane and deuterium oxide effected deuteration of

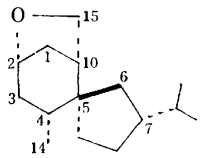
two methylene groups adjacent to the carbonyl group with concomitant hydrolysis to yield the d_5-derivative (**8**), $C_{15}H_{21}D_5O_2$; MS, *m/e* 243; IR, ν_{max} 1705 cm^{-1}. This result elucidated that a moiety $-CH_2CH(OH)CH_2-$ would be included in a six- or seven-membered ring but not in a five-membered ring. On the other hand, the monobrosylate (**6b**), on treatment with potassium *t*-butoxide in *t*-butyl alcohol, was converted into oxolane (**9**), oil. In accordance with the assigned structure, compound **9** exhibited parent and fragmentation peaks at *m/e* 222 and 179 in the mass spectrum and absorption maxima at 1105 and 912 cm^{-1},[8] and at δ 0.87, 0.89, and 1.10 (each 3H, d, J=7—7.5 Hz), 3.49 and 3.78 (each 1H, do ABq, J=10, 4.5 and 10, 0 Hz), and 4.19 (1H, narrow m, W_H=10 Hz). These results revealed the presence of a moiety $-CH_2CH(OH)CH_2CH(CHO)-$ in lubimin (**3**), implying that the proposed structure (**3'**) should be revised.



7



8



9

The ^{13}C NMR spectra of diacetyldihydrolubimin (**5a**) were then obtained at 25.2 MHz under proton noise decoupled and single-frequency off-resonance decoupled conditions, and each signal was assigned, as summarized in Table 1, on the basis of the multiplicity and chemical shift.[9] As shown in Table 1, compound **5a** contained a quaternary carbon at δ 46.7[10] besides those of the isopropenyl and two acetoxyl groups, again excluding the proposed structure (**3'**). It is noted that the carbon in question would evidently be of spiro type

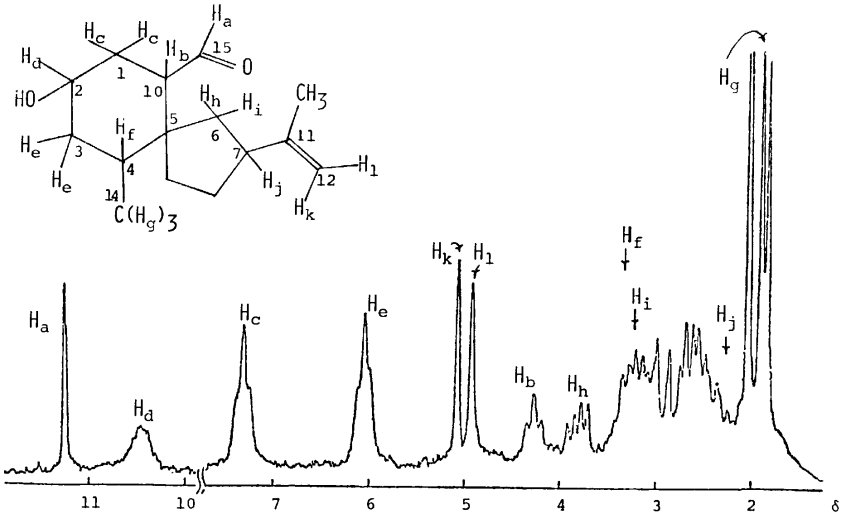

Fig. 1. The NMR spectrum of lubimin (**3**) in the presence of the shift reagent $Eu(fod)_3$ (CCl_4, 100 MHz, and the reagent: **3**=1 : 2).

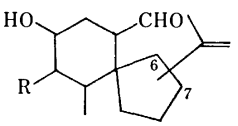
owing to the absence of a methyl group attached to the quaternary carbon atom.

The whole structure of lubimin (**3**) was finally deduced from spin-decoupling studies of its NMR spectra of lubimin (**3**) in the presence of shift reagent $Eu(fod)_3$.[11] While the ring methylene and methine protons overlapped each other and appeared as a broad multiplet without the shift reagent, addition of 0.25—1.0 mole of $Eu(fod)_3$ per mole of the compound caused down-field shifts of all the signals. The down-field shifts were approximately linear with respect to concentration of the reagent and resulted in separation of most of the protons in question, as exemplified by Fig. 1. Decoupling studies were carried out on the europium-shifted spectra (the reagent : lubimin=1 : 2 and 1 : 1), the result being summarized in Table 2. In the spectrum (the reagent : lubimin=1 : 2, Fig. 1), signals centered at δ 11.13, 10.36, and 1.90 were readily assignable to the protons due to formyl, hydroxy-methine, and secondary methyl groups, respectively. Irradiation at δ 11.13 (C<u>H</u>O) collapsed a broad triplet at δ 4.24 [C<u>H</u>(CHO)] to a sharp triplet (run 1). Conversely, by irradiation at δ 4.24, the doublet (J=2.5 Hz) at δ 11.13 and a broad triplet at δ 7.30 [C<u>H</u>$_2$CH(CHO)] were simplified to a sharp singlet and a broad singlet, respectively (run 2). Further irradiation at δ 7.30 decoupled the broad triplet signal at δ 4.24 to a broad singlet and also narrowed a broad multiplet at δ 10.36 [C<u>H</u>(OH)CH$_2$CH-(CHO)] slightly but definitely (run 3). Similar change of the signal at δ 10.36 was also observed on irradiation at δ 6.05 [C<u>H</u>$_2$CH(OH)CH$_2$CH(CHO)], which simultaneously caused change of a signal pattern near δ 3.4 [C<u>H</u>CH$_2$CH(OH)CH$_2$CH(CHO)] (run 5). Inversely, irradiation at δ 3.38 collapsed the broad triplet at δ 6.05 to a broad singlet and also decoupled a doublet at δ 1.90 [CH(C<u>H</u>$_3$)] to a singlet (run 6), indicating the presence of a moiety -(CH$_3$)CHCH$_2$CH(OH)CH$_2$-CH(CHO)-. Fortunately, the methine protone (δ 3.38) adjacent to the methyl group appeared separately as a broad multiplet at δ 4.54 in the spectrum containing an equimolar shift reagent $Eu(fod)_3$. This multiplet signal was simplified to a broad doublet (J=11 Hz) by irradiation at δ 2.50, a center of a doublet due to the methyl protons (run 12). In view of the decoupling behaviors of the signals due to two relevant methine protons adjacent to the methyl and formyl groups (runs 12, 1, and 3a) as well as the presence of a quaternary carbon atom of spiro type, the quaternary carbon in question must be flanked by these two methine carbon atoms. Hence lubimin is represented either by (planar) formula **10a** or **10b**.



10a R=H, 6-isopropenyl
10b R=H, 7-isopropenyl
10c R=OH, 7-isopropenyl

In the NMR spectrum shown in Fig. 1, a clearly separated signal centered at δ 3.82 must be a methine or one of a methylene protons in a five-membered ring. The multiplicity (do d, J=13 and 7 Hz) revealed that the proton would probably be coupled to only two protons, one being a geminal proton and another a proton on the adjacent carbon atom. In fact, irradiation at δ 3.20 and 2.30 decoupled the signal to two doublets with coupling constants of 7 and 13 Hz, respectively. Thus the proton in question (δ 3.82) must be one of the methylene protons at C_6. The remarkable europium-induced down-field shift of this proton, as compared with the other five-membered ring protons, suggested that the proton would be disposed in the neighborhood of the formyl group. This result was not compatible with formula **10a** but only with formula **10b**. On the analogy of the structure and configuration of oxylubimin (**4**) described later, lubimin is represented most favorably by the stereostructure **3**, because the three substituents, formyl, hydroxyl, and methyl groups at C_{10}, C_2, and C_4 in the A ring would evidently be oriented

equatorial.

Oxylubimin. Planar Structure. The titled compound (**4**), mp 85—86 °C and $[\alpha]_D$ +27°, had the molecular formula $C_{15}H_{24}O_3$ and gave the diacetate (**4a**), oil and $[\alpha]_D$ +22°. Reduction of oxylubimin (**4**) with sodium borohydride afforded unsaturated triol, dihydrooxylubimin (**11**), mp 170—171 °C, which formed the triacetate (**11a**), oil, and, on hydrogenation over Adams platinum, yielded saturated triol, tetrahydrooxylubimin (**12**), mp 163—165 °C. Likewise, the diacetate (**4a**) was reduced with sodium borohydride to give diacetyldihydrooxylubimin (**11b**), oil, which was converted into the triacetate (**11a**). The IR and NMR spectra of these compounds indicated that oxylubimin (**4**) contained the following structural units: $-CH(CH_3)-$ [**4** and **11b**, δ 1.08 and 0.89 (each 3H, d, J=7 Hz)]: $-CH(CHO)-$ [**4**, ν_{max} 2715 and 1715 cm^{-1}, δ 2.38 (1H, do do d, J=10, 4, and 2.5 Hz) and 9.80 (1H, d, J=2.5 Hz); **11b**, ν_{max} 3460 cm^{-1}, δ 3.34 and 3.92 (each 1H, do ABq, J=11, 8 and 11, 3 Hz)]: $-CH(CH_3)=CH_2$ [**4**, ν_{max} 1645 and 895 cm^{-1}, δ 1.72 (3H, s) and 4.75 (2H, br s); **11b**, ν_{max} 1643 and 885 cm^{-1}, δ 1.73 (3H, s) and 4.68 (2H, br s); **12**, ν_{max} 1388 and 1372 cm^{-1}]: $-CH(OH)CH(OH)-$ [**4**, positive to the HIO_4 test,[12] ν_{max} 3560, 3300, and 3080 cm^{-1}, δ 3.01 (1H, t, J= 10 Hz), 3.48 (1H, br t, J=10 Hz, W_H=20 Hz), and 3.90 (2H, br s, disappeared on addition of D_2O); **11b**, ν_{max} 3460, 1745, and 1250 cm^{-1}, δ 2.00, 2.04 (each 3H, s), and 4.76 (2H, m).

These results and the spin-decoupling studies on the NMR spectra of oxylubimin (**4**) in the absence and also in the presence of the shift reagent Eu(fod)$_3$, the results being summarized in Table 3, elucidated the presence of a moiety ■(quaternary carbon)-$CH(CH_3)$-$CH(OH)$-$CH(OH)$-CH_2-$CH(CHO)$-■ and hence oxylubimin (**4**) could be regarded as a 3β-hydroxyl derivative of lubimin (**3**). In good accord with this presumption, triacetyldihydrooxylubimin (**11a**) exhibited the ^{13}C NMR spectra (Table 1) closely similar to that of diacetyldihydrolubimin (**5a**), apart from a signal due to the 3-carbon atom, in which a quaternary carbon of spiro type was observed as a singlet peak at δ 48.0. Moreover, oxidation of triacetate (**11a**) by the Lemieux-Johnson procedure[13] gave methyl ketone (**13**), oil, which displayed a three-proton singlet and a broad one-proton peak (W_H=25 Hz) due to the acetyl and acetyl-methine protons at δ 2.16 and 2.83 in the NMR spectrum. The wide half-width of the methine proton signal indicated that the acetyl group, derived from the isopropenyl group in oxylubimin (**4**), would not be located on the carbon atom adjacent to the spiro-carbon. Hence oxylubimin must be represented by (planar) formula **10c**.

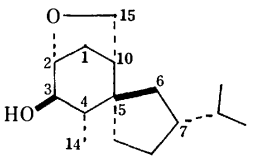
of oxylubimin (**4**) were presumed to be all equatorial on the basis of the magnitudes of the vicinal coupling constants for each of the methine, methylene, and hydroxy-methine protons ($J_{b,c}$, $J_{b,d}$, $J_{e,c}$, $J_{e,d}$, $J_{e,f}$, and $J_{f,g}$ =10, 4, 10, small, 10, and 10 Hz), estimated from the data in Table 3. Since the A ring would probably adopt a chair conformation, the relative configurations of the four substituents at C_{10}, C_2, C_3, and C_4 must be *cis*, *trans*, and *trans*, respectively. Moreover, the *trans*-diequatorial disposition between the C_3-hydroxyl and C_4-methyl groups was also deduced from the ^{13}C NMR specrum of triacetyldihydrooxylubimin (**11a**), in which the 14-methyl carbon atom was observed at a higher field (δ 11.4) as compared with the corresponding carbon (δ 16.6) in diacetyldihydrolubimin (**5a**). This high-field shift of the methyl carbon atom could be explained well as a neighboring effect due to the diequatorially-oriented acetoxyl group at C_3.[14] The absolute configrations of these substituents were decided by application of "exciton chirality method"[15] to dibenzoyldihydrooxylubimin (**11c**), mp 58—59 °C. This dibenzoate was obtained by benzoylation of oxylubimin followed by sodium borohydride reduction and exhibited a characteristic split curve in the CD spectrum (ethanol); $\Delta\varepsilon$ −19.2 (235 nm) and +5.9 (219) [*cf.*, rishitin dibenzoate, $\Delta\varepsilon$ −17.6 (235 nm) and +6.1 (218)].[16] The negative sign of the first splitting effect indicated a left-hand helix for the vicinal dibenzoate moiety, leading to assignment of α-, α-, β-, and α-configurations to the four substituents at C_{10}, C_2, C_3, and C_4 in the A ring.

Tetrahydrooxylubimin (**12**), when treated with *p*-bromobenzenesulfonyl chloride, underwent partial brosylation to give monobrosylate (**12a**), mp 98—100 °C, which on treatment with potassium *t*-butoxide in *t*-butyl alcohol at 0 °C for 30 min yielded hydroxyoxolane (**14**), oil. The mass [*m/e* 238 (M^+) and 220] and IR spectra (ν_{max} 3420, 1390, 1372, 1079, and 1010 cm^{-1}) were consistent with the assigned structure, and the NMR spectrum [δ 0.88 (6H, d, J=6.5 Hz, 12- and 13-CH_3), 1.06 (3H, d, J=8 Hz, 14-CH_3), 1.90 (1H, t, J=4.5 Hz, β-H at C_{10}), 2.36 (1H, d, J=12 Hz, β-H at C_1), 3.66 (1H, do d, J=8 and 4.5 Hz, a-H at C_{15}), 3.78 (1H, d, J=5 Hz, α-H at C_3), 3.87 (1H, d, J=8 Hz, b-H at C_{15}), and 4.18 (1H, t, J=5 Hz, β-H at C_2)], indicated the A ring to take a slightly deformed chair-form with the four substituents at C_{10}, C_2, C_3, and C_4 all axial; $J_{1\beta,1\alpha}$, $J_{1\beta,2\beta}$, $J_{1\alpha,2\beta}$, $J_{2\beta,3\alpha}$, $J_{3\alpha,4\beta}$, $J_{10\beta,1\beta}$, $J_{10\beta,1\alpha}$, $J_{10\beta,15a}$, $J_{10\beta,15b}$, and $J_{15a,14b}$=12, 0, 5, 5, 0, 0, 4.5, 4.5, 0, and 8 Hz, respectively (see formula **14**). Addition of 0.8 mol equiv of the shift reagent $Eu(dpm)_3$ effected complete separation of the NMR signals due to individual protons which were correlated to the respective signals by spin-decoupling studies (Fig. 2). As expected, most of the protons on the B ring were observed at higher fields (below δ 7.00) as compared with those on the A

Table 4. The NMR spectrum of hydroxyoxolane (**14**) in the presence of the shift reagent $Eu(dpm)_3$ (CCl_4, 100 MHz; the reagent; **14**=0.8 : 1) and spin-decoupling results

Irradiated proton (δ, Hz)	Observed proton (δ) Multiplicity change and decoupled splitting (Hz)
9.34 (H_A) (do d, J=13 and 8)	6.08 (H_B) do d ⟶ d (13); 4.69 (H_C) sex ⟶ qui (8)
6.08 (H_B) (do d, J=13 and 9)	9.34 (H_A) do d ⟶ d (13); 4.69 (H_C) sex ⟶ qui (9)
4.69 (H_C) (sex, $J\approx8$)	9.34 (H_A) do d ⟶ d (8); 6.08 (H_B) do d ⟶ d (9); 3.23 (H_D) ch
3.23 (H_D) (m)	4.69 (H_C) sex ⟶ qui (8); 2.05 and 1.96 (11- and 12-CH_3) each d ⟶ s (6.5)

ring. Only one exceptional signal at a low field, δ 9.34, was reasonably assigned to the β-proton at C_6 (H_A), because the 6-carbon atom was disposed 1,3-diaxial to the 3β-hydroxyl group.[17] Spin-decoupling studies (Table 4) confirmed that the relevant proton (H_A) and the isopropyl group were located on the vicinal carbon atoms, establishing the relative disposition of the isopropenyl group to the A ring in oxylubimin (**4**). Unfortunately, no assignments could be made to the configuration of the isopropyl group from the coupling constants ($J_{A,C}$ and $J_{B,C}$=8 and 9 Hz). However, in view of the absolute configuration (R) of the 7-carbon atom in naturally occurring vetispiranes,[18] oxylubimin must be represented correctly by formula **4**. Recently, Stoessl and coworkers[6b] completely defined the relative configruation of the whole molecule of oxylubimin on the basis of the X-ray crystallography. The present result leads to the same conclusion and also invloves decision of the absolute cofiguration.



14

Experimental

All the melting points were uncorrected. The purity of each compound was always checked by TLC over silica gel (Wakogel B-5 or Merck GF-254) with various solvent systems, and the spots were developed with cerium(IV) sulfate in dil sulfuric acid, iodine, vanilin–sulfuric acid and/or the Ehrlich reagent. The vanilin–sulfuric reagent was prepared by dissolving vanilin (250 mg) in concd sulfuric acid (100 ml), and the Ehrlich reagent by dissolving *p*-dimethylaminobenzaldehyde (100 mg) in acetone (9 ml) and concd hydrochloric acid (1 ml). The optical rotations, UV, and IR spectra were measured in 95% ethanol, in 95% ethanol, and in liquid state (oil) or in Nujol (crystals), respectively, unless otherwise stated. The NMR spectra were obtained in chloroform-*d*, unless otherwise stated, at 100 MHz, tetramethylsilane being used as an internal reference. The abbreviations "s, d, t, q, qui, sex, m, br, do, ch, and sh" in the spectral data denote "singlet, doublet, triplet, quartet, quintet, sextet, multiplet, broad, double, changed, and shoulder," respectively. The preparative TLC was carried out over silica gel (Merck GF-254), and the column chromatography over silica gel (Mallinckrodt AR-100) or alumina (Merck Active I, neutral).

*Isolation of Lubimin (**3**), Oxylubimin (**4**), and Lubiminol[7] (**5**).* The fraction E (4.8 g), yellow oil, described in the section of "Isolation of rishitin,"[1] was dissolved again in ether and shaken with 10% aq sodium carbonate to remove acidic components. The ether soln was washed with 0.1 M hydrochloric acid and water, dried, and evaporated to leave neutral substances (3.8 g), which consisted of two main components and showed two pink spots with the Ehrlich reagent on TLC, the R_f values being 0.54 and 0.47 (benzene : ether= 2 : 1). These were separated into two fractions by chromatography over silicic acid with benzene–ether (3 : 1). The less polar fraction (0.75 g) with R_f 0.54, oil, was further purified by preparative TLC, showing two bands, detected by spraying a soln of iodine in hexane, on TLC with benzene–ether (1 : 2). The more polar fraction on TLC was extracted with ethyl acetate containing a small volume of methanol to give crude lubimin, which was purified by TLC to give lubimin (**3**, 400 mg), in pure state, oil and $[\alpha]_D$ +39°; MS, *m/e* 236 (M^+), 218, 203, 193, and 175; IR and NMR, in the text; GLC, Silicone SE-52 (Chromosorb W, DMCS, 80—100 mesh), injection temp 200 °C, carrier gas nitrogen, 45 ml/min, retention time 5.8 min. Found: C, 76.65; H, 10.19%. Calcd for $C_{15}H_{24}O_2$: C, 76.22; H, 10.24%.

The fraction H (2.42 g), oil,[1] was dissolved in ether and shaken with 10% aq sodium carbonate. The ether soln was washed with 0.1 M hydrochloric acid and water, dried, and evaporated to leave oily neutral substances (2.37 g), which were again dissolved in ether and separated roughly into two fractions by chromatography over silicic acid (130 g) with ether, ether–acetone, and acetone. Fractions, eluted later with ether and then with acetone, showed a magenta spot with the Ehrlich reagent on TLC and were combined and concentrated to leave oily residue (1.34 g), showing two spots on TLC with cerium(IV) sulfate. The residue was rechromatographed over silicic acid (120 g) with mixtures of ether–ethyl acetate. Early fractions eluted with ether–ethyl acetate (9 : 1, 400 ml) gave oily materials (378 mg). Subsequent fractions eluted with the same solvent mixture (220 ml) gave a crystalline material (670 mg), showing a single spot on TLC (R_f 0.50, ether). This was purified by recrystallization from isopropyl ether to give oxylubimin (**4**, 330 mg), needles, mp 85—86 °C and $[\alpha]_D$ +27°; MS, *m/e* 252 (M^+), 234, 209, and 191; IR and NMR, in the text. Found: C, 71.48; H, 9.59%. Calcd for $C_{15}H_{24}O_3$: C, 71.39; H, 9.59%. Further fractions eluted with ether–ethyl acetate (9 : 1, 80 ml and 4 : 1, 100 ml) afforded a crude crystalline material (122 mg), which was again purified by chromatography over silicic acid (1.2 g) with a 4 : 1 mixture of ether and ethyl acetate to give a crystalline substance (92 mg), showing a single spot on TLC. This was recrystallized from ether to give lubiminol[7] (**5**, 56 mg) in pure state, mp 129—130 °C and $[\alpha]_D$ +33°; MS, *m/e* 238 (M^+), 220, 202, 187, and 107 (base); IR, ν_{max} 3410, 3140, 1642, 1048, 1036, 1009, and 884 cm^{-1}; NMR, δ 0.89 (3H,

d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.70 (3H, s, 13-C$\underline{H}_3$), 2.49 (2H, br s, 2O$\underline{H}$), 3.28 (1H, t, J=10 Hz, $\underline{H}$ at C_{15}), 3.60 (1H, br m, W_H=25 Hz, $\underline{H}$ at C_2), 3.90 (1H, do d, J=10 and 2.5 Hz, $\underline{H}$ at C_{15}), and 4.66 (2H, br s, 2$\underline{H}$ at C_{12}). Found: C, 75.77; H, 11.00%. Calcd for $C_{15}\underline{H}_{26}O_2$: C, 75.58; H, 11.00%.

*Acetyllubimin (**3a**), Diacetyloxylubimin (**4a**), and Diacetyloxylubiminol (**5a**).* (*i*) Lubimin (**3**, 39 mg) was treated with acetic anhydride (Ac_2O, 0.5 ml) and pyridine (Py, 0.5 ml) at room temp for 16 h. After addition of ethanol, the reaction mixture was worked up as usual to leave oily residue, which was purified by preparative TLC to give **3a** (23 mg), colorless oil and $[\alpha]_D$ +35°; MS, *m/e* 278 (M^+), 236, 218, 203, 191, 190, 189, and 175; IR, ν_{max} 3060, 2715, 1735, 1640, 1235, 1029, and 888 cm^{-1}; NMR, 0.95 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.69 (3H, s, 13-C$\underline{H}_3$), 4.65 (2H, s, 12-C$\underline{H}_2$), 4.70 (1H, m, W_H=25 Hz, $\underline{H}$ at C_2), and 9.76 (1H, d, J=3 Hz, C$\underline{H}$O).

(*ii*) Oxylubimin (**4**, 28 mg) was acetylated with Ac_2O (0.5 ml) and Py (0.5 ml) at room temp for 15 h to give **4a** (35 mg), colorless oil and $[\alpha]_D$+22°; MS, *m/e* 336 (M^+) and 276; IR, ν_{max} 3080, 2720, 1745, 1720, 1643, 1250, 1030, and 885 cm^{-1}; NMR, δ 0.90 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.69 (3H, s, 13-C$\underline{H}_3$), 1.96 and 1.99 (each 3H, s, 2OCOC$\underline{H}_3$), 2.35 (1H, m, $\underline{H}$ at C_{10}), 4.65 (2H, br s, 12-C$\underline{H}_2$), 4.65 (2H, m, 2$\underline{H}$ at C_2 and C_3), and 9.85 (1H, d, J=3 Hz, C$\underline{H}$O).

(*iii*) Lubiminol[7] (**5**, 30 mg) was treated with Ac_2O (0.2 ml) in Py (1.0 ml) at room temp for 23 h under stirring. The reaction mixture was worked up as usual to leave oily residue (39 mg), which was purified by chromatography over silica gel (3.0 g) with benzene–ether (30 : 1) to give **5a** (35 mg), oil and $[\alpha]_D$+43°; MS, *m/e* 262 ($M^+-C_2H_4O_2$) and 202; IR, ν_{max} 2970, 2890, 1743, 1642, 1465, 1432, 1365, 1238, 1027, and 886 cm^{-1}; NMR, 0.94 (3H, d, J=6.5 Hz, 14-C$\underline{H}_3$), 1.74 (3H, s, 13-C$\underline{H}_3$), 2.04 and 2.07 (each 3H, s, 2OCOC$\underline{H}_3$), 3.83 and 4.36 (each 1H, do ABq, J=11, 8, and 4 Hz, 2$\underline{H}$ at C_{15}), 4.69 (1H, br m, W_H=25 Hz, $\underline{H}$ at C_2), and 4.70 (2H, br s, 12-C$\underline{H}_2$).

*Dihydrolubimin (**5**) and Its Acetate (**5a**).* A soln of crude lubimin (**3**, 180 mg) in ethanol (3 ml) was treated with sodium borohydride (18 mg) at room temp for 1.5 h under stirring. The mixture was worked up as usual to leave amorphous residue (196 mg), which crystallized on trituration with isopropyl ether and was collected by filtration to give crude **5** (55 mg), mp 123—126 °C. The mother liquors were evaporated to leave oil, showing four spots on TLC, which was separated by preparative TLC over silica gel. A fraction with the smallest R_f value gave a crystalline substance (28 mg), which was recrystallized from isopropyl ether to give crude **5**, mp 124—127 °C. Both the samples **5** were combined and recrystallized from isopropyl ether to give **5** (75 mg) in pure state, mp 128—130 °C and $[\alpha]_D$ +28°. The mass, IR, and NMR spectra were identical with the corresponding spectra of lubiminol, isolated from the natural sources.

Compound **5** (83 mg), described above, was treated with Ac_2O (1 ml) and Py (1 ml) at room temp for 16 h. After being worked up as usual, the reaction mixture gave an oily product, which was purified by preparative TLC over silica gel to give **5a** (86 mg), oil and $[\alpha]_D$+35°. This sample was identical with that obtained from lubiminol in the mass, IR, and NMR spectra.

*Tetrahydrolubimin (**6**), Its 15-p-Bromobenzoate (**6a**), and Its 15-Brosylate (**6b**).* (*i*) Compound **5** (33 mg) was hydrogenated over Adams platinum (10 mg as $PtO_2 \cdot 2H_2O$) in ethanol (20 ml) at room temp for 3.5 h, when 2 mol of hydrogen had been consumed. After removal of the catalyst and solvent, the mixture gave a crystalline substance (33 mg), which was recrystallized from isopropyl ether to give **6** (27 mg), mp 145—147 °C and $[\alpha]_D$+35°; MS, *m/e* 240 (M^+), 222, 204, 197, 179, and 161; IR ($CHCl_3$), ν_{max} 3640 (sh), 3400, 1387, 1372, 1045 (sh), 1030, and 916 cm^{-1}; NMR, δ 0.86 (9H, d, J=7 Hz, 12-, 13-, and 14-C$\underline{H}_3$), 0.88 (2H, s, 2O$\underline{H}$), 3.32 and 3.90 (each 1H, do ABq, J=11, 8 and 11, 4 Hz, 2$\underline{H}$ at C_{15}), and 3.64 (1H, br m, W_H=25 Hz, $\underline{H}$ at C_2).

(*ii*) To a soln of **6** (17 mg, 7.8×10^{-5} mol) in Py (1 ml) was added dropwise a soln of *p*-bromobenzoyl chloride (14 mg, 6.3×10^{-5} mol) in Py (2.5 ml) at 0 °C under stirring. The mixture was stirred at room temp for 20 h, and then diluted with dichloromethane (25 ml) and poured slowly into 0.6 M sulfuric acid (40 ml) cooled with ice. The whole mixture was separated into two layers, and the aq layer was extracted with dichloromethane (2×30 ml). The combined organic soln was washed successively with 0.6 M sulfuric acid (2×30 ml), 10% aq sodium carbonate (2×30 ml) and water, dried, and evaporated to leave gummy solid, which was submitted to preparative TLC over silica gel with chloroform–ether (7 : 1). A fraction eluted with a low R_f value was extracted with ether containing methanol and gave a solid substance (14 mg), which was again purified by preparative TLC with benzene-ethyl acetate (5 : 1). Extraction of a band with a lower R_f value afforded a crystalline substance (11 mg), which was recrystallized from ethanol to give **6a** (10 mg), mp 106—108 °C; MS, *m/e* 424 (M^++2), 422 (M^+), 222, 204, 179, and 161; IR ($CHCl_3$), ν_{max} 3400, 1718, 1594, 1389, 1372, 1277, 1270, 1118, 1103, 1012, 963, and 847 cm^{-1}; NMR, δ 0.89 (9H, d, J=7 Hz, 12-, 13-, and 14-C$\underline{H}_3$), 3.64 (1H, br m, W_H=25 Hz, $\underline{H}$ at C_2), 3.99 and 4.46 (each 1H, do ABq, J=11, 10 and 11, 2 Hz, 2$\underline{H}$ at C_{15}), 7.73 and 7.81 (each 2H, ABq, J=8 Hz, $BrC_6\underline{H}_4CO$), and 1.60 (1H, br s, O$\underline{H}$). Extraction of a band with higher R_f value gave the 2,15-dibenzoate (8 mg), on trituration with hexane, mp 112—114 °C

(*iii*) A soln of **6** (33 mg, 1.4×10^{-4} mol) and *p*-benzenesulfonyl chloride (85 mg, 3.4×10^{-4} mol) in dry Py (1 ml) was allowed to stand at 0 °C for 10 h. The mixture was poured into ice-water and extracted with ether and then with chloroform. Both the solns were washed successively with 0.5 M hydrochloric acid (2×15 ml), 5% aq sodium hydrogencarbonate (2×15 ml), and saturated brine, combined, dried, and evaporated to leave colorless oil (45 mg), showing two spots with a UV lamp on TLC, which was separated into two fractions by preparative TLC over silica gel with benzene–ethyl acetate (9 : 1). A less polar fraction afforded colorless oil (19 mg), which showed a single spot on TLC and was presumed to be the dibrosylate; NMR, δ 0.86 (9H, d, J=7 Hz), 3.70 and 4.17 (each 1H, do ABq, J=11, 8 and 11, 4 Hz), 4.36 (1H, br m, W_H=25 Hz), and 7.67 (8H, s). A more polar fraction gave **6b** (23 mg), colorless oil, showing a single spot on TLC; MS, *m/e* 238 and 236 ($BrC_6H_4SO_3H^+$), 222 (M^+-236), 204, 189, and 161; IR ($CHCl_3$), ν_{max} 3400, 1580, 1393, 1372, 1183, 1095, 1070, 1012, 962, 945, and 820 cm^{-1}; NMR (CCl_4), δ 0.86 (9H, d, J=7 Hz, 12-, 13-, and 14-C$\underline{H}_3$), 3.64 (1H, br m, W_H=25 Hz, $\underline{H}$ at C_2), 3.70 and 4.15 (each 1H, do ABq, J=11, 8 and 11, 4 Hz, 2$\underline{H}$ at C_{15}), 7.62 and 7.73 (each 2H, ABq, J=8 Hz, $BrC_6\underline{H}_4SO_4$).

