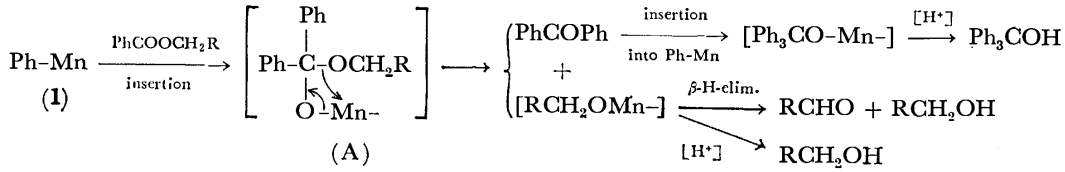
Me_2CHOH (7.85) MeCOPh (5.16)	Ph(Me)CHOH (0.4→0.7[b)])	Me_2CO (0.4)	PhH (1.6)	

a) Reactions were carried out at room temperature for 1 d. The amount of Ph_2MnPCy_3 **1** used for each reaction was about 0.1 g (0.22 mmol). b) The yield after heating the system at 70 °C for 9 h.

A similar β-oxo-alkyl type compound of gold has been reported.[18)]

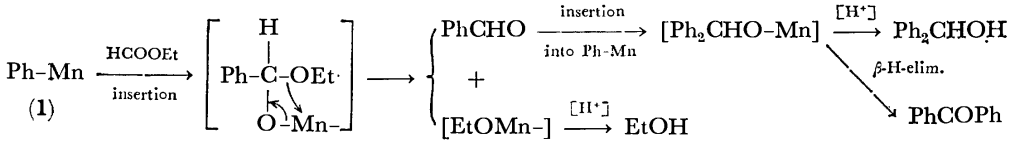
Reactions of Ph_2MnPCy_3 with Esters. The insertion reaction of the C=O double bond into Ph–Mn σ-bond was similarly observed when alkyl and benzyl benzoates, $PhCOOCH_2R$ (R=H, CH_3, Ph) were allowed to react with **1**. In these cases, benzophenone, triphenylmethanol, benzene, biphenyl, primary alcohols (RCH_2OH) and benzaldehyde (when R=Ph) were yielded as organic products (Table 3). Treatment of the reaction mixture with phenol caused the significant increase in the yields of alcohols indicating the existence of an alkoxomanganese intermediate (Ph_3COMn– and RCH_2OMn–) in the reaction mixtures as is assumed in the preceding section. Thus, the reaction between Ph_2MnPCy_3 and alkyl benzoate seems to proceed through an alkoxomanganese intermediate produced by the insertion of C=O double bond of the ester into the Ph–Mn σ-bond followed by β-alkoxy-elimination as shown in eq. 6.



(6)

The acetal type intermediate (A) in Eq. 6 may decompose to alkoxomanganese and benzophenone, the latter of which may react further with Ph–Mn species to give triphenylmethyloxomanganese compound, Ph_3C–O–Mn– (*vide supra*). These alkoxomanganese species may liberate the corresponding alcohols on treatment with phenol. Provided the reaction proceeds according to Eq. 6, the ratio of the products (PhCOPh+Ph_3COH)/(RCH_2OH+RCHO) (=γ), whould be 1.0. In fact experimental values of γ=1.5 for R=Me and γ=1.1 for R=Ph have been obtained supporting the validity of the proposed reaction scheme.

The reaction of ethyl formate with complex **1** proceeded similarly to those of alkyl benzoates.



(7)

In this case, also, the observed value of the ratio, γ=(PhCOPh+Ph_2CHOH)/(EtOH) was 1.0 in accordance with the expected value of 1.0 for the assumed mechanism.

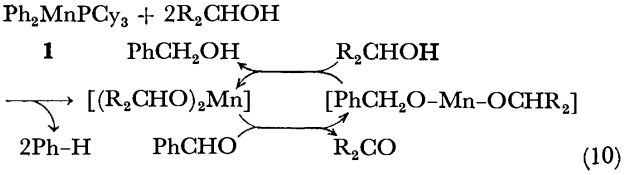
Reactions of Secondary Alcohols and Benzaldehyde or Acetophenone in the Presence of Alkoxomanganese. The above results of conversion of benzaldehyde with Ph_2MnPCy_3, **1**, into benzophenone and benzyloxomanganese (Eq. 4) prompted us to investigate the possibility of catalytic Meerwein-Pondorf type reaction in the presence of alcohol promoted by the manganese complex.

As Table 4 shows, the catalytic Meerwein-Pondorf type reaction did take place when the mixtures of benzaldehyde and diphenylmethanol and of benzaldehyde and 2-propanol were allowed to react in the presence of **1**.

$$PhCHO + Ph_2CHOH \xrightarrow{1} PhCH_2OH + Ph_2CO \quad (8)$$

$$PhCHO + Me_2CHOH \xrightarrow{1} PhCH_2OH + Me_2CO \quad (9)$$

In each case about two moles of benzene was produced per mol of **1** indicating the conversion of the diphenylmanganese into the alkoxomanganese species. The reaction path might be similar to that proposed for the Meerwein-Pondorf reaction using isopropoxoaluminium[19)] as shown below :



(10)

Table 5. Transesterification reactions using alkoxomanganese compound[a)]

Ester (PhCOOR)	Alcohol (R'OH)	Products, mol/mol of compound		
		PhCOOR'	ROH	PhH
$PhCOOCH_2Ph$ (5.3 mmol)	EtOH (34.7 mmol)	18.7 (0.63)[c)]	17.1	1.7
$PhCOOCH_2Ph$ (5.9 mmol)[d)]	EtOH (34.7 mmol)[d)]	8.7 (0.98)[c)]	8.3	—[d)]
$PhCOOCH_2Ph$ (5.3 mmol)	Me_2CHOH (13.1 mmol)	1.2	0.4	1.6
$PhCOOCH_2Ph$ (5.3 mmol)	Me_3COH (5.2 mmol)[e)]	0.0	0.0	1.4
PhCOOPh (1.1 mmol)	MeOH (71.4 mmol)	6.7 (1.0)[c)]	5.8	1.7
PhCOOPh (2.6 mmol)	Me_2CHOH (22.7 mmol)	3.2→7.4[b)] (0.73)[c)]	0.9→5.4[b)] (0.53)[c)]	1.6
PhCOOPh (2.0 mmol)	Me_3COH (5.0 mmol)[e)]	0.3	0.0	1.8
PhCOOMe (4.0 mmol)	PhOH (4.1 mmol)[e)]	0.0	0.0	1.8
$PhCOOCHMe_2$ (3.1 mmol)	PhOH (5.3 mmol)[e)]	0.0	0.0	1.6
$PhCOOCMe_3$ (2.8 mmol)	PhOH (3.6 mmol)[e)]	0.2	0.0	1.8

a) Reactions were carried out at room temperature for 1 d. The amount of Ph_2MnPCy_3, **1** used for each reaction was about 0.1 g (0.22 mmol). b) The yields were measured after heating the system at 70 °C for 15 h. c) Yields calculated on the basis of mol of PhCOOR used. d) This reaction was carried out using isolated $(PhO)_2Mn$ (0.16 g, 0.66 mmol) as catalyst at room temperature for 2 d. e) Diethyl ether was used as solvent.

Table 6. Reactions of benzaldehyde and primary alcohols in the presence of alkoxomanganese compound[a)]

PhCHO (ml)	ROH (ml)	Products (mol/mol of complex)			
		PhCOOR	$PhCH_2OH$	$PhCOOCH_2Ph$	PhH
(2.1)	MeOH (0.8)[b)]	1.6	1.2	0	1.7
(0.2)	EtOH (0.2)[b)]	1.4	1.2	0	1.7
(1.5)	EtOH (0.6)[c)]	14.3	—	14.2	1.8

a) Reactions were carried out at room temperature for 1 d. The amount of complex **1** used for each reaction was about 0.1 g (0.22 mmol). b) Diethyl ether was used as solvent. c) 0.5 ml of $PhCH_2OH$ was added together with EtOH.

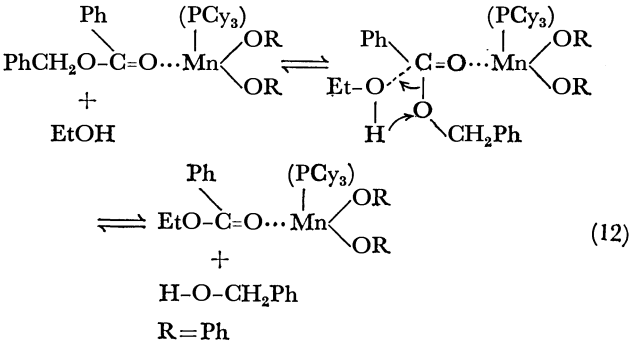
By-products of the present reaction system such as benzyl benzoate and isopropyl benzoate might be produced by Tishchenko type reaction (*vide supra*) and that followed by transesterification (alcoholysis) (*vide infra*), respectively.

When acetophenone was used in place of benzaldehyde, on the other hand, only minimal amounts of Meerwein-Pondorf type reaction products were obtained (Table 4). Even when the system which contains acetophenone and isopropyl alcohol was heated at 70 °C for 9 h in the presence of alkoxomanganese, only 0.7 mol of 1-phenylethanol per mol of Ph_2Mn-PCy_3 was produced. A steric hindrance in the transition state may affect the reactivity of the present system as was proposed for the Meerwein-Pondorf reaction using isopropoxoaluminium.

Transesterification Reactions Using Alkoxomanganese Compounds. The transesterification reactions between alkyl benzoate and various alcohols were examined using dialkoxomanganese compounds prepared *in situ* from Ph_2MnPCy_3, **1**, and alcohols.

$$PhCOOR + R'OH \xrightarrow{(R'O)_2Mn} PhCOOR' + ROH \quad (11)$$

As Table 5 shows, the catalytic reactions of the transesterification reactions proceed at room temperature when primary alcohols were used. The ease of transesterification reactions of alcohols decreased in the order of prim. alcohol≫sec. alcohol≫tert. alcohol≈phenol. This tendency corresponds to the order of the ester yields in the acid catalyzed ester formation reaction from carboxylic acid and alcohols.[20)] The isolated $(PhO)_2Mn$, which was prepared by the reaction of Ph_2MnPCy_3 with phenol, was found also to catalyze the transesterification reaction between benzyl benzoate and ethanol (Table 5, line 2). Catalyst $(PhO)_2Mn$ used in this reaction was recovered without suffering from alcoholysis with ethyl alcohol. This suggests that the reaction mechanism for the present transesterification reaction may be manganese-assisted replacement of alkoxyl group as shown below.



(12)

The transesterification reaction using transition metal compounds such as described here and that with alkoxocopper compounds[21)] have some advantages in that they act under neutral and mild conditions.

The reaction between benzaldehyde and primary alcohols to give alkyl benzoate directly through the combination of the catalytic Tishchenko type reaction and transesterification reaction was attempted and the

results are summarized in Table 6.

$$2PhCHO \xrightarrow{(RO)_2Mn} PhCOOCH_2Ph \xrightarrow[ROH]{(RO)_2Mn} PhCOOR + PhCH_2OH \quad (13)$$

Although the yield of methyl benzoate or ethyl benzoate was not high when methanol or ethanol alone was used, a high yield of ethyl benzoate was obtained when ethanol was allowed to react in the presence of benzyl alcohol. The result suggests that the (benzyloxo)manganese species have higher activity towards Tishchenko type reaction than methoxo- or ethoxomanganese species.

Some alkoxomanganese compounds which are analogous to those prepared *in situ* in the present work have been isolated, for example $(MeO)_2Mn$,[22] $(EtO)_2Mn$[23] and $(i\text{-}PrO)_2Mn$,[23] although none of their reactions has been examined.

Experimental

All reactions and manipulations were carried out under dry, oxygen-free nitrogen or *in vacuo* using Schlenk-type flasks.

Solvents were dried and purified in the usual manner and stored under an atmosphere of nitrogen. Carbon dioxide was dried by passing the gas through columns containing $CaCl_2$ and P_2O_5. Allylic compounds and esters were distilled over calcium hydride *in vacuo* and stored under nitrogen atmosphere. Aldehydes and ketones were purified by distillation under reduced pressure. Methanol and ethanol were purified by distilling over magnesium turnings. Other liquid alcohols were dried by Drierite and degassed under vacuum. $AlPh_3 \cdot Et_2O$ was prepared from PhMgBr and $AlCl_3$ according to the reported method.[24] Tris(acetylacetonato)manganese(III) (Tokyo Kasei Industrial Co.) was used as purchased without further purification. Tricyclohexylphosphine was prepared according to the literature method.[25]

Infrared spectra were recorded on a Hitachi model 295 spectrometer using KBr disks prepared under inert atmosphere. The magnetic susceptibility was measured by Gouy method using Shimadzu MB-100 apparatus at 23 °C and the diamagnetic corrections for the coordinated ligands were made on the basis of the Pascal's constants. The organic products formed in the various reactions were quantitatively analyzed by GLC using internal standard. GLC was recorded on a Shimadzu GC-3BT or GC-6A gas chromatography using SDC-550, SDC-410 and/or PEG-20M columns and helium as a carrier gas.

*Preparation of Ph_2MnPCy_3, **1**.* To the mixture of $Mn(acac)_3$ (2.1 g, 6.0 mmol), PCy_3 (2.0 g, 7.1 mmol), diethyl ether (20 ml) and toluene (5 ml) cooled at −50 °C, $AlPh_3 \cdot Et_2O$ (6.1 g, 18.3 mmol) was added. On stirring the mixture, the initial black suspension turned to a yellow suspension. After raising the temperature of the system to room temperature, the precipitate was filtered, washed with diethyl ether and dried *in vacuo*. The yellow powder thus obtained weighed 2.8 g (93% of the theoretical amount based on $Mn(acac)_3$ used). The crude product (2.0 g) was recrystallized from hot toluene (95 °C) to give yellow brown crystals of Ph_2MnPCy_3 (1.3 g, recrystallization yield, 65%). Analytical data and physical properties of **1** are mentioned in the text.

*Reaction of Ph_2MnPCy_3, **1**, with Allylic Compounds.* To a flask containing Ph_2MnPCy_3 (0.246 g, 0.502 mmol), dialkyl ether (2 ml) was added and heated at 70—80 °C for 2 h. The initial yellow suspension turned to a deep yellow solution. Allylbenzene (0.675 mmol), benzene (0.097 mmol) and biphenyl (0.057 mmol) were formed, as judged by GLC analysis. Hexane (5 ml) was added to the solution to give a pale yellow precipitate which was filtered and dried *in vacuo*. The pale yellow powder thus obtained was allowed to react with acetyl chrolide at room temperature to give allyl acetate. The other reactions of Ph_2MnPCy_3 with allylic compounds were carried out in a similar fashion.

Reaction of Ph_2MnPCy_3 with Carbon Dioxide. On bubbling carbon dioxide into the toluene suspension of Ph_2MnPCy_3 for one day at room temperature, the initial yellow suspension turned to a dark brown suspension. The precipitate was filtered and dried *in vacuo* to give a white powder of $(PhCOO)_2MnPCy_3$ **2**. Characterization of this compound was achieved as mentioned in the text.

Reactions of Ph_2MnPCy_3 with Esters, Aldehydes, and Ketones. Since the method is general, some typical reactions are described here, the organic reaction products are being listed in Tables 2 and 3.

a) Reaction with Benzyl Benzoate : To a flask containing Ph_2MnPCy_3 (0.094 g, 0.191 mmol), toluene (1 ml) and benzyl benzoate (1 ml) were added. On heating the system at 70 °C for ten minutes, the initial yellow suspension turned to a yellow solution. Formation of benzene (0.021 mmol), benzaldehyde (0.032 mmol), benzyl alcohol (0.021 mmol), biphenyl (0.013 mmol), benzophenone (0.020 mmol) and triphenylmethanol (0.068 mmol) were observed by GLC analysis. The amounts of these reaction products changed on treatment with phenol as follows : benzene (0.053 mmol), benzaldehyde (0.013 mmol), benzyl alcohol (0.098 mmol), benzophenone (0.018 mmol) and triphenylmethanol (0.107 mmol).

b) Reaction with Benzaldehyde: To a flask containing Ph_2MnPCy_3 (0.095 g, 0.194 mmol), benzaldehyde (1.5 ml, 15 mmol) was added and stirred at room temperature for one day. A dark brown solution thus formed contained benzene (0.04 mmol), benzyl alcohol (0.264 mmol), benzophenone (0.258 mmol) and benzyl benzoate (13.1 mmol) as analyzed by GLC.

c) Reaction with Acetone: To a flask containing Ph_2MnPCy_3 (0.137 g, 0.279 mmol) and diethyl ether (2 ml), acetone (75 μl, 1.02 mmol) was added and stirred for one day. A pale yellow suspension thus obtained was analyzed by GLC and found to contain benzene (0.447 mmol) and unreacted acetone (0.38 mmol). White powder (0.027 g, 0.060 mmol calculated as $(CH_3COCH_2)_2MnPCy_3$) isolated from this reaction system, reacted with methyl iodide to give ethyl methyl ketone (0.7 μl, 0.008 mmol) and acetonyl acetone (0.6 μl, 0.005 mmol).

Reactions between Alcohols and Aldehydes or Ketones in the Presence of Alkoxomanganese Compound Prepared in situ. To a flask containing Ph_2MnPCy_3 (0.099 g, 0.202 mmol) and diphenylmethanol (0.40 g, 2.16 mmol), was added diethyl ether (2 ml) to give a white suspension. Benzaldehyde (0.5 ml) was added to this system which was stirred for one day at room temperature. Benzene (0.39 mmol), benzyl alcohol (1.74 mmol), benzophenone (1.88 mmol) and benzyl benzoate (1.26 mmol) were formed, as analyzed by GLC.

The reactions listed in Tables 4 and 6 carried out similarly.

Transesterification Reactions Using Alkoxomanganese Compound Prepared in situ. To a flask containing Ph_2MnPCy_3 (0.087 g, 0.178 mmol) ethanol (1.0 ml) was added to give a pale brown suspension. Benzyl benzoate (1.0 ml, 5.3 mmol) was added to this system and the mixture was stirred for one day at room temperature. The GLC analysis of the reaction mixture revealed the formation of benzene

(0.30 mmol), benzaldehyde (0.047 mmol), benzyl alcohol (3.05 mmol) and ethyl benzoate (3.05 mmol).

The other transesterification reactions listed in Table 5 were carried out in a similar fashion.

Synthesis and Properties of Bis(cyclopropylphenyl)cyclopropenones and the Tris(*p*-cyclopropylphenyl)cyclopropenium Ion

Koichi KOMATSU, Isao TOMIOKA, and Kunio OKAMOTO*

Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

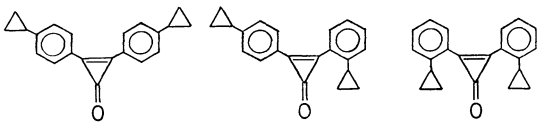
(Received September 13, 1978)

The reaction of trichlorocyclopropenium tetrachloroaluminate with cyclopropylbenzene has been found to readily afford the disubstitution products, bis(*p*-cyclopropylphenyl)- (**1a**), (*p*-cyclopropylphenyl) (*o*-cyclopropylphenyl)-, and bis(*o*-cyclopropylphenyl)cyclopropenones, each of which has been separated and fully characterized spectroscopically. The tris(*p*-cyclopropylphenyl)cyclopropenium ion (**2**) could not be obtained by the direct trisubstitution of the trichlorocyclopropenium ion with cyclopropylbenzene, but has been synthesized *via* two other routes starting from cyclopropenone **1a**. The UV and ^{13}C NMR spectral data of the cation **2** indicated the conjugative interaction of the *para*-cyclopropyl group with the cyclopropenium ring. However, the cation-stabilizing effect of the *para*-cyclopropyl group, as shown by the pK_{R^+} value (3.23 in 23% ethanol) for **2**, is much smaller than in the case of the tris(*p*-cyclopropylphenyl)methyl cation. This has been interpreted in terms of the decrease in delocalization of the positive charge to the *para*-position of the cation **2**, when compared with the triarylmethyl analogue.

The smallest-ring member of the aromatic halocarbon, the trichlorocyclopropenium ion ($C_3Cl_3^+$), was first synthesized by Tobey and West,[1a] and found to react with various aromatic rings resulting in stepwise electrophilic substitution.[1b] Recently this reaction was successfully applied to the syntheses of new cyclopropenium ions stabilized by non-benzenoid- or heteroaromatic substituents such as ferrocene,[2] azulene,[3] and thiophene rings.[4] Among the substituted benzenes, those carrying the strongly activating groups such as methoxyl, hydroxyl, and dialkylamino groups react with $C_3Cl_3^+AlCl_4^-$ to give the trisubstituted product, *i.e.* the triarylcyclopropenium ion,[1b,5] whereas the unsubstituted and weakly activated benzenes such as fluorobenzene and toluene give only the disubstituted cyclopropenones.[6]** Since the cyclopropyl group is expected to exert conjugative stabilization upon the cationic intermediate formed during the reaction,*** it was of interest to establish whether such an effect could lead to the trisubstitution of $C_3Cl_3^+$ with cyclopropylbenzene. Also having been interested in the stabilizing effect of the cyclopropyl group upon the triarylcyclopropenium ion which may be prepared by this reaction, we examined the reaction of $C_3Cl_3^+$-$AlCl_4^-$ with cyclopropylbenzene.

Results and Discussion

Bis(cyclopropylphenyl)cyclopropenones. The reaction of $C_3Cl_3^+AlCl_4^-$ with cyclopropylbenzene was examined in dichloromethane in the temperature range −60 to 40 °C. When two molar equivalents of cyclopropylbenzene were employed the disubstitution reaction occurred smoothly at −10 °C yielding a mixture of the isomeric bis(cyclopropylphenyl)cyclopropenones (**1a**, **1b**, and **1c**) after hydrolysis. Complete separation of the isomers was effected by the use of thin-layer



1a **1b** **1c**

chromatography. The R_f values of each component (**1a**, 0.14; **1b**, 0.34; **1c**, 0.64 : over silica gel developed with benzene–ether (4 : 1)) reflect the extent of molecular polarization, the *p,p*-isomer (**1a**) being the least developed due to the greatest polarization with two cyclopropyl groups located farthest away from the carbonyl group. In a representative run, the yield of the cyclopropenones was 31.2% for **1a**, 47.2% for **1b**, and 7.4% for **1c**. Assuming that the *ortho*/*para* reactivity ratio does not change between the first and the second substitutions of $C_3Cl_3^+$, it has been estimated from the yields of **1a** and **1b** that the *para*-position of cyclopropylbenzene is approximately 2.6 times more reactive to the electrophilic attack of $C_3Cl_3^+$ than the *ortho*-position. The decrease in the yield of **1c** (7.4%) to approximately half the calculated value (18%) is

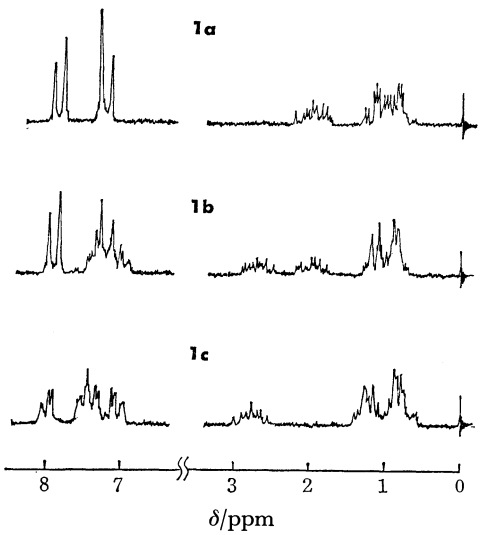


Fig. 1. ^1H NMR Spectra of the cyclopropenones **1a**, **1b**, and **1c**.

** The σ_p^+ values, which express the ability of the substituent to stabilize the cationic intermediate, are −0.778 for OCH_3, −0.92 for OH, −1.7 for NMe_2, −0.073 for F, and −0.311 for CH_3.[7]

*** The σ_p^+ value for the cyclopropyl group has been reported as −0.462.[8]

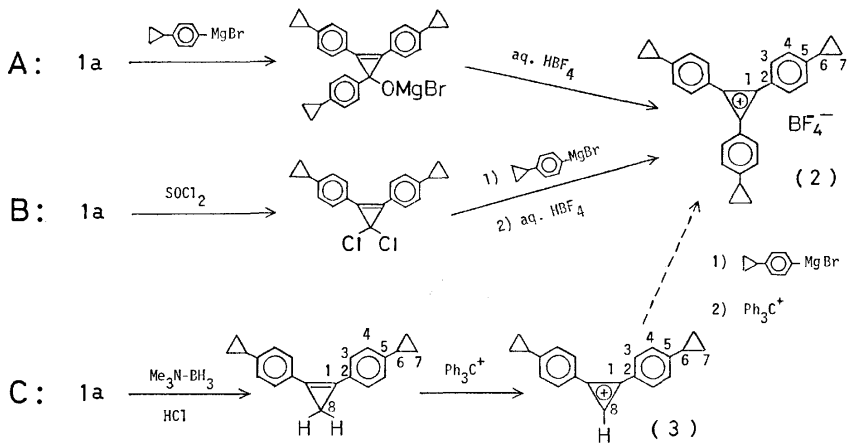
a) Taken in CD_2Cl_2.



Scheme 1.

thus ascribed to steric inhibition which operates more strongly at the second substitution step.

The physical properties of the cyclopropenones, **1a**, **1b**, and **1c**, are given in Table 1. The compounds all exhibit two broad and strong IR absorption bands at 1850 and $\approx$1610 cm^{-1}, which are diagnostic for the cyclopropenone system. The higher mp's for **1a** and **1c** are consistent with the symmetrical positions of the substituents, but stronger evidence for structure **1a**, **1b**, and **1c** is given by the ^1H NMR spectra. As is shown in Fig. 1 compound **1a** exhibits an AB quartet for the aromatic protons indicating substitution only at the *para*-position, while compound **1b** has an AB quartet plus a multiplet in the aromatic region. Furthermore, in the spectrum of **1b** one of the two cyclopropyl methine multiplets is shifted downfield, presumably due to the deshielding effect of the carbonyl group, to the same position as that of the compound **1c**, which is consistent with the assignment of **1b** and **1c** to the *o*,*p*- and *o*,*o*-isomers respectively.

*Tris(*p*-cyclopropylphenyl)cyclopropenium Ion.* In contrast to the ready formation of diarylcyclopropenones, the reaction of $C_3Cl_3^+AlCl_4^-$ with three molar equivalents of cyclopropylbenzene at low (—60 °C) or ambient temperature did not produce any evidence for trisubstitution. The reaction conducted at higher temperature (40 °C) for a prolonged time merely resulted in the formation of intractable polymeric material. Thus, attempts were made to synthesize the tris(*p*-cyclopropylphenyl)cyclopropenium ion (**2**) from cyclopropenone **1a** following the three synthetic routes shown in Scheme 1.† Methods A and B gave the tetrafluoroborate salt of the cation **2** in a low yield. On the other hand, method C afforded the bis(*p*-

† The reaction of 1,2-bis(*p*-cyclopropylphenyl)-3,3-dichlorocyclopropene with cyclopropylbenzene in the presence of silver triflate according to the method reported by Weiss *et al.*[9] afforded an inseparable mixture of the triflate (32% yield) of the cation **2** and 1,2-bis(*p*-cyclopropylphenyl)-3-(*o*-cyclopropylphenyl)cyclopropenium ion.

Table 3. ^{13}C NMR data for the triphenylcyclopropenium ion (**4**) and the tris- (**2**) and the bis(*p*-cyclopropylphenyl)cyclopropenium ions (**3**)

Cation	Chemical shift δ (CD_3CN), ppm from TMS[a]							
	C-1	C-2	C-3	C-4	C-5	C-6	C-7	C-8
4[b]	156.7 s	121.0 s	137.0 d	131.5 d	139.6 d	—	—	—
2	152.9 s [c]	118.0 s	136.8 d	128.0 d	158.6 s	17.5 d	12.9 t	—
3	161.1 s [c]	117.0 s	137.6 d	127.9 d	160.0 s	17.6 d	13.1 t	151.6 d

a) The peak multiplicity of the off-resonance spectrum is indicated by s (singlet), d (doublet), and t (triplet). b) The numbering system is similar to that used in the cation **2**. The reported values obtained in $ClSO_3H$ are 155.4(C-1), 120.1(C-2), 135.9(C-3), 131.2(C-4), and 139.2(C-5) ppm from TMS.[10] c) The assignment of these signals to C-1, not to C-5, is made based on the fact that in the proton-coupled spectra the signals are distinctly more narrow and sharp compared with those for C-5 carbons which are apparently broadened by the long-range coupling with protons attached to the C-4 and C-6 carbons.

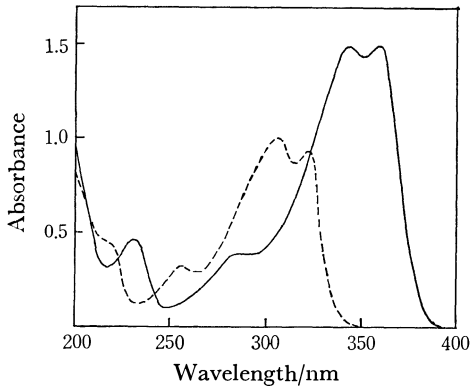


Fig. 2. UV Spectra of the tris(*p*-cyclopropylphenyl)-cyclopropenium ion (**2**, ——) and the triphenylcyclopropenium ion (**4**, – – –), 2.1×10^{-5} M in CH_3CN.

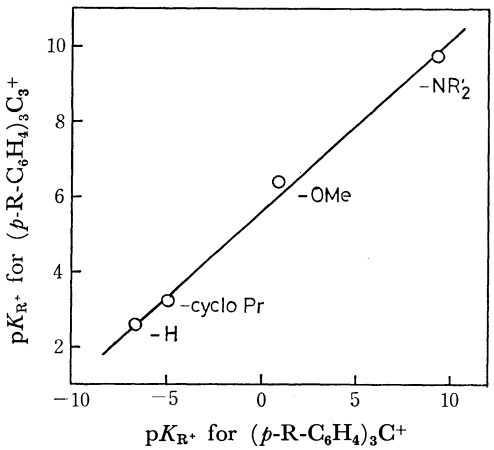

Fig. 3. Plot of the pK_{R^+} values for the *para*-substituted triarylcyclopropenium ions against those for the corresponding triarylmethyl cations. The alkyl group R′ in "$-NR'_2$" is methyl for $(p\text{-R-}C_6H_4)_3C^+$ and isopropyl for $(p\text{-R-}C_6H_4)_3C_3^+$.

cyclopropylphenyl)cyclopropenium ion (**3**) in a 59.1% overall yield, but the presence of many unfavorable side reactions in the subsequent reaction-step rendered this route impractical as a synthetic route for the cation **2**.

The spectral properties of the cations **2** and **3** are shown in Table 2. For both cations, the IR spectra exhibit broad and strong absorptions at $\approx 1410\ cm^{-1}$, which is assigned to the cyclopropenium ring stretching, and at $1050\ cm^{-1}$ due to the tetrafluoroborate anion, while the AB quartets of the aromatic protons in the ^1H NMR spectra illustrate the presence of all the cyclopropyl substituents at the *para*-position. As shown in Fig. 2 the UV spectrum of cation **2** is quite similar to that of the unsubstituted triphenylcyclopropenium ion (**4**) in general absorption pattern, but the longer-wave absorptions of the former are bathochromically shifted by *ca.* 40 nm with an apparent increase in the absorption coefficient. This shift is regarded as a result of conjugative interaction of the *para*-cyclopropyl group with the cationic central ring. The ^{13}C NMR data shown in Table 3 allow a more quantitative estimation of the conjugative effect of the *para*-cyclopropyl group : from the difference in chemical shift for the C-1 signal between the cyclopropylsubstituted cation **2** and the unsubstituted cation **4** and the Spiesecke-Schneider correlation $\Delta\delta = 160\Delta q$, the amount of the positive charge withdrawn from the cyclopropenium ring has been calculated as +0.071 or 7.3% of the amount of the positive charge (+0.969)[10] assumed to be originally present in the three-membered ring of cation **4**.

Stabilization of cation **2** resulting from the conjugative effect of the cyclopropyl group is demonstrated by the pK_{R^+} value of 3.23 (spectrophotometrical method in 23% aqueous ethanol at 25 °C) as compared with the value of 2.60[11] determined for the unsubstituted cation **4** in our laboratory. In the case of the triphenylmethyl cation system, substitution with three *para*-cyclopropyl groups has been reported to raise the pK_{R^+} value from −6.6 for the unsubstituted cation to −4.9.[12] Thus, in order to compare the effectiveness of various *para*-substituents on the stability of the triarylcyclopropenium ions with that for the triarylmethyl cations, the reported pK_{R^+} values[5,13] for the triarylcyclopropenium ions together with the present data were plotted against those[12,14] for the corresponding triarylmethyl cations. As shown in Fig. 3 there exists a reasonable linear free-energy relationship for the pK_{R^+} values between the two systems. However, the slope (0.46) is much smaller than unity, *i.e.*, the conjugative interaction of the substituent to stabilize the cationic center is apparently smaller in the triarylcyclopropenium system than in the triarylmethyl sys-

tem. This phenomenon is consistent with the results of the ^{13}C NMR measurements,[5,10] which implies that the positive charge in the triphenylcyclopropenium ion (**4**) resides mostly in the central three-membered ring to retain the "aromatic" 2π-electron ring system so that less of the charge is delocalized to the *para*-position to interact with the substituents than in the case of the triarylmethyl system, even though the coplanarity of the whole π-system is more favored in the triarylcyclopropenium system.

Experimental

General. The melting points are uncorrected. The elemental analyses were performed by the Microanalytical Center, Kyoto University, Kyoto. The IR and UV spectra were recorded on Hitachi 215 and Hitachi 200-10 spectrometers, respectively. The ^1H NMR spectra were taken with a Hitachi R-24 spectrometer with tetramethylsilane as the internal standard. The ^{13}C NMR spectra were recorded on a JEOL FX-100 spectrometer operated in the Fourier transform mode.

Materials. All the reagents employed were of reagent grade quality except when otherwise stated. Tetrachlorocyclopropene (C_3Cl_4) was supplied by Aldrich Chemical Co. Cyclopropylbenzene[15] and *p*-bromocyclopropylbenzene[16] were prepared according to the literature.

Bis(cyclopropylphenyl)cyclopropenones ***1a***, ***1b***, *and* ***1c***. To a stirred suspension of $C_3Cl_3^+AlCl_4^-$, prepared from C_3Cl_4 (1.12 g; 6.29 mmol) and $AlCl_3$ (0.67 g, 5.0 mmol) in dichloromethane (CH_2Cl_2 ; 2.5 ml), was added dropwise a solution of cyclopropylbenzene (1.32 g; 11.2 mmol) in CH_2Cl_2 (5 ml) at -60 °C under an atmosphere of nitrogen. When the temperature was raised slowly to -10 °C, rapid evolution of HCl took place accompanied by a sudden color change to dark red. The mixture was further stirred at 0 °C for 1 h and then hydrolyzed with cold water (10 ml). The aqueous layer was extracted with CH_2Cl_2 (5 ml×3). The combined organic solution was washed with 10% NaCl, dried ($MgSO_4$), and evaporated *in vacuo* to give 2.016 g of the crude product, from which was separated the cyclopropenone **1a** (0.216 g) as a white powder by washing with ether (3 ml). The remaining mixture was separated by the use of preparative TLC over SiO_2 (Merck, PF_{254}) developed with benzene–ether(4 : 1). The fraction with an R_f 0.14 afforded an additional amount of **1a** (0.231 g; total yield 31.2%). Purification was effected by recrystallization from benzene. Found: C, 88.35; H, 6.25%. Calcd for $C_{21}H_{18}O$: C, 88.08; H, 6.33%. The next TLC fraction with an R_f 0.34 gave the cyclopropenone **1b** (0.675 g; 47.2%) as a white powder from benzene. Found: C, 88.09; H, 6.25%. Calcd for $C_{21}H_{18}O$: C, 88.08; H, 6.33%. The last fraction with an R_f 0.64 afforded the cyclopropenone **1c** (0.106 g; 7.4%) as a white powder from benzene–hexane. Found: C, 88.31; H, 6.63%. Calcd for $C_{21}H_{18}O$: C, 88.08; H, 6.33%. The yields for the cyclopropenone isomers in duplicate runs were 29.8 and 23.8% for **1a**, 57.2 and 45.2% for **1b**, and 7.4 and 8.9% for **1c**.

*Tris(*p*-cyclopropylphenyl)cyclopropenium Tetrafluoroborate (***2*** BF_4^-). Method A*:[17] To a stirred solution of *p*-cyclopropylphenylmagnesium bromide, prepared from *p*-bromocyclopropylbenzene (0.592 g; 3.00 mmol) and magnesium (0.081 g; 3.3 mg atom) in dry ether (10 ml), was added a solution of the cyclopropenone **1a** (0.231 g; 0.808 mmol) in dry benzene (20 ml) during a 25-min period at 0 °C. After stirring for 1.5 h at 0 °C, the mixture was hydrolyzed with 0.2 M KH_2PO_4 (30 ml) and worked up in the usual manner. Addition of 42% aq HBF_4 (1 ml) to the stirred solution of the crude product in ether (30 ml) gave a white precipitate, which was collected, washed with ether, and vacuum-dried to give the tetrafluoroborate salt of the cation **2** as a white powder (0.006 g; 2%). Found: C, 75.88; H, 5.59%. Calcd for $C_{30}H_{27}BF_4$: C, 75.96: H, 5.74%.

Method B: A solution of the cyclopropenone **1a** (0.169 g; 0.590 mmol) and thionyl chloride (0.334 g; 2.81 mmol) in dry benzene was stirred at room temperature for 30 min and then refluxed for 15 min. Evaporation of the mixture *in vacuo* left crude 1,2-bis(*p*-cyclopropylphenyl)-3,3-dichlorocyclopropene as a brownish sludge. The dichlorocyclopropene was dissolved in dry ether (2 ml) and added to a stirred solution of *p*-cyclopropylphenylmagnesium bromide, prepared from *p*-bromocyclopropylbenzene (0.299 g ; 1.51 mmol) and magnesium (0.041 g; 1.7 mg atom) in dry ether (2 ml), at 0 °C. After stirring at 0 °C for 30 min and at room temperature for 24 h, the mixture was hydrolyzed with 0.2 M KH_2PO_4 (20 ml) and worked up. The crude product was dissolved in ether (2 ml) and treated with 1 ml of a solution of acetic anhydride–42% aq HBF_4 (10 : 1) to give the cation salt **2** BF_4^- (0.005 g; 2%).

Method C: *Synthesis of Bis(*p*-cyclopropylphenyl)cyclopropenium Tetrafluoroborate (***3*** BF_4^-)*. Following the method reported by Perkins and Wadsworth[18] for the reduction of diphenylcyclopropenone, the cyclopropenone **1a** was converted to 1,2-bis(*p*-cyclopropylphenyl)cyclopropene by reaction with borane–trimethylamine complex and HCl; mp 75.5—78.0 °C; IR ν(KBr) 1825 cm^{-1} (C=C stretching in the cyclopropene ring); ^1H NMR δ ($CDCl_3$) 7.64 (d, 4H, *o*-H), 7.14 (d, 4H, *m*-H), 1.95 (m, 2H, methine), 1.50 (s, 2H, CH_2-(cyclopropene)), 1.1—0.7 (m, 8H, CH_2(cyclopropane)); ^{13}C NMR δ 144.5 (s, C-5), 129.8 (d, C-3), 127.8 (s, C-2), 126.0 (d, C-4), 110.4 (s, C-1), 15.8 (d, C-6), 9.9 (t, C-7), 6.5 (t, C-8).

Into a refluxing solution of triphenylmethyl tetrafluoroborate[19] (1.532 g; 4.64 mmol) in CH_2Cl_2 (7 ml) was added dropwise during a 1.5-h period with stirring a solution of 1,2-bis(*p*-cyclopropylphenyl)cyclopropene (0.421 g; 1.55 mmol) in CH_2Cl_2 (10 ml). The solution was further refluxed for 10 min, and then concentrated to *ca.* 8 ml. Addition of ether (50 ml) produced a yellow precipitate, which was collected and washed with ether to give the tetrafluoroborate salt of the cation **3** as a brownish yellow powder (0.336 g; 60.6%). Found: C, 70.27; H, 5.48%. Calcd for $C_{21}H_{19}BF_4$: C, 70.42; H, 5.35%.

Determination of pK_{R^+}. The pK_{R^+} value was determined in 23% aqueous ethanol at 25 °C following the spectrophotometric method described by Breslow and Chang.[13] The cationic solution was found to be stable over the whole pH range examined. The pH values were read on a Horiba model H pH meter precalibrated with standard buffers.

Functionalization of *trans*-Decalin. II. A Synthesis of *dl*-Isopetasol from *trans*-5-Oxodecalin-8a,2-carbolactone

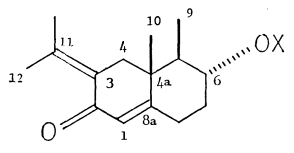
Sigeru Torii,* Tsutomu Inokuchi, and Kiyoto Kawai

Department of Industrial Chemistry, School of Engineering, Okayama University, Okayama 700

(Received September 21, 1978)

A stereocontrolled synthesis of *dl*-isopetasol (**1a**) from *trans*-5-oxodecalin-8a,2-carbolactone (**2a**) is described. The key intermediate, *trans*-5,5-ethylenedioxy-1β,8aβ-dimethyldecalin-2-one (**7b**) was prepared by reductive methylation of *trans*-5,5-ethylenedioxydecahydrocyclopropa[*d*]naphthalen-2-one (**5**) for introducing the vicinal two methyl groups at C-1 and C-8a carbon atoms. The cyclopropyl ketone **5** was obtained by reduction of the acetal of **2a** followed by (1) tosylation of the primary alcohol, (2) oxidation of the secondary alcohol with Corey's NCS–DMS reagent, and (3) cyclization with *t*-BuOK. Reduction of **5** with lithium in liquid ammonia provides initially the corresponding enolate anion, which can be trapped with methyl iodide to give *trans*-5,5-ethylenedioxy-1α,8aβ-dimethyldecalin-2-one (**7a**), smoothly. Epimerization of **7a** with MeONa in MeOH gave the desired intermediate **7b**. Reduction of **7b** with lithium in liquid ammonia gives the 2α-alcohol **8b**, stereoselectively. The conversion of **8b** into **1a** was carried out as follows: (1) deacetalization of **8b** followed with acetylation, giving *trans*-6α-acetoxy-4aβ,5β-dimethyldecalin-1-one (**9b**); (2) reduction of **9b** with $NaBH_4$ and subsequent dehydration affording the olefinic acetate **11**; (3) oxidation of **11** with CrO_3–pyridine complex, giving the enone **12**; (4) aldol condensation of **12** with acetone followed by dehydration, isomerization of double bond, and hydrolysis, providing the desired **1a**.

Previous paper from our laboratory has presented a convenient preparative method of *trans*-5-oxodecalin-8a,2-carbolactone (**2a**), provided by iodo–lactonization of *trans*-1-oxo-$\Delta^{6,7}$-octalin-4a-carboxylic acid and subsequent reduction of the carbon–iodine bond with tri-*n*-butyltin hydride.[1] As an extensible use of the intermediate **2a**, we describe here a stereocontrolled synthesis of *dl*-isopetasol (**1a**),[2] an eremophilane type sesquiterpene, isolated from *Petasites officinalis*[2a,b] and *P. japonicus* Maxim,[2c] whose carbon skeleton coincides with that of biologically active phomenone.[3]

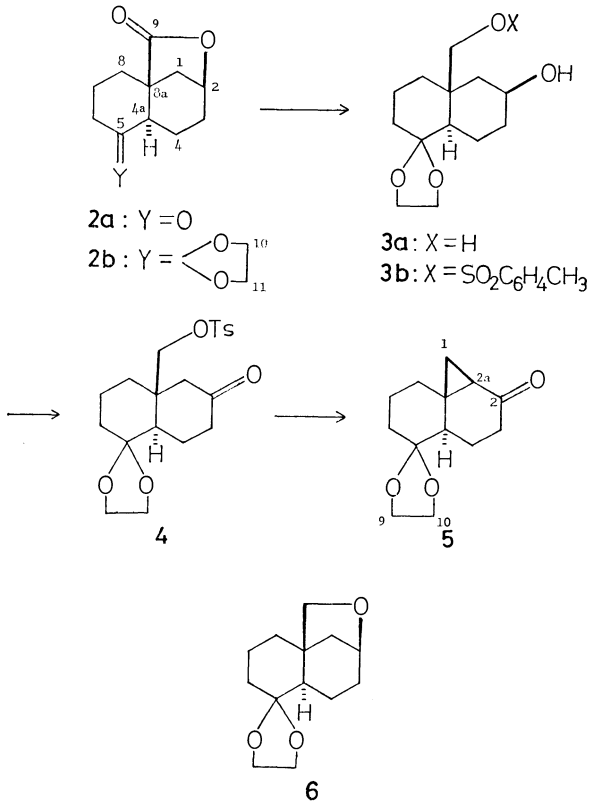


1a: X = H
1b: X = Ac
1c: X = CCH=CMe$_2$ (O)

The key starting material in our attempt is *trans*-5,5-ethylenedioxydecalin-8a,2-carbolactone (**2b**), prepared by acetalization of **2a**. The lactone function of **2b** is expected to be used for the construction of the substituents at C-4a, C-5, and C-6 carbons of **1**. In particular, the stereocontrolled formation of vicinal *cis* two methyl groups at the C-4a and C-5 carbons as well as stereoselective introduction of the α-hydroxyl group at the C-6 carbon is of interest.

Reduction of **2b** with lithium aluminum hydride (LAH) affords the acetal diol **3a** in 85% yield. Selective tosylation[4] of the primary alcohol of **3a** provides smoothly **3b** in 92% yield. The formation of cyclopropyl ketone **5** can be achieved by heating the tosylated ketone **4**, prepared from **3b** by oxidation with NCS–DMS,[5] with potassium *t*-butoxide in *t*-butyl alcohol at 78 °C. In contrast, LAH-induced reaction of either **3b** or **4** affords the corresponding etherated compound **6** as a sole product.

Reductive cleavage of the cyclopropyl ring of **5** with lithium metal in liquid ammonia and subsequent methylation of the carbanion *in situ*[6] gives the desired intermediate **7a** in 76% yield. Epimerization[7] of the C-1 axial methyl of **7a** provides **7b** exclusively after



2a: Y = O
2b: Y = ethylenedioxy
3a: X = H
3b: X = $SO_2C_6H_4CH_3$
4
5
6

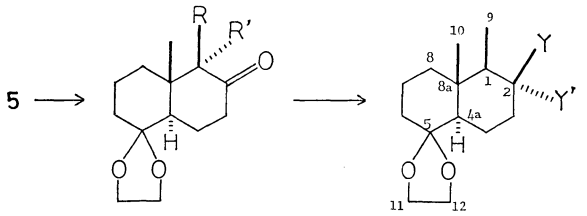
treatment with sodium methoxide at room temperature for 24 h. The reference compound **7c** can be easily obtained by the reduction of **5**.

The epimerized product **7b** is apparently homogeneous by NMR spectroscopy and is assigned the equatorial stereochemistry at the C-5 methyl group based on the comparison of ^{13}C NMR results of **7a**, **7b**, and **7c** with calculated values from Crews's substituent increment parameter[8] (Table 1). Direct evidence for the assigned structure **7b** is presented by ^{13}C NMR chemical shifts of C-1 and C-8a methyl groups appearing at 5.8 and 7.8 ppm higher fields than those of **7a**, due to steric compression effect.

Table 1. The shielding effect of ^{13}C NMR spectra of the C-8a (C-1) methyl groups of **7a**, **7b**, and **7c**

Compound	^{13}C Chemical shift, ppm		
	Obsereved		Calculated[a]
	C-8a Me	(C-1 Me)	C-8a Me
7a (*anti*-axial)	21.1	(12.9)	20.4
7b (equatorial)	13.3	(7.1)	13.1±0.5
7c	18.7		

a) Based on the Crews's substituent increment parameter as follows: the increment of the chemical shift of methyl (ax) group, being affected by the vicinal methyl groups (equatorial and *anti*-axial) is given as follows: the shielding effect of methyl (ax) with methyl (eq): +5.6±0.5 ppm; the shielding effect of methyl (ax) with *anti*-methyl (ax): −1.7 ppm.



7a: R=H, R'=Me
7b: R=Me, R'=H
7c: R=R'=H

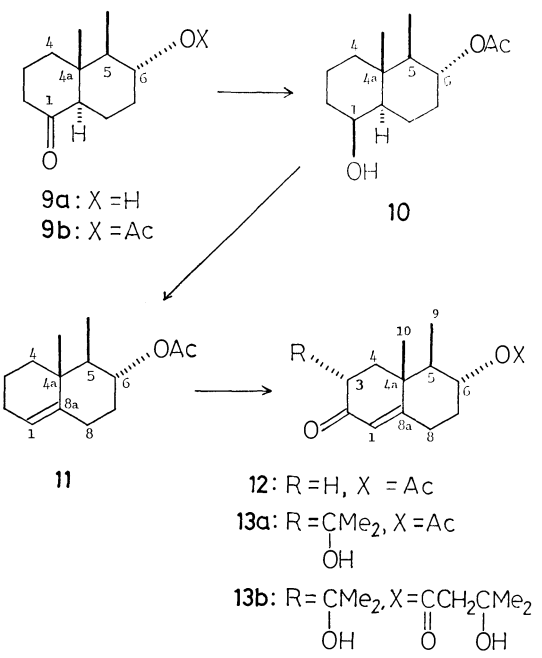
8a: Y=OH, Y'=H
8b: Y=H, Y'=OH

Stereospecific reduction of the carbonyl group of **7b** was achieved as follows. Treatment of **7b** with lithium metal in liquid ammonia with a trace of ethanol affords the thermodynamically stable equatorial alcohol **8a**[9] (92%), whereas the bulky reducing reagent such as lithium tri-*t*-butoxyaluminum hydride[10] gives the corresponding axial alcohol **8b** (98%), selectively.

The ^{13}C NMR spectra of **8** reveal that the marked downfield shifts of the C-8a methyl signals of **8a**, δ_{ax-eq} +1.4 ppm, due to 1,3-*syn*-axial interaction[11] between C-8a methyl and C-2 hydroxyl groups would account for the stereochemistry assigned to the structures of **8a** and **8b**. In addition, the structures of **8** can be rationally interpreted on the basis of 1,3-diaxial downfield shift[12] of ^1H NMR signals due to C-8a methyl protons of **8a** (δ 1.09), comparing to **8b** (δ 0.87).

The conversion of **8b** into the alcohol **10** *via* **9a** and **9b** was carried out in 91% overall yield by deacetalization with perchloric acid and subsequent reduction with sodium borohydride after treatment with acetic anhydride–pyridine. The tentative assignment of the *syn*-axial hydroxyl group of **10** is based on 1,3-diaxial downfield shift of ^1H NMR signals due to C-4a methyl protons at δ 1.01, contrasting to that of **9b** at δ 0.71.

Dehydration of the hydroxyl group of **10** attached to the C-1 carbon *via* the corresponding mesylate affords the olefin **11** in quantitative yield. Allylic oxidation of **11** with a slurry of anhydrous chromium trioxide–pyridine complex (Sarett reagent)[13] gives the promising intermediate **12** in 85% yield. Kinetically controlled aldol condensation[14] of the enone **12** with



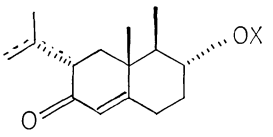
9a: X=H
9b: X=Ac

10

11

12: R=H, X=Ac
13a: R=CMe$_2$(OH), X=Ac
13b: R=CMe$_2$(OH), X=CCH$_2$CMe$_2$(O, OH)

acetone can lead smoothly to **13a** (38%) as well as **13b** (38%). Thermal decomposition of the mesylates of **13** giving the corresponding *exo* and *endo* double bond isomers **14** and subsequent isomerization from isopropenyl group to the corresponding isopropylidene group on treatment with rhodium(III) chloride[15] in ethanol at 110 °C and/or by passing an activated alumina column affords a mixture of **1b** and **1c**, precursors of *dl*-isopetasol, whose hydrolysis gives the desired *dl*-isopetasol (**1a**)[16] (46—51% from **13**).



14a: X=Ac
14b: X=CCH=CMe(O)

Experimental

Melting points and boiling points are uncorrected. Column chromatography was carried out using silica gel (100—200 mesh) unless otherwise noted. IR spectra were determined with a JASCO IRA-1 grating spectrometer. ^1H NMR spectra were determined at 60 MHz with a Hitachi Model R-24 or at 100 MHz with a JEOL Model MH-100, and ^{13}C NMR spectra were measured at 25.05 MHz with a JEOL Fourier transform spectrometer, Model FX-100. Samples were dissolved in $CDCl_3$ containing TMS as an internal standard and signals are reported in parts per million (δ) downfield from the internal standard. Elemental analyses were performed in our laboratory.

*trans-5,5-Ethylenedioxydecalin-8a,2-carbolactone (**2b**).* A solution of **2a** (388 mg, 2.0 mmol), ethylene glycol (1.2 g, 19 mmol) and *p*-toluenesulfonic acid (50 mg) in benzene (40 ml) was refluxed for 12 h using a Dean-Stark apparatus

and most of water was removed azeotropically. The mixture was washed with aqueous 5% $NaHCO_3$, dried (Na_2SO_4), and concentrated to give 369 mg (77%) of **2b** as a white solid : mp 128.5 °C (benzene); IR (Nujol) 1777 cm^{-1} (lactone) ; ^1H NMR (60 MHz) δ 0.90—2.55 (m, 13, CH_2, CH), 3.85—3.91 (m, 4, CH_2O), 4.60 (t, 1, J=5 Hz, CH-O) ; ^{13}C NMR δ 17.6 (t), 19.3 (t), 27.9 (t), 30.9 (t, C-8), 35.0 (t, C-6), 45.0 (s, C-8a), 45.6 (t, C-1), 48.2 (d, C-4a), 64.6, 66.1 (t, C-10, C-11), 74.8 (d, C-2), 108.6 (s, C-5), 178.2 (s, C-9). Found : C, 65.71; H, 7.78%. Calcd for $C_{13}H_{18}O_4$: C, 65.53; H, 7.61%.

trans-*5,5-Ethylenedioxy-8aβ-(hydroxymethyl)decalin-2β-ol (**3a**)*. To a stirred suspension of $LiAlH_4$ (230 mg, 6.1 mmol) in dry ether (10 ml) was added dropwise a solution of **2b** (720 mg, 3.0 mmol) in THF (5 ml) with cooling. After being stirred for 1 h at room temperature, the mixture was quenched with AcOEt. After workup in the usual manner, there was obtained 620 mg (85%) of **3a** as a white solid : mp 112.5—114.0 °C (hexane–benzene, 1:1); IR (Nujol) 3300 cm^{-1} (OH); ^1H NMR (60 MHz) δ 0.80—2.15 (m, 13, CH_2, CH), 3.12 (s, 2, OH), 3.87 (AB_q, 2, J=10 Hz, CH_2O), 3.65—4.07 (m, 5, CH_2O, CH-O); ^{13}C NMR δ 15.1 (t), 19.2 (t), 33.5 (t), 35.7 (t), 36.0 (t), 39.0 (s, C-8a), 43.5 (t, C-1), 51.8 (d, C-4a), 64.4, 64.7, 65.7 (t, C-9, C-10, C-11), 66.1 (d, C-2), 109.9 (s, C-5). Found: C, 64.40; H, 9.33%. Calcd for $C_{13}H_{22}O_4$: C, 64.44; H, 9.15%.

trans-*5,5-Ethylenedioxy-8aβ-(*p*-tolylsulfonyloxymethyl)decalin-2β-ol (**3b**)*. To a cold solution of **3a** (242 mg, 1.0 mmol) in pyridine (13 ml) was added *p*-toluenesulfonyl chloride (250 mg, 1.3 mmol) with stirring. The mixture was stirred for 36 h at 5 °C, taken up in AcOEt, and washed with cold aqueous 5% $NaHCO_3$. The organic phase was washed with aqueous 2% $NaHCO_3$, dried (Na_2SO_4), and rotoevaporated at 30 °C. The residue was chromatographed (hexane–AcOEt, 3 : 1) to give 364 mg (92%) of **3b** as an oil, slowly crystallized on standing: mp 97.0—98.0 °C (dec, benzene–hexane, 1 : 1); IR (Nujol) 3550 (OH), 1598 cm^{-1} (C=C); ^1H NMR (60 MHz) δ 0.85—2.35 (m, 13, CH_2, CH), 1.68 (s, 1, OH), 2.43 (s, 3, CH_3), 3.84 (broad complex 4, CH_2O), 4.06 (br s, 1, CH-O), 4.67 (AB_q, 2, J=10 Hz, CH_2O), 7.26 (d, 2, J=8 Hz, HC=C), 7.75 (d, 2, J=8 Hz, HC=C); ^{13}C NMR δ 14.4 (t), 18.1 (t), 21.6 (q, aromatic C-Me), 32.6 (t), 34.5(t, C-8), 35.6 (t, C-6), 38.4 (s, C-8a), 41.0 (t, C-1), 52.1 (d, C-4a), 64.6, 65.5 (t, C-10, C-11), 66.4 (d, C-2), 71.7 (t, C-9), 109.2 (s, C-5), 127.7 (d, 2C), 129.6 (d, 2C), 133.3 (s), 144.3 (s). trans-*5,5-Ethylenedioxy-8a-(*p*-tolylsulfonyloxymethyl)decalin-2-one (**4**)*. To a stirred suspension of *N*-chlorosuccinimide (843 mg, 6.3 mmol) and Me_2S (429 mg, 1.26 mmol) in toluene (10 ml) was added a solution of **3b** (500 mg, 1.26 mmol) in CH_2Cl_2 (7 ml) in a 15 min at −25 °C. After being stirred for 12 h at −25 °C and for 1.5 h at 5 °C, the mixture was treated with Et_3N (708 mg, 7.0 mmol), then taken up in CH_2Cl_2, washed with water, dried (Na_2SO_4), and rotoevaporated. The residue was chromatographed (hexane–AcOEt, 3 : 1) to give 415 mg (84%) of **4** as an oil, slowly crystallized on standing : mp 132.0—133.0 °C (hexane–benzene); IR (Nujol) 1708 (C=O), 1595 cm^{-1} (C=C); ^1H NMR (60 MHz) δ 1.30—2.70 (m, 13, CH_2, CH), 2.45 (s, 3, CH_3), 3.88 (br s, 4, CH_2O), 4.15 (AB_q, 2, J=10 Hz, CH_2O), 7.28 (d, 2, J=8 Hz, HC=C), 7.72 (d, 2, J=8 Hz, HC=C); ^{13}C NMR δ 18.8 (t), 19.8 (t), 21.7 (q, aromatic C-Me), 34.5 (t, C-8), 35.4 (t, C-6), 40.4 (t, C-3), 42.2 (s, C-8a), 49.9 (d, C-4a), 51.0 (t, C-1), 64.6, 65.6 (t, C-10, C-11), 69.5 (t, C-9), 109.0 (s, C-5), 127.9 (d, 2C), 129.8 (d, 2C), 132.8 (s), 144.6 (s), 208.8 (s, C-2). Found: C, 61.01; H, 6.90%. Calcd for $C_{20}H_{26}O_6S$: C, 60.90; H, 6.64%.

trans-*5,5-Ethylenedioxydecahydrocyclopropa*[d]*naphthalen-2-one (**5**)*. To a suspension of **4** (86 mg, 0.22 mmol) in *t*-BuOH (3 ml) was added a solution of *t*-BuOK (286.7 mg, 2.56 mmol) in *t*-BuOH (7 ml). The stirred mixture was heated at 75—78 °C for 20 min and then allowed to cool to room temperature. The mixture was poured into cold water (*ca.* 100 ml) and extracted with benzene–ether. The extracts were worked up in the usual manner to give 38 mg (79%) of **5** : bp 99.0—102.0 °C/0.003 Torr (Kugelrohr); IR (neat) 1690 (shoulder), 1682 cm^{-1} (C=O); ^1H NMR (60 MHz) δ 0.74—1.04 (m, 2, CH_2), 1.25—2.35 (m, 12, CH_2, CH), 3.92 (br s, 4, CH_2O), ^{13}C NMR δ 15.9 (t), 16.0 (t), 22.3 (t), 28.7 (s, C-8a), 32.1 (d, C-2a), 35.4 (t), 35.6 (t), 36.0 (t), 42.9 (d, C-4a), 64.9, 65.3 (t, C-9, C-10), 109.7 (s, C-5), 208.4 (s, C-2). Found: C, 70.19; H, 8.12%. Calcd for $C_{13}H_{18}O_3$: C, 70.24; H, 8.16%.

4,4-Ethylenedioxy-9-oxatricyclo[*8.2.1.0*^{5,11}]*dodecane (**6**)*. To a refluxing suspension of $LiAlH_4$ (50 mg, 1.32 mmol) in THF (3 ml) was added a solution of **3b** (32 mg, 0.08 mmol) in THF (1 ml) and stirring was continued for 3 h. After being cooled, the mixture was quenched with AcOEt and aqueous 5% $NaHCO_3$ and the organic layer was decanted. Removal of the solvent and following chromatography (hexane–AcOEt, 4 : 1) gave 14 mg (77%) of **6** as a white solid : mp 86.5—87.5 °C; IR (Nujol) 1143, 1090, 1041, 1005, 886 cm^{-1}; ^1H NMR (100 MHz) δ 1.12—1.90 (m, 13, CH_2, CH), 3.86 (AB_q, 2, J=8 Hz, CH_2O), 3.76—4.02 (m, 4, CH_2O), 4.24 (t, 1, J=5 Hz, CH-O). Found: C, 69.71; H, 9.21%. Calcd for $C_{13}H_{20}O_3$: C, 69.61; H, 8.99%.

Similarly, **6** was obtained in 71% yield by the reaction of **4** (37 mg, 0.094 mmol) and $LiAlH_4$ (70 mg, 1.84 mmol) in THF (3 ml) at reflux for 5 h.

trans-*5,5-Ethylenedioxy-1α,8aβ-dimethyldecalin-2-one (**7a**)*. A solution of **5** (265 mg, 1.19 mmol) and *t*-BuOH (88 mg, 1.19 mmol) in DME (5 ml) was added to a blue solution of lithium (40 mg, 5.7 mmol) in liquid NH_3 (*ca.* 40 ml). After being stirred for 30 min at −70 °C and for 10 min at −33 °C, the blue solution was quenched with an excess amount of MeI (0.75 ml, 12.1 mmol) and allowed to stand at room temperature in order to dispel most of liquid NH_3. To the residue, DME (5 ml) and HMPA (1 ml) was added and the mixture was stirred for 1 h, washed with a cold aqueous NH_4Cl, and taken up in ether–benzene. The organic phase was washed with aqueous 5% $NaHCO_3$, dried (Na_2SO_4), and concentrated. The residue was chromatographed (hexane–ether, 4 : 1) to give 216 mg (76%) of **7a** as a white solid: mp 47.5—48.5 °C; IR (Nujol) 1698 cm^{-1} (C=O); ^1H NMR (60 MHz) δ 0.98 (s, 3, CH_3), 1.09 (d, 3, J=7.5 Hz, CH_3), 0.80—2.55 (m, 12, CH_2, CH), 3.80—3.96 (m, 4, CH_2O); ^{13}C NMR δ 12.9 (q, C-9), 19.1 (t, C-7), 20.6 (t, C-6), 21.1 (q, C-10), 35.1 (t, C-4), 35.7 (t, C-8), 36.9 (t, C-3), 39.6 (s, C-8a), 42.9 (d, C-4a), 57.1 (d, C-1), 64.1, 65.5 (t, C-11, C-12), 110.3 (s, C-5), 215.8 (s, C-2). Found : C, 70.56; H, 9.35%. Calcd for $C_{14}H_{22}O_3$: C, 70.56; H, 9.30%.

trans-*5,5-Ethylenedioxy-1β,8aβ-dimethyldecalin-2-one (**7b**)*. A solution of **7a** (280 mg, 0.85 mmol) and MeONa (658.8 mg, 12.2 mmol) in MeOH (12 ml) was stirred for 24 h at room temperature. The mixture was poured into cold water and extracted with ether–benzene. The organic phase was worked up to give 269 mg (96%) of **7b** as a white solid : mp 41.0—42.0 °C; IR (Nujol) 1708 cm^{-1}; ^1H NMR (60 MHz) δ 0.81 (s, 3, CH_3), 0.89 (d, 3, J=7.0 Hz, CH_3), 0.90—2.50 (m, 12, CH_2, CH), 3.87—4.07 (m, 4, CH_2O); ^{13}C NMR δ 7.1

*6α-Acetoxy-4aβ,5β-dimethyl-$\Delta^{1,8a}$-octalin (**11**)*. To a stirred, cold solution (0—5 °C) of **10** (28 mg, 0.117 mmol) in pyridine (0.5 ml) was added methanesulfonyl chloride (148 mg, 1.29 mmol). After being stirred for 30 min at 0—5 °C and for 30 min at 40—50 °C, the mixture was quenched with water and extracted with ether–benzene. The organic phase was washed with cold aqueous 5% tartaric acid, aqueous 5% $NaHCO_3$, and brine, dried (Na_2SO_4), and concentrated. The residue was chromatographed (hexane–ether, 5 : 1) to give 26 mg (100%) of **11** as an oil : bp 99.0—101.0 °C/0.1 Torr (Kugelrohr); IR (neat) 1735 cm^{-1} (ester C=O); ^1H NMR (60 MHz) δ 0.86 (d, 3, J= 6 Hz, CH_3), 0.99 (s, 3, CH_3), 1.06—2.45 (m, 11, CH_2, CH), 2.03 (s, 3, $COCH_3$), 4.80 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 5.39 (t, 1, J=3 Hz, HC=C); ^{13}C NMR δ 10.8 (q, C-9), 18.7 (t), 19.2 (q, C-10), 21.3 (q, acetyl CH_3), 25.6 (t), 30.7 (t), 33.1 (t), 37.5 (t, C-4), 37.8 (s, C-4a), 47.3 (d, C-5). 75.1 (d, C-6), 120.6 (d, C-1), 142.1 (s, C-8a), 170.8 (s, acetyl C=O). Found: C, 75.69; H, 10.01%. Calcd for $C_{14}H_{22}O_2$: C, 75.63; H, 9.97%.

*6α-Acetoxy-4aβ,5β-dimethyl-$\Delta^{1,8a}$-octalin-2-one (**12**)*. To a solution of **11** (22 mg, 0.1 mmol) in dry CH_2Cl_2 (5 ml) was added in one portion a slurry of anhydrous CrO_3-(pyridine)$_2$ complex (800 mg, 31 mmol) in CH_2Cl_2 (5 ml) under argon. After being stirred for 24 h at room temperature, the mixture was filtered off and the solid in the flask was washed with ether. The combined filtrate and washings were washed with aqueous 5% $NaHCO_3$, cold aqueous 5% HCl, and brine, dried (Na_2SO_4), and concentrated. The residue was chromatographed (hexane–ether, 4 : 1) to give 20 mg (85%) of **12** as a solid : mp 69.0—70.5 °C; IR (Nujol) 1731 (ester C=O), 1676 (C=O), 1618 cm^{-1} (C=C); ^1H NMR (60 MHz) δ 0.82 (d, 3, J=6.5 Hz, CH_3), 1.15 (s, 3, CH_3), 1.00—2.65 (m, 9, CH_2, CH), 2.04 (s, 3, $COCH_3$), 4.71 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 5.72 (br s, 1, HC=C);

^{13}C NMR δ 10.5 (q, C-9), 17.1 (q, C-10), 21.2 (q, acetyl CH_3), 30.9 (t, C-8), 31.5 (t, C-7), 33.3 (t, C-4), 35.7 (t, C-3), 39.3 (s, C-4a), 46.7 (d, C-5), 73.4 (d, C-6), 124.6 (d, C-1), 167.6 (s, C-8a), 170.6 (s, acetyl C=O), 198.9 (s, C-2). Found: C, 71.06; H, 8.60%. Calcd for $C_{14}H_{20}O_3$: C, 71.16; H, 8.53%.

6α-Acetoxy-3α-(1-hydroxy-1-methylethyl)-4aβ,5β-dimethyl-$\Delta^{1,8a}$*-octalin-2-one (**13a**)* and *3α-(1-Hydroxy-1-methylethyl)-6α-(3-hydroxy-3-methylbutyryloxy)-4aβ,5β-dimethyl-*$\Delta^{1,8a}$*-octalin-2-one (**13b**).* To a stirred solution of *i*-Pr_2NLi (246.1 mg, 2.3 mmol) in THF (4 ml) was added dropwise a solution of **12** (115 mg, 0.49 mmol) in THF (4 ml) at −78 °C under argon. After being stirred for 1 h at −78 °C, $ZnCl_2$[17] (133 mg, 0.98 mmol) in ether (5 ml) was added and stirred for 10 min and to this mixture acetone (300 mg, 5.2 mmol) was added. The mixture was quenched with cold aqueous 5% tartaric acid and extracted with ether–benzene. The organic phase was worked up in the usual manner and the crude product was chromatographed (hexane–AcOEt, 4 : 1) to give 55 mg (38%) of **13a** and 65 mg (38%) of **13b** as an oil. Physical constants along with elemental analyses of **13a** and **13b** are as follows : **13a**; IR (neat) 3440 (OH), 3020, 1735 (ester C=O), 1650 cm^{-1} (C=O); ^1H NMR (60 MHz) δ 0.94 (d, 3, J=7 Hz, CH_3), 1.19 (s, 3, CH_3), 1.22 (s, 6, CH_3), 1.10—2.70 (m, 8, CH_2, CH), 4.83 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 5.01 (br s, 1, OH), 5.73 (br s, 1, HC=C); ^{13}C NMR δ 10.5 (q, C-9), 17.1 (q, C-10), 21.2 (q, acetyl CH_3), 24.6 (q, C-13), 28.3 (q, C-12), 30.5 (t, C-8), 31.3 (t, C-7), 38.7 (t, C-4), 40.0 (s, C-4a), 47.1 (d, C-5), 50.6 (d, C-3), 72.4 (s, C-11), 73.1 (d, C-6), 125.1 (d, C-1), 168.2 (s, C-8a), 170.6 (s, acetyl C=O), 202.8 (s, C-2). Found: C, 69.44; H, 8.92%. Calcd for $C_{17}H_{26}O_4$: C, 69.36; H, 8.90%.

13b: IR (neat) 3440 (OH), 3020, 1720 (ester C=O), 1660 cm^{-1} (C=O); ^1H NMR (60 MHz) δ 0.85 (d, 3, J= 7 Hz, CH_3), 1.00 (s, 3, CH_3), 1.21 (s, 6, CH_3), 1.20—2.75 (m, 8, CH_2, CH), 1.29 (s, 6, CH_3), 2.02 (s, 2, CH_2), 4.93 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 4.96 (br s, 1, OH), 5.31 (br s, 1, OH), 5.73 (br s, 1, HC=C). Found: C, 68.31; H, 9.11%. Calcd for $C_{20}H_{32}O_5$: C, 68.15; H, 9.15%.

Independently, the compound **13a** was prepared as follows: To a stirred solution of lithium *N*-isopropylcyclohexylamide (73.6 mg, 0.5 mmol) in THF (3 ml) was added dropwise a solution of **12** (24 mg, 0.1 mmol) in THF (3 ml) at −78 °C. After being stirred for 2.5 h at −78 °C, $ZnCl_2$ (13.6 mg, 0.1 mmol) in ether (3 ml) was added and stirred for 10 min and to this mixture acetone (0.1 ml, 13.6 mmol) was added. The mixture was quenched with cold aqueous 5% tartaric acid and worked up to give 20 mg (68%) of **13a**.

6α-Acetoxy-3-isopropylidene-4aβ,5β-dimethyl-$\Delta^{1,8a}$*-octalin-2-one (**1b**).* To a solution of **13a** (21 mg, 0.071 mmol) in pyridine (1.5 ml) was added MsCl (29.6 mg, 0.26 mmol) at 0 °C under N_2. After being stirred for 1 h at 20 °C and 2 h at 40—42 °C, the mixture was quenched with cold water and taken up in ether–benzene. The organic layer was washed with brine, dried (Na_2SO_4), and concentrated. The residue was chromatographed (hexane–AcOEt, 4 : 1) to give 3 mg of **12** and 13 mg (66%) of an *exo* and *endo* double bond mixture **14a**: IR (neat) 3070, 1735 (ester C=O), 1675 (C=O), 1630 cm^{-1} (C=C); ^1H NMR (60 MHz) δ 4.80, 4.96 (br s, H_2C=C). Without further purification, **14a** was passed through an activated alumina 300 (Nakarai Chemicals) column (hexane–AcOEt, 3 : 1) to give **1b** in a quantitative yield as a white solid : mp 78.0—79.0 °C (lit,[18] 86.0—87.0 °C); IR (Nujol) 1735 (ester C=O), 1665 (C=O), 1635 (C=C), 1242, 1030 cm^{-1}; ^1H NMR (100 MHz) δ 0.99 (d, 3, J=6 Hz, CH_3), 1.04 (s, 3, CH_3), 1.10—2.60 (m, 6, CH_2, CH), 1.85 (s, 3, CH_3), 2.07 (s, 3, $COCH_3$), 2.09 (s, 3, CH_3), 2.94 (d, 1, J=14 Hz, C=CCH), 4.88 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 5.82 (br s, 1, HC=C); ^{13}C NMR δ 10.7 (q, C-9), 17.1 (q, C-10), 21.2 (q, acetyl CH_3), 22.1 (q, C-12), 22.6 (q, C-13), 30.1 (t, C-8), 31.5 (t, C-7), 41.1 (t, C-4), 42.2 (s, C-4a), 46.0 (d, C-5), 73.6 (d, C-6), 126.7 (d, C-1), 127.0 (s, C-3), 143.4 (s, C-11), 165.0 (s, C-8a), 170.7 (s, acetyl C=O), 191.6 (s, C-2).

6α-(3,3-Dimethylacryloyloxy)-3-isopropylidene-4aβ,5β-dimethyl-$\Delta^{1,8a}$*-octalin-2-one (**1c**)* was obtained in 72% yield by dehydration with MsCl and isomerization with activated alumina 300 column of **13b** : bp 129.0—131.0 °C/0.01 Torr (Kugelrohr); IR (neat) 3020, 1712 (ester C=O), 1665 (C=O), 1630 (C=C), 1620 cm^{-1} (C=C); ^1H NMR (100 MHz) δ 0.98 (d, 3, J=7 Hz, CH_3), 1.04 (s, 3, CH_3), 1.10—2.59 (m, 6, CH_2, CH), 1.85, 1.91, 2.10, 2.18 (s, 12, CH_3), 2.92 (d, 1, J=13 Hz, C=CCH), 4.86 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 5.65 (complex s, 1, HC=C), 5.75 (d, 1, J=1 Hz, HC=C); ^{13}C NMR δ 10.7 (q, C-9), 17.2 (q, C-10), 20.3 (q, 3,3-dimethylacryl γ-CH_3), 22.1 (q, C-13), 22.6 (q, C-12), 27.5 (q, 3,3-dimethylacryl γ-CH_3), 30.2 (t, C-8), 31.8 (t, C-7), 41.2 (t, C-4), 42.2 (s, C-4a), 46.2 (d, C-5), 72.4 (d, C-6), 116.0 (d, acryl α-CH), 126.6 (d, C-1), 127.1 (s, C-3), 143.2 (s, C-11), 157.2 (s, acryl β-C), 165.3 (s, C-8a), 166.3 (s, acryl C=O), 191.6 (s, C-2). Found: C, 75.93; H, 8.97%. Calcd for $C_{20}H_{28}O_3$: C, 75.91; H, 8.92%.

*Conversion of **14a** into **1b** with $RhCl_3 \cdot 2H_2O$.* A solution of **14a** (19 mg, 0.069 mmol) and $RhCl_3 \cdot 2H_2O$ (2 mg, 0.008 mmol) in EtOH (2 ml) was heated for 12 h at 110 °C in a sealed tube. After being cooled, the mixture was filtered and the filtrate was concentrated. The residue was chromatographed (hexane–AcOEt, 4 : 1) to give 14 mg (84%) of **1b** as a white solid.

Similarly, **1c** was obtained by the reaction of **14b** and $RhCl_3 \cdot 2H_2O$ in EtOH at 110 °C for 12 h in 82% yield.

*dl-Isopetasol (**1a**).* To a solution of **1b** (21 mg, 0.076 mmol) in MeOH (2 ml) was added a solution of KOH (95 mg, 17 mmol) in H_2O (0.3 ml) at 5 °C. The mixture was stirred for 2 h at 10 °C and taken up in ether–benzene. The extract was worked up in the usual manner to give 13 mg (73%) of **1a** as white solid : mp 104.0—105.5 °C (lit,[2c] 124.0—125.0 °C, lit,[2d] 105.0—106.0 °C); IR (Nujol) 3390 (OH), 1652 (C=O), 1628 (C=C), 1608 (C=C), 1380, 1298, 1230, 1217, 1048, 890, 858 cm^{-1}; ^1H NMR (100 MHz) δ 0.99 (s, 3, CH_3), 1.12 (d, 3, J=6.5 Hz, CH_3), 1.10—1.67 (m, 3, CH_2, CH), 1.79 (s, 1, OH), 1.87 (s, 3, C=CCH_3), 2.03—2.50 (m, 3, CH_2), 2.11 (s, 3, C=CCH_3), 2.93 (d, 1, J=14 Hz, C=CCH), 3.60 (d, d, d, 1, J=10, 5, 5 Hz, CH-O), 5.82 (br s, 1, HC=C); ^{13}C NMR δ 10.8 (q, C-9), 17.3 (q, C-10), 22.1 (q, C-13), 22.6 (q, C-12), 30.5 (t, C-8), 35.3 (t, C-7), 41.2 (t, C-4), 42.0 (s, C-4a), 49.1 (d, C-5), 71.3 (d, C-6), 126.5 (d, C-1), 127.2 (s, C-3), 143.2 (s, C-11), 166.1 (s, C-8a), 191.7 (s, C-2).

Similarly, *dl*-isopetasol (**1a**) was obtained in 71% yield by hydrolysis of **1c** at room temperature for 2 h with KOH in aqueous MeOH. IR and ^1H NMR spectra data were identical with those of an authentic sample.[13]

Imidazopteridines. II.[1] Synthesis of Imidazo[1,2-*c*]pteridines with a Functional Group at the 6-Position

Takashi SUGIMOTO,* Keiko SHIBATA, and Sadao MATSUURA

Department of Chemistry, College of General Education, Nagoya University, Chikusa-ku, Nagoya 464

(Received September 28, 1978)

Several imidazo[1,2-*c*]pteridines with a functional group such as amino, alkylamino, alkoxyl, or hydroxyl group at the 6-position were synthesized by a nucleophilic replacement of 6-methylthioimidazo[1,2-*c*]pteridine with an appropriate nucleophile. The key intermediate methylthio compound was synthesized by condensation of 4-amino-2-methylthiopteridine with chloroacetaldehyde. Similarly, 4-amino-6,7-dimethyl-2-methylthiopteridine and chloroacetaldehyde gave 2,3-dimethyl-6-methylthioimidazo[1,2-*c*]pteridine, which was also used as a precursor to synthesize several imidazopteridines analogous to above.

In the course of our research programs on tricyclic imidazoazines,[1-4] we previously reported the synthesis of the parent imidazo[1,2-*c*]pteridine and its *C*-alkyl derivatives.[1] These compounds were found to be susceptible to ring-opening reaction into an 2-amino-3-(2-imidazolyl)pyrazine *via* a nucleophilic addition of water at the 6-position. This ring-opening reaction proceeded easily even in the presence of a blocking methyl group[5] at the site of addition. All these results indicated a high reactivity of the ring system toward various nucleophiles at the 6-position. This paper reports the synthesis of some 6-methylthio derivatives of the ring system and their easy derivation into a variety of imidazo[1,2-*c*]pteridines with a functional group at the 6-position.

Condensation of 4-amino-2-methylthiopteridine(**1a**) with chloroacetaldehyde at pH 6—7 gave intensive blue fluorescent 6-methylthioimidazo[1,2-*c*]pteridine-(**2a**) in about 45% yield. When the reaction was carried out at the pH values out of the above range, either higher or lower, the yield of **2a** lowered significantly, probably due to instability of **2a** under such conditions. The structure of the product was confirmed from the elemental analyses, pK_a values, and UV spectra (Table 1) which showed a characteristic bathochromic shift when the molecule was doubly protonated. The ^1H NMR spectrum of **2a** showed two singlets at δ 2.68 for the methyl group and at δ 7.86 for the imidazole ring protons and a pair of doublets at δ 8.82 and 8.92 (J=2 Hz) representing the pyrazine ring protons. Analogous treatments of 4-amino-6,7-dimethyl-2-methylthiopteridine(**1b**) with chloroacetaldehyde furnished 2,3-dimethyl-6-methylthioimidazo[1,2-*c*]-pteridine(**2b**).

These methylthioimidazopteridines(**2a** and **2b**) were found to be highly reactive toward various nucleophiles and proved to be useful precursors for the synthesis of many other imidazo[1,2-*c*]pteridines with a functional group such as amino, alkylamino, hydroxyl, or alkoxyl group at the 6-position. Aminolysis of **2a**, carried out by heating with ethanolic ammonia, gave 6-aminoimidazo[1,2-*c*]pteridine(**2c**) in a high yield. A similar aminolysis of the methylthio compound (**2a**) with methylamine, ethylamine, or 2-aminoethanol gave 6-methylamino-(**2e**), 6-ethylamino-(**2g**), and 6-(2-hydroxyethylamino)imidazo[1,2-*c*]pteridines (**2i**), respectively. The basic characters of these amino compounds were fairly strenghened compared to that of the precursor (see Table 1) on replacement of the methylthio group by an amino group. All of these aminoimidazopteridines (**2e**, **2g**, and **2i**) were of very similar UV spectra, which also showed a large bathochromic shift on double protonation. Similarly, 2,3-dimethyl-6-methylthioimidazo[1,2-*c*]pteridine (**2b**) gave the 6-amino and 6-alkylamino analogues (**2d**, **2f**, **2h**, and **2j**) on aminolysis with the corresponding amine. Conversion of the methylthio compounds (**2a** and **2b**) into 6-hydroxyimidazo[1,2-*c*]pteridines (**2k** and **2l**) was achieved by heating either in dilute aqueous sodium hydroxide or in dilute hydrochloric acid. On the other hand, 6-ethoxyimidazo[1,2-*c*]pteridine (**2m**) and its 2,3-dimethyl derivative (**2n**) were obtained in a rather unusual way from the corresponding methylthio precursors (**2a** and **2b**) by heating in ethanol with silver oxide, a reagent recently reported useful for an exchange of alkoxyl groups in several heterocyclic systems.[6] Treatment of **2a** with sodium ethoxide or hydrogen chloride in ethanol gave no ethoxy compound (**2m**); the sole product was 6-hydroxyimidazopteridine(**2k**). Similar treatments of **2a** and **2b** with silver oxide in methanol gave the corresponding 6-methoxyimidazo[1,2-*c*]pteridines (**2o** and **2p**).

Experimental

The elemental analyses were carried out at the Analytical Section, Meijo University and at the Analytical Section,

Table 1. The pK_a values and UV spectra of imidazo[1,2-*c*]pteridines

a) Ionic species in an aqueous buffer of the indicated pH are shown by −(anion), ○(neutral molecule), +(monocation), and ++(dication). b) Wavelength in nm and inflexions or shoulders in italics. c) Negatives figures are H_0 values.

Faculty of Agriculture, Nagoya University. The pK_a values were determined by a spectroscopic method. The UV spectra were measured on a Shimadzu UV-300 spectrophotometer and NMR spectra on a JEOL JNM-NH-100 spectrometer in TFA-*d* with TMS as an internal standard.

*6-Methylthioimidazo[1,2-c]pteridine(**2a**) and Its 2,3-Dimethyl Derivative(**2b**).* 4-Amino-2-mercaptopteridine[7] was methylated with dimethyl sulfate in an alkaline solution to give 4-amino-2-methylthiopteridine(**1a**) in 80% yield, mp 210.5—211.5 °C (from water) (Found: C, 43.69; H, 3.56%. Calcd for $C_7H_7N_5S$: C, 43.50; H, 3.66%). A solution of **1a** (10 g) and chloroacetaldehyde (40 g) in 50% aqueous methanol (1500 ml) was heated at 65 °C for 20 h, during which time the pH of the solution was maintained at pH 6—7 by addition of sodium acetate. The solution was evaporated to dryness under reduced pressure and the residue was extracted with hot acetone (500 ml). The extract, after evaporation to dryness, was chromatographed on a silica gel column (Wako Gel C-100, 4×40 cm) eluted first by a mixture of ethyl acetate and benzene (1 : 4) to remove a small amount of fluorescent impurities. The column was then eluted by a 1 : 1 mixture of the two solvents. The eluate was evaporated to dryness and the residue was crystallized from ethyl acetate to give ivory needles (4.9 g) of **2a**, mp 195—196 °C (Found: C, 49.81; H, 3.11; N, 32.00%. Calcd for $C_9H_7N_5S$: C, 49.75; H, 3.25; N, 32.24%).

By using 4-amino-6,7-dimethyl-2-methylthiopteridine (**1b**)[8] in stead of **1a** in the above reaction, **2b** was obtained in 36% yield as ivory needles, mp 216—216.5 °C (from ethyl acetate)(Found : C, 53.69; H, 4.40; N, 28.46%. Calcd for $C_{11}H_{11}N_5S$: C, 53.85; H, 4.53; N, 28.55%); NMR: three singlets at δ 2.50(3H), 2.56(6H), and 7.70 (2H).

*6-Aminoimidazo[1,2-c]pteridine(**2c**) and Its 2,3-Dimethyl Derivative(**2d**).* A suspension of **2a** (300 mg) in a saturated ethanolic ammonia (50 ml) was heated in a sealed tube at 100 °C for 5 h. After cooling, the solid was collected and crystallized from methanol to give colorless needles (200 mg) of **2c**, mp>300 °C (Found: C, 50.68; H, 2.92; N, 43.93%. Calcd for $C_8H_6N_6 \cdot 0.2\,H_2O$: C, 50.84; H, 3.40; N, 44.29%).

Its 2,3-dimethyl derivative(**2d**) was synthesized from **2b** in a similar way in 70% yield, mp>300 °C (Found: C, 55.78; H, 4.76; N, 39.23%. Calcd for $C_{10}H_{10}N_6$: C, 56.07; H, 4.71; N, 39.23%).

*6-Methylamino- and 6-Ethylaminoimidazo[1,2-c]pteridines (**2e** and **2g**) and Their 2,3-Dimethyl Derivatives(**2f** and **2h**).* A solution of **1a** (500 mg) and methylamine (40% aqueous solution, 10 ml) in ethanol (100 ml) was heated under reflux for 5 h. The solution was evaporated to dryness in vacuo and the residue was fractionated on a Florisil column (3.5×40 cm) eluted gradiently by 0—3% ammonia (2 l). The eluate, after evaporation and crystallization from water, gave ivory needles (280 mg) of **2e**, mp 296—297 °C (Found: C, 53.62; H, 3.96; N, 41.53%. Calcd for $C_9H_8N_6$: C, 53.98; H, 4.04; N, 41.98%).

Heating of **2a** with ethylamine as above, followed by chromatographic separation on a silica gel column eluted by ethanol–ethyl acetate (1 : 9) gave **2g** as colorless needles (75% yield), mp 211—211.5 °C (from acetone)(Found: C, 55.90; H, 4.56; N, 38.84%. Calcd for $C_{10}H_{10}N_6$: C, 56.07; H, 4.71; N, 39.23%).

Similarly, **2b** was treated with methylamine or ethylamine to give, without using chromatography, **2f** (50% yield), mp>300 °C (from ethanol)(Found : C, 57.93; H, 5.29; N, 36.63%. Calcd for $C_{11}H_{12}N_6$: C, 57.87; H, 5.31; N, 36.82%) and **2h** (65% yiled), mp 295—296 °C (from ethanol)(Found: C, 59.69; H, 5.97; N, 34.59%. Calcd for $C_{12}H_{14}N_6$: C, 59.48; H, 5.84; N, 34.69%), respectively.

*6-(2-Hydroxyethylamino)imidazo[1,2-c]pteridine (**2i**) and Its 2,3-Dimethyl Derivative(**2j**).* A solution of **2a** (500 mg) and 2-aminoethanol (2 g) in water (20 ml) was heated under reflux for 5 h. The solution was adjusted at pH 2—3 with hydrochloric acid and chromatographed on a Florisil column in a similar way to that used for **2e**. Evaporation of the eluate to dryness and crystallization of the residue from water gave colorless needles (200 mg) of **2i**, mp 244—244.5 °C(Found: C, 51.62; H, 4.33; N, 36.02%. Calcd for $C_{10}H_{10}N_6O \cdot 0.1H_2O$: C, 51.75; H, 4.44; N, 36.22%). In a similar way, **2b** and 2-aminoethanol gave **2j** (60% yield), mp 266—267 °C (from ethanol)(Found: C, 55.98; H, 5.60; N, 32.43%. Calcd for $C_{12}H_{14}N_6O$: C, 55.80; H, 5.47; N, 32.54%).

*6-Hydroxyimidazo[1,2-c]pteridine(**2k**) and Its 2,3-Dimethyl Derivative(**2l**).* A solution of **2a** (1.0 g) in 0.1 M sodium hydroxide (20 ml) was heated at 60 °C for 1.5 h. The solution was adjusted at pH 2—3 with formic acid and chilled. The solid was collected and crystallized from water to give colorless needles (0.35 g) of **2k**; the compound darkened above 205 °C without melting (Found: C, 51.03; H, 2.47; N, 37.39%. Calcd for $C_8H_7N_5O$: C, 51.33; H, 2.70; N, 37.42%). The same compound(**2k**) was obtained from **2a** by heating in 0.1 M hydrochloric acid at 60 °C, by treatment with sodium ethoxide or hydrogen chloride in ethanol at 25 °C, or by heating in 50% aqueous methanol with silver oxide.

Heating of **2b** (280 mg) in 0.2 M hydrochloric acid at 70 °C for 20 h and evaporation to dryness in vacuo gave a solid, which was dissolved in water (10 ml). The solution was adjusted at pH 3—4 with ammonia and chilled to give colorless needles (200 mg) of **2l**, mp 294—295.5 °C (from water)(Found: C, 54.30; H, 4.60; N, 31.73%). Calcd for $C_{10}H_9N_5O \cdot 0.3H_2O$: C, 54.43; H, 4.39; N, 31.75%).

*6-Ethoxy- and 6-Methoxyimidazo[1,2-c]pteridines(**2m** and **2o**) and Their 2,3-Dimethyl Derivatives(**2n** and **2p**).* A mixture of **2a** (400 mg) and silver oxide (2 g) in ethanol (150 ml) was heated under reflux for 7 h. After filtration, the filtrate was evaporated to dryness and the residue was chromatographed on a silica gel column eluted by ethanol–ethyl acetate(1 : 9). Evaporation of the eluate and crystallization from ethyl acetate gave colorless needles (200 mg) of **2m**, mp 143—143.5 °C (Found: C, 56.00; H, 4.18; N, 32.61%. Calcd for $C_{10}H_9N_5O$: C, 55.81; H, 4.22; N, 32.54%).

By using methanol in place of ethanol in the above reaction, the 6-methoxy compound(**2o**) was obtained in 30% yield, mp 238—239 °C (from ethyl acetate)(Found: C, 53.53; H, 3.33; N, 34.39%. Calcd for $C_9H_7N_5O$: C, 53.72; H, 3.51; N, 34.81%).

Similar treatments of **2b** with silver oxide in ethanol or methanol gave the ethoxy compound(**2n**) in 50% yield, mp 184—185 °C (from benzene)(Found: C, 59.22; H, 5.39; N, 28.51%. Calcd for $C_{12}H_{13}N_5O$: C, 59.24; H, 5.40; N, 28.79%), and the methoxy compound (**2p**) in 55% yield, mp 216—216.5 °C (from toluene)(Found: C, 56.13; H, 4.78; N, 29.64%. Calcd for $C_{11}H_{11}N_5O \cdot 0.3H_2O$: C, 56.29; H, 4.86; N, 29.85%), respectively.

We thank Dr. Y. Yokoyama for measuring the NMR spectra and Mrs. N. Nishioka for determining the pK_a values.

Stereochemistry of Elimination Reactions of Halohydrin Derivatives and Related Compounds with Butyllithium[1)]

Toshio SUGITA,* Junichi NAKAGAWA, Kazuhito NISHIMOTO, Yasuhiro KASAI, and Katsuhiko ICHIKAWA

Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

(Received May 24, 1978)

The *erythro* and *threo* isomers of 1-bromo-2-methoxy-1,2-diphenylethane (**1**), 1-bromo-2-acetoxy-1,2-diphenylethane (**2**), 1-bromo-2-methylsulfonyloxy-1,2-diphenylethane (**3**), 1-bromo-2-methylthio-1,2-diphenylethane (**4**), stilbene dibromide (**6**), and stilbene dichloride have been prepared. These compounds were allowed to react with butyllithium in various solvents to give *cis*- and *trans*-stilbenes. Depending on the solvent, the stereochemistry of the elimination of **1** changed from a complete *syn*-type (in nonpolar solvents) to a less-selective type. The same tendency was observed in the cases of **2** and **3**. In contrast, *anti*-elimination was favored for **4** and **6**, and a different type of solvent effect was observed. Elimination reactions with lithium metal and pentylmagnesium bromide were also carried out. Possible mechanisms for eliminations are discussed.

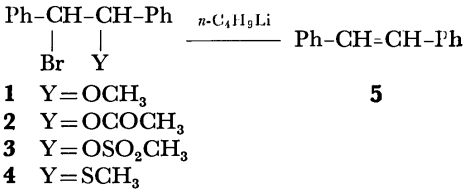
Results of extensive studies on the bimolecular elimination of halohydrin derivatives and *vicinal* dibromides with metal or metal salts have shown that the reactions display a variable stereoselectivity, depending on the nature of the metals used.[2-5)] The effects of the structure of substrates and the solvent, however, remain ambiguous. This paper reports the results of studies on the stereochemistry of the elimination of stilbene halohydrin derivatives and related compounds; in particular, the effects of the leaving group and the solvent were probed.

House and Ro have shown that the treatment of β-halo ethers and esters with zinc in aqueous ethanol or with sodium in tetrahydrofuran gave nonstereospecific elimination products.[2)] They postulated that the organometallics formed by halogen–metal exchanges give olefins by the mechanism of ElcB but not by that of E2, because OR and OCOR are poor leaving-groups. However, since the reactions of metals such as magnesium[6)] and lithium[7)] with alkyl halides to form Grignard and organolithium reagents result in the loss of stereochemical integrity, it is not clear whether the loss of stereospecificity in the reaction of halohydrin derivatives with metal occurs during the halogen–metal exchange or in the subsequent elimination process.

When the halide is treated with an alkyllithium reagent instead of lithium metal, the lithium compound formed is capable of maintaining its configuration, although the degree of retention of configuration is both solvent- and temperature-dependent.[8)] In order to preclude the loss of stereospecificity in the halogen–metal exchange stage, our eliminations were carried out by the use of butyllithium.

Results

The *erythro* and *threo* pairs of 2-substituted 1-bromo-1,2-diphenylethanes were chosen as the substrates because of their accessibility in pure form and the accuracy with which analysis of the products is possible. The *erythro* (**e**) and *threo* (**t**) isomers of 1-bromo-2-methoxy-1,2-diphenylethane (**1**), 1-bromo-2-acetoxy-1,2-diphenylethane (**2**), 1-bromo-2-methylsulfonyloxy-1,2-diphenylethane (**3**), and 1-bromo-2-methylthio-1,2-diphenylethane (**4**) have been prepared. Each compound was allowed to react with butyllithium in various kinds of solvents. The organic products were analyzed by GLPC. *cis*- (**5c**) and *trans*-Stilbenes (**5t**) produced were isolated and identified by means of GLPC, IR, and NMR. The results are summarized in Table 1.



In any attempt to account for stereoselectivity, we must remember that **5t** is much more stable than **5c** under the reaction conditions: the thermodynamical isomer ratio of *trans* to *cis* is 500 at 25 °C.[9)] The exclusive formation of **5c** from **1e** as well as **5t** from **1t** in nonpolar solvents such as diethyl ether and benzene indicates that the stereospecific *syn* elimination occurred in the reaction of **1** with butyllithium in nonpolar solvents. Although the stereospecificities were diminished, the same tendency of *syn* elimination was clearly observed in the cases of **2** and **3**.

The solvent study was limited by the insolubility of the substrates in hydrocarbon solvents. Within the limited range of solvents, however, it was observed that changing the solvent from nonpolar to better solvating ones, such as tetrahydrofuran (THF) or bis(2-methoxyethyl) ether (diglyme), diminished the stereospecificity. The addition of a cation complexing reagent, *N,N,N,N*-tetramethylethylenediamine (TMEDA), also reduced the stereospecificity. The fact that only **5c** was formed, even in the elimination reaction using an excess amount of butyllithium, can eliminate the possibility of isomerization of **5c** to **5t** in nonpolar solvents. In a separated experiment, in which **5c** was treated with an equivalent amount of butyllithium in diglyme under the reaction condition, the recovered **5** was exclusively *cis* isomer. Thus the possibility of isomerization can also be eliminated in a better solvating medium.

When **1e** in diethyl ether was treated with butyllithium at −72 °C and the reaction was quenched

Table 1. Elimination reactions of stilbene halohydrin derivatives with butyllithium

Run	Substrate (mmol)	n-C_4H_9Li (mmol)	Solvent (ml)	Additive (mmol)	React. condition		5		
					Time (min)	Temp (°C)	Yield (%)	*cis* : *trans*	
1	**1e** (1.01)	1.0	Et_2O (50)		30	0	42	100	trace

with methanol after 0.5—3 min, small amounts of 1-methoxy-1,2-diphenylethane were detected by GLPC, together with **5c** and unreacted **1e**. This GLPC peak could not be detected any more when the reaction was completed after 30 min.

As can be seen from Table 1, the stereochemical feature of elimination of 1-bromo-2-methylthio derivative (**4**) were quite different from the above-mentioned oxygen analogue (**1**). Recently Trost and Ziman reported that the elimination of 2-bromo-3-ethylthio- and 2-bromo-3-phenylthiobutanes with butyllithium proceeded with a moderate to high degree of *anti* stereoselectivity in THF solution.[10] In our case, the stereospecificity of the elimination was completely lost in nonpolar solvents such as benzene or diethyl ether, while a high *anti* stereoselectivity was observed in a

a) The reactions were carried out under reflux in 100 ml of diethyl ether.

highly cation solvating medium such as diglyme. By increasing the cation solvating ability of the solvent, the *anti* elimination was increased. When 5 equivalents of TMEDA or 1 equivalent of crown ether accompanied with 5 equivalents of 1,2-dimethoxyethane (DME) was added, moderate *anti* stereoselectivities were observed even in the diethyl ether medium.

In a similar study by Winkler on phenyllithium-induced debromination of *dl*- and *meso*-2,3-dibromobutanes, an almost exclusive *anti* elimination has been demonstrated.[11] In order to compare with these data, we investigated the stereochemistry of elimination with butyllithium on *vicinal* dibromide as well as dichloride in the present stilbene system. The results are summarized in Table 2.

The debromination of *meso*-stilbene dibromide (**6e**) produced only **5t**, but a mixture of 20% of **5c** and 80% of **5t** was obtained from the *dl*-isomer (**6t**). By the fact that the thermodynamically unstable **5c** was obtained from **6t**, it is apparent that the reaction proceeds by *anti* fashion, but the stereospecificity is considerably lower than in the case of 2,3-dibromobutane. In this case, no solvent effects on the stereochemistry were observed when the solvent was changed from diethyl ether to diglyme.

In the case of *vicinal* dichloride (**7**), the elimination was no longer stereoselective, and **5t** was virtually exclusively obtained from both the *dl* and *meso* isomers.

The present stereochemical results of elimination of bromohydrin derivatives with butyllithium markedly contrast with those using metals such as zinc and sodium, which resulted in nonstereospecific eliminations.[2] There have also been indications that certain metal debrominations may display a variable stereoselectivity, and a surface radical process has been suggested for the debromination reaction of **6** with metals.[4] In order to learn more about the discrepancy of the stereochemistry of elimination with butyllithium and with metal, we undertook the elimination reaction using lithium metal.

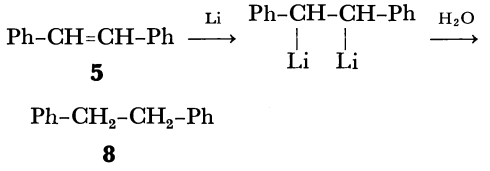
The β-bromo ether **1** was refluxed with lithium metal in diethyl ether. The amounts of **5** and 1,2-diphenylethane (**8**) produced were determined by GLPC analysis and are summarized in Table 3. As the IR spectra of the unreacted **1** recovered from the reaction mixture were superimposable with those of each starting material, the possibility of isomerization during the reaction process could be eliminated.

Since the formation of dilithio compounds from **5** and the other arylated alkenes has been reported,[12] **5t** was allowed to react with lithium metal under the reaction conditions, **8** was obtained after the work-up, as shown in Table 4. These results indicate that **8** was produced by addition of the excess lithium metal to **5** of the elimination product, followed by hydrolysis in the work-up process. Since the relative rate of formation of the dilithio compounds from **5c** and **5t** is not clear, the ratios of **5c** and **5t** in Table 3

Table 4. Reactions of **5** with lithium metal[a)]

5t (mmol)	Li (mg-atom)	Reaction time (h)	Yield of **8** (%)
2.04	18	5	37
2.04	16	30	70

a) Reactions were carried out under reflux in 100 ml of diethyl ether.



may not reflect the actual ratios of the elimination process. However, the result that **5c** was obtained only from **1e**, though the yield was not so high, indicates that *syn* elimination has occurred at least partly in the reaction using lithium metal.

Dehydrohalogenation of alkyl halide[13] and debromination of *vicinal* dibromide[4] with Grignard reagents have been investigated in only a few instances. Furthermore, β- and γ-haloalkyl phenyl ethers gave olefin and cyclopropane respectively by the reaction with Grignard reagents in the presence of cobaltous bromide.[14] On the other hand, halogen–metal interchange reactions with Grignard reagents have been established.[15] Zakharkin and his coworkers have made extensive studies of the exchange of Grignard reagents with ordinary alkyl and aryl halides.[16] Highly solvating ethers such as THF and DME favor the exchange. The rate of exchange is dependent on the polarizability of the halogens in the alkyl halides. On the basis of these studies, they have concluded that the mechanism of halogen–metal interchange reaction is the same for both organomagnesium and organolithium compounds. We thus undertook an investigation of the stereochemistry of elimination promoted by pentylmagnesium bromide. The results are given in Table 5.

TABLE 5. ELIMINATION REACTIONS OF **1** WITH PENTYLMAGNESIUM BROMIDE[a]

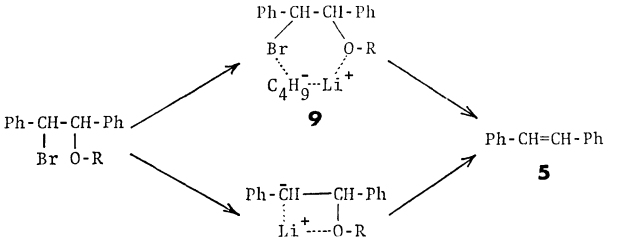
Substrate (mmol)	n-$C_5H_{11}MgBr$ (mmol)	Reaciton time (min)	**5** Yield (%)	*cis*	: *trans*
1e (1.05)	2.0	90	27	0	100
1e (1.01)	2.0	180	49	0	100
1e (1.05)	2.0	360	34	0	100
1t (1.04)	2.0	180	31	0	100
1t (1.04)	2.7	360	33	0	100

a) Reactions were carried out in 50 ml of diethyl ether at 0 °C.

As can be seen from Table 5, **5t** was an exclusive product from both **1e** and **1t**. As the IR spectra of substrates recovered from the reaction mixtures were completely identical with that of the respective starting materials, isomerization of the substrates during the reaction process can be eliminated. The isomerization of **5** also could not be detected under the experimental conditions. The present results indicate the elimination reaction of β-halo ethers promoted by a Grignard reagent to be nonstereospecific.

Discussion

Although a number of mechanistic implications have been reported for the base-catalyzed bimolecular elimination reactions, two possible routes may be considered for the butyllithium-induced *syn* elimination of halohydrin derivatives. One is the process *via* a cyclic transition state such as **9**, and the other is a mechanism which involves a carbanion or the equivalent organolithium reagent (**10**). In both cases, the factor which forces the production of **5c** from the *erythro* isomers of substrates, even against the large thermodynamical instability of the product, is expected to be the coordination between lithium and oxygen atoms. This is proved by the fact that the stereospecificity of *syn* elimination decreased by increasing the cation complexing ability of solvents. The cation complexing ability of the medium increases in the order: hexane < benzene < diethyl ether < THF < DME < diglyme,[17] and is also enhanced by the addition of cation-coordinating reagents such as TMEDA and crown ethers.[18,19]



Scheme 1.

The cyclic transition state (**9**) is similar to that postulated by Letsinger to explain the more rapid *syn* elimination of the elements of methanol when *cis*- and *trans*-1-methoxy-2-phenylcyclohexanes are heated under reflux with butyllithium in a mixture of pentane and diethyl ether.[20] The coordination between lithium and oxygen should be stronger in a nonpolar solvent such as hexane, benzene, or diethyl ether, and weaker in the coordinating solvents. Thus the reduction of stereospecificity in THF or diglyme solvent would seem to occur as a matter of course. However, the fact that considerable lower stereospecificity was observed in the reactions of **2** and **3** in nonpolar solvents in comparison with the reaction of **1** is not conceivable from a concerted mechanism *via* such a cyclic transition state, because it was recently reported by Staley and Beauchamp that the binding energy of an ester to a lithium cation is much stronger than that of an ether.[21]

The alternative mechanism involving a carbanion intermediate (**10**) appears to be more plausible, because of the poor leaving group ability of OR and OCOR. The formation of the carbanion intermediate is also evidenced by the fact that 1-methoxy-1,2-diphenylethane was detected when the reaction of **1** at −72 °C was quenched by methanol. House and Ro postulated a similar intermediate for the nonstereospecific elimination of β-halo ethers and esters with zinc and sodium.[2]

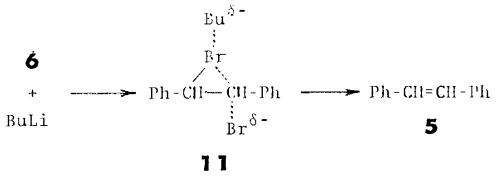
It has been demonstrated that metal–halogen exchange with butyllithium occurs with a high degree of retention of configuration.[8] While spectroscopic studies indicate a polar covalent character for the

carbon–lithium bonds in alkyllithiums, it has also been revealed that alkyllithiums exist in solution in equilibrium with different types of ion pairs: tight, solvent separated, and free ion-pairs, and that such equilibria are affected not only by the structure of the carbanion but also by the solvent polarity, temperature, and the presence of gegenion-coordinating additives.[18] Thus the *erythro*- and *threo*-carbanions (**10**) are expected to be produced from the corresponding isomers of **1**, **2**, and **3**. These carbanions will form tight ion-pairs with lithium cation in nonpolar solvents. A lithium cation, on the other side, may coordinate with the substituent oxygen. The interaction between the metal cation in a tight ion-pair and the substituent oxygen makes it a better leaving group, and appears to force *syn* elimination.

As the coordinating-ability of an OAc group to a lithium cation is stronger than that of a methoxyl group, and a stronger ability is also expected for the OSO_2CH_3 group, higher *syn* selectivities are expected for **2** and **3** than for **1**. The results summarized in Table 1 are, however, inconsistent with this expectation. These results seems to reflect the ease with which the leaving group Y are eliminated. Although there is no exact data to indicate the departing tendencies of various groups, it would be expected by analogy with the behavior of various groups in nucleophilic displacement reactions to decrease in the following order: $OSO_2CH_3 > OAc \gg OR$.[22] The weakening of the bond to the leaving group makes the carbanionic intermediate **10** unstable, so the elimination mechanism is expected to have an E2 character. The *syn* selectivities of the eliminations of **2** and **3** would thus be lower than that of **1**.

In contrast with the bromohydrin derivatives, the *vic*-dibromide (**6**) indicated *anti*-fashion stereoselectivity ; in this reaction no solvent effect was observed in the stereochemistry of elimination. Stereospecific *anti*-debromination has been reported by Winkler in the reaction of 2,3-dibromobutane with phenyllithium.[11] In the present case, due to a very weak binding energy of bromine to a lithium cation, it is expected to be much weaker than that between a phenyl group of the substrate and a lithium cation,[21] and also due to the easily-departing tendency of bromine, an intermediate such as **10** is not conceivable for the debromination of *vic*-dibromide. The fact that changing the solvent from diethyl ether to diglyme has no effect on the stereochemistry of elimination suggests that a lithium cation should not play an important role on the intermediate or the transition state for butyllithium-catalyzed debromination, and that the reaction proceeds through a concerted process.

Although a number of authors have likened dehalogenation to a base-promoted E2 reaction on the basis of stereochemistry, a more detailed approach have been recently outlined by Miller and his coworkers.[23] We believe that an analogous mechanism can be applied to the present butyllithium-induced debromination, as indicated in Scheme 2. The present results indicated lower stereospecificity than Winkler's results, but this is ignorable if the large differences of the configurational stability between the transition states



Scheme 2.

derived from **6e** and **6t** as well as the products are taken into consideration.

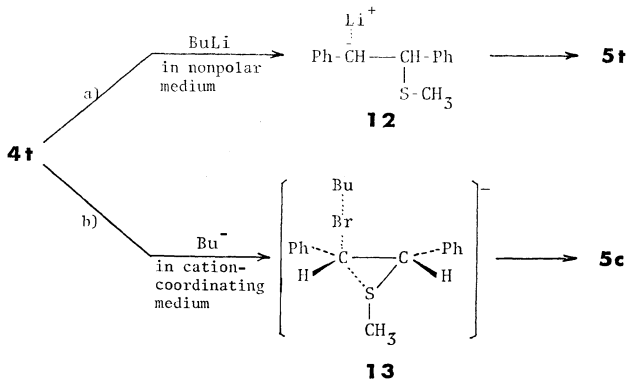
The nonstereospecific results obtained in the butyllithium-induced dechlorination of **7** do not conflict with the above mechanism, because it is well-known that neighboring group participation by chlorine is much weaker than that of bromine; thus the formation of a cyclic transition state such as **11** is difficult for the *vic*-dichloride.

The results of the elimination of **4** contrast markedly with those of the oxygen analogue (**1**), as well as those of the dihalides. In diethyl ether and benzene solvents, the elimination is nonstereospecific, *e.g.*, both *threo* and *erythro* isomers gave thermodynamically stable **5t** exclusively. In diglyme, where the oxygen analogue indicates loss of stereospecificity, however, the elimination converts **4e** into **5t**, and **4t** into 86% of **5c** and 14% of **5t**. The *anti* selectivity is increased by increasing the cation complexing ability of the solvents: THF < DME < diglyme. The addition of cation complexing reagents such as TMEDA and crown ether facilitated the *anti*-elimination. Recently, Panek reported that the rate of geometric isomerization of 1-lithio-1-phenyl-1-butene in hexane solution was enhanced by the addition of cation complexing reagents; the following order was observed: TMEDA > DME > THF > diethyl ether.[19] Furthermore, Walborsky reported that the addition of 1 equiv. dicyclohexyl-18-crown-6 with 5 equiv. of DME was very effective for complexing the lithium cation and making a free carbanion.[24]

A methylthio group may be considered as one of the groups with a lower departing tendency, similar to the methoxyl group. The butyllithium-induced elimination of **4** is thus considered to proceed *via* a carbanion intermediate.

The solvent study indicates that a nonstereospecific elimination results from the tight ion-pair intermediate derived from **4**, and the free ion or the solvent separated ion-pair provides an *anti*-elimination. The coordinating bond strength between a lithium cation and a sulfide sulfur is reported to be very weak, weaker than that between lithium cation and phenyl group.[21] Therefore, there is little effect to force the lithium cation and methylthio group into a *s-cis* conformation. The elimination reaction in nonpolar solvents proceeds *via* a carbanion intermediate (**12**) and the stereochemistry is not specific (Scheme 3, path a).

On the other hand, at present, it appears to be difficult to find a good reason why an *anti* fashion elimination resulted from the free ion of **12**. Although considerable experimental data have been accumulated which indicate that carbanions are stabilized by the adjacent sulfur atom,[25] the participation of sulfur-



Scheme 3.

containing substituents at the β-position with carbanion has rarely been reported. Recently, Kaji and his co-workers reported that the rate of base-catalyzed H–D exchange reactions of substituted cyclopropanes was enhanced by the substitution of a phenylthio group at β-position.[26] They suggested the neighboring sulfur participation in stabilization of the carbanion. Yano and Oae have shown that the rates of the base-catalyzed elimination of a series of γ-(p-substituted phenylthio)propyl bromides are slower than that of the corresponding oxygen analogues and that the ρ value obtained for the sulfur compounds is larger than that for the oxygen compounds.[27] They have suggested the non-bonding participation of a vacant d-orbital of the sulfur atom for the developing double bond to elucidate this phenomena. Furthermore, Howard has proposed a three-membered ring anion involving sulfur, in which the charge of the carbanion is delocalized to the neighboring sulfur atom, as an intermediate of the base-promoted rearrangement of diethyl dithiodiacetate.[28]

In the present case, when a 1-butanide anion pulls bromine off the substrate at the initial stage of the reaction, a vacant 3d-orbital of the sulfur atom assists the developing carbanion at the opposite side from the leaving bromine to form a three-membered ring transition state or an intermediate (**13**). Stereospecific elimination from such an intermediate has been proposed by Trost and Ziman. The desulfurization of *cis*- and *trans*-2-butene episulfides with butyllithium to the corresponding butenes proceeds stereospecifically. They suggested a three-membered ring anion similar to **13** as one of the possible transition state.[10] Thus it is conceivable that the stereospecific *anti* elimination would occur if a neighboring participation of sulfenyl group against the carbanion is taken into account.

When **1** was treated with lithium metal instead of butyllithium, the elimination proceeded with *syn* selectivity, but the selectivity was much lower than the case of organolithium reagent. It has been reported that the reaction of lithium metal with alkyl halides, in which the halogen atom is attached to a tetrahedrally hybridized carbon atom, results in the formation of lithium reagents along with much racemization.[7] Recently a more detailed discussion on the stereochemistry of halogen–lithium exchange reaction with lithium metal has been reported by Walborsky and Aronoff.[7b] Moderate retention of configuration resulted in the reaction of substituted cyclopropyl halide with very finely divided lithium metal, but the optical purity of the produced organolithium compound decreased by increasing the particle size of lithium. It has also been pointed out that the halogen–lithium exchange reaction involves a surface radical process. Thus the loss of stereospecificity in the elimination of **1** with lithium metal is considered to occur during the bromine–lithium exchange process on a lithium metal surface. The nonstereospecific results of House[2] for the use of sodium and zinc metals fit into these considerations.

Halogen–metal exchange reactions involving Grignard reagents have been reported, and it has been found that there is no fundamental difference between exchange reactions in the series of organolithium and magnesium compounds.[16] However, the stereochemistry of the exchange reaction between alkylmagnesium and an alkyl halide is not yet clear. The present result that the Grignard reagent-promoted elimination reaction proceeds nonstereospecifically would imply that the exchange proceeds with racemization. Examinations on these subjects are in progress.

Experimental

IR spectra were obtained using a Hitachi EPI-G2 spectrophotometer. NMR spectra were recorded as $CDCl_3$ solutions on a JEOL PMX-60 spectrophotometer; chemical shifts are reported in parts per million relative to TMS as an internal standard.

Solvents. GR grade diethyl ether was dried over sodium metal and distilled. GR grade THF was distilled from lithium aluminum hydride under nitrogen and stored over 4A molecular sieves. Diglyme was passed through activated alumina, and distilled before use. Bulk solvents were distilled before use.

Reagents. Butyllithium (*ca.* 20% in hexane) was purchased from Merck Co., Inc. and Aldrich Chemical Co. Inc., and titrated before use.[29] Pentylmagnesium bromide in ether was purchased from the Alfa Division of Ventron Corp. and titrated before use.[30] TMEDA was kept over solid sodium hydroxide and used with no further purification. DME was passed through activated alumina before use. Crown ether was purchased from Nippon Soda Co., and was used without further purification. Commercially available GR grade *trans*-stilbene was used without further purification. *cis*-Stilbene, bp 108.5—112.0 °C/2 mmHg, was prepared by the literature procedure.[31]

Preparations of 1-Bromo-2-methoxy-1,2-diphenylethanes (1). Following the procedure developed by House,[2] a solution of 5.4 g (0.03 mol) of **5t**, 10.8 g (0.06 mol) of *N*-bromosuccinimide, 3 ml of acetic acid, and 30 ml of acetone in 300 ml of methanol was allowed to stand for 5 h and then concentrated, diluted with water, and extracted with ether. The ether extract was washed first with water and then with aqueous sodium hydrogencarbonate solution and then dried over sodium sulfate. After removal of ether, petroleum ether was added to the residual oil. The crude bromo ether deposited was recrystallized twice from hexane, giving pure **1e**, mp 120—121 °C (lit,[2] mp 117—118 °C), yield 6.2 g (71%); NMR δ=3.20 (s, 3, OCH_3), 4.63 (d, 1, CHBr), 5.06 (d, 1, J=7 Hz, CHOR), 7.28 (s, 10, C_6H_5). Found: C, 62.12; H, 5.20; Br, 27.43%. Calcd for $C_{15}H_{15}OBr$:

C, 61.86; H, 5.19; Br, 27.45%.

In a similar manner, 5.4 g (0.03 mol) of **5c** afforded 3.7 g (42%) of **1t**, mp 85.5—86.5 °C (lit,[2] mp 86—87.5 °C), NMR δ=3.33 (s, 3, OCH_3), 4.50 (d, 1, CHBr), 5.00 (d, 1, J=8 Hz, CHOR), 7.14 (s, 10, C_6H_5). Found: C, 62.10; H, 5.11; Br, 27.52%. IR of the *threo*-isomer (**1t**) was similar to that of the *erythro*-isomer (**1e**) except for a band at 1215 cm^{-1}, where **1t** exhibited an absorption.

Preparations of 2-Bromo-1,2-diphenylethanols. *erythro*- and *threo*-2-Bromo-1,2-diphenylethanols were prepared by the method of House[32] from **5t** and *cis*-stilbene oxide respectively. The *erythro*-isomer, mp 83.5—85.0 °C (lit,[32] mp 83.5—85.0 °C), and the *threo*-isomer, mp 51.0—52.0 °C (lit,[32] mp 51—52 °C) were used for the following preparations.

Preparations of 1-Bromo-2-acetoxy-1,2-diphenylethanes (2). To 6.8 g (45 mmol) of *erythro*-2-bromo-1,2-diphenylethanol was added 6.0 ml (64 mmol) of freshly distilled acetic anhydride over a period of 10 min at room temperature. The mixture was stirred at 70 °C for 2 h. 200 ml of water was added to the cooled mixture, which was then extracted with 100 ml of ether three times. The ether extract was washed with water and dried over magnesium sulfate. After removal of ether, the residual product was recrystallized from hexane–petroleum ether, giving **2e**, mp 100.0—100.7 °C (lit,[33] mp 102 °C), yield 6.8 g (87%); NMR δ=1.89 (s, 3, $OCOCH_3$), 5.15 (d, 1, CHBr), 6.50 (d, 1, J=7.5 Hz, CHOAc), 7.23 (s, 10, C_6H_5). Found: C, 60.38; H, 4.61%. Calcd for $C_{16}H_{15}O_2Br$: C, 60.20; H, 4.74%.

In a similar manner, 3.95 g (14.2 mmol) of the *threo*-bromohydrin was treated with 4.0 ml (42.6 mmol) of acetic anhydride to give **2t**, mp 79.5—81.0 °C, yield 3.44 g (70.7%); NMR δ=2.14 (s, 3, $OCOCH_3$), 5.15 (d, 1, CHBr), 6.20 (d, 1, J=4.6 Hz, CHOAc), 7.10 and 7.15 (ds, 10, C_6H_5). Found: C, 60.02; H, 4.62%.

Preparations of 1-Bromo-2-methylsulfonyloxy-1,2-diphenylethanes (3). To a stirred solution of *erythro*-2-bromo-1,2-diphenylethanol (2.5 g, 9.0 mmol) in 25 ml of pyridine, 1.14 g (10 mmol) of methanesulfonyl chloride was added dropwise at −5 °C. After the mixture had been stirred at 0 °C for 24 h, 5 ml of water was added; then it was extracted with 50 ml each of chloroform three times. The extracts were combined and washed first with dil. sulfuric acid and then with aqueous sodium hydrogencarbonate solution, and dried over sodium sulfate. After removal of chloroform, the residual product was recrystallized from chloroform–petroleum ether. An additional crystallization afforded the pure **3e**, mp 113.5—114.0 °C, yield 1.6 g (50%). NMR δ=2.48 (s, 3, CH_3), 5.15 (d, 1, CHBr), 5.93 (d, 1, J=4.0 Hz, $CHOSO_2$), 7.37 (s, 10, C_6H_5). Found: C, 50.56; H, 4.30; S, 9.11%. Calcd for $C_{15}H_{15}O_3BrS$: C, 50.71; H, 4.26; S, 9.03%.

In a similar manner, 2.5 g of *threo*-2-bromo-1,2-diphenylethanol gave 2.0 g (62.5%) of **3t**, mp 107.0—108.0 °C, NMR δ=2.82 (s, 3, CH_3), 5.17 (d, 1, CHBr), 5.83 (d, 1, J=4.3 Hz, $CHOSO_2$), 7.13 (s, 10, C_6H_5). Found: C, 50.42; H, 4.18; S, 8.62%.

Preparations of 1-Bromo-2-methylthio-1,2-diphenylethanes (4). The method of Helmkamp[34] was applied to **5**. A solution of 5.0 g (53 mmol) of dimethyl disulfide in 120 ml of dry dichloromethane was placed in a 200 ml four-necked flask protected from moisture. The flask was kept in a cold bath at −20 to −25 °C and was protected from light during the subsequent reaction. A solution of 8.0 g (50 mmol) of bromine in 60 ml of dichloromethane was added dropwise over a period of 2 h with stirring. The mixture was allowed to warm to −15 °C during a 1 h period, then 18.1 g (100 mmol) of **5t** in 140 ml of dichloromethane was added dropwise over a period of 1 h. The mixture was allowed to stand at 0 °C for 24 h. The solvent was stripped off under a reduced pressure; the residual product was recrystallized twice from ligroin to give **4e**, mp 126—127 °C (dec), yield 15.3 g (50%), NMR δ=1.60 (s, 3, SCH_3), 4.20 (d, 1, CHS), 5.10 (d, 1, J=10 Hz, CHBr), 7.28 (s, 10, C_6H_5). Found: C, 58.88; H, 5.15; Br, 27.01; S, 10.30%. Calcd for $C_{15}H_{15}BrS$: C, 58.63; H, 4.92; Br, 26.01; S, 10.44%. Found: *m/e* 306.0085, 308.0095. Calcd for $C_{15}H_{15}BrS$: M, 306.0078; M+2, 308.0059. MS indicated that the sample contained less than 5% of **6**.

In a similar manner, 9.1 g (50.5 mmol) of **5c** gave 9.6 g (61.9%) of **4t**, mp 63 °C, NMR δ=1.91 (s, 3, SCH_3), 4.40 (d, 1, CHS), 5.28 (d, 1, J=9 Hz, CHBr), 7.13 (s, 10, C_6H_5). Found: C, 58.42; H, 4.84; Br, 26.25; S, 10.42%. Found: *m/e* 303.9932, 305.9981, 308.0025. Calcd for $C_{15}H_{15}BrS$: M−2H, 303.9922; M, 306.0078; M+2, 308.0059. MS indicated that the sample contained less than 2% of **6**.

Preparations of Stilbene Dibromides (6). The *meso*- (**6e**) and *dl*-isomers (**6t**) were prepared according to the procedures developed earlier by the addition of bromine to **5t** in diethyl ether[35] and to **5c** in carbon tetrachloride[36] respectively. The *meso*-isomer (**6e**): mp 237 °C (dec) (lit,[36] mp 237—239 °C (dec)), (Found: C, 49.41; H, 3.32%). The *dl*-isomer (**6t**): mp 110.5—111.5 °C (lit,[36] mp 110— 111 °C), NMR δ=5.44 (s, 2, CHBr), 7.13 (s, 10, C_6H_5), (Found: C, 49.01; H, 3.26%).

Preparations of Stilbene Dichlorides (7). *meso*- (**7e**) and *dl*-Stilbene dichlorides (**7t**) were prepared according to the procedure developed by Buckles[37] by treating **5t** and **5c** respectively with tetrabutylammonium iodotetrachloride. The *meso*-isomer (**7e**) : mp 190.0—190.5 °C (lit,[37] mp 191—192 °C), NMR δ=5.19 (s, 2, CHCl), 7.36 (s, 10, C_6H_5), (Found: C, 66.79; H, 4.92%). The *dl*-isomer (**7t**): mp 90.0—90.5 °C (lit,[37] mp 91—92 °C), NMR δ=5.20 (s, 2, CHCl), 7.13 (s, 10, C_6H_5), (Found: C, 66.90; H, 4.94%).

A Typical Procedure for the Elimination Reaction with Butyllithium. Reactions were done in a four-necked flask fitted with a reflux condenser, a thermometer, a gas inlet tube, a rubber septum, and a magnetic stirrer. The flask was protected from moisture. All experiments were carried out under nitrogen, passed through a Fieser's solution[38] to remove traces of oxygen, or under argon. *erythro*-1-Bromo-2-methoxy-1,2-diphenylethane (**1e**, 293 mg, 1.01 mmol) in 50 ml of diethyl ether was placed in the flask and cooled in a Dry-Ice bath. The system was flushed with argon gas for 2 h. The solution of butyllithium in hexane (3.0 ml, 1.0 mmol) was added *via* a syringe and the mixture was stirred for 30 min at 0 °C. By the addition of butyllithium, the mixture was turned pale red, but this color disappeared if the solution was flushed with air. The mixture was poured into ice-water, extracted with ether, and dried over sodium sulfate. When excess butyllithium was used, a small amount of methanol was added *via* a syringe to decompose it before treating with water. To the concentrated product, 100 mg of diphenyl ether was added as an internal standard. The mixture was analyzed by GLPC using a silicone OV-17 3% on Chromosorb-W 2 m column at column temperature 160 °C.

In a separate experiment, the reaction product was chromatographed with silica gel (Wako-gel C-200) column using hexane as an elutant, giving **5c**, bp 96—102 °C/3 mm, (Found: C, 93.08; H, 6.91%). It was identified by the comparisons of its GLPC, IR, and NMR data with those of an authentic sample.

A Typical Procedure for the Elimination Reaction with Pentylmagnesium Bromide. The equipment used in these reactions is the same as that used in the butyllithium reactions.

A solution of 295 mg (1.01 mmol) of **1e** in 50 ml of diethyl ether was placed in the flask and cooled in a Dry-Ice bath. The system was flushed with nitrogen. A solution of pentylmagnesium bromide in ether (5.0 ml, 2.0 mmol) was added *via* a syringe and the solution was stirred for 180 min at 0 °C. The reaction mixture was poured into ice-water, extracted with ether, and dried over sodium sulfate. After removal of ether, 107 mg of diphenyl ether was added as an internal standard. The products were analyzed by GLPC; decane, **5t**, and the unreacted substrate were identified. The yield of **5t** was 49%.

Separation of the products was carried out by column chromatography using neutral alumina (W-200) and petroleum ether. The obtained **5t** was contaminated with **1e**, as identified by comparing its NMR spectrum with that of a mixture of **5t** and **1e**. The recovered **1e** has a mp of 110—114 °C; its IR spectrum was superimposable with that of an authentic sample. When **1t** was used as a substrate, the recovered **1t** had a mp of 69—73 °C and its IR spectrum was superimposable with that of an authentic sample. Thus the isomerization of substrates during the reaction process could be eliminated.

In a separate experiment, 219 mg (1.22 mmol) of **5c** was stirred with pentylmagnesium bromide (5.0 ml, 2.0 mmol) for 3 h under the reaction conditions. No **5t** but **5c** alone was detected in the reaction product by means of GLPC.

A Typical Procedure for the Elimination Reaction with Lithium Metal. To a solution of 613 mg (2.11 mmol) of **1e** in 100 ml of diethyl ether was added 164 mg (24 mg-atom) of lithium metal (a lithium wire 3 mm in diameter cut into 1—2 mm lengths). The stirred mixture was refluxed for 30 h under a nitrogen atmosphere. Excess lithium metal was filtered off, and the filtrate was poured into a cold aqueous ammonium chloride solution and extracted with ether. The ether extract was dried over sodium sulfate and concentrated. After adding 108 mg of diphenyl ether as an internal standard, the product was analyzed by GLPC, giving the following yields: **8**, 9.1; **5c**, 8.7; **5t**, 58.3%; a trace of a peak expected to be diphenylacetylene. The product was chromatographed by the use of alumina (W-200) and petroleum ether, giving three fractions: the 1st fraction was **8**, which was identified by means of GLPC, NMR, and IR; the 2nd fraction, mp 124—125 °C, was **5t**, which was identified by means of GLPC and IR; the 3rd fraction was a mixture of **5c** and a trace amount of diphenylacetylene, identified by the retention times of GLPC.

The authors wish to express their thanks to Dr. Tokio Yamabe of this department for his helpful discussion. We also would like to thank Messrs. Hiroyasu Furukawa and Yukio Ueda for their assistance in the preliminary experiments of this work. This work was supported in part by a Scientific Research Grant from the Ministry of Education, Japan (No. 110305).

Polyelectrolyte Complexes of [2-(Diethylamino)ethyl]dextran Hydrochloride with Sodium Carboxymethylcellulose

Yasuo KIKUCHI* and Takashi KODA

Department of Materials Science and Engineering, Faculty of Engineering, Ōita University, 700-Dannoharu, Ōita 870

(Received July 24, 1978)

Sodium carboxymethylcellulose(*anti*-thrombogenic material)(CMC) reacted with [2-(diethylamino)ethyl]-dextran hydrochloride(*anti*-cancer material)(EA) having an opposite charge and three groups of different basicity at different hydrogen ion concentrations to form novel water-insoluble precipitates, the so-called polyelectrolyte complex(PEC) comprised of both biomedical materials, focusing on the coagulation of precipitate(PEC) produced. The mole ratio N(EA)/Na(CMC) of the reaction mixture in solution at the start coagulation increased with a lowering of hydrogen ion concentration. This depended on the change of the degree of dissociation of EA and CMC with changing hydrogen ion concentration. The nitrogen contents which describe the mole ratios of EA/CMC in each PEC thus prepared were determined to range from 1.75 to 4.51. It was established that the hydrogen ion concentration and mixing mole ratio of N/Na in solution play an important role in determining the composition ratio of EA/CMC in the PEC. The results of IR, elemental analyses, solubility measurements, degree of swelling in water, color reaction with Toluidine Blue, and blood clotting test for PEC, revealed that the molecular structure of the various PEC's differed according to the hydrogen ion concentration and the mole ratio of reaction mixture in solution, though all PEC's were prepared from the same starting materials. It appears that the degree of dissociation and conformation of EA and CMC change with hydrogen ion concentration. The blood clotting tests were performed on a slightly swelled tablet of PEC where it was found that the PEC suppressed coagulation of the blood.

The mixing of oppositely charged polyelectrolytes give rise to the formation of a polyelectrolyte complex whose properties, conformations, and biomedical characters, in general, are sensitive to such reaction conditions as the composition of the reaction mixture, the hydrogen ion concentration, the order of mixing, and the polyion concentration at which the reaction is conducted.[1,2]

The mechanism of polyion interaction, the probable structures of the PEC, and properties have been investigated in detail by Michels *et al.*[3,4]

To date, however, few papers[5] have dealt with the polyion interaction between polysaccharide, or polysaccharide and synthetic macromolecules of importance becasue of the similarities to biological systems, membranes, and industrial and biomedical applications.[6] In a previous paper[7] the chemical reaction of EA and sodium dextran sulfate (*anti*-thrombogenic material) which is a biomedical material was reported.

This paper deals with a novel chemical reaction of [2-(diethylamino)ethyl]dextran hydrochloride with sodium carboxymethylcellulose, focusing on the coagulation of the PEC produced, the general characteristics, and the process of clot formation.

Experimental

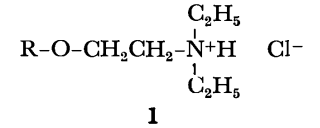
Sodium carboxymethylcellulose(*anti*-thrombogenic material, weak acid polyelectrolyte, intrinsic viscosity 0.401 dl/g in 1 M NaCl at 25 °C, sodium content 7.79%) and [2-(diethylamino)ethyl]dextran hydrochloride(*anti*-cancer material, weak basic polyelectrolyte, nitrogen content 4.97%, degree of substitution 1.11 mol/A.G.U.†) prepared by molecular weight 250000 of dextran(described later in detail), were obtained from Wako Junyaku Co., Ltd., and from Meito Sangyo Co., Ltd., Japan, respectively.

CMC and EA were highly-purified and used without further purification. CMC and EA (2 g/1000 ml) were dissolved in aqueous solution. The reaction were conducted at pH 3.0, 7.0, and 11.0, the pH of solution being adjusted to 7.0 and 11.0 with sodium hydroxide and to 3.0 with hydrochloric acid. The EA solutions were added dropwise to the CMC solutions, adjusted to the same pH as those of the EA solutions at a rate of 50 ml/30 min with stirring. The water-insoluble precipitate, the so-called PEC comprised of both biomedical materials, were thus obtained. After aging for a half hour, the precipitate was washed with water and methanol, centrifuged, and dried in vacuo at 50 °C to constant weight.

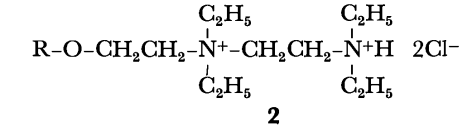
The blood clotting test was conducted according to the procedure of Imai and Nose;[8] PEC 200 mg was pressed (8 t/4.9 cm^2) in a vacuum for 10 min to make a sample tablet. The ACD blood of type A (Red Cross Hospital Blood Center) was kept in a thermostat at 4—6 °C for 3 days. The ACD blood was prepared by adding the blood to an anticoagulant citrate dextrose solution consisting of sodium citrate, citric acid and dextrose.

Elemental analyses of the PEC were performed at the Institute of Physical and Chemical Research.

The structures of **1** and **2** of EA have been proposed by Meito Sangyo Co., Ltd., Japan:



1



2

R: dextran residue.

Both groups are present in each molecule of EA *i.e.* three groups of different basicity, are reflected in the form of the titration curves in a previous paper,[7] quarternary (strong basic) and two tertiary ammonium groups in **1** and **2**, respectively.[9] Potentiometric titration studies of polybases for

† Determined at Meito Sangyo Co., Ltd., Japan.

EA have supplied information regarding the properties of the substances in solution.[10] The titration curves obtained in these experiments have been reported in a previous paper.[7] The ratio of groups **2** to group **1** was approximately 0.78 : 1. On the basis of the inflection points in the potentiometric titrations and the start, before and after of coagulation of PEC in the reaction system, subsequent experiments were conducted at pH 3.0, 7.0, 11.0, and a mole ratio N/Na of the reaction mixture in solution in Table 1.

The purple coloration is due to the reaction of CMC with a solution containing Toluidine Blue, utilized to demonstrate the CMC elution from PEC and the change of structure produced.

Results and Discussion

Experimental conditions, yields and elemental analyses for the PEC prepared at the beginning and end point, and before and after coagulation of PEC in the reaction system are given in Table 1, respectively.

The nitrogen contents which describe the molar ratios of EA/CMC in each PEC increased with an increased in the mole ratio of N/Na of the reaction mixture in solution and with a decrease in hydrogen ion concentration a direct consequence of the fact that the degree of dissociation of CMC and EA are dependent on the hydrogen ion concentration, *i.e.* the composition ratio of EA/CMC in the PEC was sensitive to the reaction conditions. Thus, the pH as well as the mole ratio of EA to CMC in the reaction mixture, played an important role in changing the ratio of the reactive group of CMC to that of EA in the PEC produced.

As seen in Fig. 1, the mole ratios N/Na of the reaction mixture in solution at the beginning point of coagulation increase with an increase in pH, *i.e.* a larger amount of EA is necessary to coagulate the CMC solution containing PEC with a lowering of hydrogen ion concentration. The reason for this is that the degree of dissociation of EA decreases and that of CMC increases with a lowering of hydrogen ion concentration, *i.e.* the decreasing of the positive net charge of EA and the increasing of the negative charge of CMC.

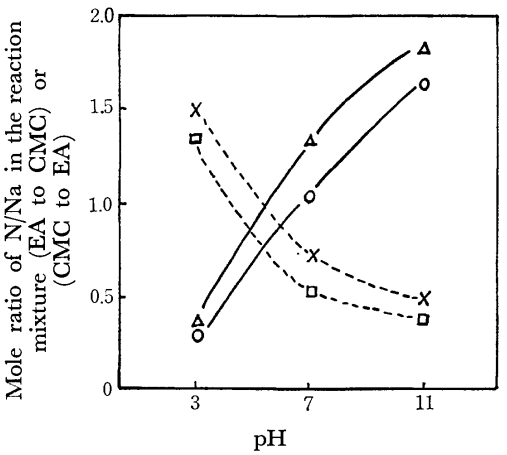


Fig. 1. Beginning and end points of coagulation. ○: Beginning point of coagulation, △: end point of coagulation (EA to CMC, N/Na).
×: Beginning point of coagulation, □: end point of coagulation (CMC to EA, Na/N).

The IR spectrum of PEC is similar to that of a mixture of CMC and EA, differing only in detail. How-

—·— : Polyelectrolyte complex prepared at pH 11.

ever, the PEC prepared at pH 3 had an absorption band at 1740 and 1240 cm^{-1}, which appeared neither in the PEC prepared at pH 7 and 11.0 nor in the mixture of EA and CMC. These absorption bands had been assigned to COOH group.[11] Furthermore, the absorption band at 3500 cm^{-1} (assigned to the OH group) of PEC prepared at pH 3 shifted to a higher wave number. In consideration hydrogen bond of formation between the OH group and other reaction groups, it is reasonable to expect shifts in frequency. In addition, the sodium and chlorine contents in the PEC are smaller than those in CMC or EA, and the nitrogen content distinctly different (Table 1). The results suggest that the amino groups in EA participate in the binding with CMC, probably through the $-COO^-$ groups, and that the molecular structures of PEC are different from one another. Actually, the PEC prepared at low hydrogen ion concentration differed appreciably from the PEC prepared at higher hydrogen ion concentration in such properties as the degree of swelling and the color reaction with Toluidine Blue as described later.

Table 2. Color reaction with Toluidine Blue[a]

Sample code	Color of solution	Color of PEC
EA	blue green	—
CMC	blue purple	—
A-1	blue purple	blue
A-2	blue purple	blue
A-3	blue purple	blue
A-4	blue purple	blue
B-1	blue green	white
B-2	blue green	white
B-3	blue green	white
B-4	blue green	white
C-1	blue green	white
C-2	blue green	white
C-3	blue green	white
C-4	blue green	white
D-1	blue purple	blue
D-2	blue green	white
D-3	blue green	white

a) Sample code corresponds to that in Table 1.

The resulting purple stain with Toluidine Blue provides a very sensitive test for CMC. Only the PEC of series A prepared at pH 3 gave a blue coloration, but not a blue purple coloration with Toluidine Blue as shown in Table 2.

The *anti*-thrombogenic CMC in the PEC produced did not elute into the solution except for PEC of series A as shown in Table 2.

PEC's are insoluble or only partially soluble in dimethyl sulfoxide or *N*,*N*-dimethylformamide on heating, partially soluble in a ternary solvent mixture (acetone/KBr/H_2O=20 : 20 : 60 wt %) on heating, and soluble in formic acid or a ternary solvent mixture (HCl/dioxane/H_2O=48 : 47 : 5 wt %) on heating. The difference in solubility however, is in discernible. The PEC's prepared at low hydrogen ion concentration are however, more soluble than those prepared at high hydrogen ion concentration.

Table 3. Swelling with water

Sample code	Degree of swelling
A-1	No swelling
A-2	No swelling
A-3	No swelling
A-4	No swelling
B-1	Slight swelling
B-2	Slight swelling
B-3	Slight swelling
B-4	Fairly large swelling
C-1	Slight swelling
C-2	Slight swelling
C-3	Slight swelling
C-4	Fairly large swelling
D-1	No swelling
D-2	Slight swelling
D-3	Fairly large swelling

a) Sample code corresponds to that in Table 1.

Swelling tests were performed with all PEC listed in Table 3. All the PEC prepared at pH 3 did not swell entirely. The degree of swelling of PEC became larger with decreasing hydrogen ion concentration and increasing mole ratio N/Na of the reaction mixture.

These experimental results support the differences in molecular structure according to the experimental conditions of hydrogen ion concentration and mole ratio of the reaction mixture, although the PEC have common constituents. It appears that the degree of dissociation and conformation of EA and CMC changes with hydrogen ion concentration.

The blood clotting tests were performed on a PEC tablet (A-4, B-3, C-2, D-1, D-2) prepared in solution (Table 1) by gravimetric measurement[8] of the amount of clot formed at the appropriate time intervals, after the addition of calcium chloride solution (0.1 M, 0.015 ml) to ACD blood (0.15 ml, A type, storage time 3 d) which had been in contact with the ma-

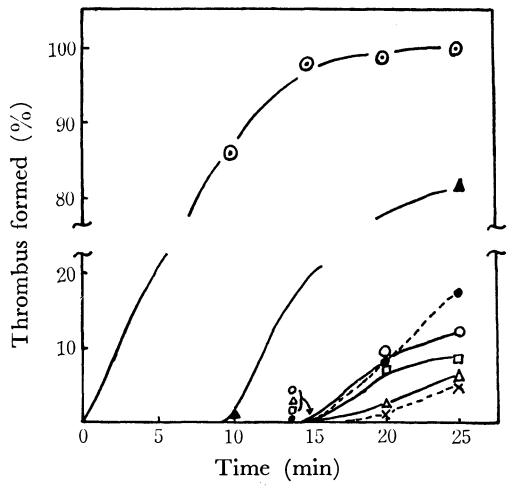

Fig. 3. Percentage of the thrombus formed on polyelectrolyte complexes compared with that on glass.

Sample codes C-2, B-3, D-1, A-3, and D-2 correspond to those in Table 1.

terials. The lightly swelled PEC could not perform the blood clotting test because of the soaking of blood into the tablet and therefore, the tests were performed on a PEC tablet with a small degree of swelling in A, B, C, and D series. The quantities of the clot formed on the PEC tablet are smaller than those formed on glass or PVC tablets. The PEC has an *anti*-thrombogenic character and supresses the coagulation of blood. Differences in *anti*-thrombogenic behavior among them is however, hardly discernible.

Photoinduced Dechlorination of β-Benzene Hexachloride in Alkaline Alcohols[1)]

Yoshiro OGATA,* Katsuhiko TAKAGI, and Yasuharu SASOH
Department of Applied Chemistry, Faculty of Engineering, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464

(Received August 9, 1978)

Photo-induced dechlorination of β-benzene hexachloride(β-BHC) in alkaline alcohols has been studied. Benzene is a major product accompanying other minor products such as chlorobenzene, alkoxybenzene, and benzyl alcohols. Their yields vary a great deal depending on the kind of alcohol. The efficiency of reaction and the selectivity of benzene increase in the order : methanol<ethanol<2-propanol. The reaction may go by way of dechlorination of β-BHC with base in the dark giving trichlorobenzenes(predominantly 1,2,4-isomer) followed by its photochemical dechlorination. The radical chain mechanism involving H-abstraction by Cl· atom is presented, since the efficiency is raised *ca.* 8 times as much as that in the dark.

Attention has recently been centered upon the photochemical decomposition of organic chlorine-containing compounds as pollutants. Several reports have appeared on the photodechlorination of polychlorinated biphenyl(PCB) in either neutral or alkaline media,[2-8)] since PCB has high stability and high resistance against thermolysis.

On the other hand, the photochemical decomposition of aliphatic chlorine-containing compounds used as insecticides, *e.g.*, Aldrin, Deldrin, Endrin or γ-BHC, is difficult on account of their transparency towards UV light over 230 nm,[9,10-12)] so that few attempts have been made to decompose the aliphatic chlorine-containing compounds. Only a qualitative study on photoinduced decomposition of γ-BHC with sodium hydroxide in 2-propanol was reported, but no attempt was made for identification of the photoproducts and no mechanistic study carried out.[12)]

The present work was undertaken to elucidate photoproducts and to present the mechanism for photoinduced decomposition of β-BHC in various alkaline alcohols.

Results and Discussion

Photodecomposition of β-BHC in Alkaline Alcohols. Irradiation of 0.01 M β-BHC in *ca.* 0.3 M alkaline alcohols with a 300 W high pressure Hg lamp (wavelength 360—600 nm) results in the decomposition of β-BHC with efficiency depending on the kind of alcohol used (Fig. 1). The efficiency increases with the change of alcohol in the order: MeOH<EtOH<2-PrOH. β-BHC is transparent at wave length over 200 nm, but on addition of alkali, a dark reaction occurs forming aromatics, so that the solution absorbs the 270—280 nm light.

The decomposition rate in 2-propanol is *ca.* 8 times as high as that in methanol, all β-BHC being completely consumed within 2 h. However, the yield of benzene still increased even after 100% consumption of β-BHC, reaching a maximum value after 6 h, implying the intervention of precursors to benzene. A slight decrease in the yield of benzene after reaching its maximum can be attributed to further degradation, *e.g.*, benzene reacts with chlorobenzene to give biphenyl.[12)]

The extent of dechlorination of β-BHC was estimated to be 4.89 of Cl atoms per one molecule of β-BHC

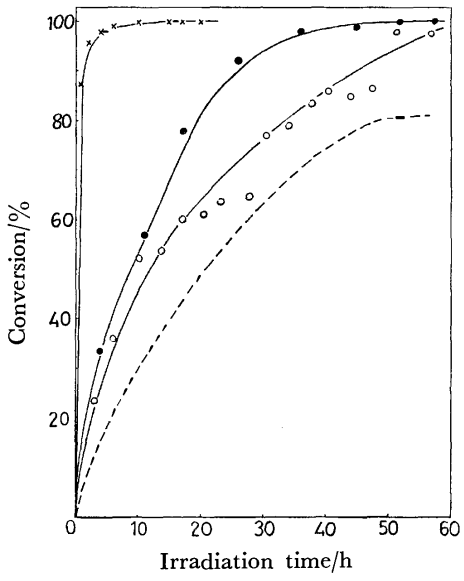

Fig. 1. Irradiation time-conversion curve of photodecomposition of β-BHC in various alkaline alcohols: methanol (—○—○—), ethanol(—●—●—), and 2-propanol(—×—×—). A curve (----) obtained on the basis of chloride ion at 15—20 °C.

decomposed (or 81% Cl^- production), indicating the formation of chlorine-containing substances in yields of 19% based on the decomposed β-BHC. Most of them could not be identified except for chlorinated benzenes such as mono-, di-, and trichlorobenzenes which appeared in the initial stage of the decomposition of β-BHC.

Scheme 1 represents the isolated and/or characterized photoproducts in various alkaline alcohols. Their yields after almost complete decomposition of β-BHC are summarized in Table 1.

Products were identified and estimated by means of GLC and GLC-MS in comparison with the corresponding authentic samples.

Formation of the corresponding carboxylic acids was observed by further oxidation of **7**'s in an aerated solution. They were characterized as their corresponding esters by addition of excess HCl to the reaction mixture; *e.g.*, methyl formate from formaldehyde.

Benzene was obtained as the major non-chlorine containing product in yields of 23.5, 37, and 48% in alkaline methanol, ethanol, and 2-propanol, re-

Table 1. Products from photolysis of β-BHC in alkaline alcohols[a)]

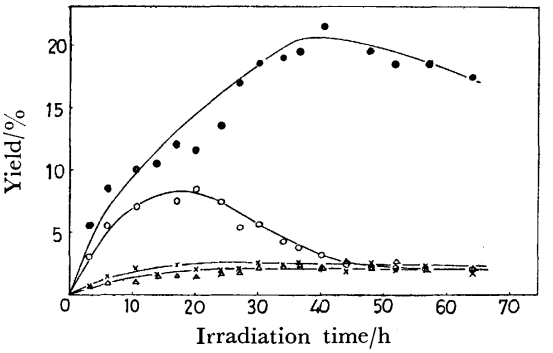

Fig. 2. Irradiation time-conversion curve of photodecomposition of β-BHC to give benzene (—●—●—), chlorobenzene (—○—○—), anisole (—×—×—), and benzyl alcohol (—△—△—) in alkaline methanol at 15—20 °C.

spectively.

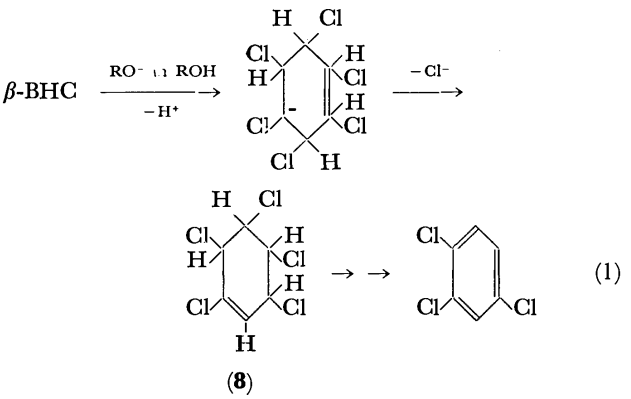
Although 81% of chlorine of β-BHC was liberated as chloride ion, the material balance calculated by means of the chloride formed deviates significantly from that on the basis of cyclic six-membered carbon compounds which comprise benzene, chlorobenzene, alkoxybenzene, benzyl alcohols, and bibenzyl. Total yields of the aromatic compounds are at most as follows: 45.5% for the case in metanol, 50% in ethanol, and 60% in 2-propanol. The loss of Cl content can be attributed to the formation of ring-ruptured chlorine-containing fragments and/or polymerized β-BHC which cannot be detected by GLC up to 250 °C. Detection of fragments or oligomers derived from β-BHC was unsuccessful even by careful GLC analysis.

Effect of Irradiation Time on Photoproducts. A typical example of photolysis of β-BHC in alkaline methanol is shown in Fig. 2. Apparently no substantial amounts of di- and trichlorobenzenes were formed even at the initial stage

Independent photolysis of 1,2,4-trichlorobenzene in alkaline ethanol generated 74% of chloride ion. It is assumed that three atoms of chlorine are liberated from one molecule of the trichlorobenzene, thus yielding benzene, chlorobenzene and phenetole (33, 45, and 22%, respectively).

Competitive dechlorination with a mixture of 1,2,4-trichloro-, 1,2-dichloro-, 1,4-dichloro-, and monochlorobenzenes showed that the 1,2,4-isomer is the most unstable towards UV light and monochlorobenzene the most stable; 1,2,4- and 1,2-halides are almost photodecomposed within 1.5 h irradiation, whereas the mono- and 1,4-dihalides require over 6 h for almost complete decomposition. This suggests that the trichlorobenzene is formed at the earliest stage, but it does not accumulate on account of its instability towards UV light in the presence of alkali.

Progressive Dechlorination of β-BHC. β-BHC is stable under UV irradiation because of its transparency to UV light over 230 nm. The initiation



(1)

necessitates UV-absorbing species. Trichlorobenzenes containing 87% of the 1,2,4-isomer are formed in the dark by treatment of β-BHC in alkaline methanol.[13] The reaction is explained by a mechanism involving a carbanion formed by deprotonation of β-BHC with alkoxide.[13] Trichlorobenzenes, however, do not undergo dechlorination with alkali in the dark, but they are easily decomposed into benzene, chlorobenzene, and alkoxybenzene on irradiation as described above.

Hence, the photolysis of β-BHC is apparently initiated by the trichlorobenzenes. Nevertheless, the photoinduced dechlorination of β-BHC cannot be explained only by the photodecomposition of trichlorobenzenes, since the photoinduced decomposition of β-BHC is *ca.* 8 times as fast as that in the dark (Fig. 3).

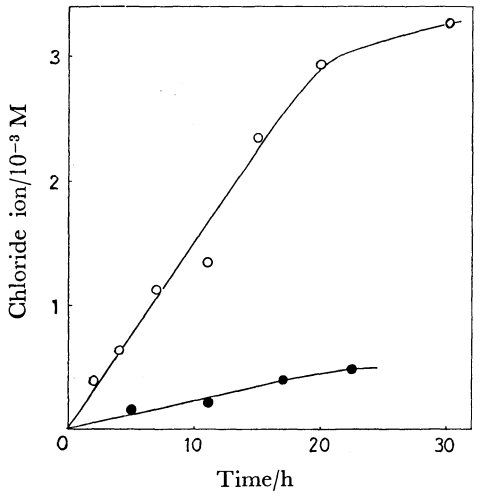


Fig. 3. The time dependence of the formation of chloride ion at 25 °C (a) on photolysis of an ethanol solution of β-BHC (0.0014 M) and sodium hydroxide (0.028 M) (—○—○—) and (b) on standing it in the dark (—●—●—) at 15—20 °C.

If only the above carbanionic dechlorination of β-BHC with alkali is operating, the efficiency of photoinduced consumption of β-BHC would not exceed that in the dark. A radical chain mechanism is conceivable in which dechlorination of β-BHC occurs mainly via a hydrogen abstraction by chlorine atom generated by photolysis of trichlorobenzenes.

$$\beta\text{-}C_6H_6Cl_6 + 3RO^- \xrightarrow[\text{dark}]{ROH} C_6H_3Cl_3 + 3ROH + 3Cl^- \quad (2)$$

$$C_6H_3Cl_3 \xrightarrow{h\nu} C_6H_3Cl_2\cdot + \cdot Cl \quad (3)$$

$$Cl\cdot + \beta\text{-}C_6H_6Cl_6 \longrightarrow HCl + C_6H_5Cl_6\cdot \quad (4)$$

$$C_6H_5Cl_6\cdot \longrightarrow C_6H_5Cl_5 + Cl\cdot \quad (5)$$

(**8**)

$$\mathbf{8} \longrightarrow C_6H_3Cl_3 + 2HCl \quad (6)$$

$$C_6H_3Cl_2\cdot + R^1R^2CHOH \longrightarrow C_6H_4Cl_2 + R^1R^2\dot{C}OH \quad (7)$$

$$R^1R^2\dot{C}OH + Cl\cdot \longrightarrow R^1R^2C{=}O + HCl \quad (8)$$

$$2R^1R^2\dot{C}OH \longrightarrow (R^1R^2C(OH)-)_2 \quad (9)$$

(pinacol)

Analogously,

$$C_6H_4Cl_2 + R^1R^2CHOH \xrightarrow{h\nu} C_6H_5Cl + R^1R^2\dot{C}OH + Cl\cdot \quad (10)$$

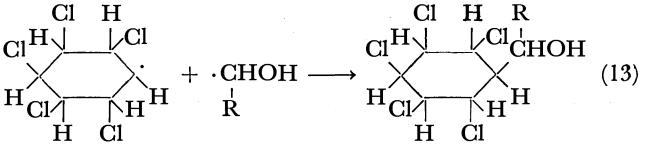
$$C_6H_5Cl + R^1R^2CHOH \xrightarrow{h\nu} C_6H_6 + R^1R^2\dot{C}OH + Cl\cdot \quad (11)$$

Pinacol was accumulated during the course of irradiation, especially in 2-propanol, 2,3-butanediol being rapidly accumulated even after 100% decomposition of β-BHC. The pinacol is derived by photoreduction of acetone in 2-propanol. The formation of biphenyl is explained by the reaction of chlorobenzene with benzene.

$$C_6H_5Cl + C_6H_6 \xrightarrow{h\nu} Ph_2 + HCl \quad (12)^{12}$$

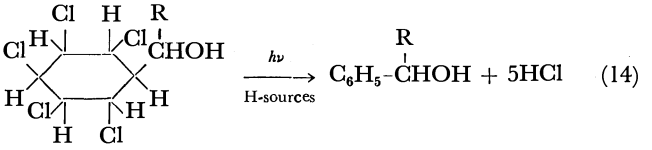
Chlorobenzene is known to be easily photodecomposed to give alkoxybenzene or phenol by photosubstitution along with benzene.[14–17] In our photoreaction, anisole (in methanol) and phenetole (in ethanol) were observed (see Table 1). However, careful analysis by GLC and GLC-MS revealed no formation of tri- or dialkoxybenzenes, and/or alkoxychlorobenzenes, suggesting that tri- or dichlorobenzenes are very rapidly dechlorinated rather than undergoing nucleophilic substitution under these conditions.

It is of interest that aromatic radical substitution occurs; *i.e.*, benzyl alcohol and 1-phenylethanol are formed during photolysis. Independent photolysis of trichlorobenzenes, or chlorobenzene under similar conditions did not afford such products; hence the substitution may originate at the stage of dechlorination of β-BHC. They may be formed as follows.



(13)

(R=H, or CH_3)



(14)

This is an evidence for the homolytic dechlorination of β-BHC to the radical $\cdot C_6H_6Cl_5$ through a radical chain mechanism involving chlorine atom as a chain carrier.

Experimental

Materials. β-BHC(extra pure grade, Tokyo Kasei Co.) was used without further purification. 2,3-Butanediol was synthesized by photolysis of acetone in 2-propanol.[18] *o*-(and *p*-)Chlorophenetoles were prepared by treatment of *o*-(and *p*-)chlorophenols with ethyl bromide in the presence of potassium carbonate.[19]

General Procedures. A Halos high-pressure 300 W Hg lamp with a water-cooling quartz jacket was used as a light source immersed in a reaction solution in a reactor (1000 ml

volume) equipped with a thermometer and a condenser. The reaction solution was adjusted to contain 0.01 M β-BHC and 0.3 M sodium alkoxide in alcohol. The reaction mixture was irradiated until the starting β-BHC disappeared. Aliquots were taken out at appropriate intervals of time, yields being estimated by means of titration and GLC technique.

Analysis of Products. Identification of products was carried out by means of GLC with a Yanagimoto gas chromatograph, Model GCG-550F operated with columns packed with either PEG 20 M (4 mm × 1.2 m) or Porapak QS (4 mm × 0.7 m) using N_2 as a carrier gas. Low-boiling products such as benzene, chlorobenzene, aldehyde, and esters were identified and estimated by means of GLC with a Porapak QS column using bromobenzene as an internal standard in comparison with the corresponding authentic specimen. High-boiling products such as polychlorobenzenes (*e.g.*, 1,2,4-trichlorobenzene), alkoxybenzene, benzyl alcohol, 1-phenylethanol, and β-BHC were identified and estimated by GLC with the PEG 20 M column using diphenylmethane as an internal standard.

The other products such as 1,2-ethanediol were characterized by means of GLC-MS with a Shimadzu GLC-MS Model 7000 as follows : *m/e* (relative yield); benzene, 78(M^+) (100); methyl formate, 60(M^+) (56), 32(100), 31(100); methyl acetate, 74(M^+) (32), 43(100); acetic acid, 60(M^+) (100), 58(13), 44(100), 43(15), 31(100), 32(69), 33(28); benzyl alcohol, 108(M^+) (100), 107(33), 79(50); ethylene glycol, 60(M^+) (25), 45(5), 44(12), 43(10), 33(75), 32(12), 31(100); 1-phenylethanol, 122(M^+) (66), 108(10), 107(100), 79(56), 78(12); butanediol, 90(M^+) (9), 75(10), 68(12), 47(12), 46(8), 45(100), 44(8), 43(8); benzene, 78(M^+) (100); chlorobenzene, 113(M^++1) (30), 112(M^+) (100), 77(45), 51(10), 50(10).

The analysis of chloride ion was carried out by addition of excess silver nitrate (10 ml × 0.016 M) to the above aliquot (10 ml), followed by titration with aqueous thiocyanate (0.016 M) after acidification by addition of excess nitric acid. The concentration of the appropriate sodium alkoxide was measured with 0.0662 M HCl using phenolphthalein as an indicator. A control experiment indicated that the covalent-bonded chlorine cannot be detected as chloride ion in the stage of titration.

On the Effects of Crystalline Planes and Purities on Working States of Vanadium Oxide Catalysts in CO-oxidation

Yoshiya KERA

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received July 1, 1977)

It was confirmed that the kinetics of CO-oxidation over powdered V_2O_5 under the condition of (P_{CO}/P_{O_2}) more than 2 differed clearly from that under the (P_{CO}/P_{O_2}) less than 2 at 450 °C. The activation energies were 5.6 kcal/mol at 250—410 °C and 13 kcal/mol at 410—490 °C under a reductive condition of $(P_{CO}/P_{O_2})=4.4$, and on the other hand 5.9 kcal/mol at 250—490 °C under an oxidative condition of $(P_{CO}/P_{O_2})=0.43$. On a thin crystalline sample, in which the (010) plane was exposed extensively to the surface, a very rapid process appeared at the initial stage but was soon followed by a steady process. The rapid process was explained well by the Elovich law. On the thin crystalline, cautiously purified, the Elovich process did not appear, but the initial rapid process was kept steadily for 10—20 min and then followed by the other steady process. Accompanied by the change in the kinetics during the reaction, the activation energy changed from 2.3 kcal/mol at 271—410 °C and 17 kcal/mol at 410—480 °C to 29 kcal/mol at 271—480 °C under the $(P_{CO}/P_{O_2})=2.1$. Based on these results, the effects of the crystalline planes and the purities on the working states of V_2O_5 crystal in CO-oxidation are discussed.

Many investigators have devoted themselves to the discussions on the working states of vanadium oxide catalysts-especially as to whether oxygen in the catalyst takes part directly in the catalysis or only adsorbed oxygen and which phases of vanadium oxide play an important role in the working state.[1–13] A unified understanding of the problem, however, has not yet been established fully for the differences from author to author in the biography of the catalysts (purity, carrier *etc.*), in the reaction systems, and in the reaction conditions. By the same reason, divergence is seen in the proposed kinetics even in such a simple reaction as CO-oxidation on vanadium oxide catalysts.[14–18]

Previously, CO-oxidation on crystalline powder of V_2O_5 has been studied by using ^{18}O-tracer[19] and the rates of isotopic exchange between the surface oxygen and ^{18}O-carbon dioxide on the crystalline powder and on the thin plate crystalline, in which the (010) plane was highly exposed to the surface, were compared with each other.[20] These results suggested clearly an important role and a high activity of the (010) plane to CO-oxidation.

In this paper, in order to obtain further information on the effects of the crystalline planes and also the purities of V_2O_5 on the catalytic activity and the working states, the rates of CO-oxidation over various kinds of V_2O_5 crystalline- powdered and thin plate, and unpurified and purified- were investigated under various reaction conditions: temperature, pressure and the ratio of CO to O_2. From the results it was deduced that the catalytic properties of the surface, especially the (010) plane, changed remarkably only by the elimination of a very little amount of impurities.

Experimetnal

Materials. V_2O_5 obtained by thermal decomposition of NH_4VO_3 (special grade, Wako Pure Chem. Co.) at 600 °C in air stream for 3 h was used as the powdered catalyst. Thin plate crystallines were prepared by a soft touched pulverization of single crystals of V_2O_5 with an agate mortar and then sieving. The single crystals, unpurified and purified, were made from the unpurified V_2O_5 and cautiously purified V_2O_5 powder, respectively, by a zone-melting method.[24] The purification was done chemically according to the methods of McCarely *et al.*[21] and Haemers.[22] The BET surface areas of the V_2O_5 catalysts are summarized in Table 1. In the unpurified single crystal, S_s-u, ESR signals ascribed to V^{4+} ions and Fe^{3+} ions[23] were found. According to a chemical analysis, the content of Fe was 0.005% (Fe/V). On the other hand, in the purified single crystal, S_s-p, no ESR signal was detected.[24]

Table 1. V_2O_5 catalysts and BET surface area

V_2O_5 catalyst			Surface area (m^2/g)
Powdered V_2O_5 (commercial, special grade)		S_p-c	2.5
Powdered V_2O_5 (dec. of NH_4VO_3, special grade)		S_p-d	8.0
Thin plate crystallines (unpurified V_2O_5)	20—42 mesh	S_s-u-1	0.09
	80—100 mesh	S_s-u-2	0.3
	170—200 mesh	S_s-u-3	1.2
Thin plate crystallines (purified V_2O_5)	20—42 mesh	S_s-p	0.09

The preparations and purifications of CO and O_2 gases were done by usual methods. In the reactants no impurity was detected mass-spectrometrically.

Apparatus and Procedures. The reaction was done statically with a cylindrical glass vessel (diameter=8 cm, length=6 cm). In the reaction apparatus, the dead volume of the trap and the manometer, V_D($\approx$25 cm^3), was kept as small as possible compared with the reaction volume, V_R ($\approx$310 cm^3). The catalysts were dispersed widely on the side wall. The changes in the pressures during the reaction were determined by reading the level of the Hg-manometer with a cathetometer. Reaction temperature were controlled within $\pm$1 °C.

For the measurement of a very rapid rate at the initial stage on S_s-u and S_s-p, a small trap, inserted between the manometer and the reaction vessel, was cooled with liq.N_2. For the measurements of a steady rate it was not cooled. The catalysts were previously heated in air and then *in vacuo* at 490 °C for 1 h. Activities of the catalysts were almost recovered by such a pretreatment. Thus, for a series of determinations of the temperature- and pressure-dependences of the rates, the same catalyst was used repeatedly.

Results

Effects of the Sizes, the Shapes, and the Purities of V_2O_5 Catalysts on the Rate of the Catalytic Oxidation of CO-a Survey of the Kinetics. CO-oxidation on the Unpurified V_2O_5- the Powdered (S_p-d) and the Thin Plate Crystalline(S_s-u): In the catalytic oxidation of carbon monoxide over the unpurified V_2O_5 catalyst, S_p-d and S_s-u, a very rapid process appeared at the initial stage but was soon followed by a slow steady process. The period of the appearance of the initial process was prolonged on a small amount of the catalysts and at a low temperature, as illustrated in Fig. 1. The rapid process, which is almost invisible at 450 °C on S_p-d of 0.122 g (Fig. 1-a), appears clearly at 450 °C on that of 0.03 g (Fig. 1-b) and at 256 °C on that of 0.116 g (Fig. 1-c).

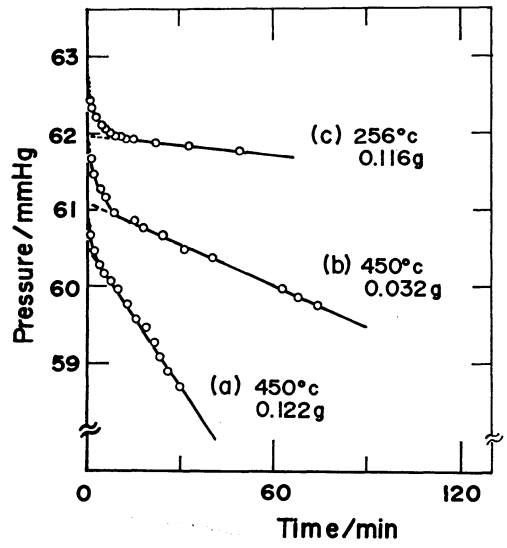

Fig. 1. Appearence of an initial fast process in CO-oxidation at a decreased temperature by use of a reduced amount of V_2O_5 catalyst.

The rapid process was recovered easily by the evacuation at 10^{-5} mmHg above 450 °C for 1 h. When the temperature of the trap, inserted between the reaction vessel and the manometer, was suddenly changed from 195 to 77 K in the steady state, the rapid process seems to be recovered again for a while. The results obtained at 434 °C on S_s-u-3 of 0.027 g are illustrated in Fig. 2. Under the condition that the produced CO_2 was always removed from the gaseous phase by the liq. N_2 trap, the period of the appearance of the process was further prolonged. The result obtained on S_s-u-1 of 0.121 g at 410 °C under the total pressure of 42 mmHg and the ratio (P_{CO}/P_{O_2}) of 2.1 is given in Fig. 3-a as an example. The analysis of the process by the "Elovich equation,"[25] $(P_0-P)/(P_0-P_\infty)=\log(t_0+t)$, is shown in Fig. 3-b, where P is the total pressure and t_0 is a parameter assumed as 5 min. The initial rapid process seems to be described well by the Elovich law. This feature of the kinetics suggests that the surface is gradually deactivated, accompanied by adsorption of the produced CO_2. However,

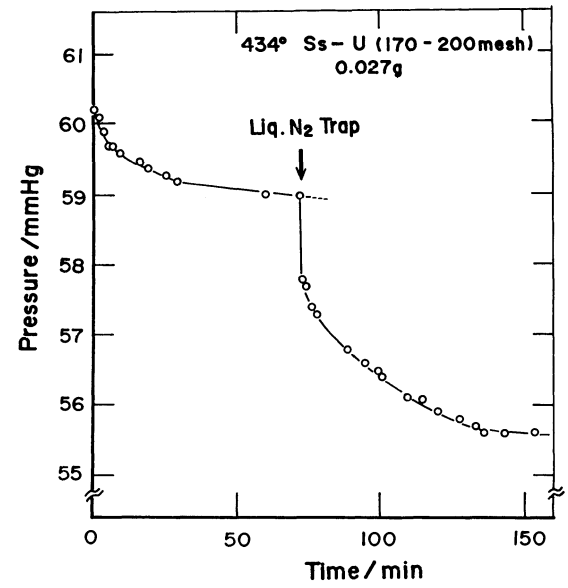

Fig. 2. Effect of elimination of produced CO_2 from gaseous phase and surface after a steady state was reached on the initial fast process.

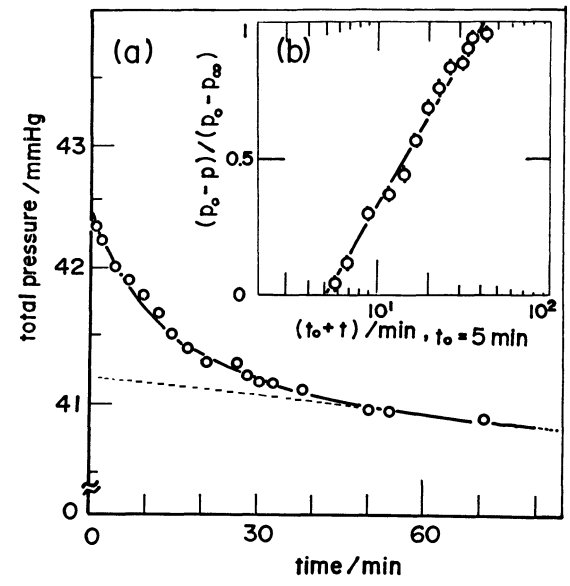

Fig. 3. A kinetical treatment of the initial fast process. (a) reaction curve of CO-oxidation on thin crystallines of V_2O_5 at initial. (b) analysis of the initial process according to Elovich low; $(P_0-P)/(P-P_\infty)=\log(t_0+t)$, where P is total pressure, P_0 and P_∞ are given by the cross point between the vertical axis and the reaction curve and the points on the dotted line at each time, respectively, t is reaction time, and t_0 is a parameter, assumed as 5 min.

no further discussion on the kinetics is done. Only the mean rates for 5 min at the start of the rapid process, measured repeatedly on S_s-u-1 of 0.121 g at various temperatures from 210 to 490 °C under the total pressure of 20 mmHg and the $(P_{CO}/P_{O_2})=2.1$, are evaluated. The results are discussed below.

The rates of the steady process were evaluated from the slope at the steady state of the reaction curves

on the catalysts of S_p-c, S_p-d, and S_s-u. The rates are summarized in Fig. 4 for comparison. In spite of the rather large differences in the particle sizes, the shapes, and the surface areas, the rates per unit surface area were very similar, especially at the lower pressures. The difference in the rates between the fresh and the repeated runs is seen in Fig. 4. The steady rate on S_p-d at 450 °C changed linearly with the increase in the amount of the catalyst from 0.03 to 0.3 g, as is shown in Fig. 5. The contribution of the diffusion process to the rate may, therefore, be ignored for the steady process.

CO-oxidation on the Purified V_2O_5-the Thin Plate Crystalline, S_s-p: CO-oxidation on the thin plate crystalline, S_s-p, of 0.075 g was examined in the temperature range from 271 °C to 480 °C under the total pressure ($(P_{CO}/P_{O_2})=2.1$) of 23 mmHg. The results are illustrated in Fig. 6. The features of the kinetics seem to be completely different from that on the unpurified catalyst, S_s-u, except for the run at 271 °C. The total pressures decrease linearly and it is noted that the slopes in the reaction curves change abruptly at 10—20 min : from given values to smaller values in the runs at 330 and 370 °C and on the contrary to larger values in the runs at 410—480 °C. The temperature dependences of the rates of the first and the second processes are discussed quantitatively below.

Pressure Dependences of the Steady Rate. The Steady Rate on S_p-d: The steady rates on S_p-d, determined

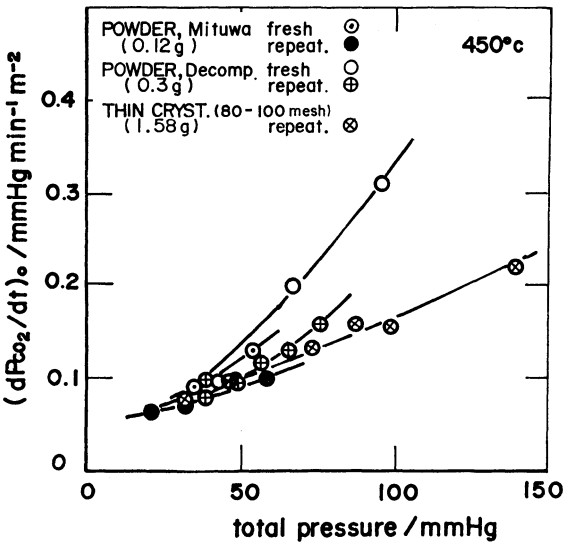

Fig. 4. Comparisons of activities of CO-oxidation among some kinds of powdered and thin crystalline V_2O_5 catalysts at 450 °C.

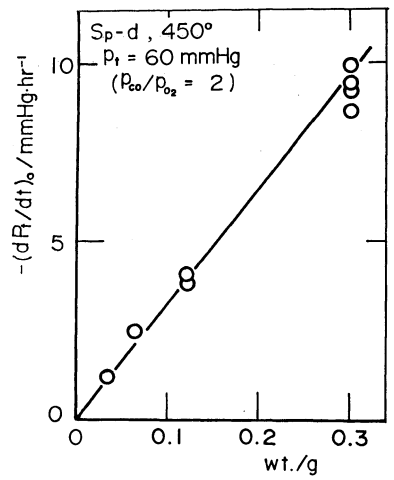

Fig. 5. Verification of linear relation of the steady rate of CO-oxidation with used amount of powdered V_2O_5, S_p-d, at 450 °C.

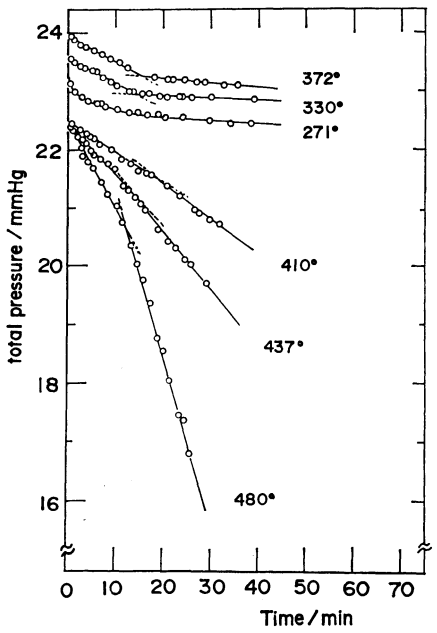

Fig. 6. Reaction curves of CO-oxidation on highly purified V_2O_5 crystallines, S_s-p. Changes in kinetical feature with reaction temperatures.

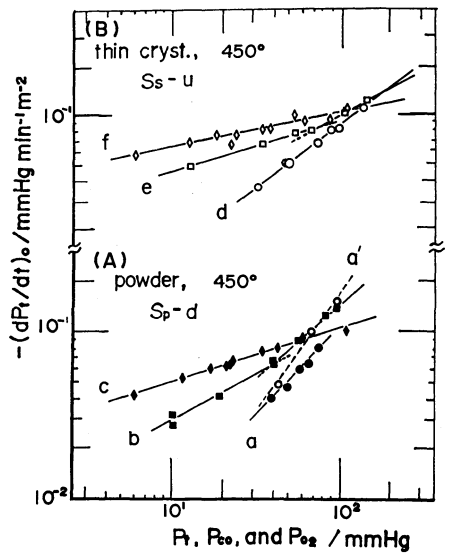

Fig. 7. Pressure dependences of the steady rate at 450 °C on unpurified powdered V_2O_5, S_p-d, (A), (a; the rate *vs.* total pressure, a'; *vs.* total pressure on fresh catalyst, b, *vs.* partial pressure of CO and c; *vs.* partial pressure of O_2) and on unpurified thin crystallines of V_2O_5, S_s-u, (B), (d; the rate *vs.* total pressure, e; *vs.* CO and f; *vs.* O_2).

at 450 °C under various pressures, are summarized in Fig. 7(A). On the vertical axis, the total pressure change (mmHg) per unit time (min) and per unit surface area (m^2) are given in a common logarithm scale. On the abscissa, the total pressure and the partial pressures of CO and O_2 (mmHg) are given in a common logarithm scale, corresponding to the curves a, b, and c, respectively. In curve a, the ratio of CO to O_2, $(P_{CO}/P_{O_2})\equiv r$, was fixed at 2 and the total pressure, P_t, was varied from 39 to 75 mmHg. The curve a′ indicates the rate on the fresh catalyst. It is known from the comparison between the curves a and a′ that the reaction order for P_t is higher on the fresh catalyst than on the catalysts used repeatedly. In the curve b, P_{O_2} was fixed at 20 mmHg and P_{CO} was varied from 10 to 95 mmHg. It should be noted that when P_{CO} exceeded 40 mmHg, that is, the ratio (P_{CO}/P_{O_2}) exceeded 2, the reaction order for P_{CO} changed at once from a given value to a larger one. In the curve c, P_{CO} was fixed at 40 mmHg and P_{O_2} was varied from 6 to 109 mmHg. The reaction order for P_{O_2} was kept constant over all the pressure ranges.

The reaction rates of the steady state can be described by an empirical equation:

$$V_{steady} = k(r)\cdot P_{CO}^{n}\cdot P_{O_2}^{m}. \quad (1)$$

In the case of the stoichiometric mixture of the reactant, $r=2$, Eq. 2 is available:

$$V_{steady} = k(2)\cdot 2^{n}\cdot 3^{-(n+m)}\cdot P_t^{(n+m)}. \quad (2)$$

The reaction orders and the apparent rate constants, evaluated by Eqs. 1 and 2, are summarized in Table 2. It is seen in the table that as soon as r exceeds 2, n increases from 0.57 to 1.0 and at the same time $k(r)$ decreases to one-fifth. The changes in the reaction order and $k(r)$ suggest a change in the working state of the catalyst from V_2O_5 to some lower oxides.

The Steady Rate on the Thin Crystalline, S_s-u: Pressure dependences of the steady rate on the thin crystallines, S_s-u-2 of 1.58 g, were examined at 450 °C. The results are also given in log-log plots in Fig. 7(B). In the curve d, the (P_{CO}/P_{O_2}) was kept constant as 2 and P_t was varied from 32 to 139 mmHg. In the curve e, P_{O_2} was fixed at 30 mmHg and P_{CO} was varied from 12 to 143 mmHg. In the curve f, P_{CO} was fixed at 60 mmHg and P_{O_2} was varied from 6 to 108 mmHg. By the repetition the activity decreased more or less. The activity for the curve d at $P_t=60$ mmHg ($r=2$) was selected as a standard. The activities for the curves e and f at the same condition as $P_t=60$ mmHg ($r=2$) were compared with the standard to estimate the correction factors. The activities of the other points in the curves e and f were evaluated by the use of the correction factors. The reaction orders and the apparent rate constants are also given in Table 2. In the case of S_s-u the changes in n and $k(r)$ are also seen at $r=2$, as shown in Fig. 7 and in Table 2.

The data on the thin plate crystallines are scattered, but the general feature of the kinetics agrees fairly well with that on the powder. The value of $k(r)$ in the former is about 10 times as large as that in the latter. On the other hand, the reaction order for P_{CO}, n, on the former was below one-half of the value on the latter, while the order for P_{O_2}, m, is nearly the same for the two cases. These differences might be caused by the difference in the extent of the (010) plane exposed to the surface between the powder and the thin plate crystalline.

Temperature Dependences of the Rates. The Steady Rates on S_p-d: The steady rates on S_p-d of 0.116 g were measured in the temperature range from 250 to 490 °C under an oxidative ($r=0.43$) and a reductive ($r=4.4$) condition; the total pressures were 70 mmHg. Arrhenius plots of the overall rates (per min and per m^2) are given in Fig. 8. The curve a indicates the

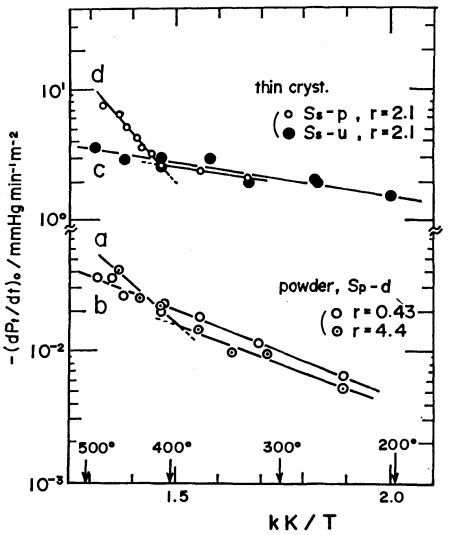

Fig. 8. Arrhenius plots of overall rates of various processes of CO-oxidation. curve-a and -b indicate the run on unpurified powdered V_2O_5, S_p-d, under $P_{CO}/P_{O_2}=4.4$ and 0.43, respectively, curve-c on unpurified thin crystallines, S_s-u, under $P_{CO}/P_{O_2}=2.1$, and curve-d on purified thin crystallines, S_s-p under $P_{CO}/P_{O_2}=2.1$.

Table 2. Changes in the reaction orders on S_p-d and S_s-u with mixing ratios of the reactant

Sample	Temp °C	The ratio P_{CO}/P_{O_2}	$m+n$	m	n	$k(r)$ molecules·cm^{-2}·s^{-1}·P_{CO}^{-n}·$P_{O_2}^{-m}$
Powdered V_2O_5		$r>2$	1.30	0.30	1.00	0.93×10^{-2}
S_p-d, 0.122 g	450	$r<2$	0.87	0.30	0.57	$4.5_4\times10^{-2}$
(0.98 m^2)		$r=2$	1.10 (1.48)[a]			
Thin plate crystallines		$r>2$	0.78	0.25	0.53	1.1×10^{-1}
S_s-u, 1.58 g	450	$r<2$	0.54	0.25	0.29	3.1×10^{-1}

TABLE 3. COMPARISON OF THE ACTIVATION ENERGIES AMONG VARIOUS PROCESSES AND CATALYSTS

Total pressure/mmHg (P_{CO}/P_{O_2} ratio)	Catalyst (process)	E_{ex}/kcal·mol^{-1}	Temp ranges/°C	Reference
70 (r=4.4)	S_p-d (at steady process)	5.6 13	250—400 400—460	Fig. 8
70 (r=0.43)	S_p-d (at steady process)	5.9	250—490	Fig. 8 curve b
20 (r=2.1)	S_s-u (at the initial stage of Elovich's process)	2.3	210—490	Fig. 8 curve c
23 (r=2.1)	S_s-p (1st process up to initial 10—20 min)	2.3 17	330—410 410—480	Fig. 8 curve d and Fig. 9
	S_s-p (2nd process after 10—20 min)	29	330—480	Fig. 9

run of r=4.4 and the curve b the run of r=0.43. Although the data are rather scattered for repeated measurements, the apparent activation energy clearly increased above 400 °C in the run of r=4.4 but was constant over all the temperature range in the run of r=0.43. The activation energies are summarized in Table 3.

Mean Rates at the Start of the Elovich Process on S_s-u: The mean rates for 5 min at the initial stage of the Elovich process on S_s-u-1 of 0.121 g (*cf.* Fig. 3), which were measured repeatedly at various temperatures from 210 to 490 °C under the pressure of 20 mmHg and the (P_{CO}/P_{O_2}) of 2.1, are plotted in Fig. 8(c). The values seem to correspond to the rates on the (010) plane without poisoning by the produced CO_2. The activation energy is as low as 2.3 kcal/mol over all the range of the temperature.

The Rates on S_s-p: The reaction rates were evaluated from the slope of the reaction curves in Fig. 6. The Arrhenius plots of the overall rates are given in Fig. 9. The circles (○) and the squares (□) denote the rates of the first and the second process, respectively. The sequence of the repetition of the measurements is indicated by the numbers given in the upper part of Fig. 9. The number 5 is missing in Fig. 9, because the run was done at 271 °C and the reaction curve did not give a linear change but seemed to correspond to the Elovich equation, as mentioned above. The number 1 indicates the run on the fresh catalyst. By comparison of the activities between the numbers 1 and 11, it is known that the activity decreases only 20—30% even after the catalyst was used eleven times insuccession. Such as extent of deactivation is inessential to the discussion given below.

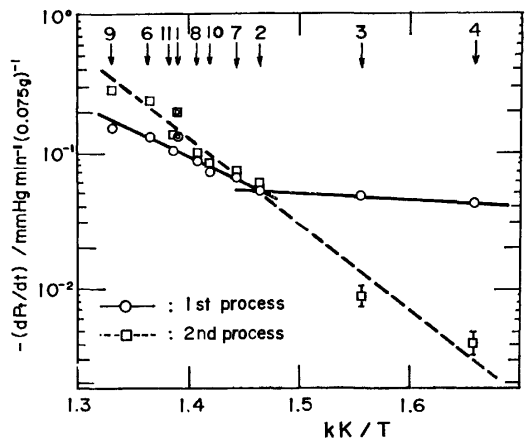

Fig. 9. Arrhenius plots of the first and second processes of CO-oxidation on highly purified thin crystallines, S_s-p. The numbers of the upper part of the Figure indicate sequence of repetition of the measurements.

It should be noted that the experimental points for the second process in the temperature regions above and below 410 °C can be connected with each other by the dotted line in Fig. 9. On the other hand, the Arrhenius plot of the first process consists of two lines crossing each other— the line above 410 °C shows a considerably larger slope than that below the temperature. The temperature dependence of the first process is also given in Fig. 8(d), for comparison.

Discussion

Hughes and Hill[14] have suggested for CO-oxidation over vanadium pentoxide catalyst that a high activation energy is required in the process in the elimination of surface oxygen by carbon monoxide and on the other hand the process in the re-oxidation by oxygen occurs easily. Boreskov *et al.*[17] have indicated that the rates of the reduction of vanadium pentoxide by carbon monoxide and the re-oxidation by oxygen largely depends upon the extent of reduction and oxidation of the surface. Based on their results, the activation energy of 13 kcal/mol, obtained on the unpurified powder above 400 °C under a reductive condition (r=4.4) (*cf.* Fig. 8 and Table 3), would arise from the process on the surface reduced to some extent. On the other hand, at the temperatures below 400 °C, even under such a reductive condition (r=4.4) the surface would be kept in an oxidative state, since the activation energy is as low as 5.6 kcal/mol and is almost the same as 5.9 kcal/mol obtained for the process under an oxidative condition (r=0.43) (*cf.* Fig. 8 and Table 3).

The change in the kinetics, which appeared as soon as the (P_{CO}/P_{O_2}) became larger than 2 with the increase

in the CO partial pressure (*cf.* Fig. 7), would also be understood favorably as corresponding to the changes in the surface state on working. That is, the surface of the powder and the thin plate crystalline, unpurified, is kept in the reduced state on working to some extent at 450 °C under the condition that the (P_{CO}/P_{O_2}) is larger than 2. The differences in the kinetic parameters, $k(r)$ and n, however, are not so small between the powder and the thin plate crystalline (*cf.* Table 2). These differences would arise from the difference in the extent of the (010) plane exposed to the surface. In the thin plate crystalline, the extent of the (010) plane was estimated roughly to be higher by about 38 times than the other planes. In the estimation it was assumed that each crystalline is a square plate with mean sides of 160 μm (*cf.* the sizes of sieves of 80 and 100 meshes, which correspond to 177 and 149 μm, respectively), and the values of 0.31 m^2/g and 3.3 g/cm^3 were used as the surface area of S_s-u-2 and as the density, respectively.

In this work, if the measurements of the oxidation rate of CO over V_2O_5 had been carried out without special attention, only the steady process could be found. On the reduced amount of the catalyst at a low temperature, a very rapid process appeared at the initial stage, as was shown in Fig. 1. On the thin plate crystalline, in which the (010) plane was highly exposed to the surface compared to the other planes, the rapid process was completely differentiated from the steady process and was analyzed well with an Elovich equation, as was shown in Fig. 3. The rapid process could occur mainly on the (010) plane, because in the thin plate crystalline the (010) is exposed to the surface much more than the other planes. Furthermore, from the fact that the rapid process is recovered easily by the evacuation at 450 °C and is prolonged on the elimination of the produced CO_2 from the gaseous phase by the insertion of the liq. N_2 trap, the initial rapid process may be attributed to a process accompanied by the poisoning of the surface by the produced CO_2. Such a process is really consistent with the physical content of the Elovich law.

On the thin plate crystalline, purified carefully, such Elovich kinetics have never been found, and inversely the rapid rate was kept for a while at the beginning but was soon followed by the second rapid process with a very high activation energy (29 kcal/mol), as is shown in Figs. 6, and 9 and Table 3. The initial mean rate for 5 min on the unpurified thin crystalline was almost the same as the rate of the first process on the purified thin crystalline and its temperature dependence was also the same as that on the latter at the temperatures lower than 410 °C (*cf.* Fig. 8). Those consistencies suggest that the active site for CO-oxidation is the same for the thin plate crystallines, unpurified and purified, at least at the start. The sites for the subsequent process, however, differ largely among the crystallines, unpurified and purified, depending upon whether there are very small amounts of impurities. That is, the site on the unpurified seems to be inhibited by the produced CO_2 mentioned above; on the other hand, the sites on the purified seem to vary easily into other sites during the oxidation, as is suggested by Figs. 6 and 9. Such a low activation energy as 2.3 kcal/mol was reported by Kazanskii *et al.*,[18] who obtained the value of 1.6 kcal/mol for a radical process on a vanadium oxide catalyst, $CO + O^-_{ads} \rightarrow CO_2$, below room temperature. From comparison of the activation energies, the very initial process on the thin plate crystallines, unpurified and purified, could be ascribed to a small cycle of reduction and oxidation on the (010) plane. Such a large activation energy as 29 kcal/mol may arise from the process on a considerably reduced surface, according to the indication by Hughes *et al.*[14] and Boreskov *et al.*[17] Thus, the large changes in the activation energies from 2.3 kcal/mol below 410 °C and 17 kcal/mol above 410 °C in the first process to 29 kcal/mol in the second process during the oxidation (*cf.* Fig. 9 and Table 3) suggest clearly the changes in the surface state on working in the purified thin plate crystalline.

In TGA of V_2O_5 in an SO_2 stream, clear-cut and stepwise weight losses were found by Kawashima *et al.*[26] Each step corresponds to a phase change from a given oxide to a different lower one. The clear-cut transitions were explained favorably on the basis of the fact that each vanadium oxide phase has a shear structure and belongs to the Magnéli phase.[27] On the other hand, the recent studies on vanadium bronzes[28] would suggest that such clear-cut transitions between the vanadium oxides are inhibited by the existence of metal impurities, even if the amount is very little. Based on these references, the clear-cut changes in the activation energies, seen only on the highly purified crystalline, could be related to a phase transition of the surface from V_2O_5 to a given lower oxide. However, the question still remains as to which states or phases of the surface are realized on working, depending upon the reaction condition.

The high activity of the (010) plane to CO-oxidation, obtained in this work, is fairly consistent with the results of the previous paper on the isotopic exchange[20] and gives support to the suggestion by Hirota[29] that the pure vanadium oxides themselves without carrier and impurity would play an important role in catalysis. The steady rate on the unpurified powder or thin plate crystalline was slower by one or two orders than the rate on the purified thin crystalline, but the former seemed to be more stable than the latter. Those features of vanadium(V) oxide should also be discussed in view of the stabilities and activities of vanadium bronzes.[28]

The author wishes to express his appreciation to Mr. Michihisa Kyoto for his help in the determination of the surface area of the V_2O_5 catalysts, and Professor Keiji Kuwata for his continued interest in this work and for his valuable suggestions.

(Received June 19, 1978)

The hexagonal phases of sodium octadecanoate–water system NaS and sodium hexadecanoate–sodium tetradecanoate–water system Na(P+M) were studied by sodium-23 NMR and spin label ESR in the temperature range 40—100 °C, covering the transition temperature of isotropic-liquid crystal T_{I-L} and that of liquid crystal-gel T_{L-G}. The ESR spectrum of liquid crystal systems aligned by the magnetic field and the center line of ^{23}Na NMR spectrum were analyzed. The motions of the alkyl chain and sodium ion are reflected on the ESR and NMR spectral shape and width. The NMR line width is predominantly determined by the local motion of the cation attached on the hydrocarbon rod. During the phase separation region its correlation time $\tau_c \simeq 10^{-10}$ s is constant, comparable to that of chain motion. The change in the local motions of these two species is similar, being continuous across T_{I-L} but drastic across T_{L-G}.

Many studies on the lyotropic liquid crystal including biological systems have been carried out by spectroscopic measurements. For example, the properties of the hydrocarbon chain have been studied by ^{1}H, ^{2}H NMR, and spin label ESR.[1a-1l] NMR of sodium-23 and other alkali metal ions has been utilized for the analysis of cation binding in soap–water systems.[2a-f] Most works have been performed by changing the concentration of components. For the study of molecular dynamics in lyotropic systems around the phase transition or phase separation point, a continuous observation through the transition point is important and variable temperature measurement is essential. Furthermore, a comparison between the dynamical properties of hydrophobic and hydrophilic parts of the amphiphile molecules especially near these transition points will give important information on the mechanisms of biological phenomena. In the present work the dynamical properties of hydrocarbon chain and counter ion in hexagonal phase of lyotropic systems have been studied through phase transition points by means of magnetic resonance.

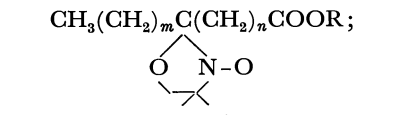
We have observed the temperature dependence of sodium-23 NMR and spin label ESR of lyotropic liquid crystals, sodium octadecanoate–water (NaS) and sodium hexadecanoate–sodium tetradecanoate–water (Na(P+M)) systems, in the range covering the isotropic liquid-liquid crystal and liquid crystal-gel transition temperatures, T_{I-L} and T_{L-G}, respectively. Choice of the soap systems and their phases is made in order to make stable lyotropic liquid crystals of low transition temperatures. The concentrations of the soaps are adjusted to form hexagonal liquid crystals of T_{I-L} below 90 °C so that the liquid crystals can be aligned under the static magnetic field below 100 °C. The use of the systems of low transition temperatures enables us to measure the spin label ESR throughout the transition temperatures including even the liquid crystal alignment by magnetic field with no noticeable label decomposition. Otherwise, the label is rapidly lost in the slightly alkaline medium above 100 °C. The ^{23}Na NMR and spin label ESR of the system through the transition points were observed continuously.

Experimental

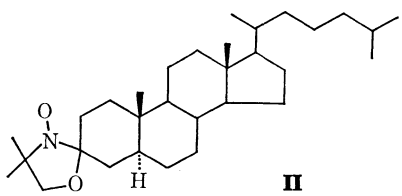
Samples. The soaps (sodium octadecanoate, hexadecanoate, and tetradecanoate) were prepared from reagent grade acids (purity 99%, Wako Chemicals Co.) by NaOH titration and reprecipitated from hot water. The sodium octadecanoate mixture used for NMR measurement was obtained as sodium salt (Kishida Chemicals, Co.) the purity being determined by gas chromatography : 70% octadecanoic, 27% hexadecanoic, and 3% of tetradecanoic and eicosanoic acids.

The sample for NMR measurement was prepared in a 10 mm OD tube with a silicone rubber stopper, being made homogeneous by repeated cooling and heating. The space between the sample mixture and stopper was kept small in order to prevent the evaporation of water. In the case of sodium octadecanoate system, the space above the sample mixture was not small as compared with sample volume so that the homogeneity of the sample might not be satisfactory. The concentration of the mixture was determined by weighing before and after each NMR measurement.

The sample for ESR measurement was prepared in a similar way with appropriate spin probe molecules, **I**, **I′**



I: $(m, n) = (12, 3)$, $R = CH_3$
I′: $(m, n) = (m, n)$, $R = H$



II

(12,3), **I′**(5,10), **I′**(1,14), and **II** (Syva), then sucked up in a capillary tube of about 1 mm diameter, both ends of capillary being sealed. Only the tubes with good sample homogeneity were used. The concentration was determined by means of isotropic-liquid crystal transition points.

The phase transition temperatures T_{I-L} and T_{L-G} were determined by laser light depolarization and scattering. The temperature for both NMR and ESR measurements was initially set above T_{I-L} in order to bring the sample to com-

plete isotropic solution, then slowly changed downwards and spectra were taken 30—60 min after each temperature setting.

NMR Measurement. For the measurement of ^{23}Na NMR signals, a JEOL PS-100 electromagnet with ^{1}H external field lock system was used with 26.45 MHz home made detector systems. Free induction decay (FID) signals were averaged 1000 times and subjected to Fourier transformation with a JEOL EC-6 or EC-100 computer. An average of three observations was taken for each temperature setting. The uncertainty in the shift data for continuous observation was within ± 0.012 ppm over a period of three days. The temperature was controlled by heated air flow (*ca.* 20 l min^{-1}). The temperature distribution across the sample was within ± 0.2 °C.

The half full width of the Fourier transformed signal was taken as the line width and the half full width times the peak height as the measure of intensity. No correction was made for intensity due to the change in the sample density at various temperature nor for the delay time (200 μs) of FID sampling. The maximum line width observable by the present instrumental setting is 500 Hz which has ample allowance for the observed width of the center line of up to 60 Hz. No ^{23}Na satellite for oriented molecules is to be detected under these experimental conditions. ^{23}Na signals of 1.1 M NaCl and 0.8 M sodium acetate aqueous solutions were taken as references.

ESR Measurement. The X-band ESR spectra of nitroxide spin probes were taken with a JEOL JES ME-X spectrometer with temperature control system JEOL JES VT-3. The variation in temperature at each setting was within ± 1 °C. The sample capillary was set perpendicular to the magnetic field so that it can easily be rotated around its axis for observation of the effect of magnetic field alignment of the amphiphile systems. Microwave power of 1.0—1.5 mW and 100 kHz field modulation of 1.0 G amplitude were used.

Results

The phase diagram of Na(P+M) system is constructed by laser light depolarization and ESR and NMR spectra (Fig. 1). It is similar to that of NaS system and its analogs such as NaP, NaM, NaL(sodium dodecanoate–water) systems with some depression in

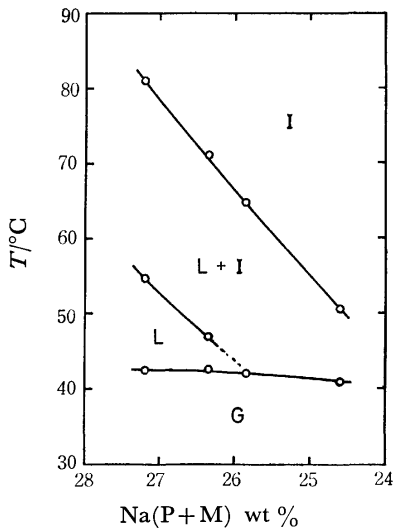


Fig. 1. Phase diagram of Na(P+M) system.

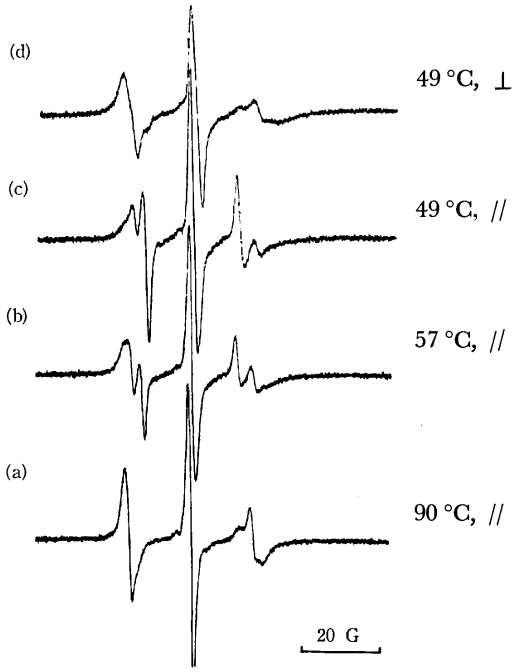

Fig. 2. ESR spectra of label **I** in Na(P+M) 27% system.

the transition point T_{I-L} as compared with that of the corresponding carbon number.

The ESR spectra of label **I** in the system of 27 weight percent aqueous solution of the equal weight mixture of sodium hexadecanoate and sodium tetradecanoate (abbreviation Na(P+M) 27% likewise will be used hereafter) is shown in Fig. 2. The spectrum above T_{I-L} consistes of one triplet due to ^{14}N hyperfine coupling constant of 14.9 G. The spectrum below T_{I-L} seems to be a superposition of two triplets: one with the coupling constant A_{iso} of 14.9 G arising from the isotropic phase and the other with a smaller coupling constant of 11.8 G from oriented molecules. The order parameter of the z axis, the direction of the largest hyperfine splitting (radical axis), for the oriented label **I** can be given by

$$S = (1/2)\langle 3\cos^2\theta - 1\rangle = (A_{//} - A_{\perp})/(A_{zz} - A_{xx})$$
$$= (3A_{//} - 2A_{xx} - A_{zz})/2(A_{zz} - A_{xx}) = -0.19,$$

where $A_{//}$(11.6 G) is the observed coupling constant, A_{xx}=6.1 G, A_{zz}=32.4 G,[1f] and θ is the angle between the radical axis and the static magnetic field. The spectral intensity of the oriented molecules increases and that of the isotropic phase decreases towards T_{L-G}. The line widths of these signals seems to be constant throughout the liquid crystal region. Below T_{L-G}, a sudden signal broadening is observed and the spectrum changes gradually to that of solid towards lower temperature.

The spectrum of label **I** in Na(P+M) 27% system with the sample capillary rotated by 90° in the magnetic field under the conditions of fixed molecular alignment below T_{I-L} shows a larger coupling constant $A_{\perp}$ than isotropic ones (Fig. 2d).

Because of high T_{I-L} of NaS system, the spin labeled compounds decompose when the sample preheating is sufficient enough to equilibrate the system in the

isotropic phase. The ESR experiment of NaS system was carried out only for the purpose of confirming whether the molecular arrangement is of similar type to that of Na(P+M) system in liquid crystal region.

The line widths, intensities, and chemical shifts of ^{23}Na NMR signals of Na(P+M) 25.9, 26.4, and 27.2% systems and NaS 17.1% and 20.0% systems were observed at various temperatures. The results of Na(P+M) 26.4, 27.2, and NaS 20.0% systems are shown in Figs. 3, 4, and 5. The temperature dependence of linewidths and intensities of these five samples are of the same type.

The linewidth in the isotropic region increases towards T_{I-L} with fall in temperature. The Arrhenius plot of the width gives the activation energy for the reorientational motion of ion or the fluctuational motion of the environment of the sodium ion provided that the motional narrowing condition is satisfied in the isotropic region. The activation energie is 18.0—20.0 kJ mol^{-1} for NaS systems and 14.6—16.8 kJ mol^{-1} for Na(P+M) systems. The signal intensity is constant in this region.

In the liquid crystal region, $T_{I-L} > T > T_{L-G}$, the line width remains constant till it starts to increase at T' ($T' > T_{L-G}$). The signal intensity decreases distinctly between T_{I-L} and T' and approaches asymptotically to about 40% of its isotropic value, while the width remains constant, keeping the 40% value till the phase transition temperature T_{L-G} is reached. The effect of sample rotation on the center line width

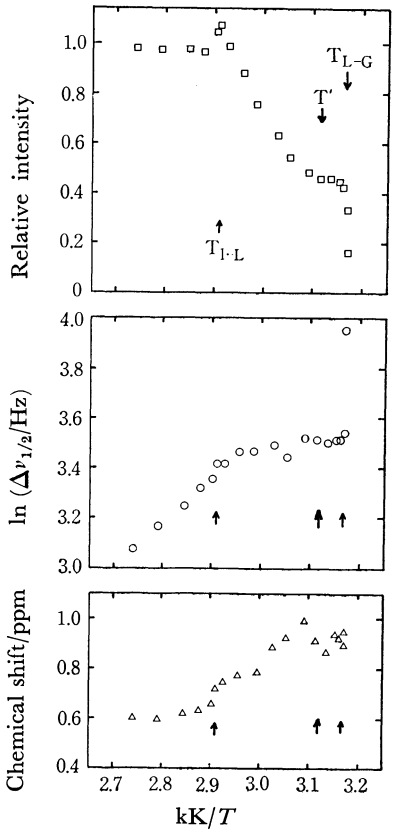

Fig. 3. ^{23}Na NMR parameters plotted against $1/T$ for Na(P+M) 26.4% system. The chemical shift is measured from an arbitrary point and its increasing number means an high field shift.

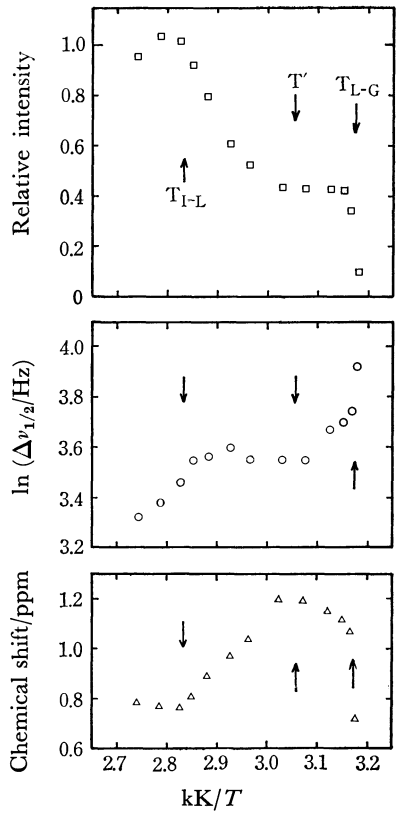

Fig. 4. ^{23}Na NMR parameters plotted against $1/T$ for Na(P+M) 27.2% system.

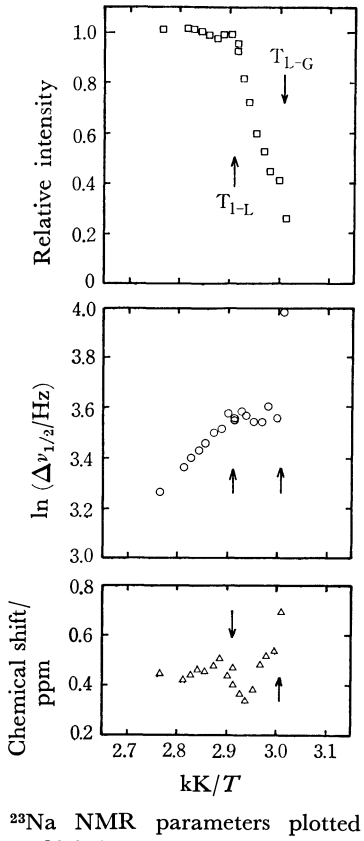

Fig. 5. ^{23}Na NMR parameters plotted against $1/T$ for NaS 20.0% system.

is expected to be negligible, neither linewidth change nor line distortion being observed.

When the temperature is set at T_{L-G}, the line width increases abruptly and the signal becomes undetectable within a few hours as the sample solidifies. No signal in the gel state could be observed.

The temperature dependence of the chemical shift of NaS system and that of Na(P+M) system are not alike. However the data within each system has a similar aspect.

Discussion

ESR Spectrum. The label **I** ESR signal in the isotropic phase is a triplet with the coupling constant A_{iso} of 14.9 G. However, the peak heights of the three lines are not the same, indicating that the phase is a micellar solution as expected. An extra small signal observed at 90 °C in the high field region is probably due to the molecules near the air- and/or glass-sample interface which tends to align while the bulk is still in isotropic state.

Two sets of triplets observed between T_{I-L} and T', one with the coupling constant of isotropic and the other of oriented state, indicates that the system is in the coexistence region of isotropic and liquid crystal phases. The variation in their relative intensities with temperature between T_{I-L} and T' is a further indication of the two phase region. The spectrum of the oriented label is comparable to that of a spin label in shear oriented hexagonal rods observed by Seelig and Limacher.[11] The order parameter S found for the oriented radical axis -0.19 is also that of the molecular axis since the direction of p electrons on N atom in the molecule **I** is parallel to the long axis of the molecule in all its trans configuration. The value $S=-0.19$ can be easily interpreted in terms of the hexagonal phase in which molecules aggregate to form rods with the rod axis parallel to the static magnetic field. The order parameter of a fictitious molecule, with the arrangement $\theta=\pi/2$ and no fluctuational motion of the molecular axis, should be -0.5. The difference between -0.5 and -0.19 is presumably due to the fluctuational motion of the chain and to a slight tilt of the radical axis or that of the molecular axis itself from the normal of the rod surface. The evidence for a magnetic field alignment of rods is obtained from the coupling constant. (1) The coupling constant $A_\perp$ of label **I** observed with sample rotated by 90° is large; $A_\perp(\text{obsd}) > A_{iso} = 14.9\text{ G} > A_{//}(\text{obsd}) = 11.8$ G. The spectrum is consistent with the calculated coupling constant $A_\perp = 16.5$ G for the rod structure with the rod axis perpendicular to the static magnetic field. (2) The spectrum of label **II** whose radical axis is perpendicular to the molecular axis is also consistent. The order parameter of the molecular axis in Na(P+M) calculated from the observed coupling constant 17.5 G and known constants $A_{xx}=6.1$ and $A_{zz}=32.1$ G[1f] is -0.3. The higher order found for molecular axis of label **II** than for label **I** is probably due to more rigid nature of the labeled molecule **II** itself.

The orders observed for the label **I**′(5, 10) and **I**′(1, 14) are lower than that of **I** and **I**′(12, 3), decreasing with the increasing distance between nitroxide group and the carboxyl group. Such a tendency is in line with the liquid crystal structure where the polar group is fixed at the surface of the rods, and resembles that observed in the chain motion in parallel bilayers of lyotropic systems.[1d,g]

The ESR line width is narrow, not changing with temperature in the liquid crystal region. A reasonable interpretation is that the motion of the chain in amphiphilic molecules is rapid enough[3] to average out the θ distribution, leaving only the effective $\langle\cos^2\theta\rangle$ in the spectrum. The increase in line width below T_{L-G} is due to that in rigidity of the chain and in the restriction of molecular rotation around its molecular axis.

No attempt was made to evaluate the equilibrium proportion of liquid crystal *vs.* isotropic liquid in the phase separation region from the apparent intensity of oriented molecules by two reasons. (1) A rather high proportion of molecules is in glass-sample interface of the capillary where the effect of the glass surface on the liquid crystal orientation should be considerable. (2) It is probable that the molecules turning into liquid crystal when their large porportion is already in an array of liquid crystal might not find ample space to form the rod in its preferred orientation along the magnetic field. The following result supports the above argument. No signal for reoriented molecule is detected 1 h after the sample capillary rotation by 90° in the static field at 55 °C while the molecular reorientation is confirmed 10 minutes after the sample rotation at 67 °C, 4 degrees below T_{I-L}, where the liquid crystal is only partly formed.

NMR Spectrum. The factor which determines the NMR line shape and relaxation times of spin 3/2 nucleus ^{23}Na is mainly the interaction between nuclear quadrupole moment Q and the electric field gradient at the nucleus expressed by a tensor $\boldsymbol{q}$.[4] The spin dipolar interaction between ^{23}Na and ^{1}H in the nearby water is negligible unless the system is almost rigid. The following discussion is based on the predominant contribution of the quadrupole interaction to the ^{23}Na spectrum.

Signal Intensities: The constant signal intensity in the isotropic phase has a value similar to that of the free ions in NaCl and in sodium acetate aqueous solutions of corresponding concentrations. No signal intensity is lost in satellites (*vide infra*).

In the liquid crystal region, the signal intensity decreases to 4/10 of isotropic value towards T' ($T' > T_{L-G}$). The phase of isotropic and liquid crystal coexistence has been known for NaS, NaP, and NaM systems in between isotropic and pure liquid crystal phases. The presence of such a phase is also demonstrated for Na(P+M) system by our ESR experiment. Gradual decrease in the NMR intensity is also an evidence of this phase. The loss of intensity is caused by the quadrupole splitting of the signal components m_s: $3/2 \rightarrow 1/2$ and m_s: $-1/2 \rightarrow -3/2$ with 3/10 of total intensity for each by the frequency $\pm\nu_Q S$, where $\nu_Q = e^2qQ/2h$, q is the principal value of the electric field gradient tensor $\boldsymbol{q}$ at the ^{23}Na nucleus, and S is the

order parameter for the principal axis of **q**, when the correlation time for the rod tumbling motion becomes longer than $(2\pi\nu_Q S)^{-1}$ by the liquid crystal formation.[4] The satellite would be out of our experimental frequency range. Evaluation of micelle tumbling rate necessary to collapse the quadrupole splittings may be helpful. The observed quadrupole splittings $\nu_Q S$ for lamellar NaL[2f] and NaP[2e] systems are 25—30 KHz. The splitting for hexagonal phase can be a half of these values[2c] or less, since the area per polar group is larger in hexagonal phase than in lamellar phase, suggesting a lower ordering. Thus $\nu_Q S$ can be estimated to be 15 kHz or less. The calculated correlation time for tumbling motion $\tau_\perp$[5] of a rod with its short axis $a=20$ Å[6] at 60 °C is 5×10^{-6} s, if the long to short axis ratio $b/a=25$, which is just short enough to average out the splitting of 30 kHz. A rod motion under the same conditions except for $b/a=50$ gives $\tau_\perp=4\times10^{-5}$ s, which satisfies $2\pi\nu_Q S\tau_\perp\simeq1$ for $\nu_Q S=4$ kHz. The rotational motion of a rod around the rod axis is also effective to collapse the splitting if the rod is not aligned parallel to the magnetic field, the motion being faster than the tumbling motion. Therefore, Na ion attached to the rod in free state, *i.e.* in the isotropic part, has a motion sufficiently fast to give a single signal even below T_{I-L}, while the ion on the rod in the aligned domain gives satellite signals.

The constant intensity 4/10 of the total in the range $T'>T>T_{L-G}$ indicates that the phase is purely liquid crystalline.

Spectrum Analysis: The line width remains constant while the liquid crystal is equilibrated with isotropic liquid($T_{I-L}>T>T'$). The intrinsic widths of both liquid crystal and isotropic parts should be indistinguishable since the width of the superposed signal is constant irrespective of a drastic composition change. A rapid local motion[2d] should be effective for determining the line width in both cases in order to meet the requirement that the width is the same regardless of the presence of a rod motion. In this case the line width is determined by the relation[1d,4]

$$\begin{aligned}1/T_2 &= (8\pi^2\nu_Q^2/5)f(\tau_c)\\ &= (8\pi^2\nu_Q^2/5)[\tau_c+(5/3)\tau_c(1+\omega_0^2\tau_c^2)^{-1}\\ &\qquad +(2/3)\tau_c(1+4\omega_0^2\tau_c^2)^{-1}],\end{aligned}\tag{1}$$

where τ_c is the correlation time for the local motion which changes the direction of the principal axis of **q**. The estimated value $\nu_Q=100$ kHz[7] is used to evaluate $f(\tau_c)$ for the observed width of 25—40 Hz. The result of $f(\tau_c)=1.4$—2.5×10^{-10} s and $\omega_0=1.6\times10^6$ s^{-1} leads to the extreme narrowing condition $f(\tau_c)=\tau_c$. The rapid local motion seems to be a wobbling motion of the principal axis of **q** for the following reasons. First, the correlation time for the local chain motion is of the same order as determined by deuterium NMR of β-CD_2 group in potassium hexadecanoate-water lamellar phase[1d] ($\tau_c\simeq10^{-10}$ s) and by the present ESR experiment ($10^{-10}\simeq\tau_c<10^{-9}$ s). Second, the observation that the order parameters and their temperature dependence of chain part and of Na^+ ion are comparable[2e,f] suggests that the Na^+ ion whose hydrated water is hydrogen bonded to carboxyl group moves as the chain moves around its equilibrium direction. The reported values of the quadrupole splittings 28—36 kHz for α-CD_2 deuterium NMR and 18—27 kHz for ^{23}Na NMR of unoriented lamellar NaL[2f] and NaP[2e] systems give the order parameters 0.11—0.14 with $\nu_Q(D)=(3/2)e^2qQ/h=250$ kHz[1d] for α-CD_2 and 0.18—0.27 with $\nu_Q(Na)=100$ kHz for Na^+. The former is about 1/3 of calculated value 1/2—1/3[2e] and the latter is about 1/4 of the calculated maximum value 1. The values of order parameters for D and Na are comparable and the observed to calculated ratios for both cases can be regarded to be similar.

The ion exchange phenomenon between rod sites or between a rod site and free state can also be considered as a mechanism of nuclear relaxation.[2a] However, the same ion exchange rate should be assumed for free and aligned rods in the liquid crystal domain in order to explain the common width for both states. This is not appropriate. The exchange phenomena, although not completely ruled out, can not be taken as an important mechanism.

Before concluding that the fast local motion contributes to the line width of the center line predominantly, it should be pointed out that the comparison of T_2 with T_1(Na) would confirm this point since the contribution of local motion to T_1 is dominant.

The broadening of the center line in the region $T'>T>T_{L-G}$ may be caused by the decreased local motion and to a certain extent by the onset of second order shift of the center line expressed by

$$\nu^{(2)} = (3/16)(\nu_Q^2/\nu_L)(\cos^2\theta-1)(9\cos^2\theta-1),\tag{2}$$

where ν_L is the Larmor frequency and θ is the angle between the principal axis of **q** and the direction of static magnetic field. The second order shift can contribute to the line width when there is appreciable distribution in θ. The constant term of (2) is 70 Hz when ν_Q is 100 and 1.8 kHz when it is 500 kHz.[2b] Since there is no observable line distortion, the signal must be the results of a time average of $\nu^{(2)}$ under the decreased local motion of **q** principal axis around θ_0, the ensemble average of θ, which is 90° for hexagonal phase unless the ion binding is in bridged form or there is some chain tilt. The average value of $\nu^{(2)}$ should appear on the chemical shift. A simple trial calculation of the θ dependent term of (2) under the conditions of uniform θ distribution[8] around θ_0 (90°) in the range between $\theta_0-\alpha$ and $\theta_0+\alpha$ shows that $\nu^{(2)}$ is a sharp function of ordering:

$$\delta(\alpha) = \langle(\cos^2\theta-1)(9\cos^2\theta-1)\rangle_\alpha,\tag{3}$$

$\delta(0)=1$(distribution around θ_0 is 0), $\delta(37°52')=0$, and $\delta(90°)=-0.53$, as shown in Fig. 6. The observed temperature dependence of chemical shift of Na(P+M) and NaS systems are not monotonous, showing no resemblance to each other at low temperature. A possible explanation for the different behavior in the two systems can be found in a slight difference in the ordering. At $T\simeq T_{L-G}$, where the local motion started to be highly restricted, the difference in shift behavior shoud be amplified. The equilibrium position $\theta_0=90°$, which gives the highest order for the hexagonal phase, takes $\nu^{(2)}=(3/16)\nu_Q^2/\nu_L$ giving rise to a low field shift. The present result

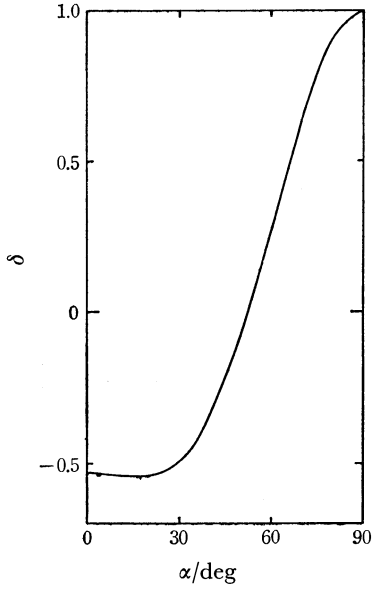

Fig. 6. Plot of $\delta(\alpha)$ against α.

	observed shift near T_{L-G}	ordering detected by ESR
Na(P+M)	low field shift	good
NaS	high field shift	poor

is explained by the difference in the ordering.

It is of importance to point out the possibility of evaluation of $\langle\cos^4\theta\rangle$ from shift data since a comparison of $\langle\cos^4\theta\rangle$ and $\langle\cos^2\theta\rangle$ can give information on the orientational direction θ_0 and the amplitude of orientational fluctuation separately, while $\langle\cos^2\theta\rangle$ available from the first order splitting of ^{23}Na satellite lines or from ESR parameter, alone gives the combined effect of these two factors.

In the gel phase, $T_{L-G} > T$, the θ distribution in (2) may be effective under the diminished time averaging effect of local motion, a contribution of the dipolar interaction bringing about further broadening.

The behavior of Na^+ ions in the Na(P+M) and NaS systems is obviously different from that of free ions even in the isotropic region, $T > T_{I-L}$. The widths of hydrated free Na^+ ions in 1.2 M NaCl and 0.8 M sodium acetate solutions are 3 and 4 Hz at 70 °C, respectively, being much narrower than those of Na(P+M) and NaS systems, 22—30 Hz (70—92 °C) and 26—36 Hz (72—89 °C), respectively. The apparent activation energies obtained by simple Arrhenius plots of these widths are 8 and 11 kJ mol^{-1} for NaCl and sodium acetate solutions while they are 16 and 19 kJ mol^{-1} for Na(P+M) and NaS systems, respectively. It is thus not probable that all or even the large portion of the counter ion is free in the isotropic region. Since there is no jump in the width at T_{I-L} in changing from isotropic to liquid crystal region, the origin of the line width and its temperature dependence should be found in the model in which all or most of the cations are attached to the micelles. The tensor q of hydrated Na^+ is not susceptible to an appreciable change in this narrow temperature range because of the high charge density at Na^+ ion.[9] The local molecular motion as in the liquid crystal region together with some contribution from a micelle tumbling motion should be responsible for the width. The increasing exchange rate (exchange between micelle sites and between micelle and free ion) at higher temperature might contribute to the apparent activation energy.

Concluding Remarks. The phase diagram of Na(P+M) system, which has not been given so far, is found to be similar to that of NaS, NaP, NaM in the concentration 26—28%. It is shown that the motions of the individual molecules and ions are reflected on the magnetic resonance spectra, and their motions change similarly across the phase trnasition points: the cation has fluctuational motions as the chain in the liquid crystal region. This observation is consistent with that of Abdolall *et al.* observed in the lamellar phase of NaP system.[2e]

The models we present for the observed phases are not completely based on concrete evidence, but they give the only interpretation consistent with both NMR and ESR data. It is desirable to have a better signal to noise ratio for further argument of line widths and shapes. T_1 data and the observation of the satellite signals are also important.

The Relative Rate Constants of Reactions of Oxygen Atoms with Several Olefins in Liquid Carbon Dioxide

Hidetoshi KARASAWA, Tai SASAMOTO, Rei YUGETA, and Shin SATO*

Department of Applied Physics, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

(Received August 19, 1978)

The relative rate constants of reactions of oxygen atoms with several olefins and 2-methylpropane have been determined in liquid carbon dioxide at −18 °C, using the γ-radiolysis of carbon dioxide in the presence of these hydrocarbons. They are : 1-butene, 1.0; *cis*-2-butene, 2.3; *trans*-2-butene, 3.0; 2-methylpropene, 2.9; 2,3-dimethyl-2-butene, 2.0; 2-methylpropane, 0.07. These relative values are very different from those obtained in the gas phase. A possible reason is discussed and a simple theoretical treatment is proposed for the competition between diffusion and reaction on the basis of the idea of a "collision set" in the liquid phase. The reaction of oxygen atoms with paraffin in liquid carbon dioxide seems to be faster than that in the gas phase. The reason is not clear at present.

The γ-radiolysis of liquid carbon dioxide is now believed to be a convenient source of oxygen atoms.[1] When an olefin is present in the γ-irradiated liquid carbon dioxide, the main products are the same compounds as those observed in the reaction of oxygen atoms with the olefin in the gas phase. By measuring the relative yields of products from a γ-irradiated liquid carbon dioxide solution in which two kinds of olefins are present, one can estimate the relative rate constants of reaction of oxygen atoms with olefins. According to Sakurai and his coworkers,[2] the relative rate constants of reaction of oxygen atoms with four olefins in liquid carbon dioxide at room temperature are 1.0 : 1.3 : 1.7 : 1.3 in the order of *cis*-2-butene, 2-methyl-2-butene, 2,3-dimethyl-2-butene, and cyclohexene. These relative values are different from those reported for the reaction of oxygen atoms in the gas phase (1.0 : 3.34 : 4.28 : 1.14).[3] This discrepancy is probably due to the fact that the diffusion process plays a role in determining the rate of reaction in the liquid phase.

The present experiment was attempted to confirm and explain this discrepancy and to gain an insight into the γ-ray-induced oxidation of olefins in liquid carbon dioxide.

Experimental

The carbon dioxide and hydrocarbons used were all purchased from the Takachiho Shoji Co. and were used after thorough degassing and distillation. No detectable impurities were observed by the gas chromatograph equipped with a 5 m dimethyl sulfolane column of 20% w/w on celite.

The sampling tube with a breakable seal attached was made of Pyrex glass, 10 mm in diameter. After a known amount of a hydrocarbon mixture had been condensed in the sampling tube at 77 K, carbon dioxide was introduced. The electron fraction of carbon dioxide in the solution was controlled at 0.98. After having been sealed, the sampling tube was transferred in a Dewar flask containing ice–sodium chloride slush at −18 °C and was shaken so as to homogenize the solute concentration in the solution.

The γ-irradiation was carried out at −18 °C at the dose rate of 1.1×10^{6} R h^{-1}, usually for two hours. After irradiation, the sampling tube was immersed into a Dewar flask containing petroleum ether slush at −80 °C and then the seal was broken. It took about one hour for the vaporization of carbon dioxide. The products thus obtained were subjected to gas chromatographic analysis after a known amount of cyclohexane or ethanol was added as the standard. The column used was 2 m polyethylene glycol 1500 of 15% w/w on Uniport B and was operated at room temperature. The products were identified by the retention time of the authentic sample.

Results

In every experiment, 1-butene was used as the competitive reactant, so that the relative rate constants were obtained against the rate constant of reaction of 1-butene with oxygen atoms. Since the gas chromatographic analysis of products was not very reproducible, as can seen from the figures, the following procedure was used for the determination of the relative rate constants and of the formation ratios of products.

The competition of two olefins A and B for oxygen atoms produced in the radiolysis of carbon dioxide may be described as follows:

$$CO_2 \rightsquigarrow CO + O \tag{1}$$

$$\left.\begin{aligned} O + A &\xrightarrow{\alpha} P_\alpha \\ &\xrightarrow{1-\alpha} P_{1-\alpha} \end{aligned}\right\} \tag{2}$$

$$\left.\begin{aligned} O + B &\xrightarrow{\beta} Q_\beta \\ &\xrightarrow{1-\beta} Q_{1-\beta} \end{aligned}\right\} \tag{3}$$

Then the G-value of the P_α product can be expressed by this equation:

$$G(P_\alpha) = G_0\frac{\alpha k_a[A]}{k_a[A]+k_b[B]}. \tag{4}$$

Here, G_0 is the total G-value of products of the reaction of oxygen atoms with two olefins, A and B, and k_a and k_b are the rate constants of reaction of oxygen atoms with two olefins. If $k_b/k_a>1$, the plots of $G(P_\alpha)$ as a function of the mole fraction of [B] give a concave curve, while if $k_b/k_a<1$, a convex curve is found.

Now let us introduce a weighted mole fraction:

$$X = \frac{f[B]}{[A]+f[B]}, \tag{5}$$

where f is a factor to be estimated. If the f factor is equal to the ratio k_b/k_a, the plots of $G(P_\alpha)$ as a

function of X will give a straight line:

$$G(\mathrm{P}_\alpha) = G_0\alpha(1-X). \quad (6)$$

A similar linearity can be obtained for the products of the reaction with B olefin:

$$G(\mathrm{Q}_\beta) = G_0\beta X. \quad (7)$$

Consequently, once an appropriate value of f is obtained, all of the addition products formed in Reactions 2 and 3 should give straight lines when the G-values

are plotted as a function of the weighted mole fraction X.

Figure 1 shows such plots for the competition of 1-butene and *cis*-2-butene. Calculations with trial and error showed that the error introduced in the estimation of f was less than 10% in all cases examined except for the mixture of 1-butene and 2-methylpropane.

When more than two addition products are formed in the reaction of oxygen atoms with olefin, the ratio

of the slopes of the two straight lines obtained from the plots of $G(P_{\alpha 1})$ and $G(P_{\alpha 2})$ corresponds to the formation ratio of the two products, $P_{\alpha 1}$ and $P_{\alpha 2}$. In the case of the mixture of 1-butene and *cis*-2-butene (Fig. 1), 2-butanone is a common product from two olefins. In such a case, the formation ratio was estimated from the intercepts of the linear relations at $X=0.0$ and 1.0.

Figures 2, 3, and 4 show the results obtained with the mixtures of 1-butene and *trans*-2-butene, 1-butene and 2-methylpropene, and 1-butene and 2,3-dimethyl-2-butene, respectively. In every case, several minor products were observed, the total yield of which was estimated as about 10% of the main addition products by measuring the peak areas in the gas chromatograms. In the case of 2,3-dimethyl-2-butene, the total *G*-value of the addition products is about 10% smaller than those obtained with other olefins. This fact is consistent with the observation that the fraction of the fragmentation products in the gas phase reaction of oxygen atoms with 2,3-dimethyl-2-butene is larger than those obtained with other olefins.[4] Figure 5 shows the largest amounts of minor products observed

Table 2. The relative rate constants of reaction of oxygen atoms with several hydrocarbons in liquid carbon dioxide and in the gas phase[3)]

Hydrocarbon	Relative rate	
	In CO_2 at -18 °C (This work)	In the gas phase at room temp[a)]
1-Butene	1.0	1.00
cis-2-Butene	2.3	4.13
trans-2-Butene	3.0	4.91
2-Methylpropene	2.9	4.35
2,3-Dimethyl-2-butene	2.0[b)]	13.8
2-Methylpropane	0.07	0.015[c)]

a) Because of the low activation energies, the relative rates shown in this Table are almost the same as those at the temperature of -18 °C. b) This value is somewhat smaller than that expected from the previous work.[2)] The explanation of the discrepancy is not yet clear. c) Calculated on the basis of $k_{\text{butane}}/k_{\text{2-methylpropene}}=0.0018$[3)] and $k_{\text{2-methylpropane}}/k_{\text{butane}}\simeq 2$.[6)]

with three different mixtures which did not show the linear relationship with X. This is probably due to the fact that these minor products are formed in the reaction of radicals produced in fragmentation processes with hydrocarbons.

Figure 6 shows the competition between 1-butene and 2-methylpropane. Since the value of f was very small, the error introduced in its estimation was probably about 20%.

The formation ratios and the relative rate constants thus obtained are summarized in Tables 1 and 2, together with those obtained in the gas phase and in liquid nitrogen.[4–6)]

Discussion

Reaction Mechanism. As Table 1 shows, the main addition products obtained in the present experiment are the same as those obtained by Cvetanović for the gas phase reaction of oxygen atoms.[4)] The difference in their formation ratios may be explained in terms of the solvent effect.

According to the Cvetanović mechanism, oxygen atoms in the ^3P state mainly add to the less substituted of the two doubly bonded carbon atoms and the initial adduct rearranges to the final products by ring closure (to form epoxide) and by migration of an H atom or alkyl group, from the C atom to which the oxygen atom becomes attached to the other C atoms of the original bond (to form carbonyl compounds). In the present reaction system, the migration of an H atom or an alkyl group may be somewhat restricted by the solvent, carbon dioxide. This effect seems to correspond with the observation that the fraction of epoxide is larger than that of carbonyl compounds, compared with that in the gas phase, in every olefin. Exactly the same effect can interpret the difference in the *cis-trans* ratio of the two 2-butene oxides produced in the reaction of 2-butene ; *i.e.*, the rotation around the C–C axis in the initial adduct is more restricted in liquid carbon dioxide than in the gas phase. In the liquid nitrogen solution, however, Hirokami and Cvetanović found that the formation ratios of epoxide/carbonyl compounds obtained with propylene, 1-butene, and 2-methylpropene are consistent with those obtained in the gas phase at room temperature.[5)] This discrepancy seems to suggest that there is a small but definite interaction between the initial adduct and carbon dioxide.