*Oxidation of **6a** into the 2-Dehydro Derivative (**7**) Followed by Deuteration.* (*i*) A soln of **6a** (7 mg) in Py (0.3 ml) was added to a slurry, prepared by adding chromium(VI) oxide (30 mg) to vigorously stirred Py (0.3 ml), under cooling with ice-bath during 15 min. The mixture was stirred at the temp for 1 h and then allowed to stand at room temp for 16 h. The reaction mixture was poured into water

(10 ml) and extracted with ether. The ether soln was worked up as usual to leave oil (6 mg), showing two spots, which was purified by preparative TLC over silica gel with benzene–ethyl acetate (10 : 1). A fraction with a higher R_f value gave **a** crystalline material, which on recrystallization from hexane yielded **7** (3 mg), mp 71—73 °C; MS, *m/e* 220 ($M^+ - BrC_6H_4CO_2H$), 205, 195, 193, and 177: IR, ν_{max} 1720, 1705, 1387, 1370, 1598, 1265, and 842 cm^{-1}; NMR, δ 0.90 (9H, d, J=7 Hz, 12-, 13-, and 14-C$\underline{H}_3$), 3.99 and 4.40 (each 1H, do ABq, J=11, 9 and 11, 3 Hz, 2$\underline{H}$ at C_{15}), 7.67 and 7.77 (each 2H, ABq, J=8 Hz, $BrC_6\underline{H}_4SO_2$).

(*ii*) A soln of **7** (5 mg) in a sodium deuteroxide soln, which had been prepared by adding sodium (50 mg) to a 2 : 1 mixture (3.2 ml) of dry dioxane and deuterium oxide, was heated at 70 °C for 15 min under a stream of nitrogen. After removal of the solvents *in vacuo*, the mixture was extracted with ether. The ether extracts, oil, were again treated in the same manner as described above. The resulting oil was dissolved in chloroform, and the chloroform soln, after being dried, and evaporated, afforded a mixture of deuterated ketones including the d_5-derivative (**8**). The mixture showed the following spectra: MS, *m/e* 243 (M^+ of **8**), 242, 241, 240, 239, 238, 225, 224, 223, 181, and 180; IR, ν_{max} 3450, 2230, 1705, 1388, and 1372 $cm.^{-1}$

*Conversion of **6b** into Oxolane (**9**).* A soln of **6b** (24 mg) in *t*-butyl alcohol (0.4 ml) was stirred with potassium *t*-butoxide in *t*-butyl alcohol (0.2 ml), which had been prepared by dissolving potassium (29.7 mg) into *t*-butyl alcohol (1 ml), at room temp for 150 min under nitrogen. The reaction mixture was poured into water and extracted with ether. The ether soln, after being worked up as usual, left oil, showing two spots, which was separated into two fractions by preparative TLC over silica gel with benzene–ethyl acetate (5 : 1). A less polar fraction gave **9** (9.5 mg), showing a single spot, oil; MS, *m/e* 222 (M^+), 207, 191, 179, 161, and 152; IR, ν_{max} 1388, 1372, 1205, 1170, 1105, 1072, 1052, 1000, 912, 895, 860, and 815 cm^{-1}; NMR, in the text.

*The Periodic Acid Test for Oxylubimin (**4**) and Its Derivatives.* To a soln of periodic acid (50 mg as H_5IO_6) in water (10 ml) were added a drop of concd nitric acid and then a soln of sample in dioxane, and the whole soln was kept at room temp for 10—15 s. To the resulting soln were added two drops of 5% aq silver nitrate: oxylubimin (**4**), dihydrooxylubimin (**11**), and rishitin (**1**) formed white ppts of silver iodate, but lubimin (**3**) and methyl palmitate formed no ppt with the reagent.

*Dihydrooxylubimin (**11**), Its 2,3,15-Triacetate (**11a**), 2,3-Diacetate (**11b**), and 2,3-Dibenzoate (**11c**).* (*i*) A soln of **4** (150 mg) in ethanol (7 ml) was treated with sodium borohydride (30 mg) at room temp for 5 h under stirring. The reaction mixture was worked up as usual to leave crystalline residue (160 mg), which was recrystallized from isopropyl ether containing methanol to give **11** (107 mg), mp 170—171 °C; MS, *m/e* 254 (M^+), 236, and 218; IR, ν_{max} 3340, 3080, 1645, 1090, 1072, 1033, 1002, and 890 cm^{-1}; NMR, δ 1.01 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.71 (3H, s, 13-C$\underline{H}_3$), and 4.66 (2H, br s, 12-C$\underline{H}_2$). Found: C, 70.59; H, 10.28%. Calcd for $C_{15}H_{26}O_3$: C, 70.83; H, 10.30%.

(*ii*) Compound **11** (120 mg) was stirred with Ac_2O (2.5 ml) and Py (2.5 ml) at room temp for 19 h. The mixture was worked up as usual to leave oily residue (187 mg), which was purified by preparative TLC over silica gel with benzene–ethyl acetate (9 : 1) to give **11a** (161 mg) in pure state, colorless oil and $[\alpha]_D$+21°; MS, *m/e* 380 (M^+), 320, 260, and 200; IR, ν_{max} 3080, 1750, 1650, and 895 cm^{-1}; NMR, δ 0.90 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.73 (3H, s, 13-C$\underline{H}_3$), 2.00 and 2.04 (3H and 6H, s, 3OCOC$\underline{H}_3$), 3.86 and 4.25 (each 1H, do ABq, J=11, 9 and 11, 4 Hz, 2$\underline{H}$ at C_{15}), 4.70 (2H, br s, 12-C$\underline{H}_2$), and 4.76 (2H, br m, W_H=30 Hz, 2$\underline{H}$ at C_2 and C_3).

(*iii*) A soln of **4a** (33 mg) in ethanol (1.5 ml) was stirred with sodium borohydride (4 mg) at room temp for 4 h. The reaction mixture was worked up as usual to give oil, which was purified by preparative TLC over silica gel to yield **11b** (18 mg) in pure state, colorless oil and $[\alpha]_D$+24°; MS, *m/e* 320 ($M^+ - H_2O$), 295, 278, 260, 218, 200, 187, and 159; IR and NMR, in the text.

(*iv*) A soln of **4** (10 mg) in chloroform (0.3 ml) and Py (0.2 ml) was stirred with benzoyl chloride (25 mg) at room temp for 3.5 h. The mixture was diluted with chloroform, washed with 0.5 M sulfuric acid, water, 5% aq sodium carbonate, and water, dried, and evaporated to leave amorphous residue, which was treated with sodium borohydride (15 mg) at room temp for 3 h. The reaction mixture was worked up as usual to leave oily residue, (19 mg), which was purified by preparative TLC over silica gel with benzene–ethyl acetate (5 : 2) to give **11c** (8.5 mg), mp 58—59 °C (from hexane): CD, $\Delta\varepsilon$ −19.2 at 235 nm and +5.9 at 219 nm (c 1.6×10^{-3} in ethanol, cell length 0.01 dm); MS, *m/e* 462 (M^+), 340 ($M^+ - C_7H_6O_2$), 322, 218, and 105 (base); IR ($CHCl_3$), ν_{max} 3480, 3080, 1720, 1643, 1607, 1452, 1315, 1280, 1175, 1115, 1024, 975, and 890 cm^{-1}; NMR, δ 0.99 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 1.75 (3H, s, 13-C$\underline{H}_3$), 3.45 and 3.99 (each 1H, do ABq, J=11, 8 and 11, 3 Hz, 2$\underline{H}$ at C_{15}), 5.15 (1H, t, J=10 Hz, $\underline{H}$ at C_3), 5.21 (1H, m, $\underline{H}$ at C_2), 7.47 and 7.93 (6H and 4H, m, $2COC_6\underline{H}_5$).

*Tetrahydrooxylubimin (**12**) and Its 15-Brosylate (**12a**).* (*i*) Compound **4** (40 mg) was hydrogenated over Adams platinum (50 mg) in ethanol (10 ml) at room temp for 3 h, when 2 mol of hydrogen had been absorbed. After being worked up as usual, the reaction mixture left amorphous residue (39 mg), which crystallized on trituration with isopropyl ether–methanol. This was recrystallized from the same solvent mixture to give **12** (18 mg), mp 163—165 °C; MS, *m/e* 256 (M^+), 238, 220, 195, and 177, IR, in the text. This compound was also obtained by hydrogenation of **11**.

(*ii*) Compound **12** (63 mg) was stirred with *p*-bromobenzenesulfonyl chloride (89 mg, 1.4 equiv) in Py (1.2 ml) at 5 °C for 22 h. The mixture was worked up as usual to leave oily residue (97 mg), which was purified by preparative TLC over silica gel with benzene–ethyl acetate (5 : 1) to give **12a** (51 mg), mp 97—100 °C. This was recrystallized from isopropyl ether for analysis: mp 98—100 °C; MS, *m/e* 458 (M^++2), 456 (M^+), 440, 438, and 236 ($M^+ - BrC_6H_4SO_3H$); IR ($CHCl_3$), ν_{max} 3360, 1583, 1373, and 1183 cm^{-1}; NMR, δ 0.84 and 0.99 (6H and 3H, each d, J=7 Hz, 12-, 13-, and 14-C$\underline{H}_3$), 2.93 (1H, do d, J=10 and 8 Hz, $\underline{H}$ at C_3), 3.41 (1H, br m, W_H=24 Hz), 3.41 and 4.27 (each 1H, do ABq, J=11, 8 and 11, 4 Hz, 2$\underline{H}$ at C_{15}), and 7.75 (4H, s, $BrC_6\underline{H}_4SO_4$).

*The Lemieux-Johnson Oxidation of **11a** to Methyl Ketone (**13**).* To a soln of **11a** (31 mg, 8.2×10^{-4} mol) in distilled dioxane (2ml) and water (0.6 ml) was added osmium tetraoxide (5 mg) at room temp under stirring. The soln became dark brown. To this soln was added sodium metaperiodate (60 mg, 2.8×10^{-3} mol) at 27 °C (bath temp) under stirring. After being kept for 2 h, the reaction mixture was diluted with water (10 ml), and the aq soln was extracted with ether (30 ml) and chloroform (20 ml). Both the solns were combined, washed with water, dried, and evaporated to leave oily residue (32 mg), which was purified by preparative TLC over silica gel with benzene–ethyl acetate (2 : 1). A main fraction gave **13** (27 mg), colorless oil and $[\alpha]$ +27 °; MS, *m/e* 382 (M^+), 367, 325, 322, 307, 280, 262, 220, 219, 160,

and 159; IR, ν_{max} 1745, 1713, 1435, 1370, 1230, 1053, and 1030 cm^{-1}; NMR δ 0.90 (3H, d, J=7 Hz, 14-C$\underline{H}_3$), 2.00 and 2.06 (3H and 6H, s, 3OCOC$\underline{H}_3$), 2.16 (3H, s, COC$\underline{H}_3$), 2.83 (1H, br m, W_H=25 Hz, $\underline{H}$ at C_7), 3.82 and 4.29 (each 1H, do ABq, J=11, 8 and 11, 3 Hz, 2$\underline{H}$ at C_{15}), 4.69 (1H, t, J=10 Hz, $\underline{H}$ at C_3), and 4.75 (1H, m, $\underline{H}$ at C_2).

Conversion of ***12a*** *into Hydroxyoxolane (****14****).* Compound **12a** (51 mg) in *t*-butyl alcohol (0.8 ml) was stirred with potassium *t*-butoxide (0.15 ml), which had been prepared by dissolving potassium (37.5 mg) into *t*-butyl alcohol (1 ml), at 0 °C for 30 min under nitrogen. The mixture was mixed with water (4 ml) and extracted with ether. The ether soln was washed with water, dried, and evaporated to leave **14** (26 mg), showing a single spot on TLC. This was purified by preparative TLC to give **14** in pure state, oil; MS, *m/e* 238 (M^+), 220, 195, 177, 151, 109, and 95 (base); IR and NMR, in the text.

Intramolecular Cyclization of 3,4-Epoxy Alcohols; Oxetane Formation

Akio MURAI, Mitsunori ONO, and Tadashi MASAMUNE
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received November 26, 1976)

1-(2,3-Epoxypropyl)-1-cyclohexanol (**1**) and its methyl analogues (**2** and **3**), when treated with base in 75% aqueous dimethyl sulfoxide, gave the corresponding oxetanes (**9**—**11**) as the main products, while treatment of compound **1** under anhydrous conditions afforded the oxolane dimer (**17**) as the sole identified product.

Intramolecular cyclization of epoxy alcohols by ring cleavage usually leads to the formation of oxiranes, oxolanes, and/or oxanes.[1] In an effort to prepare β-hydroxyoxolanes by ring closure of 3,4-epoxy alcohols with bases, we found that the reactions under controlled conditions resulted in regiospecific attack of the alkoxide anion at the 3-carbon atom to give α-hydroxyalkyloxetanes. The results were recently reported in a preliminary communication[2] and the details are described in the present paper.

Three compounds, 1-(2,3-epoxypropyl)-1-cyclohexanol (**1**) and its methyl analogues (**2** and **3**[3]), were used for the reactions. These compounds (**1**—**3**), each oil, were prepared by epoxidation[4] of the corresponding olefins (**4**,[5] **5**, and **6**) as depicted in Scheme 1, and exhibited absorption signals near δ 2.7 due to the oxirane ring protons in the NMR spectra. Contrary to the expectation, an attempted epoxidation of 1-(3-methyl-2-butenyl)-1-cyclohexanol (**7**) with perbenzoic acid[4b] failed and, instead, produced an oxolane (**8**), oil, suggesting facile cyclization to a five-membered ring under the acidic conditions used.[6] Compound **8** and its monoacetate (**8a**), oil, displayed one-proton signals at δ 4.00 (1H, t, J=7 Hz, CHOH) and 5.00 (1H, do d, J=6 and 4 Hz, CHOAc) in the respective NMR spectra.

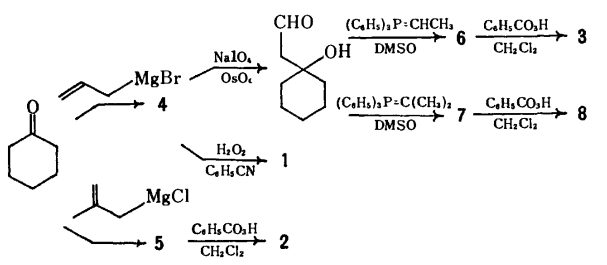

Scheme 1.

Treatment of monosubstituted oxirane (**1**) and its methyl analogues (**2** and **3**) with a base in 75% aqueous dimethyl sulfoxide[7] at 140—150 °C (bath temp) produced a mixture of the corresponding oxetanes (**9**—**11**), each oil, and the triols (**12**—**14**), each crystals, no oxolane (**15**) being detected (Table 1). Evidently, the oxetanes resulted from attack of the alkoxide anion at the 3-carbon atom, because triol **12** was not converted into oxetane **9** (recovered unchanged) under the same conditions.

Table 1. Reactions of 3,4-epoxy alcohols with bases in aqueous solvents[a]

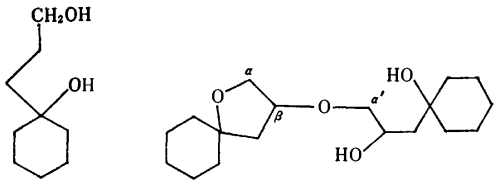
Compound	Base	Time (min)	Products (%)
1	KOH	90	**9** (49), **12** (32)
1	NaOH	45	**9** (49), **12** (32)
1	LiOH[b]	15	**9** (49), **12** (32)
2	KOH	60	**10** (67), **13** (14)
3	KOH	60	**11** (73), **14** (9)

a) The reactions were carried out by heating (bath temp, 140—150 °C) with 10 mol equiv of bases in 75% aqueous DMSO, and were ceased when the starting oxiranes were consumed. b) Slightly heterogeneous.

The structures of these products were elucidated on the basis of the chemical and spectral evidence, and one example is illustrated by oxetane **9**. The compound (**9**), $C_9H_{16}O_2$, readily formed its monoacetate (**9a**), an oil, $C_{11}H_{18}O_3$: *m/e*, **9**, 156 (M^+); **9a**, 198 (M^+). Each of these compounds (**9** and **9a**) exhibited NMR signals due to the three protons on the oxetane ring as well as that due to the hydroxy-methylene or acetoxy-methylene protons: δ, **9**, 2.22 (2H, d, J=8 Hz, 2H at C_β), 4.70 (1H, m, H at C_α), and 3.64 (2H, m, CH_2OH); **9a**, 2.08 and 2.34 (each 1H, do ABq, J=12, 5.5 and 12, 8 Hz, 2H at C_β), 4.76 (1H, m, H at C_α), and 4.18 (2H, m, CH_2OAc). Treatment of oxetane **9** with lithium aluminium hydride in a 4 : 1 mixture of dioxane and tetrahydrofuran under reflux effected cleavage of the oxetane ring[1c] to give a glycol (**16**), mp 53—54 °C, showing a triplet signal (2H, t, J=6 Hz) at δ 3.62 in the NMR spectrum. This glycol (**16**) was also obtained by hydroboration of 1-allylcyclohexanol (**4**) followed by oxida-

tion, confirming the structure of the glycol (**16**) and hence that of the oxetane (**9**).

Oxirane ring opening reactions were then examined by treatment of oxirane **1** with various bases under anhydrous conditions, the result being listed in Table 2. As shown in Table 2, the reactions effected formation of a five-membered ether and produced the oxolane dimer (**17**), oil, and oligomers (not completely identified); however, the monomer (**15**, R′=R″=H) or oxetane (**9**) could not be detected. The structure of oxolane **17** was deduced from the following evidence. The mass spectrum, *m/e* 312 (M^+), 294, and 276, indicated the compound to be a dimeric substance $C_{18}H_{32}O_4$, having two hydroxyl groups susceptible to dehydration. While the dimer (**17**), ν_{max} 3440 and 1128 cm^{-1}, was converted readily into its monoacetate (**17a**), ν_{max} 3440, 1750, and 1248 cm^{-1}, hydride reduction of oxolane **17** under the same or more severe conditions as that of oxetane **9** led to only recovery of the starting material. Moreover, these oxolanes (**17** and **17a**) revealed NMR signals due to the four alkoxyl-methylene and one alkoxy-methine protons and also that due to the hydroxy-methine or acetoxy-methine proton in the respective spectra, which were consistent with the assigned structures: δ, **17**, 3.42 (4H, m, 4H at C_α and $C_{\alpha'}$), 4.64 (1H, m, H at C_β), and 4.13 (1H, m, CHOH); **17a**, 3.54 (4H, m, 4H at C_α and $C_{\alpha'}$), 4.71 (1H, m, H at C_β), and 5.23 (1H, m, CHOAc).



16 **17**

The results in Tables 1 and 2 are summarized as follows. Treatment of 3,4-epoxy alcohol (**1**) with base in aqueous dimethyl sulfoxide produced a *monomeric four-membered* ether ring (**9**), while the treatment under anhydrous conditions (in aprotic solvents) led to formation of a *dimeric five-membered* ether ring (**17**). Moreover, it is emphasized from Table 1 that (i) the oxetanes were formed preferentially under the hydrolysis conditions,[8] regardless of the relative degree of substitution of the oxirane ring,[9] (ii) the yields of the oxetanes increased with the number of substituents on the epoxy alcohols,[10] and (iii) the reaction of oxirane **1** with different bases gave the products (**9** and **12**) in the same ratio (49 : 32) with the reaction rate varying slightly but definitely depending on the nature of the base used. Here we add the fact that these major products, the oxetane (**9**) and the oxolane (**17**), were recovered unchanged, when the former (**9**) was treated under the anhydrous conditions (NaH in THF, reflux, 11 h) and the latter (**17**) under the hydrous conditions (KOH in 75% aq DMSO, 140—150 °C, 60 min), respectively.

Recently, Stork and coworkers[11] reported intramolecular cyclization of epoxy nitriles with bases, which involved results inconsistent with usual cyclization reactions proceeding through S_N2 type transition states.[12,13] They pointed out the necessity of a proper collinear arrangement in the transition state for displacement at the oxirane carbon atom and rationalized their result, specially the small (three- and four-membered) ring formation, in terms of the collinearity requirement and the relative degree of substitution of the oxirane ring. This collinearity requirement and the preference for diaxial opening were later accentuated in intramolecular cyclization of allyl 2,3-epoxyalkyl ether to a four-membered ring (oxetane).[14] Baldwin's "rules for ring closure"[15] appears to be based on these results for the cyclization to small rings. However, the collinearity requirement for the four-membered ring formation has recently been criticized by Lallemand and Onanga,[16] who observed preferential cyclization of (4*E*)-4,5-epoxy nitriles to five-membered rings (cyclopentane), indicating the importance of "statistical and geometrical factors." All these factors seem to be useful and necessary for interpretation of their results and also of our result.

Our result constitutes the first example indicating a pronounced solvent dependency in the intramolecular ether ring formation by the oxirane ring cleavage and is not readily explained on the basis of the current "S_N mechanisms." One plausible explanation, based on the recent works, assuming that the proposed factors controlling the reaction pathway in intramolecular attack of carbanions to oxirane rings are applicable to the corresponding reactions of alkoxide anions, follows as. The cyclization in aprotic solvents (anhydrous conditions) with *low* solvating power involves attack of anions with extremely *high* nucleophilicity,[17] which

Table 2. Reactions of 3,4-epoxy alcohol (**1**) with bases in anhydrous solvents

Base	Mol	Solvent	Temp (°C)	Time (h)	Products (%)
NaH	1.5	THF	reflux	9	**1** (95)

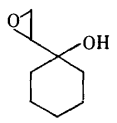
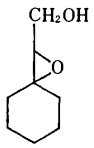
a) The remaining products were oxolane oligomers, not completely identified. b) 0.5 h at −70 °C and 1.5 h at 0 °C.

would not always require the collinearity in the transition state. Then, the reaction would proceed with displacement at the less substituted carbon of the oxirane ring, as had been illustrated by many base-catalyzed oxirane ring opening reactions,[9a] leading to formation of an oxolane ring with less steric constraint. On the other hand, the cyclization in aqueous dimethyl sulfoxide (hydrous conditions) would take place only when the collinearity is satisfied in the transition state, because of *lower* nucleophilicity of an attacking anion as well as *higher* solvating power of the solvent system as compared with those in aprotic solvents.[17,18] The observed enhanced rate in passing from potassium to lithium hydroxide would result from increasing coordinating power of the metal cation[19] to the oxirane oxygen in the relevant solution. The hypothesis undoubtedly requires evidence to be demonstrated and investigations in line with this are now in progress. In connection with this, we treated 1-(epoxylethyl)-1-cyclohexanol (**18**), prepared from 1-vinylcyclohexanol,[20] in aqueous dimethyl sulfoxide under the same conditions and isolated the corresponding oxirane (**19**) as a single product (78%). The result was consistent not only with well-known facile formation of a three-membered ring[1c,21] but also with the "collinearity" principle. Here we again emphasize that the present result offers intrinsic interest for the mechanistic studies and also constitutes a *new non-photochemical synthesis of oxetanes.*[22]



18



19

Experimental

All the melting and boiling points were uncorrected. The homogeneity of each compound was always checked by TLC over silica gel (Wakogel B-5) with various solvent systems, and the spots were developed with cerium(IV) sulfate in dil sulfuric acid and/or iodine. The IR and NMR (100 MHz) spectra were measured in liquid state and in chloroform-*d*, unless otherwise stated. The abbreviations "s, d, t, m, br, and do" in the NMR spectra denote "singlet, doublet, triplet, multiplet, broad, and double," respectively. The preparative TLC and column chromatography were carried out over silica gel (Wakogel B-5) and silicic acid (Kieselgel 60), respectively. All the solvents were distilled before use after being dried; ether, tetrahydrofuran (THF), and 1,2-dimethoxyethane (DME) from lithium aluminium hydride (LAH); dichloromethane and benzene from phosphorus pentaoxide; dimethyl sulfoxide (DMSO) and hexamethylphosphoramide (HMPA) from calcium hydride. The latter two solvents were stored over molecular sieves.

*1-Allylcyclohexanol (**4**), and Its Methyl Analogues (**5** and **6**).* *(i)* Compound **4** (7.14 g) was prepared by the Grignard reaction of cyclohexanone (6.5 g) in ether (50 ml) with allylmagnesium bromide, prepared from allyl bromide (12 g) and magnesium turnings (3.5 g) in ether (30 ml), at room temp for 3.5 h, and had bp 75—77 °C/15 Torr [lit,[5] 62—64 °C/3 Torr]; IR, ν_{max} 3400, 1605, 1000, 975, and 910 cm^{-1}; NMR, δ 2.22 (2H, d, J=7 Hz), 4.98 (1H, m), 5.20 (1H, br s, OH), and 5.93 (2H, br m).

(ii) A soln of cyclohexanone (30 g), freshly distilled, in ether (400 ml) was added to a cold suspension of 2-methylallylmagnesium chloride, prepared from 2-methylallyl chloride (90 g) and magnesium turnings (30 g) in ether (360 ml), during 2 h under stirring, and the whole mixture was stirred at room temp for 2 h. The reaction mixture was worked up as usual to leave a colorless oil (49.5 g), which was distilled to give **5** (45 g), in pure state, bp 80—85 °C/11 Torr; MS, *m/e* 154 (M^+) and 136; IR, ν_{max} 3460, 1640, and 885 cm^{-1}; NMR, δ 1.83 (3H, s), 2.16 (2H, s), 4.66 and 4.92 (each 1H, br s). Found: C, 77.71; H, 11.62%. Calcd for $C_{10}H_{18}O$: C, 77.86; H, 11.76%.

(iii) A soln of **4** (7.0 g) in a 1 : 4 mixture (150 ml) of dioxane and water was mixed with a 1 mM soln of osmium tetraoxide in dioxane (25 ml), and was stirred vigorously for 0.5 h. To the soln was added a soln of sodium periodate (25 g) in water (80 ml). The whole mixture was stirred at room temp for 2.5 h, and ppts formed were removed by filtration. The filtrate was evaporated *in vacuo* to remove dioxane and extracted with ethyl acetate repeatedly. The acetate soln was washed with water, dried, and evaporated to leave a pale brown oil, 2-cyclohexyl-2-hydroxyacetaldehyde (7.2 g); IR, ν_{max} 3440, 1743, and 1723 cm^{-1}; NMR, δ 2.59 (2H, d, J=2.5 Hz), 3.0 (1H, br, OH), and 9.82 (1H, t, J=2.5 Hz). This sample was used for the next reaction without further purification.

To a stirred soln of sodium methylsulfinylmethanide[23] in DMSO, prepared by addition of sodium hydride (NaH, 192 mg) into DMSO (4 ml) under nitrogen, was added a soln of ethyltriphenylphosphonium bromide (2.6 g) in DMSO (8 ml) under cooling in an ice-cooled bath, when the soln became deeply red, indicating formation of the ethylidenephosphorane. To the soln was added the afore-mentioned β-hydroxy aldehyde (710 mg) in DMSO (3 ml) at room temp during 15 min under stirring, and the whole mixture was further stirred at 50—60 °C for 24 h. The mixture was cooled, poured into ice-water, and extracted with ether repeatedly. The ether soln, after being washed with water and dried, was evaporated to leave an oily solid, which was separated by chromatography over silica gel to give **6** (149 mg) from benzene eluates, bp (bath temp) 90—94 °C/7 Torr; MS, *m/e* 154 (M^+) and 138; IR, ν_{max} 3420 and 1660 cm^{-1}; NMR, δ 1.66 (3H, d, J=6 Hz), 2.21 (2H, d, J=7 Hz), and 5.50 (2H, br m). Found: C, 77.88; H, 11.57%. Calcd for $C_{10}H_{18}O$: C, 77.86; H, 11.76%.

(iv) To a soln of sodium methylsulfinylmethanide in DMSO, prepared from NaH (172 mg) and DMSO (5 ml), was added a soln of isopropyltriphenylphosphonium bromide (2.8 g) in DMSO (5 ml), when the soln became deeply red. A soln of the β-hydroxy aldehyde (710 mg) in DMSO (3 ml) was added to the red soln. The whole mixture was stirred at 50—60 °C for 18 h and, after being worked up as usual, left an oily solid (330 mg), which was separated by chromatography over silicic acid to give **7** (71 mg), showing a single spot: MS, *m/e* 168 (M^+) and 150; IR, ν_{max} 3220 and 1680 cm^{-1}; NMR, δ 1.64 and 1.76 (each 3H, s), 2.14 (2H, d, J= 8 Hz), and 5.22 (2H, br m, OH and CH=).

*1-(2,3-Epoxypropyl)-1-cyclohexanol (**1**), and Its Methyl Analogues (**2** and **3**).* *(i)* A soln of **4** (6.05 g) in methanol (35 ml) and benzonitrile (4.20 g) was stirred with 30% aq hydrogen peroxide (8 ml) and potassium hydrogencarbonate (0.30 g) at room temp for 24 h and, after addition of 30% aq hydrogen peroxide (6 ml) and benzonitrile (4.0 g), was further stirred at the temp for 26 h.[4a] The reaction mixture, after being treated with 10% aq sodium thiosulfate to decompose excess of the hydrogen peroxide, was evaporated to

remove methanol and extracted with chloroform repeatedly. The chloroform extracts were washed with saturated aq sodium hydrogencarbonate, saturated brine and water, dried, and evaporated to leave an oil (**1**), which was distilled to give **1** (5.73 g) in pure state, bp 85—86 °C/2 Torr; MS, *m/e* 156 (M^+) and 138; IR, ν_{max} 3420, 980, and 965 cm^{-1}; NMR, δ 2.45 and 2.76 (each 1H, do ABq, J=5.5, 2.5 and 5.5, 4 Hz, 2H at C_γ), and 3.15 (1H, m, H at C_β). Found: C, 69.52; H, 10.49%. Calcd for $C_9H_{16}O_2$: C, 69.23; H, 10.26%.

(ii) A soln of **5** (1.5 g) in dichloromethane (50 ml) was stirred with perbenzoic acid (2.5 g, purity 97%) at room temp for 18 h.[4b] The mixture was washed with 5% aq sodium thiosulfate, 5% aq hydrogencarbonate and water, dried, and evaporated to leave a pale yellow oil, which was distilled to give **2** (1.3 g) in pure state, bp 140—143 °C/13 Torr; MS, *m/e* 170 (M^+) and 152; IR, ν_{max} 3360, 975, and 960 cm^{-1}; NMR, δ 1.44 (3H, s, CH_3), 2.66 and 2.72 (each 1H, ABq, J=5.5 Hz, 2H at C_γ). Found: C, 70.15; H, 10.23%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

(iii) Compound **6** (61 mg) in dichloromethane (3 ml) was oxidized with perbenzoic acid (86 mg) in a refrigerator (0 °C) for 24 h under stirring. The mixture was worked up as usual to leave an oil (83 mg), which was purified by distillation to yield **3** (54 mg), bp (bath temp) 130—134 °C/5 Torr; MS, *m/e* 170 (M^+) and 152; IR, ν_{max} 3420, 1250, 975, 960, and 855 cm^{-1}; NMR, δ 1.28 (3H, d, J=6 Hz, CH_3) and 3.14 (2H, m, 2H at C_β and C_γ). Found: C, 70.15; H, 10.23%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

2,2-Dimethyl-3-hydroxy-5,5-pentamethyleneoxolane (8), and Its Acetate (8a). A soln of **7** (50 mg) in dichloromethane (3 ml) was treated with perbenzoic acid (50 mg) in a refrigerator (0 °C) for 3 h. The reaction mixture was worked up as usual to leave an oil (51 mg), which was purified by passing through a short column packed with silicic acid to give **8** (45 mg); IR, ν_{max} 3460 and 1073 cm^{-1}; NMR, δ 1.22 and 1.24 (total 6H, each s, $2CH_3$), and 4.00 (1H, t, J=7 Hz, H at C_3).

Compound **8** (10 mg) was treated with acetic anhydride (Ac_2O, 50 mg) and pyridine (Py, 100 mg) at room temp for 15 h. The mixture was worked up as usual to give an oil (12 mg), which was purified by chromatography over silicic acid with benzene to yield **8a** (9 mg) in pure state; MS, *m/e* 226 (M^+), 167, 166, and 151; IR, ν_{max} 1746, 1235, 1079, and 1030 cm^{-1}; NMR, δ 1.18 and 1.23 (each 3H, s, $2CH_3$), 2.05 (3H, s, $OCOCH_3$), and 5.00 (1H, do d, J=6 and 4 Hz, H at C_3). Found: C, 68.69; H, 10.21%. Calcd for $C_{13}H_{22}O_3$: C, 68.99; H, 9.80%.

1-(Epoxyethyl)-1-cyclohexanol (18). 1-Vinylcyclohexanol (5.9 g) was prepared by the Grignard reaction of cyclohexanone (6.7 g) in THF (10 ml) with vinylmagnesium bromide, prepared from vinyl bromide (12.7 g) and magnesium turnings (3.1 g) in THF (10 ml), at room temp overnight under stirring, and had bp 68—70 °C/23 Torr [lit,[14] 66—68 °C/14 Torr]; IR, ν_{max} 3500, 1650, 965, and 920 cm^{-1}; NMR, δ 4.96 and 5.18 (each 1H, do ABq, J=17, 2 and 17, 12 Hz, 2H at C_β), and 5.92 (1H, do d, J=12 and 17 Hz, H at C_α).

The cyclohexanol (1.26 g) was treated with perbenzoic acid (2.76 g) in dichloromethane (90 ml) at room temp for 15 h under stirring. The mixture was worked up as usual to leave an oil (1.31 g), which was purified by distillation to give **18** (1.02 g) in pure state, bp 96—98 °C/12 Torr; MS, *m/e* 142 (M^+), 124, 99, and 98; IR, ν_{max} 3448, 975, and 965 cm^{-1}; NMR, δ 3.88 (3H, m, 3H at C_α and C_β). Found: C, 67.46; H, 9.94%. Calcd for $C_8H_{14}O_2$: C, 67.57; H, 9.93%.

Cleavage of Oxiranes (1—3, and 18) under Hydrous Conditions. The reaction conditions and results were summarized in Table 1 and two representative examples are described.

(i) A soln of oxirane **1** (156 mg, 1 mmol) in DMSO (30 ml) and water (10 ml) was stirred with potassium hydroxide (560 mg, 10 mmol) at 140—150 °C (bath temp) for 90 min under nitrogen, when the spot of **1** had disappeared on TLC. The mixture was cooled, poured into large excess of ice-water, and extracted with ethyl acetate repeatedly. The acetate extracts were washed with water, dried, and evaporated to leave an oil (142 mg), showing two spots on TLC, which was separated into two fractions by preparative TLC over silica gel with ethyl acetate–benzene (1 : 3). Each fraction was purified by distillation and/or recrystallization to give 2-(hydroxymethyl)-4,4-pentamethyleneoxetane (**9**, 76 mg) and 3-(1-hydroxycyclohexyl)-1,2-propanediol (**12**, 40 mg). Compound **9** had bp (bath temp) 97—99 °C/1 Torr; MS, *m/e* 156 (M^+), 138, 125, and 98; IR, ν_{max} 3400, 1017, 995, 965, 930, and 915 cm^{-1}; NMR, δ 2.22 (2H, d, J=8 Hz, 2H at C_3), 3.64 (2H, m, CH_2OH), and 4.70 (1H, m, H at C_2). Found: C, 69.54; H, 10.50%. Calcd for $C_9H_{16}O_2$: C, 69.23; H, 10.26%. Compound **12** had mp 65—66 °C (from ether); MS, *m/e* 174 (M^+), 156, 143, 125, and 107; IR, ν_{max} (Nujol) 3480 cm^{-1}; NMR, δ 3.48 (2H, m, CH_2OH), and 4.07 (1H, m, CHOH). Found: C, 62.25; H, 10.26%. Calcd for $C_9H_{18}O_3$: C, 62.07; H, 10.23%.

(ii) A soln of oxirane **18** (284 mg, 2 mmol) in DMSO (60 ml) and water (20 ml) containing potassium hydroxide (1.12 g, 20 mmol) was heated at 130—140 °C (bath temp) for 15 min under stirring. The mixture was worked up as described above to leave an oil (370 mg), showing a single spot, which still contained DMSO. The oily residue was purified by chromatography over silicic acid with ether–benzene (2 : 1) followed by distillation to give 2-(hydroxymethyl)-3,3-pentamethyleneoxirane (**19**, 225 mg) as a single product, bp (bath temp) 105—110 °C/5 Torr; MS, *m/e* 142 (M^+), 126, and 111; IR, ν_{max} 3394, 1241, 951, and 891 cm^{-1}; NMR, δ 2.96 (1H, do d, J=5 and 7 Hz, H at C_2), 3.62 and 3.84 (each 1H, do d, J=12, 5 and 12, 7 Hz, CH_2OH). Found: C, 67.62; H, 9.93%. Calcd for $C_8H_{14}O_2$: C, 67.57; H, 9.93%.

(iii) Oxetanes **10** and **11** and triols **13** and **14** had the following properties. Compound **10**, bp (bath temp) 105—108 °C/2 Torr; MS, *m/e* 170 (M^+), 139, and 99; IR, ν_{max} 3400, 1028, 1002, 952, 927, and 912 cm^{-1}; NMR, δ 1.38 (3H, s, CH_3), 1.96 and 2.36 (each 1H, ABq, J=11 Hz, 2H at C_3), and 3.42 (2H, s, CH_2OH). Found: C, 70.15; H, 10.58%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

Compound **11**, bp (bath temp) 108—112 °C/2 Torr; MS, *m/e* 170 (M^+), 125, and 98; IR, ν_{max} 3440, 1040, 996, 976, 935, and 920 cm^{-1}; NMR, δ 1.08 (3H, d, J=6 Hz, CH_3), 2.02 and 2.27 (each 1H, do ABq, J=11, 8 and 11, 7 Hz, 2H at C_3), 3.80 (1H, m, CHOH), and 4.36 (1H, m, H at C_2). Found: C, 70.47; H, 10.49%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

Compound **13**, mp 39—41 °C (from ether); MS, *m/e* 188 (M^+), 170, 157, 139, and 121; IR (Nujol), ν_{max} 3400 cm^{-1}; NMR, δ 1.40 (3H, s, CH_3), 3.34 and 3.50 (each 1H, ABq, J=11 Hz, CH_2OH). Found: C, 64.18; H, 10.60%. Calcd for $C_{10}H_{20}O_3$: C, 63.79; H, 10.71%.

Compound **14**, mp 39—41 °C (from ether); MS, *m/e* 188 (M^+), 170, 143, and 107; IR, (Nujol) ν_{max} 3400 cm^{-1}; NMR, δ 1.14 (3H, d, J=6 Hz, CH_3), and 3.64 (2H, m, 2CHOH). Found: C, 63.75; H, 10.98%. Calcd for $C_{10}H_{20}O_3$: C, 63.79; H, 10.71%.

(iv) Oxetanes **9**—**11** and oxirane **19** were converted almost quantitatively into the respective monoacetates (**9a**—

11a, and **19a**) by treatement with Ac_2O and Py at room temp, which had the following properties. Compound **9a**, bp (bath temp) 95—97 °C/2 Torr; MS, *m/e* 198 (M^+) and 138; IR, ν_{max} 1750, 1240, 1035, and 960 cm^{-1}; NMR, δ 2.11 (3H, s, $OCOC\underline{H}_3$), 2.08 and 2.34 (each 1H, do ABq, J=12, 5.5 and 12, 8 Hz, 2H at C_3), 4.18 (2H, m, $C\underline{H}_2OAc$), and 4.76 (1H, m, H at C_2).

Compound **10a**, bp (bath temp) 85—92 °C/2 Torr; MS, *m/e* 212 (M^+) and 152; IR, ν_{max} 1751, 1232, 1040, 963, and 938 cm^{-1}; NMR, δ 1.42 (3H, s, $C\underline{H}_3$), 2.10 (3H, s, $OCOC\underline{H}_3$), 2.14 and 2.26 (each 1H, ABq, J=11 Hz, 2H at C_3), and 4.00 (2H, s, $C\underline{H}_2OAc$).

Compound **11a**, bp (bath temp) 92—95 °C/2 Torr; MS, *m/e* 152 ($M^+-C_2H_4O_2$); IR, ν_{max} 1743, 1235, 1030, 1010, 970, 940, and 920 cm^{-1}; NMR, δ 1.14 (3H, d, J=6 Hz, $C\underline{H}_3$), 2.08 (3H, s, $OCOC\underline{H}_3$), 2.14 and 2.30 (each 1H, do ABq, each, J=12 and 7 Hz, 2H at C_3), 4.48 (1H, do t, J=11, 7, and 7 Hz, H at C_2), and 4.91 (1H, m, $C\underline{H}OAc$).

Compound **19a**, bp (bath temp) 95—103 °C/5 Torr; MS, *m/e* 184 (M^+); IR, ν_{max} 1751, 1230, 1033, 970, and 900 cm^{-1}; NMR, δ 2.12 (3H, s, $OCOC\underline{H}_3$), 2.98 (1H, do d, J=7 and 5 Hz, H at C_2), 4.02 and 4.32 (each 1H, do ABq, J=12, 7 and 12, 5 Hz, $C\underline{H}_2OAc$).

3-(1-Hydroxycyclohexyl)-1-propanol (**16**). *(i)* A soln of oxetane **9** (23 mg) in THF (1 ml) was added to a stirred suspension of LAH (100 mg) in a 4 : 1 mixture (10 ml) of dioxane and THF, and the mixture was refluxed for 20 h. After addition of a few drops of saturated aq ammonium chloride, the mixture was poured into ice-water, evaporated to remove most of the organic solvents, and extracted with ethyl acetate. The acetate extracts were washed with water, dried, and evaporated to leave an oil (27 mg), showing two spots on TLC, which was separated into two fractions by preparative TLC over silica gel to give **16** (10 mg) and **9** (11 mg), oil, the latter being was identified as starting oxetane. Compound **16** had mp 53—54 °C (from ether); MS, *m/e* 158 (M^+), 140, and 127; IR (Nujol), ν_{max} 3280 cm^{-1}; NMR, δ 3.62 (2H, t, J=6 Hz, $C\underline{H}_2OH$). Found: C, 68.36; H, 11.44%. Calcd for $C_9H_{18}O_2$: C, 68.35; H, 11.39%.

(ii) Into a stirred soln of olefin **4** (164 mg, 1.2 mmol) in THF (5 ml) was passed diborane, generated by addition of a soln of boron trifluoride etherate (0.75 ml, 6 mmol) in THF (3 ml) into a soln of sodium borohydride (170 mg) in THF (7.5 ml), at room temp for 10 min. The mixture was then heated at 50 °C (bath temp) for 3 h under stirring, cooled, and treated with water (1 ml) and then immediately with 30% aq hydrogen peroxide (7 ml) and 0.2 M aq sodium hydroxide (6 ml) at room temp for 48 h under stirring. After addition of 5% aq sodium thiosulfate to decompose excess of the peroxide, the reaction mixture was extracted with ether and then with ethyl acetate. The combined extracts were washed with water, dried, and evaporated to leave an oil (169 mg), which was separated by chromatography over silicic acid with benzene-ether (1 : 1) to give **16** (111 mg), mp 51—53 °C identical with the sample described above (MS, IR, NMR, and TLC).

Cleavage of Oxirane **1** *under Anhydrous Conditions.* The reaction conditions and results were summarized in Table 2, and two representative examples are described. *(i)* A soln of **1** (520 mg, 3.3 mmol) in THF (30 ml) was added dropwise to a stirred suspension of mineral oil-free sodium hydride (NaH, 200 mg, 8.3 mmol) in THF (30 ml). The mixture was refluxed gently for 11 h, cooled, and poured into ice-water, and extracted with ethyl acetate. The acetate extracts, after being worked up as usual, left a pale yellow oil (52 mg), which was separated by chromatography over silicic acid with benzene-ethyl acetate (4 : 1) to give an oxolane dimer (**17**, 311 mg) and unidentified polymers (102 mg) with smaller R_f value. The dimer had bp (bath temp) 169—172 °C/2 Torr; MS, IR, and NMR, in the text. Found: C, 69.18; H, 10.32%. Calcd for $C_{18}H_{32}O_4$: C, 68.77; H, 10.32 %.

The dimer gave its monoacetate (**17a**), bp (bath temp) 155—159 °C/2 Torr; MS, *m/e* 354 (M^+), 295, 294, and 276; IR and NMR, in the text.

(ii) A soln of lithium diisopropylamide (LDA, *ca.* 1.2 mmol), prepared by treatment of diisopropylamine (0.167 ml) with 10% butyllithium (BuLi) in hexane (0.768 ml) under cooling with Dry Ice-acetone (−78 °C), was added dropwise to a soln of **1** (156 mg, 1 mmol) and HMPA (179 mg, 1 mmol) in THF (1 ml) at −78 °C under nitrogen. The whole soln was stirred at the temp for 30 min and then at 0 °C for 2 h. The reaction mixture was worked up as usual to leave a colorless oil (171 mg), showing a single spot on TLC, which was purified by chromatography over silicic acid to give the starting oxirane (**1**, 152 mg).

Studies of the Isomerization of Unsaturated Carboxylic Acids. III.[1] Thermal Rearrangement of Dimethyl Methylenesuccinate to Dimethyl Mesaconate

Mutsuji SAKAI

Department of Fiber Chemistry, Faculty of Textile Science, Kyoto University of Industrial Arts and Textile Fibers, Matsugasaki, Sakyo-ku, Kyoto 606

(Received April 2, 1976)

Dimethyl methylenesuccinate (**1**) was found to equilibrate with dimethyl mesaconate (**3**) at elevated temperatures. Thermal rearrangements of **1** and **3** were studied kinetically and a plausible mechanism is proposed.

The rearrangement[2] and isomerization[2] of unsaturated esters in thermal[3-5] and photochemical[6-8] reactions have received much attention. In the preceding paper of this series, it was reported that some unsaturated dicarboxylic acids exhibited unique equilibrium composition during thermal reactions[2] and a plausible mechanism was proposed.[1]

On the other hand, it has been found that the corresponding unsaturated esters behave quite differently from the free acids. The present paper deals with the interconversion between dimethyl methylenesuccinate (**1**), dimethyl citraconate (**2**), and dimethyl mesaconate (**3**), and the mechanism for this interconversion will be discussed.

Experimental

All the boiling points are uncorrected.

Materials. Dimethyl methylenesuccinate (dimethyl methylenebutanedioate) (**1**), bp 105 °C/22 Torr, dimethyl citraconate (dimethyl (*Z*)-2-methyl-2-butenedioate) (**2**), bp 104 °C/25 Torr, and dimethyl mesaconate (dimethyl (*E*)-2-methyl-2-butenedioate) (**3**), bp 96 °C/20 Torr, were prepared according to the literature.[9] Organic solvents were purified by the standard methods. Other reagents were commercial materials and were used without further purification.

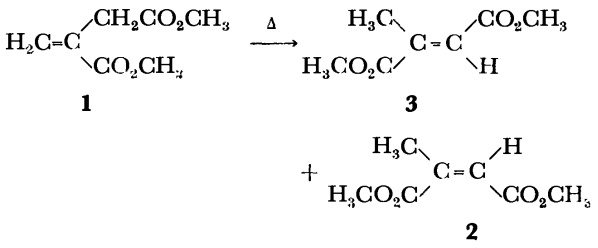
Procedure. A mixture of 0.30 g (1.9 mmol) of an unsaturated ester, 0.60 g of methanol, and a small amount of hydroquinone was sealed at atmospheric pressure in a glass tube, which was heated to an appropriate temperature in an autoclave filled with aqueous methanol. After cooling the autoclave, the tube was opened and the mixture was analyzed by GLC as described in a preceding paper.[1] When the reaction was carried out in the presence of iodine, the cooled reaction mixture was treated with aqueous sodium thiosulfate, and then the products were extracted with benzene. The benzene solution was subjected to GLC.

Reaction in Methanol-d. A mixture of 0.40 g of **1** and 1.30 g of methanol-*d* was sealed in a glass tube. After the reaction, the mixture of esters was recovered by distillation under reduced pressure. The distillate diluted with CCl_4 was subjected to NMR analysis. The deuterium content was calculated from the relative intensities of the NMR signals (in CCl_4, TMS) at δ 6.26 ($=CH_2$), 5.70 ($=CH_2$), and 3.28 ($-CH_2-$) for **1**, and 6.83 (=CH) and 2.24 ($-CH_3$) for **3**. The NMR spectra were recorded on a Varian T-60A spectrometer.

Kinetics. A mixture, consisting of 0.30 g of ester and 0.60 g of methanol, in a sealed tube was placed in an autoclave. The temperature was raised at a rate of 5 °C/min. After maintaining the mixture at an appropriate temperature for a desired period of time, the vessel was cooled immediately to room temperature. The cooled mixture was analyzed using GLC. Each run correctly followed first-order kinetics. The results at 250 °C were analyzed using equilibrium kinetics.[10]

Results

It was confirmed by GLC that the reaction mixture contained three isomers of the esters and no by-product was detected. The reaction was carried out in methanol, since thermal reaction without a solvent brought about the polymerization of **1** and the decomposition of the esters. In benzene, practically no reation occurred.



Equilibria. The reactions in methanol for **1**, **2**, and **3** were studied at 250 °C and the results are summarized in Table 1. The equilibrium composition in methanol at 250 °C were found to be 41% for **1**, 5% for **2**, and 54% for **3**. For the corresponding diethyl

Table 1. Equilibrium at 250 °C[a]

Table 3. NMR data for the reaction[a]

Starting ester	Solvent	Relative area[b]				
		H_a (δ 6.26)	H_b (5.70)	H_c (3.28)	H_d (6.83)	H_e (2.24)
1	Methanol	1.0	1.1	2.1	1.1	3.1
1	Methanol-*d*	1.0	1.1	0.98	0.30	1.5
3	Methanol	1.0	1.1	2.1	1.3	4.0
3	Methanol-*d*	1.0	1.1	1.1	0.61	2.1

a) Ester, 0.4 g; solvent, 1.3 g; temp, 250 °C; reaction time, 26 h. b) The relative area of terminal methylene of **1** (δ 6.26) is estimated to be 1.0.

(a) H, (c) $C{=}CCH_2CO_2CH_3$, (b) H, CO_2CH_3

(e) H_3C, CO_2CH_3, $C{=}C$, H_3CO_2C, H (d)

esters, the values were 27, 3, and 70%, respectively.

The addition of iodine to the reaction mixture dramatically accelerated the isomerization, whereas the rate of rearrangement remained unaffected. The results are shown in Table 2.

The results of the reactions of the esters in methanol-*d* are shown in Table 3. When **1** was heated in methanol-*d*, deuterium atoms were incorporated into the α-methylene group of **1** recovered and into the methyl group of **3** produced.

Kinetics. Kinetic studies were undertaken in the temperature range from 200 to 280 °C. In methanol, the esters were recovered in good yield even after prolonged heating. The reaction was unaffected by the presence of hydroquinone. The first-order rate constants for the disappearance of **1**, **2**, and **3** were measured at appropriate temperature. The results are listed in Table 4. It should be noted that the initial rate constants, k, obtained from an analysis using first-order kinetics (the sum of the rate constants for the forward and reverse reactions) do not differ markedly from the rate constants, k', obtained on the basis of equilibrium kinetics[10] (the rate constants for the forward reaction only). The linearity of $\ln[C]_0/[C]$ plotted against time was observed up to a conversion of about 30%. The Arrhenius plot for the rate of disappearance of **1** was correctly linear (r=0.995), from which ΔH^* and ΔS^* were calculated to be 77.8 kJ mol^{-1} and 184 J K^{-1} mol^{-1}, respectively.

Table 4. Temperature dependence of the rate constants for the disappearance of the esters[a]

Starting ester	Temp,[b] °C	Rate constant	
		$k \times 10^5$ s^{-1} [c]	$k' \times 10^5$ s^{-1} [d]
1	200	0.228	
1	230	0.984	
1	250	1.58	1.76
1	280	4.96	
3	250	1.50	1.35
2	250	1.14	1.15

a) Ester, 0.3 g; methanol, 0.6 g. b) ±1 °C. c) The error in k is expected to be in the range of 5—10%. d) First-order rate constants calculated for equilibrium systems.[10]

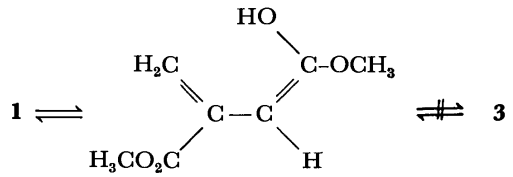
Discussion

The equilibrium composition of the esters is completely different from that of the corresponding acids, for which methylenesuccinic and mesaconic acids are the most and the least abundant materials, respectively.[1] This fact appears to indicate that the factor which governs the relative stability of the esters in equilibrium is different from that for free acids.

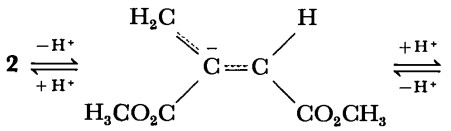
A free-radical mechanism may be disregarded in the rearrangement of the esters, because the addition of iodine as a radical source accelerated isomerization at

low temperature (200 °C), whereas little rearrangement occurred. In addition, it was found that hydroquinone affected neither the equilibrium composition nor the rate constants.

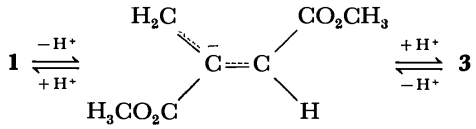
For thermal rearrangement of unsaturated esters, a mechanism has been proposed which involves enolization followed by the intramolecular rearrangement of the enol-proton to the terminal methylene group.[4] However, an inspection of the Dreiding model of enol-methylenesuccinate, a possible common intermediate of the rearrangement, reveals that the orbital of the terminal methylene is not arranged in a position suitable for accepting the enol-proton intramolecularly. In the reverse process, the intramolecular abstraction of a methyl-proton in **3** by the carbonyl-oxygen must produce a twisted enolate of **1**, in which conjugative stabilization of diene is hardly conceivable. Thus, from a consideration of the orbital arrangement, it is predicted that cyclic intramolecular process for the rearrangement is unfavorable.



Consequently, another plausible mechanism is the intervention of a carbanion, which has been proposed for the corresponding free acids:[1]



4



5

The rate-determining reaction for the formation of carbanions, **4** and **5**, under the general-base catalysis of methanol, is supported by the facile hydrogen-deuterium exchange at the position expected for these species and by first-order kinetics for the rearrangement of the esters. If the reaction proceeds for the carbonium ion under the general-acid catalysis of methanol, the protons of the terminal methylene group in **1** must be replaced by deuterium atoms faster than those of the α-methylene group, because protonation to **1** is expected to take place at the terminal methylene group. Similarly, for general-acid catalysis, the α-methylene protons in **1** formed should be replaced by deuteriums faster than the methyl protons in **3**. This is, however, is not the case. The general-base catalysis of methanol is also confirmed by preliminary results for triethylamine-catalyzed reactions of the esters.[11] Since it was observed that the addition of triethylamine accelerated both the rearrangements of **1** and **3**, the mechanism involving carbanion intermediates is the more reasonable for this reaction. Furthermore, the formation of **1** from **2** is not interpreted using the intramolecular mechanism. Once again the intramolecular mechanism appears doubtful.

The fact that the thermodynamically least-stable ester (**2**) has the smallest rate constant is compatible with the carbanion mechanism. The rate for the formation of **2** is slower than that of **3**, because carbanion **5** is more stable than **4**. It is interesting to note that **1** predominated over **3** at the initial stage of the rearrangement of **2**. Direct interconversion between carbanions, **4** and **5**, may be negligible, since the rate constant for the disappearance of **1** is larger than that of **3** and since **1** is less abundant than **3** at equilibrium. The above results show that it is unreasonable to expect facile direct isomerization between **2** and **3**.[12]

The difference between the compositions resulting from the rearrangement of the free acids and the rearrangement of the esters is accounted for as follows. Equilibrium between citraconic and methylenesuccinic acids is interpreted using the intermediate *cis*-carbanion, whose configuration is fixed by intramolecular hydrogen bonding.[1] However, the esters are free from intramolecular hydrogen bonding and the *trans*-carbanion favors the rearrangement of the esters. Consequently, **3** appears as the most abundant product.

The author wishes to thank Professor Emeritus Sango Kunichika of Kyoto University for his encouragement throughout this work. He is also grateful to Professors Shinzaburo Oka, Norito Uchino, Yasumasa Sakakibara, and Atsuyoshi Ohno for their continuous guidance and helpful discussions.

ESR Study on the Photoreduction of *N*-Acetyldiphenylmethyleneamine in 2-Propanol

Naoki Toshima, Kyoji Aoki, and Hidefumi Hirai

Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received November 27, 1976)

Photoreduction of *N*-Acetyldiphenylmethyleneamine (**1**) in 2-propanol was studied both by the ESR spectroscopy of irradiated imine **1** in a matrix solvent at −196 °C and by the deuteration analysis of acetone formed from 2-propanol-*d* in the photoreduction process. The ESR spectrum consists of a broad singlet and a quartet. The latter is assigned to the $CH_3\dot{C}H(OH)CH_2$ radical, which can be produced by β-hydrogen abstraction by the excited imine **1** from 2-propanol, but not by the excited benzophenone. Formation of acetone-*d* on irradiation of **1** in 2-propanol-*d* suggests that the imine **1** in the excited state has a hydrogen abstracting character.

When acyclic imino compounds are irradiated in 2-propanol, a C=N bond is reduced to a –CH–NH– group. This photoreduction has been studied on various derivatives as one of the fundamental photoreactions of a C=N chromophore.[1–5] Two reaction mechanisms are proposed for this photoreduction. One is the "chemical sensitization" mechanism.[3] According to this mechanism, the reaction proceeds *via* an aminoalkyl radical formed by thermal hydrogen transfer from a ketyl radical to the imine. The ketyl radical is derived from the excited triplet state of the corresponding ketone present in the starting imine as an impurity. The other is the mechanism where imine itself has a hydrogen abstracting character in the excited state.[4,5]

We have reported that the irradiation of *N*-acetyldiphenylmethyleneamine (**1**) in 2-propanol gives the amide derivative and that only the C=N bond is selectively reduced.[4]

$$Ph_2C{=}NCOCH_3 + (CH_3)_2CHOH \quad (\mathbf{1})$$
$$\xrightarrow{h\nu} Ph_2CHNHCOCH_3 + (CH_3)_2C{=}O$$

In order to decide which mechanism is reasonable in this reaction, it seems important to compare the photoreaction of the imine **1** with that of benzophenone. The reaction proceeds in a radical fashion, whichever mechanism is adopted. So we have investigated this reaction by an ESR technique to detect the intermediate radical of the reaction.

Experimental

Materials. 2-Propanol was refluxed on anhydrous barium oxide and distilled. Acetonitrile was used after distillation. 2-Propanol-*d* was obtained from E. Merck Japan Ltd. Benzophenone was recrystallized from ethanol. *N*-Acetyldiphenylmethyleneamine (**1**), bp 170—172 °C/3 Torr (lit,[6] bp 168—170 °C/1 Torr) and *N*-propionyldiphenylmethyleneamine (**2**), mp 79.3—79.9 °C (lit,[6] mp 78—79.5 °C), were prepared by the reaction of diphenylmethyleneamine with acetic anhydride and propionic anhydride, respectively, and purified before use.