Moreover, the comparison of the formation ratios listed in Table 1 suggests that the ratio between the addition of oxygen atoms to the less substituted and that to the more substituted of the two doubly bonded carbon atoms is not dependent upon the phase but on the temperature at which the reaction occurs ; *i.e.*, the yields of 2-butanone, which is the product formed through the addition reaction of oxygen atom to the more substituted carbon atom in the reactions of 1-butene and of 2-methylpropene, are very small in liquid nitrogen compared with those obtained in the gas phase and in the carbon dioxide solution -18 °C.

The quantitative analysis of the fragmentation products could not be carried out because of the experimental difficulty of the measurement of the small peaks appearing in the gas chromatogram. Only the largest minor products obtained with three systems are shown in Fig. 5. The formation of propanal from the solution containing 2-butene and of acetone from the solution containing 2-methylpropene may be explained by the decomposition of the initial adduct followed by the radical-radical reactions.

When 2-methylpropane was used as the solute, the main products observed were alcohols: 2-methyl-1-propanol and 2-methyl-2-propanol. With the increase in irradiation time, 2-methylpropene oxide and 2-methylpropanal became important products. These compounds must be formed through a secondary reaction: *i.e.*, the reaction of oxygen atoms with 2-methylpropene eventually produced in the system. A similar observation can always be made when paraffin molecules are used as the solute.[7)]

Relative Rate Constants. As Table 2 shows, the differences in relative rate constants obtained with six hydrocarbons in liquid carbon dioxide are much smaller than those obtained in the gas phase, which suggests that the diffusion process plays a role. However, the difference between 1-butene and other butenes in the relative rate constants cannot simply be explained by the assumption that all of the reactions of oxygen atoms with olefins in the liquid phase are diffusion-controlled.

It is well known that collisions between two species A and B in a solvent occur in sets. Therefore, the total collision frequency, Z_{AB}, may be expressed as the product of the average collision number, n, in a collision set and the diffusion-controlled collision frequency, k_D.

$$Z_{AB} = n\,k_D \tag{8}$$

$$k_D = 4\pi(D_A+D_B)(r_A+r_B) \tag{9}$$[8)]

Here D is the diffusion coefficient and r is the collision radius.

Now let us assume that the p fraction of the collision is effective ; then the rate constant of the reaction

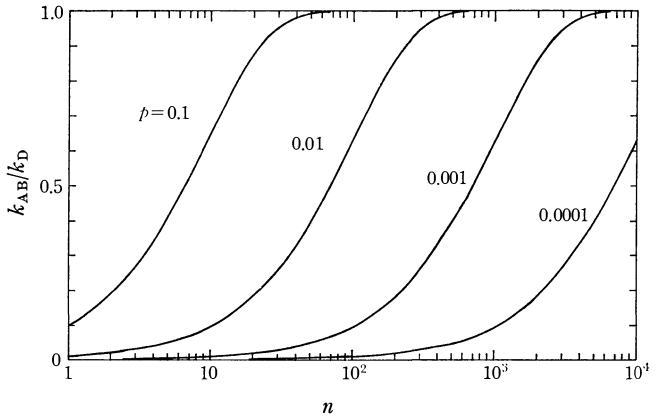

Fig. 7. The ratio of k_{AB}/k_D as a function of the average collision number n in a collision set at different values of effective collision fractions.

between A and B may be expressed as follows:

$$k_{AB} = k_D[1-(1-p)^n]. \quad (10)$$

Here, $(1-p)^n$ corresponds to the fraction of collisions which do not lead to the reaction. At the two extreme cases, $p \ll 1$ and $p \approx 1$, Eq. 10 is converted into Eqs. 11 and 12, respectively.

$$k_{AB} = npk_D = pZ_{AB} \quad (11)$$

$$k_{AB} = k_D \quad (12)$$

The former is the usual expression for the reaction-controlled reaction and the latter for the diffusion-controlled reaction. Figure 7 shows the k_{AB}/k_D ratio as a function of the average collision number in a collision set at several p values.

Recent measurements of the absolute rate constants and of the activation energies for the reaction of oxygen atoms with olefins in the gas phase[9,10] allowed us to estimate the p values. By taking 2.0×10^{11} l mol^{-1} s^{-1} as the collision frequency between oxygen atoms and olefins in the gas phase at -18 °C (the collision diameter was assumed to be 4.0 Å), we estimated the following p values : 0.01 for 1-butene, 0.05 for other butenes, and 0.3 for 2,3-dimethyl-2-butene.

On the other hand, the estimation of n is a very difficult problem. Several theoretical treatments have been proposed[11,12] and have suggested $n=10$—100 in the solutions which are not too viscous. We calculated the n values so as to satisfy the following equation:

$$\frac{k}{k_{1\text{-butene}}} = \frac{1-(1-p)^n}{1-(1-p_{1\text{-butene}})^n}. \quad (13)$$

The values obtained were 30—50 for butenes and 70 for 2,3-dimethyl-2-butene. The fact that a somewhat larger n value was obtained for 2,3-dimethyl-2-butene may be due to the fact that the value of k_D for this compound is smaller than that for butenes because of the large molecular dimension. If k_D for 2,3-dimethyl-2-butene is assumed to be 10% smaller than that for butenes, the number of 50 can be obtained for n. As the conclusion of this calculation, we may state that the reactions of oxygen atoms with *cis*-, *trans*-2-butenes, 2-methylpropene, and 2,3-dimethyl-2-butene in liquid carbon dioxide are almost diffusion-controlled.

The relative rate constant of reaction of oxygen atoms with 2-methylpropane obtained in liquid carbon dioxide was five times that obtained in the gas phase when the rate constant of 1-butene was taken as unity in both phases, as is shown in Table 2. We have recently measured the competition of cyclohexane and cyclohexene for oxygen atoms, by using a method similar to that described in the present paper, and found that k(O+cyclohexane)/k(O+cyclohexene)$=$0.03.[7] This value conforms to the present result, k(O+2-methylpropane)/k(O+1-butene)$=$0.07, because the ratio of k(O+2-methylpropane)/k(O+cyclohexane) can be estimated as about unity in the gas phase,[6] and k(O+cyclohexene) in liquid carbon dioxide is 1.3 times k(O+*cis*-2-butene).[2]

In order to apply Eq. 13 to the competition between 2-methylpropane and 1-butene, however, we have to assume that $n \approx 700$. If $n=700$ is correct, the difference between 1-butene and other olefins in relative rate constant cannot be explained. We have no proper interpretation for this discrepancy at present.

Reacting Species. In the foregoing discussion, all of the addition products are treated as the products of the reaction of oxygen atoms in the ^{3}P state with olefins. In the radiolysis of carbon dioxide, however, active species other than oxygen atoms in the ^{3}P state can be expected to be formed, such as oxygen atoms in the ^{1}D state, CO_3, and ionic species.

The present analysis is based on the experimental fact that the observed addition products are very similar to those obtained in the gas phase reaction of oxygen atoms with olefins. Consequently, if active species other than oxygen atoms in the ^{3}P state should react with olefins exactly in the same manner as do oxygen atoms, we cannot discriminate these species from the ^{3}P oxygen atoms. The species CO_3 might be a candidate.

The participation of ^{1}D oxygen atoms may be ignored because of the high quenching efficiency of carbon dioxide.[13] In the present experiment, we often observed the formation of various alcohols, the formations of which were not reported in the gas phase reaction of oxygen atoms with olefins. This fact suggests that ionic species such as O^- ions are produced in the present system, although they cannot be major reacting species.[14]

Electrochemical Behavior of the Oxygen Radical. IV. The Reaction Mechanism of the Electrogenerated Hyperoxide Ion with Bis(acetylacetonato)cobalt(II) in Dimethyl Sulfoxide and Acetone†

Setsuko KUDO†† and Akio IWASE*

Department of Chemistry, Faculty of Science, Yamagata University, Yamagata 990

(Received March 27, 1978)

The reaction mechanism of the electrogenerated hyperoxide ion with bis(acetylacetonato)cobalt(II) in dimethyl sulfoxide and acetone has been investigated. The reaction was conducted in a 0.05 mol dm^{-3} TBAP solution at 20 °C in an open system. $Co(acac)_2$ reacted with the hyperoxide ion which was generated by the controlled potential electrolysis of dissolved oxygen to afford the following product, $[(acac)_2\ Co{-}O_2{-}Co(acac)_2]^{2-}$. The complex was separated in solution by column chromatography using alumina as the adsorbent. The electronic spectrum and oxidation state are discussed.

In Part III of this series,[1] the mechanism of the polarographic catalytic reduction of disso'ved oxygen in dimethyl sulfoxide in the presence of bis(1,3-diketonato)cobalt(II) complexes was discussed. In this paper, the reaction mechanism of bis(acetylacetonato)-cobalt(II) complex, $Co(acac)_2$ with electrogenerated hyperoxide ion in dimethyl sulfoxide (DMSO) and acetone will be reported in more detail. Moreover, the reaction product, μ-peroxo-dicobalt(II) complex, has been separated by column chromatography using alumina as an adsorbent.

Experimental

Apparatus and Reagents. D.c. polarograms were recorded with a PA 101 Yanagimoto Polarograph and a PT-P8 Yanagimoto Potentiostat, by the same procedures as described in a preceding paper.[1] The capillary used had an m value of 1.057 mg/s and drop time of 5.1 s/drop at -1.0 V *vs.* SCE when measured in an air-free 0.05 mol dm^{-3} TBAP(tetrabutylammonium perchlorate)–DMSO solution at 49 cm of effective height of mercury ($m^{2/3}\ t^{1/6} = 1.364\ mg^{2/3}\ s^{-1/2}$).

Cyclic voltammetric measurements were made with a three-electrode potentiostat constructed with a LS-LC Hokuto Denko Linear Scanner and a PT-P8 Yanagimoto Potentiostat. The voltammograms were recorded on a F-32 Riken Denshi X-Y plotter. The working electrode for cyclic voltammetry was a hanging mercury drop electrode (surface area : 0.033 cm^2).

A VE-8 Yanagimoto Controlled Potential Electrolyser was used for the controlled potential electrolysis of dissolved oxygen, at -1.15 V *vs.* SCE at room temperature (*ca.* 20 °C). For the controlled potential electrolyses, a mercury pool electrode was used as cathode. The electrolytic cell was the same as reported previously.[2]

The electronic spectra were measured with a Spectronic 88-UV Shimadzu-Bausch & Lomb spectrophotometer.

All voltammetric measurements were conducted at (25± 0.2) °C.

Bis(acetylacetonato)cobalt(II) and tris(acetylacetonato)-cobalt(III) complexes of reagent grade were obtained from Dojin Yakukagaku Kenkyusho. DMSO(Wako Pure Chemical) and acetone (Koso Chemical), guaranteed reagents were used without further purification (water contents were below 0.2%). TBAP for polarography from Nakarai Chemicals was used as the supporting electrolyte.

The alumina used for the chromatographic separation of the reaction product was Alumina 60(Merk). The separation of reaction product was carried out by using an alumina column of diameter 1.2 cm and height 30 cm.

Procedure. The solution for controlled potential electrolysis (40 cm^3), containing 2×10^{-3} mol dm^{-3} $Co(acac)_2$ and 0.05 mol dm^{-3} TBAP in DMSO(B) or acetone(A), was placed in an electrolytic cell and electrolyzed for 18 min on a mercury pool electrode. Subsequently the electrolyzed solution was transferred to a clean flask and allowed to stand overnight at room temperature. This solution (30 cm^3) was fed into the top of the column bed, which had been washed with acetone or DMSO. The column was operated by the usual chromatographic procedures. In the case of solution A, one of the green complexes, A-1, was eluted with acetone and the other green complex, A-2, was eluted with DMSO. In the case of solution B, the major part of the green complex, B-1, was eluted with DMSO. In both cases, some original complex remained on top of the column under these conditions.

The eluates were used for the polarographic and the spectrophotometric measurements because of the difficulty of preparing crystals.

Results and Discussion

The typical cyclic voltammograms of dissolved oxygen in acetone and DMSO with 0.05 mol dm^{-3} TBAP are shown in Fig. 1. The rate of voltage change was 0.05 V/s. The experimental results were very similar to that reported by earlier investigators.[3] Curve 2 and curve 4 represent cyclic voltammograms for oxygen in the presence of $Co(acac)_2$. It is clear that the heights of cathodic peaks in both cases are larger than those of curves 1 and 3. This catalytic current is clearly based on the reduction of oxygen which is reproduced from the reaction of hyperoxide ion with $Co(acac)_2$ complex at the electrode surface. Conversely, the heights of the anodic peaks decreased by the addition of the complex.

For the controlled potential electrolysis in acetone and DMSO, the reaction was followed by taking the visible spectrum of the solution at different times. Those spectra are shown in Figs. 2 and 3. In Fig. 2, curve 1 was obtained from a solution containing 2×10^{-3} mol dm^{-3} $Co(acac)_2$ and 0.05 mol dm^{-3} TBAP in DMSO before electrolysis. The spectrum consists of

a peak split at 520 and 510 nm (molar absorption coefficient : $\varepsilon=30$ dm^3 mol^{-1} cm^{-1}), which corresponds to $^4T_{1g}(F)\rightarrow{}^4T_{1g}(P)$.[4] For curves 2, 3, and 4 a new strong peak appeared in the neighbourhood of 590 nm with a shoulder at 440 nm, and the intensity increased with respect to the time after electrolysis. In the case of acetone, the spectrophotometric profile of the solution after electrolysis also showed a similar tendency (Fig. 3). The new absorption band in Figs. 2 and 3 can be attributed to the absorption of the μ-peroxo-dicobalt(II) complex, formed by the disproportionation of the $Co(acac)_2O_2^-$ complex in acetone or DMSO (Scheme 1).

In Fig. 4, curves 1 and 2 are shown for complexes A-1 and B-1. In curve 1, the absorption peak appeared

at 597 nm in acetone and in curve 2, at 590 and 440 nm (shoulder) in DMSO. The band widths were usually about 110 nm. The molar absorption coefficients are unknown since it is difficult to obtain the solids. Attempts to isolate the μ-peroxodicobalt(II) complex as crystals were unsuccessful for two reasons: (1) increasing the time of electrolysis did not change the yield and (2) the complex was contaminated by TBAP and consequently difficult to crystallize under the experimental conditions. In the case of the $Co(dpm)_2$ complex, however, the $[(dpm)_2Co{-}O_2{-}Co(dpm)_2]^{2-}$ complex was isolated as crystals[5] (dpm represents an anion of dipivaloylmethane). The molar absorption coefficient and band width of the peak at 588 nm was 410 dm^3 mol^{-1} cm^{-1} and 110 nm respectively (curve 3 in Fig. 4).

It is well documented that the most common geometry of ligands around the cation in the high spin state cobalt(II) complex are octahedral, square pyramidal, and tetrahedral. Generally in an octahedral field, there are two d-d absorption bands at approximately 500 and 1200 nm. The intensity of this band is always low in octahedral complexes and it is

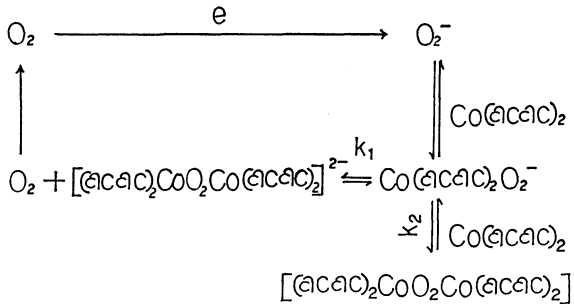
not known where the molar absorption coefficient exceeds 50 dm^3 mol^{-1} cm^{-1}.[6] It is known that the intensity in tetrahedral field is usually close to the molar absorption coefficient of 700 dm^3 mol^{-1} cm^{-1}.[6] On the other hand, the intensity at 588 nm for the $[(dpm)_2Co–O_2–Co(dpm)_2]^{2-}$ complex which has a square pyramidal structure[5,7] shows an intermediate intensity between that of tetrahedral and octahedral cobalt(II). The spectrophotometric profiles of the complexes A-1 and B-1 in the visible region are similar to the spectrum of the Co(II)-dpm complex(curve 3 in Fig. 4). Consequently, it appears that the two absorption bands at 17000 and 23000 cm^{-1} for the Co(II)-acac complexes in Fig. 4 are associated with a square pyramidal structure. From these results, we can consider A-1 and B-1 complexes as the same.

Typical polarograms of the above complex and tris(acetylacetonato)cobalt(III) complex are shown in Fig. 5. In Fig. 5, curves 1, 2, and 3 were obtained from a solution of the complexes, A-1, B-1, and Co(acac)$_3$ containing about 0.05 mol dm^{-3} TBAP. In a DMSO medium, the Co(acac)$_3$ complex undergoes stepwise reduction to Co(II) and Co(O). The half-wave potentials of the first Co(III)→Co(II) and the second Co(II)→Co(O) waves are −0.29 and −2.13 V *vs.* SCE. On the other side, for curve 1, the reduction wave at −1.8 V was caused by the reduction of aldol condensation products of acetone[8] in A-1. The complex did not show a reduction wave under these conditions. For curve 2, the reduction wave at −0.85 V can be attributed to the presence of other complexes produced during the electrolysis, namely, the μ-peroxo-dicobalt(II) complex is unreducible.

In Fig. 6, the polarogram of the complex, A-2, is shown. This complex gives two waves in DMSO containing 0.05 mol dm^{-3} TBAP, the first half-wave potential at −0.05 V corresponding to oxidation to the +3 cobalt state and the second at −0.85 V probably corresponding to the reduction to the $[Co–O_2–Co]^{2-}$ state. The limiting currents of both waves were almost equal to each other and diffusion controlled. The second wave was characteristically irreversible and the half-wave potential was the more negative side than that of the oxygen molecule under the same conditions, thought to be due to the reduction of the bridging group, $–O_2–$, in the μ-hyperoxide-dicobalt(II) complex. Recently, it has become apparent that the catalytic electrode reaction consists of two distinct simultaneous chemical reactions. Accordingly, the μ-hyperoxo-dicobalt(II) complex may also be formed simultaneously. There is no doubt that such a reaction results in a lowering of the rate of the oxygen regeneration.

The catalytic electrode reaction mechanism has been estimated as follows:



Scheme 1.

In this scheme, the k_1 path ocurred through a six coordinate intermediate, $[Co(acac)_2O_2^-]_2$. Moreover, the k_1 path was easier than the k_2 path in aprotic solvents. Thus, in the k_2 path the releasing process of the solvent molecule in a solvated complex, $Co(acac)_2(sol)_2$ is the rate-determining step.

Gas-Chromatographic Studies of the Thermal Decomposition of Nitropentaammine-, Dinitrotetraammine-, Trinitrotriammine-, Tetranitrodiammine-, and Pentanitroamminecobalt(III) Complexes in the Solid State

Sukeo ONODERA*

Department of Chemistry, Faculty of Science, Tokyo University of Science, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received July 24, 1978)

The gas-chromatographic study of the thermal decompositions of the complexes, $[Co(NO_2)(NH_3)_5]Cl_2$ (I), *cis*- (II) and *trans*-$[Co(NO_2)_2(NH_3)_4]Cl$ (III), $[Co(NO_2)_3(NH_3)_3]$ (IV), $K[Co(NO_2)_4(NH_3)_2]$ (V), and $K_2[Co(NO_2)_5NH_3]$ (VI) are reported. The EGA curves for these complexes show that the compounds decompose in two or three stages. In the first stage (*ca.* 140—240 °C), all complexes evolve nitrogen with the evolution of ammonia and/or nitrogen monoxide. The second stage (*ca.* 210—300 °C) has been ascribed to the evolution of ammonia from the intermediate dissociation products of compound I, II, and III. The third stage (*ca.* 275—350 °C) has been ascribed to the evolution of nitrogen monoxide from the solid residue with the exception of IV.

The thermal decomposition of the cobalt(III) nitroammine complexes in the solid state are usually studied by thermogravimetry (TG)[1-3] and differential thermal analysis (DTA).[2-5] The various steps in the decomposition often overlap and a mixture of gases is evolved, the composition of the mixture and the residual product depending upon temperature. In TG and DTA, these aspects are often not revealed and consequently the complexity of the decomposition is overlooked. Thus evolved gas analysis (EGA) is required in order to obtain more exact information on the decomposition processes of the compounds.

Although gas-chromatographic (GC) analysis may be expected to be useful in determining the composition of the gaseous decomposition products of the metal ammine complexes, few papers have been published on the GC study of the thermal dissociation, even in simple metal complexes.[6-8] The present work illustrates the applicability of pyrolysis-gas chromatography in elucidating the mechanism of the cobalt(III) nitroammine complexes.

Experimental

Materials. The complexes, $[Co(NO_2)(NH_3)_5]Cl_2$, *cis*- and *trans*-$[Co(NO_2)_2(NH_3)_4]Cl$, $[Co(NO_2)_3(NH_3)_3]$, $K[Co(NO_2)_4(NH_3)_2]$, and $K_2[Co(NO_2)_5NH_3]$ were prepared according to the methods given in the literature[9] and identified by infrared analysis. Samples ranging in particle size from 100 to 200 mesh were used.

Apparatus and Procedure. The EGA apparatus employed has been described previously.[8a] The procedure used for the pyrolysis of the sample and the analysis of the gaseous products are essentially the same as reported previously.[8a] The GC patterns for the various pure substances are shown in Fig. 1.

Results and Discussion

The EGA curves for the cobalt(III) nitroammine complexes in the 25 to 400 °C temperature range under helium are given in Figs. 2 and 3. The curves of water evolved have not been drawn since it was impossible to exactly determine the water in the gaseous products by means of the GC techniques employed in the present work. Although the chemical analysis of the gaseous products evolved from nitropentaammine- and trinitrotriamminecobalt(III) complexes *in vacuo* have been conducted by Clark *et al.*[10] and the EGA curves of some halogenopentaamminecobalt(III) complexes reported by Wendlandt and Smith[2] and Smith,[5] the EGA curves for *cis*- and *trans*-$[Co(NO_2)_2(NH_3)_4]Cl$, $[Co(NO_2)_3(NH_3)_3]$, $K[Co(NO_2)_4(NH_3)_2]$, and $K_2[Co(NO_2)_5NH_3]$ seem to be the first to appear. The EGA curves of the cobalt (III) nitroammine complexes were reproducible under the experimental conditions employed in the present work.

nitrogen with the evolution of ammonia and/or nitrogen monoxide. The second stage (*ca.* 210—300 °C) has been ascribed to the evolution of ammonia from the intermediate dissociation products for $[Co(NO_2)(NH_3)_5]Cl_2$ and $[Co(NO_2)_2(NH_3)_4]Cl$. The third stage (*ca.* 275—350 °C) has been ascribed to the evolution of nitrogen monoxide from the solid residue with the exception of $[Co(NO_2)_3(NH_3)_3]$. The temperature ranges and the number of peaks are in agreement with those from the DTA curves reported by earlier workers,[3-5] except that the third peak can not be found in the case of DTA.

Decomposition of the Complexes (Stage I). Upon heating the cobalt(III) nitroammine complexes under helium, the yellow-brown compounds, especially $K[Co(NO_2)_4(NH_3)_2]$ and $K_2[Co(NO_2)_5NH_3]$, changed to orange-red in the 130 to 150 °C temperature range prior to the evolution of gas. Beattie and Sathell[11] and Doron[12] concluded that this phenomenon indicates that most of the nitro-form in the complexes is thermally converted to the nitrito-form.

Upon heating the complexes to temperatures higher than 150 °C, the yellow-brown compounds, $[Co(NO_2)(NH_3)_5]Cl_2$ and $[Co(NO_2)_2(NH_3)_4]Cl$, changed to greenish yellow ones, while the orange-red compounds, $[Co(NO_2)_3(NH_3)_3]$, $K[Co(NO_2)_4(NH_3)_2]$, and $K_2[Co(NO_2)_5NH_3]$, changed to black-brown ones, with the evolution of gas. In addition, thin layer chromatograms for the greenish yellow compounds, developed by a mixed solution, $HClO_4$–DMSO–CH_3OH (0.3 : 60 : 40), on Merck's silica gel G, were characterized by the appearance of new spots, which have been attributed to the tetraamminedianiono- and triammine-trianiono-complexes.[13]

The polarograms for the greenish yellow compounds, recorded in a 0.5 mol dm^{-3} K_2SO_4 containing 0.005% gelatin by use of a Yanagimoto KM-85-3 pen recording polarograph, showed that the limiting diffusion currents of the first wave, attributed to the reduction of cobalt(III) to cobalt(II) for the nitroammine-complexes,[14] decreased in comparison with the original compound. The polarograms for the black-brown compounds were characterized by a decreasing of the limiting diffusion currents of the first wave and a slight decreasing of the second wave, which has been attributed to the reduction of cobalt(II) to cobalt(0) for the nitroammine-complexes,[14] in comparison with those of both for the original complexes.

These results described together with earlier data,[2,16,17] suggest that the thermal decomposition of cobalt(III) nitroammine complexes under helium as:

$[Co(NO_2)(NH_3)_5]Cl_2$

$\xrightarrow{150\text{—}240\,^\circ C}$ $[CoCl(NO_2)(NH_3)_4]Cl + NH_3$

$\xrightarrow{150\text{—}240\,^\circ C}$ $[CoCl_2(NO_2)(NH_3)_3] + NH_3$

$\xrightarrow{150\text{—}240\,^\circ C}$ low ammine cobalt(II) complexes

$[Co(NO_2)_2(NH_3)_4]Cl$

$\xrightarrow{150\text{—}220\,^\circ C}$ $[CoCl(NO_2)_2(NH_3)_3] + NH_3$

$\xrightarrow{150\text{—}220\,^\circ C}$ low ammine cobalt(II) complexes

for other complexes,

$$[Co(NO_2)_3(NH_3)_3] \xrightarrow{140-210\,^\circ C} Co_2O_3 + N_2 + H_2O$$

$$K[Co(NO_2)_4(NH_3)_2] \xrightarrow{150-225\,^\circ C} \begin{cases} Co_3O_4 + KNO_3 + \text{gaseous products} \\ \text{low nitro cobalt(II) complexes} \end{cases}$$

$$K_2[Co(NO_2)_5NH_3] \xrightarrow{150-230\,^\circ C} \begin{cases} Co_3O_4 + KNO_3 + \text{gaseous products} \\ \text{low nitro cobalt(II) complexes} \end{cases}$$

Since large quantities of water and nitrogen were evolved in this stage, it has been concluded that ammonium nitrite was an intermediate dissociation product.

The decomposition temperatures at which the first maximum peaks observed on the EGA curves for the cobalt(III) nitroammine complexes in Figs. 2 and 3 are in the same order as the minimum temperatures where the color changes as observed by Matsui and Nakanishi.[15] This order for the cobalt(III) nitroammine complexes in Figs. 2 and 3 is related to the polarographic reduction potentials of cobalt(III) to cobalt(II) for the complex ions reported by Willis, Friend, and Mellor.[14] Plots of the above temperatures *versus* the potentials did not however give a strick linear relationship. Since the polarographic reduction potentials of the complex ions are considered to measure the relative electron affinities of the central metal ions, it has been concluded that the thermal stability of the cobalt(III) nitroammine complexes is dependent upon the electron affinity of the central cobalt(III) ion.

Subsequent Decomposition (Stage II). Upon heating $[Co(NO_2)(NH_3)_5]Cl_2$ and $[Co(NO_2)_2(NH_3)_4]Cl$ to temperatures higher than 230 °C, it was observed that the greenish yellow compounds, formed at the first stage, subsequently changed to grayish blue ones with the evolution of gas. In addition, the polarograms for the grayish blue compounds showed that the limiting diffusion currents of the first wave disappeared and those of the second wave decreased slightly in comparison with those of the both waves for the original complexes. These results appear to indicate that the greenish yellow compounds, probably $[CoCl(NO_2)(NH_3)_4]Cl$, $[CoCl_2(NO_2)(NH_3)_3]$, and $[CoCl(NO_2)_2(NH_3)_3]$, decomposed to form Co_2O_3, which has poor solubility in water.

The second EGA peaks of $[Co(NH_3)_6]Cl_3$, $[CoCl(NH_3)_5]Cl_2$, and *trans*-$[CoCl_2(NH_3)_4]Cl$ in a previous paper[8a] were obtained in the same temperature range (280—350 °C), although the numbers of coordinated-chloride ions are different, while, the second EGA peaks of $[Co(NO_2)(NH_3)_5]Cl_2$ and $[Co(NO_2)_2(NH_3)_4]Cl$ shifted to lower temperatures with the increase in the numbers of coordinated-nitrite ions. These results indicate that $[CoCl_3(NH_3)_3]$ is an intermediate dissociation product for the above three compounds, while $[CoCl_2(NO_2)(NH_3)_3]$, is for the nitropentaammine-complex, and $[CoCl(NO_2)_2(NH_3)_3]$, is for the dinitrotetraamine-complex.

Subsequent Decomposition (Stage III). When the complexes were heated to temperatures higher than 275 °C, it was observed that the grayish blue compounds, formed by heating $[Co(NO_2)(NH_3)_5]Cl_2$ and $[Co(NO_2)_2(NH_3)_4]Cl$ in stage II, changed to blue-black ones while the black-brown compounds, formed by heating $K[Co(NO_2)_4(NH_3)_2]$ and $K_2[Co(NO_2)_5NH_3]$ in stage I, changed to black ones with the evolution of nitrogen(II) oxide. In addition, the polarograms for the above solid residues were characterized by a decrease or the complete disappearance of the limiting diffusion currents of the second wave in comparison with that in the original compounds. These results suggest that the grayish blue and black-brown compounds, may be Co(ONO)Cl, $KCo(ONO)_3$, and KNO_3, decomposed with the evolution of nitrogen(II) oxide from the compounds to form cobalt oxides, which have poor solubility in water.

Although the exact nature of the solid residues, Co(ONO)Cl and $KCo(ONO)_3$, is not known, Devrainne and Belsot[3] demonstrated that the decomposition products up to 250 °C of $K[Co(NO_2)_4(NH_3)_2]$ consisted of Co_3O_4 and KNO_3.

The author wishes to thank Professor Masaakira Iguchi, Tokyo University of Science, for his interest in this work, and also Mr. Katsumi Kimura for his polarographic and thin-layer chromatographic analyses.

The X-Ray Structure of Bis((*S,S*)-2,4-pentanediamine)platinum(II) Ion, $[Pt(SS\text{-ptn})_2]^{2+}$

Yasuji NAKAYAMA, Shun'ichiro OOI,* and Hisao KUROYA

Department of Chemistry, Faculty of Science, Osaka City University, Sumiyoshi-ku, Osaka 558

(Received September 2, 1978)

The bis((*S,S*)-2,4-pentanediamine)platinum(II) chloride monohydrate crystallizes in the space group $P2_12_12_1$ with four formula units in a unit cell of dimensions $a=12.089(3)$, $b=13.547(3)$, $c=10.697(2)$ Å. The crystal structure has been determined from diffractometer data and refined to $R=0.052$ for 1903 independent reflections. The Pt atom has a square planar coordination by four N atoms, the average value of the Pt–N distance being 2.05 Å. The complex has a pseudo two-fold axis which is perpendicular to the coordination plane defined by the four N atoms. The 6-membered chelate ring is of a chair conformation and one methyl group is axial with respect to the chelate ring, while the other is equatorial. From a comparison of the circular dichroism spectra of the diammine-(*S,S*)-2,4-pentanediamineplatinum(II) and the bis((*S,S*)-2,4-pentanediamine)platinum(II) ions, the effect of the (*S,S*)-2,4-pentanediamine on the rotatory strength of the Pt(II) complex has been found to be not additive.

The (*S,S*)-2,4-pentanediamine (*SS*-ptn) can coordinate to a metal ion yielding the 6-membered chelate ring with a skew or chair conformation, and it has been utilized in the studies of circular dichroism (CD) exhibited by the Co(III) complexes with 6-membered rings. In the crystal structure analyses made for some octahedral Co(III) chelates, the *RR*-ptn ring has been found usually to be of the λ skew conformation,[1] although a recent CD study for $[Co(NH_3)_{2n}(RR\text{-ptn})_{3-n}]^{3+}$ ($n=0$, 1, or 2) gave evidence for interconversion between the λ skew and the chair conformations in solution.[2] Appleton and Hall concluded, on the basis of the PMR study on Pt(II) chelates, that the *SS*-(or *RR*-)ptn ring in the planar complexes preferentially assumes the chair conformation.[3] The present work is an attempt to confirm their view and to study the structural parameters of the *SS*-ptn ring.

Experimental

Preparations of Complexes. *SS*-ptn·2HCl was purchased from Tokyo Kasei Co., Ltd. and used for the preparation of the complexes without further purification. $PtCl_2(SS\text{-ptn})$ was prepared by the method of Appleton and Hall[4] using the *SS*-ptn instead of *rac*-ptn.

$[Pt(NH_3)_2(SS\text{-ptn})]Cl_2$: The $PtCl_2(SS\text{-ptn})$ was suspended in water and concentrated aqueous ammonia added to the suspension at 80 °C until the dichloro complex was completely dissolved. The resulting solution was rotary evaporated. The colorless crystals were obtained by recrystallization from water–1-propanol.

Found: C, 14.75; H, 5.12; N, 13.84%. Calcd for $[Pt(NH_3)_2(C_5H_{14}N_2)]Cl_2$: C, 14.92; H, 4.97; N, 13.93%.

$[Pt(SS\text{-ptn})_2]Cl_2\cdot H_2O$: $K_2[PtCl_4]$ (1.27 g) and *SS*-ptn·2HCl (1.50 g) were dissolved in water. The solution was heated to 80 °C with stirring and then KOH solution (0.96 g in 10 ml of water) was added dropwise. The resulting solution was rotary evaporated to dryness. The separation of the Pt(II) complex from the residue was effected by extraction with methanol, the process being repeated two times to complete separation and the crystals were recrystallized from water–1-propanol.

Found: C, 24.75; H, 6.24; N, 11.59%. Calcd for $[Pt(C_5H_{14}N_2)_2]Cl_2\cdot H_2O$: C, 24.59; H, 6.15; N, 11.48%.

Spectral Measurements. Electronic spectrum was measured in aqueous solution on a Hitachi EPS-3T Recording Spectrometer. The CD spectrum in aqueous solution was obtained using a JASCO J-20 Automatic Recording Spectrometer. The FT ^{13}C NMR spectra were obtained in D_2O at 15.04 MHz with broad band proton decoupling and off-resonance proton decoupling on a JEOL JNM-FX-60 Spectrometer. Dioxane was used as an internal reference but the chemical shifts are given based on the TMS scale. In every ^{13}C NMR spectrum 4096 data points were taken over a 1-kHz spectral width. All measurements were conducted at room temperature.

Measurement of X-Ray Data of $[Pt(SS\text{-ptn})_2]Cl_2\cdot H_2O$.

Crystal Data: $C_{10}Cl_2H_{30}N_4OPt$, $F.W.=488.1$, orthorhombic, $a=12.089(3)$, $b=13.547(3)$, $c=10.697(2)$ Å, $D_m=1.85$, $D_c=1.85$ g/cm^3, $Z=4$, space group $P2_12_12_1$, $\mu(Mo\,K\alpha)=87.3$ cm^{-1}. The space group and the approximate unit cell dimensions were determined from Weissenberg photographs taken with Cu $K\alpha$ radiation. The unit cell dimensions were refined by the least-squares analysis of 15 θ values measured on a Philips PW1100 four circle diffractometer, Mo $K\alpha$ radiation being employed.

Data Collection: Diffraction intensities were measured by ω-2θ scan method on the diffractometer using graphite-monochromated Mo $K\alpha$ radiation. The crystal size was $0.28\times0.26\times0.25$ mm. The scan speed and scan width in ω were 0.017° s^{-1} and $(0.8+0.2\tan\theta)$°, respectively. Background was counted for 20 s at each end of the scan range. A total of 1903 independent reflections for which $I_t-2\sqrt{I_t}>I_b$ were collected in the $2\theta\geq55°$ range (I_t=intensity at the top of peak; I_b=mean background intensity obtained from preliminary background measurements for 5 s on both sides of the peak). A spherical absorption correction ($r=0.13$ mm) was applied. During the data collection no appreciable variations were observed in the intensities of three standard reflections (200,020,002) monitored every 2 h.

Structure Determination and Refinement. The crystal structure of $[Pt(SS\text{-ptn})_2]Cl_2\cdot H_2O$ was solved by the Patterson and Fourier method. The positional and thermal parameters were refined by a block-diagonal least-squares method, the minimized function being $\sum w(F_o-|F_c|)^2$. The weighting scheme, $w=1.0$ for $F_o\leq100.0$ and $w=(100.0/F_o)^2$ for $F_o>100.0$, were found to be optimum conditions to make the average values of $w|\Delta F_o|^2$ relatively constnat over ranges of F_o. The final R value was 0.052. In the final cycle of the refinement all parameter shifts were less than 0.2σ. Positional and thermal parameters are listed in Table 1.

Atomic scattering factors of Pt^0, Cl^-, N, C, O were taken from Ref. 5. Anomalous dispersion corrections were made for Pt^0 and Cl^-. The absolute crystal structure was determined on the basis of the configuration (*S*) of asymmetric carbon atoms. The observed and calculated structure factors are preserved at the Chemical Society of Japan (Docu-

ment No. 7909). All computations were conducted on a FACOM 270-30 computer of Osaka City University, using RSSFR-5, HBLS-IV, and DAPH programs in the UNICS.[6]

Results and Discussion

The perspective drawing and projection of the complex are shown in Figs. 1 and 2, respectively. The complex has a pseudo two-fold axis which runs through Pt and is perpendicular to the coordination plane defined by N(1), N(2), N′(1), and N′(2). The disposition of these atoms is completely planar (±0.005 Å) and the Pt atom lies on the plane, the deviation being 0.003 Å.

Each chelate ring is of a chair conformation. One methyl group is equatorial with respect to the chelate ring, while the other is axial. The interplanar angle between the coordination plane and the mean plane of N(1), C(2), C(4), and N(2) is 130°, whereas that between the coordination plane and [N′(1), C′(2), C′(4), N′(2)] plane is 133°. These values are generally smaller than those (136.3—158.6°) of the 6-membered ring of tn (=1,3-propanediamine) with a chair conformation in octahedral complexes.[7] The larger interplanar angle in the octahedral complexes could be ascribed to interligand interactions within the complex, while the smaller interplanar angle in the present complex indicates that the extent of the interaction is smaller in spite of the presence of the methyl substituents in the ring. The Pt···C(5) and Pt···C′(5) distances are 3.40 and 3.34 Å, respectively. Bond lengths and angles are given in Table 2.

Table 2. Bond lengths (l/Å) and bond angles (ϕ/°)

Pt-N(1)	2.05(1)	C(1)-C(2)	1.56(3)
Pt-N(2)	2.04(1)	C(2)-C(3)	1.55(3)

C(3)-C(4)-C(5)	112(2)	C′(3)-C′(4)-C′(5)	114(2)

In the chelate ring the N–Pt–N coordination angle is significantly greater than those (81.9—87.4°) in the 5-membered ring,[8] but slightly less than 90°. The Pt–N–C bond angles are small compared with

O_w-H···Cl(1^{I})[b)]	3.15(2)		
O_w-H···Cl(2^{I})[b)]	3·16(2)		

Roman numeral superscripts refer to the atoms in the following equivalent positions:
I $x, y, -1+z$ II $(1/2)-x, -y, -(1/2)+z$
III $(1/2)-x, 1-y, -(1/2)+z$
IV $-(1/2)+x, (1/2)-y, 1-z$

a) The positions of amino H atoms have been calculated on the assumption that the N-H distance is 1.03 Å. b) N(2)···O_w···Cl(1^{I})=103(1)°, N(2)···O_w···Cl(2^{I})=101(1)°, Cl(1^{I})···O_w···Cl(2^{I})=115(1)°.

those (116.5—121.3°) in the octahedral tn complexes.[7] This is also in harmony with the smaller interligand interaction in the planar complex, since the decrease in the interplanar angle is related to the decrease in the Pt–N–C angle. Both of C(2)–C(3)–C(4) angle and its primed analogue are significantly larger than those (111.3—116.0°) in the tn complexes[7] and this is thought due to steric repulsion between the axial methyl group and C(2)–H(axial) segment.

The crystal structure viewed down the c axis is shown in Fig. 3. Except for the axial H atom bonded to N′(1) all remaining amino H atoms participate in N–H···Cl^- or N–H···O(H_2O) hydrogen bonding, the data of which are given in Table 3.

In the ^{13}C NMR spectrum of [Pt(NH_3)$_2$(*SS*-ptn)]Cl_2 three signals, each of which is accompanied with satellites due to paltinum coupling, appear at 46.6 ($^2J_{Pt-C}$=25 Hz), 40.6 ($^3J_{Pt-C}$=21 Hz), and 21.9 ppm ($^3J_{Pt-C}$=31 Hz). These signals have been assigned

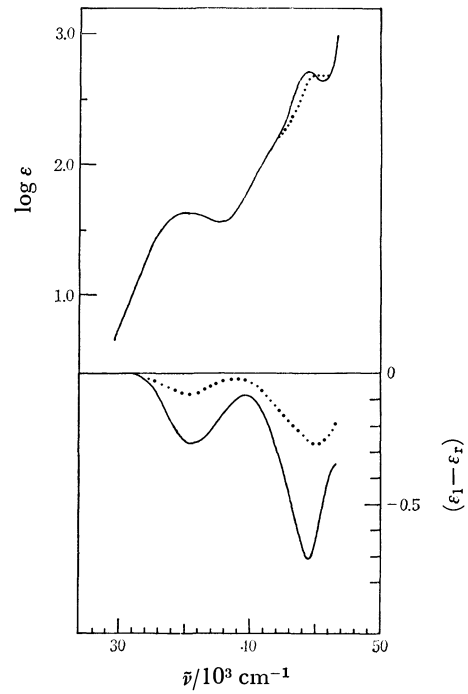

Fig. 4. The absorption (top) and CD (bottom) spectra of [Pt(NH_3)$_2$(*SS*-ptn)]Cl_2 (·····) and [Pt(*SS*-ptn)$_2$]Cl_2·H_2O (——) in aqueous solution.

to the resonances due to CH, CH_2, and CH_3 carbons, respectively, on the basis of the spectrum with off-resonance proton decoupling. The corresponding resonances appeared at 46.8, 40.7, and 21.8 ppm in [Pt(*SS*-ptn)$_2$]Cl_2·H_2O. Appleton and Hall reported that the Pt—*SS*-ptn chelate ring makes rapid chair-to-chair interconversion in solution.[3] The feature of ^{13}C NMR spectrum is compatible with this conclusion, since five carbon signals should be observed if the chelate ring is fixed in the chair conformation. According to the conformational analysis of the planar Mb_2(tn) type complex (b=a monodentate ligand), the interconversion occurs *via* a skew intermediate.[9] However, the intermediate conformer is small in population at room temperature, as the free energy difference (ΔG) between the skew and chair conformers has been estimated to be 1.6 kcal/mol.[9] In Mb_2(*SS*-ptn) both methyl groups are equatorial in the δ skew conformer, whereas they are axial in the λ one. Conformational analysis of [$CoCl_4$(*S*(or *R*-)-1,3-butanediamine)]$^-$ showed that in the case of the skew ring the chelate ring with axial methyl group has greater atom overcrowding than that with equatorial one.[10] This may also be the case for planar Mb_2(*SS*-ptn). The ΔG(chair, δ skew) value in Mb_2(*SS*-ptn) may not be very different from that in Mb_2(tn) but the ΔG(chair, λ skew) may be larger in magnitude than the ΔG(chair, δ skew).

Figure 4 shows the absorption and CD spectra of [Pt(NH_3)$_2$(*SS*-ptn)]Cl_2 and [Pt(*SS*-ptn)$_2$]Cl_2·H_2O in aqueous solution. The absorption spectra are very similar to those of the corresponding 1,2-propanediamine complexes.[11] Since the populations of the skew conformers are small as inferred from the free energy differences, the CD spectrum of the diammine

complex can be regarded as virtually arising from the vicinal effect due to the *S* asymmetric carbons.

The effect of the *SS*-ptn ligand on the CD spectra of $[Pt(NH_3)_2(SS\text{-ptn})]^{2+}$ and $[Pt(SS\text{-ptn})_2]^{2+}$ is not additive as seen in Fig. 4, indicating that the vicinal effect of the asymmetric carbons is not the only source of the CD of bis(*SS*-ptn) complex. In general the asymmetry factors responsible for the optical activity of the Pt(II) chelates of *SS*-ptn are the chirality of the asymmetric carbon in the chelate ring and the chelate ring in the skew conformation. The non-additivity suggests that the CD spectrum of the bis-chelate comprises the conformational contribution from the conformers with skew ring.

Emission Spectra and Luminescence Life Times of Uranium-Mica Type Compounds

Yoshinori SUGITANI,* Kenji KATO, and Kozo NAGASHIMA

Department of Chemistry, The University of Tsukuba, Sakura-mura, Ibaraki 300-31

(Received September 7, 1978)

A series of uranium–mica type compounds $M(UO_2)_2(XO_4)_2 \cdot nH_2O$, where M=Ca, Sr, Ba, Mg, Na_2, K_2, and $(H_3O)_2$; X=P and As, as well as the doped samples of $Mg(UO_2)_2(PO_4)_2 \cdot nH_2O$: Mn(0.03 mol %) and $Zn(UO_2)_2(PO_4)_2 \cdot nH_2O$: Cu(0.1 mol %), have been prepared and measured for emission spectra under the UV-(365 nm) excitation and decay times. Some of these samples, *e.g.*, $(H_3O)_2(UO_2)_2(AsO_4)_2 \cdot nH_2O$, have been found to give weak shoulders and a separated band, in addition to the six bands so far reported for other uranyl(VI) compounds. Samples containing AsO_4^{3-} ions in place of PO_4^{3-} gave emission spectra, where the main bands shifted by approximately 100 cm^{-1} to lower energy also giving shorter life times. The decay times of the six emission bands of $Mg(UO_2)_2(PO_4)_2 \cdot nH_2O$ have been found to have the same value of 2.5×10^{-4} s.

Uranyl(VI) compounds exhibit a highly characteristic luminescence both in the solid state and in solution. The spectral properties of uranyl(VI) compounds have been studied in great detail, since Stokes gave the first systematic investigation on light-emission and absorption in the middle of the nineteenth century.[1-4] The theoretical basis, however, for understanding the spectroscopic properties of the UO_2 group has been established only in the last two or three decades and remain incomplete.[5,6] The luminescence, which is assigned to emission from the lowest excited $^3\Pi_u$ state displays considerable sub-structure probably due to vibrational effects. Bell and Biggers,[6] who gave possibly the most comprehensive analysis of Uranyl(VI) salts, resolved the six emission bands in the luminescence spectrum of uranyl(VI) perchlorate in water. Iimori and Iwase resolved the sixteen bands of the fluorescence spectrum of natural autunite, a hydrous phosphate of uranyl (VI) and calcium, by photo techniques.[7] No further description has, however, been published on the luminescence spectrum of this mineral. In the present paper, the emission spectra and the decay times for a series of uranium–mica compounds including the synthetic and natural autunites are reported. In addition to the conventional decay time measurement, the life times of the six resolved bands have been measured separately for a sample of Mg-containing uranium–mica.

Experimental

Samples. Samples were prepared according to the literature.[8,9] The general formula of uranium–micas is given[10] as $M(UO_2)_2(XO_4)_2 \cdot nH_2O$, where M is an univalent metal ion (M^{I}) or a bivalent metal ion (M^{II}), XO_4 is a phosphate PO_4^{3-} or arsenate AsO_4^{3-}. The prepared samples are those with M=Na_2, K_2, $(H_3O)_2$, Ca, Mg, Sr, Ba, and Zn. The number of water molecules n varies according to the condition of the samples; natural autunites with bivalent metal ions have values of ranging from 8 to 12, while those with univalent ions have, to some extent, a lower value of n.

The samples were prepared by mixing the solutions containing the component ions and adjusting the temperature and pH at the appropriate values. The procedure for the preparation of $Ca(UO_2)_2(PO_4)_2 \cdot nH_2O$ is given here as an example. The reagents used were of guaranteed grade. Diluted (1.48 mol/l) phosphoric acid (5 ml) was added to a solution of $CaCl_2$ (s.g.=1.25, 500 ml), followed by boiling and the slow addition of about 10 ml of uranyl solution containing 3.7 g of $UO_2(NO_3)_2 \cdot 6H_2O$. The resultant solution was kept warm on a water bath, and the required precipitate was obtained at the bottom of a beaker in approximately 1 h. The samples were confirmed by X-ray diffractometry.

Apparatus. A block diagram for the measurement of the luminescence decay time is shown in Fig. 1. The main part of the system is composed of a microcomputer (TK-80, NEC Japan, 8080 type) and digital counters. All interface units including the digital counters have been hand-made in this laboratory within the expense of one hundred and sixty thousands yen. The microcomputer system with peripheral interfaces is connected on line to the optical system, for which some units of the multi-purpose spectrometer (SS-25, JASCO Japan) are employed. The apparatus is able to measure a wide range of decay times at weak intensity. More details of the system, especially concerning the hardware will be reported later. The measurement of emission spectra and decay times were made at room temperature.

Results and Discussion

According to McGlynn and Smith,[5] the ground state configuration of the UO_2^{2+} molecule is expressed as $(1\sigma_u^+)^2(1\sigma_g^+)^2(1\pi_u)^4(1\pi_g)^4$, leading to a totally symmetric singlet ground state $^1\Sigma_g^+$. The resolved absorptions between 20500 and 30000 cm^{-1} (visible to near UV) occur because of transitions from the ground state to the lowest excited state $^3\Pi_u$, which is split into twelve sublevels due to the symmetric stretching in the excited state (Fig. 3). The luminescence appears to occur from the lowest one or two sublevels to the ground state which is also further split due to the symmetric stretching in the ground state.[4] Figure 2 shows the emission spectra of a synthetic sample of $Mg(UO_2)_2(PO_4)_2 \cdot nH_2O$, which gives a typical spectral pattern for a series of uranium–micas prepared here. Excitation by UV light of 365 nm was found more efficient for the measurement of luminescence than 254 nm, which is understood since the closely separated sublevels arising from the triplet $^3\Pi_u$ efficiently absorb the exciting energy of 365 nm (27400 cm^{-1}), while there is not any appropriate absorbing level for 254 nm (39400 cm^{-1}) (Fig. 3).

The spectra is apparently composed of six bands with an appoximate intensity ratio of 3 : 13 : 45 : 100 : 95 : 8. Peak positions for all the prepared samples are listed in Table 1, together with the life time data. The average spacing of the five lowest energy bands

is 840±20 cm^{-1}, while the band at the highest energy is spaced only 710±40 cm^{-1} from the next lower energy band. Bell and Biggers reported the same spectral feature for the emission bands of uranyl(VI) perchlorate in water.[6] In that case the average spacing for the five lowest energy bands was 855±20 cm^{-1}, while another band was spaced 768 cm^{-1} from its neighbor. They suggested that the latter band is probably from a different origin to the other five emission bands, that is, from the second absorption level. The smaller spacings of the uranium–mica

samples compared to those of uranyl(VI) perchlorate in water may be considered as reflecting the geometry of coordination of ligand molecules around the uranyl-(VI) ion.[11]

Decay curves for the six emission bands have been recorded as shown in Fig. 5, where the logarithmic converted lines instead of the direct decay curves are given for convenience. Life time data obtained for the most intense band at 19011 cm^{-1} have the value of 2.5×10^{-4} s, which agrees with the five others within experimental error suggesting that the six emission bands emerge from the same transition mechanism.

As seen in Table 1, some of the samples have additional weak bands besides the six main bands, one of which was observed as a very weak band at the low energy side with the same spacing as the five bands. The others were observed either as shoulders or as asymmetrics of the main bands. Iimori and Iwase[7] found sixteen emission bands for a natural autunite using a photo technique in almost the same energy region as that of the six bands found here. The sixteen bands were arranged into three series, E(seven bands, very intense), B(five bands, dim), and H(four bands, very dim), each of which has the same wave-number interval of 800 cm^{-1}. The six highest energy bands in the E series coincided well with the six bands reported here.

The remaining band in the E series at the lowest energy (635 nm) found its counterpart only as a very weak and broad band in the spectra recorded here (Table 1). The shoulder bands which were found, for instance, in the spectra of $(H_3O)_2(UO_2)_2(AsO_4)_2 \cdot nH_2O$ could be related to some bands in the B or H series. However, the imprecise energy position and the limited number of shoulder bands do not allow a precise comparison between the bands. The presence of the additional bands, however, is thought to necessitate a more rigorous discussion concerning the origin of the emission bands than has hitherto appeared.[5,6]

The value of n and the changes found during measurement were not recorded however in the present study, since no significant changes were observed in the spectral patterns and in the life times during repeated measurements. The reason for this is presumably that the water molecules in the uranium–micas are located in the cavities in the $[(UO_2)(XO_4)]_n$ layer structure and having a zeolitic water character, they exert only a small influence on the UO_2 energy levels as perturbing ligands.[9]

The replacement of PO_4 by AsO_4 causes a shortening of the life time as well as a shift of the emission bands to low energy about 100 cm^{-1} in the uranium–micas of Ba, Mg, Na_2, and K_2 but the explanation of this remains unknown. It does not seem, however, to be due to paramagnetic impurities contained, for instance, in aresenic acid used in the experiment, since the doped sample of Mg-containing uranium–mica (Mn 0.03 mol %) shows a shortening in life time as a result of the transfer of the absorbed energy to the paramagnetic ion Mn^{2+}, while it does not show any band shift with respect to the sample without paramagnetic impurities.

Formation of Micelles of Hexadecyltrimethylammonium Bromide in Water–*N,N*-Dimethylformamide Solutions

Lavinel G. Ionescu,*,† Tadashi Tokuhiro, and Benjamin J. Czerniawski
Department of Chemistry, University of Detroit, Detroit, Michigan 48221, U.S.A.
(Received July 7, 1978)

The critical micellar concentration of aqueous solutions of hexadecyltrimethylammonium bromide (HTAB) containing various amounts of *N,N*-dimethylformamide (DMF) has been determined at 25 and 40 °C by means of surface tensiometric measurements. The standard free energy ($\Delta G_m°$), enthalpy ($\Delta H_m°$), and entropy ($\Delta S_m°$) of micellization were also determined. The experimental results indicate that: (1) micelle formation is somewhat hindered by a raise in temperature, and (2) DMF has an inhibitory effect on the formation of micelles of HTAB. This effect is relatively small at low DMF concentrations, but it increases drastically as the mole fraction of DMF approaches 0.33. The changes in the $\Delta G_m°$, $\Delta H_m°$, and $\Delta S_m°$ values indicate that the formation of HTAB micelles in the water–DMF mixtures is an entropy directed process at lower concentrations of DMF and the inhibitory effect of DMF on micelle formation is attributed to an increase in the orderliness of this system with increasing DMF concentration.

N,N-Dimethylformamide (DMF) is a common dipolar aprotic solvent often used as a medium for many organic reactions. Other common dipolar aprotic solvents are dimethyl sulfoxide (DMSO), *N,N*-dimethylacetamide, acetone, tetrahydrofuran, sulfolane, and dioxane. They are usually weak hydrogen bond donors and very weakly acidic. On the contrary, they may often act as strong bases. Usually aprotic solvents contain hydrogen attached to carbon and are generally dipolar in nature.[1-3] Most of them are relatively miscible with water.

As part of our study of the effect of polar solvents on the formation of micelles in aqueous solutions, we decided to also investigate the effect of DMF on the micellization of hexadecyltrimethylammonium bromide (HTAB). Our previous studies of the HTAB–H_2O–DMSO system have revealed that the addition of DMSO has an inhibitory effect on the formation of micelles in aqueous solutions.[4-6] Surface tensiometric experiments indicated that DMSO increased the critical micellar concentration of HTAB in water at low concentrations.[4] At mole fractions of DMSO higher than 0.33 micelle formation did not appear to take place. The results of spin-lattice relaxation measurements for the terminal methyl, *N*-methyl, and methylene groups of hexadecyltrimethylammonium bromide substantiated these results and showed that when the DMSO concentration is equal to a mole fraction of 0.366 the surfactant monomer molecules are essentially isolated from each other by the increased "structuring" of the water–DMSO liquid system.[5-6] Spin-lattice relaxation and chemical shift measurements performed in our laboratory also indicated that this liquid system is in its most structured state through hydrogen bonding between water and DMSO molecules when the mole fraction of DMSO is about 0.35.[7]

The mixing of DMF with water is a strongly exothermic process with a maximum value at the mole fraction of 0.66 for H_2O, while the activity coefficients for water and DMF are relatively near unity.[8] In addition, a variety of other physical properties of water–DMF solutions exhibit extrema at a mole fraction of 0.66 for water.[9-11] On the basis of cryoscopic and calorimetric measurements of aqueous solutions of *N,N*-dimethylformamide, Bougard and Jadot[8] have concluded that DMF forms both the monohydrate ($DMF \cdot H_2O$) and the dihydrate ($DMF \cdot 2H_2O$) and that the association is probably mainly through hydrogen bonding.

We have decided to study in some detail the HTAB–H_2O–DMF system because of the vast information available in the literature for the surfactant and in order to compare it to the HTAB–H_2O–DMSO system that we have previously studied. The present work essentially involved the experimental evaluation of thermodynamic functions such as the free energy, enthalpy, and entropy of micellization from the critical micellar concentration (CMC) of HTAB in various water–DMF mixtures at 25 and 40 °C determined by means of surface tensiometry.

Experimental

The DMF used was of spectro quality and was obtained from Eastman Organic Chemicals, Cleveland, Ohio 44114. It was employed without any additional treatment or purification. Hexadecyltrimethylammonium bromide (HTAB), $CH_3(CH_2)_{15}N^+(CH_3)_3Br^-$, was purchased from Aldrich Chemical Company, Milwaukee, Wisconsin 53233. It was recrystallized twice from 95% ethyl alcohol and dried under vacuum for two days. Doubly distilled water was used in the preparation of all the solutions.

The surface tension of HTAB–H_2O–DMF solutions was measured at 25 and 40 °C by means of a Fisher Model 21 Semi-Automatic Tensiometer. The solutions were prepared gravimetrically at the following mole fractions of DMF: 0.000, 0.025, 0.055, 0.091, 0.134, 0.188, 0.258, and 0.351. All of them contained at least fifteen different concentrations of HTAB. Ten milliliter aliquots of the solutions were measured in a Petri dish with a diameter of 6 cm. The tensiometer was set at a constant height. The final surface tension of any solution was the average of at least three measurements.

The CMC's were determined from plots of the surface tension of the solutions *versus* the logarithm of the concentration of HTAB. The marked change in the plots is taken as an indication of micelle formation and the inflection

0.258	—	−2.09	—

point in the curve is considered to correspond to the CMC. Linear plots are taken as an indication that micelle formation does not occur.

Results and Discussion

Some representative experimental results obtained for the surface tension of different HTAB solutions in various water–DMF mixtures at 25 °C are given in Fig. 1. Most plots of surface tension *versus* the logarithm of the concentration of HTAB exhibit an initial marked drop and subsequently level off. Similar results have been obtained for the same solutions at 40 °C. The CMC values thus determined for the different H_2O–DMF mixtures are summarized in Table 1.

As can be seen from Table 1, the effect of DMF on micelle formation is relatively small at low concentrations of DMF, but it increases drastically as the mole fraction of DMF approaches 0.33. This mole fraction corresponds to the formation of the stoichiometric hydraote DMF·2H_2O.[8] At mole fractions of DMF higher than 0.33, the formation of HTAB micelles does not appear to take place in similarity to the HTAB–H_2O–DMSO system.[4–6] We have shown conclusively by means of proton spin-lattice relaxation measurements that this was true for the latter system.[4–6]

The thermodynamics of micelle formation has been discussed and treated extensively in the literautre.[12–14] One approach assumes that the process of micellization involves the formation of a distinct micellar phase at the CMC and that the concentration of monomers in solution is constant, once micelles are formed. Then, the standard free energy of micellization, $\Delta G_m°$, is given by the following equation to a good approximation:

$$\Delta G_m° = RT \ln \text{CMC}. \quad (1)$$

If one assumes that the aggregation number and the degree of ionization of the surfactant are temperature independent, the standard enthalpy ($\Delta H_m°$) and entropy ($\Delta S_m°$) of micellization can be evaluated by temperature dependence of the CMC and the Gibbs-Helmholtz relationship. The values thus determined for $\Delta G_m°$ for the fomation of HTAB micelles in variuos water–DMF solutions at 25 °C are given in Table 2. The more approximate $\Delta H_m°$ and $\Delta S_m°$ quantities, calculated on the basis of the measurements at two temperatures only, are also shown in the same table. The experimental results show that micelle formation is slightly hindered by increasing the temperature from 25 to 40 °C. The results also indicate that the addition of DMF has an inhibitory effect on the formation of micelles of HTAB in aqueous solutions. This effect due to the cosolvent is more pronounced than the one that we have observed for dimethyl sulfoxide.[4–6] Figure 2 illustrates a comparison of the effects of DMF and DMSO at 25 °C in terms of $\Delta G_m°$.

The $\Delta G_m°$ values determined for micelle formation in the water–DMF mixed solvent system vary almost linearly from −3.68 to −2.09 kcal/mol with increasing concentration of DMF and are always less negative than those determined for the formation of HTAB micelles in pure water (Table 2). The approximate enthalpy of micellization calculated, $\Delta H_m°$, is exothermic and almost constant at concentrations of DMF betweeen 0.025 and 0.134 mole fractions. The corresponding values of the entropy of micellization,

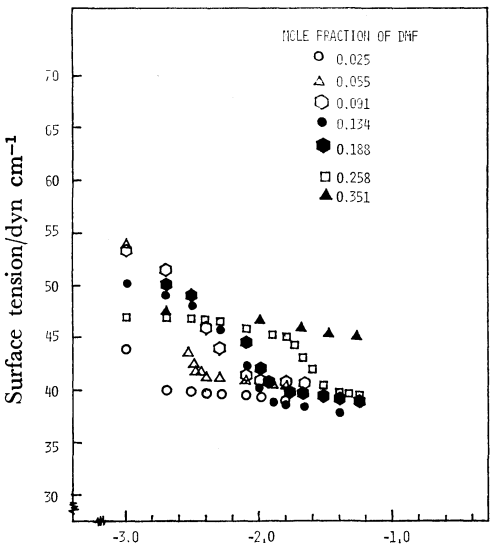

Fig. 1. Dependence of surface tension on the logarithm of the concentration of hexadecyltrimethylammonium bromide in water-*N*,*N*-dimethylformamide solutions at 25 °C.

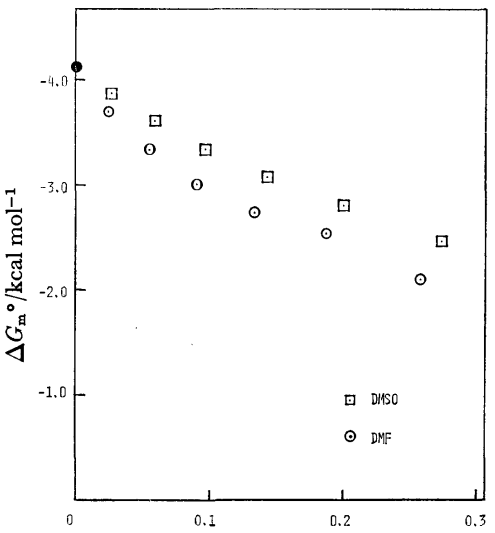

Fig. 2. Depence of the free energy of Micellization of hexadecyltrimethylammonium bromide at 25 °C on the composition of the water-dimethyl sulfoxide and water-*N*,*N*-dimethylformamide binary liquid systems.

$\Delta S_m°$, decrease gradually from 7.75 to 3.35 e.u. This means that the negative free energy of micellization is mainly due to the contribution of the entropy term in the H_2O–DMF mixed solvent system at low concentrations of DMF. This is in agreement with the general concept that micelle formation in aqueous solutions is an entropy directed process and arises mainly from the break-up of the "Frank-Evans microcrystals" of the ordered water structure by the surfactant molecules, even though the formation of aggregates by surfactant molecules is an entropy decreasing process. Since the $\Delta S_m°$ values decrease with increasing concentration of DMF (Table 2), an increase in the orderliness of the HTAB–H_2O–DMF system takes place as the mole fraction of DMF is increased. This is consistent with a strong interaction, such as hydrogen bonding, between water and DMF. As already mentioned, Bougard and Jadot[8] have confirmed the existence of the stoichiometric hydrate DMF·$2H_2O$ and suggested the presence of hydrogen bonding.

A further addition of DMF caused a significant change in the relative contributions from enthalpy and entropy, *i.e.*, at 0.188 mole fraction of DMF $\Delta H_m°$ and $\Delta S_m°$ become −5.73 kcal/mol and −10.6 e.u., respectively. A change similar to this was also observed in the water–DMSO mixed solvent system when the DMSO mole fraction was 0.275. This change implies that the driving force for micellization in both the H_2O–DMF and H_2O–DMSO mixed solvent systems containing higher concentrations of DMF or DMSO must be attributed to the enthalpic term. Why this change occurs at lower concentrations of DMF than DMSO may be explained by the fact that DMF has a more pronounced effect on the disruption of the water structure through hydrogen bonding, even though DMF is less polar than DMSO[15] (the dielectric constant of DMF at 25 °C is 36.7 while that of DMSO is 46.4). Altogether, the inhibitory effect of *N*,*N*-dimethylformamide on micelle formation can be explained in terms of a decrease of hydrophobic forces in the ternary system due to interactions between water and the cosolvent.

Chemistry of Organo Halogenic Molecules. XLVIII. Stereochemistry of Halofluorination of 1,2- and 1,4-Dihydronaphthalene

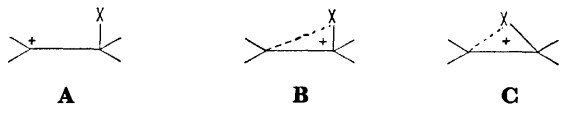
Stojan STAVBER and Marko ZUPAN*

Department of Chemistry and "J. Stefan" Institute, University of Ljubljana, Yugoslavia

(Received April 3, 1978)

Halofluorination of 1,2-dihydronaphthalene with a mixture of *N*-chlorosuccinimide or *N*-bromosuccinimide or *N*-iodosuccinimide–hydrogen fluoride–pyridine in ether proceeds with Markovnikov type regioselectivity. The reaction is stereospecifically anti, the anti adduct isomerizing to syn products under the reaction conditions. The elimination of hydrogen halide under basic conditions occurs only from the syn adduct, thus forming 1-fluoro-3,4-dihydronaphthalene. Halofluorinations of 1,4-dihydronaphthalene also occur stereospecifically anti, and elimination under basic conditions gives naphthalene.

The mechanism of electrophilic addition has been widely investigated, both from the kinetic and stereochemical points of view.[1] Apart from the relative importance of the various kinetically significant processes, it is now known that the nature of the intermediates of the addition depends on the structure of the substrate, on the halogen and on the reaction medium, ranging from strongly bridged ions (type **C**), to weakly bridged species (type **B**) or open ions like **A**.



Scheme 1.

If the cation is of the open structure (**A**, X=F), a mixture of syn and anti adducts is generally expected. However, ion pairing phenomena can cause preferential formation of the syn adduct and electronic, steric or conformational effects can cause attack at one or other side of the carbonium p-orbital of **A** to be favoured. On the other hand, the intermediate can have a bridged structure (**C**, X=Br), which will presumably be opened to form an anti adduct. Available data on the addition of "BrX" species to olefins are sparse. In the steroid series,[2,3,4] stereospecific anti addition with Markovnikov type regioselectivity is observed; on the other hand, the bromofluorination of carbohydrates[5,6] is stereospecifically syn. Using hydrogen fluoride–pyridine in conjunction with *N*-bromosuccinimide for fluorination of aliphatic olefins, Olah and his coworkers[7] observed typical Markovnikov type regioselectivity. Bromofluorination of phenyl substituted olefins proceeds with Markovnikov type regioselectivity and the reaction is stereospecifically anti for trans and nonstereospecific for cis olefins.[8] The bromofluorination of 1-phenylcyclohexene also proceeds with Markovnikov type regioselectivity and is stereospecifically anti.[9] The halofluorinations of norbornene[10] and norbornadiene[11] with a mixture of *N*-halosuccinimide–hydrogen fluoride–pyridine have also been studied. Recently we found that fluorination of 1,2-dihydro- and 1,4-dihydronaphthalene occurs in different ways,[12] which stimulated us to investigate the reaction pathways involved in halofluorination of these systems.

Results and Discussion

The preparation of fluoroalkanes presents a different problem from that of other halogenoalkanes, and necessitates a specific method of fluorination.[13] Difficulties involve the handling of anhydrous hydrogen fluoride on the laboratory scale, the need for pressure equipment and low temperatures, and the ease of polymerisation of alkenes. Bromofluorination with hydrogen fluoride–pyridine–NBS avoids some experimental difficulties,[7] *e.g.* low temperature, high pressure techniques, and polymerisation of olefins.

Halofluorination of 1,2-Dihydronaphthalene. The 3 h reaction of 1,2-dihydronaphthalene (**1**), with a mixture of *N*-chlorosuccinimide–hydrogen fluoride–pyridine in ether at room temperature resulted in the formation of a crude reaction mixture, which showed two signals in its ^{19}F NMR spectrum: $\delta F = -158.5$ and -176 in the ratio 1.78:1.

Reduction of the reaction time from 3 to 1.5 h resulted in the formation of only one product, which showed one signal in its ^{19}F NMR spectrum at $\delta F =$

Scheme 2.

−158.5. Treatment of the reaction mixture formed in a 3 h halofluorination reaction with K–O-*t*-Bu in *t*-BuOH at T=50 °C resulted in the formation of a crude reaction mixture which showed a new signal at $\delta F = -123.75$, besides the signal at $\delta F = -158.5$, with the signal ratio of 1.7:1. Separation of the reaction mixture by TLC gave two products. The major product formed showed a doublet of multiplet signal at $\delta F = -158.5$ ($^2J_{FH}$=56 Hz), in its ^{19}F NMR spectrum and in its proton spectrum two signals at lower field: $\delta H_1 = 5.4$, $\delta H_2 = 4.6$. The mass spectrum showed the following signals: *m/e*: 186 (M^++2, 20%), 184 (M^+, 60%), 148 (60), 129 (50), 122 (100), 115 (15). The second product showed a doublet signal at $\delta F = -123.75$, ^3J=15 Hz in its ^{19}F NMR, and in its mass spectrum the following signals: *m/e*: 148 (M^+, 63%), 147 (65), 146 (38), 133 (44). On the basis of the spectroscopic data we established that the crude reaction mixture formed under basic conditions contained 1-fluoro-2-chloro-1,2,3,4-tetrahydronaphthalene, and as the minor product, 1-fluoro-3,4-dihydronaphthalene (**4**). We were unable to separate the two products formed by the 3 h chlorofluorination reaction. However, on the basis of differences in their NMR spectra, which are shown in Scheme 2, and in the stability of the products under basic conditions, we have established that the major product formed (**2**) was *trans*-1-fluoro-2-chloro-1,2,3,4-tetrahydronaphthalene, while the second product, which was not formed in the case of the 1.5 h reaction, and which transformed under basic conditions to 1-fluoro-3,4-dihydronaphthalene, was found to be *cis*-1-fluoro-2-chloro-1,2,3,4-tetrahydronaphthalene (**3**).

A 3 h reaction of 1,2-dihydronaphthalene with a mixture of NBS–hydrogen fluoride–pyridine resulted in a crude reaction mixture, which showed two signals in its ^{19}F NMR spectrum: $\delta F = -149$ and -169 in the ratio 1.5:1, while reduction of the reaction time to 0.5 h resulted in the formation of only one product with the ^{19}F NMR signal at $\delta F = -149$. Under basic conditions, heating (T=50 °C) the mixture obtained in the 3 h bromofluorination reaction resulted in a mixture containing 1-fluoro-2-bromo-1,2,3,4-tetrahydronaphthalene and 1-fluoro-3,4-dihydronaphthalene (**4**) in the ratio 1.5:1. We were unable to separate the two products formed by the 3 h bromofluorination reaction. However, on the basis of differences in their NMR spectra, which are shown in Scheme 2, and in the stability of the products under basic conditions, we established that the major product formed (**2**) was *trans*-1-fluoro-2-bromo-1,2,3,4-tetrahydronaphthalene, while the second product, which was not formed in the case of a 0.5 h reaction and which was transformed under basic conditions to 1-fluoro-3,4-dihydronaphthalene, was found to be *cis*-1-fluoro-2-bromo-1,2,3,4-tetrahydronaphthalene (**3**).

Fifteen minutes iodofluorination with a mixture of *N*-iodosuccinimide–hydrogenfluoride–pyridine of 1,2-dihydronaphthalene resulted in the formation of a crude reaction mixture which showed two signals in its ^{19}F NMR spectrum, $\delta F = -139$ and -157, in the ratio 1.5:1. On the basis of a comparison (Scheme 2) of the NMR data of the products to those formed by chloro and bromofluorination, we established that the major product formed was *trans*-1-fluoro-2-iodo-1,2,3,4-tetrahydronaphthalene (**2**), and that the minor product formed was *cis*-1-fluoro-2-iodo-1,2,3,4-tetrahydronaphthalene (**3**). Reduction of the reaction time to 5 minutes resulted in the formation of product (**2**), while treatment of the reaction mixture obtained by 15 minutes iodofluorination under basic conditions resulted in a mixture containing products (**2**) and (**4**) in the ratio 1.5:1.

Halofluorination of 1,4-Dihydronaphthalene. A 5 h reaction of the mixture *N*-chlorosuccinimide–hydrogen fluoride–pyridine with 1,4-dihydronaphthalene at room temperature resulted in the formation of one product (**6**), which showed one signal in its ^{19}F NMR spectrum at $\delta F = -177.5$ (dtd, $^2J_{FH_2}$=51 Hz, $^3J_{FH_1}$=25.5 Hz, $^3J_{FH_3}$=5 Hz), and in its ^1H spectrum two signals at lower field. $\delta H_2 = 4.7$ (ddd, $^2J_{H_2F}$=51 Hz, $^3J_{H_2H_3}$= 10 Hz, $^3J_{H_1H_2}$=5 Hz), $\delta H_3 = 4.3$ (ddd, $^3J_{H_3F}$=5 Hz, $^3J_{H_3H_2}$=10 Hz, $^3J_{H_3H_4}$=5 Hz). In its mass spectrum the product showed the following signals: *m/e*: 186 (M^+ +2, 33%), 184 (M^+, 100%), 148 (53), 147 (43), 129 (85), 104 (45). 3 h heating (T=50 °C) of the adduct **6** resulted, under basic conditions, in the formation of naphthalene (**8**).

Scheme 3.

On the basis of the spectroscopic data and chemical transformation, we established that 2-fluoro-3-chloro-1,2,3,4-tetrahydronaphthalene was formed. The Newman projection formulae of two possible isomers are shown in Scheme 3. On the basis of coupling constants we have established that the trans adduct was formed and that conformation **6A** is the favoured one.

A 3 h reaction of the mixture *N*-bromosuccinimide–hydrogenfluoride–pyridine with 1,4-dihydronaphthalene resulted in the formation of one product (**6**), which

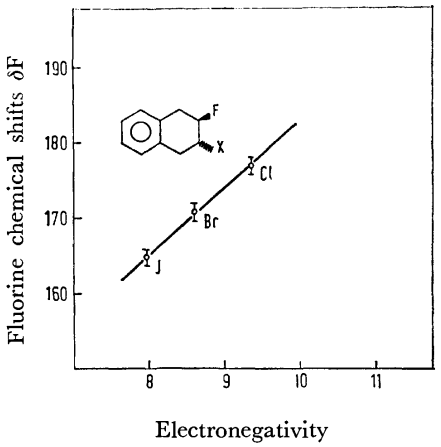

Fig. 1. Dependence of δF on electronegativity of the halogen atom.

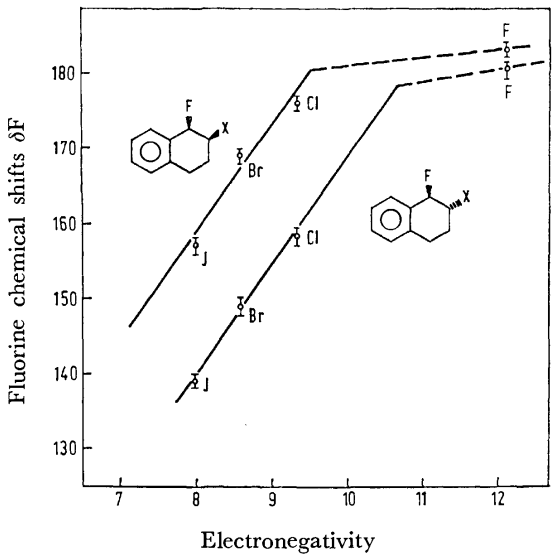

Fig. 2. Dependence of δF on electronegativity of the halogen atom.

showed one signal in its ^{19}F NMR at δF=−171 (dtd, $^{2}J_{FH_2}$=51 Hz, $^{3}J_{FH_1}$=27 Hz, $^{3}J_{FH_3}$=5 Hz) and in its proton spectrum two signals at lower field: δH_2=4.9 (ddd, $^{2}J_{H_2F}$=51 Hz, $^{3}J_{H_2H_1}$=5 Hz, $^{3}J_{H_2H_3}$=10 Hz), δH_3=4.3 (ddd, $^{3}J_{H_3F}$=5 Hz, $^{3}J_{H_3H_2}$=10 Hz, $^{3}J_{H_3H_4}$=5 Hz). In its mass spectrum, product **6** showed the following signals: *m/e*: 230 (M^++2, 60%), 228 (M^+, 60), 129 (100), 128 (50), 104 (16). Adduct **6** was also converted under basic conditions to naphthalene (**8**). On the basis of the spectroscopic data and the chemical transformation we established that *trans*-2-fluoro-3-bromo-1,2,3,4-tetrahydronaphthalene was formed. In this case also the preferential conformation is **6A**.

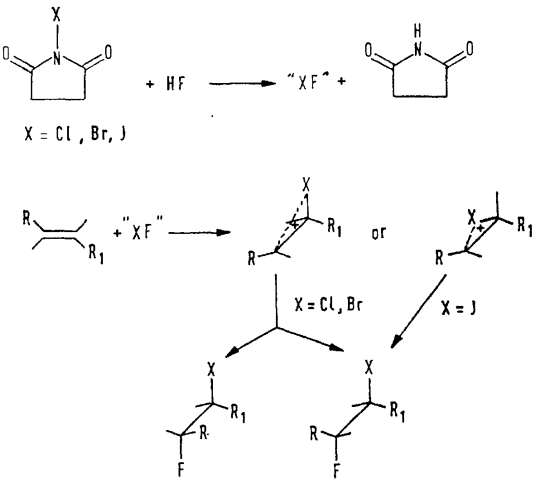
A 15-minute reaction of the mixture *N*-iodosuccinimide–hydrogenfluoride–pyridine with 1,4-dihydronaphthalene resulted in the formation of one product which showed one signal in its ^{19}F NMR spectrum at δF=−165 (dtd, $^{2}J_{FH_2}$=52 Hz, $^{3}J_{FH_1}$=26 Hz, $^{3}J_{FH_3}$=5 Hz), and in its proton spectrum two signals at lower field δH_2=5 (ddd, $^{2}J_{H_2F}$=52 Hz, $^{3}J_{H_2H_3}$=10 Hz, $^{3}J_{H_2H_1}$=5 Hz), δH_3=4.5 (ddd, $^{3}J_{H_3F}$=5 Hz, $^{3}J_{H_3H_2}$=10 Hz, $^{3}J_{H_3H_4}$=5 Hz). In its mass spectrum the product **6** showed the following signals: *m/e*: 276 (M^+, 45%), 149 (80), 130 (33), 129 (85), 128 (100), 127 (35), 115 (23). Product **6** was also converted under basic conditions to naphthalene. On the basis of the spectroscopic data and the chemical transformation, we established that *trans*-2-fluoro-3-iodo-1,2,3,4-tetrahydronaphthalene was formed. Again the preferential conformation was found to be **6A**.

The dependence of fluorine chemical shifts in *trans*-2-fluoro-3-halo-1,2,3,4-tetrahydronaphthalene on the Mulliken electronegativity of the halogen atom is presented in Fig. 1, while in Fig. 2 the influence of Mulliken electronegativity on chemical shifts of the fluorine atom in cis and trans 1-fluoro-2-halo-1,2,3,4-tetrahydronaphthalene is shown.

The correlation is good in the case of *trans*-2-fluoro-3-halo-1,2,3,4-tetrahydronaphthalene and *trans*-2-fluoro-3-halo-1,2,3,4-tetrahydronaphthalene, while in the case of cis adducts the correlation is worse. From Figs. 1 and 2 it can also be seen that the influence of different electronegativities of the halogen atom on fluorine chemical shifts is greater in the case of *trans*-1-fluoro-2-halo-1,2,3,4-tetrahydronaphthalene ($\Delta\delta$F/Δelectronegativity=13.4) than in the case of *trans*-2-fluoro-3-halo-1,2,3,4-tetrahydronaphthalene ($\Delta\delta$F/Δelectronegativity =9.4). Introduction of the values of fluorine chemical shifts[12] for cis and trans 1,2-difluoro-1,2,3,4-tetrahydronaphthalene into Figure 2 shows that these values strongly deviate from the straight line connecting the values for chloro, bromo and iodo derivatives, which could be ascribed to the different conformation of the difluoride and, or, through space interaction between fluorine atoms.

For bromofluorination with *N*-bromosuccinimide in the presence of hydrogen fluoride, reaction sequences involving a cyclic bromonium ion have been suggested.[3,4,14] In general, one can suggest a reaction between *N*-halosuccinimide and hydrogen fluoride, resulting "XF" species which can then react with the double bond, following Markovnikov type regioselectivity.

However, it is known that β-chlorocarbonium ions have only partly bridged structures, while the strongly

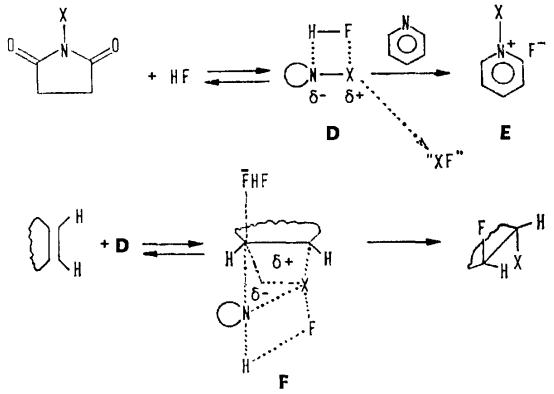


Scheme 4.

bridged halonium ions can be expected only in the case of iodofluorination with "IF" species. So, in the case of chlorofluorination and bromofluorination with "XF" species, syn and anti adducts should be observed, while in the case of iodofluorination only an anti-adduct is to be expected. We suggest a reaction pathway (Scheme 5), which can better explain the anti stereoselectivity. We propose the formation of a polarized *N*-halosuccinimide–hydrogen fluoride complex (**D**), which reacts in a reversible step with 1,2-dihydro- or 1,4-dihydronaphthalene to form a complex (**F**), decomposing in the next step to halofluorides. The reversible step, leading to complex (**F**), could explain the high degree of isomerization of cis alkenes.[8] The formation of "XF" species could be involved only in iodofluorination with the mixture of *N*-iodosuccinimide–hydrogen fluoride–pyridine.

A complex similar to (**F**) was suggested for bromination of 1-phenylcyclohexene with bromine–pyridine complex[15] and has also been proposed for E2Hal elimination of bromine from *trans*-1,2-dibromocyclohexane with benzenethiolate as base.[16] A polarized complex of NBS with olefins has been suggested in the bromination of styrene and cyclohexene with NBS in the presence of dimethylsulfoxide and methanol.[17]

A third interpretation presents the halofluorination reaction as involving the formation of the pyridinium–halide complex (**E**), reacting with 1,2- or 1,4-dihydronaphthalene with high stereoselectivity. *trans*-1-Fluoro-2-halo-1,2,3,4-tetrahydronaphthalenes, the only products formed in shorter reaction times, are unstable under the reaction conditions and isomerize to cis adducts.



Scheme 5.

Experimental

Procedure. IR spectra were recorded with a Perkin-Elmer 257 spectrometer, ^1H and ^{19}F NMR spectra with a JEOL JNM-PS-100 (CCl_4 or $CDCl_3$ as solvent and Me_4Si or CCl_3F as internal reference). Mass spectra, including high resolution measurements, were carried out on a CEC-21-110 spectrometer. GLPC was carried out with a Varian Aerograph 1800 instrument and TLC with Merck chromatoplates (PSC-Fertig-platten silica gel F-254, activated for 2 h at 120 °C before use).

Materials. A solution of pyridine–hydrogen fluoride was prepared according to Olah's procedure.[7] The pyridine used was predistilled, while hydrogen fluoride (Fluka, Purum) was used without prior purification. *N*-halosuccinimides (Fluka, Purum) were crystallised and dried (P_2O_5) before use. Diethyl ether was purified by standard methods and distilled before use. 1,2- and 1,4-dihydronaphthalene were prepared by known methods from naphthalene[18] and purified before use.

Addition and Isolation Procedures. In a mixture of hydrogen fluoride in pyridine (70% solution, 2 ml) and ether (2 ml), *N*-halosuccinimide (1.2 mmol) was dissolved with stirring at 0 °C for 10 min, and then the olefin (1 mmol) was added. The mixture was left at room temperature for various reaction times with stirring, then poured into ice-water and extracted with ether. The ether layer was washed with water, aqueous sodium hydrogencarbonate, then water again, dried (Na_2SO_4) and evaporated. The NMR spectra of crude reaction mixtures were recorded and then the pure products were obtained by preparative TLC or by crystallisation from the corresponding solvent. The structure of pure products were established from ^{19}F and ^1H NMR mass and IR spectral data.

trans-*1-Fluoro-2-chloro-1,2,3,4-tetrahydronaphthalene (**2a**)*: **2a** is an oily product (48%) (purified by preparative TLC, SiO_2; cyclohexane:chloroform:triethylamine 95:4.5:0.5). NMR: $\delta F = -158.5$ (dm), $\delta H_1 = 5.40$ (dd), $\delta H_2 = 4.60$ (m), δCH_2-$CH_2 = 2$ to 3 (m), δPh (m) $= 7.30$ $^2J_{FH_1} = 56$ Hz, $^3J_{FH_2} = 9$ Hz, $^3J_{H_1H_2} = 4$ Hz. MS: calcd for $C_{10}H_{10}ClF$ *m/e* 184.0449, found 184.0448 *m/e*: 186 ($M^+ + 2$, 20%), 184 (M^+, 60), 149 (20), 148 (60), 147 (20), 129 (50), 128 (35), 122 (100), 115 (15), 104 (10).

trans-*1-Fluoro-2-bromo-1,2,3,4-tetrahydronaphthalene (**2b**)*: White crystals (52%), mp=29—30 °C, (purified by preparative TLC under conditions mentioned below). NMR: $\delta F = -149$ (dm), $\delta H_1 = 5.60$ (dd), $\delta H_2 = 4.60$ (m), δCH_2—$CH_2 = 2.2$ to 2.8 (m), $\delta Ph = 7.30$ (m), $^2J_{FH_1} = 54$ Hz, $^3J_{FH_2} = 9$ Hz, $^3J_{H_1H_2} = 4$ Hz. MS: calcd for $C_{10}H_{10}BrF$ *m/e* 227.9964, found 227.9966, *m/e* 230 ($M^+ + 2$; 35%), 228 (M^+, 35%), 210 (16), 208 (16), 149 (40), 148 (48), 147 (25), 146 (15), 129 (100), 128 (60), 127 (24), 115 (21), 104 (10), 102 (10).

trans-*1-Fluoro-2-iodo-1,2,3,4-tetrahydronaphthalene (**2c**)*: White crystals (75%) (from ethanol) decomposing at room temperature. NMR: $\delta F = -139$ (dm), $\delta H_1 = 5.60$ (dd), $\delta H_2 = 4.60$ (m), $\delta CH_2 - CH_2 = 2.2$ to 2.8 (m), $^2J_{FH_1} = 54$ Hz, $^3J_{FH_2} = 9$ Hz, $^3J_{H_1H_2} = 4.5$ Hz. MS: calcd for $C_{10}H_{10}FJ$ *m/e* 275.9813, found 275.9816 *m/e* 276 (M^+, 28%), 149 (100), 129 (75), 128 (81), 127 (25), 115 (20), 102 (11).

trans-*2-Fluoro-3-chloro-1,2,3,4-tetrahydronaphthalene (**6a**)*: White crystals (60%), mp=29—30 °C, (purified by preparative TLC), NMR: $\delta F = -177.5$ (dtd), $\delta H_2 = 4.9$ (ddd), $\delta H_3 = 4.3$ (ddd), $\delta H_1 = 2.9$ (m), $\delta H_4 = 3.7$ (m), $\delta Ph = 7.1$ (m), $^2J_{FH_2} = 51$ Hz, $^3J_{FH_3} = 5$ Hz, $^3J_{FH_1} = 25.5$ Hz, $^3J_{FH_1'} = 25.5$ Hz, $^3J_{H_2H_3} = 10$ Hz, $^3J_{H_1H_2} = 5$ Hz, $^3J_{H_3H_4} = 5$ Hz. MS: calcd for $C_{10}H_{10}ClF$ *m/e* 184.0449, found 184.0449, *m/e*: 186 ($M^+ + 2$; 33%), 184 (M^+, 100), 149 (34), 148 (54), 147 (43), 146 (21), 129 (85), 128 (43), 127 (16), 115 (18), 104 (45), 103 (10).

trans-*2-Fluoro-3-bromo-1,2,3,4-tetrahydronaphthalene (**6b**)*: White crystals (68%), mp=35—37 °C, (purified by preparative TLC), NMR: $\delta F = -171$ (dtd), δ $H_2 = 4.9$ (ddd), δ $H_3 = 4.3$ (ddd), δ $H_1 = 2.9$ (m), δ $H_4 = 3.7$ (m), δ Ph=7.1, $^2J_{FH_2} = 54$ Hz, $^3J_{FH_3} = 5$ Hz, $^3J_{FH_1} = 27.0$ Hz, $^3J_{FH_1'} = 27.0$ Hz, $^3J_{H_2H_3} = 10$ Hz, $^3J_{H_1H_2} = 5$ Hz, $^3J_{H_3H_4} = 5$ Hz. MS: calcd for $C_{10}H_{10}BrF$ *m/e* 227.9964, found 227.9940, *m/e*: 230 ($M^+ + 2$; 60%), 228 (M^+, 60), 149 (31), 148 (35), 147 (28), 146 (17), 129 (100), 128 (50), 115 (20), 104 (16).

trans-*2-Fluoro-3-iodo-1,2,3,4-tetrahydronaphthalene (**6c**)*: White crystals (70%) (from ethanol), mp=57—58 °C.

NMR: $\delta F = -165$ (dtd), $\delta H_2 = 5.0$ (ddd), $\delta H_3 = 4.5$ (ddd), $\delta H_1 = 3.2$, $\delta H_4 = 3.7$ (m), $\delta Ph = 7.1$, $^2J_{FH_2} = 52$ Hz, $J_{FH_3} = 5$ Hz, $^3J_{FH_1} = 26$ Hz, $^3J_{FH_1'} = 26$ Hz, $^3J_{H_2H_3} = 10$ Hz, $^3J_{H_1H_2} = 5$ Hz, $^3J_{H_3H_4} = 5$ Hz. MS: calcd for $C_{10}H_{10}FJ$ *m/e* 275.9813, found 275.9825, *m/e*: 276 (M^+, 45%), 149 (80), 148 (7), 147 (14), 146 (14), 129 (85), 128 (100), 127 (35), 126 (13), 102 (20).

Treatment of the Mixture of trans- *and* cis-*1-Fluoro-2-halo-1,2,3,4-tetrahydronaphthalene with Base.* To a crude reaction mixture obtained by halofluorination of 1,2-dihydronaphthalene (longer reaction time), a solution of 1.3 mmol of potassium *t*-butoxide in *t*-butylalcohol (2 ml) was added, and the mixture heated for 3—4 h at $T = 50$ °C, then poured into water (10 ml), exacted with ether, the ether layer washed with water (5 ml twice), dried and evaporated. NMR spectra of the crude reaction mixture were recorded to obtain the product distribution, and then it was separated by preparative TLC (SiO_2, cyclohexane: chloroform: triethylamine 95:4.5:0.5). Products (**2**), and 1-fluoro-3,4-dihydronaphthalene (**4**) were isolated. Spectroscopic data for **4** were in agreement with those already published.[12]

Treatment of trans-*2-Fluoro-3-halo-1,2,3,4-tetrahydronaphthalene with Base.* To a solution of 1.5 mmol of potassium *t*-butoxide in *t*-butyl alcohol (2 ml), 1 mmol of product **6** was added and the mixture heated for 3—4 hours at 50 °C. The reaction mixture was poured into water (10 ml), extracted with ether, the ether layer washed with water (5 ml, twice), dried (Na_2SO_4) and evaporated. NMR spectra of the crude reaction mixture were recorded, showing that naphthalene (**8**) was the only product formed.

Spirans. 16. 3,3′-Spirobi[3,4-dihydro-2*H*-[1,3]oxazino[3,2-*a*]benzimidazole] and Its Thia Analogue†

Stefan Smoliński* and Agnieszka Czarny

Stereochemical Laboratory, Institute of Chemistry, Jagellonian University, 30-060 Kraków, Krupnicza 41, Poland

(Received November 10, 1977)

In order to obtain spiran the sodium derivative of *o*-phenylenediamine was subjected to reaction with 1,3-dibromo-2,2-bis(bromomethyl)propane in *N,N*-dimethylformamide. The compound was also synthesized by the reaction of the sodium derivative of 2,3-dihydro-1*H*-benzimidazol-2-one with 1,3-dibromo-2,2-bis(bromomethyl)propane. By this procedure the thia analogue of the spiran was obtained. In both cases the condensation route was unexpected. This is due to the fact that the solvent (DMF) takes part in the reaction and a stereo-electronic situation occurs, which is similar to that covered by Bredt's exclusion rule.

In order to obtain suitable tetraazaspirans the condensation of two moles of the sodium derivative of *o*-phenylenediamine, obtained by treating *o*-phenylenediamine in the presence of sodium hydride in dry dioxane with 1,3-dibromo-2,2-bis(bromomethyl)-propane in *N,N*-dimethylformamide was carried out. After heating for 100 h under reflux a product melting at 385—390 °C (with decomposition) was obtained. From elemental analysis and the molecular weight estimated from mass spectra it was found necessary to ascribe the structure of the required spiran enriched with two CO groupings to the product. Under the above conditions, it can be assumed that *N,N*-dimethylformamide reacts most likely with *o*-phenylenediamine yielding its monoformyl derivative, which gives with the other molecule of *N,N*-dimethylformamide 2,3-dihydro-1*H*-benzimidazol-2-one. Consequently it was established that spiran is formed in the condensation of the sodium derivative of 2,3-dihydro-1*H*-benzimidazol-2-one with 1,3-dibromo-2,2-bis(bromomethyl)propane in cellosolve. We have also found that 2,3-dihydro-1*H*-benzimidazol-2-one is obtained when *o*-phenylenediamine is heated with sodium hydride in dioxane with *N,N*-dimethylformamide. We have proposed two structures for the spiran compound obtained:

(**1**) a structure containing the urea grouping that has the CO group bridging in a 7-membered ring,

(**2**) a constitutionally symmetrical spiro compound of six rings containing the dihydrooxazine-benzimidazole arrangement.

In order to determine which structure is correct, the IR, UV, mass and NMR spectra were obtained. In the IR spectra the band at 1625 cm^{-1} indicates

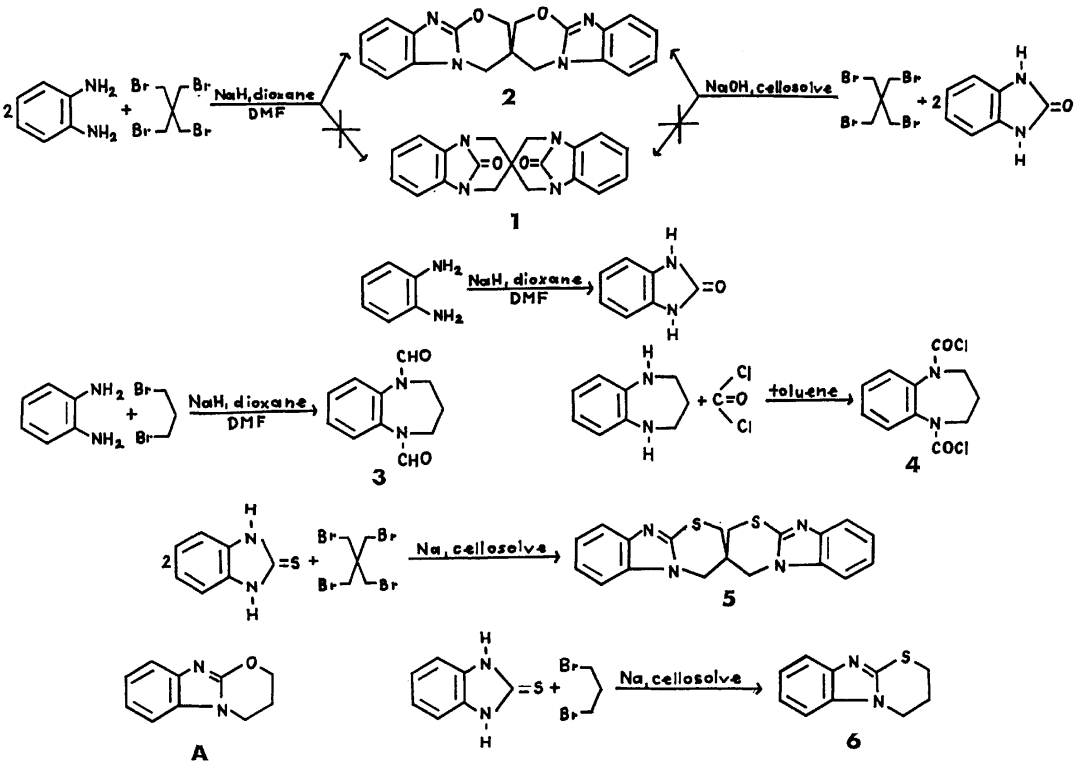

Fig. 1.

† Presented at the 26th IUPAC Congress, Tokyo (September 1977).

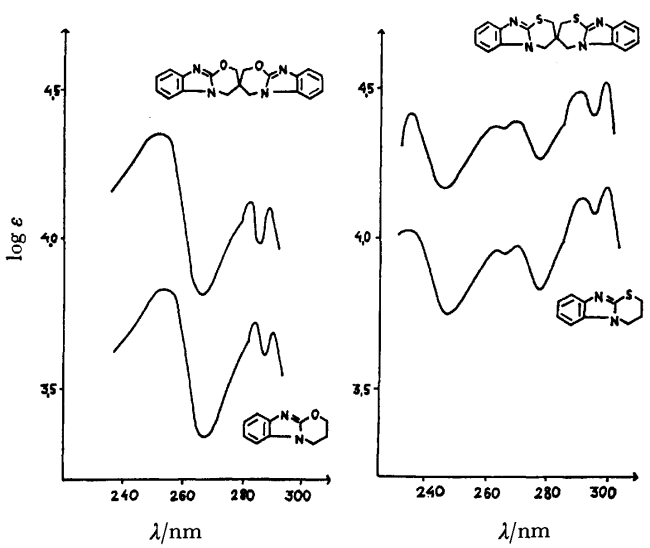

Fig. 2. UV-absorption spectra of compounds **2**—A and **5**—**6** in CH_2Cl_2.

the presence of the C=N group but not C=O; absorption bands indicate the presence of amine, methylene and aromatic groups. The NMR spectrum also suggests that structure (**2**) is correct. It was thus decided that the reported method of comparison[1-5] could be used and that the "half-compound" of the spiran obtained should be synthesized. The UV curves of the spiran and the "half-compound" could then be measured and compared. We expect them to have an analogous shape, the λ_{max} having different value in the extinction coefficient of λ_{max}. In spite of attempts, no "half-compound" of structure (**1**) could be obtained. Only compound **3** was obtained by treating 1,3-dibromopropane with *o*-phenylenediamine in the presence of sodium hydride in dioxane and *N*,*N*-dimethylformamide. 2,3,4,5-Tetrahydro-1*H*-1,5-benzodiazepine was treated with phosgene in toluene. Only product **4** was obtained. The structures of compounds **3** and **4** were confirmed by IR, NMR, and mass spectra.

2,3,4,5-Tetrahydro-1*H*-1,5-benzodiazepine was heated with *N*,*N*-dimethylformamide, but it remained unchanged. We followed the method of Htay and Meth-Cohn[6] to get the "half-compound" of the spiran **2** (structure A) by condensing the sodium derivative of 2,3-dihydro-1*H*-benzimidazol-2-one with 1,3-dibromopropane. By measuring the UV-absorption spectra of spiran **2** and compound A, low hyperchromism was found (at λ_{max}=250 nm the ratio of extinction coefficients was 1:3.25; at λ_{max}=282 nm 1:2.57; 288 nm 1:2.64) indicating that the dominant conformation of spiran **2** is as shown in Fig. 3a.

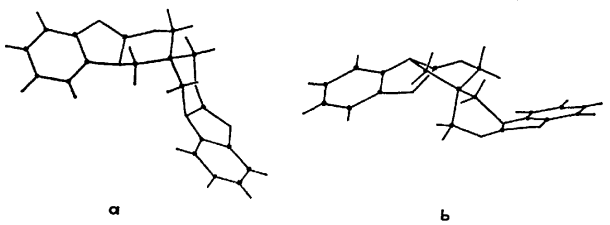

Fig. 3. The possible conformations of spiran **2**.

In conformation 3a the benzimidazole components are placed nearly orthogonally whereas the dihydrooxazine rings possess a chair conformation. Conformation 3b can be represented by two nearly parallel planes of the benzimidazole components annulated with dihydrooxazine rings in the biplanar conformation. Such geometry would have caused a higher hyperchromism.[5] Thus it is assumed that, in the reaction to obtain spiran **2**, 2,3-dihydro-1*H*-benzimidazol-2-one undergoes reaction in the tautomeric form, which in the presence of 1,3-dibromo-2,2-bis(bromomethyl)propane, forms the *O*-derivative from which spiran **2** resulted. Some analogy can be found with the experiments and results obtained by Htay and Meth-Cohn.[6]

In order to confirm the assumption we obtained the sulfur analogue of spiran **2**. 2,3-Dihydro-1*H*-benzimidazol-2-thione was heated with 1,3-dibromo-2,2-bis(bromomethyl)propane in the presence of metallic sodium in cellosolve; spiran **5**, mp 365—370 °C (with decomposition) and its dipicrate were obtained. Its "half-compound" (**6**) was synthesized in a similar way.[6] The measurement of UV-absortpion of spiran **5** and "half-compound" **6** revealed a hyperchromism of nearly the same magnitude as in the former case (at λ_{max}=235 nm the ratio of extinction coefficients was 1 : 1, 99; at λ_{max}=264 nm 1 : 2.6; 271 nm 1 : 2.6; 291 nm 1 : 2.25; 299 nm 1 : 2.2).

Considering the reactions, the following conclusion has been reached: Formation of structure (**2**) neglecting structure (**1**), is a result of the stereo-electronic effect. Structure (**1**) is inherently improbable, being of high energy due to steric inhibition of resonance the N lone pair and CO π-orbitals become necessarily orthogonal. The geometrical aspect is responsible for the case discussed being analogous with the arrangements covered by Bredt's rule concerning monocarbocyclic bridged ring system. The case is therefore considered to be included in Bredt's rule (whose nature is of stereo-electronic character), since there is no steric hindrance involved in the formation of spiran **1**.

It seems that failure[7,8] in obtaining 2-quinuclidinone and its 2-thione analogue (system [2.2.2]) which differs from the system considered here [3.2.1] but in which a similar stereo-electronic effect can be expected, confirms the assumption.

Experimental

IR spectra were measured with a Zeiss UR-10 spectrometer, UV-absorption spectra with a Unicam SP-1800, NMR spectra with a Tesla BS 487 at 80 MHz using TMS as a standard, and mass spectra with a LKB 9000 S apparatus at 70 eV.

*3,3'-Spirobi[3,4-dihydro-2*H*-[1,3]oxazino[3,2-a]benzimidazole] (**2**) from o-Phenylenediamine.* In a three necked flask 9.6 g of sodium hydride (0.2 m) in a 50% oil suspension were washed with dry benzene. 10.8 g (0.1 m) of *o*-phenylenediamine in 150 ml of dry dioxane was then added. The mixture was heated with stirring under reflux until no further hydrogen was evolved (3—4 h). A solution of 19.4 g (0.05 m) of 1,3-dibromo-2,2-bis(bromomethyl)propane in 150 ml of DMF was then added dropwise and the mixture refluxed for 100 h. The NaBr precipitate was separated and the

solvents removed by evaporation. The residue was treated with dilute hydrochloric acid (2:1). After filtering off the unreacted 1,3-dibromo-2,2-bis(bromomethyl)propane (10%) and resinous substances the spiran was precipitated from the acidic filtrate by addition of concentrated sodium hydroxide solution. The crude product was purified by sublimation at 320 °C in a high vacuum (0.1 mmHg); 510 mg (3%) of a colourless, crystalline product, mp 385—390 °C with decomposition.

From 2,3-Dihydro-1H-benzimidazol-2-one. In a thick glass tube a suspension of 4.5 g (0.025 m) of the sodium salt 2,3-dihydro-1*H*-benzimidazol-2-one in 100 ml cellosolve was prepared and 9.7 g (0.025 m, excess) of 1,3-dibromo-2,2-bis(bromomethyl)propane was added. The glass tube was sealed and heated at 120 °C for 100 h. The cellosolve was then distilled off and the spiran was purified as above; 680 mg (16%). IR(KBr): 1010, 1050 (C–O–C); 2940 (C–H aliph.); 770, 3060 (C–H arom.); 1625 cm^{-1} (C=N); UV (CH_2Cl_2): λ (logε)=250 (4.45), 282 (4.22), 288 nm (4.21); NMR(CF_3COOH): δ 4.75 (s, 4H, $-CH_2-N$), 5.2 (s, 4H, $-CH_2-O$), 7.5—7.7 (m, 8H, arom.); mass spectrum: *m/e*= 332. Found: C, 68.65; H, 4.96; N, 16.61%. Calcd for $C_{19}H_{16}N_4O_2$: C, 68.66; H, 4.85; N, 16.86%.

Dipicrate of Spiran **2**: 40 mg of the spiran **2** was treated with 10 ml of saturated picric acid solution in ethanol and refluxed for 1 h. A yellow, crystalline product (cellosolve) with a mp 235—237 °C was obtained. Found: N, 17.60%. Calcd for $C_{31}H_{32}N_{10}O_{16}$: N, 17.71%.

3,3'-Spirobi[3,4-dihydro-2H-[1,3]thiazino[3,2-a]benzimidazole] (5). 0.46 g (0.02-g atom) of metallic sodium was introduced into a thick glass tube containing 50 ml of cellosolve and then 1.5 g (0.01 m) of 2,3-dihydro-1*H*-benzimidazol-2-thione and 3.9 g (0.01 m, excess) of 1,3-dibromo-2,2-bis(bromomethyl)propane were added. The tube was sealed and heated at 120 °C for 50 h. The cellosolve was then distilled off and the spiran separated and purified as above. 880 mg (48%) of a colourless, crystalline product, mp 365—370 °C (with decomposition) were obtained. IR (KBr): 2935 (C–H aliph.); 770, 3055 (C–H arom.); 1610 cm^{-1} (C=N); UV(CH_2Cl_2): λ(log ε)=235 (4.41), 264 (4.37), 271 (4.38), 291 (4.48), 299 nm (4.50); NMR (CF_3COOH): δ 3.9 (s, 4H, $-CH_2-S$), 4.8 (s, 4H, $-CH_2-N$), 7.5—7.85 (m, 8H, arom.); mass spectrum *m/e*=364. Found: C, 62.45; H, 4.39; N, 15.13%. Calcd for $C_{19}H_{16}N_4S_2$: C, 62.61; H, 4.43; N, 15.37%.

Dipicrate of Spiran **5**: This was prepared according to the procedure for the previously described dipicrate. A yellow, crystalline product (cellosolve), mp 215—217 °C was obtained. Found: N, 16.84%. Calcd for $C_{31}H_{22}N_{10}O_{14}S_2$: N, 17.02%.

1,5-Diformyl Derivative of 2,3,4,5-Tetrahydro-1H-1,5-benzodiazepine (3). In a three necked flask, 9.6 g (0.2 m) of sodium hydride in a 50% oil suspention were washed with dry benzene, 10.8 g (0.1 m) of *o*-phenylenediamine in 150 ml of dry dioxane was then added. The mixture was heated with stirring under reflux until no further hydrogen was evolved (3—4 h). A solution 20.2 g (0.1 m) of 1,3-dibromopropane in 150 ml of DMF was then added dropwise and the mixture refluxed for 50 h. The NaBr precipitate was separated and the solvents removed by evaporation. The residue was treated with dilute hydrochloric acid (2:1). After filtration, the filtrate was treated with concentrated sodium hydroxide solution and decanted off, leaving oily impurities, and extracted with butanol. From the extract, 150 mg (0.7%) of a colourless, crystalline product (1-butanol) were recovered, mp 170—172 °C. IR(KBr): 1670 (C=O), 790, 3040 (C–H arom.), 2950 cm^{-1} (C–H aliph.); NMR ($CDCl_3$): δ 2.0 (q, 2H, $-CH_2-$), 3.8 (t, 4H, $-CH_2-N$), 7.1—7.5 (m, 4H, arom.), 8.25 (s, 2H, H–C=O); mass spectrum: *m/e*=204. Found: C, 64.58; H, 6.13; N, 13.56%. Calcd for $C_{11}H_{12}N_2O_2$: C, 64.72; H, 5.93; N, 13.74%.

1,5-Bis(chloroformyl) Derivative of 2,3,4,5-Tetrahydro-1H-1,5-benzodiazepine (4). A solution of 0.75 g (0.005 m) of 2,3,4,5-tetrahydro-1*H*-1,5-benzodiazepine in 120 ml of dry toluene was prepared in a three necked flask fitted with a reflux condenser and stirrer. While being mixed 4.2 g of a 12% solution of phosgene in toluene (0.005 m) was added and the reaction mixture stirred for 3 h. After amine hydrochloride had been removed and toluene distilled off, the solid residue was purified chromatographically on an Alox column in benzene. 120 mg (8.8%) of a colourless, crystalline product, mp 165—166 °C were obtained. IR(KBr): 2965 (C–H aliph.), 785, 3050 (C–H arom.), 675 (C–Cl), 1725 cm^{-1} (C=O); mass spectrum: *m/e*=272. Found: C, 48.46; H, 3.75; N, 10.27%. Calcd for $C_{11}H_{10}N_2O_2Cl_2$: C, 48.37; H, 3.69; N, 10.29%.

3,4-Dihydro-2H-[1,3]thiazino[3,2-a]benzimidazole (6). 0.92 g (0.04 g-atom) of metallic sodium was introduced into 50 ml of cellosolve in a three necked flask equipped with reflux condenser and stirrer and then 1.5 g (0.02 m) of 2,3-dihydro-1*H*-benzimidazol-2-thione and 4 g (0.02 m) of 1,3-dibromopropane were added. The mixture was refluxed for 3 h. The cellosolve was distilled off and the product was purified chromatographically on an Alox column in benzene. 120 mg (6.3%) of a colourless, crystalline (benzene) product, mp 133—135 °C were obtained. IR (KBr): 2935 (C–H aliph.), 775, 3040 (C–H arom.), 1610 cm^{-1} (C=N); UV (CH_2Cl_2): λ(log ε)=235 (4.12), 264 (3.95), 270 (3.97), 292 (4.13), 300 nm (4.16); NMR ($CDCl_3$): δ 2.2—2.5 (m, 2H, $-CH_2-$), 3.1 (t, 2H, $-CH_2-S$), 4.0 (t, 2H, $-CH_2-N$), 7.0—7.7 (m, 4H, arom.); mass spectrum: *m/e*=190. Found: C, 62.97; H, 5.22; N, 14.66%. Calcd for $C_{10}H_{10}N_2S$: C, 63.12; H, 5.29; N, 14.73%.

Promoting Action of Inorganic Gases on the Rate of Dehydration of 2-Propanol over Ca-Y Zeolite

Yoshio ISHINAGA, Kiyoshi OTSUKA,* and Akira MORIKAWA

Department of Chemical Engineering, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

(Received July 28, 1978)

Synopsis. The dehydration of 2-propanol over Ca-Y zeolite has been enhanced in the presence of NO_2, SO_2, and Cl_2 at 100 °C. This promoting action has been ascribed to the formation of acidic hydroxyl groups resulting from the reaction of the inorganic gases with zeolitic water or basic hydroxyl groups attached to the metal cations.

The promoting action of inorganic gases on the rate of dehydration of alcohol or hydrocarbon conversion, such as cracking, alkylation or isomerization has been recognized specifically on zeolites.[1-3] The favorable action of gases which contain hydrogen atom or atoms in their structure, such as H_2O, HCl, or H_2S, has been ascribed to their ability to generate protonic sites by the dissociation of the hydrogen atoms as follows:[4-9]

$$M^{2+} + H_2O \rightleftharpoons M(H_2O)^{2+} \rightleftharpoons M(OH)^{+} + H^{+} \quad (1)^{4,10,11}$$

$$M^{2+}Z^{2-} + HCl \rightleftharpoons \overset{Cl^- \; H^+}{\underset{|}{M^{2+}}\underset{|}{Z^{2-}}} \quad (2)^{6,7,12,13}$$

$$M^{+}Z^{-} + H_2S \rightleftharpoons \overset{SH^- \; H^+}{\underset{|}{M^{+}}\underset{|}{Z^{-}}} \quad (3)^{14}$$

where, M^{2+} or M^{+} and Z^{2-} or Z^{-} represent the exchange-able cation and the anionic framework of the zeolite, respectively. The promoting action of compounds possessing no hydrogen atoms, such as NO_2, SO_2, or Cl_2, has however not satisfactorily been interpreted.

In this work, the promoting action of NO_2, SO_2, Cl_2, CO_2, HCl, and H_2S on the dehydration of 2-propanol over Ca-Y zeolite has been studied in connection with the formation of acidic hydroxyl groups by the foreign gases. The dehydration of 2-propanol is a typical reaction catalyzed by protonic sites over zeolites[2] and consequently has been used as a test reaction.

Results and Discussion

The effect of the gases on the rate of propylene and diisopropyl ether formation, denoted by R_{prp} and R_{ether}, over Ca-Y zeolite is shown in Fig. 1, where the initial rate has been plotted as a function of the amount of adsorbed gases measured during the course of reaction. The reaction was conducted at 100 °C under 24 Torr of 2-propanol using a conventional gas circulation system. Prior to each run, the Ca-Y zeolite (79% exchanged) was calcined at 500 °C in dried oxygen and degassed for 2 h at the same temperature. After the adsorption of the foreign gas

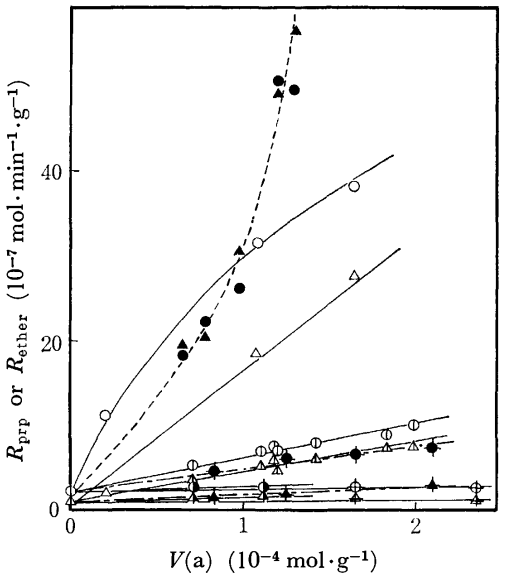

Fig. 1. Effect of inorganic gases on the rate of dehydration of 2-propanol over Ca-Y zeolite : Circle; propylene, triangle; diisopropyl ether, ●, ▲; NO_2, ○, △; Cl_2, ◑, ◭; SO_2, ◑, ◭; CO_2, ⊕, ⊕; HCl, ⊕, ⊕; H_2S.

at 100 °C for 20 min, 2-propanol was fed into the system thereby initiating reaction. The amount of gas adsorbed during the course of the reaction was calculated by measuring the amount of foreign gas in the gas-phase by gas-chromatography. The pressure of the foreign gas under the reaction conditions was less than 1.5 Torr. The Ca-Y was prepared from Na-Y (Linde SK-40) by a conventional ion-exchange method using an aqueous solution of $CaCl_2$ at 25 °C. The 2-propanol (spectro grade) and the inorganic gases (purity>99%) were purified by trap to trap distillation *in vacuo*. The results illustrated in Fig. 1 indicate that NO_2, Cl_2, SO_2, and HCl considerably enhance the dehydration of 2-propanol over Ca-Y zeolite. In the case of CO_2, the promoting action developed when the gas was pre-adsorbed at temperatures in excess of 300 °C up to 500 °C.

The formation of acidic hydroxyl groups after adsorption of the six inorganic gases onto the zeolite has been examined as follows. A wafer of the zeolite (3—4 mg/cm^2) was calcined in dried oxygen at 450 °C for 1 h, and degassed for 2 h at the same temperature. The wafer was then allowed to come into contact with D_2O vapour 9 Torr for 4 h at 200 °C in order to exchange OH by OD groups since the broad OH stretching band around 3600 cm^{-1}, probably due to

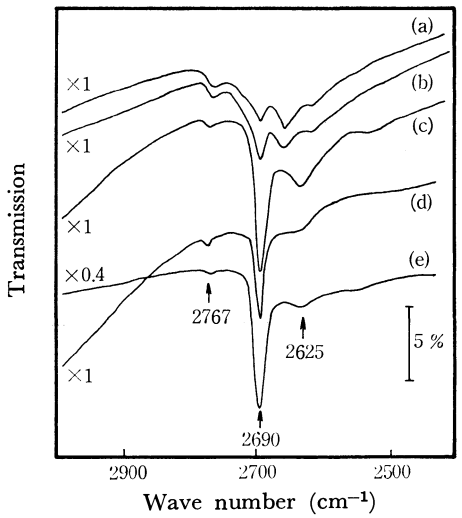

Fig. 2. Spectra of the deuteroxyl stretching vibrations of Ca-Y zeolite : (a) evacuated for 1 h at 450 °C after D_2O treatment, (b) exposed to SO_2 after (a), (c) exposed to NO_2 after (a), (d) exposed to Cl_2 after (a), (e) exposed to DCl after (a). The bands at 2767, 2690, and 2625 cm^{-1} are due to silica-type deuteroxyl groups, acidic deuteroxyl groups in supercages, and those in hexagonal prisms or sodalite cages, respectively.

strongly held water molecules on the zeolite, and the absorption of infrared beam by water in the air make it difficult to identify the different kinds of OH group. After the exchange, the wafer was degassed again for 1 h at 450 °C. Figure 2 shows the spectra of the OD stretching vibrations of Ca-Y zeolite after adsorption of NO_2, Cl_2, SO_2, and DCl for 20 min at 100 °C (16 Torr for each compound; 9 Torr for NO_2). The spectra have been measured at 100 °C after condensing the adsorbate in the gas phase in a liquid nitrogen trap. For these four compounds, it is clear that the intensity of the 2690 cm^{-1} band due to the acidic deuteroxyl groups[12] increases greatly after the adsorption of the gas. This band corresponds to the band at 3640 cm^{-1} attributed to the acidic hydroxyl groups in the supercages for the undeuterated Ca-Y zeolite.[11,15]

The high promoting action of NO_2, Cl_2, and SO_2 indicated in Fig. 1 can be ascribed to the newly formed acidic hydroxyl groups. The lower promoting action of H_2S and CO_2 can be accounted for by the low ability to generate acidic hydroxyl groups, substantiated by a very small increase in intensity of the acidic OD band after adsorption of the gas. In the case of CO_2, a much higher temperature was needed for the generation of the acidic hydroxyl groups.[2,16] The promoting action of HCl was not as large as anticipated from the evidence in Fig. 2.

The following schemes are proposed for the generation of protonic sites after the adsorption of NO_2, SO_2, and Cl_2 from an analogy to the mechanisms suggested in the case of CO_2:[2,16]

$$Ca^{2+}(H_2O)_x + A \longrightarrow Ca^{2+}[B]^{2-} + 2H^+ + (H_2O)_{x-1} \quad (4)$$

where, A is NO_2, SO_2, or Cl_2 and B is $O{\diagdown}N{=}O{\diagup}O$, $O{\diagdown}S{=}O{\diagup}O$, or $OCl{\diagup}Cl$, respectively, or

$$Ca(OH)^+ + A \longrightarrow Ca^+B^- + H^+ \quad (5)$$

where, A is NO_2, SO_2, or $1/2Cl_2$ and B is $-O-N{\diagup}{\diagdown}O$, $-O-S{\diagup}{\diagdown}O$, or OCl, respectively. $Ca^{2+}(H_2O)_x$ is the divalent cation coordinated by water, and $Ca(OH)^+$ is the basic species formed through the dissociation of hydrating water during the pretreatment of the zeolite. Further infrared spectroscopic studies on this point are in progress.

BULLETIN OF THE CHEMICAL SOCIETY OF JAPAN, VOL. 52 (3), 935—936 (1979)

Fluorescence from Bound Ionic States of Neat Molecular Crystals: *p*-Substituted *N,N*-Dimethylanilines[1)]

Kotaro ARAYA and Jun-ichi AIHARA*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received May 24, 1978)

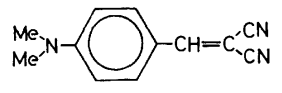
Synopsis. Fluorescences were detected from bound ionic states (*i.e.*, charge-transfer exciton states) of two neat molecular crystals, each formed by a single molecular component. These fluorescent compounds are *p*-(2,2-dicyanovinyl)-*N,N*-dimethylaniline and *p*-(2-nitrovinyl)-*N,N*-dimethylaniline. They are dimorphic in the solid state.

Interest in charge-transfer (CT) properties of molecular solids[2)] has increased greatly due to the recent observation of a high conductivity anomaly in a mixed molecular crystal TTF-TCNQ.[3)] It is now well-known that transitions to bound ionic states (*i.e.*, CT exciton states) are observed in the optical spectra of such mixed crystals.[4,5)] Here, a CT exciton means an intermolecular CT excitation in the solid.[2)] However, the corresponding states of neat molecular crystals had long eluded direct observation, until in 1968 Tanaka and Shibata detected a CT excitation in the 9,10-dichloroanthracene crystal.[6)] One of the most serious difficulties in studying CT excitons has been heavy interference from neutral Frenkel excitons (*i.e.*, excitons caused by the intramolecular excitations) energetically degenerate with them.[7)]

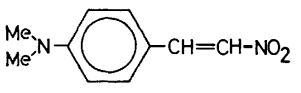
In previous papers,[8)] we showed that a CT exciton band can be shifted to the low energy side, lower than any Frenkel exciton band, if one uses an appropriate aromatic compound with a strong electron-attracting chromophore. This idea was verified by a recent X-ray crystallographic analysis of 2-(*p*-methoxyphenyl)-*p*-benzoquinone crystals.[9)] Component molecules are therein arranged so as to promote intermolecular CT interactions. In this note we report the first observation of fluorescence from the bound ionic states of neat molecular solids of this type.[10)]

Results and Discussion

After an extensive search two aromatic compounds, each with a strong electron-attracting chromophore, were found to be fluorescent in the solid state.[11)] They are *p*-(2,2-dicyanovinyl)-*N,N*-dimethylaniline (I) and *p*-(2-nitrovinyl)-*N,N*-dimethylaniline (II). Figures 1



I



II

and 2 show electronic spectra of these two compounds both in chloroform solution and in the solid state. Fluorescence spectra were recorded on a Hitachi MPA-2A fluorescence spectrophotometer, and were corrected for the spectral response of the analyzing system, unless otherwise stated. All absorption spectra were measured with a Beckman DK-2A spectrophotometer with reflectometric equipment. Solid-state absorption spectra were derived from diffuse reflection spectra of the solids dispersed in the powdered sodium chloride.

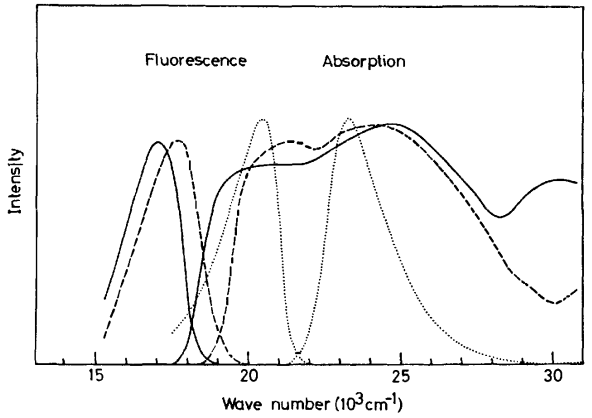


Fig. 1. Electronic spectra of Compound I in two solid states (—— and ----) and in chloroform solution (……).

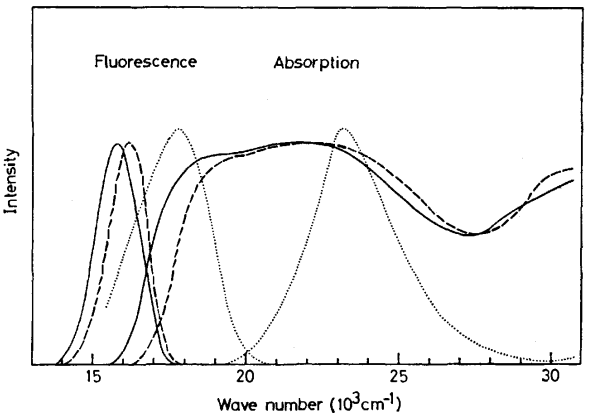

Fig. 2. Electronic spectra of Compound II in two solid states (—— and ----) and in chloroform solution (……).

Interestingly, Compound I was dimorphic. The yellow crystal was obtained from a benzene solution, whereas the orange crystal was obtained by recrystalization from methanol. The visible spectra of these solids consist of two broad absorption bands, one around 20000 cm^{-1} and one around 24000 cm^{-1}. As before,[8,12)] the first absorption band of each crystalline form can be assigned to the transition to the bound ionic state, *i.e.*, an intermolecular CT transition, because of the dual charge-transfer properties of the component molecule.[13)] The second absorption band has a counterpart in the solution absorption spectrum, and should hence be a neutral Frenkel exciton band.

The difference in color between the two crystalline forms is evidently related to a considerable shift of the CT exciton band. The spectral shift amounts to about 1000 cm^{-1}.

Here, one should note that a remarkable red shift in the fluorescence maximum of Compound I occurs on going from solution to solids. The fluorescent levels of the solids are obviously different from that of the solution. By inspection of the spectra, the fluorescence of each solid can naturally be identified as arising from the bound ionic state (*i.e.*, CT exciton state). The fluorescence maxima are located at 17700 cm^{-1} for the yellow crystal and 17000 cm^{-1} for the orange crystal. The energy difference between the two fluorescence bands is comparable to that between the corresponding CT exciton bands. In contrast to the spectral behavior, the structural difference between the two crystalline forms is too small to discern by means of the X-ray powder patterns.

Compound II also exists in two different crystalline forms. They are red and red-violet crystals obtained from the methanol and benzene solutions, respectively. As shown in Fig. 2, a CT absorption band of the red-violet crystal is about 700 cm^{-1} shifted to the low energy side compared with that of the red one. The shift of the fluorescence band due to dichromism appears to be in the same direction and of the same amount as that of the absorption edge, although these solid-state fluorescence spectra are uncorrected. The spectral shift of the bound ionic state suggests a change in the intermolecular interactions in the solid.

The importance of these bound ionic states mostly stems from their involvement in electron transfer and electron-hole recombination processes in neat molecular crystals.[2,3,13] The existence of the CT exciton level may also be responsible for the shifts of local excitation bands in the solid-state spectrum.[5] In this sense, the present finding of fluorescent CT exciton bands provides an important clue to a substantial characterization of the CT exciton state, and might help to clarify its role in electron and energy transfers in the neat molecular crystals.

Solvent Isotope Effect of H_2O and D_2O on the Partition Coefficient of 1,3-Di-*n*-alkyl-1,3-propanedione

Hitoshi WATARAI, Motoya MURAKAMI, and Nobuo SUZUKI*

Department of Chemistry, Faculty of Science, Tohoku University, Sendai 980

(Received July 1, 1978)

Synopsis. The apparent partition coefficients of seven 1,3-di-*n*-alkyl-1,3-propanediones have been determined in dodecane/H_2O and dodecane/D_2O systems. From the results, the transfer free energies of β-diketones from H_2O to D_2O, $\Delta G_{H_2O\rightarrow D_2O}$, have been calculated and are discussed in terms of the cavity formation energy.

In solvent extraction, the partition process of a metal chelate formed in an aqueous phase is one of the most important processes governing the distribution ratio of a metal ion. The partition coefficient of a metal chelate is primarily determined by the hydrophobic character which is a substantial part of the chelate formed by the reaction of a metal ion with a hydrophobic extractant. A quantitative discussion of the hydrophobicity of the extractant, however, is not thoroughly recognized. In this study the interaction between water and 1,3-di-*n*-alkyl-1,3-pentanediones has been examined, the latter compounds being well-known as extractants, by partition experiments in the dodecane/H_2O and dodecane/D_2O systems. The reason for employing β-diketones is that the size of the hydrophobic part of the reagent can be varied stepwise by changing the chain length of the *n*-alkyl group. D_2O is considered to be more structured than H_2O,[1] so that partition experiments in the two systems will provide useful information on the hydrophobic interaction between water and the reagents.

Experimental

Materials. Reagent grade acetylacetone (2,4-pentanedione) was purified by fractional distillation. Other normal chain β-diketones were synthesized by the Claisen acylation.[2] The crude products were purified by the copper salt method[3] and subsequently distilled under reduced pressure. Dodecane (Tokyo Kasei G. R.) was agitated twice with a mixture of fuming sulfuric acid and sulfuric acid (1 : 4) overnight, washed with water and distilled under reduced pressure. Redistilled water was used throughout the experiments and heavy water (Merk 99.7%) used as purchased.

Partition Experiments. A certain volume (5 ml or 4 ml) of the dodecane solution of the β-diketone (below 10^{-2} M) and an equal volume of H_2O (5 ml) or D_2O (4 ml) were stirred by a magnetic stirrer for 6 h in a thermostated glass vessel at 25±0.05 °C. After being allowed to stand for 1 h, an aliquot of the aqueous phase was pipetted into a quartz cell and the transmittance at the absorption maximum recorded for each β-diketone on a Hitachi 356 spectrophotometer. Partition coefficients were obtained from the initial concentration and the concentration in the aqueous phase determined photometrically. Partition experiments were repeated a minimum of three times.

Results and Discussion

The observed partition coefficients (P_{H_2O} and P_{D_2O}) are listed in Table 1 and as can be seen the partition coefficients appear to increase with the carbon numbers of the *n*-alkyl group. P_{D_2O} values appear to be slightly less than the P_{H_2O} values for the smaller diketones, but slightly greater for the larger diketones. The ratios of P_{D_2O}/P_{H_2O}, which are shown in Table 1, differ from unity revealing the solvent isotope effect on the partition coefficient.

From the partition coefficient data, the transfer free energy of the β-diketone from H_2O to D_2O ($\Delta G_{H_2O\rightarrow D_2O}$) has been estimated using,

$$\Delta G_{H_2O\rightarrow D_2O} = RT\ln\left(\frac{P_{D_2O}}{P_{H_2O}}\cdot\frac{V_{H_2O}}{V_{D_2O}}\right), \quad (1)$$

where V is the molar volume of the solvent. The results are also listed in the last column of Table 1. Since the diketones are in the keto and enol forms in solution and possess reactive protons, *viz.* an enol proton and a methyne proton for the enol form and methylene protons for the keto form, a change in the keto-enol equilibrium will be the result of H–D exchange and/or by the solvent effect of H_2O and D_2O. The PMR spectra of acetylacetone in D_2O provides that all the reactive protons are replaced by deuteron in D_2O. However, since the ratio of the molar ex-

tinction coefficients in H_2O and D_2O, which is thought to reflect the difference in the keto-enol equilibrium constant in the two solvent,[4] is constant (*ca.* 1.03) for most diketones, it is to be expected that the transfer free energies of the enol and keto forms will show a similar trend to the observed transfer free energy including those of the keto and enol forms. Hence, in this study the apparent transfer free energy of β-diketones will be discussed.

From Table 1, it may be seen that $\Delta G_{H_2O\to D_2O}$ is approximately zero for smaller compounds but positive for larger β-diketones. A large compound, however, does not always show a positive value of transfer free energy, *e.g.*, Jolicoeur *et al.*[5] have reported a negative value for 3-decanone (-270 ± 36 cal mol^{-1}).

The free energy of transfer can conveniently be divided into three contributions;[6]

$$\Delta G_{H_2O\to D_2O} = \Delta G(\mathrm{CAV}) + \Delta G(\mathrm{SOL}) + \Delta G(\mathrm{STR}), \quad (2)$$

where the terms on the righthand side of Eq. 2 represent the solvent isotope effect on the free energy due to CAV, the process of cavity formation in the solvent; SOL, the solvation of the polar group of the molecule; STR, the structural rearrangement of the solvent around the cavity enclosing the solute. ΔG(SOL) is expected to reflect the interactions between the solvent and both the carbonyl group of the keto form and the hydroxyl group of the enol form. Dahlberg[7] reported that the transfer free energy for acetone is close to zero and consequently there will be no serious difference between the free energies of the H-bond and D-bond to the carbonyl oxygen. Dahlberg furthermore reported the transfer free energy of benzene (0 ± 15 cal mol^{-1}) and benzyl alcohol (-9 ± 20 cal mol^{-1}) and from these data, it is expected that ΔG(SOL) for β-diketones is slightly negative and is not the dominant factor in the present situation.

The hydrogen bonding energy in D_2O is thought to be larger than that in H_2O in consideration of the greater cohesive energy density of D_2O than H_2O, and consequently the structural change around the solute molecule will be more extensive in D_2O. Hence, ΔG(STR) will show a negative value with increasing carbon number in the *n*-alkyl chain due to hydrophobic hydration around the group. This factor may be important in the case of decanone, but is not dominant here. Dahlberg reported that $\Delta G_{H_2O\to D_2O}$ for 3-methylacetylacetone showed a fairly large value ($+200$ cal mol^{-1}) and interpreted this result from the general tendency that a solute which possesses both ring and branches shows a positive value.[7] The present results appear to support this hypothesis.

Since the amount of void is greater in D_2O than in H_2O, the small solute molecules which can occupy void without excessive disruption of the hydrogen bonds in the solvent will be better accommodated in D_2O (negative ΔG(CAV)). The bulky molecules which disrupt a significant number of hydrogen bonds will show a positive ΔG(CAV). This hypothesis appears to be supported by the recent solution theory, *viz.* the scaled particle theory amended by Stillinger.[8] Lucas and Bury[9] have computed $\Delta G_{H_2O\to D_2O}$ for a nonpolar solute using this theory and plotted the result as a function of solute hard sphere diameter, a_2. The plot of the transfer free energy is slightly negative for $a_2 < \approx 3.0$ Å and positive for $a_2 > 3.0$ Å. This is consistent with the trend observed in this study.

From the above discussion, it has been concluded that the positive transfer free energy observed for the larger β-diketones is attributable to the contribution from the cavity formation work. Since the most important process in solvent extraction is the partition of the metal chelate coordinated by a hydrophobic ligand, more attention needs to be focused on the cotribution of cavity formation in the extraction process.

Electronic Properties and π-π^* Absorption Spectra of 1- and 2-Methyl-4-amino-5*H*-[1]benzopyrano[3,4-*c*]pyridin-5-one

Kozo INUZUKA* and Akira FUJIMOTO

Department of Applied Science, Faculty of Technology, Tokyo Denki University, Kanda, Chiyoda-ku, Tokyo 101

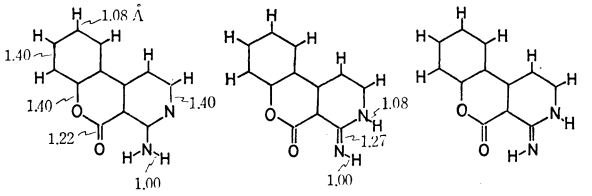
(Received August 7, 1978)

Synopsis. The tautomerization of 4-amino-5*H*-[1]-benzopyrano[3,4-*c*]pyridin-5-one (BPP) in the ground state has been briefly discussed by the CNDO/2 method. The π-π^* absorption spectra of 1-methyl-4-amino-5*H*-[1]benzo-pyrano[3,4-*c*]pyridin-5-one (1-MBPP) and 2-methyl-4-amino-5*H*-[1]benzopyrano[3,4-*c*]pyridin-5-one (2-MBPP) in solution have been obtained. Based on the MO calculations of BPP, assignment of the observed π-π^* absorption bands of 1-MBPP and 2-MBPP have been made.

Recently, the thermodynamic properties of the hydrogen bond of 1- and 2-alkyl-4-amino-5*H*-[1]benzo-pyrano[3,4-*c*]pyridin-5-one with alcohols have been studied both experimentally and theoretically.[1] Also, the fluorescence of the proton-transferred excited species (tautomer) between 2-MBPP and acetic acid has been investigated,[2] but as yet the absorption spectra of 1-MBPP and 2-MBPP have not been discussed. In this paper, the possibility of tautomerization of BPP in the ground state and the π-π^* absorption spectra of 1-MBPP and 2-MBPP are reported.

Results and Discussion

Electronic Properties in the Ground State. Dipole moments, charge densities, and π-bond orders of BPP, 1-MBPP, and 2-MBPP in the ground state have already been discussed in a previous paper.[1] In this paper the calculation of the total energies of the following three kinds of the models **1**, **2**, and **3** were conducted to clarify the tautomerization from **1** to **2** and **3** in the ground state by the CNDO/2 method using the parameters of Pople, Santry, and Segal.[3] The calculated total energies (a. u.) and dipole moments are as follows: **1**: −151.47204 (3.735 D); **2**: −151.42766 (9.483 D); **3**: −151.42170 (8.043 D).



1 **2** **3**

The energy differences between **1** and **2**, and **1** and **3** are 27.84 and 31.58 kcal/mol suggesting that the tautomerization from model **1** to **2** and **3** may be difficult in the ground state. Therefore, the most stable structure corresponds to model **1** with an intramolecular hydrogen bond between the carbonyl and amino groups as discussed in a previous paper.[1]

π-π^* Absorption Spectra of 1-MBPP and 2-MBPP. 1-MBPP, 2-MBPP, isooctane (2,2,4-trimethylpentane), and ethanol were the same as reported previously.[1]

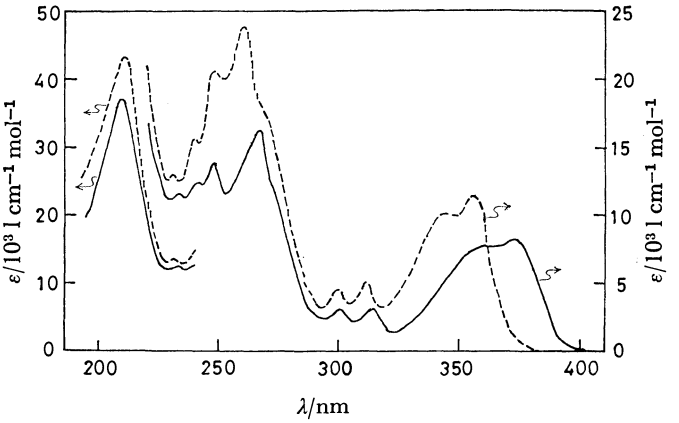


Fig. 1. Absorption spectra of 1-MBPP (——) and 2-MBPP (----) in isooctane solution.

11	5.944	209	0.085	209		210	
12	6.046	205	0.032				
13	6.135	202	0.175				
14	6.198	200	0.141				

The absorption spectra of 1-MBPP and 2-MBPP in isooctane at room temperature are shown in Fig. 1, and the band maxima and corresponding oscillator strengths are listed in Table 1. The first absorption band of 1-MBPP appears at a wavelength longer than that of 2-MBPP. A trend is found in other alkyl compounds (alkyl group: *n*-pentyl-, *n*-nonyl-).[1]

It was necessary to establish whether (1) the first excited state was of π,π^* character or not, and (2) the first absorption band of 1-alkyl compounds appeared at a wavelength longer than that of the 2-alkyl compounds or not. To this end the energies of the

Table 2. The energies of the next highest occupied molecular orbital (NHOMO), the highest occupied molecular orbital (HOMO), and the lowest unoccupied molecular orbital (LUMO) of 1-MBPP, 2-MBPP, and BPP (in a. u.)

MO	1-MBPP	2-MBPP	BPP
NHOMO	−0.4091 (n)	−0.4178 (n)	−0.4238 (n)
HOMO	−0.3930 (π)	−0.4026 (π)	−0.4040 (π)
LUMO	0.0496 (π^*)	0.0522 (π^*)	0.0498 (π^*)

highest occupied and lowest unoccupied π-molecular orbitals and the n-orbitals of BPP, 1-MBPP, and 2-MBPP[1b] were calculated using the CNDO/2 method,[3] results of which are shown in Table 2. It may be seen that the highest occupied MO is of π-character and the next occupied MO is of n-character for the three molecules. These results suggest that the lowest excited state is of π,π^* character and that the n,π^* state may be higher than the first excited π,π^* state.

The absorption spectra of 1- and 2-alkyl benzopyranopyridines are displaced to a wavelength longer by the addition of ethanol[1] and this suggests that the absorption bands may be assigned to the π-π^* transition.

The energy gap between the highest occupied and the lowest unoccupied orbitals of 2-MBPP is larger than that of 1-MBPP and BPP and indicates qualitatively that the lowest π,π^* state of 2-MBPP is higher than that of 1-MBPP, as shown in the absorption spectra in Fig. 1.

The P-P-P SCF-MO-CI method[4-6] was applied to calculate the π-π^* transition energies and corresponding oscillator strengths of BPP. The following empirical parameters were used for the present calculation:

Atom, μ	I_μ/eV	A_μ/eV
C	11.42	0.578
–N=	14.12	1.78
NH_2	27.525	13.435
=O	17.32	2.649
-O-	33.50	11.97

The value −2.10 eV was used for all the resonance integrals, and the Mataga-Nishimoto approximation[6] was adopted for the two-center Coulomb integral. The 36 singly excited configurations were built into the configuration interaction matrix elements. In the present calculation the effect of the intramolecular hydrogen bond was not taken into account.

The calculated transition energies and corresponding oscillator strengths of BPP are listed in Table 1. The calculated directions of the transition moment are shown in Fig. 2 in which the length of the transition moment is proportional to the magnitude of the oscillator strength. Referring to the calculated results in Table 1 and Fig. 2 the assignment of the absorption bands for 1-MBPP and 2-MBPP were made. The band assignments are given in Table 1.

The first band of BPP calculated at 342 nm is mainly polarized along the x axis. The second and third bands are weak and their transition moments are mainly polarized along the y axis as shown in Fig. 2. The bands near 266 nm for 1-MBPP and 263 nm for 2-MBPP correspond to the fourth band of BPP calculated at 268 nm which is polarized along the x axis, and with a relatively strong oscillator strength. The fourth band has a shoulder on the longer-wavelength side, which disappears in alcoholic solution. 2-MBPP has two bands at 240 and 231 nm in isooctane solution. These bands are observable at 241 and 233 nm in ethanol solution. The behavior of the two bands in polar solvents suggests that they belong to the different electronic states. These bands were assigned to the bands calculated at 240 and 234 nm. For 1-MBPP, the corresponding bands at 240 and 231 nm were observed at 242 and 232 nm. The strongest bands of 1-MBPP and 2-MBPP at 209 and 210 nm were tentatively assigned to the remaining transition bands from the eighth to the fourteenth transition band. The total oscillator strengths thus become equal to 0.774.

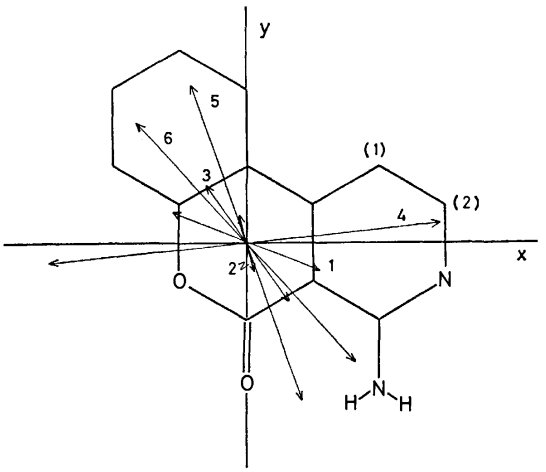

Fig. 2. Polarization directions of six π-π^* transitions in BPP predicted by the P-P-P SCF-MO-CI method.

Mechanism of the Ferroelectric Phase Transition in $K_4[Fe(CN)_6]\cdot 3H_2O$ and $K_4[Fe(CN)_6]\cdot 3D_2O$

Masaharu OGUNI, Takasuke MATSUO, Hiroshi SUGA, and Syûzô SEKI*
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received September 4, 1978)

Synopsis. Mechanism of the ferroelectric phase transition in potassium hexacyanoferrate trihydrate is discussed from static and dynamic points of view, and a new model is proposed. The model takes into account four states as accessible for a water trimer, instead of two in the earlier model. If the four states were equally probable in the disordered phase, the predicted transition entropy is R ln 4 compatible with the experimental value. It is expected that a glass transition, if possible, occurs at 50—60 K for the model. Since the anomalous heat capacity in this temperature region is effectively zero, the model is consistent with absence of a glass transition. Occupancy fractions of hydrogen sites are given for the earlier and the present models.

There are three aspects of interest in the property of orientationally disordered crystals. First, what is the molecular unit of disorder in the crystal? Second, is the disorder static or dynamic? and if dynamic, how rapid is the molecular reorientation? And third, at what temperature does the disorder change to order? The first and third are equilibrium aspects and can be studied by structural and thermodynamic methods. The second is the kinetic property and has been studied rather independently of the other two by NMR, dielectric and other spectroscopic methods. However, it has been shown recently that precise measurement of the heat capacity, a typical equilibrium property, can be used for study of molecular motion in a number of orientationally disordered crystals including molecular, ionic and hydrogen-bonded crystals.[1] The principle involved here is simple and may be summarized as follows. A relaxational heat-capacity anomaly occurs at the temperature at which the molecular relaxation time becomes comparable with the time required for a single heat-capacity measurement, typically 10^2—10^5 s. An important proviso for the anomaly, glass transition, to be observed is that orientational heat capacity has to be appreciable at that temperature. When such a situation prevails in a stable (as opposed metastable) crystal, formation of a glassy state is an unescapable result. If one does not find a glass transition in a careful measurement of the heat capacity of a substance, one can conclude that molecular reorientation is sufficiently rapid in the relevant temperature range. In this note we shall supplement the previous paper on the calorimetric study[2] of the phase transition in potassium hexacyanoferrate trihydrate $K_4[Fe(CN)_6]\cdot 3H_2O$ and the deuterate analogue in the light of above argument.

Figure 1 reproduces the anomalous heat capacity of $K_4[Fe(CN)_6]\cdot 3H_2O$ and $K_4[Fe(CN)_6]\cdot 3D_2O$. The anomaly extends from the transition temperature (250 K (H_2O), 255 K (D_2O)) down to 110 K. The entropy of transition is 12.4 J K^{-1} mol^{-1} (H_2O) and 14.3

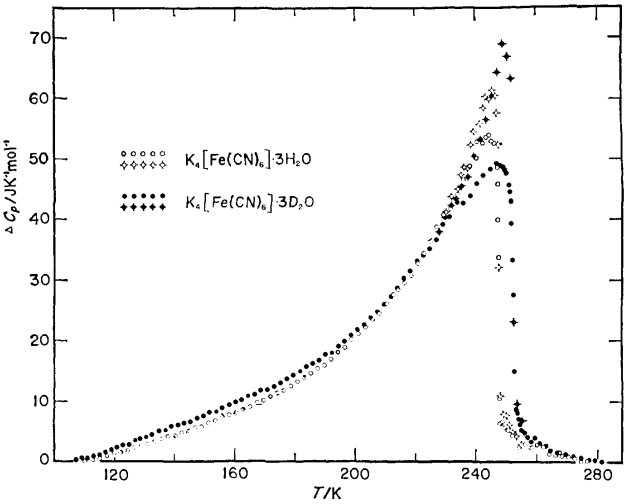

Fig. 1. Anomalous part of heat capacity of $K_4[Fe(CN)_6]\cdot 3H_2O$ and $K_4[Fe(CN)_6]\cdot 3D_2O$.

J K^{-1} mol^{-1} (D_2O) ($\approx R$ ln 4 or more). According to the neutron diffraction,[3] the crystal contains trimers of water molecules. The trimer itself is polar as shown in Fig. 2. It has been suggested that the ferroelectricity originated from the parallel alignment of the polar trimer. This model leads to the transition entropy of R ln 2 ($=5.76$ J K^{-1} mol^{-1}) because there are two orientations for each of the trimer as shown schematically in Figs. 2(a) and (d). The predicted entropy is too small to account for the experimental value.

An alternative model proposed here assumes four states per water trimer. The two states (b) and (c) of Fig. 2 are assumed in addition to the states (a) and (d). The state (a) is symmetry-related to (d) and (b) to (c), but states (a), (d) are not equivalent to (b) or (c). However, all of hydrogen atoms are engaged in hydrogen bonding in any of the four arrangements. Therefore we may neglect difference in their energy for the moment. The transition entropy is Rln4 for this model in agreement with the experiment.

The kinetic aspect of the model is considered next. Clearly the rearrangement from one state to the other proceeds through the reorientation of water molecules, and as such it is related to librational mode of water molecule. The relaxation time of such rearrangement is usually described by Arrhenius expression $\tau=\tau_0\exp(\Delta H_a/RT)$. The pre-exponential factor τ_0 will be of the order of magnitude 10^{-14}—10^{-15} s, since it may be equated to $1/(2\pi\nu)$ where ν is the vibrational frequency of the librational mode. Similar situations were found to be adequate for relaxation times in the glass transitions of orthoboric acid and stannous chloride

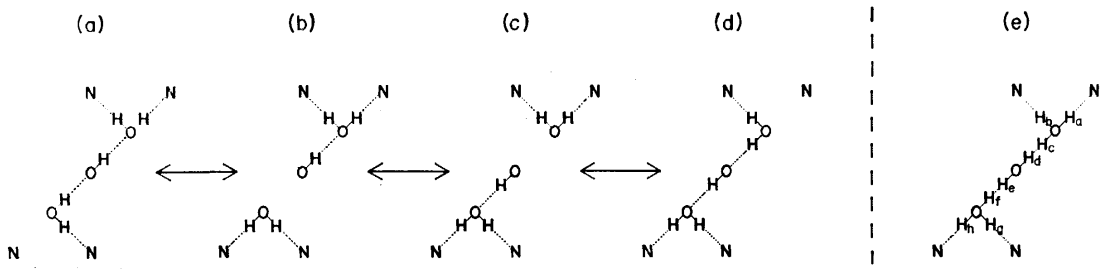

Fig. 2. Arrangements of hydrogen atoms in the hydrogen-bonded system composed of three water molecules and the surrounding nitrogen atoms.

dihydrate crystals.[4,5] The activation enthalpy may be equated to the order of the energy for breaking of the hydrogen bond. The energy of relatively long hydrogen bonds is 15—25 kJ mol^{-1}.[6] Waldstein *et al.*[7] estimated 15 kJ mol^{-1} per bond for the potential barrier hindering the reorientational motion of the molecule in ice. The same value was also found from the thermodynamic study of the glass transition in orthoboric acid crystal.[4] Therefore the activation enthalpy per bond is estimated to be 15—20 kJ mol^{-1} for the present crystals.

If the rearrangement from (a) to (d) in Fig. 2 proceeded through the simultaneous reorientation of three water molecules, then the activation enthalpy for the process would be estimated to be 45—60 kJ mol^{-1}. Since the glass transition takes place when the relaxation time becomes the order of 1 ks, this activation enthalpy corresponds to the glass transition temperature of 140—190 K. Here we took $\tau_0=8\times10^{-15}$ s from experimental value for $SnCl_2\cdot2H_2O$. If this were really the case, the glass transition would have been observed because the configurational contribution to the heat capacity is large enough in this temperature region as shown in Fig. 1. The glass transition, however, was not observed in the actual calorimetric measurement.[2] This indicates that the process assumed above is incorrect.

Next, the alternative model including states (b) and (c) is examined. The process (a)↔(b), (b)↔(c), or (c)↔(d) may be interpreted as the transfer of a Bjerrum L defect. In this case the activation enthaply will be 15—20 kJ mol^{-1} because it involves disruption of only one hydrogen bond. Using the same τ_0 as above one obtains 50—60 K for the glass transition temperature. The glass transition will not be observed in this case because the configurational heat capacity is practically zero at this temperature. This agrees with the experimental result that the glass transition does not occur in this crystal.

At the same time, the assumption that the four states (a)—(d) occur equally probably in the high temperature disordered phase would be reasonable because they all involve one L defect in common. Thus, by allowing the intermediate states (b) and (c) as well as the states (a) and (d) in the disordered phase, one can interpret consistently both the observed entropy of transition and absence of glass transition in this compound. A direct test of the model proposed here, including the validity of the energetical equivalence of the four arrangements, may be obtained from precise determination of the occupancy fraction of the hydrogen sites at different temperatures by neutron diffraction. The symbols H_a, H_b··· in Fig. 2(e) represent hydrogen sites in a water trimer. Now let α, β, γ, δ, ε, ζ, η, and θ denote the occupancy fraction for H_a, H_b, H_c, H_d, H_e, H_f, H_g, and H_h, respectively. If the energy of states (b) and (c) in Fig. 2 were higher in the disordered phase by E than that of (a) and (d), the fraction would be given as follows; $\alpha=\theta=(1/2)[1+2\exp(-E/RT)]\cdot[1+\exp(-E/RT)]^{-1}$, $\beta=\eta=1$, $\gamma=\zeta=(1/2)[1+\exp(-E/RT)]^{-1}$, and $\delta=\varepsilon=1/2$. In the earlier model taking only the states (a) and (d) as accessible into account, $\alpha=\theta=1/2$, $\beta=\eta=1$, $\gamma=\zeta=1/2$, and $\delta=\varepsilon=1/2$ in the disordered phase. In the limiting case of $E=0$, where the four states (a)-(d) in Fig. 2 are allowed equally probably, we obtain $\alpha=\theta=3/4$, $\beta=\eta=1$, $\gamma=\zeta=1/4$, and $\delta=\varepsilon=1/2$. Thus the two models predict different occupation fractions of proton or deuteron in each site. The earlier neutron diffraction data have been analysed *a priori* with $\alpha=\theta=1/2$, $\beta=\eta=1$, $\gamma=\zeta=1/2$, and $\delta=\varepsilon=1/2$. New diffraction experiment as well as reinvestigation of the earlier neutron diffraction data will be interesting because the proposed model is a modification of the half-hydrogen model of hydrogen bonding that has been used so extensively.

Separation of Barium and Radium as Their TTA-complexes by Extraction Chromatography

Kazuo JIN*,† and Toshiyasu KIBA

Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa, Ishikawa 920

(Received May 26, 1978)

Synopsis. Satisfactory separation of a trace amount of radium from miligram amount of barium was attained on a column of 1.5 M TTA–MIBK (Daiflon) system. An HETP value as low as 0.47 mm was obtained with a column $0.98\phi \times 30$ cm at flow rate of 0.17 cm³ per minute. Distribution ratio of radium estimated from this column technique was compatible with the liquid-liquid extraction data.

Solvent extraction of radium has been investigated in several extraction systems in view of synergistic effect.[1-3] However, no report seems to have appeared on the separation of radium from barium matrix, because of their similar chemical properties. The separation of tracer level radium from barium matrix is desirable in view of not only analytical chemistry but also geochemistry.

Akaza studied the extraction of barium, strontium, calcium, and magnesium with 2-thenoyltrifloworoacetone (TTA)–methyl isobutyl ketone (MIBK),[4,5] the results being extended to extraction chromatography.[5,6] In this note, a further application of the same TTA–MIBK extraction system to radium(II), the extraction chromatographic separation of radium from miligram amounts of barium, and separation of alkaline earth metal ions involving radium are described.

Experimental

Radioactive Tracers. ^{140}Ba ($t_{1/2}=12.8$ d) was used as a tracer of barium. ^{223}Ra ($t_{1/2}=11.68$ d) was obtained from ^{227}Ac by milking.

Batch Extraction of Radium(II) in TTA–MIBK. A buffer solution consisting of 0.5 M ammonium acetate–aqueous ammonia–acetic acid was employed to adjust the pH of the aqueous solution. The final pH of extraction was measured immediately after the two phases had been separated, whereas γ-activity of ^{223}Ra in each phase was counted with a NaI(Tl) scintillation counter 6 h after the separation.

Column Preparation. The column was prepared by the method previously reported.[6] A glass chromatographic column with water jacket was employed to keep the column temperature constant.

Test Solutions and Eluting Solutions. Fifty milliliters of the test solution which has a similar composition to that of eluting solution was used for the column experiment. Eluting solutions were prepared by the method reported.[6]

A fraction collector was employed to collect an adequate fraction of the eluate. In some cases, a microtube pump, Tokyo Rikagakukikai Co., Model MP-11, was used to feed a solution on the column. Tigon tube was employed for solution transport.

Results and Discussion

The extraction of radium as TTA-complex into MIBK was carried out with TTA in various concentrations. The results are shown in Fig. 1. Quantitative extraction was attained at pH 6.5< in 1.5 M TTA–MIBK, these conditions being preferable for the separation of relatively large amounts of alkaline earth metal ions from each other. The half extraction pH ($pH_{1/2}$) of radium(II) could be estimated as 6.0 in the same system, and that of barium as 5.2 from the previous data.[4] Thus, the difference between $pH_{1/2}$ values suggests the possibility of the separation of barium and radium as their TTA-complexes by extraction chromatography.

The separation of alkaline earth metal ions involving radium(II) was carried out on a 1.5 M TTA–MIBK column ($0.98\phi \times 19$ cm). The results are shown in Fig. 2. First, radium and barium were eluted with a solution of pH 6.5, giving some overlapping of two elution curves, secondly, strontium and calcium were eluted with a solution of pH 5.5, and finally magnesium with 0.1 M hydrochloric acid. The concentration of each metal ion in each fraction was determined by γ-counting for radium and barium and by atomic absorption spectrophotometry for strontium, calcium and magnesium, respectively. The results, except for radium, are in line with those reported.[5] ^{140}La was caught firmly on the column and eluted down together with magnesium (Fig. 2).

In order to achieve complete separation between radium and barium, the column was replaced by a longer one ($0.98\phi \times 30$ cm, $0.98\phi \times 40$ cm, and $0.97\phi \times 42$ cm). Figure 3 shows the results obtained.

Void volum; (a) 9±2 cm³, (b), (c) 12±2 cm³. a) Ba 0.5 mg. b) Ba 5.0 mg.

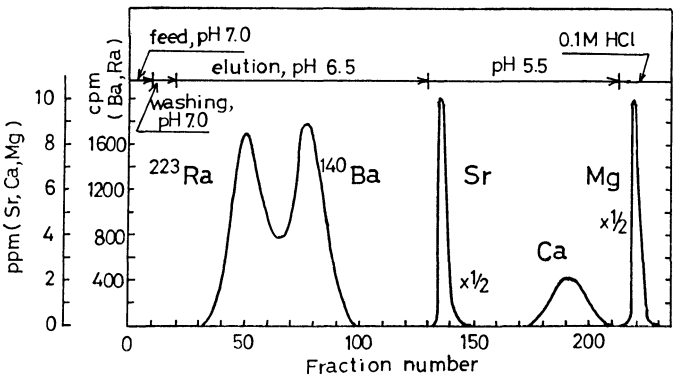

Fig. 2. Separation of alkaline earth metal ions on 1.5 M TTA-MIBK column.
Metal, loaded: 0.5 mg each (except radium), Daiflon: 5.5 g, one fraction: 5.0 g stationary phase: 7.8 cm³, temp: 20±1 °C column size: 1.0ϕ×19 cm flow rate; feed and washing: 0.2—0.3 cm³·min⁻¹ elution: 0.5 cm³·min⁻¹.

A test solution of pH 7.5 and an eluting solution of pH 6.7 were used, the flow rate of elution being 0.17-cm³ min⁻¹. Under these conditions excellent separation of trace radium(II) could be achieved from 0.5 mg, of barium(II) (Figs. 3 (a) and (b)), and also from 5.0 mg of barium(II) (Fig. 3 (3)). From these column experiments, distribution ratios of radium and barium ions were estimated (Table 1) by the well-known relation of $D=(E-F)/B$, where E is the volume of effluent in relation to the maximum of the eluted metal concentration, F the void volume of the column, and B the volume of the stationaly phase. The distribution ratio of radium shown as 44, 48, and 51 in Table 1 is somewhat large, but roughly compatible with the value 30 obtained in the liquid-liquid extraction under the same extraction pH. In order to elucidate the performance of extraction column in Fig. 3, a number of theoretical plates of column (N) and height equivalent to a theoretical plate (HETP) were estimated. N is given by the equation $N=E(E-F)/S^2$, where S is half width (ml) at 0.607 peak maximum. HETP is given by the column length divided by N. Thus the HETP value as low as 0.47 mm could be maintained on the column 0.98ϕ×30 cm long.

The elution of alkaline earth metal ions proceeds in the order of light element in conventional cation-exchange chromatography. However, elution takes place in the reversed order in extraction chromatography. Thus, the latter is appropriate for a precise

Super High Sensitivity of CuSe–Ag_2S Solid Membrane Copper(II) Ion Selective Electrode in Several Metal Buffer Solutions

Yoshio UMEZAWA,* Yuichiro IMANISHI, Katsuhiko SAWATARI, and Shizuo FUJIWARA

Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo 113

(Received July 11, 1978)

Synopsis. A CuSe–Ag_2S solid membrane Cu(II) ion electrode in certain metal buffer solutions gave detection limit of free Cu(II) ion as low as 10^{-18}M.

Nakagawa and his coworkers observed extremely high sensitivity of copper(II) ion selective electrodes-(ISE) in metal buffer solutions with the use of a CuS–Ag_2S solid membrane.[1] Similar phenomena have also been observed with the same type of electrodes by Ishibashi and Jyo.[2] It has been believed that the actual sensitivity of a cupric ion selective electrode is determined by the residual concentration of Cu(II) and Ag(I) ions at the interface.[3] Therefore, if we can lower this residual concentration as low as possible by complex formation of Cu(II) and Ag(I) ions with added ligand species, the concentration of the detection limit of the electrode may possibly be descreased. However, an inherent reaction of solid membrane itself with ligand species was found to be taken into consideration.[1] Unwanted reactions between the solid membrane and solution species may cause slow and unstable response of the ISE.

In the present study, the effect of several ligand species on the response of a CuSe–Ag_2S solid membrane Cu(II) ISE was studied with a view to examine whether or not similar phenomenon to CuS–Ag_2S is observed even with the different solid membrane material in order to generalize the behavior of the ISE in metal buffer solutions.

Experimental

The solid membrane used for a Cu(II) ISE is of CuSe–Ag_2S, where the ratio of CuSe to Ag_2S is several %. A reference used is an Ag/AgCl electrode of TOA Dempa Co. Water used is deionized and distilled. Chemicals were of analytical reagent grade. The electrochemical cell assembly employed is as follows:

$$\text{CuSe–Ag}_2\text{S} \;\Big|\; \begin{matrix}\text{Test solution}\\ \mu=0.1(\text{NaNO}_3)\end{matrix} \;\Big|\; \text{KCl(sat.)} \;\Big|\; \text{AgCl} \;\Big|\; \text{Ag}$$

Potential-time profiles of the ISE were recorded using an on-line computer controlled ISE measuring system described elsewhere,[4] where the potential from the electrode is first converted into frequency in order to increase the precision of the voltage measurement. The response time for the electrode is slowed down appreciably upon addition of certain types of ligand species in aqueous Cu(II) solution. Therefore, we employed 30 minutes waiting time for the measurement of an equilibrium potential. By doing so, the equilibrium is nearly attained in most cases except for the case of EDTA. The measurement was performed in a room thermostated at 20±0.5 °C. The solution was stirred with a magnetic stirrer.

Procedure

The procedure employed is as follows : First of all, an empirical relation between the Cu(II) concentration and the observed frequency (potential) is obtained through the calibration curve in standard Cu(II) solution,

$$f = 3.16461 \log[\text{Cu}] + 39.7125 \quad (\text{kHz}), \qquad (1)$$

where f is the frequency which is one to one equivalent to the observed potential, and [Cu] the activity of Cu(II) solution. With the use of Eq. 1, the activity of Cu(II) ion [Cu] was calculated from the observed potential values of the Cu(II) ISE in each ligand solution. Values thus obtained are compared with the theoretical one, where the latter is simply calculated from β_n through the relations as follows :

$$\frac{[\text{CuL}_n]}{[\text{Cu}][\text{L}]^n} = \beta_n,$$

$$p[\text{Cu}] = \log\beta_n + n\log[\text{L}] - \log[\text{CuL}_n],$$

$$[\text{L}] = \frac{C_\text{L}}{\alpha_{\text{L(H)}}},$$

where [L] is a function of pH and is obtained using the total concentration of the ligand C_L, and the side reaction coefficient $\alpha_{\text{L(H)}}$ which is calculated from the concentration of proton ion in the solution and the acid dissociation constants of the ligand(1,5).

Results and Discussion

In Table 1, the extremely low activity of Cu(II) ions determined by the response of a CuSe–Ag_2S Cu(II) ISE is compared with those calculated using the reported data of stability constants of Cu(II) complexes in each ligand. In most cases except EDTA, the agreement is fairly well indicating that the copper(II) ISE of the present study is actually responding to such low activities as 10^{-15} M, for example, of free Cu(II) ions. This result is to be compared with similar results obtained by Nakagawa *et al.*, where CuS–Ag_2S is used instead of CuSe–Ag_2S for the cupric ion selective electrode. In the case of EDTA as a ligand, the agreement is not good, probably due to some unknown reactions between the CuSe–Ag_2S solid membrane itself and EDTA molecules. This is partly supported by the result in Fig. 1 where the potential-time profile for the copper(II) ISE in 1×10^{-3} M Cu(II) aqueous solution is extremely slowed down by the addition of certain amount of EDTA, indicating the non-equilibrium reaction, if any, between EDTA and solid membrane material itself. Appa-

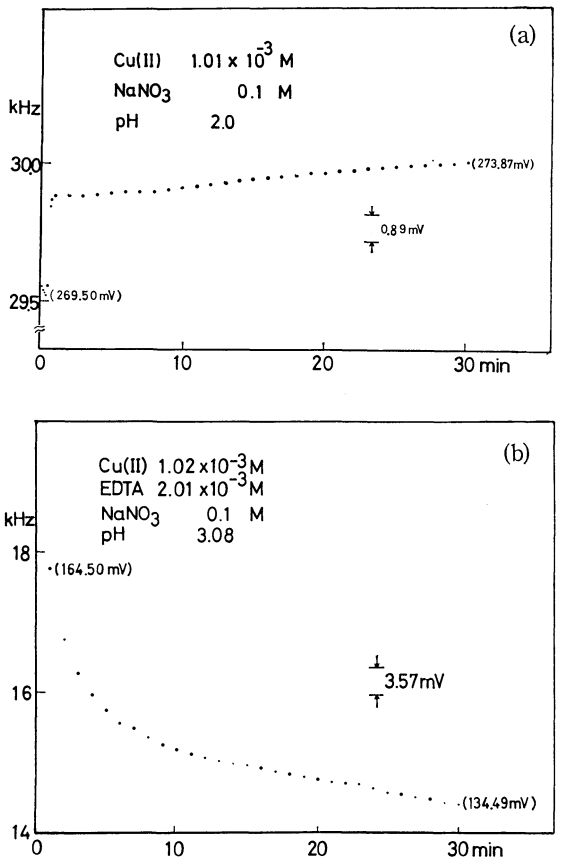

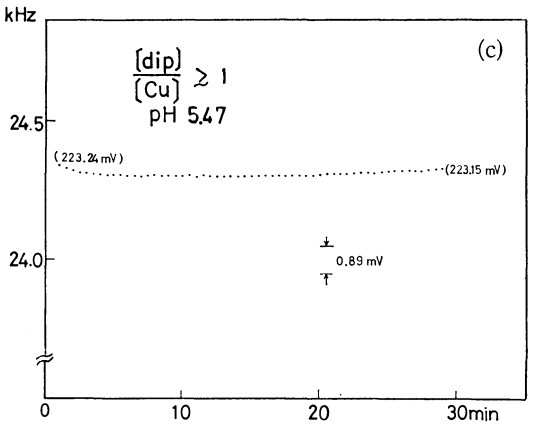

Fig. 1. Potential(Frequency)-time profiles of a CuSe-Ag_2S solid membrane Cu(II) ion selective electrode in different buffer solutions.
(a) Cu(II) ion 1.01×10^{-3} M, $NaNO_3$ 0.1 M, pH 2.0.
(b) Cu(II) ion 1.02×10^{-3} M, edta·2Na 2.01×10^{-3} M, $NaNO_3$ 0.1 M, pH 3.08.
(c) Cu(II) ion 0.99×10^{-3} M, bpy 1.00×10^{-3} M, $NaNO_3$ 0.1 M, pH 5.47.
Frequency f in kHz is equivalent to the potential E in mV as the following : $E=8.9287f+5.9184\pm2.679\times10^{-1}$.

rently, this reaction does not seem to have reached equilibrium during 30 min waiting time (Fig. 1). Also, it is interesting to note that although the activity of Cu(II) ion is generally decreased with the addition of any ligand species, the resulting response time is not necessarily slowed down and is specific to the kind of ligand species as shown in Fig. 1. Therefore, the reason why the response time is slowed down only in certain types of ligand species is attributed to some specific interaction of unknown nature between the ligand species and solid membrane materials rather than simply being due to the decrease in the activity of Cu(II) ions.

In conclusion, the CuSe–Ag_2S solid membrane electrode responds similar manner to the CuS–Ag_2S electrode in that both electrodes have the detection limit well lower than 10^{-15} M of Cu(II) ion activity in certain metal buffer solutions. Also, the response time in extremely low activity solution is not necessarily slow and is dependent on some specific chemical interaction between the ligand species and the solid membrane materials.

The authors thank Kayoko Umezawa for calculating the data.

Crystallographic Properties of $Ca_2Fe_2O_5$. Difference in Crystallographic Properties of Brownmillerite-like Compounds, $Ca_2Fe_2O_5$ and $Sr_2Fe_2O_5$, at Elevated Temperatures

Shigemitsu SHIN,* Michiko YONEMURA, and Hiroyuki IKAWA†

National Chemical Laboratory for Industry, Mita, Meguro-ku, Tokyo 153

†*Faculty of Technology, Tokyo Institute of Technology, O-okayama, Meguro-ku, Tokyo 152*

(Received September 27, 1978)

Synopsis. High-temperature X-ray diffraction analysis has revealed that $Ca_2Fe_2O_5$ remains in the original brownmillerite-like form up to *ca.* 1100 °C, whereas $Sr_2Fe_2O_5$ changes in crystal structure from brownmillerite to anion-deficient perovskite, without a change in oxygen content, above 700 °C.

It has been reported that $Sr_2Fe_2O_5$ has a cubic perovskite structure, without any change in the oxygen content, above 700 °C, whereas at room temperature this compound has an orthorhombic brownmillerite(Ca_2AlFeO_5)-like structure.[1] It has also been reported that the calcium analogue, $Ca_2Fe_2O_5$, is another brownmillerite-like compound at room temperature.[2] The crystallographic affinity between both compounds at room temperature has assumed that $Ca_2Fe_2O_5$ also has a cubic perovskite structure with the oxygen vacancies statistically disordered at elevated temperature. In this paper the existence of an oxygen-deficient perovskite phase for $Ca_2Fe_2O_5$ at elevated temperature has been examined by means of high-temperature X-ray diffraction techniques. The results have been discussed in connection with the oxygen pressure effect on the preparation of Fe^{4+}-bearing perovskites, $CaFeO_3$ and $SrFeO_3$.

Experimental

Dicalcium diiron(III) pentoxide $Ca_2Fe_2O_5$ was prepared by firing the appropriate mixture of $CaCO_3$ and α-Fe_2O_3 in air at 1200 °C, with intermediate regrinding and refiring until a single phase product was obtained. Subsequently, the powder sample of composition $Ca_2Fe_2O_5$ was mounted on a platinum specimen holder in a high-temperature X-ray diffractometer. The X-ray measurement conditions and the calculation of the lattice parameters were the same as described in Ref. 1.

Results and Discussion

The brownmillerite-like structure is referred to as an "ordered" oxygen-deficient perovskite structure.[3] Therefore, there is a crystallographic relation between the orthorhombic brownmillerite-like structure and an ideal perovskite structure with cubic symmetry as follows : $a \simeq \sqrt{2}\,a_0$, $b \simeq 4a_0$, and $c \simeq \sqrt{2}\,a_0$, where a, b, and c are the lattice constants of a brownmillerite-like phase and a_0 that for an ideal perovskite phase. On this basis new lattice parameters can be defined, a', b', and c', for the dample $Ca_2Fe_2O_5$, where the three lattice constants have such a crystallographic relationship with the original orthorhombic cell constants, a, b, and c, as $a'=a/\sqrt{2}$, $b'=b/4$, and $c'=c/\sqrt{2}$.

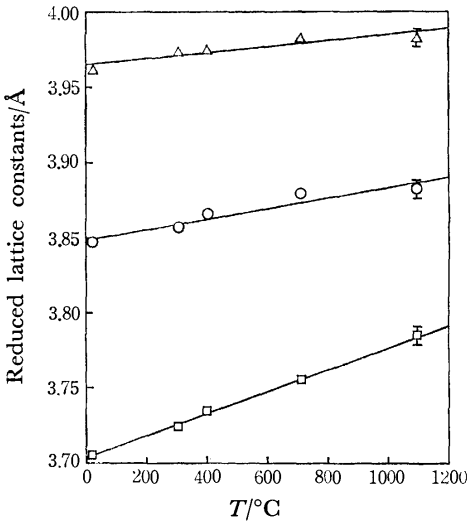

Fig. 1. Plots of reduced orthorhombic lattice constants *vs.* temperature for $Ca_2Fe_2O_5$.
△ : a′-axis, □ : b′-axis, ○ : c′-axis.

Figure 1 illustrates the reduced lattice constants of the sample of composition $Ca_2Fe_2O_5$ as a function of temperature. It may be seen that the three axes, a', b', and c', expand linearly with increase in temperature in the range of temperature from 20 to 1093 °C, and that the three lines do not intersect. In other words, $Ca_2Fe_2O_5$ does not exist as a statistically disordered oxygen-deficient perovskite structure, but remains as a brownmillerite-like phase even at elevated temperatures. This result is quite different from that of $Sr_2Fe_2O_5$ obtained in a previous work.[1]

For diiron(III) distrontium pentoxide, the a'-axis of the reduced cell begins to shrink at around 335 °C, and at 700 °C the three axes of the reduced orthorhombic cell meet, and consequently, the compound transforms to a cubic anion-deficient perovskite phase at temperatures above 700 °C (see Fig. 2, Ref. 1). From this it has been concluded that the oxygen atoms arranged regularly in the brownmillerite-like lattice begin abnormal thermal movement at around 335 °C. At 700 °C, a complete phase transition takes place as a result of the random displacement of the oxygen atoms or the vacancies throughout the oxygen lattice sites in the perovskite structure.

It is evident that the difference in movement of the oxygen ions at elevated temperatures between dicalcium and distrontium diiron(III) pentoxides is caused by differences in chemical composition between the double oxides, although the essential reason remains unclarified. The calcium ion has a smaller ionic radius

than the Sr ion, so that the electrostatic binding energy must be higher in the Ca–O bonds than in the Sr–O bonds, as implied by the melting point of CaO. This assumption may be valid for the brownmillerite-like structure. In the brownmillerite-like structure, complete rows of oxygens are regularly missing from the ideal perovskite structure, and the accompanying movements of atoms result in tetrahedral coordination of the Fe atoms, and eight- or ninefold coordination about the alkaline-earth metal atoms, not twelvefold as in perovskite.[3] Consequently, the transition of $A_2Fe_2O_5$ (A=Ca or Sr) from brownmillerite-like structure to perovskite structure must be accompanied by a breaking of the A–O bonds and rearrangement of the component atoms. Therefore, it is reasonable to speculate that the binding energy of the Ca–O bonds in $Ca_2Fe_2O_5$ is so high that cleavage is difficult, so that $Ca_2Fe_2O_5$ is not transformed to an anion-deficient perovskite structure.

The experimental results and conclusions obtained in this work may explain why $CaFeO_3$ can only be synthesized under ultra high oxygen pressures[4] whereas $SrFeO_3$ can be readily prepared under less rigorous conditions,[5,6] *i.e.*, the energy necessary to break the Ca–O bonds in $Ca_2Fe_2O_5$ to yield $CaFeO_3$ by oxidizing the iron atoms from Fe^{3+} up to Fe^{4+} is higher than that which is necessary for $Sr_2Fe_2O_5$.

The authors wish to express their thanks to Professor S. Udagawa at Tokyo Institute of Technology for his interest and support in this work.

Stereospecific Synthesis of D-Isothreonine from L-Threonine[1)]

Yasuyuki SHIMOHIGASHI, Michinori WAKI, and Nobuo IZUMIYA*

Laboratory of Biochemistry, Faculty of Science, Kyushu University 33, Higashi-ku, Fukuoka 812

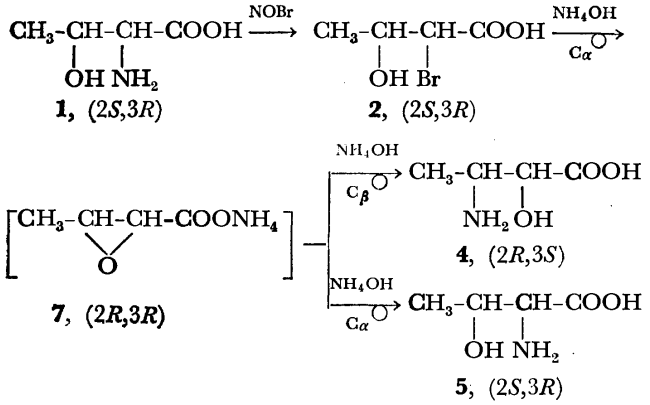
(Received December 23, 1977)

Synopsis. D-Isothreonine, (2*R*,3*S*)-3-amino-2-hydroxybutanoic acid (**4**), was readily prepared by the ammonolysis of optically active 2-bromo-3-hydroxybutanoic acid derived from L-threonine. The configuration of **4** was deduced from the shift of molecular rotation, Cotton effect in ORD curve of **4**, and NMR measurement of its oxazolidone derivative.

In recent years α-hydroxy β-amino carboxylic acids have been found in nature as constituent amino acids of biologically active peptides; L-isoserine[2)] in an antibiotic, edeine, and (2*S*,3*R*)-3-amino-2-hydroxy-4-phenylbutanoic acid[3)] in an aminopeptidase B inhibitor, bestatin. However, the syntheses of these optically active α-hydroxy β-amino carboxylic acids are tedious. L-Isoserine was prepared by optical resolution[4)] or through three steps starting from L-asparagine.[5)]

This paper deals with a convenient method of preparation of such optically active α-hydroxy β-amino carboxylic acids as exemplified by the first synthesis of (2*R*,3*S*)-3-amino-2-hydroxybutanoic acid (D-isothreonine)[6)] (**4**) through two steps starting from L-threonine (**1**).

It is known that racemic α-halo β-hydroxy carboxylic acids are converted by the action of ammonia into racemic α-hydroxy β-amino carboxylic acids, α-amino β-hydroxy carboxylic acids, or a mixture of the two.[7–9)] For the amination reactions Carter and Zirkle[8)] and Neuberg and Mayer[10)] proposed possible α,β-epoxy carboxylic acid intermediates. In fact, Liwschitz *et al.*[11)] prepared DL-*threo*-2-hydroxy-3-aminobutanoic acid without formation of *erythro* form by the reaction of racemic *cis*-2,3-epoxybutanoic acid with amine. The closure and opening of epoxide ring accompany an inversion of the configuration of carbon atom attacked by nucleophiles.[12,13)] Thus we assumed that optically active α-hydroxy β-amino carboxylic acids could be stereospecifically prepared from optically active α-halo β-hydroxy carboxylic acids. In order to confirm the prediction we attempted a simple preparation of **4** through the amination reaction of (2*S*,3*R*)-2-bromo-3-hydroxybutanoic acid (**2**) derived from **1** (Scheme 1).



Scheme 1. Stereochemical reaction route.

Compound **2** was prepared by the action of nitrosyl bromide on **1**. This reaction is known to proceed with retention of the configuration of C_α.[14)] Treatment of **2** with 28% aqueous ammonia afforded a mixture of isothreonine and threonine (92 : 8). The mixture was separated into each component by column chromatography on Dowex 50X8 (NH_4^+ form).

The configuration of C_α atom of isolated isothreonine (**4**) was confirmed to be 2*R* by the negative shift in molecular rotation on acidification[15)] and the negative Cotton effect in the region 200—240 nm.[16)] In order to determine the configuration of C_β atom of **4**, we measured the ^{1}H-NMR spectrum of 2-oxazolidone derivative (**6**) of **4**. The coupling constants ($J_{\alpha\beta}$) between the vicinal methine protons of the oxazolidone derivatives of α-amino β-hydroxy carboxylic acids are reported to be 5.0±1.0 Hz for *threo* and 9.6±0.6 Hz for *erythro* isomers in CD_3OD.[17)] Those of α-hydroxy β-amino carboxylic acids are also reported to be 4.0 Hz for *threo* and 9.0 Hz for *erythro* isomers in CD_3OD.[3)] NMR spectrum of **6** was recorded in DMSO-d_6 because of its insolubility in CD_3OD, $J_{\alpha\beta}$ value of **6** being 5.0 Hz. $J_{\alpha\beta}$ values of reference oxazolidone derivatives of L-threonine (*threo*) and L-allothreonine (*erythro*) were 4.8 and 8.5 Hz in DMSO-d_6, respectively. The values in DMSO-d_6 are almost equal to those for *threo* and *erythro* in CD_3OD, respectively. These results suggest that the configuration of **4** should be *threo* form (2*R*, 3*S*). Thus the prediction (Scheme 1) was confirmed by the first synthesis of optically active isothreonine **4**.

In a similar manner D-isoserine, (2*R*)-3-amino-2-hydroxypropanoic acid (**8**), was prepared from L-serine in optically pure state. On the basis of this fact and the result obtained by Liwschitz *et al.*,[11)] we assume that **4** should be optically pure as regards both C_α and C_β.

Experimental

The following solvent systems were used: R_f^1, pyridine–H_2O (65 : 35, v/v) for TLC and R_f^2, cyclohexylamine–H_2O–methyl ethyl ketone–*n*-BuOH (2 : 5 : 10 : 10, v/v) for paper chromatography. ^{1}H-NMR spectra were measured with a Hitachi R-20B spectrometer (60 MHz), using sodium 3-trimethylsilyl-1-propanesulfonate in D_2O or tetramethylsilane in DMSO-d_6 as an internal standard.

Synthesis of D-*Ith* (**4**). *(2S,3R)-2-Bromo-3-hydroxybutanoic Acid* (**2**): This was prepared from L-Thr (5.95 g, 50 mmol), KBr (20.9 g, 175 mmol) and sodium nitrite (5.58 g, 80 mmol) in 1.25 M H_2SO_4 (105 ml) according to the procedure of Izumiya;[18)] yield of an oil, 8.27 g (90%); R_f^1 0.64.

Mixture (**3**) *of Ith and Thr*: Compound **2** (8.20 g, 45 mmol) was dissolved in 28% aqueous ammonia (82 ml) at

0 °C. After being left to stand for 10 d at 0 °C, the solution was evaporated and the residual solid was dissolved in a small amount of water. The solution was applied on a column (2.2×20 cm) of Dowex 50X8 (H^+ form), and the column was washed with water and eluated with 2 M NH_4OH (100 ml). The eluate was evaporated and the yellowish residue was collected; yield, 2.40 g (45%); R_f^1 0.43 (major) and 0.70 (minor); R_f^2 0.40 (major), 0.56 (minor) and 0.45 (faint). R_fs of reference compounds: L-Thr, R_f^1 0.70, R_f^2 0.56; L-aThr, R_f^1 0.70, R_f^2 0.45. The ratio of major to minor component in **3** was determined as 92 : 8 based on the chromatogram of **3** on an amino acid analyzer.

D-*Ith* (*4*): The mixture (**3**) (1.0 g) was chromatographed with Dowex 50X8 (NH_4^+ form) under the following conditions: column, 1.8×80 cm; buffer, 0.2 M ammonium acetate in 40% MeOH at pH 3.50; flow rate, 14 ml/h. The eluate (340—580 ml) was collected and evaporated to a small volume. The solution was applied on a column (1.0×10 cm) of Dowex 50X8 (H^+ form). The column was washed with water and eluated with 2 M NH_4OH (30 ml). The eluate was evaporated and the residue was crystallized from H_2O–EtOH; yield, 0.69 g (31% from **1**); mp 215—216 °C (dec); $[\alpha]_D^{20}$ +23.5° (*c* 2, H_2O), +5.5° (*c* 2, 5 M HCl). NMR (D_2O) δ: 4.01 (1H, d, J=5.0 Hz, H-2), 3.54 (1H, m, H-3), 1.31 (3H, d, J=6.7 Hz, CH_3).

Found: C, 40.12; H, 7.53; N, 11.67%. Calcd for $C_4H_9NO_3$: C, 40.33; H, 7.62; N, 11.76%.

Determination of the Configuration of ***4***. *Configuration of* C_α: The molecular rotation values of **4** were calculated as +6.6° (5 M HCl) and +28.0° (H_2O) based on the observed optical rotation values at D-line. Thus the shift value in the molecular rotation of **4** on acidification is −21.4°. ORD spectrum of **4** was obtained with a JASCO spectropolarimeter model ORD-CD/UV-5 in 0.5 M HCl. The value of the specific rotation at minimum absorption (220 nm) was −900°.

Configuration of C_β: According to the procedure of Futagawa *et al.*[17] **4** (100 mg) was converted into its 2-oxazolidone derivative (**6**) by treatment with phosgene. The obtained oil (**6**) was dissolved in DMSO-d_6 and the solution was directly analyzed by NMR. The coupling constant of the vicinal methine protons was 5.0 Hz. Those of the oxazolidones derived from L-Thr and L-aThr were 4.8 Hz and 8.5 Hz in DMSO-d_6, respectively.

Synthesis of D-*Ise* (*8*). Compound **8** was prepared from L-Ser after bromination, ammonolysis and chromatographic separation in a similar manner to that used for **4**; yield, 58% from L-Ser; mp 197—199 °C (dec); $[\alpha]_D^{20}$ +32.0° (*c* 2, H_2O), +17.6° (*c* 2, 5 M HCl). NMR(D_2O) δ: 4.24 (1H, dd, J=7.6, 4.8 Hz, H-1), 3.40 (1H, dd, J=13.0, 4.8 Hz, H-2), 3.08 (1H, dd, J=13.0, 7.6 Hz, H-2). R_fs on TLC and paper chromatography of **8** were identical with those of DL-Ise prepared by the procedure of Gundermann and Holtmann.[19] Reported values for D-Ise;[4] mp 199—201 °C (dec); $[\alpha]_D$ +32.4° (*c* 10, H_2O).

Found: C, 34.03; H, 6.83; N, 13.21%. Calcd for $C_3H_7NO_3$: C, 34.28; H, 6.72; N, 13.33%.

We thank Prof. T. Yoshino and Mr. T. Shinmyozu, Kyushu University, for their ^{1}H-NMR measurements.

Electrochemical Vicinal Addition of Two Alkyl Groups to Phenyl Substituted Olefins and Diethyl Fumarate

Shōhei SATOH, Tōru TAGUCHI, the late Mitsuomi ITOH, and Masao TOKUDA*

Department of Chemical Process Engineering, Hokkaido University, Sapporo 060

(Received June 26, 1978)

Synopsis. Electrochemical reactions of styrene, 1-phenyl-1-propene, 2-phenyl-1-propene, stilbene, and diethyl fumarate with alkyl halides in hexamethylphosphoric triamide containing lithium chloride produce the corresponding vicinal adducts of two alkyl groups of alkyl halides.

Electrochemical reduction of an alkyl halide produces a radical or a carbanion intermediate, these have been employed as an useful species for a carbon-carbon bond formation. Alkyl halides also work as efficient trapping agents for the anionic intermediate generated by the electrochemical reduction of neutral organic compounds, although relatively few reports on such trapping reactions are available.[1] The work reported here was carried out to explore a carbon-carbon bond formation reaction using alkyl halide or trialkylborane by an electrochemical method.[2] In the present paper we wish to report that the electrolysis of alkyl halides with phenyl substituted olefins or diethyl fumarate produces the corresponding vicinal addition products in which two alkyl groups from alkyl halides were introduced to the double bond carbons. This reaction is of synthetic interest because an introduction of two identical alkyl groups to a carbon-carbon double bond in one step is very difficult.

Electrolysis of a mixture of styrene (**1a**) and excess methyl iodide in hexamethylphosphoric triamide (HMPA) containing lithium chloride as a supporting electrolyte produced 2-phenylbutane (**3a**) in a good yield. Phenylpropenes **1b** and **1c**, *trans*-stilbene (**1d**), and diethyl fumarate (**2**) were found to undergo similar dialkylation reactions. These representative results are summarized in Table 1. In the electrochemical reaction of **1b** with methyl iodide, 3-methyl-3-phenylpentane (**7**) was also produced in a 11% yield along with 2-methyl-2-phenylbutane (**3b**). Alkyl benzene with a chain length of C_7 was also detected by GC-mass spectroscopy. The reactions of **1a** and **1b** using a nickel cathode produced almost the same yields of **3a**, **4a**, **5a**, and **3b** as those using a platinum cathode, while diethyl fumarate (**2**) did not produce **6**. The reaction of **2** was successfully carried out by using a mercury pool as a cathode.

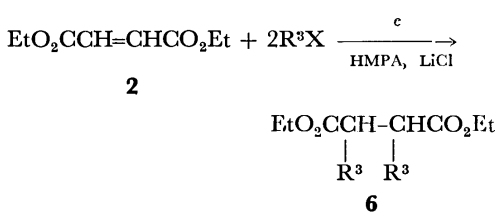
1d, $R^1=H$, $R^2=C_6H_5$



2 **6**

A detailed understanding of the electrode processes seems very difficult, since HMPA adsorption at the electrode surface sometimes prevented a direct electron transfer to substrates.[3] Hence, a voltammetric study or a controlled potential electrolysis in HMPA solution could not be carried out successfully. However, several points must be noted. First, the electrolysis using a divided cell showed that all products obtained were formed at a cathode. Second, from the fact that the reduction potential of **1** is more negative than those of alkyl halides while that of **2** is slightly more positive,[4,5] it may be said that the reaction mechanism of phenyl substituted olefins **1** is different from that of diethyl fumarate (**2**). At the same time, the difference of the reaction mechanisms between **1** and **2** may be also substantiated from the results in Table 1 in which nickel and mercury cathodes are used. Third, formation of **7** from **1b** may be elucidated by further electrochemical dialkylation of 2-phenyl-1-butene (**8**) which may be produced as the intermediate, since the electrochemical reaction of **8** with methyl iodide was found to produce **7** as a main product. Consequently, two pathways may be involved in these reactions. (a) Electron transfer to alkyl halide directly from a cathode, from a solvated electron,[3,6] or from lithium metal formed by reduction of lithium chloride[3,6b,7] produced an alkyl radical or a carbanion. Addition of these species to the olefin provided the intermediate radical or carbanion, the former of which may be further reduced to the latter. These carbanions are trapped by an excess of alkyl halide to produce the dialkylation product. (b) Electron transfer to olefin produced an anion radical,[8] which was trapped by alkyl halide to produce the intermediate radical. The resulting radical is reduced to the corresponding carbanion, which may be trapped again by alkyl halide to produce the dialkylation product. The former pathway (a) may be predominant in phenyl-substituted olefins and the latter (b) in diethyl fumarate.

A similar dialkylation reaction using an alkali metal was reported by Scilly *et al.*[9]

Experimental

All materials were distilled before use. HMPA was dried over calcium hydride and distilled before use. Quantitative GLPC analyses (SE-30, 15% on Uniport B) were carried out by an internal standard method.

General Procedure for Electrolysis. The electrolysis was carried out in the usual undivided cell equipped with two platinum plate electrodes (1×1 or 2×2 cm^2), a magnetic

a) Current density: 0.5 A/cm^2; electricity passed: 20 F/mol. b) Yields are based on **1** or **2** comsumed. c) 0.1 A/cm^2; 20 F/mol. d) 100 F/mol. e) Instead of LiCl, tetrabutylammonium iodide was used. f) Instead of LiCl, $LiClO_4$ was used.

stirring bar, and a reflux condenser. A divided cell, when needed, was used. Olefin **1** or **2** (1 mmol) and excess alkyl halides (20—30 mmol) were dissolved in 8 ml of HMPA containing 0.1—0.5 g of LiCl. The solution was electrolyzed at a constant current (0.5 A/cm^2) with the passage of electricity of approximately 20 F/mol.

*Electrochemical Reaction of Styrene (**1a**) with Alkyl Halides.* Electrolysis of **1a** and excess methyl iodide produced 2-phenylbutane (**3a**) : NMR (CCl_4) δ 0.83 (t, 3H), 1.24 (d, 3H), 1.59 (qi, 2H), 2.55 (m, 1H), 7.08 ppm (m, 5H); m/e= 134 (M^+). Spectral data of **3a** were fully identical to those of an authentic sample. A similar electrolysis of **1a** and excess ethyl iodide or ethyl bromide produced 3-phenylhexane (**4a**): NMR (CCl_4) δ 0.75 (t, 3H), 0.84 (t, 3H), 1.15 (m, 2H), 1.56 (m, 4H), 2.36 (qi, 1H), 7.06 ppm (m, 5H); m/e=162 (M^+). Electrolysis of **1a** and excess butyl bromide produced 5-phenyldecane (**5a**): NMR (CCl_4) δ 0.83 (t, 6H), 1.20 (m, 10H), 1.55 (m, 4H), 2.47 (m, 1H), 7.10 ppm (m, 5H); m/e=218 (M^+). Spectral data of **5a** were fully identical to those of an authentic sample prepared from **1a** and butyl bromide using lithium metal.[9)]

*Electrochemical Reaction of 2-Phenyl-1-propene (**1b**) with Methyl Iodide.* Electrolysis of **1b** and methyl iodide produced 2-methyl-2-phenylbutane (**3b**) [NMR (CCl_4) δ 0.67 (t, 3H), 1.27 (s, 6H), 1.64 (q, 2H), 7.16 ppm (m, 5H); m/e=148 (M^+)] and 3-methyl-3-phenylpentane (**7**) [NMR (CCl_4) δ 0.67 (t, 6H), 1.23 (s, 3H), 1.65 (m, 4H), 7.19 ppm (m, 5H); m/e=162 (M^+)]. Spectral data of the latter product **7** were identical to those of the product obtained by electrochemical reaction of 2-phenyl-1-butene (**8**) with methyl iodide.

*Electrochemical Reaction of 1-Phenyl-1-propene (**1c**) with Methyl Iodide.* Electrolysis of **1c** and methyl iodide produced 2-methyl-3-phenylbutane (**3c**): NMR (CCl_4) δ 0.75 (d, 3H), 0.94 (d, 3H), 1.23 (d, 3H), 1.79 (m, 1H), 2.38 (qi, 1H), 7.13 ppm (m, 5H); m/e=148 (M^+).

Electrochemical Reaction of trans-*Stilbene (**1d**) with Methyl Iodide.* Electrolysis of **1d** and methyl iodide produced a trace of 2,3-diphenylbutane (**3d**). The retention time and mass spectrum of **3d** were identical to those of an authentic sample prepared from **1d** and methyl iodide using lithium metal.[9)] Spectral data of **3d** are as follows: NMR (CCl_4) δ 1.02 (d, 6H, *meso*), 1.27 (d, 6H, *dl*), 2.88 (m, 2H), 6.9—7.2 ppm (m, 10H); m/e=210 (M^+).

*Electrochemical Reaction of Diethyl Fumarate (**2**) with Methyl Iodide.* Electrolysis of **2** and methyl iodide produced diethyl 2,3-dimethylbutanedioate (**6**): NMR (CCl_4) δ 1.11 (d, 6H), 1.25 (t, 6H), 2.59 (m, 2H), 4.08 ppm (q, 4H); IR (CCl_4) 1735, 1160 cm^{-1}; m/e=157 (M^+-45).

The Modified Wurtz Reaction Using Tetrakis(*p*-dimethylaminophenyl)ethylene

Yuji MIYAHARA,* Takanari SHIRAISHI, Takahiko INAZU, and Tamotsu YOSHINO

Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812

(Received September 4, 1978)

Synopsis. The Wurtz reaction has been found to be catalyzed by easily removable tetrakis(*p*-dimethylaminophenyl)ethylene. This modification facilitated the separation of products in the syntheses of [2.1.2.1.]-, [2.2.2.2]-, and [3.2.3.2]paracyclophanes, the isolated yields of which were better than in the case of tetraphenylethylene.

The Müller-Röscheisen modification of the Wurtz reaction using tetraphenylethylene(TPE)[1] has been used extensively, especially in the synthesis of cyclophanes.[2] Although the reaction has been claimed to be catalytic, TPE is gradually consumed and 1,1,2,2-tetraphenylethane **1** is formed as a reduction product. Separation of the desired cyclophanes from TPE and **1** is often troublesome owing to a similarity in properties. For the practical synthesis of cyclophanes an easily removable substitute for TPE is desirable[3] and the acid-soluble tetrakis(*p*-dimethylaminophenyl)ethylene (TDAPE) has been found suitable for the purpose.

TDAPE was readily prepared by the reductive dimerization of 4,4'-bis(dimethylamino)benzophenone with tin powder in concentrated hydrochloric acid.[4] In spite of the electron-rich nature as evidenced by the fact that in chloroform it is easily oxidized to a violet pigment, it is known to react with sodium in ether yielding a bluish green powder of the disodium adduct.[5] In tetrahydrofuran (THF) TDAPE and sodium reacted smoothly to afford a wine-colored solution which was similar in reactivity to a solution of the TPE-disodium adduct. Thus, the Wurtz reaction was catalyzed effectively by TDAPE (0.05 mol per mol of benzyl halide was sufficient) as shown in Table 1.

$$2\,PhCH_2X \xrightarrow[TDAPE,\ THF]{Na\ or\ Na\text{-}K} PhCH_2CH_2Ph$$

Table 1. The Wurtz reaction of benzyl halides

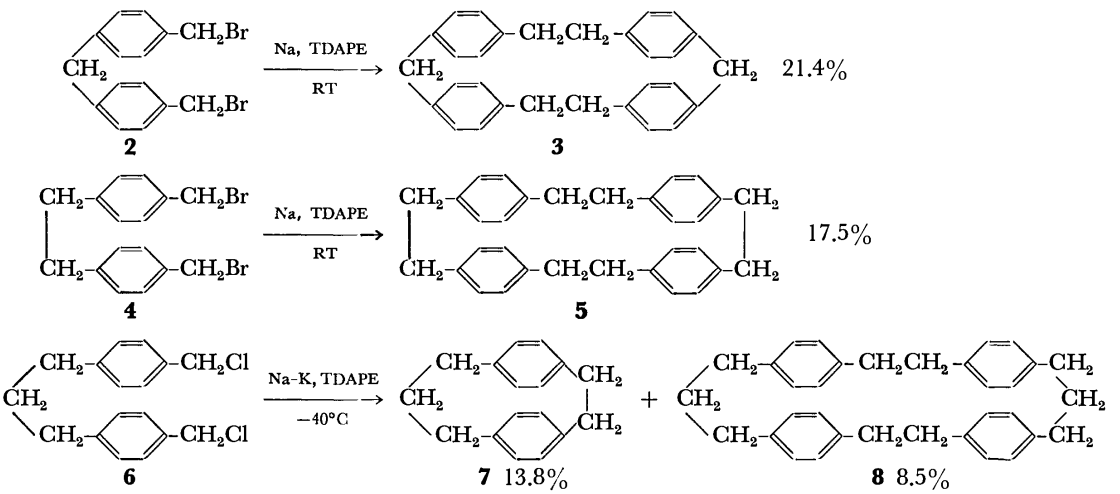
Reactant	Yields of 1,2-diphenylethane (%) TDAPE		TPE
	ca. −40 °C	Room temp	Room temp
$PhCH_2Cl$, Na-K	87	46	78[80(Na)][1]
$PhCH_2Br$, Na	77	66	(78)[1]

Although the reactions at room temperature were less fruitful compared with the corresponding TPE-catalyzed reactions, especially in the case of the chloride (see Experimental), the yields were improved by lowering the reaction temperature. The use of a liquid sodium–potassium alloy (Na–K) enabled a large metallic surface to be established and, thus, facilitated adduct formation especially at low temperatures.

To demonstrate the applicability of the modified Wurtz reaction to cyclophane synthesis several paracyclophanes have been synthesized. The cyclization was conducted by the addition over 24 h of a dihalide to a solution of the TDAPE–Na (or K) adduct at *ca.* −40 °C for the chloride **6** or, for convenience, at room temperature for the bromides **2** and **4**. Separation of the products from TDAPE was readily effected by acid-washing. The yields of **3** and **5** were satisfactory compared with those reported using TPE. The simplicity of separation without loss of yield in the Wurtz reaction will also be valuable in the synthesis of other systems.

Experimental

All the melting points are uncorrected. The PMR spectra were recorded at 60 MHz with a Hitachi R-20B spectrometer. The ^{13}C-NMR spectra were obtained at 22.6 MHz using a Hitachi R-22 spectrometer equipped with FT accessories. The mass spectra were obtained on a JEOL 01 SG mass



spectrometer.

Tetrakis(p-dimethylaminophenyl)ethylene, TDAPE.[4] To a stirred solution of 4,4'-bis(dimethylamino)benzophenone (50 g) in concd HCl (750 ml) was added tin powder (90 g) in small portions over a 3 h period at 90—100 °C. After stirring for 6 h the solution was allowed to cool and the precipitate formed was collected by filtration and treated with excess aq NaOH. The precipitate was extracted with warm benzene, washed with water, dried over Na_2SO_4, and concentrated. TDAPE was obtained as a 1/2 benzene solvate (35.5 g, 70%). Rapid crystallization of TDAPE from benzene–hexane gave yellow needles free from benzene but on standing in the solution the crystals turned gradually into prisms. The PMR spectrum(C_6D_6) and analyses indicate that the prisms are a 1/2 benzene solvate. TDAPE: yellow needles, mp 321—323 °C (sealed tube, lit,[6] mp 310—314 °C) Found: C, 80.83; H, 8.09; N, 11.17%. Calcd for $C_{34}H_{40}N_4$: C, 80.91; H, 7.99; N, 11.10%. TDAPE.1/2 benzene: greenish yellow prisms, mp 318—323 °C. Found: C, 81.67; H, 8.05; N, 10.40%. Calcd for $C_{37}H_{43}N_4$: C, 81.73; H, 7.97; N, 10.30%. A solution of TDAPE in $CDCl_3$, yellow at first, turned rapidly to violet with precipitation exibiting broad PMR peaks and a strong ESR signal, indicating the presence of radical cationic species formed by air oxidation. Therefore chloroform which was originally used for extraction is not suitable as the solvent.

The Wurtz Reaction of Benzyl Halide. To a solution of TDAPE (2.5 g, 0.005 mol) in THF (freshly distilled from sodium–benzophenone, 400 ml) was added a Na–K alloy (1 : 2 by weight, 6 ml) or sliced sodium (6 g) with stirring under nitrogen. After stirring for 30 min, to the deep wine-colored solution was added a solution of benzyl halide (0.1 mol) in THF (200 ml) at room temperature of at *ca.* −40 °C. Care was taken to prevent complete disappearance of the color of the adduct. After the addition the solution was filtered and evaporated. The residue was taken up in benzene and washed with dil HCl and water and the solution dried ($MgSO_4$), concentrated and distilled under reduced pressure yielding 1,2-diphenylethane. In the reaction of benzyl chloride at room temperature a considerable amount of residue remained after distillation, which gave, after purification through a silica gel column(chloroform), colorless prisms of high melting point and low solubility in common solvents in 8% yield. This product shows complex PMR signals at δ 6.6—7.5 and 2.3—3.3 ppm ($CDCl_3$), but MS (M^+ 362) and ^{13}C-NMR data [δ_{TMS} ($CDCl_3$) 41.0, 54.3, 125.4, 126.3, 127.7, 128.2, 128.6, 128.8, 130.7, and 133.3 ppm] indicate that it is 1,2,3,4-tetraphenylbutane **9**. The structure was confirmed by comparison with a sample of meso-**9** prepared by the reduction of tetraphenylthiophene.[7] Mp 182—183 °C (lit,[7a] 181—182 °C). Found: C, 92.65; H, 7.24%. Calcd for $C_{28}H_{26}$: C, 92.77; H, 7.23%. The formation of this product may be explained in terms of the incipient proton abstraction from benzyl chloride as follows:[8]

$$\underset{\mathbf{10}}{PhCH_2Cl} \longrightarrow PhCH^-Cl \xrightarrow{10} \underset{\mathbf{11}}{PhCHClCH_2Ph}$$

$$\xrightarrow{11} PhCH_2\overset{Ph}{\overset{|}{C}}H-\overset{Ph}{\overset{|}{C}}HCH_2Ph$$

$$\mathbf{9}$$

Synthesis of Paracyclophanes. [2.1.2.1]Paracyclophane **3** was prepared as follows. To a solution of TDAPE (2.5 g, 0.005 mol) in THF (400 ml) was added sliced sodium (11.5 g, 0.5 mol) under argon. After stirring for 30 min, to the deep wine-colored solution was added dropwise a solution of bis(*p*-bromomethylphenyl)methane **2** (17.7 g, 0.05 mol) in THF (500 ml) over a period of 24 h. The reaction mixture was decanted and evaporated and the residue dissolved in benzene, washed with dil HCl and water, dried over $MgSO_4$, and passed through a short column of silica gel to ensure removal of TDAPE. After evaporation of the solvent the residue was sublimed (230—240 °C at 0.03 Torr) and the sublimate recrystallized from benzene–hexane to give **3** as colorless prisms (2.08 g, 21.4%), mp 198—199 °C (lit,[9b] mp 199 °C, 14% yield from the corresponding chloride).

[2.2.2.2]Paracyclophane **5** was prepared analogously from 1,2-bis(*p*-bromomethylphenyl)ethane **4** in 17.5% yield, mp 179—181 °C (lit,[10] mp 185 °C, 7% yield from the corresponding chloride).

The reaction of 1,3-bis(*p*-chloromethylphenyl)propane **6** with Na–K at *ca.* −40 °C over a period of 24 h yielded **7** and **8**, the separation of which was readily effected by fractional sublimation. [3.2]Paracyclophane **7** : sublimed at 200—220 °C at atmospheric pressure, recrystallized from ethanol, colorless needles, mp 146—147 °C (lit,[11] mp 148—149 °C), 1.57 g (13.8%). MS: M^+ 222. PMR($CDCl_3$): δ 6.15, 6.39 (AA'BB' doublets, J=8 Hz, 8H), 2.95 (s, 4H), 2.9—2.5 (m, 4H), and 2.4—1.8 (m, 2H) ppm. [3.2.3.2]-Paracyclophane **8**: sublimed at 200—220 °C at 0.1 Torr, recrystallized from benzene, colorless prisms, mp 223—224 °C, 967 mg (8.5%). The compound had different properties from those reported (mp 61—62 °C[9a]) but the structure was confirmed by the following data. MS: *m/e* 444(M^+, 64), 222 (67), 131 (56), and 118 (100). PMR($CDCl_3$): δ 6.80, 6.72 (AA'BB' doublets, J=9 Hz, 16H), 2.86 (s, 8H), 2.6—2.2 (m, 8H), and 2.1—1.5 (m, 4H) ppm. Found: C, 91.64; H, 8.25%. Calcd for $C_{34}H_{36}$: C, 91.84; H, 8.16%.

Modifiction of Aminocyclitol Antibiotics. 7. Preparation of 5-Epikanamycin B

Tetsuo SUAMI* and Katsumi NAKAMURA

Department of Applied Chemistry, Faculty of Engineering, Keio University, Hiyoshi, Yokohama 223

(Received September 9, 1978)

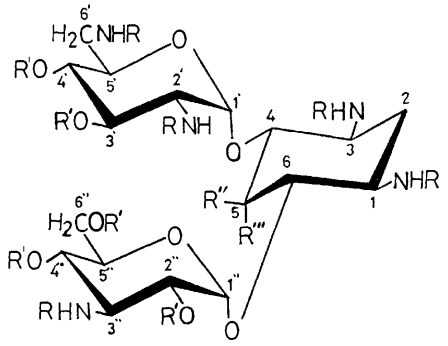
Synopsis. A configuration of the OH group on C-5 of 2-deoxystreptamine moiety of kanamycin B has been epimerized. 5-Epikanamycin B thus obtained was tested against several microorganisms. The structure of the antibiotic was elucidated by ^1H and ^{13}C NMR spectrometry.

In connection with the preceding paper of this series,[1] we have attempted to prepare 5-epikanamycin B (**4**), since 5-epineamine[2] showed an improved activity against a resistant strain of bacteria, compared to the parent neamine.

When 3′,4′,2″,4″,6″-penta-*O*-benzoyl-1,3,2′,6′,3″-pentakis-*N*-(ethoxycarbonyl)kanamycin B[1] (**1**) was treated with methanesulfonyl chloride in pyridine, a 5-*O*-mesyl derivative (**2**) was obtained. Nucleophilic substitution of **2** with an acetate ion in DMF, followed by purification afforded 5-*O*-acetyl-3′,4′,2″,4″,6″-penta-*O*-benzoyl-1,3,2′,6′,3″-pentakis-*N*-(ethoxycarbonyl)5-epikanamycin B (**3**). Hydrolysis of **3** in barium hydroxide solution, followed by purification on a CG-50(NH_4^+) resin column gave **4**, which was converted to a penta-*N*-acetyl derivative (**5**).

The ^1H NMR spectrum of **3** revealed acetoxyl methyl protons at δ 2.20 as a singlet, indicating an existence of an axial acetoxyl group, since the corresponding 5-*O*-acetylkanamycin B derivative revealed an equatorial acetoxyl methyl signal at δ 2.07.[3]

The structure of **4** was confirmed by ^{13}C NMR spectrometry. The spectrum of **4** was determined at pD above 11, showing 18 carbon signals which are assigned in accordance with the data for kanamycin B.[1,4] When the spectrum of **4** is compared with that of kanamycin B, it is obvious that the epimerization causes no appreciable shift of the signals of carbons in the aminosugar moieties, except that of C-1′, *i.e.*, the signal of C-1′ shifts to a higher field by 4.5 ppm, and analogous shifts have been described in the cases of 5-deoxykanamycin B[1] and 5-deoxyneamine.[7] While, the signals of carbons in the 2-deoxystreptamine moiety are shifted more or less to a higher field, except



1 R=C_2H_5OCO, R′=C_6H_5CO, R″=OH, R‴=H

a) In parts per million downfield from tetramethylsilane. b—e) The signals may be reversed.

that of C-2. That is, the signal of C-5 shifts by 6.8 ppm, and this is coincident with the fact that a shift of the signal of C-3 was observed between β-D-gluco and β-D-allopyranoses.[5] The signals of C-4 and 6 shift by 7.5 and 2.5 ppm, owing to a shielding effect of an adjacent axial OH group on C-5. Also, the signals of C-1 and 3 shift by 2.5 and 3.0 ppm, respectively. An analogous shielding effct of an axial OH group was described in a literature.[5,6]

When ^{13}C NMR spectrum of **4** was determined at pD 1 to find out a *N*-protonation effect,[4,8] a β-shielding effect is observed as was described in the case of kanamycin B.[1] Therefore, the inversion of the configuration has been confirmed.

Antimicrobial activities of **4** were determined against several microorganisms. The MIC (minimum inhibition concentration) values are listed in Table 2. No improvement of the activity was achieved by the epimerization of the OH group on C-5 in kanamycin B.

Experimental

General Methods. The same method was used as described in the preceding paper.[1]

3′,4′,2″,4″,6″-Penta-O-benzoyl-1,3,2′,6′,3″-pentakis-N-(ethoxycarbonyl)-5-O-mesylkanamycin B (2). To a stirred solution of 3′,4′,2″,4″,6″-penta-*O*-benzoyl-1,3,2′,6′,3″-pentakis-*N*-(ethoxycarbonyl)kanamycin B[1] (**1**, 311 mg) in pyridine (3 ml), mesyl chloride (0.5 ml) was added. After 160 h, the solution was quenched into ice–water (50 ml), and precipitates were collected by filtration. The precipitates were dissolved in $CHCl_3$, and the solution was passed through a short alumina column and evaporated. The residue was dissolved in benzene, and hexane was added to the solution to give 232 mg (71%) of **2** as amorphous powder, mp 121—126 °C, $[\alpha]_D^{21}$ +76.8° (*c* 0.5, chloroform), R_f 0.37 on TLC in 7 : 1 (v/v) benzene–methanol ^1H NMR: δ 3.32 (s, 3, SO_2CH_3).

Found: C, 57.80; H, 5.54; N, 4.90; S, 1.92%. Calcd for $C_{69}H_{79}N_5O_{27}S$: C, 57.45; H, 5.52; N, 4.86; S, 2.22%.

5-O-Acetyl-3′,4′,2″,4″,5″-penta-O-benzoyl-1,3,2′,6′,3″-pentakis-N-(ethoxycarbonyl)-5-epikanamycin B (3). A mixture of **2** (1.0 g) and sodium acetate (622 mg) in DMF (16 ml) was heated at 100 °C with agitation. After 68 h, the mixture was poured into ice–water (80 ml), and precipitates were collected by filtration. The precipitates were dissolved in chloroform, and the solution was washed with water, dried over Na_2SO_4 and evaporated. The residue was purified on a silica gel column with 20 : 1 (v/v) benzene–methanol. Fractions homogeneous on TLC (R_f 0.43) in 7 : 1 (v/v) benzene–methanol were combined and concentrated. The residue was dissolved in benzene and hexane was added to the solution to give 571 mg (54%) of **3**, mp 132—138 °C, $[\alpha]_D^{21}$ +100.6° (*c* 1.03, chloroform). ^1H NMR: δ 2.20 (s, 3, OAc).

Found: C, 59.45; H, 5.59; N, 4.70%. Calcd for $C_{70}H_{79}N_5O_{26}$: C, 59.78; H, 5.66; N, 4.98%.

5-Epikanamycin B (4). To a stirred solution of $Ba(OH)_2 \cdot 8H_2O$ (4 g) in water (14 ml), a solution of **3** (518 mg) in methanol (6 ml) was added. The mixture was heated at 100 °C for 15 h, and CO_2 was bubbled into the mixture. The precipitates were filtered off and the filtrate was concentrated. The residue was purified on a column of Amberlite CG-50 (NH_4^+) resin as described in the preceding paper[1] to give 20 mg (11%) of **4**, mp 172—178 °C (dec), $[\alpha]_D^{21}$ +159° (*c* 0.6, water).

A part of **4** (11 mg) was acetylated with acetic anhydride in methanol to give 15 mg (93%) of the penta-*N*-acetyl derivative (**5**), mp 217—223 °C (dec).

Found: C, 45.69; H, 6.88; N, 9.36%. Calcd for $C_{28}H_{47}N_5O_{15} \cdot 2H_2O$: C, 46.08; H, 7.04; N, 9.59%.

The authors wish to express their sincere thanks to Dr. Shyoji Omoto for determination of ^{13}C NMR spectra and to Mr. Saburo Nakada for elemental analyses. This work has been supported by a grant of the Asahi Glass Foundation to Industrial Technology.

Reaction of Optically Active 1-Dimethylaminoethylferrocene Palladium Complexes

Akira KASAHARA,* Taeko IZUMI, and Hiroyuki WATABE
Department of Applied Chemistry, Faculty of Engineering, Yamagata University, Yonezawa 992

(Received September 21, 1978)

Synopsis. *ortho*-Palladation products of optically active 1-dimethylaminoethylferrocene were treated with phenyl vinyl ketone and carbon monoxide and a variety of optically active 1,2-disubstituted ferrocene derivatives were obtained.

Recently, the reactions of *ortho*-palladation products from aromatic nitrogen derivatives with various reagents have been reported.[1] The carbonylation of *ortho*-palladation products of azobenzene, Schiff bases, and tertiary benzylamines usually give a variety of heterocyclic compounds.[2] The reaction of *ortho*-palladated benzylamine-type complexes with enones result in the formation of aryl-substituted enone derivatives.[3] On the other hand, it has been reported that stereoselective metallation of optically active α-ferrocenyl tertiary amines produce lithio amines with a high degree of asymmetric induction.[4] Sokolov *et al.*[5] described the *ortho*-palladation of optically active 1-dimethylaminoethylferrocene [(+)-**1** and (−)-**1**] with sodium tetrachloropalladate(II) in methanol in the presence of sodium acetate and found it to proceed with moderate stereoselectivity. For example, the *ortho*-palladation of (+)-**1** with sodium tetrachloropalladate(II) produced a mixture of two diastereoisomers [(−)-**2a** (major product) and (+)-**2b** (minor product)].[5a] The *ortho*-palladation products [(+)-**3a** and (−)-**3b**] were similarly obtained from (−)-**1**.[5b] In this paper, the reactions of optically active dimeric 2-chloropalladio-1-(1′-dimethylaminoethyl) ferrocene [(−)-**2a** and (+)-**3a**] with phenyl vinyl ketone and carbon monoxide, affording optically active 1,2-disubstituted ferrocene derivatives with a plane of chirality will be reported.

In the presence of triethylamine, the (−)-**2a** complex reacted with phenyl vinyl ketone in benzene, leading to the formation of (−)-1-(2′-benzoylvinyl)-2-(1″-dimethylaminoethyl)ferrocene (**4**). Treatment of (−)-**4** with methyl iodide resulted in the formation of (−)-1-(2′-benzoylvinyl)-2-vinylferrocene (**5**). In the presence of triphenylphosphine in ethanol, (−)-**2a** was carbonylated under carbon monoxide pressure, affording (+)-1-(1′-dimethylaminoethyl)-2-ethoxycarbonylferrocene (**6**). Elimination of the chiral center from (+)-**6** by the treatment with methyl iodide led to the formation of (+)-1-ethoxycarbonyl-2-vinyl-ferrocene (**7**).

On the other hand, the reaction of the (+)-**3a** complex with phenyl vinyl ketone, gave (+)-1-(2′-benzoylvinyl)-2-(1″-dimethylaminoethyl)ferrocene (**8**), and subsequent elimination of a chiral carbon center of (+)-**8** with methyl iodide afforded (+)-1-(2′-benzoylvinyl)-2-vinylferrocene (**9**). The carbonylation of the (+)-**3a** complex in ethanol also led to the formation of (−)-1-(1′-dimethylaminoethyl)-2-ethoxycarbonylferrocene (**10**), and subsequent treatment with methyl iodide afforded (−)-1-ethoxycarbonyl-2-vinylferrocene (**11**).

The structures of these compounds were identified by elemental analyses, IR, NMR, and MS spectra. There is no rapid interconversion (−)-**2a**⇌(+)-**2b** or (+)-**3a**⇌(−)-**3b**, the reaction of (−)-**2a** or (+)-**3a** with phenyl vinyl ketone is not the stereoselectivity determining process for (−)-**2a**→(−)-**4** or (+)-**3a**→(+)-**8** in the sence of the Curtin-Hammett principle,[6] and the carbonylation of σ-bonded palladium complexes proceeds with retention of configuration.[7] On the basis of the work of Uri,[4c] Sokolov *et al.*[5] suggested (*R*)-(*S*)-configuration to (−)-**2a** (the major product of the direct palladation of (+)-**1**). Consequently, one may assign a (*R*)-(*S*)-configuration to (−)-**4** and (+)-**6**; and *S*-configuration to (−)-**5** and (+)-**7**. It is similarly inferred that (*S*)-(*R*)-configuration to (+)-**3a** (the major product of the palladation of (−)-**1**), (+)-**8**, and (−)-**10**; and *R*-configuration to (+)-**9** and (−)-**11** were assigned.

Experimental

Materials. All melting points are uncorrected. The optically pure (1*R*)-(1*S*)-di-μ-chlorobis[2-(1′-dimethylaminoethyl)ferrocenyl]dipalladium(II) ((−)-**2a**) (mp 146 °C (dec), $[\alpha]_D^{20}$ −435.5° (*c* 0.053, $CHCl_3$)) and (1*S*)-(1*R*)-di-μ-chlorobis[2-(1′-dimethylaminoethyl)ferrocenyl]dipalladium-(II) ((+)-**3a**) (mp 145—146 °C (dec), $[\alpha]_D^{20}$ +438.1° (*c* 0.041, $CHCl_3$)) were synthesized by the methods in the literature.[5]

The Reaction of ortho-*Palladated Complexes with Phenyl Vinyl Ketone.* A mixture of complex ((1*R*)-(1*S*)-**2a** or (1*S*)-(1*R*)-**3a**) (2.0 g; 2.3 mmol), phenyl vinyl ketone (0.6 g; 4.6 mmol), and triethylamine (0.45 g; 4.6 mmol) in benzene (50 ml) was heated at 75 °C under nitrogen. The reaction mixture was then cooled and filtered to remove the precipitated palladium, benzene (100 ml) was added, and the mixture washed with water, dried over anhydrous magnesium sulfate, filtered, and concentrated under reduced pressure. The residue was then purified by column chromatography (Al_2O_3–benzene).

Photochemical Formation of Tetrahydro-2-furyl Ether in Alcohol–Tetrahydrofuran–Iron(III) Chloride System

Hideo KUROKAWA, Tatsuzo ISHIGAMI, Katsuaki MORIMOTO, and Akira SUGIMORI*

Department of Chemistry, Faculty of Science and Technology, Sophia University, Kioi-cho 7, Chiyoda-ku, Tokyo 102

(Received October 12, 1978)

Synopsis. Primary and secondary alcohols are converted into the corresponding tetrahydro-2-furyl ethers upon UV- and solar irradiation of alcohol and tetrahydrofuran in the presence of iron(III) chloride.

Preparative organic chemists have expressed increasing interest in the photoreactions which can occur in the presence of metal ions. As for the catalysis of iron(III) under illumination, methoxylation of styrene[1] and coupling of toluene[2] have been reported. Kochi reported the formation of 2-(4-chlorobutoxy)tetrahydrofuran in the photolysis of tetrahydrofuran–copper(II) system.[3] We report here the photochemical formation of tetrahydro-2-furyl ether catalyzed by iron(III) chloride. Several interesting photosubstitution reactions of tetrahydrofuran by sulfur dioxide[4] and 1,2,4,5,-tetracyanobenzene[5] have also been reported. As the method for the preparation of tetrahydro-2-furyl ethers, the reaction of alcohol with 2,3-dihydrofuran,[6] the reaction of alcohol, tetrahydrofuran, and *t*-butyl perbenzoate in the presence of copper(I) chloride[7] and the reaction of 4-formyloxybutyraldehyde with trialkyl orthoformate[8] have been reported.

Experimental

Materials. Tetrahydrofuran(THF) was purified according to Zweifel.[9] When THF was not treated with $LiAlH_4$, a small amount of tetrahydrofuryl ether was formed without irradiation. This is probably due to the reaction induced by peroxides contained in the non-purified THF, similar to the reaction induced by *t*-butyl perbenzoate in the presence of copper(I) chloride.[7] Commercially available alcohols were used after the purification by distillation or by recrystallization.

Irradiation. The general procedure is as follows. A solution containing alcohol(1.0 mmol) and iron(III) chloride (1.0 mmol) in 40 cm^3 of THF is irradiated with a low or a high pressure mercury lamp or with sunlight under nitrogen at room temperature. Quartz and glass vessels were employed in UV and sunlight irradiation, respectively.

Products. After irradiation, the reaction mixture was washed with sodium hydrogencarbonate solution and extracted with diethyl ether. The products were separated by means of thin layer chromatography. Tetrahydro-2-furyl ethers were identified on the basis of IR, NMR, and mass spectra.

Cinnamyl tetrahydro-2-furyl ether (liquid): IR 3030 (aromatic C–H), 2940, 2880 (aliphatic C–H), 1180, 1080 cm^{-1} (ether C–O) No absorption which can be assigned to O–H was observed. NMR(CCl_4) δ=1.84(4H, m, $C\underline{H}_2$ in THF moiety), 3.81(2H, t, J=3 Hz $C\underline{H}_2$ in THF moiety), 4.14 (2H, d, J=6 Hz, $C\underline{H}_2$–O in alcohol moiety), 5.06(1H, t, J=4.5 Hz, O–C$\underline{H}$–O), 6.28(2H, m, olefinic), 7.20(5H, m, phenyl). The NMR spectra are very similar to those of cinnamyl tetrahydro-2-pyranyl ether prepared from 3,4-dihydro-2*H*-pyran and cinnamyl alcohol. MS (70 eV), *m/e*(relative intensity), 204(2), 160(3), 132(4), 131(5), 118(11), 117(23, $[C_6H_5CH{=}CH_2]^+$),116(3), 115(3), 106(7), 105(7), 77(4), 72(5), 71(100, [tetrahydrofuryl]$^+$), 70(3), 57(3), 43(12). Found: C, 75.57; H, 7.94%; M^+, 204. Calcd for $C_{13}H_{16}O_2$: C, 76.44; H, 7.90%; M, 204. By refluxing the ether with hydrochloric acid, cinnamyl alcohol was obtained.

Cholesteryl tetrahydro-2-furyl ether(liquid): IR 2940, 2900, 2860(aliphatic C–H), 1090, and 1040 cm^{-1}(ether C–O); NMR(CCl_4) δ=0.7—2.3, 3.30(O–C$\underline{H}$ of cholesteryl moiety), 3.73($C\underline{H}_2$–O of THF moiety), 5.10(O–C$\underline{H}$–O), and 5.22(olefinic); Found: C, 81.03; H, 12.07%, Calcd for $C_{31}H_{54}O_2$: C, 81.16; H, 11.86%. Reflux of the ether (0.2 mmol) in aqueous ethanol in the presence of *p*-toluenesulfonic acid gave cholesterol (yield by TLC, 62%).

Other tetrahydro-2-furyl ethers were identified by the comparison of their IR and NMR spectra with those of tetrahydro-2-pyranyl ethers prepared by 3,4-dihydro-2*H*-pyran with alcohols. NMR spectra of tetrahydro-2-furyl ethers have a good correspondence with those of methyl and ethyl tetrahydro-2-furyl ether reported by Frehel and Delongchamps.[8] Hexyl,[7] cyclohexyl,[6] and benzyl[6] tetrahydro-2-furyl ethers are described in the literature.

Butyl tetrahydro-2-furyl ether (liquid): IR 2990, 2950, 2870 (aliphatic C–H), 1460, 1440 (CH_2 and CH_3), 1195, and 1040 cm^{-1} (ether C–O); NMR(CCl_4) δ=0.87(3H, t, J=6.8 Hz, $C\underline{H}_3$), 1.36(4H, m, $C\underline{H}_2$ of alcohol moiety), 1.80 (4H, m, $C\underline{H}_2$ of THF moiety), 3.1—3.9 (4H, m, $C\underline{H}_2$–O of alcohol and THF moieties), 4.92 (1H, t, J=4 Hz, O–C$\underline{H}$–O).

s-Butyl tetrahydro-2-furyl ether(liquid): IR 2950, 2900 (aliphatic C–H), 1090, and 1030 cm^{-1} (ether C–O); NMR (CCl_4) δ=0.9—1.6 (8H, ethyl and methyl of alcohol moiety), 1.80 (4H, $C\underline{H}_2$ of THF moiety), 3.5—3.7(3H, m, O–$C\underline{H}_2$ of THF moiety and O–C$\underline{H}$ of alcohol moiety), 5.08 (1H, t, J=4 Hz, O–C$\underline{H}$–O).

Hexyl tetrahydro-2-furyl ether (liquid): IR 2950, 2920, 2850 (aliphatic C–H), 1450 (CH_2 and CH_3) 1100. 1090, and 1040 cm^{-1} (ether C–O); NMR(CCl_4) δ=0.88 (3H, t, J=5.7, CH_3), 1.32 (8H, m, CH_2 of alcohol moiety), 1.80-(4H, m, $C\underline{H}_2$ of THF moiety), 3.61 (4H, m, $C\underline{H}_2$–O of alcohol and THF moieties), 4.94 (1H, t, J=4 Hz, O–C$\underline{H}$–O).

Cyclohexyl tetrahydro-2-furyl ether (liquid): IR 2930, 2850 (aliphatic C–H), 1450(CH_2), 1090, and 1040 cm^{-1} (ether C–O); NMR(CCl_4) δ=1.2—1.8 (14H, CH_2 in cyclohexyl and THF moieties), 3.2—3.8(3H, m, C$\underline{H}$–O of cyclohexyl moiety and $C\underline{H}_2$–O of THF moiety), 5.10(1H, t, J=4.5 Hz, O–C$\underline{H}$–O).

Benzyl tetrahydro-2-furyl ether(liquid) : IR 3030(aromatic C–H), 2970, 2940, 2880,(aliphatic C–H) 720, and 690 cm^{-1} (monosubstituted benzene); NMR(CCl_4) δ=1.89 (4H, m, $C\underline{H}_2$ in THF moiety), 3.82(2H, $C\underline{H}_2$–O in THF moiety), 4.55 (2H, CH_2–O of alcohol moiety), 5.10 (1H, t, J=4.5 Hz,

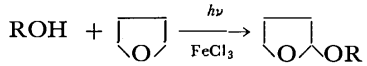
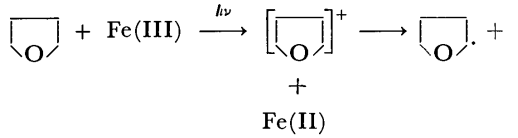
Results and Discussion

Primary and secondary alcohols react with tetrahydrofuran (THF) under irradiation in the presence of iron(III) chloride to give the corresponding tetrahydro-2-furyl ether of alcohols.

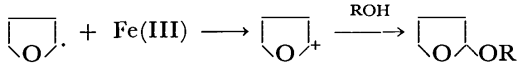


The results are shown in Table 1. Both aliphatic and aromatic alcohols give photochemically tetrahydrofuryl ether, but *t*-butyl alcohol does not undergo the photoetherification. Tetrahydro-2-furyl ethers are formed upon irradiation not only with a low or a high pressure mercury lamp, but also with sunlight. The presence of iron(III) chloride as the catalyzer in the reaction is essential, since no reaction took place in the absence of iron(III) chloride. These facts suggest that the photoreaction has a possibility for synthetic utilization of sunlight catalyzed by metal ions.[10]

The formation of tetrahydro-2-furyl ether is accompanied by that of iron(II). In the initial stage, the consumption of iron(III) is nearly twice as much as the formation of tetrahydro-2-furyl ether : in hexyl alcohol–THF–$FeCl_3$ system(hexyl alcohol : $FeCl_3$ = 1 : 1) the ratio of iron(II) to hexyl tetrahydro-2-furyl ether at 1 and 2 hours' irradiation were 2.5 and 1.8, respectively. The formation of $CH_3\dot{C}HOCH_2CH_3$ was reported in the UV-irradiation of the diethyl ether–iron(III) system.[11] One mole of iron(III) is consumed for the generation of tetrahydro-2-furyl radicals, probably *via* the electron transfer from THF to iron(III).



The second step in which iron(III) participates would be the oxidation of tetrahydro-2-furyl radicals to give tetrahydro-2-furyl cations, which react with alcohol in the following scheme.



The present work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture (No. 147026).

(Received August 8, 1977)

Synopsis. Pyrazine-2,3-dicarboxamide complexes with the perchlorates of copper(II), cobalt(II), and nickel(II) have been prepared and characterised, copper having a square planar configuration and cobalt and nickel an octahedral geometry. Bonding takes place through a ring nitrogen and the oxygen atom of the adjacent amide group.

Heterocyclic carboxamides are known to possess powerful antitubercular activity.[1] During the course of the investigation on metal ion-assisted hydrolysis of pyrazine-2,3-dicarboxamide (pzda), a paper[2] was published on several cobalt and nickel(II) complexes with both ring nitrogens of the ligand bonded to the same metal without participation of the amide groups. The structure seemed untenable to us. Since delineation of the above mentioned reaction requires knowledge of the bonding in metal complexes, this problem has been reinvestigated. In this study perchlorate has been chosen as the anion since the stereochemistry will not be affected by the anion participation.

Experimental

Preparation. To the ligand (0.2 g) dissolved in water (30 ml) on a steambath, was added the metal perchlorate (1 g). The copper compound which separated as bluish violet crystals when cooled to room temperature, was washed with cold water and recrystallised from hot water. Large orange-red crystals of the cobalt(II) complex and greenish crystals of the nickel(II) complex, however, separated on slow evaporation of the solution over concentrated H_2SO_4. The crystals were filtered, washed with dry ethanol, dried in air. The analytical data (Table 1) confirms the complexes to be $[Cu(pzda)_2](ClO_4)_2$ (I), $[Co(pzda)_2(H_2O)_2](ClO_4)_2$-(II), and $[Ni(pzda)_2(H_2O)_2](ClO_4)_2$ (III) respectively.