ESR Measurement. A solution of imine (*ca.* 250 mg) in a solvent (1 ml) was poured into an ESR tube and was degassed in four successive freeze-thaw cycles. The sealed sample tube in a transparent qaurtz Dewar bottle filled with liquid nitrogen was set in a cavity. UV light was irradiated from outside and ESR spectra were measured by using a JEOL 3BS-X type spectrometer. All irradiations were carried out with an Ushio type 500D ultrahigh pressure mercury lamp through a glass filter transparent to wavelengths longer than 320 nm. The field modulation was 100 kHz, and modulation width was 5.3 gauss during ESR measurements. *g*-Factors and hyperfine coupling constants were corrected by using a Mn^{2+} marker.

*Photoreaction of the Imine in 2-Propanol-*d. One gram of imine **1** was dissolved in 5 ml of 2-propanol-*d* in a quartz tube. Irradiation was carried out at room temperature or at −196 °C for 20 h in a similar manner as described in ESR measurements. A 2-propanol-*d* (5 ml) solution of benzophenone (260 mg) was also irradiated for 5 h at room temperature. After irradiation, the solvent was separated by vacuum distillation and mass spectra of acetone produced were measured by a Hitachi M-52 type GC-MS analyzer. The deuteration degree of the acetone was calculated from the base peak of the mass spectrum.

Results

ESR Measurements. On irradiation of imine **1** in 2-propanol at −196 °C, stable five lines were observed in an ESR spectrum as shown in Fig. 1A. When the system was warmed up to −154 °C, a broad single line remained and other four lines disappeared (Fig. 1B). The absorption and the second derivative type spectra of Fig. 1A are shown in Fig. 2A and 2B, respectively. The former indicates the intensity ratio of four lines to be *ca.* 1 : 3 : 3 : 1, and the latter indicates that four lines have the same splitting constant of 23.2 G

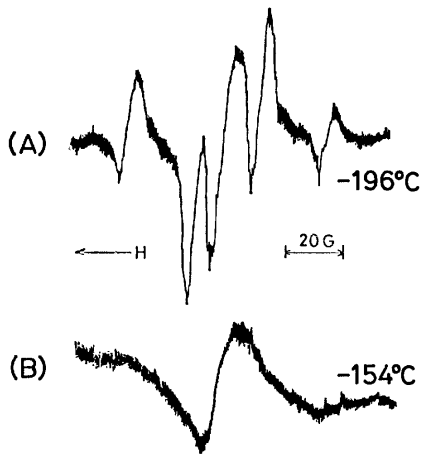

Fig. 1. ESR spectra (First Derivatives) of UV-irradiated *N*-acetyldiphenylmethyleneamine (**1**) in 2-propanol at (A) −196 °C and (B) −154 °C. Irradiations were carried out at −196 °C for 20 min.

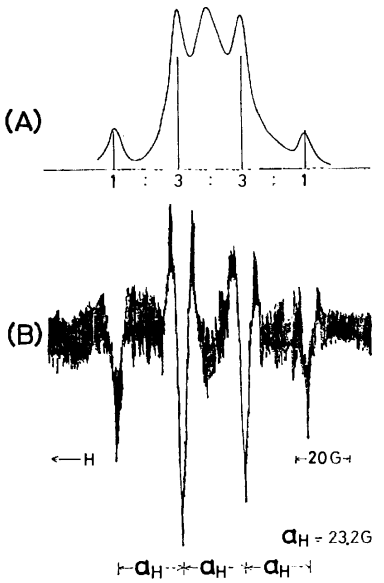

Fig. 2. Absorption (A) and 2nd derivative (B) of ESR spectra of UV-irradiated *N*-acetyldiphenylmethyleneamine (**1**) in 2-propanol at −196 °C.

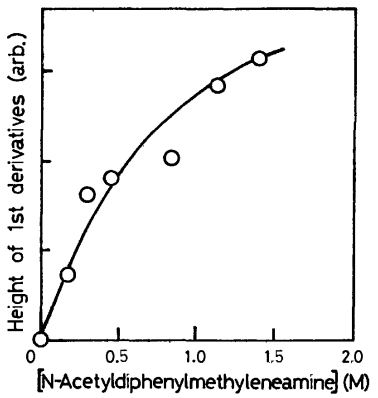

Fig. 3. Dependence of quartet intensity on the *N*-acetyldiphenylmethyleneamine (**1**) concentration. Samples of 2-propanol solution were UV-irradiated for 30 min at −196 °C with constant concentration of benzophenone (0.48 mol/l).

When *N*-propionyldiphenylmethyleneamine (**2**) was used instead of **1**, the ESR spectra of the solution gave the same signal.[7] A central singlet was broad in all cases and have no special relation to the quartet in intensity. The parameters of these ESR spectra are given in Table 1. The dependence of the intensities of a quartet upon the concentration of the imine **1** was investigated. The experiment was carried out with the constant concentration of benzophenone at each point. The heights of the outer lines of the quartet noticeably increased with the concentration of **1** as shown in Fig. 3.

*Photoreaction of Imine **1** in 2-Propanol*-d. In order to detect the position of hydrogens abstracted in 2-propanol, the deuteration degree of acetone was investigated. Acetone is formed from 2-propanol during the photoreaction of **1**. The results are shown in Table 2. The deuteration degree was small when benzophenone was used as a substrate, but relatively high when imine **1** was used .

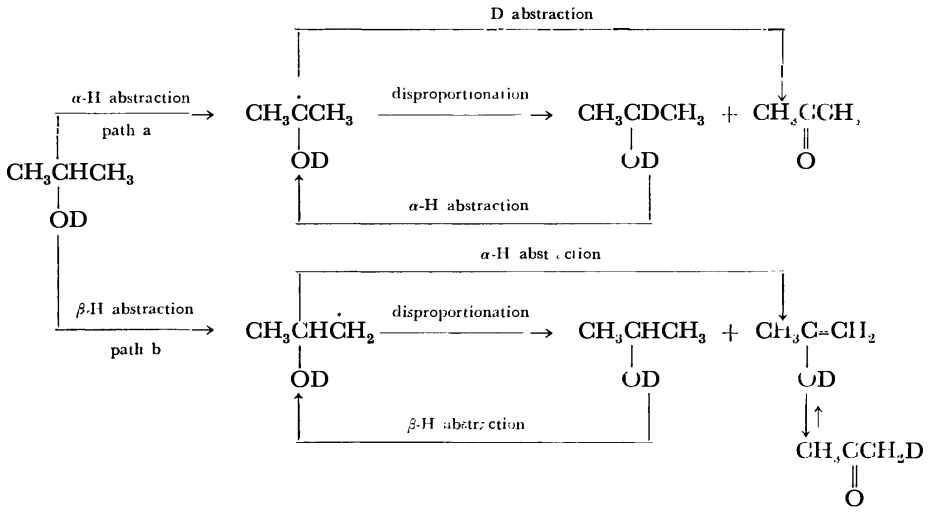
Table 2. Deuteration degrees of acetone formed by the photoreductions in 2-propanol-*d*

Substrate	Temperature	Deuteration degree of acetone (%)
Benzophenone	Room temperature	≈ 5
Imine **1**	Room temperature	≈ 15
Imine **1**	−196 °C	≈ 21

Discussion

Assignment of ESR Signals. From the temperature dependence of signals as shown in Fig. 1, it is concluded that the five lines observed on irradiation at −196 °C consist of a broad singlet and a quartet. A quartet is not due to the radical from imine because both ESR spectra from imine **1** and imine **2** show the same patterns (*cf.* Table 1, Runs A and C). As an acetonitrile solution of imines gives no quartet, the quartet is not due to a radical from acetonitrile either. Furthermore, quite different signals were observed when other alcohols than 2-propanol were used as a solvent. From these experimental facts, the quartet is attributed to a radical from 2-propanol used as a solvent. As regards 2-propanol radicals, the ESR spectra of two radicals have been reported.[8] One is an α-hydroxy radical $(CH_3)_2\dot{C}OH$ which is formed by α-hydrogen abstraction from 2-propanol with Fenton's reagent, and shows a septet signal with intensity ratio of 1 : 6 : 15 : 20 : 15 : 6 : 1 and a_H of 19.5 G. The other is a β-hydroxy radical $CH_3\dot{C}H(OH)CH_2$ by β-hydrogen abstraction and this radical shows a quartet signal with intensity ratio 1 : 3 : 3 : 1 and a_H of 22.5 G. Comparison of the experimental values (Table 1) with these reported values clearly indicates that the quartet observed in the present experiment is due to the radical $CH_3\dot{C}H(OH)CH_2$.

As regards a broad singlet, it may be attributed to



Scheme 1.

a mixed signal composed of $Ph_2\dot{C}NHCOCH_3$ from imine **1** and benzophenone ketyl radical from benzophenone as an impurity of **1**. Thus it is reported that the ESR spectra of both the ketyl radical[9] from benzophenone and the aminoalkyl radical $Ph_2\dot{C}NH_2$,[2] analogous to the radical $Ph_2\dot{C}NHCOCH_3$, were observed not to split by the coupling with the adjacent nitrogen atom and showed a broad singlet with the similar *g*-values on irradiation in a matrix solvent at a low temperature (ΔH_{msl} values of both radicals are 14 and 18 G, respectively). As the acetyl group of $Ph_2\dot{C}NHCOCH_3$ can be supposed not to effect also to the hyperfine structure of the radical in a rigid matrix, it is reasonable that $Ph_2\dot{C}NHCOCH_3$ shows a signal not so different from that of $Ph_2\dot{C}NH_2$. Therefore it is conceivable that the observed singlet is due to the mixed signal of radicals $Ph_2\dot{C}OH$ and $Ph_2\dot{C}NHCOCH_3$.

Reaction Processes. The ESR studies show the formation of the β-hydroxy radical $CH_3CH(OH)\dot{C}H_2$ on irradiation of imine **1** in 2-propanol in a rigid matrix at −196 °C. In the photoreduction of imine **1** in 2-propanol at low temperature, however, only acetone was produced from 2-propanol quantitatively, and no 2,5-hexanediol, a coupling product of the β-hydroxy radical, was detected. In order to satisfy the both facts, acetone must be formed from 2-propanol through the path b of Scheme 1. Contribution of both paths a and b to the reaction can be determined by product analysis when 2-propanol-*d* is used in the present photoreduction instead of 2-propanol.

The results show that the deuteration degree of acetone produced is low (5%) in the case of benzophenone which is recognized generally to abstract α-hydrogen of 2-propanol. In the case of the imine **1**, however, the deuteration degree is 15% when irradiation was carried out at room temperature, and 21% at −196 °C. As these values are apparently higher than that in the case of benzophenone, β-hydrogen abstraction from 2-propanol occurs more frequently in the photoreduction of the imine **1** in 2-propanol than that of benzophenone in 2-propanol.

As shown in Fig. 3, the quartet intensity of the β-hydroxy radical increased with the concentration of the imine **1**, and became zero when the concentration of the imine **1** was zero though benzophenone was exist in the solution. Since the concentration of benzophenone was equal at each point, it can be concluded that the $CH_3CH(OH)\dot{C}H_2$ radical is formed through the hydrogen abstraction from 2-propanol by the imine **1**. This conclusion is supported by the following experimental result. Thus, when the ESR spectrum of a 2-propanol solution of benzophenone was measured under irradiation in a matrix at −196 °C, the quartet due to $CH_3CH(OH)\dot{C}H_2$ was not observed, but weak outer bands of septet due to $(CH_3)_2\dot{C}OH$ and a strong broad singlet due to benzophenone ketyl radical were obtained. It is not clear why the imine **1** abstracts β-hydrogen from 2-propanol, but one of the reasons might be the specific interaction between the imine **1** and 2-propanol as a Fenton's reagent generally abstracts ω-hydrogen of alcohols.[8] It can be concluded that not the excited benzophenone, but the excited imine **1** abstracts β-hydrogen from 2-propanol especially in the photoreduction of imine **1** in 2-propanol. Namely the imine **1** in the excited state has a great deal to do with the photoreduction in contrast with the chemical sensitization mechanism.[3]

ESR Studies of the g- and D-Tensor Values of Stable *p*- and *m*-Phenylenebis(galvinoxyl) Biradicals

Kazuo MUKAI and Toshiko TAMAKI

Department of Chemistry, Faculty of Science, Ehime University, Matsuyama 790

(Received July 23, 1976)

The **g**- and **D**-tensor values of *p*- and *m*-phenylenebis(galvinoxyl) biradicals in several solvents have been determined from their asymmetric frozen ESR spectra. The spectra suggested that only one conformer out of two possible ones, "*propeller*" and "*anti-propeller*" structures, exists in each biradical. The **D**-tensor values were calculated for the two possible conformers, based on assumed molecular structures and spin distribution. The results indicate that the "*propeller*" structure with a 30° twist angle is preferable for the *m*-phenylenebis(galvinoxyl). In the case of the *p*-phenylenebis(galvinoxyl), a considerable accordance between the measured and calculated values for the two conformers with a 30° twist angle was obtained. Notable solvent effects in the **g**- and **D**-tensor values were observed for the *m*-phenylenebis(galvinoxyl), but not for the *p*-phenylenebis(galvinoxyl).

Recently, one of the present authors has reported the preparation of *p*- and *m*-phenylenebis(galvinoxyl) biradicals, (I) and (II), which are fairly stable phenoxyl biradicals; their structures are shown in Fig. 1.[1] The biradicals were produced by the PbO_2 oxidation of phenol precursors in 2-methyltetrahydrofuran (2-MTHF) under a vacuum. The fluid solution ESR spectra of the biradicals consist of nine lines due to eight equivalent meta-ring protons. Gierke *et al.* also obtained the biradicals from different phenol precursors by PbO_2 oxidation.[2] ESR zero-field splittings in rigid media at 77 K were observed, indicating the existence of the triplet state in the biradicals. However, no detailed analyses of the ESR spectra of the biradicals have been reported, although various types of information about the conformation, symmetry, and electronic state of triplet molecules have been obtained from the rigid matrix ESR spectra.[3-7]

In the present paper, the **g**- and **D**-tensor values of *p*- and *m*-phenylenebis(galvinoxyl) biradicals (I and II) in several solvents have been determined from their asymmetric frozen ESR spectra. The **D**-tensor values were calculated for two possible conformers in each biradical, based on the assumed molecular structures and spin distribution. On the basis of these data, the conformation and electronic structure of the biradicals and the solvent effect have been discussed. The hyperfine splittings of many stable hindered phenoxyl radicals, including several biradicals, have been studied by a number of investigators with the aid of the ESR spectra.[8] However, the **g**- and **D**-tensor values of these phenoxyl radicals have never been reported, as far as we know.

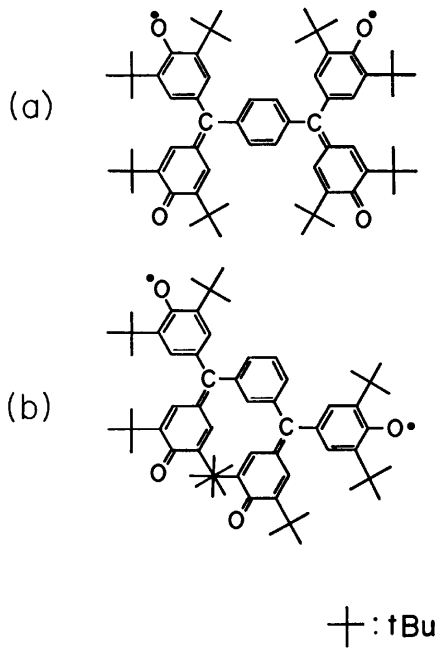

Fig. 1. Molecular structures of (a) *p*-phenylenebis(galvinoxyl) biradical (I) and (b) *m*-phenylenebis(galvinoxyl) biradical (II).

Experimental

The syntheses of *p*-bis[bis(3,5-di-*t*-butyl-4-hydroxyphenyl)-methyl]benzene (mp 290—292 °C) and *m*-bis[bis(3,5-di-*t*-butyl-4-hydroxyphenyl)methyl]benzene (mp 223—224 °C) were reported previously.[1] The *p*- and *m*-phenylenebis(galvinoxyl) biradicals (I and II) were prepared by the oxidation of the above phenol precursors with PbO_2 in the 2-MTHF solvent under a nitrogen atmosphere, with the temperature kept between 5 and 10 °C, following the method of Kharash and Joshi.[9]

All the ESR measurements were carried out using a JES-ME-3X spectrometer equipped with a Takeda-Riken microwave frequency counter. The ESR splittings were determined using $(KSO_3)_2NO$ ($a^N = 13.05 \pm 0.03$ G) as a standard. The *g*-values were measured relative to the value of Li-TCNQ powder, calibrated with $(KSO_3)_2NO$ ($g = 2.0054$).[10]

Results and Discussion

ESR Spectral Analyses. The 2-MTHF solution spectra of the *p*- and *m*-phenylenebis(galvinoxyl) radicals (I and II) show nine line hyperfine splittings due to the equivalent eight *meta*-ring protons in the two galvinoxyl rings, as has been reported previously.[1] The spectra were ascribed to a biradical whose exchange energy, J, is larger than the proton coupling constant, a_m^H ($J \gg a_m^H$; $a_m^H/2 = 0.69$ G for I and II). When the solution containing the I and II biradicals is frozen into a rigid glass (77 K), one can observe some dipolar splittings, as Figs. 2 and 3 show.

The biradical in a rigid glass can be treated as a two-spin system which forms a triplet and a singlet state. The usual spin Hamiltonian[3,6] for the triplet state is:

$$H = \beta \mathbf{H} \cdot \hat{\mathbf{g}} \cdot \mathbf{S} + \mathbf{S} \cdot \hat{\mathbf{D}} \cdot \mathbf{S}, \quad (1)$$

where $\hat{\mathbf{g}}$ is the **g** tensor, $\hat{\mathbf{D}}$ is the spin-spin dipolar interaction tensor, and the other symbols have the usual meanings. When the radical has the property of a triplet without axial symmetry, we usually observe three pairs of absorption lines, from whose separations the zero-field parameters (D and E) of the dipolar electron-electron interaction can be obtained.[3,6,7] The spectrum of the I biradical can be explained as two inner pairs of lines overlapping each other, because of the small distances between zero-field absorption lines compared with the line-width of each absorption line. In the spectrum, the high-field line of the inner pair of lines is broader than the other and has a shoulder, suggesting the overlapping of two lines. A central line at $g=2$ is attributable to the monoradical impurity. In fact, in the case of the II biradical, five out of six lines

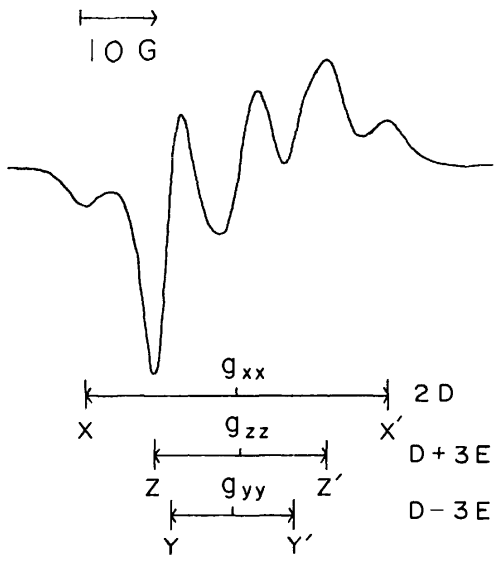

Fig. 2. ESR spectrum of the biradical (I) in 2-MTHF at 77 K.

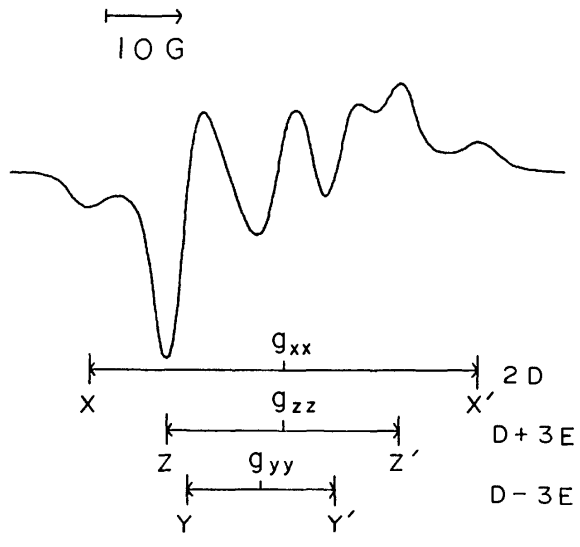

Fig. 3. ESR spectrum of the biradical (II) in 2-MTHF at 77 K.

theoretically expected for a non-axially symmetrical triplet are resolved, as is shown in Fig. 3.

In both the biradicals (I and II), the zero-field parameters (D and E) and the **g**-tensor values have been estimated from the positions of three pairs of turning points (XX', YY', and ZZ'), which are shown in Figs. 2 and 3, in the following way. The separation between the outer pair of lines (XX') in the spectrum of the I biradical is $2D=40.0\pm0.4$ G. Because of the localization of each unpaired electron on two galvinoxyl rings, as will be discussed later, the principal X axis of the **D** tensor, corresponding to the maximum value of $2D$, is probably parallel to the line connecting two carbon atoms bonded to the centered phenylene ring. Because of the symmetry of the biradical molecules, we can expect that the principal axes of the **D** and **g** tensors are coaxial. Consequently, the frequency center of these lines gives $g_{xx}=2.0045\pm0.0002$. The remaining pairs, ZZ' and YY', are separated by $(D+3E)=22.7\pm0.6$ G and $(D-3E)=16.0\pm0.6$ G respectively. Although, because of overlapping lines, this distance cannot be measured accurately, the value of $D=19.4\pm0.6$ G shows a considerable accordance with the value ($D=20.0\pm0.2$ G) from two external lines; thus, the E value was estimated to be $E=1.1\pm0.2$ G. The g-values from the frequency center of these two pairs of absorption lines are $g_1=2.0043\pm0.0002$ (ZZ') and $g_2=2.0049\pm0.0002$ (YY'). By comparing g_1 and g_2, the smaller, $g_1=2.0043$, was tentatively assigned to g_{zz}, and the larger, $g_2=2.0049$, to g_{yy}, as will be discussed later.* The isotropic g_{iso} value of the I biradical was measured in 2-MTHF at room temperature. The average g_{av} value of $(1/3)(g_{xx}+g_{yy}+g_{zz})=2.0045\pm0.0002$ is in agreement with the isotropic $g_{iso}=2.00441\pm0.00003$ value measured at room temperature, indicating that the **g**-tensor values obtained by the above analysis are reliable. All these values are summarized in Table 1. Similar analyses were performed for the frozen solution ESR spectrum of the II biradical in 2-MTHF. The **D**- and **g**-tensor values obtained are $D=26.1\pm0.2$ G, $E=1.9\pm0.2$ G, and $g_{xx}=2.0039\pm0.0002$, $g_{yy}=2.0056\pm0.0002$, $g_{zz}=2.0038\pm0.0002$, respectively. The average g_{av} value of $(1/3)(g_{xx}+g_{yy}+g_{zz})=2.0044\pm0.0002$ is in agreement with the isotropic $g_{iso}=2.00443\pm0.00003$ value measured in 2-MTHF at room temperature. The **D**- and **g**-tensor values obtained are listed in Table 2. Both the D and E values of the II biradical are larger than those of the I biradical.

The shift of the g value from that ($g_e=2.0023$) of the free electron is determined mainly by spin-orbit coupling, which may be large because of the presence of the nonbonding σ electrons of the oxygen atom. The energy due to the so-called n-π transitions may be low

* This assignment was also supported by the calculations of the dipolar splitting parameters, D and E, as will be described below. The values of the D and E parameters calculated for both the "*propeller*" and "*anti-propeller*" structures of *p*-phenylenebis(galvinoxyl) biradical are negative and positive respectively. Therefore, $D_{zz}>D_{yy}>0$, where D_{zz} and D_{yy} are the principal values of the **D**-tensor; thus, the smaller, $g_1=2.0043$, is attributable to g_{zz}.[3]

Table 1. **g**- and **D**-tensor values of the *p*-phenylenebis(galvinoxyl) biradical

Solvent	$\|D\|$[a] (G)	$\|E\|$[a] (G)	g_{xx}[b]	g_{yy}	g_{zz}	g_{av}[c]	g_{iso}[d]
2-MTHF	20.0	1.1	2.0045	2.0049	2.0043	2.0045	2.00441
Toluene	19.8	1.0	2.0044	2.0048	2.0042	2.0044	2.00443
Ethyl alcohol	19.9	1.2	2.0045	2.0049	2.0040	2.0045	2.00440
Diethyl ether	20.0	1.2	2.0045	2.0047	2.0039	2.0044	2.00441

a) The experimental errors in the values of $|D|$ and $|E|$ are ±0.2 G. b) The experimental errors in the values of g_{xx}, g_{yy}, g_{zz}, and g_{av} are ±0.0002. c) The average $g_{av}=(1/3)(g_{xx}+g_{yy}+g_{zz})$. d) The experimental errors in the values of g_{iso} are ±0.00003.

Table 2. **g**- and **D**-tensor values of the *m*-phenylenebis(galvinoxyl) biradical

Solvent	$\|D\|$[a] (G)	$\|E\|$[a] (G)	g_{xx}[b]	g_{yy}	g_{zz}	g_{av}[c]	g_{iso}[d]
2-MTHF	26.1	1.9	2.0039	2.0056	2.0038	2.0044	2.00443
Toluene	21.9	1.5	2.0043	2.0055	2.0039	2.0046	2.00441
Ethyl alcohol	26.0	1.9	2.0038	2.0054	2.0039	2.0044	2.00434
Diethyl ether	26.9	1.8	2.0039	2.0057	2.0041	2.0046	2.00441

a) The experimental errors in the values of $|D|$ and $|E|$ are ±0.2 G. b) The experimental errors in the values of g_{xx}, g_{yy}, g_{zz}, and g_{av} are ±0.0002. c) The average $g_{av}=(1/3)(g_{xx}+g_{yy}+g_{zz})$. d) The experimental errors in the values of g_{iso} are ±0.00003.

in these systems; therefore, these transitions contribute strongly to the shift in the g value.[11,12] However, in the planar aromatic radicals the contribution to the g_{zz} value (perpendicular to the molecular plane) from the n-π transitions vanishes. Therefore, the value of g_{zz} should be close to the free-spin value, while g_{xx} and g_{yy} are larger than g_e. In the *p*-phenylenebis(galvinoxyl) radical, the **g**-tensor values estimated from the frozen-solution spectrum are $g_{xx}=2.0045\pm0.0002$, $g_1=2.0043\pm0.0002$, and $g_2=2.0049\pm0.0002$. By comparing g_1 and g_2, the smaller g_1 was tentatively assigned to g_{zz}, and the larger g_2, to g_{yy}. Similarly, the **g**-tensor values of the *m*-phenylenebis(galvinoxyl) radical are $g_{xx}=2.0039\pm0.0002$, $g_{yy}=2.0056\pm0.0002$, and $g_{zz}=2.0038\pm0.0002$. The g_{zz} values of both biradicals show a large deviation from that of the free electron. This is mainly due to the nonplanar character of the I and II biradicals.

D-*Tensor Calculation with Spin Densities.* In order to clarify the molecular structures of the *p*- and *m*-phenylenebis(galvinoxyl) biradicals, and in order to determine the directions of the principal axes, X_d, Y_d, and Z_d, of the **D**-tensor in the molecules, the calculations of the dipolar splitting tensors were performed for two possible conformers in each biradical, based on the assumed molecular structures and spin distribution.

p- And *m*-phenylenebis(galvinoxyl)s (I and II) are thought to be weakly π-conjugated biradicals because of the small spin density on the central phenylene ring. The orbital containing the unpaired electron of phenylgalvinoxyl radical has, at least in the Hückel approximation, a node in the phenyl ring; in fact, a recent ENDOR study found a small hyperfine splitting ($a^H=0.207$ G) for phenyl-ring protons.[13] In such a case, the electronic structures of the two galvinoxyl rings in these biradicals must be similar to that of the phenylgalvinoxyl. The isotropic g_{iso} values also show an excellent agreement between the phenylgalvinoxyl ($g_{iso}=2.00440\pm0.00003$), the I biradical ($g_{iso}=2.00441\pm0.00003$), and the II biradical ($g_{iso}=2.00443\pm0.00003$), supporting the above anticipation. Therefore, the dipolar magnetic system of the I and II biradicals can be adequately described as an isolated two-spin system consisting of two galvinoxyl groups, each containing one unpaired electron.

The phenylgalvinoxyl radical may, on the other hand, be considered a triphenylmethyl derivative. A molecular model indicates that the main steric interaction in phenylgalvinoxyl works between the ring protons, although weak interactions can be seen between the substituted tertiary butyl groups. Thus, the radical probably adopts a propeller configuration, the twist angle of phenyl rings being estimated to be about 30° about the methyl bond.[14] The *p*-phenylenebis(galvinoxyl) radical will have a similar configuration. Because the steric interactions between the substituted tertiary butyl groups of the two galvinoxyl rings are considered to be weak (see Fig. 1), the twist angle of phenyl rings about the methyl bond will still be about 30°. Consequently, we can expect two possible conformations, (A) and (B), in *p*-phenylenebis(galvinoxyl), in which each monoradical half is considered to have a propeller configuration. In the (A) conformation, the two $2p_z$ orbitals of two triphenylmethyl carbon atoms twist by 60° each other, while in the (B) conformation, the two $2p_z$ orbitals are parallel to each other, having a 30° twist angle to the π-orbital of the centered phenylene ring. These two conformations, (A) and (B), are shown in Fig. 4 and are named as "*propeller*" and "*anti-propeller*" structures, considering the figure as a whole molecule. Similarly, two conformations can be expected in *m*-phenylenebis(galvinoxyl). However, the Stuart molecular model indicates that the "*anti-propeller*" structure is not probable in this radical because of the strong steric interaction between two galvinoxyl rings, especially through nearest-neighboring tertiary butyl groups (see Fig. 1(b)); thus, only the "*propeller*" structure is probable (see Fig. 5).

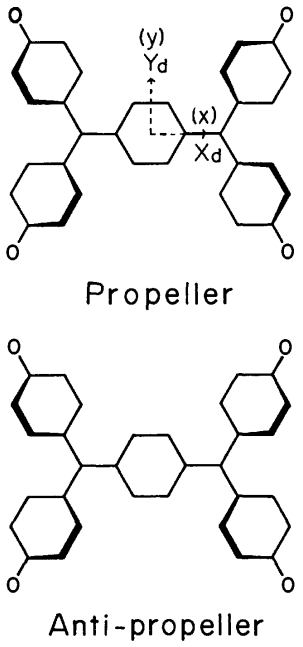

Fig. 4. "*Propeller*" and "*anti-propeller*" structures of *p*-phenylenebis(galvinoxyl) biradical, showing the molecular axes x, y, and z and the principal axes X_d, Y_d, and Z_d of the **D**-tensor.

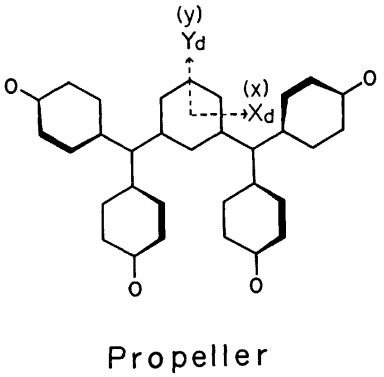

Fig. 5. "*Propeller*" structure of *m*-phenylenebis(galvinoxyl) biradical, showing the molecular axes x, y, and z and the principal axes X_d, Y_d, and Z_d of the **D**-tensor.

In the "*propeller*" structure of the I and II biradicals, to achieve symmetry, the molecular z axis is chosen perpendicular to the central phenylene ring, while the x axis parallels a line connecting the two carbon atoms bonded to the central phenylene ring. On the other hand, in the "*anti-propeller*" structure of the I biradical, while the x axis is chosen similarly, the z axis is chosen perpendicular to a plane containing four oxygen atoms. We assumed that the principal axes—X_d, Y_d, and Z_d of the **D**-tensor are parallel to the molecular axes—x, y, and z, because of the symmetry of the biradical molecules, as is shown in Figs. 4 and 5. This is a favorable situation for calculating the **D**-tensor values, because, in such a case, the matrix of the **D**-tensor can be diagonalized. Therefore, the D and E parameters of the dipolar splitting can be calculated with the aid of the following equations:[15-17]

$$D = \frac{3}{4} g_{iso}^2 \beta^2 \sum_{i,j} \frac{r_{ij}^2 - 3x_{ij}^2}{r_{ij}^5} \rho_i \rho_j \tag{2}$$

$$E = \frac{3}{4} g_{iso}^2 \beta^2 \sum_{i,j} \frac{y_{ij}^2 - z_{ij}^2}{r_{ij}^5} \rho_i \rho_j \tag{3}$$

where r_{ij} is the distance between the i and j atoms and where ρ_i and ρ_j are the π-spin densities on the i atom in one galvinoxyl group and on the j atom in the other galvinoxyl group in a molecule. Here we have chosen the following parameters: the twist angle of each phenyl ring to the $2p_z$ orbitals of the two triphenylmethyl carbon atoms is 30°, as has been described above; the C–O bond length is 1.27 Å, and the C–C bond length is 1.40 Å in the average, as obtained by an X-ray analysis of the galvinoxyl radical;[18] the McLachlan spin densities were taken from Ref. 13.

Using these parameters, the calculations of the D and E values were performed for two possible conformations, the "*propeller*" and "*anti-propeller*" structures, of the I biradical, and one possible conformation, the "*propeller*" structure, of the II biradical. The results are summarized in Table 3, together with those obtained experimentally in the 2-MTHF solvent. For the I biradical, the calculated D and E parameters are 18.0 and 0.6 G for the "*propeller*" structure, and 21.7 and 1.7 G for the "*anti-propeller*" structure, while the observed ones are 20.0 and 1.1 G in 2-MTHF respectively. For the II biradical, the calculated D and E values are 27.0 and 1.3 G for the "*propeller*" structure, while the observed ones are 26.1 and 1.9 G in 2-MTHF respectively. The *p*- and *m*-phenylenebis(galvinoxyl) biradicals (I and II) are thought to be weakly π-conjugated biradicals, with a twist angle of the phenyl rings of about 30°. Therefore, the calculations of the D and E parameters were performed by assuming that the I and II biradicals consist of isolated two galvinoxyl groups, each containing one unpaired electron, as has been described above. The considerable accordance between calculated and observed values indicates that the above assumptions for the electronic structure and the twist angle of the I and II biradicals are reliable. The results also suggest that the principal X_d axis of the **D** tensor, corresponding to the maximum $2D$ value, is parallel to the molecular x axis; this is consistent with our expectations.

TABLE 3. THE D AND E PARAMETERS (IN G) OF THE DIPOLAR SPLITTING CALCULATED FOR THE "*propeller*," "*anti-propeller*," AND "*planar*" STRUCTURES OF THE *p*- AND *m*-PHENYLENEBIS(GALVINOXYL) BIRADICALS (I AND II)

	I Biradical		II Biradical	
	$\|D\|$ (G)	$\|E\|$ (G)	$\|D\|$ (G)	$\|E\|$ (G)
Propeller	18.0	0.6	27.0	1.3
Anti-propeller	21.7	1.7	—	—
Planar	22.3	1.9	94.2	4.5
Experimental[a]	20.0	1.1	26.1	1.9

a) **D**-tensor values measured in 2-MTHF at 77 K.

The frozen-solution ESR spectrum of the I biradical in 2-MTHF (see Fig. 2) suggests that only one conformer exists in the biradical; if two conformers exist in the I biradical at the same time, we should, at least, observe a splitting in the X and/or X' absorption lines, as the results of the calculation of the D and E parameters indicate. Unfortunately, it is not possible to decide whether the I biradical molecule takes a "*propeller*" or an "*anti-propeller*" structure, because both the D and E values experimentally obtained are just the medium ones of those calculated for the two assumed conformers. By comparing the **g**-tensor values of the biradicals with those of the monoradicals, the conformations of some nitroxide biradicals have been determined recently.[5,6] The **g**-tensor values of phenoxyl monoradicals including galvinoxyl and the phenylgalvinoxyl radical have not been reported, though, as far as we know. Therefore, we can not utilize the observed **g**-tensor values of the I biradical in order to determine the conformation of the radical. The frozen-solution ESR spectrum of the II biradical in 2-MTHF (see Fig. 3) also indicates that only one conformer exists in this radical. The observed D and E parameters show a considerable accordance with those calculated for the expected "*propeller*" structure, as described above.

The discrepancy between the observed and the calculated parameters will depend mainly on the difference between the true and the presumed vector distances, that is, probably in this case, the twist angle. Therefore, calculations were also performed for the "*planar*" structure of both the biradicals for reference. In fact, in the case of the II biradical, the D and E parameters (D=94.2 and E=4.5 G) calculated for the "*planar*" structure show a large discrepancy from those (D=26.1, E=1.9 G) observed in 2-MTHF and from those (D=27.0, E=1.3 G) calculated for the "*propeller*" structure with a 30° twist angle. The results indicate that the dipolar splitting calculations are very sensitive to the twist angle, because, for instance, the nearest neighboring interatomic distances are 4.79 Å for the "*propeller*" structure and 2.42 Å for the "*planar*" structure. On the other hand, in the case of the I biradical, the dipolar splitting values are not sensitive to whether the radical molecule takes the "*planar*" or the "*non-planar*" structure, as is shown in Table 3. However, the "*planar*" structure shows the largest deviations of both the calculated D and E parameters from the experimental ones among the three structures.

Solvent Effect for the Structure of the Biradicals. Many investigations of the solvent effects of free radicals, including phenoxyl radicals, in solution have been reported.[19] The effects may be explained as a redistribution of the π-electron spin density in a radical molecule induced by the electrostatic interaction and/or the hydrogen-bond formation between radical and solvent molecules. In addition to the above effects, recent ENDOR studies of the phenylgalvinoxyl radicals in solution have provided evidence that solvent molecules may play an important role in fixing the conformation and, thus the unpaired electron distribution, of the radical molecules.[13] Based on the ENDOR data, interesting changes in conformation and symmetry for these radicals due to steric interactions and solvent effects have been discussed. Therefore, the effects of the solvent in the frozen-solution ESR spectra of the I and II biradicals have also been examined.

In the I biradical, identical spectra were obtained in frozen toluene, ethanol, and diethyl ether solutions. The observed values of the zero-field splittings, the **g** tensors, and the average g_{av} have been summarized in Table 1. The isotropic g_{iso} values of the I biradical were also measured in toluene, ethanol, and diethyl ether solvents at room temperature. In the I biradical, all these values are very close to the corresponding ones in 2-MTHF, within the limits of experimental error. This indicates that the effect of the solvent is too small to induce the change in the unpaired spin distribution and the molecular structure.

On the other hand, notable solvent dependences were observed in frozen-solution spectra of the II biradical; the results are summarized in Table 2. The observed D values are 26.1 G in 2-MTHF, 21.9 G in toluene, 26.0 G in ethanol, and 26.9±0.2 G in diethyl ether. The **g**-tensor values also appear to be slightly different from the corresponding ones in other solvents, whereas the respective average g_{av} values are close to the corresponding g_{iso} values. In addition, the g_{iso} values for the II biradical in 2-MTHF, toluene, ethanol, and diethyl ether at room temperature are 2.00443, 2.00441, 2.00434, and 2.00441±0.00003 respectively; *i. e.*, there are virtually the same, within the limits of experimental error, except for the small change in ethanol. From the values of D, the distances between the radical centers in the point-dipole approximation were estimated to be about 10.2 Å for the largest D-value in diethyl ether and 10.8 Å for the smallest D-value in toluene. These results may be explained by assuming that the twist angle between the $2p_z$ orbitals of the triphenylmethyl carbon atom and of the centered phenylene ring of the II biradical is larger in toluene than in diethyl ether.

We are very grateful to Professor Kazuhiko Ishizu and Professor Yasuo Deguchi for their kind advice and encouragement. We are also grateful to Miss Atsuko Shibayama for her kind help in the calculation of the zero-field splitting parameters.

Adsorption of Benzoic Acid on a Mercury Electrode

Isao TANIGUCHI, Koji MACHIDA, Norio SATO, and Taro SEKINE

Department of Electronic Chemistry, Graduate School at Nagatsuta, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

(Received August 23, 1976)

The differential capacity and the surface tension at the electrode-electrolyte interface of a dropping-mercury electrode were measured in 0.5 M H_2SO_4 and 0.5 M Na_2SO_4 solutions for various concentrations of benzoic acid. On the basis of the Frumkin-Damaskin theory, the adsorption of benzoic acid on mercury was studied in the acid solution, and the parameters involved in the F-D theory were determined: $A=1.6$ μJ cm^{-2} ($\Gamma_m=6.5\times10^{-10}$ mol cm^{-2}), $B_0=597$ l mol^{-1}, $a=-0.35-2.5\,E$/V, and $C'=5.95$ μF cm^{-2}. The experimental values of the capacity and the surface tension are in good agreement with the theoretical values calculated by using the parameters obtained. The absence of an anodic maximum in the capacity-potential curve in the presence of benzoic acid was determined to be associated with a strong repulsive force between the adsorbed molecules. The value obtained for the maximum surface excess of benzoic acid is explained in terms of adsorption of the acid molecules for a vertical orientation on the electrode surface. This conclusion was supported by comparing the B_0 value for benzoic acid with those for phenol and aniline. The adsorption of benzoic acid in neutral solutions is also discussed.

The adsorption of organic substances on mercury electrodes has been reported by many workers.[1,2] At present, two theories developed by Frumkin and Damaskin (F-D theory)[1] and by Bockris, Devanathan, and Müller (B-D-M theory)[3] are applicable for describing the effect of an electric field on the adsorption of organic substances on the electrode surface. The adsorption of aliphatic amines,[4] alcohols,[4,5] carboxylic acids,[6,7] aromatic amines,[8,9] and phenol[10] has been investigated on the basis of the F-D theory, since this theory gives a quantitative description of the relationship between the surface tension or the differential capacity and the electrode potential in the presence of organic substances. Good agreement between the theoretical and experimental results has usually been obtained. In addition to the above compounds, the adsorption of aliphatic ketones[11,12] was studied using a modified F-D theory.[7] However, only a few reports have been made on the adsorption of aromatic carboxylic acids. Blomgren *et al.*[13] have carried out the measurement of electrocapillary curves on a mercury electrode in 0.1 M HCl solutions containing benzoic acid at concentrations less than 10 mM with the results treated on the basis of the Langmuir isotherm. Therefore, a precise experiment is required to further clarify the adsorption behavior and to elucidate the reduction mechanism of benzoic acid.[14]

Here, the adsorption of benzoic acid on a mercury electrode in aqueous sulfuric acid and sodium sulfate solutions investigated by measuring the differential capacity at the electrode-electolyte interface and the surface tension of a dropping-mercury electrode are reported. The results are discussed on the basis of the F-D theory.

Experimental

The differential capacity of the double layer was measured by means of an AC impedance bridge possessing a large capacity to prevent DC flow through the bridge and having a choke to prevent AC flow through the DC polarization circuit. The measurements were carried out on a dropping-mercury electrode with a droplife of 11—13 s (rate of mercury flow: 0.629 mg s^{-1}), and at various frequencies (0.2—10 kHz, V_{pp}: 5 mV). In the case of benzoic acid solutions of more than 1 mM, the frequency dispersion of the capacity was not observed at the bottom of the capacity curves. At the peak of the curves, the capacity depends slightly on the frequency of the applied AC signal. The capacity at equilibrium was obtained from an extrapolation of the peak capacity to zero frequency as a function of the square root of the frequency, as described by Hansen *et al.*[15] When the electrode has a long droplife, the influence of diffusion on the measured capacity is negligible. The capacity at equilibrium obtained by extrapolation is nearly equal to the capacities measured at 0.5 or 1 kHz, and the curves measured at 0.5 and 1 kHz are considered to be the equilibrium curves for solutions of more than 10 mM of benzoic acid without introducing any appreciable error.

The surface tension of the mercury electrode was measured by the drop-time method.[16] The surface tension at the electrocapillary maximum was evaluated from the measured surface tension.[17,18]

All measurements were repeated at least three times and the average of the measured values is adopted as the final value. The uncertainty is within ±3%.

Benzoic acid (analytical GR reagent grade) was recrystallized twice from water. The test solution was freshly prepared before the measurements. The concentration of benzoic acid was determined by means of UV absorption at 230 nm. The solution in the cell was deaerated by bubbling for more than one hour with purified nitrogen that had been passed through a washing bottle containing the same solution.

The physical meanings of all symbols appearing in this paper are summarized as follows:

(Roman letters)

A	Constant equal to $RT\Gamma_m$ (μJ cm^{-2})
a	Interaction constant of adsorbed molecules; a is a function of E
a_0	Value of a at zero charge potential in the solution without benzoic acid
B	Equilibrium adsorption constant at potential E (l mol^{-1})
B_0	Value of B at zero charge potential in the solution without benzoic acid (l mol^{-1})
C	Differential capacity (μF cm^{-2})
C_0	Differential capacity of the solution without benzoic acid (μF cm^{-2})
C'	Differential capacity for full coverage of electrode with benzoic acid (μF cm^{-2})
C^{min}	Minimum differential capacity of the capacity-potential curves in the presence of benzoic acid (μF cm^{-2})
C^{max}	Peak capacity (μF cm^{-2})

c Concentration of benzoic acid (mol l^{-1})
E Electrode potential with respect to zero charge potential in the solution without benzoic acid (V)
ΔE Width of the capacity peak (V)
E^{min} Potential corresponding to the minimum capacity (V)
E^{max} Potential corresponding to the maximum capacity (V)
E_N Potential difference between the respective zero charge potentials for zero and full coverage of the electrode with benzoic acid (V)
E_Z Shift of the zero charge potential for a given coverage (V)
K_0 Integral capacity in the solution without benzoic acid (μF cm^{-2})
q_0 Charge density of the electrode surface in the solution without benzoic acid (μC cm^{-2}); q_0 was determined by graphical integration of C_0
R Gas constant (J K^{-1} mol^{-1})
r Function of a for a given fraction of the peak height
T Absolute temperature (K)
y Relative concentration of benzoic acid, $c/c_{\theta=0.5}$
(Greek letters)
β Coefficient of the potential dependence of a (V^{-1})
Γ_m Maximum surface excess of benzoic acid (mol cm^{-2})
γ Interfacial tension of the solution with benzoic acid (10^{-5} N cm^{-1})
γ_0 Interfacial tension of the solution without benzoic acid (10^{-5} N cm^{-1})
θ Surface coverage
θ^{max} Value of θ at E^{min}
ν Frequency (kHz)

Results

In Acid Solution. Examples of typical capacity-potential curves for 0.5 M H_2SO_4 solutions of various concentrations of benzoic acid are shown in Fig. 1. The capacity curves exhibit no anodic maximum.

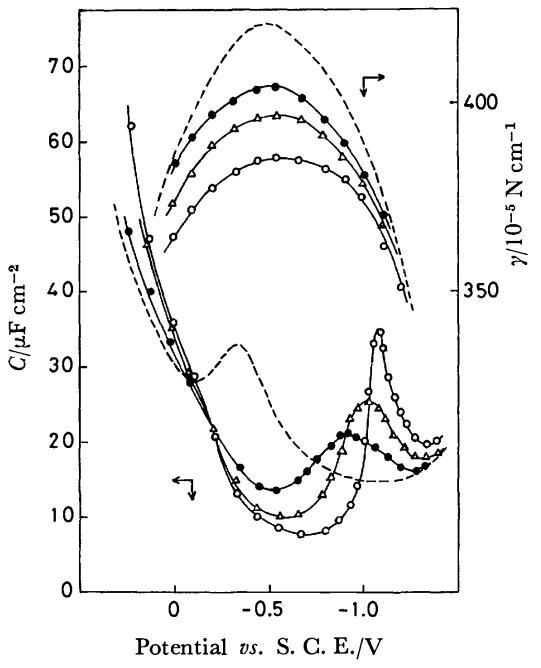

Fig. 1. Differential capacitance curves and electrocapillary curves at 1 kHz and 25 °C in solutions of 0.5 M H_2SO_4 at various concentrations of benzoic acid; ---: 0 mM, ●: 2.5 mM, △: 7.5 mM, ○: 15 mM.

At high negative potentials, the capacity-potential curves and the electrocapillary curves approach the curve obtained for a 0.5 M H_2SO_4 solution without benzoic acid, and this indicates the desorption of benzoic acid from the mercury surface.

To obtain the values of the constants characterizing the adsorption of benzoic acid on mercury, the results were treated on the basis of the Frumkin-Damaskin adsorption isotherm at the potentials corresponding to the maximum adsorption and the maximum capacity.

$$Bc = \frac{\theta}{1-\theta}\exp(-2a\theta). \quad (1)$$

The dependence of a on E was first evaluated as follows. Since the coverage is given in the potential region of maximum adsorption by

$$\theta = \frac{C_0 - C}{C_0 - C'}, \quad (2)$$

the attraction constant a was determined from the reduced adsorption isotherm[1,2]

$$y = \frac{c}{c_{\theta=0.5}} = \frac{\theta}{1-\theta}\exp[a(1-2\theta)]. \quad (3)$$

The value of C' was determined by extrapolating the plot of $1/C^{min}$ against $1/c$ to $1/c=0$.[19] The extrapolation was made by the least-squares method for the data obtained in benzoic acid solutions of more than 7.5 mM. The results are shown in Figs. 2 and 3.

The values of a at the peak potentials were calculated from ΔE using[1,2,19]

$$f(a) = \lg\frac{1-r}{1+r} - \frac{ar}{2.3} = \frac{\Delta E}{2}\left|\frac{\partial \lg c}{\partial E^{max}}\right|, \quad (4)$$

where r is a function of a for a given fraction of the peak height, that is,

$$r_{1/2} = \sqrt{\frac{2-a}{4-a}} \text{ and } r_{3/4} = \sqrt{\frac{2-a}{8-a}}, \quad (5)$$

with the subscripts indicating the function of a which should be used for r in Eq. 4 when ΔE is used either at one half or at three-quarters of the peak height. The values of a at the peak potentials were also determined from the slope of the curve of lg c *vs.* E^{max} using

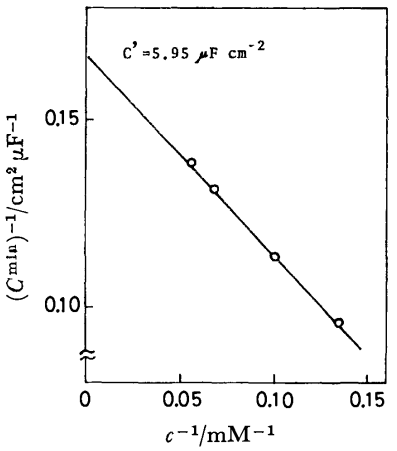

Fig. 2. The plot of the inverse of the minimum capacity against the inverse of the concentration of benzoic acid in 0.5 M H_2SO_4 solution.

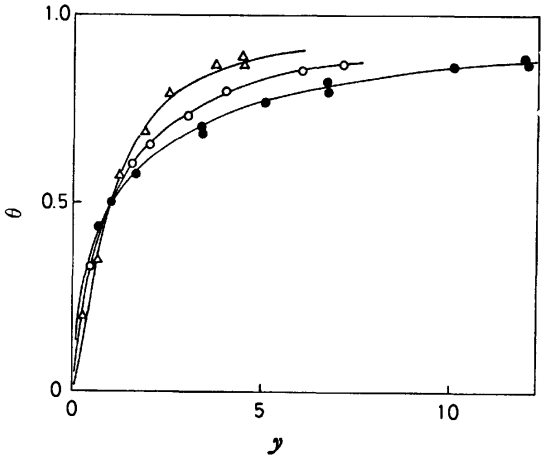

Fig. 3. Adsorption isotherm of benzoic acid in 0.5 M H_2SO_4 solution at −0.55 (●), −0.60 (○), and −0.66 (△) V *vs.* S. C. E. Solid lines are calculated from Eq. 3 with $a=-0.7$(at −0.55 V), −0.1(at −0.6 V), and 0.55(at −0.66 V).

$$\frac{\partial E^{max}}{\partial \lg c} = \frac{2.3(C_0-C')}{2-a}. \quad (6)$$

Since this treatment is applicable only to equilibrium capacity-potential curves, the data obtained at 0.5 and 1 kHz in benzoic acid solutions of concentration greater than 10 mM and those obtained by extrapolation to $\nu=0$ were used for the above calculation.

The values of a thus found are plotted against the electrode potentials in Fig. 4. When the values of a were assumed to be a linear function of E,

$$a = a_0 + \beta E, \quad (7)$$

thus (although some deviation was observed) the values of a_0 and β are found to be −0.35 and −2.5 V^{-1}, respectively.

Other parameters, such as E_N, A, and B_0, were evaluated using the following treatment. The value of E_N was determined from the electrocapillary curves[2,19] to be −0.05 V. The value of A was calculated from the following relation:[2]

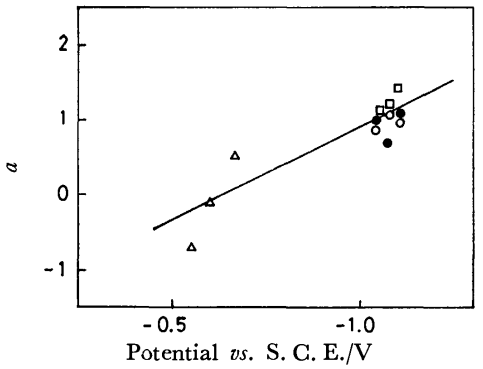

Fig. 4. Dependence of the attraction constant on potential in 0.5 M H_2SO_4 solution. The values of a were obtained from; △: the shape of the adsorption isotherm (Eq. 3), ○: the width of the capacitance peaks at half of their height (Eqs. 4 and 5), ●: the width of the capacitance peaks at three-quarters of their height (Eqs. 4 and 5), □: the slope of the curve of lg c *vs.* E^{max} (Eq. 6).

$$A = \frac{\gamma-\gamma_0}{\ln(1-\theta)+a\theta^2}. \quad (8)$$

The mean value of A was 1.60 μJ cm^{-2} in the 15 mM benzoic acid solution (Table 1). The value of B_0 was evaluated from[19]

$$\ln B_0 = -a_0 - \ln c + \frac{\int_0^{E^{max}} q_0 dE + C'E^{max}(E_N - E^{max}/2)}{A}. \quad (9)$$

The value of B_0 was also calculated by substituting the coverage θ and a into Eq. 1 for zero charge potential in the solution without benzoic acid (*i.e.*, −0.5 V *vs.* S.C.E.). The values of B_0 obtained by the different methods are in fairly good agreement with each other (Table 2).

Thus, the parameters were found to be $A=1.6$ μF cm^{-2}, $B_0=597$ l mol^{-1}, $C'=5.95$ μF cm^{-2}, $a_0=-0.35$, and $\beta=-2.5$ V^{-1}.

Table 1. Value of A calculated from Eq. 8 using the data for the 15 mM benzoic acid solution

E *vs.* SCE V	$\gamma-\gamma_0$ 10^{-5} N cm^{-1}	θ	a	A μJ cm^{-2}

	mean 597	

In Neutral Solution. The capacity-potential curves and electrocapillary curves in 0.5 M Na_2SO_4 solutions containing various amounts of benzoic acid are shown in Fig. 5 (The pH value of the solution was adjusted to 7.2 by adding an NaOH solution). Small peaks (or humps) were observed around −0.5 V (*vs.* S.C.E.) for the capacity-potential curves. A decrease in surface tension due to adsorption of benzoate anions was observed for a positively-charged surface, while for a negatively-charged surface the surface tension and the capacity approached the values obtained in a 0.5 M Na_2SO_4 solution without benzoic acid. Thus, the hump appearing in the capacity curve is regarded as the adsorption-desorption peak of the benzoate anion.

Discussion

The adsorption of benzoic acid in acid sulutions is now considered in detail. At negative potentials, an attractive force is observed between the adsorbed acid molecules. The attractive force changes to a repulsive force as the potential becomes positive (Fig. 4). A similar change in a with the potential has been

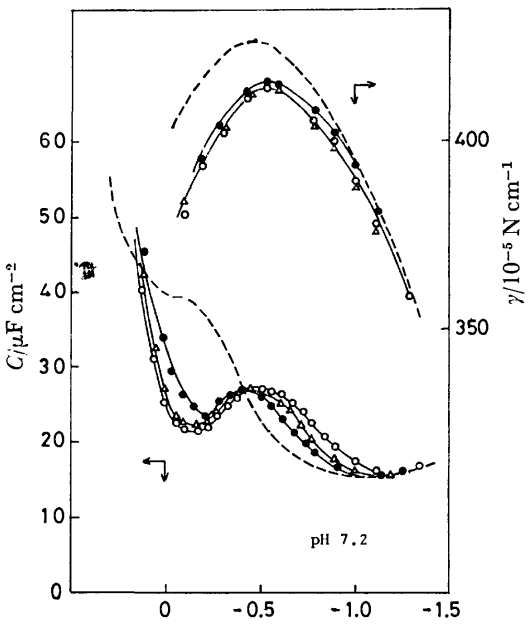

Fig. 5. Differential capacitance curves and electrocapillary curves at 1 kHz and 25 °C in solutions of 0.5 M Na_2SO_4 at various concentrations of benzoic acid; ---: 0 mM, ●: 5 mM, △: 15 mM, ○: 50 mM. The pH value of the solution was adjusted to 7.2 by adding an NaOH solution.

observed for pyridine ($\beta=-2.8\ V^{-1}$)[1,20] and phenol ($\beta=-2.05\ V^{-1}$).[10] When the value of a is considerably negative, no peak is observed in the capacity-potential curves.[19,21] It is also considered that the strong repulsion between the adsorbates observed for positive potentials causes appreciable desorption of the adsorbed benzoic acid in spite of the increase in the π-electron interaction between the adsorbed molecules and the positively-charged surface. These considerations are consistent with the experimental results for a positively-charged surface: no anodic maxima in the capacity-potential curves were observed and the degree of decrease of the surface tension became smaller with increasing potential, as is shown in Fig. 1. The potential E^{min} shifted to more negative potentials with increasing benzoic acid concentration (Fig. 1). The degree of this shift was explained using the negative β value ($-2.5\ V^{-1}$) obtained in this study according to the following relation[19] (Fig. 6)

$$\frac{\partial E^{min}}{\partial \theta^{max}} = \frac{2A\beta}{K_0 - C'}. \tag{10}$$

The experimental results were compared with the calculated capacity-potential curve and electrocapillary curve in order to examine whether or not the adsorption of benzoic acid follows the F-D theory over the entire potential region. The curves relating the capacity and the surface tension to the potential were calculated using

$$C = C_0(1-\theta) + C'\theta + \frac{[q_0 + C'(E_N - E) + \beta A(1-2\theta)]^2 h}{A}, \tag{11}$$

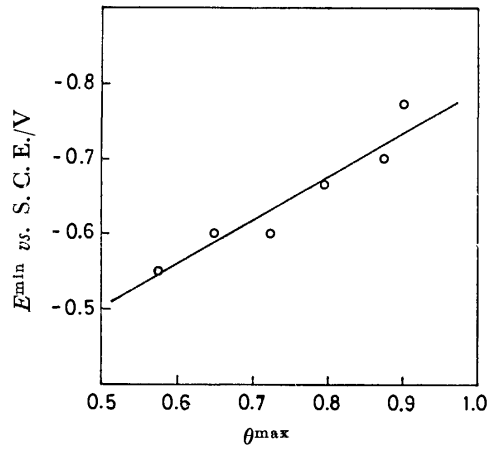

Fig. 6. Variation of the potential of minimum capacity with the coverage. Solid line indicates the theoretical dependence of E^{min} on θ^{max} calculated from Eq. 10 by assuming the value of K_0 of 20 $\mu F\ cm^{-2}$.

where

$$h = \frac{\theta(1-\theta)}{1-2a\theta(1-\theta)}, \tag{12}$$

and

$$\gamma = \gamma_0 + A[\ln(1-\theta) + a\theta^2]. \tag{13}$$

The value of θ appearing in Eqs. 11 and 13 was evaluated as follows.[2,19] The value of B was first determined using

$$B = B_0 \exp\left[-\frac{\int_0^E q_0 dE + C'E(E_N - E/2)}{A}\right]\exp(-\beta E), \tag{14}$$

for a given potential, and then θ was calculated from Eq. 1 for a given concentration of benzoic acid. As is shown in Fig. 7, good agreement is obtained between the calculated values and experimental results for the capacity and the surface tension over the potential region investigated. The discrepancy observed for positively-charged surfaces in the capacity-potential curves is probably due to the π-electron interaction. However the agreement between the experimental electrocapillary curve and the calculated curve shows that the interaction is probably rather small.