Results and Discussion

The preparation of pyrazine-2,3-dicarboxamide complexes possessed difficulties because of the poor solubility of the ligand in common organic solvents including 1-butanol used by Singh *et al.*,[2] consequently an aqueous solution of the ligand was used for preparation of the complexes. Since the copper(II) complex, cobalt(II) and nickel(II) compounds decomposed on dissolution in water, an excess of the metal perchlorates which consumed the ligand totally and hindered any dissociation was used.

Table 2 shows the important IR bands of the ligand, its deuterated form, and the metal complexes. The assignments of these bands can readily be made by comparing them with the 2-pyridine carboxamide (pya) and 2-pyrazine carboxamide (pza) complexes,[3,4] and by taking into considerations the pyrazine ring vibrations.[5] In all the complexes the asymmetric and symmetric OCN stretching bands are shifted to lower and higher frequencies respectively relative to the free ligand, indicating that coordination takes place through the oxygen atom of the amide group. Similar shifts describing coordination through amide oxygen have been observed for complexes of 2-pyridine carboxamide,[3,6,7] 2-pyridine acetamide,[8] 2-pyrazine carboxamide[9] and 8-quinoline carboxamide.[10]

The room temperature magnetic moments and electronic spectra (Table 1) are indicative of the square planar configuration of the copper complex and the octahedral geometry of the cobalt(II) and nickel(II) complexes.[11] In an aqueous solution the copper(II) complex shows only a single broad band (10520—

14300 cm^{-1}). The mull spectrum, however, shows the presence of a shoulder in addition to that observed in solution. It is expected that due to the absence of Jahn-Teller distortion more bands should appear in the visible range,[12] Ferguson has shown[13] that distinct bands observed in the polarised spectra of square planar copper(II) complexes are considerably broadened in solution. It has therefore been concluded that the square planar geometry of the copper(II) complex is retained in solution.

Regarding the nature of bonding in pyrazine-2,3-dicarboxamide complexes support is given by the X-ray crystallographic study of $[Cu(pzda)_2]$ $(ClO_4)_2$.[14]

Intercalation Compounds FeOCl(Pyridine derivatives)$_{1/n}$ and FeOCl(*n*-Propylamine)$_{1/4}$

Shinichi KIKKAWA, Fumikazu KANAMARU,† and Mitsue KOIZUMI*

The Institute of Scientific and Industrial Research, Osaka University, Suita, Osaka 565

†*Research Institute for Non-crystalline Materials, School of Engineering, Okayama University, Okayama 700*

(Received April 24, 1978)

Some pyridine derivatives were intercalated into the van der Waals gap of layered compound FeOCl. Pyridine, 2,6-dimethylpyridine, 4-aminopyridine, 2,4,6-trimethylpyridine, and *n*-propylamine were used as intercalates having different Lewis basicities. X-Ray diffraction, Mössbauer effect, electrical resistivity, ESR and electronic spectra were studied, some correlations being found between the measured parameters of these complexes and the basicities of organic intercalates. It is assumed that organic intercalates transfer their lone pair electrons on the nitrogen atom to FeOCl layers.

Iron oxychloride is a layered compound belonging to an orthorhombic space group Pmnm with $a=3.780$, $b=7.917$, $c=3.302$ Å, and $Z=2$.[1] The crystal structure consists of a stack of double layer sheet of *cis*-$FeCl_2O_4$ octahedra linked together with shared edges. The outermost atoms at each side of the layers are Cl ions. The interlayer bonding between adjacent layers is van der Waals interaction. Hagenmüller *et al.* found that FeOCl reacts with ammonia and some amine molecules.[2] Kanamaru *et al.* reported the intercalation of pyridine into FeOCl, and observed remarkable changes in electrical and magnetic properties.[3-5] The changes can be attributed to charge transfer from the nitrogen atom of the intercalated pyridine molecule to the FeOCl layer.

Transition metal dichalcogenides (MX_2) intercalate some organic bases. Their superconducting transition temperatures (T_c) change with organic intercalation. Bray and Sauer measured the lone pair electron densities on nitrogen atoms of organic bases by means of nuclear quadrupole resonance.[6] The electron densities were correlated with T_c of the intercalated MX_2. Lewis basicity of organic base is a measure of the ability to donate electrons to acids. pK_a value would be qualitatively related to the change of the property of host caused by intercalation if charge-transfer interaction is significant in the bonding between host layer and guest molecule.

Effect of pK_a on the properties of FeOCl-organic complexes can be checked by use of some pyridine derivatives having different basicities. Pyridine derivatives can act as either n- or π-donor.[7] Study on aliphatic amine is useful to distinguish the effects of these two kinds of electrons in comparison with pyridine intercalated complexes.

The present report deals with intercalation of some pyridine derivatives and *n*-propylamine into FeOCl. Electrical resistivity, Mössbauer effect, ESR and electronic spectrum were studied for these intercalated compounds. Some correlations were found between basicities of the intercalate and properties of the products. The possibility of charge transfer is discussed on FeOCl (organic compound)$_{1/n}$.

Experimental

Preparation. Iron oxychloride was prepared by heating a mixture of α-Fe_2O_3 and $FeCl_3$ with mole ratio 1 : 4/3 in a sealed Pyrex glass tube at 370 °C for two days. The product was washed with water and dried. Reddish violet and thin blade-like FeOCl crystals were obtained.

The reactions with pyridine (Py) and its derivatives, 2,6-dimethylpyridine (DMP), 4-aminopyridine (AP), and 2,4,6-trimethylpyridine (TMP), were conducted at 100 and 40 °C, respectively, in a closed system for about a week. Intercalation of *n*-propylamine (PA) was completed within 1 h at room temperature. Since Py, DMP, TMP, and PA are liquid at room temperature, FeOCl was directly soaked into these liquids. The acetone solution of AP was used for solid AP. The intercalated compounds obtained were black crystals. X-Ray diffractometry showed no unreacted FeOCl. Chemical analyses of C, H, and N showed that each intercalated compound has a stoichiometric composition. If the complex is represented by FeOCl(organic compound)$_{1/n}$, *n*-values are four for Py, DMP, AP, and PA, and six for TMP, respectively

Measurement. X-Ray analysis was carried out with a Rigaku-Denki diffractomer using Fe-filtered Co $K\alpha$ radiations. The electrical resistivities of FeOCl and its complexes were measured in the temperature range 373—200 K using carbon electrodes. The Mössbauer spectra were measured at room temperature and at liquid nitrogen temperature using radiation from ^{57}Co in Pd metal with a 200 channel multichannel analyzer. Samples were dispersed with silicon grease, the thickness being *ca.* 30 mg/cm^2. Calibration was based on the Mössbauer spectrum of Fe metal. The ESR measurements of FeOCl and its complexes were carried out on a JES-ME-2X spectrometer at 77 K and at room temperature. Ultraviolet spectra of FeOCl and the intercalated complexes were obtained by the diffuse reflectance method. Samples were dispersed in MgO. Transmission method was used for the intercalates themselves, which were diluted with cyclo hexane.

Results

The *b*-values corresponding to the interlayer distances are summarized in Table 1. Each *b*-value for the complexes is much larger than 7.92 Å for FeOCl. The expansion is explained by the insertion of organic intercalates into the van der Waals gap of FeOCl.

FeOCl is a semiconductor with resistivity of 10^6 Ω cm at room temperature. The intercalated complexes are still semiconductive, but exhibit improved electrical conductivities along their c-axis. Their electrical resistivities are 10—10^3 Ω cm at room temperature. The values are smaller than that of FeOCl by a factor of

10^{3-5}. The electrical activation energy also changes from 0.6 eV to 0.2—0.3 eV for the complexes.

Mössbauer spectra were obtained as shown in Fig. 1. The pertinent parameters at room temperature obtained with a least-squares fit computer program are summarized in Table 1. Isomer shifts of the intercalated pyridine derivative complexes are 0.40—0.44 mm/s. The values seem to increase with pK_a of organic intercalates, and are larger than 0.40 mm/s for FeOCl. Isomer shifts of Py- and PA-FeOCl complexes are also larger than that of FeOCl. Quadrupole splittings are 0.67—0.92 mm/s for the intercalated complexes, being smaller than 0.93 mm/s for pure FeOCl. Q.S. tends to decrease with increase in I.S.

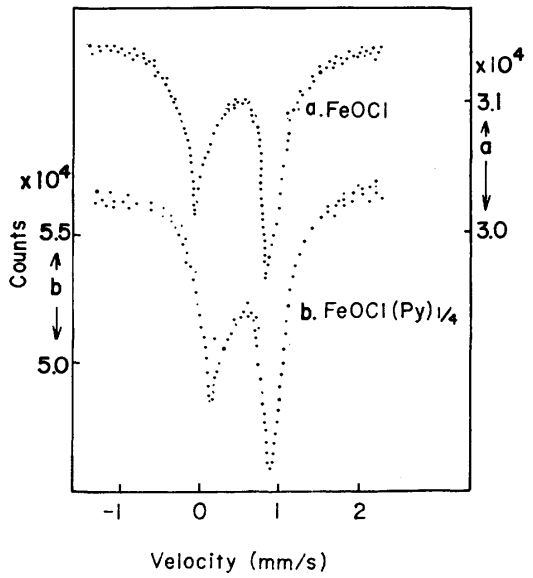

Fig. 1. Mössbauer spectra of FeOCl and FeOCl(Py)$_{1/4}$.

TABLE 1. PARAMETERS FOR FeOCl AND FeOCl(ORGANIC COMPOUND)$_{1/n}$

	pK_a	b(Å)	ρ (Ω cm)	E_a (eV)	I.S. (mm/s)	Q.S. (mm/s)	$\Delta H_{1/2}$ (G)
FeOCl		7.92	10^6	0.6	0.40	0.93	
FeOCl-(Py)$_{1/4}$	5.2	13.27	10	0.2	0.45	0.67	200
FeOCl-(DMP)$_{1/4}$	6.8	14.98	10^2	0.3	0.40	0.92	600
FeOCl-(AP)$_{1/4}$	9.2	13.57	10^3	0.2	0.42	0.84	1000
FeOCl-(TMP)$_{1/6}$	9.6	11.79	10^3	0.2	0.44	0.81	—
FeOCl-(PA)$_{1/4}$	10.5	11.89	10^2	0.2	0.44	0.68	900

The ESR spectra of FeOCl(pyridine derivative)$_{1/n}$ were recorded at room temperature and at 77 K. Except for TMP, broad singlet spectra were observed at g=2.003, their line shapes being almost Lorentzian. Neither FeOCl nor pyridine derivatives show any signals by themselves. The linewidth $\Delta H_{1/2}$ shows no change with temperature but changes with the kind of intercalate (Table 1). No signal was detected for TMP complex. In order to avoid the skin effect, some samples were dispersed in γ-alumina. Neither linewidths nor g-values were affected by dilution. Anisotropic effects were checked on highly preferred oriented samples. Signals did not change with directions of the samples to magnetic field.

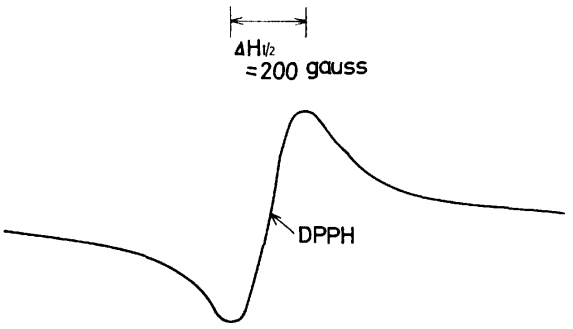

Fig. 2. ESR signal obtained for FeOCl(Py)$_{1/4}$.

Iron oxychloride shows no absorption in its ultraviolet spectrum. Pyridine has an intense $\pi \rightarrow \pi^*$ absorption at 250 nm, and a weak $n \rightarrow \pi^*$ one at 285 nm.[8] FeOCl-(Py)$_{1/4}$ complex has a broad and asymmetric absorption at about 270 nm, and FeOCl(pyridine derivative)$_{1/n}$ have absorptions around 265 nm. The latter absorptions are in almost the same regions as those of pyridine derivatives. n-Propylamine without π-electrons has an absorption at 261 nm with a shoulder at around 252 nm, but complex FeOCl(PA)$_{1/4}$ has a weak absorption at 248 nm. Furthermore, very broad absorptions around 310 nm were observed for both FeOCl(Py)$_{1/4}$ and FeOCl(PA)$_{1/4}$. Neither FeOCl nor the intercalates show any absorptions in this region; DMP, TMP, and AP complexes have no prominent absorptions.

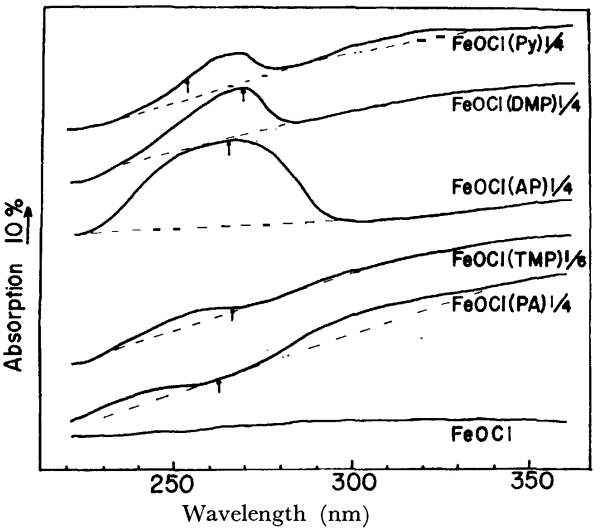

Fig. 3. Ultraviolet spectra of FeOCl and FeOCl(organic compound)$_{1/n}$. (Solid line).
Arrows show the positions of absorption maxima of organic compounds.

Discussion

Layered inorganic compound FeOCl intercalates some organic molecules. Each intercalated compound

has an expanded spacing between 11.79 and 14.98 Å (Table 1). The expanded spacings are explained by the insertion of organic intercalates into the van der Waals gap of FeOCl. Kanamaru *et al.* showed that planes of pyridine rings are perpendicular to the host layers so that nitrogen atoms face the layers in the pyridine complex.[4] However, FeOCl(PA)$_{1/4}$ seems to be in a different situation from pyridine complex since no more than approximately 4.0 Å is available between the layers. One of the sp^3 hybridized orbitals of terminal nitrogen atom, which contains lone pair electrons, faces the FeOCl layer, but the alkyl chain is nearly parallel to the host layer. For FeOCl(DMP)$_{1/4}$, FeOCl(AP)$_{1/4}$, and FeOCl-(TMP)$_{1/6}$, molecular orientations of pyridine derivatives in the interlayer space of FeOCl have been estimated using the results of one-dimensional electron density projections based on X-ray diffractions.[9] The pyridine ring of DMP is perpendicular to the host layer, but rotates a little around the center of the ring due to the steric effect of methyl groups. For FeOCl(AP)$_{1/4}$, the pyridine ring tilts slightly from a plane perpendicular to the layer. The inclination arises from a steric effect and the hydrogen bond between the amino group and the host layer. The pyridine ring of TMP is more tilted than that of DMP because of the larger steric effect of methyl groups of the former. However, in all cases, organic molecules are in the van der Waals gap so that their nitrogen atoms are as close to FeOCl layer as possible.

Parameters for FeOCl and FeOCl(organic compound)$_{1/n}$ are summarized in Table 1 with pK_a values of organic intercalates, which are values for pure organic compounds and not for the intercalated ones.[10] Formation of the complexes caused much reduction in electrical resistivity in the direction parallel to the host layer. The improved electrical conductivity can be explained by increased number of charge carriers. Mössbauer parameters change with intercalation. Isomer shifts of the complexes are slightly larger than that of FeOCl, but they are still those for ferric ions. The observed increase in I.S. values suggests the increased d-electron density around Fe atom in the intercalated FeOCl layer. However Fe^{2+} is not detected above liquid nitrogen temperature. A correlation between pK_a and I.S. is observed for pyridine derivative complexes. But FeOCl-(Py)$_{1/4}$ has the largest I.S., pyridine having the smallest pK_a. This suggests the importance of the effect of interaction between the side groups and Cl ions on the surface of FeOCl layer as well as that of pK_a. With increase of interaction between host and guest, charge carriers in the complexes tend to localize, electrical conductivity decreasing with increase in pK_a. The reduction of electrical resistivity and the increase of the isomer shift are explained by assuming the charge transfer from the nitrogen atoms of the intercalated organics to the FeOCl layer. The assumption seems to be supported by the molecular arrangements of intercalated organics in the interlayer region of FeOCl. ESR and UV spectroscopy were used in order to obtain direct evidences of the charge transfer.

Charge transfer interactions which involve formation of unpaired electrons were observed on ESR spectroscopy.[11,12] Very broad signals are detected on the intercalated FeOCl except for TMP complex. These signals are Lorentzian. They show no hyperfine, fine structures and anisotropic effects to magnetic field. *g*-Values are 2.003. Conduction electrons in metals and semiconductors sometimes show resonance of Lorentzian shape at around $g=2.003$, the linewidth becoming broader with increase of electrons.[13] ESR signal of charge transfer complex in solid state often loses its fine structure because of delocalization of the transferred electrons. In the case of FeOCl(organic compound)$_{1/n}$, the very broad ESR signal may be attributed to the conduction electrons formed in the host layer due to intercalation.

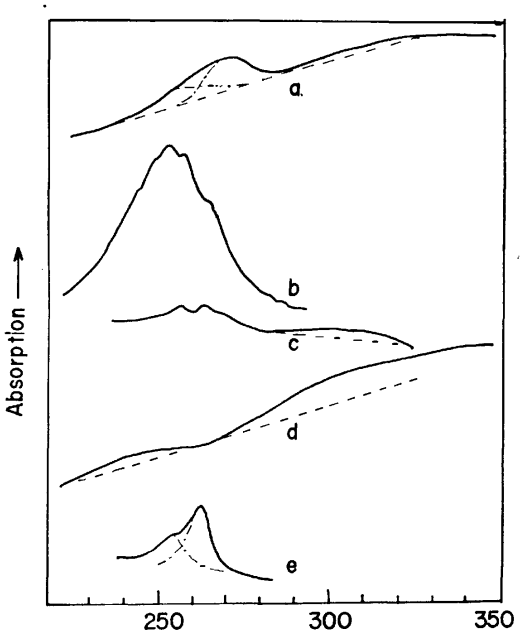

Fig. 4. Ultraviolet spectra of FeOCl(organic compound)$_{1/n}$.
a: FeOCl(Py)$_{1/4}$, b: pyridine c: $[IrOH(py)_2(NH_3)_3]^{2+}$
d: FeOCl(PA)$_{1/4}$, e: PA.

Figure 4 (a) and (d) show ultraviolet spectra of FeOCl-(Py)$_{1/4}$ and FeOCl(PA)$_{1/4}$, respectively. They have very broad absorptions around 310 nm observed in neither FeOCl nor the intercalates. These absorptions may be assigned to charge transfer bands as compared with that of $[IrOH(py)_2(NH_3)_3]^{2+}$ in which a similarly broad charge transfer band is observed at around 300 nm (Fig. 4 (c)).[14] For DMP-, AP-, and TMP-complexes, however, no clear C.T. absorptions are found in ultraviolet and visible regions. On the other hand, absorptions of the intercalates are perturbed by the intercalation into FeOCl. The pyridine $\pi \rightarrow \pi^*$ absorption in FeOCl(Py)$_{1/4}$ shifts to longer wavelength by 20 nm, turning asymmetric. Red shift of pyridine absorption is also observed on Ir–Py complexes.[14] Absorptions of the pyridine derivatives do not clearly shift by intercalation, the peaks being broad and asymmetric in the respective FeOCl complexes. The asymmetric absorption can be divided into two or more components (Fig. 4(a)). Further

analysis is difficult, since pyridine and pyridine derivatives have both lone pair and π-electrons. These two kinds of electrons can contribute to charge transfer. In order to observe the absorption of lone pair electron which is in non-bonding orbital, aliphatic amine is more suitable than pyridine derivatives. *n*-Propylamine shows an absorption from non-bonding orbital to σ^* one at 261 nm. A broad blue shifted absorption is observed at around 248 nm on the spectrum of $FeOCl(PA)_{1/4}$. Since chlorine is the outermost ion in each FeOCl layer and the nitrogen atoms of the intercalates are very close to FeOCl layer, it is reasonable to assume a certain interaction between the non-bonding orbital of the intercalated donor and the σ orbital of chlorine. The amount of blue shift of $n \rightarrow \sigma^*$ absorption is 13 nm on PA. The present value for the Cl···N pair is in the range of blue shifts of other n-donor and iodine pairs. Thiourea and thioacetoamide show blue shifts of 10 and 21 nm, respectively.[15] This suggests that the bonding between FeOCl and PA is similar to that of other n-donor and I_2 molecular complexes. A similar blue-shift of lone pair electron absorption might also contribute to the asymmetric absorption observed on FeOCl(pyridine derivative)$_{1/n}$.

$FeOCl(PA)_{1/4}$ is similar to FeOCl(pyridine derivative)$_{1/n}$ as regards electrical resistivity, Mössbauer effect and ESR. This suggests that FeOCl(pyridine derivative)$_{1/n}$ having lone pair electrons has almost the same bonding character between host and guest as $FeOCl(PA)_{1/4}$.

The charge-transfer interaction has been confirmed in the intercalated FeOCl complexes. In Mulliken's charge-transfer formulation of donor-acceptor systems, pyridine can work as either a π-donor or an n-donor.[7] Correlations are found between pK_a and properties of the obtained complexes. Thus, we assume that lone pair electrons of the nitrogen atom are involved in the donor-acceptor interactions, and pK_a values of the respective compounds can be used as a measure of n-ionization potential. A similar speculation was made by Chaudhuri and Basu for the system of iodine and many aza-aromatics.[16] They found the proportionality between the logarithm of equilibrium constants for charge transfer type interaction and pK_a values.

In conclusion, pyridine, pyridine derivatives, and propylamine molecules having nitrogen atoms are intercalated into the van der Waals gap of FeOCl. The properties of the products are explained by means of a charge-transfer model. It is assumed that lone pair electrons on the nitrogen atoms of the organic molecules transfer to FeOCl layer in the intercalated complexes.

We are grateful for the help given by Dr. R. Kikuchi and Mr. T. Sawai in the measurement of the Mössabuer effect, by Dr. T. Fujino in the C, H, and N elementary analysis, and by Mr. H. Miyamoto in the ESR measurements. A part of this research was defrayed by a Grant-in-Aid for Special Research Project from the Ministry of Education.

Studies on the Aqueous Solutions of Guanidinium Salts. IX. Activity Coefficients of Biguanide Hydrochloride and Sucrose in Aqueous Ternary Solutions at 25 °C

Koichiro MIYAJIMA,* Shigeo NAKANISHI, and Masayuki NAKAGAKI

Faculty of Pharmaceutical Sciences, Kyoto University, Yoshida-shimoadachi-cho, Sakyo-ku, Kyoto 606

(Received June 29, 1978)

Activity coefficients for the ternary system biguanide·HCl–sucrose–water were determined by the isopiestic vapor pressure method at 25 °C. Biguanide hydrochloride (Bg·HCl) and sucrose each decreased the activity coefficient of the other solute, showing a mutual salting-in effect. The excess free energy of mixing was negative and its magnitude was about twice as large as that of the system urea–sucrose–water. The pair interaction parameter $\{Bg\cdot HCl\text{–sucrose}\}_g$ was calculated to be -89.2 (cal mol^{-2} kg). Thermodynamic properties of this system were found to be similar to those of the system urea–sucrose–water, indicating that Bg·HCl exerted a structure breaking effect on the aqueous solutions of sucrose as urea did.

Biguanide (guanylguanidine) derivatives have been widely used as hypoglysemic agents. Though the direct interaction of the drugs with sugars is questionable, the physicochemical study of the ternary system Bg·HCl–sucrose–water seems to be important, especially concerning the denaturation of protein and the structure of water, because biguanide halides are known as strong protein denaturants and their effectiveness is known to be stronger than that of urea or guanidinium halides.[1] On the other hand, sugars and polyalcohol are known to stabilize the native conformation of protein.[2,3] In the urea–sucrose–water system, which contained two solutes with opposite effects for the denaturation of protein and the structure of water, each solute decreased the activity coefficient of the other.[4] In the mannitol–sucrose–water system, which has two solutes with similar stabilizing action for the conformational change of protein, each solute increased the activity coefficient of the other.[5] Uedaira reported that in the ternary system which contained two structure maker, mutual salting-out was observed, while in the system with a structure maker and a structure breaker, mutual salting-in was found.[6] From these points of view, we measured the activity coefficients of Bg·HCl and sucrose in mixed solutions. The results are interpreted in terms of the structural change of water.

Experimental

Materials. The free biguanide was prepared from biguanide sulfate dihydrate[7] (Aldrich Co., Ltd.). This was neutralized with hydrochloric acid solution and was concentrated under reduced pressure. The crude Bg·HCl was recrystallized twice from aqueous ethanol solution and dried *in vacuo* at room temperature. Sucrose (Wako Chemical Co., Ltd. reagent grade) was used without further purification and dried *in vacuo* at 90 °C. Analytical grade sodium chloride (Matsunaga Chemical Co., Ltd.) was dried *in vacuo* at 110 °C. These salts were dissolved in redistilled and deionized water.

Method. Osmotic and activity coefficients were determined by the isopiestic vapor pressure method.[8] About 1 ml of each sample solution was placed in a silver dish with dimensions $2\times2\times2$ cm^3. Similar quantities of the reference solutions were placed on a flat copper block containined in a vacuum desiccator, which was evacuated to a pressure of approximately 25 mmHg. The solutions were then allowed to equilibrate under reduced pressure for 3—10 d in a large thermostat bath, controlled to approximately 25 ± 0.05 °C. A total of 10 dishes were usually equilibrated together at once. The concentrations of sample and reference solutions were adjusted initially so as to be fairly close to the desired equilibrium values. The solutions were regarded to have reached the equilibria if the molalities of the two reference solutions differed by not more than 0.1%. Bacterial activity in dilute sucrose solutions was not experienced. The equilibrium concentrations were determined by weighing the dishes. Buoyancy corrections were made by using the densities of sodium chloride, sucrose and Bg·HCl: 2.165, 1.588, and 1.25 g cm^{-3}, respectively, while the corresponding molecular weight used were 58.443, 342.303, and 137.573.

After the equilibrium concentrations were measured, all solutions were diluted by adding several drops of water and reequilibrated in order to attain another equilibrium at more diluted concentrations. Several dilution treatments were carried out and then a new set of solutions was prepared.

Theory

Consider an aqueous ternary solution containing two solutes, 1 (1:1 electrolyte) and 2 (nonelectrolyte), and let m_s and ϕ_s be the molality and the osmotic coefficients of the solute s ($s=1$ and 2); then it is convenient to define a quantity[6,9]

$$\Delta = \nu_R m_R \phi_R - 2m_1\phi_1 - m_2\phi_2, \qquad (1)$$

where m_R and ϕ_R are the molality and the osmotic coefficient of the reference solution which is in vapor equilibrium with the ternary solution, and ν_R is the number of moles of ions or molecules produced by the dissolution of 1 mol of the reference solute.

The value of Δ/m_1m_2 is given Eq. 2.

$$\Delta/m_1m_2 = \sum_{i=0}^{3}\sum_{j=0}^{3} A_{ij}m_1^i m_2^j \quad (i+j\leq 3) \qquad (2)$$

The Δ/m_1m_2 was obtained experimentally and the coefficients A_{ij} in Eq. 2 were determined by the least-squares method.

The activity coefficients of the solute 1 and 2 in the ternary solution are given by Eqs. 3 and 4.

$$\begin{aligned}\ln\gamma_1 = \ln\gamma_1^0 &+ (1/2)A_{00}m_2 + (1/2)A_{10}m_1m_2 + (1/4)A_{01}m_2^2 \\ &+ (1/2)A_{20}m_1^2m_2 + (1/3)A_{11}m_1m_2^2 + (1/6)A_{02}m_2^3 \\ &+ (1/2)A_{30}m_1^3m_2 + (3/8)A_{21}m_1^2m_2^2 \\ &+ (1/4)A_{12}m_1m_2^3 + (1/8)A_{03}m_2^4, \qquad (3)\end{aligned}$$

and

$$\ln\gamma_2 = \ln\gamma_2^0 + A_{00}m_1 + (1/2)A_{10}m_1^2 + A_{01}m_1m_2 + (1/3)A_{20}m_1^3 + (2/3)A_{11}m_1^2m_2 + A_{02}m_1m_2^2 + (1/4)A_{30}m_1^4 + (1/2)A_{21}m_1^3m_2 + (3/4)A_{12}m_1^2m_2^2 + A_{03}m_1m_2^3, \quad (4)$$

where γ_s^0 ($s=1$ or 2) are the molal activity coefficients of binary solutions containing only solute s at molality m_s. The relation among the coefficients A_{ij} in Eqs. 2, 3, and 4 was derived by using the Gibbs-Duhem equation and the cross differential relation between solute 1 and 2. Thus the concentration dependencies of γ_1 and γ_2 for the ternary systems (Eqs. 3 and 4) can be obtained if γ_1^0 and γ_2^0 have already been measured as functions of m_1 and m_2, respectively.

The excess free energy of mixing $\Delta\ \mathrm{P}_mG^{ex}$ is the sum of the contributions from each component of the ternary solution.

$$\Delta_mG^{ex} = \Delta_mG_w^{ex} + \Delta_mG_1^{ex} + \Delta_mG_2^{ex}, \quad (5)$$

where $\Delta_mG_w^{ex}$, $\Delta_mG_1^{ex}$, $\Delta_mG_2^{ex}$, are the excess free energy of mixing for water and solute 1 and 2, respectively. $\Delta_mG_w^{ex}$ is directly related to Δ as

$$\Delta_mG_w^{ex} = -RT\Delta = -RT(A_{00}m_1m_2 + A_{10}m_1^2m_2 + A_{01}m_1m_2^2 + A_{20}m_1^3m_2 + A_{11}m_1^2m_2^2 + A_{02}m_1m_2^3 + A_{30}m_1^4m_2 + A_{21}m_1^3m_2^2 + A_{12}m_1^2m_2^3 + A_{03}m_1m_m^4), \quad (5)$$

$$\Delta_mG_1^{ex} = 2m_1RT\ln(\gamma_1/\gamma_1^0) = RT(A_{00}m_1m_2 + A_{10}m_1^2m_2 + (1/2)A_{01}m_1m_2^2 + A_{20}m_1^3m_2 + (2/3)A_{11}m_1^2m_2^2 + (1/3)A_{02}m_1m_2^3 + A_{30}m_1^4m_2 + (3/4)A_{21}m_1^3m_2^2 + (1/2)A_{12}m_1^2m_2^3 + (1/4)A_{03}m_1m_2^4), \quad (6)$$

and

$$\Delta_mG_2^{ex} = m_2RT\ln(\gamma_2/\gamma_2^0) = RT(A_{00}m_1m_2 + (1/2)A_{10}m_1^2m_2 + A_{01}m_1m_2^2 + (1/3)A_{20}m_1^3m_2 + (2/3)A_{11}m_1^2m_2^2 + A_{02}m_1m_2^3 + (1/4)A_{30}m_1^4m_2 + (1/2)A_{21}m_1^3m_2^2 + (3/4)A_{12}m_1^2m_2^3 + A_{03}m_1m_2^4). \quad (7)$$

Hence Δ_mG^{ex} is expressed as

$$\Delta_mG^{ex} = RT(A_{00}m_1m_2 + (1/2)A_{10}m_1^2m_2 + (1/2)A_{01}m_1m_2^2 + (1/3)A_{20}m_1^3m_2 + (1/3)A_{11}m_1^2m_2^2 + (1/3)A_{02}m_1m_2^3 + (1/4)A_{30}m_1^4m_2 + (1/4)A_{21}m_1^3m_2^2 + (1/4)A_{12}m_1^2m_2^3 + (1/4)A_{03}m_1m_2^4). \quad (8)$$

Cassel and Wood[10] showed that Δ_mG^{ex} was related to the interaction parameters between solute molecules, as shown in Eq. 9.

$$\Delta_mG^{ex} = 2\{AB\}_gm_1m_2 + 3\{AAB\}_gm_1^2m_2 + 3\{ABB\}_gm_1m_2^2 + \cdots, \quad (9)$$

where $\{AB\}_g$ is a pair interaction parameters, and $\{AAB\}_g$ and $\{ABB\}_g$ are triplet interaction parameters. Comparing the coefficients of Eq. 8 with those of Eq. 9, we obtain

$$2\{AB\}_g = RTA_{00}, \quad (10)$$

$$3\{AAB\}_g = RTA_{10}, \quad (11)$$

$$3\{ABB\}_g = RTA_{01}. \quad (12)$$

Results

Bg·HCl–Water System. The activity coefficients of Bg·HCl in water at 25 °C are shown in Table 1. The solubility of Bg·HCl was determined to be 2.8 mol kg^{-1}, and the values of ϕ_1^0 and γ_1^0 at higher concentrations than 2.8 mol kg^{-1} were obtained from the extrapolation.

Table 1. Osmotic and activity coefficients of Bg·HCl at 25 °C

m_1	ϕ_1^0	γ_1^0
0.1	0.919	0.760
0.2	0.891	0.693
0.3	0.871	0.647

2.5	0.722	0.367
3.0	0.701	0.341

Sucrose–Water System. Accurate isopiestic data for the sucrose–water system were reported by Robinson and Stokes[5] in the form

$$\phi_2^0 = 1 + 0.07028m_2 + 0.01847m_2^2 - 0.004045m_2^3 + 0.000228m_2^4, \quad (13)$$

$$\ln\gamma_2^0 = 0.14056m_2 + 0.02770m_2^2 - 0.00539m_2^3 + 0.000285m_2^4. \quad (14)$$

The solubility of sucrose at 25 °C is 6.053 mol kg^{-1}. In the ternary system where sucrose dissolved above this concentration, Eqs. 13 and 14 were also used for the determination of ϕ_2^0 and γ_2^0.

Bg·HCl–Sucrose–Water System. The isopiestic molalities of solute 1 (Bg·HCl) and 2 (sucrose) in the ternary solutions and of the reference solute (sucrose or sodium chloride) in reference solutions are shown in Table 2, together with the values of the experimental quantities Δ/m_1m_2. The values of osmotic coefficients for reference sodium chloride were taken from the values given by Robinson and Stokes.[12] In order to fit the experimental values of Δ/m_1m_2 to a power series of m_1 and m_2 in the form of Eq. 2, polynomials involving terms up to cubic in m_1 and m_2 were examined with a FACOM M190 computer by the least-squares method. The values of coefficients A_{ij} are shown in Table 3.

From Eqs. 3 and 4 and Table 3, we obtain

$$\ln\gamma_1 = \ln\gamma_1^0 - 0.150519m_2 + 0.057513m_1m_2 + 0.014594m_2^2 - 0.012850m_1^2m_2 - 0.005573m_1m_2^2 - 0.000844m_2^3 + 0.001518m_1^3m_2 + 0.000497m_1^2m_2^2 + 0.000166m_1m_2^3 + 0.000023m_2^4,$$

a) Reference solute: sucrose. b) Reference solute: sodium chloride. c) Calculated by Eq. 2 using the values in Table 3. d) Percentage error defined by Kelly.[9]

Table 3. The values of coefficients in Eq. 2 for the system Bg·HCl–sucrose–water

Coefficient		Coefficient	
A_{00}	−0.301038	A_{02}	−0.005065
A_{10}	0.115026	A_{30}	0.003036
A_{01}	0.058376	A_{21}	0.001324
A_{20}	−0.025700	A_{12}	0.000664
A_{11}	−0.016720	A_{03}	0.000187

$$\ln \gamma_2 = \ln \gamma_2^0 - 0.301038m_1 + 0.058377m_1m_2 + 0.057513m_1^2 - 0.005065m_1m_2^2 - 0.011146m_1^2m_2 - 0.008567m_1^3 + 0.000187m_1m_2^3 + 0.000498m_1^2m_2^2 + 0.000662m_1^3m_2 + 0.000759m_1^4,$$

for the system Bg·HCl–sucrose–water.

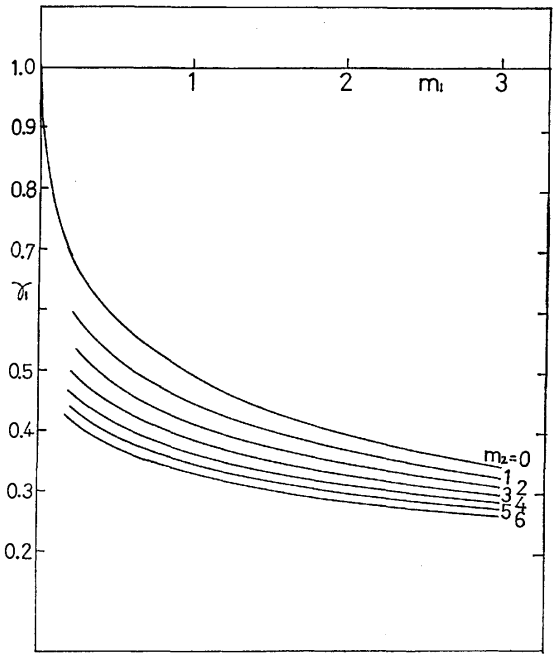

Fig. 1. Activity coefficients of Bg·HCl in sucrose solutions of various concentrations.
m_1; Molality of Bg·HCl, m_2; molality of sucrose.

The activity coefficients for Bg·HCl in binary and ternary solutions are shown in Fig. 1 and the activity coefficients of sucrose in binary and ternary solutions are given in Fig. 2. The activity coefficient of each solute decreased in the presence of the other solute.

Discussion

Bg·HCl–Water System. Biguanide is the condensed compound of two guanidine molecules and, structurally, guanidine corresponds to urea and biguanide to biuret.

Urea is known as a protein denaturant and affects the hydrophobic hydration, as in the system urea–tetrabutylammonium bromide–water,[13] and also the hydrophilic hydration, as in the system urea–sucrose–water.[4] These influences of urea on the hydrophobic and hydrophilic hydration play an important role in protein denaturation.

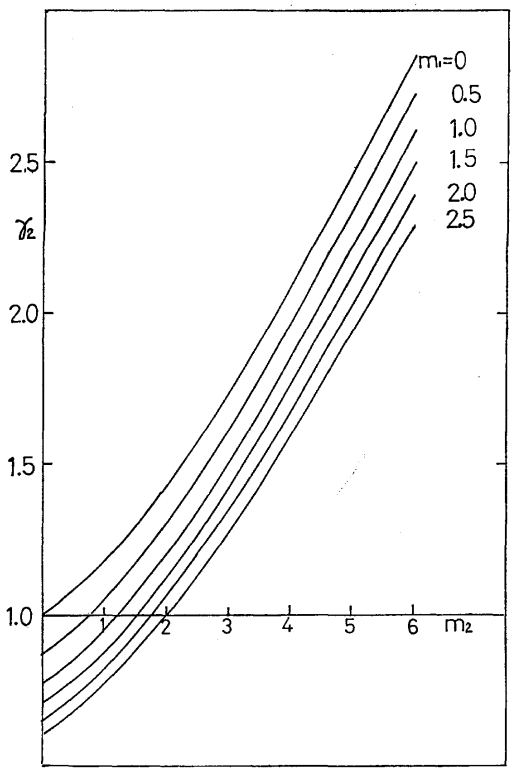

Fig. 2. Activity coefficients of sucrose in Bg·HCl solutions of various concentrations.
m_1; Molality of Bg·HCl, m_2; molality of sucrose.

Guanidinium halides are also known as protein denaturants. The properties of the guanidinium ion in aqueous solutions were studied in our laboratory and the guanidinium ion was concluded to be a strong structure breaker ion.[14–16] Biguanide halides are strong protein denaturants and their effectiveness is stronger than urea and guanidinium halides.[1] The effects of the biguanide ion on the structure of water have been studied in our laboratory. The viscosity *B*-coefficient of the biguanide ion showed no temperature dependence and the increment of the ionic *B*-coefficient arising from the change in the water structure was nearly zero, indicating the biguanide ion to be neither structure maker nor structure breaker.[17] But the temperature dependence of the Walden product obtained from the conductivity measurement was positive, indicating the biguanide ion to be a weak structure maker.[18] The activity coefficients of the biguanide salts in the aqueous solutions obtained from the isopiestic measurement were somewhat lower than those of guanidinium salts with the same counter anions. The activity coefficients of biguanide salts decreased in the order $OAc^- > Cl^- > Br^-$, as in the case of guanidinium salts, when the anion was changed.[19] These results indicate that the biguanide ion is thermodynamically a structure breaker.[15]

Bg·HCl–Sucrose–Water System. As shown in Figs. 1 and 2, the mutual salting-in was observed in this system. The free energy of transfer of trace sucrose from water to various binary solutions are shown in Fig. 3. Mannitol is regarded as a hydrophilic structure maker[5] and its structure of hydration may be similar to that of sucrose. 2-Aminobutyric acid (2-ABA) is

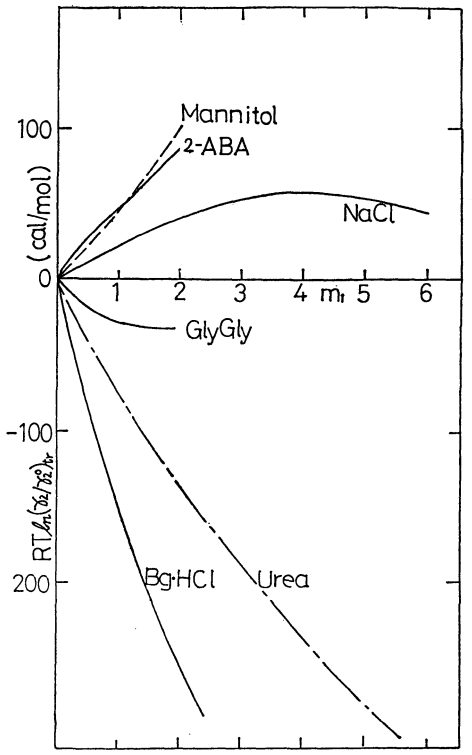

Fig. 3. Free energy of transfer of trace sucrose (solute 2) from water to aqueous solute 1 solutions at 25 °C.
m_1; Molality of solute 1 as indicated in the figure.

considered to be a weak structure maker.[6] On the other hand, glycylglycine (GlyGly)[6] and urea are regarded as structure breakers. Uedaira suggested that the mixing of two kinds of structure making solutes caused the positive free energy change of transfer, while the mixing of the structure making and the breaking solutes caused the negative free energy change of transfer for each solute in aqueous solutions.[6] As seen in Fig. 3, Bg·HCl is more structure breaking than urea and GlyGly, if Uedaira's postulation is applied to the system Bg·HCl–sucrose–water.

On the other hand, Bg·HCl is an electrolyte and its interaction with sucrose is the sum of the electrostatic and the non-electrostatic terms. Therefore it is meaningful to compare the system Bg·HCl–sucrose–water with the system NaCl–sucrose–water,[20] because the interaction involved in the system NaCl–sucrose–water may be considered to represent the electrostatic interaction for the system Bg·HCl–sucrose–water. In Fig. 4, the excess free energy of mixing for the system Bg·HCl–sucrose–water are compared with those of the system urea–sucrose–water and NaCl–sucrose–water. The excess free energy of mixing $\Delta_m G^{ex}$ is the sum of each component $\Delta_m G_w^{ex}$, $\Delta_m G_1^{ex}$, and $\Delta_m G_2^{ex}$. Figure 4 shows $\Delta_m G^{ex}$, $\Delta_m G_w^{ex}$, $\Delta_m G_1^{ex}$, and $\Delta_m G_2^{ex}$ at a total molality of 6 mol kg^{-1}. For the system urea–sucrose–water, $\Delta_m G^{ex}$, $\Delta_m G_1^{ex}$, and $\Delta_m G_2^{ex}$ are negative and $\Delta_m G_w^{ex}$ is positive, indicating a strong inter-

action between urea and sucrose. The system Bg·HCl–sucrose–water showed a similar tendency to that for the system urea–sucrose–water, though the values of $\Delta_m G^{ex}$, $\Delta_m G_w{}^{ex}$, $\Delta_m G_1{}^{ex}$, and $\Delta_m G_2{}^{ex}$ were much larger than those of the system urea–sucrose–water. There may be two kinds of interactions between sucrose and Bg·HCl, that is, the direct interaction (the formation of water soluble complex) and the interaction through the change of water structure. The free energy data do not inform us which interaction is really working. But if we take into account that both solutes are hydrophilic and that the interaction takes place in water, the possibility of the direct interaction may be small. For the system NaCl–sucrose–water, $\Delta_m G^{ex}$ and $\Delta_m G_2{}^{ex}$ were positive, while $\Delta_m G_1{}^{ex}$ changed sign as the mole fraction changed. The relation between the excess free energy changes and the mole fraction of the system Bg·HCl–sucrose–water resembled those of the system urea–sucrose–water rather than those of the system NaCl–sucrose–water. This means that a large organic salt, such as Bg·HCl, is more likely to act as a non-electrolyte like urea rather than as an inorganic electrolyte like NaCl in such a ternary system in the high concentration region. Therefore we applied Eq. 10 to the electrolyte–non-electrolyte system. The pair interaction parameter $\{AB\}_g$ of the system Bg·HCl–sucrose–water was calculated to be −89.2 and that of the system urea–sucrose–water was −37.3 in cal kg mol^{-2}.

Table 4 shows the free energy of transfer $\Delta G^t(N)$ (mole fraction scale)[21] of Bg·HCl from water to sucrose solutions of various concentrations. The trace free energy of transfer is the most negative and its magnitude is twice as large as that of urea.

As shown in Figs. 3 and 4 and Table 4, Bg·HCl exerts a more significant effect on the hydrophilic hydration than urea does. This result is consistent with the fact that Bg·HCl is a stronger denaturant than urea.

It is interesting to investigate the effect of biguanide salts on the hydrophobic hydration as observed in aqueous tetraalkylammonium salts solutions. We are currently working in this direction.

(Received July 3, 1978)

The electrophilicity of the CF_3 radical in hydrogen abstraction reactions was studied theoretically by the CNDO/2 method. The activation energy for hydrogen abstraction by the CF_3 radical from aliphatic hydrocarbons decreases with an increase in the electron density on the hydrogen atom to be abstracted. The origin of the electrophilicity of the CF_3 radical can be well understood by the stabilization energy due to delocalization of electrons (SEDE) between the radical and substrate. The electrophilic stabilization energy defined by the SEDE from substrate to the radical governs the relative reactivities of aliphatic hydrocarbons, $CH_4 < CH_3CH_3 < CH_3CH_2CH_3 < (CH_3)_3CH$, which corresponds to the order of the increase in the electron density. The results indicate that the radical is an electrophile if the relative reactivities of substrates are governed by the electrophilic stabilization energy, and a nucleophile when the reactivities are governed by the nucleophilic stabilization energy (the SEDE from the radical to substrate). SEDE was calculated for the reactions of the OH and the CH_3 radicals with CH_4 and CH_3CN; the results indicated that the OH radical is electrophilic and the CH_3 radical nucleophilic. These polarities of radical reagents are discussed in connection with their physicochemical properties such as ionization potentials and electron affinities.

The reactions of free radicals often show substituent effects[1-5] which resemble those of ionic reactions. A number of radical reactions can be correlated with the Hammett or Taft equation[1,2,5,6] and the polarity of a radical (nucleophilicity or electrophilicity) has been investigated. In rationalizing the observed trends, the polar effects concept[1,2,7] (substituent effect on the transition state) has been widely accepted for a hydrogen abstraction reaction (Eq. 1), which can be described by the three resonance structures shown in Eq. 2[8] (RH: hydrogen donor, X: radical):

$$RH + X \longrightarrow R + HX, \tag{1}$$

$$\underset{1}{[R\cdot \dot{H}\cdot X} \longleftrightarrow \underset{2}{R^{-}\!:\dot{H}^{+}X} \longleftrightarrow \underset{3}{R^{+}\dot{H}\,\ddot{:}X^{-}}] \tag{2}$$

According to Pryor *et al.*,[8] if R^+ is more stable than X^+ and X^- is more stable than R^-, then the structure 3 makes a more important contribution to the stability of the transition state than does the structure 2 and the electrophilicity would be expected. The negative ρ values were obtained for reactions of hydrogen abstractions with substituted toluenes by the radicals that were thought to be electrophilic, such as CH_3, C_6H_5, Br, and Cl, and this result has supported the polar effects concept. Moreover, Sakurai *et al.*[9] reported a linear relationship of negative ρ values for CH_3, C_6H_5, *t*-BuO, and Cl (for these radicals, HX bonds formed in Eq. 1 have nearly equal bond dissociation energies) and the electron affinities of the radicals. This evidence supports the importance of the structure 3 in the transition state. In connection with the polarity of a radical, however, quantitative investigation of structures 2 or 3 has not yet been made. Imamura has recently developed a molecular orbital (MO) method[10] which determines the polarity of a radical on the basis of the stabilization energy due to delocalization of electrons (SEDE) between a substrate and a radical. This method was applied to the reaction of OH and H radicals with benzene derivatives, and OH and H radicals were found to behave as electrophiles, in good correspondence with the experimental facts.[10] Moreover, the polarities of various radical reagents in the reaction of hydrogen and chlorine abstractions were studied by using SEDE; the interesting conclusion was reached that a radical reagent with an electrophilic nature changes its SEDE for the electrophilicity from substrate to substrate remarkably, while a radical reagent with a nucleophilic nature changes its SEDE for the nucleophilicity. That is, the electrophilicity or the nucleophilicity can be determined not by the absolute value of SEDE but by the change in SEDE from substrate to substrate.[11,12]

In the present work, along the above-mentioned line, we calculated the SEDE in hydrogen abstraction by CF_3 radical from aliphatic hydrocarbons by the MO method and attempted to clarify the factors determining the polarity of the radical. This radical is interesting from a theoretical point of view since the fluorine atoms have large electronegativity, leading to the strong electrophilicity of the radical reagent. The calculations of SEDE correspond to the evaluation of the contribution of the structure 2′ or 3′ to the stabilization of the reacting system. That is, the structure 2′ or 3′ correlates with the nucleophilicity or the electrophilicity of the radical.

$$\underset{2'}{[R\cdots H\cdots \overset{\delta-}{X}} \longleftrightarrow \underset{3'}{R\cdots H\cdots \overset{\delta-}{X}}] \tag{2'}$$

If the relative reactivities of RH are governed by the SEDE corresponding to the structure 3′, the radical is an electrophiles; it is a nucleophile when the reactivities are governed by the SEDE corresponding to the structure 2′.

Method of Calculation

The total energies for the reacting system were calculated by the UHF method[13] in the CNDO/2 approximation.[14,15] The values of the parameters included in the method are the same as those used in the original papers.[14,15]

Geometries used for calculation are as follows: for CH_4,[16] r(C–H)=1.09 Å; for CH_3CN,[17] r(C–H)=1.107, r(C–C)=1.468, and r(C–N)=1.159 Å; for CH_3CH_3, $CH_3CH_2CH_3$, and $(CH_3)_3CH$, r(C–H)=1.09 and r(C–C)=1.54 Å. The bond angle HCH for these compounds is assumed to be 109.47°.

Procedure of Analysis. The magnitude of the contribution of 2 in Eq. 2 to the reacting system is evaluated by the SEDE from a radical to substrate. This energy is a measure for the nucleophilic character of the radical, so it is defined as the nucleophilic stabilization energy. Similarly, the contribution of 3 in Eq. 2 is evaluated by the electrophilic stabilization energy (the SEDE from substrate to the radical). Here, we may mention the method of calculating the SEDE in connection with hydrogen abstraction:

$$R\uparrow\downarrow H + \uparrow X \longrightarrow [R\cdots\uparrow\downarrow\cdots H\cdots\uparrow X] \longrightarrow R\uparrow + HX,$$

where RH and X denote a substrate (hydrogen donor) and a radical, respectively. The SEDE (ΔE) is defined by Eq. 3;

$$\Delta E = E(R\cdots\uparrow\downarrow\cdots H \quad \uparrow X) - E(R\cdots\uparrow\downarrow\cdots H\cdots\uparrow X), \quad (3)$$

where the first term on the right in Eq. 3 denotes the energy of the reacting system in which the delocalization of electrons between RH and X is forbidden (absence of the dotted line between H and X). The second term includes the delocalization of electrons. The first term is obtained by the SCF calculation after dropping the resonance integrals I_{rs} between atomic orbitals (AO's) of RH, χ_r, and AO's of X, χ_s, given by Eq. 4:

$$I_{rs} = \frac{1}{2}(\beta_r+\beta_s)S_{rs}, \quad (4)$$

β denotes the bonding parameter in the CNDO/2 method.[11,13] The MO's of the reacting system (R···H··· X) thus obtained are classified into the MO's localized on R···H and the ones localized on X in Eqs. 5 and 6, respectively:

$$\psi_{RHi} = \sum_r C_{RHi,r}\chi_r, \quad (5)$$

$$\psi_{Xj} = \sum_s C_{Xj,s}\chi_s, \quad (6)$$

ψ_{RHi} is the i-th MO localized on R···H and $C_{RHi,r}$ is the coefficient of AO in the i-th MO, and ψ_{Xj} and C_{Xj}'s are for the radical X.

From Eq. 5, one obtains

$$\sum_i^{all} C_{RHi,r_1}\psi_{RHi} = \sum_r\sum_i^{all} C_{RHi,r_1}C_{RHi,r}\chi_r = \sum_r \chi_r \sum_i^{all} C_{RHi,r_1}C_{RHi,r}. \quad (7)$$

Since a set of ψ_{RHi}'s is orthonormal,

$$\sum_i^{all} C_{RHi,r_1}C_{RHi,r} = \delta_{rr_1}. \quad (8)$$

Namely

$$\chi_r = \sum_i^{all} C_{RHi,r}\psi_{RHi}, \quad (9)$$

$$\chi_s = \sum_j^{all} C_{Xj,s}\psi_{Xj}. \quad (10)$$

From Eqs. 9 and 10, one obtains the relation between the I_{rs} represented by the AO basis (χ_r, χ_s) and the I_{ij} by the MO basis (ψ_{RHi}, ψ_{Xj}):

$$I_{rs} = \int\chi_r h^\circ\chi_s d\tau = \sum_i^{all}\sum_j^{all} C_{RHi,r}C_{Xj,s}\int\psi_{RHi}h^\circ\psi_{Xj}d\tau = \sum_i^{all}\sum_j^{all} C_{RHi,r}C_{Xj,s}I_{ij}. \quad (11)$$

Instead of Eq. 11, the modified resonance integrals between AO's. I'_{rs} in Eq. 12 are used in the SCF calculation in order to include the delocalization of electrons between a particular orbital set (i_1, j_1).

$$I'_{rs} = \sum_{(i_1-j_1)} C_{RHi_1,r}C_{Xj_1,s}I_{i_1j_1}, \quad (12)$$

where $(\Sigma_{i_1-j_1})$ denotes the summation over the set. From Eq. 12, it is easily proved that the modified resonance integrals between MO's, I'_{ij}, reduces to zero except for the $I_{i_1j_1}$, which has the same value as that obtained by using Eq. 11 (I_{ij}). The proof is as follows.

$$\begin{aligned} I'_{ij} &= \sum_r\sum_s C_{RHi,r}C_{Xj,s}I'_{rs} \\ &= \sum_r\sum_s C_{RHi,r}C_{Xj,s}\sum_{(i_1-j_1)} C_{RHi_1,r}C_{Xj_1,s}I_{i_1j_1} \\ &= \sum_{(i_1-j_1)} I_{i_1j_1}\sum_r C_{RHi,r}C_{RHi_1,r}\sum_s C_{Xj,s}C_{Xj_1,s} \\ &= \sum_{(i_1-j_1)} I_{i_1j_1}\delta_{ii_1}\delta_{jj_1}. \end{aligned} \quad (13)$$

The procedure of the calculation is written as follows. (i) The total energy of the reacting system without the delocalization of electrons is calculated with the unrestricted SCF method in the CNDO/2 approximation after dropping all the resonance integrals between AO's on the fragment RH and those on the fragment X. Thus we obtain the value for the first term in Eq. 3, as well as the MO's localized on the fragments given by Eqs. 5 and 6. (ii) By using the MO's obtained in step (i), the modified resonances integrals between AO's are calculated according to Eq. 12 in order to take the delocalization of electrons between particular MO's into account. (iii) The modified resonance integrals are employed to calculate the total energy of the reacting system with the delocalization of electrons, which corresponds to the nucleophilic or the electrophilic nature of the radical reagent in question. (iv) A measure of the nucleophilicity or the electrophilicity of the radical reagent can be obtained by calculating the difference between the two energies obtained in the steps (i) and (iii), as is shown in Eq. 3.

When the vacant MO's of the substrate and the

Table 1. The schematic representation of the orbital interaction between substrate RH and radical X[a)]

Interaction	α-spin			β-spin

occupied MO's of the radical are chosen for i_1 and j_1, respectively, in Eq. 12, ΔE in Eq. 3 corresponds to the SEDE from radical to substrate. Thus, ΔE should be the nucleophilic stabilization energy; it is represented by the symbol N. When the occupied MO's of the substrate and the vacant MO's of the radical are chosen for i_1 and j_1, respectively, ΔE is the electrophilic stabilization energy; it is represented by the symbol E. Table 1 shows the schematic representation of intermolecular interaction between the MO's of RH and X obtained by dropping the resonance integrals I_{rs} (they interact electrostatically with each other but the delocalization of electrons is prohibited).

Results and Discussion

The coordinate system assumed for a hydrogen abstraction reaction by the CF_3 radical from aliphatic hydrocarbons is shown in Fig. 1. In a previous paper,[11] we examined the reaction path of the CH_4–OH system by the INDO method, and the geometry in Fig. 1 might

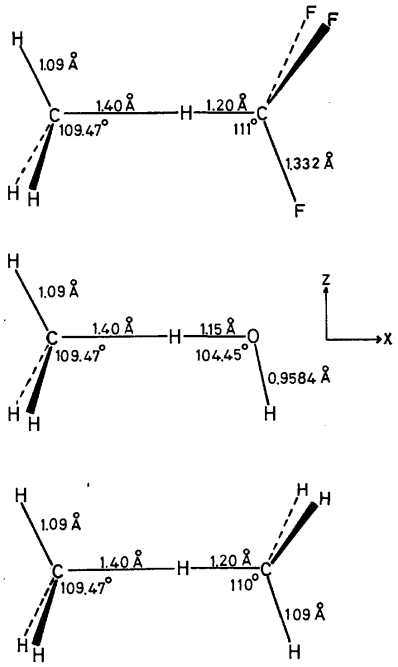

Fig. 1. The coordinate system assumed for hydrogen abstraction by the CF_3 radical from methane.

be roughly approximated as the transition state. Moreover, the electrophilicity of the OH radical in the reaction with methane deduced from the SEDE was not dependent on the reaction paths: A(1.09, 1.46), B(1.20, 1.35), C(1.30, 1.25), D(1.40, 1.15) which are specified respectively by the sets of C^1–H^5 and H^5–O distances indicated in the parenthesis. For the OH and the CH_3 radicals, therefore, we used the same geometries as in the previous paper to determine the polarity in the reaction with a series of substrates. Although the geometry in Fig. 1 is tentatively chosen for the reaction of the CF_3 radical, we believe that the result need not be revised when the geometry is changed slightly.

We may assume here without loss of generality that

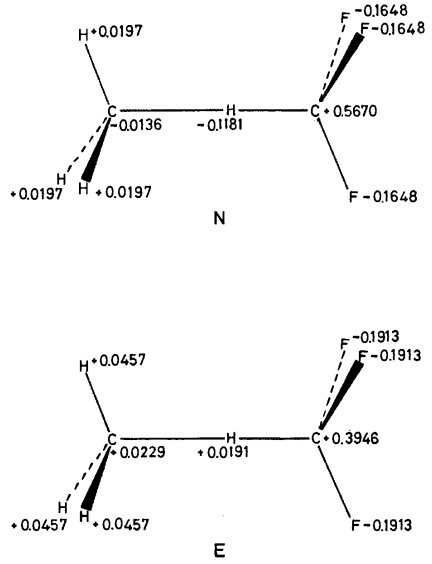

Fig. 2. The electron distribution of CH_4–CF_3 system by the orbital interaction corresponding to the nucleophilic (N) and the electrophilic (E) stabilization energy.

the CF_3 radical has thirteen valence electrons with α-spin and twelve valence electrons with β-spin. It is noticed from the electron distribution shown in Fig. 2 that the delocalization of electrons occurs from the CF_3 radical to methane by the orbital interaction N, while it occurs from methane to the CF_3 radical by the interaction E. Thus the stabilization energy defined by N or E corresponds to the direction of the delocalization of electrons occurring between a substrate and a radical. The structure 2′ or 3′ in Eq. 2′ is considered to correspond to N or E. Figure 3a shows the correlation of the activation energy[18] and the electron density on the hydrogen atom. The activation energy decreases with an increase in the electron density. The origin of the electrophilicity of the CF_3 radical can be understood by N and E, as summarized in Table 2. E increases with the increasing

number of electron-donating CH_3 groups, while N decreases. The reactivities of aliphatic hydrocarbons correlate linearly with the sum of N and E, as is shown in Fig. 3b. It should be pointed out that both N and E contribute in determining the reactivity, but the increase of E from molecule to molecule is much larger than the decrease of N. Hence E governs the relative reactivities, as is shown in Fig. 3c. The electrophilicity of the CF_3 radical suggested by the electron density is ascribable to the correlation of the electron density and E shown in Fig. 3d. The electrophilic stabilization energy is closely related with the electron affinity of a radical. Therefore the linear relationship of the negative ρ values and the electron affinities of the radical[9] supports the present conclusion that the radical is an electrophile if the relative reactivities of the substrates are governed by E.

For the study of factors which determine the polarity of radical reagents, the polarities of the OH and CH_3 radicals were subjected to the analysis by the above-mentioned procedure for the reaction with CH_4 and CH_3CN. Fig. 4 shows the difference in the polarity

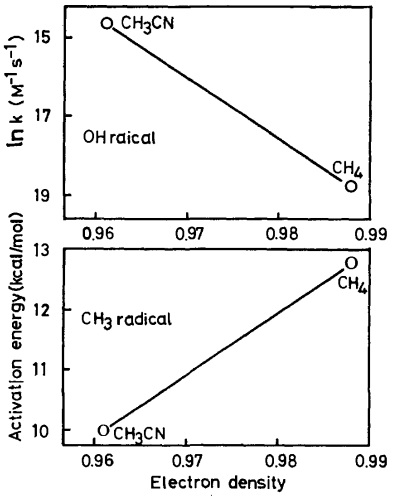

Fig. 4. The difference in the polarity between the OH and the CH_3 radicals.

TABLE 3. THE DIFFERENCE IN THE POLARITY BETWEEN THE OH AND THE CH_3 RADICALS

	Substrates	Orbital interaction[a]	Total energy[b]	SEDE[b]	ET[c]
OH radical	CH_3CN (0.0212)[d]	Zero	−46.6568	0	0
		N	−46.7480	0.0912	0.1067
		E	−46.6616	0.0048	−0.0093
	CH_4 (1.43)[d]	Zero	−28.8765	0	0

between the OH and the CH_3 radicals in hydrogen abstraction.[19] Although only two points are available, a distinct tendency is observed: the OH is electrophilic while the CH_3 radical is nucleophilic. This result is in good agreement with our previous studies on the polarity of the OH and the CH_3 radicals in the reaction with methane and a series of chloromethanes, respectively.[12] It is evident that the correlation in Fig. 4 is not explained by the bond dissociation energy of the C–H bond broken, D_{C-H}, only (D_{C-H} in CH_3CN: 86 kcal/mol,[9] CH_4: 104 kcal/mol[20]) but by the significant contribution of the polar effects. As Table 3 shows, the relative reactivities are interpreted by the sum of *N* and *E*. For the OH radical, the increase of *E* is larger than the decrease of *N* when the substrate changes from CH_3CN to CH_4, so that *E* governs the reactivities. This tendency is consistent with that of the CF_3 radical. The electrophilicity of the OH radical determined by the SEDE is in agreement with the one reported by Anbar *et al.*[6e] on the basis of the Hammett equation. For the CH_3 radical, on the other hand, the increase of *E* is smaller than the decrease of *N*, hence *N* governs the reactivities. As the difference of the ionization potential between the

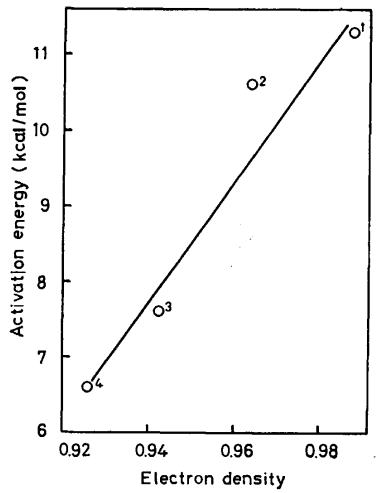

Fig. 6a. The correlation of the activation energy and the electron density for hydrogen abstraction by the CF_3 radical from chloromethane. 1: CH_4, 2: CH_3Cl, 3: CH_2Cl_2, 4: $CHCl_3$.

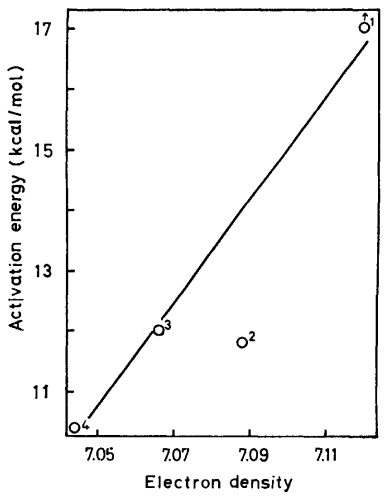

Fig. 6b. The correlation of the activation energy and the electron density for chlorine abstraction by the CF_3 radical from chloromethanes. 1: CH_3Cl, 2: CH_2Cl_2, 3: $CHCl_3$, 4: CCl_4.

OH and the CH_3 radicals (OH: 13.18,[21] CH_3: 9.86 eV[21]) is larger than that of the electron affinity[22] (OH: 1.83, CH_3: 1.4 eV), the former seems to play a dominant role in determining the polarity of the radical. The nucleophilicity of the CH_3 radical is based on its low ionization potential. In fact, i-C_3H_7 and t-C_4H_9 radicals having low potentials[21] (i-C_3H_7: 7.90, t-C_4H_9: 6.90, 7.07, 7.42 eV) have recently been found by Pryor *et al.*[8c] to react as nucleophiles in hydrogen abstractions from substituted toluenes. As Fig. 5 shows, the positive ρ value increases with a decrease in the ionization potential of a radical. This supports the conclusion that the radical is a nucleophile if the relative reactivities of the substrates are governed by N.

According to Pryor *et al.*, the CH_3 radical is slightly electrophilic in hydrogen abstraction with substituted toluenes ($\rho=-0.1$[23]), while it abstracts electron deficient α hydrogen 7.8-fold faster than β hydrogen in the reaction with propionic acid.[24] Similarly, the CF_3 radical is nucleophilic in hydrogen abstraction or chlorine abstraction with chloromethanes, as is shown in Figs. 6a and 6b.[25] The electron affinity of the CF_3 radical is nearly equal to that of the electrophilic OH radical (CF_3: 1.85, OH: 1.83 eV),[22] while its ionization potential (10.18, 8.90 eV)[21] is lower than that of the OH radical (13.18 eV[19]) and approximately the same as that of the CH_3 radical (9.86 eV).[21] This may account for the two different behaviors of the CF_3 radical in the polarity. These results show that the polarity of a radical seems to be primarily determined by its physicochemical properties (ionization potential or electron affinity), but also to depend on the nature of the substrate.

We would like to express our gratitude to the Computer Center, Tokyo University, for its generous permission to use the HITAC 8700/8800 computer.

Electron Spin-Spin Interaction and Translational Diffusion of Nitroxide Radicals in Sodium Dodecyl Sulfate Micelles

Masayuki AIZAWA,* Tsuyoshi KOMATSU, and Tsurutaro NAKAGAWA

Department of Polymer Science, Faculty of Science, Hokkaido University, Sapporo 060

(Received August 9, 1978)

The line width measurements of ESR spectra of 2,2,6,6-tetramethyl-4-benzoyloxypiperidinyl-1-oxyl (BzONO) in sodium dodecyl sulfate (SDS) micelles have been carried out at various concentrations of BzONO. The plot of the line width against the concentration of BzONO shows a line with a break at mole fraction *ca.* 0.05, as opposed to the theoretical prediction that the plot would give a straight line. In order to explain this anomalous behavior, three models for the solubilization of BzONO are considered. On the basis of two of these models, spin exchange rates of BzONO in the micelles are estimated. Translational diffusion coefficients of BzONO in the SDS micelles at 20, 31, and 38.5 °C are calculated by using the spin exchange rate constants and an appropriate diffusion model. The obtained values are of the order of 10^{-7} cm²/s.

Magnetic resonance methods have been used to study both microscopic and dynamical aspects of the solubilization of hydrophobic substances into surfactant micelles.

In the NMR method,[1] the change in chemical shifts caused by aromatic solubilizates is utilized to know a solubilizing site and its environment. Fendler and coworkers[2] have reported that benzene is mainly solubilized in the interior of sodium dodecyl sulfate (SDS) micelles, but it is located near the surface of hexadecyltrimethylammonium bromide (CTAB) micelles.

By means of another NMR technique utilizing the line broadening caused by paramagnetic counter ions, Fox and coworkers[3] have found that *p*-xylene as a solubilizate is distributed uniformly throughout the hydrophobic region of SDS micelles.

By the ESR method, besides the solubilizing site and its environment,[4] dynamical quantities such as rotational correlation times[4,5] in micelles and exchange rates[6] between micellar environment and bulk water have been obtained for nitroxide radical molecules as hydrophobic solubilizates. The values reported so far are of the order of 10^{-10} s/rad for the former and 10^4—10^5/s for the latter.

Recently, the measurement of spin exchange interaction has been applied to the study of translational diffusion in fluid media,[7] and has given very interesting results. In a fluid medium, the spin exchange is accompanied by the molecular collision between dissolved radicals. The exchange rate, therefore, can be connected with their translational diffusion coefficient.[8]

By means of this technique, McConnell and coworkers[9] have estimated that the translational diffusion coefficient of spin-labeled phospholipid molecules in lipid membranes is 6×10^{-8} cm²/s at 37 °C. Ablett and coworkers[10] have studied the hydrophobic interaction by the measurement of spin exchange rate of nitroxide radicals in both water and various organic solvents.

The purpose of the present study is to determine the translational diffusion coefficients of solubilizates in surfactant micelles by this technique, which utilizes the electron spin exchange broadening. The information about this quantity may lead to a further understanding of the solubilization phenomena and the chemical reaction in micellar environments.

Experimental

The synthesis of 2,2,6,6-tetramethyl-4-benzoyloxypiperidinyl-1-oxyl (BzONO, Fig. 1) was reported elsewhere.[11] Sodium dodecyl sulfate (SDS) of specially prepared reagent was recrystallized several times from ethanol-acetone solutions. Its CMC is 8.3×10^{-3} mol/dm³ at 25 °C.

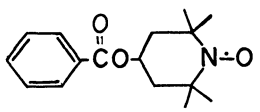

Fig. 1. BzONO.

ESR spectra were recorded on a JEOL model ME-3X spectrometer equipped with a variable temperature accessory. The accuracy of temperature measurements is ±1 K.

The concentration of aqueous SDS solutions ranges from 4 to 7 wt %. In this concentration range, the ESR spectra come only from BzONO in SDS micelles; the fraction of BzONO in bulk water is very small.

Results and Discussion

As unpaired electron spin concentration increases in a system, the electron spin-spin interaction becomes more and more important in the electron magnetic relaxation mechanism.[12] This interaction consists of two parts; one is the spin exchange interaction and the other is the dipolar interaction. The former is a contact interaction which occurs only on overlapping of the wave functions of the electron spins. In a solution, therefore, this interaction accompanies the collisional process between paramagnetic species. The latter is a classical magnetic interaction which depends on the distance between paramagnetic species.

From theoretical and experimental studies,[13] both interactions increase linearly with the spin concentration. However, in regard to an increase in T/η where T is the absolute temperature and η is the environmental viscosity, the two interactions behave differently.[14] The spin exchange interaction is proportional to the increase, and, on the other hand, the dipolar interaction is inversely proportional to it. That is to say, the electron spin relaxation rate of spin exchange interaction T_{2E}^{-1} and that of dipolar interaction T_{2D}^{-1} are given by the following formulae, respectively:

$$T_{2E}^{-1} = k_E C \propto T/\eta, \quad (1)$$

$$T_{2D}^{-1} = K_D C \propto \eta/T, \quad (2)$$

where k_E is the second order rate constant for the exchange process, C the spin concentration, and K_D is a proportionality constant.

In the case of nitroxide radicals, the net spin-spin relaxation rate T_2^{-1} takes the following form:

$$T_2^{-1} = T_{20}^{-1} + T_{2E}^{-1} + T_{2D}^{-1} = T_{20}^{-1} + (k_E + K_D)C, \quad (3)$$

where T_{20}^{-1} is the relaxation rate when no electron spin-spin interaction occurs. Thus, Eq. 3 predicts that a plot of T_2^{-1} against C will give a straight line.

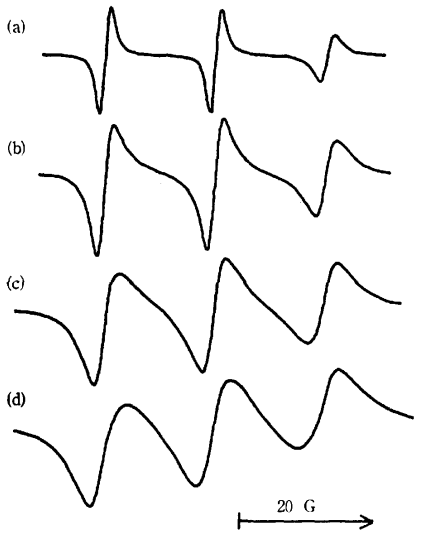

Fig. 2. ESR spectra of BzONO in 4.75 wt % aqueous SDS solutions at 20 °C. Mole fraction of BzONO in micelles: (a) 0.009, (b) 0.037, (c) 0.065, (d) 0.090.

Figure 2 shows ESR spectra of BzONO in 4.75 wt % aqueous SDS solutions at 20 °C. At this SDS concentration, the spectra can be assigned only to BzONO in the SDS micelles. The spectra consist of three lines owing to the contact interaction between an electron spin ($S=1/2$) and an ^{14}N nuclear spin ($I=1$). The three lines correspond to ^{14}N nuclear spin quantum numbers $M_I=+1$, 0, and -1, toward the high field direction. Each line width of the spectra increases with the concentration of BzONO. The broadening is due to the electron spin-spin interaction.

Figure 3 shows the plots of each line width W, equal to $(2/\sqrt{3})T_2^{-1}$, against the mole fraction X of BzONO in micelles. The obtained plots were not represented by straight lines, contrary to the foregoing theoretical consideration. Each line breaks at mole fraction *ca.* 0.05.

Recently, Barratt and coworkers[15] have reported similar results from the study of electron spin exchange of 2,2,6,6-tetramethylpiperidinyl-1-oxyl in glycerol-water mixed solvent; they give no interpretation. We will give our opinion later, though it is an open question whether the nature of their results is the same as in the present study.

The results of line width measurement with two SDS concentrations were on the same lines, as is shown in

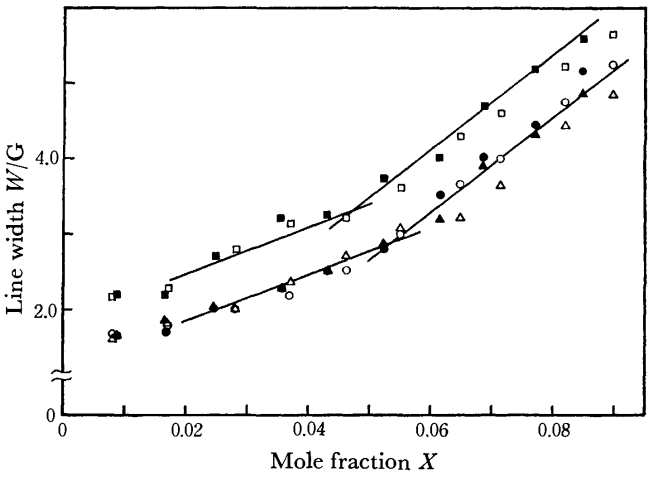

Fig. 3. Plots of W against X at 20 °C in 4.75 wt % aqueous SDS solutions (○: $M_I=+1$, △: $M_I=0$, and □: $M_I=-1$); in 7.01 wt % aqueous SDS solutions (●: $M_I=+1$, ▲: $M_I=0$, and ■: $M_I=-1$).

Fig. 3. This fact guarantees that the ESR spectra observed involve no signal from BzONO in bulk water, and indicates that the presence of the break is not caused by the interaction between electron spins belonging to different micelles.

Figures 4 and 5 show the results at 31 and 38.5 °C, respectively. At these temperatures, it was also observed that the linear plots of W against X fail. The gradients of these lines above and below mole fraction of *ca.* 0.05 are listed in Table 1. It is observed that the gradient decreases with an increase in temperature in the mole fraction range below *ca.* 0.05, whereas it increases in the higher mole fraction range. This finding can be interpreted by suggesting that below *ca.* 0.05 of X the dipolar interaction is predominant and, on the contrary, above *ca.* 0.05 of X the electron spin exchange interaction is predominant. (*cf.* Eqs. 1 and 2)

In order to understand the above-stated anomalous spin concentration dependence of the line width, three models for the solubilized state may be considered, as follows.

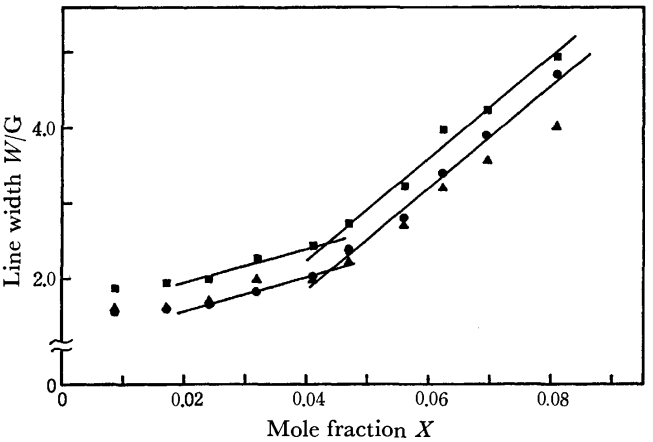

Fig. 4. Plots of W against X in 5.71 wt % aqueous SDS solutions at 31 °C (●: $M_I=+1$, ▲: $M_I=0$, and ■: $M_I=-1$).

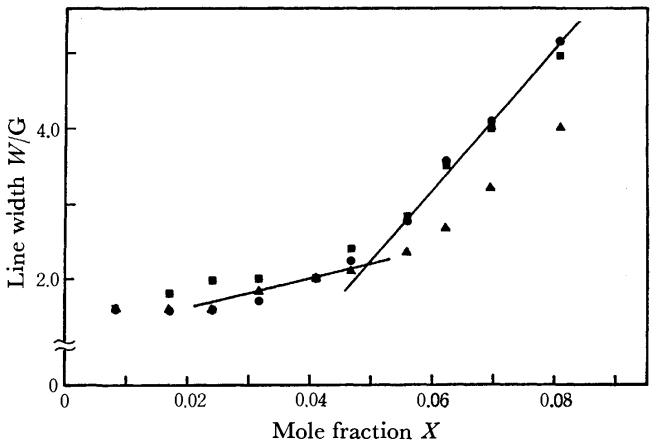

Fig. 5. Plots of W against X in 5.71 wt % aqueous SDS solutions at 38.5 °C (●: $M_I=+1$, ▲: $M_I=0$, and ■: $M_I=-1$).

TABLE 1. GRADIENTS OF W-X LINES IN TWO MOLE FRACTION RANGES

Temp (°C)	Gradient/G	
	$X<0.05$	$X>0.05$
20	30.4	62.4
31	22.4	67.2
38.5	19.2	92.8

Model 1. In this model it is considered that one SDS micelle consists of several clusters containing some SDS molecules. It is, moreover, assumed that a solubilizate molecule is bound in one of these clusters and cannot transfer from one to another. In a cluster, however, a solubilizate molecule can move easily. On this assumption, the occurrence of a break in the W-X plot can be explained as follows.

With an increase in the concentration of BzONO in SDS micelles, the number of BzONO in each cluster increases. When the number of BzONO in one micelle exceeds one, the dipolar interaction takes place, and as long as the number of BzONO in each cluster does not exceed one, only this interaction is present. The reason for this is that BzONO molecules in different clusters cannot collide with each other. When the number in one cluster exceeds one, the spin exchange interaction is superimposed to the dipolar interaction.

Thus, in the plot of line width against BzONO mole fraction, a break may occur and this point corresponds to the concentration where one cluster solubilizes just one BzONO molecule.

Since the values of mole fraction at the break in Figs. 3, 4, and 5 are almost equal to 0.05, the number N^c_{mo} of the SDS molecules constituting one cluster is estimated to be 19, satisfying $1/(1+N^c_{mo})=0.05$. Considering that the aggregation number of the SDS molecules in one SDS micelle is equal to 62,[16] it can be derived that three clusters exist in one SDS micelle.

Accoridng to the studies[17] concerning the micellar structure of ionic surfactants, the micelles at low concentration have spherical or ellipsoidal shape with a single hydrophobic core and a continuous surface. On the other hand, at high concentration (more than 10 wt %), some surfactants form a bilayer structure. Since the concentration of SDS solutions used in the present study ranges from 4 to 7 wt %, it is supposed that the micellar structure in the solutions is similar to that at low SDS concentration. In these micellar models, a continuous structure is assumed in the micelle. Therefore, the nature of the cluster proposed in this model 1 remains unexplained.

Model 2. In this model, the occurrence of spin exchange interaction above the mole fraction *ca* 0.05 is explained by a structural change in micelles caused by the solubilization of BzONO. The structural change assumed here is one which makes the hydrophobic portion of micelles more fluid-like. As was stated above, the dipolar interaction predominates over the spin exchange interaction at lower radical concentration, so that the change into fluid-like structure weakens the former and strengthens the latter. Thus, the plots of line width against BzONO concentration produce a break at the concentration of the structural change.

In the NMR study[18] on mixed solutions of a nonionic surfactant, hexa(oxyethylene)dodecyl ether, and a fluorescent dye, it was found that the line width of alkyl methylene protons decreases with an increase in the concentration of the dye and remains constant above 0.05 of the mole fraction of the dye. These findings have been explained on the basis of a change in the micelle structure caused by the electrical charge of the dye molecules trapped in the poly(oxyethylene) shell of the micelle.

Fendler and coworkers[2] found that plots of chemical shifts of a zwitterionic surfactant, 3-(*N*,*N*-dimethyldodecylammonio)-1-propanesulfonate, against the concentration of solubilizate, benzene, or nitrobenzene, exhibit a break in the region of mole fraction from 0.04 to 0.12. This break has been ascribed to an alteration in the micelle structure.

These results may support this model 2, if one assumes that the aromatic solubilizates including BzONO cause the structural change in micelle.

Model 3. In this model the occurrence of the break in the W-X curves is ascribed to a clustering of BzONO themselves in SDS micelles. The clustering, which occurs at some BzONO content, makes its local concentration higher in the micelle. Therefore, the dependence of electron spin-spin interaction on the BzONO concentration changes, producing a break. Recently, in the case of some nitroxide biradicals in lipid membranes, a clustering of radicals was observed by Rey and McConnell.[19] It is a disadvantage of this model that, in the ESR spectra in the present study, there is no signal corresponding to monomeric BzONO molecules which should exist in equilibrium with BzONO clusters.

All three models can explain, in any event, the occurrence of the breaks on the lines in Figs. 3—5. The determination of the most favorable model remains a further problem, and the simulation of the experimental spectra which will serve to solve the question is now being carried out.

On the basis of model 1 and model 2, the spin exchange rate of BzONO in SDS micelles are determined, and then the translational diffusion coefficients of BzONO in the micelles are calculated. The tanslational diffusion coefficient cannot be defined in model 3, since the spin exchange rate in this model does not reflect the diffusion process of BzONO in SDS micelles.

According to studies[20] on the relationship between the spin exchange interaction and the molecular collision process, the rate f_c of the bimolecular collision between radicals has the following relationship with the spin exchange rate T_{2E}^{-1} ($=f_E$) in a relatively viscous medium ($\eta>3$—4 cp):

$$f_c = 3T_{2E}^{-1} = 3f_E. \quad (4)$$

Since $f_E=k_EC$ in Eq. 1,

$$f_c = 3k_EX \quad (5)$$

is derived, if C is defined as the mole fraction X.

On the other hand, assuming that the surfactant molecules and solubilizate, BzONO, constitute a two-dimensional hexagonal structure in the micelle, the average number[8,21] of new solubilizate molecules encountered by a solubilizate molecule in one diffusion step is equal to $3X$, where X is the mole fraction of the solubilizate in micelles. Thus, f_c is represented by

$$f_c = 3nX, \quad (6)$$

where n is an average rate of diffusion step.

A two-dimensional diffusion coefficient D_{tr} can be written as

$$D_{tr} = n\lambda^2/4 \quad (7)$$

where λ is a mean length in one diffusion step. Substituting Eqs. 5 and 6 into Eq. 7, D_{tr} is rewritten as

$$D_{tr} = k_E\lambda^2/4. \quad (8)$$

Therefore, if k_E can be estimated from Figs. 3—5, and an appropriate diffusion model is assumed, the translational diffusion coefficient of BzONO in SDS micelles can be reasonably determined.

In model 1, k_E corresponds to a difference between the two gradients (below and above mole fraction *ca.* 0.05). Strictly speaking, the value does not correspond to k_E, since the magnitude of intra-cluster dipolar interaction may not be equal to that of inter-cluster dipolar interaction.

In model 2, k_E corresponds to the gradient above mole fraction *ca.* 0.05.

λ^2 was estimated to be 5.8×10^{-15} cm^2 from the results[22] of the surface area occupied by one polar head group in SDS micelles.

Table 2. Translational diffusion coefficents of BzONO in sodium dodecyl sulfate micelles

Temp (°C)	Model 1 $D_{tr}/10^{-7}$cm^{2}s^{-1}	Model 2 $D_{tr}/10^{-7}$cm^{2}s^{-1}
20	1.1	2.2
31	1.6	2.4
38.5	2.6	3.3

Substituting the values of k_E and λ^2 into Eq. 8, the translational diffusion coefficients of BzONO in SDS micelles were obtained. The results at 20, 31, and 38.5 °C are listed in Table 2. The increasing tendency of D_{tr} with temperature is more reasonable in model 1 than in model 2.

The translational diffusion coefficient of low-molecular weight substances in ordinary solutions is of the order of 10^{-5} cm^2/s, and that of phospholipid[21] or steroid[23] molecules in lipid membranes is of the order of 10^{-8} cm^2/s. The values obtained in the present system fall between these two.

The H/D Isotope Effect in the Reaction of Hydrogen Atoms with Olefins

Yo-ichi Ishikawa and Shin Sato*

Department of Applied Physics, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

(Received August 14, 1978)

The absolute rate constants of reaction of deuterium atoms with seven simple olefins at room temperature have been measured by using the pulse-radiolysis technique. The comparison with the rate constants of reaction of hydrogen atoms previously obtained shows that the ratios of k(D+olefin)/k(H+olefin) are in the range of 0.7—0.8. This isotope effect is theoretically discussed.

The H/D isotope effect has widely been used for the elucidation of the reaction mechanism of a complex reaction;[1] however, reliable absolute rate constants which can be utilized for the analysis of the isotope effect in an elementary reaction are not abundant. In 1975, Mihelcic *et al.* measured the absolute rate constants of the reactions between H or D atoms and C_2H_4, C_2D_4, or C_3H_6 and discussed the kinetic isotope effects.[2]

In a previous paper,[3] we obtained the absolute rate constants of reaction of hydrogen atoms with seven simple olefins by using a pulse-radiolysis technique and found that the relative rate constants obtained are in good agreement with those reported as reliable values in the literature. Since the method we used can easily be extended to the reactions of deuterium atoms, we have attempted to measure the absolute rate constants of reaction of deuterium atoms with the same seven olefins and to discuss the H/D isotope effect.

Experimental

The technique used in this study consists of that of pulse radiolysis coupled with the time resolved detection of the resonance absorption of deuterium atoms. The apparatus and procedure used are similar to those previously described for the reaction of hydrogen atoms,[3] except for the detection system. A photomultiplier tube for the vacuum ultraviolet region (Hamamatsu TV Co., R976) was mounted for the detection of Lyman-α line of D atoms. The signal/noise ratio was improved to about 20. The photomultiplier output was amplified by an operational amplifier (Harris HA-2625) and monitored by a Tektronix 475 oscilloscope.

The deuterium gas, whose nominal purity was 99.5% (Showa Denko Co.), was used after having been passed through a molecular sieve 4A at the temperature of liquid nitrogen. The research grade olefins supplied by the Takachiho Shoji Co. were used after thorough degassing.

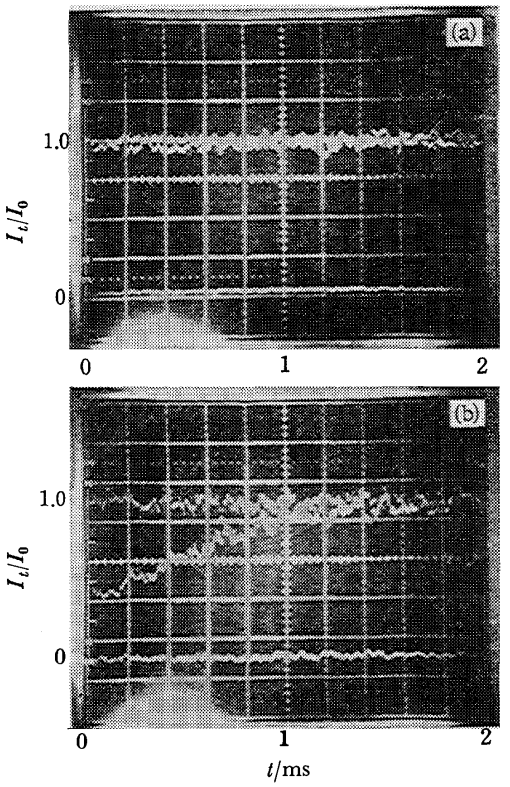

Fig. 1. a) The pulse-irradiated H_2 gas at 500 Torr was detected by the Lyman-α of D atoms. No absorption can be observed. b) Under the same condition of the lamp, the D_2 gas at 500 Torr containing 74 mTorr trans-2-butene was pulse-irradiated.

In order to ascertain the separation of Lyman-α's of H and D atoms, 500 Torr H_2 gas was pulse-irradiated and the absorption of the product at the wavelength of Lyman-α was pursued

Table 1. The absolute rate constants of reaction of hydrogen and deuterium atoms with simple olefins at room temperature

Olefin	Mihelcic *et al.*[2]			Present authors		
	k_H	k_D	k_D/k_H	k_H[3]	k_D	k_D/k_H
	10^{-12} cm^3 molecule^{-1} s^{-1}			10^{-12} cm^3 molecule^{-1} s^{-1}		
Ethylene	1.25±0.03	0.87±0.03	0.70	1.1±0.1	0.8±0.1	0.73
Ethylene-d_4	1.15±0.03	0.85±0.03	0.74			
Propylene	1.68±0.05	1.14±0.02	0.68	1.7±0.1	1.3±0.2	0.76
1-Butene				2.0±0.5	1.6±0.1	0.80
trans-2-Butene				1.1±0.1	0.8±0.1	0.73
cis-2-Butene				1.0±0.1	0.8±0.1	0.80
2-Methylpropene				5.2±0.6	3.8±0.3	0.73
2-Methyl-2-butene				2.4±0.3	2.0±0.3	0.83

by using a lamp in which D_2 gas was made to flow. As Fig. 1a shows, pratically no absorption could be observed. On the other hand, when the reactant was replaced by D_2 gas under the same condition of the lamp, a strong absorption could be observed. Figure 1b shows the decay of deuterium atoms obtained with 500 Torr D_2 and 74 mTorr *trans*-2-butene.

Results

Figure 2 shows the decay rates of deuterium atoms as functions of the concentration of olefins. From the slopes of the linear relations, the rate constants of reaction of deuterium atoms with olefins can be calculated. The results are summarized in Table 1, together with the rate constants previously obtained for hydrogen atoms and with the results obtained by Mihelcic *et al.*[2] All of the ratios k(D+olefin)/k(H+olefin) are in the range of 0.7—0.8. The experimental errors prevent us from determining whether the ratios are dependent upon the kind of olefins.

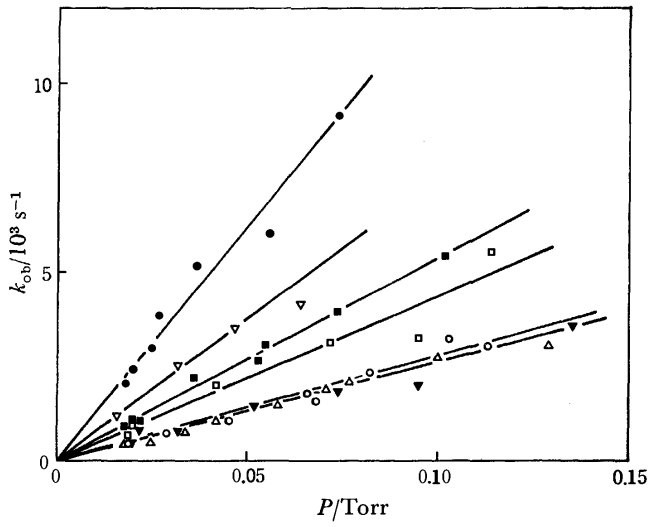

Fig. 2. Plots of the decay rates of D atoms against the olefin pressures. The deuterium pressure is around 500 Torr. ○: Ethylene, □: propylene, ■: 1-butene, △: *trans*-2-butene, ▼: *cis*-2-butene, ●: 2-methylpropene, ▽: 2-methyl-2-butene.

Discussion

Correlations between the Rate Constants and the Reaction Index Calculated by the Semi-empirical MO Method for Olefins. When Jennings and Cvetanović measured the relative rate constants of reaction of hydrogen atoms with several olefins,[4] they correlated their data with the reaction index calculated by the simple Hückel method including hyperconjugation and found a linear relationship between the logarithm of the relative rate constants and the atom localization energies of olefins.[5] Since symmetric olefins such as ethylene and *cis*- and *trans*-2-butenes have two reactive sites for the addition reaction of a hydrogen atom, the rate constants might have to be divided by two when such a correlation is examined; however, the division by two does not lead to the linear relationship.

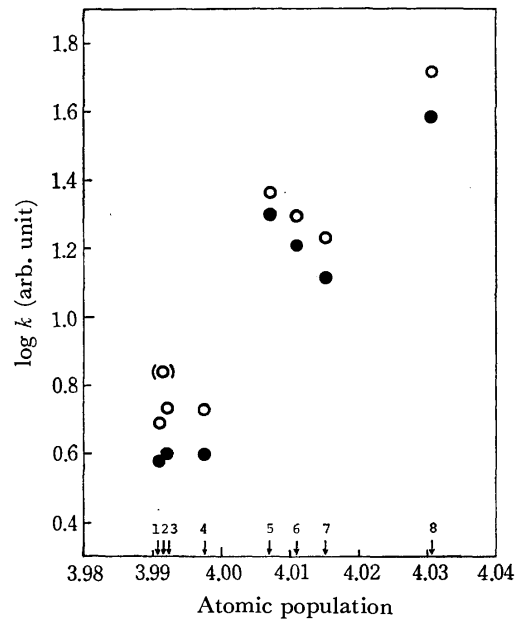

Fig. 3. The logarithm of the rate constants against the atomic populations calculated by the INDO method. 1: *cis*-2-Butene, 2: 2,3-dimethyl-2-butene (estimated from the data in Ref. 4), 3: *trans*-2-butene, 4: ethylene, 5: 2-methyl-2-butene, 6: 1-butene, 7: propylene, 8: 2-methylpropene. ○: For hydrogen atoms and ●: for deuterium atoms.

Recently Koda *et al.* showed a linear relationship between the logarithm of the relative rate constants of reaction of hydrogen atoms with simple olefins and the atomic population on the less substituted of the doubly bonded carbon atoms calculated by the CNDO/2 method.[6] In this case, they divided the relative rate constants for symmetric olefins by two. In their plots, however, 2-methyl-2-butene was not included. We, therefore, have calculated the atomic populations using the INDO method. As Fig. 3 shows, we could not find a linear relationship between the logarithm of the rate constants we obtained and the atomic population calculated.

A Simple Interpretation of the H/D Kinetic Isotope Effect. According to the recent *ab initio* calculation using STO 3G basis set for the reaction path of the addition of a hydrogen atom to ethylene, a hydrogen atom approaches one of the doubly bonded carbon atom perpendicularly to the plane of the ethylene molecule and there is no energy barrier on the reaction path.[7]

In the present experiment, however, we have found that k(H+2-methylpropene)/k(H+ethylene)=4.7 at room temperature. This large ratio cannot easily be explained by the difference in the preexponential factor of the Arrhenius equation. Moreover, recent measurements suggest that the apparent activation energy for the reaction between hydrogen atoms and ethylene is in the range of 1—3 kcal mol^{-1}.[8-10]

In the present treatment, we tentatively assume that there is a small energy barrier, E_0, on the reaction path for the approach of a hydrogen atom to ethylene and also that this type of addition reaction may be treated as a bimolecular association between an atom (H or D) and a radical (A). Then the activated complex theory

predicts the rate constant of reaction between H and A as follows:[11]

$$k_H = \kappa \frac{kT}{h} \frac{\frac{[2\pi(m_H+m_A)kT]^{3/2}}{h^3}}{\frac{(2\pi m_H kT)^{3/2}}{h^3}\frac{(2\pi m_A kT)^{3/2}}{h^3}} \frac{8\pi^2 I_{HA} kT}{\sigma h^2} e^{-E_0/RT} \quad (1)$$

Here, m_H and m_A stand for the atomic weight of hydrogen and the molecular weight of ethylene, respectively, and I_{HA} for the moment of inertia of the activated complex. Using this equation, we can easily calculate the isotope effect for k_D/k_H.

$$\frac{k_D}{k_H} = \left[\frac{m_H}{m_D}\right]^{3/2}\left[\frac{m_D+m_A}{m_H+m_A}\right]^{3/2}\left[\frac{I_{DA}}{I_{HA}}\right]$$
$$= \left[\frac{m_H}{m_D}\frac{m_D+m_A}{m_H+m_A}\right]^{1/2}$$
$$= 0.72 \quad (2)$$

Almost the same value can be obtained for k_D/k_H for other olefins. As Table 1 shows, all of the values of k_D/k_H obtained in these experiments are a little larger than the calculated one. This is probably due to the simplification made for the calculation. However, in order to make a more detailed analysis, we have to wait for the detailed calculation of the potential energy surface.

The authors wish to express their thanks to Dr. Kazuo Shimokoshi of this Institute for the use of the program of INDO calculation.

An UV-Visible Spectrophotometer Provided with a Photon Counting System for the Studies of Very Weak Absorption Spectra

Naoto YAMAMOTO,* Takanori SAWADA, and Hiroshi TSUBOMURA

Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560

(Received September 7, 1978)

An ultrasensitive UV-visible spectrophotometer, of a single-beam type provided with a photon counting system having a time resolution of 10 ns has been constructed. It has been shown that absorption spectra can be measured to within an error of 10^{-5} in optical density with this instrument. Noise levels, measured as a function of the photon count numbers, are found to agree with the theoretically expected statistical fluctuation of the photons. Absorption spectra of thin naphthacene films, 32 nm or below in thicknesses, deposited on a quartz plate, were obtained with this instrument, and found to change with the film thickness.

Most of the commercial UV-visible spectrophotometers employ a double-beam optical system. They can be used to measure absorption spectra of very weak absolute intensities or small changes in absorption, with the aid of a digital memory background corrector, for example. An absorption spectrum of a material in a cell or on a transparent substrate is obtained as a difference in optical densities of a sample containing the material and a proper reference. The optical density, d, is expressed as

$$d = \log (I_R/I_S), \quad (1)$$

where I_S and I_R indicate light intensities through the sample and the reference, respectively.

It is interesting to pursue how weak absorption is measurable spectroscopically throughout the near UV and the visible region. In the case of the double-beam spectrophotometers, the limit of exact measurement is set by the difficulty of providing highly equivalent double beams throughout the UV-visible region and from the instability of the analog amplifiers equipped. As the sample absorption becomes less and less, the requirements for a proper reference and a good alignment of the sample-reference system along the monitoring optical path in addition to the instrumental accuracy get more and more severe. Kuhn *et al.* reported on an instrument employing a single beam system and a lock-in-amplifier to measure the absorption spectra of monomolecular layers of organic dyes, and *suggested* the possibility that absorbing species of 10^{-5} in optical density was detected.[1] However, they did not give any result showing the limit of detection they reached.

We have constructed an ultrasensitive UV-visible spectrophotometer of a single-beam type having a photon counting system, in which the optical density can be represented by the following relation,

$$d = \log (N_R/N_S) = \log (T_S/T_R), \quad (2)$$

where N_S and N_R are the photon numbers passing through the sample and the reference, respectively, and T_S and T_R stand for the times required to count a given photon number for the sample and the reference. In this paper, the details of the instrument and a few experimental results obtained with it are described.

Experimental

The block diagram of the spectrophotometer is shown in Fig. 1. The light from a 25 W deuterium arc lamp or a 20 W tungsten-halogen lamp is focused with a spherical mirror onto the entrance slit of a 25 cm monochromator. The monochromatic light from it is approximately focused through a quartz lens on to the sample. The light is introduced alternately onto the sample and the reference by moving the sample-reference holder, and the intensity of the light passing through the sample or the reference is monitored with a Hamamatsu R818 photo-multiplier, a Princeton Applied Research (PAR) 1120-02 discriminator, and a PAR 1109 photon counter. The overall photon monitoring system has an 100 MHz count rate. The entrance and exit slit widths of the monochromator are manually controlled so as to set the count rate below 10^7 pps. The operation of the photon counter, the wavelength driving and the moving of the sample-reference holder are controlled by a 24 K microcomputer. The optical density was calculated using the digital data sent out from the photon counter into the computer, and then displayed on an X-Y recorder versus wavelength.

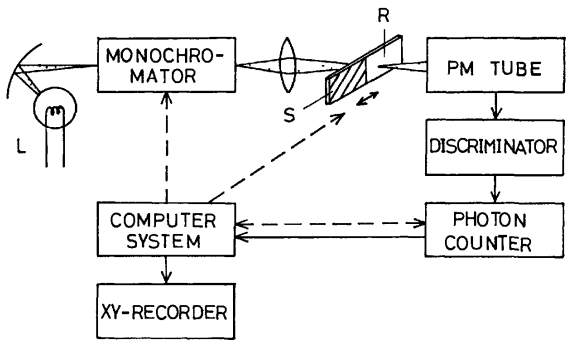

Fig. 1. Diagram of the spectrophotometer.
L: Light source, S: sample, and R: reference.

The monochromator and the sample-reference system are precisely driven with two step-motors sequentially as described below: The wavelength is set to λ_1. The sample is set into the position of light beam. Photon counting is started, and stopped when the number reaches a fixed value, say 10^7. The time required, T_S, is measured. The reference is moved into the beam position. Time, T_R required for a counting of the same number, is measured. Optical density at λ_1 is calculated from T_S and T_R and the value displayed. The wavelength is set to λ_2, different from λ_1 by a given interval, and the optical density for λ_2 is obtained by the same operation sequence as above. The spectrum can be measured in the range from 195 to 900 nm by a repetition of such procedures. The precision in the positioning of sample and reference is 1 μm or less.

Naphthacene from Wako Chemicals Co. was purified by vacuum sublimation. Naphthacene film was deposited on one

half of the surface of an optically flat 26 mm×76 mm Suprasil quartz plate by vacuum evaporation, leaving the other half as the reference.

Results and Discussion

In order to show the limit of absorbances measurable with the instrument, an absorbance measurement was run using a clean Suprasil quartz plate, half of which is regarded as a sample and the other half as a reference. The measurements were performed by sampling from 195 to 900 nm at an interval of 1.0 nm. The result gave actually the magnitude of noise, or fluctuation. It was confirmed that the noise levels, in the whole wavelength region were essentially the same as in the small region in Fig. 2, as an example. The base line was flat throughout the whole wavelength range.

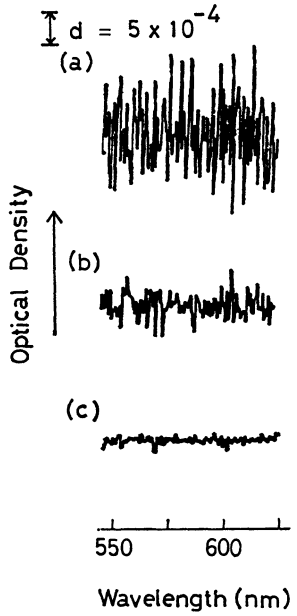

Fig. 2. Noise levels shown in an OD scale for operation between 550 and 625 nm at the photon count numbers of 10^6 for (a), 10^7 for (b) and 4×10^8 for (c), respectively.

The statistical fluctuation of the photons, ΔN, at the count number, N, is theoretically given by the following equation,

$$\Delta N/N = N^{-1/2}. \quad (3)$$

The magnitude of fluctuation in optical density, Δd, due to the statistical error can be given from Eqs. 2 and 3 as $\Delta d=(1/2.303)(\Delta N_S/N_S+\Delta N_R/N_R)$. The theoretical Δd values for the count numbers at which the noise curves (a), (b), and (c) in Fig. 2 were taken are 8.6×10^{-4}, 2.7×10^{-4}, and 4.3×10^{-5}, respectively. Comparison of these theoretical Δd values with the experimental noise levels shows that the fluctuations shown in Fig. 2 agree with the statistical fluctuations of the light intensity itself. It is, therefore, realized that all possible sources of error in our instrument, for instance, the fluctuation in the light source, the distortion and vibration of optical alignment, the sample-reference positioning imprecision, and the fluctuation of light monitoring system are not significant for the measurement of optical density of 10^{-5}.

The present instrument takes a count time of about 10 s or more for obtaining the optical density with an accuracy of the order of 10^{-5} at each of the wavelength, so that 2 h is at least necessary to get a spectrum over the region 200 to 900 nm with an interval of 1.0 nm. It is, of course, not difficult to detect absorption spectra less intense than the noise level by adopting an appropriate smoothing technique. In addition, the improvement of the time resolution of the counting system makes our absorption spectra measurements more accurate or speedy.

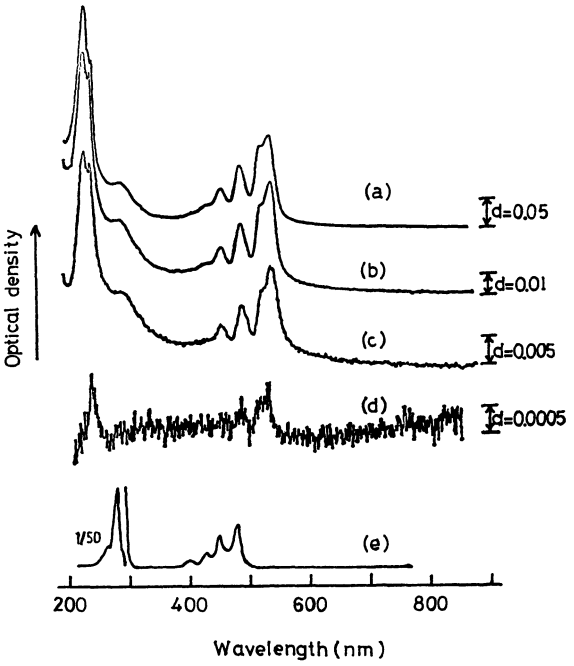

Fig. 3. Absorption spectra of naphthacene deposited on quartz plates measured at the photon count numbers of 10^7 for (a), (b) and (c), and 4×10^7 for (d), in the order of decreasing thickness. (e) is the absorption spectrum of naphthacene in an ethanol solution in an arbitrary unit.

Figure 3 shows the absorption spectra obtained for naphthacene films with various thicknesses, together with that taken in an ethanol solution with a Cary 15 spectrophotometer. The absorption in the visible region, ascribable to the ^1L_a band, of the films is largely red-shifted compared with that obtained in the solution. The spectra of the films, in the UV region, in (a), (b), and (c) have several absorption bands, presumably formed as a result of Davydov splitting of the ^1B_b band at 274 nm in the solution. The spectra of (a), (b), and (c) are essentially the same as those obtained for a naphthacene single crystal by Bree and Lyons[2] and for naphthacene films, 0.05—1 μm thick, by Maruyama and Iwasaki[3] and by us[4] at room temperature. However, there are some differences between the present spectra and others. For example, the peaks at 527 and 504 nm by Maruyama and Iwasaki are located at around 522 and 504 nm in (a), (b), and (c) in Fig. 3.

Though there is no marked shift in peak positions, the intensity ratio of the 504 peak to the 522 peak becomes small with the decreasing film thickness, (a) to (c). Similar change of the absorption intensity ratio on thickness is also found between the bands at 220 and 232 nm. These results suggest that the films are too thin to have the usual bulk properties.

The film thicknesses are roughly estimated from the peak absorption values at aroung 522 nm, assuming that the films produced are uniform in thickness. Taking the molar extinction coefficient at the peaks to be 1.0×10^4 and the density of the film to be 1.29,[2] the thicknesses are derived to be 32 nm for (a), 8.9 nm for (b), 3.3 nm for (c), and 0.13 nm for (d). The absorption spectrum of the thinnest film (d), though similar to (a), (b), and (c) in the visible region, is considerably different from them in the near UV region. It seems to lack the bands found for the thicker films at around 220 and 280 nm, and its absorption intensity in the near UV region is considerably smaller as compared to the visible band intensity. These suggest that, in the thinnest film, naphthacene molecules are separately deposited on the substrate surface: that is to say, a sub-monomolecular layer is formed. Though the reason for the decrease of the UV band intensity is not clear at present, such data for the very thin layers on solid surfaces will contribute to the elucidation of electronic structures of materials on solid surfaces.

We are also studying the absorption spectra of Langmuir films of fatty acids mixed with some organic dyes using this spectrophotometer.

In addition to the spectroscopy of thin films, this instrument will serve extensively for the accurate spectroscopy of very small quantities of materials in gaseous and liquid phases, or the spectroscopy of very weak bands arising from forbidden transitions.

The present results have shown that the optical density measurements can be performed in an accuracy of the order of 10^{-5} or better with our instrument. The limit of accuracy depends only on the performance of the photomultiplier, and the time resolution of the photon counter.

Energy Levels and g Values of Some Rare Earth Crystals with f^2 Configuration

Yoshifumi KATO* and Hirokazu TAKADA

Department of Chemistry, Faculty of Science, Kobe University, Nada-ku, Kobe 657

(Received September 28, 1978)

The energy levels of the rare earth ions in praseodymium ethyl sulfate, magnesium praseodymium nitrate, and thulium ethyl sulfate crystals are calculated by using an extended Hamiltonian for $4f^2$ configuration. The Hamiltonian includes two-body electrostatic interactions, spin-other-orbit interactions and two-body pseudo-magnetic interactions as configuration-mixing parameters in addition to the Slater, spin-orbit coupling and crystal-field parameters. The standard deviations for praseodymium ethyl sulfate, magnesium praseodymium nitrate and thulium ethyl sulfate are respectively 10.1 cm^{-1} for 25 observed levels by using 13 parameters, 3.8 cm^{-1} for 12 observed levels by using 11 parameters, and 8.9 cm^{-1} for 32 observed levels by using 13 parameters. These results are consistent with similar studies of rare earth ions doped in the $LaCl_3$ and LaF_3 crystals. Most of the calculated Zeeman splitting factors (g value) parallel to the principal axis of the crystals also are in fairly good agreement with the experimental values. Some discussion is given as to the effect of configuration interactions, the accuracy of wave functions obtained and the discrepancy between some of the calculated g values and the observed ones.

Most of early studies regarding the energy calculation of rare earth crystals were carried out by fitting both the intermediate coupling parameters (the Slater integrals F_k and spin-orbit coupling constant ζ) and the crystal-field parameters B_q^k to observed energy levels. Recently it has been recognized that the configuration interaction (CI) effects characteristic of the "free ion" levels (the center of gravity of a multiplet) of rare earth crystals is more important than those arising from the crystal-field potential. Some attempts[1-3] have been made to identify such effective interactions operating within $4f^N$ configuration that reproduce the observed electronic structure of crystals. The basic theory consists of simultaneously diagonalizing (J-mixing) both ion and crystal parts of an extended Hamiltonian matrix which involves several additional parameters introduced from the second-order perturbation theory. In recent analyses, the least-squares fits of 20 parameters to over 100 observed levels resulted in a mean error of less than 10 cm^{-1} for the energy levels of rare earth ions doped into $LaCl_3$[4-6] and that of about 20 cm^{-1} or less for the energy levels of rare earth ions doped into LaF_3.[7]

In this paper, the energy levels of praseodymium ethyl sulfate, $Pr(C_2H_5SO_4)_3 \cdot 9H_2O$ (Pr(ES)), magnesium praseodymium nitrate, $Mg_3Pr_2(NO_3)_{12} \cdot 24H_2O$ (Pr(DN)), and thulium ethyl sulfate, $Tm(C_2H_5SO_4)_3 \cdot 9H_2O$ (Tm(ES)), are calculated by the aforementioned extended Hamiltonian. The purpose of the present calculations is to determine the wavefunctions giving good agreement of both the calculated energy levels and Zeeman splitting factors (*i.e.*, g values) with the observed ones.

Calculational Procedure

Hamiltonian Structure. The theoretical formulation of electronic structures of rare earths by the tensor operator method has first been developed by Racah[8] and several authors have expanded this method to introduce the configuration mixing effects by using the second-order perturbation theory. Rajnak and Wybourne gave a detailed treatment for the second-order effect of electrostatic interactions[9] and also investigated the combined effects between spin-orbit and electrostatic interactions.[10] Furthermore Rajnak[3] discussed the relative roles of various mechanisms of CI by the application of this theory to the $4f^3$ configuration of the Pr^{2+} ion. Judd *et al.*[11,12] independently treated the intra-atomic magnetic interactions due to relativistic correction, and introduced several new parameters for spin-other-orbit interactions and electrostatically correlated spin-orbit interactions as main effects of these magnetic interactions. Here, an extended Hamiltonian on the basis of such refined tensorial method will briefly be given, especially for the second-order perturbation terms.

When we expand the wavefunction of a rare earth ion in crystals under the intermediate coupling scheme, a basis function is given as

$$|\Psi\rangle = \sum_i^N a_i \varphi_i | f^N;\ q, S, L, J, M\rangle, \tag{1}$$

where q is an additional quantum number introduced to distinguish the electronic states. The total Hamiltonian of $4f^N$ configuration can be written as

$$H = H_{\text{ion}} + H_{\text{cry}}, \tag{2}$$

where H_{ion} and H_{cry} are the ion and crystal-field parts of interactions respectively. H_{ion} for an N-electron system of rare earth ions with appreciable spin-orbit interaction may be given as

$$H_{\text{ion}} = \sum_i^N h_i + \sum_{i>j}^N e^2/r_{ij} + \sum_i^N \zeta_{4f}(\boldsymbol{s}_i \cdot \boldsymbol{l}_i), \tag{3}$$

where
$$h_i = -(\hbar^2/2m)\Delta_i - Ze^2/r_i. \tag{4}$$

The Hamiltonian may be divided into $H_{\text{ion}} = H_0 + H_1$ such that

$$H_0 = \sum_i^N (h_i + v_i), \tag{5}$$

and
$$H_1 = -\sum_i^N v_i + \sum_{i>j}^N e^2/r_{ij} + \sum_i^N \zeta_{4f}(\boldsymbol{s}_i \cdot \boldsymbol{l}_i)$$
$$= -V + G + A, \tag{6}$$

where v_i is an average potential that acts on the ith electron, while

$$V=\sum_i^N v_i,\quad G=\sum_{i>j}^N e^2/r_{ij},\quad \text{and}\quad \Lambda=\sum_i^N \zeta_{4f}(\boldsymbol{s}_i\cdot\boldsymbol{l}_i). \tag{7}$$

Within the first-order perturbation, the V term in Eq. 6 is purely radical and contributes energy shifts that are the same for all the levels belonging to a given configuration, while the G and Λ terms are different for different states of the same configuration. Hereafter, the perturbing terms, that are the same for all the levels belonging to a given configuration without affecting the energy-level structure of the configuration, are neglected because we are interested only in relative energy shift due to various interactions in the configuration. When a nonperturbing basis of $4f^N$ configuration and a perturbing basis belonging to a particular perturbing configuration are designated by $\langle\psi J|$ or $|\psi' J\rangle$ and $|mJ\rangle$ respectively, the perturbation energy E' due to the second-order perturbation theory may be expressed as

$$E'=\langle\psi J|H_1|\psi' J\rangle - \sum_m \langle\psi J|H_1|mJ\rangle\langle mJ|H_1|\psi' J\rangle/\Delta E_m. \tag{8}$$

The first-order perturbation energy in Eq. 8 is described in terms of the intermediate coupling parameters; *i.e.*, the Slater integrals $F_k(4f,4f)$ (or the equivalent E^k of Racah[8d]) and the spin-orbit coupling constant ζ_{4f}, and the reduction formula involving these parameters by the tensor method is given in a previous paper.[13]

The second-order perturbation energy in Eq. 8, exhibiting CI effects owing to the mixing levels from interacting configuration $|mJ\rangle$, consists of six distinct terms arising from substituting V, G, or Λ into the H_1 operators of matrix elements. The following three parts of them give rise to the dominant contribution:

$$-\sum_m \langle\psi J|G|mJ\rangle\langle mJ|G|\psi' J\rangle/\Delta E_m, \tag{9a}$$

$$-\sum_m \langle\psi J|\Lambda|mJ\rangle\langle mJ|\Lambda|\psi' J\rangle/\Delta E_m, \tag{9b}$$

$$-\sum_m \langle\psi J|G|mJ\rangle\langle mJ|\Lambda|\psi' J\rangle/\Delta E_m. \tag{9c}$$

Here, the terms, which may be absorbed as screening effects in the intermediate coupling parameters (F_k and ζ), are excluded. The tensorial reduction of Eq. 9a is given as[3,9]

$$\sum_{t\,\text{odd}} P(t)\langle\psi J|\sum_{i>j}(\boldsymbol{U}_i^{(t)}\cdot\boldsymbol{U}_j^{(t)})|\psi' J\rangle + \sum_{k,k'} X(kk',l')\,Y(kk',l'), \tag{10}$$

where the coefficient $X(kk',l')$ is given by

$$X(kk',l')=\sum_{k''\,\text{even}}(2k''+1)\begin{Bmatrix}k & k' & k''\\ l & l & l'\end{Bmatrix} \times\langle\psi\|\sum_{h\neq i\neq j}(\{\boldsymbol{U}_h^{(k)}\cdot\boldsymbol{U}_i^{(k'')}\}^{(k')}\cdot\boldsymbol{U}_j^{(k')})^{(0)}\|\psi'\rangle. \tag{11}$$

The first term in Eq. 10 is the same scalar two-body electrostatic interactions as those arising from the linear theory,[14,15] and, by using the properties of the Casimir operators,[16] is further simplified to the following expression,

$$\delta(\psi,\psi')[\alpha L(L+1)+\beta G(G_2)+\gamma G(R_7)], \tag{12}$$

where $G(G_2)$ and $G(R_7)$ are the eigenvalues of Casimir's operators for the group G_2 and R_7 used to classify the states of $4f^N$ configuration, and α, β, and γ are new parameters involving the radial factors and excitation energies. The second term in Eq. 10 represents effective three-body electrostatic interactions which are the nonlinear effects arising from interactions with $l^{N-1}l'$ configurations. The triple-tensor matrix elements in the coefficient $X(kk',l')$ expressing the angular dependence can be evaluated by a general expression of Rajnak.[3] $Y(kk',l')$ is a new parameter which depends on the radial integrals, excitation energies and the one-electron quantum numbers. Since there are ten distinct combinations of k, k', and k'' regarding the summation of the triple scalar product in Eq. 11 and the number of parameters is equal to the number of terms, then the number of independent $Y(kk',l')$ becomes to be ten. The combined reduction formula of Eqs. 9b and 9c by use of the algebra of tensor operators is given as

$$(-1)^{S'+L+J}\begin{Bmatrix}S' & L' & J\\ L & S & 1\end{Bmatrix}\langle qSL\|\boldsymbol{T}^{(11)}+\boldsymbol{t}^{(11)}\|q'S'L'\rangle. \tag{13}$$

In Eq. 13, the first term represents the spin-other-orbit magnetic interaction and is reduced to the form involving the Marvin integrals[17] M^k (k=0, 2, 4) as parameters, while the second term expresses the electrostatically correlated spin-orbit interaction and reduced to the form involving P^k(k=2, 4, 6) as pseudomagnetic parameters.[11]

The crystal-field potential H_{cry} in Eq. 2 may be expanded by the irreducible tensor $\boldsymbol{C}_q^{(k)}$ to give

$$H_{\text{cry}}=\sum_i^N\sum_k\sum_q B_q^k(\boldsymbol{C}_q^{(k)})_i, \tag{14}$$

where the summation including i is over all the electrons of the ion of interest and B_q^k is the crystal-field parameter to be determined from the experimental data. The reduction formula of the matrix element of H_{cry} is given in the previous paper.[13] The number of crystal-field parameters is restricted depending on the symmetry of the crystal-field potential and the maximum number of them does not exceed 27 even when an ion is at a site of no symmetry; the number is, in general, only a few for crystals with appropriate symmetry.

Within the above-mentioned framework for an effective Hamiltonian of $4f^N$ configuration, the total number of parameters necessary for energy-level fitting is less than 50; three Slater integrals F^k (k=2, 4, 6), one spin-orbit interaction ζ_{4f}, three two-body electrostatic interactions α, β, γ, ten three-body electrostatic interactions $Y(kk',l')$, three spin-other-orbit magnetic interactions M^k (k=0, 2, 4), three two-body pseudomagnetic configuration-mixing interactions P^k (k=2, 4, 6), and less than 27 crystal-field parameters B_q^k. In such semi-empirical approach, it will be seen later that the interaction energies as large as 10 cm^{-1} are taken into account for the energy fitting.

Application. The Pr^{3+} and Tm^{3+} ions have $4f^2$ and $4f^{12}$ configurations respectively. Since $4f^{12}$ configuration is complementary to $4f^2$, the Tm^{3+} ion has the same number and kind of levels as those of the Pr^{3+} ion, for which there are 13 different free-ion levels $|q,S,L,J\rangle$ under intermediate coupling. From the results of X-ray analyses, the space group and site symmetry at a rare earth ion are $P6_3/m$ (C_{6h}^2) and D_{3h} for ES,[18] and $R\bar{3}$ (C_{3i}^2) and C_{3v} for DN[19] respectively. The crystal fields of D_{3h} and C_{3v} symmetries are expanded as

a) Energy units in cm^{-1}. The ion level and the rms deviation for crystal levels denote the center of gravity in a manifold and the rms deviation from the center respectively. b) Data from Ref. 23. Although he reported to be an average deviation of 3 cm^{-1} for total levels and that of 10.2 cm^{-1} for 9 ion levels with a slight change of the parameters, the details of calculations are not given explicitly. c) Data from Ref. 24. He obtained an average deviation of 5.9 cm^{-1} for 11 crystal levels. d) The absolute value of the ground state $^3H_4(\eta=\pm 2)$. The experimental g value is 0.775 (Ref. 25).

$$H_{cry}(D_{3h}) = B_0^2 C_0^{(2)} + B_0^4 C_0^{(4)} + B_0^6 C_0^{(6)} + B_6^6 (C_6^{(6)} + C_{-6}^{(6)}), \quad (15a)$$

$$H_{cry}(C_{3v}) = H_{cry}(D_{3h}) + B_3^4 (C_{-3}^{(4)} - C_3^{(4)}) + B_3^6 (C_{-3}^{(6)} - C_3^{(6)}). \quad (15b)$$

Each free-ion level under a crystal symmetry may be classified several irreducible representations designated by the crystal quantum number (η) following Hellwege;[20] *i.e.*, $\eta=0$, ± 1, ± 2, and 3 for ES, and $\eta=0$ and ± 1 for DN, where the levels with double signs are twofold degenerate. Any three-body interaction in Eq. 10 is not necessary to be taken into account in the case of f^2 configuration. For f^2 configuration, the reduced matrix elements of the magnetic interaction $\boldsymbol{T}^{(11)}$ and pseudomagnetic interaction $\boldsymbol{t}^{(11)}$ are already given in the explicit expressions involving M^k and P^k.[11] In practice, only M^0 and P^2 were freely varied and M^k and P^k were constrained to the following ratios proposed by Crosswhite *et al.*;[4] *i.e.*, $M^2=0.56M^0$, $M^4=0.38M^0$, and $P^4=0.75P^2$, $P^6=0.50P^2$. Other reduced matrix elements of various tensor operators with respect to f^N configuration are also tabulated by Nielson and Koster.[21] The procedure to determine the parameters by an iterative method is described in the previous paper.[13]

Once the eigenvectors are determined by diagonalizing the Hamiltonian, we can evaluate the parallel component of g values as

$$g_z = \langle\phi|\mu_z|\phi\rangle = \sum_i a_i^2 M g_i(qSLJ), \quad (16)$$

where μ_z is the z component of the magnetic dipole operator along the principal axis of a crystal and $g_i(qSLJ)$ denotes the Lande g factor for an ion level. The g value defined by Eq. 16 is half the Zeeman splitting in Lorentz units $\beta_e H$ (β_e=Bohr magneton). Then the total Zeeman splitting is expressed as $2g\beta_e H$.

Results and Discussion

The final parameters determined and the standard

a) See the footnote (a) in Table 4.

deviations are given in Tables 1—3 for Pr(ES), Pr(DN) and Tm(ES) respectively, together with those obtained by other authors. Now, the root mean square (rms) deviation is defined as

$$\sigma = [\sum_i \Delta_i^2/N]^{1/2}, \quad (17)$$

where Δ_i is the difference between the observed and calculated values of the ith level, and N is the number of observed levels. The calculated numerical results are given in Tables 4—6 for Pr(ES), Pr(DN), and Tm(ES) respectively.

Energy Levels for Pr(ES). The energy levels of Pr(ES) have been investigated by several authors.[22-24] We have used 25 crystal levels assigned by experiments. As seen in Table 1, the inclusion of three two-body electrostatic interactions (case I) considerably reduces the rms deviation for 9 ion levels except the $^3H_5$, $^3H_6$, $^3F_2$, and $^1S_0$ levels from 213 to 25 cm^{-1}, when compared to the result without CI parameters by Gruber. Further improvement of the rms deviation of 20 cm^{-1} for ion levels is achieved by including one magnetic interaction M^0 and one pseudomagnetic interaction P^2 parameter (case II). This fact evidently exhibits that the CI effects arising from magnetic interactions as well as electrostatic interactions play highly important role in giving ion levels. The fit for 25 observed levels by 13 adjustable parameters (case III) yields an rms deviation of 7.8 cm^{-1}. This deviation is the same order of magnitude as that in rare earth crystals.[4-7] The parameter values in case IV are determined so as to fit both the calculated energy levels and the g value of the ground state with the observed values. Although the rms deviation of 10 cm^{-1} for all the 25 levels in case IV is slightly larger than that in case III, the former g value is only 10% larger than the value (=0.775)[25] observed by paramagnetic resonance, whereas the latter g value is 1.45 times as large as the experimental one. As to the rms deviation for 24 crystal levels given in Table 4 (deviation from the center of gravity in a manifold) and the g value of the ground state, the results in cases III and IV is rather similar to those by Gruber and by Hüfner respectively. It is easily supposed that this fact arises from the difference of the crystal-field parameters B_q^k used.

In order to make this point further clear, the main terms of the eigenvectors for the ground state, $^3H_4$ ($\eta=\pm2$), are given in Table 7, together with the ground state eigenvector determined only within the ground state manifold to fit the experimental g value by Abragam and Bleaney.[26] As seen in Table 7, the coefficients of two dominant bases, $|^3H_4(M=2)>$ and $|^3H_4(M=-4)>$, in case IV are evidently different from those by Gruber: the ours are rather close to the coefficients estimated by Abragam and Bleaney. As seen in Eq. 16, a basis function with negative M makes the g value decrease against functions with positive M. Then a slight difference of coefficients between $|^3H_4(M=2)>$ and $|^3H_4(M=-4)>$ results in fairly large difference in calculated g values. The ground state manifold with $J=4$ is split into six crystal levels owing to the D_{3h} crystal symmetry; one $\eta=0$ level, one $\eta=\pm1$ level, two $\eta=\pm2$ levels and two $\eta=3$ levels. Thus a level to be mixed predominantly in the ground state, $^3H_4(\eta=\pm2)$, should be the other $\eta=\pm2$ level in the same manifold because the lowest $^3H_4$ ion level is separated far away from other ion levels. The mixing between two crystal levels with $\eta=\pm2$ in the ground state manifold is taken into account reasonably in case IV by fitting to the observed g value of the ground state, but this mixing is not taken in other energy fits, because there is no experimental value of this level to be available. Therefore, the crystal-field parameters in case IV is considered to be more reliable than those in other cases, even though the result in case IV is not so good as that in case III. In determination of a set of crystal-field parameters, the information of the experimental levels as many as possible within a given manifold is considered to be substantially more important than performing complete J-mixing. Furthermore it is dangerous to conclude simply that in energy-level fitting by restricted experimental data the wavefunction giving better rms deviation is immediately more accurate wavefunction.

Energy Levels for Pr(DN). From the spectral analysis of Pr(DN) by Hellwege and Hellwege,[27] 12 levels of 61 crystal levels and 5 levels of 13 ion levels have only been established experimentally.

Before a definitive X-ray diffraction analysis of Ce(DN),[19] Judd[28] developed a theory for the effect of the crystalline electric field on rare earth double nitrates. The crystal field potential may be regarded as having two components; the first is a dominating potential corresponding to icosahedral symmetry and the second is a weaker residual C_{3v} symmetry potential. In pure icosahedral symmetry,

$$B_0^2 = B_0^4 = B_3^4 = 0, \quad B_3^6 = \pm 1.5275 B_0^6,$$
$$\text{and} \quad B_6^6 = -0.9211 B_0^6. \quad (18)$$

Using this icosahedral approximation, Judd[29] estimated the crystal parameters of Pr(DN) with the rms deviation of 6.1 cm^{-1} for 8 crystal levels, and Tinsley[30] obtained the rms deviation of 11.3 cm^{-1} for 18 crystal levels of Nd(DN) (Table 2). The present calculation yields the rms deviation of 1.5 cm^{-1} for 5 ion levels and that of

3.6 cm^{-1} for 11 crystal levels. The result exhibits unexpectedly good agreement between the calculated and experimental values, but does not satisfy the relation predicted by Judd (Eq. 18).

According to the crystal structure of Ce(DN),[19] 12 oxygen atoms being the nearest-neighbors of the Ce atom must be moved distances of the order of 0.5 Å to make the icosahedron regular and most of 20 triangle on the surface of an icosahedron are also considerably irregular. Therefore the icosahedral model for rare earth double nitrates should be allowed only as the first approximation. Thus the three crystal parameters, B_0^2, B_0^4, and B_3^4, might be not necessary to be small compared to the six-order parameters. However, it is not adequate to conclude immediately that the crystal parameters obtained by us are reasonable because of the lack of experimental values to be fitted.

Energy Levels for Tm(ES). The observed energy levels have been reported by several authors[31-34] and some parameter analyses[33-35] have been carried out. Here, we have adopted the quantum numbers and wavenumbers by Johnsen,[31] and by Krupke and Gruber.[34] As seen in Table 3, when the present result for ion levels is compared to previous studies, the inclusion of CI parameters reduces the rms deviation of 58 or 134 cm^{-1} for the ion levels to 9 cm^{-1}. This remarkable improvement for Tm(ES) is the same degree as that for Pr(ES). For the assignment of ion levels with $J=4$, of which eigenvectors are given in Table 8, there is a substantial discrepancy between the present result and previous ones. The ion level at 5635 cm^{-1} and that at 12475 cm^{-1} are designated respectively to $^3F_4$ and $^3H_4$ unlike all previous assignments as far as the present parameters are appropriate.

TABLE 8. EIGENVECTORS OF THE ELECTRONIC TERMS WITH $J=4$ OF $Tm(C_2H_5SO_4)_3 \cdot 9H_2O$

	$\|^3H_4\rangle$	$\|^1G_4\rangle$	$\|^3F_4\rangle$	
5635	−0.2799	0.5348	0.7973	$^3F_4$
12475	0.7766	−0.3621	0.5155	$^3H_4$
21089	0.5644	0.7635	−0.3140	$^1G_4$

For crystal levels, our result yielding an rms deviation of 4.7 cm^{-1} improves fairly previous results[33-35] which were obtained only within a given manifold by using the first-order perturbation theory. This improvement might simply be considered to be due to complete J-mixing. However, it is seen by examining the present result in somewhat details as well as previous results of crystals with f^3 configuration[13,36] that the mixing of an ion level into other ion levels of different J through crystal field perturbation is still fairly small. This will be plausible when we consider that the energy separation between most of lower excited ion levels well established by experiments is of the order of 10^3—10^4 cm^{-1}, whilst the interaction energy due to crystal field perturbation is of the order of 10—100 cm^{-1} and do not exceed 300 cm^{-1} at most, although the admixing due to crystal fields are, in principle possible for the most part of levels with different J. Thus if all the crystal levels within a manifold with relatively large J value are known completely from the experiments, the crystal-field parameters determined only within this manifold may be fairly reliable. This fact is obviously seen in Er(ES),[13] in which the energy calculation by complete J-mixing does not bring any improvement of the rms deviation when compared to that by crystal-field parameters determined only from the ground state manifold, where all of 8 crystal levels are known by experiments.

From the above consideration, it is more important than a least-squares fit including complete J-mixing for determination of reliable crystal parameters that there exists at least one manifold with J value as large as possible, of which most of the crystal levels are settled by experiments.

a) Values in parentheses are those from paramagnetic resonances. See Refs. 25 and 38 for Pr(ES) and Pr(DN) respectively. b) See Refs. 40 and 39 for Pr(ES) and Pr(DN), and Tm(ES) respectively. c) Values by Wong and Richman. See Ref. 33. d) The value that Wong and Richman (Ref. 33) recalculated using the datum of the Zeeman splitting obtained by Johnsen (Ref. 31). Johnsen reported for this g value to be 1.0 ± 0.2.

Estimate of g Values. The experimental g values of Pr(ES), Pr(DN), and Tm(ES) have been obtained by the Zeeman effects,[22,31,37] paramagnetic resonances,[25,38] and recently magnetic circular dichroisms (MCD).[39,40] The comparison of the calculating g values to these experimental values are tabulated in

Table 10. Summary of calculated g values for crystals with f^3 configuration[a)]

Crystal	No. of fitted level	rms dev. (cm^{-1})	No. of g with dev. over 35%
Nd(ES)[b)]	43	3.6	1(7)
Er(ES)[b)]	50	3.6	2(14)
Nd: $LaCl_3$[c)]	66	4.9	4(33)
Nd(DN)[d)]	18	10.9	12(34)

a) Values in parentheses are total number of calculated g values compared to the observed ones. b) Data from Ref. 13. c) Data from Ref. 36. d) Data from Ref. 30.

Table 9. The calculated g values except those of the $^1D_2(\eta=\pm 2)$ level in Pr(ES) and the $^1G_4(\eta=\pm 2')$ level in Tm(ES) are in good agreement within 30% with the experimental values. Similar situation is found in rare earth crystals with f^3 configuration as shown in Table 10, where some of g values are very different from the experimental values.

It is not easy to find why only some of calculate g values involve large discrepancy although almost all of those are fairly consistent with experimental values. Undoubtedly, one of the origins may still be in experimental errors due to the misclassification of observed crystal levels, the broadening of the Zeeman lines and the overlap of the MCD curves. The other may arise from the inadequacy of crystal parameters due to the lack of energy levels to be available as pointed out in Pr(ES). Obviously the theoretical evaluation of some physical quantities, such as g value, exclusively depends on the accuracy of wavefunctions used. The present semiempirical procedure by the tensor method turns out to get a set of wavefunctions which are in good agreement with the average value of r^{-1}, because the main part of the Hamiltonian consists of the Coulomb interactions and the radial integrals as parameters contained in the Hamiltonian are determined to reproduce the experimental energy levels. On the other hand, the evaluation of g value given in Eq. 16 comes to estimate the average value of r^0; *i.e.*, a sum of overlap-type integrals. A basis $|J,M>$ under intermediate coupling is transformed to $|J',M'>$ on operation of the magnetic dipole moment operator $\mu=\beta_e(L+2S)$, where J' and M' are respectively equal to J and M or different from J and M by one unit, since both orbital and spin operators are a tensor operator of rank one. Consequently, the operation of magnetic dipole moment on a ket vector is to yield a new ket vector, then the average value of the magnetic dipole moment is reduced to a sum of several overlap-type integrals. Thus the wavefunction being fitted to energy levels may be better charge density in the region of r^{-1}, but it is not assured to give also better charge density in the region of r^0. In principle, exact wave function should give exact value for physical quantities as well as for the energy. However, an approximate wave function which is better regarding the energy levels does not necessarily yield better physical quantities. Such circumstances are, of course, manifested already for theoretical estimate of physical quantities of a number of simple molecules.[41] Such disadvantage is considered to be impossible to avoid in semiempirical method depending on solely energy level fitting. In practical purpose, it will be desirable that there are fairly amount of experimental energy levels to be available. However, it might be stated that the calculated g value can, at least, be taken as a reference when no experimental value is available.

Magnetic Circular Dichroism of Praseodymium Ethyl Sulfate and Praseodymium-Magnesium Double Nitrate

Yoshifumi KATO* and Motoshi ASANO

Department of Chemistry, Faculty of Science, Kobe University, Nada-ku, Kobe 657

(Received October 7, 1978)

The magnetic circular dichroism of praseodymium ethyl sulfate and praseodymium–magnesium double nitrate was measured in the visible wave number region at low temperatures down to 17 K. Analysis was carried out for six absorption bands of praseodymium ethyl sulfate and three bands of praseodymium–magnesium double nitrate. With available information on energy levels, the g values of the crystal-field levels relevant to absorptions were derived from the MCD parameters obtained. These values are in good agreement with those from other methods.

During the passed ten years the utility of magnetic circular dicroism (MCD) studies has been presented by many authors,[1] especially for clarifying spectroscopic assignments and characterizing the symmetry and angular momentum properties of both ground and excited states of molecules and ions. However, there are only a few evidences to judge the reliability of the results. It was pointed out that MCD provides fairly reliable spectroscopic splitting factors (g value) of some rare earth crystals with the aid of well-established energy levels even when no direct Zeeman components of a transition are resolved.[2–4]

We have measured the MCD spectra of praseodymium ethyl sulfate, $Pr(C_2H_5SO_4)_3\cdot 9H_2O$ (Pr(ES)), and praseodymium–magnesium double nitrate, $Mg_3Pr_2(NO_3)_{12}\cdot 24H_2O$ (Pr(DN)) at low temperatures, and obtained the g values for several crystal-field levels of these crystals.

Results and Discussion

The preparation of the Pr(ES) crystal has been reported.[2] Pr(DN) was prepared by the method described by Jantsch.[5] An aqueous solution of stoichiometric amount of $Pr(NO_3)_3\cdot 6H_2O$ and $Mg(NO_3)_2\cdot 6H_2O$ was allowed to evaporate slowly. After a month, a transparent single crystal of double nitrate grew in the form of a thick hexagonal plate $30\times 30\times 8$ mm^3, with a well-developed face perpendicular to the principal axis of the crystal. The details of absorption and MCD measurements at low temperatures with use of a metal Dewar vessel have been reported.[2,3] The temperature of crystals cooled by thermal conduction was measured with an Au–Co *versus* chromel thermocouple with one junction pressed directly against the crystal and found to be 80 ± 1 and 17 ± 1 K at liquid nitrogen and helium temperatures, respectively.

The general expression for the MCD of an absorption[6,7] can be applied to a uniaxial crystal such as Pr(ES) and Pr(DN). The ellipticity accompanied by an electronic transition is given by

$$\theta = -\frac{4}{3}\gamma N_a[Af_1/\hbar + (B+C/kT)f_0]H. \qquad (1)$$

The explicit expressions for the MCD parameters A, B, and C are given elsewhere.[1,2] The condition assumed in the derivation of Eq. 1 (the Zeeman energy is less than the zero-field state separation, line width and kT) are still satisfied in the present measurements. The ratios of the MCD parameters to the dipole strength D $(=(1/d_a)|\langle a|\boldsymbol{m}|j\rangle|^2)$ are related to the g values of the ground a and excited j states in a transition as[8]

$$|A/D| = |g_j - g_a|, \quad |C/D| = |g_a|, \qquad (2)$$

where the Zeeman splitting is taken as $2g\beta H$ since there are no multiplets except for the doublet in both Pr(ES) and Pr(DN). We see that term C can arise only when the ground state is degenerate, whereas term A has the value when the ground and/or excited states are degenerate.

There are 13 ion levels for a trivalent Pr ion with $4f^2$ configuration in the aforementioned crystals, an ion level placed in a crystal-field splitting into several crystal-field levels designated by the crystal quantum number η after Hellwege.[9] From the results of X-ray analyses,[10] the site symmetries around a Pr^{3+} ion in the ethyl sulfate and double nitrate crystals are known to be D_{3h} and C_{3v}, respectively. Thus the crystal-field levels in Pr(ES) and Pr(DN) are classified by $\eta=0, \pm 1, \pm 2$, and 3, and $\eta=0$ and ± 1 respectively, where the levels with double signs are twofold degenerate. The crystal levels in the visible region of Pr(ES)[11,12] and Pr(DN)[13,14] have been determined. The energy level diagrams of these crystals relevant to the present analysis are shown in Fig. 1, in which σ-transitions observed in the present experiments are indicated by lines with arrow. The absorption and MCD spectra

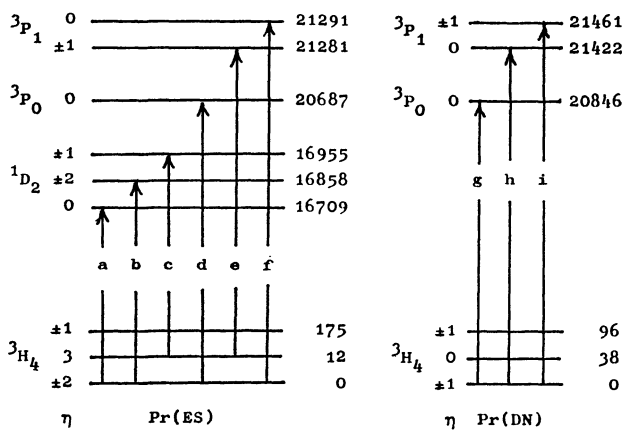

Fig. 1. Energy level diagrams of Pr(ES) and Pr(DN). The units of energy are in cm^{-1}. Allowed σ-transitions are indicated by arrows.

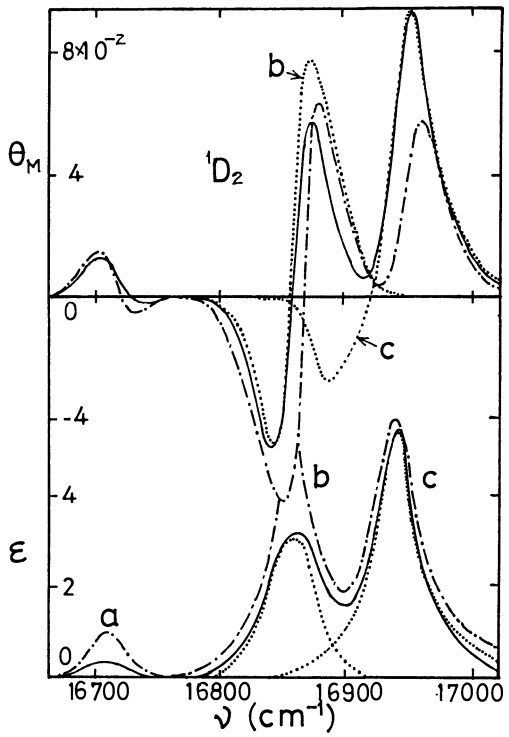

Fig. 2. Absorption and MCD spectra for the $^3H_4 \rightarrow {}^1D_2$ transition of Pr(ES) at 17 (solid line) and 80 K (chain line). The curves shown by dotted lines are those resolved into the constituent curves at 17 K. θ_M and ε are the MCD in molar ellipticity units (K dl dm^{-1} mol^{-1}) per unit gauss and molar extinction coefficient respectively.

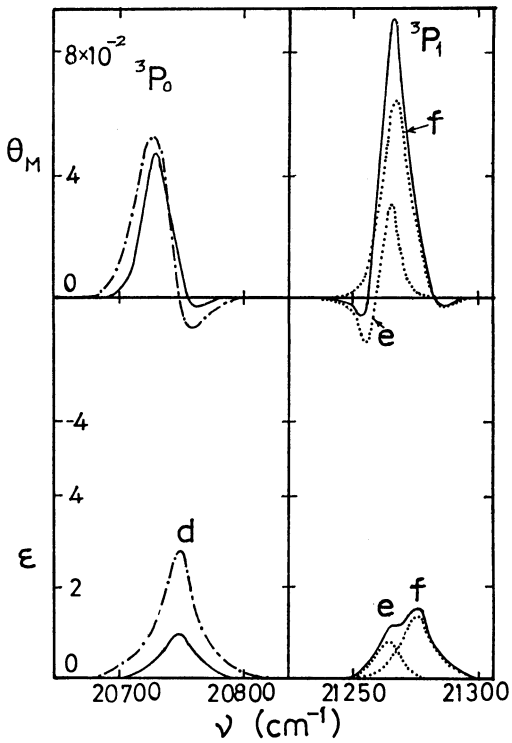

Fig. 3. Absorption and MCD spectra for the $^3H_4 \rightarrow {}^3P_0$, $^3P_1$ transitions of Pr(ES) at 17 (solid line) and 80 K (chain line). See the note in Fig. 2.

observed are shown in Figs. 2—4, where molar extiction coefficient ε and molar ellipticity θ_M in terms of K dl dm^{-1} mol^{-1} G^{-1} are used for the sake of convenience. The lowest crystal-field level of the $^3H_4$ state of Pr(ES) is doubly degenerate ($\eta=\pm 2$), and the population of the next level ($\eta=3$), which is 12 cm^{-1} higher than the lowest level, is 36% that of the latter at 17 K. Thus it is necessary to take account of σ-transitions from these two levels for Pr(ES) (Fig. 1). On the other hand, all the absorption bands of Pr(DN) at 17 K might arise from only the lowest crystal-field level $^3H_4$ ($\eta=\pm 1$), since the population of the next level ($\eta=0$), 38 cm^{-1} higher than the lowest level, is 4% that of the latter at 17 K.

A summary of the MCD parameters derived from the method of moments[7,15] is given in Table 1. Separation of term C from term B can be performed by means of the temperature dependence of θ_M as shown in Fig. 5. The A/D value for a transition should be independent

of temperature. This is satisfied for both Pr(ES) and Pr(DN) (Table 1). Absolute C/D values for various transitions from the same lower level should be identical, indicating the $|g|$ value of this level. Although the absorption bands (b) and (c) in Pr(ES) overlap each other (Fig. 2), separation of the experimental MCD into the MCD's corresponding to these absorption bands is possible when we take the $|C/D|$ values of the $\eta=\pm 2$

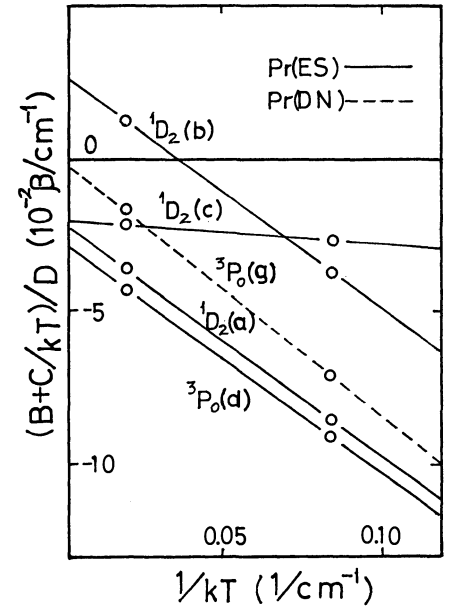

Fig. 5. Temperature dependence of $(B+C/kT)/D$ of Pr(ES) (solid line) and Pr(DN) (broken line) obtained by the moment analysis.

and 3 levels of the $^3H_4$ state to be 0.77 β and 0 β, respectively. The former is the average value obtained from the band (a) and (d), for which all the $|A/D|$ and $|C/D|$ values should be equal since both bands correspond to the transitions from the lowest crystal-field level $^3H_4$ ($\eta=\pm 2$) to non-degenerate excited levels. The latter value should, in principle, be zero since the lower level $^3H_4(\eta=3)$ is non-degenerate. The absorption and MCD curves for each of the bands (b) and (c) (dotted lines, Fig. 2) originate from a curve fitting by using the values given in Table 1 for central frequencies, half-widths and dipole strengths, and by adopting the above values for $|C/D|$ values, the Gaussian form for the shape function f_0 and then the rigid shift model[7] ($f_1=df_0/d\nu$) in Eq. 1. For both absorption and MCD, the sum of two constituent curves reproduces satisfactorily the experimental curve. A similar treatment is applied to the separation of other overlapping absorption and MCD curves into the constituent curves; *i.e.*, the (e) and (f) bands in Pr(ES), and the (h) and (i) bands in Pr(DN). Thus all the MCD parameters for observed bands can be determined. As expected, B terms due to higher-order perturbation are small as compared to the other terms, the contribution of B terms to θ_M not being sizable for paramagnetic salts. Ultimately the absolute g value of the ground state of Pr(ES) and that of Pr(DN) are estimated to be 0.77 β and 0.79 β, respectively. The g values for excited crystal-field levels can be evaluated by using Eq. 2. The absolute g values thus obtained are compared with other experimental values by the Zeeman splittings[13,14] and paramagnetic resonances,[16,17] and theoretical values[18] in Table 2. The g values from MCD are in good agreement with the other experimental ones within the experimental error (*ca.* 15%). The theoretical values also agree with the experimental ones except for the g value of the $^1D_2(\eta=\pm 2)$ level in Pr(ES), which is 1.6 times larger than the experimental value. For theoretical g values of rare earth crystals by the wavefunctions determined so as to get the best agreement of calculated energies

Table 2. Comparison of the g values in Pr(ES) and Pr(DN)

Level	Energy (cm^{-1})	Absolute value of g		
		MCD[a]	Zeeman[b]	Calcd[c]
Pr(ES)				
$^3H_4(\pm 2)$	0	0.77	0.85(0.775)	0.86
$^1D_2(\pm 2)$	16858	1.30	1.30	2.07
(± 1)	16955	1.09		1.03
$^3P_1(\pm 1)$	21281	1.61	1.39	1.50
Pr(DN)				
$^3H_4(\pm 1)$	0	0.79	0.72(0.725)	0.67
$^3P_1(\pm 1)$	21461	1.24	1.17	1.50

a) As the g value of an excited level, two kinds of values are derived from Eq. 2, the value close to those by the other methods being adopted. b) The values from Refs. 13 and 14 for Pr(ES) and Pr(DN), respectively. The values by paramagnetic resonances are given in parentheses. See Refs. 16 and 17 for Pr(ES) and Pr(DN), respectively. c) The values from Ref. 18.

with the observed values obtained from crystal spectra, it frequently occurs that only for few specific crystal-field levels the calculated g values differ considerably from the observed ones, although there is good agreement between both values for most crystal-field levels.[19,20] This problem is further discussed elsewhere.[18] The present analysis has confirmed previous results,[2-4] *viz.*, with available information on energy levels, the g values obtained from the MCD measurement of Pr crystals as well as those from the Zeeman effects and paramagnetic resonances are reliable.

Metachromasy. V.† The Effect of the Chain Length of Polyphosphate on the Metachromatic Behavior of Crystal Violet and Trypaflavine with Emphasis on the Binding Curve and the Spectra of Bound Dyes

Mineo TAKATSUKI and Kiwamu YAMAOKA*

Faculty of Science, Hiroshima University, Higashisenda-machi, Hiroshima 730

(Received October 6, 1978)

Absorption spectra of two metachromatic dyes, Crystal Violet, CV, and Trypaflavine, TF, were measured in the presence of three sodium polyphosphates, NaPP, of different chain lengths. The optical titrations of these systems were performed at the phosphate residue-to-dye ratios, P/D, between 0: 1 and about 1: 1, where isosbestic points are present in the absorption spectra. The apparent molar absorption coefficients of the two dyes in each system changed sigmoidally with the increase in P/D. The extended principal component analysis was applied to the observed spectra of each dye–NaPP system in order to determine both the equilibrium constant for the binding reaction between the dye and the polymer and the pure spectra of the bound dyes. An empirical parameter α was introduced into the expression for the equilibrium constant, $K=$[complex]/[free dye][unoccupied binding site]$^{\alpha}$, to reproduce the sigmoidal titration curve ($\alpha>1$). The amount of the bound CV and TF increased with the increase in the chain length of NaPP at a given P/D, although the pure spectra of those bound dyes were independent of the chain length for low P/D values. The binding behavior of those dyes for high P/D values was also discussed by comparing the previous data with the binding curves calculated in this work.

The striking change in the absorption spectrum of a metachromatic dye in the presence of polyelectrolyte is generally characteristic of the specific nature of the polymer. For example, such a change has been related to the chain length,[1-3] overall or local conformation,[4-8] and functional or ionizable group of individual polymers.[4,9,10] The interaction between dye and polymer is effected by adjusting the experimental conditions such as pH, temperature, ionic strength, and the molar mixing ratio of polymer residues to dye, P/D. Therefore, detailed studies which take into account these factors quantitatively are necessary for full understanding of both the metachromatic behavior of dyes and the dye–polymer interaction.

The method of extended principal component analysis, the PCA method,[11] was successfully applied to the complicated equilibrium systems of cationic dyes (Crystal Violet, CV, and Trypaflavine, TF) and various polyanions, in order to determine the number of dye species in equilibrium, the equilibrium constants, and the absorption spectra of the bound-dye species.[4] Experimentally, the successive titration method was employed in a series of measurements to ensure the accuracy of the dye concentration within 1%. Since the metachromatic behavior of CV and TF has been shown to depend on the number-average degree of polymerization, $\bar{n}$, of sodium polyphosphate over a wide P/D range of 0—2000,[2,3] the purpose of this article is to apply the extended PCA method to the CV– and TF–NaPP ($\bar{n}=11$, 24, and 64) systems in order to clarify the relationship between the metachromatic behavior of these dyes and the chain length of NaPP.

In this work, the equilibrium constants and the pure absorption spectra of the bound-dye species could be determined for those systems. The optical titration curves of all the systems were sigmoidal within the P/D range from zero to about one. In order to analyze the sigmoidal titration behavior, an equilibrium expression with an empirical parameter α was utilized in the same manner as in the previous work.[4] The present results clearly indicate that the equilibrium constant and the value of α both depend on the combination of dyes and NaPP samples. On the contrary, the pure spectra of the bound-dye species are independent of the chain length of NaPP in the low P/D range. The fraction of the bound dye was calculated against P/D by using the equilibrium constant and the parameter α obtained for each dye–NaPP system. By comparing the binding fraction *vs.* P/D curves with previous data,[2,3] it was concluded that two or more bound-dye species should be present over the entire P/D range. The mechanism of the chain-length dependence on the metachromasy was also discussed quantitatively in terms of the amount of the bound dye and its absorption spectrum. Lastly, the empirical parameter α was qualitatively related to the cooperative parameter q which was defined by Schwarz.[12]

Experimental

Materials. All the NaPP samples ($\bar{n}=11$, 24, and 64) used in this work are the same refractionated preparations as described elsewhere.[2,3] The cationic dyes, CV ($\varepsilon=9.20\times10^4$ at 592 nm) and TF ($\varepsilon=4.67\times10^4$ at 452 nm), are also those used in the previous work.[4]

Procedures and Measurements. A Hitachi EPS-3T recording spectrophotometer was used together with a matched pair of 1 and 2 cm long quartz cells. The temperature was set at 25 °C by circulating regulated water through a cell holder. Procedures of the optical titration and other precautions for measurements were described in Ref. 4. The observed data were analyzed by the extended PCA method, which was described in detail in the previous papers.[4,11]

Results

Absorption Spectra and Optical Titration Curves. The absorption spectra were measured at the different stages of titration with a titrant NaPP solution up to a P/D

† For the preceding paper of this series, see Ref. 4.

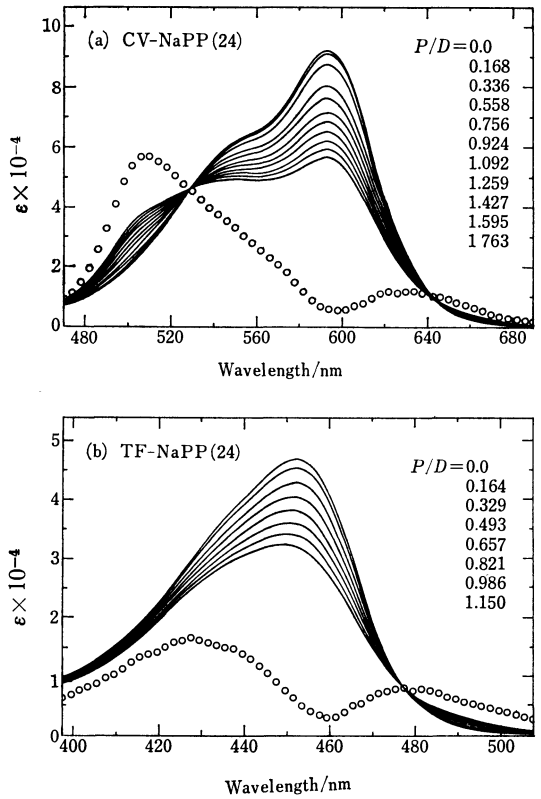

Fig. 1. Absorption spectra of CV (a) and TF (b) in the presence and absence of NaPP(24) and the pure absorption spectra of bound dyes (open circles). The initial concentrations of CV and TF are 8.86 and 11.0 μM (1μM=1×10⁻⁶ mol dm⁻³) respectively. The concentrations of NaPP are given in the respective figures in terms of *P/D*, the order of which corresponds to the order of the decrease in the maximum absorbance.

value near one. Figures 1(a) and (b) show the absorption spectra of CV and TF in the presence of NaPP whose $\bar{n}$ is 24 (hereafter denoted as NaPP (24)). For other CV- and TF-NaPP (11 and 64) systems, the series of absorption spectra were similarly obtained. Since the observed spectrum of a dye-NaPP solution is a composite of the component spectra of the known free and unknown bound dyes, the apparent molar absorption coefficients, ε, were calculated on the basis of the analytical concentration of the dye in solution. The spectra of CV-NaPP (24) show only a shoulder at 510 nm, as is shown in Fig. 1(a), although the metachromasy band was clearly observed at 510 nm for NaPP(64) and NaPP(154). (The absorption spectra for CV-NaPP(154) and for TF-NaPP(216) and TF-NaPP(154) were shown in Refs. 2 and 4, and Refs. 3 and 4, respectively. They will hereafter be quoted without the references.) In the TF-NaPP(24) system which is shown in Fig. 1(b), the maximum absorption band at 452 nm is shifted gradually with increasing *P/D* toward the shorter wavelength with no explicit metachromasy band.

Three and two isosbestic points are observed at 460, 529, and 639 nm and at 371 and 476 nm for the CV- and TF-NaPP(11, 24, 64, and 154) systems, respectively. These isosbestic points predict the presence of two absorbing components in each system, free dye and a bound-dye species, between the *P/D* values of zero and about one. It should also be noted that the ε and position of those isosbestic points remain unchanged regardless of the chain length of NaPP. These findings suggest that the pure spectra of the bound-dye species may not depend on the chain length of NaPP for low *P/D* values.

The optical titration curves are plotted against *P/D* at 592 nm for CV and at 450 nm for TF in the presence of NaPP with the varying degree of polymerization in Figs. 2(a) and (b). All the titration curves change sigmoidally, but not monotonously, with *P/D* in a manner similar to the NaPP(154) systems. The values of the apparent ε at a given *P/D* (*e.g.*, *P/D*=1) decrease with the increase in the chain length of NaPP for both CV- and TF-NaPP systems.

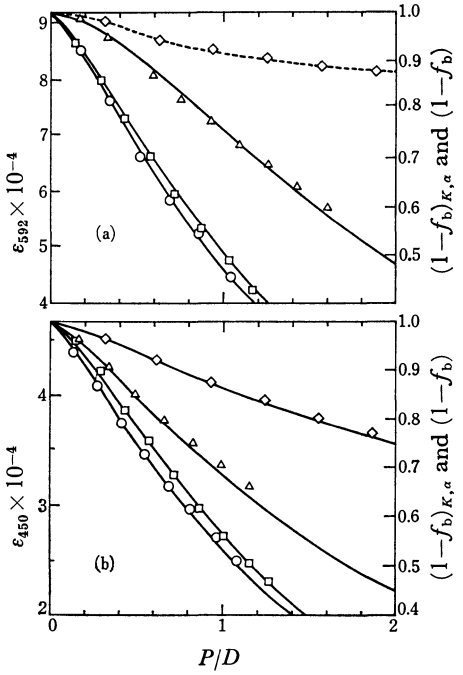

Fig. 2. Optical titration data and calculated binding curves for CV (a) and TF (b). The optical titration data (open symbols) are plotted against *P/D* in terms of ε_λ at 592 nm for CV and 450 nm for TF (left ordinate). The fractions of free dyes calculated from those data (open symbols) are also indicated in terms of $(1-f_b)$ (right ordinate). □: NaPP(64), △: NaPP (24), ◇: NaPP(11), and ○: NaPP(154). The calculated binding curves (solid lines) are shown in terms of $(1-f_b)_{K,\alpha}$ (right ordinate). The dashed line for the CV-NaPP(11) indicates that the $(1-f_b)_{K,\alpha}$ curve could not be calculated by the PCA method (see text for detail).

Pure Spectra of Bound-dye Species and Equilibrium Constants. The extended PCA method is especially useful for the determination of the equilibrium scheme for binding of dye to polyelectrolyte of relatively low molecular weight which cannot be retained by a semipermeable membrane in equilibrium dialysis.[4,11] Therefore, the absorption spectra of all dye-NaPP systems obtained in this work were analyzed by the same method. The number of the absorbing components was first deter-

mined to be two, free and bound dyes, for all the systems which are expected from the presence of isosbestic points. In order to reproduce the observed sigmoidal and monotonous titration curves, an empirical parameter α was introduced into the equilibrium equation for a dye–NaPP system consisting of such two absorbing components as follows:[4]

$$K = \frac{[DP^*]}{[D][P]^{\alpha}}. \quad (1)$$

In this expression D is the free, unbound dye; P means the unoccupied binding site of NaPP; DP* is the bound dye which gives rise to an absorption spectrum different from that of the free dye; the brackets denote the equilibrium concentration. When the value of α is greater than one, the sigmoidal titration curve can be obtained. The pure spectrum of the bound-dye species, equilibrium constant, and empirical parameter were all determined simultaneously from a series of absorption spectra of a particular dye–NaPP system.[4]

Figure 3(a) shows the pure spectra of the CV bound

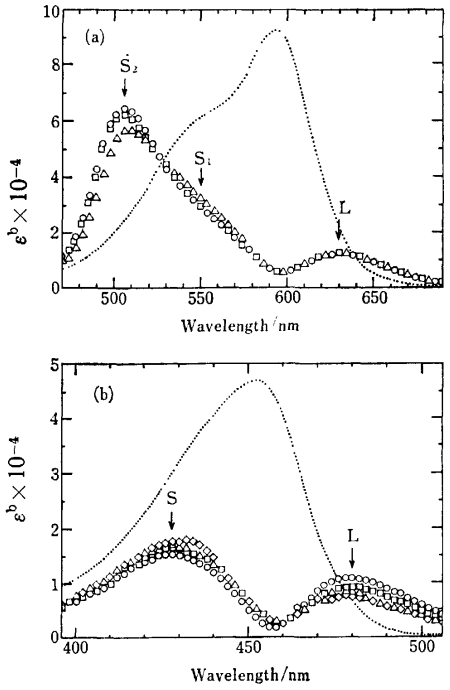

Fig. 3. Pure absorption spectra of CV (a) and TF (b) bound to NaPP's with different chain lengths. □: NaPP(64), △: NaPP(24), ◇: NaPP(11), and ○: NaPP(154). The spectra of free dyes (……) are also shown.

to NaPP(24), NaPP(64), and NaPP(154), thus obtained by the PCA method, together with the free CV for comparison. The pure spectrum of the bound CV for CV–NaPP(11) system could not be obtained from a set of the absorption spectra because their variation was only slight. For all the CV–NaPP systems, the spectra of bound CV exhibit three metachromasy bands: they are designated as the Meta S_2, S_1, and L bands which are located at 506, 550, and 630 nm, respectively, and are indicated by arrows in Fig. 3(a). (The Meta S_1 and S_2 bands are for the short-wavelength ones relative to the peak of the free CV, while the Meta L band is for the long-wavelength one; the numbering is from the one closest to the peak position of the free dye.) The pure spectra of TF bound to NaPP(11), NaPP(24), NaPP(64), and NaPP(154) are shown in Fig. 3(b). They exhibit two metachromasy bands: the Meta S band at 428 nm and the Meta L band at 480 nm. The pure spectra of the bound-dye species show pronounced metachromasy bands (or peaks), in spite of the fact that such bands have not been observed in the spectra for the CV–NaPP(24) or for all of the TF–NaPP systems. Furthermore, the spectral profiles of the bound dyes and the positions of the Meta bands are all independent of the chain length of NaPP bound by either CV and TF. It should be noted that the pure spectra of the bound-dye species have been unraveled in detail by the extended PCA method.

The values of α and of the equilibrium constant K in Eq. 1 were calculated from the series of the absorption spectra of CV– and TF–NaPP systems and are listed in Table 1. It should be noted that the values of α are always greater than one for the sigmoidal titration curves (Figs. 2(a) and (b)). Furthermore, the values of α depend on the combination between dyes and NaPP's with varying $\bar{n}$ values. The binding of dye to NaPP may be affected by the chemical structure of the dye and by the chain length of NaPP with the identical residue structure. Since the chain length may affect the electrostatic potential field of NaPP, the parameter α may be considered as an indicator which reflects the binding mode of dyes. The values of equilibrium constant listed in Table 1 vary widely, because the dimension of K ($=[dm^3\ mol^{-1}]^{\alpha}$) now depends on α. Therefore, the values of K of the different dye–NaPP systems cannot be readily compared with each other to characterize them. However, the equilibrium constant K defined in Eq. 1 may be related to the frequently postulated equilibrium constant K' in such that $K' = [DP^*]/[D][P] = K[P]^{\alpha-1}$. The values of K' were calculated at a representative P/D of 1 and are listed

Table 1. Empirical parameters, α, and equilibrium constants, K and K' at 25 °C for CV– and TF–NaPP systems

$\bar{n}$ of NaPP	CV			TF		
	α	K[a]	K'[b]	α	K[a]	K'[b]
154	1.5	1.0×10^8	2.1×10^5	1.5	5.1×10^7	1.3×10^5
64	1.5	0.98×10^8	2.1×10^5	1.3	7.7×10^6	1.1×10^5
24	1.9	2.2×10^9	0.49×10^5	1.3	2.3×10^6	0.66×10^5
11	—	—	—	1.2	2.1×10^5	0.20×10^5

a) The dimension is given by $[dm^3\ mol^{-1}]^{\alpha}$. b) $K' = K[P]^{\alpha-1}$ at $P/D = 1$.

in Table 1. For both CV and TF, the values of K' increase with the increase in the chain length of NaPP. Thus, the greater part of either dye should be bound to the longer chain of NaPP (*vide infra*).

Binding Curves. The fraction of bound dye, f_b, defined as the ratio of the concentration of bound dye, C_b, to the sum total of the concentrations of the bound and free dyes in solution, C_0, can be calculated at a given P/D in three ways. First, the f_b is obtained with the values of K and α by solving the following equation, which is derived from Eq. 1, for f_b by the Newton method:

$$(1-f_b) = \frac{f_b}{K\{C_0(P/D-f_b)\}^\alpha}. \quad (2)$$

The $(1-f_b)$, *i.e.*, the fraction of free dye, calculated from Eq. 2 is denoted as $(1-f_b)_{K,\alpha}$. The values of $(1-f_b)_{K,\alpha}$ for CV and TF are shown with solid curves in Figs. 2(a) and (b) respectively.

Figures 2(a) and (b) show an excellent agreement between the calculated curve $(1-f_b)_{K,\alpha}$ and the observed points of ε_λ for each dye–NaPP system. Secondly, the fraction of bound dye, f_b, can be calculated from the observed ε_λ at a selected wavelength, according to Lambert-Beer's law, as follows:

$$(1-f_b)_\lambda = \frac{\varepsilon_\lambda - \varepsilon_\lambda{}^b}{\varepsilon_\lambda{}^f - \varepsilon_\lambda{}^b}, \quad (3)$$

where $\varepsilon_\lambda{}^b$ and $\varepsilon_\lambda{}^f$ are the molar absorption coefficients of bound and free dyes at the wavelength λ respectively. Thirdly, the mean value of $(1-f_b)_\lambda$ (*cf.* Eq. 6 in Ref. 4) may be defined as follows:

$$(1-f_b) = \frac{1}{n}\sum_{i=1}^{n}(1-f_b)_{\lambda_i} \quad (n=56), \quad (4)$$

where n denotes the number of selected wavelengths. The $(1-f_b)$ is determined for a given absorption spectrum at a given P/D by the PCA method.[11] The calculated $(1-f_b)_{K,\alpha}$ agrees with the $(1-f_b)$ at all P/D values in Figs. 2(a) and (b). It should be noted that the sigmoidal decrease of the observed ε_λ can be reproduced by $(1-f_b)_{K,\alpha}$ for each system with the value of α larger than one. Hence, the α should be a useful parameter to represent the binding of dye to polyelectrolyte.

The binding curves (solid lines) calculated with the aid of Eq. 2 together with the appropriate α and K in Table 1 are plotted against P/D in Figs. 4(a) and (b). In these figures, the open symbols indicate the points of $(1-f_b)$ which were obtained by analyzing the present optical titration data by the PCA method, while the closed symbols represent the points of $(1-f_b)_\lambda$, $\lambda=592$ and 450 nm for CV and TF respectively, which were calculated from the previous data over a wide P/D range[2,3] with the aid of Eq. 3 together with the values of ε_λ, $\varepsilon_\lambda{}^f$, and $\varepsilon_\lambda{}^b$ (the last was determined in this work by the PCA method). The points of $(1-f_b)_\lambda$ and $(1-f_b)$ obtained from the observed spectra of dye–NaPP fall on the binding curves $(1-f_b)_{K,\alpha}$, which were calculated from Eq. 2, in the P/D range between 0 and 2—3. The $(1-f_b)_{K,\alpha}$ curves approach the limiting value of zero, as the P/D values further increase.

On the contrary, the points of $(1-f_b)_\lambda$ deviate from the $(1-f_b)_{K,\alpha}$ curves and gradually ascend back to the original value of unity[2,3] passing through the minima in the P/D ranges of 2—8 for CV–NaPP and 3—10 for TF–NaPP. (The P/D values for the minima slightly depend on the chain length of NaPP). In addition, the isosbestic points remaining at the low P/D values of less than *ca.* 2 tend to disappear gradually in those intermediate P/D ranges. Both the deviation of the $(1-f_b)_\lambda$ points from the calculated binding curve (solid line) and the concurrent disappearance of the isosbestic points strongly indicate that some unknown bound-dye species are being formed in the dye–NaPP solution with the increase in P/D. These results also eliminate the possibility that the bound dye begins to dissociate from the polymer site. (If this were the case, the isosbestic points should remain.) Thus, it is most reasonable to conclude that two or more of the bound-dye species are present in the dye–NaPP solution in the intermediate P/D range 2—30. Since the pure spectrum of one of them has already been determined in the previous section (Fig. 3), it is worth now finding out the pure spectrum of the other bound-dye species.

At present, the pure spectrum of the unknown bound-dye species cannot be determined uniquely, because both the number of the bound-dye species and the fraction of each bound-dye species are not available yet in the intermediate P/D range. The sum total of the bound-dye species, however, can be estimated from the calculated binding curve. Therefore, the apparent spectrum of the mixture of bound-dye species, *i.e.*, the mixed spectrum of the bound dyes, may be calculated by using the f_b value, which is obtained from the calculated binding curve, $(1-f_b)_{K,\alpha}$, (solid line in Fig. 4), and the observed spectrum of the dye–NaPP solution, ε_λ, at a given P/D value as follows:

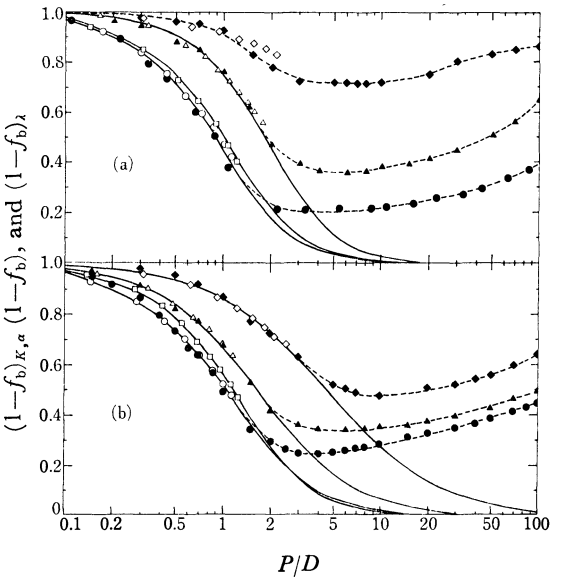

Fig. 4. Binding curves of CV (a) and TF (b) to NaPP's with different chain lengths. The binding curves were calculated in three ways: solid lines for $(1-f_b)_{K,\alpha}$, open symbols for $(1-f_b)$; and closed symbols with dashed lines for $(1-f_b)_\lambda$ ($\lambda=592$ nm for CV and 450 nm for TF). For details, see text. □: NaPP(64), △: NaPP-(24), ◇: NaPP(11), and ○: NaPP(154) for CV and NaPP(216) for TF.

$$\varepsilon_\lambda^{mb} = \varepsilon_\lambda^{f} + \frac{\varepsilon_\lambda - \varepsilon_\lambda^{f}}{f_b} \quad (5)$$

where ε_λ^{mb} is the apparent molar absorption coefficient of the mixture of bound-dye species at a wavelength of λ. For each dye–NaPP system, the mixed spectrum of bound dyes, ε_λ^{mb}, was calculated at the minimum point of the observed $(1-f_b)_\lambda$ *vs.* P/D curve (dashed line in Fig. 4), where no isosbestic point exists. The results are shown for the bound CV and TF in Figs. 5(a) and (b), respectively. Figure 5 shows that the separation between the Meta S and L bands of the mixed spectrum of multiple bound-dye species is apparently narrower than that of the corresponding pure spectrum of a single bound-dye species obtained in the low P/D range (*cf.* Fig. 3), and that the values of ε_λ^{mb} are generally greater than those of ε_λ^{b} in the wavelengths where the peak of the spectrum of free dye is located.

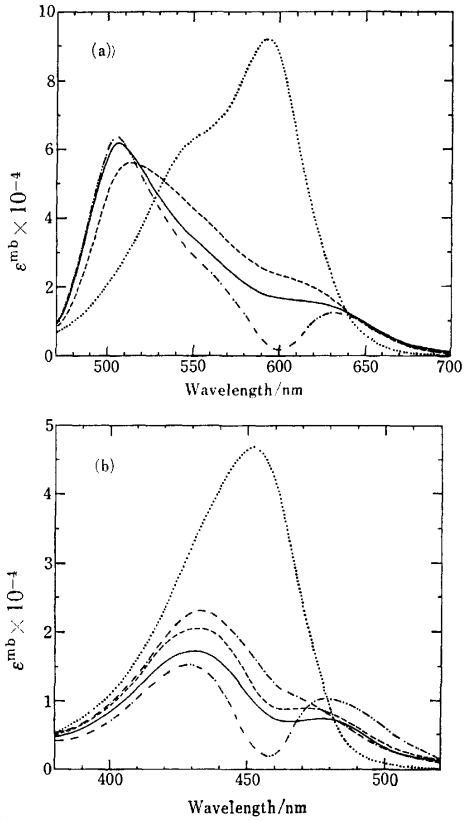

Fig. 5. The mixed bound-spectra of CV (a) and TF (b) calculated at the minimum values of P/D in the $(1-f_b)_\lambda$ *vs.* P/D curves in Fig. 4. CV–NaPP(154) and TF–NaPP(216) at $P/D=3$ (——), CV- and TF–NaPP(24) at $P/D=4$ (– – –), and CV- and TF–NaPP(11) at $P/D=10$ (–·–·–). Pure absorption spectra of a single bound-dye species obtained in the low P/D region (–··–··–) and the respective free dyes (·····) are also shown.

Discussion

Absorption Spectra of Bound CV and TF. The peaks or shoulders of the pure spectra of the bound CV or TF (at 506, 550, and 630 nm for CV, and at 428 and 480 nm for TF) are independent of the chain length of NaPP (Figs. 3(a) and (b)). On the other hand, the values of ε_λ^{b} for the metachromasy bands vary slightly with the chain length of the NaPP to which CV or TF is bound. However, their difference is probably due to the experimental errors, which include the readout of a series of overlapping spectra.[11] Hence, together with the fact that the isosbestic points exist at the constant wavelengths for all the families of the absorption spectra of either CV or TF in the presence of NaPP with the varying value of $\bar{n}$, the spectrum of bound CV or TF can now be concluded to be independent of the chain length of the NaPP samples ($\bar{n}=11$—154) in the low P/D range of 0—*ca.* 2. This conclusion excludes, at least in the low P/D range, one of two possible hypotheses: that the "flexibility" of the polymer backbone, to which dyes are bound, is responsible for the origin of metachromasy.[2]

Shirai *et al.*[9] investigated the metachromasy of Methylene Blue in the presence of potassium poly(ethylene sulfate)s which were different in the degree of sulfation. The metachromasy band of Methylene Blue shifted to the longer wavelength region with the decrease in the degree of sulfation of the polyanion. In the previous report,[4] the position of the metachromasy band was shown to vary considerably with the conformation of polyanion, even if their residue structures are identical or closely related. This situation is especially remarkable in the dye–NaPP and –DNA systems in which the peak positions of the metachromasy bands of bound CV (and also TF) are different, although both NaPP and DNA have the ionized phosphate residues as the binding site for those dyes. On the other hand, the positions of the metachromasy bands of bound CV and TF do not vary with the chain length of NaPP's, each of which has the identical backbone structure and binding site for dyes (Fig. 3). These results all lead to the conclusion that the peak positions of the metachromasy bands of a metachromatic dye depend on the local conformation of the binding site of polymers. It is also reasonable to conclude that the configuration of the π electrons of the bound dye may be affected by the mean distance between the binding sites of a particular polyanion.

Empirical Parameter α and Sigmoidal Titration Curve. As shown in Figs. 2(a) and (b), the ε_λ and $(1-f_b)_{\kappa,\alpha}$ decrease sigmoidally with the increase in P/D from zero to about one in all cases. The empirical parameter α was introduced to reproduce a sigmoidal or monotonous titration curve.[4] Schwarz[12] proposed a theory for the binding of a dye to a linear lattice in which cooperative interaction is restricted to the nearest neighbor binding sites. Subsequently, Schwarz *et al.*[15,16] applied the theory to the monotonous titration curves of some Proflavine-polyanion systems and determined the cooperative binding constant and the parameters, g (the number of the binding sites per segment of polymer) and q (a factor measuring the strength of cooperativity). However, it is obvious that the sigmoidal titration curve cannot be reproduced by using those parameters q and g, which are assumed to be constant for a given dye–polyanion system. The sigmoidal titration curve means that the binding of dye is inhibited near the limiting P/D value ($P/D=0$), and gradually

accelerated with the increase in P/D, whereas a monotonous one means that the binding of dye is either independent of P/D or retarded with the increase in P/D. In Schwarz's theory, the titration curves with $q>1$ indicate positive cooperativity, while those with $q<1$ indicate negative cooperativity. Therefore, the following qualitative relations may be summarized between the empirical parameter α and Schwarz's cooperative parameter q: (i) for $\alpha>1$ (sigmoidal), the parameter q increases continuously with increasing P/D, which contradicts Schwarz's assumption that q is a constant; (ii) for $\alpha=1$ (monotonous), the q is constant; and (iii) for $\alpha<1$ (monotonous), the q decreases continuously with increasing P/D, which also contradicts his assumption.

Binding Curves. The binding curves (solid lines) shown in Figs. 2(a) and (b) reveal that the fraction of the bound dye increases at a low P/D value with the increase in the chain length of NaPP. On the other hand, the spectra of bound CV and TF are independent of the chain length of NaPP in the same low P/D range ($P/D<ca.$ 2) where a single bound-dye species exists. Since the ε_λ is related to the fraction of bound dye by Eq. 3, the dependence of the observed metachromasy on the chain length of NaPP in the low P/D range can be attributed to the difference in the fraction of CV (or TF) bound to the NaPP with different chain lengths. This view is supported from the fact that the $(1-f_b)_{\kappa,\alpha}$ *vs.* P/D curves coincide with the points of various symbols in Figs 4(a) and (b).

The result that the fraction of bound CV and TF varies with the chain length of NaPP is an interesting problem. Schindewolf[13] reported that the degree of dissociation of the Na^+ counter-ion from NaPP decreases sharply with the increase in the chain length in aqueous solution. Kielman and Leyte[14] measured the longitudinal relaxation time, T_1, of the $^{23}Na^+$ ion in NaPP solution by NMR. Since the value of $(T_1)^{-1}$ can be related to the amount of the bound and free Na^+ ions, its sharp increase clearly indicates that the amount of the bound Na^+ ions increases with the increasing chain length of NaPP up to $\bar{n}\approx 60$. Two alternative views on the binding mechanism of a dye to NaPP are considered below.

The first view is that the dye competes with the Na^+ ion upon binding to NaPP. The aforementioned results suggest that larger amounts of both the dye and Na^+ ion are bound to the NaPP with the longer chain length. If both the dye and Na^+ ion are bound to NaPP by the electrostatic force, and if the force becomes stronger with the increase in the chain length of NaPP, the dye would compete with the Na^+ ion in binding to the ionized group of NaPP in the low P/D range. In order to examine the competitive binding between the dye and Na^+ ion to NaPP, the concentration of the free counter-ion has to be measured in the presence of dye. The second view is that the counter-ion Na^+ participates in the formation of a dye–polymer site complex directly, as is described by Eq. 13 of Ref. 4, or indirectly, as is indicated by Eq. 1 in this work. The direct participation of the Na^+ ion in the binding between a cationic dye and an ionized phosphate residue of NaPP may be examined by means of electrophoresis of the dye–NaPP solution. On the other hand, the indirect participation of the Na^+ ion (*e.g.*, the charge neutralization of the nearest neighbor phosphate residue) may be studied by the potentiometric[17] and conductometric[2,3] measurements. Certainly these are the interesting subjects to be investigated in detail.

The experimental points (various symbols) in Figs. 4(a) and (b) begin to deviate from the calculated binding curves (solid lines), as the P/D value reaches about 2 to 3. When the curves approach zero, the points ascend again in the higher P/D range, as if the dye were dissociating from NaPP. Concurrently the isosbestic points disappear in the absorption spectra as the P/D becomes larger than about 2—3; that is, there are three or more dye species in a dye–NaPP solution. The ultrafiltration of TF–NaPP(216) has verified that TF is still bound to NaPP at a high P/D value of 1000.[3] Furthermore, the new isosbestic points appear at 636 nm for CV and at 374 and 479 nm for TF in the P/D range higher than *ca.* 30. Thus, it is concluded that there are probably two kinds of bound-dye species in this P/D range. As a consequence, the experimental binding curves (dashed lines) may be classified into three P/D ranges: (i) the low P/D range of 0—near 2 where free dye and only one type of the bound-dye species are present, (ii) the intermediate P/D range of 2—30 where the free and two or more types of bound-dye species are present, and (iii) the high P/D range where two or more types of bound-dye species are present probably without the free dye.

The change of the absorption spectrum with P/D in the high P/D range may be due to the redistribution of the bound-dye species on polymer sites as the sites increase relative to the bound dye. Although many authors[12,18-20] have treated statistically the redistribution of bound dyes on a polyelectrolyte chain assuming an infinitely long chain length, there remain many questions to be answered, *e.g.*, the number and absorption spectra of bound-dye species and the scheme for the redistribution of the bound-dye species on a single (or multiple) polymer chain of finite length. The application of the extended PCA method to the precise experimental data covering a wide P/D range will shed light on these problems.

The Mixed Bound-spectrum. The mixed spectrum of bound-dye species (Figs. 5(a) and (b)) may be composed of two or more absorbing components, one of which is present in the low P/D range. The bound-dye species newly appearing in the intermediate and high P/D ranges should show an absorption spectrum in which the separation between the Meta S and L bands is small. If the energy separation between the two bands is directly proportional to the perturbation of the π electronic system of bound CV or TF resulting from the interaction between the dye and the polymer site or between the bound dyes themselves, such perturbation may be smaller in the intermediate and high P/D ranges than in the low P/D range possibly because of the redistribution of the bound dyes on the polymer.

From the fact that the pure spectra of a single CV or TF species in the low P/D range are independent

of the chain lengths of NaPP (Fig. 3), the difference in the mixed spectra of the multiple CV or TF species (Fig. 5) should result from the polyelectrolyte property of NaPP. In other words, the chain lengths of those NaPP samples ($\bar{n}$=216, 154, 64, 24, and 11) may be responsible for the formation of the bound dye species with the varying types upon the possible redistribution on the polymer sites with the increase in P/D. The effect of the chain length of NaPP on the metachromatic behavior of CV and TF[2,3] is now confirmed quantitatively to originate from a complicated interplay between the free dye and two or more bound-dye species. That is, the pronounced changes in the ε_λ *vs.* P/D curves given in Figs. 3 and 5 of Ref. 1, in Fig. 3 of Ref. 2, and in Fig. 3 of Ref. 3, and the $(1-f_b)_\lambda$ *vs.* P/D curves in Fig. 4 of this work should result from the variation of the relative amounts not only between free and a single bound-dye species (P/D=0—*ca.* 2) but also between multicomponent bound-dye species ($P/D \geq 2$) themselves. Since the extended PCA method is powerful in the multicomponent system,[4] its application to the series of the absorption spectra of the metachromatic dye–polyelectrolyte system over an entire P/D range should yield information leading to the fuller understanding of metachromasy.

Conclusion

The dependence of the chain length of NaPP on metachromasy of CV and TF was quantitatively clarified for the first time. The equilibrium constant, an empirical parameter, α, and the pure absorption spectra of the bound CV and TF species were determined by the PCA method. Both the equilibrium constant and the value of α depend on the chain length of NaPP, while the pure spectra of bound CV and TF are independent of it. Two or more of the bound-dye species should exist over the entire P/D range. From the profiles of the mixed spectra of the multiple bound-dye species, the effect of the chain length of NaPP on metachromasy was concluded to be such that the redistribution of the bound dyes would be promoted with the increase in the chain length.

Dual Fluorescence and Excited-state Double Proton Transfer in the Dimer of 3,5-Dialkyl-4-hydroxybenzylidenemalononitrile

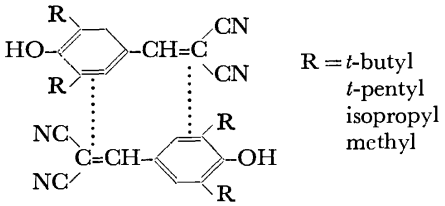
Michiya Itoh,* Kenji Inoue, Tomoko Kuzuhara, and Tomoko Kusui
Faculty of Pharmaceutical Sciences, Kanazawa University, Takara-machi, Kanazawa 920
(Received October 24, 1978)

Dual fluorescence of the dimer of 3,5-dialkyl-4-hydroxybenzylidenemalononitrile (HO-BMN) was investigated by steady-state and nanosecond fluorescence spectroscopies. The dimerization of the compounds in 3-methylpentane (MP) solution was confirmed by concentration dependence of absorption and fluorescence spectra at low temperature (<150 K). While the MP solutions of the compounds are almost non-fluorescent at room temperature, the dimer exhibits a short-lived fluorescence (τ=4—9 ns) at 450—520 nm and a long-lived fluorescence (τ=21—34 ns) at 490—550 nm. The short-lived fluorescence was ascribed to a sandwich type dimer (D*) with a center of symmetry. An orientational relaxation leading to the double proton transfer reaction seems to occur in the excited state of the dimer. The long-lived fluorescence in the dimer was tentatively ascribed to the excited species (T*) generated by the double proton transfer reaction in D*. The excited-state proton transfer is discussed in terms of the effect of deuterium substitution of a 4-hydroxyl hydrogen upon fluorescence lifetimes of the dimer.

Taylor *et al.*,[1] and Ingham and El-Bayoumi[2] reported extensive studies of the hydrogen-bonded dimer formation in 3-methylpentane (MP) of 7-azaindole and the photoinduced double proton transfer reaction in the excited state of the dimer at low temperature. They observed a weak dimer fluorescence and a strong tautomer fluorescence generated by the double proton transfer reaction in the excited state. On the other hand, numerous investigations of dual fluorescence of aromatic hydrocarbons in nonpolar solvents consisting of the dimer and excimer fluorescence were reported.[3-5]

Recently, 3,5-dialkyl-4-hydroxybenzylidenemalononitrile (HO-BMN) was reported to be an active uncoupler of the oxidative phosphorylation,[6] and to show a remarkable pH dependence of absorption spectra.[7] The HO-BMN molecule exhibits an absorption band at 350—360 nm and a very weak fluorescence (almost non-fluorescent) in such a nonpolar solvent as MP. In strong hydrogen-bonding solvents, however, a proton transfer occurs from 4-hydroxy group to a proton acceptor to form an anion form of HO-BMN which reveals an absorption band at 450—460 nm and a corresponding fluorescence at 480—500 nm. Similar highly polar molecule, 3,5-dialkyl-4-methoxybenzylidenemalononitrile (MO-BMN) in MP solution exhibits very similar absorption band at 330—350 nm to that of the corresponding HO-BMN (a neutral form).[8] In MO-BMN, however, neither absorption (450—460 nm) nor fluorescence (480—500 nm) due to the anion form of HO-BMN was detected in such a highly polar solvent as alcohol. Recently, Itoh, *et al.*[9] reported the crystal structure of 3,5-di-*t*-butyl-4-hydroxybenzylidenemalononitrile (*t*-Bu_2-HO-BMN), and the excited-state proton transfer in the crystals. The crystalline *t*-Bu_2-HO-BMN exhibits a strong green fluorescence at 490—500 nm at low temperature, which was ascribed to the excited-state proton transfer between *t*-Bu_2-HO-BMN molecules in the crystals.

This paper describes the dimer formation of HO-BMN in the ground state in MP solution at low temperature, and dual fluorescence consisting of a short-lived fluorescence at 450—520 nm and a long-lived one at 490—550 nm. The former fluorescence in HO-BMN is ascribed to the dimer (D*) of the compound. The latter fluorescence is attributable to the excited species (T*) generated by the double proton transfer reaction in the excited state of the dimer,[10] while in MO-BMN to the excimer-type dimer by an orientational relaxation in D* as reported previously.[8] By taking account of the crystal structure, the structure of the dimer is proposed to be a sandwich-type dimer with a center of symmetry as follows:



The dimer formation of these compounds seems to be attributable to an exciton interaction as well as a charge-transfer (CT) interaction between two component molecules in the dimer. Here, an orientational relaxation leading to the double proton transfer reaction maybe occur in the excited state of the dimer. In the HO-BMN dimer, the effect of deuterium substitution of a 4-hydroxyl hydrogen upon fluorescence lifetimes of the dimer (D*) was observed. The excited-state double proton transfer in the HO-BMN dimer is discussed in comparison with the orientational relaxation in the excited state of the MO-BMN dimer.

Experimental

At the initial stage of the experiment, 3,5-di-*t*-butyl-4-hydroxybenzylidenemalononitrile was given by Prof. Y. Anraku (Department of Botany, The University of Tokyo). All of 3,5-dialkyl-4-hydroxybenzylidenemalononitrile were prepared by known procedures.[11] Pure samples were obtained by chromatography and recrystallization before use. Deuterium substitution of 4-OH hydrogen was performed by CH_3OD (CEA, deuterium grade 99.0%) in a vacuum system. After removing CH_3OD, 3-methylpentane was added through a vacuum system. Proton NMR gave an isotope purity of approximately 85—90%.

Solutions of samples were contained in rectangular quartz cells (1 cm) equipped with graded seals, and degassed by freeze-thaw cycles (several times) at 10^{-5} Torr. All of the

optical absorption and fluorescence spectra were recorded by Hitachi 323 and MPF-4 spectrophotometers. Determination of their spectra at several temperatures was carried out by the method described previously.[12] The fluorescence lifetimes were determined by analyzing exponential decay curves measured by an oscilloscope, and by a coaxial N_2 laser as described previously,[13] and analyzed by a deconvolution method.[14]

Results and Discussion

Dimer Formation in the Ground State. The MP solution of *t*-Bu_2-HO-BMN shows an absorption band in the 340—360 nm region at room temperature, while shows considerable red-shift at low temperature (<150 K) as shown in Fig. 1. Figure 2 shows concentration dependence of absorption spectra of MP solutions of *t*-Bu_2-HO-BMN at 77 K. Here, a monomer-dimer equilibrium of *t*-Bu_2-HO-BMN in MP solution is assumed, and an association constant (K) can be written as follows:

$$K = [D]/([C]-2[D])^2,$$

where [C] and [D] are concentrations of the monomer and dimer. If an absorption band at 400 nm is assumed to be owing to the dimer as shown in Fig. 2, an absorbance (A) at 400 nm is expressed as $A=\varepsilon[D]l$, where ε is a molar extinction coefficient at this wavelength, and l is a light-path length. The following equation is obtained;[2,15]

$$[C]/A = 2/\varepsilon + (1/\varepsilon K)^{1/2}(1/A)^{1/2}.$$

An MP solution of considerable concentration of *t*-Bu_2-HO-BMN exhibits a strong green fluorescence at 77 K as shown in Fig. 1, while the solution is almost non-fluorescent at room temperature. Figure 1 also shows the fluorescence spectrum of this compound in 2-methyltetrahydrofuran (MTHF) at 77 K. The MTHF solution exhibits no significant temperature dependence of fluorescence and absorption spectra.[16] The green fluorescence in the MP solution markedly increases and a fluorescence spectrum at 400—430 nm decreases in intensity with increasing concentration of *t*-Bu_2-HO-BMN, as shown in Fig. 3. The excitation spectrum of the former fluorescence corresponds to an absorption band at 390 nm, while that of the latter to a band at 350—360 nm. Then, the fluorescence at 400—430 nm is tentatively ascribed to the monomer and the green one to the dimer of *t*-Bu_2-HO-BMN.[17] Intensity (I) of the green fluorescence may be proportional to the concentration of the dimer [D], though the green fluorescence consists of a short-lived fluorescence (D*) and a long-lived one (T*) as will be mentioned later. Therefore, the following equation is obtained for the monomer-dimer equilibrium;

$$[C]/I = 2/q + (1/qK)^{1/2}(1/I)^{1/2},$$

where q is a constant including several experimental factors. Plots of [C]/A and [C]/I exhibit linear relationship against $(1/A)^{1/2}$ and $(1/I)^{1/2}$, respectively, as

Table 1. Fluorescence maxima and lifetimes of D* and T*, and the effect of deuterium substitution of a 4-OH hydrogen at 77 K
Equilibrium constants for the dimerization of dialkyl HO-BMN (MO-BMN) in MP at 77 K.

Dialkyl HO-BMN	λ_{max}/nm[a]		τ/ns[b]		K/M^{-1}
	D*	T*	D*	T*	
t-Pe$_2$-HO-BMN	470	510	6(9)	34(34)	5.1×10^{4}[c]
t-Bu$_2$-HO-BMN	470	500	6(7—8)	32(32)	3.5×10^{4}[c]
i-Pr$_2$-HO-BMN	510	530	8(9)	25(25)	4.9×10^{4}[d]
Me$_2$-HO-BMN	515	547	7(8)	34(34)	1.6×10^{5}[e]
Me$_2$-MO-BMN[f]	490	505	4	21	4.8×10^{4}

a) Determined by time-resolved fluorescence spectra, error approximately ±5 nm. b) Determined by a computer deconvolution. Data in parenthese are those of the deuterium substituted samples of HO-BMN, error approximately ±5%. c) Determined by absorption spectra, monitored at 400 nm. d) Determined by absorption spectra, monitored at 410 nm. e) Determined by fluorescence spectra, monitored at 520 nm. f) Ref. 9.

shown in Figs. 2 and 3. Two straight lines confirm an assumption of the monomer-dimer equilibrium, and afford equilibrium constants; $K=4.9\times10^{4}$ M^{-1} from plots of the fluorescence spectra and $K=3.5\times10^{4}$ M^{-1} from those of the absorption spectra. Concentration dependence of absorption and fluorescence spectra of other alkyl HO-BMN in MP solutions also reveals the dimer formation at low temperature, whose equilibrium constants are summarized in Table 1. The absorption spectra of several concentrations of 3,5-dimethyl-4-methoxybenzylidenemalononitrile (Me$_2$-MO-BMN) in MP solutions at 77 K were reported to indicate the dimer formation of this compound. The equilibrium constant is also shown in Table 1 in comparison. An MP solution of Me$_2$-MO-BMN exhibits a strong green fluorescence in 460—500 nm at 77 K consisting of short and long components of decay. The former and the latter were ascribed to the dimer and the excimer fluorescence, respectively, as reported in the previous paper.

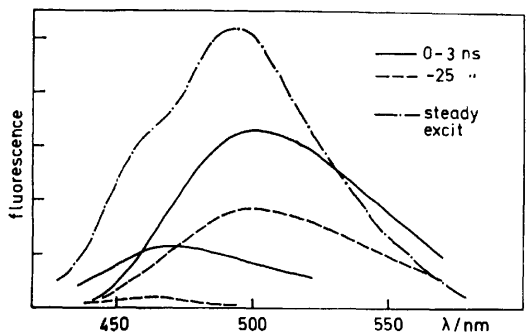

Fig. 4. A steady-state fluorescence and time-resolved fluorescence spectra of an MP solution of t-Bu$_2$-HO-BMN (3×10^{-5} M) at 77 K, which were depicted by a deconvolution method. The time indicated is virtually after a signal maximum of the fluorescence.

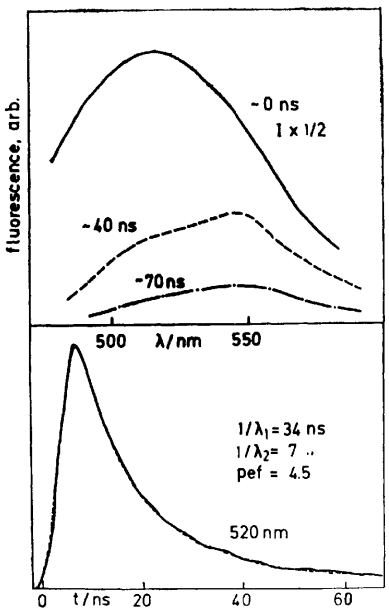

Fig. 5. Time-resolved fluorescence spectra and time evolution of fluorescence (at 520 nm) of an MP solution of Me$_2$-HO-BMN at 77 K; (——) and (– – –) are observed and simulated decay curves based on the obtained time constants and pre-exponential factor (pef), respectively. The time indicated in the time-resolved fluorescence spectra is virtually after a signal maximum of the fluorescence.

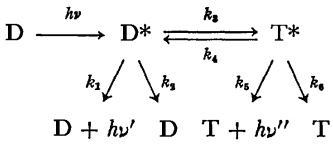
Excited-state Double Proton Transfer in HO-BMN Dimer. Nanosecond time-resolved fluorescence spectra of an MP solution of t-Bu$_2$-HO-BMN at 77 K shown in Fig. 4 demonstrate that the green fluorescence consists of two fluorescence spectra; a short-lived fluorescence ($\tau_D=6$ ns, $\lambda_{max}=470$ nm) and a long-lived fluorescence ($\tau_T=32$ ns, $\lambda_{max}=500$ nm). The dual fluorescence of the dimer was also observed in other dialkyl HO-BMN (3,5-di-t-pentyl, 3,5-diisopropyl- and 3,5-dimethyl HO-BMN). Figure 5 shows time-resolved fluorescence spectra and decay curve of an MP solution of Me$_2$-HO-BMN at 77 K. Table 1 summarizes the fluorescence maxima determined by time-resolved fluorescence spectra and lifetimes in the dimers of these compounds at 77 K. The excitation spectra of the short-lived and long-lived fluorescence are identical each other, and corresponding to the dimer absorption band. The spectral behavior in the case of t-Bu$_2$-HO-BMN is shown in Fig. 1. From the large Stokes shift of the long-lived fluorescence, the fluorescence may be tentatively ascribed to the excited species (T*) generated from the excited state of the HO-BMN dimer (D*), while the short-lived one to the dimer.

The photochemical reaction scheme of the excited state of the dimer (D*), and the excited species T* generated from D* is as follows:



Time-depedent concentrations of D* and T* are ex-

pressed by the following equations;[18,19]

$$[D^*] = c_1 \exp(-\lambda_1 t) + c_2 \exp(-\lambda_2 t), \quad (1)$$

$$[T^*] = c_3 \exp(-\lambda_1 t) - c_3 \exp(-\lambda_2 t), \quad (2)$$

$$\lambda_{1,2} = \frac{1}{2}[k_1+k_2+k_3+k_4+k_5+k_6 \mp (\{k_1+k_2+k_3-(k_4+k_5+k_6)\}^2+4k_3k_4)^{1/2}].$$

Since two fluorescence decay curves of D* and T* at a certain wavelength overlap each other, actual decay curves at several wavelengths were analyzed by the following equation:

$$[D^*] + [T^*] \propto \exp(-\lambda_1 t) + (c_2-c_3)\exp(-\lambda_2 t)/(c_1+c_3).$$

Here, if $k_3 \gg k_4$, and k_4 is negligible, fluorescence lifetimes of D* and T* were determined to be 6 ns and 32 ns from λ_2 and λ_1, respectively. If a pre-exponential factor (pef), $(c_2-c_3)/(c_1+c_3)$ is obtained to be negative, T* should show the fluorescence rise. Unfortunately, the fluorescence rise of T* was not significant as shown in Fig. 6, because the D* fluorescence overlaps on the decay curve of T* even at 600 nm.

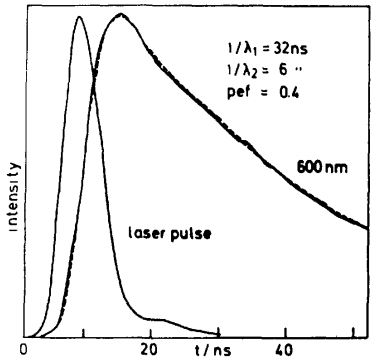


Fig. 6. Time evolution of fluorescence observed at 600 nm of an MP solution of *t*-Bu_2-HO-BMN at 77 K, and a computer simulation (-----) from time constants and pre-exponential factor obtained (concentration, 2×10^{-5} M).

The crystal structure of *t*-Bu_2-HO-BMN demonstrated that the molecule is almost planar and packed along the b axis with a spacing of 3.69 Å in a monoclinic unit cell, as reported in a previous paper.[9] Two molecules packed along the b axis are considered to be a sandwich-type dimer with a center of symmetry. Therefore, the structure of the dimer in solution may be similar to that in the crystals. In the excited state of the dimer, an orientational relaxation maybe occur eeading to the formation of the excited species T*. Here, it is likely that the double proton transfer reaction is involved in the orientational relaxation in the excited state of the dimer. On the other hand, there seems to be a possibility that the excited species T* might be ascribed to an ordinary excimer-type dimer, where no proton transfer is involved. However, this was excluded by the effect of deuterium substitution of a 4-OH hydrogen of HO-BMN upon fluorescence lifetimes of D*. Fluorescence lifetimes of D* and T* in several dialkyl HO-BMN and their deuterium substituted HO-BMN at 77 K were determined and analyzed by computer simulation mentioned above. The results are summarized in Table 1. All of fluorescence lifetimes of D* somewhat increase by deuterium substitution of 4-OH protons, while those of T* remain almost unaltered. The significant effects of deuterium substitution upon fluorescence quantum yield or proton transfer rate in 2-naphthol,[20] 2-naphthylamine, and carbazol[21] were reported by several investigators. El-Bayoumi and his coworkers[2,22] reported that the rate constant (k_3) of the double proton transfer in 7-azaindole dimer was decreased by deuterium substitution. In the excited-state proton transfer reaction reported here, increases of fluorescence lifetimes and pre-exponential factor (pef) mentioned above may be attributable to the effect of the deuterium substitution upon the proton transfer rate constant k_3.

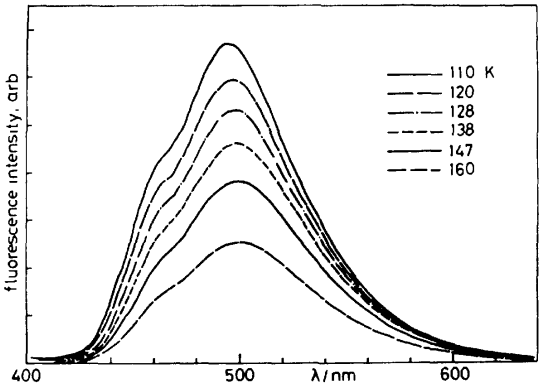

Fig. 7. Temperature dependence of fluorescence spectra of an MP solution of *t*-Bu_2-HO-BMN (concentration, 5×10^{-5} M) excited at 390 nm.

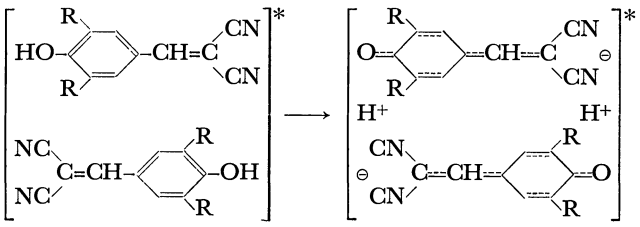
On the other hand, an MP solution of considerable concentration of *t*-Bu_2-HO-BMN reveals temperature dependence of fluorescence spectra, as shown in Fig. 7. The D* fluorescence at 450—490 nm decreases in intensity slightly more than the T* fluorescence at 480—550 nm with increasing temperature (77 K to 150 K). Since most of molecules are virtually present as dimers trapped in the MP matrix, and since no monomer fluorescence is detected under these conditions, the temperature dependence suggests that there seems to be very small activation barrier between these two fluorescent states. However, the energy was too small to be estimated from the fluorescence spectra. The fact is compared with the results in Me_2-MO-BMN (0.9 kcal mol^{-1}) reported previously.

The structure of the dimers of dialkyl-HO-BMN is conclusively considered to be a sandwich type with a center of symmetry from the crystal structure reported previously. The dimer formation of nonpolar molecules such as anthracene and tetracene may be attributable to the exciton interaction as well as the charge transfer (or charge resonance) interaction. In the highly polar molecules reported here, the charge transfer character between two component molecules in the dimer seems to increase in the excited state. Further, it is likely that an orientational relaxation from the short-lived dimer state to the fluorescent excimer occurs in the excited state. Here, the simultaneous double

proton transfer reaction leading to the formation of T* may occur in the orientational relaxation process in the excited state dimer of HO-BMN as follows:



The effect of deuterium substitution of the 4-hydroxyl hydrogen upon fluorescence lifetimes of D* confirms the excited-state proton transfer reaction. On the other hand, the difference of fluorescence band maxima between D* and T* (E*) was observed to be somewhat greater in the HO-BMN dimer than in the MO-BMN dimer as seen in Table 1. Further, the activation barrier of D* to T* seems to be smaller in the HO-BMN system than that of D* to E* in the MO-BMN system, as mentioned above. These results of the fluorescence behavior are instructive for understanding of the electronic structure of T* as well as E*, though it is not obvious at this stage.

The authors wish to express their thanks to Professor S. Nagakura, The Institute for Solid State Physics, The University of Tokyo, for valuable discussion, and to Professor Y. Anraku, Department of Botany, The University of Tokyo, for samples of *t*-Bu_2-HO-BMN at the early stage of this work. They are also indebted to Drs. Y. Tanimoto and K. Fuke for valuable discussions and for computer deconvolutions. The work was partly supported by the Grant-in-Aid (#221611) of the Ministry of Education.

Far-infrared Spectra of Low- and High-temperature Phases of $CsCuCl_3$

Kenji AKIYAMA, Yoshiyuki MORIOKA, and Ichiro NAKAGAWA*

Department of Chemistry, Faculty of Science, Tohoku University, Aoba, Aramaki, Sendai 980

(Received November 1, 1978)

Polarized far-infrared reflection spectra of the $CsCuCl_3$ single crystal have been recorded with the electric vector parallel and perpendicular to the c axis at room temperature. Polarized far-infrared transmission spectra have been measured at liquid-nitrogen temperature. The observed spectra have been interpreted using the factor group analysis based on the space group D_6^2. Far-infrared transmission spectra of the powder sample have also been measured over the temperature range from 175 °C to liquid-nitrogen temperature. The spectrum at 175 °C consists of five bands and reveals a typical feature characteristic of the $CsNiCl_3$ structure (D_{6h}^4). The spectral change due to the phase transition has been interpreted based on the structural distortion of the crystal.

A number of double salts of the AMX_3 type, where A and M are univalent and divalent metal ions, respectively, and X is a halogen ion, crystallize in a hexagonal $CsNiCl_3$ structure with the space group D_{6h}^4-($P6_3/mmc$).[1] Almost all of these crystals do not undergo a phase transition down to liquid helium temperature, with the exception of $CsCuCl_3$. $CsCuCl_3$ transforms from the high-temperature $CsNiCl_3$ structure to a more complex one around 423 K[2-4]. According to the crystal structural analysis of the low-temperature phase of $CsCuCl_3$, the displacement of the atoms caused by the phase transition at 423 K can be expressed as the helical distortion around the c axis of the high-temperature structure. In relation to that remarkable structural change of $CsCuCl_3$, the studies on the optical activity, the X-ray and neutron scattering, the dielectric constant and the sound velocity have been made.[5]

From the vibrational spectroscopic point of view, the spectral change at the transition temperature and the relation between the high- and low-temperature spectra are interesting. The infrared spectrum of $CsCuCl_3$ reported so far has been limited to the transmission spectrum of the polycrystalline sample at room temperature by McPherson and Chang.[6] In their study the high-temperature spectrum and the spectral change due to the phase transition have not been remarked. The present paper reports the results of the polarized far-infrared transmission and reflection spectra of a single crystal for the low-temperature phase. The Raman spectrum at low temperature is given as complementary data. The far-infrared transmission spectra of the powder sample have been measured at various temperatures in the range from 175 °C to liquid-nitrogen temperature in order to persue the spectral change due to the structural phase transition.

Crystal Structure and Factor Group Analysis

The structure of the high-temperature phase of $CsCuCl_3$ is the $CsNiCl_3$ type, for which the details of the structure and the factor group analysis are described in our previous paper.[7] The structure of the low temperature phase is a helically distorted structure of the $CsNiCl_3$ structure, with the space group D_6^2 ($P6_122$) or its enantiomorph D_6^3 ($P6_522$), with six formula units in a Bravais primitive cell, as shown in Fig. 1.[8] The factor group for both of the D_6^2 and D_6^3 groups is isomorphous to the point group D_6 and the result of the factor group analysis is summarized in Table 1.

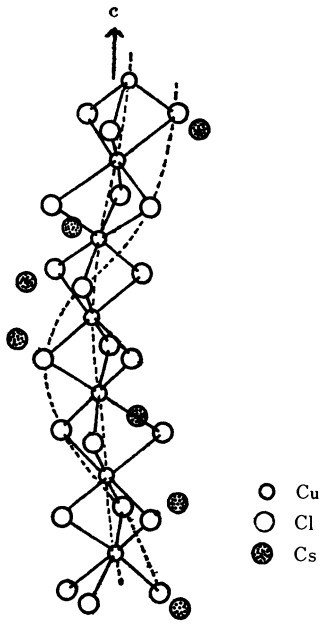

Fig. 1. Crystal structure of the low-temperature phase of $CsCuCl_3$.

* X and Y axes are perpendicular, and a Z axis is parallel to the crystallographic c axis, respectively.

Experimental

The powder sample of $CsCuCl_3$ was obtained by evaporation of the hot concentrated aqueous solution of CsCl and

$CuCl_2 \cdot 2H_2O$ in a 1 : 1 mole ratio or in a slight excess of $CuCl_2 \cdot 2H_2O$. The single crystal was grown from a saturated aqueous solution by the temperature difference method. The hexagonal bipyramidal crystal about $7 \times 7 \times 15$ mm^3 in size was obtained after 2 weeks. The plane including the c axis was polished and used for the reflection measurement. The specimen for the transmission measurement is about 0.1 mm thick.

Far-infrared spectra were recorded using a Hitachi 070 far-infrared interferometer equipped with a wire-grid polarizer. For the measurement below 50 cm^{-1}, a high-sensitive liquid-helium cooled germanium bolometer was used as a detector. A Raman spectrum was obtained with a Spex 401 double monochromator using 647.1 nm excitation from a Kr ion laser.

Results and Discussion

Spectra of the Low-temperature Phase. The polarized far-infrared transmission spectra of a single crystal at liquid-nitrogen temperature are shown in Fig. 2. The polarized far-infrared reflection spectra at room temperature are shown in Fig. 3a. The $\varepsilon'(\nu)$ and $\varepsilon''(\nu)$ curves obtained by the Kramers-Kronig analysis are shown in

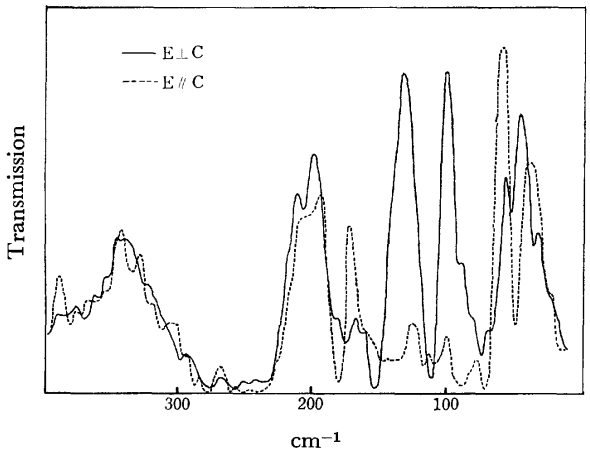

Fig. 2a. Single crystal far-infrared transmission spectra of $CsCuCl_3$ (400—20 cm^{-1}).

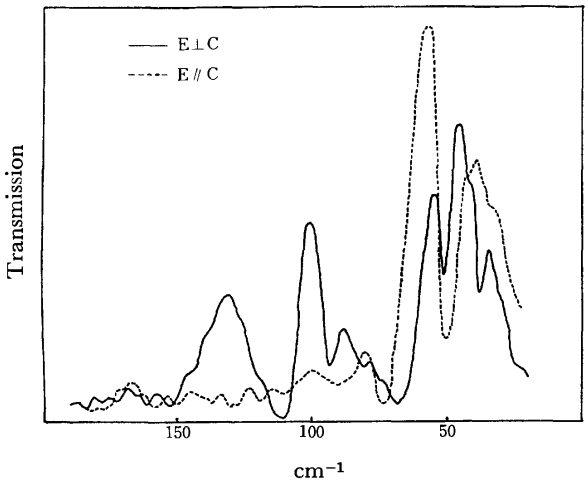

Fig. 2b. Single crystal far-infrared transmission spectra of $CsCuCl_3$ (200—20 cm^{-1}).

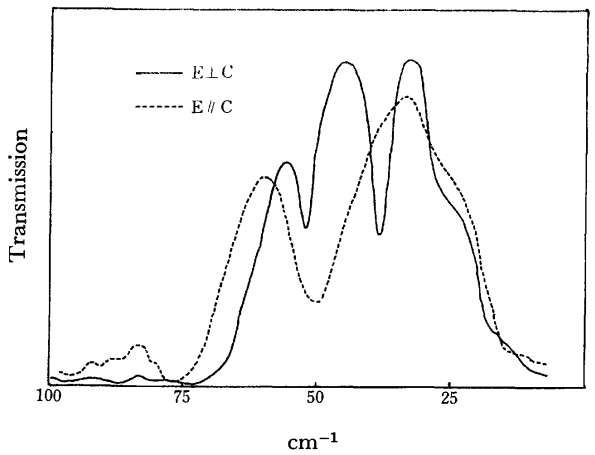

Fig. 2c. Single crystal far-infrared transmission spectra of $CsCuCl_3$ (100—10 cm^{-1}).

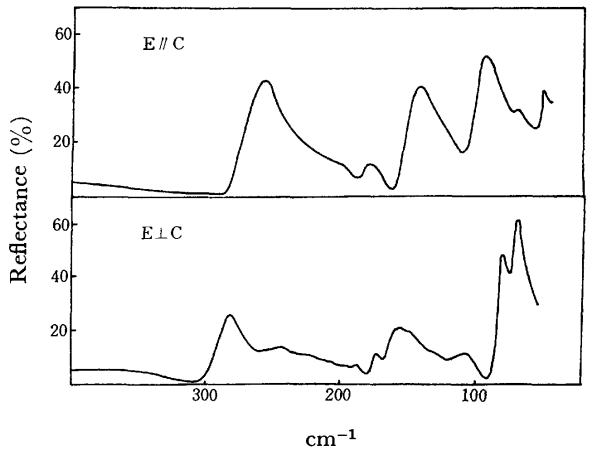

Fig. 3a. Single crystal far-infrared reflection spectra of $CsCuCl_3$.

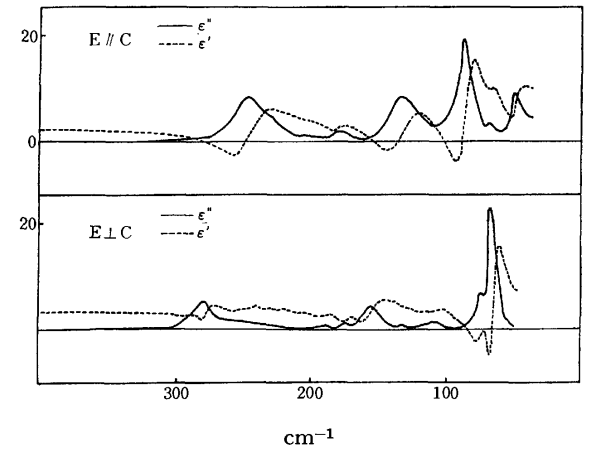

Fig. 3b. $\varepsilon'(\nu)$ and $\varepsilon''(\nu)$ obtained from reflection spectra of $CsCuCl_3$.

Fig. 3b, where the maxima of $\varepsilon''(\nu)$ give the transverse frequencies. The transmission spectra above 200 cm^{-1} are uninformative, since the absorptions are too strong and saturated. From the maxima of $\varepsilon''(\nu)$ in Fig. 3b, 247 and 279 cm^{-1} are assigned to the A_2 and E_1 modes,

* Too strong absorption and the frequencies may not be determined.

respectively. In the frequency region below 200 cm^{-1}, the absorption bands at 179, 140, 119, 90, 72, and 51 cm^{-1} are attributed to the A_2 modes, and those at 187, 174, 163, 152, 111, 94, 80, 68, 54, and 39 cm^{-1} to the E_1 modes as shown in Figs. 2a—2c. The $7A_2$ modes and $11E_1$ modes are now determined, while a factor group analysis predicts $8A_2$ and $14E_1$ modes. Table 2 summarizes the observed frequencies obtained from the single crystal transmission and reflection spectra. The frequencies determined by the two different methods agree well, as a whole, with each other.

The frequencies at which $\varepsilon'(\nu)$ changes the sign from negative to positive, *i.e.* 278, 154, and 102 cm^{-1} for E//C, and 85 and 73 cm^{-1} for E⊥C, correspond to the longitudinal frequencies. However, it is difficult to determine all the longitudinal frequencies, because of the complex structure of the crystal and the fairly large damping at room temperature. Therefore, no further discussion will be done on the longitudinal frequencies.

Figure 4 shows the transmission spectra of the powder sample at room and liquid-nitrogen temperatures. The room temperature spectrum is essentially the same as the spectrum reported by McPherson and Chang. With lowering the temperature, the absorption bandwidth becomes narrower considerably. In the spectrum at liquid-nitrogen temperature 13 absorption bands are observed, and the vibrational assignment of each band is definitely determined as listed in Table 2, on referring to the single crystal spectra described before.

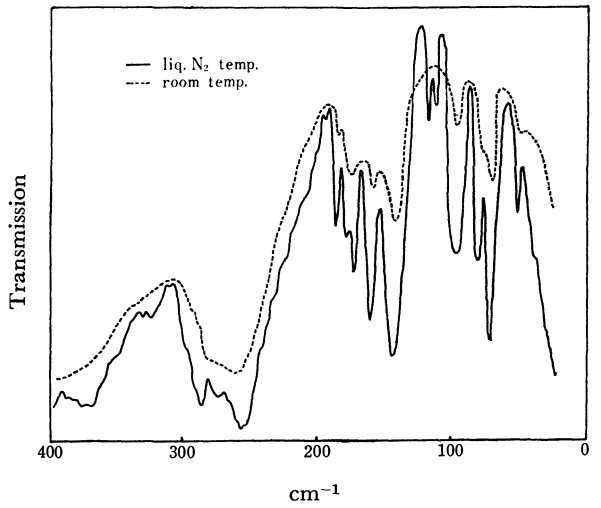

Fig. 4. Far-infrared transmission spectra of the powder sample of $CsCuCl_3$ at room and liquid-nitrogen temperatures.

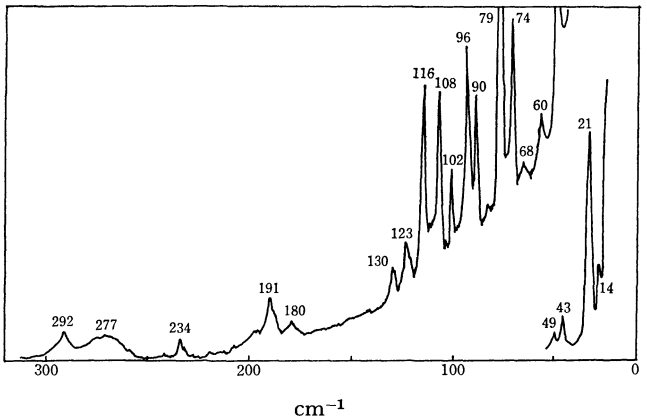

Fig. 5. Raman spectrum of the powder sample of $CsCuCl_3$ at 30 K.

The Raman spectrum of the powder sample observed at 30 K are shown in Fig. 5. Twenty Raman lines are observed, while 35 ($6A_1+14E_1+15E_2$) are expected from the factor group analysis. The E_1 modes are active both in the infrared and Raman spectra. However, a definite assignment of the Raman lines is difficult from this powder Raman spectrum only.

Spectra of the High-temperature Phase and Spectral Change Due to the Phase Transition. Figure 6 shows the far-infrared transmission spectrum of the powder sample at 175 °C. This spectrum which consists of five bands is attributable to the high-temperature phase of $CsCuCl_3$ and reveals a typical feature characteristic of the $CsNiCl_3$ type structure. The band assignment to the symmetry species is possible, on referring to the results of the polarization measurements for the $CsNiCl_3$ type crystals by Adams and Smardzewski,[9] and by the present authors.[7,10] (See Table 3.)

Figure 7 shows the far-infrared transmission spectra of the powder sample at various temperatures. The absorption bands at 52 and 39 cm^{-1} of the low-temperature phase decrease their intensities with raising temperature and disappear above 140 °C, and the new band at 42 appears in the temperature range from 140 to 150 °C. The two bands at 82 and 76 cm^{-1} in the low-temperature phase are shifted to the

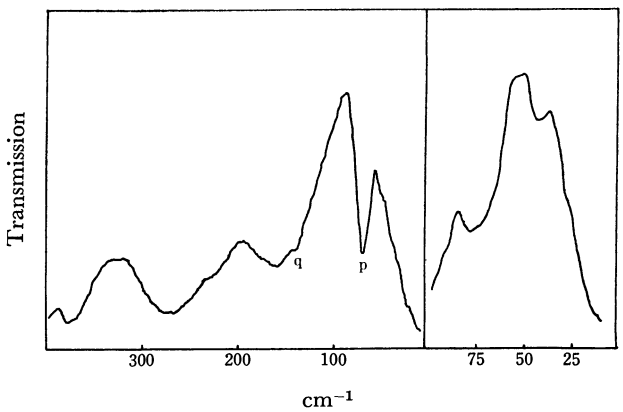

Fig. 6. Far-infrared transmission spectrum of the powder sample of $CsCuCl_3$ at 175 °C. (q and p are the absorptions by quartz and polyethylene, respectively.)

Table 3. Vibrational frequencies (cm^{-1}) of the high-temperature phase of $CsCuCl_3$

270	E_{1u}
220	A_{2u}
160	E_{1u}
70	E_{1u}
42	A_{2u}

lower frequency side and merged into one at 70 cm^{-1} on transition to the high-temperature phase. The strong absorption band at 146 cm^{-1} also disappears around 140 °C and the four bands at 188, 180, 175, and 163 cm^{-1} become unresolved and are replaced by a single broad band centered at 160 cm^{-1}. The lower frequency side of the broad bands around 280—250 cm^{-1} loses its intensity, and above 140 °C only one band around 270 cm^{-1} with an unresolved shoulder around 220 cm^{-1} is observed.

Among the five bands of the high-temperature phase the 270, 220, and 160 cm^{-1} bands are rather broad, comparing with the corresponding bands of $CsNiCl_3$ crystal,[7] which is isomorphous to the high-temperature phase of $CsCuCl_3$. This fact supports the presence of a local tetragonal distortion of $CuCl_6$-octahedra suggested based on the EPR study.[3] It might be noted that the other two bands at 70 and 42 cm^{-1}, associated with the Cs^+ ion displacements, are not so broad.

The authors wish to express their sincere thanks to Dr. Issei Harada of the University of Tokyo for his kind guidance in the measurement of Raman spectrum. A part of this work was supported by Kurata Science Foundation.

Thermodynamics of the Redox Equilibria and the Site Preference in $(Fe_{1-y}Al_y)_{3-\delta}O_4$

Akio NAKAMURA,** Shigeru YAMAUCHI,* Kazuo FUEKI, and Takashi MUKAIBO

Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received May 18, 1978)

In order to elucidate the defect model in the spinel ferrites, the nonstoichiometry in magnetite and its solid solutions, $(Fe_{1-y}Al_y)_{3-\delta}O_4$, ($y$=0.0, 0.25, 0.33), was determined at temperatures between 1300 and 1550 °C. The redox equilibria between Fe^{2+} and Fe^{3+} and the site preference of Fe^{2+}, Fe^{3+}, and Al^{3+} ions and cation vacancies were investigated and sixteen kinds of models were examined. The "best" model was chosen using the criteria that the dependence of the equilibrium constant on δ and y should be as small as possible. In the selected model, Fe^{2+} ions on B-sites are regarded as electron donors in a narrow 3-d band formed by Fe ions in B-sites. The following expression for the defect equilibrium was found:

$$\frac{2}{3(1-y)}Fe_A^{2+} + \frac{2(2-3y)}{3(1-y)}e_B^- + \frac{1}{2}O_2(g) \rightleftarrows \frac{2}{3(1-y)}Fe_A^{3+} + \frac{1}{4}V_A + \frac{1}{2}V_B + O_L^{2-}.$$

The thermodynamic properties of the Fe–O system have been studied in relation to the metallurgy and corrosion of steels. Among the oxides of iron, magnetite (Fe_3O_4) has a wide nonstoichiometric range; this attracted much attention in the field of solid state chemistry.[1-3] Magnetite is also regarded as a model compound of spinel-type ferrites, which are industrially important as magnetic oxide materials.

Electrical and magnetic properties of ferrites are largely affected by the charge and distribution of cations and lattice defects, which can be controlled during fabrication processes. Therefore, information about lattice defects in magnetite and ferrites is necessary for the production of ferrites with desired properties.

Magnetite and its solid solutions with $FeAl_2O_4$ have a wide nonstoichiometric composition with cation deficiency at high oxygen pressures.[4] Al^{3+} ions are stable in the spinel structure, so the charge distribution among cations in the spinel ferrite is simpler than in the other ferrites, such as manganese or copper ferrites.

The purpose of this paper is to determine the nonstoichiometry of spinel-type solid solutions of Fe_3O_4 and $FeAl_2O_4$, and to interpret the result on the basis of statistical thermodynamics.

Experimental

Materials. Magnetite was prepared by heating the cold-pressed hematite of 99.99% purity at 1500 °C in air. Solid solutions $(Fe_{1-y}Al_y)_3O_4$ (y=0.25 and 0.33) were formed by heating the cold-pressed powder mixtures of 99.99% pure hematite and alumina in a platinum crucible at 1500 °C in air for 12 h. The X-ray powder diffraction study revealed that the resulting materials were spinel-type solid solutions in a single phase. The weight increase observed when the ferrite specimens were oxidized into alumina and hematite coincided with the values calculated from the composition, within experimental error. The compacts were crushed to grains, 1—2 mm in diameter, and used as samples for the nonstoichiometric measurement.

Measurement of Nonstoichiometry. The apparatus for thermogravimetric measurement has been described elsewhere.[5] About 1 g of crushed oxide sample was placed in a platinum basket suspended from the balance to the furnace heated by a silicon carbide tubular heater. The temperature of the furnace was controlled within ±0.5 °C and the partial pressure of oxygen was controlled within 1—10^{-4} atm by mixing purified oxygen and argon gases.

For the determination of δ-values in $(Fe_{1-y}Al_y)_{3-\delta}O_4$, it was assumed that δ is zero at the phase boundary between wüstite and the ferrites.[5] Such a condition was realized by adjusting the ratio of CO to CO_2 in CO–CO_2 gas mixtures. The nonstoichiometry δ was calculated from the difference in weight.

Corrections for bouyancy, thermomolecular force, and evaporation of platinum were made, based on the results of preliminary experiments.

Results

Nonstoichiometric data of $(Fe_{1-y}Al_y)_{3-\delta}O_4$ (y=0.25, 0.33) obtained in this research are shown in Figs. 1 and 2 as the isothermal curves of log δ *versus* log P_{O_2}. Nonstoichiometric data of magnetite have already been reported,[5] so they are not presented here again. At a constant oxygen partial pressure, the nonstoichiometry decreased with the increase in temperature. The same tendency was observed for Fe_3O_4. The value of δ increased with the increase in aluminum content at an oxygen partial pressure. The slope $(\partial \ln\delta/\partial \ln P_{O_2})$ seems

to decrease slightly with the increase in aluminium content. Thus the same defect model as was suggested for magnetite can perhaps interpret the nonstoichiometry of these solid solutions.

Defect Model

Nonstoichiometry. In the spinel structure, the anion sublattice forms the fcc lattice; thirty two oxide ions are contained in an unit cell. The unit cell also has sixty four tetrahedral cation sites (A-sites) and thirty two octahedral cation sites (B-sites). These cation sites are not completely occupied: only eight A-sites and sixteen B-sites are occupied.[6]

Magnetite is a metal-deficient type oxide. According to Roiter,[4] $Fe_{3-\delta}O_4$ and $FeAl_2O_4$ form a solid solution, which would be a metal-deficit type oxide, in analogy with magnetite. Effective negative charges created by cation vacancy formation are compensated by the conversion of Fe^{2+} ions into Fe^{3+} by the reaction

$$2Fe^{2+} + \frac{1}{2}O_2(g) \longrightarrow 2Fe^{3+} + \frac{3}{4}V_C + O_L^{2-}, \quad (1)$$

where V_C denotes a vacancy on a cation lattice site (A site or B site) and O_L^{2-} denotes an oxide ion on an anion sublattice site.

The mass action law for equilibrium (1) is given by

$$K_1 = \frac{[Fe^{3+}]^2[V_C]^{3/4}}{[Fe^{2+}]^2 P_{O_2}^{1/2}}. \quad (2)$$

Equation 2 implies that δ is proportional to $P_{O_2}^{2/3}$ as δ is proportional to V_C. The nonstoichiometric data reported so far[1-3] indicate the 2/3 power dependence on P_{O_2} in a small δ range. However, the exponent of P_{O_2} decreases with the increase in δ and reaches 0.33 for magnetite and 0.25 for spinel ferrites. Although Eq. 1 can interpret the nonstoichiometry in magnetite and spinel ferrites qualitatively, internal equilibria and site preference of cations and vacancies have to be taken into account to establish the defect equilibria in spinel ferrite. Thus the analysis was made considering the distribution of cations on A and B sublattices.

Site Preference and Random Distribution of Cations. As mentioned above, the solid solutions have two kinds of cation sites, A-sites and B-sites, on which Fe^{2+}, Fe^{3+}, Al^{3+}, and V_C are distributed. The numbers of Fe^{2+}, Al^{3+}, and V_C on the sublattice are regarded as independent variables. As a pliausble approximation, it can be assumed that the above cations and cation vacancies are distributed either preferentially on A-sites or B-sites or randomly on both sites. The combination of these three kinds of cations and vacancy and the three ways of distribution yields $27(=3^3)$ defect models. Investigations reported so far have elucidated the site preference of each kind of cation in spinel lattices. These results reduce the number of possible defect models. In the following the observed site preference is briefly reviewed.

A recent Mössbauer spectroscopy study by Daniels and Rosencweig[7] has shown that magnetite has an inverse spinel type crystal structure and Fe^{2+} and V_C has a B-site preference at room temperature. On the other hand, Takeuchi and Furukawa[8] suggested that Fe^{2+} is randomly distributed on A- and B-sites at high temperatures. Flood and Hill[9] also assumed a random distribution of Fe^{2+} ions. Dieckmann and Schmalzried[10] have recently analysed the nonstoichiometric data of magnetite based on their tracer diffusion data of Fe and concluded that Fe^{2+} is randomly distributed over A- and B-sites. Although a definite conclusion was not given on the site preference of cation vacancies, they have pointed out that the random distribution of cation vacancies is the most reasonable one to presume.

Trivalent aluminum ions have relatively strong B-site preference, as shown by the normal spinel structure of $FeAl_2O_4$. From his neutron diffraction study and magnetic susceptibility measurements on $FeAl_2O_4$, Roth[11] stated that the structure of $FeAl_2O_4$ can be expressed as $Fe_{0.923}Al_{0.077}(Fe_{0.077}Al_{1.923})O_4$.

Navrotsky and Kleppa[12] reviewed site preference in spinel lattice and evaluated the enthalpy change associated with the reaction:

$$Fe_A^{2+} + Al_B^{3+} \rightleftarrows Fe_B^{2+} + Al_A^{3+}$$

as 9.2 kcal mol^{-1}. They also evaluated the site preference energy of various kinds of cations in the spinel lattice and concluded that Al^{3+} ions have the strongest B-site preference among Fe^{2+}, Fe^{3+}, and Al^{3+} ions.

In summarizing the above investigations, it is concluded that Fe^{2+} and Al^{3+} ions and vacancies prefer B-sites at low temperatures and both ions and vacancy are likely to be distributed randomly at high temperatures. Thus, the twenty seven defect models are reduced to eight defect models. Table 1 shows the description of these eight defect models and the expressions of concentrations of Fe^{2+}, Fe^{3+}, Al^{3+} ions and vacancies V_C on A- and B-sites in terms of moles per mole of $(Fe_{1-y}Al_y)_{3-\delta}O_4$. Notations R and B designate the random distribution and the B-site preference, respectively. Details of the assignment of the concentration are given in Appendix A.

Equilibrium Constants. To determine which one of the eight models listed in Table 1 best interprets the observed nonstoichiometric data, we employed two methods of calculation, the quasi-chemical model (Q.C. model) and the band electron model (B.E. model).

Calculation by the Q.C. Model: In this model Fe^{2+}, Fe^{3+}, and Al^{3+} ions and vacancies are assumed to form an ideal solution in the cation sublattice.

TABLE 1. DESCRIPTION OF POSSIBLE MODELS AND CONCENTRATIONS OF CATIONS AND VACANCIES

a) R designates random distribution and B designates localization on B-sites.

The chemical potential of the oxygen equilibrated with the oxide can be obtained by the following equation:

$$\frac{1}{2}(\mu_{O_2}^{\circ}+kT\ln P_{O_2}) = \frac{\partial G(N_1, N_2, N_3, N_4, N_5)}{\partial N_5}, \quad (3)$$

where N_i's with subscripts 1, 2, 3, 4, and 5 are numbers of Fe^{2+}, Fe^{3+}, V_C, Al^{3+}, and O^{2-} in the crystal, respectively, and G is the Gibbs energy of the crystal. The number of sites to be occupied by vacancies is given by the equation

$$N_3 = \frac{3}{4}N_5 - (N_1+N_2+N_4) \equiv \frac{3}{4}(N_5-N_5^{\circ}), \quad (4)$$

where N_5° is the number of oxide ions at the stoichiometric composition. If cations and vacancies form an ideal solution, the Gibbs energy is expressed as follows:

$$G = \frac{N_5^{\circ}}{4}G^{\circ}(N_3=0) + N_3 g_V - TS_{config}, \quad (5)$$

where g_V is the Gibbs energy of forming a cation vacancy, G° is the Gibbs energy of the crystal when $\delta=0$. S_{config} is expressed by

$$S_{config} = k\ln W_A W_B = k\ln \frac{(N_5/4)}{N_1^A!N_2^A!N_3^A!N_4^A!}\frac{(N_5/2)}{N_1^B!N_2^B!N_3^B!N_4^B!}, \quad (6)$$

where superscripts A and B designate A- and B-sites.

Substituting Eqs. 4, 5, and 6 into Eq. 3, the following expression is obtained by a standard calculation:

$$\frac{1}{2}(\mu_{O_2}^{\circ}+kT\ln P_{O_2}) = \frac{3}{4}g_V - kT\sum_{i=1}^{4}\left[\left(\frac{\partial N_i^A}{\partial N_5}\right)\ln\left(\frac{4N_i^A}{N_5}\right) - \left(\frac{\partial N_i^B}{\partial N_5}\right)\ln\left(\frac{2N_i^B}{N_5}\right)\right]. \quad (7)$$

If we express the concentration, the number of moles in one of $(Fe_{1-y}Al_y)_{3-\delta}O_4$, by the notation C_i^j, using a meaning similar to N_i^j, C_i^j can be related to N_i^j and N_5 as follows:

$$C_i^j = 4N_i^j/N_5 \quad (j=A, B;\ i=1, 2, 3, 4). \quad (8)$$

The differentials $(\partial N_i^j/\partial N_5)$ can be expressed by C_i^j

and as follows:

$$\left(\frac{\partial N_i^{\mathrm{j}}}{\partial N_5}\right) = \frac{1}{4}\left(\frac{\partial C_i^{\mathrm{j}} N_5}{\partial N_5}\right) = \frac{1}{4}\left(C_i^{\mathrm{j}} + N_5\frac{\partial C_i^{\mathrm{j}}}{\partial N_5}\right)$$
$$= \frac{1}{4}\left(C_i^{\mathrm{j}} + \frac{3}{4}N_5\frac{\partial C_i^{\mathrm{j}}}{\partial N_3}\right)$$
$$= \frac{1}{4}\left(C_i^{\mathrm{j}} + 3N_5\frac{N_5^\circ}{N_5^2}\frac{\partial C_i^{\mathrm{j}}}{\partial\delta}\right)$$
$$= \frac{1}{4}\left[C_i^{\mathrm{j}} + \frac{3\left(N_5 - \frac{4}{3}N_3\right)}{N_5}\left(\frac{\partial C_i^{\mathrm{j}}}{\partial\delta}\right)\right]$$
$$= \frac{1}{4}\left[C_i^{\mathrm{j}} + (3-\delta)\left(\frac{\partial C_i^{\mathrm{j}}}{\partial\delta}\right)\right]. \quad (9)$$

In the above calculations the following relations are used, besides Eqs. 4 and 8:

$$\delta = \frac{4N_3}{N_5} = \frac{4N_3}{N_5^\circ + \frac{4}{3}N_3},$$

$$\mathrm{d}\delta = \frac{4N_5^\circ}{N_5^2}\mathrm{d}N_3.$$

Substituting Eqs. 8 and 9 into Eq. 7, we obtain the following expression:

$$\frac{1}{2}(\mu_{\mathrm{O}_2}^\circ + kT\ln P_{\mathrm{O}_2}) = \frac{3}{4}g_{\mathrm{V}} - kT\sum_{i=1}^{4}\left[\left(C_i^{\mathrm{A}} + (3-\delta)\frac{\partial C_i^{\mathrm{A}}}{\partial\delta}\right)\right.$$
$$\left.\times\ln C_i^{\mathrm{A}} + \left(C_i^{\mathrm{B}} + (3-\delta)\frac{\partial C_i^{\mathrm{B}}}{\partial\delta}\right)\ln(C_i^{\mathrm{B}}/2)\right].$$

Putting

$$\nu_i^{\mathrm{j}} \equiv \left(\frac{\partial N_i^{\mathrm{j}}}{\partial N_5}\right) = \frac{1}{4}\left[C_i^{\mathrm{j}} + (3-\delta)\frac{\partial C_i^{\mathrm{j}}}{\partial\delta}\right] \quad (10)$$
$$i = 1, 2, 3, 4;\ \mathrm{j} = \mathrm{A}, \mathrm{B},$$

we obtain

$$\prod_{i=1}^{4}(C_i^{\mathrm{A}})^{-\nu_i^{\mathrm{A}}}\prod_{i=1}^{4}(C_i^{\mathrm{B}}/2)^{-\nu_i^{\mathrm{B}}}P_{\mathrm{O}_2}^{-1/2}$$
$$= \exp\left[\left(\frac{1}{2}\mu_{\mathrm{O}_2}^\circ - \frac{3}{4}g_{\mathrm{V}}\right)\Big/kT\right].$$
$$\equiv K(\mathrm{QC}) \quad (11)$$

Equation 11 is the mass action law for the following defect equilibrium:

$$\nu_1^{\mathrm{A}}\mathrm{Fe_A}^{2+} + \nu_2^{\mathrm{A}}\mathrm{Fe_A}^{3+} + \nu_3^{\mathrm{A}}\mathrm{V_A} + \nu_4^{\mathrm{A}}\mathrm{Al_A}^{3+} + \nu_1^{\mathrm{B}}\mathrm{Fe_B}^{2+}$$
$$+ \nu_2^{\mathrm{B}}\mathrm{Fe_B}^{3+} + \nu_3^{\mathrm{B}}\mathrm{V_B} + \nu_4^{\mathrm{B}}\mathrm{Al}^{3+} + \frac{1}{2}\mathrm{O_2(g)} = 0. \quad (12)$$

By using the expressions for C_i^{j} in Table 1, the stoichiometric coefficient ν_i^{j} is calculated by Eq. 10. The results are given in Table 2. Details are given in Appendix B. Let us term the defect models described by Eq. 12 as QC-1, QC-2, ···, QC-8 models.

Thus the defect equilibrium equations and the mass action laws can be written explicitly. For example, the equilibrium for model QC-3 is

$$\frac{1}{4}\frac{7+3\delta}{3-\delta}\mathrm{Fe_A}^{2+} + \frac{17-11\delta}{4(3-\delta)}\mathrm{Fe_B}^{2+} + \frac{y}{4}\mathrm{Al_B}^{3+} + \frac{1}{2}\mathrm{O_2(g)}$$
$$\rightleftarrows \left[\frac{5+\delta}{2(3-\delta)} - \frac{y}{2}\right]\mathrm{Fe_A}^{3+} + \left[\frac{7-5\delta}{2(3-\delta)} + \frac{y}{2}\right]\mathrm{Fe_B}^{3+}$$
$$+ \frac{3}{4}\mathrm{V_B} + \frac{y}{4}\mathrm{Al_A}^{3+} + \mathrm{O_L}^{2-}.$$

In this equation the stoichiometric coefficients depend on δ. When equilibrium constants are calculated using Eq. 11 and the expressions of concentration listed in Table 1, δ is canceled in the powers of concentrations and simple expressions are obtained. For example, the equilibrium constant for model QC-3 can be expressed as

$$K(\mathrm{QC\text{-}3}) = \left(\frac{2}{2-\delta}\right)^{1/4}\left(\frac{2+2\delta-(3-\delta)y}{1-3\delta}\right)^2\left(\frac{\delta}{2}\right)^{3/4}P_{\mathrm{O}_2}^{-1/2}$$

Thus equilibrium constants are easily calculated using observed values of δ and P_{O_2}.

Equilibrium Constants Calculated by the B. E. Model: In the band electron model, Fe^{2+} ions on B-sites are regarded as electron donors in a 3-d band. This is a consequence of the observation that the electric conduction in magnetite and spinel ferrites is caused by the electron movements in a narrow 3-d band formed by Fe ions on B-sites.[13]

Samokhvalov and his co-investigators[14] have measured the electrical conductivity and thermoelectric power of solid solutions of the zinc ferrite-magnetite and nickel ferritemagnetite systems and derived the following expression for the chemical potential of an electron on a B-site:

$$\mu_{e_B^-} = E_C - kT\ln\frac{1}{2}\left[\frac{N_O}{N_D} - 1 + \sqrt{\left(1-\frac{N_O}{N_D}\right)^2 + 4\left(\frac{N_O}{N_D}\right)\exp(E_D/kT)}\right], \quad (13)$$

where E_D is the difference in energy level between the bottom of the conduction band and the donor level, and N_O and N_D are the densities of state of the conduction band and the donor level, respectively. In the present system, N_O and N_D are given as follows:

$$N_O = [Fe_B^{2+}] + [Fe_B^{3+}],$$
$$N_D = [F_Be^{2+}].$$

At high temperatures, the second term in the square root in Eq. 13 can be eliminated and Eq. 13 can be reduced to

$$\mu_{e_B^-} = E_C + kT\ln\frac{N_D}{N_O} = E_C + kT\ln\frac{C_1^B}{C_1^B+C_2^B}. \quad (14)$$

As Fe^{2+} is regarded as $e_B^- + Fe_B^{3+}$, the defect equilibrium is expressed by replacing Fe_B^{2+} in Eq. 12 by $e_B^- + Fe_B^{3+}$. Thus,

$$\nu_1^A Fe_A^{2+} + \nu_2^A Fe_A^{3+} + \nu_3^A V_A + \nu_4^A Al_A^{3+} + \nu_1^B e_B^- + (\nu_1^B+\nu_2^B)Fe_B^{3+} + \nu_3^B V_B + \nu_4^B Al_B^{3+} + \frac{1}{2}O_2 = 0. \quad (15)$$

The mass action law for Eq. 15 is

$$K(BE) = \prod_{i=1}^{4}(C_i^A)^{-\nu_i^A}\prod_{i=1}^{4}(C_i^B/2)^{-\nu_i^B}\left(\frac{C_2^B}{C_1^B+C_2^B}\right)^{-\nu_1^B} = K(QC)\left(\frac{C_2^B}{C_1^B+C_2^B}\right)^{-\nu_1^B}. \quad (16)$$

Fundamental aspects of Eqs. 15 and 16 are described in Appendix B. Let us term the defect models described by Eq. 16 as BE-1, BE-2, ···, and BE-8 models.†

The defect equilibrium equation and mass action law for model BE-3 are, for example,

$$\frac{7+3\delta}{4(3-\delta)}Fe_A^{2+} + \frac{17-11\delta}{4(3-\delta)}e_B^- + \frac{1}{4}(1-2y)Fe_B^{3+} + \frac{y}{4}Al_B^{3+} + \frac{1}{2}O_2 \rightleftarrows \frac{5+\delta}{2(3-\delta)}Fe_A^{3+} + \frac{y}{4}Al_A^{3+} + \frac{3}{4}V_B + O_L^{2-}$$

and

$$K(BE\text{-}3) = \left(\frac{2}{2-\delta}\right)^{1/4}\left(\frac{2+2\delta-y(3-\delta)}{1-3\delta}\right)^2\left(\frac{\delta}{2}\right)^{3/4} \times\left[\frac{2(1+\delta)-y(3-\delta)}{(3-\delta)(1-y)}\right]^{17-11\delta/4(3-\delta)} P_{O_2}^{-1/2}.$$

In this way equilibrium constants for each respective model can be easily calculated by using Eq. 16, using the expressions of ν_i^j and C_i^j in Tables 1 and 2, and the experimental values of δ and P_{O_2}.

† There may arise a question about applying Eq. 14 to models 5—8, where $C_2^B \leq C_1^B$. As no observation has been reported as to the characteristics of an electron band on B-sites if $[Fe_B^{3+}] \lesssim [Fe_B^{2+}]$, Eq. 14 was provisionally assumed to work for models 5—8.

Discussion

Criteria for the Selection of the "best" Model. In order to select the best one of these sixteen defect models, some criteria are necessary. Usually the slope of the log δ *vs.* log P_{O_2} plot is used for the selection. However, the slopes are 2/3 at small values of δ for several models, and also vary with δ. Thus this simple criterion is inadequate for the present purpose. Since the equilibrium constant K should be constant if the model is appropriate, the criteria that the dependence of ln$K$ on δ, as well as the dependence of ln$K$ on y, should be smallest for the "best" model were adopted for the selection. The advantage of this criteria is that one can easily detect the differences among the defect models.

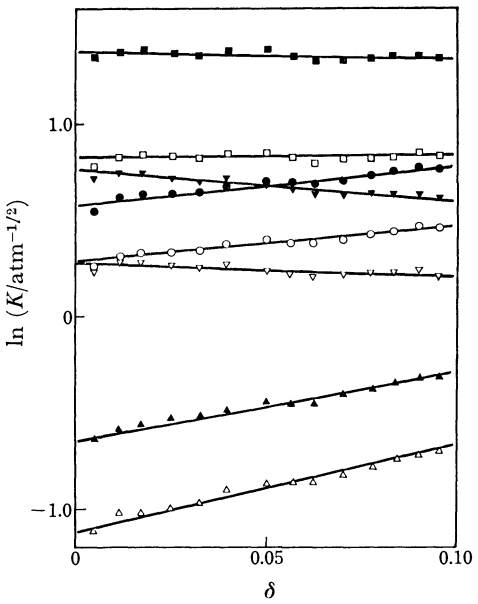

Fig. 3. Values of ln$K$ for respective defect model of $Fe_{3-\delta}O_4$.

Analysis of Nonstoichiometric Deta. The equilibrium constants for equilibria 1 to 8 were calculated using Eqs. 11 and 16 and the observed values of δ and P_{O_2}. Figure 3 illustrates the dependence of ln$K$ on δ for $Fe_{3-\delta}O_4$ at 1400 °C. As $y=0$ for magnetite, only the eight equilibrium constants given in this figure were calculated. As is easily seen, ln$K$ changes almost linearly with δ for all the models. The equilibrium constants changed similarly with δ for solid solutions with aluminum ferrite. Thus the relationship between ln$K$ and δ can approximately be represented by the equation

$$\ln K = \alpha\delta + \beta. \quad (17)$$

The value α gives the slope of the ln$K$-δ plot and, according to the critetia adopted above, the model with the samllest absolute value of α is the "best" one.

Figure 4 illustrates the values of α for $(Fe_{0.75}Al_{0.25})_{3-\delta}$-

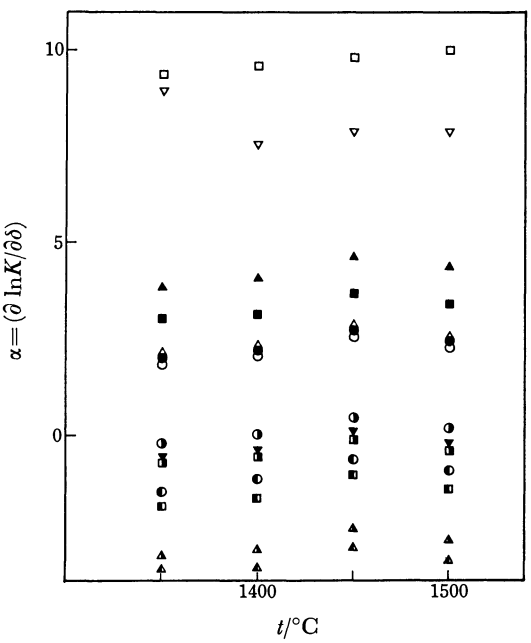

Fig. 4. Values of α for respective defect model of $(Fe_{0.75}Al_{0.25})_{3-\delta}O_4$.
○: QC-1, ●: QC-3, △: QC-4, ▲: QC-5, □: QC-6, ■: QC-7, ▽: QC-8 ▼: BE-1, ◑: BE-2, ◐: BE-3, ◨: BE-5 ◧: BE-6, ◭: BE-7, ◮: BE-8.

O_4. Those for model QC-2 are not given because K(QC-2) has the same value as K(QC-1). Those for model BE-4 are also excluded, since their absolute values are too large. As is easily seen in this figure, the value for QC-1 was the smallest among the QC models, although the differences from those for the QC-3 and QC-4 models. are small. A Similar conclusion has been reached by Dieckmann and Schmalzried[10] in their analysis of the tracer diffusion and nonstoichiometry of magnetite.

The α values for the BE-1 and BE-2 models are very small. They are smaller then those for the QC-1 model and it is concluded that the "best" model would be either the BE-1 or the BE-2 model. But it is difficult to choose the better one of the two only from this figure. A similar calculation was made for $Fe_{3-\delta}O_4$ and $(Fe_{0.67}Al_{0.33})_{3-\delta}O_4$. Figure 5 shows the values of α for K(BE-1)

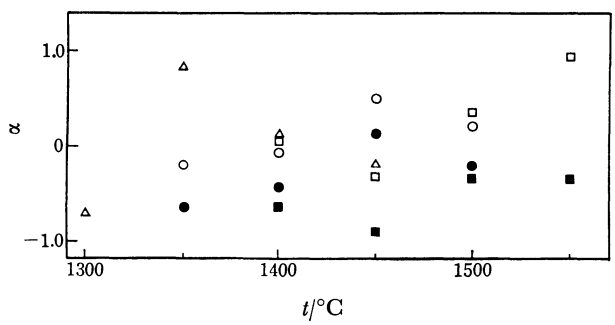

Fig. 5. Values of α for BE-1 and BE-2 models. The open and the solid marks denote the values for BE-1 and BE-2 models, respectively.
△ and ▲: $Fe_{3-\delta}O_4$, ○ and ●: $(Fe_{0.75}Al_{0.25})_{3-\delta}O_4$, □ and ■: $(Fe_{0.67}Al_{0.33})_{3-\delta}O_4$.

and K(BE-2). As is seen from Table 2, values of ν_i^j are the same for models 1 and 2 if $y=0$: Thus the values of α of the BE-1 and BE-2 models are the same for $Fe_{3-\delta}O_4$.

Except for some cases (1500 °C for $y=0.25$, and 1500 and 1550 °C for $y=0.33$), the absolute values of α are smaller for the BE-2 model than for the BE-1 model. This preference for the BE-2 model is also supported by the dependence of $\ln K$ on y. Figure 6 shows the plot of $\ln K$ against y. Clearly equilibrium constants for the BE-2 model depend less on y than those for the BE-1 model. The result indicates that the BE-2 model is better than the BE-1 model and, therefore, the BE-2 model was chosen as the "best" model in this investigation.

BE-2 Model and Equilibrium Constant. The BE-2 model which has been chosen as the "best" model can be characterized as follows:
(1) Fe^{2+}, Fe^{3+} ions, and vacancies distribute randomly on A- and B-sites.
(2) Al^{3+} ions are localized on B-sites.
(3) Fe^{2+} and Fe^{3+} ions on B-sites provide a narrow d-band whose Fermi level can be approximated by Eq. 14.
The explicit expression of the defect equilibrium and

Table 3. Values of $\ln K$(BE-2)

T/°C	$\ln(K/\mathrm{atm}^{-1/2})$		
	$y=0$	$y=0.25$	$y=0.33$
1300	1.767± 0.007		
1350	1.219± 0.002	1.493± 0.006	
1400	0.833± 0.01	1.11± 0.01	1.231± 0.002
1450	0.547± 0.003	0.709± 0.01	0.843± 0.008
1500		0.305± 0.0002	0.463± 0.007
1550			0.110± 0.004
$\Delta H°$/kcal mol^{-1}	−43.7± 3.6	−45.3± 1.3	−45.7± 0.9
$\Delta S°$/cal K^{-1} mol^{-1}	−24.4± 2.2	−24.9± 0.8	−24.9± 0.5

Figures after ± signs are standard deviations.

the equilibrium constant are given as follows:

$$\frac{2}{3(1-y)}Fe_A^{2+} + \frac{2(2-3y)}{3(1-y)}e_B^- + \frac{1}{2}O_2(g) \rightleftarrows \frac{2}{3(1-y)}Fe_A^{3+} + \frac{1}{4}V_A + \frac{1}{2}V_B + O_L^{2-}, \quad (18)$$

$$K(\text{BE-2}) = \left[\frac{(3-\delta)(1-y)}{1-3\delta}\right]^{2(2-3y)/3(1-y)} \times \left[\frac{2+2\delta-y(3-\delta)}{1-3\delta}\right]^{2/3(1-y)} \left(\frac{\delta}{3}\right)^{3/4} P_{O_2}^{-1/3}. \quad (19)$$

Table 3 gives the values of $\ln K(\text{BE-2})$ together with values of $\Delta H°$ and $\Delta S°$ for Reaction 18. It is noteworthy that $\Delta H°$ and $\Delta S°$ are negative and almost independent of y.

The large negative values of $\Delta S°$ would be due to the disappearance of $O_2(g)$ and e_B^- in Reaction 18. The large negative value of $\Delta H°$ comes mainly from the negative partial molar enthalpy of oxygen in magnetite and its solid solutions with $FeAl_2O_4$.

Appendix

A. Assignment of Concentration of Ions and Vacancy. The concentrations of ions and vacancies for respective model are given in Table 1 in terms of moles in one mole of $(Fe_{1-y}Al_y)_{3-\delta}O_4$. One mole of $(Fe_{1-y}Al_y)_{3-\delta}O_4$ has 1 and 2 mol of A- and B-sites, respectively. Over these 3 mol of cation sites, $1-\delta$, $[2(1+\delta)-y(3-\delta)]$, $y(3-\delta)$, and δ mol of Fe^{2+}, Fe^{3+}, Al^{3+} ions, and vacancies, respectively, are distributed.

To elucidate the concentrations on the A- and B-sites the following procedure was adopted.

1) First, the concentration of vacancies was assigned. In the case of random distribution vacancies were assumed to be distributed in the ratio of 1:2 over A and B sites. If the vacancy is localized on a B-site, the concentration of the B-site is δ and that on the A-site is 0.

2) Concentrations of localized Fe^{2+} and/or Al^{3+} ions are assigned in the second step. When they are localized on a B-site, the concentrations on the B-site are $1-3\delta$ and $y(3-\delta)$ for Fe^{2+} and Al^{3+} ions, respectively. Concentrations on an A-site are 0 when they are localized on a B-site.

3) Concentrations of randomly distributed Fe^{2+} and/or Al^{3+} ions are determined in the third step. In this calculation, it was assumed that the concentration on A- or B-site is proportional to the number of sites still remaining at this step. For example, in model 5 the concentrations of Fe^{2+} and V_C are already assigned and the numbers of remaining sites are $1-\delta/3$ and $(3+7\delta)/3$ for A- and B-sites, respectively. Thus the concentration of Al^{3+} on A-site is calculated as

$$y(3-\delta) \times \frac{(1-\delta/3)}{(1-\delta/3)+(3+7\delta)/3} = \frac{y(3-\delta)^2}{6(1+\delta)}.$$

4) Finally the concentration of Fe^{3+} ion is assigned by allotting them on the remaining cationic sites.

B. Stiochiometric Coefficients and Equilibrium Conditions.

Equation 11 implies that a mass action law holds between the defects in the crystal of $(Fe_{1-y}Al_y)_{3-\delta}O_4$. The stoichiometric coefficients can be calculated by using Eq. 10. An illustration is given below for model 2.

The expressions for stoichimetric coefficients, ν_i^j's are calculated by using the expressions in Table 1 for C_i^j's. For example, ν_1^A is calculated as follows:

$$\nu_1^A = \frac{1}{4}\left[C_1^A + (3-\delta)\frac{\partial C_1^A}{\partial \delta}\right] = \left[\frac{1-3\delta}{3(1-y)} + (3-\delta)\frac{-3}{3(1-y)}\right]\Big/4 = -2/3(1-y).$$

Other coefficients are calculated in the same way; the results are given in Table 2. Using these values of ν_i^j's, Eq. 11 is written as follows:

$$(C_1^A)^{-2/3(1-y)} \cdot (C_2^A)^{2/3(1-y)} \cdot (C_3^A)^{1/4} \cdot (C_1^B/2)^{-2(2-3y)/3(1-y)} \times (C_2^B/2)^{2(2-3y)/3(1-y)} \cdot (C_3^B/2)^{1/2} \cdot P_{O_2}^{-1/2} = \frac{[V_A]^{1/4}[Fe_A^{3+}]^{2/3(1-y)}([V_B]/2)^{1/2}([Fe_B^{3+}]/2)^{2(2-3y)/3(1-y)}}{[Fe_A^{2+}]^{2/3(1-y)}([Fe_B^{2+}]/2)^{2(2-3y)/3(1-y)} P_{O_2}^{1/2}} = \exp\left[\frac{1}{2}\left(\mu_{O_2}^\circ - \frac{3}{4}g_v\right)\Big/kT\right]. \quad (A\text{-}1)$$

Equation A-1 implies that the defect equilibrium for this model can be described by the following chemical equilibrium:

$$\frac{2}{3(1-y)}Fe_A^{2+} + \frac{2(2-3y)}{3(1-y)}Fe_B^{2+} + \frac{1}{2}O_2 \rightleftarrows \frac{2}{3(1-y)}Fe_A^{3+} + \frac{2(2-3y)}{3(1-y)}Fe_B^{3+} + \frac{1}{4}V_A + \frac{1}{2}V_B. \quad (A\text{-}2)$$

The equilibrium condition for Eq. A-2 can also be expressed in terms of chemical potential of defects as follows:

$$\frac{2}{3(1-y)}\mu(Fe_A^{3+}) + \frac{2(2-3y)}{3(1-y)}\mu(Fe_B^{3+}) + \frac{1}{4}\mu(V_A) + \frac{1}{2}\mu(V_B) - \frac{2}{3(1-y)}\mu(Fe_A^{2+}) - \frac{2(2-3y)}{3(1-y)}\mu(Fe_B^{2+}) - \frac{1}{2}\mu_{O_2} = 0. \quad (A\text{-}3)$$

Thus the general expression of the defect equilibria, Eq. 11, implies the equilibrium condition in terms of the chemical potential, μ_i^j, of the i-th ion on the j site.

$$\frac{1}{2}\mu_{O_2} + \sum_{\substack{j=A,B \\ i=1,2,3,4}} \nu_i^j \mu_i^j = 0. \quad (A\text{-}4)$$

The conduction electrons in the BE models are considered to be created by the ionization of Fe_B^{2+} ions and the following virtual equilibrium is conceived.

$$Fe_B^{2+} \rightleftarrows Fe_B^{3+} + e_B^-. \quad (A\text{-}5)$$

For this equilibrium the following expression holds for the chemical potential of Fe_B^{2+} ions:

$$\mu(Fe_B^{2+}) = \mu(Fe_B^{3+}) + \mu_{e_B^-}. \quad (A\text{-}6)$$

Incorporating Eq. A-6 into A-4, an equilibrium conditions for BE modles is obtained:

$$\frac{1}{2}\mu_{O_2} + \nu_{Fe^{2+}}^A\mu(Fe_A^{2+}) + \nu_{Fe^{3+}}^A\mu(Fe_A^{3+}) + \nu_{V_C}^A\mu(V_A) + \nu_{Al^{3+}}^A\mu(Al_A^{3+}) + \nu_{Fe^{2+}}^B[\mu(Fe_B^{3+}) + \mu_{e_B^-}] + \nu_{Fe^{3+}}^B\mu(Fe_B^{3+}) + \nu_{V_C}^B\mu(V_B) + \nu_{Al^{3+}}^B\mu(Al_B^{3+}) = 0. \quad (A\text{-}7)$$

Equation A-7 implies the mass action law, Eq. 16, and the equilibrium equation, Eq. 15, for defect equilibrium, when BE models are adopted.

The Solvent Extraction of Bivalent Metal Picrates by 15-Crown-5, 18-Crown-6, and Dibenzo-18-crown-6

Yasuyuki TAKEDA* and Hisanori KATŌ

Department of Chemistry, Faculty of Science, Chiba University, Yayoi-chō, Chiba 280

(Received August 30, 1978)

The overall extraction equilibrium constants (K_{ex}) for the 1 : 1 : 2 complexes of 15-crown-5 (15C5), 18-crown-6 (18C6), and dibenzo-18-crown-6 (DB18C6) with several bivalent metal picrates between benzene and water have been determined at 25 °C. The K_{ex} sequences of the bivalent metal ions with 15C5, 18C6, and DB18C6 are $Pb^{2+}>Sr^{2+}>Ba^{2+}>Ca^{2+}$, $Pb^{2+}\gg Ba^{2+}=Sr^{2+}>Hg^{2+}>Ca^{2+}$, and $Pb^{2+}>Hg^{2+}>Sr^{2+}>Ca^{2+}$ respectively. To clarify the role of the crown ether in the extraction process, the three constituent equilibria have been investigated: the stability and the extractability of the bivalent metal ion–crown ether complex, and the distribution coefficient of the crown ether. The extractability of the bivalent metal ion–crown ether complex about the same bivalent metal ion increases with increasing size of the crown ether, and appears to be dependent on the chemical nature of the bivalent metal ion trapped in the cavity of the crown ether.

The complex reaction between crown ethers and cations has been widely studied by different methods *e.g.* conductance,[1] calorimetry,[2] potentiometry,[3] spectroscopy,[4] and solvent extraction.[5] It has been found that the crown ether has a remarkable capacity to form stable stoichiometric complexes with certain cations, particularly with the alkali and alkaline earths.

Solvent extraction is a useful method to investigate the complexing power of crown ethers towards cations, though it is not direct. Some solvent extraction studies of crown ether complexes with alkali metal ions have been reported,[5] but there are very little data on bivalent metals. In terms of the analytical application, it is important to investigate the selectivity of crown ethers for various bivalent metal ions in solvent extraction systems. The present study was undertaken to determine the extraction constants for the crown ether–bivalent metal picrate systems between benzene and water, and to clarify the role of the crown ether in the extraction process. The crown ethers included in this work are 15-crown-5 (15C5), 18-crown-6 (18C6), and dibenzo-18-crown-6 (DB18C6). The sizes of these three compounds differ from one another. The cavity size of DB18C6 is equal to that of the 18C6,[3] though the former has two benzo groups. In the cases of DB18C6 and 18C6, it is interesting to investigate the ligand ring substituent effect on the extraction equilibrium. Since a large anion is easily extracted into low dielectric constant solvents,[5d] the picrate anion was used as the counter ion. Benzene was used as the diluent because of its nonpolar nature.

Experimental

Apparatus. Emission and absorption measurements were conducted on Seiko atomic absorption spectrophotometers, models SAS-720 and SAS-725. pH-measurements were made on a Hitachi-Horiba pH meter, model F-5.

Materials. 15C5 and 18C6 were obtained from Nisso Co., Ltd., and DB18C6 from Aldrich Chemical Co., Inc. 15C5 was used without further purification. 18C6 was recrystallized from petroleum ether twice, and dried in a vacuum oven before use. The method of purification of DB18C6 has been described in the literature.[1b] Benzene, HNO_3, $Ca(NO_3)_2\cdot 4H_2O$, $Sr(NO_3)_2$, $Ba(NO_3)_2$, $Hg(NO_3)_2\cdot xH_2O$, and $Pb(NO_3)_2$ were special grade reagents from Wako-Pure Chemicals Ltd., and picric acid from Koso Chemical Co., Ltd. The purity of the bivalent metal nitrates and the concentration of the picric acid solution were determined by EDTA and basic titration, respectively. Benzene was washed twice with distilled water.

Procedure. The organic solution of the crown ether (2×10^{-5}—3×10^{-2} M), the aqueous solution of the bivalent metal nitrate (5×10^{-4}—2.5×10^{-2} M), picric acid (1.5×10^{-4}—1.7×10^{-2} M), and nitric acid (2×10^{-3} M) were placed in stoppered glass tubes (volume 30 ml). The initial volume of each phase was 10 ml in all cases. The two phases in the tubes were shaken in a thermostatted water bath for approx. 30 min at 25±0.2 °C, and centrifuged. An approx. 8 ml portion was removed from the aqueous phase, transferred to a 10 ml beaker and the hydrogen ion concentration determined by a pH meter. All extractions were conducted in the pH range 1.5—3.0. For the systems 15C5–Ca, Sr, Pb, and 18C6–Ca, Sr, Hg, Pb, a 8 ml portion was pipetted from the organic phase, transferred to a 50 ml beaker, and left for several days, until evaporation was complete. The residue was dissolved in 0.01 M nitric acid 8 ml, and the metal concentration determined by atomic absorption. In the 15C5 and 18C6–Ba, and DB18C6–Ca, Sr, Hg, Pb systems, the residue did not dissolve. Consequently, the bivalent metal in the organic phase was back-extracted into 1 M nitric acid 8 ml and the Ba concentration of this aqueous phase determined by flame photometry. For the 15C5–Hg system, it was impossible to extract any Hg into the organic phase. For the DB18C6–Ba system, turbidity was always found in the interface between benzene and water under all experimental conditions.

The Distribution Coefficient of the Crown Ether. A portion of the benzene solution containing the crown ether and an equal volume of distilled water were placed in a stoppered glass tube and shaken under the same conditions as before. The concentration ranges of 15C5 and 18C6 were from 5.1×10^{-2} to 3.3×10^{-1} M, and from 2.8×10^{-2} to 3.1×10^{-1} M, respectively. After the two phases had been separated by centrifuging, a portion of the organic phase 12 ml was transferred to a 10 ml beaker, left for several days until evaporation was complete, and the residue weighed. The average distribution coefficients determined in this way are listed in Table 1, together with the equilibrium constants of the bivalent metal ion–crown ether complexes.

Results

The overall extraction equilibrium between an

aqueous phase containing the bivalent metal cation, M^{2+}, the picrate anion, A^-, and the hydrogen ion, H^+, and an organic phase of the crown ether, L, may be represented by the following equation:

$$M^{2+} + L_0 + 2HA_0 \rightleftarrows MLA_{2,0} + 2H^+$$

$$K_{ex} = \frac{[MLA_2]_0[H^+]^2}{[M^{2+}][L]_0[HA]_0^2}, \quad (1)$$

where MLA_2 represents the ion pair between the bivalent metal–crown ether cation, ML^{2+}, and the picrate anion; the subscript "0" and the absence of subscript denote the organic phase and aqueous phase, respectively. The overall extraction equilibrium is thought to consist of the following equilibria:

○ the distribution of the free crown ether between the two phases

$$L \rightleftarrows L_0 \qquad K_{D,L} = \frac{[L]_0}{[L]}, \quad (2)$$

○ the complex reaction of the bivalent metal ion with the crown ether

$$M^{2+} + L \rightleftarrows ML^{2+} \qquad K_{ML} = \frac{[ML^{2+}]}{[M^{2+}][L]}. \quad (3)$$

Several stability constants of bivalent metal ion–crown ether complexes have been reported.[2a,2b,2c,4] They are listed in Table 1.

○The distribution of picric acid between the two phases

$$HA \rightleftarrows HA_0 \qquad K_{D,HA} = \frac{[HA]_0}{[HA]}, \quad (4)$$

○ the association of picric acid

$$H^+ + A^- \rightleftarrows HA \qquad K_{HA} = \frac{[HA]}{[H^+][A^-]}, \quad (5)$$

○ the association of the complexed cation with the picrate anion

$$ML^{2+} + 2A^- \rightleftarrows MLA_2 \qquad K_{MLA_2} = \frac{[MLA_2]}{[ML^{2+}][A^-]^2}, \quad (6)$$

○ the distribution of the ion pair between the two phases

$$MLA_2 \rightleftarrows MLA_{2,0} \qquad K_{D,MLA_2} = \frac{[MLA_2]_0}{[MLA_2]}. \quad (7)$$

Since benzene is a nonpolar solvent (ε=2.275 at 25 °C[6]), dissociation of the ion pair, MLA_2, has been assumed negligible. Thus,

$$K_{ex} = K_{D.L}^{-1}K_{ML}K_{D.HA}^{-2}K_{HA}^{-2}K_{ex'}, \quad (8)$$

where $$K_{ex'} = K_{MLA_2}K_{D.MLA_2} = \frac{[MLA_2]_0}{[ML^{2+}][A^-]^2}. \quad (9)$$

The all-activity coefficients of the chemical species in this work have been assumed as unity.

The distribution ratio of the bivalent metal has been defined as follows and calculated from the experimental data,

$$D_M = \frac{[M]_{0,total}}{[M]_{total}},$$

where $[M]_{0,total}$ and $[M]_{total}$ are the total bivalent metal concentrations in the organic and aqueous phases, respectively. Assuming that the association between ML^{2+} and A^- is negligible in the aqueous phase;

$$D_M = \frac{[MLA_2]_0}{[M^{2+}]+[ML^{2+}]}. \quad (10)$$

In the case of $[M^{2+}] \gg [ML^{2+}]$, Eq. 10 becomes

$$D_M = K_{ex}K_{HA}^2K_{D.HA}^2[A^-]^2[L]_0, \quad (11)$$

where $K_{HA}K_{D,HA}$ is the extraction equilibrium constant of picric acid. The value of $K_{HA}K_{D,HA}$ in the benzene–water system at 25 °C has been determined to be 247 by spectroscopy using the association constant of picric acid, K_{HA}=1.95.[7] $[A^-]$ in Eq. 11 was calculated from Eq. 12, for the systems of 15C5–Sr, Ba, Pb, and 18C6–Sr, Ba, Hg, Pb, $[L]_0$ in Eq. 11 from Eq. 13 using the stability constants, K_{ML}'[2b] given in Table 2, and for the others $[L]_0$ by Eq. 14.

$$[A^-] = \frac{[HA]_{i.t.}-2[MLA_2]_0}{1+(1+K_{D,HA})K_{HA}[H^+]}, \quad (12)$$

$$[L]_0 = \frac{[L]_{i.t.}-[MLA_2]_0}{1+K_{D.L}^{-1}+K_{ML}K_{D.L}^{-1}[M^{2+}]}, \quad (13)$$

$$[L]_0 = \frac{[L]_{i.t.}-[MLA_2]_0}{1+K_{D.L}^{-1}}, \quad (14)$$

where $[HA]_{i.t.}$ and $[L]_{i.t.}$ are the initial total concentrations of picric acid and crown ether, respectively. $\log(D_M/[A^-]^2)$ *vs.* $\log[L]_0$ plots are illustrated in Figs. 1—3. Figures 1, 2, and 3 correspond to 15C5, 18C6, and DB18C6 respectively. From Figs. 1—3 it may be seen that the plots are linear with a slope of unity. $\log(D_M/[L]_0)$ *vs.* $\log[A^-]$ curves in Fig. 4 are linear with a slope of 2. It has then been concluded that the overall

○: 15C5, ⊙: 18C6, ●: DB18C6.

extraction equilibrium, K_{ex}, in the present study is described by Eq. 1. For each system the value of the overall extraction equilibrium constant calculated from the data of Figs. 1—3 was found to agree well with that of Fig. 4. The K_{ex} values are given in Table 1.

Discussion

The crystal ionic radii of the bivalent metals and the cavity radii of the crown ethers are listed in Table 2. It may be noted from Tables 1 and 2 that for the 18C6 system $\log K_{ex}$ for Sr^{2+} is identical with that of Ba^{2+} which has a more optimum size for the 18C6 cavity than Sr^{2+}. The $\log K_{ex}$ and $\log K_{ML}$ values have been plotted *vs.* the crystal ionic radius in Fig. 5. As can be

Table 1. Equilibrium constants at 25 °C

Crown ether	$K_{D,L}$	Cation	$\log K_{ex}$	$\log K_{ML}$	$\log K_{ex'}$
15C5	0.15_6	Ca^{2+}	−1.07	—	—
		Sr^{2+}	0.91	1.95[2b]	2.94
		Ba^{2+}	0.41	1.71[2b]	2.68

Table 2. Crystal ionic radii of bivalent metals and cavity radii of crown ethers (Å)

Cation	Crystal ionic radius	Crown ether	Cavity radius[3]
Ca^{2+}	0.99[8]	15-crown-5	0.85—1.1
Sr^{2+}	1.13[8]	18-crown-6	1.3 —1.6
Ba^{2+}	1.35[8]		
Hg^{2+}	1.10[8]		
Pb^{2+}	1.20[9]		

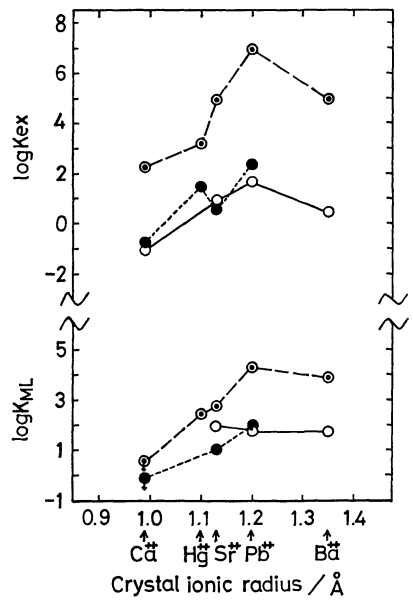

Fig. 5. Plots of $\log K_{ex}$ and $\log K_{ML}$ *vs.* crystal ionic radius of bivalent metal.
○: 15C5, ⊙: 18C6, ●: DB18C6.

seen from Fig. 5, the $\log K_{ex}$ value of Ca^{2+}, whose crystal radius is much smaller than the cavity radius of 18C6 in comparison with the other bivalent metal ions (Table 2), is smallest for the 18C6 and the DB18C6 systems. For the 15C5 system, although the crystal radius of Ca^{2+} is nearly equal to the cavity radius of 15C5 (Table 2), the $\log K_{ex}$ value of Ca^{2+} is also the smallest. The size of Pb^{2+} is larger than the cavity size of 15C5, and Ba^{2+} fits more closely into the 18C6 cavity than Pb^{2+} (Table 2). In Fig. 5 however, 15C5 and 18C6 show the largest

$\log K_{ex}$ value for Pb^{2+}.

The most pronounced substituent effect of the two benzo groups attached to 18C6 on the extractability of Hg^{2+} and Sr^{2+} can be seen in Fig. 5, *i.e.* the $\log K_{ex}$ sequence for Hg^{2+} and Sr^{2+} with 18C6 is $Hg^{2+}<Sr^{2+}$, while that with DB18C6 is $Hg^{2+}>Sr^{2+}$, although the crystal radii of Hg^{2+} (1.10 Å[8]) and Sr^{2+} (1.13 Å[8]) are nearly equal.

From the data it appears that the ratio of the size of the bivalent metal ion to that of the crown ether cavity is not always the dominant factor in the extractability of the bivalent metal-crown ether picrate complex.

Equation 8 shows that the trend for K_{ex} for the same crown ether and different bivalent metal ions reflects the stability and the extractability of the bivalent metal ion–crown ether complex in the aqueous phase. The $\log K_{ex'}$ values calculated from Eq. 8 are given in Table 1. It is interesting that in each crown ether system the largest $\log K_{ex'}$ value is seen for Pb^{2+}. Table 1 shows that in the case of 15C5, the $\log K_{ex}$ sequence of Sr^{2+} and Ba^{2+} is $Sr^{2+}>Ba^{2+}$ and this sequence is determined by both the $\log K_{ML}$ and the $\log K_{ex'}$ sequences, and that the largest $\log K_{ex}$ value for Pb^{2+} is largely attributed to the largest $\log K_{ex'}$ value. In the case of 18C6 the larger $\log K_{ex'}$ value for Sr^{2+} entirely contributes to the larger and equal extractability of Sr^{2+} compared to Hg^{2+} and Ba^{2+}, respectively. It may be noted from Fig. 5 and Table 1 that for the 18C6–all the bivalent metal ions and the DB18C6–Ca^{2+}, Sr^{2+}, and Pb^{2+} systems, the $\log K_{ex}$ sequences largely depend on $\log K_{ML}$. The most remarkable extraction selectivities of 18C6 and DB18C6 for Pb^{2+} are due to the high stability and high extractability of the Pb^{2+}–crown ether complex.

The considerably different $\log K_{ex'}$ values for the bivalent metal ions about the same crown ether can be seen from Table 1, suggesting that the extractability of the bivalent metal ion–crown ether complex is not necessarily independent of the chemical nature of the bivalent metal ion trapped in the cavity of the crown ether.

Among the crown ethers, the $\log K_{ex'}$ value series about Sr^{2+} and Pb^{2+} are in the order 15C5<18C6<DB18C6, and about Ca^{2+} and Ba^{2+} 18C6<DB18C6 and 15C5< 18C6, respectively (Table 1). The size sequences of the crown ethers are 15C5<18C6<DB18C6. These results indicate that the $\log K_{ex'}$ value of the same bivalent metal ion increases with an increase in the size of the crown ether.

The distribution coefficient of the crown ether, $K_{D,L}$, in Eq. 8 is also an important factor which determines the magnitude of K_{ex} for bivalent metal ions. Table 1 shows that about the same bivalent metal ion the difference between the $\log K_{ML}$ value of 15C5 and that of DB18C6 is not great and the difference in $\log K_{D,L}$ values of DB18C6 and 15C5 is comparable to that in $\log K_{ex'}$ value of DB18C6 and 15C5, indicating that the $\log K_{ex}$ values for 15C5 and DB18C6 are nearly identical (Fig. 5). About the same bivalent metal ion, the $\log K_{ML}$ value for 18C6 is larger than the others; the $\log K_{ex'}$ value of 18C6 is much larger than that of 15C5, and moreover the $\log K_{D,L}$ value of 18C6 is smaller than that of 15C5; the $\log K_{ex'}$ value of 18C6 is very small compared with DB18C6, however, the $\log K_{D,L}$ value of 18C6 is exceedingly small compared with DB18C6, indicating that the $\log K_{ex}$ value of 18C6 is consistently much larger than the others (Fig. 5).

Fluorescence Quenching of Naphthalene and Its Derivatives by Acetyl Chloride

Takashi TAMAKI

Research Institute for Polymers and Textiles, Sawatari 4-1, Kanagawa-ku, Yokohama 221

(Received September 27, 1978)

The fluorescence of naphthalene and its methyl or methoxy derivatives has been found to be quenched by acetyl chloride. The quenching constants, determined by the Stern-Volmer treatment of the emission intensity and lifetime have been found to be in good agreement within experimental error. The quenching rate constants have been correlated with the energy terms of electron-donating forces in the excited states of these naphthalenes. The results suggest that the quenching mechanism involves a charge-transfer stabilized complex, in which the excited naphthyl compounds act as donors. Exciplex formation has been supported by oxygen quenching experiments.

The fluorescence quenching of aromatic molecules by carbonyl compounds is a current topic of research, a special interest of which is that some quenchings occur through non-classical energy transfer to a variety of acids, aldehydes, or ketones, which are of higher singlet excitation energy than those of the fluorescers.[1-3] Although these quenching systems reveal no exciplex emission, studies of the linear-free-energy relationship of the quenching efficiency indicate the validity of an exciplex, formed from excited aromatic compounds (electron donor) and electrophilic carbonyl groups (electron acceptor). This has been related to the anthracene–benzoyl chloride system, which is an example of the Friedel-Crafts-type photoreaction.[4] In addition to the Hammett correlation of the quenching ability of substituted benzoyl chloride, the complete interruption of the photoreaction by oxygen indicated that the exciplex is involved in the fluorescence quenching of anthracene and successive photochemical processes.

This paper reports the fluorescence quenching behavior of naphthalenes by acetyl chloride, based on the Stern-Volmer treatment of the fluorescence intensity and lifetime, and on oxygen quenching experiments, which are method for demonstrating the presence of a non-fluorescent exciplex.[5]

Experimental

All naphthyl compounds examined were purified by recrystallization from benzene or successive vacuum distillation. Distilled acetyl chloride was carefully kept from atmospheric moisture. Acetonitrile was dried and purified by fractional distillation over phosphorus pentoxide.

The fluorescence spectra measurements were made using a Hitachi MPF-2A spectrofluorometer at 21 °C. Samples were prepared in 1 cm square quartz cells with a 5 cm-length cylindrical neck which could be stoppered. The quencher concentrations employed were 0.02—0.4 M and the concentration of naphthalenes was 10^{-5} M. The excitation wavelength was 310 nm, where the absorption of the quencher was negligible. The emission spectra were generally the same both in the absence and presence of quencher and consequently the relative fluorescence intensity was determined by measurements of the height of the peak maxima. The experimental errors were 10%. Unless otherwise reported, the oxygen dissolved in the sample solution was purged by flushing with argon prior to measurement. A time of 10 min was required for complete elimination of oxygen-induced quenching under the conditions.

The fluorescence lifetime measurements were conducted using an ORTEC SP-3 nanosecond spectrometer at 25 °C, the sample preparation being the same as described above. The excitation was made by the 313 nm light and with this instrument, the fluorescence lifetime of quinine sulfate (10^{-5} M) has been estimated to be 20 ns (lit,[6] 19.2 ns).

Results and Discussion

In table 1 the results of the Stern-Volmer treatment for the fluorescence quenching of naphthalene and its methyl and methoxy derivatives by acetyl chloride are listed. The values of K_{sv} have been estimated from the initial slopes of the Stern-Volmer plots, which exhibited upward curvature above 0.1 M. The quenching rate constant, k_q, has been calculated by using the fluorescence lifetime observed.

It appears unlikely that static quenching is important since no new absorption band could be detected for the mixed solutions of naphthalenes and acetyl chloride. This is further supported by the quenching experiments of the fluorescence lifetime. The formation of a non-emissive complex prior to photoexcitation would enable the quenching to affect the fluorescence intensity, but not the fluorescence lifetime. However, this is not the case. As is shown in Table 1, the values of K_{sv} derived from the lifetime measurements are in good agreement with those of the intensity measurements within experimental error. The Stern-Volmer plots found here indicate the formation of the ground-state complex in high quencher concentrations[7] and consequently the dynamic property may be strictly pertinent to the quenching behaviors in low quencher concentrations.

The first excited states of carboxylic acids and derivatives are known to be n-π^* transitions, which are of higher energy than the corresponding transitions of aldehydes and ketones.[8] The singlet n-π^* transition energy of acetyl chloride is 121 kcal/mol (log ε 1.7),[9] which is higher than that of the naphthyl compounds ($<$92 kcal/mol). Thus, there is no region of spectral overlap between the donor fluorescence and the quencher absorption indicating the impossibility of triavial or resonance energy transfer. The quenching data listed in Table 1 reveals that k_q decreases with increase in the excitation energy of the fluorescers, and so endothermic energy transfer through collisional exchanges[10] can be excluded.

a) Measured under deoxygenated conditions. b) Determined from the absorption and fluorescence spectra.
c) Obtained from Ref. 16. d) Calculated[17] from the polarographic potential.[18]

These cosiderations suggest that the fluorescence quenching is due to exciplex formation, as in the case of the anthracene–benzoyl chloride system.[4] If an exciplex is formed, in which the excited molecules act as the electron donor with the same electron acceptor, the values of $\ln k_q$ should correlate with the energy terms of the electron-donating force, $IP_D-{}^1E_D$,[11] where IP_D and ^1E_D represent the ionization potential and the singlet excitation energy of the donor, respectively. Figure 1 shows the plots of $\ln k_q$ *vs.* $IP_D-{}^1E_D$, calculated for the naphthalenes examined. The linearity of the plots is remarkable, except for Compounds **10** and **11**. The electron transfer in the excited state is then primarily responsible for the fluorescence quenching.

Therefore, the quenching results can be accounted for by the following equations,

$$N \xrightarrow{h\nu} {}^1N^*, \quad (1)$$

$$^1N^* \xrightarrow{k_f} N + h\nu', \quad (2)$$

$$^1N^* \xrightarrow{k_{isc}} {}^3N^*, \quad (3)$$

$$^1N^* \xrightarrow{k_{ic}} N, \quad (3')$$

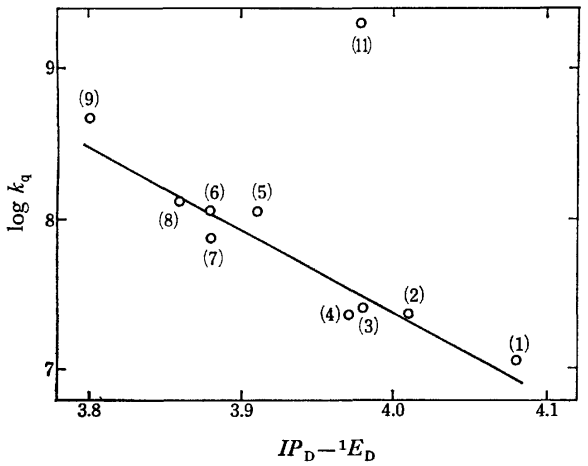

Fig. 1. Plots of log k_q as a function of $IP_D-{}^1E_D$. The values of k_q from the lifetime measurements were used. The numbers in parentheses refer to those in Table 1.

$$^1N^* + A \underset{k_{-e}}{\overset{k_e}{\rightleftharpoons}} [N\cdots A]^* \xrightarrow{k_{de}} N + A \text{ or products}, \quad (4)$$

where N and A represent the naphthyl compounds and acetyl chloride, respectively, $[N\cdots A]^*$ represents an exciplex, and k_q refers to $k_ek_{de}/(k_{-e}+k_{de})$.

If an exciplex is non-fluorescent and its formation is reversible, the oxygen quenching method is convenient for demonstrating the presence of the exciplex.[5] When oxygen is allowed into the sample solutions, both the excited monomer and exciplex are appreciably intercepted with a rate which is diffusion-controlled.

$$^1N^* + O_2 \xrightarrow{k_{qm}} N + O_2, \quad (5)$$

$$[N\cdots A]^* + O_2 \xrightarrow{k_{qe}} N + A + O_2. \quad (6)$$

From Eqs. 1—6, the Stern-Volmer equation is derived.

$$\phi_f^\circ/\phi_f = 1 + k_{qm}\tau^\circ[O_2] + k_ep\tau^\circ[A],$$
$$p = (k_{de}+k_{qe}[O_2])/(k_{-e}+k_{de}+k_{qe}[O_2]),$$

where $\phi_f^\circ=k_f/(k_f+k_{isc}+k_{ic})=k_f\tau^\circ$, ϕ_f represents the fluorescence quantum yield in the presence of the quencher and oxygen, and p is the fraction of the exciplex which does not regenerate an excited monomer. The Stern-Volmer relation of the fluorescence lifetime is the same as that of the fluorescence intensity. If the exciplex formation were irreversible, *i.e.*, $k_{-e}\ll k_{de}$, then the product k_ep approximates to k_q. The oxygen-induced quenching would be strictly competitive with quenching by A and the Stern-Volmer slopes as a function of [A] would be identical, irrespective of oxygen. If the exciplex is reversibly formed, the value of p may increase in the presence of oxygen, resulting in an increase of slope. As shown in Fig. 2, the fluorescence quenching of naphthalene by acetyl chloride is apparently enhanced by dissolved oxygen, strongly supporting the presence of a reversibly formed exciplex. As shown in Table 2, the quenching enhancement decreases with increase in the electron-donating ability of the excited naphthyl compound and consequently the reversibility of exciplex formation becomes less important with electron-rich aromatics.

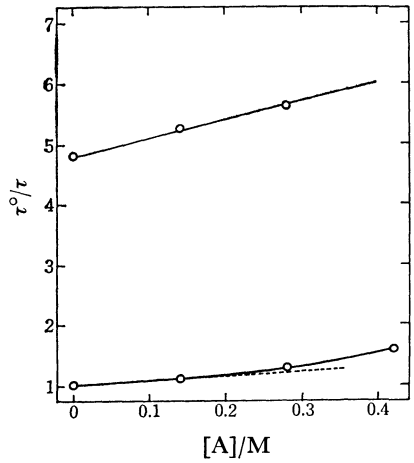

Fig. 2. Fluorescence quenching of naphthalene by acetyl chloride: lower, deoxygenated; upper, aerated.

Table 2. Results of the oxygen quenching experiments

Donor	K_{sv} [a] (M^{-1})	K_{sv} [b] (M^{-1})	$k_e\tau/k_q$
Naphthalene	3.0	3.2	3.0
2-Methylnaphthalene	2.3	1.8	1.8
1-Methylnaphthalene	2.0	2.1	1.2
Acenaphthene	—	21	1.1

a) Determined from lifetime measurements. b) Determined from intensity measurements.

Irradiation of the mixture of naphthalenes and acetyl chloride in benzene with 313 nm light produced an appreciable loss of the starting materials, indicating that the exciplex decays mainly through chemical transformations analogous to the photoreaction of anthracene with benzoyl chloride.[4] Attempts to isolate characterizable products by TLC were, however, unsuccessful. The large k_q values obtained for methoxynaphthalenes are thought due to the increased rates of such chemical changes. Preliminary experiments, in fact, showed that the initial rate of acetyl chloride loss monitored by the iron(III) hydroximate method[12] was larger than that for the methylnaphthalenes, although no precise evaluation of the quantum yield could be made because of the appearance of new intense absorption bands near the excitation wavelength.

Quenching behavior is of interest in view of structure-reactivity relationships. In contrast with the quenching of the excited aromatic hydrocarbons by aromatic ketones or aldehydes,[3] systems involving acyl chlorides as quencher do not necessarily require the assertion that the quencher should have a conjugated system capable of frontier orbital overlap with the aromatic fluorescer. It appears certain that in addition to the electron-withdrawing properties of the carbonyl group of acyl chlorides the chemical reactivity of activated acyl C–Cl bonds play an important role in the quenching processes. This may recall the concept concerned with bimolecular interactions between electron-rich aromatics and chlorinated compounds as the quenching center, *e.g.*, indole–methyl chloroacetate,[13] 1,4-dimethoxybenzene–benzyl chloride,[14] and methoxynaphthalenes–chloroacetonitrile systems.[15] These studies have emphasized that the rate of exciplex decay to chemical transformation is dominant in limiting an overall quenching rate. The CT interaction is of importance, however, giving rise to the association of an exciplex. The quenching mechanism in the present work is related to these instances.

Conditions of the Formation of Rare Earth Phosphates and the Colors of Their Powders

Mitsutomo TSUHAKO,* Sayuri IKEUCHI, Tsuneo MATSUO, Itaru MOTOOKA,** and Masamitsu KOBAYASHI**

Kobe Women's College of Pharmacy, Motoyama, Higashinada-ku, Kobe 658

***Department of Chemistry, Faculty of General Education, Kobe University, Tsurukabuto, Nada-ku, Kobe 657*

(Received July 3, 1978)

Rare earth oxides, such as La_2O_3, Pr_6O_{11}, Nd_2O_3, and Sm_2O_3, can react with phosphoric acid to give four kinds of rare earth phosphates (orthophosphates $LnPO_4 \cdot 0.5H_2O$ and $LnPO_4$, *catena*-polyphosphates $Ln(PO_3)_3$ and ultraphosphates LnP_5O_{14}), while in the reaction of CeO_2 with phosphoric acid there are formed five kinds of phosphates (orthophosphate $CePO_4$, pyrophosphate CeP_2O_7, two types of *catena*-polyphosphate $Ce(PO_3)_3$ and $Ce(PO_3)_4$, and ultraphosphate CeP_5O_{14}). The formation of these products in the CeO_2–H_3PO_4 system are notably different from these in other systems, showing that cerium(III) phosphates as well as cerium(IV) phosphates can exist stably. It can be seen from the X-ray diffraction patterns that each corresponding phosphate (ortho, *catena*-poly, and ultraphosphates) of lanthanum, cerium(III), praseodymium, neodymium, and samarium is isomorphous. This may be caused by the facts that the valencies of all these metals are +3 and that their ionic radii are almost equal to one another (La(III) 1.06 Å—Sm(III) 0.96 Å). The conditions of the formation of each phosphate were investigated, and the colors of the crystals, the densities, and the infrared absorption spectra of various rare earth phosphates were also examined.

The chemistry of rare earth phosphates has developed rapidly in the last few years. Such rapid development may be attributed, first of all, to the use of neodymium ultraphosphate as a laser material.[1-4] Also, it may be attributed to the following circumstances. As for ultraphosphates, the existence of sodium[5,6] and calcium ultraphosphates[7,8] has been hitherto known, but they are unstable structures. However, stable rare earth ultraphosphates were reported by Jaulmes[9] in 1969 and by Bagieu-Beucher and Tranqui[10] in 1970, and their crystallographical interest has occasioned active studies of ultraphosphates.[11,12] Thus, the crystal structures of several rare earth ultraphosphates have been elucidated.[13] However, there have as yet been few systematic studies of rare earth phosphates, various problems regarding their chemical formulae, chemical names, species, methods of preparation, and physical properties remain unsolved. For instance ultraphosphate [$P_5O_{14}^{3-}$] is often called pentaphosphate,[14,15] but this name is unreasonable, for it invites confusion with non-branched chain pentaphosphate [$P_5O_{16}^{7-}$]. In phosphate chemistry, the term "ultraphosphate" is often used as a popular name of phosphates with a net-work structure; therefore, in the present paper [$P_5O_{14}^{3-}$] is designated "ultraphosphate." According to their definition, ultraphosphates, obviously differing from non-branched chain pentaphosphate, are phosphates with P/Ln>3, where Ln=a trivalent rare earth metal, and have some branched P in their structures to form net-work structures.[5,7,16,17] On the other hand, the term "pentaphosphate" usually indicates non-branched chain phosphate [$P_5O_{16}^{7-}$] and not branched phosphate [$P_5O_{14}^{3-}$]. For neodymium *catena*-polyphosphate the chemical formula "NdP_3O_9" is often used,[11] but this formula properly indicates neodymium *cyclo*-triphosphate. Neodymium *catena*-polyphosphate is a long-chain polymer and should be indicated as $[Nd(PO_3)_3]_n$. However, because it is usually indicated as $Nd(PO_3)_3$, in the present study also $Nd(PO_3)_3$ will be used. However, it must be noted that NdP_3O_9 and $Nd(PO_3)_3$ obviously indicate several different compounds. Such being the case, there remain many obscurities regarding rare earth phosphates; moreover, no systematic studies of their preparation have been made at all. Further, it is considered that the establishment of preparation methods for various rare earth phosphates may contribute greatly to the development of the chemistry of rare earth phosphates. Thus, the present authors have investigated in detail the conditions of the formation of orthophosphates, pyrophosphate, *catena*-polyphosphates and ultraphosphates by the reactions of rare earth oxides with phosphoric acid; they have thus established the conditions of the formation of these phosphates.

Experimental

Preparation of Rare Earth Phosphates. In a gold or porcelain crucible, 99.9% portions of rare earth oxides (La_2O_3, CeO_2, Pr_6O_{11}, and Sm_2O_3 made by Shin-etsu Kagaku Co., Ltd.) was mixed with 85% orthophosphoric acid of a special grade in an atomic ratio P/Ln (R)=1—40, where Ln=La, Ce, Pr, and Sm; each mixture was dehydrated by heating with a weak flame. Each mixture gradually became viscous and gave a transparent liquid. However, in the region of R=1—3, an exothermic reaction occurred only by mixing each oxide with phosphoric acid, and the mixture solidified. Lanthanum oxide La_2O_3 reacted especially actively, while CeO_2 was inactive. Transparent liquids and matter obtained by the manner described above were heated in an electric furnace at 300—800 °C for 20 h to obtain rare earth phosphates (this is designated the thermal synthetic method). The color of each product obtained varied according to its metallic ion, its atomic ratio, its heating temperature, and its particle size. Rare earth phosphates prepared by the above method were generally hard, especially those prepared at high temperatures above 500 °C with R=1—5. Thus, these products were roughly crushed in a mortar, pulverized for about 30 min with a grinder, washed with distilled water, dried in a desiccator on silica gel, and then used for the following experiments.

Apparatus and Methods. *X-Ray Analysis*: X-Ray analysis was carried out with a Rigaku Denki Geigerflex X-ray

diffractometer, using Ni-filtered Cu $K\alpha$ radiation. The following conditions were used for the X-ray analysis: voltage 40 kV; current, 7 mA; counter range, 1000 c.p.s; time constant, 1 s, and scanning speed 1, 0.25, and 0.125°/min. The amounts of rare earth orthophosphate $LnPO_4 \cdot 0.5H_2O$ and $LnPO_4$, *catena*-polyphosphate $Ln(PO_3)_3$, ultraphosphate LnP_5O_{14}, cerium(IV) pyrophosphate CeP_2O_7 and *catena*-polyphosphate $Ce(IV)(PO_3)_4$ formed by the thermal synthetic method were determined from the integrated intensities of their characteristic X-ray diffraction peaks; *i.e.*, $LnPO_4 \cdot 0.5H_2O$ was determined by the peak at d=4.46 Å; $LnPO_4$, by that at 3.31 Å; $Ln(PO_3)_3$, by that at 3.43 Å; LnP_5O_{14}, by that at 3.72 Å; CeP_2O_7, by that at 4.33 Å, and $Ce(PO_3)_4$, by that at 4.04 Å.

Colorimetry. Colorimetry was carried out by the use of a color-difference meter (ND-101 type) made by the Nippon Denshoku Kogyo Co., Ltd. By using a halogen lamp as the light source, diffuse reflection light was collected with an integrating sphere and detected. In these experiments, the thickness of the sample layer in the measuring cell was always maintained above 10 mm, so that the reflectivity was not affected by the thickness of the layer. Also, the deviation of the reflectivity caused by the state of the sample layer was negligibly small. All experiments were carried out for samples with a particle size of 250—300 mesh.

Infrared Absorption Spectroscopy: A Hitachi EPI-S2 spectrophotometer was used for the infrared absorption spectroscopy, the spectra being taken by means of a KBr tablet or on Nujol mulls.

The densities of various rare earth phosphates were measured by means of a Beckmann air-comparison pycnometer.

Results and Discussion

Formation of Various Rare Earth Phosphates. In the La_2O_3, Pr_6O_{11}, and Sm_2O_3–H_3PO_4 systems four kinds of phosphates were formed; two kinds of orthophosphate $LnPO_4 \cdot 0.5H_2O$ (hexagonal) and $LnPO_4$ (monoclinic), *catena*-polyphosphate $Ln(PO_3)_3$, and ultraphosphate LnP_5O_{14}, while in the CeO_2–H_3PO_4 system, differing notably from the above systems, five kinds of phosphates —orthophosphate $CePO_4$, pyrophosphate CeP_2O_7, two types of *catena*-polyphosphate $Ce(III)(PO_3)_3$, and $Ce(IV)(PO_3)_4$, and ultraphosphate CeP_5O_{14}—were formed. The difference in the products of the CeO_2 system and those of the other systems may be caused by the fact that cerium can give stable phosphates of both Ce(III) and Ce(IV). On the contrary, lanthanum, praseodymium, neodymium, and samarium give only stable phosphates of La(III), Pr(III), Nd(III), and Sm(III), while no phosphates of Pr(IV) and Sm(II) were formed at all. Figure 1 shows some X-ray diffraction patterns of *catena*-polyphosphates. In this figure, the results for *catena*-polyphosphates of La, Pr, and Sm are shown as examples. However, for *catena*-polyphosphates of other metals (Ce(III) and Nd), X-ray diffraction patterns quite similar to those shown in Fig. 1 were also obtained. As can be seen from this figure, it is obvious that the series of *catena*-polyphosphates of all these rare earth metals are isomorphous, though slight deviations of diffraction peaks caused by the difference in the ionic radii of metals can be observed. That is, the X-ray diffraction peaks shifted toward smaller angles (larger d-values) with the increase in the ionic radii of rare earth metals. It was also proved that crystals of $LnPO_4 \cdot 0.5H_2O$ and $LnPO_4$ as well as crystals of LnP_5O_{14} were isomorphous.

Relationship between Atomic Ratio P/Ln (R) and the Yields of Products. The reaction products of rare earth oxides with phosphoric acid seem to vary notably with the mixing ratio of the two components. The amounts of samarium ortho, *catena*-poly and ultraphosphates prepared in the Sm_2O_3–H_3PO_4 system at 700 °C for 20 h were determined from the integrated intensities of their characteristic X-ray diffraction peaks; the results are shown as a function of the mixing rate R=P/Sm in

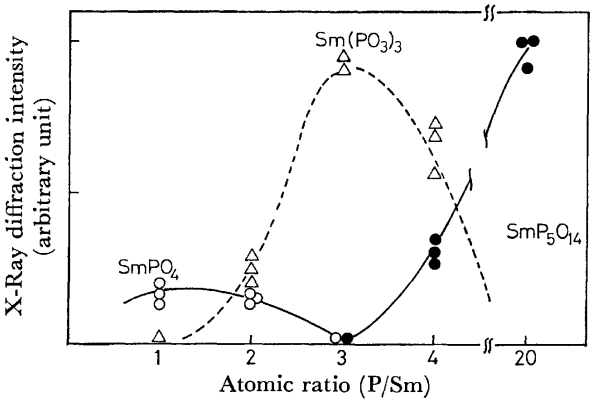

Fig. 2. Relationship between the yields of samarium phosphates and atomic ratio at 700 °C.

Fig. 2. As can be seen, at 700 °C three kinds of phosphates, $SmPO_4$, $Sm(PO_3)_3$, and SmP_5O_{14}, were formed. Orthophosphate $SmPO_4$ was formed in the R=1—2 range, while with R-values above 3 its formation was not observed at all. *catena*-Polyphosphate $Sm(PO_3)_3$ was formed in the range of R=2—8, in especially good yields in the R=3 range. This may be caused by the fact that P/Sm=3 just corresponds to the meta-composition. On the other hand, ultraphosphate began to form with R=4, and with R values above 10 was obtained in a pure form. Further, $SmPO_4 \cdot 0.5H_2O$ was formed with R= 1—2 at relatively low temperatures below 500 °C, while

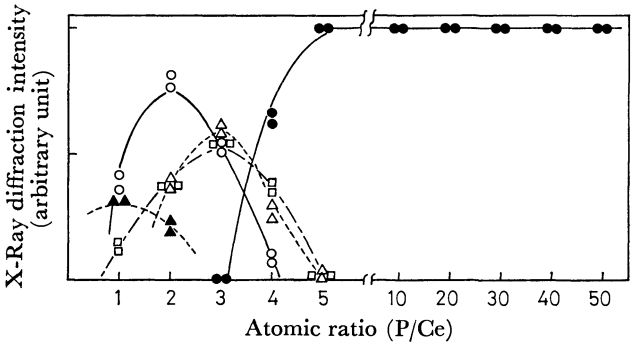

Fig. 3. Relationship between atomic ratio (P/Ce) and the yields of cerium phosphates at 800 °C. --▲--: $CePO_4$, —○—: CeP_2O_7, -—□—; $Ce(PO_3)_3$, --△--: $Ce(PO_3)_4$, —●—: CeP_5O_{14}.

at temperatures above 600 °C its formation could not be observed at all. In the La_2O_3, Nd_2O_3, and Pr_6O_{11}–H_3PO_4 systems, almost the same tendency as that in the Sm_2O_3–H_3PO_4 system was observed. On the other hand, in the CeO_2–H_3PO_4 system a tendency markedly different from that in other systems was found, as is shown in Fig. 3, in which results obtained by heating a mixture of CeO_2 and H_3PO_4 at 800 °C for 20 h are shown. Orthophosphate $CePO_4$ was formed in the R= 1—2 range, CeP_2O_7, in the R=1—4 range, $Ce(PO_3)_3$, in the R=1—4 range, and $Ce(PO_3)_4$, in the R=2—4 range. Thus, in the range of R=1—4 all these compounds were formed as mixtures, and it was impossible to obtain any of them in a pure form. On the other hand, CeP_5O_{14}, which was formed beginning at R=4, could be obtained purely at R above 5. Further, the present authors investigated the formation of cerium phosphates in the range of R=50—200 and at high temperatures (above 600 °C); only ultraphosphate was found to be obtained in all experiments. Also, no formation of $CePO_4 \cdot 0.5H_2O$ could be observed at all in the CeO_2–H_3PO_4 system.

Relationship between Heating Temperature and Products. The relation between the amounts of products and the heating temperature in the CeO_2–H_3PO_4 system with R=4 is shown in Fig. 4. As can be seen, cerium phosphates formed with R=4 were of four kinds: CeP_2O_7, $Ce(PO_3)_4$, $Ce(PO_3)_3$, and CeP_5O_{14}, and the formation of these compounds was strongly affected by the heating

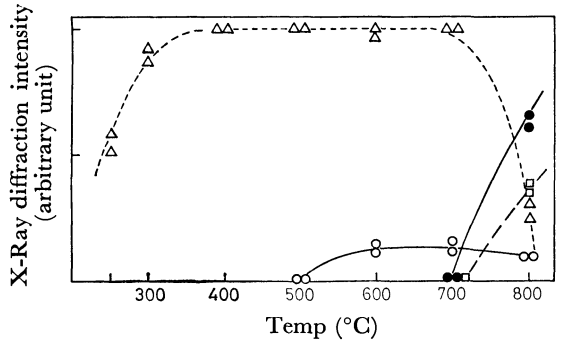

Fig. 4. Relationship between heating temperature and the yields of cerium phosphates in P/Ce=4. —○—: CeP_2O_7, --□--: $Ce(PO_3)_3$, --△--: $Ce(PO_3)_4$, —●—: CeP_5O_{14}.

temperature. Pyrophosphate CeP_2O_7 was formed above 600 °C, but its yield was very small compared with those of the other products. This may be caused by the fact that the amount of phosphoric acid corresponding to R=4 is too much for the preparation of pyrophosphate, but lies in the ultra-component region. *catena*-Polyphosphate $Ce(PO_3)_4$ was formed in a wide temperature range (250—800 °C); especially, it could be obtained purely at 400—500 °C. At 600—700 °C, cerium *catena*-polyphosphate was contaminated with pyrophosphate. Further, at temperatures above 800 °C, the yield of $Ce(PO_3)_4$ decreased rapidly, and corresponding to its decrease, the formation of $Ce(PO_3)_3$ and CeP_5O_{14} was predominant. This phenomenon may be attributed to the transformation of Ce(IV) into Ce(III) through the decomposition of $Ce(PO_3)_4$, accompanied with oxygen evolution. Further studies of the decomposition mechanism and of the effects of the heating temperature and the heating atmosphere are now in progress. The relation between the heating temperature and the product in the R range from 1 to 50 is summarized in Fig. 5, in which the amount of each

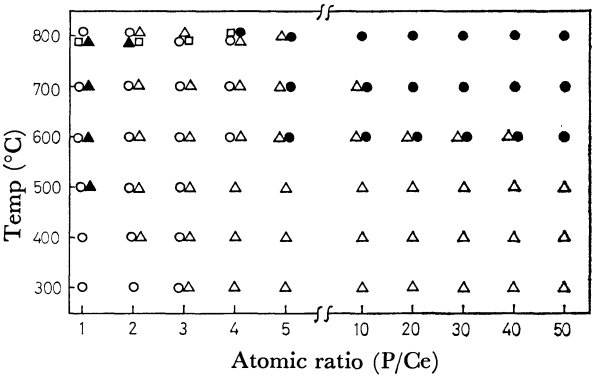

Fig. 5. Relationship of the species of cerium phosphates to heating temperature and atomic ratio. ▲: $CePO_4$, ○: CeP_2O_7, □: $Ce(PO_3)_3$, △: $Ce(PO_3)_4$, ●: CeP_5O_{14}.

cerium phosphate obtained is wholly omitted. Cerium orthophosphate $CePO_4$ was formed with R=1 above 500 °C, while with R=2, it was formed at 800 °C. Pyrophosphate CeP_2O_7 was formed in the range R= 1—3, regardless of the heating temperature, while with R=4, it was formed only at high temperatures (above 600 °C). On the other hand, the region of the formation of $Ce(PO_3)_4$ was wide as compared with those of the other cerium phosphates. It was proved that $Ce(PO_3)_4$ could be obtained in a pure form, especially at low temperatures below 500 °C with a large R, that is, in a much phosphoric acid region. However, with R-values of more than 20, because of the excess phosphoric acid a fairly long time (2—5 weeks) was necessary to form $Ce(PO_3)_4$ crystals; accordingly, the yield was decreased. It was also proved that $Ce(PO_3)_3$ was formed in the R range of 1—4 at high temperatures (above 800 °C) in the CeO_2–H_3PO_4 system; there existed no regions in which $Ce(PO_3)_3$ could be purely synthesized. Also, the formation of this compound could not be observed at all below 700 °C. On the other hand, CeP_5O_{14} was formed above 600 °C and $R \geqq 5$, in an especially large

amount at 700—800 °C with R above 20. As has been reported previously, in the Nd_2O_3–H_3PO_4 system[18] the temperature of the formation of NdP_5O_{14} shifted toward the lower-temperature side with an increase in the P/Nd atomic ratio, that is, with an increase in the amount of phosphoric acid. For instance, with P/Nd= 4—5, the lower-temperature limit of NdP_5O_{14} formation was 500 °C, while with P/Nd above 10, the temperature of the formation has lowered to 400 °C. The temperature of the formation of CeP_5O_{14} in the CeO_2–H_3PO_4 system was quite high (above 600 °C), and no shift toward the lower-temperature side with an increase of R could be observed. This may be caused by the fact that only $Ce(PO_3)_4$ can exist stably at temperatures below 600 °C. It was also found that products in the CeO_2–H_3PO_4 system was notably different from those in the La_2O_3, Pr_6O_{11}, Nd_2O_3, and Sm_2O_3–H_3PO_4 systems. This difference may be explained as follows. In the CeO_2–H_3PO_4 system, both trivalent and quadrivalent cerium phosphates, that is, cerium(III) ortho, *catena*-poly, and ultraphosphates, as well as cerium(IV) pyro and *catena*-polyphosphates, can exist stably. On the other hand, all the phosphates of La, Pr, Nd, and Sm obtained in the present study were trivalent rare earth metal phosphates. The crystal structures (X-ray diffraction patterns and infrared absorption spectra) and properties (thermal change) of Ce(III) ortho, *catena*-poly, and ultraphosphates were

similar to those of the corresponding phosphates of La, Pr, Nd, and Sm. In the lanthanum, cerium, praseodymium, neodymium, and samarium systems, experimental results on the preparation of the various rare earth phosphates described above are summarized in Table 1.

Results of studies of the formation of various crystalline phosphates prepared by the reactions of La_2O_3, CeO_2, Pr_6O_{11}, Nd_2O_3, or Sm_2O_3 with phosphoric acid (the thermal synthetic method), as well as those prepared by the reactions of aqueous solutions of $LaCl_3$, $CeCl_3$, $Ce(SO_4)_2$, $PrCl_3$, $NdCl_3$, or $SmCl_3$ with orthophosphoric acid or aqueous solutions of various sodium phosphates (this is designated as the aqueous solution reaction method) are summarized in Table 2. The compounds formed by the thermal synthetic method were $LnPO_4 \cdot 0.5H_2O$, $LnPO_4$, $Ln(PO_3)_3$, and LnP_5O_{14} in the lanthanum, praseodymium, neodymium, and samarium systems, and $CePO_4$, CeP_2O_7, $Ce(PO_3)_3$, $Ce(PO_3)_4$, and CeP_5O_{14} in the cerium system. On the other hand, the crystalline compounds formed by the aqueous solution reaction method were $LnPO_4 \cdot 0.5H_2O$, $LnP_3O_9 \cdot xH_2O$, and $Ln_4(P_4O_{12})_3 \cdot xH_2O$.

As La(III), Ce(III), Pr(III), Nd(III), and Sm(III) are almost equal in their ionic radii, they give isomorphic crystals of ortho, *cyclo*-tri, *cyclo*-tetra, *catena*-poly, and ultraphosphates. On the contrary, as crystalline phosphates of Ce(IV) only CeP_2O_7[19] and $Ce(PO_3)_4$[20] are known at present.

Colors of Rare Earth Phosphate Powders. Generally, the colors of rare earth phosphates prepared by the thermal synthetic method vary considerably depending on their preparation conditions (for example, the mixing rate of metallic oxides and phosphoric acid, or the heating temperature) and also on the sizes of their crystalline particles. However, the particle sizes were kept constant (250—300 mesh) in the present study, so the colors of the phosphates may depend strongly on the species of the products. In the lanthanum system, white crystals were obtained regardless of the atomic ratio and the heating temperature. In the cerium system, a light yellow cerium phosphate was obtained at low temperatures (below 500 °C), while above 500 °C with $R \geqq 10$ a white cerium phosphate was formed. In the neodymium system also, the colors of the crystals formed varied in the range from light blue to pink, according to the atomic ratio. In the praseodymium system, dark grey crystals were obtained with a small R, while with an increase in R, *i.e.*, with an increase in the amount of phosphoric acid, more yellowish green crystals were formed. In the samarium system, light yellow crystals were formed regardless of the atomic ratio and the heating temperature. The color changes

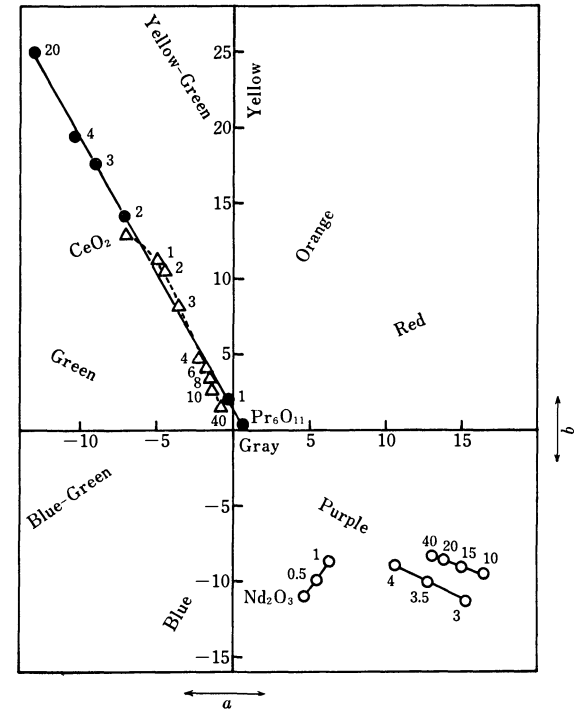

Fig. 6a. Changes of chromaticity coordinates (a and b) of cerium, praseodymium, and neodymium phosphates. --△--: Cerium, —●—: praseodymium, —○—: neodymium.

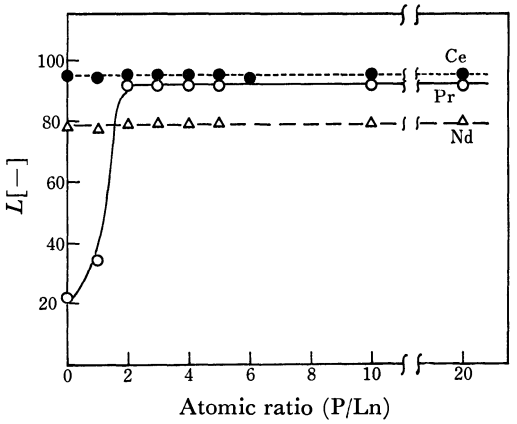

Fig. 6b. Relationship between atomic ratio and the lightness(L) of cerium, praseodymium, and neodymium phosphates.

of these rare earth phosphates will henceforth be expressed with the Lab system,[21,22] which is frequently used in colorimetry. The Lab system has perceptively almost uniform paces, and each color is expressed as a point in a three-dimensional color space. In the Lab system, L shows lightness and a, b show chromaticity coordinates, while a hue is expressed with $\theta=\tan^{-1} b/a$, and saturation, with $\sqrt{a^2+b^2}$. The Lab patterns of the phosphates obtained in the cerium, praseodymium, and neodymium systems are plotted against the atomic ratio in Figs. 6-a, b. The phosphates shown in Fig. 6 were prepared by heating at 700 °C for 20 h. In the cerium system, the product obtained at $R=0$—3 is light yellow, but with the increase in R it gradually becomes whitish. This is also supported by the results of colorimetry. It is found that the starting material (CeO_2) is light yellow, and with the increase in R (in other words, with the increase in the yields of CeP_2O_7, $Ce(PO_3)_4$, and CeP_5O_{14}), cerium phosphate approaches the hue of grey white, that is, to an achromatic color (saturation $\sqrt{a^2+b^2}=0$). However, the lightness, L, depends little on the atomic ratio, R.

In the praseodymium system, the color change is the reverse of that in the cerium system. That is, in the praseodymium system the color of the crystals changes from black (an achromatic color) to yellowish green. With R between 1 and 2, a and b change remarkably, while when R reaches 2, the product begins to turn yellowish green. This result corresponds to the increase in the yield of $Pr(PO_3)_3$, as is shown by the results of X-ray analysis. As the saturation increases with the increase in R, that is, with the successive formation of $PrPO_4 \rightarrow Pr(PO_3)_3 \rightarrow PrP_5O_{14}$, it is understandable that the product gains a brilliant hue. However, as $\theta=\tan^{-1} b/a$ is constant, no change in the hue of the product can be observed at all. On the other hand, as the lightness L varies rapidly in the R range of 0—2, the product obviously turns from black to white.

In the neodymium system, it is clearly observed that, with the increase in R, the color of the neodymium phosphates changes from blue through violet to pink; the results of colorimetry also show the existence of three different types of color changes. It is proved that the color of particles changes from blue to violet in the $R=0$—1 range, while in the $R=3$—4 range the product becomes more purple. However, in the R range from 3 to 4, as the saturation decreases it is apparent that the product approaches an achromatic color. Further, as the straight line on the a—b plane corresponding to $R=10$—40 shifts from that corresponding to $R=3$—4 toward the a-axis, the color of the product obviously changes from purple to red. While L is almost independent of R, the hues of the products with $R=0$—1, 3—4, and 10—40 are quite different from one another. This phenomenon suggests that, in the neodymium system, because of the wide variation in the color tones of the products from blue to red, the color of the particles is strongly affected by the species of neodymium phosphates formed; consequently, three different types of color changes are observed, as is shown in the figure.

Densities of Various Rare Earth Phosphates. The densities of the orthophosphates $LnPO_4$, *catena*-polyphosphates $Ln(PO_3)_3$, and ultraphosphates LnP_5O_{14} of La(III), Ce(III), Pr(III), Nd(III), and Sm(III), as well as of cerium(IV) *catena*-polyphosphate $Ce(PO_3)_4$, prepared by the thermal synthetic method are given in Table 3. The densities of rare earth orthophosphates, reported in detail by Mooney[23] and Weigel *et al.*,[24] are also given in the table for reference. For each metal, the density decreases in this order: $LnPO_4 \rightarrow Ln(PO_3)_3 \rightarrow LnP_5O_{14}$, showing that the P/Ln atomic ratio increases in the same order; the metallic ion content in unit cell of each crystal decreases accordingly.

Table 3. Densities of rare earth phosphates

Infrared Absorption Spectra (IRS). Figure 7 shows the IRS of $La(PO_3)_3$, $Ce(PO_3)_3$ (prepared by the reaction of $CeCl_3$ with H_3PO_4), $Nd(PO_3)_3$, and $Ce(PO_3)_4$, while Fig. 8 shows those of LaP_5O_{14}, CeP_5O_{14}, and NdP_5O_{14}. As can be seen from Figs. 7 and 8, the IRS of each phosphate is quite similar to those of the others; this fact strongly supports the above-presented conclusion of the X-ray diffraction study that each series of phosphates is crystallographically isomorphous. In the spectra of $Ln(PO_3)_3$, the absorption peaks at 1265—1300 cm^{-1} must be assigned to P=O; those at 1100—1200, 1000, and about 600 cm^{-1} to PO_3, and

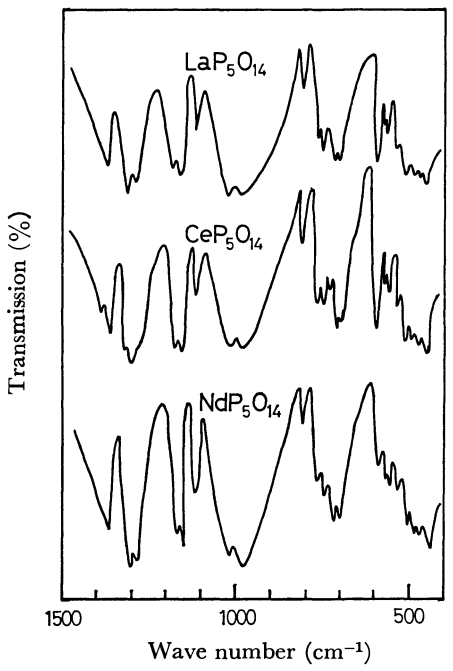

Fig. 8. IRS of LnP_5O_{14}.

those at 970 and about 830—750 cm^{-1}, to the P–O–P linkage. Further, the absorption spectrum of $Ce(PO_3)_4$ differs entirely from that of $Ce(PO_3)_3$, suggesting that the two compounds differ in bonding states from each other. However, for ultraphosphates the assignment of each absorption is not yet clear.

Conclusion

The experimental results can be summarized as follows:

1) In the La_2O_3, Pr_6O_{11}, and Sm_2O_3–H_3PO_4 systems, orthophosphate, *catena*-polyphosphate, and ultraphosphate are obtained.

2) In the CeO_2–H_3PO_4 system, trivalent and quadrivalent cerium phosphates, *i.e.*, cerium(III) ortho, *catena*-poly, and ultraphosphates, as well as cerium(IV) pyro and *catena*-polyphosphates can be prepared. The main products in this system are CeP_2O_7, $Ce(PO_3)_4$, and CeP_5O_{14}.

3) The crystal of each corresponding phosphate (ortho, *catena*-poly, and ultraphosphates) of La, Ce(III), Pr, Nd, and Sm is isomorphous.

4) In the lanthanum, praseodymium, and samarium systems, $LnPO_4 \cdot 0.5H_2O$ is readily formed at 300 °C with an atomic ratio of $R=1$, while $LnPO_4$ is formed at high temperatures (above 600 °C) with $R=1$. *catena*-Polyphosphate $Ln(PO_3)_3$ can be prepared above 500 °C with $R=3$ or by heating at 300 °C for 2—7 d with $R \geqq 10$. Ultraphosphate LnP_5O_{14} is obtained by heating at temperatures above 500 °C with $R \geqq 10$.

5) Cerium pyrophosphate CeP_2O_7 is formed with $R=1$—3, regardless of the heating temperature, while $Ce(PO_3)_4$ is easily obtained at low temperatures (below 500 °C) over a larger R region. Ultraphosphate CeP_5O_{14} can be synthesized purely at 700—800 °C with $R \geqq 20$.

6) Lanthanum phosphates are white, while cerium(IV) and cerium(III) phosphates are yellow and white respectively. Praseodymium phosphates are green, neodymium phosphates with a small R are bluish violet, those with a larger R are pink, and samarium phosphates are light yellow.

The authors wish to express their deep thanks to Assistant Professor Yoshihisa Matsuda of Kobe Women's College of Pharmacy for his many helpful discussions.

The Chemistry of Americium. IV. The Stability of Am(V) and Am(VI) in Nitric Acid Solutions and in the Solutions Containing Ozone Gas, Fluoride, or Phosphate Ions

Mitsuo HARA* and Shin SUZUKI

The Research Institute for Iron, Steel, and Other Metals, Tohoku University, Katahira 2-chome, Sendai 980

(Received July 31, 1978)

The coprecipitation technique with $BiPO_4$ and ThF_4 was applied to studying the stability of Am(V) and Am(VI) at concentrations lower than 10^{-6} M. It was found that ^{241}Am(V) and ^{241}Am(VI) were rapidly reduced to ^{241}Am(III) in nitric acid solutions at low acidities and at high temperatures, but the reduction was effectively inhibited by the presence of ozone gas or fluoride ions. On the other hand, ^{243}Am(V) and ^{243}Am(VI) were found to be rather stable in nitric acid solutions, while they were readily reduced to ^{243}Am(III) in phosphate solutions in the same manner as ^{241}Am(V) and ^{241}Am(VI).

Most investigations on the chemical properties of Am(V) and Am(VI) have been carried out by the use of an α-emitter ^{241}Am($t_{1/2}$=433 y); its α-decay leads to the radiolytic reduction of Am(V) and Am(VI). In an Am(V) solution, Am(III) is observed as a product. Here the variation of Am(III) and Am(V) concentrations with time is expressed by an empirical equation:

$$-\frac{d[Am(V)]}{dt} = \frac{d[Am(III)]}{dt} = k_1[Am]_T, \quad (1)$$

where k_1 is an apparent rate constant and $[Am]_T$ means the total americium concentration.

In an Am(VI) solution, Am(V) and Am(III) are observed as products. The decrease in the Am(VI) concentration with time can be expressed by an empirical equation:

$$-\frac{d[Am(VI)]}{dt} = k_2[Am]_T, \quad (2)$$

where k_2 is an apparent rate constant. If no reactions other than the radiolytic reduction proceed, the growth of Am(V) can be expressed by an equation:

$$\frac{d[Am(V)]}{dt} = (k_2-k_1)[Am]_T. \quad (3)$$

Values for k_1 and k_2 have been estimated to be 0.01 and 0.03 h^{-1}, respectively, in dilute acid solutions.[1,2]

When the long-lived isotope ^{243}Am($t_{1/2}$=7400 y) is used, the radiolytic reduction is not so remarkable as that in ^{241}Am solutions.[3] On the other hand, ^{241}Am(V) and ^{243}Am(V) disproportionate to Am(VI) and Am(III) in moderately concentrated acids. The rate of disproportionation of ^{241}Am(V) in various media is expressed by the following equation,[4,5] but the rate law is rather complicated when ^{243}Am(V) is used:[3]

$$-\frac{d[Am(V)]}{dt} = k_3[Am(V)]^2[H^+]^4, \quad (4)$$

where k_3 is an apparent rate constant.

This result has been obtained by the application of spectrophotometry to the ^{241}Am and ^{243}Am solutions at concentrations of 10^{-3} M or above. The ^{241}Am and ^{243}Am solutions diluted to about 10^{-7} M and 10^{-6} M, respectively, can be studied by radiometry. In dilute solutions, Am(V) may be free from any disproportionation, while the radiolytic reduction of ^{241}Am(V) and ^{241}Am(VI) may proceed, as suggested by Eqs. 1—4. Furthermore, Am(V) and Am(VI) may be reduced by small amounts of impurities.

The information concerning the instability of Am(V) and Am(VI) at low concentrations is rather poor. Only a little information was obtained by previous works[6,7] in which the instability of Am(V) in several media was studied by means of solvent extraction with 2-thenoyltrifluoroacetone and of column chromatography using bis(2-ethylhexyl) hydrogenphosphate (HDEHP) as an extractant, where the rapid reduction of ^{241}Am(VI) by HDEHP was observed.

When the solutions of Am(V) and Am(VI) were submitted to the coprecipitation method with some fluorides and phosphates at 0—5 °C, no change of oxidation states of americium was observed.[8,9] However, this finding can not always promise the high stability of Am(V) and Am(VI) in fluoride and phosphate solutions at room temperature or above.

In this work, the instability of Am(V) and Am(VI) in nitric acid solutions and in solutions containing ozone gas, fluoride, or phosphate ions was investigated. The change of oxidation state of americium with time was traced by means of the coprecipitation method with bismuth(III) phosphate and thorium(IV) fluoride.

Experimental

Reagents. Nitric acid solutions of ^{241}Am(III) and ^{243}Am(III) were prepared by the manners described before,[6,7] and the concentrations of ^{241}Am and ^{243}Am were determined by α-spectrometry using an Si detector connected to a multichannel pulse-height analyzer. Bismuth(V) sodium oxide was added in quantities of 10 mg/ml to a 0.1 M HNO_3 solution of Am(III), and the mixture was mechanically stirred for 50 min at room temperature and for additional 10 min at 0 °C. An Am(VI) solution was obtained by filtration of the mixture with a glass fibre filter-paper, Whatman GF/A.[10]

An Am(V) solution was prepared at 0 °C by passing the Am(VI) solution through a column of Celite 545 containing HDEHP as an extractant.[7] The solutions of nitric acid and ammonium fluoride or sodium dihydrogenphosphate were added to the Am(V) and Am(VI) solutions, making concentrations up to about 10^{-7} M and 10^{-6} M with respect to ^{241}Am and ^{243}Am, respectively.

Bismuth(V) sodium oxide, min 80 wt %, was used as an oxidant. For the coprecipitation test, bismuth(III) and thorium(IV) nitrates, sodium dihydrogenphosphate, and am-

monium fluoride were used. These and other chemicals were of G.R. grade. Ozone gas, which was bubbled through the required solutions in order to eliminate as many reducing materials as possible, was supplied by an ozone generator.

Procedure. The Am(V) and Am(VI) solutions were stocked in a thermostat at a temperature kept constant with an accuracy of ± 0.5 °C. Appropriate aliquots of the stock solutions were submitted to the coprecipitation test which was carried out under such conditions that Am(III) was quantitatively carried down, while most of Am(V) and Am-(VI) remained in the solution.

Bismuth(III) phosphate and thorium(IV) fluoride were precipitated at 0 °C from the americium solution containing bismuth(III) and thorium(IV) ions, respectively, by the addition of excess precipitants under the following conditions:

Precipitate	$BiPO_4$	ThF_4
Volume	5 ml	3 ml
Acidity	0.5 M	0.1 M
Amounts of metal ion	Bi^{3+} 10 mg	Th^{4+} 1 mg
Time of mixing	7 min	10 min

The mixture was either filtered by glass fibre filter-paper or centrifuged at 6000 rpm for 5 min. The fraction of americium carried, Y, was determined by measuring the γ-activity in the mixture and the filtrate (or the supernatant). The γ-ray assay was performed by the use of a flat-type NaI(Tl) scintillation probe connected to a scaler or by the use of a Ge(Li) detector connected to a multi-channel pulse-height analyzer.

Results and Discussion

Stability of Am(V) and Am(VI) in HNO_3 Solutions. The $BiPO_4$ coprecipitation test was carried out on the nitric acid solutions of ^{241}Am(V) and ^{241}Am(VI) at proper time intervals. The results on the 0.5 M HNO_3 solutions at 0—40 °C and on the (0.125—2 M) HNO_3 solutions at 30 °C are shown in Figs. 1 and 2, respectively. The measured value for Y increased with time of storage, especially at high temperatures and at low acidities. Dependence of the increase in Y on acidity was found only for the Am(VI) solutions at temperatures higher than 20 °C.

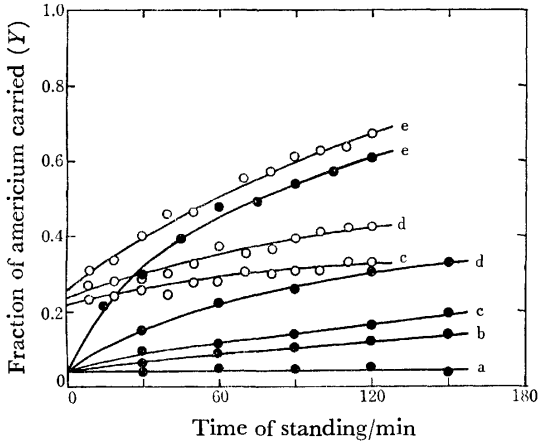

Fig. 1. The result of the $BiPO_4$ coprecipitation test carried out on the 0.5 M HNO_3 solutions of ^{241}Am(V) (○) and ^{241}Am(VI) (●) at 0 °C(a), 10 °C(b), 20 °C(c), 30 °C(d), and 40 °C(e).

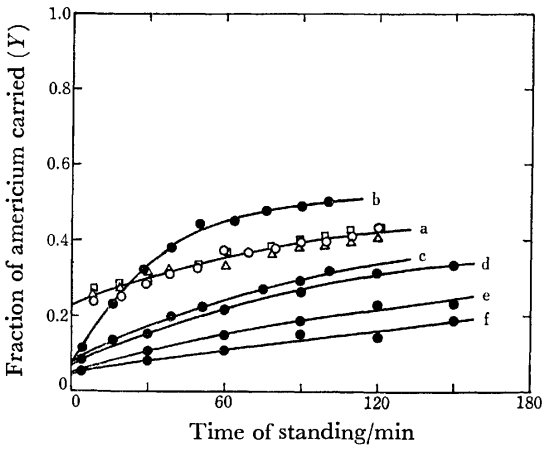

Fig. 2. The result of the $BiPO_4$ coprecipitation test carried out on the ^{241}Am(V) and ^{241}Am(VI) solutions at 30 °C.
a): ^{241}Am(V) solutions at the acidity of 0.125 M(○), 0.25 M(△), and 0.5 M(□). ●: ^{241}Am(VI) solutions at the acidity of 0.125 M(b), 0.25 M(c), 0.5 M(d), 1.0 M(e), and 2.0 M(f).

The increase in Y may be caused by the reduction of Am(V) and Am(VI) to Am(III) in the stock solutions, because Am(III) is more effectively carried by $BiPO_4$ than the others. When the mole fraction of each oxidation state of americium in the stock solution is expressed as f_X(X=III, V, and VI), Y may be given by the equation:[8]

$$Y = f_{III}Y_{III} + f_V Y_V + f_{VI}Y_{VI}, \quad (5)$$

where Y_X(X=III, V, and VI) means the fraction of Am(X) carried, which can be determined by the coprecipitation test on the corresponding single-component solution. The values for Y_X were determined as follows; $Y_{III}=0.99\pm0.01$, $Y_V=0.25\pm0.03$, and $Y_{VI}=0.05\pm0.02$ by the $BiPO_4$ coprecipitation test, and $Y_{III}=0.99\pm0.01$, $Y_V=0.12\pm0.02$, and $Y_{VI}=0.30\pm0.02$ by the ThF_4 coprecipitation test.

If the radiolytic reduction proceeds predominantly in the stock solutions of ^{241}Am, Eq. 5 can be expressed by the following equations, using the solutions of Eqs. 1—3: for the case of ^{241}Am(V) solutions,

$$Y = Y_V + (Y_{III} - Y_V)k_1 t \quad (6)$$

and for the case of ^{241}Am(VI) solutions,

$$Y = Y_{VI} + \{(Y_{III} - Y_{VI})k_1 + (Y_V - Y_{VI})k_2\}t. \quad (7)$$

Unfortunately, the linear relations expected by Eqs. 6 and 7 were valid only for the results on the stock solutions of high acidities and at low temperatures, as are shown in Figs. 1 and 2. It is clear that some reactions other than the radiolytic reduction also proceeded, especially at low acidities and at high temperatures. These reactions are assumed to be first-order reactions such as Am(VI)→Am(V) and Am(V)→Am(III), while the radiolytic reduction of Am(V) and Am(VI) are zero-order reactions with respect to Am(V) and Am-(VI).

In contrast to Eqs. 1—3, the rate law for the above-mentioned reactions can be expressed as follows:
in the case of ^{241}Am(V) solutions,

$$-\frac{d[Am(V)]}{dt} = \frac{d[Am(III)]}{dt} = k_1'[Am(V)] \quad (8)$$

and in the case of ^{241}Am(VI) solutions,

$$-\frac{d[Am(VI)]}{dt} = k_2'[Am(VI)], \quad (9)$$

and $$\frac{d[Am(V)]}{dt} = k_2'[Am(VI)] - k_1'[Am(V)], \quad (10)$$

where k_1' and k_2' are apparent rate constants.

If first-order reactions proceed predominantly in the stock solutions, Eq. 5 can be written as follows, using the solutions of Eqs. 8—10:
for the case of ^{241}Am(V) solutions,

$$Y_{III} - Y = (Y_{III} - Y_V) \exp(-k_1't), \quad (11)$$

and for the case of ^{241}Am(VI) solutions,

$$Y_{III} - Y = \frac{(Y_{III} - Y_V)k_2'}{k_2' - k_1'} \exp(-k_1't) + \left\{(Y_{III} - Y_{VI}) + \frac{(Y_{III} - Y_V)k_2'}{k_1' - k_2'}\right\} \exp(-k_2't). \quad (12)$$

As Y_{III} is nearly equal to unity, Figs. 3 and 4 illustrate the plot of $\log(1-Y)$ *vs.* t, using the data shown in Figs. 1 and 2. The relationship expected by Eqs. 11 and 12 was confirmed for the stock solutions of low acidities and at high temperatures. Thus, it is reasonable to assume that the radiolytic reduction and first-order reactions compete in the dilute ^{241}Am solutions.

The values for k_1' and k_2' were estimated by means of curve-fitting techniques; the results are shown in Table 1. The values for k_1' and k_2' fluctuated, undoubtedly depending upon whether a nitric acid solution had been used to prepare the stock solutions just after or a little after the dilution of concd nitric acid. Therefore, a certain material which induced first-order reaction had been probably introduced into the stock solutions from the nitric acid.

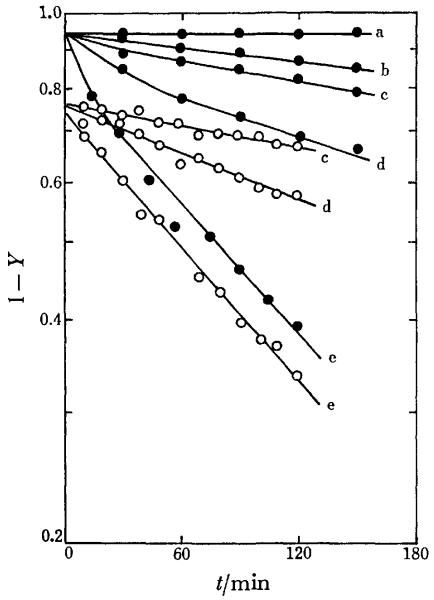

Fig. 3. The plot of $\log(1-Y)$ *vs.* t for the 0.5 M HNO_3 solutions of ^{241}Am(V)(○) and ^{241}Am(VI)(●) at 0 °C(a), 10 °C(b), 20 °C(c), 30 °C(d), and 40 °C(e).

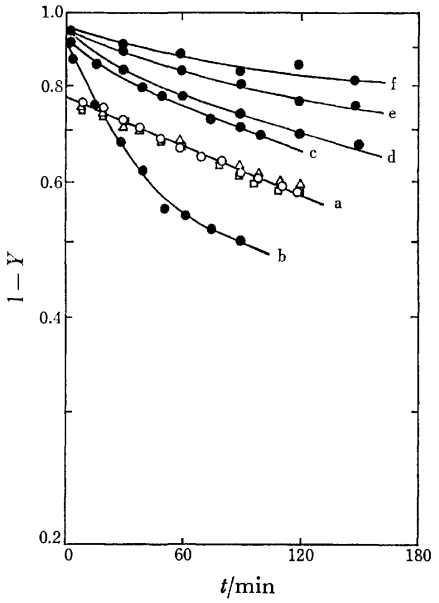

Fig. 4. The plot of $\log(1-Y)$ *vs.* t for the ^{241}Am(V) and ^{241}Am(VI) solutions at 30 °C. a): ^{241}Am(V) solutions at the acidity of 0.125 M(○), 0.25 M(△), and 0.5 M(□). ●: ^{241}Am(VI) solutions at the acidity of 0.125 M(b), 0.25 M(c), 0.5 M(d), 1.0 M(e), and 2.0 M(f).

Table 1. Apparent rate constants for the reduction of ^{241}Am(V) and ^{241}Am(VI) in HNO_3 solutions

$[HNO_3]$ M	Temperature °C	Apparent rate constant/h^{-1}

0.5	40	0.40±0.01	0.30±0.05	2.00±0.34

a) Result for Am(V) solutions. b) Result for Am(VI) solutions.

When the 0.05 M HNO_3 solutions of ^{243}Am(V) and ^{243}Am(VI) were investigated, no change in Y with time was observed even on the stock solutions at 30 °C. This finding may be explained only by the serious difference in emission rate of α-particles between ^{241}Am and ^{243}Am. Thus, first-order reactions are considered to be the radiation-induced reactions which may be caused by a product resulting from the interaction between the radiolysis product and the material introduced from the nitric acid.

This assumption was supported by a finding for the ^{241}Am(V) and ^{241}Am(VI) solutions containing ozone gas; that is, Y was constant for the time of storage during which the stimulative smell of ozone gas was still hanging about the vessel of the stock solutions. It can be said that ozone gas effectively eliminates any reducible materials in the same way as chlorine gas does.[4]

Stability of Am(V) and Am(VI) in HNO_3–NH_4F Solutions. The coprecipitation test with ThF_4 was carried out on the 0.05 M HNO_3 solutions of ^{241}Am(V) and ^{241}Am(VI) containing the fluoride at 30 °C, and the result is shown in Fig. 5. The Y for the stock solutions

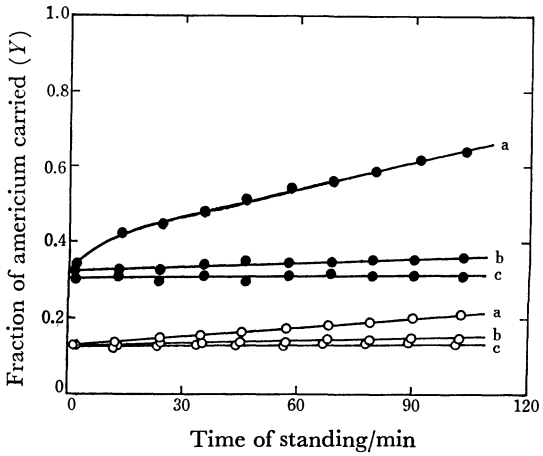

Fig. 5. The result of the ThF_4 coprecipitation test carried out on the 0.05 M HNO_3 solutions of ^{241}Am-(V)(○) and ^{241}Am(VI)(●) at 30 °C. [NH_4F]: a) 0 M, b) 0.05 M, and c) 0.5 M.

containing the fluoride increased more slowly than for the case free from fluoride, and no change in Y was observed for the 0.5 M NH_4F solutions. The stock solutions of acidity higher than 0.05 M called for rather high concentrations of the fluoride in order to minimize the variation in Y.

This finding can be explained by the suggestion that ^{241}Am(V) and ^{241}Am(VI) become free from all reduction reactions if they form fluoro complexes, as in the cases of the acetate[7] and the chloride solutions[11] of ^{241}Am(V). The excellent stability of ^{243}Am(V) and ^{243}Am(VI) in the ozonized fluoride solutions was also confirmed as expected.

Stability of Am(V) and Am(VI) in HNO_3–NaH_2PO_4 Ozonized Solutions. The coprecipitation test with $BiPO_4$ was carried out on the 0.05 M HNO_3–(0—2 M) NaH_2PO_4 and the (0.025—0.2 M) HNO_3–0.5 M NaH_2PO_4 solutions of ^{241}Am(V) and ^{241}Am(VI) at 30 °C.

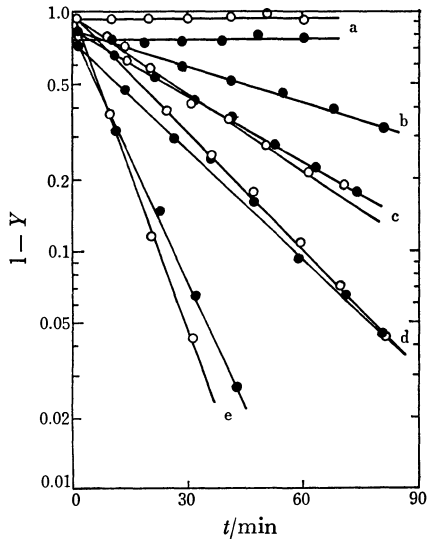

Fig. 6. The plot of $\log(1-Y)$ *vs.* t for the 0.05 M HNO_3 solutions of ^{241}Am(V)(○) and ^{241}Am(VI)(●) at 30 °C. [NaH_2PO_4]: a) 0 M, b) 0.1 M, c) 0.5 M, d) 1.0 M, and e) 2.0 M.

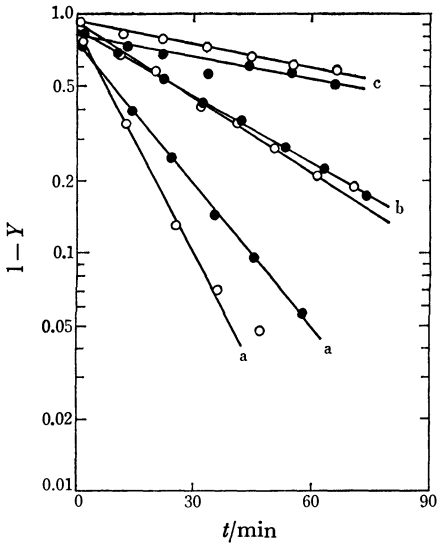

Fig. 7. The plot of $\log(1-Y)$ *vs.* t for the 0.5 M NaH_2PO_4 solutions of ^{241}Am(V)(○) and ^{241}Am(VI)(●) at 30 °C. [HNO_3]: a) 0.025 M, b) 0.05 M, and c) 0.2 M.

The Y for these ozonized solutions increased rapidly with time of storage, especially at low acidities and at high phosphate concentrations. Figures 6 and 7 illustrate the plot of $\log(1-Y)$ *vs.* t; a good linearity was obtained in most cases.

The same result was obtained both for the 0.05 M HNO_3–0.5 M NaH_2PO_4 solutions of ^{241}Am(V) and ^{241}Am(VI) at 0—40 °C and for the (0.05—0.5 M) HNO_3–1 M NaH_2PO_4 solutions of ^{243}Am(V) and ^{243}Am-(VI) at 30 °C. Evidently, the variation in Y with time for the ozonized phosphate solutions of ^{241}Am(VI) and ^{243}Am(VI) can be explained neither by Eq. 7 nor by Eq. 12.

It is known that Am(VI) at such high concentrations as 2×10^{-3} M (^{243}Am 85% and ^{241}Am 15%) is reduced to Am(III) in phosphoric acid.[12] Then, it may be assumed that Am(V) and Am(VI) at low concentrations are also reduced to Am(III) in the ozonized phosphate solutions, and that the reduction rates are given by the following equations:

$$-\frac{d[Am(V)]}{dt} = \frac{d[Am(III)]}{dt} = k_1''[Am(V)], \quad (13)$$

and

$$-\frac{d[Am(VI)]}{dt} = \frac{d[Am(III)]}{dt} = k_2''[Am(VI)], \quad (14)$$

where k_1'' and k_2'' are apparent rate constants. If the change of oxidation states of americium in the ozonized phosphate solutions is predominantly caused by these reactions, Y can be expressed as follows, using the solutions of Eqs. 13 and 14:

for the case of Am(V) solutions,

$$Y_{III} - Y = \exp(-k_1''t) \quad (15)$$

and for the case of Am(VI) solutions,

$$Y_{III} - Y = \exp(-k_2''t). \quad (16)$$

As Y_{III} is nearly equal to unity, Eqs. 15 and 16 can explain the linearity obtained by the plot $\log(1-Y)$ *vs.* t, as are shown in Figs. 6 and 7. Therefore, it seems to be reasonable to assume that Am(V) and Am(VI) are reduced to Am(III) in the ozonized phosphate solutions.

a) Result for ^{241}Am solutions except as otherwise noted.
b) Result for ^{243}Am solutions.

Values for k_1'' and k_2'' were obtained from the slope of the straight lines. They were found to be rather large for the stock solutions of low acidities, at high phosphate concentrations, and at high temperatures, as are summarized in Table 2. The reduction of ^{243}Am(V) and ^{243}Am(VI) preceeded more rapidly than that of ^{241}Am-(V) and ^{241}Am(VI) because the ^{243}Am concentration was about ten times higher than the ^{241}Am concentration.

The available information concerning the behavior of americium in phosphoric acid[12] and the phosphato-complex formation of neptunium and plutonium[13,14] suggests that Am(V) and Am(VI) may form the phosphato complexes such as $AmO_2H_2PO_4$ and $AmO_2H_2PO_4^+$, respectively, in the phosphate solutions examined. Therefore, the rapid reduction of Am(V) and Am(VI) might result from the intramolecular electron transfer in phosphato complexes.

Rate of Ligand Exchange of Tris(acetylacetonato)iron(III) with 2-Thenoyltrifluoroacetone in Organic Solvents

Tatsuya SEKINE,* Hiroshi HONDA, Masakazu KOKISO, and Teruyuki TOSAKA

Department of Chemistry, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received August 2, 1978)

The rate of exchange of acetylacetonate ions ($acac^-$) in tris(acetylacetonato)iron(III) with 2-thenoyltrifluoroacetonate ions (tta^-) has been measured in several organic solvents. The rate was independent of the concentration of Hacac and Htta and nearly the same in carbon tetrachloride, benzene, acetone, and 4-methyl-2-pentanone. However, the rate was much greater in ethanol. The rate of exchange in carbon tetrachloride, benzene, and acetone was found to be enhanced by water, ethanol, and several acids. The enhancement was smaller in acetone than in nonpolar solvents and the stronger the acid, the greater the catalytic effect. The rate controlling step of the exchange reaction was the rupture of an acetylacetonate ion from iron(III) in the complex. These observations have been discussed and possible mechanisms proposed.

In the course of studies of the chemical equilibria of metal complexes in organic solvents, it was found that exchanging the ligand of tris(acetylacetonato)iron(III) in organic solvents with other chelating ligands proceeded rather slowly. In the present paper, the rate of exchange with 2-thenoyltrifluoroacetonate ions has been studied photometrically.

Experimental

Reagents. All reagents were of reagent grade. The tris(acetylacetonato)iron(III) ($Fe(acac)_3$), acetylacetone (Hacac), 2-thenoyltrifluoroacetone (Htta), and trioctylphosphine oxide (TOPO) were supplied by Dojindo Co., Kumamoto. The organic solvents were also of analytical grade and subsequently passed through a dehydrating column containing an ion-exchanger resin supplied by Mitsubishi Kasei Co., Tokyo, and distilled.

Procedure. The experiments were conducted in a thermostatted room or in a thermostatted bath. A portion of the solvent containing a $Fe(acac)_3$ was added to another portion of the same solvent containing Htta. In several experiments, certain amounts of other materials such as an acid, TOPO, acetone, an alcohol, and/or water were added to the $Fe(acac)_3$ solution. The solution was agitated and transfferred to a glass cell (1 cm path). The change in the optical density of the solution at 550 nm was measured with a spectrophotometer (Hitachi double wavelength double beam spectrophotometer type-556 or Hitachi UV-VIS spectrophotometer type-101 or type-139) as a function of time and the increase in the $Fe(acac)_3$ concentration obtained. The water content was checked by the Karl Fischer titration.

Results

The temperature of the experiments in this study was 25 ± 0.3 °C except when the effect of the temperature was examined. All the data were found to indicate that the reaction was first order with respect to $Fe(acac)_3$ in the initial stage.

Dependence on Hacac Concentration. The rate of exchange of $acac^-$ in $Fe(acac)_3$ with tta^- was measured at several concentrations of Hacac. It was found that the rate was always independent of the co-existing Hacac concentration, at least below 0.1 mol dm^{-3}. When the Htta solution was added to the $Fe(acac)_3$ solution in the absence of Hacac the results were reproducible, at least within 5 min of the dissolution of the $Fe(acac)_3$ crystals. $Fe(acac)_3$ solutions containing no Hacac however were not stable on standing for a long time, especially under light. The addition of, for example, 10^{-3} mol dm^{-3} of Hacac to a solution of 10^{-4} mol dm^{-3} of $Fe(acac)_3$ stabilized the solution. Thus in the present study, ten to hundred times of Hacac to $Fe(acac)_3$ by molar ratio was added to the initial solution.

Dependence on Htta Concentration. The rate was measured in the concentration range of Htta from 10^{-4} to 2×10^{-1} mol dm^{-3} where it was found that the rate was independent of the Htta concentration unless it was below 10^{-3} mol dm^{-3}. This was however found to be an apparent effect; under such conditions the exchange was thermodynamically incomplete and this has been discussed later.

Effect of Solvent. The rate of exchange was measured in carbon tetrachloride and in four other solvents. The rate in ethanol was too high to be measured by the method employed but that in benzene as well as in acetone and 4-methyl-2-pentanone (MIBK) was measurable. No determination was made in water because of low solubilities of the complexes and ligands but the rate in water would be expected to be too high for the measurement as will be seen from the description on the effect of water.

From the experimental results, the rate may be written as

$$v_0 = -d[Fe(acac)_3]/dt = k_0[Fe(acac)_3]. \quad (1)$$

The rate constants in these solvents obtained from the slope of the plot of $\log [Fe(acac)_3]$ *vs.* time are listed in Table 1(a).

Effect of Water. The effect of water in the solvent was examined in carbon tetrachloride, benzene, and acetone and Fig. 1 gives the results. The rates in dehydrated carbon tetrachloride and benzene were identical with each other and increased with increase in the water content and became 2.0 and 3.7 times greater in water-saturated carbon tetrachloride and benzene, respectively. The explanation for this is in terms of the amount of water in the water-saturated solvents. The increase in the rate by water was smaller in acetone than in the two nonpolar solvents. Determination of the water content in the "dehydrated" solvents (experimental section) was not possible but the content was presumed to be lower than 10^{-4} mol dm^{-3}.

TABLE 1. SUMMARY OF CONSTANTS

$v=[Fe(acac)_3](k_0+k_c[C])$. k_c represents k_w, $k_{alc.}$, and k_{acid}, respectively (*cf.* Eqs. 2, 4, and 5).

(a) Rate constant

Solvent	log (k_0/s^{-1})
Carbon tetrachloride	−3.2
Benzene	−3.2
Acetone	−3.5
4-Methyl-2-pentanone	−3.2
Ethanol	too high to be measured
Water	too high to be measured

(b) Catalytic constant

Catalyzer	log $(k_c/s^{-1}\ mol^{-1}\ dm^3)$ Solvent		
	CCl_4	C_6H_6	$(CH_3)_2CO$
Water	−1.2	−1.2	−2.4
Ethanol	−0.8	−0.8	−2.0
Methanol	−0.8	—	—

(c) Catalytic constant in carbon tetrachloride

Acid	pK_a[a]	log $(k_c/s^{-1}\ mol^{-1}\ dm^3)$
Trichloroacetic acid	0.64	1.5
Dichloroacetic acid	1.26	1.2
Chloroacetic acid	2.87	0.6
Bromoacetic acid	2.90	0.6
1-Naphthoic acid	3.70	0.4

a) Taken from L. G. Sillen and A. E. Martell, "Stability Constants," The Chemical Society Spec. Pud., **17** (1964).

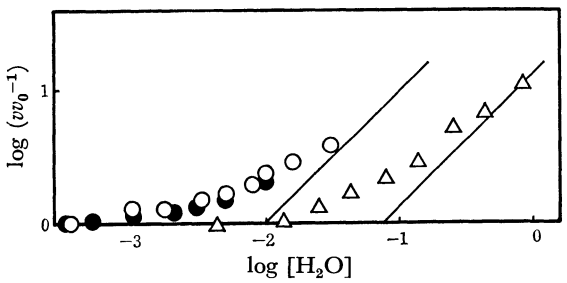

Fig. 1. Effect of water on the rate of exchange with tta^-. v is the rate in the presence of water and v_0 is that in the dehydrated solvent otherwise identical conditions. ●: CCl_4, ○: C_6H_6, △: $(CH_3)_2CO$.

The rate of reaction enhanced by water may be written as

$$v_w = -d[Fe(acac)_3]/dt = k_w[Fe(acac)_3][H_2O]^a. \quad (2)$$

The overall rate is then;

$$v = v_0 + v_w = [Fe(acac)_3](k_0+k_w[H_2O]^a). \quad (3)$$

The plot of log v *vs.* log $[H_2O]$ reached an asymptote and thus log v=log k_w+log $[H_2O]$; "a" was concluded to be unity. The values of k_w are listed in Table 1(b).

Effect of Alcohol. The effect of ethanol was examined in carbon tetrachloride, benzene, and acetone. Some experiments were conducted on the effect of methanol in carbon tetrachloride. The rate of exchange was enhanced by the alcohols and may be written as

$$v_{alc.} = -d[Fe(acac)_3]/dt = k_{alc.}[Fe(acac)_3][alcohol]^a. \quad (4)$$

The results were analyzed and from the analysis, "a" was concluded to be unity. The values for the constant $k_{alc.}$ were determined in a similar manner to that for water and the values are listed in Table 1(b).

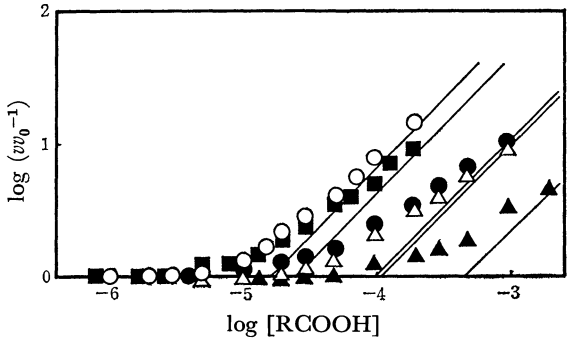

Fig. 2. Enhancement of the rate by acids in CCl_4. v is the rate in the presence of the acid and v_0 is that in the absence otherwise identical conditions. ○: CCl_3COOH, ■: $CHCl_2COOH$, ●: $CH_2ClCOOH$, △: $CH_2BrCOOH$, and ▲: 1-naphthoic acid. The straight lines of slope +1 give the calculated asymptotes, log (vv_0^{-1})=log $k_{acid}k_0^{-1}$[RCOOH] (*cf.* Eq. 6).

Effect of Acids. The rate was enhanced by various carboxylic acids. Figure 2 gives the results in carbon tetrachloride. The rate of reaction catalyzed by acids may be written as

$$v_{acid} = -d[Fe(acac)_3]/dt = k_{acid}[Fe(acac)_3][RCOOH]^a. \quad (5)$$

From an analysis of the results, "a" was concluded to be unity in all cases and the rate may be thus written

$$v = v_0 + v_{acid} = [Fe(acac)_3](k_0+k_{acid}[RCOOH]). \quad (6)$$

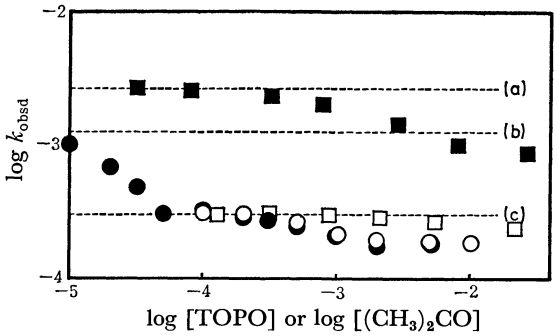

Fig. 3. Effect of TOPO and acetone on the rate. k_{obsd} is $v[Fe(acac)_3]^{-1}=(k_0+k_{acid}[RCOOH])$ (*cf.* Eq. 6). Open symbols give the effect of TOPO (circles) and acetone (squares) on the rate in the absence of any acid in CCl_4. Closed squares give the effect of acetone on the rate in the presence of 2.0×10^{-4} mol dm^{-3} of dichloroacetic acid in CCl_4. Closed circles give the effect of TOPO on the rate in the presence of 4.2×10^{-5} mol dm^{-3} of trichloroacetic acid in CCl_4. Dotted lines show the values of k_{obsd} when the concentration of dichloroacetic acid was 2.0×10^{-4} mol dm^{-3} in the absence of acetone (a), the concentration of trichloroacetic acid was 4.2×10^{-5} mol dm^{-3} in the absence of TOPO (b), and when the solvent contained none of these materials (c). When the molar ratio of TOPO and trichloroacetic acid is 1: 1, the catalysis disappeared.

The values for the constant k_{acid} are given in Table 1(c).

Effect of Temperature. The rate of exchange was also determined at 15 and 35 °C. From these data and that at 25 °C, the activation energies were determined and the values of activation enthalpy (ΔH^*) and entropy (ΔS^*) for k_0 and k_c calculated the values of which given in Table 2.

TABLE 2. SUMMARY OF ACTIVATION PARAMETERS FOR k_c IN CARBON TETRACHLORIDE AT 25 °C[a)]

Catalyzer	ΔH^* (kJ mol^{-1})	ΔS^* (J K^{-1} mol^{-1})
Water	18±3	−223±20
Methanol	23±3	−182±15
Ethanol	23±3	−176±16
Trichloroacetic acid	22±2	−160±14

a) The values of ΔH^* and ΔS^* for k_0 in carbon tetrachloride at 25 °C were found to be 24±3 (kJ mol^{-1}) and −226±20 (J K^{-1} mol^{-1}), respectively.

Effect of TOPO, Acetone, and Water on Acid Catlaysis. The rate in carbon tetrachloride was determined as a function of the concentration of TOPO or acetone, the other concentrations being kept constant. The hydrogen-bond acceptors had little effect on the rate in the absence of acid catalyzers as seen from Fig. 3. However, in the presence of an acid catalyzer, the added TOPO lowered the rate and when the molar concentration of TOPO reached that of the acid catalyzer, the catalytic effect disappeared. Acetone also exhibited such an effect on the acid catalysis although the effect was much smaller than that with TOPO. Figure 3 illustrates the effect of acetone on the acid catalysis. Similar experiments were made on the catalysis by water but the effects of TOPO and acetone were, however, not large even in the water-saturated solvent.

Discussion

As described in a previous paper,[1)] the equilibrium constants for the ligand exchange in a given water-saturated solvent,

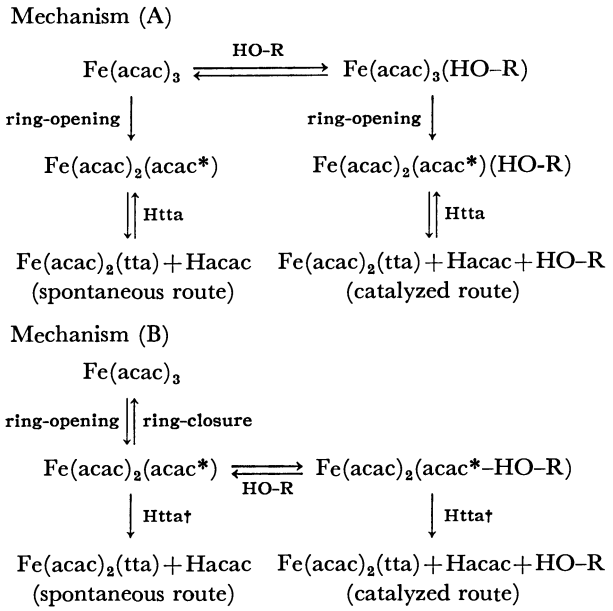
$$K_n = ([Fe(acac)_{3-n}(tta)_n]/[Fe(acac)_3]) \times ([Hacac]/[Htta])^n \quad (7)$$

can be calculated from the solvent extraction constants of iron(III) with Hacac and Htta in the same solvent. From separate experiments and previous data[2)] the value for K_3 in carbon tetrachloride was calculated as $10^{4.1}$. From this value it was statistically calculated that more than 99% of iron(III) at equilibrium was in the form of $Fe(tta)_3$ whenever the ratio [Htta]/[Hacac] was higher than 10. No such values for the equilibrium constants are available in the other solvents. However, since the extraction constants are little affected by the solvent if there are no special interactions between the complex and the solvent molecules, similar assumptions may also be possible in the other solvents. The spectra at equilibrium also indicated the complete change of the complex into $Fe(tta)_3$ when the ratio [Htta]/[Hacac] was higher than 10. Furthermore, all the spectra observed during the exchange reactions were found to be expainable in terms of two species, $Fe(acac)_3$ and $Fe(tta)_3$. Thus the correction for mixed complexes should be unnecessary in the data analysis.

Since the rate is independent of the concentrations of both ligands, Hacac and Htta, it is assumed that the rate-determining step is the isolation of the first acetylacetonate ion. The catalytic effect by the acids, alcohols, and water can be explained by both the following two mechanisms, (A) and (B). Since the catalyzers are assumed to be hydrogen-bond donors, they will be denoted as HO–R.

(A) The hydroxyl group of the catalyzer works as a hydrogen-bond donor to one of the oxygens of acetylacetonate ions which are coordinating with the central metal ion and form a hydrogen-bond complex $Fe(acac)_3$(HO–R). This hydrogen-bond formation between the catalyzer and the oxygen of the chelating acetylacetonate ion weakens the coordination bond and thus accelerate ring-opening.

(B) Among the tris(acetylacetonato)iron(III) molecules, a certain fraction is in a five-coordinated state and an equilibrium is established between the six- and five-coordinated complexes (the unidentate acetylacetonate ion will be denoted by an asterisk as $Fe(acac)_2$(acac*)). The hydroxyl group works as a hydrogen-bond donor to the oxygen being octahedral at the free end of the unidentate ligand. The formation of the hydrogen-bond complex in such a way, $Fe(acac)_2$(acac*–HO–R), prevents the recombination of the oxygen at the free end with the central metal ion. Thus the relative concentration of the five-coordinated complex is increased and/or accelerates the isolation of the



† Addition of tta$^-$ ligand occures after the isolation of the unidentate acac$^-$ ligand which controls the reaction.

Fig. 4. Plausible reaction mechanisms. (acac* denotes unidentate acetylacetonato ligand, HO–R denotes a hydrogen-bond donating catalyzer such as water, alcohol, and carboxylic acid.)

acetylacetonate ion from the complex. The two mechanisms are summarized in Fig. 4.

In both of the mechanisms, the catalytic effect is caused by hydrogen-bond formation and the stronger the acid, the greater the catalytic effect, *i.e.* the greater tendency of a strong acid to form a hydrogen-bond complex than a weak one. A similar tendency was reported in a solvent extraction study where the oxygen in TOPO formed a more stable hydrogen-bond complex in a nonpolar solvent with a strong carboxylic acid as opposed to a weak one.[3] However, the difference in catalysis due to the difference in the acid strength became smaller among the weaker acids; water and alcohols, which are very weak acids catalyze the reaction. This supports the fact that TOPO and various oxygen-containing solvent molecules form hydrogen-bond complexes with water in nonpolar organic solvents. The two β-diketones, Hacac and Htta, have also a hydroxyl group in the enol form and are weak acids (pK_a 9.0 and 6.3 approximately, respectively) but they did not catalyze the exchange reaction as is seen that the rate was not dependent on the concentrations of these materials. This is probably due to the fact that the enolic proton of these materials in nonpolar solvents is hydrogen-bonded with the other oxygen in the same molecule and forms an intramolecular chelate.

In mechanism (A), the rate-determining step is the first ring-opening and in mechanism (B) it is the isolation of the first acetylacetonate ion by breaking the second bond in the chelate. When mechanism (A) operates, the ΔH^* for k_c should be different from that for k_0 and dependent on the catalyzers. When mechanism (B) operates, the ΔH^* for k_c should not be dependent on the catalyzers. However, the experimental errors in the values of ΔH^* are too large to conclude whether mechanism (A) or (B) is operating in the reactions.

The formation of adducts of the $Fe(acac)_3$ chelate with TOPO and various other oxygen-coordinating reagents such as ketones is concluded to be only slight since "synergism" in solvent extraction of tris(β-diketonato)iron(III) is negligible.[4] This is reasonable since TOPO and ketones did not catalyze the reaction by mechanism (A). These reagents could occupy the vacant site of the five-coordinated complex and could accelerate the reaction by preventing the recombination of oxygen at the free end of the unidentate ligand in mechanism (B). However, since no catalytic effect was observed, such an effect would be very slight.

TOPO greatly inhibited the catalysis attributed to the formation of a stable hydrogen-bond complex between TOPO and the catalyzer in the solvent. The catalysis completely disappeared by the addition of TOPO at a 1:1 molar ratio agrees with the previous result that TOPO formed a very stable 1:1 hydrogen-bond complex with carboxylic acids in a nonpolar solvent.[4] Acetone inhibited the catalysis to a much smaller extent than TOPO attributable to the fact that the oxygen of acetone is a much weaker hydrogen-bond acceptor. The limited extent of the catalysis of water and ethanol in acetone may be due to the same reason.

According to the literature,[3,5] the dimerization of the acids is only slight in the solvents when the concentration is lower than 10^{-3} mol dm^{-3}. Such a dimerization effect of the acids on catalysis should be negligible under the conditions of the present study. The intramolecular association of water or alcohol in these solvents is also slight[3,5] and its effect on the catalysis should also be negligible.

When both water and an acid catalyzer co-exist in a solvent, each work as a hydrogen-bond donating catalyzer and, at the same time, as a hydrogen-bond accepting inhibitor for the catalysis. However, as already described, this was not clear in the present study, probably a consequence of the low concentrations.

The isotopic ligand exchange of metal chelates has been studied in several polar solvents and in some nonpolar solvents.[6-16] In the present study, the ligand exchange was not isotopic and no direct comparison with previous results may be possible. However, the following observations in these previous studies may reasonably be compared with the present results.

In nonpolar solvents, especially in the dehydrated ones, the presence of isolated ions should be negligible. Thus the role of protons or hydronium ions in the reaction mechanism should also be negligible and the tendency observed among the catalyzers in the present study that the stronger the acid, the greater the catalytic effect, can be explained only in terms of the higher stabilities of the hydrogen-bond complex by the stronger acids, as already described. Based on this assumption, it can be concluded that water and alcohols are the same type of catalyzers as acids such as trichloroacetic acid although the hydrogen-bonds are weaker. Water was assumed not to assist the acid catalysis. This is quite different from the mechanism proposed for the reactions in polar solvents.[9,10,16]

Solvation of the vacant site of the five-coordinated complex produced by the ring-opening of a chelate ligand was reported to accelerate the reaction by preventing ring closure[10,16] which corresponds to mechanism (B).

In the isotopic exchange reaction of tetrakis(acetylacetonato) or tetrakis(trifluoroacetylacetonato)zirconium(IV) or hafnium(IV) in nonpolar solvents, the rate was dependent on both the metal complex and the free ligand concentration and the presence of an intermediate complex which was coordinated by both the leaving and incoming ligands as unidentate ligands and a transfer of the proton between the two unidentate ligands was assumed.[6] The dependence of the rate on the ligand concentration was also reported in other papers and mechanisms explaining this observation were proposed.[9,13,15]

A kinetic study on the ligand exchange of tris(*N*-benzoyl-*N*-phenylhydroxylaminato)oxovanadium(V) in chloroform or 1,2-dichloroethane with tropolonate ion added as the acid form tropolone was reported.[17] This appears to be the only report of the systematic kinetic study of an exchange reaction of a metal chelate with a different ligand in nonpolar solvents. However, the reaction mechanism was not definitively proposed and a comparative discussion of the results with the present study seems to be difficult.

Preparative Study on Chiral Orthotelluratobis(diamine)cobalt(III) Complexes and Their Condensation Products

Yutaka Hosokawa* and Yoichi Shimura

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received November 9, 1978)

Five chiral cobalt(III) complexes coordinating an orthotellurate or a ditellurate ligand have been prepared and their optically active isomers isolated. They belong to one of the three following types: first a "mononuclear" $[Co(TeO_6H_4)(diamine)_2]^+$ type (diamine=ethylenediamine (en) and (*R*)-(−)-1,2-propanediamine); second a "dinuclear" $[Co(diamine)_2(Te_2O_{10}H_4)Co(diamine)_2]^{2+}$ one (diamine=en and (*R,R*)-(−)-*trans*-1,2-cyclohexanediamine); and lastly a "tetranuclear" $[\{Co(diamine)_2\}_2(Te_2O_{10})\{Co(diamine)_2\}_2]^{4+}$ one (diamine=en). The structures of these complexes have been discussed from the visible to ultraviolet absorption and circular dichroism spectra.

Orthotellurate anion $[TeO_6H_{6-n}]^{n-}$ is capable of coordinating with a cobalt(III) center as a bidentate ligand, as was exemplified by the isolation of $K_3[Co(TeO_6H_3)_2(H_2O)_2]$.[1] Also the anion has a tendency to condense easily in solution. One of the condensation products, tetrahydrogenditellurate anion, $Te_2O_{10}H_4^{4-}$, was proved to occur in its potassium salt, in which each tellurium atom is surrounded by six oxygen atoms in an octahedral arrangement, two such octahedra having one edge in common.[2] Thus the anion is a promising ligand for the synthesis of new polynuclear compounds of a hybrid type between metal chelate and heteropoly oxoanion, such as $H_3[Co_4I_3O_{18}(en)_3]\cdot 5H_2O$[3] and $Na_5[Co(Nb_6O_{19})(dien)]$[4]. That is, the mononuclear cobalt(III) complex with the orthotellurate ligand will be able to polymerize into some polynuclear complexes by the dehydration condensation of the coordinated orthotellurate moiety. The present study is concerned with the preparation of such new polynuclear telluratocobalt(III) complexes with configurational and/or vicinal chirality and of their starting mononuclear complex, $[Co(TeO_6H_4)(diamine)_2]^+$, along with electronic absorption and circular dichroism (CD) investigations. The bidentate diamine used are ethylenediamine (en), (*R*)-(−)-1,2-propanediamine (*l*-pn), and (*R,R*)-(−)-*trans*-1,2-cyclohexanediamine (*l*-chxn). This study has been partly reported in a preliminary letter.[5]

Experimental

Preparation, Separation, and Optical Resolution of Complexes.

(1) $[Co(TeO_6H_4)(en)_2]_2SO_4\cdot H_2O$: A solution of 2.3 g (10 mmol) of $Te(OH)_6$ in 25 cm³ of water was added to a solution of 2.9 g (5 mmol) of $[Co(CO_3)(en)_2]_2SO_4$ in 20 cm³ of water. The mixture was stirred mechanically at about 55 °C for an hour, from which a light red product deposited. After the solution had been kept in a refrigerator for a few hours, the product was separated by filtration, washed several times with water, methanol and then acetone, and dried in a desiccator over $CaCl_2$. Found: C, 10.64; H, 4.44; N, 11.99; Co, 12.9; Te, 27.6; SO_4^{2-}, 10.9%. Calcd for $[Co(TeO_6H_4)(en)_2]_2SO_4\cdot H_2O$: C, 10.35; H, 4.57; N, 12.08; Co, 12.7; Te, 27.5; SO_4^{2-}, 10.4%. Cobalt was weighed as Co_3O_4, tellurium as the metal, and sulfate ion as AgCl after being substituted to chloride ion with anion exchange resin (Dowex 1-X8, Cl^- form).

(2) $[Co(TeO_6H_4)(en)_2]Cl\cdot 3H_2O$: A solution of 1.15 g (5 mmol) of $Te(OH)_6$ in 15 cm³ of water was added to a solution of 1.43 g (5 mmol) of *cis*-$[CoCl_2(en)_2]Cl$ in 10 cm³ of water, and to the mixture was added 0.24 g (10 mmol) of LiOH. After stirring mechanically at about 35 °C for an hour, the solution was cooled to room temperature and an appropriate amount of ethanol was gradually added to it. After the solution had been kept in a refrigerator overnight, the light red precipitate deposited was separated by a centrifuge. This was dissolved in a small amount of water and the solution was poured into a column (3 cm×60 cm) of strong acid cation exchanger (SP Sephadex C-25, Li^+ form). The adsorbed band was eluted with 0.25 M LiCl solution, which was adjusted in advance to pH 10 by 1 M LiOH solution. During the elution the column was cooled by flushing ice-water. Two red bands, E_1 and E_2, were eluted in this order. The later eluate (E_2) was treated as in (3) to obtain another complex. The earlier eluate (E_1) was concentrated by freeze-drying method. The product obtained was recrystallized from water (pH 10 by LiOH) at 0 °C by adding ethanol, and washed repeatedly with methanol and acetone. Found: C, 9.49; H, 4.76; N, 11.26%. Calcd for $[Co(TeO_6H_4)(en)_2]Cl\cdot 3H_2O$: C, 9.68; H, 5.29; N, 11.29%. This complex was also obtained predominantly by using DMSO as solvent as follows: A solution of 2.86 g (10 mmol) of *cis*-$[CoCl_2(en)_2]Cl$ in 30 cm³ of DMSO was added with stirring to a solution of 2.30 g (10 mmol) of $Te(OH)_6$ in 40 cm³ of DMSO, and to the mixture was added 0.5 g (20 mmol) of LiOH in 10 cm³ of water. The solution was stirred mechanically at about 35 °C for a few hours. The light red precipitate deposited was separated by filtration. The chromatography of the product showed only one red band (E_1). The absorption spectrum of the eluate was the same as that of the E_1 complex prepared in water.

(3) $[Co(en)_2(Te_2O_{10}H_4)Co(en)_2]Cl_2\cdot CH_3OH\cdot 4H_2O$: The later eluate ($E_2$) from the chromatography in (2) was concentrated at 15 °C in a rotary evaporator, and a large volume of ethanol was added to the concentrated solution. After the solution had been kept in a refrigerator overnight, the red product deposited was collected by a centrifuge. The product was recrystallized from an aqueous LiOH solution of pH 10 at 0 °C by adding acetone–methanol mixture and washed repeatedly with ethanol and acetone. Found: C, 11.28; H, 4.74; N, 11.55%; Co/Te (molar ratio)=1.1. Calcd for $[Co(en)_2(Te_2O_{10}H_4)Co(en)_2]Cl_2\cdot CH_3OH\cdot 4H_2O$: C, 11.34; H, 5.09; N, 11.77%; Co/Te=1.0. Cobalt and tellurium were determined for the eluates from the column. The E_2 complex was also obtained predominantly by raising the reaction temperature to *ca.* 60 °C.

(4) $[\{Co(en)_2\}_2(Te_2O_{10})\{Co(en)_2\}_2]Cl_4\cdot CH_3OH\cdot 12H_2O$: The similar procedure to that for E_1 and E_2 complexes was adopted in water using 1.15 g (5 mmol) of $Te(OH)_6$, 2.86 g

(10 mmol) of *cis*-$[CoCl_2(en)_2]Cl$, and 0.48 g (20 mmol) of LiOH. The reaction was carried out at 60 °C, and the reaction solution was poured into a column directly. The products separated on the column consisted of two red bands, E_2 and a new E_3 in this order, when eluted with 0.35 M LiCl solution (pH 10 by 1 M LiOH). The E_3 complex was purified by the same method as that of E_2 complex. Found: C, 13.58; H,6.07; N, 14.55%; Co/Te (molar ratio)=2.1. Calcd for $[\{Co(en)_2\}_2(Te_2O_{10})\{Co(en)_2\}_2]Cl_4 \cdot CH_3OH \cdot 12H_2O$: C, 13.42; H, 6.10; N, 14.73%; Co/Te=2.0. The metal analyses were carried out using the eluate from the column.

(5) Optical Resolution of E_1, E_2, and E_3 Complexes: Optically active E_1 and E_2 complexes were obtained by the preparation procedure starting from $(+)_{589}$-$[CoCl_2(en)_2]^+$.[7] The $(+)^{CD}_{589}$-E_1 and $(+)^{CD}_{589}$-E_2 complexes have $\Delta\varepsilon=+0.18$ and $+0.44$, respectively, at the Na D line. The optical resolution of E_3 complex was made by the solubility difference between diastereomers: A solution of 0.015 g of $K_2[Sb_2(d\text{-}C_4H_2O_6)_2] \cdot 3H_2O$ in 5 cm^3 of water was gradually added with stirring to a solution of 0.07 g of E_3 complex in 10 cm^3 of LiOH solution of pH 10 on an ice bath. To the mixture was added an appropriate amount of acetone, and the solution was kept in a refrigerator overnight. The light red diastereomer deposited was isolated by a centrifuge and washed with methanol a few times. This less soluble diastereomer was stirred at 0 °C in LiOH solution of pH 10 containing anion-exchange Sephadex (QAE A-25, Cl^- form). The solution was filtered to remove Sephadex, and CD of the filtrate was measured. The $(+)^{CD}_{589}$-E_3 complex has $\Delta\varepsilon=+0.18$ at Na D line.

(6) $[Co(TeO_6H_4)(l\text{-}pn)_2]Cl \cdot 1/2CH_3OH \cdot 3H_2O$: A solution of 0.42 g (2 mmol) of $Te(OH)_6$ in 10 cm^3 of water was added to a solution of 0.63 g (2 mmol) of *cis*-$[CoCl_2(l\text{-}pn)_2]Cl$ in 10 cm^3 of water, and to the mixture was added 0.16 g (4 mmol) of NaOH. After stirring mechanically at about 35 °C for half an hour, the solution was poured into a column (3 cm × 60 cm) of strong acid cation exchanger (SP Sephadex C-25, Li^+ form). The adsorbed band was eluted with 0.25 M LiCl solution, which was adjusted in advance to pH 10 by 1 M LiCl solution. During the elution the column was cooled by flushing ice–water. Two red bands were eluted, and the absorption spectrum of each eluate was similar with that of ethylenediamine E_1 and E_2 complexes, respectively. It was difficult to isolate the crystals from the later eluate. The earlier eluate was poured once more into another similar column and eluted with 0.5 M LiCl solution (pH 10). To the earlier eluate was added a large amount of acetone. After the solution had been kept in a refrigerator overnight, the light red precipitate deposited was separated by a centrifuge. The product was recrystallized from water (pH 10 by LiOH) at 0 °C by adding methanol–acetone mixture and acetone. Found: C, 14.25; H, 5.38; N, 10.28%. Calcd for $[Co(TeO_6H_4)(l\text{-}pn)_2]Cl \cdot 1/2CH_3OH \cdot 3H_2O$: C, 14.45; H, 5.98; N, 10.37%.

Two diastereomeric isomers of this complex were separated also by the column chromatography. When eluted with 0.2 M LiCl solution (pH 10 by 1 M LiOH), the red band further separated gradually into two bands, Pl and P2 (denoted by elution order). Pl and P2 complexes have $\Delta\varepsilon=+0.28$ and -0.20, respectively, at Na D line. These CD values were calculated referring to molar absorption coefficient of the unresolved complex.

(7) $[Co(l\text{-}chxn)_2(Te_2O_{10}H_4)Co(l\text{-}chxn)_2]Cl_2 \cdot 8H_2O$: A solution of 0.57 g (2.5 mmol) of $Te(OH)_6$ in 10 cm^3 of water was added to a solution of 0.98 g (2.5 mmol) of *trans*-$[CoCl_2(l\text{-}chxn)_2]Cl$ in 10 cm^3 of water, and to the mixture was added 0.2 g (5 mmol) of NaOH. After stirring mechanically at about 40 °C for an hour, the solution was cooled in a refrigerator. The red precipitate deposited was separated by filtration, recrystallized from a cold water (pH 10 by LiOH) by adding acetone, and washed with methanol–acetone mixture and ether. Found: C, 24.02; H, 6.52; N, 9.28; Te, 19.9%. Calcd for $[Co(l\text{-}chxn)_2(Te_2O_{10}H_4)Co(l\text{-}chxn)_2]Cl_2 \cdot 8H_2O$: C, 23.85; H, 6.35; N, 9.27; Te, 21.1%.

The filtrate from the red precipitate was poured into a column of SP Sephadex C-25 (Li^+ form) and eluted with 0.225 M LiCl solution (pH 10 by 1 M LiOH). Three red bands, Cl, C2, and C3, were eluted in this order. The absorption spectra of three eluates were similar to that of the corresponding ethylenediamine E_2 complex. Furthermore, the absorption and CD spectra of the first red precipitate, $[Co(l\text{-}chxn)_2(Te_2O_{10}H_4)Co(l\text{-}chen)_2]Cl_2 \cdot 8H_2O$, were the same as those of Cl eluate. Cl, C2, and C3 complexes have $\Delta\varepsilon=-0.90$, -0.41, and -1.42, respectively, at Na D line. These CD values were calculated referring to the molar absorption coefficient of the first red precipitate. In this case, the complex corresponding to E_1 complex of ethylenediamine was not obtained.

Measurements. The visible and ultraviolet absorption measurements were made by a Shimadzu UV-200 spectrophotometer in aqueous solutions. The CD spectra were recoreded on a JASCO MOE-1 spectropolarimeter.

Results and Discussion

The tellurato Co(III) complexes newly obtained are summerized in Tables 1 and 2 with their d-d absorption and CD data. Other highly condensed complexes were observed in trace amounts on the column, but they were too unstable to be isolated. All the complexes obtained are unstable in solution at room temperature, and their solutions were carefully handled below 5 °C. E_1 complex is particularly unstable to reequilibration, and converted rapidly into E_2 complex in aqueous solution at room temperature. This rapid conversion corresponds to the dehydration condensation of the "mononuclear" complex $[Co(TeO_6H_4)(en)_2]^+$ into the "dinuclear" one $[Co(en)_2(Te_2O_{10}H_4)Co(en)_2]^{2+}$. E_1 and E_2 complexes

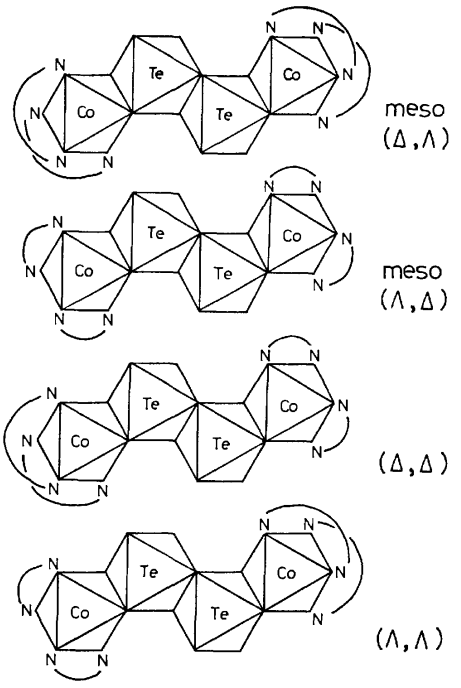

Fig. 2. Proposed structures for the four diastereomeric isomers of $[Co(diamine)_2(Te_2O_{10}H_4)Co(diamine)_2]^{2+}$.

were prepared as their chlorides from the reaction of *cis*-$[CoCl_2(en)_2]^+$ and $Te(OH)_6$ at 35 °C. The formation ratio changed with the reaction temperature. At 60 °C, the former was not obtained at all, and the latter predominantly. The E_1 sulfate $[Co(TeO_6H_4)(en)_2]_2SO_4$ is sparingly soluble in water, but can be converted into the chloride solution by the anion exchange resin Dowex 1-X8 (Cl^- form) at 0 °C. The absorption and CD data of E_1 complex previously reported[5] have been corrected in this paper.

As is seen in Table 1 and Fig. 1, the absorption spectrum of $[Co(TeO_6H_4)(en)_2]^+$ complex shows a characteristic feature of the *cis*-CoN_4O_2 type and is similar to that of $[Co(CO_3)(en)_2]^+$ (σ_{max} = 19500 and 27700 cm^{-1})[6] in the d-d absorption band region. Thus it is concluded that the ligand $TeO_6H_4^{2-}$ stands near after CO_3^{2-} in the spectrochemical series. The second absorption bands of E_2 and E_3 complexes appear as a shoulder because of overlapping with an absorption band at 30000—35000 cm^{-1}. The latter band is assigned to the ditellurate band modified by coordination, since the free ditellurate ion has its longest wavelength absorption band at about 38000 cm^{-1} as a shoulder in contrast to the free orthotellurate ion which scarcely absorbs in the region of 35000—42000 cm^{-1} (Fig. 1). The occurrence of the ditellurate band for E_2 complex and the E_1 to E_2 conversion in solution support that E_2 complex $[Co(en)_2(Te_2-$

	21.5(+0.26)	

a) In the unit of 10^3 cm^{-1}. b) Partly resolved complex.

$O_{10}H_4)Co(en)_2]^{2+}$ corresponds to the condensation product of E_1 complex $[Co(TeO_6H_4)(en)_2]^+$ (see Fig. 2). Similarly, it is supposed that E_3 complex $[\{Co(en)_2\}_2(Te_2O_{10})\{Co(en)_2\}_2]^{4+}$ is a condensation product of $[Co(en)_2(TeO_6H_2)Co(en)_2]^{2+}$, which has not been isolated in this work.

The optically active forms were obtained for E_1, E_2, and E_3 complexes, and two diastereomeric isomers of $[Co(TeO_6H_4)(l\text{-pn})_2]^+$, P1 and P2, were separated by column chromatography. Furthermore, three diastereomeric isomers of $[Co(l\text{-chxn})_2(Te_2O_{10}H_4)Co(l\text{-chxn})_2]^{2+}$, C1, C2, and C3, were obtained. Among several possible structures for the "dinuclear" complex, $[Co(diamine)_2(Te_2O_{10}H_4)Co(diamine)_2]^{2+}$, the most probable ones are those shown in Fig. 2. In this type of condensation, four diastereomeric isomers are possible, which have *meso*-(Δ,Λ), *meso*-(Λ,Δ), (Δ,Δ), and (Λ,Λ) configurations, respectively, in regard to skew pairs of two diamine chelate rings. Many optical isomers are possible for $[\{Co(en)_2\}_2(Te_2O_{10})\{Co(en)_2\}_2]^{4+}$, but further investigation on this complex has not been intended in the present study, because it seems the optical resolution was successful only partly.

The CD data of the present complexes are summerized in Table 2 and Figs. 3—6. The CD patterns of the $[Co(TeO_6H_4)(en)_2]^+$ and $[Co(en)_2(Te_2O_{10}H_4)Co(en)_2]^{2+}$ complexes are similar to that of Λ-$[Co(CO_3)(en)_2]^+$ ($\Delta\varepsilon = +3.7$ at 18900 cm^{-1})[6] in the d-d absorption band region, and show only one CD band in the first band region (Figs. 4 and 6). Thus, the absolute configurations of $(+)^{CD}_{589}$-E_1 and $(+)^{CD}_{589}$-E_2 complexes are assigned to be Λ and (Λ,Λ), respectively. This corresponds well to the fact that the optically active E_1 and E_2 complexes have been obtained from $(+)_{589}$-$[CoCl_2(en)_2]^+$ (Λ configuration)[6,8]. The CD curves of two diastereomeric isomers, P1 and P2, of $[Co(TeO_6H_4)(l\text{-pn})_2]^+$ are shown in Fig. 3. Their CD patterns somewhat differ from that of $[Co(TeO_6H_4)(en)_2]^+$, because of the presence of vicinal contribution due to the (*R*)-1,2-propanediamine ligand. It has been well known that the configurational and vicinal CD contributions are separable for many kinds of cobalt(III) complexes by utilizing an additivity rule for a pair of CD curves of diastereomeric isomers.[9] When the additivity rule is applied for the CD curves of P1 and P2 isomers, the calculated configurational CD curve agrees well with the observed CD curve of E_1 complex (Fig. 4). Thus the sign pattern of $(+)^{CD}_{589}$-E_1 complex (Λ configuration) suggests that P1 and P2 isomers are Λ and Δ configurations, respectively.

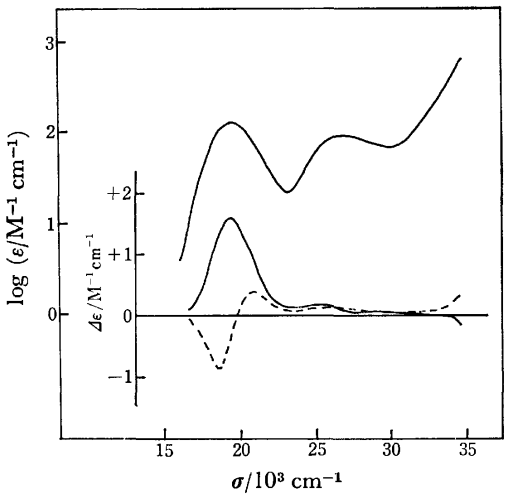

Fig. 3. Absorption and CD spectra of $[Co(TeO_6H_4)(l\text{-pn})_2]^+$: P1 (——) and P2 (– – –) isomers.

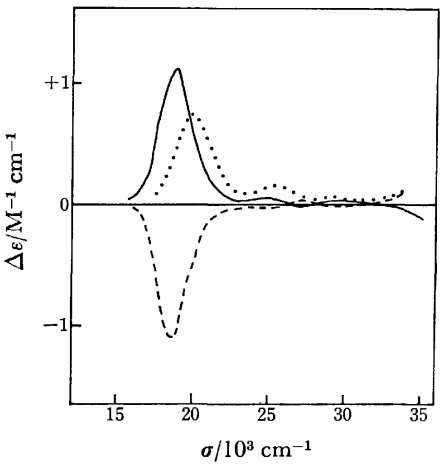

Fig. 4. Calculated configurational (– – –) and vicinal (·····) CD curves of $(-)^{CD}_{589}$-$[Co(TeO_6H_4)(l\text{-pn})_2]^+$, and observed CD curve (——) of $(+)^{CD}_{589}$-$[Co(TeO_6H_4)(en)_2]^+$.

As is seen in Fig. 5, the CD curves of three diastereomeric isomers, C1, C2, and C3, of $[Co(l\text{-chxn})_2(Te_2O_{10}H_4)Co(l\text{-chxn})_2]^{2+}$ differ from that of E_2 complex by the same reason as in the case of P1 and P2 complexes. By the application of the additivity rule for the CD curves of C2 and C3 isomers, the calculated configu-

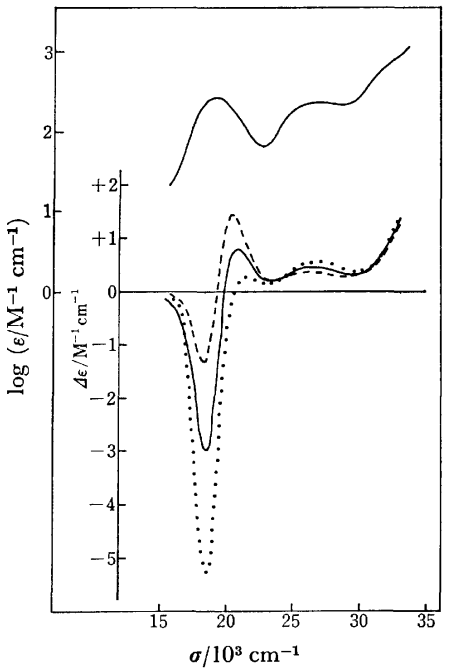

Fig. 5. Absorption and CD spectra of $[Co(l\text{-chxn})_2(Te_2O_{10}H_4)Co(l\text{-chxn})_2]^{2+}$: C1 (——), C2 (– – –), and C3 (·····) isomers.

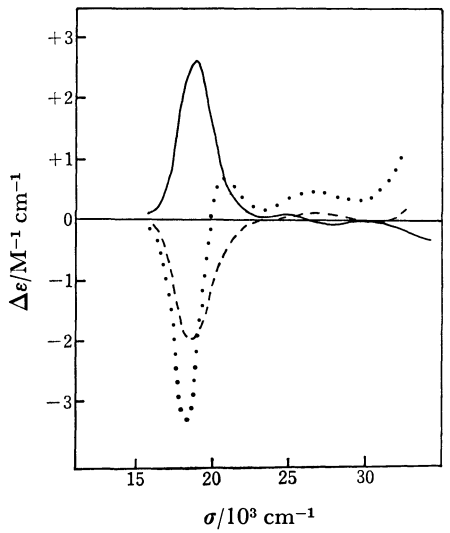

Fig. 6. Calculated configurational (——) and vicinal (……) CD curves of $[Co(l\text{-chxn})_2(Te_2O_{10}H_4)Co(l\text{-chxn})_2]^{2+}$(C3 isomer), and observed CD curve (——) of $(+)^{CD}_{589}$-$[Co(en)_2(Te_2O_{10}H_4)Co(en)_2]^{2+}$.

rational and vicinal CD curves agree well with the observed CD curves of E_2 complex and C1 isomer, respectively (Fig. 6). Thus the CD of C1 isomer is contributed only by the vicinal effect due to the four (*R*,*R*)-*trans*-1,2-cyclohexanediamine ligands; namely C1 isomer corresponds to a *meso* one, (Δ,Λ) or (Λ,Δ) in Fig. 2, or to a mixture of the two *meso* ones. Furthermore, by comparison of the sign patterns of C2 and C3 isomers to that of $(+)^{CD}_{589}$-(Λ,Λ)-$[Co(en)_2(Te_2O_{10}H_4)Co(en)_2]^{2+}$ complex, it is confirmed that C2 isomer has (Λ,Λ) configuration, and C3 isomer (Δ,Δ) one.

Differential Pulse Polarographic Determination of Tellurium by Use of Maximum Wave

Kiyoshi HASEBE

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received September 7, 1978)

A differential pulse polarographic method for the rapid and simple determination of tellurium by use of maximum wave has been studied. Differential pulse polarographic (DP) peak of tellurium(IV) in 1 mol dm^{-3} phosphoric acid is observed in the potential range −0.7——1.0 V *vs.* SCE. The peak current is very large in comparison with that in d.c. mode, or in normal pulse mode, being proportional to the concentration of tellurium(IV) between 10^{-8} and 10^{-7} mol dm^{-3} contents. The relative standard deviation for 3.94×10^{-8} mol dm^{-3} tellurium(IV) under representative sets of good conditions was 0.0342. The method has been applied to the determination of tellurium in carbon steel.

Tellurium is an important substance in the steel industry and alloy production. However, tellurites and hydrogen telluride are more toxic and dangerous than the corresponding selenium compounds. Thus it is most important to know the tellurium content in the fields of toxicology, industrial hygiene, and environmental pollution. Determination of tellurium can be carried out by the solvent extraction-spectrophotometric[1] and spectrophotometric[2] methods by use of Bismuthiol II (3-phenyl-5-mercapto-1,3,4-thiadiazole-2-thione). However, these methods involve complicated steps for clean-up and color development, requiring much time. On the other hand, differential pulse (DP) polarography as well as atomic absorption spectrometry[3] provide reliable determination of the micro-amount of tellurium.

Since polarographic investigation was carried out in 1935 by Schwaer and Suchy,[4] many reports have appeared on the reduction of tellurium concerning the polarographic maximum wave, mainly in view of establishing reaction mechanisms.[5–14]

For the purpose of working out a reliable analytical method, the author has studied the effect of supporting electrolytes, coexisting ions and surfactants on the DP peak, the effects of instrumental parameters such as modulation amplitude (ΔE) and scan rate (ν) in the DP mode, and also sensitivity and relative standard deviation for tellurium.

Experimental

Reagents. Chemicals used were of reagent grade and dissolved in deionized water. A standard tellurium solution (1.00×10^{-2} mol dm^{-3}) was prepared by dissolving 0.1276 g of tellurium lump (purity 99.999%, Wako Chemical Ind. Ltd.) in 50 cm^3 of 7 mol dm^{-3} nitric acid and diluting to 100 cm^3. All dilute solutions were prepared from a stock solution.

Apparatus. The pulse polarographic determination was carried out with a Model 174A polarographic analyzer and a Model 174/70 drop timer (Princeton Applied Research, U.S.A.) and an Omnigraphic 2000 Recorder (Houston Instrument, U.S.A.). The polarographic solutions were deaerated before and during the course of electrolysis with pure nitrogen by passing through a trap containing a solution of the same supporting electrolyte. Except for temperature dependence studies, all the measurements were carried out at room temperature (21±1) °C. Conditions for the dropping mercury electrode (d.m.e.): drop time t=3.66 s (open circuit in 1 mol dm^{-3} phosphoric acid), rate of mercury flow m=2.156 mg s^{-1}, height of mercury reservoir h=79 cm. The electrolysis circuit was a three electrode system consisting of a d.m.e., a carbon rod as counter electrode and a SCE. Small volumes of tellurium(IV) solutions were supplied from Eppendorf micropipetters.

Results and Discussion

Characteristics of Tellurium(IV) Reduction. Reduction wave or peak of tellurium with catalytic hydrogen evolution was observed in the potential range −0.7—−1.0 V. The mechanism of electrode processes has been discussed by many investigators.[5,6,8,11,12] According to Shinagawa *et al.*,[11] and Volaire *et al.*,[12] the electrode process after the reduction of Te(IV)—Te(0) is as follows:

$$Te^0_{ads} + 2H_{ads} = HTe^-_{ads} + H^+$$
$$HTe^-_{ads} + e = 1/2H_2 + Te^{2-}_{ads}$$
$$Te^{2-}_{ads} + H^+ = HTe^-_{ads}$$

If tellurium undergoes two-electron reduction due to formation of telluride as a whole, we can reexamine the process by means of the dependence of peak half width, $W_{1/2}$, on pulse amplitude, ΔE, for various values of n[15] in order to confirm total number of electrons in electrode reaction, n. The results for the $W_{1/2}$-ΔE dependence are given in Table 1. The values agree with the theoretical ones for n=2. The instantaneous current-time curve of 1×10^{-6} mol dm^{-3} tellurium(IV) in 1 mol dm^{-3} phosphoric acid was observed in the potential in the range −0.70——0.94 V by the potential-step method. The slope of lg i-lg t was 0.480, lying in the range between the maximum of first kind and the kinetic current. No brown mist formed on the d.m.e., convection in the vicinity of the d.m.e., not being observed

Table 1. Dependence of modulation amplitude on DP peak half width for n=2

$W_{1/2}$ (mV)	Modulation amplitude, ΔE (mV)		
	−10	−25	−50
Theoretical	46	50	63
Observed	48	50	70

Concentration: 1.00×10^{-7} mol dm^{-3} Te(IV); scan rate, ν: 5 mV s^{-1}; mechanically controlled drop time, t_d: 1 s.

because of the low concentration of tellurium(IV).[11] The relative temperature coefficient of the DP peak current for tellurium-reduction in the temperature range 1—44 °C was 3.02% K^{-1} at 20 °C, the value being reasonable because of maximum wave. No maximum wave was observed in the potential range −1.0——1.9 V in 1 mol dm^{-3} sodium hydroxide. The reduction is irreversible, the slope of $\lg i/(i_d-i)$ *vs.* potential, E in normal pulse (NP) mode and the peak half width, $W_{1/2}$ in DP mode being 80 and 144 mV, respectively, at $\Delta E=-50$ mV. The peak current in 1 mol dm^{-3} sodium hydroxide is much less than that in 1 mol dm^{-3} phosphoric acid.

Choice of Supporting Electrolyte. Several investigators have recommended alkaline or ammoniacal supporting electrolytes for the determination of tellurium.[6-8,11] Itsuki *et al.*[9] used phosphoric acid for s.w. polarographic determination of tellurium in crude copper, silver and selenium. Maienthal and Taylor[10] determined tellurium in cartridge brass and in white cast iron by cathode-ray polarography in 1.5 mol dm^{-3} phosphoric acid, getting good results. Milner and Slee[16] recommended phosphoric acid as a suitable supporting electrolyte for square wave (s.w.) polarographic determination of heavy metals. Phosphoric acid was thus chosen as the supporting electrolyte. In solutions with phosphoric acid, there was no variation in DP current in the concentration range 0.1—2 mol dm^{-3}.

In a.c. mode, the background current practically does not change because of the irreversible reduction of dissolved oxygen in acid solutions,[17] nevertheless that in DP mode altered remarkably and affected the DP current of tellurium(IV) markedly. Thus it was necessary to monitor the residual current in order to make analytical error minimum. The effects of hydrochloric acid, sulfuric acid and nitric acid were studied. The DP peak for 1×10^{-7} mol dm^{-3} tellurium(IV) remained constant even in the presence of 1 mol dm^{-3} nitric acid in the polarographic solution. The presence of 0.1 mol dm^{-3} hydrochloric acid or 0.1 mol dm^{-3} sulfuric acid in the solution gave practically no influence on the DP peak current.

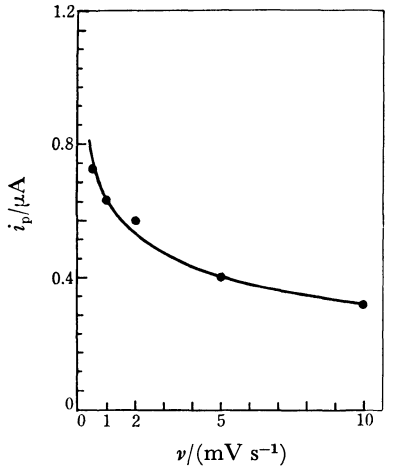

Fig. 1. Effect of scan rate on DP peak of tellurium(IV). Concentration: 1.00×10^{-7} mol dm^{-3} Te(IV); modulation amplitude, ΔE: −50 mV; mechanically controlled drop time, t_d: 1 s.

Effect of Modulation Amplitude and Scan Rate. For the reduction process with catalytic reaction, the peak height-pulse amplitude relationship was found to be linear up to 100 mV pulse amplitude. In general, small pulse amplitude gives better resolution and less instrumental error.[15] However, it is more advantageous to work at larger pulse amplitudes in order to obtain better sensitivity.

Figure 1 shows the effect of scan rate on DP peak height for the reduction of tellurium(IV). It should be noted that the specially slow scan rate for the reduction of tellurium(IV) gives better sensitivity sufficiently reliable for routine analytical operation but its use is time consuming and tedious. However, in the case of lower concentrations as low as 10^{-9} mol dm^{-3} content, it is desirable to use lower scan rates of 0.1—0.5 mV s^{-1}.

Table 2. Effect of maximum suppressor concentration on DP peak

Concentration of Triton X-100(%)	Tellurium concentration (mol dm^{-3})	
	1.00×10^{-7}	1.00×10^{-6}
None	1.00[a]	1.00[a]
5×10^{-4}	0.99	—
1×10^{-3}	0.96	—
5×10^{-3}	0.93	0.99
1×10^{-2}	—	0.60
2×10^{-2}	—	0.31

a) Relative value against the peak current without Triton X-100. Conditions as in Table 1.

Effect of Surfactants. If surfactants are present in the polarographic solution, the current should decrease due to change in interfacial phenomena such as adsorption. Table 2 gives the effect of surfactants on the maximum peak current for the reduction of tellurium(IV). In general, gelatine and Triton X-100 are used for maximum suppressor at concentration lower than 10^{-2}%. These concentrations usually suppress the maximum wave sufficiently. However, none of them affected the current at concentrations less than 10^{-3}% in spite of the fact that the depolarizer concentration was as low as 10^{-7} mol dm^{-3}. In the present method it is not necessary to pay attention to the presence of surfactants. The results of the DP peak current-concentration of Triton X-100 relationship are similar to those obtained in the "suspension polarogram" of tellurium powder in 1 mol dm^{-3} ammonium chloride and in 4×10^{-4} mol dm^{-3} K_2TeO_3.[11]

Calibration Curve. Figure 2 shows typical DP polarograms of tellurium(IV) in 1 mol dm^{-3} phosphoric acid. The DP peak height is proportional to the concentration of tellurium(IV) between 5×10^{-8} and 4×10^{-7} mol dm^{-3} (Fig. 3). The relative standard deviation for 3.94×10^{-8} mol dm^{-3} tellurium(IV) was 0.0342. If the current offset in the instrument, modulation amplitude of −100 mV, and scan rate of 0.5 mV s^{-1} as low as possible are used, detection limits are about 10^{-9} mol dm^{-3} content. The large amount of iron(III) and

Table 3. Contents of constituents of carbon steel specimen

Specimen	Concentration (%)										
No. 1	C	Si	Mn	P	S	Ni	Cr	Cu	Mo	Te	Se
	0.20	0.24	0.59	0.012	0.013	0.15	0.15	0.18	0.05	0.020	0.020

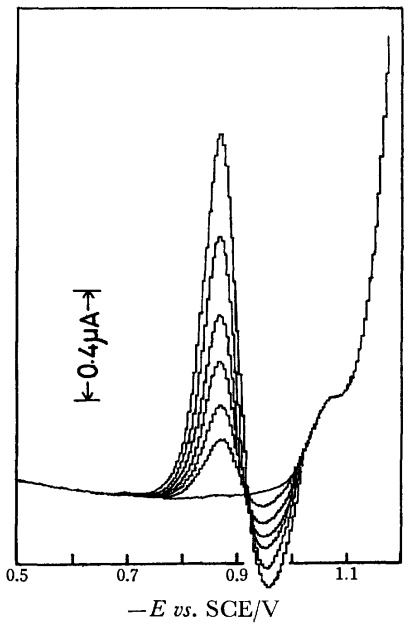

Fig. 2. Differential pulse polarograms of tellurium(IV) in 1 mol dm^{-3} phosphoric acid.
Concentration: 0, 5.00, 10.00, 15.00, 20.00, 30.00, and 40.00×10^{-8} mol dm^{-3} Te(IV); scan rate, v: 5 mV s^{-1}; ΔE: −50 mV; t_d: 1 s.

the elements given in Table 3 did not interfere with the determination of tellurium(IV).

The maximum wave was also observed in NP mode, but it was difficult to measure the wave height accurately.

Analytical Application. An analytical procedure was established from the results. Contents of constituents of carbon steel used as a sample are given in Table 3.

Dissolve *ca.* 0.1 g of the sample weighed accurately in a mixture of 3 cm^3 of nitric acid and 0.1 cm^3 of hydrochloric acid, and keep it in a water-ice bath to prevent fuming. Filter through a No. 5C filter paper when necessary. Wash the paper with a few cm^3 of 4 mol dm^{-3} nitric acid, and dilute to 10 cm^3 accurately with 4 mol dm^{-3} nitric acid. Pipette an adequate amount of the sample solution into the supporting electrolyte solution. After deaeration, measure the tellurium peak in DP mode in the potential range −0.7——1.0 V, and then calibrate the amount by means of a calibration curve or standard addition method. The results of analyses, given in Table 4, are in good agreement with the prescription of sample within experimental error.

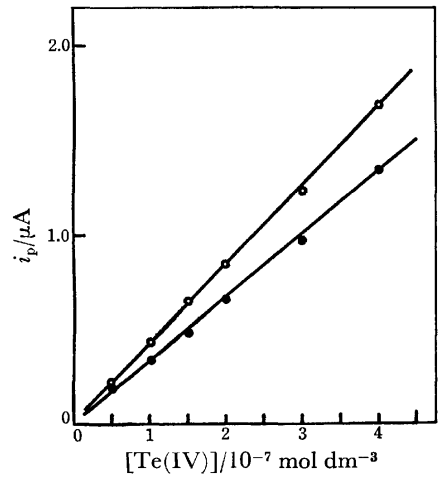

Fig. 3. Calibration curve of tellurium(IV) by DP mode.
Conditions are the same as in Fig. 2.
○: Current measured as a height of peak-to-peak.
●: Current measured as a height of background-to-the peak at more positive potential.

Table 4. Analysis of carbon steel

Method	Found values of tellurium (%), $\times10^2$		
Calibration curve	1.95	1.96	1.95
Standard addition	1.97	1.98	1.96

Conditions are the same as in Fig. 2.

As compared to many analytical procedures the present one was found to be the simplest, giving the highest reliability as the anodic stripping voltammetry for heavy metal determination.

The author is grateful to Profs. S. Hikime, H. Yoshida, and M. Taga for their interest and encouragement, and to Prof. T. Kambara for his comments.

The carbon steel was supplied by Japan Steel Work Co. through Prof. S. Hikime.

Color Reactions of Aqua(ethylenediaminetetraacetato)ruthenate(III) with Sulfur Compounds. Kinetic Study of Thiosulfate Anation[1)]

Yukichi Yoshino,* Takashi Uehiro, and Masami Saito

Department of Chemistry, College of General Education, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153

(Received September 18, 1978)

New color reactions of aqua(ethylenediaminetetraacetato)ruthenate(III) with sulfur compounds such as thiols, thiourea and thiosulfate have been found and investigated. It has been established that the coloration is due to the anation of the complex with sulfur compounds. In the case of thiosulfate, the reaction is first order in either reactant and independent of $[H^+]$ in the pH range 4 to 6. The rate constant (k_{AN}) was found to be 2.94 ± 0.11 M^{-1} s^{-1} at 30 °C and $I=0.1$. For a pH>6, the rate decreases with increase in pH due to the formation of a hydroxo complex. In the higher pH region, the reverse reaction, $[Ru(edta)(S_2O_3)]^{3-}+OH^- \rightleftarrows [Ru(edta)(OH)]^{2-}+S_2O_3^{2-}$ takes place. From the value of the equilibrium constant (K_{eq}) for this reaction, the equilibrium constant (K_{AN}) for thiosulfate anation has been estimated as, $\log K_{AN}=5.02$ at 30 °C and $I=0.1$.

In the course of the study on the redox reaction of ethylenediaminetetraacetatoruthenate(III),[2)] it was found that the complex solution gave an intense red color by the addition of sulfur compounds, such as cysteine, thiourea and thiosulfate. Examination revealed that the coloration was due to the substitution of a water molecule in the complex for sulfur-containing anions. The color develops instantaneously, except in the case of thiosulfate where it is rather slow. In order to elucidate the nature of the color reaction, a kinetic examination has been conducted.

Experimental

Preparation of Aquahydrogen(ethylenediaminetetraacetato)ruthenium(III), [Ru(Hedta)(H₂O)]. The method of Mukaida *et al.*[3)] has been modified as follows. Ruthenium(IV) oxide (5 mmol, Japan Engelhard Co., Ltd.) was dissolved in concd HCl and after repeated heating to dryness on a water bath the residue was dissolved in concd HCl (20 ml). To the solution was added EDTA (5.3 mmol, free acid) and the mixture heated to dryness several times. From a 6 M HCl solution of the residue, $H[RuEl_2(H_2edte)]\cdot 5H_2O$ crystallized out. The recrystallized solid was dissolved in water and the solution added with an equimolar amount of NaOH and evaporated to dryness twice. On the addition of ethanol, a yellow solid precipitated which was dissolved in water and the solution repeatedly evaporated. This lead to the crystallization of $[Ru(Hedta)(H_2O)]$ (yield; 60%). The purity of the complex was checked by alkalimetric titration.

Other Chemicals. All chemicals used were "special grade" from Wako Chemicals Co. and purified by recrystallization or distillation when necessary. Twice-distilled water was used throughout the experiments.

Kinetics and Equilibrium Measurements. The majority of the measurements were conducted at 30 °C and an ionic strength of 0.1. Since perchlorate, nitrate and chloride react slowly with $[Ru(Hedta)(H_2O)]$, the pH and ionic strength of the solution were adjusted by adding calculated amounts of buffer solutions (acetate, phosphate, carbonate and borate buffers). Care was taken to avoid the possible photochemical oxidation of the complex solution.[2)]

The buffered solutions of either reactant, thermostated separately in the dark, were mixed together, and the mixture transferred to a 10 mm path quartz cell. The increase in the optical density of the solution at 495 nm was followed on a spectrophotometer at constant temperature. The pseudo-first order rate constant, k_{obsd}, was evaluated by plotting $\log(D_\infty - D_t)$ against time t, where D_t and D_∞ are the optical densities at time t and infinity, respectively.

Physical Measurements. The electronic spectra and the color development were recorded on a Hitachi 124 spectrophotometer with an attached thermostatted cell compartment. CD spectra were obtained by a JASCO J20 recording spectrophotometer and IR spectra on a JASCO 403G infrared spectrophotometer. The magnetic susceptibility was measured on a Gouy magnetic balance and the pH on a Toa Denpa Digital pH meter, Type HM-8 and HM-20B.

Results and Discussion

Color Reaction. Of the sulfur compounds investigated, it was found that alkanethiols, cysteine, phenylmethanethiol, *O*-ethyl dithiocarbonate, diethyldithiocarbamate, thiourea and thiosulfate gave pink to reddish brown colors, while the benzenethiols gave blue colors. Sulfides and disulfides did not react at all. It may be noted that there is a parallel between this color reaction and the iodine-azide reaction of thiols and thiocarbonyl compounds.[4)]

As may be seen from Fig. 1, the mole ratio of the ruthenium(III) complex to sulfur compound was found to be 1 : 1.

The colored mixture of the complex and cysteine gave

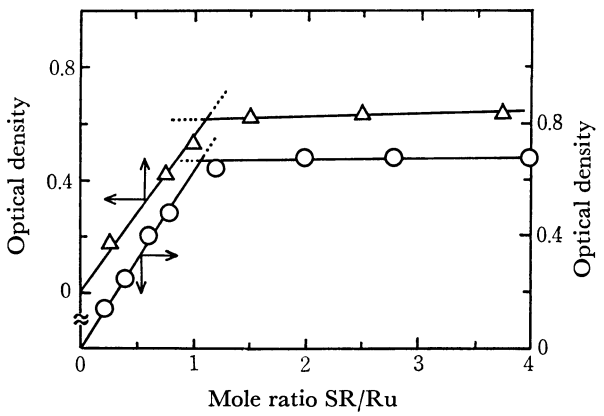

Fig. 1. Mole ratio plot.
$[Ru(Hedta)(H_2O)]$: 2.0×10^{-4} M.
—△—: $S_2O_3^{2-}$; —○—: cysteine.

new CD peaks at 516 nm (+0.64), 436 nm (−0.41), 380 nm (+0.25) and 335 nm (−0.33) where the figures in parentheses represent $\Delta\varepsilon$ values. The reaction products were paramagnetic in both solution and solid states. The magnetic moment of ruthenium in the colored solution (0.1 M Ru) was calculated as; μ_{eff}= 1.91 B.M. at 24.2 °C and therefore it may be said that the +3 state of Ru is retained throughout the reaction. The existence of Ru–carboxylate bonding was confirmed by a strong infrared absorption band at 1620 cm^{-1}. In addition, the elemental analysis of the colored solid gave the atomic ratio C/N as 4.20, which may be compared to the calculated value 4.33 for a 1 : 1 complex of Ru–EDTA and cysteine.

On the basis of these observations, it has been assumed that the color reaction is an anation reaction of the following type;

$$Ru(edta)(H_2O)^- + SR^{n-} \rightleftarrows Ru(edta)(SR)^{(n+1)-} + H_2O, \quad (1)$$

where SR denotes a sulfur-containing compound. The nature of the color change may be a charge transfer between sulfur and ruthenium(III) in the complex.

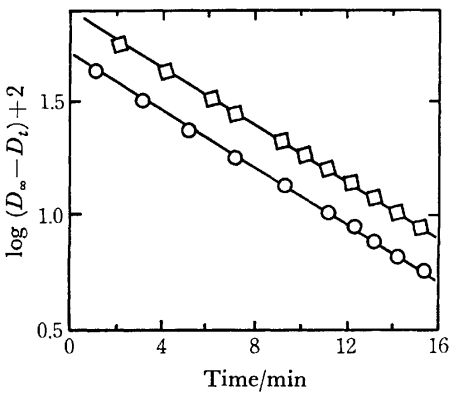

Fig. 2. Pseudo-first-order plot for color reaction of Ru(edta)(H$_2$O)$^-$ with $S_2O_3^{2-}$ at 30 °C, pH 4.7 and I=0.1. [$S_2O_3^{2-}$]$_0$=8.0×10^{-4} M. —◇—: [Ru(edta)(H$_2$O)$^-$]$_0$=2.0×10^{-4} M; —○—: [Ru(edta)(H$_2$O)$^-$]$_0$= 1.2×10^{-4} M.

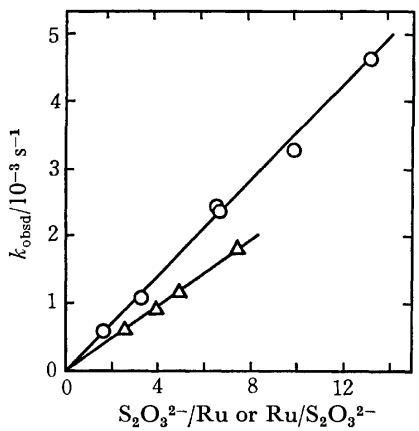

Fig. 3. Dependence of k_{obsd} on the concentration of the excess reactants.
—○—: $S_2O_3^{2-}$ is excess; [Ru(edta)(H$_2$O)$^-$]$_0$=1.2×10^{-4} M; —△—: Ru(edta)(H$_2$O)$^-$ is excess; [$S_2O_3^{2-}$]$_0$= 0.8×10^{-4} M.

Kinetics of Thiosulfate Anation. Of the various sulfur compounds investigated, the color reaction of thiosulfate is relatively slow and the rate could be followed photometrically. The reaction is first order in each reactant (Fig. 2) and the rate is independent of the hydrogen ion concentration in the pH range 4—6. Figure 3 illustrates the dependence of k_{obsd} on the concentration of the excess reactant, thiosulfate or Ru(III)–EDTA complex. A linear relationship is seen to hold in both cases. From the slopes of these straight lines, the rate constant, k_{AN}, of the thiosulfate anation has been evaluated as;

$$k_{AN} = 2.94 \pm 0.11 \text{ M}^{-1} \text{ s}^{-1} \text{ at } 30 \text{ °C and } I = 0.1.$$

In the presence of an excess of thiosulfate ([S_2O_3]/[Ru–EDTA]=6.7), the Arrhenius plot of k_{obsd} at 22, 30, and 40 °C gave the activation energy as, E_a= 37±2 kJ mol^{-1}.

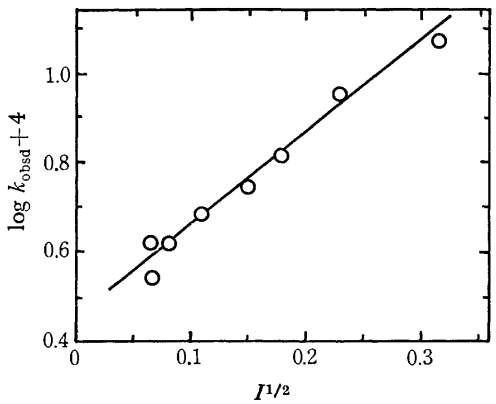

Fig. 4. Dependence of k_{obsd} on the ionic strength.

As illustrated in Fig. 4, a plot of log k_{obsd} *vs.* $I^{1/2}$ gives a straight line with a slope of nearly 2.[5] Taking into consideration the pK values of Ru(Hedta)(H$_2$O) (pK_1=2.75 and pK_2=7.50 at 30 °C and I=0.1) this result is consistent with the reaction of uni-bivalent anions as

$$Ru(edta)(H_2O)^- + S_2O_3^{2-} \rightleftarrows Ru(edta)(S_2O_3)^{3-} + H_2O. \quad (2)$$

The value of the rate constant for this reaction is surprisingly large compared with the halide anation of ruthenium(III)–ethylenediamine and related complexes ($k_{AN}\approx$10^{-3} M^{-1} s^{-1}).[6] However, it has been noted before that substitution reactions at the sixth coordination site of quinquedentate EDTA complexes of Cr(III) and related complexes are remarkably fast.[7,8] Similar labilizing effect due to quinquedentate EDTA may be expected for Ru(edta)(H$_2$O)$^-$.

In the kinetic measurements, k_{obsd} increased linearly with increase in the thiosulfate concentration up to 0.1 M, the concentration range investigated here and no saturation of the rate was observed. Consequently it is not possible to anticipate further the mechanism of the anation.

As reported earlier, the rate of color development is independent of [H$^+$] in the pH range 4—6. However,

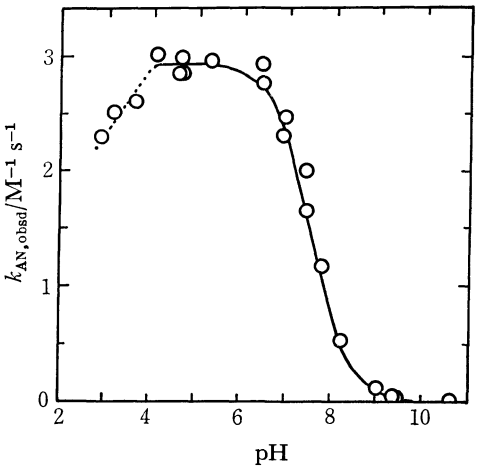

Fig. 5. Dependence of $k_{AN,obsd}$ on pH of the solutions.
○: experimental point; —: calculated curve.

it was found in the region of pH 6—10 that the rate decreases with increase in pH, as illustrated in Fig. 5. (Experimental points are shown by open circles). Since the pK_2 of Ru(Hedta)(H_2O) is known to have the value of 7.50, this result is expected to arise from the decrease in the concentration of the aqua complex with increase in pH. This leads to

$$k_{AN,obsd} = (k_{AN}+k'_{AN}K_2/[H^+])/(1+K_2/[H^+]),$$

where $k_{AN,obsd}$ denotes the observed rate constant in the range pH$>\approx$6 and k_{AN} and k_{AN} are the anation rate constants for Ru(edta)(H_2O)$^-$ and Ru(edta)-(OH)$^{2-}$, respectively. Substituting the values, k_{AN}= 2.94 $M^{-1}\,s^{-1}$, $k'_{AN}\approx 0$ and $K_2=10^{-7.50}$ M, the values of $k_{AN,obsd}$ as a function of pH have been calculated and the results plotted in Fig. 5 (solid line). The agreement between experimental and calculated values is satisfactory.

In the pH range$<$4, $k_{AN,obsd}$ decreases with increase in [H^+]. This may be explained by considering the participation of the less reactive protonated complex, Ru(Hedta)(H_2O) in the reaction, thus

$$k_{AN,obsd} = (k_{AN}+k''_{AN}[H^+]/K_1)/(1+[H^+]/K_1+K_2/[H^+]),$$

where k''_{obsd} refers to the anation rate constant for Ru-(Hedta)(H_2O). The evaluation of k''_{AN} from the rate data in the acidic range (pH$<$4) is, however, difficult owing to the possible decomposition of the thiosulfate in acidic solution.

Equilibrium Study. In the higher pH range (pH$>\approx$8), it was found that the optical densities at infinite time decrease as illustrated in Fig. 6. This may be ascribed to the existence of the following equilibrium;

$$Ru(edta)(S_2O_3)^{3-} + OH^- \rightleftarrows Ru(edta)(OH)^{2-} + S_2O_3^{2-} \quad (3)$$

At 495 nm the only colored species is Ru(edta)(S_2O_3)$^{3-}$ with a molar extinction coefficient, ε, at this wavelength of 3.13×10^3 $M^{-1}\,cm^{-1}$. Using the spectral data of

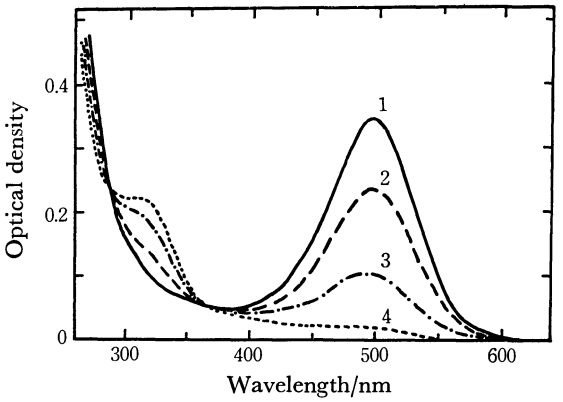

Fig. 6. Change of absorption spectra in the higher pH region.
1: pH 8.57, 2: pH 9.29, 3: pH 9.91, 4: pH 10.81.

Fig. 6, the equilibrium constant (K_{eq}) for Reaction 3 has been calculated as; K_{eq}=19.1 at 30 °C and I=0.1. Since the pK_2 value for Ru(Hedta)(H_2O) is known, the equilibrium constant (K_{AN}) for the thiosulfate anation (Reaction 2) may be calculated using the following relationship:

$$K_{AN} = [Ru(edta)(S_2O_3)^{3-}]/[Ru(edta)(H_2O)^-][S_2O_3^{2-}] = K_2/K_{eq}\cdot K_w,$$

where K_w denotes the ionic product of water. Substituting the values; $K_2=10^{-7.50}$, $K_{eq}=10^{1.28}$ and $K_w=10^{-13.8}$;

$$\log K_{AN} = 5.02 \text{ at } 30\,^\circ C \text{ and } I = 0.1.$$

This value may be compared with that estimated from the spectral data in the mole ratio plot of the optical densities in Fig. 1 (log K_{AN}=5.16).

The authors wish to thank Professor A. Ouchi for his discussion and supply of some sulfur compounds.

Pyrolysis of Tetrasulfur Tetraimide

Shuichi HAMADA* and Yoshiyuki KUDO

Department of Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received September 27, 1978)

Tetrasulfur tetraimide was pyrolyzed into sulfur, tetrasulfur tetranitride, tetrasulfur dinitride, ammonia, and nitrogen even below its apparent melting point, 143 °C, under atmospheric pressure; a small amount of heptasulfur imide was also observable. The tetrasulfur dinitride and nitrogen were formed from subsequent reactions between products. The overall pyrolysis consisted of the primary decomposition and the following subsequent ones, as judged from the stoichiometric relationships among the pyrolytic products: $3S_4(NH)_4=4S+2S_4N_4+4NH_3$, $S_4N_4=S_4N_2+N_2$ (in the presence of sulfur), and $S_4N_2=4S+N_2$. Partial pressures of ammonia at the primary pyrolysis were estimated to be 8.5×10^{-2}, 2.1×10^{-1}, 5.2×10^{-1}, and 1.4 Pa at 60, 70, 80, and 90 °C respectively.

Sasaki *et al.*[1] have reported that tetrasulfur tetraimide, $S_4(NH)_4$, melted at 152 °C with an accompanying decomposition on moderately rapid heating, while it was stable in air at room temperature. They have proposed that tetrasulfur tetraimide pyrolyzed as follows over the temperatures from 110 to 135 °C *in vacuo*:

$$3S_4(NH)_4 = 4S + 2S_4N_4 + 4NH_3$$

In this work, the pyrolysis of tetrasulfur tetraimide was studied under atmospheric pressure because there have been few investigations under these conditions.

Experimental

Materials. The tetrasulfur tetraimide was prepared by the method described by Meuwsen[2] as follows: the tetrasulfur tetranitride, S_4N_4,[3] was reduced by adding an ethanolic solution of tin(II) chloride into its benzene solution. A crude product was purified by repeated recrystallization from an acetone and a methanol solution. The tetrasulfur tetraimide thus obtained was confirmed to be pure enough to use in this work by thin-layer chromatography.

Procedures. A differential thermal analysis and a thermal gravimetry of the tetrasulfur tetraimide were carried out at the heating rate of 3 °C/min in an argon atmosphere with a Rigaku Denki Thermoflex, model 8002, differential thermal analyzer. Solid pyrolytic products of the tetrasulfur tetraimide were identified by the TLC as follows: a sample was heated in the argon flow up to the specified temperatures in the DTA equipment, and then was identified by using chlorobenzene, cyclohexane, and carbon tetrachloride as developing solvents. A silver nitrate solution was used as a detecting reagent after quenching. An infrared spectrum of the heat-treated sample was also taken to identify the pyrolytic products, using an IR spectrophotometer, model DS-403G, from the Japan Spectroscopic Co.

The sample was pyrolyzed to identify gaseous products and to estimate their amounts; a glass vessel with a small dead space was employed at the specified temperatures. The gaseous products were identified with a gas chromatograph, model 80, from the Yanagimoto Seisakusho. A silica gel column was used as a stationary phase and helium as a carrier gas. The amount of ammonia, one of the gaseous products, was estimated coulometrically[4,5] during the pyrolysis in the argon and carbon dioxide atmospheres. The amount of nitrogen, another one of the gaseous products, was estimated with an azotometer by using the carbon dioxide as the carrier gas, after removing the accompanying ammonia into diluted perchloric acid.

The partial pressure of ammonia during the pyrolysis was measured over the temperatures from 60 to 90 °C in the argon and the nitrogen atmospheres by a method of transpiration.[6,7] The specified temperature of the sample was kept within a precision of ±0.05 °C. The flow rate of the carrier gas was controlled automatically over the range from 77.4 to 125 cm³/min. The total volume of the carrier gas was measured with a wet-type gas flowmeter, model WK-0.5, from the Shinagawa Seisakusho. The amount of ammonia in the carrier gas was estimated coulometrically after the gas flow was passed through an ice-cold trap to remove volatile solid products.

Results

The Solid Pyrolytic Products of Tetrasulfur Tetraimide. The solid pyrolytic products were identified to be sulfur, tetrasulfur tetranitride, tetrasulfur dinitride, S_4N_2, and heptasulfur imide, S_7NH, by the TLC, as shown in Table 1. Both the tetrasulfur tetranitride[8,9] and the tetrasulfur dinitride[10] were also confirmed by the IR spectrometry, though the heptasulfur imide was unde-

Table 1. Results of TLC on solid pyrolytic products of tetrasulfur tetraimide

Solvent	R_f value				
	S_8	S_4N_4	S_4N_2	S_7NH	$S_4(NH)_4$
Chlorobenzene	1.0 (1.0)[a]	0.61 (0.61)		0.88 (0.88)	0.15 (0.15)
Carbon tetrachloride	0.92 (0.92)	0.47 (0.42)		0.70 (0.68)	0.0 (0.0)
Cyclohexane	0.80 (0.82)	0.16 (0.14)	0.66 (0.67)	0.35 (0.36)	0.0 (0.0)

a) The R_f values in parentheses were previously determined for each species.

a) Very small amount.

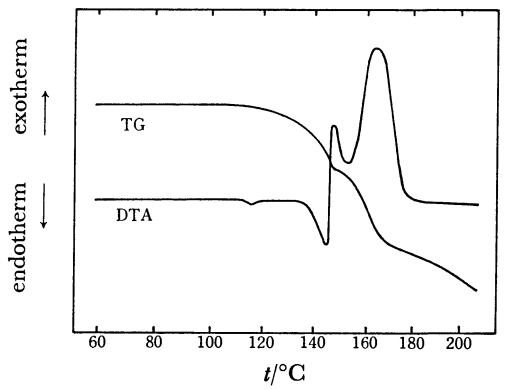

Fig. 1. DTA and TG patterns of tetrasulfur tetraimide.

tectable because of its small amount. The kinds of products at each temperature are shown in Table 2.

Figure 1 shows the DTA and the TG patterns of the tetrasulfur tetraimide taken in the argon atmosphere. An endothermic peak at 143 °C was confirmed to be caused by fusion of tetrasulfur tetraimide,[1] while the apparent melting point increased with increasing the heating rate, *e.g.*, 143, 149, and 152 °C at 3, 5, and 10 °C/min respectively. The tetrasulfur tetraimide was pyrolyzed even below its apparent melting point, judging from a weight loss in the TG and the results in Table 2. The tetrasulfur tetraimide disappeared at 160 °C under these conditions as is shown in Table 2, though it vanished even at 150 °C by heating for 1 h. The sample pre-heated at 150 °C showed only the exothermic peak at 165 °C, besides a small endothermic peak around 115 °C arising from the fusion of sulfur. Judging from these results, the exothermic peaks at 147 and 165 °C were attributable to a vigorous decomposition of tetrasulfur tetraimide and a subsequent decomposition of the pyrolytic products respectively: the contribution of heptasulfur imide to the DTA pattern was obscure because of its small amount.

The weight loss in the TG from about 105 to 147 °C was considered to originate mainly from the primary pyrolysis of the tetrasulfur tetraimide, which was accompanied by evolution of the gas and sublimation of the resulting tetrasulfur tetranitride.[7] The weight loss at the second stage above 147 °C was chiefly attributable to the subsequent decomposition of the pyrolytic products which accompanied the formation of the gas and was followed in turn by vaporization of molten sulfur. Judging from the weight loss, about 30 wt % at 140 °C, at the first stage and the kinds of the pyrolytic products, the subsequent decomposition was also expected to occur even below 147 °C.

Amounts of the tetrasulfur tetranitride and the sulfur in the sample heated at 110 °C for 1.5 h were estimated to be 0.431 and 1.69 respectively, as the molar ratios to the original tetrasulfur tetraimide. A spectrophotometric technique was used after separating the materials chromatographically by using a silica gel column. These values disagreed with those proposed by Sasaki *et al.*[1] The amount of the tetrasulfur dinitride could not be estimated because the tetrasulfur dinitride was easily hydrolyzed in the silica gel column, which contained about 6% water, during the chromatographic separation. Goehring *et al.*[11] have reported that tetrasulfur dinitride produced an equivalent amount of ammonia on its hydrolysis. Therefore, the amount of the tetrasulfur dinitride could be deduced to be 0.257 mol against 1 mol of tetrasulfur tetraimide from a mass balance of nitrogen. The amount of the heptasulfur imide was also estimated to be 0.027 as the molar ratio to the original material: the amount of hydrogen in the observed heptasulfur imide was less than 0.7 mol % against that in the original tetrasulfur tetraimide, so that the formation of heptasulfur imide could be neglected in this case.

The Gaseous Pyrolytic Products of Tetrasulfur Tetraimide. The gaseous products were identified to be ammonia and nitrogen by the gas chromatography on the pyrolysis at 120 °C for 2 h in the argon and the carbon dioxide atmospheres, while neither hydrogen nor hydrogen sulfide was observable. Both ammonia and nitrogen were also detected even at 80 °C in the same atmospheres.

The tetrasulfur tetraimide was pyrolyzed in order to estimate the amount of ammonia over the temperatures from 80 to 160 °C for 1.5—6 h in the argon and the carbon dioxide flows. The molar ratio of the ammonia to the original tetrasulfur tetraimide was estimated to be 1.33 ± 0.008 under these conditions; this value did not depend on the temperature or on the kinds of the carrier gases. Therefore, all the hydrogen atoms in tetrasulfur tetraimide were considered to be released in the form of ammonia by the pyrolysis, though a negligibly small part of the hydrogen was converted into the form of heptasulfur imide. The amount of the nitrogen was estimated with the azotometer over the temperatures from 80 to 170 °C in the carbon dioxide flow, after the accompanying ammonia was absorbed into diluted perchloric acid. Figure 2 shows the molar ratio of the produced nitrogen to the original tetrasulfur tetraimide against the temperature. The molar ratio increased linearly with increasing the temperature up to about 140 °C and then further increased with a steeper slope above 140 °C. This temperature nearly corresponded to the apparent melting point of tetrasulfur tetraimide, so that the increase in the formation of nitrogen above

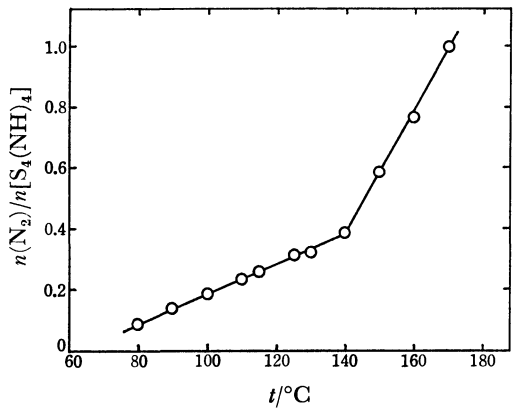

Fig. 2. Molar ratio of produced nitrogen to tetrasulfur tetraimide against temperature.

140 °C was considered to be due to the vigorous decomposition of tetrasulfur tetraimide after fusion and the subsequent decomposition of the pyrolytic products.

The Partial Pressure of Ammonia during the Pyrolysis. In order to estimate apparent partial pressures of ammonia by the method of transpiration,[6,7] the tetrasulfur tetraimide was homogeneously mixed with the tetrasulfur tetranitride to keep proper vapor pressures of tetrasulfur tetranitride at given temperatures[7] in the reaction vessel. A sufficient amount of the ammonia was directly absorbed into an electrolytic solution for the coulometric titration, *i.e.*, 6.5—37.0 μg. The total volume of the carrier gas ranged from 2.4 to 15.0 dm^3 (from 30 to 120 min) as the standard state. The apparent partial pressure, p, of the ammonia was calculated by the following equation, on the assumption that the law of partial pressure was obeyed: $p=nRT(P+p')/[nRT+(P+p''-p_w)V]$. Where P is the atmospheric pressure, p', the excess pressure in the reaction vessel, p'', the excess pressure in the gas flowmeter, p_w, the vapor pressure of water in the gas flowmeter, n, the number of moles of the ammonia, V, the volume of the carrier gas, and R, the gas constant.

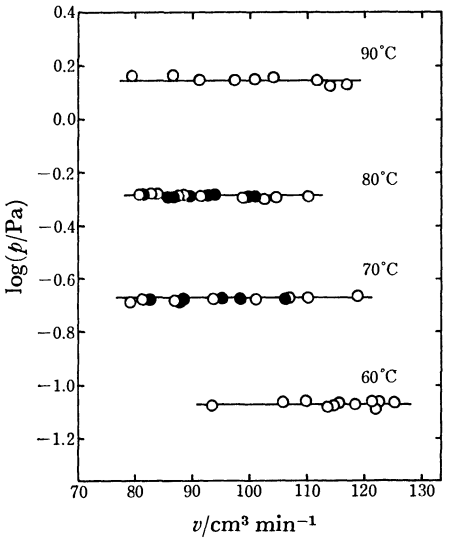

Fig. 3. Relationship between apparent partial pressure of ammonia and flow rate of carrier gas.
○: Estimated in Ar atmosphere, ●: estimated in N_2 atmosphere.

Figure 3 shows the relationship between the apparent partial pressure of the ammonia and the flow rate of the carrier gas. The values of the apparent partial pressures were almost equal at each temperature within these flow rate. Accordingly, it can be concluded that the formation of the ammonia in this system was in an equilibrium state. Therefore, the partial pressures of the ammonia during the pyrolysis were estimated to be 8.5×10^{-2}, 2.1×10^{-1}, 5.2×10^{-1}, and 1.4 Pa at 60, 70, 80, and 90 °C respectively; these are the averages of the apparent values estimated in the argon atmosphere (open circles). The apparent partial pressures estimated in the nitrogen atmosphere (closed circles) agreed with those estimated in the argon atmosphere at 70 and 80 °C, as is shown in Fig. 3. The partial pressures of the ammonia during the pyrolysis were not affected by the kinds of the carrier gases, *i.e.*, argon and nitrogen.

Discussion

The overall pyrolysis of tetrasulfur tetraimide under atmospheric pressure was not so simple as that reported by Sasaki *et al.*[1] All the hydrogen atoms in imide groups of tetrasulfur tetraimide were converted into those in the form of ammonia, judging from their stoichiometric relationship, while a very small part of the imide group remained in the form of heptasulfur imide. On the contrary, the nitrogen atoms were converted into not only the form of tetrasulfur tetranitride but also the forms of nitrogen and tetrasulfur dinitride during the pyrolysis, and a simple stoichiometric relationship could not be obtained among them.

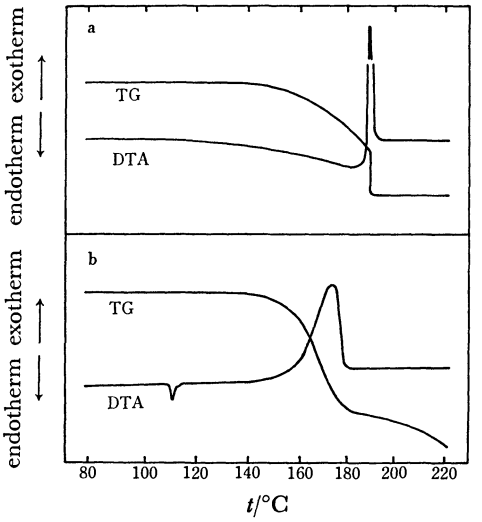

Fig. 4. DTA and TG patterns of tetrasulfur tetranitride
a: S_4N_4, b: $S_4N_4+S_8$ (molar ratio, 4: 1).

The tetrasulfur tetranitride showed a very sharp exothermic peak at 190 °C, along with an abrupt weight loss in the argon atmosphere on its DTA and TG, as is shown in Fig. 4a: it decomposed explosively into its elements at this temperature. No nitrogen could be detected below this temperature, though Goehring *et al.*[12] have reported that it decomposed above 130 °C. Heal[13] has described that tetrasulfur tetranitride decomposed gently above 120 °C when it was mixed with a large amount of sulfur. Figure 4b shows a DTA pattern of the tetrasulfur tetranitride mixed with the sulfur at the molar ratio of 4: 1 in the argon atmosphere. A broad exothermic peak was observed at 174 °C in the DTA instead of the sharp one at 190 °C for the pure tetrasulfur tetranitride, besides a small endothermic peak around 110 °C attributable to the fusion of sulfur. Furthermore, the exothermic peak temperature of the mixed sample decreased from 174 to 165 °C upon increasing the molar ratio of the sulfur from 4: 1 to 1: 4. Backens[14] has reported that tetrasulfur dinitride was produced by the gentle decomposition of tetrasulfur

tetranitride mixed with sulfur above 125 °C. The tetrasulfur dinitride was observed on the pyrolysis of the tetrasulfur tetranitride mixed with the sulfur at 160 °C in the argon atmosphere. An evolution of nitrogen was also confirmed during the pyrolysis of the same sample even at 140 °C. Consequently, the pyrolysis of tetrasulfur tetranitride was concluded to be accelerated in the presence of sulfur. The exothermic peak at 165 °C in Fig. 1 was confirmed to be attributable to this reaction.

It can be concluded that the formations of tetrasulfur dinitride and nitrogen originate from the subsequent pyrolysis of the tetrasulfur tetranitride in the presence of the sulfur, followed by the decomposition of the tetrasulfur dinitride because of its instability,[15] as follows:

$$S_4N_4 = S_4N_2 + N_2 \text{ (in the presence of sulfur)}, \quad (1)$$

$$S_4N_2 = 4S + N_2. \quad (2)$$

This consideration can be supported by the fact that the apparent partial pressures of the ammonia during the pyrolysis were independent of the kinds of the carrier gases, *i.e.*, argon and nitrogen.

TABLE 3. MOLAR RATIOS OF PYROLYTIC PRODUCTS TO TETRASULFUR TETRAIMIDE AT 110 °C

	S	S_4N_4	NH_3	N_2	S_4N_2	S_7NH
Overall reaction	1.69	0.431	1.33	0.235	0.257[a]	0.027
Primary reaction	—[b]	0.666[c]	1.33			
Sasaki *et al.*[1]	1.33	0.667	1.33			

a) Deduced. b) Unestimated. c) Calculated.

The amount of the tetrasulfur tetranitride produced at the primary pyrolysis can be calculated from the estimated amounts of the species and Eqs. 1 and 2, as is shown in Table 3. The amount of the sulfur to be produced at the first stage, however, could not be deduced because of the complicated hydrolysis of tetrasulfur dinitride with respect to sulfur atoms.[11,16] The primary pyrolysis of tetrasulfur tetraimide is considered to be the same as that reported by Sasaki *et al.*,[1] judging from the results in Table 3 and the process of the pyrolysis:

$$3S_4(NH)_4 = 4S + 2S_4N_4 + 4NH_3. \quad (3)$$

The van't Hoff plots of the partial pressure of the ammonia showed a good linear relationship, while the value at 90 °C was overestimated to some degree because of the extra formation of ammonia arising from the reaction between a trace amount of tetrasulfur dinitride and water.[11]

A Rate Study on the Oxidative Addition Reactions of Iodine toward Tetrakis(2,4,6-trimethylphenyl and *t*-butyl isocyanide)-rhodium(I) Perchlorates

Ryosho KUWAE and Toshio TANAKA*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 565

(Received August 31, 1978)

The reaction of $[RhL_4]ClO_4$ (L=2,4,6-$Me_3C_6H_2NC$ and *t*-BuNC) with an equimolar amount of iodine yields a *trans* adduct, $[RhI_2L_4]ClO_4$. The rate of this reaction in acetonitrile was measured employing a stopped-flow technique under pseudo-first-order conditions with excess iodine. The result indicates that the reaction proceeds *via* an intermediate which is presumably assigned to *cis*-$[RhI_2L_4]ClO_4$, followed by intramolecular isomerization to the *trans* adduct.

Kinetics of oxidative addition reactions of various molecules such as hydrogen[1,2] and olefins[2-4] to rhodium(I) substrates have been reported by several research groups. The rate of addition reaction of halogen to rhodium(I) complexes has, however, been little measured, although a number of halogen adducts with Rh(I) are known.[5-7] Our recent kinetic study[8] has shown that the addition of iodine to $Rh(S_2CNMe_2)$-(2,4,6-$Me_3C_6H_2NC)_2$ proceeds *via* a charge transfer complex formed between the sulfur atom of the S_2CNMe_2 ligand (donor) and iodine (acceptor), which is rearranged to *cis*-$RhI_2(S_2CNMe_2)$(2,4,6-$Me_3C_6H_2NC)_2$, followed by isomerization to the *trans* adduct with respect to the iodide anions. It is of interest to examine whether the formation of a *cis* adduct in advance of a *trans* one is general in the addition reaction of iodine to Rh(I) substrates.

This paper reports the rate study on the reactions of tetrakis(2,4,6-trimethylphenyl and *t*-butyl isocyanide)-rhodium(I) perchlorates, $[RhL_4]ClO_4$, with iodine giving *trans*-$[RhI_2L_4]ClO_4$.

Experimental

Materials and Spectra. Iodine was sublimed three times. Acetonitrile and acetone were dried over phosphorus pentaoxide and Drierite, respectively. Dichloromethane was purified by the usual method.[9] $[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ was prepared as follows; a methanol (10 ml) solution of 2,4,6-$Me_3C_6H_2NC$ (4 mmol) was added dropwise to a suspension of $[RhCl(1,5\text{-}C_8H_{12})]_2$ (0.5 mmol) in methanol (5 ml). The mixture was stirred for 2 h, followed by the addition of a methanol (10 ml) solution of sodium perchlorate monohydrate (2 mmol). The resulting precipitate was recrystallized from a mixture of dichloromethane with ligroin to give yellowish orange plates in a 73% yield. ν(NC) 2142 cm^{-1}. λ_{max} 402 nm (ε 7500), 339 nm (ε 56300), and 252 nm (ε 66200). Found: C, 61.44; H, 5.74; N, 7.40%. Calcd for $C_{40}H_{44}ClN_4O_4Rh$: C, 61.35; H, 5.66; N, 7.15%. $[Rh(t\text{-}BuNC)_4]ClO_4$ was similarly prepared by the use of *t*-BuNC for 2,4,6-$Me_3C_6H_2NC$, 74% yield. ν(NC) 2156 cm^{-1}. λ_{max} 381 nm (ε 9600) and 309 nm (ε 27900). Found: C, 45.10; H, 6.83; N, 10.37%. Calcd for $C_{20}H_{36}ClN_4O_4Rh$: C, 44.91; H, 6.78; N, 10.47%.

Infrared and electronic spectra were measured with Hitachi-Perkin Elmer 225 and Hitachi 124 spectrophotometers, respectively. ^1H NMR spectra were recorded on a JEOL JNM-PS-100 spectrometer.

Equimolar Reaction of $[RhL_4]ClO_4$ (L=2,4,6-$Me_3C_6H_2NC$ and t-BuNC) with Iodine. An acetonitrile (10 ml) solution of I_2 (0.5 mmol) was added to $[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ (0.5 mmol) in acetonitrile (20 ml). After stirred for 1 h, the solution was evaporated to dryness under reduced pressure. The resulting product was recrystallized from dichloromethane–petroleum ether to give orange plates of $[RhI_2(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ in an 87% yield. ν(NC) 2216 cm^{-1}. λ_{max} 391 nm (ε 9500) and 256 nm (ε 86000). Found: C, 46.44; H, 4.39; N, 5.19%. Calcd for $C_{40}H_{44}ClI_2N_4O_4Rh$: C, 46.33; H, 4.28; N, 5.40%.

$[RhI_2(t\text{-}BuNC)_4]ClO_4$ was similarly obtained by reaction of $[Rh(t\text{-}BuNC)_4]ClO_4$ with an equimolar amount of I_2 in acetonitrile, 68% yield. ν(NC) 2231 cm^{-1}. λ_{max} 384 nm (ε 10000) and 277 nm (ε 42000). Found: C, 30.85; H, 4.70; N, 6.99%. Calcd for $C_{20}H_{36}ClI_2N_4O_4Rh$: C, 30.46; H, 4.60; N, 7.10%.

Reaction of $[RhL_4]ClO_4$ with Excess Iodine. To an acetonitrile (10 ml) solution of $[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ (0.3 mmol) was added excess I_2 (3 mmol) in acetonitrile (25 ml). After stirred for 15 h, the solution was evaporated to dryness under reduced pressure. The product obtained was washed with diethyl ether to remove unreacted I_2, followed by recrystallization from dichloromethane–ligroin to give brown plates of $RhI_5(2,4,6\text{-}Me_3C_6H_2NC)_4$ in a 64% yield. ν(NC) 2214 cm^{-1}. Found: C, 36.48; H, 3.28; N, 4.24%. Calcd for $C_{40}H_{44}I_5N_4Rh$: C, 36.45; H, 3.36; N, 4.25%.

$RhI_5(t\text{-}BuNC)_4$ was similarly obtained by reaction of $[Rh(t\text{-}BuNC)_4]ClO_4$ with excess I_2 in acetonitrile, 66% yield. ν(NC) 2227 cm^{-1}. Found: C, 22.43; H, 3.35; N, 5.28%. Calcd for $C_{20}H_{36}I_5N_4Rh$: C, 22.45; H, 3.29; N, 5.24%.

These complexes were also obtained by reaction of $[RhI_2L_4]ClO_4$ with excess I_2.

Kinetic Measurements. Kinetic runs were carried out under pseudo-first-order conditions by mixing an acetonitrile solution of $[RhL_4]ClO_4$ (2.0×10^{-4} M) with excess I_2 in acetonitrile ($2.0-10.0\times10^{-3}$ M). The reaction rate was followed by measuring absorbances of the reaction mixture, using a Union RA-413 stopped flow-rapid scanning spectrophotometer equipped with a 0.2 cm quartz cell in a cell holder thermostated to ±0.2 °C. At least five reaction curves were accumulated by a Union System-71 kinetic data processor and an average curve was recorded on a National VP-6421A X-Y recorder.

Results and Discussion

Characterization of the Iodine Adducts. The four iodine adducts, $[RhI_2L_4]ClO_4$ and RhI_5L_4 (L=2,4,6-$Me_3C_6H_2NC$ and *t*-BuNC), exhibit only a ν(N≡C) band, whose frequency is higher than that of the corresponding

Rh(I) substrate. This confirms the occurrence of oxidative addition reactions[8] of I_2 to Rh(I) with retention of D_{4h} symmetry of the four isocyanide ligands centered at the metal. Thus, $[RhI_2L_4]ClO_4$ (L=2,4,6-$Me_3C_6H_2NC$, *t*-BuNC) assumes an octahedral geometry, in which the two iodide ligands are in mutual *trans* positions. A similar *trans* configuration was reported for $[RhI_2(t\text{-BuNC})_4]PF_6$.[10] Complexes of the RhI_5L_4 type behave as electrolytes in acetonitrile; molar conductivities are 151 (L=2,4,6-$Me_3C_6H_2NC$, 1.0×10^{-4} M) and 176 $cm^2\,ohm^{-1}\,mol^{-1}$ (L=*t*-BuNC, 1.0×10^{-4} M). These complexes may be formulated as *trans*-$[RhI_2L_4]I_3$ since their ν(NC) frequencies were essentially identical with those of the corresponding perchlorate salts and their electronic spectra in acetonitrile appeared as a superposition of the spectrum of the I_3^- anion on that of the *trans*-$[RhI_2L_4]^+$ cation.

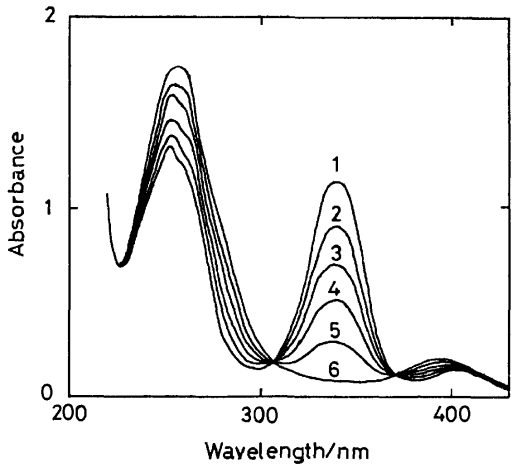

Fig. 1. Electronic spectra of $[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ (2.0×10^{-4} M) in acetonitrile containing varying amounts of iodine; (**1**) 0, (**2**) 0.4×10^{-4} M, (**3**) 0.8×10^{-4} M, (**4**) 1.2×10^{-4} M, (**5**) 1.6×10^{-4} M, (**6**) 2.0×10^{-4} M; cell length=0.1 cm.

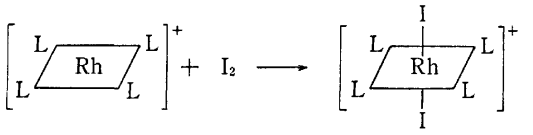
Stoichiometry. The electronic spectra of $[RhL_4]ClO_4$ in acetonitrile obeyed the Lambert-Beer law over the concentration range from 3×10^{-6} to 4×10^{-4} M. Self-association of these square-planar Rh(I) cations is, therefore, negligible in this range, though such phenomenon has been reported to occur in some Rh(I) complexes at relatively high concentrations.[11] Electronic spectra of acetonitrile solutions containing $[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ and varying amounts of I_2 are shown in Fig. 1. The spectrum of a solution containing equimolar amounts of the Rh(I) substrate and I_2 (**6** in Fig. 1) was essentially same as that of an acetonitrile solution of the *trans*-$[RhI_2(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$ adduct. In addition, there was seen no appreciable change in the spectrum even in a solution containing the Rh(I) substrate and I_2 with the mole ratio of 1:2. As shown in Fig. 2, the mole ratio method using the absorbances at 339 and 256 nm indicates the composition of the adduct to be 1:1. The same result was obtained in the $[Rh(t\text{-BuNC})_4]ClO_4$–$I_2$ system. Thus, the stoichiometry for equimolar reaction of I_2 with the Rh(I) substrate is expressed by



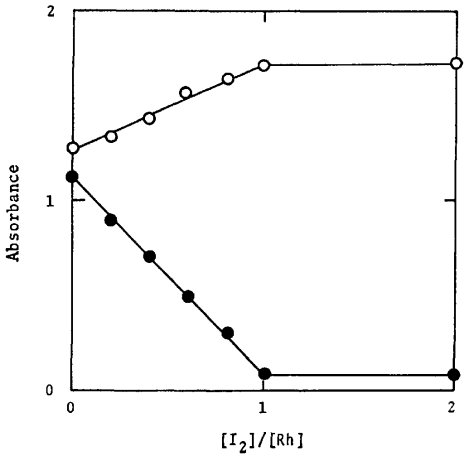


Fig. 2. A plot of the absorbances at 339 (●) and 256 nm (○) *vs.* the mole ratio $[I_2]/[\mathbf{Rh}]$ in acetonitrile; $[\mathbf{Rh}]=2.0\times10^{-4}$ M (**Rh**=$[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$).

Kinetics and Mechanism. Rapid scanning spectra of the solution after mixing $[Rh(t\text{-BuNC})_4]ClO_4$ (2.0×10^{-4} M) with excess I_2 (2.0×10^{-3} M) in acetonitrile is illustrated in Fig. 3, which shows decay of the absorption maxima at 282 and 376 nm both with half-lives of about 1 s. The spectrum finally obtained shows the absorption maxima at 277 and 384 nm due to *trans*-$[RhI_2(t\text{-BuNC})_4]ClO_4$. As $[Rh(t\text{-BuNC})_4]ClO_4$ and I_2 exhibit no band maximum at 282 and 376 nm, the bands observed at these wavelengths may be associated with a reaction intermediate which is formed during the dead time of the instrument. Similarly, an intermediate

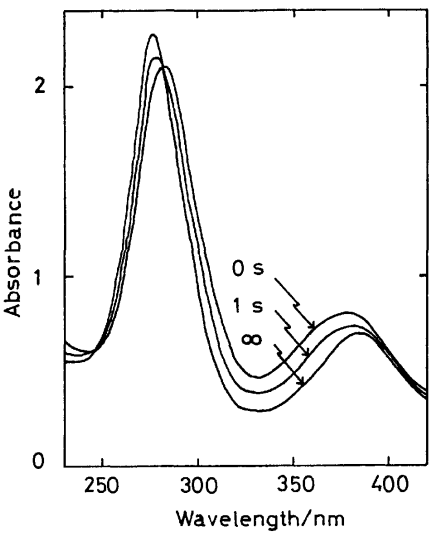

Fig. 3. Rapid scanning spectra after mixing $[Rh(t\text{-BuNC})_4]ClO_4$ (2.0×10^{-4} M) with excess I_2 (2.0×10^{-3} M) in acetonitrile at 25.0 °C, cell length=0.2 cm.

Fig. 4. The ^{1}H NMR spectrum of an equimolar mixture (5.0×10^{-2} M) of [Rh(*t*-BuNC)$_4$]ClO$_4$ and I_2 in acetonitrile-d_3 at −40 °C; the solution was prepared at this temperature.

with absorption maxima at 256 and 375 nm was observed in the reaction of [Rh(2,4,6-$Me_3C_6H_2NC)_4$]-ClO$_4$ with I_2. The discordant wavelengths of the short-lived absorptions observed in the two reaction systems imply that the intermediates are not a common species such as the I_3^- anion.

In order to obtain some knowledge of the intermediate, ^{1}H NMR and infrared spectra were measured for solutions of the mixture of reactants at low temperatures because the intermediate might be stabilized at low temperatures. Figure 4 shows the ^{1}H NMR spectrum of an acetonitrile-d_3 solution containing equimolar amounts (5.0×10^{-2} M) of [Rh(*t*-BuNC)$_4$]ClO$_4$ and I_2 immediately after preparing at −40 °C. There appear two methyl signals, of which the upfield one is ascribed to the intermediate because this signal decreases in intensity with ascending temperature and disappears at −10 °C completely, while the downfield signal assignable to *trans*-[RhI$_2$(*t*-BuNC)$_4$]ClO$_4$ remains unchanged even at room temperature. Figure 5 shows the infrared spectra in the ν(N≡C) region for two acetone solutions both containing equimolar quantities (2.5×10^{-2} M) of [Rh(*t*-BuNC)$_4$]ClO$_4$ and I_2; one was prepared by rapid introduction of the reactant solutions into a cell at −60 °C (solution **a**), and the other was prepared at room temperature, followed by cooling down to −60 °C (solution **b**). The 2231 cm^{-1} band observed in **b** is attributable to *trans*-[RhI$_2$(*t*-BuNC)$_4$]-ClO$_4$ because of its coincidence in position with the band of this compound in acetone at room temperature. The same assignment is given to the high frequency band (2231 cm^{-1}) found in **a**. On the other hand, the low frequency band (2217 cm^{-1}) may be due to the intermediate since it disappeared after solution **a** was allowed to stand at room temperature for more than 20 min and recooled to −60 °C. It is to be noted that the position of the 2217 cm^{-1} band is 61 cm^{-1} higher than that of ν(N≡C) of the starting complex [Rh(*t*-BuNC)$_4$]-ClO$_4$ (2156 cm^{-1}). The magnitude of this high frequency shift is larger than that observed in one electron oxidation (35—50 cm^{-1}) of some Rh(I)–isocyanide complexes, and is close to that in the two electron oxidation (65—80 cm^{-1}).[12] This indicates that the rhodium metal of the intermediate is oxidized with I_2. Thus, two possible configurations, **A** and **B**, are proposed for the intermediate, though the oxidation number of the rhodium metal in **A** is ambiguous. A configuration with metal–iodine interaction like **A** has been suggested as an intermediate in the reactions of I_2 with Pt(acac)$_2$[13] and $Me_3SnCr(CO)_3(\eta\text{-}C_5H_5)$,[14] although no direct spectral evidence for the existence of such an intermediate has been obtained, probably because of its low stability. On the other hand, the half-life of the intermediate (about 1 s) in the present reaction is compared with that of *cis*-[Cr(CO)$_2$($Ph_2PCH_2PPh_2$)$_2$]$^+$ (about 0.6 s) which isomerizes to a *trans* cation.[15] In addition, the electronic spectrum of the present intermediate resembles that of the *trans* adduct (Fig. 3), suggesting that they are at least structurally similar to each other. This is supported from the similarity between the spectra of *cis*- and *trans*-RuCl$_2$(4-$MeC_6H_4NC)_2(PPh_3)_2$ prepared by the literature method,[16] as shown in Fig. 6. In view of these facts, the intermediate is presumably assigned to the *cis* adduct **B** in the present reactions.