When benzoic acid molecules are adsorbed on the electrode in either the vertical or the flat orientations, the two-condensers-in-parallel model (F-D theory) may be applied. If benzoic acid molecules are adsorbed on the electrode for both orientations, the three-condensers-in-parallel model would be applicable.[2] Both the two- and three-condenser models were tested by plotting the shift of the zero charge potential, E_z, against the coverage. For the two-condenser model, E_z is a function of θ:[2]

$$E_z = \frac{E_N\theta}{(C_0/C')(1-\theta)+\theta}. \tag{15}$$

On the other hand, the relationship between E_z and θ derived for the three-condenser model is[2,22]

$$E_z = \frac{E_{N1}\theta[(E_{N2}/E_{N1})(1-\theta)+\theta]}{(C_0/C')(1-\theta)+\theta}, \tag{16}$$

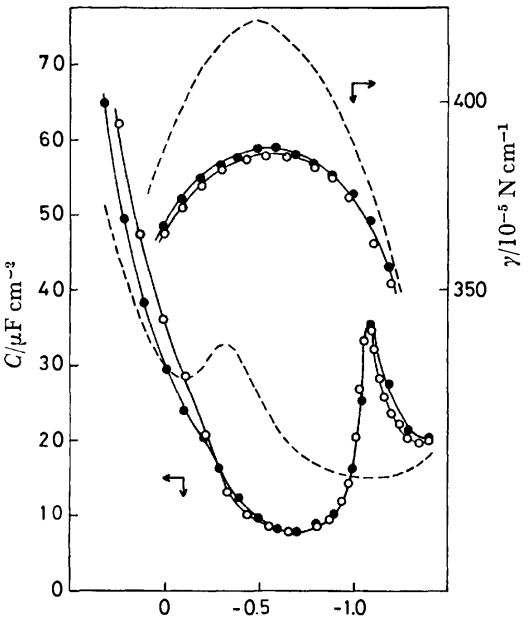

Fig. 7. Differential capacitance curves and electrocapillary curves in 0.5 M H_2SO_4 solution (broken line) containing 15 mM of benzoic acid. ○: experimental results at 1 kHz, ●: calculated from Eqs. 11 and 13.

where E_{N1} and E_{N2} are the shifts of the zero charge potential when the electrode is fully covered by adsorbed molecules in the vertical and flat orientations, respectively. E_{N2} was calculated to be −0.72 V from[2]

$$\beta = \frac{-C'(E_{N1}-E_{N2})}{A}, \qquad (17)$$

assuming $E_{N1}=E_N=-0.05$ V.

The experimental results for the relation between E_z and θ are shown in Fig. 8, together with the theoretical curves given by Eqs. 15 and 16. The two-condenser model is more successful in explaining the experimental results.

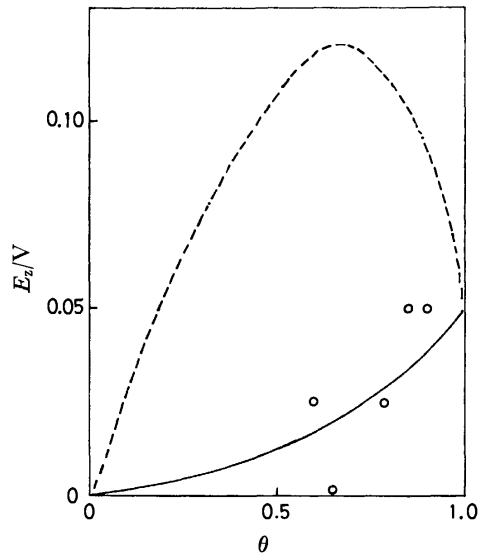

Fig. 8. Dependence of the point of zero charge on surface coverage with adsorbed benzoic acid in 0.5 M H_2SO_4 solution. Solid and broken lines are calculated from Eqs. 15 and 16.

From the above arguments, it is concluded that the adsorption of benzoic acid molecules follows the F-D theory of the two-condenser model and that the values of the parameters obtained are reasonable.

Orientation of Adsorbed Molecules. The orientation of the adsorbed benzoic acid molecules on the electrode surface can be discussed on the basis of the values of A, because A is related to the maximum surface excess. The experimental value of A corresponds to a maximum surface excess of 6.5×10^{-10} mol cm^{-2}. In the case of monolayer adsorption, the area occupied by one molecule of benzoic acid is calculated to be 26 Å^2 (1 Å=0.1 nm). According to the Fisher-Taylor-Hirschfelder model,[13] one molecule of benzoic acid occupies 56 Å^2 for flat orientation and 20 Å^2 for vertical orientation. The area estimated from the A value indicates that for adsorption, benzoic acid has a vertical orientation.

The vertical orientation of the adsorbed benzoic acid molecules is also supported by the value of B_0 as follows. The value of B_0 is related to the standard free energy of adsorption, $-\Delta G_A^\circ$, by[2]

$$-\Delta G_A^\circ = RT\ln(55.5\,B_0/1\ \text{mol}^{-1}). \qquad (18)$$

The calculated $-\Delta G_A^\circ$ value is 26 kJ mol^{-1} (6.2 kcal mol^{-1}). The value of B_0 (597 l mol^{-1}) obtained is less than that of phenol[10] (1640 l mol^{-1}) for the flat orientation and is larger than that of aniline[9] (191 l mol^{-1}) for the vertical orientation. The $-\Delta G_A^\circ$ and B_0 values decrease when the π-electron interaction between the adsorbate and the electrode decrease, and the specific interaction between functional groups and a mercury surface is considered to result in a change in orientation from flat to vertical. Taking into account the specific interaction of functional groups of aliphatic compounds with a mercury surface (the order of specific interaction has been reported to be -OH<-COOH<-NH_2),[7] the decrease of B_0 values in the order, phenol>benzoic acid>aniline, is explained reasonably well in terms of the change in orientation from flat to vertical. Since some phenol molecules can undergo adsorption in the vertical orientation,[15,22] benzoic acid is expected to be adsorbed in the vertical orientation. This is because benzoic acid has a greater possibility of existing in the vertical orientation than phenol, because of its smaller value of B_0 and the stronger interaction of a carboxyl group with a mercury surface than a hydroxyl group. This conclusion agrees with that derived from the evaluation of the maximum surface excess.

In the neutral solution (0.5 M Na_2SO_4, pH 7.2), the value $a<-4$ obtained from the shape of the hump indicates that there is a strong repulsive force between the adsorbates in the potential region of the hump. Since the pK_a of benzoic acid is 4.2,[23] the adsorbed species at pH 7.2 should be the benzoate anion. The repulsive force may be caused by the Coulombic interaction between adsorbed benzoate anions, because no strong repulsive force was observed in the acid solution. The low and broad humps in the capacity-potential curves due to desorption extend to −0.25 V

(*vs.* S.C.E.), and this fact indicates that desorption occurs even on a positively-charged surface because of the significantly large repulsive force between the adsorbed anions. The capacity-potential curves and electrocapillary curves are almost independent of the concentration of benzoate anion. These phenomena suggest that the adsorbed anions covered the electrode surface almost completely in the solution of a low concentration of benzoic acid.

(Received September 28, 1976)

In order to determine the optimum irradiation conditions to produce the ^{61}Cu for nuclear medical use, excitation curves and thick-target yield curves were determined for the α reactions producing ^{61}Cu, ^{57}Co, and ^{58}Co, and ^{3}He reactions producing ^{61}Cu, ^{56}Co, ^{57}Co, and ^{58}Co, both from natural cobalt. The ^{59}Co(α, 2n) ^{61}Cu and the ^{59}Co(^{3}He, n) ^{61}Cu reactions give cross section peaks of 340 mb and 6 mb at 25 MeV and 35 MeV, respectively. The ^{61}Cu thick-target yields for these reactions at 40 MeV were 6 mCi/μAh and 110 μCi/μAh, respectively. A simple and reliable anion-exchange method was developed to provide carrier-free ^{61}Cu. The purity of ^{61}Cu was determined with a Ge(Li) spectrometer. Photopeak efficiencies have been calculated at principal γ-ray energies of ^{61}Cu, ^{64}Cu, and ^{67}Cu, for a 1/2 in. NaI scintillation camera. Alternative nuclear reactions and the methods for producing ^{61}Cu are compared.

^{61}Cu has better nuclear properties for use in nuclear medicine.[1] Its 3.32 h half-life and 284 keV γ-ray make it a particularly useful diagnostic scanning agent giving a much lower absorbed dose for a given count rate than the more readily available ^{64}Cu and ^{67}Cu. ^{61}Cu can be produced with a cyclotron by a ^{59}Co(α,2n) ^{61}Cu reaction: this reaction results in a maximum of 6 mCi/μAh for 40 MeV α bombardment.[1] Bombardment of cobalt has an additional advantage in that the inexpensive monoisotopic element cobalt can be used.

In producing a short-lived radionuclide for use in clinical diagnostic procedures, two factors of prime importance are the yield of the desired nuclide and the degree of contamination with other isotopes, particularly those which have relatively long half-lives and which cannot be separated chemically. To determine the optimum irradiation condition to maximize the yield of the desired nuclide and to minimize the yield of other by-product nuclides, the excitation curves for the reactions concerned must be known.

We have investigated the excitation curves and the thick-target yield curves of ^{61}Cu and by-product nuclides such as ^{56}Co, ^{57}Co, and ^{58}Co. Photopeak efficiencies have been calculated at γ-ray energies of these nuclides for sodium iodide crystals. This is of interest in the design of γ-ray taking devices such as a scintillation camera. The information would be of value to users of medical cyclotron interested in the production of ^{61}Cu.

Experimental

Target Preparation. A thin cobalt target (15—25 mg/cm^2) was electro-deposited from a cobalt sulfate solution ($CoSO_4 \cdot 7H_2O$ 500 g/l, NaCl 17 g/l, H_3BO_4 45 g/l) onto a disk of electrolytic copper foil (35 μ thick). The electro-deposition was performed at 20—28 °C in a 30 mm diam cell with a platinum wire anode at the current density of 50 mA/cm^2 for 170—380 min. After electro-deposition the cobalt foils were carfeully removed from the cathode, washed, dried, and weighed. About ten to fifteen foils were stacked on a brass target-holder with water cooled pipes.

Bombardment. The stacked target was attached to the beam duct of No. 2 of IPCR cyclotron and bombarded with 0.5—1 μA beam of 40 MeV α and ^{3}He particles. A collimater situated in front of the target reduced the spead in width of beam to *ca.* 1.5 × 1.5 cm^2. The beam current was measured with a beam current integrator. There was 8% excess in the reading owing to the secondary electrons in the slit edge, the target and of α and ^{3}He particles scattering at the slit edge[2]. The duration of bombardment was 30—60 min.

Measurement. After bombardment, γ-ray spectra of each foil were measured with a 15 cm^3 Ge(Li) detector, which had been accurately calibrated using IAEA γ-ray standard sources. The specific γ-rays and half-lives were sufficiently distinguished without chemical separation. The principal photopeaks of nuclide were followed in order to determine the half-life and confirm the identity of the nuclides. The dead time losses were always less than 10%. For the sake of obtaining better sensitivities the longer-lived nuclides (^{56}Co, ^{57}Co, and ^{58}Co) were analyzed after the decay of ^{61}Cu was complete. The yields of the nuclides produced in each target were calculated in terms of μCi/μAh at the end of bombardment. The data, foil thickness and the result of beam current measurement were used to calculate the reaction cross sections for all the nuclides observed in each foil. The energy and the intensity of the photopeaks: ^{61}Cu (284 keV, 12%), ^{56}Co (847 keV, 100%), ^{57}Co (122 keV, 87%), ^{58}Co (810 keV, 99%).

Results and Discussion

γ-Ray Spectra. A representative example of the γ-ray spectra is shown in Fig. 1. The upper curve was taken 3.3 h after the end of α bombardment. The median energy in this foil was 28.8 MeV. The lower curve was taken 6 days after the end of bombardment. γ-Rays from the decay of the longer-lived radionuclide ^{57}Co can be identified in addition to the 511 keV annihilation quanta from positron emitters such as ^{61}Cu and ^{58}Co. No peaks which seem to be due to impurities were observed. The spectra of γ-rays from a ^{3}He bombardment foil in which the median ^{3}He energy was 38.8 MeV are shown in Fig. 2. In addition to γ-rays from ^{61}Cu, ^{57}Co, and ^{58}Co, photopeaks from ^{56}Co can be identified. The Q values for the nuclear reaction concerned are given in Table 1.

Excitation Curves and Thick-target Yield Curves.

α Reactions: The yields of ^{61}Cu, ^{57}Co, and ^{58}Co in each target were calculated in terms of μCi/μAh at the end of bombardment. The reaction cross sections were then calculated by means of the relation:

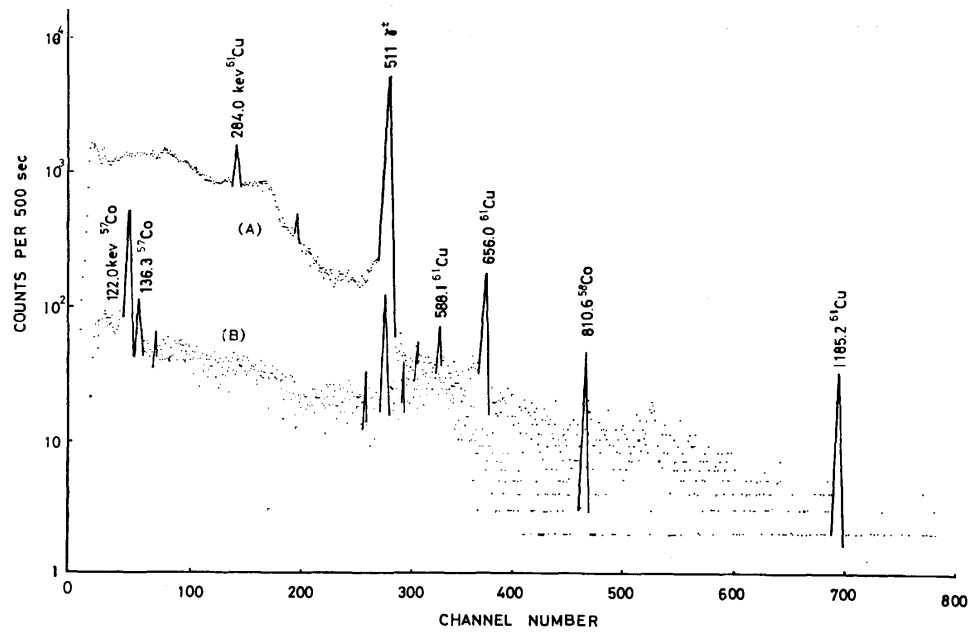

Fig. 1. γ-Ray spectra for α bombarded target of cobalt. A) taken 3.3 h after bombardment, B) taken 6 d after bombardment.

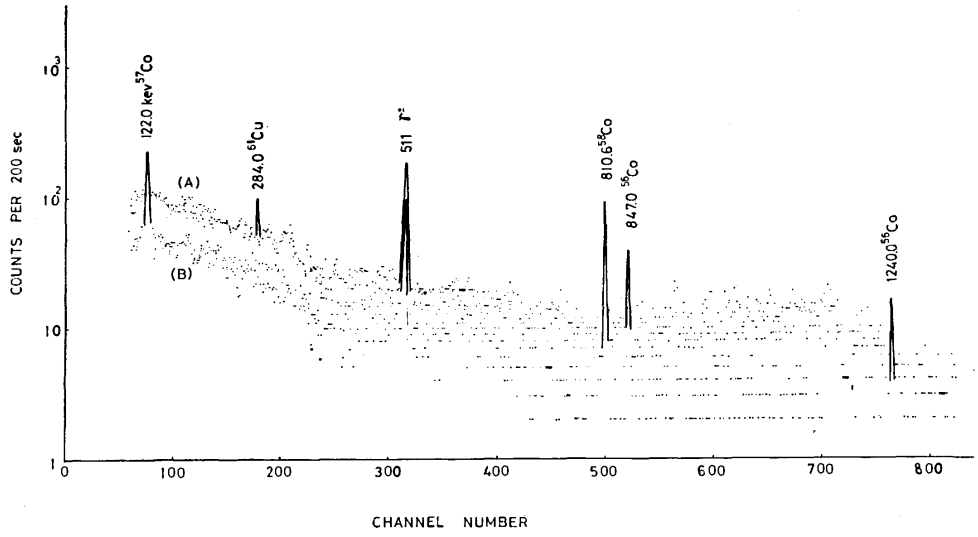

Fig. 2. γ-Ray spectra for ^{3}He bombarded target of cobalt. A) taken 3.3 h after bombardment, B) taken 3 d after bombardment.

$$\sigma_E = \frac{A_0}{(1-e^{-\lambda t})\cdot N\cdot\phi},$$

where

σ_E=the cross section for the reaction at energy E,
A_0=activity in dps at the end of bombardment,
N=number of target nuclei of cobalt target,
ϕ=particle flux,
λ=decay constant for the nuclide,
t=duration of bombardment.

The excitation curves for the production of ^{61}Cu by α bombardment on cobalt are shown in Fig. 3. The maximum cross section of 350 mb is shown at 25 MeV. Above 25 MeV the cross section for ^{61}Cu production decreases; probably because the ^{59}Co(α,αn)^{58}Co and ^{59}Co(α,α2n)^{57}Co reactions are more probable than the ^{59}Co(α,2n)^{61}Cu reaction in this energy region (Fig. 4).

The thick-target yield curves were obtained by integrating the thin-target yield *vs.* target depth curves. The thick-target yield curves of ^{61}Cu, ^{57}Co, and ^{58}Co for α bombardment of cobalt are given in Figs. 3 and 5.

^{3}He Reactions: The yields of ^{61}Cu, ^{56}Co, ^{57}Co, and ^{58}Co were calculated in terms of μCi/μAh and the reaction cross sections were calculated exactly in the same way as for the α particle bombardment described above. The excitation curves for these reactions are plotted in Figs. 6 and 7. The Coulomb barrier for the interaction of ^{3}He with ^{58}Co is about 9.72 MeV, whereas the Q values for the ^{59}Co(^{3}He,n)^{61}Cu, ^{59}Co-(^{3}He,α)^{58}Co, ^{59}Co(^{3}He,αn)^{57}Co, and ^{59}Co(^{3}He,α2n)^{56}Co

Table 1. α and ^{3}He reactions with cobalt target

α Reactions	Q Value (MeV)	^{3}He Reactions	Q Value (MeV)
^{59}Co(α, n)^{62}Cu	−5.4	^{59}Co(^{3}He, n)^{61}Cu	+6.6
(α, 2n)^{61}Cu	−14.0	(^{3}He, 2n)^{60}Cu	−5.1
(α, 3n)^{60}Cu	−25.6	(^{3}He, 3n)^{59}Cu	−15.2
(α, 4n)^{59}Cu	−37.7	(^{3}He, 4n)^{58}Cu	−27.9
(α, p)^{62}Ni	−0.4	(^{3}He, p)^{61}Ni	+9.6
(α, pn)^{61}Ni	−10.9	(^{3}He, pn)^{60}Ni	+1.8
(α, p2n)^{60}Ni	−18.7	(^{3}He, p2n)^{59}Ni	−9.6
(α, p3n)^{59}Ni	−30.1	(^{3}He, p3n)^{58}Ni	−18.6
(α, αn)^{58}Co	−10.4	(^{3}He, α)^{58}Co	+10.1

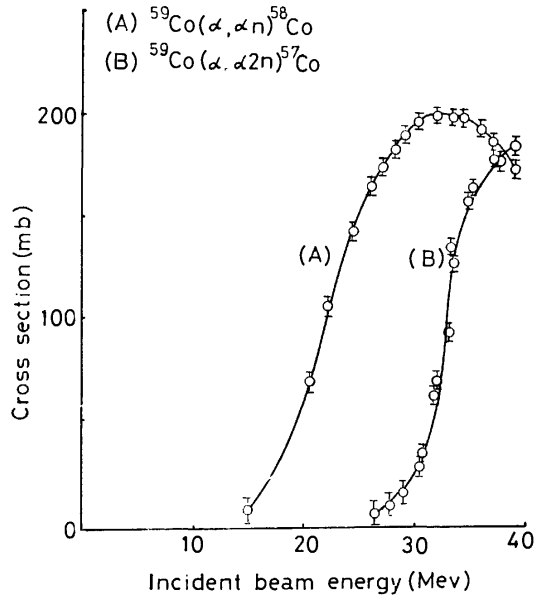

Fig. 4. Excitation curves for α reaction on cobalt producing ^{57}Co and ^{58}Co.

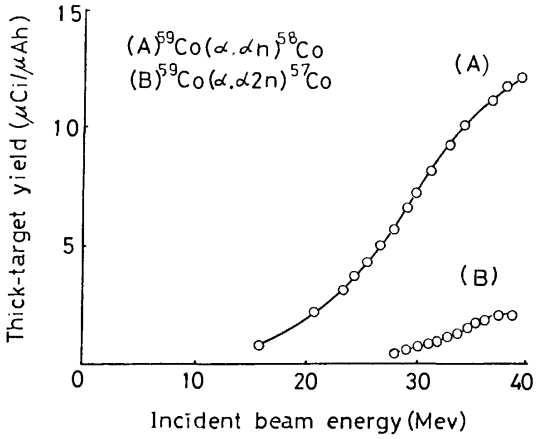

Fig. 5. Thick-target yield curves for α reactions on cobalt producing ^{57}Co and ^{58}Co.

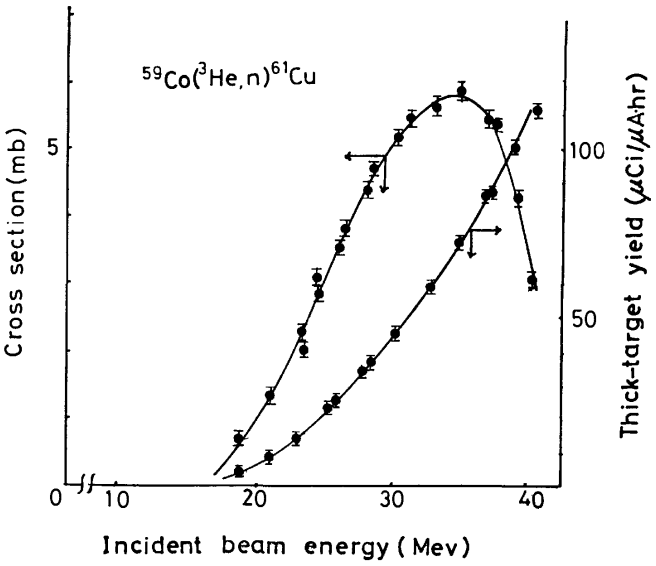

Fig. 6. Excitation curve and thick-target yield curve for ^{3}He reaction on cobalt producing ^{61}Cu.

reactions are +6.6, +10.1, +1.5, and −9.4 MeV, respectively (Table 1). This indicates that, for the ^{3}He particles with sufficient kinetic energy to cross the Coulomb barrier, the cross section for the first reaction is negligibly small.

The ^{59}Co(α,2n)^{61}Cu and the ^{59}Co(^{3}He,n)^{61}Cu reactions have cross section peaks of 340 and 6 mb at 25 and 35 MeV, respectively. The ^{61}Cu thick-target yields for these reactions were 6 mCi/μAh and 110 μCi/μAh, respectively. This shows that α bombardment is more advantageous than ^{3}He bombardment for the production of ^{61}Cu.

Chemical Separation and Radionuclidic Purity. In order to separate ^{61}Cu from ^{56}Co, ^{57}Co, ^{58}Co, and target material, we used the anion-exchange method.[1] The method has been simplified, with completely satisfactory results, and used for routine production as follows: After 4 h cooling period required to allow the short-lived nuclides such as ^{60}Cu(23.4 m) and ^{62}Cu(9.76 m) to decay almost completely, irradiated

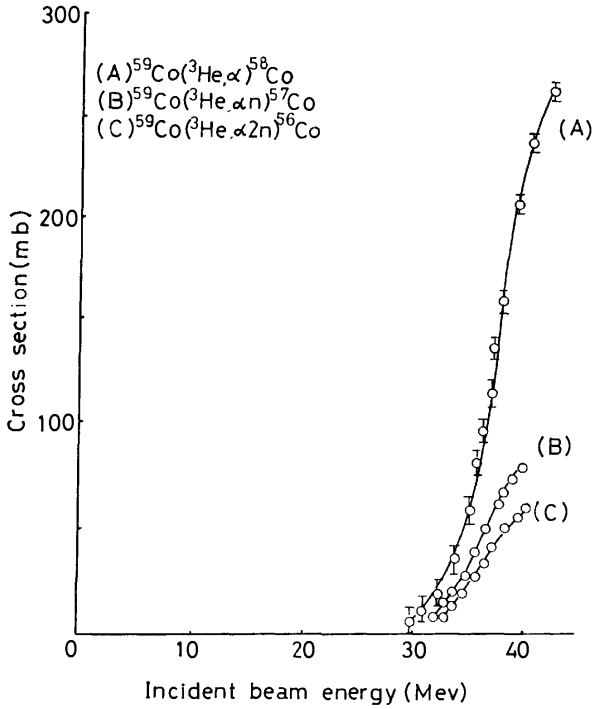

Fig. 7. Excitation curves for ^{3}He reactions on cobalt producing ^{56}Co, ^{57}Co, and ^{58}Co.

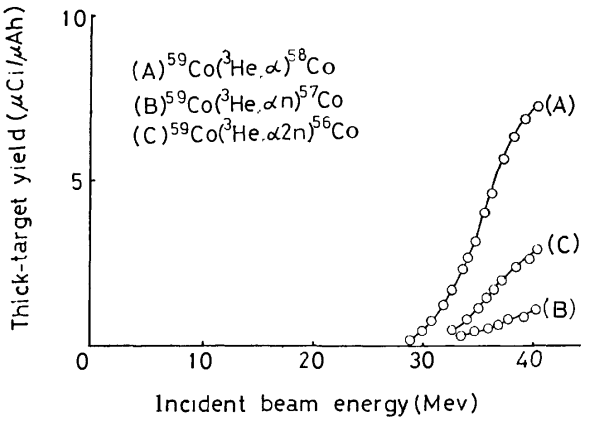

Fig. 8. Thick-target yield curves for ^{3}He reactions on cobalt producing ^{56}Co, ^{57}Co, and ^{58}Co.

cobalt target (150 mg) was dissolved in a mixture of 2 ml of 4M HNO_3 and a few ml of 6M HCl to which a drop of bromine had been added in order to oxidize copper ions. The solution was evaporated nearly to dryness in order to remove excess HNO_3 and Br_2. Twenty-five ml of 8M HCl was added to form chloride complexes of Cu^{2+} and Co^{2+}. The solution was then transferred into a 150 mm × 13 mm column of Dowex 1-X8 anion-exchanger resin,chloride form, 100—200 mesh. Under these conditions, Co^{2+} and Cu^{2+} are adsorbed on the resin but not Ni^{2+}.[1,4] Co^{2+} and Cu^{2+} can be eluted from the column with 25 ml of 4M HCl and 2M HCl, respectively. Carrier-free ^{61}Cu is recovered as a radionuclidically pure material in 25 ml of 2M HCl solution, which can be easily evaporated to dryness. This make it possible to convert the tracer into a suitable chemical form. The radiochemical yield was 95%. The procedure is simple, taking less than 150 min. The high radionuclidic purity of ^{61}Cu attained was determined by γ-ray spectrometry using a Ge(Li) detector. No radionuclides of longer-life could be detected.

Comparison of Nuclear Reactions for Producing ^{61}Cu.

Deuteron Bombardment of Natural Zinc Targets: The thick-target yield of ^{61}Cu from deuteron bombardment of natural zinc target was *ca.* 1.2 mCi/μAh at 15 MeV.[5] However, the purity of ^{61}Cu produced by the ^{64}Zn(d,αn)^{61}Cu is restricted by ^{64}Cu produced by the ^{66}Zn(d,α)^{64}Cu, ^{67}Zn(d,αn)^{64}Cu, and ^{64}Zn(d,2p)^{64}Cu reactions and ^{67}Cu produced by the ^{68}Zn(d,^{3}He)^{67}Cu and ^{67}Zn(d,2p)^{67}Cu reactions. At a bombardment energy of 15 MeV, the maximum levels of ^{64}Cu and ^{67}Cu contaminants were 45 and 30%, respectively.

^{3}He Bombardment of Natural Copper Targets: The maximum cross section for the ^{63}Cu(^{3}He,αn)^{61}Cu reaction is 88.2 mb at 19.6 MeV, whereas those for the ^{63}Cu(^{3}He,2p)^{64}Cu and the ^{63}Cu(^{3}He,α)^{62}Cu reactions are 126 mb at 21.7 MeV and 42.7 mb at 22.4 MeV, respectively.[6] The results indicate that the purity of ^{61}Cu produced by this method is not suitable for *in vivo* studies, even if other by-product nuclides such as ^{65}Ga, ^{66}Ga, ^{67}Ga, ^{62}Zn, ^{63}Zn, and ^{65}Zn are chemically separable.

Proton Bombardment of Natural Copper Targets: ^{61}Cu is also produced by the ^{63}Cu(p,p2n)^{61}Cu and the ^{65}Cu(p,p4n)^{61}Cu reactions. A limitation of the above nuclear reactions is that the required particle energies (*e.g.* 35—60 MeV protons) are not attainable with compact cyclotrons suitable for routine production. Only the cyclotron of the National Institute of Radiological Science can be used. The maximum cross sections for these reactions are approximately 3 times less than that for the ^{59}Co(α,2n)^{61}Cu reaction. The experimental data available show that the maximum cross sections for the ^{63}Cu(p,p2n)^{61}Cu and the ^{65}Cu(p,p4n)^{61}Cu reactions are 130 mb at 35 MeV and 100 mb at 60 MeV, respectively.[7] This indicates that the yield of these reactions are not practical for routine production.

α Bombardment of Enriched Nickel Targets: A relatively high cross section has been reported for the ^{58}Ni(α,p)^{61}Cu reaction which has a maximum value of 310 mb at particle energy 11 MeV.[8] However, the method is not practical, because of the use of a Van de Graaff accelerator and highly enriched nickel isotope (98.4%).