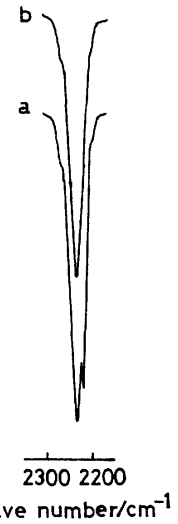

Fig. 5. Infrared spectra of acetone solutions containing equimolar quantities (2.5×10^{-2} M) of [Rh(*t*-BuNC)$_4$]-ClO$_4$ and I_2 at low temperatures; **a** and **b** are the solutions prepared at −60 °C and at room temperature, respectively.

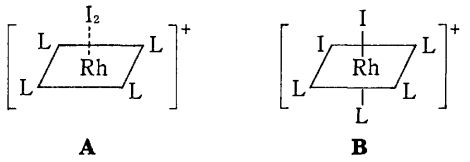

A **B**

Unsatisfactory solubility of [Rh(2,4,6-$Me_3C_6H_2NC)_4$]-ClO$_4$ in polar solvents such as acetonitrile and acetone at low temperatures has prevented ^{1}H NMR and infrared spectral measurements, as described above, for the [Rh(2,4,6-$Me_3C_6H_2NC)_4$]ClO$_4$–I_2 system.

The rate of reaction of [Rh(2,4,6-$Me_3C_6H_2NC)_4$]ClO$_4$ with I_2 was followed by measuring the decay of absorb-

a) In dichloromethane, k_{obsd} values for the reactions of $[RhL_4]ClO_4$ (2.0×10^{-4} M) with I_2 (2.0×10^{-3} M) are $2.98\ s^{-1}$ (L=2,4,6-$Me_3C_6H_2NC$) and $7.08\ s^{-1}$ (L=*t*-BuNC) at 25.0 °C.

ances at both 360 and 300 nm after mixing their acetonitrile solutions. With $[Rh(t\text{-}BuNC)_4]ClO_4$, the reaction was monitored by the absorbance at 290 nm. Plots of $\ln(A_t-A_\infty)$ *vs.* time were found to be linear, where A_t and A_∞ are absorbances at the time "t" and at the end of reaction. Pseudo-first-order rate constants, k_{obsd}, were obtained by the least-squares method. The results are shown in Table 1. The k_{obsd} value in each reaction is essentially independent of the concentration of I_2 at a given temperature. This is consistent with the assumption that the reaction of $[RhL_4]ClO_4$ with I_2 proceeds *via* the *cis* adduct. Furthermore, the formation of the *cis* adduct as an intermediate is compatible with the result that the k_{obsd} value is considerably larger in dichloromethane than in acetonitrile (see the footnote of Table 1), owing to destabilization of the *cis* adduct more polar than the *trans* one in less polar solvent dichloromethane. Thus, the present reaction may be expressed by Eq. 1 which involves *cis-trans* isomerization.

$$[RhL_4]ClO_4 + I_2 \xrightarrow{k} cis\text{-}[RhI_2L_4]ClO_4 \xrightarrow{k'} trans\text{-}[RhI_2L_4]ClO_4 \quad (1)$$

As the first step, though it has not been clarified mechanistically in the present study, is much faster than the second one, k_{obsd} is equal to k'.

The Arrhenius plots gave activation parameters for the *cis-trans* isomerization: $\Delta H^{\ddagger}_{298}=74.0\pm1.3$ kJ mol^{-1}, $\Delta S^{\ddagger}_{298}=-1.3\pm4.2$ J mol^{-1} K^{-1} for the $[Rh(2,4,6\text{-}Me_3C_6H_2NC)_4]ClO_4$–$I_2$ system, and $\Delta H^{\ddagger}_{298}=73.6\pm1.6$ kJ mol^{-1}, $\Delta S^{\ddagger}_{298}=-3.2\pm5.4$ J mol^{-1} K^{-1} for the $[Rh(t\text{-}BuNC)_4]ClO_4$–$I_2$ system. The small negative values of $\Delta S^{\ddagger}_{298}$ in both reactions suggest the isomerization to proceed intramolecularly, probably *via* a twist mechanism. Moreover, the $\Delta H^{\ddagger}_{298}$ values obtained are compared with that of the *cis-trans* isomerization of $RhI_2(S_2CNMe_2)(2,4,6\text{-}Me_3C_6H_2NC)_2$ (75.5 kJ mol^{-1}),[8] reinforcing the assignment of the intermediate as *cis*-$[RhI_2L_4]ClO_4$.

Finally, it should be mentioned that the formation of *trans*-$[RhI_2L_4]ClO_4$ was followed by a much slower reaction which takes about 8 h to completion at 28 °C, giving *trans*-$[RhI_2L_4]I_3$. This reaction, however, has not been kinetically analyzed because we have been interested in the addition reaction.

Synthesis and Electrical Resistivity of Bis(dialkyldithiocarbamato)-gold(III) Cation-TCNQ Radical Anion Salts

Yoshiji YUMOTO, Futoshi KATO, and Toshio TANAKA*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 565

(Received November 13, 1978)

Seven simple salts and one complex salt of $TCNQ^{\cdot}$ radical anion with bis(dialkyldithiocarbamato)gold(III) cations, $[Au(S_2CNR_2)_2]^+TCNQ^{\cdot}$ (R=Me, Et, *n*-Pr, *n*-Bu, *n*-C_6H_{13}, *n*-C_8H_{17}, and $CH_2C_6H_5$) and $[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}$, were prepared. The complex salt was also obtained as an acetonitrile solvate, $[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}\cdot MeCN$. The electrical resistivity of the simple salt with R=$CH_2C_6H_5$ (2.9×10^4 ohm cm in compacted sample) is much lower than those of the remaining simple salts (1.1×10^7—2.2×10^{10} ohm cm). The resistivities of two complex salts are in the order of 10^2 ohm cm. Electronic absorption spectra and magnetic susceptibility measurements in the solid state indicate that the simple salts with R=Me, Et, *n*-Pr, *n*-C_6H_{13}, and $CH_2C_6H_5$ involve the $TCNQ^{\cdot}$ radical anion monomer, whereas those with R=*n*-Bu and *n*-C_8H_{17} involve dimeric $(TCNQ)_2^{2-}$. The interaction between $TCNQ^{\cdot}$ radical anion and neutral TCNQ in the complex salts is extremely weak, as suggested from no appreciable absorption band in the near-infrared region.

Much attention has been paid to unusual electrical propeties exhibited by one-dimensional materials in both fields of organic and inorganic chemistry.[1] Up to the present time, the most successful organic materials in this area have been based on the radical anion salts of 7,7,8,8-tetracyanoquinodimethane (TCNQ),[2] while a prominent example in the inorganic field is partially oxidized platinum cyanide complexes ($K_2Pt(CN)_4\cdot X_{0.3}\cdot 3H_2O$, X=Cl, Br).[3] However, only a few $TCNQ^{\cdot}$ radical anion salts containing transition metal complexes have been reported so far.[4]

It is well known that some square-planar d^8 transition metal complexes with 1,1-dithiolato ligands not only assume a columnar structure in the crystalline state, but also undergo reversible oxidation and reduction electrochemically in solution.[5] These facts prompted us to prepare $TCNQ^{\cdot}$ radical anion salts of bis(dialkyldithiocarbamato)gold(III) cations. This paper reports the synthesis and electrical resistivity of some simple and complex salts of $TCNQ^{\cdot}$ with these cations, $[Au(S_2CNR_2)_2]^+TCNQ^{\cdot}$ (R=Me, Et, *n*-Pr, *n*-Bu, *n*-C_6H_{13}, *n*-C_8H_{17}, and $CH_2C_6H_5$), $[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}$ and $[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}\cdot MeCN$. Electronic spectra and magnetic properties of these salts in the solid state are also discussed in terms of the stacking of $TCNQ^{\cdot}$.

Experimental

Bis(dialkyldithiocarbamato)gold(III) chlorides, $[Au(S_2CNR_2)_2]^+Cl^-$ (R=Me, Et, *n*-Pr, *n*-C_6H_{13}, *n*-C_8H_{17}, and $CH_2C_6H_5$), were prepared by the reaction of $NaAuCl_4\cdot2H_2O$ with the appropriate thiuram disulfide, $(R_2NC(S)S)_2$, in a mannar similar to the method[6] for $[Au(S_2CN(n\text{-}Bu)_2)_2]^+Br^-$; an oily product obtained was dissolved in dichloromethane, followed by the addition of diethyl ether to give a yellowish orange precipitate in 78—89% yields.

Bis(dialkyldithiocarbamato)gold(III)-TCNQ Simple Salts, $[Au(S_2CNR_2)_2]^+TCNQ^{\cdot}$ (R=Me (1), Et (2), n-Pr (3), n-Bu (4), n-C_6H_{13} (5), n-C_8H_{11} (6), and $CH_2C_6H_5$ (7)). To a solution of $Li^+TCNQ^{\cdot}$ (0.52 g, 25 mmol) in boiling ethanol (40 ml) was added a hot ethanol (30 ml) solution of $[Au(S_2CNMe_2)_2]^+Cl^-$ (1.1 g, 25 mmol). The mixture was allowed to stand at room temperature. The resulting precipitate was recrystallized from acetonitrile to give **1** in a 56% yield.

TABLE 1. PROPERTIES AND ANALYTICAL DATA OF THE $TCNQ^{\cdot}$ SALTS

No.	Salt	Color	Mp(dec) °C	Found (Calcd) % C	H	N
1	$[Au(S_2CNMe_2)_2]^+TCNQ^{\cdot}$	Dark-green needles	212—213	33.76 (33.70)	2.57 (2.51)	13.27 (13.10)
2	$[Au(S_2CNEt_2)_2]^+TCNQ^{\cdot}$	Dark-green needles	201—202	37.90 (37.87)	3.46 (3.47)	12.05 (12.05)
3	$[Au(S_2CN(n\text{-}Pr)_2)_2]^+TCNQ^{\cdot}$	Dark-green needles	174—177	41.22 (41.43)	4.17 (4.28)	11.05 (11.15)
4	$[Au(S_2CN(n\text{-}Bu)_2)_2]^+TCNQ^{\cdot}$	Violet needles	148—150	44.18 (44.49)	4.90 (4.99)	10.40 (10.38)
5	$[Au(S_2CN(n\text{-}C_6H_{13})_2)_2]^+TCNQ^{\cdot}$	Dark-green needles	86—87	49.40 (49.50)	6.12 (6.25)	9.11 (9.11)
6	$[Au(S_2CN(n\text{-}C_8H_{17})_2)_2]^+TCNQ^{\cdot}$	Black microcrystals	55—57	53.01 (53.42)	7.05 (7.02)	8.20 (8.13)
7	$[Au(S_2CN(CH_2C_6H_5)_2)_2]^+TCNQ^{\cdot}$	Black microcrystals	186—188	53.22 (53.33)	3.40 (3.41)	9.18 (8.88)
8	$[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}$	Dark-blue needles	211—213	56.48 (56.38)	3.15 (3.16)	12.12 (12.18)
9	$[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}\cdot(MeCN)$	Black needles	212—214	56.18 (56.42)	3.22 (3.38)	12.93 (12.93)

Other six simple salts, **2**—**7**, were similarly prepared by the equimolar reaction of TCNQ$^{\cdot}$ in ethanol with the appropriate bis(dialkyldithiocarbamato)gold(III) cation in acetonitrile, 77—90% yields.

Bis(dibenzyldithiocarbamato)gold(III)-TCNQ Complex Salts, $[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}$ (8) and $[Au(S_2CN(CH_2C_6H_5)_2)_2]^+(TCNQ)_2^{\cdot}\cdot MeCN$ (9). To a boiling acetonitrile (60 ml) solution of **7** (0.53 g, 0.56 mmol) was added two equivalent amounts of neutral TCNQ (0.23 g, 1.1 mmol) in boiling acetonitrile (40 ml). After filtration, the mixture was allowed to stand in a refrigerator overnight to afford microcrystals of **8** in a 87% yield. Acetonitrile solvate salt **9** was obtained on recrystallization of **8** from acetonitrile, 57% yield on the basis of **8**.

Physical Measurements. Electrical resistivities, electronic and infrared spectra, and magnetic susceptibilities were measured as described previously.[7]

Results and Discussion

Preparation and Characterization. Simple salt **7** reacted with additional neutral TCNQ in acetonitrile to yield complex salt **8**, while in the reactions of the remaining simple salts (**1**—**6**) with neutral TCNQ in the same solvent the starting materials have only been recovered, respectively. Acetonitrile solvate complex salt **9** was characterized by elemental analysis, infrared spectrum, and differential scanning calorimetry (DSC); **9** in the solid state released acetonitrile on heating to 90 °C in a DSC cell, as confirmed by the fact that the infrared spectrum of **9** after heating coincides with that of **8**.

Electrical Properties. Temperature dependence of electrical resistivities for the simple and complex salts (compacted samples) are illustrated in Fig. 1; the results were satisfactorily reproducible. All the simple and complex salts show typical semiconducting behavior in the temperature range measured. Table 2 summarizes the specific resistivities (ρ) of these salts at 25 °C and the activation energies (E_a) obtained from the Arrhenius plots of the temperature dependence of resistivities, $\rho = \rho_0 \exp(E_a/kT)$, together with the magnetic susceptibility (χ_M). The ρ values of **1**—**6** fall in the range of 10^7—10^{10} ohm cm, which are much larger than the resistivities of alkali metal salts of TCNQ$^{\cdot}$ (10^2—10^5 ohm cm).[8] Simple salt **7** behaves a smaller ρ value by three to six orders of magnitude than **1**—**6**. This is suggestive of the stacking of TCNQ$^{\cdot}$ in **7** being different from those in **1**—**6**.

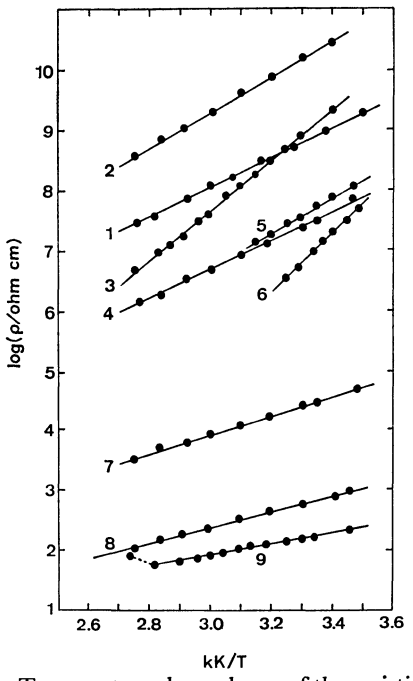

Fig. 1. Temperature dependence of the resistivity of the TCNQ$^{\cdot}$ salts.

Table 2. Electrical resistivity (ρ), activation energy (E_a), and magnetic susceptibility (χ_M) of the TCNQ$^{\cdot}$ salts

Salt	$\rho_{25°C}$ / ohm cm	E_a / eV	χ_M / emu mol^{-1}
Simple salt			
1	8.9×10^{8}	0.50	7.1×10^{-4}

Complex salt			
8	6.6×10^{2}	0.26	9.8×10^{-4}
9	1.6×10^{2}	0.13	4.0×10^{-4}

One of the authors has previously reported the preparation of *N,N*-dialkyl-1,3-dithiolan-2-iminium–TCNQ$^{\cdot}$ simple salts, $(CH_2)_2\langle S \rangle C{=}\overset{+}{N}R_2\cdot TCNQ^{\cdot}$ (R=Me, *n*-Pr, *n*-C_6H_{13}, and *n*-C_8H_{17}), whose electrical resistivity (2.2×10^5—1.9×10^9 ohm cm) increases in the order of bulkiness of substituents on the iminium nitrogen atom.[7,9] In contrast to this, the resistivity of the present simple salts seems to decrease as substituents on the carbamato nitrogen atom are bulky. Explanation for this unusual tendency has to await X-ray structure analysis of these simple salts.

The ρ values of complex salts **8** and **9** ($\approx10^2$ ohm cm) are smaller by two orders of magnitude than the corresponding simple salt **7**. Both the resistivity and activation energy of acetonitrile solvate complex salt **9** seem to be smaller than those of **8**, though these values fall in the same order.

Electronic and Magnetic Properties. All the simple salts in acetonitrile exhibited absorption maxima at *ca.* 12000 and 24000 cm^{-1} in the electronic spectra, regardless of the difference of substituents R in the $[Au(S_2CNR_2)_2]^+$ cations. Appearance of the spectra closely resembles that of M$^+$TCNQ$^{\cdot}$ (M=alkali metal or ammonium cation) in acetonitrile, where they are known to dissociate into the monomeric TCNQ$^{\cdot}$ radical anion and the M$^+$ cation.[10] The bands at *ca.* 12000 and 24000 cm^{-1} in acetonitrile have been assigned to locally-excited transitions of the TCNQ$^{\cdot}$ moiety, LE_1 and LE_2, respectively.[11]

Figure 2 illustrates the electronic absorption spectra

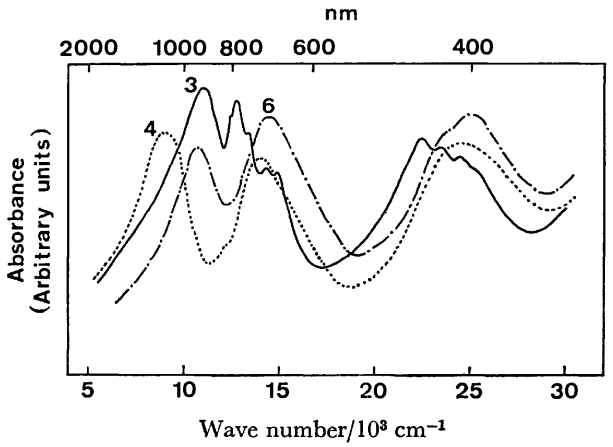

Fig. 2. Electronic absorption spectra of **3**, **4**, and **6** in Nujol mulls.

of **3**, **4**, and **6** in the solid state. The spectrum of **3** is similar in appearance to that of this salt in acetonitrile, indicating that the $TCNQ^{\cdot}$ radical anion in solid **3** may exist as monomeric species. This is compatible with the paramagnetic property of **3** in the solid state at room temperature (Table 2). The presence of the discrete $TCNQ^{\cdot}$ radical anion in the solid state is suggested also for **1**, **2**, and **5** on the basis of their solid state spectra similar to that of **3** and their paramagnetism at room temperature. These assumptions may be consistent with electrically high resistivities and large activation energies of **1**—**3** and **5**, which predict an alternate stacking of the $[Au(S_2CNR_2)_2]^+$ cation and the $TCNQ^{\cdot}$ radical anion ($D^+A^{\cdot}D^+A^{\cdot}\cdots$). Both simple salts **4** and **6** exhibited three absorption maxima at *ca.* 9900, 14000, and 24000 cm^{-1} (Table 3). The spectral patterns closely resemble not only those of simple salts formed between *N*,*N*-dialkyl-1,3-dichalcogenacycloalkan-2-iminium and $TCNQ^{\cdot}$, $(CH_2)_n\langle^{Y}_{Y}\rangle C{=}\overset{+}{N}R_2\cdot TCNQ^{\cdot}$ (n=2, 3; Y=S, Se; R=Me, Et),[7] but also the reflectance spectra of some simple $TCNQ^{\cdot}$ salts with Li^+, NH_4^+, and $MePh_3P^+$,[10] all of which have been reported to involve dimeric $(TCNQ)_2^{2-}$ on the basis of spectral assignments that the lowest energy band may be due to the CT transition between $TCNQ^{\cdot}$ radical anions and that the remaining two to the $(TCNQ)_2^{2-}$ dimer.[10,11] It is therefore suggested that the $(TCNQ)_2^{2-}$ dimer exists in solid **4** and **6**. This is supported also from their diamagnetic properties in the solid state at room temperature (Table 2). Such diamagnetism may confirm that two $TCNQ^{\cdot}$ radical anions are coupled completely with each other. The fact that the CT band of **6** was fairly blue-shifted (*ca.* 2000 cm^{-1}) compared with that of **4** may be correlated with a larger activation energy in **6** than in **4** (Table 1).

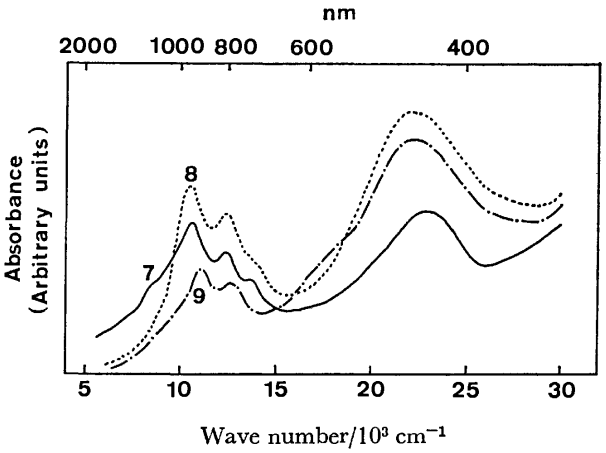

Fig. 3. Electronic absorption spectra of **7**, **8**, and **9** in Nujol mulls.

Figure 3 shows the electronic absorption spectra of simple salt **7** and complex salts **8** and **9** in the solid state. The spectrum of **7** is similar to that of **3**, while no fine structure has been observed in **7**. In fact, **7** exhibited paramagnetic susceptibility at room temperature. Its electrical resistivity, however, is much smaller than those of **1**—**6**, suggesting a segregated columnar stacking of the $TCNQ^{\cdot}$ radical anion in **7**.

The electronic spectra of **8** and **9** show three absorption maxima at *ca.* 11000, 12500, and 22000 cm^{-1} (Table 3). The highest energy band is contributed from the electronic transitions in both the $TCNQ^{\cdot}$ radical anion and neutral TCNQ.[11] The remaining two bands may be due to the $TCNQ^{\cdot}$ monomer, as previously described in the reflectance spectra of some $TCNQ^{\cdot}$ complex salts.[10] The presence of monomeric $TCNQ^{\cdot}$ is consistent with the fact that **8** and **9** exhibited paramagnetic susceptibilities in the solid state at room temperature. In addition, both **8** and **9** have not clearly shown a broad absorption band in the 5000 to 2500 cm^{-1} range; the band has been observed in many $TCNQ^{\cdot}$ complex salts and assigned to the CT transition between

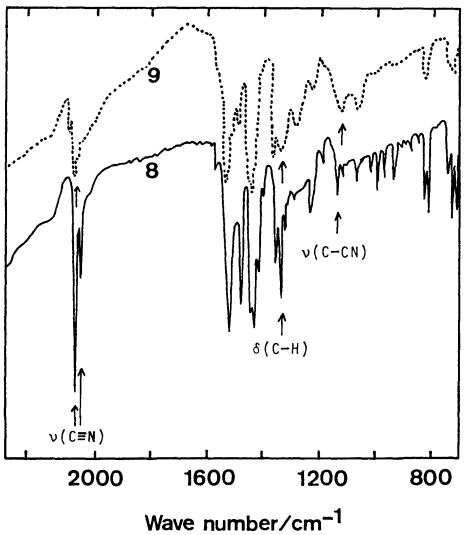

Fig. 4. Infrared spectra of **8** and **9** in Nujol mulls.

TCNQ$^{\tau}$ and neutral TCNQ.[10] It may therefore be concluded that the interaction between TCNQ$^{\tau}$ and neutral TCNQ in **8** and **9** is extremely weak. It should be mentioned, however, that the infrared spectrum of **9** shows considerably broad bands due to ν(C≡N), δ(C–H), and ν(C–CN) compared with that of **8**, as shown in Fig. 4. This sort of broadening observed in the spectra of many TCNQ$^{\tau}$ complex salts has been taken as an evidence for the resonance between TCNQ$^{\tau}$ and neutral TCNQ.[12] Thus, the interaction between TCNQ$^{\tau}$ and neutral TCNQ may be somewhat stronger in **9** than in **8**.

The Synthesis and Crystal Structure of Bis(cyclo-L-histidyl-L-histidyl)copper(II) Perchlorate Tetrahydrate

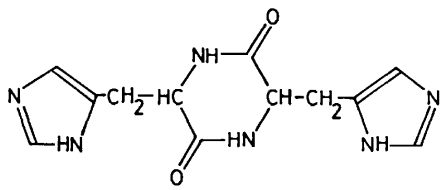
Fumio Hori, Yoshitane Kojima, Keiji Matsumoto, Shun'ichiro Ooi,* and Hisao Kuroya

Department of Chemistry, Faculty of Science, Osaka City University, Sumiyoshi-ku, Osaka 558

(Received September 16, 1978)

The title compound was prepared, and its structure then determined by X-ray structure analysis. The crystal is trigonal with the space group $P3_221$, $a=8.450(3)$, $c=42.00(6)$Å, and $Z=3$. The crystal structure has been determined from the diffractometer data and refined by a least-squares method to an R value of 0.103 for 1349 independent reflections with $I>3\sigma(I)$. The cyclo-L-histidyl-L-histidyl is coordinated to the Cu atom *via* the N atoms of the respective imidazolyl groups. The coordination of Cu is not planar but distorted toward the tetrahedral configuration, the interplanar angle between $Cu<^{N}_{N}$ planes being 29°. The complex has virtually D_2 symmetry: there are two pseudo two-fold axes and one crystallographically imposed two-fold axis which relates two chelate rings. The chelate rings assume the δ conformation, and the ligating cyclo-L-histidyl-L-histidyl is of a folded form with a bowsprit-boat 2,5-piperazinedione ring. The electronic and circular dichroism spectra in the visible region are presented.

Histidine and its cyclic dipeptide play an important role in biological systems. Langenbeck *et al.* found that these substances catalyze the oxidation of DOPA and that the addition of the Cu^{2+} ion to the reaction system accerelates the oxidation.[1] As structural information is indispensable for an understanding of the function of the L-histidine residue in a biological process, we have attempted to make a structural investigation of cyclo-L-histidyl-L-histidyl [=(3*S*,6*S*)-bis(4-imidazolylmethyl)-2,5-piperazinedione, hereafter abbreviated as cyhis], and



cyhis

its metal chelates. Two of the present authors (Y. K. and K. M.) previously reported the crystal structure of aquabis(cyclo-L-histidyl-L-histidylato)dicopper(II) perchlorate hydrate,[2] which had been obtained from the reaction of $Cu(ClO_4)_2$, cyhis, and LiOH in a 1 : 1 : 1 mole ratio. The reaction of $Cu(ClO_4)_2$ with twice as many moles of the cyhis in methanol yielded a violet compound which was analysed to be $Cu(cyhis)_2(ClO_4)_2\cdot 4H_2O$. This compound has been characterized by means of X-ray structure analysis and its visible and circular dichroism (CD) spectra.

Experimental

Preparation of $Cu(cyhis)_2(ClO_4)_2\cdot 4H_2O$. A suspension of $Cu(ClO_4)_2\cdot 6H_2O$ (0.371 g, 1 mmol) and the cyhis·$2H_2O$ (0.585 g, 2 mmol) in methanol was stirred at room temperature until these compounds were completely dissolved. The violet crystals were then separated out and recrystallized from hot water. Yield, 0.590 g (67%).

Found: C, 32.73; H, 4.11; N, 19.12%. Calcd for $Cu(C_{12}H_{14}N_6O_2)_2(ClO_4)_2\cdot 4H_2O$: C, 32.64; H, 4.11; N, 19.03%.

The compound is different in color from $Cu(cyhis)_2SO_4\cdot 5H_2O$(blue), which was prepared by Losse *et al.*[1]

Spectral Measurements. The absorption and CD spectra in an aqueous solution were recorded at room temperature on a Hitachi EPS 3T Recording Spectrometer and a JASCO J-20 Automatic Recording Spectrometer respectively.

X-Ray Data Measurements. Crystal Data: $C_{24}CuCl_2H_{36}N_{12}O_{16}$, Trigonal, $a=8.450(3)$, $c=42.00(6)$Å, $U=2597.7(2)$ Å^3, $D_m=1.68$, $D_c=1.67$ g/cm^3, $Z=3$, $\mu(Cu\,K\alpha)=32.0$ cm^{-1}, space group $P3_221$. The Laue symmetry, space-group extinctions, and approximate unit-cell dimensions were obtained from Weissenberg and precession photographs. The cell dimensions were refined by the leasts-quares analysis of 22 θ values measured on a Philips PW1100 diffractometer by the use of Cu $K\alpha$ radiation. The space group was determined on the basis of the configuration (*S*) of the asymmetric carbon atom in the cyhis ligand.

Data Collection: The intensity data were collected on the diffractometer using graphite-monochromated Cu $K\alpha$ radiation. The specimen size was $0.20\times 0.20\times 0.18$ mm^3. A scan speed of 0.033 s^{-1} and a scan width of $(0.8+0.2\tan\theta)°$ in ω were chosen. The background was counted for 10 s at each end of scan range. Of the independent reflections collected in the $2\theta\leq 120°$ range, 1349 reflections with $I>3\sigma(I)$ were used for the structure analysis. The number of reflections corresponds to *ca.* 70% of the total number of independent reflections within the range. No appreciable decay was observed in the intensities of the standard reflections monitored every 5 h throughout the data collection. Intensity data were also corrected for Lp factor.[3] A spherical absorption correction ($r=0.10$ mm) was applied.

Structure Determination and Refinement. The crystal structure was solved by the heavy-atom method. The positional and thermal parameters were refined by the block-diagonal least-squares method, anisotropic temperature factors being used for the Cu and Cl atoms. The minimized function was $\sum w(F_o-|F_c|)^2$. The weighting scheme of $w=1.0$ for $F_o\leq F_{max}$ and $w=(F_{max}/F_o)^2$ for $F_o>F_{max}$ was used. The F_{max} value of 30.0 was found to be best for making $w(\Delta F_o)^2$ relatively constant over the whole range of F_o. The final R value was 0.103 ($R'=[\sum w(F_o-|F_c|)^2/\sum wF_o^2]=0.139$). In the final cycle of refinements, all the parameter shifts were less than 0.2σ. The large temperature factors of the O atoms in the ClO_4^- ions are indicative of a disorder in the arrangement of ClO_4^-. The atomic parameters are listed in Table 1. A table of the observed and calculated structure factors is preserved by the Chemical Society of Japan (Document No. 7912). The atomic scattering factors for Cu^0, Cl^-, O, N, and C atoms were taken from Ref. 4, with corrections for

the anomalous scattering for Cu and Cl atoms. All computations were carried out by using programs in the UNICS.[5]

In order to confirm the structure, further least-squares calculations were performed, anisotropic temperature factors being used for all the atoms. The R and R' values reached 0.070 and 0.108 respectively. The difference Fourier map showed no peaks greater than 0.4 e/Å^3.

Results and Discussion

Figures 1a and b show the projection and elevation of the complex. Another elevation (half of the complex) is presented in Fig. 2(a). The complex has a crystallographically imposed two-fold axis; it is parallel to the a axis, runs through the Cu atom, and bisects the N(2)–Cu–N′(2) angle as well as the N(6)–Cu–N′(6) angle. Moreover, there are two pseudo two-fold axes. One bisects the N(6)–Cu–N′(2) (and N(2)–Cu–N′(6)) angle (Fig. 1b), and the other passes through the Cu atom and the center of the 2,5-piperazinedione ring (DKP ring) composed of N(3), C(5), C(6), N(4), C(7), and C(8). These three axes perpendicularly intersect one another at the position of the Cu atom; hence, the complex virtually possesses a D_2 symmetry.

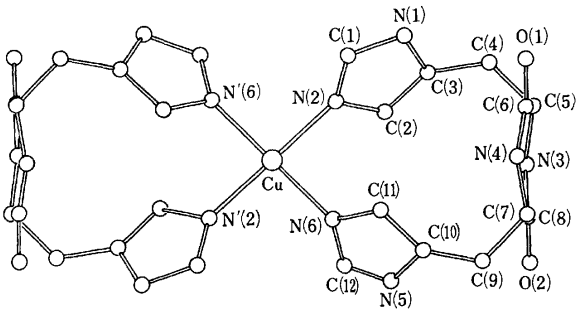

Fig. 1a. The structure of the complex viewed along the a axis.

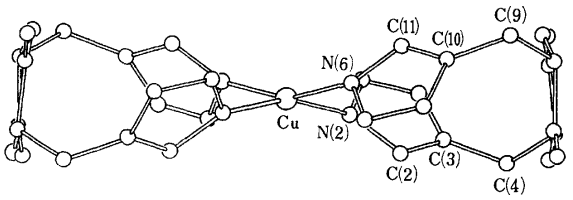

Fig. 1b. An elevation of the complex.

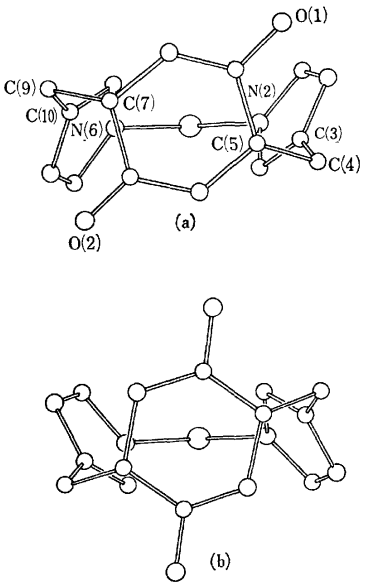

Fig. 2. (a) An elevation of the chelate ring (δ conformation. (b) λ chelate ring.

The Cu atom is surrounded by 4 N atoms of the respective imidazolyl groups. The disposition of the 4 N atoms is not planar, but distorted toward a tetrahedral configuration (Fig. 1b), the interplanar angle between [N(2), Cu, N(6)] and [N′(2), Cu, N′(6)] planes being 29°. The two Cu–N bond lengths are substancially identical and are in agreement with those in the sulfate[6] and perchlorate[7] of tetrakis(imidazole)copper(II), and with the Cu(B)–N(5) distance in the aquabis(cyclo-L-histidyl-L-histidylato)dicopper(II) perchlorate hydrate.[2] Above and below the Cu atom (Fig. 1b) there are no atoms within 3.4 Å. The bond lengths and angles are listed in Table 2.

As has been described above, the chelate ring has a

pseudo two-fold axis. Every pair of bonds related to each other by the axis agrees well in length. This is also the case for such a pair of bond angles. The bond lengths and angles in the imidazole moieties are comparable to those in the imidazole at −150 °C[8] and the tetrakis(imidazole)copper(II) complexes.[6,7] The Cu–N bond does not lie on the imidazole plane; the Cu–N(2) bond makes an angle of 12° with the [N(2), C(1), N(1), C(3), C(2)] plane, while the Cu–N(6) bond deviates from the [N(6), C(12), N(5), C(10), C(11)] plane by 17°. Several important interplanar angles are listed in Table 3, where the deviations of atoms from least-squares planes are also given.

The DKP ring is slightly buckled toward a boat conformation. The torsion angles (Table 4) rather resemble those of the DKP ring in cyclo(L-alanyl-L-alanyl), which was found to be the bowsprit-boat conformation.[9] The C(5)–C(4) and C(7)–C(9) bonds are quasi-equatorial with respect to the ring. As indicated by χ^1 values, both imidazolylmethyl side chains have a folded conformation. The ligating cyhis molecule thus assumes a folded form with a bowsprit-boat DKP ring. The structural parameters of the DKP ring are comparable to those in cyclo(L-threonyl-L-histidyl) dihydrate.[10]

As may be seen in Fig. 2 (a), the chelate ring has δ chirality. That the crystals comprise solely a (δ,δ)-conformer is indicative of the selective formation of this isomer. The λ chelate ring (Fig. 2 (b)) can be derived from the cyhis ligand of the δ conformation (Fig. 2 (a)) in the following way: i) counter-clockwise rotation (72°)[11] of the C(4)–C(3)–imidazole and C(9)–C(10)–imidazole fragments about the C(5)–C(4) and C(7)–C(9) bonds respectively, followed by ii) the rotation (180°) of the respective imidazole rings about the C(4)–C(3) and C(9)–C(10) bonds, and iii) linking the Cu atom to N(2)

and N(6). These operations can be performed without changing the bond lengths and angles. A comparison of the scaled models of δ and λ chelate rings indicates that there is no appreciable difference between the nonbonded interaction energy in the δ ring and that in the λ ring. However, the δ ring is different from the λ one in the dispositions of the imidazole ring and the polar N(imidazole)–H bond relative to the C=O bond of the DKP ring, which might be partly responsible for the selective formation of the (δ,δ)-conformer.

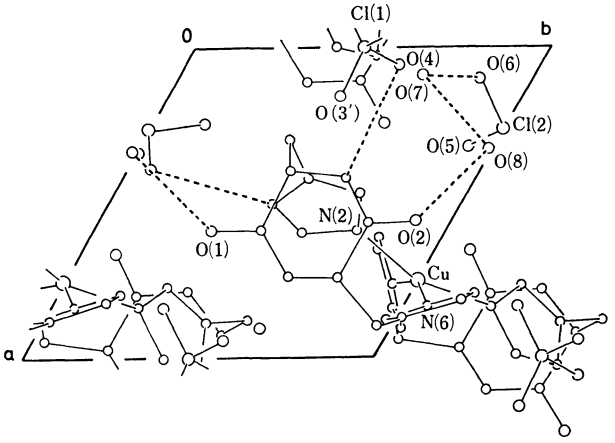

Fig. 3. The bounded projection (z=0.52—0.92) of crystal structure viewed down the c axis. The O(3) at ($-x$, $y-x$, $1\frac{2}{3}-z$) equivalent position is shown by O(3').

A part of the crystal structure is shown in Fig. 3, where the broken lines indicate hydrogen bonds, the data of which are summarized in Table 2.

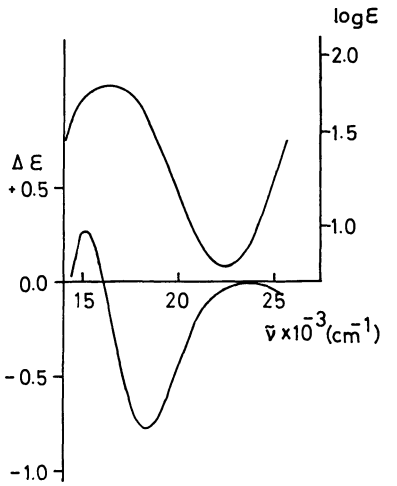

Fig. 4. Absorption (top) and CD (bottom) spectra.

Figure 4 shows the absorption and CD spectra. No appreciable variation in the CD curve was observed within 24 h. The absorption band at 16500 cm^{-1} is assignable to d→d transition. Although, in the crystal structure, the disposition of the 4 N atoms around the Cu atom deviates significantly from a planar configuration toward a tetrahedral one, the intensity and energy of the band are similar to those of tetragonal [Cu(*R*-pn)$_2$](ClO$_4$)$_2$;[12] but different from those of the bis(dipyrromethene)copper(II) complex,[13] in which 4 N donor atoms have a flattened tetrahedral configuration (the interplanar angle between Cu$\langle_{\rm N}^{\rm N}$ planes is 68°).[14] By analogy with the CD of [Cu(*R*-pn)$_2$](ClO$_4$)$_2$ the major CD band at 18300 cm^{-1} may be assigned to d_{xz}, $d_{yz}\rightarrow d_{x^2-y^2}$ transition.[12] The minor band at 15500 cm^{-1} can be regarded as arising from the $d_{xy}\rightarrow d_{x^2-y^2}$ transition, since the $d_{z^2}\rightarrow d_{x^2-y^2}$ transition is magnetically forbidden in D_2 symmetry. As the asymmetric C atoms in the present complex are distant from the Cu atom, the chiral disposition of four imidazolyl groups may be mainly responsible for the d electron optical activity.

The Formation of the Cd-bearing Ferrite by the Air Oxidation of an Aqueous Suspension

Ken KANEKO,* Katsumori TAKEI, Yutaka TAMAURA, Tadao KANZAKI, and Takashi KATSURA

Department of Chemistry, Tokyo Institute of Technology, Meguro-ku, Tokyo 152

(Received October 4, 1978)

When the Cd^{2+}/Fe_{total} ratio in the initial solution is below 0.1, almost all cadmium ions are incorporated into the ferrite with the spinel-type structure by the air oxidation of an aqueous suspension at a pH 9.0 and at 65 °C. The Cd-bearing ferrite thus obtained is a ferromagnet and is oxidized to form a completely oxidized Cd-bearing ferrite at 150 °C in the air; this ferrite is still a ferromagnet and belongs to the Fe_2O_3–$CdFe_2O_4$ binary system, with the same spinel type structure. When the Cd^{2+}/Fe_{total} ratio in the initial solution increases to 0.5, the crystalline phases formed is complicatedly changed; the products are also significantly affected by the pH value of the suspension. The most favorable pH value at 65 °C to form the Cd-bearing ferrite is proposed to be 10.0.

Feitknecht[1] has found that Fe_3O_4 with the spinel-type structure is formed by the air oxidation of the iron(II) hydroxide, $Fe(OH)_2$, in a suspended solution at a pH of about 8.5. Kiyama[2] reported that the temperature increase of the suspension is favorable for the formation of Fe_3O_4. Recently, more favorable conditions for the formation from the suspension have been studied by Tamaura *et al.*[3] by using a dispersing reagent such as sucrose. Ferrite, the solid solution of $(Fe, M)_3O_4$ with a spinel-type structure composed of iron and other metal ions M, was also synthesized at temperature above 60 °C. Yasuoka *et al.*,[4] Hamamura *et al.*,[5] and Kiyama[6] have succeeded in synthesizing Mn- and $ZnFe_2O_4$, $BaFe_2O_4$, and Mn-, Co-ferrites respectively. Katsura *et al.*[7,8] and Kaneko and Katsura[9] have also studied the formation of a solid solution of $FeCr_2O_4$–Fe_3O_4, Fe_2TiO_4–Fe_3O_4, and $MgFe_2O_4$–Fe_3O_4. In their paper, Kaneko and Katsura[9] have clarified that the magnesium ion is incorporated in only a limited amount at 65 °C and pH 9.0, and that no Mg-ferrite is formed at pH values below 8.0. Kiyama[6] has shown that the amount of cobalt ion incorporated into the ferrite structure increases as the R value($NaOH/FeSO_4$) of the suspension increases. The ferrite formation from the suspensions and the content of metals other than iron in the ferrite seem to be influenced by such reaction conditions as the pH value, the temperature, and the metal concentration in the reaction solution.

In this paper, the reaction conditions for the formation of the Cd-bearing ferrite from the suspension are investigated, and the most favorable reaction condition for forming it are discussed. The Cd-bearing ferrite means the ferrite containing the cadmium ions more or less in its crystal structure to form the solid solution between Fe_3O_4 and $CdFe_2O_4$; we will call the Cd-bearing ferrite simply Cd-ferrite; we do not mean the $CdFe_2O_4$ compound.

Experimental

Reagents. Chemical reagents of analytical grades were used. A 2-mol/dm^3 sodium hydroxide solution was prepared by dissolving sodium hydroxide in distilled water free from carbon dioxide and oxygen. A 0.863 mol/dm^3 cadmium sulfate solution was prepared from $CdSO_4 \cdot 7H_2O$.

Apparatus. The reaction vessel of the Dewar type used in this study was the same as that employed in a previous study.[9]

Procedure. After adding the distilled water, cadmium sulfate, and sodium sulfate to the reaction vessel, nitrogen gas was bubbled into the solution while it was being stirred at 1000 r.p.m. for 1 h to remove the dissolved gases of carbon dioxide and oxygen. Then a 12.0-g portion of $FeSO_4 \cdot 7H_2O$ was added to the solution. The resultant volume of the solution was set at 200 cm^3, and the total concentration of the sulfate ion was fixed at 65 mmol/200 cm^3 (we call this solution the initial solution). The subsequent procedures were just the same as those described in the previous paper.[9] The Precipitate A means the product obtained after the air oxidation. The Precipitate B was obtained by lowering the pH value of the suspension containing the Precipitate A to pH 5.0. The procedure was described in detail in the previous report.[9]

Chemical Analysis. The Cd^{2+} content was determined gravimetrically after precipitating bis(8-quinolinolato)Cd(II). The amounts of Fe^{2+} and Fe^{3+} ions were determined by the method described previously.[9]

The Precipitates A and B were examined by the X-ray powder diffraction method by using Fe $K\alpha$ radiation and electron microscopy.

Results and Discussion

The X-Ray Powder Diffraction Data at pH *9.0.* Figure 1 shows the X-ray powder diffraction patterns of the Precipitates A obtained at various concentrations of Cd^{2+} in the initial solutions and at pH 9.0. At the Cd^{2+}/Fe_{total} ratios of 0.03 and 0.1 in the initial solutions, only the peaks corresponding to the compound with the spinel structure are seen (the patterns A and B in Fig. 1). However, at a ratio of 0.2, the peaks of the spinel-type compound become fairly small and the peaks of α-FeOOH are seen (the C pattern in Fig. 1). At a ratio of 0.15 the pattern was the same as that of the ratio of 0.10. At a ratio of 0.30, no peaks were observed in the X-ray powder diffraction pattern; this means that no crystalline compounds are formed. However, at a ratio of 0.40, as may be seen in the D pattern in Fig. 1, cadmium hydroxide was crystallized, together with the spinel-type compound.

Figure 2 shows the X-ray powder diffraction patterns of the Precipitates B. At the ratios of Cd^{2+}/Fe_{total} from

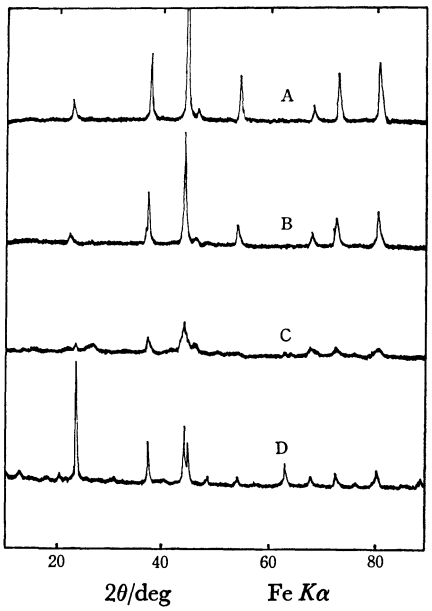

Fig. 1. The X-ray powder diffraction patterns of the Precipitates A obtained at the Cd^{2+}/Fe_{total} molar ratios of 0.03(pattern A), 0.10(pattern B), 0.20(pettarn C), and 0.40(pattern D), respectively.

0.03 to 0.10 in the initial solution, the patterns are similar to those of the Precipitates A (the A and B patterns in Figs. 1 and 2). At the ratio of 0.20, however, the two small peaks due to the presence of the α-FeOOH and the spinel-type compound both seem to be slightly stronger than those of the Precipitate A (the C patterns in Figs. 1 and 2). This indicates that some soluble compounds such as cadmium hydroxide are formed in the Precipitate A, together with α-FeOOH and the spinel-type compounds. At the ratio of 0.40, as may be seen in the D patterns in both Figs. 1 and 2, the cadmium hydroxide in the Precipitate A is completely dissolved by lowering the pH value to 5.0.

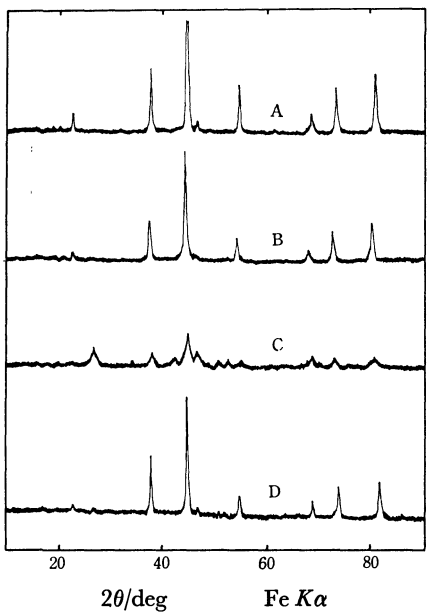

Fig. 2. The X-ray powder diffraction patterns of the Precipitates B obtained at the Cd^{2+}/Fe_{total} molar ratios of 0.03(pattern A), 0.10(pattern B), 0.20(pattern C) and 0.40(pattern D), respectively.

In view of the results presented above, the oxidation reactions of the $Fe(OH)_2$ suspension in the presence of Cd^{2+} at pH 9.0 and at 65 °C may be classified into the four processes: (1) the formation of only the spinel-type compound at the Cd^{2+}/Fe_{total} ratio in the initial solution below 0.10; (2) the formation of α-FeOOH, the spinel compound, and cadmium hydroxide at the ratios from 0.15 to 0.20; (3) the formation of only amorphous materials at the ratio of 0.30, and (4) the formation of the cadmium hydroxide crystal together with the spinel-type compound at the ratios above 0.40.

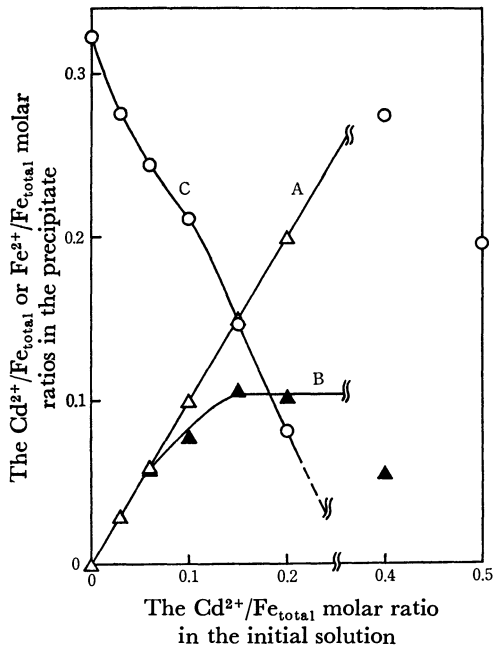

Fig. 3. The relationship between the Cd^{2+}/Fe_{total} molar ratio in the initial solution and the Cd^{2+}/Fe_{total} or the Fe^{2+}/Fe_{total} molar ratio in the Precipitates A and B. The curve A: the Cd^{2+}/Fe_{total} molar ratio in the Precipitate A, the curve B: the Cd^{2+}/Fe_{total} molar ratio in the Precipitate B, the curve C: the Fe^{2+}/Fe_{total} molar ratio in the Precipitate B.

Chemical Composition of the Oxidation Products at pH *9.0.*

Figure 3 shows the relationship between the Cd^{2+}/Fe_{total} molar ratio in the initial solution and the Cd^{2+}/Fe_{total} or Fe^{2+}/Fe_{total} molar ratio in the Precipitates A and B. As may be seen in Fig. 3, Curve A, the Cd^{2+} content in the Precipitate A increases linearly with an increase in the Cd^{2+} concentration in the initial solution. The Cd^{2+} in the initial solution was completely extracted by the Precipitate A over the range from 0 to 0.3 of the Cd^{2+}/Fe_{total} ratio in the initial solution.

As may be seen in Curve B, the Cd^{2+} content in the Precipitate B increases with an increase in the Cd^{2+}/Fe_{total} ratio within a limited range from 0 to 0.1, but approaches a constant Cd^{2+}/Fe_{total} ratio, approximately 0.1, in the range from 0.15 to 0.20 in the initial solution. This suggests that all the Cd^{2+} in the initial solution is taken into the Cd-ferrite at ratios below 0.10. This

process corresponds to the oxidation reaction (1) in the previous section. At the ratios from 0.15 to 0.20, it is likely that some variable amount of the precipitate of cadmium hydroxide which is soluble at pH 5.0 is formed in the Precipitate A. This corresponds to the oxidation reaction (2). At the ratio of 0.30, we could not obtain a constant content of Cd^{2+} after duplicated analyses of the Precipitate B. This may correspond to the oxidation reaction (3). At the ratio of 0.40, the Cd^{2+}/Fe_{total} ratio in the Precipitate B was 0.057, which is smaller than those at the ratios from 0.05 to 0.20. This indicates that the incorporation of the cadmium ion into the Cd-ferrite is rather reduced at ratios above 0.40. This corresponds to the oxidation reaction (4).

Curve C in Fig. 3 shows the Fe^{2+}/Fe_{total} ratio in the Precipitate B. Since no iron ions were detected in the solutions coexisting with both the Precipitate A and B, the iron oxides formed in the Precipitate A seem hardly to be dissolved at all at pH 5.0. As may be seen in Curve C, the Fe(II) content in the Precipitate B decreases with an increase in the Cd^{2+}/Fe_{total} ratio in the initial solution; this may suggest that the cadmium ion replaces the Fe(II) ion in the spinel-type structure at Cd^{2+}/Fe_{total} ratios from 0 to 0.10 in the initial solution. The further decrease in the Fe^{2+}/Fe_{total} ratio at higher ratios of Cd^{2+}/Fe_{total} in the initial solution (0.10 to 0.20) is due to the gradual formation of α-FeOOH, together with the formation of oxidized Cd-ferrite.

Lattice Constant. Figure 4 shows the relationship between the lattice constant of the Cd-ferrite obtained from the Precipitates B and the Cd^{2+}/Fe_{total} ratio in the initial solution at pH 9.0. As may be seen in Fig. 4, Curve A, the lattice constant of the Precipitate B increases almost linearly with an increase in the amount of Cd^{2+} in the initial solution with the Cd^{2+}/Fe_{total} ratios from 0 to 0.15. This shows that the cadmium ion is incorporated into the ferrite. However, at ratios above 0.15 the lattice constant gives a constant value, 0.8510 nm. Curve B in Fig. 4 shows the relationship between the lattice constant of the completely oxidized-Precipitates B obtained by heating at 150 °C in the air and the Cd^{2+}/Fe_{total} ratio in the initial solution. The X-ray diffraction patterns were identical with those of the Precipitates B, but each peak belonging to the spinel-type structure was shifted to a higher angle. The lattice constant of the oxidized-Precipitates B increases with an increase in the Cd^{2+}/Fe_{total} ratios in the initial solution from 0 to 0.20. As has been mentioned before, at the ratio of 0.30 the Precipitate B was composed of only an amorphous product, and even if we heated this at 150 °C for a day, we could not obtain a crystalline phase. At the ratio of 0.40, the lattice constant of the oxidized-Precipitate B was 0.8429 ± 0.0001 nm. This value is somewhat lower than that at 0.20. At present, we are not able to interpret whether or not this difference is significant.

From these experiments, we may say that the Precipitates B obtained from the initial solutions with the Cd^{2+}/Fe_{total} ratios from 0 to 0.20 comprise a limited solid solution between Fe_3O_4 and $CdFe_2O_4$, that the further $CdFe_2O_4$ component is never incorporated in the spinel structure under the present experimental conditions, that this solid solution is unstable at higher temperatures, say, above 100 °C, in the air, and that it is interestingly oxidized completely to form a limited solid solution between γ-Fe_2O_3 and $CdFe_2O_4$. Figure 5 shows the relationship between the lattice constant and the mole fraction x of the $CdFe_2O_4$ component in the solid solution. The lattice constants of γ-Fe_2O_3 and

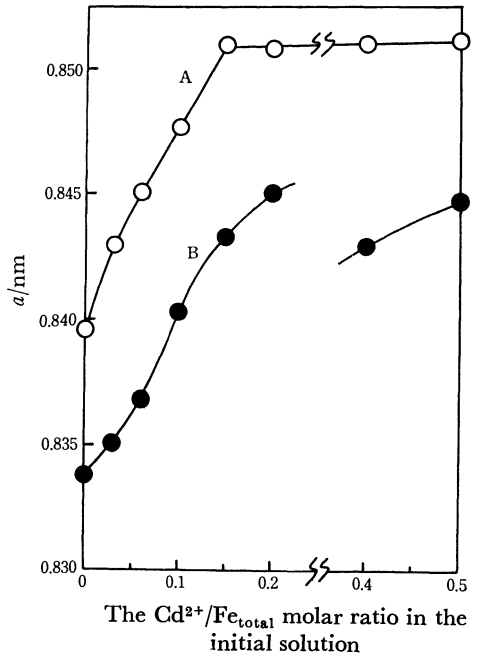

Fig. 4. The relationship between the Cd^{2+}/Fe_{total} molar ratio in the initial solution and the lattice constant of the Precipitate B or the oxidized-Precipitate B. The curve A: Precipitate B, the curve B: the oxidized-Precipitate B. a: Lattice constant.

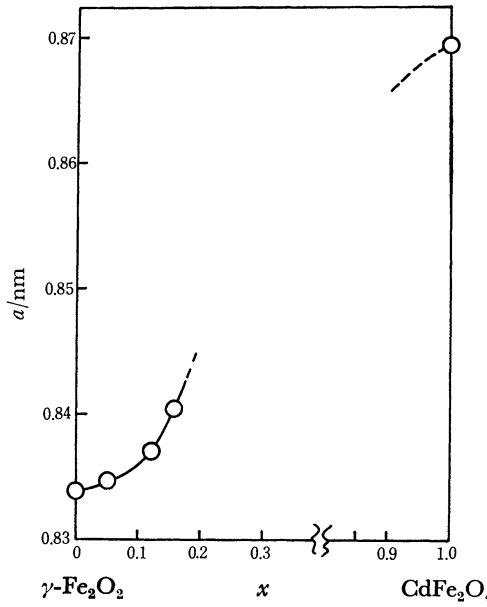

Fig. 5. The relationship between the lattice constant and the x value of the oxidized-Precipitate B. The x represents the molar ratio of $CdFe_2O_4$ to ($CdFe_2O_4$+γ-Fe_2O_3). a: Lattice constant.

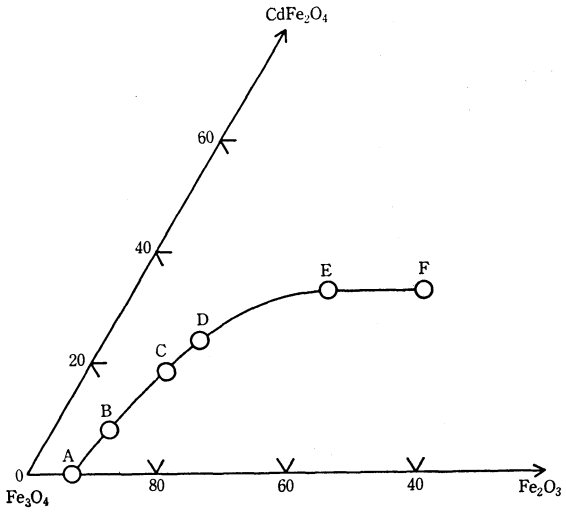

Fig. 6. The chemical compositions of the Precipitate B expressed as the Fe_3O_4–Fe_2O_3–$CdFe_2O_4$ system. Points A, B, C, D, E and F were obtained at the Cd^{2+}/Fe_{total} molar ratios of 0.00, 0.03, 0.06, 0.10, 0.15 and 0.20, respectively.

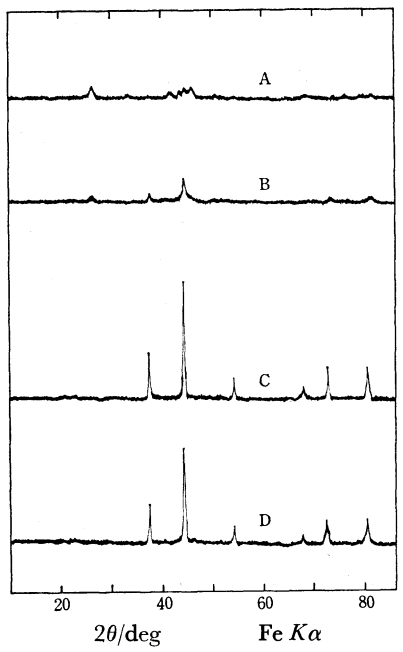

Fig. 7. The X-ray powder diffraction patterns of the Precipitates A obtained at pH 7.0(patternA), 8.0-(pattern B), 10.0(pattern C) and 11.0(pattern D). The Cd^{2+}/Fe_{total} molar ratio was fixed to 0.10.

$CdFe_2O_4$ were determined by Schrader and Buttner[10] and Roberts *et al.*[11] respectively. As may be seen in Fig. 5, the lattice constants of the oxidized-Precipitates B fall between those of γ-Fe_2O_3 and $CdFe_2O_4$.

Composition Diagram for the Precipitates B. Figure 6 shows the composition diagram for the Precipitates B formed at pH 9.0. For convenience, Fe_3O_4, Fe_2O_3 and $CdFe_2O_4$ are selected as the three component systems. As may be seen in Fig. 6, the Precipitates B all significantly deviate from their stoichiometric compositions. Under the present conditions, it seems to be next to impossible to synthesize the stoichiometric solid solution. This was also true for the Fe_3O_4–Fe_2TiO_4 and the Fe_3O_4–$MgFe_2O_4$ systems, which were studied by Katsura *et al.*[8] and by Kaneko and Katsura[9] respectively.

pH *Dependence on the Formation of the Precipitates A and B.* In the preceding section, we discussed the properties of the Precipitates A and B formed at pH 9.0 and at 65 °C. We also studied the pH dependence on the formation of the Precipitates A and B by changing

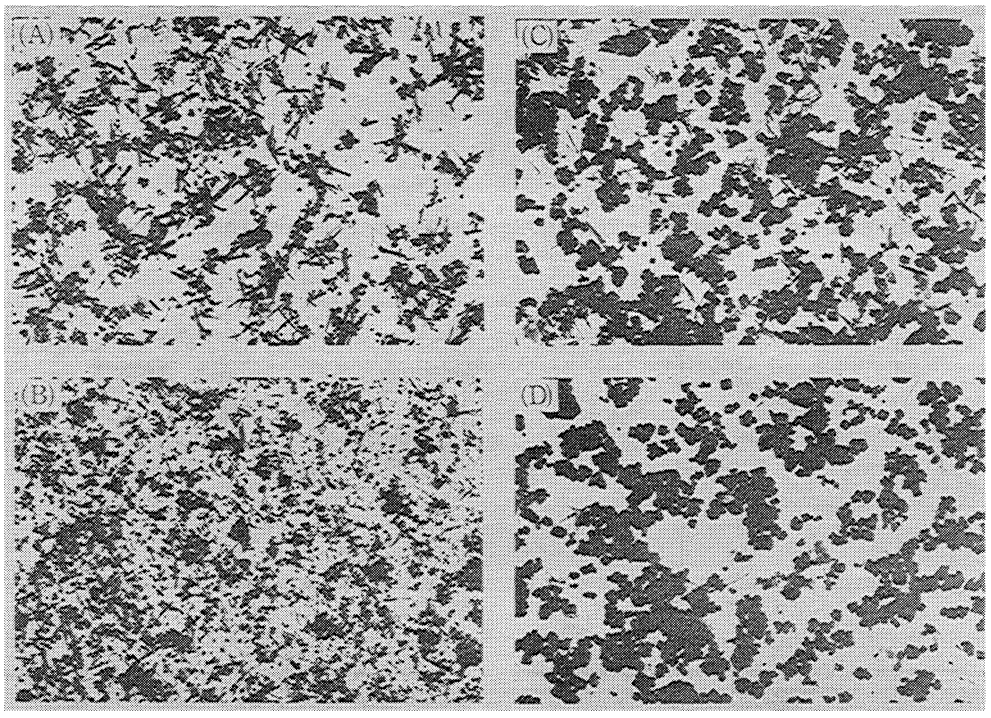

Fig. 8. The electron-micrographs of the Precipitates B obtained at pH 7.0(A), 8.0(B), 10.0(C) and 11.0(D). The Cd^{2+}/Fe_{total} molar ratio was fixed to 0.10.

the pH values from 7.0 to 11.0 at 65 °C. Figure 7 shows the X-ray diffraction patterns of the Precipitates A obtained at pH 7.0, 8.0, 10.0, and 11.0. At pH 9.0 (the patterns B in Fig. 1), 10.0, and 11.0, very sharp peaks caused by the presence of the ferrite structure are seen, while at pH 7.0 and 8.0 the peaks flatten out. It is presumed that the ferrite crystal with a small particle size and the α-FeOOH phase are formed at pH 7.0 and 8.0. The same X-ray patterns were obtained for the Precipitates B. Figure 8 shows the electron micrographs of the Precipitates B obtained at pH 7.0, 8.0, 10.0, and 11.0. As may be seen in Fig. 8, the large-size Cd-ferrite (0.12 μm) is formed together with a little amount of the needle-like crystals. However, the particle of the Cd-ferrite crystal becomes small at pH 7.0 and 8.0, and the amount of the needle-like crystals increases. These needle-like crystals seem to be composed of α-FeOOH. Thus, the results obtained by the electron microscopy agree very well with those obtained from the X-ray diffraction patterns.

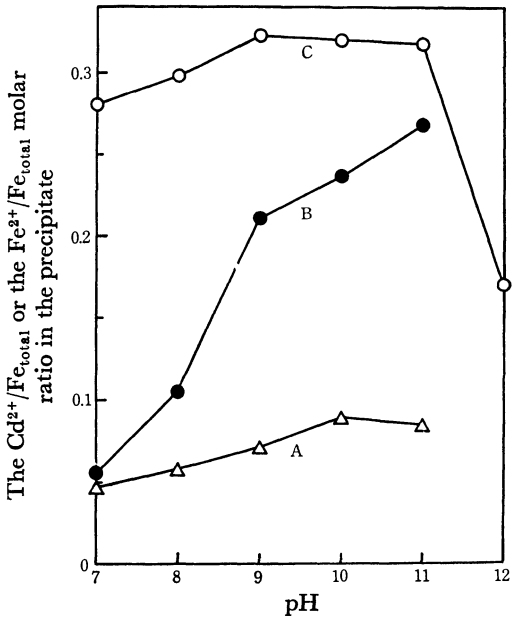

Fig. 9. The relationship between the pH value of the suspension and the chemical composition of the Precipitate B. The Cd^{2+}/Fe_{total} molar ratio in the initial solution is fixed to 0.10. The curve A: the Cd^{2+}/Fe_{total} ratio in the Precipitate B, the curve B: the Fe^{2+}/Fe_{total} ratio in the Precipitate B, the curve C: the Fe^{2+}/Fe_{total} ratio of the Precipitate B formed without Cd^{2+}.

Figure 9 illustrates the relationship between the Cd^{2+}/Fe_{total} or the Fe^{2+}/Fe_{total} ratio in the Precipitate B and the pH value of the suspension. As may be seen in Fig. 9, Curve A, approximately half of the Cd^{2+} added to the initial solution was taken into the Precipitate B at any pH value. However, considering the precision in the present chemical analysis, it is evident that the Cd^{2+}/Fe_{total} ratio in the Precipitate B gives its maximum value at pH 10.0. As seen in Fig. 9, Curve B, the Fe^{2+}/Fe_{total} ratio in the Precipitate B increases abruptly at pH 9.0, and then increases gradually from 9.0 to 11.0. The lower ratio at a lower pH range (from 7.0 to 8.0) is the result of the formation of α-FeOOH, together with the further oxidation of the Cd-ferrite with a small particle size (see Fig. 8). Curve C in Fig. 9 shows the pH dependence of the chemical composition of Fe_3O_4 (Cd=0) for the sake of comparison. As may be seen in Curve C, the Fe^{2+}/Fe_{total} ratios fall in a narrow range from 0.28 to 0.32 (in stoichiometric composition, the ratio is 0.333) at the pH intervals from 7.0 to 11.0. Thus in the presence of Cd^{2+} in the initial solution, α-FeOOH is liable to be formed together with the Cd-ferrite. However, only a small amount of α-FeOOH is crystallized, together with a large amount of the Cd-ferrite, when the pH value increases to 11.0. In addition, we can safely conclude that, at pH 11.0, th e cadmium ion intrinsically replaces the Fe(II) ion in the crystal lattice of the spinel-type structure.

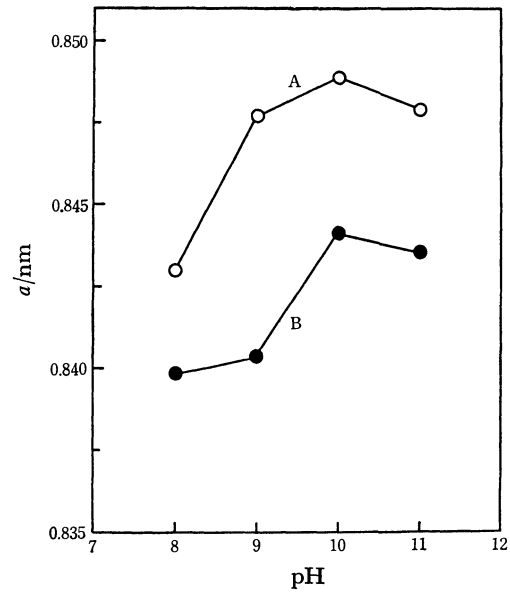

Fig. 10. The relationship between the pH value of the suspension and the lattice constant of the Precipitate B or the oxidized-Precipitate B obtained at the Cd^{2+}/Fe_{total} molar ratio of 0.10. a: Lattice constant.

Figure 10 shows the relationship between the lattice constants of the Precipitate B and the oxidized-Precipitate B and the pH value at which the Precipitate B is formed. As may be seen in Fig. 10, Curve A, the lattice constant of the Precipitate B increases irregularly with an increase in the pH value from 8.0 to 10.0, and attains its maximum value, 0.8489 nm, at pH 10.0. Thereafter, at pH 11.0, the lattice constant decreases slightly. It seems likely that the Cd-ferrite is most favorably formed at pH 10.0, because the more the cadmium ion replaces the Fe(II) ion, the more the lattice constant increases. However, we have to consider also the grades of oxidation of the Cd-ferrite at various pH values in the suspension. As was mentioned in the previous section, the Cd-ferrite formed at low pH values, 7.0 and 8.0, is small in particle size and so is oxidized easily during the air oxidation, while maintaining the spinel-type structure. For example, as may be seen in Fig. 10, the lattice constants of the Cd-ferrites formed

at pH 8.0 and 9.0 are quite different from each other (Curve A). We assume that the Cd-ferrite formed at pH 8.0 is oxidized significantly during the air oxidation. As may be seen in Fig. 10, Curve B, the lattice constants of the completely oxidized-Precipitates B at pH 8.0 and 9.0 are nearly the same amount of cadmium ion is incorporated into the ferrite at both pH values. Furthermore, we have confirmed that the pH value of 10.0 is the most favorable for forming the Cd-ferrite at 65 °C. Here, we should emphasize that the formation of the (Fe, M)$_3$O$_4$ type of ferrite is sensitively affected by the pH value in the suspension.

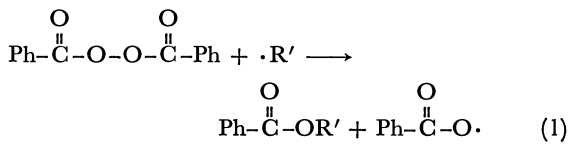
A Semi-empirical MO Study of Radical-induced Decomposition of Dibenzoyl Peroxide. The Charge-transfer Character and Reaction Mechanism

Osamu KIKUCHI,* Keizo SUZUKI, and Katsumi TOKUMARU
Institute of Chemistry, The University of Tsukuba, Sakura-mura, Ibaraki 300-31
(Received September 30, 1977)

Radical-induced decomposition reactions of diacyl peroxides were investigated on the basis of the electronic structure of the peroxide-radical systems which were calculated using an approximate restricted open-shell SCF MO method in the MINDO/3 approximation, and on the basis of configuration analysis of the transition state of the reaction. For the transition state, (1) the change in peroxy O–O bond length is expected to be small, (2) the odd-electron density on the leaving group of the S_H2 displacement is expected to be very small, although appreciable odd-electron delocalization from the radical to the peroxide was observed, (3) the charge-transfer (CT) interactions which correspond to electron transfer from the radical to the peroxide was found to be important in the transition state. The trends observed in the orbital energies of the LUMO of substituted dibenzoyl peroxides and in the CT character of the transition state, which involves the singly-occupied MO of the radical and the $2p\sigma^*$ MO of the peroxide, agree well with the experimental facts, and strongly support a previous postulate that an important role is played by the $2p\sigma^*$ MO of the peroxy O–O group in the reaction.

Dibenzoyl peroxide (BPO) is one of the most frequently used sources of free radicals,[1] and its various modes of decomposition are an interesting subject of investigation. One typical process involving BPO is redical-induced decomposition:



(1)

Extensive experimental studies[1-4] have contributed to the elucidation of the mechanism of this reaction. Step (1) is S_H2 substitution in which the radical attack occurs at the peroxy oxygen atom.[2] An electron-withdrawing substituent in BPO[3] and an electron-donating substituent in the radical[4] both enhance the reaction rate. The ionic character of the transition state of (1) has been pointed out.[3] The mechanism of step (1) has theoretically been considered by Tokumaru and Simamura[5] on the basis of experimental facts regarding the induced decomposition of peroxides by radicals. It has been suggested[5] that an interaction of the charge-transfer (CT) type, involving a singly-occupied MO (SOMO) of the attacking radical and the $2p\sigma^*$ antibonding orbital of the peroxy oxygen atoms, contributes to a lowering of the activation energy of the reaction.

In spite of these extensive experimental studies and qualitative explanations of the mechanism, no MO-theoretical investigations of the interacting BPO-radical system have been reported.[6] The purposes of the present note are: (i) to examine the reaction path of the radical-induced decomposition of BPO by means of a restricted open-shell method in the MINDO/3 approximation; (ii) to clarify the electronic structure of the transition state by means of configuration analysis for the wavefunction of the transition state, and (iii) to elucidate the substituent effect on the induced decomposition of BPO.

Method of Calculation

The electronic structure of the peroxide-radical systems were calculated in an approximate SCF version for open-shell systems which was proposed by Longuet-Higgins and Pople[7] and which has since been applied to all-valence-electron systems by one of the present authors.[8] For evaluating the electron integrals involved, the MINDO/3 approximation[9] was employed. The size of the BPO-radical system is too large to permit solving the problem even if the semi-empirical method is employed. In the present study, the reaction mechanism and the electronic structure of the transition state were considered using rather drastic approximations for the model system and its molecular structure. Diformyl peroxide (FPO), the simplest diacyl peroxide, and the methyl radical were adopted as model substances. The molecular parameters of the –COO group were fixed to those of BPO which were reported in a previous paper,[10] and a value of 90°[11] was used for the dihedral angle between the two RCOO planes. The conformation of C_{3v} CH_3 was optimized during the course of the reaction, the CH bond length being fixed at 1.087 Å, the optimized value for the D_{3h} methyl radical.

The substituent effect on radical-induced decomposition of BPO was elucidated on the basis of the electronic structure of substituted BPO in isolated states and on the basis of the CT character of the transition state of the BPO-methyl system. It is of note that CT from the radical to BPO will be underestimated in the transition state, since the ionization potential of the methyl radical is very large in comparison with those of the radicals currently used in actual experimental studies.

Configuration analysis was performed to clarify the electronic structure of the transition state. The wave function of the transition state (Ψ_T) was expanded in terms of doublet configurations (Ψ°) constructed from reference MO of the peroxide and of the planar methyl radical, thus

$$\Psi_T = C_g\Psi^\circ_g + \sum_i\sum_k C_{ik}\Psi^\circ_{i\to k} + \sum_j\sum_l C_{jl}\Psi^\circ_{j\to l} + \sum_j C_{jm}\Psi^\circ_{j\to m} + \sum_l C_{ml}\Psi^\circ_{m\to l} + \sum_k C_{mk}\Psi^\circ_{m\to k} + \sum_i C_{im}\Psi^\circ_{i\to m} + \sum_i\sum_l C_{il}\Psi^\circ_{i\to l} + \sum_j\sum_k C_{jk}\Psi^\circ_{j\to k}, \quad (2)$$

where Ψ°_g is the slater determinant for the ground-state

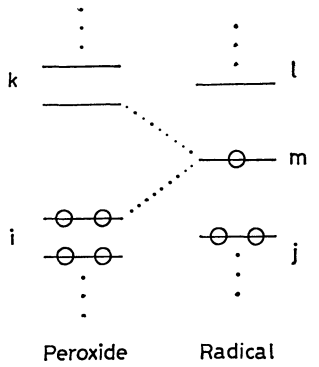


Fig. 1. Orbital interaction between a closed-shell molecule and a radical.

configuration of the peroxide-radical system, $\Psi^{\circ}_{i\to k}$ corresponds to one-electron exitation of the peroxide, $\Psi^{\circ}_{j\to l}$ $\Psi^{\circ}_{j\to m}$, and $\Psi^{\circ}_{m\to l}$ correspond to one-electron excitation of the radical, and the last four terms are CT configurations between the peroxide and the radical. The definition of indices, i, j, k, l, and m is given in Fig. 1. In Eq. 2, $\Psi^{\circ}_{a\to b}$ $(a\neq m,\ b\neq m)$ includes two independent wave functions corresponding to the $a\to b$ excited configuration. Neglecting the overlap between the MO in different molecules, the expansion coefficients in Eq. 2 were calculated using the following equations which were derived from the general formula given by Baba *et al.*,[12]

$$\begin{aligned} C_{a\to m} &= D^{m}_{0}D^{m-1}_{am},\\ C_{m\to b} &= D^{m}_{mb}D^{m-1}_{0}, \quad (a\neq m,\ b\neq m)\\ C_{a\to b} &= (f_1^2+f_2^2)^{1/2}, \qquad (3)\\ f_1 &= \frac{1}{\sqrt{2}}\{D^{m}_{0}D^{m-1}_{ab}+D^{m}_{ab}D^{m-1}_{0}\} \end{aligned}$$

and $$f_2 = \frac{1}{\sqrt{6}}\{D^{m}_{0}D^{m-1}_{ab}-D^{m}_{ab}D^{m-1}_{0}+2D^{m}_{mb}D^{m-1}_{am}\},$$

where $D_0{}^m$ is the determinant derived from the occupied α-spin MO of the interacting and non-interacting peroxide-radical systems, and $D_0{}^{m-1}$ is that derived from the β-spin MO of the systems. The other notations are same as those given in Ref. 12.

Results and Discussion

Reaction Path. The decomposition of FPO induced by the methyl radical was examined. Since the radical attack occurs at one of the peroxy oxygen atoms,[2] several interacting patterns, shown in Fig. 2, were examined. The interaction energy for each pattern was calculated by changing the distance between the peroxy oxygen atom and the methyl carbon atom. The conformation of the methyl radical is fixed for each pattern so that the SOMO of CH_3 is directed toward the oxygen atom to be attacked. The interaction energies at $R_{O\text{-}C}=2.0$ Å are shown in Fig. 2. When the radical attack occurs within the HCOO plane (Fig. 2, A—C), attack from the C direction is the most favorable. However, the C pattern of interaction is not expected in actual systems such as the BPO-triphenylmethyl system, since the large substituents in the peroxide and in the radical make this approach impossible.

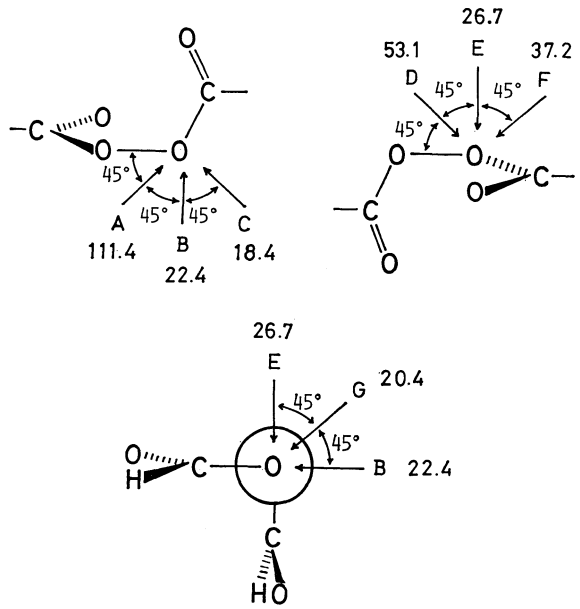

Fig. 2. Several interaction patterns between FPO and the methyl radical, and their interaction energies (kcal/mol) calculated at O–C=2.0 Å.

The G-pattern, for which the radical attack occurs in the plane which bisects the dihedral angle between the two RCOO planes and which is perpendicular to the peroxy O–O bond, may be most favorable in actual BPO-radical systems.

The potential energy surface for the G-approach[13] was calculated as a function of the peroxy O–O distance and of the O–C distance, other molecular parameters in FPO being fixed. The energy map obtained is shown in Fig. 3. For the transition state, the change (0.03 Å)

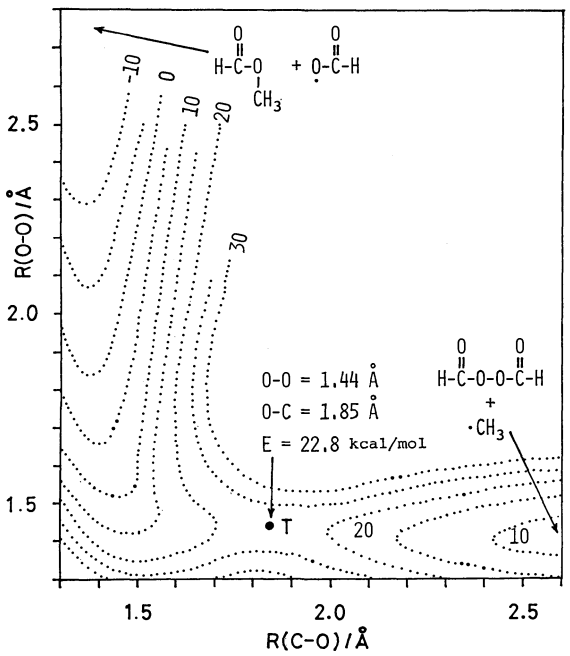

Fig. 3. Energy contours for the FPO–CH_3 system. The zero of energy (kcal/mol) is that of (FPO+CH_3) at infinite distance.

in the peroxy O–O bond length is expected to be small, while the O–C separation is large. The activation energy was estimated to be 23 kcal/mol which is somewhat larger than the observed values ($\simeq$10 kcal/mol, solvent dependent).[1,3]

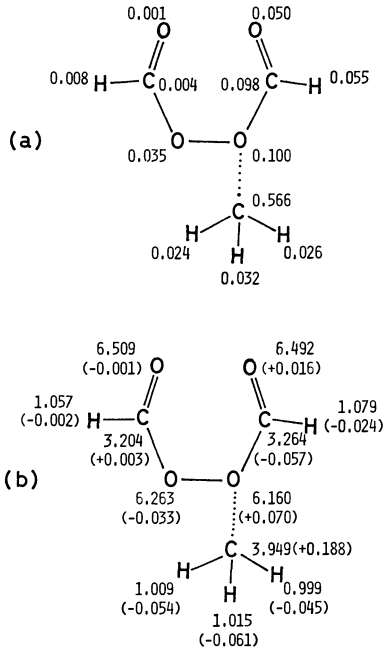

Fig. 4. Atomic spin densities (a) and atomic electron densities (b) of the FPO–CH_3 system in its transition state. The increases of the net charges are shown in parentheses.

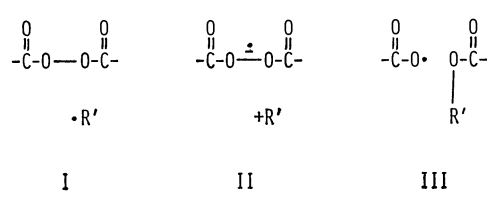
Electronic Structure of the Transition State. The odd-electron and atomic electron distributions of the transition state are shown in Fig. 4. The changes in the atomic net charge densities caused by the peroxide-radical interaction are also shown in Fig. 4-b. Although large odd-electron delocalizations (35%) from the methyl radical to FPO are observed in the transition state, the odd-electron density on the leaving HCOO group is very small. This indicates that the contribution of structure III to the transition state is small. The ionic character of the transition state, for which the attacking group acts as an electron-donor, has been pointed out by Suehiro *et al.*[3] From Fig. 4, an ionic character is expected for the transition state, although its magnitude is not large for the present model system. The electronic structure of the transition state can thus be expressed as three structures, I, II, and III, whose contributions are in the order: I$\gg$II$>$III. This does *not* imply that the decomposition of diacyl peroxide by a radical gives the CT intermediate and then the carbonium ion (+R′)



as reaction products. The contribution of II to the electronic structure of the transition state would be larger in actual BPO-radical systems, such as the BPO-triphenylmethyl system, than in the present model system, because the methyl radical is a poorer electron donor than the substituted alkyl radicals.

Configuration Analysis. As may be seen from the general interaction scheme (Fig. 1) between a closed-shell molecule and a radical, the SOMO interactions of CH_3 with both the occupied and unoccupied MO of FPO are expected to be very important for the transition state of the reaction. This was demonstrated by the configuration analysis, in which the wave function of the transition state was expressed in terms of the reference wave functions constructed of the MO of two non-interacting molecules. The electron configurations of the C_2 FPO and D_{3h} CH_3 are:

for FPO (^{1}A), $\cdots(8b)^2(9a)^2(9b)^0(10a)^0\cdots$

and for CH_3 ($^2A_2''$), $\cdots(a_2'')^1(2a_1')^0\cdots$

The qualitative pictures of three MO of FPO are shown in Fig. 5. The a_2'' orbital is the SOMO of the methyl radical. All the "one-electron excited" and "one-electron transfered" configurations of the two reactants were employed in the expansion of the wave function of the transition state. The contributions calculated are listed in Table 1. Since the total contribution accounts for 97%, the contributions of other configurations are small.

The contribution of the ground-state configuration (Ψ_g°) is dominant (48%). The large contribution due to the polarization ($\Psi_{m\to t}^\circ$) of the CH_3 radical comes from the geometrical change of CH_3 from D_{3h} to C_{3v} for the transition state.[14] The CT configurations from FPO to CH_3 (15%) are very important for the transition state, while the polarization interactions for FPO ($\Psi_{i\to k}^\circ$) are relatively small. It is notable that the most important of the CT configurations corresponds to electron transfer from the SOMO of the radical to the LUMO of the peroxide, which has an anti-bonding character with respect to the peroxy O–O bond. This supports the assumption that CT plays an important

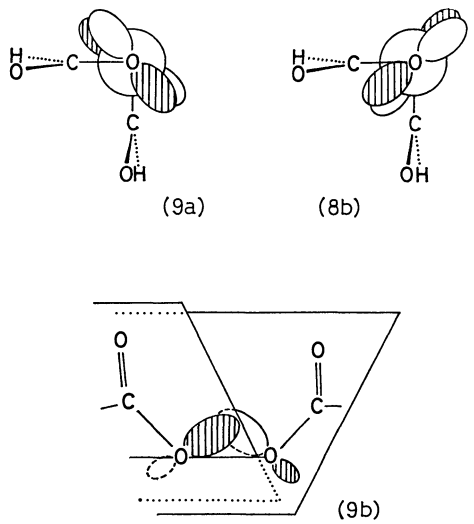


Fig. 5. Qualitative pictures of three MO's of FPO. The shape of each MO is drawn only in the peroxy oxygen region.

Table 1. Configuration analysis of the wave function of the FPO–CH_3 system for the transition state

Character of configurations[a]	Weight	Main configurations	Weight
ground	0.4798	ground	0.4798
$i \rightarrow m$	0.0824	$8b \rightarrow a_2''$	0.0319
		$4a \rightarrow a_2''$	0.0192
		$7a \rightarrow a_2''$	0.0157
$j \rightarrow m$	0.0087	—	—
$m \rightarrow k$	0.1489	$a_2'' \rightarrow 9b$	0.1005
		$a_2'' \rightarrow 10a$	0.0300
$m \rightarrow l$	0.1489	$a_2'' \rightarrow 2a_1'$	0.1487
$i \rightarrow k$	0.0467	$8b \rightarrow 9b$	0.0109
$j \rightarrow l$	0.0041	—	—
$i \rightarrow l$	0.0430	$8b \rightarrow 2a_1'$	0.0169
$j \rightarrow k$	0.0115	—	—
Total	0.9739		

a) i denotes the 17 occupied MO of FPO, j the 3 occupied MO of CH_3, k the 9 unoccupied MO of FPO, l the 3 unoccupied MO of CH_3, and m the singly-occupied MO of CH_3. Thus, $m \rightarrow k$, for example, indicates all the configurations which correspond to charge-transfer configurations from the SOMO of CH_3 to the unoccupied MO of FPO.

role in the induced decomposition of peroxides, as has been suggested by Tokumaru and Simamura.[5]

Substituent Effect on the Induced Decomposition of BPO. The rate constant of the induced decomposition of BPO is enhanced by an electron-withdrawing group in the phenyl group.[3] The important CT interaction at the transition state indicates that the electron-withdrawing group lowers the energy level of the $2p\sigma^*$ orbital of the peroxy O–O bond and increases the CT character of the transition state of the BPO-radical system. The orbital energies of several substituted BPO were calculated for predicted geometries.[10] The results are shown in Table 2. Strictly speaking, the LUMO of BPO is not the $2p\sigma^*$ of the peroxy O–O bond but is an unoccupied MO of the phenyl groups. In Table 2, the unoccupied MO which correspond to the $2p\sigma^*$ MO of FPO are called "LUMO." A very clear correlation between the orbital energies of the LUMO of substituted BPO and the electron-withdrawing character of the substituent is seen in Table 2. The CT character of the transition state was calculated using the geometry estimated for the FPO–CH_3 system. The CT interaction of the *p,p'*-dinitro BPO and CH_3 system is larger than that of unsubstituted BPO, while that for the *p,p'*-dimethoxy BPO–CH_4 system is smaller. This trend is parallel to that observed for the orbital energies of the LUMO of substituted BPO. The trends observed for the orbital energies of the LUMO of substituted BPO and for the CT character of the transition state agree well with the prediction given by Tokumaru and Simamura.[5]

Table 2. Orbital energies of the LUMO and the CT character of the transition state for *p,p'*-di-substituted BPO

Substituents *p-*	Substituents *p'-*	ε(LUMO)[a]	CT character for the transition state $m \rightarrow k$[b]	CT character for the transition state $m \rightarrow \sigma^*$[c]

11) X-Ray studies of dibenzoyl peroxide and acetylbenzoyl peroxide indicate a dihedral angle of about 90° (See G. A. Jeffery, R. K. McMullan, and M. Sax, *J. Am. Chem. Soc.*, **86**, 949 (1964), M. Sax and R. K. McMullan, *Acta Crystallogr.*, **22**, 281 (1964) and N. J. Karch, E. T. Koh, B. L. Whitsel, and J. M. McBride, *J. Am. Chem. Soc.*, **97**, 6729 (1975)), while MINDO/3 calculations give a value of 115° (Ref. 10).

12) H. Baba, S. Suzuki, and T. Takemura, *J. Chem. Phys.*, **50**, 2078 (1969).

13) The approach of the methyl radical from the in-plane B-direction gave a similar potential map.

14) The conformation of the FPO fragment for the transition state closely resembles the isolated FPO, while that of CH_3 (C_{3v} with an angle of 109° between the symmetry axis and each C-H bond) differs considerably from the planar CH_3 structure. The large contribution of the $m \rightarrow l$ configurations in Table 1 come from the direct application of configuration analysis[12] to the process accompanied by molecular deformation. When sp^3, instead of planar, conformation, was used as the reference structure of the methyl radical, the contribution of the $m \rightarrow l$ configurations was very small; in this case, all other features appeared in Table 1 and the conclusions obtained here remain unaffected. For a more correct treatment of the configuration analysis for the process accompanied by molecular deformation, see Ref. 15.

Formose Reactions. VI. Formose Synthesis in Methanol

Yoshihiro SHIGEMASA,* Yoshinobu MATSUDA, Chikahiro SAKAZAWA, Ruka NAKASHIMA, and Teruo MATSUURA†

Department of Industrial Chemistry, Faculty of Engineering, Tottori University, Tottori 680
†*Department of Synthetic Chemistry, Faculty of Engineering, Kyoto University, Kyoto 606*

(Received January 6, 1978)

The formose reaction in methanol was compared with that in an aqueous solution. The reaction can occur in aqueous methanol even at a low [CaO]/[HCHO] ratio (0.05), at which the reaction does not take place in an aqueous solution, and the formaldehyde consumption rate decreases with an increase in the methanol concentration. Contrary to the formose reaction in an aqueous solution, the sugar yield in methanol becomes higher with an increase in the formaldehyde concentration. The rates of the sugar degradation and the formaldehyde consumption increase with an increase in the pH. The distribution of products is different from that in an aqueous solution, but both of them are very complex and essentially nonselective.

The formose reaction which forms a complex mixture of sugars from aqueous formaldehyde in the presence of a base, usually $Ca(OH)_2$, has been invesitigated by many workers. Among them, the effects of a nonaqueous solvent, especially methanol, on the reaction have received some attention, mainly in connection with attempts to improve the sugar yield and the selectivity in product formation.[1-4] One significant observation obtained in these studies has been that the sugar yield was found to increase upon the addition of methanol.[2-4] Concerning the effect of methanol on the rate of the formose reaction, two inconsistent experimental results have been reported. Pfeil *et al.*[2] carried out the formose reaction catalyzed by TlOH in aqueous media containing 7—40% of methanol, where the rate of the formaldehyde consumption increased with an increase in the concentration of methanol. Nakai *et al.*[4] reported that the addition of methanol slowed down the rate of the reaction catalyzed by $Ca(OH)_2$ and considered that the accelerating effect of methanol found by Pfeil might be due to impurities in the methanol.

As we have already reported,[5-7] in the formose reaction with $Ca(OH)_2$ in an aqueous solution, the sugar yield varies with the extent of the Cannizzaro reaction occurring, especially during the induction period, and when the ratio $[Ca(OH)_2]/[HCHO]$ is too small (0.05), the formose reaction does not take place. The latter phenomenon has been partly interpreted in terms of pH lowering due to the formation of formic acid by the Cannizzaro reaction. In view of the above results, it seemed interesting to see how the formose reaction is affected by the depression of the Cannizzaro reaction resulting from the addition of methanol. Another aim of the present work is to characterize the formose reaction in a methanol solvent, focussing on the effects of the formaldehyde concentration, the catalyst amount, and the pH on the sugar yield and on the rate of formaldehyde consumption.

Experimental

Materials. The formaldehyde solution in methanol was prepared as follows. After a suspension of 200 g of paraformaldehyde (Merck Co.) in 400 ml of methanol had been refluxed for 7 h, the mixture was filtered. The concentration of formaldehyde in the filtrate was *ca.* 12 M. When the formose reaction was carried out in a 1.0 M formaldehyde solution in methanol in the presence of 0.3 mol/l of a catalyst (CaO, $Ca(OH)_2$, or $CaCO_3$) at 60 °C, the consumption of formaldehyde after 2 h was 67, 41%, or negligible respectively. Thus, the most active CaO was used as the catalyst throughout this work; the catalyst was freshly calcined at 1000 °C for 3 h prior to use to avoid the poor reproducibility caused by the absorption of CO_2 and moisture from air. The methanol was distilled, and the other reagents were of an analytical grade.

Procedure. The reaction was carried out as has been described previously[5,7] and aliquots taken from the reaction mixture at intervals were cooled instantly in a Dry Ice–acetone bath to stop the reaction and were then immediately analyzed. The oxidation-reduction potential (ORP) and pH of the reaction mixture, the formaldehyde consumption, and the sugar yield were measured as has been reported previously.[5,7]

The amount of organic acids (as formic acid) (x M) formed by the Cannizzaro reaction was determined as follows. To a ml of the reaction solution, b ml of 0.05 M HCl was added; after the solution had been back-titrated with 0.05 M KOH (c ml), the amount of calcium ions was determined by titration with 0.01 M EDTA[9] (d ml):

$$x = (0.05c + 2 \times 0.01d - 0.05b)/a.$$

The consumption rate of formaldehyde, $-\mathrm{d[HCHO]}/\mathrm{d}t$ (M/min), was determined from the maximum slope of the formaldehyde consumption curve. The products were trimethylsilylated by Sweeley's method[10] and the TMS derivatives were analyzed by gas chromatography as has been described previously.[8]

Results and Discussion

Effect of Methanol Concentration. Figure 1 shows the effects of the methanol content on the formose reaction which was carried out at [CaO]/[HCHO]= 0.05 in aqueous methanol. As has been reported previously,[5-7] the formose reaction did not proceed at this [CaO]/[HCHO] ratio unless methanol was added, but the Cannizzaro reaction occurred preferentially. Under these conditions, the formaldehyde consumption was found to be approximately equal to the amount of formaldehyde consumed by the Cannizzaro reaction. The addition of methanol brought about the consumption of the formaldehyde resulting from the formation of sugars. When the methanol content varied in the range from 25 to 100%, the amount of formaldehyde consumed by the Cannizzaro reaction became smaller,

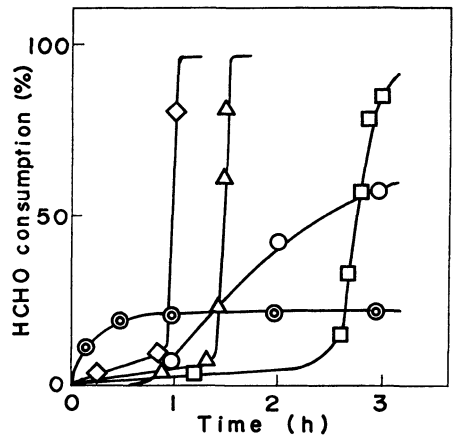

Fig. 1. Effect of methanol concentration on the formose reaction.
[HCHO]=1.0 M; [CaO]=0.05 mol/l; temp, 60 °C; total volume=200 ml. HCHO consumption, [MeOH] (vol %): ◎, 0; ◇, 25; △, 50; □, 75; ○, 100.

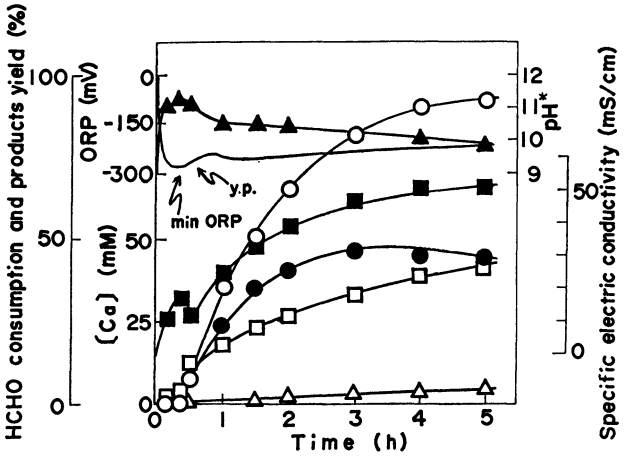

Fig. 2. Potentiometric and products analyses of the formose reaction in methanol.
[HCHO]=1.0 M; [CaO]=0.3 mol/l; temp, 60 °C; total volume=880 ml; ○, formaldehyde; ●, total sugars; △, organic acids; □, [Ca]; ■, electric conductivity; ▲, pH* (apparent pH in methanol); —, ORP.

that is, from *ca.* 12 to 5% for the total formaldehyde consumption. Since methanol obviously prevents the formation of formic acid, the addition of methanol will not appreciably change the pH of the reaction mixture, so the reaction mixture can keep the necessary concentration of $CaOH^+$, which has previously been shown to be the effective catalytic species during the induction period.[6] Figure 1 reveals further that, with an increase in the methanol content, the induction period is prolonged and the formaldehyde consumption rate becomes slower. In 100% methanol, however, the induction period is much more shortened than that in 75% aqueous methanol. This kinetic difference between the reactions in 75 and 100% methanol led us to assume that not only the pH, but also the solvent polarity, may influence the progress of the formose reaction. The solvent-polarity effect on the formose reaction will be reported elsewhere.

The Formose Reaction in 100% Methanol. A typical time-course of the reaction in 100% methanol with respect to physical measures, such as the pH, the oxidation-reduction potential (ORP), and the electric conductivity, and chemical measures, such as the formaldehyde consumption, the sugar yield, the organic acid formation, and the amount of dissolved calcium, is shown in Fig. 2. It has been previously shown that the ORP minimum and maximum indicate the end of the induction period and that of the sugar-forming step respectively in the formose reaction using a $Ca(OH)_2$–H_2O system.[7] The method was found to be applicable to the CaO–MeOH system only for determining the end of the induction period. In an aqueous solution, the yellowing point is observable at the end of the sugar-forming step, where the sugar yield reaches its maximum,[5,7] whereas, in methanol, the end of the sugar-forming step is in accord with neither the yellowing point nor the ORP maximum. As the sugar formation proceeds, the pH of the reaction mixture decreases and the amount of dissolved calcium increases, as was observed in the formose reaction in an aqueous solution.[6] A characteristic change was observed in the electric conductivity with a small drop between the ORP minimum and the yellowing point. Since the electric conductivity increases in parallel with the amount of dissolved calcium ion, it is assumed that the observed drop is due to a change in the dissolved calcium-ion species, such as the formation of a complex between calcium and a product which may be a catalytic species in the formose reaction.[12] This assumption is supported by the fact that the electric conductivity of a 0.1 M methanol solution of calcium chloride decreased from 38 to 23 mS/cm upon the addition of fructose (0.5 M).

As is to be expected from the inhibitory role of methanol on the Cannizzaro reaction, the formation of organic acids (mainly formic acid) is depressed, but the sugar yield does not increase so much as expected. This fact indicates that the sugar yield in methanol would be influenced also by factors other than the Cannizzaro reaction. One such possible factor is a competition between the formation and the degradation of formose sugars. This is supported by the facts that the formaldehyde consumption rate (possibly the formose-forming rate) in methanol is much slower than that in aqueous solution, and that the yellowing point, which implies the degradation of products, appears at an early stage of the total formose reaction in methanol, as is shown in Fig. 2.

In order to obtain further information on the formose-degradation process, the reaction was followed by measuring the ultraviolet spectrum of aliquots. Although no ultraviolet absorption was observed until the yellowing point, a broad absorption maximum at *ca.* 300 nm became observable thereafter and gradually increased. The absorption maximum is shifted from *ca.* 300 to *ca.* 260 nm when the apparent pH (pH*) of the solution is changed from 13.0 to 1.0. The Tilman reagent is reduced strongly by the reaction mixture. On the basis

Table 1. Effects of [HCHO] and [CaO] on the formose reaction in methanol[a)]

[CaO] (mol/l)	[HCHO] (M)	T_{min} (min)	T_{max}[b)] (min)	Sugar yield at T_{max} (%)	r_c (M/min)
0.15	0.2	60	$(17)_{300}$[c)]	13	0.01×10^{-2}
0.15	0.4	20	$(72)_{240}$[c)]	32	0.19×10^{-2}
0.15	1.0	12	240	44	0.55×10^{-2}
0.15	2.0	14	180	52	2.23×10^{-2}
0.15	3.0	22	150	56	2.51×10^{-2}
0.15	5.0	60	$(67)_{300}$[c)]	57	3.16×10^{-2}
0.05	0.5	30	$(59)_{290}$[c)]	36	0.14×10^{-2}
0.2	0.5	20	$(72)_{180}$[c)]	32	0.20×10^{-2}

0.5	3.0	140	220	42	2.41×10^{-2}
0.5	5.0	150	240	50	7.93×10^{-2}

a) Temp, 60 °C; total volume, 200 ml. b) The time when the sugar yield became highest and the HCHO consumption was above 95%. c) The number in parentheses is the HCHO consumption (%) at the time (min) shown by the subscript.

of these results, one of the degradation products is assumed to be a reductone (Triose reductone: λ_{max}, 266 nm (pH, 1.8); 314 (13.5)).[11)] Formose reactions in methanol were carried out with various CaO amounts and formaldehyde concentrations; the results obtained are summarized in Table 1. At a constant formaldehyde concentration ([CaO]/[HCHO]>0.1), the sugar yields are virtually independent of the CaO amount. At a constant CaO amount, the sugar yield increases with an increase in the formaldehyde concentration, but the sugar yield is independent of the formaldehyde concentration when the concentration is high (>2.0 M). These features are significantly different from those in an aqueous solution. The sugar yield in an aqueous solution is known to decrease with an increase in the formaldehyde concentration.[5)] These differences are mainly attributable to an inhibitory effect of methanol on the Cannizzaro reaction.

Since the formaldehyde consumption rate (r_c) in methanol is relatively slow, as has been noted above (Table 1), the product degradation rate (r_d) may appreciably influence the sugar yield. (Because of the complex nature of formose decomposition, the quantitative evaluation of r_d was difficult. Therefore, the decrease in the sugar content analyzed by the known method[13)] was regarded as a rough measure of r_d.) Considering that the observed pH decreases as the formation of sugars progresses (Fig. 2), the high sugar yield at a high level of formaldehyde might be attributable to a slower r_d resulting from the pH lowering, accompanied by the progress of the sugar formation. On the other hand, the sugar yield is rather independent of r_d in an aqueous solution, because the r_c in the formose-forming step is very fast. For example, $r_c=37.5\times10^{-2}$ M/min at [HCHO]=1.0 M and $[Ca(OH)_2]=0.13$ mol/l.[7)] It seems likely that the sugar yield in methanol is also largely dependent on r_c. This idea is supported by the fact that the sugar yield increases with an increase in r_c (Table 1).

Table 2. Effect of the pH on the formose reaction in methanol

[HCHO]=1.0 M; temp, 60 °C

[Ca] (M)	pH*[a)]	T_{min} (min)	T_{max} (min)	Sugar yield at T_{max} (%)	r_c (M/min)
0.05	9.0	84	300	58	0.95×10^{-2}
0.05	9.5	22	150	57	1.58×10^{-2}
0.05	10.0	10	150	50	1.70×10^{-2}

0.1[b)]	9.5	16	80	56	2.51×10^{-2}
0.1[b)]	10.0	7	60	49	3.98×10^{-2}

a) The apparent pH in methanol measured by electrodes adjusted with aqueous buffers. b) The reaction mixture became heterogeneous near the yellowing point.

In order to examine the effect of the pH on the formose reaction, $CaCl_2$ was used instead of CaO and the pH of the solution was adjusted by methanolic KOH. The results obtained are shown in Table 2. Under the conditions at low calcium concentrations (<0.1 M), the reaction mixture is homogeneous. The sugar yield increases with a decrease in the pH, though r_c slows down at a lower pH. Both r_c and r_d will vary with a change in the pH, and, at a very low pH (pH*=8.5), r_d is assumed to be extremely slow compared with r_c.

The pH and the catalyst concentration were found to affect the induction period in a homogeneous system. As is shown in Table 2, the induction period, T_{min} (the time up to the ORP minimum), becomes shorter with increases in the pH and the calcium concentration. This indicates that the induction step of the formose reaction in methanol may also be catalyzed mainly by $CaOH^+$, as in aqueous media.[6)] Although the sugar yield in an aqueous solution increases as the induction

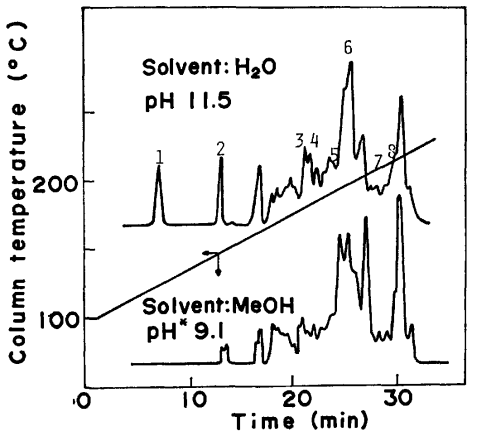

Fig. 3. Gas chromatograms of TMS derivatives of products. Column, SE-30 on Chromosorb W (60—80 mesh); N_2 flow rate, 60 ml/min; [HCHO]=1.0 M; [$CaCl_2$]=0.1 M; temp, 60 °C.
1, Glycerol; 2, 2-hydroxymethylglycerol; 3, xylose; 4, xylitol; 5, fructose; 6, 3-hydroxymethyl-1,2,3,4,5-pentanepentol; 7, solbitol, mannitol; 8, glucose.

period becomes shorter,[5,6] there was no relationship between the sugar yield and the length of the induction step in methanol. Although in an aqueous solution, the sugar yield is greatly affected by the amount of formaldehyde consumed by the Cannizzaro reaction occurring in the induction period, in methanol it is mostly influenced by the difference between r_c and r_d.

In summary, in order to obtain formose in a good yield in methanol, the formose reaction should be carried out under conditions in which the concentrations of formaldehyde and calcium ion are as high as possible and the pH is maintained at low values, such as pH*=8.5 (apparent pH).

Product Distribution. Figure 3 shows gas chromatograms of the TMS derivatives of the products obtained in aqueous and methanol solutions. The identities of some of the peaks were assigned by comparison with the retention times for authentic samples. The formation of sugar alcohols in methanol suggests that methanol strongly depresses the Cannizzaro reaction of formaldehyde, but not the cross-Cannizzaro reaction involving the aldoses formed. A comparison of these gas chromatograms indicates that the reaction in methanol produces a smaller amount of sugar alcohols than those in water, and that the product distribution is quite different, although both cases are essentially nonselective.

Inositol Derivatives. 11. Synthesis of Dianhydroinositols[1]

Seiichiro OGAWA,* Shuichi OKI, and Tetsuo SUAMI

Department of Applied Chemistry, Faculty of Engineering, Keio University, Hiyoshi, Yokohama 223

(Received March 17, 1978)

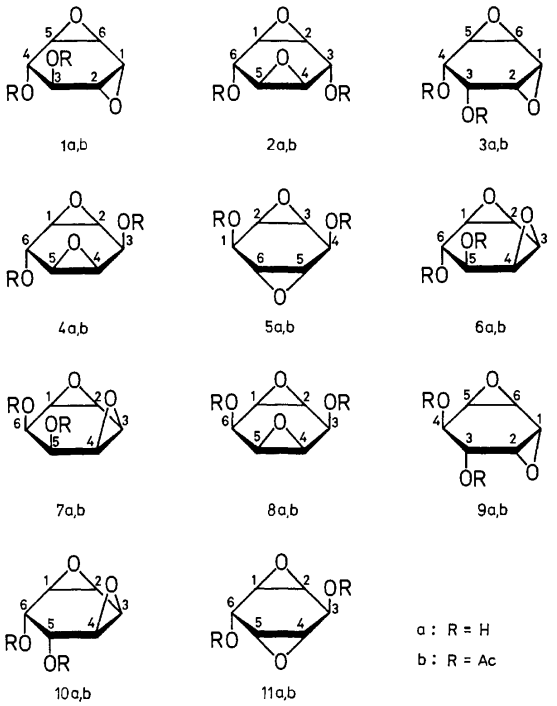
All the predicted isomers of 1,2: 3,4- and 1,2: 4,5-dianhydrocyclohexanehexols (5 racemates and 6 meso-compounds) were synthesized from appropriate inositol ditosylates and dimesylate by treatment with sodium methoxide.

A diepoxycyclohexane tumor inhibitor, crotepoxide was isolated from *Croton macrostachys*[2] and later from *Piper futokazura*,[3] and an antibiotic LL-Z 1220 was found to contain a *cis*-diepoxycyclohexene structure.[4] Recently, much interest has been taken in the reactivity and stereochemistry of highly mutagenic 7,8-dihydroxy-9,10-epoxide of benzo[*a*]pyrene and analogous substances.[5]

We have studied the structure-activity relationship of diepoxycyclohexanes by preparing diepoxycyclohexanediol as a model compound. We report herewith the details of synthetic studies on all the predicted diastereomers of dianhydrocyclohexanehexol (inositol).[6]

Sixteen isomers (5 racemates and 6 *meso*-compounds) are theoretically possible for dianhydroinositols: 1,2: 3,4-(**1a**, **3a**, **6a**, **7a**, **9a**, and **10a**) and 1,2: 4,5-dianhydrocyclohexanehexols (**2a**, **4a**, **5a**, **8a**, and **11a**), excluding isomers with a 1,3- or 1,4-anhydro ring.

None of these isomers has been described in literature, except for three of their *O*-cyclohexylidene derivatives.[7]

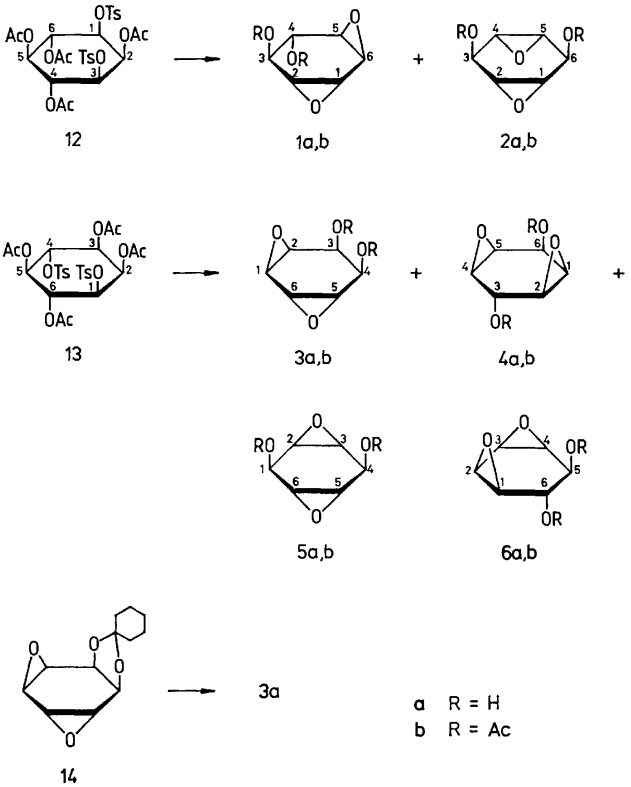


Scheme 1. The sixteen isomers of dianhydroinositol.[a]
a) Isomers **2**, **4**, **5**, **7**, **8**, and **10**, having a plane of symmetry, are meso forms. Of the five racemic diastereomers, **1**, **3**, **6**, **9**, and **11**, the enantiomer is depicted which allows clockwise assignment of positional numbers.

Seven isomers were synthesized from *myo*-inositol ditosylates and other four from *chiro*- and *muco*-inositol ditosylates and dimesylates. Structural elucidation of dianhydroinositols obtained was carried out by means of ^{1}H NMR spectroscopy and consideration of reaction mechanisms.

1,2: 5,6-Dianhydro-chiro- *(1) and 1,2: 4,5-Dianhydro*-muco-*inositols (2).* Treatment of tetra-*O*-acetyl-1, 3-di-*O*-tosyl-*myo*-inositol (**12**)[8] with a slight excess of sodium methoxide in chloroform–methanol at ambient temperature led to the formation of two major and one minor components. The mixture was separated by column chromatography, giving syrupy **1a** and crystalline **2a** in 21 and 15% yields, respectively, which were further characterized by conversion into their crystalline di-*O*-acetyl derivatives (**1b** and **2b**).

We see from the reaction mechanism that the two diepoxy diols can be obtained from **12** through the displacement of tosyloxyl functions with anionic oxygens. Compounds **1a** and **2a** are interconvertible by migration of an oxirane ring in basic media.[9] Structures of the products were determined on the basis of the ^{1}H NMR spectra, taking advantage of the symmetry of molecules. A part



Scheme 2.

of the spectral data are given in Table 1.

In the spectrum of **1b** in deuteriochloroform ($CDCl_3$), a two-proton doublet of triplets at δ 3.18 and a two-proton doublet of doublets at δ 3.58 are attributed to magnetically equivalent H-1 and H-6, and H-2 and H-5, respectively. Appearance of a two-proton relatively narrow triplet at δ 5.11 due to H-3 and H-4 indicates that the acetoxyl and epoxy groups are arranged in trans positions.[10] In the spectrum of **2a** in deuterium oxide (D_2O), the six ring protons appear as a four-proton triplet (δ 3.29) and a two-proton quintet (δ 4.56), showing the presence of magnetically equivalent two epoxy and two hydroxyl groups. The spectral data are consistent with the assigned structures.

A crystalline mixture of the diepoxy diacetates derived by direct acetylation of the intact epoxydation products from **12** was shown to be a 4: 5 mixture of **1a** and **2a** by estimation of the relative intensity of the signals due to each acetoxyl group. On the other hand, when **1b** was *O*-deacetylated with methanolic sodium methoxide, the resulting reaction mixture was found to contain **1a** and **2a** in about 1: 1 ratio by visual observation on TLC. The results give an evidence for the proposed structures of **1a** and **2a**. It is difficult to decide which product is formed first from **12**, because of the ready isomerization resulting from an oxirane ring migration under the conditions in this synthesis.

1,2: 5,6-Dianhydro-allo-*(3)*, *1,2: 4,5-Dianhydro*-epi-*(4)*, *and 2,3: 5,6-Dianhydro*-allo-*inositols (5)*. Under similar conditions with use of sodium methoxide, tetra-*O*-acetyl-1,4-di-*O*-tosyl-*myo*-inositol (**13**)[11] gave, upon separation by column chromatography, three crystalline diepoxy diols **3a** (23%), **4a** (8%), and **5a** (21%). Four diepoxy diols (**3a**, **4a**, **5a**, and **6a**) might be formed from **13**, and two pairs interconvertible in basic media. Both **4a** and **5a** have a plane of symmetry. In the ^1H NMR spectrum of **3a**, two protons on C-3 and C-4 appear as a doublet of doublets and a doublet of doublets of doublets, coupled with each other at δ 4.06 and 4.35, respectively, indicating that **3a** should be a 1,3-diepoxide. The structure of **3a** was confirmed by identification with the compound obtained by a mild acid hydrolysis of 1,2: 5,6-dianhydro-3,4-*O*-cyclohexylidene-*allo*-inositol (**14**).[12] Under these conditions no epoxide group migration occurs. The results also show that **4a**, formed from **3a** by base-catalyzed isomerization, possesses the assigned structure demonstrated by the symmetric pattern of the signals due to the ring protons in its ^1H NMR spectrum. Thus, **4a** shows a four-proton narrow triplet (δ 3.45) and a two-proton broad singlet (δ 4.53), its two hydroxyl groups being found not to be magnetically equivalent by the spectrum of the diacetate **4b**. Compound **5a** exhibits three two-proton narrow multiplets for the methine protons, indicating the presence of a plane of symmetry. Thus, its structure was assigned as 2,3: 5,6-dianhydro-*allo*-inositol. Later, **6a** was found to be transformed completely into **5a** in basic media.

1,2: 3,4- (7) and 1,2: 4,5-Dianhydro-cis-*inositols (8)*. Similar epoxidation of 1,2,5-tri-*O*-acetyl-3-*O*-benzoyl-4,6-di-*O*-tosyl-*myo*-inositol (**15**)[13] gave two diepoxy diols **7a** (4%) and **8a** (37%), together with 2,3-anhydro-6-*O*-tosyl-*epi*-inositol (**17**, 4%).[14] The structure of **17** was

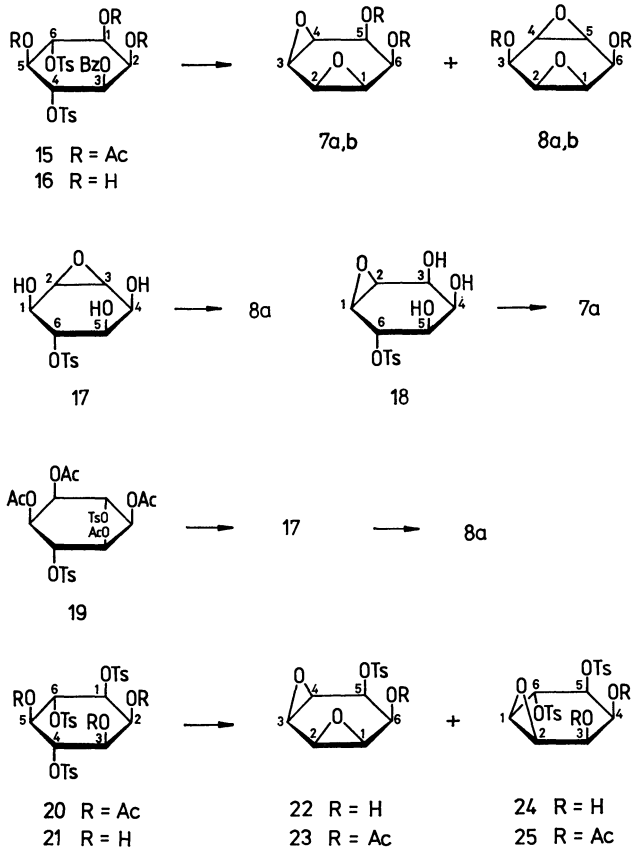
a) Chemical shifts are given in terms of δ-values. Values in parentheses show number of protons. b) Unless otherwise noted, the spectra were measured in D_2O. c) Measured in $CDCl_3$. d) The spectrum of the diol was measured in $CDCl_3$.

confirmed by conversion into **8a** on further treatment with sodium methoxide. Characterization of **7a** and **8a** was carried out by their ^1H NMR spectra. Thus, **8a** shows a four-proton doublet of doublets due to H-1, H-2, H-4, and H-5 appearing at δ 3.51, and a seven-line signal due to H-3 and H-6 at δ 4.48, confirming the assigned structure of **8a**. The spectrum of **7a** exhibits three two-proton narrow multiplets at δ 3.46, 3.65, and 4.15. The A_2B_2 pattern observed for H-1 and H-4, and H-5 and H-6 signals is compatible with the assigned structure of **7a**.

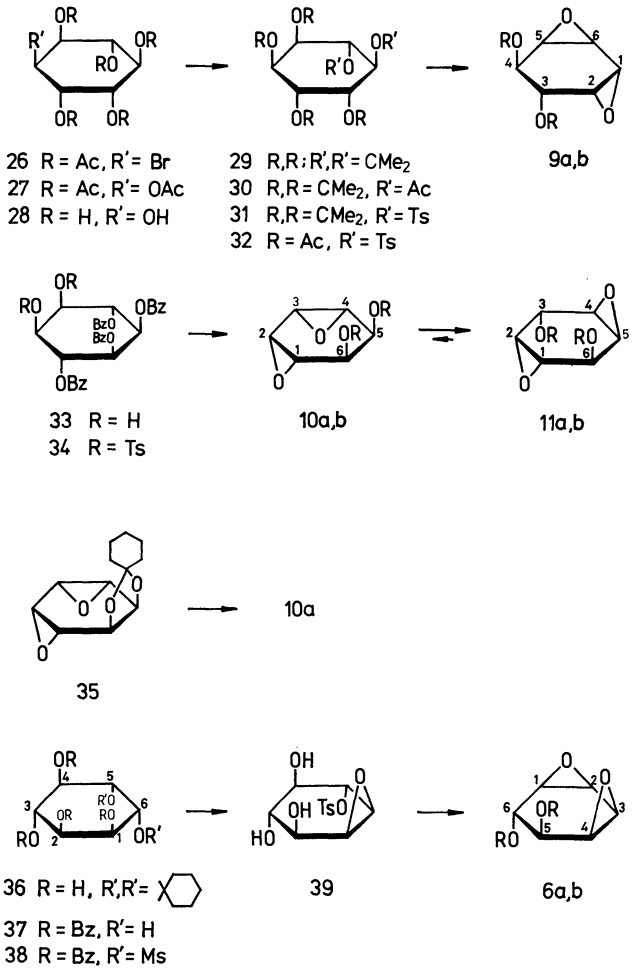
In contrast to the above results, when *O*-deacetylated compound, 1-*O*-benzoyl-4,6-di-*O*-tosyl-*myo*-inositol (**16**)[13] was subjected to epoxidation, **7a** was obtained in 36% yield, together with a trace of **8a**. This might be accounted for by assuming an attack of the C-5 anionic oxygen at C-4 or C-6 giving 1,2-anhydro-6-*O*-tosyl-*epi*-inositol (**18**) as an intermediate for **7a**. In the case of **15**, **17** might be a major intermediate presumably resulting from an attack of the C-1 or C-3 anionic oxygen formed first by *O*-deacylation at C-6 or C-4. The evidence for these assumption was furnished by using tetra-*O*-acetyl-3,6-di-*O*-tosyl-*muco*-inositol (**19**)[15] that would generate only **17** intermediary under the epoxidation conditions. In fact, **19** gave **8a** selectively in 36% yield.

In order to estimate the reactivity of *myo*-inositol ditosylates, we studied the epoxidation of tri-*O*-acetyl-1, 4,6-tri-*O*-tosyl-*myo*-inositol (**20**) and its *O*-deacetylated compound (**21**).[11]



Scheme 3.

Treatment of **20** with an excess of sodium methoxide in chloroform–methanol gave the diepoxide (**22**) preferentially in 50% yield. The corresponding *O*-acetyl derivative (**23**) revealed an ^1H NMR spectrum very similar to that of **7b**, suggesting it to be 1,2: 3,4-dianhydro-5-*O*-tosyl-*cis*-inositol. On the other hand, **21** reacted with sodium methoxide to give the monoepoxide (**24**) in 24% yield, together with a trace of **22**. The di-*O*-acetyl derivative (**25**) of **24** showed, in the ^1H NMR spectrum, a doublet of doublets and a doublet due to two protons on carbon atoms bearing the tosyloxyl functions at δ 4.58 and 4.96, respectively, showing that one of the tosyloxyls is adjacent to the epoxy group in trans orientation. These data allow us to assign the structure of **25** to 3,4-di-*O*-acetyl-1,2-anhydro-5,6-di-*O*-tosyl-*epi*-inositol. In the case of **20**, the C-3 acetoxyl seems to be *O*-deacylated first leading to the 3,4-epoxide, an intermediate for **22**. The preferential formation of the 3,4- or 4,5-epoxide is in line with that observed for **15** and **16**.



Scheme 4.

1,2: 5,6-Dianhydro-neo-*inositol (9).* Tetra-*O*-acetyl-3,4-di-*O*-tosyl-*chiro*-inositol (**32**), an intermediate compound for **9a**, was synthesized in the following sequences. Penta-*O*-acetyl-1-bromo-1-deoxy-*chiro*-inositol (**26**) derived by bromination of *myo*-inositol with acetyl bromide in acetic anhydride[16] was treated with

sodium acetate in boiling aqueous 2-methoxyethanol to give, after acetylation, hexa-*O*-acetyl-*chiro*-inositol (**27**)[17] in 65% yield. Hydrolysis of **27** with 4 M hydrochloric acid gave *chiro*-inositol (**28**) in 95% yield. Acetonation of **28** by the procedure of Angyal and MacDonald[18] gave the tri-*O*-isopropylidene derivative (**29**) in 30% yield, together with the desired 1,2: 5,6-di-*O*-isopropylidene derivative isolated as the di-*O*-acetyl derivative (**30**) in 18% yield. Compound **30** was *O*-deacylated with sodium methoxide and then tosylated to give the corresponding di-*O*-tosyl derivative (**31**) in 59% yield. On mild acid hydrolysis and successive acetylation **31** gave **32** in 95% yield.

By a similar treatment with sodium methoxide followed by acetylation, **32** gave crystalline di-*O*-acetyl-1,2: 5,6-dianhydro-*neo*-inositol (**9b**) in 48% yield, which was converted into the free diepoxy diol (**9a**) in 35% yield. The ^{1}H NMR spectrum of **9a** contains two-proton doublets of doublets at δ 3.46 and 3.81, and a two-proton singlet at δ 3.94. Characteristic A_2B_2 pattern of the former due to H-1, H-2, H-5, and H-6 supports the assigned structure.

1,2: 3,4-Dianhydro-allo- *(10) and 1,2: 4,5-Dianhydro*-neo-*inositols (11).* A similar epoxidation of tetra-*O*-benzoyl-1,2-di-*O*-tosyl-*muco*-inositol (**34**) derived from the corresponding tetra-*O*-benzoyl derivative (**33**)[19] is considered to afford **10a** and **11a**. However, the equilibrium between **10a** and **11a** in basic media was found to shift almost completely to the latter, **34** giving on epoxidation **11a** as the sole product in 39% yield. The ^{1}H NMR spectrum of **11a** showed three two-proton multiplets at δ 3.26, 3.47, and 4.47.

Preparation of **10a** was accomplished by mild acid hydrolysis of 1,2: 3,4-dianhydro-5,6-*O*-cyclohexylidene-*allo*-inositol (**35**).[11] When **10a** and **11a** were dissolved in 0.1 M methanolic sodium methoxide, respectively, only **10a** was detected in both reaction mixture at ambient temperature. This established the proposed structures of **10a** and **11a**. Compound **10a** showed, in the ^{1}H NMR spectrum, three two-proton multiplets at δ 3.31, 3.68, and 3.95.

1,2: 3,4-Dianhydro-epi-*inositol (6).* Tetra-*O*-benzoyl-1,2-di-*O*-mesyl-*chiro*-inositol (**38**) was prepared from 1,2-*O*-cyclohexylidene-*chiro*-inositol (**36**)[19] by benzoylation and removal of cyclohexylidene group followed by mesylation. Epoxidation between C-1 and C-6 of **38** was assumed to occur first, since the 6-OH and 1-OTs groups are located in diaxial positions in the favored conformation. In order to obtain **6a**, conditions for the next epoxidation should be carefully selected in order to suppress the epoxide migration to **5a**.

First, **38** was treated with 1.1 molar equiv. of sodium methoxide for the conversion into monoepoxide (**39**) which was then, without further purification, passed through a short column of Amberlite IRA-400 (OH^-) in a methanol solution several times until **39** disappeared in the effluent, subjected to monitoring by TLC. The crude product thus obtained consists of **6a** and a trace of **5a**, which were separated by column chromatography to give **6a** in 25% yield. Treatment of **6a** with sodium methoxide gave exclusively **5a**. The ^{1}H NMR spectrum of **6a** revealed two one-proton doublets of doublets at δ 3.69 and 4.12 attributable to H-5 and H-6, indicating that **6a** has an unsymmetric structure.

Experimental

All the compounds treated were racemic except for meso compounds. Diepoxy diols **1**, **3**, **6**, **9**, and **11** were synthesized as racemates. All the formulas depict one enantiomer of the respective racemates.

Unless otherwise stated, melting points were determined on a Mitamura Riken micro hot stage and are uncorrected. Solutions were evaporated under reduced pressure at 40—50 °C. IR spectra were determined for potassium bromide disks with a JASCO IR-E spectrophotometer. ^{1}H NMR spectra were measured at 60 MHz on a Varian A-60D spectrometer in deuteriochloroform ($CDCl_3$) or deuterium oxide (D_2O) with reference to tetramethylsilane or sodium 4,4-dimethyl-4-silapentane-1-sulfonate, respectively, as an internal standard, the peak positions being given in terms of δ. Values given for chemical shifts and coupling constants are of first-order. TLC was performed on silica gel (Wakogel B 10, Wako Pure Chemical Industries, Ltd.) using benzene–ethyl acetate (1: 2, v/v) as an eluent unless otherwise stated. Column chromatography was carried out on Wakogel C-200.

The synthetic reactions were not always conducted under optimum conditions. The isolated yields of the pure diepoxy diols are given for all cases.

1,2: 5,6-Dianhydro-chiro- *(1a) and 1,2: 4,5-Dianhydro*-muco-*inositols (2a).* *a)*: To a solution of tetra-*O*-acetyl-1,3-di-*O*-tosyl-*myo*-inositol (**12**)[8] (5 g) in a mixture of chloroform (50 ml) and methanol (40 ml) was added 1 M methanolic sodium methoxide (24 ml, 3 molar equiv.) and the mixture was allowed to stand at ambient temperature overnight. TLC indicated the formation of two major components (R_f 0.3 and 0.1) and one minor component (R_f 0.15). The reaction mixture was filtered in order to remove sodium *p*-toluenesulfonate precipitated, the filtrate being evaporated to dryness. The syrupy residue was dissolved in methanol (10 ml), mixed with silica gel (5 g), and the mixture was thoroughly dried with a rotary evaporator. The powder obtained was then transfered to the top of a silica-gel column (70 g) packed with benzene–ethyl acetate (1: 2, v/v), which was eluted with the same solvent system. Three fractions were separated according to examination by TLC. The faster-moving component (R_f 0.3) was obtained as a homogeneous syrup (**1a**) by removal of the solvent. The syrupy **1a** was treated with acetic anhydride (5 ml) in pyridine (10 ml) at ambient temperature overnight. The mixture was poured into ice–water (100 ml) and extracted with chloroform (3×20 ml). The extracts were washed with 1M hydrochloric acid, 10% aqueous sodium carbonate, and water, successively, and dried over anhydrous sodium sulfate. The solution was evaporated to give crystals which were recrystallized from chloroform–ethanol to give the diacetate (**1b**, 0.36 g, 21%) as rods, mp 125—127 °C.

Found: C, 52.58; H, 5.14%. Calcd for $C_{16}H_{12}O_6$: C, 52.63; H, 5.30%.

The second fraction consisting mainly of a minor component (R_f 0.15) did not crystallize and its characterization was not attempted.

The third fraction gave crystals which were recrystallized from methanol to give **2a** (0.17 g, 15%) as rods, mp 169—171 °C.

Found: C, 50.17; H, 5.51%. Calcd for $C_6H_8O_4$: C, 50.00; H, 5.60%.

Acetylation of **2a** (60 mg) as described for **1b** gave, after

crystallization from ethanol, the diacetate (**2b**, 58 mg, 76%) as plates, mp 108—109.5 °C.

Found: C, 52.90; H, 5.02%.

b): Compound **12** (2.5 g) was treated with sodium methoxide as described above. The crude product was shown by TLC to be a *ca.* 1:1 mixture of **1a** and **2a**. It was acetylated in the usual manner to give a crystalline mixture (0.33 g, 37%), which was found to be a 4:5 mixture of **1b** and **2b** estimation of the relative intensity of each acetyl signals in the ^{1}H NMR spectrum.

1,2: 5,6-Dianhydro-allo- *(3a)*, *1,2: 4,5-Dianhydro*-epi- *(4a)*, *and 2,3:5,6-Dianhydro*-allo-*inositols (5a)*. To a solution of tetra-*O*-acetyl-1,4-di-*O*-tosyl-*myo*-inositol (**13**)[11] (10 g) in a mixture of chloroform (100 ml) and methanol (80 ml) was added 1 M methanolic sodium methoxide (40 ml, 2.5 molar equiv.), and the mixture was allowed to stand at ambient temperature overnight. TLC showed the formation of three components: R_f 0.18, 0.15, and 0.05. The reaction mixture was processed as described in the epoxidation of **12** and the products were separated in a similar way by chromatography on silica gel with benzene–ethyl acetate (1:1, v/v) as an eluent. Three fractions were obtained. The first fraction gave crystals which were recrystallized from ethanol to give **3a** (0.48 g, 23%) as rods, mp 78—79 °C.

Found: C, 50.38; H, 5.60%.

Compound **3a** (80 mg) was acetylated in the usual way and the product was recrystallized from ethanol to give the diacetate (**3b**, 0.12 g, 90%) as plates, mp 121—121.5 °C.

Found: C, 52.60; H, 5.09%.

The second fraction gave crystals which were recrystallized from ethanol–ether to give **5a** (0.34 g, 15%) as needles, mp 75—76 °C. From the mother liquor, the second crop was obtained as prisms, mp 91—93 °C, weighing 0.13 g (total yield, 21%). These two dimorphic crystals were found to be identical by ^{1}H NMR spectroscopy.

Found: C, 50.16; H, 5.83%.

Acetylation of **5a** (0.18 g) gave, after recrystallization from ethyl acetate, the diacetate (**5b**, 0.22 g, 77%) as rods, mp 110—111.5 °C.

Found: C, 52.66; H, 5.02%.

The third fraction gave crystals which were recrystallized from ethanol to give **4a** (0.18 g, 8%) as plates, mp 124—124.5 °C.

Found: C, 50.42; H, 5.65%.

Acetylation of **4a** (24 mg) gave, after recrystallization from ethanol, the diacetate (**4b**, 28 mg, 73%), mp 136 °C.

Found: C, 52.47; H, 5.07%.

Compound **3a**, as well as **4a**, gave by TLC a *ca.* 3:2 mixture of **3a** and **4a** on treatment with methanolic sodium methoxide. Compound **5a**, however, remained unchanged under similar conditions.

O-Decyclohexylidenation of 1,2: 5,6-Dianhydro-3,4-O-cyclohexylidene-allo-*inositol (14)*.[12] A mixture of **14** (1 g) and 20% aqueous acetic acid (50 ml) was heated under reflux for 0.5 h. After having been cooled, the solution was neutralized with 5% aqueous sodium hydroxide and then evaporated to dryness. The residue was extracted with ethanol (50 ml) and the extract was concentrated to one half volume. TLC indicated the formation of **3a**, together with several minor components, but none of **4a**. The solution was filtered and the filtrate was chromatographed on silica gel (30 g) with benzene–ethyl acetate (1:2, v/v) as an eluent. The main fraction gave a syrup, which crystallized from methanol to give **3a** (0.24 g, 37%), mp 75—77 °C, identical with the compound obtained before.

1,2:3,4- (7a) and 1,2: 4,5-Dianhydro-cis-*inositols (8a)*. *a)*: 1,2,5-Tri-*O*-acetyl-3-*O*-benzoyl-4,6-di-*O*-tosyl-*myo*-inositol (**15**)[13] (3 g) was treated with 1 M methanolic sodium methoxide (11 ml, 2.5 molar equiv.) in a mixture of chloroform (18 ml) and methanol (12 ml) at ambient temperature overnight. TLC showed the formation of three components: one minor (R_f 0.2) and two major components (R_f 0.16 and 0.06). The reaction mixture was processed similarly and the products were fractionated as described in the separation of **1a** and **2a**. The faster-moving component, 2,3-anhydro-6-*O*-tosyl-*allo*-inositol (**17**), was obtained as needles (59 mg, 4.4%), mp 155—156 °C, after crystallization from ethanol–ether. ^{1}H NMR (D_2O): δ 2.47 (3H, s, tosyl CH_3), 3.8—4.4 (6H, m, methine protons).

Found: C, 49.65; H, 5.46%. Calcd for $C_{13}H_{16}O_7S$: C, 49.35; H, 5.11%.

The second fraction was evaporated and the residue was crystallized from ethanol–ether to give **7a** (26 mg, 4.3%) as needles, mp 103—104 °C.

Found: C, 50.00; H, 5.33%.

Acetylation of **7a** (25 mg) gave, after crystallization from ethanol, the diacetate (**7b**, 32 mg, 81%) as needles, mp 142.5—144 °C.

Found: C, 52.89; H, 5.12%.

The third fraction gave crystals which were recrystallized from methanol–ether to give **8a** (0.22 g, 37%) as plates, mp 178—180 °C.

Found: C, 50.39; H, 5.72%.

Acetylation of **8a** (24 mg) gave, after recrystallization from ethanol, the diacetate (**8b**, 24 mg, 63%) as plates, mp 153—154 °C.

Found: C, 52.86; H, 5.14%.

Compound **17** was found by TLC to be selectively converted into **8a** on treatment with methanolic sodium methoxide.

b): 1-*O*-Benzoyl-4,6-di-*O*-tosyl-*myo*-inositol (**16**)[13] (0.8 g) was treated similarly with 1 M methanolic sodium methoxide (3.4 ml, 2.5 molar equiv.) in a mixture of butanone (50 ml) and methanol (50 ml) at ambient temperature overnight. TLC indicated the formation of **7a** (R_f 0.2), together with traces of **8a** and **17**. The products were fractionated by chromatography on silica gel to give **7a** (70 mg, 36%), mp 101.5—103 °C.

The same results as described in (a) were obtained when **15** was treated with methanolic sodium methoxide in the solvent used for the epoxidation of **16**.

Tetra-O-acetyl-3,6-di-O-tosyl-muco-*inositol (19)*. 3,6-Di-*O*-tosyl-*muco*-inositol[15] (0.2 g) was treated with acetic anhydride (2 ml) in pyridine (2 ml) at ambient temperature overnight. The reaction mixture was poured into ice–water and the resulting crystals were recrystallized from chloroform–ethanol to give **19** (0.26 g, 96%) as plates, mp 189—190 °C.

Found: C, 51.41; H, 5.03; S, 9.97%. Calcd for $C_{28}H_{32}O_{14}S_2$: C, 51.20; H, 4.91; S, 9.77%.

Reaction of 19 with Sodium Methoxide. Compound **19** (7 g) was treated with 1 M methanolic sodium methoxide (28 ml, 2.5 molar equiv.) in a mixture of chloroform (100 ml) and methanol (80 ml) at ambient temperature overnight. TLC showed the formation of one major component (R_f 0.06) and one minor one (R_f 0.11). The reaction mixture was processed similarly and the products were separated by chromatography on silica gel to give **8a** (0.55 g, 36%), mp 178—180 °C, as the main product. The minor component was obtained as needles (16 mg), mp 157—159 °C, after crystallization from ethanol; the IR spectrum showed no absorption in the region of tosyloxyl function. No further characterization was carried out owing to a minute amount.

Reaction of Tri-O-acetyl-1,4,6-tri-O-tosyl-myo-*inositol (20)*[11] *and Its O-Deacetylated Derivative (21)*[11] *with Sodium Methoxide.*

a): Compound **20** (0.3 g) was treated with 1 M methanolic sodium methoxide (0.33 ml, 2.5 molar equiv.) in a mixture of chloroform (10 ml) and methanol (2 ml) at ambient temperature overnight. TLC indicated the formation of one major component and one minor one. The reaction mixture was evaporated and the residue was extracted with hot ethyl acetate (3×10 ml). The extracts were evaporated and the residue was crystallized from chloroform–ethanol to give 1,2: 3,4-dianhydro-5-*O*-tosyl-*cis*-inositol (**22**, 59 mg, 50%) as plates, mp 176—177 °C.

Found: C, 52.76; H, 4.99; S, 10.36%. Calcd for $C_{13}H_{14}O_6S$: C, 52.32; H, 4.73; S, 10.75%.

Acetylation of **22** (40 mg) gave, after crystallization from chloroform–ethanol, the acetate (**23**, 36 mg, 79%) as needles, mp 173—174 °C. ^{1}H NMR ($CDCl_3$) δ 2.05 (3H, s, OAc), 2.47 (3H, s, tosyl CH_3), 3.25 (2H, m) and 3.43 (2H, m) (H-1, H-2, H-3, and H-4), 5.12 (2H, m, H-5 and H-6).

Found: C, 52.69; H, 4.74; S, 9.73%. Calcd for $C_{15}H_{16}O_7S$: C, 52.91; H, 4.74; S, 9.42%.

b): Compound **21** (0.5 g) was treated with 1 M methanolic sodium methoxide (1.5 ml, 2.5 molar equiv.) in a mixture of butanone (30 ml) and methanol (10 ml) at ambient temperature overnight. TLC indicated the formation of one major component, together with a trace of **22**. The reaction mixture was worked up as described above and the product was crystallized from ethanol–ether to give 1,2-anhydro-5,6-di-*O*-tosyl-*epi*-inositol (**24**, 90 mg, 25%) as prisms, mp 167—168 °C.

Found: C, 51.29; H, 4.79; S, 13.62%. Calcd for $C_{20}H_{22}O_9S_2$: C, 51.05; H, 4.72; S, 13.64%.

Acetylation of **24** (40 mg) gave, after crystallization from ethanol, the diacetate (**25**, 47 mg, 99%) as plates, mp 159—159.5 °C. ^{1}H NMR ($CDCl_3$) δ 2.05 (6H, s, two OAc), 2.49 (6H, s, two tosyl CH_3), 3.35 (1H, m, H-2), 3.45 (1H, d, $J_{1,2}$=3.5 Hz, H-1), 4.58 (1H, dd, $J_{4,5}$=2.5 Hz, $J_{5,6}$=9 Hz, H-5).

Found: C, 52.00; H, 4.72; S, 11.59%. Calcd for $C_{24}H_{26}O_{11}S_2$: C, 51.97; H, 4.73; S, 11.56%.

chiro-*Inositol (28)*. Penta-*O*-acetyl-1-bromo-1-deoxy-*chiro*-inositol (**26**, 2.3 g), mp 114—116 °C, prepared by the modified method of McCasland and Horswill,[16] was treated with anhydrous sodium acetate (2.3 g) in boiling 90% aqueous 2-methoxyethanol (30 ml) for 18 h. The reaction mixture was evaporated to dryness and the residue was treated with acetic anhydride (10 ml) and pyridine (10 ml) at ambient temperature overnight. The reaction mixture was filtered to remove an insoluble matter. The filtrate was evaporated to give a syrup, which was purified by passing through a short alumina column with ethyl acetate. The eluate was evaporated and the syrupy product was crystallized from ethanol to give hexa-*O*-acetyl-*chiro*-inositol (**27**, 1.43 g, 65%) as crystals, mp 110—112 °C (lit,[16] 110—111 °C).

Compound **27** (5.6 g) was treated with boiling 4 M hydrochloric acid (100 ml) for 2.5 h. The reaction mixture was evaporated and the residue was crystallized from ethanol to give **28** (2.2 g, 95%) as crystals, mp 245—246 °C (lit,[16] 243 °C).

Acetonation of 28. The reaction was carried out following the method of Angyal and MacDonald.[18] A mixture of finely powdered **28** (2 g), anhydrous zinc chloride (10 g), acetic acid (10 ml), and acetone (80 ml) was heated under reflux for 5.5 h. Pyridine (20 ml) was added to the cooled mixture, and the precipitates were removed by filtration and washed with chloroform (30 ml). The filtrate and washings were combined and evaporated to dryness. The residue was treated with acetic anhydride (10 ml) and pyridine (10 ml) and the reaction mixture was worked up by the usual method. The product was crystallized from ethanol to give 1,2: 3,4: 5,6-tri-*O*-isopropylidene-*chiro*-inositol (**29**, 0.99 g, 30%) as plates, mp 140 °C.

Found: C, 60.30; H, 8.05%. Calcd for $C_{15}H_{24}O_6$· C, 60.00; H, 8.05%.

The mother liquor of **29** was evaporated and the residue was crystallized from ethanol to give 3,4-di-*O*-acetyl-1,2: 5,6-di-*O*-isopropylidene-*chiro*-inositol (**30**, 0.69 g, 18%) as needles, mp 111—112 °C. ^{1}H NMR ($CDCl_3$) δ 1.21 (3H, s) and 1.55 (3H, s) (isopropylidene CH_3), 2.06 (6H, s, two OAc), 5.06 (2H, dd, J=3 and 5 Hz, H-3 and H-4).

Found: C, 56.04; H, 6.84%. Calcd for $C_{16}H_{24}O_8$: C, 55.80; H, 7.04%.

Tetra-O-*acetyl-3,4-di*-O-*tosyl*-chiro-*inositol (32)*. Compound **30** (0.65 g) was treated with a catalytic amount of methanolic sodium methoxide in a mixture of chloroform (5 ml) and methanol (5 ml) at ambient temperature overnight. The mixture was evaporated to dryness and the residue was treated with tosyl chloride (2.9 g) in pyridine (10 ml) at 40 °C for four days. The reaction mixture was poured into ice–water, and the resulting crystals were collected and recrystallized from chloroform–ethanol to give 1,2: 5,6-di-*O*-isopropylidene-3,4-di-*O*-tosyl-*chiro*-inositol (**31**, 0.63 g, 59%) as plates, mp 174—176 °C. ^{1}H NMR ($CDCl_3$) δ 1.24 (3H, s) and 1.44 (3H, s) (isopropylidene CH_3), 2.45 (6H, s, two tosyl CH_3), 4.63 (2H, m, J=2.5 and 4 Hz, H-3 and H-4).

Found: C, 54.92; H, 5.86; S, 11.23%. Calcd for $C_{26}H_{32}O_{10}S_2$: C, 54.91; H, 5.68; S, 11.27%.

Compound **31** (0.55 g) was treated with 50% aqueous acetic acid (20 ml) at reflux for 2 h. The reaction mixture was evaporated to dryness and the residue was acetylated in the usual way. The product was recrystallized from chloroform–ethanol to give **32** (0.6 g, 94%) as needles, mp 216—216.5 °C.

Found: C, 51.48; H, 5.12; S, 9.74%. Calcd for $C_{28}H_{22}O_{14}S_2$: C, 51.20; H, 4.91; S, 9.77%.

1,2: 5,6-Dianhydro-neo-*inositol (9a)*. Compound **32** (0.5 g) was treated with 1 M methanolic sodium methoxide (2 ml, 2.5 molar equiv.) in a mixture of chloroform (10 ml) and methanol (5 ml) at ambient temperature overnight. The reaction mixture was evaporated and the residue was acetylated in the usual manner. The product was crystallized from ethanol to give the diacetate (**5b**, 83 mg, 48%), mp 96—97 °C.

Found: C, 52.94; H, 5.47%.

Compound **5b** (80 mg) was treated with a catalytic amount of methanolic sodium methoxide in methanol (4 ml) and the mixture was then treated with Amberlite IR-120 (H^+) and evaporated to dryness. The residue was crystallized from ethanol–ether to give **5a** (18 mg, 35%) as plates, mp 121.5—122.5 °C.

Found: C, 49.88; H, 5.73%.

1,2,3,6-Tetra-O-*benzoyl-4,5-di*-O-*tosyl*-muco-*inositol (34)*. 1,2,3,4,6-Tetra-*O*-benzoyl-*muco*-inositol (**33**)[19] (4 g) was treated with tosyl chloride (6.6 g, 5 molar equiv.) in pyridine (100 ml) at ambient temperature for 2 days. The reaction mixture was poured into ice–water and the precipitates were recrystallized from chloroform–ethanol to give **34** (5.6 g, 93%), mp 194—195 °C. ^{1}H NMR ($CDCl_3$): δ 2.32 (6H, s, two tosyl CH_3).

Found: C, 63.96; H, 4.59; S, 6.69%. Calcd for $C_{48}H_{40}O_{14}S_2$: C, 63.71; H, 4.46; S, 7.09%.

1,2: 4,5-Dianhydro-neo-*inositol (11a)*. Compound **34** (7 g) was treated with 1 M methanolic sodium methoxide (20 ml, 2.5 molar equiv.) in a mixture of chloroform (40 ml) and methanol (50 ml) at ambient temperature overnight. The reaction mixture was worked up similarly and the product was purified by chromatography on silica gel with benzene–

ethyl acetate (1: 1, v/v) as an eluent. The product was crystallized from ethanol to give **11a** (0.44 g, 39%) as plates, mp 150—151 °C. Found: C, 50.30; H, 5.83%.

Compound **11a** (0.1 g) was converted into the diacetate (**11b**, 0.12 g, 83%) as plates, mp 138—139 °C, crystallized from ethanol. Found: C, 52.98; H, 5.14%.

1,2: 3,4-Dianhydro-allo-*inositol (10a)*. 1,2: 3,4-Dianhydro-5,6-*O*-cyclohexylidene-*allo*-inositol (**35**)[12] was prepared in an improved yield (80%) from 1,2-*O*-cyclohexylidene-3,5-di-*O*-tosyl-*myo*-inositol by treatment with 2.5 molar equiv. of methanolic sodium methoxide in boiling 2-methoxyethanol. Compound **35** (1.2 g) was treated with boiling 20% aqueous acetic acid (50 ml) for 45 min. The reaction mixture was then processed as described in the preparation of **3a**. The crude product was purified by chromatography on silica gel with benzene–ethyl acetate (1: 2, v/v) as an eluent and crystallized from ethanol–ether to give **10a** (0.23 g, 30%) as crystals, mp 105—106 °C. Found: C, 50.22; H, 5.53%.

On acetylation, **10a** was converted into the syrupy diacetate (**10b**, 52 mg, 87%). Compound **10a** was found by TLC to give **11a** exclusively on treatment with methanolic sodium methoxide.

1,2,3,4-Tetra-O-*benzoyl*-chiro-*inositol (37)*. 1,2-*O*-Cyclohexylidene-*chiro*-inositol (**36**)[19] (0.1 g) was treated with benzoyl chloride (0.41 ml, 12 molar equiv.) in pyridine (10 ml) at ambient temperature overnight. The reaction mixture was poured into ice–water to give crude tetra-*O*-benzoyl derivative as a white powder. It was treated with boiling 80% aqueous acetic acid (20 ml) for 2 h. The product was purified by chromatography on silica gel with butanone–toluene (1: 5, v/v) as an eluent. The main fraction gave crystals which were recrystallized from ethyl acetate–petroleum ether to give **37** (0.17 g, 72%) as needles, mp 148—150 °C.

Found: C, 68.26%; H, 4.82%. Calcd for $C_{34}H_{28}O_{10}$: C, 68.47; H, 4.73%.

1,2,3,4-Tetra-O-*benzoyl-5,6-di*-O-*mesyl*-chiro-*inositol (38)*.

a): Compound **37** (0.1 g) was treated with mesyl chloride (0.1 ml, 8 molar equiv.) in pyridine (5 ml) at ambient temperature overnight. The reaction mixture was poured into ice–water and the precipitates were crystallized from chloroform–ethanol to give **38** (0.07 g, 55%) as crystals, mp 189—191 °C. ^{1}H NMR ($CDCl_3$): δ 3.04 (3H, s) and 3.36 (3H, s) (mesyl CH_3). Found: C, 57.38; H, 4.35; S, 8.60%. Calcd for $C_{36}H_{32}O_{14}S_2$: C, 57.34; H, 4.29; S, 8.52%.

b): Compound **36** (1.5 g) was treated with benzoyl chloride (8 ml, 12 molar equiv.) in pyridine (120 ml) at ambient temperature overnight and then at 60 °C for 0.5 h. The mixture was poured into ice–water and the resulting gum was extracted with chloroform. The extract was evaporated to give crude **37** (1.5 g), which was treated successively with boiling 80% aqueous acetic acid and with mesyl chloride (1.1 ml) in pyridine (30 ml) to give crude **38** (3.6 g). Recrystallization from chloroform–ethanol gave pure **38** (3.1 g, 72% yield based on **36** used), mp 189—191 °C.

1,2: 3,4-Dianhydro-epi-*inositol (6a)*. A solution of **38** (1.04 g) in a mixture of chloroform (15 ml) and methanol (20 ml) was treated with 1 M methanolic sodium methoxide (1.6 ml, 1.1 molar equiv.) at ambient temperature overnight. TLC showed the formation of one major component (R_f 0.07) and one minor one (R_f 0.12). The reaction mixture was evaporated to dryness and the residue was dissolved in methanol (30 ml) and treated with Amberlite MB-3. The solution was evaporated to give a crude monoepoxide (**39**), which was without further purification dissolved in methanol (30 ml). The solution was passed through a short column of Amberlite IRA-400 (OH^-) several times until **39** disappeared in the effluent subjected to monitoring by TLC. TLC showed the formation of one major component (R_f 0.12) and two minor ones (R_f 0.15 and 0.07). The mixture was fractionated by chromatography on silica gel with benzene–ethyl acetate (1: 2, v/v) as an eluent. The first fraction gave a small amount of syrup, which crystallized to give **5a**, mp 108—110 °C, identical with the compound obtained before. The second fraction gave crystals, which were recrystallized from ethanol to give **6a** (49 mg, 25%) as plates, mp 132—134 °C.

Found: C, 50.14; H, 5.62%.

Acetylation of **6a** gave a syrupy diacetate **6b**.

Compound **6a** was shown by TLC to give **5a** exclusively on treatment with methanolic sodium methoxide.

The authors wish to thank Mr. Shukichi Muto for assistance in preparative experiments. Thanks are due to Mr. Saburo Nakada for elemental analyses.

On the Behavior of Sulfonyl Imide as a Reactive Intermediate. The Reaction with Enamines

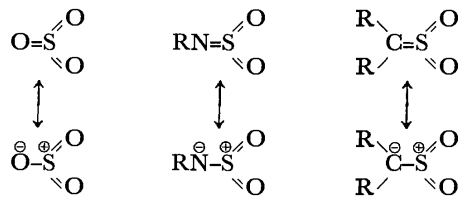
Toshikazu NAGAI, Tadao SHINGAKI,* Masao INAGAKI, and Tetsuya OHSHIMA

College of General Education, Osaka University, Toyonaka, Osaka 560

(Received March 30, 1978)

The reactions of *N*-alkylsulfamoyl chloride with enamines in the presence of triethylamine showed the presence of *N*-alkylsulfonyl imide ($RN{=}SO_2$) as a reaction intermediate to give either acyclic (sulfonamides) or cyclic products (1,2-thiazetidine 1,1-dioxides), depending upon the enamines used. The enamines leading to the acyclic products possess either a methylene group on the α-carbon or a hydrogen on the β-carbon of the enamine; the enamine leading to the cyclic product has no such available hydrogen atom. It is thought that the products are formed *via* a zwitter ionic intermediate provided by the electrophilic attack of the sulfonyl imide sulfur atom on the β-carbon atom of the enamine.

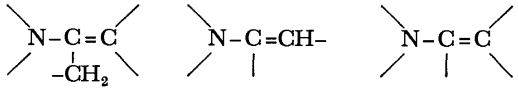
Sulfonyl imides,[1] $RN{=}SO_2$, are isoelectronic with sulfur trioxide and sulfenes, and are located between sulfenes and sulfur trioxide in regard to the electronegativities of the elements adjacent to the reaction centers. An attractive sulfonyl imide synthesis was



achieved by Burgess[2] in 1967, though the imide had been proposed as an intermediate in the photolysis of benzenesulfonyl azide.[3] Dehydrohalogenation of ethylsulfamoyl chloride by triethylamine at −78 °C led to the generation of *N*-ethylsulfonyl imide, whose interception was accomplished by the addition of aniline to give the sulfamide. *N*-Ethylsulfonyl imide, furthermore, was found to react with strongly nucleophilic olefins such as 2-(dichloromethylene)-1,3-dioxolane[2] and the pyrrolidine enamine of isobutyraldehyde[4] to afford cycloadducts. In this study on sulfonyl imides, the reaction of alkylsulfonyl imides with enamines give acyclic or cyclic adducts depending on the type of the enamine used, and the sulfonyl imides undergo oligomerization in the presence of less nucleophilic olefins or in the absence of the substrates.

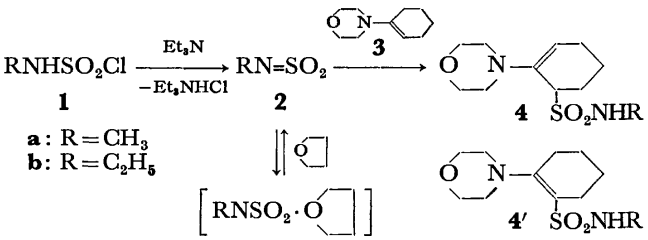
Results and Discussion

The reactions of *N*-alkylsulfonyl imide (**2**) with three types of enamines (Types A, B, and C) were conducted.



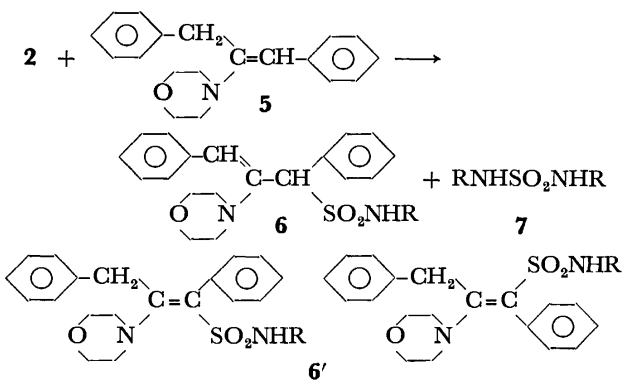
Type A Type B Type C

Reaction of 2 with Type A Enamine. A solution of an alkylsulfamoyl chloride (**1**) in tetrahydrofuran (THF) was added dropwise with stirring to a solution of 1-morpholinocyclohexene (**3**) and triethylamine in THF at −78 °C. Triethylamine hydrochloride was formed nearly quantitatively and removed by filtration. Treatment of the filtrate afforded a colorless crystalline compound characterized not as 1-alkylsulfamoyl-2-morpholinocyclohexene (**4'**) but as the 3-alkylsulfamoyl isomer (**4**) in about 60% yield.



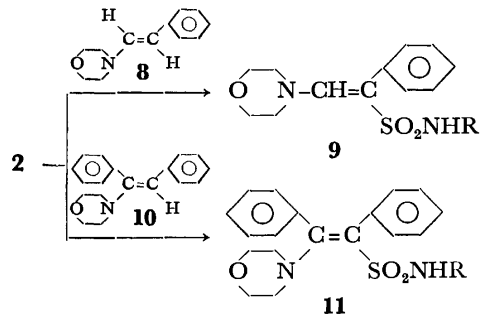
The structure of **4** was established by IR, NMR, and mass spectra analyses (experimental section). Subsequently, a THF solution of triethylamine was added dropwise to a stirred THF solution of **1** at −78 °C. After the removal of the amine hydrochloride at −78 °C, the addition of **3** to the filtrate (maintained at the same temperature) led to **4**, the yield of which varied with the age of the filtrate. These results suggest the intermediacy of *N*-alkylsulfonyl imide (**2**), which may be stabilized in a mode similar to the THF complex of *N*-methoxycarbonyl imide.[5]

The addition of 2-morpholino-1,3-diphenylpropene (**5**) to a THF solution of **2a** at −78 °C produced 3-methylsulfamoyl-2-morpholino-1,3-diphenylpropene (**6a**) rather than the isomeric sulfonamide **6'**, **6a** was isolated in a 26% yield together with *N,N'*-dimethylsulfamide (**7a**) in a 65% yield. When **1a** was added to a mixture of **5** and triethylamine in THF at an elevated temperature, 20 °C, the yield of **6a** increased to 67% and that of **7a** decreased to 7%. In the same manner,

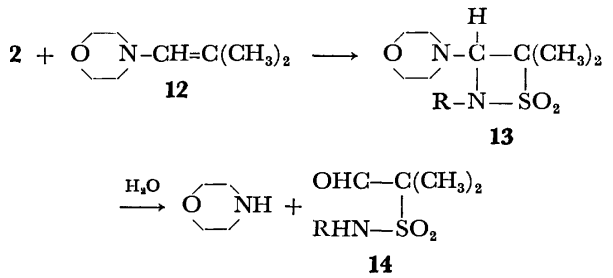


6b was given in a 68% yield from **1b** at 20 °C. That **5** is less reactive than **3** is interpreted in terms of a smaller nucleophilic character due to the phenyl ring on the enamine double bond.

Reaction of 2 with Type B Enamine. The reaction of **2** with either (*E*)-β-morpholinostyrene (**8**) or (*E*)-morpholinostilbene (**10**) provided the 1-alkylsulfamoyl-2-morpholinoethylene derivative (**9** or **11**) in a moderate yield (**9a**: 46%, **9b**: 58%, **11a**: 47%, **11b**: 56%), at 20 °C. The reaction did not take place at −78 °C. In a similar mode as the reaction with the enamines **3** and **5**, the hydrogen atom β to the morpholino moiety served in the formation of the acyclic products:

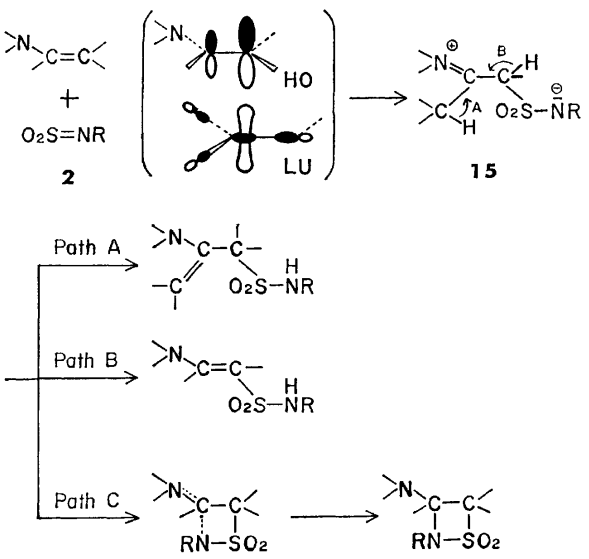


Reaction of 2 with Type C Enamine. From the above results, the cycloadduct formation in reaction of **2** appears to require an enamine having no available hydrogen atom. When **2** was generated at −78 °C in the presence of 2-methyl-1-morpholinopropene (**12**), the expected cycloadduct, 2-alkyl-4,4-dimethyl-3-morpholino-1,2-thiazetidine 1,1-dioxide (**13**) was obtained. Since **13a** and **13b** were very sensitive to moisture,[6] attempts at purification were unsuccessful. The structures of **13** were established on the basis of the IR and NMR spectra and by their subsequent hydrolyses. The IR spectra of **13** showed no ν_{NH} and exhibited ν_{SO_2}



at 1320 and 1125 cm^{-1}. The NMR spectrum ($CDCl_3$, 60 MHz) of **13b** was very similar to that of 4,4-dimethyl-2-ethyl-3-(1-pyrrolidinyl)-1,2-thiazetidine 1,1-dioxide.[4] Chromatographs of **13a** and **13b** over silica gel led to the hydrolyses, giving **14a** and **14b** in 55 and 62% yields respectively.

Reaction Pathway. The reactions of the *N*-alkylsulfonyl imides (**2**) with the enamines provided three kinds of the products, the 3-sulfamoylpropene derivative, the sulfamoylethylene derivative, and the cycloadduct, depending upon the enamine used. The formation of these products can be explained by a mechanism *via* a zwitter ionic intermediate (**15**) shown in Scheme 1.



Scheme 1.

The reaction is initiated by an electrophilic attack of the sulfur atom of the sulfonyl imide on the β-carbon of the enamines, leading to **15**. In the cases of Type A and B enamines, prototropy followed by the formation of a new olefinic linkage (Path A) or prototropy followed by the reformation of the olefinic linkage (Path B) takes place to give the corresponding acyclic products. In the reaction with Type A enamine, the exclusive formation of the sulfonamide **4** or **6** which arises from the proton transfer of the methylene, instead of the isomeric sulfonamide **4′** or **6′** ascribable to the transfer of the olefinic proton, may be considered as follows: Both the sulfonamides **4′** and **6′** are destabilized by the steric inhibition of the resonance involving the nitrogen lone pair and the double bond.[9] On the other hand, the zwitter ionic intermediate resulting from the Type C enamine affords the cyclic adduct since there is no mobile proton (Path C).

As an alternative mechanism, the formation of the cycloadduct may be envisaged as resulting from a concerted thermal [$_\pi 2_s + _\pi 2_a$] process.[10] However, in the cycloaddition of *N*-methoxycarbonylsulfonyl imide with variously substituted alkenes to afford the corresponding 1,2-thiazetidines and 2,3-dihydro-1,4,5-oxathiazines, the one-step multi-center cycloaddition has not been accepted on the basis of the adduct distribution with solvent change.[5] Moreover, the addition of sulfene, which closely resembles sulfonyl imide, to enamines has been explained not by a concerted mechanism but by a nonconcerted process on the basis of the stereoselectivity of the cycloaddition and of the product distribution between the cyclic and acyclic adducts.[9]

Oligomerization of 2. The reaction of **2** with the enamine (**5**) possessing a phenyl ring on the double bond gave dimethylsulfamide (**7**) in a significant yield, especially at low temperatures. A dimer of sulfonyl imide which had failed to react with the enamine present might be subjected to hydrolysis to afford **7** with the loss of sulfuric acid. When **1a** was added dropwise to triethylamine in either benzene or ether in the absence

$$2CH_3NSO_2 \longrightarrow (CH_3NSO_2)_2 \xrightarrow[-H_2SO_4]{2H_2O} CH_3NHSO_2NHCH_3$$

2a **7a**

of enamine followed by chromatography, **7a** was isolated in a 90% yield respectively. Furthermore, the reactions of **2a** with less nucleophilic olefins, *e.g. trans*-stilbene and dimethyl fumarate, in THF gave no adduct, affording the amine hydrochloride in the theoretical amount and an unidentified solid which appears to be a polymerization product of **2a**. In addition, the olefins were recovered nearly quantitatively.

The explanation for the favored oligomerization, as well as the preferred tendency of prototropy to form the acyclic compound with enamine, of sulfonyl imide, compared with sulfene, is based on the following consideration: owing to the larger electronegativity of the nitrogen atom than that of the carbon atom, sulfonyl imide and the zwitter ionic intermediate (**15**) are more stabilized and have a longer lifetime than sulfene and the resulting intermediate[9] (like **15**).

Experimental

The IR spectra were recorded on Hitachi EP-S and Hitachi 215 spectrophotometers, and the NMR spectra on a Varian EM-360 (60 MHz) instrument, using tetramethylsilane as an internal standard. The NMR spectra of the products, except for dimethylsulfamide, were measured in chloroform-*d* and all the chemical shifts were given in δ values. The melting points are uncorrected.

Materials. Alkylsulfamoyl chlorides (**1**) were prepared according to the reported method:[13] **1a**; 67 °C/0.03 mmHg, **1b**: 70 °C/0.03 mmHg (lit,[14] 52 °C/0.05 mmHg). All of the enamines, **3**,[15] **5**,[16] **8**,[17] **10**,[18] and **12**[19] were prepared by the respective methods in the literature. *trans*-Stilbene and dimethyl fumarate were commercial materials and used after recrystallizations from 95% ethanol and from methanol respectively. Triethylamine and the solvents were obtained commercially and used after purification by the published direction.[20]

Reactions of 1 with Enamines. Method A: A sulfamoyl chloride (10 mmol) in THF (30 ml) was added dropwise over a period of 1 h to a stirred solution containing an enamine (10 mmol) and triethylamine (10 mmol) in THF (70 ml) at the desired temperature. After the addition, the mixture was stirred for 1 h at that temperature. The precipitates of triethylamine hydrochloride (quantitative amount) were removed by filtration, and the solvent was evaporated under reduced pressure leaving an oily substance tinged with yellow. The addition of methanol to the residue gave the sulfamoyl imide-enamine adduct as a precipitate. The reaction temperatures were maintained at −78 °C in the reactions with enamines **3** and **12**, and at 20 °C for enamines **5**, **8**, and **10**. Method B: A solution of triethylamine (10 mmol) in THF (20 ml) was added dropwise over 15 min to a stirred solution of **1** (10 mmol) in THF (60 ml) at −78 °C. After further stirring for 15 min, to the stirred solution kept at −78 °C was added a solution of the enamine (10 mmol) in THF (20 ml) dropwise over a period of 30 min. After the resulting mixture was stirred for an additional 15 min, the mixture was allowed to attain room temperature. The precipitates of the amine hydrochloride (quantitative amount) were removed by filtration and the solvent evaporated from the filtrate under reduced pressure. Methanol was added to the residual oily substance and the sulfamoyl imide-enamine adduct was obtained as a precipitate.

Reaction with 1-Morpholinocyclohexene (3): By Method A, 3-methylsulfamoyl- and 3-ethylsulfamoyl-2-morpholinocyclohexenes (**4a** and **4b**) were isolated in 1.5 g (58%) and 1.5 g (55%) yields respectively. By Method B, **4a** and **4b** were isolated in 1.3 g (50%) and 1.4 g (51%) yields respectively. As a modification of Method B, when the amine hydrochloride was removed at −78 °C prior to the addition of enamine **3**–THF solution, **4a** and **4b** were obtained in 1.2 g (46%) and 1.1 g (40%) yields respectively. **4a**: mp 120—122 °C. IR (Nujol, cm^{-1}); 3280 (NH), 1645 (C=C), 1315 and 1160 (SO_2). NMR; 1.6—3.2 (m, 10H, NCH_2 and CH_2), 3.65—3.95 (m, 5H, OCH_2 and SO_2CH), 5.05 (bs, 1H, NH), 5.38 (t, 1H, J=4 Hz, vinyl H). MS (70 eV); *m/e* 260 (M^+). Found: C, 50.31; H, 7.72; N, 10.57%. Calcd for $C_{11}H_{20}N_2O_3S$: C, 50.75; H, 7.74; N, 10.76%. **4b**: white crystal, mp 89—90 °C. IR (Nujol, cm^{-1}); 3260 (NH), 1645 (C=C), 1315 and 1160 (SO_2). NMR; 1.22 (t, 3H, J=7 Hz, CH_3), 1.5—3.4 (m, 12H, NCH_2 and CH_2), 3.73 (m, 5H, OCH_2 and SO_2CH), 5.10 (bt, 1H, NH), 5.35 (t, 1H, J=4 Hz, vinyl H). Found: C, 52.84; H, 8.10; N, 10.20%. Calcd for $C_{12}H_{22}N_2O_3S$: C, 52.54; H, 8.08; N, 10.21%.

Reactions with 2-Morpholino-1,3-diphenylpropene (5): The reaction of **1a** was run as in Methods A and B. By Method A, 2.5 g (67%) of 3-methylsulfamoyl-2-morpholino-1,3-diphenylpropene (**6a**) was yielded as the precipitate. The filtrate was evaporated under reduced pressure to give a brownish, oily substance. The residue was chromatographed on silica gel, and 0.04 g (7%) of *N,N'*-dimethylsulfamide (**7a**) was eluted with chloroform. The recrystallization of **6a** from methanol gave colorless needles; mp 153—154 °C. IR (KBr, cm^{-1}): 3200 (NH), 1320 and 1140 (SO_2). NMR: 2.70 (d, 3H, J=5 Hz, CH_3), 2.65—2.90 (m, 4H, NCH_2), 3.55—3.75 (m, 4H, OCH_2), 4.29 (bs, 1H, NH), 5.10 (s, 1H, vinyl H), 6.81 (s, 1H, SO_2CH), 7.2—7.8 (m, 10H, benzene ring). MS (70 eV): *m/e* 372 (M^+). Found: C, 64.23; H, 6.61; N, 7.54%. Calcd for $C_{20}H_{24}N_2O_3S$: C, 64.49; H, 6.49; N, 7.52%. The recrystallization of **7a** from benzene gave colorless leaflets; mp 78—79 °C.[13] IR (KBr, cm^{-1}): 3320 (NH), 1325 and 1160 (SO_2). NMR (DMSO-d_6): 2.47 (d, 6H, J=5 Hz, CH_3), 6.70 (bs, 2H, NH). MS (70 eV): *m/e* 124 (M^+). Found: C, 19.21; H, 6.37; N, 22.97%. Calcd for $C_2H_8N_2O_2S$: C, 19.35; H, 6.49; N, 22.56%. Method B gave **6a** and **7a** in 1.0 g (26%) and 0.4 g (65%) yields respectively. When the reaction of **1b** was run as in Method A, 3-ethylsulfamoyl-2-morpholino-1,3-diphenylpropene (**6b**) was isolated in 2.6 g (68%) yield. The recrystallization from methanol gave colorless needles; mp 133—134 °C. IR (KBr, cm^{-1}): 3250 (NH), 1310 and 1140 (SO_2). NMR: 1.10 (t, 3H, J=7 Hz, CH_3), 2.65—3.30 (m, 6H, NCH_2), 3.60—3.75 (m, 4H, OCH_2), 4.36 (bt, 1H, NH), 5.00 (s, 1H, vinyl H), 6.85 (s, 1H, SO_2CH), 7.3—7.9 (m, 10H, benzene ring). MS (70 eV): *m/e* 386 (M^+). Found: C, 65.15; H, 6.85; N, 7.26%. Calcd for $C_{21}H_{26}N_2O_3S$: C, 65.27; H, 6.78; N, 7.25%.

Reactions with (E)-β-Morpholinostyrene (8): The reactions of **1a** and **1b** gave α-methylsulfamoyl- and α-ethylsulfamoyl-β-morpholinostyrenes (**9a** and **9b**) in 1.3 g (46%) and 1.7 g (58%) yields, respectively, Method A. The recrystallization of **9a** from methanol gave colorless prisms; mp 144—145 °C. IR (KBr, cm^{-1}): 3240 (NH), 1622 (C=C), 1300 and 1130 (SO_2). NMR: 2.62 (d, 3H, J=5 Hz, CH_3), 2.9—3.1 (m, 4H, NCH_2), 3.45—3.65 (m, 4H, OCH_2), 3.65—4.0 (bs, 1H, NH), 7.26 (s, 1H, vinyl H), 7.35 (s, 5H, benzene ring). MS (70 eV): *m/e* 282 (M^+). Found: C, 55.04; H, 6.41; N, 9.90%. Calcd for $C_{13}H_{18}N_2O_3S$: C, 55.31; H, 6.43; N, 9.92%. The recrystallization of **9b** from methanol gave

colorless prisms; mp 117—118 °C. IR (KBr, cm^{-1}): 3260 (NH), 1622 (C=C), 1300 and 1130 (SO_2). NMR: 1.10 (t, 3H, J=7 Hz, CH_3), 2.8—3.1 (m, 6H, NCH_2), 3.45—3.65 (m, 4H, OCH_2), 3.65—3.9 (bs, 1H, NH), 7.22 (s, 1H, vinyl H,) 7.33 (s, 5H, benzene ring). Found: C, 56.45; H, 6.76; N, 9.37%. Calcd for $C_{14}H_{20}N_2O_3S$: C, 56.74; H, 6.80; N, 9.45%.

Reactions with (E)-Morpholinostilbene (10): The reactions of **1a** and **1b** were run as in Method A. Methylsulfamoyl- and ethylsulfamoyl-morpholinostilbenes (**11a** and **11b**) were isolated in yields of 2.6 g (47%) and 2.1 g (56%) respectively. The recrystallization of **11a** gave pale yellow prisms: mp 153—154 °C. IR (KBr, cm^{-1}): 3275 (NH), 1539 (C=C), 1309 and 1140 (SO_2). NMR: 2.46 (d, 3H, J=5 Hz, CH_3), 2.5—2.7 (m, 4H, NCH_2), 3.3—3.5 (m, 4H, OCH_2), 3.7 (bs, 1H, NH), 7.2—7.5 (m, 10H, benzene ring). MS (70 eV): *m/e* 358 (M^+). Found: C, 63.48; H, 6.18; N, 7.74%. Calcd for $C_{19}H_{22}N_2O_3S$: C, 63.67; H, 6.19; N, 7.82%. **11b**: colorless prisms (from methanol), mp 140—142 °C. IR (KBr, cm^{-1}); 3250 (NH), 1545 (C=C), 1297 and 1138 (SO_2). NMR; 0.93 (t, 3H, J=7 Hz, CH_3), 2.5—2.7 (m, 4H, morpholino ring NCH_2), 2.92 (q, 2H, J=7 Hz, NCH_2), 3.33—3.53 (m, 4H, OCH_2), 3.70 (bs, 1H, NH), 7.3—7.5 (m, 10H, benzene ring). MS (70 eV); *m/e* 372 (M^+). Found: C, 64.38; H, 6.50; N, 7.65%. Calcd for $C_{20}H_{24}N_2O_3S$: C, 64.50; H, 6.50; N, 7.52%.

Reactions with 2-Methyl-1-morpholinopropene (12): The reactions of **1a** and **1b** were run as in Method A. The precipitates of triethylamine hydrochloride were removed from the reaction mixture by filtration and the solvent evaporated under reduced pressure, the last traces of solvent being removed at a pressure of 0.1 mmHg. The residual oily, impure 2,4,4-trimethyl-3-morpholino-1,2-thiazetidine 1,1-dioxide (**13a**) displayed the following NMR spectrum: 1.56 (s, 6H, C-CH_3), 2.50—3.13 (m, 4H, NCH_2), 2.76 (s, 3H, NCH_3), 3.31 (s, 1H, CH), 3.60—3.83 (m, 4H, OCH_2). Since attempts to crystallize **13a** were unsuccessful, the oil was chromatographed over silica gel. Elution with benzene gave α-(methylsulfamoyl)isobutyraldehyde (**14a**) as a colorless oil in a yield of 0.9 g (55%). IR (neat, cm^{-1}): 3340 (NH), 1730 (C=O), 1318 and 1130 (SO_2). NMR: 1.53 (s, 6H, CH_3), 2.76 (d, 3H, J=5 Hz, NCH_3), 4.63 (bs, 1H, NH), 9.63 (s, 1H, CHO). From the reaction of **1b**, 2-ethyl-4,4-dimethyl-3-morpholino-1,2-thiazetidine 1,1-dioxide (**13b**) was obtained as an oily residue. IR (neat, cm^{-1}): 1320 and 1122 (SO_2). NMR: 1.26 (t, 3H, J=7 Hz, CH_3), 1.56 (s, 6H, CH_3), 2.50—3.13 (m, 4H, NCH_2), 3.46 (s, 1H, CH), 3.60—3.83 (m, 4H, OCH_2), 3.25 (q, 2H, J=7 Hz, CH_2). The impure **13b** was chromatographed over silica gel to give colorless, oily α-(ethylsulfamoyl)isobutyraldehyde (**14b**): yield 1.1 g (62%). IR (neat, cm^{-1}): 3280 (NH), 1725 (C=O), 1315 and 1130 (SO_2). NMR; 1.17 (t, 3H, J=7 Hz, CH_3), 1.50 (s, 6H, CH_3), 3.18 (q, 2H, J=7 Hz, CH_2), 5.07 (bs, 1H, NH), 9.68 (s, 1H, CHO).

Reaction of 1a in Benzene and in Ether. A benzene (0.5 mol, 39 g) solution of **1a** (20 mmol, 2.6 g) was added dropwise over a period of 1 h to a stirred benzene (0.5 mol) solution of triethylamine (20 mmol, 2.1 g) at 20 °C. The reaction mixture was stirred for a further hour at the temperature and the precipitates of triethylamine hydrochloride were collected by filtration (weighed 2.7 g, 98%). Evaporation of the solvent under reduced pressure gave a yellow oil, which was chromatographed over silica gel. The fraction eluted by chloroform gave 1.05 g (85%) of **7a**, which was recrystallized from benzene. The reaction in ether gave 1.12 g (91%) of **7a**.

Attempted Reactions with trans-*Stilbene and with Dimethyl Fumarate.* The reactions of **1a** were run as in Method A at 20 °C using double the molar quantities of the reactants and the solvent. The reaction with *trans*-stilbene gave 2.64 g (96%) of the amine hydrochloride, and the evaporation of the solvent under reduced pressure gave a yellow solid, which was extracted with benzene. Removal of benzene gave 5.3 g (95%) of the recovered stilbene. Chromatography of the benzene insoluble part on silica gel using chloroform as an eluent gave one gram of a white solid, the NMR of which showed no absorption for protons resulting from the incorporation of stilbene. The reaction with dimethyl fumarate gave 2.5 g (91%) of the amine hydrochloride. Evaporation of the solvent followed by trituration with methanol gave 2.6 g (91%) of the recovered ester. From the methanol solution, the solvent was removed under reduced pressure to give a pale yellow solid, the chromatography of which over silica gel gave 0.8 g of a white product similar to that obtained in the reaction with stilbene.

The Reaction of Vicinal Dinitro Compounds with Tin(II) Chloride

Kimitoshi FUKUNAGA* and Makoto KIMURA

Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube, Yamaguchi 755

(Received April 5, 1978)

The reactions of vicinal dinitro compounds with tin(II) chloride have been studied. The reactions of α,β-diaryl vicinal dinitro compounds and tin(II) chloride in polar solvents gave the corresponding olefins in good yields. The aliphatic vicinal dinitro compounds did not react with tin(II) chloride under the same reaction conditions. A reaction mechanism of elimination involving a radical anion intermediate has been proposed.

The bimolecular removal of two atoms or groups from vicinal dihalides,[1,2] vicinal diols,[3] and vicinal dicarboxylates[4] have been investigated extensively, but there have been few papers on the bimolecular elimination reactions of vicinal dinitro compounds. Kornblum *et al.* reported the denitration of purely aliphatic vicinal dinitro compounds to alkenes with sodium sufide or sodium benzenethiolate.[5]

It has been reported that 1,2-diaryl-1,2-dinitroethanes (**1**) react with tin(II) compounds in ethanol to give 1,2-diarylethylenes (**2**)[6] and this paper will report the reaction in detail.

Scheme 1.

Results and Discussion

Syntheses of **1**. 1,2-Diaryl-1,2-dinitroethane (**1b**—**f**) has been prepared by the reaction of the sodium or potassium salt of α-arylnitromethane with potassium peroxodisulfate. Two isomeric structures are possible for the vicinal dinitro compounds. Figure 1 shows the NMR spectra of the configurationally known *dl*-1,2-dinitro-1,2-diphenylethane (*dl*-**1b**) and *meso*-**1b** pairs.[7] The methine proton of *meso*-**1b** at δ 3.74 is broad compared with that of *dl*-**1b**. These results indicate that the stereochemical assignment can possibly be made for the isomeric **1b**—**f** on the basis of the band width of the methine proton peaks.

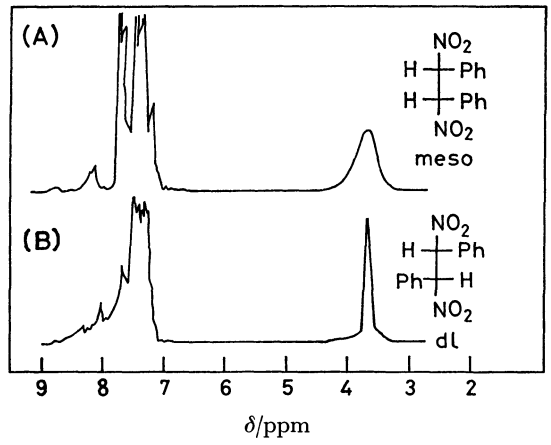

Fig. 1. NMR spectra of **1b** in $(CD_3)_2NCD$; (A): for *meso*-**1b**; (B): for *dl*-**1b**.

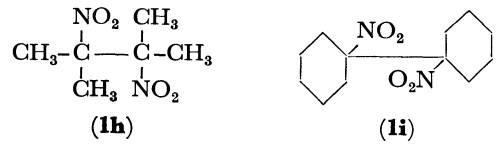
2,3-Dinitro-2,3-diphenylbutane (**1g**) was prepared as a mixture of the *dl* and *meso* forms by the reaction of the sodium salt of 1-nitro-1-phenylethane with silver nitrate. The ratio of the stereoisomers in this product has been determined by NMR in $CDCl_3$ which exhibited resonances at δ 2.30 and 2.22 due to two kinds of methyl groups. Other vicinal dinitro compounds (9,9'-dinitro-9,9'-bifluorenyl (**1a**), 2,3-dinitro-2,3-dimethylbutane (**1h**), and 1,1'-dinitrobicyclohexyl (**1i**)) have been prepared by the methods reported in the literature.[6,8]

The analytical data for **1a**—**i** are summarized in Table 1.

Reaction of **1** *with Tin(II) Chloride.* α,β-Diaryl vicinal dinitro compounds (**1a**—**f**) react readily with tin(II) chloride in boiling ethanol to give the corresponding 1,2-diarylethylenes (**2a**—**f**). The products thus obtained were identified with authentic samples by mixed melting point determination and a comparison of IR spectra. The β-elimination products, such as α-nitrostilbenes, were not obtained. Refluxing of the purely aliphatic vicinal dinitro compound, **1h** or **1i** with tin(II) chloride in ethanol gave the starting materials unchanged, even after 48 h. Thus, the presence of the aromatic ring attached to the carbon atom bearing the nitro group is essential for denitration.



1h **1i**

Scheme 2.

The results of this reaction are shown in Table 2.

The reaction of **1a** with tin(II) chloride has been conducted in various solvents. As shown in Table 3, the reaction is remarkably affected by the polarity of the solvent, and proceeds smoothly with a solvent more polar than ethyl acetate (ε=6.0). In dipolar aprotic solvents, the reaction proceeds more readily, and lower temperature being sufficient for reaction. A vigorous evolution of nitrogen oxide was observed during the reaction employing acetic acid or ethyl acetate as

solvent. The formation of nitrogen oxide in acidic medium indicates the formation of the nitrite ion during the reaction. In order to find the optimum reaction conditions, several runs were conducted with **1a** and *dl*-**1b** employing ethanol or DMF as the solvent. An solution of ethanol or DMF solution and **2a** had an intense absorption maximum at 453 nm (ε_{max} 2.4×10^4 in EtOH, ε_{max} 3.0×10^4 in DMF). A very small absorption and weak absorption were observed at this wavelength for a solution of tin(II) chloride and **1a** respectively. Therefore, the spectrophotometric determination of **2a** in the reaction mixture from **1a** and tin(II) chloride has been conducted at 453 nm. In the reaction with *dl*-**1b**, the yield of **2b** was determined by GLPC, the results of which are summarized in Tables 4 and 5. As can be seen from the Tables, the best result were obtained with a mole ratio of tin(II) chloride to **1** greater than 4 to 1 was used. Longer reaction time did not significantly increase the yield of elimination product, **2**. It has been reported that a solution of tin(II), except for tin(II) fluoride is oxidized on exposure to air.[9] Consequently an excess of tin(II) chloride has been used.

Stereochemistry of Elimination. Table 6 shows that the product of the reaction of **1b** was solely the *trans* isomer (*trans*-**2b**) regardless of the stereochemical nature of the starting material or the condition of the reaction. The isomerization of *cis*-**2b** to *trans*-**2b** was not observed under these reaction conditions. Similarly a series of *dl*-1,2-diaryl-1,2-dinitroethanes (*dl*-**1c—f**) were treated

to give *trans*-1,2-diarylethylenes (*trans*-**2c**—**f**), some typical results of which are summarized in Table 2. In the reactions of **1g**, *dl*-**1g** gave a mixture of *cis* and *trans*-2,3-diphenyl-2-butene (*cis* and *trans*-**2g**) in a ratio of 54 to 46, and a mixture of *dl* and *meso*-**1g** in a ratio of 51 to 49, respectively (Table 6). These results suggest that present elimination reaction is not stereospecific.

Table 6. Reactions of *dl*-**1b**, *meso*-**1b**, *dl*-**1g**, and *meso*-**1g** with tin(II) chloride

Run	Substrate[a]	Solvent (10 ml)	Reaction conditions		Yield of olefin	
			Time (h)	Temp (°C)	*cis* (%)	*trans* (%)

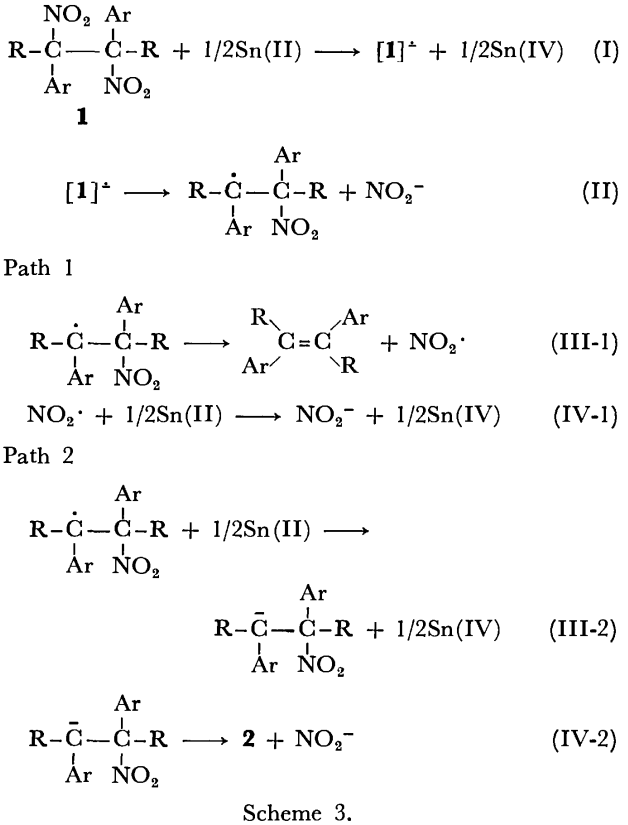
Reaction Mechanism. Since no dehydronitration of **1b**—**f** was observed, there appears to be little, if any, formation of an ionic intermediate. On the basis of the stereochemical results, it appears probable that the elimination is not concerted and that a labile mononitro intermediate is involved. Furthermore, the stoichiometric results indicate that the reaction is markedly affected by the concentration of tin(II) chloride. Therefore the carbanion (E1cb), unimolecular (E1), and concerted bimolecular (E2) elimination mechanisms are not possible mechanisms in the elimination.[10] A possible mechanism is Scheme 3:



Scheme 3.

The favored coordination numbers for tin(II) are three[11,12] and for tin(IV) four to six,[13] and the tin(II) is coordinated to the oxygen of the nitro group. The first coordination process involving a neutral species should be aided by solvents of high polarity. Under such conditions electron transfer takes place from tin(II) to the nitro group of the vicinal dinitro compounds (Step I), and radical intermediates are formed (Step II). In the thermodynamically controlled conformation, they then react with a second molecule of tin(II) to give the final products (Steps III and IV). In Scheme 3, two mechanisms for the elimination of the second nitro group from the radical intermediate are presented. One is based on the reductive elimination of $\cdot NO_2$, and the other, on the intermediate formation of a carbanion that subsequently loses a nitrite ion. It appears probable that the elimination reaction in Step III proceeds *via* a carbanion mechanism rather than a radical mechanism when the second leaving group is a group such as an acetoxyl group that is not easily lost with its bonding

Table 7. The influence of nitro aromatics and sulfur on the reaction of **1a** with tin(II) chloride

Run	Added inhibitor	mmol	Yield of **2a** (%)[b]
1	None	0	96.2
2	$PhNO_2$	0.125	97.0
3	*m*-DNB	0.063	94.5
4	*m*-DNB	0.250	95.1
5	*p*-DNB	0.125	96.7
6	Sulfur	1.25	97.6

a) In ethanol (30 ml) at reflux temp for 0.5 h using **1a** (1.25 mmol) and tin(II) chloride (5.00 mmol). b) Yield was determined spectrophotometrically.

electron pair.[10] It should be noted here that the reaction of *threo*-1-acetoxy-2-nitro-1,2-diphenylethane with tin(II) chloride afforded no *trans*-**2b** under the same conditions.[14] Therefore, the elimination of the second nitro group proceeds *via* a radical mechanism (Steps III-1 and IV-1 in Scheme 3). Kwok and Miller[15] previously proposed a similar sequence for the reaction of stilbene dibromide with tin(II) chloride. Kornblum *et al.*[5] reported that similar reactions of purely aliphatic vicinal dinitro compounds with sodium sulfide are inhibited by the presence of dinitrobenzene (DNB) or sulfur. In the reactions here of **1a** with tin(II) chloride, however, the presence of DNB or sulfur had no influence on the product yield, as shown in Table 7. Norris and Girdler[16] reported that the reaction of the lithium salt of 2-nitropropane with *p*-nitrobenzylidene diacetate in DMSO was not catalyzed by light, nor was it inhibited by oxygen or *p*-DNB. Presumably the greater stability of the nitroaromatic radical stabilized by α-aromatic substituent allows sufficient time for successful competition between electron transfer and loss of the nitrite ion. Therefore, the difference in the reactivity of α,β-diaryl vicinal dinitro compounds (**1a**—**g**) and purely aliphatic vicinal dinitro compounds (**1h** and **1i**) with tin(II) chloride may be attributed to the stability of the intermediate radical.

Experimental

All melting points are uncorrected. The products were identified, unless otherwise mentioned, by mixed melting point determination and comparing the IR and NMR spectra data with those of authentic samples. The IR, UV, and NMR spectra were measured with a Hitachi Model IR-215 spectrometer, a Shimadzu Model UV-200 spectrometer, and a JNM-MH 100 spectrometer using tetramethylsilane as an internal standard. Gas-liquid partition chromatographic (GLPC) analysis was conducted on a Hitachi Model 063 gas chromatograph.

Materials. Anhydrous tin(II) chloride was prepared from commercial tin(II) chloride dihydrate according to the method of Stephen.[17] Phenylnitromethane, (*o*-chlorophenyl)nitromethane, 1-naphthylnitromethane, and *o*-tolylnitromethane were prepared from corresponding arylacetonitriles[18] with methyl nitrate according to the method of Black and Baker.[19] *p*-Tolylnitromethane was synthesized according to the method previously reported.[20] 1-Nitro-1-phenylethane was prepared from α-methylbenzyl bromide with sodium nitrite in DMSO.[21] 2-Nitropropane, nitrocyclohexane, and diphenylmethane were commercial materials and used without further purification. *cis*-Stilbene and *trans*-2,3-diphenyl-2-butene were prepared from the corresponding diols.[3] Organic solvents were purified by standard methods and the commercial inorganic materials were used without purification.

Preparations of Vicinal Dinitro Compounds (1). Vicinal dinitro compounds, **1b**—**f**, **1h**, and **1i** were prepared according to the method of Dornow *et al.*[8] Each product **1b**—**f** showed a sharp singlet at δ 4.2—3.5 (2H, methine protons) and assigned to the *dl* form. *meso*-1,2-Dinitro-1,2-diphenylethane (*meso*-**1b**) was prepared by the reaction of *trans*-**2b** and dinitrogen tetraoxide in benzene.[22]

The synthesis of **1a** has been described.[6] Compound **1g** was synthesized by the reaction of the sodium salt of 1-nitro-1-phenylethane with silver nitrate, and NMR revealed *dl*- and *meso*-**1g**. The isomer ratio was determined as 73:27 by integration of the NMR spectra on the assumptions that the methyl protons of *dl*-**1g**, being *cis* to the vicinal phenyl group, are shielded by the phenyl group and appear at higher field than that of the *meso* isomer. Pure *dl*-**1g** was separated by repeated fractional recrystallization from methanol-water, and the melting point and IR spectrum were identical with those published.[23] The physical properties and analytical data of **1** are summarized in Table 1.

Reactions of Vicinal Dinitro Compounds (1) with Tin(II) Chloride. General Procedure: The following example shows a typical run. A mixture of *meso*- or *dl*-**1b** (2.50 mmol) and tin(II) chloride (10 mmol) was refluxed in ethanol (10 ml) for 0.5 h. After the solvent had been removed *in vacuo*, the residue was triturated with cold 2 M sodium hydroxide (50 ml) and the resulting organic product extracted with benzene. The extract was washed with water, and dried over anhydrous sodium sulfate, and the solvent removed *in vacuo* to give a crude reaction product. The UV and NMR spectra of this product [UV(EtOH) λ_{max} 295, 308, 320 (shoulder) nm; NMR ($CDCl_3$) δ 7.1 (2H, s, -CH=CH-), 7.2—7.6 (10H, m, $2C_6H_5$)] were characteristic of *trans*-**2b** free of the *cis* isomer. Recrystallization from ethanol afforded colorless fine crystals of *trans*-**2b**, mp 122—123 °C (lit,[24] 123—124 °C). The products obtained by the same procedure were 9,9'-bifluorenylidene (**2a**): Mp 182—183 °C (lit,[25] 189—190 °C); *trans*-4,4'-dimethylstilbene (*trans*-**2c**): Mp 179—180 °C (lit,[26] 179—180 °C); *trans*-2,2'-dimethylstilbene (*trans*-**2d**): Mp 80—81 °C (lit,[26] 82.5—83.5 °C); *trans*-2,2'-dichlorostilbene (*trans*-**2e**): Mp 95—96 °C (lit,[27] 96—97.2 °C); *trans*-1,2-di-(1-naphthyl)ethene (*trans*-**2f**): Mp 160—161 °C (lit,[26] 158—159 °C). The 2,3-diphenyl-2-butene (**2g**) obtained was found to be a *ca.* 1:1 mixture of the *cis* and *trans* isomers from the NMR spectra. In the case of the reaction of **1h** and **1i** the starting material was recovered unchanged.

Reaction of dl-*1b with Tin(II) Chloride in Ethanol*: A mixture of *dl*-**1b** (2.50 mmol) and tin(II) chloride (1.80—10.3 mmol) was refluxed in ethanol (10 ml) for 0.5—3 h. The reaction product, after the usual work up procedure, was analyzed by GLPC with diphenylmethane as an internal standard using a Tenax GC column 2 m long (steel tube) at 245 °C (He as a carrier gas). Retension time: *dl*-**1b**, 7 min; diphenylmethane, 23 min; *trans*-**2b**, 56 min.

Reaction of dl-*1b with Tin(II) Chloride in DMF*: A DMF (10 ml) solution containing *dl*-**1b** (2.50 mmol) and tin(II) chloride (10.25 and 11.4 mmol) was stirred at room temperature for 2 h. The solution was poured into cold 2 M sodium hydroxide (100 ml). After the usual work up, the organic extract was submitted for GLPC analysis.

Isomerization of cis-*Stilbene (*cis-**2b**) *during the Reaction.* A mixture of *cis*-**2b** (2.50 mmol) and tin(II) chloride (10 mmol) in ethanol (10 ml) was refluxed for 0.5 h, and analysis of the product was conducted using GLPC and NMR. *cis*-Stilbene was unchanged under the reaction conditions.

The Influence of Dinitrobenzene or Sulfur on the Reaction of **1a** *with Tin(II) Chloride.* A mixture of **1a** (1.25 mmol) and tin(II) chloride (5.0 mmol) was refluxed in ethanol (30 ml) for 0.5 h in the presence of various amounts of an inhibitor. The yields of **2a** were determined spectrophotometrically employing ethanol as a solvent. The various additives did not affect the yield of **2a** (Table 7).

(Received June 3, 1978)

The effect of pressure on the rates of solvolyses of substituted 1-phenylethyl and benzyl chlorides has been investigated in an ethanol–water mixture at 25 °C. The activation volumes have been calculated and the dependence of these values on the number and size of the substituents have been interpreted in terms of the competitive contribution of the steric inhibition of resonance and steric hindrance to solvation in the transition states.

The effect of hydrostatic pressure on the rates of solvolytic displacement reactions have been investigated by many research groups.[1–12] In general, the solvolyses of alkyl halides and arenesulfonates have negative activation volumes ascribable to the electrostriction of solvent molecules by the polar transition states. Attention has also been paid to the substituent dependence of activation volume.[7–12] In most cases, the activation volume was linearly related to the substituent constants, σ^+ and σ^*.[7,8,11] These observations were interpreted in terms of the degree of charge delocalization, taking into account the contribution of electrostrictive volume contraction, *i.e.*, the more the charge delocalizes in the transition state, the less negative the values of activation volume become.[7]

A further characteristic is the rate acceleration of sterically hindered reactions by pressure. It has been said that a more sterically hindered reaction revealed a more negative activation volume.[13,14]

The present investigation concerns the pressure effect on the hydrolysis rates of some substituted 1-phenylethyl and benzyl chlorides in order to elucidate the relationships between steric and pressure effect in solvolytic reactions.

Experimental

The high pressure apparatus has been described elsewhere.[7] The kinetic solvent was ethanol–water (80: 20, v/v) and all reactions were conducted at 25.00±0.02 °C, and followed conductimetrically under pressure. The initial concentration of the kinetic solution was approximately 0.01 mol per liter. Rate constants were calculated by the Guggenheim method[15] or by the first-order rate equation.[16]

Results and Discussion

Solvolyses of the substrates under pressure followed first-order kinetics. In the case of 1-arylethyl chlorides, plots of the logarithm of the rate constants against pressure showed linearity over the range of pressure employed. Accordingly, activation volumes were calculated by the following equation; $RT(\delta \ln k/\delta P)_T = -\Delta V_0^*$, where k is the rate constant and ΔV_0^* is the activation volume at atmospheric pressure and 25 °C. For trialkylbenzyl chlorides, plots of $\ln k$ against pressure revealed curvatures. In these cases the activation volume was calculated assuming the following second-order polynomial equation; $\ln k = a + bP + cP^2$ and the curves fitted using the least-squares method. Since the enthalpies and entropies of activation for the hydrolyses of 1-arylethyl chlorides in 80% ethanol were not available, solvolyses have been conducted at 15.00, 25.00, 35.00, and 45.00±0.01 °C under atmospheric pressure.

For solvolytic reactions, the relationship between steric hindrance and activation volume has not been fully investigated. LeNoble and Shurpic examined the pressure effect on the solvolysis of several sterically hindered cycloalkyl arenesulfonates but unfortunately the difference in the values of the activation volume for hindered and unhindered substrates was small.[4]

TABLE 1. PRESSURE DEPENDENCE OF FIRST-ORDER RATE CONSTANTS FOR THE SOLVOLYSIS OF 1-ARYLETHYL CHLORIDES IN ETHANOL–WATER (80: 20, v/v) AT 25.0 °C

Pressure / kg cm^{-2}	Rate constant/10^{-5} s^{-1} Ar			
	Phenyl	*o*-Tolyl	*p*-Tolyl	2,6-Xylyl
1	1.14	12.8	54.9	26.5
250	1.27	14.9	63.2	30.2
500	1.58	17.6	72.3	34.2
750	1.64	18.6	78.9	38.2
1000	1.87	23.0	85.2	42.5
ΔV_0^* / cm^3/mol	−12.6	−14.1	−11.1	−11.8

The activation volumes for the hydrolyses of 1-arylethyl chlorides are listed in Table 1. The activation volume of the parent 1-phenylethyl chloride was found to be −12.6 cm^3/mol. For 1-(*p*-tolyl)ethyl chloride a rather loose solvation shell might be expected in the transition state where the developing charge is highly delocalized by the resonance effect and hence the activation volume became less negative (−11.4 cm^3/mol). The introduction of one methyl group at the ortho position in the parent chloride showed a rate enhancement of 11 fold, a value lower than expected due to the steric inhibition of resonance (compare to 45 fold by *p*-methyl group). Thus, the activation volume was found to be −14.1 cm^3/mol, more negative than the parent chloride. The volume contraction in this case resulted from a tight transition state solvation shell around the reaction center where some charge localization appears as a result of the steric inhibition of

Table 2. First-order rate constants for the solvolysis of 1-arylethyl chlorides in ethanol–water (80: 20, v/v)

Temperature °C	Rate constant/10^{-5} s^{-1} Ar			
	Phenyl	*o*-Tolyl	*p*-Tolyl	2,6-Xylyl
15.0	—	3.60	15.3	9.00
25.0	1.14	12.1	51.8	25.9
35.0	3.10	43.3	198	98.9
45.0	9.82	—	—	—
$\Delta H^{\ddagger}_{25°C}$ / kcal mol^{-1}	21.3	21.3	21.8	20.5
$\Delta S^{\ddagger}_{25°C}$ / e.u.	−10.2	−4.9	−0.3	−10.2

resonance. This violation of a general understand ing—the more reactive, the less negative,[7,8]—stems from steric reasons.

The additional introduction of the second methyl group at the ortho position revealed a smaller rate enhancement (2 fold); *i.e.* the steric inhibition of resonance operated more strongly making the charge more localized. Consequently, electrostrictive interaction with the solvent molecules should be strong so that a more negative activation volume is expected. However, this was not the case. The observed value was −11.8 cm^3/mol, less negative than that for 1-(*o*-tolyl)-ethyl chloride. A reasonable explanation is that the solvation at the reaction center is strongly restricted by the two ortho substituents and thus the desolvation effect is responsible for the less contracted transition state volume.

Recently, the hydrolyses of 2,4,6-trialkylbenzyl chlorides have been reported,[17] and these chlorides offer a good model to demonstrate sterically hindered solvolysis. As shown in Table 3, the hydrolysis rate of 2,4,6-triisopropylbenzyl chloride was somewhat smaller than that of 2,4,6-trimethylbenzyl chloride. The reason of this rate retardation is complex: the possible operation of steric inhibition of resonance, decreasing hyperconjugative effect, and increasing inductive effect. Considering the bulkiness of the isopropyl groups, the steric effect may predominate. The value of the activation volume for the triisopropyl compound was found as −18.4 cm^3/mol, a value more negative than that for the trimethyl compound (−17.3 cm^3/mol). Again, sterically inhibited resonance is associated with a more negative activation volume. The reactivity of tri-*t*-butylbenzyl chloride was unexpectedly high as shown in Table 3. The presence of steric acceleration in this solvolysis is highly possible,[15] and the value of the activation entropy implies the existence of steric hindrance to solvation. The examination of solvolysis under pressure gave an activation volume of −15.7 cm^3/mol. Thus, as in the case of 1-(2,6-xylyl)ethyl chloride, the presence of bulky substituents near the reaction center results in a less negative activation volume. This observation should be strong evidence for the large steric hindrance by substituents to solvation.

Table 3. Pressure dependence of first-order rate constants for the solvolysis of trialkylbenzyl chlorides in ethanol–water (80: 20, v/v) at 25.0 °C

Pressure bar	Rate constant/10^{-5} s^{-1}		
	2,4,6-Trimethyl-	2,4,6-Triisopropyl-	2,4,6-Tri-*t*-butyl-
1	3.61	0.996	19.8
250	4.29	1.16	24.2
500	5.12	1.42	26.4
750	5.70	1.61	29.7
1000	6.83	1.87	32.8
1250	7.54	2.25	35.7
1500	8.45	2.50	37.3
$\Delta V^{\ddagger}_{0}$ / cm^3 mol^{-1}	−17.3	−18.4	−15.7
$\Delta S^{\ddagger}_{25°C}$ [a] / e.u.	−11.0	−10.4	+0.3

a) See Ref. 17.

Electrostriction is the phenomenon where a strong electrostatic interaction is exerted between a highly polar species and solvent molecules, and consequently the entropy of the system in general decreases. Actually in some reactions which have large negative activation volumes, the activation entropies are large and negative.[1] In some instances, an approximate proportionality between activation volume and activation entropy has been observed.[7] In the present reactions, however, Tables 2 and 3 show that there is no correlation between these two activation parameters.

In conslusion, it appears that the steric inhibition of resonance results in a more negative activation volume. However, with bulkier substituents the steric hindrance to solvation becomes predominant, and consequently a less negative activation volume is observed.

The present work has been supported in part by a Grant-in-Aid for Scientific Research (247021, 1977) from the Ministry of Education and Grants for Fundamental Research in Chemistry (1976).

The Beckmann Rearrangement in Concentrated Sulfuric Acid. Studies by Means of NMR and Kinetic Isotope Effect

Seung-Geon KIM,† Takeo KAWAKAMI, Takashi ANDO,* and Yasuhide YUKAWA

The Institute of Scientific and Industrial Research, Osaka University, Yamadakami, Suita, Osaka 565

(Received June 14, 1978)

The mechanism of the Beckmann rearrangement of acetophenone (a) and 1-phenyl-2-propanone (b) oximes in concd sulfuric acid was elucidated by means of NMR spectroscopy and the carbon-14 kinetic isotope effect. For (a), the postulated reactive species acetophenone oxime hydrogensulfate was detected, the absence of hydrolysis of the oxime during the course of the reaction being verified. Positive carbon-14 kinetic isotope effect at the phenyl-1, $k^{12}/k^{14}=1.026$ at 40 °C and 1.019 ± 0.005 at 60 °C, confirmed a definite change in bonding of the phenyl-1 carbon in the transition state of the reaction. Concertedness of the rearrangement was thus established. For (b), sulfonation of the benzene ring prior to the rearrangement was observed, kinetic isotope effect study being found to be useless.

The Beckmann rearrangement, the reaction of ketoximes to give amides by the action of many kinds of acidic reagents, has been extensively studied for many years.[1,2] Stereochemical studies showed that the reaction is an intramolecular trans rearrangement. The kinetics of the reaction of *O*-picryl ethers of substituted benzophenone[3] and acetophenone oximes[4] in organic solvents revealed the nucleophilic nature of the rearrangement; electron-donating groups accelerate the reaction. However, the actual rearranging species are still not clear in many cases. Concertedness of the reaction has also not been verified completely. Gregory *et al.* reported a kinetic study on the rearrangement of substituted acetophenone oximes in sulfuric acid.[5] They proposed that the reactive species in concd sulfuric acid (>70%) is an oxime hydrogensulfate and that the transition state has a phenonium ion-like structure in which the leaving hydrogensulfate ion is still partially bonded to the nitrogen atom. This mechanism is substantially similar to the one postulated by Huisgen *et al.*[4] for the rearrangement of acetophenone oxime *O*-picryl ethers in 1,4-dichlorobutane.

On the other hand, studies on kinetic isotope effects give the most decisive information on the structure of transition state. A study on the Beckmann rearrangement along these lines was reported in the reaction of acetophenone and *anti*-1-phenyl-2-propanone oximes labeled with carbon-14 in concd sulfuric acid.[6] However, reverse isotope effects in both cases of acetophenone-*phenyl*-1-^{14}C oxime ($k^{12}/k^{14}=0.893$) and *anti*-1-phenyl-2-propanone-1-^{14}C oxime ($k^{12}/k^{14}=0.951$) were disproved by Glover and Raaen.[7] They claimed that acetophenone oxime is partially hydrolyzed to acetophenone during the course of the reaction, and that kinetic isotope effect study is meaningless under these conditions.

In this paper, evidence for the absence of hydrolysis under the reaction conditions is presented.[8] The mechanism of the rearrangement is discussed using the revised data of carbon-14 kinetic isotope effects.

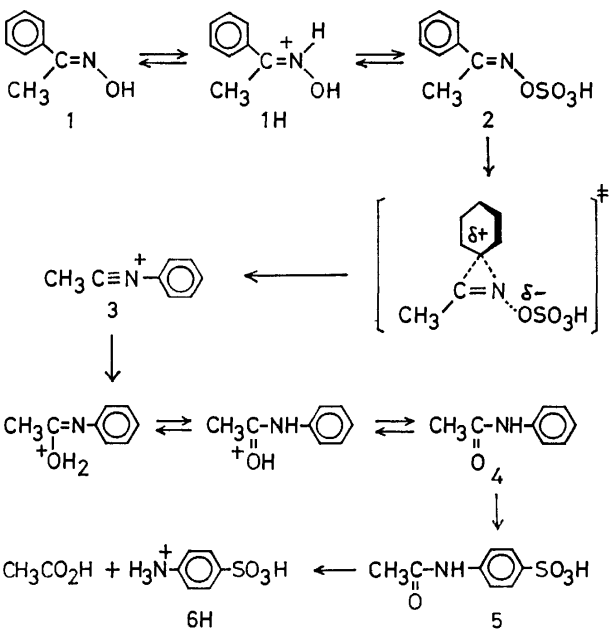
Results and Discussion

NMR Study. When a solution of acetophenone oxime (**1**) in 99.0% sulfuric acid (210 mg in 6 ml) was placed in a NMR probe preheated at 60 °C, the first change observed was the appearance of a new methyl signal at 3.17 ppm from tetramethylsilane as an external standard, together with that of the oxime at 2.88 ppm (Figs. 1a and b). The signal at 3.17 ppm was neither one of the methyl signals of acetanilide (**4**) nor that of acetophenone (**7**); the spectrum of **4** taken for comparison showed the methyl signals at 2.70 and 2.38 ppm in the same solvent (Fig. 1i). As the reaction proceeded, the signals of the rearranged product **4** appeared as expected but decreased again (Figs. 1c, d, and e). The new signals taking the place of those of **4** had an aromatic AA'BB' pattern (Fig. 1f), which was identified as that of 4-acetylaminobenzenesulfonic acid (**5**) by comparison with the spectrum of the authentic sample (Fig. 1j). It was not the final product, however, slow hydrolysis of **5** to acetic acid and 4-aminobenzenesulfonic acid (**6**)



Scheme 1.

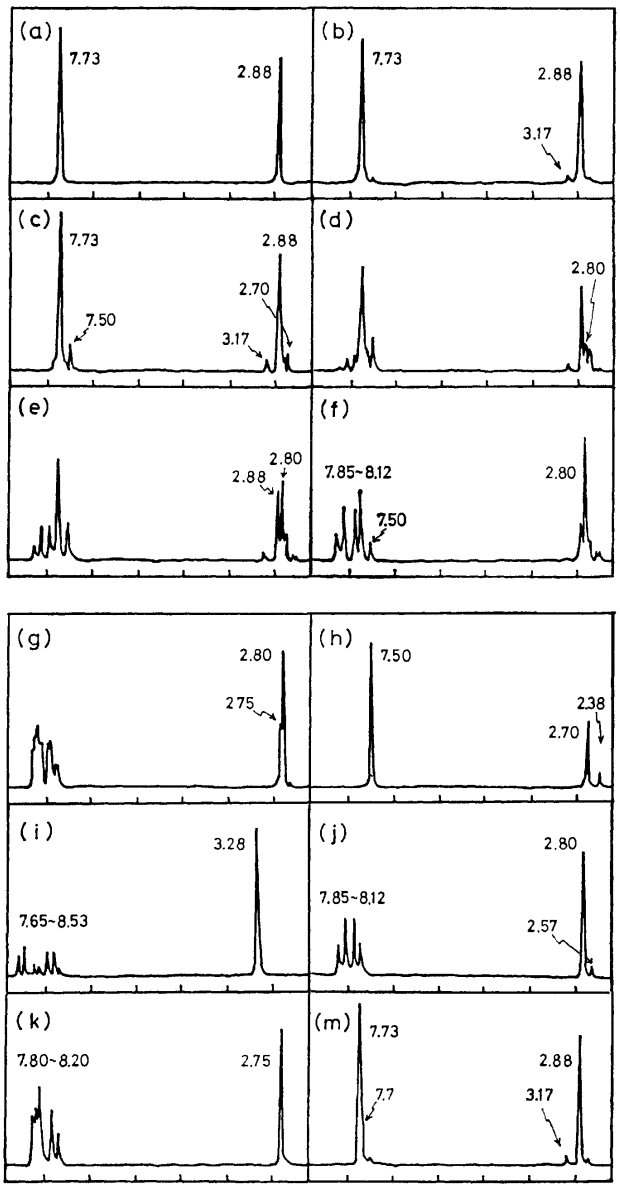


Fig. 1. NMR spectra of the reaction of acetophenone oxime (**1**) in 99.0% sulfuric acid at 60 °C and of reference compounds. (a) Acetophenone oxime (**1**); (b) after 2 min; (c) at 20% reaction; (d) at 40% reaction; (e) at 60% reaction; (f) at 80% reaction; (g) at "infinity"; (h) acetanilide (**4**); (i) acetophenone (**7**); (j) 4-acetylaminobenzenesulfonic acid (**5**); (k) 4-aminobenzenesulfonic acid (**6**) and acetic acid; (m) acetophenone oxime hydrogensulfate (**2**). ppm values from external tetramethylsilane are cited.

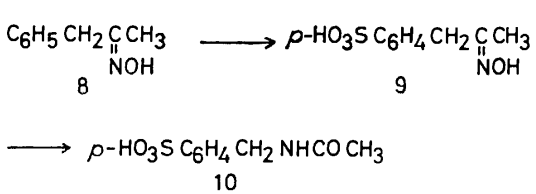
being observed later (Figs. 1g and k). The observations lead to a mechanistic scheme (Scheme 1) similar to that of Gregory *et al.*[5]

The structure of the species showing a methyl resonance at 3.17 ppm should be clarified. Gregory *et al.* also detected intermediates spectroscopically in the rearrangement of the oximes of 2-bromo-, 2-iodo-, 2-methyl-, and 2,4,6-trimethylbenzophenone, and 5,6,7,8,-9,10-hexahydrobenzocyclooctene-5-one. From kinetic and spectroscopic evidences, they concluded that the structure of the intermediates should be *N*-arylnitrilium ions. The chemical shifts of the α-methyl groups of these ions were reported to be 3.65—3.85 ppm, which are distinct from 3.17 ppm we observed. The difference of 0.5—0.7 ppm is too large to be attributed to the substituent effect. The species which shows methyl resonance at 3.17 ppm thus would not be *N*-phenylnitrilium ion (**3**). For the sake of comparison, acetophenone oxime hydrogensulfate (**2**) was prepared[9] and dissolved in concd sulfuric acid. The spectrum obtained was similar to that of the reaction solution at an early stage (Fig. 1m); a small methyl signal at 3.17 and a large one at 2.88 ppm, indicating that most of **2** was hydrolyzed to the original oxime in the solution. The intensity ratio of the two peaks remained constant at *ca.* 1 : 10 until 60% of the reaction was completed, after which the peak at 3.17 ppm was too small to be measured accurately. Kinetic treatment of NMR intensities of these methyl signals gave a linear plot with $k=(2.0\pm 0.1)\times 10^{-4}\ s^{-1}$ when the compound showing an absorption at 3.17 ppm was regarded as a species before the rearrangement step. The rate constant agrees fairly well with the value obtained by the gravimetric method, $k=(1.90\pm 0.01)\times 10^{-4}\ s^{-1}$, under the same conditions (*vide infra*). These results indicate that the observed species is acetophenone oxime hydrogensulfate (**2**), which has been postulated to be the reactive species of the rearrangement in concd sulfuric acid.[5]

Throughout the reaction, no signal due to acetophenone (**7**) was detected at all. Furthermore, the reaction solution after 40 h at 60 °C was negative to the 2,4-dinitrophenylhydrazine test. As acetophenone was confirmed to be stable under the reaction conditions, the results prove that acetophenone oxime is not hydrolyzed in 99% sulfuric acid. It is in line with the observations by Gregory *et al.*, who studied the kinetics of the hydrolysis of acetophenone oxime in sulfuric acid of concentration less than 70%.[5,10] Glover and Raaen gave no experimental detail; they might have mistaken the hydrolysis during isolation for that during reaction.[7]

A similar experiment on *anti*-1-phenyl-2-propanone oxime (**8**) at 50 °C showed that the first stage of the reaction in 99.0% sulfuric acid is rapid sulfonation of the benzene ring mainly at the para-position to give 4-(2-hydroxyiminopropyl)benzenesulfonic acid (**9**). The sulfonated benzyl group in **9** rearranges very slowly to 4-(acetylaminomethyl)benzenesulfonic acid (**10**) in the next stage (Scheme 2). Other minor peaks were observed at each stage of the reaction, most of which may be attributed to the presence of isomers other than the para sulfonated ones. Since **9** gave no precipitate of the 2,4-dinitrophenylhydrazone, the gravimetric method followed sulfonation and not rearrangement. Kinetic isotope effect study has no meaning in this case.[6,7]

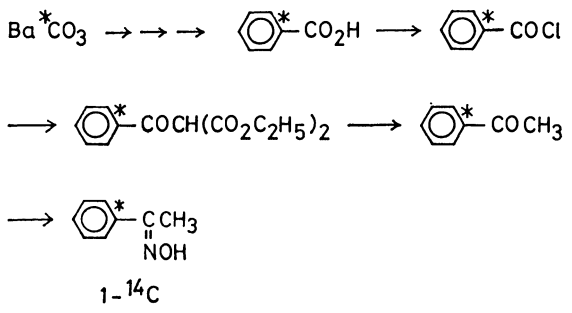


Scheme 2.

Differences in the observations by Gregory *et al.*[5] and by us are interesting; they detected *N*-arylnitrilium ions by UV and NMR and we observed the oxime hydrogensulfate by NMR. However, the two observations do not seem to be in conflict with each other. They recognized that ortho substituents were necessary for the detection of *N*-arylnitrilium ions. On the contrary, oxime hydrogensulfates should have no characteristic absorptions differing from those of oximes in the UV region. We have obtained information that the esterification equilibrium of oximes with sulfuric acid seems to be very sensitive to the concentration of sulfuric acid and the structure of the oximes. NMR spectroscopy is known to be less effective for detecting a small quantity of species present in solution.

Isotope Effect Study. Since the absence of hydrolysis of acetophenone oxime (**1**) under the reaction conditions was established, carbon-14 isotope effects were reexamined. In a previous work, the radioactivity was measured by G. M. counting of barium carbonate disks prepared by wet oxidation of the 2,4-dinitrophenylhydrazone (**11**) derived from the unreacted acetophenone oxime.[6] This is a well-established but old-fashioned method and said to be "the least sensitive and the least precise" one.[11a] In the present reinvestigation, the carbon dioxide gas prepared by wet oxidation of **11** was assayed for radioactivity by the ionization-chamber counting method. The ionization current was measured with a vibrating-reed electrometer by the rate-of-charge method.[11b] By use of this method, the accuracy of the measured radioactivity was much improved.

Acetophenone-*phenyl*-1-^{14}C (**7**-^{14}C) was prepared from benzoyl-*phenyl*-1-^{14}C chloride.[12] Benzoic-*phenyl*-1-^{14}C acid was prepared by the multi-step synthesis from barium carbonate-^{14}C.[13] The overall yield of acetophenone-*phenyl*-1-^{14}C oxime (**1**-^{14}C) from barium carbonate-^{14}C was *ca.* 4.5% (Scheme 3).



Scheme 3.

In order to measure the rates of rearrangement by the gravimetric method, quantitative isolation of the unreacted **1** as **11** was confirmed under the conditions similar to those applied in the reaction. Yield of **11** were 100.5±0.5% for 40—120 mg of **1**.

The rearrangement of **1** in 99.0% sulfuric acid at 0.25 M concentration was followed at 40 and 60 °C. Aliquots of the reaction solution were pipetted out at appropriate time intervals and poured into 0.4% solutions of 2,4-dinitrophenylhydrazine in 2 M hydrochloric acid. First-order rate plots by the gravimetric method using **11** gave straight lines throughout 85% reaction with correlation coefficients greater than 0.9996. The rate constants obtained were $(1.47\pm0.03)\times10^{-5}$ s^{-1} at 40.00±0.01 °C (average of three runs) and $(1.90\pm0.01)\times10^{-4}$ s^{-1} at 60.00±0.01 °C (average of four runs).

The reaction of the labeled compound (**1**-^{14}C) was carried out in the same way. The rate constants were $(1.42\pm0.01)\times10^{-5}$ s^{-1} and $(1.85\pm0.02)\times10^{-4}$ s^{-1} at 40 and 60 °C, respectively. The radioactivity of the purified samples of **11**-^{14}C was assayed with a Nuclear-Chicago Model 6000 Dynacon electrometer system by the rate-of-charge method using a Model T4 interval timer. Oxidation of the samples to carbon dioxide was performed with a Model GW-1 glassware system by the modified Van Slyke-Folch wet combustion method.[14]

Table 1. Reaction percentage and specific radioactivities in the rearrangement of **1**-^{14}C at 40.00±0.01 °C

No.	t/min	x[a]/%	n[b]	A_x[c]/mCi mol^{-1}
1	0	0	5	1.397
2	240	18.2	2	1.405
3	420	30.4	2	1.410
4	600	40.7	2	1.414
5	780	49.3	2	1.418
6	1020	58.6	2	1.430
7	1320	67.7	2	1.436
8	1740	77.0	2	1.450

a) Fraction of reaction. b) Number of measurements. c) Specific radioactivity.

Table 2. Reaction percentage and specific radioactivities in the rearrangement of **1**-^{14}C at 60.00±0.01 °C

No.	t/min	x[a]/%	n[b]	A_x[c]/mCi mol^{-1}
1	0	0	8	1.300
2	21	18.7	3	1.310
3	31	27.8	3	1.307
4	44	38.2	2	1.307
5	60	48.7	2	1.311
6	78	58.5	3	1.311
7	103	68.3	3	1.332
8	141.5	78.6	2	1.326

a) Fraction of reaction. b) Number of measurements. c) Specific radioactivity.

The results obtained are given in Tables 1 and 2. The specific radioactivities cited are the mean values of two to eight measurements of oxidation analysis for each sample with standard deviations within 0.5%.[15] Kinetic isotope effects were calculated by the linear regression method by means of

$$\log A_x = \log A_0 - [1-(k^{14}/k^{12})]\log(1-x), \quad (1)$$

where x is the fraction of reaction and A_0 and A_x are the specific activities of **11**-^{14}C at $x=0$ and $x=x$, respectively. The calculated isotope effects are given by

$$k^{12}/k^{14} = 1.026 \pm 0.001 \ (40\,^{\circ}C)$$

and

Table 3. Reaction percentage and specific radioactivities in the rearrangement of 1-^{14}C at 59.99±0.01 °C

No.	t/min	$x^{a)}$/%	$n^{b)}$	$A_x^{c)}$/mCi mol^{-1}
1	0	0	1	1.582
2	29	28.5	1	1.594
3	55	48.1	1	1.595
4	80	62.2	1	1.635
5	105	71.8	1	1.655
6	130.5	79.3	1	1.631
7	160	85.4	1	1.647

a) Fraction of reaction. b) Number of measurements. c) Specific radioactivity.

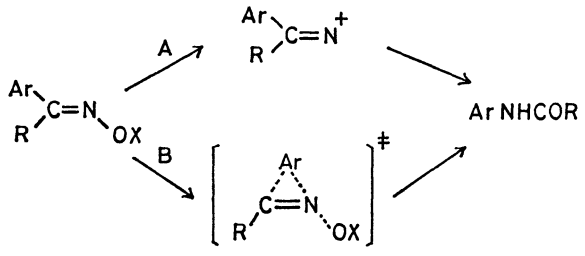
$$k^{12}/k^{14} = 1.014 \pm 0.003 \quad (60\,°C).$$

In order to make the results more reliable, another series of experiment at 60 °C was carried out using another lot of materials. The results are given in Table 3. The calculated isotope effect is given by

$$k^{12}/k^{14} = 1.023 \pm 0.006 \quad (60\,°C).$$

Calculation using the data reported by Glover and Raaen[7] by means of Eq. 1 gave the phenyl-1-^{14}C isotope effect of 1.028±0.006 at 62±1 °C, although the data are scanty. From the results of the present reinvestigation and of Glover and Raaen, all the data reported earlier[6] should have been accompanied by large errors inherent to old techniques and should be retracted.

Carbon-14 kinetic isotope effects of 1.4—2.6% are too large to be classified as secondary effects,[17] and should reflect some change in the bonding of the phenyl-1 carbon in the rate-determining transition state of the rearrangement. As has been verified from the tracer study using ^{18}O that the loss of the oxygen function from an oxime occurs in an irreversible step,[5] the present results of kinetic isotope effects are inconsistent with the stepwise mechanism (path A), giving an evidence for the concerted nature (path B) of the rearrangement (Scheme 4).



Scheme 4.

The large positive values of the resonance parameter, r, in the LArSR (linear aromatic substituent-reactivity) relationship (Eq. 2) of the Beckmann rearrangement (r=0.60—0.63) also indicate the additional conjugation effect to the reaction center in the transition state.[4,18-20]

$$\log k/k_0 = \rho(\sigma^\circ + r\Delta\bar{\sigma}_R^+) \qquad (2)$$

Thus, the mechanism (Scheme 1) has been further ensured.

The fact that the carbon-14 kinetic isotope effect at the phenyl-1 position is normal (positive) should be discussed. Decrease in force constant in the transition state leads in the direction of a normal isotope effect, an increased one in the direction of an inverse effect.[21,22] Bond formation between the phenyl-1 carbon and the nitrogen may cause an increase in bonding of the carbon. Nevertheless, actual observation of the normal effects at the phenyl-1 carbon can be attributed to a great extent to a decrease in bonding as a result of insulation of the carbon from the aromatic conjugation present at the initial state. Inverse carbon isotope effects caused by the appearance of additional bonding of conjugation have been reported in some cases.[23] Weakening of the bond between the phenyl-1 and carbonyl carbons might make some contribution to the phenomenon. Similar phenomena were observed in some other 1,2-nucleophilic rearrangements as well as in solvolysis with neighboring phenyl participation.[20,24,25] The normal temperature dependence, a larger isotope effect at a lower temperature, though not obvious because of an experimental error, is also considered to be an indication of a decrease in bonding at the transition state. In the case of bond rupture the temperature-dependent factor of the kinetic isotope effect is considered to increase from the higher temperature limit of unity with lowering in temperature.[25,26]

No reexamination was carried out on the kinetic isotope effect at the carbonyl carbon of acetophenone oxime.[6] However, treatment of the data of Glover and Raaen with use of Eq. 1 gave a normal isotope effect at this carbon, k^{12}/k^{14}=1.028±0.004, at 62 °C.[7] This indicates that bonding of this carbon also changes at the transition state of the rearrangement.[25] On the other hand, calculation of the isotope effects using the data of Glover and Raaen on the reaction of *anti*-1-phenyl-2-propanone oxime (**8**) shows that no effects are observed at both the methylene (k^{12}/k^{14}=1.002±0.002) and carbonyl (k^{12}/k^{14}=1.004±0.004) carbons. This is quite natural since the reaction that followed was actually the sulfonation of the benzene ring, and no bonding change at these two carbons is expected for the reaction.

Experimental

Materials. Acetophenone oxime hydrogensulfate (**2**) was prepared according to the procedure of Pearson and Ball[9] and dried over phosphorus pentaoxide in a vacuum at a low temperature. 4-Acetylaminobenzenesulfonic acid (**5**) was dried for many days in a vacuum at 100 °C before the NMR measurement.[27] *Anti*-1-phenyl-2-propanone oxime (**8**) was prepared according to the procedure of Kotera *et al.*:[28] mp 69.5—70.5 °C. All the compounds except **2** were subjected to elemental analysis, giving satisfactory results. Commercial sulfuric acid (99.0%, Wako guaranteed reagent) was used without further purification.

NMR Monitoring of the Reactions. NMR spectra were recorded on a Varian A-60 spectrometer at 60 MHz with tetramethylsilane as an external standard. All the samples were measured in concentrations of 3—5 (w/v)%. Operating temperature was calibrated using ethylene glycol signals. The NMR data are summarized in Table 4.

a) ppm from external tetramethylsilane.

*Preparation of Acetophenone-*phenyl-*1-*^{14}C *Oxime (1-*^{14}C*).* Benzoic-*phenyl*-1-^{14}*C* acid (4.45 g, 13.6 mCi/mol) was prepared from 7 mCi of barium carbonate-^{14}*C* by the multistep syntheses,[13] radiochemical yield being 7.1%. After dilution with nine times an unlabeled benzoic acid, 15 g of the acid (1.36 mCi/mol) was dissolved in 60 ml of dry ether. After addition of 23 g of thionyl chloride, the mixture was refluxed for 1 h. Benzoyl-*phenyl*-1-^{14}*C* chloride (16.5 g) was isolated by distillation: bp 97—98 °C/30 Torr.