An alternative method was studied in order to obtain ^{61}Cu by the ^{3}He bombardment on natural nickel target. The results of preliminary studies are satisfactory and have advantages over the above mentioned ^{58}Ni(α,p)^{61}Cu, primarily because its thick-target yield is 4.9 mCi/μAh with ^{3}He particle bombardment energy of 40 MeV.[9]

Relative Detection Efficiency. The average absorbed dose delivered to the total body, spleen, kidneys, liver, heart, and brain by ^{61}Cu, ^{64}Cu, and ^{67}Cu has been calculated.[1] The results show that ^{61}Cu

Table 2. Percentage of usable γ-rays of ^{61}Cu, ^{64}Cu, and ^{67}Cu

Radionuclide	Decay mode	γ-Ray Energy (MeV)	γ-Ray Intensity (%)	Transmission (%)	Detection efficiency (%)	Usable γ-ray (%)
^{61}Cu(3.32 h)	β^+ 60%	0.284	12	62	58	4.3
	β^- 30%	0.511	120	63	35	26.5
		1.19	5	53	21	0.5
^{64}Cu(12.8 h)	β^+ 19%	0.511	38	63	35	8.3
	β^- 38%	1.34	0.5	53	19	0.05
	EC43%					
^{67}Cu(61.7 h)	β^-	0.092	23	53	99	12.1
		0.184	40	59	58	13.7

has the lowest absorbed dose to various organs and tissues. The relative photopeak efficiencies have been calculated at several γ-ray energies of ^{61}Cu, ^{64}Cu, and ^{67}Cu for a 1/2 in. NaI scintillation camera. The photopeak detection efficiencies for 1/2 in. NaI crystal,[10] intensity[3] and the tissue attenuation of γ-rays were used to calculate the relative usable γ-ray flux. The results of these calculations are given in Table 2. Usable γ-ray flux from ^{61}Cu was higher than that from an equal amount of ^{64}Cu. With the scintillation camera, the 284 keV γ-ray of ^{61}Cu provides 4.3% usable γ-ray, while the 1340 keV γ-ray of ^{64}Cu gives as small as 0.05% usable γ-ray. This indicates that the principal γ-ray of ^{61}Cu(284 keV) is more intense and in an energy range that is more advantageous for scinti-scanning than that of ^{64}Cu.

On the other hand, five millicuries of ^{67}Cu is produced by the reaction ^{68}Zn(γ,p)^{67}Cu for 48 h irradiation of natural zinc in the bremsstrahlung beam from a linear accelerator.[11] ^{67}Cu has the advantage that the relative detection efficiency for its intense 184 keV γ-ray (40%) is 13.7%. However, its absorbed dose is too high to be used *in vivo* clinical studies,[1] even if high specific activity ^{67}Cu, having a half-life of 61.7 h, is useful in particularly time consuming biochemical studies.

The 284 keV γ-ray of ^{61}Cu approaches an optimum energy that is low enough to be efficiently counted with thin NaI crystals allowing use of high resolution collimators, but high enough to obtain necessary tissue penetration. These characteristics make this nuclide highly desirable for nuclear medical application.

Conclusion

We found the bombardment of cobalt at 40 MeV to be the best method to produce ^{61}Cu in sufficient quantity for radiopharmaceutical studies. Advantages are the relatively high yield as compared with other methods, and the high radionuclidic purity of carrier-free ^{61}Cu. For routine production we have chosen the following bombardment conditions: energy of the incident particles 40 MeV, target thickness 250 mg/cm,^{2} beam current 5μA. The irradiation time varies according to the required quantity of ^{61}Cu from 1—2 h. Under these conditions, the yield of ^{61}Cu obtained at the end of 1 and 2 h of bombardment is *ca.* 13 and 26 mCi, respectively, corrected for losses during the course of recovery.

The authors wish to thank Dr. Tadashi Nozaki and members of the cyclotron group of the Institute of Physical and Chemical Research for their valuable discussions and cooperation.

Interaction between Aromatics and Zinc Chloride in the Molten State. The Formation of σ-Complexes and Radicals

Mikio MORITA, Kunio HIROSAWA, and Toshio SATO

Government Industrial Development Laboratory, Hokkaido, Higashitsukisamu, Toyohira-ku, Sapporo-shi, Hokkaido 061-61

(Received October 8, 1976)

The electronic absorption spectra of naphthalene, anthracene, and naphthacene in dried, molten zinc chloride were measured and found to be almost the same as those of aromatics–aluminum chloride complexes in the solid state. ESR measurements were also made; they confirmed the presence of radicals. From these results, it was concluded that the aromatics reacted with molten zinc chloride to form EDA-complexes, *i. e.*, σ-complexes and cation radicals.

It has been known that a massive quantity of zinc chloride used in the molten state is a superior catalyst for the hydrocracking of polycondensed aromatics into gasoline fractions, although partial hydrogenation is predominant when the amount of zinc chloride is relatively small; the activity of the catalyst has been considered to originate in a proton produced by the dissociation of water coordinated to the zinc chloride molecule.[1–4]

However, when aromatics come into contact with dried, molten zinc chloride under a vacuum, colored products are observed to be produced. This suggests that the products are complexes of the electron donor-acceptor type and might also play a role in the hydrocracking of aromatics as reaction intermediates, because we have already confirmed that, in the hydrocracking of aromatics with molten zinc chloride, the conversion is correlated with their ionization potentials.[2]

The measured electronic spectra of aromatics–zinc chloride complexes were almost the same as those of aromatics–aluminum chloride complexes in the solid state observed by Perkampus and Kranz[5] and by Sato and Aoyama.[6] Furthermore, the complexes gave strong ESR signals of the singlet type.

From these results, aromatics and zinc chloride in the molten state were found to form σ-complexes, radicals, and additional intermediates between the σ-complexes and the aromatics.

Experimental

Materials. Zinc chloride, naphthalene, anthracene, and naphthacene of the G. R. grade were used without purification.

Electronic Absorption Spectra. Zinc chloride, after having been introduced into the rectangular quartz cell shown in Fig. 1, was heated at 200±10 °C under a vacuum below 10^{-3} Torr in an electric furnace for 2—3 h. After the cell has then cooled to room temperature, an aromatic compound sample in a vacuum stopcock (*cf.* Fig. 1) was dropped into the cell. The cell was then evacuated again at about 10^{-3} Torr, and the upper neck of the cell was sealed off by fusion. The cell containing the sample was then heated in an electric furnace above 280 °C to melt it. When this molten zinc chloride was placed in sufficient contact with aromatics, colored products were observed to develop in the transparent molten zinc chloride. This sample cell was mounted in a specially constructed cell holder kept at 300±10 °C, and the absorption spectra were measured with a Hitachi 624-type spectrophotometer.

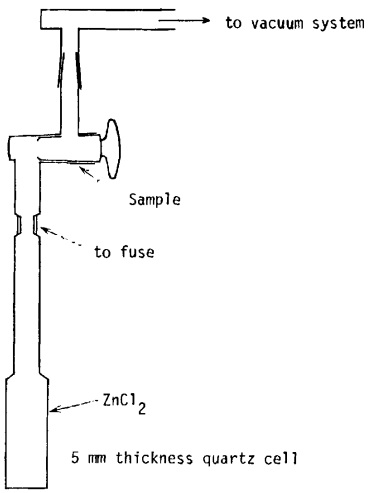

Fig. 1. Apparatus for the absorption spectroscopic study.

To confirm more exactly the formation of colored products of the σ-type, anhydrous zinc chloride was carefully prepared from silver chloride and metallic zinc powder in a vacuum according to a procedure similar to Wallace and Willard's for the preparation of anhydrous aluminum chloride;[7] it was then reacted with anthracene in a sealed glass tube.

ESR. Samples for the ESR measurements were prepared in ESR tubes in a way similar to that described above. The ESR signals were measured with a Jasco model ME-type spectrometer at room temperature, while the *g*-values were determined by the use of MnO as the reference substance.

Results and Discussion

Electronic Absorption Spectra. The absorption spectra of the colored products in molten zinc chloride for naphthalene, anthracene, and naphthacene are shown in Fig. 2 and are summarized in Table 1 for purposes of comparison.

The spectrum of molten zinc chloride only (Fig. 2-(1)) did not show any special absorption bands within the range in question. Upon reaction with molten zinc chloride, anthracene gave three absorption bands at 425, 620, and 725 nm (Fig. 2-(3)), naphthalene gave two weak absorption bands at 385 and 590 nm (Fig. 2-(2)), and naphthacene gave strong absorption bands at 360 and 460 nm (Fig. 2-(4)). After prolonged contact, a new band at 705 nm for naphthalene (Fig. 2-(2')) and one at 710 nm for naphthacene (Fig. 2-(4'))

Table 1. Comparison of the absorption bands of the σ-complexes, radicals, $HF-BF_3$, BF-1,2-dichloroethane, and Na- or K-THF systems

Species	System	Naphthalene	Anthracene	Naphthacene
σ-Complex	A	385	425	460
	B	380	420	468
	D		423	452
Proton-addition complex	C	390	408	435
Radical, monopositive ion, or negative ion	A	705	725	710
	B		735	355, 385, 395, 670, 769, 850
	E	366, 735, 813	369, 715	359, 403, 704
Dinegative ion or others	A	590	620	360
	B		665	
	E		333, 613	353, 398, 621
			(unit; nm)	

A; Molten zinc chloride. B; Aluminum chloride.[5,6] C; $HF-BF_3$.[10,11] D; BF_3-1,2-Dichloroethane.[9] E; Sodium- or Potassium-THF.[16,17]

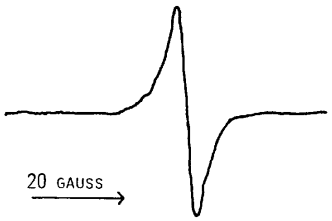

Fig. 3. ESR spectrum of naphthalene cation radical formed in molten zinc chloride.

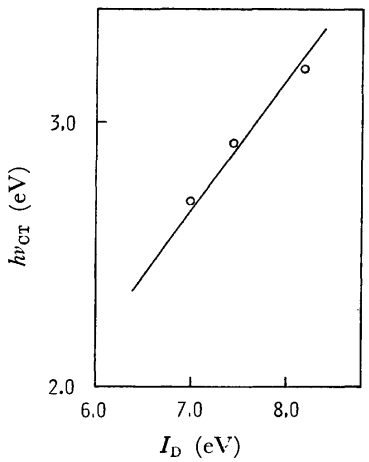

Fig. 4. Dependence of the position of CT bands on ionization potentials of donors.

were observed to develop.

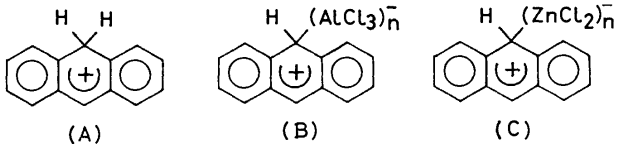
ESR Signals. All the samples gave strong and broad singlets with the *g*-values of 2.0028, 2.0031, and 2.0030 for naphthalene, anthracene, and naphthacene respectively (*cf.* Fig. 3).

σ-Complex Formation. As may be seen in Table 1, the absorption bands at 385 nm for naphthalene, 425 nm for anthracene, and 460 nm for naphthacene in molten zinc chloride were found to be almost the same as those of the corresponding aromatics–aluminum chloride complexes in the solid state, the latter being confirmed as σ-complexes(π, v-complexes according to their notation) by Perkampus and Kranz.[5]

Figure 4 shows the linear correlation between their absorption energy, $h\nu_{CT}$, and the ionization potential, I_D, of the corresponding aromatics; this correlation suggests EDA-complex, *i.e.*, σ-complex formation, as in the case of aromatics–ethanol–zinc chloride–chloroform system investigated previously by the present authors.[8]

However, since the proton-addition complexes are quite similar to the σ-complexes in the position of the absorption band (Table 1),[9-11] we tried to eliminate the effect of the trace amount of water on the complex formation in the present system; it could be confirmed that a colored product was produced by the reaction of anthracene with anhydrous molten zinc chloride carefully prepared from zinc metal and silver chloride in a vacuum.

These results strongly suggest that aromatics directly react with molten zinc chloride to form EDA-complexes, *i.e.*, σ-complexes. Accordingly, the absorption bands at 385 nm for naphthalene, 425 nm for anthracene, and 460 nm for naphthacene can be attributed to the formation of aromatics–zinc chloride σ-complexes.



(A) (B) (C)

The structure of the proton-addition complexes of aromatics proposed by Gold and Tye[12] has been both experimentally and theoretically confirmed;[11,13,14] for example, the proton-addition complex of anthracene has been fomulated in the form of (A). Perkampus and Kranz proposed the (B) structure for the anthracene–aluminum chloride complex on the basis of the similarity in the absorption spectrum.[5] The (C) structure can also be proposed for the anthracene–zinc chloride complex on the basis of the similarity of the absorption spectrum of anthracene in molten zinc chloride with that in aluminum chloride in the solid state.

Ion or Radical Formation. Naphthalene in molten zinc chloride has a paramagnetic property and a characteristic color which gradually changes from purple to dark green.[15] It gave an absorption band at 705 nm quite different from the absorption band for sodium[16] or potassium[17] naphthalenide in the THF solution assigned as a free radical. However, this band is assumed to correspond to the naphthalene cation radical, because it is more difficult for naphthalene to form a radical than for the other two aromatics and because the band at 705 nm in the spectrum of Fig. 2-(2′) and the strong ESR signal appeared only when naphthalene was in sufficient contact with molten zinc chloride. The band at 590 nm in the spectrum of Fig. 2-(2) or (2′) has been attributed to the dipositive ion or an intermediate between naphthalene and the naphthalene–zinc chloride σ-complex, as Sato predicted,[6] but further investigation is necessary for a certain assignment.

Distler and Hohlneicher showed that the anthracene cation radical has absorption maximum at 735 nm, and the naphthacene radical, at 348, 397, 667, 752, and 833 nm.[18] The present work confirmed that anthracene, when in sufficient contact with molten zinc chloride, showed a characteristic deep green color[15] and was strongly paramagnetic. The absorption band at 725 nm can thus be attributed to the formation of the cation radical derived by the ionization of the σ-complex (C). The absorption band at 620 nm seemed to correspond to that observed on the silica–alumina surface[19] and that observed for the anthracene–aluminum chloride complex.[6] Hall[19] supposed that the 665 nm species might be a dipositive anthranium ion on the basis of Aalbersbers's work[20] and from the calculations of Balk *et al.*[21] Sato and Aoyama proposed that it might be a secondary σ- or π-complex produced by anthracene and the anthracene–aluminum chloride σ-complex. In the case of the anthracene–molten zinc chloride system, further investigation is necessary to assign the band at 620 nm.

In the case of naphthacene, the formation of the cation radical was also confirmed by the production of ESR signals and the characteristic blue color.[15] The absorption spectrum (Fig. 2-(4)) did not show any special band within the range between 500 and 800 nm, but a weak absorption band around 710 nm (Fig. 2-(4′)) grew with prolonged contact. This band may be attributed to one band of the naphthacene cation radical. The absorption band about 360 nm may be supposed to be overlapped with the absorption bands of naphthacene itself, the cation radical, and the dipositive ion.

The Structure of the Cyclodextrin Complex. IV. The Crystal Structure of *a*-Cyclodextrin–Sodium 1-Propanesulfonate Nonahydrate

Kazuaki HARATA

Research Institute for Polymers and Textiles, Sawatari-4, Kanagawa-ku, Yokohama 221

(Received October 20, 1976)

α-Cyclodextrin, which is a cyclic oligosaccharide consisting of six D-glucose residues, forms a 1 : 1 complex with sodium 1-propanesulfonate. The crystal structure was determined by the X-ray method. The crystal is orthorhombic, and the space group is $P2_12_12$ with cell dimensions of $a=21.608(2)$, $b=16.700(2)$, and $c=8.302(1)$ Å, and $Z=2$. The structure was solved on the basis of 2219 diffractometer data and refined by the block-diagonal least-squares method to the final R-value of 0.077. The α-cyclodextrin molecule is nearly hexagonal with diagonal distances of 8.40—8.59 Å between the glycosidic oxygen atoms. The framework of the crystal is built up of a stack of α-cyclodextrin rings along the c axis in head-to-tail arrangement, with channel-type structure. The adjacent α-cyclodextrin molecules along the channel are linked by six O(3)···O(6) hydrogen bonds. The guest 1-propanesulfonate anions are located in channels, having statistical disorder. The primary hydroxyl groups of α-cyclodextrin exhibit *gauche-trans* conformation, and they form hydrogen bonds with the sulfonato group resulting in oxygen-oxygen distances of 2.72—2.80 Å. The propyl group is in contact with the O(2), O(3) side of the α-cyclodextrin ring. The sodium ion is located outside the channel, and is surrounded by five oxygen atoms which form a distorted trigonal bipyramid.

α-Cyclodextrin (α-CDx) is a cyclic oligosaccharide consisting of six D-glucose residues. It has a cylindrical cavity with a diameter of about 5 Å and a height of 8 Å in the center of the molecule. At both ends of the cavity, the hydroxyl groups are located, while in the interior of the ring the twelve C–H groups are oriented to the center of the cavity. Therefore, the cavity is of relatively hydrophobic nature. α-CDx forms a number of inclusion complexes with a variety of guest molecules which range from polar ones, such as potassium acetate, to non-polar ones, such as the rare gases.[1–4] The complexing ability has been considered to be largely determined by the relative size of the guest molecule. Recent X-ray analyses have revealed that the guest molecules are situated in the interior of the cavity, and that the macro-cyclic conformation of the α-CDx ring changes with the dimension and the shape of the guest molecule.[5–16] The α-CDx ring in the 1-propanol complex[8] is nearly hexagonal, but remarkable deformation of the α-CDx ring is observed in the water complex.[6]

α-CDx has been used as an enzyme model,[3] since it exhibits catalytic properties for some chemical reactions. The interaction between α-CDx and the guest molecule is of interest in relation to the enzyme-substrate interaction. Saenger and his coworkers[6–9] have proposed the inclusion mechanism on the basis of the fact that the driving force for the complex formation is derived from the difference between the conformational energy of α-CDx for the "tense" state and that for the "relaxed" state. On the other hand, a theoretical calculation of the complex formation energy[15] has shown that the stability of the complex is mainly determined by the difference between the solvation energy for the complexed state and that for the uncomplexed state, and that the inclusion of the hydrophobic group gives a more stable complex than does the inclusion of the hydrophilic group. Sodium 1-propanesulfonate (PSNa) consists of a hydrophobic propyl group and a hydrophilic sulfonato group. An X-ray analysis of the α-CDx–PSNa complex was performed to investigate the conformation of α-CDx and the interaction between α-CDx and PSNa, in comparison with those of other α-CDx complexes.

Experimental

Crystals of the α-CDx–PSNa complex were obtained by cooling an aqueous solution containing α-CDx and PSNa with a 1 : 1 molar ratio. These are colorless and orthorhombic prisms elongated along the c axis. The density was measured by the flotation method in a mixture of chloroform and dioxane. The diffraction measurements were carried out with the crystal enclosed in a quartz capillary containing a small amount of water, since the crystal decomposes in air. The crystal data are given in Table 1. The intensity data were obtained on a Rigaku automatic four-circle diffractometer using graphite monochromatized Cu$K\alpha$ radiation and the θ-2θ scan technique. 2570 independent reflections were obtained up to 120° in 2θ, but 351 reflections with $|F_o|<3\sigma(F)$ were treated as unobserved, where $\sigma(F)$ is the standard deviation estimated from counting statistics. No correction was made for absorption and extinction.

Determination and Refinement of the Structure

The crystal structure of the α-CDx–PSNa complex was solved on the basis of the assumption that the location of the α-CDx molecule is same as that of the isomorphous crystal of the sodium benzenesulfonate (BSNa) complex[15]. The atomic parameters of α-CDx were refined by the block-diagonal least-squares method, starting from those of the BSNa complex. Then, a

Fourier map was calculated, and the PSNa and water molecules were found from it. The 1-propanesulfonate anion is statistically disordered on the two-fold axis. Unreasonably short intermolecular distances were found for Na···O(W6), O(W3)···O(W6), O(W5)···O(W7), and O(W6)···O(W7), indicating that the locations of these atoms are statistically disordered. An average population of 0.5 is assigned to the sodium ion, since there are only two PSNa molecules per unit cell in spite of the four equivalent positions. The population of O(W6) is also 0.5 since the O(W6) atom occupies the position when the sodium ion is absent. Then, the abnormally short distances for O(W3)···O(W6), O(W5)···O(W7), and O(W6)···O(W7) can be reasonably interpreted by assigning 0.5 to the respective occupancies of O(W3), O(W5), and O(W7). The 27 hydrogen atoms were found on the difference-Fourier map. A refinement of the atomic parameters was carried out by the block-diagonal least-squares method. The isotropic thermal factors of hydrogen atoms were taken to be equal to those of the carbon or oxygen atoms to which the hydrogen atoms are bonded, and were not refined. The final R-value is 0.077 for the 2219 reflections. The quantity minimized was $\Sigma w(|F_o|-|F_c|)^2$ with $w=1.0$ for all reflections used. The atomic scattering factors were taken from "International Tables for X-ray Crystallography."[17] The atomic parameters are shown in Tables 2 and 3. The observed and calculated structure factors are given in Table 4.*

TABLE 2. ATOMIC PARAMETERS ($\times 10^4$) FOR NON-HYDROGEN ATOMS

The anisotropic thermal factors are of the form: $\exp[-(B_{11}h^2+B_{22}k^2+B_{33}l^2+B_{12}hk+B_{23}kl+B_{31}lh)]$.

Description and Discussion of the Structure

The structure and numbering scheme of the α-CDx–PSNa complex are shown in Fig. 1. The α-CDx molecule is nearly hexagonal. The 1-propanesulfonate anion is located in the channel which is formed by the stacking of the α-CDx rings (Fig. 2). Bond distances, angles, and conformation angles are given in Table 5. The geometrical data describing the macro-cyclic conformation of α-CDx ring are shown in Tables 6 and 7. The crystal structure and hydrogen-bonding scheme are shown in Figs. 4—7.

Bond Distances and Angles. The bond distances and angles for α-CDx in the present complex are not significantly different from those for the potassium acetate (ACK) complex,[13] the Methyl Orange complexes,[14] and the BSNa complex[15] which have channel-type structures. The average bond lengths for the three glucose residues are in good agreement with the average values for the α-D-glucose residues given by Arnott and Scott.[18] However, regarding bond angles, the average value for C(3)–C(4)–O(4) in α-CDx is 105.2°, which is smaller than the Arnott and Scott value of 110.4°. The C(1)–O(4′)–C(4′) angles of 117.5—119.0° are larger than those for the disaccharides.[18] These C(3)–C(4)–O(4) and C(1)–O(4′)–C(4′), however, are commonly observed in α-CDx complexes.

The abnormally short bond length and large angles are found in the 1-propanesulfonate anion (Fig. 3). This may be due to the disorder of the anion on the two-fold axis. The C(1, PS) atom is found to lie on the two-fold axis, but the thermal factor is relatively

* Table 4 is kept as a Document at the office of The Chemical Society of Japan. (Document No. 7706).

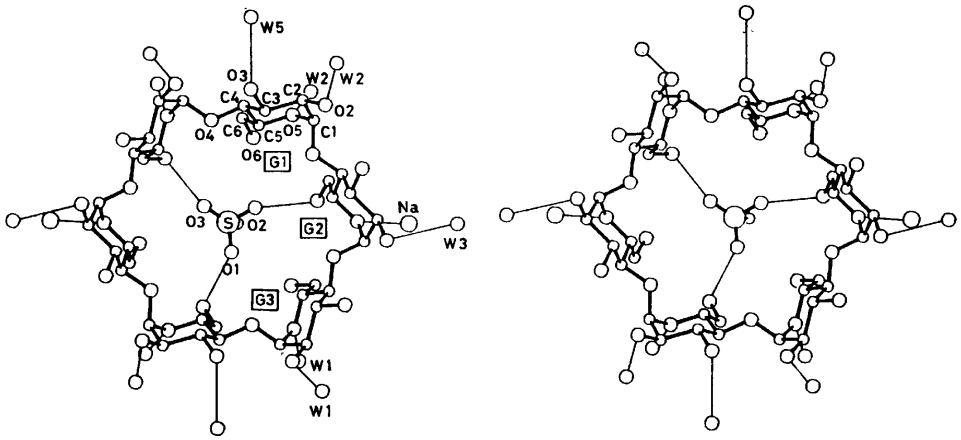

Fig. 1. A stereoview of the α-CDx–PSNa complex. Intermolecular O···O and O···Na contacts less than 3.0 Å are shown with thin lines. W1, W2, W3, and W5 denote oxygen atoms in water molecules.

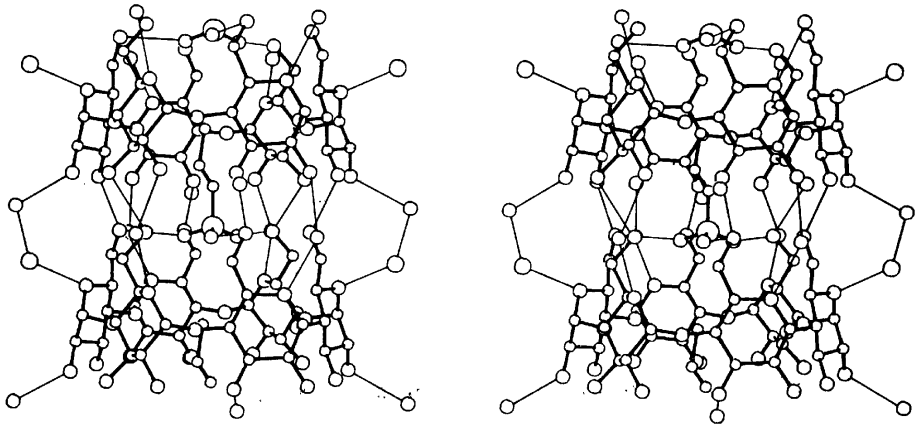

Fig. 2. A stereoview showing the stacking feature of α-CDx molecules. Intermolecular O···O and O···Na contacts less than 3.0 Å are shown with thin lines. Circles, in order of decreasing size, represent sulfur, sodium, oxygen, and carbon atoms.

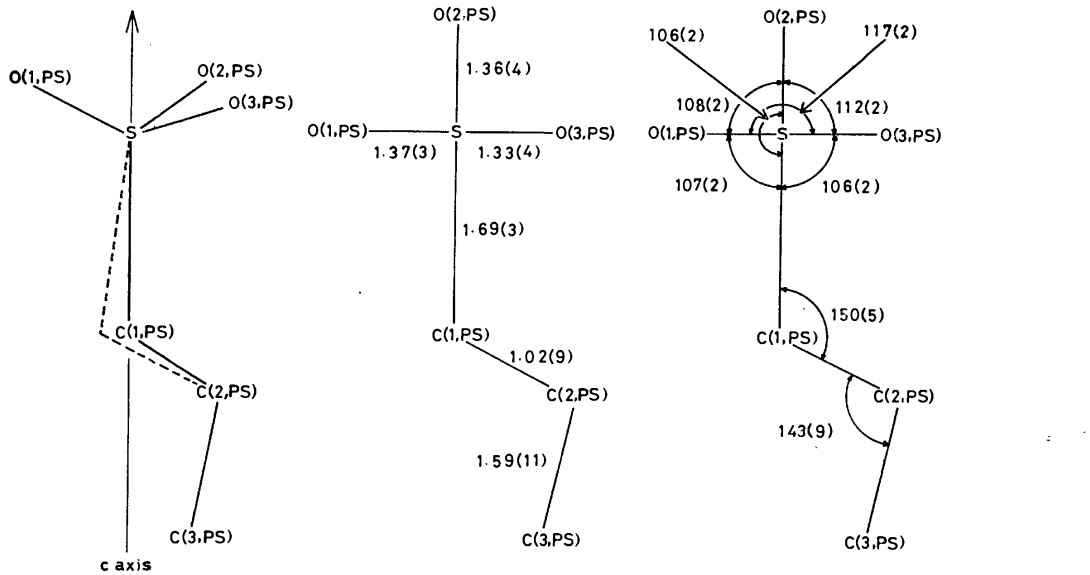

Fig. 3. Bond distances (l/Å) and angles (ϕ/°) in the 1-propanesulfonate anion. The short C(1,PS)–C(2,PS) distances and large valence angles of C(1,PS) and C(2,PS) are due to the small displacement of C(1,PS) from the c axis, as shown with the broken line.

TABLE 5. BOND DISTANCES (l/Å), ANGLES (ϕ/°), AND CONFORMATION ANGLES (ϕ/°) IN α-CYCLODEXTRIN

A prime (′) denotes the atom in the adjacent glucose residue.

a) Methyl Orange sodium salt. b) Methyl Orange potassium salt.

large (the isotropic thermal factor is 13.2 Å^2). The short C(1, PS)–C(2, PS) distance and large angles for S–C(1, PS)–C(2, PS) and C(1, PS)–C(2, PS)–C(3, PS) are reasonably explained as being due to a slight deviation of the C(1, PS) atom from the fwo-fold axis, as shown in Fig. 3, although this was not resolved on the electron-density map.

Conformation of α-Cyclodextrin. Each glucose residue is in a C1 chair conformation, and is α-1,4-linked. The primary hydroxyl groups show a *gauche-trans* conformation. None of the conformation angles in the glucose residues deviates from the mean value of the three glucose residues by more than 2.3°. The conformation angles in the pyranose ring are in good agreement with the Arnott and Scott values.[18] The α-CDx ring in the PSNa complex is more symmetrical than those in the ACK,[13] Methyl Orange,[14] and BSNa[15] complexes. The diagonal distances between the glycosidic oxygen atoms are 8.40, 8.45, and 8.59 Å (Table 7). In the Methyl Orange complexes and the BSNa complex, the α-CDx rings are elliptical due to the inclusion of the planar group; the O(4, G3)···O(4*, G3) distances are longer than the O(4, G1)···O(4*, G1) distances by 0.6—0.8 Å. The conformation angles involving C(1)–O(4′)–C(4′) linkages are in good agreement with each other for complexes having a channel-type structure. Therefore, the distortion of the α-CDx ring is not described by the conformation angles involving the glycosidic linkages.