Magnesium ethoxide was prepared from 2.7 g of a magnesium ribbon, 2.5 ml of anhydrous ethanol, and a few drops of carbon tetrachloride in 40 ml of dry ether. Diethyl malonate (17.1 g) in 10 ml each of anhydrous ethanol and ether was added to the above mixture and refluxed until all the magnesium was consumed. The benzoyl-*phenyl*-1-^{14}*C* chloride obtained above was added to this mixture with a small amount of ether and refluxed for 30 min. The reaction mixture was cooled and acidified with 20% sulfuric acid. The ether layer and the ether extract were combined and washed with water, and the solvent was distilled. To the residue was added a mixture of 30 ml of acetic acid, 3.8 ml of concd sulfuric acid, and 30 ml of water, and the mixture was refluxed for several hours until decarboxylation was complete. The reaction mixture was cooled in an ice-bath, made alkaline with 20% sodium hydroxide solution, and extracted with several portions of ether. The ether layer was washed with water and dried with anhydrous sodium sulfate, the solvent being removed. Acetophenone-*phenyl*-1-^{14}*C* (**7**-^{14}*C*: 11.0 g) was obtained by distillation: bp 100.0—101.5 °C/27—28 Torr.

7-^{14}*C* (11.0 g) was treated with 29.7 g of hydroxylamine hydrochloride and 55 g of potassium carbonate in a mixture of 100 ml of water and 500 ml of ethanol in the usual way. Acetophenone-*phenyl*-1-^{14}*C* oxime (**1**-^{14}*C*) obtained (10.8 g) was recrystallized from petroleum ether seven times, when the sample showed a constant radioactivity (1.300±0.003 mCi/mol): mp 60 °C.

Quantitative Isolation of Acetophenone Oxime (1) as the 2,4-Dinitrophenylhydrazone Derivative (11). Forty to 120 mg of **1** was taken in a 150-ml Erlenmeyer flask equipped with a ground glass stopper. Sixty ml of 0.4% 2,4-dinitrophenylhydrazine solution in 2 M hydrochloric acid was added and the resulting solution was kept at 50 °C for 24 h. After addition of 10 ml of distilled water, precipitates of **11** were filtered while warm with a glass filtering crucible, washed thoroughly with warm 2 M hydrochloric acid and then with warm distilled water. The crucible was dried in an oven at 85 °C for 24 h, cooled in a desiccator, and weighed. For repeated measurements, yields of **11** were 100.5±0.5% of the theoretical values.

Gravimetric Rate Measurement. Concd sulfuric acid (*ca.* 30 ml) was added to a weighed sample of **1** (*ca.* 1 g) and weighed. After being thoroughly shaken, the mixture was transferred to a reaction flask which had been heated in a thermostated bath. Aliquots of the solution were pipetted out at appropriate time intervals and poured rapidly into 0.4% solutions of 2,4-dinitrophenylhydrazine in 2 M hydrochloric acid. The quantities of the solutions pipetted out were determined by weighing the flasks before and after the addition. Precipitates of **11** were treated as mentioned above. The fractions of reaction were thus calculated from the observed and theoretical weights of **11**.

Radioactivity Measurement. Samples of the purified **11**-^{14}*C* (7—10 mg) were oxidized to carbon dioxide by the modified Van Slyke-Folch wet combustion method with a Nuclear-Chicago Model GW-1 glassware system. The radioactivities of the carbon dioxide gases collected in an ionization chamber were measured with a Nuclear-Chicago Model 6000 Dynacon electrometer system by the rate-of-charge method using a Model T4 interval timer. The samples were assayed after recrystallization three or four times from ethyl acetate–chloroform (2: 1). For the samples obtained at several stages of the reaction, it was confirmed that further recrystallization does not change the radioactivities beyond experimental errors (±0.5%).

15) Measurements of the radioactivities were performed in 1965 and 1966. At present we can measure the activities as accurately as with standard deviations of 0.1—0.3% by use of the dry combustion method and with a new electrometer system. Thus, the accuracy of the kinetic isotope effect has been improved.[16] The level of inaccuracy in the present investigation does not affect the conclusion of this paper.

An ESR Study of Polysubstituted *N*-Aryl-*N*-(arylthio)aminyls[1]

Yozo MIURA,* Yosuke KATSURA, and Masayoshi KINOSHITA

Department of Applied Chemistry, Faculty of Engineering, Osaka City University, Sumiyoshi-ku, Osaka 558

(Received June 26, 1978)

An ESR spectroscopic investigation of *N*-(2,4,6-trimethyl-, trimethoxy-, triisopropyl-, and tri-*t*-butylphenyl)-*N*-(arylthio)aminyls (**2**), ArṄSAr′, is described. The aminyls are generated from the corresponding *N*-arylarenesulfenamides, ArNHSAr′, by hydrogen-abstraction, the a_N values of which are 9.10—12.30 G and the *g*-values 2.0056—2.0067. On the basis of the ESR parameters the conformations for **2** have been discussed. Decay kinetic studies on **2** were conducted in benzene, and **2** were found to be persistent aminyls—particularly the *t*-butyl-substituted aminyl, *N*-(2,4,6-tri-*t*-butylphenyl)-*N*-(4-nitrophenylthio)aminyl.

A new family of nitrogen-centered free radicals has been investigated in which one or two divalent sulfur atoms are adjacent to the central nitrogens.[2] In previous ESR studies on *N*-aryl-*N*-(arylthio)aminyls,[3,4] ArṄSAr′, it was established that, in the aminyls, the unpaired electron resides predominantly on the central nitrogen and the *N*-phenyl ring.

The present investigation was directed toward obtaining and isolating persistent *N*-aryl-*N*-(arylthio)-aminyls and for this purpose, several sterically protected thioaminyls have been prepared. In this report the ESR study on *N*-(2,4,6-trimethyl-, trimethoxy-, triisopropyl-, and tri-*t*-butylphenyl)-*N*-(arylthio)aminyls (**2**) is described.

Results and Discussion

Generation of Aminyls. The generation of **2** was achieved through hydrogen-abstraction from the appropriate *N*-arylarenesulfenamides (**1**, Eq. 2). Sulfenamides **1a**—**g** were obtained by the reaction of sulfenyl chlorides with two equivalents of anilines or one equivalent of anilines in the presence of triethylamine (Eq. 1). Sulfenamide **1h** was unobtainable by these procedures.

The hydrogen-abstraction of **1** was performed by two procedures: the photolysis of **1** in the presence of di-*t*-butyl peroxide,[5] and the treatment of **1** with lead dioxide in the presence of potassium carbonate. The ESR parameters obtained for **2** are listed in Table 1, and a typical ESR spectrum is illustrated in Fig. 1.

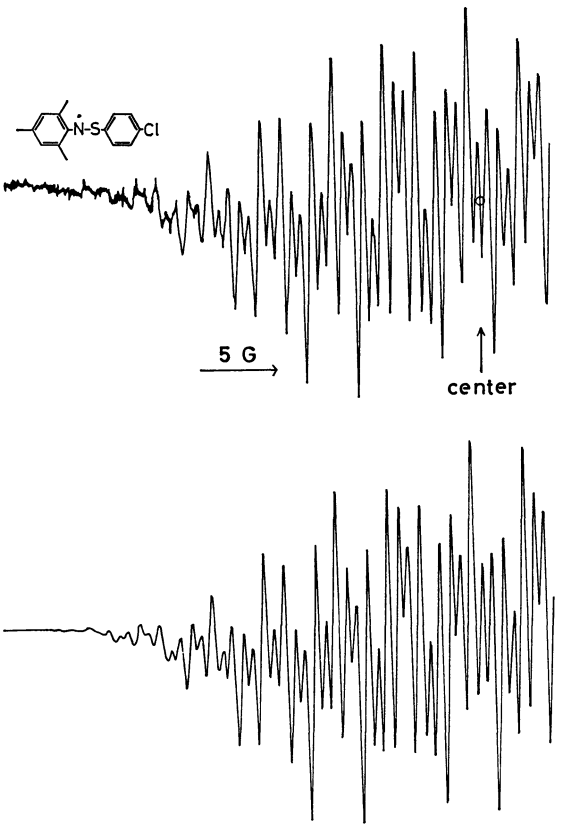

Fig. 1. Experimental ESR spectrum (low-field half) of **2a** in benzene (upper), and computer simulation, using Lorentzian line shapes and a line width of 0.52 G (lower).

Although **1h** could not be isolated as described above, the residue, resulting from filtration and subsequent concentration of the reaction mixture, gave rise to a strong 1:1:1 triplet ESR signal (12.27 G). The a_N value is in good agreement with that for the structurally similar aminyl, **2g** (12.30 G), and is quite different from that for the corresponding nitroxide, **3** (a_N: 16.40

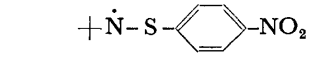
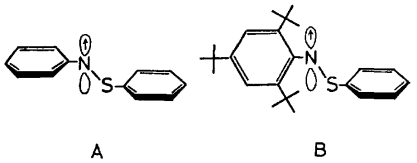
G, *g*-value: 2.0068 in benzene).[6] On the basis of these results, the species has been assigned as **2h**.

In the oxidation of the sulfenamides with lead dioxide, some of them gave purple or brown colored solutions.[7] For example, a benzene solution of **1a** immediately turned purple. Similarly, a solution of **1f** which was pale yellow turned reddish brown, and the pale yellow solution of **1g** turned dark brown. The colorled solutions gave rise to a strong ESR signal due to **2**. In the cases of **2a** and **2f**, the color faded in 10—20 min, and the resulting colorless (**2a**) or light orange solution (**2f**) no longer gave rise to a strong ESR signal. The brown color observed for **2g** persisted for several hours and, under deoxygenated conditions, persisted for several weeks without any apparent fading.

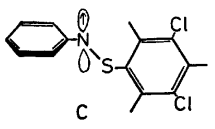
ESR Parameters. As may be seen from Table 1, the a_N values for **2a**—**f** are in the range 9.10—9.84 G, and the *g*-values in the range 2.0056—2.0057, being close to the value for the unsubstituted aminyl, **2i**. Thus, in these aminyls, the unpaired electron resides predominantly on the central nitrogen and the *N*-phenyl ring, as well as in **2i**. The a_N values for the *t*-butyl-substituted aminyls, **2g** and **2h**, are in the range 12.27—12.30 G, being 2.5—3.2 G larger than for the other aminyls, they are rather close to that (11.89 G) observed for *N*-(4-nitrophenylthio)-*t*-butylaminyl (**4**).[8] The



4



A B

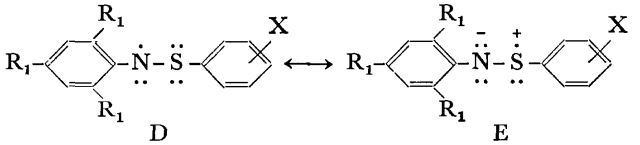


C

Fig. 2.

relatively large a_N values observed for **2g** and **2h** may be explained as follows: in **2i**, the *N*-phenyl ring is probably perpendicular or nearly perpendicular with respect to the nitrogen $2p_z$ orbital containing the unpaired electron (conformation A). The aminyls **2g** and **2h** cannot adopt such a conformation because of the steric repulsion between the two *ortho-t*-butyl groups and the sulfur atom (and/or the ortho-protons in the *S*-pheny ring), as shown by a molecular model (Stuart model). Thus, the steric effect results in the *N*-phenyl ring twisting to be parallel or nearly parallel with respect to the nitrogen $2p_z$ orbital (conformation B). Therefore, in **2g** and **2h**, the unpaired electron is not effectively delocalized onto the *N*-phenyl ring, differing from the other aminyls, leading to an increase in the magnitude of the a_N values. The *g*-values (2.0066—2.0067) observed for **2g** and **2h** are larger than those for the other aminyls (2.0056—2.0059), indicating that the spin density on the sulfur atoms in **2g** and **2h** is greater compared with the other aminyls.[9] Thus, the steric situation assumed for **2g** and **2h** may be also supported by the relatively large *g*-values.

The a_N values for **2a** and **2b** are smaller by 0.3—0.5 G compared with that for **2i**, suggesting that the aminyls adopt conformation A, despite the introduction of methyl or methoxyl groups into the ortho-positions of the *N*-phenyl ring. In a previous report,[10] *N*-aryl-*N*-(phenylthio)aminyls, in terms of Walter's criteria, were classified as class *S*, *i.e.* the magnitude of the a_N values is determined predominantly by the degree of delocalization of the unpaired electron onto the substituents in the *N*-phenyl rings, and the polar effect is of secondary importance (Scheme 1). Therefore, the reduction in the magnitude of the a_N values observed for **2a** and **2b** is interpreted in terms of the delocalization of the unpaired electron onto the methyl and methoxyl groups.



D E

Scheme 1.

The a_N value for **2f** is slightly larger (0.2 G) compared with that for **2i**, suggesting that the *N*-phenyl ring in **2f** is twisted to some extent due to the steric repulsion from the relatively large isopropyl groups in the *N*-phenyl ring.

The a_N values for **2c**, **2d**, and **2e** are larger by 0.18—0.26 G compared with those for the aminyls, **2a**, **2b**, and **2i**. These increases are interpreted in two ways: a) increase in the relative importance of the resonance form D caused by the inductive effect of the substituents in the *S*-phenyl rings, and b) twisting of the *S*-phenyl rings caused by the steric repulsion from the *ortho*-methyl groups in the *S*-phenyl rings. With respect to the inductive effect, the total σ value for the substituents in the *S*-phenyl rings is calculated to be 0.23 ($3\sigma_{p\text{-CH}_3}+2\sigma_{Cl}$),[11] which is identical to the $\sigma_{p\text{-Cl}}$ value. From a comparison of the a_N value for **2k**[12] with that for **2j**,[3] it may be seen that the magnitude of the a_N value for **2k** is little affected by the chlorine atom in the *S*-phenyl ring. Thus, the increases observed for **2c**, **2d**, and **2e** are not due to the inductive effect, but should be interpreted in terms of the twisting of the *S*-phenyl rings (conformation C). Since the spin density on the *S*-phenyl rings of these aminyls is very small, as can be seen from the a_H values due to the *S*-phenyl aromatic protons (0.27—0.84 G), the increase in magnitude of the a_N values caused by the twisting of the *S*-phenyl rings, is not as large as in **2g** and **2h**.

2j: a_N=9.55 G

2k: a_N=9.52 G

Decay Kinetics of 2. Decay kinetic studies on **2a**, **2c**, and **2g** were conducted at 19 °C in the dark. A benzene solution containing **1** and di-*t*-butyl peroxide was irradiated with a high-pressure mercury lamp, and the decay rates were followed by measuring the ESR signal intensities. The results are illustrated in Fig. 3. The aminyl **2a** decayed initially at a relatively fast rate which was followed by a slower decay, and persisted for several weeks. Similarly, the aminyl **2c** decayed rapidly for *ca.* 500 min after which the decay slowed down, and persisted for several weeks. The aminyl **2g** decayed very little over several days, even at a relatively high radical concentration. The unsubstituted aminyl, **2i**, on the contrary, decayed immediately and completely upon interruption of the photolysis.[3] From the decay kinetic studies of the aminyls, it has been demonstrated that the polysubstituted aminyls are well protected by the methyl and *t*-butyl groups, **2g** is in particular very interesting.

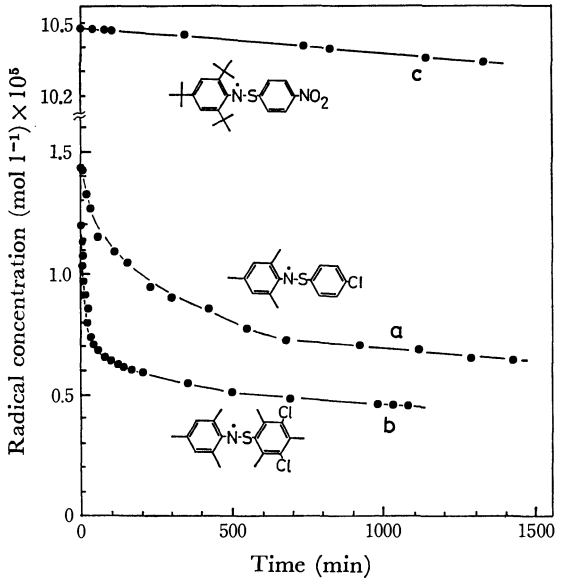


Fig. 3. Decay plots of **2a** (a), **2c** (b), and **2g** (c) in deoxygenated benzene at 19 °C.

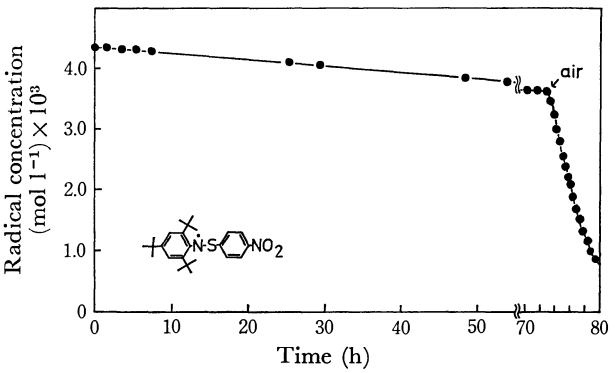

Fig. 4. Decay plots of **2g** in benzene at 19 °C in the absence and presence of oxygen.

Generation of 2g with Lead Dioxide. In order to isolate **2g**, it was generated by oxidation of **1g** with lead dioxide. The procedure was as follows: **1g** (0.10 mmol) was stirred in benzene for 5—15 min in the presence of lead dioxide and potassium carbonate, providing a dark brown solution containing **2g** in a concentration of 4.3 mmol l^{-1}. This value corresponds to 43% based on the **1g** used. On standing for 3 days in a deoxygenated ESR tube, the radical concentration in the solution remained at 3.6 mmol l^{-1} (Fig. 4), indicating little decomposition of **2g**. On the introduction of air, however, the aminyl began to decompose at a relatively fast rate, indicating that **2g** reacts with oxygen. In the range 0.13 to 3.60 mmol l^{-1} of **2g**, the reaction rate with oxygen was measured in benzene saturated with air,[13] and it was found that **2g** decayed with a pseudo first-order kinetics ($k=7.2\times10^{-5}$ s^{-1} at 19 °C).

For the other aminyls, the radical concentrations obtained by oxidation of **1** with lead dioxide were no more than 1% based on the **1** used.

In order to isolate **2g**, benzene was removed from the solution by freeze-drying, affording a dark brown crystalline powder in an almost quantitative yield. The powder gave a strong broad ESR signal (g=2.0068, ΔH=14.7 G) and contained **2g** in a concentration of 40 wt %. When the powder was dissolved in benzene, the resulting brown solution containing **2g** in a concent-

ration of 3.9 mmol l^{-1} (39%), indicating that **2g** was little decomposed during the operation of freeze-drying. The aminyl in the solid was also little decomposed under deoxygenated conditions for one week. On contact with air, however, the solid **2g** was decomposed gradually ($\tau_{1/2}$: half a day) and gave orange decomposition products. From these results, it has been established that **2g** is very stable, even in the solid. The aminyl however has not been isolated as a pure crystal.

Experimental

All melting points are uncorrected. IR spectra were conducted on a JASCO Model IR-G spectrometer. Visible spectra were recorded with a Hitachi recording spectrometer Model ESP-3T and NMR spectra with a Hitachi-Perkin Elmer R-20 spectrometer using TMS as an internal standard.

4-Nitro-[14] and 2,4,6-trimethylbenzenethiols,[15] 2,4,6-trimethoxy-,[16] 2,4,6-triisopropyl-,[17,18] 2,4,6-tri-*t*-butylanilines,[19] and 2,4,6-tri-*t*-butylnitrosobenzene[20] were prepared by reported methods. 2,4,6-Trimethylaniline, 4-chlorobenzenethiol, and di-*t*-butyl peroxide were obtained commercially and used without further purification.

*N-(2,4,6-Trimethylphenyl)-4-chlorobenzenesulfenamide (**1a**).* 4-Chlorobenzenethiol (6.36 g, 0.044 mol) was treated with chlorine gas in dry chloroform (100 ml) at 0 °C. After removal of the solvent, the resulting crude sulfenyl chloride was dissolved in dry ether (100 ml), and the solution was added dropwise to a stirred solution of 2,4,6-trimethylaniline (13.0 g, 0.096 mol) in dry ether (300 ml) at −30——40 °C. After stirring for 30 min, the reaction mixture was filtered and solvent was evaporated to give colorless needles. Recrystallization from hexane afforded colorless needles (11.1 g, 91%) mp 86—87 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 2.15 (s, *o*-CH_3, 6H), 2.22 (s, *p*-CH_3, 3H), 4.76 (br s, NH, 1H), 6.82 (s, C_6H_2, 2H), and 7.29 (s, C_6H_4, 4H). Found: C, 65.02; H, 5.80; N, 5.14%. Calcd for $C_{15}H_{16}NClS$: C, 64.84; H, 5.82; N, 5.04%.

*N-(2,4,6-Trimethoxyphenyl)-4-chlorobenzenesulfenamide (**1b**).* The 4-chlorobenzenesulfenyl chloride, prepared from 4-chlorobenzenethiol (4.60 g, 0.032 mol) as described above, was dissolved in dry ether (80 ml), and the solution was added dropwise to a stirred solution of 2,4,6-trimethoxyaniline (13.1 g, 0.072 mol) in dry ether (300 ml) at −30——40 °C. After stirring for 30 min, the reaction mixture was filtered, and solvent was evaporated to give a light brown crystalline residue. Recrystallization from hexane afforded light brown needles (6.30 g, 60%) with mp 77—78 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 3.70 (s, *o*-CH_3O, 6H), 3.75 (s, *p*-CH_3O, 3H), 5.14 (br s, NH, 1H), 6.19 (s, C_6H_2, 2H), and 7.28—7.32 (m, C_6H_4, 4H). Found: C, 55.20; H, 4.86; N, 4.36%. Calcd for $C_{15}H_{16}NO_3ClS$: C, 55.29; H, 4.95; N, 4.29%.

*N-(2,4,6-Trimethylphenyl)-3,5-dichloro-2,4,6-trimethylbenzenesulfenamide (**1c**).*[21] 2,4,6-Trimethylbenzenethiol (6.00 g, 0.039 mol) was treated with chlorine gas as described for **1a**. After removal of the solvent, the resulting sulfenyl chloride was dissolved in dry ether (100 ml), and the solution was added dropwise to a stirred solution of 2,4,6-trimethylaniline (11.6 g, 0.086 ml) at −30——40 °C. After stirring for 30 min, the reaction mixture was filtered, and solvent was evaporated to give a dark brown oily residue. Repeated recrystallization from hexane afforded colorless prisms (1.30 g, 9.4%) with mp 130—131 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 2.02 [s, *o*-CH_3(*N*-Ph), 6H], 2.19 [s, *p*-CH_3(*N*-Ph), 3H], 2.48 and 2.50 [s, *o*- and *p*-CH_3 (*S*-Ph), 9H], 4.38 (br s, NH, 1H), and 6.72 (s, C_6H_2, 2H). MS (50 eV), *m/e* 353 (M^+). Found: C, 60.90; H, 5.69; N, 3.74; Cl, 20.06; S, 9.26%. Calcd for $C_{18}H_{21}NCl_2S$: C, 61.01; H, 5.97; N, 3.95; Cl, 20.01; S, 9.05%.

*N-(2,4,6-Trimethoxyphenyl)-3,5-dichloro-2,4,6-trimethylbenzenesulfenamide (**1d**).*[21] The sulfenyl chloride, prepared from 2,4,6-trimethylbenzenethiol (5.00 g, 0.033 mol) as described for **1c**, was dissolved in dry ether (100 ml), and the solution was added dropwise to a stirred solution of 2,4,6-trimethoxyaniline (13.3 g, 0.073 mol) in dry ether (400 ml) at −30——40 °C. After stirring for 30 min, the reaction mixture was filtered, and solvent was evaporated to give a dark brown oily residue. Repeated recrystallization from hexane afforded light brown prisms (0.53 g, 4%) with mp 119—120 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 2.45 (s, *p*-CH_3, 3H), 2.54 (s, *o*-CH_3, 6H), 3.58 (s, *o*-OCH_3, 6H), 3.72 (s, *p*-OCH_3, 3H), 4.99 (br s, NH, 1H), and 5.98 (s, C_6H_2, 2H). Found: C, 54.22; H, 5.12; N, 3.55%. Calcd for $C_{18}H_{21}NO_3Cl_2S$: C, 53.73; H, 5.28; N, 3.48%.

*N-Phenyl-3,5-dichloro-2,4,6-trimethylbenzenesulfenamide (**1e**).*[21] The sulfenyl chloride, prepared from 2,4,6-trimethylbenzenethiol (2.00 g, 0.013 mol) as described for **1c**, was dissolved in dry ether (50 ml), and the solution was added dropwise to a stirred solution of aniline (2.50 g, 0.027 mol) in dry ether (200 ml) at −40——50 °C. After stirring for 30 min, the reaction mixture was filtered, and solvent was evaporated to give a dark brown oily residue. Repeated recrystallization from hexane afforded light brown plates (0.15 g, 4%) with mp 110—112 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 2.39 (s, *p*-CH_3, 3H), 2.75 (s, *o*-CH_3, 6H), 4.90 (br s, NH, 1H), and 6.85—7.30 (m, C_6H_5, 5H). Found: C, 58.10; H, 4.76; N, 4.64%. Calcd for $C_{15}H_{15}NCl_2S$: C, 57.69; H, 4.84; N, 4.49%.

*N-(2,4,6-Triisopropylphenyl)-4-nitrobenzenesulfenamide (**1f**).* The sulfenyl chloride, prepared from 4-nitrobenzenethiol (2.02 g, 0.013 mol) as described for **1a**, was dissolved in dry ether (50 ml), and the solution was added dropwise to a stirred solution of 2,4,6-triisopropylaniline (2.80 g, 0.013 mol) and triethylamine (1.94 g, 0.019 mol) in dry ether (250 ml) at −5—0 °C. After addition of the sulfenyl chloride, the reaction mixture was stirred for 5 h at room temperature. Filtration of the reaction mixture, and evaporation of solvent gave a yellow powdery residue, which was chromatographed on alumina [E. Merck, Art 1097, eluent: benzene/hexane (1/4), column size: 3×30 cm]. Recrystallization from hexane afforded light yellow prisms (2.5 g, 53%) with mp 132—133 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 1.18 [d, J=10 Hz, *p*-$CH(C\underline{H}_3)_2$, 6H], 1.25 [d, J=10 Hz, *o*-$CH(C\underline{H}_3)_2$, 12H], 2.75—3.42 [m, $C\underline{H}(CH_3)_2$, 3H], 4.88 (br s, NH, 1H), and 6.99—8.28 (m, C_6H_2 and C_6H_4, 6H). Found: C, 67.28; H, 7.57; N, 7.41%. Calcd for $C_{21}H_{28}N_2O_2S$: C, 67.71; H, 7.58; N, 7.52%.

*N-(2,4,6-Tri-t-butylphenyl)-4-nitrobenzenesulfenamide (**1g**).* The sulfenyl chloride, prepared from 4-nitrobenzenethiol (2.53 g, 0.016 mol) as described for **1a**, was dissolved in dry ether (50 ml), and the solution was added dropwise to a stirred solution of 2,4,6-tri-*t*-butylaniline (4.30 g, 0.016 mol) and triethylamine (2.50 g, 0.025 mol) in dry ether (300 ml) at −5—0 °C. After addition of the sulfenyl chloride, the reaction mixture was stirred for 5 h at room temperature. Filtration of the reaction mixture, and evaporation of solvent gave a yellow powdery residue, which was chromatographed on alumina as described for **1f**. Recrystallization from hexane and then methanol afforded yellow prisms (2.93 g, 46%) with mp 152—153 °C. IR (KBr): 3300 cm^{-1} (NH). NMR ($CDCl_3$): δ 1.30 (s, *p*-*t*-Bu, 9H), 1.50 (s, *o*-*t*-Bu, 18H),

5.20 (br s, NH, 1H), and 7.23—8.23 (m, C_6H_2 and C_6H_4, 6H). Found: C, 69.64; H, 8.27; N, 6.78%. Calcd for $C_{24}H_{34}N_2O_2S$: C, 69.53; H, 8.27; N, 6.76%.

Generation of Aminyls. a) Photolysis: sulfenamide (**1**, 5.0 mg) and a benzene solution (0.20 ml) of di-*t*-butyl peroxide (10% in vol) were placed in an ESR tube and the tube degassed by three freeze-pump-thaw cycles and then sealed. The ESR spectra were recorded during direct irradiation of the solution in the cavity of an ESR instrument with a high-pressure mercury lamp (JES-UV-1, 100W); b) oxidation with lead dioxide: **1** (6.0 mg) was stirred in benzene (3.0 ml) for 1—15 min in the presence of lead dioxide (0.2 g) and potassium carbonate (0.2 g). After filtration, 0.20 ml of the filtrate was placed in an ESR tube and degassed as described above and then sealed.

*Oxidation of **1g** with Lead Dioxide.* Sulfenamide **1g** (42.3 mg) in benzene (10 ml) was stirred for 5—15 min in the presence of lead dioxide (0.5 g) and potassium carbonate (0.5 g). After filtration, the benzene was removed from the filtrate by freeze-drying, giving a dark brown powder in an almost quantitative yield. For measurements of ESR spectra of the filtrate and the powder, 0.20 ml of the filtrate, and 4—5 mg of the powder were used, respectively.

*Generation of Nitroxide **3**.* Nitroxide **3** was generated by the procedure of Konaka *et al.*,[6] *i.e.* 2,4,6-tri-*t*-butylnitrosobenzene (3.0 mg), bis(4-chlorophenyl) disulfide (20.0 mg), and benzene (0.40 ml) were placed in an ESR tube, and degassed as described above, then sealed. ESR spectra were recorded during direct irradiation of the solution with the high-pressure mercury lamp.

*Decay Kinetics of **2**.* Decay kinetic studies on **2** were conducted at 19 °C in the dark. Sample preparation was as follows: **1** (5.0 mg) and a benzene solution (0.20 ml) of di-*t*-butyl peroxide (10% in vol) were placed in an ESR tube, and degassed as described above and then sealed. After the solution was irradiated for 10—20 min in the cavity of an ESR instrument with the high-pressure mercury lamp, the light source was turned off, and the decay rates were measured by monitoring the ESR signal intensities. Integration of the ESR signals was conducted with a Model JES-ID-2 integrator using a benzene solution of 3,4-dihydro-2,4,6-triphenyl-2*H*-1,2,4,5-tetrazin-1-yl (1,3,5-triphenylverdazyl)[22] as a standard.

ESR spectra were recorded at room tempcrature on a JES-ME-3X spectrometer with an X-band microwave unit and a 100 kHz field modulation. Coupling constatns and *g*-values were determined by comparison with the a_N value (13.09 G)[23] and the *g*-value (2.0057)[24] of Fremy's salt.

Computer simulation of spectra was performed using a FACOM 230-60 computer equipped with a FACOM F-6201D plotter.

Reactions of 2-Chlorothiophene with Cation Exchange Resin and 100% Orthophosphoric Acid. Formation of the Dimer Type Products Containing a Tetrahydro-2-thiophenone Moiety[1)]

Tyo SONE,* Osamu SHIROMARU, Shin-ichi IGARASHI, Eiichi KATO, and Mutsuo SAWARA
Department of Applied Chemistry, Faculty of Engineering, Yamagata University, Yonezawa 992
(Received July 3, 1978)

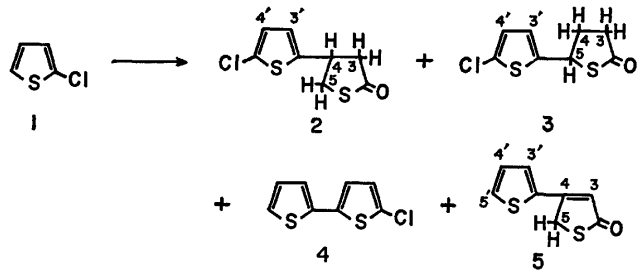
It has been found that 2-chlorothiophene is converted into the dimer type products by Amberlyst 15 or 100% orthophosphoric acid, the reaction yielding 4- and 5-(5-chloro-2-thienyl)tetrahydro-2-thiophenones and 4-(2-thienyl)-2(5*H*)-thiophenone together with 5-chloro-2,2′-bithienyl. The distribution of the products is considerably affected by the acid used and in the presence of phenol or anisole the reaction affords additionally 4-[5-(*p*-hydroxyphenyl)-2-thienyl]tetrahydro-2-thiophenone or 4-[5-(*p*-methoxyphenyl)-2-thienyl]tetrahydro-2-thiophenone, respectively.

Simple thiophenes have been known to polymerize on treatment with certain acidic materials;[2)] in most cases amorphous, highly insoluble polymers were obtained. Since the products may form a potential source of oligothienylenes, efforts have been made to produce simple oligomers by the use of this type of reaction. Moreover, the oligomerization may supply information regarding the reactivity of thiophene as a conjugated diene which has not been well understood. However, few reports have appeared in the literature, *e.g.*, thiophene reacts with 100% orthophosphoric acid to yield the so-called "thiophene trimers" and "pentamer,"[3)] and with sulfuryl chloride and iron powder to yield the chlorinated bithienyls.[4)]

A novel reaction will be reported here, namely, the reaction of 2-chlorothiophene (**1**) with cation exchange resin and 100% orthophosphoric acid leading to dimer type products containing a tetrahydro-2-thiophenone ring. This result is in contrast to that obtained by the reactions of **1** with sulfuric acid,[5)] and aluminium chloride and copper(II) chloride;[6)] in both cases the major product obtained even under mild conditions was a polymeric material possessing a complicated structure. This reaction also offers a novel example of the conversion of thiophenes to other heterocycles.

2-Chlorothiophene (**1**) was treated with half its own weight of Amberlyst 15 at 120 °C for 4 h. Evolution of hydrogen chloride gas was observed during the reaction. The oily product was shown by thin-layer chromatography (TLC) to consist of two principal components, which were isolated by column chromatography. The component of high R_f value was found to be 5-chloro-2,2′-bithienyl (**4**, 21% based on reacted **1** at 70% conversion) by comparison with the authentic sample. Careful chromatography of the component of low R_f value gave 4-(5-chloro-2-thienyl)tetrahydro-2-thiophenone(**2**, 34%) as a colorless oil together with a small amount of 5-(5-chloro-2-thienyl)tetrahydro-2-thiophenone (**3**, 3.5 %) as colorless crystals. Some 4-(2-thienyl)-2(5*H*)-thiophenone (**5**, 1.5%) was also isolated.

Similar treatment of **1** with an equivalent weight of freshly prepared 100% orthophosphoric acid afforded the same products at 82% conversion. The distribution of products, however, was different from that with Amberlyst 15, *i.e.*, **2** (11.5%), **3** (11%), **4** (7%), and **5** (≈1%), respectively (Scheme 1).



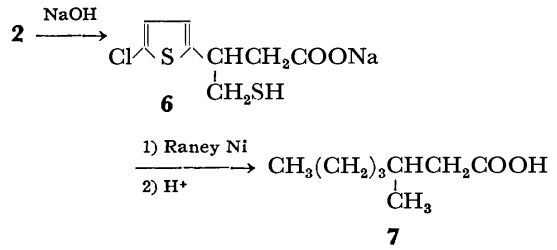
Scheme 1.

The structures of the thiophenones have been assigned on the basis of the following evidence.

The IR spectrum (CCl_4) of **2** indicated carbonyl absorption at 1715 cm^{-1} but no absorption attributable to hydroxyl groups. The UV spectrum [λ_{max}(MeOH) 242 nm (log ε 4.07)] suggested an unconjugated thiophene ring. Compound **2** did not react with ordinary ketonic reagents. When heated with dilute sodium hydroxide solution, it easily dissolved producing a clear solution, but was partially regenerated from the alkaline solution on acidification with hydrochloric acid. The mass spectrum showed the molecular ion at *m/e* 218 (relative intensity 72%) and characteristic M+2 peak (30%) indicative of a structure containing two sulfur atoms and one chlorine atom. Other prominent peaks were *m/e* 144 (base peak; M^+-CH_2SCO) and 109 ($M^+-CH_2SCO-Cl$). These findings suggest a tetrahydro-2-thiophenone substituted by a 5-chloro-2-thienyl moiety. The NMR spectrum (CCl_4) showed, in addition to an AB quartet (J=3.8 Hz) for the two protons of 2,5-disubstituted thiophene ring,[7)] a typical AB octet (centered at approx. δ 2.7) of an ABX spin system for a methylene group, and a three-proton multiplet (δ 3.2—4.1) due to the methine (the X-proton of the ABX system) and a methylene group. The large geminal coupling constant ($J_{a,b}$=16.6 Hz) of the AB octet together with the position indicated that the methylene proton were adjacent to a carbonyl group.[8)] The downfield methylene protons were strongly deshielded indicating that the protons were adjacent to a sulfur atom. Thus the thienyl moiety must be located at the 4-position of the tetrahydro-2-thiophenone ring. A shift reagent [Eu(fod)$_3$] experiment agreed with the assignment; upon addition of the reagent the octet underwent a greater downfield shift and the three-proton multiplet

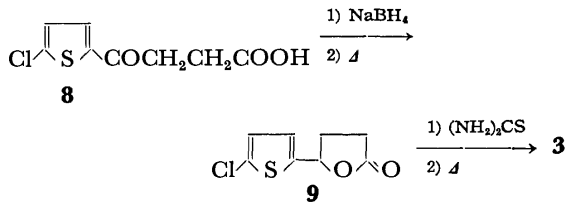
separated with a smaller shift into a one-proton multiplet for the methine proton and an AB octet for the methylene protons.

The structure assignment was substantiated by the alkaline hydrolysis of **2** followed by reductive desulfurization (Raney nickel) of the resulting mercaptoacid (**6**) which gave 3-methylheptanoic acid (**7**), which was identical with an authentic sample (Scheme 2).



Scheme 2.

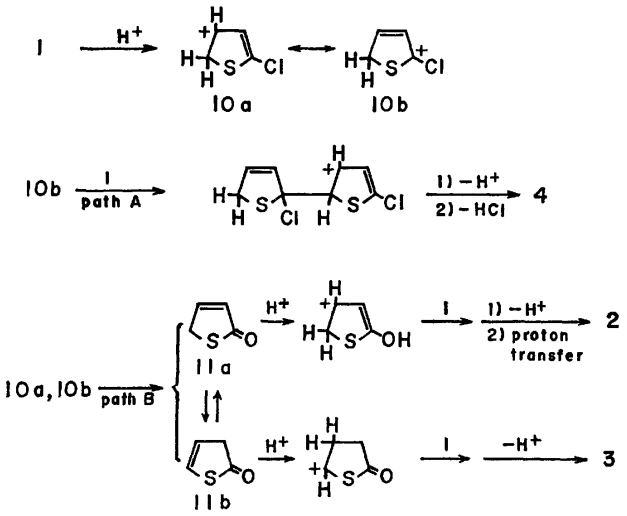
Compound **3** had the same molecular weight as that of **2**, and similar IR (CCl_4; ν_{CO} 1715 cm^{-1}), UV [λ_{max} (MeOH) 244 nm (4.09)], and chemical properties, indicating that **3** is an isomer of **2**. The NMR and mass spectra were appreciably different from that of **2**. The mass spectrum showed significant peaks at *m/e* 218 (base peak; M^+), 158 (M^+ — SCO), 157 (M^+ — SCO — H), and 123 (M^+ — SCO—Cl). The NMR spectrum ($CDCl_3$) exhibited, besides the resonance for two protons of a 2,5-disubstituted thiophene ring, a four-proton multiplet (δ 1.9—3.0) due to two adjacent, similarly shielded methylene groups and a multiplet (δ 5.0—5.3) due to a methine proton. The strongly deshielded position of the methine absorption indicates that the methine proton is adjacent to both the sulfur atom and the thienyl group. Upon gradual addition of the shift reagent the four-proton multiplet separated into two methylene multiplets; one (due to the methylene proton α to the carbonyl group) underwent a greater downfield shift relative to the other (due to the β methylene protons) and the methine multiplet. These facts are compatible with structure **3**, which was finally established by comparison of the spectral data and the melting point with those of an authentic sample synthesized according to Scheme



Scheme 3.

The minor product **5** was thought to contain a thiophene ring conjugated with an enone group on the basis of the UV [λ_{max}(MeOH) 277 (3.96), 327 (4.19)] and IR spectra [KBr; $\nu_{C=C}$ 1600, ν_{CO} 1660 cm^{-1}]. The NMR spectrum ($CDCl_3$) displayed significant resonances as follows; signals for three ring protons, a triplet for an olefinic proton at δ 6.49, and a methylene doublet at δ 4.39. Decoupling of the doublet caused the triplet to collapse to a singlet, indicating that the olefinic and the methylene protons were mutually spin-coupled with a coupling constant J=1.5 Hz in an allylic group (–CH=C–CH_2–). These data together with the mass spectrum [*m/e* 182 (base peak; M^+), 154 (M^+— CO), 153 (M^+— CO — H), 108 (M^+— CH_2SCO)] and the elemental analysis confirmed structure **5**.

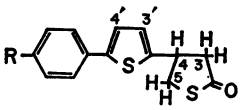
The formation of **4** can be explained by the mechanism illustrated in Scheme 4 (path A). The entire reaction pathway leading to the thiophenone derivatives is not clear at this stage. Of interest in this regard, however, is the fact that both **2** and **3** were formed in the reaction and the **2**/**3** ratio varied considerably depending upon the acid and the reaction conditions employed. A probable mechanism which is compatible with these facts may involve the intermediacy of 2-thiophenone tautomers,[9] 2(5*H*)-(**11a**) and 2(3*H*)-thiophenones (**11b**), in the reaction: protonation of **11a** and **11b** followed by the reaction of the resulting carbonium ions with **1** and then the loss of a proton affords **2** and **3**, respectively (path B). The reaction of **10b** with **11b** would similarly yield **5**. The tautomers could be produced from **1** by a reaction analogous to hydrolytic conversion of chlorocyclopentadiene to the corresponding cyclopentenone.[10]



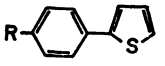
Scheme 4.

It was anticipated from the suggested mechanism that, when the reaction was conducted in the presence of an aromatic compound which is reactive but inert to the resin, the corresponding arylthiophene and/or aryl-substituted tetrahydro-2-thiophenone would be formed. Thus, in the presence of an equimolar amount of phenol the reaction using Amberlyst 15 as an acid resulted in 73% conversion of **1** yielding 4-[5-(*p*-hydroxyphenyl)-2-thienyl]tetrahydro-2-thiophenone (**12**; 28% based on reacted **1**) in addition to **2** (22%) and **4** (7%). The presence of 2-(hydroxyphenyl)thiophene (presumably **13**) and 4-[(*p*-)hydroxyphenyl]tetrahydro-2-thiophenone as the minor products were also detected by mass spectral analysis. Similarly, the reaction in the presence of anisole afforded 4-[5-(*p*-methoxyphenyl)-2-thienyl]tetrahydro-2-thiophenone (**14**; 17% based on reacted **1** at 46% conversion), 2-(*p*-methoxyphenyl)thiophene (**15**;

10%), **2** (20%), and **4** (6%). The structure of **12** and **14** have been assigned on the basis of their mass and NMR spectra, which indicated the presence of one *p*-substituted phenyl, one 2,5-disubstituted thiophene, and one 4-substituted tetrahydro-2-thiophenone ring. The formation of the unexpected tetrahydro-2-thiophenones, **12** and **14**, can be accounted for by a process similar to that of the formation of **2** as shown in Scheme 4. This involves the initial formation of arylthiophene intermediates, **13** and **15**, which react with the protonated **11a** to afford **12** and **14**, respectively.



12: R=OH
14: R=OCH_3



13: R=OH
15: R=OCH_3

In conclusion, it was found that the dimer type products consisting of the unexpected thiophenone derivatives (**2**, **3**, and **5**) and the coupling product (**4**) were formed in the acid-catalyzed reaction of **1** with a cation exchange resin and 100% orthophosphoric acid. In the reaction the thiophene ring clearly behaves as a conjugated diene as well as a heteroaromatic ring. Furthermore, it should be noted that the reaction could be effected with a cation exchange resin. To the authors' knowledge no report in the literature has appeared on the use of cation exchange resins as catalysts for acid-catalyzed oligomerization of aromatic or heteroaromatic nuclei, although the resins have received wide application in organic reactions. It is possible that simple oligomers are formed in the reactions of other properly substituted thiophenes with the resins as well.

Experimental

All melting and boiling points are uncorrected. The NMR spectra were obtained on a Hitachi R-22 spectrometer at 90 MHz, using TMS as an internal reference. The UV, IR, and mass (70 eV) spectra were recorded on Hitachi EPU-2A, Hitachi EPI-S2, and Hitachi UMU-6MG spectrometers, respectively.

2-Chlorothiophene (**1**) was prepared by the method described in the literature.[11] Commercial Amberlyst 15 was used without any treatment. In drying the Amberlyst over phosphorus pentaoxide (115 °C/10—15 mmHg, 24 h), 2—3% weight loss was observed, which was presumably due to loss of water.

*Reaction of **1** with Cation Exchange Resin.* A suspension of Amberlyst 15 (5 g) in **1** (10 g, 0.0843 mol) was stirred at 120 °C for 4 h. Evolution of hydrogen chloride was observed during the reaction. The reaction mixture was extracted with chloroform in a Soxhlet extractor. After the solvent and the unchanged **1** (3.0 g) were distilled off, the residual oil was chromatographed (silica gel, benzene) to give three fractions which are in order of decreasing R_f values: 1) the chlorinated 2,2′-bithienyl, **4**, (1.3 g, 21% based on **1** reacted; contaminated with a small amount of another isomer as shown by GLC), bp 100—110 °C (bath)/3—4 mmHg (lit,[12] 55 °C (bath)/0.05 mmHg); 2) a mixture of the tetrahydrothiophenones, **2** and **3**, (2.4 g, 36%; **2**:**3**=91:9 as determined by NMR analysis); 3) the thiophenone, **5**, (0.08 g, 1.5%), mp 157—159 °C. The spectral and physical properties are described below.

*Reaction of **1** with 100% Orthophosphoric Acid.* A mixture of **1** (10 g) and the phosphoric acid (prepared immediately prior to use by heating a mixture of 85% orthophosphoric acid (7.5 g) and phosphorus pentaoxide (3 g) at 100 °C for 1 h) was stirred at 110 °C for 6 h. Hydrogen chloride gas was evolved throughout the reaction. After cooling, the greenish brown reaction mixture was poured into cold water, and extracted with chloroform. The extract was washed successively with water, 5% sodium hydrogencarbonate solution and again with water, and dried. After the solvent and unchanged **1** (1.8 g) had been removed, the residual oil was chromatographed (silica gel, benzene) to give **4** (0.5 g, 7%; contaminated with a small amount of another isomer), a mixture of **2** and **3** (1.7 g, 22.5%; **2**:**3**=51:49), and **5** (0.05 g, ≈1%).

The isomeric tetrahydrothiophenones were separated by repeated chromatography (silica gel, benzene/ligroin (3:1)).

2: Colorless oil, bp 85—87 °C/5×10^{-4} mmHg. NMR (CCl_4) δ 6.77 (1H, d, $J_{3',4'}$=3.8 Hz, 4′-H), 6.71 (1H, dd, $J_{3',4'}$= 3.8 Hz, $J_{3',4}$=0.7 Hz, 3′-H), 4.1—3.2 (3H, m, 4-H and 5-H_a,H_b), 2.82, 2.62 (2H, ABX octet, $J_{a,b}$=16.6 Hz, $J_{a,4}$=10.1 Hz, $J_{b,4}$=6.6 Hz, 3-H_a,H_b); (CCl_4; in the presence of 0.36 equivalent mol of Eu(fod)$_3$) δ 7.37 (1H, dd, 3′-H), 6.97 (1H, d, 4′-H), 6.76, 6.50 (2H, ABX octet, 3-H_a,H_b), 5.8—5.3 (1H, m, 4-H), 5.06, 4.98 (2H, ABX octet, $J_{a,b}$=11.0 Hz, $J_{a,4}$=8.1 Hz, $J_{b,4}$=6.7 Hz, 5-H_a, H_b). Found: C, 44.05; H, 3.45%. Calcd for $C_8H_7ClOS_2$: C, 43.93; H, 3.23%.

3: Colorless crystals, mp 51.5—52.5 °C (light petroleum ether–ether). NMR ($CDCl_3$) δ 6.83 (1H, dd, $J_{3',4'}$=3.7 Hz, $J_{3',5}$=0.7 Hz, 3′-H), 6.74 (1H, d, $J_{3',4'}$=3.7 Hz, 4′-H) 5.0—5.3 (1H, m, 5-H), 1.9—3.0 (4H, m, 3-H_a,H_b and 4-H_a,H_b); ($CDCl_3$; in the presence of 0.25 equivalent mol of Eu(fod)$_3$ δ 7.20 (1H, dd, 3′-H), 6.91 (1H, d, 4′-H), 5.91 (1H, ABX q, $J_{a,4}+J_{b,4}$=14.4 Hz, 5-H), 5.0—4.3 (2H, m, 3-H_a,H_b), 3.6—2.8 (2H, m, 4-H_a, H_b). Found: C, 43.94; H, 3.03%. Calcd for $C_8H_7ClOS_2$: C, 43.93; H, 3.23%.

5: Pale yellow crystals, mp 165—166 °C (ligroin–benzene). NMR ($CDCl_3$) δ 7.50, 7.39 (2H, ABX octet, $J_{3',5'}$=1.1 Hz, $J_{3',4'}$=3.7 Hz, $J_{4',5'}$=4.8 Hz, 3′-H and 5′-H), 7.11 (1H, ABX q, $J_{3',4'}$=3.7 Hz, $J_{4',5'}$=4.8 Hz, 4′-H), 6.49 (1H, t, $J_{3,5}$=1.5 Hz, 3-H), 4.39 (2H, d, $J_{3,5}$=1.5 Hz, 5-H_2). Found: C, 52.72; H, 3.15%. Calcd for $C_8H_6OS_2$: C, 52.71; H, 3.31%.

*Desulfurization of **2** with Raney Nickel.* The tetrahydrothiophenone **2** (0.93 g, 4.25 mmol) was dissolved in 20% sodium hydroxide solution (50 ml) by heating, and the solution diluted with water (50 ml). W-7 Raney nickel (prepared from 15 g of the alloy) was added to the cooled solution and the mixture stirred at 70 °C for 5 h. The reaction mixture was filtered and the nickel washed with water (300 ml). The filtrate and the washings were combined and evaporated to *ca.* 100 ml. The solution was acidified with hydrochloric acid in the cold to give an oil. Work-up and distillation *in vacuo* afforded 3-methylheptanoic acid (**7**; 0.50 g, 82%) as a colorless liquid, bp 130—140 °C (bath)/15 mmHg (lit,[13] 121 °C/15 mmHg); the IR and NMR spectra were identical with those of the authentic sample.[13]

*5-(5-Chloro-2-thienyl)tetrahydro-2-furanone (**9**).* Sodium borohydride (1.9 g, 0.05 mol) was added with stirring to a mixture of 3-(5-chloro-2-thenoyl)propionic acid[14] (**8**; 10.9 g, 0.05 mol) and sodium hydroxide (1.6 g) in water (80 ml), while the temperature of the reaction mixture being maintained below 40 °C during the addition. The mixture was stirred for 4 h at room temperature, added to water, and acidified with hydrochloric acid. After extraction with ether and the usual work-up, the oily product was distilled under reduced

pressure and the distillate (bp 117—127 °C/1 × 10^{-4} mmHg chromatographed (silica gel, chloroform) to give **9** (4.7 g, 46%) and 4-(5-chloro-2-thienyl)-3-butenoic acid (1.8 g, 17%).

9: Colorless oil, bp 112—114 °C/1 × 10^{-4} mmHg. MS *m/e* 202 (M^+). IR (CCl_4) ν_{CO} 1800 cm^{-1}. NMR ($CDCl_3$) δ 6.83 (1H, d, $J_{3,4'}$=3.8 Hz, thiophene 3'-H), 6.76 (1H, d, $J_{3',4'}$=3.8 Hz, thiophene 4'-H), 5.54 (1H, t, 5-H), 2.9—2.0 (4H, m, 3-H_2 and 4-H_2). Found: C, 47.66; H, 3.48%. Calcd for $C_8H_7ClO_2S$: C, 47.41; H, 3.48%.

4-(5-Chloro-2-thienyl)-3-butenoic Acid: Colorless crystals, mp 84—85 °C (benzene–hexane). MS *m/e* 202 (M^+). IR (KBr) ν_{CO} 1700 cm^{-1}. NMR ($CDCl_3$) δ 9.97 (1H, br s, COOH), 6.71 (1H, d, $J_{3',4'}$=4.0 Hz, thiophene 4'-H), 6.64 (1H, d, $J_{3',4'}$=4.0 Hz, thiophene 3'-H), 6.47 (1H, dd, $J_{3,4}$=15.9 Hz, $J_{2,4}$=1.0 Hz, 4-H), 5.92 (1H, dt, $J_{3,4}$=15.9 Hz, $J_{2,3}$=7.0 Hz, 3-H), 3.19 (2H, dd, $J_{2,3}$=7.0 Hz, $J_{2,4}$=1.0 Hz, 2-CH_2). Found: C, 47.34; H, 3.46%. Calcd for $C_8H_7ClO_2S$: C, 47.41; H, 3.48%.

Preparation of 3 from 9. To a suspension of the lactone **9** (1.0 g, 5 mmol) in 48% hydrobromic acid (2.5 g) was added thiourea (0.4 g, 5 mmol) with shaking. A white solid formed within several minutes and was allowed to stand overnight. A sodium hydroxide solution (0.6 g, in 5 ml of water) was added and the mixture gently refluxed for 70 min. The organic layer was separated, and the aqueous layer acidified and extracted with ether. The organic layer and the ether extracts were combined and dried. After removal of the solvent the residual oil was heated at 160—170 °C under reduced pressure (20 mmHg) for 1 h. The oily product was chromatographed (silica gel, chloroform/benzene (4: 1)) to give **3** (mp 51—52 °C; 160 mg, 15%). The IR and NMR spectra were identical with those of **3** obtained by the acid-catalyzed reaction of **1**, and the mixed melting point exhibited no depression.

Reaction of 1 with Cation Exchange Resin in the Presence of Phenol. A mixture of **1** (4.8 g, 0.04 mol), phenol (3.8 g, 0.04 mol) and Amberlyst 15 (2.4 g) was stirred at 120 °C for 4 h. The dark brown reaction mixture was extracted with aceton in a Soxhlet extractor. After removal of the solvent the unchanged **1** (1.3 g) and phenol (1.9 g) were recovered by distillation under reduced pressure. The residual oil was chromatographed (silica gel, benzene/acetone (9: 1)) to give 4-[5-(*p*-hydroxyphenyl)-2-thienyl]tetrahydro-2-thiophenone (**12**; mp 159—166 °C, 1.1 g, 28% based on reacted **1**), **2** (0.7 g, 22%), **4** (0.2 g, 7%), and polymeric material (0.8 g) Mass spectroscopy suggested the presence of 4-[(*p*-)hydroxyphenyl]tetrahydro-2-thiophenone [*m/e* 194 (M^+), 120 ($M^+ - CH_2SCO$)] and 2-[(*p*-)hydroxyphenyl]thiophene [**13**; *m/e* 176 (M^+), 147 (M^+-CO-H), 131 (M^+-HCS), 115 ($M^+-CO-H-S$)], which were isolated in the impure form by preparative TLC. There was, however, insufficient material for further purification.

12: Pale yellow crystals, mp 171—172 °C (methanol). MS *m/e* 276 (M^+), 202 (M^+-CH_2SCO), 45 (base peak; HCS^+). UV λ_{max}^{MeOH} 304 (4.22). IR (KBr) ν_{CO} 1660, ν_{OH} 3225 cm^{-1}. NMR ($(CD_3)_2CO$): δ 8.46 (1H, s, OH), 7.48, 7.39 (2H, AA'XX' m, *p*-substituted phenyl), 7.10 (1H, d, $J_{3',4'}$=3.8 Hz, 4'-H), 6.96 (1H, dd, $J_{3',4'}$=3.8 Hz, $J_{3',4}$=1.0 Hz, 3'-H), 6.90, 6.80 (2H, AA'XX' m, *p*-substituted phenyl), 4.2—3.2 (3H, m, 4-H and 5-H_a, H_b), 2.92, 2.80 (2H, ABX octet, $J_{a,b}$=16.7 Hz, $J_{a,4}$=10.0 Hz, $J_{b,4}$=7.2 Hz, 3-H_a,H_b). Found: C, 61.01; H, 3.97%. Calcd for $C_{14}H_{12}O_2S_2$: C, 60.84; H, 4.37%.

Reaction of 1 with Cation Exchange Resin in the Presence of Anisole. A mixture of **1** (4.8 g, 0.04 mol), anisole (4.3 g, 0.04 mol) and Amberlyst 15 (2.4 g) was stirred at 120 °C for 4 h and the reaction mixture extracted with chloroform in a Soxhlet extractor. After removal of the solvent, the unchanged **1** (2.6 g) and anisole (3.3 g) were recovered by distillation under reduced pressure. The residual oil was chromatographed (silica gel, hexane/acetone (4: 1)) to afford 4-[5-(*p*-methoxyphenyl)-2-thienyl]tetrahydro-2-thiophenone (**14**; mp 104—107 °C; 0.45 g, 17% based on reacted **1**), 2-(*p*-methoxyphenyl)thiophene (**15**; mp 101—103 °C; 0.35 g, 10%), **2** (0.4 g, 20%), and **4** (0.1 g, 6%). Other traces were detected by TLC but colud not be separated.

15: Colorless crystals, mp 110—111 °C (methanol; lit,[15] 107—108 °C). MS *m/e* 190 (base peak, M^+), 175 (M^+-CH_3), 147 (M^+-CH_3-CO). NMR ($CDCl_3$) δ 7.51, 7.42 (2H, AA'XX' m, *p*-substituted phenyl), 7.2—6.9 (3H, m, monosubstituted thiophene), 6.89, 6.80 (2H, AA'XX' m, *p*-substituted phenyl), 3.79 (3H, s, $-OCH_3$).

14: Pale yellow crystals, mp 115—116 °C (methanol). MS *m/e* 290 (base peak, M^+), 216 (M^+-CH_2SCO), 201 ($M^+-CH_2SCO-CH_3$), 173 ($M^+-CH_2SCO-CH_3-CO$). UV λ_{max}^{MeOH} 300 (4.36). IR (KBr) ν_{CO} 1705 cm^{-1}. NMR ($CDCl_3$) δ, 7.51, 7.41 (2H, AA'XX' m, *p*-substituted phenyl), 7.01 (1H, d $J_{3',4'}$=3.7 Hz, 4'-H), 6.94, 6.84 (2H, AA'XX' m, *p*-substituted phenyl), 6.84 (1H, dd, $J_{3',4'}$=3.7 Hz, $J_{3',4}$=0.9 Hz, 3'-H), 3.80 (1H, s, $-OCH_3$), 4.4—3.3 (1H, m, 4-H and 5-H_a,H_b), 2.92, 2.77 (2H, ABX octet, $J_{a,b}$=16.8 Hz, $J_{a,4}$=11.0 Hz, $J_{b,4}$=6.0 Hz, 3-H_a,H_b). Found: C, 62.28; H, 4.67%. Calcd for $C_{15}H_{14}O_2S_2$: C, 62.03; H, 4.87%.

The authors wish to thank Professor H. Obara, Yamagata University, for his valuable advice. They would also like to thank Dr. J. Onodera, Yamagata University, and Mr. K. Sakai, Hitachi Research Laboratory, Hitachi Ltd., for mass spectral measurements, and Professor K. Takahashi, Nagoya Institute of Technology, and Mr. K. Fujieda, Naka Works, Hitachi Ltd., for NMR spectral measurements.

An Improved Synthesis of 3′,4′-Dideoxykanamycin B

Toshio YONETA,* Seiji SHIBAHARA, Tomio MATSUNO, Susumu TOHMA, Shuzo FUKATSU, Shigeo SEKI, and Hamao UMEZAWA†

Central Research Laboratories, Meiji Seika Kaisha, Ltd., Morooka-cho, Kohoku-ku, Yokohama 222

†*Institute of Microbial Chemistry, Shinagawa-ku, Tokyo 141*

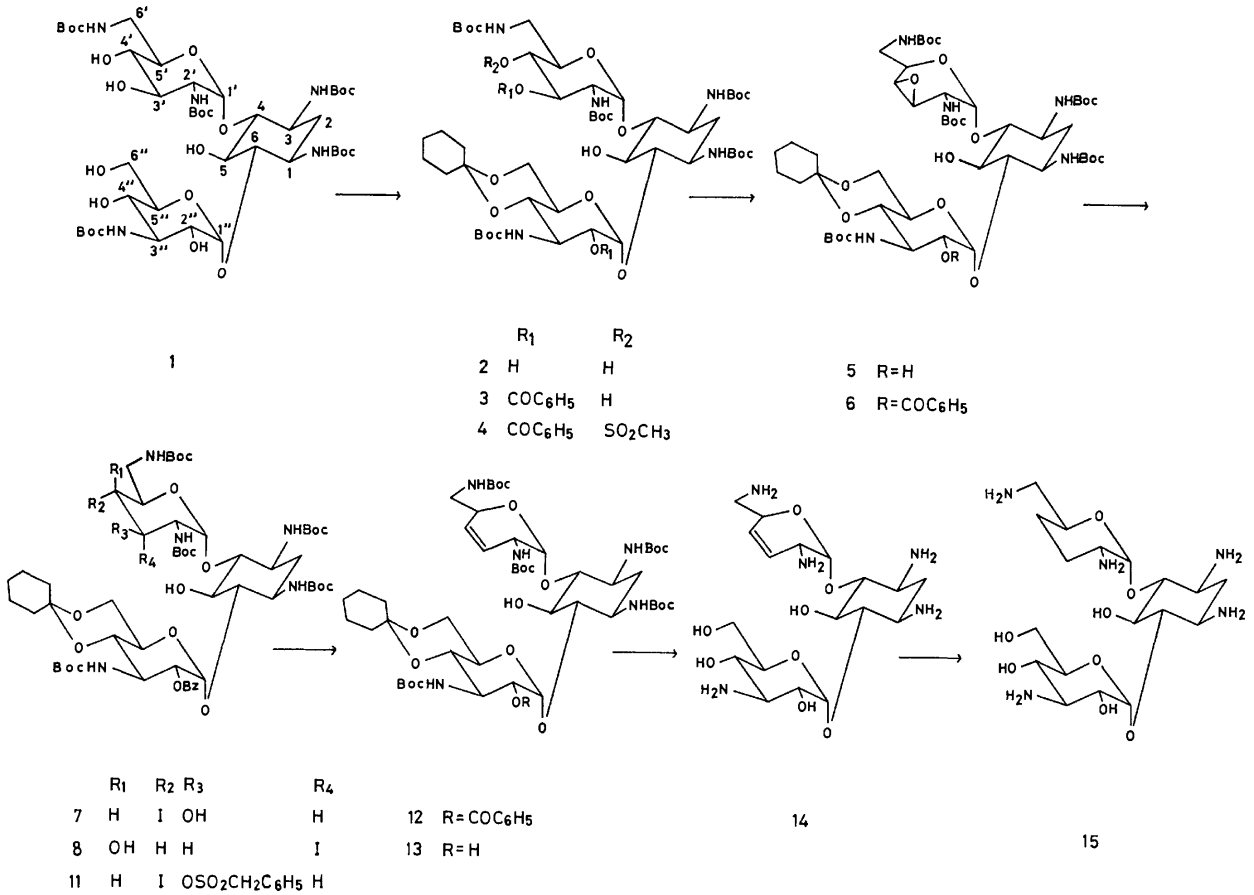
(Received July 15, 1978)

A new synthetic route has been exploited for the large scale production of 3′,4′-dideoxykanamycin B starting with kanamycin B. The key stage in the synthesis involves the formation in excellent yield of the 3′,4′-anhydro-4′-*epi* derivative (**5**) followed by convertion to the 3′-*ene* derivative through the iodohydrin. Compound **5** was prepared by the treatment of 3′,2″-di-*O*-benzoyl-4″,6″-*O*-cyclohexylidene-4′-*O*-methylsulfonyl-penta-*N*-*t*-butoxycarbonyl-kanamycin B with sodium methoxide.

The resistance mechanism of most strains resistant to kanamycin has been elucidated by Umezawa *et al.* and attributed to the transphosphorylation from adenosine triphosphate to the 3′-hydroxyl group of kanamycin by intracellular enzymes produced by the resistant organisms.[1-3] 3′-Deoxykanamycin[4] and 3′,4′-dideoxykanamycin B (**15**)[5,6] prepared on the basis of this mechanism have been shown able to inhibit growth of these resistant strains. The latter has already been clinically used for infections of resistant bacteria.

A previous method for the preparation of 3′,4′-dideoxykanamycin B (**15**) involves the treatment of the 3′,4′-di-*O*-sulfonyl derivative with sodium iodide and zinc according to the Tipson-Cohen method.[7] In the present paper, other methods which do not require zinc for the 3′-*ene* formation have been investigated and it has been found that Watanabe's method,[8,9] involving the cleavage of an epoxide ring to iodohydrin followed by *O*-sulfonylation is one method for the large scale preparation of the 3′-*ene* compound.

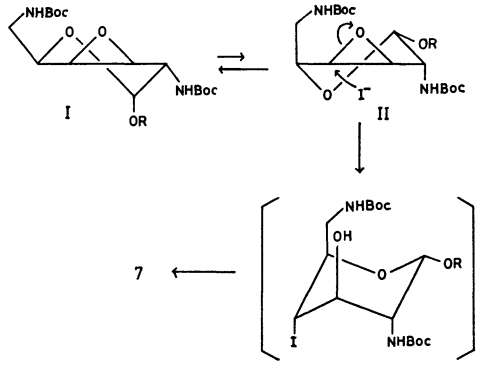
The five amino groups of kanamycin B were protected by the *t*-butoxycarbonyl (Boc) group using *O*-*t*-butyl *S*-4,6-dimethyl-2-pyrimidinyl thiocarbonate (Boc-*S* reagent)[10] to yield quantitatively the *N*-penta-Boc derivative (**1**). The protecting group can be readily removed under mild acidic conditions without ureide formation[6] at *N*-1 and *N*-3 of the 2-deoxystreptamine, which occured during removal of the *N*-ethoxycarbonyl group. The 4″- and 6″-hydroxyl groups of **1** were selectively protected by the formation of the cyclohexylidene



Scheme 1.

derivative in the usual manner.[6] Since the 4-hydroxyl group of hexopyranosides is generally least reactive toward benzoylation with benzoyl chloride in pyridine,[11] the 3′- and 2″-hydroxyl groups of the 4″,6″-*O*-cyclohexylidene derivative (**2**) were preferentially benzoylated with benzoyl chloride (2.7 mol to **2**) in pyridine at 5 °C to give the expected 3′,2″-dibenzoate product (**3**) in 73% yield. The reaction of the dibenzoate **3** with methylsulfonyl chloride gave the 4′-methylsulfonate (**4**) whose NMR spectrum showed the presence of two benzoyl and one methylsulfonyl group. The treatment of **4** with methanolic sodium methoxide gave the desired 3′,4′-anhydro-4′-*epi* derivative (**5**) in a quantitative yield, which was subsequently converted into the 2″-benzoate (**6**) by re-*O*-benzoylation. Successive treatment of **6** with sodium iodide, sodium acetate and acetic acid in acetone[8,9] afforded the iodohydrin (**7**) bearing both iodo and hydroxyl groups in equatorial positions. Formation of the anhydro-ring opening isomer (**8**) was not observed in this reaction.

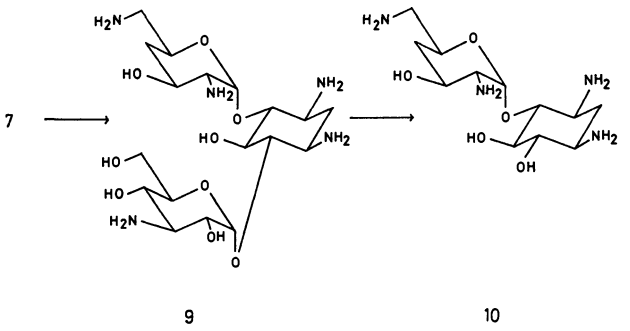
The structure of **7** was established by conversion into 4′-deoxykanamycin B (**9**). Catalytic hydrogenation of the crude iodohydrin (**7**) followed by successive treatment with methanolic sodium methoxide and 95% trifluoroacetic acid gave **9** and a small amount of less polar compounds. Hydrolysis of **9** with 6 M hydrochloric acid afforded 4′-deoxyneamine (**10**) which was identical with seldomycin factor 2,[12] showing that the hydroxyl and iodo groups of **7** are located at the 3′- and 4′-positions, respectively, in both equatorial positions.



Scheme 2.

The conformation of **6** could be represented as **I** and **II**, as shown in Scheme 2. The trans-diequatorial iodohydrin (**7**) derives from conformer **II** by the attack of the iodide ion and subsequent ring inversion of the product. It has been reported[13] that the direction of the ring opening of 3,4-anhydro-*galacto*-hexopyranosides is controlled by the bulkiness of the entering reagents. In the present case, the attack of the bulky iodide ion is seriously hindered by the anomeric axial group in conformer **I** and hence conformer **II**, with the less-hindered 4′-position is more susceptible to attack although the latter is expected to be less stable than the former.

The iodohydrin (**7**) was treated with α-toluenesulfonyl chloride[6] in pyridine and the resulting 3′-α-toluenesulfonate (**11**) was heated at 90 °C for 20—30 min to give the 3′-*ene*-derivative (**12**) in 76% yield. When the corresponding 3′-methylsulfonate or 3′-*p*-toluenesulfonate was used, only a poor yield of **12** was obtained.



Scheme 3.

Removal of the 2″-*O*-benzoyl group in **12** with methanolic sodium methoxide afforded compound **13**. *N*-*t*-Butoxycarbonyl and 4″,6″-*O*-cyclohexylidene groups of **13** were removed by treatment with 95% trifluoroacetic acid to afford the 3′-*ene*-kanamycin B (**14**). Catalytic hydrogenation of **14** afforded 3′,4′-dideoxykanamycin B (**15**), the NMR, TLC and biological activity of which were identical with that of an authentic sample.[5] The total yield of **15** from kanamycin B was more than 40% on a large scale.[14]

Experimental

All melting points are uncorrected. Optical rotations were measured with a Perkin-Elmer Model 241 polarimeter and NMR spectra with a Varuan XL-100 spectrometer at 100 MHz. Thin-layer chromatography (TLC) was performed on Merck silica gel plate No. 5714.

Penta-N-t-*butoxycarbonylkanamycin B (1).* To a solution of kanamycin B (4.98 g) in aqueous triethylamine (34%, 35 ml), was added Boc-S reagent (18.7 g) in 1,4-dioxane (36 ml) and the mixture stirred for 24 h at room temperature. The syrupy mixture was poured into water (200 ml) and the resulting precipitate filtered, washed successively with 0.1 M-hydrochloric acid and water, and dried to give a white powder of **1** (9.88 g, 97%). The crude product was dissolved in hot ethanol and the solution cooled to give analytically pure **1** as a white powder; mp 253—260 °C (dec), $[\alpha]_D^{25}+70°$ (*c* 1.0, DMF).

Found: C, 52.31; H, 7.62; N, 7.24%. Calcd for $C_{43}H_{77}N_5O_{20}$: C, 52.47; H, 7.90; N, 7.12%.

*4″,6″-*O*-Cyclohexylidene-penta-*N*-t-butoxycarbonylkanamycin B (2).* To a solution of **1** (1.48 g) in *N*,*N*-dimethylformamide (7.4 ml), was added *p*-toluenesulfonic acid hydrate (75 mg) and 1,1-dimethoxycyclohexane (2.1 ml). The mixture was allowed to stand at room temperature overnight. The resulting solution contained three compounds [TLC, chloroform–methanol (15: 1), R_f 0.22 (**2**), R_f 0.35 (trace), R_f 0.07 (starting material)]. After neutralization with triethylamine (0.6 ml), the solution was concentrated to a syrup and water added. The resulting precipitate was filtered, washed with water and dried. The crude product was dissolved in hot methanol and the solution cooled to give pure **2** (1.48 g, 93%); mp 245 °C (dec), $[\alpha]_D^{25}+74°$ (*c* 1.0, DMF).

Found: C, 54.83; H, 8.08; N, 6.24%. Calcd for $C_{49}H_{85}N_5O_{20}$: C, 55.29; H, 8.06; N, 6.58%.

*3′,2″-Di-*O*-benzoyl-4″,6″-*O*-cyclohexylidene-penta-*N*-t-butoxycarbonylkanamycin B (3).* To a solution of **2** (1.63 g) in

dry pyridine (16 ml), was added benzoyl chloride (0.27 ml) and the mixture kept overnight at 5 °C. Benzoyl chloride (0.2 ml) was added dropwise at 5 °C until the starting material disappeared. After the addition of water (0.15 ml), the solution was concentrated to a syrup and water added. The resulting precipitate was filtered, washed with water and dried (2.0 g). Column chromatography over silica gel (50 g) with chloroform–methanol (130: 1) afforded a white powder of **3** (1.42 g, 73%) together with the compound (160 mg) showed a high R_f value. Mp 164—167 °C, $[\alpha]_D^{25}+86°$ (*c* 1.0, $CHCl_3$); NMR (CD_3OD): δ 7.34—8.16 (10H, m, C_6H_5).

Found: C, 59.54; H, 7.20; N, 5.04%. Calcd for $C_{63}H_{93}N_5O_{22}$: C, 59.45; H, 7.38; N, 5.50%.

3′,2″-Di-O-benzoyl-4″,6″-O-cyclohexylidene-4′-O-methylsulfonyl-penta-N-t-*butoxycarbonylkanamycin B (4).* A solution of **3** (966 mg) and methylsulfonyl chloride (0.29 ml) in pyridine (11.3 ml) was kept at 40 °C for 1 h. After the addition of water (0.1 ml), the solution was concentrated to a syrup and water added. The resulting precipitate was filtered, washed with water and dried (1.0 g). Column chromatography over silica gel (30 g) with chloroform–methanol (150: 1) afforded a white powder of **4** (647 mg, 67%); mp 218—221 °C (dec), $[\alpha]_D^{25}+92°$ (*c* 1.0, $CHCl_3$); NMR ($CDCl_3$): δ 2.90 (3H, s, SO_2CH_3), 7.38—8.20 (10H, m, C_6H_5).

Found: C, 56.79, H; 6.93; N, 4.71; S, 2.76%. Calcd for $C_{64}H_{95}N_5O_{24}S$: C, 56.92; H, 7.09; N, 5.18; S, 2.37%.

3′,4′-Anhydro-4″,6″-O-cyclohexylidene-4′-epi-penta-N-t-*butoxycarbonylkanamycin B (5).* To a solution of **4** (1.28 g) in methanol (10.5 ml), was added sodium methoxide (524 mg), and the solution stirred at room temperature for 3 h. After neutralization with concd hydrochloric acid at 0 °C, the resulting suspension was concentrated and precipitated by the addition of water. The resulting precipitate was filtered, washed with water and dried (1.03 g, quantitative). The crude product was dissolved in hot ethanol and the solution cooled to give analytically pure **5** as a white powder; mp 232—234 °C (dec), $[\alpha]_D^{25}+44°$ (*c* 0.5, DMF).

Found: C, 55.93; H, 8.06; N, 6.43%. Calcd for $C_{49}H_{83}N_5O_{19}$: C, 56.24; H, 8.01; N, 6.69%.

3′,4′-Anhydro-2″-O-benzoyl-4″,6″-O-cyclohexylidene-4′-epi-penta-N-t-*butoxycarbonylkanamycin B (6) and the Iodohydrin Formation.* To a solution of **5** (1.28 g) in dry pyridine (20 ml), was added benzoyl chloride (0.5 ml), and the solution kept at 5 °C for 30 min. After the addition of water (0.2 ml), the solution was concentrated to a syrup and water added. The resulting precipitate was filtered, washed with water and dried to give a white powder of **6** (1.39 g, one spot on TLC). A mixture of **6** (1.39 g), sodium iodide (907 mg), sodium acetate (52 mg), acetic acid (0.9 ml) and acetone (39 ml) was refluxed for 6.5 h. The solvent was removed by evaporation under reduced pressure and the residue triturated with water. The resulting precipitate was filtered, washed with water and dried (1.51 g). Column chromatography on silica gel (55 g) with chloroform–methanol (150: 1) gave a white powder (816 mg, 52%) of the crude iodohydrin containing **7**.

Found: I, 10.39%. Calcd for $C_{56}H_{88}IN_5O_{22}$: I, 9.95%.

4′-Deoxykanamycin B (9). The crude iodohydrin (550 mg) in a mixture of methanol (10 ml), 1,4-dioxane (6 ml) and water (5 ml) was hydrogenated for 6 h under atmospheric pressure with Raney nickel (2.3 g). After removal of the catalyst, sodium methoxide (60 mg) was added and the solution kept at room temperature for 2 h. After neutralization with 1 M hydrochloric acid, the solution was concentrated to dryness and the residue triturated with water. The resulting precipitate was filtered, washed with water and dried. The white powder (451 mg) was dissolved in 95% trifluoroacetic acid (4.5 ml) and allowed to stand at room temperature for 30 min. The resulting solution contained three compounds [TLC, 1-butanol–ethanol–chloroform–17% ammonium hydroxide (4: 5: 2: 5), R_f 0.23 (major), R_f 0.21 (minor), R_f 0.17 (minor)] was concentrated to dryness and the residue dissolved in water (13 ml). The aqueous solution was neutralized with 4 M sodium hydroxide and charged onto a column of Amberlite CG-50 (NH_4^+ form, 6 ml). After washing with water, the column was developed with 0.3 M ammonium hydroxide. A mixture of minor components was eluted first (32 mg). From the next fraction 119 mg of the compound **9** was obtained as a colorless solid; mp 227 °C (dec), $[\alpha]_D^{25}+128°$ (*c* 1.3, H_2O); NMR (D_2O): δ 5.83 (1H, d, J=4 Hz, H-1′), 5.55 (1H, d, J=4 Hz, H-1″), 3.45 (1H, q, J=4 and 10.5 Hz, H-2′), 2.38—2.71 and 1.68—2.10 (each 2H, m, H-2 and H-4′).

Found: C, 42.64; H, 7.82; N, 13.41%. Calcd for $C_{18}H_{37}N_5O_9\cdot H_2CO_3$: C, 43.08; H, 7.49; N, 13.23%.

4′-Deoxyneamine (10). A solution of **9** (217 mg) in 6 M hydrochloric acid (4 ml) was kept at 100 °C for 45 min. The solution was concentrated to dryness, water (7 ml) added to the residue followed by neutralization with 1M sodium hydroxide. The solution was charged onto a column of Amberlite CG-50 (NH_4^+ form, 6 ml). The column was washed with water and developed with 0.3 M ammonium hydroxide. The eluate containing **10** was concentrated to give 128 mg of a colorless powder; mp 206 °C (dec), $[\alpha]_D^{25}+80°$ (*c* 0.5, H_2O) [lit,[12] mp 208—209 °C (dec), $[\alpha]_D^{25}+90°$ (*c* 1.0, H_2O)]; NMR (D_2O): δ 5.80 (1H, d, J=4 Hz, H-1′), 3.20 (1H, q, J=4 and 10 Hz, H-2′), 1.85 (1H, q, J=11.2 and 11.6 Hz, H-4′ axial).

Found: C, 44.20; H, 8.05; N, 16.26%. Calcd for $C_{12}H_{26}N_4O_5\cdot\frac{1}{2}H_2CO_3$: C, 44.49; H, 8.08; N, 16.60%.

2″-O-Benzoyl-4″,6″-O-cyclohexylidene-3′,4′-dideoxy-3′-ene-penta-N-t-*butoxycarbonylkanamycin B (12).* To a solution of the crude iodohydrin **7** (954 mg) in pyridine (18 ml), was added α-toluenesulfonyl chloride (643 mg), and the solution kept at 5 °C for 30 min. After the addition of methanol (0.36 ml), the resulting solution was heated at 90 °C for 30 min. The solution was concentrated and mixed with water and the resulting precipitate filtered, washed with water and dried (987 mg). Column chromatography on silica gel (30 g) with chloroform–methanol (150: 1) afforded the pure compound **12** (645 mg, 76%) as a white powder; mp 219 °C (dec), $[\alpha]_D^{25}+32°$ (*c* 0.2, CH_3OH); NMR (C_5D_5N): δ 5.96 (2H, s, olefinic protons).

Found: C, 59.44; H, 7.77; N, 5.90%. Calcd for $C_{56}H_{87}N_5O_{19}$: C, 59.30; H, 7.73; N, 6.17%.

4″,6″-O-Cyclohexylidene-3′,4′-dideoxy-3′-ene-penta-N-t-*butoxycarbonylkanamycin B (13).* To a solution of **12** (397 mg) in methanol (20 ml), was added sodium methoxide (90 mg), and the solution kept at room temperature for 30 min. After neutralization with 1 M hydrochloric acid, the solvent was removed by evaporation and the residue triturated with water. The resulting precipitate was filtered, washed with water and dried (371 mg). Reprecipitation from ethanol–water afforded a white powder (278 mg, 79%) of **13**; mp 215—217 °C, $[\alpha]_D^{25}+30°$ (*c* 1.0, CH_3OH).

Found: C, 57.20; H, 8.07; N, 6.38%. Calcd for $C_{49}H_{83}N_5O_{18}$: C, 57.11; H, 8.14; N, 6.80%.

3′,4′-Dideoxy-3′-enekanamycin B (14). A solution of **13** (398 mg) in 95% trifluoroacetic acid (4 ml) was kept at room temperature for 30 min. The solvent was removed by evaporation and the residue dissolved in water (10 ml). The aqueous solution was neutralized with 1M sodium hydroxide and charged onto a column of Amberlite CG-50 (NH_4^+ form, 9 ml). The column was washed with water and developed

with 0.3 M ammonium hydroxide. The eluate containing **14** was evaporated to give a colorless solid (130 mg, 81%); mp 161—181 °C (dec), $[\alpha]_D^{25}+48.8°$ (*c* 0.9, H_2O); NMR (D_2O): δ 5.55 (1H, d, $J=4$ Hz, H-1″), 5.88 (1H, d, $J=4$ Hz, H-1′), 6.10 (2H, s, olefinic protons).

Found: C, 44.18; H, 7.71; N, 14.52%. Calcd for $C_{18}H_{35}N_5O_8\cdot\frac{1}{2}H_2CO_3\cdot H_2O$: C, 44.57; H, 7.63; N, 14.06%.

3′,4′-Dideoxykanamycin B (15). Compound **14** (114 mg) in water (5 ml), was hydrogenated with platinum oxide (8 mg) under atmospheric pressure overnight. After removal of the catalyst, the solution was charged onto a column of Amberlite CG-50 (NH_4^+ form, 3 ml). After washing with water, the column was eluted with 0.3 M ammonium hydroxide to give a colorless solid (103 mg, 90%) of **15**, $[\alpha]_D^{25}+130°$ (*c* 1.0, H_2O).

This compound was confirmed to be identical with an authentic sample of 3′,4′-dideoxykanamycin B in all respects including biological activity.

The authors wish to thank Dr. Sumio Umezawa of the Institute of Bio-organic Chemistry, for his helpful discussion. We also would like to thank Mr. Katsuyoshi Iwamatsu for the decoupling experiments.

Photochemical Reactions of *N*-Acyl-2,3-dihydrobenzoxazol-2-ones

Sadahiro ISHIDA, Yoji HASHIDA, Haruo SHIZUKA, and Kohji MATSUI*

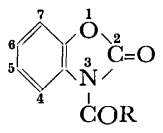
Department of Chemistry, Faculty of Engineering, Gunma University, Kiryu, Gunma 376

(Received August 2, 1978)

Photo-Fries rearrangements of *N*-acyl-2,3-dihydrobenzoxazol-2-ones are described. Irradiation of *N*-acyl-2,3-dihydrobenzoxazol-2-ones in acetonitrile afforded a mixture of 2-acyl-2,3-dihydrobenzoxazol-2-one and 6-acyl-2,3-dihydrobenzoxazol-2-one together with other minor products. However, 2,3-dihydrobenzoxazol-2-one and *N*-methyl-2,3-dihydrobenzoxazol-2-one were very photostable. The reaction scheme involving Norrish type I dissociation has been discussed.

The photochemical reactions of carbonyl compounds have been extensively studied; among them the photo-Fries rearrangement has been studied in detail for various aryl esters and *N*-arylamides.[1] In the photochemical reactions of acetoanilide[2] and its related compounds,[3] it has been shown that, in the liquid phase, the photo-Fries rearrangement originates from the lowest excited singlet state $S_1(\pi\pi^*)$ forming pair radicals which efficiently recombine in a solvent cage into the original substance, ortho- and para-isomers. The photo-Fries rearrangements of some heteroaromatic compounds, such as aryloxy-1,3,5-triazines,[4] 2-aryloxybenzazoles,[5] and *N*-acetylcarbazole[6] have been reported. The photochemical reactions of imides have been the subject of numerous recent studies; photochemical rearrangements of *N*-alkylphthalimides, which involve ring expansion *via* the Norrish type II process, have been reported by Kanaoka *et al.*,[7] and Mazzocchi *et al.*[8]

This paper will report on the photochemistry of *N*-acyl-2,3-dihydrobenzoxazol-2-ones (**1**) having a semicyclic imide skeleton. The photochemical behavior of these compounds is of interest to ascertain where dissociation occurs upon irradiation and what the photoproducts are.



(**1**)

Results and Discussion

Photo-Fries Rearrangement of N-*Acyl-2,3-dihydrobenzoxazol-2-ones.* *N*-Acyl-2,3-dihydrobenzoxazol-2-ones have been prepared by treating 2,3-dihydrobenzoxazol-2-one with acyl halide in pyridine, the details of which are listed in Table 1.

When the substituent at the 3-position is H (**1a**) or CH_3 (**1b**), no photochemical reaction was observed even after prolonged irradiation; this is particularly interesting because ordinary arylamides and arylesters are known to undergo photoreaction involving bond cleavage at –N–CO–[2d] and –O–CO–.[9]

When the substituent is an acyl group, a regular spectral change was observed upon irradiation in every case, a typical example of a spectral change being shown in Fig. 1 for the *N*-benzoyl derivative (**1g**).

In the case of the *N*-benzoyl compound (**1g**), a clean photo-chemical reaction took place to afford five photoproducts (**2g**, **3g**, **4**, **5**, **6**). The two products (**2g** and **3g**) were found to be positional isomers of the starting material (**1g**) which gave aminohydroxybenzophenones on treatment with hydrochloric acid. Spectral data showed that the compounds are benzene-ring-benzoylated products resulting from N→C migration of the benzoyl group, *i.e.* the reaction was a photo-Fries rearrangement. In the ordinary photo-Fries rearrangement of *N*-arylamides, the acyl group migrates to the ortho and para positions relative to the amino group. Therefore, the two isomeric products obtained have been assumed to be the ortho and para benzoylated products.

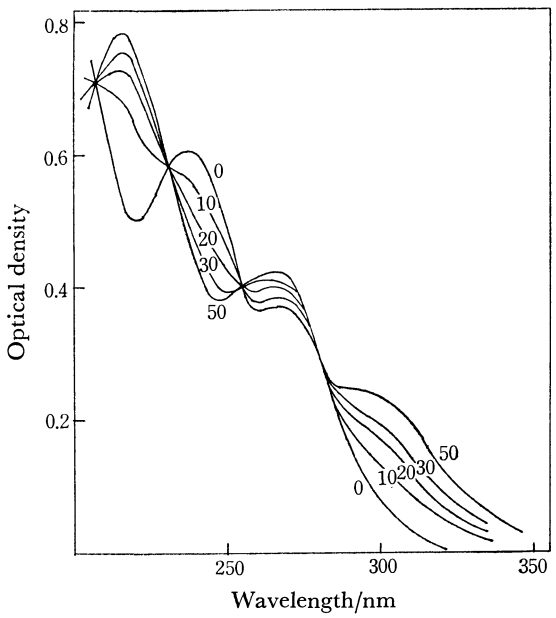

Fig. 1. Spectral change of an ethanol solution of 3-benzoyl-2,3-dihydrobenzoxazol-2-one by irradiation with a low-pressure mercury lamp. Numbers refer to time at a measurement in seconds.

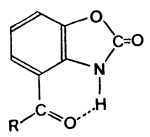
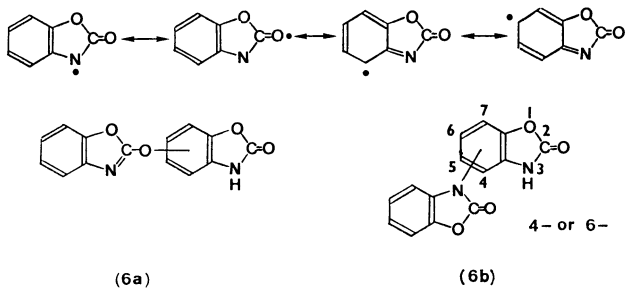
In the ortho rearranged product, the formation of an intramolecular hydrogen bond as shown (**2**) may be possible:



2

One product (**3g**) readily dissociated in the presence of alkali, while the other (**2g**) did not. In addition, the weaker acidic product (**2g**) has a NMR band attributable to an NH proton at a lower magnetic field. On this basis the isomer (**2g**) has been identified as the ortho-rearranged product while the other (**3g**) corresponds to the para-benzoylated product. Other products obtained were benzoic acid (**4**) and 2,3-dihydrobenzoxazol-2-ones (**5**). At the same time a derivative of 2,3-dihydrobenzoxazol-2-one which does not contain benzoyl group was obtained in a low yield. This compound was also obtained in the case of other *N*-acyl derivatives (**1c, 1h**), and was shown to be a dimer (**6**) of benzoxazolin-2-one. It appears that the dimer resulted from the coupling of two benzoxazolonyl radicals. This radical have four reactive positions, *viz*:



Thus, between the two radicals various types of coupling may be expected resulting in the formation of various dimers. One dimer was however obtained, showing that the coupling was regiospecific. This regiospecific nature of benzoxazolonyl radicals may be ascribed in part to their high selectivity caused by the delocalization as shown above. NMR spectra show that the dimer has seven aromatic protons and one active hydrogen atom, consequently, two possible formulas (**6a** and **6b**) for the dimer have to be considered. However, since 2-aryloxybenzoxazoles readily rearrange to give 2-(2- and/or 4-hydroxyaryl)benzoxazoles upon irradiation,[5] (**6a**) seems less probable than (**6b**). Furthermore, the 6-(2-oxo-2,3-dihydrobenzoxazol-3-yl)-2,3-dihydrobenzoxazol-2-one derivative is preferable to the 4-isomer since there is less steric hindrance and the corresponding odd π-electron density is high at the 6-position.[10] The dimer formation is evidence that the reaction proceeds *via* Norrish type I dissociation in the liquid phase.[11]

Similar photoreactions have been observed for other *N*-acyl derivatives, the yields and products of which are listed in Table 2. Table 2 shows that the ratios of ortho and para rearranged products is about 1. The reaction

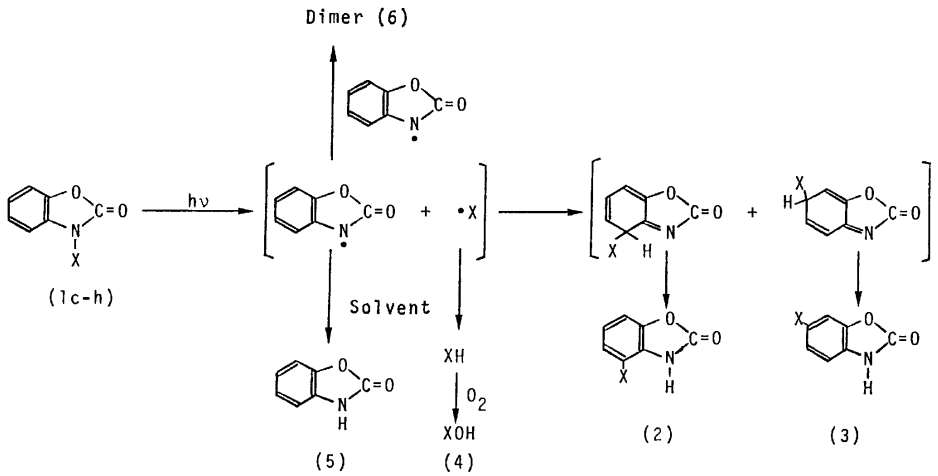

Scheme 1.

appears to proceed *via* the following Scheme *i.e.*, i) a Norrish type I fission of the N–COR bond which may originate from the lowest excited singlet state $S_1(\pi\pi^*)$[2,3] to give benzoxazolonyl and acyl radicals, ii) the attack by the acyl radical upon the 4 and 6 positions in a solvent cage yielding the corresponding products, and iii) the escape of the radicals from the solvent cage reacting differently depending upon the nature of radicals. A part of the benzoxazolonyl radical abstracts hydrogen atoms from the solvent (acetonitrile) resulting in the formation of 2,3-dihydrobenzoxazol-2-one. A part of the benzoxazolonyl radical couples to each other to give the dimer. While the acyl radical gave the corresponding acid, presumably *via* oxidation of the intermediary aldehyde resulted from the hydrogen abstruction of acyl radical from the solvent.

In the photo-Fries rearrangement of aryloxy-1,3,5-triazines,[7a] the viscosity of solvent scarcely affected the ortho-rearrangement, but considerably affected the para-rearrangement. The viscosity dependence of the solvent upon the photochemical rearrangements has been examined in a EtOH–glycerol mixture. In the photolysis of **4f**, the para/ortho (6-/4-) ratios decreased with an increase in the glycerol contents; the ratios were 1.22, 0.88, and 0.55 in zero, 30, 60 glycerol volume percent respectively. This indicates that the dependence of the 6-rearrangement on the stiffness of the solvent cage is larger than that of the 4-rearrangement because the 6-position is separated by a longer path.

In summary, it has been shown that, in *N*-acyl-2, 3-dihydroxybenzoxazol-2-ones, Norrish type I fission takes place at the 3–8 bond to give photo-Fries rearrangement products, demonstrating that the 2,3-dihydrobenzoxazol-2-one skeleton is very photostable. This apparent photostability of 2,3-dihydrobenzoxazol-2-one may be interpreted as follows. If the fission of the 1–2 or 2–3 bond takes place upon irradiation, the free migration of the acyl radical to positions where odd π electron densities are large is hindered by the bond to the benzene nucleus through the hetero atom. Consequently the rate of back reaction to give the starting material would dominate other reactions. The lifetime and fluorescence quantum yield of this molecule **1a** is about 2 ns and $5(\pm 2)\times 10^{-2}$ in ethanol at room temperature respectively, indicating that the radiationless processes in the excited state of **1a**, other than the reaction predominant. The fluorescence quantum yield of **1f** was very small (approx. 10^2 less than that of **1a**), and the lifetime was unobservable.

Experimental

All melting points are uncorrected.

Materials. 2,3-Dihydrobenzoxazol-2-one was prepared according to the literature method.[12] *N*-Methyl-2,3-dihydrobenzoxazol-2-one was prepared by the alkylation of 2,3-dihydrobenzoxazol-2-one with dimethylsulfate, and *N*-acyl-2,3-dihydrobenzoxazol-2-ones by treatment of 2,3-dihydrobenzoxazol-2-one with acyl halide. A typical preparation is shown in the case of *N*-isobutyryl-2,3-dihydrobenzoxazol-2-one (**1f**). Isobutryl chloride (7.46 g, 0.07 mol) was added dropwise into a cold solution of 2,3-dihydrobenzoxazol-2-one (6.76 g, 0.05 mol) in pyridine (50 ml). After stirring for 1 h at room temperature, the mixture was poured into ice water and the resulting precipitate filtered and dried. Recrystallization from petroleum ether gave a pure sample (yield, 90%).

Irradiation. All irradiations were conducted with a low-pressure mercury lamp (30 W×2) and a typical reaction is shown in the case of *N*-benzoyl-2,3-dihydrobenzoxazol-2-one: A solution containing *N*-benzoyl-2,3-dihydrobenzoxazol-2-one (2.00 g, 8.36 mmol) in acetonitrile (100 ml) was irradiated for 48 h and the photochemical reaction monitored by TLC. After removal of the solvent, the residue was chromatographed on a silica gel column using a benzene–acetone mixture (10: 1, v/v) as an eluent and gave the following products: a) starting material (0.30 g, 1.26 mmol) which was identified by a mixed-melting point test with an authentic sample. b) 6-Benzoyl-2,3-dihydrobenzoxazol-2-one (recrystallized from benzene): yield, 0.31 g (18%); MS *m/e* 239 (M^+); PMR ($CDCl_3$), δ 6.93—7.88 (m, 8H), 10.70, (broad, 1H); IR (KBr), 3200 (–NH), 1780 (C=O, ring), 1640 cm^{-1} (C=O). Found: C, 69.92; H, 3.78; N, 5.66%. Calcd for $C_{14}H_9NO_3$: C, 70.29; H, 3.79; N, 5.86%. This compound was decomposed in refluxing hydrochloric acid (20 wt %) for 40 h to give crude 4-amino-3-hydroxybenzophenone. Recrystallization from benzene gave a pure sample: yield, 0.33 g (88%); mp 134—135 °C; MS *m/e* 213 (M^+);

IR (KBr), 3480, 3360 (OH), 3150 cm^{-1} (NH_2). Found: C, 73.35; H, 5.21; N, 6.80%. Calcd for $C_{13}H_{11}NO_2$: C, 73.22; H, 5.20; N, 6.57%. c) 4-Benzoyl-2,3-dihydrobenzoxazol-2-one (recrystallized from benzene): yield, 0.35 g (21%); MS *m/e* 239 (M^+); PMR ($CDCl_3$), δ 6.97—7.85 (m, 8H), 10.00 (broad, 1H); IR (KBr), 3120, 3040 (NH), 1850 (C=O, ring), 1640 cm^{-1} (C=O). Found: C, 70.14; H, 3.83; N, 5.96%. Calcd for $C_{14}H_9NO_3$: C, 70.29; H, 3.79; N, 5.86%. This compound was decomposed in refluxing hydrochloric acid for 10 h to give 2-amino-3-hydroxybenzophenone. Yield, 0.30 g (68%); mp 129.5—130.5 °C; MS *m/e* 213 (M^+). Found: C, 73.29; H, 5.28; N, 6.72%. Calcd for $C_{13}H_{11}NO_2$: C, 73.22; H, 5.20; N, 6.57%. d) Dimer (recrystallized from methanol): yield, 0.069 g (6%); mp 258—259 °C; MS *m/e* 268 (M^+); PMR (*p*-dioxane), δ 7.0—8.0 (m, 7H), 9.97 (broad, 1H); IR (KBr), 3250 (NH), 1780, 1760 cm^{-1} (C=O, ring). Found: C, 62.91; H, 3.11; N, 10.33%. Calcd for $C_{14}H_8N_2O_4$: C, 62.91: H, 3.11; N, 10.45%. e) Benzoic acid (sublimed under reduced pressure) which was identified by a mixed-melting point test with an authentic sample: yield, 0.15 g (17%).

Measurements of the Isomer Ratios. After irradiation in a given solvent, the products were seperated by silica gel TLC using a mixture of benzene and acetone (20: 1 in volume) as the developing solvent. From the chromatogram each isomer was extracted and diluted with ethanol to a fixed volume and the extinction measured spectrophotometrically.

Measurements of Fluorescence Lifetime. The experimental procedure is reported elsewhere.[13]

Interactions between Sulfur Ylides and Electrophilic Monosulfides[1)]

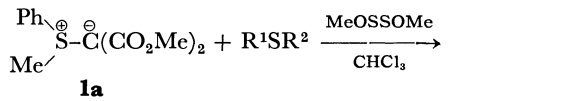
Haruo MATSUYAMA,* Masae MATSUMOTO, Michio KOBAYASHI, and (the late) Hiroshi MINATO

Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya, Tokyo 158

(Received August 3, 1978)

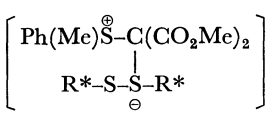
The catalytic activities of electrophilic monosulfides, Ar–S–R* (R*=CN, CF_3, OMe), for the transylidation reactions of sulfur ylide, $Ph(Me)\overset{\oplus}{S}-\overset{\ominus}{C}(CO_2Me)_2$, with alkyl sulfides and pyridines were investigated. Among these monosulfides, methyl arenesulfenates reacted with dimethylsulfonium phenacylide (or dimethylsulfonium ethoxycarbonylmethylide) to give α-(arylthio)phenacylides (or α-(arylthio)ethoxycarbonylmethylides) and methanol. The ^{13}C-NMR spectra of several sulfur ylides and aryl thiocyanates were investigated in $CDCl_3$, and the presence of *S*-ylide–thiocyanate adduct intermediates was established.

Electrophilic sulfides, $\overset{\delta-}{R}{}^*\leftarrow\overset{\delta+}{S}\rightarrow\overset{\delta-}{R}{}^*$ (R*=electron-withdrawing substituents), are very interesting compounds. We have previously reported that the disulfides containing electron-withdrawing substituents, $\overset{\delta-}{R}\leftarrow\overset{\delta+}{S}-\overset{\delta+}{S}\rightarrow\overset{\delta-}{R}{}^*$ (R*=OMe, CN, CF_3, and COPh), react as novel catalysts in several reactions of sulfur ylides.[2–5)] Particularly, in the presence of dimethoxy disulfide (R*=OMe), transylidation reactions take place smoothly at room temperature, as is shown below:[2)]

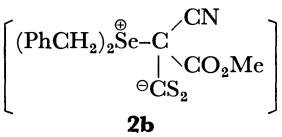


1a

R^1SR^2: Me_2S, MeSEt, MeSBu-*n*, MeSPr-*i*, $MeSC_8H_{17}$-2, $MeSCH_2Ph$, Et_2S, $MeSCH_2SMe$, 
Tamagaki *et al.* reported that carbon disulfide acts as a catalyst for the transylidation reaction of selenonium ylide with alkyl sulfides.[6)] In both reactions, the formation of ylide-catalyst adducts (**2a** and **2b**) and the subsequent nucleophilic attack of alkyl sulfides on the adducts to afford the new ylides were postulated.[2,6)]



2a

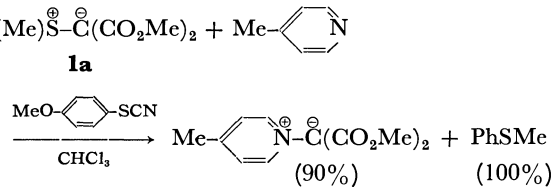


2b

Hitherto, the catalytic ability of the monosulfides for the transylidation reaction of sulfur ylides has not been investigated. Recently, we have found that the monosulfides containing electron-withdrawing substituents, Ar–S–R* (R*=CN, CF_3, and OMe), act as catalysts for the transylidation reaction of sulfur ylide **1a**. In this paper, we wish to report how to produce interaction between sulfur ylides and electrophilic monosulfides which act as catalysts on transylidation reactions.

Results and Discussion

Transylidation. In the presence of aryl thiocyanates (Ar–S–CN), phenylmethylsulfonium bis(methoxycarbonyl)methylide **1a** reacted with 4-methylpyridine to give a new 4-methylpyridinium ylide in chloroform at room temperature.



(90%) (100%)

In the absence of aryl thiocyanates, **1a** is very stable and shows no transylidation when it is mixed with pyridine at 35 °C. After the reaction was over, aryl thiocyanates were recovered from its solution by the PLC (preparative layer chromatography) method. The reaction between 4-methylpyridine and ylide **1a** was slow enough for its rate to be determined. The effects of the concentrations of the reactants and the catalyst were examined. The results are summarized in Table 1. The first-order rate constants calculated by assuming $-d[\mathbf{1a}]/dt=k[\mathbf{1a}]$ increased with the initial concentration of 4-methylpyridine; apparently the rate depends on 4-methylpyridine. The rates increased also with the

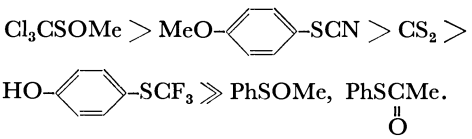
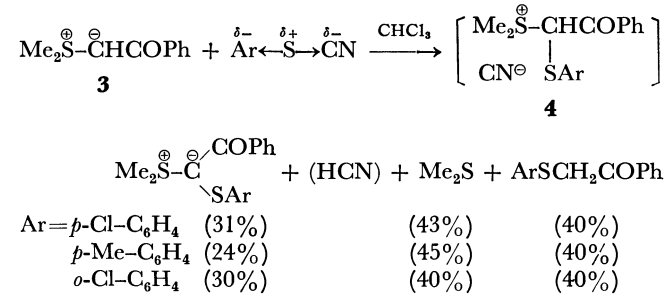
initial concentration of *p*-methoxyphenyl thiocyanate.

Various monosulfides were examined as regards their catalytic activity in this transylidation. Neither *S*-phenylthioacetate nor methyl benzenesulfenate was effective, methyl trichloromethanesulfenate and *p*-trifluoromethylphenol possessed a catalytic activity similar to that of aryl thiocyanate. Carbon disulfide also acted as catalyst in this transylidation (Table 2). The order of catalytic activity was:



Reactions of Dimethylsulfonium Phenacylide **3** *with Aryl Thiocyanates.* It was found that *p*-chlorophenyl thiocyanate (Ar=*p*-Cl-C_6H_4) reacted very slowly with ylide **3** to give dimethylsulfonium α-(*p*-chlorophenylthio)phenacylide (31%), methyl sulfide (43%), and *p*-chlorophenyl phenacyl sulfide (40%) after 4 days. These reaction products can be explained by assuming the formation of the sulfonium ion **4**.[8]



Ar=*p*-Cl-C_6H_4	(31%)	(43%)	(40%)
p-Me-C_6H_4	(24%)	(45%)	(40%)

Reactions of the **3** *and* **5** *Sulfur Ylides with Methyl Arenesulfenates.* In contrast to aryl thiocyanates, methyl arenesulfenates, ArSOMe, did not act as catalysts for transylidation. However, they reacted instantaneously at room temperature with phenacylide **3** (or ethoxycarbonylmethylide **5**), which contains only one electron-withdrawing substituent, in chloroform and gave the sulfenylated products, dimethylsulfonium α-(arylthio)-phenacylide[19] (or α-(arylthio)ethoxycarbonylmethylide[19]). The results are shown in Table 3.

Carbon-13 NMR Spectra of Ylide-catalyst Adducts. In order to obtain spectroscopic evidence for the formation of the sulfur ylide–electrophilic sulfides adducts, we investigated the carbon-13 NMR spectra of solutions of several sulfur ylides and aryl thiocyanates which are active catalysts. Carbon-13 chemical shifts provide some information on the electronic state of carbon atoms in molecules. The chemical shifts of disubstituted sulfur ylides, **1a** and **1b**, are little affected by solvents.[7] On

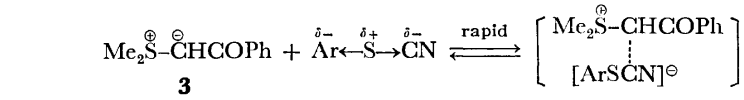
a) δ_c, ppm from TMS (accurate to ±0.13).
b) $\Delta\delta = (\delta^{ArSCN}_{CDCl_3} - \delta^{none}_{CDCl_3})$.

the other hand, the chemical shifts of the ylide carbon of dimethylsulfonium phenacylide, **3**, which contains only one electron-withdrawing substituent and which acts as a reactive carbanion, are dependent on the kind of solvent (Table 4).

When ylide **3** and aryl thiocyanate are mixed in chloroform, the downfield shifts (0.6—3.3 ppm) of the ylide carbon of phenacylide **3** were observed. Though the values of the shifts of ylide carbon were small, the NMR data can be explained by assuming that the formation of the adduct **6** from the ylide **3** and aryl thiocyanate is reversible and rapid.



3 **6**

By the formation of the dipole-dipole interaction complex **6**, the negative charge on the ylide carbanion is withdrawn toward the catalytic sulfide, and the nucleophilic attack of a sulfide (or a pyridine) on the sulfonium atom is facilitated.[5] Therefore, monosulfides possessing strongly electronegative substituents can act as the catalysts for transylidation.

Experimental

Materials. Sulfonium bis(methoxycarbonyl)methylide **1a** and **1b** were prepared by the copper sulfate-catalyzed decomposition of dimethyl diazomalonate in a large excess of sulfides.[9] The dimethylsulfonium ylides **3**[10a] and **5**[10b] were prepared by the methods described in the literature. Methyl trichloromethanesulfenate was obtained by the drop-by-drop addition of a CCl_4 solution of trichloromethanesulfenyl chloride (10 mmol; prepared by the reaction of carbon disulfide and chlorine; bp 148 °C) to a CCl_4 solution of methanol (12 mmol) and pyridine (12 mmol) at 0 °C. Cl_3CSOMe, bp 25 °C/5 mmHg; NMR ($CDCl_3$), δ=4.19 (s, OMe). *p*-Methoxyphenyl thiocyanate (mp 33—35 °C (lit,[11] 33—34 °C), IR (KBr), 2180 cm^{-1} (ν_{SCN}); NMR ($CDCl_3$), δ=3.82 (3H, s, OMe) and 6.82—7.55 (4H, q, aromatic-H)), *p*-dimethylaminophenyl thiocyanate (mp 73—74 °C (lit,[12] 73—74 °C); IR (KBr), 2160 cm^{-1} (ν_{SCN}); NMR; ($CDCl_3$), δ=2.96 (6H, s, NMe_2) and 6.55—7.44 (4H, q, aromatic-H)), and *o*-chlorophenyl thiocyanate (bp 98—100 °C/4 mmHg (lit,[13] 160 °C/42 mmHg); IR (neat), 2190 cm^{-1} (ν_{SCN}) were prepared by the methods described in the literature. *p*-Tolyl thiocyanate (bp 92—96 °C/1 mmHg (lit,[14] 117—118 °C/20 mmHg); IR (neat), 2160 cm^{-1} (ν_{SCN})) and *p*-chlorophenyl thiocyanate (bp 101—105 °C/1 mmHg) were prepared by the reaction of formamide and sulfenyl chloride ArSCl (Ar=*p*-Me-C_6H_4, *p*-Cl-C_6H_4) in the presence of $SOCl_2$.[14] Methyl arenesulfenates ArSOMe (Ar-Ph, bp 50 °C/2 mmHg (lit,[15a] 54 °C/10 mmHg); NMR ($CDCl_3$), δ=3.70 (3H, s, OMe) and 7.30 (5H, s, Ph); Ar=*p*-Me-C_6H_4, bp 55 °C/3 mmHg; NMR ($CDCl_3$), δ=2.34 (3H, s, *p*-Me), 3.65 (3H, s, OMe) and 7.28 (4H, s, aromatic-H); and Ar=*p*-Cl-C_6H_4, bp 76—77 °C/3 mmHg; NMR ($CDCl_3$), δ=3.70 (3H, s, OMe) and 7.29 (4H, broad s, aromatic-H) were synthesized by the drop-by-drop addition of an ether solution of the corresponding arenesulfenyl chlorides[15b] to an ether solution of methanol and triethylamine at 0 °C under a nitrogen atmosphere. *p*-(Trifluoromethylthio)phenol (mp 57—58 °C lit,[16] 57—58 °C)) was prepared by the reaction of phenol (0.94 g) and trifluoromethanesulfenyl chloride[17] (in a CCl_4 solution) at 0 °C in the presence of pyridine (0.8 g). *S*-Phenyl thioacetate (bp 82—84 °C/7 mmHg) was obtained by the condensation of thiophenol and acetyl chloride.[18] Carbon disulfide was of reagent grade and was used without purification.

Transylidation. The NMR spectra were determined by means of a Hitachi NMR spectrometer R-20B (60 MHz). A $CDCl_3$ solution of ylide **1a** (0.5 M), dimethyl sulfide (1.5 M), and a catalyst (2.0 M) was placed in an NMR tube at 35 °C, and the intensity changes of the signals of the original ylide, **1a**, the new ylide, **1b**, and the new sulfide, PhSMe, were followed. After the original ylide, **1a**, had completely disappeared, hexane was added to the reaction mixture. The ylide crystals thus precipitated were filtered and recrystallized from methanol. The melting points, IR, and NMR spectra of the ylide obtained were identical with those reported in the literature.[9] The results are listed in Table 2.

Carbon-13 NMR Measurement. The ylide **3** and thiocyanate were dissolved in $CDCl_3$ (usually 100—150 mg/cm^3) containing 1—5% tetramethylsilane as a reference. Solutions were examined in 10-mm tubes using a JEOL-FX-60 NMR spectrometer in the Fourier transform mode. Several hundred transients were typically accummulated with an acquisition time of 3.0 s. The line positions were determined automatically by computer software. The results are shown in Table 4.

*Reactions of Sulfur Ylide **3** with Aryl Thiocyanates in Chloroform.* (a) A chloroform (7 ml) solution of ylide **3** (0.90 g, 5.0 mmol) was mixed with *p*-chlorophenyl thiocyanate (0.86 g, 5.0 mmol) at room temperature. After 90 h the NMR spectra of the reaction mixture showed the presence of dimethyl sulfide (δ=2.10, s; 43%) and $Me_2\overset{\oplus}{S}-\overset{\ominus}{C}$(*p*-Cl-$C_6H_4S$)COPh ($\delta$=2.55, s; 31%). The low-boiling fractions from the mixture were trapped in liquid nitrogen, and the presence of Me_2S was shown by NMR spectroscopy (δ=2.11, s). When CCl_4 was added to the residue, the ylide crystals were precipitated; mp 148—149 °C. The CCl_4 solutions were concentrated *in vacuo*, and the residue was chromatographed by preparative thick-layer chromatography on silica gel, using a 2:1 mixture of hexane–ether as an eluent; the yellowish crystals (R_f=0.41) thus obtained were found to be *p*-Cl-$C_6H_4SCH_2COPh$ (0.52 g, 0.20 mmol; 40%); mp 81—82 °C; IR (KBr), 1680 cm^{-1} (ν_{CO}); NMR ($CDCl_3$), δ=4.25 (2H, s, S-CH_2-CO) and 7.26—8.0 (9H, m, aromatic-H). *p*-Chlorophenyl phenacyl sulfide was prepared independently by the reaction of phenacyl bromide and sodium *p*-chlorophenylmethanethiolate in methanol, and its physical data (mp, NMR and IR spectra) were identified with the above product. (b) Similarly, a chloroform (7 ml) solution of ylide **3** (0.90 g, 5.0 mmol) was mixed with *p*-tolyl thiocyanate (0.75 g, 5.0 mmol) at room temperature. After 6 days, the NMR spectra of the reaction mixture showed the presence of methyl sulfide (δ=2.10, s; 45%) and $Me_2\overset{\oplus}{S}-\overset{\ominus}{C}$(*p*-Me-$C_6H_4S$)COPh ($\delta$=2.54, s; 24%). When CCl_4 was added to the residue, the ylide crystals (mp 136—138 °C) were precipitated. The CCl_4 solutions were concentrated *in vacuo*, and the residue was chromatographed by preparative thick-layer chromatography on silica gel, using a 2:1 mixture of hexane–ether as an eluent; the oil (R_f=0.50) thus obtained was found to be *p*-Me-C_6H_4S-CH_2COPh (0.48 g, 0.20 mmol; 40%); IR (neat), 1680 cm^{-1} (ν_{CO}); NMR ($CDCl_3$), δ=2.28 (3H, s, *p*-Me), 4.20 (2H, s, S-CH_2-CO) and 7.17—8.0 (9H, m, aromatic-H). *p*-Tolyl phenacyl sulfide was prepared independently by the reaction of phenacyl bromide and *p*-tolyl mercaptane sodium salt on methanol, and its spectral data (IR and NMR) were identified with the above product. (c) A chloroform (5 ml) solution of

ylide **3** (1.0 g, 6.6 mmol) was mixed with *o*-chlorophenyl thiocyanate (1.12 g, 6.6 mmol) at room temperature. After 70 h, the NMR spectra of the reaction mixture showed the presence of dimethyl sulfide (δ=2.06, s; 40%) and $\underline{Me_2}\overset{\oplus}{S}-\overset{\ominus}{C}(o\text{-Cl-}C_6H_4\text{-S})COPh$ (δ=2.52, s; 30%). The low-boiling fractions from the mixture were trapped in liquid nitrogen, and the presence of Me_2S was shown by NMR spectroscopy (δ=2.11, s). The high-boiling fractions were chromatographed by preparative thick-layer chromatography on silica gel, using a 2: 1 mixture of hexane–ether as an eluent; the white crystals (R_f=0.25) thus obtained were found to be o-Cl-$C_6H_4SCH_2COPh$ (0.69 g, 2.6 mmol; 40%); mp 91.5—92.5 °C; IR (KBr), 1680 cm^{-1} (ν_{CO}); NMR ($CDCl_3$), δ=4.30 (2H, s, S-CH_2-CO) and 7.0—8.0 (9H, m, aromatic-H). Found: C, 63.26; H, 4.44%. Calcd for $C_{14}H_{11}OClS$: C, 63.99; H, 4.22%.

*Reactions of Sulfur Ylides **3** and **5** with Methyl Arenesulfenates in Chloroform.* (a) A chloroform (5 ml) solution of ylide **3** (0.5 g, 2.8 mmol; $Me_2\overset{\oplus}{S}-$, δ=2.85, s) was mixed with PhSOMe (0.39 g, 2.8 mmol) at room temperature. The NMR spectra of the reaction mixture showed the presence of a new ylide, $Me_2\overset{\oplus}{S}-\overset{\ominus}{C}(SPh)COPh$ (δ=2.54, s), and MeOH (δ=3.38, s). The removal of the solvent *in vacuo* at 25 °C gave white solids. Yield, 0.75 g (75%); recrystallized from benzene; mp 138—140 °C (lit,[19] 136 °C); IR (KBr), 1520 cm^{-1} (ν_{CO}). (b) A chloroform (5 ml) solution of ylide **5** (1.0 g, 6.8 mmol; $Me_2\overset{\oplus}{S}-$, δ=2.74, s) was mixed with PhSOMe (0.95 g, 6.8 mmol) at room temperature. The NMR spectra of the reaction mixture showed the presence of a new ylide, $Me_2\overset{\oplus}{S}-\overset{\ominus}{C}(SPh)CO_2Et$ (δ=2.53), and MeOH (δ=3.40, s). The removal of the solvent *in vacuo* at 25 °C gave white solids. Yield, 0.72 g (42%); mp 126—127 °C (lit,[19c] 126—127 °C); IR (KBr), 1600 cm^{-1} (ν_{OC}). Similarly, various α-(arylthio)phenacylides (or α-(arylthio)ethoxycarbonylmethylides) were obtained by the reactions of ylides **3** (or **5**) with methyl *p*-toluenesulfenate and methyl *p*-chlorobenzenesulfenate. The results are listed in Table 3. The products were identified by means of their NMR and IR spectra.

*The Determination of the Rate of the Transylidation of Ylide **1a** with 4-Methylpyridine (or Dimethyl Sulfide).* A $CDCl_3$ solution of **1a** and a suitable amount of a catalyst and 4-methylpyridine (or dimethyl sulfide) were mixed in a NMR tube. After nitromethane (0.79 mmol; δ=4.33 ppm) had been added as the internal standard, more $CDCl_3$ was added with a microsyringe so that the total volume became 800 μl. The disappearance of **1a** was followed by observing the decrease in $Ph\underline{Me}\overset{\oplus}{S}-$ (δ=3.20 ppm).

Synthesis of Methyl Substituted Chromanol. An Analogue of Vitamin K[1)]

Kazuhiro MARUYAMA,* Takamasa TOBIMATSU, and Yoshinori NARUTA
Department of Chemistry, Faculty of Science, Kyoto University, Kyoto 606
(Received August 7, 1978)

Methylation of 2,2-dimethyl-3,4-dihydro-2*H*-benzo[*h*]chromen-6-ol (**1**) is examined to yield 2,2,3-trimethyl-3,4-dihidro-2*H*-benzo[*h*]chromen-6-ol (**2**). The compound **2** is prepared by Mannich reaction followed by hydrogenative cleavage of the Mannich bases, which are obtained in the reaction with three kinds of amine. Chloromethylation of **1** quantitatively gave a dimer of naphthoquinone methide.

Vitamin K_1 and K_2 are widely distributed in natural products which are contributing in diverse biological processes such as blood clotting, electron transport and oxidative phosphorylation.[2)] Especially an association of vitamin K with the electron transport chain and a coupled phosphorylation in *Mycobacterium phlei* has been reported. The chromanol derivatives of vitamin K, to which noncyclized vitamin is enzymatically cyclized in bacterial system, is the acting vitamin of *M. phlei*.[3)]

We have recently reported the photochemical introduction of 2-alkenoyl group to 1,4-naphthoquinone and the facile preparation of 2,2-dimethyl-3,4-dihydro-2*H*-benzo[*h*]chromen-6-ol **1** ("benzochromanol") by the subsequent reactions (path a).[4)] Introduction of methyl group to the 5-position of **1** is of interest in view of the synthesis of a vitamin K methabolite in bacterial system.

The ortho position of phenol in β- and γ-tocopherols has been methylated by Mannich condensation followed by the successive reduction.[5)] However, in the case of tocopherols high pressure and high temperature were needed in the step of reductive cleavage of the Mannich bases. Therefore, secondary amines liberated from Mannich beses at reduction process were found to induce destruction of tocopherols.

In this paper, we wish to report a successful methylation of benzochromanol **1** *via* the milder hydrogenative cleavage of the Mannich bases.

Result and Discussion

Chromanol **1** was prepared by the following two routes (paths a[4)] and b). With use of three kinds of secondary amine; dimethylamine, piperidine, and morpholine, Mannich beses **6a—c** were prepared in yields of 75, 81, and 84%, respectively. 5-Dimethylaminomethyl derivative **6a** shows chracteristic ^{1}H-NMR signals due to amino benzylic protons at δ 3.70, and IR absorption due to hydrogen bonded hydroxyl group at the region of 3000—2500 cm^{-1}. The corresponding spectra were observed similarly in other Mannich bases, **6b** and **6c**.

Three Mannich bases **6a—c** were catalytically hydrogenated in ethanol similar to that of benzylic amine.[6)] Hydrogenation of these bases at atmospheric pressure and ambident temperature in the presence of 5% Pd–C resulted, however, recovery of the starting chromanol **6** without any hydrogenated products after four days. On the other hand, catalytic hydrogenation under a medium pressure (H_2, 5 kg/cm^2) applying an elevated temperature (80 °C) proceeded smoothly, and after 1 h the reaction was completed to give 2,2,5-trimethyl-3,4-dihydro-2*H*-benzo[*h*]chromen-6-ol **2** in a good yield. (Table 1) Since the obtained chromanol **2** was difficult to purify for its air sensibility, the hydrogenated solution was concentrated directly *in vacuo* and treated with Ac_2O–pyridine solution to give its acetate **7**.

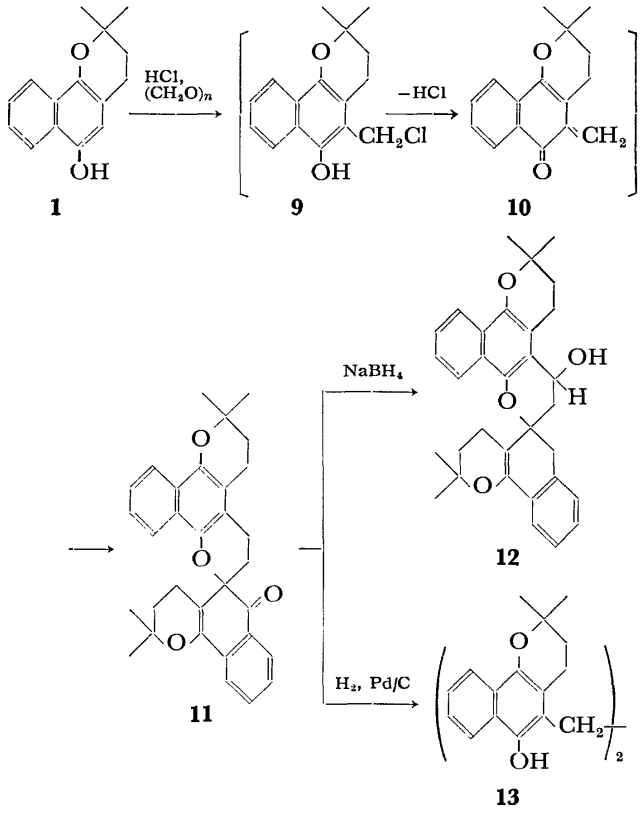
c		81

a) Isolated yield after purification.

formaldehyde at 0—5 °C. After 2 h a product was isolated in a yield of 78%. The structure was assigned to dimer **11** on the basis of the following spectral and chemical evidences.



Scheme 2.

The ^{1}H-NMR spectrum of **11** exhibits three singlets at δ 1.32 (6H), 1.37 (3H), 1.38 (3H), representing four methyl groups and multiplets at δ 1.00—2.66, representing twelve methylene protons. The IR spectrum shows an absorption at 1695 cm^{-1} ($\nu_{C=O}$).[7] Mass spectrum and analytical result of **11** were also consistent with the structure of dimer **11**. Reduction of **11** by $NaBH_4$ gave an alcohol **12**. The ^{1}H-NMR of **12** exhibits two singlets at δ 3.62 (1H) and 5.15 (1H), representing a hydroxyl proton and a methine proton, respectively, and the IR spectrum shows an absorption at 3435 cm^{-1} (ν_{OH}). Dimer **11** absorbed equimolecular hydrogen under the conditions of catalytic hydrogenation[7] to give 2,2,2′,2′-tetramethyl-3,4,3′,4′-tetrahydro-5,5′-ethylenedi(2*H*-naphtho[1,2-*b*]pyran)-6,6′-diol (**13**), quantitatively. The ^{1}H-NMR of **13** shows a broad singlet due to phenolic OH at δ 6.32, and the IR spectrum, being compatible with the structure. Thus, the dimeric product **11** obtained by chloromethylation of **1** corresponds to the structure of naphthoquinone methide dimer. The dimer has been prepared independently by oxidizing **2** with potassium hexacyanoferrate(III).[7] Our reaction may be explained taking into consideration of that the 5-chloromethyl-2,2-dimethyl-3,4-dihydro-2*H*-benzo[*h*]chromen-6-ol (**9**) is formed initially and despite in a strong acidic conditions **9** was hydrolized to *o*-naphthoquinone methide **10**.[10] These evidences are also supported by the fact that α-methylenecyclanones and *o*-quinone methides easily dimerize to the corresponding dihydropyran derivatives.[11]

Experimental

All melting points are uncorrected. The elemental analyses were performed at the Microanalysis Center of Kyoto University. ^{1}H-NMR spectra were measured with a JEOL PS-100 with TMS as an internal standard, infrared spectra with a JASCO 402G or a IRA-1, mass spectra with a Hitachi M-52. Analytical gas chromatographs were obtained with a JEOL JGC-20K instrument with a flame ionization detecter using a column (5% SE-30 silicon rubber on 60—80 mesh Celite 545, 3 mm × 1 m).

*2,2-Dimethyl-3,4-dihydro-2*H*-benzo*[h]*chromen-6-ol (1).* was prepared by the photochemical method (path a)[4] and a series of the following reactions (path b). 4-Hydroxy-1-naphthyl acetate **4** was prepared by the similar method to the literature.[8] **4**; Mp 130—131.5 °C. **4** (1.01 g, 5 mmol) and zinc chloride (0.1 g) were dissolved in chloroform (40 ml) under nitrogen. The solution was refluxed and the chloroform solution (5 ml) of 1-bromo-3-methyl-2-butene[9] (745 mg, 5 mmol) was slowly added, after refluxing for thirty minutes the solution was poured into ice water and was washed twice with 2 M hydrochloric acid and once with brine, and dried over Na_2SO_4. The mixture was purified with a use of Wakogel C-200 (30 g) eluted by 4.5% ether–hexane. 6-Acetoxy-2,2-dimethyl-3,4-dihydro-2*H*-benzo[*h*]chromen **5** was obtained (isolated yield; 60%. GLPC yield; 78%); Mp 66.9—67.1 °C. ^{1}H-NMR ($CDCl_3$): δ 1.36 (s, 6H, $2CH_3$), 1.77 (t, 2H, J=7 Hz, O–C–CH_2), 2.34 (s, 3H, $COCH_3$), 2.75 (t, 2H, J=7 Hz, Ar–CH_2), 6.87 (s, 1H, arom. H), 7.28—7.46 (m, 2H, arom. H), 7.57—7.73 (m, 1H, arom. H). IR: ν_{max}^{KBr} 2975 (vs), 1747 (vs), 1367 (vs), and 1189 cm^{-1} (vs).

The ethereal solution (30 ml) of chromanol acetate derivative **5** (2.703 g, 0.01 mol) was treated with lithium aluminum hydride (0.35 g) in ether (30 ml). After usual work-up, the obtained benzochromanol **1** was used without further purification.

*5-Dimethylaminomethyl-2,2-dimethyl-3,4-dihydro-2*H*-benzo*[h]*-chromen-6-ol (6a).* The dioxane solution (25 ml) of benzochromanol **1** (228 mg, 0.01 mol) was cooled in ice water under N_2, and dimethylamine solution (3.7 ml, 40% in water) and formalin solution (2.5 ml, 37% in water) were added and the mixture was stirred for one hour at room temperature and then at gentle refluxing for 4 h. After evaporation of solvent, the residue was extracted with ether, and the ethereal solution was washed several times with brine, dried over Na_2SO_4, and concentrated *in vacuo*. To the residual oil a few ml of ethanol was added, then white crystals of **6a** were obtained (214 mg, 75%): Mp 110.5—113.0 °C (from hexane–ether). ^{1}H-NMR ($CDCl_3$): δ 1.38 (s, 6H, $2CH_3$), 1.88 (t, 2H, J=7 Hz, O–C–CH_2), 2.38 (s, 6H, $N(CH_3)_2$), 2.68 (t, 2H, J=7 Hz, Ar–CH_2–C), 3.70 (s, 2H, Ar–CH_2–N), 7.40 (m, 2H, arom. H), 8.14 (m, 2H, arom. H). IR: ν_{max}^{KBr} 2978(vs), 2830 (bs),

2780 (s), 1592 cm^{-1} (s). MS (20 eV); *m/e* 285 (M^+), 240 ($M^+-NH(CH_3)_2$). Found: C, 75.69; H, 8.26; N, 4.91%. Calcd for $C_{18}H_{23}NO_2$: C, 75.75; H, 8.12; N, 4.91%.

Crude Mannich base **6a** was acetylated with acetic anhydride and pyridine. 6-Acetoxy-5-dimethylaminomethyl-2,2-dimethyl-3,4-dihydro-2*H*-benzo[*h*]chromen **8a**: Mp ≈210 °C (dec) ^{1}H-NMR ($CDCl_3$): δ 1.42 (s, 6H, $2CH_3$), 1.88 (t, 2H, J=7 Hz, O-C-CH_2), 2.17 (s, 6H, $N(CH_3)_2$), 2.36 (s, 3H, $COCH_3$), 2.99 (t, 2H, J=7 Hz, Ar-CH_2-C), 3.31 (s, 2H, Ar-CH_2-N), 7.30—7.52 (m, 3H, arom. H), 8.04—8.20 (m, 1H, arom. H). IR: ν_{max}^{KBr} 2950 (s), 1765 (vs), 1370 (vs), 1208 (vs), 1183 cm^{-1} (s).

2,2-Dimethyl-5-piperidinomethyl-3,4-dihydro-2H-benzo[h]*chromen-6-ol (6b).* To a mixture of benzochromanol **1** (228 mg, 0.01 mol), piperidine (4 ml, 0.04 mol), and dioxane (30 ml), formalin solution (3 ml) was added at 10 °C, and allowed to react as described above. Colorless crystals **6b** (1.311 g, 81%) was obtained: Mp 133.5—134.2 °C (from aceton). ^{1}H-NMR ($CDCl_3$): δ 1.39 (s, 6H, $2CH_3$), 1.40—1.77 (m, 6H, $(CH_2)_3$), 1.86 (t, 2H, J=7 Hz, O-C-CH_2), 2.46—2.68 (m, 4H, $N(CH_2)_3$), 2.70 (t, 2H, Ar-CH_2-C), 3.76 (s, 2H, Ar-CH_2-N), 7.32—7.48 (m, 2H, arom. H), 8.08—8.24 (m, 2H, arom. H). IR: ν_{max}^{KBr} 2940 (vs), 2800 (s), 1593 (s), 1450 (vs), 1381 cm^{-1} (vs). MS (20 eV); *m/e* 325 (M^+). Found: C, 77.41; H, 8.30; N, 4.14%. Calcd for $C_{21}H_{27}NO_2$: C, 77.50; H, 8.36; N, 4.30%. **6b** was acetylated with acetic anhydride and pyridine. 6-Acetoxy-2,2-dimethyl-5-piperidinomethyl-3,4-dihydro-2*H*-benzo[*h*]chromen **8b**: Mp 155—157 °C (from acetone). ^{1}H-NMR ($CDCl_3$); δ 1.26—1.64 (m, 12H, $2CH_3$ and $(CH_2)_3$), 1.88 (t, 2H, J=7 Hz, O-C-CH_2), 2.22—2.44 (m, 7H, $COCH_3$ and $N(CH_2)_2$), 2.95 (t, 2H, J=7 Hz, Ar-CH_2-C), 3.36 (s, 2H, Ar-CH_2-N), 7.22—7.50 (m, 3H, arom. H), 7.94—8.16 (m, 1H, arom. H). IR: ν_{max}^{KBr} 2920 (vs), 1778 (vs), 1369 (vs), 1263 (vs), 1177 cm^{-1} (vs). MS (20 eV); *m/e* 367 (M^+). Found: C, 74.97; H, 8.13; N, 3.68%. Calcd for $C_{23}H_{29}NO_3$: C, 75.17; H, 7.95; N, 3.81%.

2,2-Dimethyl-5-morpholinomethyl-3,4-dihydro-2H-benzo[h]*chromen-6-ol (6c).* To a mixture of benzochromanol **1** (228 mg, 0.01 mol), morpholine (4 ml, 0.046 mol), and dioxane (20 ml), formalin solution (3 ml) was added at 10 °C. After 20 min at room temperature, white precipitate was observed in the reaction mixture. After the solution was stirred for 1 h at room temperature, it was refluxed for 3 h. After solvent was removed *in vacuo*, white crystals **6c** (2.74 g, 84%) were obtained in ethereal solution. **6c**: Mp 149—151 °C from acetone. ^{1}H-NMR ($CDCl_3$); δ 1.35 (s, 6H, $2CH_3$), 1.89 (t, 2H, J=7 Hz, O-C-CH_2), 2.57—2.90 (m, 6H, $N(CH_2)_2$ and Ar-CH_2-C), 3.68—3.84 (m, 6H, Ar-CH_2-N and CH_2-OCH_2), 7.28—7.43 (m, 2H, arom. H), 8.00—8.12 (m, 2H, arom. H). IR; ν_{max}^{KBr} 2960 (vs), 2895 (vs), 2830 (s), 1592 (vs), 1450 (vs), 1380 (vs), 1323 (vs), 1163 (vs), 1111 (vs), 976 cm^{-1} (s). MS (20 eV); *m/e* 327 (M^+), 240 ($M^+-HN\langle\rangle O$). Found: C, 73.21; H, 7.68; N, 4.22%. Calcd for $C_{20}H_{25}NO_3$: C, 73.36; H, 7.70; N, 4.28%.

6-Acetoxy-2,2-dimethyl-5-morpholinomethyl-3,4-dihydro-2*H*-benzo[*h*]chromen **8c**: Mp 151.5—153.0 °C (from acetone). ^{1}H-NMR ($CDCl_3$); δ 1.41 (s, 6H, $2CH_3$), 1.90 (t, 2H, J=7 Hz, O-C-CH_2), 2.36—2.50 (m, 7H, $COCH_3$ and CH_2N-CH_2), 2.98 (t, 2H, J=7 Hz, Ar-CH_2-C), 3.44—3.67 (m, 6H, Ar-CH_2-N and CH_2OCH_2), 7.36—7.60 (m, 3H, arom. H), 8.12—8.24 (m, 1H, arom. H). IR; ν_{max}^{KBr} 2930 (vs), 2865 (vs), 1770 (vs), 1450 (s), 1368 (vs), 1200 (vs), 1180 (vs), 1113 cm^{-1} (vs). MS (20 eV); *m/e* 369 (M^+). Found: C, 71.51; H, 7.44; N, 3.76%. Calcd for $C_{22}H_{27}NO_4$; C, 71.52; H, 7.39; N, 3.79%.

6-Acetoxy-2,2,5-trimethyl-3,4-dihydro-2H-benzo[h]*chromen (7) from 6a—c.* Aminomethylchromanol derivatives **6a—c** (1.7 mmol) were hydrogenated (5% Pd-C, 150 mg in 50 ml ethanol, H_2 5 kg/cm^2 at 80 °C for 2 h) to give **2**. **2**: ^{1}H-NMR ($CDCl_3$); δ 1.38 (s, 6H, $2CH_3$), 1.89 (t, 2H, J=7 Hz, O-C-CH_2), 2.27 (bs, 3H, Ar-CH_3), 2.60—3.00 (m, 2H, Ar-CH_2), 3.80 (bs, 1H, OH), 7.32—7.48 (m, 2H, arom. H), 7.88—8.24 (m, 2H, arom. H). IR; ν_{max}^{KBr} 3250 (vs), 2980 (s), 2920 (s), 1586 (s), 1396 (vs), 1323 (vs), 1161 (vs), 1019 cm^{-1} (vs). MS (20 eV); *m/e* 242 (M^+), 240 (M^+-H_2), 186 ($M^+-C_4H_8$).

Since **2** was very unstable in air, it was directly acetylated in acetic anhydride–pyridene to give **7** in each case of **6a**, **b**, and **c**. After usual work-up, **7** was obtained in the yield of 68, 83, and 81%, respectively (based on **6a**, **b**, and **c**). **7**; Mp 91.4—92.4 °C (from hexane). ^{1}H-NMR ($CDCl_3$) δ 1.39 (s, 6H, $2CH_3$), 1.87 (t, 2H, J=7 Hz, O-C-CH_2), 2.11 (s, 3H, Ar-CH_3), 2.36 (s, 3H, $COCH_3$), 2.71 (t, 2H, J=7 Hz, Ar-CH_2), 7.23—7.56 (m, 3H, arom. H), 8.00—8.14 (m, 1H, arom. H). IR; ν_{max}^{KBr} 2920 (s), 1754 (vs), 1362 (vs), 1206 (vs), 1162 cm^{-1} (vs). MS (20 eV); *m/e* 284 (M^+), 242. Found; C, 76.21; H, 7.04%. Calcd for $C_{18}H_{20}O_3$; C, 76.03; H, 7.09%.

Chloromethylation of 1. The ethereal solution (40 ml) of benzochromanol **1** (1 mmol) and paraformaldehyde (0.8 g) was chilled and dry hydrogen chloride was bubbled into the mixture for 2 h. The reaction mixture was poured into ice (20 g) and ethereal solution was separated, aqueous layer, was extracted with ether. The combined solution was washed with water and dried over Na_2SO_4. Products were separated by Wakogel C-200 column chromatography, dimer **11** was isolated (188 mg, 78%). **11**; Mp 177.5—178.0 °C (lit,[7] 160—161 °C). ^{1}H-NMR (CCl_4); δ 1.32 (s, 6H, $2CH_3$), 1.37 (s, 3H, CH_3), 1.38 (s, 3H, CH_3), 1.60—1.80 (m, 4H), 1.80—2.33 (m, 4H), 2.33—2.66 (m, 4H), 7.19 (m, 4H, arom. H), 7.43, 7.68 (each 1H, m, arom. H), 7.95 (m, 2H, arom. H). IR; ν_{max}^{KBr} 2980 (s), 2930 (s), 1695 (vs), 1658 (m), 1637 (w), 1595 (vs), 1385 (vs), 1162 cm^{-1} (vs). MS (20 eV); *m/e* 480 (M^+), 240 ($M^+/2$), 197 ($M^+/2-C_2H_3O$). Found; C, 79.95; H, 6.76%. Calcd for $C_{32}H_{32}O_4$; C, 79.97; H, 6.71%.

Hydride Reduction of the Dimer (11). The ethanol solution (30 ml) of the dimer **11** (404 mg, 0.92 mmol) and $NaBH_4$ (40 mg) was stirred for 1 h at ambident temperature, and after the usual work-up, **12** was quantitatively obtained. **12**; Mp 169—170 °C (from ether-hexane). ^{1}H-NMR ($CDCl_3$); δ 1.26 (s, 3H, CH_3), 1.35 (s, 6H, $2CH_3$), 1.41 (s, 3H, CH_3), 2.47—2.77 (m, 12H, $6CH_2$), 3.62 (bs, 1H, OH), 5.15 (s, 1H, CH), 7.10—7.56 (m, 6H, arom. H), 7.96—8.12 (m, 2H, arom. H). IR; ν_{max}^{KBr} 3435 (vs), 2935 (vs), 1385 (vs), 1162 cm^{-1} (s). MS (20 eV); *m/e* 482 (M^+). Found: C, 79.64; H, 7.15%. Calcd for $C_{32}H_{34}O_4$; C, 79.64, H, 7.10%.

Catalytic Hydrogenation of the Dimer (11). The dimer **11** (201 mg, 0.42 mmol) was hydrogenated (5% Pd-C 60 mg in 50 ml ethanol, H_2, 4 kg/cm^2 at 50 °C for 4 h) quantitatively to give 2,2,2′2′-tetramethyl-3,4,3′,4′-tetrahydro-5,5′-ethylene-di(2*H*-naphtho[1,2-*b*]-pyran)-6,6′-diol **13**. **13**; Mp >270 °C (dec). ^{1}H-NMR ($CDCl_3$); δ 1.39 (s, 12H, $4CH_3$), 1.92 (t, 4H, J=7 Hz, 2O-C-CH_2), 2.68—3.12 (m, 8H, 4Ar-CH_2), 6.32 (bs, 2H, 2OH), 7.32—7.54 (m, 4H, arom. H), 7.92—8.34 m, 4H, arom. H). IR; ν_{max}^{KBr} 3450 (s), 2995 (s), 1660 (s), 1587 (vs), 1388 cm^{-1} (s). Found; C, 79.46; H, 7.16%. Calcd for $C_{32}H_{34}O_4$; C, 79.64; H, 7.10%.

Studies of Polymeric Flocculants. IX.[1] The Formation of Poly(methacrylohydrazide)-Copper(II) Complexes

Takamasa NONAKA,* Eiji MOMONO, and Hiroaki EGAWA

Department of Industrial Chemistry, Faculty of Engineering, Kumamoto University, Kurokami, Kumamoto 860

(Received August 22, 1978)

Formation constants for the complexes of poly(methacrylohydrazide) (PMH) with the copper(II) ion were measured by using a modification of Bjerrum's method proposed by Gregor and his coworkers. The pK_{a1} and pK_{a2} values of PMH determined in an aqueous solution with an ionic strength of 0.1 (KNO_3) at 25 °C were 3.20 and 10.61 respectively. Therefore, when the PMH–copper(II) complexes were formed above pH 7, the average number of ligands combined with one metal ion could be calculated approximately without using the first acid dissociation constant. The pK_{a2} value decreased with an increase in the ionic strength and temperature. The formation curves of the complexes showed that one copper(II) ion formed a coordination compound with six hydrazide groups in a high pH region (about pH 9). The formation constants increased with an increase in T_{Cu}/T_{HL} (the ratio of the total concentration of the copper(II) ion to the total concentration of the ligand) in the range higher than 0.1. The formation constants were unaffected by the degree of polymerization of PMH in the range from 64.1 to 5470, but the formation constants were affected by the kind of anion in copper(II) salts and neutral salts added and they increased in the order of $NO_3^- < SO_4^{2-} < Cl^-$. The thermodynamic parameters for the above reaction were determined by Ringbom's method.

The formation constants for polyelectrolytes–copper(II) complexes have been studied by many investigators.[2-7] However, the formation constants for poly(methacrylohydrazide)–metal(II) complexes had not been studied. In our preceding papers[1,8] we reported that poly(methacrylohydrazide) (PMH) could easily form water-insoluble complexes with heavy metals, especially with mercury(II), over a wide pH region and that mercury(II) could be removed from the solutions containing mercury(II) only or together with other metals. We also reported the formation constants for the complexes of PMH with bivalent transition metal ions and the average number of ligand combined with each metal ion, obtained by using a modification of Bjerrum's method. The formation curves for PMH–copper(II) complexes showed that one copper(II) ion formed a coordination compound with six hydrazide groups in a high pH region. In the present paper, in order to study in detail the formation of PMH–copper(II) complexes, the effect of T_{Cu}/T_{HL} ratio, the degree of polymerization of PMH, and the kind of anion in copper(II) salts and neutral salts added on the formation constants were investigated in an aqueous solution with an ionic strength of 0.1 at 25 °C. The changes in entropy, enthalpy, and free energy for the above reaction were also determined by Ringbom's method.

Experimental

Poly(methyl methacrylate) was prepared by solution polymerization initiated by benzoyl peroxide or α,α'-azobisisobutyronitrile in carbon tetrachloride, 1-dodecanol, and 1-dodecanethiol. Poly(methyl methacrylate) was purified by the conventional method, using acetone and methanol as solvent and precipitant respectively. The number average molecular weight of polymers was calculated by means of the following equation: $[\eta]=K M_n^a$.[9] The intrinsic viscosity was measured in benzene at 30 °C.

PMH was prepared by the hydrazinolysis of poly(methyl methacrylate) (1 g) with hydrazine hydrate (20 ml) at 175 °C for 7 h. The reaction mixture was poured into an excess of methanol in order to precipitate PMH. The PMH was purified by Soxhlet extraction with methanol for 80—100 h. The conversion was calculated on the basis of the nitrogen content of the PMH, itself determined by elemental analysis. Isobutyrohydrazide was selected as a monomeric model of PMH. Isobutyrohydrazide was prepared by treating ethyl isobutylate with anhydrous hydrazine at 90 °C for 6 h. It was purified by recrystallization from benzene. Found: C, 47.43; H, 9.63; N, 26.71%. Calcd for $C_4H_{10}N_2O$: C, 47.06; H, 9.80; N, 27.45%. All the other reagents were of a special reagent grade, and they were used without further purification.

Potentiometric Titration. In spite of the good solubility of PMH in water, the PMH–copper(II) complexes were apparently insoluble in water. Gregor *et al.*[2,3] showed that the binding phenomena are essentially the same whether the polymeric chelates precipitate or not, if the system is in equilibrium. Therefore, potentiometric titration was carried out by a batch method. The procedure was as follows: 5 ml of a 1 g/l PMH solution, 25 ml of a 0.2 mol/l neutral salt solution, and the desired amounts of a 0.005 mol/l potassium hydroxide solution were added into 100 ml stoppered flasks. Water was finally added to each flask until the total volume amounted to 50 ml. After nitrogen had been fully introduced into each flask in order to remove the CO_2, each flask was shaken by means of an incubator at 25 °C for 24 h. After shaking, the pH values of the solutions were measured by means of a Hitachi-Horiba F-7 pH meter at 25 °C under a nitrogen atmosphere. In the case of the complex formation from PMH and the copper(II) ion, a solution of copper(II) nitrate was added to each solution containing PMH and potassium nitrate. Then, the procedure described above was carried out.

Results and Discussion

PMH. The results of the synthesis of PMH are shown in Table 1. When Kern *et al.*[10] reported the synthesis and structure of poly(acrylohydrazide), they considered that each hydrazide group in the polymers contained 2/3 H_2O, even after the polymers had been dried *in vacuo*. It was found by thermo-balance analysis that PMH also contained about 1/3 H_2O per hydrazide group. It was recognized from the IR spectra (C=O, 1720 cm^{-1}) of the polymers obtained that the hydrazino-

		Calcd	47.7	8.1	22.0	22.2			

lysis of poly(methyl methacrylate) did not proceed completely under the present conditions. The calculated values of the elements in PMH shown in Table 1 were determined on the basis of the conversion and water content of PMH.

Acid Dissociation Constants of PMH. Albert *et al.*[11] and Nagano *et al.*[12] reported in detail the acid dissociation constants of hydrazide compound, they reported that the hydrazide compounds had two acid dissociation constants, *i.e.*, K_{a_1} in a low pH region and K_{a_2} in a high pH region. When the acid dissociation constants of PMH were measured in an aqueous solution with an ionic strength of 0.1(KNO_3) at 25 °C, the pK_{a_1} and pK_{a_2} values became 3.20 and 10.61 respectively.

It was proposed by Bjerrum that the average number of ligands combined with one metal ion can be calculated by means of Eq. 1, when the compounds with two acid dissociation constants such as hydrazide compounds form complexes with metal ions:

$$\bar{n} = \frac{[A_t] - ([H^+]^2/K_{a_1}K_{a_2} + [H^+]/K_{a_2} + 1)[A^-]}{[M_t]}, \quad (1)$$

where $[A^-]$, which represents the concentration of the free hydrazide groups in the polymers not combined with metal ions, can be calculated using the following equation:

$$[A^-] = \frac{(2-\alpha)[A_t] - [H^+] + [OH^-]}{2[H^+]^2/K_{a_1}K_{a_2} + [H^+]/K_{a_2}}. \quad (2)$$

$[A_t]$ is the total concentration of hydrazide groups in the polymers added, $[M_t]$ is the total concentration of the metal ions added, and K_{a_1} and K_{a_2} are the first and second acid dissociation constants respectively. α is the degree of neutralization. When the acid dissociation constants of isobutyrohydrazide were measured in an aqueous solution with an ionic strength of 0.1(KNO_3) at 25 °C, the pK_{a_1} and pK_{a_2} values became 3.27 and 10.74 respectively. It was found that the hydrogen ion due to the formation of complexes were released above pH 6.3. Therefore, in a higher pH region than 6.3, Eq. 1 can be approximated by

$$\bar{n} = \frac{[A_t] - ([H^+]/K_{a_2} + 1)[A^-]}{[M_t]}, \quad (3)$$

where

$$[A^-] = \frac{(1-\alpha)[A_t] - [H^+] + [OH^-]}{[H^+]/K_{a_2}}. \quad (4)$$

Thus, it is considered that the average number of ligands combined with one metal ion can be calculated by means of Eq. 3 without using pK_{a_1}. Consequently, the second acid dissociation constant, pK_{a_2}, of PMH was determined in detail.

Katchalsky and many other investigators have studied the potentiometric titration of polyelectrolytes,[13-15] they have shown that the experimental results for titra-

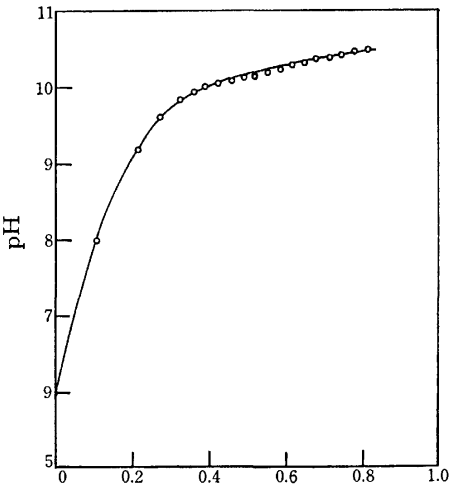

Fig. 1. The pH titration curve of PMH.
PMH ($\bar{P}_n$=5470): 8.64×10^{-4} unit mol/l, 25 °C, μ=0.10(KNO_3).

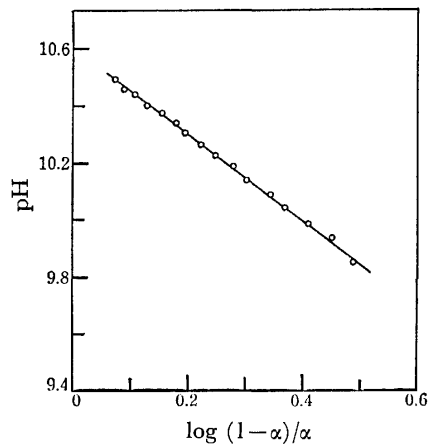

Fig. 2. Henderson-Hassebalch plots of PMH.
PMH ($\bar{P}_n$=5470): 8.64×10^{-4} unit mol/l, 25 °C, μ=0.10(KNO_3).

Table 2. pK_{a2} and n (25 °C, $\mu=0.10$)

Polymer	Neutral salt	pK_{a2}	n
Poly(methacrylohydrazide)	KNO_3	10.61	1.54
	K_2SO_4	10.58	1.48
	KCl	10.45	1.08

tion can be expressed by a modification of the Henderson-Hasselbach equation, $pH=pK_{a_1}-n \log (1-\alpha)$, where n is a constant. The pH titration curve of PMH with KOH in the solution with an ionic strength of 0.1(KNO_3) is shown in Fig. 1, while the Henderson-Hasselbach plots are shown in Fig. 2. The plots of pH *vs.* $\log (1-\alpha)/\alpha$ are linear in the range of the degree of neutralization from 0.3 to 0.8. The pK_{a_1} and n values of PMH were determined in solutions containing different neutral salts at 25 °C; the results are shown in Table 2. In a KCl aqueous solution, the pK_{a_1} and n values determined were smaller than those in the solutions of other neutral salts. Similar phenomena have been observed by Gregor *et al.*[2] for poly(acrylic acid). These pK_{a_1} values show that PMH behaves as a very weak acid, similarly to poly(vinyl alcohol),[4] poly(propenehydraxamic acid),[5] and poly(acrylaldehyde oxime)[6] under the present conditions. Machida *et al.*[16] reported that poly(acrylohydrazide) (conversion *ca.* 50%), which had been prepared by the hydrazinolysis of polyacrylamide with hydrazine hydrate, had a pK_{a_1} value of 10.64 and an n value of 1.36 at the ionic strength of 0.01(KCl) at 25 °C.

Table 3. Effect of the degree of polymerization of poly(methacrylohydrazide) on pK_{a2} and n

Polymer	$\bar{P}_n$	pK_{a2}	n
PMH-1	5470	10.61	1.54
PMH-2	991	10.64	1.55
PMH-3	456	10.60	1.53
PMH-4	64.1	10.61	1.49

Polymer concentration: *ca.* 8×10^{-4} unit mol/l, 25 °C, $\mu=0.1(KNO_3)$.

The pK_{a_1} and n values of PMH with different degrees of polymerization were determined at the ionic strength of 0.1(KNO_3); the results are shown in Table 3. Those results show that the degree of polymerization of PMH, ranging from 64.1 to 5470, did not affect the pK_{a_1} and n values.

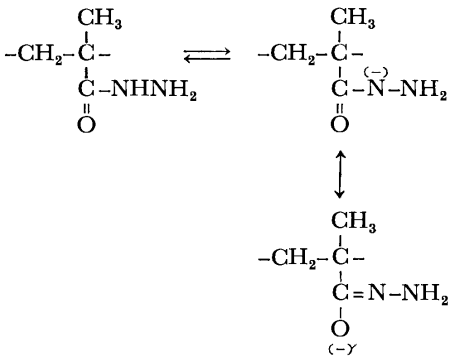
The pK_{a_1} and n values of PMH were determined at different temperatures (20—35 °C) and at different ionic strengths (0.01—0.1). The results are shown in Table 4. At the same temperature, the pK_{a_1} values decreased with an increase in the ionic strength, and at the same ionic strength, the pK_{a_1} values decreased with an increase in the temperature. These results suggest that the hydrazide groups of PMH in an aqueous solution are liable to dissociate with increases in the temperature and ionic strength. The n values were unaffected by either the temperature or the ionic strength under the present conditions. The plots of pK_{a_1} *vs.* $\sqrt[3]{\mu}$ at each temperature gave straight lines.[1] The thermodynamic acid dissociation constants, which were determined by an extrapolation of the linear pK_{a_1} *vs.* $\sqrt[3]{\mu}$ plots to the intercept, are shown in Table 5.

Table 5. pK°_{a2} of poly(methacrylohydrazide)

Temp (°C)	20	25	30	35
pK°_{a2}	10.90	10.76	10.62	10.46

Polymer ($\bar{P}_n=5470$): 8.64×10^{-4} unit mol/l.

Calculation of the Formation Constants. The formation constants for PMH–metal(II) complexes were calculated by a modification of Bjerrum's method proposed by Gregor *et al.*[2] It is considered that the hydrazide groups of PMH dissociate as follows in a pH region higher than pH 7:



(5)

If the hydrazide groups of PMH are represented by HA, the above equilibrium can be represented by the following simplified equation:

$$HA \rightleftarrows A^- + H^+ \quad (6)$$

and the second acid dissociation constant, K_{a_1} can be represented by the following equation:

$$K_{a_1} = \frac{[A^-][H^+]}{[HA]}. \quad (7)$$

Table 4. Effect of temperature and ionic strength on pK_{a2} and n

Ionic strength	20 °C		25 °C		30 °C		35 °C	
	pK_{a2}	n	pK_{a2}	n	pK_{a2}	n	pK_{a2}	n
0.01	10.83	1.49	10.69	1.56	10.55	1.51	10.39	1.48
0.02	10.80	1.51	10.67	1.53	10.52	1.51	10.36	1.50
0.05	10.77	1.51	10.63	1.52	10.48	1.48	10.33	1.50
0.10	10.74	1.48	10.61	1.54	10.46	1.51	10.30	1.50

Poly(methacrylohydrazide): $\bar{P}_n=5470$, 8.64×10^{-4} unit mol/l.
Neutral salt: KNO_3.

In the case under discussion, the formation of the complexes can be represented by the following equation:

$$HA + MA_{j-1} \rightleftarrows MA_j + H^+. \quad (8)$$

The equilibrium constants, b_j, pertaining to the above equation are represented as:

$$b_j = \frac{[MA_j][H^+]}{[MA_{j-1}][HA]}, \quad (9)$$

$$b_j = K_{a_2}k_j, \quad (10)$$

where K_{a_2} is the second acid dissociation constant of PMH and k_j is the successive formation constant of the complexes. By simple manipulations, Bjerrum formation function can be expressed in terms of the b_j's:

$$\bar{n} = \frac{\sum_{i=1}^{N} iB_i\left(\frac{[HA]}{[H^+]}\right)^i}{1+\sum_{i=1}^{N}B_i\left(\frac{[HA]}{[H^+]}\right)^i}, \quad (11)$$

$$B_i = \prod_{t=1}^{i} B_j. \quad (12)$$

The average number of ligands combined with one copper(II) ion, $\bar{n}$, is given by its definition as:

$$\bar{n} = \frac{[A_t]-[HA]-[A^-]}{[M_t]}. \quad (13)$$

The only unknown $[A^-]$ was calculated from the following equation, Eq. 14, by an iterative procedure for the PMH–copper(II) complexes:

$$K_{a_2} = \frac{[H^+][A^-]}{[HA]}\left(\frac{[A^-]}{[A_t]-[A^-]}\right)^{n-1} \quad (14)$$

where n is the value calculated from the modified Henderson-Hasselbach plots.

From the conservation equations and electroneutrality relation [HA], the concentration of undissociated PMH is found to be:

$$[HA] = [A_t](1-\alpha) + [OH^-] - [H^+] \quad (15)$$

where α is the degree of neutralization. $[H^+]$ and $[OH^-]$ are calculated from the measured pH values and the ionization constant of water, with a correction for the activity coefficients.[17]

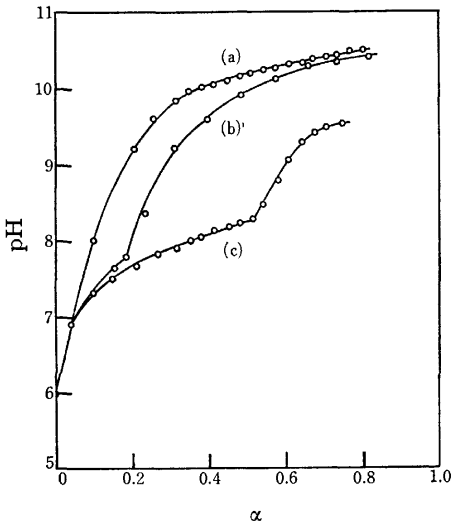


Fig. 3. The pH titration curves.
(a): PMH($\bar{P}_n$=5470) 8.64×10^{-4} unit mol/l, (b): $Cu(NO_3)_2$ 8.00×10^{-5} mol/l, (c): (a)+(b). 25 °C, μ=0.10(KNO_3).

Chelate Formation. Figure 3 shows the titration curves for PMH in the absence and in the presence of copper(II) ions at the ionic strength of 0.1(KNO_3) at 25 °C. PMH–copper(II) complexes precipitated throughout the pH range below about pH 8.5. Above pH 8.5, it was found that the precipitates redissolved into the solution. This shows that the precipitates were not copper(II) hydroxides. It is not always obvious why the precipitates became soluble in water above about pH 8.5. However, it is probably the result of the reversal of the charge of the complexes. From Fig. 3, it may be seen that the release of hydrogen ions caused by the formation of PMH–copper(II) complexes began at about pH 7 and continued up to pH 9, and that the six hydrogen ions per copper(II) ion were released.

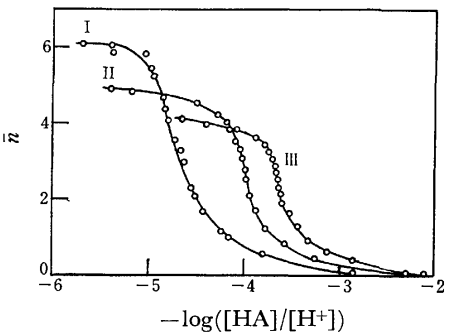

Fig. 4. Effect of T_{Cu}/T_{HL} on modified Bjerrum plots.
PMH($\bar{P}_n$=5470): 8.28×10^{-4} unit mol/l, 25 °C, μ=0.10(KNO_3).
T_{Cu}/T_{HL}; I: 0.024—0.097, II: 0.145, III: 0.193.

The Effect of the T_{Cu}/T_{HL} Ratio on the Modified Bjerrum Plots. The formation of PMH–copper(II) complexes was investigated in the range of the T_{Cu}/T_{HL} values from 0.024 to 0.193. The modified formation curves are shown in Fig. 4. From Fig. 4, it may be seen that the modified Bjerrum plots obtained in the range from 0.024 to 0.097 of the T_{Cu}/T_{HL} values fell on nearly the same curve. The plots show a definite tendency to flatten out toward a value of $\bar{n}$=6 as $-\log([HA]/[H^+])$ becomes more negative. This result suggests that one copper(II) ion forms a coordination compound with six hydrazide groups. However, when the T_{Cu}/T_{HL} values increased above 0.145, the modified formation curves moved to a less negative value of $-\log([HA]/[H^+])$. It was also found that $\bar{n}$ decreased from 6 to 4 with an increase in the T_{Cu}/T_{HL} values. In a previous paper,[1] we also reported that a copper(II) ion formed a coordination compound with six hydrazide groups of isobutyrohydrazide when the formation of isobutyrohydrazide–copper(II) complexes was investigated in the T_{Cu}/T_{HL} value of 0.1. Figure 5 shows the relationship between the successive formation constants and $\log(T_{Cu}/T_{HL})$. The successive formation constants had nearly the same values in the region below $\log(T_{Cu}/T_{HL})$ value of −1, but they increased remarkably in the region above $\log(T_{Cu}/T_{HL})$ value of −1. This suggests that the formation of PMH–copper(II) complexes is favored when the T_{Cu}/T_{HL} values become larger than 0.1.

The Effect of the Degree of Polymerization on the Modified Bjerrum Plots. The formation of PMH–copper(II)

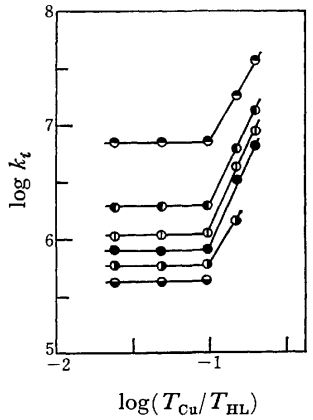

Fig. 5. Relation between formation constants and log-(T_{Cu}/T_{HL}). PMH($\bar{P}_n$=5470): 8.28×10^{-4} unit mol/l, 25 °C, μ=0.10(KNO_3).

complexes was investigated for PMH with different degrees of polymerization. The modified Bjerrum plots all fell on nearly the same curve irrespective of the degree of polymerization of PMH. That is, the formation constants for PMH–copper(II) complexes were unaffected by the degrees of polymerization ranging from 64.1 to 5470.

The Effect of the Kind of Anion on the Modified Bjerrum Plots. The formation of PMH–copper(II) complexes was investigated in a solution with the ionic strength of 0.1 by varying the anion (NO_3^-, Cl^-, SO_4^{2-}) in the copper(II) salts and neutral salts added. The modified Bjerrum plots are shown in Fig. 6, while the formation constants are listed in Table 6. It may be seen that the formation constants increased in this order: $NO_3^-<SO_4^{2-}<Cl^-$. As is already known, a complexation reaction in an aqueous solution is a replacement reaction between the ligands in the polymers and aqua-complexes of metals. Therefore, it is considered that the change in the structure of aqua-complexes of metals caused by counter anions and surrounding anions in the solution affected the formation constants. Hojo *et al.*[4] reported analogous phenomena for poly(vinyl alcohol)–copper(II) complexes, but they reported that the formation constants increased in the order of: $SO_4^{2-}<Cl^-<NO_3^-$. The difference in the order of formation constants between poly(vinyl alcohol)–copper(II) complexes and PMH–copper(II) complexes can not be explained at present.

Table 6 also lists the formation constants for isobutyrohydrazide determined in a solution with the ionic strength of 0.1(KNO_3); the data for isobutyrohydrazide were determined in a manner exactly analogous to that used for PMH described above. The data show that the isobutyrohydrazide–copper(II) complexes were more stable than PMH–copper(II) complexes. Such phenomena as that a monomeric analogue forms more stable complexes than its polymer have been observed for poly(acrylaldehyde oxime)[6] or poly(4-pentene-2,3-dione dioxime).[18]

Entropy and Enthalpy for Complexation for PMH–Copper-(II). Entropy and enthalpy changes for the complexation reaction between PMH and copper(II) ions were studied by using Ringbom's method.[19] The formation of PMH–copper(II) complexes was inves-

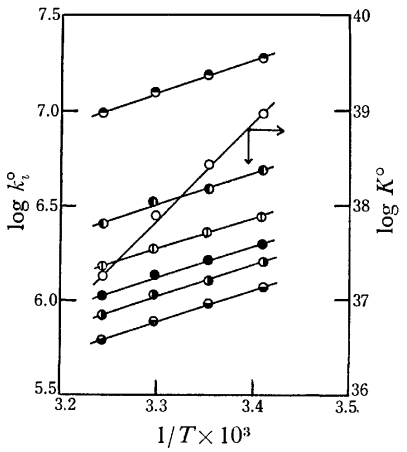

Fig. 8. Formation constants *vs.* $1/T$ plots PMH($\bar{P}_n$= 5470): 8.64×10^{-4} unit mol/l, $Cu(NO_3)_2$: 8.00×10^{-5} mol/l. ◓: log k_1°, ◐: log k_2°, ◑: log k_3°, ●: log k_4°, ◑: log k_5°, ◒: log k_6°, ○: log K°.

tigated at an ionic strength of 0.01—0.1 and a temperature of 20—35 °C. The relationship between the equilibrium constants, b_j, determined from the modified Bjerrum plots and $\sqrt{\mu}$ are shown in Fig. 7. It is found that the plots of log b_j *vs.* $\sqrt{\mu}$ are linear in the range from 0.01 to 0.1 of the ionic strength. The log b_i° was determined by the extrapolation of the linear log b_i *vs.* $\sqrt{\mu}$ plots to the intercept. The plots of log k_i° calculated from Eq. 10 *vs.* $1/T$ are shown in Fig. 8. In all cases, the plots of log k_i° *vs.* $1/T$ gave straight lines.

ΔH°, ΔG°, and ΔS° have the following equations:

$$\Delta G^\circ = -RT\ln K^\circ, \tag{16}$$

$$\ln K^\circ = \frac{-\Delta H^\circ}{RT} + C, \tag{17}$$

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ. \tag{18}$$

Here, from the slope of the plots of log K_i° *vs.* $1/T$, ΔH° for the reaction was obtained, ΔG° was obtained from the value of ln k_i° at 25 °C, and ΔS° was calculated from the difference between ΔH° and ΔG°. The results are shown in Table 7. All the ΔH° values are negative; this suggests that the formation reaction of PMH–copper(II) complexes is an exothermic reaction. Moreover, these values were five times as large as those for poly(vinyl alcohol)–copper(II) complexes.[4] This suggests that the PMH–copper(II) complexes are more stable than the poly(vinyl alcohol)–copper(II) complexes. The ΔS° values are positive, and they decrease as follows: $\Delta S_1^\circ > \Delta S_2^\circ > \cdots > \Delta S_6^\circ$. Generally, entropy increases because of the release of water, which is coordinated with copper(II) ions and polymeric ligands, as a result of the formation of PMH–copper(II) complexes. On the other hand, the degree of freedom of copper(II) ions and polymeric ligands decreases because of the coordination of copper(II) ions with hydrazide groups. Therefore, it is considered that the entropy changes for PMH–copper(II) complexes finally decreased in the order presented above. These phenomena have also been reported for poly(vinyl alcohol)–copper(II) complexes.[4]

Table 7. The thermodynamic parameters of PMH–copper(II) complexes

i	log k_i°	$-\Delta G_i^\circ$ (kcal/mol)	$-\Delta H_i^\circ$ (kcal/mol)	ΔS_i° (cal/deg·mol)
1	7.19	9.81	7.58	7.48
2	6.59	8.99	7.26	5.81
3	6.36	8.67	7.67	3.36
4	6.21	8.47	7.56	3.05
5	6.11	8.33	7.50	2.79
6	5.97	8.14	7.35	2.65
$\sum_{i=1}^{6} i$	38.43	52.41	44.63	26.11

PMH($\bar{P}_n$=5470): 8.64×10^{-4} unit mol/l, $Cu(NO_3)_2$: 8.00×10^{-5} mol/l. 1) HA + $Cu^{2+} \rightleftarrows CuA^+ + H^+$ 2) HA + $CuA^+ \rightleftarrows CuA_2 + H^+$ ……6) HA + $CuA_5^{3-} \rightleftarrows CuA_6^{4-} + H^+$.

From the results described above, it can be seen that one copper(II) ion formed a coordination compound with six hydrazide groups of PMH in a high pH region (about pH 9) when the T_{Cu}/T_{HL} values became less than 0.1. The formation constants were unaffected by the degree of polymerization of PMH, but were affected by the kind of anion of copper(II) salts and neutral salts added. From the thermodynamic data, it was recognized that the formation reaction of PMH–copper(II) was an exothermic reaction.

New C_{31} Secodammarane-type Triterpenoids, Alnuseric Acid and Alnuselide, in the Male Flowers of *Alnus serrulatoides*

Takayuki SUGA* and Toshifumi HIRATA

Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Hiroshima 730

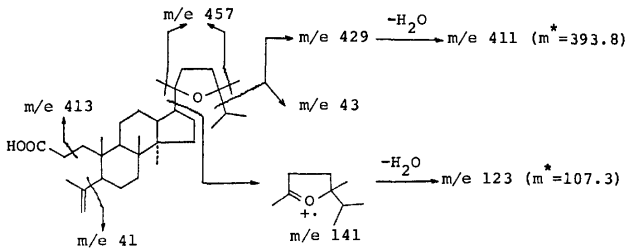
(Received September 4, 1978)

Two novel C_{31} 3,4-secodammarane-type triterpenoids, alnuseric acid and alnuselide, were isolated from the male flowers of *Alnus serrulatoides* Call. (Betulaceae); their structures were elucidated to be (20*S*,24*R*)-20,24-epoxy-24-methyl-3,4-secodammar-4(28)-en-3-oic acid and (11*R*,20*S*,24*R*)-20,24-epoxy-24-methyl-3,4-secodammar-4(28)-en-3,11α-olactone, respectively, by a combination of chemical and spectroscopic methods.

In connection with the chemical and biochemical studies on pollination of *Alnus* species,[1] we investigated chemical constituents of the male flowers of *Alnus serrulatoides* Call. (Japanese name: Kawara-hannoki) and reported the presence of novel C_{31} dammarane-type dihydroxy keto and 11α-hydroxylated triterpenoids.[2-4] A further investigation on constituents of the male flowers has led to the isolation of two novel triterpenic acid and triterpene lactone, named alnuseric acid and alnuselide, and preliminary accounts of the structural work have been presented in the previous papers, respectively.[5,6] We here wish to report *en bloc* detailed evidence which led to the establishment of the structures of these novel triterpenoids, which are featured in the C_{31} 3,4-secodammarane form.

Results and Discussion

The ether soluble fraction of the male flowers on separation by means of a centrifugal liquid chromatograph and then a preparative TLC gave alnuseric acid (I) and alnuselide (II), along with several dammarane-type triterpenoids, alnincanone,[2,7] alnuserol,[4] and alnuserrudiolone.[2]



Scheme 1. The mass spectral fragmentation pattern of alnuseric acid (I).

Alnuseric acid (I), $C_{31}H_{52}O_3$, showed IR absorption bands of a terminal methylene and a carboxyl group. The CMR spectrum in $CDCl_3$ also indicated the presence of the terminal methylene, the carboxyl, the ether ring, and eight methyl carbons. The peaks at *m/e* 141 (base), 123, and 43 in the mass spectrum was similar to those in it of alnincanone (III), a naturally occurring dammarane-type triterpenoid with a tetrahydrofuran ring. Ryabinin *et al.*[8] has proved the occurrence of such ions from the tetrahydrofuran ring of alnincanone (III). This has also been established in the mass spectra of alnuserol (IV)[4] and various compounds with a tetrahydrofuran ring.[9,10] Therefore, the occurrence of the peaks in the mass spectrum of alnuseric acid (Scheme 1) indicates clearly that this acid includes a side chain comprised of a tetrahydrofuran ring similarly to III and IV.

The molecular formula indicated that alnuseric acid has four rings, in contrast to alnincanone (III) and alnuserol (IV). Accordingly, alnuseric acid surely contains no ring A located with a carbonyl or hydroxyl group at position 3, though such functional groups appear almost without exception in plant triterpenoids. These structural features of alnuseric acid may result from the cleavage of ring A of a 3-keto triterpenoid having a side chain comprised of a tetrahydrofuran ring as III and IV. To the alnuseric acid, we here propose a biogenetically acceptable structure (I),[11] which is probably formed biologically from alnincanone by ring-cleavage at the 3,4-position.

The structure (I) proposed for alnuseric acid was confirmed by its synthesis starting from alnincanone (III) following the method established for ring-cleavage at the 3,4-position in ring A of β-amyrenone.[12] Alnincanone (III) was transformed to the corresponding ketoxime, which then was treated with *p*-toluenesulfonyl

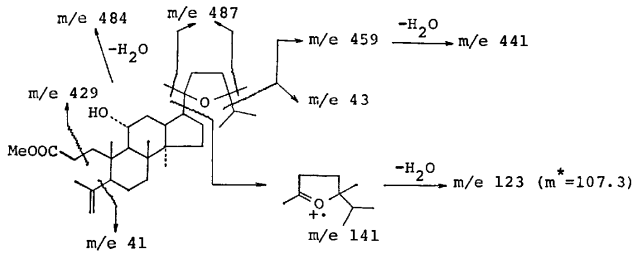
chloride in pyridine to yield an abnormal Beckmann rearrangement product (V) with infrared bands due to a cyano group and a terminal methylene. Alkaline hydrolysis of this product (V) under milder conditions gave (20*S*,24*R*)-20,24-epoxy-24-methyl-3,4-secodammar-4(28)-en-3-oic acid. Identity of this authentic acid with the naturally occurring alnuseric acid was established by comparison of the mixed melting point and spectral data. The structure of alnuseric acid has been elucidated to be in **I**.

Alnuselide (II), $C_{31}H_{50}O_3$, showed IR absorption bands due to a terminal methylene. The CMR spectrum indicated the presence of an ester or a lactone carbonyl, a terminal methylene, and eight methyl carbons in addition to two quaternary carbons bearing an oxygen atom. Appearance of the IR absorption band at 1740 cm^{-1} in CCl_4 suggested the presence of a six- or a seven-membered lactone moiety. This was confirmed by the formation of a hydroxy acid VI from II on hydrolysis with KOH/MeOH and the reproduction of II from VI on acidification with HCl/MeOH. Methylation of VI with CH_2N_2 yielded a hydroxy methyl ester VII, which exhibited the CMR signal at δ 71.2 ppm (d) due to the carbon atom occupied with a secondary hydroxyl group. The mass spectrum of VII (Scheme 2) showed the



Scheme 2. The mass spectral fragmentation pattern of hydroxy methyl ester VII derived from alnuselide (II).

fragmentation pattern quite similar to that of alnuseric acid methyl ester (VIII). This suggested a secodammarane-type triterpenoid with the side chain comprised of a tetrahydrofuran ring. The seco-form was also indicated by the molecular formula revealing that VII comprises four rings. Accordingly, the hydroxy methyl ester (VII) may be a 6- or a 11-hydroxylated derivative of VIII, because alnuselide (II) is found to involve a six- or a seven-membered lactone comprised of a secondary hydroxyl group as described above. The agreement between the carbon signals due to the C, D, and tetrahydrofuran rings of VII and the signals due to these rings of alnuserol (IV)[4] demonstrated that the secondary hydroxyl group should be located on C-11 of VII. Structure VII is assigned to the hydroxy methyl ester, and structure II is proposed for alnuselide, a novel triterpenoid lactone.

The structure (II) was confirmed by means of its synthesis involving the cleavage of the A-ring of alnuserol (IV)[4] followed by the lactonization of the resulting hydroxy acid. The oxime derivative of alnuseryl acetate (IX) prepared from alnuserol (IV) in the usual manner was treated[12] with *p*-toluenesulfonyl chloride in pyridine to yield a product (X) resulting from the abnormal Beckmann rearrangement. The hydrolysis of the product (X) with KOH/MeOH gave a hydroxy acid. This hydroxy acid on dissolving in ether saturated with 5% hydrochloric acid and then standing at room temperature suffered lactonization to form (11*R*,20*S*,24*R*)-20,24-epoxy-24-methyl-3,4-secodammar-4(28)-en-3,11α-olactone. Identity of naturally occurring alnuselide with this authentic sample was established by comparisons of the mixed melting point, and spectral data. Thus, the structure of alnuselide has been elucidated to be II. Biogenetically, it is fascinating to note that biological cleavage of ring A in alnuserol (IV), similarly to the case of alnuseric acid (I), followed by lactonization between the 3-carboxyl and the 11-hydroxyl groups might result in the formation of alnuselide (II).

Experimental

The mass spectral analyses were performed on a Hitachi RMS-4 mass spectrometer at 70 eV. The PMR spectra were taken with a Varian T-60 spectrometer using TMS as an internal standard. The CMR spectra were determined with a JEOL JNM FX-100 spectrometer operating at 15.1 MHz ($\delta_{TMS}=0$).

Extraction and Isolation. The male flowers (10.3 kg) of *Alnus serrulatoides* Call. grown wildly on a river side in suburbs of Hiroshima city were collected just before the flowering in late February. After minced mechanically, the flowers were immersed in acetone at room temp for 2 months. Removal of the solvent from the acetone solution gave a viscous sirup, which was extracted with ether to give a viscous oil (66.7 g). A part (20.0 g) of the viscous oil was subjected to a centrifugal liquid chromatography (silica gel; 3 mm in thickness) with a hexane–EtOAc mixture with EtOAc increasing 0 to 30% and then to preparative TLC (silica gel; 0.75 mm in thickness) with hexane–EtOAc (7: 3 v/v) to give alnuseric acid (I) (144 mg) and alnuselide (II) (198 mg).

Alnuseric Acid (I). Mp 107—109 °C; $[\alpha]_D^{25}$+24.3° (*c* 0.21, MeOH); IR (KBr) ν_{max} 3300—2800, 1708 (COOH), 3077, 1638, and 888 cm^{-1} (>C=CH$_2$), 1084 (C–O–C); PMR ($CDCl_3$) δ 0.8—1.2 (7×Me), 1.75 (3H, broad s, C(4)–Me), 4.70 and 4.85 (2H, broad s, >C=CH$_2$); CMR ($CDCl_3$) δ 180.2 (s, C-3), 147.4 (s, C-4), 113.4 (t, C-28), 85.8 and 85.3 (s, C-20 and C-24), 25.1, 23.2, 22.9, 20.1, 18.8, 17.6, 16.3, 15.4 (q, 8×Me); MS *m/e* (rel. intensity) 472 (M^+, 1), 457 (3), 429 (20), 411 (8), 141 (100), 123 (61), 43 (63), 41 (52). Found: C, 79.06; H, 11.01%. Calcd for $C_{31}H_{52}O_3$: C, 78.76; H, 11.09%. Methylation of I with CH_2N_2 gave the methyl ester (VIII): IR (liquid film) ν_{max} 1735 (ester), 3078, 1637, and 890 cm^{-1} (>C=CH$_2$); PMR ($CDCl_3$) δ 0.8—1.2 (7×Me), 1.76 (3H, broad s, C(4)–Me), 3.36 (3H, s, OMe), 4.72 and 4.86 (2H, broad s, >C=CH$_2$); MS *m/e* (rel. intensity) 486 (M^+, 2), 471 (3), 141 (100), 123 (60), 43 (65), 41 (59).

Alnuselide (II). Mp 139—140 °C; $[\alpha]_D^{25}$+ 107° (*c* 0.33, MeOH); IR (KBr) ν_{max} 1735 (lactone), 3066, 1635, and 877 cm^{-1} (>C=CH$_2$); UV (MeOH) λ_{max} 220 nm (ε 34.9); PMR ($CDCl_3$) δ 0.8—1.2 (7×Me), 1.79 (3H, broad s, C(4)–Me), 4.73 and 4.88 (2H, broad s, >C=CH$_2$); CMR ($CDCl_3$) δ 176.2 (s, C-3), 146.7 (s, C-4), 114.1 (t, C-28), 85.4 and 84.9 (s, C-20 and C-24), 76.5 (d, C-11), 24.9, 23.7, 22.9, 18.8, 18.7, 17.5, 17.0, and 15.6 (s, 8×Me); MS *m/e* (rel. intensity) 470 (M^+, 2), 426 (60), 408 (18), 141 (100), 123 (62), 43 (60), 41 (67), 28 (83); ORD (*c* 0.33, MeOH) $[\Phi]_{400}$+2090°, $[\Phi]_{219}$ +12300°; CD (*c* 0.33, MeOH) $[\theta]_{219}$+203°. Found: C, 79.01; H, 10.93%. Calcd for $C_{31}H_{50}O_3$: C, 79.10; H, 10.71%.

Preparation of Hydroxy Methyl Ester VII from Alnuselide. A solution of II (20 mg) in 5% NaOH/MeOH (5 ml) was reflux-

ed for 30 min. The reaction mixture, after acidification, was extracted with ether to give a crude product (18 mg), which was then purified by preparative TLC [silica gel; hexane–EtOAc (7:3 v/v)] to afford hydroxy acid VI (15 mg): IR (Nujol) ν_{max} 3350—2500 and 1710 cm^{-1} (OH and COOH). The hydroxy acid (VI) (4.0 mg) was treated for 12 h at room temp with ether (3 ml) saturated with 5% hydrochloric acid to reproduce the original lactone (II) (3.3 mg): mp and mixed mp 139—140 °C. Treatment of the hydroxy acid (VI) (10 mg) with CH_2N_2 gave hydroxy methyl ester VII (10 mg): IR (Nujol) ν_{max} 3350 (OH), 1731 (ester), 3080, 1635, and 883 cm^{-1} (>C=CH_2); MS *m/e* (rel. intensity) 502 (M^+, 0.5), 487 (2), 484 (4), 141 (100), 123 (71), 43 (45), 41 (47); PMR ($CDCl_3$) δ 1.77 (3H, broad s, C(4)–Me), 3.35 (3H, s, OMe), 4.71 and 4.87 (2H, broad s, >C=CH_2); CMR ($CDCl_3$) δ 175.8 (s, C-3), 147.4 (s, C-4), 113.7 (t, C-28), 85.3 (s, C-20 and C-24), 71.2 (d, C-11), 51.4 (q, OMe), 24.6, 23.1, 22.9, 20.4, 18.7, 17.5, 16.4, 16.0 (q, 8×Me). Found: C, 76.69; H, 10.70%. Calcd for $C_{32}H_{54}O_4$: C, 76.45; H, 10.83%.

Synthesis of I. *i) Cleavage of the A Ring of Alnincanone (III)*: According to the previously-described procedure,[12] a mixture of alnincanone oxime (30 mg; prepared from alnincanone (III)[2,7] and hydroxylamine hydrochloride in pyridine) and *p*-toluenesulfonyl chloride (30 mg) in dry pyridine (1.0 ml) was kept for 20 h at room temp. After addition of a few drops of water, the mixture was stirred for 30 min at room temp. The reaction mixture on acidification with 5% hydrochloric acid (10 ml) was extracted with ether to give a solid mass (27 mg), which was subjected to preparative TLC to give 3-cyano-20,24-epoxy-24-methyl-3,4-secodammar-4-(28)-ene (V) (8.2 mg): mp 101—103 °C; IR (Nujol) ν_{max} 2240 (C≡N), 3075, 1632, and 899 cm^{-1} (>C=CH_2); PMR ($CDCl_3$) δ 1.79 (3H, broad s, C(4)–Me) and 4.75 and 4.94 (2H, broad s, >C=CH_2). Found: C, 82.16; H, 11.20%. Calcd for $C_{31}H_{51}ON$: C, 82.06; H, 11.33%. This reaction, as has been described previously,[12] yielded an undesired product, aza-A-homodammarane derivative (12 mg): mp 195—197 °C; IR (Nujol) ν_{max} 1665 cm^{-1} (amide), which was not further investigated.

ii) Hydrolysis of V: A solution of V (5.0 mg) in 20% KOH/EtOH (2 ml) was refluxed for 6 h. The reaction mixture, after acidification was extracted with ether to give 20,24-epoxy-24-methyl-3,4-secodammar-4(28)-en-3-oic acid (I) (3.9 mg): mp 107—109 °C; IR (Nujol) 3300—2800 and 1710 (COOH), 3079, 1638, and 890 cm^{-1} (>C=CH_2); MS *m/e* (rel. intensity) 472 (M^+, 2), 141 (100), 123 (78), 43 (49), 41 (45); PMR ($CDCl_3$) δ 1.75 (3H, broad s, C(4)–Me), 4.70 and 4.85 (2H, broad s, >C=CH_2).

Synthesis of II. *i) Cleavage of the A Ring of Alnuserol (IV)*: By the same procedure as described above, the oxime derivative (228 mg) of alnuseryl acetate (IX)[4] was treated with *p*-toluenesulfonyl chloride (140 mg) in dry pyridine (10 ml) to give 11-acetoxy-3-cyano-20,24-epoxy-24-methyl-3,4-secodammar-4(28)-ene (X) (66 mg): mp 160—162 °C; IR (Nujol) ν_{max} 2245 (C≡N), 1730 (OAc), 3076, 1639, and 890 cm^{-1} (>C=CH_2); PMR ($CDCl_3$) δ 1.77 (3H, broad s, C(4)–Me), 2.07 (3H, s, OAc), 4.72 and 4.92 (2H, broad s, >C=CH_2). Found: C, 77.66; H, 10.51%. Calcd for $C_{33}H_{53}O_3N$: C, 77.45; H, 10.44%. In a similar manner as above, this reaction gave the undesired aza-A-homodammarane derivative (48 mg): mp 225—226 °C; IR (Nujol) ν_{max} 1666 cm^{-1} (amide).

ii) Hydrolysis of X: A solution of X (20 mg) in 20% KOH/MeOH (5 ml) was refluxed for 12 h. The reaction mixture on usual work-up gave 20,24-epoxy-11-hydroxy-24-methyl-3,4-secodammar-4(28)-en-3-oic acid (VI): IR (Nujol) 3350—2500 (OH and COOH), 1708 (COOH), 3080, 1640, and 890 cm^{-1} (>C=CH_2); PMR ($CDCl_3$) δ 1.73 (3H, broad s, C(4)–Me), 4.71 and 4.86 (2H, broad s, >C=CH_2).

iii) Lactonization of VI: Hydroxy acid VI (10 mg) dissolved in ether (5 ml) saturated with 5% hydrochloric acid was left stand for 12 h at room temp to give (11*R*, 20*S*, 24*R*)-20,24-epoxy-24-methyl-3,4-secodammar-4(28)-en-3,11α-olactone (II) (9.0 mg): mp 139—140 °C; IR (Nujol) ν_{max} 1735 (lactone), 3080, 1635, and 890 cm^{-1} (>C=CH_2); MS *m/e* (rel. intensity) 470 (M^+, 2), 141 (100), 123 (68), 43 (59), 41 (67); PMR ($CDCl_3$) δ 1.80 (3H, broad s, C(4)–Me), 4.73 and 4.89 (2H, broad s, >C=CH_2).

We thank Miss Reiko Ideo for having charge of a part of the experiments and JEOL Co., Ltd. for obtaining the ^{13}C-NMR spectra. The present work was partially supported by a Grant-in-Aid for Scientic Research from the Ministry of Education (Nos. 247027 and 234033 to T.S.) and Matsunaga Science Foundation in 1977 (to T.H.).

Reactive Troponoids and *o*-Aminophenol. III. The Reaction of 2-Bromo-7-methoxytropone[1]

Tetsuo NOZOE, Taichi SOMEYA,* and Harue OKAI†

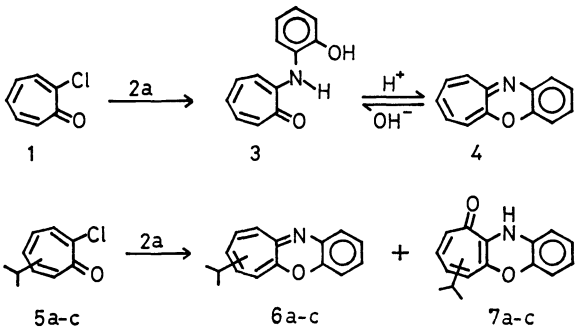
Central Research Laboratory of Takasago Perfumery Co., Ltd., Kamata, Ohta-ku, Tokyo 144

† *Tokyo Research Laboratory of Kao Soap Co., Ltd., Bunka, Sumida-ku, Tokyo 131*

(Received September 9, 1978)

The reaction of 2-bromo-7-methoxytropone with *o*-aminophenol gave 2-bromo-7-(*o*-hydroxyanilino)tropone (**9**), besides small amounts of cyclohepta[*b*][1,4]benzoxazin-6(11*H*)-one (**10**) and 15*H*-[1,4]benzoxazino[3′,2′: 3,4]-cyclohepta[2,1-*b*][1,4]benzoxazine (**11**). The heating of **9** with a strong acid afforded 6-bromocyclohepta[*b*][1,4]-benzoxazine (**13**) quantitatively. On the other hand, the heating of **13** with *o*-aminophenol in ethanol gave **10**, while in acetic acid a mixture of **10** and **11** was obtained. The mechanism of the formation of these products is discussed.

We have previously reported that the reaction of 2-chlorotropone (**1**) with *o*-aminophenol (**2a**) afforded 2-(*o*-hydroxyanilino)tropone (**3**) and cyclohepta[*b*][1,4]-benzoxazine (**4**).[2] The reactions of 4-, 5-, and 6-isopropyl-2-chlorotropones (**5a**—**c**) with *o*-aminophenol gave isopropylcyclohepta[*b*][1,4]benzoxazines (**6a**—**c**), besides a small amount of cyclohepta[*b*][1,4]benzoxazin-10(11*H*)-ones (**7a**—**c**). We also found that, in these reactions, the amino group of *o*-aminophenol attacked the 1- and 2-positions of the tropone ring equally.[3]

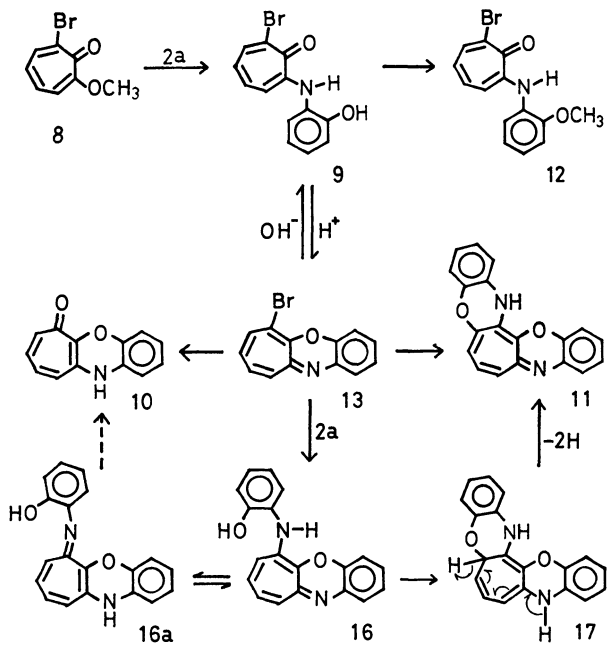


In the present investigation, the reaction of *o*-aminophenol with 2-bromo-7-methoxytropone (**8**), which has two leaving groups, was carried out to find which of two groups, bromo or methoxyl, reacted preferentially and to see if the use of an excess of *o*-aminophenol would give a seven-membered tropylium compound with two oxazine rings.

Results and Discussion

The refluxing of **8** with *o*-aminophenol (**2a**) in acetic acid for 2 h gave yellow prisms (**9**, 82%), orange yellow needles (**10**, 4.7%), and dark violet needles (**11**, 0.5%). The methylation of **9** with diazomethane gave a product which agreed with the 2-bromo-7-(*o*-methoxyanilino)-tropone (**12**) obtained by the reaction of **8** with *o*-methoxyaniline (**2b**) (Scheme 1).

The heating of **9** in acetic acid, in the presence of concd sulfuric acid, resulted in the quantitative formation of **13**, which then easily reverted to **9** on being heated in dilute ethanolic alkali. The catalytic reduction of **13** gave cyclohepta[*b*][1,4]benzoxazine (**4**).[2] These pieces of evidence indicate that **9** is 7-bromo-2-(*o*-hydroxyanilino)tropone and that **13** is 6-bromocyclo-



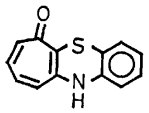
Scheme 1.

hepta[*b*][1,4]benzoxazine. These structures were also supported by the results of the elemental analyses and by the spectral data.

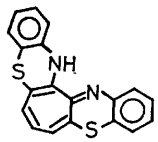
The electronic spectrum of **10** (M^+, 211; $C_{13}H_9NO_2$) is very similar to that of cyclohepta[*b*][1,4]benzothiazin-6(11*H*)-one (**14**).[4] The IR spectrum of **10** shows absorptions at 3300 (NH) and at 1650 cm^{-1} (C=O), which correspond well with those at 3280 (NH) and at 1633 cm^{-1} (C=O) in the IR spectrum of **14**.[4] Consequently, **10** was determined to be cyclohepta[*b*][1,4]-benzoxazin-6(11*H*)-one.

The IR spectrum of **11** (M^+, 300; $C_{19}H_{12}N_2O_2$) shows an absorption at 3250 cm^{-1} (NH). Since the further heating of **13** with **2a** in acetic acid afforded **11** besides **10**, **11** was assumed to be 15*H*-[1,4]benzoxazino[3′,2′: 3,4]cyclohepta[2,1-*b*][1,4]benzoxazine. The visible absorption maximum at 500 nm in **11** corresponds well with that at 490—500 nm in **15**, a tropylium compound with two condensed thiazine rings, which was obtained by the reaction of 3,5-dibromotropolone with *o*-amino-benzenethiol.[4]

The bromo compound **13** was fairly stable on heating in strong acids and did not undergo any change, but the



14



15

refluxing of **13** with **2a** in acetic acid resulted in the formation of **10** and **11**, although it should be noted that the refluxing of **13** with **2a** in ethanol gave mainly **10**, and no **11**. It is interesting to note that, although **13** does not change in strong acids, **13** loses bromine by the reaction with almost neutral **2a** even in ethanol and that the bromine atom is replaced with an oxygen atom. The experiments mentioned above suggest that the saponification of the bromine atom in **13** should be preceded by substitution with **2a**, giving the 6-(*o*-hydroxyanilino) compound (**16**). The Schiff base **16a**, a tautomeric form of **16**, could be saponified under dilute acidic conditions to give the ketone (**10**).

However, since the ketone (**10**) was not obtained by the reaction of **13** with aniline under the same reaction conditions, the hydroxyl group in the substituent at C-6 in **16** seems to participate in the formation of **10**. A study of the mechanism of the ketone (**10**) is now under investigation.

Compound **16** would also be cyclized at the 7-position to form **17**, which then undergoes dehydrogenation to form the more stable **11**.

It is quite notable that the hydroxyanilino group bonded to the seven-membered ring undergoes cyclization on the seven-membered ring not containing a functional group.[3]

Experimental

If not otherwise stated, the instruments and methods are as previously described.[2]

Reaction of 2-Bromo-7-methoxytropone (8) with 2a. A mixture of **8** (1.5 g, 7.0 mmol), **2a** (0.9 g, 8.4 mmol), and acetic acid (4.5 ml) was refluxed for 2 h. After the removal of the acetic acid under reduced pressure, a small amount of ethanol was added to the residue and the precipitate was filtered. The recrystallization of the crude crystals from ethanol gave 1.23 g of **9**. The filtrate and the mother liquor of the recrystallization were chromatographed on a silica gel column. Then, **11** (10 mg, 0.5%), **10** (70 mg, 4.7%), and **9** (370 mg) were obtained from the benzene, benzene–ether (1: 1), and ether fractions respectively.

2-Bromo-7-(o-hydroxyanilino)tropone (9): Yellow prisms; mp 202 °C; λ_{max}^{MeOH} nm (log ε): 205 (4.52), 250 (4.38)^{sh}, 260 (4.39), 346 (3.98), and 418 (4.20); $\lambda_{max}^{MeOH+NaOH}$ nm (log ε): 240 (4.72), 346 (3.98), and 423 (4.20); IR (KBr): 3280 (NH), 3200 (OH), and 1585 cm^{-1} (C=O); NMR (60 MHz in DMSO-d_6): δ 10.0 (s, 1H, OH), 9.25 (s, 1H, NH), 8.24 (dd, 1H, J=10 and 1 Hz, C_3–H), 7.15—7.55 (m, 2H, $C_{5,6}$–H), 6.80—7.15 (m, 4H, benzene ring), and 6.55 ppm (t, 1H, J=10 and 10 Hz, C_4–H). Found: C, 53.40; H, 3.54; N, 4.62%; M$^+$, 293. Calcd for $C_{13}H_{10}NO_2Br$: C, 53.44; H, 3.45; N, 4.80%; M, 293.

Cyclohepta[b][1,4]benzoxazin-6(11H)-one (10): Orange yellow needles; mp 115 °C (from hexane); λ_{max}^{MeOH} nm (log ε): 207 (4.28), 227 (4.43), 275 (3.88), 310 (3.48), and 435 (3.74); IR (KBr): 3300 (NH) and 1650 cm^{-1} (C=O); NMR (60 MHz in $CDCl_3$): δ 9.10 (s, 1H, NH) and 6.30—7.05 ppm (m, 8H). Found: C, 73.64; H, 4.27; N, 6.70%; M$^+$, 211. Calcd for $C_{13}H_9NO_2$: C, 73.92; H, 4.30; N, 6.63%; M, 211.

15H-[1,4]Benzoxazino[3',2': 3,4]cyclohepta[2,1-b][1,4]benzoxazine (11): Dark violet needles; mp 245 °C (from hexane); λ_{max}^{MeOH} nm (log ε): 207 (4.10), 254 (3.99), 350—360 (3.43), and 500 (3.68); $\lambda_{max}^{MeOH+HCl}$ nm (log ε): 207 (4.08), 223 (4.02), 275 (4.00), 325 (3.57)^{sh}, 410 (3.68), and 535 (3.54); IR (KBr): 3250 cm^{-1} (NH); NMR (60 MHz in DMSO-d_6): δ 6.70—6.45 (m, 8H, benzene ring) and 5.72 ppm (m, 3H, cycloheptatriene ring). Found: C, 76.25; H, 4.09; N, 9.38%; M$^+$, 300. Calcd for $C_{19}H_{12}N_2O_2$: C, 75.99; H, 4.03; N, 9.33%; M, 300.

2-Bromo-7-(o-methoxyanilino)tropone (12). a) An ether solution of diazomethane (0.51 mmol) was added to a solution of **9** (0.1 g, 0.34 mmol) in ether (20 ml), and the mixture was stirred for 5 min at room temp. After the removal of the ether, the recrystallization of the residue from benzene gave 0.1 g (95%) of **12**.

b) A mixture of **8** (0.1 g, 0.45 mmol), **2b** (66 mg, 0.54 mmol), and acetic acid (1 ml) was refluxed for 5 h. After the removal of the acetic acid under reduced pressure, the residue was dissolved in benzene. The benzene solution was washed with aq $NaHCO_3$ and water, dried over Na_2SO_4, and evaporated. The residue was chromatographed on a silica gel column; then **12** (61 mg, 91%) and **9** (53 mg) were obtained from the benzene–ether (3: 1) and ether fractions respectively. **12**: Yellow needles; mp 132 °C; λ_{max}^{MeOH} nm (log ε): 205 (4.46), 244 (4.33), 260 (4.34), 348 (4.10), and 420 (4.31); IR (KBr): 3260 (NH) and 1680 cm^{-1} (C=O); NMR (60 MHz in DMSO-d_6): δ 9.25 (s, 1H, NH), 8.20 (d, 1H, J= 10 Hz, C_3–H), 7.20—7.52 (m, 2H, $C_{5,6}$–H), 6.85—7.20 (m, 4H, benzene ring), and 6.57 ppm (m, 1H, C_4–H). Found: C, 55.17; H, 4.07; N, 4.40; Br, 26.16%; M$^+$, 307. Calcd for $C_{14}H_{12}NO_2Br$: C, 54.92; H, 3.95; N, 4.58; Br, 26.10%; M, 307.

6-Bromocyclohepta[b][1,4]benzoxazine (13). A solution of **9** (0.7 g, 2.4 mmol), acetic acid (5 ml), and a small amount of concd H_2SO_4 was refluxed for 1 h. After the removal of the acetic acid under reduced pressure, the residue was dissolved in benzene. The benzene solution was washed with aq $NaHCO_3$ and water, dried over Na_2SO_4, and evaporated. The recrystallization of the residue from hexane gave 0.65 g (98%) of **13** as brown needles; mp 119 °C; λ_{max}^{MeOH} nm (log ε): 208 (4.30), 227 (4.31), 262 (4.43), 268 (4.42), and 410 (4.08); NMR (60 MHz in CCl_4): δ 6.40—6.75 (m, 4H, benzene ring) and 5.30—6.55 ppm (m, 4H, cycloheptatriene ring); NMR (in CF_3COOH): δ 7.75 (d, 1H, J=11 Hz, C_7–H) and 6.45—7.40 ppm (m, 7H). Found: C, 57.08; H, 2.84; N, 5.06; Br, 29.27%; M$^+$, 275. Calcd for $C_{13}H_8NOBr$: C, 56.96; H, 2.94; N, 5.11; Br, 29.15%; M, 275.

The hydrogenation of **13** in ethyl acetate and a small amount of pyridine with palladium carbon (5%) as a catalyst under normal pressure at room temp gave cyclohepta[*b*][1,4]benzoxazine[2] as brown needles; mp 93 °C.

Conversion of 13 into 9. A solution of **13** (50 mg) in EtOH (1 ml) and 1 M NaOH (1 ml) was refluxed for 1 h. After the removal of the ethanol, water (2 ml) was added to the residue, and the mixture was washed with benzene. The water layer was neutralized with 1 M HCl and extracted with benzene. The extract was washed with water, dried, and evaporated to dryness. Recrystallization from hexane gave 45 mg (84%) of **9**.

Reaction of 13 with 2a. A mixture of **13** (55 mg, 0.2 mmol), **2a** (26 mg, 0.24 mmol), and acetic acid (5 ml) was

refluxed for 4 h. After the removal of the acetic acid under reduced pressure, the residue was extracted with benzene. From the extract, 10 mg (17%) of **11** and 15 mg (36%) of **10** were obtained by preparative TLC developed with benzene. On the other hand, a mixture of **13** (85 mg), **2a** (45 mg), and EtOH (5 ml) was refluxed for 3 h. By the method described above, a 50-mg portion (76%) of **10** was obtained.

The authors wish to express their thanks to Dr. Isao Kawamoto and the Sankyo Co., Ltd., for measuring some of the mass spectra and for their elemental analyses.

The Conformation and the Ring Inversion of 8,9,10,11-Tetrahydro-7*H*-cycloocta[*de*]naphthalene

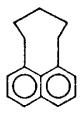
Toshihiro KAMADA* and Osamu YAMAMOTO

National Chemical Laboratory for Industry, Honmachi, Shibuya-ku, Tokyo 151

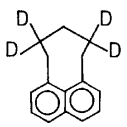
(Received September 12, 1978)

The ^{1}H-NMR spectra of 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene (**1**) and its 8,8,10,10-tetradeuterio derivative have been studied at various temperatures. The NMR parameters of compound **1** were determined accurately by means of computer analysis of the low-temperature spectrum. It was found that the ground-state conformation of **1** is a boat, which is somewhat in a distorted form (puckering) as a result of the steric repulsion between the interior benzyl protons. Activation parameters $\Delta G^{\ddagger}$, $\Delta H^{\ddagger}$, and $\Delta S^{\ddagger}$, for the boat inversion process in the molecule were obtained by the line-shape analysis method as 14.5, 16.1 kcal/mol and 5.4 e.u., respectively. These results are best explained in terms of a conformational interconversion process in which the pseudorotations of the peri bonds are involved. Some discussion is also made on the conformational properties of compound **1** in comparison with those of the structurally analogous benzocyclic compound 6,7,8,9-tetrahydro-5*H*-benzocycloheptene.

Recently, as parts of our studies on the chemistry of pericyclic naphthalenes, we have studied the conformations of several derivatives of the 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene system.[1,2] In the course of these studies, it was found that the eight-membered peri rings in these compounds are rather strained due to the peri interaction inherent in the peri-substituted naphthalenes.[3] In the present paper, in order to determine accurately the effects of the peri strains on the ring geometry of the 8-membered pericyclized naphthalenic compound and to study in detail the ring inversion of this system, a study has been made on the conformation of the parent compound **1**.



1



2

Since the knowledge of conformational properties of compound **1** is fundamental and very important for studies of the chemistry of the 8-membered pericyclized naphthalene system, it is worthwhile to discuss fully on the conformation and the ring inversion of this molecule based on the accurate and reliable experimental data, though some brief discussion on these points has already been made by Nelsen and Gillespie[4] using the approximate NMR methods (first order approximation and coalescence temperature method).

In this paper, we study the ^{1}H-NMR spectra of compound **1** and its 8,8,10,10-tetradeuterated derivative **2** at various temperatures. The computer analysis of the low-temperature spectrum is performed to determine the accurate NMR parameters of **1**, from which the precise geometry of the stable ground-state conformation of **1** is defined. Further, we report the results of the complete line shape analysis of the temperature-dependent ^{1}H-NMR spectra of **1** by means of the density matrix method, and present the kinetic parameters of the ring inversion process in **1**. We will also discuss about the ^{1}H-NMR result and the conformational properties of **1** by comparing with those of the structurally analogous 6,7,8,9-tetrahydro-5*H*-benzocycloheptene (**3**).

Results

The room-temperature ^{1}H-NMR spectrum of the alkyl portion of 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]-naphthalene-8,8,10,10-d_4 (**2**) in *ca.* 10% solution in the deuteriochloroform consists of a singlet at δ 1.24 for the C_9-protons (2H) and a broad hump centered at δ 3.47 for the C_7- and C_{11}-protons (4H). As the temperature of the sample is progressively lowered each methylene signal broadens and then splits into an AB quartet characterized by the chemical-shift difference ($\Delta\delta$) of 0.314 and 1.035 ppm ($J_{AB}=-14.4$ Hz), respectively. The lower-field signal of the benzylic AB pattern can be assigned to the interior protons (H_{in}) on C_7 and C_{11} positions of the peri ring, since these protons are expected to have a large steric interaction owing to their proximity with each other.[1,2,4]

The aromatic region of the spectrum of **2** consists of three quartets of equal intensities (2H) which show almost no change in their appearence on the variation of temperature. From the peak area and the values of the chemical shifts and coupling constants, these signals can be assigned most reasonably as is shown in Table 2.[1]

The room-temperature ^{1}H-NMR spectrum of the aliphatic region of 8,9,10,11-tetrahydro-7*H*-cycloocta-[*de*]naphthalene (**1**) dissolved (*ca.* 10%) in a mixture of deuteriochloroform and carbon disulfide (3: 1) consists of a broad band at δ 2.6—3.2 for the benzylic protons (4H), a somewhat broad quintet at δ 1.86 (4H, J=*ca.* 6.6 Hz) for the C_8- and C_{10}-protons and a multiplet centered at δ 1.30 for the C_9-protons (2H). As the temperature is decreased the spectrum undergoes a change such that at −44.7 °C the benzyl methylene signals are separated into two distinct absorption bands of equal intensities, consisting of eight lines, whereas the signals centered at δ 1.86 and 1.30 are changed into more complex multiplets resonating at δ 1.6—2.2 and 0.8—1.8, respectively. These signals remained unchanged on further decrease in temperature (*ca.* −100 °C).

Figure 1a shows the low-temperature ^{1}H-NMR spectrum of the benzyl methylene groups of **1**, where

TABLE 1. NMR PARAMETERS OF THE BENZYLIC METHYLENE PROTONS OF **1**

	Chemical shifts (ppm)[a]		Coupling constants (Hz)				
	δ_{7in}[d]	δ_{7ex}	J_{7gem}	$J_{7in,8eq}$	$J_{7ex,8ax}$	$J_{7in,8ax}$	$J_{7ex,8eq}$
1[b]	3.9742	2.9406	−14.23	12.88	1.28	6.49	6.82
2[c]	3.975 (4.8)	2.940 (2.9)	−14.4				

a) δ from internal standard TMS. b) Obtained from the computer simulation of the spectrum of **1** at −44.7 °C. c) Obtained by the first order analysis of the spectrum of **2** at −26.7 °C; the figures in the parentheses are the values of the line widths of the signals (in Hz). d) The numbers refer to the carbon position on the ring and the letters are as follows; in (interior), ex (exterior), eq (equatorial) and ax (axial).

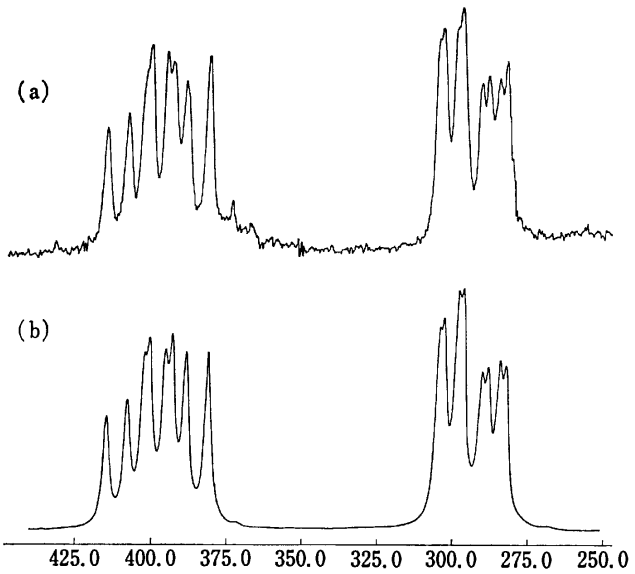


Fig. 1. The observed (a) and the calculated (b) NMR spectra of the benzylic methylene protons of **1** at −44.7 °C.

the low-field signal is assigned to the interior protons and the high-field one to the exterior protons as described above. Analysis of this spectrum as AB part of an ABCD spin system using LAOCOON MBYH program[5] afforded chemical shifts and coupling constants of the benzyl protons of **1** listed in Table 1. The calculated spectrum (Fig. 1b) obtained from these NMR parameters agrees well with the observed one (Fig. 1a). Computer analyses were also attempted for the spectra of the C_8- and C_9-protons but unsuccessful, since these signals are very complex because of their small shift differences.

On the other hand, when the temperature of the sample is elevated, the broad band of the benzylic protons of **1** sharpens and then splits into a triplet (J=6.8 Hz) above 70 °C. The chemical shift (δ=3.45) and coupling constant (J=6.8 Hz) of the benzyl protons of **1** obtained from the high-temperature spectrum are in good agreement with the values (δ=3.46 and J= 6.7 and 7.1 Hz) obtained by averaging the low-temperature data in Table 1.

From the temperature-dependent ^{1}H-NMR spectra of compounds **1** and **2** described above, it is indicated that the 8-membered peri ring of **1** undergoes the conformational change in the temperature range studied, by which the interior and exterior benzyl protons are interchanged. Figure 2a illustrates the gradual spectral changes observed for the benzyl methylene protons of **1** at various temperatures. In order to determine the kinetic parameters for the conformational change of **1**, the complete line shape analysis of the benzyl proton signals of **1** was performed by means of the density

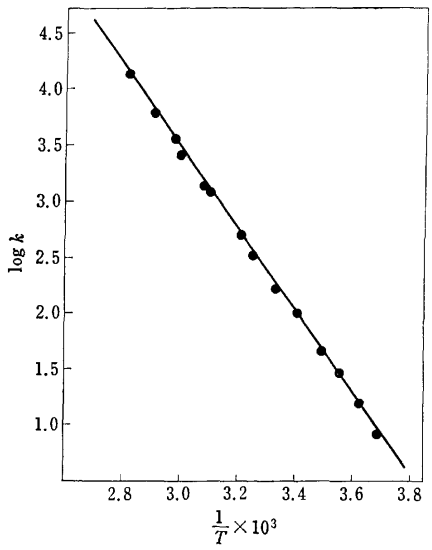

Fig. 3. Arrhenius plot for the ring inversion of **1**.

matrix method[6] using INVERS EX2 program[7] developed by the author (O. Yamamoto) previously. By computer simulation of the temperature-dependent spectra of the benzyl methylene protons, using the NMR parameters given in Table 1, the rate constants (k) for exchanging the benzyl protons of **1** at various temperatures were obtained. Figure 2b shows an example of the best fits between the observed and calculated spectra. The rate constants thus obtained within -10 to 90 °C are then plotted as $\ln k$ *vs.* $1/T$ in Fig. 3, from which the Arrhenius and Eyring activation parameters were calculated through the least-squares method. The results are shown below.

$$E_a = 16.7 \pm 0.5 \text{ kcal/mol}$$
$$\Delta G^{\ddagger} = 14.5 \pm 0.1 \text{ kcal/mol at } 30\,^{\circ}\text{C}$$
$$\Delta H^{\ddagger} = 16.1 \pm 0.5 \text{ kcal/mol}$$
$$\Delta S^{\ddagger} = 5.4 \pm 1.7 \text{ e.u.}$$

Discussion

The relatively simple NMR spectra of 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene (**1**) and its 8,8,10,10-tetradeuterated derivative **2** at low temperatures suggest that, in the ground state, the 8-membered peri ring of compound **1** exists in one conformation, either the boat (**B**) or the chair (**C**), which has a mirror plane (Cs) passing through the C_9 and angular carbon atoms of the naphthalene nucleus.[1] The twist-boat conformation (**TB**) with a C_2 symmetry is excluded from the ground-state conformation of **1**, since the methylene protons on C_9 distinctly show an AB signal in the low-temperature spectrum of **2**.[1]

As can be seen from the Newman projections in Fig. 4, the interior benzyl proton in the boat conformation is situated in a position *trans* to an adjacent equatorial proton, while the exterior proton in the chair has a dihedral angle of about 0° with respect to an adjacent equatrial proton. In light of this and Karplus equation about the dihedral angles and spin coupling constants of

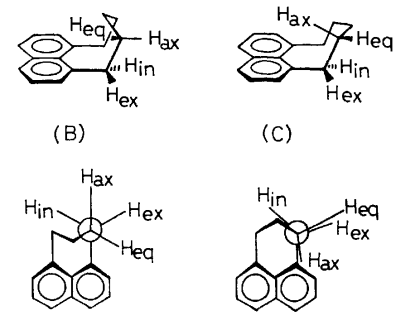

Fig. 4. The boat (**B**) and the chair (**C**) conformations for **1** and their Newman projections about the C_7–C_8 (C_{10}–C_{11}) bonds.

the carbocyclic ring,[8] the fact that the interior benzyl protons of **1** show a considerably large vicinal coupling constant (J=12.88 Hz) clearly suggests that compound **1** assumes the boat (**B**) as the ground-state conformation. This is also indicated from the spectra of the deuterated derivative **2**, where the signal of the interior benzyl proton is much broader (4.8 Hz) than that of the exterior proton (2.9 Hz) in reflection of the strong coupling between the interior proton and the equatorial deuterium which are in *trans* to each other in the boat conformation.

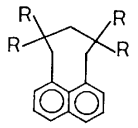
Consequently, the changes in the variable-temperature NMR spectra of **1** are interpreted in terms of the interconverting boat conformations. The predominance of the boat conformation over the chair observed in **1** seems reasonable, since the boat lacks the eclipsing strains about the C_7–C_8 and C_{10}–C_{11} bonds present in the chair.[1,2,4] This is in striking contrast to the case of structurally analogous 6,7,8,9-tetrahydro-5*H*-benzocycloheptene (**3**) which exists only in the chair conformation in the ground state.[9,10]

3

Now that the boat conformation for **1** has been established, the assignment of the C_9–AB signal of **2** is straightforward. That is, the high-field doublet is assigned to the axial proton, H_{9a}, and the low-field one to the equatorial proton, H_{9e}, of the C_9-methylene group of **1**, since the H_{9a}, which lies spatially closer to the naphthalene ring than the H_{9e} proton in the boat conformation, is expected to be more shielded than the H_{9e} proton not only by the effect of the magnetic anisotropies of adjacent C–C bondings but also by the effect of the ring current induced by the naphthalene nucleus.[1] Actually, the H_{9a} proton of **2** resonates at appreciably higher field (δ=1.081) than the corresponding H_{7ax} proton (δ=1.580) on the analogous position of the benzocyclic compound **3**, which exists in the chair conformation.[10] This suggests that the H_{9a} proton of **1** is substantially shielded by the ring current of naphthalene and is a further evidence in

favor of the boat conformation for **1**. The predominance of the boat conformation in **1** is also supported by the line widths of the C_9-protons of **2**, where the signal of the H_{9a} proton is greatly broadened (5.5 Hz) as compared to that of the H_{9e} proton (2.8 Hz) in reflection of the *trans* steric relationship between the H_{9a} and adjacent axial protons (on C_8 and C_{10}) in the boat conformation.

We have already studied the NMR spectra of the boat conformations of several 8,8,10,10-tetrasubstituted 8,9,-10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalenes (**4**).[1]



4

Comparing the NMR data of these compounds with those of the unsubstituted compound **1**, the chemical shift of the H_{9a} proton of **1** (δ=1.081) is somewhat larger than those of the substituted compounds (δ=−0.032—1.071).[1] Moreover, the chemical-shift difference ($\Delta\delta$) of the C_9-methylene protons of **1** ($\Delta\delta$=0.314) is small as compared to those of **4** ($\Delta\delta$=0.85—1.2)[1] and also to the $\Delta\delta$ value (1.32—1.92) calculated for the boat conformation of the 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene ring.[1] The shift difference observed between **1** and **4** results possibly from the direct and/or indirect (changes in geometry of the peri ring associated with the introduction of the substituents) effects of the substituting groups, which might cause some differences in the magnetic environments around the C_9-methylene group of the boat conformation between these compounds. Although details are not known at present, the rather large deviation of the $\Delta\delta$ value in **1** from the calculated value might be related partly to the ring distortion inherent in the eight-membered pericyclized naphthalene system as described below.

The chemical shift of the exterior benzyl protons of **1** is almost comparable to those of the benzyl protons (δ=2.827 and 2.721)[10] of the benzocyclic compound **3**, whereas the signal of the interior protons of **1** is shifted markedly (δ=3.9742) to lower field as a result of the steric compression effect. From a calculation similar to that reported by Corey and Sneen,[11] it is revealed that the interatomic distance between the two interior benzyl protons of the boat conformation is 0.652 Å, much smaller than the sum of the van der Waals radii of the two hydrogens (2.4 Å). This suggests that although the boat is the most favored conformation for **1**, it still involves a severe steric repuslion between the two interior protons. Therefore, it is expected that the boat conformation of **1** is somewhat in a distorted form [**B**], in which the two interior protons are pushed apart mutually to avoid the steric interaction between them. This is strongly supported by the observation that the vicinal coupling constant, $J_{7ex,8ax}$ (1.28 Hz) is very small as compared to the value of $J_{7in,8ax}$ (6.49 Hz), since, as is seen in Fig. 5, these couplings are explained much better by the dihedral angles (H_{7ex}/H_{8ax}; $\theta>60°$, H_{7in}/H_{8ax}; $\theta<60°$) in the distorted molecule [**B**] than by the dihedral angles ($\theta\simeq60°$) in the normal boat conformation (**B**).

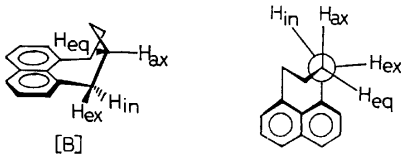


Fig. 5. The distorted boat conformation [**B**] for **1** and its Newman projection about the C_7–C_8 (C_{10}–C_{11}) bond.

Recently, the *R* method has been proposed for the determination of ring geometry in six-membered rings.[12] The *R* value is defined as a ratio of averaged vicinal coupling constants J_{trans}/J_{cis} where $J_{trans}=1/2(J_{aa}+J_{ee})$ and $J_{cis}=1/2(J_{ae}+J_{ea})$ for a $-CH_2CH_2-$ fragment of the ring system. This parameter has not yet been applied or tested for the eight-membered ring.

In order to determine accurately the ring geometry of the 8-membered pericyclic compound **1**, the dihedral arrangement about the C_7–C_8 bond of this molecule was examined by means of the *R* method. For the boat conformation of the 8,9,10,11-tetrahydro-7*H*-cycloocta-[*de*]naphthalene system, the *R* value about the C_7–C_8 bond can be obtained from the expression; $R=J_{trans}/J_{cis}=(J_{7in,8eq}+J_{7ex,8ax})/(J_{7in,8ax}+J_{7ex,8eq})$, using the individual coupling obtained from the low-temperature spectrum. The *R* value can also be obtained from the high-temperature averaged spectrum, where only the time-averaged couplings, $J_{trans}(J_{7in,8eq}\rightleftarrows J_{7ex,8ax})$ and $J_{cis}(J_{7in,8ax}\rightleftarrows J_{7ex,8eq})$ are observed as a result of the rapid boat-boat interconversion.[2]

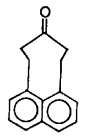
Thus, from the low-temperature data in Table 1, the *R* value for **1** is calculated to be 1.06, while under the condition of the rapid boat inversion it is calculated to be 1.0 ($J_{trans}=J_{cis}$=6.8 Hz). The two *R* values obtained from the two different temperature spectra agree very well with each other. These values are rather small as compared to the value (2.16) obtained for the cyclohexane chair which has an almost perfect staggered conformation.[12] This suggests that the internal dihedral angle (Ψ) about the C_7–C_8 (and C_{10}–C_{11}) bond of the boat conformation of **1** is appreciably decreased as compared to the case of the cyclohexane ring ($\Psi=58°$).[12]

It is considered that the X–CH_2CH_2–Y fragment in the C_7 and C_8 positions of the 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene ring possesses the pseudo-trigonal projection symmetry as in the six-membered rings.[12] Therefore, the dihedral angles around this bond of compound **1** including Ψ can be estimated from the relationship; $\cos\Psi=(3/(2+4R))^{1/2}$.[12] Using R=1.06, the following angles characterizing the structure of **1** are obtained: $\Psi=46°$, $H_{7in}/H_{8ax}=H_{7ex}/H_{8eq}=46°$, $H_{7ex}/H_{8ax}=74°$, and $H_{7in}/H_{8eq}=166°$.

From this it is apparent that compound **1** exists in the distorted boat [**B**] rather than in the normal boat (**B**) as a result of the steric interaction between the interior benzyl protons. Here, it should be noted that this distortion is puckering, not flattening, in sharp contrast to the cases of the previously studied compounds such

as the six-membered rings[12] or seven-membered rings.[10] This is ascribable to the difference in the ring system, and is a unique feature of the 8-membered pericyclized naphthalene system.

The free energy of activation (ΔG^*) for boat inversion of **1** is 14.5 kcal/mol, which is somewhat higher than the ΔG^* value (12.4 kcal/mol)[2] observed for the boat inversion of the ketone **5**. Since it is known that com-



5

pounds **1** and **5** have very similar ring structures in their ground states (based on the discussion similar to that described above, it is clear that compound **5** also exists in the puckered boat in the ground state)[2] and both undergo the ring inversions through the same mechanism,[2] the entropy of activation (ΔS^*) obtained for **1** (5.4 e.u.) can be considered to be also characteristic of **5**.[13] It is therefore justifiable to assume that ΔG^* difference observed between **1** and **5** is entirely enthalpic in origin ($\Delta\Delta G^* = \Delta\Delta H^*$).

It has recently been suggested that the boat-to-boat interconversion of the 8,9,10,11-tetrahydro-7*H*-cycloocta-[*de*]naphthalene ring proceeds by pseudorotations of the peri bonds through the twist-boat (**TB**) as an intermediate,[2,4] the highest energy conformation being possibly (**TS**), which effectively contains six coplanar carbon atoms[2] (Fig. 6). This process involves rotations about the C_8–C_9 and C_9–C_{10} bonds in the conversions of (**B**)⇄(**TS**) and (**TS**)*⇄(**B**)*, respectively.

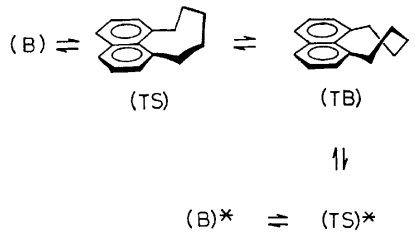


Fig. 6. Pathways for boat inversion of **1** (asterisks* indicate the inverted forms).

Thus, considering the barriers to methyl rotation in propane (3.3 kcal/mol)[14] and acetone (0.8 kcal/mol),[15] it is expected that if the boat inversion of the 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene ring occurs indeed by the pseudorotations of the peri bonds as described above, the energies necessary for reaching the transition states in **5** are smaller than in the case of **1** by the value approximately equal to the difference in the barriers between propane and acetone. Actually, the difference in energy barrier observed between **1** and **5** is almost comparable to that observed in propane and acetone. This strongly supports the idea that the boat inversion is caused by pseudorotations of the peri bonds in the 8-membered pericyclized naphthalene system.

The activation energy for boat inversion of **1** is much higher than the ΔG^* value (10.7 kcal/mol)[16] observed for the chair inversion of **3**. This suggests that although the ground state of **1** is destabilized considerably by the steric interaction between the interior benzyl protons, the transition state of **1** is destabilized to a greater extent because of the peri strains involved.

Experimental

Materials. 8,9,10,11-Tetrahydro-7*H*-cycloocta[*de*]-naphthalene (**1**) was prepared by the Clemmensen reduction of 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalen-9-one (**5**) as described previously.[18] 8,9,10,11-Tetrahydro-7*H*-cycloocta[*de*]naphthalene-8,8,10,10-d_4 (**2**) was prepared from the 8,8,10,10-tetradeuterated derivative of **5** using the procedures described below.

Compound **5** (1.5 g) was refluxed with a solution of potassium carbonate (1.5 g) in deuterium oxide (15 ml) and dioxane (25 ml) for 3 days. The mixture was poured into ice-hydrochloric acid, and the resulting crystalline precipitate was collected by filtration, washed with water and dried *in vacuo*. The above deuterium exchange reaction was repeated twice to afford the completely deuterated ketone, 8,8,10,10-tetradeuterio-8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalen-9-one (1.46 g); mp 193.5—195 °C (**5**; mp 195—196 °C[18]), whose structure was evidenced by the complete absence of the NMR signal due to the α protons.[18] The above deuterated ketone (0.93 g) was stirred overnight with excess sodium borohydride in ethanol (120 ml) at room temperature. The reaction mixture was worked up in the same manner as described above to yield 8,8,10,10-tetradeuterio-8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalen-9-ol (0.89 g); mp 148—149 °C; IR (Nujol): ν_{max} 3364 and 3284 cm^{-1} due to OH. This alcohol (0.89 g) was then stirred with methanesulfonyl chloride (2.5 ml) in pyridine (9.5 ml) for 4 h at room temperature with an occasional heating on water bath. The mixture was worked up as above to give 9-mesyloxy-8,8,10,10-tetradeuterio-8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene (1.2 g); mp 133.5—134.5 °C; IR (Nujol): ν_{max} 1348 and 1173 cm^{-1} (mesyl ester). The mesylate (1.0 g) was then stirred under reflux with lithium aluminum hydride (2.8 g) in ether (250 ml) and benzene (20 ml) for 5 days. The mixture was poured into ice–hydrochloric acid and the mixture was extracted with ethyl acetate. The acetate extracts were worked up as usual to leave a brown paste, which was purified by chromatography on alumina. Elution with hexane gave the hydrocarbon **2** (130 mg), whose structure was confirmed by the TLC (SiO_2–hexane), mp (56.5—57.5 °C, **1**; mp 55—56 °C[4] and 57.5—58 °C[18]) and its spectra (IR, NMR). Further elution with hexane yielded 10,11-dihydro-7*H*-cycloocta[*de*]-naphthalene-8,10,10-d_3 (50 mg; mp 64.5—65.5 °C), details of which will be reported elsewhere. Further elution with ethyl acetate afforded another crystal (104 mg), which, based on the TLC, mp, and IR, was identified to the 8,8,10,10-tetradeuterio-9-ol described above.

Measurements. The IR spectra were determined on a JASCO IR-G spectrometer calibrated with polystyrene. The ^{1}H-NMR spectra were determined on a Varian HA-100D spectrometer (at 100 MHz) in a temperature range between −100—110 °C, using a *ca.* 10% solution in a mixture of deuteriochloroform–carbon disulfide (3:1) (compound **1**) or in deuteriochloroform (compound **2**). The sample temperature was measured by use of the temperature dependent chemical shift of the OH proton of methanol or ethylene glycol.[19] The analysis of the NMR spectra at slow exchange limit and

the calculations of the theoretical line shape were made using a FACOM 270/30 computer.

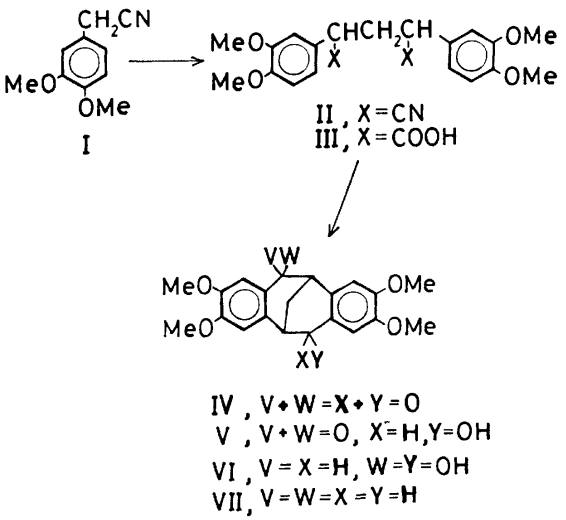
(Received September 20, 1978)

The title compound (VII) was synthesized in an optically active form and the chiroptical properties were recorded. The absolute configuration was determined by chemical correlation method.

The title compound (VII) has a novel type of rigid bicyclo[3.3.1]nonadiene cage skeleton and holds two veratrole chromophores in a twisted spacial position. Formally VII could be transformed to alkaloid argemonine by substituting the methanobridge with an *N*-methyl group. The optical activity of argemonine[1] was discussed in connection with the absolute configuration[2] but not fully understood yet. The perfect C_2-symmetry and pure carbocyclic structure make VII one of the best model for the study of chiroptical properties of organic molecules containing two separate aromatic chromophores.

This paper deals with the synthesis, optical resolution and determination of absolute configuration by chemical means concerning VII and its derivatives.

Synthesis and Optical Resolution. The route of synthesis was outlined in Scheme 1. 3,4-Dimethoxyphenylacetonitrile (I) was allowed to react in THF with diiodomethane in the presence of sodium methoxide to yield 2,4-bis(3,4-dimethoxyphenyl)glutaronitrile (II) which was a mixture of racemic and meso forms. Fractional recrystallization of the crude dinitrile from methanol afforded two kinds of crystals. Higher melting crystals were assigned to the racemate and lower melting ones to the meso form on the basis of splitting patterns of methylene proton singnals in their ^{1}H-NMR spectra.[3] The dicarboxylic acid (III) obtained by alkaline hydrolysis of crude II was cyclized to the diketone (IV) with polyphosphoric acid. Dehydrative cyclization with concd sulfuric acid gave poor results, because of rapid sulfonation to benzene rings activated by two methoxyl groups. The diketone (IV) was reduced to the glycol (VI) with $LiAlH_4$ in THF. The ketol (V) could be obtained along with VI when catalytic reduction of IV over the Adams catalyst was interrupted after one equivalent hydrogen was absorbed.



Scheme 1.

Optical resolution was carried out *via* camphanate of the ketol (V) or the glycol (VI). Bis-camphanate prepared from (+)-VI and ω-camphanoyl chloride was fractionally recrystallized eleven times from ethanol to yield optically pure crystals. The camphanate derived from (+)-V could be fractionated more effectively than the bis-camphanate of VI. Thus almost optically pure crystals were obtained after one recrystallization from ethanol. Pure (+)-V and (+)-VI were obtained by alkaline hydrolysis of their camphanates. Catalytic reduction of (+)-V over the Adams catalyst afforded

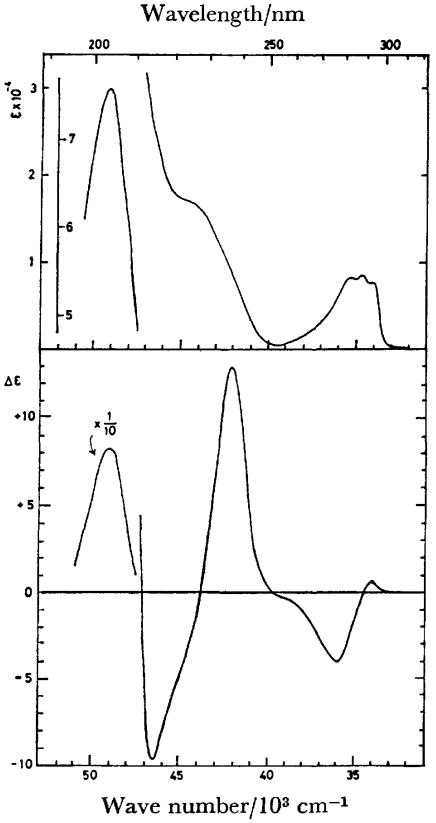


Fig. 1. UV (top) and CD (bottom) spectra of (+)-5,6,11,12-tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[*a*,*e*]cyclooctatetraene (VII) in ethanol.

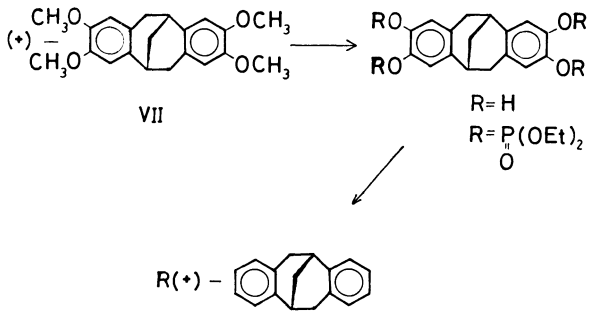
† A preliminary report of this work was presented at the 37th National Meeting of the Chemical Society of Japan, Tokyo, April 1978.

†† Present address: Department of Applied Chemistry, Faculty of Engineering, Hiroshima University, Hiroshima 730.

(+)-VI and (−)-IV was obtained from (+)-VI by the Jones oxidation. All of (−)-IV, (+)-V and (+)-VI could be converted easily to the desired compound, (+)-VII, under condition of the Clemmensen reduction.

Optical Activity and Absolute Configuration. The CD spectra of (+)-VII was shown in Fig. 1. Beautiful positive couplets were observed in both α- and p-band regions and a strong positive band appeared in $^1E_{1u}$ region.

The absolute configuration was estimated to be *R* by usual exciton theoretical CD analysis, in which the transition moments of each band were assumed to lie in the center and in the direction of the short or long axis of benzene rings according to the spectroscopic moments theory.[4] The molecular structural parameters of VII were assumed to be the same as those of 5,6,11,12-tetrahydro-5,11-methanodibenzo[*a*,*e*]cyclooctatetraene, VIII.[5]



Scheme 2.

The absolute configuration of (+)-VII was determined to be (*R*) by a chemical correlation (Scheme 2). Demethylation of (+)-VII with BBr_3 followed by diethoxyphosphinylation with diethyl phosphonate afforded a tetrakis-phosphate. The phosphate was reduced by sodium metal in liq ammonia to yield (+)-VIII, whose absolute configuration was proven to be *R*.[3,5] Thus the result of CD analysis was in good agreement with that of the chemical correlation.

Experimental

The melting points were measured on a Mettler FP2 apparatus and are uncorrected. Purified and anhydrous solvents were used, unless otherwise stated. The IR spectra were obtained on a Hitachi EPI-2, EPI-G3, and a JASCO DS-301 spectrometers, electronic spectra on a Hitachi EPS-3T and a Zeiss PMQIIM4QIIId spectrometers, ^{1}H-NMR spectra in deuteriochloroform unless otherwise stated on a Varian XL-100, A-60D or Hitachi R-24 spectrometer using TMS as an internal standard and given in δ-unit. The optical rotations were obtained on a Union Giken High Precision polarimeter PM-71 at 20 °C unless otherwise stated. CD spectra were obtained on a JASCO J-20 spectrometer. Shoulders and inflections are denoted by an asterisk.

3,4-Dimethoxybenzyl Cyanide (I): Veratraldehyde (100 g, 0.6 mol) in ether (500 ml) was added dropwise to an ice-cold ether solution (300 ml) of $LiAlH_4$ (13.7 g). Stirring was continued for further 2 h at room temperature. Ethyl acetate (20 ml) and water (20 ml) were added dropwise with stirring and ice-cooling. The resulting mixture was stirred for a while at room temperature. Colorless gelatinous precipitates formed were removed with suction filtration and washed with ethyl acetate (300 ml). Combined filtrate and washings were concentrated and distilled under reduced pressure to afford 3,4-dimethoxybenzyl alcohol as a colorless oil, bp 155 °C/533 Pa (98 g, 96%).

A cold mixture of the alcohol (82.6 g), dichloromethane (100 ml) and concd HCl (100 ml) was stirred vigorously for 20 min at 0—10 °C. Further amount of CH_2Cl_2 (100 ml) was added to the mixture with stirring. The organic layer separated was dried over $CaCl_2$ for 30 min and concentrated under reduced pressure. 3,4-Dimethoxybenzyl chloride obtained was used immediately for further reaction without purification.

Powdered sodium cyanide (48 g) and potassium iodide (6 g) were added to the chloride in acetone (300 ml). The mixture was refluxed for 20 h and filtered with suction after cooling down. The filtrate concentrated under reduced pressure was poured into water and extracted with benzene. The combined extracts were washed with water, dried and concentrated under reduced pressure. Vaccum distillation afforded I as a colorless oil, bp 160 °C/533 Pa (65.0 g, 75%). ^{1}H-NMR (CCl_4): 3.55 (s, 2H, methylene), 3.75 (s, 6H, methoxy), 6.70 (s, 3H, aromatic).

2,4-Bis(3,4-dimethoxyphenyl)glutaronitrile (II): Dry sodium methoxide prepared from sodium (1.8 g, 0.078 g atom) and methanol (100 ml) was suspended in THF (100 ml) and mixed with I (13.5 g, 0.076 mol) and diiodomethane (11.5 g, 0.043 mol). After being refluxed for 1 h with stirring, the mixture was concentrated under reduced pressure and extracted with dichloromethane. After usual work up, the extract was concentrated *in vacuo* to yield a brown oil, which was purified with a column of silica gel (80 g). From benzene–ethyl acetate (1: 1) eluate, II (8.6 g, 61%) was obtained as a diastereomeric mixture of racemic and meso from. Repeated recrystallization of the crude nitrile from methanol gave racemate as colorless needles and meso form as colorless plates.

Racemate: mp 141—142 °C. ^{1}H-NMR: 2.45 (t, J=8 Hz, 2H, methylene), 3.89, 3.91 (two s, 12H, methoxyl), 4.00 (t, J=8 Hz, 2H, methine), 6.80—6.90 (m, 6H, aromatic). Found: C, 68.64; H, 6.11; N, 7.75%. Calcd for $C_{21}H_{22}O_4N_2$: C, 68.83; H, 6.05; N, 7.65%. *meso*-Isomer: mp 101 °C. ^{1}H-NMR: 2.20—2.90 (m, 2H, methylene), 3.91 (br s, 12H, methoxyl), 3.75 (apparent t, 2H, methine), 6.85—6.90 (m, 6H, aromatic). Found: C, 68.77; H, 6.01; N, 7.68%. Calcd for $C_{21}H_{22}O_4N_2$: C, 68.83; H, 6.05; N, 7.65%.

2,4-Bis(3,4-dimethoxyphenyl)glutaric Acid (III) and Its Methyl Ester: The crude dinitrile (II, 1.0 g) dissolved in 95% ethanol (20 ml) was mixed with KOH (5 g) in 50% EtOH (20 ml) and heated to reflux for 20 h. After removal of ethanol under reduced pressure, the mixture was poured into water (100 ml) and washed three times with dichloromethane. Alkaline aqueous layer was decolorized with active charcoal, and acidified with concd HCl. Precipitates formed were extracted with dichloromethane. After usual work up, a colorless solid of III (0.9 g, 81%) was obtained from the extract. Reflux with methanol and concd sulfuric acid gave colorless crystals of dimethyl ester, mp 116—117 °C (from methanol). ^{1}H-NMR: 1.9—2.9 (m, 2H, methylene), 3.4 (t, 2H, methine), 3.65 (s, 6H, methyl), 3.85 (s, 12H, methoxyl), 6.75 (br s, 6H, aromatic). Found: C, 63.84; H, 6.54%. Calcd for $C_{23}H_{28}O_8$: C, 63.88; H, 6.53%.

5,6,11,12-Tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo-[a,e]cyclooctateraene-6,12-dione (IV): *a) With Polyphosphoric Acid*: Crude dicarboxylic acid (III, 1.8 g, 0.0049 mol) was mixed with polyphosphoric acid (30 g) and stirred for

5 min at 80 °C. The reaction mixture was poured onto ice (100 g) and precipitates separated were extracted with CH_2Cl_2. Combined extracts were washed with brine, 10% aq NaOH, and brine, successively, and dried over $MgSO_4$. Solvent was removed under reduced pressure to yield IV as a colorless solid, which was recrystallized from dichloromethane–ethanol, mp 261—262 °C. ^{1}H-NMR: 3.0 (t, J=3 Hz, 2H, methylene), 3.95, 3.85 (two s, 12H, methoxyl, signals of methine protons (2H) were overlapped with those signals), 6.9, 7.4 (two s, 4H aromatic). IR (Nujol mull): 1670 ($\nu_{C=O}$) cm^{-1}. Found: C, 68.18; H, 5.46%. Calcd for $C_{21}H_{20}O_6$: C, 68.47; H, 5.47%.

b) With Concd Sulfuric Acid: Crude III (0.6 g) was dissolved in concd sulfuric acid and cooled to −15 °C. The mixture was stirred for 2 h at the temperature and mixed with water (30 ml). Precipitated product was extracted with benzene. Combined extracts were washed with water, 5% aq $NaHCO_3$, and water, successively, and dried over Na_2SO_4. Evaporation of solvent *in vacuo* and trituration with ethanol afforded crude crystals (0.15 g, 27%), whose spectroscopic properties were identical with those of the authentic diketone (IV). The acidic component obtained from the above mentioned $NaHCO_3$ washings were converted with a usual procedure to methyl ester, mp 159—160 °C. ^{1}H-NMR: 2.35—2.80 (m, 2H, methylene), 3.75 (s, 3H, methyl), 3.8, 3.9 (two s, 12H, methoxyl), 3.5—4.2 (m, 2H, methine), 6.7—6.8 (m, 4H, aromatic), 7.5 (s, 1H, aromatic). Found: C, 65.77; H, 6.06%. Calcd for $C_{22}H_{24}O_7$: C, 65.99; H, 6.04%. The ester was assigned to methyl 3-(3,4-dimethoxyphenyl)-4-oxo-6,7-dimethoxy-1,2,3,4-tetrahydro-1-naphthoate on the basis of its ^{1}H-NMR spectra.

12-Hydroxy-5,6,11,12-tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraen-6-one (V)*: Diketone IV (2.164 g, 0.0057 mol) dissolved in dichloromethane (70 ml) and ethanol (100 ml) was catalytically reduced over the Adams catalyst at room temperature. In 40 min *ca.* 165 ml of hydrogen was absorbed and the catalyst was removed to stop the reduction.

Evaporation of solvents under reduced pressure yielded a colorless solid, which was chromatographed on a column of silica gel (50 g) with dichloromethane. Recovered IV (0.380 g, 17%), desired ketol (V, 1.28 g, 59%) and the diol (VI, 0.500 g, 23%) were eluted successively. Recrystallization from methanol afforded colorless needles of V, mp 206 °C. ^{1}H-NMR: 1.6 (d, 1H, OH), 2.5 (m, 2H, methylene), 3.6 (m, 2H, bridgehead methine), 3.7—3.9 (four singlets, 12H, methoxyl), 5.0 (q, 1H, methine), 6.7—7.4 (four singlets, 4H, aromatic) IR (Nujol mull): 3400 (ν_{OH}), 1655 ($\nu_{C=O}$) cm^{-1}. Found: C, 67.94; H, 5.94%. Calcd for $C_{21}H_{22}O_6$: C, 68.09; H, 5.99%.

Optical Resolution of 12-Hydroxy-5,6,11,12-tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraen-6-one (V)*: *dl*-Ketol (V, 3.8 g, 0.01 mol) dissolved in pyridine (50 ml) was mixed with freshly prepared ω-camphanoyl chloride (2.40 g) and stirred overnight at room temperature. The mixture was poured into water (100 ml) and extracted with dichloromethane (50 ml) and ether (100 ml). Combined extracts were washed thoroughly with 1 M HCl, brine, saturated aq $NaHCO_3$, and brine, successively. After being dried over Na_2SO_4, solvents were removed under reduceds pressure to yield a colorless solid. The solid was recrystallized four times from ethanol or dichloromethane–ethanol to give (−)-camphanate of V with constant optical rotations as colorless needles (1.68 g). Mp 235—237 °C, $[\alpha]_D^{15}$ − 15.8°, $[\alpha]_{405}^{15}$ − 192.8° (*c* 0.448, $CHCl_3$). Found: C, 67.42; H, 6.32%. Calcd for $C_{31}H_{34}O_9$: C, 67.62; H, 6.22%.

Pure(−)-camphanate (1.68 g) was heated to reflux for 1 h with aq methanolic KOH. Evaporation of methanol afforded crude crystals of (+)-V (1.09 g, 96%). Recrystallization from ethanol yielded colorless needles. Mp 222 °C, $[\alpha]_D^{18}$ + 26°, $[\alpha]_{405}^{18}$ − 258° (*c* 0.270, $CHCl_3$), ^{1}H-NMR: Identical with the racemate, UV: λ_{max}^{EtOH} (ε) 360 (1000), 321 (8200), 280 (11000) 237 (28400), 204.5 (40800) nm, CD: λ_{max}^{EtOH} ($\Delta\varepsilon$) 359 (−1.72), 348 (−1.43), 326 (−3.94), 287 (−6.74), 267 (+11.1), 242 (+26.9), 229 (−18.7), 208 (+45.9) nm. Found: C, 67.82; H, 6.00%. Calcd for $C_{21}H_{22}O_6$: C, 68.09; H, 5.99%.

(+)-5,6,11,12-Tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraene-6,12-diol (VI)*: (+)-Ketol (V, 0.120 g, 0.320 mmol) dissolved in acetic acid (20 ml) and ethanol (30 ml) was catalytically reduced over the Adams catalyst for 3 h under ordinary pressure and temperature. After the catalyst was removed by filtration and the residue was chromatographed on a column of silica gel (20 g) with CH_2Cl_2 and ethyl acetate. Recovered (+)-ketol (0.055 g) and (+)-VI (0.060 g) were eluted successively. (+)-Diol was recrystallized from ethanol. mp 220 °C, $[\alpha]_D^{18}$ + 115,° $[\alpha]_{405}^{18}$ + 327° (*c* 0.163, $CHCl_3$), ^{1}H-NMR: identical with racemate, UV: λ_{max}^{EtOH}(ε) 289 (6600), 284 (6900), 280 (6200), 234 (15300), 207 (70700) nm, CD: λ_{max}^{EtOH} ($\Delta\varepsilon$) 289 (+3.0), 243 (+16.0), 213 (+34.8), 199 (−44.0) nm. Found: C, 67.54: H, 6.42%. Calcd for $C_{21}H_{21}O_3$: C, 67.73: H, 6.50%.

5,6,11,12-Tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraene-6,15-diol (VI)*: A THF solution (150 ml) of the diketone IV (1.5 g, 0.004 mol) was added dropwise to an ice-cold THF solution (120 ml) of $LiAlH_4$ (1.0 g). The mixture was stirred for 3 h at room temperature and decomposed with ethyl acetate (2 ml), water (2 ml) and saturated aq ammonium chloride successively. Gelatinous precipitates formed were removed by suction filtration and the filtrate was concentrated under reduced pressure. The crude product obtained was recrystallized from benzene to yield colorless needles (1.45 g, 95%) of *dl*-VI, mp 210—211 °C, ^{1}H-NMR: 1.6 (d, 2H, OH), 2.4 (t, 2H, methlene), 3.3 (m, 2H, bridgehead methine), 3.8, 3.9 (s, 12H, methoxyl), 4.9 (q, 2H, methine) 6.7, 7.0 (s, 4H aromatic), IR (Nujol mull): 3350 (ν_{OH}) cm^{-1}. Found: C, 67.57; H, 6.51%. Calcd for $C_{21}H_{24}O_6$: C, 67.73; 6.50%.

Optical Resolution of 5,6,11,12-Tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraene-6,12-diol (VI)*: *dl*-Diol (VI, 0.50 g, 1.6 mmol) dissolved in pyridine (3 ml) was mixed with freshly prepared ω-camphanoyl chloride (1.0 g) and the mixture was stirred overnight at room temperature. Water was added to the mixture and extracted with dichloromethane and ether. Combined extracts were washed thoroughly with 1 M HCl and brine. After being dried over magnesium sulfate, solvents were removed under reduced pressure to yield a colorless oil (0.88 g, 90%), which was crystallized by trituration with ethanol.

Repeated fractional recrystallization (11 times) afforded optically pure (−)-bis-camphanate of VI as colorless needles (0.08 g). $[\alpha]_D^{18}$ − 25°, $[\alpha]_{405}^{18}$ − 45° (*c* 0.910, $CHCl_3$). Pure (−)-bis-camphanate obtained was heated to reflux in aq methanolic KOH solution. Crystals appeared on evaporation of methanol were collected by suction filtration and recrystallized from EtOH to yield optically pure (+)-VI (0.030 g), mp 220 °C. $[\alpha]_D^{18}$ + 110°, $[\alpha]_{405}^{18}$ + 330° (*c* 0.370, $CHCl_3$).

(−)-5,6,11,12-Tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraene-6,12-dione (IV)*: Chromium trioxide (0.4 g) in water (2 ml) was added dropwise at room temperature to a well stirred solution of (+)-ketol (VI, 0.430 g, 1.3 mmol) in acetic acid (30 ml). The mixture was diluted with water (50 ml) and extracted with dichloromethane.

Combined extracts were washed with water, saturated aq $NaHCO_3$, and water, successively, and dried over sodium sulfate. On concentration under reduced pressure, a yellow solid was obtained. A dichloromethane solution of the solid was passed through a short column of silica gel (10 g) to remove colored impurities. Recrystallization from ethanol afforded colorless crystals of (−)-IV (0.270 g, 63%). Mp 222—223 °C, $[\alpha]_D^{18}$ − 246°, $[\alpha]_{405}^{18}$ −3290° (*c* 0.06, $CHCl_3$), UV: $\lambda_{max}^{dioxane}(\varepsilon)$ 366* (1050), 348* (3070), 339* (3940), 316 (13600), 284 (19800), 270 (29600), 240 (24700) nm. $\lambda_{max}^{EtOH}(\varepsilon)$ 340* (4700), 315 (12900), 285* (21000), 271 (26900), 238 (23600), 206 (26300) nm. CD: $\lambda_{max}^{dioxane}(\Delta\varepsilon)$ 365 (−13.8), 347 (−50.7), 336.5 (−47.3) 313 (+36.7), 285 (+55.8), 254 (−19.8), 230 (−26.6), 210 (+40.4) nm. λ_{max}^{EtOH} ($\Delta\varepsilon$) 340 (−52.9), 310 (+31.8), 285 (+56.7), 253 (−16.9), 230 (−22.2), 209 (+40.7) nm. Found: C 68.57; H, 5.49%. Calcd for $C_{21}H_{20}O_6$: C, 68.47; H, 5.47%.

(+)-5,6,11,12-Tetrahydro-2,3,8,9-tetramethoxy-5,11-methanodibenzo[a,e]*cyclooctatetraene (VII)*: Granules of zinc (1.0 g) was amalgamated by a standard method[6] and used immediately as follows. A benzene solution of (−)-diketone IV (50 mg) was added to a stirred mixture of the amalgamated zinc, water (0.5 ml), and concd HCl (1 ml). The mixture was refluxed for 4 h, diluted with water, and extracted with dichloromethane and ether. Combined extracts were washed with water, saturated aq $NaHCO_3$ and water, successively, and dried over Na_2SO_4. Solvents were removed under reduced pressure and the residue was passed through a short column of silica gel (10 g) as a CH_2Cl_2 solution. A colorless oil (34 mg, 74%) obtained was crystallized in methanol. Mp 209—210 °C, UV: $\lambda_{max}^{EtOH}(\varepsilon)$ 292 (7700), 288 (8600), 283 (8300), 223* (17300), 204 (76000) nm. CD: $\lambda_{max}^{EtOH}(\Delta\varepsilon)$ 294 (+1.0), 267.5 (−4.0), 237.5 (+13.0), 216 (−9.7), 204 (+82.5) nm. Found: C, 73.66; H, 7.10%. Calcd for $C_{21}H_{24}O_4$: C, 74.09: H, 7.11%.

(R)-(+)-5,6,11,12-Tetrahydro-5,11-metahnodibenzo[a,e]*cyclooctatetraene (VIII)*: As shown in Scheme 2, (+)-VII was converted to (*R*)-(+)-VIII.

Demethylation: A dichloromethane solution (12.5 ml) of (+)-VII (0.431 g, 1.27 mmol) was added with stirring to an ice-cold solution of BBr_3 (1.818 g, 7.26 mmol) in CH_2Cl_2 (15.6 ml). The mixture was stirred overnight at room temperature. Gelatinous precipitates were formed in the case of racemate. After addition of water (30 ml), the reaction mixture was stirred for 30 min and extracted with ether. Combined extracts were washed with saturated aq $NaHCO_3$ and brine, successively, and dried over Na_2SO_4. Upon concentration of the fraction *in vacuo*, the tetrol was obtained as faintly pink powder (0.352 g). Acidification of $NaHCO_3$ washings followed by extraction with ether gave further amount of the tetrol (0.052 g, total 0.404 g quantitative). Alkaline extraction should be avoided because of unstable nature of the phenol. ^{1}H-NMR (acetone-d_6); 2.35—3.27 (m, 8H, methylene and methine), 6.35, 6.62 (two singlets, 4H, aromatic), 7.05 (br s, 4H, OH). The phenol was used directly for further reaction without purification.

Dehydroxylation via *Diethoxyphosphinylation*: The tetrol (0.404 g, 1.421 mmol) was mixed with diethylphosphonate (0.862 g, 8.124 mmol) in CCl_4 (11 ml) and triethylamine (1 ml) and stirred for 48 h at room temperature. Colorless precipitates were formed. The mixture was mixed with water and extracted with chloroform. Combined extracts were washed with 1 M HCl, 5% aq $NaHCO_3$ and water, successively, and dried over Na_2SO_4. Evaporation of solvents under reduced pressure afforded a faintly yellow oil (1.42 g) which showed single spot on a TLC plate. The crude phosphate (1.42 g) dissolved in THF (50 ml) was added to liq NH_3 (50 ml). Sodium metal (0.5 g) was added in small pieces to the solution with stirring until blue color of the solution persisted. Crystals of ammonium chloride were added to the mixture to stop the reaction. Ammonia was evaporated by warming up the solution to room temperature. The residue was diluted with water and extracted with ether. Combined extracts were washed with cold 3% aq KOH and brine successively and dried over Na_2SO_4. On evaporation of solvents *in vacuo*, a light yellow solid was obtained. The crude product was dissolved in benzene and passed through a short column of silica gel (10 g).

The crystals obtained were again purified by high pressure liquid chromatography (machine: Hitachi 635; column: 8 × 500 mm × 2 packed with Merck Lichrosorb S2-100; solvent: hexane; flow rate: 2.6 ml/min; pressure: 110 kg/cm^2; retention time: 45 min) and recrystallized from methanol or pentane. mp 100.5—101.5 °C, ^{1}H-NMR: 2.00 (t, J=3 Hz, 2H, methano-bridge), 2.62—3.52 (m, 6H, methine and benzylic methylene), 6.85—7.22 (m, 8H, aromatic), UV: $\lambda_{max}^{isooctane}(\varepsilon)$: 273 (1500), 266 (1230), 261.5 (800), 259.5 (790), 219 (15500), 214 (17800), 196 (66800) nm. CD: $\lambda_{max}^{isooctane}(\Delta\varepsilon)$: 273 (−1.89), 265.5 (−1.69), 260 (−1.02), 225 (+0.90), 222 (−1.81), 218 (+8.00), 214 (+7.29), 195 (+115.0) nm. Found: C, 92.37; H, 7.33%. Calcd for $C_{17}H_{16}$: C, 92.68; H, 7.32%.

The Acid-catalyzed Reactions of 4-Chromanones with Formaldehyde[1)]

Akira NINAGAWA,* Ryoki NOMURA, and Haruo MATSUDA

Department of Petroleum Chemistry, Faculty of Engineering, Osaka University, Yamadakami, Suita, Osaka 565

(Received October 2, 1978)

The reactions of several methyl substituted 4-chromanones, such as 4-chromanone (**1a**), 6-(**1b**), and 8-methyl-(**1c**), as well as 5,7-(**1d**) and 6,8-dimethyl-4-chromanone(**1e**) with formaldehyde were carried out in dioxane or mixed solutions of acetic acid and benzene or cyclohexane in the presence of sulfuric acid as a catalyst. The reactions involved an aldol condensation analogous to the Prins reaction, affording acetoxymethyl derivatives and 1,3-dioxanes. It was found that the formation of products was strongly influenced by the substituents on the 4-chromanones and solvents. In a mixed solution of acetic acid and benzene, **1b** and **1e** gave acetoxymethyl derivatives and 1,3-dioxanes, **1a** and **1c** only 1,3-dioxanes, and **1d** a resinous substance. In a dioxane solution, **1b** and **1e** gave 1,3-dioxanes, while **1c** gave a polymer. Bromination of **1e** in 35 and 96% sulfuric acids gave 3- and 5-bromo-6,8-dimethyl-4-chromanones, respectively. The acid-catalyzed reactions were compared with those in 96% sulfuric acid on the basis of the duterium exchange rates of 4-chromanones.

In previous papers,[2,3)] reports were given on the reactions of 4-chromanones with formaldehyde carried out in the presence of 96% sulfuric acid. The reaction products of 4-chromanone (**1a**), 6-(**1b**) as well as 8-methyl-(**1c**) and 5,7-dimethyl-4-chromanone (**1d**) with formaldehyde were the polymers linked by methylene bridges, while those of 6,8-dimethyl-4-chromanone (**1e**) were 5-hydroxymethyl-6,8-dimethyl-4-chromanone (**4**), along with small amounts of the methylene- and methyleneoxymethylene-bridged dimers.

The present investigation deals with the reactions of 4-chromanones with formaldehyde in dioxane or mixed solutions of acetic acid and benzene or cyclohexane in the presence of sulfuric acids as a catalyst. The reactions in 35% sulfuric acid are compared with those in 96% sulfuric acid.

Results and Discussion

Reaction Products of 4-Chromanones with Formaldehyde. The reactions of 4-chromanones with formaldehyde were carried out with different molar ratios of the reactants in a mixture of acetic acid and benzene in the presence of H_2SO_4 as a catalyst. The results are summarized in Table 1.

The reaction of **1a** with formaldehyde in a 1 : 3 molar ratio gave 6-benzylspiro(chroman-3,5′-[1,3]dioxane)-4-one (**3f**), and that in a 1 : 1 molar ratio caused the recovery of **1a** in 68% yield.

The reaction of **1b** with formaldehyde in a 1 : 1 molar ratio gave 3,3-bis(acetoxymethyl)-6-methyl-4-chromanone (**2b**) and that in a 1 : 3.3 molar ratio gave 6-methylspiro(chroman-3,5′-[1,3]dioxane)-4-one (**3b**).

Similarly, the reactions of **1c** in 1 : 3.3 and 1 : 5 molar ratios gave 6-benzyl-8-methylspiro(chroman-3,5′-[1,3]-dioxane)-4-one (**3g**). The reaction in a 1 : 1 molar ratio afforded a small amount of product which was isolated

a) **1e** recovered in 95% yield. The reaction products were diphenylmethane and its homologues. b) A resinous product was obtained, yield 2.51 g.

with difficulty from the reaction mixture.

The reaction of **1e** with formaldehyde in a 1 : 1 molar ratio gave 3,3-bis(acetoxymethyl)-6,8-dimethyl-4-chromanone (**2e**) and 6,8-dimethylspiro(chroman-3,5′-[1,3]dioxane)-4-one (**3e**), while that in a 1 : 3.3 molar ratio gave **3e** in high yield. **3e** was changed into 6,8-dimethylspiro(chroman-3,5′-[1,3]dioxane)-4-ol (**3e′**) by use of sodium borohydride. The reaction of **1d**, however, gave a resinous substance.

The reactions were examined as regards the effects of the solvents and their acidity. The results are summarized in Table 2.

In the reaction of **1e** with formaldehyde, the use of propionic acid–benzene or benzyl acetate–benzene mixture, acetic acid, or dioxane as solvent gave **3e**, along with resinous substance. When the reaction was carried out in a benzene solution, diphenylmethane and its homologues were obtained, **1e** being recovered in 95% yield. The use of a large amount of H_2SO_4 (Runs 13 and 16) gave **4**, analogous to the case of the use of 96% H_2SO_4.[3]

The reaction of **1b** in dioxane gave only **3b**. The reaction of **1c** in a mixed solution of acetic acid and cyclohexane gave 6-acetoxymethyl-8-methylspiro-(chroman-3,5′-[1,3]dioxane)-4-one (**3h**), and that in dioxane a resinous material.

Bromination of 1e. The bromination of **1e** in acetic acid solution in the presence of H_2SO_4 gave 3-bromo-6,8-dimethyl-4-chromanone (**5**), while that in 96% H_2SO_4 gave 5-bromo-6,8-dimethyl-4-chromanone (**6**).

Deuterium Exchange of 4-Chromanones. Rates of the deuterium exchange of **1e** were observed by means of ^{1}H-NMR spectra. The results obtained in 35% D_2SO_4 (in CH_3CO_2D), 85% D_2SO_4 (in D_2O), and 96% D_2SO_4 are shown in Figs. 1a, 1b, and 1c, respectively. The deuterium atom % was calculated on the basis of the integral value in the C-2 methylene protons of **1e**. There is a clear difference between 1a and 1c. In 35% D_2SO_4, deuterium is incorporated into the C-3 methylene protons faster than the C-5 aromatic proton, while in the case of 96% D_2SO_4, the opposite tendency is

Table 4. ^{13}C-NMR spectra of **1e** in 96% H_2SO_4, 35% H_2SO_4 (in CH_3CO_2H), and $CDCl_3$[a]

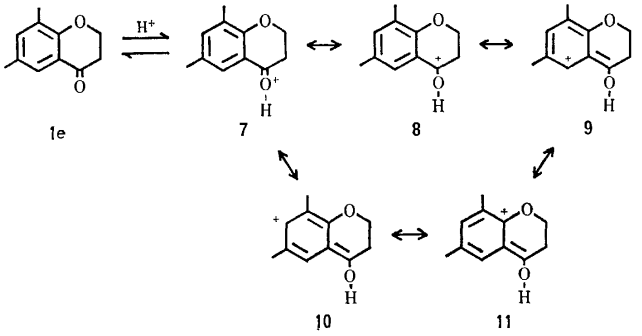
Solvent	Concn, wt %	C-2	C-3	C-4	C-5	C-6	C-7	C-8	C-9	C-10	6-CH_3	8-CH_3
96% H_2SO_4	11.9	65.7	31.4	202.7	125.0	133.9	151.9	129.9	168.0	114.6	19.5	14.3
35% H_2SO_4	17.9	67.4	37.4	197.6	125.0	131.1	140.3	128.1	160.2	120.5	20.4	15.5
$CDCl_3$	36.5	66.5	37.2	190.8	123.6	129.1	137.0	126.0	157.6	120.2	19.7	14.9
Δ_1		−0.8	−5.8	11.9	1.4	4.8	14.9	3.9	10.4	−5.6	−0.2	−0.6
Δ_2		0.9	0.2	6.8	1.4	2.0	3.3	2.1	2.6	0.3	0.7	0.6

a) Chemical shifts are reported in ppm relative to Me_4Si. Δ_1=(96% H_2SO_4–$CDCl_3$) and Δ_2=(35% H_2SO_4–$CDCl_3$) are the chemical shift differences.

observed. It was found that the deuterium atom % of the C-5 position in 35% D_2SO_4 is in equilibrium at 10%, but that of the C-3 methylene in 96% D_2SO_4 slowly increases with time. The results of the deuterium exchange of other 4-chromanones are summarized in Table 3. 20% D_2SO_4 preferentially leads to exchange of the C-3 methylene protons, and 96% D_2SO_4 leads to the aromatic protons, but the difference between 20% D_2SO_4 and 96% D_2SO_4 is not as large as in the case of **1e**. The deuterium exchange of **1c** in 20% D_2SO_4 occurred in the order 3>6>8, and that in 96% D_2SO_4 in the order 6>3>8.

^{13}C-NMR Spectra of **1e**. Table 4 gives the carbon-13 chemical shifts obtained in 96% H_2SO_4, 35% H_2SO_4 (in CH_3CO_2H), and $CDCl_3$, as well as the chemical shift differences, Δ_1 and Δ_2, between H_2SO_4 solutions and $CDCl_3$ solution. Assigments of resonance positions to individual carbon atoms were made on the basis of substituent effects,[4] splitting patterns in proton coupled spectra, and internal consistency. A positive Δ indicates that the resonance is deshielded in H_2SO_4 relative to $CDCl_3$. In 96% H_2SO_4, larger deshielding trends of 10—15 ppm are observed for C-4, C-7, and C-9. Deshielding of 6.8 ppm for C-4 is observed in 35% H_2SO_4 solution.

The observed chemical shift trends in 96% H_2SO_4 are interpreted to result predominantly from protonation of the carbonyl oxygen (**7**) (Scheme 1). A deshielding effect is associated with a loss of charge density for carbons of similar hybridization.[5]

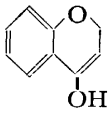


Scheme 1.

Reaction Path. Some papers on the acid-catalyzed condensation of cycloalkanones with formaldehyde[6] have reported the formation of hydroxymethyl derivatives and 1,3-dioxanes.

In the reactions of 4-chromanones with formaldehyde in solvents in the presence of sulfuric acid, the condensation products for the C-3 position were obtained even though **1a**, **1b**, and **1c** gave the aromatic substituted products containing 1,3-dioxanes. The deuterium exchange of 4-chromanones in various concentrations of sulfuric acid suggests that the C-3 methylene protons are more reactive than the aromatic protons.

These results obtained in the low concentrations of sulfuric acid can be explained by the aldol condensation mechanism.[7] The intermediate enol (**12**) is formed by the direct removal of a proton from the protonated intermediate (**8**) by bases (HSO_4^- and/or $CH_3CO_2^-$), reacting with hydroxymethyl cation($\overset{+}{C}H_2OH$)[8] to produce hydroxymethyl derivatives. Diacetates were obtained when the molar quantity of formaldehyde as against that of 4-chromanones was small.



12

Bromination of **1e** in 35 and 96% H_2SO_4 using molecular bromine as an electrophilic substituting agent gave 3- and 5-bromo derivatives, respectively. The different reactivity of 4-chromanones in various concentrations of sulfuric acid might be utilized in synthetic reactions by use of other electrophilic agents.

The aromatic substituted products formed by the addition of formaldehyde to the benzene rings of 4-chromanones proceeds by an electrophilic aromatic substitution.

The results given in Table 1 suggest that the methyl substituents attached to the 6- and/or 8-positions of 4-chromanones play an important role in the formation of aromatic substituted products. **1e** fixed by the two methyl groups gave 3-substituted products only, **1d** containing the reactive 6- and 8-positions a polymer, while **1a** gave the 6-benzyl product. The results are also in line with the rates of deuterium exchange.

Experimental

General. Melting points are uncorrected. IR spectra were obtained on a Hitachi EPI-G2 spectrometer, ^{1}H-NMR spectra on a JEOR Model PS-100 spectrometer with tetramethylsilane(Me_4Si) as an internal standard, and ^{13}C-NMR spectra on a JNM-FX60 spectrometer. Chemical shifts in $CDCl_3$ and 35% H_2SO_4 (in CH_3CO_2H) were measured using Me_4Si as an internal standard. Chemical shifts in 96% H_2SO_4 were obtained relative to external $CDCl_3$ and converted into the Me_4Si scale by the relationship $\delta Me_4Si=\delta CDCl_3+$

77.1. Mass spectra were determined on a Hitachi RUM-6 mass spectrometer operating at 70 eV. Molecular weight was determined with a Mechrolab Model 301A vapor pressure osmometer in *N,N*-dimethylformamide at 65 °C.

Materials. 4-Chromanones were prepared from phenols according to the published procedure.[2,9] Commercial 1,3,5 trioxane, sulfuric acids, and solvents were used.

Reactions of 4-Chromanones with Formaldehyde. The general procedure is as follows. To a mixture of acetic acid and benzene were added 4-chromanones, 1,3,5-trioxane, and H_2SO_4 in this order, and the mixture was stirred at 60 °C. The reaction mixture was poured into cold water, and extracted with benzene. The benzene solution was washed with aqueous sodium hydroxide, aqueous hydrochloric acid, and water successively. After removal of the solvents, the residual oil was separated by column chromatography on silica gel (Wako-gel C-200; developing solvent, chloroform) to some fractions in which the first fractions were starting 4-chromanones, unless otherwise stated. The reaction conditions and products of these reactions are given in Tables 1 and 2.

From ***1a***. The reaction of **1a** with formaldehyde in a 1:3 molar ratio gave a pale yellow oil from the second fraction. The fraction could not be separated further. However, it gave **3f** containing a small amount of **1a**.

3f: IR (neat) 2770, 1670, 1090, 1040, 840, 705 cm^{-1}; ^1H NMR (CCl_4) δ=7.57 (1H, d, J=3.0 Hz, 5-H), 7.10 (5H, m, Ph), 7.06 (1H, dd, 7-H), 6.76 (1H, d, J=9.0 Hz, 8-H), 4.75 (2H, AB-q, J=6.0 Hz, $-OCH_2O-$), 4.53 (2H, s, 2-H), 3.88 (4H, s, $-CH_2O-$), 3.84 (2H, s, 6-CH_2); MS *m/e* 310 (M^+, 60), 211 (100).

From ***1b***. The reaction product obtained in a 1:1 molar ratio was subjected to fractional distillation under reduced pressure. From the first fraction unreacted **1b** was recovered at 86—87 °C/0.5 mmHg, and from the second fraction a yellow viscous oil at 165—166 °C/0.5 mmHg, which was separated by column chromatography to give a mixture of **2b** and **1b**. The distillation residue was a mixture of **3b** and other unknown products. The third fraction of the product obtained in a 1:3.3 molar ratio gave a pale yellow oil, which crystallized after being left to stand overnight. The crystals were recrystallized from cyclohexane to give **3b**.

2b: Oil; IR (neat) 1730, 1680, 1040, 880, 830 cm^{-1}; MS *m/e* 306 (M^+, 5), 174 (100).

3b: Mp 93—94 °C; IR (KBr) 2780, 1680, 1100, 1030, 890, 825 cm^{-1}; ^1H-NMR (CCl_4) δ=7.50 (1H, d, J=2.7 Hz, 5-H), 7.18 (1H, dd, 7-H), 6.80 (1H, d, J=9.1 Hz, 8-H), 4.76 (2H, AB-q, J=6.4 Hz, $-OCH_2O-$), 4.54 (2H, s, 2-H), 3.89 (4H, s, $-CH_2O-$), 2.29 (3H, s, 6-CH_3); MS *m/e* 234 (M^+, 41), 135 (100). Found: C, 66.45; H, 5.97%. Calcd for $C_{13}H_{14}O_4$: C, 66.66; H, 6.02%.

From ***1c***. The yellow oils obtained in 1:3.3 and 1:5 molar ratios in a mixed solution of acetic acid and benzene were separated into three fractions. A crystalline product (**3g**) was isolated from the second fraction, and a small amount of polymer from the third fraction. The first fraction of the product obtained in a 1:5 molar ratio in a mixture of acetic acid and cyclohexane gave **3h**.

3g: Mp 153—154 °C (from ligroin); IR (KBr) 2760, 1670, 1100, 1040, 830, 700 cm^{-1}; ^1H-NMR (CCl_4) δ=7.42 (1H, d, 5-H), 7.04 (1H, d, 7-H), 7.12 (5H, m, Ph), 4.78 (2H, AB-q, J=6.1 Hz, $-OCH_2O-$), 4.58 (2H, s, 2-H), 3.91 (2H, s, $-CH_2O-$), 3.48 (2H, s, 6-CH_2), 2.22 (3H, s, 8-CH_3); MS *m/e* 324 (M^+, 93), 225 (100). Found: C, 74.29; H, 6.32%. Calcd for $C_{20}H_{20}O_4$: C, 74.06; H, 6.22%.

3h: Mp 99—99.5 °C (from ligroin); IR (KBr) 2780, 1680, 1095, 1035, 1025, 820 cm^{-1}; ^1H-NMR (CCl_4) δ=7.52 (1H, d, 5-H), 7.26 (1H, d, 7-H), 4.87 (2H, s, 6-CH_2), 4.75 (2H, AB-q, J=6.0 Hz, $-OCH_2O-$), 4.60 (2H, s, 2-H), 3.89 (4H, s, $-CH_2O-$), 2.26 (3H, s, 8-CH_3), 2.00 (3H, s, $COCH_3$); MS *m/e* 306 (M^+, 77), 207 (100). Found: C, 62.80; H, 5.83%. Calcd for $C_{16}H_{18}O_6$: C, 62.74; H, 5.92%.

From ***1d***. The reaction product obtained in a 1:1 molar ratio gave a resinous substance which could be isolated with difficulty from the reaction mixture: yield 1.5 g; mp 80 °C; molecular weight 420; IR (KBr) 1670, 1100, 1020 cm^{-1}. The absorption due to benzyl group at 3.9 ($C\underline{H}_2Ph$) and 7.2 (Ph) ppm was observed by the ^1H-NMR spectrum. The reaction product obtained in a 1:3 molar ratio gave a resinous substance: yield 2.7 g; mp 100 °C; molecular weight 630; IR (KBr) 1725, 1660, 1095, 1030 cm^{-1}. The absorption due to the benzyl group at 3.9 ($C\underline{H}_2Ph$) and 7.2 (Ph) ppm, and the 1,3-dioxane ring at 5.0 and 4.8 ($-OCH_2O-$) ppm was observed by the ^1H-NMR spectrum.

From ***1e***. The reaction products obtained in Runs 8, 9, 10, 11, and 12 were isolated by column chromatography to three fractions. The second white crystalline fraction and the third yellow oil fraction gave **3e** and **2e**, respectively. The reaction mixtures in Runs 13, 15, and 16 were extracted with chloroform and recrystallized from ligroin to give **3e** or **4**.

2e: Yellow oil; IR (neat) 1730, 1670, 1030, 870 cm^{-1}; ^1H-NMR (CCl_4) δ=7.44 (1H, d, 5-H), 7.04 (1H, d, 7-H), 4.35 (2H, s, 2-H), 4.24 (4H, s, $-CH_2OCO-$), 2.26 (3H, s, 6-CH_3), 2.08 (3H, s, 8-CH_3), 2.00 (6H, s, $-OCOCH_3$); MS *m/e* 320 (M^+, 37), 148 (100). Found: C, 63.98; H, 6.30%. Calcd for $C_{17}H_{20}O_6$: C, 63.74; H, 6.29%.

3e: Mp 146.5—148 °C (from acetone); IR (KBr) 2760, 1660, 1100, 1030, 880 cm^{-1}; ^1H-NMR (CCl_4) δ=7.34 (1H, d, 5-H), 7.08 (1H, d, 7-H), 4.78 (2H, AB-q, J=6.0 Hz, $-OCH_2O-$), 4.56 (2H, s, 2-H), 3.90 (4H, s, $-CH_2O-$), 2.26 (3H, s, 6-CH_3), 2.22 (3H, s, 8-CH_3); MS *m/e* 248 (M^+, 69), 149 (100); ^{13}C-NMR ($CDCl_3$) δ=192.4 (s, 4-C), 157.7 (s, 9-C), 138.5 (d, 7-C), 130.3 (s, 6-C), 127.0 (s, 8-C), 124.3 (d, 5-C), 119.2 (s, 10-C), 94.0 (t, 2′-C), 69.7 (t, 2-C), 67.5 (t, 4′- and 6′-C), 45.2 (s, 3-C), 20.3 (q, 6-CH_3), 15.3 (q, 8-CH_3). The assignments are based on the data of Chauhan and Still,[10] and the procedure of Levy and Nelson.[11] Found: C, 67.61; H, 6.49%. Calcd for $C_{14}H_{16}O_4$: C, 67.73; H, 6.50%.

4: Mp 95—97 °C (lit,[9] mp 95—97 °C). The structure of this product was confirmed by ^1H-NMR and mass spectra.

Reduction of ***3e***. Sodium borohydride (0.14 g, 3.6 mmol) was added to **3e** (1.24 g, 5 mmol) in ethanol (20 ml). The mixture was heated under reflux at 80 °C for 4 h. The reaction mixture was neutralized with acetic acid and then extracted with ether. The ether layer was washed with aqueous sodium hydroxide, aqueous hydrochloric acid, and water and then dried *in vacuo*. The residue was recrystallized from hexane to give **3e′** in a 68% yield: mp 109 °C; IR (KBr) 3400, 2760, 1030, 870 cm^{-1}; ^1H-NMR (CCl_4) δ=6.76 (2H, bd, 5- and 7-H), 4.70 (2H, AB-q, J=6.1 Hz, $-OCH_2O-$), 4.12 (2H, AB-q, J=10.1 Hz, 2-H), 3.67 (4H, AB-q, J=12.1 Hz, $-CH_2O-$), 4.22 (1H, s, OH), 3.80 (1H, s, 4-H), 2.22 (3H, s, 6-CH_3), 2.14 (3H, s, 8-CH_3); MS *m/e* 250 (M^+, 71), 150 (100). Found: C, 66.94; H, 7.39%. Calcd for $C_{14}H_{18}O_4$: C, 67.18; H, 7.25%.

Preparation of ***5***. To a solution of 96% H_2SO_4 (5 ml) and acetic acid (50 ml) was added **1e** (1.76 g, 10 mmol), and the mixture was cooled in an ice-bath. A solution of bromine (0.80 g, 10 mmol) and acetic acid (5 ml) was then added dropwise over a period of 30 min to the mixture with stirring, and the mixture was stirred for 30 min at 0 °C. The reaction mixture was poured into water and extracted with benzene. The organic layer was washed with aqueous sodium hydroxide and water, and dried *in vacuo* to give a yellow oil. The oil

was recrystallized twice from ligroin to give **5**: yield 17%; mp 86—87 °C, IR (KBr) 1680, 1020, 890, 550 cm^{-1}; ^1H-NMR (CCl_4) δ=7.46 (1H, d, 5-H), 7.10 (1H, d, 7-H), 4.54 (2H, d, J=4.5 Hz, 2-H), 4.42 (1H, t, 3-H), 2.27 (3H, s, 6-CH_3), 2.21 (3H, s, 8-CH_3); MS *m/e* 254 (M^+, 31), 148 (100). Found: C, 51.77; H, 4.33; Br, 31.16%. Calcd for $C_{11}H_{11}O_2Br$: C, 51.79; H, 4.35; Br, 31.32%.

Preparation of ***6***. **1e** (3.52 g, 20 mmol) was dissolved in 96% H_2SO_4 (30 ml), and the mixture was cooled in an ice-bath. Bromine (3.2 g, 40 mmol) was added over a period of 30 min to the mixture with stirring, and the mixture was stirred for 30 min at 0 °C. The reaction mixture was treated as described in the preparation of **5**. The product was recrystallized three time from ligroin to give **6**: yield 23%; mp 102—103 °C; IR (KBr) 1680, 1020, 870, 570 cm^{-1}; ^1H-NMR (CCl_4) δ=7.08 (1H, s, 7-H), 4.49 (2H, t, J=6.0 Hz, 2-H), 2.76 (2H, t, 3-H), 2.32 (3H, s, 6-CH_3), 2.14 (3H, s, 8-CH_3); MS *m/e* 254 (M^+, 100), 226 (83). Found: C, 51.63; H, 4.24; Br, 31.23%.

Pseudo-sugars. 4. A Facile Synthesis of DL-Validamine and Its Derivative[1]

Seiichiro OGAWA,* Koji NAKAMOTO, Masaaki TAKAHARA, Yoshio TANNO, Noritaka CHIDA, and Tetsuo SUAMI

Department of Applied Chemistry, Faculty of Engineering, Keio University, Hiyoshi, Yokohama 223

(Received October 3, 1978)

Penta-*N,O*-acetyl-DL-validamine was prepared from readily available *endo*-2, *exo*-3-diacetoxy-*endo*-6-acetoxymethyl-7-oxabicyclo[2.2.1]heptane in three steps in an overall yield of 36%.

As a part of a synthetic study of antibiotic validamycins,[2] we wish to report a facile synthesis of DL-validamine, starting from tri-*O*-acetyl-(1,3/2,4,6)-4-bromo-6-bromomethyl-1,2,3-cyclohexanetriol (**7**), which was readily obtained by the bromination of *endo*-2, *exo*-3-diacetoxy-*endo*-6-acetoxymethyl-7-oxabicyclo[2.2.1]-heptane (**4**).[3]

The *exo*-3-acetoxy (**4**), *exo*-3-methoxy (**5**), and *exo*-3-tosyloxy derivatives (**6**) of *endo*-2-acetoxy-*endo*-6-acetoxymethyl-7-oxabicyclo[2.2.1]heptane were prepared in high yields by lithium aluminium hydride (LAH) reduction followed by acetylation of the corresponding lactones (**1**,[3,4] **2**, and **3**). Treatment of **4** with 15% hydrogen bromide in acetic acid in a sealed tube at 75 °C for 24 h led to a cleavage of the anhydro ring to give single crystalline **7** in 70% yield. Under the similar reaction conditions, **5** also gave **7** in 59% yield. The structure of **7** was established on the basis of elemental and ^{1}H NMR analyses, and analogy of the bromination of the corresponding *exo*-3-bromo derivative.[5] Thus, the ^{1}H NMR spectrum contained three singlets (δ 1.99, 2.04, and 2.07) due to the acetoxyl methyl protons and the relatively narrow three-proton multiplet (δ 5.00) due to the protons on the carbon atoms bearing the acetoxyl groups. The one-proton symmetric broad multiplet (δ 3.90) could be attributable to H-4, indicating that the ring bromine atom was in an equatorial position in the favored conformation. The previous results[5] suggested that the anhydro ring of this system would be cleaved by a bromide ion at the carbon atom (C-4) adjacent to the ring methylene group.

The similar bromination of **6** yielded in 62% yield the sole crystalline dibromo diacetate (**8**) which contained a tosyloxyl function. Reaction of **8** with methanolic sodium methoxide followed by acetylation gave the dibromo epoxy acetate (**12**), which was also derived by the same treatment of 1,2-di-*O*-acetyl-(1,3/2,4,6)-3,4-dibromo-6-bromomethyl-1,2-cyclohexanediol.[5] These results allowed to assign **8** as 1,2-di-*O*-acetyl-3-*O*-tosyl-(1,3/2,4,6)-4-bromo-6-bromomethyl-1,2,3-cyclohexanetriol.

Preferential substitution of the primary bromo substituent of **7** by an acetate or an azide ion was effected by treatment with a slight excess of its sodium salt in aqueous 2-methoxyethanol giving the corresponding 7-acetoxy (**9**, 72%) or 7-azido compounds (**11**, 91%). On the other hand, reaction of **7** and **9** with an excess of sodium azide in *N,N*-dimethylformamide resulted in displacement of the C-4 bromine atom by an azido group *via* S_N2 fashion to give selectively the diazido (**13**, 76%) as crystals and the azido compounds (**14**, 96%) as a syrup, respectively. Catalytic hydrogenation of **14** in the presence of Raney nickel[6] in methanol containing acetic anhydride gave the known penta-*N,O*-acetyl-(1,3,4/2,6)-4-amino-6-hydroxymethyl-1,2,3-cyclohexanetriol (DL-validamine) (**16**)[3,5] in 53% yield. Its 7-amino-7-deoxy derivative (**17**) was obtained by the similar hydrogenation of **13** in 51% yield. These data also confirmed the structure of **13** and **14**.

Compound **8** was converted similarly to the corresponding 7-acetoxy derivative (**10**) in 63% yield. On treatment with a slight excess of sodium azide in *N,N*-dimethylformamide **10** gave a syrupy azide tosylate (**15**), which, without further purification, was hydrogenated as described above to the crystalline amide tosylate (**18**) in an over all yield of 35%. In this case, replacement of the C-4 bromine atom by an azide ion seemed to occur faster than that of C-3 tosyloxyl group *via* an anchimeric reaction.[7] Treatment of **18** with methanolic sodium methoxide gave the epoxide, which was directly acetylated by a mixture of acetic anhydride and pyridine followed by the usual work-up giving **16** in 74% yield.

Experimental

Melting points were measured in a capillary in a liquid bath and are uncorrected. Solutions were evaporated under diminished pressure at 40—50 °C. ^{1}H NMR spectra were measured at 60 MHz on a Varian A-60D spectrometer in $CDCl_3$ with reference to tetramethylsilane as an internal standard and the peak positions are given in δ-values. Values given for coupling constants are of first-order. TLC was performed on silica gel (Wakogel B-10, Wako Pure Chemical Industries, Ltd.). Elemental analyses were performed by Mr. Saburo Nakada, to whom our thanks are due.

exo-*9-Methoxy-2,7-dioxatricyclo[4.2.1.0^{4,8}]nonan-3-one (2).* A mixture of *exo*-9-hydroxy-2,7-dioxatricyclo[4.2.1.0^{4,8}]nonan-3-one (**1**)[3,4] (5 g), methyl iodide (10 ml), and silver oxide (10 g) in *N,N*-dimethylformamide (20 ml) was vigorously stirred at a room temperature under dark for 20 h. Acetone was added to the reaction mixture, an insoluble material was removed by filtration, and the filtrate was evaporated to give a solid product. Crystallization from ethanol gave **2** (4.2 g, 77%) as needles: mp 85—86 °C; ^{1}H NMR δ 1.86 (1H, dd, $J_{4,5\text{endo}}$=3 Hz, $J_{5\text{gem}}$=12.5 Hz, H-5endo), 2.21 (1H, ddd, $J_{4,5\text{exo}}$=10 Hz, $J_{5\text{exo},6}$=5 Hz, H-5exo), 2.69 (1H, ddd, $J_{4,8}$=5 Hz, H-4), 3.37 (3H, s, OMe), 3.43 (1H, s, H-9), 4.59 (2H, t, $J_{1,8}$=5 Hz, H-1 and H-6), 5.29 (1H, t, H-8).

Found: C, 56.42; H, 5.92%. Calcd for $C_8H_{10}O_4$: C, 56.46; H, 5.92%.

exo-*9-Tosyloxy-2,7-dioxatricyclo[4.2.1.0^{4,8}]nonan-3-one (3).* Compound **1** (1 g) was treated with tosyl chloride (2.5 g, 2 mol equiv) in pyridine (5 ml) at a room temperature overnight. The reaction mixture was poured into ice-water, and the precipitates were collected and recrystallized from ethyl acetate to give **3** (1.4 g, 71%) as needles: mp 174—175 °C. ^{1}H NMR δ 2.48 (3H, s, tosyl Me), 4.51 (1H, s, H-9), 4.60 (1H, d, $J_{1,8}$=5 Hz, H-1), 4.77 (1H, d, $J_{5\text{exo},6}$=5 Hz, H-6), 5.33 (1H, t, $J_{4,8}$=5 Hz, H-8).

Found: C, 53.95; H, 4.56; S, 10.06%. Calcd for $C_{14}H_{14}O_6S$: C, 54.18; H, 4.55; S, 10.33%.

endo-*2*, exo-*3-Diacetoxy*-endo-*6-acetoxymethyl-7-oxabicyclo[2.2.1]heptane (4).* To a stirred mixture of LAH (3 g, 2.5 mol equiv) in dry tetrahydrofuran (THF) (100 ml) was added in several portions pulverized **1** (5 g) under external ice-cooling. The reaction mixture was stirred at this temperature for 15 min and then at a room temperature for 2 h. An excess hydride was destroyed by addition of water (10 ml), and the precipitates were filtered and washed thoroughly with a mixture of acetone and water. The filtrate and washings were combined and evaporated to dryness. The residue was treated with a mixture of acetic anhydride (20 ml) and pyridine (20 ml) at a room temperature overnight. An insoluble material was removed by filtration, and the filtrate was evaporated and co-distilled with toluene to give a syrup, which was dissolved in chloroform and passed through a short alumina column. Evaporation of the solvent gave **4** (8.4 g, 93%) as a practically homogeneous syrup, whose IR and ^{1}H NMR spectra were identical to those of an authentic sample.[3]

endo-*2-Acetoxy*-endo-*6-acetoxymethyl*-exo-*3-methoxy-7-oxabicyclo[2.2.1]heptane (5).* Compound **2** (5 g) was reduced with LAH (1.2 g) in THF (100 ml) similarly as described above and the product was successively acetylated in the usual manner. Crystallization of the crude product from ethyl acetate–hexane gave **5** (5.9 g, 78%) as needles: mp 58—59 °C; ^{1}H NMR δ 1.16 (1H, dd, $J_{5\text{endo},6}$=5 Hz, $J_{5\text{gem}}$=11 Hz, H-5endo), 2.01 (3H, s) and 2.03 (3H, s) (OAc), 3.31 (3H, s, OMe), 3.42 (1H, d, $J_{2,3}$=2 Hz, H-3), 4.22 (2H, dd, C<u>H</u>$_2$OAc), 4.48 (1H, d, $J_{4,5\text{exo}}$=6 Hz, H-4), 4.60 (1H, t, $J_{1,2}$=$J_{1,6}$=4 Hz, H-1), 4.90 (1H, broad d, H-2).

Found: C, 55.89; H, 6.93%. Calcd for $C_{12}H_{18}O_6$: C, 55.80; H, 7.03%.

endo-*2-Acetoxy*-endo-*6-acetoxymethyl*-exo-*3-tosyloxy-7-oxabicyclo[2.2.1]heptane (6).* Compound **3** (5 g) was reduced with LAH (0.67 g) in THF (130 ml) similarly as described in the preparation of **4** and the product was acetylated as usual. Crystallization of the crude product from ethyl acetate gave **6** (4.3 g, 67%) as needles: mp 117—118 °C; ^{1}H NMR δ 1.23 (1H, dd, $J_{5\text{endo},6}$=5 Hz, $J_{5\text{gem}}$=12 Hz, H-5endo), 1.94 (3H, s) and 1.99 (3H, s) (OAc), 2.44 (3H, s, tosyl Me), 4.18 (2H, dd, C<u>H</u>$_2$OAc).

Found: C, 54.37; H, 5.39; S, 7.88%. Calcd for $C_{18}H_{22}O_8S$: C, 54.26; H, 5.57; S, 8.05%.

Tri-O-acetyl-(1,3/2,4,6)-4-bromo-6-bromomethyl-1,2,3-cyclohexanetriol (7). a) A mixture of **4** (2.5 g) and 15% hydrogen bromide in acetic acid (20 ml) was heated in a sealed tube at 75 °C for 24 h. The brown reaction mixture was poured into ice–water (1 l), and the resulting crystals were collected and washed thoroughly with water. The crude crystals were recrystallized from ethanol to give **7** (2.6 g, 70%) as needles or prisms: mp 162—163 °C; ^{1}H NMR δ 1.99 (3H, s), 2.04 (3H, s), and 2.07 (3H, s) (OAc), 3.30 (2H, m, C<u>H</u>$_2$Br), 3.90 (1H, m, H-4), 5.00 (3H, m, H-1, H-2, and H-3).

Found: C, 36.37; H, 4.18; Br, 36.95%. Calcd for $C_{13}H_{18}O_6Br_2$: C, 36.30; H, 4.22; Br, 37.16%.

b) Compound **5** (4.5 g) was treated similarly with 15% hydrogen bromide in acetic acid (35 ml) at 80 °C for 50 h, and the reaction mixture was processed as described above. The crude product was crystallized from isopropyl alcohol to give **7** (4.4 g, 59%) as needles: mp 159—161 °C

1,2-Di-O-acetyl-3-O-tosyl-(1,3/2,4,6)-4-bromo-6-bromomethyl-1,2,3-cyclohexanetriol (8). Compound **6** (1 g) was treated with 15% hydrogen bromide in acetic acid (6 ml) as described in the preparation of **7**. The product was crystallized from ethanol to give **8** (0.85 g, 62%) as needles: mp 161—163 °C; ^{1}H NMR δ 2.03 (6H, s, OAc), 2.42 (3H, s, tosyl Me), 3.85 (1H, m, H-4).

Found: C, 40.05; H, 4.06%. Calcd for $C_{18}H_{22}O_7Br_2S$: C, 39.87: H, 4.09%.

1-O-Acetyl-2,3-anhydro-(1/2,3,4,6)-4-bromo-6-bromomethyl-1,2,3-cyclohexanetriol (12). a) Compound **8** (0.7 g) was dissolved in a mixture of chloroform (3 ml) and methanol (5 ml) and the solution was treated with 1.3 M methanolic sodium methoxide (10 ml) at a room temperature for 3 h. The reaction mixture was evaporated to dryness and the residual product was acetylated in the usual manner. The crude acetyl derivative was crystallized from ethanol to give **12** (0.12 g, 50%) as needles: mp 83—84.5 °C; ^{1}H NMR δ 2.15 (3H, s, OAc), 3.3—3.6 (4H, m, C<u>H</u>$_2$Br, H-2, and H-3), 4.43 (1H, m, H-4), 4.93 (1H, m, H-1).

Found: C, 32.85; H, 3.64; Br, 48.84%. Calcd for $C_5H_{12}O_3Br_2$: C, 32.96; H, 3.69; Br, 48.72%.

b) Treatment of di-*O*-acetyl-(1,3/2,4,6)-3,4-dibromo-6-bromomethyl-1,2-cyclohexanediol[5] (1.35 g) with methanolic sodium methoxide as described above gave **12** (0.76 g, 78%), identical with the compound obtained above.

Tetra-O-acetyl-(1,3/2,4,6)-4-bromo-6-hydroxymethyl-1,2,3-cyclohexanetriol (9). A mixture of **7** (2 g), anhydrous sodium acetate (1.5 g, 3.5 mol equiv), and 90% aqueous 2-methoxyethanol (50 ml) was heated at 80 °C with stirring for 24 h, and evaporated to dryness. The residue was acetylated as usual and the solid product was extracted with chloroform. TLC (1: 15 acetone–benzene, v/v) showed the product to be consist of one major (R_f 0.42) and two minor components (R_f 0.58 and 0.30). The extracts were filtered through a short alumina column and evaporated to give a syrup, which

crystallized from isopropyl alcohol affording **9** (1.4 g, 72%) as needles: mp 119—120 °C; ^{1}H NMR δ 1.97 (3H, s), 2.00 (3H, s), and 2.06 (6H, s) (OAc), 3.8—4.2 (3H, m, C$\underline{H}_2$OAc and H-4), 5.01 (1H, t, $J_{1,2}=J_{1,6}=11$ Hz, H-1), 5.10 (1H, t, $J_{2,3}=J_{3,4}=11$ Hz, H-3), 5.20 (1H, t, H-2).

Found: C, 43.72; H, 5.06; Br, 19.82%. Calcd for $C_{15}H_{21}O_8Br$: C, 44.02; H, 5.17; Br, 19.53%.

1,2,7-Tri-O-*acetyl-3*-O-*tosyl-(1,3/2,4,6)-4-bromo-6-hydroxymethyl-1,2,3-cyclohexanetriol (**10**).* Compound **8** (1 g) was treated with anhydrous sodium acetate (1.2 g) in 90% aqueous 2-methoxyethanol (50 ml) at 90 °C for 2 days. The reaction mixture was processed similarly and the product was acetylated. Crystallization of the acetate from ethanol gave **10** (0.61 g, 63%) as prisms: mp 179—180 °C; ^{1}H NMR δ 2.04 (6H, s) and 2.08 (3H, s) (OAc), 2.45 (3H, s, tosyl Me), 4.00 (2H, broad s, C$\underline{H}_2$OAc).

Found: C, 45.85; H, 4.76%. Calcd for $C_{20}H_{25}O_9BrS$: C, 46.07; H, 4.83%.

Tri-O-*acetyl-(1,3/2,4,6)-6-azidomethyl-4-bromo-1,2,3-cyclohexanetriol (**11**).* A mixture of **7** (1 g), sodium azide (0.45 g), and 90% aqueous 2-methoxyethanol (15 ml) was heated at 95 °C for 2 h, and evaporated to dryness. The residual solid was acetylated as usual and the crude product was purified by passage through a short alumina column with chloroform. Crystallization from ligroin gave **11** (1.7 g, 91%) as needles: mp 136—138 °C; ^{1}H NMR δ 1.95 (3H, s), 2.01 (3H, s), and 2.03 (3H, s) (OAc), *ca.* 3.3 (2H, m, C$\underline{H}_2N_3$), 3.95 (1H, m, H-4).

Found: C, 39.78; H, 4.67; N, 10.85; Br, 20.66%. Calcd for $C_{13}H_{18}N_3O_6Br$: C, 39.81; H, 4.64; N, 10.71; Br, 20.37%.

Penta-N,O-*acetyl-(1,3,4/2,6)-4-amino-6-hydroxymethyl-1,2,3-cyclohexanetriol (**16**).* A mixture of **9** (3 g), sodium azide (1.9 g), and *N,N*-dimethylformamide (100 ml) was heated at 90 °C for 24 h, and evaporated to dryness. The solid residue was extracted with chloroform and the extracts were filtered through a short alumina column. The filtrate was evaporated to give **14** (2.6 g, 96%) as a homogeneous syrup: IR (neat) 2100 (N_3), 1745 cm^{-1} (ester); ^{1}H NMR δ 2.00 (6H, s) and 2.02 (6H, s) (OAc), 5.01 (1H, dd, $J_{1,2}=9.5$ Hz, $J_{1,6}=5.5$ Hz, H-1), 5.39 (1H, t, $J_{2,3}=9.5$ Hz, H-2).

A solution of the crude **14** (2.8 g) in methanol (50 ml) containing acetic anhydride (2 ml) was hydrogenated in a Parr shaker apparatus in the presence of Raney nickel T-4[6] at hydrogen pressure of 3 kg·cm^{-2} at a room temperature overnight. The catalyst was removed by filtration and the filtrate was evaporated to give a crystalline residue. Recrystallization from ethanol gave **16** (1.5 g, 53%) as plates: mp 197—198 °C. This compound was identical with an authentic sample[3] in all respects.

Tri-O-*acetyl-(1,3,4/2,6)-4-azido-6-azidomethyl-1,2,3-cyclohexanetriol (**13**).* Compound **7** (1 g) was treated with sodium azide (0.9 g, 6 mol equiv) in *N,N*-dimethylformamide (40 ml) at 85 °C for 20 h. The reaction mixture was processed similarly as described above and the product was acetylated. Crystallization of the crude acetate from ligroin gave **13** (0.62 g, 76%) as prisms: mp 120—121 °C; ^{1}H NMR δ 2.00 (3H, s), 2.05 (3H, s), and 2.07 (3H, s) (OAc), 3.30 (2H, d, $J=4$ Hz, C$\underline{H}_2N_3$), 4.11 (1H, q, $J=3$ Hz, H-4), 4.82 (1H, t, $J_{1,2}=J_{1,6}=9.5$ Hz, H-1), 4.93 (1H, dd, $J_{2,3}=9.5$ Hz, H-3), 5.37 (1H, t, H-2).

Found: C, 44.23; H, 5.18; N, 23.48%. Calcd for $C_{13}H_{18}N_6O_6$: C, 44.06; H, 5.13; N, 23.72%.

Penta-N,O-*acetyl-(1,3,4/2,6)-4-amino-6-aminomethyl-1,2,3-cyclohexanetriol (**17**).* Compound **13** (0.5 g) was hydrogenated similarly as described in the preparation of **16**. The crude product was crystallized from ethyl acetate to give **17** (0.28 g, 51%) as needles: mp 258—259 °C (lit,[4] 246—248 °C). This compound was identified with an authentic sample[3] by comparison with IR and ^{1}H NMR spectra.

1,2,7-Tri-O-*acetyl-3*-O-*tosyl-(1,3,4/2,6)-4-acetamido-6-hydroxymethyl-1,2,3-cyclohexanetriol (**18**).* Compound **10** (1 g) was treated with sodium azide (0.6 g) in *N,N*-dimethylformamide (20 ml) at 85 °C for 24 h. The product was acetylated and purified by chromatography on alumina with chloroform to give the azide (**15**, 0.9 g, 97%) as a practically pure syrup: ^{1}H NMR δ 1.93 (3H, s), 2.00 (3H, s), and 2.06 (3H, s) (OAc), 2.45 (3H, s, tosyl Me).

The crude **15** (0.78 g) was hydrogenated as described in the preparation of **16**. The product was crystallized from ethanol to give **18** (0.28 g, 34% based on **10** used) as needles: mp 157—158 °C; ^{1}H NMR δ 1.90 (3H, s, NAc), 1.96 (3H, s), 2.00 (3H, s), and 2.06 (3H, s) (OAc), 2.54 (3H, s, tosyl Me), 3.96 (2H, narrow m, C$\underline{H}_2$OAc), 6.38 (1H, d, $J=7$ Hz, N$\underline{H}$).

Found: C, 53.05; H, 5.89; N, 2.62; S, 6.57%. Calcd for $C_{22}H_{29}NO_{10}S$: C, 52.90; H, 5.85; N, 2.80; S, 6.42%.

Compound **18** (0.13 g) was treated with methanolic sodium methoxide as described in the preparation of **12**. The product was treated with acetic anhydride (7 ml) and pyridine (7 ml) at 50 °C for 2 h, and the mixture was worked up in the usual manner. The product was crystallized from ethanol to give **16** (0.073 g, 74%) as prisms: mp 194—196 °C, identical with the compound obtained before in all respects.

The financial support from the Ministry of Education for this work is gratefully acknowledged.

Preparation of *N*-Acetylmuramyl-L-[U-^{14}C]alanyl-D-isoglutamine *via* a Novel Synthetic Route[1)]

Shoichi KUSUMOTO, Kazuhiro IKENAKA, and Tetsuo SHIBA*

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received October 16, 1978)

For the investigation on the action mechanism of immunoadjuvant active *N*-acetylmuramyl-L-alanyl-D-isoglutamine, its labeled compound, *i.e.*, *N*-acetylmuramyl-L-[U-^{14}C]alanyl-D-isoglutamine was synthesized. For this purpose, an entirely novel synthetic route for the muramyl dipeptide was exploited using cold materials and applied to the preparation of the labeled compound. A convenient synthetic procedure of isoglutamine derivatives is also described.

It has been known that the biologically important immune reactions, which participate in the self-defence mechanisms of living bodies against non-self materials, can be stimulated by immunoadjuvant substances such as bacterial cell walls. The common active structure in the cell walls was recently elucidated to be *N*-acetylmuramyl-L-alanyl-D-isoglutamine (**1**) by the synthetic studies by us[2)] and Merser *et al.*[3)] The muramyl dipeptide (**1**) exhibited remarkable activities not only for antibody production and delayed-type hypersensitivity, but also for so many other immunological systems.[4)]

However, in spite of the current importance of the adjuvant activity in the immunological and therapeutic fields, little has been known about the mechanism for this biological action. This seems to be mainly due to the fact that all the hitherto known natural adjuvants are high molecular materials of unknown or complex structures. Now, we can replace the cell walls with synthetic *N*-acetylmuramyl-L-alanyl-D-isoglutamine (**1**) as an effective adjuvant in many immuno reactions. Therefore, preparation of a labeled compound of the muramyl dipeptide (**1**) has been much urged for investigation of its action mechanism. We thus intended to prepare *N*-acetylmuramyl-L-[U-^{14}C]alanyl-D-isoglutamine (**1a**) of extremely high specific radioactivity, since we aimed a whole body autoradiographic study as a preliminary approach to obtain informations for its local distribution. For this reason, the synthesis must be carried out in μmol scale and preferably in a one-flask system starting from the commercial L-alanine labeled uniformly with ^{14}C with highest specific activity available. Our previous method[2)] can not be applied for this purpose because of several technical disadvantages. Thus, a novel synthetic route to the muramyl dipeptide (**1**) was established in this investigation and the labeled compound (**1a**) was successfully prepared by its application. It should be noted that this new route also serves as an alternative method for a facile and convenient preparation of cold muramyl dipeptide (**1**).

The new synthetic route designed for the preparation of *N*-acetylmuramyl-L-[U-^{14}C]alanyl-D-isoglutamine (**1a**) must fulfil the following requirements. i) The synthesis must be throughout performed in a μmol scale without experimental difficulties. ii) Excess reagents should be used in all reaction steps in order to utilize the radioactive fragments as effective as possible. iii) By-products and excess reagents are better removed by simple procedures such as evaporation or extraction so that the products can be subjected to the successive reactions without transfer into other vessels. Taking account of these principles, the basic strategy of the synthesis was adopted first to prepare a free dipeptide, L-alanyl-D-isoglutamine (**2**), and then to couple it with a muramic acid derivative by means of an active ester method. Only acid-labile protective groups were employed in order to avoid the procedure of hydrogenolysis where an adsorption to the catalyst might occur causing considerable loss of materials.

The synthetic route based on the above principles was first examined with cold materials in preparative scales. The dipeptide, L-alanyl-D-isoglutamine (**2**) was prepared from *t*-butoxycarbonyl(Boc)-L-alanine (**3**) and D-isoglutamine *t*-butyl ester (**5**). To avoid the undesirable dehydration of the isoglutamine moiety by excess condensation reagent, Boc-L-alanine was converted into 1-succinimidyl ester (**4**) in advance and then coupled with **5** giving Boc-L-alanyl-D-isoglutamine *t*-butyl ester (**6**). The product was then treated with trifluoroacetic acid (TFA) to afford pure dipeptide (**2**) TFA salt. This was identified with the authentic sample obtained previously.[2)]

The following alternative pathway for the preparation of the dipeptide (**2**) was also examined. Thus, an isoglutamine derivative in which 4,4′-dimethoxybenzhydryl group[5)] was employed for amide protection, *i.e.*, D-glutamic acid α-4,4′-dimethoxybenzhydrylamide γ-*t*-butyl ester (**7**), was condensed with Boc-L-alanine (**3**) by means of dicyclohexylcarbodiimide (DCC)–*N*-hydroxysuccinimide (HONSu). However, several unknown by-products were formed in this coupling reaction unexpectedly and the pure protected dipeptide, Boc-L-alanyl-D-glutamic acid α-4,4′-dimethoxybenzhydrylamide γ-*t*-butyl ester (**8**), could be obtained only after repeated recrystallization. Although **8** could be converted into the free dipeptide (**2**) by action of dry hydrogen chloride in acetic acid, this second route seemed not to be advantageous for the purpose of preparation of the labeled compound because of the difficulty of purification of **8**.

Nevertheless, the preparative methods of the D-isoglutamine derivatives (**5** and **7**) used in the above syntheses are worthwhile to be described here, since they were both prepared from benzyloxycarbonyl(Z)-D-isoglutamine (**9**) which was obtained *via* a new convenient procedure. Ammonia gas was introduced into a solution of Z-D-glutamic acid anhydride in THF, and the resulting mixture of α- and γ-amide was recrystallized

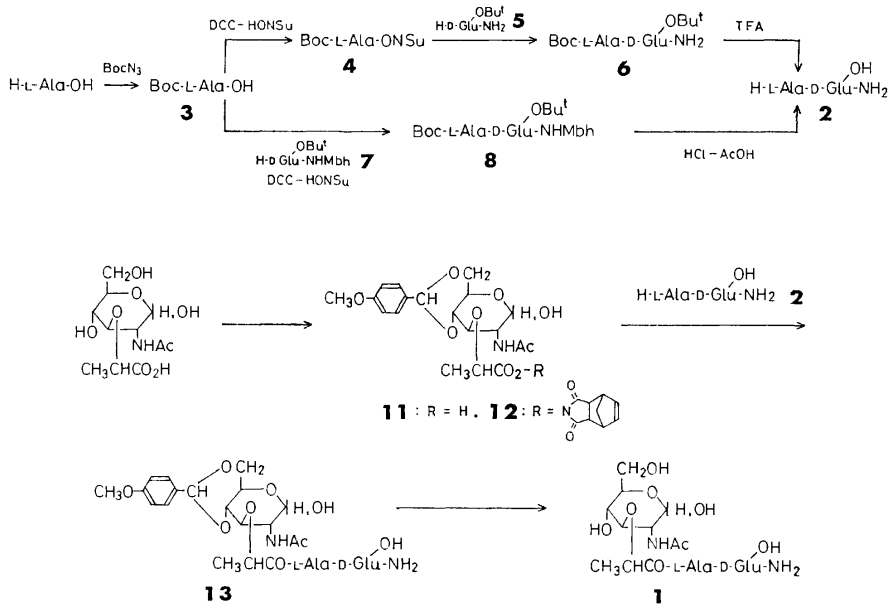
from methanol–ether. Pure Z-D-isoglutamine (**9**) ammonium salt was readily isolated in 64% yield after this simple recrystallization, while isomeric Z-D-glutamine remained in the mother liquor.[6] Hydrogenolysis of **9** followed by the perchloric acid-catalyzed transesterification with *t*-butyl acetate afforded D-isoglutamine *t*-butyl ester (**5**). D-Glutamic acid α-4,4′-dimethoxybenzhydrylamide γ-*t*-butyl ester (**7**) was also obtained as follows. Condensation of **9** with 4,4′-dimethoxybenzhydrol in the presence of sulfuric acid afforded Z-D-glutamic acid α-4,4′-dimethoxybenzhydrylamide (**10**). Hydrogenolytic removal of Z-group[7] in **10** followed by transesterification with *t*-butyl acetate afforded **7** in a good yield.

For the coupling of the muramic acid moiety with the dipeptide (**2**) obtained by the first method described above, *N*-hydroxy-5-norbornene-2,3-dicarboximide (HONb)[8] was employed as a carboxyl activating agent, which was known to give good condensation yields particularly in aqueous media.[8,9] In order to prevent a formation of the undesirable intramolecular ester in the muramic acid moiety, its 4-hydroxyl group was protected with the *p*-anisylidene group, which can be removed afterward under a very mild acidic conditions. Thus, *N*-acetylmuramic acid was treated with *p*-anisaldehyde dimethyl acetal in *N*,*N*-dimethylformamide (DMF) in the presence of *p*-toluenesulfonic acid to give 4,6-*O*-*p*-anisylidene-*N*-acetylmuramic acid (**11**), which was then converted into HONb ester (**12**) in a usual manner. It was found to be advantageous to transform **11** without isolation directly into the active ester (**12**), since the *p*-anisylidene group was so highly acid-labile that it was slowly but spontaneously cleaved at **11** by action of the free carboxyl group on the own molecule.

The coupling of the muramic acid active ester (**12**) with the peptide moiety and the successive deprotection to the free muramyl dipeptide (**1**) were performed as follows. A solution of L-alanyl-D-isoglutamine (**2**) in aqueous dioxane was treated with an excess of the *p*-anisylidenemuramic acid active ester (**12**) until all the dipeptide was consumed. Evaporation of the solvent afforded a mixture of 4,6-*O*-*p*-anisylidene-*N*-acetylmuramyl-L-alanyl-D-isoglutamine (**13**) and 4,6-*O*-*p*-anisylidene-*N*-acetylmuramic acid (**11**).[10] The mixture was then treated with aqueous acetic acid to remove the anisylidene group. After evaporation of the solvent, the residue was subjected to preparative TLC on silica gel, and the desired *N*-acetylmuramyl-L-alanyl-D-isoglutamine (**1**) was separated from *N*-acetylmuramic acid and other by-products by developing with 1-butanol–acetic acid–butyl acetate–water (80:20:7:40). The final product (**1**) thus obtained was identified with the sample prepared in the previous work[2] in respects of TLC, NMR, and $[\alpha]_D$. In this preparative scale synthesis, the muramyl dipeptide (**1**) was obtained in a fairly good overall yield (41%) from the Boc-L-alanine active ester (**4**).

An application of this novel route to a small scale synthesis was next examined using still cold materials. Thus, a pyrex test tube (15×130 mm) with a standard ground-glass joint was used as a reaction flask. Extraction and evaporation of solvents were carried out by the procedures described in the experimental section.

L-Alanine could be quantitatively converted into the Boc derivative in μmol scale by use of Boc azide. The transformation from Boc-L-alanine (**3**) (1.89 mg, 10 μmol) to L-alanyl-D-isoglutamine (**2**) was then investigated in a one-flask procedure *via* three steps. DCC was also used in this experiment for the preparation of the active ester (**4**). *N*,*N*′-Dicyclohexylurea formed in the reaction course was removed in the final step after deprotection of the dipeptide.[11] The all operations could be carried out without difficulty as described in



Boc = *t*-butoxycarbonyl
Mbh = 4,4′-dimethoxybenzhydryl
HONSu = *N*-hydroxysuccinimide
Bu^t = *t*-butyl
DCC = dicyclohexylcarbodiimide
Ac = acetyl

the experimental section. The chromatographically pure free dipeptide (**2**) was obtained in a total yield of 90% from Boc-L-alanine as calculated on the basis of amino acid analysis.

TLC examination revealed that the successive steps up to the muramyl dipeptide (**1**) from **2** could be also achieved satisfactorily even in a small scale experiment. Therefore, the new synthetic route became promissing for the preparation of labeled muramyl dipeptide (**1a**) in an extremely small scale. However, in order to apply the new procedure to a radioactive material, one more preliminary experiment prior to the final one was tried starting from diluted labeled L-alanine (10 μmol, 30 μCi) according to the same procedure. In this synthesis, overall 26% (7.7 μCi) of labeled muramyl dipeptide (**1a**) was obtained. The radiochemical purities of **2a** and **1a** were confirmed by a combined technique of TLC and a liquid scintillation counter.

On the basis of the successful results in the series of above experiments, the ultimate synthesis of the strongly labeled compound *via* the novel route was finally carried out. The commercial L-[U-^{14}C]alanine with highest specific activity available[12] was used as a starting material without dilution. All operations except the removal of *N,N'*-dicyclohexylurea were carried out in one test tube without transfer of labeled intermediates to other vessels. The procedures of actual synthesis are described in the experimental section. From 0.97 mCi of L-[U-^{14}C]alanine, *N*-acetylmuramyl-L-[U-^{14}C]alanyl-D-isoglutamine (**1a**) was obtained in a total yield of 46% (0.45 mCi) after purification with TLC.

Experimental

All melting points are uncorrected. TLC was performed on silica gel G, Merck, unless otherwise stated. For each synthesis of the labeled compound as well as the preliminary experiment with cold material in a μmol scale, all operations were carried out in a pyrex test tube (15×130 mm) with a standard ground-glass stopper. Extraction was carried out by mixing two phases in the test tube by means of an electric vibrator and then withdrawing the upper phase with a pipette. The solvent was evaporated by introduction of air stream through a capillary tube on surface of the solution in the tube under reduced pressure.

Boc-L-alanyl-D-isoglutamine t-Butyl Ester (6). *t*-Butoxycarbonyl(Boc)-L-alanine 1-succinimidyl ester (**4**) (0.86 g, 3.0 mmol) was added to an ice-cooled mixture of D-isoglutamine *t*-butyl ester (**5**) perchlorate[13] (0.96 g, 3.0 mmol) and triethylamine (0.42 ml, 3.0 mmol) in THF (20 ml). The mixture was stirred at room temperature overnight and then the solvent was evaporated *in vacuo*. The residue was taken up in ethyl acetate and worked up as usual. The product was crystallyzed from ethyl acetate–ether–hexane; yield, 0.93 g (83%); mp 132—134 °C. A sample for elemental analysis was obtained by further recrystallization from ethyl acetate–hexane; mp 132.5—133.5 °C; $[\alpha]_D^{26}$ −0.23°, $[\alpha]_{365}^{26}$ +3.94° (*c* 2.13, ethyl acetate).

Found: C, 54.75; H, 8.37; N, 11.11%. Calcd for $C_{17}H_{31}O_6N_3$: C, 54.67; H, 8.37; N, 11.25%.

L-Alanyl-D-isoglutamine (2) Trifluoroacetate from 6. Compound **6** (0.186 g, 0.50 mmol) was dissolved in trifluoroacetic acid (1.0 ml) and allowed to stand at room temperature for 30 min. Abs ether was added to the mixture to afford hygroscopic white powder, which was collected by filtration; yield, 166 mg (quantitative); mp 72 °C (dec) (with sintering at around 55 °C and resolidifying thereafter); $[\alpha]_D^{26}$ +18.7° (*c* 1.98, H_2O).[14]

Boc-L-alanyl-D-glutamic Acid α-4,4'-Dimethoxybenzhydrylamide γ-t-Butyl Ester (8). One molar solution of triethylamine in dioxane (0.45 ml, 0.45 mmol) was added to a stirred mixture of Boc-L-alanine (**3**) (0.076 g, 0.40 mmol), D-glutamic acid α-4,4'-dimethoxybenzhydrylamide γ-*t*-butyl ester (**7**) hydrochloride[13] (0.200 g, 0.43 mmol) and *N*-hydroxysuccinimide (HONSu) (0.058 g, 0.50 mmol) in dioxane (10 ml) and tetrahydrofuran (THF) (5 ml). After addition of dicyclohexylcarbodiimide (DCC) (0.103 g, 0.50 mmol) under ice-cooling, the mixture was stirred at room temperature overnight. Usual work-up and crystallization from methanol–acetone–water afforded a crude product, which was recrystallized twice from acetone–water; yield, 0.151 g (63%); mp 146—147 °C. A pure sample was only obtained after two more repetitions of recrystallization from ethyl acetate–hexane; mp 146.5—147.5 °C; $[\alpha]_D^{28}$ −3.3° (*c* 1.94, ethyl acetate).

Found: C, 64.18; H, 7.58; N, 7.01%. Calcd for $C_{32}H_{45}O_8N_3$: C, 64.09; H, 7.56; N, 7.01%.

L-Alanyl-D-isoglutamine (2) from 8. Compound **8** (6.0 mg, 0.01 mmol) was dissolved in 2 M dry HCl in acetic acid (1.0 ml, 2 mmol) and allowed to stand at room temperature for 40 h. After evaporation of the solvent *in vacuo*, the residue was dissolved in water and washed with ether. Evaporation of water *in vacuo* afforded **2** hydrochloride. This was identified with a sample obtained above from **6** by means of TLC (1-butanol–acetic acid–water, 4:1:2) and amino acid analysis.

Z-D-isoglutamine (9). DCC (5.49 g, 26.6 mmol) was added to an ice-cooled solution of Z-D-glutamic acid (6.23 g, 22.2 mmol) in THF (50 ml) with stirring. After the mixture had been stirred in an ice bath for 7 h, *N,N'*-dicyclohexylurea was filtered off. The filtrate was again cooled in an ice-salt bath, and ammonia gas was introduced with stirring for 15 min. After evaporation of the solvent *in vacuo*, the residue was crystallized from methanol–ether to give pure **9** ammonium salt; yield, 4.21 g (64%).

This ammonium salt (4.00 g, 13.5 mmol) was well ground and shaken with ethyl acetate (200 ml) and 1 M HCl (20 ml). The organic layer was washed with 1 M HCl and water, then dried over $MgSO_4$ and concentrated *in vacuo*. The colorless crystals were collected by filtration; yield, 3.29 g (87%); mp 174.5—175.5 °C. These were recrystallized from methanol–ether–hexane; mp 175—176 °C; $[\alpha]_D^{30}$ +5.61° (*c* 2.05, methanol)

Found: C, 55.60; H, 5.74; N, 9.95%. Calcd for $C_{13}H_{16}O_5N_2$: C, 55.71; H, 5.75; N, 10.00%.

D-Isoglutamine t-Butyl Ester (5) Perchlorate. Z-D-isoglutamine (**9**) (3.30 g, 11.8 mmol) was hydrogenolyzed in a mixture of methanol (100 ml) and water (60 ml) in the presence of palladium black catalyst. After usual work-up, recrystallization from water–acetone afforded D-isoglutamine; yield, 1.62 g (94%); mp 188.5—189 °C (dec). This compound (1.62 g, 11.1 mmol) was added to *t*-butyl acetate (150 ml) with stirring in the presence of 70% perchloric acid (1.5 ml, 13 mmol) at room temperature. As the starting material dissolved in about 30 min, another colorless crystals separated out slowly. After 18 h, the crystals were collected by filtration and recrystallized from methanol–ether; yield, 2.93 g (82% from **9**); mp 141—142 °C (dec); $[\alpha]_D^{26}$ −13.6° (*c* 2.00, H_2O).

Found: C, 35.65; H, 6.38; N, 9.17; Cl, 11.65%. Calcd for $C_9H_{18}O_3N_2\cdot HClO_4$: C, 35.71; H, 6.33; N, 9.25; Cl, 11.71%.

Z-D-glutamic Acid α-4,4'-Dimethoxybenzhydrylamide (10). To a solution of **9** (1.40 g, 5.0 mmol) in acetic acid (20 ml) was added 4,4'-dimethoxybenzhydrol (1.22 g, 5.0 mmol) and conc H_2SO_4 (0.02 ml). The mixture was stirred at room temperature overnight. Addition of abs ether afforded a

crystalline material, which was filtered and recrystallized from THF–hexane; yield, 2.04 g (81%); mp 209.5—210.5 °C; $[\alpha]_D^{26}$ −4.6° (*c* 2.05, THF).

Found: C, 66.51; H, 6.01; N, 5.46%. Calcd for $C_{28}H_{30}O_7N_2$: C, 66.39; H, 5.97; N, 5.53%.

D-Glutamic Acid α-4,4'-Dimethoxybenzhydrylamide γ-t-Butyl Ester (7) Hydrochloride. Compound **10** (2.53 g, 5.0 mmol) was suspended in acetic acid (25 ml) and hydrogenolyzed in the presence of palladium black catalyst. After evaporation of the solvent, the residue was crystallized from ethanol–ether to afford D-glutamic acid α-4,4'-dimethoxybenzhydrylamide as hygroscopic powder; yield, 1.55 g (83%).

This compound (0.74 g, 2.0 mmol) was dissolved in *t*-butyl acetate (20 ml) and stirred at room temperature in the presence of 70 % perchloric acid (0.24 ml, 2.1 mmol) for 3 days. After addition of ethyl acetate, the mixture was washed successively with saturated aqueous solution of $NaHCO_3$ and NaCl, dried and evaporated *in vacuo*. The residual syrup was dissolved in abs ether, and 2 M dry HCl in ethyl acetate (1.0 ml, 2.0 mmol) was added. Addition of hexane to the mixture afforded **7** hydrochloride, which was recrystallized from methanol–ether–hexane; yield, 0.31 g (33%); mp 210 °C (dec); $[\alpha]_D^{26}$ −6.0° (*c* 1.01, methanol).

Found: C, 61.37; H, 7.16; N, 5.86; Cl, 7.60%. Calcd for $C_{24}H_{32}O_5N_2 \cdot HCl \cdot 1/4H_2O$: C, 61.40; H, 6.98; N, 5.97; Cl, 7.55%.

4,6-O-p-Anisylidene-N-acetylmuramic Acid (11). *p*-Toluenesulfonic acid (27 mg, 0.14 mmol) was dissolved in a mixture of DMF and benzene (1: 1, 10 ml). From this solution, benzene was evaporated *in vacuo* to remove water completely. To the remaining solution, *N*-acetylmuramic acid[15] (0.40 g, 1.4 mmol) and *p*-anisaldehyde dimethyl acetal (0.95 g, 5.2 mmol) were added. The mixture was kept on a rotary evaporator at 15 mmHg and 40 °C for 2.5 h to remove resulting water, and then most of DMF was evaporated at 3 mmHg. The residue was dissolved in ether, washed with water and dried over $MgSO_4$. After evaporation of the solvent *in vacuo*, benzene was added to the residue. The gelatinous solid formed was filtered and recrystallized from methanol–ether–hexane; yield, 0.31 g (54%); mp 192 °C (dec).

Found: C, 55.65; H, 6.15; N, 3.31%. Calcd for $C_{19}H_{25}O_9N$: C, 55.47; H, 6.13; N, 3.40%.

4,6-O-p-Anisylidene-N-acetylmuramic Acid N-Hydroxy-5-norbornene-2,3-dicarboximide (HONb) Ester (12). DCC (0.17 g, 0.83 mmol) was added to an ice-cooled solution of **11** (0.28 g, 0.68 mmol) and HONb (0.15 g, 0.84 mmol) in THF (10 ml). The mixture was stirred overnight at room temperature. *N,N'*-dicyclohexylurea was filtered off and the solvent was evaporated *in vacuo*. The residue was dissolved in ethyl acetate, washed successively with saturated aqueous solution of $NaHCO_3$ and NaCl, and then dried over $MgSO_4$. After evaporation of the solvent, the residue was subjected to silica gel column chromatography. Elution with $CHCl_3$–acetone (4: 1) and complete evaporation of the solvent afforded pure **12** as white powder; yield, 0.17 g (44%); mp 115 °C.

In an alternative way, the same compound (**12**) was prepared directly from *N*-acetylmuramic acid without isolation of the anisylidene derivative (**11**) as the intermediate. Thus, after formation of **11**, the reaction mixture was neutralized with triethylamine, and then treated with HONb and DCC. In this case, starting from *N*-acetylmuramic acid (0.15 g, 0.51 mmol), **12** was obtained in a rather better yield (0.17 g, 58 %).

N-Acetylmuramyl-L-alanyl-D-isoglutamine (1). L-Alanyl-D-isoglutamine (**2**) trifluoroacetate (54 mg, 0.16 mmol) was dissolved in water (0.5 ml). To this solution were added 1 M triethylamine in dioxane (0.32 ml, 0.32 mmol) and **12** (92 mg, 0.16 mmol) in dioxane (0.6 ml). The mixture was allowed to stand at room temperature for 20 h, then 1 M triethylamine in dioxane (0.30 ml, 0.30 mmol) and **12** (79 mg, 0.14 mmol) in dioxane (0.5 ml) were again added. After the mixture had been allowed to stand at room temperature for further 20 h, the solvent was removed *in vacuo*. The residue was dissolved in a mixture of acetic acid (6 ml) and water (3 ml) and left stand at room temperature for 18 h. After removal of the solvent *in vacuo*, the residue was dissolved in water and washed with ether. Evaporation of the aqueous phase *in vacuo* afforded a pale yellow syrup, which was subjected to preparative TLC; commercial pre-coated silica gel plates were used (seven plates of Wako-gel F_{254}, 0.25 mm thickness, 20×20 cm, Wako Pure Chemicals Co., Ltd.)[16] with a solvent system of 1-butanol–acetic acid–butyl acetate–water (80:20:7:40). The main band was extracted with 80% ethanol, the solvent was evaporated *in vacuo* and the residue was triturated with 99% ethanol. After removal of the insoluble material, ethanol was again evaporated *in vacuo*. The remaining substance was dissolved in water and passed through a short column of Amberlite IRC50 (H^+ form). Lyophilization of the eluate afforded **1**; yield, 39 mg (50% from **2**); $[\alpha]_D^{25}$ +34.4° (*c* 0.550, H_2O after equilibration). This product was identified by TLC and NMR spectrum with the sample ($[\alpha]_D^{15}$ +33.1° (*c* 0.51, H_2O)) obtained previously.[2]

Small Scale Preparation of L-Alanyl-D-isoglutamine (2) from Boc-L-alanine. To a solution of Boc-L-alanine (1.89 mg, 10 μmol) and HONSu (1.96 mg, 17 μmol) in THF (0.27 ml) was added DCC (3.57 mg, 17 μmol) in THF (0.17 ml) under ice-cooling. After the mixture had been allowed to stand overnight, the solvent was evaporated *in vacuo*. The residue was dissolved in $CHCl_3$ (1.5 ml) and the excess DCC was decomposed with acetic acid. The solution was then washed with aqueous $NaHCO_3$ and water. After evaporation of the solvent *in vacuo*, $CHCl_3$ (1 ml) was added to the residue and evaporated again *in vacuo* to remove the remaining water. To the residue were added D-isoglutamine *t*-butyl ester (**5**) perchlorate (5.6 mg, 18.5 μmol) and 0.1 M solution of triethylamine in $CHCl_3$ (0.20 ml, 20 μmol). The mixture was allowed to stand at room temperature for 20 h, then diluted with $CHCl_3$ (1.5 ml) and washed successively with aqueous $NaHCO_3$, 1 M HCl and water. The residue obtained after evaporation of the solvent *in vacuo* was dissolved in TFA (1 ml). After 1.5 h at room temperature, TFA was removed *in vacuo*, the residue was dissolved in water, and insoluble *N,N'*-dicyclohexylurea was removed by filtration through a sintered glass filter. Evaporation of water from the filtrate afforded **2** TFA salt, which showed a single ninhydrin-positive spot on TLC. The yield was deduced to be 90% by means of amino acid analyser.

N-Acetylmuramyl-L-[U-^{14}C]alanyl-D-isoglutamine (1a). To a solution of L-[U-^{14}C]alanine (0.97 mCi, 5.9 μmol)[12] in water (0.5 ml) were added 0.1 M solution of triethylamine in dioxane (0.5 ml, 50 μmol) and Boc azide (10 μl, 74 μmol). While the mixture was allowed to stand at room temperature for 50 h, Boc azide (74 μmol×2) and triethylamine (20 μmol) were again added. After evaporation of the solvent, the residue was dissolved in water (1 ml) and washed with ether. After complete removal of water by coevaporation with ethanol and $CHCl_3$, dry HCl (4.8 μM) in THF (0.12 ml) and HONSu (1.15 mg, 10 μmol) in THF (0.1 ml) were added to the residue. To this mixture was added DCC (2.1 mg, 10 μmol) in THF (0.1 ml) under cooling in an ice bath. Thereafter, the mixture was treated in the same manner as described above for the cold material. Thus, the active ester (**4a**) was coupled with **5** HCl salt (2.4 mg, 10 μmol) in $CHCl_3$ in the presence of triethylamine and the resulting protected dipeptide (**6a**) was

treated with TFA (1 ml). After *N,N'*-dicyclohexylurea had been removed by filtration, the filtrate was condensed to give the free dipeptide (**2a**), which was again dissolved in water (0.3 ml). To this solution were added 4,6-*O*-*p*-anisylidene-*N*-acetylmuramic acid HONb ester (**12**) (3.6 mg, 6.3 μmol) in dioxane (0.3 ml) and triethylamine (60 μmol). During next 26 h, two portions of **12** (6.1 and 3.2 μmol) were added and the final mixture was left to stand overnight. The solvent was then removed by evaporation, and the residue was treated with 66 % aqueous acetic acid (1 ml) for 6 h. After evaporation, the residue was dissolved in water (1 ml), washed with ether and again evaporated. The residue was dissolved in methanol and subjected to preparative TLC as described for the preparation of cold **1** using one 20×20 cm plate. The location of the radioactive substance on the plate was detected with a Geiger-Müller counter and the corresponding band was extracted with 80% ethanol to give chromatographically pure **1a**; total activity 0.45 mCi (overall 46 %).

Furanoeremophilan-14β,6α-olide. A New Furanosesquiterpene Lactone of an Eremophilane-type from *Ligularia Hodgsoni* Hook, f.[1]

Yoshiaki Ishizaki, Yoshiaki Tanahashi, Takahiko Tsuyuki,
Takeyoshi Takahashi,* and Kazuo Tori**

Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
***Shionogi Research Laboratory, Shionogi & Co., Ltd., Fukushima-ku, Osaka 553*

(Received October 21, 1978)

A new sesquiterpene lactone of an eremophilane-type was isolated from *Ligularia Hodgsoni* Hook, f., and the structure including the absolute stereochemistry was shown to be furanoeremophilan-14β,6α-olide.

In connection with chemical investigations[2] on plants of the genus *Ligularia* (Compositae), we examined sesquiterpene constituents of *Ligularia Hodgsoni* Hook, f. (Japanese name: Tōgebuki), and isolated a new sesquiterpene lactone together with furanoeremophilane,[3,4] bakkenolide-A[5] (fukinanolide[6]) and eremophilenolide.[4,7] This paper describes the structure determination leading to furanoeremophilan-14β,6α-olide (**1**) for this new sesquiterpene lactone.

A benzene extract of dried roots of the plant was further treated with petroleum ether and the petroleum ether-soluble fraction was subjected to purification by sublimation and recrystallization to afford a furanolactone (**1**) (pink color to the Ehrlich test) as crystals, mp 136—138 °C. Elemental analysis and the mass spectrum indicate the formula $C_{15}H_{18}O_3$. The IR, UV, and ^1H NMR spectra showed the presence of a tertiary methyl, an olefinic methyl, a γ-lactone, and a β-methyl-substituted furan moiety with an α-proton.[8] Signals due to a secondary methyl was absent (*cf.* Table 1 and Experimental).

The lactone (**1**), on reduction with lithium aluminium hydride, gave a diol (**2**), which was readily converted into an ether (**3**) by treatment with *p*-toluenesulfonyl chloride in pyridine. The ^1H NMR spectrum of **3** showed signals due to the AB part of an ABX spin system; this implies the presence of methylene protons in the α-position and of a methine proton in the β-position to the ether oxygen atom. The presence of a tertiary methyl and a proton on a carbon atom bearing the ether oxygen atom was also shown in the NMR spectrum (Table 1).

The carbon skeleton and the absolute configuration of the lactone (**1**) were shown by the following transformation. The lactone (**1**) was subjected to hydrogenolysis in the presence of 10% palladium-charcoal in ethanol to afford a carboxylic acid (**4**). The presence of the carboxyl group and the absence of the hydroxyl group in **4** were suggested by the IR spectrum and the formation of an ester. Reduction of the carboxylic acid

(**4**) with lithium aluminium hydride gave an alcohol (**5**), which was subsequently converted into a tosylate (**6**). The tosylate (**6**) was treated with lithium aluminium hydride to furnish the known furanoeremophilane (**7**).[3,9]

Since the basic skeleton of the lactone (**1**) was shown to consist of furanoeremophilane, the structure, furanoeremophilan-14β,6ξ-olide, is suggested for this lactone on the basis of the spectral data, showing the absence of the secondary methyl and the presence of the γ-lactone. The structure **3** for the ether is compatible with the spectral data. However, the configuration of the carbon atom in the 6-position bearing the ether-type oxygen atom in the lactone moiety was still obscure. The configuration at C-6 and the stereostructure could be established by the NMR measurement using spin-decoupling experiments and intramolecular nuclear Overhauser effect (NOE) measurements.[10] The result on **1** is shown in Tables 1 and 2. The fact that 6-H is only coupled weakly ($^5J<2$ Hz) to the allylic 9α- and 9β-protons, suggests that the 6-H is adjacent to the furan ring and that the other neighbor, C-5, bears no proton. On saturation of the signals due to the tertiary methyl at C-5β and the β-methyl on the furan ring, the signal due to the 6-H showed increases by 28 and 6% in area, respectively. These observations imply that the 6-H is situated *cis* to the tertiary methyl, indicating 6β-H orientation, and is attached to the other β-position on the furan ring. On triple irradiation at the resonance frequencies of 6-H and 12-H in acetone-d_6, the signals due to 9α-H and 9β-H exhibited the AB part of an ABX spin system, which gave $^2J_{9\alpha,9\beta}=-17.3$, $^3J_{9\alpha,10}=11.3$, and $^3J_{9\beta,10}=5.9$ Hz. Therefore, one of the methylene protons on C-9 was shown to be in *trans* or eclipsed conformation with respect to 10β-H. Triple irradiation on 12-H and 11-methyl signals determined two homoallylic coupling constants, $^5J_{6,9\alpha}=1.8$ and $^5J_{6,9\beta}=1.2$ Hz.[11] These two large ^5J values indicate that the 6-H has a quasi-axial conformation.

Interpretation of the NMR spectrum of **3**, as shown in Table 1, is in full accord with that of the data on the lactone (**1**). This means that no stereochemical change occurred during the transformation of **1** to **3**. The β-configuration of C-14 methylene was supported by the following NOE measurement. On saturation of the signal due to the 5β-methyl by double irradiation, the signal due to one of the methylene protons, 14β-H, at δ 3.53 ($^3J_{4,14\beta}=11.3$ and $^2J_{14\alpha,14\beta}=-7.4$ Hz) showed a substantial increase in area, while 14α-H signal at δ 3.91 ($^3J_{4,14\alpha}=7.3$ and $^2J_{14\alpha,14\beta}=-7.4$ Hz) caused no increase in area (Table 2).

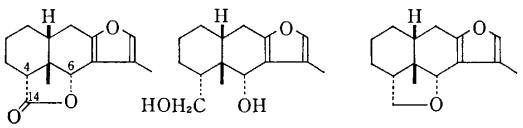
Table 2. Nuclear overhauser effects
(±2%, in $CDCl_3$)

Observed proton	Saturated proton	1	3	8	10
12-H	11-Methyl	22	17	22	16
6β-H	11-Methyl	6	7	4	6
6β-H	5-Methyl	28	23	20	16
14β-H	5-Methyl	—	8	—	8
14α-H	5-Methyl	—	−2	—	0
9β-H	5-Methyl	a)	a)	a)	0
4-H	5-Methyl	b)	b)	≈15	b)

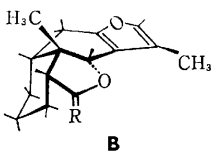
a) Not measured. b) Unobservable.

It is concluded that the structure including the absolute configuration of the new lactone (**1**) should be formulated as furanoeremophilan-14β,6α-olide and the stereostructure could be depicted as shown in **A**.

During the purification of the lactone (**1**), it was shown that the lactone (**1**) isomerizes easily into franoeremophilan-14α,6α-olide (**8**) on treatment with a base. The lactone (**1**) in benzene was kept contacting with basic alumina for 6 h and eluted with benzene. The eluent was examined by GLC and was shown to be a mixture of **1** and **8** in a ratio of 1 : 5. Prolonged contact with alumina resulted in a preferential isomerization into **8** accompanying concomitant hydrolysis of the lactones. Repetition of fractional recrystallization of the isomeric mixture of **1** and **8** gave pure furanoeremophilan-14α,6α-olide (**8**). The isomerized lactone (**8**) showed similar spectral features (Table 1) to those of **1**, and gave an ether (**10**) by the same treatment as in the case of **1**. Reduction of **8** with lithium aluminium hydride gave



8 9 10



B

8 R = O
10 R = H₂

a diol (**9**; not identical with **2**), which, on dehydration with *p*-toluenesulfonyl chloride in pyridine, afforded the ether (**10**; not identical with **3**). From these observations, the isomerized lactone (**8**) was inferred to be a 4-epimer of **1**.

Proton magnetic double and triple resonance experiments gave the information on the stereochemistry of **8** and **10**. On triple irradiation at the resonance frequencies of 6-H and 12-H in **8**, the signals of 9α-H and 9β-H exhibited the AB part of an ABX spin system, which gave coupling constants, $^2J_{9\alpha,9\beta}=-17.1$, $^3J_{9\alpha,10}=1.7$, and $^3J_{9\beta,10}=6.3$ Hz. Irradiation on 12-H revealed the presence of the two homoallylic coupling constants, $^5J_{6,9\alpha}\leq 0.3$ and $^5J_{6,9\beta}=1.5$ Hz, between 6-H and the methylene protons on C-9. On triple irradiation at the resonance frequencies of 6-H and 11-methyl, the signal due to 12-H showed a quartet as the X part of an ABX spin system. This observation indicates the presence of a long-range coupling between 12-H and the methylene protons on C-9 ($^5J_{9\alpha,12}\leq 0.5$ and $^5J_{9\beta,12}=0.9$ Hz). On saturation of the signal due to the 5-methyl group by double irradiation, a triplet signal at δ 2.67 caused an increase in area (Table 2), indicating that the triplet could be assignable to 4β-H and, therefore, the lactone carbonyl grouping in **8** is oriented in the α-configuration.

The fact that the NMR spectrum of the ether (**10**) is similar to that of the epimerized lactone (**8**) indicates that there is no apparent conformational difference between **10** and **8**. In comparison of the NMR spectra of **1** and **3** with those of **8** and **10**, the following differences are seen: 1) the $^3J_{9\alpha,10}$ values of **8** and **10** (1.7 and 1.9, respectively) are small compared with those of **1** and **3** (11.3 and 11.5 Hz, respectively); 2) the $^3J_{4,14\beta}$ value of **3** (11.3) is larger than that of **10** (3.6 Hz); and 3) in the spectrum of **10**, the 6-H signal is shifted to a higher field by −0.46 ppm in $CDCl_3$ than that of **3**. The NOEs observed for **8** and **10** are quite similar to those observed for **1** and **3**, respectively, except for the data of 4-H (Table 2). From these observations, conformation **B** can be suggested to be the most popular in solution for furanoeremophilan-14α,6α-olide (**8**) and the ether (**10**).

Experimental

General Procedures. All melting points were measured on a hot block, unless otherwise stated, and reported uncorrected. IR spectra were taken on a Hitachi EPI-G2 spectrometer. UV absorption spectra were determined in a methanol solution on a Hitachi EPS-3 spectrometer. ORD curves were measured on a JASCO Model ORD/UV-5 spectrometer. Measurements of optical rotation were carried out using a JASCO-SL polarimeter. ^{1}H NMR spectra were taken on a JNM-3H-60, a JNM-4H-100 spectrometer (JEOL), or a Varian HA-100 spectrometer in the internal TMS-locked mode. Proton magnetic double and triple resonance experiments were performed using the Varian HA-100 spectrometer with two Hewlett-Packerd HP-200 ABR audio-oscillators and an HP-5212A electronic counter. NOEs were measured by % increases in integrated signal intensities with necessary caution.[10] Chemical shifts are expressed in δ (ppm downfield from internal TMS) and coupling constants in Hz. Accuracies are *ca.* ±0.02 ppm for δ and ±0.2 Hz for *J* values. Mass spectra were measured on a Hitachi RMU-6-Tokugata mass spectrometer at 70 eV with a direct inlet system, unless otherwise stated.

GLC analyses were carried out using a Shimadzu GC-4APF equipped with a hydrogen flame ionization detector (column: Diasolid H-523 (2 m), temp 230 °C). Column chromatography was carried out on silica gel (Wakogel C-200) or on activated alumina (Showa Chemicals). Kieselgel G (E. Merck) was used for analytical (in 0.25 mm thickness) and preparative (in 0.5 mm thickness) TLC.

Isolation. Dried roots (1.7 kg) of *Ligularia Hodgsoni* Hook, f. were extracted with benzene (2.5 l) for 4 days. The extraction under the same conditions was repeated three times and the extracts were combined and concentrated to give a dark brown tar (54 g). The residue was dissolved in petroleum ether with warming and insoluble materials were removed by decantation. The organic layer, on evaporation, gave a residue (46 g), which was sublimed under reduced pressure. Recrystallization of the sublimate (11 g), which was obtained at 100—120 °C (bath temperature), from ethyl acetate afforded furanoeremophilan-14β,6α-olide (**1**; *ca.* 10 g) as white needles, mp 136—138 °C (in a sealed tube); $[\alpha]_D$ −45° (*c* 0.45, dioxane); UV λ_{max} 217 nm (ε 8500); IR (Nujol) 3140, 3090, 1767, 1634, 1564, and 1082 cm^{-1}; NMR (Table 1); MS *m/e* (%) 246 (M^+; 41), 202 (100), 187 (72), 173 (36), 159 (88), 145 (85), 131 (20), 115 (22), 95 (48), 91 (44), 79 (25), 77 (35), 67 (23), 65 (21), and 43 (15); ORD (*c* 0.45, dioxane) $[\alpha]^{20}$ (at λ nm) −38° (650), −58° (500), −67° (400), −15° (330), +45° (310), +336° (280), +1000° (260), +4980° (238), +5040° (234), and +4540° (228); Found: C, 73.10; H, 7.35 %. Calcd for $C_{15}H_{18}O_3$: C, 73.14; H, 7.37 %.

The materials sublimed below 100 °C and the mother liquor of the recrystallization were combined (total weight: 11 g) and chromatographed over silica gel (400 g). Elution with petroleum ether gave furanoeremophilane (*ca.* 50 mg).[3,4] Further elution with petroleum ether–benzene (100: 3) provided bakkenolide-A (690 mg),[5,6] additional furanoeremophilan-14β,6α-olide (**1**; 2.9 g), and eremophilenolide (10 mg, after purification by sublimation).[4,7]

Reduction of Furanoeremophilan-14β,6α-olide (1) with Lithium Aluminium Hydride. A mixture of **1** (500 mg) and lithium aluminium hydride (700 mg) in dry ether was heated under reflux for 2 h. Usual treatment and crystallization from ether gave a diol (**2**; 400 mg) as a white powder, mp 197—198 °C; UV λ_{max} 224 nm (ε 7500); IR (Nujol) 3200, 1638, and 1552 cm^{-1}; ^{1}H NMR [$(CD_3)_2CO$] δ 1.16 (3H, s; *t*-Me), 1.97 (3H, d; –C=C–Me), 4.3 and 4.5 (2H, m; –CH–C<u>H</u>$_2$–OH), 4.68 (1H, br s; –C<u>H</u>–OH), 5.55 and 5.72 (each 1H, s; –OH), and 7.11 (1H, t; –C=C–H); Found: C, 71.72; H, 8.64%. Calcd for $C_{15}H_{22}O_3$: C, 71.97; H, 8.86%. The mass spectrum was the same as that of the ether (**3**).

Dehydration of the Diol (2). A mixture of diol (**2**; 200 mg) and *p*-toluenesulfonyl chloride (350 mg) in pyridine (3 ml) was allowed to stand at room temperature overnight. The reaction product was extracted with ether and the extract was evaporated to afford a yellow residue (200 mg), which was chromatographed over silica gel (6 g). Elution with benzene gave an ether (**3**; 110 mg) as white needles, mp 114—115 °C (from petroleum ether); $[\alpha]_D^{21}$ −65° (*c* 0.40, dioxane); UV λ_{max} 218 nm (ε 7000); IR (Nujol) 3140, 3100, 1640, 1567, and 1084 cm^{-1}; NMR (Table 1); MS *m/e* (%) 232 (M^+; 97), 217 (30), 202 (35), 187 (72), 173 (36), 159 (88), 145 (100), 119 (59), 95 (58), 91 (88), 79 (56), 77 (64), 67 (60), 65 (41), and 55 (40); ORD (*c* 0.40, dioxane) $[\alpha]_D^{21.5}$ (at λ nm) −55° (650), −90° (500), −128° (400), −145° (350), −108° (300), +325° (260), +800° (250), +2190°

(240), and +1630° (230); Found: C, 77.64; H, 8.75%. Calcd for $C_{15}H_{20}O_2$: C, 77.55; H, 8.68%.

Acetylation of the Diol (2). Acetic anhydride (0.2 ml) was added to a solution of diol (**2**; 77 mg) in pyridine (3 ml) and the reaction mixture was allowed to stand at room temperature overnight. Methanol (0.2 ml) was added to the mixture and the reaction product was extracted with ether. The ethereal extract was evaporated to afford a residue, which showed three spots on TLC. Only major product (38 mg) was isolated as a colorless oil by column chromatography on alumina (3 g). The structure was revealed to be a 14-acetoxy derivative of the diol (**2**) by the NMR spectrum. IR (neat) 3400, 1740, 1640, and 1560 cm^{-1}; NMR (C_6D_6) δ 0.85 (3H, s; *t*-Me), 2.07 (3H, d, J=1.2 Hz; -C=C-Me), 1.66 (3H, s; -CO-Me), 4.0 and 4.5 (dd, $J_{14\alpha,14\beta}=-11$, $J_{4,14\alpha}=7$, and $J_{4,14\beta}=4$ Hz; -CH-C<u>H</u>$_2$-O-), 4.22 (1H, br s; -C<u>H</u>-OH), and 7.05 (1H, br s; -C=C-H).

Hydrogenolysis of Furanoeremophilan-14β,6α-olide (1). A solution of furanoeremophilan-14β,6α-olide (**1**; 1.16 g) in ethanol (40 ml) was stirred under an atmospheric pressure of hydrogen in the presence of 10% palladium-charcoal (300 mg) at room temperature for 2 h. Usual work-up afforded a residue (1.2 g), which was sublimed under reduced pressure at 80—100 °C to give a crude carboxylic acid (**4**) as a white powder. The crude product was shown to contain unchanged starting material by TLC. Repetition of chromatography on silica gel furnished analytically pure carboxylic acid (**4**) as a colorless glass, UV λ_{max} 221 nm (ε 6800); IR (Nujol) 2900, 1710, 1650, and 1570 cm^{-1}; NMR ($CDCl_3$) δ 1.20 (3H, s; *t*-Me), 1.90 (3H, d, J=1.2 Hz; -C=C-Me), 7.08 (1H, br s; -C=C-H), and 7.37 (1H, s; -COOH); MS *m/e* (%) 248 (M^+; 38), 230 (3), 202 (3), 147 (36), 119 (9), 109 (24), 108 (100), 96 (13), 91 (14), 79 (17), 77 (15), 55 (22), and 43 (37); Found: C, 72.60; H, 7.90%. Calcd for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12%.

Methyl Ester of the Carboxylic Acid (4). Carboxylic acid (**4**; 115 mg) was treated with diazomethane in ether (2 ml). The ether solution was concentrated and subjected to separation by preparative TLC (developed with benzene–chloroform, 1: 1) to afford a methyl ester (60 mg) as a colorless oil, IR (neat) 1735, 1648, 1566, and 1150 cm^{-1}, no absorption band due to hydroxyl group was observed. NMR ($CDCl_3$) δ 1.02 (3H, s; *t*-Me), 1.92 (3H, d, J=1.2 Hz; -C=C-Me), 3.70 (3H, s; -COOMe), and 7.13 (1H, br s; -C=C-H); MS *m/e* (%) 262 (M^+; 26), 231 (3), 215 (4), 198 (6), 170 (12), 155 (25), 147 (37), 142 (35), 141 (100), 128 (19), 115 (25), 108 (70), 69 (20), 57 (40), 55 (34), and 43 (51).

Reduction of the Carboxylic Acid (4) with Lithium Aluminium Hydride. A mixture of carboxylic acid (**4**; 430 mg) and lithium aluminium hydride (600 mg) in ether (30 ml) was heated under reflux for 1 h. The reaction mixture was worked up in usual way and chromatographed on silica gel (15 g). Elution with benzene afforded an alcohol (**5**; 350 mg) as a colorless oil, UV λ_{max} 221 nm (ε 7600); IR (neat) 3350, 1642, and 1562 cm^{-1}; NMR ($CDCl_3$) δ 0.99 (3H, s; *t*-Me), 1.48 (1H, s; -OH), 1.92 (3H, d, J=1.1 Hz; -C=C-Me), 3.7 and 3.9 (dd, $J_{14\alpha,14\beta}=-11$, $J_{4,14\alpha}=5$, and $J_{4,14\beta}=8$ Hz; -CH-C<u>H</u>$_2$-O-), and 7.07 (1H, q; -C=C-H); MS *m/e* (%) 234 (M^+; 20), 218 (6), 138 (5), 122 (8), 109 (25), 108 (98), 74 (40), 59 (65), 45 (60), and 31 (100).

Furanoeremophilane (7) from the Alcohol (5). A mixture of the alcohol (**5**; 250 mg) and *p*-toluenesulfonyl chloride (300 mg) in pyridine (4 ml) was allowed to stand at room temperature overnight. After usual work-up, an orange crude oil (300 mg) was dissolved in benzene and subjected to separation by preparative TLC (developed with chloroform–ether, 5: 1) to afford a tosylate (**6**; 130 mg) as a yellow oil, IR (neat) 1647, 1568, 1600, 1188, and 1176 cm^{-1}.

The tosylate (**6**), above obtained, was reduced with lithium aluminium hydride (500 mg) in ether for 2 h. The reaction mixture was treated as usual and chromatographed on silica gel (4 g). Elution with petroleum ether provided furanoeremophilane (**7**; 53 mg) as a colorless oil, $[\alpha]_D^{23}$ −11° (*c* 0.42, $CHCl_3$); UV λ_{max} 221 nm (ε 7000); IR (neat) 1649, 1568, and 1094 cm^{-1}; NMR ($CDCl_3$) δ 0.95 (3H, s; *t*-Me), 0.99 (3H, d, J=7.0 Hz; *s*-Me), 1.99 (3H, d, J=1.1 Hz; -C=C-Me), and 7.13 (1H, q; -C=C-H); MS *m/e* (%) 218 (M^+; 40), 203 (3), 190 (3), 133 (6), 123 (13), 122 (72), 109 (68), 108 (100), 105 (10), 91 (16), 79 (24), 77 (17), 67 (12), 55 (15), and 53 (13); ORD (*c* 0.42, $CHCl_3$) $[\alpha]^{23}$ (at λ nm) −10° (650), −12° (500), −16° (450), −23° (400), and −32° (350); Found: C, 82.56; H, 10.31%. Calcd for $C_{15}H_{22}O$: C, 82.51; H, 10.16%.

Isomerization of Furanoeremophilan-14β,6α-olide (1) into Furanoeremophilan-14α,6α-olide (8). Furanoeremophilan-14β, 6α-olide (**1**; 900 mg) was dissolved in benzene and adsorbed on basic alumina (15 g) for 6 h. The fraction eluted with the same solvent was shown to be a mixture of furanoeremophilan-14β,6α-olide (**1**) and -14α,6α-olide (**8**) in a ratio of 1: 5 by GLC examination. Repetition of fractional crystallization from ether–petroleum ether afforded **8** (300 mg), mp 124—125 °C, $[\alpha]^{18}$ −147° (*c* 0.33, dioxane); UV λ_{max} 216 nm (ε 7900); IR (Nujol) 3140, 3090, 1759, 1640, 1566, and 1083 cm^{-1}; NMR (Table 1); MS *m/e* (%) 246 (M^+; 48), 202 (64), 187 (62), 173 (24), 159 (56), 145 (64), 124 (32), 115 (34), 95 (100), 77 (54), 67 (40), and 55 (34); ORD (*c* 0.33, dioxane) $[\alpha]^{18.5}$ (at λ nm) −120° (650), −209° (500), −345° (400), −495° (350), −690° (300), −810° (270), −675° (250), and −390° (242); Found: C, 73.08; H, 7.41%. Calcd for $C_{15}H_{18}O_3$: C, 73.14; H, 7.37%.

Reduction of Furanoeremophilan-14α,6α-olide (8) with Lithium Aluminium Hydride. A mixture of furanoeremophilan-14α, 6α-olide (**8**; 240 mg) and lithium aluminium hydride (500 mg) in ether (30 ml) was refluxed for 1 h and the reaction mixture was worked up as usual. The residue (240 mg) was crystallized from petroleum ether to give a diol (**9**; 180 mg) as white wooly crystals, mp 123.5—125 °C; UV λ_{max} 219 nm (ε 9000); IR (Nujol) 3320, 1646, and 1571 cm^{-1}; NMR (DMSO) δ 0.94 (3H, s; *t*-Me), 1.92 (3H, d, J=1.2 Hz; -C=C-Me), 2.3 and 2.8 (dd, $J_{9\alpha,9\beta}$=*ca.* −17, $J_{9\alpha,10}$=*ca.* 1.5, and $J_{9\beta,10}$=*ca.* 5.5 Hz; -C=C-C<u>H</u>$_2$-CH-), 3.78 (2H, m; -C<u>H</u>$_2$-OH), 4.31 (1H, d, J=5.4 Hz; -C<u>H</u>-OH), 4.66 (1H, d, J=5.4 Hz; -CH-O<u>H</u>), 4.85 (1H, t, J=4.8 Hz; -CH$_2$-O<u>H</u>), and 7.17 (1H, br. s; -C=C-H); MS *m/e* (%) (by a direct inlet) 250 (M^+; 6), 232 (4), 159 (3), 149 (5), 123 (100), 91 (4), 67 (7), and 57 (7); (by an indirect inlet) 232 (38), 202 (4), 187 (6), 159 (40), 145 (11), 124 (22), 109 (100), 91 (18), 81 (18), 79 (15), 77 (15), 67 (86), and 55 (32).

Dehydration of the Diol (9). A solution of the diol (**9**; 185 mg) and *p*-toluenesulfonyl chloride (350 mg) in pyridine (5 ml) was heated at 65—70 °C for 1.5 h. Benzene was added to the mixture and the solvents were evaporated under reduced pressure. The residue was dissolved in benzene and chromatographed on silica gel (10 g). 4-Epiether (**10**; 130 mg) was obtained by elution with benzene as a colorless oil, UV λ_{max} 218 nm (ε 6900); IR (neat) 3140, 3090, 1642, 1567, and 1082 cm^{-1}; NMR (Table 1); MS *m/e* (%) 232 (M^+; 100), 217 (7), 202 (5), 199 (16), 187 (7), 159 (40), 145 (8), 124 (13), 109 (40), 91 (6), 85 (19), 83 (29), 67 (16), and 57 (10).

Reaction of Coordinated Phosphines. V. Aryl and Alkyl Transfer from Tertiary Phosphine to Transition Metal[1)]

Kiyoshi KIKUKAWA, Toru YAMANE, Yoshihiro OHBE, Makoto TAKAGI, and Tsutomu MATSUDA*

Department of Organic Synthesis, Faculty of Engineering, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812

(Received October 24, 1978)

A carbon–phosphorus bond cleavage was observed in the reaction of $MCl_2(PR_3)_2$ (M=Ni, Co, or Pd, R=Ph, n-C_8H_{17}) with p-tolyllithium, p-tolylmagnesium halide, lithium aluminum hydride, or magnesium amalgam, and the reactivity was most pronounced with Ni followed by Co and Pd. Reaction of $NiCl_2(PPh_3)_2$ with p-tolyllithium gave biphenyl and 4-methylbiphenyl, along with 4,4′-dimethylbiphenyl. Phenyllithium was formed in the reaction mixture, and the recovered tertiary phosphine contained tri-p-tolylphosphine, di-p-tolylphenylphosphine, and p-tolyldiphenylphosphine as well as triphenylphosphine. 1-Octene was formed in the reaction of $NiCl_2\{P(n\text{-}C_8H_{17})_3\}_2$ with p-tolyllithium. Thermal decomposition of Ni(mesityl)$X(PEt_3)_2$ (X=mesityl or Br) and Co(mesityl)$_2(PPhEt_2)_2$ at 30 °C gave vinyl mesitylene.

Tertiary phosphine is a ligand frequently used in organotransition metal complexes due to its versatility in donor-acceptor properties, and its carbon–phosphorus bonds had been considered to be chemically stable under usual reaction conditions. However, the decomposition of triarylphosphines in which the aryl group transfers from phosphorus to transition metal has become recently known for reactions of palladium,[1,2-4)] nickel,[5-8)] osmium[9)] and other metal complexes.[10)] Low-valent metals are involved in most of them, but there is a case where divalent palladium is undoubtedly responsible for the activation of aryl–P bond.[1,2b,11)] Though a transition metal-assisted C–P bond fission still remains to be rather uncommon reaction in organotransition metal chemistry, it deserves serious attention, not only concerning the basic mechanism involved but also with regards to the scope of the practical occurrence of this type of reaction, since it may have some relevance to the process such as catalyst decay or induction of side reactions in certain catalytic processes. In the present study, a system in which aryl–P bond is cleaved and re-formed under the influence of low-valent Ni, Co, and Pd is described. Evidences are also collected for the alkyl–P bond cleavage facilitated by Ni, Co, and Pd complexes.

Results and Discussion

Reaction of Dichlorobis(triphenylphosphine)metal(II) with p-*Tolyllithium and* p-*Tolylmagnesium Bromide.* The reaction of tertiary phosphine-coordinated transition metal halides with organic derivatives of lithium, magnesium or sodium has been widely used in the synthesis of low-valent transition metal complexes, in which the tertiary phosphines remained on the metal without any chemical transformations in themselves. However, $NiCl_2(PPh_3)_2$ (**1**), $CoCl_2(PPh_3)_2$ (**2**), and $PdCl_2(PPh_3)_2$ (**3**) reacted with p-tolyllithium or p-

b) A considerable amount of PPh_2Ar was detected in all cases.

tolylmagnesium bromide at room temperature to give the organic products including biphenyl, 4-methylbiphenyl, tri-*p*-tolylphosphine, di-*p*-tolylphenylphosphine, and *p*-tolyldiphenylphosphine, indicating that the aryl–P bond was cleaved and reformed by the influence of transition metal. Typical results are summarized in Tables 1 and 2. Total yield of biaryls and the amount of phenyl group carried into biaryls are shown in Figs. 1 and 2, respectively. The yield of biaryls increased with the increase of molar ratio of *p*-tolyllithium to $MCl_2(PPh_3)_2$ for all of the three transition metals (Fig. 1). The amount of phenyl group transferred into biaryls increased excepting for Pd as the yield of biaryls increased (Fig. 2). Excess organolithium reagent decreased the amount of recovered tertiary phosphines markedly, only 1 to 2% of triarylphosphines being recovered when 8-fold *p*-tolyllithium over nickel complex was used.

The time course of the reaction was studied for nickel system by direct GLC analysis of the reaction mixture for biaryls. The analysis was also made after the mixture had been treated with excess acetone or iodine to determine the amount of aryllithium present. The results obtained in the reaction at room temperature indicated that most of the biaryls and phenyllithium

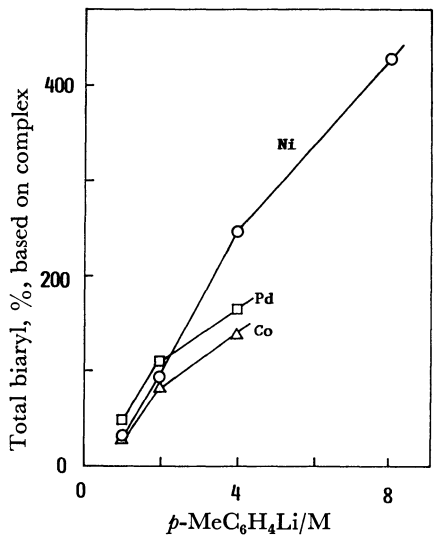

Fig. 1. Reaction of $MCl_2(PPh_3)_2$ with *p*-tolyllithium. Total yield of biaryls as a function of *p*-tolyllithium/M. Ordinate: (total mol of biaryls/mol of $MCl_2(PPh_3)_2$ employed) × 100. See Table 1 for conditions.

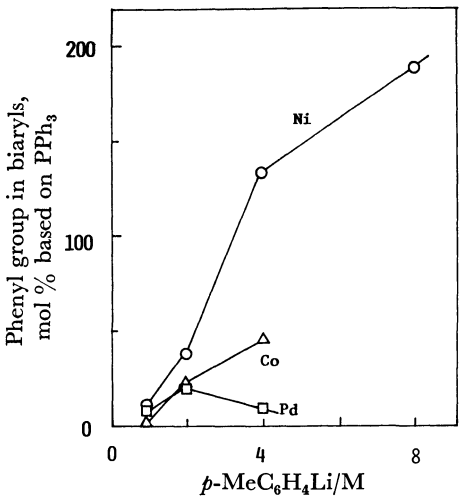

Fig. 2. Reaction of $MCl_2(PPh_3)_2$ with *p*-tolyllithium. Amount of phenyl group found in biaryls. Ordinate: (total mol of phenyl group found in biaryls/mol of PPh_3 employed as metal complex) × 100.

were formed within 10 min after the addition of the lithium reagent to the metal complex. A slow reaction then followed, and the mixture reached an apparent equilibrium after 10 h, which persisted at least for 5 days. The reaction is illustrated by:

$$\mathrm{NiCl_2(PPh_3)_2\ (\mathbf{1})} + 8\mathrm{ArLi} \xrightarrow{\text{ether, r.t., 10 h—4 days}}$$
$$1.0\mathrm{ArLi} + 0.5\mathrm{PhLi} + 0.8\mathrm{Ph\text{–}Ph} + 1.5\mathrm{Ph\text{–}Ar} + 1.9\mathrm{Ar\text{–}Ar} + 0.008\mathrm{PPh_3} + 0.008\mathrm{PPh_2Ar} + 0.004\mathrm{PPhAr_2} \quad (\mathrm{Ar}=p\text{-tolyl}) \qquad (1)$$

The relative yield of each biaryl varied from run to run, but the combined yield remained constant under specified reaction conditions. Similar study at Dry Ice–methanol temperature gave the result:

$$\underset{0.5}{\mathbf{1}} + \underset{4.0\ \mathrm{mmol}}{8\mathrm{ArLi}} \xrightarrow[-70\,^\circ\mathrm{C}]{\text{1) 55 min in ether}} \xrightarrow{\text{2) 5 ml of acetone}} \xrightarrow{\text{3) 16 h, room temp, then aq NH}_4\mathrm{Cl}}$$
$$\underset{0.0}{\mathrm{Ph(CH_3)_2OH}} + \underset{5.5}{\mathrm{ArC(CH_3)_2OH}} + \underset{0.024}{\mathrm{Ph\text{–}Ph}} + \underset{0.032}{\mathrm{Ph\text{–}Ar}} + \underset{1.0\ \mathrm{mmol}}{\mathrm{Ar\text{–}Ar}} \quad (\mathrm{Ar}=p\text{-tolyl}) \qquad (2)$$

GLC analysis of the reaction mixture for sample solutions extracted at earlier reaction stage gave the result illustrated in Fig. 3. The reaction mixture at −70 °C was a yellow-brown solution, and on raising the temperature it quickly darkened to give a blackish, turbid mixture. Since the extracted sample solutions were brought to high temperature during analysis, it was conceivable that the 100% yield of 4,4′-dimethylbiphenyl at 1.5 h reaction in Fig. 3 was an artifact from the thermal decomposition of $Ni(p\text{-tolyl})_2(PPh_3)_2$. It is obvious from Fig. 3 and Reaction 2 that aryl–P bond rearrangement takes place not at −70 °C but only at elevated temperatures around 0 °C or above. The presence of excess lithium reagent is important for this

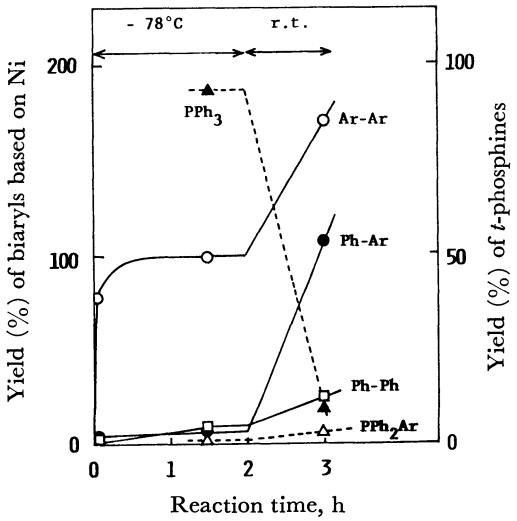

Fig. 3. Time course of the reaction of $NiCl_2(PPh_3)_2$ with *p*-tolyllithium.

process since the yield of biphenyl or 4-methylbiphenyl is low at a low ratio of *p*-tolyllithium to **1**.

Reaction of $MCl_2(PPh_3)_2$ with Magnesium Amalgam and $LiAlH_4$. Similar C–P bond cleavage was observed in the reaction of **1**, **2** and **3** with magnesium amalgam or $LiAlH_4$. The reaction with the amalgam took place in THF but not in ether. Typical results are summarized in Table 3, Ni and Co complexes being much active than Pd complex. A considerable decomposition of triphenylphosphine in the Reaction 1 seem ssomewhat contradictory to the report[12] that reduction of the corresponding bromide complex with sodium amalgam in acetonitrile produced bis(triphenylphosphine)nickel-(0). A difference in solvent combined with a longer reaction time would be responsible for this discrepancy.

Table 3. Reaction of $MCl_2(PPh_3)_2$ with $LiAlH_4$ or magnesium amalgam[a]

	Complex	Solvent	Reaction time/h	Product/% Ph–Ph	Benzene

	CCl_4	trace	2	95	—	trace

a) At 30 °C for 3 h. b) Balance was mostly the unreacted complex.

When *trans*-bis(triethylphosphine)mesitylnickel(II) bromide (**4**), *trans*-bis(triethylphosphine)dimesitylnickel-(II) (**5**), and *trans*-bis(diethylphenylphosphine)dimesitylcobalt(II) (**6**) was stirred in ether, benzene or carbon tetrachloride at 30 °C, 2,4,6-trimethylstyrene (**7**) was formed together with mesitylene (**8**), bimesityl (**9**), mesityl bromide (**10**) or mesityl chloride (**11**) (Table 4). The compound **7** presumably resulted *via* ethyl transfer from phosphorus to metal. Reaction of $NiCl_2\{P(n\text{-}C_8H_{17})_3\}_2$ with an 8-fold molar excess of *p*-tolyllithium gave 1-octene (5% on molar basis on the phosphine used) along with 4,4'-dimethylbiphenyl (≈100% on molar basis on the complex used).

Alkyl–P bond fission using Pd complex was not successful under the similar reductive conditions, but had been achieved under oxidative conditions. Thus, simply by heating the equimolar mixture of trialkylphosphine and $Pd(OAc)_2$ in acetic acid at 90 °C, a considerable amount of olefins and carbonyl compounds were formed.[1]

Mechanism. Though the present report concerns with factual description rather than discussion of mechanism operating in the current reactions, some idea on the mechanism is invoked in the following in order to help a correlation among the experimental facts. Typical C–P bond cleavage disclosed in this study is those of $MCl_2(PPh_3)_2$–*p*-tolyllithium system, and seems to be more complicated than that of PAr_3–$Pd(OAc)_2$ system previously reported.[1] The reaction of 1 mol of **1** with 2 mol of *p*-tolyllithium produced nearly stoichiometric amount (0.95 mol) of biaryls on the basis that the diarylnickel compound decomposes into biaryl and zero-valent nickel (Table 1). However, on increasing the ratio of *p*-tolyllithium/**1** more biaryl is formed, the amount exceeding 4 mol per mol of **1** when the ratio is 8, and the recovery of tertiary phosphines decreased concurrently. These observations combined with the results in Reactions 1 and 2 suggest that the Reaction 3 was effected under the catalysis of low (probably zero) valent nickel. The examination of the amount of

$$Ph_3P + ArLi \xrightarrow{Ni(0)} Ph_2PLi + Ar\text{–}Ph \qquad (3)$$

biaryl formed indicates that the resulting Ph_2PLi further reacted with excess ArLi, giving Ph–Ar and

presumably $PhPLi_2$. Direct evidence for the formation of Ph_2PLi or $PhPLi_2$ was not obtained because of its strong tendency to associate with nickel. It should be noted that the reaction like 3 does not proceed in the absence of Ni complex (Table 1, the last low).

It is conceivable that the catalysis of nickel in Reaction 3 resides in the oxidative addition of Ph–P bond to zero-valent Ni (Reaction 4). A further reaction of the resulting Ni complex with ArLi gives Ph_2PLi and ArPhNi, and the decomposition of the latter affords Ar–Ph with reproduction of zero-valent Ni (Reactions 5 and 6). The formation of the mixed tertiary phosphines suggests that the Reactions 4 and 5 are reversible, and phenyllithium may be produced *via* the Reaction 7.

$$Ph_3P + Ni \rightleftarrows Ph_2P\text{–}Ni\text{–}Ph \quad (4)$$

$$Ph_2P\text{–}Ni\text{–}Ph + ArLi \rightleftarrows Ph_2PLi + Ar\text{–}Ni\text{–}Ph \quad (5)$$

$$Ar\text{–}Ni\text{–}Ph \longrightarrow Ar\text{–}Ph + Ni \quad (6)$$

$$Ph_2P\text{–}Ni\text{–}Ph + ArLi \rightleftarrows Ph_2P\text{–}Ni\text{–}Ar + PhLi \quad (7)$$

The oxidative addition of Ar_2P–Ar bond to Ni(0) or Ni(I) has been claimed in the literature.[5,6] Coordinative unsaturation on the metal seems to be one of the essential factors for this type of reactions to take place. The complex $Ni(Ph_3P)_3$ is unstable in solution, and the structure containing Ph_2P–Ni bond has been suggested for the decomposition product.[13] With regard to the use of excess organolithium reagent in our study, a possible involvement of the ate-type complex of Ni(0)[14] may not be overlooked, but its importance in the C–P bond cleavage[7] is yet to be investigated.

Experimental

Materials. Bis(tertiary phosphine) complexes of transition metal dichlorides were prepared by conventional methods from the corresponding metal chlorides and phosphine ligands and characterized by elemental analysis as well as by ordinary spectroscopic methods. Diaryl transition metal complexes; **4**, **5** and **6**, were prepared from the corresponding dichloro complexes according to the literatures.[15,16]

Reaction of $MCl_2(PPh_3)_2$ with p-*Tolyllithium.* An ethereal 0.6—0.7 M organolithium solution was prepared by a conventional method from *p*-tolyl bromide and lithium. The solution was standardized by acid titration, and the amount of by-product (4,4′-dimethylbiphenyl) was determined by GLC with hexadecane as an internal standard. A calculated amount of the organolithium reagent was added under stirring to a suspension of $MCl_2(PPh_3)_2$ (1 mmol) in 10 ml ether containing hexadecane (internal standard). After stirred for several hours under dry nitrogen, the mixture was treated with aqueous ammonium chloride and excess potassium cyanide. The organic layer was worked up in a conventional manner and analyzed by GLC. Since some portion of tertiary phosphines had been converted into the oxides during the work-up, the product was reduced with trichlorosilane–triethylamine in benzene before the analysis for phosphines. Eicosane was employed as an internal standard. All the products were characterized either by direct comparison on GLC with authentic samples or by isolation from a large-scale run followed by a conventional spectroscopic study. By the addition of acetone or iodine to the reaction mixture, aryllithium were converted to 2-aryl-2-propanol or aryl iodides, respectively. They were analyzed by GLC after conventional work-up.

Other Reactions. Reaction of $MCl_2(PPh_3)_2$ with *p*-tolylmagnesium bromide was conducted in a similar manner as with *p*-tolyllithium. The reaction with magnesium amalgam (0.34 g of magnesium in 30 g of mercury) was carried out with 5 mmol of $MCl_2(PPh_3)_2$ in 100 ml of THF or ether. Benzene obtained from the reaction with $LiAlH_4$ was analyzed by GLC with toluene as an internal standard. The thermal decomposition of aryl transition metal complexes **4**, **5**, and **6** was conducted as described in the literature. The products from these reactions were characterized in a usual manner either by comparison with authentic samples or by isolation followed by instrumental study and elemental analysis.

Studies on Nucleosides and Nucleotides. VII.[1] Preparation of Pyrimidine Nucleoside 5′-Phosphates and N^3,5′-Purine Cyclonucleosides by Selective Activation of the 5′-Hydroxyl Group

Junji KIMURA, Yoshiyuki FUJISAWA, Toyokichi YOSHIZAWA, Kazuhiro FUKUDA, and Oyo MITSUNOBU*

Department of Chemistry, College of Science and Engineering, Aoyama Gakuin University, Chitosedai, Setagaya-ku, Tokyo 157

(Received November 6, 1978)

The reaction of thymidine or uridine with 1.5 molar equivalents each of dibenzyl hydrogenphosphate, diethyl azodicarboxylate, and triphenylphosphine in HMPT at room temperature for 1 day, followed by debenzylation, afforded dpT and pU in 73 and 78% yields, respectively. Neither nucleoside 3′-phosphate nor 3′,5′-diphosphate was formed. 5′-*O*-Benzoylthymidine 3′-(2-cyanoethyl)phosphate also reacted smoothly with thymidine at room temperature giving d-bzT3′p(CNEt)5′T in a 54% yield. Adenosine and Guanosine gave the corresponding N^3,5′-cyclonucleosides as main products, less than 1% pA and pG being formed.

In relation to biosynthesis and genetic control, there is a need for oligo- and polynucleotides of definite and specific sequences. For the synthesis of oligonucleotides, suitably protected nucleosides and/or nucleotides were condensed with each other to form 3′—5′ phosphodiester bonds.[2] While many organic dehydrating reagents have been developed so far, only a few are effective in nucleotides and oligonucleotides syntheses.[3] Since the condensation of nucleosides with phosphate esters and with nucleotides by these reagents involves initial activation of phosphate components, a side reaction occurs to produce pyrophosphate which in turn afford undesirable by-products.[4] In some cases, undesirable side reactions also take place under the conditions necessary for deprotection.[5] A procedure for selective phosphorylation of unprotected nucleosides would thus be desirable.

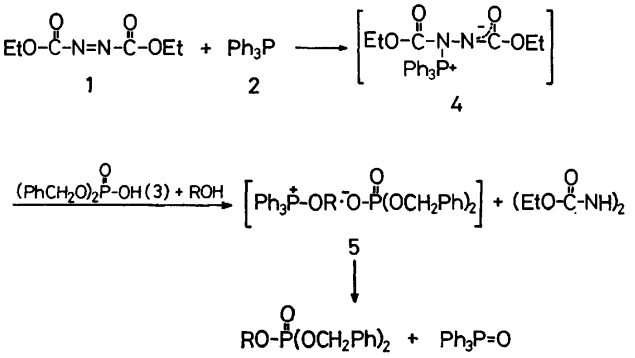
Recently, the triester method has been reported to have some advantages over the diester one.[2,6] Because of the lower reactivity of phosphate diesters as compared to phosphate monoesters, only arenesulfonyl chlorides and their derivatives can be utilized in the triester method. In the triester method, however, these reagents, except for arylsulfonyltetrazoles,[7] are slow in completing the condensation reactions.[8]

An alternative route for the preparation of nucleotides is also known in which nucleosides are converted into activated forms at the first stage of the reaction followed by the reaction with phosphate esters. In this case, pyrophosphate formation can, at least in principle, be avoided. Several attempts have been made to synthesize nucleotides by this procedure, the reaction conditions being so drastic as to cause side reactions such as 3′—2′ phosphoryl group migration.[9]

In this paper, we wish to report selective formation of pyrimidine nucleoside 5′-phosphates and cyclization of purine nucleosides by the use of diethyl azodicarboxylate (**1**) and triphenylphosphine (**2**). The reaction proceeds through initial activation of the 5′-hydroxyl group of nucleosides under mild conditions. At the outset of our work,[10] there was only one procedure available for predominant formation of 3′—5′ internucleotidic phosphate linkage from unprotected nucleosides and protected nucleotides.[11] The present method has been worked out on the basis of the following facts.

1) Because of the steric hindrance of three bulky aryl group, the reaction of triarylmethyl chlorides with nucleosides mainly gave 5′-*O*-triarylmethylnucleosides.[12]

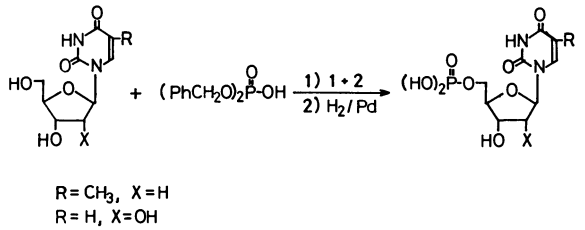
2) The reaction of an alcohol with dibenzyl hydrogenphosphate (**3**) in the presence of **1** and **2** at room temperature, followed by debenzylation, resulted in the formation of the corresponding alkyl dihydrogenphosphate in an excellent yield. It was assumed that the 1 : 1 adduct (**4**) of **1** and **2** initially formed was converted into an alkoxyphosphonium salt (**5**) which collapsed to the phosphate triester as shown in Scheme 1.[13]



Scheme 1.

When an unprotected nucleoside, instead of an alcohol, is used in this reaction, the nucleophilic attack of the 5′-hydroxyl group of the nucleoside on the sterically crowded phosphorus cation of **4** would be expected to be more favourable than that of 3′- and/or 2′-hydroxyl ones affording the corresponding nucleoside 5′-phosphate. In fact, the reagent formed by combination of **1** and **2** has been found to be effective for the condensation of 5′-hydroxyl group of unprotected thymidine and uridine with **3**.

Thymidine was allowed to react with 1.5 molar equivalents each of **1**, **2**, and **3** in tetrahydrofuran (THF) at room temperature for 1 day, the benzyl group being removed by hydrogenolysis. Examination of the resulting solution by paper chromatography revealed the presence of dpT (47%) and thymidine, with no

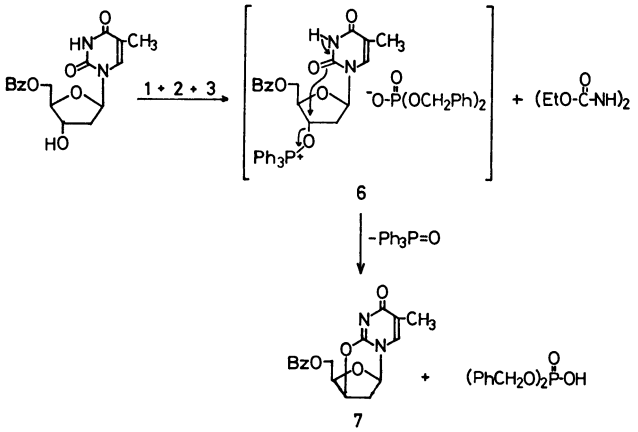


Scheme 2.

formation of dTp and dpTp.[14,15] When the reaction was carried out in dioxane (60 °C) and in hexamethylphosphoric triamide (HMPT; room temperature) for 1 day, followed by debenzylation, dpT was formed in 62 and 73% yields, respectively. Under the same conditions, uridine also reacted smoothly with **3** in dioxane (60 °C) and in HMPT (room temperature) to give pU in 68 and 78% yields, respectively. The analysis of the crude reaction solution obtained after debenzylation was performed by paper chromatography to indicate the absence of by-products derived from the nucleoside (Scheme 2). On the other hand, when thymidine was allowed to react with 3 molar equivalents each of **1**, **2**, and **3** in HMPT at room temperature, followed by hydrogenolysis, the formation of a small amount of a by-product was detected by paper chromatography. The by-product gave a similar UV absorption spectrum, as eluted from paper chromatogram, to that of thymidine, but with twice the electrophretic mobility of dpT at pH 3.2. The by-product was tentatively assigned to be dpTp or 1-(2-deoxy-3,5-bis-*O*-dihydroxyphosphinyl-β-D-xylofuranosyl)thymine. The reaction in pyridine made the solution turn dark, giving dpT in a 19% yield along with several by-products. This would be the result of nucleophilic attack of the solvent to phosphonium salts.[16] The by-products were not characterized.

In order to examine the reactivity of 3′-hydroxyl group of nucleosides, 5′-*O*-benzoylthymidine (dbzT) was allowed to react with **1**, **2**, and **3** in THF at room temperature, a white precipitate being separated from the solution as the reaction proceeded. The precipitate was found to be 5′-*O*-benzoyl-O^2,3′-cyclothymidine (**7**, 46%), 36% of dbzT being recovered.[17] This result indicates that the 3′-hydroxyl group of dbzT can also enter into the reaction to form the corresponding phosphonium salt (**6**), in which an intramolecular displacement leading to **7** takes place more readily than intermolecular phosphate attack on 3′-carbon atom (Scheme 3). The results are summarized in Table 1.

Contrary to the case of pyrimidine nucleosides, purine nucleosides were scarcely converted into 5′-phosphates, the main products being N^3,5′-cyclonucleo-



Scheme 3.

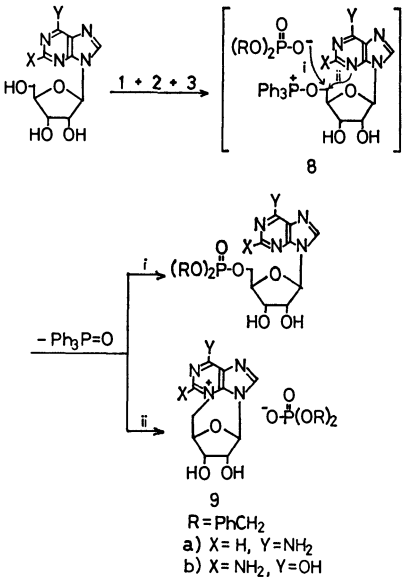
G	DMF	N^3,5′-Cycloguanosine	24	75

a) Unless otherwise stated, nucleoside was allowed to react with 1.5 molar equivalents each of **1**, **2**, and **3** at room temperature, the yields being determined by paper chromatography. b) The reaction was carried out at 60 °C. c) Three molar equivalents of **1**, **2**, and **3** were used; A by-product was formed in a small amount. d) Isolated yields.

sides (**9**). For example, the reaction of adenosine with **1**, **2**, and **3** in HMPT at room temperature resulted in the formation of pA and N^3,5′-cycloadenosine (**9a**) in 0.5 and 67% yields, respectively. The yield of **9a** increased to 86% when the reaction was carriet out in DMF.[18] Similarly guanosine afforded pG and N^3,5′-cycloguanosine (**9b**) in 0.2 and 49% yields. The results are summarized in Table 1.

The formation of **9** can be explained by assuming intermediacy of a quaternary phosphonium salt (**8**), cyclized by nucleophilic attack of the purine base to 5′-carbon atom (Scheme 4, path ii). The predominant formation of the purine cyclonucleoside would be attributed, at least in part, to electrostatic interaction between the phosphorus cation and purine base of **8** which brought the reaction site (5′-*C* and 3-*N*) so close together as to favor cyclization.[19]

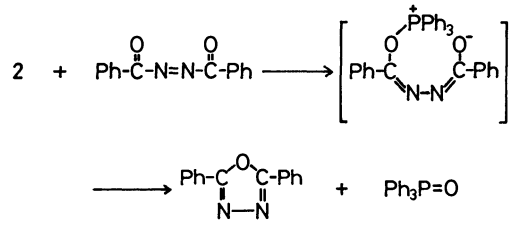


Scheme 4.

Since the intermolecular dehydration described above couples with an oxidation-reduction system,[20] the redox potentials of reagents are expected to play an important role. In order to find the best combination, uridine was allowed to react with **3** in the presence of **2** and various azo compounds for 3 h at room temperature. After hydrogenolysis, the yield of pU was determined by paper chromatography. The results are summarized in Table 2. We see that the combination of **1** and **2** affords the best result. When dibenzoyldiazene was used, 2,5-diphenyl-1,3,5-oxadiazole was isolated in a 50% yield. The formation of the oxadiazole could be explained in terms of the deoxygenation-cyclization process *via* *O*-phosphonium salt (**10**) as shown in Scheme 5.[21] The oxadiazole was also isolated by the reaction of dibenzoyldiazene with **2** in nearly quantitative yield.

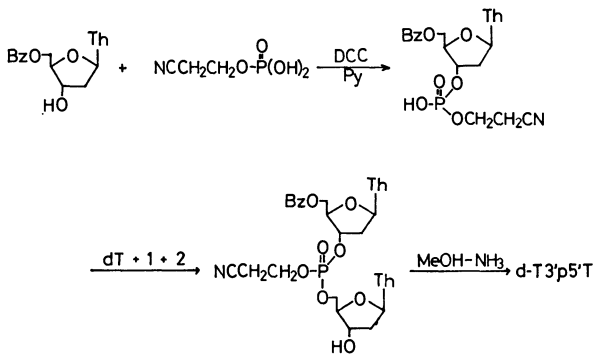
Table 2. Reaction of uridine with **3** in the presence of **2** and azo compounds

R–C(=O)–N=N–C(=O)–R	Yield of pU, %	Recovered U, %
EtO	60	27
Ph	3.5	90
	0	94



Scheme 5.

In order to cofirm that the present system is applicable to the formation of internucleosidic phosphate linkage, the reaction of 5′-*O*-benzoylthymidine 3′-(2-cyanoethyl)-phosphate [dbzTp(CNEt)] with thymidine was carried out. The dbzTp(CNEt) reacted smoothly with thymidine in the presence of **1** and **2** in HMPT at room temperature. After the solution had been kept stirring overnight, d-bzT3′p(CNEt)5′T was isolated in a 54% yield by column chromatography. Removal of the protecting groups afforded d-T3′p5′T which was completely degraded to dT and dpT by snake venom phosphodiesterase (Scheme 6).



Scheme 6.

The results indicate that the condensation reaction by the use of **1** and **2** proceeds through the initial activation of nucleosides. The system is effective in the selective formation of nucleoside 5′-phosphates and of 3′—5′ internucleotidic linkage by the triester method under mild neutral conditions with the following limitation. 1) Pyrimidine nucleosides selectively give the corresponding nucleoside 5′-phosphates, while purine nucleosides mainly affords N^3,5′-cyclonucleosides. 2) Phosphate diesters can also be activated giving pyrophosphates when hindered nucleosides are used.[22] 3) Since the selectivity originates from the difference in steric requirements between 5′- and 3′(or 2′)-hydroxyl groups, the 3′-hydroxyl group can also enter into the reaction giving nucleoside diphosphates and/or O^2,3′-pyrimidine cyclonucleosides. On hydrolysis, the latter compounds are converted into xylofuranosylnucleoside. 2′-Hydroxy groups would also undergo the same reaction affording O^2,2′-cyclonucleosides which are hydrolyzed to arabino epimers.[23] The use of excess condensing reagent should be avoided.

In spite of several limitations, the selective preparation of pyrimidinenucleoside 5'-phosphates by the use of **1** and **2** was successfully applied to the synthesis of d-T3'p5'T. In order to extend the nucleoside activation process, a method of preventing the intramolecular cyclization of nucleosides should be worked out.[24]

Experimental

Diethyl azodicarboxylate (**1**),[25] dibenzoyldiazene,[26] bis(morpholinocarbonyl)diazene,[27] dibenzyl hydrogenphosphate,[28] and 2-cyanoethyl dihydrogenphosphate[29] were prepared by the known procedure. Unless otherwise stated, the reaction was carried out at room temperature. Paper chromatography was performed by ascending technique using Toyoroshi No. 51A paper. Solvent systems: A, 1-propanol–2 M HCl=5: 1; B, 1-propanol–concd NH_3–H_2O=6: 3: 1; C, 1-butanol–acetic acid–H_2O=5: 2: 3; D, 2-propanol–concd NH_3–H_2O=7: 1: 2. The R_f values of different compounds are given in Table 3. Ultraviolet absorption spectra were obtained on a Hitachi EPS-3T recording spectrometer; the extinction coefficients used in calculating yields are given in Table 3. Tetrahydrofuran (THF) was distilled from Na; stored over Na and distilled from CaH_2 immediately before use. Hexamethylphosphoric triamide (HMPT) was distilled from CaH_2 immediately before use. Dioxane was distilled from Na and stored over Na. It is essential that moisture be excluded from all coupling reaction systems.

Preparation of Pyrimidinenucleoside 5'-Phosphates. A solution of **1** (261 mg, 1.5 mmol) in THF (1 ml) was added dropwise over a period of 1 h to a suspension of nucleoside (1 mmol), **2** (393 mg, 1.5 mmol) and **3** (417 mg, 1.5 mmol) in THF (1 ml).[30] The nucleoside dissolved on addition of **1**. After the solution had been kept stirring overnight, the solvent was removed under reduced pressure. The residue was dissolved in 75 % ethanol (20 ml) and subjected to hydrogenolysis over PdO (200 mg). After the theoretical amount of hydrogen had been absorbed, the catalyst was removed by filtration, the filtrate being made up to 50 ml. A measured volume of the solution was chromatographed for the determination of the amounts of nucleoside 5'-phosphate and the recovered nucleoside. The spots and appropriate blank areas of the paper were eluted after being cut into short pieces by soaking in standard volume of water for about 12 h, and their concentrations were determined spectrophotometrically.

When the reaction was carried out in dioxane, a solution of **1** was added over a period of 1 h to a suspension of nucleoside, **2**, and **3** in dioxane at 60 °C with stirring. Before the work-up, the mixture was held at 60 °C for 2 h and then kept stirring overnight at room temperature.

Thymidine and uridine (1 mmol) nearly completely dissolved in HMPT (1 ml). Triphenylphosphine oxide which separated was removed by filtration before hydrogenolysis. The results are summarized in Table 1.

Comparison of the Combination of Various Azo Compounds with Triphenylphosphine. A solution of azo compound (1.5 mmol) and **3** (1.5 mmol) in HMPT (2 ml) was added dropwise to a solution of uridine (1 mmol) and **2** (1.5 mmol) in HMPT (1 ml) over a period of 2 h at room temperature. After the solution had been kept stirring for 1 h, followed by hydrogenolysis, the yield of pU was determined by paperchromatography. 5 ml of HMPT was required to dissolve bis(morpholinocarbonyl)diazene. The results are summarized in Table 2.

Isolation of 2,5-Diphenyl-1,3,4-oxadiazole. Uridine (1 mmol) was allowed to react with 1.5 molar equivalents each of **2**, **3**, and dibenzoyldiazene. The mixture was poured into water (15 ml) with continuous shaking and left to stand overnight. The aqueous layer was removed by decantation, the residue being washed with water (10 ml). To the residue was added benzene and 4 % aqueous $NaHCO_3$ solution (5 ml), partitioned, and the aqueous phase was extracted with ethyl acetate. The combined extracts were dried, evaporated, and applied to silica gel plates (Merck PF_{254}, 20 cm×20 cm). 2,5-Diphenyl-1,3,4-oxadiazole was isolated by developing the plates with chloroform, 165 mg, 50%, mp 138 °C (ligroin). MS; *m/e* 222 (M^+), 166, 165. The oxadiazole was identified by comparison of its IR spectrum with a standard chart.

Reaction of Dibenzoyldiazene with Triphenylphosphine. A solution of dibenzoyldiazene (238 mg, 1 mmol) in THF (2 ml) was added dropwise to a solution of **2** (262 mg, 1 mmol) in THF (2 ml). After the reaction solution had been kept stirring for 6 h, the solution was chromatographed on silica gel plates (Merck PF_{254}, 20 cm×20 cm, $CHCl_3$) giving 2,5-diphenyl-1,3,4-oxadiazole (214 mg, 96%, mp 136—137.5 °C) and triphenylphosphine oxide (211 mg, 76 %).

Reaction of Purine Nucleosides with 1, 2, and 3. A solution of **1** (270 mg, 1.55 mmol) and **3** (417 mg, 1.5 mmol) in HMPT (1 ml) was added dropwise over a period of 1 h to a suspension

Table 3. R_f values and extinction coefficients used for the calculation of yields

	λ_{max}/nm (Solvent)	$\varepsilon \times 10^{-3}$	R_f value in system[a]			
			A	B	C	D
dT	267 (H_2O)	9.65				0.64

pG	256 (0.05 M HCl)	12.2		0.04		
N^3,5'-Cycloguanosine	250 (0.05 M HCl)	11.8				0.11

a) The solvent systems are; A, 1-propanol–2 M HCl=5: 1; B, 1-propanol–concd NH_3–H_2O= 6: 3: 1; C, 1-butanol–acetic acid–H_2O=5: 2: 3; D, 2-propanol–concd NH_3–H_2O=7: 1: 2.

of adenosine (267 mg, 1 mmol) and **2** (393 mg, 1.5 mmol) in HMPT (2 ml). A virtually clear solution was obtained. Precipitation took place shortly afterwards. After the mixture had been kept stirring overnight, triphenylphosphine oxide was removed by filtration and washed with small quantities of HMPT and water successively. The combined filtrate and washing were made up to 25 ml with ethanol and water (solution A). A measured volume was applied to Toyoroshi No. 51A paper which was developed in system C. Two bands corresponding to unchanged adenosine and N^3,5′-cycloadenosine were eluted with water and 0.05 M hydrochloric acid, respectively, and subjected to analysis. The yield of pA was also determined by paper chromatography after the solution A (20 ml) had been subjected to hydrogenolysis over Pd–C (300 mg).

When the reaction was carried out in DMF, no precipitation of triphenylphosphine oxide took place.

In a similar manner, the reactions of guanosine with **1**, **2**, and **3** were carried out in HMPT and in DMF and the yields of products were estimated by paper chromatography. The chromatograms were developed in system D for the estimation of N^3,5′-cycloguanosine and guanosine, and in system B for pG. Respective bands were eluted with 0.05 M HCl. When the reaction was carried out in HMPT, a virtually clear solution was obtained with the progress of reaction. On the other hand, guanosine was hardly soluble in DMF, the undissolved guanosine (65%) being filtered off before analysis.

The results are summarized in Table 1.

Preparation of dbzTp(CNEt). A mixture of 2-cyanoethyl dihydrogenphosphate (10 mmol) and dbzT (692 mg, 2 mmol)[31] was dried by repeated evaporation of added portion of pyridine, dissolved in pyridine (40 ml), and treated with dicyclohexylcarbodiimide (DCC, 30 mmol) for 2 days at room temperature. Water (40 ml) was added and, after allowing the mixture to stand at room temperature for several hours, *N,N′*-dicyclohexylurea was removed by filtration. The filtrate was extracted with petroleum ether (three 40 ml portion) in order to remove DCC. The residual aqueous pyridine solution was passed through a column of Dowex-50 (H^+) ion exchange resine and the column was washed with water. The total effluent was adjusted to pH 7.5 with 0.05 M $Ba(OH)_2$ at 0 °C. The solution was concentrated to *ca.* 5 ml (below 40 °C) and excess 2-cyanoethyl dihydrogenphosphate (barium salt) was removed by precipitation with three volume of ethanol and centrifugation. The supernatant layer was concentrated *in vacuo* (below 30 °C) giving a crystalline product. In order to remove barium ion, the product was applied to Dowex-50 (H^+) ion exchange resin column and effluent was lyophilized affording paper chromatographically homogenious dbzTp(CNEt); 680 mg, 71%, R_f (system C) 0.70.

Preparation of d-bzT3′p(CNEt)5′T. A solution of **1** (174 mg, 1 mmol) in HMPT (1.5 ml) was added dropwise over a period of 1 h to a solution of dbzTp(CNEt) (240 mg, 0.5 mmol), thymidine (242 mg, 1 mmol), and **2** (262 mg, 1 mmol) in HMPT (1.5 ml) at room temperature. After the solution had been kept stirring overnight, triphenylphosphine oxide precipitated was removed by filtration. Solids separated by addition of water (80 ml) to the filtrate. However, on centrifugation followed by removal of the supernatant liquid, the solids became gum which was taken up in THF (3 ml). On addition of ethyl acetate (20 ml), white solids precipitated. They were collected and purified by means of Sephadex LH-20 column (3×40 cm, eluted with THF), giving chromatographically homogenious d-bzT3′p(CNEt)5′T in a 54 % yield; softened at 137 °C, turning a clear melt at 150 °C; R_f (system C) 0.78.

The d-bzT3′p(CNEt)5′T thus obtained was treated with methanol saturated with NH_3 overnight at room temperature. The solution was applied to Toyoroshi No. 51A paper and developed in system C. The band with R_f 0.32 was eluted and the effluent was liophilized giving d-T3′p5′T, which was completely degraded to dT and dpT (1:1 ratio) by snake venom phosphodiesterase (tris buffer, pH 8.1 at 37 °C).

This work was supported financially by the Ministry of Education Japan.

Carbon-Carbon Bond Formation by Use of Chloroiodomethane as a C_1 Unit. I. Formation of Chloromethyltriphenylphosphonium Iodide, and Its Application for the Wittig Chloromethylenation of Aldehydes and Ketones[1)]

Sotaro MIYANO,* Yu IZUMI, Katsuo FUJII, Yutaka OHNO, and Harukichi HASHIMOTO
Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Aramaki-Aoba, Sendai 980
(Received September 12, 1978)

Chloromethyltriphenylphosphonium iodide has been prepared by the reaction of chloroiodomethane with triphenylphosphine. Upon treatment with potassium *t*-butoxide in *t*-butyl alcohol, the phosphonium iodide was converted into chloromethylenetriphenylphosphorane; this in turn was used for the Wittig reaction of aldehydes and ketones into the corresponding chloroolefins of the type RCH=CHCl and RR'C=CHCl in good to moderate yields. The configurations of these chloroolefins were assigned on the basis of NMR spectral studies. Direct conversion of benzaldehyde into phenylacetylene was also achieved using the phosphonium salt and excess potassium *t*-butoxide.

Chloroiodomethane can be easily obtained in large quantities from dichloromethane *via* a halogen exchange reaction with sodium iodide in dipolar aprotic media,[2,3)] or under phase-transfer conditions.[4)] It is useful as a methylene source for the cyclopropanation[5)] of olefins as well as for the methylenation[6)] of aldehydes *via* organozinc intermediates.

As is well recognized, the Wittig olefination reaction of carbonyl function is one of the most successful synthetic routes to a wide variety of unsaturated compounds. Chloroolefins are also accessible by the chloromethylenation of carbonyl compounds with chloromethylenetriphenylphosphorane (Ph_3P=CHCl, **2**).[7)] However, the requisite precursor chloromethyltriphenylphosphonium salts ($(Ph_3\overset{+}{P}CH_2Cl)\bar{X}$) have only been prepared by somewhat complicated procedures, such as those described by Seyferth *et al.*,[8)] by Wittig and Schlosser,[9)] and by Appel and Morbach.[10)] Chlorocarbene: CHCl generated from dichloromethane and butyllithium adds to triphenylphosphine to form the phosphorane (**2**),[8,11)] but it is said that troublesome isolation of the phosphorane from residual triphenylphosphine is necessary to obtain chloroolefins in good yields.[8b)] This problem can be avoided to some extent by use of (bromochloromethyl)phenylmercury as the carbene source; nevertheless, the yields are moderate.[12)]

During the course of our investigation on the carbon-carbon bond formation utilizing chloroiodomethane as a C_1 unit, we found that it smoothly reacts with triphenylphosphine to afford chloromethyltriphenylphosphonium iodide (**1**) as a white precipitate.[1)] We report here another convenient method for the conversion of aldehydes and ketones into chloroolefins using the phosphonium iodide (**1**) for the Wittig reaction.**

Results and Discussion

Formation of Chloromethyltriphenylphosphonium Iodide (1) from Chloroiodomethane and Triphenylphosphine. Table 1 shows the results of the reaction of chloroiodomethane and triphenylphosphine in several solvents. When the reaction was carried out in THF, **1** began to precipitate as white solids in the course of the initial 1/2 h heating at reflux. The phosphonium salt amounted to a 60% isolated yield after an 8 h reaction, and to a 70% yield after 20 h (Eq. 1):

Table 1. Preparation of chloromethyltriphenylphosphonium iodide (**1**)

Ph_3P (mmol)	CH_2ClI (mmol)	Solvent	(ml)	Temp (°C)	Time (h)	Yield of **1**[a)] (%)
10	12	Et_2O	20	20—25	20	8
10	11	THF	10	50	20	34
120	150	THF	150	67	8	60
120	150	THF	150	67	20	70
50	70	*t*-BuOH	50	83	6	72
100	110	DMF	120	100	8	0

a) Isolated yield based on Ph_3P.

$$CH_2ClI + Ph_3P \longrightarrow \underset{\mathbf{1}}{(Ph_3\overset{+}{P}CH_2Cl)\bar{I}} \quad (1)$$

This phosphonium salt showed an IR spectrum quite similar to that of chloromethyltriphenylphosphonium chloride over the range from 4000 to 625 cm^{-1}.[13)] It gave satisfactory elemental analysis data, and was converted into the known tetraphenylborate.[8,9)] In refluxing *t*-butyl alcohol, the reaction time was somewhat shortened, probably due to a higher reaction temperature, while the resulting precipitate had to be washed well with THF to remove residual triphenylphosphine. When a mixture of chloroiodomethane and triphenylphosphine in DMF was heated, it turned dark brown, but no precipitate was formed.

Chloromethylenation of Aldehydes and Ketones with Chloromethyltriphenylphosphonium Iodide (1) and Base. Tables 2 and 3 summarize the results of the chloromethylenation of several carbonyl compounds by the Wittig reaction. It can be seen that some aldehydes and ketones can be easily converted into the corresponding chloroolefins of the type RCH=CHCl and RR'C=CHCl in good to moderate yields by use of **1** and potassium *t*-butoxide in *t*-butyl alcohol (Scheme 1).

** After this work had been submitted for publication, the authors learned that fluoromethylenation with $(Ph_3\overset{+}{P}CH_2F)\bar{I}$ had been reported: D. J. Burton and P. E. Greenlimb, *J. Org. Chem.*, **40**, 2796 (1975).

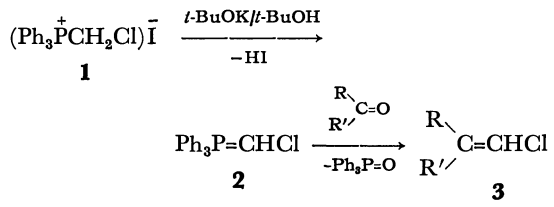
a) *t*-BuOH (50—70 ml) was used as solvent unless otherwise noted. RCHO,20 mmol; **1**, 25 mmol. In the case of benzaldehydes (**h**—**l**), the styrene ArCH=CH$_2$ was also detected in 3—5% yield. b) See footnotes b) and c) in Table 2. c) Solvent, EtOH, 50 ml. d) The *E*- and *Z*-isomer could not be sufficiently well separated from each other on GLC (but $E<Z$).

Upon addition of **1** to a potassium *t*-butoxide solution in *t*-butyl alcohol under nitrogen, the orange-red color characteristic of phosphinemethylene reagents developed. To this mixture was added *ca.* 0.8 molar equivalent amount of a carbonyl compound. For example, after 4 h stirring at ambient temperature, all of the cyclohexanone reacted to afford chloromethylenecyclohexane (**3a**) in as high as 94% yield. Small amounts of methylenecyclohexane was also formed a sa by-product, showing some reduction had occurred during the process. The exact nature of the reduction is not yet clear,[14] but the methylenation reaction was dependent



Scheme 1.

on the substrate carbonyl compounds as well as on the reaction medium; menthone and acetophenones gave relatively large amounts of methylenated products, and the EtONa/EtOH system seemed to suppress the reduction.

When the chloromethylenation was carried out in ethyl alcohol using sodium ethoxide as the base, the chloromethylenephosphorane (**2**) showed diminished reactivity. Thus, with this solvent-base combination, reactive substrates such as cyclohexanone and benzaldehyde gave chloroolefins in good yields, but almost all of the menthone was recovered unchanged. A solid-liquid two phase system[16] using 18-crown-6 as the phase-transfer catalyst and sodium carbonate powder as the base did not work well. Organolithium reagents have been used conventionally in the Wittig chloromethylenation reaction under rather severe reaction conditions.[8,9,11] In preliminary experiments, however, chloromethylenation of cyclohexanone with butyllithium was complicated by the occurrence of an alkylation reaction to pentylidenecyclohexane, and no further investigation was conducted.

The Wittig methylenation of cycloheptanone is reported to have resulted in poor yields,[17] but chloromethylenecycloheptane (**3b**) was obtained in a reasonable yield by use of about twice as much of the phosphorane (**2**).

NMR Spectral Studies of 1-Chloroolefins. In the reaction with aldehydes and unsymmetrical ketones, two geometric isomers of 1-chloroolefins were formed in roughly comparable yields, showing that the chloromethylenephosphorane (**2**) is one of the semistabilized ylids.[18] In a given pair of isomeric chloroolefins, the component which eluted first on GLC (Apiezon Grease L column) was assigned to the *Z*-configuration on the

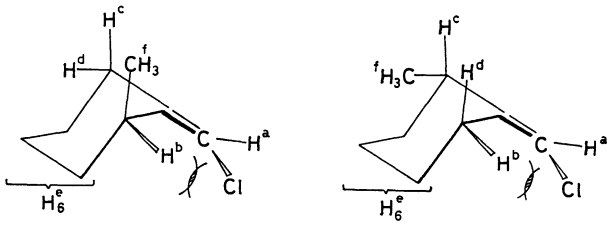
b) Rather sharp signal.

basis of NMR studies (Table 4). Chemical shifts of vinylic protons of these 1-chloroolefins were correlated well with the known empirical formula of Pascual, Meier, and Simons.[19] In the case of β-chlorostyrenes (**3e**—**3l**), in general, the proton which locates in the *geminal* position to the chlorine atom in the *E*-isomer resonanced at a lower magnetic field than that in the *Z*-isomer. The NMR spectra of (*E*)- and (*Z*)-chloromethylene-2-methylcyclohexane (**3c**) were assigned as summarized in Scheme 2:



Z-**3c** *E*-**3c**

Z-**3c**	*E*-**3c**
H_a: δ5.63 (d, J_{ac}=1.8 Hz)	H_a: δ5.62 (m, J_{ac}=1.5 Hz)
H_b: 2.9—3.4 (m)	H_b: 2.5—2.9 (m)
H_c+H_d: 1.9—2.4 (m)	H_c: 2.0—2.3 (m)

H_f: 1.05 (d, J_{bf}=7 Hz)	H_f: 1.02 (d, J_{cf}=7 Hz)

Scheme 2.

The PCK model shows considerable steric interaction between the Cl and the H_b atom. Thus, the methyl substituent attached to the C_2 atom of the *Z*-isomer seemed to be restrained to the axial position. The remarkable downfield shift of the H_b protons of each isomer can be explained by the steric compression effect (van der Waal's shift) and/or the anisotropic effect of the nearby Cl atom.[20,21] The H_a proton of the *E*-isomer showed a multiplet, but rather narrow signal; this was sharpened by irradiation of the H_c proton, showing a magnetic interaction between H_c and H_a. Similar allylic long-range couplings are documented.[22]

The vinylic protons of (*E*)-1-chloro-1-decene (*E*-**3m**) showed a somewhat confusing NMR spectrum. It can be characterized as shown in the last line of Table 4 on the assumption that each vinylic proton resonanced at almost the same magnetic field, reducing the apparent J_{trans} to zero.[23]

Conversion of Benzaldehyde into Phenylacetylene. From benzaldehydes, phenylacetylenes as well as β-chlorostyrenes were formed in the chloromethylenation reaction (Table 3). From the results of the reaction of benzaldehyde conducted in the presence of excess amounts of alkoxides and employing longer reaction periods, it is concluded that the phenylacetylene was formed *via* dehydrochlorination of the initially formed β-chlorostyrenes, the *Z*-isomer reacting much faster than the *E*-counterpart. The dehydrochlorination with sodium or potassium ethoxide in ethyl alcohol consumed only the *Z*-isomer under the reaction conditions, leaving the other chloride intact, while both were converted to phenylacetylene by refluxing with *t*-butoxide in *t*-butyl alcohol.[24] It is known that dehydrohalogenation from olefinic halides with alkoxides proceeds mainly through an E2 mechanism *via trans*-elimination, and in many instances the relative rate ratio of *Z*- to *E*-isomer ranges from 10^4 to 10^6.[25] On the other hand, Schlosser and Ladenberger reported that (*E*)-β-chlorostyrenes are more sensitive to phenyllithium than the corresponding *Z*-isomer, suggesting an E2cB mechanism for the dehydrochlorination.[26]

Irrespective of the precise mechanism involved, it is noteworthy that the formyl function of benzaldehydes can be converted into the acetylenic grouping in a one-pot reaction. Further studies are now in progress. Multistep formyl to ethynyl conversions have been reported by Villieras *et al.*[27] and by Corey and Fuchs.[28]

Experimental

The IR spectra were recorded on a Shimadzu IR 430 spectrometer. The NMR spectra were determined using a Hitachi R-24A spectrometer (60 MHz), with hexamethyldisiloxane as an internal standard. GLC analyses were carried out with a Shimadzu GC-3AF or a Shimadzu GC-3BT apparatus using a Silicone DC 550 (20%), an Apiezon Grease L (20%), or a Silicone DC 410 (20%) on Diasolid M (60—80 meshes) column. A Shimadzu GC-2C apparatus was used for the preparative GLC using an Apiezon Grease L column.

Materials. Chloroiodomethane was obtained by the procedure described before.[2] Commercial ketones and aldehydes except *p*-chlorobenzaldehyde, which was used as purchased, were dried over magnesium sulfate, and distilled at reduced pressure and stored under nitrogen. Triphenylphosphine (mp 80.5 °C), sodium tetraphenylborate, and 18-crown-6 were used without further purification. Solvents were purified as usual before use.

Preparation of Chloromethyltriphenylphosphonium Iodide (1). Triphenylphosphine (120 mmol) was dissolved in 150 ml of THF in a 500 ml round-bottomed flask equipped with a magnetic stirrer, a pressure-equilibrating dropping funnel, a thermometer, and a Widmer reflux condenser topped with a nitrogen inlet tube. The mixture was stirred rapidly while chloroiodomethane (150 mmol) was added. The flask was immersed in an oil bath and the mixture was heated at reflux for *ca.* 20 h. The resulting white precipitate was filtered, and

the solids were washed thoroughly with 5×50 ml of THF in a nitrogen atmosphere. The phosphonium salt was dried *in vacuo* at 50—60 °C for several hour; it was then stored in a Schlenk tube under nitrogen. The dried product weighed 37 g (70 % yield based on triphenylphosphine). Mp 185—187 °C (dec). Found: C, 51.58; H, 3.82 %. Calcd for $C_{19}H_{17}ClIP$: C, 52.02; H, 3.91 %. IR (KBr, cm^{-1}): 3030 (w), 2890 (m), 2850 (m), 2770 (w, sh), 1580 (m), 1480 (m), 1440 (s), 1350 (w), 1330 (w), 1250 (w), 1170 (m), 1125 (vs), 1005 (m), 940 (w), 920 (w), 880 (m), 820 (w), 770 (s), 750 (m), 740 (m), 730 (m), 705 (s), 545 (s), 530 (s), 505 (m), 506 (w, sh).

Chloromethyltriphenylphosphonium Tetraphenylborate. A sample of the phosphonium iodide (**1**) (1.0 mmol) was placed in 30 ml of water and stirred vigorously. To this suspension was added a solution of sodium tetraphenylborate (1.5 mmol) in 20 ml of 1:1 ethyl alcohol–water. Another 250 ml of ethyl alcohol was added, and then the mixture was stirred at reflux for 2 h. After filtration, the filtrate was kept overnight at −78 °C. The resulting white precipitate was collected, recrystalized from ethyl alcohol (150 ml)–ether (150 ml), washed several times with small portions of alcohol–ether, and dried *in vacuo*. Mp 190—193 °C (dec) (lit, mp 189—192 °C (dec),[8a] 222—223.8 °C[9]). Found: C, 81.85; H, 6.22; Cl, 4.90 %. Calcd for $C_{43}H_{37}BClP$: C, 81.85; H, 5.91; Cl, 5.62 %.

Generation of Chloromethylenetriphenylphosphorane (2) and the Wittig Chloromethylenation of Carbonyl Compounds. The general procedure is described below. Under a nitrogen atmosphere, *t*-butyl alcohol (25 ml) was placed in a 100 ml three-neck round-bottomed flask equipped with a magnetic stirrer, a thermometer, and a Widmer reflux condenser topped with a nitrogen inlet tube. Potassium (30 mg-atom) was added, and the mixture was heated at reflux for *ca.* 1 h to afford a potassium *t*-butoxide solution. The reaction flask was then immersed in a water bath. A powder dropping funnel[29] which contained 25 mmol of **1** was attached to the flask, and the **1** was dropped to the solution over 5 min. The funnel was washed with another 15 ml of *t*-butyl alcohol to bring the residual phosphonium salt into the reaction flask. The mixture was stirred for 1.5 h at ambient temperature; during this time it turned from white to an orange-red slurry. After the formation of **2** was completed, the powder dropping funnel was replaced with a pressure-equilibrating dropping funnel which contained a substrate carbonyl compound (20 mmol) in 10 ml of *t*-butyl alcohol. The carbonyl compound was added over 20 min, while retaining the reaction temperature below 25 °C. The mixture was stirred for another 3 h 40 min at ambient temperature (20—25 °C). At the end of the reaction, the mixture was shaken with 50 ml of pentane and 50 ml of water, filtered, and the layers were separated. The aqueous layer was extracted with 3×50 ml of pentane. The combined organic phase was washed with 3×30 ml of water, and dried over magnesium sulfate. An aliquot of the sample was used for the quantitative determination of the reaction products by GLC, employing experimentally determined calibration curves. After removal of the solvents by distillation *in vacuo*, the volatile products were collected in a cold trap, and subjected to a preparative GLC for the recovery of each component. Reaction products were identified and characterized by means of GLC, NMR (Tables 4 and 5), and IR spectrometry, and elemental analyses (Table 6).

Financial support of this work by a Grant-in-Aid (C-35536) from the Ministry of Education, Japan, is gratefully acknowledged (S. M.).

Synthesis of Some Naturally Occurring Acetylchromenes

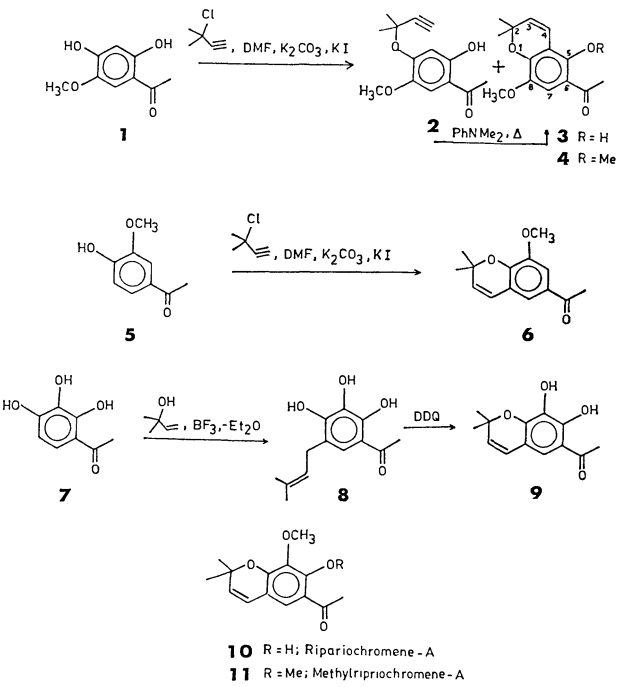
Amolak Chand JAIN,* Rajesh KHAZANCHI, and Ashwani KUMAR
Department of Chemistry, Himachal Pradesh University, Summer Hill, Simla 171005, India
(Received December 19, 1977)

2,4-Dihydroxy-5-methoxyacetophenone on treatment with 3-chloro-3-methyl-1-butyne in the presence of K_2CO_3, KI, and DMF yielded its 4-(1,1-dimethyl-2-propynyl) ether (**2**) and the naturally occurring 6-acetyl-5-hydroxy-8-methoxy-2,2-dimethylchromene (**3**). More of the chromene (**3**) could be obtained by the thermal cyclisation of the acetophenone (**2**). Methylation of **3** yielded another natural chromene. 4-Hydroxy-3-methoxyacetophenone, on similar treatment with 3-chloro-3-methyl-1-butyne, gave directly natural 6-acetyl-8-methoxy-2,2-dimethylchromene. 2,3,4-Trihydroxy-5-(3-methyl-2-butenyl)acetophenone, on cyclodehydrogenation followed by methylation with 1 mol of dimethyl sulfate, yielded natural riparіochromene-A. Further methylation provided methylriparіochromene-A.

From a Mexican plant *Ageratina scorodonioides* (Gray) King et Rob., Bohlmann *et al.*[1] isolated 6-acetyl-5-hydroxy-8-methoxy-2,2-dimethylchromene (**3**) and its methyl ether (**4**). The former was also reported to occur in *Flourensia cernua* D.C.[2] Obviously, both seem to be derived in nature from 2,4-dihydroxy-5-methoxyacetophenone (**1**). They are now synthesised from this ketone **1** by heating with 3-chloro-3-methyl-1-butyne in the presence of K_2CO_3, KI, and DMF, when a mixture of two compounds resulted. The major compound proved to be the required natural chromene **3** on the basis of its NMR spectrum and positive ferric chloride reaction. Thus, it showed a characteristic doublet of two olefinic protons at δ 5.50 and 6.70 and a singlet of only one aromatic proton at δ 7.05. Further it was found to be identical in all respects with the description of the natural sample. The minor component was characterised as 2-hydroxy-5-methoxy-4-(1,1-dimethyl-2-propynyloxy)acetophenone (**2**) on the basis of resonance signals of one acetylenic proton at δ 2.70 and of two *para*-coupled aromatic protons at δ 6.88 and 7.20. The yield of the natural chromene **3** was raised by heating **2** with *N,N*-dimethylaniline. When the chromene (**3**) was methylated with excess of dimethyl sulfate in the presence of ignited K_2CO_3 and acetone, the fully methylated chromene **4** identical with the natural sample was obtained.

From *A. scorodonioides*, Bohlmann *et al.*[1] isolated still another chromene to which they gave the constitution of 2,2-dimethyl-6-acetyl-8-methoxychromene (**6**) on the basis of its NMR spectrum. It is now prepared from 4-hydroxy-3-methoxyacetophenone (**5**) by heating it with 3-chloro-3-methyl-1-butyne in the presence of DMF, K_2CO_3, and KI, when the natural chromene (**6**) was straight away obtained identical in all respects with the description of the natural substance.

From *Eupatorium riparium* Regel., Anthonsen[3] isolated two chromenes called riparіochromene-A and methylriparіochromene-A. They were assigned structures as 6-acetyl-7-hydroxy-8-methoxy-2,2-dimethylchromene (**10**) and its methyl ether (**11**) respectively mainly on the basis of their NMR data. More recently, these two compounds have also been isolated from the above mentioned species of *Ageratina*.[1] Methylriparіochromene-A **11** has also been obtained from the dried leaves of *Stevia serrata* by Kohda *et al.*[4] who



concluded this structure from a study of nuclear Overhauser effect in its PMR spectrum and its ^{13}C NMR spectrum.

These two compounds **10** and **11** have now been synthesised starting from 2,3,4-trihydroxyacetophenone **1** which, on reacting with 2-methyl-3-buten-2-ol in the presence of BF_3-etherate according to the procedure of Bajwa *et al.*,[5] gave 2,3,4-trihydroxy-5-(3-methyl-2-butenylacetophenone (**8**) as the main product. Cyclodehydrogenation of **8** with DDQ afforded 6-acetyl-7,8-dihydroxy-2,2-dimethylchromene (**9**) in nearly quantitative yield. Its structure was established on the basis of its NMR spectrum which showed 2 doublets at δ 5.53 and 6.20 and an aromatic proton at δ 7.25. Partial methylation of **9** with dimethyl sulfate, K_2CO_3 and acetone yielded riparіochromene-A **10**, while complete methylation with excess of dimethyl sulfate afforded methylriparіochromene-A **11** both identical with the natural samples.

Experimental

All melting points are uncorrected. Unless otherwise stated, PMR spectra were determined on a BS 487 C spectrometer (80 MHz) with reference to tetramethylsilane as an

internal standard; the chemical shifts are expressed in δ values; light petroleum used had boiling range 60—80 °C; silica gel was used for column chromatography and silica gel-G for TLC; R_f values refer to TLC using one of the following solvent systems: (A) toluene–ethyl formate–formic acid (5:4:1); (B) benzene; (C) benzene–ethyl acetate (9:1); spraying of TLC plates was carried out with 10% aq H_2SO_4 and/or 1% alcoholic $FeCl_3$.

*Reaction of 2,4-Dihydroxy-5-methoxyacetophenone (**1**) with 3-Chloro-3-methyl-1-butyne.* A mixture of the ketone[6] (**1**, 0.5 g) 3-chloro-3-methyl-1-butyne (0.4 ml), ignited potassium carbonate (2.5 g), anhydrous potassium iodide (1 g) and *N,N*-dimethylformamide (40 ml) was heated at 80—85 °C for 40 h. The solvent was removed *in vacuo*, the residue treated with water (200 ml) and the whole mixture extracted with ether. The ether residue on column chromatography and successive elution with benzene–light petroleum (1:1) and benzene alone gave two fractions A and B.

Fraction-A crystallized from benzene-light petroleum mixture to afford *6-acetyl-5-hydroxy-8-methoxy-2,2-dimethylchromene* (**3**, 200 mg) as yellow needles, mp 87—88 °C (lit,[2] mp 88 °C); R_f 0.45 (solvent B), brown ferric reaction; PMR ($CDCl_3$): 1.48 (6H, s, $(CH_3)_2C\langle$), 2.46 (3H, s, $-COCH_3$), 3.74 (3H, s, $-OCH_3$), 5.50 (1H, d, J=10 Hz, H-3), 6.70 (1H, d, J=10 Hz, H-4), 7.05 (1H, s, H-7) and 12.55 (1H s, chelated OH); UV_{max} (MeOH): 255 nm (log ε 4.31), 320 (3.31), 3.40 (3.74). (Found: C, 68.0; H, 6.2%). These data agree with those of the natural substance.

Fraction-B gave *2-hydroxy-5-methoxy-4-(1,1-dimethyl-2-propenyloxy)acetophenone* (**2**) as a yellow oil (100 mg); R_f 0.4 (solvent B); green ferric reaction; PMR (CCl_4): 1.25; 1.41 (6H, 2s, $(CH_3)_2C\langle$), 2.50 (3H, s, $-COCH_3$), 2.70 (1H, s, $-C\equiv\underline{C}H$), 3.80 (3H, s, $O\underline{C}H_3$), 6.88 (1H, d, J=1.5 Hz, H-3) and 7.20 (1H, d, J=1.5 Hz, H-6); UV_{max} (MeOH): 281 nm (log ε 4.2), 302 (3.9). Found: C, 68.2; H, 6.8. Calcd for $C_{14}H_{16}O_4$: C, 67.7; H, 6.5%.

*6-Acetyl-5-hydroxy-8-methoxy-2,2-dimethylchromene (**3**).* The above acetophenone (**2**) (50 mg) was heated in *N,N*-dimethylaniline at 210—220 °C for 3 h. The mixture was cooled and treated with dil HCl (1:1, 20 ml). The resulting solid crystallized from benzene–light petroleum mixture to give **3** as yellow needles (40 mg), identical in mp and mmp with the sample prepared above.

*6-Acetyl-5,8-dimethoxy-2,2-dimethylchromene (**4**).* A solution of **3** (100 mg) in acetone (20 ml) was refluxed with dimethyl sulfate (0.06 ml) and ignited K_2CO_3 (400 mg) for 4 h. Acetone was evaporated and water added to the residue. The resulting solid crystallised from ether–light petroleum mixture to give **4** as yellow crystals, mp 62—63 °C (lit,[1] mp 63 °C); R_f 0.55 (solvent B); PMR (CCl_4): 1.48 (6H, s, $(CH_3)_2C\langle$), 2.50 (3H, s, $-COC\underline{H}_3$), 3.77 (6H, s, two $-OC\underline{H}_3$), 5.53 (1H, d, J=10 Hz, H-3) 6.48 (1H, d, J=10 Hz, H-4) and 7.22 (1H, s, H-7); UV_{max} (MeOH): 270 nm (log ε 3.2), 281 (3.1), 310 (3.9). (Found: C, 68.8; H, 7.21%). These data agree with those described for the natural sample.

*6-Acetyl-8-methoxy-2,2-dimethylychromene (**6**).* A mixture of 4-hydroxy-3-methoxyacetophenone[7] (**5**, 500 mg), 3-chloro-3-methyl-1-butyne (0.2 ml), K_2CO_3(2 g), KI (1 g), and DMF (20 ml) was heated on a steam bath for 45 h. The product gave **6** as a colourless oil (300 mg), R_f 0.6 (solvent C); PMR ($CDCl_3$): 1.48 (6H, s, $(CH_3)_2C\langle$), 2.57 (3H, s, $-COCH_3$), 3.90 (3H, s, $-OCH_3$), 5.55 (1H, d, J=10 Hz, H-3), 6.30 (1H, d, J=10 Hz, H-4) 7.25 (1H, d, J=2 Hz, H-7), and 7.50 (1H, d, J=2 Hz, H-5); UV_{max} (MeOH): 225 nm (log ε 3.31), 302 (3.90). These data are in accord with those of the natural substance.[1]

*6-Acetyl-7,8-dihydroxy-2,2-dimethylchromene (**9**).* To a solution of 2,3,4-trihydroxy-5-(3-methyl-2-butenyl) acetophenone[5] (**8**, 1 g) in dry benzene (50 ml) was added DDQ (1 g) and the resulting mixture refluxed for 15 min, when colorless hydroquinone separated out. It was filtered while hot and the filtrate after removal of the solvent left a viscous mass which was purified by column chromatography. Elution with benzene–light petroleum (1:1) gave **9** as a dense yellow oil (850 mg); R_f 0.83 (solvent A); dark brown ferric reaction; PMR ($CDCl_3$): 1.47 (6H, s, $(CH_3)_2C\langle$), 2.50 (3H, s, $-COCH_3$), 5.53 (1H, d, J=10 Hz, H-3), 6.20 (1H, d, J=10 Hz, H-4), 7.25 (1H, s, H-5) and 12.30 (1H, s, chelated OH); UV_{max} (MeOH); 230 nm(log ε 4.2), 246 (3.9) and 270 (3.1).

*Riparіochromene-A (**10**).* A solution of the above chromene (**9**, 130 mg) in dry acetone (20 ml) was refluxed with dimethyl sulfate (0.06 ml) and ignited K_2CO_3 for 3 h. The product crystallised from ethyl acetate–light petroleum mixture to give **10** as yellow crystals (100 mg), mp 88—89 °C (lit,[1] mp 88.5 °C); R_f 0.65 (solvent C); brown ferric chloride reaction; PMR ($CDCl_3$): 1.45 (6H, s, $(CH_3)_2C\langle$), 2.58 (3H, s, $COCH_3$), 3.83 (3H, s, $OC\underline{H}_3$), 5.55 (1H, d, J=10 Hz, H-3), 6.30 (1H, d, J=10 Hz, H-4), and 7.20 (1H, s, H-5); UV_{max} (MeOH); 242 nm (log ε 3.2), 292 (3.1). (Found: C, 68.0; H, 6.2%). These data agree with those described for the natural compound.[1]

*Methylriparіochromene-A (**11**).* An acetone solution of the chromene (**9**, 130 mg) was refluxed with dimethyl sulfate (0.15 ml) and ignited K_2CO_3 for 5 h. The product (**11**) was obtained as a light yellow oil (100 mg), R_f 0.75 (solvent A); PMR ($CDCl_3$): 1.45 (6H, s, $(CH_3)_2C\langle$), 2.48 (3H, s, $-COCH_3$), 3.75 (6H, s, two $-OC\underline{H}_3$), 5.55 (1H, d, J=10 Hz, H-3), 6.24 (1H, d, J=10 Hz, H-4) and 7.27 ppm (1H, s, H-5); UV_{max} (MeOH): 255 nm (log ε 3.6), 286 (3.2). (Found: C, 68.8; H, 7.4%). It agreed with the natural substance.[1]

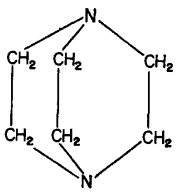
^{14}N Nuclear Quadrupole Relaxation Near the Plastic Transition Point in the Low-temperature Phase of 1,4-Diazabicyclo[2.2.2]octane

Hisao NEGITA,* Michio MAEKAWA, Tsuneo KUBO, and Tsutomu OKUDA
Department of Chemistry, Faculty of Science, Hiroshima University, Hiroshima 730
(Received June 5, 1978)

Synopsis. The relaxation mechanism near the plastic transition in the low-temperature phase of 1,4-diazabicyclo-[2.2.2]octane is attributed to the overall molecular tumbling. The activation energy is 23.0 kJ mol^{-1}, which is nearly equal to the value of 22.2 kJ mol^{-1} in the proton NMR in the plastic phase.

1,4-Diazabicyclo[2.2.2]octane (triethylenediamine), $(CH_2CH_2)_3N_2$, is known as a globular molecule. In the room-temperature phase, the crystal is hexagonal, with two molecule per unit cell.[1] At 351 K it is transformed into a plastic form. Smith[2] studied the proton NMR of 1,4-diazabicyclo[2.2.2]octane and made a few measurements of the spin-lattice relaxation time (T_1) between 77 and 160 K. Soda and Chihara[3] also studied the proton NMR of 1,4-diazabicyclo[2.2.2]-octane and measured the T_1 between 77 K and the melting point. There is no dip of T_1 on approaching the plastic transition point (T_t) from the low-temperature side. The ^{14}N NQR in 1,4-diazabicyclo[2.2.2]-octane was discovered by Haigh and Guibé.[4] Zussman and Alexander investigated this resonance from 77 K to the plastic transition and measured the spin-lattice relaxation time (T_1), the linewidth, and the resonance frequency.[5] According to them, T_1 decreases rapidly towards the plastic transition point, but the behavior near T_t has not been clarified in detail. Therefore, we have measured the T_1 near T_t in detail in order to examine the relaxation mechanism thoroughly.



Experimental

The ^{14}N NQR measurements were carried out using a pulsed spectrometer consisting of a Matec gating modulator, Model 5100, a R. F. gated amplifier, Model 515, and a tuned receiver, Model 615, which was designed by Petersen.[6,7] The spin-lattice relaxation times were determined by the repeating 90° pulse method.[8] The pulse width was about 50 μs. The free induction decay signal was averaged in a Nicolet Instrument, Model 527, signal averager. The rf coil containing the sample was enclosed in a cylindrical brass can. This can was placed inside a cylindrical copper container with insulating spacers. The heating wire was wound on this container and connected to a slide-contact voltage regulator. The container was immersed in a large Dewar vessel containing edible oil. The temperature was measured by the use of a copper-constantan thermocouple and stabilized within ±0.1 K.

1,4-Diazabicyclo[2.2.2]octane of an extra pure reagent grade was purchased from the Katayama Chemical Ind. Co. and was purified by sublimation in an evacuated vessel several times. About a 20-g portion of the reagent was used for the measurements.

Results and Discussion

The temperature dependence of the spin-lattice relaxation time (T_1) is shown in Fig. 1. T_1 falls just below the transition point (T_t). The NQR signal becomes progressively weaker as the temperature approaches T_t, and no signal is observed above T_t, presumably because of the "melting" of the molecular orientation, which averages out the electric-field gradients. The relaxation times in our sample are in good agreement with those of Zussman and Alexander throughout the temperature range studied.

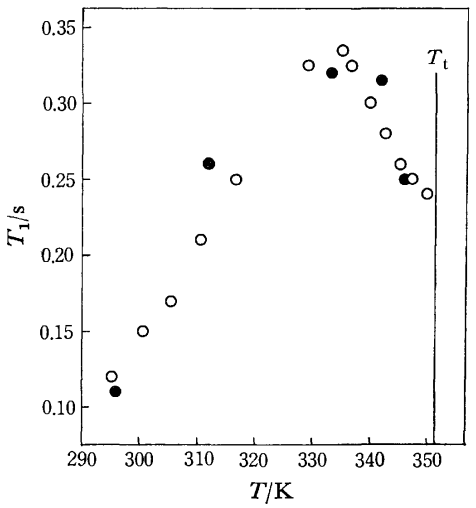


Fig. 1. Temperature dependence of the spin-lattice relaxation times near T_t. Zussman and Alexander's data are shown by the solid circles.

In the room-temperature phase, the N–N axis lies along the hexagonal c axis, and the restricted reorientation of the molecule about the N–N axis is accompanied by a small additional "wobbling" of the N–N axis. In the high-temperature phase above T_t, 351 K, a general molecular reorientation and self-diffusion occur.[2] According to Nimmo *et al.*,[9] molecules at each lattice site undergo hindered reorientations between eight equally weighted orientations at 354 K. It can be said that the "melting" of the molecular orientation or the

overall molecular tumbling occurs at T_t. According to the NMR results in the plastic phase reported by Soda and Chihara,[3] the relaxation mechanism is attributable to the overall molecular tumbling near T_t and to the self-diffusion near the melting point (T_m). As the transition temperature, T_t, is approached, this overall molecular tumbling occurs at an increasing rate, which reduces the T_1 of ^{14}N before it affects the T_1 of ^1H. A similar phenomenon has been found in the temperature dependence of the T_1 and $T_{1\rho}$ of the protons near T_t for $(CH_3)_3CCOOD$.[10] In this case, the relaxation formula is expressed as follows:[5,11]

$$1/T_1 = C\tau/(1+\omega_Q^2\tau^2) \quad (1)$$

and

$$\tau = \tau_0 \exp(E_a/RT), \quad (2)$$

where C is a constant which describes the strength of the interaction, ω_Q is the resonance angular frequency, τ is the correlation time of the motion which changes according to the Arrhenius' relation (2), τ_0 is the inverse frequency factor, and E_a is the activation energy of the motion.

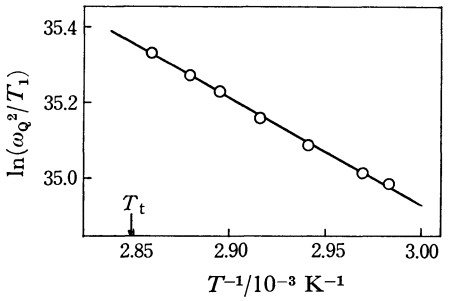

Fig. 2. $\ln(\omega_Q^2/T_1)$ *versus* $10^3/T$.

In the low-temperature region of the T_1 minimum, where $\omega_Q\tau \gg 1$, the following equation is obtained:

$$\ln(\omega_Q^2/T_1) = -E_a/RT + \ln(C/\tau_0) \quad (3)$$

In the plot of $\ln(\omega_Q^2/T_1)$ *versus* $1/T$, seen in Fig. 2, the slope of the straight line gives the activation energy, E_a. This was found to be 23.0 ± 2.3 kJ mol^{-1}. In the plastic phase, the activation energy of the overall molecular tumbling was found by the proton NMR to be 22.2 kJ mol^{-1}.[3] Accordingly, the reduction of T_1 of ^{14}N is attributed to the overall molecular tumbling.

An Approach to the Interpretation of the Mass Spectra of Aliphatic Acids

Hiroshi NAKASHIMA* and Katsunobu OKAMOTO

Laboratory of Chemistry, School of Paramedicine, Kanazawa University, Kanazawa 920

(Received August 7, 1978)

Synopsis. A method of comparing the sum of the total energies of fragment molecules has been applied to the interpretation of simple cleavage and rearrangement reactions in electron-impact mass spectrometry for the straight chain aliphatic acids.

The quasi-equilibrium theory has been successful in explaining the mass spectra of saturated hydrocarbons.[1] This theory is based on the hypothesis that the active molecular ion is first formed and the energy is distributed throughout the ion. The molecular ion subsequently decomposes when the ion is in the proper configuration and possesses a sufficient amount of vibrational energy. As long as the quasi-equilibrium theory holds in mass spectra, a comparison of the sum of the total energies of the fragments will be able to predict fragmentation. Ichikawa and Ogata used the method to predict the most probable course of bond-scission by comparing the sum of the total energies of the fragments thus produced.[2]

In this paper, the method has been applied to formic, acetic, propionic, and butyric acids. Mass spectrometric studies of those carboxylic acids have been conducted by several investigators, and the fragment ions studied using isotopic labelled compounds and the detection of metastable ion peaks.[3] The total energies of the fragment molecules have been calculated by the CNDO/2 method, the parameters of which were the same as in the paper of Pople and Segal.[4] The total energy may vary with the structure but it is difficult to know the structure of the radical and ionic species. The possible configurational changes were considered to take place to those appropriate forms (*e.g.*, $sp^3 \rightarrow sp^2$), in the cationic and radical molecules and the most stable energy adopted after calculation of the probable configurations. In the present calculation, the following bond lengths (Å) have been assumed: $C(sp^3)$–$C(sp^3)$, 1.54; $C(sp^3)$–$C(sp,sp^2)$, 1.50; $C(sp^2)$–C(sp), 1.45; C=C, 1.35; C–O, 1.32; C=O, 1.25; C≡O, 1.15; C–H, 1.09; O–H, 0.96. Bond angles have been taken to be $109°28'(sp^3)$; $120°(sp^2)$; $110°(<COH)$.

Results and Discussion

The total energies of the molecules, cations and radicals (eV) obtained by the CNDO/2 method are listed in Table 1. Combinations of the fragments listed in Table 1 would give a variety of fragmentation processes. From the point of view of energy comparison, the decomposition reactions appeared to occur more in the production of two fragments than in three fragments. Therefore, only the processes producing two fragments have been discussed here. The difference in energy between molecules and cations indicate the ionization potentials (IP). The IP values obtained were a little greater than that reported in the literature. The CNDO/2 method is not well suited for the estimation of the total energy, but this method proved sufficiently useful for the elucidation of mass spectra. A comparison of the sum of the total energies of the fragments produced and the relative intensities of the peaks are shown in Table 2 where the peak height of the most abundant species has been set at 100. The breakdown patterns of the mass spectra have been classified into simple

R indicates rearrangement breakdown. vs, s, m, and w indicate relative intensities as follows: vs; 100—76, s; 75—51, m; 50—26, w; 25—10.

cleavage and rearrangement reactions, the rearrangement processes being denoted by the letter R.

In the mass spectrum of HCOOH, the peak at *m/e* 29 (HCO^+) was predicted as a simple fragment ion. The ion *m/e*=45, as shown in Table 1, $COOH^+$ was calculated to be more stable than $HCOO^+$. Ono *et al.*, however, reported that $HCOO^+$ and $COOH^+$ occurred in equal abundance in the spectrum of HCOOH.[3]

In the mass spectrum of CH_3COOH, the ions CH_3CO^+ (*m/e*=43) and $COOH^+$ (*m/e*=45) were predicted to appear abundantly from simple cleavage, and CH_2CO^+ (*m/e*=42) from rearrangement.

In the mass spectrum of C_2H_5COOH, the ions $C_2H_5CO^+$ (*m/e*=57), $C_2H_5^+$ (*m/e*=29), $COOH^+$ (*m/e*=45) were predicted to appear abundantly as simple fragment ions.

In the mass spectrum of C_3H_7COOH, the following ion peaks were considered as simple fragment ions: $C_3H_7CO^+$ (*m/e*=81), $C_2H_5^+$ (*m/e*=29), $C_3H_7^+$ (*m/e*=43), $COOH^+$ (*m/e*=45), $CH_2CH_2COOH^+$ (*m/e*=73). The ions CH_3COOH^+ (*m/e*=60), $CH_2{=}C(OH)_2^+$ (*m/e*=60) were considered as rearrangement ions. The peak at *m/e* 60 is known as the McLafferty rearrangement ion $CH_2{=}C(OH)_2^+$. Levsen and Schwarz reported that there is no isomerization, or only minor isomerization of $CH_2{=}C(OH)_2^+$ to CH_3COOH^+.[5]

The first process which straight chain aliphatic acids undergo upon electron-impact is the removal of one of the lone pair electron on the oxygen atom. The active molecular ions vibrate and bond-scission occurs statistically in terms of energy. In the mass spectra of the carboxylic acids, $R\text{–}C{\equiv}O^+$, is predicted to appear in appreciable amounts from simple cleavage. The peak heights of $C_2H_5CO^+$ from C_2H_5COOH and $C_3H_7CO^+$ from C_3H_7COOH were, however, not as high as expected. Concerning the $C_2H_5CO^+$ and $C_3H_7CO^+$ ions, the secondary decomposition processes were examined by comparing the sum of the total energies of the fragment molecules, the results of which are shown in Table 2. The probable fragment ions $C_2H_5^+$, HCO^+ (*m/e*=29) from $C_2H_5CO^+$ and $C_2H_5^+$ (*m/e*=29), $CH_2{=}COH^+$ (*m/e*=43) from $C_3H_7CO^+$ were found respectively in the mass spectrum. It is suggested that the $C_2H_5CO^+$, $C_3H_7CO^+$ ions may be unstable, decomposing immediately.

The main peaks in the electron-impact mass spectra are concordant with the results for simple cleavage, but not so good for the rearrangement reactions. The configurational structure may play an important role in the occurrence of rearrangement ions.

The authors thank Dr. Juro Maruha of the Faculty of Liberal Art, Kanazawa University, for his advice in this work. The computations were conducted on a FACOM M-160 computer at the data processing center, Kanazawa University.

The X-Ray Structure Determination of Heptaethylene Glycol-$Sr(SCN)_2$

Hideyo OHMOTO, Yasushi KAI, Noritake YASUOKA,† Nobutami KASAI,*

(Received September 12, 1978)

Synopsis. The crystal structure of heptaethylene glycol-$Sr(SCN)_2$ has been determined by X-ray diffraction. The Sr ion is coordinated by eight oxygen atoms arising from the heptaethylene glycol moiety and a nitrogen atom from one of SCN groups. The coordination polyhedron is irregular, Sr–O distances ranging from 2.56 to 2.73 Å.

It is well known that macrocyclic ethers interact with alkali and alkaline earth metal ions to give complexes, some structures of which have been determined by X-ray crystallography.[1-3] On the other hand, linear poly(oxyethylene) (POE) derivatives also have a chelating ability to metal cations.[4] The structures of various glymes with $HgCl_2$ and $CdCl_2$ have been investigated by Iwamoto[5,6] in connection with structural studies of polyethylene glycol–$HgCl_2$ complexes.[7,8] Recently, POE deraviatives with the appropriate number of oxyethylene units have been found to form complexes with alkali and alkaline earth metal thiocyanates.[9] In order to investigate the chlating behavior of POE, X-ray diffraction studies have been made and here the structure of heptaethylene glycol–$Sr(SCN)_2$ is presented.

The crystals, colorless and transparent prisms, were obtained by recrystallization from an acetone solution.

Crystal Data: $(C_{14}H_{30}O_8)\cdot Sr(SCN)_2$, *F.W.*=530.2, monoclinic, space group $P2_1/c$, a=11.368(3), b=14.311(2), c=17.665(6) Å, β=122.13(2)°, V=2434(2) Å^3, D_m=1.45 g cm^{-3} (flotation in dichloromethane–carbon tetrachloride), D_c=1.45 g cm^{-3} for Z=4, μ(Mo $K\alpha$)=23.6 cm^{-1}.

Intensity data were measured on a Rigaku diffractometer with graphite monochromatized Mo $K\alpha$ radiation employing the ω scan technique. The integrated intensity was determined by scanning the peak at a rate of 2°/min along the ω axis. A total of 5313 reflections were obtained, of which 3151 reflections were $F_o > 3\sigma(F_o)$. Lorentz and polarization corrections were made, but no absorption correction was applied, which might limit the accuracy of the present structure determination.

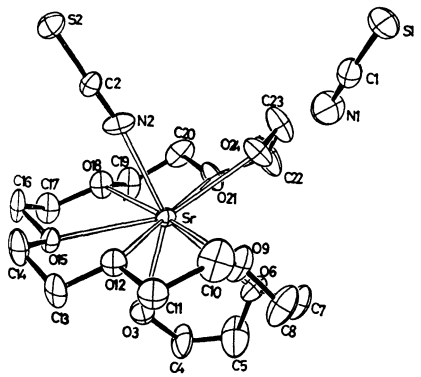

Fig. 1. An ORTEP drawing of the $Sr(SCN)_2$–EO7 molecule together with the numbering scheme.

The structure was solved by the heavy atom method, and refined by the block-diagonal least-squares method with HBLS V[10] program. The atomic scattering factors used in all the computations were taken from the International Tables of X-Ray Crystallography.[11] The refinement was converged to a rather high R value of 0.113 for 3151 reflections and this will be discussed later.

An *ORTEP* drawing of the complex molecule is shown in Fig. 1, together with the numbering system. The bond lengths and bond angles are listed in Table 1.††

Coordination Geometry: Eight oxygen atoms from heptaethylene glycol (EO7) and one nitrogen atom from a SCN anion are coordinated to the Sr ion. The coordination polyhedron is irregular. It is difficult to express the polyhedron in simple terms, although a nine

coordinated distorted tricapped trigonal prisms or eight coordinated bicapped trigonal prism have been reported.[12,13] The Sr–O bond lengths range from 2.56 to 2.73 Å. The Sr–O(3) and Sr–O(24) distances are rather short, possibly attributable to the two oxygen atoms at both ends of the EO7 chain being more basic.

Conformations of EO7 Chain: The C–C bond distances found in the EO7 chain are rather short, the mean value being 1.45 Å. The C(4)–C(5) distance of 1.31 Å is abnormally short. The thermal ellipsoids of the atoms are large, and the largest directions are approximately normal to the O(3)–C(4)–C(5)–O(6) plane. Moreover, the torsion angle is −15°, a value which cannot be considered real. It is most probable that partial disorder is present in this part of the chain. Consider a plane made by passing through the Sr, O(3), O(6) atoms and the midpoint between C(4) and C(5). If C(4) lies above the plane, then C(5) must lie below the plane as shown in Fig. 2(a), or *vice versa* (Fig. 2(b)). There may be no energy difference between the two conformations if other conditions are similar. It is most probable that partial disorder, caused by the two conformations is present in the crystal. Some residual peaks were found in the difference map, but attempts to locate the disordered atoms were not successful; possibly real situation is more complex. This may also explain the rather high observed R value. Such apparent bond shortening due to thermal libration and partial disorder has also been discussed by Dunitz, *et al.*[2]

The torsion angles in the EO7 chain are listed in Table 2, and in the central part a TGT–T$\bar{G}$T–TGT conformation is observed. This may be the most stable conformation, a conformation also found in the TGM·$HgCl_2$ complex. Both ends of the chain assume a different conformation, since the TGT–T$\bar{G}$T–TGT conformation results in a helical form of an EO7 chain.

Hydrogen Bonding: Two hydrogen atoms at both ends of the EO7 chain possibly serve as donors to form hydrogen bonding. The N(1) atom in a free SCN group

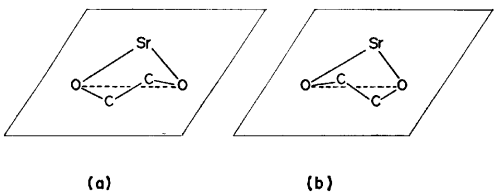

Fig. 2. Two plausible conformations of the –O–CH_2–CH_2–O group.

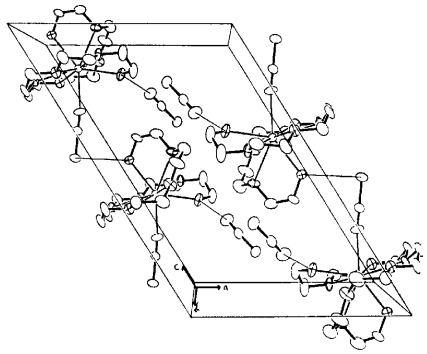

Fig. 3. An ORTEP drawing of the contents of a unit cell.

is located at a distance of 2.73 Å from O(24). Another SCN group is coordinated to the Sr atom *via* N(2) as described above, and S(2) is bonded to the O(3) atom in a neighbouring molecule, the hydrogen bond distance being 3.26 Å. The crystal structure is shown in Fig. 3.

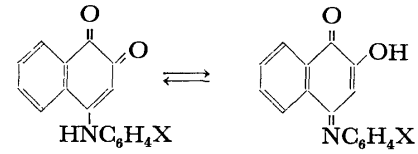
(Received September 18, 1978)

Synopsis. On the basis of vibrational spectra, especially in the region from 3050 to 3350 cm^{-1}, solid 4-anilino-1,2-naphthoquinones carrying substituents on the phenyl ring are classified into two groups. The *p*-methyl and *p*-ethyl derivatives are dimorphic and can be members of both the groups.

We have previously examined the vibrational spectra of a number of the derivatives of 2-anilino-1,4-naphthoquinones which carry substituents on the phenyl ring.[1] On the basis of the location and the sharpness of the single band appearing in the region from 3150 to 3350 cm^{-1}, most of the derivatives could be classified into two groups. Furthermore, over ten derivatives were shown to be dimorphic. One of the dimorphic forms exhibits a relatively sharp band near 3300 cm^{-1}; the other, a relatively broad one at a lower wave number. Thus these derivatives can belong to either group. Here, the results of our work extended to the isomeric compounds, the derivatives of 4-anilino-1,2-naphthoquinones, will be presented.

The condensation reaction between 1,2-naphthoquinone and anilines was carried out in warm or boiling ethanol as reported by Zincke or Elsbach.[2,3] The vibrational spectra in the rock-salt region and the electronic spectra in the visible region were measured by the procedures described in the previous paper.[1] The search for dimorphic forms was made by comparing the vibrational spectrum of the crystals deposited from a reaction mixture with that of the sample sublimed in a vacuum. When they were clearly different, recrystallization of the former sample was attempted.

The crystals of the *p*-methyl derivative as deposited from a reaction mixture and also those recrystallized from ethanol are reddish orange. As is shown in Fig. 1a, the vibrational spectrum shows a single band at 3315 cm^{-1}, which may be assigned to the N–H stretching. By sublimation in a vacuum, the color turns deep red and the single vibrational band is replaced by a complicated pattern consisting of at least four bands, appearing at 3070, 3120, 3185, and 3220 cm^{-1}, probably arising from nonequivalent N–H bonds (see Fig. 1b). As the single band and/or the pattern noted here are also observed with the other derivatives, the form giving the former spectrum will be named, for the sake of convenience, form I, and that giving the latter, form II. The spectra of these two in the region below 1700 cm^{-1} are not very different from each other. Therefore, the difference in vibrational spectrum seems to be attributed to a change in the molecular configuration centered round the N–H group, as has been concluded for the case of 2-anilino-1,4-naphthoquinones, rather than the tautomerism involving *o*-quinonoid and *p*-quinonoid forms:



This conclusion seems to be in accordance with the finding by Harmon *et al.* that 4-anilino-1,2-naphthoquinones in aqueous solutions exist predominantly in the aminoquinone form except in strongly acidic solutions, where the hydroxyquinone imine form becomes more stable.[4] Figure 2 presents the Kubelka-Munk plots of the electronic spectra of the dimorphic forms and also the absorption spectrum of the same compound dissolved in chloroform. Form I gives two maxima located at about 515 and 545 nm and form II gives a maximum at 500 nm, with a shoulder around 540 nm.

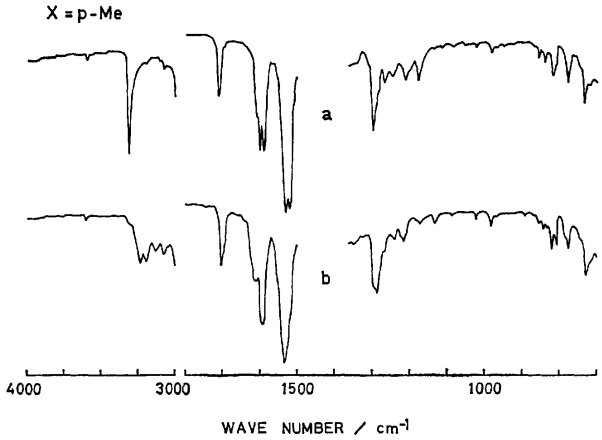


Fig. 1. Vibrational spectra of 4-(*p*-methylanilino)-1,2-naphthoquinone: (a) the form I (recrystallized from ethanol) and (b) the form II (sublimed in a vacuum).

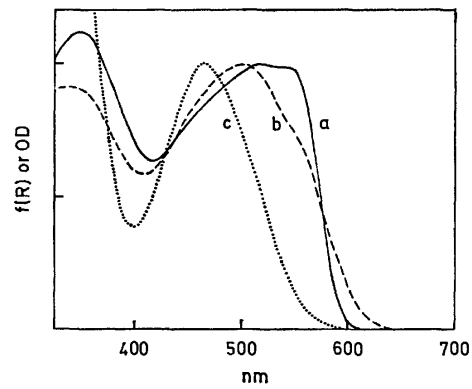

Fig. 2. Electronic spectra of 4-(*p*-methylanilino)-1,2-naphthoquinone: (a) the form I (recrystallized from ethanol), (b) the form II (sublimed in a vacuum), and (c) the compound dissolved in chloroform. The maximum in the visible region was arbitrarily taken as 1.00 in each spectrum.

On the other hand, the maximum of the absorption band is observed at about 463 nm with a chloroform solution. Thus, the band seems to shift to about 500 nm upon the solidification. Since the molecule consists of an electron-donating moiety and an accepting one, this electronic transition is probably of the intramolecular charge-transfer type. The additional bands appearing in the solid-state spectra may be assigned to the intermolecular charge-transfer transition. The location and the intensity of such an absorption are supposed to depend on the mode of molecular stacking in the crystals, as we have reported for a number of cases.[1,5,6]

Form I was found for only three more derivatives: the unsubstituted compound (3320 cm^{-1}), the *p*-ethyl (3310), and the 2,3-dimethyl (3300) derivatives. Among them, the *p*-ethyl derivative was found to be dimorphic, but the other two are not. The *p*-ethyl derivative crystallizes in form I from ethanol and is transformed into form II by vacuum sublimation. The former crystals are reddish brown and the latter are brown. The maxima of the electronic absorption are at about 510 and 500 nm, respectively. In this case too, the intensity in the spectrum of form I changes more steeply in the long-wavelength side than that of form II.

The second group of compounds, obtained only in the form II, consists of a number of derivatives: *o*-methyl, *m*-methyl, *p*-propyl, *m*-chloro, *p*-chloro, *p*-iodo, *m*-methoxy, *p*-methoxy, *m*-ethoxy, *p*-ethoxy, *m*-carboxy, *p*-carboxy, 2,4-dimethyl, 2,5-dimethyl, 3,4-dimethyl, and 2,4,5-trimethyl derivatives. Thus the classification does not seem to be correlated with the electronic nature of the substituents. Their absorption bands are rather broad and the maxima are located around 500 nm. The compounds available in form II are generally darker than those in form I because the absorption bands extend to the longer wavelengths.

Carbon-13 NMR Spectra of Di-*t*-alkyl Ethers and Related Hindered Ethers

Hiromitsu MASADA* and Yoshiharu MUROTANI

Department of Industrial Chemistry, Faculty of Engineering, Kanazawa University, Kodatsuno, Kanazawa 920

(Received October 12, 1978)

Synopsis. The C-13 NMR spectra of hindered *t*-alkyl ethers and dineopentyl ether have been presented and the electronic and steric effects discussed. The resonances for the α-, methylene β-, and methyl β-carbons of di-*t*-alkyl ethers shifted downfield by +45, +1.2, and −0.2 ppm, respectively, relative to the corresponding alkanes.

The C-13 NMR spectra of primary and secondary alkyl ethers have been investigated in detail.[1,2] However, the spectra of hindered *t*-alkyl ethers except di-*t*-butyl ether[3] have not been reported. This paper deals with the elucidation of the skeletal structures of several hindered ethers together with a spectroscopic study of their electronic and steric effects.

Results and Discussion

Table 1 shows the C-13 NMR chemical shifts of di-*t*-butyl ether (**1**), di-*t*-pentyl ether (**2**), bis(1,1-dimethylbutyl) ether (**3**), bis(1,1-dimethylpentyl) ether (**4**), and bis(1,1-dimethylhexyl) ether (**5**). The values in parentheses indicate the differences in chemical shifts between the di-*t*-alkyl ethers and the corresponding alkanes in which a methyl group has replaced the alkoxyl function. The chemical shifts of the alkanes were the values reported by Lindeman and Adams.[4] The resonance signals for the α-carbons (C-1) of di-*t*-alkyl ethers shifted downfield by 44.8—45.6 ppm relative to the alkanes. The downfield shifts are smaller than in the cases of the corresponding linear and secondary alkyl ethers containing more than eight carbons (48—50 ppm).[2] The difference in the α-effect may be due to steric hindrance of the *t*-alkyl group and variations in the electron density with branching of the alkyl chain. The resonances for the methylene β-carbons of the ethers (C-2) shifted downfield by 0.9—1.5 ppm, while those for the methyl β-carbons (C-2a) shifted upfield by 0.1—0.4 ppm, relative to the alkanes. The chemical shifts of the γ carbons (C-3) and more remote carbons (C-4, C-5, and C-6), in most cases, agreed reasonably with those of the alkanes.

Table 2 shows the C-13 NMR chemical shifts for bis(1-ethyl-1-methylpropyl) ether (**6**), bis(1-ethyl-1-methylbutyl) ether (**7**), *t*-butyl α,α-dimethylbenzyl ether (**8**), and dineopentyl ether (**9**). The resonance shifts of more-crowded di-*t*-alkyl ethers, **6** and **7**, exhibit a similar tendency to those of **1**—**5**. The shielding of a phenyl substituent is observed in **8**. The resonance for the α-carbon attached to the phenyl group (C-1a) moved downfield by 1.2 ppm relative to that for the α-carbon (C-1) in **8**. The effect of the phenyl group was, however, hardly observed on the β-carbon (C-2a). The α-carbon resonance of the hindered primary ether, **9**, shifted by approx. 45 ppm, as much as that of the isomeric di-*t*-pentyl ether. Furthermore, the β- and γ-carbon resonances deviated by +2.1 and −1.9 ppm, respectively, from those of the corresponding alkane. The unusual deviations have been attributed to the steric effect of the neopentyl group, which is also observed to some extent in the case of neopentyl propyl

ether.[2)]

Experimental

Materials and Preparation. Barium and sodium were commercial extra pure reagents (purity 99%). 2-Chloro-2-phenylpropane was derived from 2-phenylpropene.[5)] Neopentyl tosylate was prepared from neopentyl alcohol and tosyl chloride in pyridine. Organic chemicals were distilled from calcium hydride before use and the purity confirmed by GLPC. Di-*t*-alkyl ethers (**1**—**7**) were prepared from *t*-alkyl chlorides and silver carbonate by the method reported previously.[6)] The ethers, **8** and **9**, were prepared and identified by their physical constants, ^{1}H-NMR, IR, and mass spectra, as described below. Proton NMR spectra were conducted on a JEOL-PS-100 spectrometer operating at 100 MHz using TMS as an internal standard. IR spectra were conducted on a JASCO DS-301 spectrometer and mass spectra on a JEOL-JMS-01SG spectrometer. GLPC analyses were performed on a Shimadzu GC-3AH chromatograph using 3 m×3 mm columns packed with 5 % DNDP and 5 % Silicone DC 550.

t-Butyl α,α-Dimethylbenzyl Ether (8): A mixture of barium (3.30 g, 24 mg-atom) and *t*-butyl alcohol (40 cm^3) was refluxed for 8 h to give barium *t*-butoxide. The solution was cooled to 20 °C and 2-chloro-2-phenylpropane (6.18 g, 40 mmol) added. The mixture was stirred for 6 h, hydrolyzed, and extracted with pentane (30 cm^3×3). The organic layer was washed with water (50 cm^3×8), dried over sodium sulfate, and fractionated *in vacuo* to give 1.29 g (17 %) of pure *t*-butyl α,α-dimethylbenzyl ether: bp 97—98 °C/17 Torr; IR (neat) 1150 (C–O–C) and 768, 702 (aromatic) cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=1.08 (9H, s, *t*-Bu), 1.56 (6H, s, *gem*-CH_3), and 7.1—7.5 (5H, m, aromatic).

Dineopentyl Ether (9): Prepared by a modification of the literature procedures.[7,8)] A mixture of sodium (0.55 g, 24 mg-atom) and neopentyl alcohol (8.82 g, 0.1 mol) was refluxed for 0.5 h, and a solution of neopentyl tosylate (4.84 g, 20 mmol) in dimethyl sulfoxide (10 cm^3) added. The mixture was stirred for 4 h at 120 °C, cooled, hydrolyzed with 1 M hydrochloric acid, and extracted with pentane (20 cm^3×3). The organic layer was washed with ethylene glycol (20 cm^3×8) and water, dried over sodium sulfate, and fractionated to give 1.96 g (62 %) of pure dineopentyl ether: bp 138 °C; IR (neat) 1126 (C–O–C) cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.91 (18H, s, CH_3) and 3.02 (4H, s, CH_2); MS (75 eV), *m/e* (rel. intensity), 158 (M^+, 7), 101 (15), and 71 (100).

C-13 NMR Spectra. C-13 NMR spectra were conducted on a JEOL model PFT-100 pulse-Fourier transform NMR spectrometer at 25.15 MHz locked on deuterium using 10 mmϕ sample tubes. Data were obtained for 2 M solutions in $CDCl_3$ at 25 °C. Measurement conditions were as follows: pulse width, 12 μs (*ca.* 45°); repetition time, 4 s; spectral width, 5000 Hz; data points, 8191; delay time, 330 μs. The resonance assignments were confirmed by off-resonance decoupling experiments. Chemical shifts are expressed in δ ppm downfield from the internal TMS.

The authors are grateful to Mr. Yoshitaka Itatani of Kanazawa University for the C-13 NMR measurements.

The Extraction Spectrophotometric Determination of Cobalt(II) with 4-(2-Thiazolylazo)resorcinol and Zephiramin

Kazumasa UEDA

Department of Industrial Chemistry, Faculty of Technology, Kanazawa University, Kodatsuno, Kanazawa 920

(Received June 2, 1978)

Synopsis. The cobalt(II)–4-(2-thiazolylazo)resorcinol chelate anion is quantitatively extracted into chloroform with a cation of zephiramin as an ion-pair complex. This process was applied to the spectrophotometric determination of cobalt. The effective separation and the sensitive determination for a trace amount of cobalt could be confirmed even in the presence of high concentrations of masking agents.

There are several ternary chelate extraction systems using *o*-hydroxyphenylazo dyes. Yotsuyanagi and Hoshino[1] systematically studied the 4-(2-pyridylazo)-resorcinol (PAR) chelates and found that the molar absorptivity of the ion-pair chelate increased when the non-coordinative *p*-hydroxyl group dissociated once. The homologous 4-(2-thiazolylazo)resorcinol (TAR) also has a noncoordinative *p*-hydroxyl group. The color reaction of TAR with cobalt[2] and its stability[3] in the aqueous phase have been investigated. The author[4] also studied the solvent extraction of 3d type transition metal–TAR chelate anions with the cation of zephiramin(Z^+Cl^-) and recognized that TAR is superior as an ion-pair extraction reagent, especially for cobalt. In this research, the fundamental conditions for the spectrophotometric determination of cobalt were investigated. The interferences from the other transition metals could be effectively removed.

Experimental

Reagents. TAR (Dojindo Co., Ltd.) was twice recrystallized from a 50 % ethanol–water mixture. Z^+Cl^-(Dojindo Co., Ltd.) was used as obtained. The standard cobalt(II) solution was prepared from cobalt sulfate and was standardized by EDTA titration.

Apparatus. A sample solution was prepared in a 50 ml graduated centrifuge tube with a glass-stopper; the solution was shaken in an Iwaki-KM type reciprocating shaker. A Kubota K-80 type centrifuge with 5000 r.p.m. was used for phase separation. A Hitachi-Horiba model M-5 pH meter equipped with a combined glass electrode was used for pH measurements. Absorption spectra and absorbance were measured with a Hitachi 124 recording spectrophotometer and a Hitachi Perkin Elmer 139 spectrophotometer using 10-mm quartz cells.

Standard Procedure. Transfer the sample solution containing up to 20 μg of cobalt in a centrifuge tube along with 1 ml of 0.05 % TAR, 2 ml of 0.1% Z^+Cl^-, and a suitable masking agent(*e.g.*, 5 ml of 10 % sodium salt of citrate, tartrate, or acetate). Adjust the pH of the solution to 8.0 with 2 ml of 0.05 M borax–phosphate buffer and dilute to 20 ml with redistilled water. Allow the solution to stand for 10 min, and shake it with 10 ml of chloroform for 10 min. After centrifugal separation, transfer the extract into an absorption cell, and measure the absorbance at 550 nm against the reagent blank.

Results and Discussion

Absorption Spectra. The Co–TAR chelate anion and its ion-pair with Z^+Cl^- in the aqueous phase have their absorption maxima at 540 nm; these shift to 550 nm in the chloroform extract.

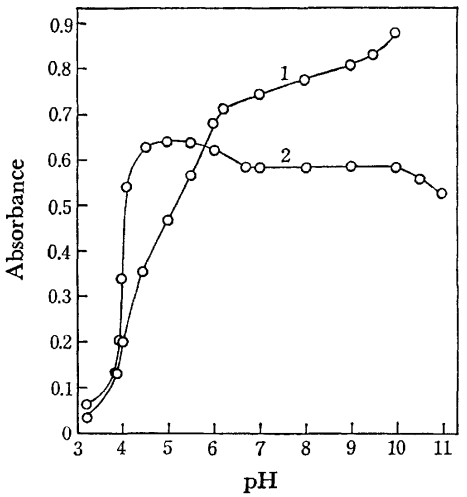

Fig. 1. Effect of pH on the extraction of Co–TAR–Z^+Cl^- chelate.
1: Reagent blank (reference; chloroform), 2: Co; 10.1 μg (reference; reagent blank). 0.05% TAR: 1 ml, 0.1 % Z^+Cl^-: 2 ml. pH 3.5—6.0: 0.025 M succinic acid–borax, pH 6.0—9.2: 0.05 M borax–phosphate buffer.

Effect of pH. The effect of pH on the extraction of the ternary chelate was examined as shown in Fig. 1. The extract shows a constant absorbance at pH 6.7—10.0 with a broad peak at pH 5, where the absorbance of the reagent blank changes remarkably with an increase in pH. When hexamine–nitric acid buffer is used, the extract has a molar absorptivity of about 7×10^4 at 535 nm. An extractable higher order chelate, perhaps the quaternary chelate, may be formed. However, we could not obtain reproducible conditions because the complexation conditions were complicated.

The Effect of TAR Concentration. The effect of TAR concentration was examined and the constant absorbance was obtained by adding from 0.7 to 4 ml of 0.05% TAR solution for 10 μg of cobalt in 20 ml solution.

The Effect of the Z^+Cl^- Concentration. The extract showed a constant absorbance with the addition of 0.1% Z^+Cl^- over the ranges of 0.5—5 ml. The ternary chelate partially dissolved into aqueous phase upon the further addition of Z^+Cl^-.

The Effect of Shaking Time, Color Stability, and the Aqueous Phase Volume. The absorbance of the extract was constant for shaking times from 5 min to one hour. The extracted species was very stable and its absorbance was constant for at least 24 h at room temperature. A constant absorbance was also obtained up to 40 ml of the aqueous phase volume.

Organic Solvents. The chelate was effectively extracted into such polar solvents as chloroform, dichloromethane (2.92×10^4, 552 nm), 1,2-dichloroethane (2.80×10^4, 550 nm), and ethyl acetate (3.27×10^4, 543 nm), but not into such nonpolar solvents as carbon tetrachloride, carbon disulfide, and hexane. The chelate was also extracted into such aromatic hydrocarbons as benzene, toluene, xylene, and chlorobenzene, where the extracts show a brilliant red color, but contain insoluble components. The other ketones and esters formed an emulsion or a third phase at the interface.

Extractability and Molar Absorptivity. The extractability of the ternary chelate was examined by the atomic absorption spectrometry; it was found that 99.6% of cobalt was extracted by a single extraction. The molar absorptivity of the ternary chelate is 3.42×10^4 $l\ mol^{-1}\ cm^{-1}$, which is more sensitive than the ion-pair extraction methods, such as 1-(2-pyridylazo)-2-naphthol–Triton X-100 (1.90×10^4),[5] but less sensitive than that of PAR–Z^+Cl^- (5.9×10^4)[6] methods.

Calibration Curve. A calibration curve for the determination of cobalt was made under the optimum conditions. The curve obeys Beer's law up to 20 μg of cobalt per 10 ml of chloroform, and Sandell's sensitivity for the absorbance of 0.001 is 0.0017 $\mu g\ cm^{-2}$. The variation coefficient of the absorbance is 0.92% for the 8 measurements.

Effect of Masking Agents. A constant absorbance is obtained in the presence of 5 ml each of 10% sodium salt of citrate, tartrate, acetate, oxalate, and thiourea. When the extract is washed with 5 ml of 0.05 M EDTA, the absorbance is constant because the chelate is rather stable once extracted. In the presence of sodium chloride, the extractions of ternary complexes of nickel, copper, and zinc were rapidly decreased as the number of the chloride ions increased, while the extraction of the cobalt complex was scarcely affected.[4] Thus, in the present method, the combined use of high concentrations of various masking agents is possible.

Table 1. Effect of diverse ions

Ions added	Tolerance limit, ppm
Mn(II), Zn(II),[a] Cd(II),[a] Al(III), Ti(IV),[b] Pb(II), Sb(V), Cr(VI), Mo(VI), W(VI), As(V), Se(IV), Rh(III), Ca(II), Mg(II), Sr(II), Ba(II)	100
Fe(II),[a] Fe(III),[a] Ni(II),[a] Cu(II),[c] Hg(II),[a] Cr(III), Sc(III),[d] In(III), Zr(IV), Hf(IV), Sn(IV), Th(IV)	50
Sn(II),[b] Ru(III), CN^-, SCN^-	20
Be(II), Bi(III), Pt(IV)	10

Cobalt taken: 1.01 ppm. a) Extracts were washed with 5 ml of 0.05 M EDTA solution. b), c), and d): Five ml each of 10% citric acid, thiourea, and tartaric acid solution were added, respectively.

Effect of Diverse Ions. The effect of diverse ions was investigated as shown in Table 1, where the tolerance limit was set to ±3% for cobalt recovery. Up to 10-fold amounts of nickel, and 20-fold of iron(II) and iron(III), were also tolerated by the addition of 5 ml each of 1% dimethylglyoxime and 5% sodium pyrophosphate, respectively. Five-fold amounts of nickel, and 2-fold of copper and zinc were left in the aqueous phase in the presence of 1 g of sodium chloride. Of the anions tested, chloride, sulfate, and nitrate did not interfere.

BULLETIN OF THE CHEMICAL SOCIETY OF JAPAN, VOL. 52 (4), 1217—1218 (1979)

Formation of Vaterite by the Reaction of Calcium Methoxide with Aqueous Sodium Carbonate Solution

Osamu YAMAGUCHI,* Noriyuki TAKASHITA, and Kiyoshi SHIMIZU*

Department of Applied Chemistry, Faculty of Engineering, Doshisha University, Karasuma Imadegawa, Kamigyo-ku, Kyoto 602

(Received July 15, 1978)

Synopsis. A mixture of vaterite and calcite was formed by the reaction of calcium methoxide with aqueous sodium carbonate solutions. The reaction temperature was found to be a dominant factor for the formation of vaterite. The kinetics of the transformation of vaterite into calcite was studied.

Calcium carbonate exists in three polymorphic modifications: calcite(hexagonal), aragonite(orthorhombic) and vaterite(hexagonal). Calcite is stable at ordinary temperature and pressure. Both aragonite and vaterite are transformed into calcite on heating. Although the formation of calcite and aragonite has been studied by many investigators, only a few papers[1-4] have appeared on the formation of vaterite. It was found that the mixture of vaterite and calcite is formed by the reaction of calcium methoxide with aqueous sodium carbonate solution. The present study deals with the conditions on the formation of vaterite and the kinetics of the transformation of vaterite into calcite.

Experimental

The starting material calcium methoxide was prepared by heating calcium metal in an excess dehydrated methanol:

$$Ca + 2CH_3OH \xrightarrow[64\,^\circ C,\ 5\,h]{CH_3OH} Ca(OCH_3)_2 + H_2 \qquad (1)$$

Calcium metal of purity 99 % was used. 20 cm^3 of a methanolic solution containing 1 g calcium methoxide was added rapidly to the stirred 100 cm^3 aqueous sodium carbonate solution, and the resulting colloid was stirred for 5 min. The product was separated immediately from the suspension by filtration, washed repeatedly with hot water, and dried at 40 °C under reduced pressure. The product was examined by means of X-ray diffraction using nickel filtered copper $K\alpha$ radiation and differential thermal analysis.

Results and Discussion

All the products obtained under various conditions were identified as calcium carbonate, which is a mixture of vaterite and calcite. No aragonite was formed. The yield was about 96%. Figure 1 shows the X-ray diffraction patterns of calcium carbonate. No line broadening was observed. The fraction of the two modifications for each calcium carbonate powder is given in Table 1. The fraction was determined from Eqs. 2[4,5] and 3 by measuring the intensity of the (104) reflection of calcite and the intensities of the (110), (112), and (114) reflections of vaterite:

$$f_c = \frac{I_{104(c)}}{I_{110(v)} + I_{112(v)} + I_{104(c)} + I_{114(v)}} \qquad (2)$$

$$f_c + f_v = 1 \qquad (3)$$

where f_c and f_v are the fraction of calcite and vaterite, respectively. For all the concentrations of aqueous sodium carbonate solutions, the fraction of vaterite increased with rise in reaction temperature up to 90 °C, no product consisting of only vaterite being formed. Formation of vaterite at low temperature was promoted with increase in the concentration of aqueous sodium

carbonate solution, but not at high temperature. The reaction temperature is a dominant factor in the formation of vaterite. It is important to consider two stages for the formation of calcium carbonate: (a) aggregation velocity of ions; (b) crystallization velocity at which the ions in colloidal state form crystals. The aggregation velocity is considered to be very high. On the other hand, a period of a few seconds to a few minutes is required for crystallization. Increase in the reaction temperature reduces the time of transformation from colloid into crystal. The formation of vaterite seems to be determined by the crystallization velocity which changes with the reaction temperature. Differential thermal analysis was carried out in the air from room temperature to 600 °C. An exothermic reaction was observed in the temperature range 390—430 °C. From the results of X-ray diffraction, the reaction was found to be the transformation of vaterite to calcite. Figure 2 shows the fraction of the transformation of vaterite to calcite (Table 1, run 12) as a function of time at different temperatures. The average particle size of the specimen was 0.14 μm. Transformation isotherms were characterized by sigmoidal shape, the kinetics being best described by the Avrami equation[6] (Fig. 3),

$$\ln(1-\alpha) = -kt^n \quad n = (2.8-3.1) = 3 \qquad (4)$$

where α, t, k, and n are the fraction of transformation, time, rate constant, and proportionality constant, respectively. The activation energy calculated by the

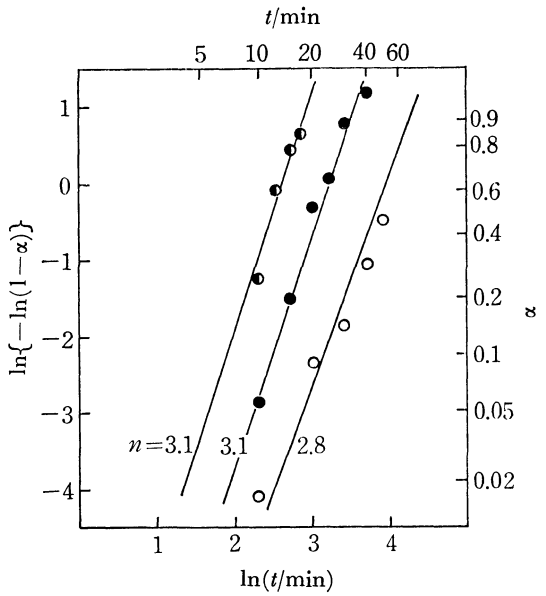

Fig. 3. Plot of $\ln(1-\alpha)$ *vs.* time t.

Arrhenius plot is *ca.* 130 kJ/mol, representing that of the nucleation growth of calcite. Rao[5] reported that vaterite prepared by the same method as that given by McConnel[1] is transformed into calcite in the temperature range 540—580 °C, the kinetic data being represented by the Avrami equation with $n=4/3$. Higher activation energy 356 kJ/mol was required for the progress of transformation. Our results do not agree with those of Rao.[5] The discrepancy might be attributed to difference in type of impurity and the average particle size of vaterite, which affects the temperature and kinetics of transformation.

(Received August 16, 1978)

Synopsis. A new air–propane nebulizer burner, by the use of which the sensitivity and precision for atomic absorption measurements was approximately equal to those with an air–hydrogen nebulizer burner, has been developed. The flame with this burner has other characteristic features, such as low auditory noise, high stability, and low radiation noise in the OH band.

Various kinds of chemical flames have been widely used for atomic emission, absorption, and fluorescence spectrometry. There are two types of burners,[1–3] that is, the nebulizer burner and the premix burner. Recently the premix burner has been most often used because it is silent in operation and has a high efficiency[4,5] in atomizing.

However, the nebulizer burner has many merits: less clogging of the burner with high concentrations of various solutes, no necessity to change the burning conditions between aqueous and organic solvents because of the energetic flame, smaller volume of sample consumption for measurement, freedom from flashback, and simplicity in cleaning and use. Another merit is that a strongly acidic or alkaline sample solution can be nebulized directly, without any trouble like corrosion, as the solution passes through only the capillary. The material of the capillary can also be easily changed according to the solution.

It is well known that the exhaust speed of an oxidant of a nebulizer burner is very high. Therefore, some flames with a high burning velocity[2] (*e.g.*, oxygen–acetylene, oxygen–hydrogen, and air–hydrogen flames) have been obtained with the nebulizer burner, while flames of a low burning velocity have blown out.

The maximum temperature of an air–propane flame has been reported to be 2200 K,[1,6] about 100 K lower than that of a relatively low-temperature air–hydrogen flame (*i.e.*, 2300,[1] 2290 K[7]).

In this paper the construction of a new type of nebulizer burner for flames of low-burning velocity, such as an air–propane flame, and its characteristics are reported.

Construction and Experimental

A cross-sectional diagram of the newly constructed nebulizer burner is shown in Fig. 1. By thoroughly mixing propane with air and by equipping the burner with the side cover (H), we prevent the air–propane flame from blowing out. The propane enters from its inlet portion (A) and then passes through a nozzle (D) 0.2 mm in dia., with 12 holes (E) 2 mm in dia. and 16 holes (F) 1.6 mm in dia., into the flame. The propane is concurrently diluted with air from 6 holes (C) 2.5 mm in dia. and thoroughly mixed in the space (G). The side cover (H) has 24 holes 2.5 mm in diameter.

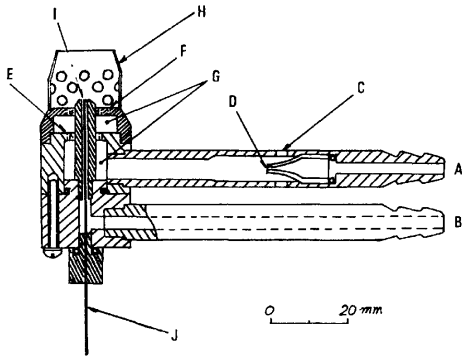

Fig. 1. Cross-sectional diagram of the air–propane nebulizer burner.
A; Fuel inlet, B; air inlet, C; holes, D; nozzle, E; holes, F; holes, G; mixing chamber, H; side cover, I; nozzle, J; capillary.

As an oxidant propane requires about ten times as much air (in volume) than does hydrogen for stoichiometrical burning at its maximum burning velocity. Therefore, we must mix propane with air to a great extent before the propane reaches the flame. The holes of the side cover (H) also serve as a cooler for the sidecover by the stream of entrained air. The burner is made of stainless steel; this makes in significant any contamination in the determination of iron, chromium, and nickel.

The solution passes through a platinum–rhodium capillary (J) 0.55 mm in inside dia. and 0.8 mm in outside dia., and is then sprayed by the air at the nozzle (I) 1.1 mm in diameter. The pressures of air and propane at the inlet ports (B) and (A) are 0.8×10^5 and 2.0×10^5 Pa respectively. The air–propane flame concurrently provides suitable flame conditions in terms of stability and sensitivity for the atomic absorption measurements of several elements.

An atomic absorption and emission spectrophotometer AA-1E (Nippon Jarrell-Ash Co., Ltd.) equipped with a 0.5-m monochromator was used for getting the emission spectra and the other spectra. A photomultiplier, R456 (Hamamatsu T.V. Co., Ltd.), and a grating with 1200 grooves/mm, blazed wavelength 300 nm were used. The voltage applied to the photomultiplier was 500 V. The slit width of the monochromator was 100 μm for both entrance and exit, while the scanning speed of wavelength was 12.5 nm/min. An air–hydrogen flame with a Hetco burner (conventional nebulizer burner, Nippon Jarrell-Ash Co., Ltd.) was used for comparison. The burning gas conditions were 1.0×10^5 Pa and 0.5×10^5 Pa in pressure for air and hydrogen respectively, as usual. Both flames were measured 50 mm above the burner tops, where the highest sensitivities were obtained with both flames for most of the elements listed in Table 1.

Table 1. Sensitivities of several elements with atomizer burners

Element (Wavelength nm)	Sensitivities (ppm/1% absorption)[a]

a) Obtained with a single path.

Results and Discussion

The flame emission spectra scanned, originating from the air–hydrogen and the air–propane flames with the nebulizer burners under the same analytical conditions except for the burning-gas conditions, are shown in Fig. 2. The air–propane flame proved relatively smaller in its OH-band spectrum and inversely larger in its swan-band spectra. The spectrum of the oxygen–acetylene flame with the Hetco burner under the same measurement conditions almost scaled out (not shown).

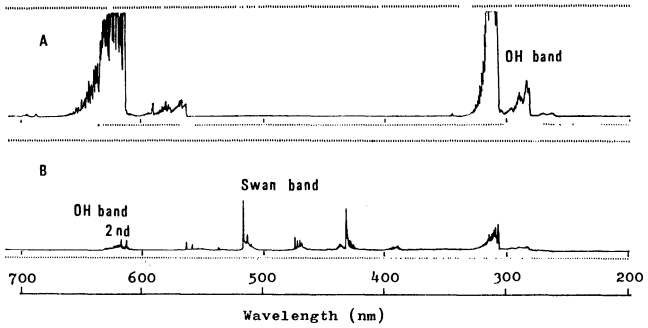

Fig. 2. Emission spectra of (A) air–hydrogen flame and (B) air–propane flame using atomizer burners.
Burning gas conditions: (A) air; 1.0×10^5 Pa, hydrogen; 0.5×10^5 Pa (B) air; 0.8×10^5 Pa, propane; 2.0×10^5 Pa.

The precision and sensitivity were investigated by means of atomic absorption measurements. The coefficient of variation at 4 ppm magnesium in an aqueous solution was 0.9% ($n=10$). Table 1 shows the sensitivities of several elements with the air–propane nebulizer burner (Hetco burner). There was no significant difference in sensitivities for the elements investigated between the two burners. It is apparent that a decrease of about 100 K in the flame temperature, as has been described earlier, leads to something of a loss in sensitivity for magnesium, calcium, strontium, and chromium, which form a relatively stable oxide. A lower sensitivity for cesium was obtained with the air–propane flame than with the air–hydrogen flame, though among the alkali metals cesium was expected to give a higher sensitivity in terms of the ionization potential.

Furthermore, no flashback of the flame occurred at any pressure ratio of air to propane. An air–town gas flame can be obtained by using this burner without holes (C) and nozzle (D). The audible noise of the air–propane and air–town gas flames with this nebulizer burner was much less than that of the air–hydrogen flame with a conventional nebulizer burner. As the background at the OH band is small, this burner can also be used for emission and atomic fluorescence spectrophotometry.

The authors wish to thank Dr. Shohei Tamura of Tokyo University for his helpful discussion.

Dissolution of Metallic Copper in Ethylenediaminetetraacetate Solution in the Presence of Hydrogen Peroxide

Kunio OHZEKI, Koji TAKEUCHI, and Tomihito KAMBARA*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received October 5, 1978)

Synopsis. A 50 mg portion of metallic copper (100 mesh) placed in 50 ml of a neutral solution containing 0.1 mol dm^{-3} ethylenediaminetetraacetate (EDTA) was quantitatively dissolved within 20 min at 50 °C after the addition of a small amount of hydrogen peroxide, resulting in blue coloration of the copper(II)–edta complex.

Copper dissolves readily in aqueous ammonia in the presence of oxygen to form copper(II)–ammine complex.[1] A similar reaction is expected in an aqueous solution containing a chelating agent. Quantitative dissolution of copper in EDTA solution in the presence of hydrogen peroxide is reported.

Experimental

Reagents. The following reagents were used. Disodium and tetrasodium salts of ethylenediaminetetraacetic acid (Dotite reagents, Dojindo Laboratories), metallic copper powder of spectrographic standard (99.999 %, 100 mesh, Mitsuwa Pure Chemicals Inc.), and copper(I) oxide (chemically pure grade, Kanto Chemicals Inc.). Other reagents used were of guaranteed grade.

Procedure. A 50 mg portion of copper powder was taken into 50 ml of a 0.1 M (1 M = 1 mol dm^{-3}) EDTA solution in a 100-ml Erlenmeyer flask placed in a thermostat kept at 50 °C, a small amount of hydrogen peroxide being added to the solution with stirring. The course of the reaction was followed by pipetting out a 3-ml portion of the reaction solution at certain time intervals and determining the concentration of copper(II)–edta complex spectrophotometrically at 720 nm with a Shimadzu Spectronic 88 spectrophotometer. The amount of dissolved copper was evaluated from the calibration curve obtained by means of copper sulfate in a solution of the same composition as the reaction solution. After the absorption measurement the solution was returned quickly to the reaction vessel to keep the volume constant.

Results and Discussion

Effect of Hydrogen Peroxide. In the presence of dissolved oxygen, copper reacts slowly with EDTA to form a blue colored copper(II)–edta complex, but no copper dissolves when oxygen is purged by nitrogen. Addition of a small amount of hydrogen peroxide was highly effective in promoting the dissolution (Fig. 1). A 50 mg portion of copper in 50 ml of a 0.1 M Na_2H_2-edta solution (pH 4.8) was quantitatively dissolved within 20 min after the addition of 0.4—2.4 ml of 30% hydrogen peroxide solution when the reaction solution was stirred at 50 °C. At a higher initial concentration of hydrogen peroxide, evolution of oxygen took place in the solution, the dissolution of copper being depressed.

Effect of pH. The pH dependence of the reaction was examined by varying the concentration of hydrogen

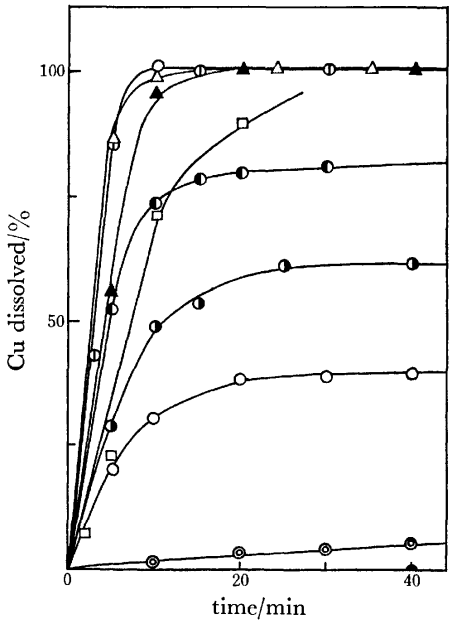

Fig. 1. Effect of hydrogen peroxide on the dissolution of a 50-mg portion of metallic copper in 0.1 M EDTA solution (50 ml, pH 4.8) at 50 °C. Amounts of 30% H_2O_2 solution added; ○: 0.05, ◑: 0.10, ◐: 0.20, ⓘ: 0.5, △: 1.0, ▲: 2.5, □: 5.0 ml, ◎: without H_2O_2, ●: the solution deaerated and without H_2O_2.

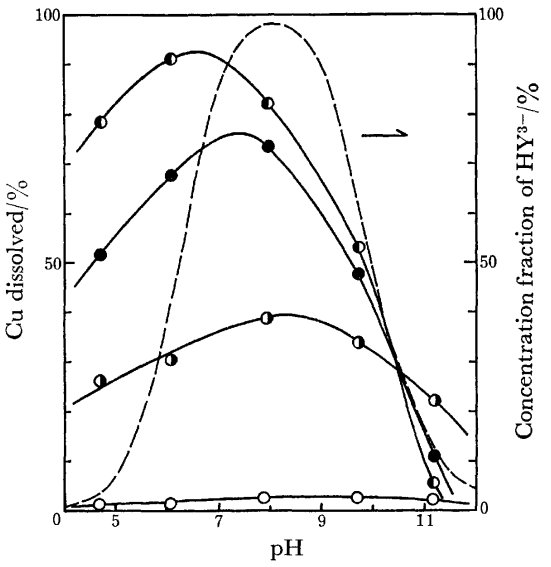

Fig. 2. Effect of pH on the 10-min dissolution of a 50-mg portion of metallic copper. Solution pH was adjusted with mixing 0.1 M EDTA disodium (pH 4.8) and tetrasodium (pH 11.3) salt solutions. Amounts of 30% H_2O_2 solution added; ○: 0, ◑: 0.10, ●: 0.20, ◐: 0.5 ml. The dashed curve indicates the concentration fraction of the HY^{3-} species.

peroxide. The reaction solution was gently shaken in an incubator. Rapid dissolution of copper took place in the pH range 6—8, as shown in Fig. 2, in which the proportion of copper dissolved during the first 10 min is plotted against pH of the initial solution. After quantitative dissolution of copper, the pH of solution was found to increase by *ca.* one unit. The rate of dissolution depends upon the concentration of $Hedta^{3-}$. When the pH was higher than 9, the decomposition of hydrogen peroxide took place with increase in the initial concentration of hydrogen peroxide, no quantitative dissolution of copper taking place.

Dissolution Reaction. The kinetics of the corrosion of copper in aqueous solution was reported by Hill.[2] In the presence of oxygen, copper is oxidized to copper(I) ion, forming copper(I) oxide. The formation of copper-(I) oxide is hindered in the presence of acetate ion owing to the absorption of acetate ion on the copper surface.

Thus the following sequence of reactions is suggested in the presence of hydrogen peroxide and EDTA.

$$2Cu + H_2O_2 + 2H^+ \longrightarrow 2Cu^+ + 2H_2O, \quad (1)$$

$$2Cu^+ + H_2O_2 + 2HY^{3-} \longrightarrow 2CuY^{2-} + 2H_2O, \quad (2)$$

where HY^{3-} denotes EDTA anion predominating near pH 8. The overall reaction is given by

$$Cu + HY^{3-} + H_2O_2 + H^+ \longrightarrow CuY^{2-} + 2H_2O. \quad (3)$$

This indicates the consumption of proton, experimentally confirmed as the increase in pH after the dissolution of copper.

Reaction of Copper Oxide with EDTA. The reactions of copper(I) and copper(II) oxides with EDTA solution were tested. Each sample of the oxides containing 7.89×10^{-4} mol copper was taken into a 0.1 M Na_2H_2-edta solution. Copper(I) oxide reacts readily with EDTA in an air-saturated solution, an appreciable dissolution taking place even in a deaerated EDTA solution. On the other hand, copper(II) oxide dissolves slightly into an EDTA solution even in the presence of hydrogen peroxide.

BULLETIN OF THE CHEMICAL SOCIETY OF JAPAN, VOL. 52 (4), 1223—1224 (1979)

An X-Ray Diffraction Study on the Structure of Hexaamminecadmium(II) Ion in Aqueous Solution

Toshio YAMAGUCHI and Hitoshi OHTAKI*

Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta, Nagatsuta-cho, Midori-ku, Yokohama 227

(Received November 6, 1978)

Synopsis. The structure of the hexaamminecadmium(II) ion in an ammoniacal aqueous solution of cadmium chloride was determined by the X-ray diffraction method at the NH_3/Cd mole ratio of 9.9. The result showed that a cadmium(II) ion is octahedrally surrounded by six ammonia molecules at the distance of (2.37±0.03) Å.

A number of equilibrium studies have been reported[1] for the complex formation between cadmium(II) ion and ammonia molecules, and structures of the complexes have mainly been investigated by spectroscopic ways.[2-5] The structure of the hexaamminecadmium(II) complex in the solid phase has also been studied by the Raman spectroscopy.[3] However, no X-ray crystallographic data are available, because no stable single crystal of the hexaamminecadmium(II) complex, as well as other cadmium ammine complexes, could be prepared. Therefore, we undertook to determine the structure of the hexaamminecadmium(II) complex in an aqueous solution by the X-ray diffraction method. An ammoniacal aqueous solution of $CdCl_2$ at the NH_3/Cd mole ratio of 9.9 has been used as a sample solution. In solutions of the NH_3/Cd mole ratio lower than 9.9, various ammine complexes can coexist, and thus, structural analyses of such solutions are not examined in the present work.

Experimental

The sample solution was prepared as previously described.[6] The solution was almost saturated with both cadmium(II) ion and ammonia. The concentration of cadmium(II) ion in the solution was determined both by EDTA titration using a BT indicator and by electrogravimetry. The results obtained by the two methods agreed each other within 0.2 %. Concentrations of ammonia and chloride ions were determined as described previously.[6] The atomic composition of the sample solution is given in Table 1.

X-Ray scattering data were obtained at (25±1) °C with a θ-θ diffractometer (JEOL Co., Tokyo) equipped with a Philips Mo-tube (Mo $K\alpha$: λ=0.7107 Å). Details of measurements and treatment of data are described elsewhere.[6,7] A Raman spectrum of the sample solution was measured with a JEOL JRS-S1 spectrophotometer using the 4880 Å Ar^+ laser excitation.

Results and Discussion

The $(D(r)-4\pi r^2\rho_0)$ and $D(r)$ curves obtained for the solution are shown in Figs. 1a and 1b, respectively. As can be seen from Fig. 1a, five peaks appear around 1.0, 2.4, 2.8, 3.2 and 4.6 Å (indicated by arrows). The small and broad peak at 1.0 Å is due to both O–H and N–H bonds within water and ammonia molecules, respectively. A shoulder locates at *ca.* 2.4 Å, the position being expected from the sum of the sizes of a cadmium(II) ion and an ammonia molecule (0.97 Å[8]+1.40 Å[9]= 2.37 Å). The peak around 3.2 Å can be ascribed to the Cl–O bond within the hydrated chloride ion.[10] The nearest O–O contacts in the bulk water-structure contribute to the shoulder around 2.8 Å.[11] The interatomic N–O distance of the NH_3–H_2O contacts in the ammoniacal aqueous solution[9] is almost the same as the O–O distance of the H_2O–H_2O contacts in the bulk.

In order to deduce the peak due to the Cd–N bond, the contributions of the nearest O–O and N–O contacts in the bulk medium and the Cl–O bonds within the hydrated chloride ions were subtracted from the $D(r)$ curve according to the following procedures. Since the X-ray method could hardly distinguish O from N atoms, the effective scattering factor, $f_X(s)=xf_N(s)+(1-x)f_O(s)$, was introduced in order to calculate the H_2O–H_2O and NH_3–H_2O interactions in the bulk phase (the NH_3–NH_3 contact was neglected because of the relatively low concentration of ammonia compared with the water concentration). The same scattering factor was used for the calculation of theoretical intensities of scattered X-rays from chloride ions solvated with water and, possibly, ammonia molecules. x represents the mole fraction of free ammonia: $x=[NH_3]_F/([NH_3]_F+[H_2O]_T)$, where $[NH_3]_F$ is assumed to be $[NH_3]_T-6[Cd^{2+}]_T$,[12] subscript T denoting the total concentration. f_N and f_O are the scattering factors of nitrogen and oxygen atoms, respectively. The values of 2.78 Å and 0.008 Å² were used as the distance and the temperature factor, respectively, of the H_2O–H_2O interaction in aqueous ammonia solution.[11] The same distance and temperature factor were used for the calculation of the NH_3–H_2O contacts.[9] The result is shown in Fig. 1b. Figure 1c shows the theoretical peak shapes of the atoms pairs which are taken into account in the present consideration. In this picture X means either O or N. A definite peak at 2.4 Å (chain line in Fig. 1b) can be ascribed to the Cd–N bond. The area under the peak

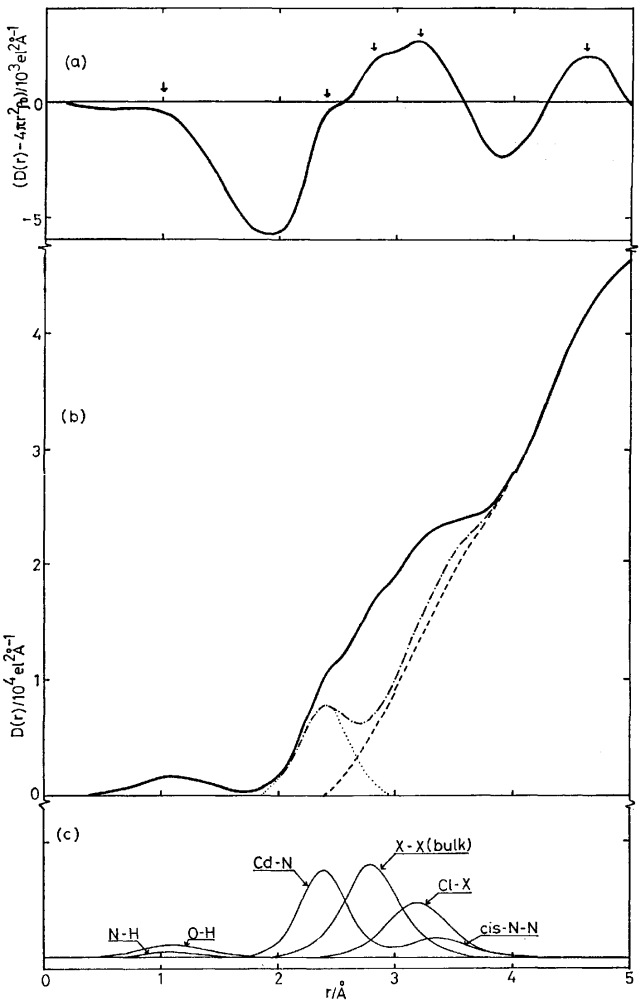

Fig. 1. The radial distribution curve of the sample solution. (a) The $(D(r)-4\pi r^2\rho_0)$ curve. (b) The $D(r)$ curve (solid line). The chain line shows the curve after subtraction of the theoretical peak shapes for the O–H and N–H bonds within H_2O and NH_3 molecules, respectively, the nearest neighbors X–X (*i.e.*, O–O and N–O) interactions in the bulk structure and the Cl–X bonds within the solvated chloride ions from the $D(r)$ curve. The dashed line shows the residual curve after subtraction of the theoretical peak shapes for the Cd–N and *cis*-N–N interactions within the hexaamminecadmium(II) complex. The dotted line is drawn by assuming that the curve having the maximum at 2.4 Å is Gaussian. (c) Theoretical peak shapes for each atom pair.

(dotted line) gave about six ammonia molecules neighboring with the central cadmium(II) ion. The peak can also be explained in terms of the formation of the $Cd(NH_3)_5(OH_2)^{2+}$ complex, because we cannot distinguish $Cd(NH_3)_6^{2+}$ ion from $Cd(NH_3)_5(OH_2)^{2+}$ ion by the present X-ray diffraction technique as far as the Cd–N bond length does not significantly differ from the length of the Cd–O bond. However, the Raman spectrum of the solution revealed a polarized band at (341 ± 2) cm^{-1}, which is assigned to the totally symmetric Cd–N stretching vibration. The frequency agreed well with that of the hexaamminecadmium(II) complex in the solid phase.[3] Therefore, we concluded that the hexaamminecadmium(II) complex is the main species in the present sample solution and that the peak at 2.4 Å is due to six Cd–NH_3 bonds. Subtraction of the theoretical peak due to the Cd–NH_3 bonds, together with the peak due to the *cis*-N–N contacts within the complex, from the residual curve (chain line in Fig. 1b) led to a smooth background curve (dashed line). The Cd–N bond distance finally determined was (2.37 ± 0.03) Å. The bond is slightly longer than the Cd–OH_2 bond (2.31 Å) within the hexaaquacadmium(II) ion.[7]

No other intramolecular interaction could be found, since no appreciable peak was observed in the background curve in the range of $r<4$ Å.

The broad peak around 4.6 Å may be related to the interactions between cadmium(II) ions and ligand molecules (water and ammonia molecules and chloride ions) in the second coordination layer.

The present work has been partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education.

Studies on 1,2,4-Thiadiazolidine Derivatives. IV.[1] The Isomers of 2,4-Disubstituted 3,5-(Disubstituted imino)-1,2,4-thiadiazolidines

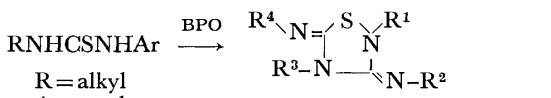
Takeshi KINOSHITA,* Sadao SATO, and Chihiro TAMURA

Central Research Laboratories, Sankyo Co., Ltd., Hiromachi Shinagawa-ku, Tokyo 140

(Received April 21, 1978)

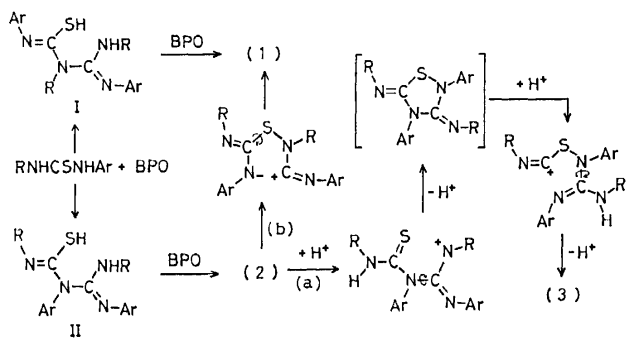
Synopsis. Several 2-alkyl-5-alkylimino-4-aryl-3-arylimino-1,2,4-thiadiazolidines and 4-alkyl-5-alkylimino-2-aryl-3-arylimino-1,2,4-thiadiazolidines were synthesized by the oxidation of 1-alkyl-3-arylthioureas with benzoyl peroxide along with 2,4-dialkyl-3,5-bis(arylimino)-1,2,4-thiadiazolidines.

In a previous paper,[2] we reported that the oxidation of 1-alkyl-3-arylthioureas with benzoyl peroxide (BPO) was found to afford 2,4-dialkyl-3,5-bis(arylimino)-1,2,4-thiadiazolidines (**1**) and their isomers (**2** and **3**), and the three positional isomers of **1**,[2] **2**,[3] and **3**[4] were determined by X-ray analyses.



1; $R^1=R^3=$alkyl, $R^2=R^4=$aryl
2; $R^1=R^4=$alkyl, $R^2=R^3=$aryl
3; $R^1=R^2=$aryl, $R^3=R^4=$alkyl

In the course of the studies on 1,2,4-thiadiazolidines, **2** was found to be rearranged into **1** and/or **3** depending on the reaction conditions, whereas **1** and **3** could not be further converted into any of the other type isomers, which are reported herein. When the following solutions of **2** were allowed to stand for a week at room temperature, each solution gave the mixture of 1,2,4-thiadiazolidines (%): **2a** (1.5 mg) in CH_2Cl_2–AcOH (500 μl–50 μl); **1a**: **2a**: **3a**=8: 0: 92, **2a** (1.5 mg) in CH_2Cl_2–AcOH–pyridine (500 μl–50 μl–50 μl); **1a**: **2a**: **3a**=68: 18: 14, **2a** (1.5 mg) in CH_2Cl_2–AcOH–pyridine (500 μl–50 μl–100 μl); **1a**: **2a**: **3a**=53: 44: 3.



Scheme 1.

From the above results, it may be concluded that the rate of the isomerization of **2** to **3** is accelerated by acid but decelerated by the addition of base. Furthermore the more the base added, the less **3** and the more **1** are produced. However, the total rate of the rearrangement of **2** is reduced when a base is added. Consequently, for the purpose of obtaining **3** from the oxidation of thioureas with BPO, no addition of base is preferable, whereas for the purpose of obtaining the labile isomer **2**, the addition of base to the reaction system is preferable. Table 1 shows the ratio of these products for the oxidation of some thioureas with BPO in dichloromethane–pyridine (8: 1). As shown in Table 1, **2** was gradually converted mainly into **1** in the presence of pyridine, whereas in the acidic medium† converted mainly into **3**. In view of these results the formation of **1** and **2** is expected to proceed through the intermediates I and II,[5] and in the case of **3**, it may be formed through route (a) as shown in Scheme 1. There is no definitive information on a driving force for the isomerization of **2** to **1** (route (b)). The physical properties and analytical data for the 1,2,4-thiadiazolidines (**2** and **3**) are summarized in Table 2.

produce the other type isomers (**2** and **3**) under their experimental conditions.

Experimental

Materials. Commercially available benzoyl peroxide of a reagent grade was used. Thiourea derivatives were prepared according to methods in the literature.[7]

Preparation of 2-Alkyl-5-alkylimino-4-aryl-3-arylimino-1,2,4-thiadiazolidines (2). The following procedure illustrates the general method. From a dropping funnel, a solution of BPO (1.4 g, 5.8 mmol) in CH_2Cl_2–pyridine (80 ml: 10 ml) was added to a solution of 1-methyl-3-phenylthiourea (0.83 g, 5 mmol) in CH_2Cl_2–pyridine (80 ml: 10 ml) at 5—10 °C, and the reaction mixture was stirred for 1 h at 5—10 °C. The reaction mixture was washed with an aqueous solution of NaOH to remove benzoic acid, and the solvent was evaporated *in vacuo*, and the residue was subjected to preparative TLC on alumina eluting with ethyl acetate–petroleum ether (1: 3) to give 0.11 g of 2-methyl-5-methylimino-4-phenyl-3-phenylimino-1,2,4-thiadiazolidine (**2a**) along with 0.25 g of **1a** and 0.04 g of **3a**. An analytical sample was recrystallized from ether.

Preparation of 4-Alkyl-5-alkylimino-2-aryl-3-arylimino-1,2,4-thiadiazolidines (3). A typical run is as follows: a solution of BPO (14 g, 58 mmol) in CH_2Cl_2 (200 ml) was added dropwise to a solution of 1-methyl-3-phenylthiourea (8.3 g, 50 mmol) in CH_2Cl_2 (200 ml) at 5—10 °C, and the reaction mixture was stirred for 1 h at 5—10 °C and allowed to stand for 14 days at 15—20 °C. The reaction mixture was washed with an aqueous solution of NaOH, and the solvent was evaporated *in vacuo*, and the residue was dissolved in cold acetone and filtered to remove the insoluble sulfur. The filtrate was subjected to column chromatography on silica gel eluting with ethyl acetate–petroleum ether (1: 6) to give 2.8 g of 4-methyl-5-methylimino-2-phenyl-3-phenylimino-1,2,4-thiadiazolidine (**3a**) along with 4.1 g of **1a**. An analytical sample was recrystallized from ethanol.

Asymmetric Synthesis of Alanine by Hydrogenolytic Asymmetric Transamination between (*R*)-2-Amino-2-phenylethanol and Ethyl Pyruvate[1)]

Kaoru HARADA* and Minoru TAMURA

Department of Chemistry, The University of Tsukuba, Niihari-gun, Ibaraki 300-31

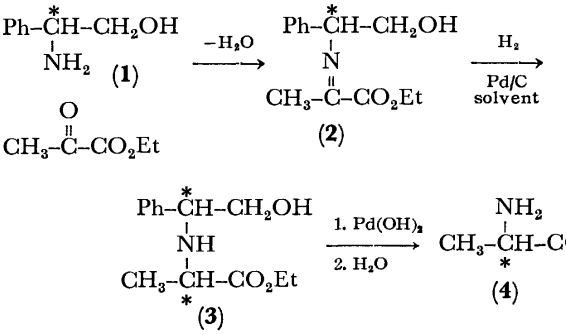
(Received August 4, 1978)

Synopsis. Hydrogenolytic asymmetric transamination between (*R*)-2-amino-2-phenylethanol and ethyl pyruvate was studied. The optical purity of the resulting alanine was in the range 10—62 %. The effect of solvents and the asymmetric moieties in the syntheses were explained by the chelation hypothesis based on the substrate-catalyst complex.

In the previous study from this laboratory, hydrogenolytic asymmetric transaminations between optically active α-alkylbenzylamines, (*R*)-phenylglycine, or alkyl (*R*)-phenylglycinate and ethyl pyruvate were studied.[2-5)] The effect of the asymmetric moieties and the solvents used in the asymmetric syntheses was explained by the chelation hypothesis.[2-5)]

In the present study, in order to extend the application of the chelation hypothesis, the asymmetric transamination between optically active amino alcohol (**1**) and ethyl pyruvate was carried out. (*R*)-2-Amino-2-phenylethanol (**1**) was prepared from ethyl (*R*)-phenylglycinate by reduction with lithium aluminium hydride. Alcohol **1** and ethyl pyruvate were dissolved in benzene to form the Schiff base (**2**), which was hydrogenated by the use of palladium on charcoal in various solvents and then hydrogenolyzed with palladium hydroxide on charcoal and the reaction product was hydrolyzed to form alanine. The resulting alanine was purified by the use of a Dowex 50 column; The yield was in the range 46—73%. A part of alanine was converted into DNP-alanine with 2,4-dinitrofluorobenzene and the resulting DNP-alanine was purified by celite column chromatography. The optical purity of DNP-alanine was in the range 10—62%. The results are summarized in Table 1.

In all these kinds of reactions, the configuration of the resulting alanine was (*S*). When a polar solvent was used, the optical purity was lower and when a less polar solvent was used, the optical purity of alanine increased steadily (Fig. 1, R=CH_2OH). The results could be explained by assuming the substrate-catalyst complex as in the previous studies (Fig. 2).[2-5)] In a less polar solvent, the substrate-catalyst complex (**2a**) could be formed prior to hydrogenation. However, in a polar solvent, the amount of **2a** would decrease and the non-chelated structure **2b** would increase because of the



Scheme 1.

a) Calculation based on ethyl pyruvate. b) Optical purity (O.P.) was difined as ($[\alpha]_D$ obsed/$[\alpha]_D$ in literature) ×100. DNP-(*S*)(+)-alanine, $[\alpha]_D^{25}$ +143.9 °C (1 M NaOH). c) The reaction mixtures were not homogeneous solutions.

stronger solvation of the substrate. In both structures **2a** and **2b**, the substrate would be adsorbed at the less bulky side of the molecules and then the hydrogenation would take place. In the case of **2a**, the adsorption would involve the rotation of the C–N bond. From the structures **2a** and **2b**, (*S*)- and (*R*)-alanine, respectively, were expected to form. The relationship between the R group (Fig. 2) of the asymmetric center and the optical activity was compared with the results obtained from the previous studies using (*S*)-α-methylbenzylamine[4] or methyl (*R*)-phenylglycinate[5] (Fig. 1). As the R group of **2a** becomes small, the difference in bulkiness between phenyl and the R groups increases, the optical purity of the resulting alanine would become higher. When the R group becomes larger, the optical activity would decrease. It was found in the present reactions (R= CH_2OH) that the optical purities were lower than those of the reactions using (*S*)-α-methylbenzylamine (R= CH_3)[4] and were higher than those of the reactions using methyl (*R*)-phenylglycinate (R=$COOCH_3$).[5] This suggests that the hydroxymethyl group would be in the bulkiness between methyl and carboxy methyl groups. These results indicate that the chelation hypothesis could also be applied to the hydrogenolytic transamination between alcohol (**1**) and ethyl pyruvate.

Experimental

The NMR spectra were obtained by using a Hitachi H-60 instrument, and the IR spectra were measured with a Hitachi 215 type grating infrared spectrophotometer. The specific rotations were measured with a JASCO DIP-181 type digital polarimeter using a 50 mm cell.

(R)-2-Amino-2-phenylethanol (1). A mixture of (*R*)-phenylglycine ($[\alpha]_D^{25}$ −163° [*c*=1.13, 5 M HCl])[6] (20 g, 0.133 mol) and absolute ethanol (300 ml) was treated with thionyl chloride at temperatures from −5 to −10 °C for 1 h. The temperature was allowed to rise to 40 °C at which it was kept for 4 h. The resulting mixture was evaporated to dryness. The residual white solid was dissolved in a small amount of water and the solution was made alkaline by adding 3 M NaOH and 50% potassium carbonate with stirring at −10 °C. The separated ethyl (*R*)-phenylglycinate was extracted with ether twice. The ether layer was dried with sodium sulfate in a refrigerator overnight and the ester was distilled under reduced pressure 98—99 °C/2 Torr, yield 18.5 g (77%) $[\alpha]_D^{25}$ −125° (*c*=1.42, EtOH).[7] δ ($CDCl_3$): 1.15 (3H, t, *J*= 6.6 Hz), 1.90 (2H, s), 4.10 (2H, q, *J*=6.6 Hz), 4.50 (1H, s), 7.25 (1H, s). Ethyl-(*R*)-phenylglycinate (14.2 g, 0.08 mol) was dissolved in 100 ml of dry ether and the solution was added dropwise to a mixture of lithium aluminium hydride (9.0 g, 0.24 mol) and 300 ml of dry ether under vigorous stirring. After being stirred for 2 h, the mixture was cooled to −10 °C and a small amount of water was added with stirring. The aluminium hydroxide precipitated was removed by filtration and the precipitate was washed thoroughly with ether three times. The combined ether solution was evaporated to dryness, and the residual oil crystallized by washing with hexane. The slightly yellow crystals (**1**) (yield 9.57 g, 87%) were recrystallized from benzene to yield colorless needles. Mp 75—76 °C, $[\alpha]_D^{25}$ −27.3° (*c*=1.08, methanol).[8] Found: C, 70.17; H, 8.09; N, 10.04 %. Calcd for $C_8H_{11}NO$: C, 70.04; H, 8.08; N, 10.21%. IR(KBr): 3310, 3250, 2900, 2820, 1600, 1490, and 1450 cm^{-1}; δ($CDCl_3$): 2.70 (3H, br, s, NH_2 and OH), 3.3—4.2 (3H, ABC multiplet), 7.2 (5H, s).

Alanine (4). The aminoalcohol **1** (1.0 g, 7.3 mmol) and ethyl pyruvate (0.847 g, 7.3 mmol) were dissolved in 20 ml of dry benzene. The mixture was stirred at room temperature for 4 h with anhydrous sodium sulfate. After separation of sodium sulfate by filtration, the filtrate was evaporated to dryness. The residual light yellow oil (**2**) was dissolved in 20 ml of dry benzene and hydrogenated with 5% palladium on charcoal (1.5 g) for 24 h at 1 atm. After the reaction was over, the catalyst was removed by filtration and washed with 3 M hydrochloric acid. The combined solution was evaporated to dryness under reduced pressure. The residue was dissolved in a small amount of water and the pH was adjusted to about 4.5 with the use of sodium hydrogen carbonate. Palladium hydroxide on charcoal (1.0 g) was added to the solution and hydrogenolysis was carried out for 24 h. After the reaction was completed, the catalyst was removed by filtration and the filtrate was evaporated to dryness. The resulting ethyl alaninate was hydrolyzed with 3 M hydrochloric acid under reflux for 4 h. After evaporation of hydrochloric acid under reduced pressure, the residue was dissolved in a small amount of water and the solution was applied to a Dowex 50 column (H^+ form). The column was eluted with 3 M aqueous ammonia and the solution was evaporated to dryness under reduced pressure. The residue was dissolved in 4% sodium hydrogencarbonate and washed with ethyl acetate three times to remove a small amount of **1**. The aqueous solution was acidified with 3 M hydrochloric acid and evaporated to dryness and the residue was extracted with absolute ethanol. The alcoholic solution was evaporated to dryness *in vacuo* and free alanine was obtained by using a Dowex 50 column. The yield of the resulting alanine[9] was 0.366 g (56 %). The alanine was converted into DNP 2,4-dinitrophenylalanine in the usual way,[2] and the resulting DNP derivative was purified by the use of a celite column treated with pH 6.8 phosphate buffer. The specific rotation of the DNP-(*S*)-alanine was: $[\alpha]_D^{25}$ +89.6° (*c*=1.00, 1 M NaOH); optical purity 62%.

Liquid Phase Peptide Synthesis by the Fragment Condensation on Soluble Polymer Support. II.[1] The Azide Method

Mitsuaki NARITA

Department of Industrial Chemistry, Tokyo University of Agriculture and Technology, Nakamachi, Koganei, Tokyo 184

(Received August 10, 1978)

Synopsis. Fragment condensation on a soluble polymer support by the azide method gave rise to the efficient coupling (94—99% yield) of an *N*-protected tetrapeptide azide with the amino acid anchored to the soluble polymer support. Bulkiness of amino acid residues on the polymer support did not affect the reactivity toward the peptide azide.

The azide method[2] is one of the most important coupling procedures for the formation of the peptide bond and has been used for over 70 years. The major reason for its wide use in peptide synthesis is the fact that it is free from racemization during the course of coupling reaction, allowing the synthesis of long peptide fragments with minimum protection on the amino acid side chains.[3] However, the method was not extensively used in solid phase peptide synthesis because the procedure involves a process of isolation or the extraction of the azide, and the coupling yield is not very high (about 50—80%).[4-7] We report here an efficient fragment condensation procedure on the soluble polymer support by a modified azide method of Mazur and Schlatter[8] in a nonaqueous system without the extraction of azide.

In order to test the efficiency of the azide coupling reaction on the soluble polymer support, the tetrapeptide azide, Boc–Tyr(Bzl)–Gly–Gly–Phe–N_3 (**1**),[9] was allowed to react with H–Leu–OCH_2–resin, H–Gly–OCH_2–resin, and H–Val–OCH_2–resin (H–A·A–OCH_2–resin) as shown in Scheme 1.

Boc–Tyr(Bzl)–Gly–Gly–Phe–$NHNH_2$

1. Neutralization of HCl with Et_3N, 2. H–A·A–OCH_2–resin; −30——35 °C, 1 day; −8——15 °C, 2 days, in DMF

Boc–Tyr(Bzl)–Gly–Gly–Phe–A·A–OCH_2–resin

Scheme 1.

The tetrapeptide hydrazide, Boc–Tyr(Bzl)–Gly–Gly–Phe–$NHNH_2$, was converted into **1** in nonaqueous system (DMF) by treatment with hydrogen chloride followed by butylnitrite at −30——40 °C for 40 min. After neutralization of hydrogen chloride with triethylamine, H–A·A–OCH_2–resin was reacted with **1** at −30——35 °C for 1 day and at −8——15 °C for 2 days. The solution was poured into methanol to precipitate peptide resin. In each case, the recovery of the resulting peptide resin by pouring the reaction mixture into methanol was more than 95% on the assumption that the reaction proceeded quantitatively. Amino acid ratios in acid hydrolysates of the resulting peptide resins are summarized in Table 1. The yields in the coupling reactions of the azide **1** with H–Leu–OCH_2–resin, H–Gly–OCH_2–resin, and H–Val–OCH_2–resin were 95, 99, and 94%, respectively, on the basis of the average values of amino acid ratios.

Table 1. Amino acid analyses[a] of Boc–Tyr(Bzl)–Gly–Gly–Phe–A·A–OCH_2–resins and coupling yields of the azide method

H–A·A–OCH_2–resin	Amino acid content (mmol/g)					Average yield of coupling[b] (%)
	Tyr[c]	Gly	Phe	Leu	Val

H–Gly–OCH_2–resin	0.31	1.06	0.35			99
H–Val–OCH_2–resin	0.44	0.99	0.49		0.52	94

a) Carried out under the following conditions: resin, 19—23 mg; propionic acid, 4 ml; 12 M HCl, 2 ml; 115 °C; 35 h. b) Determined with use of average values of Gly and Phe contents. c) Acid hydrolysis of tyrosyl peptides usually give low recovery of Tyr.[10]

The results indicate that the azide method enables efficient coupling of the *N*-protected peptide azide with amino free terminals on the soluble polymer support, and that the bulkiness of amino acid residues on amino free terminals does not affect the reactivity of the peptide azide.

Experimental

Soluble chloromethylated polystyrene, H–Leu–OCH_2–resin (Leu content, 0.62 mmol/g), and Boc–Tyr(Bzl)–Gly–Gly–Phe–OMe, prepared previously were used; DMF was purified as reported.[1] Optical rotations were taken in a 1-dm cell on a Jasco Model ORD/UV-5 optical rotatory dispersion recorder. Amino acid analysis was carried out on a Hitachi Liquid Chromatograph, Model 034. Hydrolysis of peptide resins was carried out on 19—23 mg samples of resins with propionic acid–12 M HCl (2: 1 v/v) at 115 °C for 35 h.

H–Gly–OCH_2–resin and H–Val–OCH_2–resin. Esterification of the chloromethylated polystyrene with Boc–Gly–OH and Boc–Val–OH was carried out at room temperature for 5 days. After attachment of Gly and Val to the polymer supports, residual benzylic chlorides were removed by the reaction with sodium acetate in DMF at 105 °C for 24 h. The final chlorine contents were less than 0.02 mmol/g. Removal of Boc group with HCl–THF and neutralization of HCl with triethylamine were performed according to the procedure given by Green and Garson.[11] H–Gly–OCH_2–resin: Gly content, 0.41 mmol/g; H–Val–OCH_2–resin: Val content, 0.69

mmol/g (amino acid analysis).

Boc–Tyr(Bzl)–Gly–Gly–Phe–NHNH$_2$. To Boc–Tyr-(Bzl)–Gly–Gly–Phe–OMe (2.80 g, 4 mmol) in 30 ml of methanol was added 1 ml of 80% hydrazine hydrate and the solution was allowed to stand for 40 h at room temperature. To this was added 100 ml of ether and the solution was kept in a refrigerator overnight. The precipitate was filtered off to give 1.50 g of a substance, the additional hydrazide (0.58 g) being obtained from the mother liquor. Recrystallization from methanol gave the substance: mp 188—190°C, $[\alpha]_D^{21} = +12.4°$ ($c=1.0$, CH_3COOH). Found: C, 62.23; H, 6.31; N, 13.46 %. Calcd for $C_{34}H_{42}N_6O_7$: C, 63.14; H, 6.55; N, 13.00 %. Amino acid ratios: Gly 1.94, Tyr 0.89, and Phe 0.99.

Coupling Reaction of Boc–Tyr(Bzl)–Gly–Gly–Phe–N$_3$ with H–Leu–OCH$_2$–resin, H–Gly–OCH$_2$–resin, and H–Val–OCH$_2$–resin. In a typical experiment, 223 mg (0.36 mmol) of Boc–Tyr(Bzl)–Gly–Gly–Phe–NHNH$_2$ in 20 ml of DMF was cooled to −40 °C with stirring. 565 mg of THF containing 130 mg (3.6 mmol) of hydrogen chloride was added followed by 37 mg (0.36 mmol) of butyl nitrite in 2 ml of DMF. After being kept at −30——40 °C for 40 min, 400 mg (4.0 mmol) of triethylamine in 3 ml of DMF was added. To the peptide azide solution in threefold excess was then added H–Leu–OCH$_2$–resin (200 mg, Leu content: 0.124 mmol). The mixture was stirred at −30——40 °C for 30 min and kept at −30——35 °C for 1 day and −8——15 °C for 2 days. The reaction mixture was poured into 200 ml of methanol followed by the addition of 30 ml of saturated aqueous sodium chloride in order to precipitate the peptide resin. The precipitates were filtered off, and washed successively with water and methanol in order to remove the soluble reactants. The coupling reactions of Boc–Tyr(Bzl)–Gly–Gly–Phe–N$_3$ with H–Gly–OCH$_2$–resin and H–Val–OCH$_2$–resin were carried out in the same manner. Racemization under the reaction conditions mentioned above was tested by the Izumiya method.[12] Less than 0.5 mol % of Gly–D-Ala–L-Leu was detected by ion exchange chromatography.

Photolyses of Azidotriazines in Organic Nitro Compounds

Tsuruji GOKA, Yoji HASHIDA, and Kohji MATSUI*

Department of Chemistry, Faculty of Engineering, Gunma University, Kiryu, Gunma 376

(Received August 11, 1978)

Synopsis. Triazinylnitrenes were found to be inert towards nitro compounds. They afforded the products derived from the combination of two molecules of the starting materials.

Nitrene chemistry has been extensively studied and well established.[1] Recently, we reported some photochemical reactions of azidotriazines in aprotic solvents such as nitriles,[2] acetone,[3] and DMSO;[4] triazinyl nitrene reacts with nitriles and acetone to yield a cycloaddition product, while its reaction with DMSO give an ylide. We now wish to report the photochemical reaction of azidotriazines in nitro compounds.

Experimental

Azidotriazines (**1**) were prepared by treating the corresponding chlorotriazines with sodium azide[5] (Table 1).

The experimental produre was almost the same as those described previously.[2-4]

TABLE 1. 4,6-DISUBSTITUTED 2-AZIDO-1,3,5-TRIAZINE[a]

Compound	Substituent 4-	Substituent 6-	Mp(°C)	Solvent for recryst.
1a	OMe	OMe	85—85.5[b]	Ligroin
1b	OEt	OEt	31—32	Petroleum ether
1c	O-*i*-Pr	O-*i*-Pr	30—31	Petroleum ether
1d	OMe	NMe_2	116—117	Ligroin
1e	NMe_2	NMe_2	106—107[b]	Benzene

a) Satisfactory chemical analyses (±0.5%) were obtained for all compounds. b) Ref. 5.

Results and Discussion

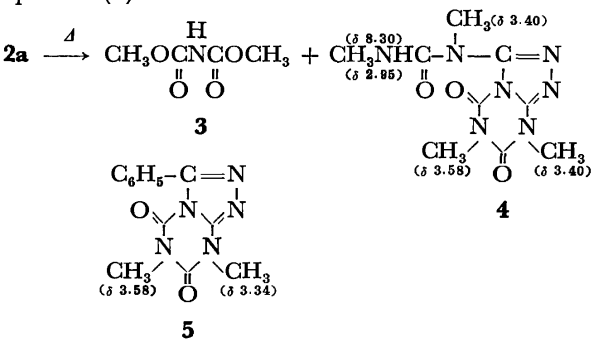
*Photolyses of 2-Azido-4,6-dimethoxy-1,3,5-triazine (**1a**) in Nitro Compounds.* When 2-azido-4,6-dimethoxy-1,3,5-triazine (**1a**) was irradiated in several nitro compounds, the same photoproduct (**2a**) was obtained regardless of the solvents employed (Table 2).

TABLE 2. THE PHOTOCHEMICAL REACTIONS OF 2-AZIDO-4,6-DIMETHOXY-1,3,5-TRIAZINE

Solvent	Yield (%) of **2a**
$MeNO_2$	26
$EtNO_2$	32
i-$PrNO_2$	40
$PhNO_2$	23

The mass spectrum of **2a** has a parent peak at *m/e* 311. The PMR spectrum indicates the presence of one active hydrogen atom and 4 kinds of methyl groups, each of which was observed as a singlet.

2g gave a dimethylester (**3**)[6] of dimethyl iminodicarbonate and **4** upon heating in cumene at 190 °C, indicating that **2a** has a skeleton of **4**. The structure of **4** was assigned on the basis of its mass spectrum and by a comparison of its PMR spectrum to those of the known compound (**5**).[2]



Moreover, **2a** gave **3** as the major product in a very good yield (1 mol of **2a** gave 1.7 mol of **3**) when treated with diluted hydrochloric acid at 40 °C. The results suggest that i) in **2a** the methyl groups in the triazine ring exist as methoxyl groups, and ii) **2a** does not have a aromatic stabilization, because ordinary 1,3,5-triazine derivatives are known to be stable to a treatment with dilute acid.

Effects of Substituents in Triazine Nucleus. Substituents in the triazine nucleus were found to affect the photochemical reactions of azidotriazines in nitro compounds (Table 3). The physical and analytical data of compounds (**2**) are collected in Table 4. In the cases of azidotriazines (**1d** and **1e**), in which the electron-donating NMe_2 groups are found, the corresponding reactions did not take place. In addition, when **1b** was irradiated in the presence of benzophenone, the corresponding aminotriazine was obtained in 18% yield. These results clearly suggest that the reaction to give **2a** involves singlet triazinylnitrene, which has an electrophilic character.[1,4] In the reactions of azidotriazine (**1b**) containing OEt groups, a similar photoproduct was also obtained. On the other hand, the yield

TABLE 3. THE PHOTOCHEMICAL REACTIONS OF AZIDOTRIAZINES

Azidotriazine	Condition	Yield(%) of **2**(product)
1a	a)	26 (**2a**)
1b	a)	19 (**2b**)

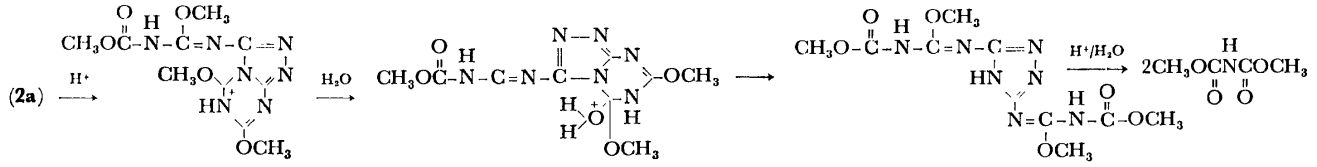
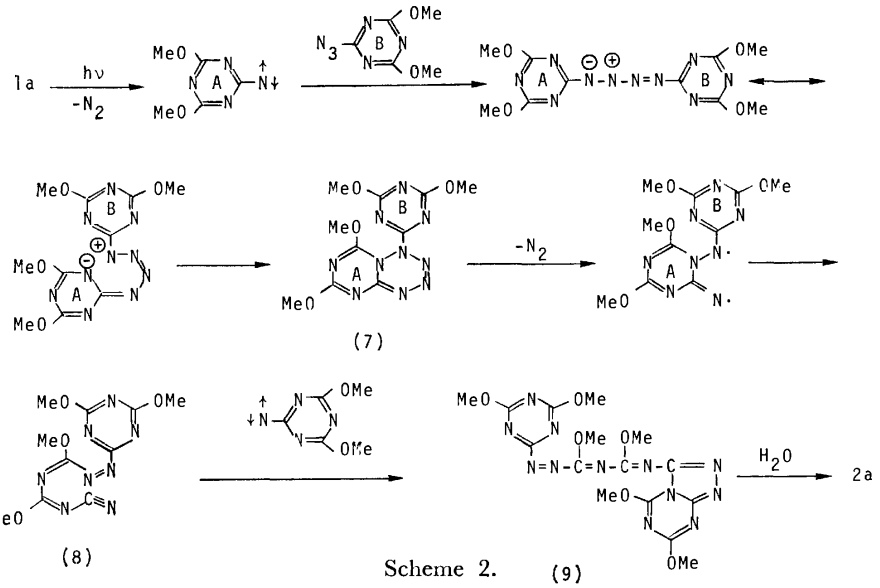
1e	a)	—

a) Irradiation was performed in nitroethane. b) Neat sample was irradiated. c) Irradiation was performed in water. d) Irradiation was performed in nitroethane under bubbling oxygen.



Scheme 1.

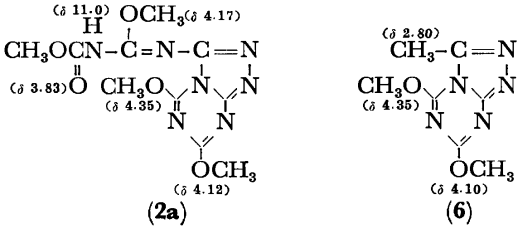


Scheme 2.

Table 4. The physical and analytical data of compounds (**2**)

2	Mp(°C)	Solvent for recryst.	Found (Calcd)% C	H	N	MS *m/e*
2a	198—199	Chloroform	38.65 (38.59	4.55 4.21	31.97 31.50)	311
2b	184—185	Benzene	45.98 (45.77	5.95 5.76	26.91 26.69)	367
2c	162—163	Benzene	51.37 (51.05	7.12 6.90	29.36 23.15)	423

of photoproduct increased considerably when a small amount of water was added into the reaction mixture, showing that water participates in the reaction. From the results described above and a comparison of the PMR data of **2** with those of the known compound (**6**),[2] the constitution of **2a** was assumed to be as shown below:



(**2a**)

(**6**)

A probable process of the decomposition of **2a** in the presence of hydrochloric acid is shown in Scheme 1.

On the other hand, in the reactions of azidotriazine (**1c**) in nitroethane in the presence of oxygen, a remarkable decrease in the yield of the photoproduct was observed (Table 3), indicating that the reaction involves the radical process.

Although several pathways could account for the formation of **2**, the most likely one is shown in Scheme 2. That is, singlet triazinylnitrene produced by the photolysis of azidotriazine electrophilically attacks upon the terminal nitrogen of azido group[7] to yield an ylide which cyclizes to give a pentazine (**7**). Then the intermediate (**7**) gives a derivative of nitrile (**8**) under a cleavage of nitrogen and a ring opening of the triazine nucleus (A). Electrophilic attack of singlet triazinylnitrene may occur not only at the azido group but also at the nitrile group of **8**. However, the nucleophilic reactivity of the –CN group in **8** would be much higher than that of the azido group of **1a**, because the –CN group is attached to a conjugated position involving two strong +R(–OCH_3) groups, while the azido group is connected to the electron-withdrawing triazine nucleus. Therefore, electrophilic attack of the singlet triazinyl nitrene should occur upon the –CN group preferentially to give a cycloaddition product (**9**). Finally, the product (**9**) hydrolyzes by water to give the final product (**2a**).

BULLETIN OF THE CHEMICAL SOCIETY OF JAPAN, VOL. 52 (4), 1233—1234 (1979)

The Cross-Aldol Reaction of 3-Alkoxy-2-cyclohexen-1-ones with α,β-Enals. A Synthesis of 4-(*trans*-2-Butenylidene)-3,5,5-trimethyl-2-cyclohexen-1-ones

Sigeru Torii,* Tsutomu Inokuchi, and Hidenori Ogawa

Department of Industrial Chemistry, School of Engineering, Okayama University, Tsushima, Okayama 700

(Received October 5, 1978)

Synopsis. The cross-aldol reaction of 3-alkoxy-2-cyclohexen-1-ones with α,β-enals afforded the corresponding 3-alkoxy-6-(1-hydroxy-2-alkenyl(or aryl)-2-cyclohexen-1-ones in 78—98 % yields. The condensation of a kinetic enolate anion of 3-ethoxy-5,5-dimethyl-2-cyclohexen-1-one with *trans*-2-butenal, and subsequent dehydration together with methylation, afforded 4-(*trans*-2-butenylidene)-3,5,5-trimethyl-2-cyclohexen-1-ones, one of the most important constituents of tobacco flavour, in a 74% yield.

Vinylogous aldols have recently become available by means of the cross-aldol reaction of α,β-enones[1a] and alkanals[1b] with a kinetic enolate anion of 1,3-diketone enol ether. In this paper, we will describe their reactions with alicyclic 1,3-diketone enol ethers and α,β-enals as well as the preparation of 4-(*trans*-2-butenylidene)-3,5,5-trimethyl-2-cyclohexen-1-ones (**4**),[2] characteristic flavouring components of Burley[2a,b] as well as Greek[2c] and Turkish[2d] tobaccos.

The cross-coupling[3] of a kinetic enolate anion of **1a** with *trans*-2-butenal at −78 °C for 5 min gave the corresponding aldol **2a** (R^1=Me, R^2=Et, R^3=–HC=CHMe) in a 98% yield. The yields and the *threo/erythro* ratios of the cross-aldol condensation of **1** with various α,β-enals are shown in Table 1.

Table 1. Yields of aldols and *threo/erythro* ratios

1,3-Diketone enol ether **1**	α,β-Enal	Product **2**	Yield, %	*threo/erythro* Ratio
1a	*trans*-2-butenal	**2a**	98	93/7[a]
1a	citral	**2b**	98	89/11[a]
1b	*trans*-2-butenal	**2c**	92	90/10[a]
1c	benzaldehyde	**2d**	96	67/33[b]
1c	2-furaldehyde	**2e**	78	67/33[c]

a) The gross ratios of *threo/erythro* were estimated by comparison with the heights of the ^{13}C NMR signals at the carbon of CH–OH of each compound measured in a NNE mode under the conditions of a 60 ° pulse and a 30 s pulse repetition. b) Estimated by the separation of each isomer through column chromatography on SiO_2 on the bases of ^1H NMR signals at δ 4.77 (d, J=9 Hz), and 5.51 (d, J=3Hz). c) Estimated by comparison with the ^1H NMR signals at 4.86 (d, J=9 Hz) and 5.38 (d, J=3 Hz).

The treatment of a *threo/erythro* mixture of **2a** (R^1=Me, R^2=Et, R^3=–HC=CHMe) with methanesulfonyl chloride in pyridine at 0 °C for 1 h, and subsequent heating at 45—50 °C for 2 h, afforded the dehydrated product **3** in an 89% yield. The reaction of the enone **3**, without isolating each geometrical isomer at the C-7 carbon, with methyllithium at 0 °C in ether, followed by stirring at room temperature for 1 h, gave a mixture of **4a** and **4b** in an 85% yield. The gross abundance of the isomers **4a** and **4b**[4] was estimated from the heights of the ^{13}C NMR signals at the C-10 methyl group, giving the ratio of 7 to 4.

We have found that the reaction of the kinetic enolate anion of **1** with α,β-enals is completed within a few minutes at −78 °C without the use of a chelating reagent. It is reasonable to argue that the electron-donating nature of the alkoxyl group for the conjugated enone systems would contribute to the stabilization of lithium alcoholate, which is assumed to be the bidentate chelate **5**, and that this would prevent the progress of the counter-aldol reaction of the condensate **2**. In contrast to the alkoxyl-stabilized enone systems, aldols derived from the reaction of kinetic enolate anions of simple α,β-enones with carbonyl compounds are generally unobtainable without employing a chelating reagent.[5]

We have found that the aldols **2** consist 67—93% of *threo*-rich stereomers (Table 1), which are assumed to suggest a transition state which implies the specified orientation of the enolates of **1** and enals. Therefore, it is necessary to postulate that the favorable attack of the carbanion of **1** would occur on the less hindered side of the carbonyl group of enals.

Experimental

The melting and boiling points are uncorrected. The instruments used in analyses have been described elsewhere.[1b]

*3-Ethoxy-6-(*trans*-1-hydroxy-2-butenyl)-5,5-dimethyl-2-cyclohexen-1-one (**2a**, R^1=Me, R^2=Et, R^3=–HC=CHMe).* To a cold solution (−78 °C) of *i*-Pr_2NLi (578 mg, 5.4 mmol) in THF (6 ml) we added a solution of **1a** (505 mg, 3.0 mmol) in THF (3 ml). After the mixture had been stirred for 6 h, *trans*-2-butenal (316 mg, 4.5 mmol) was added and the solution was stirred for 5 min at −78 °C. The mixture was

The Reaction of 3,5-Diphenyl-1,2-dithiolium Perchlorate with Active Methylenes

Isao SHIBUYA

National Chemical Laboratory for Industry, 2-19-19 Mita, Meguro-ku, Tokyo 153

(Received August 21, 1978)

Synopsis. 3,5-Diphenyl-1,2-dithiolium perchlorate (**1**) was synthesized in a new, convenient way, and the reaction of **1** with several active methylene compounds was studied. The compounds possessing no less than one ester group gave novel products, 3-substituted 4,6-diphenyl-2*H*-thiopyran-2-ones, while those possessing a carbamoyl group gave 3-substituted 2-hydroxy-4,6-diphenylpyridines or 3-cyano-1,4,6-triphenyl-2-pyridone. Malononitrile, however, gave 1-mercapto-1,3-diphenyl-4,4-dicyanobutadiene (**10**). On treatment with methyl iodide or *p*-chlorobenzyl chloride, **10** gave 1-methylthio- or 1-(*p*-chlorobenzylthio)-1,3-diphenyl-4,4-dicyanobutadiene, and also led to bis(1,3-diphenyl-4,4-dicyanobutadienyl) disulfide on treatment with hydrogen peroxide.

The reaction of 3-alkylthio-1,2-dithiolium salts or 1,2-dithiol-3-thiones with active methylenes gives 1,2-dithiol-3-ylidene derivatives with the liberation of methanethiol or hydrogen sulfide.[1] However, it is difficult to suppose that 3,5-diaryl- or 3,5-dialkyl-1,2-dithiolium salts give 1,2-dithiol-3-ylidenes by the same reaction course. There is thus an interest in the study of the behavior of these salts toward active methylenes. In this investigation, the reaction of 3,5-diphenyl-1,2-dithiolium perchlorate (**1**) with several active methylenes was checked, and some new information was obtained.

Results and Discussion

The synthesis of **1** has already been done by two methods.[2,3] In this study, another new method was applied: hydrogen sulfide was passed into a dibenzoylmethane–iron bromide(III) mixture in chlorobenzene, and simultaneously bromine was added drop by drop.

Methyl cyanoacetate, dimethyl malonate, ethyl benzoylacetate, ethyl carbamoylacetate, and methyl acetoacetate were refluxed with **1** in methanol to give novel products, **2**—**6** respectively, in good yields. According to their mass spectra, the molecular weights were measured and found to be 289, 322, 368, 307, and 306 respectively. The IR spectra of **2**—**6** resembled each other. The absorption assigned to an ester group was absent in the spectra of **2**, **4**—**6**; this fact suggested that an ester group of these reagents participated in these reactions. On treatment with *p*-toluenesulfonic acid, **4** easily gave 2,4,6-triphenylpyrylium salt, while releasing carbonyl sulfide. These spectral results, the chemical evidence, and their analytical data confirm that **2**—**6** are 3-cyano, 3-methoxycarbonyl, 3-benzoyl, 3-carbamoyl, and 3-acetyl-4,6-diphenyl-2*H*-thiopyran-2-one. The reaction courses seem to be shown in Scheme 1. This recyclization process resembles the reaction of 1,3-diphenyl-2-propyn-1-one with dimethyl malonate, which affords 3-methoxycarbonyl-4,6-diphenyl-2-pyrone.[4]

Cyanoacetamide, benzoylacetamide, or cyanoacetanilide was treated with **1** to give **7**, **8**, or **9** in a good yield. **7** and **8** were identified by direct comparison with the authentic samples and found to be 2-hydroxy-3-cyano- and 2-hydroxy-3-benzoyl-4,6-diphenylpyridines respectively.[5,6] With regard to **9**, its molecular weight was measured as 348. The IR spectrum and the

analytical data confirmed that **9** is 3-cyano-1,4,6-triphenyl-2-pyridone. The reaction course seems to be similar to the course by which thiopyran-2-ones are given; however, hydrogen sulfide is eliminated during the recyclization process.

Malononitrile gave only a thiol, **10**, on treatment with **1**. **10** remained unchanged on treatment because the cyano group of **10** may have no ability of cyclization. The reaction of **10** with methyl iodide or *p*-chlorobenzyl chloride afforded an alkylthiobutadiene, **11** or **12**, with the liberation of a hydrogen halide. **10** was easily oxidized by hydrogen peroxide to give a disulfide, **13**. The structures of **10**—**13** were identified by means of their IR and mass spectra and analytical data. The reaction of **1** with other active methylenes, such as dibenzoylmethane, nitromethane, 1,3-indandione, and benzoylacetonitrile, was also attempted, but it is failed to give any stable products.

Hence, it is proved that the reaction of 3,5-diphenyl-1,2-dithiolium perchlorate, **1**, with active methylenes proceeds as shown in Scheme 1.

Experimental

Preparation of 3,5-Diphenyl-1,2-dithiolium Perchlorate (1). Into a solution of dibenzoylmethane (23 g) and iron bromide-(III) (45 g) in chlorobenzene (175 ml), hydrogen sulfide was passed; simultaneously bromine (20 g) was stirred in, drop by drop, over a 30-min period. After that, the reaction temperature was gradually elevated to 110 °C, and maintained at that point for 2 h; the introduction of hydrogen sulfide was stopped. After having been refluxed for another hour, the reaction mixture was allowed to stand in a refrigerator overnight. The resulting precipitate was filtered, dried *in vacuo*, washed with water, and dissolved again in hot ethanol. The solution was filtered to remove any insoluble substances, poured into an ethanol solution of sodium perchlorate, and allowed to stand overnight. This gave 22 g (61.9 %) of yellow needles of **1** (mp 260.4 °C).

Reaction of 1 with Active Methylenes. Into a mixture of an active methylene (2.4 mmol) and 0.72 g (2 mmol) of **1** in 3 ml of methanol, we stirred 2.5 mol dm^{-3} MeONa–MeOH (2 ml) at room temperature; after a while, the mixture was refluxed for 1 h and poured into dilute hydrochloric acid. The resulting precipitate was filtered and purified by recrystallization from an appropriate solvent. The data of **2**—**6**, **9**, and **10**, are summarized in Table 1, while their IR and mass spectra are shown in Table 2. When the procedure described above has used, cyanoacetamide or benzoylacetamide gave 2-hydroxy-3-cyano-4,6-diphenylpyridine (**7**) or 2-hydroxy-3-benzoyl-4,6-diphenylpyridine (**8**) in a 68.2 or 64.2 % yield respectively. Their IR spectra could be completely superimposed on those of authentic samples.

Conversion of 4 to 2,4,6-Triphenylpyrylium Tetrafluoroborate. A mixture of **4** (0.50 g) and *p*-toluenesulfonic acid (5.00 g) was heated at 140 °C for 2 h, and then poured into 50 ml of 1 mol dm^{-3} tetrafluoroboric acid. The resulting precipitate was collected by filtration to give 2,4,6-triphenylpyrylium tetrafluoroborate almost quantitatively; its IR spectrum completely agreed with that of the authentic sample.[7]

1-Methylthio- or 1-(p-Chlorobenzylthio)-1,3-diphenyl-4,4-dicyanobutadiene (11 or 12). Into a mixture of malononitrile (0.16 g), 0.72 g (2 mmol) of **1**, and 3 mmol of methyl iodide or *p*-chlorobenzyl chloride in 3 ml of methanol we stirred 2.5 mol dm^{-3} MeONa–MeOH (2 ml) at room temperature. The reaction mixture was allowed to stand overnight and then poured into dilute hydrochloric acid. The resulting precipitate was filtered and purified by recrystallization to give **11** or **12**. These results are also shown in Tables 1 and 2.

Bis(1,3-diphenyl-4,4-dicyanobutadienyl) Disulfide (13). Into a solution of **10** (0.58 g) in DMF (5 ml), an aqueous solution of 30 % hydrogen peroxide (1 ml) was stirred drop by drop. The reaction mixture was kept at 50 °C for 2 h and then poured into water. The resulting precipitate was filtered and purified by recrystallization to give **13**. These data are also shown in Tables 1 and 2.

The Reductions of Carbonyl Compounds with Sodium 1-Benzyl-3-carbamoyl-1,4-dihydropyridine-4-sulfinate

Hiroo INOUE,* Ichiro SONODA, and Eiji IMOTO

Department of Applied Chemistry, College of Engineering, University of Osaka Prefecture, Sakai, Osaka 591

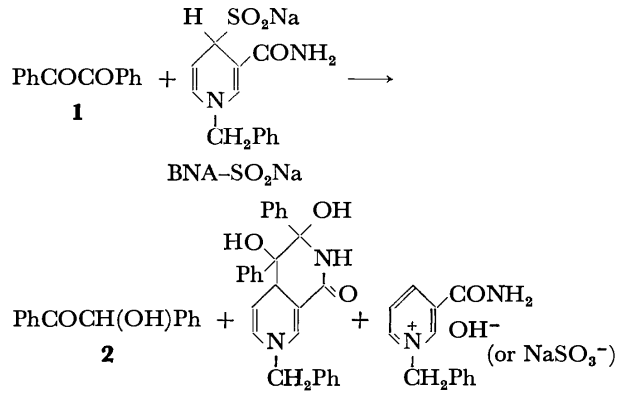
(Received September 8, 1978)

Synopsis. It is found that sodium 1-benzyl-3-carbamoyl-1,4-dihydropyridine-4-sulfinate reduces α-keto carbonyl compounds to α-hydroxy carbonyl compounds with the assistance of $MgCl_2$ and reacts with 9-fluorenone to give an adduct.

Although sodium 1-benzyl-3-carbamoyl-1,4-dihydropyridine-4-sulfinate (BNA-SO_2Na) is of interest as a reducing agent, not a great deal is yet known about the chemical reactivity of BNA-SO_2Na. Recently we reported that BNA-SO_2Na can undergo reductions of α-halo ketones to the parent ketones[1] and that of acridine to 9,9'-bi(9,10-dihydroacridine)[2] in a protic solvent. In analogy with sodium hydroxymethanesulfinate[3] and thiourea dioxide,[4] the carbon-sulfur bond of BNA-SO_2Na is cleaved in the reduction process. Our interest in the reactivity of BNA-SO_2Na prompted us to examine the capability of BNA-SO_2Na for the reductions of the carbonyl compounds. We now wish to report several results giving information on the reactivity of BNA-SO_2Na caused by its unique structure.

Results and Discussion

Reactions of BNA-SO_2Na with α-Keto Carbonyl Compounds. BNA-SO_2Na reacted under nitrogen with benzil (**1**) in 80 vol % aqueous methanol at 25 °C for 12 min to give α-hydroxydeoxybenzoin (**2**) and a thermally unstable adduct (**3**) in isolated yields of 80 and 19% respectively. In this reaction, BNA-SO_2Na was converted to 1-benzyl-3-carbamoylpyridinium salt[5] in a 92% yield, based on **1**. The amount of the salt produced indicates that BNA-SO_2Na undergoes a two-electron reduction of **1**. When the reaction mixture was allowed to stand at 25 °C for a prolonged reaction



time (20 h), the yield of **2** (88%) increased with a decrease in that of **3** (5%). On the other hand, the reaction of **1** with BNA-SO_2Na in a 0.6 M sodium hydroxide solution (80 vol % aqueous methanol) gave **3** as the only product in a 92% yield.

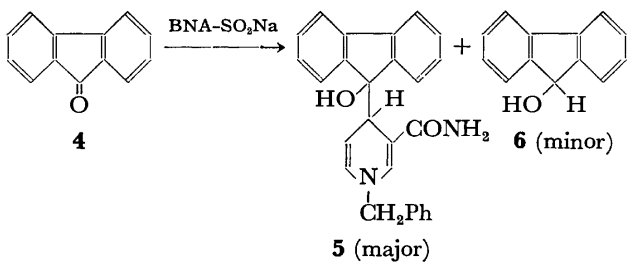
The addition of $MgCl_2$ to the reaction system containing **1** and BNA-SO_2Na (the molar ratio of $MgCl_2$: BNA-SO_2Na: **1**=5: 2: 1) resulted in the selective formation of **2** in a high yield, as Table 1 shows. Furthermore, **3** reacted with $MgCl_2$ to give **2** in a high yield (87% at 25 °C for 17 h). These facts indicate that **3** is converted to **2** with the assistance of $MgCl_2$. The results of the reductions of the other α-keto carbonyl compounds by the BNA-SO_2Na–$MgCl_2$ system are summarized in Table 1. In the absence of $MgCl_2$, the yields of the α-hydroxy carbonyl compounds became much lower because of the formation of adducts and unproved by-products. Thus, the BNA-SO_2Na–$MgCl_2$ system is effective as a reducing system for the conversion of α-keto carbonyl compounds to α-hydroxy carbonyl compounds.

Table 1. The yields of α-hydroxy carbonyl compounds in the reduction of α-keto carbonyl compounds with the BNA-SO_2Na–$MgCl_2$ system[a]

Substance	Time, h	Product (%)[b]
PhCOCOPh	1	PhCOCH(OH)Ph (92)
PhCOCOOEt	17	PhCH(OH)COOEt (70)
PhCOCHO	18	$PhCOCH_2OH$ (55)
$C_3H_7COCOC_3H_7$	1	$C_3H_7COCH(OH)C_3H_7$ (61)
	2	 (49)

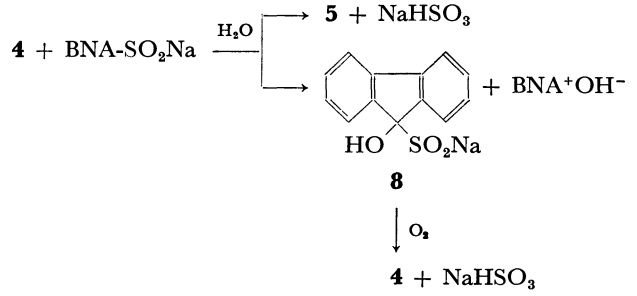
a) Molar ratio of $MgCl_2$: BNA-SO_2Na: substance= 5: 2: 1. Concentration of the substance: 0.06 mol/l. 80 vol % aqueous methanol. 25 °C. b) Isolated yield.

Reactions of BNA-SO_2Na with Diaryl Ketones. The reaction of BNA-SO_2Na with 9-fluorenone (**4**) in 80 vol % aqueous methanol was carried out under conditions similar to those in the case of **1**. With a BNA-SO_2Na : **4** molar ratio of 2: 1, an adduct (**5**) and



9-fluorenol (**6**) were obtained in 30 and 1% yields respectively, with a 62% recovery of **4**. [9,9'-Bi-9*H*-fluorene]-9,9'-diol (**7**) was not obtained at all. BNA-SO_2Na was converted to 1-benzyl-3-carbamoylpyridinium salt in a 72% yield, based on **4**. The yield of the salt was approximately comparable to the recovery

% of **4**. Even with a BNA-SO_2Na: **4** molar ratio of 5: 1, the yields of **5** and **6** did not increase, as Table 2 shows. These facts suggest that the reaction proceeds through the cleavage of the carbon-sulfur bond of BNA-SO_2Na to give an unstable SO_2Na-adduct (**8**) in addition to **5**. The **8** must be converted to **4** and $NaHSO_3$ by hydrolysis, accompanied by oxidation with air on the separation of the products.



In an alkaline medium, the yield of **5** became better. Furthermore, $MgCl_2$ was ineffective in the reduction of **4** to **6** and **7** by BNA-SO_2Na. When $Mg(OCH_3)_2$ was used with BNA-SO_2Na, **5** was obtained in a good yield (Table 2).

Table 2. The reaction of **4** with BNA-SO_2Na[a]

Additive	Molar ratio Additive/**4**	Yield, %[b]			Recovered **4**, %[b]
		5	**6**	**7**	
None[c]	0	30	1	0	62

$MgCl_2$[d]	5	3	0	4	85
$Mg(OCH_3)_2$[e]	1	75	0	0	21

a) Concentration of **4**: 0.06 mol/l. BNA-SO_2Na: **4** molar ratio=2: 1. 80 vol % aqueous methanol. 1 h. 25 °C. b) Isolated yield. c) In the BNA-SO_2Na: **4** molar ratio of 5: 1, **5** was obtained in a 35% yield, with a 62% recovery of **4**. d) 20 h. e) MeOH solvent.

Benzophenone did not react with BNA-SO_2Na, even in an alkaline medium at 25 °C, and was recovered unreacted. When the temperature was raised to 90 °C, however, benzhydrol was found to be obtained in a 16% yield.[6] Thus, BNA-SO_2Na was not effective as a reducing agent for the reductions of monoketones to alcohols.

$$PhCOPh \xrightarrow[90\,^\circ C]{BNA\text{-}SO_2Na} Ph_2CHOH$$

Experimental

Material. The BNA-SO_2Na was prepared according to the procedures described in our preceding paper.[1]

Reaction of 1 with BNA-SO_2Na. A typical experiment was as follows: to a solution of 3 mmol of **1** in 50 cm^3 of 80 vol % aqueous methanol we added 5.9 mmol of BNA-SO_2Na. The solution was stirred under nitrogen at 25 °C for 12 min. A pale yellow precipitate of **3** was removed by filtration, washed under nitrogen with 80 vol % aqueous methanol, and dried *in vacuo*. The yield of **3** (mp 132—134 °C), was 19%. **3** exhibited NMR (DMSO-d_6) signals at δ=3.9 (d, 1H, H_4), 4.4 (s, 2H, CH_2), 4.7 (d, 1H, H_5), 5.95 (d, 1H, H_6), 7.02 (s, 5H, aromatic protons), 7.23 (s, 10H, aromatic protons), and 7.5 ppm (d, 1H, H_2), and an IR (KBr) peaks at 3450 (OH), 3200—3250 (NH), and 1680 cm^{-1} (CO).

Found: C, 74.51; H, 5.84; N, 6.56%. Calcd for $C_{27}H_{24}N_2O_3$1/2 H_2O: C, 74.78; H, 5.81; N, 6.47 %.

The removal of the methanol from the filtrate gave 80% of **2** (mp 131—132 °C), which was identified by comparing its IR and NMR spectra with those of authentic specimens. After the removal of the methanol, the residual solution was developed on an anion-exchange resin (Amberlite IRA-400) to yield 92% of BNA^+Cl^-, based on **1**. Similar procedures were used for the reaction of **1** with BNA-SO_2Na in an alkaline medium and the reactions of **1** and the other α-keto carbonyl compounds with the BNA-SO_2Na–$MgCl_2$ system.

Reaction of 4 with BNA-SO_2Na. To a solution of 3 mmol of **4** in 50 cm^3 of 80 vol % aqueous methanol we added 5.7 mmol of BNA-SO_2Na. After the solution had been stirred under nitrogen at 25 °C for 1 h, the mixture was neutralized by dilute hydrochloric acid, the methanol was removed *in vacuo*, and the resinous material was extracted with benzene. After the removal of the benzene *in vacuo*, the residue was chromatographed on silica gel. Elution with benzene and then chloroform gave **4**, **5**, and **6** in 62, 30, and 1% yields respectively. The purification of **5** was carried out as follows: a solution of **5** in chloroform was placed on the silica gel column and eluted with 15 % acetone in chloroform to give the purified **5** (mp 88 °C (dec)); **5** exhibited NMR ($CDCl_3$) signals at δ=2.2 (s, 1H, OH), 3.85 (s, 2H, CH_2), 4.2 (d, 1H, H_4), 5.2 (d, 1H, H_5), 6.35 (d, 1H, H_6), 6.5—6.7 (m, 2H, NH_2), and 7.0—7.5 (m, 14H, aromatic protons and H_2), and IR (KBr) peaks at 3300—3350 and 3170—3200 (NH_2) and 1680 cm^{-1} (CO).

Found: C, 78.99; H, 5.75; N, 7.14%. Calcd for $C_{25}H_{22}N_2O_2$: C, 79.14; H, 5.62; N, 7.10 %.

In the reactions of **4** with BNA-SO_2Na in the presence of NaOH, $MgCl_2$, and $Mg(OCH_3)_2$, the procedures of the reactions and the isolation of the products were carried out in a manner similar to that described above.

Reaction of Benzophenone with BNA-SO_2Na. To a solution containing 6 mmol of sodium hydroxide in 100 cm^3 of 80 vol % aqueous methanol we added 2 mmol of benzophenone and then 10 mmol of BNA-SO_2Na. The solution was heated under nitrogen at 90 °C for 2 h. The white precipitate was then removed by filtration, and the methanol was evaporated *in vacuo*. The residual solution, containing a solid, was extracted with benzene. After the removal of the benzene, the residue was placed on the silica gel column and eluted with benzene and then chloroform to give benzophenone (81%) and benzhydrol (16%).

Cobalt Metallocycles. VII.[1] η^5-Cyclopentadienyl-η^4-iminocyclopentadienecobalt Complexes from a Reaction of Cobaltacyclopentadienes with Isocyanides

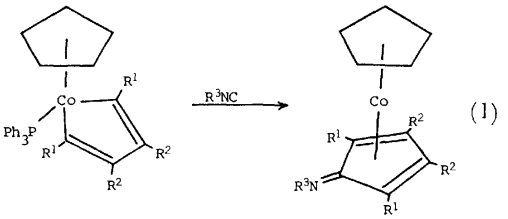
Hiroshi YAMAZAKI* and Yasuo WAKATSUKI
The Institute of Physical and Chemical Research, Wako-shi, Saitama 351

(Received November 22, 1978)

Synopsis. The reaction of (η^5-cyclopentadienyl)(triphenylphosphine)cobaltacyclopentadienes with isocyanides gives η^5-cyclopentadienyl-η^4-iminocyclopentadienecobalt complexes in good yields. Treatment of the product with HBF_4 or CH_3I yields the corresponding aminocobalticinium salt.

Cyclopentadienone–metal complexes have been isolated and characterized from the reactions of metal carbonyls with alkynes and direct reaction with substituted cyclopentadienones.[2] However, few examples of the imino analog *i.e.* iminocyclopentadiene–metal complexes are known. Weiss and Hubel reported that $Fe(CO)_5$ reacts with phenyliminotetraphenylcyclopentadiene to yield an iron tricarbonyl complex.[3] More recently, *t*-butylimino-tetrakis(trifluoromethyl)cyclopentadiene complexes of Mo and W have been reported.[4] Previous work in this laboratory has shown that carbon monoxide reacts with (η^5-cyclopentadienyl)(triphenylphosphine)cobaltacyclopentadienes (**1**) to afford the cyclopentadienone complexes. Consequently it has been predicted that isocyanides would be incorporated into the ring. The synthetic procedure for the preparation of iminocyclopentadienecobalt has the advantage that substituents can be introduced into the iminocyclopentadiene ring, since the parent cobaltacyclopentadienes with corresponding substituents are readily accessible.[5] Some reactions of the obtained iminocyclopentadiene–cobalt complexes are reported, which indicate the strong polarization of the coordinated iminocyclopentadiene ring.

A benzene solution of (η^5-cyclopentadienyl)(triphenylphosphine)tetraphenylcobaltacyclopentadiene (**1a**) and *t*-butyl isocyanide when heated at 70 °C gradually turned dark-brown, and crystals of **2a** (air stable) were isolated in good yield. IR, NMR, and elemental analysis, indicated **2a** to be (η^5-cyclopentadienyl)(η^4-*t*-butyliminotetraphenylcyclopentadiene)cobalt. Other cobaltacyclopentadiene complexes similarly reacted with isocyanides, but higher temperatures were required to complete reaction due to the presence of electron withdrawing substituents in the cobalt metallocycles. The complexes are summarized in Table 1.



(1)

1a R^1,R^2=Ph **2a—2e**
1b R^1=Ph, R^2=Me
1c R^1=Ph, R^2=CO_2Me

The iminocyclopentadiene ligand in these complexes is strongly coordinated to the cobalt. An attempt to liberate the coordinated iminocyclopentadiene in **2c** by carbon monoxide (40 atm, 120 °C) resulted in the formation of a small amount of the desired product, most of the complex remaining unreacted.

In the iminocyclopentadiene–cobalt complexes, by analogy with the cyclopentadienone analogs,[6] an ionic resonance contribution **2'** may be expected. In agreement with this expectation, the ν(C=N) absorption in 2,6-xylyliminotetraphenylcyclopentadiene (1630 cm^{-1}) was markedly reduced on coordination to cobalt (1575 cm^{-1}).

Furthermore, complex **2** readily forms aminocobalticinium salts (**3**) on protonation and methylation (Eq. 2). The protonation by fluoroboric acid was performed by shaking a benzene solution of **2** with the acid. The ν(C=N) peak was absent in the IR spectrum of the resulting complex while the ν(N–H) appeared at 3300—

Experimental

IR spectra were recorded on a Shimadzu IR-27G and NMR spectra on a Varian HA-100 spectrometer. Melting points were determined on a Mitamura micro-melting point apparatus. (η^5-Cyclopentadienyl)(triphenylphosphine)cobaltacyclopentadiene complexes were prepared by the methods reported.[5]

Preparation of (η^5-Cyclopentadienyl)(η^4-iminocyclopentadiene)-cobalt. A solution of **1a** (0.742 g, 1.0 mmol) and *t*-BuNC (0.4 ml) in benzene (10 ml) was heated at 70 °C for 8 h. The volume of the solvent was reduced *in vacuo* and hexane added to give black crystals of **2a** (0.473 g).

Similar treatment of cobaltacyclopentadiene complexes with isocyanides gave the corresponding iminocyclopentadiene–cobalt complexes (Table 1). Preparation of **2e** was conducted at 130 °C.

*Reaction of **2c** with Carbon Monoxide.* A solution of **2c** (0.122 g, 0.2 mmol) in benzene (20 ml) was placed in an autoclave and carbon monoxide introduced (40 atm). After heating at 120 °C for 8 h, the solution was concentrated. The addition of hexane afforded the starting cobalt complex (0.06 g, 49% recovery). The mother liquid was chromatographed on alumina and a red fraction eluted with benzene/hexane (1: 1). Evaporation of the solvent, followed by crystalization from hexane gave dark-red crystals of 2,6-xylyliminotetraphenylcyclopentadiene (0.018 g, 18%), mp 190 °C. Found: C, 91.11; H, 6.03; N, 2.79%; mol wt, 487 (mass spectrum). Calcd for $C_{37}H_{29}N$: C, 91.13; H, 5.99; N, 2.87%; mol wt, 487. NMR ($CDCl_3$): δ 1.99 (s, 9H); 6.5—7.2 (multiplet, Ph protons) ppm. IR (KBr): ν(C=N), 1630 cm^{-1}.

*Reaction of **2** with Fluoroboric Acid.* To a solution of **2a** (0.10 g, 0.18 mmol) in benzene (10 ml) was added a few drops of fluoroboric acid (42 %, aq solution). The mixture turned pale immediately after shaking and an orange-red solid precipitated. Extraction of the solid with a small amount of CH_2Cl_2 followed by the addition of benzene gave red crystals of **3b** (0.083 g, 73%). **3a** was similarly prepared (46%). The physical properties of the complexes are summarized in Table 2.

*Reaction of **2** with Iodomethane.* A solution of **2a** (0.056 g, 0.1 mmol) and iodomethane (0.2 ml) in benzene (10 ml) was left overnight at room temperature. The resulting dark red-brown solution was concentrated *in vacuo* to give dark red brown crystals of **3c** (0.063 g, 89%). **3d** was similarly obtained.

The Silver(I) Salt-promoted Benzylation of Silyl Enol Ethers

Hidetsugu TAKAGAKI, Nobuyoshi YASUDA, Morio ASAOKA, and Hisashi TAKEI*

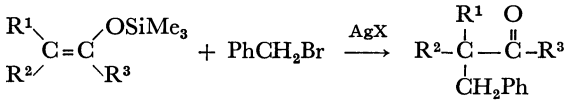
Department of Life Chemistry, Tokyo Institute of Technology, Nagatsutacho, Midori-ku, Yokohama 227

(Received September 1, 1978)

Synopsis. Various silyl enol ethers gave the corresponding mono benzyl products in moderate to good yields by the reaction with benzyl bromide in the presence of silver perchlorate in dichloromethane at −78—0 °C.

Silyl enol ethers are known to be useful intermediates for the alkylation of carbonyl compounds; the alkylation is usually performed through the enolate anion generated by the treatment with MeLi[1] or $R_4N^+F^-$.[2] On the other hand, the *t*-butylation of silyl enol ethers was recently accomplished by the use of Lewis-acid catalysts.[3]

Silver(I) salts are well known to activate the halogenated compounds. Therefore, it seemed possible to alkylate the silyl enol ethers with alkyl halides activated by silver(I) salt. In this paper, we will describe the silver(I) salt-promoted benzylation of silyl enol ethers.[4]



Results and Discussion

First, we examined the reaction of 1-trimethylsiloxycyclohexene and benzyl bromide in dichloromethane as a model reaction. When the reaction was carried out in the presence of silver(I) oxide or silver(I) nitrate, no alkylated product was obtained. However, 2-benzylcyclohexanone was obtained in 9% (Ag_2O) or 15% ($AgNO_3$) yield by the addition of a catalytic amount of zinc chloride to the reaction mixture. Therefore, in order to ascertain the best conditions for the reaction, various silver(I) salts, Lewis acids, and reaction temperatures were examined. These results are summarized in Table 1.

As shown in Table 1, a combination of silver perchlorate and boron trifluoride etherate was the best one. Moreover, it was found that the reaction could proceed without a Lewis-acid catalyst when silver perchlorate or silver tetrafluoroborate was used. In the case of the reaction of 1-phenyl-1-trimethylsiloxyethene and benzyl bromide, silver perchlorate alone gave the best result (44%), although the addition of boron trifluoride etherate, zinc chloride, or magnesium chloride gave the corresponding benzylated product in 21, 41, or 34% yield respectively. The reaction of several silyl enol ethers and benzyl bromide in the presence of silver perchlorate was also examined; the results are listed in Table 2.

Table 1. Reaction of 1-trimethylsiloxycyclohexene with benzyl bromide in dichloromethane

Silver(I) salt (1 equiv)	Catalyst[c]	Temp/°C	Time/h	Isolated yield/%
Ag_2O	$ZnCl_2$	room temp	20	9[a]
$AgNO_3$	$ZnCl_2$	room temp	20	15[a]
$AgClO_4$	$ZnCl_2$	room temp	20	21[a]
$AgNO_3$	$ZnCl_2$	−78—0	14	11[b]
$AgNO_3$	$TiCl_4$	−78—0	14	14[b]
$AgNO_3$	$SnCl_4$	−78—0	14	22[b]
$AgNO_3$	$BF_3\cdot Et_2O$	−78—0	14	49[b]
$AgClO_4$	$BF_3\cdot Et_2O$	−78—0	14	82[b]
$AgClO_4$	—	−78—0	14	64[b]
$AgBF_4$	$BF_3\cdot Et_2O$	−78—0	14	32[b]
$AgBF_4$	—	−78—0	14	51[b]

a) 1-Trimethylsiloxycyclohexene (1 equiv) and benzyl bromide (1.1 equiv) were used. b) 1-Trimethylsiloxycyclohexene (1.2 equiv) and benzyl bromide (1 equiv) were used. c) A catalytic amount of Lewis acid was used.

Table 2. Benzylation of various silyl enol ethers[a]

Silyl enol ether	Product[6]	Isolated yield/%
		69
		82[b]
		44
		35

a) Silyl enol ether (1.2 equiv) and benzyl bromide (1 equiv) were used in dichloromethane at −78—0 °C for 14 h in the presence of $AgClO_4$ (1 equiv). b) A catalytic amount of $BF_3\cdot Et_2O$ was used.

These yields are well in accordance with the order of the electron density of the carbon-carbon double bond of silyl enol ethers. Therefore, it is reasonable to assume that the reaction is an electrophilic one. Under similar reaction conditions, we examined the alkylation of 1-phenyl-1-trimethylsiloxyethene using other alkyl halides. However, all attempts failed in the cases of isopropyl iodide, allyl brimide, and butyl iodide. The only successful case except for benzyl bromide was that of methyl iodide (51%).

To ascertain the regioselectivity of the reaction, we also examined the reaction of 6-methyl-1-trimethylsiloxycyclohexene with benzyl bromide. However, the reaction was found not to be regioselective even under rather basic conditions.

Table 3. Reaction of 6-methyl-1-trimethylsiloxycyclohexene with benzyl bromide[a)]

Additive	Product[6)] Yield(%)[b)] *cis*	*trans*	Yield/%[b)]	Total yield/%

a) 6-Methyl-1-trimethylsiloxycyclohexene (1.1 equiv) and benzyl bromide (1 equiv) were used in dichloromethane at −78—0 °C for 14 h in the presence of $AgClO_4$ (1 equiv). b) Isolated yield.

Experimental

A typical procedure for the benzylation of silyl enol ethers[5)] was as follows.

2-Benzylcyclohexanone. A dichloromethane solution (2 ml) of 1-trimethylsiloxycyclohexene (204 mg, 1.2 mmol) and benzyl bromide (171 mg, 1 mmol) was added to silver perchlorate (208 mg, 1 mmol) at −78 °C under argon atmosphere. The mixture was then allowed to warm to 0 °C over about 14 h. The silver salts were filtered off, and water was added. The solution was then extracted with ether, and the organic layer was dried over sodium sulfate and evaporated. 2-Benzylcyclohexanone was obtained by using TLC (hexane: ether =10: 1, R_f=0.4); 119 mg (64%).

Investigation of CdS Photoanode Reaction in the Electrolyte Solution Containing Sulfide Ion

Tooru INOUE,* Tadashi WATANABE, Akira FUJISHIMA, and Kenichi HONDA

Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received July 19, 1978)

The study of the photoanodic reaction in the CdS/S^{2-} system was carried out by means of the rotating ring-disk electrode (RRDE) technique. The photoanodic reactions at an n-type CdS electrode are divided into two types; the photoanodic oxidation of redox agents in the electrolyte solution and the photoanodic dissolution of CdS electrode surface. The stabilization of a CdS photoanode could be attained through the preferential progress of the former of these two processes. The ratio between these two processes depends upon the concentration of S^{2-} in the electrolyte solution and the light intensity. Sulfide ion in the electrolyte solution stabilizes CdS photoanode and gives rise to the shift of the flatband potential of CdS electrode by *ca.* −60 mV/log[S^{2-}]. This dependence of the flatband potential on sulfide ions can be explained by an adsorptive dissociation equilibrium at a CdS electrode surface. The results of the photoanodic reaction were disscussed referring to the charge transfer process with the participation of some surface energy state within a bandgap.

The behavior of the reactions at an illuminated semiconductor electrode has been recently drawing attention of a number of investigators primarily in connection with the solar energy conversion into electrical and chemical energy, that is, the electrochemical photocell as a solar energy converting device.[1-24]

At TiO_2 electrode[1-10] and other stable semiconductor electrodes,[11-14] the photosensitized electrolytic oxidation of water[1-14] and various reducing agents such as I^-, Br^-, Cl^-, $Fe(CN)_6^{4-}$, hydroquinone, and Fe^{2+} [15-25] occurs by the action of the excess holes photogenerated at the electrode surface, according to the following reactions.

$$2H_2O + 4h^+ \longrightarrow O_2 + 4H^+ \quad (1)$$

$$Red + n\,h^+ \longrightarrow Ox \quad (2)$$

These semiconductors possess relatively wide bandgaps except WO_3[8] and Fe_2O_3[4,13] and hence can not efficiently utilize the solar energy. In this respect, cadmium sulfide[15-21] seems to be a promising material since it shows a strong absorption in wavelength shorter than 520 nm. However, the anodic reaction at an illuminated CdS electrode is known to be the dissolution[26,27] of the electrode surface, according to

$$CdS + h\nu \longrightarrow CdS(h^+_{val} + e^-_{cond}), \quad (3)$$

$$2h^+_{val} + CdS \longrightarrow S_{ad} + Cd^{2+}, \quad (4)$$

where h^+_{val}, e^-_{cond} and S_{ad} denote a hole in the valence band, an electron in the conduction band, and a sulfur atom deposited on the electrode surface, respectively.

Hence, from the stand-point of practical application of CdS photoanode to the electrochemical photocell, it is desired to stabilize the CdS photoanode. In the previous paper[15] we investigated the suppression of surface dissolution of CdS photoanode by reducing agents through the competitive oxidation between the process (2) and (4).

Some reducing agents had the various efficiencies of the dissolution suppression and especially S^{2-}, SO_3^{2-}, and $S_2O_3^{2-}$ could markedly stabilize the CdS photoanode.[15] Wrighton *et al.*[19] reported that the cadmium calcogenide (CdX) photoanodes are stabilized through the oxidation of the calcogenide ions (S^{2-}, Se^{2-}, and Te^{2-}) in the electrolyte solution and the output power characteristics of the electrochemical photocell can be enhanced by using the CdX/X^{2-} systems.

Miller and Heller[21] also reported the power characteristics of the photocells with CdS and Bi_2S_3 polycrystal photoanodes/sulfide. Minoura *et al.*[16] reported that the dissolved Cd^{2+} and S^{2-} ions cause the shift of the flatband potential of CdS and CdS photoanode is stabilized by the diffusion of S^{2-} to the electrode surface. Memming[20] investigated the oxidation efficiency of a ferrous cyanide at the CdS photoanode surface against pH variation by means of a rotating platinum-semiconductor RRDE technique.

As for the effect of the illumination intensity on the electrochemical photolysis of water at TiO_2 and on the conversion of the light energy to the electricity at CdS, the power charateristics (photovoltages and photocurrents) of the electrochemical photocells were investigated well.[19,28] However, a quantitative dependence of the light intensity on the stability of CdS photoanode has not been investigated in detail.

In this study,[45] we investigated more precisely the dependence of a flat band potential on the dissolved sulfide ion and the dependence of the competitive reaction between the dissolution of CdS photoanode and the oxidation of the dissolved sulfide ions on the light intensity by means of a RRDE technique and others. We show the results that the stabilization of the CdS photoanode can be elucidated based upon the function of the concentration of the sulfide ions and the number of the incident photons. Then we discussed the charge transfer across the semiconductor/electrolyte interface based upon the number of the carriers in both phases.

Experimental

Ring-disk electrode were constructed with single crystal of n-type CdS disk electrode together with Cu(Hg) as the ring electrode. General experimental procedures including electrode pretreatments, establishment of ohmic contacts and RRDE assembly have described elsewhere.[15,29]

The measurement principle of the RRDE method is schematically illustrated in Fig. 1. In the absence of a reducing agent (S^{2-}) in the electrolyte solution (A), Cd^{2+} ion is pro-

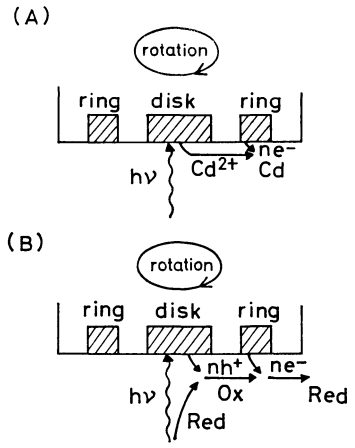

Fig. 1. Schematic diagram of the RRDE system. (A) a detection of the dissolution product of CdS electrode surface, (B) a detection of the oxidation product of a reducing agent.

duced at the disk electrode through the photoelectrochemical process (4), and a part of which, determined by the collection efficiency, is reduced at the Cu(Hg) ring electrode. If a reducing agent is added (B), it undergoes the competitive oxidation of S^{2-} by photogenerated holes, and the oxidized species discharges at the ring electrode.

Dependence of the flatband potential of CdS photoanode on the concentration of the sulfide ion was given by the capacitance measurement of the interface of CdS electrode/electrolyte solution containing sulfide ion, whose method is described in elewhere.[30]

Results and Discussion

Variation of Flatband Potential of CdS Electrode. Figure 2 shows typical $1/C^2$ *vs.* E plots for the CdS electrode in the aqueous electrolyte solution with sulfide ions, obtained by the impedance measurement. The interface capacitance is assumed that the capacitance of a space charge layer is much smaller than any other regions. When a depletion layer is formed for majority carriers (electrons) for n-type semiconductor such a condition can be attained at the anodic polarization. So the determination of the flatband potential of CdS

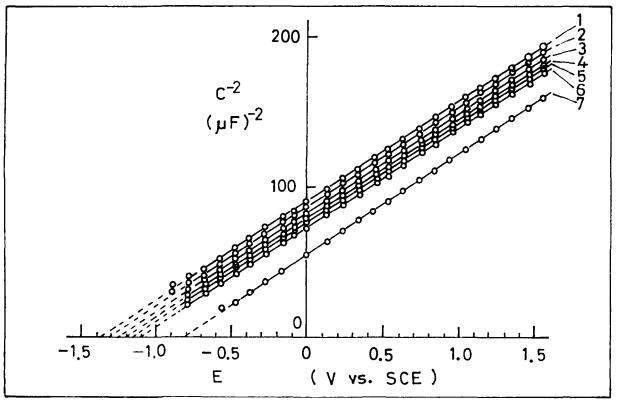

Fig. 2. Mott-Schottky plots for CdS electrode. 1: 1.0 M S^{2-}, 2: 10^{-2} M S^{2-}, 3: 10^{-2} M S^{2-}, 4: 10^{-3} M S^{2-}, 5: 10^{-4} M S^{2-}, 6: 10^{-5} M S^{2-}, 7: 0.0 M S^{2-}. All in 0.2 M Na_2SO_4 aqueous solution.

electrode is based upon the application of Mott-Schottky relationship[31] which is expressed as

$$\frac{1}{C_s^2} = \frac{2}{qee_0N}\left(E - E_{fb} - \frac{kT}{q}\right), \tag{5}$$

where C_s represents the space charge differential capacitance per unit area, q the electric charge, e the dielectric constant of semiconductor, e_0 the permittivity of vacuum, N the carrier concentration (practically equals the donor concentration in the present case (7.4×10^{16} cm^{-3})), E the electrode potential and E_{fb} the flatband potential. Thus the intercept of the E axis of the $1/C^2$ (approximately equals $1/C_s^2$) *vs.* E curves gives a potential differing from the flatband potential by kT/q.

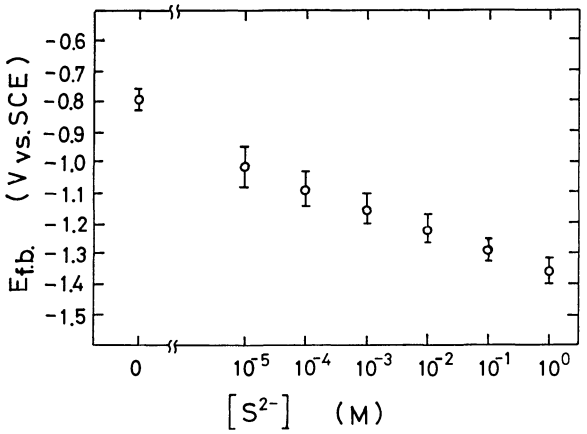

Fig. 3. Dependence of the flatband potential of CdS electrode on the concentration of S^{2-}.

The flatband potentials of CdS electrode thus determined is shown in Fig. 3 as a function of the concentration of S^{2-} with the slope *ca.* -60 mV/log[S^{2-}]. The value of this slope is approximately the same as that reported by others.[32] Otherwise, the flatband potentials of TiO_2 and ZnO depend upon the pH of the electrolyte solution with a slope of -59 mV/pH, which is explained in view of the following dissociation equilibrium established at the semiconductor electrode surface,[33] for example

$$\text{Ti-O}^{2-} + \text{H}^+ \rightleftharpoons \text{Ti-OH}^-, \tag{6}$$

$$\Delta\phi = \text{const} + \frac{RT}{E}\ln\frac{a_{\text{TiO}^{2-}}}{a_{\text{TiOH}^-}} - \frac{2.3RT}{F}\text{pH},$$

where Ti–O^{2-} represents an element of the TiO_2 lattice at the surface, H^+ a proton in the bulk of the electrolyte solution, and Ti–OH^- the lattice element protonated. From the thermodynamic theory, the flatband potential is reasoned with the inner potential difference of the interface between the electrode surface and the electrolyte solution. In the case of CdS electrode in the present study, the same consideration may well be taken.

$$-\text{Cd}_L^{\delta+} + \text{S}^{2-}_{\text{soln}} \rightleftharpoons -\text{Cd}_L^{(\delta-1)+}\rangle\text{S}_{\text{ad}} \tag{8}$$

where $-Cd_L^{\delta+}$ represents the lattice cadmium element of the CdS lattice at the surface, S^{2-}_{soln} a sulfide ion in

the electrolyte solution, $-Cd_L^{\delta(-1)+}\rangle S_{ad}$ the lattice cadmium element adsorbed by a sulfide ion. That is, the interfacial potential difference ($\Delta\phi$) generated by a surface adsorptive dissociation equilibrium of a sulfide ion at the CdS electrode surface depends upon the concentration of the sulfide ion in the bulk of the electrolyte solution and then changes the flatband potential of CdS electrode according to the following equation[34]

$$E_{fb} \simeq \Delta\phi = \text{const} - \frac{RT}{F}\ln\frac{C(N^\circ - N)}{C^\circ N}, \quad (9)$$

where N° and N represent the surface concentrations of adsorbed sulfide ions for maximal coverage and for the equilibrium state, C and C° the concentration of sulfide ions in solution and that in the standard state.

Consequently, the fact that the flatband potential of CdS photoanode shifts to the negative potential implies that the power characteristics, especially the photo-output voltage, of an electrochemical photocell can be increased, because the onset potential of the photocurrent based upon a photoanodic reaction corresponds to the flatband potential of a photoanode.

Current-potential Characteristics of Cu(Hg)/CdS RRDE. An anomalous behavior of the CdS disk photocurrent was observed uniquely on addition of S^{2-} in the electrolyte solution. Figure 4 shows the change of the current-potential characteristics of CdS photoanode with the change in S^{2-} concentration. It is seen that the onset potential for the photocurrent is shifted to more negative potential as S^{2-} concentration increases, corresponding to the flatband potential in Fig. 3, and the photocurrent appears as the twostep wave in lower S^{2-} concentrations. In the dark, the anodic photocurrent does not appear, but under illumination the anodic photocurrents appear at the negative onset potentials. In the absence of the sulfide ion in the electrolyte solution, the limiting anodic photocurrent is controlled by the photogenerated holes at the electrode surface. On the other hand, the first wave of the photocurrent observed in a lower concentration of S^{2-} increases with an increase in the concentration of S^{2-} in the electrolyte solution. In a high concentration of S^{2-}, the photoanodic current becomes one-step wave again. This phenomenon of appearance of a two-step wave photocurrent is considered to be originated from two different reactions at CdS electrode. Minoura and Tsuiki have also reported two- or three-step wave photocurrent in the solution containing S^{2-}, SO_3^{2-}, and $S_2O_3^{2-}$.[35,36] In TiO_2 electrode, a two-step wave photocurrent, it is reported,[37] appears at high pH values of the electrolyte solution, and it is explained that the first wave photocurrent is controlled by the diffusion of a hydroxyl ion (OH^-) to the TiO_2 surface and the second one by that of water (H_2O).

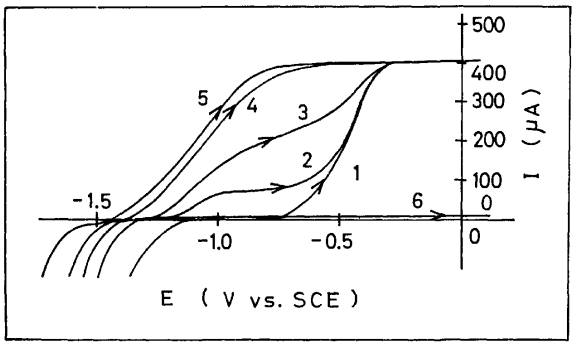

Fig. 4. Current-potential curves of a rotating CdS electrode at 1000 rpm in the electrolyte solution containing various concentrations of S^{2-}.
1: 0.0 M S^{2-}, 2: 7×10^{-4} M S^{2-}, 3: 10^{-3} M S^{2-}, 4: 10^{-2} M S^{2-}, 5: 10^{-1} M S^{2-}, above 1—5; at illuminated, 6: in the dark. All in 0.2 M Na_2SO_4 solution.

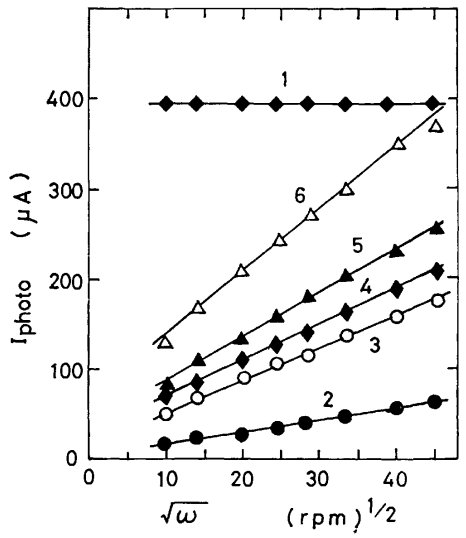

Fig. 5. Dependence of photocurrents on the root of a rotating speed of CdS disk electrode.
1: With and without S^{2-}, potentials at 0.0 V (*vs.* SCE), 2: 10^{-4} M S^{2-}, at −0.8 V, 3: 5×10^{-4} M S^{2-}, at −0.8 V, 4: 7×10^{-4} M S^{2-}, at −0.8 V. 5: 10^{-3} M S^{2-}, at −0.8 V, 6: 1.5×10^{-3} M S^{2-}, at −0.8 V. All in 0.2 M Na_2SO_4 solution.

Concerning the appearance of the two-step wave of an anodic photocurrent, the dependence of the first and the second waves on the rotation speed (ω) was measured and the results are illustrated in Fig. 5. The magnitude of the second wave shows practically no change with ω, which means that the rate-determining step is the formation of photoholes in the valence band. On the contrary, the magnitude, I_{photo}, of the first wave varies linearly with the square root of ω, and increases in an increase of S^{2-} concentration. I_{photo} can be approximated by the following formula,

$$I_{photo} = \text{const} \times [S^{2-}]\omega^{1/2} \quad (10)$$

which, according to the theory of Levich,[38] indicates that the process corresponding to the first wave is controlled by the diffusion of S^{2-} from the solution to the CdS electrode surface. Therefore, the first wave photocurrent is considered to occur from the following reactions

$$nS^{2-} + 2(n-1)h^+ \longrightarrow S_n^{2-} \quad (n=2, 3, 4, 5), \quad (11)$$

or

$$S^{2-} + 2h^+ \longrightarrow S,$$
$$S + S^{2-} \longrightarrow S_2^{2-}. \quad (12)$$

This photoanodic oxidation at CdS photoanode was also reported by Wrighton *et al.*[19] Miller and Heller,[21] and Minoura *et al.*[16]

Figure 6 shows the dependence of the disk (I_D) and ring (I_R) currents on the ring potential (E_R), with or without S^{2-} added in the electrolyte solution. In the dark (curves 1, 3), negligibly small currents are observed at the CdS disk electrode fixed at +1.0 V *vs.* SCE, while hydrogen evolution ($E_R < -1.5$ V) occurs at the Cu(Hg) ring electrode. Illumination of the CdS disk gives rise to an anodic photocurrent (curve 2) and at the same time a reduction current appears at the Cu(Hg) ring electrode in the potential range more negative than −0.6 V *vs.* SCE. The latter current corresponds to the reduction of Cd^{2+} produced by the dissolution reaction of the CdS photoanode (4). Since the ratio of the limiting reduction current at the Cu(Hg) ring electrode to an anodic photocurrent at the CdS disk electrode fairly coincides with the theoretical collection efficiency for the ring-disk electrode employed, it is evident that the process (4) is totally responsible for the anodic photocurrents. By addition of 0.1 M Na_2S in the electrolyte solution, the magnitude of the disk photocurrent undergoes practically no change, while a reduction current of Cd^{2+} disappears and a new ring current (curve 4) appears at potentials more negative than −1.2 V *vs.* SCE, corresponding to the reduction (13) of S_n^{2-} generated by the process (11) or (12).

$$S_n^{2-} + 2(n-1)e^- \longrightarrow nS^{2-} \quad (13)$$

The occurrence of this process can also be verified by the dependence of the disk and ring currents on the disk potential (E_D), with the ring potential fixed at −1.8 V for S_n^{2-} reduction and at −0.8 to −1.1 V for Cd^{2+} reduction, with or without S^{2-} added in the electrolyte solution, as shown in Fig. 7. In Fig. 7(A), in the absence of S^{2-} in the electrolyte solution both reduction currents (curves 1, 2) at the Cu(Hg) ring electrode are corresponding to the reduction of Cd^{2+}. In Fig. 7(B), in the presence of 5×10^{-4} M S^{2-} added in the electrolyte solution the reduction current (curve 1) at the Cu(Hg) ring electrode appears at the same time in occurance of the second wave of the anodic photocurrent at the CdS disk electrode. Then the reduction current (curve 2) at the ring electrode shows a two-step wave similar to the anodic photocurrent at the CdS disk electrode. This first wave of a reduction current is deduced from the reduction of S_n^{2-}. In Fig. 7(C), in the presence of 0.1 M S^{2-} in the electrolyte solution the reduction (curve 1) of Cd^{2+} at the ring electrode disappears, while the reduction current (curve 2) of S_n^{2-} at the ring electrode shows one wave and its value coincides with the theoretical collection of the disk photocurrent for the ring-disk electrode. Therefore, it is evident that the process (11) or (12) is totally responsible for the anodic photocurrent at the CdS electrode.

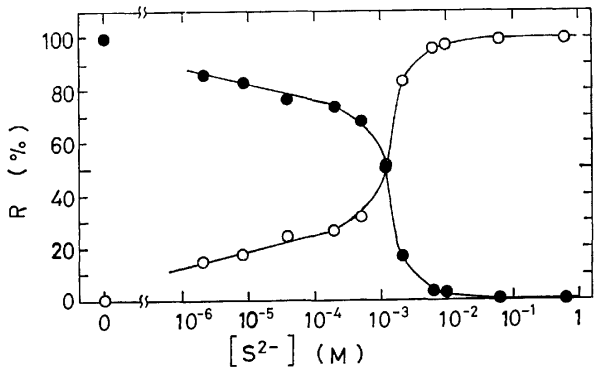

Fig. 8. Dependence of the ratio (R) of a competitive reaction on the concentration of a sulfide ion.
—●—: A dissolution of CdS electrode, —○—: an oxidation of S^{2-} in an electrolyte solution.

If we denote the magnitude of the total ring current by I_R°, that due to Cd^{2+} reduction by $I_{R,Cd}$, and that due to S_n^{2-} reduction by $I_{R,S}$, then $100I_{R,Cd}/I_R^\circ$ and $100I_{R,S}/I_R^\circ$ can be termed as the competition ratio (R) between CdS surface dissolution and oxidation of S^{2-} in the course of the photoelectrochemical process at the CdS photoanode. Figure 8 shows the ratio (R) of the competitive oxidation between CdS photonode and S^{2-} as a function of S^{2-} concentration in the electrolyte solution. It is seen that the value of R for the competitive oxidation of S^{2-} increases with the increase in $[S^{2-}]$ and the value of R for the dissolution of CdS photoanode decreases with the increase in $[S^{2-}]$. This result suggests that in a high concentration of S^{2-} added in the electrolyte solution the dissolution of CdS photoanode can be suppressed, which has been partly reported in a previous paper.[15]

Dependence of Electrode Reactions on Light Intensity. Above results were observed under the constant intensity (*ca.* 3.5×10^{15} photon/s) of illumination (wavelength range from 300 to 410 nm), while the dependence of the two-step wave photocurrent at CdS electrode on the intensity of illumination was observed, as shown in Fig. 9. In Fig. 9(A), with a concentration of 1×10^{-4} M S^{2-} added in the electrolyte solution, in a low intensity of illumination one-step wave photocurrents (curves 1 and 2) appear which are controlled by the number of photoholes formed, and in a high intensity of illumination the two-step wave photocurrents (curves 3 and 4) appear where the first wave photocurrent is constant against the intensity of illumination, however, the second wave photocurrent increases by an increase of the illumination intensity.

In the presence of sufficient sulfide ions in the electrolyte solution, the photocurrent-potential curves become one step waves as shown in Fig. 9(B). In this stage, anodic photocurrents were totally caused by the oxidation of sulfide ions supplied to the CdS electrode surface and the values of photocurrents depend on the number of the incident photons.

The dependence of the two-step wave anodic photocurrents on the intensity of illumination in various concentrations of S^{2-} is shown in Fig. 10. The dots

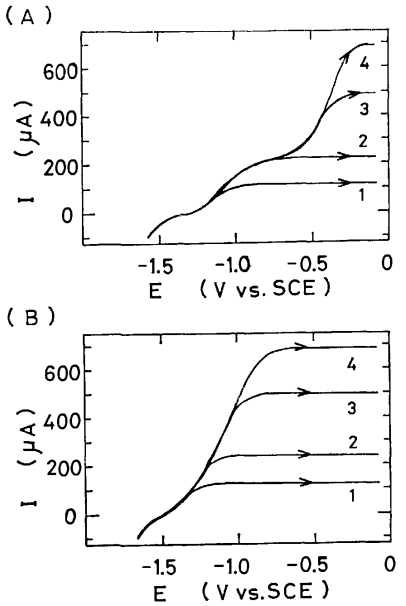

Fig. 9. Dependence of current-potential curves on the intensity (L) of illumination

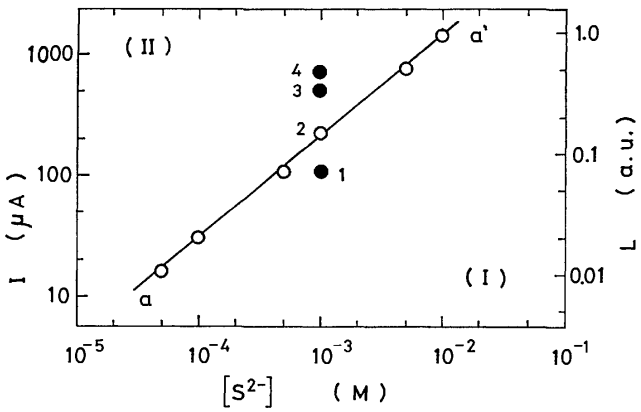

Fig. 10. Dependence of the photocurrents on the illumination intensity (L) and that of the first wave photocurrents on $[S^{2-}]$.

(1, 2, 3, and 4) correspond to the limiting values of the photocurrents in Fig. 9(A), respectively. The curve (a-a') shows the dependence of the limiting photocurrents of the first waves on $[S^{2-}]$. In the region (I) below the curve (a-a'), only a one-step wave photocurrent appears even if the illumination intensity is high, where the oxidation of S^{2-} is controlled by the number of the photogenerated holes. On the contrary, in the region (II) above the curve (a-a'), the second wave photocurrent appears based on the dissolution of CdS photoanode occurs. The oxidation ratio of a sulfide ion depends on the quantitative correlation between the concentration of a sulfide ion and the number of the incident photons.

So we can say that the CdS photoanode can be stabilized when excess sulfide ions are dissolved in the electrolyte solution versus the number of the photo-

TABLE 1. RELATIONS BETWEEN THE THEORETICAL LIMITTING CURRENTS (I_L) AND THE FIRST WAVE-PHOTOCURRENTS (I_P)

$\frac{[S^{2-}]}{mol/l}$	10^{-5}	5×10^{-5}	10^{-4}	5×10^{-4}	10^{-3}	5×10^{-3}	10^{-2}

generated holes at the electrode surface.

Here, we approximate the flow rate (J_L) of the sulfide ion towards the CdS electrode surface and the limiting oxidation current (I_L) of the sulfide ion employing the following equations

$$J_L = 1.95\, D^{2/3}\nu^{-1/6}\omega^{1/2}[S^{2-}]r^2, \quad (14)$$

$$I_L = nFJ_L, \quad (15)$$

where D denotes the diffusion coefficient, ν the dynamic viscosity, r the radius of the rotating disk electrode, n the covalent number, and F Faraday constant, respectively. Substituting the experimental conditions, $D=10^{-5}$ cm^2/s, $\nu=10^{-2}$ cm^2/s, $\omega=1000$ rpm, $r=0.3$ cm, $n=2$, and $F=96500$, into the Eqs. 14 and 15, we obtain the numerical results for the first-wave photocurrents as shown in Table 1. The oxidation currents($I_{D,ox}$) of varous concentration of $Fe(CN)_6^{4-}$ at the ratating Pt disk electrode with the same diameter as the CdS disk electrode are also shown in Table 1 in order to compare with the magnitude of photocurrents (I_P). From the results of Table 1, we can consider that the first wave photocurrents are controlled almost by the limitting diffusion of sulfide ions and increase with the increase of the sulfide concentration. Reflecting the facts that the flatband potential of CdS and the onset potential of the first wave photocurrent make shifts to the negative potential with the increase of the sulfide concentration, the photogenerated holes may transfer to sulfides *via* the active sites which may be caused by the adsorption of sulfides or by the imperfections (for example, kink sites, step sites or dislocations) on the CdS surface.[39]

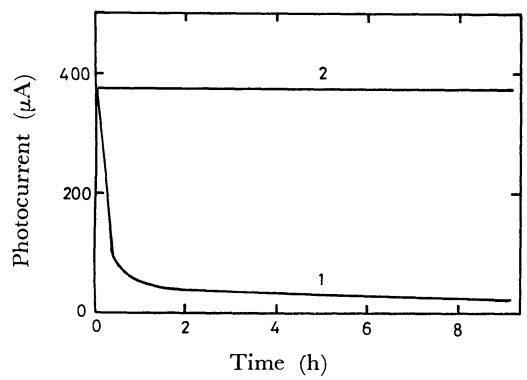

Fig. 11. Time-dependence of photocurrents at CdS electrode. 1: In 0.2 M Na_2SO_4, 2: in 0.2 M Na_2SO_4 +1.0 M Na_2S.

Stabilized CdS Photoanode. From the results in Figs. 8 and 10, we suggest that a stable photocurrent flows at a high concentration of S^{2-} added in the electrolyte solution where the ratio of the competitive oxidation of S^{2-} is almost 100% even if under the high intensity (*ca.* 1×10^{17} photon/cm^2 s) of illumination.

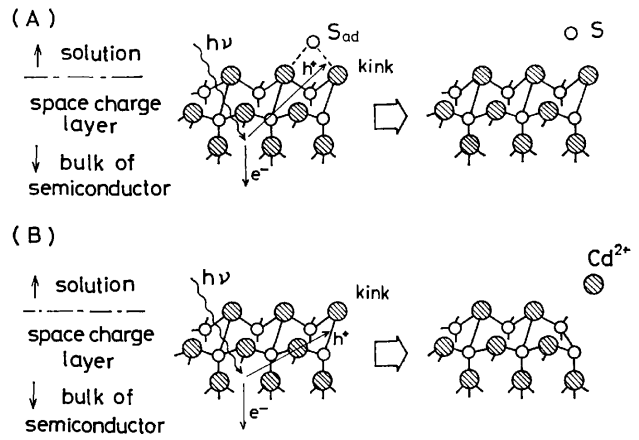

Fig. 13. Schematic diagram of CdS photoanode reactions.
(A) Stabilization of CdS surface with sulfide ions in solution, (B) Oxidation dissolution of CdS surface without sulfide ions in solution.

We show the photocurrent-time characteristics for the electrolyte solution with and without 1.0 M Na_2S in Fig. 11. In the absence of a reducing agent (S^{2-}) in the electrolyte solution, the photocurrent (curve 1) at CdS photoanode usually shows an abrupt decay with time. This phenomenon is attributed to the deposition of sulfur, which acts as a light filter on the electrode surface, produced according to reaction (4). In the presence of a reducing agent (S^{2-}) the photocurrent continues to flow remarkably stably for a long period, as expected above, hence the stabilization of the electrode surface is attained.

The stabilization of CdS photoanode can be visualised by comparing the scanning electron microscopy (SEM) pictures of a CdS surface after photoelectrolysis for 2 hours with (Fig. 12 (B)) and without (Fig. 12(A)) 0.5 M S^{2-} in the electrolyte solution. A rough reticulate structure in (A) might reflect the deposition of sulfur produced by the dissolution reaction (4). The photoanodic reactions at the CdS electrode can be described schematically as shown in Fig. 13, where kink denotes an imperfection site as the example of the active site.

Conclusion

We show in Fig. 14 the schematic diagram of the correlation of the energy levels between a semiconductor (CdS) electrode and reducing agents in the electrolyte solution. E_D in the figure denotes the redox potential of CdS calculated from the thermodynamic data according to the following equation[40]

$$CdS \rightleftharpoons Cd^{2+} + S + 2e^-, \quad E_D = 0.08 \text{ (V } vs. \text{ SCE)}. \quad (14)$$

Concerning the competition ratios[14] of various reducing agents and the values of the reorganization energy (0.7—1.8 eV)[41] of them the charge transfer across the interface is considered to proceed in the participation of some surface energy level.[42]

We propose the schemes in Fig. 15 for the elucidation of the current-potential behaviour of CdS photoanode in contact with an electrolyte solution containing

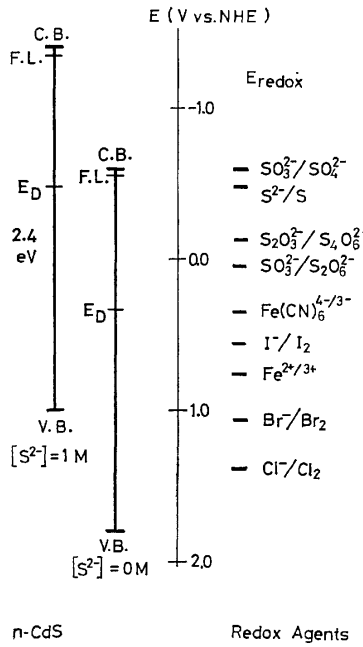

Fig. 14. Schematic diagram of the correlation of the energy levels between a semiconductor (CdS) electrode and reducing agents in the electrolyte solution.

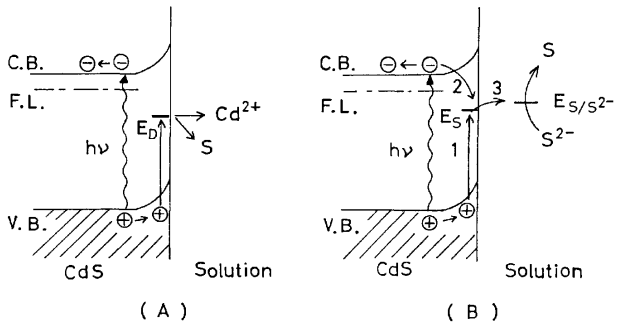

Fig. 15. Schematic diagram of the charge transfer across CdS/electrolyte solution interface.
(A) Dissolution of the CdS electrode surface. (B) Competition between dissolution of the CdS electrode surface and oxidation of S^{2-}.

S^{2-}. Without S^{2-} in solution CdS photoanode can be oxidized by photogenerated holes as shown schematically in Fig. 15(A). In the scheme of Fig. 15(B) it is postulated that a surface state, capable of acting as the recombination center for the photoelectron hole pairs, is induced upon adsorption of S^{2-} on the CdS surface. At potentials differing little from the falt-band potential, both the conduction electron (path 2) and hole (path 1) are easily transferred to such a recombination center. A part of the transferred holes, not undergoing recombination, can oxidize S^{2-} by the path 3 at the rate controlled by the diffusion of S^{2-} to the electrode surface (first wave). When the anodic polarization exceeds a critical value, the probability of the path 2 becomes negligible.[43] At this stage, the excess holes begin to oxidize the electrode itself causing dissolution (second wave), since the rate of oxidation of S^{2-} (path 3) is diffusionally controlled. When the electrolyte solution contains excess sulfide

ions against the incident photons the oxidation of a sulfide ion precedes the dissolution of CdS photoanode through the above competitive reaction scheme, which can elucidate the stabilization of the CdS photoanode.[44]

However, the concrete characteristics of the surface state have not been well known, and are currently under investigation in this laboratory.

Study of Metal–Polycarboxylate Complexes Employing Ion-selective Electrodes. III. Complex Formation between Maleic Acid Copolymers and Bivalent Transition Metal Ions

Fumitaka YAMASHITA,* Tsuyoshi KOMATSU, and Tsurutaro NAKAGAWA
Department of Polymer Science, Faculty of Science, Hokkaido University, Sapporo 060
(Received July 27, 1978)

The complex formation of bivalent transition metal ions, Mn(II), Co(II), Ni(II), Cu(II), and Zn(II), with copoly(maleic acid–ethylene) and copoly(maleic acid–styrene) in aqueous solution was studied by potentiometric titration at 25 °C and the ionic strength of 0.1. The systems containing copper(II) ions were investigated by potentiometry employing the copper(II) ion-selective electrode. The titration curves of the bivalent metal–copoly(maleic acid–ethylene) systems were situated in a lower pH region than in the absence of the metal ions. The complex formed involves two carboxylate groups: primary and secondary. The equilibrium constant of the copper(II) complex was estimated to be $10^{-2.6}$. In copoly(maleic acid–styrene) systems, however, the titration curves in the absence and presence of bivalent metal ions overlapped partly in the first neutralization step. From the potentiometric results employing the ion-selective electrode, it was observed that the concentrations of copper(II) ions decrease slightly in the region of overlap. This anomalous behavior is due to the acid dissociation influenced by the conformational transition, including the effect of the side groups of the polymers.

The study of solution properties of the aqueous polyelectrolytes containing various counterions has been well established, especially in the cases of poly(acrylic acid) and poly(methacrylic acid), from the viewpoints of the counterion binding and the conformational transition of polyelectrolytes. Since the various hydrophobic residues of maleic acid copolymers can be relatively easily introduced in polymer chains as comonomers, they are of interest in connection with the short range interaction of the side groups and have been extensively studied.

In addition, the succinic acid residues derived from maleic anhydride units are also of interest as a polymeric ligand consisting of carboxyl pairs, because the acid dissociation constants of these carboxyl groups are found to be quite different. The interaction and complex formation with metal ions, especially with bivalent ones, are important and have been studied by some workers.[1–5]

In our previous papers,[6,7] the systems consisting of copper(II) ions and poly(itaconic acid), whose monomer unit has two carboxyl groups, have been studied by potentiometric titration employing the copper(II) ion-selective electrode. It was concluded that bis(carboxylato)copper(II) complexes are formed and that one of chelating carboxylate groups is the secondary carboxyl group, even in the first neutralization step. In a recent paper,[8] the systems of maleic acid–styrene copolymer were studied and the anomalous overlap of the titration curves in the absence and presence of the bivalent metal ions was observed.

In the present paper, the overlap in maleic acid–styrene copolymer systems was investigated by potentiometry employing an ion-selective electrode, and the maleic acid–ethylene copolymer, in which the hydrophobic side groups are absent, was studied for comparison.

Experimental

Materials. Copoly(maleic acid–ethylene), MAEt, was obtained by hydrolysis of the alternating 1 : 1 copolymer of maleic anhydride with ethylene; this was Monsanto Chemical Co.'s Grade 31. Its characterization was outlined in Technical Bulletin I-261 of the company.

Copoly(maleicanhydride–styrene) was prepared and reprecipitated by the procedures of Ohno and coworkers,[9] and the copolymer was hydrolyzed to obtain copoly(maleic acid–styrene), MASt, in water at 60 °C for 24 h. The aqueous solution of MASt was purified by dialysis using cellophane tubing. The 1 : 1 composition of comonomers was confirmed by elemental analysis, and the molecular weight was found to be 10^5 by viscometry.[9]

The other chemicals and bivalent metal nitrate salts used were guaranteed reagent grade.

Potentiometric Titration. The pH measurements were performed by use of a Yokogawa Model KPH-51A pH meter equipped with Toadenpa Model HG-4005 galss and Model HC-2005 calomel electrodes. The titrations were carried out with about 0.1 mol/l aqueous solution of carbonate-free NaOH at 25±0.05 °C and ionic strength of 0.1(KNO_3) under nitrogen atmosphere.

The activity measurements of free copper(II) ions were carried out by use of an Orion Model 801A digital ion meter equipped with Beckman Model 39612 Cupric and Horiba Model 2010-05T calomel electrodes. The corrections and determination of the concentrations of copper(II) ions were carried out with the calibration curve obtained by potentiometric measurements of the systems free from polymeric ligands.

Each system measured consists of about 5×10^{-3} monomol/l polyacid, 1×10^{-1} mol/l KNO_3, and about 1×10^{-3} mol/l bivalent metal ions.

All the potentiometric measurements were operated in the pH region less than 6.00 because of the precision of pH titration of this weak polyacid and the formation of bivalent metal hydroxides.

Results and Discussion

Titration Behaviors of Copolymers without Complexing Metal Ions. The apparent dissociation constant $pK_{1,app}$ of the primary carboxyl groups is given as

$$pK_{1,app} = pH - \log \alpha_1/(1-\alpha_1),$$

where α_1 is the degree of dissociation of the primary carboxyl groups. The α_1 dependences of $pK_{1,app}$ of MAEt and MASt are shown in Fig. 1. The shapes

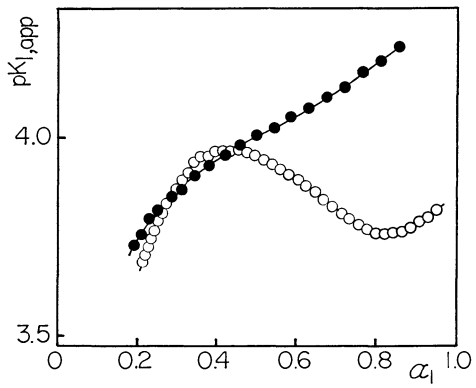

Fig. 1. Apparent dissociation constant, $pK_{1,app}$, as a function of α_1 for MAEt and MASt at the ionic strength of 0.1(KNO_3): (●) MAEt(0.00498 monomol/l); (○) MASt(0.00432 monomol/l).

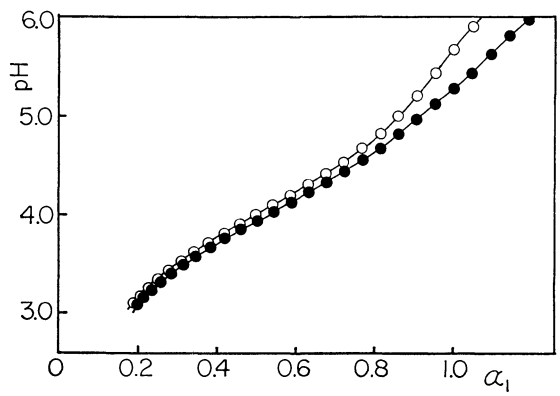

Fig. 2. Titration curves of MAEt(0.00498 monomol/l) in (○) the absence and (●) the presence of zinc(II) ions(1×10^{-3} mol/l $Zn(NO_3)_2$) at the ionic strength of 0.1(KNO_3).

of these curves are similar to those of the same samples observed by some other authors,[9,10] and small discrepancies of $pK_{1,app}$ values may correspond to the difference of concentrations of neutral salts added.

The values of $pK_{1,app}$ of MAEt are linearly dependent on α_1, which shows that the acid dissociation is influenced only by the change of charge density on polyions and that interaction of side groups is absent, as can be concluded from its chemical structure. And the fact that the slope of the $pK_{1,app}$ curve is smaller than that of other homopolymers confirms the dependence on charge density.

In the case of MASt, an anomalous dependence of $pK_{1,app}$ on α_1, the so-called pH-induced conformational transition, is observed. This anomaly was discussed in detail by Ohno and coworkers,[9,11,12] who interpret this anomalous behavior as due to the conformational transition from the compact form, which is stabilized by the hydrophobic interaction between the phenyl groups, to the extended coil form of the copolymer chain. This interpretation is probably reasonable, but it is strange that the decrease of $pK_{1,app}$ with increasing in α_1 is apparently observed in the range from 0.4 to 0.8. This behavior is also observed in the case of poly(methacrylic acid). Such a tendency implies that there occurs some promotion of dissociation with α_1, which is generally improbable. In this dissociation range, the fact that the polymer chain extends suddenly was observed in the viscometric data by Ohno. In such a case, the hydrophobic interaction may decrease, and the local effective dielectric constant may vary; its effect may be reflected in the decrease of the acid dissociation constant, although this point must be confirmed by other experiments.

Titration Behaviors of Systems Containing Bivalent Metal Ions. The titration curves of MAEt in the absence and presence of zinc(II) ions are shown in Fig. 2; the cases of the other bivalent metal ions are similar to this. When complex formation occurs, it is generally observed that the titration curves in the presence of transition metal ions are situated in a lower pH region than in the case of such simple salts as the alkali metal salts. It can be seen from Fig. 2 that a complex is formed between the carboxylate groups of MAEt and zinc(II) ions. In the cases of the other metal ions, the same result was obtained.

Furthermore, the first equivalence point of the titration curve in the presence of the metal ions is observed a little beyond 1.0 of α_1. As is discussed in the previous papers,[7,8] the point at $\alpha_1=1$ corresponds to the end of the titration of the primary carboxyl groups. It is considered that the deviation of the equivalence point from $\alpha_1=1.0$ results from the complex formation including the secondary carboxyl groups.

Thus, it can be concluded that the complex formed involves two carboxylate groups in the same succinic unit : one is a primary carboxylate group and the other a secondary one, even in the first neutralization step; this conclusion agrees with those of Felber[2,3] and Delben.[4,5]

The titration curves of MASt in the absence and presence of zinc(II) ions are shown in Fig. 3. The curves for the other metal ions are similar to this figure, except those of copper(II) ions. Around at $\alpha_1=1.0$, behaviors like those of MAEt systems are observed: there is an apparent shift of the first equivalence point. Thus it can be concluded that bis(carboxylato)zinc(II) complexes which have both the primary and secondary

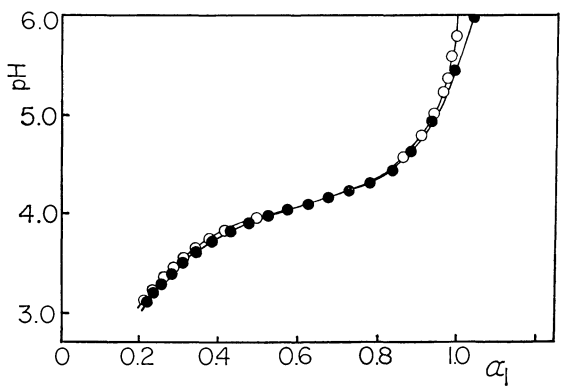

Fig. 3. Titration curves of MASt(0.00432 monomol/l) in (○) the absence and (●) the presence of zinc(II) ions (1×10^{-3} mol/l $Zn(NO_3)_2$) at the ionic strength of 0.1(KNO_3).

carboxylate groups are formed.

In the neighborhood of $\alpha_1=0.7$, a behavior quite different from the case of MAEt is observed; this is shown in Fig. 3. In this region of α_1, the titration curves of MASt in the absence and presence of the metal ions overlap partly, which suggests that the carboxylate groups are released from the metal ions by some effect. However, it is well known that the carboxylate groups produce relatively stable complexes with bivalent transition metal ions. In order to elucidate this point, the results of potentiometry employing the ion-selective electrode were examined.

Titrations Employing a Copper(II) Ion-selective Electrode. Since there is some complexity in the response of this electrode,[6,13] the reproducibility and stability of the response were confirmed again in the present study by measurements of the solutions containing copper(II) ions of known concentrations under similar conditions without the added copolymer.

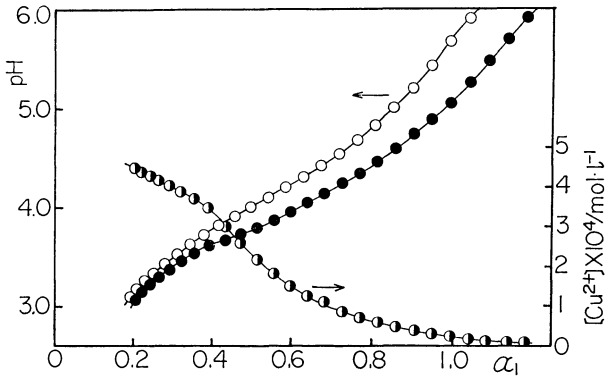

Fig. 4. Dependence of concentration of free copper(II) ions on α_1 (◑), and titration curves of MAEt (0.00498 monomol/l) in (○) the absence and (●) the presence of copper(II) ions (5×10^{-4} mol/l $Cu(NO_3)_2$) at the ionic strength of 0.1(KNO_3).

In Fig. 4, the titration curves of MAEt in the absence and presence of copper(II) ions and the dependence of the concentrations of free copper(II) ions, $[Cu^{2+}]$, on α_1 are shown. In this figure, the initial concentration of copper(II) ions is 5.00×10^{-4} mol/l. The α_1 dependence of the pH difference, ΔpH, between the values in the absence and presence of copper(II) ions at the same value of α_1 corresponds well to the dependence of $[Cu^{2+}]$. This fact shows that the complex formation proceeds along with the increase in α_1. Relatively stable complexes are formed in the α_1 range above 0.35. But when the total concentration of copper(II) ions added is relatively high: more than 10^{-3} mol/l, it was confirmed that the complexes are formed from the first titration step.

Just as in MAEt–zinc(II) systems or poly(itaconic acid)–copper(II) systems,[6] it can be concluded that relatively stable complexes are formed between MAEt and copper(II) ions and that the complex involves both the primary and secondary carboxylate groups in the same succinic acid unit.

In Fig. 5, the dependences of pH and concentrations of free copper(II) ions on α_1 in the case of MASt are

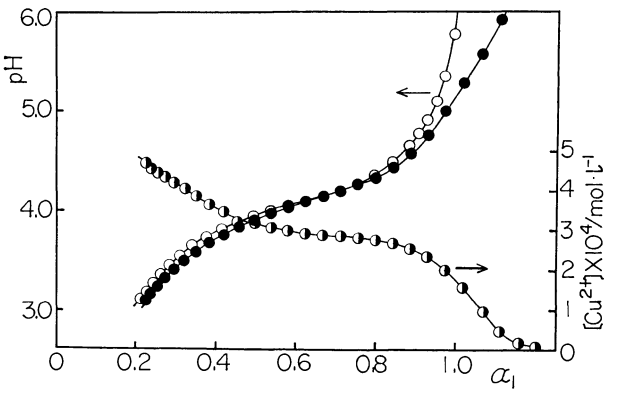

Fig. 5. Dependence of concentration of free copper(II) ions on α_1 (◑), and titration curves of MASt (0.00432 monomol/l) in (○) the absence and (●) the presence of copper(II) ions (5×10^{-4} mol/l $Cu(NO_3)_2$) at the ionic strength of 0.1(KNO_3).

shown. The anomalous overlap of the titration curves, as in MASt–zinc(II) systems, is observed in the α_1 ranging from 0.6 to 0.8, which shows that the complexes once formed are broken. In the same α_1 range, on the other hand, the concentration of free copper(II) ions decreases slightly, which shows that the complexes are not broken and do not change to free copper(II) ions. These two results are incompatible with each other. Considering that rather stable complexes are generally formed between the carboxylate groups of the other polyelectrolytes and copper(II) ions, and that the concentration of carboxylate groups as a ligand increases with α_1, it is difficult to conclude that the complexes once formed may break up.

Thus, one of causes of the anomalous overlap may lie in the character of the dissociation equilibrium of MASt, because this overlap corresponds to the α_1 range where the values of $pK_{1,app}$ are decreasing. The equilibrium constant of the complex formation can be described as the products of the acid dissociation constant, K_a, and the stability constant, β, of the complex; for example:

$$B_2=\frac{[MA_2][H^+]^2}{[M^{2+}][HA]^2}=\frac{[MA_2]}{[M^{2+}][A^-]^2}\frac{[A^-]^2[H^+]^2}{[HA]^2}$$
$$=\beta_2\times(K_a)^2.$$

If the equilibrium constant is only slightly dependent on α_1, the value of β decreases with the decrease in pK_a. In the neighborhood of $\alpha_1=0.7$, where the overlap occurs, such a relation of each constant can be assumed, and the concentration of the complexes scarcely increases, because of the cancelling between the decrease of β and the increase of the concentration of the free carboxylate groups. Such a discussion interprets the variation of the concentration of free copper(II) ions. In order to explain the anomalous overlap of the titration curves sufficiently, it is necessary to have more detailed knowledge of the conformational transition not only of the MASt chain itself but also of the chain which contains the complexing metal ions.

Stability of Complexes. The stability of the

metal complex can be compared by use of the pH difference, ΔpH, between the values in the absence and presence of the bivalent metal ions at the same metal concentration and at the same degree of dissociation. In Table 1, ΔpH of MAEt systems where the initial concentration of each metal ion added is about 1×10^{-3} mol/l are given. The copper(II) complex is much more stable than the others, and the stabilities of each metal complex are roughly in the order of Cu(II)≫Zn(II)>Ni(II)≃Co(II)≃Mn(II). This result agrees approximately with the results for the same systems of Felber[2] and Delben[5] and those for the poly(methacrylic acid) of Sunahara.[14]

In Table 2, the values of ΔpH of MASt systems are given. The stabilities of the MASt complex are in the order of Cu(II)≫Zn(II)≃Ni(II)≃Co(II)>Mn(II). These results are reasonable, except for manganese(II).

1.0	6.0_2	0.2_4	0.3_7	0.4_3	0.4_7	1.1_3

The stability or formation constant of the complex must be estimated for detailed comparison. In the case of the MAEt–copper(II) complex, since the concentration of copper(II) ions can be obtained from potentiometry employing an ion-selective electrode, and since $pK_{1,app}$ of MAEt changes relatively linearly with α_1, the formation constant B_2 can be estimated by the scheme proposed in the previous paper.[6] Here, the constant B_2 is defined as follows:

$$Cu^{2+} + 2HA \rightleftharpoons CuA_2 + 2H^+,\ B_2 = \frac{[CuA_2][H^+]^2}{[Cu^{2+}][HA]^2}.$$

In the α_1 range less than 0.65, the real average coordination number $\bar{n}_x$ of the copper(II)–MAEt system is equal to about two, and each value of $\log B_2$ evaluated from titration is constant and equal to −2.6.

On the other hand, $pK_{1,app}$ of MASt shows a complicated dependence on α_1, so that the reference plot method proposed by Mandel and Leyte[15] cannot be applied. But the value of $\log B_2$ of the copper(II) complex was roughly estimated to be −4.

Thus, it is concluded that the bis(carboxylato) bivalent transition metal complex is formed, in fact, in the first neutralization step of MAEt and MASt, and that the copper(II) complex is the most stable one.

The authors would like to thank Mitsubishi Monsanto Chem. Co., Ltd. and Monsanto Chem. Co. in U. S. A. for a generous supply of MAEt sample.

The unrestricted Hartree-Fock perturbation technique was applied to the calculation of spin densities in many hydrocarbon radicals. The method is similar to that of McLachlan but contains partly the SCF and projection procedures. The results agree with the more rigorous SCF ones.

Spin density distributions in conjugated radicals and ions can be successfully explained by the simplified unrestricted McLachlan method.[1] Though approximate UHF functions without projection are used, the spin densities thus obtained are in good agreement with experiment. A discussion on this has been given by Snyder and Amos.[2] They concluded that this might be caused by compensating errors, the use of a single SCF iteration and the failure to project or annihilate. The McLachlan method does not appear to be theoretically well founded. Modified versions of the method have been presented by many authors[3–9] without due attention to theory.

This paper presents an alternative form of the McLachlan method within the perturbed Hückel approximation. Since our approach still contains the SCF and projection procedures, the spin densities in π-electron radicals and ions calculated can be compared with the results obtained by the more rigorous UHF method.

Theory

Let us consider a doublet ground state for a conjugated radical. According to Brickstock and Pople[9] the SCF π-electron Hamiltonian matrix elements are given by

$$\left.\begin{aligned} F^{\alpha(\beta)}_{\mu\mu} &= U_{\mu\mu} + P^{\beta(\alpha)}_{\mu\mu}\gamma_{\mu\mu} + \sum_{\nu\neq\mu}(P_{\nu\nu}-Z_\nu)\gamma_{\mu\nu} \\ F^{\alpha(\beta)}_{\mu\nu} &= \beta_{\mu\nu} - P^{\alpha(\beta)}_{\mu\nu}\gamma_{\mu\nu} \qquad (\mu\neq\nu) \end{aligned}\right\} \quad (1)$$

where

$$P^{\alpha(\beta)}_{\mu\nu} = \sum_{i}^{\text{occ.}} C^{\alpha(\beta)}_{i\mu}C^{\alpha(\beta)}_{i\nu}$$

$$P_{\mu\nu} = P^{\alpha}_{\mu\nu} + P^{\beta}_{\mu\nu}$$

and the superscripts α and β refer to α and β electrons respectively. Throughout this paper, Greek suffixes will be used for atomic orbitals and italics for molecular orbitals. Let us take the arithmetical mean values of the matrix elements given by Eq. 1 as

$$\left.\begin{aligned} \bar{F}_{\mu\mu} &= \frac{1}{2}(F^{\alpha}_{\mu\mu}+F^{\beta}_{\mu\mu}) = U_{\mu\mu} + \frac{1}{2}P_{\mu\mu}\gamma_{\mu\mu} \\ &\quad + \sum_{\nu\neq\mu}(P_{\nu\nu}-Z_\nu)\gamma_{\mu\nu} \\ \bar{F}_{\mu\nu} &= \frac{1}{2}(F^{\alpha}_{\mu\nu}+F^{\beta}_{\mu\nu}) = \beta_{\mu\nu} - \frac{1}{2}P_{\mu\nu}\gamma_{\mu\nu} \\ &\quad (\mu\neq\nu). \end{aligned}\right\} \quad (2)$$

These matrix elements are just those defined by Longuet-Higgins and Pople.[10] From Eqs. 1 and 2 we obtain

$$\left.\begin{aligned} \Delta F^{\alpha}_{\mu\nu} &= F^{\alpha}_{\mu\nu} - \bar{F}_{\mu\nu} = -\frac{1}{2}\rho_{\mu\nu}\gamma_{\mu\nu} \\ \Delta F^{\beta}_{\mu\nu} &= F^{\beta}_{\mu\nu} - \bar{F}_{\mu\nu} = \frac{1}{2}\rho_{\mu\nu}\gamma_{\mu\nu} \end{aligned}\right\} \quad (3)$$

where

$$\rho_{\mu\nu} = P^{\alpha}_{\mu\nu} - P^{\beta}_{\mu\nu}. \quad (4)$$

Equation 3 suggests that the approximate restricted Hartree-Fock method of Longuet-Higgins and Pople[10] is a good starting point for perturbation treatment of the UHF method.

We are now in a position to formulate the spin density by means of perturbation theory. Equation 4 is modified as

$$\begin{aligned} \rho_{\mu\nu} &= (\overline{P^{\alpha}_{\mu\nu}}-\overline{P^{\beta}_{\mu\nu}}) + (\Delta P^{\alpha}_{\mu\nu}-\Delta P^{\beta}_{\mu\nu}) \\ &= \rho^{\circ}_{\mu\nu} + (\Delta P^{\alpha}_{\mu\nu}-\Delta P^{\beta}_{\mu\nu}) \end{aligned} \quad (5)$$

where

$$\overline{P^{\alpha}_{\mu\nu}} - \overline{P^{\beta}_{\mu\nu}} = C_{0\mu}C_{0\nu} = \rho^{\circ}_{\mu\nu}$$

$$\Delta P^{\alpha(\beta)}_{\mu\nu} = P^{\alpha(\beta)}_{\mu\nu} - \overline{P^{\alpha(\beta)}_{\mu\nu}}$$

$\overline{P^{\alpha(\beta)}_{\mu\nu}}$ and $\rho^{\circ}_{\mu\nu}$ stand for the corresponding quantities of $P^{\alpha(\beta)}_{\mu\nu}$ and $\rho_{\mu\nu}$, respectively, within the RHF scheme. We can put

$$\Delta P^{\alpha(\beta)}_{\mu\nu} = \sum_{\kappa\lambda}\Pi^{\alpha(\beta)}_{\mu\nu,\kappa\lambda}\Delta F^{\alpha(\beta)}_{\kappa\lambda} \quad (6)$$

where the polarizability $\Pi^{\alpha(\beta)}_{\mu\nu,\kappa\lambda}$ can be defined as

$$\Pi^{\alpha(\beta)}_{\mu\nu,\kappa\lambda} = \partial\overline{P^{\alpha(\beta)}_{\mu\nu}}/\partial\bar{F}_{\kappa\lambda}.$$

Since

$$\overline{P^{\alpha}_{\mu\nu}} + \overline{P^{\beta}_{\mu\nu}} = \overline{P_{\mu\nu}}$$

we obtain

$$\partial\overline{P_{\mu\nu}}/\partial\overline{F_{\kappa\lambda}} = \Pi^{\alpha}_{\mu\nu,\kappa\lambda} + \Pi^{\beta}_{\mu\nu,\kappa\lambda} \equiv \Pi_{\mu\nu,\kappa\lambda}. \quad (7)$$

Using Eqs. 3, 6, and 7, the resulting expression for the spin density matrix elements is reduced to

$$\rho_{\mu\nu} = \rho^{\circ}_{\mu\nu} - \frac{1}{2}\sum\Pi_{\mu\nu,\kappa\lambda}\rho_{\kappa\lambda}\gamma_{\kappa\lambda}. \quad (8)$$

If we restrict ourselves to the consideration of atom spin densities only, Eq. 8 becomes

$$\rho_{\mu\mu} = \rho^{\circ}_{\mu\mu} - \frac{1}{2}\sum_{\nu}\Pi_{\mu\mu,\nu\nu}\rho_{\nu\nu}\gamma_{\nu\nu}. \quad (9)$$

Since Hückel-type and SCF-type MO's do not differ significantly, according to McLachlan,[1] the Hückel-type MO's can be applied introducing a parameter λ. Thus Eq. 9 can be written as

$$\rho_{\mu\mu} = \rho^{\circ}_{\mu\mu} - \lambda\sum_{\nu}\Pi_{\mu\nu}\rho_{\nu\nu} \quad (10)$$

where the $\Pi_{\mu\nu}$ are dimensionless atom-atom polarizabilities. From Eq. 7, they are defined by

$$\Pi_{\mu\nu} = 4\sum_{i}^{\text{doubly occ.}}\sum_{j\neq i}^{\text{all}}\frac{C_{i\mu}C_{j\mu}C_{i\nu}C_{j\nu}}{\varepsilon_i-\varepsilon_j} + 2\sum_{k\neq 0}^{\text{all}}\frac{C_{0\mu}C_{k\mu}C_{0\nu}C_{k\nu}}{\varepsilon_0-\varepsilon_k} \quad (11)$$

or

$$\Pi_{\mu\nu} = \Pi^{(0)}_{\mu\nu} + \Pi^{(1)}_{\mu\nu} \tag{12}$$

where

$$\left.\begin{aligned}\Pi^{(0)}_{\mu\nu} &= 4 \sum_{i}^{\text{doubly occ.}} \sum_{j}^{\text{vac.}} \frac{C_{i\mu}C_{j\mu}C_{i\nu}C_{j\nu}}{\varepsilon_i - \varepsilon_j} \\ \Pi^{(1)}_{\mu\nu} &= \sum_{i}^{\text{doubly occ.}} \frac{C_{i\mu}C_{0\mu}C_{i\nu}C_{0\nu}}{\varepsilon_i - \varepsilon_0} + 2\sum_{j}^{\text{vac.}} \frac{C_{0\mu}C_{j\mu}C_{0\nu}C_{j\nu}}{\varepsilon_0 - \varepsilon_j}.\end{aligned}\right\} \tag{13}$$

Subscript 0 refers to the odd electron orbital. The polarizability defined by Eq. 11 or 12 is not that for closed shell molecules but is valid for radicals and ions. A similar definition of polarizability has also been proposed by Devolder,[8] but it was incorrect.[7] It is easy to show that the pairing theorem holds for alternant hydrocarbons, even if the polarizability defined above is used in our theory; that is, the spin density distributions in the anion and cation of an even alternant are expected to be identical.

Equation 10 is similar to the McLachlan formula,[1] but is in principle a simultaneous equation. The explicit solution of Eq. 10 can be written as

$$\rho^{\text{UHF}}_{\mu\mu} = \sum_{\nu} X_{\mu\nu}\rho^{\circ}_{\nu\nu} \tag{14}$$

where

$$X_{\mu\nu} = (-1)^{\mu+\nu}\Delta_{\mu\nu}/\Delta$$
$$\Delta = \det\{\delta_{\mu\nu} + \lambda\Pi_{\mu\nu}\}.$$

$\Delta_{\mu\nu}$ is the determinant obtained by striking out the μth column and νth row from the determinant Δ. The equation can be rewritten as

$$\rho^{\text{UHF}}_{\mu\mu} = \rho^{\circ}_{\mu\mu} - \lambda \sum \Pi^{\text{SCF}}_{\mu\nu}\rho^{\circ}_{\nu\nu} \tag{15}$$

where

$$\Pi^{\text{SCF}}_{\mu\nu} = (\delta_{\mu\nu} - X_{\mu\nu})/\lambda. \tag{16}$$

The $\rho^{\text{UHF}}_{\mu\mu}$ thus obtained approximately corresponds to the spin density for the SCF UHF function, though a perturbation theory is used in our approach where the SCF procedure is partly introduced by solving the simultaneous equation instead of iterations. Such an SCF perturbation theory was applied successfully to the bond order problem by Coulson and Golebiewski.[11] Validity of the procedure is confirmed by the numerical results.

In general, UHF spin densities do not agree with experiment because of spin contamination. Let us now introduce the projection procedure to our approach. To the first order of perturbation theory, the spin density for the projected UHF function is given by

$$\rho^{\text{PUHF}}_{\mu\mu} = \rho^{\circ}_{\mu\mu} - \frac{1}{3}\lambda \sum_{\nu} \Pi^{(0)}_{\mu\nu}\rho^{\circ}_{\nu\nu} - \lambda \sum_{\nu} \Pi^{(1)}_{\mu\nu}\rho^{\circ}_{\nu\nu} \tag{17}$$

where the last term comes from the pure doublet configurations, so it is left through a projection.[2,12-15] However, within the SCF perturbation theory, such a procedure as separating the last two terms of Eq. 17 may be cumbersome; our aim is to obtain a simplified formula. Fortunately, Snyder and Amos[2] suggested that the following approximation is practically reasonable.

$$\rho^{\text{PUHF}}_{\mu\mu} \approx \rho^{\circ}_{\mu\mu} - \frac{1}{3}\lambda \sum_{\nu} \Pi^{\text{SCF}}_{\mu\nu}\rho^{\circ}_{\nu\nu} \tag{18}$$

Therefore we may approximate the projected spin density as above.

Let us deal with the next difinition of spin density. If the $\rho_{\nu\nu}$ which appears in the second term of Eq. 10 can be approximated as the $\rho^{0}_{\nu\nu}$, we have

$$\rho^{\text{MMc}}_{\mu\mu} = \rho^{\circ}_{\mu\mu} - \lambda \sum_{\nu} \Pi_{\mu\nu}\rho^{\circ}_{\nu\nu}. \tag{19}$$

The approximation indicates the use of the usual perturbation theory instead of the SCF one. Equation 19 is now formally reduced to the McLachlan formula.[1] However, our formula is different from McLachlan's in the definition of polarizabilities, which is given by Eq. 11 or 12.

Calculations and Results

First let us evaluate the adjustable parameter λ. McLachlan obtained $\lambda = \gamma/2|\beta| \approx 1.2$ using the parameter of Pariser and Parr $\gamma = 10.53$ eV. However, Gutfreund and Little[16] concluded from the consideration of the screened potential that the γ values are of the order of 7—9 eV in most cases for large π-electron systems, depending on the position of the given atomic site in the molecule. To a cruder approximation, we can neglect the small variation of β and position dependence of γ, taking the average value of γ. The λ values then become proportional to the constant γ. It can be inferred that the average value of γ for the anion is smaller than for the corresponding cation and the neutral radical falls into the middle, since the γ values can be considered to be proportional to the screening constants. On this assumption, the spin density distributions for the anion and the corresponding cation differ from each other, indicating a violation of the pairing theorem. However, the pairing theorem should be valid only within certain approximations; a more rigorous theory violates it. For instance, a renouncement of the approximations of zero-differential overlap or an introduction of penetration energies into the term $U_{\mu\mu}$ which appears in Eq. 1 or 2 leads to breakdown of the pairing theorem. Our assumption is thus reasonable.

On the other hand, the experimental fact that the proton hyperfine splittings of the anions and the corresponding cations of even alternants are not identical has so far been accounted for by using the Colpa-Bolton (CB) relationship[17] which includes the charge effect or the Giacometti-Nordio-Pavan (GNP) effect[18] including that of the nearest-neighbor bond spin densities. However, both relations fail to explain the fact that the lower splittings (for example, at the 2 position of anthracene and naphthacene in Tables 1 and 2) for cations are generally smaller in magnitude than for the corresponding anions in contrast to what is found for the higher splititngs.

In view of the discussion above we will introduce partly the small difference between cations and the corresponding anions into our theory by adjusting the parameter λ. Let us take the λ values as $\lambda = 1.1$, 1.0, and 0.9 for cations, neutral radicals and anions, respec-

tively. The test calculation is carried out for the cations and anions of anthracene and naphthacene. The proton hyperfine splittings and the spin densities calculated are given in Tables 1 and 2, respectively. We see that our calculation gives better agreement with experiment than the others. It should especially be noted that our calculation predicts the relative magnitudes of splittings at the 2 positions of the cations and anions except for the GNP relationship, though the magnitudes are too low. This seems to support our assumption. We will therefore employ the values above throughout this paper.

Secondly, let us see whether the $\rho_{\mu\mu}^{\mathrm{UHF}}$ values defined by Eq. 14 or 15 coincide with the spin densities obtained by means of the more elaborate UHF method. The values of $\rho_{\mu\mu}^{\mathrm{UHF}}$ for a number of hydrocarbon radicals and ions are computed and compared with the spin densities (before annihilation) obtained by Snyder and Amos[2] (Table 2). The spin densities agree reasonably well with each other except for some positions of benzil. This seems to justify our SCF perturbation treatment. Moreover, if it is borne in mind that the perturbed Hückel MO's are used in our treatment, and the SCF MO's in theirs, it may be regarded as an unexpected success.

We have computed the spin densities $\rho_{\mu\mu}^{\mathrm{PUHF}}$ and $\rho_{\mu\mu}^{\mathrm{MMc}}$ defined by Eqs. 18 and 19 respectively, for a number of hydrocarbon radicals and ions in order to compare the results with the ones obtained by Snyder and Amos[2] and by McLachlan[1] (Table 2). A close inspection of Table 2 shows the following :

1) As a whole the values of the four different expressions of spin densities $\rho_{\mu\mu}^{\mathrm{PUHF}}$, $\rho_{\mu\mu}^{\mathrm{MMc}}$, $\rho_{\mathrm{aa}}^{\mathrm{SA}}$, and ρ^{Mc} agree fairly well with each other.

2) In particular agreement between $\rho_{\mu\mu}^{\mathrm{MMc}}$ and ρ^{Mc}, and between $\rho_{\mu\mu}^{\mathrm{PUHF}}$ and $\rho_{\mathrm{aa}}^{\mathrm{SA}}$ is quantitatively good.

3) The values of $\rho_{\mu\mu}^{\mathrm{PUHF}}$ and $\rho_{\mu\mu}^{\mathrm{MMc}}$ are in good agreement with each other in spite of different difinitions.

The discrepancy between the $\rho_{\mu\mu}^{\mathrm{MMc}}$ and ρ^{Mc} spin densities is due to the use of different values of λ and $\Pi_{\mu\nu}$ except for odd alternant hydrocarbon radicals. A similar discussion applies to a comparison of the $\rho_{\mu\mu}^{\mathrm{PUHF}}$ and $\rho_{\mathrm{aa}}^{\mathrm{SA}}$ values.

Let us now compare the $\rho_{\mu\mu}^{\mathrm{PUHF}}$ and $\rho_{\mu\mu}^{\mathrm{MMc}}$ spin densities. The important difference between the two is that the projected UHF functions and the SCF perturbation theory are used for the former, and unprojected ones and a simple perturbation theory for the latter. Nevertheless the two give almost equivalent spin densities. This seems to give numerical evidence of the validity of the McLachlan-type formulas. The theoretical basis of the formulas is not yet established, but agreement between them may probably be due to accidental cancellation in errors when a perturbation method is used. The problem has been discussed by Snyder and Amos.[2]

Discussion

Our theory employs the perturbed Hückel approach with use of the SCF and projection procedures. The McLachlan-type formulas are therefore obtained as a special case. We wish to clarify the correlation between the McLachlan-type formulas and ours.

Since $\lambda \approx 1$ and usually $|\Pi_{\mu\nu}| < 1$, we may expand the SCF polarizability $\Pi_{\mu\nu}^{\mathrm{SCF}}$ as

$$\Pi_{\mu\nu}^{\mathrm{SCF}} = \Pi_{\mu\nu} - \lambda \sum_{\kappa} \Pi_{\nu\kappa}\Pi_{\kappa\nu} + \cdots \tag{20}$$

Substituting Eq. 20 into Eq. 15, we obtain

$$\rho_{\mu\mu}^{\mathrm{UHF}} = \rho_{\mu}^{\circ} - \lambda \sum_{\nu} \Pi_{\mu\nu}\rho_{\nu\nu}^{\circ} + \lambda^2 \sum_{\nu\kappa} \Pi_{\mu\kappa}\Pi_{\kappa\nu}\rho_{\nu}^{\circ} + \cdots \tag{21}$$

By comparing Eq. 21 with Eq. 19 we see that the difference between the UHF spin density $\rho_{\mu\mu}^{\mathrm{UHF}}$ and the modified McLachlan-type one $\rho_{\mu\mu}^{\mathrm{MMc}}$ is the quadratic and higher order terms of polarizabilities. The contributions from these higher order terms to the spin density appear to be rather small. However, the order of magnitude of the $\Pi_{\mu\nu}$ $(\Pi_{\mu\mu}+\Pi_{\nu\nu})$ which appears in the second term of Eq. 20 can be compared with the one of the first term $\Pi_{\mu\nu}$. Actually the order

of magnitude of $\Pi_{\mu\nu}^{SCF}$ is fairly greater than the one of $\Pi_{\mu\nu}$ in many cases. Our result confirms this; the $\rho_{\mu\mu}^{MMc}$ spin density is far from the $\rho_{\mu\mu}^{UHF}$ one at many positions of radicals (Table 2). In the following we will discuss the question why such a crude model as the McLachlan method can successfully interpret experimental results.

Marshall[12] showed that the unprojected spin density should be closer to experimental result than the projected one under certain conditions. On the other hand, Snyder and Amos[2] showed that in first order to Lowdin's extended Hartree-Fock scheme,[19] in terms of our theory, the spin density can be approximated as[20]

$$\rho_{\mu\mu}^{EXT} \approx \rho_{\mu\mu}^{\circ} - K\lambda \sum_{\nu} \Pi_{\mu\nu}^{SCF} \rho_{\nu\nu}^{\circ} \qquad (22)$$

where K is a dimensionless coefficient which can be expressed as some ratio of energy terms; if $K=1$ the $\rho_{\mu\mu}^{EXT}$ is reduced to the $\rho_{\mu\mu}^{UHF}$ and if $K=1/3$ to the $\rho_{\mu\mu}^{PUHF}$. Most radicals fall between these extremes, the conjugated hydrocarbon radicals appearing to approximate the second case. They suggested that the McLachlan spin density, which falls between the unprojected UHF spin densities and projected ones in most cases, can be good approximations to the ones obtained by the extended Hartree-Fock method. Our results also confirm the suggestion; since $|\Pi_{\mu\nu}| \lesssim |\Pi_{\mu\nu}^{SCF}|$ in many cases, if $K \lesssim 1$ the $\rho_{\mu\mu}^{MMc}$ might agree with the $\rho_{\mu\mu}^{EXT}$. This condition is practically satisfied together with that $K \gtrsim 1/3$ in most cases. Harriman and Sando[21] demonstrated explicitly that this is true in many cases by their numerical results, though K is rather closer to unity.

A comparison is given between our approach and that given in other works. Recently Amos *et al.*[22] suggested a method for improving the spin densities obtained from UHF wave functions. Their procedure differs from ours; they have employed the usual perturbation theory, while we take the self-consistency effect into consideration. Nakatsuji and Hirao[23] have proposed a pseudo-orbital theory which corresponds to an extension of UHF and spin-extended HF theories, containing self-consistency terms.

X-Ray Fluorescence Spectroscopy of Inorganic Solids. III. Si K_α and K_β Spectra in Binary Silicates

Niro KIKUCHI, Takashi MAEKAWA, and Toshio YOKOKAWA*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received August 15, 1978)

The Si K_α and K_β spectra of several silicates were measured. The K_α spectra showed negative energy shifts referred to SiO_2; these are consistent with the results for the binary silicate glasses. On the other hand, the K_β shifts were positive and the absolute values were about ten times as large as the K_α shifts in each compound. A linear relation was observed between K_α and K_β energy shifts. The Si 1s energy shift for the orthosilicate was estimated from the K_β spectral splitting of $Na_2Si_2O_5$. The stability of the silicon–oxygen bond was discussed with the aid of the shifts in K_β and the Si 1s. The above linear relation suggests that the silicon–oxygen bond strength is lowered (the K_β energy is increased) with decreasing Coulombic interaction (lowering K_α energy) between silicon and oxygen in the silicates.

Recently the chemical state analysis by means of X-ray fluorescence spectroscopy has been extensively developed. In the previous paper, we reported the variations of the Si K_α energy in binary silicate glasses as functions of the concentration and the kind of the basic oxides.[1] However, in order to discuss the nature of the silicon–oxygen bond, it is necessary to investigate further the K_β spectra in these materials. The Si K_β spectra correspond to the transition from Si 3p to 1s and they naturally bring out more valuable information about the electronic states in the silicon–oxygen bond than the K_α spectra do.

Dodd and Glen explained the origin of the Si K_β spectra in silicates by means of an MO theory and defined the destabilization energy of the silicon–oxygen bond.[2] Urch[3] and Tossell[4,5] extended this MO treatment by a more quantitative calculation and discussed the details of the nature of the silicon–oxygen bond. However, they were concerned mainly with SiO_2 and orthosilicates, whose spectra are simple and can be explained by assumming the tetrahedral cluster around silicon atoms. Sakka and Matusita measured the Si K_β spectra of simple binary silicate glasses of different compositions and discussed the chemical shifts and the changes of the band width in terms of the destabilization energy of the silicon–oxygen bond strength and the difference of the state of the silicon atoms, *i.e.* degree of the polymerization.[6] When we applied an improved two-crystal spectrometer to measure the Si K_β spectra of silicates, we found some appreciable changes of the spectral profile, as well as the spectrum width and the frequency, which have not been reported. The Si K_β energy shifts were also measured and discussed in terms of the destabilization of the Si–O bond caused by an introduction of the basic oxides to the silica network.

Experimental

Samples. Commercial α-quartz and other single oxides or carbonates were used to prepare the silicate glasses and crystals. Na_2SiO_3 was prepared by dehydrating a commercial $Na_2SiO_3 \cdot 9H_2O$. These synthesized samples were all checked by the X-ray powder diffraction method. Commercial Na_4SiO_4, $Al_2Si_3O_9$, $Mg_2Si_3O_8 \cdot 5H_2O$, and kaolinite were also used. The crystalline samples were ground and pressed into pellets within a polyvinyl chloride ring. The glassy samples were prepared by melting crystalline compounds or the mixtures of the component oxides and pouring them onto a stainless steel plate. The flat glasses were directly introduced into the spectrometer.

Apparatus. The spectrometer used in this experiment was of the two-crystal type. The analyzing crystal was ADP, and the Cr or Rh X-ray tubes were used for the primary X-ray source. The details of the apparatus were described in previous papers.[1,7]

K_α Chemical Shifts. In a previous paper we employed a fourth order equation for curve fitting to the upper part of the K_α spectra in order to evaluate the chemical shift. However, there is a better way to evaluate the shift than the curve fitting method when the K_α spectra of a series of compounds are different from each other only in absolute energy and are quite similar in their profiles. In this paper the following method was adopted. It consists of 4 steps. (See also Fig. 1.)

(i) The "standard" spectrum with a detailed profile of the reference material is obtained.

(ii) A sandwiched series of a "sample" and the "reference" spectra for the sample and for the reference materials respectively is obtained.

(iii) Both spectra are normalized.

(iv) Both spectra are displaced along the energy abscissa to fit the "standard" spectrum. The difference of the energy displacements evaluated with the least square method gives the chemical shift.

An energy discrepancy between the "standard" and "reference" spectra is usually found, partly because the former is obtained with a much greater number of scan

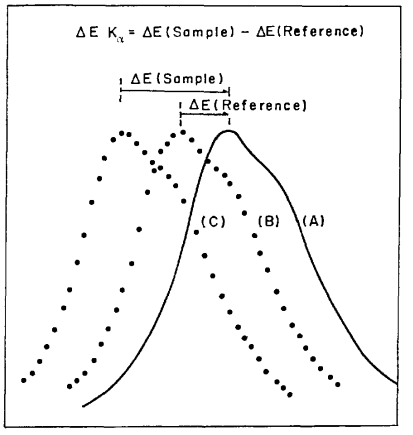

Fig. 1. Determination of the K_α energy shifts.
(A) "Standard" spectrum; (B) "reference" spectrum; (C) "sample" spectrum.

repeats than the "reference" and partly because the performance of the instrument changes from day to day.

K_β Energy Shifts. As the K_β spectra were complex in line shape the shift was evaluated from the energy of the center of gravity of the spectrum. Any complex spectrum was assumed to be composed of two to four Lorentzian curves of various positions and heights. The temperature fluctuation of the analysing crystal(ADP) causes errors of 0.04 eV/deg, which were corrected.

Results

The Si K_α energy shifts of silicates referred to α-quartz are listed in Table 1. All chemical shifts are negative. Generally the absolute values of the chemical shifts are large in samples with high alkali content whenever the comparison is possible. This tendency is in good agreement with the previous findings.[1] Table 1 also shows the K_β energy shifts referred to α-quartz. The shifts are positive and the absolute values are ten times as large as the corresponding K_α energy shifts. These values generally agree well with previous values.[6]

Figure 2 shows Si K_β spectra of several sodium silicates crystals as well as α-quartz and α-cristobalite. No difference between the latter two was detected. The profile becomes complex with Na_2O content and then returns to a single peak of different energy at Na_4SiO_4 composition. Similarly the CaO–SiO_2 system shows a complex profile at intermediate composition, followed by a single peak at the orthosilicate. Table 2 shows the results of Ca K_α, which were also measured for the discussion of ionic charges in silicates.

Table 1. Chemical shifts of Si K_α and K_β energy of silicon compounds

No.	Sample	ΔE K_α/eV	ΔE K_β/eV
1	α-Quartz	—	—
2	α-Cristobalite	−0.002	−0.11

Discussion

Si–O–Si and Si–O⁻ Bonds in Silicates and the Profiles of the K_β Spectra. The molecular orbital of SiO_4^{4-} ion has been constructed to assign the Si K_β spectra of silicates.[4] The Si K_β spectra involve the transition from Si 3p to Si 1s. According to the selection rule, however, the electrons in the molecular orbital of t_2 symmetry can take part in the transition if the tetrahedral geometry is considered. According to Tossell[4] the main bonding orbital $4t_2$ consists of Si 3p and O 2p atomic orbitals and the transition from this to Si 1s is the origin of the K_β main peak. The peak of higher energy than the main peak, which is shown as a shoulder in SiO_2, corresponds to the transition from $5t_2$ non-bonding orbital, which consists mainly of O 2p with a small mixing of Si 3p, to Si 1s. Further, the transition from $3t_2$ (O 2s+Si 3p) produces the spectrum on the energy side lower than the main peak. This has been called the K_β' satellite peak, but it is out of the spectral range covered by the present study.

It is understood that the silica network is modified by an introduction of a basic oxide, as expressed by the following chemical reaction.[8]

$$\equiv Si\text{-}O\text{-}Si\equiv + M_2O = 2\equiv Si\text{-}O^- + 2M^+$$

Thus there are two types of silicon–oxygen bonds: one is Si–O–Si and the other Si–O$^-$. The oxygen in the former type is called a bridging oxygen and in the latter is called a non-bridging oxygen; these are designated by O^0 and O$^-$ respectively. Considering only the nearest neighbor oxygens, the structure around the silicon atom can be considered as Si[O^0]$_4$ and Si[O$^-$]$_4$ for SiO_2 and orthosilicate respectively. In the compounds of intermediate composition, the general structure around a Si atom can be described as Si[O^0]$_n$[O$^-$]$_{4-n}$, when the chemical formula of the compounds is $M_{4-n}SiO_{4-n/2}$ (M; univalent cation).† The experimental spectra for Na_4SiO_4, Ca_2SiO_4 and SiO_2 can be well understood by the T_d symmetry, while in $Na_2Si_2O_5$ there are two intense peaks. The positions are located near the same positions as those of SiO_2 (Si–O–Si only) and Na_4SiO_4(Si–O$^-$ only). A complex profile is also seen in the spectrum of Na_2SiO_3, which consists of a peak and two or more shoulders. The fact that the higher energy peak increases with the concetration of the basic oxides also suggests that the shape of the K_β spectra could be resolved into two main components, one corresponding to the Si–O–Si type and the other to the Si–O$^-$ type bond.

Shifts of the Si 1s Energy. A discussion of the stability of the silicon–oxygen bond has been developed in terms of energy shifts of the K_β spectra.[2,6] The X-ray spectra do not give an absolute orbital energy, but give only a energy difference among levels. It is necessary to take the energy shift of the 1s level into consideration in order to discuss the stability of a bond from a K_β spectrum. In the following we will show one way of estimation of the 1s level shifts from the X-ray spectra.

In the proceeding section we assummed that the double peaks of Si K_β in $Na_2Si_2O_5$ could be assigned to the transition from Si–O–Si and Si–O$^-$ type bonding orbitals. All silicon atoms in the crystalline materials are identical and they are bound to one non-bridging oxygen and three bridging oxygens in a first coordination shell. The 1s electron of the silicon atom is under the average shielding effects of Si 3p (+O 2s and O 2p) electrons. This implies that the separation of two peaks of K_β spectrum of $Na_2Si_2O_5$ corresponds to the difference of the orbital energies of Si–O–Si and Si–O$^-$ bonds, since the two peaks correspond to the transitions to the same Si 1s level. This energy difference is evaluated to be 2.4 eV.

Thus,

$$E_\sigma(\text{Si-O}^-, Na_2Si_2O_5) - E_\sigma(\text{Si-O-Si}, Na_2Si_2O_5) = 2.4\,\text{eV}. \quad (1)$$

E_σ's are the orbital energies of the bonding orbitals of the two types of Si–O bonds. On the other hand, the K_β energies of SiO_2 and Na_4SiO_4 are given by

$$E_{K_\beta}(\text{Si-O-Si}, SiO_2) = E_\sigma(\text{Si-O-Si}, SiO_2) - E_{1s}(SiO_2) \quad (2)$$

$$E_{K_\beta}(\text{Si-O}^-, Na_4SiO_4) = E_\sigma(\text{Si-O}^-, Na_4SiO_4) - E_{1s}(Na_4SiO_4) \quad (3)$$

† $n/2+(4-n)=4-n/2=$(Total number of oxygen atoms per silicon atom in the compound); for example, $n=2$ and 3 for Na_2SiO_3 and $Na_2Si_2O_5$ respectively.

respectively. If ΔE_{1s} is defined by

$$\Delta E_{1s} \equiv E_{1s}(Na_4SiO_4) - E_{1s}(SiO_2), \quad (4)$$

ΔE_{1s} is the energy difference of the 1s level between SiO_2 and Na_4SiO_4. From Eqs. 2 to 4,

$$\begin{aligned}\Delta E_{K_\beta}(\text{Si-O}^-, Na_4SiO) &\equiv E_{K_\beta}(\text{Si-O}^-, Na_4SiO_4) \\ &\quad - E_{K_\beta}(\text{Si-O-Si}, SiO_2) \\ &= E_\sigma(\text{Si-O}^-, Na_4Si_4) \\ &\quad - E_\sigma(\text{Si-O-Si}, SiO_2) - \Delta E_{1s}.\end{aligned} \quad (5)$$

If the first two terms of the right hand side in Eq. 5 are replaced by Eq. 1,

$$\begin{aligned}\Delta E_{K_\beta}(\text{Si-O}^-, Na_4SiO_4) &= 2.4 - \Delta E_{1s} \\ &= 1.6 \text{ (see Table 1).}\end{aligned} \quad (6)$$

Thus the energy shift of Si 1s of Na_4SiO_4 referred to SiO_2 can be estimated to be about 0.8 eV. In this argument the energies of Si–O in Si–O–Si and Si–O$^-$ are assumed to be constant irrespective of the molecular symmetry. Nefedov *et al.* obtained the binding energy of 2p electrons of silicon of many silicon compounds from ESCA measurement.[9] In the SiO_4^{4-} type silicates, the 2p level is destabilized about 0.5—1.1 eV from that of SiO_2. By combining the X-ray K_α energy shifts of these materials (about −0.1 eV), the 1s level energy shifts are calculated to be 0.6—1.2 eV. The present value of 0.8 eV agrees well with these experimental findings.

Heat of Formation of the Silicates and the Silicon–Oxygen Bond Strength. In alkali silicates and silicate minerals, the Si K_β energy is larger than that of SiO_2. This is interpreted in terms of the destabilization of the silicon–oxygen bond in these materials. White and Gibbs observed a linear relation between K_β energy shifts and the silicon–oxygen bond length.[10] Dodd

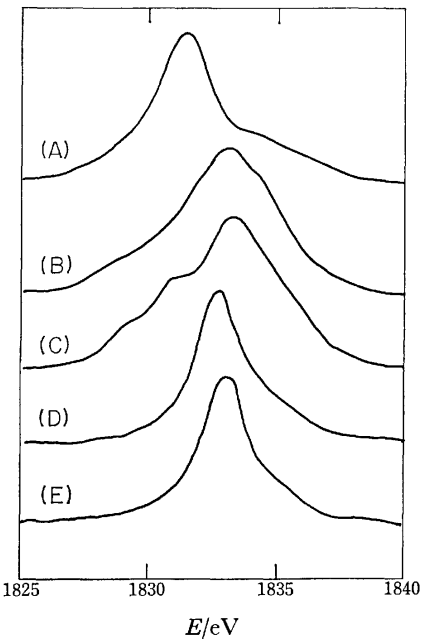

Fig. 3. Si K_β spectra of the CaO-SiO_2 system.
(A) α-Quartz; (B) β-$CaSiO_3$; (C) α-$CaSiO_3$; (D) β-Ca_2SiO_4; (E) γ-Ca_2SiO_4.

and Glen defined the relative destabilization energy of silicon–oxygen bonds from the X-ray K_β energy shifts.[2] However, according to the above argument, the relative destabilization energy of a bonding orbital is better redefined as

$$\Delta \equiv \Delta E_{K_\beta} + \Delta E_{1s}. \quad (7)$$

One obtains a larger destabilization energy for silicates than the previous value deduced only from the K_β chemical shifts.

It is worthwhile to note that when SiO_2 reacts with a basic oxide MO, the Si–O bond becomes weak in spite of the observation that the reaction is usually exothermic. Tossell explained this by an increase of the M–O bond strength.[11] As seen from the Ca K_α sequence measured in the present study (Table 2), the K_α energy shifts to a lower value when the counter F atom is replaced by a less electronegative O and S. In other words, Ca K_α decreases with the decrease of the positive charge on that atom. This means the charge of Ca in silicates $CaSiO_3$ and Ca_2SiO_4 is higher than that of CaO. Therefore the destabilization of the Si–O bond will possibly be counterbalanced by stabilization of the Ca–silicate anion coulombic energy.

Relation between K_α Shifts and K_β Shifts. From the argument that Si K_α energy shifts reflect the degree of the cationic charge on silicon atoms, a relation between Si K_α and K_β energy shifts is expected among silicon compounds. The two quantities are plotted in Fig. 4, whose reference is silicon metal. Except for Na_2SiF_6, which is octahedral in coordination, a quadratic relation was obtained. A linear relation was obtained among silicates where the nearest neighbors are always 4 oxygen atoms and the charges on Si do not change much; this result was independent of the next nearest neighbor cations. (See Fig. 5.)

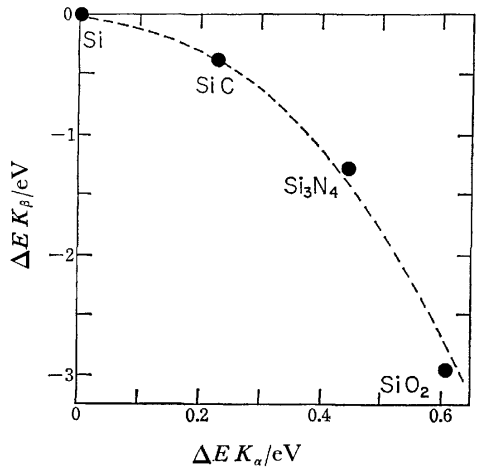

Fig. 4. Relation between Si K_α and K_β energy shifts for the several silicon compounds. The reference material is Si metal.

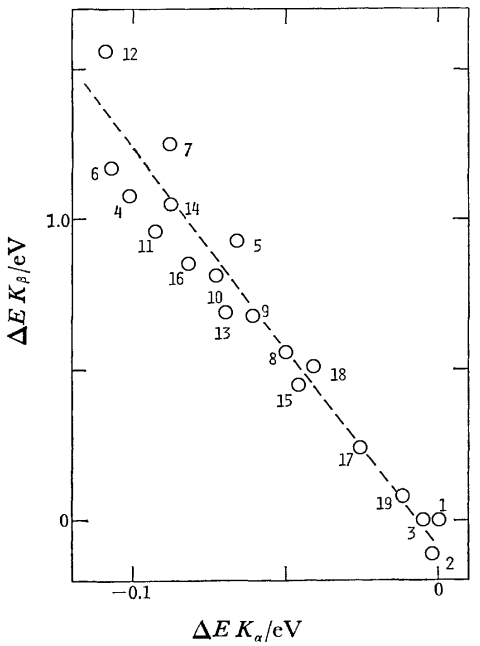

Fig. 5. Relation between Si K_α and K_β energy shifts for the silicates. The reference material is α-quartz. Numbers indicated in the figure correspond to the compounds in Table 1.

ESR Spectrum of Bis(dibenzoylmethanato)oxovanadium(IV) Dissolved in Molten and Crystalline Charge Transfer Complexes

Kotaro ARAYA, Yoshio MATSUNAGA,* and Eiji OCHI

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received August 18, 1978)

The ESR spectrum of bis(dibenzoylmethanato)oxovanadium(IV) dissolved in a number of pyrene and fluoranthene complexes with aromatic polynitro compounds just above their melting points indicates that the motion of the spin probe is more or less restricted. In some favorable cases, the high effective viscosity of the melts can be partially attributed to the association of the electron donor and acceptor molecules. No abrupt change in the ESR spectral pattern is noted upon solidification and the motion of the probe gradually ceases upon lowering the temperature. Therefore, the lattice appears to be not rigid in these crystalline complexes. On the other hand, the ESR spectrum observed in the molten naphthalene–dinitrophenol complex is not far from isotropic at the melting point. Because of the segregation of the probe upon solidification, the measurements on this solid complex could not be made.

When a phase diagram indicates the formation of a 1 : 1 complex with a congruent melting point, it does not necessarily follow that the complex is stable in the molten state. The greater the extent of dissociation, the more flat the curve for the region between the eutectic points is expected, in general, to be.[1–3] However, nothing more can be safely inferred in the absence of any definite information regarding the dissociation of the complex in the molten state. As reported by one of the present authors,[4] all the patterns from the isotropic ESR spectrum to the anisotropic one of oxovanadium chelates can be recorded by employing molten *o*-terphenyl as a solvent. The observed anisotropic molecular motion of the spin probe has been speculated to be evidence for the restricted motion of the host molecules, in other words, the formation of clusters. Therefore, one may hope that the ESR spectral measurement of oxovanadium chelates is equally capable of detecting molecular association in molten charge-transfer complexes. The larger the chelate molecule, the more difficult the motion; thus bis(dibenzoylmethanato)oxovanadium(IV) may be the probe which is effective in the widest temperature range among the three chelates examined before. As will be described below, this chelate was found to be incorporated into the crystalline pyrene, fluoranthene, and phenanthrene complexes with aromatic polynitro compounds and to be a probe for the molecular motion in solids as well.

Experimental

Materials. The bis(dibenzoylmethanato)oxovanadium(IV) ($VO(dbm)_2$) was prepared following the procedure reported by Selbin *et al.*[5] The donors employed were pyrene, fluoranthene, phenanthrene, and naphthalene and the acceptors were *m*-dinitrobenzene (DNB), 2,4-dinitrofluorobenzene (DNF), 2,4-dinitrochlorobenzene (DNC), 2,4-dinitrotoluene (DNT), 2,4-dinitrophenol (DNP), 2,4,6-trinitrochlorobenzene (TNC), and 2,4,6-trinitrotoluene (TNT). The pyrene, Eastman white label, and TNT, Eastman yellow label, were recrystallized from appropriate solvents. The phenanthrene, Eastman white label, was boiled with maleic anhydride in xylene to remove any anthracene.[6] The other reagents were used without further purification. The complexes were prepared by melting mixtures of equimolar amounts of the component compounds. Their melting points were read from calorimetric curves recorded on a Rigaku Denki differential scanning calorimeter, Model 8001 SL/C, at a heating rate of 3 °C min^{-1}. As the paramagnetic probe is not very stable above 150 °C, the complexes with relatively low melting points were selected for the present work.

Measurements. The ESR spectra were recorded on a JEOL model JES-ME-3X (X-band) spectrometer with 100 kHz modulation in the range from temperatures well above the melting point of each complex to the temperature where the probe precipitates from the solid complex. The magnetic-field scan was calibrated with Mn^{2+}-doped MgO powder.

Results and Discussion

The ESR spectra of $VO(dbm)_2$ recorded in most of the pyrene complexes kept just above their melting points deviate markedly from the isotropic one. For example, the first derivative of the spectrum in pyrene–DNC (mp 87 °C) recorded at 88.5 °C is shown in Fig. 1. In this spectrum one may locate more lines than the eight expected for the isotropic spectrum. Thus it is apparent that the motion of the probe is restricted. The parameter, S, defined by

$$S = (A_{\parallel}' - a)/(A_{\parallel} - a)$$

will be employed as a measure of the molecular motion of $VO(dbm)_2$. Here, $A_{\parallel}$ is the component parallel to the V=O bond direction of the approximately axial hyperfine tensor of the spin probe, a is the iso-

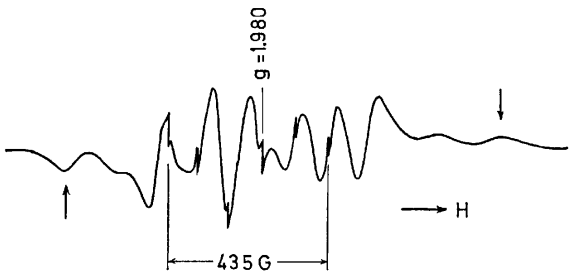

Fig. 1. ESR spectrum of bis(dibenzoylmethanato)-oxovanadium(IV) observed at X-band in pyrene–dinitrochlorobenzene at 88.5 °C. The superimposed small signals are due to the marker, Mn^{2+}-doped MgO powder.

tropic hyperfine constant, and $A_{\parallel}'$ is one-seventh of the separation of the outer hyperfine extrema (these are indicated by arrows in Fig. 1). They are signals from the ensemble of the probe molecules oriented with the applied field, on the average, parallel to the V=O bond direction. The parameter is equal to zero if the probe molecules are tumbling rapidly and unity if they are immobilized in a medium. With the values of $A_{\parallel}$ and a observed in molten *o*-terphenyl, namely, 188 and 108 G (1G=10^{-4} T), the S value for the spectrum in Fig. 1 is estimated to be 0.71. The spectra recorded at higher temperatures indicate a shorter distance for $7A_{\parallel}'$. This means an increased molecular motion. It was not possible to locate the corresponding signals above 114 °C. The probe was found to be dissolved even in the crystalline complex. The spectra recorded below the melting point are still intermediate between the anisotropic and isotropic ones. In this way, the plots given in Fig. 2 were obtained. The open and shaded circles are for two runs with independently-prepared solutions. It must be noted that no discontinuity in the S value is found at the melting point of the complex. This observation may imply that the change of the motional behavior upon solidification is not large or that the motion is slow on an ESR time scale in both the phases. From the macroscopic standpoint, the restriction may be attributed to the high viscosity of the medium, η. Assuming that the η/T value of the medium can be approximated by that of molten *o*-terphenyl at the same S value, the effective viscosity of the molten complex was estimated as 12.2 cP (1cP=10^{-3} Pa s) at the melting point. The viscosity value of *o*-terphenyl required for this estimation was calculated by means of the equation of Greet and Turnbull.[7] It must be added that, if special interactions are conceivable between the probe and solvent molecules, viscosity alone may not account for the deviation from the isotropic ESR spectrum. Therefore, the effective viscosity estimated here may be larger than the actual one.

The S values observed with solidified samples are

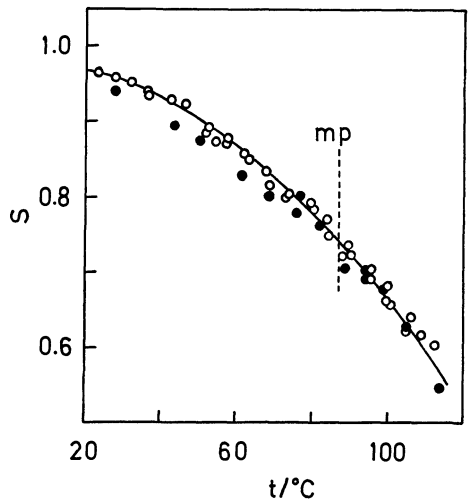

Fig. 2. Temperature dependence of the parameter S in pyrene–dinitrochlorobenzene. The open and shaded circles are for two independent runs.

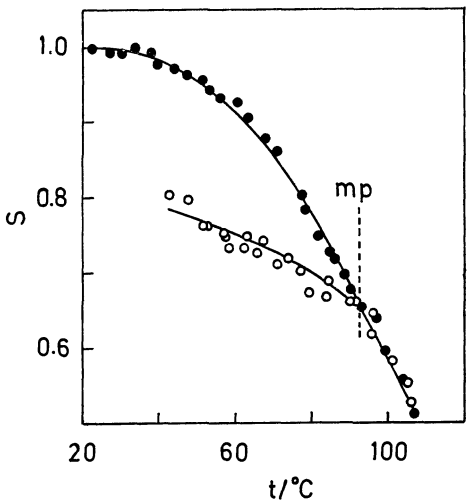

Fig. 3. Temperature dependence of the parameter S in pyrene–dinitrotoluene. The open and shaded circles are for two independent runs.

not very reproducible. In Fig. 3, two independent measurements with the DNT complex are plotted against the temperature. Both the measurements give the same S value, 0.67, at the melting point, 92.5 °C. The open and shaded circles fit on to one curve above this temperature but not below it, suggesting the absence of supercooling of the molten complex. It is unlikely that the difference observed below the melting point arises from a small deviation from the 1 : 1 stoichiometry in the complex for which the lower S values were found. When the complex contains an excess of one of the components, the solid 1 : 1 complex and a liquid coexist in the temperature range from the melting point to the eutectic point. As the probe is generally more soluble in the liquid than in the solid, the observed S value may be largely of the probe in the former phase. If this happens, one expects, in contrast to the observation, that the open circles would lie on the extrapolation of the S-t relation above the melting point. When the temperature is lowered still further, the probe will be more concentrated, eventually leading to the segregation at the eutectic point. As the matter of fact, the segregation was observed at 43 °C, far below the eutectic points, which are 89 °C in the hydrocarbon-rich region and 57.5 °C in the DNT-rich region.[8] Consequently, the large difference in the S values given by these two measurements can be best interpreted in terms of the degree of disorder surrounding the $VO(dbm)_2$ molecules in the solid.

It is well known that dislocations function as a natural haven for solid-state impurities.[9] The large probe molecules may be more satisfactorily accommodated in the expanded region of the dislocation cores and more mobile than elsewhere in the host lattice. On the other hand, Möhwald and Böhm have shown that various guest acceptor molecules can be accommodated in the naphthalene-tetracyanobenzene complex assuming the same very homogeneous orientation as the host donor molecules.[10] In this situation, the motion of the probe molecules does not always occur readily, unless the neighboring host molecules have a large

degree of motion. Thus, the motional behavior of the probe may be dependent upon where the molecules are accommodated which, in turn, may depend on how the melt is quenched.

In addition to the 1 : 1 complex with a congruent melting point, four more pyrene–TNC complexes with mole ratios of 4 : 3, 2 : 1, 3 : 1, and 4 : 1 are known to be formed.[11] The 4 : 3 and 2 : 1 complexes decompose to the solid 1 : 1 complex and a liquid at 136 °C, and the 3 : 1 and 4 : 1 complexes decompose to the solid 2 : 1 complex and a liquid at 126 °C, which is practically the same as the eutectic point. The results obtained with the 1 : 1 and 2 : 1 complexes are illustrated in Fig. 4. The S value at the melting point of the former complex (154.5 °C) is 0.53 and that at the decomposition point of the latter, 0.59. However, the value observed with the 2 : 1 complex at a given temperature above 100 °C is consistently lower than that with the 1 : 1 complex. Thus, the probe molecules are made more mobile as a result of the presence of an excess pyrene in both the molten and solid states. The same tendency was observed with the other TNC complexes containing more pyrene than the 1 : 1 mole ratio. Around 100 °C the S value in the 2 : 1 complex abruptly increases and then becomes almost the same as the value in the 1 : 1 complex. On raising the temperature, a change in the reverse direction occurs between 118 and 125 °C. This change may be associated with the solid-solid transition which was reported earlier to take place at 126 °C.

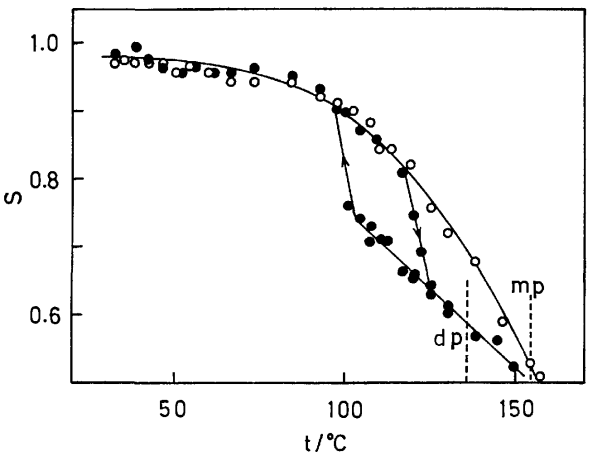

Fig. 4. Temperature dependence of the parameter S in pyrene–trinitrochlorobenzene, the 1 : 1 complex (open circles) and the 2 : 1 complex (shaded circles).

The pyrene complexes with all the aromatic polynitro compounds examined are listed in Table 1 with the S values observed at their melting points. In no case does the value change discontinuously upon solidification. When the molten DNP and TNT complexes are employed as solvents, the outer hyperfine extrema cannot be detected in the ESR spectra near their melting points; however, the extrapolation of the S-t relation obtained with the solid complexes indicates that the required S values are not far from 0.50. Thus, the rapid tumbling of $VO(dbm)_2$ occurs

Table 1. The S values of $VO(dbm)_2$ dissolved in the 1 : 1 molecular complexes at their melting points (Mp), the effective viscosities (η_{eff}) at the same temperatures, and Shinomiya's melting point elevations (τ) (1 cP = 10^{-3} Pa s)

in none of these molecular assemblages at their melting points. The parameter S measures the motion around two axes lying in the flat plane including the vanadium atom. When the probe is dissolved in a liquid, this motion is largely governed by the volume of the solvent to be displaced by the probe molecule.[12] The ESR spectrum of $VO(dbm)_2$ dissolved in molten pyrene is essentially isotropic, that is, $S \fallingdotseq 0$. Therefore, the restricted motion in the TNC and TNT complexes, which have melting points a little higher than that of the hydrocarbon, may be considered as evidence for the association of the electron donor and acceptor molecules in the melts. The magnitude of the S value may depend not only on the size of such clusters but also on the concentration. When the melting point of a pyrene complex is much lower than 150 °C, we must deal with the question of how large the temperature dependence of the viscosity is for each complex. As the answer is not available at present, it is difficult to say in such cases whether the effect of cluster formation is really large enough to increase the S value or not. Nevertheless, if two complexes with nearly the same melting points show significantly different S values, the extent of molecular association may be larger in the complex with a larger S value. Three pyrene complexes have their melting points near 90 °C (363 K). Among them the DNC complex exhibits a much larger S value than those of the other two. Furthermore, the viscosity value estimated for the DNF complex is as large as that for the DNC complex, in spite of the melting point being higher by 32 °C. These observations lead qualitatively to the suggestion that the molecular association in these two complexes is considerable.

With the exception of the DNB complex, the pyrene complexes employed here are known to show rather small enthalpies of melting.[13,14] The broad-line NMR measurements clearly indicate the onset of a large degree of thermal motion in the crystalline complexes

upon polymorphic transitions.[14] The motion of $VO(dbm)_2$ observed in these complexes seems to be consistent with these earlier results. The enthalpy of melting for the DNB complex not included in our previous work was determined to be 29 kJ mol^{-1} which is slightly larger than the others.[15] Except in the case of the 2 : 1 TNC complex shown in Fig. 4, the solid-solid transition could not be detected by the variation of S with temperature. This observation is probably due to the fact that the high-temperature forms can be readily supercooled.[13]

The ESR measurements were extended to the fluoranthene complexes where the donor molecule is isomeric to pyrene. Their enthalpies of melting are as low as those of the pyrene complexes; namely, 18 to 35 kJ mol^{-1}.[15] The S values measured at the melting points and the effective viscosities at the same temperatures are summarized in Table 1. The fluoranthene complexes melt at lower temperatures by 16 to 52 °C compared with the corresponding pyrene complexes. The difference in the melting point is especially large when the acceptors are DNC and DNP. Since the DNC complex melts at an exceptionally low temperature and gives an unusually high S value and effective viscosity, measurements can be made over a wide temperature range for this particular melt. The composition of the clusters was assumed to be determined by locating the maximum in the S-composition isotherms; therefore, the mixtures with mole ratios of 3 : 2 and 2 : 3 were also examined for this interesting combination. Unfortunately, no deviation from the curve for the 1 : 1 complex could be established. This complex provides a further clue as to the possible molecular association. Fig. 5 shows a plot of the logarithm of effective viscosity against the reciprocal temperature for the 1 : 1 complex. The exponential temperature dependence can be noted above 60 °C, but the increase of the viscosity is considerably greater on approaching and passing the melting point. This behavior may be considered as an indication that molecules pack into clusters, following the argument by Ubbelohde *et al.* made for molten *o*-terphenyl.[16,17]

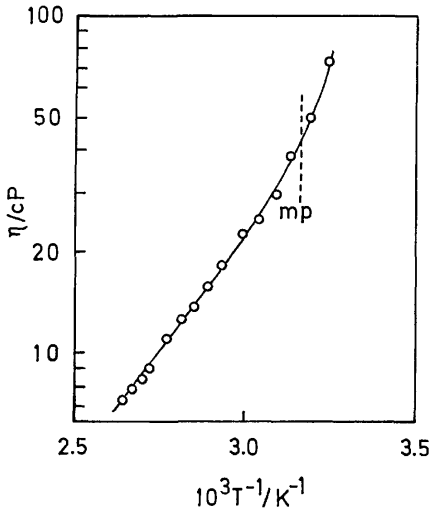

Fig. 5. Temperature dependence of the effective viscosity in fluoranthene-dinitrochlorobenzene.

Nevertheless, it must be emphasized that the high viscosity is largely due to the low melting point and that the value at the melting point may be as large as 36 cP even if the molecular association is absent.

If a complex composed of smaller molecules is selected, the molecular motion above the melting point may be fast enough on an ESR time scale to produce an abrupt increase of the S value upon solidification. With the hope of fulfilling this condition, we examined the ESR spectra of $VO(dbm)_2$ dissolved in the phenanthrene–TNC complex melting at 88 °C and the naphthalene-DNP complex melting at 95 °C. The S value in the former complex varies continuously through the melting point. In the melt of the latter, the ESR spectrum of the probe is essentially isotropic at 106 °C, but slightly deviates from it below this temperature. The value in the crystalline state could not be measured because of the segregation of the probe upon solidification.

As we mentioned already, the congruent melting point of a 1 : 1 complex is expected to be lowered when the association in the melt is less extensive. In order to compare the sequence of the complex formation, Shinomiya defined the melting point elevation for a 1 : 1 complex by

$$\tau = t_C - (t_D + t_A)/2,$$

where t_C is the melting point of the complex and t_D and t_A are the melting points of the donor and acceptor compounds respectively.[18] As we have seen, the large S value of a complex with a low melting point is mostly attributable to the exponential temperature dependence of the viscosity of the medium; therefore, no correlation between the parameters τ and S could be found.

An ESR Study on the Working States of a Pure V_2O_5 Crystal under the CO-oxidation

Yoshiya KERA* and Keiji KUWATA

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received August 29, 1978)

The V_2O_5 crystal, prepared from the pure V_2O_5 powder by a zone-melting method in the air, did not show any ESR signal. When the crystal came into contact with a mixture of CO and O_2 ($(CO/O_2)\geq 4$), an ESR spectrum with the hfs of 15-lines ($g_{//}=1.932$, $g_{\perp}=1.978$; $\langle g\rangle=1.963$), which has been previously ascribed to an oxygen defect, was found at the beginning, but after prolonged contact a sharp spectrum ($\langle g\rangle=1.954$) appeared. The intensity of the hf-lines was constant but that of the sharp spectrum increased with the contact time. The *g*-value and line shape of both spectra did not change with the contact time. The same spectra were also found in the crystal grown under a mixture of CO and O_2. On the thermal decomposition of pure NH_4VO_3 *in vacuo* a similar spectrum with a sharp line was found. The *g*-value became lower in the sample reduced further by SO_2 after the thermal decomposition. With reference to the data of TGA, DTA, magnetic susceptibility (χ_{mol}), and X-ray analysis of the vanadium oxides, the sharp spectrum was ascribed to a lower oxide or oxide state such as V_3O_7. Based on the ESR results, the working state of pure V_2O_5 crystal under CO-oxidation and its catalytic property are discussed.

Many phases, described by the general formulas of $V_{2m}O_{5m-2}$ ($m=3$, 4, (5), and 6)[1] and V_nO_{2n-1} ($n=3$—9),[2,3] have been found for the vanadium oxides (V_2O_5–V_2O_3). The phase transitions between them have been well explained by the insertions and eliminations of the oxygen planes through the crystal from one side to the other, that is, by "shear planes."[4,5] The excellent properties of the vanadium oxides as catalysts,[6–8] for instance, high selectivities on the partial oxidations of hydrocarbons and the very long life, have been connected to this feature of the vanadium oxides, that the insertions and the eliminations of the oxygen can occur easily and reversibly during the phase transitions. Many authors[9–20] have discussed the catalytic mechanisms and the working states of vanadium oxide catalysts.

Recently, the X-ray analyses on the crystal structures of V_3O_7[21] and V_4O_9[22] have been accurately done. The crystal structures of the oxides were not so simple as to be induced from that of V_2O_5 based on the idea of the shear plane. The recent TGA and DTA studies on the vanadium–oxygen system have shown that the appearances and disappearances of the intermediate phases depend delicately upon the experimental conditions.[23–25] Furthermore, it has recently been made clear that vanadium oxides easily take several kinds of metals into the lattices and form several types of "vanadium bronzes."[26] The properties of the bronzes complicatedly depend upon the kinds and the contents of metallic impurities. Therefore, catalytic properties of vanadium oxide should be further investigated by taking the results, obtained recently on the oxide, into consideration.

Our kinetic work,[27] which was carried out on several types of the V_2O_5 crystals over wide ranges of the (CO/O_2) ratios, the total pressures, and the temperatures, suggested that even small amounts of metal impurities gave great effects to the catalytic activities and to the working states of the surface. Especially, it was noticed that, during the course of CO-oxidation on the highly purified thin plate crystallines of V_2O_5, the activation energy changed abruptly from a low (2.3 kcal/mol) to a high value (29 kcal/mol) even under the stoichiometric mixture of CO and O_2; the $(CO/O_2)=2.1$. The change in the activation energy suggested the change in the working state from V_2O_5 to some lower oxide.

In the present paper, the working states of the highly purified V_2O_5 crystal during the CO-oxidation was investigated by means of ESR spectroscopy. The problem of which phase or state of vanadium oxides is effective for promoting the catalysis is discussed, especially for the pure crystal.

Experimental

Materials. NH_4VO_3 was chemically purified according to the procedures of McCarley *et al.*[28] and Haemers.[29] Pure V_2O_5 powder was obtained by the thermal decomposition of the purified NH_4VO_3. The single crystals of the pure V_2O_5 were prepared by a zone-melting method, as is mentioned in detail below.

Procedures. The single crystals of V_2O_5 were prepared as follows: a Pt-boat, which contained the purified V_2O_5 powder of about 5.3 g, was placed in a quartz tube (volume, *ca.* 157 cm^3) and then a zone-melting furnance was driven along the quartz tube. The atmosphere in the tube was controlled by varying the ratio and the total pressure of the mixture of CO and O_2. In the preparation under the air, one end of the tube was opened to the air. The width of the melting zone and the maximum temperature in the zone were 1.5 cm and 720 °C, respectively.

The single crystal of V_2O_5, which was prepared in the air and cut down in the proper size, was taken into a quartz tube (0.4 cm in inner diameter) for the measurement of ESR. The tube was gradually jointed with a glass tube (0.8 cm in the inner diameter) for the connection to a vacuum line. After the sample tube was heated preliminarily *in vacuo*, a given amount of the reaction gas was introduced at room temperature, and then the tube was sealed. The reaction tube was heated and was quenched in ice–water just before the ESR measurements. The reaction conditions are summarized in Table 1.

Some purified NH_4VO_3 powder, 0.123 g, was taken in each of the three quartz tubes for the ESR measurements. One of the tubes was opened to the air and the others were connected to a vacuum line. They were heated at 550 °C for 3 h. After heating, both the open tube and one of the

S-S-4	32	8	4	0.115	0.006

a) "excess-CO": the amount of CO which remained after the equilibrium of the CO-oxidation, $CO+O_2/2=CO_2$, was achieved.

evacuated tubes were sealed and then the ESR were measured. The other evacuated tube was filled with SO_2 gas at 724 Torr (1 Torr$=1.333\times10^2$ Pa) after it was cooled down to room temperature and then was sealed. The inner volume of the tube was about 4 cm^3. The sample tube was again heated at 585 °C and, after quenching the tube in ice–water, ESR measurements were done.

ESR Measurements. ESR measurements and the determinations of the spin concentrations were done with the same procedure as was mentioned in the previous papers.[30]

Results

ESR Spectra in the V_2O_5 Crystal Prepared under Various Atmospheres. No ESR spectrum was found for the V_2O_5 crystal prepared in the air. In the V_2O_5 crystal prepared under the mixture of CO and O_2 $(CO/O_2=4)$ at the total pressure of 200 Torr, however, a spectrum with the well-resolved hfs of 15-lines ($A_{//}=8.2$, $A_\perp=4.6$ mT) was found, as was illustrated in Fig. 1(a). On the other hand, in the crystal, prepared under the mixture of CO and O_2 $(CO/O_2=16)$ at the total pressure of 350 Torr, a new sharp line appeared near the center of the hfs of 15-lines, as was shown in Fig. 1(b). In this case, the resolution of the hfs-lines was also good, although the crystallinities seemed to be not so good as for the single crystal.

Those samples showed neither fine structure nor the half resonance in ESR due to the spin-spin interaction for the spin state of $S=1$ or higher. Thus, both spectra could be ascribed to the state of $S=1/2$.

The ESR parameters—the g-values, hf-coupling constants, and the line widths—are given in Table 2. Table 2 indicates that the center of the sharp line differs a little bit from that of the hfs. The relative intensities of the hfs-lines to DPPH in Figs. 1(a) and 1(b) seem to be approximately equal to each other.

Table 2. ESR spectra in the pure V_2O_5 crystals grown under various atmospheres

Conditions of preparation	ESR parameters: g-tensor $\langle g\rangle$	ESR parameters: A-tensor $\langle A\rangle$(mT)	Line widths (mT)[a]: low field	Line widths (mT)[a]: high field

The ESR Spectrum for the Highly Purified V_2O_5 Crystal in Contact with the Mixture of CO and O_2. The ESR spectra which appeared for the pure V_2O_5 crystals in contact with the mixture of CO and O_2 are illustrated in Fig. 2. In the Figure, the larger the (CO/O_2) ratio and the total pressure and the longer the contact time, the larger the intensity of the sharp line becomes. In the S-S-4 after the contact of 49 h at 460 °C, only the spectrum with the hfs of 15-lines is seen, but in the S-S-3 after the contact of 49 h, a sharp line appeared together with the hfs-lines, although it is rather weak. In the S-S-2 after the contact of 72 h and in

TABLE 3. ESR SPECTRA IN THE PURE V_2O_5 CRYSTALS IN CONTACT WITH THE REACTANTS OF CO AND O_2

Sample	Condition of reaction	ESR parameters		Line widths (mT)	
		g-tensor $\langle g \rangle$	A-tensor A(mT)	low field	high field
S-S-4	460 °C 49 h	1.963 $g_{//} \approx 1.932$ $g_{\perp} \approx 1.978$	$A_{//} \approx 8.2$ $A_{\perp}$ —	—	—
S-S-3	460 °C 49 h	1.954	—	37	43
S-S-1 —S-S-4	460 °C 250 h	1.954 ±0.002	—	34	50
S-S-1 —S-S-4	560 °C 240 h	1.954 ±0.002	—	34	47

the S-S-1 after the contact of 115 h, the intensity of the sharp line increased considerably.

Figures 2(a)—2(d) indicate that the intensity of the sharp line increases depending upon contact time and the amount of the excess-CO, and, on the other hand, that of the hfs-lines does not depend on the contact time or on the amount of the excess-CO. This is seen in comparisons of the intensities of the spectra with that of DPPH. During the contact for 250 h an increase in the intensities of the sharp spectrum was found in all samples, S-S-1—S-S-4, but the line shape and the position of the center did not deviate from those at the very start. Even during further contact for 240 h at 560 °C, the intensities of the spectrum in all samples still increased and the shape and the position of the center were also kept constant. The ESR parameters of the spectra are summarized in Table 3.

The line shape of the sharp spectrum varied with the temperature of the measurements : the linewidth became larger at 300 K than that at 77 K. As an example, the spectrum in the S-S-3 after the contact for 240 h at 560 °C is given in Fig. 3. The broadening of the spectrum at room temperature would be caused by the shortening of the spin-lattice relaxation time. The growth of the sharp spectrum in the S-S-1—the S-S-4 at 460 °C and 560 °C are shown in Fig. 4. The growth of the sharp spectrum is seen at 560 °C to be linear against the amount of the excess-CO for

Fig. 3. The changes in the line width of the sharp spectrum with the temperatures of measurement.

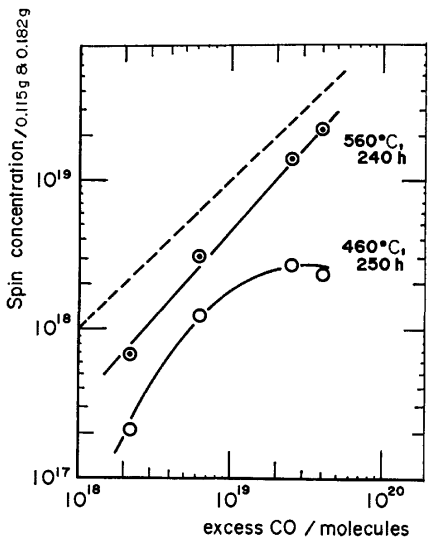

Fig. 4. The relations of the intensities of the sharp spectrum with the excess-CO. The dotted line indicates the spin concentration, expected in the crystal on complete consumption of the excess-CO.

the contact for 240 h, but at 460 °C in the runs with the higher contents of CO (S-S-3 and S-S-4) such linearity is not found. These findings might correspond to the fact that at 460 °C the process in the reduction of the surface is more rapid than the process in the diffusion into the bulk, while at 560 °C both processes are comparable. Table 3 shows that the ESR parameters of the sharp spectrum are constant without regard to the intensity of the spectrum, as was pointed out above.

After the contact with the mixture of CO and O_2 for a long time, the color of the crystal changed from bright brown to dark brown, but the brilliance of the (010) plane exposed to the surface from the start still remained after such treatments. The result was similar to that for the contact with the mixture of SO_2 and O_2.[30]

ESR Spectra in the Vanadium Oxides, Obtained by the Thermal Decomposition of the Highly Purified NH_4VO_3 and Then by the Reduction with SO_2. In the sample obtained by the thermal decomposition of the purified NH_4VO_3 powder in the air, no ESR signal was found, *cf.* Fig. 5(a). After treatment of the sample with SO_2

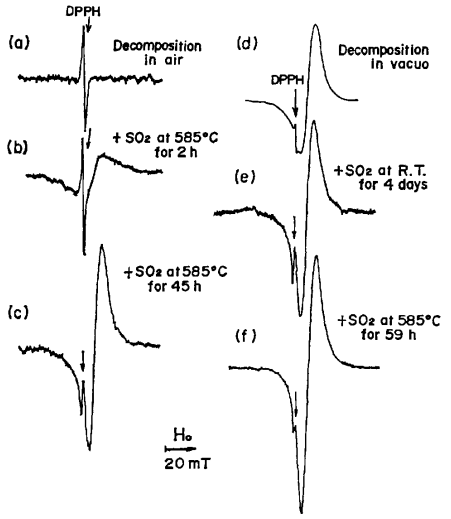

Fig. 5. ESR spectrum found on the thermal decompositions of the pure NH_4VO_3 and then the changes in the spectrum by the contact with SO_2.