French and Murphy[19] have discussed the deformation of the pyranose ring of the α-D-glucose residue in terms of the O(1)···O(4) distance and the torsion-angle index; the torsion-angle index is defined by $|\phi(C(1)-C(2))|+|\phi(C(2)-C(3))|+|\phi(C(5)-O(5))|+|\phi(O(5)-C(1))|-|\phi(C(3)-C(4))|-|\phi(C(4)-C(5))|$ when the torsion-angle of C(1)–C(2)–C(3)–C(4) is expressed by $\phi(C(2)-C(3))$. They have also shown that the O(1)···O(4) distance is closely related to the torsion-angle index. The O(4)···O(4′) distances in the PSNa complex are 4.24±0.03 Å, and this value agrees with 4.25 Å predicted for the α-CDx having regular hexagonal symmetry.[20] In the Methyl Orange complexes and the BSNa complex, the O(4)···O(4′) distances in the G2 residues are shorter by 0.24—0.31 Å than those in the G1 residues, although the average values are close to 4.25 Å. The different conformations of the pyranose ring result in different torsion-angle indices. In the PSNa complex, the torsion-angle indices are 126.6—128.5°. In the Methyl Orange complexes and the BSNa complex, the torsion-angle indices of the G2 residues are greater by 4.7—15.1° than those of the G1 residues. Therefore, the elliptical structure of α-CDx in the Methyl Orange complexes and the BSNa complex is ascribed to a deformation of the pyranose rings, that is, a difference between the conformation angles in the pyranose rings. No significant difference was observed for the O(2)···O(3′) distances, indicating that the distortion of the α-CDx ring does not affect the intramolecular hydrogen bonds in complexes with channel-type structures.

Geometry of Inclusion. α-CDx molecules are stacked in a head-to-tail arrangement, and form endless channels along the c axis. The α-CDx molecule has two-fold symmetry, but the asymmetric 1-propanesulfonate anion is located in a channel with statistical disorder on the two-fold axis. The anion is in contact with two α-CDx molecules. The propyl group contacts with the O(2), O(3) side of the α-CDx ring (Fig. 2). The sulfonato group is hydrogen-bonded to three of the primary hydroxyl groups, O(6*, G1), O(6, G2), and O(6*, G3) with oxygen-oxygen distances of 2.72, 2.80, and 2.75 Å, respectively. A different hydrogen-bonding contact was observed in the BSNa complex.[15] The sulfonato group forms hydrogen bonds with four of the primary hydroxyl groups, O(6, G1), O(6, G3), O(6*, G1), and O(6*, G3), with the respective distances being 2.80, 2.86, 2.71, and 2.86 Å. The primary hydroxyl groups of the G2 residues in the BSNa complex do not form hydrogen bonds because of the elliptical structure of α-CDx. In the ACK complex and the Methyl Orange complexes, the primary hydroxyl groups are also hydrogen-bonded to the ionized group of the guest molecule. It is noted that the sulfonato group and the acetate ion are nearly trigonal. The trigonal group fits well into the O(6) side of the α-CDx ring, as is shown in Figs. 1 and 2.

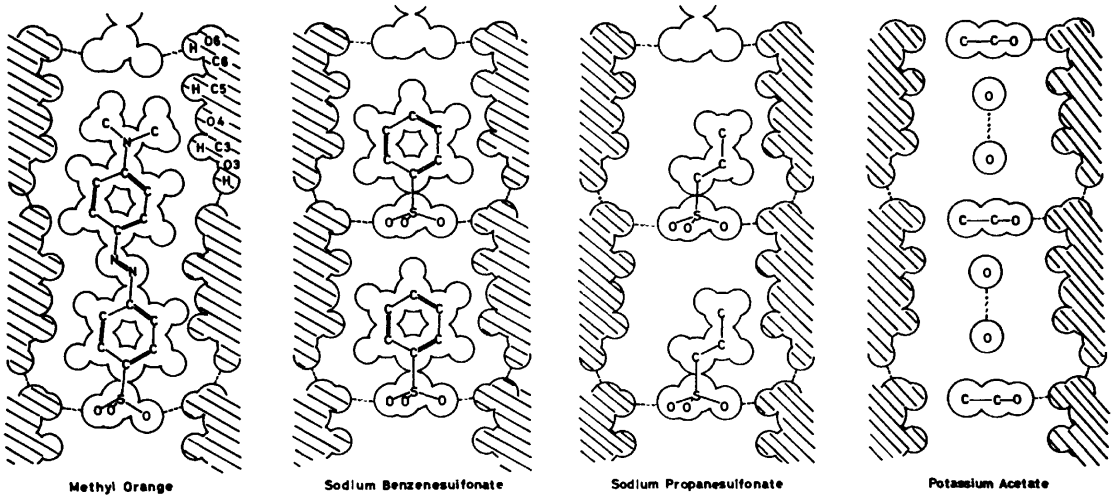

Fig. 4. A comparison of the arrangements of guest molecules in the channel. Broken lines denote hydrogen bonds.

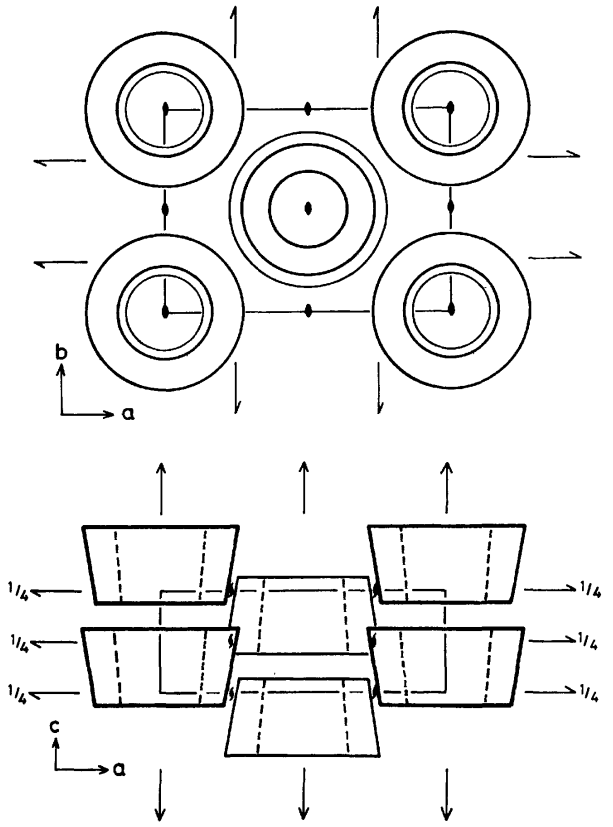

Fig. 5. A packing feature of α-CDx molecules in the crystal.

Schematic drawings of the arrangements of the guest molecules in the channel are shown in Fig. 4. A long molecule, as well as a small molecule, can be situated in the channel. In the ACK complex,[13] the acetate anion is so small that the empty space in the cavity is filled with two water molecules. On the other hand, a long guest anion extends through two α-CDx rings in the Methyl Orange complexes. For bulky guest molecules, the suitability of the guest molecule to the cavity may determine the geometry of the complex. In the interior of the cavity, the C(3)–H and C(5)–H groups are oriented at the center of the α-CDx cavity. The circle composed of six hydrogen atoms attached to the C(5) atoms forms the neck of the cavity. In the Methyl Orange complexes, the azo group is situated at the neck, but in the other complexes the guest molecules are not located at the neck. The conformation of the α-CDx ring in cage-type structures[5–9] changes remarkably with the dimension and the shape of the guest molecule. In channel-type structures,[13–15] however, the conformation change is quite small. This may be due to the fact that the framework of the α-CDx ring is held together by the hydrogen bonds between the α-CDx molecules and between α-CDx and the ionized group.

Crystal Structure and Hydrogen Bonds. The framework of the crystal is built up of endless cylinders formed by stacks of the α-CDx rings, as is shown in Fig. 5. The space outside the channel is filled with cations and water molecules (Fig. 6). The two adjacent α-CDx molecules are linked by O(2, G3)···O(W1)···O(5, G3), O(2, G1)···O(W2)···O(5, G1), and O(2, G2)···O(W3)···Na···O(5, G2) linkages except for O(3)···O(6) hydrogen bonds. The sodium ion is surrounded by five oxygen atoms, O(W1), O(W2), O(W3), O(W7), and O(5, G2), which form a distorted trigonal bipyramid (Fig. 7). The Na···O distance varies from 2.36 to 2.58 Å. These values are in good agreement with those of 2.34—2.55 Å found for the BSNa complex.[15] In the ACK complex[13] and the Methyl Orange complexes,[14] the cations are surrounded by six oxygen atoms which form a distorted octahedron (Fig. 8).

The hydrogen-bonding scheme is similar to that of the BSNa complex (Fig. 9). In the G1 residue, O(2, G1) and O(5, G1) are hydrogen-bonded to O(W2), while O(3, G1) is bonded to O(W5). Both of O(2,G3)

and O(5, G3) in the G3 residue form hydrogen bonds with O(W1). In the G2 residue, only O(2, G2) is involved in the hydrogen-bonding with water. The primary hydroxyl groups do not form hydrogen bonds with water, but they form hydrogen bonds with O(3) atoms in the adjacent α-CDx molecule.

Conclusions

So far, three channel-type structures with head-to-tail arrangement of α-CDx have been revealed; the ACK complex,[13] the Methyl Orange complex,[14] and the BSNa complex.[15] The PSNa complex has been

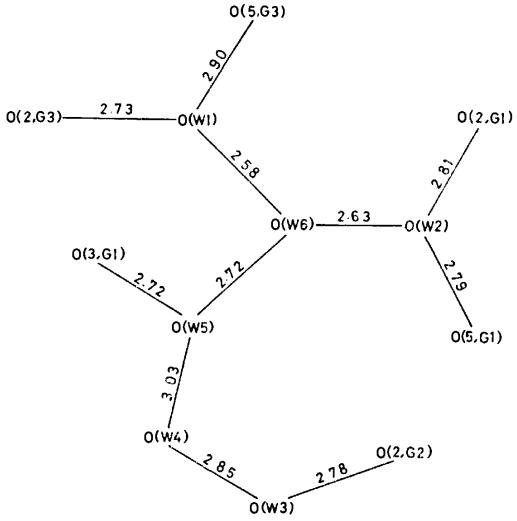

Fig. 9. The hydrogen-bonding scheme in crystals of α-CDx-PSNa nonahydrate.

shown to have the same crystal structure. It is noteworthy that these complexes crystallize in approximately isomorphous structures, although the shapes and dimensions of the guest molecules are quite different. The adjacent α-CDx molecules along the channel are connected by O(3)···O(6) hydrogen bonds. The hexagonal structure of α-CDx may be stabilized by hydrogen-bonding with the ionized group, which has a trigonal structures. The change in the macro-cyclic conformation of α-CDx, which is caused by the inclusion of the planar group, affects the lattice parameters. The elliptical α-CDx ring is parallel to the ac plane, and the long axis is oriented along the a axis. Therefore, the *a* dimensions of crystals of the Methyl Orange complexes and the BSNa complex are longer by 0.22—0.51 Å than that of the PSNa complex, while the *b* dimensions are shorter by 0.17—0.34 Å.

Another type of channel-type structure has been found in the α-CDx–polyiodide complexes.[16] In this case, the α-CDx molecules are arranged in a head-to-head fashion, that is, the O(2), O(3) side of the α-CDx ring is facing the same side of the adjacent α-CDx ring, and the O(6) side is facing the O(6) side. The conformation of the primary hydroxyl groups is *gauche-gauche*, and thus, these groups cannot form hydrogen bonds including the guest molecule. In the channel, the guest molecules are arranged with statistical disorder, forming an infinite polyiodide chain.

In both types of channel-type structures, the guest anions are included in the cavity, but the cations are located outside the α-CDx ring. This may be due to the fact that the α-CDx cavity has a relatively positively-charged character. The interior of the cavity contains C(3)–H, C(5)–H, H–C(6)–H, and O(4) whose charges were estimated to be 0.11, 0.14, 0.14, and −0.25, respectively.[15] Moreover, the C(3)–H and C-(5)–H groups are oriented to the center of the α-CDx ring. Therefore, it appears that the inclusion of an anion is more favorable than the inclusion of a cation. Outside the channel, the oxygen atoms surrounding the

cation form the coordination shell.

The geometry of the PSNa complex is similar to that of the BSNa complex. The hydrophobic propyl group is in contact with the O(2), O(3) side of the α-CDx ring, while the sulfonato group is hydrogen-bonded to the primary hydroxyl groups. When we consider a structure in an aqueous solution, the solvation effect is important as has been shown in a previous paper.[15] The transfer of the propyl group from the water environment to the interior of the cavity will reduce the solvation energy of PSNa, since the propyl group may be more likely to be found in the hydrophobic and nonpolar cavity than in the water environment. When the sulfonato group is included in the cavity, it may form hydrogen bonds with the primary hydroxyl groups. But, as has been suggested by Griffiths and Bender,[3] the hydrogen bonds do not appear to be important in the stabilization of the complex, since the sulfonato group may be hydrogen-bonded to water molecules in the uncomplexed state. Therefore, the inclusion of the propyl group will give a more stable complex than the inclusion of the sulfonato group in an aqueous solution.

The author would like to acknowledge the helpfull suggestions of Dr. Alfred D. French. The author also wishes to thank Dr. Hisashi Uedaira for supporting this study and for useful discussions. The stereoviews were drawn on a Hewlett-Packard 7200A graphic plotter. The computation was done on a HITAC 8450 computer in this laboratory.

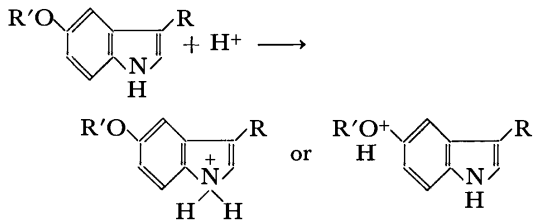
Electronic Absorption and Fluorescence Spectra of 5-Hydroxytryptamine (Serotonin). Protonation in the Excited State

Tohru KISHI,* Masashi TANAKA, and Jiro TANAKA
Department of Chemistry, Faculty of Science, Nagoya University, Chikusa, Nagoya 464
(Received October 28, 1976)

The fluorescence spectra of 5-hydroxytryptamine (serotonin) in acidic media have been studied by means of fluorescence polarization, temperature dependence of fluorescence, and kinetics of the protonation in H_2O and D_2O. The red-shifted emission appearing by protonation in the excited state is ascribed to the protonated form of serotonin at C_4. In order to confirm the assignment of electronic spectra, the absorption spectra of the single crystal of 5-methoxyindole-3-acetic acid have been measured by means of reflection technique, the directions of transition moments being determined by polarization analysis. Calculation was carried out on the energy levels of the excited state for serotonin and its protonated forms, and the directions of transition moments were compared with the experimental results.

5-Hydroxytryptamine (serotonin) found in many mammal tissues has several unknown physiological effects, such as on nervous impulse transmission and mental activity.[1] The fluorescence assay of serotonin is important in biomedical analysis. Udenfriend *et al.*[2] found that the fluorescence of serotonin in a strongly acidic solution appears at 18000 cm^{-1} in the visible region, and at 30000 cm^{-1} in a neutral solution. Bridges and Williams,[3] and Chen[4] studied the mechanism of this anomalous fluorescence and postulated that the emitting species is the protonated excited state form of serotonin. However, no detail of the protonated structure was established, the postulate remaining unsettled.



We have attempted to clarify the structure of the protonated form on the basis of (1) polarization measurement of the fluorescence, (2) temperature dependence of the fluorescence in the acidic media, (3) lifetime measurement of the fluorescence of both unprotonated and protonated serotonin in the acidic media, (4) polarization measurement of the reflection spectra of a crystal of serotonin derivative, and (5) theoretical calculation on serotonin and its protonated forms.

The electronic states and structures of serotonin and its protonated form were clarified from the results. The results are discussed in connection with the electronic spectra of the parent molecule, indole.

Experimental

Material. Serotonin creatinine sulfate (Nakarai Chemical Co.) was purified by repeated recrystallization from water. Ethylene glycol–water (7 : 3) (EGW) with 1.2 M HCl was used as a solvent for the fluorescence polarization measurement. The fluorescence lifetime were measured with solutions of 2×10^{-5} M in H_2O or D_2O by adding appropriate amounts of HCl or DCl. 5-Methoxyindole-3-acetic acid (pfs grade, Sigma Chemical Co.) was recrystallized from methanol–water. The compound was supplied by Prof. K. Tomita of Osaka University.

Methods. The temperature dependence of the fluorescence was measured in a thermostated cell with a Carl Zeiss spectrofluorometer in the temperature range −56—6 °C. A HTV-R446UR photomultiplier tube was used, no correction being made for the spectral responce of the detecting system. The polarization of the fluorescence was measured with the same apparatus combined with a calcite polarizer for excitation and a polacoat polarizer for analysis at −52 °C. The polarization characteristic of the polacoat polarizer was checked before the measurement, the stray light being less than 1%. The instrumental depolarization effect was corrected following the procedure of Azumi and McGlynn.[5] Fluorescence lifetimes were measured with an Ortec 9200 photon counting system. An Ortec nanosecond light pulser was used as an excitation source through a Toshiba DV-25 filter, with 20% $NiSO_4$ solution and 0.2% K_2CrO_4 solution of each 1 cm path. The fluorescence was detected through filters of a Toshiba UV-D1B and a Nd glass for the 29600 cm^{-1} band and a Fuji Color SC-52 for the 17800 cm^{-1} band. The reflection spectra were recorded by the microscopic reflecting system constructed in this laboratory.

Results and Discussion

The fluorescence spectra of indole in polar solvents exhibit a conspicuous red shift.[6–11] It is considered that the second excited level is stabilized and the fluorescence occurs from this state. The absorption and fluorescence spectra of serotonin are shown in Fig. 1 together with the polarization values for the excitation and emission. There are more than three absorption bands in the 31000—47000 cm^{-1} region. The first band appears in the 31000—34000 cm^{-1} range, the second band overlapping with it at 33000 cm^{-1} and extending to the 37000 cm^{-1} region, and the third band appearing with a maximum at 45300 cm^{-1}. Although the first and the second bands overlap in the 33000 cm^{-1} range, their maxima appear at different energies, differing from the case of indole where they overlap strongly.

The fluorescence spectra measured at −52 °C in an acidic media are shown in Fig. 1. The emission band with a maximum at 29800 cm^{-1} is ascribed to a neutral molecule and the band appearing at 17800 cm^{-1}

* Present address: National Research Institute of Police Science, 6, Sanban-cho, Chiyoda, Tokyo 102.

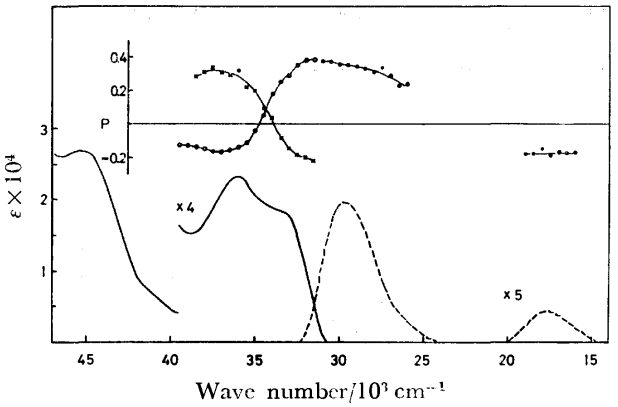


Fig. 1. The absorption (——), emission (---), and polarization spectra of serotonin in EGW with 1.2M HCl at −52 °C.
The fluorescence polarization (FP) spectra (-●-●-) were measured by exciting at 32500 cm^{-1}. The fluorescence excitation polarization (APF) spectra were recorded by monitoring the fluorescence at 30000 cm^{-1} (-O-O-) and at 18000 cm^{-1} (-×-×-).

is assigned to the protonated form. The maximum of this emission shifted to 17600 cm^{-1} when correction was made on the response of the photomultiplier tube.

Polarization Measurement of Fluorescence. The fluorescence excitation polarization (APF) spectra for the neutral molecule were measured by setting the detecting monochromator at 30000 cm^{-1}. It was found that the first absorption band shows p-values of 0.4—0.2. This indicates that the fluorescence originates from the first excited state. The second absorption band showed negative p-values of −0.12——0.17. Thus the direction of the transition moment is considered to be nearly perpendicular to the first band.

The fluorescence polarization (FP) of 29800 cm^{-1} emission band was measured by exciting at 32500 cm^{-1}, the p-valucs being always positive (0.4—0.25) in the range 31000—26000 cm^{-1}. This shows that the emission band consists of a unique origin, namely the fluorescence occurs from the lowest excited state.

The emission bands at 17800 cm^{-1} appearing in a strongly acidic solution showed a quite different polarization character as compared to the 29800 cm^{-1} band, its FP spectra measured by exciting at 32500 cm^{-1} showing a constant negative p-value of −0.18. In line with this results, the APF spectra in the first absorption region showed negative p-values of −0.2——0.1, while the second absorption band showed positive p-values of 0.2—0.3 in the 35000—39000 cm^{-1} range.

The 17800 cm^{-1} band is considered to be due to the protonated form of serotonin.[4] The present results show that the rotational motion of serotonin molecule in the excited state is frozen at −52 °C in EGW to give definite p-values, while the proton transfer occurs under these conditions and the protonated serotonin is formed consequently. The long wavelength fluorescence shows a different polarization character as compared to the parent molecule. The absorption spectra of serotonin in 1M HCl solution was almost the same as those in neutral solution. It was confirmed that the protonation occurs after the excitation of the neutral molecule, since a close correlation was found between the absorption and polarization spectra of the parent molecule and the protonated form. The direction of the transition moment of the protonated emitting species was shown to be nearly perpendicular to the first absorption band and parallel to the second absorption band.

Temperature Dependence of Fluorescence. The temperature dependence of the fluorescence in acidic media is shown in Fig. 2, the solution being excited at 33500 cm^{-1}. At 6 °C the peaks for neutral and protonated species were found at 29600 cm^{-1} and 17800 cm^{-1}, respectively. By lowering the temperature the intensity of the fluorescence from the neutral form increased, the peak showed a blue shift of 200 cm^{-1}, and the emission from the protonated form diminished. The results are explained by a retardation of the protonation in terms of increase in the viscosity of the solvent caused by fall of temperature. The disappearance of the visible fluorescence at −196 °C was reported by Chen.[4] This provides another evidence that the emission occurs from the protonated species.

Lifetime of Fluorescence. The rise and decay of fluorescence of the neutral and protonated forms are shown in Fig. 3. The lifetime of neutral species

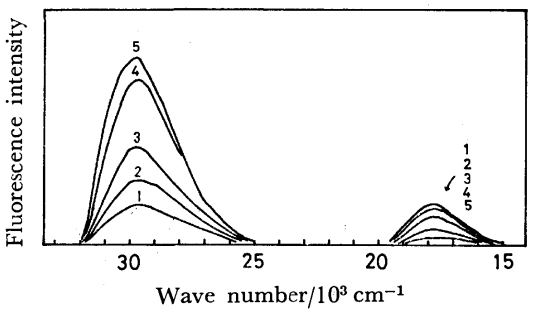

Fig. 2. The temperature dependence of the fluorescence of serotonin in EGW with 1.2 M HCl.
1. 6 °C; 2. −9 °C; 3. −19 °C; 4. −40 °C; 5. −56 °C.

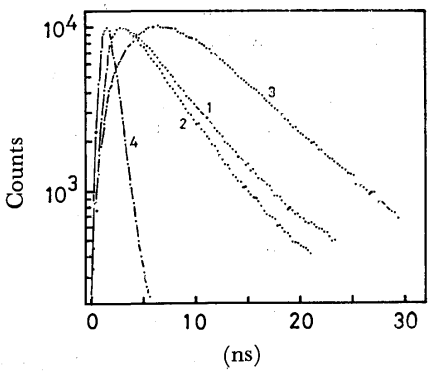

Fig. 3. The rise and decay curves of the fluorescence of the free and protonated serotonin in 0.04 M DCl.
1. Fluorescence intensity of serotonin measured at 30000 cm^{-1}, 2. Fluorescence intensity of serotonin with 0.04 M DCl measured at 30000 cm^{-1}, 3. Fluorescence intensity of protonated form of serotonin with 0.04 M DCl measured at 18000 cm^{-1}, 4. The flash profile.

decreases with increase in acid concentration. The rise and decay curves of the lower energy emission indicate that the excited species were produced after the excitation *via* the protonation of serotonin in the excited state.

Following Chen's[4] scheme, the reaction of the excited species is written as

$$\begin{array}{ccccc} S^* + H^+ & \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} & SH^{+*} & & \\ \downarrow k_f \quad \searrow k_q & & \downarrow k_f' \quad \searrow k_q' & & \\ S + h\nu \qquad S & & SH^+ + h\nu' & & SH^+ \end{array} \tag{1}$$

where S* is the excited serotonin, k_1 and k_{-1} are the rate constants for the protonation and deprotonation reactions, respectively, k_f and k_f', and k_q and k_q' are the rate constants for radiative and radiationless processes of neutral and protonated species, respectively. If we assume that $k_1[H^+] \gg k_{-1}$, then the lifetime τ of the excited neutral molecule S* is given by

$$1/\tau = k_f + k_q + k_1[H^+]. \tag{2}$$

The change of the fluorescence lifetime at 20 °C with increase in the hydrogen ion concentration is given in Table 1. The fluorescence quenching by the counter ion Cl^- was examined. It was found that the effect is negligible in the concentration range of Cl^- less than 0.1 M. The plot of $1/\tau$ against $[H^+]$ or $[D^+]$ gives the rate constant, $k_1(H)$ and $k_1(D)$. The results are

$$k_1(H) = 2.9\times10^9\ s^{-1}\ M^{-1},$$
$$k_1(D) = 1.6\times10^9\ s^{-1}\ M^{-1},$$

and

$$k_1(H)/k_1(D) = 1.8.$$

The linear relation between $1/\tau$ and $[H^+]$ or $[D^+]$ supports Scheme 1 for the reaction of the excited species. The kinetic isotope effect found in these reactions can be correlated with the motion of the hydrogen ion in an aqueous solution, since the reaction seems to be a diffusion controlled process. The ratio of

Table 1. Fluorescence lifetime of serotonin in the acidic media

$[H^+]$	In H_2O	In D_2O
0 mM	4.65 ns	5.57 ns
40	3.72	4.81
60	3.30	4.43
80	2.99	4.13

the rate constants $k_1(H)/k_1(D)$ shows a normal isotope effect.[12] It is interesting that the value is close to the ratio of the mobilities of proton and deuteron, $\mu(H^+)/\mu(D^+)$ (1.44) at 25 °C.[13] It might imply that the proton transfer occurs in the charge-separated excited species through the Grotthuss mechanism.[14]

Theoretical Calculation of Electronic State. The electronic energy levels of serotonin and its protonated forms were calculated by the Pariser-Parr-Pople method[15,16] by using the Nishimoto-Mataga potential[17] and taking into account the configuration interaction. The calculated transition energy, size and direction of the transition moments are given in Table 2 and Fig. 4. The directions of ^1L_b and ^1L_a transitions

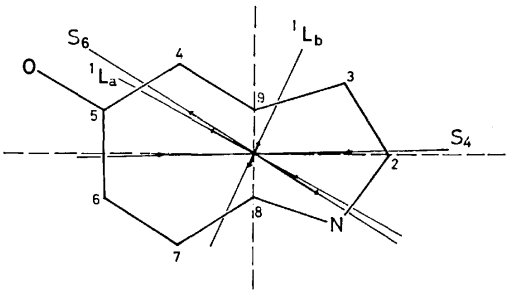

Fig. 4. The theoretical prediction of the direction of transition moments of the excited singlet states (^1L_a and ^1L_b) of serotonin and its protonated forms. S_4 or S_6 are is direction of the transition moment of the lowest singlet state of the protonated forms by adding proton at C_4 or C_6 positions, respectively.

Table 2. Theoretical calculations of the singlet excited states of serotonin and its protonated forms

	State symbols	State energy cm^{-1}	Transition-moment length R_x	Transition-moment length R_y	Oscillator strength f	Observed values cm^{-1} (f)

(Fig. 4) are given for serotonin; the transition moment to the ^1L_b state makes 85° with that of the ^1L_a, while the observed value estimated from the p-values and the relation between the p-value and the angle θ made of transition moments[18,19] given by

$$p = \frac{3\cos^2\theta - 1}{3 + \cos^2\theta} \qquad (3)$$

is 90°. The agreement between these two values is satisfactory, since the depolarization and other possible experimental errors might not be completely corrected.

Calculation for the protonated forms was carried out by assuming that the proton attack at C_4 or C_6 position of the indole ring and positive charge was put on oxygen atom (Table 2). The positions of proton attack were presumed since these protons are known to be easily deuterated in acidic media. The lowest energy transitions were calculated for C_4 and C_6 adducts at 22750 cm^{-1} and 21890 cm^{-1}, respectively. These values are in good agreement with the position of the fluorescence band when we consider a mirror image relationship between the absorption and emission spectra. The directions of transition moments from these levels to the ground state are along S_4 or S_6 (Fig. 4). A comparison of the calculated directions with the p-values suggests that the lowest state of the protonated form has a transition moment along S_4. As an example, from the observed p-values, the first and second transitions of parent molecule (^1L_b and ^1L_a) make 69° and 31°, respectively, with the direction of the emission of protonated form, while the calculated values with S_4 direction are 65° and 31°, respectively. In contrast, the transition moments to the ^1L_b and ^1L_a states makes 82° and 2°, respectively, with S_6 direction. Thus the position of proton attack may be assigned at C_4. However, an alternative choice remains at C_6 since a quantitative coincidence of p-values may not be easily realized, and the values can be affected by experimental artefact. Chen[4] presumed that the proton attack occurs at C_6 position, on the basis of the calculated charge density by DeVoe, who showed that the charge density in the excited state is the largest at this position. In spite of this the predicted p-values by the C_6 adduct are −0.32 and +0.5 for the first and the second bands, while the observed values are −0.18 and +0.32, respectively. The calculated values by the C_4 adduct are −0.15 and +0.33, respectively, the C_4 protonated form thus being more plausible than the C_6 adduct. We have calculated the charge density in the lowest excited state, the result of which is shown in Fig. 5. We see that the proton attack at C_4 is a reasonable process in view of charge distribution. The NMR spectra of serotonin in acidic media have been studied by Daly and Witkop[20] who found that the C_4 proton is most labile in an acidic media. This is in line with our conclusion that the proton attacks at C_4 position in the excited state of 5-hydroxyindole derivatives in an acidic media.

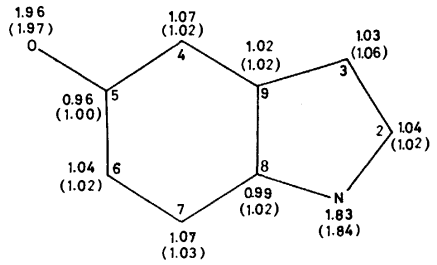

Fig. 5. The charge density of serotonin in the lowest excited state.
The charge density in the ground state was also shown in parenthesis.

Thus the excited-state reaction of 5-hydroxyindole derivatives can be depicted as:
