As is shown in Table 2, there is no great difference in the contribution of the dative structure (c^2) between the thioether and amine complexes. However, it is obvious that the amount of the ionic structure (b^2) for the thioether complexes is less than that for the amine complexes. This result is quite reasonable, for amine cations (N^+) have a larger electron affinity than thioether cations (S^+) and, therefore, attract more electrons from the bridging iodine atom (I_A) than do S^+.

It is interesting to interpret the charge densities on the I_A and I_B atoms and the nature of the CT bond on the basis of the simple LCAO-MO theory. The MO treatment of the delocalized three-center four-electron bond has been successfully applied to the halogen NQR results for amine–halogen or –interhalogen complexes.[25] Therefore, we have also applied the same procedure to our thioether–iodine complexes and compared the results with those for the amine–iodine complexes. According to Bowmaker and Hacobian,[25] the secular equation for the S···I_A–I_B configuration can be written as:

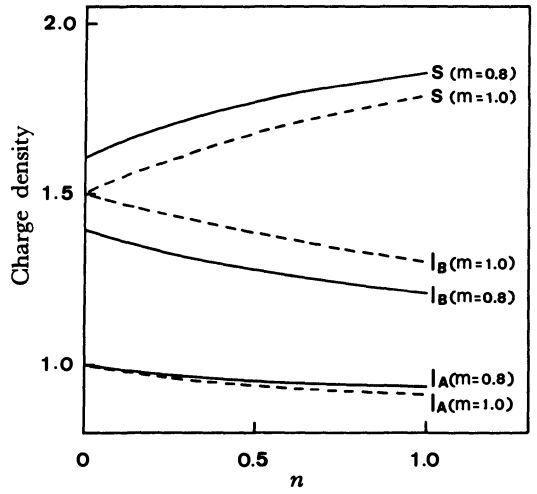

Fig. 4. Charge densities on the sulfur (S), bridging iodine (I_A), and terminal iodine (I_B) atoms as a function of the Coulomb parameter n.

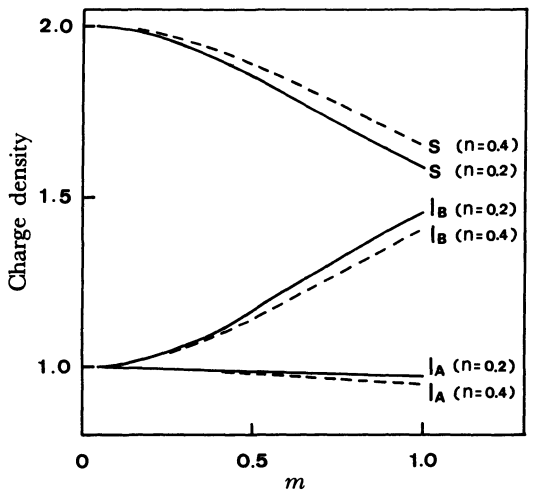

Fig. 5. Charge densities on the sulfur (S), bridging iodine (I_A), and terminal iodine (I_B) atoms as a function of the resonance integral parameter m.

$$\begin{vmatrix} \alpha + n\beta - E & m\beta & 0 \\ m\beta & \alpha - E & \beta \\ 0 & \beta & \alpha - E \end{vmatrix} = 0$$

where α is the Coulomb integral for the valence p_z orbital of iodine and β, the resonance integral between two valence p_z orbitals of iodine; n refers to the Coulomb parameter of sulfur and m, to the resonance integral parameter for the S···I_A bond.

The charge densities on each atom calculated are shown in Fig. 4 as a function of n in the cases of 0.8 (—) and 1.0 (----) for m. The charge density on the sulfur atom increases with an increase in the n value, which depends on the difference in electronegativity between the donor (sulfur) and iodine atoms. In the amine-iodine complexes, the n value for nitrogen is estimated to be 0.9 from the charge densities on the bridging and terminal iodine atoms.[25] Since the electronegativity of sulfur is smaller than that of nitrogen, a smaller n value for sulfur is required. When the n values are taken to be 0.2 (—) and 0.4 (---), the charge densities calculated as a function of m are shown in Fig. 5. It is found that an increase in the m value causes a decrease in the charge density on sulfur. The transferred charges from sulfur are localized on the terminal iodine atom (I_B), and the bridging iodine atom (I_A) has slightly positive charges. Judging from the charge densities on the I_B atoms obtained from the Mössbauer results, the appropriate value of the Coulomb parameter n seems to be about 0.2 for the sulfur atoms in the thioethers. This value seems reasonable, because the electronegativity of sulfur is only slightly larger than that of iodine. In the range of 0.75 to 0.95 for the m value, the charge densities on the I_B atoms calculated are in good agreement with those obtained experimentally. The appropriate m value is estimated to be 0.9 for the amine–iodine complexes.[25] When the n and m values are 0.2 and 0.9 respectively, the charge density on the I_A atom is calculated to be 0.97 (positively charged by 0.03). Considering that the simple LCAO-MO calculation is used for these complexes, the n and m values which seem chemically reasonable give a good agreement between the calculated and experimentally observed charge densities on each atom. Therefore, the S···I–I bonding is described mainly in terms of the delocalized three-center four-electron bond in the electronic ground state, such as the bonding in the triiodide anion. The quantity of the transferred charges depends strongly on the Coulomb integral of the donor atom and the resonance integral of the bond between the donor and the bridging iodine atoms.

We are very grateful to Professors Takenobu Higashimura and Hitoshi Yamaoka (Research Reactor Institute, Kyoto University) for their useful discussions and encouragement.

The Crystal and Molecular Structures of 4-Ethyl-3,5-bis(phenylimino)-1,2,4-dithiazolidine and 2-Ethyl-4-phenyl-5-phenylimino-1,2,4-thiadiazolidin-3-thione

Mineo KURIYAMA, Noritake YASUOKA,† Nobutami KASAI,* Mitsuo KOMATSU, Yoshiki OHSHIRO, and Toshio AGAWA

(Received October 30, 1985)

The molecular structures of title compounds, two of the three isomeric products in the reaction of 2-ethyl-3-phenyloxaziridine with phenyl isothiocyanate, have been determined by means of X-ray diffraction. 4-Ethyl-3,5-bis(phenylimino)-1,2,4-dithiazolidine (**6b**), orthorhombic, space group *Pcab*, a=27.171(1), b=10.213(2), c=11.421(1) Å, Z=8; 2-Ethyl-4-phenyl-5-phenylimino-1,2,4-thiadiazolidin-3-thione (**8b**), monoclinic, space group $P2_1/n$, a=9.278(1), b=27.525(3), c=5.826(1) Å, β=92.74(1)°, Z=4. Both structures were solved by the heavy atom method, and refined anisotropically by the block-diagonal least-squares procedure (R=0.066 and 0.060, respectively). The results corrected the reaction scheme proposed for the reaction of *N*-alkyloxaziridine with phenyl isothiacyanate.

It has been reported that the reaction of *N*-alkyloxaziridine (**1**) with phenyl isothiocyanate (**2**) gave heterocyclic compounds with incorporation of alkylnitrene.[1] However, stimulated by extensive studies by L'Abbé and co-workers on similar reactions of alkyl azides with isothiocyanates,[2,3] the structures of the cyclic adducts (R≠*t*-Bu) were reexamined by ^{13}CNMR. It indicated that the former assignment for **3** and **4** structures was not correct. In order to obtain the exact information on the molecular structures of the cyclic products, **6b** and **8b** (previously assigned as **3b** and **4b**), have been determined by means of X-ray diffraction.

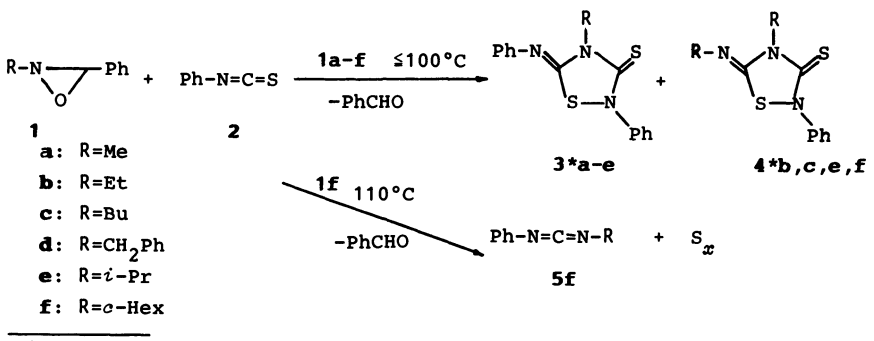
Experimental

Crystal Data. **6b**, $C_{16}H_{15}N_3S_2$, M 313.3, orthorhombic, space group *Pcab* (No. 61, absent reflections, $0kl$: l=2n+1, $h0l$: h=2n+1, $hk0$:k=2n+1), a=27.171(1), b=10.213(2), c=11.421(1)Å, D_m=1.30 g cm^{-3}, D_c=1.31 g cm^{-3} for Z=8, μ(Mo $K\alpha$)=3.3 cm^{-1}; **8b**, $C_{16}H_{15}N_3S_2$, M 313.3, monoclinic, space group $P2_1/n$ (No. 14, absent reflections, $h0l$:h+l=2n+1, $0k0$:k=2n+1), a=9.278(1), b=27.525(3), c=5.826(1)Å, β=92.74(1)°, D_m=1.33 g cm^{-3}, D_c=1.34 g cm^{-3} for Z=4, μ(Cu $K\alpha$)=29.6 cm^{-1}.

A Rigaku automated, four-circle diffractometer equipped with graphite monochromator was used for X-ray experiments. The crystals used had approximate dimensions of 0.2×0.2×0.2 (**6b**) and 0.2×0.2×0.3 mm (**8b**). Unit-cell dimensions of both crystals were determined by the least-squares fit of 2θ values of higher order reflections. Integrated intensities were measured on the diffractometer by the θ-2θ scan technique at a 2θ rate of 4° min^{-1}. Scan width for **6b** was $\Delta 2\theta$=(2.0+0.7tanθ)° for Mo $K\alpha$ radiation (λ=0.71069Å) and for **8b** $\Delta 2\theta$=(2.0+0.3tanθ)° for Cu $K\alpha$ (λ=1.5418Å). Backgrounds were counted for 7.5 s at both ends of a scan. Three standard reflections were measured after every 60 reflections, which showed no intensity decrease during intensity measurements on both crystals. Totals of 3470 and 2342 reflections were measured, of which 1292 and 2044 were observed ($|F_o|>3\sigma(F_o)$) for **6b** and **8b**, respectively. The usual Lorentz and polarization corrections were applied ignoring absorption correction. Densities were measured by flotation method in carbon tetrachloride-hexane mixed solutions.

Structure Solution and Refinement

Both structures were solved by the heavy atom method, and refined anisotropically by the block-diagonal least-squares procedure minimizing $\sum w(\Delta F)^2$ (*HBLS* V).[4] All hydrogen atoms were located on the difference Fourier map, which were refined isotropically. Three



†Present address: Himeji Institute of Technology, Shosha, Himeji, Hyogo 671-22.

reflections (020, 002, and 302), which were considered affected by the extinction largely, were excluded at the final stage. Final R values are 0.066 and 0.060 for **6b** and **8b**, respectively. Unit weights were employed only at the early stage of the refinement and the weighting schemes used at the final cycles were $w=\{\sigma^2(F_o)-1.1709|F_o|+0.0518|F_o|^2\}^{-1}$ for **6b** and $w=\{\sigma^2(F_o)-0.0762|F_o|+0.0095|F_o|^2\}^{-1}$ for **8b**, where σ is the standard deviation obtained by the counting statistics. Atomic scattering factors used were taken from International Tables for X-Ray Crystallography[5] for non-hydrogen atoms and from Stewart and coworkers[6] for hydrogen atoms. Final atomic coordinates are given in Table 1.††

Computations were done on an ACOS 850 computer at the Crystallographic Research Center, Institute for Protein Research Center, Osaka University.

Results and Discussion

Reaction Scheme. The conclusive evidence for the structure of the molecules formerly assigned as **3** and **4** has been obtained by the present X-ray crystal structure analysis. As is clearly seen in Fig. 1, the molecule assigned as **3b** (R=Et) is found to be 4-ethyl-3,5-bis(phenylimino)-1,2,4-dithiazolidine (**6b**) and that as **4b** (R=Et) is 2-ethyl-4-phenyl-5-phenylimino-1,2,4-thiadiazolidin-3-thione (**8b**). Therefore, the reaction scheme proposed formerly[1] should be corrected as follows.[8]

††Tables of anisotropic thermal parameters, coordinates of hydrogen atoms and tables of observed and calculated structure factors are kept at the Chemical Society of Japan, Document No. 8624.

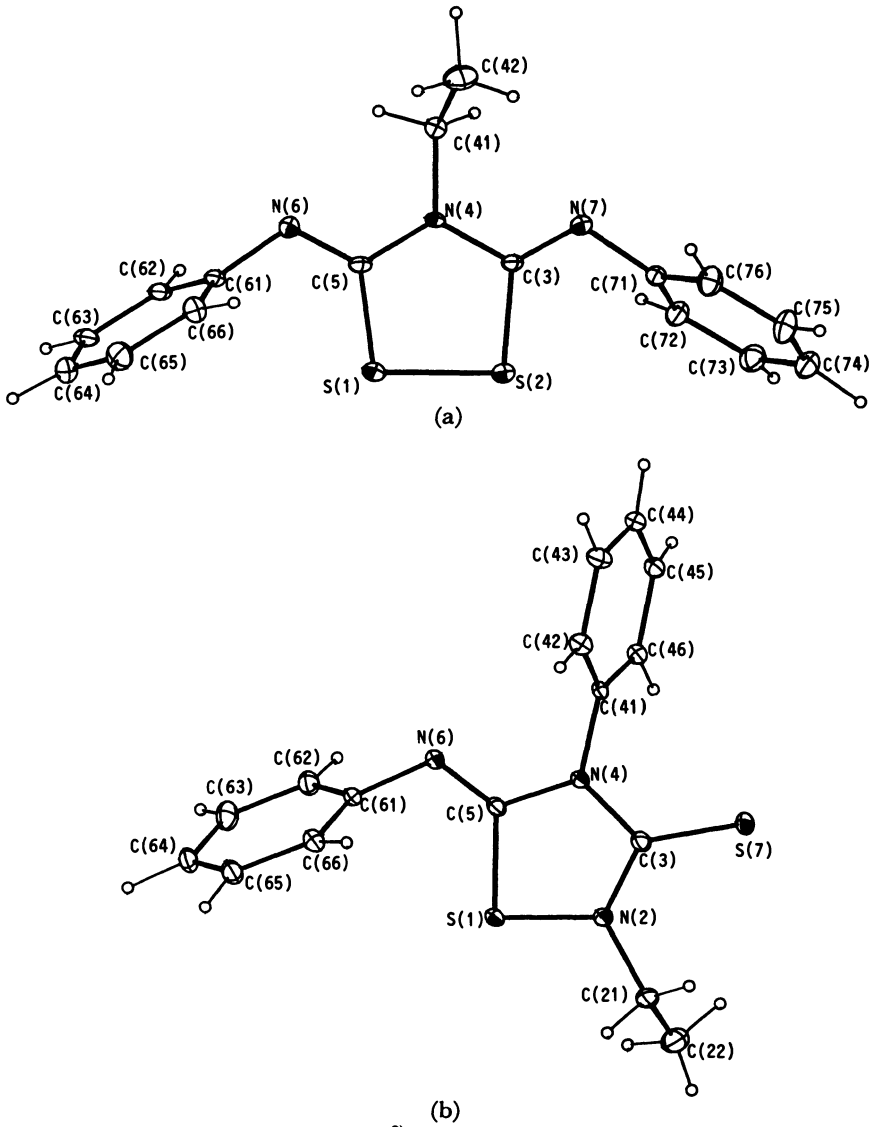

Fig. 1. Molecular structures.[9]
Non-hydrogen atoms are expressed as thermal ellipsoids with 10% probability level and hydrogen atoms as spheres with B=1.0 Å^2.
(a) **6b**, (b) **8b**.

Molecular Structure. Selected bond lengths and bond angles in the **6b** and **8b** molecules are given in Table 2.

The symmetrical **6b** molecule has an approximate two-fold axis except the ethyl group attached to the N(4) atom. 1,2,4-Dithiazolidine ring is planar, the maximum deviation of the atoms from the plane being 0.033 Å at the C(5) atom. In the ring, the S–S bond has a single bond length, 2.063(2) Å. Two C–N bonds are equal in length [1.388(5) and 1.392(5) Å], however, the S(1)–C(5) bond [1.744(4) Å] is slightly shorter than the S(2)–C(3) bond [1.775(5) Å]. Two S–S–C [96.1(2) and 95.5(2)°] and two S–C–N [114.5(3) and 113.9(4)°] bond angles are equal to each other. This structural feature is very similar to that of the dithiazolidine ring in 4-benzyl-3,5-bis(phenylimino)-1,2,4-dithiazolidine[10] except for the S(1)–C(5) bond length, but differs from those of the 1,2,4-dithiazolidines containing four colinear sulfur atoms.[11,12] In the phenylimino groups attached to the dithiazolidine ring of **6b**, two C=N bond lengths [1.267(6) and 1.258(6) Å] and C=N–C(Ph) angles [117.4(4) and 117.5(4)°] are respectively equal. Two phenyl groups make different angles of 106.1 and 94.8° with the dithiazolidine ring.

The 1,2,4-thiadiazolidine ring of **8b** is also planar, maximum deviation of the atom from the plane being 0.030 Å at C(5). The S(1)–N(2) bond length is 1.711(3) Å, which seems to be an intermediate value among those in 1,2,4-thiadiazolidines[13–15] and 2,4-dimethyl-1,2,4-thidiazolidin-3,5-dithione.[16] This bond length is comparable with those in 2,3,3,5-tetraphenyl-1,2,5-thiadiazolidin-4-one [1.726(11) and 1.701(9) Å][17] and also to one of the S–N bonds in 2-diphenylmethylene-3,5,7,7-tetraphenyl-2,3,6,7-tetrahydro-5H-1,4,3,5-

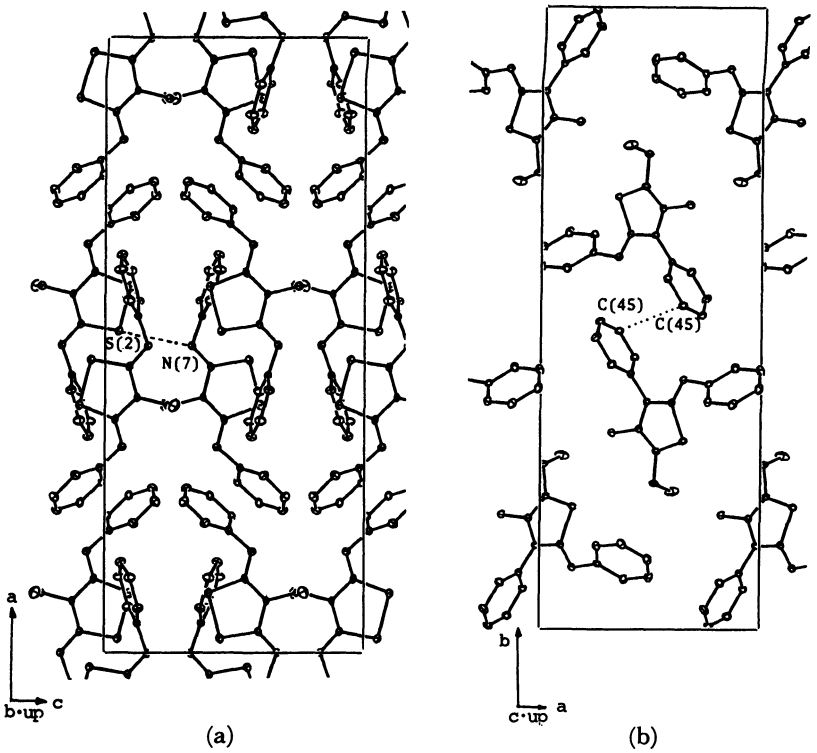

Fig. 2. Crystal structures.[9]
Non-hydrogen atoms are expressed as thermal ellipsoids with 10% probability level. Hydrogen atoms are omitted for clarity.
(a) **6b**, projected along the *b* axis, (b) **8b**, projected along the *c* axis

oxathiadiazepin-6-one [1.718(8)Å].[18] The S(1)–C(5) bond length of 1.767(3)Å is equal to those in the 1,2,4-thiadiazolidines and also equal to the S(2)–C(3) length in **6b**. Of the three C–N bonds in the ring, the C(3)–N(4) and C(5)–N(4) bonds have equal lengths [1.384(4) and 1.393(4)Å], which can be compared with the corresponding lengths in **6b**. The C(3)–N(2) [1.341(4)Å] and the C(3)=S(7) [1.654(3)Å] lengths are respectively equal to those in the 1,2,4-thiadiazolidin-3,5-dithione [1.347(5) and 1.655(4)Å]. The N(2)–S(1)–C(5) angle [90.0(2)°] is smaller than those in the 1,2,4-thiadiazolidines and the 1,2,4-thiadiazolidin-3,5-dithione. Bond angles around the N(2) and C(3) atoms are respectively equal to the corresponding angles in the 1,2,4-thiadiazolidin-3,5-dithione, and those around the N(4) and C(5) are equal to the corresponding angles in the 1,2,4-thiadiazolidines.

Crystal Structure. The packing modes of molecules in both crystals are shown in Fig. 2. In the **6b** crystal molecules are packed rather tightly (Fig. 2a), the closest intermolecular contact between non-hydrogen atoms being 3.272(4)Å(N(7)(x, y, z)···S(2)(1−x, 0.5−y, −0.5+z)). The loose packing of molecules are observed in the **8b** crystal (Fig. 2b), the shortest contact being 3.405Å between the C(45)(x, y, z) and C(45)($\bar{x}$, $\bar{y}$, $\bar{z}$) atoms (Table 3).

Fluorescence Quenching of Perfluoronaphthalene by Triethylamine

Koji KANO,* Masaru YANAGIMOTO, Hisashi URAKI, Bin ZHOU, and Shizunobu HASHIMOTO
Department of Applied Chemistry, Faculty of Engineering, Doshisha University, Kamikyo-ku, Kyoto 602
(Received November 8, 1985)

The relatively fast fluorescence quenching of perfluoronaphthalene by triethylamine as well as the lack of the exciplex emission of this system has been interpreted in terms of the electron transfer from triethylamine to photoexcited perfluoronaphthalene, where the electron donor-acceptor pair takes a loose geometric configuration.

Some hydrocarbons have been known to yield exciplexes through a charge-transfer interaction with aromatic or aliphatic amines.[1] In some cases, the exciplexes show broad fluorescence bands at longer wavelengths in nonpolar solvents.[2] The possibility of a direct electron transfer which yields a solvent-separated ion pair has been accounted for the absence of exciplex emission in strongly polar solvents.[3] The exciplex formation is also affected by the structures of amines as electron donors. Although aromatic amines such as *N,N*-dimethyl- and *N,N*-diethylanilines form the exciplexes with hydrocarbons with diffusion-controlled rates,[4] the rates of exciplex formation for aliphatic amines are smaller by one order of magnitude.[5] The conformational change of aliphatic amine from pyramidal to planar is required for exciplex formation. Such geometric requirement causes larger activation energy for exciplex formation.[5] Some hydrocarbons such as pyrene and naphthalene are known to form the fluorescent exciplexes with aliphatic amines.[5,6]

The present study deals with the effects of the fluorine substituents attached to the naphthalene ring on photoinduced electron transfer and exciplex formation. The results suggest an electron transfer from triethylamine (TEA) to perfluorinated naphthalene in the excited state prior to exciplex formation.

Experimental

Materials. Octafluoronaphthalene (perfluoronaphthalene, PFN, Tokyo Kasei) was recrystallized from cyclohexane. Naphthalene (Nakarai) was purified by sublimation. 1-Fluoronaphthalene (1-FN, Tokyo Kasei), triethylamine (TEA, Nakarai), and perfluorohexane (PFH, PCR Research Chemicals) were purchased and used without further purification. All solvents used were analytical or reagent grades.

Measurements. The absorption spectra were taken on a Shimadzu UV-200S spectrophotometer. The fluorescence emission and excitation spectra were measured on a Shimadzu RF-540 or a Hitachi 650-60 spectrofluorometers whose cell compartments were thermostated at 298 K. The phosphorescence spectra were taken on a Hitachi 650-60 spectrofluorometer using an attachment 650-0175 for phosphorescence measurement at 77 K. The fluorescence spectra at 77 K were measured on a Shimadzu RF-540 spectrofluorometer using a Dewar vessel described previously.[7] The fluorescence lifetimes were determined by using an Ortec-PRA single-photon counting appratus.[8] The fluorescence quantum yields were determined by measuring the corrected fluorescence spectra on a Hitachi 650-60 spectrofluorometer and using quinine sulfate as a standard.[9]

Results and Discussion

Absorption and Fluorescence Spectra. Introduction of the fluorine substituents into the naphthalene ring causes red shifts of the ^1L_a and ^1L_b bands, broadening of the vibronic structures of these bands, and increase in the intensities of the ^1L_b bands. The extinction coefficients of the 0–0 bands of naphthalene, 1-FN, and PFN in cyclohexane are 274 $M^{-1}cm^{-1}$ at 311.5 nm, 631 $M^{-1}cm^{-1}$ at 317 nm, and 2367 $M^{-1}cm^{-1}$ at 323 nm, respectively.

The fluorescence maxima in hexane are 313(sh), 323, 332(sh), 336, and 344(sh) nm for naphthalene, 317, 321(sh), 332, 336(sh), and 348 nm for 1-FN, and 348 nm for PFN. PFN shows a structureless fluorescence in solutions at 25 °C. The fluorescence quantum yield (Φ_f) of 1-FN determined in degassed hexane (0.23±0.010) is the same as that of naphthalene (0.22±0.010) and Φ_f of PFN (0.10±0.015) is about half of those of naphthalene and 1-FN. The fluorine substituents introduced to the naphthalene ring markedly reduce the fluorescence lifetimes (τ_f), the τ_f values of naphthalene, 1-FN, and PFN being 120, 42.5, and 3.1 ns, respectively. The rate constants for the emission process ($k_f=\Phi_f/\tau_f$) increased in the order of naphthalene ($1.8\times10^6\,s^{-1}$), 1-FN ($5.4\times10^6\,s^{-1}$), and PFN ($3.2\times10^7\,s^{-1}$). The S_0–S_1 transition of naphthalene is orbital symmetry forbidden. For PFN, however, this transition may be partially allowed.

Fluorescence Quenching. The fluorescence of naphthalene, 1-FN, and PFN were quenched by TEA and the data could be treated by a simple Stern-Volmer equation. The rate constants for fluorescence quenching (k_q) determined from the plots of I_0/I vs. [TEA] are listed in Table 1, where I_0 and I are the fluorescence intensities in the absence and presence of quencher, respectively.

As the TEA concentration increased, the broad exciplex emissions appeared at longer wavelengths in the cases of naphthalene and 1-FN when ethyl acetate, cyclohexane, hexane, and PFH were used as the solvents. The emission maxima of the exciplexes are shown in Table 1. Of course, no exciplex emission was observed in polar solvents such as ethanol and

Table 1. Rate Constants for Fluorescence Quenching (10^{-9} k_q, $mol^{-1}dm^3s^{-1}$) of Naphthalene, 1-FN, and PFN by TEA and Fluorescence Maxima (λ_{max}, nm) of Exciplexes of These Naphthalene Derivatives and TEA in Various Solvents at 298 K

Solvent	Naphthalene		1-FN		PFN	
	k_q	λ_{max}	k_q	λ_{max}	k_q	λ_{max}
Acetonitrile	5.5	a	8.7	a	10.8	a
Ethanol	1.0	a	1.5	a	3.5	a
Ethyl acetate	4.9	473	6.9	482	10.8	a

Hexane	1.0	413	5.8	418	14.3	a
Perfluorohexane	5.7	402	7.6	417	19.0	a

a) No exciplex emission was observed.

acetonitrile. Interestingly, PFN did not show the exciplex emission in any solvents used in spite of the quenching of the monomer fluorescence by TEA. Van and Hammond reported the dipole moment of the naphthalene–TEA exciplex to be 11.1 D,[6] which has been determined from a plot of energies of exciplex emission maxima vs. solvent polarity parameters ($f(\varepsilon,n)$).[10] The same plot provided a dipole moment of an exciplex of 1-FN and TEA to be 11.6 D. Since an electron transfers almost completely from donor to acceptor in the exciplex system, no effect of a fluorine substituent of the acceptor molecule seems to be observed.

As Table 1 shows, the fluorine substituents introduced to the naphthalene ring enhanced the fluorescence quenching. In agreement with the results obtained by Van and Hammond,[6] the rate of fluorescence quenching of naphthalene by TEA in each nonpolar solvent was smaller than the diffusion-controlled rate, which may be attributed to the higher activation energy for forming exciplexes because of a conformational change of aliphatic amines to form exciplexes.[5] By the way, relatively large k_q values were obtained for the quenching in acetonitrile. In strongly polar solvents, electron transfer is known to occur from loose electron donor–acceptor pairs prior to exciplex formation.[3] A major factor which dominates the k_q values in strongly polar solvents including acetonitrile, therefore, may be the diffusion rates of both donor and acceptor molecules. The fluorescence quenching of 1-FN by TEA occurred more efficiently than that of naphthalene. Extremely fast fluorescence quenching proceeded in the case of PFN where the k_q value in each solvent is very close to the diffusion-controlled rate constant. In the system where an exciplex needs forming upon fluorescence quenching, the quenching should be accelerated by substituent(s) if the substituent(s) can stabilize the exciplex state. This may be the case for the fluorescence quenching of 1-FN in nonpolar solvents. A fluorine substituent, a strongly electronegative substituent, should stabilize an anionic form of the naphthalene moiety in the exciplex leading to lowering of the activation energy for exciplex formation. The situation of PFN seems to be different from those of naphthalene and 1-FN because no exciplex emission was detected in this system. No ground-state interaction between donor and acceptor molecules was suggested for all cases by means of the absorption spectroscopy.

Irreversible photoreactions of PFN (1×10^{-4} mol dm^{-3}) took place in both hexane and acetonitrile solutions containing TEA (1×10^{-3} mol dm^{-3}) under anaerobic conditions. Upon irradiation with an Hg lamp, a photoproduct having absorption maximum at around 380 nm was generated. Although we did not determine the reaction product(s) in the present study, the radical ion pairs of PFN and TEA should be generated as the intermediates. Dehalogenation is the most plausible photoreactions.[11]

Fluorescence at 77 K. In methylcyclohexane matrices at 77 K, the relative fluorescence intensity of the naphthalene derivatives decreased in the order of 1-FN, naphthalene, and PFN and weak phosphorescence emissions of these naphthalene derivatives were observed at longer wavelengths (Fig. 1). The difference in the fluorescence and phosphorescence yields between these naphthalene derivatives is appreciable, but not very large.

In glassy TEA at 77 K, the relatively strong monomer fluorescence emissions of naphthalene and 1-FN were observed along with the weak exciplex fluorescence and monomer phosphorescence emissions (Fig. 2). The monomer fluorescence of PFN, however, was quenched almost completely and very weak exciplex emission centered at 420 nm was observed in neat TEA at 77 K. The exciplex emissions of naphthalene and 1-FN in the TEA matrices decayed multiexponentially without rise (the data are not shown), suggesting that several exciplex states are formed immediately upon photoexcitation. Some of the naphthalene and 1-FN molecules may make pairs with TEA molecules which have preferable geometric configurations for exciplex formation. Large amounts of the naphthalene and 1-FN molecules seem to exist without any interaction with surrounding TEA molecules. In the case of PFN, however, most of the PFN molecules were quenched by surrounding TEA molecules, whose mobility was strictly restricted. It is reasonable, therefore, to assume a

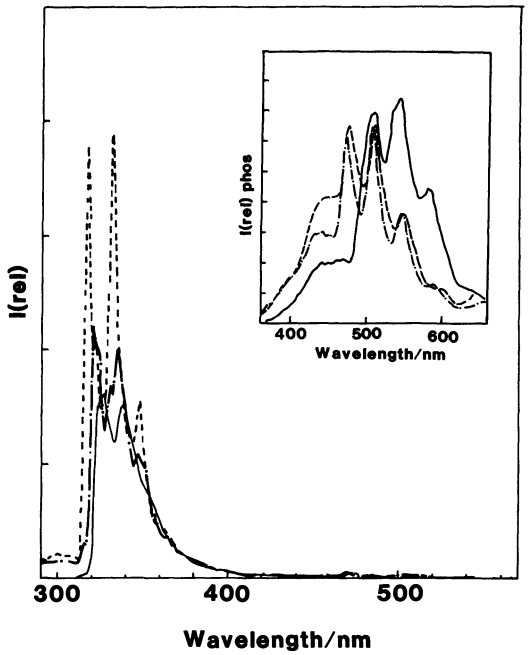

Fig. 1. Fluorescence and phosphorescence spectra of naphthalene (—·—), 1-FN (---), and PFN (——) in methylcyclohexane at 77 K. Naphthalene, 1-FN, and PFN (1×10^{-5} mol dm^{-3}) were excited at 278, 281, and 290 nm, respectively. The insert shows the phosphorescence spectra.

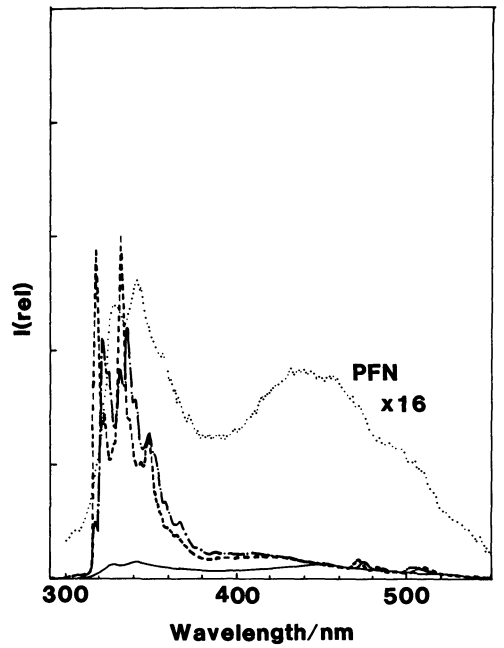

Fig. 2. Fluorescence spectra of naphthalene (—·—), 1-FN (---), and PFN (——) in TEA at 77 K. Naphthalene, 1-FN, and PFN (1×10^{-5} mol dm^{-3}) were excited at 279, 282, and 290 nm, respectively.

long-distance interaction between PFN and TEA. It is noteworthy that the exciplex emission for the PFN–TEA system is observed only in the TEA matrix. PFN can form a fluorescent exciplex with TEA if these two molecules take an appropriate configuration

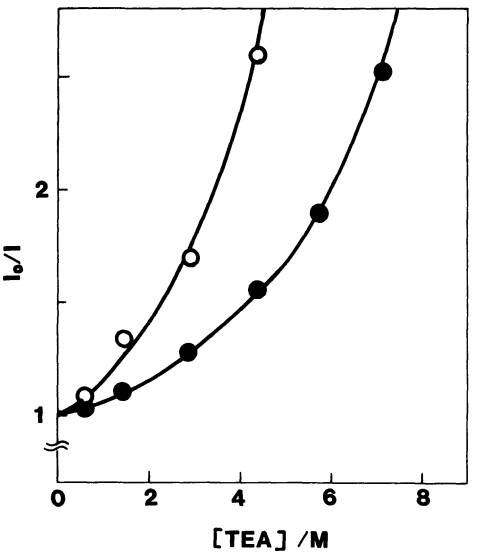

Fig. 3. Plots of I_0/I vs. [TEA] for the fluorescence quenching of naphthalene (●) and PFN (○) in EPA at 77 K.

for forming an exciplex. In fluid organic solvents, however, no exciplex emission of this donor-acceptor pair was observed at any TEA concentrations. These observations strongly suggest the fluorescence quenching of PFN by TEA prior to the exciplex formation.

Figure 3 shows the plots of I_0/I vs. [TEA] for the fluorescence quenching of naphthalene and PFN in the EPA (diethyl ether:isopentane:ethanol=5:5:2) matrices at 77 K. Although a Stern-Volmer linear relationship was observed in fluid media, the plots were deviated upward from the straight lines for the fluorescence quenching in the rigid matrices. Since both fluorescer and quencher molecules cannot move freely in glassy EPA, only donor-acceptor pairs within an interaction radius can participate in fluorescence quenching. The fluorescent state of PFN was quenched more efficiently than that of naphthalene at each quencher concentration in rigid medium. This clearly indicates that an interaction radius for the PFN–TEA system is larger than that for the naphthalene–TEA system. The data shown in Fig. 3, therefore, support a long-distance electron transfer via a loose donor-acceptor pair in the PFN–TEA system.

Ion-Chromatographic Determination of Valproic Acid

Hisaaki ITOH,* Yoshio SHINBORI, and Norihiro TAMURA†
Faculty of Pharmaceutical Sciences, Josai University, Sakado, Saitama 350-02
†Josai Dental University, Sakado, Saitama 350-02
(Received October 15, 1985)

A new direct chromatographic assay method of valproic acid (2-propylpentanoic acid) using a carbonic acid solution as the eluent and conductivity detection was developed and applied to its determination in Depakene tablets and human plasma. The analytical recovery and the coefficients of variation of the method obtained by the use of drug-free plasma samples spiked with various amounts of valproic acid were ranged from 96.5 to 104% and from 3.2% at 12.4μg cm^{-3} to 0.8% at 124μg cm^{-3}, respectively. No interference from the plasma constituents or from other anticonvulsants was observed. The procedure is simple, fast, specific, and precise. The plasma levels of valproic acid obtained from patients receiving sodium valproate together with other anticonvulsants are indicated.

Valproic acid is the free-acid form of the drug marketed under the names of Valerin, Depakene and Sodium Valproate; it is clinically used as an anticonvulsant in the treatment of epilepsy.

Recently, several methods have been described in the literature for the analysis of valproic acid in plasma. These include gas chromatography (GC),[1-7] high-performance liquid chromatograpny (HPLC),[8-13] and enzyme immunoassay (EMIT).[14-17] Although a number of methods have been reported, certain problems still remain such as the assay being time-consuming, expensive, nonspecific, and/or insensitive. Three major characteristics of valproic acid which have restricted the development of an analytical method are its poor ultraviolet absorbance, its high volatility as a free acid, and its relatively high adsorptive power onto the GC column packings.[1,5] Because of this poor ultraviolet absorption, a direct sensitive assay of valproic acid by HPLC is difficult. In order to overcome this problem, derivatization to a chromophoric species, such as phenacyl,[10,13] 4-bromophenacyl[12] and 2-naphthylcarbonylmethyl esters,[11] has been necessary.

On the other hand, the GC methods are usable for the direct analysis of carboxylic acids. However, these methods are mostly limited to short-chain fatty acids. In order to improve the separation characteristics and the detection sensitivity of valproic acid, many efforts have been made.[2,5,7] More recently, Rege et al.[6] have reported that, for the GC method, the derivatization of valproic acid to the phenacyl ester was effective in its determination in plasma, although the method required extraction and evaporation steps.

The EMIT method is simple and fast, but requires some expensive reagents. However, a critical comparision of the GC and EMIT methods has been reported recently showing that, although the two methods produced no statistical differences in control samples, there was a highly significant proportional error of 26% when the same patient sample was split and analyzed by both methods.[17] The higher EMIT values for patients' samples than those with GC were probably due to the cross-reactivity of some unsaturated metabolites of valproic acid, which may interfere with the enzyme immunoassay.

In this paper, we describe a novel method for the analysis of valproic acid in drug and human plasma. Having noticed that valproic acid is a fatty acid and has the pK_a of 2.5,[18] we examined its determination by the ion-exclusion technique using a carbonic acid solution as the eluent and conductivity detection.[19] The procedure is simple, fast, specific, and precise.

Experimental

Materials. The sodium valproate was obtained from Kyowa Hakko (Tokyo, Japan). The depakene tablets were from commercial sources. All the other chemicals were of an analytical grade. A stock solution of sodium valproate was prepared by dissolving the salt in distilled and deionized water. Plasma samples were stored at −20°C.

Chromatographic System. Analyses were performed using a Dionex M-10 Ion Chromatograph equipped with a conductivity detector. The details of the modification of the system, except for a guard and a separator column, have been described in a previous paper.[19] The guard column was made by packing the Aminex Q-150S resin, which is a high-capacity cation exchanger, into a glass column(3 mm i.d.×50 mm). On the other hand, the separator column was made by repacking the Dionex ICE separator resin[19] as a slurry into a glass column(6 mm i.d.×65 mm). The column conditioning was performed as follows. At the flow rate of 0.7 cm^3 min^{-1}, both columns were first rinsed with deionized water for 60 min, then with a 0.5 mol dm^{-3} sulfuric acid solution for 40 min, and again with deionized water for 40 min, and then finally they were equilibrated with an eluent solution.

Procedures. Drug Sample: A tablet of Depakene (200 mg as sodium valproate) was dissolved in deionized water in a volumetric flask(500 cm^3). 5 cm^3 of the solution was diluted to 100 cm^3 with deionized water. This diluted solution was injected onto the chromatograph through the filter(0.42 μm).

Plasma Sample: A plasma sample was mixed with an equivolume of a 0.1 mol dm^{-3} sodium hydroxide solution and then with eight volumes of acetonitrile by means of a Voltex-type mixer. After centrifugation for 5 min at 3000 rpm, the supernatant was diluted with an equivolume of deionized water. An aliquot of the solution was then injected onto the

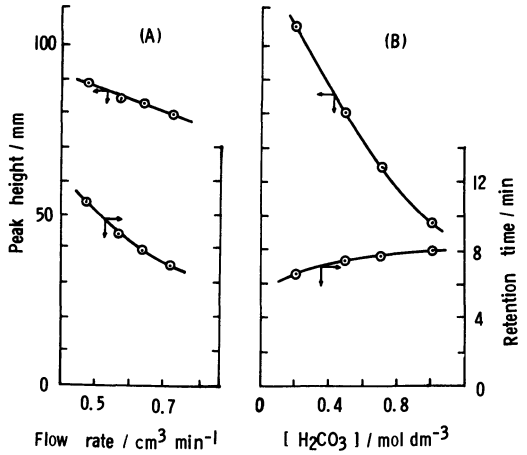

Fig. 1. Variations in the retention time and in the peak height of valproic acid with the flow rate(A) and with the concentration of carbonic acid in the eluent. All chromatographic conditions are the same as shown in Table 1 except for the flow rate(A) and the concentration of carbonic acid in eluent(B). Valproic acid: 10.0 μg cm^{-3}.

chromatograph.

Results and Discussion

1. Elution Behavior of Valproic Acid. At first, as a separator, we tried to use a Dionex ICE separator column(9 mm i.d.×200 mm), which has been used for the separation of low-molecular-weight organic acids.[19,20] However, in this case, using a 0.5 mmol dm^{-3} H_2CO_3 eluent at a flow rate of 0.7 cm^3 min^{-1}, valproic acid was eluted as a broad peak at about 60 min. After considerable exploratory experiments directed at faster elution and a more sensitive detection of valproic acid, we found that the small column described above was fit for our purposes. By the use of this small column, the elution characteristics of valproic acid were investigated. Figure 1 shows the variations in the retention time and in the peak height of valproic acid with the flow rate(A) and with the concentration of carbonic acid in the eluent(B). With the increase in the concentration of carbonic acid in the eluent, — that is, with the decrease in the pH of the eluent[19] accompanied by an increase in the background conductivity, the variation in the retention time is not very much, but the decrease in the peak height, that is, the detector response, is quite large. On the other hand, the increase in the flow rate does not appreciably affect the peak height, but makes the retention time decrease sharply. In other words, the use of a low concentration of carbonic acid in the eluent is effective for the more sensitive detection of, and the higher flow rate is effective for the faster elution of, valproic acid. Thus, the chromatographic conditions were set as shown in Table 1.

2. Valproic Acid in Drugs. The calibration curve constructed by the use of the peak height of a standard solution was linear from 0.2 to 25 μg cm^{-3}. The detection limit of the assay was 50 ng cm^{-3} of valproic acid in the sample solution. Figure 2 shows a typical chromatogram obtained from the analysis of valproic acid in a Depakene® sample solution.

Table 1. Chromatographic Conditions

Eluent	:	0.5 mmol dm^{-3} H_2CO_3
Guard column	:	3 mm i.d.×50 mm Aminex Q-150S resin column
Separator	:	6 mm i.d.×65 mm Dionex ICE separator resin column
Flow rate	:	0.7 cm^{-3} min^{-1}
Sample loop	:	50 mm^3
Meter setting	:	1 μS

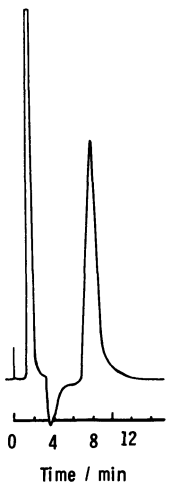

Fig. 2. Chromatogram of valproic acid in Depakene® tablet sample solution.
All chromatographic conditions are the same as shown in Table 1.

The precision and accuracy of the method were examined by analyzing valproic acid in Depakene® tablets. Against the calculated value (17.35 μg cm^{-3}) from the appended content table, the assay for three sample solutions prepared by following the procedure indicated 17.37—17.44 μg cm^{-3}. Furthermore three Depakene® sample solutions spiked with valproic acid (5 μg cm^{-3}) were also analyzed. Recoveries ranging from 99.4% to 100.2% was obtained. It was thus proven that the method was satisfactorily precise and accurate.

3. Valproic Acid in Plasma. In analyzing biological samples by the chromatographic method, it is always a great problem how to carry out deproteinization while retaining an adequate recovery of the material of interest. In order to ascertain the optimal conditions for deproteinization, a study using a drug-free plasma sample spiked with valproic acid (40 μg) was performed.

Optimization of Deproteinization Conditions. Afer considerable exploratory experiments by the use of such solutions as methanol, acetonitrile, hydrochloric

acid, and sodium hydroxide and/or SEP-PAK® C_{18} cartridges (Waters Associates, Massachusetts), it was found that the complete recovery of valproic acid could be obtained by the addition of 0.1 mol dm^{-3} of a sodium hydroxide solution with a volume ratio of 0.8 or more(sodium hydroxide solution to plasma) prior to the addition of acetonitrile, as is shown in Fig. 3. In this case, the valproic acid recovery was calculated by comparing the peak height of the valproic acid obtained from the sample solution prepared by spiking with valproic acid before and after the deproteinization treatment.

Calibration Curve. The calibration curve was constructed by the use of a drug-free plasma spiked with valproic acid. The curve using the peak height was linear over the concentration range of 5—200 μg of valproic acid in 1.0 cm^3 of plasma. The detection limit of the plasma assay was 2 μg cm^{-3} of valproic acid.

Analytical Recovery and Precision. The analytical recovery and precision of the method were determined by analyzing plasma samples spiked with various known amounts of valproic acid. The results are shown in Table 2. The recovery of valproic acid was in the range from 96.5% to 104%. The coefficients of variation ranged from 3.2% at 12.4 μg cm^{-3} to 0.8% at 124 μg cm^{-3}. The procedure was found to be satisfactorily reproducible and precise.

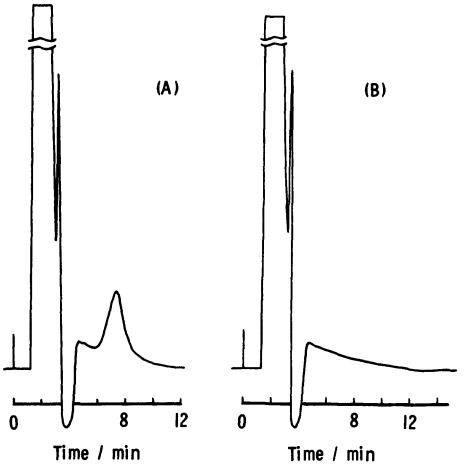

Fig. 4. Chromatograms of valproic acid in human plasma.
All chromatographic conditions are the same as shown in Table 1. (A): plasma from a patient receiving treatment with sodium valproate together with other anticonvulsants. (B): plasma from a patient receiving treatment with some anticonvulsants other than sodium valproate.

Figure 4(A) shows a typical chromatogram obtained from the analysis of valproic acid in a plasma sample containing other anticonvulsants(primidone, ethotoin, clonazepam, and acetazolamide). Figure 4(B) also shows a chromatogram obtained by means of a plasma sample from a patient receiving treatment with primidone, ethotoin, sulthiame, and clonazepam. No interference from the plasma constituents or other anticonvulsants was observed.

Valproic-Acid Levels in Patient Plasma. The assay was performed on plasma from patients receiving sodium valproate together with various anticonvulsants, such as primidone, sulthiame, ethotoin, phenytoin, clonazepam, diazepam, acetazolamide, and carbamazepine. The results are shown in Table 3. These data indicated that the plasma levels of valproic acid were in the range of 24—74 mg dm^{-3} when daily medication was between 10—91 mg kg^{-1}. There were, however, marked variations among different patients in the relationship between drug dose and plasma level.

The authors wish to express their thanks to Mr. Toshio Nishida of the Shimoshizu Byoin National Sanatorium, and Professor Naosi Maeshiro, Department of Psychiatry, Saitama Medical University, for kindly supplying the plasma samples. We also would like to thank Professor Shigero Ikeda of Osaka University for his helpful suggestions.

Table 3. Plasma Levels of Valproic Acid from Patients Receiving Sodium Valproate

Patient	Weight	Daily medication		Time after administration	Plasma level
	kg	mg	mg kg^{-1}	h	mg dm^{-3}
1	23	2100	91	2.0	68
				15.0	39

(Received November 5, 1985)

New quadridentate ligands having two chiral phosphorus donor atoms, 2,11-diphenyl-5,8-diaza-2,11-diphosphadodecane (mp-PNNP) and (4*S*,9*S*)-4,9-dimethyl-2,11-diphenyl-5,8-diaza-2,11-diphosphadodecane (*SS*(C)-mp-PNNP), and their cobalt(III) complexes, *trans*-$[CoCl_2$(mp- or *SS*(C)-mp-PNNP)$]^+$ and *cis*β-[Co(acac)(mp- or *SS*(C)-mp-PNNP)$]^{2+}$ (acac=2,4-pentanedionate ion) were prepared and characterized. For both mp- and *SS*(C)-mp-PNNP, the dichloro and acac complexes formed three and four isomers, respectively, which were separated by column chromatography or fractional crystallization. No *cis*α-acac complex was yielded. The acac complexes of *SS*(C)-mp-PNNP formed a Λ-isomer stereoselectively. The absolute configurations of the phosphorus donor atoms in the *SS*(C)-mp-PNNP complexes were assigned on the basis of the ^1H NMR and CD spectra. It was shown that the phosphorus donor atoms at chemically unequivalent coordination positions in *cis*β-[Co(acac)(*SS*(C)-mp-PNNP)$]^{2+}$ give remarkably different vicinal effects on the CD spectra.

In previous papers, we have reported preparation and stereochemistry of octahedral cobalt(III) complexes containing new quadridentate phosphine ligands of the PNNP type, $(R_2PCH_2CH_2NHCH_2-)_2$ (R=CH_3: mm-PNNP, R=C_6H_5: pp-PNNP),[1] and the optically active methyl-substituted derivatives, $(R_2PCH_2CH(CH_3)NHCH_2-)_2$ (R=CH_3: *SS*(C)-mm-PNNP, R=C_6H_5: *SS*(C)-pp-PNNP).[2] These PNNP complexes formed selectively particular geometrical or optical isomers. Introduction of asymmetric phosphorus donor atoms into the PNNP-type ligands will cause new stereoselectivity in the complex formation, and will give useful information for studying chiral phosphine complexes, which have little been studied.[3] This paper concerns preparation and stereochemistry of two new chiral phosphine ligands, 2,11-diphenyl-5,8-diaza-2,11-diphosphadodecane (mp-PNNP) and (4*S*,9*S*)-4,9-dimethyl-2,11-diphenyl-5,8-diaza-2,11-diphosphadodecane (*SS*(C)-mp-PNNP), and their cobalt(III) complexes, *trans*-$[CoCl_2$(mp- or *SS*(C)-mp-PNNP)$]^+$ and *cis*β-[Co(acac)(mp- or *SS*(C)-mp-PNNP)$]^{2+}$ (acac=2,4-pentanedionate ion).

Experimental

Phosphine ligands, mp-PNNP and *SS*(C)-mp-PNNP were prepared and handled under an atmosphere of nitrogen until they formed cobalt(III) complexes. All solvents used for the preparation were made oxygen-free by bubbling nitrogen for 20 min immediately before use. Absorption, circular dichroism (CD) and ^1H NMR spectra were recorded on a Hitachi 323 spectrometer, a Jasco J-40CS spectropolarimeter and a Jeol JNM PMX-60 spectrometer, respectively.

Preparation of Ligands. 2,11-Diphenyl-5,8-diaza-2,11-diphosphadodecane (*RS*(P)- and *RR,SS*(P)-mp-PNNP). To liquid ammonia (200 cm^3) in a 500 cm^3 three-necked, round-bottom flask with a mechanical stirrer and a nitrogen inlet was added metallic sodium (1.33 g, 49.1 mmol) with stirring at −78 °C. After 1 h $PH(CH_3)(C_6H_5)$[4] (1.33 g, 49.1 mmol) was added dropwise and the mixture was stirred for 20 min. To the resulting yellow solution of $NaP(CH_3)(C_6H_5)$ was added $(ClCH_2CH_2NHCH_2-)_2\cdot 2HCl$[5] (3.16 g, 12.3 mmol) in small portions with stirring. Stirring was continued for 2.5 h, and then liquid ammonia was evaporated. Water (30 cm^3) and then diethyl ether (40 cm^3) were added to the residue with stirring. The ethereal layer was separated from the aqueous layer and dried over $MgSO_4$ (1.5 g). The solvent and unreacted $PH(CH_3)(C_6H_5)$ were removed by distillation (83 °C, 1300 Pa). The colorless oily residue (3.71 g) thus obtained was a mixture of *RS*(P)- and *RR,SS*(P)-mp-PNNP and used for preparing the cobalt(III) complexes without further purification and separation of the isomers.

(4*S*,9*S*)-4,9-Dimethyl-2,11-diphenyl-5,8-diaza-2,11-diphosphadodecane (*RS*(P)-, *RR*(P)-, and *SS*(P)-*SS*(C)-mp-PNNP). This ligand was obtained as oily substance by the same method as that for mp-PNNP in a yield of 2.70 g, using liquid ammonia (150 cm^3), metallic sodium (0.83 g, 36 mmol), $PH(CH_3)(C_6H_5)$ (4.5 g, 36 mmol), and (2*S*,7*S*)-2,7-dimethyl-1,8-dichloro-3,6-diazaoctane dihydrochloride[2] (2.95 g, 9.05 mmol).

Preparation of Complexes. *trans*-$[CoCl_2$(*RS*(P)-mp-PNNP)$]ClO_4$ (F-1), *trans*-$[CoCl_2$(*RR,SS*(P)-mp-PNNP)$]ClO_4$ (F-2), and *trans*-$[CoCl_2$(*RR,SS*(P)-mp-PNNP)$]ClO_4\cdot 1.5H_2O$ (F-3).[6] To *cis*-$[CoCl_2(en)_2]Cl$[7] (0.96 g, 3.36 mmol) (en: ethylenediamine) in methanol (50 cm^3) was added a mixture of *RS*(P)- and *RR,SS*(P)-mp-PNNP (1.0 g, 2.77 mmol) with stirring at room temperature. After 15 min concd HCl (1 cm^3) was added and the solution was stirred overnight at room temperature. The resulting solution was filtered to remove $[Co(en)_3]Cl_3$ precipitated. The filtrate was mixed with water (300 cm^3) and the unreacted phosphine ligand was extracted with diethyl ether (ca. 50 cm^3). The green aqueous layer was mixed with $NaClO_4\cdot H_2O$ (10 g) and the green complex was extracted twice with CH_2Cl_2 (50 cm^3×2). The extract was evaporated to dryness under reduced pressure and the residue was dissolved in methanol (100 cm^3). The solution was diluted with water (1 dm^3) and applied on a column (φ2.5 cm×120 cm) of SP-Sephadex C-25. The adsorbed product was eluted with 0.05 mol dm^{-3} HCl, giving three green bands F-1, F-2, and F-3. The eluate

containing each green band was collected, $NaClO_4 \cdot H_2O$ (5 g) was added to it, and the complex was extracted with CH_2Cl_2 (50 cm^3). The extract was evaporated to dryness under reduced pressure and the residue was dissolved again in a small amount of methanol. On addition of excess $NaClO_4 \cdot H_2O$ the solution gave green crystals, which were filtered, washed with water and air-dried. The complex obtained from the first band (F-1) was a racemic pair of $[CoCl_2(RS(P)\text{-mp-PNNP})]^+$ (*RR*(N)*RS*(P) and *SS*(N)*SR*(P) isomers), and those from the second (F-2) and the third (F-3) bands are two racemic pairs of $[CoCl_2(RR,SS(P)\text{-mp-PNNP})]^+$ (*RR*(N)*SS*(P) and *SS*(N)*RR*(P), and (*RR*(N)-*RR*(P) and *SS*(N)*SS*(P) isomers) (vide infra). Yield (F-1): 245 mg. Found: C, 40.87; H, 5.19; N, 4.39%. Calcd for $C_{20}H_{30}N_2Cl_3CoO_4P_2$: C, 40.74; H, 5.13; N, 4.75%. Yield (F-2): 100 mg. Found: C, 40.67; H, 5.05; N, 4.40%. Calcd for $C_{20}H_{30}N_2Cl_3CoO_4P_2$: C, 40.74; H, 5.13; N, 4.75%. Yield (F-3): 95 mg. Found: C, 38.98; H, 5.16; N, 4.23%. Calcd for $C_{20}H_{33}N_2Cl_3CoO_{5.5}P_2$: C, 38.95; H, 5.39; N, 4.54%. All the complexes are soluble in methanol, acetone and dichloromethane, slightly in water, but not in diethyl ether and benzene.

Λ[*RS*(P)]Δ[*SR*(P)]-*cis*β-[Co(acac)(*RS*(P)-mp-PNNP)](ClO$_4$)$_2$ and Λ[*SR*(P)]Δ[*RS*(P)]-*cis*β-[Co(acac)(*RS*(P)-mp-PNNP)](ClO$_4$)$_2$·1.5H$_2$O (see Fig. 5). A methanol solution (30 cm^3) containing *trans*-$[CoCl_2(RS(P)\text{-mp-PNNP})]ClO_4$ (100 mg, 0.17 mmol) and Li(acac) (60 mg, 0.57 mmol) was stirred for 12 h at room temperature. The resulting red solution was diluted with water (200 cm^3) and applied on a column (ϕ2.5 cm×100 cm) of SP-Sephadex C-25. The adsorbed product was eluted with 0.2 mol dm^{-3} NaCl, giving two red bands. The eluate containing each band was collected, evaporated to dryness under reduced pressure, and the complex in the residue was extracted with ethanol (50 cm^3). The extract was evaporated to dryness, and the residue was dissolved in water (10 cm^3). On addition of $NaClO_4 \cdot H_2O$ (ca. 1.0 g) the solution gave a red precipitate, which was filtered, washed with a small amount of cold water, and dried in vacuo. The complex obtained from the first band is the Λ[*RS*(P)]Δ[*SR*(P)] isomer and that from the second band the Λ[*SR*(P)]Δ[*RS*(P)] isomer (see Fig. 5). Yield (the Λ[*RS*(P)]Δ-[*SR*(P)] isomer): 11 mg. Found: C, 42.03; H, 5.18; N, 4.11%. Calcd for $C_{25}H_{37}N_2Cl_2CoO_{10}P_2$: C, 41.85; H, 5.20; N, 3.91%. Yield (the Λ[*SR*(P)]Δ[*RS*(P)] isomer): 40 mg. Found: C, 40.18; H, 5.31; N, 3.55%. Calcd for $C_{25}H_{40}N_2Cl_2CoO_{11.5}P_2$: C, 40.34; H, 5.42; N, 3.76%.

Λ[*SS*(P)]Δ[*RR*(P)]-*cis*β-[Co(acac)(*RR,SS*(P)-mp-PNNP)](ClO$_4$)$_2$ and Λ[*RR*(P)]Δ[*SS*(P)]-*cis*β-[Co(acac)(*RR,SS*(P)-mp-PNNP)](ClO$_4$)$_2$·0.5H$_2$O. These complexes were obtained from *trans*-$[CoCl_2(RR,SS(P)\text{-mp-PNNP})]ClO_4$ (F-2) (95 mg, 0.161 mmol) or *trans*-$[CoCl_2(RR,SS(P)\text{-mp-PNNP})]ClO_4 \cdot 1.5H_2O$ (F-3) (100 mg, 0.162 mmol) and Li(acac) (60 mg, 0.57 mmol) by the same method as that for the corresponding *RS*(P)-mp-PNNP complex. The complex obtained from the first band is the Λ[*SS*(P)]Δ[*RR*(P)] isomer and that from the second band the Λ[*RR*(P)]Δ[*SS*(P)] isomer. Yield (the Λ[*SS*(P)]Δ[*RR*(P)] isomer): 17 mg. Found: C, 41.71; H, 5.41; N, 3.85%. Calcd for $C_{25}H_{37}N_2Cl_2CoO_{10}P_2$: C, 41.85; H, 5.20; N, 3.91%. Yield (the Λ[*RR*(P)]Δ[*SS*(P)] isomer): 36 mg. Found: C, 41.36; H, 5.24; N, 3.89%. Calcd for $C_{25}H_{38}N_2Cl_2CoO_{10.5}P_2$: C, 41.34; H, 5.27; N 3.86%. All the $[Co(acac)(mp\text{-}PNNP)]^{2+}$ complexes are soluble in water, methanol, acetone and dichloromethane, but not in diethyl ether and benzene.

***trans*-[CoCl$_2$(*RS*(P)-*SS*(C)-mp-PNNP)]ClO$_4$·NaClO$_4$·H$_2$O and a Pseudo Racemate of *trans*-[CoCl$_2$(*RR,SS*(P)-*SS*(C)-mp-PNNP)]ClO$_4$·H$_2$O.** To *cis*-$[CoCl_2(en)_2]Cl$ (220 mg, 0.77 mmol) in methanol (150 cm^3) was added a mixture of *RS*(P)-, *RR*(P)- and *SS*(P)-*SS*(C)-mp-PNNP (300 mg, 0.77 mmol) with stirring at room temperature. After 30 min concd HCl (2 cm^3) was added to the resulting green solution, and the mixture was stirred overnight at room temperature. The solution was filtered, and the filtrate was concentrated to 50 cm^3 under reduced pressure. To the concentrate were added $NaClO_4 \cdot H_2O$ (6.0 g) and water (200 cm^3), and the complex was extracted twice with CH_2Cl_2 (30 cm^3×2). The green extract was evaporated to dryness under reduced pressure, and the residue was dissolved in hot methanol (20 cm^3, 60 °C). To the solution was added $NaClO_4 \cdot H_2O$ (2.0 g), and the mixture was allowed to stand at room temperature to yield a green precipitate, which was filtered, washed with water and air-dried. The filtrate was preserved because it contains the other isomer. Yield: 138 mg. Found: C, 41.80; H, 5.88; N, 4.15%. Calcd for $C_{22}H_{36}N_2Cl_3CoO_5P_2$: C, 41.56; H, 5.71; N, 4.41%. This complex was assigned to a pseudo racemate of *trans*-$[CoCl_2(RR,SS(P)\text{-}SS(C)\text{-mp-PNNP})]^+$ from the ^1H NMR spectrum. From the filtrate green crystals were formed by addition of a large excess of diethyl ether (ca. 80 cm^3), filtered, washed with water and air-dried. Yield: 100 mg. Found: C, 34.74; H, 4.56; N, 3.48%. Calcd for $C_{22}H_{36}N_2Cl_4CoNaO_9P_2$: C, 34.85; H, 4.79; N, 3.69%. This complex was assigned to the *trans*-$[CoCl_2(RS(P)\text{-}SS(C)\text{-mp-PNNP})]^+$ isomer from the ^1H NMR spectrum. Both dichloro complexes are soluble in methanol and dichloromethane, slightly in water, but not in diethyl ether.

***trans*-[CoCl$_2$(*SS*(P)-*SS*(C)-mp-PNNP)]ClO$_4$ and *trans*-[CoCl$_2$(*RR*(P)-*SS*(C)-mp-PNNP)]ClO$_4$·0.5H$_2$O.** A pseudo racemate of *trans*-$[CoCl_2(RR,SS(P)\text{-}SS(C)\text{-mp-PNNP})]ClO_4 \cdot H_2O$ (340 mg, 0.540 mmol) obtained above was converted into the chloride by stirring with Dowex 1X8 (Cl^- form, 6 g) in methanol (50 cm^3) for 6 h at room temperature. The mixture was filtered, the filtrate was diluted with water (500 cm^3), and the solution was applied on a column (ϕ2.5 cm×100 cm) of SP-Sephadex C-25. By elution with 0.05 mol dm^{-3} HCl, two green bands appeared. The eluate containing each band was collected, mixed with $NaClO_4 \cdot H_2O$ (ca. 10 g), and the complex was extracted with CH_2Cl_2. The green extract was evaporated to dryness under reduced pressure. The residue was dissolved in methanol (20 cm^3), and $NaClO_4 \cdot H_2O$ (2 g) was added to the solution. On standing at room temperature, the solution obtained from the first band yielded green crystals of *trans*-$[CoCl_2(SS(P)\text{-}SS(C)\text{-mp-PNNP})]ClO_4$, which were filtered, washed with water and air-dried. Yield: 80 mg. Found: C, 42.35; H, 5.45; N, 4.48%. Calcd for $C_{22}H_{34}N_2Cl_3CoO_4P_2$: C, 42.77; H, 5.55; N, 4.53%. The methanol solution containing $NaClO_4 \cdot H_2O$ obtained from the second band gave a green precipitate by addition of water. It was filtered, washed with water and air-dried. Yield: 65 mg. Found: C, 41.93; H, 5.33; N, 4.37%. Calcd for $C_{22}H_{35}N_2Cl_3CoO_{4.5}P_2$: C, 42.16; H, 5.63; N, 4.47%. The pruduct is *trans*-$[CoCl_2(RR(P)\text{-}SS(C)\text{-mp-PNNP})]ClO_4 \cdot 0.5H_2O$.

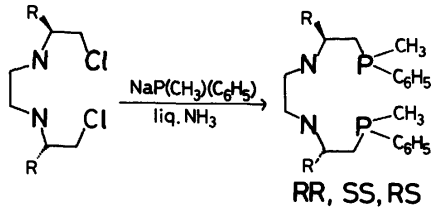
Λ-*cis*β-[Co(acac)(*SS*(P)-*SS*(C)-mp-PNNP)](ClO$_4$)$_2$·1.5H$_2$O and Λ-*cis*β-[Co(acac)(*RR*(P)-*SS*(C)-mp-PNNP)](ClO$_4$)$_2$·H$_2$O. A methanol solution (30 cm^3) containing a pseudo racemate of *trans*-$[CoCl_2(RR,SS(P)\text{-}SS(C)\text{-mp-PNNP})]ClO_4 \cdot H_2O$ (200 mg, 0.314 mmol) and Li(acac) (100 mg, 0.945 mmol)

was stirred for 8 h at room temperature. The resulting red solution was diluted with water (1 dm^3) and the solution applied on a column (ϕ2.5 cm×25 cm) of SE-Toyopearl. By elution with 0.1 mol dm^{-3} Na_2SO_4, two red bands appeared. The eluate of each band was collected, concentrated to nearly dryness under reduced pressure, and the complex was extracted with ethanol (50 cm^3). The extract was evaporated to dryness under reduced pressure, and the residue was dissolved in water (10 cm^3). On addition of $NaClO_4 \cdot H_2O$ (1.5 g) in water (5 cm^3), the solution gave a red precipitate, which was filtered, washed with a small amount of cold water and air-dried. The complex obtained from the first band is *Λ-cisβ*-[Co(acac)(*SS*(P)-*SS*(C)-mp-PNNP)]$(ClO_4)_2 \cdot 1.5H_2O$ and that from the second band *Λ-cisβ*-[Co(acac)-(*RR*(P)-*SS*(C)-mp-PNNP)]$(ClO_4)_2 \cdot H_2O$. These complexes were also prepared separately from trans-dichloro complexes of *SS*(P)- and *RR*(P)-*SS*(C)-mp-PNNP. Yield (the *SS*(P)-isomer): 59 mg. Found: C, 42.15; H, 6.05; N, 3.66%. Calcd for $C_{27}H_{44}N_2Cl_2CoO_{11.5}P_2$: C, 41.98; H, 5.74; N, 3.63%. Yield (the *RR*(P)-isomer): 45 mg. Found: C, 42.48; H, 6.04; N, 3.69%. Calcd for $C_{27}H_{43}N_2Cl_2CoO_{11}P_2$: C, 42.48; H, 5.68; N, 3.67%. The complexes are soluble in water, methanol and dichloromethane, but not in diethyl ether and benzene.

***Λ*[*RS*(P)]-*cisβ*-[Co(acac)(*RS*(P)-*SS*(C)-mp-PNNP)](ClO$_4$)$_2$ and *Λ*[*SR*(P)]-*cisβ*-[Co(acac)(*RS*(P)-*SS*(C)-mp-PNNP)](ClO$_4$)$_2 \cdot 1.5H_2O$ (see Fig. 5).** These complexes were prepared from *trans*-[$CoCl_2$(*RS*(P)-*SS*(C)-mp-PNNP)]$ClO_4 \cdot NaClO_4 \cdot H_2O$ (285 mg, 0.376 mmol) and Li(acac) (40 mg, 0.377 mmol) according to a method similar to that for the corresponding *RR*(P)- and *SS*(P)-*SS*(C)-mp-PNNP complexes. In column chromatography, the *Λ*[*RS*(P)]-isomer was eluted faster than the *Λ*[*SR*(P)]-isomer. Yield (the *Λ*[*RS*(P)]-isomer): 31 mg. Found: C, 43.76; H, 5.73; N, 3.80%. Calcd for $C_{27}H_{41}N_2Cl_2CoO_{10}P_2$: C, 43.51; H, 5.54; N, 3.76%. Yield (the *Λ*[*SR*(P)]-isomer): 20 mg. Found: C, 42.00; H, 5.75; N, 4.16%. Calcd for $C_{27}H_{44}N_2Cl_2CoO_{11.5}P_2$: C, 41.98; H, 5.74; N, 3.63%. The complexes are soluble in water, methanol and dichloromethane, but not in diethyl ether and benzene.

Results and Discussion

Quadridentate ligands having chiral phosphorus donor atoms, mp-PNNP and *SS*(C)-mp-PNNP were prepared according to methods similar to those for 1,1,10,10-tetraphenyl-4,7-diaza-1,10-diphosphadecane (pp-PNNP)[1] and (3*S*,8*S*)-3,8-dimethyl-1,1,10,10-tetraphenyl-4,7-diaza-1,10-diphosphadecane (*SS*(C)-pp-PNNP),[2] respectively (Scheme). The ligands have two chiral phosphorus atoms. The mp-PNNP ligand exists in two diastereomers, *RR*,*SS*(P) (racemic) and



R = H : mp-PNNP

R = CH_3: SS(C)-mp-PNNP

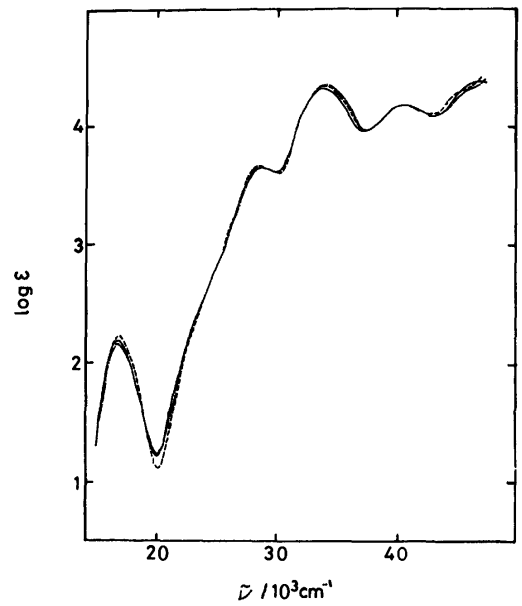


Fig. 1. Absorption spectra of *trans*-[$CoCl_2$(*RS*(P)-mp-PNNP)]$^+$ (F-1) (——), *trans*-[$CoCl_2$(*RR*,*SS*(P)-mp-PNNP)]$^+$ (F-2) (—·—·—), and *trans*-[$CoCl_2$(*RR*,*SS*-(P)-mp-PNNP)]$^+$ (F-3) (– – –).

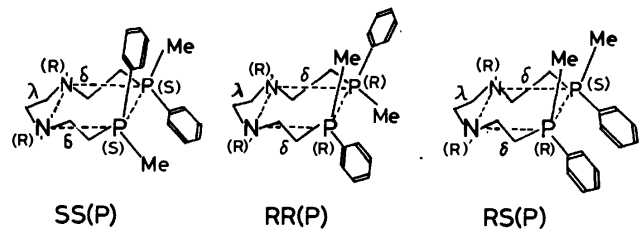

trans-RR(N)-[$CoCl_2$(mp-PNNP)]$^+$

Fig. 2. Three possible diastereomers of *trans*-[$CoCl_2$(mp- or *SS*(C)-mp-PNNP)]$^+$.

RS(P) (meso), and the *SS*(C)-mp-PNNP ligand in three optically active diastereomers, *RR*(P)-*SS*(C), *SS*(P)-*SS*(C), and *RS*(P)-*SS*(C). The separation of these diastereomers was not attempted for the free lignds because they are easily oxidized in the air, but done successfully through complexation with Co(III). The Co(III) complexes with these chiral phosphine ligands were prepared by methods similar to those for the previous PNNP complexes.[1,2]

The [$CoCl_2$(mp-PNNP)]$^+$ complex was separated into three green isomers, F-1, F-2, and F-3 by SP-Sephadex C-25 column chromatography. Figure 1 shows absorption spectra of these isomers. The spectra are essentially the same and show a pattern characteristic of the *trans*(Cl,Cl), *cis*(P,P)-[$CoCl_2N_2P_2$]-type complex.[8,9] Thus all of the isomers can be assigned to have the *trans*(Cl,Cl) configuration. For *trans*-[$CoCl_2$(mp-PNNP)]$^+$, there are three possible isomers as shown in Fig. 2. All the isomers exist in a pair of enantiomers, in which the two chiral nitrogen

atoms have the same absolute configutation (*RR* or *SS*) and all the chelate rings take a gauche conformation (δ or λ). The *RS*(N) isomers, in which the N–N chelate ring takes an envelop (ε) conformation as found for 3,6-diazaoctane-1,8-diamine (trien) complex,[10] are also probable. However, they can be excluded by considering stereoisomers of the trans-dichloro complexes of *SS*(C)-mp-PNNP and of the acac complexes derived from the *trans*-dichloro complexes (vide infra). In ^{1}H NMR spectra, isomer F-1 shows a P-CH_3 signal at 1.92(t) ppm, while isomers F-2 and F-3 give the signals at a remarkably high field, 1.37(t) and 1.32(t) ppm, respectively. As shown in Fig. 2, the methyl groups of the two isomers containing *RR*,*SS*(P)-mp-PNNP are disposed to the same direction as the phenyl group on the other P atom to face with each other. The high field shift of the mehtyl groups of isomers F-2 and F-3 will be attributable to the shielding effect of this phenyl group. The isomer containing *RS*(P)-mp-PNNP has no such a shielded methyl group. Thus isomers F-2 and F-3 can be assigned to the complexes containing *RR*,*SS*(P)-mp-PNNP, and isomer F-1, which shows the P-CH_3 signal at a lower field, to the complex containing *RS*(P)-mp-PNNP. Grocott and Wild[11] assigned the configurations of donor atoms of *o*-phenylenebis(methylphenylarsine) and its phosphorus analogue in Ru(II) complexes on the basis of similar high field shifts of the methyl group. All of the isomers do not show optical activity. Thus isomer F-1 is assigned to a racemate of the *RR*(N)-*RS*(P)- and *SS*(N)-*SR*(P)-mp-PNNP complexes. Assignment of the *RR*(N)-*SS*(P)-, *SS*(N)-*RR*(P)-mp-PNNP, and the *RR*(N)-*RR*(P)-, *SS*(N)-*SS*(P)-mp-PNNP complexes in Fig. 2 to the two isomers, F-2 and F-3 can not be made at present. Both isomers were obtained in nearly the same yield. There will be little difference in stability between them. To assign the isomers, the circular dichroism (CD) spectra will be needed. Attempts to resolve the isomers were unsuccessfull.

The $[CoCl_2$(*SS*(C)-mp-PNNP)$]^+$ complex also yielded three green isomers. These isomers will correspond to the above three isomers of *trans*-$[CoCl_2$(mp-PNNP)$]^+$, since the absorption spectra of six isomers are very similar (Fig. 3). The chelate ring of the N–P moiety of *SS*(C)-mp-PNNP will be stabilized in a δ-gauche conformation with the equatorial methyl group, and the ligand will form a $\delta\lambda\delta$ conformation preferentially. Hence all of the isomers are expected to be optically pure and the structures should be those given in Fig. 2.

The three isomers of *trans*-$[CoCl_2$(*SS*(C)-mp-PNNP$)]^+$ were separated by fractional crystallization and column chromatography. A pseudo racemate of the *RR*(P)-*SS*(C)- and *SS*(P)-*SS*(C)-mp-PNNP complexes was precipitated from a methanol solution containing the three isomers by the addition of excess $NaClO_4 \cdot H_2O$. The precipitate gives the P-CH_3 signal at a higher field (around 1.30(m) ppm). From the methanol solution filtered off the precipitate, the *RS*(P)-*SS*(C)-mp-PNNP complex was obtained by adding large excess diethyl ether. The product shows the P-CH_3 signal at 1.84(t) ppm. Thus the complexes containing *RR*(P)-*SS*(C)- and *SS*(P)-*SS*(C)-mp-PNNP, and *RS*(P)-*SS*(C)-mp-PNNP can be easily separated by the solubility difference in methanol. The separation of the *RR*(P)-*SS*(C)- and *SS*(P)-*SS*(C)-mp-PNNP complexes was achieved by SP-Sephadex C-25 column chromatography using 0.05 mol dm^{-3} HCl as an eluent; the *SS*(P)-*SS*(C)-mp-PNNP complex was eluted faster than the other complex. The absolute configurations of the two isomers were assigned from the CD spectra described below. The P-CH_3 signals of the *RR*(P)-*SS*(C)- and *SS*(P)-*SS*(C)-mp-PNNP complexes were observed at 1.30(t) and 1.38(t) ppm, respectively.

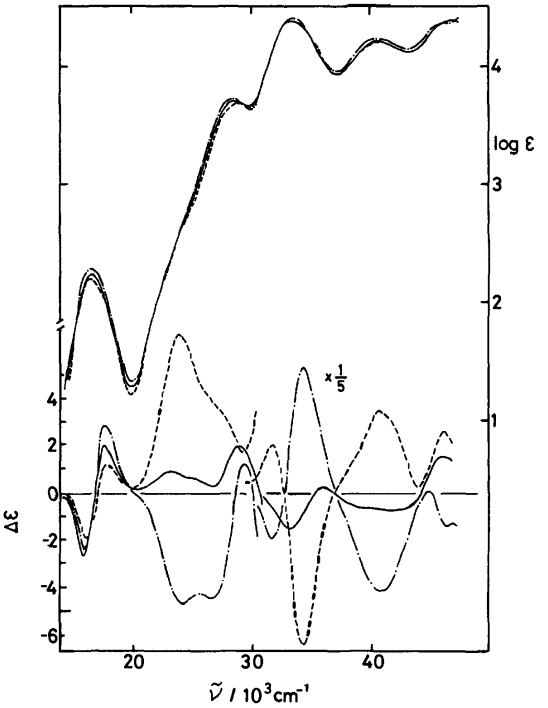

Fig. 3. Absorption and CD spectra of *trans*-$[CoCl_2$(*RS*(P)-*SS*(C)-mp-PNNP$)]^+$ (——), *trans*-$[CoCl_2$(*SS*(P)-*SS*(C)-mp-PNNP$)]^+$ (----), and *trans*-$[CoCl_2$(*RR*(P)-*SS*(C)-mp-PNNP$)]^+$ (-·—·-).

Figure 3 compares CD spectra of the three isomers of *trans*-$[CoCl_2$(*SS*(C)-mp-PNNP$)]^+$. The spectra show similar patterns in the region of 15000 to 20000 cm^{-1} (Ia absorption band region[2]). In the higher energy region, however, the *RR*(P)-*SS*(C)- and *SS*(P)-*SS*(C)-mp-PNNP complexes exhibit fairly strong CD nearly enantiomeric to each other, while the *RS*(P)-*SS*(C)-mp-PNNP complex shows rather weak CD. The similarity in the three spectra in the Ia band region indicates that these dichroisms arise mainly from the vicinal effects of the (*R*,*R*)-nitrogen donor atoms and the $\delta\lambda\delta$ conformation which are common chiralities among the three complexes. Figure 4 shows the CD spectrum of

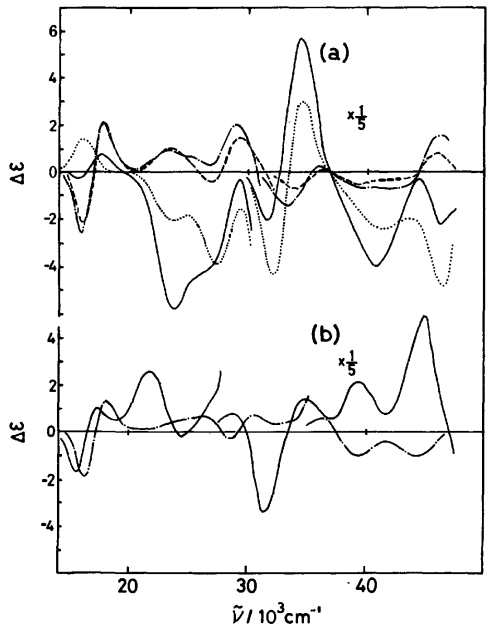

Fig. 4. a) Calculated vicinal effects of asymmetric phosphorus donors, Δε[*RR*(P)] (——) and Δε[*RR*(N),*SS*(C),*δλδ*] (– – –), and CD spectra of *trans*-[$CoCl_2$(*R*-ebpp)$_2$]$^+$ (·····) and *trans*-[$CoCl_2$(*RS*(P)-*SS*(C)-mp-PNNP)]$^+$ (–·—·–). b) CD spectra of *trans*-[$CoCl_2$(*SS*(C)-pp-PNNP)]$^+$ (——) and *trans*-[$CoCl_2$-(*SS*(C)-mm-PNNP)]$^+$ (–·—·–).

trans(Cl,Cl), *cis*(P,P)-[$CoCl_2$(*R*-ebpp)$_2$]$^+$ (*R*-ebpp=(*R*)-(2-aminoethyl)butylphenylphosphine) whose absolute configuration was determined by the X-ray method.[8] The complex exhibits rather strong negative bands in the region of 22000 to 28000 cm^{-1} and strong bands with opposite signs in the region of 30000 to 37000 cm^{-1}. The CD patterns of the *RR*(P)-*SS*(C)- and *SS*(P)-*SS*(C)-mp-PNNP complexes are similar and enantiomeric to that of the *R*-ebpp complex in these regions, respectively. From a comparison of these spectra, the isomer which was eluted faster in column chromatography is assigned to the *SS*(P)-*SS*(C)-mp-PNNP complex, and the other to the *RR*(P)-*SS*(C)-mp-PNNP complex.

When the additivity of the vicinal effects due to the chiral P, C, and N atoms and the chiral chelate conformation is assumed, the effect of the two chiral P atoms can be estimated by the equation, Δε[*RR*(P)]= 1/2{Δε[*RR*(N), *RR*(P), *SS*(C), *δλδ*-isomer]−Δε[*RR*(N), *SS*(P), *SS*(C), *δλδ*-isomer]} (1), and the effect of the sum of the chiral two N and two C atoms and the *δλδ* conformation by the equation, Δε[*RR*(N), *SS*(C), *δλδ*]=1/2{Δε[*RR*(N), *RR*(P), *SS*(C), *δλδ*-isomer]+ Δε[*RR*(N), *SS*(P), *SS*(C), *δλδ*-isomer]} (2). The calculated curves of effects (1) and (2) are given in Fig. 4. The curve of effect (1) (Δε[*RR*(P)]) is similar in pattern to the spectrum of *trans*(Cl,Cl), *cis*(P,P)-[$CoCl_2$(*R*-ebpp)$_2$]$^+$, in which the chiral source is only at the P atom, since the chiral conformational effect seems to be very small.[8] The curve of effect (2) (Δε[*RR*(N), *SS*(C),*δλδ*]) is nearly the same as the spectrum of *trans*-[$CoCl_2$(*RS*(P)-*SS*(C)-mp-PNNP)]$^+$ in which the effect of the chiral P atoms should be cancelled. The curve is also very similar to those of *trans*-[$CoCl_2$(*SS*(C)-mm-PNNP or *SS*(C)-pp-PNNP)]$^+$ [2] which have the same chiralities (*RR*(N), *SS*(C), *δλδ*).[2] The results indicate that the additivity of the vicinal effects due to various chiral sources holds in CD spectra of these trans-dichloro-phosphine complexes.

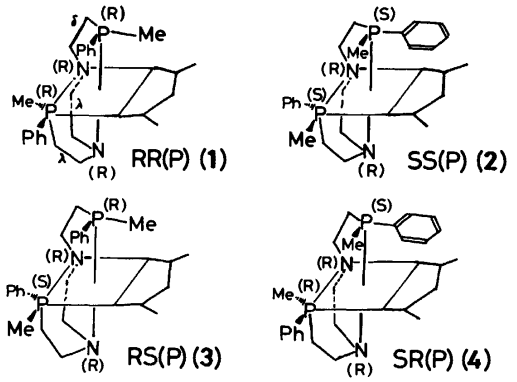

Fig. 5. Four diastereomers of *cisβ*-[Co(acac)(mp- or *SS*(C)-mp-PNNP)]$^{2+}$.

The [Co(acac)(mp-PNNP or *SS*(C)-mp-PNNP)]$^{2+}$ complexes were obtained from the corresponding trans-dichloro complexes and Li(acac). All of the acac complexes can be assigned to the *cisβ*-isomer from the ^{1}H NMR and absorption spectra (Table 1). The *cisα*-isomer which has two mutually trans P donor atoms will be unstable because of the strong trans influence of the phosphine ligand.[1,2,12]

The *cisβ*-[Co(acac)(mp-PNNP)]$^{2+}$ complex has four possible isomers as shown in Fig. 5. All the isomers have their antipodes. The notation *RS*(P) and *SR*(P) are used for two isomers of the *RS*(P)-mp-PNNP (meso) complex; the first symbol *R* or *S* denotes the absolute configuration of the P atom at the apical coordination position with respect to the acac ligand. Each of *trans*-[$CoCl_2$(*RS*(P)-mp-PNNP)]$^+$ (F-1) and *trans*-[$CoCl_2$(*RR*,*SS*(P)-mp-PNNP)]$^+$ (F-2 and F-3) yielded two isomers by reaction with Li(acac), and the isomers were separated by SP-Sephadex C-25 column chromatography. Of these isomers, one *RS*(P)-mp-PNNP and one *RR*,*SS*(P)-mp-PNNP complexes show the methine proton signal of acac at a remarkably high field, *δ* 5.00 and 5.08, respectively, while the other *RS*(P)-mp-PNNP and *RR*,*SS*(P)-mp-PNNP complexes give the signal at *δ* 5.90 and 5.97, respectively. As seen in Fig. 5, in the *Λ*[*SR*(P)](*Δ*[*RS*(P)]) and *Λ*[*SS*(P)]-(*Δ*[*RR*(P)]) isomers, one of the two phenyl groups is disposed over the acac ring and will shield the methine proton to make its signal shift to a high field. Thus the isomers whose methine proton signals show the high field shift can be assigned to the *Λ*[*SR*(P)](*Δ*[*RS*(P)]) and *Λ*[*SS*(P)](*Δ*[*RR*(P)]) configurations, and the other

isomers to the *Λ*[*RS*(P)](*Δ*[*SR*(P)]) and *Λ*[*RR*(P)](*Δ*-[*SS*(P)]) configurations which have a methyl group over the acac ring. Similar high field shifts of the methine proton of acac have been reported for several phenyl-substituted phosphine-acac complexes.[9,13] Attempts to resolve the isomers by SP-Sephadex C-25 column chromatography with $Na_2[Sb_2(d\text{-tartrate})_2]$ were unsuccessfull, although the *Λ*[*RR*(P)]*Δ*[*SS*(P)] and *Λ*[*SR*(P)]*Δ*[*RS*(P)] isomers were partially resolved.

Each of *trans*-[$CoCl_2$(*RR*,*SS*(P)-*SS*(C)-mp-PNNP)]$^+$ (a pseudo racemate) and *trans*-[$CoCl_2$(*RS*(P)-*SS*(C)-mp-PNNP)]$^+$ yielded two isomers of the acac complex by reaction with Li(acac). The isomers were separated by SE-Toyopearl column chromatography. The two isomers, the *RR*(P)- and *SS*(P)-SS(C)-mp-PNNP complexes were also prepared separately from the trans-dichloro-*RR*(P)-*SS*(C)-mp-PNNP and -*SS*(P)-*SS*(C)-mp-PNNP complexes, respectively. All the isomers are optically pure and show a large positive and a small negative CD bands in the first absorption band region, indicating the *Λ* configuration (vide infra). The ^1H NMR spectra show all the isomers to have the cis*β* structure. The selective formation of the *Λ*-cis*β* isomers was also observed for analogous acac complexes of *SS*(C)-mm-PNNP and *SS*(C)-pp-PNNP.[2] The X-ray structure analysis on [Co(acac)(*SS*(C)-mm-PNNP)]$^{2+}$ revealed that the complex has the *Λ*-cis*β*, *RR*(N), *SS*(C) configuration, distorted gauche ($\delta\lambda\lambda$) conformations for the three chelate rings formed by PNNP, and the axial methyl group on carbon of the *λ*-(P–N) chelate ring.[2] The skeletal structures of all the isomers of [Co(acac)(*SS*(C)-mp-PNNP)]$^{2+}$ will be the same as those found in this *SS*(C)-mm-PNNP complex.

The *SS*(P)-*SS*(C)-mp-PNNP complex and one of two isomers of the *RS*(P)-mp-PNNP complex exhibit the methine proton signal of acac at a high field, *δ* 5.20 and 5.00, respectively. The methine protons in these isomers should be shielded by the phenyl group disposed over the acac chelate ring. The methine protons of the *RR*(P)-*SS*(C)-mp-PNNP complex (*δ* 5.85) and of the other isomer of the *RS*(P)-*SS*(C)-mp-PNNP complex (*δ* 5.93) do not show such a high field shift. The results confirm that the configurational structures of the four isomers are those given in Fig. 5. Each absorption spectrum of the isomers given in Fig. 6 is very similar to that of the corresponding isomer of the

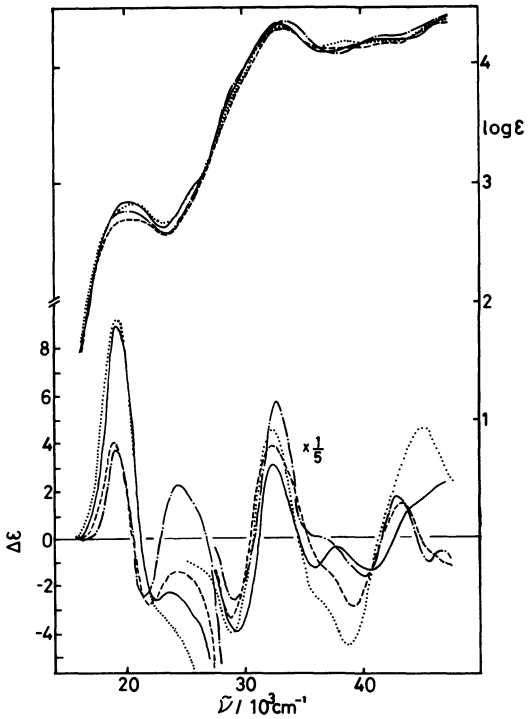

Fig. 6. Absorption and CD spectra of *Λ-cisβ*-[Co(acac)(*SS*(C)-mp-PNNP)]$^{2+}$: *SS*(P)-isomer (——), *RR*(P)-isomer (----), *SR*(P)-isomer (·····), and *RS*(P)-isomer (-·—·-).

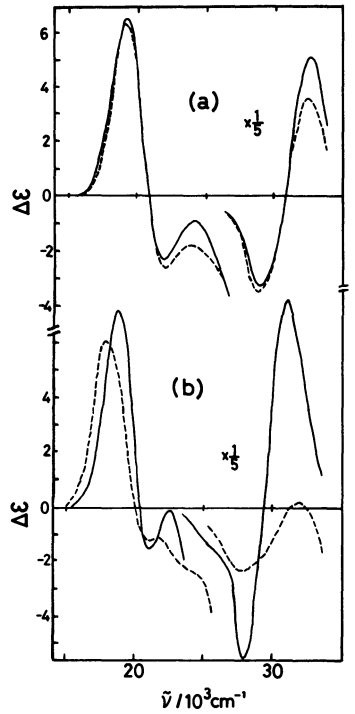

Fig. 7. a) Calculated curves for the effect of the sum, *Λ*, *SS*(C), *RR*(N), and *δλλ* (Δε[*Λ*,*SS*(C),*RR*(N), *δλλ*]): 1/2{Δε[isomer(**3**)]+Δε[isomer(**4**)]} (——) and 1/2{Δε[isomer(**1**)]+Δε[isomer(**2**)]} (----). b) CD spectra of *Λ-cisβ*-[Co(acac)(*SS*(C)-pp-PNNP)]$^{2+}$ (——) and *Λ-cisβ*-[Co(acac)(*SS*(C)-mm-PNNP)]$^{2+}$ (----).

mp-PNNP complex, especially in the first absorption band region, where the spectral patterns are fairly different among the isomers.

Figure 6 shows the CD spectra of four isomers of the *SS*(C)-mp-PNNP complex. The spectra have similar patterns and show a large positive and a small negative bands in the first absorption band region. Thus all the isomers will have the same skeletal configuration, *Λ-cisβ*. However, the positive CD bands of the *SS*(P)- and *SR*(P)-*SS*(C)-mp-PNNP complexes are much larger than those of the *RR*(P)- and *RS*(P)-*SS*(C)-mp-PNNP complexes. The former two complexes have a phenyl group disposed over the acac chelate ring, whereas the latter two complexes a methyl group in place of the phenyl group. The *SR*(P)- and *RS*(P)-*SS*(C)-mp-PNNP complexes show the positive CD band largely different in strength. These results indicate that the magnitude of the vicinal effect of the chiral P atom at one coordination position is remarkably different from that at the other chemically unequivalent coordination position. When the two effects are similar, the *SR*(P)-and *RS*(P)-*SS*(C)-mp-PNNP complexes will give similar CD spectra by cancellation of the effects due to the (*S*)- and (*R*)-P atoms.

Isomers (**1**) to (**4**) in Fig. 5 have common chiralities, *Λ*, *SS*(C), *RR*(N) and *δλλ*, and the following chiralities for the P atoms; (**1**) *R*(P_a), *R*(P_p), (**2**) *S*(P_a), *S*(P_p), (**3**) *R*(P_a), *S*(P_p), and (**4**) *S*(P_a), *R*(P_p), where P_a and P_p denote

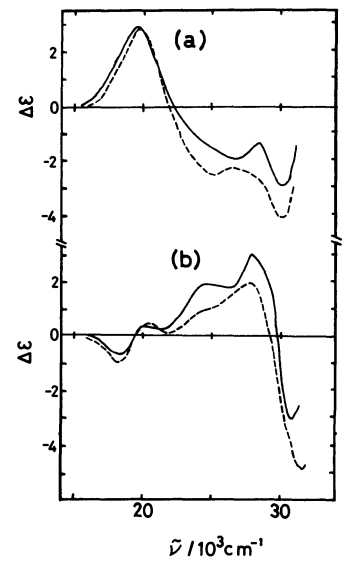

Fig. 8. a) Calculated vicinal effects of (*S*)-P atom at the apical position (Δε[*S*(P_a)]): 1/2{Δε[isomer(**4**)]−Δε[isomer(**1**)]} (——) and 1/2{Δε[isomer(**2**)]−Δε[isomer(**3**)]} (----). b) Calculated vicinal effect of (*S*)-P atom at the planar position (Δε[*S*(P_p)]): 1/2{Δε[isomer(**3**)]−Δε[isomer(**1**)]} (——) and 1/2{Δε-[isomer(**2**)]−Δε[isomer(**4**)]} (----).

P atoms at the apical and planar coordination positions, respectively with respect to the acac ligand. The effect of the sum of common chiralities, *Λ*, *SS*(C),

RR(N) and $\delta\lambda\lambda$ can be estimated by $\Delta\varepsilon[\Lambda, SS(C), RR(N), \delta\lambda\lambda]=1/2\{\Delta\varepsilon[\text{isomer}(\mathbf{1})]+\Delta\varepsilon[\text{isomer}(\mathbf{2})]\}$ (3a) or $\Delta\varepsilon[\Lambda, SS(C), RR(N), \delta\lambda\lambda]=1/2\{\Delta\varepsilon[\text{isomer}(\mathbf{3})]+\Delta\varepsilon[\text{isomer}(\mathbf{4})]\}$ (3b). Figure 7(a) shows two curves of $\Delta\varepsilon[\Lambda, SS(C), RR(N), \delta\lambda\lambda]$ calculated from (3a) and (3b). The vicinal effect of the apical (*S*)-P atom can be estimated by $\Delta\varepsilon[S(P_a)]=1/2\{\Delta\varepsilon[\text{isomer}(\mathbf{2})]-\Delta\varepsilon[\text{isomer}(\mathbf{3})]\}$ (4a) or $\Delta\varepsilon[S(P_a)]=1/2\{\Delta\varepsilon[\text{isomer}(\mathbf{4})]-\Delta\varepsilon[\text{isomer}(\mathbf{1})]\}$ (4b), and the effect of the planar (*S*)-P atom by $\Delta\varepsilon[S(P_p)]=1/2\{\Delta\varepsilon[\text{isomer}(\mathbf{3})]-\Delta\varepsilon[\text{isomer}(\mathbf{1})]\}$ (5a) or $\Delta\varepsilon[S(P_p)]=1/2\{\Delta\varepsilon[\text{isomer}(\mathbf{2})]-\Delta\varepsilon[\text{isomer}(\mathbf{4})]\}$ (5b). The curves of $\Delta\varepsilon[S(P_a)]$ calculated from (4a) and (4b) are given in Fig. 8(a), and those of $\Delta\varepsilon[S(P_p)]$ from (5a) and (5b) in Fig. 8(b). The two curves for each chiral effect are very similar, and the results indicate that the additivity of the three effects, $\Delta\varepsilon[\Lambda, SS(C), RR(N), \delta\lambda\lambda]$, $\Delta\varepsilon[S(P_a)]$ and $\Delta\varepsilon[S(P_p)]$ holds for the CD spectra of four isomers of $[Co(acac)(SS(C)\text{-mp-PNNP})]^{2+}$.

The $\Delta\varepsilon[\Lambda, SS(C), RR(N), \delta\lambda\lambda]$ curve in Fig. 7(a) shows a large positive and a small negative bands in the first absorption band region. This pattern has been observed for a number of Λ-complexes of Co(III). Thus it is suggested that the effects of *SS*(C), *RR*(N) and $\delta\lambda\lambda$ are fairly small compared with the Λ configurational effect. Figure 7(b) shows CD spectra of Λ-*cis*β-$[Co(acac)(L)]^{2+}$ (L=*SS*(C)-mm-PNNP, *SS*(C)-pp-PNNP).[2] The spectra are very similar to the $\Delta\varepsilon[\Lambda, SS(C), RR(N), \delta\lambda\lambda]$ curve, although the *SS*(C)-mm-PNNP complex shows a somewhat different spectrum in the high energy region. The difference will be attributable to the difference in substituent on the P atom, methyl or phenyl. The absolute configuration (Λ, Λ) of the $[Co(acac)(PNNP)]^{2+}$-type complex can be safely assigned from the CD sign in the first absorption band region.

The curves of $\Delta\varepsilon[S(P_a)]$ and $\Delta\varepsilon[S(P_p)]$ in Fig. 8(a) and 8(b) are those for chiral donor P atoms with the same *S* configuration. However, the curves are quite different and almost enantiomeric to each other. In the first absorption band region, the $\Delta\varepsilon[S(P_a)]$ curve shows a band much larger than that in the $\Delta\varepsilon[S(P_p)]$ curve. The vicinal effect of the chiral P donor atom depends largely on its coordination position in $[Co(acac)((SS(C)\text{-mp-PNNP})]^{2+}$. To our knowledge, there has been no report on such a coordination position dependence for the vicinal effect of a chiral donor atom. Care must be taken when the absolute configuration of a chiral donor atom is assigned by CD spectroscopy.

Calorimetric and Raman Spectroscopic Studies on Formation of Cadmium(II) Thiocyanato Complexes in Aqueous Solution

Shin-ichi ISHIGURO, Kiyoshi YAMAMOTO, and Hitoshi OHTAKI*
Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta,
4259, Nagatsuta-cho, Midori-ku, Yokohama 227
(Received November 8, 1985)

Complex formation equilibria between cadmium(II) and thiocyanate ions have been calorimetrically studied at 25 °C in aqueous solution containing $NaClO_4$ in order to keep 3 mol dm^{-3} ionic strength in the test solutions. Calorimetric titration curves thus obtained were well explained in terms of formation of dinuclear $[Cd_2X]^{3+}$ (X=SCN) and mononuclear $[CdX_n]^{(2-n)+}$ (n=1—4) complexes, and their formation constants, enthalpies and entropies were determined. The stepwise enthalpy and entropy values at the third consecutive step were largely positive, indicating that water molecules solvating Cd(II) ion were extensivelyl liberated at this step. It was thus suggested that the coordination symmetry around Cd(II) ion changed from octahedral to tetrahedral at the formation of $[CdX_3]^-$. Raman spectra of the C-S and C-N stretching vibrations of SCN^- ion were measured in cadmium(II) thiocyanate solutions with varying molar ratios of the metal to ligand ions. It was shown that SCN^- ion coordinated to Cd(II) ion through the N atom at the first step of the complex formation, and the S atom at the second, N at the third and then S at the last. The suggested bonding type of SCN^- ion with Cd(II) ion within each cadmium(II) thiocyanato complex was supported by the thermodynamic data.

In a previous paper,[1] we elucidated the structures of the tetrathiocyanato complexes of the Group 2B metal ions, Zn(II), Cd(II), and Hg(II), in aqueous solutions by X-ray scattering, Raman and ^{13}C- and ^{14}N-NMR measurements.

Thiocyanate (SCN^-) ion binds with metal ions through either the sulfur or nitrogen atom depending on the softness or hardness of metal ions. Relatively hard zinc(II) and soft mercury(II) ions are coordinated with the N and S atoms, respectively, of SCN^- ions within $[Zn(NCS)_4]^{2-}$ and $[Hg(SCN)_4]^{2-}$.

On the other hand, cadmium(II) ion shows an intermediate character between Zn(II) and Hg(II) ions. Then, it has been indicated that, within the tetrathiocyanatocadmate(II) ion, cadmium(II) ion is linked to two N and two S atoms of SCN^- ions to form $[Cd(SCN)_2(NCS)_2]^{2-}$ in aqueous solution.

Raman and infrared spectroscopic measurements so far carried out for various cadmium(II) thiocyanate solutions provided evidence of formation of mono- and polynuclear complexes of Cd(II) having different types of bonding of SCN^- ion.[2-6] Recently, Antić-Jovanović et al.[7] reported Raman spectra of the cadmium(II) thiocyanate aqueous solutions and assigned the band at 2132 cm^{-1} to the C-N stretching vibration within $[Cd(SCN)]^+$ and the bands at 2102 and 784 cm^{-1} to the C-N and C-S stretching vibrations within the higher $[Cd(NCS)_n]^{(2-n)+}$ (n>2) complexes.

Enthalpies and entropies of formation of thiocyanato complexes of metal ions also afford us useful information on the coordination structures of the complexes. Ahrland and Kullberg[8] indicated that SCN^- ion coordinated to Zn(II) ion through the N atom and to Hg(II) ion through the S atom. However, as to the thiocyanato complexes of Cd(II) in aqueous solution, no reliable data for enthalpies and entropies of formation of the complexes have been obtained yet.

In this study, therefore, we aimed at obtaining thermodynamic quantities of formation of thiocyanato complexes of Cd(II) in aqueous solution by calorimetry at 25 °C. A computer-controlled on-line system for calorimetry was employed.[9] Raman spectral measurements were also carried out in cadmium(II) thiocyanate aqueous solutions with varying ratios of the metal to ligand ions. The coordination structure within each thiocyanato complex of cadmium(II) ion is discussed on the basis of the thermodynamic and Raman spectroscopic data obtained.

Experimetal

Reagents. All chemicals used were of reagent grade. *Cadmium(II) perchlorate* was prepared by dissolving cadmium oxide into perchloric acid of super special grade and recrystallized twice from water. *Sodium thiocyanate* was recrystallized twice from ethanol. *Sodium perchlorate* was purified by the method described elsewhere.[10]

The concentration of metal ions in the cadmium(II) perchlorate stock solution was determined by titration with EDTA.

Calorimetric Measurements. Calorimetric measurements were carried out in a thermostated bath controlled at (25.000±0.007) °C placed in a room at (25.0±0.2) °C.

Cadmium(II) perchlorate solutions with varying concentrations of the metal ion in the range 10—400 mmol dm^{-3} were prepared, all the solutions containing 3 mol dm^{-3} $NaClO_4$ as a constant ionic medium. A 1 mol dm^{-3} NaSCN solution containing 2 mol dm^{-3} $NaClO_4$ as an ionic medium was used as a titrant solution. 100 cm^3 of a cadmium(II) perchlorate solution was placed in a Dewar vessel, and then, was titrated with the 1 mol dm^{-3} NaSCN titrant solution.

Back titration procedures were also employed. Four NaSCN solutions of 1.0, 1.5, 2.0, and 3.0 mol dm^{-3} were prepared, each solution containing $NaClO_4$ in order to adjust its ionic strength to 3 mol dm^{-3}. A 0.25 mol dm^{-3} $Cd(ClO_4)_2$ solution containing 3 mol dm^{-3} $NaClO_4$ was employed as a titrant solution.

Heats of dilution were determined by titrating a 3 mol dm^{-3} $NaClO_4$ solution with each titrant solution used. In each case, heat of dilution at the addition of an aliquot (δv cm^3) of the titrant solution slightly varied with the total volume (v cm^3) of the titrant added. Thus, the heat of dilution was represented as a function of v and δv as follows:

$$q_{dil} = \int_{v}^{v+\delta v} (a_0 + a_1 u)\mathrm{d}u, \quad (1)$$

where a_0 and a_1 denote constants, which were evaluated by the least-squares method to be -0.365 J cm^{-3} and 2.68×10^{-3} J cm^{-6}, respectively, for the NaSCN titrant solution and -0.317 J cm^{-3} and 1.85×10^{-3} J cm^{-6}, respectively, for the $Cd(ClO_4)_2$ titrant solution.

Heat evolved q_{obsd} at each titration point was thus corrected by knowing the q_{dil} value as follows:

$$q_{corr} = q_{obsd} - q_{dil}, \quad (2)$$

and the q_{corr} values thus obtained were used for the evaluation of formation constants and enthalpies of formation of cadmium(II) thiocyanato complexes in aqueous solution.

The specific heat C_p and the heat transfer coefficient λ of the test solutions, which were used for analyzing a set of temperature changes at each titration point, slightly varied with volumes of the test solution during the titrations, and thus, the C_p and λ values were determined at the addition of every 10 cm^3 of the titrant. The volume of an aliquot of the titrant solution added at each titration point was changed in the range 1—5 cm^3 depending on the extent of heat evolved during the titrations. The whole titration procedure was carried out by using a fully automatic on-line system for calorimetry as described elsewhere.[9]

Raman Spectral Measurements. Raman spectral measurements were carried out in cadmium(II) thiocyanate solutions with varying ratios of the metal to ligand ions as summarized in Table 1. Raman spectra were recorded on a JEOL JRS-S1 spectrometer using 514.5 nm line of NEC GLG-3200 argon ion Laser in a room at (25.0±0.2) °C.

Analysis of Colorimetric Data. The analytical method used for the calorimetric data obtained was similar to that used in a previous paper.[9] However, since titration curves obtained in the present work were not explainable in terms of formation of a series of mononuclear complexes, the formation of polynuclear thiocyanato complexes of Cd(II) was also taken into account.

Results and Discussion

Calorimetric titration curves obtained by titrating cadmium(II) perchlorate solutions having different concentrations of the metal ion with the NaSCN titrant solution are depicted in Fig. 1. Enthalpies $\Delta H°$ calculated by $\Delta H° = -q_{corr}/(\delta v C_{X,tit})$, where δv and $C_{X,tit}$ denote the volume of an aliquot of the titrant added and the concentration of NaSCN in the titrant solution, respectively, were plotted against the ratio C_X/C_M in the test solution at each titration point, where C_X and C_M stand for total concentations of SCN^- and Cd(II) ions, respectively, in a solution.

Table 1. Total Concentrations C_M and C_X of Cd^{2+} and SCN^- Ions, Respectively, in Cadmium(II) Thiocyanate Aqueous Solutions Used for Raman Spectroscopic Measurements

Solution	C_M/mol dm^{-3}	C_X/mol dm^{-3}	C_X/C_M

7	0.913	0.0727	0.08
8	2.090	0.0716	0.034

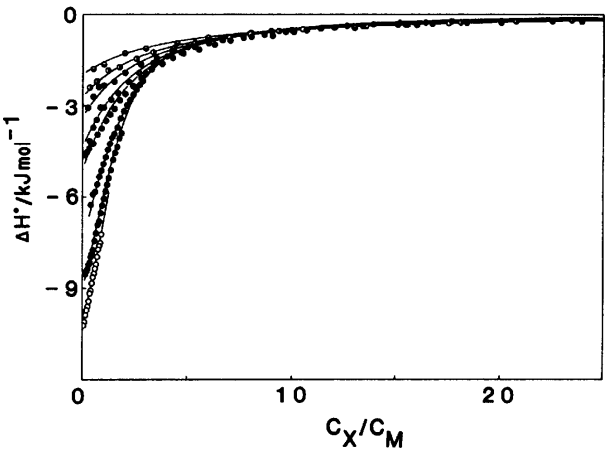

Fig. 1. Calorimetric titration curves of cadmium(II) thiocyanate solutions containing 3 mol dm^{-3} $NaClO_4$ at 25 °C. Initial concentrations of cadmium(II) perchlorate (C_M/mmol dm^{-3}): 10.04(◒), 14.93(◑), 20.02(⊕), 29.96(◘), 39.96(◉), 100.1(◎), 200.1(●), and 400.1(○). The solid lines show the curves calculated by using the constants of case 2 in Table 2.

The calorimetric data thus obtained were first analyzed by assuming the only formation of mononuclear $[CdX_n]^{(2-n)+}$ (X=SCN and n=1—4) complexes. The formation constants of the third and fourth complexes estimated from the data were rather uncertain. However, as seen in Fig. 2 where the titration curves in Fig. 1 are expanded over the range C_X/C_M= 0—4, we see some deviation of the experimental points from the theoretical curves (the broken lines) calculated by assuming the only formation of $[CdX]^+$ and $[CdX_2]$ at relatively higher concentrations of the metal ion in the range $C_X/C_M<1$. The deviation suggested the formation of polynuclear thiocyanato complexes of Cd(II) in aqueous solution.

Since the formation of $[CdX_3]^-$ and $[CdX_4]^{2-}$ was not conclusive from the data in Fig. 1, titrations of sodium thiocyanate solutions with the 0.25 mol dm^{-3} $Cd(ClO_4)_2$ solution were carried out, where the $[CdX_3]^-$ and $[CdX_4]^{2-}$ complexes were expected to form at the initial stage of the titrations. Calorimetric titration curves thus obtained are illustrated in Fig. 3, in which enthalpies $\Delta H°$ ($=-q_{corr}/(\delta v C_{M,tit})$ where

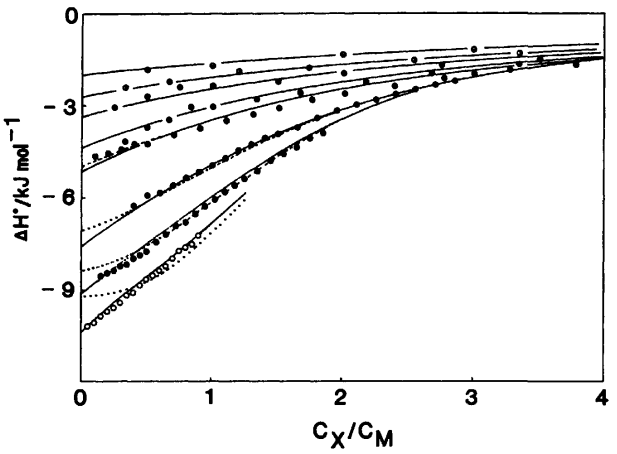

Fig. 2. Calorimetric titration curves of cadmium(II) thiocyanate solution expanded over the range C_X/C_M=0—4. Symbols used are the same as those in Fig. 1. The solid lines show the curves calculated by using the constants of case 2 in Table 2. The broken lines show the curves calculated by assuming the formation of the only mononuclear complexes.

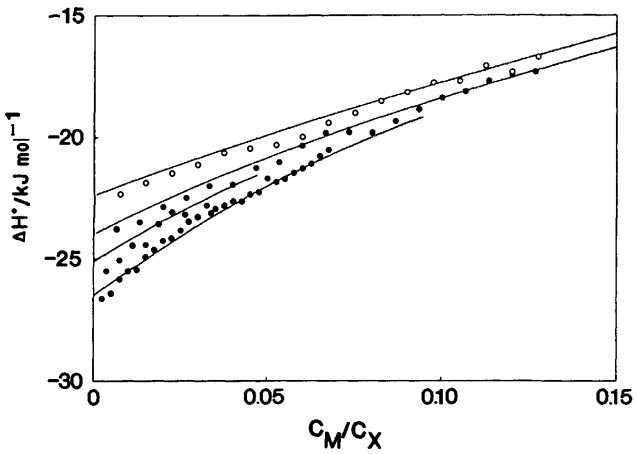

Fig. 3. Calorimetric titration curves obtained by titrating NaSCN solutions with $Cd(ClO_4)_2$ solution. Initial concentrations of sodium thiocyanate (C_X/mol dm^{-3}): 1.0(○), 1.5(●), 2.0(◎), and 3.0(◉). The solid lines show the curves calculated by using the constants of case 2 in Table 2.

$C_{M,tit}$ denotes the concentration of Cd(II) ion in the titrant), were plotted against the ratio C_M/C_X in the test solution at each titration point.

All the calorimetric data thus obtained were simultaneously analyzed by assuming the formation of mono- and polynuclear thiocyanato complexes of Cd(II) and their formation constants and enthalpies were obtained by the least-squares method. Among various cases examined by assuming the formation of different sets of complexes, two cases gave relatively small error-square sums. The results are summarized in Table 2, in which we assumed the formation of $[Cd_2X]^{3+}$ and $[CdX_n]^{(2-n)+}$ (n=1,2 and 4) in case 1, and the formation of $[Cd_2X]^{3+}$ and $[CdX_n]^{(2-n)+}$ (n=1—4)

a) This work. b) Ref. 11. c) Ref. 9. d) Ref. 12.

in case 2. Theoretical curves calculated by using the constants of case 2 in Table 2 are drawn by the solid lines in Figs. 1—3, which well reproduced the experimental points over the whole range of C_X/C_M and C_M/C_X examined here. On the other hand, although the error-square sum U of case 1 was not too large compared with that of case 2, theoretical curves calculated by using the constants of case 1 did not well reproduce the experimental points in Fig. 3. Therefore, we concluded that the formation of $[CdX_3]^-$ should not be neglected even if the complex was not significantly formed under the present experimental conditions.

The stepwise formation constants $\log(K_n$/mol^{-1} dm$^3)$ of formation of $[CdX_n]^{(2-n)+}$ (X=SCN and n=1—4) thus obtained are summarized in Table 3, together with those of $[ZnX_n]^{(2-n)+}$ in water,[9] and $[CdX_n]^{(2-n)+}$ and $[ZnX_n]^{(2-n)+}$ in DMSO[11,12] for comparison. The formation constants of $[CdX_n]^{(2-n)+}$ have also been reported by Gerding[13-15] in aqueous solution containing various ionic media, and the log K_n values in 3 mol dm^{-3} $NaClO_4$ ionic medium are 1.41, 0.83, 0.24, and 0.0 for n=1, 2, 3, and 4, respectively. The log

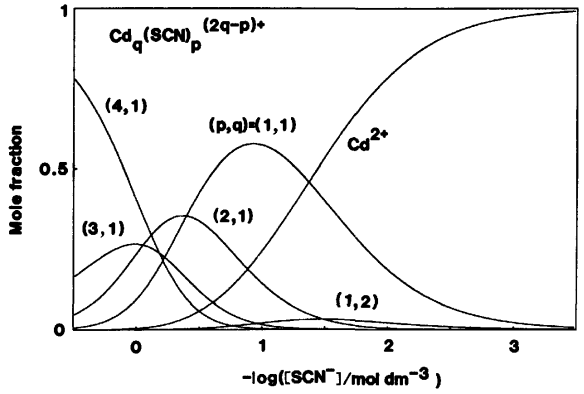

Fig. 4. Distribution of cadmium(II) thiocyanato complexes in 3 mol dm^{-3} $NaClO_4$ aqueous solution containing 0.1 mol dm^{-3} Cd(II) ion at 25 °C. (p, q) represents the number of ions within the $[Cd_qX_p]^{(2q-p)+}$ (X=SCN) complex.

K_1 value is in good agreement with ours, but the log K_n (n=2—4) values are appreciably different from the results of the present work. Particularly, the value of log K_2 according to Gerding is remarkably large compared to that obtained in our work.

In Table 3, one finds that the log K_1 value of $[CdX]^+$ is larger than that of $[ZnX]^+$ but stepwise formation constants of the other $[CdX_n]^{(2-n)+}$ complexes were smaller than those of the corresponding zinc(II) complex in water and in DMSO.

We also found the formation of dinuclear $[Cd_2X]^{3+}$ complex in solutions of relatively high concentrations of the metal ion at $C_X/C_M<1$. The log K value for the reaction, $Cd^{2+}+[CdX]^+=[Cd_2X]^{3+}$, was −0.12 and the corresponding $\Delta G°$, $\Delta H°$, and $\Delta S°$ values for the reaction being 0.7 and −4.6 kJ mol^{-1} and −18 J K^{-1} mol^{-1}, respectively.

Distribution of species in cadmium(II) thiocyanate solutions containing 0.1 mol dm^{-3} Cd(II) ions is illustrated in Fig. 4.

Raman Spectra of Cadmium(II) Thiocyanate Solutions. Raman spectra of the C-N and C-S stretching vibrations of SCN^- ion measured in cadmium(II) thiocyanate aqueous solutions with varying ratios of C_X/C_M are shown in Figs. 5 and 6, respectively. The Raman bands observed were assigned by taking into account the distribution of species in each cadmium(II) thiocyanate solution.

The Raman spectra in Fig. 5 show three peaks at ca. 2070, 2105, and 2130 cm^{-1}, the first band being ascribed to the vibration of free SCN^- ion. It was expected from the result of the formation constants obtained that $[CdX]^+$ and $[Cd_2X]^{3+}$ (X=SCN) were formed in cadmium(II) thiocyanate solutions at $C_X/C_M<1$ and the $[Cd_2X]^{3+}$ complex predominated in the solutions with lowering ratio of C_X/C_M and with increasing C_M as examined here. Two peaks at 2105 and 2130 cm^{-1} were observed in the solution of C_X/C_M=0.08, while the former peak disappeared in the solution

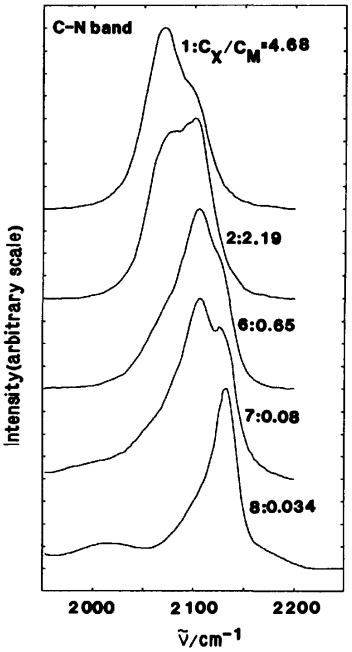

Fig. 5 Raman spectra of the C-N stretching vibration of SCN^- ion measured in various cadmium(II) thiocyanate solutions.

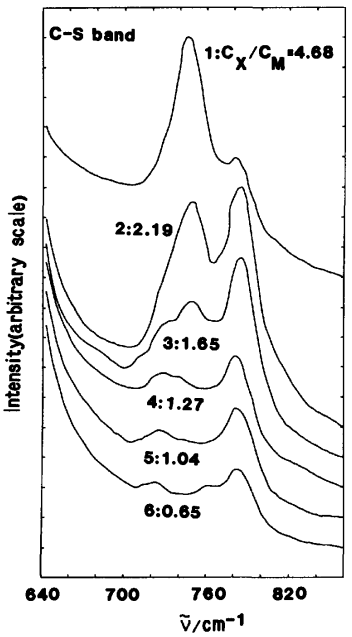

Fig. 6. Raman spectra of the C-S stretching vibration of SCN^- ion measured in various cadmium(II) thiocyanate solutions.

of C_X/C_M=0.034. Thus the 2105 and 2130 cm^{-1} bands were assigned to the C-N vibration within $[CdX]^+$ and $[Cd_2X]^{3+}$, respectively.

The Raman spectra in Fig. 6 show predominant peaks at ca. 720, 740, and 780 cm^{-1}, the second band being attributable to the vibration of free SCN^- ion. In the solutions of C_X/C_M=0.65—2.19 examined, the intensity of the 780 cm^{-1} band relative to that of the

Table 4. Thermodynamic Quantities, $\log(\beta_{41}/\text{mol}^{-1}\,\text{dm}^3)$, $\Delta G^\circ_{\beta41}/\text{kJ mol}^{-1}$, $\Delta H^\circ_{\beta41}/\text{kJ mol}^{-1}$, and $\Delta S^\circ_{\beta41}/\text{J K}^{-1}\,\text{mol}^{-1}$, for the Overall Reaction, $M^{2+}+4X^-=[MX_4]^{2-}$ (X=SCN and M=Zn, Cd and Hg) in Aqueous Solutions at 25 °C

	Zn(II)[a]	Cd(II)	Hg(II)[b]

$\Delta S^\circ_{\beta41}$	5	−64	−60

a) Ref. 12. b) Ref. 18.

720 cm^{-1} band increased with increasing ratios of C_X/C_M, and thus, these two bands should be assigned to the vibrations of, at least, two different species. Since it was indicated from the distribution of the cadmium(II) thiocyanato complexes in the solutions that $[CdX]^+$ was present as the main species and the concentration of the complex increased with increasing ratios of C_X/C_M in the range 0.65—1.65, the 780 cm^{-1} band was assigned to the C-N stretching vibration within $[CdX]^+$. Since it was indicated from the thermodynamic data that the $[Cd_2X]^{3+}$ complex was appreciably formed in the solutions of C_X/C_M=0.65—1.04 and the $[CdX_2]$ complex in the solutions of C_X/C_M=1.27—2.19, a weak band at 720 cm^{-1} may be ascribed to the C-S stretching vibration of the $[Cd_2X]^{3+}$ and $[CdX_2]$ species.

Thermodynamic Quantities of Formation of Thiocyanato Complexes of Cd(II). Thermodynamic quantities of formation of the tetrathiocyanato complexes of Zn(II), Cd(II), and Hg(II) are summarized in Table 4. The overall formation constant $\log\beta_{41}$ varied in the sequence Zn(II)>Cd(II)<Hg(II), and thus, the formation of $[CdX_4]^{2-}$ (X=SCN) is the least favorable within the metal complex in aqueous solution. The corresponding $\Delta H^\circ_{\beta41}$ and $\Delta S^\circ_{\beta41}$ values vary in the sequence, Zn(II)>Cd(II)$\gg$Hg(II) and Zn(II)$\gg$Cd(II)$\approx$Hg(II), respectively. The less favorable formation of $[CdX_4]^{2-}$ than that of $[ZnX_4]^{2-}$ is thus ascribed to the small entropy term, i.e., the $\Delta S^\circ_{\beta41}$ value of the former complex is largely negative compared to that of the latter.

Among tetrahalogeno complexes of Cd(II) in aqueous solution, $\Delta H^\circ_{\beta41}$ becomes negative in the only case of the complex with soft iodide ions (−29 kJ mol^{-1}).[16] The fact that the $\Delta H^\circ_{\beta41}$ value of the tetrathiocyanatocadmate(II) complex was also negative in aqueous solution, therefore, suggests that cadmium(II) ion has some bonds with the soft *S* atoms within the ligating SCN^- ions. However, the $\Delta S^\circ_{\beta41}$ value of the tetraiodocadmate(II) complex is much more positive (26 J $\text{K}^{-1}\,\text{mol}^{-1}$)[16] than that of the corresponding thiocyanato complex in aqueous solution. The larger difference in the entropy values may mainly be ascribed to the loss of vibrational and rotational freedoms of triatomic SCN^- ion on coordination to Cd(II) ion. Such a difference in the entropies of formation of the halogeno and thiocyanato complexes of Cd(II) has also been observed in DMSO.[11]

Table 5. Thermodynamic Quantities, $\Delta G^\circ_n/\text{kJ mol}^{-1}$, $\Delta H^\circ_n/\text{kJ mol}^{-1}$, and $\Delta S^\circ_n/\text{J K}^{-1}\,\text{mol}^{-1}$, for the Stepwise Reaction, $[MX_{n-1}]^{(3-n)+}+X^-=[MXn]^{(2-n)+}$ (M=Zn or Cd, X=SCN and n=1—4), in Water and in Dimethyl Sulfoxide at 25 °C

a) This work. b) Ref. 11. c) Ref. 9. d) Ref. 12.

Coordination Structures of $[Cd_2X]^{3+}$ and $[CdX_n]^{(2-n)+}$ (X=SCN). It has been known that the C-S stretching vibration of SCN^- ion shifts toward the higher and lower frequencies, respectively, within metal complexes than that of the free ion as the result of the coordination of SCN^- ion to a matal ion through the N and S atoms.[2-7] The Raman bands observed at ca. 720 and 780 cm^{-1} thus indicated the formation of the complexes having the Cd-S and Cd-N bonds.

Thermodynamic quantities, $\Delta G^\circ_n/\text{kJ mol}^{-1}$, $\Delta H^\circ_n/\text{kJ mol}^{-1}$ and $\Delta S^\circ_n/\text{J K}^{-1}\,\text{mol}^{-1}$, for the stepwise reaction, $[MX_{n-1}]^{(3-n)+}+X^-=[MX_n]^{(2-n)+}$ (M=Zn and Cd, X=SCN and n=1—4), in aqueous solutions are summarized in Table 5, together with those in DMSO for comparison.[11,12] The ΔH°_n and ΔS°_n values for the $[CdX_n]^{(2-n)+}$ complexes in aqueous solution irregularly varied with n and they mostly compensated each other to result in rather smooth changes in ΔG°_n. The irregularities of ΔH°_n and ΔS°_n with n might be correlated to the bonding type of SCN^- ions with Cd(II) ion as well as a structural change in the cadmium(II) thiocyanato complexes in aqueous solution.

$[Cd(SCN)Cd]^{3+}$. It is expected that two cadmium(II) ions are bridged by an SCN^- ion within the dinuclear complex. A similar bridged structure -[Cd-SCN-Cd]- is found in $Cd(SCN)_2$ crystal. The $[Cd(SCN)Cd]^{3+}$ complex has both Cd-S and Cd-N bonds, and thus, showed the C-S vibrational band at 720 cm^{-1} which is an indicative of the Cd-S bond formation within the complex.

$[Cd(NCS)]^+$. Since the 780 cm^{-1} band is assigned to the C-S stretching vibration within the monothiocyanatocadmium(II) complex predominantly formed in the solutions of C_X/C_M=0.65—2.19 in Fig. 6, the coordination structure $[Cd(NCS)]^+$ is suggested

for the complex. The ΔS_1° value for the formation of the monothiocyanatocadmium(II) complex is comparable with that of $[Zn(NCS)]^+$ in aqueous solution. The result may also support the formation of $[Cd(NCS)]^+$, instead of $[Cd(SCN)]^+$.

$[Cd(SCN)(NCS)]$. In the cadmium(II) thiocyanate solutions of C_X/C_M=1.27—2.19, the mono- and dithiocyanatocadmium(II) complexes are formed but the formation of the dinuclear complex is negligible. Therefore, the 720 cm^{-1} band still observed in the solutions may arise from the formation of the Cd-S bond within the dithiocyanatocadmium(II) complex. Consequently, the structure $[Cd(SCN)(NCS)]$ having both Cd-S and Cd-N bonds is suggested. The stepwise ΔH_2° and ΔS_2° values for the reaction, $[Cd(NCS)]^+ + SCN^- = [Cd(SCN)(NCS)]$, are largely negative, which is probably due to the formation of a covalent-type bond between moderately soft Cd(II) ion and the soft S atom of SCN^- ion.

$[Cd(SCN)(NCS)_2]^-$. Although there is no evidence on the coordination structure of the trithiocyanatocadmate(II) complex from Raman spectroscopic data, the structure $[Cd(SCN)(NCS)_2]^-$ is suggested, because the tetrathiocyanatocadmate(II) complex may be formed from the trithiocyanato complex with an SCN^- ion by bonding through the S atom as discussed below.

$[Cd(SCN)_2(NCS)_2]^{2-}$. The coordination structure of the tetrathiocyanatocadmate(II) complex has been elucidated by a previous X-ray scattering measurement to be $[Cd(SCN)_2(NCS)_2]^{2-}$. The ΔH_4° and ΔS_4° values were similar to the ΔH_2° and ΔS_2° values, respectively, the result indicating that the Cd-S bond may form at the formation of the tetrathiocyanatocadmate(II) complex in aqueous solution. From this result we concluded that the third complex is $[Cd(SCN)(NCS)_2]^-$, from which an additional Cd-S bond is formed to produce $[Cd(SCN)_2(NCS)_2]^{2-}$.

Change in the Coordination Symmetry around Cd(II). Relatively largely positive ΔH_3° and ΔS_3° values observed at the third consecutive step of formation of $[Cd(SCN)(NCS)_2]^-$ suggest the change in the coordination symmetry around Cd(II) ion from octahedral to tetrahedral.

It is known that cadmium(II) ion is tetrahedrally coordinated with four SCN^- ions and no solvent molecules in the first coordination sphere within the tetrathiocyanatocadmate(II) complex in aqueous solution.[1] On the other hand, aquàcadmium(II) ion is octahedrally coordinated with six water molecules in aqueous solution.[17] Thus, the coordination symmetry around Cd(II) ion changes at a certain step of formation of the thiocyanato complexes of the metal ion. When the symmetry changes from octahedral to tetrahedral, more than one (three in this case) water molecules should be replaced to an entering SCN^- ion. Such an extensive dehydration process should be accompanied with a relatively large entropy gain. At the same time, a large absorption of heat should result due to the rupture of many metal-solvent bonds. As seen in Table 5, the same trend in the variation of ΔH_n° has been observed in the formation of the thiocyanto complexes of Cd(II) in DMSO.[11]

It is noted that the ΔH_2° and ΔS_2° values are largely positive in the complex formation reaction of the zinc(II) thiocyante system in both water[9] and DMSO,[12] and the result suggests that the coordination symmetry around zinc(II) ion may be changed at the second step of the complex formation. The structure change occurring at a different stage of the complex formation in the zinc(II) thiocyanate system from that in the cadmium(II) system may be due to a smaller ionic size of zinc(II) ion than that of cadmium(II) ion.

The work has been supported by the Grant-in-Aid for Scientific Research No. 59540386 from the Ministry of Education, Science and Culture.

(Received November 18, 1985)

The structure of the title complex was determined by the single-crystal X-ray-diffraction method. It is triclinic, with the space group $P\bar{1}$; the cell constants were a=12.529(2), b=15.044(4), c=10.063(1) Å, α=104.15(2), β=98.73(1), and γ=87.16(2)°; Z=1, and the final R value was 0.053. The central metal atom is in a tricapped trigonal-prism geometry and is ennea-coordinated with seven oxygen atoms of the carboxylate ligands and with each oxygen atom of one water and one ethanol molecule. The complex is dimeric and the metal atoms are bridged with four carboxylate ions; two of them act as bidentates, and the other two, as tridentates, where one oxygen atom is coordinated to both metal atoms. The other carboxylate ion makes a chelate ring with each metal atom. The dimer is connected through hydrogen bondings to the atoms on both sides along the c-axis.

It has already been reported by several authors that carboxylate complexes of lanthanoids(III) take many kinds of geometries.[1-5] In cases of the aromatic carboxylates,[1,3] as well as of some nicotinates and isonicotinates,[4,6] the central metal is in a square-antiprism geometry and is octa-coordinated, where the squares of the complex molecules are parallel and are lined up along one axis. They are dimeric or linear polymeric bridged by the carboxylate ligands. On the other hand, acetates of some heavy lanthanoids[5] and cerium(III) *m*-hydroxybenzoate,[7] for example, take the tricapped trigonal prism geometry, and the central metal atoms are ennea-coordinated. The geometries of the complexes are thought to depend on the size of the ligand compared with that of the metal atom, as well as on the substituted groups of the carboxylate ions, which affect the mutual interaction of the ligand molecules. In a previous paper, we have reported about the interesting structures of some lanthanoid 2-naphthalenesulfonates, where the hydrophobic layer of the naphthalene rings makes a sheet between the hydrophilic metal complex cores, which form network layers bridged by hydrogen bondings via water molecules.[8] Along this line of research, we have tried to determine the structure of the title complex, where the ligand molecule has a naphthalene ring as well as a carboxyl group, using the single-crystal X-ray-diffraction method.

Experimental

Synthesis of Tetrakis(μ-1-hydroxy-2-naphthoato)-bis{aqua(ethanol)(1-hydroxy-2-naphthoato)neodymium(III)}-water-ethanol (1/2/2) (1). Neodymium(III) chloride hexahydrate (0.72 g, 2.0 mmol) was dissolved in water, and an excess of sodium hydroxide (in an aqueous solution) was added. The hydroxide thus precipitated was filtered off, washed with water, and warmed (60 °C) in 20 cm³ of an ethanol–water mixture (2:1=v/v), together with 1-hydroxy-2-naphthoic acid (1.13 g, 6.0 mmol), for 30 min: The solution obtained was then filtered off. The filtrate was left standing for several days at ambient temperature, thus precipitating the crystals. The crystals thus obtained effloresced in a few min when they were separated from their mother liquor; however, they are stable for several weeks if they are not dried. By the same way of synthesis, praseodymium, samarium, dysprosium, and erbium complexes were obtained in a crystalline state, but all of them effloresce rapidly, too. Especially the crystals of the erbium complex cleave even when they are left in pure ethanol, water, or a mixture of them. The elemental analysis of the complex after it has dried for 24 h on a vacuum silica-gel desiccator shows it to be the dihydrate; all the ethanol is removed. Found: Nd, 19.80: C, 53.58: H, 3.29%. Calcd for $NdC_{33}H_{25}O_{11}$: Nd, 19.44: C, 53.43: H, 3.40%. The mass-loss of the rapidly washed and dried sample after it has been left standing on the vacuum silica-gel desiccator for 24 h: Found: 11.11%. Calcd for the difference between $NdC_{37}H_{37}O_{13}$ and $NdC_{33}H_{25}O_{11}$ (corresponding to two ethanols per neodymium) : 11.05%.

Thermal Analysis. Simultaneous thermogravimetric (TG) and differential thermal analyses (DTA) were carried out with a Rigaku-Denki "Thermoflex" M-8075, using a sample of about 10 mg in each run, with reference to Al_2O_3, at the heating rate of 10 K min^{-1}.

Single-Crystal X-Ray Analysis. A crystal 0.45×0.30×0.20 mm³ in size was used as the sample. It was sealed in a glass capillary immediately after having been picked out from the mother liquor. Crystallographic data: $Nd_2C_{74}H_{74}O_{26}$, F.W. 1667.86, triclinic, space group $P\bar{1}$, a=12.529(2), b=15.044(4), c=10.063(1) Å, α=104.15(2), β=98.73(1), γ=87.16(2)°, U=1817.7(6) Å³, Z=1, D_x=1.52, D_m=1.52(3) Mg m^{-3} by floatation in a CH_2BrCH_2Br–CCl_4 mixture, μ(Mo $K\alpha$)=1.51 mm^{-1}. The reflections were collected on a Rigaku AFC-6A automated four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation (0.7107 Å), in the range of $3°<2\theta<65°$, the ω—2θ scan technique being employed (scan speed: 4° min^{-1} (θ): scan width: $(1.25+0.5\tan\theta)°$). Of the 13315 independent reflections observed, 10370 $|F_o|>3\sigma(|F_o|)$ reflections were used for the refinement. The intensities were corrected for

the Lorentz and polarization factors, but no correction was made for absorption or extinction.

Structure Determination. The structure was solved by the heavy-atom method. The positions of the metal and some oxygen atoms were deduced from the three-dimensional Patterson map. The positional and thermal parameters were refined successively by the repeated block-diagonal least-squares method and by Fourier syntheses. At the end, all the non-hydrogen atoms were found. An uncoordinated water molecule was found to be disordered and to have been divided into two: The occupancy factors of O(W2A) and O(W2B) were determined to be 0.66 and 0.34, respectively. The atoms of one ethanol molecule, O(E2), C(E3), and C(E4), are fixed assuming their isotropic temperature parameters to be 8.0. The positions of the naphthalene hydrogen atoms were calculated by assuming the C-H bond length to be 1.08 Å; their B_{iso}'s were assumed to be 6.0. The parameters of the hydrogen atoms were also fixed in the refinement. The final R value was 0.053, R_w=0.065, and S=4.07.[9]

All the calculations were carried out on a HITAC M-280H apparatus at the Computer Center of The University of Tokyo, using the local version of the UNICS program.[10] The atomic-scattering factors were taken from Ref. 11.

Infrared-Absorption-Spectrum Measurement. The infrared-absorption spectra were obtained by means of a JASCO A202 grating infrared spectrophotometer, using Nujol and hexachloro-1,3-butadiene mull.

Results and Discussion

The final atomic parameters are listed in Table 1, while some bond lengths and bond angles, as well as some interatomic distances which are thought to be the hydrogen-bonding ones, are tabulated in Table 2. The projection of the unit-cell along the a-axis, the perspective drawing along the metal–metal axis, and the schematic presentation of the coordination geometry around the central metal atom are shown in Figs. 1, 2, and 3.[12]

The complex is dimeric, with a center of inversion between the metal atoms, bridged by four carboxylate ligands. As is depicted in Fig. 3, the metal atom is ennea-coordinated and is in a deformed tricapped trigonal prism geometry, where seven oxygen atoms of five carboxylate ligands and two oxygen atoms of ethanol and water molecules are bound to the metal atom.

A pair of carboxylates span two neodymium atoms through both oxygen atoms of each carboxyl group. As is shown in Table 1, the C–O and Nd–O bond lengths of two oxygen atoms of this type of ligand are not equal. The longer C–O bonding has the longer Nd–O bond; therefore, the double-bonding oxygen atom, not the single-bonding oxygen atom, of the carboxyl group bonds with the metal atom more strongly. The other pair of carboxylate ligands act as a "tridentate" bridge: one of the oxygen atoms is bridging two metal atoms, and the other oxygen atom is coordinating to one of the metal atoms to form a chelate ring at the same time.

Keys to the symmetric operations: i, 1−x, 1−y, 1−z, ii, 1−x, 1−y, −z.

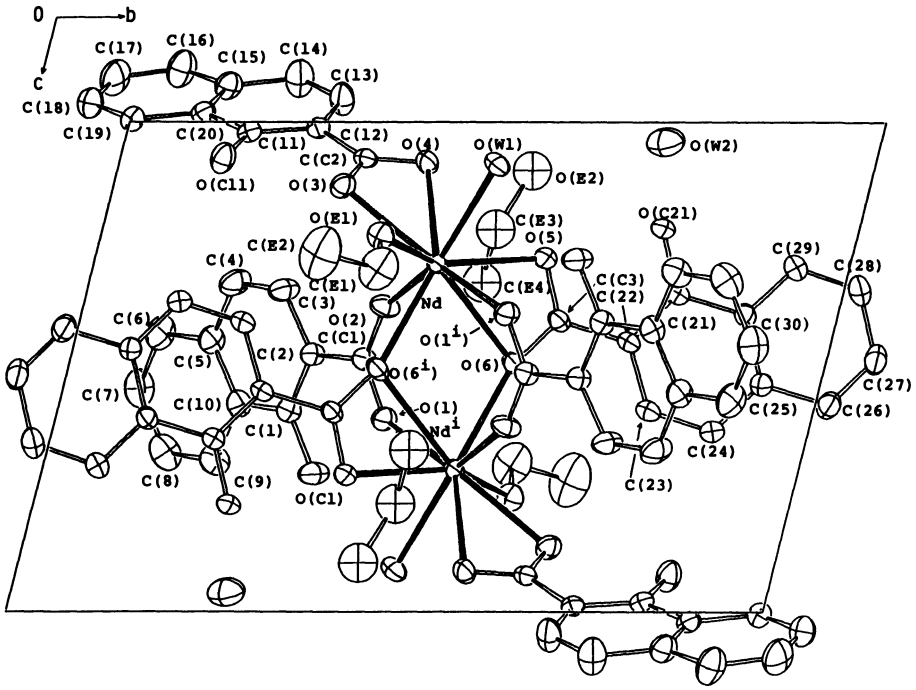

Fig. 1. The projection ot the unit cell along a-axis with the numbering scheme. (O(W2B) is neglected. Key to the symmetry operation: i, 1−x, 1−y, 1−z).

Its C-O bond lengths, as well as the bridging Nd-O lengths of the respective oxygen atoms, are almost the same; however, the third Nd-O bond, Nd-O(6), is longer than the other two.

The other carboxylate ligand chelates to the metal atom, forming a four-membered ring. The two C-O bond lengths of the ligand are not equal, and the oxygen atom of the longer C-O bond has the shorter Nd-O bond; this shows that its C=O double bond is localized. The chelate spans one edge of the bottom triangle of the prism; although the structures of some lanthanoid carboxylates taking the tricapped trigonal prism geometry have been reported, the chelating carboxylate is apt to span an apex of the prism and the cap position; therefore, the spanning position of this complex is exceptional.

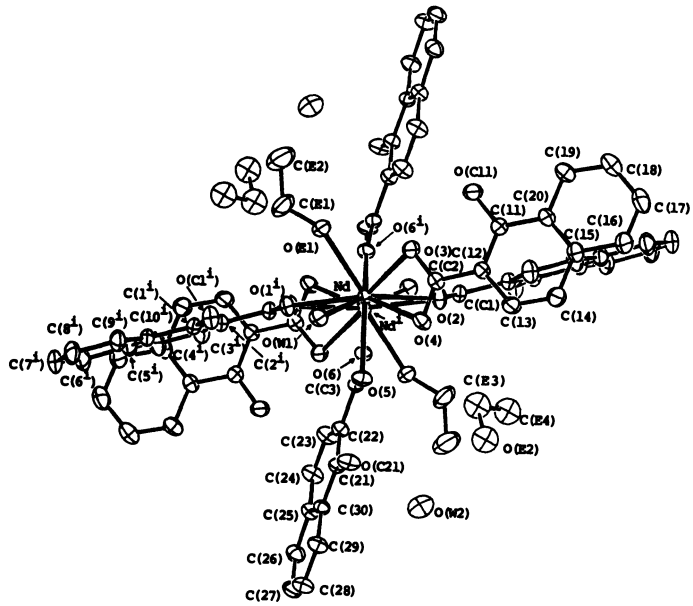

Fig. 2. The perspective of the complex along Nd-Nd^{i} axis.

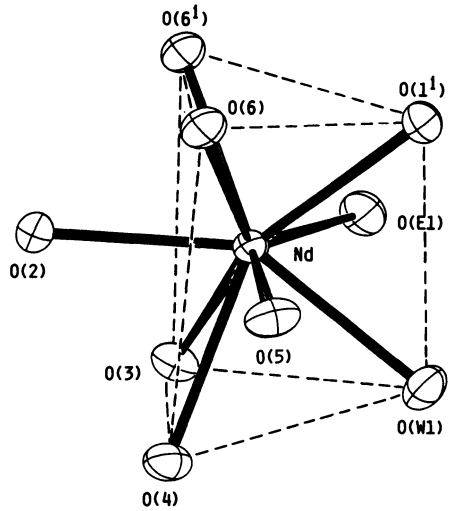

Fig. 3. The schematic presentation of the coordination geometry of the central metal atom.

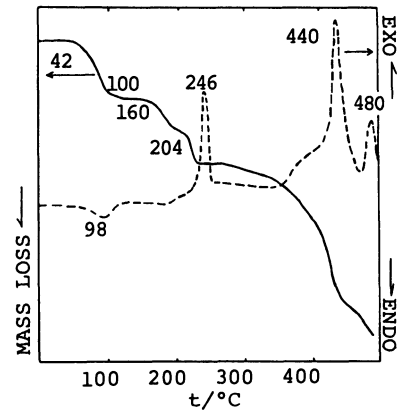

Fig. 4. TG(——) and DTA(---) curves of the complex. Mass loss of TG was taken downwards, and the exothermal change of DTA was taken upwards.

As is depicted in Fig. 2, the naphthylene group of the bridging carboxylates are arrayed radially from the line of the metal atoms. The dihedral angle between the planes of C(1)···C(10) and C(21^{i})···C(30^{i}) is 62.6° The C(11)···C(20) naphthalene ring is lying over the C(1)···C(10) ring, with a dihedral angle of 81.6°.

The Nd-O bond length to the water oxygen atom is almost the same as that to the ethanol oxygen atom; 2.501(4) and 2.503(4) Å, respectively. The distances are almost the same as the average Nd-O bond length to the seven carboxyl oxygen atoms (2.501 Å). Generally, the water molecules are bound more strongly to lanthanoid metal atoms than are those of ethanol; therefore, it is necessary to use an anhydrous medium to synthesize their alcohol complexes. This is the first case in which water and alcohol are coordinated at the same time to one lanthanoid atom, although the ethanol is quite easily removed in open air. As is shown in Fig. 2, the ethanol ligands are surrounded by the naphthalene rings. Probably the large naphthylene group of the carboxylates around the core of the complex makes the moiety more feasible for the ethanol molecule to be kept between them.

As is shown in Table 2, the coordinating water molecule forms a hydrogen bond with the carboxyl oxygen atom of the neighboring complex along the c-axis. The crystals contain uncoordinated ethanol and water molecules. These are bound to the complex through hydrogen bonds with the coordinated water molecule and the hydroxyl group of the naphthalene ring, as is shown in Table 2. The water molecule was found to be disordered, and the position of ethanol is nebulous. Furthermore, the interatomic distance of

O(E2)···O(W2B) is too short (1.976(15) Å). This phenomenon may be due to the only partial occupancy of ethanol, a result of the efflorescence of the crystal.

The results of thermogravimetric (TG), and differential thermal analyses (DTA) simultaneous measurements are depicted in Fig. 4. The TG curve shows that, when the complex is heated, the ethanol and also all of the water molecules seem to be removed in the first step, from 42 °C to about 100 °C. The anhydrous salt thus formed is stable up to about 160 °C; then the decomposition of the ligand starts to occur.

The ν_{as}(COO) band as well as the ν_{s}(COO) band in the infrared spectrum of the title complex is split. The former is split into three peaks: 1632(m), 1580(s), and 1550(sh) cm^{-1}. The relatively low-wavenumber bands may correspond to the bridging carboxyl groups. The latter band is also split into three peaks: 1470(m), 1440(s), and 1412(s) cm^{-1}.

The authors wish to thank heartily the Shin-Etsu Chemical Ind. Co., Ltd., for presenting the highly pure lanthanoid oxides.

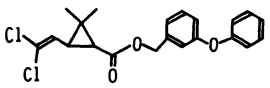
Transformation of 3-(2,2-Dichloroethenyl)-2,2-dimethylcyclopropanecarboxylates to the Corresponding 2,2-Dibromoethenyl Analogs by Halogen Exchange Reaction[1)]

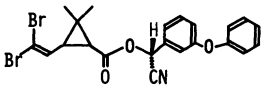
Kiyohide MATSUI,* Akemi SAITO, and Kiyosi KONDO
Sagami Chemical Research Center, Nishi-Ohnuma 4-4-1, Sagamihara, Kanagawa 229
(Received October 3, 1985)

The title transformation is effected with aluminium tribromide or related reagents in over 80% yields without cis-trans isomerization or epimerization. Efficient removal of hydrogen bromide is essential for optimum yields of the desired products. Use of boron tribromide instead of aluminium tribromide results in opening of the cyclopropane ring with no halogen exchange.

A new artificial pyrethroid having 2,2-dichloroethenyl substituent, i.e., permethrin (**1**),[2)] is now one of the common agricultural insecticides thanks to its moderate stability and high insecticidal activity. Its dibromoethenyl analog, decamethrin (**2**), is found by Elliott et al.[3)] and revealed to be more than ten times as active as permethrin.



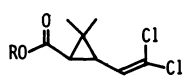
permethrin (**1**)
(cis-, trans- and racemic mixture)



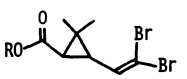
decamethrin (**2**)
(ester of (1*R*)-cis acid)

To the synthesis of permethrin, we developed a convenient process, which involved the addition of carbon tetrachloride to 3,3-dimethyl-4-pentenoates (**3**) and successive dehydrochlorination and cyclization of 4,6,6,6-tetrachloro-3,3-dimethylhexanoates (**4**) with a base to afford 3-(2,2-dichloroethenyl)-2,2-dimethylcyclopropanecarboxylates (**5**).[4)]

In the case of decamethrin synthesis, the method was applied with less synthetic value because of the following drawbacks: (a) The addition of carbon tetrabromide to **3** was relatively inefficient; (b) Trans-rich 3-(2,2-dibromoethenyl)-2,2-dimethylcyclopropanecarboxylates (**6**) was usually produced upon base-treatment of the resulting adduct.[4)]



5



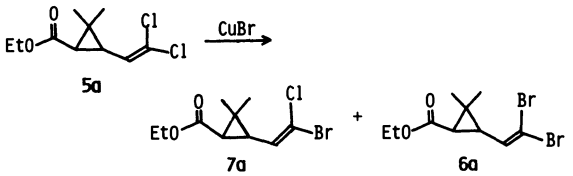
6

a: R=Et, b: R=Me, c: R=H

The processes developed so far by other groups also involve such serious disadvantages as low product yields, high cost and/or tedious operations.[3,5)]

This paper details the conversion of dichloroethenyl compounds **5** to the corresponding dibromoethenyl analogs **6** by halogen exchange which provides a convenient route to decamethrin.

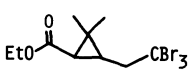
Exchange of the halogen of haloethenes has been usually performed with copper(I) halides in dipolar aprotic solvents.[6)] We first attempted the reaction of **5a** with copper(I) bromide under various conditions and obtained a mixture of dichloro-, bromochloro-, and dibromoethenylcyclopropanecarboxylates (**5a**, **7a**, and **6a**, respectively). For example, treatment of **5a** with copper(I) bromide (8 equiv) in DMF at 150 °C for 8 h afforded a mixture of **5a** (77%), **7a** (16%), and **6a** (1%). The prolonged treatment usually induced the decomposition of the products and the total recovery of **5a**, **6a**, and **7a** diminished. Use of a large excess of copper(I) bromide gave no significant change in product distribution.



5a **7a** **6a**

Aluminium tribromide and boron tribromide are also capable of halogen exchange.[7)] They are active for the halogen exchange of relatively stable compounds such as simple alkyl halides,[8)] gem-polyhalogenated compounds,[9)] bridgehead-halogenated bicyclic compounds,[10)] and a few haloethenes.[11)]

We found aluminium tribromide did promote the halogen exchange of **5a** without affecting the ester group or cyclopropane ring as follows: Treatment of **5a** with commercial aluminium tribromide in 1,2-dibromoethane under ice-water cooling afforded **6a** (area % on GLPC=88%) and **7a** (5%) along with a by-product (6%). The structure of this by-product was assigned to 2,2,2-tibromoethyl compound **8a** by the GLPC-MS data and by its conversion to **6a** with DBU. A 76% yield of **6a** with 95% purity was attained by transforming the concomitant **8a** into **6a**.



8a

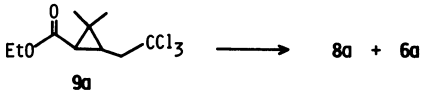
The formation of **8a** suggests the possibility that the halogen exchange is initiated by the addition of hydrogen bromide to the dichloroethenyl moiety of **5a**.[12)] This hypothesis prompted us to study the halogen exchange of 2,2,2-trichloroethyl compound **9a** with aluminium tribromide. The reaction in fact pro-

Table 1. Direct Conversion of **9a** and **5a** to **6a** Using HBr Scavenger

Substrate	HBr scavenger	Time	Yield (GLPC)/%		
		h	**6a**	**8a**	**7a**
9a	Al metal	7.5	23.4	15.5	0.8
9a	Pyridine	4.5	49.3	33.1	4.7
9a	Na_2CO_3	7.0	56.7	26.5	4.1
9a	Argon[a]	6.0	82.9	11.8	3.7
9a	Argon, red. press.[b]	3.0	95.6	4.2	—
5a	Argon, red. press.[b]	4.0	91.0	1.8	1.7

a) Argon=The reaction mixture was bubbled with argon gas under ice-water cooling. b) Argon, red. press.=The reaction mixture was bubbled with argon gas under reduced pressure (≈20 mmHg) under ice-water cooling.

ceeded smoothly in dibromomethane, and tribromoethyl compound **8a** was produced in 62% yield accompanied by ca. 30% of dibromoethenyl compound **6a**.



9a

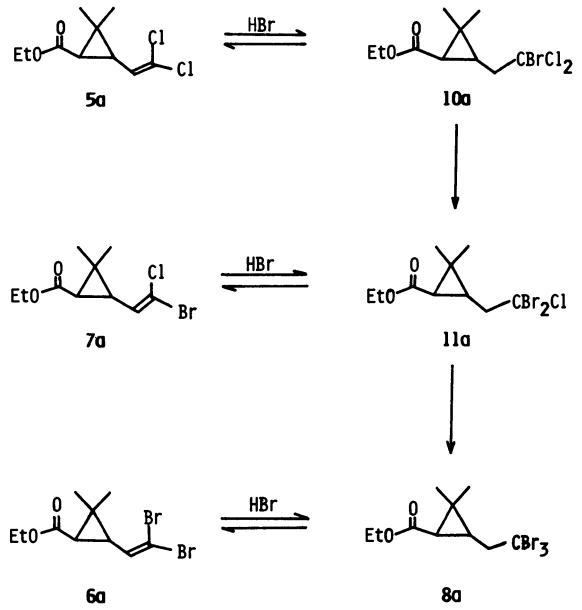
The formation of **6a** suggests that the aluminium trihalides promotes also the dehydrobromination of the tribromoethyl moiety.

Therefore, we then studied the conversion of **9a** into **6a** and the complete transformation of **5a** into **6a**. Such hydrogen bromide scavenger as aluminium metal, pyridine or sodium carbonate turned out ineffective in the transformation of **9a** into **6a** (Table 1). In order to purge the hydrogen bromide, the reaction mixture was bubbled by an argon gas with promising results. Finally, argon bubbling under reduced pressure was found to be most effective, and the contaminating **8a** was reduced to below 5% (Table 1). By using this technique, **9a** and **5a** were successfully transformed into **6a** as shown in Table 1.

The reagent generated from aluminium metal and 1,2-dibromoethane (or bromine, or hydrogen bromide) was found also effective for the transformation of **5a** to **6a**. Furthermore, aluminium trichloride could be used instead of aluminium tribromide when hydrogen bromide was introduced during the reaction. In practical view point, the aluminium metal-hydrogen bromide reagent (91% yield, 95% purity) and aluminium trichloride-hydrogen bromide reagent (92% yield, 91% purity) were most useful. Other metal bromides, e.g., $ZnBr_2$, $FeBr_3$, $CuBr_2$, $BiBr_3$, $SbBr_3$, $HgBr_2$, $TiBr_4$, were almost ineffective for this halogen exchange.

Brominated hydrocarbon, e.g., dibromomethane, or 1,2-dibromoethane, was the most appropriate solvent and the use of aromatic halides and carbon disulfide gave comparable results. In dichloromethane, the halogen exchange was not so effective as in the case of dibromomethane. The optimum amount of the aluminium reagent was found to be ca. 1.5 molar equivalents of the substrate in view of the product yield and the purity. The halogen exchange did not occur with less than one molar equivalent of the reagent. The product yield decreased with a large excess reagent.

These findings may suggest the reaction mechanism for the halogen exchange reaction as illustrated in Scheme 1: (1) Addition of hydrogen bromide to the dichloroethenyl moiety.[13] (2) Halogen exchange of the trihaloethyl intermediates (**10a**, **11a**, and **8a**). (3) Dehydrobromination of these intermediates. The aluminium reagents should have played an important role in the above every step.



Scheme 1.

The chlorine-bromine exchange reaction is applicable as well to the methyl ester **5b** or free acid **5c**. The yields of the corresponding dibromoethenyl compound **6b** or **6c** were also satisfactory. The exchange reaction of the free acid **5c** proceeded faster than that of the corresponding esters. Actually, the halogen exchange of **5c** almost finished when the addition of the substrate to aluminium tribromide was completed. In this acid case, the formation of tribromoethyl acid **8c** was remarkable as compared with the ester cases (**6c**/**8c**=1/2). The rapid halogen exchange and the presence of a larger amount of **8c** is attributed to the hydrogen bromide generated by the initial contact of the starting acid **5c** with the aluminium reagent. Efficient removal of hydrogen bromide from the reaction mixture by argon bubbling was, therefore, necessary for optimum yield of dibromoethenyl acid **6c** (90—95%).

In order to apply this halogen exchange to the preparation of the acid part of decamethrin, it is essential that cis-trans isomerization or epimerization should not take place during the reaction.

Table 2. Stereochemistry in Transformation of **5** to **6**

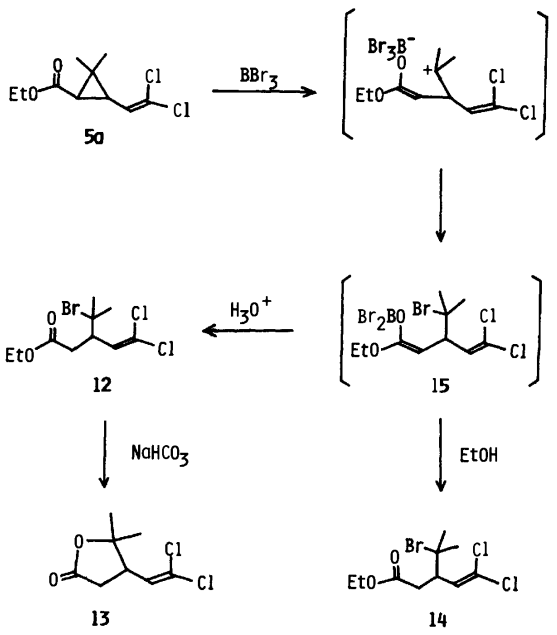
5	(cis/trans)	Reagent	6 Yield/%	6 cis/trans	6 Purity/%[a]
5a	(77/23)	Al-HBr	92	77/23	95
5b	(99/1)	Al-HBr	90	99/1	92
5c	(0/100)	$AlBr_3$	93	0/100	96
5c	(100/0)	$AlBr_3$	94	100/0	96
5c	(0/100)[b]	$AlBr_3$	93	0/100[c]	96

a) Based on GLPC area %. b) $[\alpha]_D$=−36.3° ($CHCl_3$). c) $[\alpha]_D$=−37.2° ($CHCl_3$).

The halogen exchange upon the dichloroethenyl compounds **5a—c** of various cis/trans ratio showed complete preservation of the original stereochemistry as shown in Table 2.

For example, 100% *trans*-dibromoethenyl acid **6c** was obtained by the treatment of 100% *trans*-dichloroethenyl acid **5c** with aluminium tribromide. Similarly, 100% *cis*-**5c** was stereospecifically converted into 100% *cis*-**6c** in an excellent yield. The retention of the stereochemistry was also verified in the last example. Acid *trans*-**5c** with ca. 98% optical purity was transformed into **6c** having over 90% optical purity.[14]

Boron tribromide is also known to be capable of halogen exchange.[11] When dichloroethenyl compound **5a** was treated with boron tribromide in dibromomethane at room temperature, **5a** disappeared completely after stirring overnight. Acidification of the reaction mixture followed by usual work-up afforded only a carboxylic acid which was readily transformed into a neutral compound by treating with aqueous sodium hydrogencarbonate. The former carboxylic acid was assigned to ring-opened acid **12** and the neutral compound to **13** (Scheme 2). The yields of the two products were 65 and 63%, respectively, based on **5a**. When the reaction mixture was quenched with dry ethanol, the ester **14** was obtained in 89% yield. Scheme 2 shows possible routes to these products. The coordination of boron tribromide to the ester carbonyl followed by the ring opening and the transfer of bromide ion to the cationic carbon produces intermediary ethenyl borate **15**.[18] Hydrolysis or ethanolysis of **15** affords **12** or **14** as the final product. No halogen exchange was observed during this reaction. The stronger Lewis acidity of boron tribromide than aluminium tribromide would account for the observed different reactivity between them.



Scheme 2.

Experimental

General. All the melting points and boiling points are uncorrected. IR spectra were recoreded on a Hitachi EPI-G3 grating spectrophotometer. ^1H NMR spectra were measured with Varian HA-100 spectrometer and Hitach-Perkin-Elmer R-20B using TMS as an internal standard. Mass spectra were recoreded on Hitachi RMU-6E mass spectrometer (70 eV). Analytical determinations by GLPC were performed on a Hitachi 163 gas chromatograph (5 mm o.d.×1 m, 2% EGA on Uniport B or diasolid ZS).

Attempted Halogen Exchange of Ethyl 3-(2,2-Dichloroethenyl)-2,2-dimethylcyclopropanecarboxylate (5a) with CuBr. A solution (DMF or DMSO) of **5a** (0.47 g, 2.0 mmol) was added to a mixture of CuBr (16—40 mmol) in the same solvent (total 5 ml). The resulting mixture was heated at 130—150 °C for 8—55.5 h under an argon atmosphere. The composition of the reaction mixture was checked by GLPC at intervals.

Halogen Exchange of 5a with $AlBr_3$ in 1,2-Dibromoethane and Succesive Dehydrobromination with DBU. A solution of $AlBr_3$ (Kishida Kagaku, GR) (25 g, 94 mmol) in 1,2-dibromoethane (20 ml) was added dropwise to a solution of **5a** (15 g, 63 mmol) in 1,2-dibromoethane (30 ml) under ice-water cooling. After 4.5 h the reaction mixture was poured into ice-water and extracted with ether. The ethereal layer was washed with water, aq $NaHCO_3$, and finally with brine, and dried ($MgSO_4$). GLPC analysis of the crude product showed mainly three products whose area % were 5, 88, and 6% in the order of the retention time.

The solvent was evaporated and the residue dissolved in DMF (30 ml) was treated with DBU (1.5 g, 10 mmol) under ice-water cooling. After having been stirred for 3.5 h the reaction mixture was poured into ice-cooled dil HCl and extracted with ether. The ethereal layer was worked up as described above. Distillation gave 16 g of ethyl 3-(2,2-dibromoethenyl)-2,2-dimethylcyclopropanecarboxylate (**6a**)[4] (95% purity based on IR, ^1H NMR, GLPC, and GLPC-MS analyses). Bp 104—105 °C/0.28 mmHg (1 mmHg= 133.322Pa). The minor product (6%) with the latest retention time was converted to **6a** by the DBU treatment being attributed to ethyl 2,2-dimethyl-3-(2,2,2-tribromoethyl)cyclopropanecarboxylate (**8a**). Its retention time on GLPC and GLPC-MS data were coincident with those of an authentic sample.[4] Another minor component (5%) with fastest retention time isolated by GLPC separation was assigned to ethyl 3-(2-bromo-2-chloroethenyl)-2,2-dimethylcyclopropanecarboxylate (**7a**). ^1H NMR (CCl_4) δ=6.38 (dd), 5.73 (dd)(total 1H), 4.03 (q, 2H), 2.3—1.5 (m, 2H), 1.4—1.1 (m, 9H). MS *m/z* 281

(M+), 41 (base). Found: C, 42.43; H, 4.96%. Calcd for $C_{10}H_{14}BrClO_2$: C, 42.66; H, 5.01%.

Halogen Exchange of Ethyl 2,2-Dimethyl-3-(2,2,2-trichloroethyl)cyclopropanecarboxylate (9a).[15] To a solution of **9a** (0.55 g, 2.0 mmol) in dibromomethane (3 ml) was added a solution of $AlBr_3$ (0.53 g, 2.0 mmol) in dibromomethane (1 ml) under ice-water cooling. The composition of the reaction mixture was analysed by GLPC (diasolid ZS) at appropriate time intervals. The products (area %) formed after 45 min were **8a** (62%) and **6a** (29%).

Examination of the Effect of HBr Scavenger. a) Addition of Al Metal: A solution of $AlBr_3$ (0.80 g, 3.0 mmol) in dibromomethane (2 ml) was added to a solution of **9a** (0.55 g, 2 mmol) in dibromomethane under ice-water cooling. Small pieces of Al foil (ca. 50 mg) was added to the reaction mixture. After having been stirred for 7.5 h the reaction mixture was poured into ice-water and extracted with ether. Usual work-up, followed by GLPC (diasolid ZS) assay (octadecane (0.25 g) as an internal standard) gave the results cited in Table 1.

b) Bubbling with Argon Gas at Atmospheric Pressure: After the halogen exchange of **9a** was carried out in a similar manner as described above, argon gas was introduced to the reaction mixture. After 6 h the product yields were determined by GLPC.

c) Bubbling with Argon Gas under Reduced Pressure: The reaction was carried out in a similar manner as described in section b. After argon gas was introduced for 15 min the pressure of the reaction system was gradually reduced to 20 mmHg. The flow of argon gas was controlled so as to maintain moderate bubbling under ice-water cooling. After 3 h the reaction mixture was worked up.

Direct Conversion of Dichloroethenyl Compound 5a to 6a. To a solution of **5a** (0.48 g) in dibromomethane (2 ml) was added dropwise a solution of $AlBr_3$ (0.80 g, 3.0 mmol) in dibromomethane (3 ml) under ice-water cooling. After 1.5 h the pressure of reaction system was reduced to 20 mmHg under moderate argon bubbling for 4 h.

General Procedure for the Reaction of 5a with Various Metal Bromides. A solution of **5a** (0.47 g, 2.0 mmol) in dibromomethane (2 ml) was added dropwise to a mixture of a metal bromide (3.0 mmol) in dibromomethane (3 ml) under ice-water cooling. When no change of the composition of the reaction mixture was observed on GLPC analysis, the reaction temperature was raised to room temperature, 60 °C, and finally to the refluxing temperature. The composition of the mixture was analyzed by GLPC at every temperature.

Halogen Exchange of 5a with Aluminium Compound Other than Commercial $AlBr_3$. a) Al-$BrCH_2CH_2Br$ Method: A small amount of bromine (ca. 40 mg) was added to two pieces (ca. 30 mg) of Al foil (Showa Aluminium Co., cut into small pieces) in 1,2-dibromoethane (5 ml) and the mixture was heated by open flame until an exothermic reaction started. After the reaction had started, remaining Al foil (total 0.41 g, 15 mmol) was added one by one. After all Al foil had been dissolved, the resulting black mixture was transferred into a dropping funnel which was attached to a second flask in which a solution of **5a** (2.4 g, 10 mmol) in 1,2-dibromoethane (10 ml) was placed. After the addition of the complex prepared above under ice-water cooling, the reaction mixture was allowed to warm to 20 °C. The reaction mixture was stirred for 9.5 h and then poured into ice-water and worked up as usual. Distillation of the crude product gave 2.7 g of a pale yellow oil which was composed of **6a** (89%), **7a** (3%), and **8a** (5%), bp 101—106.5 °C/0.27 mmHg.

b) Al-Br_2 Method: Bromine (2.6 g, 16 mmol) was added to one piece of Al foil suspended in dibromomethane (8 ml) and the mixture was heated by open flame until an exothermic reaction started. Then, remaining Al foil (total 0.43 g, 16 mmol) was added one by one. After all Al foil had been dissolved, the resulting black solution was transferred into a syringe and was added dropwise to a solution of **5a** (2.4 g, 10 mmol) in dibromomethane under ice-water cooling. After the addition was completed, the reaction mixture was allowed to warm to 10 °C. Then, the reaction mixture was stirred overnight at room temperature. GLPC analysis showed that the reaction mixture was composed of **6a** (47%) and **8a** (35%) along with a small amount of **7a**.

c) Al-HBr Method: To a mixture of Al metal [Al ribbon (Merck, GR) was cut into small pieces] (0.40 g, 15 mmol) in dibromomethane (10 ml) was introduced HBr gas through gas inlet tube at 30 °C (water bath). After 5 min an exothermic reaction started and brown solids formed gradually. After all Al metal had disappeared, the resulting brown suspension was heated until the reaction mixture became a brown clear solution. Then, the mixture was cooled with ice-water and a solution of **5a** (2.4 g, 10 mmol) in dibromomethane (10 ml) was added dropwise to the cooled mixture. The introduction of HBr was continued until the color of the reaction mixture changed to reddish black (ca. 10 min after the addition of the substrate). After the completion of the reaction was confirmed by GLPC (2 h after the addition of the substrate), the pressure of the reaction system was reduced to 20 mmHg, argon gas being gently introduced. After 2.5 h (GLPC check) the reaction mixture was worked up. Distillation afforded 2.8 g (86%) of **6a**, bp 108—110 °C/0.3 mmHg (purity 96%).

d) $AlCl_3$-HBr Method: To a suspension of $AlCl_3$ (Kishida Kagaku, GR) (0.99 g, 7.5 mmol) in dibromomethane (6 ml) was introduced HBr gas at 30 °C. After 30 min a solution of **5a** (1.2 g, 5.1 mmol) in dibromomethane (4 ml) was added dropwise to the resulting suspension under ice-water cooling. The introduction of HBr was continued until the color of the reaction mixture changed to reddish black (ca. 1.5 h after the addition of the substrate). After the completion of the reaction was confirmed by GLPC (4 h after the addition of the substrate), the pressure of the reaction system was reduced to 20 mmHg under argon bubbling. After 3.5 h, the reaction mixture was worked up. Distillation afforded 1.5 g (90%) of **6a**, bp 105—109 °C/0.25 mmHg (purity 95%).

Methyl 3-(2,2-Dibromoethenyl)-2,2-dimethylcyclopropanecarboxylate (6b). This reaction was carried out as described above (Al-HBr method), starting from methyl 3-(2,2-dichloroethenyl)-2,2-dimethylcyclopropanecarboxylate (**5b**) (2.2 g, 10 mmol) and Al metal (0.40 g, 15 mmol). Distillation of crude product afforded 2.8 g (90%) of **6b**, bp 101—103 °C/0.26 mmHg (purity 96%). The structure was confirmed by the comparison with an authentic sample.[15]

3-(2,2-Dibromoethenyl)-2,2-dimethylcyclopropanecarboxylic Acid (6c). a) $AlBr_3$ Method: A solution of 3-(2,2-dichloroethenyl)-2,2-dimethylcyclopropanecarboxylic acid (**5c**) (trans 100%)[15] (4.2 g, 20 mmol) in dibromomethane (20 ml) was added dropwise to a solution of $AlBr_3$ (8.0 g, 30 mmol) in dibromomethane (20 ml) over a period of 15 min under ice-water cooling. After the addition was completed, argon gas was introduced to the reaction mixture through syringe needle for 15 min. The pressure of the reaction system was then gradually reduced to 20 mmHg under argon bubbling.

After 2.5 h the reaction mixture was poured into ice-water. Then, dil HCl was added and the resulting mixture was extracted with ether-AcOEt (ca. 4:1). The organic layer was washed with dil HCl and brine, and then dried ($MgSO_4$). After removal of the solvents, the crude product was extracted with hot hexane and insoluble parts were filtered off. Removal of the solvent afforded 5.5 g (93%) of yellow solids assigned to **6c** by the comparison of the spectral data with those of authentic sample.[5a,15] Purity was 96%, and isomeric purity was 100% trans based on GLPC analysis after esterification with CH_2N_2. Mp 118—120 °C (hexane). lit,[5a] 117—118 °C (ethanol-water). Similarly, 5.6 g (94%) of *cis*-**6c** (purity 96%, 100% cis) was obtained starting from 4.2 g of 100% *cis*-**5c**. The isomeric purity was also checked by GLPC analysis. Mp 108—111 °C (hexane). lit,[15] 112—114 °C (hexane). Halogen exchange of (−)-*trans*-**5c** was similarly carried out, starting from 2.0 g (9.5 mmol) of (−)-*trans*-**5c** ($[\alpha]_D$=−36.3° ($CHCl_3$), lit,[17] $[\alpha]_D$=−36.6° ($CHCl_3$)) by means of $AlBr_3$ (3.8 g, 14 mmol). After extraction with hot hexane, removal of the solvent afforded 2.6 g (93%) of yellow solids. GLPC analysis of the product after esterification by CH_2N_2 showed that the product obtained was composed of 96% of **6c** (trans 100%). $[\alpha]_D$=−37.5° ($CHCl_3$). lit,[5b] $[\alpha]_D$=−40.5° ($CHCl_3$).

b) Al-HBr Method: An aliquot of Al ribbon cut into small pieces (5.1 g in total, 0.19 mmol) in dibromomethane (125 ml) was warmed to 30 °C and HBr gas was introduced. When an exothermic reaction started, the rest of Al metal was added portionwise to maintain the reaction temperature between 60—65 °C. After all Al metal had dissolved (ca. 1.5 h), the gas inlet tube was replaced by a dropping funnel through which a solution of *cis*-**5c** (26 g, 0.13 mol) in dibromomethane (100 ml) was added dropwise at 5—7 °C. When the completion of the halogen exchange was confirmed by GLPC (ca. 2 h from the start of the addition), the pressure in the reaction flask was reduced to 20 mmHg under usual argon bubbling (ice-water bath). After 4.5 h (GLPC check) the reaction mixture was worked up. Removal of the solvent afforded 33 g (89%) of *cis*-**6c** as brown solids, whose purity was 93% on GLPC, mp 105—108 °C (hexane).

3-(1-Bromo-1-methylethyl)-5,5-dichloro-4-pentenoic Acid (12). A solution of BBr_3 (0.6 ml) in dibromomethane (4 ml) was added dropwise to a solution of **5a** (0.95 g, 4.0 mmol) in dibromomethane under ice-water cooling. After the addition was completed, the reaction mixture was allowed to warm to room temperature and stirred overnight. The mixture was poured into cold dil HCl and extracted with ether-AcOEt (4:1). The organic layer was washed with water (twice) and brine, and dried ($MgSO_4$). Recrystallization (hexane) gave 0.75 g (65%) of **12** as slightly brown crystals, (needles), mp 81—82 °C. IR (KBr disk): 3200—2600, 1700, 1620, 1310, 875 cm^{-1}. ^1H NMR (CCl_4) δ=5.94 (d, 1H), 3.25—2.8 (m, 2H), 2.48 (dd, 1H), 1.84 (s, 3H), 1.77 (s, 3H). MS *m/z* 288 (M^+), 122 (base). Found: C, 33.32; H, 3.79%. Calcd for $C_8H_{11}BrCl_2O_2$: C, 33.14; H, 3.82%.

3-(2,2-Dichloroethenyl)-4-methyl-4-pentanolide (13). The reaction of **5a** (4.7 g, 20 mmol) with BBr_3 (3.0 ml) in dibromomethane was carried out as described above. The reaction mixture after having been stirred overnight was poured into ice-water and extracted with ether. The ethereal layer was washed with brine and aq $NaHCO_3$ (three times). The aqueous layer was extracted with ether and the combined ethereal layer was washed with brine (twice) and dried ($MgSO_4$). Recrystallization (hexane : AcOEt=5:1) afforded 2.6 g (63%) of **13**, mp 118—119 °C (lit,[14] 115—117 °C). IR (neat): 1770, 1625, 1280, 1260, 1100, 890 cm^{-1}. ^1H NMR (CCl_4) δ=5.89 (d, 1H), 3.36 (m, 1H), 2.95—2.3 (m, 2H), 1.52 (s, 3H), 1.35 (s, 3H). MS *m/z* 208 (M^+), 122 (base).

Ethyl 3-(1-Bromo-1-methylethyl)-5,5-dichloro-4-pentenoate (14). After the overnight reaction of **5a** (2.4 g, 10 mmol) with BBr_3 (1.5 ml) the reaction mixture was concentrated in vacuo. The residue was dissolved in 3 ml of dry ethanol. After 30 min the resulting mixture was diluted with ether, washed with water (twice) and brine, and dried ($MgSO_4$). Distillation of the crude product afforded 2.8 g (88%) of **14**, bp 93—94 °C/0.17 mmHg. IR (neat): 1740, 1620, 1255, 1175, 1115, 880 cm^{-1}. ^1H NMR (CCl_4) δ=5.89 (d, 1H), 4.12 (q, 2H), 3.15—2.65 (m, 2H), 2.35 (dd, 1H), 1.82 (s, 3H), 1.77 (s, 3H), 1.26 (t, 3H). MS *m/z* 317 (M^+), 237 (base). Found: C, 37.89; H, 4.66%. Calcd for $C_{10}H_{15}BrCl_2O_2$: C, 37.77; H, 4.75%.

12) The hydrogen bromide is considered to be generated by the decomposition of the aluminium tribromide used.

13) The addition of hydrogen bromide to dichloroethenyl compound **5a** did not occur in the absence of the aluminium ion. Thus, coordination of alminium trihalide most probably to carbonyl oxygen first occurred and then assisted the addition of HBr. The coordinated aluminium trihalide would be inactive for halogen exchange.

14) Exact optical purity was not determined. However, purified product (purity 99% on GLPC) by repeated

recrystallization had specific rotation of −40.3° which was almost equal to the one of pure (−)-*trans*-**6c**.

Synthesis of Aspartyl Pentapeptide Esters in Relation to Structural Features of Sweet Peptides

Yasuo ARIYOSHI
Central Research Laboratories, Ajinomoto Co., Inc. Suzuki-cho, Kawasaki-ku, Kawasaki 210
(Received November 13, 1985)

A series of seven analogues of aspartyl pentapeptides has been synthesized in relation to the structural features of sweet peptides. The rule in the structure-taste relationships of di-, tri-, and tetrapeptides is inapplicable to the pentapeptides. All the pentapeptides were devoid of sweetness, though they satisfied the requirements for sweet peptides. The result indicates that oligopeptides can not fit a deep receptor pocket. The mode of interactions between sweet peptides and the receptor is drawn schematically.

In a previous paper,[1] the tastes of aspartyl dipeptide esters have been rationalized through Fischer projection formulas. Recently, in order to deduce the mode of interactions between the sweet peptides and the receptor site, various aspartyl tri- and tetrapeptide esters have been synthesized.[2,3] In the structures (Ia, II, and III), a small alkyl group (S or R^2) has been considered to participate in binding with the receptor through a hydrophobic interaction. Another hydrophobic interaction at R^4 with the receptor has also been suggested.[2] The carboxyl and amino groups serve as a proton acceptor and a proton donor, respectively, in the hydrogen bonding with the receptor. Another hydrogen bonding at the peptide bond with the receptor has also been suggested by the fact that any modification of the peptide bond resulted in a complete loss of sweetness.[4,5] The shape and size of a molecule are important, since the receptor site is considered to be in the shape of a deep pocket[6] or a narrow cleft.[7] Another important factor, common to all sweet compounds, is the hydrophilic-hydrophobic balance in a molecule. In this paper, a series of seven analogues of aspartyl pentapeptides was synthesized in order to obtain further information about the mode of interactions between the sweet peptides and the receptor site.

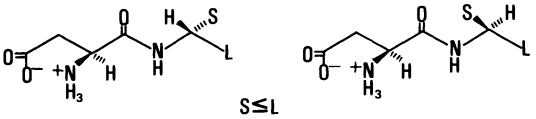

Fig. 1. General structure for sweet aspartyl dipeptide esters: S=small hydrophobic group (1—4 atoms); L=larger hydrophobic group (3—6 atoms).[1,2]

Synthesis

Syntheses of Boc-tripeptide esters and the removal of the Boc group were carried out according to the method described in a previous paper.[3] The protected tetrapeptides in Table 1 were prepared by condensation of the appropriate tripeptide ester with a Boc-amino

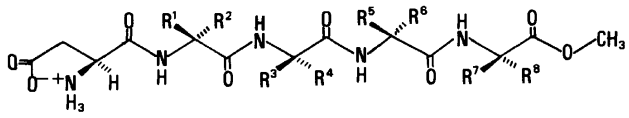
acid *N*-hydroxysuccinimide ester. The Boc group of the tetrapeptide esters was removed with *p*-toluenesulfonic acid (TosOH) in methanol.[8] The protected pentapeptide esters in Table 2 were prepared by condensation of *N*-benzyloxycarbonyl-L-aspartic acid β-benzyl α-succinimide ester (Z-L-Asp(OBzl)-ONSu)[2] with the appropriate tetrapeptide ester. The desired pentapeptide esters in Table 3 were obtained by deprotection of the benzyloxycarbonyl and benzyl groups from the protected pentapeptides in Table 2 by hydrogenation over palladium on charcoal.



IV

Fig. 4. L-α-Aspartyl pentapeptide esters.

Results and Discussion

In order for aspartyl tri- and tetrapeptides to be sweet, the second amino acid must have a D-configuration and a small alkyl side chain.[2,3] Therefore, a small alkyl group was introduced at R^2 so as to meet the sweet structure (II). In structural variation, a pentapeptide (**21**) with an opposite configuration at the chiral center was also synthesized. An L-antipode was introduced for the third amino acid, because the modification of tripeptides (II) showed that an L-configuration at the third amino acid was required for a potent sweet taste.

Most of the pentapeptides were predicted not to be sweet, since aspartyl peptides while elongating their peptide bonds significantly decrease their sweetness potencies and in some cases lose their sweet tastes. As expected, all the pentapeptides synthesized here were essentially tasteless or faintly bitter (Table 4).

The rule in the structure-taste relationships of di-, tri-, and tetrapeptides is inapplicable to pentapeptides. With increasing the length of a peptide, it becomes difficult to fit the narrow receptor pocket. This may be a major reason that some of the tetrapeptides and all of the pentapeptides were not sweet but bitter or tasteless, though they satisfied the requirements for sweet peptides. As a typical case, a series of L-α-aspartyl oligoalanine esters is illustrated in Table 5, in which the sweetness potencies suddenly fall off when the peptide bond is elongated. The taste of aspartyl peptides while elongating their peptide bonds tends to follow Ney's rule[9] for bitter peptides, in which peptides can be classified as bitter or nonbitter, depending upon the magnitude of the hydrophobicity of their side chains.[9] Accordingly, the results obtained for the pentapeptides, in conjunction with the results of di-, tri-, and tetrapeptides, have further supported the previous idea that the receptor site is

in the shape of a deep pocket with the binding sites inside. The mode of interactions between the sweet peptides and the receptor is illustrated in Fig. 5; here, the case of tripeptides is shown. In the case of Aspartame (L-α-Asp-L-Phe-OMe), the methyl ester group corresponds to R^2 and will interact with the receptor through a hydrophobic interaction, and the phenyl moiety will interact with the receptor at the partner of R^4 through a hydrophobic interaction. These hydrophobic interactions increased the sweetness potency.[1-3] As mentioned above, by increasing the length of a sweet peptide, it becomes difficult to fit the deep receptor. The decrease in its binding ability to the receptor reduces or loses the sweetness potency.

Experimental

All the melting points were taken on a Yanagimoto capillary melting point apparatus Model MP-21 and are uncorrected. Optical rotations were measured on a JASCO DIP-140 digital polarimeter with a 10 cm water-jacketed cell at 25 °C and a 1% concentration. Thin-layer chromatography (TLC) was performed on precoated silica gel $60F_{254}$ plates (E. Merck) and spots were detected with ninhydrin. All compounds were homogeneous on TLC. All of the pentapeptides were almost tasteless or faintly bitter. Therefore, it was judged only whether a peptide was sweet, bitter, or tasteless by tasting crystals of each pentapeptide.

Materials. Boc-amino acids were purchased from Peptide Institute Inc. Esters of L-Ala and L-Leu, and Z-L-Asp(OBzl)-OH were purchased from Kokusan Chemical Works Ltd.

Protected Tetrapeptides (1—7). A typical run (**3** in Table 1) was as follows: To a solution of Boc-L-Val-L-Ala-L-Ala-OMe (2.05 g, 5.5 mmol) in 15 ml of methanol was added TosOH·H_2O (1.26 g, 6.6 mmol). The mixture was stirred at 35 °C for 5 h. The solvent was evaporated under reduced pressure at a bath temperature of 50 °C to give H-L-Val-L-Ala-L-Ala-OMe·TosOH as a semisolid residue. The residue was dissolved in chloroform and the solvent was evaporated under reduced pressure to leave a semisolid residue. The residue was dissolved in 40 ml of chloroform and cooled in an ice-bath. To this solution was added triethylamine (Et_3N, 0.67 g, 6.6 mmol), followed by Boc-D-Ala-ONSu (1.43 g, 5 mmol) with stirring. The mixture was stirred at room temperature for 3 h and then kept standing overnight. The reaction mixture was washed successively with water, a 10% citric acid solution, a 5% sodium hydrogencarbonate solution, and water, and then concentrated under reduced pressure to leave Boc-D-Ala-L-Val-L-Ala-L-Ala-OMe (**3**) as a solid. The solid was crystallized from ethyl acetate–hexane to give **3** as needles. Recrystallization was carried out from ethyl acetate. The data are given in Table 1.

Protected Pentapeptide Esters (8—14). A typical run (**10** in Table 2) was as follows: To a solution of Boc-D-Ala-L-Val-L-Ala-L-Ala-OMe (**3**, 1.10 g, 2.5 mmol) in 20 ml of methanol was added TosOH·H_2O (1.00 g, 5.3 mmol). The mixture was stirred at 40 °C for 4 h. The solvent was evaporated under reduced pressure at a bath temperature of 50 °C to give H-D-Ala-L-Val-L-Ala-L-Ala-OMe·TosOH as an oily residue. The residue was dissolved in chloroform and the solvent was evaporated under reduced pressure. The procedure was repeated twice. The crystalline residue, thus obtained, was suspended in 50 ml of chloroform at room temperature. To this suspension was added Et_3N (0.54 g, 5.3 mmol), followed by Z-L-Asp(OBzl)-ONSu[2] (1.10 g, 2.4 mmol) with stirring. The mixture was stirred for 3 h and then kept standing overnight. A geratinous material appeared was dissolved by

adding 100 ml of chloroform with warming. The reaction mixture was washed successively with water, 1 M HCl (1 M=1 mol dm^{-3}), a 5% sodium hydrogencarbonate solution, and water, and then concentrated under reduced pressure to leave a solid residue. The residue was triturated with ethyl acetate and collected by filtration. The residue was recrystallized from ethyl acetate. The data are given in Table 2.

Pentapeptide Esters (15—21). A typical run (**17** in Table 3) was as follows: Z-L-Asp(OBzl)-D-Ala-L-Val-L-Ala-L-Ala-OMe (**10**, 1.20 g) was dissolved in a mixture of acetic acid (45 ml) and water (10 ml), and hydrogenated in the presence of 5% Pd/C (0.50 g) with stirring at atmospheric pressure and 35°C for 5 h. The reaction mixture was filtered and the filtrate was concentrated to dryness under reduced pressure. The residue was dissolved in water and the solvent was evaporated under reduced pressure to remove the trace amount of remaining acetic acid. The procedure was repeated three times. The residue was recrystallized from water-acetone. The data are given in Table 3.

Synthesis and Characterization of Macrocyclic Polyaza(2,5)pyridinophanes Possessing Vitamin B_6 Functionality

Masaaki IWATA* and Hiroyoshi KUZUHARA
Riken (The Institute of Physical and Chemical Research), Wako, Saitama 351-01
(Received November 14, 1985)

Series of macrocyclic polyaza[*m*](2,5)pyridinophanes (poly=tri, tetra, penta; *m*=9, 12, 15)(**8—10**) and polyaza[*m*]paracyclophanes (**11—13**) were synthesized in excellent yields by the reaction of dichloropyridoxine derivatives (**4**) and α,α'-dibromo-*p*-xylene (**5**), respectively, with a series of 1,2-ethanediamine derivatives (**1—3**). These phanes were characterized on the basis of ^{1}H NMR spectra. The methyl group at C_6 of the pyridoxine moiety (a-series) revealed restricted rotation for all bridge sizes (*m*=9—15). In **8—10** without the methyl group (b-series), *m*=12 was the boundary between restricted and free rotation. In series **11—13**, only **11** (*m*=9) showed restricted rotation. Atomic group equivalence was discussed in terms of boundary restricted rotation and an empirical rule for the prediction of the relationship between the bridge size and restricted rotation was proposed.

Along the line of our continuing interest in chemical congeners for coenzyme-B_6, dithia(2,5)pyridinophanes[1] and diaza(2,5)pyridinophanes[2] have been prepared and characterized. Their properties have been compared with those of coemzyme-B_6. These artificial coenzymes feature outstanding stability and efficiency in comparison with natural coenzyme, with excellent stereoselectivity for specific amino acids. By functionalizing the bridge moiety, we have designed new artificial coenzymes with additional sites for complexation in consideration of host-guest complexation.[3] In terms of the previously reported relationship between restricted rotation and the length of the bridge chain[2b] and predictable synthetic feasibility owing to molecular symmetry, we selected 1,2-ethanediamine derivatives (**1—3**) as the bridge moiety. In the present report, we would like to describe the details of synthesis and properties of macrocyclic polyaza(2,5)pyridinophanes and -paracyclophanes.

Results and Discussion

Preparation of 1,2-Ethanediamine Derivatives (1—3). It was expected that chain elongation of the 1,2-ethanediamine could be achieved by iterative reaction of *N*-(2-bromoethyl)tosylamide (**6**) with *N,N'*-ditosyl-1,2-ethanediamine (**7**). It was difficult, however, to prepare pure *N,N*-bis[2-(tosylamino)ethyl]tosylamide (**1**), since further alkylation occurred to give the higher homologues, **2** and **3**. Thus, **1—3** were obtained by chromatographic separation of the reaction mixture. ^{1}H NMR spectral data of **1—3** are summarized in Fig. 1.

6 **7**

Scheme. 1. Synthesis of poly(*N*-tosyl-1,2-ethanediamine) derivatives (**1—3**).

Synthesis of Polyaza[*m*](2,5)pyridinophanes (8—10) and Polyaza[*m*]paracyclophanes (11—13) (*m*=9, 12, 15).[4] The synthetic procedure was based on a previously reported method[2] except that the reaction temperature was lowered to room temperature and the sulfonamide was not metallated before the reaction but reacted directly in the presence of excess potassium carbonate. Therefore, 1,2-ethanediamine derivatives (**1—3**) reacted independently in DMF with protected dichloropyridoxine hydrochloride (**4**) at room temperature to give polyaza[*m*](2,5)pyridinophanes (**8—10**) (*m*=9, 12, 15). Work-up was just the same as in the preceding report.[2b] Likewise, **1—3** reacted with α,α'-dibromo-*p*-xylene (**5**) to afford polyaza[*m*]pracyclophanes (**11—13**) (*m*=9, 12, 15). The results obtained are summarized in Table 1.

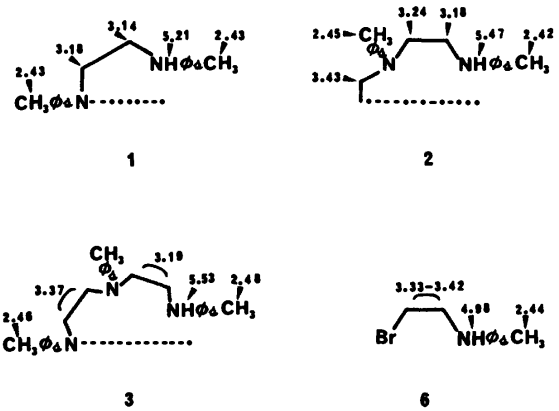

Fig. 1. ^{1}H NMR spectral data of open chain *p*-tosylamides **1**, **2**, **3**, and **6** (δ, in $CDCl_3$); the structure shown is a half part of the molecule due to its molecular symmetry for **1**, **2**, and **3**.

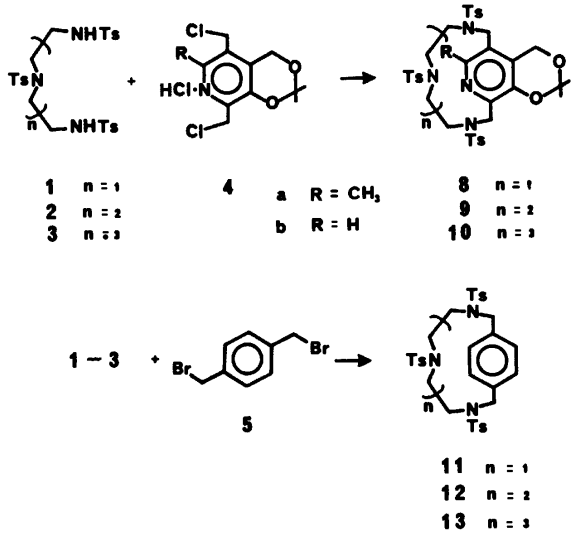
Although the reaction conditions were not optimized, product yields were unexpectedly excellent. The compounds, **11** and **12**, were incidentally purified by one recrystallization of the reaction mixture after work-up without the necessity of silica-gel chromatography.

Properties. Referred to the present design, it is of special importance to characterize the property with regard to relationship between induced restricted rotation and miximum numbers of nitrogen atoms included on the bridge chain. The presence of restricted rotation has been judged by the simple criteria based on



Scheme 2. Preparation of polyaza[m](2,5)pyridinophanes (**8**—**10**) and polyaza[m]paracyclophanes (**11**—**13**) (poly=tri, tetra, penta).

Table 1. Preparation of Polyaza[m](2,5)pyridinophanes and Polyaza[m]paracyclophanes

Compd	Yield[a] %	Mp θ_m/°C	Rotation[b]	Bridge size[c]/m	Included N atom
8a	94	230[d]	R	9	3
9a	70	126—128	R	12	4
10a	47	155—157	R	15	5
8b	95	230—232[d]	R	9	3
9b	98	247—249[d]	B	12	4
10b	68	133—135	F	15	5
11	96	274—275	B	9	3
12	96	282—284	F	12	4
13	72	131—133	F	15	5

a) Isolated yield after purification. b) Represents the presence or the absence of molecular rotation judged from ^{1}H NMR spectral signal (see Table 2). c) Numbers of the disposed atoms on the bridge chain. d) Decomposed.

^{1}H NMR spectral analysis.[1a,g,2b] The methyl protons in the isopropylidene group are informative as well for the judgment of restricted rotation. They appear as two separate sharp singlets if restricted rotation is induced. They become broadening to be one singlet signal if the bridge is in the boundary length. A sharp singlet signal is detected if free rotation is allowed. On the basis of these empirical criteria, rotational properties of the polyaza[m](2,5)pyridinophanes (**8**—**10**) and polyaza[m]paracyclophanes (**11**—**13**) are clearly determined. In Figs. 2, 3, and 4, parts of ^{1}H NMR spectra are depicted in the region δ 2.5—5.5. These signals are assignable to the methylene protons attached to the aromatic ring and to the methylene protons in the bridge. In Fig. 2, it is common feature that the methylene protons contiguous to the pyridine ring are split into AB quartet patterns though the methylene protons contiguous to the oxygen atom appear as incidental singlet (spectrum a) at δ 4.78 and signal overlapping

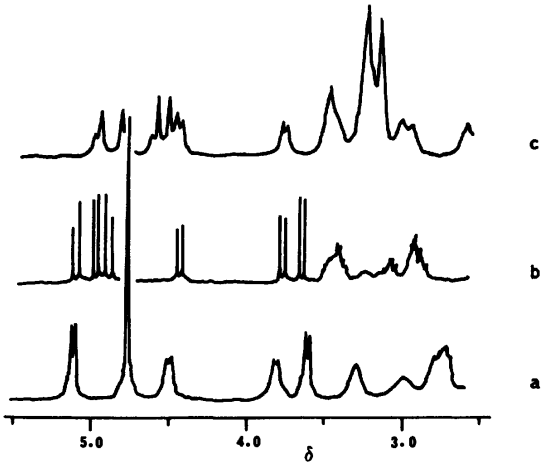


Fig. 2. ^{1}H NMR spectra of methyl-polyaza[m](2,5)-pyridinophanes (a-series) in the region δ=2.5—5.5; **a** for **8a** (m=9), **b** for **9a** (m=12), and **c** for **10a** (m=15) ($CDCl_3$, 18°C).

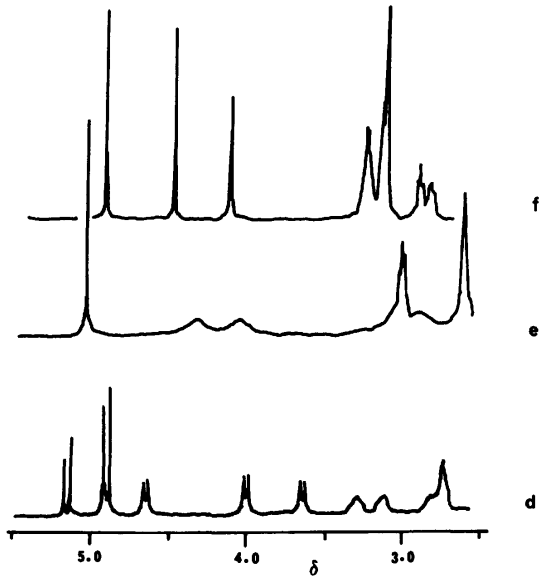

Fig. 3. ^{1}H NMR spectra of polyaza[m](2,5)pyridinophanes (b-series) in the region δ=2.5—5.5; **d** for **8b** (m=9), **e** for **9b** (m=12), and **f** for **10b** (m=15) ($CDCl_3$, 18°C).

is observable (spectrum c). In Fig. 3, three typical patterns of restricted rotation (spectrum d), boundary (spectrum e), and free rotation (spectrum f) are incidentally demonstrated. Since polyaza[m]paracyclophanes (**11**—**13**) have symmetry element in each case, it would not be chiral in any case. However, restricted rotation resulting in line-broadening are detectable in **11** (spectrum g in Fig. 4).

Relationship between restricted rotation and bridge chain length for all series of (2,5)pyridinophanes so far investigated is summarized in Table 2. This presents information about practical spherical bulk of atomic groups, S, N, and CH_2, and about prediction rule for restricted rotation of unsynthesized congeners. In comparison of dithiapyridinophanes (S-series)[1a,b,g]

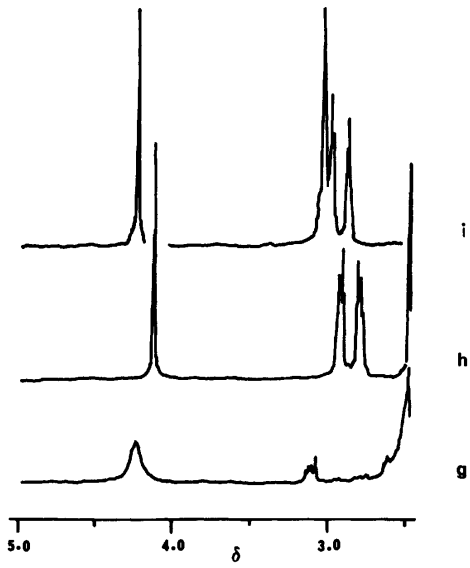

Fig. 4. ^{1}H NMR spectra of polyaza[m]paracyclophanes in the region δ=2.5—5.0; **g** for **11** (m=9), **h** for **12** (m=12), and **i** for **13** (m=15) ($CDCl_3$, 18°C).

with diazapyridinophanes (N-series),[2b] it is found that spherical bulk of two sulfur atoms is correlated nearly to that of two nitrogen atoms plus one methylene group. Equivalence of spherical bulk of one nitrogen atom to that of one methylene group could be seen when diazapyridinophanes (N-series)[2b] and polyazapyridinophanes (N-pAz-series), or methyl-diazapyridinophanes (Me-N-series)[2b] and methyl-polyazapyridinophanes (Me-N-pAz-series) are compared. Furthermore, it is seen that introduction of the methyl group into the pyridine ring at C_6-position provides expansion of the bridge chain required for restricted rotation by three to four methylene units (compare N-series with methyl-diazapyridinophanes (Me-N-series)[2b] or N-pAz-series with Me-N-pAz-series). Therefore, it is predictable that methyl-dithiapyridinophanes (Me-S-series), in which complete set of comparable series of congeners has not been synthesized, would show boundary bridge size at m=14 for restricted rotation. In addition, empirical conclusion drawn from the consideration of spherical bulk of atomic groups is well coincident with theoretical result calculated from covalent radii for individual atoms as has been previously pointed out.[2b]

It is of special significance that methyl-pentaaza[15]-(2,5)pyridinophane (**10a**) still retains restricted rotation since this contains five nitrogen atoms on the bridge probably enough to incorporate a guest in a mechanism of peripheral complexation proposed for catecholamine-macrocyclic polyamine complex.[3b] Since appropriate guests should be a matter of choice, polyaza[m]paracyclophanes (**11**—**13**) would contribute to provide informations about selection of guest molecules and mechanism of complexation.

Table 2. Relationship between Restricted Rotation and Bridge Chain Length in [m](2,5)Pyridinophanes Based on ^{1}H NMR Spectra
(F; free rotation, R; restricted rotation, B; boundary)

$(CH_2)_n$ n	Bridge Size/m	Compound Types[a]					
		S	Me-S	*N*	Me-N	N-pAz	Me-N-pAz
4	8	R					
5	9	R		R	R	R	R
6	10	R		R	R		
7	11	B[b]		R	R		
8	12	F	R	B	R	B	R
9	13		R[b]	F	R		
10	14		B[b]	F	R		
11	15		F[b]		B[b]	F	R
12	16			F	F		

a) S and N stand for pyridinophane with sulfur and nitrogen atoms at juncture point. Prefix Me- represents the presence of the methyl substituent on pyridoxine moiety at C_6-position. Suffix -pAz shows polyaza-containing bridge repeated by the iminoethylene group. See actual structures in Ref. 1a, b, g) for S, in Ref. 2b) for Me-S, N, and Me-N, and in the present report for N-pAz (**8a**—**10a**) and Me-N-pAz (**8b**—**10b**). b) Based on the empirical rule for the prediction of spherical bulk of the atomic group.

Experimental

The ^{1}H NMR spectra ware recorded in $CDCl_3$ on a JEOL JNM-GX 400 (400 MHz) spectrometer with Me_4Si as the internal standard; chemical shifts (δ) and coupling constants (J) are in parts per million and Herz, respectively. Infrared spectra (IR) were obtained as KBr disks on a Shimadzu IR-27G spectrophotometer. Mass spectra (MS, rel intensity) were obtained on a Hitachi RMU 6-MG spectrometer by using a direct-inlet method, an ionizing potential of 20 eV, and sample and chamber temperatures of 230°C. Merck silica gel 60 (Art. 7734, 0.063—0.20) was used for column chromatography, and Merck precoated silica gel 60 F_{254} plates (Art. 5715, 20×20 cm) were used for thin-layer chromatography (TLC). Two solvent systems were used for column chromatography and TLC unless otherwise mentioned; benzene-acetone 9:1 v/v (solvent A) and chloroform-acetone 93:7 v/v (solvent B). Product spots on TLC were detected either with a UV-lamp or in an iodine vapor bath. *N,N*-Dimethylformamide (DMF) was dried over molecular sieves (Type A), and the supernate was used directly for the reaction. The uncorrected melting points were measured with a micro melting point apparatus (Yanagimoto Seisakusho, Serial No. 2647). *N,N'*-Ditosyl-1,2-ethanediamine (**7**) was prepared from 1,2-ethanediamine according to a method previously reported.[5] 5'-Deoxy-2',5'-dichloro-3,4'-*O*-isopropylidene-6-methylpyridoxine hydrochloride (**4a**)[6] and 5'-deoxy-2',5'-dichloro-3,4'-*O*-isopropylidenepyridoxine (**4b**)[2b] were prepared immediately preceding the coupling reaction to sulfonamides from the corresponding dihydroxypyridoxine derivatives.

***N*-(2-Bromoethyl)-*p*-toluenesulfonamide (6).**[7] To a stirred solution of 2-bromoethylamine hydrobromide (40.0 g, 0.195 mol) in 320 ml of pyridine at 0—5°C, *p*-toluenesulfonyl chloride (48.38 g, 0.245 mol; 1.3 equiv) was added at once. The reaction was monitored by TLC (solvent B) every ten

min. When the absence of HBr-free 2-bromoethylamine was detected by spraying ninhydrin at R_f=0 (3 h), the mixture was poured into 2.6 l of water containing NaCl and stirred for ca. 1 h. The precipitate was collected by filtration and recrystallized from chloroform–cyclohexane to give 49.13 g of **6** (91%) as colorless leaflets: mp 93.5—94.5 °C (lit,[7] mp 88—90 °C); Calcd for $C_9H_{12}O_2NSBr$: C, 38.86; H, 4.35; N, 5.04; S, 11.53; Br, 28.73. Found: C, 38.99; H, 4.36; N, 5.01; S, 11.45; Br, 28.60. The yield of **6** was dependent on reaction temperature and time; at ambient temperature, the reaction mixture included considerable amounts of the corresponding dimer, *N*-(2-bromoethyl)-*N,N'*-ditosyl-1,2-ethanediamine. It was difficult to separate this from **6**, either on TLC or by recrystallization. Thus, the purity marker of **6** was elemental analyses and ^{1}H NMR. ^{1}H NMR data are shown in Fig. 1.

1,2-Ethanediamine Derivatives (1—3). Method A. To a suspended mixture of disodium *N,N'*-ditosyl-1,2-ethanediamine in DMF (55 ml) which was prepared by the reaction of *N,N'*-ditosyl-1,2-ethanediamine (2.0 g) with sodium metal (0.29 g, 2.3 equiv) in ethanol (30 ml) (refluxed for 1.5 h) followed by evaporation of ethanol, *N*-(2-bromoethyl)-*p*-toluenesulfonamide (**6**) (3.02 g, 2 equiv) in 20 ml of DMF was added dropwise at ca. 80 °C and then stirred until **6** disappeared. The reaction mixture was poured into 200 ml of water and the precipitate was collected by filtration. Silica-gel chromatography eluting with benzene–ethyl acetate (4:1 v/v) provided 1.26 g (63%) of the starting *N,N'*-ditosyl-1,2-ethanediamine, 0.47 g (15%) (R_f=0.3) of **1**, and 0.9 g (22%) (R_f=0.4) of **2** were isolated. Recrystallization of **1** from ethanol gave colorless crystals; mp 164—166 °C. Calcd for $C_{25}H_{31}O_6N_3S_3$: C, 53.07; H, 5.52; N, 7.43; S, 17.00. Found: C, 52.87; H, 5.58; N, 7.37; S, 16.96. MS: *m/z* 410 (the highest peak, 1.2%, M^+−155(Ts)) and 184 (100%, CH_2NHTs). IR: 3290(NH), and 1325 and 1150(SO_2) cm^{-1}. ^{1}H NMR spectral data are shown in Fig. 1. Recrystallization of **2** from ethanol gave colorless crystals; mp 193—195 °C. Calcd for $C_{34}H_{42}O_8N_4S_4$: C, 53.52; H, 5.55; N, 7.34; S, 16.81. Found: C, 53.57; H, 5.53; N, 7.20; S, 16.45. IR: 3290(NH), and 1325 and 1155(SO_2) cm^{-1}. ^{1}H NMR spectral data are shown in Fig. 1.

Method B. (a) A mixture of *N,N'*-ditosyl-1,2-ethanediamine (7.00 g), *N*-(2-bromoethyl)-*p*-toluenesulfonamide (5.813 g, 1.1 equiv) and 7.88 g (3 equiv) of anhydrous potassium carbonate in 250 ml of DMF was stirred at room temperature for 16 h. The reaction mixture was poured into 2.5 l of water and the precipitate was collected by filtration. Chromatography on silica gel eluting with chloroform–acetone (15:1 to 12:1 to 10:1 to 85:15 v/v) gave **1**, **2**, and **3** in the ratio 5:4:1. Recrystallization of **3** from chloroform–metahnol gave colorless crystals; mp 166—167 °C. Calcd for $C_{43}H_{53}O_{10}N_5S_5$: C, 53.78; H, 5.56; N, 7.29; S, 16.70. Found: C, 53.64; H, 5.53; N, 7.29; S, 16.58. IR: 3280(NH), and 1340 and 1155(SO_2) cm^{-1}. ^{1}H NMR spectral data are shown in Fig. 1.

(b) A mixture of **1** (2.03 g), *N*-(2-bromoethyl)-*p*-toluenesulfonamide (1.098 g, 1.1 equiv) and 0.99 g (2 equiv) of anhydrous potassium carbonate in 50 ml of DMF was stirred at room temperature for 53 h. After work-up as before, the residue was chromatographed on silica gel eluting with chloroform–acetone (10:1 to 9:1 v/v) to give recovered **1** (0.5 g), **2** (1.7 g), and **3** (0.4 g).

General Preparation Method of Polyaza(2,5)pyridinophanes and Polyazaparacyclophanes. To a stirred mixture of *N*-tosylated 1,2-ethanediamine derivatives (**1—3**) and excess anhydrous potassium carbonate (14 equiv mol to **1—3**) in DMF (1.5 g of **1—3**/150 ml of DMF) at room temperature, dichloropyridoxine (**4a,b**) (1 equiv) dissolved in DMF (0.5 g of **4a,b**/15 ml of DMF) was added dropwise (1 h). The stirring was continued for 12 h. The reaction mixture was poured into water containing NaCl. The resulting precipitate was collected by filtration followed by purification with silica-gel chromatography, unless otherwise noted. The product yield and mp are listed in Table 1. Line shapes of their ^{1}H NMR spectra are depicted comparatively in Figs. 2, 3, and 4 at δ 2.5=5.5. IR spectra of **8a—10a, 8b—10b,** and **11—13** are commonly characterized by bands at ca. 1600, 1340, and 1155(SO_2), and ca. 1380($C(CH_3)_2$) cm^{-1}. Specifically reported IR data are limited to the bands in the region 900—500 cm^{-1}.

N^2,N^5,N^8-Tritosyl-14-hydroxy-15-hydroxymethyl-14,15'-*O*-isopropylidene-11-methyl-2,5,8-triaza[9](2,5)pyridinophane (8a). Starting from **1** (1.186 g) and **4a** prepared from the corresponding dihydroxy-6-methylpyridoxine derivative (0.52 g, 1.04 equiv) in the presence of anhydrous potassium carbonate (4.056 g, 14 equiv) in 50 ml of DMF, 1.51 g (94%) of **8a** was obtained. Recrystallization from ethanol gave colorless crystals; Calcd for $C_{37}H_{44}O_8N_4S_3$: C, 57.53; H, 6.10; N, 6.95; S, 11.94. Found: C, 57.33; H, 5.96; N, 6.74; S, 12.13. R_f=0.73 (chloroform–acetone 85:15 v/v). (Received October 9, 1985)

The wet oxidation of sodium dithionate was carried out at an elevated temperature between 100 and 300 °C. The decomposition of the dithionate solution proceeded rapidly at 150—170 °C and (approximately) a complete decomposition occurred at temperatures greater than 200 °C within 30 min. The removed percentage of the dithionate under a large excess of air was independent of the concentration. The addition of iron(II) sulfate and hydrogen peroxide accelerated the decomposition. Wet oxidation was effective for the disposal of wastewater containing dithionates.

Sulfoxylates, except for sulfate in wastewater arising from wet SO_x removal facilities for exhaust gas, are refractory components for COD (chemical oxygen demand) removal (because of their reducing powers). In particular, dithionates comprise 60—85% of total sulfur compounds but are decomposed by oxidizing agents such as chlorine and ozone to an extent which varies from only several % to 40%, in spite of chemical reducing substances.[1,2] Therefore, it has been proposed to treat them by means of ion-exchange, electro-dialysis, and reverse-osmosis methods as well as coagulation and biological disposals.[3,4] However, problems regarding the great quantities of chemicals used and the waste products remained unsolved in those treatments.[3,4]

On the other hand, wet oxidation that is valid for resistant organic matter at an elevated temperature (150—350°C) and under a high pressure (3—25 MPa), has been put to practical use as a Zimmerman process in the field of wastewater treatment.[5-12] Wet oxidation is especially effective for the treatment of refractory substances for biological decompositions and is capable of recovering inorganic compounds. Furthermore, it is easy to recover energy on the basis of a heat exchange and there are few problems regarding inorganic salts in comparison with the pyrocombution method.

Lack of investigations regarding materials and corrosion for the facilities, however, retarded the application to a wide range of wastewater treatment.[13] Therefore, there have been several studies[14-17] on wet oxidation with catalysts, in order to enhance the decomposition rate or to reduce temperature and pressure used. Wet oxidation using Fenton's reagent[18,19] for refractory organic compounds and its reaction mechanism[20,21] were reported.

This paper deals with the wet oxidation of sodium dithionate as a model experiment for the wastewater treatment of SO_x removal facilities, including refractory dithionates. For practical use, the additive and temperature effects of Fenton's reagent and the protection of apparatus from corrosion due to by-product sulfuric acid have also been examined.

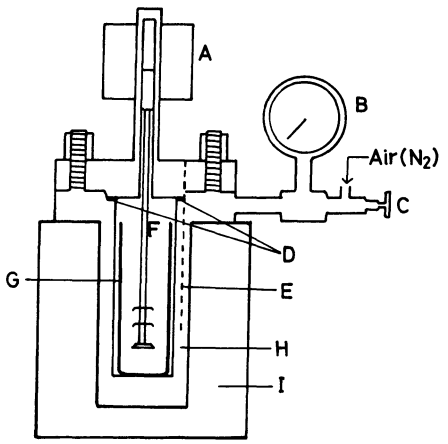

Fig. 1. Apparatus for wet oxidation: A, magnetic coil; B, pressure gauge; C, valve; D, copper packing; E, thermocouples; F, magnet drive rotating axis; G, glass tube; H, reactor; I, electric furnace. The glass tube was used only in Table 6.

Experimental

Apparatus. Wet oxidation and decomposition were carried out in a 200-ml Sakashita SE stainless autoclave equipped with a magnetic stirrer (Fig. 1).

Reagents. Commercial sodium dithionate (Extra Pure) and other chemicals (Guaranteed Reagent) were used without further purification.

Procedures. In the case of wet oxidation, the reaction vessel was charged with a 100-ml aqueous solution of sodium dithionate containing dithionate ion of 3500—35000 mg l^{-1} (or COD_{Mn} of 100—1000 mg l^{-1}) and, subsequently, an initial air pressure of 0.10—8.21 Mpa. Then, the solution was heated to a prescribed temperature between 100 and 300°C without stirring for 30 min. Finally, the temperature was maintained with stirring for 30 min. Wet decomposition was carried out in the same way as described above, except for an initial nitrogen pressure of 2.13 Mpa. Immediately after the required reaction time, the resulting sulfur dioxide was fixed by connecting three-jointed impingers (sodium hydroxide 1 wt/v % 20 ml×3) during reduced pressure. Sulfuric and sulfurous acids produced in the wet oxidation and decomposition were converted to sodium sulfate and sulfite by pouring an aqueous solution of sodium hydroxide into the autoclave, respectively. They

Table 1. Effect of Temperature on the Wet Oxidation of Sodium Dithionate under an Excess of Air[a)]

Temp	Pressure/MPa		COD_{Mn}[b)]/mg l^{-1}	Removed
°C	t=0[c)]	t=30[c)]	After oxidn.	%
100	2.7	2.8	95.8	0.6
140	2.8	3.5	62.7	35.0
145	3.0	3.6	49.3	48.9
150	3.0	3.9	31.6	67.2
155	3.0	3.9	14.9	84.5
170	3.2	4.0	4.5	95.3
200	3.6	4.4	2.3	97.6
250	4.5	6.2	1.8	98.1
300	6.4	9.1	0.8	99.2

a) Sample of 100 ml containing dithionate ion of 3500 mg l^{-1} was decomposed during promotion time 30 min and reaction time 30 min. The initial pressure of air at 20 °C was 2.13 MPa. b) The COD_{Mn} value for the sample prepared before the oxidation was 96.4 mg l^{-1}. c) The symbols of t=0 and t=30 stand for the reaction at time 0 and 30 min, respectively.

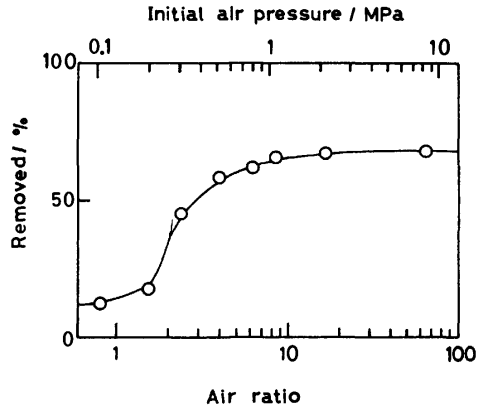

Fig. 2. Correlation of the removed percentage of sodium dithionate with the air ratio or the initial air pressure measured at 20 °C for the wet oxidation of the dithionate at 150 °C under air whose volume was 100 ml. Sample of 100 ml containing dithionate ion of 3500 mg l^{-1} was charged in the reactor.

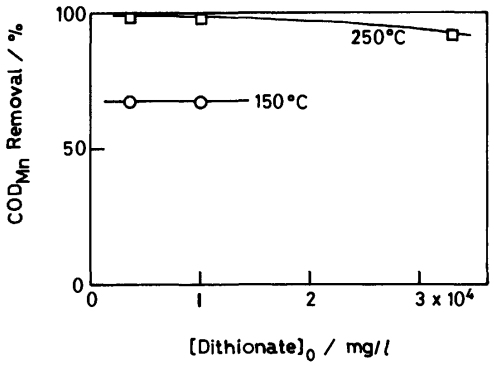

Fig. 3. Correlation of the initial concentration of dithionate with its removed percentage for the wet oxidation of sodium dithionate. The initial pressure of air at 20 °C was 2.1 MPa.

were then subjected to the chemical analyses described below.

Analyses. COD_{Mn} was determined on the basis of the oxygen demand by means of potassium permanganate at 100 °C (JIS K 0102(1981) 17). In the case of coexisting iron(II) ions and/or hydrogen peroxide, the solution was oxidized at room temperature by potassium permanganate; then, the COD_{Mn} was determined as described above. The dithionate concentration was determined from the oxygen demand during the potassium dichromate method (JIS K 0102, 20); its concentration in the presence of sulfite was obtained by subtracting the concentration of sulfite based on the iodine back titration method (JIS K 0102, 40) from the concentration of the both ($S_2O_6^{2-}$+SO_3^{2-}) by the dichromate method. The sulfate concentration was determined by means of the barium chromate method (JIS K 0102, 40-1); in the case of coexisting sulfite, the sulfate concentration was obtained by the subtraction of the sulfite concentration, estimated as described above, from the total concentration of the solution which was oxidized by ozone and then boiled, on the basis of the barium chromate method. The composition of red mud was determined by a fluorescent X-ray analysis of glass beads sintered at 1000 °C within 30 min. The amounts of components involved were: Na_2O, 7.42; K_2O, 0.19; MgO, 0.45; CaO, 1.70; Al_2O_3, 19.97; Fe_2O_3, 28.73; TiO_2, 3.52; SiO_2, 21.97; others, 4.55; Ig loss of carbonate and organic matters, 11.50%.

Results and Discussion

The Wet Oxidation of Sodium Dithionate. Table 1 lists the effect of temperature (100—300 °C) on the wet oxidation of an aqueous solution containing dithionate ions of 3500 mg l^{-1} at an initial air pressure of 2.13 MPa within 30 min. The decomposition of a sodium dithionate solution hardly proceeded at a temperature lower than 100 °C; however, it proceeded rapidly between 150 and 170 °C, at which a dithionate of 95% was removed. An approximately complete decomposition occurred at a temperature higher than 200 °C within 30 min. The change of promotion time, reaching a required reaction temperature, from 15 to 200 min without stirring, scarcely affected the removed percentage of sodium dithionate under stirring conditions.

If the wet oxidation of sodium dithionate proceeded according to Eq. 1, the theoretical pressure of air, P MPa, necessary to complete the decomposition of the dithionate ions (A mg) at t °C is approximately given by Eq. 2.

$$2S_2O_6^{2-} + O_2 + 2H_2O \longrightarrow 2SO_4^{2-} + 2H_2SO_4 \quad (1)$$

$$P = 1.208 \times 10^{-7}(273.15+t)A/V \quad (2)$$

Here, V denotes the volume of air expressed in liters. The air ratio is defined as the ratio of the initial air pressure charged to the theoretical air pressure.

Figure 2 shows the effect of the air ratio on the wet oxidation of sodium dithionate. The removed percentage of dithionate increased remarkably until

a) Sample of 100 ml containing dithionate of ca. 3400 mg l^{-1} was decomposed during promotion time 30 min and reaction time 30 min. The initial pressure of nitrogen at 20 °C was 2.1 MPa. Various components before and after the reaction are listed in mg in the sample of 100 ml. b) Sum of the resulting sulfate and sulfate equivalent. c) The symbols of t=0 and t=30 represent the reaction at time 0 and 30 min, respectively. d) The amount of sulfate equivalent to that of the corresponding ion is shown in parenthesis.

the air ratio reached ca. 4 and was almost unchanged at an air ratio of more than 10. In general, organic compounds are completely oxidized with a theoretical amount of air under suitable temperatures and pressure conditions. In the wet oxidation of sodium dithionate, however, dissolved oxygen attacks not only the starting dithionate but also the intermediate sulfurous acid to form sulfuric acid. Therefore, the effect of air on the wet oxidation of dithionate became weaker in comparison with that of general organic compounds.

Figure 3 shows a correlation of the dithionate concentration with its removed percentage. In the case of a constant temperature, the removed percentage of the dithionate was independent of its concentration if the air ratio was more than 6. These results are consistent with the fact that the decomposition rate of dithionic acid was proportional to its concentration.[22-27] When the initial concentration of the dithionate was 33000 mg l^{-1}, the decreased removed percentage could be ascribed to a low air ratio of 1.8, as is clear from Fig. 2.

The Wet Decomposition of Sodium Dithionate. In order to clarify the action of oxygen, the wet decomposition of sodium dithionate was examined under an inert gas: in this case, a nitrogen atmosphere. Table 2 lists the respective components before and after the wet decomposition of the dithionate aqueous solution containing dithionate ion of 3400 mg l^{-1} under a nitrogen atmosphere. Since the sum of the respective components calculated in the sulfate equivalent after the reaction was almost equal to the amount of dithionate in the sulfate equivalent before the reaction, the decomposition of the dithionate solution under a nitrogen atmosphere is

$$S_2O_6^{2-} + H_2O \longrightarrow SO_4^{2-} + H_2SO_3. \quad (3)$$

The removed percentage of dithionate increased considerably at temperatures higher than 180°C; its percentage in the wet decomposition under an inert gas was of the same order as that in wet oxidation at a lower temperature (by 30—50°C).

The Mechanism of the Wet Oxidation of Sodium Dithionate. In the case of a neutral aqueous solution, the first step consists of a decomposition of dithionate into sulfate and sulfur dioxide.[22] The resulting sulfur dioxide in an aqueous solution is in equilibrium with the sulfurous acid. When an excess of air is present, sulfurous acid is oxidized to sulfuric acid. Therefore,

$$SO_2 + H_2O + 1/2O_2 = H_2SO_4. \quad (4)$$

The overall reaction is expressed by

$$S_2O_6^{2-} \xrightarrow{k_1} SO_4^{2-} + SO_2 \xrightarrow[+H_2O,\,O_2]{k_2} SO_4^{2-} + H_2SO_4, \quad (5)$$

where k_1 and k_2 are the rate constants.

The decomposition rate of dithionic acid into sulfuric and sulfurous acids in the presence of hydrochloric or perchloric acid was proportional to the concentrations of dithionic acid and of the hydrogen ion.[22-26] The activation energy estimated from the decomposition rate in the presence of hydrochloric acid was reported to be 29.8 kcal mol^{-1} (1 cal=4.184 J); similarly, in an alkaline solution the activation energy was evaluated to be 25 kcal mol^{-1}.[25]

From Arrhenius plots between the rate constants calculated on the basis of the first-order reaction of the dithionate concentration, i.e., $k_1 \ll k_2$ in Eq. 5, and the absolute temperature, the activation energy of the decomposition over the range 100—155°C (Table 1) was evaluated to be 32.5 kcal mol^{-1}.[28] The decomposition percentage at a temperature of 170 °C or greater was lower than that estimated from the activation energy. Although the magnitude of the evaluated activation energy was the same as that for the decomposition of dithionic acid,[25] an extreme assumption may be insufficient for our system, probably because an accumulation of the resulting sulfuric acid accelerates the decomposition of the dithionate. The pH for an aqueous solution contain-

180	3.4	3.7	2.5	1.4	114	1.3	98.9

a) Sample of 100 ml containing dithionate ion of ca. 3500 mg l^{-1} was decomposed during promotion time 30 min and reaction time 30 min. The initial pressure of air at 20°C was 2.1 MPa; $[H_2O_2]_0$/COD-O oxygen ratio=1.0, $[FeSO_4]_0/[H_2O_2]_0$ molar ratio=1.0. b) The symbols of t=0 and t=30 indicate the reaction at 0 and 30 min, respectively.

ing dithionate ions (3500 mg l^{-1} at 20°C) varied from 5.8 (before decomposition) to 1.5 (after complete decomposition). The fact that the decomposition percentage of the dithionate increased with an increasing air ratio can be ascribed to the increased concentration of the resulting hydrogen ions.

Since the accumulating sulfuric acid in a wet oxidation is a stronger acid than the sulfurous acid produced in a wet decomposition, it is reasonable from a comparison of the hydrogen ion concentration that the decomposition rate of the dithionate at the same temperature was higher in the former than in the latter. In other words, the wet oxidation of sodium dithionate under an excess of air proceeds at a lower temperature than does wet decomposition under a nitrogen atmosphere.

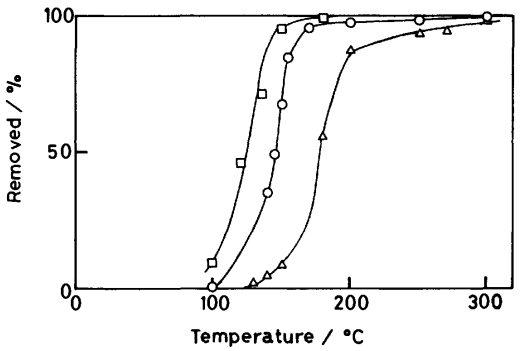

Fig. 4. Effect of temperature on the removed percentage of sodium dithionate for the wet oxidation and decomposition: □, in the presence of Fenton's reagent; ○, under air; △, under nitrogen atmosphere.

The Wet Catalytic Oxidation of Sodium Dithionate Using Fenton's Reagent. Fenton's reagent has a strong oxidation power on the basis of an electron acceptor of the hydroxyl radical produced from hydrogen peroxide in the presence of iron(II) salts. The resulting iron(III) ions are reduced to the starting iron(II) ions by use of hydrogen peroxide and/or a reducing radical produced during the oxidation-reduction process. Most transition metals can be applied as redox catalysts because of their valence transformation abilities. However, it is only the iron(II) ions among the transition metals that do not cause problems during an after treatment.

Table 3 lists the additive effect of catalysts such as hydrogen peroxide and iron(II) sulfate on the removed percentage of the dithionate. The addition of both hydrogen peroxide and iron(II) sulfate brought about a considerably higher decomposition of the dithionate than that in the absence of the additives at the same temperature. The optimum molar ratio of $[FeSO_4]_0$/

8	50	15.8	180	Water	108	5.1	95.3

a) Sample containing dithionate ion of ca. 3500 mg l^{-1} was decomposed during promotion time 30 min and reaction time 30 min. Run 1 and the other Runs were carried out without and with a glass tube, respectively. b) Between the glass tube and the high pressure vessel shown in Fig. 1.

$[H_2O_2]_0$ was 1.0 for this system although its value was reported to be 0.2 for the decomposition of organic compounds.[20]

The temperature effect on decomposition was examined under the optimum conditions (Table 4). Figure 4 shows the temperature dependence of the removed percentages on the wet catalytic oxidation using Fenton's reagent, on the wet oxidation under air, and on the wet decomposition under a nitrogen atmosphere. Figure 4 suggests that the decomposition of the dithionate using Fenton's reagent proceeded at a lower temperature (by ca. 20 °C) compared to that of the wet oxidation without a catalyst.

Treatment of By-Product Sulfuric Acid. The wet oxidation of sodium dithionate resulted in equimolecular amounts of sulfuric acid and sodium sulfate. In the case of the complete decomposition of the aqueous solution containing dithionate ions (3500 mg l^{-1}), the concentration of the resulting sulfuric acid became 0.022 mol l^{-1}. In order to neutralize the acid, the additive effect of bases (such as calcium carbonate and red mud) on the wet oxidation of the dithionate was investigated (Table 5). When a solution after a reaction was weakly basic (pH 8.0—8.2), the decomposition proceeded only by 25.1—33.1%. More acidic conditions for a system after reaction (with the addition of a smaller amount of a base) favor a decomposition.

Protection of Apparatus from Corrosion with a Combined Glass Tube. In the case of purge water drained from S-removal circuit lines for coke-oven gas, titanium containing 0.2% of palladium has been used for the main equipment due to the resulting sulfuric acid and ammonium sulfate.[13] We examined the wet oxidation using a glass tube in an autoclave (Table 6). The magnitude of the removed percentage of dithionate in a glass tube at 150 °C was less than half of that in an autoclave at the same temperature. However, the former (used at 160 °C) produced almost the same results as the latter at 150 °C. Since the removal difference can be ascribed to a lowering of the thermal conductivity, based on the gap between the glass tube and the high pressure vessel, the removed percentage was improved by filling the gap with water (see in Fig. 1). Corrosion of the autoclave due to the resulting sulfuric acid was not observed during repeated experiments using the glass tube.

Table 7. The Wet Oxidation of Wastewater Involving Dithionate at 180 °C[a]

Water	pH	COD_{Mn}/mg l^{-1}	Removed/%
Wastewater	5.4	475	
Treated water	0.2	15	96.8

a) The initial pressure of air at 20 °C=2.1 MPa, reaction time=60 min.

The Wet Oxidation Treatment of Wastewater from SO_x Removal Facilities. In light of the above investigations, the wet oxidation of actual wastewater was examined. As Table 7 shows, an almost complete decomposition (97%) occurred. The COD_{Mn} value (475 mg l^{-1}) of the wastewater suggests that the concentration of the dithionate ion was ca. 16600 mg l^{-1}.[29]

A higher temperature enhances the decomposition percentage and makes it possible to obtain a treated-water COD_{Mn} of less than 10 mg l^{-1}.

Conclusions

The wet oxidation of sodium dithionate, as a model of wastewater involving dithionates from SO_x removal facilities, is summarized as follows.

1. The wet oxidation of an aqueous dithionate solution depends remarkably on the temperature. The wet oxidation did not proceed at a temperature lower than 100°C, even after long time. However, it rapidly proceeded at 150—170°C. Approximately a complete decomposition was observed at temperatures higher than 200°C.
2. The promotion time (15—120 min) reaching a required temperature did not affect the removed percentage of the dithionate unless the solution was stirred during the time.
3. The decomposition percentage of the dithionate under a large excess of air was independent of its concentration.
4. Wet decomposition of the dithionate under a nitrogen atmosphere produced sulfurous acid and wet oxidation under an excess of air produced sulfuric acid. The latter oxidation proceeded at a lower temperature than the former decomposition because of the accelerating effect of the resulting hydrogen ions.
5. Sodium dithionate in aqueous solution was easily decomposed at lower temperatures by using Fenton's reagent. The optimum molar ratio of iron(II) sulfate to hydrogen peroxide was 1.0.
6. The neutralization of the by-product sulfuric acid by using a solid base, resulted in the lowering of the decomposition percentage. A combined glass tube was useful in protecting the reaction vessel from corrosion due to sulfuric acid.
7. In the wet oxidation of actual wastewater at 180°C, a decomposition percentage of 97% was obtained. It is possible to obtain a treated-water COD_{Mn} of less than 10 mg l^{-1}.

Grateful acknowledgement is made to several students of Aichi Institute of Technology, Noriyuki SAKAI, Toshio TAMURA, Akira IDA, and Hidenori KAWAMURA for their collaboration.

Active Carbon-Supported Aluminium Copper(I) Chloride as Solid Carbon Monoxide Adsorbent

Hidefumi HIRAI,* Keiichiro WADA, and Makoto KOMIYAMA
Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received October 21, 1985)

Active carbon-supported aluminium copper(I) chloride ($AlCuCl_4$) is prepared by mixing active carbon with toluene solution of $AlCuCl_4$, followed by the removal of the liquid phase at 6 mmHg, 100 °C. The active carbon-supported $AlCuCl_4$ rapidly adsorbs carbon monoxide (CO) at 20 °C under 1 atm from 9:1 CO-N_2 mixture and the equilibrium molar ratio of adsorbed CO to $AlCuCl_4$ is 1.03. Adsorbed CO is desorbed either by reducing pressure or by elevating temperature. In the second adsorption, which is carried out after the desorption at 6 mmHg, 20 °C for 10 min, the molar ratio of adsorbed CO to $AlCuCl_4$ is 0.51. The molar ratios are constant at 0.51 in the third and later adsorptions. The CO adsorbing ability of the active carbon-supported $AlCuCl_4$ remains virtually unchanged on repeated contacts with nitrogen gas containing 9000 ppm of water.

Carbon monoxide (CO), a valuable raw material in chemical industry,[1] is produced in large scale by partial oxidation and water gas reaction of petroleum or coal.[2] In addition, considerable amounts of CO are present in exhausted gases from various chemical plants. Since all of these sources of CO are gas mixtures with methane, hydrogen, nitrogen, carbon dioxide, and water, separation and purification of CO from gas mixtures are necessary.[2,3]

Many liquid absorbents for CO have been proposed.[2-8] The toluene solution of polystyrene-aluminium copper(I) chloride ($AlCuCl_4$) complex, devised by the present authors,[7,8] has reversibly absorbed CO under mild conditions. $AlCuCl_4$, which is highly reactive with water vapor, is protected from water vapor by the polystyrene in the polymer-metal complex, and thus separation of CO from gas mixtures containing water vapor is successfully achieved with the absorbent.

In contrast to a number of proposals on liquid CO absorbents, reports on solid adsorbents for CO are scanty. Although Y zeolite-supported Cu(I) ion adsorbed CO, the adsorption was so strong that adsorbed CO did not effectively desorb even at 10^{-4} mmHg (1.0 mmHg=1.33×10^2 Pa).[9] In the case of the adsorbents composed of Cu(I) ion and zeolites having high SiO_2/Al_2O_3 molar ratios,[10] the amounts of Cu(I) ion, and thus the amounts of adsorbed CO, per 1 g adsorbents were small due to small ion-exchange capacities of the zeolites.

In preliminary communications, the authors reported solid CO adsorbents composed of $AlCuCl_4$ and active carbon[11] or polystyrene resin.[12] These adsorbents exhibited reversible adsorptions of CO under mild conditions and were stable against water in gas mixtures.

In this paper, CO adsorbing and desorbing abilities of adsorbents composed of $AlCuCl_4$ and active carbon as well as their water-resistance are reported in detail. The selectivity of the adsorbents for the adsorption of CO with respect to the adsorptions of other gases is shown. Furthermore, results of measurements of pore size distributions both for the adsorbents and for the original active carbon are presented. The mechanism of the water-resistance of the present adsorbents is discussed in terms of these results.

Experimental

Materials. Active carbon, prepared from petroleum pitch, was obtained from Kureha Chemical Industry Co. (BAC G-70R, Lot No. 810117, average diameter ca. 0.7 mm), and was subjected to a reduced pressure (6 mmHg) at 200 °C immediately before use.

Aluminium chloride (Kishida Chemical Co., guaranteed grade) was purified by sublimation. Copper(I) chloride (Koso Chemical Co., guaranteed grade) was reprecipitated from concentrated hydrochloric acid solution by the addition of water, followed by washing successively with ethanol and diethyl ether, and then was dried in vacuo.[13] Toluene was dried over metallic sodium and was distilled.

Carbon monoxide gas and nitrogen gas, which had purities of 99.95 and 99.999%, respectively, were passed through the columns of molecular sieve 3 A immediately before use.

Preparation of Adsorbent. 20.0 mmol of aluminium chloride and 20.0 mmol of copper(I) chloride were magnetically stirred in 20 cm^3 of toluene at 50 °C for 4 h under dry nitrogen. The resultant homogeneous dark-colored toluene solution of $AlCuCl_4$ was added to 10 g of active carbon, kept in an evacuated 100 cm^3 vessel, avoiding contamination of air with the use of a dropping funnel. The mixture was stirred with a magnetic stirrer for 1 h, and then the liquid phase was thoroughly removed at 6 mmHg, 100 °C for 1 h. The adsorbents were obtained as black to grey beads.

Solid of $AlCuCl_4$ without active carbon was prepared as described above except for the absence of active carbon. The solid was white to grey aggregates.

Determination of the Amount of Metal Salt in the Adsorbent. The adsorbent was thoroughly washed by stirring for 6 h in three portions of aqueous hydrochloric acid solution (3 mol dm^{-3}, total volume 1500 cm^3). The total amounts of copper atoms in the solution were evaluated by atomic absorption spectroscopy (Shimadzu Co., model AA-646).

Measurement of BET Surface Area and Pore Size Distribution. BET surface area was calculated from desorption isotherm of nitrogen at 77 K. Pore size distribution was determined also from the isotherm by the method of Dollimore.[14] The method takes advantage of capillary condensation theory and is based on the assumption of cylindrical pores with

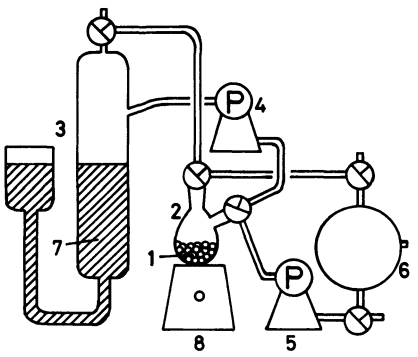

Fig. 1. Apparatus for measuring the amount of CO adsorbed by the adsorbents or desorbed from them; **1**: adsorbent; **2**: flask; **3**: gas burette; **4**: gas pump A; **5**: gas pump B; **6**: gas reservoir for nitrogen containing water; **7**: leveling liquid (toluene); **8**: magnetic stirrer.

radius r. The value $\Delta v/\Delta r$ is obtained as a function of r, where Δv is sum of volume for the pores having radii between r and $r+\Delta r$. Desorption isotherm of nitrogen at 77 K was measured on a Calroerba Co. Sorptomatic Series 1800.

Measurement of CO Adsorption and Desorption. The adsorptions of CO from CO-N_2 mixtures by the adsorbents were carried out at 20 °C under the atmospheric pressure using the apparatus depicted in Fig. 1. Uptake of CO was followed by a gas burette (3) using toluene as leveling liquid (7). The flask (2) containing the adsorbent (1) under nitrogen was connected with CO or CO-N_2 mixtures, and the adsorption was initiated by circulating the gas with the use of gas pump A (4). The circulation was effected for the first 10 min at a rate of 30 $cm^3 s^{-1}$ in order to mix the gas phase sufficiently.

The desorption of the adsorbed CO was carried out either by reducing the total pressure in the flask at 20 °C for 10 min or by elevating temperature from 20 °C to a predetermined temperature.

Contacts of the Adsorbent with Water Vapor. The contact of the adsorbent with water vapor was effected by circulating 5000 cm^3 of nitrogen gas, which had total pressure of 1 atm and contained 2.0 mmol of water (water content 9000 ppm), for 10 min on the magnetically stirred adsorbent with the use of a gas pump B (5). The nitrogen-water mixture was prepared by the introduction of water into an evacuated 5000 cm^3 vessel ((6) in Fig. 1) using a microsyringe, followed by the addition of dry nitrogen gas in an amount required to make the total pressure atmospheric.

Results

Preparation of Active Carbon-Supported $AlCuCl_4$. Toluene solutions of $AlCuCl_4$ were obtained as homogeneous dark-colored solutions by heating aluminium chloride and copper(I) chloride at charged molar ratio unity in toluene. On the addition of the toluene solution of $AlCuCl_4$ to active carbon, the color of the liquid phase rapidly decolorized. This result shows specific interactions between active carbon and $AlCuCl_4$. On removal of the liquid phase, active carbon-supported $AlCuCl_4$ was obtained as black to grey beads.

Table 1. BET Surface Areas of Adsorbents

Adsorbent	BET surface area / $m^2 g^{-1}$
Active carbon-supported $AlCuCl_4$[a)]	870
Original active carbon	1230

a) The adsorbent was prepared from 20.0 mmol of $AlCuCl_4$ and 10 g /of active carbon, and contained 17.2 mmol of $AlCuCl_4$.

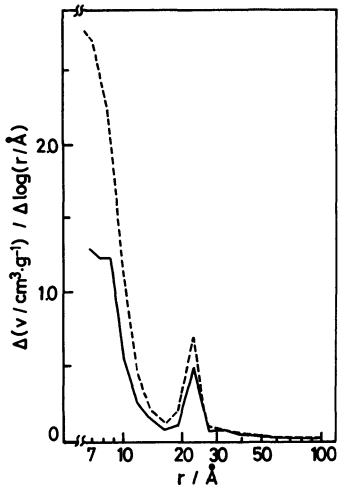

Fig. 2. Pore size distributions in the active carbon-supported $AlCuCl_4$ (——) and original active carbon (---): Δv is sum of volume for the pores having radii between r and $r+\Delta r$.

The atomic absorption spectroscopy showed that 17.2 mmol of $AlCuCl_4$ was supported to 10 g of active carbon, when 20.0 mmol of $AlCuCl_4$ in 20 cm^3 of toluene was treated with the active carbon. Thus, 86% of the charged $AlCuCl_4$ was supported to the active carbon under these conditions.

Table 1 shows the results on the measurement of BET surface area. The surface area (870 $m^2 g^{-1}$) for the adsorbent is about 70% of the value (1230 $m^2 g^{-1}$) for the original active carbon.

Figure 2 depicts pore size distribution either in the present adsorbent (the solid line) or in the original active carbon (the dotted line). The ordinate ($\Delta v/\Delta r$) approximately corresponds to number of pores. The number of pores with radii smaller than 15 Å for the present adsorbent is significantly smaller than the value for the original active carbon. In contrast, the number of pores with radii larger than 15 Å is almost identical with the value for the original active carbon. This result shows that small BET surface area (870 $m^2 g^{-1}$) of the present adsorbent, compared with the value (1230 $m^2 g^{-1}$) of the original active carbon, is almost totally attributable to decrease in the number of pores with radii smaller than 15 Å.

Adsorption and Desorption of CO by the Active Carbon-Supported $AlCuCl_4$. As shown by the open

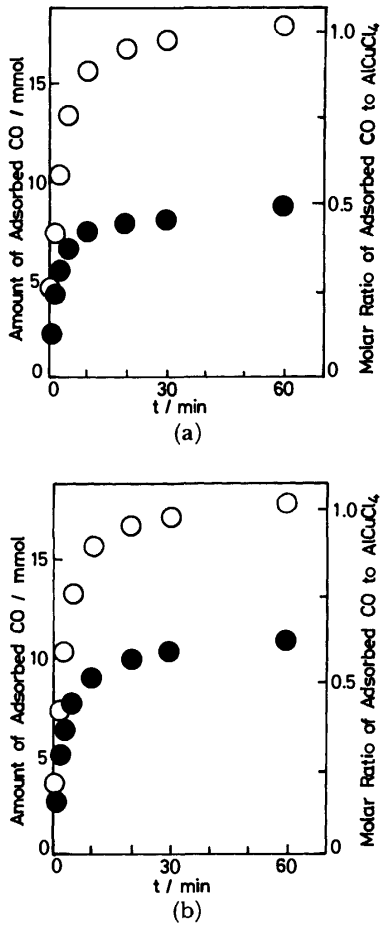

Fig. 3. Adsorption of CO by the active carbon-supported $AlCuCl_4$ at 20°C under 1 atm: the desorption conditions were 6 mmHg at 20°C for 10 min for (a), and 100°C, 1 atm for (b); the first adsorption by a virgin adsorbent (○); the second adsorption by the adsorbent which was subjected to the desorption conditions after the first adsorption (●); the adsorbent was prepared from 20.0 mmol of $AlCuCl_4$ and 10 g of active carbon, and contained 17.2 mmol of $AlCuCl_4$; the initial volume of gas mixture was 1500 cm^3 and the initial partial pressures of CO and N_2 were 0.9 and 0.1 atm, respectively.

circles in Fig. 3(a), the adsorbent rapidly adsorbs CO on the contact with 9:1 CO–N_2 mixture at 20°C under 1 atm. After 10 min, the amount of adsorbed CO is 15.6 mmol, which is 88% of the equilibrium value (17.7 mmol) determined after 60 min. The equilibrium molar ratio of adsorbed CO to the $AlCuCl_4$ supported to active carbon is 1.03; the amount of the supported $AlCuCl_4$ is 17.2 mmol.

After being subjected to a reduced pressure (6 mmHg) at 20°C for 10 min, the adsorbent was again contacted with 9:1 CO–N_2 mixture. The adsorbent showed a rapid adsorption and the equilibrium value of adsorbed CO was 8.8 mmol (● in Fig. 3(a)). The equilibrium value for the third adsorption by the adsorbent, which was subjected to a reduced pressure (6 mmHg) at 20°C for 10 min after the second adsorption, was

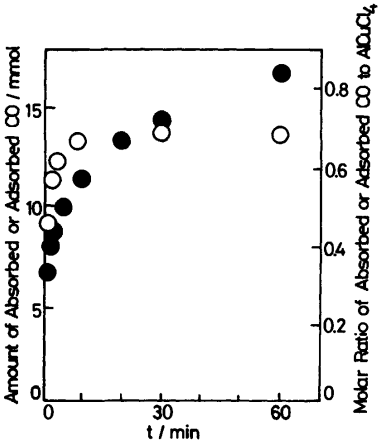

Fig. 4. Absorption or adsorption of CO by a toluene solution of $AlCuCl_4$ (○) or by a solid of $AlCuCl_4$ (●) at 20°C under 1 atm: the initial partial pressure of CO for the absorption by the toluene solution was 0.8 atm, whereas that for the adsorption by the solid was 0.9 atm; the amount of $AlCuCl_4$, 20.0 mmol.

also 8.8 mmol. The CO adsorption-desorption cycle, composed of the adsorption of 8.8 mmol of CO at 760 mmHg and the desorption of almost the identical amount of CO at 6 mmHg, was repeated five (the maximum number examined) times without measurable deterioration.

The adsorbed CO was also desorbed by elevating temperature (Fig. 3(b)). The active carbon-supported $AlCuCl_4$, which was prepared separately, adsorbed 17.7 mmol of CO on the first contact with 9:1 CO–N_2 mixture at 20°C (the open circles). On the elevation of temperature from 20 to 100°C under 1 atm, the adsorbent rapidly desorbed 11.0 mmol of CO. In the following adsorption, the equilibrium value of the adsorbed CO was 11.0 mmol (the closed circles in Fig. 3(b)). The cycle involving the adsorption of 11.0 mmol of CO at 20°C, followed by the desorption of 11.0 mmol of CO at 100°C, was repeated five times without deterioration.

Table 2 shows the dependence of the amount of CO adsorbed by the active carbon-supported $AlCuCl_4$ on the partial pressure of CO in CO–N_2 mixtures. The molar ratio of the adsorbed CO to $AlCuCl_4$, supported to active carbon, decreases with decreasing partial

Table 3. Adsorbing Capacities of the CO Adsorbents and Absorbent[a)]

Adsorbent or absorbent	CO adsorbed in 60 min	
	Amount/mmol	Molar ratio to $AlCuCl_4$
Active carbon-supported $AlCuCl_4$[b,c)]	17.7	1.03
Solid of $AlCuCl_4$[b)]	14.6[d)]	0.85
Toluene solution of $AlCuCl_4$[b)]	14.4	0.84
Original active carbon[c)]	3.3[e)]	—

a) At 20°C; initial volume of gas mixture 1500 cm^3; initial partial pressures of CO and N_2, respectively, were 0.9 and 0.1 atm. b) $AlCuCl_4$, 17.2 mmol. c) Active carbon, 10 g. d) This value was estimated from the result in Fig. 4, using the fact that the amount of adsorbed CO was proportional to the amount of $AlCuCl_4$. e) The measurement was carried out using helium, in place of nitrogen, as balance, since the magnitudes of adsorptions of CO and N_2 to active carbon were comparable with each other, and adsorption of helium was negligibly small (Table 5).

pressure from 1.05 at 760 mmHg to 0.13 at 152 mmHg.

For the purpose of comparison, the time course of the CO absorption by a toluene solution of $AlCuCl_4$ (○) and the time course of the adsorption by a solid of $AlCuCl_4$ (●) without active carbon are depicted in Fig. 4. The toluene solution of 20.0 mmol of $AlCuCl_4$ in 20 cm^3 of toluene rapidly absorbs CO from 8:2 CO–N_2 mixture. The equilibrium amount of absorbed CO, determined after 60 min, is 14.0 mmol ($CO/AlCuCl_4$= 0.70). The solid of 20.0 mmol of $AlCuCl_4$ also adsorbs CO on the contact with 9:1 CO–N_2 mixture. The rate of adsorption, however, is much smaller than the value for the active carbon-supported $AlCuCl_4$ adsorbent, and the adsorption does not attain an equilibrium even after 6 h.

Table 3 lists the amounts of CO adsorbed or absorbed for 60 min by the three types of the adsorbents and absorbent as well as the value for the original active carbon. The active carbon-supported $AlCuCl_4$ adsorbs CO about equimolar to $AlCuCl_4$, and shows larger adsorbing capacity either than the toluene solution of $AlCuCl_4$ or than the solid of $AlCuCl_4$. The CO adsorbing ability of the original active carbon itself is small under these conditions.

Desorption of Adsorbed CO under Various Desorption Conditions. The effect of desorption conditions on the degree of desorption of adsorbed CO from the adsorbent is shown in Table 4. Here, the degrees of desorption under the specified conditions are expressed in terms of the ratios of the amounts of desorbed CO to the capacities of the adsorbent (the amounts of CO adsorbed in the first adsorption by a virgin adsorbent). The first adsorption and the second one by the adsorbent, which was subjected to the specified desorption conditions after the first adsorption, were carried out, keeping the adsorption conditions constant: 20°C and the initial CO pressure 0.9 atm. The amount of the CO desorbed under the desorption conditions was evaluated from the amount of CO adsorbed in the second adsorption.

When the desorption conditions are 20°C, 6.0 mmHg, the amount of adsorbed CO in the second and later adsorptions is 8.8 mmol, as depicted in Fig. 3(a). Thus, 50% of CO with respect to the amount (17.7 mmol) adsorbed in the first adsorption is desorbed under the above conditions.

Table 4. Dependence of the Amount of Desorbed CO on the Desorption Conditions for the Active Carbon-Supported $AlCuCl_4$[a)]

Desorption conditions		Ratio of amount of desorbed CO to adsorbing capacity[b)]
T/°C	Pressure/mmHg	
20	6.0	0.50
20	0.4	0.61
100	0.4	0.91
180	0.4	0.99
180	760.0	0.72
100	760.0	0.62

a) $AlCuCl_4$, 17.2 mmol; active carbon, 10 g. b) The ratio of the amount of desorbed CO under specified conditions to the amount of CO adsorbed in the first adsorption by a virgin adsorbent.

Table 5. Adsorbing Capacities of the Active Carbon-Supported $AlCuCl_4$ and the Original Active Carbon for Various Kinds of Gases[a)]

Gas	Amount of gas adsorbed by 1 g of Adsorbent/$cm^3\,g^{-1}$	
	Active carbon-supported $AlCuCl_4$	Original active carbon
H_2	0.0	0.0
He	0.0	0.0
N_2	0.8	7.2
Ar	0.9	6.3
CH_4	4.2	21.5
CO	24.1	9.5

a) Gas pressure 1 atm, 20°C.

Almost all of the adsorbed CO is desorbed at a reduced pressure and a high temperature: 0.4 mmHg and 180°C. When these desorption conditions are used, 17.7 mmol of CO is separated by each of adsorption-desorption cycles.

Selectivity of CO Adsorption for the Active Carbon-Supported $AlCuCl_4$. Table 5 shows adsorbing capacities on various gases for the active carbon-supported $AlCuCl_4$. The adsorbent exhibits no measurable ad-

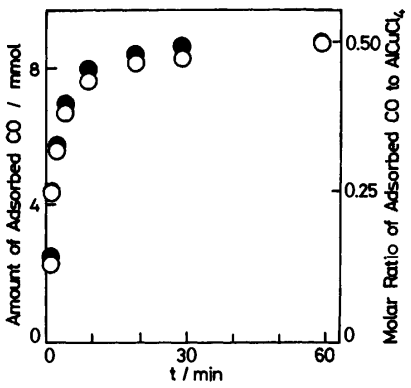

Fig. 5. CO adsorbing capacity of the active carbon-supported $AlCuCl_4$ before (○) and after (●) the contact of the adsorbent with 5000 cm^3 nitrogen gas containing 2.0 mmol of water (water content 9000 ppm) for 10 min: The adsorptions of CO were carried out by the contacts with 9:1 $CO-N_2$ gas mixtures at 20 °C, 1 atm; the desorptions of CO were achieved at 20 °C, 6 mmHg for 10 min.

sorption of hydrogen or helium at 1 atm, 20 °C. Adsorption of nitrogen or argon is not significant either. The amount of methane adsorbed is only 17% of the value of CO.

In contrast, the amount of methane adsorbed by the original active carbon is more than two times as large as the value of CO. The active carbon also shows considerable adsorptions on nitrogen and argon, although the adsorptions of hydrogen and helium are minimal.

Water-Resistivity of the Active Carbon-Supported $AlCuCl_4$. The open circles in Fig. 5 exhibit the adsorption of CO by the active carbon-supported $AlCuCl_4$, which has adsorbed 17.7 mmol of CO on the first contact with 9:1 $CO-N_2$ mixture (see Fig. 3), and then has been subjected to a reduced pressure (6 mmHg) at 20 °C for 10 min. Without contacts of the adsorbent with water vapor, almost identical time courses were obtained for repeated CO adsorptions (Fig. 3(a)).

The closed circles in Fig. 5, which are for the adsorption after the contact of the adsorbent with nitrogen containing 2.0 mmol of water (water content 9000 ppm) for 10 min, almost perfectly superimpose the open circles for the adsorption prior to the contact. Thus, water vapor has no measurable effects on the activity of the active carbon-supported $AlCuCl_4$ with respect to both the rate of CO adsorption and the adsorbed amount. Even after the contacts of the adsorbent with nitrogen gas containing 2.0 mmol of water, prepared separately for each contact, are repeated five times (total period of the contact is 50 min and total amount of water is 10 mmol), both the rate of adsorption and the equilibrium value of adsorbed CO are also identical with the values prior to the contacts (Table 6).

In contrast, the CO adsorbing activity of solid of $AlCuCl_4$ without active carbon largely decreases on the contacts with water vapor, as also shown in Table 6.

Table 6. Water Resistivities of the Adsorbents[a)]

Number of repeated contacts of the adsorbents with water vapor	Relative adsorbing capacity[b)]	
	Active carbon-supported $AlCuCl_4$[c)]	$AlCuCl_4$ solid[d)]
0	100	100

Discussion

Preparation of Active Carbon-Supported $AlCuCl_4$. Significant decrease (360 $m^2 g^{-1}$) of the BET surface area of active carbon on the formation of the adsorbent from active carbon and $AlCuCl_4$ (Table 1) shows that the double salt is supported on the surface of the pores in the active carbon. $AlCuCl_4$ largely exists in the pores with radii smaller than 15 Å, as clearly seen by the decrease of number of these small pores on the formation of the adsorbent (Fig. 2). Thus, the double salts in the adsorbents are mostly in their monomeric or dimeric forms. A possibility of formation of large aggregates of the salts is ruled out, since they are too large to be accommodated in these small pores.

Rough estimation, based on the decrease (360 $m^2 g^{-1}$) of the BET surface area and the amount (17.2 mmol) of $AlCuCl_4$ supported to 10 g of active carbon, indicates that one molecule of the double salt occupies around 35 $Å^2$ of the surface area of the active carbon. The double salts are separated from each other by about 6 Å on the surface.

Presence of $AlCuCl_4$ in such a close proximity without mutual aggregation is attributable to specific and strong interactions between the double salt and the condensed aromatic rings of active carbon. $AlCuCl_4$ forms charge-transfer complexes with various aromatic compounds such as benzene,[15] toluene,[16] and mesitylene,[16] and thus easily dissolves in these aromatic solvents.

Adsorption and Desorption of CO by the Active Carbon-Supported $AlCuCl_4$. The adsorption of CO by the adsorbent is ascribed to complex formation of $AlCuCl_4$ with CO. Active carbon alone exhibits a small adsorption of CO (Table 3). Physical adsorption of CO by the adsorbent is ruled out, since the adsorptions of gases other than CO, e.g. methane, nitrogen, and argon, by the present adsorbent are, in con-

trast with promotion of CO adsorption, less efficient than the adsorptions by the original active carbon (Table 5).

High selectivity of CO adsorption for the present adsorbent (Table 5) is attributable to effective coverage of the surface of active carbon by $AlCuCl_4$. CO is sufficiently adsorbed by coordination to the double salt (vide infra), whereas physical adsorptions of other gases by the active carbon is suppressed by the $AlCuCl_4$.

The rate of adsorption of CO by the present adsorbent is almost identical with the value for the toluene solution of $AlCuCl_4$ (Figs. 3 and 4). This is ascribed to high and virtually molecular dispersion of $AlCuCl_4$ on the surface of the active carbon. In addition, CO can effectively diffuse to the double metal salt through the pores in the active carbon. The adsorption by solid $AlCuCl_4$ (Fig. 4), which has not a high dispersion, is much slower than that by the active carbon-supported $AlCuCl_4$.

Larger amount of the adsorbed CO for the active carbon-supported $AlCuCl_4$ (103 mol% with respect to $AlCuCl_4$: Table 3) than that (84 mol%) for the toluene solution of $AlCuCl_4$ is associated with absence of competition between CO and toluene in the complex formation with $AlCuCl_4$. On the CO absorption by the toluene solution, CO coordinates to $AlCuCl_4$ by replacing a toluene molecule which is originally complexing with the double salt.[16]

The adsorption of CO by the adsorbent takes place by the coordination of CO to the vacant coordination site at copper(I) ion in $AlCuCl_4$. The vacant coordination site is produced during the process of the preparation of the adsorbent. Here, $AlCuCl_4$, in which the copper(I) ion is complexing with toluene, is first supported on the surface of the active carbon, and then the toluene is removed by evaporation. By the coordination of CO to the vacant site, the copper(I) ion takes the most stable tetrahedral and four-coordinate state.[17]

Desorption of the adsorbed CO is accompanied by the structural change of the copper(I) ion from the stable four-coordinate state to less stable three-coordinate state. This process requires a considerable activation energy and thus rather severe conditions (180 °C, 0.4 mmHg) are required to desorb all the adsorbed CO during the desorption period 10 min employed in the present study (Table 4). The amount (50 mol% with respect to $AlCuCl_4$) of CO desorbed at 20 °C, 6 mmHg for 10 min (Table 4) is considerably smaller than the value (90 mol%) estimated for milder desorption conditions (20 °C, 152 mmHg) under the assumption that an equilibrium is attained in 10 min for desorption. If this assumption were valid, the desorbed amount at 20 °C, 152 mmHg should be the difference (90 mol%) between the amount (103 mol%) adsorbed at 20 °C, 684 mmHg (the CO partial pressure in 9:1 $CO-N_2$ mixture at 1 atm) and the value (13 mol%) adsorbed at 20 °C, 152 mmHg (see Table 2).

A prolonged desorption (3 h) at 20 °C, 6 mmHg increased the amount of desorbed CO from the value (50 mol%) for the 10 min desorption to 57 mol%.

With the present solid adsorbent, pressure-swing separation, which takes advantage of change in partial pressure of CO and is not possible with the use of liquid absorbents, is successfully carried out (Fig. 3 (a)) in addition to thermal-swing separation using change in temperature (Fig. 3 (b)). By use of adsorption-desorption cycles composed of the adsorption at 20 °C, 1 atm from 9:1 $CO-N_2$ mixture and the desorption at 20 °C, 6 mmHg, 8.8 mmol of CO is separated. Each of the cycles involving the adsorption at 20 °C, 1 atm and the desorption at 180 °C, 0.4 mmHg separates 17.7 mmol of CO (Table 4).

Water-Resistivity of Active Carbon-Supported $AlCuCl_4$. Stability of the present adsorbent against water vapor, clearly shown in Fig. 5 and Table 6, is attributable to protection of the double metal salt by active carbon, since the solid of $AlCuCl_4$ without active carbon is rapidly deactivated with water vapor (Table 6). Toluene solutions of $AlCuCl_4$ are also easily deactivated by water vapor.[5-8] In the present adsorbent, $AlCuCl_4$ is almost molecularly dispersed and is located in the micropores with radii smaller than 15 Å (Fig. 2). The inside of the micropores is rather hydrophobic, since the pores are surrounded by the walls of fused aromatic rings. Thus, $AlCuCl_4$ can be shielded from water vapor in the micropores. In addition, diffusion of water vapor to the inside of quite small micropores through hydrophobic pores should be less efficient, which is also favorable for the stability of the double metal salt.

The argument is consistent with the previous result[12] that cross-linked polystyrene-supported $AlCuCl_4$ is also a water-resistant CO adsorbent. There, $AlCuCl_4$ is located in the micropores of the polystyrene resin, and is protected by the hydrophobic aromatic rings.

Water-resistivity of the present adsorbent is quite important from the viewpoints of practical applications, since the sources of CO in industry are usually saturated with water. With this adsorbent, separation of CO from the gas mixtures containing water can be achieved without severe dehydration of the feed gases by pretreatments.

The authors would like to thank Dr. Toshio Osawa at the University of Tokyo for his assistance in the measurements of the BET surface area and pore size distribution.

Polymer-Protected Metal Complex for Gas Separation. II. Cross-Linked Polystyrene-Supported Aluminium Copper(I) Halide as Solid Carbon Monoxide Adsorbent

Hidefumi HIRAI,* Susumu HARA, and Makoto KOMIYAMA
Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received December 9, 1985)

Macroreticular (MR) type cross-linked polystyrene-supported aluminium copper(I) chloride is prepared by refluxing MR type polystyrene (divinylbenzene content 20%), aluminium chloride, and copper(I) chloride in benzene, toluene, carbon disulfide, or dichloromethane, followed by evaporation of the liquid phase. All the polystyrene-supported aluminium copper(I) chloride exhibit rapid and reversible adsorptions of carbon monoxide (CO). For the adsorbent prepared by using toluene as solvent, the equilibrium molar ratio of adsorbed CO to the charged copper(I) chloride is 0.83 at 20 °C under 1 atm (initial partial pressure of CO: 0.90 atm). Desorption of CO is carried out at 7 mmHg, 20 °C for 10 min. The equilibrium molar ratio of adsorbed CO to the charged copper(I) chloride in the second adsorption is 0.56. In the following adsorptions, the equilibrium molar ratios are virtually constant at 0.56. Usage of either gel type cross-linked polystyrenes or a linear polystyrene in place of the MR type cross-linked polystyrene results in CO adsorbents having poor abilities with respect to both adsorption rates and capacities. The adsorbing capacities of the CO adsorbents prepared from aluminium halide, copper(I) halide, and the MR type cross-linked polystyrene decrease as follows: $AlCl_3$-CuCl system > $AlBr_3$-CuBr system $\gg$ AlI_3-CuI system $\approx$ $AlCl_3$-CuI system $\approx$ AlI_3-CuCl system ≈ 0.

Carbon monoxide (CO), which is one of the important raw materials in chemical industry,[1] is usually obtained as gas mixtures.[2] Thus, separation of CO from gas mixtures is required for effective utilization of CO.

Previously,[3,4] the authors reported on CO absorbents composed of linear polystyrene, aluminium chloride ($AlCl_3$), copper(I) chloride (CuCl), and toluene. The absorbents reversibly absorbed CO under mild conditions, and were stable against water vapor due to protection of water-sensitive aluminium copper(I) chloride ($AlCuCl_4$), a double salt formed from $AlCl_3$ and CuCl, by the polystyrene. Separation of CO from gas mixtures containing water vapor was successfully achieved with the use of the absorbents.

In spite of many proposals on liquid CO absorbents,[2-5] informations on solid adsorbents of CO are rather scanty. Although Y zeolite-supported copper(I) ions adsorbed CO, the adsorption was so strong that the adsorbed CO was not sufficiently released even at 10^{-4} mmHg (1 mmHg=133.3 Pa).[6] A patent[7] claimed that copper(I) ions supported on zeolites having high SiO_2/Al_2O_3 molar ratios adsorbed CO. The equilibrium amount of CO adsorbed by 1 g of the adsorbent at 50 °C was 16 cm^3 (standard temperature and pressure), which was almost independent of partial pressure of CO at the partial pressure 100 mmHg or larger.

In preliminary communications,[8,9] the authors showed that the macroreticular (MR) type cross-linked polystyrene-supported $AlCuCl_4$ adsorbed and desorbed CO under mild conditions.

This paper describes the results of detailed studies on the MR type cross-linked polystyrene-supported $AlCuCl_4$. Dependences of CO adsorbing capacities of the adsorbents either on adsorbing temperature, on partial pressure of CO, or on the preparation solvent are described. The adsorbing and desorbing abilities of the adsorbents are compared with those for the adsorbents prepared by use of gel type cross-linked polystyrene or linear polystyrene in place of MR type cross-linked polystyrene. Furthermore, the adsorbing capacities of the adsorbents prepared from various aluminium halides, copper(I) halides, and MR type cross-linked polystyrene are shown.

Experimental

Materials. A macroreticular (MR) type cross-linked polystyrene (styrene-divinylbenzene (DVB) copolymer, divinylbenzene content 20%; 20—50 mesh; diameter, 296—740 μm; average pore diameter, 9 nm; surface area, 300 m^2/g)[10] was obtained from Bio-Rad Laboratories (Bio-Beads SM-2). A cross-linked (DVB 12%) gel type polystyrene (200—400 mesh; diameter, 37—74 μm) and a cross-linked (DVB 1%) gel type polystyrene (200—400 mesh; diameter, 37—74 μm) were purchased also from Bio-Rad Laboratories (Bio-Beads S-X12 and Bio-Beads S-X1, respectively). They were purified by stirring successively in the following solvents under the specified conditions: aqueous hydrochloric acid solution, 4 mol dm^{-3}, 55 °C, 2 h; aqueous sodium hydroxide solution, 2 mol dm^{-3}, 55 °C, 2 h; distilled water, 55 °C, 2 h; methanol, room temperature, 1 h; dichloromethane, room temperature, 1 h. The resins were dried in vacuo at 80 °C for 12 h.

Linear polystyrene, purchased from Wako Pure Chemical Co., was reprecipitated using the chloroform–methanol system and was dried in vacuo at 60 °C for 12 h. The number-averaged molecular weight and the weight-averaged molecular weight were 4.4×10^4 and 1.5×10^5, respectively, as determined by the gel permeation chromatography using columns of TSK-GEL, G5000H+G3000H, Toyo Soda Manufacturing Co.

Aluminium chloride (Kishida Chemical Co.) was purified by sublimation. Copper(I) chloride (Koso Chemical Co.) was reprecipitated from an aqueous concentrated hydrochloric

acid solution by the addition of distilled water, followed by washing successively with ethanol and diethyl ether, and then was dried overnight in vacuo at 100 °C. Aluminium bromide, copper(I) bromide, aluminium iodide, and copper(I) iodide were commercially obtained (guaranteed grades) and were used without further purification.

Carbon disulfide and dichloromethane were dried over diphosphorus pentaoxide and were distilled. Toluene and benzene were distilled after being dried over metallic sodium.

Carbon monoxide gas and nitrogen gas, which had purities of 99.95 and 99.999%, respectively, were passed through columns of molecular sieve 3A immediately before use.

Preparation of CO Adsorbents. Preparation of the solid CO adsorbent was carried out as follows. Aluminium halide, copper(I) halide, and the macroreticular type polystyrene resin were refluxed in various solvents under dry nitrogen for 4—6 h, during which the mixture was magnetically stirred. Then, the solvent was thoroughly removed from the mixture by evaporation at 4 mmHg for several hours. Evaporation temperature was gradually elevated from room temperature to 60 °C, as the evaporation proceeded.

Charged molar ratio of aluminium halide to copper(I) halide was 1.0 unless otherwise noted and the ratio of phenyl residue in the polystyrene resin to copper(I) halide was 1.2—2.0.

Adsorption and Desorption of CO. Adsorption of CO by the adsorbent (1), continuously stirred by use of a magnetic stirrer (3), from atmospheric CO or CO-N_2 mixtures (total pressure: 1 atm) was carried out under 1 atm, using the apparatus depicted in Fig. 1. The amount of adsorbed CO was determined by a gas burette (4) using liquid paraffin as leveling liquid (5). Adsorption from atmospheric CO was initiated by introduction of CO to a flask containing the adsorbent. The flask was evacuated to 7 mmHg prior to the introduction. In case of adsorption from CO-N_2 mixtures, the gas mixtures were made to flow over the adsorbent by use of a gas-circulating pump (6) for the first 10 min in the adsorption.

Desorption of CO from the adsorbent was carried out at 7 mmHg for 10 min at room temperature or prescribed temperatures.

Fourier Transfer Infrared (FT-IR) Spectroscopy. FT-IR spectra were taken at room temperature with a JEOL FT-IR model 10 spectrometer at various CO pressures. Specimen was prepared from 2.05 g (15.4 mmol) of $AlCl_3$, 1.52 g (15.4 mmol) of CuCl, and 3.35 g (30.7 mequiv in phenyl residue) of the macroreticular type cross-linked polystyrene by use of 10 cm^3 of carbon disulfide as solvent. The adsorbent was mixed with silica gel (Cab-O-Sil, Wako Pure Chemical Co.) after being thoroughly ground. The content of copper atom in disk was 2.5 wt%.

Results

Preparation of Macroreticular Type Polystyrene-Supported $AlCuCl_4$. When $AlCl_3$, CuCl, and the macroreticular type polystyrene resin (DVB 20%) were refluxed in toluene or benzene for 6 h, both the polystyrene beads and the liquid phase turned dark brown. Solid adsorbents were obtained as yellowish green beads by evaporating the solvents thoroughly at 4 mmHg from the mixtures.

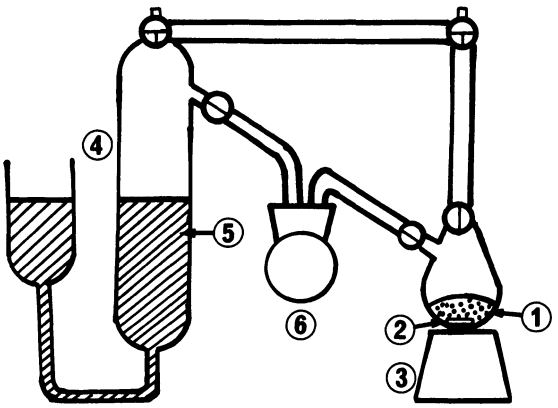

Fig. 1. Apparatus for measuring the amounts of carbon monoxide adsorbed by the adsorbents; 1: CO adsorbent, 2: rotor, 3: magnetic stirrer, 4: gas burette, 5: leveling liquid (liquid paraffin), 6: gas-circulating pump.

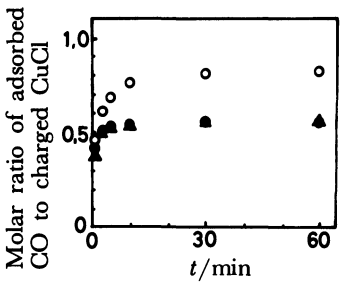

Fig. 2. Adsorption of carbon monoxide from 9:1 CO-N_2 mixture at 20 °C under 1 atm by the macroreticular (MR) type polystyrene-supported aluminium copper(I) chloride prepared by use of toluene as solvent: The first adsorption (○), the second adsorption (●), and the third adsorption (▲); the desorption of CO was carried out at 7 mmHg for 10 min; the adsorbent was prepared from 5.21 g (39.1 mmol) of $AlCl_3$, 3.87 g (39.1 mmol) of CuCl, and 7.04 g (64.6 mequiv in phenyl residue) of the MR type polystyrene with the use of 20 cm^3 of toluene; the initial volume of the gas mixture was 2000 cm^3 with initial pressures of CO and N_2, 0.9 and 0.1 atm, respectively.

On the refluxing of $AlCl_3$, CuCl, and the polystyrene resin in carbon disulfide or dichloromethane, however, only the polystyrene beads turned dark brown after refluxing. The liquid phase was almost transparent with quite a faint dark orange color. The adsorbents obtained after evaporation of the solvent were reddish brown beads.

Depositions of metal salts on the inside walls of the flasks, used for the preparation of the adsorbents, were hardly observed in any of these cases. These results show that almost all of the charged metal salts are incorporated to the adsorbents.

CO Adsorbing and Desorbing Abilities of Macroreticular Type Polystyrene-Supported $AlCuCl_4$. Figure 2 depicts the adsorption of CO at 20 °C from 9:1 CO-N_2 mixture (initial partial pressure of CO: 0.9 atm) under 1 atm by the adsorbent prepared from 5.21

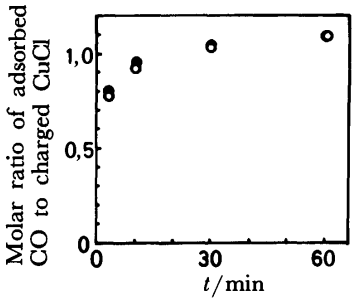

Fig. 3. Adsorption of carbon monoxide from atmospheric CO at 20°C under 1 atm by the macroreticular (MR) type polystyrene-supported aluminium copper(I) chloride prepared by use of toluene as solvent: The first adsorption (○), and the second adsorption (●); the desorption of CO was carried out at 7 mmHg, 90°C for 30 min after the first adsorption; the adsorbent was prepared from 2.75 g (20.6 mmol) of $AlCl_3$, 2.04 g (20.6 mmol) of CuCl, and 2.58 g (23.7 mequiv in phenyl residue) of the MR type polystyrene using 10 cm^3 of toluene.

g (39.1 mmol) of $AlCl_3$, 3.87 g (39.1 mmol) of CuCl, and 7.04 g (64.6 mequiv in phenyl residue) of the macroreticular type polystyrene resin with the use of 20 cm^3 of toluene. As shown by the open circles, the adsorbent rapidly adsorbs CO and the equilibrium molar ratio of the adsorbed CO to the charged CuCl is 0.83 (45 cm^3 (standard temperature and pressure) of CO per 1 g of the adsorbent).

Desorption of adsorbed CO is carried out at 7 mmHg, 20°C for 10 min. On the second contact with 9:1 CO–N_2 mixture, the adsorbent rapidly adsorbs CO and the equilibrium molar ratio of adsorbed CO to the charged CuCl is 0.56 (31 cm^3 (standard temperature and pressure) of CO per 1 g of the adsorbent; solid circles in Fig. 2).

The third adsorption of CO by the adsorbent, which is subjected to a reduced pressure (7 mmHg) at 20°C for 10 min after the second adsorption, from 9:1 CO–N_2 mixture is also rapid and the equilibrium molar ratio of adsorbed CO to the charged CuCl is 0.57 (solid triangles in Fig. 2). This molar ratio is identical with the value (0.56) in the second adsorption within experimental error.

The open circles in Fig. 3 depict CO adsorption by the adsorbent, prepared separately using toluene as solvent, from atmospheric CO at 20°C. The adsorption is rapid and the equilibrium molar ratio of adsorbed CO to the charged CuCl is 1.10 (69 cm^3 (standard temperature and pressure) of CO per 1 g of the adsorbent). The adsorbed CO is desorbed by heating the adsorbent at 90°C under 7 mmHg for 30 min. In the second adsorption, shown by the closed circles, the equilibrium molar ratio of adsorbed CO to the charged CuCl is 1.10, which is identical with the value for the first adsorption.

Effect of Preparation Solvent on CO Adsorbing Capacity of Macroreticular Type Polystyrene-Supported $AlCuCl_4$. Table 1 shows the equilibrium molar ratios of adsorbed CO to the charged CuCl for the polystyrene-supported $AlCuCl_4$ prepared by using various solvents. All the adsorbents, except for the one prepared by use of tetrachloromethane as solvent, adsorb CO around equimolar to the charged CuCl in the first adsorptions. The equilibrium amounts of the adsorbed CO in the second adsorptions are about one half to one third of the values in the first adsorptions. The desorptions are carried out at 7 mmHg, room temperature for 10 min.

Table 1. CO Adsorbing Capacities of the Macroreticular Type Polystyrene-Supported Aluminium Copper(I) Chloride Prepared by Use of Various Solvents[a)]

Preparation solvent	Molar ratio[b)]	
	1st[c)]	2nd[d)]
Toluene	1.05	0.55
Benzene	1.03	0.43
Carbon disulfide	1.07	0.54
Dichloromethane	1.11	0.35
Tetrachloromethane	0.55	0.23

a) Charged molar ratios of $AlCl_3$ and phenyl residue in the cross-linked polystyrene to CuCl are 1.0 and 1.2, respectively. b) Equilibrium molar ratios of adsorbed CO to the charged CuCl at room temperature under 1 atm of CO. c) The value in the first adsorption by a virgin adsorbent. d) The value in the second adsorption by the adsorbent which has been subjected to a reduced pressure (7 mmHg) for 10 min at room temperature after the first adsorption.

When the desorptions were achieved at 7 mmHg, 90°C for 30 min, the amount of adsorbed CO in the second adsorption for the adsorbent prepared by use of carbon disulfide as solvent was 67% of the value in the first adsorption.

On the usage of tetrachloromethane as solvent, liquid phase gradually turned black on refluxing and gray precipitates were formed. The adsorbent, obtained as black beads after evaporation, showed considerably smaller CO adsorbing capacity than the adsorbents prepared by use of toluene, benzene, carbon disulfide, and dichloromethane (Table 1).

Effects of Adsorbing Temperature and CO Partial Pressure on Adsorbing Capacity of Macroreticular Type Polystyrene-Supported $AlCuCl_4$. Open circles in Fig. 4 show the plot of the equilibrium molar ratio of adsorbed CO to the charged CuCl vs. adsorption temperature for the adsorbent prepared by using dichloromethane. Below 50°C, the molar ratio is larger than unity. The adsorbing capacity markedly decreases with increasing temperature above 70°C and the amount of adsorbed CO at 145°C is nearly zero.

Solid circles in Fig. 4 are for the second adsorptions by the adsorbent which desorbs CO at 7 mmHg for 10 min after the first adsorptions. The desorptions are carried out at the same temperatures as the first adsorptions are achieved. The amounts of CO adsorbed in the second adsorptions are almost identical with

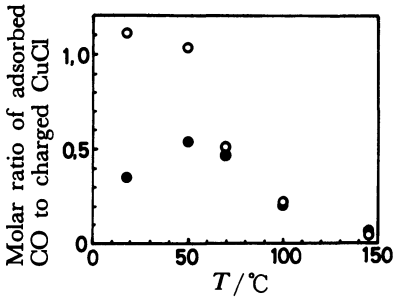

Fig. 4. Temperature dependence of the adsorbing capacity for the macroreticular (MR) type polystyrene-supported aluminium copper(I) chloride prepared by use of dichloromethane as solvent: The first adsorption at a prescribed temperature under 1 atm (○) and the second adsorption at the same temperature (●); prior to the second adsorption, the adsorbed CO was desorbed at 7 mmHg for 10 min at the temperature that was employed for the first and the second adsorptions; the charged molar ratios of $AlCl_3$ and phenyl residues in the polystyrene to CuCl were 1.0 and 1.2, respectively.

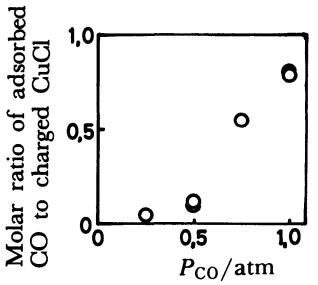

Fig. 5. Effect of partial pressure (P_{CO}) of carbon monoxide on the carbon monoxide adsorption at room temperature by the MR type polystyrene-supported aluminium copper(I) chloride prepared using dichloromethane as solvent: The adsorbent was subjected to a reduced pressure (7 mmHg) at 90 °C for 60 min after a CO adsorption in order to desorb virtually all of the adsorbed CO, and was then used for the following adsorption at a different partial pressure of carbon monoxide; the adsorbent was prepared from 1.35 g (10.1 mmol) of $AlCl_3$, 1.00 g (10.1 mmol) of CuCl, and 1.05 g (9.6 mequiv in phenyl residue) of the MR type polystyrene with the use of 10 cm^3 of dichloromethane.

those in the first adsorptions, when the desorption temperatures are 70 °C or higher. This result shows that almost all of the adsorbed CO is desorbed at 7 mmHg at a temperature higher than 70 °C.

Figure 5 depicts dependence of the equilibrium molar ratio of adsorbed CO to the charged CuCl on CO partial pressure. The amount of adsorbed CO gradually decreases with decreasing CO partial pressure. Decrease in CO partial pressure during CO adsorption was at most 0.02 atm.

CO Adsorbing Abilities of Adsorbents Prepared from Macroreticular Type Polystyrene, Various Aluminium Halides, and Various Copper(I) Halides. The adsorbent, prepared from 11.8 g (44.2 mmol) of aluminium bromide, 6.35 g (44.3 mmol) of copper(I) bromide, and 4.60 g (42.2 mequiv in phenyl residue) of the macroreticular (MR) type polystyrene resin using 20 cm^3 of toluene as solvent, adsorbs CO from 9:1 CO-N_2 mixture (partial pressure of CO: 0.9 atm) at 30 °C, as shown in Fig. 6. The equilibrium molar ratio of the adsorbed CO to the charged copper(I) ion is 0.38, which is smaller than that (0.83) of the MR type polystyrene-supported $AlCuCl_4$. The adsorption of CO by the MR type polystyrene-supported $AlCuBr_4$ is considerably slower than that by the MR type polystyrene-supported $AlCuCl_4$.

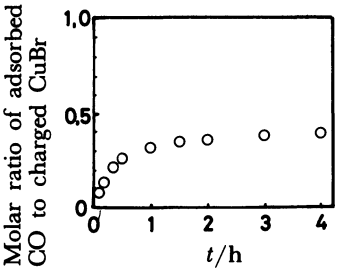

Fig. 6. Adsorption of carbon monoxide from 9:1 CO-N_2 mixture at 30 °C under 1 atm by the macroreticular (MR) type polystyrene-supported aluminium copper(I) bromide prepared by use of toluene as solvent: The adsorbent was prepared from 11.80 g (44.2 mmol) of $AlBr_3$, 6.35 g (44.3 mmol) of CuBr, and 4.60 g (42.2 mequiv in phenyl residue) of the MR type polystyrene using 20 cm^3 of toluene.

The adsorbent, prepared from aluminium iodide, copper(I) iodide, and the MR type polystyrene resin using carbon disulfide as solvent, showed quite a small capacity of CO adsorption : The molar ratio of the CO adsorbed in 3 h to the charged copper(I) iodide was 0.01. Either the adsorbent prepared from aluminium iodide, copper(I) chloride, and the resin or the one from aluminium chloride, copper(I) iodide, and the resin exhibited no measurable CO adsorption.

FT-IR Spectra of CO Adsorbed by Macroreticular Type Cross-Linked Polystyrene-Supported $AlCuCl_4$. A peak appeared at 2121 cm^{-1} on the contact of the adsorbent with 20 mmHg of CO (Fig. 7 (a)). The peak completely disappeared when CO was pumped off from the adsorbent at 10^{-4} mmHg, as shown in Fig. 7 (b). The height of the peak increased with increasing pressure of CO: (d, 760 mmHg)>(c, 300 mmHg)>(a, 20 mmHg)>(b, 10^{-4} mmHg)=0. This signal is definitely attributable to stretching vibration of CO, which is adsorbed by the adsorbent.

The bands in the 1600—2050 cm^{-1} region are assignable to the vibrations for the MR type polystyrene backbone.

Effect of Molar Ratio of $AlCl_3$ to CuCl on CO Adsorbing Ability. The CO adsorbent, prepared as white beads from CuCl and the macroreticular type polystyrene resin in the absence of $AlCl_3$ using carbon

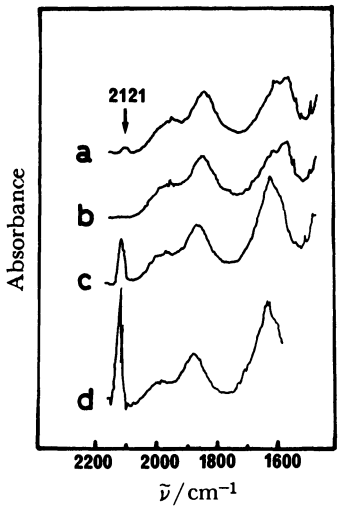

Fig. 7. Partial FT-IR spectra of the macroreticular type polystyrene-supported aluminium copper(I) chloride at various partial pressures of CO: Partial pressures of CO were 20 mmHg (a), 10^{-4} mmHg (b), 300 mmHg (c), and 760 mmHg (d); the spectra were measured in the order of a, b, c, and d.

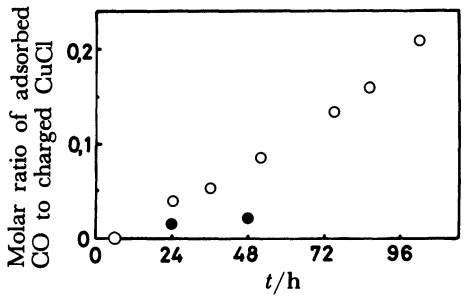

Fig. 8. Adsorption of carbon monoxide at room temperature under 1 atm by the macroreticular (MR) type polystyrene-supported copper(I) chloride prepared in the absence of aluminium chloride by use of carbon disulfide (○) or concentrated hydrochloric acid solution (●) as solvent: The adsorbents were prepared from 2.00 g (20.2 mmol) of CuCl and 2.58 g (23.7 mequiv in phenyl residue) of the MR type polystyrene, using 13 cm^3 of carbon disulfide and 40 cm^3 of concentrated hydrochloric acid solution, respectively, as solvents.

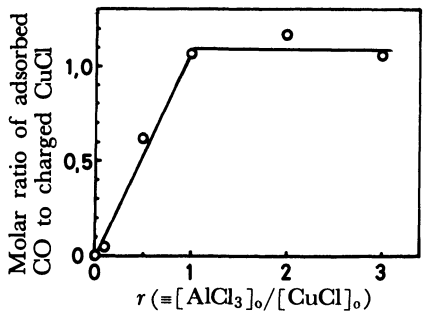

Fig. 9. Plot of the molar ratio of adsorbed carbon monoxide to the charged copper(I) chloride vs. the charged molar ratio (r) of AlCl$_3$ to CuCl for the macroreticular (MR) type polystyrene-supported AlCuCl$_4$: The adsorption at 25 °C under 1 atm for 60 min by the adsorbent prepared from the MR type polystyrene, AlCl$_3$, and CuCl using carbon disulfide; the charged molar ratio of phenyl residue in the polystyrene to CuCl was 1.2.

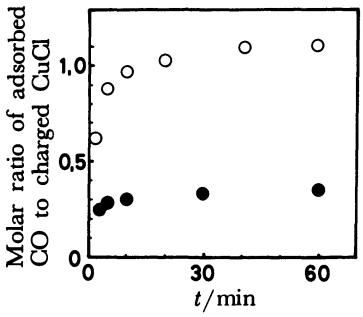

Fig. 10. Adsorption of carbon monoxide at 18 °C under 1 atm by the adsorbent prepared from the macroreticular (MR) type (DVB 20%) polystyrene, AlCl$_3$, and CuCl by use of dichloromethane as solvent: The first adsorption (○) and the second adsorption (●); the desorption of CO was carried out at 18 °C for 10 min under 7 mmHg after the first adsorption; the adsorbent was prepared from 2.47 g (18.5 mmol) of AlCl$_3$, 1.83 g (18.5 mmol) of CuCl, and 2.31 g (21.2 mequiv in phenyl residue) of the MR type polystyrene with the use of 10 cm^3 of dichloromethane.

disulfide (open circles) or concentrated hydrochloric acid (solid circles) as solvent, exhibited very small adsorbing ability (Fig. 8). The molar ratios of the CO adsorbed in 24 h to the charged CuCl were 0.04 and 0.02, respectively.

Figure 9 shows the plot of the molar ratio of the adsorbed CO to the charged CuCl as a function of the charged molar ratio (r) of AlCl$_3$ to CuCl for the adsorbents composed of AlCl$_3$, CuCl, and the macroreticular type polystyrene resin. Here, the charged amount of AlCl$_3$ is changed, keeping the amounts of CuCl and the polystyrene resin constant. The amount of adsorbed CO proportionally increases with increasing ratio r in the range of r value from 0.0 to 1.0. At the r value larger than 1.0, however, the amount is almost independent of r.

Adsorbing Abilities of CO Adsorbents Prepared from AlCl$_3$, CuCl, and Various Polystyrenes. Figure 10 depicts the adsorption of CO by the reddish brown adsorbent prepared from AlCl$_3$, CuCl, and the macroreticular (MR) type polystyrene by use of dichloromethane as solvent.

Yellowish brown beads were obtained as CO adsorbents, when AlCl$_3$, CuCl, and gel type polystyrene resins (divinylbenzene (DVB) contents; 1 and 12%) were refluxed in dichloromethane for 6 h and then the liquid phase was removed by evaporation. Figures 11 and 12 show the adsorptions of CO by these adsorbents. The adsorptions are much slower than that (Fig. 10) for the adsorbent prepared from the macroreticular (MR) type polystyrene resin as support.

Table 2. CO Adsorbing Capacities of Adsorbents Prepared from Various Types of Polystyrenes, $AlCl_3$, and CuCl[a)]

Polystyrene		Preparation solvent	Molar ratio of adsorbed CO to charged CuCl[b)]	
Type	DVB content / %		at 10 min	at 60 min
MR	20	Carbon disulfide	0.99	1.07
Gel	1		0.60	0.77
Gel	12		0.55	0.64
None	—		0.63	0.79
MR	20	Toluene	0.92	1.05
Gel	1		0.30	0.71
Gel	12		0.58	0.76
None	—		0.44	0.76
MR	20	Dichloromethane	0.97	1.11
Gel	1		0.52	0.64
Gel	12		0.51	0.63
Linear	0		0.02	0.02
None	—		0.66	0.78

a) Charged molar ratios of $AlCl_3$ and phenyl residue in polystyrene to CuCl are 1.0 and 1.2, respectively. b) The first adsorption of CO by a virgin adsorbent at room temperature under 1 atm.

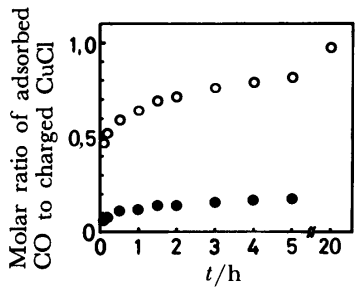

Fig. 11. Adsorption of carbon monoxide at 25°C under 1 atm by the adsorbent prepared from the gel type (DVB 1%) polystyrene, $AlCl_3$, and CuCl by use of dichloromethane as solvent: The first adsorption (○) and the second adsorption (●); the desorption of CO was carried out at 25°C for 10 min under 7 mmHg after the first adsorption; the adsorbent was prepared from 3.96 g (29.7 mmol) of $AlCl_3$, 2.94 g (29.7 mmol) of CuCl, and 3.71 g (35.5 mequiv in phenyl residue) of the gel type (DVB 1%) polystyrene with the use of 40 cm^3 of dichloromethane.

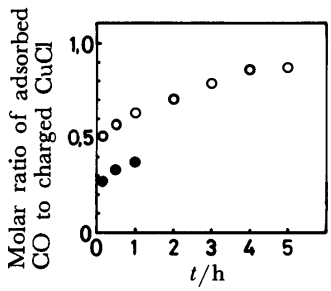

Fig. 12. Adsorption of carbon monoxide at 25°C under 1 atm by the adsorbent prepared from the gel type (DVB 12%) polystyrene, $AlCl_3$, and CuCl by use of dichloromethane as solvent: The first adsorption (○) and the second adsorption (●); the desorption of CO was carried out at 25°C for 10 min under 7 mmHg after the first adsorption; the adsorbent was prepared from 3.50 g (26.3 mmol) of $AlCl_3$, 2.60 g (26.3 mmol) of CuCl, and 3.28 g (30.9 mequiv in phenyl residue) of the gel type (DVB 12%) polystyrene with the use of 20 cm^3 of dichloromethane.

On the refluxing of linear polystyrene, $AlCl_3$, and CuCl in dichloromethane, dark orange precipitates were formed under a yellow solution after refluxing. On the evaporation of dichloromethane, dark yellow aggregates were produced. The aggregates, however, did not show measurable adsorption of CO.

When $AlCl_3$ and CuCl were refluxed in dichloromethane in the absence of polystyrene and the liquid phase was evaporated, solid of $AlCuCl_4$ was obtained as a dark yellowish green powder. The solid without polystyrene support showed only a slow adsorption of CO (Fig. 13).

Table 2 lists the molar ratios of the CO adsorbed in 10 and 60 min to the charged CuCl for the adsorbents prepared from various types of polystyrenes. All the molar ratios for the MR type polystyrene-supported $AlCuCl_4$, prepared by use of either carbon disulfide, toluene, or dichloromethane, are significantly larger than the corresponding values both for the adsorbents prepared from gel type polystyrenes or linear polystyrene and for the adsorbents prepared in the absence of polystyrene. The adsorptions by the MR type polystyrene-supported $AlCuCl_4$ are much faster than those by the other adsorbents. Here, the rates of adsorption are evaluated from the ratio of the value at 10 min to that at 60 min.

A film, prepared by evaporation of the solvent from a toluene solution of linear polystyrene-protected

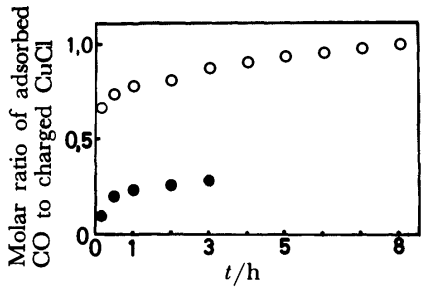

Fig. 13. Adsorption of carbon monoxide at 25 °C under 1 atm by the adsorbent prepared from $AlCl_3$ and CuCl in the absence of polystyrene by use of dichloromethane as solvent: The first adsorption (○) and the second adsorption (●); the desorption of CO was carried out at 25 °C for 10 min under 7 mmHg after the first adsorption; the adsorbent was prepared from 3.32 g (24.9 mmol) of $AlCl_3$ and 2.46 g (24.9 mmol) of CuCl with the use of 15 cm^3 of dichloromethane.

$AlCuCl_4$, did not adsorb CO.

Discussion

Preparation of CO Adsorbents. Carbon disulfide and dichloromethane are good solvents for macroreticular (MR) type polystyrene resin, whereas they are poor solvents for $AlCuCl_4$. When $AlCl_3$, CuCl, and the MR type polystyrene resin are refluxed in these solvents, the metal salts are effectively incorporated into the resin during refluxing. Thus, almost transparent liquid phase, which does not contain the metal salts any more, is obtained after refluxing, prior to evaporation of the liquid phase. $AlCuCl_4$ promptly penetrates into the polystyrene beads, since it favorably interacts with aromatic rings of the polystyrene due to formation of molecular complexes. $AlCuCl_4$ forms molecular complexes with various aromatic compounds such as benzene,[11,12] toluene,[12] and mesitylene.[12] The color of the adsorbents, reddish brown, is in accord with the position of the charge transfer absorption band (λ_{max}: 460 nm)[13] for the molecular complex between $AlCuCl_4$ and linear polystyrene in toluene solutions.

On the usage of toluene or benzene as preparation solvent, however, both the polystyrene beads and the solution part were colored after refluxing. Here, a considerable portion of the $AlCuCl_4$ remains in the liquid phase and only the rest penetrates into the polystyrene resin, since both toluene and benzene are quite good solvents for $AlCuCl_4$. On evaporation of the solvents, the $AlCuCl_4$ in the liquid phase deposits at the surface of the beads.

These arguments are confirmed by the results of a scanning electron microscopy and an energy dispersive X-ray microanalysis.[14,15] For the polystyrene-supported $AlCuCl_4$, prepared by use of carbon disulfide as solvent, $AlCuCl_4$ uniformly distributes in the beads of the adsorbent. For the polystyrene-supported $AlCuCl_4$ prepared with toluene, however, distribution of the double salt in the beads is not uniform and considerable amounts of $AlCuCl_4$ are located on the surface of the beads.

In the present adsorbents with the charged molar ratio unity of $AlCl_3$ to CuCl, most of the charged CuCl and $AlCl_3$ form a double salt $AlCuCl_4$. If only small part of the charged metal salts were forming $AlCuCl_4$ and large part were present as the single salts, the adsorbing capacity at the charged molar ratio 1.0 should be significantly smaller than the values at the charged molar ratios larger than 1.0, due to smaller amount of $AlCuCl_4$, the active species for adsorption (vide infra). Obviously, it is not the case (see Fig. 9).

Adsorption of CO. The plot of the adsorbing capacity vs. the charged molar ratio (r) of $AlCl_3$ to CuCl (Fig. 9), which involves linear increase of the capacity with increasing r below r=1 and virtually constant capacity irrespective of r above r=1, shows that the active component in the polystyrene-supported $AlCuCl_4$ is the double salt $AlCuCl_4$, composed of CuCl and $AlCl_3$ in a molar ratio 1:1. On the CO adsorption by the adsorbent, CO forms a complex with $AlCuCl_4$, where CO coordinates to the copper(I) ion.

Terminal coordination of CO to $AlCuCl_4$ in the polystyrene-supported $AlCuCl_4$ is supported by the fact that the frequency (2121 cm^{-1}) of the stretching vibration of the adsorbed CO (Fig. 7) is smaller than the value (2143 cm^{-1}) for free CO.[16] This decrease in frequency is mainly attributable to back donation from the copper(I) ion in $AlCuCl_4$ to the CO, which decreases bond order of the C–O bond. The frequency for the CO adsorbed by the present adsorbent is slightly smaller than the value (2135 cm^{-1}) for the CO absorbed by toluene solution of linear polystyrene-protected $AlCuCl_4$.[4]

Formation of a bridging CO from CO and two $AlCuCl_4$ molecules in the adsorbents is ruled out by the stretching frequency (2121 cm^{-1}) of the adsorbed CO. Bridging CO should exhibit stretching vibration mode around 1800 cm^{-1}.[16]

In the macroreticular (MR) type polystyrene-supported $AlCuCl_4$, high dispersion of $AlCuCl_4$ in the beads of the polystyrene, due to formation of molecular complexes of the double salt with the aromatic rings, promotes adsorption of CO. In the absence of $AlCl_3$, however, dispersion of CuCl in the polystyrene beads is not sufficient, resulting in an adsorbent with poor ability (Fig. 8). Furthermore, effective adsorption of CO by the MR type polystyrene-supported $AlCuCl_4$ is associated with decrease of electron density on the copper(I) ion by the formation of the double salt. The decrease of electron density enhances electron donation from CO to the copper(I) ion. On the complex formation of CO with $AlCuCl_4$, contribution of donation from CO to the copper(I) ion is larger than that of back donation from the ion to CO.[4]

The amounts (103—111 mol% with respect to the charged CuCl: Table 1) of CO adsorbed by the macro-

reticular type polystyrene-supported $AlCuCl_4$, prepared using benzene, toluene, carbon disulfide, or dichloromethane, are larger than the amount (85 mol%) of CO absorbed by toluene solution of linear polystyrene-protected $AlCuCl_4$.[4] This is ascribed to absence of competition between CO and toluene in the coordination to $AlCuCl_4$ for the solid adsorbents. In the CO absorption by the toluene solutions, CO coordinates to $AlCuCl_4$ by replacing a toluene molecule which originally coordinates to the $AlCuCl_4$.[12]

The macroreticular type polystyrene-supported $AlCuCl_4$ prepared using carbon disulfide adsorbs 67 cm^3 (standard temperature and pressure) of CO per 1 g of the adsorbent under 1 atm of CO at 25 °C. When the cycles involving adsorption of CO at 760 mmHg, 25 °C and desorption at 7 mmHg, 25 °C are repeated using the adsorbent, 34 cm^3 (standard temperature and pressure) of CO is separated for each of the cycles per 1 g of the adsorbent.

The order in the adsorbing capacities of various adsorbents, prepared from the macroreticular type cross-linked polystyrene, aluminium halides, and copper(I) halides, is as follows: $AlCl_3$–CuCl system > $AlBr_3$–CuBr system $\gg$ AlI_3–CuI system ≈ 0. This order is identical with that in the absorbing capacities for toluene solutions of linear polystyrene-protected aluminium copper(I) halide.[4]

Effect of Polystyrene Support on CO Adsorbing and Desorbing Abilities. Efficient adsorption and desorption of CO for the macroreticular (MR) type polystyrene-supported $AlCuCl_4$ (Figs. 2, 3, and 10 and Table 2) are attributable to the presence of macroporosity and microporosity in the MR type resin.[17] Through the porosities, $AlCuCl_4$ is effectively introduced into the polystyrene beads in preparation of the adsorbent. The porosities are also important for prompt diffusion of CO either to the metal salt on CO adsorption or from the metal salt on CO desorption. Furthermore, $AlCuCl_4$ is highly dispersed in the adsorbent due to large surface area (300 m^2/g) of the MR type polystyrene, providing sufficient contact of the double salt with CO.

These arguments are confirmed by quite slow adsorptions of the gel type polystyrene-supported $AlCuCl_4$ (Figs. 11 and 12). Here, $AlCuCl_4$ is poorly dispersed in the gel type polystyrene beads having so small surface area. CO can not promptly diffuse to the $AlCuCl_4$ in the adsorbent due to absence of porosity, since porosity of the gel type resin exists only in swollen states in good solvents.[17,18] Absence of porosity is also responsible for inefficient desorption of adsorbed CO.

Either the adsorbent, prepared from the linear polystyrene, $AlCl_3$, and CuCl or the film of linear polystyrene–$AlCuCl_4$ complex, prepared by evaporating toluene solution of linear polystyrene-protected $AlCuCl_4$,[3,4] which has no porosity, exhibits no measurable adsorbing capacity. The CO adsorption by $AlCuCl_4$ solid without polystyrene (Fig. 13) is much slower than that by the MR type polystyrene-supported $AlCuCl_4$ (Fig. 10).

In conclusion, usage of macroreticular type cross-linked polystyrene as support is essential for the preparation of CO adsorbents having large abilities both in adsorption and desorption.

The authors wish to express their thanks to Professor Makoto Misono and Dr. Toshio Okuhara at the University of Tokyo for their kind assistance in the FT-IR spectroscopy.

Study of Short Hydrogen Bonds. I. Structures of 4-Methylpiperidinium Hydrogen Bis(*p*-methylbenzoate) and Piperidinium Hydrogen Bis(*p*-methylbenzoate)

Shintaro MISAKI, Setsuo KASHINO,* and Masao HAISA
Department of Chemistry, Faculty of Science, Okayama University, Tsushima, Okayama 700
(Received October 17, 1985)

The crystal structures of 4-methylpiperidinium hydrogen bis(*p*-methylbenzoate) **1** and piperidinium hydrogen bis(*p*-methylbenzoate) **2** have been determined by X-ray diffraction method. Crystal data: **1**, monoclinic, $P2_1/n$ (No. 14), $a=19.260(2)$, $b=8.0061(5)$, $c=14.065(1)$ Å, $\beta=94.391(7)°$, $V=2162.5(3)$ Å^3, $Z=4$, $D_x=1.141$ g cm^{-3}; **2**, orthorhombic, *Pcan* (No. 60), $a=10.292(1)$, $b=25.248(4)$, $c=7.763(2)$ Å, $V=2017.2(5)$ Å^3, $Z=4$, $D_x=1.177$ g cm^{-3}. Final R values for **1** and **2** are 0.088 and 0.065 for 3446 and 1510 unique reflections, respectively. In both crystals the piperidinium cations and the hydrogen bis(benzoate) anions are held together by two kinds of N-H···O hydrogen bonds. The structure of **2** is disordered around a two-fold axis. Two benzoate residues in the anions are linked by the very short O-H···O hydrogen bonds; in **1** asymmetric [O···O 2.505(3), O-H 1.07(5), H···O 1.48(5) Å, O-H···O 158(5)°]; in **2** crystallographically symmetric [O···O related by the two-fold axis 2.473(4), O···H 1.25(5) Å, O···H···O 163(5)°]. The short hydrogen bonds in hydrogen bis(carboxylate) anions are discussed with reference to the crystal structures of **1** and **2**.

Very short hydrogen bonds with O···O distances between 2.4 and 2.5 Å are of interest in connection with the nature of hydrogen bonding.[1] In general, hydrogen bis(carboxylate) anions tend to form the very short hydrogen bonds in the crystals.[1-29] In many cases the anions have crystallographic symmetry $\bar{1}$ or 2,[1-19] but it is difficult to determine whether the hydrogen atoms participating in the hydrogen bonds are situated at the midpoint of the two oxygen atoms or not, because either ordered or disordered structure involving the hydrogen atoms makes possible to account for the observations. The genuine symmetry has been proposed for some crystallographically symmetric hydrogen bonds,[7,9,13] but the range of the O···O distances can not be differentiated from those found in crystallographically asymmetric hydrogen bonds. Therefore, it is desirable to examine more thoroughly the geometric details of the symmetric hydrogen bonds and the asymmetric ones. In the present work crystals of **1** and **2**, which contain the same anions but have different symmetry, have been studied.

Experimental

Experimental details for **1** and **2** are listed in Table 1. The compounds were prepared by the same procedure as reported previously.[30] Systematic absences were determined from the Weissenberg photographs. The intensities were collected on a Rigaku AFC-5 four-circle diffractometer equipped with rotating anode using Ni filtered Cu $K\alpha$ ($\lambda=1.5418$ Å) with ω—2θ scan method [scan speed 4° min^{-1} in ω, scan range $\Delta 2\theta=1.2°+0.15°\tan\theta$]. Background was measured for 4 s on either side of peak. Three standard reflections were recorded after every 57 reflections; their fluctuation was within 3% in F. Lorentz and polarization correction were applied,

but no absorption correction.

Structure Determination and Refinement

The structure of **1** was solved by *MULTAN* 78, and refined by block-diagonal least-squares method. All the unique reflections within $2\theta_{max}$ were used for the refinement. The value minimized was $\sum w(|F_o|-|F_c|)^2$, where $w=1/[\sigma(F_o)^2+0.0006|F_o|+0.0040|F_o|^2]$ for $|F_o|>0$, and $w=0.608$ for $|F_o|=0$. All the hydrogen atoms were located on a difference Fourier map. The non-hydrogen atoms were refined anisotropically and the hydrogen atoms isotropically. Correction for the secondary extinction was applied for the strongest 26 reflections according to the equation: $I_{corr}=I_o(1+gI_c)$, where $g=2.74\times10^{-5}$. Final R was 0.088 for 3446 unique reflections. In the final difference Fourier map $\Delta\rho_{max}$ and $\Delta\rho_{min}$ were +0.20 and −0.23 eÅ^{-3}, respectively.

For **2**, orientation and position of the anion were found from a three-dimensional Patterson map. The non-hydrogen atoms of the cation were found by successive application of Fourier and difference Fourier syntheses. Since the space group is *Pcan* and $Z=4$, a twist form having a two-fold symmetry was assumed for the cation at first. After refinement by block-diagonal least-squares method, a difference Fourier map showed some peaks in the region of the cation, which could not be explained as those of the hydrogen atoms. Thus, the conformation of the cation was changed to a chair form, and a disordered structure around a two-fold axis was assumed. All the hydrogen atoms were located on a difference Fourier map. Full-matrix least-squares calculations were performed, the N-C, C-C, and N-H lengths of the cation being restrained to 1.51, 1.53, and 1.00 Å, respectively. The positional parameters of the hydrogen atoms attached to the carbon atoms of the cation were fixed. The other hydrogen atoms were refined isotropically and the non-hydrogen atoms anisotropically using 1428 non-zero reflections. The $\sum w(|F_o|-|F_c|)^2$ was minimized, where $w=1/\sigma(F_o)^2$. The extinction correction was applied with $g=2.49\times10^{-5}$ for the strongest 12 reflections. Final R was 0.065 for 1510 unique reflections. The $\Delta\rho_{max}$ and $\Delta\rho_{min}$ were +0.23 and −0.30, respectively.

The atomic scattering factors were taken from International Tables for X-Ray Crystallography.[31] Programs used were *MULTAN* 78,[32] *RSSFR*-5,[33] *HBLS*-V,[34] *FMLS*,[34] modified version of *CRLS*,[35] *DAPH*,[34] *MOLCON*,[36] and *ORTEP*.[37] Computations were carried out at Okayama University Computer Center.

Results and Discussion

The final atomic parameters for **1** and **2** are listed in Table 2.[38] The thermal ellipsoids of the molecules are shown in Fig. 1 with numbering of the atoms, and the stereo views of the crystal structures in Fig. 2. Bond lengths and angles are listed in Table 3. The geometries of the hydrogen bonds are summarized in Table 4.

Crystal Structure. In the crystal of **1**, the O(10) and O(20) atoms of the hydrogen bis(carboxylate) anion are linked together by an asymmetric O-H···O hydrogen bond. The O(19) of the anion accepts two hydrogen bonds from N(21) and N(21^{ii}) to form a

a) Symmetry code: for **1**, (i) x, y, z; (ii) $1/2-x$, $-1/2+y$, $1/2-z$; for **2**, (i) x, y, z; (ii) x, $-y$, $1/2-z$; (iii) $-x$, y, $1/2+z$; (iv) $-x$, $-y$, $-z$.

ribbon along a two-fold screw axis. The ribbons related by a center of symmetry form a sheet along the [101] by van der Waals interactions. The sheets related by an n glide plane are stacked along the [10$\bar{1}$] to form the $P2_1/n$ structure. Crystals of many acid salts[9,21,22,24,28] with the asymmetric hydrogen bond adopt this space group.

The structure of **2** is disordered around a two-fold axis. This disordered structure adopts the same space group as potassium hydrogen bis(*p*-methoxybenzoate)[5] [*Pcan*, Z=4, a=7.05(7), b=35.77(10), c=6.16(6), O···O 2.48(2) Å]. The O···O distances in them are equal to within the experimental errors. The disordered structure may be split into two fundamental structures: types *A* and *B*, by eliminating the two-fold axis, resulting in two possible N-H···O hydrogen-bond systems as shown in Fig. 3. The center of symmetry is retained in the type *A*, while the c glide plane is retained in the type *B*. This means that the elimination of the two-fold axis gives rise to the descent of the space group to its maximal subgroups, $P2_1/a$ for the type *A* and $Pca2_1$ or $Pc2_1n$ for the type *B*. In both cases the environments of the O(9) and O(9^{ii}) are different. For the type *A*, the O(9) and O(9^{ii}) accept hydrogen bonds from N(11^{iv}) and N(11), respectively, in the different way. For the type *B*, only the O(9^{ii}) accepts two kinds of hydrogen bonds from N(11) and N(11^{iii}). Thus, the hydrogen bond O(10)···H(10)···O(10^{ii}) is not the "centered,"[1] but the disordered. In fact, though H(10) was found on the two-fold axis, the peak in the difference Fourier map was as low as 0.21 eÅ^{-3}. The O···O distance is significantly shorter than that in **1**, probably depending on their crystallographic symmetry, because the same trend is also seen in ammonium hydrogen bis(acetate)[6] [2.474(6) Å for $\bar{1}$, 2.517(4) Å for asymmetric] and in potassium hydrogen

meso-tartrate[13)] [2.440(8) and 2.474(8) Å for $\bar{1}$, 2.521(5) Å for asymmetric].

Molecular Structure. For **1** the anion is composed of ionized and neutral residues. The C-O and C=O bond lengths of the neutral residue are close to those in some benzoic acids,[39,40)] which display no disorder in the carboxyl groups. The C(17)-O(19) bond in the ionized residue is longer than 1.22—1.25 Å found in acidic salts of alkaline metals in which the corresponding O atoms accept no hydrogen bond. The piperidinium ring takes a chair conformation as in piperidinium benzoates:[41,42)] N(21) and C(24) deviate by −0.644 and 0.661 Å from the plane through C(22), C(23), C(25), and C(26). The methyl group is equatorially bonded to the ring: the torsion angle C(22)-C(23)-C(24)-C(27)=180.0 (4)° and C(26)-C(25)-C(24)-C(27)=−179.6(4)°.

For **2** the bond lengths of C(7)-O(9) and C(7)-O(10) correspond to the average for the ionized and neutral residues because of disordering. The piperidinium ring takes a chair conformation as in **1**.

The Short Hydrogen Bonds of Hydrogen Bis(carboxylate) Anions. The O···O distances for crystallographically symmetric hydrogen bonds are listed in Table 5, where the H···O distances and the O···H···O angles are not given, because the hydrogen atom is assumed to lie on $\bar{1}$ or 2 in most of the structure analyses. The geometries of the hydrogen bonds for some asymmetric hydrogen bonds are shown in Table 6. It is seen from Tables 5 and 6 that (i) the intermolecular O···O distances range from 2.51 to 2.43 Å and 2.57 to 2.44 Å for the symmetric and asymmetric hydrogen bonds, respectively, (ii) the lower limit of the O···O distances is expected to be about 2.4 Å for both the symmetric and asymmetric bonds as shown for general O-H···O hydrogen bonds,[43)] and (iii) for the ionized residues the C(17)-O(20) bond participating in the hydrogen bond is longer than C(17)-O(19). The effects of a decrease in the O···O distance can be confirmed from Table 6: (i) the O-H distance is increased, while the H···O distance is decreased,[43,44)] (ii) the C(7)-O(10) length in the neutral residue is decreased while the C(7)=O(9) length is increased, and (iii) difference in the bond lengths of C(7)-O(10) and C(17)-O(20) is

decreased, as for the lengths of C(7)–O(9) and C(17)–O(19). These tendencies show that with a decrease in the O···O distance, the hydrogen atom comes closer to the midpoint.[43,44] However, the "asymmetric-centered"[1] hydrogen bond has never been reported. Even at the O···O distance of 2.388(4) Å the intramolecular hydrogen bond in lithium hydrogen phthalate is the "asymmetric-noncentered."[45] Thus, the bond symmetry should be introduced by a crystallographic symmetry.[46]

For the symmetric hydrogen bonds in the compounds with alkaline metals as cations, it has been impossible to distinguish the disordered symmetry from genuine one by diffraction methods, but the present study of **2** with the piperidinium cation makes it possible to conclude that the hydrogen bond in the crystals of **2** is disordered and still not the "symmetric-centered."[1]

(Received October 17, 1985)

Actual procedures for the preparation of black phosphorus single crystals by a bismuth flux method have been explored and the details are described. The anisotropy and the temperature dependence of the electrical conductivity and the Raman scattering spectra of the crystals obtained by the above-method have been measured. The reflection spectra of crystals which were prepared by a high pressure technique have also been observed and compared with the calculated data. Several preliminary attempts for synthesizing black phosphorus intercalation compounds have been carried out for the first time. Evidence for the intercalation by an X-ray analysis is presented.

Some interesting properties of black phosphorus (BP) single crystals have been extensively explored after the recent success of single-crystal preparation.[1,2] During the first stage of the present study, we started to prepare BP single crystals by the bismuth flux method and measured the electrical and optical properties of these crystals.[1] After that, Shirotani succeeded in the preparation of larger BP crystals by the use of the melt-growth technique under high pressure.[2] Narita's group followed and developed the Shirotani's method,[3] and has revealed the fundamental quantities regarding charge-carrier transport (such as Hall mobilities and effective masses) and structural and transport behaviors under the high pressure of a large BP single crystal.[4,5] It is easier to handle a large crystal; thus, the successful preparation of such large crystals has motivated further studies of BP crystals. Large crystals have showed, not only qualitatively but also quantitatively in some cases, similar behaviors to small crystals prepared by the bismuth flux method. However, some details regarding the properties of these two kinds of the crystals, e.g. temperature-dependence details of the electrical conductivities or the crystal qualities, might not necessarily coincide with each other.

BP is one modification of the phosphorus polymorphs and the BP phase was discovered by Bridgman under high pressure.[6] Some electrical and optical properties of polycrystalline BP were studied by Keys[7] and Warschauer[8] and the crystal structure was reported by Brown and Rundqvist.[9] It crystallizes in orthorhombic form and takes on an infinite puckered-layer structure in which every layer overlaps the next layer and is shifted by a/2 units (Fig. 1).

Crystalline BP is known to undergo phase transitions from the orthorhombic form (semiconducting) to the rhombohedral form (semi-metallic) at ≈60 kbar and, finally, to the simple cubic form (metallic) at ≈110 kbar,[10] in which superconductivity (T_c=6 K) was observed.[11,12] Very recently, a more precise measurement of the pressure dependence of electrical properties revealed that a semiconductor-to-semimetal transition occurs at 17 kbar,[13] and T_c for superconduction increases up to 13 K at 300 Kbar for quenched samples.[14]

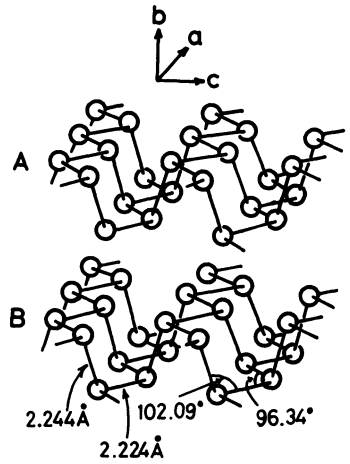

Fig. 1. Layer structure of black phosphorus crystal. B layer is shifted by 1/2 unit along the a axis relative to A layer.

Moreover, electrical transport properties of BP single crystals, such as the temperature dependence of the conductivities, magnetoresistance,[1] charge-carrier mobilities by Hall effect,[4] effective masses by cyclotron resonance method,[5] and 2-dimensional Anderson localization at low temperature[15] have been reported. The elaborate theoretical calculations for the electron band structure,[16] and the frequencies and the dispersion relations of the phonon modes[17] of BP have been carried out by Morita et al.

In this paper, we report on the actual procedures for single-crystal preparation by the bismuth flux method, the anisotropic properties in the electrical conductivities, and the optical reflection spectra and microscope Raman spectra of BP single crystals. Preliminary results of attempts to synthesize the intercalation compounds of BP are also described.

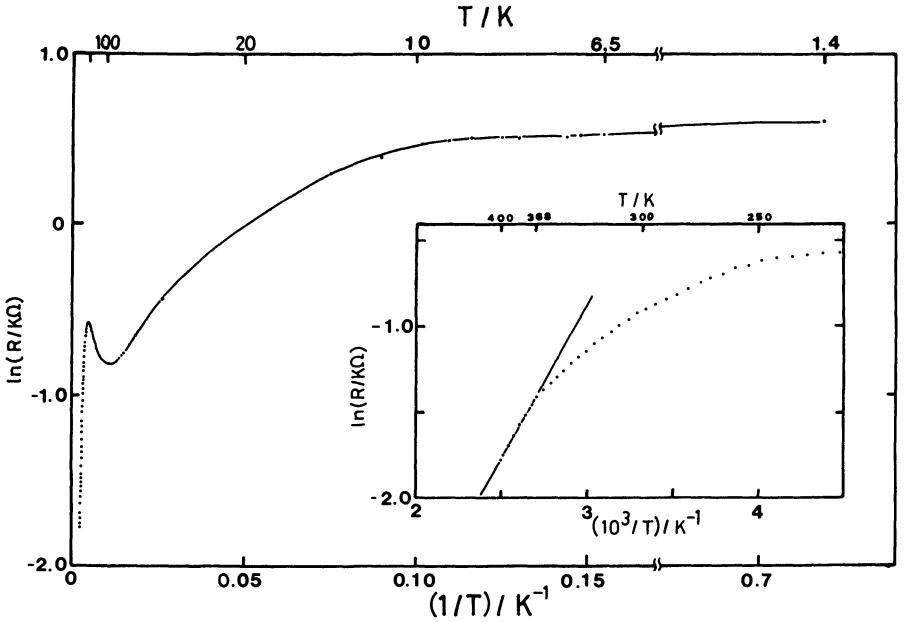

Fig. 2. Temperature dependence of the electrical resistance (a-direction) of a black phosphorus single crystal prepared by the bismuth flux method.

Experimental

In the course of this experiment, we used two kinds of single crystals; one was grown in melted bismuth[1] and the other was melt-grown under high pressure.[2] The former was obtained in rather thin rod or needle form, 10X0.2X0.05 mm^3 and the latter was in a block form, the size of which was determined by the size of the high-pressure cell. The typical size of the latter single crystal was 5X5X0.5 mm^3.

The details of the preparation procedure from bismuth solution are as follows : Amorphous or polycrystalline BP, 0.25 g, obtained by the conversion of red phosphorus under high pressure, was mixed with high-purity bismuth (37 g) in a Pyrex tube filled with 1/2 atm helium gas (atomic ratio of Bi to P is ≈22). It was kept at 400 °C for 44 h and then gradually cooled to room temperature at the rate of 0.2 °C min^{-1}. The crystals, obtained as a residue after dissolving the bismuth matrix with 30% nitric acid, were generally needle shaped with the needle axis coincident with the crystallographic a-axis. Even in melt-grown crystals, such a crystal habit is often recognizable on the cleaved ac-plane. One can determine the a- and c-axes of a crystal by carefully observing the fine stripes near the edges of the surface. Purified white phosphorus was also used as a starting material instead of BP powder.

We measured the anisotropy of the electrical conductivities for the thin rod crystals. Silver paste was used as electrodes. For the measurement along the a-axis only a four-probe method could be applied. The anisotropy of the melt-grown crystals has already been reported by Shirotani,[2] and Akahama et al.[4]

Polarized reflection spectra of a melt-grown crystal were observed in the 400—2000 nm wavelength region using an OLYMPUS MMSP microscope reflectophotometer. Polarized Raman spectra were also observed using the High-Resolution Microscope Raman Scattering Measuring System of Prof. Tominaga's laboratory in Ochanomizu University. The 5145 Å line of an Ar^+ laser (NEC GLG 3200) was used as the exciting light.

As an attempt to chemically modify the BP, intercalations with cesium, lithium, and iodine were tried. In the case of cesium or iodine, a vapor-phase reaction was carried out. The electrolytic method was employed for lithium intercalation. The cathode and anode were a BP crystal and lithium metal, respectively, and a 0.2 mol l^{-1} THF solution of $LiClO_4$ was used for the electrolyte. Electrolysis was carried out under an argon atmosphere in a dry box. Intercalated specimens were directly transferred to a measurement vessel (a cryostat) without being exposed to air.

Thin-rod crystals which were reacted with cesium vapor were analyzed using an X-ray diffraction oscillation camera method. Weak but definitely new spots were recognized and ascribed to a change of the lattice constant for the interlayer direction, b.

Results and Discussion

1. Electrical Conduction. The temperature dependence of the electrical resistance in the a-direction is shown in Fig. 2. The overall behavior of the curve was just like a typical impurity semiconductor[18] and the intrinsic band gap was estimated to be 0.34 eV from the slope of plots of ln R vs. $1/T$ in the high-temperature region (see the inset of Fig. 2).

The anisotropy of electrical conductivities at room temperature is shown in Table 1 for our thin-rod crystals and large melt-grown crystals under high pressure. The large anisotropy between the a- and b-directions (which was observed for our crystals) could not be found for the crystals of Narita's group. They have measured Hall mobilities and effective masses (Table 1). Morita et al. recently showed that the anomalous relationships in the anisotropies of the mobilities and the effective masses along the a- and b-axes, which

Table 1. Anisotropy in the Electrical Properties (Holes)

had not been well understood, could be explained by a theoretical calculation involving an electron-phonon interaction in the regime of a deformation potential model.[19] However, the large difference in the conductivities along the b axis (interlayer direction, see Fig. 1) between our crystals and the crystals of Narita's group has not yet been elucidated. The possible interpretations are defect effects, interlayer misfits, difficulties to obtain proper electrode contacts, and so on. Anyhow, the reliability of the observed values in the interlayer direction may be lower than other directions because of the inapplicability of the four-probe method to measurements in this direction. The needle-like crystals prepared by the bismuth flux method has a two-dimensional Anderson localization character at low temperature, as reported by Iwasaki et al.[15] On the contrary, the temperature dependence of the a-axis conductivity of a Narita crystal does not fit a logarithmic temperature dependence in the corresponding temperature region (below 10 K) which should be observed in the two-dimensional Anderson localization regime.

2. Reflection Spectra. Polarized reflection spectra were measured for a cleaved flake of a melt-grown crystal. The observed results are shown in Fig. 3 and are compared with the calculated curves by Asahina and Morita.[20] The absolute values of the reflectances do not coincide with each other, but the overall qualitative features correspond well, except for the low-energy region of the a-polarized reflectance. According to Asahina and Morita,[20] an optical transition around this region may occur through the effect of an interlayer interaction. Thus, the rising reflectance in this region might be caused by a phonon-assisted indirect transition. We measured the temperature dependence of the reflectance down to 40 K and revealed that an enhancement with temperature is more significant in the a-polarized spectra than in the c-polarized spectra (Fig. 4).

3. Raman Spectra. A microscope Raman-scattering technique was applied for the thin-rod crystals in order to detect Raman-active lattice phonons of BP. The obtained results are almost coincident with those reported by Sugai et al.[21] The 442 cm^{-1} band was

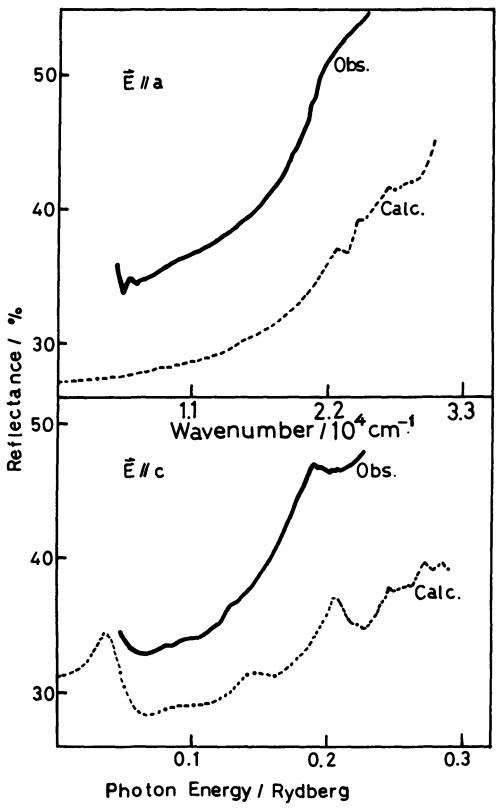

Fig. 3. Polarized reflectances of the ac plane of a black phosphorus single crystal.

assigned to the B_{2g} mode by Sugai et al,[21] however, recent calculations have shown that there could be two closely located bands, 439 and 441 cm^{-1}. They should be assigned to B_{2g} and B_{3g}, respectively.[17] These two bands could not be separated in our experiment since the microscope optical path reduced the polarization of the scattered light. The origin of the lower band (below 100 cm^{-1}) has not yet been determined.

4. Intercalation Compounds. A single crystal obtained by the bismuth flux method was set in a very thin glass capillary and fully exposed to a cesium vapor at 150°C for 14 d. In the photographs taken by an X-ray diffraction oscillation camera, the weak spots which correspond neither to BP nor cesium metal were

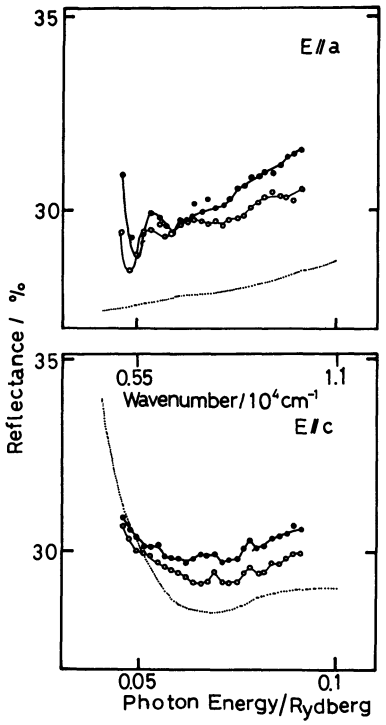

Fig. 4. Temperature dependence of the polarized reflectances.
●: At room temperature, O: at 40 K, ····: calculated spectra.

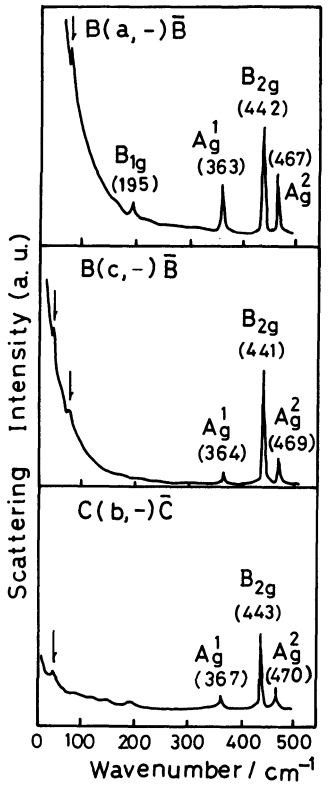

Fig. 5. Raman spectra of a black phosphorus single crystal.

recognized. The cesium vapor was introduced mostly through the cross section of one end of the crystal.

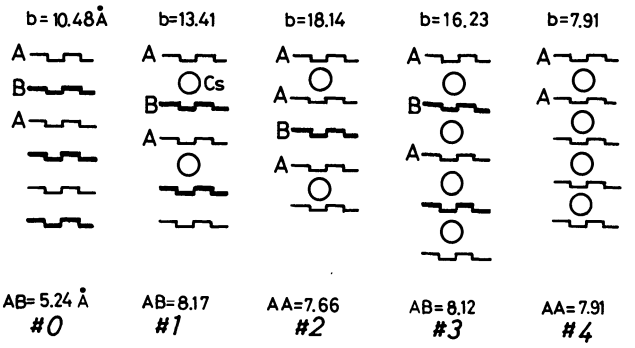

Fig. 6. Possible intercalated structures of various stages for Cs-black phosphorus.

Cesium diffusion was so slow that the other end of the crystal was still unchanged after a long exposure to cesium vapor (until the front end changed to an amorphous structure by the complete reaction). Successive X-ray analyses of the crystal (from one end to the other) revealed corresponding layer structures (illustrated in Fig. 6).

The alternately piled up structure (AB type) of a genuine BP crystal (#0) is transformed to a simple overlap structure (AA type) by the highest degree introduction of cesium atoms (or ions) (#4) similar to the first-stage structure (AA type) of graphite intercalation compounds. Other possible structures are also shown in this figure. In the next rank of an intercalation (#3), an AB-type piling is retained, even after a full intercalation of cesium. The interlayer spacing is a little larger than the AA type. In this experiment, four different b-lattice constants were identified in one piece of crystal together with the original b-axis length of a BP crystal.

Further investigations regarding homogeneous intercalation are now being undertaken. The effect of a cesium intercalation on the electrical conductivity of BP was also examined. The best reaction conditions have not yet been established for a cesium intercalation; therefore, we only present typical examples in Fig. 7. The reaction proceeded under the homogeneous heating of a sample tube in which cesium metal and a BP crystal were present. In the case of Fig. 7 (a), the reaction started at the upper-right (point A). With a raising temperature, the resistance decreased remarkably. It should be noted that both the effect of the reaction and the intrinsic change in the BP resistance due to heating are involved in this process.

On the other hand, the process from B to C corresponds to the intrinsic temperature dependence of the resistance of the cesium-intercalated BP crystal. The sample resistance showed almost no change within this temperature range (C–B). This means that this compound has almost a metallic character. However, only two samples showed this type behavior during several attempts. Another example is shown in Fig. 7 (b). In this case, the net change due to a cesium reaction was rather small. The conditions for obtaining a

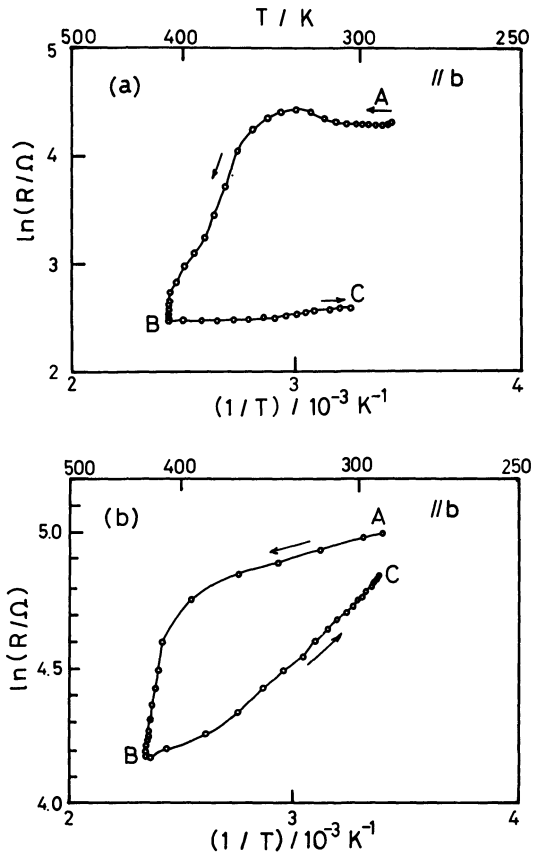

Fig. 7. Temperature dependence of $\ln(R/\Omega)$ of Cs-black phosphorus.

reproducible result are now being pursued.

To introduce lithium into BP, we empolyed two kinds of electrolytic methods. In the first method, a hexane solution of butyllithium was used as the electrolyte solution; the electrodes were a BP single crystal and a platinum plate. The second type cell consisted of a BP crystal and a lithium metal rod for the electrodes and a $LiClO_4$–THF solution for the electrolyte. In both cases, a swelling of the crystal was observed. The resistances decreased at first to 80—90% and then increased to the values that were higher than the original ones. The latter effect may be due to the partial breakdown of the crystal or the contacts between the crystal and the lead wires. A further investigation is also required to establish the intercalation conditions for the case of lithium. We have also tried to introduce iodine, pyridine, or ammonia into BP. About 20% decreases in the resistance were observed in these cases. Further study is going on, especially for an iodine intercalation.

In summary, we have prepared black phosphorus single crystals from a black or white phosphorus bismuth solution, and have observed electrical and optical properties of these crystals. We have also used crystals prepared under high pressure. We have tried to synthesize novel intercalation compounds between black phosphorus and cesium, lithium, iodine, pyridine, or ammonia. Homogeneous and stable intercalation compounds have not yet been obtained, but evidence for intercalation has been acquired by an X-ray diffraction method. Some increases in the electrical conductivities and the their different temperature dependecies in these intercalation compounds have been observed. Further investigation regarding the characterization of the intercalation compounds of black phosphorus and measurements of their physical properties are now under way.

We are very grateful to Prof. A. Morita for his important theoretical discussion. We thank to Prof. Y. Sasada and Prof. Y. Ohashi for their kind cooperation in the X-ray diffraction measurement, to Prof. H. Yakushi for the optical reflection measurement, and to Prof. Y. Tominaga for the Raman spectra measurement. This work was partly supported by the Grant-in-Aid for the Special Research on the Property of Molecular Assemblies (No. 59212044) from the ministry of Education, Science and Culture.

A Calorimetric Study on the Formation of $[CuCl_n]^{(2-n)+}$ (n=1—4) in Acetonitrile-*N,N*-Dimethylformamide Mixtures

Shin-ichi ISHIGURO, Bojana G. JELIAZKOVA,† and Hitoshi OHTAKI*
Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta, 4259, Nagatsuta-cho, Midori-ku, Yokohama 227
†Department of Analytical Chemistry, Sofia University, Anton Ivanov 1, Sofia, Bulgaria
(Received August 29, 1985)

Complex formation equilibria between copper(II) and chloride ions have been studied by calorimetry in various acetonitrile(AN)-*N,N*-dimethylformamide(DMF) mixtures containing 0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a constant ionic medium at 25 °C. Calorimetric titration curves in each AN-DMF mixture examined were well explained in terms of formation of $[CuCl_n]^{(2-n)+}$ (n=1—4), and their formation constants, enthalpies, and entropies were determined. The overall enthalpy $\Delta H^\circ_{\beta 4}$ in any mixture, even in the acetonitrile-rich 0.025 mole fraction DMF mixture, was practically the same as that (19.2 kJ mol^{-1}) in pure DMF, but largely different from that (−54.5 kJ mol^{-1}) in pure AN. The result indicated that copper(II) ion was markedly preferentially solvated with DMF molecules in AN-DMF mixtures. On the other hand, the overall entropy value $\Delta S^\circ_{\beta 4}$ in any AN-DMF mixture was significantly larger than the values in both pure solvents. As to thermodynamic quantities of stepwise formation of $[CuCl_n]^{(2-n)+}$ (n=1—4), a remarkable change was found at the second step with varying solvent compositions. The stepwise enthalpy and entropy values of formation of $[CuCl_2]$ became more positive as the DMF content of the mixture decreased. Enthalpies of solution of anhydrous $CuCl_2$ crystals were also measured in the same AN-DMF mixtures. The enthalpy $\Delta H^\circ_s(CuCl_2)$ of solution of the neutral $[CuCl_2]$ complex largely changed depending on the solvent composition, while $\Delta H^\circ_s(Cu^{2+}, 2Cl^-)$, which is the sum of enthalpies of solution of relevant ions, remained practically unchanged. The result for the $[CuCl_2]$ complex indicated that the complex was not strongly preferentially solvated with DMF molecules in contrast to copper(II) ion in the AN-DMF mixtures.

In both acetonitrile (AN) and *N,N*-dimethylformamide (DMF), copper(II) ion forms a series of four mononuclear complexes with chloride ions, although the formation of the complex is more favorable in the former solvent than in the latter.[1-4]

The donor property of AN (the donor number (D_N)= 14.1) is much weaker than that of DMF (D_N=26.6), while the acceptor property is similar in both solvents (the acceptor number (A_N)=19.3 and 16.0 for AN and DMF, respectively).[5] Consequently, copper(II) ion is more strongly solvated with DMF than with AN. On the other hand, since the enthalpy of transfer of the chloride ion from AN to DMF is close to zero,[6] the extent of solvation of the ion may not largely differ in these solvents. Therefore, more favorable formation of the copper(II) chloro complexes in AN than in DMF is mainly ascribed to a weaker solvation of copper(II) ion in the former solvent than in the latter.

Copper(II) ion is strongly coordinated with four DMF molecules in its first coordination sphere to form the $[Cu(dmf)_4]^{2+}$ solvate even in acetonitrile-rich AN-DMF mixtures.[7]

Copper(II) ion within its chloro complexes except for $[CuCl_4]^{2-}$ may be also solvated with solvent molecules in the first solvation sphere of the metal ion in AN-DMF mixtures. The metal ion prefers DMF owing to a stronger donicity of DMF than that of AN. However, the electron acceptor ability of copper(II) ion decreases with increasing number of chloride ions within the complexes due to the electron donation from the ligands to the metal ion. Thus, the strength of the metal-DMF bonds is weakened with increasing number of chloride ions within the $[CuCl_n]^{(2-n)+}$ complex.[8]

In the present work, complex formation equilibria between copper(II) and chloride ions have been calorimetrically studied in various AN-DMF mixtures. Heats of solution of anhydrous $CuCl_2$ crystals have also been measured in the AN-DMF mixtures. Thermodynamic behavior of formation of $[CuCl_n]^{(2-n)+}$ (n=1—4) in the AN-DMF mixtures will be discussed in connection with the change in solvation of the metal ion and the complexes with varying solvent compositions.

Experimental

Reagent. All chemicals used were of reagent grade. Methods of preparation and purification of the chemicals were the same as those described in previous papers.[1,2]

Measurements. Calorimetric measurements were carried out in a thermostated bath controlled at (25.000±0.007)°C placed in a room thermostated at (25.0±0.2)°C.

All solutions used for calorimetric measurements contained 0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a constant ionic medium. In each calorimetric measurement, 100 cm^3 of a copper(II) perchlorate solution of a given solvent composition was placed in a Dewar vessel filled with nitrogen gas and prevented from moisture with a P_2O_5 guard-tube, and then, was titrated with a 0.2 mol dm^{-3} $(C_2H_5)_4NCl$ solution of the same solvent composition. Concentrations of copper(II) perchlorate in initial test solutions were varied in the range 5—30 mmol dm^{-3}. Heat evolved at each titration point was measured in the range −5—5 J with a certainty ±0.05 J. Since heats of dilution of chloride ions in any AN-DMF mixture examined were found to be negligible by separate experiments, they were neglected in the course of the data treatments of heats measured.

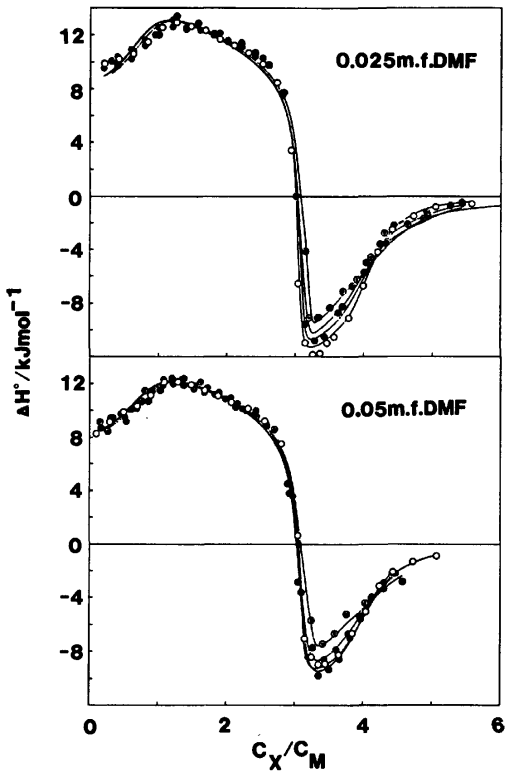

Fig. 1. Calorimetric titration curves of copper(II) chloride solutions in the AN-DMF mixtures of 0.025 and 0.05 mole fraction DMF containing 0.2 mol dm^{-3} $(C_2N_5)_4NClO_4$. Initial concentrations of copper(II) perchlorate (C_M/mol dm^{-3}): 4.55 (⊙), 7.14 (◎), 10.19 (●), and 19.25 (○) in the 0.025 mole fraction DMF mixture, and 6.05 (⊙), 11.83 (●), 20.48 (○), and 26.37 (◎), in the 0.05 mole fraction DMF mixture.

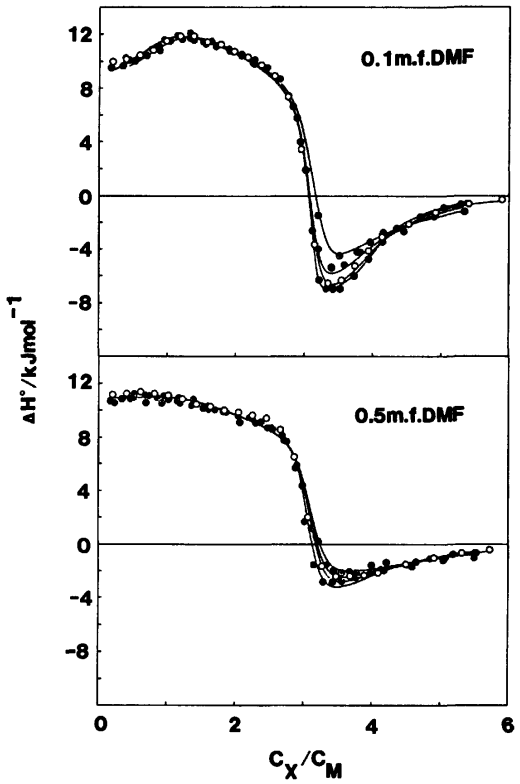

Fig. 2. Calorimetric titration curves of copper(II) chloride solutions in the AN-DMF mixtures of 0.1 and 0.5 mole fraction DMF containing 0.2 mol dm^{-3} $(C_2N_5)_4NClO_4$. Initial concentrations of copper(II) perchlorate (C_M/mol dm^{-3}): 4.59 (⊙), 10.69 (◎), 20.50 (○), and 29.23 (●) in the 0.1 mole fraction DMF mixture and 8.87 (⊙), 13.75 (◎), 19.81 (○), and 29.94 (●) in the 0.5 mole fraction DMF mixture.

Heats of solution of anhydrous $CuCl_2$ crystals were measured in the same AN-DMF mixtures as those used for the calorimetric titrations, but the mixtures involved no ionic medium, and the enthalpies $\Delta H_s^\circ(Cu^{2+},2Cl^-)$ and $\Delta H_s^\circ(CuCl_2)$ for the reactions, $CuCl_2(c)=Cu^{2+}(s)+2Cl^-(s)$ and $CuCl_2(c)=CuCl_2(s)$, respectively, were evaluated, where c and s stand for the crystalline and solution states, respectively.

Both titration and solution calorimetric measurements were carried out by using fully automatic on-line systems developed in our laboratory.[9-11]

Analysis of Calorimetric Data. The analytical method used for the calorimetric titration data was the same as that described in previous papers.[1,2]

The enthalpy of solution $\Delta H_{s,obsd}^\circ$ ($=-q_s/m$, where q_s and m denote the heat of solution measured and the number of moles of $CuCl_2$ dissolved, respectively) varied with the salt concentration in a solvent mixture because of the complex formation equilibria between copper(II) and chloride ions in the solvent. Therefore, the enthalpies $\Delta H_s^\circ(Cu^{2+},2Cl^-)$ and $\Delta H_s^\circ(CuCl_2)$ of solution were obtained by using the measured enthalpy of solution $\Delta H_{s,obsd}^\circ$ and the formation constants and enthalpies of formation of $[CuCl_n]^{(2-n)+}$ in each AN-DMF mixture as follows:

$$\Delta H_s^\circ(Cu^{2+},2Cl^-) = \Delta H_{s,obsd}^\circ - \sum_n \alpha_n \Delta H_{\beta n}^\circ, \quad (1)$$

$$\Delta H_s^\circ(CuCl_2) = \Delta H_s^\circ(Cu^{2+},2Cl^-) + \Delta H_{\beta 2}^\circ, \quad (2)$$

where α_n denotes the mole fraction of the $[CuCl_n]^{(2-n)+}$ complex. The α_n (n=1—4) values in a given solvent mixture were calculated in each measurement by knowing the formation constants of the $[CuCl_n]^{(2-n)+}$ (n=1—4) complexes and the total concentration of $CuCl_2$ dissolved in the solvent mixture.

Results and Discussion

Calorimetric titration curves in AN-DMF mixtures of 0.025, 0.05, 0.1, and 0.5 mole fraction DMF examined are illustrated in Figs. 1 and 2. In each solvent mixture, enthalpies ΔH° ($=-q/(vC_{X,tit})$ where v and $C_{X,tit}$ stand for the volume of an aliquot of the titrant added and the concentration of chloride ion in the titrant, respectively) were plotted against the ratio C_X/C_M in the test solution at each titration point.

As seen in Figs. 1 and 2, the ΔH° value was positive in the range $C_X/C_M<3$ but was turned to negative in the range $C_X/C_M>3$ in all the AN-DMF mixtures examined. The trend in the variation of ΔH° is similar to that in pure DMF, but different from that in pure AN where the ΔH° value is negative over the whole range of C_X/C_M.[2] Calorimetric titration curves in the 0.5 mole fraction DMF mixture were essentially the same as

Table 1. The Least-Squares Refinement of Formation Constants, β_n/mol^{-n}dm^{3n}, and Enthalpies, $\Delta H^\circ_{\beta n}$/kJ mol^{-1}, of Formation of Copper(II) Chloro Complexes in Acetonitrile-*N*,*N*-Dimethylformamide Mixtures Containing 0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a Constant Ionic Medium at 25 °C

Values in parentheses refer to standard deviations. a) The number of data points. b) The error-square sum.

those in pure DMF.[1] However, the titration curve noticeably changed with further decreasing the DMF content, i.e., the ΔH° values became more positive in the range C_X/C_M=1—2, but more negative in the range C_X/C_M=3—4 in the AN-DMF mixtures of lower DMF contents.

Calorimetric data in any AN-DMF mixture examined, as well as those in pure AN and DMF, were well explained in terms of the formation of $[CuCl_n]^{(2-n)+}$ (n=1—4). The formation constants and enthalpies of formation of the complexes obtained in each mixture are summarized in Table 1. As illustrated by the solid lines in Figs. 1 and 2, theoretical curves calculated by using the constants in Table 1 well reproduced the experimental points in each AN-DMF mixture examined.

Formation of the $[CuCl_4]^{2-}$ Complex. The $[CuCl_4]^{2-}$ complex is not solvated in the first solvation sphere of the metal ion in AN and in DMF.[1,2,8] The solvation energy of chloride ion in AN does not significantly differ from that in DMF because these solvents have a relatively poor acceptor property.[5] Consequently, the energy of formation of $[CuCl_4]^{2-}$ mainly depends on the solvation energy of the metal ion, especially in its first solvation sphere, in these solvents.

Thermodynamic quantities for the overall reaction, $Cu^{2+}+4Cl^-=[CuCl_4]^{2-}$, in the AN-DMF mixtures are summarized in Table 2, together with those in AN and in DMF for comparison. As seen in Table 2, the $\Delta G^\circ_{\beta 4}$, $\Delta H^\circ_{\beta 4}$, and $\Delta S^\circ_{\beta 4}$ values even in the acetonitrile-rich AN-DMF mixtures, such as the 0.025 mole fraction DMF mixture, were remarkably different from those in AN. Particularly, the $\Delta H^\circ_{\beta 4}$ value drastically changed from negative in pure AN to positive in the mixtures. Besides, the $\Delta S^\circ_{\beta 4}$ values in all the AN-DMF mixtures examined were much larger than those in AN and in DMF.

Table 2. a) 0.1 mol dm^{-3} $(C_2H_5)_4NClO_4$ ionic medium, Ref. 2. b) Ref. 1.

The thermodynamic quantities for the reaction, $[Cu(dmf)_4]^{2+}+4Cl^-=[CuCl_4]^{2-}+4dmf$, in AN can be calculated by combining those for two reactions, $Cu^{2+}+4Cl^-=[CuCl_4]^{2-}$ and $Cu^{2+}+4dmf=[Cu(dmf)_4]^{2+}$,[7] in the solvent. The enthalpy $\Delta H^{\circ *}_{\beta 4}$ and entropy $\Delta S^{\circ *}_{\beta 4}$ values thus calculated are 19.1 kJ mol^{-1} and 409 J K^{-1} mol^{-1}, respectively, which may be compared with the $\Delta H^\circ_{\beta 4}$ and $\Delta S^\circ_{\beta 4}$ values in the AN-DMF mixtures. The result indicates that a large difference of the $\Delta H^\circ_{\beta 4}$ and $\Delta S^\circ_{\beta 4}$ values found in the AN-DMF mixtures from those in pure AN may mainly be interpreted in terms of the preferential solvation of copper(II) ion with four DMF molecules in the mixtures.

Stepwise Formation of $[CuCl_n]^{(2-n)+}$ (n=1—4). Thermodynamic quantities, log(K_n/mol^{-1}dm^3), ΔG°_n/kJ mol^{-1}, ΔH°_n/kJ mol^{-1}, and ΔS°_n/J K^{-1} mol^{-1}, for the stepwise reaction, $[CuCl_{n-1}]^{(3-n)+}+Cl^-=[CuCl_n]^{(2-n)+}$ (n=1—4), are summarized in Table 3. Distribution of species

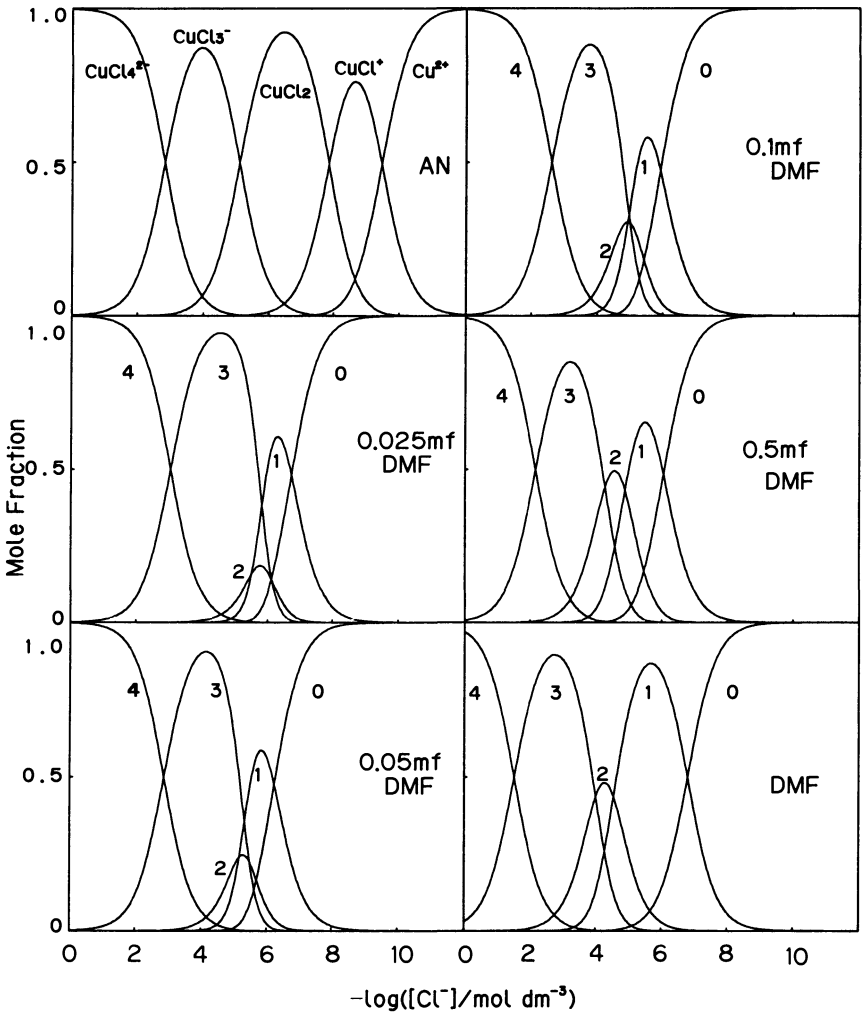

Fig. 3. Distribution curves of the copper(II) chloro complexes in various AN-DMF mixtures containing 0.2 mol dm^{-3} $(C_2N_5)_4NClO_4$ at 25 °C.

calculated by using the formation constants in each AN–DMF mixture examined is depicted in Fig. 3, together with those in the pure solvents for comparison.

The ΔH_1° and ΔS_1° values were both positive and practically kept constant in all the mixtures examined. The ΔH_1° value in any mixture was more positive by ca. 20 kJ mol^{-1} than that in pure AN, the magnitude is about one fourth of the overall enthalpy of formation of $[Cu(dmf)_4]^{2+}$ in AN.[7] It is thus plausible that one DMF molecule within $[Cu(dmf)_4]^{2+}$ is replaced with a chloride ion and $[CuCl(dmf)_3]^+$ is formed.

The ΔH_2° and ΔS_2° values became markedly positive in the AN-DMF mixtures of low DMF contents. The result indicates that the desolvation of DMF molecules from $[CuCl(dmf)_3]^+$ takes place in a different manner in each mixture depending on the solvent composition. On the other hand, the ΔH_3° value became less positive with lowering DMF contents in the mixtures and the $(\Delta H_2^\circ+\Delta H_3^\circ)$ value was practically independent of the solvent composition. The result indicates that total number of DMF molecules desolvating at the second and third steps may be kept constant in all the mixtures examined. As discussed later, the $[CuCl_3(dmf)]^-$ species is expected to be present in all the AN–DMF mixtures examined. Therefore, two DMF molecules may be liberated at the second and third consecutive steps, but the desolvating scheme depends on the solvent composition in the mixtures. We propose:

$$[CuCl(dmf)_3]^+ + Cl^- = [CuCl_2(dmf)_2] + dmf, \quad (3)$$

$$[CuCl_2(dmf)_2] + Cl^- = [CuCl_3(dmf)]^- + dmf, \quad (4)$$

in a mixture of a high DMF content, while in a mixture of a relatively low DMF content,

$$[CuCl(dmf)_3]^+ + Cl^- = [CuCl_2(dmf)] + 2dmf, \quad (5)$$

$$[CuCl_2(dmf)] + Cl^- = [CuCl_3(dmf)]^-. \quad (6)$$

Accordingly, the dichlorocopper(II) complex may be solvated with one or two DMF molecules in the first coordination sphere of the metal ion, and thus, an equilibrium as represented by reaction 7 is established between the two solvate species of the dichloro

Table 4. Enthalpies of Solution, ΔH_s°/kJ mol^{-1}, of Anhydrous Copper(II) Chloride Salt in Various Acetonitrile-*N*,*N*-Dimethylformamide Mixtures at 25 °C

complex,

$$[CuCl_2(dmf)] + dmf = [CuCl_2(dmf)_2], \quad (7)$$

and the equilibrium shifts depending on the DMF content in the AN-DMF mixtures.

The ΔH_4° value was negative in any AN-DMF mixture examined and became slightly more negative with lowering DMF contents in the mixtures, but it remained much less negative than that in pure AN. The ΔS_4° value was positive and was practically independent of the solvent composition in all the mixtures examined, while the ΔS_4° value in AN was largely negative. The result suggests that one DMF molecule still coordinates to copper(II) ion within the trichlorocuprate(II) complex and $[CuCl_3(dmf)]^-$ is formed in all the mixtures.

Enthalpies of Solution of Anhydrous $CuCl_2$ Crystal. Copper(II) chloride dissolved in an AN-DMF mixture is mostly associated to form various chloro complexes of Cu(II), the distribution of which can be calculated by knowing the formation constants of the complexes and the total concentration of $CuCl_2$ dissolved in a solution. Therefore, by using the procedure described in the Experimental section, the enthalpies $\Delta H_s^\circ(Cu^{2+}, 2Cl^-)$ and $\Delta H_s^\circ(CuCl_2)$ of solution have been determined in various AN-DMF mixtures, the former being the sum of enthalpies of solution of relevant ions and the latter the enthalpy of the neutral complex. The results are summarized in Table 4 and also depicted in Fig. 4.

Although the enthalpies of transfer of both copper(II) and chloride ions from AN to any AN-DMF mixture have not been known, the change in $\Delta H_s^\circ(Cu^{2+}, 2Cl^-)$ with varying solvent compositions may mainly reflect the change in enthalpy of solvation of copper(II) ion because the acceptor properties (the property of solvating anions) of AN and DMF are weak and not appreciably different.

As seen in Table 4, the $\Delta H_s^\circ(Cu^{2+},2Cl^-)$ values in all the mixtures examined were largely negative. They are compared with the value in pure DMF, but are very different from the value in pure AN. This also indicates that copper(II) ion is preferentially solvated with DMF molecules in a wide range of the solvent composition of the AN-DMF mixtures.

The $\Delta H_s^\circ(CuCl_2)$ value in the 0.025 mole fraction DMF mixture was close to the value in pure AN, but the value in the 0.5 mole fraction DMF mixture was close to that in pure DMF as seen in Table 4. The values in the 0.05 and 0.1 mole fraction DMF mixture were laid just in the middle of the values in AN and in DMF. The variation of $\Delta H_s^\circ(CuCl_2)$ with solvent composition indicates that solvation of $[CuCl_2]$ with DMF molecules markedly weakens in an AN-DMF mixture of a low DMF content. Therefore, we concluded that the $[CuCl_2]$ complex was not markedly preferentially solvated with DMF molecules in contrast to copper(II) ion in the AN-DMF mixtures. This is not unexpected, considering that an electron donation from the ligands to the central metal ion within $[CuCl_2]$ may reduce the acceptor ability of copper(II) ion to lead to a weakened interaction of the metal ion with DMF molecules. The conclusion obtained here is also consistent with the result obtained in a preceding section that the ΔH_2° value of stepwise formation of $[CuCl_2]$ became more positive with lowering DMF contents in the AN-DMF mixtures.

The work has been supported by the Grant-in-Aid for Scientific Research No. 59540386 from the Ministry of Education, Science and Culture.

ESR and Mössbauer Studies of Crystallization Process of Iron Phosphate Glass

Katsuhisa TANAKA, Naohiro SOGA,* Rikuo OTA, and Kazuyuki HIRAO
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606
(Received November 11, 1985)

$0.7Fe_2O_3$-$0.3P_2O_5$ glass was prepared by using a twin-roller method and the crystallization process of this glass was followed by means of ESR and Mössbauer spectroscopy in order to understand the state and the behavior of iron ions in the glass. The ESR line shape of the quenched $0.7Fe_2O_3$-$0.3P_2O_5$ glass was much broader than that of the crystallized glass heat-treated at 710 °C for 5 h. Moreover, the linewidth of Mössbauer spectra decreased monotonously through the crystallization process. These facts indicated that there existed a distribution of ligand fields around iron ions in the glass. The Mössbauer parameters, that is the isomer shift and the quadrupole splitting, of the $0.7Fe_2O_3$-$0.3P_2O_5$ glass showed that Fe^{3+} ions in this glass were laid on distorted octahedral ligand fields. The magnetic interaction working in the $0.7Fe_2O_3$-$0.3P_2O_5$ glass at room temperature was dipole-dipole interaction. Besides, the Mössbauer spectrum of the glass exhibited no internal field line at room temperature. Hence, the glass is considered paramagnetic at room temperature. At the first stage of crystallization process, the α-Fe_2O_3 particles precipitated were sufficiently small and so the specimen was superparamagnetic, as revealed from the ESR and Mössbauer spectra of heat-treated specimens.

Spin glass behavior of oxide glasses containing large amounts of iron(III) or iron(II) ions has attracted much attention recently as a number of attempts have been made to characterize their magnetic properties as well as the state of iron ions in these glasses. Although most of the studies carried out so far indicate that these glasses exhibit antiferromagnetic properties at low temperatures,[1-10] several papers[7-9] report that well below the freezing temperature, individual spins are frozen in random directions and a new magnetic phase, which shows speromagnetism,[11,12] appears. Thus, the magnetic structure of iron-containing oxide glass has not been completely clarified. More detailed informations about the state of iron ions in these glasses are needed to comprehend the characteristics of their magnetic properties. One approach is to use such a method as ESR or Mössbauer spectroscopy, which is sensitive to the local change around iron ions and to follow the change occurring during the crystallization process of iron-containing glasses.[13]

In the present work, Fe_2O_3-P_2O_5 binary glasses containing a much larger amount of iron oxide than that in the previously studied glasses were prepared by using a rapid quenching method. The choice of phosphate glass comes from the fact that P_2O_5 forms glass most easily with transition metal oxides. The ESR and Mössbauer spectra of these glasses were obtained to find out a glass structure having no trace of microcrystals. Then, the glass was subjected to heat treatment and the change in the state of iron ions was followed in detail by means of ESR and Mössbauer effect measurements in order to discuss the structure of glass containing a very large amount of iron oxide.

Experimental

The glass samples were prepared by using reagent-grade Fe_2O_3 and $FePO_4$ hydrate as starting materials. $FePO_4$ hydrate was kept in an electric furnace at 400 °C for several hours for the purpose of excluding water, and then it was mixed thoroughly with Fe_2O_3 in suitable proportions (Table 1) and sintered at 800—900 °C for 3 h in air. The resultant material was melted by heating it in an image furnace with a xenon lamp and the melt was rapidly quenched by falling it on a twin-roller rotating at 3000 rpm. The cooling rate of this method is about 10^5 K s^{-1}. The specimen obtained was a thin film of about 20 μm thickness. X-Ray diffraction measurements were employed to determine whether the specimen was amorphous or not.

Table 1. Compositions of Fe_2O_3-P_2O_5 Binary System and Results of X-Ray Diffraction Analysis

Composition/mol%		Results of X-ray diffraction
Fe_2O_3	P_2O_5	
50	50	Amorphous
60	40	Amorphous
70	30	Amorphous
75	25	Amorphous
76	24	Amorphous
77	23	Fe_3O_4 precipitated
80	20	Fe_3O_4 precipitated

For the heat treatment experiments, the $0.7Fe_2O_3$-$0.3P_2O_5$ glass was used. The heat treatment was carried out in an electric furnace at various temperatures from 220 to 710 °C for 5 h in air. The crystals precipitated in the heat treatment process were ascertained by X-ray diffraction analysis.

The ESR measurements were made using a JEOL PE-2X spectrometer operating at X-band frequency (ν=9.4 GHz) with 1.0×10^{-4} T magnetic modulation width at room temperature. Reference signals of Mn^{2+} ions in MgO were used as the standards for the linewidth and effective g-value.

The Mössbauer effect measurements were carried out at room temperature. As the γ-ray source, a 10 mCi ^{57}Co in metallic rhodium was used. The velocity calibration and the calculation of the isomer shift were made from the spectra of pure iron foil.

Results

Glass Forming Limit. The compositions of the specimens prepared to select a glass having no trace

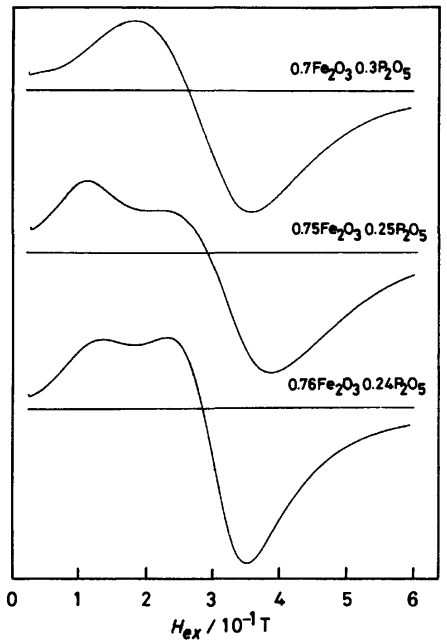

Fig. 1. ESR spectra of $0.7Fe_2O_3$–$0.3P_2O_5$, $0.75Fe_2O_3$–$0.25P_2O_5$, and $0.76Fe_2O_3$–$0.24P_2O_5$.

Table 2. ESR Linewidth and Effective g-Value of $0.7Fe_2O_3$–$0.3P_2O_5$, $0.75Fe_2O_3$–$0.25P_2O_5$, and $0.76Fe_2O_3$–$0.24P_2O_5$

Composition/mol%		ΔH	g_{eff}

75	25	1.61	2.18
		0.46	4.29
76	24	1.23	2.18
		0.51	4.28

of microcrystals are summarized in Table 1 along with the results of X-ray diffraction analysis. The X-ray diffraction pattern of the specimen exhibited an amorphous state until the concentration of Fe_2O_3 reached up to 76 mol% and showed the appearance of Fe_3O_4 when the content of Fe_2O_3 exceeded 77 mol%. However, in the X-ray diffraction patterns of $0.75Fe_2O_3$–$0.25P_2O_5$ and $0.76Fe_2O_3$–$0.24P_2O_5$ one very weak peak was noticed in the halo pattern. The existence of a minute amount of some microcrystalline phase was confirmed by employing ESR and Mössbauer effect measurements on the three specimens, $0.7Fe_2O_3$–$0.3P_2O_5$, $0.75Fe_2O_3$–$0.25P_2O_5$, and $0.76Fe_2O_3$–$0.24P_2O_5$.

ESR spectra of these specimens are shown in Fig. 1. The linewidth and effective g-value obtained from these spectra are summarized in Table 2. As seen in Fig. 1, the spectra of $0.75Fe_2O_3$–$0.25P_2O_5$ and $0.76Fe_2O_3$–$0.24P_2O_5$ were different from that of $0.7Fe_2O_3$–$0.3P_2O_5$. The latter consisted of only one broad peak centered at g=2.0, but the former spectra were composed of two

Table 3. Results of Mössbauer Effect Measurements of $0.7Fe_2O_3$–$0.3P_2O_5$, $0.75Fe_2O_3$–$0.25P_2O_5$, and $0.76Fe_2O_3$–$0.24P_2O_5$

a) T_A and t_A mean heat treatment temperature and heat treatment time, respectively.

peaks at g=4.3 and 2.0. These peaks are attributable to the resonance of Fe^{3+} ion whose spin state is $^6S_{5/2}$.

Table 3 shows the results of Mössbauer effect measurements. Fe^{2+} ions, which were not detectable in the ESR spectra, were detected in all the specimens. It is apparent from this table that the values of the quadrupole splitting of Fe^{3+} ions in both $0.75Fe_2O_3$–$0.25P_2O_5$ and $0.76Fe_2O_3$–$0.24P_2O_5$ are significantly smaller than that in $0.7Fe_2O_3$–$0.3P_2O_5$. This fact means that the symmetry of Fe^{3+} ion sites is more distorted in $0.7Fe_2O_3$–$0.3P_2O_5$ than in $0.75Fe_2O_3$–$0.25P_2O_5$ or $0.76Fe_2O_3$–$0.24P_2O_5$, because the quadrupole splitting is a measure of the symmetry of the environment around an iron ion. This result of Mössbauer effect measurements indicates the precipitation of some microcrystals in both $0.75Fe_2O_3$–$0.25P_2O_5$ and $0.76Fe_2O_3$–$0.24P_2O_5$, while no crystalline phase existed in the $0.7Fe_2O_3$–$0.3P_2O_5$ specimen. Thus, this composition was used for the following heat treatment experiments.

Change of ESR and Mössbauer Spectra upon Heat Treatment. The kinds of crystals, precipitated in the $0.7Fe_2O_3$–$0.3P_2O_5$ specimen during the crystallization process are summarized in Table 4. As seen in this table, α-Fe_2O_3 precipitated at 420 °C, and at 500 °C Fe^{2+} ions formed iron metaphosphate $Fe(PO_3)_2$.

Figure 2 shows the ESR spectra of the quenched $0.7Fe_2O_3$–$0.3P_2O_5$ glass and the specimen heat-treated at 710 °C. The former is apparently much broader than the latter.

The change in linewidth of ESR spectra appearing

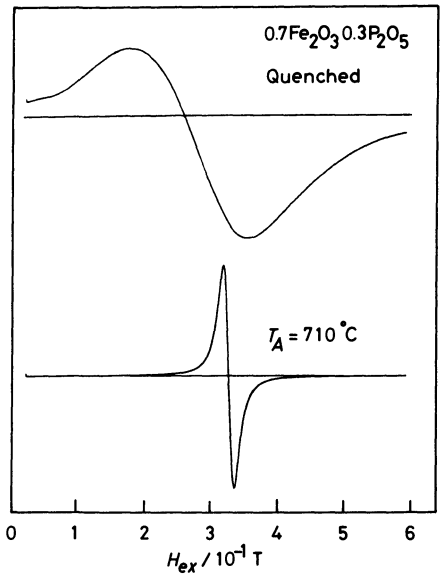

Fig. 2. ESR spectra of $0.7Fe_2O_3$-$0.3P_2O_5$ quenched glass and heat-treated at 710°C. T_A means the heat treatment temperature.

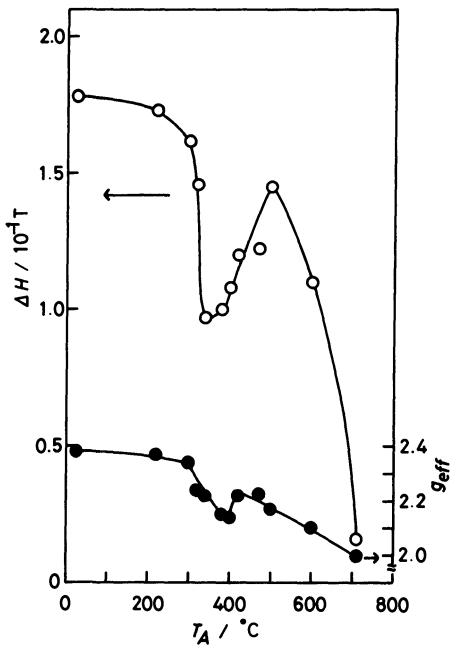

Fig. 3. Change on linewidth and effective g-value of ESR spectrum through the crystallization process of $0.7Fe_2O_3$-$0.3P_2O_5$ glass.

during the heat treatment process is shown in Fig. 3, along with the change of effective g-value. The linewidth started to decrease at about 300°C and took a minimum at about 340°C, beyond which it increased. When the heat treatment temperature exceeded 500°C, it decreased again rapidly. A similar tendency was seen on the change of effective g-value.

The change in linewidth of Mössbauer spectra appearing during the heat treatment process is shown in Fig. 4. The linewidth of Fe^{3+} did not change until

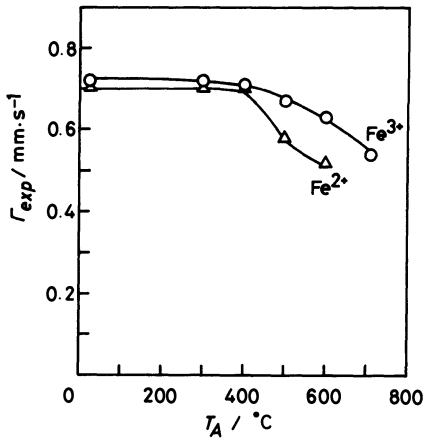

Fig. 4. Change on linewidth of Mössbauer spectra through the crystallization process.

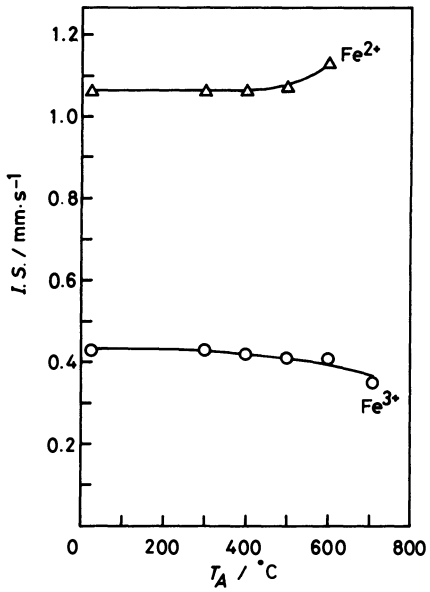

Fig. 5. Change on isomer shift of Fe^{3+} and Fe^{2+} through the crystallization process.

the heat treatment temperature reached up to 300°C and decreased monotonously when the heat treatment temperature exceeded 400°C, at which α-Fe_2O_3 microcrystals started to precipitate according to the X-ray diffraction measurements. The linewidth of Fe^{2+} also decreased at 400°C.

The change of isomer shift is shown in Fig. 5. The isomer shift of Fe^{3+} in the quenched $0.7Fe_2O_3$-$0.3P_2O_5$ glass was 0.43 mm s^{-1} when referred to pure iron. The isomer shift of Fe^{3+} decreased slowly through the crystallization process. On the contrary, the isomer shift of Fe^{2+} increased with increasing heat treatment temperature.

The change of quadrupole splitting, which is a measure of symmetry of the shape of electron clouds around an iron ion, is shown in Fig. 6. The quadrupole splitting of Fe^{2+} decreased at first and then increased as $Fe(PO_3)_2$ crystal grew. This change corresponds to

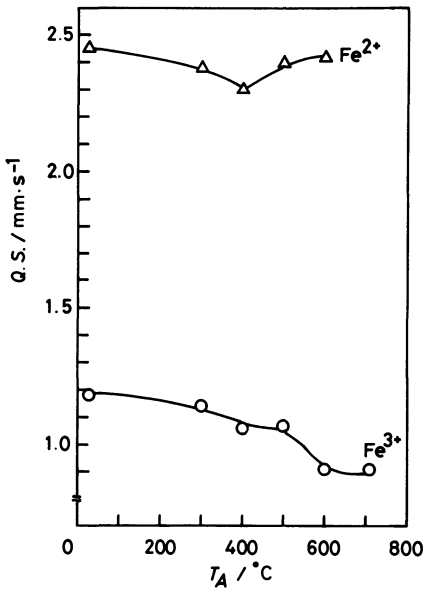

Fig. 6. Change on quadrupole splitting of Fe^{3+} and Fe^{2+} through the crystallization process.

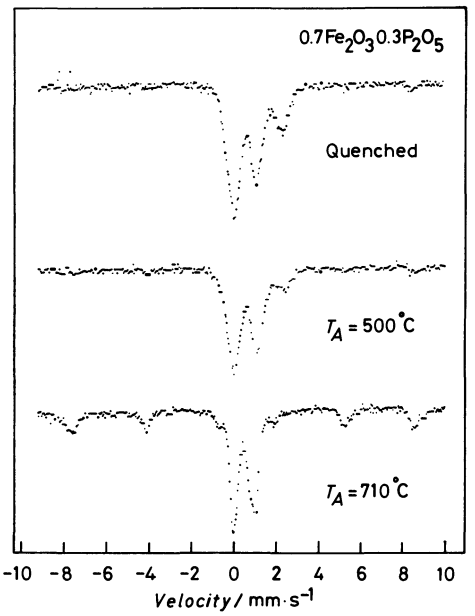

Fig. 7. Mössbauer spectra of quenched, heat-treated at 500°C, and heat-treated at 710°C, $0.7Fe_2O_3$–$0.3P_2O_5$ glass.

the change of isomer shift.

Discussion

ESR Spectra and Structural Change. The quenched glass showed much broader ESR spectra than the heat-treated specimen (Fig. 2). This fact indicates that the ligand field around Fe^{3+} fluctuates in $0.7Fe_2O_3$–$0.3P_2O_5$ glass. Generally, Hamiltonian yielding the energy levels of spin is written as follows:

$$H = g\beta HS + D\left\{S_z^2 - \frac{1}{3}S(S+1)\right\} + E(S_x^2 - S_y^2) + \frac{1}{6}a\left\{S_x^4 + S_y^4 + S_z^4 - \frac{1}{5}S(S+1)(3S^2+3S-1)\right\} + H_{ss} + H_{hf} + H_Q. \quad (1)$$

The first term is Zeeman energy and the second and the third terms are ligand field energies. The fourth term is fourth dimensional one of spin peculiar to Fe^{3+}, spin quantum number of which is larger than 2. H_{ss}, H_{hf}, and H_Q correspond to Hamiltonian representing spin–spin interaction, hyperfine interaction, and quadrupole interaction of nucleus, respectively. If there exists a variation of ligand fields, the crystal field parameters D and E are not uniform but fluctuate. So, Hamiltonian must be affected by the fluctuation, and the eigenvalue of Hamiltonian, that is the energy level of spin, should have a distribution. Therefore, the ESR spectrum of $0.7Fe_2O_3$–$0.3P_2O_5$ glass is expected to exhibit a very broad tail as observed in Fig. 2.

The linewidth of the quenched $0.7Fe_2O_3$–$0.3P_2O_5$ glass was 1.78×10^{-1} T, which is much larger than that of the specimen heat-treated at 710°C (1.60×10^{-2} T). The latter is attributable to the parasitic ferromagnetism of α-Fe_2O_3,[14,15] which causes a strong superexchange interaction at room temperature. According to the Anderson-Weiss theory,[16] the observed linewidth is represented as follows:

$$\Delta H = \frac{\frac{10}{3}(\Delta H_p)^2 + (\Delta H_H)^2}{\Delta H_e}, \quad (2)$$

where ΔH_p, ΔH_e, and ΔH_H represent the linewidth due to dipole–dipole interaction, exchange (superexchange) interaction, and fine structure field, respectively. Therefore, the linewidth of the specimen heat-treated at 710 °C should become very narrow due to the precipitation of α-Fe_2O_3. On the other hand, dipole–dipole interaction governs the magnetic interaction between iron ions in the quenched glass. Consequently, the linewidth of the quenched glass becomes broadened as indicated in Eq. 2.

A complicated change of linewidth with heat treatment temperature shown in Fig. 3 requires another mechanism of line narrowing than the superexchange interaction in the precipitated α-Fe_2O_3. According to Néel,[17] α-Fe_2O_3 is also known as a compound which shows superparamagnetism when the size of the particles is sufficiently small.

The smallness of the size of α-Fe_2O_3 precipitated in this temperature range can be demonstrated by the result of Mössbauer effect measurements. The Mössbauer spectrum of the specimen heat-treated at 500°C is drawn in Fig. 7 along with the spectra of the quenched glass as well as the specimen heat-treated at 710°C. Although α-Fe_2O_3 has already precipitated in

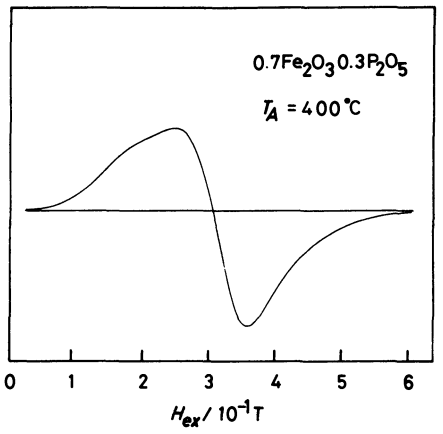

Fig. 8. ESR spectrum of $0.7Fe_2O_3$-$0.3P_2O_5$ glass heat-treated at 400°C.

the specimen heat-treated at 500°C as ascertained by X-ray diffraction analysis shown in Table 4, the sextet peak due to the internal field in α-Fe_2O_3 did not appear in this specimen. This fact indicates that α-Fe_2O_3 in this specimen is small and shows superparamagnetic. The existence of superparamagnetism can be seen in the ESR spectrum of the specimen heat-treated at 400°C shown in Fig. 8. The shoulder at about 1.8×10^{-1} T is attributable to Fe^{3+} ions which still exist in the glassy state in this specimen, and the peak at the higher field is due to Fe^{3+} ions in the superparamagnetic α-Fe_2O_3 particle. This ESR spectrum is very similar to that of ultrafine particles of Fe_3O_4 in various liquid observed by Sharma and Waldner.[18]

The line narrowing due to superparamagnetism was observed by Sharma and Waldner,[18] who investigated ultrafine particles of Fe_3O_4 in various ferrofluids by means of X-band ESR measurements. They defined the superparamagnetic narrowing factor f as follows:

$$f = \tau_{sp}/\tau_L = M_S V/\gamma k T \tau_L, \quad (3)$$

where τ_{sp} and τ_L are the superparamagnetic relaxation time and Larmor precession time, respectively, M_S is the saturation magnetization, V is the volume of the superparamagnetic particle, and γ is the gyromagnetic ratio. The proportional relation between the superparamagnetic narrowing linewidth and the volume of the particle was demonstrated by the data measured by Aharoni and Litt.[19] The increase in linewidth with increasing heat treatment temperature from 340 to 500°C observed in the present study is attributable to the growth of α-Fe_2O_3 crystallites.

When the heat treatment temperature exceeded 500°C, the linewidth decreased sharply. As described above, this narrowing is assigned to superexchange interaction owing to Fe^{3+} in α-Fe_2O_3 particles, the size of which is large enough not to show superparamagnetism. This interpretation agrees with the Mössbauer spectrum of the specimen heat-treated at 710°C in Fig. 7, which exhibited internal field lines. The internal field of α-Fe_2O_3 in this specimen is estimated to be 506 kOe (1kOe=$10^6/4\pi$ A m^{-1}).

As for the effective g-value, it was 2.00 for the specimen heat-treated at 710°C. This value is reasonable for Fe^{3+} ions because the spin state of Fe^{3+} is $^6S_{5/2}$ and its orbital angular momentum is zero. The effective g-value of the quenched $0.7Fe_2O_3$-$0.3P_2O_5$ glass was 2.38, larger than 2.00. This deviation from g=2.00 is ascribed to the contribution of orbital angular momentum to the g-value. The fraction of the orbital angular momentum in the total angular momentum, which is the sum of orbital angular momentum and spin angular momentum, is represented by the following relation:[20,21]

$$\varepsilon = \frac{1}{2}g - 1. \quad (4)$$

In the case of $0.7Fe_2O_3$-$0.3P_2O_5$ glass, ε=0.19. As described above, however, the orbital angular momentum quantum number of Fe^{3+} is zero, so that ε should be zero. The reason why ε was not zero in the $0.7Fe_2O_3$-$0.3P_2O_5$ glass is not clear at present, but might be related to the existence of Fe^{2+} ions in this glass. Fe^{2+} is known as an ion which is magnetically extremely anisotropic. The spin state of Fe^{2+} is S=2, L=2, indicating that the orbital angular momentum remains. In a general crystal such as an ionic crystal, this orbital angular momentum is quenched because of strong orbital-lattice interaction. Since there is a distribution of ligand field in this glass as described above, it is predictable that quenching of orbital angular momentum is not complete. Moreover, it may be presumed that there exists a resonance structure in this glass like the next one:

$$Fe^{2+}\text{-}O^{2-}\text{-}Fe^{3+} \rightleftarrows Fe^{3+}\text{-}O^{2-}\text{-}Fe^{2+}. \quad (5)$$

It is considered that Fe^{2+} has an effect on Fe^{3+} by way of such a resonance. As a result, the effective g-value becomes significantly larger than 2.00.

Mössbauer Parameters and State of Iron Ions. The linewidth of Mössbauer spectrum of $0.7Fe_2O_3$-$0.3P_2O_5$ glass was broader than that of the crystallized specimen (Fig. 4). This demonstrates a distribution of electric field gradient around both Fe^{3+} and Fe^{2+} ions in this glass. Eibschütz et al.[22] studied vitreous yttrium iron garnet by Mössbauer effect measurements and succeeded in fitting the computed absorption line to the experimental spectrum by assuming an asymmetric non-Gaussian distribution of electric field gradient. The existence of distribution of electric field gradient, that is a fluctuation of ligand field around Fe^{3+} ions, is ascertained by the shape of ESR spectra as described above.

The isomer shift of Fe^{3+} in the quenched $0.7Fe_2O_3$-$0.3P_2O_5$ glass (0.43 mm s^{-1}) shows that Fe^{3+} ions in this glass are coordinated by six O^{2-} ions as indi-

cated by Kurkjian and Sigety.[23] The change of isomer shift reflects the change in distance between an iron ion and an O^{2-} ion.[24] A smaller value of isomer shift shows a higher density of 4s-electrons around an iron ion, indicating the shorter distance between an iron ion and an O^{2-} ion. Therefore, the decrease of isomer shift of Fe^{3+} exhibits the decrease of the distance between Fe^{3+} and O^{2-} ions through the crystallization process and the increase of isomer shift of Fe^{2+} shows that the distance between Fe^{2+} and O^{2-} ions in $0.7Fe_2O_3$–$0.3P_2O_5$ glass is smaller than that in $Fe(PO_3)_2$ polycrystal.

The quadrupole splitting of Fe^{3+} directly reflects the geometrical symmetry of the coordination state of O^{2-} ions, because the 3d-orbitals of Fe^{3+} is half filled and the electric field gradient caused by 3d-electrons is tetrahedrally symmetrical. Hence, the decrease of quadrupole splitting of Fe^{3+} through the crystallization process reveals that the coordination state of O^{2-} ions around Fe^{3+} in $0.7Fe_2O_3$–$0.3P_2O_5$ glass is more asymmetrical than that in α-Fe_2O_3.

The increase of isomer shift of Fe^{2+} after $Fe(PO_3)_2$ precipitated may be explained by the decrease of 4s-electron density of Fe^{2+} as described above. Because of the decrease of 4s-electron density, the nucleus of iron in Fe^{2+} interacts more easily with 3d-electrons. Since five 3d-orbitals of Fe^{2+} is filled with six electrons, the electric field gradient induced by 3d-electrons of Fe^{2+} is significantly asymmetrical. So, the quadrupole splitting of Fe^{2+} increases with decreasing 4s-electron density as $Fe(PO_3)_2$ crystals grow.

Structure of $0.7Fe_2O_3$–$0.3P_2O_5$ Glass. The structure and magnetic properties of $0.44Fe_2O_3$–$0.56P_2O_5$ glass were investigated by Egami et al.[2] using susceptibility measurements and neutron diffraction analysis, and by Wedgwood and Wright[3] using neutron diffraction analysis. Although Egami et al. suggested that it is microcrystalline, Wedgwood and Wright gave a different interpretation and proposed that the glass is composed of two phases, one of which is a silica-like network containing alternate FeO_4 and PO_4 tetrahedra and another is chains of PO_4.

For $0.7Fe_2O_3$–$0.3P_2O_5$ glass studied in the present paper, the glass structure of a silica-like network composed of alternate FeO_4 and PO_4 tetrahedra is not suitable, because the coordination number of O^{2-} ion around Fe^{3+} is 6 as shown by the Mössbauer effect measurements. The glass consists of FeO_6 octahedra instead of FeO_4 tetrahedra.

Furthermore, no microcrystalline phase was detected in the present $0.7Fe_2O_3$–$0.3P_2O_5$ glass. As shown by the broader line shape of ESR spectrum and the broader linewidth of Mössbauer spectrum for $0.7Fe_2O_3$–$0.3P_2O_5$ glass, there is a distribution of ligand fields around iron ions in the glass. Moreover, the coordination state around iron ions in the glass is more unsymmetrical than that in the precipitated crystal. These facts show that $0.7Fe_2O_3$–$0.3P_2O_5$ glass is not microcrystalline but has a disordered state.

Besides, the magnetic interaction between iron ions working in $0.7Fe_2O_3$–$0.3P_2O_5$ glass at room temperature was dipole-dipole interaction, indicating that this glass is paramagnetic at room temperature. This fact also ruled out the existence of microcrystals in this glass. If microcrystals were to exist and the glass were superparamagnetic at room temperature, the superparamagnetic line of ESR spectrum would have been detected in this glass and its linewidth would have been narrow as observed at the first stage of precipitation of α-Fe_2O_3 in the crystallization process.

At the present moment it is considered that $0.7Fe_2O_3$–$0.3P_2O_5$ glass contains an assemblage of Fe^{3+} and Fe^{2+} which definitely has a magnetic anisotropy. Although it is still uncertain whether such assemblage is possible in a completely random state or not, it seems easier to make a resonance structure of Fe^{3+} and Fe^{2+} from a slightly disordered state, or *pseudo*-microcrystal or *quasi*-microcrystal structure (like monodomains proposed by Verhelst et al.[25]), which fluctuates a little in the glass.

The authors express their great thanks to Dr. Yasuhito Isozumi at the Kyoto University Radioisotope Research Center for the Mössbauer effect measurements and his kind advice on the discussion.

Synthesis of Stable 1,2-Diazocines, 4,7-Disubstituted 3,8-Diaryl-1,2-diazacycloocta-2,4,6,8-tetraenes, and Their Thermolysis

Seiichi YOGI,* Kozo HOKAMA, Kazunori UENO,† and Otohiko TSUGE†,*

(Received November 16, 1985)

Stable 1,2-diazocines, 3,8-diaryl-4,6-dichloro-1,2-diazacycloocta-2,4,6,8-tetraenes, were prepared via a chlorination-dehydrochlorination sequence starting from readily-available 3,8-diaryl-1,2-diazacycloocta-2,8-dienes. When reacted with metal carboxylates in benzene under reflux, the dichloro-1,2-diazocines were converted into stable 4-acyloxy- and/or 4,7-bis(acyloxy)-1,2-diazocines. On the thermolysis in toluene under reflux, all the diazocines gave only pyridine derivatives with extrusion of the corresponding benzonitriles. The thermal behavior of the diazocines are also discussed.

In contrast to the rich chemistry of cyclooctatetraenes,[1] 1,2-diazacycloocta-2,4,6,8-tetraenes (1,2-diazocines) have not attracted much attention. Dibenzo[*c*,*g*][1,2]diazocine[2] and substituted dibenzo[*d*,*f*]-[1,2]diazocines[3] have been prepared and found to be stable, but 1,2-diazocines free of benzo groups were not known until Trost et al.[4] succeeded in an elegant synthesis of the parent 1,2-diazocine **1**, which decomposes slowly in solution at room temperature and rapidly neat, by irradiation of a polycyclic azoalkane (Eq. 1). On the other hand, an attempt to isolate substituted 1,2-diazocines by thermal valence tautomerization of diazabicyclooctatrienes was unsuccessful, but instead substituted benzenes were obtained with the elimination of nitrogen[5] (Eq. 2). Thus, substituted monocyclic 1,2-diazocines have not been prepared up to date.

R¹=H, R²=Ph; R¹=Me, R²=Ph; R¹=R²=Me

As part of the investigation of halogenation-dehydrohalogenations of cyclic azines,[6-8] we have investigated the chlorination–dehydrochlorination of readily-available 3,8-diaryl-1,2-diazacycloocta-2,8-dienes, and it has been found that this classical reaction sequence provided a convenient method for the preparation of chlorinated monocyclic 1,2-diazocines. This is in contrast to an unsuccessful attempt to prepare **1** via a halogenation–dehydrohalogenation sequence through 1,2-bis(*t*-butoxycarbonyl)-1,2-diazacyclooct-5-ene.[9]

This paper describes the preparation of 4,7-dichloro-3,8-diaryl-1,2-diazocines and the conversion of the 4,7-dichloride into acyloxy 1,2-diazocines. In addition. thermolysis of 4,7-disubstituted 1,2-diazocines obtained above is also presented.[10]

Results and Discussion

Preparation of 4,7-Dichloro-3,8-diaryl-1,2-diazocines. Eight-membered cyclic azines, 3,8-diaryl-1,2-diazacycloocta-2,8-dienes, **3a—f**, were prepared by the reaction of 1,4-diaroylbutanes, **2a—f**, with hydrazine hydrate. After several attempted chlorinations under various conditions, it was found that the corresponding 4,4,7,7-tetrachlorides, **4a—f**, were obtained by the chlorination of **3** with sulfuryl chloride (4 equiv) in dichloromethane at room temperature for 1 h.

Dehydrochlorinations of the tetrachloride **4a** were next investigated using various bases. Treatment of **4a** with sodium hydroxide, sodium ethoxide, DBU or ethyl sodiomalonate (each 4 equiv) in refluxing ethanol gave 4,7-dichloro-3,8-diphenyl-1,2-diazocine **5a** as yellow prisms in 76, 79, 61, or 81% yield, respectively. On similar treatment with triethylamine, however, **4a** was unchanged. When treated with ethyl sodiomalonate which was the most effective reagent for the dehydrochlorination of **4a**, other tetrachlorides, **4b—f**, afforded the corresponding stable 1,2-diazocines, **5b—f** (Scheme 1).

a) The 1,2-diazocine **5** was heated in dry toluene under reflux for 4 h. b) Analyses of the pyridine(s) and benzonitrile(s) were conducted by vapor-phase chromatography and mass fragmentgraphy, respectively.

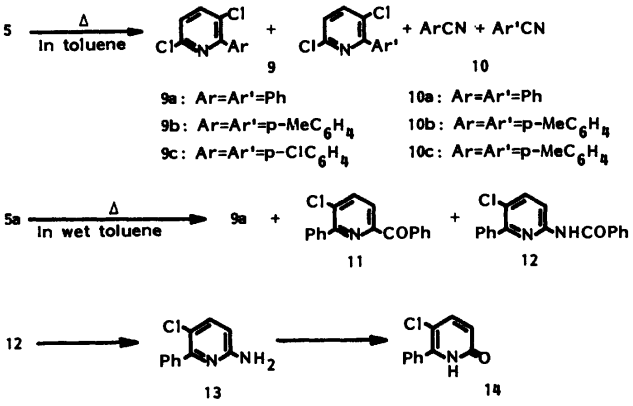
in 25% yield, together with bis(isobutyryloxy)-1,2-diazocine **7b** and unchanged **6a**. In the reaction of **6a** with silver pivalate, however, bis(pivaloyloxy)-1,2-diazocine **7c** was obtained as the sole isolated product in 60% yield.

The reaction pathway for the nucleophilic substitution with a carboxylate anion will be described later.

Structural elucidation of **6—8** was accomplished on the basis of spectral data.

Thermolysis of 1,2-Diazocines. Trost et al.[4] reported that the parent 1,2-diazocine **1** thermally decomposed to benzene and pyridine with comparable rates. Thus, we have investigated thermolysis of stable 1,2-diazocines, **5—7**, in order to compare with the thermal behavior of **1**.

We have first investigated thermolysis of 4,7-dichloro-1,2-diazocines **5**. When **5a** was heated without solvent at 160—165 °C (bath temp) for 15 min, 3,6-dichloro-2-phenylpyridine **9a** and benzonitrile **10a** were isolated in 82 and 64% yields, respectively. Although **5a** was stable in refluxing benzene, it decomposed in dry toluene under reflux to give the pyridine **9a** and nitrile **10a**. Similarly, other dichloro-1,2-diazocines, **5b—f**, decomposed to give the corresponding pyridine(s) **9** and benzonitrile(s) **10** under the same conditions (Scheme 3). As shown in Table 4, two pyridines **9** and two benzonitriles **10** were formed in the thermolysis of unsymmetrical 1,2-diazocines, **5d—f**.



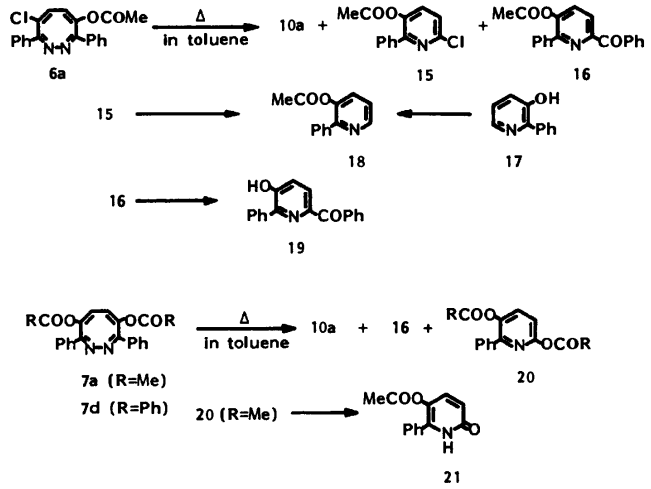
Scheme 3.

It should be emphasized that in contrast with **1** thermolysis of **5** exclusively gave the pyridine **9** with the extrusion of the benzonitrile **10**, and no benzene derivative (terphenyl) was detected in all cases.

On the other hand, when heated in wet toluene under reflux for 2 h, **5a** afforded **9a**, 6-benzoyl-3-chloro-2-phenylpyridine **11**, and 6-benzoylamino-3-chloro-2-phenylpyridine **12** in 16, 25, and 6% yields, respectively, together with the nitrile **10a** (7%) and unidentified oily products. Hydrolysis of **12** with an ethanolic alkali solution gave 6-amino-3-chloro-2-phenylpyridine **13** which was then converted, by diazotization, into 5-chloro-6-phenyl-2-pyridone **14**. The formation of **11** and **12** provides a significant information for the ring-contraction of **5a**.

Next, thermal decomposition of mono(acyloxy)-

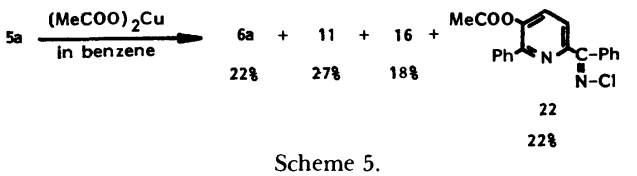
and bis(acyloxy)-1,2-diazocines was investigated. In dry toluene under reflux for 6 h, 4-acetoxy-7-chloro-1,2-diazocine **6a** gave the nitrile **10a** (5%) and 3-acetoxy-6-benzoyl-2-phenylpyridine **16** (27%), together with a trace amount of 3-acetoxy-6-chloro-2-phenylpyridine **15**. The pyridine **16** was also obtained in 63% yield in the thermolysis of **6a** in wet toluene under reflux. Reduction of **15** with zinc dust in acetic acid gave 3-acetoxy-2-phenylpyridine **18**, which was identical with an authentic sample prepared from 2-phenyl-3-pyridinol **17**.[11] Hydrolysis of **16** with an ethanolic potassium hydroxide solution under reflux gave 6-benzoyl-2-phenyl-3-pyridinol **19** (Scheme 4).



Scheme 4.

Thermolysis of di(acetoxy)-1,2-diazocine **7a** in dry toluene under reflux afforded the nitrile **10a**, benzoylpyridine **16**, and 3,6-di(acetoxy)-2-phenylpyridine **20** (R=Me) in 18, 9, and 30% yields, respectively. Under similar conditions, bis(benzoyloxy)-1,2-diazocine **7a** gave a 43% yield of 3,6-bis(benzoyloxy)-2-phenylpyridine **20** (R=Ph) as the sole isolated product. Hydrolysis of **20** (R=Me) with an ethanolic alkali solution gave 5-acetoxy-6-phenyl-2-pyridone **21** (Scheme 4).

In contrast to the reaction with silver or lead acetate, heating dichloro-1,2-diazocine **5a** with copper(II) acetate in benzene under reflux gave three pyridine derivatives, **11**, **16**, and 3-acetoxy-6-(*N*-chlorobenzimidoyl)-2-phenylpyridine **22**, besides **6a** (Scheme 5). It is evident that the pyridine **11** arises from the thermolysis of **5a** itself, and the pyridines **16** and **22** are the pyrolysates of mono(acyloxy)-1,2-diazocine **6a**. In this case di(acetoxy)-1,2-diazocine **7a** was not formed. The above



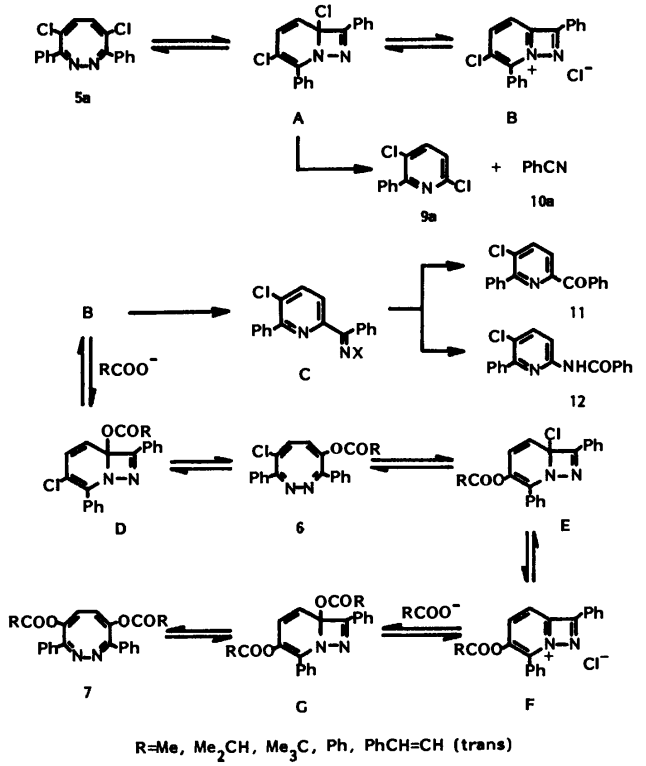
Scheme 5.

results indicate that **5a** and **6a** are pyrolyzed in the presence of copper(II) acetate even in benzene under reflux.

Structural elucidation of products, **9** and **11**—**22**, was accomplished on the basis of spectral data and/or chemical conversion. The pathway for the formation of various pyridines from 1,2-diazocines, **5**—**7**, will be discussed below.

Pathways for the Thermal Reactions of 1,2-Diazocines. On the basis of the above results, it is reasonable to conclude that the thermal reactions of 1,2-diazocines, **5**—**7**, proceed via valence isomers, 1,8-diazabicyclo[4.2.0]octatrienes.

The pathways for the thermal reactions of **5a** are illustrated as the representative example (Scheme 6). 1,2-Diazocine **5a** is thermally isomerized into its valence isomer, diazabicyclooctatriene **A**. The diazabicyclooctatriene **A** decomposes by two routes: One is the formation of the pyridine **9a** with the extrusion of benzonitrile **10a**, and the other the ring opening to an imidoylpyridine **C** (X=Cl or OH) via the azonia intermediate **B**. The benzoyl- **11** and benzoylaminopyridine **12** which were obtained in thermolysis in wet toluene, correspond to the hydrolytic compound of **C** and to the Beckmann rearrangement product of oxime **C** (X=OH), respectively. In addition, the isolation of *N*-(chlorobenzimidoyl)pyridine **22** (Scheme 5) strongly supports the intervension of **A** and **B**.



Scheme 6.

The formation of acyloxy-substituted 1,2-diazocines **6** and **7** from **5a** is readily understood by the processes, **5a**→**B**→**D**→**6** and **6**→**E**→**F**→**G**→**7**, respectively. Diazabicyclooctatrienes **D**, **E**, and **G**, and azonia

compound **F** are intervened in these processes.[12]

Experimental

IR spectra were obtained on a JASCO A-302 spectrometer. ^{1}H-NMR spectra were recorded on a Hitachi R-24 or a JEOL FX-100 instrument, and ^{13}C-NMR spectra were measured on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical Shifts are expressed in parts per million downfield from tetramethylsilane. Mass spectra were taken with a Hitachi RMU-6L spectrometer at 70 eV ionization energy. Elemental analyses were performed on a Yanaco MT 2 CHN corder instrument.

Materials. 5-Benzoyl-, 5-(*p*-toluoyl)-, and 5-(*p*-chlorobenzoyl)valeric acids were prepared from the Friedel-Crafts acylation of the corresponding benzene with 5-(ethoxycarbonyl)valeroyl chloride[13] according to the reported method[14] for the preparation of benzoyl derivative. 5-Benzoylvaleric acid: Mp 70—71 °C (lit,[14] mp 71 °C); colorless prisms. 5-(*p*-Toluoyl)valeric acid: Mp 155—156 °C; colorless prisms; IR (KBr) 1734, 1668 cm^{-1}. Found: C, 70.61; H, 7.34%. Calcd for $C_{13}H_{16}O_3$: C, 70.89; H, 7.32%. 5-(*p*-Chlorobenzoyl)valeric acid: Mp 138—139 °C; colorless prisms; IR (KBr) 1719, 1669 cm^{-1}. Found: C 60.13; H, 5.59%. Calcd for $C_{12}H_{13}O_3Cl$: C, 59.88; H, 5.45%. Metal carboxylates were commercially available.

Symmetrical 1,4-Diaroylbutanes. 1,4-Dibenzoyl- **2a**, 1,4-di-(*p*-toluoyl)- **2b**, and 1,4-bis(*p*-chlorobenzoyl)butane **2c** were prepared by the Friedel-Crafts acylation of the corresponding benzene with adipoyl dichloride according to the procedure that was employed by Fuson and Walker[15] for **2a**. **2a**: Mp 106—107 °C (lit,[15] mp 106—107 °C); colorless prisms. **2b**: Mp 133—134 °C; colorless prisms; IR (KBr) 1669 cm^{-1}. Found: C, 81.63; H, 7.45%. Calcd for $C_{20}H_{22}O_2$: C, 81.60; H, 7.53%. **2c**: Mp 175—176 °C; colorless prisms; IR (KBr) 1676 cm^{-1}. Found: C, 64.25; H, 4.70%. Calcd for $C_{18}H_{16}O_2Cl_2$: C, 64.48; H, 4.81%.

Unsymmetrical 1,4-Diaroylbutanes. Typical run is illustrated for the preparation of 1-benzoyl-4-(*p*-toluoyl)-butane **2d**. A solution of 5-(*p*-toluoyl)valeric acid (10 g, 45 mmol) in dry benzene (100 ml) was stirred with phosphorus pentachloride (12 g, 50 mmol) at room temperature for 3 h, and the solution was degassed with dry nitrogen. The above solution of the valeroyl chloride was added over a 30 min period to a stirred mixture of aluminum chloride (20 g, 150 mmol) in benzene (50 ml) at 0—5 °C. Stirring was continued at room temperature for 2 h, and the mixture was then poured onto a mixture of ice and hydrochloric acid. The benzene layer was washed with a 10% aqueous sodium carbonate solution, then with water, and dried over magnesium sulfate. The benzene solution was concentrated in vacuo, and the residue was recrystallized from ethanol to give 7.76 g (62%) of **2d** as colorless prisms: Mp 120—121 °C; IR (KBr) 1673 cm^{-1}. Found: C, 81.19; H, 6.98%. Calcd for $C_{19}H_{20}O_2$: C, 81.39; H, 7.19%.

1-Benzoyl-4-(*p*-chlorobenzoyl)butane **2e** and 1-(*p*-chlorobenzoyl)-4-(*p*-toluoyl)butane **2f** were prepared from the reactions of 5-(*p*-chlorobenzoyl)valeroyl chloride with benzene, and of 5-(*p*-toluoyl)valeroyl chloride with chlorobenzene, respectively.

2e: Yield 73%; mp 125—126 °C; colorless prisms; IR (KBr) 1676 cm^{-1}. Found: C, 71.81; H, 5.52%. Calcd for $C_{18}H_{17}O_2Cl$: C, 71.87; H, 5.70%.

2f: Yield 41%; mp 148—149 °C; colorless prisms; IR (KBr) 1671 cm^{-1}. Found: C, 72.22; H, 6.28%. Calcd for $C_{19}H_{19}O_2Cl$: C, 72.49; H, 6.08%.

3,8-Diaryl-1,2-diazacycloocta-2,8-dienes. Typical run is illustrated for the preparation of 3,8-diphenyl-1,2-diazacycloocta-2,8-diene **3a**. After a solution of 1,4-dibenzoylbutane **2a** (10.6 g, 40 mmol) and hydrazine hydrate (2.0 g, 40 mmol) in dry ethanol (150 ml) was refluxed with concd hydrochloric acid (0.8 ml) for 4 h, the solution was poured into ice water. The slightly yellow-colored solid was collected, and recrystallized from acetone to give 9.1 g (87%) of pure **3a** as colorless prisms: Mp 135—136 °C (lit, [16] mp 136—137 °C).

3,8-Diaryl-1,2-diazacycloocta-2,8-dienes, **3b—f**, were prepared from the reaction of the corresponding 1,4-diaroylbutanes, **2b—f**, with hydrazine hydrate under similar conditions.

3,8-Di(*p*-tolyl)diazacyclooctadiene 3b: Yield 70%; mp 173—174 °C; colorless prisms; MS *m/z* 290 (M$^+$). Found: C, 82.99; H, 7.65; N, 9.62%. Calcd for $C_{20}H_{22}N_2$: C, 82.72; H, 7.64; N, 9.65%.

3,8-Bis(*p*-chlorophenyl)diazacyclooctadiene 3c: Yield 85%; mp 186—187 °C; colorless prisms; MS *m/z* 334, 332, 330 (M$^+$). Found: C, 64.98; H, 5.01; N, 8.26%. Calcd for $C_{18}H_{16}N_2Cl_2$: C, 65.26; H, 4.87; N, 8.46%.

3-Phenyl-8-(*p*-tolyl)diazacyclooctadiene 3d: Yield 75%; mp 124—125 °C; pale yellow prisms; MS *m/z* 276 (M$^+$). Found: C, 82.29; H, 7.38; N, 10.35%. Calcd for $C_{19}H_{20}N_2$: C, 82.57; H, 7.29; N, 10.14%.

3-Phenyl-8-(*p*-chlorophenyl)diazacyclooctadiene 3e: Yield 80%; mp 144—145 °C; pale yellow prisms; MS *m/z* 298, 296 (M$^+$). Found: C, 72.56; H, 5.70; N, 9.15%. Calcd for $C_{18}H_{17}N_2Cl$: C, 72.84; H, 5.77; N, 9.44%.

3-(*p*-Chlorophenyl)-8-(*p*-tolyl)diazacyclooctadiene 3f: Yield 56%; mp 170—171 °C; pale yellow prisms; MS *m/z* 312, 310 (M$^+$). Found: C, 73.57; H, 6.37; N, 9.21%. Calcd for $C_{19}H_{19}N_2Cl$: C, 73.42; H, 6.16; N, 9.01%.

3,8-Diaryl-4,4,7,7-tetrachloro-1,2-diazacycloocta-2,8-dienes 4. A solution of 3,8-diphenyl-1,2-diazacyclooctadiene **3a** (1.3 g, 5 mmol) in dichloromethane (40 ml) was stirred with sulfuryl chloride (2,6 g, 20 mmol) at room temperature for 1 h. The reaction mixture was concentrated in vacuo, and the residue was recrystallized from acetone to give 1.65 g (83%) of 4,4,7,7-tetrachloride **4a**.

Chlorinations of other 3,8-diaryl-1,2-diazacyclooctadienes, **3b—f**, with sulfuryl chloride under similar conditions gave the corresponding tetrachlorides, **4b—f**. The yields, physical and analytical data of tetrachlorides, **4a—f**, are summarized in Table 1.

Dehydrochlorination of Tetrachlorides 4. A solution of tetrachloride **4a** (1.99 g, 5 mmol) in benzene (50 ml) was added into a solution of ethyl sodiomalonate, which was prepared from metallic sodium (0.46 g, 0.02 atom) and diethyl malonate (3.2 g, 20 mmol) in dry ethanol (30 ml), and the resultant mixture was refluxed for 2 h. The mixture was poured into water, and then extracted with benzene (50 ml×2). The benzene extract was dried over magnesium sulfate and concentrated in vacuo. Recrystallization of the residue from ethanol gave 1.3 g (81%) of 4,7-dichloro-3,8-diphenyldiazacyclooctatetraene **5a**.

Dehydrochlorinations of other tetrachlorides, **4b—f**, under similar conditions afforded the corresponding dichlorodiazacyclooctatetraenes, **5b—f**. The yields, physi-

cal and analytical data of dichlorides, **5a—f**, are listed in Table 2.

Reaction of Dichlorodiazacyclooctatetraene 5a with Metal Carboxylates. i) With Silver Acetate. A solution of **5a** (0.65 g, 2 mmol) in benzene (40 ml) was refluxed with silver acetate (2.0 g, 12 mmol) for 6 h. The reaction mixture was filtered, and the precipitate was washed with benzene (50 ml). The combined benzene solution was concentrated in vacuo, and the residue was chromatographed on silica gel to give 0.04 g (5%) of monoacetoxydiazocine **6a** (from benzene elution) and 0.46 g (61%) of diacetoxydiazocine **7a** (from chloroform elution), together with unidentified reddish resinous materials.

6a: Mp 138—139°C (decomp); colorless prisms; IR (KBr) 1760 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=1.96 (3H, s, CH_3), 6.20, 6.54 (each 1H, d, =CH, J=4.2 Hz), 7.3—7.5 (6H, m), 7.6—7.8 (4H, m); MS m/z 352, 350 (M^+). Found: C, 68.17; H, 4.38; N, 7.74%. Calcd for $C_{20}H_{15}N_2O_2Cl$: C, 68.47; H, 4.31; N, 4.31%.

7a: Mp 186—188°C (decomp); colorless prisms; IR (KBr) 1760 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=1.96 (6H, s, CH_3), 6.23 (2H, s, =CH), 7.2—7.5 (6H, m), 7.6—7.8 (4H, m); ^{13}C-NMR ($CDCl_3$) δ=20.5 (q, CH_3), 118.3 (d, 5- and 6-C), 127.8, 128.4, 130.0 (each d), 133.5 (s), 145.1 (s, 4- and 7-C), 149.0 (s, C=N), 166.9 (s, C=O); MS m/z 374 (M^+). Found: C, 70.36; H, 4.82, N, 7.32%. Calcd for $C_{22}H_{18}N_2O_4$: C, 70.58; H, 4.85; N, 7.48%.

ii) With Lead Acetate. A solution of **5a** (0.32 g, 1 mmol) in benzene (20 ml) was refluxed with lead acetate (1.3 g, 4 mmol) for 6 h. Similar work-up of the reaction mixture gave 25 mg (7%) of **6a** and 258 mg (69%) of **7a**. The result of the reaction for 3 h is shown in Table 3.

iii) With Silver Isobutyrate. A solution of **5a** (0.65 g, 2 mmol) and silver isobutyrate (2.4 g, 12 mmol) in benzene (40 ml) was refluxed for 6 h. Similar work-up gave 80 mg (11%) of mono(isobutyryloxy)diazocine **6b** and 0.37 g (43%) of bis(isobutyryloxy)diazocine **7b**.

6b: Mp 135—136°C (decomp); colorless prisms; IR (KBr) 1744 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.85, 0.94 (each 3H, d, CH_3, J=7.6 Hz), 2.40 (1H, m, CH), 6.18, 6.53 (each 1H, d, =CH, J=4.2 Hz), 7.2—7.5 (6H, m), 7.5—7.9 (4H, m); MS m/z 380, 378 (M^+). Found: C, 69.53; H, 5.09; N, 7.06%. Calcd for $C_{22}H_{19}N_2O_2Cl$: C, 69.74; H, 5.06; N, 7.40%.

7b: Mp 160—162°C (decomp); colorless needles; IR (KBr) 1757 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.89, 0.99 (each 6H, d, CH_3, J=7.6 Hz), 2.46 (2H, m, CH), 6.23 (2H, s, =CH), 7.2—7.5 (6H, m), 7.5—7.9 (4H, m); MS m/z 430 (M^+). Found: C, 72.55; H, 6.37; N, 6.60%. Calcd for $C_{26}H_{26}N_2O_4$: C, 72.54; H, 6.09; N, 6.51%.

The result of the reaction for 3 h is shown in Table 3.

iv) With Silver Pivalate. A mixture of **5a** (0.65 g, 2 mmol) and silver pivalate (2.5 g, 12 mmol) in benzene (40 ml) was refluxed for 6 h. Similar work-up afforded 70 mg (9%) of mono(pivaloyloxy)diazocine **6c** and 0.55 g (60%) of bis(pivaloyloxy)diazocine **7c**.

6c: Mp 154—156°C (decomp); colorless needles; IR (KBr) 1743 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.97 (9H, s, CH_3), 6.13, 6.55 (each 1H, d, =CH, J=4.8 Hz), 7.3—7.5 (6H, m), 7.5—7.9 (4H, m); MS m/z 394, 392 (M^+). Found: C, 70.06; H, 5.41; N, 6.92%. Calcd for $C_{23}H_{21}N_2O_2Cl$: C, 70.31; H, 5.39; N, 7.13%.

7c: Mp 186—188°C (decomp); colorless needles; IR (KBr) 1753 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.97 (18H, s, CH_3), 6.22 (2H, s, =CH), 7.2—7.5 (6H, m), 7.6—7.9 (4H, m); MS m/z 458 (M^+). Found: C, 73.07; H, 6.87; N, 6.01%. Calcd for $C_{28}H_{30}N_2O_4$: C, 73.34; H, 6.59; N, 6.11%.

The result of the reaction for 3 h is given in Table 3.

v) With Silver Benzoate. The similar reaction of **5a** (0.65 g, 2 mmol) with silver benzoate (2.7 g, 12 mmol) in benzene (40 ml) under reflux for 6 h afforded 0.12 g (15%) of mono(benzoyloxy)diazocine **6d** and 0.51 g (52%) of bis(benzoyloxy)diazocine **7d**.

6d: Mp 151—152°C (decomp); colorless needles; IR (KBr) 1735 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=6.42, 6.63 (each 1H, d, =CH, J=4.2 Hz), 7.2—7.6 (9H, m), 7.6—8.1 (6H, m); MS m/z 414, 412 (M^+). Found: C, 72.43; H, 4.21; N, 6.54%. Calcd for $C_{25}H_{17}N_2O_2Cl$: C, 72.72; H, 4.15, N, 6.79%.

7d: Mp 207—208°C; colorless needles; IR (KBr) 1730 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=6.20 (2H, s, =CH), 7.2—7.5 (12H, m), 7.6—8.1 (8H, m); MS m/z 498 (M^+). Found: 76.93; H, 4.59; N, 5.49%. Calcd for $C_{32}H_{22}N_2O_4$: C, 77.09; H, 4.45; N, 5.62%.

The result of the reaction for 3 h is shown in Table 3.

vi) With Silver Cinnamate. The similar reaction of **5a** (0.32 g, 1 mmol) with silver cinnamate (1.53 g, 6 mmol) in benzene (20 ml) under reflux for 3 h gave 48 mg (11%) of mono(cinnamoyloxy)diazocine **6e** and 166 mg (30%) of bis(cinnamoyloxy)diazocine **7e**, together with recovery of 51 mg (16%) of **5a**.

6e: Mp 153—155°C (decomp); colorless needles; IR (KBr) 1730 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=6.23 (1H, d, CH=CHCO, J=15.0 Hz), 6.30, 6.56 (each 1H, d, =CH, J=4.8 Hz), 7.70 (1H, d, CH=CHCO, J=15.0 Hz), 7.2—7.5 (16H, m), 7.6—7.9 (4H, m); MS m/z 440, 438 (M^+). Found: C, 73.77; H, 4.62; N, 6.25%. Calcd for $C_{27}H_{19}N_2O_2Cl$: C, 73.89; H, 4.36; N, 6.38%.

7e: Mp 196—197°C (decomp); colorless needles; IR (KBr) 1730 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=6.25 (1H, d, CH=CHCO, J=15.0 Hz), 6.41 (2H, s, =CH), 7.62 (1H, d, CH=CHCO, J=15.0 Hz), 7.2—7.5 (16H, m), 7.6—7.9 (4H, m); MS m/z 550 (M^+). Found: C, 78.77; H, 5.03; N, 4.92%. Calcd for $C_{36}H_{26}N_2O_4$: C, 78.53; H, 4.76; N, 5.09%.

Reaction of Monoacetoxydiazocine 6a with Silver Isobutyrate. A solution of **6a** (0.22 g, 0.6 mmol) in benzene (20 ml) was refluxed with silver isobutyrate (1.0 g, 5 mmol) for 3 h. The reaction mixture was filtered, and the precipitate was washed with benzene (50 ml). The combined benzene solution was concentrated in vacuo, and the residue was recrystallized from benzene-petr. ether (1:1) to give 60 mg (25%) of 4-acetoxy-7-(isobutyryloxy)diazocine **8**. The mother liquor contained unchanged **6a** and bis(isobutyryloxy)diazocine **7b**, but further purification was not carried out.

8: Mp 173—175°C (decomp); colorless needles; IR (KBr) 1760, 1752 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.89, 1.10 (each 3H, d, CH_3), 1.96 (3H, s, $COCH_3$), 2.43 (1H, m, CH), 6.22 (2H, s, =CH), 7.3—7.6 (6H, m), 7.6—8.0 (4H, m); MS m/z 402 (M^+). Found: C, 71.59; H, 5.46; N, 6.74%. Calcd for $C_{24}H_{22}N_2O_4$: C, 71.62; H, 5.51; N, 6.96%.

Similar reaction of **6a** (0.35 g, 1 mmol) with silver pivalate (1.0 g, 4.8 mmol) in benzene (20 ml) gave 0.28 g (60%) of bis(pivaloyloxy)diazocine **7c**.

Thermolysis of Dichlorodiazocine 5a. i) Without Solvent. Dichlorodiazocine **5a** (1.0 g, 3 mmol) in a test tube was heated at 160—165°C (bath temp) for 15 min. The pyrolysate was chromatographed on alumina (benzene) to give 0.5 g (82%) of 3,6-dichloro-2-phenylpyridine **9a** and 0.2 g (64%) of benzonitrile **10a**.

9a: Mp 100—101 °C; colorless needles; ^{1}H-NMR ($CDCl_3$) δ=7.10, 7.59 (each 1H, d, pyridine ring **H**, J=8.0 Hz), 7.3—7.8 (5H, m); MS m/z 227, 225, 223 (M^+). Found: C, 59.17; H, 3.33; N, 6.17%. Calcd for $C_{11}H_7NCl_2$: C, 58.95; H, 3.15; N, 6.25%.

ii) In Dry Toluene. A solution of **5a** (1.0 g) in dry toluene (20 ml) was refluxed for 3 h. The reaction mixture was concentrated in vacuo, and the residue was chromatographed on alumina to give **10a** (0.18 g, 57%) and the pyridine **9a** (0.48 g, 70%) (from benzene elution), and unidentified viscous materials (0.2 g).

iii) In Wet Toluene. A solution of **5a** (3.0 g) in toluene (30 ml) containing 3 drops of water was refluxed for 3 h. Chromatography (Al_2O_3) of the residue gave **10a** (0.07 g, 7%), **9a** (0.43 g, 16%), 6-benzoyl-3-chloro-2-phenylpyridine **11** (0.52 g, 25%) from benzene elution, and 6-benzoylamino-3-chloro-2-phenylpyridine **12** (0.16 g, 6%) from chloroform elution.

11: Mp 119—120 °C; colorless needles; IR (KBr) 1650 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=7.2—8.2 (10H, m), 7.98 (2H, s, pyridine ring **H**); ^{13}C-NMR ($CDCl_3$) δ=123.76, 127.97, 129.05, 129.45, 131.04 (each d), 132.86, 135.86, 137.32 (each s), 139.08 (d), 152.76, 154.76, 192.04 (each s); MS m/z 295, 293 (M^+). Found: C, 73.51; H, 4.30; N, 4.68%. Calcd for $C_{18}H_{12}NOCl$: C, 73.60; H, 4.12; N, 4.77%.

12: Mp 135—136 °C; yellow prisms; IR (KBr) 3320, 1665 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=7.76, 8.27 (each 1H, d, pyridine ring **H**, J=8.4 Hz), 7.3—8.0 (10H, m), 8.70 (1H, broad s, N**H**); MS m/z 310, 308 (M^+). Found: C, 69.97; H, 4.13; N, 8.91%. Calcd for $C_{18}H_{13}ON_2Cl$: C, 70.02; H, 4.24; N, 9.07%.

Conversion of the Pyridine 12 into 5-Chloro-6-phenyl-2-pyridone 14. A solution of **12** (0.1 g) in ethanol (30 ml) containing potassium hydroxide (0.2 g) was refluxed for 4 h. The reaction mixture was concentrated in vacuo, and water (10 ml) was added to the residue which was extracted with chloroform (30 ml). The extract was concentrated in vacuo, and the residue was chromatographed on silica gel to give 40 mg (67%) of 6-amino-3-chloro-2-phenylpyridine **13** from the chloroform elution.

13: Mp 94—95 °C; yellow needles; IR (KBr) 3460 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=4.60 (2H, broad s, N**H**$_2$), 6.34, 7.42 (each 1H, d, pyridine ring **H**, J=8.4 Hz), 7.24—7.74 (5H, m); MS m/z 206, 204 (M^+). Found: C, 64.56; H, 4.35; N, 13.87%. Calcd for $C_{11}H_9N_2Cl$: C, 64.46; H, 4.43; N, 13.69%.

After diazotization of the pyridine **13** (40 mg) with sodium nitrite in aqueous sulfuric acid (concd H_2SO_4 (1 ml) and H_2O (5 ml)) at 0—5 °C, the reaction mixture was heated at 50—60 °C for 1 h. The mixture was extracted with chloroform (20 ml×2) and the extract was concentrated in vacuo to leave 13 mg (32%) of 5-chloro-6-phenyl-2-pyridone **14**.

14: Mp 204—206 °C; colorless needles; IR (KBr) 2700—3100, 1660, 1635 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=6.42, 7.35 (each 1H, d, pyridine ring **H**, J=9.0 Hz), 7.48 (5H, m). Found: C, 63.99; H, 4.05; N, 6.81%. Calcd for $C_{11}H_8NOCl$: C, 64.24; H, 3.92; N, 6.81%.

Thermolysis of Dichlorodiazocine 5b. A solution of **5b** (0.5 g, 1.4 mmol) in dry toluene (10 ml) was refluxed for 4 h. A similar work-up and chromatography (Al_2O_3) of the pyrolysate gave 30 mg (18%) of tolunitrile **10b** and 0.11 g (41.5%) of 3,6-dichloro-2-(*p*-tolyl)pyridine **9b** (from benzene elution) and unidentified viscous materials (0.25 g).

9b: Mp 63—64 °C; colorless needles; ^{1}H-NMR ($CDCl_3$) δ=2.42 (3H, s), 7.19, 7.65 (each 1H, d, pyridine ring **H**, J=8.1 Hz), 7.1—7.8 (4H, m); MS m/z 241, 240, 239, 238, 237 (M^+). Found: C, 60.66; H, 4.08; N, 5.70%. Calcd for $C_{12}H_9NCl_2$: C, 60.53; H, 3.81; N, 5.88%.

Tolunitrile **10b** was identified by comparison of an authentic sample.

Thermolysis of Dichlorodiazocine 5c. A solution of **5c** (0.5 g, 1.3 mmol) in dry toluene (10 ml) was refluxed for 4 h. By the similar work-up *p*-chlorobenzonitrile **10c** (90 mg, 52%) and 3,6-dichloro-2-(*p*-chlorophenyl)pyridine **9c** (0.23 g, 70%) were obtained together with unidentified viscous materials (0.1 g).

9c: Mp 125—126 °C; yellow needles; ^{1}H-NMR (CCl_4) δ=7.12, 7.62 (each 1H, d, pyridine ring **H**, J=8.1 Hz), 7.2—7.8 (4H, m); MS m/z 263, 261, 259, 257 (M^+). Found: C, 50.89; H, 2.08; N, 5.47%. Calcd for $C_{12}H_6NCl_3$: C, 51.10; H, 2.38; N, 5.42%.

p-Chlorobenzonitrile **10c** was identified by comparison of an authentic sample.

Thermolysis of unsymmetrical diazocines, **5d—f**, was performed in toluene under the similar conditions, and the pyrolysates were analyzed using gas chromatography. The results are shown in Table 4.

Thermolysis of 4-Acetoxy-7-chlorodiazocine 6a. i) In Dry Toluene. A solution of **6a** (0.73 g, 2.1 mmol) in dry toluene (20 ml) was refluxed for 6 h. The similar work-up of the pyrolysate gave 10 mg (ca. 5%) of benzonitrile **10a**, a trace amount of 3-acetoxy-6-chloro-2-phenylpyridine **15**, and 0.22 g (27%) of 3-acetoxy-6-benzoyl-2-phenylpyridine **16**, together with intractable materials.

ii) In Wet Toluene. A solution of **6a** (0.35 g) in toluene (10 ml) containing 2 drops of water was refluxed for 6 h. By the similar work-up 0.25 g (63%) of the pyridine **16** was only isolated.

15: Oil; IR (neat) 1770 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=2.10 (3H, s), 7.15—7.95 (7H, m); MS m/z 249, 247 (M^+).

16: Mp 60—61 °C; pale yellow needles; IR (KBr) 1760, 1670 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=2.20 (3H, s), 7.25—8.3 (12H, m); MS m/z 317 (M^+). Found: C, 75.92; H, 4.84; N, 4.54%. Calcd for $C_{20}H_{15}NO_3$: C, 75.69; H, 4.76; N, 4.41%.

3-Acetoxy-2-phenylpyridine 18. A solution of the pyridine **15** (0.16 g) in acetic acid (20 ml) was refluxed with zinc dust for 5 h. After filtration, the filtrate was poured into water, and extracted with benzene. The benzene extract was washed with water, dried over magnesium sulfate, and then concentrated in vacuo. The residue was chromatographed on silica gel to give 0.05 g (36%) of **18** from the chloroform elution. The compound **18** was identical with an authentic sample prepared from the acetylation of 2-phenyl-3-pyridinol **17**[11]: Oil; ^{1}H-NMR ($CDCl_3$) δ=2.15 (3H, s), 6.98—7.85 (7H, m), 8.52 (1H, dd, pyridine ring **H**, J=2.2, 4.4 Hz); MS m/z 213 (M^+).

Hydolysis of the Pyridine 16. A solution of **16** (0.2 g) in ethanol (10 ml) containing potassium hydroxide (0.1 g) was refluxed for 2 h. The reaction mixture was poured into water, and extracted with benzene. The benzene extract was concentrated in vacuo, and recrystallization of the residue from ethanol gave 0.1 g (73%) of 6-benzoyl-2-phenyl-3-pyridinol **19**.

19: Mp 172—173 °C; colorless prisms; IR (KBr) 3100, 1625 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=4.50 (1H, br, O**H**), 7.25—8.25 (12H, m); ^{13}C-NMR ($CDCl_3$) δ=124.60, 126.13, 128.13, 128.25, 128.72, 129.19, 131.86, 132.89 (each d), 136.25, 136.95, 145.13, 145.54, 154.29, 193.54 (each s); MS m/z 275 (M^+).

Found: C, 78.83; H, 4.65; N, 5.09%. Calcd for $C_{18}H_{13}NO_2$: C, 78.53; H, 4.76; N, 5.09%.

Thermolysis of 4,7-Di(acetoxy)diazocine 7a. A solution of **7a** (0.61 g, 1.6 mmol) in dry toluene (20 ml) was refluxed for 6 h. By the similar work-up 0.13 g (30%) of 3,6-di-(acetoxy)-2-phenylpyridine **20** (R=Me) was isolated together with benzonitrile **10a** (30 mg, 18%) and the benzoylpyridine **16** (50 mg, 9%).

Hydrolysis of **20** (R=Me, 0.2 g) with an ethanolic alkali solution (0.2 g $NaHCO_3$ in 20 ml EtOH) under reflux gave 0.11 g (65%) of 5-acetoxy-6-phenyl-2-pyridone **21**.

20 (R=Me): Oil; IR (neat) 1755, 1710 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=2.11, 2.28 (each 3H, s), 7.03, 7.53 (each 1H, d, pyridine ring **H**, J=7.8 Hz), 7.25—7.8 (5H, m).

21: Mp 176—177 °C; colorless needles; IR (KBr) 2900, 2832, 1757, 1658, 1640 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=2.07 (3H, s), 6.41, 7.23 (each 1H, d, pyridine ring **H**, J=10.8 Hz), 7.41 (5H, m); MS m/z 229 (M^+). Found: C, 68.31; H, 5.00; N, 6.33%. Calcd for $C_{13}H_{11}NO_3$: C, 68.11; H, 4.84; N, 6.11%.

Thermolysis of 4,7-Bis(benzoyloxy)diazocine 7d. A solution of **7d** (0.3 g, 0.6 mmol) in dry toluene (20 ml) was refluxed for 6 h. The similar work-up afforded 0.1 g (43%) of 3,6-bis(benzoyloxy)-2-phenylpyridine **20** (R=Ph) as the sole isolated product: Mp 175—176 °C; colorless needles; IR (KBr) 1733 cm^{-1}. Found: C, 75.83; H, 4.06; N, 3.44%. Calcd for $C_{25}H_{17}NO_4$: C, 75.94; H, 4.33; N, 3.54%.

Reaction of Dichlorodiazocine 5a with Copper(II) Acetate. A solution of **5a** (0.32 g, 1 mmol) in benzene (20 ml) was refluxed with copper(II) acetate (0.72 g, 4 mmol) for 6 h. The reaction mixture was filtered, and the precipitate was washed with benzene (30 ml). The combined benzene solution was dried over magnesium sulfate, and concentrated in vacuo. The residue was chromatographed on silica gel using benzene as an eluent to give 80 mg (27%) of 6-benzoyl-3-chloro-2-phenylpyridine **11**, 60 mg (18%) of 3-acetyl-6-benzoyl-2-phenylpyridine **16**, 80 mg (22%) of 4-acetoxy-6-chloro-3,7-diphenylidiazocine **6a**, and 70 mg (22%) of 3-acetoxy-6-(*N*-chlorobenzimidoyl)-2-phenylpyridine **22**. The compound **22** was readily hydrolyzed into a mixture of **16** and **19**.

22: Mp 139—141 °C; pale yellow needles; IR (KBr) 1755 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=2.13 (3H, s), 7.2—7.5 (10H, m), 7.43, 8.00 (each 1H, d, pyridine ring **H**, J=8.0 Hz). Found: C, 68.18; H, 4.40; N, 8.01%. Calcd for $C_{20}H_{15}N_2O_2Cl$: C, 68.47; H, 4.31; N, 7.99%.

Anthracene Derivatives as Acceptors of the Reaction Intermediate Generated by the Decomposition of Tropone Tosylhydrazone Sodium Salt. Regioselective Cycloaddition Reactions of Cycloheptatrienylidene or 1,2,4,6-Cycloheptatetraene with 9-Substituted Anthracene Derivatives

Katsuhiro SAITO* and Hiraku ISHIHARA
Department of Chemistry, Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466
(Received July 25, 1985)

The rearrangement of the carbene, cycloheptatrienylidene, to the allene, 1,2,4,6-cycloheptatetraene, was investigated. Tropone tosylhydrazone sodium salt, the precursor of cycloheptatrienylidene was decomposed in the presence of various kinds of 9-substituted anthracene derivatives to afford cycloaddition products, whose structures show that the carbenic carbon atom or the allenic carbon atom of the carbene or the allene attacks the carbon atoms at the 10-position of the anthracenes. It is obvious that the electronic natures of the substituents on the anthracenes have no effect on the regioselectivity of the addition reaction, suggesting that the reaction proceeds via 1,2,4,6-cycloheptatetraene, which is derived from the cycloheptatrienylidene initially generated from the tosylhydrazone.

The structure of the nucleophilic singlet carbene, cycloheptatrienylidene (**2**), is considered to be the 6π-electron aromatic structure (**2a**) bearing the divalent carbenic carbon atom of sp^2 hybridization (**2b**).[1] The experimental facts that **2** adds to maleonitrile and fumaronitrile with stereospecificity[1b,c] and that the relative rate constants of the addition reaction of **2** with styrene derivatives correlate well with the Hammet equation ($\rho=+1.05$)[1d] prove the singlet and the nucleophilic natures of **2** respectively.

Recently, the possibility of interconversion between **2** and the allene, 1,2,4,6-cycloheptatetraene (**4**), which has a twisted structure bearing the sp hybridized allenic carbon atom (**4a**), has attracted the attention of chemists, and a number of papers have been published.[2] One of them says that **2** does not represent an energy minimum; instead, it is the transition state for the interconversion of enantiometric allenes.[2d,g,h] Previously, the present authors reported an example of the rearrangement of **2** to **4**, in connection with the [4+2]-type cycloaddition reactions of **2** with a variety of enophiles.[2c,e,f] We have now examined the reaction of **2** with various kinds of 9-substituted anthracene derivatives in order to get additional evidence on the rearrangement with the expectation that, if the reaction proceeds via the nucleophilic carbene **2**, the introduction of the electron-donating or the electron-attracting substituents on anthracene will affect the regioselectivity or the product yields of the reaction. Here the result of these reactions will be reported.

Results and Discussion

When tropone tosylhydrazone sodium salt (**1**) was decomposed at 125 °C for 15 min in anhydrous diglyme in the presence of one molar equivalent of the anthracene derivatives (**5a—g**), the respective adducts (**6a—g**) were obtained together with quantitative amounts of nitrogen gas and sodium *p*-toluenesulfinate (**3**). The yields, the chemical shifts, and the coupling constants in the NMR spectra of the adducts are summarized in the table.

The structures of the adducts were determined on the basis of their physical properties and confirmed by a comparison of the spectral properties, especially the NMR spectral properties, with those of the analogous compounds.[2e,3] The singlet signals due to the methine proton (H_a) in the NMR spectra definitely show the arrangement of the double bonds in the cycloheptatriene moiety of the adducts, showing the regioselectivity of the reaction.

These structures of the adducts show that the carbenic carbon atom of **2** or the allenic carbon atom of **4** selectively attacks the carbon atoms at the 10-position of the anthracene derivatives.

Two possible mechanisms may be thought of for

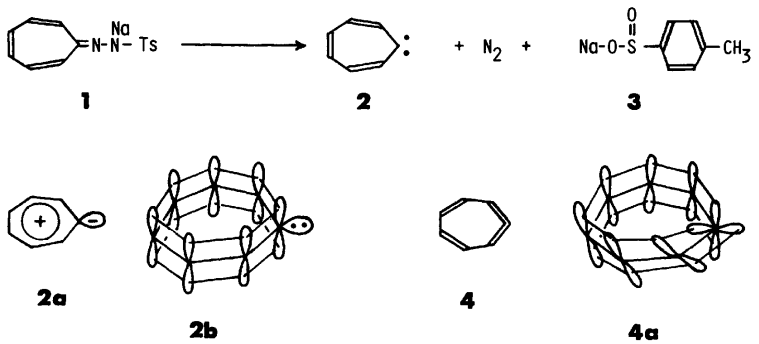

Fig. 1.

the reaction. Pathway A includes the carbene intermediate **2**, which reacts with **5** to afford the tropylium cation intermediate (**7**). Subsequent cyclization reaction of the intermediate leads to the formation of **6**. Closer examination into Pathway A, however, reveals that it does not adequately explain the observed products. That the intermediate **2** is proved to be a nucleophilic carbene; therefore, it seems reasonable that the carbenic carbon atom of **2** attacks the electron-deficient carbon atoms at the 10-position of **5b—g**, which have electron-withdrawing groups, to give the observed adducts, **6b—g**, via the intermediates **7b—g**. However, as for the other substance, anthracene **5a**, which has the electron-donating group, the carbenic carbon atom of **2** should attack the carbon atom at the 9-position to give the imaginary adducts **8a**, for in this anthracene the electron density at the 9-position is less than that at the 10-position. The experimental result shows that the attacking positions are the same at the 10-position for all of the **5**, without distinction of the electronic natures of the substituents. The lack of any obvious effect on the product yields by the electronic natures of the substituents also seems to suggest that the reaction does not proceed via **2**.

Table 1. Yields and NMR Spectral Data of the Adducts

Pathway B involves the rearrangement of **2** to the allene intermediate **4**. Allenes are known to proceed radical-type reactions.[4] The radical-type attack of the allenic carbon atom of **4** on the carbon atom at the 10-position of **5** gives the diradical intermediate **9**, which then cyclizes to form **6**. When the allenic carbon atom attacks the 9-position carbon of **5**, the imaginary adduct **8** might be formed via the diradical intermediate **10**. It is, however, obvious that the diradical intermediate **9** is more stable than **10**; therefore the preferential product should be **6**.

The facts that some carbenes are known to rearrange to the corresponding allenes,[5] and that anthracenes are active acceptors in addition reactions with allenes,[6] seem also to support the estimation that these reac-

tions are addition reactions between the anthracene derivatives and the allene intermediate **4**.[7]

Experimental

All the melting and boiling points are uncorrected. The NMR spectra were measured with a Hitachi R-20B or a Varian XL 200 spectrometer, with tetramethylsilane as the internal standard. The mass spectra were recorded with a Hitachi M-52 or a JMS-DX300 spectrometer. The UV and IR spectra were measured with Hitachi 220A and DS-701G spectrometers respectively. Wako gel C-200 and Wako gel B5-F were used for the column and thin-layer chromatography respectively. The diglyme was dried over Molecular Sieves 3A 1/16.

Reaction of 1 with 5a. A mixture of 1 (14.80 g, 50 mmol), **5a** (9.60 g, 50 mmol), and anhydrous diglyme (100 ml) was heated at 120 °C for 15 min. After the evolution of a quantitative amount of nitrogen gas had ceased (1.1 l), a quantitative amount of a brown powder of **3** (8.85 g) was removed by filtration. The filtrate was diluted with ether, washed several times with water and brine, and dried over anhydrous sodium sulfate. After filtration, the solvent was removed on a rotary evaporator to give a tarry material, which was chromatographed on silica gel to give crystals of the recovered **5a** (7.44 g) when pet ether was used and yellow crystals **6a** (1.65 g, 12%) by the use of pet ether–benzene (9:1). Recrystallization from benzene gave pure **6a**.

6a: Mp 134—135 °C. Found: *m/z* 283.1404. Calcd for $C_{22}H_{18}$: 283.1417. Mass *m/z* (rel intensity): 283 (M^+, 96), 267 (52), 192 (100). IR (KBr): 3020, 2950, 1460, 1380 cm^{-1}. UV (EtOH): 273 nm (log ε, 3.70).

Reaction of 1 with 5b. A mixture of 1 (14.80 g, 50 mmol), **5b** (12.70 g, 50 mmol), and anhydrous diglyme (100 ml) was heated at 120 °C for 15 min to evolve a quantitative amount of nitrogen gas (1.1 l). After the removal of **3** (8.60 g, 97%) by filtration, the filtrate was treated as usual to give a mixture of crystals and an oil. The crystals of the recovered **5b** (11.13 g) were removed by filtration, and the filtrate was chromatographed on silica gel to yield a pale yellow oil **6b** (0.67 g, 4%) by the use of pet ether–benzene (8:2). The oil **6b** was further purified by thin-layer chromatography on silica gel, using pet ether–benzene (9:1) as the developing solvent (R_f=0.75).

6b: Found: *m/z* 344.1568. Calcd for $C_{27}H_{24}$: 344.1564. Mass (rel intensity): 344 (M^+, 100), 268 (13), 253 (60). IR (oil): 3020, 2950, 1160, 1460 cm^{-1}. UV (EtOH): 253 nm (log ε, 3.66).

Reaction of 1 with 5c. A mixture of 1 (14.80 g, 50 mmol), **5c** (10.65 g, 50 mmol), and anhydrous diglyme (100 ml) was heated at 120 °C for 15 min to evolve a quantitative amount of nitrogen gas (1.1 l). After the separation of **3** (8.13 g, 91%) by filtration, the filtrate was treated as usual to give a mixture of crystals and an oil. The crystals of the recovered **5c** (2.81 g) were removed by filtration, and the filtrate was chromatographed on silica gel to give crystals of the recovered **5c** (6.46 g) when pet ether was used and a pale yellow oil **6c** (1.17 g, 8%) when pet ether–benzene (9:1) was used. The oil **6c** was further purified by thin-layer chromatography, using pet ether–benzene (9:1) as the developing solvent (R_f=0.40).

6c: Found: *m/z* 302.0839. Calcd for $C_{21}H_{15}Cl$: 302.0861. Mass *m/z* (rel intensity): 302 (M^+, 55), 267 (90), 252 (36), 212 (100). IR (oil): 3040, 2950, 1460 cm^{-1}. UV (EtOH): 275 nm (log ε, 3.91).

Reaction of 1 with 5d. A mixture of 1 (14.80 g, 50 mmol), **5d** (12.90 g, 50 mmol), and anhydrous diglyme (100 ml) was heated at 120 °C for 15 min to evolve a quantitative amount of nitrogen gas (1.1 l). After the separation of **3** (8.85 g, 99%) by filtration, the filtrate was treated as usual to give a mixture of crystals and an oil. The crystals of the recovered **5d** (7.30 g) were removed by filtration, and the filtrate was chromatographed on silica gel to give crystals of the recovered **5d** (4.10 g) when pet ether was used and a yellow oil **6d** (2.15 g, 13%) when pet ether–benzene (8:2) was used. The oil **6d** was further purified by thin-layer chromatography on silica gel, using pet ether–benzene (8:2) as the developing solvent (R_f=0.60).

6d: Found: *m/z* 346.0355. Calcd for $C_{21}H_{15}Br$: 346.0375. Mass *m/z* (rel intensity): 348 (M^+, ^{81}Br, 65), 346 (M^+, ^{79}Br, 69), 268 (100), 259 (43), 257 (43). IR (oil): 3030, 2960, 1450 cm^{-1}. UV (EtOH): 273 nm (log ε, 3.84).

Reaction of 1 with 5e. A mixture of 1 (14.80 g, 50 mmol), **5e** (11.00 g, 50 mmol), and anhydrous diglyme (100 ml) was heated at 120 °C for 15 min to evolve a quantitative amount of nitrogen gas (1.1 l). After the separation of a quantitative amount of **3** (8.90 g) by filtration, the filtrate was treated as usual to give a tarry material, which was then chromatographed on silica gel to give a yellow oil **6e** (2.11 g, 14%) when pet ether–benzene (7:3) was used and crystals of the recovered **5e** (6.91 g) when pet ether–benzene (6:4) was used. The oil **6e** was further purified by

thin-layer chromatography, using pet ether–benzene (7:3) as the developing solvent (R_f=0.60).

6e: Found: *m/z* 310.1350. Calcd for $C_{23}H_{18}O$: 310.1356. Mass *m/z* (rel intensity): 310 (M^+, 31), 267 (100), 220 (28), 205 (52). IR (oil): 3030, 2950, 1710, 1455 cm^{-1}. UV (EtOH): 246 nm (log ε, 4.41).

Reaction of 1 with 5f. A mixture of **1** (5.92 g, 20 mmol), **5f** (4.06 g, 20 mmol), and anhydrous diglyme (50 ml) was heated at 120 °C for 15 min to evolve a quantitative amount of nitrogen gas (0.45 l). After the separation of a quantitative amount of **3** (3.55 g), the filtrate was treated as usual to give a mixture of crystals and an oil. The crystals of the recovered **5f** (1.85 g) were removed by filtration, and the filtrate was chromatographed on silica gel to give a pale yellow oil **6f** (480 mg, 8%) when pet ether–benzene (5:5) was used and crystals of the recovered **5f** (1.65 g) when pet ether–benzene (4:6) was used. The oil **6f** was further purified by thin-layer chromatography, using pet ether–benzene (5:5) as the developing solvent.

6f: Found: *m/z* 293.1194. Calcd for $C_{22}H_{15}N$: 239.1204. Mass *m/z* (rel intensity): 293 (M^+, 81), 265 (7), 203 (43), 117 (100). IR (oil): 3030, 2950, 2220, 1460 cm^{-1}. UV (EtOH): 273 nm (log ε, 4.16).

Reaction of 1 with 5g. A mixture of **1** (14.80 g, 50 mmol), **5g** (11.20 g, 50 mmol), and anhydrous diglyme (100 ml) was heated at 120 °C for 15 min to evolve a quantitative amount of nitrogen gas (1.1 l). After the separation of a quantitative amount of **3** (3.55 g) by filtration, the filtrate was treated as usual to give a tarry material, which was then chromatographed on silica gel to yield crystals **6g** (3.84 g, 25%) when pet ether–benzene (7:3) was used and crystals of the recovered **5g** (6.98 g) when pet ether–benzene (6:4) was used. Recrystallization from benzene gave pure **6g**.

6g: Mp 105—106 °C. Found: *m/z* 313.1083. Calcd for $C_{21}H_{15}NO_2$: 313.1103. Mass *m/z* (rel intensity): 313 (M^+, 100), 267 (75), 253 (12), 208 (10). IR (KBr): 3030, 2960, 1540, 1460 cm^{-1}. UV (EtOH): 273 nm (log ε, 3.52).

The authors are indebted to Professor Toshio Mukai of Tohoku University, Professor Takashi Toda of Utsunomiya University, and Professor Tomoo Nakazawa of the Medical University of Yamanashi for their fruitful suggestions.

7) A referee has pointed out the possibility of the secondary formation of **6** via 1,5-hydrogen shifts or Berson-Willcott rearrangements in the tropylidene moiety of **8**, which, in this case, should be the initial addition product. According to the literature,[8] the quantitative proceedings of these rearrangements usually need the reaction conditions of heating at a higher temperature for longer periods than those of our reaction conditions (for example, the rearrangement of 1,3,6-triphenyltropylidene to 2,5,7-triphenyltropylidene is not completed even after heating at 121 °C for 70 h[8c]). Because of the mild reaction conditions (120 °C, 15 min) and because we detected no adduct of the **8** type, we consider **6** to be the initial addition product. We are indebted to the referee for his sugestion.

Quantitative Analysis of Effects of Substituted Phenols on Membrane Characteristics of Lecithin Liposomes

Hideto MIYOSHI, Takaaki NISHIOKA, and Toshio FUJITA*
Department of Agricultural Chemistry, Faculty of Agriculture, Kyoto University, Sakyo-ku, Kyoto 606
(Received November 1, 1985)

The partition coefficient of a series of substituted phenols in a lecithin liposome/water system, P(L/W), and the effects of these compounds on the perturbation of liposomal membranes were quantitatively investigated using physicochemical molecular parameters. Partition behavior is primarily governed by hydrophobicity, represented in terms of the 1-octanol/water partition coefficient. Steric and electronic characters also were of significance. Potency in perturbation of liposomal membranes was governed by the degree of partitioning to the membrane and the steric bulkiness of the phenol. This kind of quantitative procedure was very helpful in investigating the effects of organic molecules on membrane characteristics.

A variety of medicinal and agricultural chemicals interact with cell membranes as a part of their pharmacological or physiological effects. Thus, characterization of such interactions is important for understanding their overall mechanisms of action. Substituted phenols have fungicidal activity due to their causing an abnormal release of intracellular substances during their incorporation into the cell membranes.[1-3] The relationship between their fungicidal activity index and a hydrophobicity parameter derived from their partition coefficient in organic solvent/water systems is linear.[4-6] These studies suggest that the hydrophobicity of substituted phenols is most important, but the effect of other factors such as steric bulk and electronic property on the interaction with cell membranes should not be overlooked.

Here, we selected the lecithin liposome as a model of the cell membrane, since the effect of solutes is easily analyzed physicochemically with this system, the components of which are chemically uniform. We measured the partition coefficient of a number of substituted phenols between the lecithin liposome and an external aqueous phase. The substituents were chosen so that their steric and electronic characters would be as different as possible under experimental conditions. We also evaluated the degree of perturbation of the liposomal membrane by phenols, in terms of the change in the membrane permeability to glucose. Using physicochemical parameters of substituents and regression analysis, we first examined factors influencing their partitioning into the lecithin liposome. Then we analyzed the degree of liposomal membrane perturbation in terms of the liposome–aqueous phase partition coefficient, along with other parameters.

Experimental

Materials. Lecithin was prepared from fresh egg yolk and purified by the method of Singleton.[7] Phenols were purchased from the Nakarai Chemical Co. and purified before use. Hexokinase (EC 2.7.1.1), glucose 6-phosphate dehydrogenase (EC 1.1.1.49), and ADP were obtained from the Oriental Yeast Co. *N*-Dansylhexadecylamine (DSHA) was bought from the Sigma Chemical Co.

Preparation of Bilayered Liposome. Lecithin, 100 mg, was dissolved in 1 ml of $CHCl_3$ and placed in a 30 ml flask under Ar gas. The solvent was removed in vacuo. The lipid film was suspended in 20 ml of pH 7.2 Tris buffer (10 mM Tris-HCl, 50 mM NaCl (1 M=1 mol dm^{-3}), 0.2 mM EDTA) and sonicated with a Type 4280 sonicator (Kaijodenki Co.) in an ice-cooled bath under Ar gas to avoid oxidation of lecithin. Bilayered liposome was separated from the undispersed lecithin by centrifugation of the suspension at 15000 rpm for 30 min, and from multilayered liposome by gel filtration on Sepharose 4B at 4 °C.[8] The amount of lecithin was calculated from that of phosphorus by a modification of the Bartlett method.[9] The resultant solution of liposome contained about 1 mg lecithin/ml. Electron microscopy (JME-100C) was used to study the liposome negatively stained with 2% sodium tungstophosphate.

Measurement of Partition Coefficient. The partition coefficient, P(L/W), of substituted phenols between the liposome and the external aqueous phase was measured by equilibrium dialysis.[10] The solution of phenols was prepared with the same pH 7.2 Tris-HCl buffer as for the liposome solution. For phenols other than those that were alkyl-substituted, the pH of the buffer was adjusted by addition of dilute HCl so that they would exist as the nonionized form, except for 2,4-$(NO_2)_2$ and 2-*s*-Bu-4,6-$(NO_2)_2$ derivatives, which ionize by 3—10% even at pH 3.0. The concentration of the phenol in the buffer was 10^{-5} to 10^{-4} M. The pH of the liposome solution was adjusted to that of the phenol solution. Using an equilibrium dialysis cell (10×1 ml chambers, Sanko Plastic Co.), we equilibrated the liposome suspension (1 ml) with the phenol solution (1 ml) through a cellophane dialysis membrane at 25 °C for 12 h. The partition coefficient, P(L/W), was calculated by Eq. 1,

$$P(\mathrm{L/W}) = \frac{2(C_o - C)}{C \times C_L}\left[\frac{\text{mol phenol/kg lecithin}}{\text{mol phenol/l external solution}}\right], \quad (1)$$

where C is the concentration of phenol in a liposome-free chamber at equilibrium, C_o is that of phenol in a control experiment in which the phenol solution was equilibrated with the Tris buffer without liposome, and C_L is the concentration of lecithin (kg l^{-1}) in the liposome suspension. The total amount of lecithin in 1 ml of the liposome suspension was about 1 mg. The concentration of the phenol was measured spectrophotometrically on a Shimadzu UV-360

spectrophotometer. The P(L/W) value was calculated at least three times with different initial phenol concentrations, and the log P(L/W) values were averaged. For 2,4-dinitro- and 2-*s*-butyl-4,6-dinitrophenols, the partition coefficient is an apparent value for a mixture of ionized and nonionized species in the aqueous phase. For these two derivatives, the effect of variation in pH was examined.

Measurement of Glucose Permeability. The permeability of the liposomal membrane to glucose was calculated as the rate of release of glucose from the internal aqueous phase to the external aqueous phase at 25°C. Liposome enclosing glucose internally (glucose-liposome) was prepared by sonication of lecithin in pH 7.2 Tris buffer (10 mM Tris-HCl, 0.2 mM EDTA) containing 0.15 M glucose, and then separated with Sepharose 4B gel filtration. Glucose, which remained in the outer phase, was quickly removed with further gel filtration using Sephadex G25. An enzyme mixture for the glucose-assay was prepared in a quartz cell for fluorescence measurement.[11] The mixture consisted of 2.5 ml of pH 7.2 buffer (10 mM Tris-HCl, 0.2 mM EDTA, and 0.15 M NaCl), 0.2 ml of 0.02 M magnesium acetate, 0.1 ml of 0.02 M ATP, 0.1 ml of 0.01 M $NADP^+$, and 20 µl of aqueous solution containing 100 IU of hexokinase and 250 IU of glucose 6-phosphate dehydrogenase. After the addition of 80—130 µl of a stock solution in which various amounts of a phenol was dissolved in pH 7.2 Tris buffer, 0.5 ml (about 0.1 mg of lecithin) of the glucose-liposome suspension was quickly added to the cell. The final pH of the reaction mixture was 5.3. The amount of the phenol stock solution to be added was decided so as to cover the lower concentration region for highly effective compounds and the higher region for less effective compounds, in a range of final concentrations between 0.08 and 17 mM. The concentration of glucose in the outer phase was assayed at intervals with gentle stirring from the fluorescence intensity at 460 nm (ex. at 340 nm) arising from the NADPH produced from $NADP^+$ with glucose 6-phosphate dehydrogenase in the presence of the glucose 6-phosphate that is in turn derived from glucose with hexokinase and ATP. Fluorescence was recorded on a Shimadzu RF-503A spectrofluorophotometer. At 30 min after the start of the reaction, 10% Triton-X100 aqueous solution (300 µl) was added to the reaction mixture, and the glucose-liposome was completely disrupted to release the enclosed glucose. The fluorescence intensity after the disruption corresponded to the total amount of glucose. The course over time for the 4-*t*-Bu derivative is shown in Fig. 1 as an example. The total volume of the internal aqueous phase of liposome was calculated from the total amount of glucose in the entire reaction mixture and from the initial concentration of glucose (0.15 M) enclosed in the glucose-liposome. The pH of the external solution where the enzymatic reaction proceeds did not vary in this experimental period. Phenols used here are mostly not ionized at the final pH of 5.3 except for the 2-*s*-Bu-4,6-$(NO_2)_2$ derivative.

Estimation of Polarity of the Liposomal Membrane Surface. The variations in the polarity of membrane surface were estimated as the change of the λ_{max} of the emission spectrum of DSHA at 25°C. A chloroform solution of DSHA was added to lecithin at the molar ratio of 1:50 for DSHA to lecithin.[12] Chloroform was removed in vacuo and liposome (DSHA-liposome) was prepared in a similar way. The λ_{max} of the DSHA-liposome was recorded with excitation at 330 nm.

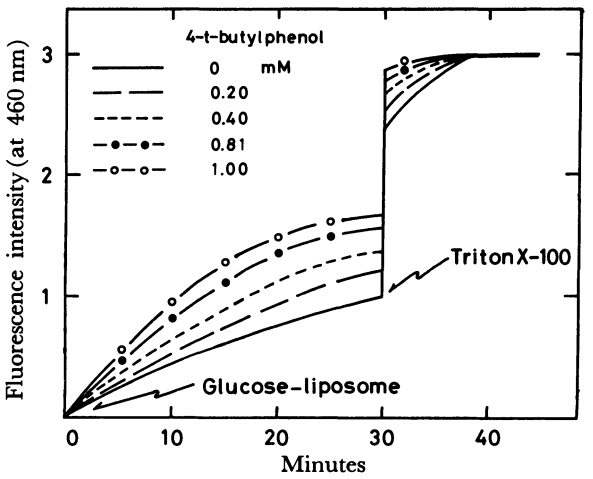

Fig. 1. Spectrofluorophotometric assay for glucose released from liposome in the presence of 4-*t*-butylphenol. Glucose-liposomes were added to experimental (+$NADP^+$) and control (−$NADP^+$) cuvettes at time zero. Triton X-100 (300 µl) to give the final concentration of 1% was added to the cuvettes at 30 min. Fluorescence intensity values were corrected for dilution following the addition of Triton X-100.

Table 1. log P(L/W) of 2,4-$(NO_2)_2$ Derivatives at Different pH

pH	2,4-$(NO_2)_2$ [pK_A=4.09]		2-*s*-Bu-4,6-$(NO_2)_2$ [pK_A=4.40]	
	% ionized	log P(L/W)	% ionized	log P(L/W)
7.2	99.9	1.90	99.8	2.95
5.3	94.2	2.00	88.8	3.16
3.0	7.5	2.42	3.8	3.33
Neutral		2.46[a]		3.35[a]

a) Estimated by correcting log P(L/W) at pH 3.0 according to the pH-partitioning model by adding $\log\{(K_A+[H^+])/[H^+]\}$, where K_A is the dissociation constant and $[H^+]$ is the hydrogen ion concentration.

Results

Characterization of Liposome. Electron microscopy showed that liposomes prepared in this way did indeed have an internal space surrounded by a spherical bilayered membrane. The diameter of the liposomes was between 150 and 300 Å, which agrees with that reported in the literature.[13] The volume of the internal cavity of the liposomes estimated from the total volume for the glucose-liposomes was 2.6 (±0.3)× 10^{-4} cm^3 μmol^{-1} lecithin, which is close to the 3.1×10^{-4} cm^3 μmol^{-1} lecithin obtained by Brunner.[14]

Partition Coefficient. The partition coefficient, P(L/W), of some representative phenols was measured with different initial concentrations in the external aqueous phase from 5×10^{-6} to 10^{-3} M under conditions where they exist as the nonionized form. For the 4-Cl and 4-*t*-Bu derivatives, the log P(L/W) values were

almost constant regardless of the initial concentration in the aqueous phase, varying only slightly from 2.75 to 2.81 for the 4-Cl and from 3.19 to 3.28 for the 4-t-Bu compounds. For the 2,4-dinitrophenols, the P(L/W) value was measured at pH 7.2, 5.3, and 3.0. As shown in Table 1, these phenols were partitioned into the liposome membrane even from the aqueous phase where they exist almost always in the ionized form. Judging from the difference in log P(L/W) value between higher pH and a pH of 3.0, the partition of the phenolate ions is lower than that of the neutral phenols, but the difference does not seem to be very large. Although the partitioning system with liposomes seems to work according to a simple partition model as far as the nonionized species are concerned, it does not obey the pH-partition model.[15] The log P(L/W) value of 2,4-dinitro- and 2-s-butyl-4,6-dinitrophenols at pH 3.0 was "corrected" for the ionization according to the pH-partition model, since the "corrected" valus is thought to be the highest estimate for the valus for the nonionized neutral molecule. The log P(L/W) valus found at pH 3.0 did not differ much from the corrected value shown in Table 1 and was used without correction along with those for other compounds for further analyses, as an approximate value for the neutral form.

The log P(L/W) value was listed in Table 2. The total volume of the internal cavity of vesicles is very small compared with that of the external aqueous phase. Even the partition into the cavity for the least hydrophobic phenols used here having the log P(L/W) value at about 1.00 can be neglected. The log P value measured with the 1-octanol/water system, log P(O/W), has been widely used as a standard for the hydrophobic parameter of the molecule.[16] We plotted the log P(L/W) value against the log P(O/W) for each phenol in Fig. 2, for which Eq. 2 was derived by regression analysis.

$$\log P(\mathrm{L/W}) = \underset{(\pm 0.102)}{0.767} \log P(\mathrm{O/W}) + \underset{(\pm 0.283)}{0.781} \quad (2)$$

$$(n = 26,\ s = 0.195,\ r = 0.953)$$

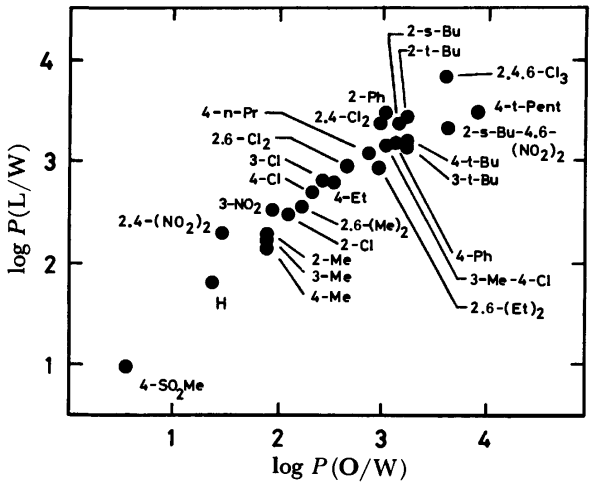

Fig. 2. Plot of log P(liposome/water) vs. log P(1-octanol/water) of substituted phenols.

In this and the following equations, n is the number of substituted phenols, s is the standard deviation, and r is the correlation coefficient. The figures in parentheses are the 95% confidence interval.

Although Eq. 2 seems to show reasonable correlation, slight negative deviations were observed for meta and para isomers. The deviations suggest contributions from factors other than the hydrophobicity of the molecule. Regression analysis was repeated using additional terms for steric and electronic factors of substituents. As the steric parameter, the van der Waals volume of substituents, ΔV_w (V_w relative to that of H and multiplied by 0.1 in order to make it equiscalar with other parameters), was found to delineate the effects best among steric parameters such as STERIMOL, E_s, and E_s^c.[17] The $\Delta\log K_A$ value ($\log K_A$ relative to that of the unsubstituted phenol) was used as the electronic parameter of substituents. Eq. 3 had the best correlation.

$$\log P(\mathrm{L/W}) = \underset{(\pm 0.070)}{0.870}\log P(\mathrm{O/W}) - \underset{(\pm 0.042)}{0.111}\,\Delta V_w(\text{di-ortho}) - \underset{(\pm 0.033)}{0.074}\,\Delta V_w(\mathrm{m,p}) + \underset{(\pm 0.029)}{0.064}\,\Delta\log K_A + \underset{(\pm 0.182)}{0.629} \quad (3)$$

$$(n = 26,\ s = 0.117,\ r = 0.986)$$

ΔV_w(di-ortho) is the sum of the parameters of both ortho substituents for di-ortho-substituted phenols. ΔV_w(m,p) is for the meta and para substituents. The addition of each of the ΔV_w and $\Delta\log K_A$ terms to Eq. 2 was justified at a level higher than 99.5%. The addition of the ΔV_w value for the mono-ortho-substituted compounds was not statistically significant. The coefficient of the log P(O/W) term in Eq. 3 is closer to 1 than that in Eq. 2. This is reasonable, since the degree of desolvation during partitioning from the aqueous to the organic phase is thought to be similar between the two partitioning systems. In the liposome/aqueous system, however, additional factors are significant. The ΔV_w terms suggest that the partitioning into liposomal membrane is slightly but significantly lowered by the bulkiness of substituents and that the effect is dependent upon the substitution patterns. From the regression coefficients, it appears that the effect of two ortho substituents is about double that of meta and para substituents. Interestingly enough, the single ortho substituent in monosubstituted compounds does not have this type of steric effect. The significance of the electronic term means that electron withdrawal from substituents favors partitioning. It should be noted that the electronic effect is not related to that on ionization, since the partition coefficient is that for the nonionized form. The electronic effect of substituents probably reflects a difference in the hydrogen bonding factor of the nonionized OH group with sites that can accept hydrogen between 1-octanol and lecithin.

Glucose Permeability. The rate of glucose release from liposome depends on the concentration of glucose in the internal aqueous phase. It follows first-order kinetics, as in Eq. 4.[14]

$$\text{Rate of glucose release} = k_p[\text{glucose}]_t^i, \quad (4)$$

where $[\text{glucose}]_t^i$ is the internal concentration of glucose at time t and k_p is the first-order rate constant. The integrated form of this equation cover the time t is shown as Eq. 5.

$$\ln\{[\text{glucose}]_{t=0}^i/[\text{glucose}]_t^i\} = k_p \cdot t. \quad (5)$$

Glucose released to the outer aqueous phase is converted into glucose 6-phosphate, which produces NADPH. Since the conversion is also a rate process, and since the glucose concentration of the outer phase is also governed by both permeation and the enzymatic reaction, the concentration of NADPH that is found experimentally does not correspond with that of the glucose in the outer phase. If the overall enzymatic reaction of the glucose assay system is approximated to follow first order kinetics, the [NADPH] at time t is formulated as Eq. 6:

$$[\text{NADPH}]_t = [\text{glucose}]_t^o\{1 - \exp(-k_e \cdot t)\}, \quad (6)$$

where $[\text{glucose}]_t^o$ is the concentration of glucose in the external medium at time t and k_e is the rate constant of the enzymatic reactions. Since $[\text{glucose}]_t^i$ is related to $[\text{glucose}]_t^o$ by Eq. 7,

$$[\text{glucose}]_t^i = [\text{glucose}]_{t=0}^i - [\text{glucose}]_t^o \cdot (V_o/V_i). \quad (7)$$

Eq. 8 is derived by substituting Eq. 7 into Eq. 5, where V_o and V_i are the volume of the external and internal liposome, respectively.

$$\ln \frac{[\text{glucose}]_{t=0}^i}{[\text{glucose}]_{t=0}^i - [\text{NADPH}]_t\{1-\exp(-k_e \cdot t)\}^{-1}(V_o/V_i)} = k_p \cdot t \quad (8)$$

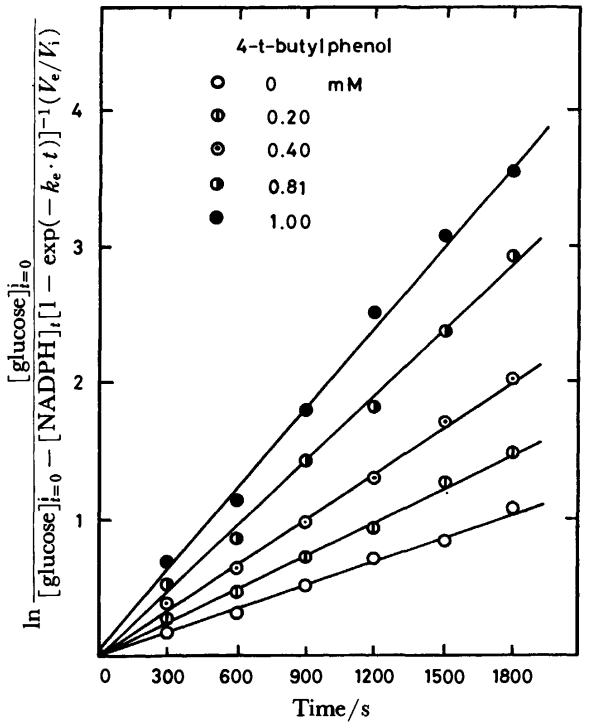

Fig. 3. Release kinetics of glucose. Data were plotted using Eq. 8.

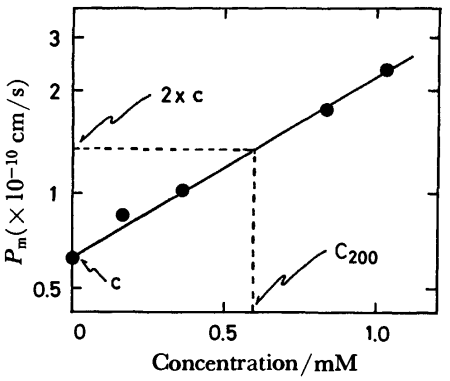

Fig. 4. Plot of the permeability coefficient of glucose vs. the concentration of 4-*t*-butylphenol. Data were analyzed by the least squares method using Eq. 10.

The k_e value might be as a constant regardless of the phenols used. In fact, it varies depending upon the structure of the phenols, since the enzymatic reaction is more or less inhibited by individual phenols. The k_e value was determined under the same experimental conditions as the glucose release assay for different concentrations of each phenol in the presence of 1.5×10^{-5}M glucose without glucose-liposome. It ranged between 5×10^{-4}s^{-1} and 3×10^{-3}s^{-1} (data not shown). The plot of the left side of Eq. 8 against time t was linear, as shown in Fig. 3 for 4-*t*-butylphenol. When we neglected the effect of the enzymatic rate process by using $k_e \gg k_p$, the denominator of the ln term in Eq. 8 reduced to $[\text{glucose}]^{i}_{t=0}-[\text{NADPH}]_t$ (V_o/V_i). The plot with this modification against t was not linear. This means that the approximation made for Eq. 6 was in fact appropriate.

The permeability coefficient, P_m, is defined by Eq. 9, where A is the surface area of liposome and k_p is evaluated according to Eq. 8.

$$P_m = k_p \cdot V_i/A \tag{9}$$

The average surface area of liposome was calculated to be 2.0×10^3cm^{2}μmol^{-1} lecithin from the average diameter of vesicles, estimated by electron microscopy. The mean value of the P_m of glucose, from 30 runs, was $6.6\pm1.3\times10^{-11}$cm s^{-1}. This value is close to the $3.0\pm2.0\times10^{-11}$ cm s^{-1} observed by Brunner.[15]

The P_m value of glucose increases with successive additions of phenols in the outer phase, as shown in Table 3. We defined a parameter, C_{200}, for each phenol to represent potency of accelerating the release of glucose to twice that of the control in terms of the initial external concentration. For some phenols, the C_{200} concentration could not be found because of their limited solubility. In that case, we estimated this concentration by an empirical relationship such as that of Eq. 10 between P_m and the initial external concentrations of each phenol (C).

$$\log P_m = aC + c \tag{10}$$

Equation 10 holds for the 18 phenols used here with a correlation coefficient higher than 0.96 and a standard deviation smaller than 0.06. An example of the relationship is shown in Fig. 4. This relationship can be understood if we consider that the free energy of activation for the permeation process of glucose decreases linearly with the amount of each phenol partitioned into the liposomal membrane that is proportional to the external concentration. The a and c values in Eq. 10 were estimated by the least squares method and the quality of the correlation is shown in Table 4. The C_{200} value was calculated as $(\log 2)/a$ and listed in Table 4 as the logarithm.

The partitioning of organic solutes with a liposome/aqueous system reaches an equilibrium within a few minutes.[19] Since glucose release in this study obeys first-order kinetics very well, the effect of the conditions before equilibrium could be neglected. Release proceeds mostly under equilibrated conditions with respect to the partition of phenols. In fact, the C_{200} value (in log form) is almost identical to the value corrected for the partition equilibrium for each phenol. As an index for potency in perturbing the liposome membrane structure, it was suitable to use $\log(1/C_{200})$.

At pH 5.3, the phenols used here, except for 2-*s*-butyl-4,6-dinitrophenol, exist almost entirely as the neutral form. The $\log 1/C_{200}$ value of phenols other than this exception had a good linear relationship with log P(O/W) for the nonionized phenols, that of as Eq. 11.

$$\log 1/C_{200} = 0.912 \log P(\text{O/W}) + 0.162 \tag{11}$$
$$(\pm0.170) \qquad (\pm0.480)$$
$$(n = 17, s = 0.192, r = 0.947)$$

3-NO_2	0.050[i] (0.031)	−10.522 (0.215)	0.064	0.980	2.21	2.13	6.82
2-*s*-Bu-4,6-$(NO_2)_2$	0.700 (0.338)	−10.085 (0.077)	0.027	0.967	3.37	0.621	12.34

a) log P(L/W) and log P(O/W) values at pH 5.3 used in Eqs. 11 and 12 are equal to values for the neutral form listed in Table 2 except for 2-*s*-Bu-4,6-$(NO_2)_2$. log P(L/W) value at pH 5.3 of 2-*s*-Bu-4,6-$(NO_2)_2$ is 3.16. b) Slope and intercept in Eq. 10. Unless otherwise noted, the correlation was justified above the 99.5% level; figures in parentheses are the 95% confidence interval. c) Standard deviation of the correlation according to Eq. 10. d) Coefficient of correlation accoding to Eq. 10. e) The C_{200} value was calculated as (log 2)/a from Eq. 10. f) The concentration of phenols in the liposomal membrane equilibrated with C_{200}. g) The van der Waals volume of compounds estimated according to A. Bondi, *J. Phys. Chem*, **68**, 441 (1964). h) Justified at the 99% level. i) Justified at the 97.5% level.

This equation means that the potency of membrane perturbation is linearly dependent on the hydrophobicity of phenols in terms of log P(O/W). The addition of other parameters does not further improve the correlation. To incorporate 2-*s*-butyl-4,6-dinitrophenol into the analysis, the log P(L/W) value found at pH 5.3 was used as the independent variable, since the partitioning occurring during the glucose release is better simulated by the P(L/W) value. For 2-*s*-butyl-4,6-dinitrophenol, log P(L/W) is the value for the ionization equilibrium mixture, since the liposome can incorporate both species. Equation 12 was derived for perturbation potency.

$$\log 1/C_{200} = 0.868 \log P(\mathrm{L/W}) + 0.119\, V_w - 0.794 \quad (12)$$
$$(\pm 0.136) \qquad (\pm 0.035) \quad (\pm 0.280)$$
$$(n = 18,\ s = 0.086,\ r = 0.991)$$

In Eq. 12, the term of steric parameter V_w for the entire molecular volume is also significant, which indicates that perturbation potency is governed not only by partitioning into liposome but also by the steric bulkiness of the phenols. Although the collinearity between log P(L/W) and V_w is rather high (r^2=0.514) in this set of compounds, the addition of the V_w term is significant at a level higher than 99.5%.

Polarity of the Liposomal Membrane Surface. The fluorescent probe DSHA is thought to be buried in the lecithin bilayer in such a way that its polar dansyl group is directed toward the surface and the hydrophobic long alkyl chain is arranged along the alkyl chain of lecithin.[12] The emission maximum of DSHA has been used as an indicator of the surface polarity of liposomal membranes.[12] It was observed at 520 nm for the liposome suspension here. The maximum in methanol was at 518 nm and that in the 2:1 methanol-water mixture at 522 nm. Therefore, the surface region of liposomal membrane is probably more polar than methanol and less polar than 2:1 methanol-water. In this study, we examined the effect of the 2-*t*-butyl-, 4-methyl-, 4-propyl- and 4-*t*-butylphenols on the emission maximum. As shown in Fig. 5 for the 4-*t*-Bu derivative, the maximum was shifted to the polar side by the addition of substituted phenols. When the concentration increased, it approached to 528—529 nm, which corresponds to that of 1:1 methanol-water. The concentration range where the maximum shift was observed varied depending upon the structure of the phenol (data not shown). In terms of the concentration in the membrane phase, however, it was located in the range of 1.5—2.5 mol kg^{-1} lecithin.

Discussion

Several studies examined the partition behavior of

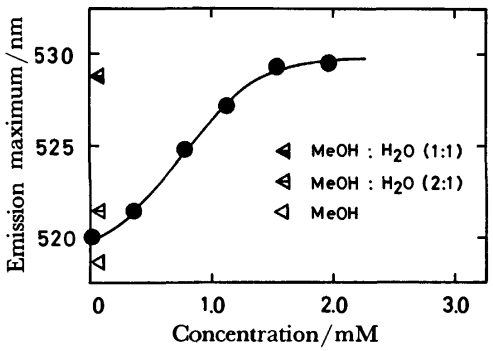

Fig. 5. Position of the fluorescence emission maximum of DSHA incorporated in liposomal membrane in the presence of 4-*t*-butylphenol. Emission maximum of DSHA in 1:1 MeOH-H_2O, in 2:1 MeOH-H_2O, and in MeOH are shown for reference.

various organic solutes in the liposome/water system as a model of biological membranes. Diamond and Katz[18] and Jain and his coworkers[19] found that the effects of the substituents and the substructural features such as chain-branching on the liposome/water partition coefficient are qualitatively similar to those observed for organic solvent/water partition systems. They also noticed that the effect of chain-branching in aliphatic alcohols in lowering the partition coefficient is greater in a liposome/water system than in systems with organic solvents such as olive oil and 1-octanol. They stated that this difference is due to steric repulsion on the more or less parallel arrangement of hydrocarbon tails in the interior of liposomal membranes. There seemed to be an extra steric effect when partition coefficients of liposome/water and organic solvent/water systems were compared.

The quantitative result formulated for substituted phenols in Eq. 3 seems to conform to these previous general findings. Phenol molecules are dehydrated in the lecithin membrane to a degree close to that occurring in the 1-octanol/water partitioning process. However, the steric bulkiness of substituents in terms of the group van der Waals volume lowers the partitioning into liposome more than into the octanol phase. The effect of ortho substituents is most important when they occupy both ortho positions, but not significant in mono-ortho-substituted derivatives, so that the bulkiest substituents, such 2-*t*-Bu, 2-*s*-Bu, and 2-Ph, alone have no significant steric effect. The effect of meta and para substituents is significant but less important than that of di-ortho substitution. From these positional specificities in the steric effect, the following model for the orientation of phenols in the liposomal membrane can be proposed. The substituted phenols are buried from the side of the substituted benzene ring holding the polar OH group toward the external aqueous phase. In this situation, meta and para substituents have an unfavorable effect on packing of the lecithin molecules, in proportion to their volume. For ortho-substituted derivatives, the OH and the single ortho substituent would be located together close to the outside of the membrane where the lecithin polar head groups are loosely packed, having no significant steric effect on the packing structure of the membrane. This kind of orientation would no longer be possible for di-ortho-substituted derivatives. In such compounds, interaction of the OH group with the polar head substituents of lecithin could be hindered. Since the di-ortho-substituted derivatives could behave as less polar molecules than the other substituted phenols, they tend to be buried deeper in the membrane structure. Thus, the steric effect of two ortho substituents acting as a wedge against the parallel arrangement of lecithin molecules is significant. As shown in Eq. 3, electron-withdrawing substituents are more favorable to the partitioning into liposome than into the 1-octanol phase. This could be rationalized by the fact that the basicity of the hydrogen-bond acceptor in liposome (perhaps phosphate anion) is higher than that of the oxygen of 1-octanol.

This orientation model is consistent with information from surface polarity measurements. The marked increase in the surface polarity of the membrane caused by substituted phenols shows that the interactions between polar head groups are weakened due to disorder of the membrane structure near the surface where phenols are buried, and the hydration around the head groups increases greatly. These results seems to be in accord with those obtained earlier,[20] where substituted phenols such as BHT (2,6-di-*t*-butyl-4-methylphenol) and its analogs disturbed molecular packing primarily near the polar head-group region of the lecithin bilayer.

Liposomal membrane perturbation caused by phenols, studied in terms of the increase in passive glucose permeability, was affected by partitioning into the membrane phase and steric bulkiness. The higher the partition coefficient and the steric bulkiness, the higher the degree of perturbation, leading to higher glucose permeability. Lipid-soluble drug molecules generally stabilize the membrane structure, to decrease permeability to permeants.[20-22] This stabilization is thought to be the origin of the antihemolytic activity on erythrocytes of various organic compounds, including anesthetics and tranquilizers. This kind of effects, however, was observed in concentration ranges that had a threshold, and high concentrations of organic molecules irreversibly disordered the membrane structure to increase permeability, as in haemolysis.[23] In this study, glucose permeability did not decrease in the lower range of phenol concentrations. The experimental system could inherently be such that no membrane stabilization was observable, requiring concentrations higher than the "threshold" to cause membrane perturbation.

Steric bulkiness increases the perturbation of the liposomal membrane, as shown in Eq. 12. We ex-

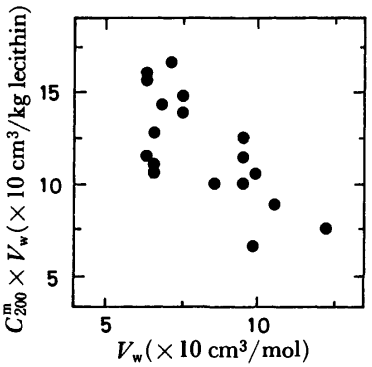

Fig. 6. Plot of the occupying volume in liposomal membrane vs. van der Waals volume of phenols. The scale of V_w was multiplied by 0.1.

amined the nature of this steric effect in terms of the occupying volume of substituted phenols in the membrane phase, and derived Eq. 13, where C^m_{200} is the concentration of phenols in the liposomal membrane (mol phenol/kg lecithin) equilibrated at the C_{200} concentration estimated from the log P(L/W) value, and where V_w is the molecular van der Waals volume of compounds.

$$C^m_{200} \cdot V_w = -1.133\, V_w + 21.141 \quad (13)$$
$$(\pm 0.626) \qquad (\pm 5.229)$$
$$(n = 18,\ s = 2.193,\ r = 0.692)$$

Although the correlation coefficient is not very high, the V_w term is significant above the 99.5% confidence level. As shown in Fig. 6, there is a clear trend in which the larger the steric bulk of the molecule, the smaller is the occupying volume with the equivalent degree of membrane perturbation potency. This may mean that the effect of steric bulk is caused not by the bulk itself, but that the effect is enhanced proportionally to the bulk.

This study indicates that the separation of various effects is very helpful to understand the mechanisms of membrane phase partitioning and the membrane structure perturbation of organic compounds. Understanding can be achieved only by quantitative analysis using physicochemical molecular parameters. The effect of substituted phenols on these membrane characteristics can be separated in terms of the hydrophobicity and the steric bulk relative to these for appropriate reference systems. Work in progress in this laboratory indicates that a procedure of this sort can be used in analysis of the effect of the same series of compounds on the proton permeability across the lecithin bilayer, simulating the inner mitochondrial membrane.

The calculations were performed with a FACOM M382 computer at the Data Processing Center of this University. We thank Professor Hiroshi Terada, the Faculty of Pharmaceutical Sciences, Tokushima University for his invaluable discussions.

Synthetic Photochemistry. XXXIV.[1] Synthetic Strategy of 5-8-5-Membered Tricyclic Higher Terpenoids Based on the Condensation of Two Optically-Active Iridoids, C_{10}-Synthons Obtained from Photo-Cycloadduct of Methyl 2,4-Dioxopentanoate-Isoprene, and Its Application to a Synthesis of the Basic Carbon Skeleton of Fusicoccane[2]

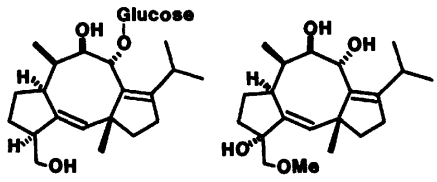
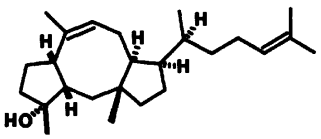
(Received October 22, 1985)

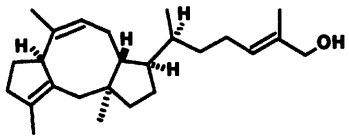
One of the photocycloadducts obtained during methyl 2,4-dioxopentanoate to isoprene was converted to optically active iridoids. Using a $CrCl_2$ reductive-coupling reaction, proper combinations of two kinds of enantiomeric iridoids, 1-iriden-7-al and 9-benzyloxy-7-chloro-1-iridene, produced versatile intermediates for various types of 5-8-5-membered tricyclic natural products. From one such product, fusicocca-2,8,10(14)-triene (**1**) was synthesized by sequential transformations.

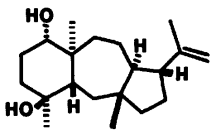
There are several higher terpenoids that have 5-8-5-membered tricyclic frameworks e.g, fusicoccins (**A**) and cotylenins (**B**),[3] ophiobolins (**C**),[4] ceroplastols (**D**),[5] and several other recently found derivatives.[6,7] From their stereochemical characteristics, one can say that i) these tricyclic skeletons can be divided into two iridoid blocks, and ii) depending on their origins, these natural products possess different stereochemistries involving a basic carbon skeleton. Therefore, a synthetic strategy based on the dimerization of iridoid synthons to natural products, many of which possess heavy oxygenated functions, and are reported to be physiologically or biologically active, should be attractive. In addition, there are related tricyclic derivatives, e.g., marine metabolites, 6-7-5-membered tricyclo compounds, clavularenes (**E**) isolated from *Clavularia inflata*.[8] Their total synthesis might also be achieved by a slight modification of this method. Recently, we developed a facile preparation of iridoid synthons from the photoadduct of methyl 2,4-dioxopentanoate (**F**) to isoprene (**G**)[9] via titanium(II) chloride-mediated retro-ozonolysis.[10]

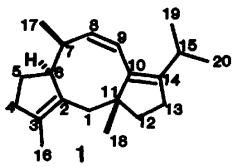
In this paper, the first synthesis of fusicocca-2,8,10(14)-triene (**1**) is described.[11] It is thought to be the missing link in the biogenesis of natural fusicoccins,[2] all of which possess the trans-8β,9α-diol function.[3]











Scheme 1.

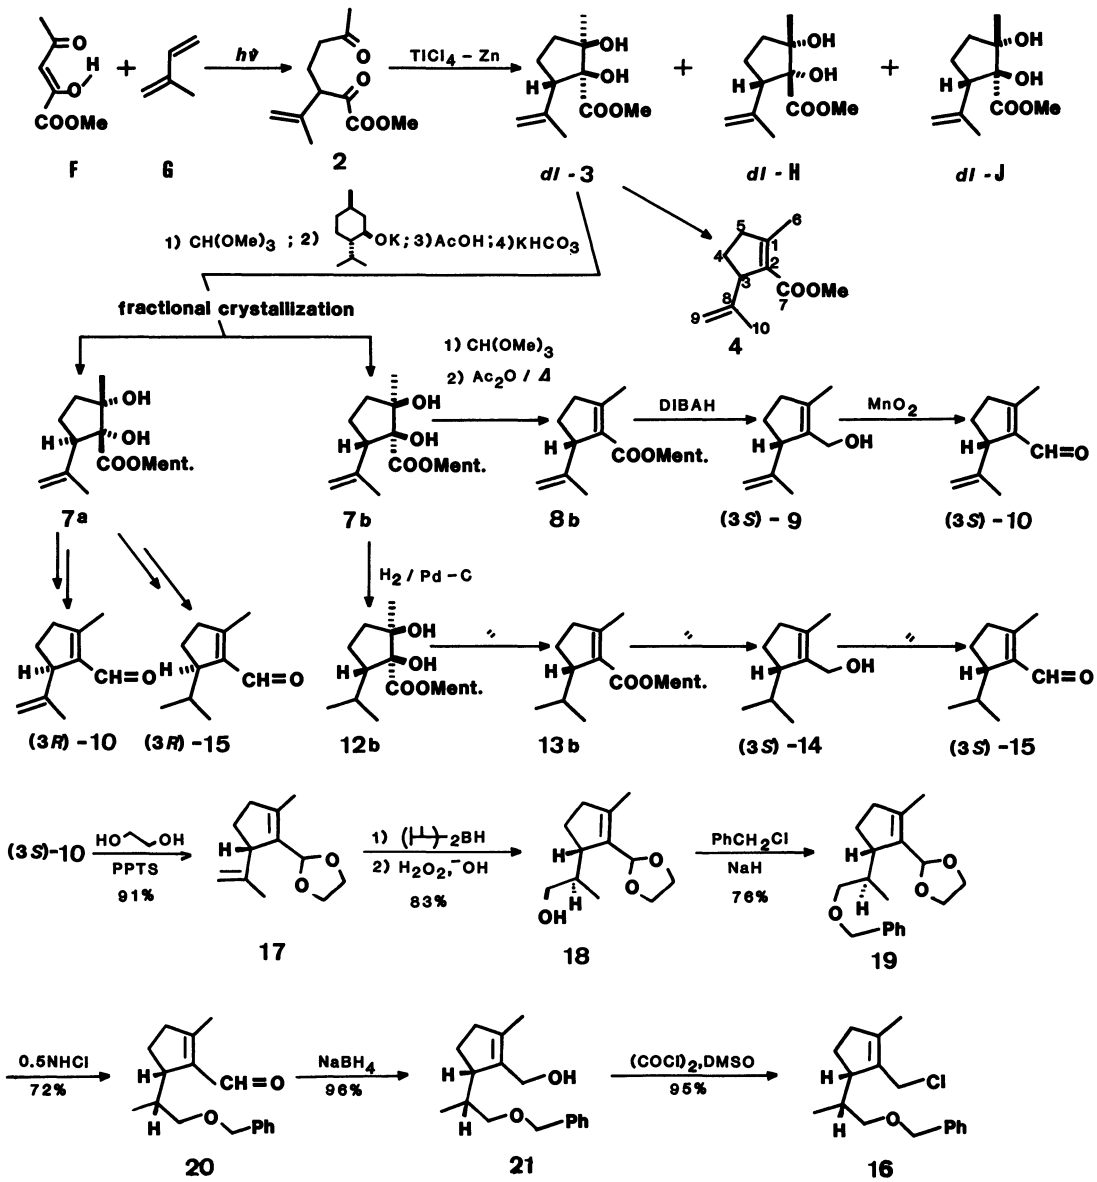
Results and Discussion

Optical Resolution. As previously described,[13] Mukaiyama's titanium(II) chloride-mediated reductive cyclization of photoadduct (**2**) from **F** to **G** gave three 1,2-diol derivatives (**3**, **H**, and **J**), among which the major product, **3**, was convertible to the olefin (**4**) in good yield. Since diols are appropriate for introducing an optically active segment for the resolution, we first investigated the optical resolution of these iridoids to minimize the number of isomers of the dimeric condensates in the subsequent steps. The **3** was treated with trimethoxymethane (**5**) and pyridinium *p*-toluenesulfonate (PPTS) in benzene and with potassium salt of *l*-menthol (**6**) followed by aqueous acetic acid-hydrolysis to form, via an orthoester, *l*-menthyl 1,2-dihydroxy-8-iriden-7-oates (**7a** and **7b**).[14]

Fractional recrystallization of **7a** and **7b** easily enabled the resolution; the isomer with a higher-melting point, mp 97—97.5 °C, showed $[\alpha]_D=-57.1°$, while the isomer with a lower-melting point, mp 81.5—82 °C, showed $[\alpha]_D=-40.8°$. The former was (3*S*)-**7b** and the latter was (3*R*)-**7a** based on the following transformations. The (3*S*)-**7b** was consecutively treated with **5** and PPTS and then with acetic anhydride under reflux[15] to give *l*-menthyl (3*S*)-1,8-iridadien-7-oate ((3*S*)-**8b**). This was, according to a known procedure, transformed to (3*S*)-1,8-iridadien-7-ol ((3*S*)-**9**) by diisobutylaluminum hydride (DIBAH)-reduction and (3*S*)-1,8-iridadien-7-al ((3*S*)-**10**) by manganese(IV) oxide-oxidation.[16] Previously, enantiomeric **10** was prepared and the absolute stereochemistry clarified.[16] For the preparation of **10** from **9**, a Collins oxidation produced a poor result due to the formation of a byproduct, (3*S*)-1,2-epoxy-8-iriden-7-ol (**11**). A catalytic reduction of (3*S*)-**7b** gave a dihydro derivative, *l*-menthyl (1*R*,2*S*,3*S*)-1,2-dihydroxyiridan-7-oate (**12b**), which, upon similar treatment with **5** and PPTS, followed by thermolytic deoxygenation, DIBAH-reduction and oxidation, formed *l*-menthyl (3*S*)-1-iriden-7-oate ((3*S*)-**13b**), (3*S*)-1-iriden-7-ol ((3*S*)-**14**), and (3*S*)-1-iriden-7-al ((3*S*)-**15**). The same transformations starting from (3*R*)-**7a** were carried out.

Chromium(II) Chloride-Mediated Coupling of Two Iridoids and the Stereochemistry. For the chromium(II) chloride-mediated coupling reaction, the required (3*S*)-9-benzyloxy-7-chloro-1-iridene ((3*S*)-**16**) was prepared by (3*S*)-**10** by treating 1,2-ethanediol to give an acetal (**17**), stereoselective hydroboration[9] to (3*S*,8*R*)-7,7-ethylenedioxy-1-iriden-9-ol (**18**), benzylation to 9-benzyloxy derivative (**19**), hydrolysis to 9-benzyloxy-1-iriden-7-al (**20**), reduction to 9-benzyloxy-1-iriden-7-ol (**21**), and treatment with oxalyl dichloride and dimethyl sulfoxide (DMSO)[17] to (3*S*)-**16**.

When (3*S*)-**15** and (3*S*)-**16** were treated with chromi-



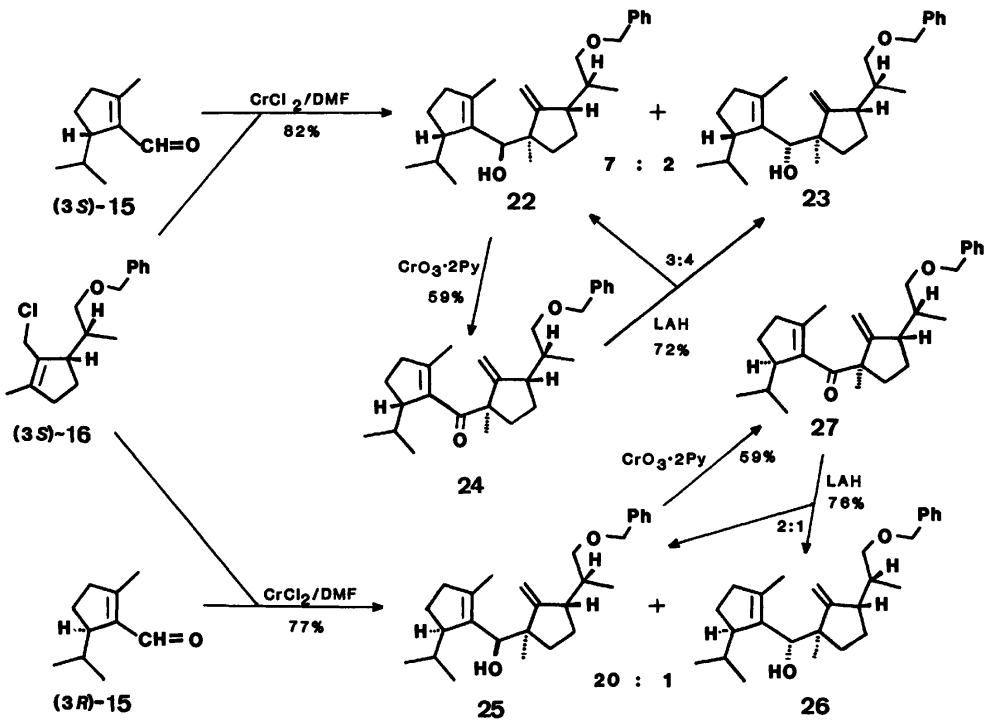
Scheme 2.

um(II) chloride in *N*,*N*-dimethylformamide (DMF), two condensates (**22** and **23**) were obtained in 82% yield with a ratio of 7:2. Collins oxidation of **22** gave a dehydro ketone (**24**), and its lithium aluminum hydride (LAH)-reduction in tetrahydrofuran (THF) reproduced **22** and **23** in a ratio of 3:4. Therefore, **22** and **23** are epimeric. In parallel, (3*R*)-**15** and (3*S*)-**16** also gave two condensates (**25** and **26**) in 20:1, and by Collins oxidation, the former, **25**, yielded another dehydro ketone (**27**) which was reduced to **25** and **26** by LAH.

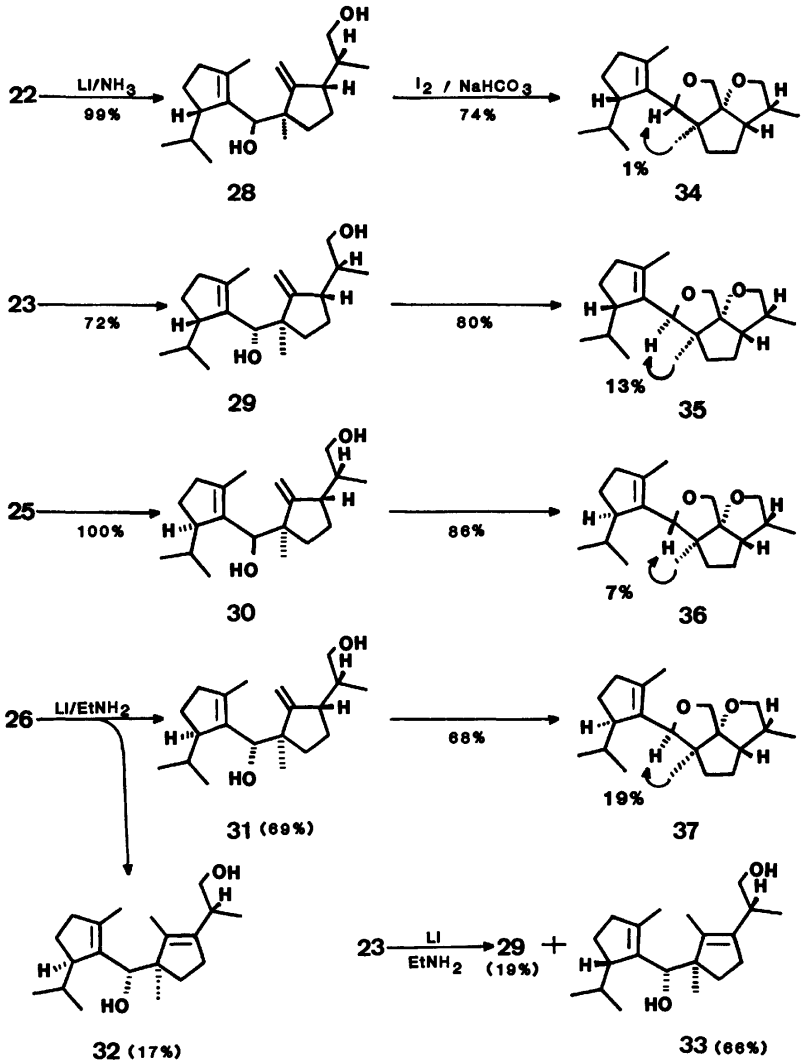
Nevertheless, in both cases the chromium(II) chloride condensation yielded only a pair of epimers. The observed product distributions might indicate the stereochemistry of the C–C bonding site as being an attack of carboanion from the less hindered side to produce a cis-relationship for the quaternary methyl and isopropyl groups.

This has been verified unambiguously as follows. The four condensates (**22**, **23**, **25**, and **26**) were easily debenzylated by a Birch reduction to give 1,2-diols (**28**, **29**, **30**, and **31**) in good yields. When the Birch reduction of **26** was carried out in ethylamine, the products were **31** and its bond-migrated isomer (**32**) with two tetrasubstituted double bonds. This was also the case when **23** was reduced in ethyl amine; the debenzylated products were **29** and the isomeric diene (**33**), the major product (66% yield). All of these (**28** to **31**) formed iodine-free bis-ether derivatives (**34**, **35**, **36**, and **37**). Since these are triply fused five-membered ring systems, their ring junctures should all be cis. From this requirement, quaternary methyl and isopropyl groups are cis, as depicted. The stereochemistry of the secondary hydroxyl groups were determined by the nuclear Overhauser effect between each singlet methyl signal and the proton signal from the carbinyl carbon. The observed enhancement of carbinyl proton signals upon irradiation with radio frequencies corresponding to the chemical shifts ascribable to the quaternary methyl singlets were shown to be 1% for **34**, 13% for **35**, 7% for **36**, and 19% for **37**, respectively. Thus, **35** and **37** possessed a cis-configuration, while their counterparts, **34** and **36**, showed a trans-relationship. The original stereochemistry of **22**, **23**, **25**, and **26** was established as shown.

Cope Rearrangement and the Singlet-Oxygen Oxidation. At first, the recently developed anionic *oxy*-Cope rearrangement[19] was attempted, but gave an inferior result. For instance, the thermolysis of the oxy anion species derived from a potassium hydride treatment of **25** in anhydrous THF caused the fragmentation to two iridoids ((3*R*)-**15** and **38**) and only a small amount of the products (**39a** and **39b**) were obtained as a mixture. The ^{1}H NMR spectra of **38** and **39** revealed that their structures are in agreement with those predicted from the reaction mechanism. On the other hand, the Cope rearrangement was dramatically improved when the secondary hydroxyl was protected by the trimethylsilyl (TMS) group. In this case, the TMS derivative (**40**, **42**, or **43**) prepared from **22**, **25**, or **26**, at 190 °C in a sealed tube, a single thermolysate (**44**, **45**, or **46**) was produced each time. However, in the case of **41**, for the TMS derivative of **23**, it was necessary to heat above 200 °C for 4 d to produce two products (**47** and **48**). This stereochemical behavior is attributable to the



Scheme 3.

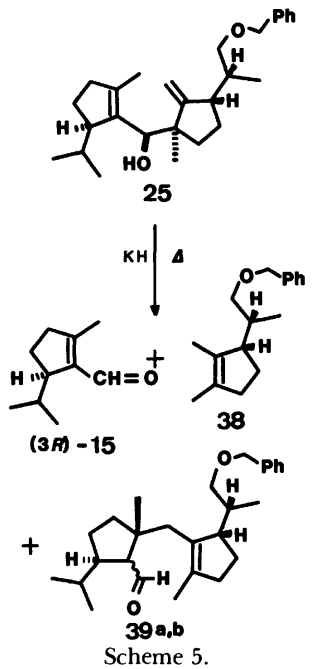


Scheme 4.

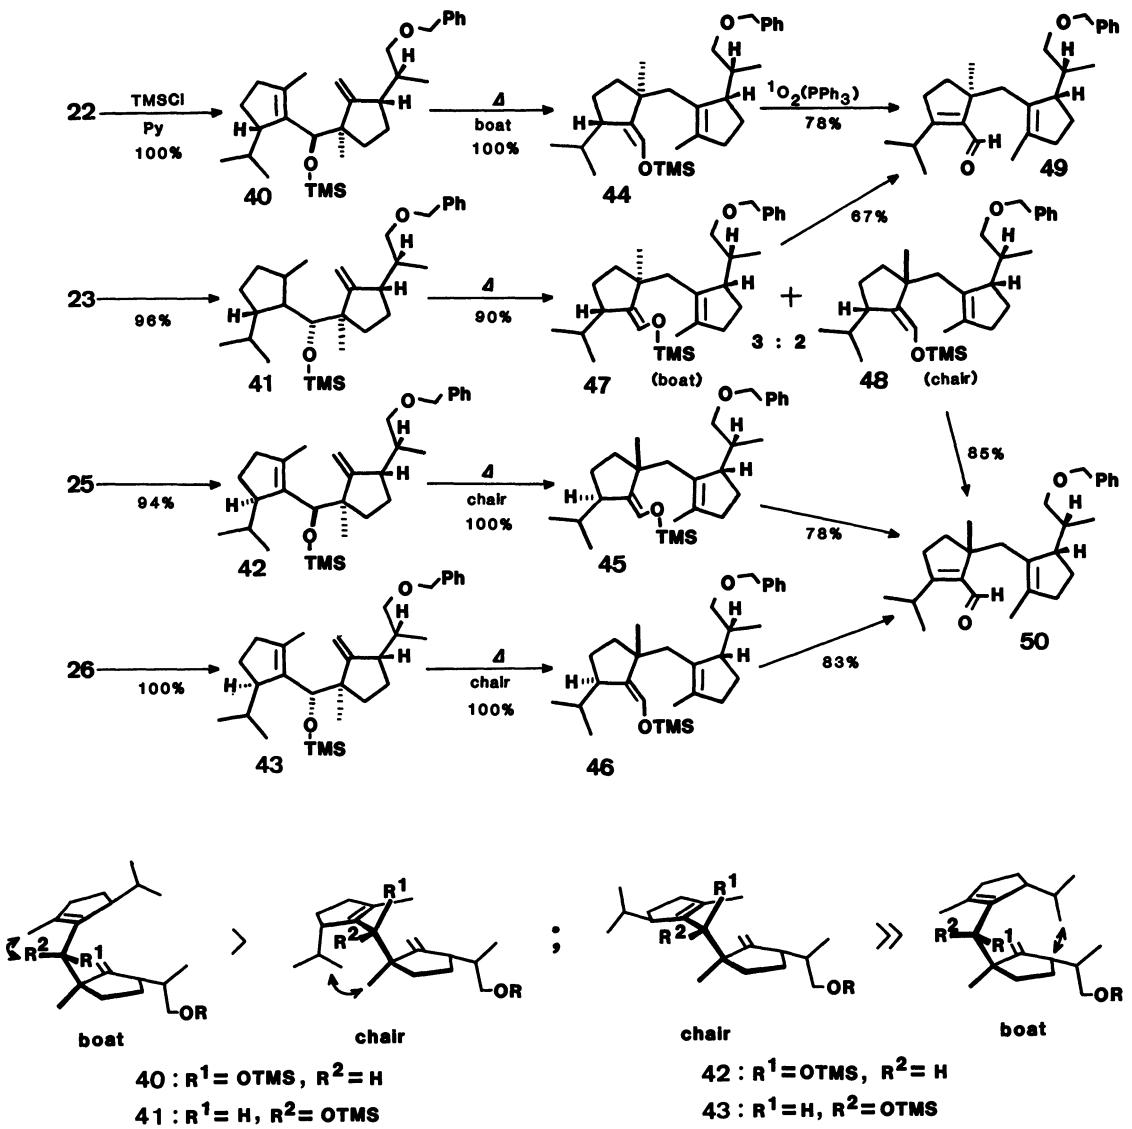
geometry of the transition state in the rearrangement, a concerted [3,3] sigmatropy.

According to a study using molecular models, it is certain that the predominant conformers in the transition state of the rearrangement should be chair-like for **42** and **43**, respectively (Scheme 6). Alternative boat-like conformers suffer heavy nonbonding interactions. On the other hand, the chair-like conformers for **40** and **41** suffer nonbonding interactions and, furthermore, in the boat-like conformer of **41** a considerable interaction also exists between the newly-formed quaternary methyl group and the trimethylsiloxy (TMSO) group due to a 1,3-diaxial mode. As a result, both conformations which are required for an electrocyclic reaction are more unstable than any other extended conformers. Indeed, the thermolysis of **41** required more severe conditions than others and gave two thermolysates, **47** and **48**, via the different transition states.

Although the reaction conditions were different and reflected the geometries of the transition states of



Scheme 5.



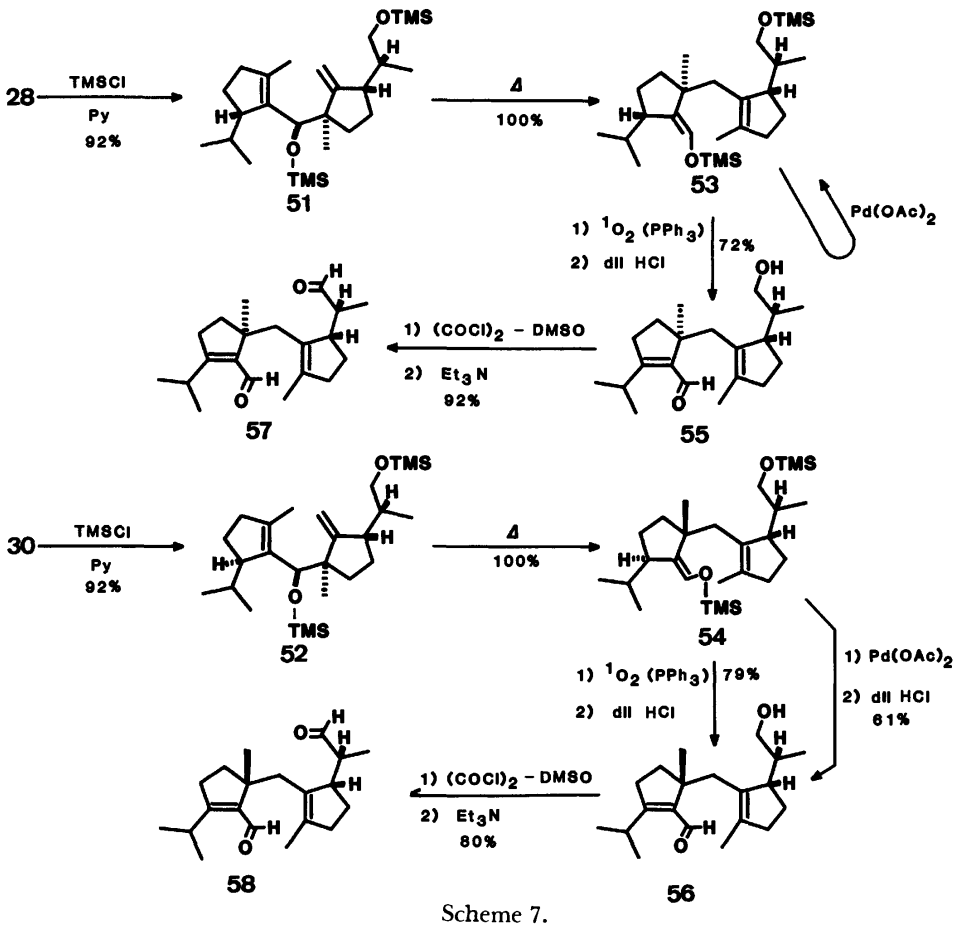
Scheme 6.

the compounds, the reaction mixture remained clean and neat, and the yields of the thermolysates were satisfactory.

Thus, Cope rearrangement worked to not only transfer an oxygen function to the required position for subsequent cyclization, but also worked to adjust the stereochemistry of fused tricyclic frameworks. This means one can synthesize various stereoisomers with or without a Cope rearrangement. In view of the oxidation state around the ring C of fusicoccane derivatives and for the sake of a convenient structural analysis, thermolysates were oxidized to α,β-unsaturated aldehydes (**49** and **50**). For this purpose either singlet oxygen ($^1O_2$)-oxidation[19] or palladium(II) acetate-oxidation[20] might be suitable. The former gave the better result. It is particularly advantageous that, at least for a preparative purpose, the separation of $CrCl_2$-induced condensation products was not necessary. The subsequent transformation of **25** and **26** resulted in the formation of the same compounds, while the thermolysis conditions of **22** and **23** were greatly different.

Dialdehyde Formation. Based on the establishment of a stereoelectronic course for the Cope rearrangement, we then investigated the thermolysis with more suitable reactants than the benzyloxy derivatives (**40**, **41**, **42**, and **43**): The bis-TMS derivatives (**51** and **52**) derived from **28** and **30**. Indeed, a clean stereospecific rearrangement occurred forming **53** and **54**. In parallel to **40**, and **42**, **53**, and **54** were each oxidized with $^1O_2$ to α,β-unsaturated aldehydes (**55** and **56**) which, by the advantage of TMS derivatives, generated the primary hydroxyl groups during the workup. An alternative palladium(II) acetate oxidation gave **56** from **54** in fair yield, but gave no **55** from **53**.

The Swern oxidation[17] of **55** and **56** gave the desired dialdehydes (**57** and **58**) in good yields. From its stereostructure, **58** should be a precursor of diterpenoids such as cotylenins or fusicoccins while **57** should be a good precursor for sesterterpenoids such as ophio-

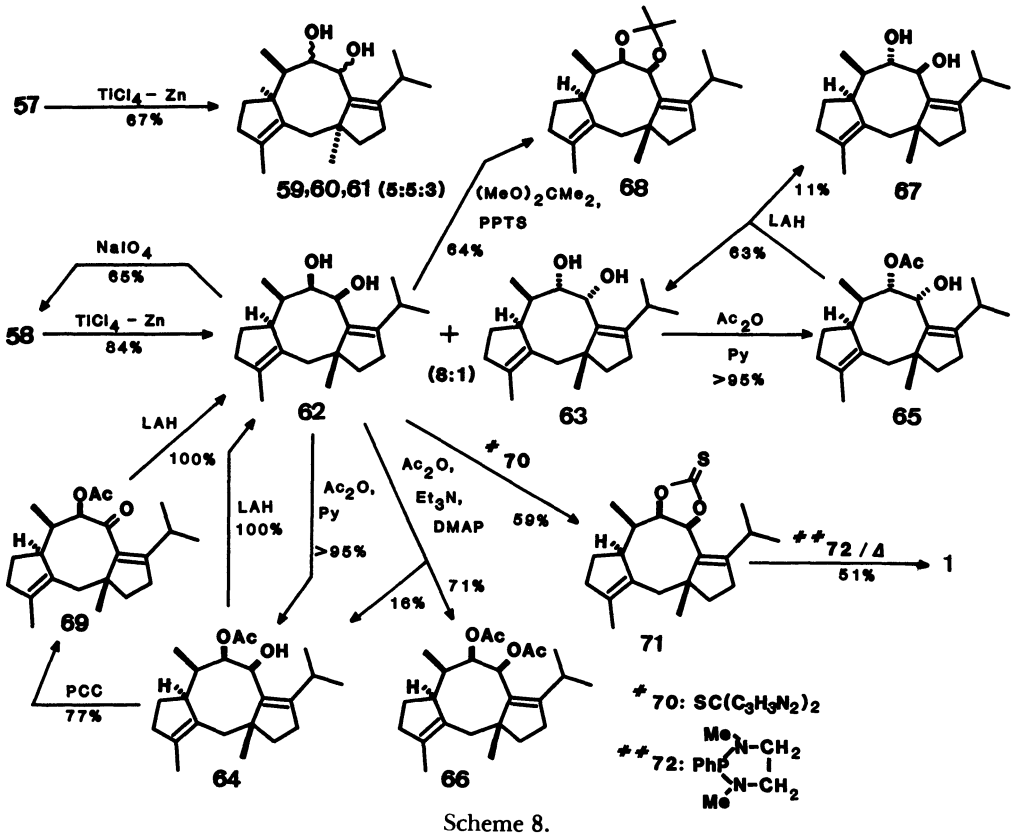


Scheme 7.

bolanes or ceroplastanes. This is true even though further transformations are required to furnish the correct stereochemistry on the side chains. Recently, several diterpenoids with a "sesterterpenoid-like" ring systems have been isolated.[7]

Titanium(II) Chloride-Mediated Reductive Cyclization. When **57** was reduced with titanium(II) chloride (generated in THF by Mukaiyama's method),[10] three cyclisates (**59**, **60**, and **61**) were formed (5:5:3) with a combined yield of 68%. However, it required high-dilution conditions to prevent an intermolecular condensation. Although the central eight-membered B-ring might be conformationally flexible, a careful inspection of the ^{1}H NMR spectra showed their stereostructures. Both **60** and **61** revealed large vicinal couplings (J=9 Hz) between the protons on the carbons of 1,2-diol functions, making them to be trans-diols. The **59** revealed a small coupling constant (J=4 Hz), indicating a cis-diol structure. Moreover, **59** and **61** exhibited relatively lower signals which were ascribable to the quaternary methyl singlets at δ=1.20, while the signal of the corresponding methyl of **60** was at 0.98. Accordingly, the quaternary methyl and C-9 hydroxyl of **59** and **61** are in cis-direction, and, thus, have a 1,3-diaxial relationship. From these facts, **59**, **60**, and **61** must be 8α,9α-diol, 8α,9β-diol, and 8β,9α-diol, respectively. The chemical shifts of their secondary methyl groups at C-7, were 0.93 for **59**, 0.96 for **60**, and 0.98 for **61**. These were also explainable in terms of an anisotropic effect due to adjacent C-8 hydroxyl groups.

On the other hand, the titanium(II) chloride-induced cyclization of **58** was much superior with respect to product distributions; it gave almost one product (**62**) in a yield greater than 80%. Although a byproduct (**63**) could not be isolated as diol, its formation was confirmed after silica-gel column chromatography of the monoacetates (**64** and **65**) prepared from a mixture of the cyclisates. Its yield was estimated to be ca. 11%. A diacetate (**66**) was obtained by the acetylation of **62** with acetic anhydride and 4-(dimethylamino)pyridine (DMAP) together with some amount of **64**. The removal of the acetyl group of **65** by LAH-reduction resulted in a solvolytic rearrangement; the major product was indeed **63** whose ^{1}H NMR spectrum had a close resemblance to that of **65**. The byproduct (**67**) showed the signal for the quaternary methyl group at relatively low-field to indicate an epimerization of C-9 hydroxyl to form 8α,9β-diol. It is certain that the original mixture did not contain **67**. A smooth sodium periodate-oxidation of **62** afforded **58**; therefore, the original configuration was retained during the cyclization. The structure of **62** resembles that of the natural fusicoccins; only the differences are orientation



Scheme 8.

of C-9 hydroxyl and the position of the double bond in the A/B rings. The stereochemistry of the 1,2-diol function of **62** was further confirmed by the formation of an acetonide (**68**) which could be prepared by a PPTS-treatment of **62** and 2,2-dimethoxypropane. The central eight-membered ring of **68** became rigid and showed sharp ^{1}H NMR signals which revealed the coupling patterns of the methine protons, i.e., the signals at δ=4.20 and 5.17 mutually coupled with 9 Hz to clarify the cis relationship. Also the former signal showed an additional coupling (1 Hz) to the vicinal methine proton at a carbon bearing the secondary methyl group. We tried hard to invert the hydroxyl group at C-9; for example, when the keto acetate (**69**), prepared from **64** by pyridinium chlorochromate (PCC)-oxidation, was reduced by LAH. The isolable product was only regenerated **62**. We are still studying this matter.[21]

Synthesis of Fusicoccatriene. According to the biogenetic concept, the C-8 and C-9 positions of these terpenoids correspond to one of the head-to-tail junctures of the isoprene units.[22] Therefore, in the original precursors (geranylgeraniol or geranylfarnesol) they were the sp^3-carbons. This means that the 1,2-diol function was derived via a dehydrogenation followed by epoxidation and hydrolysis. Consequently, the reductive elimination of the 1,2-diol to an olefin (**1**) should constitute a synthesis of a common intermediate during biogenesis. Following Corey's procedure,[23] **62** was converted by 1,1'-(thiocarbonyl)bis[diimidazole] (**70**) to a thiocarbonate (**71**). After several unsuccessful attempts, **71** was finally converted to **1**. Its heating in benzene to reflux with a thiophile, 1,3-dimethyl-2-phenyl-1,3,2-diazaphospholidine (**72**),[24] afforded a hydrocarbon whose NMR features and molecular weight (by mass spectrometry) were fully consistent with the structure of **1**.

Up to now, several synthetic studies regarding these tricyclic higher terpenoids have been reported, but most of the current effort seems to be concerned with the construction of model system.[25-27]

Experimental

All mps (measured by means of a Yanagimoto Micro-mp Apparatus) are uncorrected. Elemental analyses were performed by Miss S. Hirashima of Research Institute of Industrial Science, Kyushu University. The purity of the each analytical specimen was checked by high-pressure liquid chromatography (HPLC) on a Nippon Waters ALC 244 Model apparatus with a prepacked Micropolasil column (stainless steel, diameter; 7.8 mm, and length; 300 mm). Gas-liquid chromatography (GLC) was carried out by means of a Yanagimoto Model G 80 apparatus with a thermal-conductivity detector. Optical rotations were measured by means of a Union Model PM-101 apparatus. The NMR spectra were measured using a JEOL FX 100 Spectrometer with a $CDCl_3$ solutions. Chemical shifts measured were expressed in δ units from the internal Me_4Si. The mass spectra were measured by means of a JEOL 01SG-2 Spectrometer. The IR spectra were taken in either as KBr disks or as liquid film (NaCl plates) using a JASCO

IR-A 102 Spectrometer.

Optical Resolution of 3. A mixture of **3** (1.54g), **4** (15 cm³), and PPTS (100 mg) was kept room temperature for 16 h. Then, the mixture was partitioned between a 1:1-mixture of hexane and AcOEt and aqueous $NaHCO_3$. The organic layer was washed with brine, dried on $MgSO_4$ and chromatographed on a silica-gel column with AcOEt–hexane (1:8) to give a colorless oil (1.80 g; 98%). To a THF solution (25 cm³) containing potassium salt of **6** (prepared from **6** (7.5 g) and potassium (500 mg)), a THF solution (18 cm³) of the above oily product was added and refluxed under an N_2 atmosphere for 20 min with the gradual removal of THF (18 cm³). Subsequently, aqueous NH_4Cl was added to the cooled mixture and extracted with AcOEt and hexane (1:5). The organic extract was washed with aqueous $NaHCO_3$, water and brine and dried on $MgSO_4$. The evaporation of the solvent left a pale-yellow oil which was chromatographed on a silica-gel column to remove an excess of **6** from a diastereomeric mixture of *l*-menthyl ester (2.50 g; 94%).

This was dissolved in a mixture (40 cm³) of AcOH, THF, and water (2:2:1) and refluxed for 2 h. After dilution with water, K_2CO_3 was introduced to neutralize AcOH in the mixture. The mixture was then extracted with AcOEt and heated in vacuo to give a yellow-oily diastereomeric mixture of formates, which was further treated with saturated aqueous $KHCO_3$ (5 cm³) in MeOH (30 cm³) at room temperature for 45 min. After removal of MeOH in vacuo. The residue was diluted with water and extracted with AcOEt. A yellow oil from the extract was chromatographed on a silica-gel column to give a mixture of a *l*-menthyl ester of 1,2-dihydroxy-8-iriden-7-oate, **7a** and **7b** (2.125 g). Fractional recrystallizations from hexane by alternate seeding of **7a** and **7b** afforded, after repeating the operation several times, (3*S*)-**7b** [colorless prisms, mp 97—97.5°C, 1.007 g; 95%. Found: C, 71.21; H, 10.24%. Calcd for $C_{20}H_{34}O_4$: C, 70.97; H, 10.12%. $[\alpha]_D=-57.1°$ (*c* 2.10, $CHCl_3$). ^1H NMR δ=0.74 (3H, d, *J*=7 Hz), 0.91 (6H, d, *J*=7 Hz), 1.25 (3H, s), 1.73 (3H, br s), 3.02 (1H, br s, OH), 3.18 (1H, br m), 3.56 (1H, s, OH), 4.73 (1H, td, *J*=10, 4 Hz), 4.79 (1H, m), and 4.87 (1H, m). ^{13}C NMR δ=15.6, 20.8, 22.0, 22.5, 22.9, 24.7, 25.5, 25.8, 31.4, 34.2, 38.8, 40.6, 46.8, 51.4, 76.5, 81.2, 85.0, 112.8, 143.7, and 173.8. DIBAH-Reduction of (3*S*)-13b to (3*S*)-14. Similar to the case of **8** to **9**, (3*S*)-**13b** (132 mg) was treated with DIBAH to give (3*S*)-**14** [a colorless oil, 61 mg; 92%. Found: M. W., 154.1367. Calcd for $C_{10}H_{18}O$: 154.1357. $[\alpha]_D=+17.6°$ (*c* 3.76, $CHCl_3$). ^1H NMR δ=0.67 (3H, d, *J*=7 Hz), 0.92 (3H, d, *J*=7 Hz), 1.70 (3H, br s), 2.82 (1H, br m), 3.99 (1H, d, *J*=12 Hz), and 4.26 (1H, d, *J*=12 Hz). ^{13}C NMR δ=13.9, 15.9, 21.4, 21.8, 28.7, 38.0, 51.8, 57.3, 136.4, and 137.0. IR ν: 3350, 2900, 1470, 1380, 1360, and 1000 cm^{-1}].

MnO_2 Oxidation of (3*S*)-14 to (3*S*)-1-Iriden-7-al ((3*S*)-15). Similar to the case of **9** to **10**, (3*S*)-**14** (1.00 g) was oxidized with MnO_2 (10 g) in CH_2Cl_2 (40 cm^3) to (3*S*)-**15**[29] [a colorless oil, 893 mg; 90%. Found: M.W., 152.1199. Calcd for $C_{10}H_{16}O$: 152.1200. $[\alpha]_D=-5.5°$ (*c* 5.47, $CHCl_3$). ^1H NMR δ=0.65 (3H, d, *J*=7 Hz), 0.88 (3H, d, *J*=7 Hz), 2.14 (3H, s), 3.00 (1H, br m), and 9.97 (1H, s). ^{13}C NMR δ=14.3, 16.4, 21.3, 22.1, 28.9, 40.1, 50.0, 140.0, 163.1, and 188.2. IR ν: 2980, 1670, and 760 cm^{-1}].

Conversion of (3*R*)-13a to (3*R*)-15 via (3*R*)-14. Similarly, (3*R*)-**13a** was converted to (3*R*)-**14** [a colorless oil, 95%. $[\alpha]_D=-17.9°$ (*c* 2.79, $CHCl_3$)], which was then oxidized to (3*R*)-**15**[30] [a colorless oil, 70%. $[\alpha]_D=+6.9°$ (*c* 3.77, $CHCl_3$)].

Preparation of Ethylenedioxy Acetal of 1,8-Iridadien-7-al (17). An anhydrous benzene solution (330 cm^3) of (3*S*)-**10** (23.5 g) and 1,2-ethanediol (50 cm^3) was refluxed in the presence of PPTS (3.2 g) for 9 h along with the removal of liberated water by means of a Dean-Stark apparatus. To the mixture, aqueous $NaHCO_3$ was added and extracted with benzene. The organic extract was dried on K_2CO_3 and evaporated to leave a brown oil which was purified by distillation in vacuo (bp 60—70°C/2 mmHg) to give **17** [a colorless oil, 27.7 g; 91%. Found: M.W., 194.1315. Calcd for $C_{12}H_{18}O_2$: 194.1306. ^1H NMR δ=1.64 (3H, br s), 1.81 (3H, br s), 3.50 (1H, br m), 3.72—4.08 (4H, m), 4.58 (1H, br s), 4.67 (1H, br s), and 5.49 (1H, s). ^{13}C NMR δ=14.1, 18.7, 28.7, 38.6, 53.5, 64.8, 65.3, 100.3, 109.4, 132.9, 142.5, and 149.1. IR ν: 3070, 2945, 2890, 1677, 1642, 1437, 1390, 1185, 1100, 1055, 943, and 881 cm^{-1}].

Hydroboration of 17. To an anhydrous diethylene glycol dimethyl ether solution (40 cm^3) containing $NaBH_4$ (1.62 g), 2-methyl-2-butene (13.0 cm^3) was introduced at 0°C. Subsequently, BF_3-etherate (5.9 cm^3) was added dropwise and stirred at 0°C for 2 h. After this, an anhydrous diglyme solution (10 cm^3) of **17** (5.34 g) was added dropwise within a 20-min period. After keeping 0°C for another 30 min, the mixture was warmed to room temperature with stirring for 2 h. Then, the mixture was cooled again to below 0°C, aqueous 3M[†] NaOH (28 cm^3) was introduced, 30% H_2O_2 (25 cm^3) was also introduced within a 40-min period at 50°C, and further stirred for 1 h. The mixture was then extracted with ether, dried on K_2CO_3 and distilled by means of a Kugelrohr apparatus in vacuo to give **18** [a colorless oil, 4.86 g; 83%]. The sample obtained by this workup was suitable for subsequent reaction, but the analytical sample [Found: M.W., 212.1416. Calcd for $C_{12}H_{20}O_3$: 212.1411. ^1H NMR δ=0.88 (3H, d, *J*=7 Hz), 1.76 (3H, br s), 2.63 (1H, br, OH), 3.01 (1H, br m), 3.2—3.7 (2H, m) which changed to 3.31 (1H, dd, *J*=10.9, 7.8 Hz), and 3.54 (1H, dd, *J*=10.9, 5.9 Hz) by addition of D_2O, 3.8—4.2 (4H, m), and 5.51 (1H, s). ^{13}C NMR δ=13.8, 15.9, 23.2, 38.0, 38.2, 48.4, 63.9, 64.4, 64.6, 100.2, 131.1, and 143.3. Preparation of 9-Benzyloxy-1-iriden-7-al (20) via Its Ethylenedioxy Acetal (19). To an anhydrous DMF solution (280 cm^3) of NaH (1.4 g), a DMF solution (20 cm^3) of **18** (4.45 g) was added and stirred for 1 h. Then, benzyl chloride (4.0 cm^3) was added and stirred at room temperature for 96 h. Ether extraction of the mixture yielded **19** [a colorless oil, 4.82 g; 76%. ^1H NMR δ=1.02 (3H, d, *J*=7 Hz), 1.75 (3H, br s), 3.00 (1H, br m), 3.19 (1H, t, *J*=9 Hz), 3.49 (1H, dd, *J*=9, 4 Hz), 3.7—4.0 (4H, m), 4.39 (1H, d, *J*=12 Hz), 4.47 (1H, d, *J*=12 Hz), 5.47 (1H, s), and 7.27 (5H, br s). ^{13}C NMR δ=14.2, 16.6, 23.9, 35.8, 38.3, 49.4, 64.4, 64.9, 72.7, 72.8, 100.6, 127.1, 127.3 (2C), 128.1 (2C), 131.6, 139.1, and 143.0. IR ν: 2955, 2880, 1677, 1498, 1455, 1095, 943, 735, and 696 cm^{-1}], which was without purification, treated with 0.5 M HCl (80 cm^3) in ether (150 cm^3) for 4 h. Subsequently, the mixture was treated with 10%-$NaHCO_3$, extracted with ether, chromatographed on a silica-gel column to give **20** [colorless needles, mp 53—53.5°C, 3.10 g; 72%. Found: C, 78.74; H, 8.76%. Calcd for $C_{17}H_{22}O_2$: C, 79.03; H, 8.58%. $[\alpha]_D=-12.2°$ (*c* 5.72, $CHCl_3$). ^1H NMR δ=0.95 (3H, d, *J*=7 Hz), 2.07 (3H, br s), 3.14 (1H, br m), 3.20 (1H, dd, *J*=9, 7 Hz), 3.34 (1H, dd, *J*=9, 5.5 Hz), 4.39 (2H, br s), 7.24 (5H, br s), and 9.92 (1H, s). ^{13}C NMR δ=14.3, 16.0, 24.2, 35.2, 39.6, 47.1, 72.7, 73.0, 127.2 (3C), 128.1 (2C), 138.7, 139.3, 163.4, and 188.1. IR ν: 2950, 2850, 2730, 1655, 1618, 1493, 1450, 1425, 1365, 1210, 1088, 990, 758, and 700 cm^{-1}].

Preparation of 9-Benzyloxy-1-iriden-7-ol (21). An MeOH solution (130 cm^3) of **20** (5.07 g) was reduced with $NaBH_4$ (750 mg) to give **21** [colorless liquid, 4.947 g; 96.5%. Found: C, 78.45; H, 9.32%. Calcd for $C_{17}H_{24}O_2$: C, 78.42; H, 9.29%. ^1H NMR δ=0.91 (3H, d, *J*=7 Hz), 1.68 (3H, br s), 2.70 (1H, dd, *J*=7, 6 Hz, OH), 2.84 (1H, br m), 3.25 (1H, dd, *J*=9, 6 Hz), 3.36 (1H, dd, *J*=9, 7 Hz), 4.08 (2H, br m), 4.36 (1H, d, *J*=12 Hz), 4.45 (1H, d, *J*=12 Hz), and 7.25 (5H, br s). ^{13}C NMR δ=14.0, 16.6, 23.3, 35.5, 37.6, 50.6, 57.7, 72.9, 73.2, 127.5, 127.6 (2C),

[†] 1 M=1 mol dm^{-3}.

128.7 (2C), 136.1, 137.1, and 138.1. IR ν: 3410, 2960, 1677, 1498, 1457, 1096, 1005, 736, and 698 cm^{-1}].

Preparation of 9-Benzyloxy-7-chloro-1-iridene (16). To an anhydrous CH_2Cl_2 solution (30 cm^3) of $(COCl)_2$ (0.8 cm^3), anhydrous DMSO (1.3 cm^3) was added at −60 °C with stirring. After 5 min, an anhydrous CH_2Cl_2 solution (2 cm^3) of **21** (1.984 g) was added dropwise during a 15-min period. The mixture was then gradually warmed to 0 °C within 1 h, extracted with ether, dried on $MgSO_4$, and distilled in vacuo to remove the solvent to leave **16** [pale yellow oil, 2.01 g; 95%. ^1H NMR δ=1.02 (3H, d, J=7 Hz), 1.71 (3H, br s), 2.93 (1H, br m), 3.20 (1H, dd, J=9, 7 Hz), 3.34 (1H, dd, J=9, 5 Hz), 4.05 (1H, br d, J=12 Hz), 4.20 (1H, d, J=12 Hz), 4.41 (2H, br s), and 7.25 (5H, br s)], which was very sensitive towards the acidic species that it prevented a further purification.

$CrCl_2$-Mediated Condensation of (3*S*)-16 and (3*S*)-15. To an anhydrous THF suspension (30 cm^3) of $CrCl_3$ (3.76 g) under an N_2 atmosphere at 0 °C, LAH (440 mg) was added to form $CrCl_2$. After 30 min, the medium was changed, in vacuo, from THF to anhydrous DMF (40 cm^3) by transfer. Subsequently, a DMF solution (5 cm^3) of (3*S*)-**15** (1.80 g) and a DMF solution (5 cm^3) of (3*S*)-**16** (2.02 g) was added consecutively at 0 °C. After 5 h under stirring, the mixture was treated with water, and extracted with ether. The organic extract was dried on K_2CO_3 and the solvent removed in vacuo, treated with $NaBH_4$ in MeOH to reduce any excess amount of (3*S*)-**15**, and chromatographed on a silica-gel column to give **22** [a colorless oil, 1.92 g; 64%. Found: C, 82.06; H, 10.36%. Calcd for $C_{27}H_{40}O_2$: C, 81.77; H, 10.17%. ^1H NMR δ=0.73 (3H, d, J=7 Hz), 0.90 (3H, d, J=7 Hz), 1.11 (3H, d, J=7 Hz), 1.15 (3H, s), 1.68 (3H, br s), 2.82 (1H, br m), 3.20 (1H, dd, J=9, 8 Hz), 3.45 (1H, dd, J=9, 4 Hz), 4.31 (1H, br s), 4.45 (2H, br s), 4.93 (1H, d, J=2.5 Hz), 5.03 (1H, d, J=3 Hz), and 7.28 (5H, br s). ^{13}C NMR δ=15.0, 15.7, 17.1, 21.5, 21.9, 22.1, 24.9, 30.4, 35.2, 35.7, 38.0, 47.6, 51.9, 53.4, 72.6, 73.0 (2C), 106.0, 127.3, 127.4 (2C), 128.2 (2C), 135.9, 138.7, 138.8, and 162.1. IR ν: 3545, 2955, 1642, 1498, 1467, 1456, 1367, 1099, 1012, 895, 733, and 697 cm^{-1}], and **23** [a colorless oil, 1.35 g; 18%. Found: C, 81.87; H, 10.32%. ^1H NMR δ= 0.75 (3H, d, J=7 Hz), 0.92 (3H, s), 0.93 (3H, d, J=7 Hz), 1.11 (3H, d, J=7 Hz), 1.88 (3H, br s), 2.48 (2H, br m), 3.21 (1H, dd, J=9, 8.5 Hz), 3.46 (1H, dd, J=9, 4 Hz), 4.26 (1H, br s), 4.41 (1H, d, J=12 Hz), 4.48 (1H, d, J=12 Hz), 4.93 (1H, d, J= 3 Hz), 4.96 (1H, d, J=2.5 Hz), and 7.28 (5H, br s). ^{13}C NMR δ=16.2, 16.8, 17.0, 21.7, 22.5, 24.9, 25.1, 29.4, 32.6, 34.6, 39.3, 49.6, 54.0, 56.5, 72.6, 72.9, 75.1, 104.4, 127.2, 127.3 (2C), 128.1 (2C), 136.3, 138.7, and 160.4. IR ν: 3570, 3500, 2955, 2875, 1642, 1498, 1465, 1457, 1368, 1100, 1029, 886, 735, and 698 cm^{-1}].

Collins Oxidation of 22 to 24. To an anhydrous CH_2Cl_2 solution (2 cm^3) containing CrO_3 (150 mg) and pyridine (245 mg), CH_2Cl_2 solution (2 cm^3) of **22** (95 mg) was added and stirred at room temperature for 1 h. The mixture was then diluted with ether, and passed through a Florisil column to remove inorganic material. The removal of the solvent in vacuo left a colorless oil, which was purified by a silica-gel column chromatography to yield **24** [a colorless oil, 56 mg; 59%. Found: C, 82.18; H, 9.80%. Calcd for $C_{27}H_{38}O_2$: C, 82.18; H, 9.71%. ^1H NMR δ=0.72 (3H, d, J=7 Hz), 0.84 (3H, d, J=7 Hz), 1.09 (3H, d, J=7 Hz), 1.21 (3H, s), 1.60 (3H, br s), 2.45 (1H, br m), 2.92 (1H, br m), 3.21 (1H, dd, J=9, 8 Hz), 3.45 (1H, dd, J=9, 4 Hz), 4.41 (1H, d, J=12 Hz), 4.46 (1H, d, J=12 Hz), 4.96 (1H, d, J=2.5 Hz), 4.99 (1H, d, J=3 Hz), and 7.26 (5H, br s). ^{13}C NMR δ=15.4, 16.5, 17.1, 21.3, 23.4, 25.3, 25.7, 30.8, 34.9, 35.7, 37.8, 48.4, 55.5, 59.5, 72.7, 73.0, 108.1, 127.4 (3C), 128.2 (2C), 138.7, 139.8, 141.4, 156.2, and 211.3. IR ν: 2960, 2875, 1677, 1455, 1368, 1098, 895, 735, and 696 cm^{-1}].

LAH-Reduction of 24. An anhydrous THF solution (2 cm^3) of **24** (50 mg) was reduced with LAH (10 mg) in THF (1 cm^3) at room temperature for 50 min. An ordinary work up of the mixture yielded **22** (15 mg; 30%) and **23** (21 mg; 42%), whose identity with the authentic samples were confirmed by direct comparisons.

$CrCl_2$-Mediated Condensation of (3*S*)-16 and (3*R*)-15. Similarly, (3*R*)-**15** (5.11 g) and (3*S*)-**16** (6.39 g) were condensed with $CrCl_2$, prepared from $CrCl_3$ (10.64 g), in DMF (80 cm^3) to form **25** [a colorless oil, 7.02 g; 73%. Found: C, 82.01; H, 10.25%. ^1H NMR δ=0.70 (3H, d, J=7 Hz), 0.85 (3H, d, J=7 Hz), 1.09 (3H, s), 1.10 (3H, d, J=7 Hz), 1.90 (3H, br s), 2.45 (2H, br s), 3.18 (1H, dd, J=9, 8 Hz), 3.45 (1H, dd, J=9, 4 Hz), 4.04 (1H, br s), 4.42 (1H, d, J=12 Hz), 4.47 (1H, d, J=12 Hz), 4.91 (1H, d, J=2.5 Hz), 4.99 (1H, d, J=3 Hz), and 7.27 (5H, br s). ^{13}C NMR δ=15.8, 16.9, 17.3, 21.7, 22.2, 23.5, 25.4, 28.9, 34.4, 35.2, 39.2, 48.4, 52.7, 55.8, 72.7, 72.9, 74.9, 105.9, 127.4 (3C), 128.2 (2C), 136.6, 137.4, 138.7, and 160.5. IR ν: 3510, 2955, 1643, 1599, 1455, 1367, 1098, 1028, 734, and 695 cm^{-1}], and **26** [a colorless oil, 0.37 g; 4%. Found: C, 81.98; H, 10.41%. ^1H NMR δ=0.71 (3H, d, J=7 Hz), 0.77 (3H, s), 0.87 (3H, d, J=7 Hz), 1.11 (3H, d, J=7 Hz), 1.73 (3H, br s), 2.72 (1H, br m), 3.21 (1H, t, J=9 Hz), 3.47 (1H, dd, J=9, 4 Hz), 4.42 (1H, d, J=12 Hz), 4.47 (1H, d, J=12 Hz), 4.65 (1H, br s), 4.96 (1H, d, J=2.5 Hz), 4.99 (1H, d, J=3 Hz), and 7.27 (5H, br s). ^{13}C NMR δ=15.0, 15.7, 17.2, 22.0, 22.1, 25.4 (2C), 30.4, 32.2, 38.0, 49.8, 52.5, 53.1, 72.7, 73.0, 75.2, 104.0, 127.4 (3C), 128.2 (2C), 135.4, 138.7, 139.1, and 161.4. IR ν: 3575, 3510, 2875, 1642, 1498, 1455, 1366, 1098, 1018, 882, 732, and 695 cm^{-1}].

Collins Oxidation of 25 to 27. Similarly, **25** (1.00 g) was oxidized with CrO_3 (1.5 g) and pyridine (245 mg) in CH_2Cl_2 (30 cm^3) to form **27** [a colorless oil, 585 mg; 59%. Found: C, 81.91; H, 9.68%. ^1H NMR δ=0.71 (3H, d, J=7 Hz), 0.80 (3H, d, J=7 Hz), 1.12 (3H, d, J=7 Hz), 1.17 (3H, s), 1.60 (3H, br s), 2.57 (1H, br m), 2.80 (1H, br m), 3.24 (1H, dd, J=9, 8 Hz), 3.46 (1H, dd, J=9, 4 Hz), 4.41 (1H, d, J=12 Hz), 4.46 (1H, d, J=12 Hz), 4.87 (1H, d, J=3 Hz), 4.92 (1H, d, J=2.5 Hz), and 7.27 (5H, br s). ^{13}C NMR δ=15.2, 15.9, 17.0, 21.5, 22.8, 24.7, 26.2, 30.1, 34.6, 35.9, 37.9, 48.8, 55.1, 59.5, 72.6, 72.9, 107.7, 127.3 (3C), 128.1 (2C), 138.6, 140.4, 141.0, 156.5, and 209.5. IR ν: 2960, 1677, 1455, 1368, 1098, 895, 735, and 696 cm^{-1}].

LAH-Reduction of 27 to 25 and 26. Similarly, **27** (315 mg) was treated in THF (5 cm^3) with LAH (100 mg) in THF (5 cm^3) to give **25** (167 mg; 53%) and **26** (72 mg; 23%). Their identities with the authentic samples were confirmed by direct comparisons.

Birch Reduction of 22 to 28. To liquid NH_3 (30 cm^3) containing lithium (50 mg), an anhydrous ether solution (2 cm^3) of **22** (780 mg) was added dropwise and refluxed for 2 h. The mixture was then treated with NH_4Cl and water, and almost all of NH_3 was allowed to evaporate. The residue was extracted with ether and dried on K_2CO_3. Silica-gel column chromatography of the mixture yielded, beside recovered **22** (30 mg; 3.8%), **28** [a colorless oil, 598 mg; 99.5%. Found: C, 78.48; H, 11.24%. Calcd for $C_{20}H_{34}O_2$: C, 78.38; H, 11.18%. ^1H NMR δ=0.71 (3H, d, J=7 Hz), 0.88 (3H, d, J=7 Hz), 1.05 (3H, d, J=7 Hz), 1.17 (3H, s), 1.67 (3H, br s), 2.82 (1H, br m),

3.36 (1H, dd, J=10, 8 Hz), 3.64 (1H, dd, J=10, 5 Hz), 4.31 (1H, br s), 4.97 (1H, d, J=2.5 Hz), and 5.07 (1H, d, J=3 HZ). ^{13}C NMR δ=14.9, 15.7, 16.6, 21.9 (2C), 22.1, 24.6, 30.4, 35.2, 37.9, 38.0, 47.6, 51.8, 53.3, 64.6, 73.2, 106.0, 136.1, 138.6, and 162.3. IR ν: 3410, 2960, 1645, 1470, 1385, 1370, 1020, and 900 cm^{-1}].

Birch Reduction of 23 to 29. Similarly, **23** (286 mg) was reduced to **29** [a colorless oil, 160 mg; 72%. Found: C, 78.21; H, 11.39%. ^{1}H NMR δ=0.76 (3H, d, J=7 Hz), 0.93 (3H, d, J=7 Hz), 0.96 (3H, s), 1.07 (3H, d, J=7 Hz), 1.90 (3H, br s), 2.51 (2H, br m), 3.40 (1H, dd, J=10, 8 Hz), 3.68 (1H, dd, J=10, 5 Hz), 4.28 (1H, br s), 4.98 (1H, d, J=3 Hz), and 5.03 (1H, d, J=2.5 Hz). ^{13}C NMR δ=16.2, 16.5, 16.8, 21.8, 22.6, 24.6, 25.2, 29.4, 32.6, 36.7, 39.4, 49.5, 54.0, 56.6, 64.9, 75.1, 104.5, 136.3, 136.9, and 160.8. IR ν: 3410, 2955, 1643, 1467, 1369, 1032, and 884 cm^{-1}].

Birch Reduction of 25 to 30. Similarly, **25** (7.39 g) was reduced with lithium (390 mg) in liquid NH_3 (250 cm^3) to give **30** [a colorless oil, 5.12 g; 100%. Found: C, 78.24; H, 11.24%. ^{1}H NMR δ=0.71 (3H, d, J=7 Hz), 0.87 (3H, d, J=7 Hz), 1.06 (3H, d, J=7 Hz), 1.12 (3H, s), 1.91 (3H, br s), 3.33 (1H, dd, J=10, 8 Hz), 3.64 (1H, dd, J=10, 5 Hz), 4.07 (1H, br s), 4.97 (1H, d, J=2.5 Hz), and 5.04 (1H, d, J=3 Hz). ^{13}C NMR δ=15.9, 16.8, 16.9, 21.7, 22.3, 23.5, 25.0, 29.0, 34.5, 37.4, 39.2, 48.4, 52.8, 55.9, 65.1, 74.9, 106.0, 136.6, 137.5, and 161.1. IR ν: 3410, 2960, 2880, 1644, 1465, 1368, 1024, and 893 cm^{-1}] together with the recovered **25** (866 mg; 12%).

Birch Reduction of 26 to 31 and 32. To an anhydrous $EtNH_2$ solution (8 cm^3) of lithium (100 mg), an anhydrous ether solution (2 cm^3) of **26** (85 mg) was added and stirred at 0 °C for 2 h. The usual work up yielded a C=C bond-migrated diol (**32**) [a colorless oil, 11 mg; 17%. ^{1}H NMR δ=0.72 (3H, d, J=7 Hz), 0.84 (3H, d, J=7 Hz), 0.89 (3H, d, J=7 Hz), 0.99 (3H, s) 1.64 (3H, t, J=1 Hz), 1.70 (3H, br s), 2.78 (1H, br m), 2.81 (1H, sext, J=7 Hz), 3.45 (2H, br s), and 4.61 (1H, br s)], and **31** [a colorless oil, 45 mg; 69%. Found: C, 78.25; H, 11.32%. ^{1}H NMR δ=0.70 (3H, d, J=7 Hz), 0.81 (3H, s), 0.87 (3H, d, J=7 Hz), 1.06 (3H, d, J=7 Hz), 1.73 (3H, br s), 3.36 (1H, dd, J=10, 8 Hz), 3.68 (1H, dd, J=10, 5 Hz), 4.68 (1H, br s), and 5.03 (2H, br d, J=2.5 Hz). ^{13}C NMR δ=15.0, 15.7, 16.7, 22.0, 22.2, 25.0, 25.6, 30.5, 32.1, 36.3, 38.1, 49.8, 52.5, 53.1, 65.2, 75.3, 104.1, 135.3, 139.4, and 162.2. IR ν: 3400, 2950, 1645, 1470, 1025, and 885 cm^{-1}] was obtained.

The Birch Reduction of 23 in Ethylamine. Formation of 29 and Its Isomer, 33. Similar to this, the reduction of **23** (67 mg) in $EtNH_2$ (10 cm^3) with lithium (25 mg) afforded **29** (a colorless oil, 10 mg; 19%) and **33** [colorless prisms, mp 119.5—120 °C, 34 mg; 66%. Found: C, 78.52; H, 11.29%. ^{1}H NMR δ=0.74 (3H, d, J=7 Hz), 0.91 (3H, d, J=7 Hz), 0.98 (3H, d, J=7 Hz), 1.03 (3H, s), 1.63 (3H, t, J=1 Hz), 1.92 (3H, br s), 2.45 (1H, br m), 2.71 (1H, sext, J=7 Hz), 3.45 (2H, br m), and 4.16 (1H, br s). ^{13}C NMR δ=10.3, 15.2, 16.1, 16.5, 21.7, 22.5, 22.9, 29.0, 29.5, 32.3, 35.7, 39.4, 56.0, 57.9, 66.0, 73.2, 136.5, 137.2, 138.7, and 138.9. IR ν: 3300, 2950, 1667, 1465, 1452, 1366, 1020, 1000, and 765 cm^{-1}].

Bis-Etherification of 28 to 34 with I_2 and a Base. To an ether solution (10 cm^3) of **28** (240 mg), saturated $NaHCO_3$ (20 cm^3) and an excess of I_2 were added and kept room temperature for 3 h. The mixture was then treated with $NaHSO_3$ and saturated K_2CO_3 and extracted with ether. Silica-gel column chromatography of the extract afforded **34** [a colorless oil, 192 mg; 74%. Found: C, 78.98; H, 10.71%. Calcd for $C_{20}H_{32}O_2$: C, 78.90; H, 10.59%. ^{1}H NMR δ=0.69 (3H, d, J=7 Hz), 0.83 (3H, s), 0.88 (3H, d, J=7 Hz), 0.95 (3H, d, J=7 Hz), 1.65 (3H, br s), 2.68 (1H, br m), 3.23 (1H, dd, J=10, 8 Hz), 3.71 (1H, d, J=9 Hz), 3.80 (1H, d, J=9 Hz), 3.88 (1H, dd, J=8, 7 Hz), and 4.64 (1H, br s). ^{13}C NMR δ=11.2, 14.9, 15.8, 16.4, 22.3, 22.7, 24.9, 30.5, 36.2, 38.1, 40.3, 53.4, 53.8, 57.7, 74.1, 76.8, 86.4, 102.2, 135.8, and 136.3. IR ν: 2960, 2880, 1470, 1455, 1380, and 1053 cm^{-1}].

Bis-Etherification of 29 to 35 with I_2 and a Base. A similar treatment of **29** (40 mg) with I_2 (55 mg) and saturated $NaHCO_3$ solution (4 cm^3) yielded **35** [a colorless oil, 35 mg; 80%. Found: C, 79.04; H, 10.70%. ^{1}H NMR δ=0.71 (3H, d, J=7 Hz), 0.87 (3H, d, J=7 Hz), 0.94 (3H, d, J=7 Hz), 1.01 (3H, s), 1.89 (3H, br s), 2.60 (1H, br m), 3.28 (1H, dd, J=10, 8 Hz), 3.31 (1H, d, J=9 Hz), 3.81 (1H, d, J=9 Hz), 3.86 (1H, dd, J=8, 7 Hz), and 4.00 (1H, br s). ^{13}C NMR δ=10.8, 15.3, 15.7, 18.8, 21.6, 21.9, 24.6, 28.6, 35.3, 35.5, 39.4, 53.6, 55.6, 55.8, 73.2, 76.1, 87.7, 101.1, 132.0, and 136.0. IR ν: 2960, 2845, 1465, 1379, 1063, and 995 cm^{-1}].

Bis-Etherification of 30 to 36 with I_2 and a Base. Similarly, **30** (60 mg) was converted to **36** [a colorless oil, 51 mg; 86%. Found: C, 78.98; H, 10.82%. ^{1}H NMR δ=0.73 (3H, d, J=7 Hz), 0.87 (3H, s), 0.89 (3H, d, J=7 Hz), 0.96 (3H, d, J=7 Hz), 1.85 (3H, br s), 3.25 (1H, dd, J=10, 8 Hz), 3.67 (1H, d, J=9 Hz), 3.90 (1H, dd, J=8, 7 Hz), 3.93 (1H, d, J=9 Hz), and 4.21 (1H, br s). IR ν: 2955, 2875, 1466, 1455, 1378, and 1050 cm^{-1}].

Bis-Etherification of 31 to 37 with I_2 and a Base. Similarly, **31** (22 mg) was converted to **37** [colorless needles, mp 69.5—70 °C, 15 mg, 68%. Found: C, 79.02; H, 10.81%. ^{1}H NMR δ=0.67 (3H, d, J=7 Hz), 0.85 (3H, d, J=7 Hz), 0.88 (3H, s), 0.94 (3H, d, J=7 Hz), 1.68 (3H, br s), 2.70 (1H, br m), 3.23 (1H, dd, J=10.5, 8 Hz), 3.37 (1H, d, J=9 Hz), 3.83 (1H, d, J=9 Hz), 3.85 (1H, dd, J=8, 7 Hz), and 4.23 (1H, br s). IR ν: 2960, 2840, 1460, 1373, and 1051 cm^{-1}].

Attempted Anionic Oxy-Cope Rearrangement with 25. To an anhydrous THF suspension (3 cm^3) of KH (35% in a mineral oil, 100 mg), **25** (55 mg) was added under ice-cooling. After standing at room temperature for 20 h, the mixture was treated with aqueous ether and extracted. HPLC with AcOEt–hexane eluted **38** [a colorless oil, 3 mg; 11%. ^{1}H NMR δ=1.01 (3H, d, J=7 Hz), 1.56 (6H, br s), 2.56 (1H, br m), 3.16 (1H, t, J=10 Hz), 3.30 (1H, dd, J=10, 4 Hz), 4.42 (2H, br s), and 7.30 (5H, br s)], a colorless-oily mixture of **39a** and **39b** (1:1) [10 mg; 23%. ^{1}H NMR δ=0.82 (1.5H, d, J=7 Hz), 0.83 (1.5H, d, J=7 Hz), 0.87 (1.5H, d, J=7 Hz), 0.92 (1.5H, d, J=7 Hz), 0.97 (1.5H, s), 1.01 (1.5H, s), 1.02 (3H, d, J=7 Hz), 1.58 (3H, br s), 3.07 (0.5H, t, J=9.5 Hz), 3.09 (0.5H, t, J=9.5 Hz), 3.22 (0.5H, dd, J=9.5, 4.5 Hz), 3.24 (0.5H, dd, J=9.5, 4.5 Hz), 4.40 (2H, br s), 7.27 (5H, br s), 9.65 (0.5H, d, J=7 Hz), and 9.66 (0.5H, d, J=4 Hz)], (3*R*)-**15** (1 mg; 6%), and the recovered **25** (11 mg; 20%), which were identified by direct comparisons.

Preparation of the TMS Derivative (40) from 22. To a pyridine solution (1 cm^3) of **22** (15 mg), trimethylsilyl chloride (TMSCl, 200 mg) was added and stirred at 15—25 °C for 24 h. The mixture was then treated with aqueous $NaHCO_3$, extracted with hexane–ether, dried on K_2CO_3, and chromatographed on a silica-gel column to give colorless oily **40** [18 mg; 100%. Found: C, 76.83; H, 10.44%. Calcd for $C_{30}H_{48}O_2Si$: C, 76.86; H, 10.32%. ^{1}H NMR δ=0.04 (9H, s), 0.67 (3H, d, J=7 Hz), 0.86 (3H, d, J=7 Hz), 1.09 (3H, d, J=7 Hz), 1.11 (3H, s), 1.64 (3H, br s), 2.77 (1H, br m), 3.17 (1H, t, J=9 Hz), 3.46 (1H, dd, J=9, 4 Hz), 4.30 (1H, s), 4.40 (1H, d, J=12 Hz), 4.48 (1H, d, J=12 Hz), 4.80 (2H, br d, J=2.5 Hz), and 7.28 (5H, br s). ^{13}C NMR δ=0.7 (3C), 15.1, 16.1, 17.3, 21.9,

22.4, 23.9, 25.0, 29.5, 34.9, 35.3, 37.8, 47.9, 51.2, 53.1, 72.9 (2C), 74.5, 106.0, 127.2, 127.4 (2C), 128.2 (2C), 136.8, 136.9, 138.8, and 160.2. IR ν: 2960, 2875, 1645, 1455, 1250, 1062, 880, 837, and 695 cm^{-1}].

Preparation of the TMS Derivative (41) from 23. Similarly, **23** (29 mg) was converted to **41** [a colorless oil, 33 mg; 96%. Found: C, 77.08; H, 10.34%. ^1H NMR δ=0.03 (9H, s), 0.75 (3H, d, J=7 Hz), 0.92 (3H, d, J=7 Hz), 0.92 (3H, s), 1.11 (3H, d, J=7 Hz), 1.84 (3H, br s), 3.21 (1H, dd, J=9, 8 Hz), 3.48 (1H, dd, J=9, 4 Hz), 4.24 (1H, br s), 4.43 (1H, d, J=12 Hz), 4.45 (1H, d, J=12 Hz), 4.82 (2H, br d, J=2.5 Hz), and 7.28 (5H, br s). ^{13}C NMR δ=0.4 (3C), 16.3, 16.5, 17.3, 22.4 (2C), 25.0, 25.5, 29.5, 33.4, 34.8, 39.6, 49.8, 54.0, 56.2, 73.0, 73.2, 77.1, 103.8, 127.3, 127.4 (2C), 128.2 (2C), 136.5, 137.7, 139.1, and 161.5. IR ν: 2955, 2865, 1645, 1366, 1246, 1077, 876, 835, 745, 730, and 694 cm^{-1}].

Preparation of the TMS Derivative (42) from 25. Similarly, **25** (77 mg) was treated with TMSCl (200 mg) to give **42** [a colorless oil, 85 mg; 94%. Found: C, 76.89; H, 10.36%. ^1H NMR δ=0.08 (9H, s), 0.71 (3H, d, J=7 Hz), 0.82 (3H, d, J=7 Hz), 1.01 (3H, s), 1.08 (3H, d, J=7 Hz), 1.84 (3H, br s), 3.18 (1H, dd, J=9, 8 Hz), 3.47 (1H, dd, J=9, 4 Hz), 4.12 (1H, br s), 4.40 (1H, d, J=12 Hz), 4.48 (1H, d, J=12 Hz), 4.81 (1H, d, J=2 Hz), 4.87 (1H, d, J=3 Hz), and 7.28 (5H, br s). ^{13}C NMR δ=0.3 (3C), 15.9, 16.8, 17.3, 22.1, 22.3, 25.7, 26.7, 28.8, 33.1, 34.7, 39.3, 49.5, 52.6, 55.4, 72.9, 73.1, 77.8, 105.4, 127.3, 127.4 (2C), 128.2 (2C), 136.9, 137.0, 138.8, and 160.2. IR ν: 2960, 2880, 1645, 1456, 1250, 1066, 880, 835, and 695 cm^{-1}].

Preparation of the TMS Derivative (43) from 26. Similarly, **26** (24 mg) was converted to **43** [colorless prisms, mp 67—67.5 °C, 29 mg; 100%. Found: C, 76.71; H, 10.26%. ^1H NMR δ=0.01 (9H, s), 0.66 (3H, d, J=7 Hz), 0.72 (3H, s), 0.84 (1H, d, J=7 Hz), 1.11 (3H, d, J=7 Hz), 1.60 (3H, br s), 2.64 (1H, br s), 3.19 (1H, dd, J=8.8, 8.5 Hz), 3.49 (dd, J=8.8, 3.5 Hz), 4.42 (1H, d, J=12 Hz), 4.49 (1H, d, J=12 Hz), 4.54 (1H, s), 4.83 (1H, d, J=2.5 Hz), 4.89 (1H, d, J=3 Hz), and 7.27 (5H, br s). ^{13}C NMR δ=0.5 (3C), 14.7, 16.1, 17.6, 22.1, 26.1 (2C), 29.7, 32.3, 33.7, 37.9, 50.3, 51.2, 52.7, 72.9 (2C), 136.7, 136.9, 138.8, and 162.7. IR ν: 2955, 2865, 1644, 1453, 1368, 1246, 1101, 1064, 878, 833, 745, and 696 cm^{-1}].

Cope Rearrangement of 40 to 44. An anhydrous oxygen-free toluene solution (5 cm^3) of **40** (18 mg) was sealed and heated in an autoclave at 190 °C for 12 h. The mixture was then distilled in vacuo to remove the solvent. The residue was practically pure thermolysate, **44** [a colorless oil, 18 mg; 100%. ^1H NMR δ=0.16 (9H, s), 0.74 (3H, d, J=7 Hz), 0.89 (3H, d, J=7 Hz), 1.03 (3H, d, J=7 Hz), 1.04 (3H, s), 1.58 (3H, br s), 2.75 (2H, br m), 3.08 (1H, dd, J=9, 8 Hz), 3.27 (1H, dd, J=9, 4 Hz), 4.39 (1H, d, J=12 Hz), 4.44 (1H, d, J=12 Hz), 6.03 (1H, d, J=2 Hz), and 7.25 (5H, br s)].

Cope Rearrangmement of 42. Formation of 45. Similarly, a toluene solution (5 cm^3) of **42** (82 mg) was heated in an autoclave at 190 °C for 8 h to give **45** [a colorless oil, 82 mg; 100%. ^1H NMR δ=0.19 (9H, s), 0.81 (3H, d, J=7 Hz), 1.02 (3H, d, J=7 Hz), 1.05 (3H, s), 1.62 (3H, br s), 2.68 (1H, d, J=14 Hz), 2.74 (1H, br m), 3.10 (1H, t, J=9 Hz), 3.27 (1H, dd, J=9, 4 Hz), 4.36 (1H, d, J=12 Hz), 4.46 (1H, d, J=12 Hz), 5.93 (1H, d, J=2 Hz), and 7.26 (5H, br s)].

Cope Rearrangement of 43. Formation 46. Similarly, a toluene solution of **43** (29 mg) was heated at 190 °C for 8 h in an autoclave to give **46** [a colorless oil, 29 mg; 100%. ^1H NMR δ=0.16 (9H, s), 0.75 (3H, d, J=7 Hz), 0.88 (3H, d, J=7 Hz), 0.94 (3H, s), 1.00 (3H, d, J=7 Hz), 1.58 (3H, br s), 3.08 (1H, t, J=9 Hz), 3.26 (1H, dd, J=9, 4 Hz), 4.36 (1H, d, J=12 Hz), 4.45 (1H, d, J=12 Hz), 6.08 (1H, d, J=2 Hz), and 7.24 (5H, br s)].

Cope Rearrangement of 41. Formation of 47 and 48. A toluene solution of **41** (74 mg) was heated at 200 °C for 4 d in an autoclave to give a mixture of **47** and **48** (3:2, 67 mg; 90%), which was separated by GLC (SE 30 column, 300 cm in length; column temperature, 285 °C; and He-flow, 25 $cm^3 min^{-1}$) to obtain **47** [a colorless oil. ^1H NMR δ=0.16 (9H, s), 0.80 (3H, d, J=7 Hz), 0.90 (3H, d, J=7 Hz), 1.03 (3H, d, J=7 Hz), 1.17 (3H, s), 1.56 (3H, br s), 2.78 (1H, br m), 3.10 (1H, t, J=9 Hz), 3.28 (1H, dd, J=9, 4 Hz), 4.33 (1H, d, J=12 Hz), 4.46 (1H, d, J=12 Hz), 5.97 (1H, d, J=2 Hz), and 7.24 (5H, br s)] and **48** [a colorless oil. ^1H NMR δ=0.16 (9H, s), 0.81 (3H, d, J=7 Hz), 0.89 (3H, d, J=7 Hz), 0.93 (3H, s), 1.02 (3H, d, J=7 Hz), 1.60 (3H, br s), 3.08 (1H, t, J=9 Hz), 3.25 (1H, dd, J=9, 4 Hz), 4.36 (1H, d, J=12 Hz), 4.43 (1H, d, J=12 Hz), 6.10 (1H, d, J=2 Hz), 7.25 (5H, br s)].

The $^1O_2$-Oxidation of 44. Formation of 49. An anhydrous toluene solution (5 cm^3) of **44** (82 mg), pyridine (0.03 cm^3), *meso*-5,10,15,20-tetraphenylporphine (TPP, 2 mg) was externally irradiated by means of a 500-W tungsten lamp with an O_2-stream under ice-cooling for 50 min. The mixture was then treated with PPh_3 to neutralize peroxy derivatives, solvent removed in vacuo, and chromatographed on a silica-gel column to give **49** [a colorless oil, 54 mg; 78%. Found: C, 82.38; H, 9.96%. Calcd for $C_{27}H_{38}O_2$: C, 82.18; H, 9.71%. ^1H NMR δ=1.01 (3H, d, J=7 Hz), 1.03 (3H, d, J=7 Hz), 1.10 (3H, d, J=7 Hz), 1.29 (3H, s), 1.47 (3H, br s), 2.68 (1H, br m), 3.09 (1H, t, J=9 Hz), 3.24 (1H, dd, J=9, 4.5 Hz), 3.38 (1H, sept, J=7 Hz), 4.37 (1H, d, J=12 Hz), 4.44 (1H, d, J=12 Hz), 7.25 (5H, br s), and 9.95 (1H, s). ^{13}C NMR δ=15.2, 16.9, 21.2, 21.5, 23.8, 26.7, 27.3, 30.0, 35.0 (2C), 36.3, 37.2, 51.1, 52.8, 72.2, 127.2, 127.4 (2C), 128.2 (2C), 134.6, 135.8, 138.8, 141.4, 171.8, and 188.2. IR ν: 2970, 2940, 2875, 2745, 1670, 1615, 1456, 1373, 1100, 732, and 695 cm^{-1}].

The $^1O_2$-Oxidation of 45. Formation of 50. Similarly, an anhydrous benzene solution (5 cm^3) of **45** (82 mg) and pyridine (0.03 cm^3) was irradiated 50 min under an O_2 atmosphere; after PPh_3-treatment, the mixture was chromatographed on a silica-gel column to give **50** [a colorless oil, 54 mg; 78%. Found: C, 82.42; H, 9.94%. ^1H NMR δ=0.87 (3H, d, J=7 Hz), 1.08 (6H, d, J=7 Hz), 1.18 (3H, s), 1.62 (3H, br s), 3.07 (1H, dd, J=9, 8 Hz), 3.21 (1H, dd, J=9, 4 Hz), 3.40 (1H, sept, J=7 Hz), 4.34 (1H, d, J=12 Hz), 4.42 (1H, d, J=12 Hz), 7.25 (5H, br s), 9.96 (1H, s). ^{13}C NMR δ=14.8, 17.0, 21.1, 21.5, 23.2, 26.2, 26.7, 30.1, 34.3 (2C), 36.2, 37.0, 50.7, 52.0, 72.1, 72.9, 127.1, 127.3 (2C), 128.1 (2C), 134.8, 135.4, 138.9, 141.7, 171.4, 188.1. IR ν: 2960, 2740, 1670, 1455, 1100, 735, 696 cm^{-1}].

The $^1O_2$-Oxidation of 46. Formation of 50. Similarly, **46** (29 mg) was converted to **50** (20 mg; 83%).

The $^1O_2$-Oxidation of 47. Formation of 49. Similarly, **47** (7.0 mg) was oxidized with $^1O_2$ by irradiation for 5 min to give **49** (a colorless oil, 4.0 mg; 67%).

The $^1O_2$-Oxidation of 48. Formation of 50. Similarly, **48** (7.0 mg) was converted to **50** (5.0 mg; 85%).

Preparation of the TMS Derivative (51) from 28. To an anhydrous pyridine solution (5 cm^3) of **28** (298 mg), TMSCl (0.7 cm^3) was added dropwise at room temperature. After being stirred for 12 h, the mixture was then diluted with water, extracted with hexane-ether (1:1), dried on K_2CO_3, and distilled in vacuo to remove the solvent. The residue was chromatographed quickly on a silica-gel column to give

51 [a colorless oil, 405 mg; 92%. Found: C, 69.38; H, 11.27%. Calcd for $C_{26}H_{50}O_2Si_2$: C, 69.27; H, 11.18%. ^{1}H NMR δ= 0.04 (9H, s), 0.09 (9H, s), 0.86 (3H, d, J=7 Hz), 1.03 (3H, d, J=7 Hz), 1.13 (3H, s), 1.65 (3H, br s), 2.80 (2H, br m), 3.21 (1H, t, J=9.5 Hz), 3.59 (1H, dd, J=9.5, 4 Hz), 4.31 (1H, s), and 4.82 (2H, br d, J=2.5 Hz). ^{13}C NMR δ=−0.4 (3C), 0.7 (3C), 15.1, 16.1, 16.8, 21.9, 22.4, 23.9, 24.8, 29.5, 35.0, 37.6, 37.8, 47.7, 51.3, 53.1, 64.6, 74.4, 106.0, 136.8, 137.0, and 160.3. IR ν: 2955, 1647, 1468, 1250, 1087, 1066, 879, and 746 cm^{-1}].

Preparation of the TMS Derivative (52) from 30. Similarly, **30** (5.123 g) in pyridine (35 cm^3) was treated with TMSCl (7.5 cm^3) to give **52** [a colorless oil, 6.913 g; 92%. Found: C, 69.56; H, 11.23%. ^{1}H NMR δ=0.09 (18H, s), 0.71 (3H, d, J=7 Hz), 0.82 (3H, d, J=7 Hz), 1.02 (3H, d, J=7 Hz), 1.04 (3H, s), 1.84 (3H, br s), 3.22 (1H, t, J=9.5 Hz), 3.60 (1H, dd, J=9.5, 4 Hz), 4.12 (1H, br s), 4.82 (1H, d, J=2 Hz), and 4.88 (1H, d, J=2.5 Hz). ^{13}C NMR δ=−0.4 (3C), 0.3 (3C), 15.9, 16.8 (2C), 22.1, 22.3, 25.6, 26.8, 28.9, 33.3, 37.1, 39.4, 49.4, 52.7, 55.5, 64.9, 77.9, 105.5, 137.2, 137.3, and 160.6. IR ν: 2955, 2875, 1643, 1250, 1068, 878, and 836 cm^{-1}].

Cope Rearrangement of 51 to 53. An anhydrous toluene solution (5 cm^3) of **51** (857 mg) was placed in a sealed tube and heated in an autoclave at 190 °C for 12 h. The mixture was then heated in vacuo to remove the solvent to give **53** [a colorless oil, 857 mg; 100%. Found: C, 69.33; H, 11.19%. ^{1}H NMR δ=0.08 (9H, s), 0.16 (9H, s), 0.75 (3H, d, J=7 Hz), 0.88 (3H, d, J=7 Hz), 0.95 (3H, d, J=7 Hz), 1.04 (3H, s), 1.60 (3H, br s), 2.74 (2H, br m), 3.15 (1H, t, J=10 Hz), 3.38 (1H, dd, J=10, 4 Hz), and 6.05 (1H, d, J=2.5 Hz). ^{13}C NMR δ=−0.4(6C), 15.1, 16.6, 18.0, 21.8, 23.4, 23.9, 27.9, 28.4, 37.0, 37.4, 38.4, 38.6, 46.2, 47.9, 52.7, 64.1, 132.7, 134.9, and 135.5 (2C). IR ν: 2955, 2875, 1667, 1252, 1154, 1081, 873, 838, and 748 cm^{-1}].

Cope Rearrangement of 52 to 54. Similarly, a toluene solution of **52** (238 mg) was heated in an autoclave to give **54** [a colorless oil, 238 mg; 100%. Found: C, 69.02; H, 11.09%. ^{1}H NMR δ=0.06 (9H, s), 0.18 (9H, s), 0.79 (3H, d, J=7 Hz), 0.92 (6H, d, J=7 Hz), 1.04 (3H, s), 1.63 (3H, br s), 2.70 (1H, br m), 2.66 (1H, d, J=14 Hz), 3.12 (1H, t, J=10 Hz), 3.37 (1H, dd, J=10, 4 Hz), and 5.91 (1H, d, J=2 Hz). ^{13}C NMR δ=−0.5 (3C), −0.4 (3C), 14.8, 16.8 (2C), 22.0, 23.2, 24.8, 24.9, 28.7, 34.5, 36.6, 37.2, 38.5, 46.4, 49.4, 51.9, 63.9, 132.2, 132.5, 134.3, and 136.1. IR ν: 2960, 2875, 1668, 1252, 1160, 1082, 872, 840, and 748 cm^{-1}].

Conversion of 53 to Unsaturated Aldehyde (55). An anhydrous toluene solution (25 cm^3) of **53** (857 mg), TPP (9 mg), and pyridine (0.05 cm^3) was irradiated with a 500-W tungsten lamp under an O_2 atmosphere at −70 °C for 30 min. The mixture was then treated with PPh_3 and extracted with ether. The ether extract was hydrolyzed with dil HCl and chromatographed on a silica-gel column, from benzene–hexane (2:1) to hexane–AcOEt (5:1), to give **55** [a colorless oil, 417 mg; 72%. Found: C, 78.95; H, 10.68%. Calcd for $C_{20}H_{32}O_2$: C, 78.90; H, 10.60%. ^{1}H NMR δ=0.97 (3H, d, J=7 Hz), 1.08 (3H, d, J=7 Hz), 1.13 (3H, d, J=7 Hz), 1.32 (3H, s), 1.53 (3H, br s), 2.73 (1H, br m), 3.26 (1H, dd, J=11, 7.5 Hz), 3.41 (1H, sept, J=7 Hz), 3.50 (1H, dd, J=11, 6 Hz), and 9.97 (1H, s). ^{13}C NMR δ=14.9, 16.2, 21.0, 21.2, 23.2, 26.4, 26.9, 29.8, 34.7, 36.0, 37.0 (2C), 50.8, 52.5, 64.0, 134.7, 135.6, 141.1, 172.0, and 188.0. IR ν: 3430, 2950, 1670, 1613, 1460, and 1025 cm^{-1}].

Conversion of 54 to Unsaturated Aldehyde (56). a) Similarly, **54** (223 mg) was oxidized with $^1O_2$ and hydrolyzed with dil HCl to give **56** [a colorless oil, 119 mg; 79%. Found: C, 78.77; H, 10.77%. ^{1}H NMR δ=0.84 (3H, d, J=7 Hz), 1.09 (6H, d, J=7 Hz), 1.20 (3H, s), 1.62 (3H, br s), 3.21 (1H, dd, J=10.5, 7 Hz), 3.40 (1H, sept, J=7 Hz), 3.46 (1H, dd, J=10.5, 6 Hz), and 9.97 (1H, s). ^{13}C NMR δ=14.8, 16.5, 21.1, 21.5, 22.9, 26.6, 26.7, 30.2, 34.3, 35.9, 36.7, 37.1, 50.7, 51.9, 64.7, 135.6, 135.7, 141.6, 171.9, and 188.3. IR ν: 3440, 2960, 2870, 1670, 1610, 1465, 1455, and 1025 cm^{-1}].

b) An acetonitrile solution (10 cm^3) of **54** (778 mg) was mixed with $Pd(OAc)_2$ (420 mg) and maintained at room temperature for 72 h. The mixture was then extracted with ether, hydrolyzed with dil HCl in aqueous ether, washed with water and dried on K_2CO_3. Silica-gel column chromatography of the organic extract gave **56** (322 mg; 61%).

The Oxidation of 55 to a Dialdehyde (57). To an anhydrous CH_2Cl_2 solution (10 cm^3) of $(COCl)_2$ (72 mg), DMSO (122 mg) was added at −70 °C, and stirred for 5 min. Then CH_2Cl_2 solution (2 cm^3) of **55** (202 mg) was introduced to the mixture. After stirring for another 20 min at this temperature it was further stirred with NEt_3 (650 mg) added. The reaction mixture was warmed to room temperature, extracted with ether, and chromatographed on a silica-gel column to give **57** [a colorless oil, 186 mg; 92%. Found: M.W., 302.2247. Calcd for $C_{20}H_{30}O_2$: 302.2244. ^{1}H NMR δ=1.03 (3H, d, J= 7 Hz), 1.08 (3H, d, J=7 Hz), 1.13 (3H, d, J=7 Hz), 1.31 (3H, s), 1.55 (3H, br s), 2.98 (1H, br m), 3.41 (1H, sept, J=7 Hz), 9.53 (1H, d, J=1 Hz), and 9.96 (1H, s). ^{13}C NMR δ=12.0, 15.1, 21.3, 21.5, 25.0, 26.7, 26.8, 29.9, 34.9, 36.3, 37.0, 47.8, 51.3, 52.1, 133.5, 137.5, 141.7, 172.0, 188.2, and 206.0. IR ν: 2970, 2940, 2875, 2840, 2740, 1722, 1668, 1612, and 1460 cm^{-1}].

The Oxidation of 56 to a Dialdehyde (58). Similarly, **56** (119 mg) was oxidized with $(COCl)_2$ (40 mg) and DMSO (70 mg) to give **58** [a colorless oil, 80 mg; 80%. Found: M.W., 302.2245. ^{1}H NMR δ=0.93 (3H, d, J=7 Hz), 1.05 (6H, d, J=7 Hz), 1.22 (3H, s), 1.62 (3H, br s), 3.41 (1H, sept, J= 7 Hz), 9.48 (1H, br s), and 10.00 (1H, s). ^{13}C NMR δ=12.3, 14.8, 21.3, 21.5, 24.3, 26.8 (2C), 30.2, 34.5, 35.7, 38.8, 47.1, 50.8, 51.3, 133.9, 137.0, 141.4, 172.3, 188.2, and 206.4. IR ν: 2970, 2750, 1725, 1668, 1613, and 1460 cm^{-1}].

$TiCl_2$-Mediated Cyclization of 57. To an anhydrous THF solution (60 cm^3) of $TiCl_4$ (1 cm^3) prepared at 0 °C, pyridine (0.5 cm^3) and powdered Zn (1.3 g) were added in portions, and stirred for 30 min. Then, a THF solution (15 cm^3) of **57** (184 mg) was slowly introduced over a 2-h period to maintain high-dilution conditions, and stirred for another 40 min. The mixture was then treated with aqueous K_2CO_3, extracted with ether and dried on K_2CO_3. Silica-gel column chromatography and further HPLC of the extract afforded **59** [a colorless oil, 47 mg; 25%. Found: C, 78.76; H, 10.73%. Calcd for $C_{20}H_{32}O_2$: C, 78.90; H, 10.60%. ^{1}H NMR δ=0.92 (3H, d, J=7 Hz), 0.93 (6H, d, J=7 Hz), 1.20 (3H, s), 1.64 (3H, br s), 2.61 (1H, sept, J=7 Hz), 2.98 (1H, br), 3.53 (1H, dd, J=6, 4 Hz), and 4.97 (1H, d, J=4 Hz). IR ν: 3450, 2950, 1470, 1382, and 1105 cm^{-1}], **60** [colorless prisms, mp 146.5—148 °C, 53 mg; 28%. Found: C, 78.93; H, 10.67%. ^{1}H NMR δ=0.86 (3H, d, J=7 Hz), 0.96 (6H, d, J=7 Hz), 0.98 (3H, s), 1.64 (3H, br s), 2.85 (2H, br), 3.04 (1H, sept, J=7 Hz), 3.76 (1H, dd, J=9, 2 Hz), and 4.10 (1H, d, J=9 Hz). IR ν: 3420, 2950, 1465, 1450, 1375, 1200, 1013, and 983 cm^{-1}], and **61** [a colorless oil, 27 mg; 14%. Found: M.W., 304.2388. Calcd for $C_{20}H_{32}O_2$: 304.2401. ^{1}H NMR δ=0.76 (3H, d, J=7 Hz), 0.95 (3H, d, J=7 Hz), 0.98 (3H, d, J=7 Hz), 1.20 (3H, s), 1.64 (3H, br s), 2.80 (1H, br), 2.82 (1H, sept, J=7 Hz), 4.18 (1H, d, J=9 Hz), and 4.49 (1H, d, J=9 Hz). IR ν: 3610, 3570, 2960, 2930, 1463, 1370, and 996 cm^{-1}].

$TiCl_2$-Mediated Cyclization of 58. To an anhydrous THF

solution (5 cm³) of $TiCl_4$ (106 mg) prepared carefully at 0 °C, pyridine (51 mg) and powdered Zn (126 mg) were added, and stirred for 30 min. Then, the THF solution (2 cm³) of **58** (97 mg) was introduced dropwise under stirring for 1 h. After being diluted with aqueous K_2CO_3, the mixture was extracted with ether and chromatographed on a silica-gel column to give **62** [a colorless oil, 82 mg; 84%. Found: M.W., 304.2404. ^1H NMR δ=0.94 (3H, d, J=7 Hz), 0.97 (3H, d, J=7 Hz), 1.14 (3H, d, J=7 Hz), 1.24 (3H, s), 1.67 (3H, br s), 3.54 (1H, br t, J=5 Hz), and 4.87 (1H, br). IR ν: 3350, 2950, 2880, 1460, 1385, 1370, and 1030 cm^{-1}].

Acetylation of a Mixture of 62 and 63. A pyridine solution (4 cm³) of the whole product (485 mg) was mixed with Ac_2O (0.5 cm³) and kept at room temperature for 16 h. The mixture was then diluted with water, extracted with hexane–ether (9:1) and chromatographed on a silica-gel column to give **64** [a colorless oil, 461 mg; 84%. Found: M.W., 346.2515. Calcd for $C_{22}H_{34}O_3$: 346.2506. ^1H NMR δ=0.92 (3H, d, J=7 Hz), 1.02 (6H, d, J=7 Hz), 1.21 (3H, s), 1.62 (3H, br s), 2.11 (3H, s), 2.64 (1H, sept, J=7 Hz), 4.76 (1H, br t, J=5 Hz), and 5.04 (1H, br). IR ν: 3550, 2950, 2870, 1745, 1720, 1465, 1384, 1370, 1242, 1028, and 964 cm^{-1}], and **65** [colorless needles, mp 117—120 °C, 72 mg; 13%. Found: M.W., 346.2510. ^1H NMR δ=0.93 (3H, d, J=7 Hz), 0.98 (3H, d, J=7 Hz), 1.01 (3H, d, J=7 Hz), 1.07 (3H, s), 1.60 (3H, br s), 2.10 (3H, s), 3.18 (1H, sept, J=7 Hz), 4.29 (1H, d, J=11 Hz), and 5.28 (1H, br). IR ν: 3490, 2950, 1725, 1452, 1377, 1260, and 1030 cm^{-1}].

Hydrolysis of 65. An anhydrous ether solution (3 cm³) of **65** (20 mg) was treated with LAH (10 mg) at room temperature for 1 h, after which the mixture was extracted with ether. Silica-gel column chromatography of the extract gave **63** [a colorless oil, 11 mg; 63%. Found: M.W., 304.2388. ^1H NMR δ=0.97 (9H, br d, J=7 Hz), 1.06 (3H, br s), 1.62 (3H, br s), 3.18 (1H, br), 3.90 (1H, br), and 4.23 (1H, br)] and an isomer, **67** [a colorless oil, 2 mg; 11%. Found: M.W., 304.2404. ^1H NMR δ=0.96 (6H, d, J=7 Hz), 1.02 (3H, d, J=7 Hz), 1.16 (3H, s), 1.61 (3H, br s), 2.59 (1H, br), 2.88 (1H, sept, J=7 Hz), 2.97 (1H, br), 3.97 (1H, dd, J=10, 8 Hz), and 4.38 (1H, d, J=10 Hz). IR ν: 3630, 3600, 2960, 2880, 1460, 1380, 1240, 1015 cm^{-1}].

Acetylation of 62 to a Diacetate (66). An anhydrous CH_2Cl_2 solution (3 cm³) of **62** (246 mg), DMAP (20 mg), Ac_2O (300 mg) and Et_3N (100 mg) was kept at room temperature for 16 h. The mixture was then diluted with water, extracted with ether, and chromatographed on a silica-gel column to give **64** (46 mg; 16%) and **66** [a colorless oil, 223 mg; 71%. Found: C, 74.14; H, 9.36%. Calcd for $C_{24}H_{36}O_4$: C, 74.19; H, 9.34%. ^1H NMR δ=0.92 (3H, d, J=7 Hz), 1.00 (3H, s), 1.04 (3H, d, J=7 Hz), 1.07 (3H, d, J=7 Hz), 1.60 (3H, br s), 2.01 (3H, s), 2.08 (3H, s), 2.78 (1H, br), 2.84 (1H, sept, J=7 Hz), 4.80 (1H, dd, J=5.5, 3 Hz), and 6.30 (1H, br). IR ν: 2950, 2870, 1750, 1460, 1370, 1245, 1230, and 1030 cm^{-1}].

Hydrolysis of 64. Similarly, **64** (20 mg) was reduced with LAH in ether to give **62** (19 mg; 100%).

Formation of Dimethyl Acetal, 68, from 62. To an anhydrous benzene solution (4 cm³) of **62** (46 mg), $Me_2C(OMe)_2$ (1 cm³) was added and stirred with PPTS (3 mg) at room temperature for 72 h. The mixture was then treated with aqueous K_2CO_3 and extracted with ether. Silica-gel column chromatography of the extract yielded **68** [a colorless oil, 33 mg; 64%. Found: M.W., 344.2716. Calcd for $C_{23}H_{36}O_2$: 344.2713. ^1H NMR δ=0.94 (3H, d, J=7 Hz), 1.00 (3H, d, J=7 Hz), 1.11 (3H, d, J=7 Hz), 1.24 (3H, s), 1.28 (3H, s), 1.37 (3H, s), 1.60 (3H, br s), 2.52 (1H, sept, J=7 Hz), 2.59 (1H, br), 4.20 (1H, dd, J=9, 1 Hz), and 5.17 (1H, br d, J=9 Hz). IR ν: 2950, 1460, 1380, 1205, 1042, and 886 cm^{-1}].

$NaIO_4$-Cleavage of 62. Formation of 58. A THF solution (2 cm³) of **62** (29 mg) was treated with $NaIO_4$ (40 mg) dissolved in water (2 cm³) at room temperature for 12 h. The mixture was then, diluted with water and extracted with ether. Silica-gel column chromatography of the extract afforded **58** (19 mg; 65%), which was identical with the authentic sample in every respect.

PCC-Oxidation of 64 to 69. To an anhydrous CH_2Cl_2 suspension (2 cm³) of PCC (64 mg), NaOAc (9 mg), and Celite (40 mg), a CH_2Cl_2 solution of **64** (5 mg) was added dropwise. After 3 h, the mixture was diluted with ether and filtered on a short Florisil column to give **69** [a colorless oil, 33 mg; 77%. Found: M.W., 344.2353. Calcd for $C_{22}H_{32}O_3$: 344.2350. ^1H NMR δ=0.96 (6H, d, J=7 Hz), 1.06 (3H, d, J=7 Hz), 1.16 (3H, s), 1.60 (3H, br s), 2.15 (3H, s), 2.80 (1H, br), 3.10 (1H, br), and 5.25 (1H, d, J=5 Hz). IR ν: 2950, 1753, 1705, 1460, 1372, 1240, 1045, and 808 cm^{-1}].

LAH-Reduction of 69 to 62. An anhydrous ether solution of **69** (5.0 mg) was treated with LAH (5 mg) to give **62** (4.5 mg; 100%), whose identity as the authentic sample was confirmed by direct comparisons.

Conversion of 62 to Fusicoccatriene (1) via Elimination of Cyclic Thiocarbonate (71). To an anhydrous toluene solution (4 cm³) of **62** (277 mg), 1,1′-(thiocarbonyl)bis[imidazole] (**70**, 540 mg; 90%) was added and refluxed for 5 h. The mixture was then diluted with ether, passed through a short silica-gel filter, heated in vacuo to remove the solvent, and chromatographed to obtain **71** [a colorless oil, 185 mg; 59%. Found: M.W., 346.1963. Calcd for $C_{21}H_{30}O_2S$: 346.1965. ^1H NMR δ=0.95 (3H, d, J=7 Hz), 1.01 (3H, d, J=7 Hz), 1.16 (3H, d, J=7 Hz), 1.27 (3H, s), 1.66 (3H, br s), 4.91 (1H, dd, J=10, 1 Hz), and 5.82 (1H, d, J=10 Hz)]. Without further purification, **71** (174 mg) was dissolved together with 1,3-dimethyl-2-phenyl-1,3,2-diazaphospholidine (**72**, 1 cm³) in benzene (1.5 cm³), and refluxed for 9 h. After dilution with ether, the extract was passed through a short silica-gel column to obtain **1** [a colorless oil, 65 mg; 51%. Found: M.W., 270.2347. Calcd for $C_{20}H_{30}$: 270.2346. ^1H NMR δ=0.92 (6H, d, J=7 Hz), 0.95 (3H, s), 0.96 (3H, d, J=7 Hz), 1.58 (3H, br s), 2.51 (1H, sept, J=7 Hz), 2.60 (1H, br), 5.40 (1H, br dd, J=11, 7 Hz), and 5.79 (1H, br d, J=11 Hz). IR ν: 2960, 2880, 1460, 1370, 1110, and 1025 cm^{-1}], together with the recovered **71** (46 mg; 26%).

The authors are grateful to the Ministry of Education, Science and Culture for financial assistance through a Grant-in-Aid for the Scientific Research, No. 59740260 (to N. K.) and No. 59104006 (to H. T.), by which, part of the expenses were defrayed.

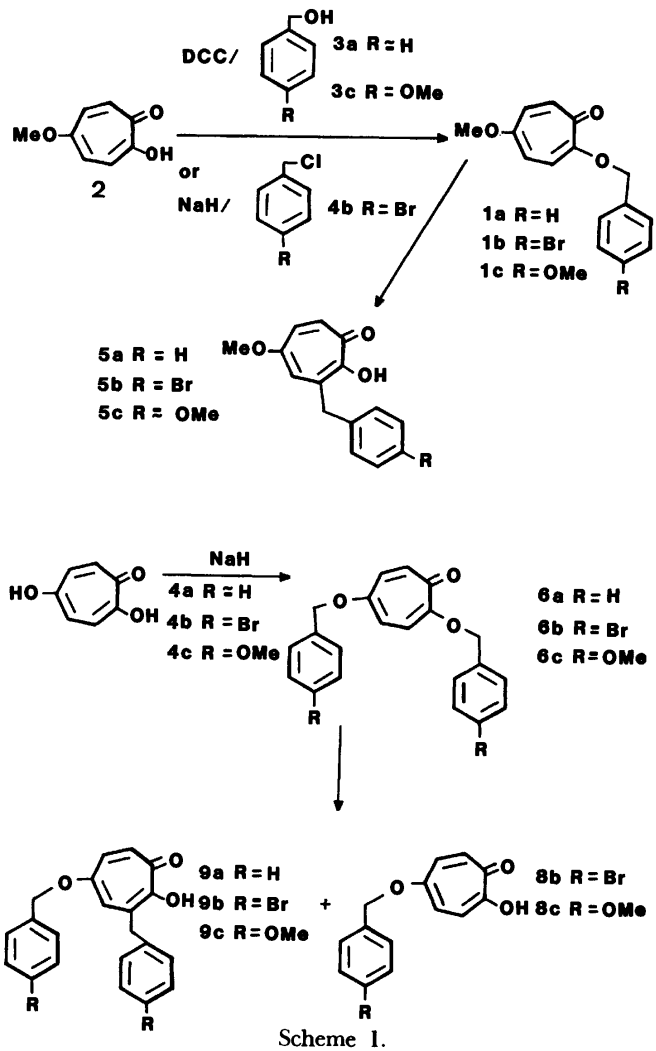
(Received November 11, 1985)

The 3-(arylmethyl)-*p*-tropoquinones were synthesized by starting from the homolytic thermal rearrangement of 2-(arylmethoxy)-5-methoxytropones or 2,5-bis(arylmethoxy)tropones, followed by hydrolysis and oxidation. The half-wave potentials of these tropoquinones were determined by cyclic voltammetry. A remote substituent effect was observed for 3-(4-hydroxybenzyl)-*p*-tropoquinone, which may be attributable to intermolecular hydrogen bonding.

Recently, we have synthesized several halo-, alkyl-, and alkenyl-substituted *p*-tropoquinones,[1] and have measured their reduction potentials by cyclic voltammetry (CV)[2] to show the typical quinone character of *p*-tropoquinones; indeed, tropoquinones revealed stronger oxidizing ability than the benzoquinone derivatives carrying similar substituents.[3] However, an additional oxidation wave appeared around zero V together with two pairs of reduction-oxidation waves. The appearance of these new waves was more or less common to *p*-tropoquinones, and relatively intense waves were observed in 3-substituted derivatives. We have now synthesized another group of derivatives, 3-(arylmethyl)-*p*-tropoquinones, by application of the recently-found homolytic rearrangement of 2-(arylmethoxy)tropones to 3-(arylmethyl)tropolones.[4] The CV measurement of these 3-(arylmethyl)tropoquinones disclosed intense waves in that region. The findings will be described herein.

Synthesis of 3-(Arylmethyl)-*p*-tropoquinones. 2-(Arylmethoxy)-5-methoxytropones (**1**) were prepared in good yields from 5-methoxytropolone (**2**) and appropriate arylmethanols (**3**) by the dicyclohexylcarbodiimide (DCC)-condensation[5] or by condensation of **2** and arylmethyl chloride (**4**) in the presence of sodium hydride in hexamethylphosphoric triamide (HMPA).[4] Thermolysis of **1** proceeded in a manner similar to that of 2-(arylmethoxy)tropones,[4] or in even better yields; the only by-product identified was the debenzylated tropolone, **2**. The structures of the products (**5**) were obviously 3-(arylmethyl)-5-methoxytropolones from the known reaction mechanism, and characterized by their ^{1}H- and ^{13}C NMR spectra. Particularly, there is a distinct long-range coupling between the protons on the C-4 and C-6 of each product and a regular change of the ^{13}C chemical shift from the parent **2** in the vicinity of the substituents.

In view of the specificity of the homolytic rearrangement for 2-benzyloxy group, 2,5-bis(arylmethoxy)-tropone (**6**) prepared directly from 5-hydroxytropolone (**7**), could also be used for the present purpose. However, for the preparation of the 3-(4-methoxybenzyl) derivative, lc was better than 2,5-bis(4-methoxybenzyloxy)tropone (**6c**), from which, the major product was the debenzylated 5-(4-methoxybenzyloxy)-tropolone (**8c**); the desired 3-(4-methoxybenzyl)-5-(4-methoxybenzyloxy)tropolone (**9c**) was obtained only in a 10% yield. The yield of rearrangement products from the other two pairs of reactants (**1a** vs. **6a** and **1b** vs. **6b**) were not significantly different. Subsequently, the hydrolysis of **5** or **9** with hydrobromic acid in acetic acid afforded the desired 3-(arylmethyl)-5-hydroxytropolone (**10**) in good yields. In the case of **5c**, the methoxyl group on the benzene ring was



Scheme 1.

Table 1. Half-Wave Potentials of **11**[a] and Reference *p*-Tropoquinones

	E_1	E_2	$\Sigma(E_1+E_2)$	$\Delta(E_1-E_2)$
11a	−0.26	−1.04	−1.30	+0.78
11b	−0.24	−0.80	−1.04	+0.56
11d	−0.19	−0.72	−0.91	+0.53
12	−0.21	−1.10	−1.31	+0.89
13	−0.28	−1.15	−1.43	+0.87

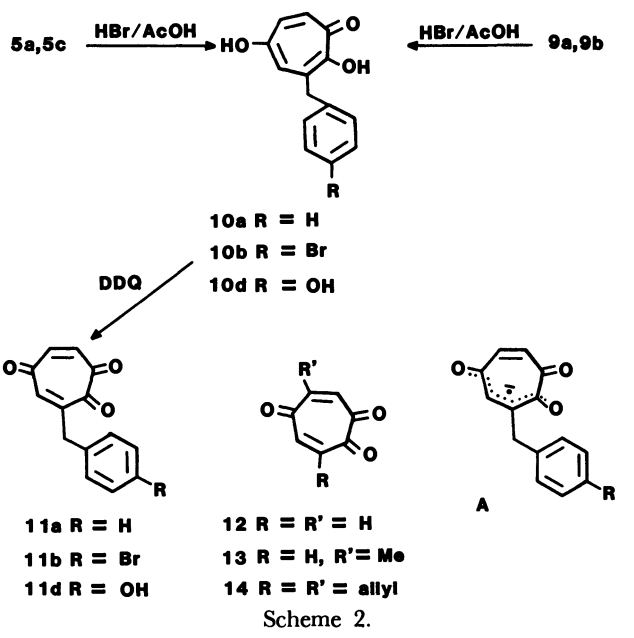
a) CV measurements were carried out at the concentrations of 1.09×10^{-3} mmol cm^{-3} for **11a**, 1.03×10^{-3} mmol cm^{-3} for **11b**, and 8.18×10^{-4} mmol cm^{-3} for **11d**.

simultaneously demethylated to form 5-hydroxy-3-(4-hydroxybenzyl)tropolone (**10d**). By the DDQ (2,3-dichloro-5,6-dicyano-*p*-benzoquinone)-oxidation, **10** yielded corresponding quinones (**11**).

Measurement of the Cyclic Voltammetry. The half-wave potentials were determined by the CV and are summarized in Table 1 together with those of *p*-tropoquinone (**12**) and 4-methyl-*p*-tropoquinone (**13**).[2] The values were corrected with an internal standard for the redox potential of ferrocenium/ferrocene couple, +0.465 V vs. Ag/AgCl. Similar to other 3-substituted tropoquinones,[2] the CV of all **11** disclosed oxidation waves around +0.11 to +0.135 V. The intensities of these waves, which indicated an electrochemical formation of a different species, were as large as that of 3,6-diallyl-*p*-tropoquinone (**14**)[1b] and were even comparable to their first oxidation waves. The responsibility of the anion radical species (**A**) for these waves was verified by scanning between +0.3 to −0.5 V for CV of **11d**. It is likely that the species responsible for the waves are coupling products derived from **A**. As previously reported, treatment of 5-hydroxy-2-methoxytropones or 5-hydroxytropolones with a one-electron oxidation agent, such as cerium(IV) ammonium nitrate or silver acetate, led to a facile formation of several dimerization products.[2,6,7] For elucidation of the structures of the coupling products, preparative electrolytic study is being undertaken.

As in the benzoquinones,[8] a hydroxyl group of **11d** at a remote position caused an enhancement of the reduction potential. Although the mesomeric electron transmission through the benzene ring was blocked by the methylene group as has been indicated by the similar first reduction potentials of **11a**, **11b**, and **13**,[1b] the potential of **11d** exceeded the value not only of **11a** but also of unsubstituted **12**. Since intramolecular hydrogen bonding was sterically prohibited, this enhancement of the reduction potential may be attributed to intermolecular hydrogen bonding[8] to increase the electron affinity of the quinonoid carbonyl groups.

In conclusion, since the *p*-tropoquinones are stronger oxidizing agents than benzoquinones, it is interesting to prepare *p*-tropoquinone derivatives having stronger oxidizing ability than DDQ. In this respect, the present observations on the substituent effects suggested an approach. Furthermore, this easy method for the synthesis of benzyl-*p*-tropoquinones should be applicable to preparation of the polymer-supported tropoquinones, which is our current interest.



Scheme 2.

Experimental

All the mps, measured with a Yanagimoto Micro-mp apparatus, are uncorrected. Elemental analyses were performed by Miss S. Hirashima of the Research Institute of Industrial Science, Kyushu University. The CV were measured by Yanaco Polarographic Analyzer Model P-1100 apparatus in a standard three-electrode cell with a standard Ag/AgCl reference electrode in anhydrous *N,N*-dimethylformamide (DMF) solutions in the presence of 0.1 M[†] Bu_4NBF_4 under N_2. The scan rate was 100 mV/s at 22—23 °C. The NMR spectra were measured by means of a JEOL FX 100 Spectrometer in $CDCl_3$ solutions unless otherwise specified, and the chemical shifts were expressed in δ units from the internal Me_4Si. The mass spectra were measured by means of a JEOL OlSG-2 Spectrometer.

2-Benzyloxy-5-methoxytropone (1a). A mixture of **3a** (0.3 cm^3) and DCC (663 mg) was kept at 60 °C for 14 h with CuCl (5 mg). Then, a benzene solution (0.5 cm^3) of **2** (301 mg) was added and kept at 60 °C for 16 h. After removal of the precipitates, the mixture was chromatographed on a silica-gel column with AcOEt–benzene (1:5) to give **1a** [yellow crystals, mp 102—103 °C, 441.5 mg; 92%. Found: C, 74.46; H, 5.90%. Calcd for $C_{15}H_{14}O_3$: C, 74.36; H, 5.83%. ^{1}H NMR δ=3.68 (3H, s), 5.16 (2H, s), 6.18 (1H, dd, J=11, 2.5 Hz), 6.99 (1H, dd, J=13.5, 2.5 Hz), 7.18 (1H, d, J=13.5 Hz), and 7.25—7.5 (6H, m). ^{13}C NMR δ=55.5, 71.0, 107.1, 117.6, 127.2 (2C), 128.0, 128.5 (2C), 132.6, 136.2, 137.8, 158.6, 159.7, and 179.7. IR ν: 1570 and 1202 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=24000), 252 (7500, sh), 328 (11200), 347 (10200), 361 (9300, sh), and 376 (6400, sh)].

2-(4-Bromobenzyloxy)-5-methoxytropone (1b). To an

† 1 M=1 mol dm^{-3}.

HMPA solution (3 cm³) of **2** (203 mg) and NaH (50%, 81 mg), **4b** (341 mg) was added at 60 °C. The mixture was kept at 60 °C for further 13 h, the reaction mixture was poured into water to precipitate **1b** [yellow crystals, mp 157—159 °C, 329 mg; 77%. Found: C, 55.80; H, 4.06%. Calcd for $C_{15}H_{13}O_3Br$: C, 56.09; H, 4.08%. ^1H NMR δ=3.72 (3H, s), 5.10 (2H, s), 6.18 (1H, dd, J=11, 2.5 Hz), 6.78 (1H, d, J=11 Hz), 7.06 (1H, dd, J=13, 2.5 Hz), 7.18 (1H, d, J=13 Hz), 7.26 (2H, d, J=8.5 Hz), and 7.46 (2H, d, J=8.5 Hz). ^{13}C NMR δ=55.5, 70.3, 106.8, 118.3, 121.9, 128.9 (2C), 131.7 (2C), 132.7, 135.3, 138.1, 158.3, 160.0, and 179.7. IR ν: 1570 and 1200 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=16500), 252 (4100, sh), 327 (5900), 332 (5900), 341 (5600), 362 (4800, sh), and 376 (3400, sh)].

2-(4-Methoxybenzyloxy)-5-methoxytropone (1c). To a mixture prepared from **3c** (380 mg), DCC (615 mg), and CuCl (5 mg) by warming at 60 °C for 10 h a benzene solution (0.5 cm³) of **2** (297 mg) was added. After standing at 60 °C for 30 min, the precipitates were removed by filtration, the filtrate was heated in vacuo to remove the volatile material, and the residue was recrystallized from a mixture of benzene and hexane (2:1) to give **1c** [yellow needles, mp 157—158.5 °C, 527 mg; 99%. Found: M. W., 272.1033. Calcd for $C_{16}H_{16}O_4$: 272.1048. ^1H NMR δ=3.72 (3H, s), 3.78 (3H, s), 5.12 (2H, s), 6.20 (1H, dd, J=11, 2.8 Hz), 6.82 (1H, d, J=11 Hz), 6.86 (2H, d, J=9 Hz), 7.00 (1H, dd, J=13, 2.8 Hz), 7.18 (1H, d, J=13 Hz), and 7.52 (2H, d, J=9 Hz). ^{13}C NMR δ=55.3, 55.5, 70.8, 107.3, 114.0 (2C), 118.1, 128.2, 129.0 (2C), 132.6, 137.8, 158.7, 159.5, 159.8, and 179.8. IR ν: 1610, 1573, 1520, 1237, 1200, 1108, and 825 cm^{-1}. UV λ_{max}^{MeOH}: 229 nm (ε=15200), 252 (4200, sh), 274 (1300), 282 (1500), 327 (5400), 332 (5400), 348 (4900), 362 (4200, sh), and 378 (3100, sh)].

2,5-Bis(benzyloxy)tropone (6a). To an HMPA solution (12 cm³) prepared from **7** (500 mg) and NaH (392 mg) by warming at 60 °C for 3 h, **4a** (1.2 cm³) was added. After 13 h, the mixture was poured into water, and the resultant precipitates were collected by filtration. Recrystallizations from a mixed solution of benzene and hexane yielded **6a** [yellow crystals, mp 114—115 °C, 915 mg; 80%. Found: C, 79.30; H, 5.67%. Calcd for $C_{21}H_{18}O_3$: C, 79.22; H, 5.70%. ^1H NMR δ=4.95 (2H, s), 5.18 (2H, s), 6.30 (1H, ddd, J=11, 2, 1 Hz), 6.78 (1H, d, J=11 Hz), 7.07 (1H, dd, J=13, 2 Hz), 7.25 (1H, dd, J=13, 1 Hz), and 7.35 (10H, br s). ^{13}C NMR δ=70.4, 71.0, 108.7, 117.3, 127.2 (2C), 127.4 (2C), 128.0, 128.4, 128.6 (2C), 128.7 (2C), 132.8, 135.4, 136.1, 137.9, 158.8 (2C), and 179.7. IR ν: 1601, 1566, 1233, 1193, 1126, 849, and 759 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=13300), 253 (5200, sh), 327 (6300), 332 (6300), 344 (5700), 360 (4900, sh), and 370 (3400, sh)].

2,5-Bis(4-bromobenzyloxy)tropone (6b). Similarly, **7** (276 mg) in HMPA (4 cm³) with NaH (218 mg) was treated with **4b** (1070 mg) in HMPA (4 cm³) to give **6b** [yellow crystals, mp 142—143 °C, 903 mg; 95%. Found: C, 52.87; H, 3.44%. Calcd for $C_{21}H_{16}O_3Br_2$: C, 52.97; H, 3.39%. ^1H NMR δ=4.88 (2H, s), 5.08 (2H, s), 6.24 (1H, d, J=11 Hz), 6.72 (1H, d, J=11 Hz), 7.12 (2H, s), 7.20 (2H, d, J=9 Hz), 7.22 (2H, d, J=9 Hz), 7.42 (2H, d, J=9 Hz), and 7.44 (2H, d, J=9 Hz). ^{13}C NMR δ=69.6, 70.2, 108.6, 117.6, 122.0, 122.4, 129.0 (4C), 131.7 (2C), 131.8 (2C), 132.8, 134.4, 135.1, 138.1, 158.7 (2C), and 179.6. IR ν: 1630, 1595, 1570, 1516, 1245, 1190, and 1010 cm^{-1}. UV λ_{max}^{MeOH}: 228 nm (ε=38700), 254 (9600, sh), 327 (11700), 346 (10300, sh), 360 (8900, sh), and 376 (5900, sh)].

2,5-Bis(4-methoxybenzyloxy)tropone (6c). In a similar manner to **6b**, **7** (411 mg) was converted to **6c** [yellow needles, mp 145—148 °C, 1060 mg; 94%. Found: C, 73.02; H, 5.85%. Calcd for $C_{23}H_{22}O_5$: C, 73.00; H, 5.86%. ^1H NMR δ=3.76 (3H, s), 3.78 (3H, s), 4.86 (2H, s), 5.10 (2H, s), 6.30 (1H, ddd, J=11, 2.5, 1 Hz), 6.78 (1H, d, J=11 Hz), 6.84 (2H, d, J=9 Hz), 6.88 (2H, d, J=9 Hz), 7.04 (1H, dd, J=13, 2.5 Hz), 7.20 (1H, dd, J=13, 1 Hz), 7.26 (2H, d, J=9 Hz), and 7.30 (2H, d, J=9 Hz). ^{13}C NMR δ=55.3 (2C), 70.3, 70.8, 108.7, 114.0 (2C), 114.1 (2C), 117.7, 124.1, 127.4, 128.9 (2C), 129.2 (2C), 132.8, 137.9, 158.9, 159.4, 159.7, 168.3, and 179.8. IR ν: 1612, 1518, 1252, 1232, 1185, and 1175 cm^{-1}. UV λ_{max}^{MeOH}: 229 nm (ε=41200), 253 (10700, sh), 330 (12200), and 382 (6100, sh)].

3-Benzyl-5-methoxytropolone (5a). A decalin solution (9 cm³) of **1a** (225 mg) was refluxed for 4.5 h. The mixture was then chromatographed on a silica-gel column to give **5a** [yellow needles, mp 86—88 °C, 98 mg; 44%. Found: C, 74.46; H, 5.64%. Calcd for $C_{15}H_{14}O_3$: C, 74.36; H, 5.83%. ^1H NMR δ=3.70 (3H, s), 4.13 (2H, s), 6.70 (1H, dd, J=11, 2.5 Hz), 7.09 (1H, d, J=2.5 Hz), 7.24 (5H, s), and 7.26 (1H, d, J=11 Hz). ^{13}C NMR δ=40.8, 55.8, 117.4, 120.3, 126.8, 128.8 (2C), 129.4 (2C), 129.5, 139.2, 141.7, 158.7, 162.9, and 171.3. IR ν: 1608, 1529, and 1210 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=11900), 253 (7500), 322 (3400), 372 (2900), and 386 (2800)] and **2** (16.7 mg; 12%).

3-(4-Bromobenzyloxy)-5-methoxytropolone (5b). Similarly, **1b** (148 mg) was converted to **5b** [yellow crystals, mp 109—111 °C, 84.5 mg; 57%. Found: M.W., 319.9975 and 322.0017. Calcd for $C_{15}H_{13}O_3Br$: 320.0028 and 322.0048. ^1H NMR δ=3.73 (3H, s), 4.08 (2H, s), 6.70 (1H, dd, J=11.5, 3 Hz), 7.08 (1H, d, J=3 Hz), 7.18 (2H, d, J=9 Hz), 7.26 (1H, d, J=11.5 Hz), and 7.38 (2H, d, J=9 Hz). ^{13}C NMR δ=40.5, 55.8, 116.7, 119.8, 129.9, 130.9 (2C), 131.6 (2C), 135.0, 138.0, 141.1, 158.5, 162.2, and 171.4. IR ν: 1609, 1515, 1484, 1450, 1400, and 1207 cm^{-1}. UV λ_{max}^{MeOH}: 228 nm (ε=21100), 241 (21100), 271 (6700, sh), 330 (7600), 370 (5400), and 384 (4800, sh)]. In this case, **2** could not be isolated.

3-(4-Methoxybenzyloxy)-5-methoxytropolone (5c). Similarly, **1c** (54 mg) was converted to **5c** [yellow crystals, mp 78—80 °C, 30 mg; 56%. Found: C, 70.80; H, 6.08%. Calcd for $C_{16}H_{16}O_4$: C, 70.57; H, 5.92%. ^1H NMR δ=3.72 (3H, s), 3.78 (3H, s), 4.10 (2H, s), 6.72 (1H, dd, J=11, 3 Hz), 6.82 (2H, d, J=8.5 Hz), 7.10 (1H, d, J=3 Hz), 7.18 (2H, d, J=8.5 Hz), and 7.28 (1H, d, J=11 Hz). ^{13}C NMR δ=40.0, 55.2, 55.7, 114.0 (2C), 116.9, 119.9, 129.3, 130.2 (2C), 130.8, 142.0, 158.3, 158.5, 162.4, and 171.1. IR ν: 1605, 1508, 1453, 1397, 1247, 1040, and 740 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=24300), 240 (21200, sh), 251 (14900, sh), 276 (4200), 330 (7300), 371 (6100), and 387 (6100)] and **2** (5.4 mg; 18%).

3-Benzyl-5-benzyloxytropolone (9a). Similarly, **6a** (727 mg) was converted to **9a** [pale yellow crystals, mp 79—80 °C, 361 mg; 50%. Found: C, 79.38; H, 5.71%. Calcd for $C_{21}H_{18}O_3$: C, 79.22; H, 5.70%. ^1H NMR δ=4.12 (2H, s), 4.94 (2H, s), 6.83 (1H, dd, J=11.5, 3 Hz), 7.23 (6H, br s), 7.24 (1H, d, J=11.5 Hz), and 7.30 (5H, s). ^{13}C NMR δ=40.8, 70.8, 120.1, 121.0, 126.7, 127.6 (2C), 128.4, 128.7 (2C), 128.8 (2C), 129.2 (2C), 129.5, 135.6, 139.0, 141.1, 157.8, 163.9, and 170.3. IR ν: 1608, 1548, 1458, 1400, and 1192 cm^{-1}. UV λ_{max}^{MeOH}: 237 nm (ε=22600), 250 (18800, sh), 332 (8600), 370 (6100), and 387 (5900)].

Thermolysis of 6b to 3-(4-Bromobenzyl)-5-(4-bromobenzyloxy)-tropolone (9b) and 5-(4-Bromobenzyloxy)tropolone (8b). Similarly, **6b** (80.6 mg) was heated. Silica-gel column chromatography of the mixture yielded **9b** [yellow crystals, mp 62 °C, 32.8 mg; 41%. Found: M.W., 473.9484, 475.9440, and 477.9440. Calcd for $C_{21}H_{16}O_3Br_2$: 473.9466, 475.9447, and 477.9427. ^1H NMR δ=4.04 (2H, s), 4.90 (2H, s), 6.80

(1H, dd, J=11, 3 Hz), 7.06 (2H, d, J=9 Hz), 7.12 (1H, d, J=3 Hz), 7.17 (2H, d, J=9 Hz), 7.22 (1H, d, J=11 Hz), 7.35 (2H, d, J=9 Hz), and 7.47 (2H, d, J=9 Hz). ^{13}C NMR δ=40.4, 70.2, 119.4, 120.4, 120.7, 122.6, 129.2 (2C), 130.0, 131.0 (2C), 131.8 (2C), 132.1 (2C), 134.7, 138.1, 140.8, 157.4, 163.5, and 171.1. IR ν: 1608, 1555, 1488, 1456, 1398, 1367, 1259, 1015, 1188, and 804 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=29300), 241 (24100, sh), 250 (19700, sh), 332 (8300), 370 (5800), 387 (5600), and 422 (1400)] and **8b** [yellow crystals, mp 121—123 °C. 8.7 mg; 11%. Found: M.W., 305.9878 and 307.9871. Calcd for $C_{14}H_{11}O_3Br$: 305.9889 and 307.9871. ^{1}H NMR δ=4.98 (2H, s), 7.00 (2H, d, J=12 Hz), 7.24 (2H, d, J=9 Hz), 7.28 (2H, d, J=12 Hz), and 7.52 (2H, d, J=9 Hz)].

Thermolysis of 6c to 3-(4-Methoxybenzyl)-5-(4-methoxybenzyloxy)tropolone (9c) and 5-(4-Methoxybenzyloxy)-tropolone (8c). Similarly, **6c** (549.5 mg) was converted to **9c** [a yellow oil, 55.6 mg; 10%. Found: M.W., 378.1462. Calcd for $C_{23}H_{22}O_5$: 378.1464. ^{1}H NMR δ=3.74 (3H, s), 3.80 (3H, s), 4.06 (2H, s), 4.88 (2H, s), 6.7—7.0 (6H, m), and 7.05—7.3 (5H, m). ^{13}C NMR δ=40.4, 55.2 (2C), 70.7, 113.7, 114.0 (2C), 114.1 (2C), 119.5, 120.5, 127.6, 129.3 (2C), 129.6, 130.2 (2C), 130.9, 141.4, 157.7, 158.3, 163.5, and 170.5] and **8c** [colorless crystals, mp 181.5 °C (decomp), 274.5 mg; 73%. Found: C, 69.86; H, 5.47%. Calcd for $C_{15}H_{14}O_4$: C, 69.75; H, 5.46%. ^{1}H NMR δ=3.80 (3H, s), 4.94 (2H, s), 6.90 (2H, d, J=9 Hz), 7.00 (2H, d, J=12 Hz), 7.26 (2H, d, J=12 Hz), and 7.30 (2H, d, J=9 Hz). ^{13}C NMR δ=40.0, 55.3, 114.1 (2C), 124.1 (2C), 124.2 (2C), 127.4, 129.3 (2C), 158.8, 159.7, and 168.3 (2C). IR ν: 1618, 1547, 1454, 1269, 1254, 1190, and 1173 cm^{-1}].

Demethylation of 5a to 3-Benzyl-5-hydroxytropolone (10a). A 1:1-mixture of conc HBr–AcOH (1.2 cm^3) and **5a** (30.6 mg) were heated. The product mixture was then poured into water, and extracted with AcOEt. Recrystallizations from a mixed solution of acetone and ether yielded **10a** [yellow crystals, mp 192 °C (decomp), 12 mg; 42%. Found: M.W., 228.0787. Calcd for $C_{14}H_{12}O_3$: 228.0787. ^{1}H NMR (DMF-d_7) δ=4.11 (2H, s), 6.96 (1H, dd, J=11, 3 Hz), 7.23 (1H, d, J=3 Hz), and 7.28 (6H, br s). ^{13}C NMR δ=40.9, 120.3, 121.2, 126.9, 129.0 (2C), 129.8 (2C), 130.3, 140.6, 143.6, 158.2, 159.4, and 171.3. IR ν: 1605, 1376, 1277, 1215, and 962 cm^{-1}. UV λ_{max}^{MeOH}: 239 nm (ε=21200), 270 (3900, sh), 342 (8700), 380 (7300, sh), 393 (7700), and 422 (2600, sh)].

Debenzylation of 9a to 10a. Similarly, **9a** (48.3 mg) was hydrolyzed to **10a** (25.2 mg; 73%).

Debenzylation of 9b to 10b. Similarly, **9b** (284 mg) was converted to **10b** [yellow needles, mp 161 °C (decomp), 78 mg; 42%. Found: C, 54.51; H, 3.76%. Calcd for $C_{14}H_{11}O_3Br$: C, 54.75; H, 3.61%. ^{1}H NMR (CD_3OD) δ=4.07 (2H, s), 6.94 (1H, dd, J=11, 2.5 Hz), 7.15 (2H, d, J=8.5 Hz), 7.16 (1H, d, J=2.5 Hz), 7.28 (1H, d, J=11 Hz), and 7.39 (2H, d, J=8.5 Hz). ^{13}C NMR δ=41.0, 121.2, 123.9, 124.8, 129.8, 132.0 (2C), 132.6 (2C), 140.0, 142.5, 159.3, 166.1, and 169.6. IR ν: 1605, 1370, 1277, and 1214 cm^{-1}. UV λ_{max}^{MeOH}: 230 nm (ε=23700, sh), 237 (23800), 336 (8100), 379 (7200), and 394 (7400)].

Demethylation of 5c to 10d. Similarly, **5c** (110 mg) was converted to **10d** [yellow crystals, mp 191 °C (decomp), 54.4 mg; 55%. Found: M.W., 244.0733. Calcd for $C_{14}H_{12}O_4$: 244.0733. ^{1}H NMR (CD_3OD) δ=4.01 (2H, s), 6.70 (2H, d, J=9 Hz), 6.94 (1H, dd, J=11.5, 3 Hz), 7.05 (2H, d, J=9 Hz), 7.12 (1H, d, J=3 Hz), and 7.24 (1H, d, J=11.5 Hz). ^{13}C NMR δ=40.7, 116.6 (2C), 124.0, 125.2, 129.7, 131.5 (3C), 144.3, 157.3, 159.7, 166.4, and 169.7. IR ν: 1610, 1518, 1373, 1214, and 1201 cm^{-1}. UV λ_{max}^{MeOH}: 229 nm (ε=21000), 239 (20800), 280 (3900, sh), 344 (8500), 395 (6800), and 422 (3100, sh)].

3-Benzyl-*p*-tropoquinone (11a). An acetone solution (10 cm^3) of **10a** (104.5 mg) was treated with DDQ (121 mg) at 20—25 °C for 2 to 5 h. Silica-gel column chromatography of the mixture afforded **11a** [a yellow oil, 93.8 mg; 91%. Found: M.W., 226.0630. Calcd for $C_{14}H_{10}O_3$: 226.0630. ^{1}H NMR δ=3.84 (2H, d, J=1.5 Hz), 6.57 (1H, br s), 6.77 (2H, s), and 7.0—7.4 (5H, m). ^{13}C NMR δ=38.8, 127.3, 129.0 (2C), 129.3 (2C), 133.6, 135.6, 136.9, 139.5, 147.7, 187.7, 189.1, and 189.9. IR ν: 1680, 1644, and 1615 cm^{-1}. UV $\lambda_{max}^{CHCl_3}$: 252 nm (ε=12600) and 272 (7600)].

3-(4-Bromobenzyl)-*p*-tropoquinone (11b). Similarly, **10b** (101.7 mg) was oxidized to **11b** [yellow crystals, mp 97.5—99.5 °C, 76.7 mg; 76%. Found: M.W., 303.9758 and 305.9729. Calcd for $C_{14}H_9O_3Br$: 303.9735 and 305.9715. ^{1}H NMR δ=3.80 (2H, d, J=1.5 Hz), 6.57 (1H, q, J=1.5 Hz), 6.80 (2H, s), 7.03 (2H, d, J=9 Hz), and 7.42 (2H, d, J=9 Hz). ^{13}C NMR δ=38.3, 121.4, 131.0 (2C), 132.2 (2C), 133.7, 134.7, 137.1, 139.4, 147.0, 187.5, 188.7, and 189.4. IR ν: 1665, 1630, and 1600 cm^{-1}. UV $\lambda_{max}^{CHCl_3}$: 253 nm (ε=19200), 258 (19800), 265 (19200), and 271 (16700)].

3-(4-Hydroxybenzyl)-*p*-tropoquinone (11d). Similarly, **10d** (37.4 mg) was oxidized with DDQ (39.7 mg) to give **11d** [a yellow oil, 35.2 mg; 95%. Found: C, 68.12; H, 4.68%.[9] Calcd for $C_{14}H_{10}O_4 \cdot C_{14}H_{12}O_4 + 1/3H_2O$: C, 68.29; H, 4.61%. m/z, 278 (M^++36), 244 (M^++2), and 242 (M^+). ^{1}H NMR δ=3.78 (2H, d, J=1.5 Hz), 6.57 (1H, q, J=1.5 Hz), 6.74 (2H, d, J=9 Hz), 6.80 (2H, s), and 7.01 (2H, d, J=9 Hz). ^{13}C NMR δ=38.1, 116.0 (2C), 127.5, 130.6 (2C), 133.6, 136.7, 139.7, 148.2, 154.9, 187.9, 189.2, and 190.0. IR ν: 1680, 1640, 1615, and 1515 cm^{-1}].

NMR Study on Inclusion Complexes of L-Phenylalanine and Aspartame with Cyclodextrins in Aqueous Solution

Shin-ichiro TAKAHASHI,* Ei-ichiro SUZUKI, and Nobuya NAGASHIMA
Central Research Laboratories, Ajinomoto Co., Inc., Suzuki-cho, Kawasaki-ku, Kawasaki 210
(Received November 22, 1985)

The interactions of Phenylalanine and Aspartame (*N*-L-α-Aspartyl-L-phenylalaninel-methyl ester, APM) with α- and β-cyclodextrins (CD) in aqueous solutions were investigated by ^{1}H and ^{15}N NMR techniques. The changes in chemical shift of CD protons on going from free CD to the mixture with phenylalanine and APM indicate that the phenyl ring is included in the cavity of CD in the complex states. The changes in the chemical shift of the β-protons of phenylalanine and APM following the binding to α- and β-CD indicate that the simple association constants (K_a) are not applicable to these systems except for the case of APM/β-CD (K_a=90), and that the large changes of the rotamer fractional population of APM side-chain occur for APM/β-CD system. The analysis with Asp-Phe(^{15}N)-OMe suggests that the torsional angles of the main chain of APM are unchanged on the formation of the inclusion complex. The low-field shifts of amide proton and its nitrogen resonances of Asp-Phe(^{15}N)-OMe in the complex formation suggest that the amide part of APM is hydrogen-bonded to the C2 or C3 hydroxyl group of β-CD.

APM (*N*-L-α-Aspartyl-L-phenylalaninel-methyl ester) is a well-known dipeptide used as a sweetner. We have obtained a crystal of the equimolar inclusion compound of APM with β-CD, and examined the crystal by Raman and solid-state ^{13}C NMR spectroscopy.[1] In the crystal state the phenyl ring of APM was found to be included in the cavity of β-CD. Also in aqueous solution the relatively hydrophobic environment of CD cavity seems to be favorable for the inclusion of the phenyl ring of phenylalanine and APM. We tried to elucidate the intermolecular interaction in aqueous solution by ^{1}H and ^{15}N NMR. In the past a number of papers investigated about the guest/CD interaction in solution by NMR examination.[2-10] Most of them pay attention to the conformational changes of CD molecule with which guests are included. In the present paper we report mainly on the conformational change of APM molecule which is included with β-CD as studied by the use of NMR techniques.

Experimental

Materials. Phenylalanine and APM were prepared in our laboratories. CD were purchased from Sanraku-Ocean CO., LTD. Asp-Phe(^{15}N)-OMe synthesized in the previous study[1] was used.

Apparatus. ^{1}H and ^{15}N NMR spectra were recorded on a JEOL GX-400 spectrometer operating at 399.55 MHz for ^{1}H and 40.40 MHz for ^{15}N. The proton chemical shifts were referenced to internal sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) and the nitrogen chemical shifts were to external 5 M† ammonium nitrate.

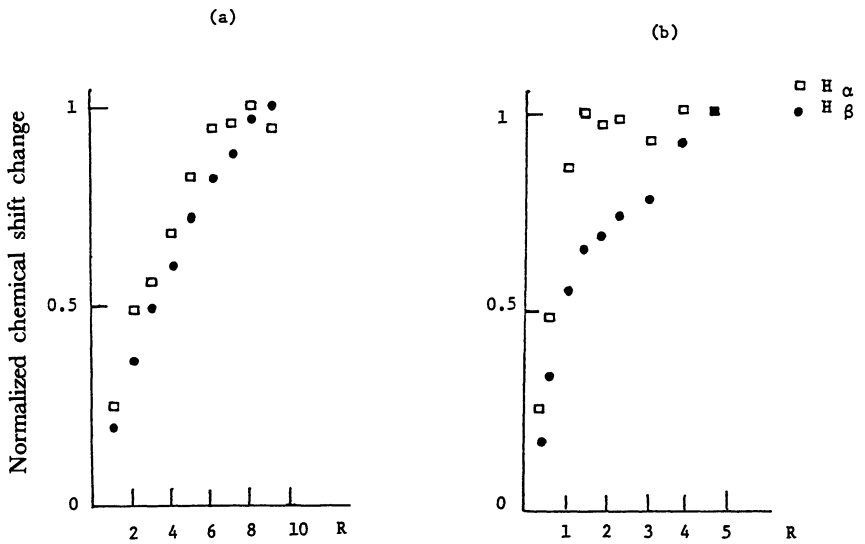

Fig. 1. CD-induced shifts of the chemical shifts of β-protons of Phe (a: α-CD, b: β-CD) in an aqueous solution at pH 6.0. R is [CD]:[Phe] molar ratio. The chemical shift changes are normalized with that at the highest molar ratio [CD]/[Phe].

† 1 M=1 mol dm^{-3}.

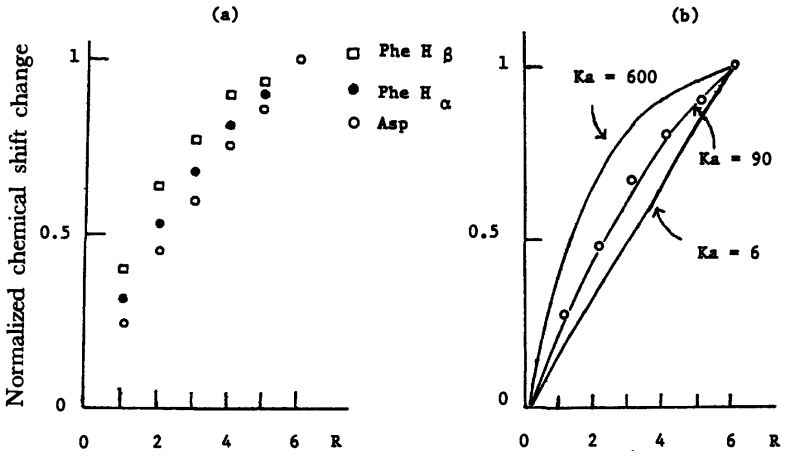

Fig. 2. CD-induced shifts of the chemical shifts of β-protons of Asp and Phe residues of APM (a: α-CD, b: β-CD) pH 6.0 in an aqueous solution. Solid lines in Fig. 2 b show variation of chemical shift changes with R for three association constants, calculated assuming a 1:1 adduct stoichiometry.

Results

(a) Binding of Phenylalanine and APM to CD. Figure 1 shows the chemical shift of β-protons of phenylalanine as a function of [α-CD]/[Phe] (Fig. 1(a)) and [β-CD]/[Phe] (Fig. 1(b)). The changes in the chemical shift are normalized to the values obtained at the highest molar ratio [CD]/[Phe]. The values for the two β-protons do not lie on the same line for α- and β-CD indicating that the simple association constant (K_a) for the complexation with CD is not applicable to these models. Figure 2 shows the chemical shift of methylene protons of Asp and Phe residues of APM as a function of [α-CD]/[APM] (Fig. 2(a)) and [β-CD]/[APM] (b). It is seen from Fig. 2(a) that the curves for four protons in [α-CD]/[APM] system are different and do not give the simple association constant while in Fig. 2(b) it is seen that in [β-CD]/[APM] the data points lie on the same curve so that the description on one association constant applies to [β-CD]/[APM] system. In Fig. 2(b) the curves corresponding to three K_a values (K_a=6, 90, 600 M^{-1}) are also shown. From those the value K_a=90 is obtained as a best fit.

(b) Depth of Inclusion of APM in the Cavity of β-CD. Figure 3 shows the changes of the ^1H NMR spectrum of β-CD on the complexation with APM in D_2O solution at pH 6.0. The upfield shifts of H3 and H5 located in the inner surface of β-CD were observed. We interprete that the shifts are due to the phenyl ring current and that the phenyl ring of APM is included in the cavity of β-CD. Then the most probable position of APM in the β-CD cavity in an aqueous solution can be determined from the Johnson-Bovey equation[11] when the intrinsic chemical shifts (δ_{int}) of H3 and H5 as defined as $\delta_b-\delta_o$ with δ_b and δ_o being the chemical shifts in fully

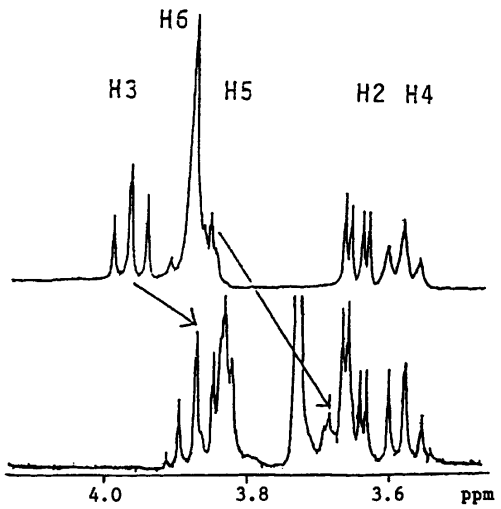

Fig. 3. 400 MHz ^1H NMR spectra of β-CD (top) and β-CD plus APM (bottom:molar ratio 1:20=CD:APM, [β-CD] 1.7 mM) in D_2O.

complexed and free state, respectively, are known. The values of δ_b and thus δ_{int} were estimated from the chemical shifts at known concentration of β-CD and APM with the aid of K_a value determined in section (a). Thus the estimated distance between the center of the phenyl ring and the plane containing seven H3 of β-CD is +1.7 Å. (the positive sign corresponds to the direction H3→H5 plane.) (Fig. 4)

(c) The Change of the Side-Chain and Backbone of APM in Complex Formation with β-CD. Table 1 summarized the vicinal coupling constants of the side-chain and the fractional populations of the rotamer in the free and complexed states in an aqueous solution. The fractional populations of three rotamers, PI, PII, and PIII were calculated using the following equations:

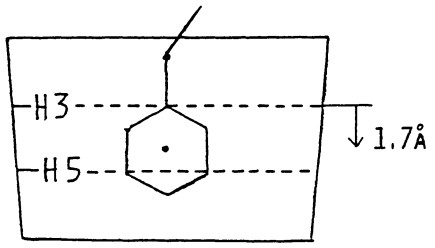

Fig. 4. Time-averaged conformation of the inclusion complex of APM with β-CD in an aqueous solution.

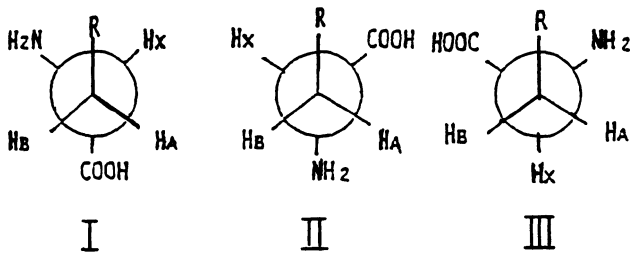
Table 1. Vicinal Coupling Constants (Hz) and Rotamer Fractional Populations for APM at pH 5.2

		Free	Complex
	J_{AX}	4.6	6.6
	J_{BX}	8.7	7.2
Asp	PI	0.56	0.43
	PII	0.19	0.36
	PIII	0.25	0.21
	J_{AX}	5.6	8.0
	J_{BX}	9.0	7.8
Phe	PI	0.59	0.47
	PII	0.27	0.49
	PIII	0.14	0.04



I II III

$$PI = (J_{BX}-J_g)/(J_t-J_g),$$

$$PII = (J_{AX}-J_g)/(J_t-J_g),$$

$$PIII = 1 - PI - PII,$$

where J_t=13.6 Hz, J_g=2.56 Hz.[12] The coupling constants and therefore the fractional population of the rotamer change on forming the inclusion with β-CD. In Table 2 are compared the three coupling constants $^1J15_{NH}$, $^3J15_{NCCH}$, and $^3J_H15_{NCH}$ of Asp-Phe(^{15}N)-OMe in the free and complexed state to indicate the effect of the backbone dihedral angles. The three coupling constants do not change on the complex formation. It suggests that the backbone dihedral angles of APM do not vary in the complex. Table 2 also shows the chemical shifts of amide proton and amide nitrogen of Asp-Phe(^{15}N)-OMe in the free and complexed states in H_2O. The low-field shifts in the complex formation were observed suggesting that the amide part of APM is hydrogen-bonded to the C2 or C3 hydroxyl group of β-CD in the complex.

Discussion

A number of papers on the investigation of the host/CD interaction by NMR examination have been published.[2-10] Komiyama and Hirai estimated time-averaged position of phenol derivatives in the cavity of β-CD in aqueous solution with the Johnson-Bovey equation.[8] The estimated distance between the center of the aromatic ring of phenol and the plane containing the seven H-3 atoms of β-CD is 1.8 Å. The value is very close to the present result of 1.7 Å. A number of papers about the association constants of guest molecules with β-CD with ^{1}H and ^{13}C NMR[2-7] are published. The reported values range between 100 and 1000 and our result is within this range. The molecular size of the guest molecules examined in the past on complexation with β-CD is comparatively small. On the other hand the guest molecule now in question is a large-sized dipeptide and so we have the problem of the conformational change of the guest molecule on complexation with β-CD. ^{15}N labeling of the amide nitrogen is useful technique for the examination of the conformation of dipeptides. The study of the preferred conformation of APM in an aqueous solution by using the same method as that described in this paper was reported.[13] The torsional angles of ψ and ϕ, (Fig. 5) in the free state are −150° and −90°, respectively. The results differed from those by F. Lelj et al, which were derived from the potential energy calculations.[14] The present results (section c) suggest that the torsional angles ϕ, ψ, and ω of APM do not change on the complexation with β-CD. On the other hand the rotamer fractional populations of both Phe and Asp residues do change in the complex formation. Figure 6 shows the conformation of APM in the various states. The upper figure shows the preferred conformation in the free state and the middle one is the preferred conformation in the complex and the lower one is the least preferred conformation in the complex. The

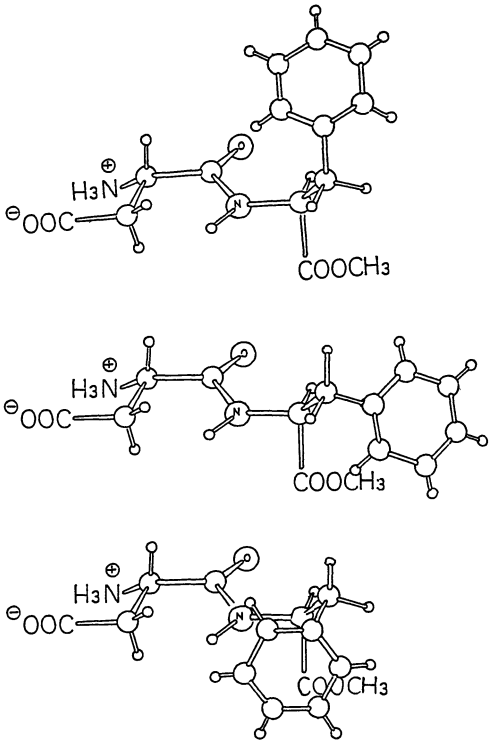

Fig. 6. The conformations of APM molucule in an aqueous solution, (upper) the preferred one in the free state (middle) the preferred one in the complexed state with β-CD (bottom) the least preferred one in the complexed state with β-CD.

preferred conformation in the complex is seen to be rod like and is suitable for the inclusion in the cavity of β-CD. The stereo model of this conformer based on Fig. 6 shows that the amide part of APM is so close to the C2 or C3 hydroxyl group that the hydrogen bonding is possible between them. The least preferred conformer in the complex formation is also reasonable because the phenyl ring is so close to the backbone of APM in this conformer that APM can not be included within β-CD.

In conclusion

(1) The phenyl ring of APM is included with β-CD with the association constant K_a=90 in an aqueous solution.

(2) The estimated distance between the center of the phenyl ring of APM and the plane containing seven H-3 of β-CD is 1.7 Å.

(3) The backbone conformation of APM is not varied in the complexed formation with β-CD.

(4) The side chain of APM is changed to the extented conformation in the complexed formation with β-CD.

Photochemical Reactions of Aromatic Compounds. XLII.[1] Photosensitized Reactions of Some Selected Diarylcyclobutanes by Aromatic Nitriles and Chloranil. Implications of Charge-Transfer Contributions on Exciplex Reactivities

Chyongjin PAC,* Tomohito OHTSUKI, Yozo SHIOTA, Shozo YANAGIDA, and Hiroshi SAKURAI
Department of Chemical Process Engineering, Faculty of Engineering, Osaka University, Suita, Osaka 565
(Received December 9, 1985)

Photosensitized reactions of *cis*- and *trans*-1,2-diphenylcyclobutane and *cis-transoid-cis*-cyclobuta[1,2-*a*:4,3-*a'*]diindene by 1-cyanonaphthalene, 9,10-dicyanoanthrancene, 1,4-dicyanonaphthalene, and chloranil, which mainly give the ring-splitting product (styrene or indene), have been investigated to explore steric and electronic requirements of the reactions associated with charge-transfer and excitation-resonance contributions of exciplex intermediates. The reaction efficiencies increase with an increase in the electron-accepting power of the sensitizers irrespective of the spin states. The formation of 1-phenyltetralin in the photosensitized reactions of the diphenylcyclobutanes occurs from the polar singlet exciplex with the dicyanoarenes but not at all from the less polar exciplex with 1-cyanonaphthalene nor from the triplet chloranil exciplex of high charge-transfer nature. Exciplex reactivities are discussed in terms of roles of charge-transfer contributions in exciplex decay channels as well as in terms of configurational and conformational effects on orbital interactions in the cyclobutanes.

Splitting of the cyclobutane ring is a typical prototype for theoretical predictions of chemical reaction courses.[2] More importantly this reaction can provide an excellent probe to explore chemical and dynamic behaviors of reactive states and/or intermediates as well as to manifest steric and electronic factors operating reaction courses.[1,3-12] Recently we reported the redox-photosensitized ring-splitting reactions of some diarylcyclobutanes,[7a-c] a novel type of photosensitization that is initiated by photochemical electron transfer from an aromatic hydrocarbon (ArH) to an electron acceptor, typically *p*-dicyanobenzene (DCNB).[7a-c,13] A key mechanistic pathway is the formation of a π complex between a cyclobutane (CB) and the cation radical of ArH, by which a positive charge is populated on CB to effect the cleavage of the cyclobutane ring in cases where the both ends of a ring sigma bond bear π or *n*-electron systems as substituents.

$$\mathrm{ArH + DCNB} \xrightarrow{h\nu} {}^1\mathrm{ArH^*ArH^* + DCNB} \longrightarrow \mathrm{ArH^{+\cdot} + DCNB^{-\cdot}}$$

$$\mathrm{ArH^{+\cdot} + CB} \longrightarrow \mathrm{[ArH \cdot CB]^{+\cdot}} \longrightarrow \mathrm{ArH^{+\cdot} + Products}$$

Likewise the population of a positive charge on CB can be achieved by the exciplex formation with an electron-accepting molecule, thus resulting in a ring-splitting reaction of CB depending on charge-transfer (CT) contributions.[7d,8c] Since exciplexes are electronically excited species unlike the π complexes, however, chemical behaviors should be different between them. In other words exciplex decays are associated with exciplex reactivities that may be controlled by electronic properties of exciplexes, i.e., CT and excitation-resonance (ER) contributions, as has been discussed for the exciplex isomerization of quadricyclane to norbornadiene.[11-12a]

$$\mathrm{S + CB} \xrightarrow{h\nu} \mathrm{S^* + CB} \longrightarrow \mathrm{[S \cdot CB]^*} \longrightarrow \mathrm{S + Products}$$

(S=electron acceptors and CB=cyclobutanes.)

$$\mathrm{[S \cdot CB]^* \equiv S^*CB \longleftrightarrow S \cdot CB^* \longleftrightarrow S^-CB^+} \quad (1)$$

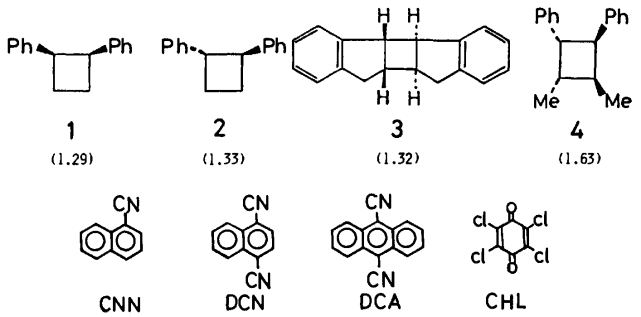

Fig. 1. Structures of the diarylcyclobutanes and the sensitizers. In parentheses are oxidation potentials of the cyclobutanes vs. Ag/Ag^+ in acetonitrile.

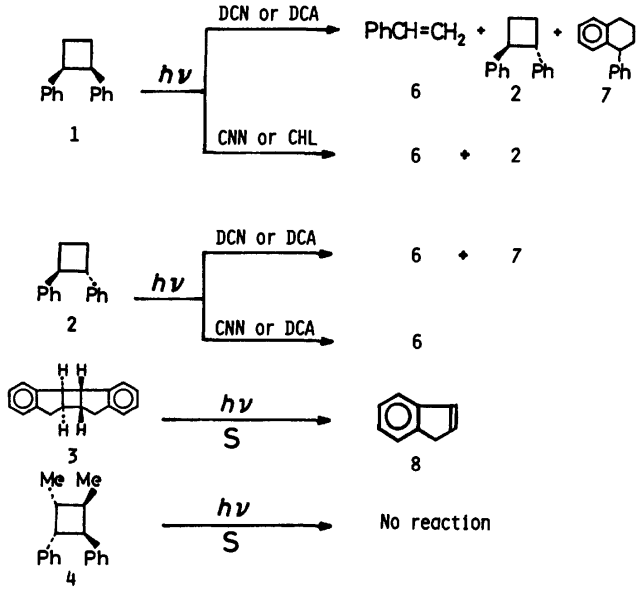
From this point of view, we attempted photosensitized reactions of some diarylcyclobutanes (CB; **1**—**4**) by 1-cyanonaphthalene (CNN), 1,4-dicyanonaphthalene (DCN), 9,10-dicyanoanthracene (DCA), and chloranil (CHL); these sensitizers (S) are typical electron acceptors which have different excitation energies (E^*) and reduction potentials in the ground and excited states ($E_{1/2}^{red}$ and E_{red}^*) (Table 1). Figure 1 shows the structures of S and CB together with the observed

oxidation potentials of CB. Major aims of the present investigation are focussed on (1) relative importance of CT and ER contributions of putative exciplex intermediates in bond-cleavage reactions of CB, (2) spin effects on the photoreactions, and (3) relationships of reactivities with structures of CB in the exciplex chemistry.

Results

Photoproducts. Photoreactions were carried out by irradiation of benzene solution at 313 nm for the CNN and DCN runs or at 366 nm for the DCA and CHL runs, and the progress of the photoreactions was followed by gas chromatography. The photoproducts are shown in Scheme 1.



Scheme 1.

Styrene (**6**) was mainly formed by the photosensitized reactions of either **1** or **2**. All the photosensitizers (S) commonly effected the photoisomerization of **1** to **2** but not at all the reverse isomerization, whereas the rearrangement of either **1** or **2** to 1-phenyltetralin (**7**) occurred with DCN or DCA but not at all with CNN or CHL. In the case of **3**, all the sensitizers effected the ring-splitting reaction to give indene (**8**) as the sole product. At low conversions (<10%), material balances were better than 90% without any consumption of the sensitizers, though other unreclaimed reactions increasingly occurred at higher conversions. Interestingly, **4** remained virtually unchanged even upon extensive irradiation in the presence of any of the sensitizers, a puzzling observation that is hardly expected from the configurational similarity to **2** and **3**.

Quantum Yields. Limiting quantum yields that are significant for discussions of exciplex reactivities were determined for the olefin formation from **1** or **3** by usual double-reciprocal plots of quantum yield vs. concentration of CB (Fig. 2) in the case of CHL and in cases where fluorescence quenching is inefficient (vide infra). Such plots were not taken for the formation of **2** and **7** from **1** as well as for the photosensitized reactions of **2** because of poor reproducibilities of data, particularly at low concentrations of CB due to low quantum efficiencies. In the case of the DCN-**1** or **3** pair, the observed quantum yield at [**1**] or [**3**]= 0.3 M† was used in place of the limiting quantum yield, since the fluorescence quenching was complete at [CB]≥0.2 M. Table 2 lists the intercepts (I) and the intercept-to-slope ratios (I/S) of the plots in Fig. 2 together with the limiting quantum yields for the olefin formation (ϕ_{ol}^{∞}). In Table 3 are shown the observed quantum yields of the products in the photosensitized reactions of **1** at [**1**]=0.3 M.

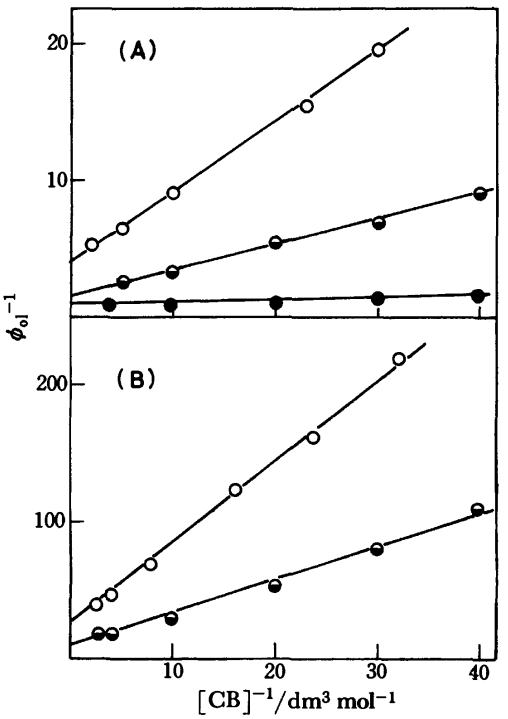


Fig. 2. Double-reciprocal plots of quantum yield for the olefin formation vs. concentration of CB: (A) CNN-**3** (—○—), DCA-**3** (—◒—), and CHL-**1** (—●—) pairs; (B) CNN-**1** (—○—) and DCA-**1** (—◒—) pairs.

Fluorescence Quenching. The fluorescence of the aromatic nitriles was quenched by CB following linear Stern-Volmer relationships. Table 2 includes the Stern-Volmer constants (K_{SV}) and the fluorescence-quenching rate constants (k_e) calculated from K_{SV} and the fluorescence lifetimes (τ). It is of mechanistic significance to note that the quenching of the CNN fluorescence by either **1** or **2** is accompanied by the appearance of weak exciplex emission at longer wavelength as is shown in Fig. 3A. A very weak exciplex

emission was also detected in the case of the DCA-1 pair. Interestingly, the quenching of the DCN fluorescence by the unreactive cyclobutane, 4, was accompanied by a relatively strong exciplex emission (Fig. 3B), though no exciplex emission was detected in the quenching of the DCN fluorescence by the reactive cyclobutanes. Moreover, it should be noted that the fluorescence quenching by 3 revealed no exciplex emission at all in any case.

Discussion

Mechanism. It is no doubt that the photosensitization by the aromatic nitriles proceeds via the excited-singlet state, since the fluorescence of DCN is quenched by either 1 or 3 near a diffusion-controlled limit and since the intercept-to-slope ratios obtained from quantum-yield measurements for the CNN and DCA-1 or 3 pairs show reasonable agreements with the K_{SV} values for the fluorescence quenching. Moreover, the appearance of exciplex emissions strongly suggests that singlet exciplexes are involved as the intermediates of the photoreactions. In this regard, it should be noted that relatively strong exciplex emissions were detected with the unreactive DCN-4 pair and also with the least reactive CNN-1 pair, whereas the more reactive DCA-1 pair shows a much weaker exciplex emission. In contrast, no exciplex emission was detected at all with the very reactive DCN-1 pair as well as in the fluorescence quenching by 3 which is more reactive than 1. These opposite behaviors be-

tween exciplex-emission efficiencies and reactivities suggest that the chemical reaction of CB occurs as a nonradiative decay of the sensitizer-CB exciplexes in competition with the emission pathway.

On the basis of these arguments, essential mechanistic pathways for the photosensitized reactions of CB by the aromatic nitriles are shown in Scheme 2. A usual kinetic treatment gives Eqs. 2—4.

$$S \xrightarrow{h\nu} {}^1S^*$$

$${}^1S^* \xrightarrow{\tau^{-1}} S$$

$${}^1S^* + CB \xrightarrow{k_e} {}^1[S\cdot CB]^*$$

$${}^1[S\cdot CB]^* \xrightarrow[(CB=1)]{k_1} S + \mathbf{2} + \mathbf{7}$$

$${}^1[S\cdot CB]^* \xrightarrow{k_f} S + CB + h\nu'$$

$${}^1[S\cdot CB]^* \xrightarrow{k_d} S + CB$$

(S = CNN, DCA, and DCN.)

Scheme 2.

$$\frac{1}{\phi_{o1}} = \frac{1}{\phi_{o1}^{\infty}}\left(1+\frac{1}{k_e\tau[CB]}\right) \tag{2}$$

$$\phi_{o1}^{\infty} = \frac{2k_{o1}}{k_{o1}+k_1+k_d+k_f} \tag{3}$$

$$I_F^0/I_F = 1 + K_{SV}[CB] = 1 + k_e\tau[CB] \tag{4}$$

On the other hand, a triplet mechanism should operate in the CHL-photosensitized reaction of **1**, since the intersystem crossing of excited-singlet CHL to the triplet is extremely fast ($>10^{10}\,s^{-1}$).[14] However, classical excitation transfer from triplet CHL to **1** is unlikely to occur, since no photoreaction of **1** was effected at all by the photosensitization using acetophenone which has a much higher triplet energy (309 kJ mol^{-1})[15] than CHL (261 kJ mol^{-1}).[16] Consequently, a triplet exciplex mechanism seems to be a reasonable choice. The high reduction potential of triplet CHL may give a benefit to the formation of an exciplex. Scheme 3 shows a possible mechanism for the CHL-photosensitized reaction of **1**, which is very similar to Scheme 2 except for the spin state.

$$CHL \xrightarrow{h\nu} {}^1CHL^* \xrightarrow{>10^{10}\,s^{-1}} {}^3CHL^*$$

$${}^3CHL^* \xrightarrow{\tau_T^{-1}} CHL$$

$${}^3CHL^* + \mathbf{1} \xrightarrow{k_e} {}^3[CHL\cdot\mathbf{1}]^*$$

$${}^3[CHL\cdot\mathbf{1}]^* \xrightarrow{k_{o1}} CHL + 2\ \mathbf{6}$$

$${}^3[CHL\cdot\mathbf{1}]^* \xrightarrow{k_1} CHL + \mathbf{2}$$

$${}^3[CHL\cdot\mathbf{1}]^* \xrightarrow{k_d} CHL + \mathbf{1}$$

Scheme 3.

$$\frac{1}{\phi_{o1}} = \frac{1}{\phi_{o1}^{\infty}}\left(1+\frac{1}{k_e\tau_T[CB]}\right) \tag{5}$$

$$\phi_{o1}^{\infty} = \frac{2k_{o1}}{k_{o1}+k_1+k_d} \tag{6}$$

Electronic Properties and Reactivities of Exciplexes. Electronic properties of exciplexes are approximately described by Eq. 1, in which CT and ER contributions can be qualitatively estimated by E_{red}^* and E^* respectively. Since the excitation energies of excited-singlet CB are commonly ≈440 kJ mol^{-1} (105 kcal mol^{-1} (1 cal=4.184 J)) as determined by the fluorescence spectra,[17] differences of excited-singlet excitation energy between CB and S are ≈66 kJ mol^{-1} for the CNN–CB pairs, ≈100 kJ mol^{-1} for the DCN–CB pairs, and ≈160 kJ mol^{-1} for the DCA–CB pairs. Since the energy differences for the DCA–CB pairs are too large to allow significant ER, the binding origin of the DCA exciplexes should exclusively come from CT contributions. For the DCN exciplexes, CT contributions are certainly dominant because of the high E_{red}^* value of DCN, whereas the CNN exciplexes have higher ER contributions but less CT contributions compared with the other exciplexes. Although the CHL-**1** exciplex appears to be of dominant CT nature, a significant ER contribution might be indicated by a relatively small energy difference between the triplets of CHL and **1** (37—62 kJ mol^{-1}).[18]

As shown in Tables 2 and 3, the quantum yields strongly depend on E_{red}^* but not significantly on E^*, thus demonstrating that reactivities of the exciplexes are mainly controlled by CT contributions irrespective of the spin states. Moreover, the formation of **7** occurs from the more polar exciplexes of DCN and DCA but not at all from the CNN exciplex of a less CT contribution. Interestingly, **7** is not formed again from the triplet CHL-**1** exciplex of polar nature. Presumably, the rearrangement to **7** would proceed via a very polar state on singlet hypersurface in a way different from the decay pathways for the formation of **6** and **2**, while no decay channel for the formation of **7** is available in the triplet state.

Comparisons of the exciplex chemistry with other types of photoreactions of CB may be diagnostic for discussing decay channels of the exciplexes which should depend on CT contributions. The redox-photosensitized reaction of **1** gives only **7** without any formation of **6** and **2**,[19] revealing behaviors different from the exciplex chemistry. This difference appears to reflect different reaction surfaces since key chemical events in the former reaction occur in the ground state. On the other hand, the ratios of ϕ_6 to ϕ_2 in the photosensitized reactions of **1** by the aromatic nitriles are similar to that of the direct photolysis (7.2)[18b] but still higher than those of the acetone-photosensitized reaction (2.6) and the thermal reaction (2.0).[18b] It is

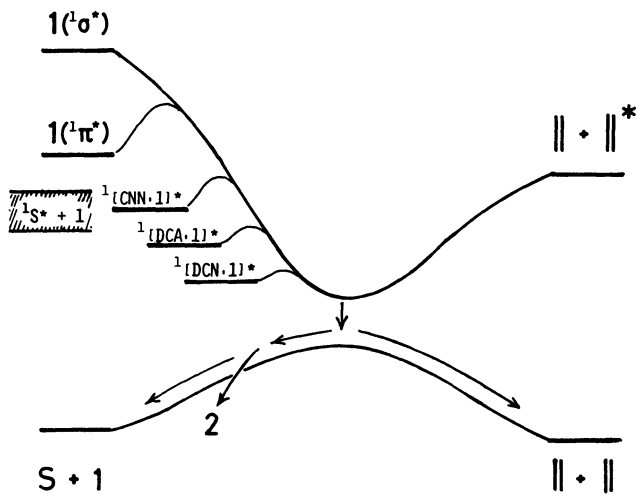

Fig. 4. A schematic potential hypersurface diagram for singlet photochemistry of **1**.

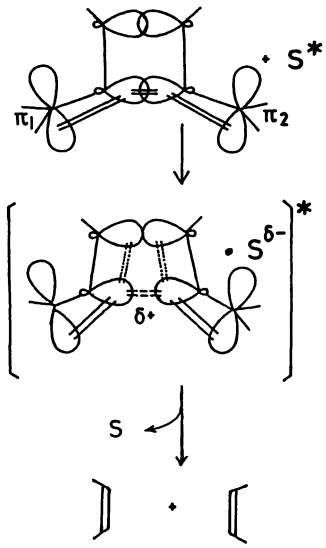
therefore suggested that the singlet exciplexes cross to the reaction surface involved in the direct photolysis to reach a common pericyclic minimum.

Figure 4 shows hypothetical reaction hypersurfaces for the singlet photochemistry of **1**, which are qualitatively illustrated on the basis of the Michl's prediction concerning [2+2] cycloaddition and cycloreversion.[20] The exciplex formation should lead to the population of a positive charge on **1** by CT contributions. As is shown in Scheme 4, this positive



Scheme 4.

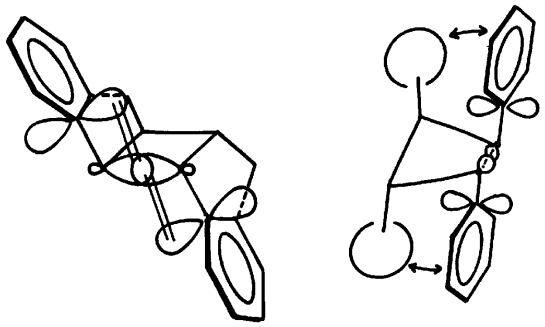
charge on CB is delocalized mostly on the π_1–C–C–π_2 orbital array since the π_1 and π_2-electron systems interact with each other through the ring C–C sigma orbitals.[7,21] This means that the ring sigma bond should be weakened by a decrease of electron density depending on CT contributions. As a result, an exciplex state of higher CT nature might be located closer to the reaction surface, and activation barriers for the crossing to the reaction surface would be decreased with an increase of CT contributions.

On the other hand, it is of interest to note that the direct photoexcitation of **1** is much less effective to cause the reaction than the exciplex formation; $\phi_6+\phi_2\cong0.02$ in the direct photolysis.[18b] Since the UV-absorption and fluorescence spectra of **1** and the other cyclobutanes are essentially identical with those of simple alkylbenzenes,[17] the electronic excitation of **1** in the spectroscopic state is almost localized on the isolated π-electron chromophore. In other words, little perturbation of the ring C–C bond might occur in the spectroscopic state, thus implying that crossing to the reaction surface perhaps requires a high activation barrier because of the extremely high σ^* level compared with the π^* level. This may also give a rationale to interpret minor roles of ER contributions in the exciplex chemistry.

On the other hand, the decay channels of the triplet CHL-**1** exciplex can not be straightforwardly interpreted, since the ϕ_6/ϕ_2 value is substantially greater than that of the acetone-photosensitized reaction and since **7** is not formed regardless of the polar nature of the exciplex. Although the triplet exciplex can efficiently go into reactive states, the decay pathways are not the same as those of the triplet state of **1**. A plausible interpretation is that the triplet exciplex would competitively cross to both singlet and triplet reaction surfaces. The former crossing requires a prior spin flip, which may be facilitated by high CT interactions[22] and/or by a considerable distortion of the cyclobutane ring in the exciplex state.[23]

Relationships of Exciplex Reactivities with Structures of CB. In previous papers,[7a–c] we demonstrated that through-bond interactions between vicinally substituted π or n-electron systems are essential to determine reactivities of cyclobutanes in the redox-photosensitized ring-splitting reactions. For example, **3** is very reactive because of the head-to-head structure favorable for efficient through-bond interactions, while no photosensitized reaction occurs at all with the head-to-tail isomer of **3** for which such interactions are configurationally forbidden. Interestingly, however, the complete lack of any reaction of **4** in the exciplex chemistry would apparently disagree with this concept, since this cyclobutane has a head-to-head structure. Actually, the methyl substituents sterically inhibit the phenyl groups from taking conformations favorable for through-bond interactions.[21] In other words, through-bond interactions are conformationally disallowed, a conclusion supported by the oxidation potential of **4** (1.63 V) which is considerably higher than those of the reactive cyclobutanes. Therefore, the through-bond-interaction concept is valid to interpret reactivities of CB in the exciplex chemistry as well.

Another significant feature in structure-reactivity relationships is that **3** is much more reactive than **1** and **2**, though they have similar oxidation potentials and fluorescence-quenching capabilities. Apparently,



this difference arises from the rigid tricyclic structure of **3** compared with the more flexible monocyclic structure of **1** and **2**, since free rotation around the C–Ph bond is certainly unfavorable for through-bond interactions. Moreover, conformational rigidity of **3** is again favorable for orbital interactions between the Cl(C2) and C4(C3) sigma orbitals which are required for splitting of the cyclobutane ring to occur. In cases of **1** and **2**, on the other hand, the cyclobutane ring may be distorted unfavorably for such orbital interactions as the C1–C2 bond is elongated by the exciplex formation; the isomerization reactions of **1** and **2** perhaps occur as the consequences of ring distortion. As a result, the exciplexes of **3** can cross to the reaction surface with lower activation barriers than the exciplexes of **1** or **2** can do. This would also interpret why the CNN and DCA-**1** exciplexes can emit even in low efficiencies and why the exciplexes of **3** can not at all.

Conclusions

It is suggested that the photosensitized reactions of **1**—**3** proceed via the singlet exciplexes of the aromatic nitriles or the triplet CHL exciplex. CT contributions are essential to control the exciplex chemistry as the consequences of the population of a positive charge on the π_1–Clσ–C2σ–π_2 orbital array which weakens the ring C–C bond. It is speculated that such bond-weakening effects lower activation barriers for the crossing from the singlet-exciplex state to a reaction hypersurface involved in the direct photolysis, whereas the decay channels of the triplet chloranil exciplex are not the same as those of the triplet state of CB. On the other hand, a different pathway is indicated for the formation of **7** from the singlet exciplexes of **1** or **2**, involving a very polar state which is not realized from the triplet CHL exciplex.

The lack of any reaction of **4** by the exciplex formation is attributed to conformations unfavorable for through-bond interactions between the two π-electron systems. Higher reactivities of **3** compared with **1** and **2** are associated with the rigid tricyclic structure that facilitates orbital overlaps between the Cl(C2)–C4(C3) sigma orbitals in the progress of the reaction.

Experimental

Instruments. Gas chromatography was performed on a Shimadzu GC-7A gas chromatograph using a 2-m column of 25% PEG 20M on Shimalite NAW for analyses of **6** and **8** and a 2-m column of 2% OV-17 on Chromosorb W for analyses of **7** and the cyclobutanes. Oxidation and reduction potentials were determined by cyclic voltammetry vs. $Ag/AgNO_3$ in acetonitrile using tetraethylammonium tetrafluoroborate as the supporting electrolyte; the instrument and methods are the same as those reported previously.[7a] IR, UV, and ^1H NMR spectra were obtained on Hitachi 260-10, Hitachi 220-A, and JEOL JNM-PMX60 spectrometers, respectively. A Hitachi MPF-4 spectrofluorometer equipped with a data processor (612-0085) was used for fluorescence measurements; all the fluorescence spectra were recorded after the correction of spectral responses of the instrument.

Materials. Commercial 1-cyanonaphthalene (Tokyo Kasei) was thoroughly purified by the method described in a previous paper.[24] Both chloranil and 9,10-dicyanoanthracene (Tokyo Kasei) were purified by repeated recrystallization from benzene followed by vacuum sublimation. 1,4-Dicyanonaphthalene was prepared according to the literature method[25] and was purified by repeated recrystallization from benzene followed by vacuum sublimation. The indene dimer (**3**)[26] and the diphenylcyclobutanes (**1** and **2**)[27] were prepared according to the literature methods. The purification of **1** and **3** was performed by repeated recrystallization from methanol.

***r*-1,*t*-2-Dimethyl-*t*-3,*c*-4-diphenylcyclobutane (4).** Dimethyl *t*-3,*c*-4-diphenyl-*r*-1,*t*-2-cyclobutanedicarboxylate (dimethyl μ-truxinate), which had been prepared by the photoaddition of dimethyl fumarate to *trans*-stilbene,[28] was reduced by an excess of $LiAlH_4$ in tetrahydrofuran to give *r*-1,*t*-2-bis(hydroxymethyl)-*t*-3,*c*-4-diphenylcyclobutane (mp 130—132 °C from a benzene–hexane mixture); ^1H NMR δ=1.6 (t, 2H, OH×2), 2.6 (m, 2H, H-1 and H-2), 3.5 (d-d, 4H, CH_2×2), 4.2 (m, 2H, H-3 and H-4), 8.2 (m, 10H, C_6H_5×2). This dialcohol was converted to the ditosylate, which was then reduced by an excess of $LiAlH_4$ in tetrahydrofuran to give the dimethyldiphenylcyclobutane in a 60% yield based on the truxinate (bp 108—110°C/0.15 Torr†); ^1H NMR δ=0.9 (d, 6H, CH_3×2), 2.3 (m, 2H, H-1 and H-2), 4.1 (m, 2H, H-3 and H-4), 7.2 (m, 10H, C_6H_5×2).

Found: C, 91.14; H, 8.63%. Calcd for $C_{18}H_{20}$: C, 91.47; H, 8.53%.

Photoreactions and Determination of Quantum Yields. Photoirradiation was carried out with an Eikosha PIH-300 high-pressure Hg lamp under cooling with water using appropriate light filters and a "merry-go-round" turntable. A pottassium chromate solution (0.2 g dm^{-3}, 10-mm path length) was used to isolate the 313-nm light, whereas the 366-nm light was obtained by the passage through an uranyl glass and a solution (10-mm path length) obtained by the dissolution of $CoCl_2 \cdot 6H_2O$ (45.2 g), $NiCl_2 \cdot 6H_2O$ (22.7 g), and a concentrated hydrochloric acid (15 cm^3) in a mixture of ethanol (52.5 cm^3), acetone (37.5 cm^3), and water (60 cm^3).[29] A 2-hexanone actinometer[30] and a benzophenone–benzhydrol actinometer[31] were used for the determination of quan-

† 1 Torr≈133.322 Pa.

tum yields at 313 nm for the CNN and DCN-photosensitized reactions and at 366 nm for the DCA and CHL runs respectively. Concentrations of the aromatic nitriles and CHL were set in 5×10^{-4}—10^{-3} M and $\approx10^{-2}$ M, respectively, which were confirmed to be high enough for the complete absorption of the incident light under photoreaction conditions. Pyrex tubes (8 mm i.d.) were used as the common vessels for the photoreactions and for the actinometry. Benzene solutions of the reactants (3 cm^3) and actinometer solutions (3 cm^3) were irradiated, and the progress of the photoreactions was followed by gas chromatography.

Molecular Motions in Plastic Phase of 2-Methyl-2-nitropropane, $(CH_3)_3CNO_2$, by Pressure and Temperature Dependences of ^1H-NMR Spin-Lattice Relaxation

Tooru HASEBE* and Hideaki CHIHARA†
Department of Chemistry, Faculty of Education, Fukushima University, Matsukawa-machi, Fukushima 960-12
†Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received November 15, 1985)

Proton NMR spin-lattice relaxation time, T_1, in the plastic phase of 2-methyl-2-nitropropane $(CH_3)_3CNO_2$ was measured at 10 MHz up to 150 MPa between 262 and 320 K. The overall molecular reorientation with an activation enthalpy of ΔH^*_r=6.8±1.0 kJ mol^{-1} and an activation volume of ΔV^*_r= (0.07±0.02)V_m did not show significant pressure dependence up to 140 MPa, where V_m is the molar volume of $(CH_3)_3CNO_2$ at 273.2 K. The self-diffusion, which was treated by the Torrey's isotropic diffusion model, showed large pressure dependence; the activation enthalpy, ΔH^*_d, changed from 46±4 kJ mol^{-1} under saturated vapor pressure of the sample to 95±8 kJ mol^{-1} under 100 MPa and the activation volume, ΔV^*_d, changed from V_m at 278.0 K to 0.8V_m at 320.0 K. These results strongly suggest monovacancy mechanism for self-diffusion. The phase diagram of liquid-plastic and plastic-brittle phase transitions is also given.

The study of NMR spin-lattice relaxation time, T_1, brings us valuable information of structure and dynamics of molecules. The method is particularly useful in plastic crystals for studying both reorientational and translational molecular motions. Solids, of which the constituent molecules have a globular shape, generally form a plastic crystalline phase before melting. The plastic phase, in which the motion of overall molecular reorientation is already excited, has a cubic or hexagonal close-packed structure in a majority of cases and is mainly characterized by a low entropy of fusion ($\Delta S \lesssim 20$ J K^{-1} mol^{-1}). 2-Methyl-2-nitropropane is one of such globular molecules, but its plastic phase belongs to the orthorhombic system (a=0.612 nm, b=0.617 nm, and c=0.879 nm, $a \cong b \cong c/\sqrt{2}$) with two molecules in the unit cell.[1] This phase exists between 260.1 K and the melting point (299.2 K) with the entropy of fusion, 8.66 J K^{-1} mol^{-1}.

The molecular motions in this phase have been studied by a number of experimental methods. Dielectric relaxation study reported the potential barrier hindering rotation of the molecular electric dipole (3.77 D* at 299 K)[2] as 6.78±0.84 kJ mol^{-1} [3] and its correlation time (from 8.7×10^{-12} s at the melting point to $\approx 5\times10^{-12}$ s near the transition point).[4] On the other hand, far infrared absorption study[5] reported that the residence time of a librator in the potential well was 10×10^{-12} s at 294 K.

Recently we reported the NMR study[6] of molecular motions in solid $(CH_3)_3CNO_2$. In our previous study[6] we obtained the values of the activation parameters, E_a=46.5±0.9 kJ mol^{-1} and $\tau_0=(4.6\pm1.8)\times10^{-15}$ s for self-diffusion and the mean jump time (6×10^{-7} s) of the molecule at the melting point; however, we did not get enough information on the molecular reorientation and mechanism of self-diffusion in the plastic phase.

To get such information we measured temperature- and pressure-dependence of spin-lattice relaxation time in the plastic phase. In this paper we report on the molecular motions and their roles in the spin-lattice relaxation in the plastic phase, and on the phase diagram of 2-methyl-2-nitropropane.

*1D=3.33×10^{-30} C m.

Experimental

2-Methyl-2-nitropropane (Aldrich Chemicals Co., Inc.) was purified by a preparative gas chromatograph. The purity of this specimen was estimated to be higher than 99.87 mol per cent by a gas chromatographic analysis. Furthermore the specimen was subjucted to dehydration using Molecular Sieve 4A, vacuum distillation, and degassing by the conventional freeze-pump-thaw technique and then transferred into the NMR pressure vessel via a specially designed adapter which was already reported.[7]

Proton spin-lattice relaxation time was measured using $(\pi/2)_{satn}$-τ-$\pi/2$ pulse sequences with an operating frequency of 10.0 MHz. The working pressure and temperature ranges over which T_1 was measured were between the saturated vapor pressure of the sample and 150 MPa and between 262.0 K and 320.0 K, respectively. The pressure was measured with a manganin gauge.[7] The uncertainty of the pressure value in the present study was estimated to be within 1.4 MPa. The temperature was controlled to within 0.1 K and measured with a Chromel-P/Constantan thermocouple attached to the NMR pressure vessel.

Results and Discussion

Molecular Motions. The results of experimental determination of T_1 under various pressures are given in Fig. 1. The upper and lower bounds of the existence of the plastic phase of 2-methyl-2-nitropropane are indicated by vertical dotted lines. The T_1 curves in Fig. 1 do not directly correspond to the results of a continuous run under a given pressure, except the one at the saturated vapor pressure of the sample, because the pressure inside the vessel changed when the temperature of the sample changed. Therefore, the primary results were rearranged to show the temperature dependence of T_1 under a constant pressure

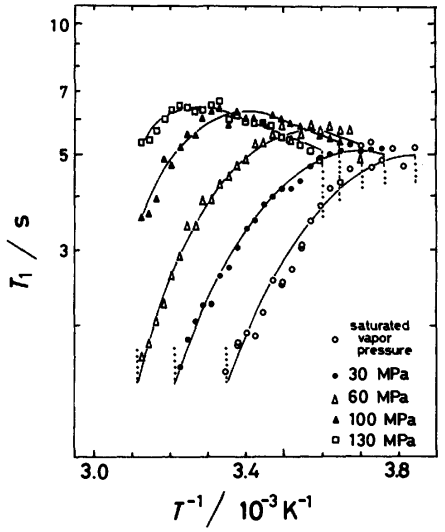

Fig. 1. Temperature dependence of T_1 under various pressures in plastic 2-methyl-2-nitropropane. The upper and lower bounds of the existence of the plastic phase of $(CH_3)_3CNO_2$ are indicated by vertical dotted lines.

in Fig. 1.

It is seen from Fig. 1 that the T_1 at a constant pressure of larger than 60 MPa has a maximum; it indicates that a change occurs in the molecular motion that is responsible for the relaxation on either side of the maximum. It is interpreted to be a change from overall molecular reorientation to translational self-diffusion as reported in our previous NMR study.[6] When such two different relaxation mechanisms contribute to the observed T_1 and if we can treat the motions independently, the relaxation rate, $T_1(\text{obsd})^{-1}$, can be expressed by the sum of the two relaxation rates as follows:

$$T_1(\text{obsd})^{-1} = T_{1r}^{-1} + T_{1d}^{-1}, \tag{1}$$

where the subscripts, r and d, denote overall molecular reorientation and molecular translational self-diffusion, respectively. At this stage it is necessary to separate T_{1r} and T_{1d} from $T_1(\text{obsd})$. Here the value of T_{1r} may be estimated by extrapolating from the T_1 data at 130 MPa from the low temperature side of the maximum, since the pressure dependence of the temperature coefficient of T_1 on the lower temperature side of the T_1 maximum was not large at pressure values below 140 MPa. The T_{1r} is related to the correlation time τ_r associated with overall molecular reorientation as follows:

$$T_{1r}^{-1} \propto \tau_r \ (\omega\tau_r \ll 1). \tag{2}$$

On the other hand, the T_{1d} (in this case, $\omega\tau_d \gg 1$) is given by Torrey's isotropic diffusion model[8,9] as follows:

$$T_{1d}^{-1} = 2.67\,\gamma^2 \langle \Delta M_2 \rangle / (\omega^2 \tau_d), \tag{3}$$

where γ is the gyromagnetic ratio of proton, $\langle \Delta M_2 \rangle$ is the part of the second moment (in Gauss unit**) that is modulated by translational self-diffusion, and τ_d is the mean diffusional jump time of molecules. Boden et al.[10] reported that Torrey's isotropic diffusion model was a good model especially for organic plastic crystals with a low value of the entropy of fusion; the entropy of fusion of $(CH_3)_3CNO_2$ is only 8.66 J K^{-1} mol^{-1}.[11]

For thermally activated motions, the correlation time τ should obey the relation of Arrhenius type,

$$\tau = \tau_0 \exp(\Delta G^*/RT), \tag{4}$$

where ΔG^*, the Gibbs energy of activation, is defined by

$$\Delta G^* = \Delta H^* - T\Delta S^*. \tag{5}$$

According to thermodynamics, the activation volume is defined by

$$\Delta V^* = (\partial \Delta G^*/\partial P)_T, \tag{6}$$

so that, if one assumes that the pressure dependence of τ_0 is negligible,[11] the values of τ derived by fitting the experimental data to Eqs. 2 and 3 may be used to obtain ΔV^* and ΔH^* through the relation,

$$\Delta V^* = RT(\partial \ln \tau/\partial P)_T, \tag{7}$$

and

$$\Delta H^* = R\{\partial \ln \tau/\partial(1/T)\}_P. \tag{8}$$

The volume of the plastic phase decreased linearly with increasing pressure up to ≈73 MPa at 291 K, and it was described by a constant isothermal compressibility $(7.1\pm0.8)\times10^{-4}$ MPa^{-1}, which was determined from the distance of the piston plunger traveled into the pressure vessel upon compression.

When one attempts to calculate the value of τ_d under various pressures using Eq. 3, one should consider a change of $\langle \Delta M_2 \rangle$ by the pressure. Because the second moment $\langle \Delta M_2 \rangle$ is inversely proportional to the square of the volume of the unit cell, one expects the value of $\langle \Delta M_2 \rangle$ to increase with increasing pressure. This would be the case only if the effect of pressure is such as to decrease the intermolecular distance rather than to decrease the number of vacancies that exist in plastic crystals, e.g. in solid argon and krypton[12] or even in solid chlorine.[13] Actually, as is seen from Fig. 1, the T_{1d} increases with pressure at a constant temperature, which fact, together with the large value of compressibility, suggests that the second moment is not significantly affected by the application of pressure. An approximate estimate indicates that the T_{1d} at 73 MPa would be 10% smaller than the T_{1d} under the

**1G=10^{-4} T.

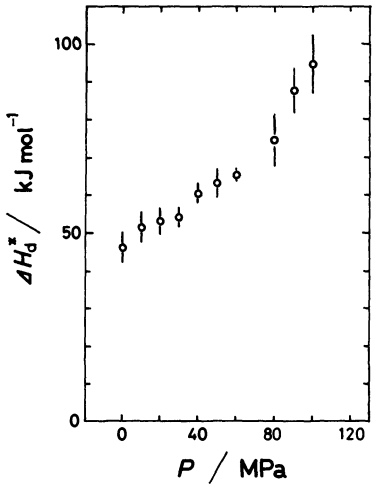

Fig. 2. Pressure dependence of activation enthalpy, ΔH_d^*, for the molecular self-diffusion in plastic $(CH_3)_3CNO_2$.

saturated vapor pressure if the pressure compressed the intermolecular distance. We now use the value of $\langle \Delta M_2 \rangle = 1.0\,G^2$ ($0.01\,mT^2$) calculated from $T_{1\rho}$ minimum value[6] under saturated vapor pressure of the sample, in calculating τ_d using T_1 data and Eq. 3.

The activation enthalpy of self-diffusion (ΔH_d^*) obtained in this study shows remarkable pressure dependence from 46±4 kJ mol^{-1} under saturated vapor pressure to 95±8 kJ mol^{-1} under 100 MPa as shown in Fig. 2; These can be compared with the cases of 2,2,3,3-tetramethylbutane (from 70 kJ mol^{-1} to 90 kJ mol^{-1}) and hexamethyldisilane (from 40 kJ mol^{-1} to 50 kJ mol^{-1}) in the same pressure range. The value of ΔV_d^* decreased gradually from 101±35 cm^3 mol^{-1} at 278 K {this value of ΔV_d^* is equal to V_m (=101 cm^3 mol^{-1}) which is the molar volume at 273.2 K} to 77±6 cm^3 mol^{-1} ($\approx 0.8 V_m$) at 320.0 K with increasing temperature. This tendency is very similar to the case of plastic phases of 2,2,3,3-tetramethylbutane and hexamethyldisilane,[14] and thus these values of the activation volume strongly suggest the monovacancy mechanism for self-diffusion.[14] Figure 3 shows the calculated correlation time, τ_d, of the molecular self-diffusion at the melting point and at the plastic-brittle phase transition point under various pressures. In contranst to the behavior of the values of τ_d at the melting point, which is almost constant ($\approx 9\times10^{-7}$ s), the values at the plastic-brittle phase transition increase as the transition point moves to higher temperatures (from 1.5×10^{-5} s under the saturated vapor pressure to 2×10^{-4} s under 80 MPa). These results suggest that the self-diffusion is the direct trigger of the fusion phenomenon but it is not a direct trigger of the plastic-brittle phase transition.

On the other hand, the activation enthalpy for overall molecular reorientation, ΔH_r^*, was obtained to be 6.8±1.0 kJ mol^{-1} which did not show remarkable pressure dependence up to 140 MPa. The activation

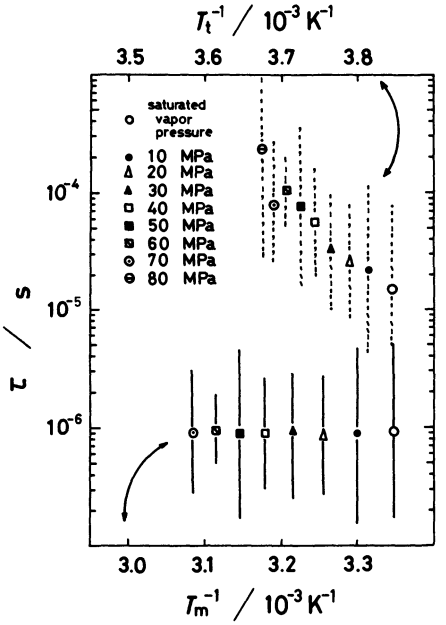

Fig. 3. The correlation time of molecular self-diffusion at the melting points (T_m) and the plastic-brittle phase transition points (T_t) under different pressures in $(CH_3)_3CNO_2$.

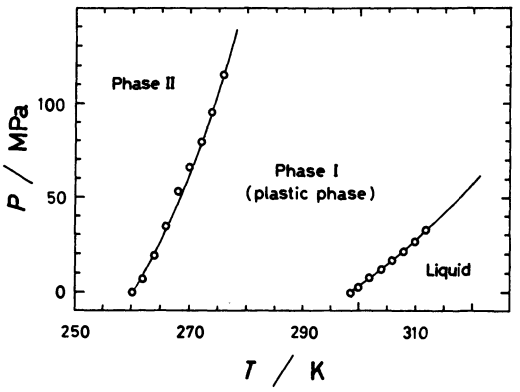

Fig. 4. Phase diagram of 2-methyl-2-nitropropane.

volume of the overall molecular reorientation, ΔV_r^*, increased slightly with increasing temperature from 7±2 cm^3 mol^{-1} at 274.0 K to 8±1 cm^3 mol^{-1} at 320.0 K. However, the ratio of ΔV_r^* to the molar volume V_m is expected to be a constant value of 0.07±0.02, because the value of V_m, which depends on the lattice spacing, would also be expected to increase with increasing temperature. The value of the ratio, 0.065, is in good agreement with results on overall molecular reorientation in other plastic crystals; in cases[7,11] of norbornane, cyclohexane, 2,2,3,3-tetramethylbutane, and 2-methylpropanoic acid, the ratios are 0.04, 0.07, 0.07—0.09, and 0.12, respectively.

Phase Diagram. The phase diagram is shown in Fig. 4, which was obtained by determining the temperature of phase changes from the jumps of the T_1 values. Figure 4 shows that the two curves become further separated as the pressure increases, and this

separation is more remarkable than in the case of $(CH_3)_3CCOOH$.[7] The average slopes of the boundary curves are

$$\frac{dP}{dT} = 7.65 \text{ MPa K}^{-1} \text{ (on the plastic-brittle phase transition curve: } \Delta S = 17.9 \text{ J K}^{-1} \text{ mol}^{-1})$$
$$= 2.5 \text{ MPa K}^{-1} \text{ (on the melting curve: } \Delta S = 8.66 \text{ J K}^{-1} \text{ mol}^{-1}).$$

The average slope for the melting in $(CH_3)_3CNO_2$ is very similar to the slope (2.22 MPa K^{-1}) in $(CH_3)_3CCOOH$ but the slope for the plastic-brittle phase transition is about twice as large as that (3.26 MPa K^{-1}) of $(CH_3)_3CCOOH$. The volume changes at these transition points were calculated by the use of the Clapeyron-Clausius equation from the entropy changes; they were 2.34 $cm^3 mol^{-1}$ for the plastic-brittle phase transition and 3.46 $cm^3 mol^{-1}$ for the melting. It is interesting to note that an application of external pressure displaces the region of the existence of the plastic crystal phase to a higher and a wider temperature, and that the volume changes of $(CH_3)_3CNO_2$ and $(CH_3)_3CCOOH$ at their melting points are not so different from each other but their volume changes at the respective plastic-brittle phase transition points are very different. Different crystal conditions of the two brittle crystal phases are reflected in the latter difference of the volume change. By comparison of $(CH_3)_3CNO_2$ with $(CH_3)_3CCl$ and $(CH_3)_3CBr$, it is also interesting to note that the temperature region (ΔT) of existence of their plastic phase relates to the entropy of fusion, i.e. ΔT=24.7 K and ΔS_m=7.53 J K^{-1} mol^{-1} for $(CH_3)_3CBr$, ΔT=29.0 K and ΔS_m=7.99 J K^{-1} mol^{-1} for $(CH_3)_3CCl$, and ΔT=39.1 K and ΔS_m=8.66 J K^{-1} mol^{-1} for $(CH_3)_3CNO_2$, respectively.

Three cobalt(III) complexes of [Co(sexidentate-N_2,S_2,O_2)] and [Co(terdentate-$N,S,O)_2$] types were prepared; where sexidentate-N_2,S_2,O_2 denotes *S,S'*-ethylenebis(L-homocysteinate) (L,L-ebhc) and *S,S'*-trimethylenebis(L-homocysteinate) (L,L-tbhc), and terdentate-*N,S,O* denotes L-ethioninate (L-eth). Each of the L,L-ebhc and L,L-tbhc complexes was chromatographically separated into two isomers, *trans(O)* and *trans(N)*, and the L-eth complex was separated into three isomers, *trans(O)*, *trans(N)*, and *trans(S)*. These isomers were characterized by their electronic absorption, CD, and ^{13}C NMR spectra. The stereoselectivity in the formation of each geometrical isomer for the L,L-ebhc and L,L-tbhc complexes is discussed in relation to the flexibilities of the *S,S*-bridged backbone chelate ring and the L-homocysteinate moiety.

Cobalt(III) complexes with sexidentate-N_2,S_2,O_2 ligands such as *S,S'*-ethylenebis(L-cysteinate) (L,L-ebc), *S,S'*-trimethylenebis(L-cysteinate) (L,L-tbc), *N,N'*-ethylenebis(*S*-methyl-L-cysteinate) (L,L-ebsmc), *N,N'*-trimethylenebis(*S*-methyl-L-cysteinate) (L,L-tbsmc), and *N,N'*-ethylenebis(L-methioninate) (L,L-ebm) exhibit an extreme *trans(O)* selectivity concerning the formation of the geometrical isomers,[1-3] where the expectant isomers are *trans(O)* and *trans(N)* for the *S,S*-bridge complexes, and *trans(O)* and *trans(S)* for the *N,N*-bridge ones.[4] Of these complexes the *N,N*-bridge L,L-tbsmc one revealed the formation of the *trans(S)* isomer which isomerized rapidly to the *trans(O)* one.[1] This stereoselective behavior seems to relate not only to the flexibility of the bridged ethylene or trimethylene backbone chelate ring of the sexidentate-N_2,S_2,O_2 ligand but also to that of the L-cysteinate or L-homocysteinate moiety of the ligand. The present work was undertaken in continuation of the previous work[1] in order to investigate the stereoselectivity in the formation of the geometrical isomers.

In the present paper, the cobalt(III) complexes with sexidentate-N_2,S_2,O_2 ligands, *S,S'*-ethylenebis(L-homocysteinate) (L,L-ebhc) and *S,S'*-trimethylenebis(L-homocysteinate) (L,L-tbhc), $[Co(L,L\text{-ebhc})]^+$ and $[Co(L,L\text{-tbhc})]^+$, were prepared and chromatographically separated into two geometrical isomers, *trans(O)* and *trans(N)*, respectively. All isomers were characterized by their electronic absorption, CD, and ^{13}C NMR spectra, and their stereochemical and spectrochemical features are discussed. Bis(L-ethioninato)cobalt(III) complex, $[Co(L\text{-eth})_2]^+$, which corresponds to the non-bridge type of the above *S,S*-bridge complexes, was also prepared and separated into the *trans(O)*, *trans(N)*, and *trans(S)* isomers. Their spectral behaviors are compared with those of the three isomers of $[Co(L\text{-met})_2]^+$ [5] in order to investigate the influence due to the change of the substituent on the sulfur donor atom in the L-terdentate-*N,S,O* ligand.

Experimental

Preparation of Ligands. 1) *S,S'*-Ethylenebis(L-homocysteine) was prepared by a procedure modified from that used for the preparation of *S*-(carboxymethyl)-L-homocysteinate,[6,7] using 1,2-dibromoethane instead of chloroacetic acid. L-Methionine (30 g) and 1,2-dibromoethane (8.6 cm^3) were dissolved in 400 cm^3 of concentrated hydrochloric acid and the solution was refluxed for 24 h. The solution was concentrated with a rotary evaporator until it became syrupy and then neutralized with 28% aqueous ammonia. The resultant crystalline product was filtered, washed well with water, and dried in a vacuum desiccator. Yield; 9.5 g (32%). Found: C, 40.28; H, 6.80; N, 9.42%. Calcd for L,L-H_2ebhc=$C_{10}H_{20}N_2O_4S_2$: C, 40.28; H, 6.76; N, 9.39%.

2) *S,S'*-Trimethylenebis(L-homocysteine) was prepared by the same procedure as in 1), using 1,3-dibromopropane instead of 1,2-dibromoethane. Found: C, 30.68; H, 8.08; N, 6.40%. Calcd for L,L-H_2tbhc·6.5H_2O=$C_{11}H_{35}N_2O_{10.5}S_2$: C, 30.90; H, 8.26; N, 6.55%.

Preparation of Complexes. 3) [*S,S'*-Ethylenebis(L-homocysteinato)]cobalt(III) Bromide and Perchlorate: [Co(L,L-ebhc)]X; X=Br^- and ClO_4^-. A suspension containing 4.0 g of L,L-H_2ebhc in 50 cm^3 of water was adjusted to pH 9 with a 1 mol dm^{-3} aqueous solution of NaOH. To this were added a solution containing 4.0 g of $CoCl_2·6H_2O$ in 10 cm^3 of water, 2.0 g of PbO_2, and 0.2 g of activated charcoal. The mixture was stirred at ca. 60 °C for 30 min and then filtered. The filtrate was poured onto a column of SP-Sephadex C-25 (Na^+ form, 5 cm×43 cm). After sweeping the column with water, the adsorbed band was eluted with a 0.1 mol dm^{-3} aqueous solution of KBr. Two colored bands, brown (A-1) and violet (A-2), were eluted in this order. It was found from the absorption and CD spectral measurements that the eluates A-1 and A-2 contained *trans(N)*- and *trans(O)*-$[Co(L,L\text{-ebhc})]^+$, respectively. The formation ratio of the isomers, *trans(N)*:*trans(O)*, was about 1:1. Each of the eluates A-1 and A-2 was concentrated to a small volume with a rotary evaporator below 25 °C and the deposited KBr was filtered off. Each filtrate was passed through a column of Sephadex G-10 (3 cm×53 cm), and eluted with water in order to eliminate KBr. Each eluate was concentrated to a small volume. To the eluate A-1 was added a small amount of ethanol and the solution was kept in a refrigerator for several days. The resultant violet crystals were

collected by filtration. To the eluate A-2 an excess amount of aqueous solution of $NaClO_4$ was added and then a small amount of acetone. The solution was kept in a refrigerator for 4 d. The brown crystals which appeared were collected by filtration and obtained as perchlorate salt. Found for A-1: C, 22.74; H, 4.32; N, 5.36%. Calcd for $[Co(L,L\text{-ebhc})]Br \cdot 0.4KBr \cdot 2.5H_2O = CoC_{10}H_{18}N_2O_4S_2Br \cdot 0.4KBr \cdot 2.5H_2O$: C, 22.84; H, 4.41; N, 5.33%. Found for A-2: C, 25.49; H, 4.29; N, 5.94%. Calcd for $[Co(L,L\text{-ebhc})]ClO_4 \cdot H_2O$: C, 25.51; H, 4.28; N, 5.95%.

4) [*S,S'*-Trimethylenebis(L-homocysteinato)]cobalt(III) Perchlorate: [Co(L,L-tbhc)]ClO$_4$. This complex was prepared and chromatographed by the same procedure as in **3)**, using L,L-H_2tbhc instead of L,L-H_2ebhc. Two colored bands, brown (B-1) and violet (B-2), were eluted in this order. It was found from the absorption and CD spectral measurements that the eluates B-1 and B-2 contained *trans(N)*- and *trans(O)*-$[Co(L,L\text{-tbhc})]^+$, respectively. The formation ratio of the isomers, *trans(N)* and *trans(O)*, was about 1:14. The B-1 isomer could not be isolated as a solid, because the fast-moving band (B-1) contained a very small amount. Therefore, the concentration of the B-1 isomer was measured by a plasma emission spectral analysis. The eluate B-2 was converted into the perchlorate salt by use of an anion-exchange column (ClO_4^- form). Found for B-2: C, 26.46; H, 4.53; N, 5.59%. Calcd for $[Co(L,L\text{-tbhc})]ClO_4 \cdot 1.5H_2O = CoC_{11}H_{20}N_2O_8S_2Cl \cdot 1.5H_2O$: C, 26.75; H, 4.70; N, 5.67%.

5) Bis(L-ethioninato)cobalt(III) Bromide: [Co(L-eth)$_2$]Br. This complex was prepared by the same procedure as that used for $[Co(L\text{-met})_2]Br$,[5] using L-Heth instead of L-Hmet. The reaction mixture was poured onto a column of Dowex 50W-X8 (200—400 mesh, NH_4^+ form, 3.5 cm×40 cm). After sweeping the column with water, the adsorbed band was eluted with a 0.1 mol dm^{-3} aqueous solution of NH_4Br. Three colored bands, dark-red (C-1), brown-red (C-2), and red-violet (C-3), were eluted in this order. The eluates C-1, C-2, and C-3 contained *trans(S)*-, *trans(N)*-, and *trans-(O)*-$[Co(L\text{-eth})_2]^+$, respectively. Each of the three eluates was separately concentrated with a rotary evaporator below 30°C. The deposited NH_4Br was filtered off and a large amount of ethanol was added to the filtrate. The crude isomers, C-1, C-2, and C-3, were recrystallized from as little water as possible by adding ethanol, respectively. Found for C-1:

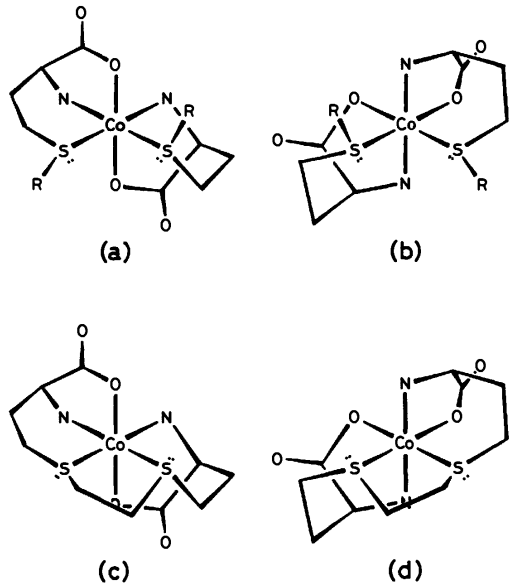

Fig. 1. Probable configurations of *trans(O)* and *trans(N)* for $[Co(L\text{-eth})_2]^+$ (R=C_2H_5): (a) *trans(O)*-*R(S),R(S)* and (b) *trans(N)*-*S(S),S(S)*, and for $[Co(L,L\text{-ebhc})]^+$: (c) *trans(O)*-*R(S),R(S)* and (d) *trans(N)*-*S(S),S(S)*.

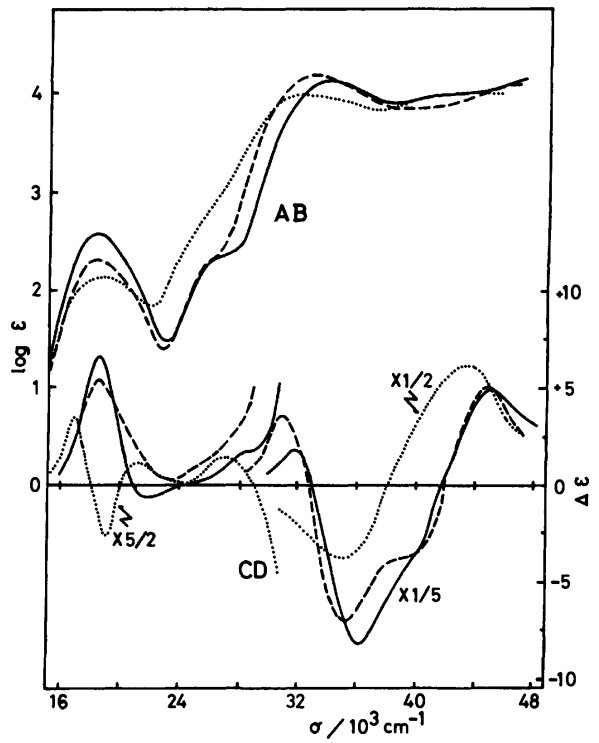

Fig. 2. Absorption and CD spectra of the *trans(O)* isomer for $[Co(L,L\text{-ebhc})]^+$ (——), $[Co(L,L\text{-tbhc})]^+$ (-----), and $[Co(L\text{-eth})_2]^+$ (·····).

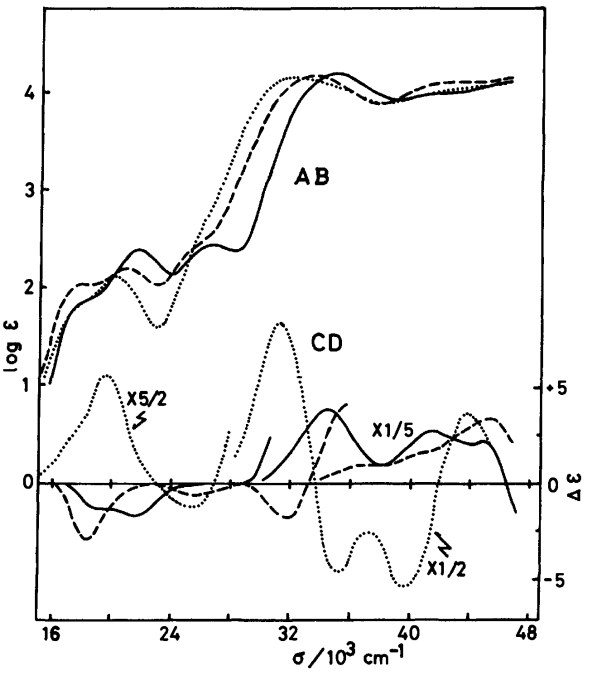

Fig. 3. Absorption and CD spectra of the *trans(N)* isomer for $[Co(L,L\text{-ebhc})]^+$ (——), $[Co(L,L\text{-tbhc})]^+$ (-----), and $[Co(L\text{-eth})_2]^+$ (·····).

C, 31.62; H, 5.42; N, 5.90%. Calcd for [Co(L-eth)$_2$]Br·0.25C_2H_5OH=$CoC_{12}H_{24}N_2O_4S_2Br$·0.25$C_2H_5OH$: C, 31.40; H, 5.79; N, 5.89%. Found for C-2: C, 27.86; H, 5.80; N, 5.42%. Calcd for [Co(L-eth)$_2$]Br·3H_2O: C, 27.84; H, 5.86; N, 5.43%. Found for C-3: C, 28.64; H, 5.51; N, 5.63%. Calcd for [Co(L-eth)$_2$]Br·2H_2O: C, 28.87; H, 5.61; N, 5.61%.

Measurements. The electronic absorption spectra were recorded with JASCO UVIDEC-1 and UVIDEC-610 spectrophotometers and the CD spectra with a JASCO J-20 spectropolarimeter. All measurements were carried out in aqueous solution at room temperature. The concentration of *trans(N)*-[Co(L,L-tbhc)]$^+$ was measured with a Jarrel-Ash Model 96—975 Plasma Atom Co. The ^{13}C NMR spectra were recorded in deuterium oxide on a JEOL JNM-FX-100 NMR spectrometer at the probe temperature. Sodium 2,2-dimethyl-2-silapentate-5-sulfonate (DSS) was used as an internal reference.

Results and Discussion

Structural Assignments. *S,S*-Bridge (L,L-sexidentate-N_2,S_2,O_2) Type Complexes. For each of the *S,S*-bridge complexes, [Co(L,L-ebhc)]$^+$ and [Co(L,L-tbhc)]$^+$, two geometrical isomers, *trans(O)* and *trans(N)*, are expected (Fig. 1). The absorption and CD spectra of the A-1, A-2, B-1, and B-2 isomers are shown in Figs. 2 and 3, and their data are summarized in Tables 1 and 2 together with those of *trans(O)*-, *trans(N)*-, and *trans(S)*-[Co(L-eth)$_2$]$^+$. Four isomers of the *S,S*-bridge complexes exhibit commonly the sulfur-to-metal charge transfer bands in the region of 33—35×10^3 cm^{-1}, indicating that all isomers have a *cis(S)* configuration.[1,8-13] In the first d-d absorption band

Table 1. Absorption Spectral Data of [Co(sexidentate-N_2,S_2,O_2)]$^+$ and [Co(terdentate-N,S,O)$_2$]$^+$ Type Complexes

Complex	First band	Second band	Charge transfer band
trans(O)-[Co(L,L-ebhc)]$^+$	18.42 (2.58)	26.67 (2.34 sh)	34.25 (4.13)
trans(N)-[Co(L,L-ebhc)]$^+$	17.86 (1.85 sh)	26.74 (2.43)	34.72 (4.21)

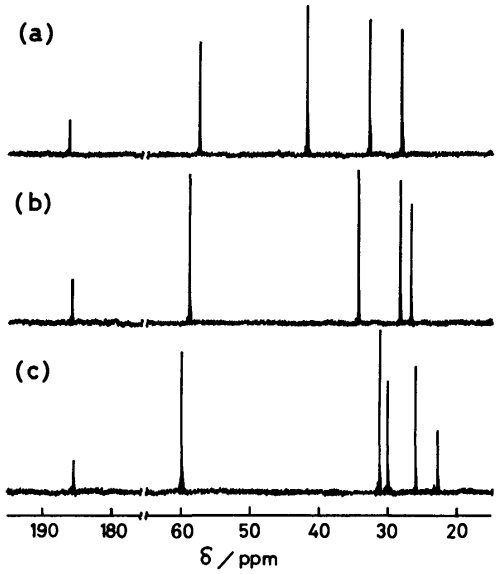

Fig. 4. ^{13}CNMR spectra of [Co(sexidentate-N_2,S_2,O_2)]$^+$: (a) *trans(N)* L,L-ebhc, (b) *trans(O)* L,L-ebhc, and (c) *trans(O)* L,L-tbhc.

region of [Co(L,L-ebhc)]$^+$, the A-1 isomer exhibits a band with an explicit shoulder on the lower energy side of the major peak and the A-2 one a broad band with a vague shoulder on the higher energy side (Figs. 2 and 3). These splittings of the first d-d absorption bands indicate that the A-1 and A-2 isomers are *trans(N)* and *trans(O)*, respectively.[1,13] The same relationship in absorption spectrum as the L,L-ebhc isomers is also observed for the B-1 and B-2 isomers of [Co(L,L-tbhc)]$^+$ (Figs. 2 and 3, and Table 1). Accordingly, the B-1 isomer can be assigned to *trans(N)* and the B-2 one to *trans(O)*.

The ^{13}CNMR spectra of the *S,S*-bridge complexes were measured in order to estimate the configuration, *R(S)* or *S(S)*, of the sulfur donor atom (Fig. 4). *trans(N)*- and *trans(O)*-[Co(L,L-ebhc)]$^+$ exhibit five resonance lines for ten carbon atoms (Fig. 4 (a) and (b)), and *trans(O)*-[Co(L,L-tbhc)]$^+$ exhibits six lines for eleven carbon ones (Fig. 4 (c)). These facts indicate that all isomers have C_2 symmetry, namely, the conformation of the *S,S*-bridged backbone chelate ring takes a gauche form for the ethylene bridge in the L,L-ebhc complex and a skew form for the trimethylene bridge in the L,L-tbhc one. It is considered, therefore, that each of the four isomers takes either the *R(S)*,-*R(S)* or *S(S)*,*S(S)* configuration with respect to the two asymmetric sulfur donor atoms. The model constructions reveal that the two sulfur donor atoms of the *trans(N)* L,L-ebhc or *trans(N)* L,L-tbhc isomer take the *S(S)*,*S(S)* configuration. On the other hand, the two *trans(O)* isomers are possible to take both of the *R(S)*,-*R(S)* and *S(S)*,*S(S)* configurations, however, the *R(S)*,-*R(S)* one is more preferable than the other because there is less strain of the *S,S*-bridged backbone chelate ring.

Bis(L-ethioninato) Complexes. In order to investigate the spectral behavior due to the change of the substituent on the sulfur donor atom of the ligand, *trans(N)*-, *trans(S)*-, and *trans(O)*-[Co(L-eth)$_2$]$^+$ were prepared. Their absorption and CD data are summarized in Tables 1 and 2. Splittings of the first d-d absorption bands and the maximum positions (28—33×10^3 cm^{-1}) of the sulfur-to-metal charge transfer bands of the three isomers agree well with those of the corresponding three isomers of [Co(L-met)$_2$]$^+$, respectively.[5] The behavior of these absorption spectra confirms that the C-1, C-2, and C-3 isomers are *trans(S)*, *trans(N)*, and *trans(O)*, respectively.[14] Each of the three isomers exhibits a similar CD spectrum to that of the corresponding isomer of [Co(L-met)$_2$]$^+$,[5] suggesting that the CD contribution due to the change of the substituent on the two sulfur donor atoms is inconspicuous.

The ^{13}CNMR spectrum of *trans(S)*-[Co(L-eth)$_2$]$^+$ exhibits six resonance lines (13.00, 27.90, 30.45, 32.61, 58.40, and 186.03 ppm) for twelve carbon atoms, the *trans(N)* isomer fourteen lines (13.27, 14.30, 25.73, 26.06, 26.55, 27.79, 28.06, 28.98, 31.75, 32.56, 59.10, 60.78, 185.49, and 186.58 ppm), and the *trans(O)* isomer eight lines (14.36, 25.79, 26.98, 27.20, 28.66, 57.70, 187.44, and 187.93 ppm). Taking the configuration, *R(S)* or *S(S)*, of the sulfur donor atom into consideration, the ^{13}C NMR spectrum of the *R(S)*,*R(S)* or *S(S)*,*S(S)* isomer having a twofold axis can be expected to exhibit six resonance lines, while the *R(S)*,-*S(S)* isomer to exhibit twelve. The present results suggest that the *trans(S)* isomer is either *S(S)*,*S(S)* or *R(S)*,*R(S)* and the other two isomers are a mixture of *R(S)*,*S(S)*, *R(S)*,*R(S)*, and/or *S(S)*,*S(S)*. These trends are in accord with those of the [Co(L-met)$_2$]$^+$ isomers.[5] Accordingly, taking the model constructions and the similarity in CD spectrum with the [Co(L-met)$_2$]$^+$ isomers into consideration, the *trans(S)* isomer prefers the *S(S)*,*S(S)* configuration, the *trans(N)* isomer a mixture of the *R(S)*,*S(S)* and *S(S)*,*S(S)* ones, and the *trans(O)* isomer takes a mixture of the *R(S)*,*R(S)*, *R(S)*,-*S(S)*, and *S(S)*,*S(S)* ones, as in the case of [Co(L-met)$_2$]$^+$.[5] These results seem to support that the CD spectra of the three isomers of [Co(L-eth)$_2$]$^+$ resemble the corresponding isomers of [Co(L-met)$_2$]$^+$, respectively.

Formation of Isomers. The *trans(O)* and *trans(N)* isomers were formed for each [Co(L,L-ebhc)]$^+$ and [Co(L,L-tbhc)]$^+$ in this work, though the *trans(N)* L,L-tbhc isomer could not be isolated as a solid because of the very small amount. Contrary to the L,L-ebhc and L,L-tbhc complexes, only the *trans(O)* isomer was selectively formed for each of [Co(L,L-ebc)]$^+$ and [Co(L,L-tbc)]$^+$.[1] These results are probably related to the difference in flexibility between the N-S chelate rings of the L,L-ebhc or L,L-tbhc complex and the L,L-ebc or L,L-tbc one. For [Co(L,L-ebhc)]$^+$ and [Co(L,L-tbhc)]$^+$, namely, the ethylene and trimethylene bridges span the two sulfur donor atoms of the rather flexible six-membered N-S rings of the L-homocysteinate

moieties, while the bridges in [Co(L,L-ebc)]$^+$ and [Co(L,L-tbc)]$^+$ span the sulfur donor atoms of the rigid five-membered N–S rings of the L-cysteinate moieties. In the case of the *N,N*-bridge L,L-sexidentate-N_2,S_2,O_2 type complexes,[1-3] on the other hand, of the expectant *trans(O)* and *trans(S)* isomers only the *trans(O)* one was selectively formed for the ethylene bridge complexes, [Co(L,L-ebsmc)]$^+$ and [Co(L,L-ebm)]$^+$, while the two geometrical isomers were formed for the trimethylene bridge complex, [Co(L,L-tbsmc)]$^+$, though the *trans(S)* isomer could not be isolated because of the isomerization to the *trans(O)* species during the procedure after elution.[1] These results are obviously caused by the difference in flexibility between the ethylene and trimethylene bridges, because both of the bridges span the nitrogen donor atoms of the rigid five-membered N–O rings of the ligands. From these results, it can be deduced that the selective formation of the isomers for the *S,S*-bridge complexes depends mainly on the flexibility of the N–S chelate rings of the ligand and the difference between the ethylene and trimethylene backbone bridges is a minor factor for the selective formation of the isomers.

Absorption and CD Spectra. The three geometrical isomers of [Co(L-eth)$_2$]$^+$ exhibit similar absorption and CD spectral behaviors to the corresponding isomers of [Co(L-met)$_2$]$^+$,[5] over the whole region, indicating that their spectra hardly change with the substitution of ethyl group for methyl one on the sulfur donor atoms (Tables 1 and 2). The CD spectra of the *trans(O)* and *trans(N)* isomers of [Co(L,L-ebhc)]$^+$ and [Co(L,L-tbhc)]$^+$ deviate significantly from those of the corresponding isomers of [Co(L-eth)$_2$]$^+$, respectively, although the absorption spectral patterns of the former isomers are similar to those of the latter, respectively, as shown in Figs. 2 and 3.

The absorption maxima of the sulfur-to-metal charge transfer bands (32—35×10^3 cm^{-1} for the *cis(S)* isomers) are shifted to lower energy in the order of L,L-ebhc>L,L-tbhc>non-bridge complex in either of the *trans(O)* and *trans(N)* isomers (Figs. 2 and 3). This order coincides with that for the *cis*·*cis*·*cis*-[Co(*R,S*-ebp)]$^+$, -[Co(*R,S*-tbp)]$^+$, -[Co(*R,S*-tetp)]$^+$, and -[Co(*R*-smp) (*S*-smp)]$^+$.[15] This behavior reflects the order of the rigidities of the *S,S*-bridged backbone chelate rings. The first d-d absorption bands of the present *S,S*-bridge *trans(O)* isomers are almost unchanged from that of *trans(O)*-[Co(L-eth)$_2$]$^+$ as in the case of *trans(O)*-[Co(L,L-ebc)]$^+$, -[Co(L,L-tbc)]$^+$, and -[Co(L-smc)$_2$]$^+$, where L-smc denotes *S*-methyl-L-cysteinate.[1] However, the first absorption bands of the *S,S*-bridge *trans(N)* isomers significantly change from that of the *trans(N)* L-eth isomer, namely, the absorption components in the higher energy side are shifted to lower energy in accordance with the absorption spectral behavior of the sulfur-to-metal charge transfer bands mentioned above, though the components (ca. 17.9×10^3 cm^{-1}) in the lower energy side remain unchanged.

The deviation in CD spectrum between the *trans(O)* L,L-ebhc or L,L-tbhc isomer and *trans(O)*-[Co(L-eth)$_2$]$^+$ is quite similar to that between the *trans(O)* L,L-ebc or L,L-tbc isomer and *trans(O)*-[Co(L-smc)$_2$]$^+$ which possess a rigid L-cysteinate framework.[1] Accordingly, this deviation is attributed to the CD contribution due to the fixation of two sulfur donor atoms located in the cis position. In contrast to the *trans(O)* isomers, the CD spectra of the *S,S*-bridge *trans(N)* isomers change drastically from that of *trans(N)*-[Co(L-eth)$_2$]$^+$ (Fig. 3 and Table 2). In the first d-d absorption band region, *trans(N)*-[Co(L-eth)$_2$]$^+$ exhibits a positive CD band (19.61×10^3 cm^{-1}) with a shoulder in the lower energy side, while the *S,S*-bridge *trans(N)* isomers exhibit negative CD bands (19.2 sh and 21.56×10^3 cm^{-1} for the L,L-ebhc isomer and 18.32×10^3 cm^{-1} for the L,L-tbhc one) which correspond to the two absorption components. In the ligand band region (36—48×10^3 cm^{-1}) where the bridge L,L-isomer usually exhibits a similar CD pattern to that of the non-bridge L-isomer,[1,2] the *trans(N)* L,L-ebhc and L,L-tbhc isomers exhibit a reversed CD pattern to that of *trans(N)*-[Co(L-eth)$_2$]$^+$ (Fig. 3). Considered from another viewpoint, the CD spectra of the *S,S*-bridge *trans(N)* isomers seem roughly enantiomeric to those of the *S,S*-bridge *trans(O)* ones. These CD spectral changes of the *trans(N)* isomers seem to indicate an additional CD contribution besides that due to the fixation of the two sulfur donor atoms in the cis position. On this viewpoint, the present results may be considered as follows. When the two sulfur donor atoms of the non-bridge isomer are spanned by ethylene or trimethylene, the *S,S*-bridge *trans(O)* isomers retain the net configurational chirality of the non-bridge *trans(O)* one. While, the *S,S*-bridge *trans(N)* isomers obtain a configurational chirality of the L,L-sexidentate type which is quasi-enantiomeric geometrical isomers to the *S,S*-bridge *trans(O)* ones, though *trans(N)*-[Co(L-eth)$_2$]$^+$ is not quasi-enantiomeric to the *trans(O)* isomer. As a result, the *S,S*-bridge *trans(N)* isomers exhibit approximately enantiomeric CD spectra to the *S,S*-bridge *trans(O)* ones. The CD spectral behavior of the *trans(N)* isomers in this work suggest that care must be taken in relating the CD spectra to the absolute configurations of the complexes with sulfur-containing terdentate amino carboxylates and their sexidentate derivatives.

The authors wish to express thanks to Miss Shino Takahashi and Mrs. Yoko Koizumi for their aid in the experiment. This work was supported by a Grant-in-Aid for Scientific Research No. 60470043 from the ministry of Education, Science and Culture.

Voltammetric Determination of Dialkylammonium Ion in the Presence of Monoalkylammonium Ion by Addition of 18-Crown-6

Tomokazu MATSUE, Uichi AKIBA, and Tetsuo OSA*
Pharmaceutical Institute, Tohoku University, Aobayama, Sendai 980
(Received December 9, 1985)

The addition of 18-crown-6 to the electrolyte solution discriminated the reduction current peak for dialkylammonium ions from that for monoalkylammonium homologues, which made it possible to determine voltammetrically the dialkylammonium ions in the presence of the monoalkylammonium ions.

Voltammetry has been widely used as an effective method for determination of a specific electroactive species in the presence of others. Reliable results for such a system have been obtained when the reduction (or oxidation) potential of the species to be determined differs from those of others by $\gtrsim$0.1 V. If the separation in the potentials is unsatisfactory, one should use a procedure to diminish the undesired influences of the interfering species. This may be accomplished by use of a potential-shifting additive[1] which affects chemical reactions prior to and/or following electron transfer. If the interfering species are structually and chemically similar to the species to be determined, a high recognition ability of substrate is required for the potential-shifting additive. In this paper, we wish to report the voltammetric determination of dialkylammonium (secondary ammonium) ions in the presence of monoalkylammonium (primary ammonium) ions by taking advantage of the recognition ability of 18-crown-6 (18CR6) for ammonium cations. Although crown ethers have been used for ion-selective electrodes aimed at determining a specific alkali metal ion,[2] this potentiometric method is essentially unsuitable for detection of secondary ammonium ions. Amperometric method can be used for the purpose but coexistence of primary ammonium ions reduces the reliability since reduction current for the primary ions overlaps that for the secondary ions. In such a case, the addition of crown ethers, especially 18CR6 derivatives, to the electrolyte solution discriminates the two reduction currents and makes it possible to determine the secondary ammonium ion even though the primary homologues are present in the solution.

Experimental

Differential pulse voltammetry was carried out using a Yanaco voltammetric analyzer model P-1000 at room temperature. Cyclic voltammetry was also performed with conventional instruments. The working electrode was a 3 mm diameter Pt disk sealed into a soft glass tube and it was polished finally with 0.3 μm alumina powder (Buehler Co.) to give a mirror-like surface. The reference electrode was an Ag wire immersed in 0.10 mol dm^{-3} tetraethylammonium perchlorate (TEAP)/0.010 mol dm^{-3} $AgNO_3$ in acetonitrile and a Pt wire was used as the counter electrode. All chemicals (GR grade) were obtained commercially and used without further purification.

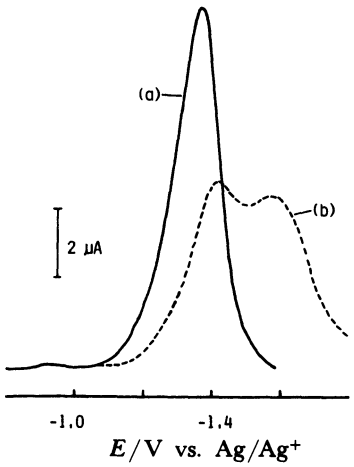

Fig. 1. Differential pulse voltammograms of a mixture of 1.0 mmol dm^{-3} $Me_2NH_2^+Cl^-$ and 1.0 mmol dm^{-3} $EtNH_3^+Cl^-$ in the absence (a) and presence (b) of 40 mmol dm^{-3} 18CR6.
Scan rate: 5 mV s^{-1}. Modulation amplitude: 50 mV. Pulse interval: 1.0 s. Electrode: Pt disk. Electrolyte: 0.1 mol dm^{-3} TEAP/acetonitrile.

Results and Discussion

Figure 1 shows differential pulse voltammograms of a mixture of 1.0 mmol dm^{-3} dimethylammonium chloride ($Me_2NH_2^+Cl^-$) and its structual isomer, 1.0 mmol dm^{-3} ethylammonium chloride ($EtNH_3^+Cl^-$). The reduction potentials of the two ions are close each other, so only single wave was observed on the voltammogram. However, the addition of 18CR6 to the electrolyte solution changes the sole peak to the splitting two peaks. The reduction peak at −1.42 V is originated from the electrochemical reduction of $Me_2NH_2^+$ and the other peak from the reduction of $EtNH_3^+$. The large shift in the reduction potential for $EtNH_3^+$ is resulted from its strong complexation with 18CR6. Only a few reports[3] have been published on the effect of crown ethers on the electroreduction of NH_4^+. From these results, the following mechanism can be deduced for the electrochemical reduction of $EtNH_3^+$ in the presence of 18CR6:

$$EtNH_3^+ + CR \rightleftharpoons EtNH_3^+ \cdot CR \quad (1)$$

$$EtNH_3^+ + e^- \longrightarrow EtNH_2 + 1/2\,H_2. \quad (2)$$

Since the preceding reaction (1) exists before the electron-transfer process (2) (so-called CE mechanism), the apparant half-wave potential for the reduction shifts to the negative direction as the concentration of 18CR6 in the electrolyte solution increases. The formation constant for the CR complex can be determined by these potential shifts[4] and the value was roughly estimated to be $\gtrsim$2000 $dm^3 mol^{-1}$ assuming fast chemical reaction and irreversible electron-transfer step (C_rE_i mechanism). Thus almost all $EtNH_3^+$ exists as the complexed form under the present conditions. The addition of 18CR6 also caused a decrease of the reduction peak current on the voltammogram because the effective diffusion coefficient is reduced by the complexation[5] of $EtNH_3^+$ with large 18CR6 molecule. This phenomenon also plays an important role on the clear appearance of the reduction wave for $Me_2NH_2^+$ on the voltammogram. On the other hand, the effect of the added 18CR6 on the reduction of $Me_2NH_2^+$ was small. The shift in the reduction potential was only 0.03 V (cyclic voltammetry) by the addition of 40 mmol dm^{-3} 18CR6. The consideration with the CPK molecular model shows that $Me_2NH_2^+$ forms no clear complex but only sits on the ether ring.

Figure 2 shows the relationship between the current at -1.42 V and the concentration of $Me_2NH_2^+$ in the presence of 1.0 mmol dm^{-3} $EtNH_3^+$ and 40 mmol dm^{-3} 18CR6. A good linearity over the concentration range measured indicates that the concentration of $Me_2NH_2^+$ can be determined by addition of 18CR6 to the electrolyte solution even though the sample contains $EtNH_3^+$ ion. A small current at the intercept of the current axis is due to the residual reduction of $EtNH_3^+$. When the concentration of $Me_2NH_2^+$ is largely excess over that of $EtNH_3^+$, the undesired influence from the residual current is negligible. Although the contribution of the residual current becomes large as the concentration of $EtNH_3^+$ increases, it can be estimated by $0.18i_p$ where i_p is the peak current for the reduction of $EtNH_3^+$ at -1.58 V. Thus, the concentration of $Me_2NH_2^+$ can be determined by considering this residual effect. The present analysis will give reliable results if the concentration of $Me_2NH_2^+$ is larger than one-tenth that of $EtNH_3^+$.

Table 1 shows the shifts of the peak potential caused by the addition of crown ethers in cyclic voltammetry. All crown ethers used had a remarkable ability for shifting the peak potentials of the primary ammonium ions in acetonitrile. However, the shifts observed in dimethylformamide (DMF) were relatively small, reflecting low binding ability of the crown ethers in this solvent. It is also notable that the shift in the peak potential, i.e., binding ability, depends greatly on the structure of the crown ether. The tendency observed here is in accord with those reported previously.[6,7] The complexation of ammonium ions is stabilized by forming tetrahedral conformation via three hydrogen bondings between ammonium hydrogens and ether

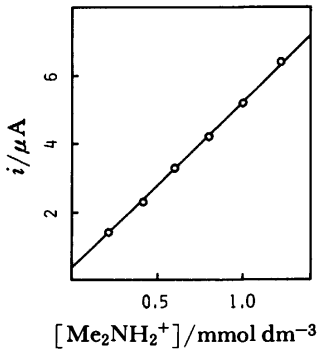

Fig. 2. Relationship between the current at -1.42 V and the concentration of $Me_2NH_2^+Cl^-$ in the presence of 1.0 mmol dm^{-3} $EtNH_3^+Cl^-$ and 40 mmol dm^{-3} 18CR6. The current was measured by the differential pulse voltammetry under the same experimental conditions described in Fig. 1.

Table 1. The Shifts in the Peak Potential (V) Induced by the Addition of 20 mmol dm^{-3} Crown Ethers in Cyclic Voltammetry[a]

CR	$R-NH_3^+$ R=	Solvent	
		acetonitrile	DMF
18CR6	Me	0.21	0.09
	Et	0.20	0.08
	Pr	0.20	0.08
B18CR6[b]	Me	0.20	0.09
DB18CR6[c]	Me	0.10	0.09
	Et	0.11	
	Pr	0.14	
15CR5[d]	Me	0.08	

a) Scan rate: 0.1 V s^{-1}. Concentration of substrate: 1.0 mmol dm^{-3}. Other conditions are same as those in Fig. 1. b) Benzo-18-crown-6. c) Dibenzo-18-crown-6. d) 15-crown-5.

oxygens.[6] Thus, 15CR5 is obviously inferior to 18CR6 derivatives in binding ability since only two hydrogen bondings are operative in the 15CR5 complexes. Another important factor governing the binding strength is electron density on the oxygen atoms in the ether rings. Replacement of ethylene groups by aryl groups reduces the binding ability[7] due to slight delocalization of the aryl oxygen electron into the aryl π system.

These effects of crown ethers are very small for the electroreduction of secondary ammonium ions. The largest influence of 18CR6 was observed on the reduction of $Me_2NH_2^+$ and it decreased rapidly with length of the alkyl chains. 18CR6 had only negligible effect on the reduction of $Et_2NH_2^+$ in terms of the peak potential and peak current. The above results indicate that there are pronounced difference[8] in the formation constants for primary and secondary ammonium ions. However, it is difficult to determine the exact values of these constants by the shifts in the peak potential induced by the complexation since the detailed mechanism of this electrochemical reaction

is unclear. For the present purpose to determine secondary ammonium ion, it is not essential to obtain the formation constants. If the peak separation is unsatisfactory, further addition of crown ethers will provide a better resolution. This procedure is applicable to the determination of other secondary ammonium ions in the presence of primary homologues, and can be extended to the analysis of tertiary ammonium (trialkylammonium) ions.

An X-Ray Diffraction Investigation of the Coordination Structure of Mn(II) Ions in Highly Concentrated Aqueous $MnBr_2$ and $MnCl_2$ Solutions

Yoshichika TAJIRI, Mitsuyoshi ICHIHASHI,† Takeharu MIBUCHI,†† and Hisanobu WAKITA*
Department of Chemistry, Faculty of Science, Fukuoka University, Nanakuma, Jonan-ku, Fukuoka 814-01
(Received August 15, 1985)

The solute structures of highly concentrated aqueous 5.087 and 2.744 mol dm^{-3} $MnBr_2$, and 4.744 and 2.732 mol dm^{-3} $MnCl_2$ solutions were determined by the analysis of the radial-distribution function curves of X-ray diffraction experiments. Mixed-ligand aquahalogenomanganese(II) complexes were found to be present in these solutions, holding a distorted octahedral geometry. The interatomic distances of the aquabromo complex are 2.178—2.184 Å for Mn-OH_2 and 2.596—2.643 Å for Mn-Br; those of the aquachloro complex are 2.183—2.185 Å for Mn-OH_2 and 2.492—2.496 Å for Mn-Cl. The interatomic distances of Mn-OH_2 are shorter than those of the $MnBr_2 \cdot 4H_2O$ and $MnCl_2 \cdot 4H_2O$ crystals and are consistent with those of the $Mn(OH_2)_6(NO_3)_2$ crystal. The length of the Mn-Cl bond here determined is practically the same as that within the $MnCl_2 \cdot 4H_2O$ crystal, but the Mn-Br bond found is shorter than that within the $MnBr_2 \cdot 4H_2O$ crystal. The average coordination number of the Mn-Br contact per Mn(II) increased from 1.104 to 1.212 with an increase in the Br/Mn ratio from 2.076 to 3.269, while the number of the Mn-Cl contact per Mn(II) increased from 1.259 to 1.501 with an increase in the Cl/Mn ratio from 2.000 to 3.352. In all solutions, the aquamonohalogeno and aquadihalogeno complexes exist as the main species, but the aquadihalogeno complex is more dominant in the $MnCl_2$ solution than in the $MnBr_2$ solution.

The aquahalogenomanganese(II) complex in octahedral environments has a very characteristic visible spectrum which gives rise only to spin-forbidden d-d transitions. As its most striking feature is the extreme weakness of the bands, spectroscopic investigations of solution equilibria must be done in highly concentrated solutions, although the solutions may be more or less contaminated by impurities.[1,2] Therefore, the equilibrium constants, e.g., K_1, range from 0.14—3.89 $mol^{-1}\,dm^3$ for the aqueous ca. 1 mol dm^{-3} $MnCl_2$ solution and from 0.08—1.86 $mol^{-1}\,dm^3$ for the aqueous ca. 1 mol dm^{-3} $MnBr_2$ solution.[5] Thus, a "hard" element, manganese, is placed at different positions in the order of hardness by different investigations.[6]

The results of the X-ray crystal structural analysis of $MnCl_2 \cdot 4H_2O$ and $MnBr_2 \cdot 4H_2O$ show that manganese(II) in the crystals exists as a *cis*-dihalogenotetraaqua complex. In this paper, in oder to determine the structures of aquahalogeno complexes of the manganese(II) ion and the coordination number of manganese(II), and also in order to show the difference in the structures with different bases, such as Br and Cl, an X-ray diffraction investigation has been carried out in highly concentrated aqueous $MnBr_2$ and $MnCl_2$ solutions.

Experimental

All the reagents were of a reagent-grade and were obtained from Wako Pure Chemical Industries.

Aqueous Manganese(II) Bromide Solutions. Manganese(II) bromide was prepared by crystallizing the Mn(II) bromide obtained by dissolving $MnCO_3$ with a purified aqueous hydrobromic acid solution. The Br-1 sample solution was prepared by dissolving the manganese(II) bromide in degasified distilled water. The Br-2 sample solution was prepared by dissolving the manganese(II) bromide in a purified aqueous hydrobromic acid solution and by then diluting the solution with degasified distilled water.

Table 1. Solution Composition (mol dm^{-3}) and the Stoichiometric Volume V per Manganese Atom in Solutions

Solution	Br-1	Br-2	Cl-1	Cl-2
Mn	5.087	2.744	4.744	2.732
X	10.56	8.971	9.488	9.157
H_2O	42.19	44.52	46.08	46.64
ρ/g cm^{-3}	1.859	1.673	1.445	1.319
μ/cm^{-1}	76.68	63.40	13.90	9.923
V/Å^3	326.4	605.2	350.0	607.9

ρ: Density; μ: linear absorption coefficient of the solutions for Mo $K\alpha$ radiation.

Aqueous Manganese(II) Chloride Solutions. The Cl-1 and Cl-2 sample solutions were prepared in ways similar to those described in the preceding section.

The results obtained in the manganese(II) bromide system were compared with those of Fe(II) and Co(II) systems reported in our previous paper.[9] Furthermore, Br-1 and Cl-1 solutions are saturated solutions; thus, the coordination structures of the Mn(II) complexes in the solution may be compared with those in the $MnBr_2 \cdot 4H_2O$ and $MnCl_2 \cdot 4H_2O$ crystals respectively.

The concentrations of manganese(II) and halide ions in the solutions were determined by EDTA titration and the Volhard method respectively. The composition of the sample solutions is shown in Table 1.

X-Ray Diffraction Measurements and Data Treatments. X-Ray diffraction measurements were carried out under an N_2 atmosphere; the N_2 gas was purified by passing it through an alkaline pyrogallol.[9] The scattered intensities were measured at every 0.5° from θ=70° to 36°, at every

†Present address: Yokohama Laboratory, Fine Chemicals Division, Chisso Corporation, 2 Kamariya-cho, Kanazawa-ku, Yokohama 236.
††Present address: Central Institute, Idemitsu Kosan Co., Ltd., Kamiizumi, Sodegaura-machi, Kimitsu-gun, Chiba 292-01.

0.25° from 36° to 18°, and at every 0.1° from 18° to 0.5°; 2θ was the scattering angle. The time required for accumulating 40000 counts was recorded for the Br-2 and Cl-2 solutions, and that for accumulating 80000 counts, for the Br-1 and Cl-1 solutions. The measurements and the treatment of the diffraction intensity data were carried out in the same way described in a previous paper.[10]

The radial distribution function $D(r)$ is given in Eq. 1;

$$D(r) = 4\pi r^2\rho_0 + \frac{2r}{\pi}\int_0^{15} s\cdot i(s)\cdot M(s)\cdot\sin(r\cdot s)\cdot ds, \qquad (1)$$

where ρ_0 is the average scattering density of the sample solution and is given in the electron unit, and where s is equal to $4\pi\sin\theta/\lambda(\lambda=0.7107\text{ Å})$. The modification function, $M(s)$, was the same as that employed previously. The intensities due to the interatomic interactions were:

$$i(s)_{\text{calcd}} = \sum_i^{i\neq j}\sum_j n_{ij}\cdot f_i(s)\cdot f_j(s)\frac{\sin(r_{ij}\cdot s)}{r_{ij}\cdot s}\exp(-b_{ij}\cdot s^2), \qquad (2)$$

where $f_i(s)$ and $f_j(s)$ are the atomic scattering factors of the i and j atoms; n_{ij}, r_{ij}, and b_{ij} are, respectively, the frequency factor, the distance, and the temperature factor of the interaction between the i and j atoms.

In order to attain more precisely the structure parameter values, the above parameter values were refined by the least-squares refinement so as to minimize the difference between $i(s)_{\text{calcd}}$ and observed $i(s)$.

Results

Aqueous Manganese(II) Bromide Solutions. The radial-distribution function curves, $D(r)$ and $D(r)-4\pi r^2\rho_0$ of the Br-1 and Br-2 solutions are shown in Figs. 1 and 2. The radial distribution curve of the Br-1 solution and that of each atom-pair in it are depicted in Fig. 3. Four peaks are seen in the curves at ca. 1.0, 2.2, 2.7, and 3.5 Å; these are probably closely connected with intra- and inter-molecular atomic interactions of the solute complex and solvent H_2O molecules. The distance of the first peak at 1.0 Å is consistent with that of the O–H bond in water molecules.[11] The second peak at 2.2 Å can be ascribed to the Mn–O interaction in the solute complexes, the distance having been reported in the aqueous solution of 2.612 mol dm^{-3} $Mn(ClO_4)_2$.[12] The peak at 2.7 Å may be attributed to the Mn–Br interaction, because the distance is very close to the sum of the ionic radii of Mn^{2+} and Br^-, i.e., 2.79 Å {=0.970 Å(Mn^{2+})+1.82 Å(Br^-)};[13] the distance is also close to the values of 2.802 and 2.913 Å in the $MnBr_2\cdot 4H_2O$ crystal.[8]

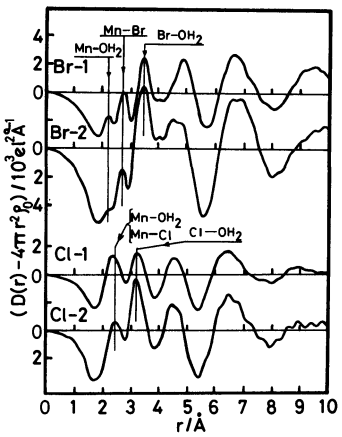

Fig. 2. The $D(r)-4\pi r^2\rho_0$ curves of Br-1, Br-2, Cl-1, and Cl-2 solutions.

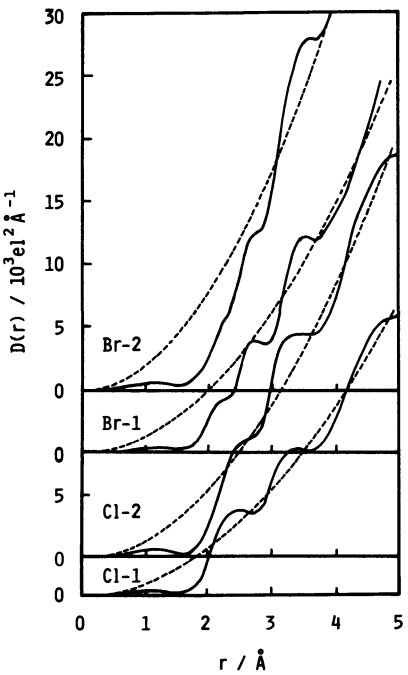

Fig. 1. The radial distribution curves, $D(r)$, for Br-1, Br-2, Cl-1, and Cl-2 solutions. The curves of $4\pi r^2\rho_0$ are shown by dashed lines.

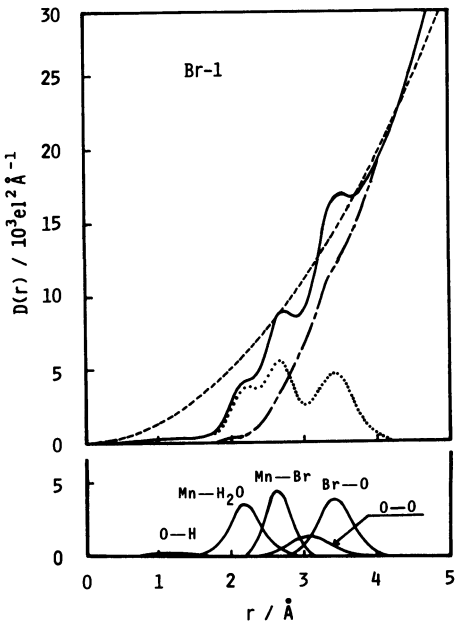

Fig. 3. The residual (——) $D(r)$ curves obtained by subtracting calculated $D(r)$ curves (……) from observed $D(r)$ curve (——) for solution Br-1.

The peak at 3.5 Å can be attributed to the Br–OH_2 interaction, because no comparable peak in this region on the radial-distribution curves is observed for the aqueous 2.612 mol dm^{-3} $Mn(ClO_4)_2$ solution, while a clear peak due to the Br–OH_2 interaction is observed at 3.4 Å for the aqueous 2.5 mol kg^{-1} LiBr solution.[14]

Aqueous Manganese(II) Chloride Solutions. The radial-distribution function curves, $D(r)$ and $D(r)-4\pi r^2\rho_0$, of the Cl-1 and Cl-2 solutions are shown in Figs. 1 and 2. The radial-distribution curve of the Cl-1 solution and that of each atom-pair are shown in Fig. 4. Three peaks are seen in these curves at ca. 1.0, 2.5, and 3.3 Å. The first peak is also consistent with that of the O–H bond in water molecules.[11] The second peak at 2.5 Å may include the Mn–OH_2 and Mn–Cl interactions, because this peak shifted to longer distance with an increase in the concentration of chloride ions, and the position of this peak is close to the sum of the ionic radii of Mn^{2+} and Cl^-, i.e., 2.64 Å{=0.97 Å(Mn^{2+})+1.67 Å(Cl^-)},[13] and it is close to the values of 2.475 and 2.500 Å of Mn–Cl in the $MnCl_2\cdot 4H_2O$ crystal.[7] The Mn–OH_2 interaction observed in the aqueous 2.612 mol dm^{-3} $Mn(ClO_4)_2$ solution at 2.20 Å[12] also appears in the $MnCl_2\cdot 4H_2O$ crystal at 2.22—2.19 Å. Therefore, the peak at 2.5 Å may tentatively be ascribed to the sum of those of the Mn–Cl and Mn–OH_2 interactions.

The peak at 3.3 Å can be ascribed to the Cl–OH_2 interaction, because no comparable peak in this region on the $D(r)$ curve is observed for the aqueous 2.612 mol dm^{-3} $Mn(ClO_4)_2$ solution,[12] but a clear peak due to the Cl–OH_2 interaction is observed at 3.2 Å for the aqueous LiCl solution (mole ratio H_2O: LiCl=3).[15]

From the above considerations, the parameter values on the interatomic distances and frequency and temperature factors of these interactions have been refined. The final parameters are listed in Table 2.

Discussion

Figures 5 and 6 show that the $s\cdot i(s)$ curves calculated from these final data are in good agreement with the observed $s\cdot i(s)$ curves in the region above $s>5$ Å^{-1}. Calculations for the $s\cdot i(s)$ curves made by taking into consideration the Br(Cl)–Br(Cl) or Br(Cl)–H_2O interactions within the *cis*- or *trans*-dihalogeno complexes of manganese(II) did not appreciably improve the results. However, the final data for intramolecular interactions are, we believe, reliable enough, because we obtained smooth background curves in the radial-distribution curves of Br-1 and Cl-1 in the $r<3$ Å region; the disagreement found in the $s\cdot i(s)$ curves of the sample solutions at $s<5$ Å^{-1} is, therefore, due to long-range interactions which we did not take into account in the present calculation.

Aqueous Manganese(II) Bromide Solutions. Since the frequency factors, that is, the mean coordination numbers, n, of Br^- to Mn(II) for Br-1 and Br-2 solutions of Table 2 are 1.104 and 1.212 respectively, not only the monobromoaqua complex but also higher-

bromoaqua complexes should be formed in these solutions. From a visible-spectrum investigation of the aqueous 4.5 mol dm^{-3} $MnBr_2$ solution, Ito[2] determined the equilibrium constants, K_1 and K_2, to be $K_1=K_2=$ 1.1 mol^{-1} dm^3. Libuś et al.[3,4] also reported the formation constant, K_1, of an aqueous 3.0 mol kg^{-1} $MnBr_2$ solution to be 0.19 mol^{-1} kg. If the K_3 and K_4 of our Br-1 solution are equal to zero, the mean coordination number is calculated as n=1.46 from these constant values;[2] this is close to the value obtained for the bromide solution by the X-ray diffraction experiment, if we take into consideration the different experimental conditions. From the present n value, we can conclude that the monobromoaqua complex is the predominant one in the solution, but that a small amount of the dibromoaqua complex may coexist. Little of the tri- and tetrabromo complexes presumably exist. The coordination numbers of the manganese(II) bromide solutions and those of the iron(II), cobalt(II), nickel(II), and copper(II) bromide solutions[9] suggest that the tendency of metal ions to form bromo complexes is in this order; Cu(II)>Mn(II)>Fe(II)>Co(II)>Ni(II).

Aqueous Manganese(II) Chloride Solutions. Since the mean coordination numbers, n, of Mn(II) with Cl^- in Cl-1 and Cl-2 solutions given in Table 2 are 1.259 and 1.501 respectively, some higher-chloroaqua complexes should exist besides the monochloroaqua complex in these solutions. The equilibrium constants of Mn(II) and Cl^- were determined by Ito[2] to be K_1=3.6 mol^{-1} dm^3 and K_2=2.4 mol^{-1} dm^3. The average coordination number in the Cl-1 solution calculated from these constants is 1.96, which is not too greatly different from the value obtained by the X-ray diffraction experiment. From the n-value results, the predominant solute species in the chloride solutions can be said to be the monochloroaqua complex, as a small amount of the dichloroaqua complex is also present. The concentrations of the tri- and tetrachloro complexes are presumably negligible in these solutions.

X-Ray diffraction measurements at different concentrations of solutions showed that the average coordination number of the Mn–X (X=Br,Cl) contact per Mn(II) increased slightly with an increase in the X/Mn ratios.

Since we could not prepare appropriate solutions for the structural analysis of the dihalogeno complexes because of the lack of reliable stability constants, we employed two saturated solutions, Br-1 and Cl-1, in order to determine the structure of the dihalogeno complexes in these solutions. However, we could not conclude whether the structure of the dihalogeno complexes in the solutions has a *cis*- or *trans*-geometry for the configuration of halogen, since calculated $s \cdot i(s)$ curves from both models of the *cis*- and *trans*-geometries of halogen agreed with the observed curves over the same s regions.

The Mn–OH_2 bond distances are 2.178 and 2.184 Å for the Br-1 and Br-2 solutions respectively, and 2.185 and 2.183 Å for the Cl-1 and Cl-2 solutions respectively. They are well consistent with those within the $Mn(H_2O)_6(NO_3)_2$ crystal[16] (2.157—2.211 Å) (average, 2.181 Å), and are shorter than those of the $MnBr_2 \cdot 4H_2O$ crystal[8] (2.221—2.475 Å) and the $MnCl_2 \cdot 4H_2O$ crystal[7] (2.185—2.224 Å) (average, 2.206 Å). The shortening of the Mn–OH_2 bond distances in these solutions may be understood by the explanation that the water molecules of the Mn–OH_2 bonds are attracted by other water molecules or halide ions less strongly in the solutions than in $MnX_2 \cdot 4H_2O$ crystals. The Mn–X bond distances are 2.643 and 2.596 Å for the Br-1 and Br-2 solutions respectively, and 2.492 and 2.496 Å for the Cl-1 and Cl-2 solutions respectively. The Mn–Cl bond distances are well consistent with those of the $MnCl_2 \cdot 4H_2O$ crystal, 2.475 and 2.500 Å. However, the Mn–Br bond in solution is appreciably shorter than those in the $MnBr_2 \cdot 4H_2O$ crystal (2.802 and 2.913 Å). The shortening of the Mn–Br bond distances in $MnBr_2$ solutions may also be understood by the explanation that the attraction between the bromine atoms of the Mn–Br bonds and water molecules coordinated to other Mn(II) bonds is less strong in the solutions than in the $MnBr_2 \cdot 4H_2O$ crystal, but in the case of the chlorine atoms of the Mn–Cl bonds, the analogous attractions in $MnCl_2$ solutions and in the $MnCl_2 \cdot 4H_2O$ crystal are nearly equal in strength.

Solution Properties of Phycoerythrin. I. Characterization of Phycoerythrin

Haruo MIZUNO,* Naomichi ISO, Takahide SAITO, Fumiaki OHZEKI,† Hiroo OGAWA,†† and Zao WANG†††
Department of Food Science and Technology, Tokyo University of Fisheries, Minato-ku, Tokyo 108
(Received July 29, 1985)

Phycoerythrin, one of the chromoproteins, from the red alga *Porphyra yezoensis* has been characterized by physicochemical measurement. The value of the sedimentation constant was 12s and it did not change with the change in pH from 5.4 to 6.8. This was assumed from the fact that the phycoerythrin did not undergo reversible dissociation-association reaction under these conditions. The weight average molecular weight of phycoerythrin was determined to be 2.2×10^5, and the intrinsic viscosity of phycoerythrin was determined to be 2.29×10^{-2} (10^{-1} dm^3/g). From these values, the molecular shape of phycoerythrin was inferred to be globular based on the Scheraga-Mandelkern equation. The SDS-polyacrylamide gel electrophoresis of phycoerythrin showed that the phycoerythrin consisted of two subunits with molecular weights of 3.8×10^4 and 2.3×10^4. The sedimentation behavior of phycoerythrin suggested that the phycoerythrin solution was multicomponent. The phycoerythrin dissociated into two molecular species on treatment with sodium dodecyl sulfate. Their sedimentation constants were 12s and 2s. The 2s species was supposed to be phycoerythrin monomer.

Phycoerythrin, which is found widely in red and blue-green algae, is one of the photosynthetic accessory chromoproteins similar to phycocyanin. The function of phycoerythrin in the algal cell is to harvest the light energy during photosynthesis. The properties of the chromoproteins isolated from various algae have been studied extensively by several researchers in various fields of science.[1-4]

We have reported previously on the physicochemical properties, such as the molecular weight, molecular shape and size, dissociation-association behavior, and on the sedimentation and viscosity behavior of phycocyanin isolated from *Porphyra tenera* or *Porphyra yezoensis*.[5-10] Compared with phycocyanin, the physicochemical properties of phycoerythrin from *Porphyra tenera* or *Porphyra yezoensis* have not been studied as extensively, therefore, some points still remain to be clarified.

In this study, we investigated several characteristic properties of phycoerythrin isolated from *Porphyra yezoensis* based on absoption spectra measurement, sedimentation transportation and equilibrium measurements, viscosity measurements, electrophoresis measurements, and amino acid composition analysis.

Experimental

Sample Preparation. The phycoerythrin used in this study was isolated from the dried red alga, *Porphyra yezoensis*, by repeated precipitation with ammonium sulfate. The procedure was essentially the same as that used for the purification of phycocyanin.[5] The ultraviolet and visible absorption spectra of purified phycoerythrin exhibited characteristic peaks at 280, 497, and 565 nm, as shown in Fig. 1, which was the typical spectrum of phycoerythrin.[11] The ratio of the optical density at 565 nm to that at 280 nm has been used to judge the purity of phycoerythrin: The phycoerythrin which had a ratio of more than 5.0 was considered sufficiently pure.[12] The ratio was 5.0 or greater for the phycoerythrin used in this study. The purified sample was stored in a refrigerator at 5 °C as a precipitate with 40% saturated ammonium sulfate. Prior to use, the sample of phycoerythrin was dissolved in water and dialyzed against a phosphate or acetate buffer at 5 °C. Dialysis was continued for at least 48 h, with an occasional change of the external solution.

Ultracentrifugation. The sedimentation velocity measurements were performed on a Hitachi 282 ultracentrifuge. Double sectorial cells were used for all measurements. The rotor speed was set at 47000 rpm, and the temperature was maintained at 25 °C. Schlieren optics was used for the sedimentation velocity measurement. The Schlieren pattern was taken as a photograph on Fuji medical imaging film type FX. The position of the peak in the Schlieren pattern was measured using a Sinko-12 Projector. The sedimentation constant was calculated by the usual method. Phosphate buffer, pH 6.8 and I(ionic strength) 0.1, and acetate buffer, pH 5.4 and I 0.1, were used as solvents. The sedimentation equilibrium experiments were performed on the same ultracentrifuge apparatus as for the sedimentation velocity measurements. All measurements were made at a given speed for approximately 20 h, so as to ensure that an equilibrium was established in a liquid column of about 3 mm. The rotor speeds were set at approximately 9000—12000 rpm, and a temperature of 25 °C was maintained. Interference optics were used for the sedimentation equilibrium measurement. The interference pattern was taken as a photograph on the same film as was used for photographing the Schlieren pattern. The concentration at a radial distance in the cell was calculated from the concentration difference by the use of the formula

$$\Delta c = \Delta J/K$$

where Δc is the concentration difference, ΔJ the number of fringe counted from the meniscus, K the apparatus constant. The number of fringes were measured using the projector. The value of K was determined from the interference pattern of a phycoerythrin solution of known concentration. The weight average molecular weights were calculated by the usual method. The partial specific volume of phycoerythrin, $\bar{v}$, was calculated after ascertaining the

amino acid composition by the Cohn and Edsall method;[13] it was also calculated from the density of the phycoerythrin solutions which were measured by using the Sibayama Model SS-D-200-EXT precision densimeter at various concentrations of phycoerythrin. The value of 0.73 $cm^3 g^{-1}$ was obtained for the partial specific volume from the amino acid composition as shown in Table 1, and the value of 0.72 $cm^3 g^{-1}$ as the partial specific volume was obtained from the density measurement. These values are similar to the value of 0.73 $cm^3 g^{-1}$ reported by MacColl et al.[12] The value of 0.73 $cm^3 g^{-1}$ was used for the calculation of the molecular weight.

Determination of Concentration. The protein concentrations were determined by weighing the substances which were obtained from the aliquots of protein solution by drying at 105 °C until a constant weight. They were also determined by the semi-micro-Kjeldahl method.

Viscosity Measurement. Viscosity measurements were made for phycoerythrin in phosphate buffer solutions of pH 6.8 and I 0.1, at 25 °C. An Ubbelohde dilution type viscometer with a flow time for water ca. 120 s was used for the measurements.

Acrylamide Disc Gel Electrophoresis. Disc electrophoresis of native phycoerythrin was performed according to the method of Davis.[14] A 0.005 mol dm^{-3} Tris-0.0038 mol dm^{-3} glycine system adjusted to pH 8.3 was used for the running buffer solution. The phycoerythrin sample was applied to 4.5 to 7.0% acrylamide gels with the constant ratio of *N,N'*-methylenebis[acrylamide] to acryamide contents. The gel was calibrated by using the following reference proteins: bovine albumin (molecular weight, M_w, 6.8×10^4), catalase (M_w, 2.4×10^5), and ferritin (M_w, 4.5×10^5).

SDS-Polyacrylamide Gel Electrophoresis. The SDS-polyacrylamide gel electrophoresis procedure of Weber and Osborn[15] was employed to measure the molecular weight of the phycoerythrin subunit. The phycoerythrin sample was incubated overnight at room temperature in a 0.01 mol dm^{-3} phosphate buffer solution with 1% 2-mercaptoethanol. The following proteins were used as molecular weight calibration markers: cytochrome c (M_w, 1.25×10^4), chymotrypsinogen (M_w, 2.5×10^4), trypsin inhibitor (M_w, 2.8×10^4), egg albumin (M_w, 4.5×10^4), bovine serum albumin (M_w, 6.8×10^4).

Amino Acid Analysis. The amino acid analysis of phycoerythrin was performed on a JEOL JLC-6AS amino acid analyzer with a Hokusin Laboratory recorder R140-O-D.

Results and Discussion

The sedimentation velocity pattern of phycoerythrin obtained by using Schlieren optics showed a single boundary in phosphate and acetate buffer solutions, respectively. The plot of the sedimentation coefficient versus the concentration of protein was linear over the concentration region of 0.025—0.44 g/10^{-1} dm^3 as shown in Fig. 2. As is seen in this figure, the sedimentation coefficient did not significantly change despite the change in pH of the solution. The concentration dependence of the sedimentation coefficient was not observed at any of the concentrations that were studied. The sedimentation constant of this protein was determined to be 12.2 s at pH 6.8 and 11.9 s at pH 5.4, respectively. These values were

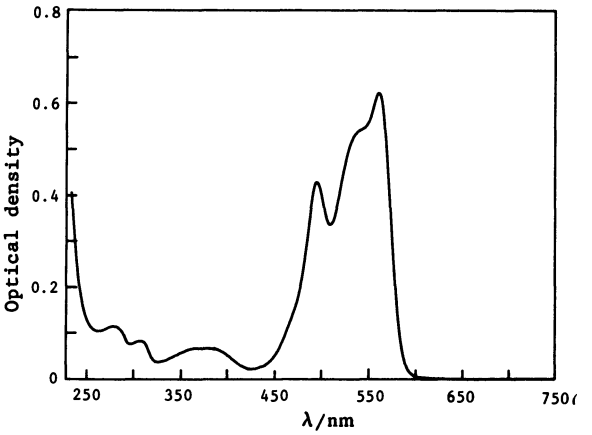

Fig. 1. Typical absorption spectrum of phycoerythrin solution at pH 6.8 and I 0.1.

△: phosphate buffer solution, pH 6.8 and I, 0.1,
○: acetate buffer solution, pH 5.4 and I 0.1.

considered to be almost the same and were in good agreement with the value of 10.8 s for phycocyanin in acetate buffer solutions at pH 5.4 and I 0.1.[5] It is well known that the sedimentation constant of phycocyanin changes with the change in pH of the solution because of the self-dissociation-association reaction.[5,16] Namely, the phycocyanin existed predominantly in the form of a hexamer at pH 5.4, and predominantly in the form of a trimer or tetramer at pH 6.8. The sedimentation constant of the hexamer is 11.3 s, and that of the trimer or tetramer is 6.3 s.[5] Therefore, it seems from the result of this study that the phycoerythrin solution is a single component solution over the pH range of 5.4 to 6.8. The phycoerythrin does not undergo any reversible self-dissociation-association reactions under these pH conditions.

Figure 3 shows the plot of the logarithm of concentration of the protein versus the square of the radial distance in the sedimentation equilibrium cell. It was drawn from the analysis of the sedimentation equilibrium pattern for the phycoerythrin at pH 5.4 and I 0.1. As is clearly seen from the figure, the plot

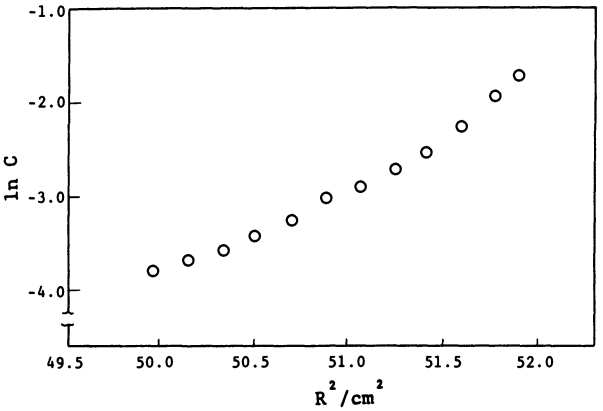

Fig. 3. Plot of the logarithm of concentration versus the square of radial distance in sedimentation equilibrium cell.

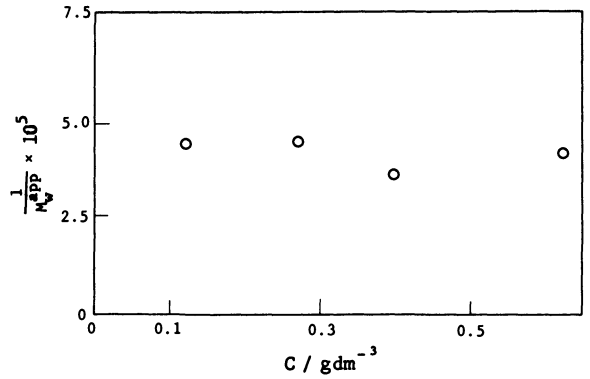

Fig. 4. Plot of the reciprocal of apparent weight average molecular weight versus concentration.

has a curvature. This sedimentation equilibrium behavior means that the phycoerythrin solution is a multicomponent solution at pH 5.4 and I 0.1. This result is inconsistent with that from the sedimentation velocity measurements. It may be reasonable to consider that the minor components in the phycoerythrin solution, probably phycoerythrin monomer and its associated species, were not found in the Schlieren pattern under our experimental conditions because the concentration of these minor components is very low.

Figure 4 shows the plot of the reciprocal of the apparent weight average molecular weight of phycoerythrin, $1/M_w^{app}$, versus concentration. The weight-average molecular weight of phycoerythrin was determined to be 2.2×10^5 from the plot. This value agrees with that reported by Svedberg et al.[1] The second virial coefficient, A_2, was estimated to be 1.1×10^{-5} ($cm^3 mol/g^2$). Therefore, the phycoerythrin solution may be considered to be a pseudo-ideal solution similar to a phycocyanin solution. This property is characteristic of globular proteins.

Figure 5 shows the result of the viscosity measurements for phycoerythrin performed at pH 6.8 and I 0.1. The intrinsic viscosity of phycoerythrin was found

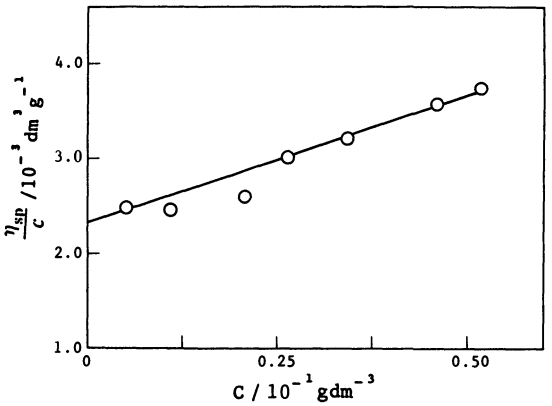

Fig. 5. Plot of the reduced viscosity of phycoerythrin in phosphate buffer versus concentration.

to be 2.29×10^{-2} ($10^{-1} dm^3/g$). Tanford has stated that the values of the intrinsic viscosity of globular proteins lie between 3.3×10^{-2} ($10^{-1} dm^3/g$) and 4.0×10^{-2} ($10^{-1} dm^3/g$) regardless of the molecular weight of the protein.[17] The value of the intrinsic viscosity of phycoerythrin did not differ greatly from that of the globular proteins.

Scheraga and Mandelkern derived the following equation for a revolutional ellipsoid:[18]

$$s_0[\eta]^{1/3} = \frac{M^{2/3}(1-\bar{v}\rho)\beta}{N_A\eta_0}, \quad (1)$$

where s_0 is the sedimentation constant, $[\eta]$ the intrinsic viscosity, M the molecular weight, $\bar{v}$ the partial specific volume of the solute, ρ the density of the solvent, N_A Avogadro's number and η_0 the viscosity of the solvent. The quantity β is a function of the axial ratio of ellipsoid, and has a value of $2.12—2.20\times10^6$ for a prolate ellipsoid when the axial ratio is less than 5.

The β value for the phycoerythrin was calculated to be 2.16×10^6 using Eq. 1. Therefore, it is reasonable to assume from the values of A_2, $[\eta]$, and β, that the phycoerythrin is a globular protein.

Disc gel electrophoresis for phycoerythrin exhibited two bands. The molecular weight of each band was calculated to be 2.3×10^5 and 2.4×10^5 from the calibration plot as shown in Fig. 6. Although the values of the molecular weights of the two bands are nearly the same, the result suggests that the phycoerythrin solution is a multicomponent solution. Also, the result corresponds to the sedimentation equilibrium behavior observed for phycoerythrin in this study. It may be assumed that the appearance of two bands is due to some denaturation occurred during the disc electrophoresis or some difference in their structure. However, these points are not clear.

SDS-polyacrylamide gel electrophoresis for phycoerythrin exhibited two bands, with the molecular weights of 3.8×10^4 and 2.3×10^4 as is shown in Fig. 7. Those molecular weights might correspond to

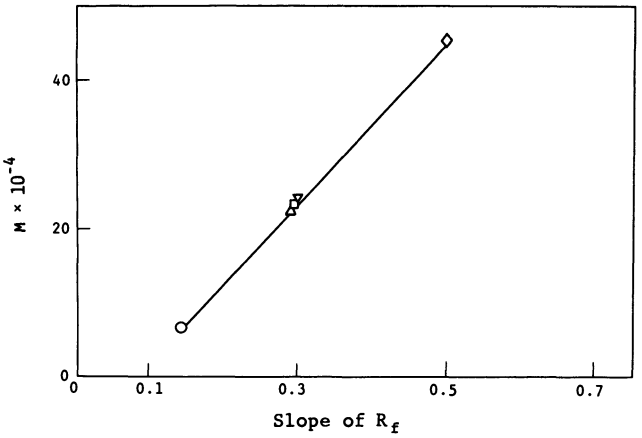

Fig. 6. Molecular weight determination of native phycoerythrin by disc electrophoresis. Three marker proteins used were, bovine serum albumin, catalase and ferritin. All proteins were run on various different concentrations of gel, and the slope (axis of abscissa) was obtained from the plot of the R_f-value versus concentration.

the subunits which have been reported for phycoerythrin from *Porphyridium cruentum* by Glazer et al.[3] O'Carra and Killilea have observed two polypeptides for phycoerythrin from *Phormidium persicinum* by polyacrylamide gel electrophoresis in SDS solution. They suggested that the phycoerythrin existed as a polypeptide dimer composed of two different types of chain with a molecular weight of 1.97×10^4 and 2.20×10^4.[19] MacColl et al. have proposed that the phycoerythrin from *Rhodomonas lens* was composed of two pairs of subunits ($\alpha_2\beta_2$), and the molecular weights of α and β are 9.8×10^3 and 1.7×10^4, respectively.[12] It may be said that the phycoerythrin

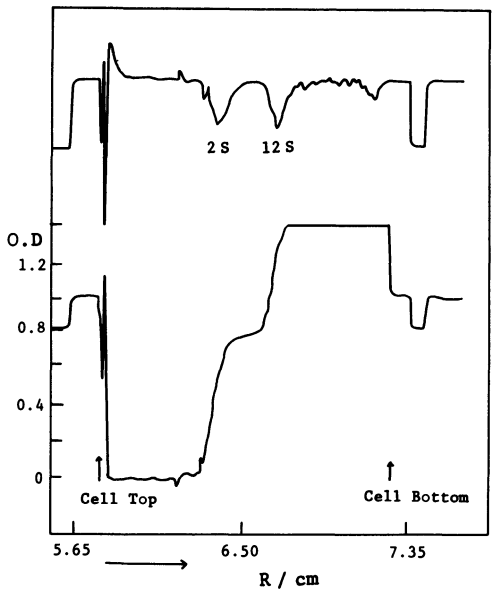

Fig. 8. Absorbance distribution and absorbance gradient distribution corresponding to the concentration distribution in the sedimentation velocity measurement for the denatured phycoerythrin. The curve in the under side and in the upper side represents the absorbance distribution and absorbance gradient distribution, respectively. The abscissa represents the radial distance, R, in the ultracentrifuge cell.

from *Porphyra yezoensis* is composed of two subunits similar to the other phycoerythrin from various different algae.

Figure 8 represents the result of the sedimentation velocity measurement for the denatured phycoerythrin treated with sodium dodecyl sulfate at a concentration of 0.005 mol dm^{-3}. The curves of absorbance distribution (under side) and of its differentiation (upper side) in the ultracentrifuge cell were drawn by the recorder connected with the absorption scanner. In this figure, two boundaries with a sedimentation coefficient of approximately 12 and 2 s were observed for the denatured phycoerythrin. The value of 12 s is close to that of phycoerythrin in the phosphate and acetate buffers obtained in this study. It is supposed that the 12 s component is probably a native phycoerythrin which was not affected by the sodium dodecyl sulfate treatment. It is also supposed that the appearance of the 2 s component can be attributed to the dissociation of the phycoerythrin. The 12 s component may correspond to the band in the disc electrophoresis. Hattori et al. have reported the value of 3.2 s for the phycocyanin monomer.[16] Although the value of 2 s is somewhat lower than that of the phycocyanin monomer, it may be said that the 2 s component corresponds to the phycoerythrin monomer composed of two subunits which appeared in the SDS electrophoresis observed in this study. The 2 s component may expand a little by interaction with the sodium dodecyl sulfate so that the sedimentation velocity decreases.

Thus, it is likely that the phycoerythrin from *Porphyra yezoensis* is a globular protein and its solution is a multicomponent solution although the concentration of the minor component is very low. Phycoerythrin seems to be stable compared with phycocyanin in solution over the pH range of 5.4 to 6.8. Unlike phycocyanin, there is no evidence that phycoerythrin undergoes a reversible self-associating reaction with change of pH from 5.4 to 6.8.

An Electric-Field-Pulse Relaxation Study of the Electron-Donor-Acceptor Complex Formation Involving 7,7,8,8-Tetracyanoquinodimethane Solubilized at the Surfactant Bilayer/Magnetite Particle Interface

Tetsuya IKEDA,* Shoji HARADA, and Tatsuya YASUNAGA
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730
(Received October 11, 1985)

Ultrafine magnetite particle (Fe_3O_4) which adsorbed the 7,7,8,8-tetracyanoquinodimethane (TCNQ)-dioctadecyldimethylammonium bromide (DODAB) bilayer on the surface were prepared in an aqueous solution by sonication. A single relaxation was found by using the electric-field-pulse method and was attributed to the association-dissociation process of the electron-donor-acceptor complexes involving TCNQ solubilized at the DODAB bilayer/magnetite particle interface.

In a previous paper,[1] we have shown that tungstic acid particles incorporated with a dioctadecyldimethylammonium bromide (DODAB) bilayer exhibit unique properties. Surfactants can solubilize various organic materials in the lamellar layer.[2] The kinetic studies of various reactions in the lamellar layer of the vesicles have made a significant contribution to various research fields, e.g., colloid chemistry and photochemistry.[2-5] The surfactants sonicated with the ultrafine particles form a rigid lamellar layer on the dispersed particle surface. In order to understand the dynamic behavior of solubilized molecules and electrons in the lamellar layer of the surfactant, one must study the kinetics of various reactions in the lamellar layer around the ultrafine particles. The ultrafine magnetite particle we chose for such a study is a suitable material, for it has monodispersity and easily adsorbs the surfactant bilayer onto the particle surface.

In this paper, we present our findings on the electric-field-pulse relaxation kinetics of the electron-donor-acceptor complex formation involving TCNQ solubilized at the DODAB bilayer/magnetite particle interface.

Experimental

The 7,7,8,8-tetracyanoquinodimethane (TCNQ) and dioctadecyldimethylammonium bromide (DODAB) were purchased from the Kodak Co.

The ultrafine magnetite particles (Fe_3O_4) were prepared from an aqueous solution containing 1.51 g $FeCl_3$ and 0.64 g $FeCl_2$.[6] During stirring, the pH of the solution was kept in the range of 10—11 by the drop-by-drop addition of 7.5% NH_4OH; the solution was then heated to about 60 °C in a water bath for 15 min. The precipitate was washed several times with distilled water by using the centrifugation of 10000 g for 10 min and was then dispersed in an aqueous solution. The large particles which aggregated were removed by using a membrane filter (pore size, 0.2 μm).

The magnetite particles which adsorbed TCNQ-containing DODAB were prepared as follows. DODAB of 10 mg and the required amount of TCNQ were dispersed in chloroform. After the evaporation of the chloroform, the residue was dispersed in distilled water (10 ml). The turbid suspension was added to the magnetite suspension and was sonicated by a horn-type ultrasonic homogenizer (28 kHz, Choonpa Co.) for 20 min at a temperature of about 60 °C. The magnetite particles are stabilized for a few days by the adsorption of the surfactant bilayer onto the solid surface. The size of the ultrafine magnetite particle studied here is less than 0.2 μm. The values of the pH after the preparation were in the range of 6.5—7. The details of the electric-field-pulse apparatus have been described elsewhere.[7] The transient optical-transmittance change caused by the applied electric field was recorded with a transient recorder. The strength and the length of the electric-square pulse were 20 kV/cm and 25 μs respectively.

The ζ-potential of the magnetite particles incorporating the DODAB bilayer was measured by means of microelectrophoresis method.

The temperature of all the kinetic and spectral experiments was controlled at 25 °C.

Results and Discussion

To make clear the surface character of the present materials, microelectrophoretic measurements were carried out. It was found that the DODAB/magnetite particles which appeared in the microscope field moved toward the negative electrode in the pH range of 3—11. The values of the ζ-potential of the DODAB/magnetite particle system solubilized TCNQ were determined to be 70±3 mV in this pH range. This experimental result shows that no negatively charged particles exist in the basic region. Taking into account the fact that the pH_{zpc} value of the magnetite particle in an aqueous solution is nearly 7, one can see that the negative charge due to the surface functional groups of the magnetite particle is counteracted by the positive DODAB molecule of the bilayer under the present experimental conditions. Furthermore, it is seen that the surface charge may originate from only the DODAB molecule of the bilayer adsorbed on the particle surface or entrapping the particle in the vesicle.

Figure 1 shows the absorption spectrum of the TCNQ–DODAB system incorporating the magnetite particles. In this figure, three absorption bands appear at the wavelengths of 680, 750, and 850 nm, in agreement with those of the anion radical of TCNQ

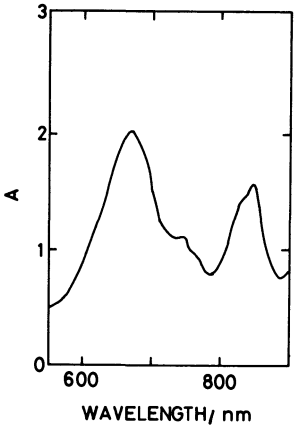

Fig. 1. Electronic absorption spectrum of the DODAB bilayer/magnetite particle system solubilized TCNQ. [TCNQ]=2.95×10^{-5} mol dm^{-3}, [DODAB]=2.54×10^{-3} mol dm^{-3}, particle concentration=0.36 g dm^{-3}, path length=1 cm.

Table 1. Kinetic Data of the Electric-Field Pulse Experiment in the TCNQ-DODAB/Magnetite System at 25 °C[a)]

[TCNQ]	[DODAB]	C_p	τ^{-1}
10^{-5} mol dm^{-3}	10^{-3} mol dm^{-3}	g dm^{-3}	10^4 s^{-1}
0.74	0.63	0.91	9.5±0.5
1.23	0.63	0.91	9.8±0.4
1.23	1.59	2.28	9.2±0.4
1.72	0.63	0.91	10.8±0.1
1.85	1.59	2.28	10.7±0.7

3.08	1.59	2.28	9.8±0.5
4.31	1.59	2.28	11.0±0.5
4.92	2.54	3.64	9.9±0.3
6.89	2.54	3.64	11.1±0.1

a) Each point is the mean value of the five lowest individual determinations. The experimental error stands for the standard deviation.

which have been reported by Melby et al.[8] However, the TCNQ-DODAB system without particles and the TCNQ/magnetite particle system in chloroform do not show the absorption peak at 850 nm. Since TCNQ is insoluble in an aqueous solution, and since the steric hindrance of the DODAB molecule is too large to form an electron-donor-acceptor complex of DODAB with TCNQ in the DODAB bilayer solubilized TCNQ, an electron donor in this system may be the magnetite particles. Thus, one can see that an electron transfer from the magnetite particle to the solubilized TCNQ molecule takes place in the DODAB bilayer adsorbed on the magnetite-particle surface. In this reaction, the DODAB bilayer is not related to the complex formation, but provides only the reaction field.

A single relaxation was observed in the TCNQ-DODAB/magnetite system at the wavelength of 630—650 nm by using the electric-field-pulse method, in which the relaxation signal indicates an increase in the transmittance of the sample solution during the application of the electric field. No relaxation was observed in the aqueous solutions of DODAB-solubilized TCNQ or in the aqueous suspensions of only the DODAB/magnetite system. The value of the relaxation time, τ, in the presence of the electric field is equal to that in the absence of the electric field. The dependences of τ^{-1} on the concentrations of TCNQ and DODAB are given in Table 1. As can be seen from this table, the value of τ^{-1} increases slightly with an increase in concentration of TCNQ. In view of the lack of relaxation in both the DODAB/magnetite and the TCNQ-DODAB systems, it may be suggested that the single relaxation observed relates to an interfacial process at the DODAB bilayer/magnetite particle interface.

The formation of the electron-donor-acceptor complex at the bilayer/particle interface can be written schematically as:

$$(\mathrm{TCNQ})_{\mathrm{bilayer}} + \mathrm{Fe_3O_4} \overset{K}{\rightleftharpoons} (\mathrm{TCNQ^{\cdot-}\cdots Fe_3O_4^{+}})_{\mathrm{bilayer}}, \quad [\mathrm{I}]$$

with:

$$K = \frac{[(\mathrm{TCNQ^{\cdot-}\cdots Fe_3O_4^{+}})_{\mathrm{bilayer}}]}{[\mathrm{Fe_3O_4}][(\mathrm{TCNQ})_{\mathrm{bilayer}}]}, \quad (1)$$

where ( )$_{\mathrm{bilayer}}$ stands for "in the bilayer." TCNQ$^{\cdot-}$ is the anion radical of TCNQ, and K is the equilibrium constant. For the condition $C_P \gg C_{TCNQ}$, one can obtain the following equation:

$$\frac{C_{\mathrm{TCNQ}}}{A_{850}} = \frac{1}{\varepsilon_{850}}\left\{\frac{1}{KC_p}+1\right\}, \quad (2)$$

where C_{TCNQ}, C_P, A_{850}, and ε_{850} are the total concentration of TCNQ, the total concentration of the magnetite particle, the absorbance, and the molar extinction coefficient of the anion radical of TCNQ at the wavelength of 850 nm respectively. The plot of C_{TCNQ}/A_{850} vs. $1/C_P$ yields a straight line, as is shown in Fig. 2a. From the intercept of the straight line, the value of ε_{850} was obtained as 44000. This value is in good agreement with that of 43300 reported by Melby et al.[8] The value of the slope in this plot is close to zero, indicating a very high value for K. Thus, all of the TCNQ molecules form an electron-donor-acceptor complex with magnetite at the interface of the DODAB bilayer.

For the reaction at the interface (Mechanism II),

$$2(\mathrm{TCNQ^{\cdot-}\cdots Fe_3O_4^{+}})_{\mathrm{bilayer}} \underset{k_b}{\overset{k_f}{\rightleftharpoons}} (\mathrm{TCNQ^{\cdot-}\cdots Fe_3O_4^{+}})_{\mathrm{bilayer},2} \quad [\mathrm{II}]$$

the reciprocal relaxation time is written as:

$$(\tau^{-1})^2 = 8k_fk_bC_{\mathrm{TCNQ}} + (k_b)^2. \quad (3)$$

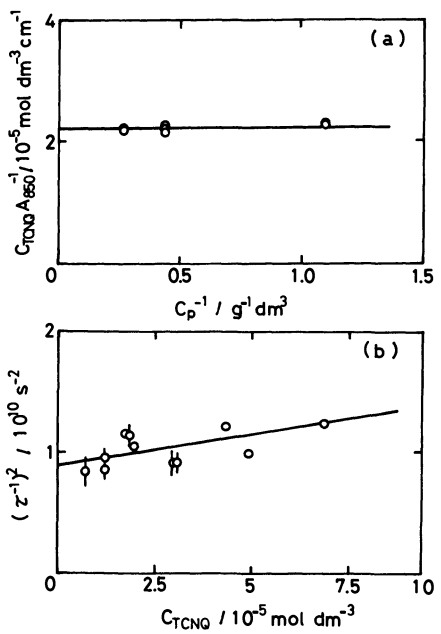

Fig. 2. (a) Plot of C_{TCNQ}/A_{850} vs. $1/C_p$ in Eq. 2. (b) Plot of $(\tau^{-1})^2$ vs. C_{TCNQ} in Eq. 3.

The plot of $(\tau^{-1})^2$ vs. C_{TCNQ}, shown in Fig. 2b, yields a straight line. This linearity leads to the conclusion that the single relaxation phenomenon observed may be attributed to Mechanism II. The values of the rate constants, k_f and k_b, obtained from the values of the slope and the intercept of the straight line in Fig. 2b are as follows: $k_f=6.6\times10^7$ mol^{-1} dm^{3}s^{-1}; $k_b=9.5\times10^4$ s^{-1}. The anion radical of the TCNQ molecule, which has the absorption peak at 850 nm, could not be found in the TCNQ–DODAB system. This fact indicates that it is too hard to form an electron-donor-acceptor complex in the bilayer because of the lack of an electron donor. Since the DODAB bilayer/magnetite particle interface was made by incorporating the particle, we are led to the conclusion that the interface may act as a reaction field for the electron-donor-acceptor complex formation between the magnetite particle and the TCNQ molecule.

The authors are grateful to Professor Z. A. Schelly in the University of Texas at Arlington for his critical reading of the manuscript and for his helpful discussion.

Molecular Motion in $GeCl_4$ as Studied by ^{35}Cl Nuclear Quadrupole Resonance

Hirokazu NAKAYAMA, Nobuo NAKAMURA, and Hideaki CHIHARA*
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received November 12, 1985)

Temperature dependence of ^{35}Cl nuclear quadrupole resonance frequencies and quadrupole relaxation time was measured of $GeCl_4$ in the metastable phase. Above 160 K, molecular reorientation is seen active; its activation energy is 63.5 kJ mol^{-1}. This energy probably prevents $GeCl_4$ from undergoing a rotational phase transition.

Although a series of molecules MCl_4 (M=C, Si, Ge, Sn) are nearly globular assuming Td symmetry in gas phase, they do not solidify into plastic crystal except CCl_4[1] nor undergo any solid-solid phase transitions.[2-4]

In a series of works on the dynamical properties and the stability of plastic crystals, we recognized that $GeCl_4$ shows an interesting thermal behavior: This material was reported to crystallize into two phases, stable and metastable, although the condition of the preparation of each phase has not been established. The stable phase melts at 223.7 K and the metastable phase melts at 221.4 K.[5] In the heat capacity measurements[6] of the so-called metastable phase of this compound an exothermic phenomenon was observed near its melting point which appeared to be a kind of relaxation. This thermal effect may be a manifestation of some phase properties similar to the case of carbon tetrachloride[7] where the metastable cubic phase is transformed into the stable rhombohedral phase spontaneously. Such consideration led us to study of the temperature dependence of the NQR frequencies and of the spin-lattice relaxation times in $GeCl_4$.

Experimental

Commercially available specimen of $GeCl_4$ (Soekawa Chemical Co., Ltd, stated purity 99.999999%) was vacuum distilled and sealed in a glass ampoule with 13 Pa He gas. This sample is of the same origin as that used for the previous heat capacity measurements.[6]

All the measurements were made using a MATEC pulsed spectrometer system by the FT method to determine the frequencies of three closely spaced resonance lines, the error being ±0.2 kHz. The nuclear quadrupolar spin-lattice relaxation time T_1 was measured with the $\pi/2-\tau-\pi/2$ method with an estimated error of ±10 percent.

The temperature dependence was determined by using a simple cryostat with liquid nitrogen as the refrigerant. The temperature was kept constant within ±0.1 K during the measurement and measured with Chromel-P vs. Constantan thermocouples, calibrated against the standard platinum resistance thermometer.

Results and Discussion

In our experiment only one of the two phases reported so far could be obtained by both rapid quenching and slow cooling. The solid samples prepared by different cooling rates gave the same NQR spectrum and their melting points were 221.6 K. Therefore, we identified our specimen as the "metastable phase."

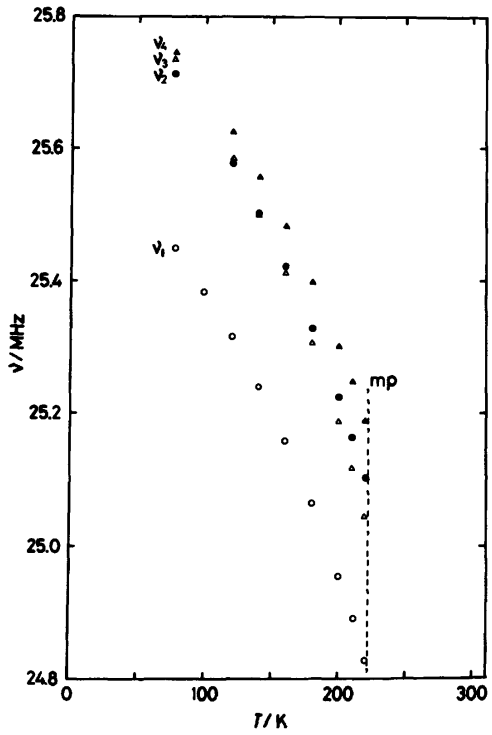

Fig. 1. Temperature dependence of ^{35}Cl NQR frequencies in $GeCl_4$.

Four ^{35}Cl nuclear quadrupole resonance lines were observed at 77 K and their frequencies (ν_1=25.4491 MHz, ν_2=25.7131 MHz, ν_3=25.7356 MHz, ν_4=25.7463 MHz) agree with those reported by S. Sengupta et al.[8] within ±0.2 kHz. Temperature dependence of the resonance frequencies is shown in Fig. 1.

At around 120 K only three resonance signals are observed because of accidental overlap of two of the resonance lines. The NQR signals broadened above 210 K and disappeared just below the melting point. This broadening is induced by the molecular reorientation as will be discussed later.

Because the upper three resonance lines (ν_2, ν_3, and ν_4) occurred in a very narrow frequency range, their spin-lattice relaxation times could not be measured accurately. The temperature dependence of the spin-lattice relaxation time for the lowest resonance line

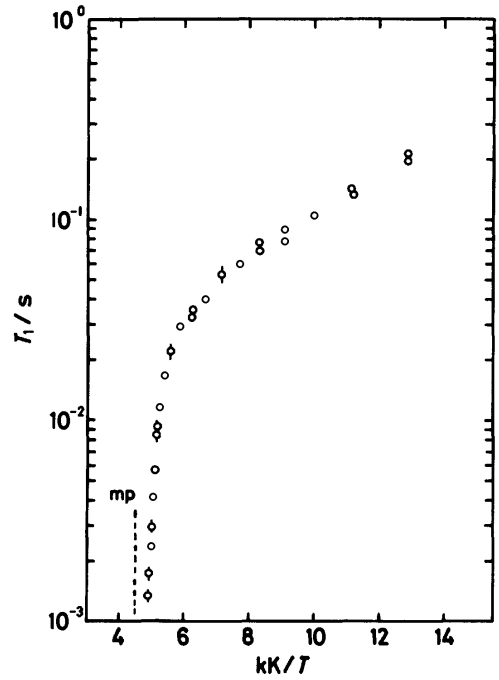

Fig. 2. Temperature dependence of ^{35}Cl spin-lattice relaxation time for the line ν_1 in $GeCl_4$.

(ν_1) is shown in Fig. 2. The plot of the relaxation rate T_1^{-1} vs. T^2 gives a straight line below 160 K, suggesting that the librational motion[9] of $GeCl_4$ molecules governs the spin-lattice relaxation below 160 K. Above 160 K a sharp decrease in the spin-lattice relaxation time was observed due to molecular reorientational motion.[10] The spin-lattice relaxation time T_1 can be reproduced by the expression

$$T_1^{-1}/s^{-1} = 9.77 \cdot 10^{-4} \cdot (T/K)^2 + 1.30 \cdot 10^{19} \exp(-63.5\ kJ\ mol^{-1}/RT). \quad (1)$$

The first term is the contribution of librational motion of the molecule, which is dominant below 160 K. The second term is brought about by the molecular reorientation with the activation energy of 63.5 kJ mol^{-1} and is dominant above 160 K. The correlation time, τ_c, can be related to T_1 by assuming an isotropic sudden jump process between four nearly tetrahedral sites as[10]

$$\tau_c \simeq (3/4) T_1. \quad (2)$$

The τ_c thus obtained is plotted in Fig. 3 as a function of the reciprocal temperature; it gives the pre-exponential factor τ_0 a value of $5.76 \cdot 10^{-20}$ s. The correlation time, τ_c, at the melting point is $5.4 \cdot 10^{-5}$ s.

In globular molecules having tetrahedral or octahedral symmetry, which show plastic phases, the correlation time of the molecular overall reorientation at the brittle-plastic phase transition lies usually in the range between $7 \cdot 10^{-9}$ and 10^{-11} s,[11-14] whereas, τ_c for $GeCl_4$ is as long as 10^{-5} s even at the melting

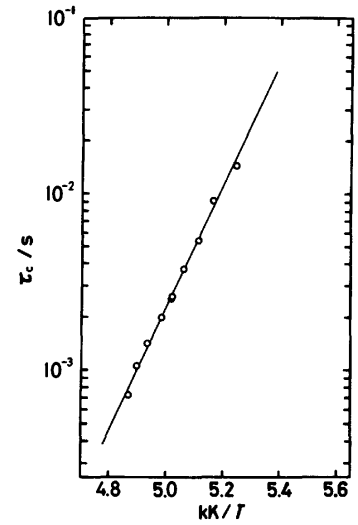

Fig. 3. Temperature dependence of the correlation time for the overall rotation in $GeCl_4$.

point. This fact shows that in $GeCl_4$ the molecular reorientation is not so sufficiently excited that the crystal undergoes a rotational transition to a plastic phase even at the melting point. If we use the empirical relation[15] $E_r = \alpha \cdot R \cdot T_c$ to derive the hypothetical rotational transition point T_c from the rotational activation energy E_r, the rotational transition would not occur until about 1000 K is reached, using $\alpha = 7.5$ for the brittle phase.[15] Although the origin of the very high E_r is not known at the present stage, it prevents the $GeCl_4$ crystal from undergoing a rotational transition despite the fact that the each molecule is globular.

As mentioned in the introduction, an interesting thermal relaxation was observed above 190 K during the heat capacity measurements.[6] Thus, a small but distinct exothermic phenomenon occurs with a time constant of 40 min at 190 K, 2 h at 200 K and 10 h at 210 K. Hence we attempted to detect some effect of such a thermal relaxation phenomenon on the NQR parameters. Because of the very long (≈700 μs) free induction signal and short T_1 (≈1 ms) it was not possible to measure T_1 above 205 K. We, therefore, searched for a possible change of the ^{35}Cl NQR line shape with time: At 200, 205, 210, and 212 K, any variation of the line shape was not detected during twice the thermal time constant in each temperature. The reason why NQR did not see the corresponding anomaly is not apparent at present.

Among MX_4 compounds (M=Si, Ge, Sn; X=halogen), $SnCl_4$[16] and $SnBr_4$[17] show $P2_1/c$ structures with $Z=4$. The unit cell contains four crystallographically inequivalent halogen atoms. These two compounds as well as most of other tetrahalo compounds including $GeCl_4$ give similar NQR spectra, i.e., there are four NQR lines[18,19] of which three higher frequency lines are closely spaced and the lowest frequency line is far removed from the three upper lines. Thus, the NQR

Table 1. Values of the Ratio of Atomic Radii

	F	Cl	Br	I
C	0.24	0.17	0.16	0.14
Si	0.34	0.24	0.22	0.19
Ge	0.45	0.32	0.29	0.26
Sn	0.58	0.41	0.38	0.33

spectrum of $GeCl_4$ suggests strongly that the crystal assumes the crystal structure isomorphous with $SnCl_4$ and $SnBr_4$, i.e., $P2_1/c$. A recent Zeeman NQR study of $GeCl_4$[7] claimed that the metastable phase is orthorhombic with *mmm* or D_{2h} symmetry. Close examination of the result of their Zeeman effect study reveals, however, that the direction cosines of the twelve principal Z axes of the EFG (electric field gradient) could be classified into two sets: The angles between the principal Z axes of equivalent chlorines were calculated to be 124, 140, and 121°, for each set, corresponding to those in $SnBr_4$[16] and $SnCl_4$,[15] i.e., 125, 140, and 125° according to the X-ray structure data. The Zeeman effect data may well be interpreted by the $P2_1/c$ structure if the single crystal used in their experiment happened to have a twin texture.

It is interesting to try to understand why some of the MX_4 molecules form a plastic crystal while others do not. Detailed molecular dynamical calculation will be able to disclose the overall picture but we have discovered an interesting relation between the molecular shape and the crystal structure such as the one that exists among alkali halide crystals.

Table 1 shows values of the ratio of atomic radii[20] $r(M)/r(X)$. The dotted line across the Table separates the regions of the existence of a plastic phase. The limiting radius ratio below which the atom M can fit into the cavity formed by a close-packed tetrahedron of four X atoms is 0.23. Table 1 suggests that if the ratio is larger than 0.24, the molecule does not form a plastic crystal; it is presumably because the interaction between molecular octupoles, which is the lowest possible electric multipole for such a tetrahedral molecule,[21] is then so large that reorientation of molecules can not average the directional character of interaction. Carbon tetrafluoride is an exception to this rule but it is very close to the limiting case. It will be interesting to examine germanium iodide for existence of a plastic phase since it also lies close to the borderline.

The Effect of the Pressure on Proton Jumps in Ethanol-Water Mixtures at 25 °C

Masakatsu UENO,* Kazunori ITO, Noriaki TSUCHIHASHI, and Kiyoshi SHIMIZU
Department of Applied Chemistry, Faculty of Engineering, Doshisha University,
Karasuma Imadegawa, Kamigyo-ku, Kyoto 602
(Received November 13, 1985)

The limiting molar conductances of hydrochloric acid in 0, 5, 10, 20, 30, and 80 mol% ethanol-water mixtures, and those of potassium chloride in 80 mol% of ethanol, were determined at 25 °C as a function of the pressure up to 2000 kgf cm^{-2} (1 kgf cm^{-2}=0.9807×10^5 Pa) from the conductances measured in a dilute concentration range. In each solvent except for 80 mol% of ethanol, the limiting molar conductances of the proton, $\lambda^\circ(H^+)$, are about four to six times larger than those of the potassium ion, $\lambda^\circ(K^+)$, at all the pressures studied; in 80 mol% of ethanol, the value of $\lambda^\circ(H^+)$ is very close to that of $\lambda^\circ(K^+)$ at atmospheric pressure. The results suggest that the proton-jump mechanism acts in the water-rich region, but not in the ethanol-rich region. The excess proton conductances at an infinite dilution, λ°_E, as estimated by $[\lambda^\circ_E=\lambda^\circ(H^+)-\lambda^\circ(K^+)]$, were found to increase with an increase in the pressure. The pressure dependence of the excess proton conductances normalized to their values at 1 atm, $\lambda^\circ_E{}^{(P)}/\lambda^\circ_E{}^{(1)}$, is most prominent in 5 mol% of ethanol; its magnitude decreases in this order; 5>0>10≫20≫30 mol% of ethanol. These results are discussed in relation to the effect of ethanol molecules on the water structure in the mixtures; a small addition of ethanol to water stabilizes the three-dimensional networks of water, while a further addition of ethanol makes it difficult to form them.

The proton is a much better probe than any other usual ion for a study of the solvent structure in hydrogen-bonded solvents, since protons are transferred through the hydrogen-bonded networks in addition to the hydrodynamic migration. In a previous paper,[1] the conductances of HCl and KCl in water were measured at 0 °C as a function of the pressure, and it was found that the excess proton conductance, λ°_E, increases with an increase in the pressure and that the rate of the increase in λ°_E becomes larger with a decrease in the temperature. The lower the temperature, the more significant the water structure. Therefore, the pressure dependence of λ°_E is considered to be closely related to the structural stability of water at atmospheric pressure. The structure of water is dominated by the directional attractive intermolecular potential and is sensitive to any change in pressure or temperature. Another way to change the structure is the introduction of organic molecules into the water. Alcohol-water mixtures have, in particular, attracted many researchers since structural effects appear to be significant in the water-rich region of these mixtures.[2,3] Recently computer experiments on these systems (5 mol% of methanol[4] and 3 mol% of *t*-butyl alcohol[5]) have been carried out, and structural promotion of water has been observed in radial-distribution functions. Accordingly, it seemed that it would be interesting to study the excess proton conductance in compressed alcohol-water mixtures in order to elucidate the influence of alcohol molecules on the water structure. Here, ethanol-water mixtures are used since the physical properties of the mixtures can be used for the analysis of the data on the conductances at high pressures.

Experimental

Chemicals and Solutions. The purification of the water and the ethanol, and the preparation of dilute KCl solutions, were the same as have been described in the previous papers.[6,7] Hydrochloric acid of an ultrapure grade was supplied by Merck. All the dilute solutions of HCl were prepared gravimetrically in a dry box under a nitrogen atmosphere by diluting an aqueous stock solution of HCl [ca. 1×10^{-2} M (1 M=1 mol dm^{-3})] with conductivity water and ethanol. The concentration of the stock solution was determined by measuring the conductance of the solution and by using the empirical equation proposed by Shedlovsky.[8] The concentrations of the dilute HCl soluti ns at each pressure were calculated by using the density of the stock solution at atmospheric pressure and assuming that the

densities of the dilute HCl solutions were equal to that of the solvent. To examine the validity of this assumption, the densities of the aqueous HCl solutions, ρ(HCl), were measured as a function of the concentration at 25 °C and at atmospheric pressure by means of a digital vibrating densimeter (SS-D-200 twin-type) manufactured by the Shibayama Scientific Co., Ltd. The following empirical equation was obtained:

$$\rho(\mathrm{HCl}) = 0.9970_6 + 0.018_1 c, \quad (1)$$

where ρ(HCl) is in g cm^{-3} and where c is the concentration of solution in M. The use of the density of water instead of those of the solutions leads to an increase in the conductances of the dilute HCl solutions of only about 0.02%, indicating that the assumption is not unreasonable.

Apparatus. An acid-proof Teflon cell (capacity, 12 cm^3) with unplatinized electrodes and the glass cell (capacity, 10 cm^3) described in the previous paper[7] were employed, respectively, for the conductance measurements of HCl and KCl aqueous mixtures. As is shown in Fig. 1, the Teflon cell has a membrane thin enough to transmit the oil pressure to the solution in the cell. The cell constants at atmospheric pressure were determined with an accuracy of ±0.03% by using 6×10^{-4}, 1×10^{-3}, 5×10^{-3}, and 1×10^{-2} M aqueous KCl solutions;[9] their values were 0.5592 cm^{-1} for the Teflon cell and 0.3872 cm^{-1} for the glass cell. The cell constant of the glass cell was assumed to be invariant with the pressure. On the other hand, Teflon is compressible, and so the cell constant varies with pressure. Since it is somewhat ambiguous to estimate corrections to the cell constant from the interpolation of the compression data on Teflon,[10] as the phase transition occurs below 2000 kgf cm^{-2} at 25 °C,[11] correction factors as a function of the pressure were determined by comparing the conductances of 2×10^{-3} and 1×10^{-2} M aqueous KCl solutions obtained with the Teflon and glass cells. Table 1 shows the correction factors, $f^{(P)}=K^{(P)}/K^{(1)}$, in which $K^{(P)}$ and $K^{(1)}$ are the cell constant at pressure P and at atmospheric pressure respectively. The values of $f^{(P)}$ determined by this method are smaller than those estimated from the compression data[10] by about 0.5%.

The details of the experimental apparatus and procedure were described in a previous paper.[7]

Results and Discussion

The physical properties of the various solvent mixtures, such as the density, ρ;[12,13] the dielectric constant, ε,[14,15] and the viscosity, η,[16,13,17] used in the present work are collected in Table 2. The molar conductances, Λ, of HCl and KCl in ethanol-water mixtures were determined in the concentration range of (0.6—6)×10^{-3} M for HCl and (2—8)×10^{-4} M for KCl after solvent corrections. The conductance data obtained had a maximum deviation of ±0.1%. The data on the Λ of HCl summarized in Table 3 were analyzed by the Fuoss-Onsager conductance equation for unassociated electrolytes,[18,19] which is expressed thus:

$$\Lambda = \Lambda^\circ - Sc^{1/2} + Ec\log c + Jc, \quad (2)$$

where Λ° is the limiting molar conductance, c is the molar concentration (M), and S, E, and J have the usual meanings. On the other hand, it has been found that KCl is slightly associated in ethanol-water mixtures above 15 mol% of ethanol.[7] Therefore, the Shedlovsky equation:[20]

$$1/\Lambda S(z) = 1/\Lambda^\circ + K_\Lambda c\Lambda S(z) f_\pm^2/\Lambda^{\circ 2}, \quad (3)$$

where:

$$S(z) = \{z/2 + [1+(z/2)^2]^{1/2}\}^2, \quad (4)$$

$$z = [8.204\times 10^5 \Lambda^\circ/(\varepsilon T)^{3/2} + 82.5/\eta(\varepsilon T)^{1/2}] \times (c\Lambda/\Lambda^{\circ 3})^{1/2}, \quad (5)$$

somewhat larger than the literature one,[22] 44.6. The pressure dependence of $\Lambda°$(HCl) in water agrees well with the literature values[23,24] within ±0.1% up to 1500 kgf cm^{-2}, but at 2000 kgf cm^{-2} our value is smaller by (0.3—0.4)% than theirs. No high-pressure data are available for comparison in ethanol-water mixtures, however. As is shown in Table 3, $\Lambda°$(HCl) increases monotonously with an increase in the pressure in 0, 5, and 10 mol% of ethanol, irrespective of the pressure dependence of the solvent viscosity, but in 20 mol% of ethanol and above, $\Lambda°$(HCl) diminishes with an increase in the pressure. The variation in $\Lambda°$(HCl) in each solvent with the pressure is mainly to be ascribed to the pressure dependence of the limiting molar conductance of the proton, as is shown below.

The limiting ionic molar conductances, $\lambda°$, of the proton under the various conditions were determined by using $\Lambda°$(HCl), $\Lambda°$(KCl),[7] and the limiting cation-transference number for KCl, $t°(K^+)$,[6,7] as follows:

$$\lambda°(K^+) = \Lambda°(KCl)t°(K^+), \quad (7)$$

$$\lambda°(Cl^-) = \Lambda°(KCl) - \lambda°(K^+), \quad (8)$$

and:

$$\lambda°(H^+) = \Lambda°(HCl) - \lambda°(Cl^-). \quad (9)$$

The values of $\lambda°(H^+)$ thus obtained are listed in Table 5, together with those of $\lambda°(K^+)$ and $\lambda°(Cl^-)$, in which the values of $\lambda°(K^+)$ and $\lambda°(Cl^-)$ at 2000 kgf cm^{-2} in the mixtures below 30 mol% of ethanol were obtained by expressing the data on $\Lambda°$(KCl) and $t°(K^+)$ up to 1500 kgf cm^{-2} [7] as quadratic equations of pressure. The standard deviations of the empirical equations were (0.01—0.06) conductance units for $\Lambda°$(KCl) and (1—7)×10^{-4} for $t°(K^+)$. No data are available for $t°(K^+)$ in 80 mol% of ethanol except at atmospheric pressure.[25] As is shown in Table 5, the values of $\lambda°(H^+)$ are about four to six times larger than those of $\lambda°(K^+)$ in 5, 10, 20, and 30 mol% of ethanol as well as in water, indicating that the proton-jump mechanism works well in these mixtures and that it dominates the conductance of the proton. However, the value of $\lambda°(H^+)$ is very close to that of $\lambda°(K^+)$ in 80 mol% of ethanol.

The excess proton conductance due to the proton jump, $\lambda°_E$, was estimated thus:

$$\lambda^\circ_E = \lambda^\circ(H^+) - \lambda^\circ(K^+) = \Lambda^\circ(HCl) - \Lambda^\circ(KCl), \quad (10)$$

where the translational mobility of the proton, i.e., the oxonium ion, H_3O^+, is approximated by that of the K^+ ion because of their similarity in size. The values of λ°_E are also shown in Table 5. Here, one problem is whether the protons are present as the oxonium ions in ethanol–water mixtures. The distribution of the protons between water and ethanol molecules for this reaction:

$$C_2H_5OH + H_3O^+ \rightleftharpoons C_2H_5OH_2^+ + H_2O, \quad (11)$$

has been investigated in the ethanol-rich region by the conductivity method[26,27] and by the use of an acid-base indicator[28] at 25 °C and at atmospheric pressure. The equilibrium constant for the reaction, $K=c(EtOH_2^+)c(H_2O)/c(H_3O^+)$, in which c(i) is the concentration of the species i in M, is in the range of (0.052—0.059) M, which indicates that the protons are present almost entirely as H_3O^+ under the experimental conditions studied here; even in 80 mol% of ethanol, the percentage of protons present as $C_2H_5OH_2^+$ is estimated to be below 1.5%. Therefore, it seems reasonable to consider that almost all the protons are transferred from the H_3O^+ ions to water molecules, and that the excess proton conductances reflect the variation in the hydrogen bonds between water molecules with the ethanol content and/or the pressure.

It has been proved that the rotation of hydrogen-bonded water molecules near the H_3O^+ ion is the rate-determining step in the proton-jump mechanism.[29] This mechanism of the proton jump has been confirmed[23] by comparing the pressure dependence of the excess proton conductance with that of the reorientational relaxation time of water molecules derived approximately from the NMR spin-lattice relaxation time;[30] the increase in the excess proton conductance with the pressure has been ascribed to the distortion and weakness of the hydrogen bonds between water molecules caused by the pressure.[1] As is shown in Table 5, λ°_E increases with an increase in the pressure, especially in the water-rich region. Therefore, it can be said that the reorientation of water molecules is promoted by the pressure in the ethanol–water mixtures as well as in water until it becomes retarded by an increase in the number of nearest neighbors.

The values of λ°_E themselves decrease markedly with an increase in the ethanol content at each pressure. Factors responsible for that would be: (i) the reorientation of water molecules becomes slower with an increase in the ethanol content, as is suggested by the dielectric relaxation time measured at atmospheric pressure,[31] and (ii) the fraction of water molecules adjacent to the H_3O^+ ion decreases with an increase in the ethanol content, and consequently the frequency of the proton transfer from the H_3O^+ ion to the water

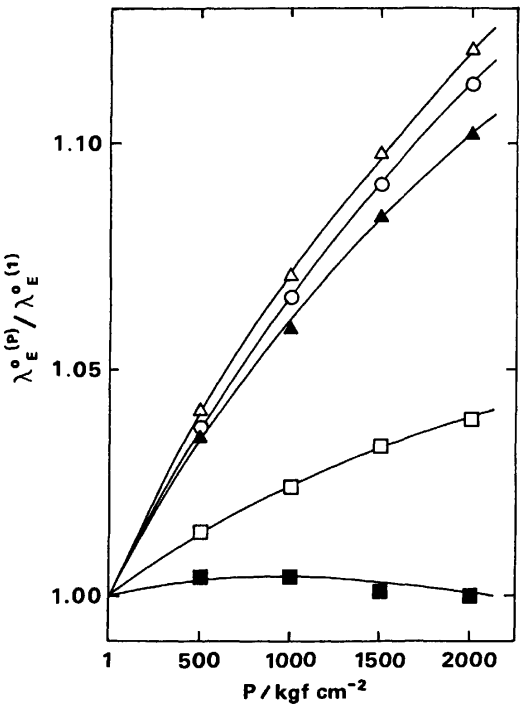

Fig. 2. Excess proton conductances normalized to their values at 1 atm as a function of the pressure. ○: Water, △: 5 mol%, ▲: 10 mol%, □: 20 mol%, ■: 30 mol% of ethanol.

molecules diminishes with an increase in the ethanol content. Thus, the excess proton conductances, normalized to their values at 1 atm, $\lambda^\circ_{E(P)}/\lambda^\circ_{E(1)}$, were calculated in each solvent; they are shown in Fig. 2 as a function of the pressure as a step toward determining the pressure effect on the excess proton conductance for one rotator, i.e., one water molecule adjacent to the H_3O^+ ion. Figure 2 shows that the pressure dependence of $\lambda^\circ_{E(P)}/\lambda^\circ_{E(1)}$ is most prominent in 5 mol% of ethanol and that its magnitude decreases in this order; 5>0>10≫20≫30 mol% of ethanol. It has been found in pure water that the pressure dependence of $\lambda^\circ_{E(P)}/\lambda^\circ_{E(1)}$ becomes larger with a decrease in the temperature.[1,23] Since the hydrogen bonds between water molecules become more stable and are strengthened at lower temperatures because of the weaker thermal motion of water molecules, the water structure is more stabilized and enhanced at lower temperatures. Therefore, it is reasonable to consider that the pressure effect on $\lambda^\circ_{E(P)}/\lambda^\circ_{E(1)}$ is closely related to the structural stability of water: The more stable the hydrogen bonds between water molecules at atmospheric pressure, the more prominent the pressure effect on $\lambda^\circ_{E(P)}/\lambda^\circ_{E(1)}$. If this finding is applied to the results in ethanol–water mixtures, the fact that the pressure dependence of $\lambda^\circ_{E(P)}/\lambda^\circ_{E(1)}$ is larger in 5 mol% of ethanol than in water will confirm the viewpoint that a small addition of ethanol to water stabilizes the three-dimensional networks of water, mainly because of the hydrophobic hydration around the ethyl group.

With an increase in the ethanol content, it seems to become difficult to form stable bonds, as may be seen in 30 mol% of ethanol in Fig. 2. Furthermore, in 80 mol% of ethanol the value of $\lambda^\circ(H^+)$ is close to that of $\lambda^\circ(K^+)$, as has been mentioned above. In this case, the contribution of the proton jump may be very small, and that of the hydrodynamic migration may be dominant. Thus, the increase in the Walden product, $\Lambda^\circ\eta$, of HCl and KCl with the pressure may be explained qualitatively in terms of the dielectric friction theory,[32] described in a previous paper.[7]

The Solvent Effects on the Optical Rotatory Properties of 1,7-Diaryl-5-hydroxy-3-heptanones and Related Compounds

Shinji OHTA
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730
(Received September 17, 1985)

The ORD and CD curves of (*S*)-1,7-diphenyl-5-hydroxy-3-heptanone, (*S*)-1,7-bis(3,4-dimethoxyphenyl)-5-hydroxy-3-heptanone, and the related model compounds were obtained in selected solvents with different polarity. Causing the 1,7-diaryl-5-hydroxy-3-heptanones dextro-rotatory in chloroform was attributed to the formation of the intramolecular hydrogen bond between the C-3 carbonyl and C-5 hydroxyl groups, regardless of the presence of the phenyl groups. On the other hand, causing the compounds levo-rotatory in methanol was proved to necessitate simultaneously the breaking of the intramolecular hydrogen bond followed by solvation to the carbonyl and/or hydroxyl groups, as well as the presence of the phenyl groups. The ca. 30% of the solvent effect on the optical rotation was based on the change in the rotational strength associated with the $n\rightarrow\pi^*$ transition of the carbonyl group as changing a solvent. The residual 70% was based on the change in the rotational strength associated with the electronic transitions at around 200 nm of the carbonyl and/or hydroxyl groups.

Previously, the absolute structures of five diarylheptanoids isolated from *Alnus serrulatoides* Call.[1,2] and one isolated from *A. sieboldiana* Matsum.[3] were elucidated. In the course of the determination of their absolute configuration, the reversal in the sense of the optical rotation was observed for 1,7-diaryl-5-hydroxy-3-heptanones, such as (*S*)-1,7-diphenyl-5-hydroxy-3-heptanone (**1**)[3] and (*S*)-1,7-bis(3,4-dimethoxyphenyl)-5-hydroxy-3-heptanone (**2**),[1,2] when their optical rotations were measured in the selected solvents, such as chloroform and methanol, with different polarity. The reversal in the sense of the optical rotation is also reported for some natural compounds.[4,5] However, causes for this phenomenon have not been solved yet. In this paper, the author wishes to describe the solvent effects on the optical rotatory properties of the 1,7-diaryl-5-hydroxy-3-heptanones and related compounds. The results are in part outlined in the form of a preliminary communication.[6]

Results and Discussion

The compounds **1** and **2** were dextro-rotatory in chloroform and levo-rotatory in methanol, while their acetates **3** and **4** were dextro-rotatory in both of the solvents (Table 1). These observations suggest that the interaction between the solvent and the β-ketol moiety of the compounds **1** and **2** is responsible for the reversal in the sense of their optical rotations.

The Relationships between the Molecular Rotations

of the Compounds 1 and 2 and Solvatochromic Parameters. The effect of the solvents on the optical rotation of the compounds **1** and **2** were examined by a solvatochromic comparison method[7] with the solvents (a)—(m) given in Table 2. The molecular rotations $[M]_D$ of the compounds **1** and **2** in these solvents were independent of the concentration (0.005—0.1 mol dm^{-3}) and truly constant. The relationship between the $[M]_D$ of the compound **1** (Table 2) and the solvatochromic parameters π^*, α, and β[†] was represented by the following least-squares regression equation,

$$[M]_D=49.6-k_1(65.7\pi^*+14.1\alpha+9.7\beta).$$

A plot of $[M]_D$ vs. $65.7\pi^*+14.1\alpha+9.7\beta$ is shown in Fig. 1, and the constant k_1 was 0.2 for the solvents (a)—(e) and 1.0 for the solvents (f)—(m). Separate correlation lines were observed for the individual solvent families. The similar facts were observed for the compound **2**. The relationship between the $[M]_D$ of the compound **2** (Table 2) and the solvatochromic parameters was represented by the following equation,

$$[M]_D=50.9-k_2(64.4\pi^*+17.2\alpha+10.7\beta).$$

A plot of $[M]_D$ vs. $64.4\pi^*+17.2\alpha+10.7\beta$ is shown in Fig. 2, and the constant k_2 was 0.1 for the solvents (a)—(e) and 1.0 for the solvents (f)—(m). The $[M]_D$ of the both compounds was dextro-rotatory in the solvents (a)—(e). The β values are very small (0—0.11)[7] for the solvents (a)—(e). Thus, the ability of the solvents to accept the proton from the C-5 hydroxyl group of the compounds **1** and **2** is so small that there is a fair chance of the formation of the intramolecular hydrogen bond between the C-3 carbonyl and C-5 hydroxyl groups in such solvents. On the other hand, the $[M]_D$ obtained in the solvents (f)—(m) changed from dextro-rotatory to levo-rotatory with the change in the values of the solvatochromic parameters. The β values for the solvents (f)—(m) are 0.31—0.95[7] and higher than those for the solvents (a)—(e). In the solvents (f)—(m), therefore, the proton of the C-5 hydroxyl group of the compounds **1** and **2** is strongly attracted to the solvent molecules. Accordingly, there is a fair possibility of the breaking of the intramolecular hydrogen bond in the solvents (f)—(m). Therefore, the variation in the $[M]_D$ of the compounds **1** and **2** in the solvents (f)—(m) can be attributed to the solvation to the β-ketol moiety. The relative contribution of each solvent property to the $[M]_D$ of the compounds **1** and **2** was estimated by the method described in the literature.[8] The relative contributions of the π^*, α, and β were 67, 20, and 13%, respectively, for the compound **1**, and 65, 22, and 13%, respectively, for the compound **2**. The superiority of the contribution of the π^* indicates a great contribution of the ability of the solvents to stabilize the dipole[7] of the compounds **1** and **2** to the variation in the $[M]_D$ of the compounds in the solvents (f)—(m). So, the fact that the compounds **1** and **2** were dextro-rotatory in the solvents (f), (g), and (h) could be rationalized in terms of the very weak interaction of these solvents to the β-ketol moiety of the compounds **1** and **2**. Such a solute/solvent interaction is weakened by the formation of the intramolecular hydrogen bond between the carbonyl and hydroxyl groups. Thus, the variation in the $[M]_D$ of the compounds **1** and **2** is minimized in the solvents (a)—(e).

The Formation and Breaking of the Intramolecular Hydrogen Bond. A more definite study for demonstrating the formation and breaking of the intramo-

[†] π^*, α, and β are a measure of solvent dipolarity/polarizability, that of solvent hydrogen bond donor acidity, and that of solvent hydrogen bond acceptor basicity, respectively.[7]

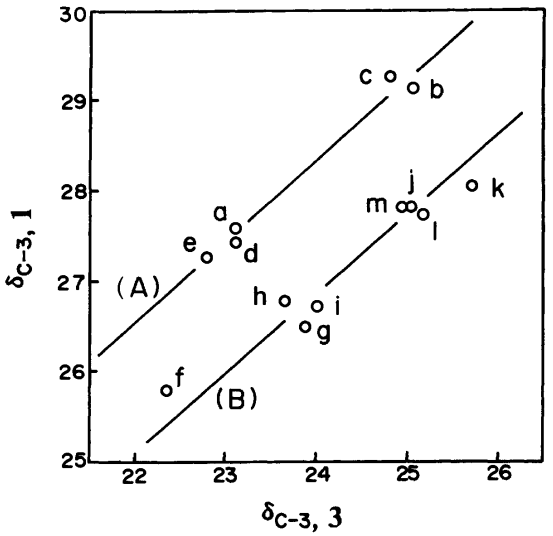

Fig. 3. A plot of δ_{C-3} for 1 vs. δ_{C-3} for **3** in the selected solvents (ppm with respect to an external reference of $CH_3{}^{13}CO_2Na$). For the symbols of the data points, see Table 2.

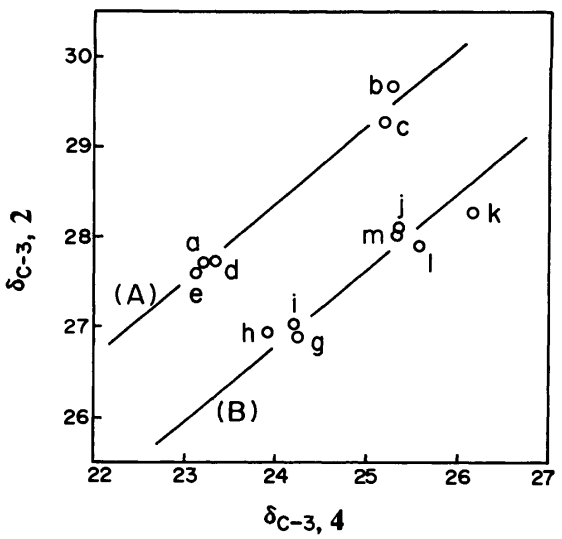

Fig. 4. A plot of δ_{C-3} for **2** vs. δ_{C-3} for **4** in the selected solvents (ppm with respect to an external reference of $CH_3{}^{13}CO_2Na$). For the symbols of the data points, see Table 2.

lecular hydrogen bond in the compounds **1** and **2** was carried out by a combination of IR and ^{13}CNMR spectroscopies. The IR spectra of the compounds **1** and **2** in carbon tetrachloride exhibited the presence of an intramolecular hydrogen-bonded OH absorption band at 3556 and 3563 cm^{-1}, respectively, which were independent of the concentration (0.005—0.1 mol dm^{-3}). Figure 3 shows the relation of the ^{13}CNMR chemical shift (Table 2) between the C-3 carbonyl carbons of the compound **1** and its acetate (**3**) in the solvents (a)—(m). The data points for the solvents (a)—(e) and the solvents (f)—(m) are situated along by lines (A) and (B), respectively. The line (A) is shifted by ca. 1.5 ppm to a lower field, compared with the line (B). The similar relation was also found for the compound **2** and its acetate (**4**) as shown in Fig. 4. These lower-field shifts[9] indicate clearly the formation of the intramolecular hydrogen bond between the C-3 carbonyl and C-5 hydroxyl groups in the solvents (a)—(e) and the formation of the intermolecular hydrogen bond between the solvent and the β-ketol group in the solvents (f)—(m). It was thus confirmed that the formation of the intramolecular hydrogen bond between the C-3 carbonyl and C-5 hydroxyl groups causes the compounds **1** and **2** dextro-rotatory in the solvents (a)—(e), while the breaking of the intramolecular hydrogen bond followed by the solvation to the β-ketol moiety causes the compounds **1** and **2** levo-rotatory in the solvents (i)—(m).

The Roles of the β-Ketol Moiety and the Phenyl Groups. The participation of the β-ketol moiety and the phenyl groups in determining the sense of the optical rotation cannot be ignored, and this was examined with the model compounds, such as (*S*)-6-hydroxy-4-nonanone (**5**), (*R*)-1,7-diphenyl-3-heptanol (**6**), (*R*)-1,7-bis(3,4-dimethoxyphenyl)-3-heptanol (**7**), and (*S*)-4-nonanol (**8**) by means of ORD measurements. Figure 5 shows the ORD curves of the compounds **1**, **2**, and **5**—**8** in chloroform and methanol. The ORD curves of the compounds **1**, **2**, and **5** showed the solvent dependence, whereas the curves of the compounds **6**—**8** were not the case. This finding indicates the indispensability of the β-ketol moiety for occurrence of the solvent effect on the optical rotation. On the other hand, the compounds **6** and **7** were levo-rotatory in 400—600 nm in chloroform and methanol, while the compound **8** was dextro-rotatory in these solvents. This fact indicates unambiguously that, in addition to the breaking of the hydrogen bond followed by the solvation, the presence of the phenyl groups in the molecules of the compounds **1**, **2**, **6**, and **7** is essential for the appearance of levo-rotation.

The Conformational Analysis in the β-Ketol Moiety. The variations in the optical rotation are presumably caused by the conformational changes in the β-ketol moiety; the conformational changes are associated with the formation and breaking of the intramolecular hydrogen bond and with the solvational effect. Such conformational changes should be effectively analyzed by means of CD measurement. The CD curves of the compound **1** in the selected solvents were shown in Fig. 6. These CD curves are complicated, because of the overlapping of the CD bands associated with the electronic transitions of the carbonyl and phenyl groups. So, the CD spectra of the model compounds **5** and **6** were examined and shown in Fig. 6. The CD curves of the compound **5** showed remarkable changes as changing the solvent, while the compound **6** showed solvent independent, negative CD maxima at 263—265 and 257—259 nm. These observations indicate that the CD maxima at 263—

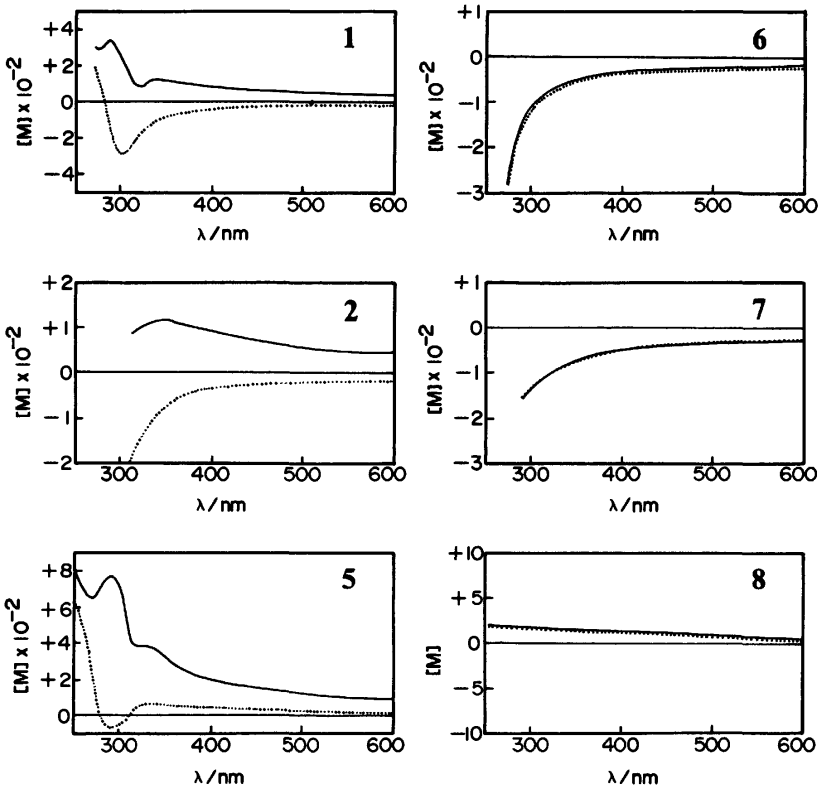

Fig. 5. ORD curves of 1, 2, and 5—8: —— in chloroform, ------ in methanol.

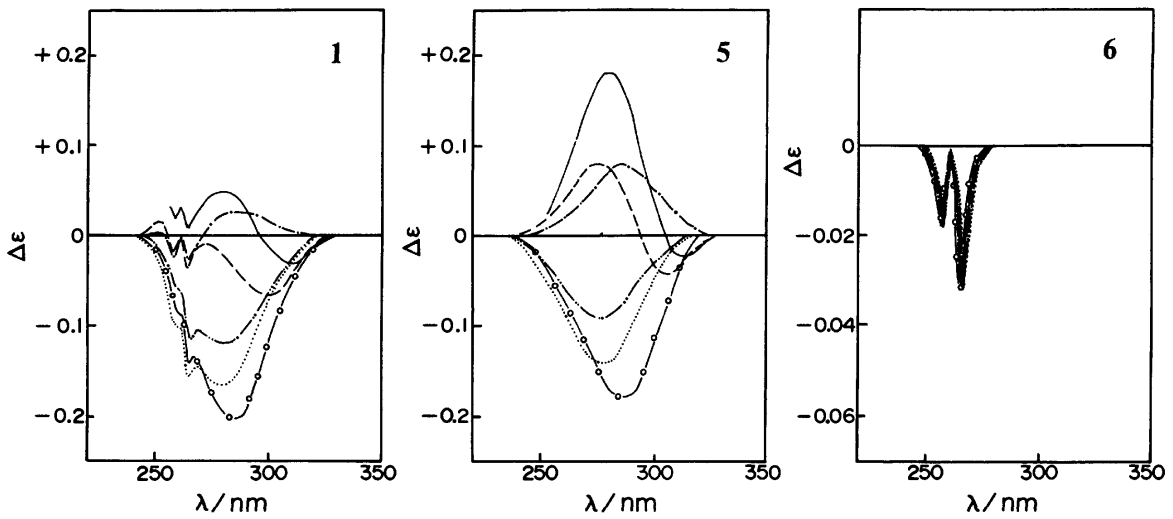

Fig. 6. CD curves of 1, 5, and 6: — in carbon tetrachloride (a), —— in chloroform (b), —·—· in diethyl ether (f), —··—·· in dioxane (g), —o—o in acetonitrile (j), ····· in methanol (k).

265 and 257—259 nm in the compound **1** are associated with the phenyl $\pi \rightarrow \pi^*$ transition and the other CD maxima with the carbonyl $n \rightarrow \pi^*$ transition, only the latter CD maxima vary as changing the solvent. This indication was supported by the good fit between the CD curve of the compound **5** and the CD curve obtained by subtracting the CD curve of the compound **6** from that of the compound **1** in each solvent.

So, the conformational analysis was performed for the compound **5** as follows. The formation of the intramolecular hydrogen bond in the solvents (a) and (b) and the breaking in the solvents (f), (g), (j), and (k) were confirmed by a combination of the IR and ^{13}CNMR spectroscopies. The values for conformational energy differences in the compound **5** were estimated by a semiempirical molecular orbital calculation based upon the CNDO/2 approximation. When the intramolecular hydrogen bond is broken, this compound seems to prefer the eclipsed conformation of the carbonyl and α-alkyl groups. Such a conformation is known to be a predominant one for acyclic carbonyl compounds.[10,11] Thus, three confor-

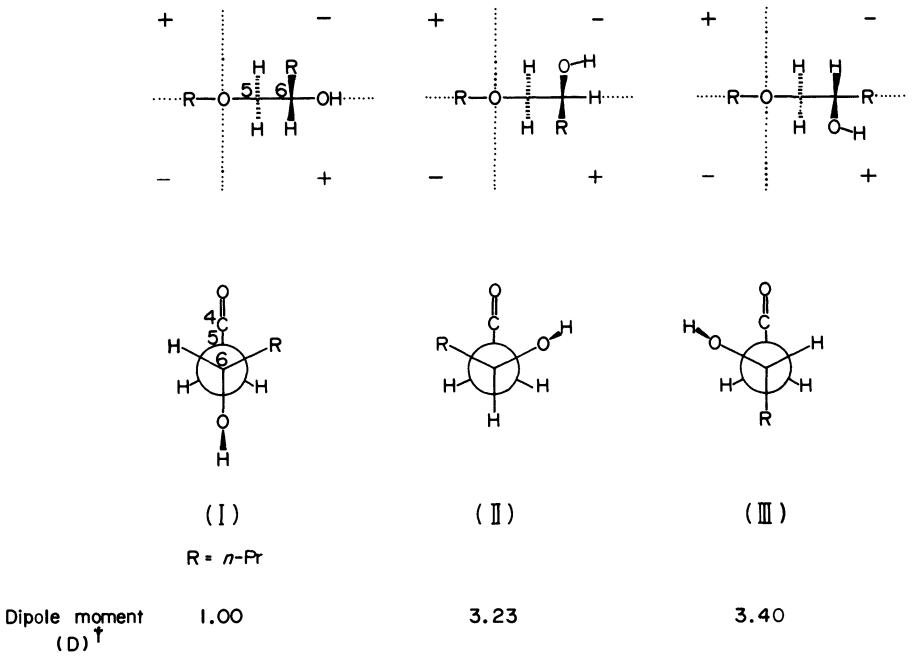

Fig. 7. Conformational isomers of **5** in the case that the intramolecular hydrogen bond is broken.
† 1 D=3.335×10^{-30} C m.

mational isomers(I)—(III) with respect to the C(5)–C(6) bond could be considered as stable ones, as illustrated in Fig. 7. The conformer(I) having the hydroxyl group in the trans position with respect to the carbonyl bond is 0.4 and 0.7 kcal mol^{-1}†† more stable than the conformers(II) and (III) having the gauche hydroxyl group, respectively. The signs for the Cotton effect of the conformers(I) and (III) can be predicted to be positive and negative, respectively, by assuming that the alkyl group R in the conformer(I) and the hydroxyl group in the conformer(III) fall into the front octants as shown in Fig. 7. For the conformer(II), its Cotton effect is predicted to be nearly nil. Hence, the Cotton effect of the compound **5** should be positive in the isolated state when the intramolecular hydrogen bond is broken. This predicted sign for the Cotton effect is in agreement with the sign observed in the solvent (f) as shown in Fig. 6. So, the positive CD band observed in the solvent (f) can be attributed to the conformer(I). However, the negative Cotton effect was observed in the solvents (g), (j), and (k). Since the conformers(II) and (III) are more dipolar than the conformer(I) as shown in Fig. 7, the relative stabilities of the conformers(II) and (III) are predicted to be enhanced by the strong solvational effect in solution.[12] Therefore, the negative CD band is expected to be attributed to the conformer(III) stabilized by the solvational energies. On the other hand, the conformer(IV) is the most predominant one in the case that the intramolecular hydrogen bond between the carbonyl and hydroxyl groups is formed as shown in Fig. 8. The conformer(IV) is 3.9 kcal mol^{-1} more

†† 1 cal=4.184 J.

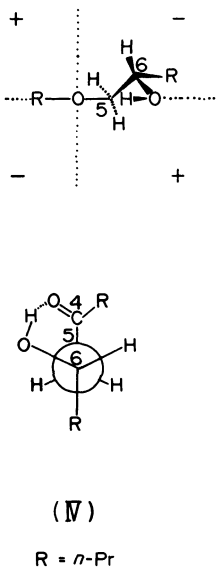

Fig. 8. The most stable conformation of **5** in the case that the intramolecular hydrogen bond is formed.

stable than the conformer(I). In the conformer(IV), the hydroxyl group is coplanar to the carbonyl one. The positive CD band at shorter wavelength in the solvents (a) and (b) can be attributed to the conformer(IV), while the negative one at longer wavelength is presumably attributed to the conformer(III) which is stabilized by the large solvational energies.

Accordingly, there is the conformational equilibrium between the intramolecularly hydrogen-bonded and solvated forms in the solvents (a) and (b), and the former hydrogen-bonded form is predominant. On the other hand, there is the conformational equi-

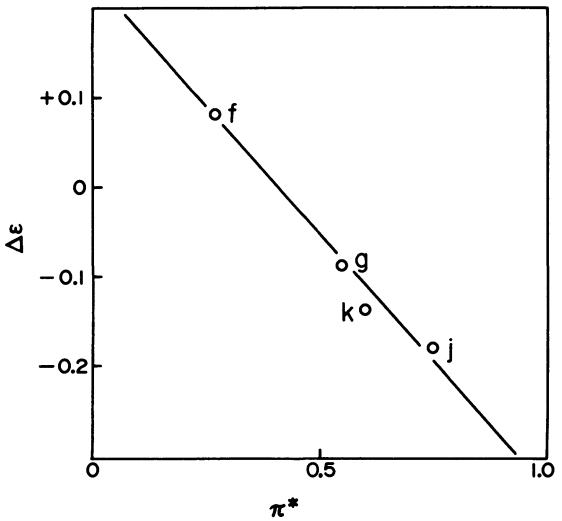

Fig. 9. A plot of CD maximum ($\Delta\varepsilon$) for **5** vs. π^* in the selected solvents. For the symbols of the data points, see Table 2.

librium among the three solvated forms in the solvents (f), (g), (j), and (k). This conformational equilibrium is dominated by the solvational effect, which is supported by the existence of a good correlation between the CD maximum ($\Delta\varepsilon$) and the solvatochromic parameter π^* as shown in Fig. 9. These results were also the case for the compound **1**.

The Contribution of the Carbonyl n→π* Cotton Effect to the Molecular Rotation. The contribution of the Cotton effect associated with the n→π* transition of a carbonyl chromophore to the molecular rotation was calculated by a simplified Kronig-Kramer's equation.[13,14] When a CD band of the compound **1** overlapped with a benzenoid band of the phenyl group, Gaussian band associated with an only n→π* transition of the carbonyl group was obtained by a graphic method. The relationships between the contribution to the molecular rotation, $[M]_D$(n→π* component), and the observed molecular rotation, $[M]_D$(obsd), were obtained for the compounds **1** and **5** in the selected solvents (a), (b), (f), (g), (j), and (k). As shown in Fig. 10, the $[M]_D$(n→π* component) was correlated with the $[M]_D$(obsd) for both the compounds. The slope of the correlation line represents the contribution of the solvent effect on the Cotton effect to the solvent effect on the molecular rotation. Both the slopes for the compounds **1** and **5** were ca. 0.3. Accordingly, ca. 30% of the solvent effect on the molecular rotations of these β-hydroxy ketones is found to be based on the solvent effect on the Cotton effect associated with the n→π* transition of the carbonyl group. The residual 70% of the solvent effect on the molecular rotation was probably based on the solvent effect on the Cotton effect at shorter wavelength (below 230 nm) associated with the electronic transitions of the carbonyl and/or hydroxyl groups. Here, it is noted that the deviation in the correlation is too large to be ignored, as shown in Fig. 10. This deviation might be

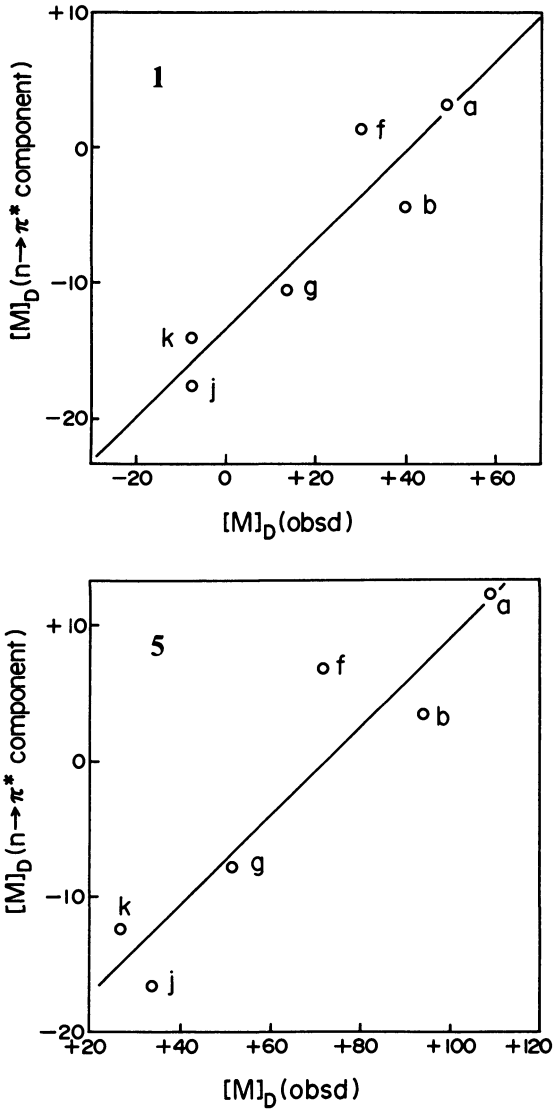

Fig. 10. A plot of $[M]_D$(n→π* component) vs. $[M]_D$(obsd) for **1** and **5**. For the symbols of the data points, see Table 2.

due to the difference in the nature between the solvent effect on the Cotton effect at 280 nm and that on the Cotton effect below 230 nm.

The Wavelength of the Cotton Effect below 230 nm. Since there is a good correlation between the $[M]_D$ of the compound **1** and that of the compound **5** in the selected solvents (a), (b), (f), (g), (j), and (k), the Cotton effect below 230 nm was examined for the compound **5** free of the phenyl group, instead of the compound **1**. The wavelength (λc) of the Cotton effect below 230 nm was calculated by use of a one-term Drude equation[15] as follows. The ORD data, [M(λ)](dif), used in the Drude analysis were derived from the difference between the observed ORD data, [M(λ)](obsd), and the contribution of the carbonyl n→π* Cotton effect to the molecular rotation, [M(λ)](n→π* component), in both chloroform and methanol. The [M(λ)](n→π* component) were calculated by use of the simplified Kronig-Kramer's equation described above. The [M(λ)]-

(dif) in the wavelength region of 340 to 600 nm were used for the calculation, because the compound **5** showed a plain ORD curve in the region in both the solvents. When the λc was assumed to be 200±10 nm, the [M(λ)](dif) from 340 to 600 nm fit the one-term Drude equation well in both chloroform and methanol. This suggests that a strong Cotton effect presents at around 200 nm, and the solvent effect on the Cotton effect largely affects the solvent effect on the optical rotation at sodium-D line. This CD band will probably correspond to carbonyl and/or hydroxyl CD bands at 185—200 nm.[16,17] The similar results is expected for the compound **1**, because there is the good correlation between $[M]_D$ of the compound **1** and that of the compound **5** as mentioned above.

In conclusion, it was found that causing the 1,7-diaryl-5-hydroxy-3-heptanones dextro-rotatory in chloroform was attributed to the formation of the intramolecular hydrogen bond between the C-3 carbonyl and C-5 hydroxyl groups in the molecules, and the presence of the phenyl groups did not affect the determination of the sense of their optical rotations. On the other hand, causing the compounds levo-rotatory in methanol was proved to be attributed to the breaking of the intramolecular hydrogen bond followed by solvation to the carbonyl and/or hydroxyl groups, as well as the presence of the phenyl groups. The ca. 30% of the solvent effect on the optical rotation is based on the change in the rotational strength associated with the $n\rightarrow\pi^*$ transition of the carbonyl group as changing a solvent. This change is caused by the conformational equilibrium. The formation and breaking of the intramolecular hydrogen bond is dominated by the ability of the solvents to accept the proton from the C-5 hydroxyl group of the compounds. When the intramolecular hydrogen bond is broken, the conformation of the compounds is dominated by the dielectric effect of the solvents. The residual 70% of the solvent effect on the optical rotation is based on the change in the rotational strength associated with the electronic transitions at around 200 nm of the carbonyl and/or hydroxyl groups.

Experimental

General. The ^{1}H NMR spectra were obtained on a Hitachi R-600 FT NMR (60 MHz) spectrometer using TMS as an internal standard. The ^{13}C NMR spectra were obtained on a Hitachi R-42 FT NMR (22.6 MHz) spectrometer. Tris[3-(2,2,2-trifluoro-1-hydroxyethylidene)-*d*-camphorato]europium [Eu(tfc)$_3$] was obtained from Merck. The mass spectra were obtained on a Shimadzu QP-1000 spectrometer with an EI ion source at 70 eV and a CI ion source with isobutane. The analytical GLC was carried out with a Shimadzu GC-6A gas chromatograph using a glass column (3 mm×2 m) packed with 2% OV-17 on Chromosorb W (AW-DMCS; 80—100 mesh). The optical rotation was measured with a JASCO DIP-360 digital polarimeter, using a 1.0-dm cell. The CD spectra were recorded on a JASCO J-40 spectropolarimeter. The ORD curves were recorded on a JASCO ORD/UV-5 spectropolarimeter at 25 °C in a quartz cell of 1.0-cm path length. The UV spectra were obtained on a Shimadzu UV-240 spectrometer. Solvents were either spectrophotometric grade or distilled immediately before use.

(*S*)-6-Hydroxy-4-nonanone (5). Into a slurry of pyridinium chlorochromate (710 mg) in 10 cm^3 of dry dichloromethane, (4*S*,6*S*)-4,6-nonanediol (506 mg) (see below) dissolved in 10 cm^3 of dry dichloromethane was added all at once, after which the mixture was kept for 3 h with stirring at room temperature. The reaction mixture was then added to dry diethyl ether (30 cm^3), and the resulting slurry was kept for another hour under stirring. The slurry was then passed through a column packed with 20 g of Florisil, and the eluate was concentrated under a reduced pressure at room temperature. The condensate was purified on a silica-gel column with diethyl ether–hexane (1:4) and then distilled at 88 °C (bath temperature) at 5 Torr (1 Torr=133.322 Pa) through a short-path distillation apparatus to afford **5** (313 mg, 63%) as colorless oil: $[\alpha]_D^{25}$ +59.3±0.5° (*c* 0.39, chloroform); $[\alpha]_D^{25}$ +16.9±0.5° (*c* 0.40, methanol); IR (neat) 3420 (OH) and 1705 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=0.92 (6H, t, *J*=7 Hz, Me×2), 1.23—1.90 (6H, m, >CH_2×3), 2.29—2.57 (4H, m, >CH_2×2), 3.04 (1H, brs, OH), and 4.04 (1H, m, >C<u>H</u>OH); EI-MS *m/z* (rel intensity) 140 (2, M^+-H_2O), 115 (14), 97 (10), 71 (65), and 43 (100); CI-MS *m/z* (rel intensity) 159 (62, M^++H) and 141 (100, M^+-H_2O+H). The GLC (90 °C) showed a single peak (retention time 16 min). The optical purity of **5** was determined by measuring the ^{1}H NMR with a soln of its acetate (5 mg) and Eu(tfc)$_3$ (3 molar equivalents to the acetate) in $CDCl_3$ (0.4 cm^3). The acetate showed no detectable signal of the enantiomer.

Preparation of (4*S*,6*S*)-4,6-Nonanediol. 4,6-Nonanedione (5.96 g), prepared from methyl butyrate and 2-pentanone by the method previously reported,[18] was hydrogenated with an asymmetrically modified Raney nickel [(*S*,*S*)-TA-NaBr-MRNi][19,20] followed by crystallization from hexane to afford (4*S*,6*S*)-4,6-nonanediol (1.04 g, 17%) as colorless needles: mp 52—53 °C (lit,[20] 58—59 °C); $[\alpha]_D^{25}$ +20.5±0.2° (*c* 10, ethanol) (lit,[20] $[\alpha]_D^{20}$ +21.2°); IR (KBr) 3340 cm^{-1} (OH); ^{1}H NMR ($CDCl_3$) δ=0.74—1.12 (6H, m, Me×2), 1.18—1.68 (10H, m, >CH_2×5), 2.50—2.67 (2H, br, OH×2), 3.93 (2H, m, >C<u>H</u>OH×2); EI-MS *m/z* (rel intensity) 117 (16, M^+-43), 99 (35), 81 (83), and 73 (100); CI-MS *m/z* (rel intensity) 161 (17, M^++H), 160 (14, M^+), 143 (27, M^+-H_2O+H), and 125 (100, M^+-2H_2O+H). Found: C, 67.65; H, 12.76%. Calcd for $C_9H_{20}O_2$: C, 67.45; H, 12.58%. The GLC (120 °C) showed a single peak (retention time 8 min).

(*R*)-1,7-Diphenyl-3-heptanol (6). A solution of *p*-toluenesulfonyl chloride (220 mg) in dry pyridine (3 cm^3) was added to a solution of (3*S*,5*S*)-1,7-diphenyl-3,5-heptanediol (300 mg), prepared as shown below, in dry pyridine at 0 °C. The solution was allowed to stand at 4 °C for 3 d, poured into ice-cold 5% HCl, and then extracted with diethyl ether. The solution was washed with cold 5% HCl, 5% $NaHCO_3$, and saturated NaCl solutions, successively, and then dried over Na_2SO_4 followed by concentration in vacuo. The tosylate obtained was used for the next preparation without further purification. A solution of the optically active tosylate in dry THF (20 cm^3) was added to a slurry of $LiAlH_4$ (0.5 g) in dry THF (10 cm^3). The mixture was then heated under reflux for 5 h. An excess of $LiAlH_4$ was decomposed with a solution of methanol in diethyl ether and then 5% HCl.

The mixture was extracted with diethyl ether. The diethyl ether solution was washed with 5% HCl and saturated NaCl solutions, successively, and then dried (Na_2SO_4) followed by concentration in vacuo. The residue was purified on a silica-gel column with a mixture of ethyl acetate and hexane (1:4) to afford **6** (170 mg, 60%) as colorless needles: mp 60—61 °C; $[\alpha]_D^{25}$ −5.8±0.1° (*c* 1.70, chloroform) (lit,[21] $[\alpha]_D^{25}$ −4.3±2.9° (*c* 0.14, chloroform)); $[\alpha]_D^{25}$ −7.3±0.1° (*c* 1.70, methanol); UV (ethanol) 268 (log ε 2.51), 261 (2.64), 255 (2.57), 248 (2.44), and 243 nm (2.29); IR (KBr) 3340 (OH), 1598 and 1492 cm^{-1} (aromatic ring); ^1H NMR (CCl_4) δ= 1.06 (1H, brs, OH), 1.30—1.84 (8H, m, $>CH_2$×4), 2.45—2.81 (4H, m, $>CH_2$×2), 3.48 (1H, m, >CHOH), 7.13 (10H, m, aromatic H); EI-MS *m/z* (rel intensity) 250 (62, M^+-H_2O), 159 (10), 145 (8), 131 (9), 117 (31), 104 (57), and 91 (100); CI-MS *m/z* (rel intensity) 267 (65, M^+-H) and 251 (100, M^+-H_2O+H). Found: C, 85.25; H, 9.21%. Calcd for $C_{19}H_{24}O$: C, 85.02; H, 9.01%. The optical purity of **6** was determined by the same method as described for the determination of the optical purity of **5**. The acetate derived from **6** showed no detectable signal of the enantiomer.

Preparation of (3*S*,5*S*)-1,7-Diphenyl-3,5-heptanediol. 1,7-Diphenyl-3,5-heptanedione (2.70 g) prepared with the method previously reported[22] was hydrogenated with the asymmetrically modified Raney nickel described for the preparation of (4*S*,6*S*)-4,6-nonanediol followed by crystallization from hexane to afford (3*S*,5*S*)-1,7-diphenyl-3,5-heptanediol (1.10 g, 40%) as colorless needles: mp 89.5—90.5 °C; $[\alpha]_D^{25}$ −11.1±0.2° (*c* 1.06, ethanol); UV (ethanol) 268 (log ε 2.50), 261 (2.63), 255 (2.55), 249 (2.39), 243 nm (2.16); IR (KBr) 3350 (OH), 1600 and 1490 cm^{-1} (aromatic ring); ^1H NMR (CCl_4) δ=1.45—1.88 (6H, m, $>CH_2$×3), 2.52—2.81 (6H, m, $>CH_2$×2 and OH×2), 3.87 (2H, m, >CHOH×2), 7.13 (10H, m, aromatic H); EI-MS *m/z* (rel intensity) 266 (9, M^+-H_2O), 248 (17, M^+-2H_2O), and 91 (100); CI-MS *m/z* (rel intensity) 285 (50, M^++H), 267 (72, M^+-H_2O+H), and 249 (100, M^+-2H_2O+H). Found: C, 80.41; H, 8.77%. Calcd for $C_{19}H_{24}O_2$: C, 80.24; H, 8.51%. The optical purity of this diol was determined by measuring the ^1H NMR with a soln of its diacetate (5 mg) and Eu(tfc)$_3$ (3 molar equivalents to the diacetate) in $CDCl_3$ (0.4 cm^3). The diacetate showed no detectable signal of the enantiomer.

(*R*)-1,7-Bis(3,4-dimethoxyphenyl)-3-heptanol (7). Compound **7** was prepared following the previously reported method.[21] The reduction of the carbonyl group of the compound **2** (69 mg) with $TsNHNH_2$ (35 mg) and $NaBH_4$ (300 mg) in methanol gave **7** (51 mg, 77%): mp 67—69 °C; $[\alpha]_D^{25}$ −4.7±0.4° (*c* 0.51, chloroform); $[\alpha]_D^{25}$ −5.5±0.4° (*c* 0.51, methanol); UV (ethanol) 280 (log ε 3.70), 229 nm (4.13); IR (KBr) 3430 (OH), 1587 and 1515 cm^{-1} (aromatic ring); ^1H NMR ($CDCl_3$) δ=1.25—1.90 (8H, m, $>CH_2$×4), 1.70 (1H, brs, OH), 2.38—2.81 (4H, m, $>CH_2$×2), 3.60 (1H, m, >CHOH), 3.84 and 3.85 (12H, each s, OMe×4), 6.68—6.82 (6H, m, aromatic H); EI-MS *m/z* (rel intensity) 388 (32, M^+), 370 (2, M^+-H_2O), 177 (8), 164 (7), and 151 (100). Found: C, 71.14; H, 8.29%. Calcd for $C_{23}H_{32}O_5$: C, 71.10; H, 8.30%.

(*S*)-4-Nonanol (8). The tosylation of (4*S*,6*S*)-4,6-nonanediol (465 mg), prepared as shown above, followed by the reduction with $LiAlH_4$ was carried out in the same manner described for the preparation of **6**. The distillation of the product at 68 °C (bath temperature) at 4 Torr through a short-path distillation apparatus afforded **8** (191 mg, 46%) as colorless oil: $[\alpha]_D^{25}$ +0.6±0.2° (*c* 2.25, chloroform); $[\alpha]_D^{25}$ +0.5±0.2° (*c* 2.25, methanol) (lit,[23] $[\alpha]_D^{25}$ +0.57°); IR (neat) 3350 cm^{-1} (OH); ^1H NMR ($CDCl_3$) δ=0.70—1.04 (6H, m, Me×2), 1.16—1.53 (12H, m, $>CH_2$×6), 1.73 (1H, brs, OH), 3.61 (1H, m, >CHOH); EI-MS *m/z* (rel intensity) 126 (1, M^+-H_2O), 101 (9), 83 (34), 73 (40), and 55 (100); CI-MS *m/z* (rel intensity) 143 (11, M^+-H) and 127 (100, M^+-H_2O+H). The GLC (90 °C) showed a single peak at 6 min of retention time.

The author wishes to express his hearty gratitude to Professor Takayuki Suga of Hiroshima University for his continual guidance and encouragement throughout the course of this work and to Dr. Toshifumi Hirata of Hiroshima University and Dr. Tadashi Aoki of Suzugamine Women's College for their valuable discussions.

Molecular Complexes of *N,N,N',N'*-Tetraisopropyloxamide. Crystal Structures of Its 1:1 Adduct with *m*-Cresol, and Its 1:1 and 1:2 Adducts with *p*-Cresol

Fumio Toda,* Yasunori Tagami, and Thomas C. W. Mak*,†

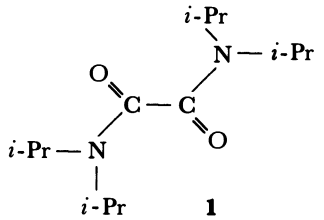
Department of Industrial Chemistry, Faculty of Engineering, Ehime University, Matsuyama 790

†Department of Chemistry, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong

(Received October 2, 1985)

The crystal structures of a 1:1 complex (I) of *N,N,N',N'*-tetraisopropyloxamide with *m*-cresol, a 1:1 complex (**II**) with *p*-cresol, and a 1:2 complex (**III**) with *p*-cresol have been determined by X-ray crystallography. The crystal data are: **I**, $C_{21}H_{36}N_2O_3$, $P2_1/c$, a=12.104(4), b=6.860(3) c=27.186(8) Å, β=93.46(2)°, Z=4, and R_F=0.093 for 1661 observed Mo$K\alpha$ data; **II**, $C_{21}H_{36}N_2O_3$, $P2_1/n$, a=7.825(2), b=11.379(4), c=25.39(1) Å, β=91.01(2)°, Z=4, and R_F=0.105 for 1326 data; **III**, $C_{28}H_{44}N_2O_4$, $C2/c$, a=11.744(3), b=10.658(2), c=23.576(4) Å, β=102.07(2)°, Z=4, R_F=0.045 for 1382 data. The stoichiometric formulas faithfully represent the structures of all three complexes, with each phenolic OH group forming a donor hydrogen bond to an O atom of the oxamide host molecule.

Recently we reported that *N,N,N',N'*-tetraisopropyloxamide (**1**) forms crystalline inclusion compounds of 1:1 stoichiometry with a variety of aromatic guest molecules such as benzene, *m*- and *p*-xylenes, phenol, *m*- and *p*-cresols, naphthalene, 1- and 2-methylnaphthalenes, and 1- and 2-naphthols.[1] X-Ray analysis of its 1:1 complex (**IV**) with 1-methylnaphthalene showed that the aromatic molecules are accommodated in channels, with no significant interaction between host and guest components other than dispersion forces.[1] For a better understanding of the inclusion properties of **1**, we have carried out crystal structure determinations of its 1:1 complexes (**I** and **II** respectively) with *m*- and *p*-cresols, with anticipation of hydrogen bonding but uncertainty as to whether host-guest or guest-guest association would be the dominating factor. In the course of our studies we further isolated a 1:2 crystalline adduct (**III**) of **1** with *p*-cresol, whose structure is also reported in the present paper.



1

Experimental

Diamide **1** (mp 102—103°C) was synthesized from oxalyl dichloride and diisopropylamine according to a literature method.[2] Complexes **I—III** were obtained as colorless prisms from slow evaporation of a solution of **1** and the appropriate cresol in hexane. Complexes **II** and **III** were prepared separately by using different stoichiometric amounts of *p*-cresol, and crystals of **II** ($\nu_{C=O}$ 1615, 1648 cm^{-1}) are generally bigger and better formed than those of **III** ($\nu_{C=O}$ 1625 cm^{-1}).

X-Ray Data Collection. All three complexes quickly turned milky upon exposure to air, and each selected crystal was therefore enclosed inside an 0.5 mm Lindemann glass capillary. Intensity measurement[3] was performed on a Nicolet R3m four-circle diffractometer[4] using graphite-monochromatized Mo$K\alpha$ radiation (λ=0.71069 Å). Accurate unit-cell parameters were derived from a least-squares fit of the angular settings for 25 reflections in the range $14° < 2\theta < 18°$. Reflection intensities were recorded at an ambient laboratory temperature of 22°C, and three standards monitored every 50 data measurements showed only random fluctuations within ±2% of their mean values. The raw intensities were processed with the learnt-profile procedure.[5] No absorption correction was applied. The crystal data and processing parameters for **I—III** are summarized in Table 1.

Structure Determination and Refinement

For each complex the statistical distributions of the normalized structure factors strongly favoured a centrosymmetric space group, and structure solution was achieved by direct phase determination based on negative quartets.[6]

The structures of **I** and **II** were refined in the same manner. The N, O, and methyl C atoms were varied anisotropically, and the remaining C atoms isotropically. In view of the unfavorable data-to-parameter ratio,[7] the phenyl ring was treated as a rigid group (regular hexagon of side 1.395 Å). All H atoms were generated geometrically (C–H=0.96 Å) and included in structure factor calculations with fixed isotropic temperature factors.

In complex **III**, the oxamide molecule **1** is located on a crystallographic diad. All non-hydrogen atoms in the asymmetric unit (half of an oxamide molecule and one *p*-cresol) were refined anisotropically. A difference Fourier map revealed the proton belonging to the phenolic group at a reasonable location, and all H atoms were included with assigned isotropic thermal parameters in subsequent refinement.

Computations were performed on a Data General Corporation Nova 3/12 minicomputer using the SHELXTL program package.[8] Analytic expressions of atomic scattering factors were employed, and anomalous dispersion corrections were incorporated.[9] Blocked-cascade least-squares refinement[10] converged to the R indices and parameters listed in Table 1.

Table 1. Data Collection and Processing Parameters

Complex	I	II	III

Results and Discussion

Perspective views, each with atom labelling, of the asymmetric units in complexes **I** and **III** are shown in Figs. 1 and 2, respectively. Figure 1 is also applicable to complex **II**, except that C(21) is bonded to C(18) instead of C(19). The final atomic parameters are listed in Table 2 and 3,[11,12] and molecular dimensions tabulated in Tables 4 and 5.

The crystal structures of **I**—**III** are illustrated in Fig. 3—5, respectively. A common feature is the exclusive occurrence of host-guest, rather than guest-guest,* hydrogen bonding, giving rise to discrete molecular aggregates which are dimeric in **I** and **II** and trimeric [two-fold axis passing through the center of the C(1)-C(1)' bond] in **III**. In the two 1:1 com-

*Hydrogen bonding involving cresol molecules exclusively might be expected to yield a zigzag polymeric arrangement which fits the chennel structure of **IV**.

a) Symmetry transformation for generating the primed atom: $1-x$, y, $1/2-z$.

plexes, only one of the two amido groups of **1** is involved in acceptor hydrogen bonding [O(1)···O(3)= 2.694(8) and 2.67(1)Å, respectively], whereas both amide groups of the C_2 host molecule in **III** interact with the phenolic groups of a pair of *p*-cresol molecules [O(1)···O(2)=2.699(4)Å]. These modes of hydrogen bonding provide a rationale for the observed stoichiometries and infrared absorption spectra in the inclusion of *p*-cresol by **1**.

The oxamide host **1** adopts very similar configurations and molecular dimensions in this series of complexes, a planar bond configuration being found about each N atom (Tables 4 and 5). The O-C-C-O torsion angles take the values 91.8(6), 95.3(10) and −85.4(2)° for **I**—**III**, respectively, so that the two planar amide moieties of each host molecule behave as separate π systems with negligible conjugation across the central C-C single bond [1.518(8), 1.50(1), and 1.525(5) Å, respectively]. It is also noted that the involvement of either one or two amido groups in acceptor hydrogen bonding, as in complexes **II** and **III**, corresponds to a difference of about 10° (absolute value) in the O-C-C-O torsion angle.

Comparison of the present structures with that of the 1:1 complex (**IV**) of **1** with 1-methylnaphthalene (see Fig. 1 of Ref. 1) leads to the conclusion that the host system **1** adapts itself readily to the nature of the guest species present, forming crystalline lattices which are determined primarily by the bonding characteristics and steric requirement of the latter.

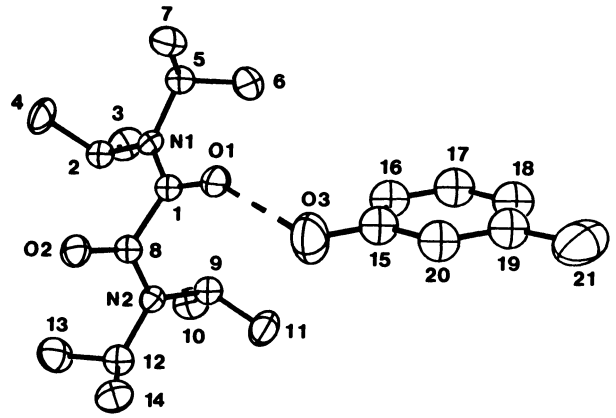

Fig. 1. Perspective view and atom labelling of the asymmetric unit in the 1:1 complex (**I**) of **1** with *m*-cresol. The atoms are represented as 30% thermal ellipsoids, and the hydrogen bond by a broken line. This figure also applies to the 1:1 complex (**II**) of **1** with *p*-cresol, with the modification that C(21) now bonds to C(18).

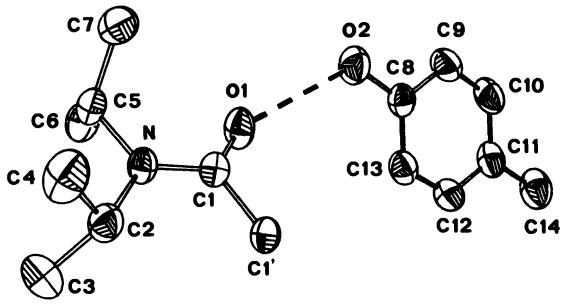

Fig. 2. Perspective view and atom labelling of the asymmetric unit in the 1:2 complex (**III**) of **1** with *p*-cresol. The atoms are represented as 35% thermal ellipsoids, and the hydrogen bond by a broken line. The primed atom is related to the unprimed one by the symmetry transformation $1-x$, y, $1/2-z$.

Photochemical Hydroxymethylation of Alicyclic and Aliphatic Alkenes Induced by a Eu^{III}/Eu^{II} Photoredox System in Methanol

Akito ISHIDA,* Shinya YAMASHITA, Susumu TOKI, and Setsuo TAKAMUKU
The Institute of Scientific and Industrial Research, Osaka University, Ibaraki, Osaka 567
(Received November 1, 1985)

The photoirradiation of a methanol solution of $EuCl_3$ and alkenes such as cyclohexene, cyclooctene, cyclododecene, and tetramethylethylene afforded (hydroxymethyl) alkane. The dihydro dimer of alkene, hydrogen, and ethylene glycol are also formed. Reactions proceed via a radical mechanism induced by hydrogen atoms and hydroxymethyl radicals, which are produced by a photoredox reaction of Eu^{III}/Eu^{II} in methanol.

Transition-metal organometallic chemistry has become important, principally due to the usefulness of members of this class of compounds for catalyzing or assisting in the transformation of organic substrates. However, photochemistry related to this field seems to be restricted to classical coordination compounds in aqueous solutions.[1] In recent years much attention has been paid to the decomposition of water into hydrogen and oxygen using metal catalysts from the viewpoint of the utilization of solar energy.[2] A few photochemical studies have been conducted on the metal compounds or metal complexes which can lead to catalytically and synthetically useful transformations of organic compounds.[3,4] The photochemistry of lanthanoids such as cerium, europium, or samarium has almost been restricted to spectroscopic investigations in aqueous systems,[5] there are a few applications regarding organic syntheses.

We have investigated the photoredox reactions of a Eu^{III}/Eu^{II} system in alcohols in the presence of some organic substrates in order to apply such a redox system of metal ions to organic photochemical reactions. Recently, we reported the formation of a dihydro dimer and a 2:1 styrene–methanol adduct via a radical mechanism when styrene and its derivatives are used as the substrate.[6] On the other hand, when uracil and its derivatives are used, a regioselective hydroxymethylation took place via an electron-transfer mechanism.[7] Here, we report on a photoreaction of europium chloride in the presence of alicyclic or aliphatic alkenes in methanol as a series which shows the scope and limitations for this reaction.

Results and Discussion

Photoreaction of $EuCl_3$ in Methanol. $EuCl_3$ does not absorb light of a longer wavelength than 250 nm in an aqueous solution, but has an absorption band around 280 nm in methanol. This might be due to a solvent-to-metal charge transfer. Upon irradiation of a methanol solution of $EuCl_3$ with a high-pressure mercury lamp through a Pyrex filter, a new absorption band appeared at 320 nm and was assigned to Eu^{II} on the basis of spectroscopic data.[6] Figure 1 shows the absorption spectra before and after irradiation. Hydrogen gas and ethylene glycol were formed

——: Before, -----: atfer 8 h irradiation. -·-·-·-: differential spectrum enlarged by a factor of 3.

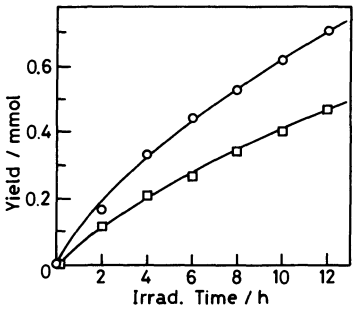

Fig. 2. Yields of hydrogen (—○—) and ethylene glycol (—□—) vs. time plot for the photoreaction of 5 mmol dm^{-3} solution of $EuCl_3$ 5 mL of methanol.

monotonously with the irradiation time. The yield of ethylene glycol was less than that of hydrogen (Fig. 2). The formation of formaldehyde was also detected upon the addition of 2,4-dinitrophenylhydrazine to the reaction mixture. After irradiation for 10 h, the yields of these products (based on the $EuCl_3$ used) reached 2000 and 1500%, respectively. This indicates that $EuCl_3$ operated catalytically. Taking the reaction mechanism in an aqueous solution into consideration,[5d] the following reaction scheme is suggested for the present system.

$$Eu^{3+} - CH_3OH \xrightarrow{h\nu} Eu^{2+} + CH_3O\cdot + H^+ \quad (1)$$

$$Eu^{2+} \xrightarrow{h\nu} Eu^{2+*} \quad (2)$$

$$Eu^{2+*} + H^+ \longrightarrow Eu^{3+} + H \quad (3)$$

$$CH_3O\cdot + CH_3OH \longrightarrow CH_3OH + \cdot CH_2OH \quad (4)$$

$$H + CH_3OH \longrightarrow H_2 + \cdot CH_2OH \quad (5)$$

$$2\cdot CH_2OH \longrightarrow HO(CH_2)_2OH \quad (6)$$

$$Eu^{3+} + \cdot CH_2OH \longrightarrow Eu^{2+} + HCHO + H^+ \quad (7)$$

The methoxyl radical formed in Reaction 1 is very reactive because of the large O–H bond-dissociation energy of methanol (435 kJ mol^{-1} [8]) and promptly abstracts H atoms from methanol to give hydroxymethyl radicals (Reaction 4). In the Eu^{III}/Eu^{II} photoredox systems, therefore, it is clear that H atoms and hydroxymethyl radicals are effectively formed. Hydrogen atoms and hydroxymethyl radicals formed by the reactions (Reactions 1—6) should afford equimolecular amounts of hydrogen and ethylene glycol. The hydroxymethyl radical, however, probably reacts with the Eu^{III} ion and decomposes into protons and formaldehyde.

Photoreaction of $EuCl_3$ in the Presence of Alkene in Methanol. The present photoredox system of Eu^{III}/Eu^{II} in methanol was applied to the reaction of alkene. A methanol solution of alkene (**1a—d**: 100 mmol dm^{-3}) and $EuCl_3$ (5 mmol dm^{-3}) was irradiated under an argon atmosphere at λ>300 nm. The methanol adduct of **1** (**2**) and the dihydro dimer of **1** (**3**) were obtained as the main products along with a large amount of hydrogen gas and ethylene glycol. In the absence of $EuCl_3$, the alkene was recovered unchanged from methanol after irradiation for 8 h.

$$R^1R^2C{=}CR^1R^2 \xrightarrow[EuCl_3,\,CH_3OH,\,8h]{h\nu,\,\lambda>300\,nm} R^1R^2CHCR^1R^2CH_2OH + (R^1R^2CHCR^1R^2-)_2$$

1 → **2** + **3**

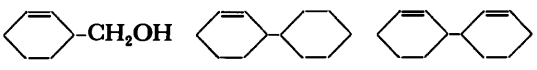
a : $R^1 = H$ $R^2\text{-}R^2 = -(CH_2)_4-$

b : $R^1 = H$ $R^2\text{-}R^2 = -(CH_2)_6-$

c : $R^1 = H$ $R^2\text{-}R^2 = -(CH_2)_{10}-$

d : $R^1 = R^2 = CH_3$

The results are shown in Table 1. **4a**, **5a**, and **6a** from cyclohexene (**1a**) were obtained as minor products. In the case of tetramethylethylene (**1d**), **7d** was formed as one of the main products.



4a **5a** **6a**

$(CH_3)_2CHCH(CH_3)_2$

7d

The formation of these main products (**2** and **3**) can be reasonably explained as the results of the efficient trapping of primarily formed radicals from methanol (H and $\cdot CH_2OH$) by the added alkene (Reactions 8—10).

Table 1. The Photoreaction of Eu^{III} and Alkene in Methanol[a]

$$\cdot R\text{-}CH_2OH \xrightarrow{[H]} H\text{-}R\text{-}CH_2OH\ (\mathbf{2}) \quad (11)$$

The addition of a H atom to alkene (Reaction 8) competes with the abstraction of a H atom from methanol (Reaction 5). These competitive processes depend on the concentration of the alkene used, The product ratio (**2**:**3**) was found to be very sensitive to the concentration of the alkene (Fig. 3). At a low alkene concentration, hydrogen mainly abstracts the hydrogen from methanol, producing hydrogen molecules and hydroxymethyl radicals. Thus, the main reaction becomes the hydroxymethylation of the alkene. With an increase in the concentration of alkene, the addition of a hydrogen atom to alkene becomes competitive and the yield of the dihydro dimer (**3**) increases to 61% at 0.3 mol dm^{-3} in the case of cyclododecene (**1c**). These reulsts are also consistent with the estimation on the basis of the kinetic data reported.[9]

The unsaturated products, **4a—6a** formed consider-

ably in the case of cyclohexene. It has been known that the allylic hydrogens of cyclohexene are much more reactive toward abstraction than those of other alkenes. This fact had been explained by the coplanarity of the cyclohexenyl radical and was substantiated by results reported by Mayo et al.[10] The ratios of k_{ab} (rate of H atom abstraction from alkene) to k_{ad} (rate of addition to alkene) were 16, 0.4, 1.5, and 1.2 for cyclohexene, cyclooctene, cyclododecene, and tetramethylethylene, respectively. The unsaturated products (**4a**, **5a**, and **6a**) might have been formed via the cyclohexenyl radicals. In the case of tetramethylethylene, the reduction of **1d** took place to afford 2,3-dimethylbutane (**7d**). The radical **8d** formed by the addition of a hydrogen atom to **1d** was a tertiary alkyl radical. The steric repulsion by an isopropyl and two methyl groups was anticipated as making the coupling reaction difficult. For a *t*-butyl radical (similar to **8d**), the disproportionation prevailed over the coupling in solution, whereas for alicyclic alkyl radicals, the former was interior to the latter.[11] These facts suggest that the hydrogenation of alkene occurs mainly in tetramethylethylene and are consistent with the experimental results.

$(CH_3)_2\dot{C}CH(CH_3)_2$

8d

In order to obtain an insight into this reaction, experiments were carried out using deuterium-labelled compounds. The results are summarized in Table 2.

The europium chloride used contained 6 gram-equivalent H_2O as the water of crystallization. However, its quantity was less than 0.1 wt% of the methanol and the effects of the water are presumed to be negligible. The yields of **2c** and **3c** did not differ greatly in CH_3OH and CH_3OD. When CD_3OH was used, however, **2c** decreased significantly with an increase of **3c**. The evolution of hydrogen gas was also reduced in the case of CD_3OH. The initial processes (Reactions 1—3) were regarded as not being influenced by the deuterium labelling. A reaction for which deuterium-isotope effects are expected is the hydrogen atom abstraction from methanol by hydrogen atom (Reaction 5) among the initial processes. The retardation of Reaction 5 in CD_3OH leads to a decrease in the yields of the hydroxymethyl radical as well as the hydrogen evolution with corresponding increases in the yields of the cyclododecyl radical. These explanations are in accord with the experimental results given in Table 2.

Concerning the hydrogen source for the formation of **2c** from the 2-(hydroxymethyl)cyclododecyl radical (**9c**) (Reaction 11), there are three possibilities: (1) recombination with a hydrogen atom, (2) disproportionation with other radicals, and (3) the abstraction of hydrogen from methanol. The first case seems to be not so important because the concentrations of hydrogen atoms and the radical **9c** are very low. The second and the third cases are of some importance for the present reaction conditions. Especially, considering the dissociation energies of the C–H bond in cyclohexane (402 kJ mol^{-1})[12] and the C–H bond in methanol (394 kJ mol^{-1}),[13] hydrogen abstraction from methanol becomes more exothermic than that from cyclohexane by 8 kJ mol^{-1}. Therefore, for this process, the effects of deuterium isotopes might be important. This interpretation is in accord with the fact that in the case of styrene, a 2:1 styrene–methanol adduct and a dihydro dimer were obtained as the main products, however, a 1:1 adduct was not detected. The benzyl-type radical derived from styrenes can not abstract H atom from methanol because the C–H bond energy of the benzylic C–H bond is low, 356 kJ mol^{-1}.[13] Therefore, the benzyl radical can only terminate by coupling with another benzyl radical.

An example of photochemical hydroxymethylation is known for norbornene in which hydroxymethylation proceeds by a xylene-sensitization in methanol via a radical mechanism.[14] On the contrary, cyclohexene and cycloheptene undergo a dipolar addition of methanol to give methoxy products.[14] The reactions are selective for cyclic six- and seven-membered rings. The present photoreactions of Eu-alkene systems in methnol are able to efficiently transform aliphatic and alicyclic alkenes to (hydroxymethyl) alkanes, in which europium ions act as an efficient sensitizer. The photoreaction of Eu(III) and alkene in methanol is useful as a general synthetic method for the hydroxymethylation of alkenes.

Experimental

Instruments. GLC analyses were carried out on a Shimadzu GC-7A gas chromatograph with OV-17 (2 m) for cyclohexene, cyclooctene, and cyclododecene, with a Porapak-

type QS (40 cm) or a Porapak-type T (40 cm) for tetramethylethylene and ethylene glycol. ^1H and ^{13}C NMR spectra were recorded in a $CDCl_3$ solution on a Bruker WM-360 spectrometer using TMS as an internal standard. The mass spectra were run on a JEOL JMS-DX300 (Gas chromatograph-Mass spectrometer) using the same columns as for the GC analysis. UV-spectra were recorded on a Hitachi 323 spectrophotometer.

Materials. Cyclohexene, cyclooctene, cyclododecene, and tetramethylethylene (Nakarai) were distilled over sodium prior to use and $EuCl_3\ 6H_2O$ (Nakarai) was used without further purification. Methanol was distilled over CaH_2. Isotopically labelled methanols (Merck) were used without further purification.

Spectral Change for the Eu^{III}–Methanol System by Irradiation. A methanol solution of $EuCl_3$ (2 mmol dm^{-3}) was irradiated under an argon atmosphere through a Pyrex filter with a 350-W high-pressure mercury lamp at running-water temperature. Absorption spectra were measured before irradiation and subsequently at regular time intervals. During the irradiation evolution of hydrogen gas was observed.

General Procedure. Photoreaction of a Methanol Solution of Eu^{III} and Alkenes. A methanol solution of alkene (**1**: 100 mmol dm^{-3}) and $EuCl_3$ (5 mmol dm^{-3}) was placed in a Pyrex cell connected to a gas syringe through a capillary tube to collect evolved hydrogen gas and irradiated under an argon atmosphere with a 350-W high-pressure mercury lamp for 8 h. After irradiation, the solution was concentrated under reduced pressure. The identification of products was carried out by a direct comparison of GLC and MS with those of available authentic samples. The following products were isolated by means of preparative gas chromatography (OV-17, 2 m) or the column chromatography on silica gel with hexane and benzene and were identified by spectral data.

Hydroxymethylcyclohexane (2a): Viscous oil; MS *m/z* (rel intensity) 96 (M^+-18, 7%), 83(16), 81(13), 67(28), 55(63), 41(100), 39(96), 31(66).

3-Hydroxymethylcyclohexene (4a): Viscous oil; **4a** was transformed into **2a** by hydrogenation of the reaction solution mixture by palladium-carbon. MS *m/z* (rel intensity) 94 (M^+-18, 2%), 81(11), 79(21), 66(5), 53(11), 41(12), 39(32), 31(100).

Bicyclohexyl (3a), 2-Cyclohexyl-cyclohexene (5a), 3,3'-Bicyclohexene (6a): **6a** was obtained by a photoreaction of **1a** and benzophenone, and hydrogenated by palladium-carbon to give new peaks coinciding with **3a** and **5a** at an early stage and concentrated at one peak after the end of the reaction.

3a: Viscous oil; MS *m/z* (rel intensity) 166 (M^+, 45%), 109(19), 96(29), 83(97), 82(100), 67(90), 53(39).

5a: MS *m/z* (rel intensity) 164(M^+, 2%), 91(13), 82(22), 81(54), 79(72), 77(35), 67(24), 55(100), 53(54), 41(94), 39(81).

6a: MS *m/z* (rel intensity) 162(M^+, 1%), 91(11), 82(7), 81(100), 79(89), 77(43), 66(20), 55(22), 53(51), 41(92), 39(69).

Hydroxymethylcyclooctane (2b): ^1H NMR ($CDCl_3$) δ= 1.33 (m, 14H), 1.83 (m, 1H), 2.47 (bs, 1H), 3.42 (d, J=6 Hz, 2H), 2,4-dinitrobenzoate of **2b**: mp 63—64 °C; MS *m/z* (rel intensity) 336(M^+, vw), 306(3), 195(12), 149(13), 124(15), 111(21), 96(100).

Bicyclooctyl (3b): Colorless needles; mp 46—47 °C; MS *m/z* (rel intensity) 222(M^+, vw), 111(100), 110(40), 82(36), 69(98), 55(42), 41(22); ^1H NMR ($CDCl_3$) δ=1.26—1.72(m); ^{13}C NMR ($CDCl_3$, off-resonance) δ=44.5(d), 30.9(t), 27.0(t).

Hydroxymethylcyclododecane (2c): Viscous oil; ^1H NMR ($CDCl_3$) δ=1.32 (m, 22H), 1.63 (t, J=6 Hz, 1H), 1.90 (bs, 1H), 3.47 (d, J=6 Hz, 2H); MS *m/z* (rel intensity) 198(M^+, vw), 180(7), 166(6), 152(6), 137(6), 123(11), 111(37), 97(70), 83(87), 69(73), 55(100). ^{13}C NMR ($CDCl_3$, off-resonance) δ=69.27(t), 40.67(d), 30.04(t), 29.73(t), 27.36(t), 26.88(t), 25.99(t).

Bicyclododecyl (3c): Needles; mp 117—118 °C; MS *m/z* (rel intensity) 334(M^+, 30), 166(100), 111(26), 97(48), 96(37), 83(43), 82(30), 69(30), 55(41); ^{13}C NMR ($CDCl_3$, off-resonance) δ=33.46(d), 26.26(t), 24.14(t), 23.93(t), 23.74(t), 22.92(t), 22.86(t); Found: C, 86.14; H, 13.86%. Calcd for $C_{24}H_{46}$: C, 86.13; H, 13.62%.

2,3-Dimethylbutane (7d) and 2,3,3,4,4,5-Hexamethylhexane (3d): **4d** was identified by the comparion of GC and MS with those of authentic sample obtained by a hydrogenation of tetramethylethylene. **3d** was identified based on GC-Mass data.

2,2,3-Trimethyl-1-butanol (2d): Viscous oil; ^1H NMR ($CDCl_3$) δ=0.82 (s, 6H), 0.85 (d, J=7 Hz, 6H), 1.64 (q, J= 7 Hz, 1H), 1.90 (bs, 1H), 3.37 (s, 2H); ^{13}C NMR ($CDCl_3$, off-resonance) δ=17.40(q), 30.00(q), 32.65(d), 37.36(s), 70.92(t).

The authors wish to thank the members of Material Analysis Center in the Institute of Scientific and Industrial Research, Osaka University, for the NMR and mass-spectra measurements and the elemental analyses.

Syntheses of Cyclic Decapeptides with Four Ornithyl Residues Related to Gramicidin S[1)]

Setsuko ANDO,* Hiroshi NISHIKAWA, Hideo TAKIGUCHI, and Nobuo IZUMIYA†
Department of Chemistry, Faculty of Science, Fukuoka University, Jonan-ku, Fukuoka 814-01
†Laboratory of Chemistry, Kurume Institute of Technology, Kamitsu-machi, Kurume 830
(Received December 7, 1985)

Three cyclic decapeptides with four L-ornithyl residues related to gramicidin S (GS), *cyclo*(-Orn-Leu-Orn-D-Phe-Pro-)$_2$ (**D-L-12**), *cyclo*(-Orn-Leu-Orn-Phe-Pro-)$_2$ (**L-L-12**), and *cyclo*(-Orn-Leu-Orn-Phe-D-Pro-)$_2$ (**L-D-12**), were synthesized to investigate the contribution of increase of the basic amino acid residues and of configurations of phenylalanyl and prolyl residues toward antibacterial activity. These GS-like analogs were synthesized by the solution method of peptide synthesis. Protected cyclic decapeptides were synthesized through a cyclization reaction of linear decapeptide azide in pyridine. Hydrogenolysis of the protected cyclic decapeptides afforded crystalline tetrahydrochlorides of the desired analogs. In the experiment of circular dichroism, **D-L-12** gave a curve similar to that of GS, while **L-L-12** and **L-D-12** gave different curves. Antibacterial assays showed **L-L-12** exhibited substantial activities against Gram-negative bacteria, whereas **D-L-12** and **L-D-12** negligible activity.

Gramicidin S (Fig. 1) is a cyclic decapeptide antibiotic, and exhibits the activity against Gram-positive bacteria. Its decapeptide backbone holds a rigid β-sheet structure stabilized with four hydrogen bonds as shown in Fig. 2. In the previous paper, we reported new function of a GS analog; [D-Dap$^{4,4'}$]GS exhibited the activity against Gram-negative bacteria such as Escherichia coli and Salmonella typhosa, whereas GS shows no activity for these bacteria (Table 1).[2,3)] We also observed that GS-like cyclic tetradecapeptide, *cyclo*(-Leu-Orn-Leu-Orn-Leu-D-Phe-Pro-)$_2$ (**LOP**), exhibited the activity against Gram-negative bacteria.[4)] [D-Dap$^{4,4'}$]GS and LOP contain four basic amino acid residues and hold the β-sheet conformation similar to that of GS. It would be noteworthy that [D-Dap-(β-*Z*)$^{4,4'}$]GS, which contains two ornithyl residues and holds GS-like conformation, exhibited no activity against Gram-negative bacteria, but the activity against Gram-positive ones.[3)]

In the course of studies on the new function of GS analogs, we designed a GS-like analog containing four L-ornithyl residues, *cyclo*(-Orn-Leu-Orn-D-Phe-Pro-)$_2$ (**D-L-12** in Fig. 1). We assumed that **D-L-12** with D-Phe-L-Pro sequence holds GS-like conformation as shown in Fig. 2, then **D-L-12** possesses the activity against Gram-negative bacteria as [D-Dap$^{4,4'}$]GS or **LOP**. Additionally, we planned to synthesize two optical diastereomers of **D-L-12**, namely **L-L-12** with L-Phe-L-Pro and **L-D-12** with L-Phe-D-Pro sequence (Fig. 1); we were interested in examining possible activity for Gram-negative or positive bacteria though we could not speculate on the conformation for two GS-like analogs.

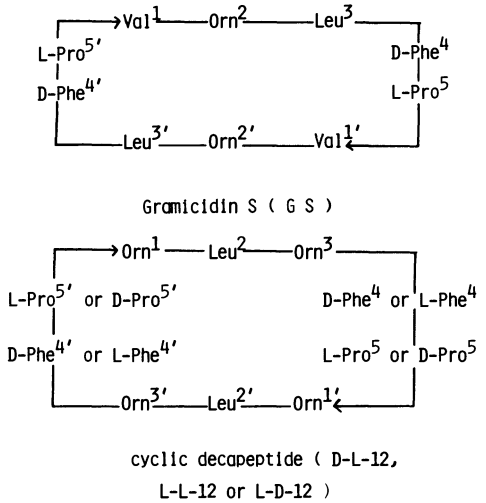

Fig. 1. Structures of GS and GS-like analogs. **D-L-12**, **L-L-12**, and **L-D-12** contain D-Phe-L-Pro, L-Phe-L-Pro, and L-Phe-D-Pro sequences, respectively.

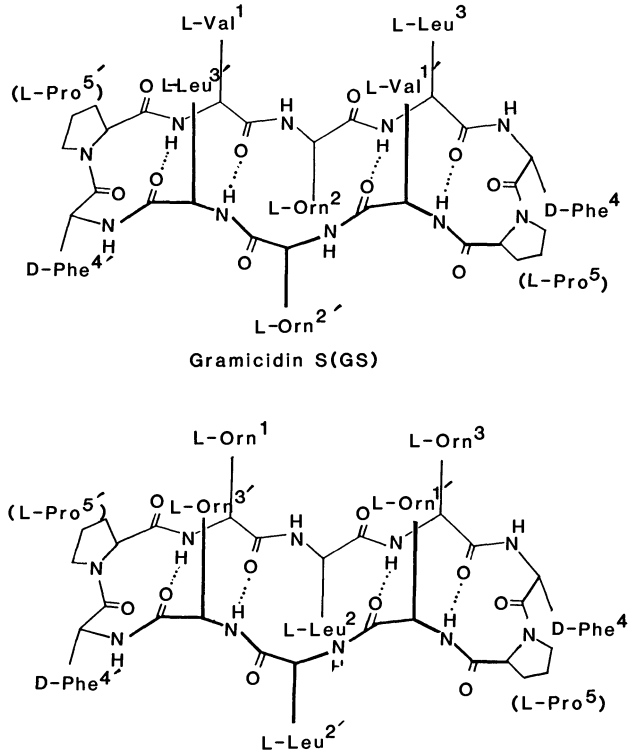

Fig. 2. Conformation of GS and assumed one of **D-L-12**.

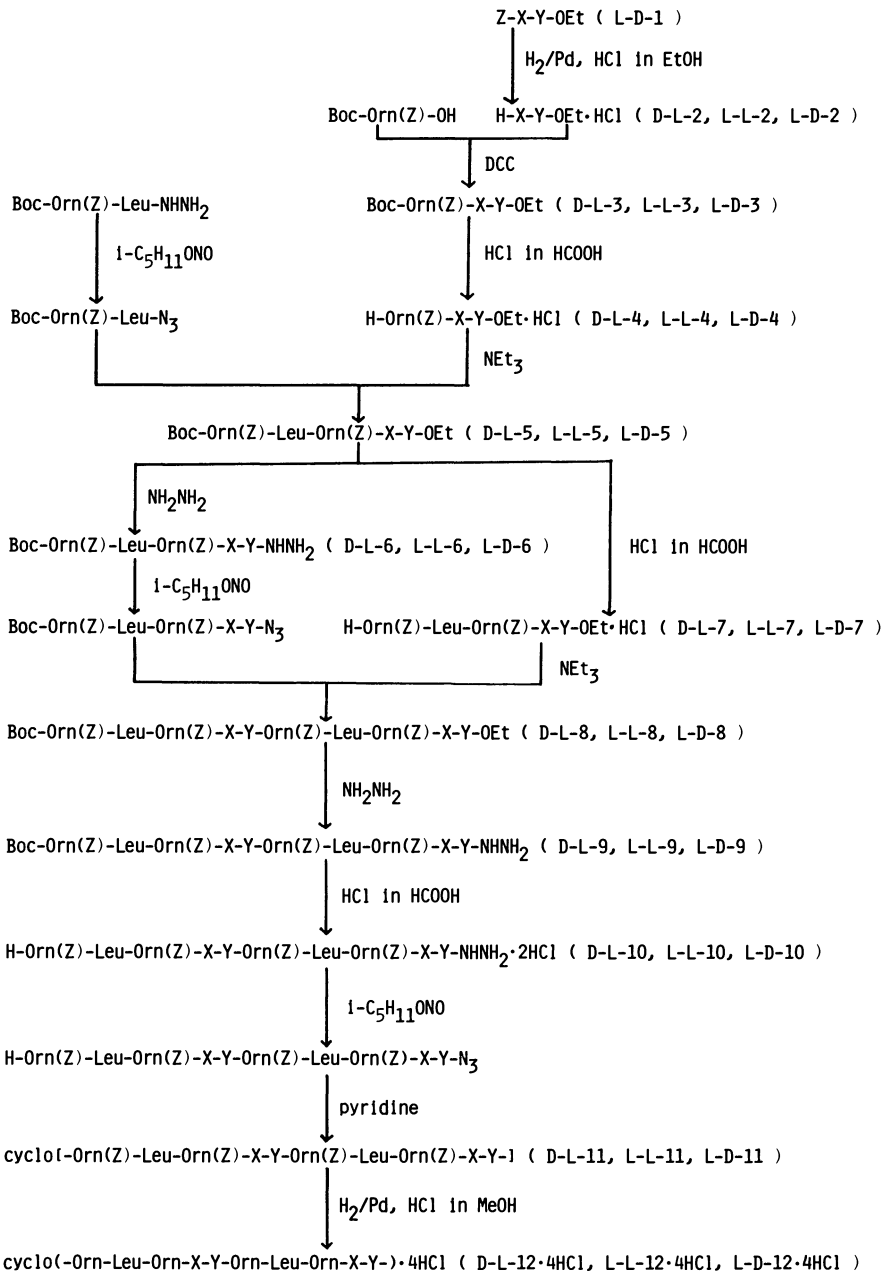

Fig. 3. Syntheses of GS-like analogs. **D-L**-series; X=D-Phe, Y=L-Pro. **L-L**-series; X=L-Phe, Y=L-Pro. **L-D**-series; X=L-Phe, Y=D-Pro.

Syntheses of tetrahydrochlorides of three analogs are outlined in Fig. 3. Boc-pentapeptide ester (**5**) was prepared by the coupling of Boc-dipeptide azide with H-tripeptide ester (**4**). A part of **5** was converted into Boc-pentapeptide hydrazide (**6**), and **6** was changed to the corresponding azide. Coupling of the azide and H-pentapeptide ester (**7**) afforded Boc-decapeptide ester (**8**) which was converted to the corresponding hydrazide (**9**). The Boc-hydrazide **9** was converted to H-decapeptide hydrazide (**10**), and **10** was changed to H-decapeptide azide. Then, the azide was subjected to cyclization in pyridine, and the protected cyclic decapeptide (**11**) was obtained in 49% yield for **D-L-11**, 45% **L-L-11** or 55% **L-D-11**. It should be noted that we could obtain pure cyclic decapeptide (**L-L-11**) with all L-amino acid residues in a good yield (45%) from the cyclization product of H-decapeptide azide though several investigators only isolated cyclic decapeptide in poor yield by the cyclization of H-peptide active ester with all L-amino acid residues.[5] Desired crystalline **D-L-12·4HCl**, **L-L-12·4HCl** or **L-D-12·4HCl** was obtained by hydrogenolysis of each **11** in methanol containing hydrogen chloride.

The homogeneity of **11** and **12·4HCl** was ascertained by several analytical experiments such as TLC, paper electrophoresis and amino acid analysis. The fact that **11** and then **12·4HCl** are a cyclic monomer was confirmed by determination of molecular weight

a) Numerals show the minimum inhibitory concentration ($\mu g\,cm^{-3}$). b) Data are cited from the literature.[3)] c) Data are cited from the literature.[4)] **LOP** represents *cyclo*(-Leu-Orn-Leu-Orn-Leu-D-Phe-Pro-)$_2$.

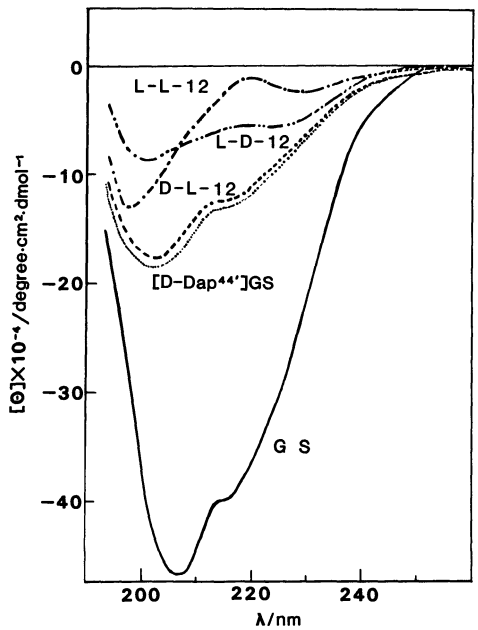

Fig. 4. CD spectra of GS-like analogs and GS in MeOH at 25 °C. Curve of [D-Dap$^{4,4'}$]GS is cited from the literature.[3)]

by an osmometer for **11**, and by a fast atom bombardment (FAB) mass spectroscopy for **12**·4HCl.

Figure 4 shows CD curves of synthesized analogs and GS. The analog **D-L-12** exhibited the similar pattern for GS as expected, though the troughs (203 and 216 nm) were shallower than those of GS; the result suggested that the conformation of peptide-backbone is not changed significantly by the presence of L-Orn-L-Leu-L-Orn instead of L-Val-L-Orn-L-Leu sequence in GS. The CD curve of **D-L-12** is very similar to that of [D-Dap$^{4,4'}$]GS (Fig. 4).[3)] Other analogs, **L-L-12** and **L-D-12**, exhibited the CD curves different from that of GS; the result suggests that the changes in conformation are due to presence of L-Phe-L-Pro and L-Phe-D-Pro sequence.

Results of the antibacterial assay are shown in Table 1. Unexpectedly, **D-L-12** showed negligible activity against Gram-negative bacteria such as Escherichia coli and Salmonella typhosa and also against Gram-positive bacteria such as Staphylococcus aureus and Bacillus subtilis. On the other hand, **L-L-12** showed substantial activity against several Gram-negative bacteria, and even some activity for Gram-positive bacteria. Level of the activities for Gram-negative and -positive bacteria by **L-L-12** is similar to those by [D-Dap$^{4,4'}$]GS. Analog **L-D-12** showed weak activity against a Gram-positive bacteria, Bacillus subtilis PCI 219.

In the previous papers, we reported that [D-Dap$^{4,4'}$]GS and LOP containing four basic amino acid residues possess the activity against Gram-negative bacteria and hold GS-like conformation.[3,4)] However, present cyclic decapeptide **D-L-12** satisfying two requirements (four basic amino acid residues and GS-like conformation) should no activity against Gram-negative bacteria. Whereas, the **L-L-12** holding a certain conformation other than that of GS exhibited the activity. At present, we can not give definite explanation why **D-L-12** shows no activity while **L-L-12** the activity. In this connection, it would be noteworthy that cyclic polymyxins, known for their activity against Gram-negative bacteria, contain six basic amino acid residues of all L-configuration out of ten component amino acid residues.[6)]

Experimental

All melting points are uncorrected. Prior to analysis, compounds were dried over P_2O_5 at 80 °C and 2 mmHg†. Linear and cyclic decapeptide derivatives were dried over P_2O_5 at 25 °C in a desiccator. TLC was carried out on Merck silica gel G with following solvent system: R_f 1-butanol-acetic acid-pyridine-water (4:1:1:2, v/v).

Z-Phe-D-Pro-OEt (L-D-1). To a solution of Z-Phe-OH (14.93 g, 50 mmol) in chloroform (70 cm^3) was added DCC (11.57 g, 55 mmol) at −5 °C. After several min, H-D-Pro-OEt·TsOH (15.77 g, 50 mmol) and triethylamine (7 cm^3, 50 mmol) in chloroform (70 cm^3) was added to the solution. After the mixture was stirred for 45 h at 5 °C, resulting *N,N'*-dicyclohexylurea was filtered off and the filtrate was evaporated to dryness in vacuo. Oily residue was dissolved in ethyl acetate (200 cm^3), and the solution was washed successively with 4% $NaHCO_3$, 2% HCl, water, and dried (Na_2SO_4). The filtrate from the salt was evaporated, and product was obtained as an oil; yield, 19.24 g (90%); R_f=0.97.

H-Phe-Pro-OEt·HCl (L-L-2). Z-Phe-Pro-OEt[7)] (16.88 g, 40 mmol) in 1.7 M†† HCl in ethanol (34 cm^3) was hydrogenated in the presence of Pd black. The filtrate was

† 1 mmHg≈133.322 Pa.
†† 1 M=1 mol dm^{-3}.

evaporated, and the resulting crystals were collected by filtration with the aid of ether; yield, 10.3 g (87%); mp 153—154 °C; $[\alpha]_D^{25}$ −22° (*c* 1, DMF); R_f=0.78.

Found: C, 58.01; H, 7.39; N, 8.35%. Calcd for $C_{16}H_{23}O_3N_2Cl \cdot 1/4H_2O$: C, 58.00; H, 7.15; N, 8.45%.

H-Phe-D-Pro-OEt·HCl (L-D-2). This compound was prepared from **L-D-1** (19.24 g, 45 mmol) as described for the preparation of **L-L-2**. Product was obtained as an oil; yield, 14.71 g (100%); R_f=0.77.

Boc-Orn(Z)-D-Phe-Pro-OEt (D-L-3). To a solution of Boc-Orn(*Z*)-OH (13.0 g, 35.5 mmol) in chloroform (60 cm³) was added DCC (7.21 g, 35.5 mmol) at −5 °C. After several min, **D-L-2**[8] (12.9 g, 35.5 mmol) and triethylamine (4.97 cm³, 35.5 mmol) in chloroform (60 cm³) was added to the solution. The mixture was stirred for 3 d at 5 °C, the filtrate from *N,N'*-dicyclohexylurea was evaporated, and oily residue was dissolved in ethyl acetate (150 cm³). The solution was washed successively with 4% $NaHCO_3$, 0.5 M citric acid, water, and dried (Na_2SO_4). The filtrate was evaporated and product was obtained as an oil; yield, 17.2 g (76%); R_f= 0.97.

Boc-Orn(Z)-Phe-Pro-OEt (L-L-3). This compound was obtained from Boc-Orn(*Z*)-OH (10.5 g, 28.7 mmol) and **L-L-2** (10.4 g, 28.7 mmol) as described for the preparation of **D-L-3**; yield of an oil, 17.4 g (95%); R_f=0.93.

Boc-Orn(Z)-Phe-D-Pro-OEt (L-D-3). This compound was obtained from Boc-Orn(*Z*)-OH (11.0 g, 30 mmol) and **L-D-2** (9.93 g, 30 mmol) as an oil; yield, 17.4 g (90%); R_f=0.95.

H-Orn(Z)-D-Phe-Pro-OEt·HCl (D-L-4). Compound **D-L-3** (17.3 g, 26.9 mmol) was dissolved in 0.183 M HCl in formic acid (177 cm³). After standing at room temperature for 20 min, the solution was evaporated to dryness. Product was obtained as an oil; yield, 15.5 g (100%); R_f=0.81.

H-Orn(Z)-Phe-Pro-OEt·HCl (L-L-4). This compound was obtained from **L-L-3** (16.9 g, 25.0 mmol) as described for the preparation of **D-L-4**. Product was obtained as an oil; yield, 13.7 g (90%); R_f=0.85.

H-Orn(Z)-Phe-D-Pro-OEt·HCl (L-D-4). This compound was obtained from **L-D-3** (17.4 g, 27.0 mmol) as an oil; yield, 15.5 g (100%); R_f=0.84.

Boc-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-OEt (D-L-5). To a solution of Boc-Orn(*Z*)-Leu-$NHNH_2$[9] (11.3 g, 22.9 mmol) in DMF (70 cm³) at −20 °C were added 2.02 M HCl in dioxane (34 cm³) and isopentyl nitrite (3.44 cm³, 25.2 mmol). After 5 min, the solution was neutralized with *N*-methylmorpholine (7.56 cm³, 68.7 mmol). To this solution was added a chilled solution of **D-L-4** (14.0 g, 22.9 mmol) and *N*-methylmorpholine (2.77 cm³, 25.2 mmol) in DMF (70 cm³). The mixture was stirred at 0 °C for 7 d and evaporated in vacuo. Residual solid was dissolved in ethyl acetate (150 cm³), and the solution was washed successively with 0.5 M citric acid, 4% $NaHCO_3$, water, and dried (Na_2SO_4). The filtrate was evaporated and oily residue solidified upon the addition of ether. Product was obtained as crystalline solid; yield, 15.9 g (71%); mp 108—110 °C; $[\alpha]_D^{25}$ −64° (*c* 0.1, MeOH); R_f=0.98.

Found: C, 63.59; H, 7.58; N, 9.71%. Calcd for $C_{53}H_{73}O_{12}N_7$: C, 63.65; N, 7.36; N, 9.80%.

Boc-Orn(Z)-Leu-Orn(Z)-Phe-Pro-OEt (L-L-5). Azide derived from Boc-Orn(*Z*)-Leu-$NHNH_2$[9] (9.87 g, 20 mmol) was coupled with **L-L-4** (13.7 g, 22.4 mmol) as described for the preparation of **D-L-5**. Product was recrystallized from ethyl acetate-ether-petroleum ether; yield, 14.1 g (68%); mp 98—99 °C; $[\alpha]_D^{25}$ −68° (*c* 0.2, MeOH); R_f=0.93.

Found: C, 62.96; H, 7.65; N, 9.55%. Calcd for $C_{53}H_{73}O_{12}N_7 \cdot 1/2H_2O$: C, 63.08; H, 7.39; N, 9.72%.

Boc-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-OEt (L-D-5). Azide derived from Boc-Orn(*Z*)-Leu-$NHNH_2$[9] (6.18 g, 12.6 mmol) was coupled with **L-D-4** (7.67 g, 12.6 mmol) as described for the preparation of **D-L-5**. Product was obtained as crystalline solid; yield, 12.2 g (97%); mp 107—108 °C; $[\alpha]_D^{25}$ −3.58° (*c* 0.2, DMF); R_f=0.93.

Found: C, 62.87; H, 7.55; N, 10.06%. Calcd for $C_{53}H_{73}O_{12}N_7$: C, 63.65; H, 7.36; N, 9.80%.

Boc-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-$NHNH_2$ (D-L-6). A solution of **D-L-5** (8.29 g, 8.3 mmol) and hydrazine hydrate (16.1 cm³, 332 mmol) in DMF (40 cm³) was allowed to stand at room temperature for 7 d. Excess hydrazine was evaporated in vacuo, and water (60 cm³) was added to the residue. Resulting solid was collected by filtration; yield, 7.93 g (97%); mp 136—138 °C; $[\alpha]_D^{25}$ −45° (*c* 0.3, AcOH); R_f=0.97.

Found: C, 61.77; H, 7.50; N, 12.83%. Calcd for $C_{51}H_{71}O_{11}N_9$: C, 62.11; H, 7.26; N, 12.78%.

Boc-Orn(Z)-Leu-Orn(Z)-Phe-Pro-$NHNH_2$ (L-L-6). This hydrazide was obtained from **L-L-5** (10.4 g, 10 mmol) as described for the preparation of **D-L-6**; yield, 6.38 g (95%); mp 111—112 °C; $[\alpha]_D^{25}$ −47° (*c* 0.5, AcOH); R_f=0.93.

Found: C, 61.37; H, 7.55; N, 12.61%. Calcd for $C_{51}H_{71}O_{11}N_9 \cdot 1/2H_2O$: C, 61.66; H, 7.29; N, 12.67%.

Boc-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-$NHNH_2$ (L-D-6). This hydrazide was obtained from **L-D-5** (8.24 g, 8.24 mmol); yield, 7.92 g (96%); mp 119—120 °C; $[\alpha]_D^{25}$ −19.7° (*c* 0.5, AcOH); R_f=0.93.

Found: C, 60.07; H, 7.07; N, 12.63%. Calcd for $C_{51}H_{71}O_{11}N_9 \cdot 3/2H_2O$: C, 60.46; H, 7.33; N, 12.44%.

H-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-OEt·HCl (D-L-7). This compound was obtained from **D-L-5** (5.18 g, 5 mmol) as described for the preparation of **D-L-4**; yield of an oil, 4.68 g (100%); R_f=0.83.

H-Orn(Z)-Leu-Orn(Z)-Phe-Pro-OEt·HCl (L-L-7). This compound was obtained from **L-L-5** (5.11 g, 5 mmol); yield of an oil; 4.68 g (100%); R_f=0.83.

H-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-OEt·HCl (L-D-7). This compound was obtained from **L-D-5** (3.80 g, 3.8 mmol); yield of an oil; 3.50 g (100%); R_f=0.83.

Boc[-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-]$_2$OEt (D-L-8). Azide derived from **D-L-6** (5.11 g, 5 mmol) was coupled with **D-L-7** (4.88 g, 5 mmol) as described for the preparation of **D-L-5**. Product was recrystallized from ethyl acetate-ether; yield, 5.78 g (62%); mp 139—142 °C; $[\alpha]_D^{25}$ −33° (*c* 0.2, MeOH); R_f= 0.95.

Found: C, 63.61; H, 7.42; N, 10.26%. Calcd for $C_{99}H_{132}O_{21}N_{14} \cdot 3/2H_2O$: C, 63.61; H, 7.15; N, 10.31%.

Boc[-Orn(Z)-Leu-Orn(Z)-Phe-Pro-]$_2$OEt (L-L-8). Azide derived from **L-L-6** (5.11 g, 5 mmol) was coupled with **L-L-7** (4.88 g, 5 mmol). Product was obtained as crystalline solid; yield, 6.60 g (70%); mp 151—154 °C; $[\alpha]_D^{25}$ −53° (*c* 0.2, MeOH); R_f=0.98.

Found: C, 62.87; H, 7.40; N, 10.39%. Calcd for $C_{99}H_{132}O_{21}N_{14} \cdot 3H_2O$: C,62.72; H, 7.21; N, 10.16%.

Boc[-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-]$_2$OEt (L-D-8). Azide derived from **L-D-6** (2.76 g, 2.8 mmol) was coupled with **L-D-7** (2.62 g, 2.8 mmol); yield of crystalline solid, 4.34 g (82%); mp 129—132 °C; $[\alpha]_D^{25}$ −8.36° (*c* 0.2, MeOH); R_f=0.97.

Found: C, 63.32; H, 7.47; N, 10.42%. Calcd for $C_{99}H_{132}O_{21}N_{14} \cdot 2H_2O$: C, 63.31; H, 7.17; N, 10.26%.

Boc[-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-]$_2$NHNH$_2$ (D-L-9). This compound was obtained from **D-L-8** (5.58 g, 2.98 mmol) as described for the preparation of **D-L-6**. Product was recrystallized from ethyl acetate-ether; yield, 4.94 g (90%); mp 107—110 °C; $[\alpha]_D^{25}$ −46° (*c* 0.5, AcOH); R_f=0.98.

Found: C, 61.54; H, 7.49; N, 12.13%. Calcd for $C_{97}H_{130}O_{20}N_{16}\cdot 3H_2O$: C, 61.51; H, 7.24; N, 11.83%.

Boc[-Orn(Z)-Leu-Orn(Z)-Phe-Pro-]$_2$NHNH$_2$ (L-L-9). This hydrazide was obtained from **L-L-8** (3.72 g, 2.0 mmol); yield, 3.65 g (99%); mp 145—147 °C; $[\alpha]_D^{25}$ −49° (*c* 0.5, AcOH); R_f=0.98.

Found: C, 61.49; H, 7.18; N, 12.04%. Calcd for $C_{97}H_{130}O_{20}N_{16}\cdot 3H_2O$: C, 61.51; H, 7.24; N, 11.83%.

Boc[-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-]$_2$NHNH$_2$ (L-D-9). This hydrazide was obtained from **L-D-8** (3.72 g, 2.0 mmol); yield, 3.39 g (80%); mp 139—142 °C; $[\alpha]_D^{25}$ −10.8° (*c* 0.5, AcOH); R_f=0.98.

Found: C, 61.53; H, 7.38; N, 12.76%. Calcd for $C_{97}H_{130}O_{20}N_{16}\cdot 3H_2O$: C, 61.51; H, 7.24; N, 11.83%.

H[-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-]$_2$NHNH$_2\cdot$2HCl (D-L-10). This compound was obtained from **D-L-9** (1.84 g, 1 mmol) as described for the preparation of **D-L-4**; yield of an oil, 1.81 g (100%); R_f=0.82.

H[-Orn(Z)-Leu-Orn(Z)-Phe-Pro-]$_2$NHNH$_2\cdot$2HCl (L-L-10). This compound was obtained from **L-L-9** (1.81 g, 1.0 mmol); yield of an oil, 1.81 g (100%); R_f=0.82.

H[-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-]$_2$NHNH$_2\cdot$2HCl (L-D-10). This compound was obtained from **L-D-9** (1.10 g, 0.6 mmol); yield of an oil, 1.10 g (100%); R_f=0.82.

***cyclo*[-Orn(Z)-Leu-Orn(Z)-D-Phe-Pro-]$_2$ (D-L-11).** To a solution of **D-L-10** (1.81 g, 1 mmol) in DMF (30 cm^3) at −20 °C, were added 1.71 M HCl in dioxane (1.75 cm^3) and isopentyl nitrite (0.15 cm^3, 1.1 mmol). After stirred at −20 °C until a hydrazine test became negative, this solution was added dropwise into pyridine (500 cm^3) at 0 °C for 5 min, and stirring was continued for 2 h at 0 °C and for 65 h at 5 °C. After the solvent was removed, the residue was dissolved in a mixture (280 cm^3, 6:1 v/v) of methanol and water, the solution was passed through the columns of Dowex 1 (OH^- form) and 50 (H^+ form). The columns were washed with the same solvent (560 cm^3), and effluent was evaporated to dryness. The residue was collected by filtration with the aid of water. For purification, solution of the crude product (1.02 g) in DMF (6 cm^3) was applied to a column (25×845 mm) with Sephadex LH-20, and development continued with DMF. Elution was carried out at room temperature at flow rate of 20 cm^3/h; a 3 cm^3 fraction was collected in each test tube. Peptide content in the fractions was determined with LKB 2138 Uvicord S at 245 nm. Fractions 55—65 containing **D-L-11** were evaporated, and product was collected by filtration with the aid of water; yield, 837 mg (49%); mp 107—109 °C; $[\alpha]_D^{25}$ −71° (*c* 0.1, MeOH); R_f=0.98.

Found: C, 61.15; H, 7.03; N, 11.27%. Calcd for $C_{92}H_{118}O_{18}N_{14}\cdot 5H_2O$: C, 61.45; H, 7.18; N, 10.91%.

***cyclo*[-Orn(Z)-Leu-Orn(Z)-Phe-Pro-]$_2$ (L-L-11).** This compound was prepared from **L-L-10** (1.81 g, 1 mmol) as described for the preparation of **D-L-11**. Product was collected by filtration with the aid of water; yield, 775 mg (45%); mp 135—140 °C; $[\alpha]_D^{25}$ −43° (*c* 0.1, MeOH); R_f=0.97.

Found: C, 64.80; H, 7.22; N, 11.18%. Calcd for $C_{92}H_{118}O_{18}N_{14}$: C, 64.49; H, 7.22; N, 11.48%.

***cyclo*[-Orn(Z)-Leu-Orn(Z)-Phe-D-Pro-]$_2$ (L-D-11).** This compound was prepared from **L-D-10** (1.09 g, 0.6 mmol); yield, 568 mg (55%); mp 139—141 °C; $[\alpha]_D^{25}$ −37.5° (*c* 0.1, MeOH); R_f=0.98.

Found: C, 62.16; H, 6.99; N, 11.32%. Calcd for $C_{92}H_{118}O_{18}N_{14}\cdot 4H_2O$: C, 62.08; H, 7.13; N, 11.02%.

***cyclo*(-Orn-Leu-Orn-D-Phe-Pro-)$_2\cdot$4HCl (D-L-12·4HCl).** Compound **D-L-11** (200 mg, 0.12 mmol) in 0.094 M HCl in methanol (6.2 cm^3) was hydrogenated in presence of Pd black. The filtrate was evaporated and resulting crystals were collected by filtration with the aid of ether. Product was recrystallized from methanol-ether; yield, 129 mg (82%); mp 209—211 °C; $[\alpha]_D^{25}$ −68° (*c* 0.1, MeOH); R_f=0.78. Amino acid ratios: Orn, 1.98; Leu, 1.04; Phe, 1.00; Pro, 0.97.

Found: C, 48.40; H, 7.72; N, 12.90%. Calcd for $C_{60}H_{98}O_{10}N_{14}Cl_4\cdot 10H_2O$: C, 48.12; H, 7.94; N, 13.09%.

***cyclo*(-Orn-Leu-Orn-Phe-Pro-)$_2\cdot$4HCl (L-L-12·4HCl).** This compound was prepared from **L-L-11** (200 mg, 0.12 mmol); yield, 101 mg (65%); mp 192—194 °C; $[\alpha]_D^{25}$ −46° (*c* 0.1, MeOH); R_f=0.75. Amino acid ratios: Orn, 1.96; Leu, 1.06; Phe, 1.00; Pro, 0.99.

Found: C, 50.66; H, 7.88, N, 13.50%. Calcd for $C_{60}H_{98}O_{10}N_{14}Cl_4\cdot 6H_2O$: C, 50.56; H,7.78; N, 13.76%.

***cyclo*(-Orn-Leu-Orn-Phe-D-Pro-)$_2\cdot$4HCl (L-D-12·4HCl).** This compound was prepared from **L-D-11** (200 mg, 0.12 mmol); yield, 104 mg (68%); mp 194—196 °C; $[\alpha]_D^{25}$ −30° (*c* 0.1, MeOH); R_f=0.73. Amino acid ratios: Orn, 2.03; Leu, 0.98; Phe, 1.00; Pro, 0.96.

Found: C, 50.64; H, 7.83; N, 13.60%. Calcd for $C_{60}H_{98}O_{10}N_{14}Cl_4\cdot 6H_2O$: C, 50.56; H, 7.78; N, 13.76%.

Molecular Weight Determination. Molecular weight (MW) of *Z*-substituted cyclic decapeptides was determined by the use of CORONA osmometer type 117 in DMF as a solvent. The values of MW for three analogs (**D-L-11**, **L-L-11**, and **L-D-11**) were 1788, 1698, and 1720, respectively, whereas the calculated value is 1708. FAB mass spectra of three analogs were obtained by the use of JEOL JMS-DX300. The values of *m/z* 1172 were observed, whereas the calculated value as [$C_{60}H_{95}O_{10}N_{14}$ (M+H)$^+$] is 1172.

Amino Acid Analysis. Analyses were carried out using JASCO HPLC amino acid analysis system, after hydrolysis of the peptides in 6 M HCl at 110 °C for 24 h.

Electrophoresis. Electrophoresis on Toyo Roshi No. 52 paper was carried out with the solvent system, formic acid-acetic acid-methanol-water (1:3:6:10, v/v; pH 1.8), for 2 h at 500 V/30 cm. Each of three analogs gave single spot. Ratios of mobility of **D-L-12**, **L-L-12**, and **L-D-12** toward GS were 1.43, 1.44, and 1.44, respectively.

CD Measurement. Measurement of CD spectra was performed with JASCO Model J-40 over a wavelength range of 190 to 260 nm in methanol as a solvent at 25 °C. Cell of 0.01 and 0.1 cm path length was used. In Fig. 5 are shown CD spectra of the analogs and GS.

Antibacterial Assays. Minimum amount of peptides necessary for the complete inhibition of growth was determined by a dilution method with Bouillon agar medium. Results are shown in Table 1.

Authors thank the staffs of Takeda Chemical Industries, Ltd. for the antibacterial assays. Authors are indebted to Assoc. Prof. Norikazu Nishino of Kyushu Institute of Technology for measurement of FAB mass spectra. Present work was partially supported by a grant from Central Research Institute of Fukuoka

University.

Basic Study on Lithium Recovery from Lithium Containing Solution

Tetsutaro YOSHINAGA,* Kentaro KAWANO, and Hirotsugu IMOTO†
Department of Environmental Science, Faculty of Engineering, Kyushu Institute of Technology, Sensuicho, Tobata-ku, Kitakyushu 804
(Received September 12, 1985)

Basic study of Li recovery using high purity sodium aluminate solution as coprecipitating agent has been made. Al concentration, pH and temperature greatly affect the Li recovery, and in this study the temperature was maintained constant (25 °C). For reference lithium solution, the optimum (initial) pH obtained increased with an increase in Al concentration. Optimum pH=11.0—12.5 for [Al]=50—1000 mg dm^{-3}. The optimum pH values obtained were lower than those in the previous work by about one pH unit. The following relationship was found between the Al concentration C_{Al} (mg dm^{-3}) and the optimum pH; Opt. $pH^{exp}=8.23+1.5 \log C_{Al}$. Furthermore, these experimental pH values were in fair agreement with the pH values calculated from the solubility product of aluminium hydroxide, $K_{sp}(HAlO_2)=[H^+][AlO_2^-]=10^{-13.2}$, i.e., $pH^{calcd}=9.5+\log C_{Al}$. Effects of coexistent ions on Li recovery were examined. Sodium and potassium ions did not interfere, while calcium, magnesium, and monosilicate ions did. However, the interference from Ba^{2+} ions was small. Especially, interference by calcium and monosilicate ions were significant. Bubbling of CO_2 gas into the Li solution with proper Al concentration made a remarkable improvement on Li recovery. Accordingly, the influence of water soluble carbonates on Li recovery was investigated. The carbonates (Na_2CO_3, K_2CO_3, $(NH_4)_2CO_3$) used were found to be very effective for Li recovery. The addition of sodium aluminate solution (500 mg dm^{-3}) to untreated geothermal water showed around 70% of Li recovery at the best. This incomplete recovery of lithium is due to the matrix effect of geothermal water. For reference Li solution with Al concentration of 500 mg dm^{-3}, optimum pH was 12.5, while for Ca, SiO_2-free geothermal water the same pH gave very low Li recovery. However, when a pH value of 11.5 is chosen, a remarkable increase in Li recovery was obtained (98—99%). The silica component in geothermal water interfered with the Li recovery, but the influence was relatively small. The silica in the geothermal water in this case, was polymerized and showed some buffering action, such as prevention of interference from calcium ions. This is the significant difference between poly and monosilicate ions which do not show any buffering action. The addition of sodium carbonate to the Ca,SiO_2-free geothermal water caused a remarkable acceleration of the Li recovery, similar to that for the reference Li solution.

Lithium has been widely used in recent years in batteries, glass, ceramics, aluminium refinning and other industries. A world wide increase in demand is expected in future. In addition to these commercial uses, lithium is also anticipated to be the fuel for nuclear fusion and a blanket material in fusion reactors[1] in the 21 century. The estimated lithium resources are not enough when the increase in future demand is taken into account. Lithium recovery from geothermal water using a coprecipitation method has been studied as a part of the basic investigation of lithium extraction from brines.[2] The results have taught us that among the coprecipitating agents used in the previous work, aluminium salts showed the best performance. The appropriate pH for Li recovery is in the high pH region of 10—13. Thus, from the operational point of view, the use of $NaAlO_2$ seemed better than that of $AlCl_3$. In the previous work, the $NaAlO_2$ addition method was partly applied. However, the salt was added in a powdered form and the data obtained showed some scatter, although the trends were probably real. Commercially obtained $NaAlO_2$ was used as the coprecipitating agent in the form of a highly alkaline solution.[3] Provided the same lot number of $NaAlO_2$ is used, the data showed relatively good reproducibility, but the data obtained from different lots showed large discrepancies. The reason could be: (1) a difference in the ratio of Al to NaOH, for example Al/NaOH=0.76—0.82, (2) the presence of impurities. In this study, a $NaAlO_2$ solution of high purity, except for NaOH, was prepared as coprecipitating agent for lithium recovery.

Experimental

Reagents. The special grade LiCl, NaCl, KCl, $CaCl_2 \cdot 2H_2O$, $MgCl_2 \cdot 6H_2O$, $BaCl_2 \cdot 2H_2O$, Na_2CO_3, K_2CO_3, $(NH_4)_2CO_3$ were obtained from Wako Pure Chemical Industries, Ltd. Al plates (99.99%) and $Na_2SiO_3 \cdot 9H_2O$ were obtained from Wako pure Chemical Industries, Ltd. All other reagents used were also obtained from Wako Pure Chemical Industries, Ltd.

Measurements and Apparatus. The concentration of lithium, sodium, potassium, calcium and magnesium were measured on a Japan-Jarrel Ash AA-8200 atomic absorption spectrophotometer. Silica was measured on a Shimadzu UV-200 double beam spectrophotometer, according to the JIS method.[4] pHs of solutions containing lithium were measured with an Instrument Co.Ltd., digital pH meter, DP-1400. An Ikeda Rika six-series magnetic stirrer was used to stir solutions.

Sample Solutions. a) Li Solution: The proper amount of LiCl was dissolved in distilled water, and adjusted to a Li concentration of 10 mg dm^{-3} ($[Li^+]_0$=10 mg dm^{-3}).

b) Geothermal Water: Geothermal water was sampled from a reservoir pond at mixed wells at the Hatchobaru power plant in Ohita prefecture, in January, 1983. Geothermal water was used in the laboratory six months after sampling.

Coprecipitating Agent. Prior to the preparation of the

† Present address: Division of Magnetic Recording Material, Toda Kogyo Corporation, Shinmachi, Yokokawa, Hiroshima 733.

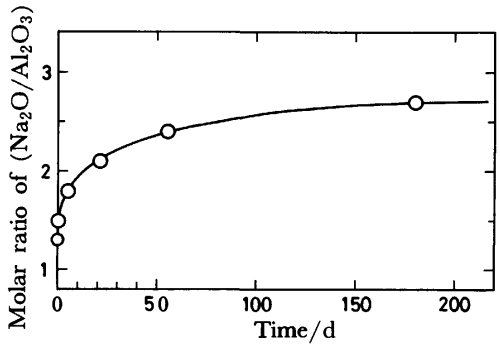

Fig. 1. Spontaneous decomposition of sodium aluminate solution with various (Na_2O/Al_2O_3) molar ratios at room temperature. [Na_2O]: 150 (g dm^{-3}).

$NaAlO_2$ coprecipitating agent, a preliminary test was made to examine the stability of the $NaAlO_2$ solution. The $NaAlO_2$ solution is said to be unstable at an Na_2O concentration of less than 90 g dm^{-3} and molar ratio of Na_2O to Al_2O_3 less than 1.3 at 25—50 °C, but when the ratio of $(Na_2O/Al_2O_3)_{mol}$ is set between 1.5—2.5, it is relatively stable at room temperature.[5] In the present work, the Na_2O concentration was fixed at 150 g dm^{-3}, and the value of $(Na_2O/Al_2O_3)_{mol}$ was changed between 1.3—2.7 taking into account the results obtained by Shimizu et al.[5] The stability of the sodium aluminate solution prepared as described above was examined at room temperature (around 25 °C) as shown in Fig. 1. It was found that the relationship between the spontaneous decomposition time, t (in day) and the molar ratio, R[=$(Na_2O/Al_2O_3)_{mol}$] was given by:

$$\log t = 1.78R - 2.504$$

Thus, the $NaAlO_2$ stock solution was adjusted to be; [NaOH]=200 g dm^{-3}, [Al]=50 g dm^{-3} and $(Na_2O/Al_2O_3)_{mol}$=2.7.

High grade Al plates were washed with acetone and water, dipped in alkaline solution(1 M*-NaOH), washed with water, dipped in acidic solution (1M-HCl), washed with water, and finally washed with acetone and/or ether. The plates were then stored in a desiccator. Al (25g) was taken into the solution in which 100 g of NaOH was dissolved with 400 ml of distilled water, and the solution was stirred. After the complete dissolution of the aluminium plates, the solution was filtrated with a sintered-glass filter (G-4), washed and transfered to a 500 ml volumetric flask to be diluted to the mark.

Procedure. The similar experimental procedure on Li recovery was used as was described in the previous work.[2] In the present study, the Li containing solutions were placed in a thermostat (25 °C) to be free from temperature effect. The initial pH was adjusted using 1 M-HCl solution. Carbonates were added after the addition of coprecipitating agents to examine their effects. The pHs were then adjusted. When the influence of coexistent ions was being examined, the ions were just added to the Li solution. Subsequently the same procedure was followed as for the solution which were free from coexistent ions.

Treatment of Geothermal Water. Geothermal water was treated in the same way as that described above.[2] Ca-free geothermal water was prepared as follows; 30 ml of saturated $Na_2C_2O_4$ solution was added to the 1 liter of geothermal water, stirred for 2 h; the CaC_2O_4 precipitate that formed was filtrated with a glass filter (G-4). Silicate-free geothermal water was prepared as follows; $FeCl_3$ was added to be Fe concentration of 1000 mg dm^{-3}, and pH was adjusted (pH=9.5) with 5 M-NaOH solution. After being stirred for 2 h, the precipitate formed was filtered with filter paper (No. 131). Ca,SiO_2-free geothermal water was prepared by combining the above procedures, that is, by first removing calcium ions, and then silicate ions. The main components of the geothermal water are shown in Table 1.

Results and Discussion

The Relationship betweem Al Concentration and Optimum pH on Li Recovery for Li Solution. pH dependence on Li recovery at various Al concentrations (50—1000 mg dm^{-3}) was examined. Figure 2 (1) shows the data for Al concentration of 300 mg dm^{-3} as an example. In the upper half of the left side of the figure(a) are given the residual Li concentrations as a function of time elapsed at various pHs. In the lower half of the left side of the figure(b) are given the time traces of pHs for the Li containing solutions with six initial pHs. Those solutions with initial pHs of 10—11.5 show rapid increase in pHs at the beginning, while those with initial pHs of 12—12.5 change slowly. The relationship between the initial pH and the percent recovery of lithium is shown in the right side of the figure(c). After 3 h, the curve with initial pH of 12 shows the maximum percent recovery of lithium among those with several pHs. At pH 12, around 86% of lithium was recovered after 6 h, while after 24 h, 100% was recovered. The data for other Al concentrations are shown in Fig.2 (2). The relationship between the Al concentration and the optimum pH for Li recovery thus obtained are shown as a solid line in Fig. 3, where at the appropriate pH if maximum recovery of lithium is obtained we designate that the optimum pH. For a Li solution, as the figure shows, the optimum initial pH obtained increases continuously with increase in Al concentration, where the optimum pH is 11.0—12.5 for [Al]= 50—1000 mg dm^{-3}. The optimum pH values obtained were lower than those obtained in the previous work[2] by about one pH unit. The following empirical formula

* 1 M=1 mol dm^{-3}.

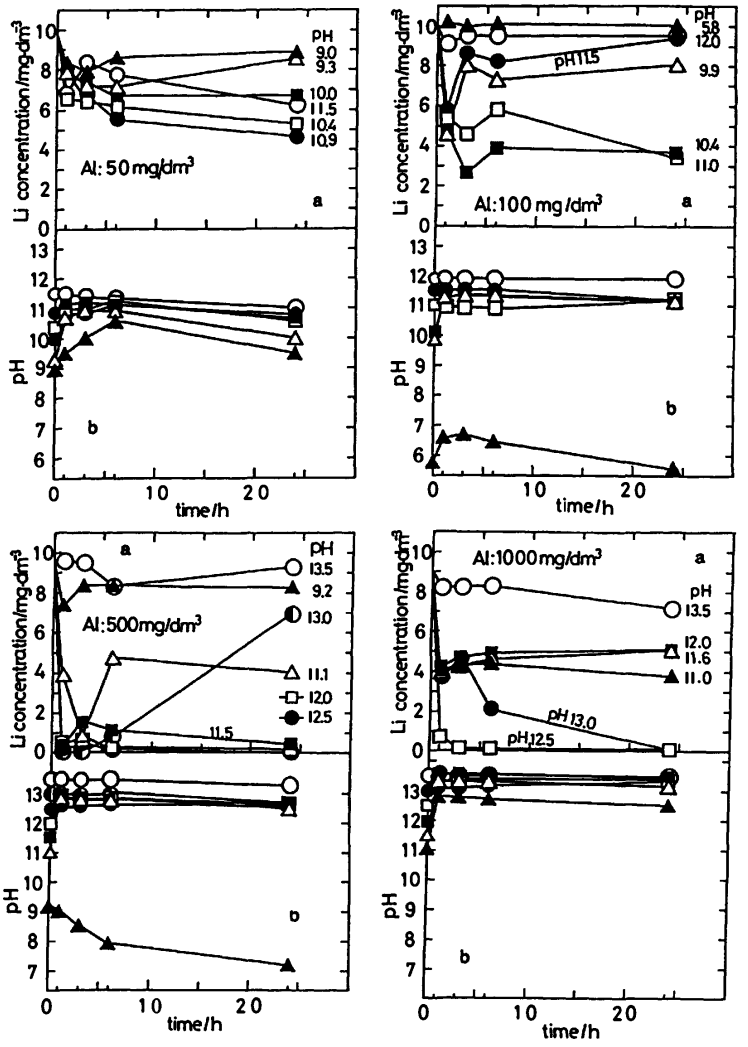

Fig. 2.(2) Initial pH dependence on Li recovery at various Al concentrations at 25°C.

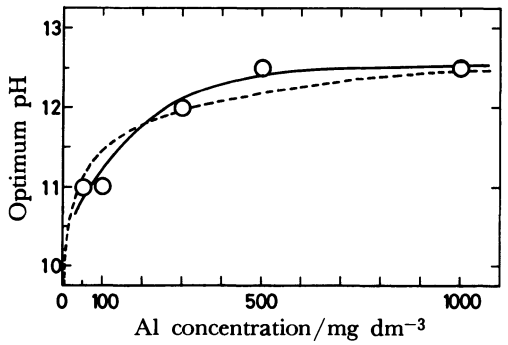

Fig. 3. The relationship between Al concentration and optimum initial pH for Li concentration of 10 (mg dm^{-3}) solution at 25°C. ——: Experimental curve, -----: Theoretical curve obtained using solubility product of aluminium hydroxide $\{K_{sp}(HAlO_2)=[H^+][AlO_2^-]=10^{-13.2}\}$.

was found between the Al concentration C_{Al}(mg dm^{-3}) and the optimum pH;

$$pH_{opt}^{exp}([Li]_0 = 10\ mg\ dm^{-3}:25°C) = 8.23 + 1.5 \log C_{Al}$$

These experimental optimum pH values were in fair agreement with the pH values calculated from the solubility product of aluminium hydroxide, $K_{sp}(HAlO_2)=[H^+][AlO_2^-]=10^{-13.2}$ that is, $pH^{calcd}=9.5+\log C_{Al}$. The broken line in Fig. 3 was plotted using these calculated values. This characteristic correspondence suggests that the optimum pH for Li recovery using the coprecipitation method will have some relation to the solubility product of aluminium hydroxide.

Influence of Coexistent Ions. Ca^{2+} and Mg^{2+} ions were known to interfere with the precipitation of lithium ions as aluminate.[6] The influence of Na^+, (K^+), Ca^{2+}, Mg^{2+}, (Ba^{2+}), and monosilicate ions on the Li recovery was investigated using freshly prepared high purity $NaAlO_2$ solution. The results are shown in Fig. 4. Sodium ions seem to behave differently in comparison with the Li solution. However, after 24 h, nearly the same percent recovery was obtained. Potassium ions seemed not to have any influence on Li recovery although its concentration is low, about two orders comparing with sodium ions. Alkaline earth metal ions, Ca^{2+} and Mg^{2+} ions interfere

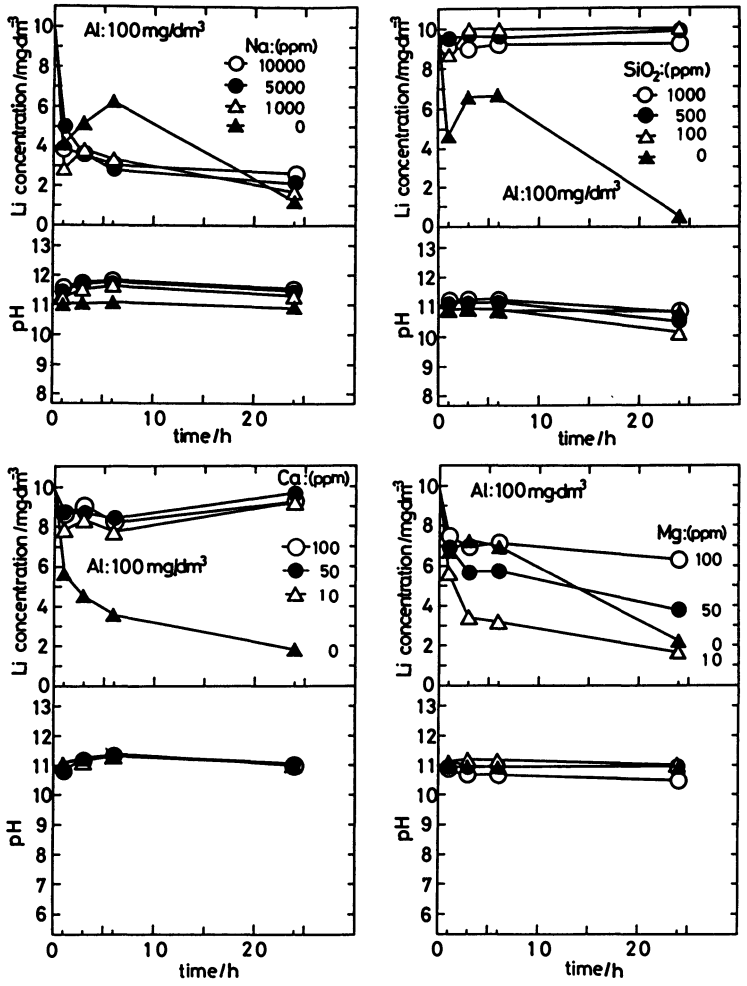

Fig. 4. Influence of coexistent ions on Li recovery at 25°C. Interference ions illustrated were; [Na^+], [Ca^{2+}], [Mg^{2+}], [SiO_3^{2-}]. Counter ions used were Cl^- for cations, Na^+ for anions.

with the Li recovery as is shown in the figure. Especially, Ca^{2+} ions give large interference. Even a Ca concentration as low as 10 mg dm^{-3}, prevented the recovery of lithium. To examine the uptake of Ca ions into aluminate precipitates in detail, the residual Ca concentration in the Li containing solutions was measured. Figure 5 shows the results. For the solution with an initial Ca concentration of 10 mg dm^{-3}, the maximal uptake was 99%, while for Ca concentrations of 50 and 100 mg dm^{-3}, it was 94 and 70%, respectively. If Ca^{2+} ions were taken up into the precipitate in the form of $Ca(AlO_2)_2$, the total calcium content which corresponds to 74 mg Ca dm^{-3} will be incorporated into the precipitates, assuming that the calcium aluminate is completely insoluble. Considering these results, when a Ca salt is added to a Ca concentration of 10 mg dm^{-3}, there should remain enough room for the aluminate ions to react with lithium ions. In practice, however, very little lithium was recovered. The reason is not clear at present. But one possible explanation is that the calcium aluminate precipitated accelerates the formation of aluminium hydroxide, and the aluminate covers the surface of hydroxide. Interference from Mg^{2+} ions is not so large as is easily recognized in Fig. 4. Even for a Mg concentration of 50 mg dm^{-3}, a Li recovery of 60% (24 h) was obtained, and for 100 mg dm^{-3}, 36% (24 h). If Mg^{2+} ions were precipitated completely as $Mg(AlO_2)_2$, magnesium corresponding to a Mg concentration of up to 45 mg dm^{-3} would be taken up completely for 100 mg dm^{-3} of Al. Therefore, it seems that Ca $(AlO_2)_2$ is only slightly soluble in water, while $Mg(AlO_2)_2$ is more soluble than Ca $(AlO_2)_2$. Nevertheless, the residual Mg concentration in the solution became zero within 1 h at any initial Mg concentration. This phenomenon might be interpreted by the occulusion of magnesium ions into magnesium and/or lithium aluminate precipitates and by adsorption on aluminium hydroxide. Interference from Ba^{2+} ions was also studied but no meaningful influence was found. The influence of addition of monosilicate ions is also shown in Fig. 4. Monosilicate ions differ greatly from the polysilicate ions in geothermal water as is described later. This difference will be attributed to the reactivities of silicate ions with aluminate ions.

Effects of Carbonate Ions. We found that the blowing of CO_2 gas into the Li solution with appropriate Al concentration raised the Li recovery remarkably. Thus, three kind of water soluble carbonates were used to examine whether carbonate ions are effective or not on Li recovery. Concentrations of carbonates were chosen to be 0.2, 0.6, 1.0, and 2.0 g dm^{-3}. Figure 6 illustrates the effects of carbonates. The figure evidently shows the effectiveness of carbonate addition; the more carbonate, the better the Li recovery. The effects of potassium and ammonium salts seems to be superior to sodium salt although the

results of ammonium salt was not shown here. However, the difference in univalent (alkaline) cations seems not to have any appreciable influence on Li recovery, as is already stated above. The effects of carbonate addition on Li recovery is significant but the reason is not clear. Three reasons are considered as follows: First, carbonate ions affect the surface conditions of aluminium hydroxide which is simultaneously formed with lithium aluminate to raise the adsorption capacity for lithium uptake (i.e., amorphous aluminium hydroxide which is very effective on Li adsorption[7] will be stably maintained). Second, the addition of carbonates lowers the solubility of the lithium aluminate formed. Thirdly, the optimum pH might be maintained by a pH buffer action due to the carbonate ions.

Mechanism. A mechanism for the Li recovery using the coprecipitation method was proposed in the previous paper.[2] That is, lithium is recovered by the formation of lithium aluminate and by adsorption on aluminium hydroxide. However, it seems that all the properties found in the study will not be explained satisfactorily by this mechanism. More detail discussion will be made in the following paper.

Lithium Recovery from Geothermal Water. The results of pH dependence on Li recovery from geothermal waters (nontreated and treated) is shown in Fig. 7. For an Li solution, optimum pH value for an Al concentration of 500 mg dm^{-3} was 12.5. However, for Ca,SiO_2-free geothermal water, the same pH gave only low recovery of 32—12% after 1—3 h from the beginning of Al salt addition. In this Ca,SiO_2-free geothermal water, the optimum pH was 11.5 which is lower than that of Li solution by one pH unit, and a high percent recovery of 98—99% was obtained after 1—3 h. The results for Ca-free, SiO_2-free, Ca,SiO_2-free and nontreated geothermal waters at an initial pH of 11.5 are shown in Fig. 8. The figure shows that there is little difference between nontreated and Ca-free geothermal waters. That is to say, the influence of polymerized silica is not large on Li recovery. However, for SiO_2-free geothermal water, the percent recovery of lithium is poorer compared with non-treated geothermal water because of the presence of calcium ions. The reason is that as the polysilicate ions have a buffer action, silicate ions prevent the interference from Ca ions to form calcium silicate although the polymerized silica itself exhibits some interference on Li recovery.

Effects of Carbonate Addition on Ca,SiO_2-free Geothermal Water. Sodium aluminate was added to generate an Al concentration of 100 mg dm^{-3} in Ca,SiO_2-free geothermal water in order to examine the effectiveness of Na_2CO_3 addition on Li recovery. As the optimum pH for the Li solution with an Al concentration of 100 mg dm^{-3} is 11.0, an initial pH of 10.0 was chosen for this solution. As Fig. 9 shows, the

effect of the Na_2CO_3 addition is clearly recognized. The reason for the improvement in Li recovery found on Ca,SiO_2-free geothermal water will be the same as that for the Li solution.

The authors would like to express their thanks to Dr. Kenjiro Yanagase for help with the sampling of the geothermal water.

The Studies on the Hydration Energy and Water Structures in Dilute Aqueous Solution

Myung Jun MOON and Mu Shik JHON*
Department of Chemistry, Korea Advanced Institute of Science and Technology,
P. O. Box 150, Cheongyangni, Seoul, Korea
(Received May 10, 1985)

Thermodynamic properties of dilute aqueous solutions are influenced by the interactions between ions and water molecules as well as the change of the water structure around the ion. To obtain hydration energies of monoatomic ions and local water structures around the ions, we make use of the discrete-continuum method. The calculated values for the hydration energies of ions are in good agreement with experimental values. The hydration energies of monoatomic cations can be qualitatively correlated with the sum of the successive ionization potentials from its atomic state to the ionic state. From their correlations, we can classify various ions as three groups. It is also found that the main factors which determine the stability of water structures around the ions are the charges and dimensions of ions.

The properties of aqueous electrolyte solution in chemical processes are strongly influenced by ions and their surrounding water molecules.[1-3] In particular, we would like to chemically classify various ions into three groups by correlating the hydration energies of ions with the sum of successive ionization potentials from its atomic state to ionic state[4] and into two groups by comparing the intermolecular interaction energies among water molecules in aqueous solution with those in pure water.[5-7]

Recent progresses in the ab initio quantum mechanical method,[8-11] statistical thermodynamics,[12,13] and the simulation using computer technology[14-17] have given the remarkable information for local water structures around ions.

In order to understand the local water structures around ions, we have calculated hydration energies of ions using the empirical potential function.[18-22] Earlier theoretical approaches calculating thermodynamic properties of aqueous solution can be divided into the discrete[23-25] and continuum methods.[10,14,15] Since it is possible to make accurate studies of solvation effects using relatively small clusters[16] and it takes much computing time to include all water molecules in calculation, we make use of the discrete-continuum method.[13,18] In this method, the water molecules interacting strongly with an ion are discretely treated, while the remaining water molecules are considered as a polarizable dielectric continuum.

Especially, if the interaction energies of water molecules oriented by the electric field of an ion are compared with those of pure water molecules, the enhancement of the water structure around the ion can be quantitatively known. The foci of our studies are to understand the experimental observation on aqueous ionic solution according to the characteristics of ions.

Model System. I) Hydration Scheme: According to the idea presented by Frank and Wen,[5] the environment of a dissolved ion is divided into three regions. As shown in Fig. 1, the ion is discretely surrounded by several water molecules within the first hydration shell, the second hydration shell water and bulk water are treated as the dielectric continuum. Dielectric saturation is assumed to occur in the secondary hydration shell water, but the dielectric constant of bulk water is equal to that of pure water.

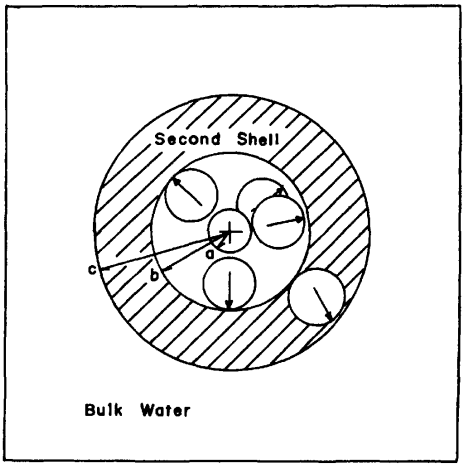

Fig. 1. Schematic diagram to indicate that an ion is enveloped by the first hydration shell (b), the second hydration shell (c), and the bulk water which is equivalent to pure water.

One of the arrangements of water molecules in the first hydration shell can be assumed to be either one of the tetrahedral, trigonal bipyramidal, and octahedral structure, which have been shown by ab initio calculations.[10] As the water molecules are discretely added outside the first hydration shell according to the hydration number, geometrical features could be recognized by the results of Monte Carlo simulations[17] for aqueous solutions of alkali metal and halide ions.

The hydration schemes of water molecules in the first hydration shell around the ion are determined by the given hydration number and can be defined by the variables θ_w and Φ_w which are shown in Fig. 2.

II) Water Molecule. The water molecule is taken to be isotropic polarizable sphere which ignores the detailed charge distribution and has the permanent off-centered dipole.[20] Multipoles higher than the di-

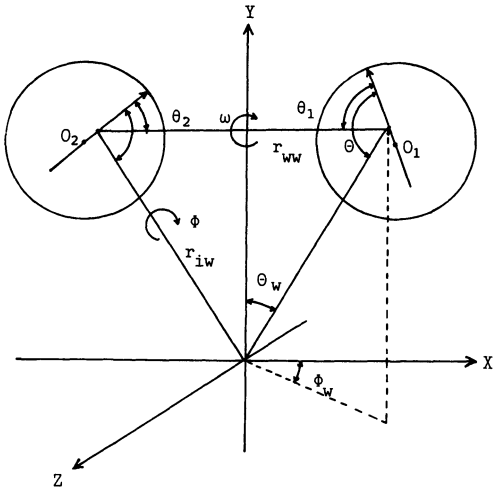

Fig. 2. Geometric features for the water dipole around the point charge. The distance between O_1 and O_2 is equal to the distance between oxygens of water molecules.

Fig. 3. Permanent electrostatic distribution in water from gas phase calibration data (since μ=1.85×10^{-18} esu cm, $q=\mu/2a$=0.1926e).

pole are not considered in this work, because its inclusion for potential functions is arbitrary and the use of multipoles would not alter the final results significantly. The model of water molecule[20] is described by estimating three parameters, namely the length of the off-centered dipole (2a), the amount by which the dipole is off-centered(s) and the van der Waals radius of water molecule (r_w).

The water model and the values of the parameters used in this work are shown in Fig. 3. The parameters are empirically obtained by fitting the oxygen–oxygen distance and the energy of water dimer.[26-28] The computed results are −21.25 kJ mol^{-1} and 2.77 Å for the dimerization energy and oxygen–oxygen distance, respectively.

The value of the permanent dipole moment of water molecule is used as 1.85D (1D = 3.325×10^{-30} Cm) which is experimentally determined.[29]

For the polarizability of water, there are important contributions to the static polarizability, α_w, from intra- and intermolecular motions. It should be noted that we have used the value of α_w which includes the electronic polarizability of water (=1.44×10^{-24} cm^3) as well as the small increment of 0.16×10^{-24} cm^3 according to the effect of intramolecular motions.[26,30]

III) Ion. The ions in solution are taken to be charged conducting spheres. The choice of X-ray crystallographic radii for ions brings out a good approximation to the respective radii of the bare ions in solution.[21] Since ion–solvent interaction energies in a strong polar solvent are similar to those between cations and anions in crystals, it is reasonable that the ion in the solution may be compressed to its crystallographic radius.[31] We have used the effective ionic radii which are measured according to the coordination number of ion.[32] The coordination number of ion corresponds to the number of water molecules in the first hydration shell of ion. The hydration numbers in our work are taken from the X-ray diffraction data on structures of metal complexes in solution.[33] The hydration numbers of ions not included in Ref.33 are decided by fitting the hydration energies of ion.

Potential Function.[34-36] The energies of the dipole–dipole interaction, E_{dd}, and the dipole-induced dipole interaction, E_{did}, will be calculated by using Eqs. 1 and 2.

$$E_{dd} = -\frac{\mu^2}{Dr_{ww}^3}(2\cos\theta_1\cos\theta_2 - \sin\theta_1\sin\theta_2\cos\omega), \quad (1)$$

$$E_{did} = -\frac{1}{2}\frac{\mu^2\alpha_w}{Dr_{ww}^6}(3\cos^2\theta_1 + 1). \quad (2)$$

Geometrical parameters for the dipole–dipole interaction are shown in Fig. 2, D is the dielectric constant, α_w is the polarizability, and μ is the permanent dipole moment of water molecule. The energies of the ion-dipole interaction, E_{id}, and the ion-induced dipole interaction, E_{iid} will be calculated by using Eqs. 3 and 4.

$$E_{id} = -\frac{q\mu}{Dr_{iw}^2}\cos\theta, \quad (3)$$

$$E_{iid} = -\frac{q^2\alpha_w}{2Dr_{iw}^4}, \quad (4)$$

where q is the ionic charge, r_{iw} is the distance between the ion and the dipole.

The dielectric constant is represented by Eq. 5.[34]

$$D = \left(\frac{\varepsilon_0-\varepsilon_1}{c-a}\right)r_{iw} + \varepsilon_1 - \left(\frac{\varepsilon_0-\varepsilon_1}{c-a}\right)a, \quad (5)$$

where D means the dielectric constant at the distance separated from the ion, ε_1 and ε_0 denote the dielectric constant at the surface of ion, and that of bulk water, respectively. a and c are the radius of ion and the distance from a point charge to bulk water, respectively.

The nonbonded interaction energies, E_{nb}, between

a) From Ref. 32. b) From Ref. 41. c) From Ref. 39.

ion and water and between water molecules are calculated by using the familiar Lennard-Jones 6-12 potential and are given by Eq. 6.

$$E_{nb} = -K_6(i,j)/Z_{ij}^6(1-0.5/Z_{ij}^6) \quad (6)$$

where $k_6(i,j)=C(i,j)/r_{ij}^{06}$ and $Z_{ij}=r_{ij}/r_{ij}^0$, r_{ij}^0 is the sum of the van der Waals radii of the interacting molecules and $C(i,j)$ is calculated by using London-Margenau formulas.[38]

The values of effective ionization potential used in the nonbonded energy term could be obtained by multiplying the true ionization potential by a suitable coefficient.[40] In this work, we obtained new coefficients in the process of fitting the dimerization energy of water molecule and the heat of hydration of all ions. The correction coefficients which would be used in this calculation are 4.5 for the water molecule and 3.0 for all ions.

The radii, true ionization potentials, and polarizabilities for the water molecule and all ions are summarized in Table 1.

The polarization energy for the continuous medium outside the first hydration shell is given by Eq. 7[12,24,25]

$$E_{pol} = \frac{1}{2}\left\{\left(\frac{1-\varepsilon_b'}{\varepsilon_b'}\right)\frac{q^2}{b} + \left(\frac{1-\varepsilon_0}{\varepsilon_0}\right)\frac{q^2}{c}\right\}, \quad (7)$$

where

$$\varepsilon_b' = \varepsilon_b\left(\frac{(1-\varepsilon_b)(1-\varepsilon_c)}{\varepsilon_c}\frac{b}{c}+1\right)^{-1}$$

and

$$\varepsilon_b = \varepsilon_m/\varepsilon_1$$
$$\varepsilon_c = \varepsilon_0/\varepsilon_m.$$

The first hydration shell of radius b is surrounded by a water layer of thickness $(c-b)$, which is immersed in the bulk water of dielectric constant ε_0. The relative permittivity ε_m between $\varepsilon_1=1$ and $\varepsilon_0=78.5$ is calculated by using Eq. 5. The thickness of the secondary layer $(c-b)$ was taken as the diameter of water molecule.

Hydration Energy Analysis.[14,20] The energy for the process of transferring an ion from vacuum into a position inside the liquid water, ΔE_{hyd}, can be obtained from the energies of intermolecular interaction in pure water and dilute aqueous solution. The thermodynamic cycle of this process is shown in Fig. 4.[20] The total energy of solution is composed of the ion-water interaction, E_{iw}, the water-water interaction in aqueous solution, E_{ww}, and that of the pure water, E_{ww}°. The energy of hydration is given by[14,42]

$$\Delta E_{hyd} = E_{iw} + E_{ww} - E_{ww}^\circ. \quad (8)$$

The ion-water interaction energy, E_{iw}, can be divided into the contributions exclusively arising from the first shell water molecules, E_{fw}, and from the polarization of the water molecules outside the first hydration shell, E_{pol}.

$$E_{iw} = E_{fw} + E_{pol}. \quad (9)$$

Also, the water-water interaction can be considered as being composed of three components representing the first hydration shell-first hydration shell interaction, E_{ff}, the first hydration shell-remaining water interaction, E_{fr}, and the remaining water-remaining water interaction, E_{rr}.

$$E_{ww} = E_{ff} + E_{fr} + E_{rr}. \quad (10)$$

As the reference system, the pure water was also considered as a dilute solution containing a water solute.[14,15,42] Since the average number of hydrogen bonds per a water molecule in pure water is about 4,[44] we considered that the water solute is surrounded with four water molecules in a tetrahedral configuration and this water cluster may be successively surrounded

by the other water molecules.

The total intermolecular interaction energy in pure water is expressed as

$$E^{\circ}_{ww} = E^{\circ}_{fw} + E^{\circ}_{ff} + E^{\circ}_{fr} + E^{\circ}_{rr}, \quad (11)$$

where E°_{fw} is the interaction energy for the water solute-surrounding water molecules, E°_{ff} for the first hydration shell-first hydration shell, E°_{fr} for the first hydration shell-remaining water, and E°_{rr} for the remaining water-remaining water.

E°_{fw} is the sum of the energies of separating $n+1$ water molecules from pure water to make a room for the ion of which the hydration number is n. This value is equal to the dissociation energy in the gas phase.

$$E^{\circ}_{fw} = nE^{\circ}_{1}, \quad (12)$$

where $E_1{}^{\circ}$ is the average hydrogen bond energy which is calculated from the water cluster with the ice-like structure. The calculated value of $E_1{}^{\circ}$ in this work is -18.24 kJ mol^{-1}.

E°_{ff} is the sum of the interaction energies between the first hydration water molecules around the water solute, which is the same as the sum of the interaction energies between the secondary neighbor water molecules in the water cluster. The interaction energy between the secondary neighbor water molecules in pure water is -1.84 kJ mol^{-1}.

E°_{fr} is the interaction energy between the water molecules in the first hydration shell and the remaining water, which is the energy forming a cavity in the supermolecule-approach.[20] E°_{fr} in Eq. 11 arises from some changes of the water structure at the second hydration shell in transferring the solvated ion into the cavity inside the bulk water. Since the nature and extent of the second hydration shell is not well understood at this time, it is very difficult to calculate the energies of E°_{fr} and E_{fr} quantitatively. If E°_{fr} in pure water is compared with E_{fr} in the ionic solution, the difference of these energies is qualitatively estimated to be about 41.84 kJ mol^{-1}.[13,20] Therefore, we can assume that the water structure in the second hydration shell is not variant in transferring of ion from vacuum into pure water.

Finally, one water molecule in vacuum has to be returned to the aqueous solution to complete the cycle by checking the thermodynamic cycle in Fig. 4. The exchange of energy involved in this process is equal to the work of condensation, ΔH_{con}. This value can be taken from the latent heat of condensation to be about 44.76 kJ mol^{-1}.[20] Thus, the total hydration energy, ΔE_{hyd}, is represented as

$$\begin{aligned}\Delta E_{hyd} &= E_{fw} + E_{pol} - E^{\circ}_{fw} + E_{ff} - E^{\circ}_{ff} + \Delta H_{con} \\ &= E_{fw} + E_{pol} - E^{\circ}_{fw} + \Delta E_{ww} + \Delta H_{con}, \end{aligned} \quad (13)$$

where

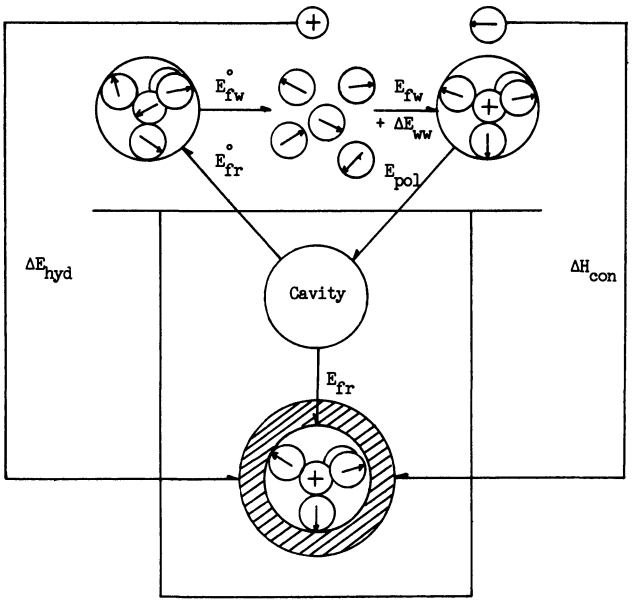

Fig. 4. The total hydration energy of ion (ΔE_{hyd}) separated into the various steps.

$$\Delta E_{ww} = E_{ff} - E^{\circ}_{ff}. \quad (14)$$

ΔE_{ww} is the energy which indicates the change of local water structures around the ion. Therefore, the phenomena of structure making and breaking of ions can be explained by the quantity of these values.

Free Energy Analysis.[3] The free energy of hydration of an ion at constant volume and pressure is given by

$$\Delta F_{hyd} \simeq \Delta E_{hyd} + T\Delta S_{hyd}. \quad (15)$$

The entropy of hydration for the ion is given by

$$\Delta S_{hyd} = \Delta S_f + S_{pol}, \quad (16)$$

where ΔS_f is the contribution from the water molecules in the first hydration shell and estimated by Frank and Evans.[45,46] The second term is the contribution from the water molecules outside the first hydration shell and is given by[12,25]

$$S_{pol} = -\frac{q^2}{2}\left\{\frac{(b-c)}{bc}\frac{1}{\varepsilon_m^2}\left(\frac{\partial \varepsilon_m}{\partial T}\right)_p - \frac{1}{c}\frac{1}{\varepsilon_0^2}\left(\frac{\partial \varepsilon_0}{\partial T}\right)_p\right\}, \quad (17)$$

where q is the ionic charge, $(\partial\varepsilon_m/\partial T)_p$ is the temperature variation of the local relative permittivity and $(\partial\varepsilon_0/\partial T)_p$ is that of the bulk dielectric constant. Of the parameters, the values of $(\partial\varepsilon_m/\partial T)_p$ and $(\partial\varepsilon_0/\partial T)_p$ for water are -0.00160 K^{-1} and -0.3595 K^{-1}, respectively.[25]

Results and Discussion

The hydration energies of ions are obtained by one by one optimizing r_{iw},θ, and ϕ which indicate the position of water molecules around the ion. The calcu-

lated hydration energies and free energies of ions are summarized in Table 2. Comparing the calculated hydration energy with the experimental data, ΔH_{exp}, the difference of energies may be about ±42 kJ mol^{-1}. From the calculated results, the hydration energies of monoatomic cations can be qualitatively correlated with the sum of the successive ionization energies from its atomic state to the ionic state.[4] From inspecting the plots in Figs. 5 and 6, we classify the cations into three groups in terms of the hydration energy and free energy of ion, respectively. In Table 3, since the correlation coefficients for linearity of the plots in Figs. 5 and 6 are about 1.0, the present classification can be proven.[49]

The cationic species are classified as group(a) belonging to IA-IIIA groups including Al^{3+} in IIIB group, group(b) belonging to VIA-IIB groups, and group(c) belonging to IIB-IVB groups in the periodic table. This classification is in good agreement with

the result obtained by Matsuda and Notoya.[4]

It is interesting to empirically investigate the chemical characteristics of each group. The present classification of cationic species originates from the consideration of the different shape of nonbonded energy curve between ion and water. The contributive components for interaction between ion and water molecule are given in Table 4. In the same charge ions, it is found that the nonbonded term in the potential energy plays an essential role in classifying the ionic species. The variations of the nonbonded energy term between ion and one water molecule depending on the ion-oxygen distance are minutely represented in Fig. 7. The ions of group(c) have the stronger nonbonded energy than those of groups(a) and (b). It is mainly due to the low ionization potential of two electrons in 6s configuration. The lower ionization potential and larger polarizability the ion has, the larger nonbonded energy the ion has. The ions of group(c) have been considered as soft acids in the principle of hard and soft acids and bases.[50]

In the case of the ions of group(b), their 3d electrons are distributed among 3d orbitals. For Mn^{2+} with five 3d electrons and Zn^{2+} with a completely filled 3d shell, the hydration energies mainly depend on the electrostatic energy term in the potential energy, since their polarizabilities and radii are small.

Since the ions of group(a) have no 3d electrons and are small in size and low in the polarizability (relatively large core charges, less shielded nucleus), the ions have the large electrostatic energies and low nonbonded energies (see Fig. 7). From the above results, the ions of group(a) have been recognized as the hard acids in the principle of hard and soft acids and bases.

The interaction energies among water molecules around an ion are expressed as ΔE_{ww} in Tables 4 and 5. Since the water molecule in our model is an isotropically polarizable sphere including only dipole, the geometric approach[15] for a hydrogen bonding is not reasonable. Therefore, comparison of the interaction energies among water molecules around the ion with those around the water solute in pure water gives the information about enhancement of the structures of water molecules in the first hydration shell. The intermolecular interaction energy changes due to the

structure making and breaking ions are represented as the negative and positive values from Eq.14, respectively.

In alkali metal ions, Li^+ and Na^+ are the structure making ions of which the surrounding water molecules are more stable than the pure water. On the other hand, K^+, Rb^+, and Cs^+ are the structure breaking ions. Here, it is found that the water structure around the ion was gradually broken according to the increment of the ionic radius. This result correspondes to the tendency of the B-coefficient of the Jones-Dole equation in electrolyte solution.[51)] Compared with the alkali metal ions, the halide ions have the structure breaking effect which arises from the expansion of the first hydration shell due to the change of the direction of dipole.

Since multiple charged ions, such as Zn^{2+}, Ni^{2+}, and Fe^{3+}, strongly attract the surrounding water molecules, the distances among water molecules in the first hydration are shorter than that in pure water and the water structure around these ions are enhanced. Therefore, these ions are structure making ions.

On the other hand, since Be^{2+}, Mg^{2+}, and Al^{3+} are very small ions and the interactions between ion and water molecules are very strong, the ion and surrounding water molecules are close to the aquo complex compounds. In these ions, it is difficult to explain the structure enhancement by only water molecules in the first hydration shell.

Jorgensen's Monte Carlo calculation suggested that structure makers may not be explained by a pronounced increase in solvent-solvent hydrogen bonding.[14)] The structure making effect in our method can be explained not by the increment of hydrogen bonding but by the comparison of average energy in the first hydration shell of an ion in aqueous solution with those of pure water. Although the formation of the first hydration shell represents a significant change in water structure, the contribution to the total hydration energy of the ion is not remarkable.

Our calculation leads to conclusions that the classification of ions into three groups is accomplished by the values of the nonbonded energy which involves the sum of ionization potential and polarizability of the ions. And the main factors which determine whether the ions will be structure makers or structure breakers in aqueous solution are the interaction energy of the ions with water molecules in the first hydration shell and the dimension of the ions characterized by the polarizability.

We thank Dr. A. Matsuda and Dr. R. Notoya, Hokkaido University for providing us the experimental data.

Spectrophotometric Determination of Micro-Amounts of Ruthenium(III) and Platinum(IV) with Acenaphthenequinone Mono(thiosemicarbazone)

Shailendra Kumar SINGH, Rakesh Kumar SHARMA, and Sharwan Kumar SINDHWANI*
Department of Chemistry, University of Delhi, Delhi-110007, India
(Received February 19, 1985)

Ruthenium(III) and platinum(IV) form 1:2 (metal:ligand) complexes with acenaphthenequinone mono(thiosemicarbazone) (AQTS). The complexes are soluble in 70% *N*,*N*-dimethylformamide (DMF). The reagent has been used for the spectrophotometric determination of Ru(III) and Pt(IV). The optimum ranges of concentration for the determination of Ru(III) and Pt(IV) are 2.02—7.09 and 2.83—11.6 ppm over the pH range 5.3—6.8 and 1.9—4.1, respectively. The Sandell sensitivities for the determination of Ru(III) and Pt(IV) are 0.01 and 0.016 μg cm^{-2}, respectively. The determination has also been carried out in the presence of foreign ions.

When the solution of acenaphthenequinone mono (thiosemicarbazone) was added to Ru(III) or Pt(IV) solution, a yellowish green or yellowish orange colored complex was formed. The present study was undertaken to investigate the possibility of the use of AQTS as a reagent for spectrophotometric determination of ruthenium or platinum. Optimum conditions for maximum color development, composition of the complex and possibility of determination of ruthenium(III) or platinum(IV) alone or in the presence of diverse ions have also been investigated. Further, attempts to increase the selectivity by the use of masking agents have been made. To ascertain the selectivity of the reagent the method was successfully used for the determination in alloys.

Experimental

Reagents and Apparatus. Preparation of acenaphthenequinone mono(thiosemicarbazone) (AQTS) has been reported earlier.[1] The 3.2×10^{-3}M (1M=1 mol dm^{-3}) solution of AQTS was prepared in *N*, *N*-dimethylformamide.

In the pH range 3.42—5.89, walpole buffers[2] prepared by mixing 0.2 M acetic acid and 0.2 M sodium acetate in various proportions, were used. Below and above these pH values, dilute solutions of acetic acid, hydrochloric acid, or sodium hydroxide were added for pH variations.

Standard Ruthenium(III) Solution. A required amount of ruthenium(III) chloride (Johnson Matthey, London) was dissolved in doubly distilled water, containing sufficient hydrochloric acid to give the final concentration of 1M HCl. Since the ruthenium(III) has a tendency to burn dark brown on keeping due to oxidation, the stock solution was obtained by refluxing for 3—5 h with hydrochloric acid and ethanol. The ruthenium content was determined gravimetrically by precipitating ruthenium as the hydrated oxide, followed by careful ignition in the air. The oxide was reduced to the metal in the presence of hydrogen and by cooling in an atmosphere of carbon dioxide. Subsequent dilutions were made from the stock solution according to requirements. In no case, the solutions older than 10 d were used.

Standard Platinum(IV) Solution. One gram of grade I platinum thermocouple wire (99.99%) was dissolved in aqua regia. The resultant solution was evaporated almost to dryness and a small amount of hydrochloric acid was added. The solution was again evaporated to dryness. This treatment was repeated 3 or 4 times in order to distroy any nitroso complexes. After the final evaporation, 5 cm^3 of hydrochloric acid was added and the solution was made upto 100 cm^3 with doubly distilled water. More dilute solutions, as required, were prepared by diluting the stock solution. Two standard platinum solutions prepared by exactly the same procedure were found to give the same spectrophotometric readings.

Reagent grade chemicals were used in the study of interferences. Doubly distilled water was used throughout the work. A Unicam, SP 600, spectrophotometer, with a tungsten filament lamp and matched glass cells of 10-mm light path, were used for absorbance measurements. An ECIL expanded scale pH-meter, PH821A, was used for pH adjustment.

Absorption Spectra and Effect of pH. Both ruthenium and platinum show maximum absorption at 655 and 515 nm, respectively (Figs. 1 and 2). Subsequent studies have carried out at these wavelengths. A plot of absorbance vs. pH shows that the absrobances remain constant in the pH range 5.3—6.8 and 1.9—4.1 for Ru(III) and Pt(IV), respectively. Further studies have been carried out at pH 6.1 and 2.8 for ruthenium and platinum, respectively.

Rate of Color Development and Stability of the Complexes. The rate of reaction between metal and AQTS is slow at room temperature. The color intensity was found to increase when the solutions containing a fixed amount of Ru(III) or Pt(IV) and excess of reagents were heated on a water bath for various intervals of time and absorbance was measured at 655 or 515 nm for Ru or Pt, respectively. Results of this study show that complete complex formation takes place on heating the contents for about 2.5 h and 40 min for ruthenium and platinum, respectively.

Effect of DMF Concentration. The complexes were found to be soluble in *N*, *N*-dimethylformamide. Increasing volumes of DMF added it was observed that complete dissolution of precipitate takes place in 70% DMF medium. Higher percentage of DMF had no effect on the absorbance. In subsequent work, the percentage of DMF was maintained at 70.

Effect of Reagent Concentration. A plot of absorbance vs. moles of ligand shows that at least five and seven times molar excess of the reagent is required for maximum complex formation for ruthenium and platinum, respectively (Figs. 3 and 4). In further studies ten times molar excess of the reagent was used for both metals.

Adherence to Beer's Law, Optimum Range and Sensitivity. Beer's law is obeyed upto 9.39 and 13.58 ppm (1 ppm=

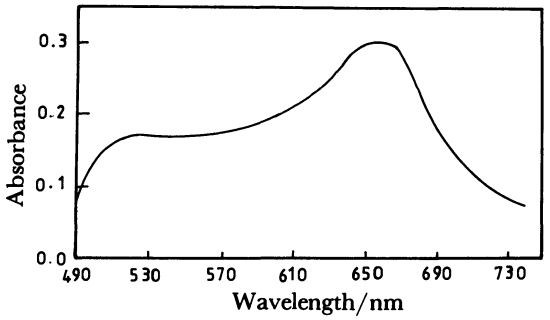

Fig. 1. Absorption spectra of ruthenium(III) complex vs. reagent.
Ru(III): 3.2×10^{-5} M, AQTS: 3.2×10^{-4} M, pH: 5.9.

Pt(IV): 2.5×10^{-5} M.

1 $\mu g\,cm^{-1}$) while the optimum concentration ranges for accurate determination, as deduced from Ringbom plot (Figs. 5 and 6), are 2.01—7.09 ppm and 2.83—11.6 ppm for

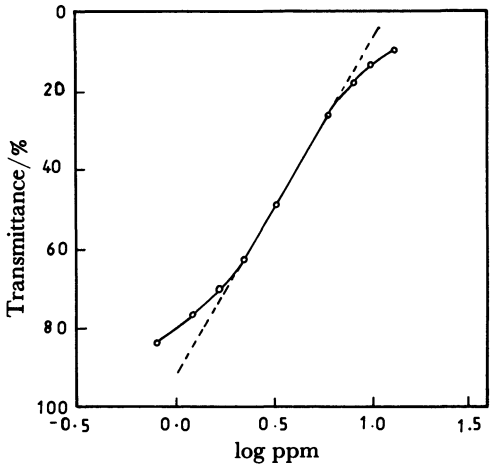

Fig. 5. Ringbom plot for Ru(III)-AQTS complex.

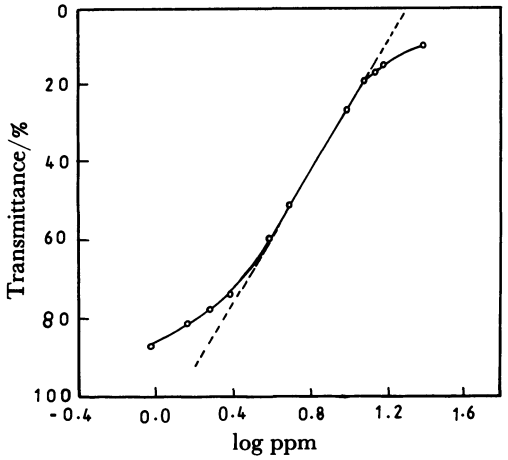

Fig. 6. Ringbom plot for Pt(IV)-AQTS complex.

ruthenium and platinum, respectively. The sensitivity in terms of Sandell's definition is 0.01 μg Ru/cm^2 and 0.01 μg Pt/cm^2 for log I_o/I=0.001 with molar absorptivity 9843.9 and 12000 $mol^{-1}cm^2$, respectively.

Recommended Procedure. To a suitable aliquot containing 50.25—177.25 μg of Ru(III) or 70.8—290 μg of Pt(IV) is added to ten times molar excess of reagent. The pH is adjusted between 5.3—6.8 for ruthenium and 1.9—4.1 for platinum with acetate buffer and dilute solution of sodium hydroxide. The mixture is heated on a boiling water-bath for 2.5 h and 40 min respectively for ruthenium and platinum, and it is cooled to room temperature (30±0.5 °C). The total volume is raised to 25 cm^3 with doubly distilled water, keeping 70% *N,N*-dimethylformamide concentration. The absorbance of the solution is measured at 655 nm for ruthenium and 515 nm for platinum against reagent blank prepared under similar conditions. The amount of ruthenium and platinum is deduced from the calibration curve.

Molar Composition of the Complexes. The composition of the complexes were determined by Job's method of continuous variations[3,4] (Figs. 7 and 8) and mole ratio method[5] (Figs. 3 and 4). Both of these methods show that the stoichiometric ratio of metal to AQTS in the (Ru: AQTS) and (Pt: AQTS) complex is 1:2.

Absorbance Deviations. The precision of the procedure was checked by measuring absorbance of eight samples, each

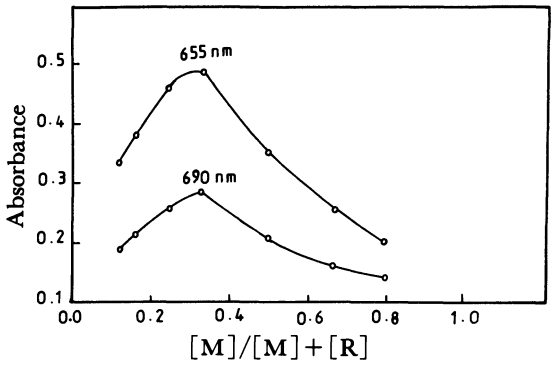

Fig. 7. Composition of Ru(III)-AQTS complex by Job's method.
Total molarity: 2.4×10^{-4} M.

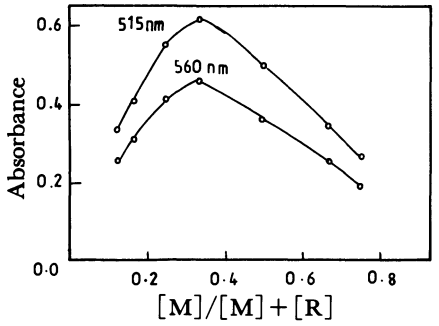

Fig. 8. Composition of Pt(IV)-AQTS complex by Job's method.
Total molarity: 3.2×10^{-4} M.

containing 3.37 ppm of ruthenium. The average relative deviation was found to be 0.33% with standard deviation of 3.6×10^{-3}. In case of platinum eight samples each containing 4.89 ppm of platinum gave average relative deviation 0.53% with standard deviation of 4.18×10^{-3}.

Effect of Diverse Ions. The effect of diverse ions was studied in the determination of ruthenium and platinum following the recommended procedure. The amounts (in ppm) of ions which do not cause any interference with 3.37 ppm of ruthenium(III) are summarized in Table 1. However nitrite, copper(II) and rhodium(III) interfere seriously.

Platinum(IV) has been determined in synthetic solution, each containing 4.89 ppm of platinum and varying amounts of foreign ions. The amounts of different ions tolerated are shown in Table 2. Among anions, iodide and thiourea interfere seriously and among cations copper(II), rhodium(III) and palladium(II) could not be masked. Masking agents were used wherever necessary.

Table 1. Effect of Diverse Ions in the Determination of Ruthenium(III)
Ruthenium Taken=3.37 ppm

Diverse ion added	Amount tolerated (in ppm)	Diverse ion added	Amount tolerated (in ppm)
Chloride	550	Calcium(II)	65

		Aluminium(III)	60

a) Masked with chloride. b) Masked with cyanide.
c) Masked with thiocyanate.

Discussion

Many organic reagents have been employed for the spectrophotometric determination of ruthenium(III) and platinum(IV), but most of them lack in selectivity or sensitivity or both, and there are objectionable interferences from many of the bases and noble metals. The most sensitive method yet reported is a catalytic method,[6] but this method is lengthy and offers no special advantage over others except for its sensitivity. Thiocyanate,[7] 2,4,6-tri(2-pyridyl)-1,3,5-triazine,[8] and 2,3-diaminopyridine[9] have been suggested for the determination of ruthenium, but they require controlled parameters and the selectivity of these methods is not very high. Thiocyanate method has the disadvantage that the determination of ruthenium

Table 3. Comparison of the Sensitivities of Reagents for Ru and Pt Determination

Table 4. Determination of Pt(IV) in Synthetic Solutions

Mixture	Pt taken	Metal ion added/ppm		Pt found	Error/%
	ppm	Ni	W	ppm	
Pt-Ni alloy	(I) 6.0	4.0		5.97	−0.50
	(II) 4.5	5.5		4.48	−0.44
	(III) 3.0	2.0		3.01	+0.33
Pt-W alloy	(I) 2.0		0.09	2.00	0.00
	(II) 3.0		0.14	3.00	0.00
	(III) 5.0		0.23	5.02	+0.40

has to be carried out after the extraction of its tetraoxide in carbon tetrachloride. Oxidation of ruthenium to tetraoxide is a critical step in this method. 4-Hydroxy-2*H*-1-benzopyran-2-one oxime[10] has low sensitivity. 4-Hydroxyimino-4-phenyl-2-butanone[11] has low sensitivity (0.018 μg cm^{-2}/470 nm) and iron, platinum, and palladium interfere. 4-Hydroxyimino-2-pentanone,[12] phenothiazine,[13] and 2-thiophenecarbaldehyde oxime[14] methods have low sensitivity. As for the 3-(4-dimethylaminophenyl)-3-hydroxy-1-phenyltriazene[15] method, pH range is narrow (7.7—7.8). Tin(II) chloride[16] method is not selective, Pd(II), Rh(III), Ir(IV), Fe(III), Cu(II), Co(II), and SO_4^{2-}, NO_3^-, PO_4^{3-} interfere seriously. In furil α-dioxime[17] method other platinum metals and iron interfere.

For the determination of platinum with *N,N*-dimethyl-*p*-nitrosoaniline,[18] time of heating, pH changes and amount of buffer used are critical factors. Most of the associated metals interfere. Potassium iodide[18] is a useful reagent for platinum but it is less selective. Anthranilic acid[19] is not sensitive and large amount of reagent result in decrease of absorbance. In *o*-phenylenediamine[18] associated base metals and platinum metals interfere and also the complex is stable only for 1 h. In case of 4-hydroxy-2*H*-1-benzopyran-2-one oxime,[20] sensitivity is poor. Os, Pd, and Ru must be removed initially in 3,4-diaminobenzoic acid.[21]

The present method, using acenaphthenequinone mono(thiosemicarbazone) involves simple technique. The method is quite sensitive and the complexes formed are stable for many hours. Other factors such as heating time, pH, effect of buffer, and amount of reagent do not have any effect on the absorbance. Most of the associated metals do not interfere. The sensitivity is comparable (Table 3) with other methods known for the purpose.

Determination of Platinum in Synthetic Mixtures. To ascertain the selectivity of the reagent the method was successfully used for the determination of platinum in alloys. Analyzed sample of platinum–nickel and platinum–tungsten alloy were not available. Synthetic solutions similar to these alloys of platinum were prepared and the amount of platinum was determined following the recommended procedure. The results are summarised in Table 4.

1,1′-Bis(thiocyanatomercurio)ferrocene as Ligand towards $M(NCS)_2$[M=Mn(II), Co(II), Ni(II), Cu(II), Zn(II)]

Pashupati Prasad SINGH* and Meena SINGH
Chemistry Department, M. L. K. College, Balrampur-271 201, India
(Received February 28, 1985)

Complexes having three different metal atoms have been prepared by reacting 1,1′-bis(thiocyanatomercurio)-ferrocene with $M(NCS)_2$ [M=Mn(II), Co(II), Ni(II), Cu(II), Zn(II)]. The complexes have been referred to as Lewis acid and have molecular formula $Fe(C_5H_4HgSCN)_2M(NCS)_2$. They have unsaturation at M, hence have been reacted with nicotinamide and 2,2′-bipyridyl and adducts of molecular formula $Fe(C_5H_4HgSCN)_2M(NCS)_2L_x$ [x=2 when nicotinamide and 1 when bipyridyl] have been isolated. The Lewis acids and the adducts have been characterized by elemental analysis, molar conductance, magnetic moment, infrared and electronic spectral studies. These studies reveal that the coordination geometry of M is tetrahedral in the Lewis acids of cobalt, zinc, and manganese. The geometry around M in the Lewis acids of nickel and copper is octahedral through axial bonding. The adducts have a bridged structure and the geometry around M is octahedral. Quantitative softness parameters have also been applied to derive certain information.

Complexes having two different metals have recently been reported.[1-3] Attempts have also been made[4,5] to prepare trimetallic complexes but no systematic studies could be made. In this paper, a new class of complexes having three different metals have been prepared and studied for the first time.

Experimental

Reagent grade solvents were purified before use. $M(NCS)_2 \cdot 2nia$ [M=Mn(II), Co(II), Ni(II), Cu(II), Zn(II) nia=nicotinamide] were prepared by direct reaction of nicotinamide and $M(NCS)_2$ in ethanol. 2,2′-Bipyridyl (bpy) was used from fresh bottle. 1,1′-Bis(thiocyanatomercurio)-ferrocene (FBMT) was prepared as given below.

Preparation of 1,1′-Bis(thiocyanatomercurio)ferrocene. 9.2 g (0.25 mole) ferrocene was dissolved in 50 ml of benzene in a two necked flask. A homogenesous suspension of 16 g (0.25 mole) of mercury(II) acetate in 200 ml of methanol was separately prepared. This suspension was very slowly added to the solution of ferrocene through a dropping funnel, with continuous stirring. A dark brown clear solution was obtained. To this, a solution of 4.8 g (0.25 mole) KSCN in 10 ml of water was added, and stirred for 30 min. A yellow precipitate was formed which was filtered on büchner funnel and washed with petroleum ether. This yellow compound was a mixture of (thiocyanatomercurio) ferrocene and 1,1′-bis-(thiocyanatomercurio)ferrocene.

Separation of Mono and Bis Derivatives. The yellow mass was placed in upper disc of the Soxhlet apparatus and the flask was filled with 25 ml of 1,2-dichloroethane and extracted for 30 min. A portion of yellow mass dissolved in 1,2-dichloroethane and its color became yellow. The yellow solution was collected and fresh 25 ml of pure 1,2-dichloroethane was added and again extracted for 30 min. The process was continued till there was no change in the color of 1,2-dichloroethane. On evaporation of the yellow extract impure (thiocyanatomercurio)ferrocene was obtained. The undissolved yellow residue was FBMT. This compound was purified by dissolving in dimethylsulfoxide (DMSO) and isolating the pure compound by addition of water. The analytical data of the bis derivative are; mp 145 °C (decomp), sulfur calcd. 9.14%, found 8.85%, nitrogen calcd. 4% found 3.72%, mercury calcd. 57.14% found 56.01%.

Preparation of Lewis Acids: "$Fe(C_5H_4HgSCN)_2M(NCS)_2$" [M=Mn(II), Co(II), Ni(II), Cu(II), and Zn(II)]. FBMT was dissolved in a small quantity of DMSO and diluted to 200 ml by acetone. $M(NCS)_2$ were similarly dissolved either in acetone or DMSO-acetone mixture separately. $Mn(NCS)_2$ was however, dissolved in ethyl acetate. The solutions of FBMT and $M(NCS)_2$ were mixed in 1:1 molar ratio and stirred for 24 h. Precipitate appeared in each case. When the quantity of DMSO became more the precipitates were obtained by addition of ethanol. The precipitates were filtered, washed with ethanol, and dried in vacuum. The compounds were recrystallized from acetone-ethanol mixture.

Preparation of Adducts: $Fe(C_5H_4HgSCN)_2M(NCS)_2L_x$[$x$=2 when L is nia and 1 when bpy]. The adducts were prepared by two methods. (1) A suspension or solution of the Lewis acids was prepared in acetone-ethanol mixture and mixed with an ethanol solution of nicotinamide in 1:2 molar ratio or with 2,2′-bipyridyl in 1:1 molar ratio and stirred for 24 h. In each case precipitate was formed, filtered, washed with ethanol, and dried in vacuum. The compounds were recrystallized from acetone-ethanol mixture. (2) $M(NCS)_2 \cdot 2nia$ was dissolved in acetone. The corresponding manganese compound was dissolved in ethyl acetate. FBMT was dissolved in DMSO-acetone mixture. The solutions of $M(NCS)_2 \cdot 2nia$ and FBMT were mixed in 1:1 molar ratio and stirred for 48 h. Precipitate was formed in each case which was filtered, washed with ethanol, and dried in vacuum. Recrystallized from acetone-ethanol mixture. The copper analog could not be prepared by this method.

Analysis of the Complexes. The complexes were analyzed for cobalt as anthranilate, and for nickel as dimethylglyoximate. Sulfur as sulfate and mercury as sulfide. Nitrogen was estimated by semimicro Kjeldahl's method. Analytical results along with melting points are presented in Table 1.

Physical Measurements. The molar conductance of the complexes were measured in DMSO using a Philip conductivity bridge model PR-9500. The molecular weights were determined in DMSO solution by cryoscopic method. The magnetic susceptibility measurements were made at room temperature by Gouy's method using $CoHg(SCN)_4$ as standard. The diamagnetic corrections were made using Pascal's constants. Infrared spectra of the complexes were recorded as nujol mulls or as KBr pellets on a Pye Unicam sp 3-300 spectrophotometer in the range 4000—200 cm^{-1}. Elec-

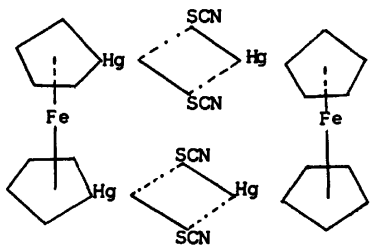
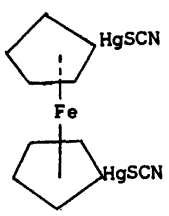
tronic spectra in the range 200—990 nm were recorded on Pye Unicam sp 5-500. The thermodynamics stability constant (log K), has been determined by spectrophotometric method.

Results and Discussion

The spectra of FBMT were recorded in solid and solution phase. The solid phase spectra show the presence of three bands at 2190, 2120, and 2100 cm^{-1} in ν(CN) region, two bands at 730 and 720 cm^{-1} in ν(CS) region and two bands at 460 and 410 cm^{-1} in δ(NCS) region. The band at 2190 cm^{-1} disappears in solution. This shows that FBMT exists as dimer in solid phase like CH_3HgSCN[6] as shown below.



(Dimer in solid)



(Monomer in solution)

In solution phase the thiocyanato bridge is broken and this becomes a monomer. The solution spectra have therefore, been taken for the purpose of comparison. The band at about 2120 cm^{-1} in ν(CN) region, at about 740 cm^{-1} in ν(CS) region and at about 450 cm^{-1} in δ(NCS) indicate the presence of S-bonded thiocyanate in FBMT.

Lewis acids: $Fe(C_5H_4HgSCN)_2M(NCS)_2$[M = Mn(II), Co(II), Ni(II), Cu(II), Zn(II)].

The FBMT has been used as ligand and reacted with $M(NCS)_2$. This results in the formation of a complex of general formula $Fe(C_5H_4HgSCN)_2M(NCS)_2$. These compounds have been referred to as Lewis acids. Comparison of the infrared spectra of the FBMT with the Lewis acids shows that the position of ν(CN), ν(CS), and δ(NCS) bands are changed. The ν(CN) band moves to about 2190 cm^{-1}, ν(CS) band to about 790 cm^{-1} and δ(NCS) band to about 480 cm^{-1}. The positions of these bands are indicative of the presence of thiocyanato bridge.[7] A band is also observed in 2070 cm^{-1} to 2010 cm^{-1} region. Band in this region is assigned to N-bonded terminal thiocyanate arising from ν(M-NCS).[8]

The electronic spectra of the Lewis acid where M is Co(II), show the presence of two intense bands in the region 17450 cm^{-1} and 10640 cm^{-1} which are assigned to $^4A_2 \rightarrow {}^4T_2(F)$ (ν_3) and $^4A_2 \rightarrow {}^4T_1(P)$ (ν_2) transitions, respectively (Table 2). The D_q value derived from ν_3 and ν_2 bands is 541 cm^{-1}. The positions of these bands and the magnetic moment values show that the cobalt is in tetrahedral geometry. The compound is nonconducting in nature. On the basis of these results the following structure (Fig. 1) can be proposed for this Lewis acid.

The infrared spectra of the Lewis acids where M is Zn(II) or Mn(II) are similar to the Lewis acid where M is cobalt(II). It can, therefore, be presumed that the structure of these Lewis acids is also similar to that in Fig. 1. The electronic spectra of Lewis acid where M is Ni(II) show the presence of three bands in the region 27790, 16650, and 10400 cm^{-1} which are assigned to $^3A_{2g} \rightarrow {}^3T_{1g}(P)(\nu_3)$, $^3A_{2g} \rightarrow {}^3T_{1g}(F)(\nu_2)$, and $^3A_{2g} \rightarrow {}^3T_{2g}(F)(\nu_1)$, respectively. The D_q value derived from ν_2 and ν_3 bands is 1020 cm^{-1} (Table 2). The spectra and magnetic moment values indicate the

Fig. 2.

presence of octahedral coordination geometry around nickel. The electronic spectra and the magnetic moment values where M is Cu(II) are also indicative of the presence of octahedral coordination geometry around Cu(II). Both these metal ions acquire octahedral geometry through axial coordination.[9] These complexes are nonconducting in dimethyl sulfoxide. On the basis of these results the structure as shown in Fig. 2 can be proposed.

Adducts: $Fe(C_5H_4HgSCN)_2M(NCS)_2L_x$($x$=2 when L is nia and 1 when bpy). The coordination number of M in the Lewis acid where M is Co(II), Zn(II), or Mn(II) is four against the maximum of six. Due to this unsaturation at M, they have been named as Lewis acid. Where M is Ni(II) or Cu(II) the coordination number six has been achieved through weak axial bonding which can easily be replaced by ligands. Accordingly both types of Lewis acids have been reacted with nicotinamide and 2,2-bipyridyl and adducts of general formula $Fe(C_5H_4HgSCN)_2M(NCS)_2L_x$ have been prepared.

The infrared spectra of the adducts where M is Ni(II) or Cu(II) show that there is no significant change in the positions of ν(CN), ν(CS), δ(NCS), and ν(M-NCS) bands. This shows that the bridging nature of thiocyanate and octahedral coordination geometry around M are retained. The infrared spectra of the adducts where M is Co(II), Zn(II) or Mn(II) also show that the

1.	$Fe(C_5H_4HgSCN)_2Ni(NCS)_2$	−3.10	−11.16	8.06	6.66	15.72
2.	$Fe(C_5H_4HgSCN)_2Co(NCS)_2$	−3.56	−11.16	7.60	4.55	12.15
3.	$Fe(C_5H_4HgSCN)_2Zn(NCS)_2$	−4.92	−11.16	6.24	—	6.24
4.	$Fe(C_5H_4HgSCN)_2Mn(NCS)_2$	−9.01	−11.16	2.15	—	2.15

bridging nature of the thiocyanate is retained but a negative shift is observed in ν(M–NCS) band. This negative shift is on account of change in tetrahedral geometry around M to octahedral.[8,10] Such a change is not observed where M is Ni(II) or Cu(II), because the geometry around M, in these cases, remains octahedral in the Lewis acid and the adducts as well. The electronic spectral data of all adducts, their assignments, various spectral parameters, and magnetic moment values, as presented in Table 2, indicate that the coordination geometry around M is octahedral. All the adducts are nonconducting in nature. On the basis of these results the structure as shown in Fig. 3 can be proposed for the adducts.

Comparison with the Complexes of RHgSCN: (R=*p*-tolyl, *p*-naphthyl, phenyl, ethoxy, methoxy, *p*-chlorophenyl). RHgSCN have been reported to act as Lewis bases towards $M(NCS)_2$. The base strength of RHgSCN changes on change of R. The following sequence of base strength on the basis of various physicochemical studies has been established.[11]

p-tolyl > *p*-naphthyl > phenyl > ethoxy > methoxy > *p*-chlorophenyl

The FBMT also acts as a base towards $M(NCS)_2$. This base has two thiocyanato groups as donor sites, and consequently the complexes formed by this base are more stable. The D_q values of Co(II) and Ni(II) Lewis acids are 541 cm^{-1} and 1020 cm^{-1}. These values are higher than the D_q values of the corresponding complexes of the RHgSCN. This fact is also demonstrated experimentally. The thiocyanato bridge between Hg(II) and M(II) in the Lewis acids of RHgSCN is ruptured on reaction with 2,2′-bipyridyl, resulting in the formation of cationic-anionic complexes of general formula $[M(bpy)_3][RHg(SCN)_2]_2$. The Lewis acids of the present series, however, form adducts on such a reaction, and the thiocyanato bridge between M(II) and Hg(II) is retained. This shows that the base strength of this compound is higher than any of the RHgSCN.

Quantitative Softness Parameters: The effective softness $E^{\ddagger}_{n(eff)}$ value of M in $Fe(C_5H_4HgSCN)_2M(NCS)_2$, $E^{\ddagger}_{m(eff)}$ value of N-end of nicotinamide and 2,2′-bipyridyl and of N-end of FBMT have been evaluated by the method described elsewhere,[12] and the results are included in Table 3. The FBMT reacts with $M(NCS)_2$ and forms Lewis acid of general formula $Fe(C_5H_4HgSCN)_2M(NCS)_2$. The difference ($\Delta E^{\ddagger}_{nm}$) between $E^{\ddagger}_{m(eff)}$ of N-end of FBMT and $E^{\ddagger}_{n(eff)}$ of M in $M(NCS)_2$ have been evaluated by the following equation:

$$\Delta E^{+}_{nm} = \left| E^{+}_{n(eff)} - E^{+}_{m(eff)} \right|$$

The $\Delta E^{\ddagger}_{nm}$ value is the highest when M is Ni(II) and the lowest when Mn(II). The $\Delta E^{\ddagger}_{nm}$ between $E^{\ddagger}_{n(eff)}$ of M in Lewis acids and $E^{\ddagger}_{m(eff)}$ of nicotinamide and 2,2′-bipyridyl and the matching constant values have been derived in order to find out which out of the two ligands forms more stable bond with M and which out of the various M forms more stable bond with nicotinamide or bipyridyl. The results are included in Table 3. The $\Delta E^{\ddagger}_{nm}$ values show that bipyridyl forms more stable M–L bond than nicotinamide which is in concurrence with the established fact. $\Delta E^{\ddagger}_{nm}$ values are the highest when M=Ni(II) and the lowest when M=Mn(II). The sequence with other M is as follows:

Nickel > Cobalt > Zinc > Manganese.

Table 4. $\Delta E^{\ddagger}_{nm}$ Derived from $E^{\ddagger}_{n(eff)}$ of M in $Fe(C_5H_4HgSCN)_2M(NCS)_2$ and $E^{\ddagger}_{m(eff)}$ of the Ligand in the Formation of Adducts

Complex	$E^{\ddagger}_{n(eff)}$ of M in Lewis Acid	$E^{\ddagger}_{m(eff)}$ of nia	$\Delta E^{\ddagger}_{nm}$	CFSE	Matching Constant	log K
$Fe(C_5H_4HgSCN)_2Ni(NCS)_2(nia)_2$	−2.28	−11.47	11.49	6.42	17.91	5.16
$Fe(C_5H_4HgSCN)_2Co(NCS)_2(nia)_2$	−2.83	−11.47	10.94	4.29	15.23	5.09
$Fe(C_5H_4HgSCN)_2Zn(NCS)_2(nia)_2$	−4.11	−11.47	9.66	—	9.66	4.92
$Fe(C_5H_4HgSCN)_2Mn(NCS)_2(nia)_2$	−8.90	−11.47	4.87	—	4.87	4.43

nia = nicotinamide.

The stability of metal ligand bond in case of transition metal ions has been expressed in terms of matching constant, by adopting the following relation:

$$\text{Matching constant} = \Delta E^{\ddagger}_{nm} + \text{CFSE}$$

The matching constant values are presented in Table 4, along with thermodynamic stability constant (log K). Both the values indicate that most stable M–L bond is formed where M is Ni(II) and sequence is as follows:

Nickel(II), Cobalt(II), Zinc(II), and Manganese(II).

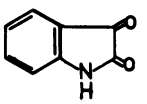
(Received September 1, 1984)

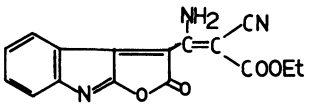
Isatin reacted with diethyl 3-amino-2-cyano-2-pentenedioate in ethanol and in presence of Et_3N to give 3-(1-amino-2-cyano-2-ethoxycarbonylethenyl-2*H*-furo[2,3-*b*]indol-2-one. The reaction of (2-oxo-3-indolinylidene)-malononitrile (**3a**) with the diethyl ester gave a mixture of diethyl 3-amino-4-(2-amino-3-cyano-4-quinolyl-carbonyl)-2-cyano-2-pentenedioate (80%) and diethyl 3-amino-4-(2-amino-3-cyano-3a*H*-furo[2,3-*b*]indol-3a-yl)-2-cyano-2-pentanedioate (20%). Treatment of **3a** and 3-[cyano(ethoxycarbonyl)]methylene-2-indolinone (**3b**) with 2-(ethoxycarbonylmethyl)-2-thiazolin-4-one gave the corresponding two pyrano[4′,5′-*c*] and furo[2″,3″-*b*]indole compounds, respectively. When **3a** and **3b** also reacted, with 3-methyl-2-pyrazolin-5-one or 3-methyl-1-phenyl-2-pyrazolin-5-one, the corresponding four spiro indoline-3,4′-(1′*H*)-pyrano[2, 3-*c*]pyrazol products were obtained. The reaction of **3b** with benzoylacetonitrile gave ethyl 2-amino-3a-[benzoyl(cyano)methyl]-3a*H*-furo[2,3-*b*]indole-3-carboxylate.

It is well known that indole itself and some of its derivatives are known to induce leuckaemia in rodents.[1] Polynuclear indoles are used as potential carcinogenic and/or leuckaemogenic.[2]

The present paper constitutes a study on a novel synthesis of these compounds involving condensation of nucleophiles with isatin or its ylidene derivatives. Treatment of isatin (**1**) with diethyl 3-amino-2-cyano-2-pentenedioate in the presence of triethylamine (Et_3N) as basic catalyst gave the corresponding 3-(1-amino-2-cyano-2-ethoxycarbonylethenyl)-2*H*-furo[2,3-*b*]indol-2-one (**2**) (through Knoevenagel condensation followed by cyclization).



1



The structure of compound **2** has been confirmed by its IR absorption spectrum which showed broad band extending at 3300—3150 cm^{-1} (NH_2), at 2205 cm^{-1} (C≡N), at 1710, 1750 cm^{-1} (C=O of the ester and ring) and broad band extending at 3020—2900 cm^{-1} (CH_2, CH_3 stretches). The ^{1}H-NMR spectrum revealed the following signals: multiplet extending at δ 7.6—8.3 (m, 4H; aromatic protons), triplet at δ 2.2 (t, 3H, ester CH_3), quartet at δ 4.1 (q, 2H, ester CH_2), and singlet at δ 3.7 (s, 2H, NH_2). Similarly, treatment of (2-oxo-3-indolinylidene)malononitrile[3] (**3a**) with the diethyl ester in the presence of Et_3N produced a mixture of diethyl 3-amino-4-(2-amino-3-cyano-4-quinolylcarbonyl)-2-cyano-2-pentenedioate (**4**) (yield 80%) and diethyl 3-amino-4-(2-amino-3-cyano-3a*H*-furo[2,3-*b*]indol-3a-yl)-2-cyano-2-pentenedioate (**5**) (20% yield), respectively.

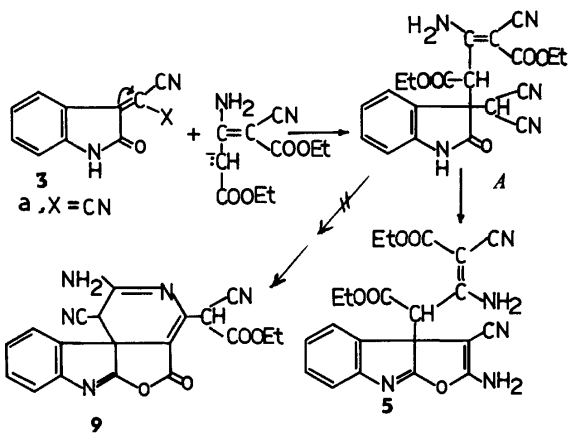
5

Formation of the quinoline derivative (**4**) may be rationalized in terms of a carbanion attack at the carbonyl carbon of (2-oxo-3-indolinylidene)malononitrile followed by ring opening and recyclization affording the structure **4** according to the mechanism discussed in a previous paper.[4] Compound **5** was suggested to be formed by the carbanion attack at the olefinic carbon of the ylidene followed by cyclization producing the final product (Scheme 1).

The assigned structure of compound **4** was based on its IR spectrum which showed broad band at 3300—3150 cm^{-1} (NH_2), 2250, 2200 cm^{-1} (C≡N), broad band extending at 1740—1700 cm^{-1} (C=O), and 3000—2950 cm^{-1} (CH_2, CH_3 stretches). Moreover, ^{1}H-NMR spectrum of compound **4** revealed singlet at δ 3.7 (s, 2H, NH_2), quartet at δ 4—4.4 (q, 4H for 2 ester CH_2), triplet at δ 1.2 (t, 3H ester CH_3); triplet at δ 1.5 (t, 3H, CH_3 of the other ester group), and multiplet extending at δ 6.9—7.5 (m, 5H, 4H aromatic protons and CH proton.[5] Further proof for the suggested structure was derived from its electronic spectrum which exhibits characteristic quinoline maxima at λ_{max}360 nm (log ε 4.88), 285 (5.32), and 235 (5.30),[6] although with some bathochromic shift due to substituent effects.

The assigned structure of compound **5** was inferred from its IR spectrum which showed broad band at 3300—3150 cm^{-1} for NH_2, at 2210 cm^{-1} for C≡N, a broad band at 1750—1710 cm^{-1} for C=O, and a broad band extending at 3010—2950 cm^{-1} for CH_2, CH_3 stretches. It may be suggested that the final separated product formed should be through the suggested intermediate structure **A** (Scheme 1). However, probable formation of **9** from **A** is excluded on bases of analytical data reported.



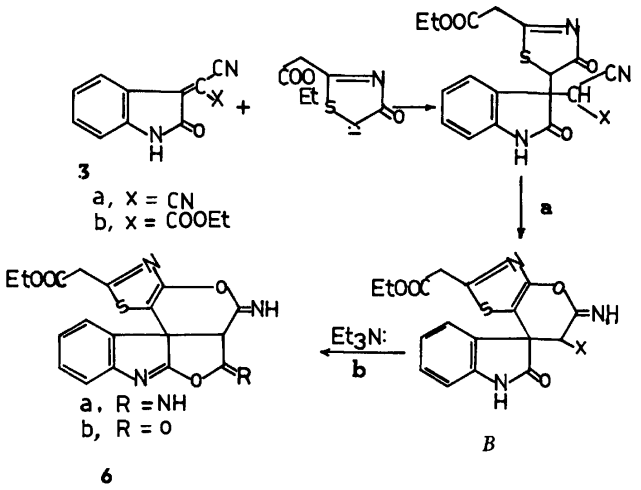
Scheme 1.

In the same manner, when **3a** and **3b** reacted with 2-(ethoxycarbonylmethyl)-2-thiazolin-4-one gave the corresponding compounds **6a** and **6b**, respectively. The formation of compounds **6a, b** was assumed to proceed via the attack of the carbanion nucleophile on the olefinic carbon of the ylidene, followed by the cycloaddition of highly acidic thiazole (OH) on the cyano group to form the suggested intermediate spiro compound (**B**) (Step a) followed by cycloaddition of the less acidic indole (OH) on the second cyano or the ester group to form the final isolated products, ethyl 5,6-diimino-thiazolo[4,5-*b*]pyrano[4′, 5′-*c*]furo[2″,3″-*b*]indole-2-acetate (**6a**) and ethyl 5-imino-thiazolo[4, 5-*b*]pyrano[4′,5′-*c*]furo[2″,3″-*b*]indole-6-one-2-acetate (**6b**), respectively (Step b) (Sheme 2). The suggested preliminary formation of intermediate spiro compound (**B**) although not separated in such mechanism had been proved through the separation of their analogues (**7a—d**) when cyclization proceeded in the absence of Et_3N which is discussed later.

The structure of compound **6a** agrees with its IR spectrum which showed broad band at 3200—3100 cm^{-1} NH), 3000—2900 cm^{-1} (CH_2, CH_3 stretches), 1700 cm^{-1} (C=O), and 1660 cm^{-1} (C=N–). Moreover, its ^{1}H-NMR spectrum in DMSO gives a clue for the assigned structure showing the following signals: triplet at δ 1.3 (t, 3H, ester CH_3), singlet at δ 2.8 (s, 2H, CH_2 group), quartet at δ 4—4.3 (q, 2H ester CH_2), singlet at δ 5.7 (s, 1H, CH proton), multiplet at δ 6.9—7.4 (m, 4H, aromatic protons), and two singlet at δ 8.1 and 9 (s, 2H, 2NH protons). The UV spectrum of **6a** in ethanol showed absorption bands at λ_{max} 425 nm (log ε 4.91), 270 (4.58), and 258 (3.76).

The IR spectrum of compound **6b** agrees well with the assigned structure which showed characteristic absorption bands at 3300, 3346 cm^{-1} (NH), 3000—2900 cm^{-1} (CH_2, CH_3 stretches), 1730, 1700 cm^{-1} (C=O ring and ester), and 1660 cm^{-1} (C=N). Its ^{1}H-NMR spectrum showed the following signals: triplet at δ 0.9 (t, 3H, ester CH_3), singlet at δ 2.7 (s, 2H, CH_2), quartet at δ 4.00 (q, 2H, ester CH_2), multiplet at δ 6.7—7.4 (m, 5H, CH proton and 4 aromatic protons), and singlet at δ 9.1 (s, 1H, NH proton). The UV spectrum of **6b** showed the following bands at λ_{max} 414 nm (log ε 5.76), 279 (5.396), and 262 (5.98).

When **3a** or **3b** was treated with 3-methyl-2-pyrazolin-5-one or 3-methyl-1-phenyl-2-pyrazolin-5-one in ethanol or dioxane and in the absence of Et_3N, it gave the corresponding spiro products, namely, 6′-amino-5′-cyano-3′-methylspiro[indoline-3,4′(1′*H*)-pyrono[2,3-*c*]pyrazol]-2-one (**7a**); ethyl 6′-amino-3′-methyl-2-oxospiro[indoline-3, 4′(1′*H*)-pyrano[2,3-*c*]-pyrazole]-5′-carboxylate (**7b**), 6′-amino-5′-cyano-3′-methyl-1′-phenylspiro[indoline-3, 4′(1′*H*)-pyrano[2,3-*c*]-pyrazol]-2-one (**7c**), and ethyl 6′-amino-3′-methyl-2-oxo-1′-phenylspiro[indoline-3,4′(1′*H*)-pyrano[2,3-*c*]-pyrazole]-5′-carboxylate (**7d**) which is rationalized in terms of the addition of active methylene group on the olefinic double bond followed by cyclization on the same bases as in (Step a) of Scheme 2.



Scheme 2.

The structure of compound **7a** was confirmed by its IR spectrum which showed absorption bands at 3400, 3150 cm^{-1} (NH and NH_2), 2205 cm^{-1} (C≡N), at 1720 cm^{-1} (C=O), and 1650 cm^{-1} (C=N). Moreover, its ^{1}H-NMR spectrum in DMSO gave further confirmation which showed the following signals: singlet at δ 1.6 (s, 3H, CH_3 group), multiplet at δ 6.9—7.5 (m, 6H, 4H aromatic protons and NH_2 protons) and two singlets at δ 10.6 and 12.2 (s, 2H, 2NH proton) (Table 1). Similarly, ^{1}H-NMR spectra of **7b—d**, Table 1 showed the corresponding characteristic signals confirming its assigned structures.

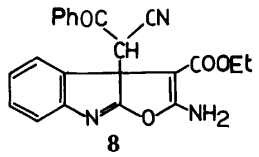
Table 1. UV, IR, and ^{1}H-NMR Spectral Measurements for the Compounds **7a—c**

Compound	UV spectra[a] λ_{max}/nm (log ε)	IR (KBr) ν/cm^{-1}	^{1}H-NMR (DMSO)[b,c] δ/ppm
7a	253 (4.18)	3400, 3150(NH, NH_2), 2205(C≡N), 1720(C=O), 1650(-C=N)	1.6(s, 3H, CH_3), 6.9—7.5(m, 6H, 4 aromatic protons, NH_2), 10.6, 12.2(s, 2H, 2NH)
7b	248.5(4.23)	3450, 3300(NH, NH_2), 1750, 1720 (C=O), 1630 (-C=N)	0.9(t, 3H, ester CH_3), 1.2(s, 3H, pyrazole CH_3), 4.0(q, 2H, ester CH_2), 6.9—7.8(m, 6H, 4 aromatic protons and NH_2), 10.8 (s, 2H, 2NH)
7c	246 (4.94)	3440, 3280, 3140(NH, NH_2), 2150 (C≡N), 1695(ring C=O), 1650(-C=N)	1.6(s, 3H, CH_3), 6.8—7.8(m, 11H aromatic and NH_2), 11(s, 1H, NH)
7d	248 (4.91)	3350, 3150(NH, NH_2), br 1720—1690 (ester and ring carbonyl)	1.1(t, 3H, ester CH_3), 1.6(s, 3H, CH_3), 4.1(q, 2H, CH_2), 6.9—7.8(m, 11H, aromatic and NH_2), 11(s, 1H, NH)

a) In absolute ethanol solvent. b) Dimethyl sulfoxide-d_6 solvent. c) s=Singlet, m=multiplet; q=quartet, t=triplet.

Treatment of **3b** with benzoylacetonitrile in ethanol and in the absence of Et_3N to give ethyl 2-amino-3a-[benzoyl(cyano)methyl]-3a*H*-furo[2,3-*b*]indole-3-carboxylate (**8**) (through an addition and cyclization mechanism on the same bases as that suggested in Scheme 1.

The structure of compound **8** was elucidated by its IR spectrum which showed broad band at 3500—3000 cm^{-1} for NH_2 group, 2205 cm^{-1} for CN, and 1740, 1710 cm^{-1} for C=O groups of ester and of ketone, respectively.



8

The biological activity of the new compounds thus obtained is still under study and will be published elsewhere.

Experimental

Melting points are uncorrected. IR spectrum (KBr) were recorded on Shimadzu 408 Spectrophotometer. ^{1}H-NMR spectra were recorded on EM-390, 90 MHz and A-60, 60 MHz Spectrometer.

General Procedure. Isatin (0.1 mol) or its derivatives was treated under reflux in ethanol (40 ml) with 0.1 mol of the reagent in the presence of two drops of Et_3N/ and in the absence of Et_3N for 1 h, left to cool then filtered. The solid thus obtained was crystallized from the proper solvent.

3-(1-Amino-2-cyano-2-ethoxycarbonylethenyl)-2*H*-furo(2,3-*b*)-indol-2-one (2). It is obtained as red crystals from DMF, mp 270 °C; yield is ca. 60%. Found: C, 62.2; H, 3.5; N, 13.8%. Calcd for $C_{16}H_{11}N_3O_4$: C, 62.13; H, 3.55; N, 13.59%.

Diethyl 3-Amino-4-(2-amino-3-cyano-4-quinolylcarbonyl)-2-cyano-2-pentenedioate (4). It is formed as yellow crystals from acetone mp 258 °C; yield is ca; 80%. Found: C, 59.9; H, 4.4; N, 16.5%. Calcd for $C_{21}H_{19}N_5O_5$: C, 59.8; H, 4.5; N, 16.6%.

Diethyl 3-Amino-4-(2-amino-3-cyano-3a*H*-furo[2,3-*b*]indol-3a-yl)-2-cyano-2-pentenedioate (5). It is obtained by evaporation of the acetone mother liquor of the product **4** crystallization, then poured onto water to give a solid product which crystallized from dilute ethanol as brown crystals, mp 160 °C; yield is ca. 20%. Found: C, 59.80; H, 4.5; N, 16.4%. Calcd for $C_{21}H_{19}N_5O_5$: C, 59.85; H, 4.51; N, 16.6%.

Ethyl 5,6-Diimino-thiazolo[4,5-*b*]pyrano[4′,5′-*c*]furo[2″,3″-*b*]indole-2-acetate (6a). It is isolated as red crystals from DMF-H_2O, mp 300 °C, yield is ca. 80%. Found: C, 56.29; H, 3.5; N, 14.5%. Calcd for $C_{18}H_{14}N_4O_4S$: C, 56.51; H, 3.66; N, 14.65%.

Ethyl 5-Imino-thiazolo[4,5-*b*]pyrano[4′,5′-*c*]furo[2″,3″-*b*]indole-6-one-2-acetate (6b). It is formed as red crystals of mp 280 °C from DMF-H_2O, yield is ca. 70%. Found: C, 56.5; H, 3.5; N, 10.8%. Calcd for $C_{18}H_{13}N_3O_5S$: C, 56.39; H, 3.39; N, 10.96%.

6′-Amino-5′-cyano-3′-methylspiro[indoline-3,4′(1′*H*)-pyrano-[2,3-*c*]pyrazol]-2-one (7a). It is formed as colorless crystals from acetone, mp 275 °C; yield is ca. 70%. Found: C, 61.8; H, 4.0; N, 23.85%. Calcd for $C_{15}H_{11}N_5O_2$: C, 61.6; H, 3.75; N, 23.89%.

Ethyl 6′-Amino-3′-methyl-2-oxospiro[indoline-3,4′(1′*H*)-pyrano[2,3-*c*]pyrazole]-5′-carboxylate (7b). It is obtained from acetone as colorless crystals of mp 212 °C; yield is ca. 72%. Found: C, 60.3; H, 4.6; N, 16.7%. Calcd for $C_{17}H_{16}N_4O_4$: C, 60.0; H, 4.7; N, 16.5%.

6′-Amino-5′-cyano-3′-methyl-1′-phenylspiro[indoline-3,4′(1′*H*)-pyrano[2,3-*c*]pyrazole]-2-one (7c). Obtained as colorless crystals from acetone, mp 220 °C, yield 70%. Found: C, 68.1; H, 3.9; N, 18.88%. Calcd for $C_{21}H_{15}N_5O_2$: C, 68.29; H, 4.06; N, 18.96%.

Ethyl 6′-Amino-3′-methyl-2-oxo-1′-phenylspiro[indoline-3,4′-(1′*H*)-pyrano[2,3-*c*]pyrazole]-5′-carboxylate (7d). It is isolated as pale yellow crystals from acetone, mp 205 °C; yield is ca. 83%. Found: C, 66.6; H, 5.0; N, 13.4%. Calcd for $C_{23}H_{20}N_4O_4$: C, 66.34; H, 4.8; N, 13.46%.

Ethyl 2-Amino-3a[benzoyl(cyano)methyl]-3a*H*-furo[2,3-*b*]indole-3-carboxylate (8). It is obtained as brown crystals from acetone, mp 218 °C, yield is 67%. Found: C, 68.6; H, 4.3; N, 10.69%. Calcd for $C_{22}H_{17}N_3O_4$: C, 68.2; H, 4.3; N, 10.8%.

Thanks are due to Professor Dr. Y. S. Mohammed, Department of Chemistry, Faculty of Science, El-Minia University, for his valuable discussions.

Reaction of Azomethine *N*-Oxides. III.[1] Reactions of Some Azomethine *N*-Oxides with Fluoranil, Phenyl Vinyl Sulfone, and β-Nitrostyrene

Ahmed Moukhtar Nour El-Din
Chemistry Department, Faculty of Science, El-Minia University, El-Minia, Egypt
(Received December 22, 1984)

Isomerization of 3*H*-indole 1-oxides in the presence of tetrafluoro-2,5-cyclohexadiene-1,4-dione (fluoranil) to the thermodynamically more stable lactams was found to proceed via formation of charge-transfer complexes. However, addition of fluoranil to some open chain nitrones did not give the corresponding amides. Both electron-deficient β-nitrostyrene and phenyl vinyl sulfone did not form charge-transfer complexes with nitrones, but instead they undergo 1,3-dipolar cycloaddition giving 4- or 5-substituted isoxazolidines.

Döpp et al.[2,3] have shown that electron-deficient nitriles, ethentetracarbonitrile (TCNE) or oxiranetetracarbonitrile (TCNO) accelerate isomerization of the 3*H*-indole 1-oxide (**1a**) into the lactam (**3a**). Two reaction pathways for this isomerization were postulated.[2,3] The first is the cycloaddition of the nitrone (**1a**) with the cyano group of TCNE or TCNO, followed by fission of the cycloadduct and 1, 2-oxygen migration. The second is the complexation of the 3*H*-indole 1-oxide (**1a**) with the electron-deficient compounds followed by oxygen and hydrogen atoms shifts.[3]

We have recently reported[4–6] that nitrones form charge-transfer complexes with various electron-deficient compounds such as TCNE and 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ). This result has urged us to investigate[2,3] about formation and chemical behavior of the complexes between the 3*H*-indole 1-oxides (**1a,b**) and the electron-deficient fluoranil (**2**), together with some analogous reaction systems.

Additions of **1a** and **1b** to equimolar quantities of fluoranil (**2**) in dichloromethane at room temperature have given rise to greenish orange colored solutions, which show two absorption shoulders in the visible region at λ_{max} 490 and 505 nm for **1a** and **1b**, respectively (Table 1). These two absorptions are due to complexation[4–6] between each of the 3*H*-indole 1-oxides (**1a**·or **1b**), and the electron-deficient fluoranil. The decomposition of the charge-transfer complexes by heating has led to the thermodynamically more stable lactams (**3a,b**).[7,8] The structures of the lactams (**3a,b**) were varified by both the relevant physical and spectrometric data given in Tables 1 and 2. This result implies that the formation of the charge-transfer complexes between each of 3*H*-indole 1-oxides (**1a,b**) and fluoranil is the first step in the isomerization of **1a** and **1b** to the lactams (**3a,b**). Since the fluoranil does not contain any cyano group, the suggestion[2,3] of the cycloaddition of the 3*H*-indole 1-oxides (**1a,b**) with cyano group in the electron-deficient nitrile compounds can be ruled out. Instead, the too fast isomerization[2] of the 3*H*-indole 1-oxide (**1a**) into the lactam (**3a**) in the presence of TCNE can be attributed to the higher electron affinity of the TCNE compared with that of fluoranil.[9]

The formation of the lactams (**3a,b**) are likely to take place via formation of charge-transfer complexes (**4a,b**) and removal of one electron out of the highest occupied molecular orbital (HOMO) of the 3*H*-indole 1-oxides (**1a,b**). Such an electron transfer facilitates the migration of the oxygen atom from the nitrogen atom to the α-carbon atom, which is followed by an 1,2-hydrogen shift and additional bond reorganization (Fig. 1).

On addition of equimolar quantity of the pyrrole 1-oxide (**12**) to fluoranil in dichloromethane, a pale yellow color developed, and no band for charge-transfer complex was observed in the spectra of the pale yellow solution obtained. Heating of this mixture did not lead to the formation of the corresponding lactam, instead the starting compounds **12** and **2** were recovered. This result reinforces the suggestion that, the rearrangement of the indole 1-oxides (**1a,b**) to lactams (**3a,b**) proceeds via charge-transfer complex formation.

Table 1. Maximum Absorption Wavelengths λ_{max}/nm of Change-Transfer Complexes Formed between the Nitrones (**1a**, **b**; **8a**, **b**, **c**, **d**) and Tetrafluoro-2,5-cyclohexadiene-1,4-dione (**2**) in Dichloromethane at 25 °C

3-(2-Methylphenyl)-2-phenyl-4-(phenylsulfonyl)isoxazolidine (**14a**)	89	112—114 (Ethanol-hexane)	$C_{22}H_{21}NSO_3$	69.55 (69.63	5.47 5.58	3.51 3.69)
3-(3-Methylphenyl)-2-phenyl-4-(phenylsulfonyl)isoxazolidine (**14b**)	82	87—89 (Ethanol-hexane)	$C_{22}H_{21}NSO_3$	69.58 (69.63	5.52 5.58	3.54 3.69)
6,6-Dimethyl-2,3,3a,4,5,6-hexahydro-5-phenyl-2-(phenylsulfonyl)pyrrolo-[1,2-*b*]isoxazole (**15**)	87	173—174 (Ethanol-hexane)	$C_{20}H_{23}NSO_3$	67.16 (67.21	6.39 6.48	3.80 3.92)

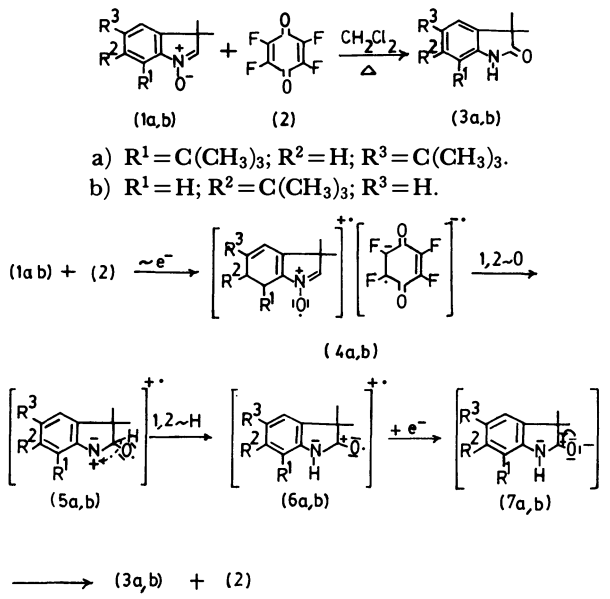

Fig. 1.

A new broad band in the visible spectrum, 475—498 nm, was observed immediately on mixing equimolar solutions of the fluoranil with each of the open chain nitrones (**8a,b,d,e**) in dichloromethatne (Table 1). These absorptions were ascribed to the charge-transfer complexes formation, since neither the fluoranil nor the nitrones (**8a,b,d,e**) alone absorb in this region (Table 1). However, the separation of the mixtures by preparative layer chromatography (PLC) did not give the corresponding amides even after prolonged heating, but the starting materials were recovered. Attempts to isolate these nitrone-fluoranil complexes in crystalline form were failed. These results may suggest that the charge-transfer interaction between the open chain nitrones and fluoranil are weak[9] to undergo rearrangement of **8a—c** to their corresponding amides.

On addition of the electron-deficient β-nitrostyrene (**9**) to each of the nitrones (**8a—c**) in dichloromethane at room temperature, pale yellow colored solutions were obtained, which gave no characteristic absorption band for charge-transfer complexes. This behavior can be ascribed to the relatively low electron affinity of the β-nitrostyrene.[9-11] After heating of the mixture of each of nitrones (**8a—c**) with β-nitrostyrene in toluene, only stable 4-nitroisoxazolidines (**10a—c**) were obtained, regiospecifically. This result is consistent with the

Table 3. Spectroscopic Data of Products Listed in Table 2

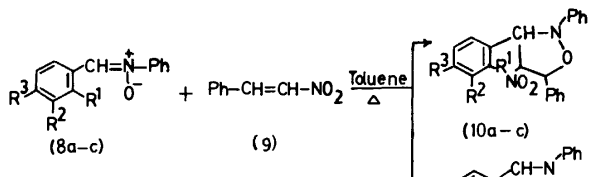
14b	1305, 1145 (SO_2)	($CDCl_3$): 2.25 (3H, s, CH_3), 4.22 (CH_2, dd, *J*=4 and 7Hz, H-5), 4.41 (1H, dd, *J*=7 and 4Hz, H-4), 4.9 (1H, d, *J*=4Hz, H-3), 6.68—7.95 (14H, m, phenyl protons)	379 (12, M^+), 363 (5), 141 (32), 77 (100)
15	1308, 1142 (SO_2)	($CDCl_3$): 0.75 (3H, s, CH_3), 1.1 (3H, s, CH_3), 1.8—2.8 (3H, m, CH_2-3 and H-4), 3.05—3.6 (2H, m, H-4 and H-5), 3.75—4.45 (1H, m, H-3a), 5.25 (1H, dd, *J*=3 and 9Hz, H-2), 6.95—8.11 (10H, m, phenyl protons)	357 (6, M^+), 341 (2), 187 (29), 170 (17), 141 (35), 77 (100)

interaction between the frontier orbitals of the nitrones and the frontier orbitals of the electron-deficient dipolarophiles.[10,11] The observation of the methine proton signal of the 5-H at δ 5.25—5.75 for the cycloadducts (**10a—c**) respectively (Table 3) is indicative of the methine group being located between an oxygen atom and a nitro group.[10] Moreover, besides the molecular ions at *m/z* 360, 360, and 389 for the products (**10a—c**) respectively, an interesting fragment *m/z* 106 (20—26%), probably for the C_6H_5CHO structure (Table 3) was observed in their mass spectroscopic data. This is another strong evidence confirming the structure of the products, 4-nitroisoxazolidine isomers (**10a—c**).

Treatment of the nitrones **8a,b**, and **12** with phenyl vinyl sulfone (**13**) did not form charge-transfer



a) $R^1=CH_3$; $R^2=R^3=H$.
b) $R^1=H$; $R^2=CH_3$; $R^3=H$.
c) $R^1=R^2=H$; $R^3=(CH_3)_2N$.
d) $R^1=OCH_3$; $R^2=H$; $R^3=OCH_3$.
e) $R^1=H$; $R^2=OCH_3$; $R^3=OCH_3$.

Fig. 2.

complexes, but instead they undergo 1,3-dipolar cycloaddition reactions giving the cycloadducts (**14a,** b), and (**15**). This behavior can also be attributed to the lower electron affinity of the phenyl vinyl

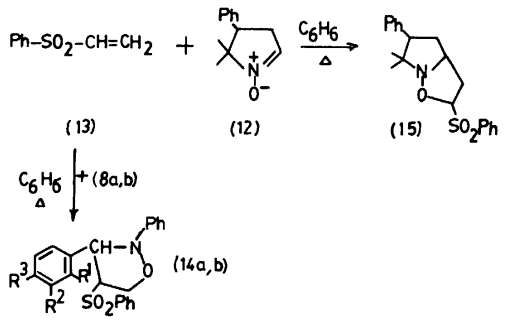


Fig. 3.

sulfone (0.8 eV) than that of fluoranil (0.97 eV).[9,10]

While the reaction of the electron-deficient **13** with the nitrones (**8a,b**) afforded the 4-(phenylsulfonyl)-isoxazolidines (**14a,b**), a dipole highest occupied–dipolarophile lowest unoccupied controlled product, 5-(phenylsulfonyl)isoxazolidine (**15**), a dipole lowest unoccupied–dipolarophile highest occupied controlled product was obtained from the addition reaction of **13** to the nitrone **12**. The reversal of the regioselectivity in the case of the open chain nitrones may be ascribed to their high orbital energies, which favor of the 4-substituted isomers.[10]

The distinction between the 4- and 5-(phenylsulfonyl)isoxazolidines (**14a,b**, and **15**, respectively), was provided by the chemical shift[10] of the methylene protons. The signal for the CH_2 protons of the 4-(phenylsulfonyl)isoxazolidines (**14a,b**) appears at relatively low magnetic field δ 3.85 and 4.22, respectively, while the corresponding signal for the 5-(phenylsulfonyl)isoxazolidine (**15**) occurs at δ 1.18—2.80 (Table 3).

When each of the electron-deficient dipolarophiles (**9** and **13**) was added to the indole 1-oxides (**1a,b**) in dichloromethane (equimolar ratio), the solution turned pale yellow in color. Such solution gave no broad band for charge-transfer complexes. It is plausible to suggest that the results can be ascribed to the low electron affinity of the electron-deficient dipolarophiles (**9** and **13**). Heating of the solutions gave yellow unstable products, which could not be obtained in a pure form.

Experimental

All melting points are uncorrected. IR spectra were recorded (KBr) on a Perkin-Elmer 283 spectrophotometer. UV and visible spectra were measured with a Beckman spectrophotometer model 26. ^{1}H-NMR spectra were recorded on Varian EM-360 (60 MHz) NMR spectrometer using TMS as the standard. Mass spectra were obtained on a MAT 311A spectrometer operating at 70 eV. Elemental analysis were performed by the Microanalytical Unit of Cairo University. The nitrones **1a,b**,[7,12] **8a—e**[13], and **12**[14] were prepared according to literature procedures.

Reaction of Nitrones (1a,b) with Tetrafluoro-2,5-cyclohexadiene-1,4-dione (2). General Procedure: To a solution of **1a** or **1b** (1 mmol) in 5 ml dry dichloromethane, 180 mg (1 mmol) fluoranil was added. The mixture was refluxed for 3 h and then the solvent was evaporated. The residue was chromatographed on a preparative layer chromatography (PLC) of silica gel, using a mixture of benzene–ethyl acetate (9:1) as eluent, to give one zone. Extraction with acetone and recrystallization from the appropriate solvent (Table 2) gave **3a** or **3b**.

Reaction of 5,5-Dimethyl-4-phenyl-Δ^1-pyrroline 1-Oxide (12) with 2. To a stirred solution of 100 mg (0.53 mmol) of **12** in 5 ml dry dichloromethane, 95 mg (0.53 mmol) of **2** in 2 ml of dichloromethane was added. The reaction mixture was refluxed for 12 h and then the solvent was evaporated. The residue was separated on PLC of silica gel, using a mixture of benzene–ethyl acetate (10:1) as eluent, to give two zones. Extraction with acetone and recrystallization from ethanol–hexane gave the starting materials **12** and **2**.

Charge-Transfer Complexes of Nitrones (8a,b,d,e) with 2. To a stirred solution of each of nitrones (**8a,b,d,e**) (0.5 mmol) in dry dichloromethane, 0.5 mmol of **2** in dichloromethane was added. A greenish-orange color appeared. The colored solution was refluxed for 12 h. The solvent was evaporated and the residue was chromatographed on PLC (benzene–ethyl acetate, (10:1). The starting materials, nitrones (**8a,b,d,e**) as well as fluoranil (**2**) were recovered.

Reaction of Nitrones (8a—c) with β-Nitrostyrene (9). Mixture of nitrone (**8a—c**) (1 mmol), β-nitrostyrene (**9**) (1 mmol) and dry toluene (10 ml) was heated to reflux for 12 h. The solvent was evaporated and the residue was separated on PLC (benzene). Extraction with acetone and recrystallization from the proper solvent (Table 2) afforded the products (**10a—c**).

Reaction of Nitrones (8a,b) and (12) with Phenyl Vinyl Sulfone (13). To a solution of each of nitrones (**8a,b**) and **12** (1 mmol) in 10 ml dry benzene, 168 mg (1 mmol) of phenyl vinyl sulfone was added. The reaction mixture was refluxed for 8 h and then the solvent was evaporated. The residue was separated on PLC (benzene) to give one zone. Extraction with acetone and recrystallization from a proper solvent gave the cycloadducts (**14a,b**, and **15**).

Reaction of Nitrones (1a,b) with 9. General Procedure: A solution of **1a** or **1b** (1 mmol) in 4 ml dichloromethane was added to a solution of **9** (1 mmol) in 4 ml dichloromethane. The resulting mixture was refluxed for 24 h. Evaporation of the solvent under reduced presure with rotary evaporator and chromatography of the residue on PLC of silica gel, using a mixture of benzene–ethyl acetate (10:1) as eluent, gave yellow unstable products, which could not be obtained in pure form.

Reaction of Nitrones (1a,b) with 13. Applying the same reaction conditons used for the reaction **1a,b** with **9**, the addition of **1a** or **1b** (1 mmol) to **13** (1 mmol) in dichloromethane gave also unstable products, which could not be identified.

Synthesis of 2-(Alkyl and Aryl)thiazolo[4,5-*b*]quinoxaline Derivatives and Study of Their Fluorescent Properties

Ravindra Chintaman PHADKE and Dinesh Wamanrao RANGNEKAR*
Dyes Research Laboratory, Department of Chemical Technology,
University of Bombay, Matunga, Bombay-400 019, India
(Received March 18, 1985)

Synthesis of 2-(alkyl and aryl)thiazolo[4,5-*b*]quinoxaline derivatives has been achieved by reacting 2, 3-dichloroquinoxaline derivatives with various thiocarboxylic acid amides. The resulting compounds have been studied for their fluorescent properties. Some of these compounds have been applied as fluorescent dyes on polyester fiber having fair dyeing properties.

In the recent years newer heterocyclic compounds are being synthesised and investigated as dyes and fluorescent brighteners. Quinoxaline derivatives have been described in literature as useful reactive dyes,[1] cyanine dyes,[2] azo dyes,[3] fluorescent dyes,[4,5] and pigments.[6] With the exception of a report of application of 1,4-oxazino[2,3-*b*]quinoxaline as fluorescent brighteners described,[7] there has been no investigation of quioxaline derivatives in the field of fluorescent brighteners.

We report here the synthesis of 2-(alkyl and aryl)-thiazolo[4,5-*b*]quinoxaline derivatives and the study of their fluorescent properties. The 2-(alkyl and aryl)-thiazolo[4,5-*b*]quinoxaline derivatives were synthesized by the reaction of 2,3-dichloroquinoxaline derivative with appropriate thiocarboxylic acid amides in refluxing *N*,*N*-dimethylformamide. The compounds **IIIa** and **IIIb** were obtained from thioacetamide and 4-methoxythiobenzamide, respectively. The products obtained were characterized by elemental anlyses and superimposable infrared spectra. The compound **IIIa** was further confirmed by recording its mass spectrum which showed molecular ion peak (*m/z*) at 201 corresponding to the molecular weight of **IIIa**. The compound **IIIb** was further confirmed by recording its ^{1}H NMR in trifluoroacetic acid: singlet at δ 3.95 (3H) corresponding to $-OCH_3$ group and multiplet δ 7.6—8.05 (4H) corresponding to all the aromatic protons.

The compounds **IIIa** and **IIIb** did not possess strong fluorescence. In order to obtain compounds which have stronger fluorescence, it was intended to prepare derivatives of **IIIa** and **IIIb** and observe the changes in the fluorescence properties. It is known that incorporation of certain groups in a given compound increases its possibility of enhancing fluorescence. An amino group in appropriate position is many a times helpful. It was, therefore, proposed to synthesise compounds with an amino group at the 7-position of the thiazolo[4,5-*b*]quinoxaline.

The 7-amino derivatives of **IIIa** and **IIIb** were prepared via its 7-nitro derivatives. The 7-nitro derivatives **IIIc** and **IIId** were prepared by reaction of 2,3-dichloro-6-nitroquinoxaline with thioacetamide and 4-methoxythiobenzamide, respectively, in refluxing *N*,*N*-dimethylformamide. The nitro derivatives were characterized by their elemental

analyses and their superimposable infrared spectra. The nitro derivatives **IIIc** and **IIId** were subsequently reduced by zinc dust and acetic acid to yield the 7-amino derivatives **IVa** and **IVb**. The compounds **IVa** and **IVb** were characterised by their elemental analyses and infrared spectra (two peaks at 3280 and 3220 cm^{-1} corresponding to the amino group). The absorption maxima showed a shift to the lower wavelength (see Table 1). In order to shift the fluorescent towards the blue region which is desired in the case of fluorescent brighteners, the amino derivatives **IVa** and **IVb** were converted to the *N*-acetyl derivatives **Va** and **Vb** by refluxing in acetic anhydride. The compounds **Va** and **Vb** were characterized by their elemental analyses and infrared spectra (absence of two peaks corresponding to amino group, presence of a peak at 3300 cm^{-1} corresponding to -NH group, and a peak at 1720 cm^{-1} corresponding to the carbonyl group). The emission maxima of these derivatives shifted towards the blue region(see Table 1).

All the compounds synthesised in general showed fluorescence in greenish blue region (439 to 471 nm) (see Table 1). As the compounds were coloured, some of these were applied on polyester fibers as fluorescent dyes. The compounds **IIIc** dyed the fiber in orange red shade whereas **IIIb** and **Va** gave light greenish yellow and pale yellow shades with fair dyeing properties.

Experimental

All melting points are uncorrected. The IR sprctra were recorded on Perkin Elmer-397 spectrophotometer in Nujol mull. The UV and fluorescence spectra were recorded on Beckman Model-25 spectrophotometer and Aminco Bowman spectrophotofluorometer, respectively. The ^1H NMR spectra was recorded on Varian-60 MHz.

2,3-Dichloroquinoxaline,[8] 2,3-dichloro-6-nitroquinoxaline,[9] and 4-methoxythiobenzamide[10] were prepared by the methods reported.

General Procedure of Synthesising Thiazolo[4,5-*b*]-quinoxaline Derivatives (IIIa and IIIb). In a 50ml R.B. flask were placed 2,3-dichloroquinoxaline derivatives (**Ia** and **Ib**) (0.005mol), appropriate thiocarboxylic acid amides (**IIa** and **IIb**) (0.005mol), and *N*,*N*-dimethylformamide (5—7ml). The reaction mixture was refluxed till the reaction was complete (4—5h) (checked by TLC). The reaction mixture was slowly added to ice water mixture when the product precipitated. The yield, mp, and recrystallization solvents are given in the Table 1.

General Procedure of Synthesising 7-Aminothiazolo[4,5-*b*]-quinoxaline Derivatives (IVa and IVb). In a 50ml R.B. flask was placed 7-nitrothiazolo[4,5-*b*]quinoxaline (**IIIa** and **IIIb**) (0.005mol). Acetic acid (10ml) and concentrated hydrochloric acid (0.5—1ml) were subsequently added. The reaction mixture was stirred and slowly heated so that the temperature was 80°C. To this hot reaction mixture, zinc dust (0.006mol) was added in portions over a period of 30—45 min. At the end of the addition the contents were refluxed (115—112°C) under stirring for 3—4h, till the reaction was complete (checked by TLC). The reaction mixture was then filtered hot and after cooling the filtrate was slowly added to a stirred ice-water mixture. The product was filtered, washed thoroughly with water, and dried. The yield, mp, and recrystallization solvents are given in the Table 1.

General Procedure of 7-Acetamidothiazolo[4,5-*b*]quinoxaline Derivatives (Va and Vb). The 7-aminothiazolo[4,5-*b*]-quinoxaline (**IVa** and **IVb**) (0.005mol) was placed in a R.B. flask, and to this acetic anhydride (2—3ml) and acetic acid (1—2ml) were added. The reaction mixture was heated in an oil bath so that it gently refluxed. The reaction mixture was refluxed for 3—4h till the reaction was complete (checked by TLC). On cooling the reaction mixture was slowly poured over ice-water mixtuer with continuous stirring when product precipitated. The compound was filtered, washed with water, and dried. The yield, mp, and recrystallization solvents are given in Table 1.

One of us (R.C.P) is thankful to C.S.I.R., New Delhi for the award of a junior research fellowship and senior research fellowship.

Ab Initio MO Theoretical Studies on Direct Fragmentation of Organic Ions Produced by Electron-Bombardment

Hiroshi ICHIKAWA* and Atsushi SHIGIHARA
Hoshi College of Pharmacy, Shinagawa, Tokyo 142
(Received November 8, 1985)

Synopsis. The possibility of bond-scission within a single vibration (direct fragmentation) in a molecular ion produced by electron-bombardment has been studied. MP2/6-31G* calculations have shown that a direct fragmentation in the ground-state ion is possible for the C–H bonds of hydrocarbons.

So far, fragmentations which are caused by vibrational excitations have been well-studied from both theoretical and experimental standpoints. Much knowledge about such fragmentations has been accumulated and it is recognized that most fragmentations take place in the ground electronic state, consuming a lot of time (more than 10^{-13} s).[1] However, we do not have any information on fragmentation within a single vibration, termed direct fragmentation. It is uncertain whether direct fragmentation actually occurs. However, an apparent difference in the mass spectra between lower and higher ionization energies suggests the existence of direct fragmentations. Such a difference is not a proof.

The electron-impact (EI) ionization takes place by a resonance between the wave of an electron in a molecule and that of an impinging electron; those electrons are indistinguishable. Therefore, any kind of excited state can possibly take place during electron-bombardment. Two types of direct fragmentation are possible according to the Franck-Condon principle: A direct fragmentation at the ground electronic state and that due to antibonding states (Fig. 1). We examined the former case using the second order Mϕller-Plesset perturbation method[2] based on the 6-31G* basis set[3] (MP2/6-31G*).[4]

Previous work on intramolecular rearrangements in smaller systems has indicated that relative energies (including up to third order of Mϕller-Plesset perturbation (MP3)) are in good agreement (less than 5 kJ mol^{-1}) with the results of a full coupled-cluster calculation.[5] We estimate a similar error for a MP2/6-31G* calculation, since it is shown that the difference of the effect of electron correlation between MP2 and MP3 are almost the same.[6]

The investigation method for the ground-state process is rather straightforward since it is sufficient to consider the potential energies referring to the potential energy curves of the molecule and the ions in the ground state, whatever the process is (see Fig. 1).

Most molecules are in the ν_0 state (the ground vibrational state) while maintaining a near-equilibrium distance (r_0). Vertical ionization reaches the point p_0 of the ground-state potential-energy curve of the molecular ions. If the potential energy at $p_0(V_0)$ is higher than that after dissociation (V_∞), i.e. ΔV ($=V_0-V_\infty$) is positive, ions can possibly undergo ground state direct fragmentation; if ΔV is negative,

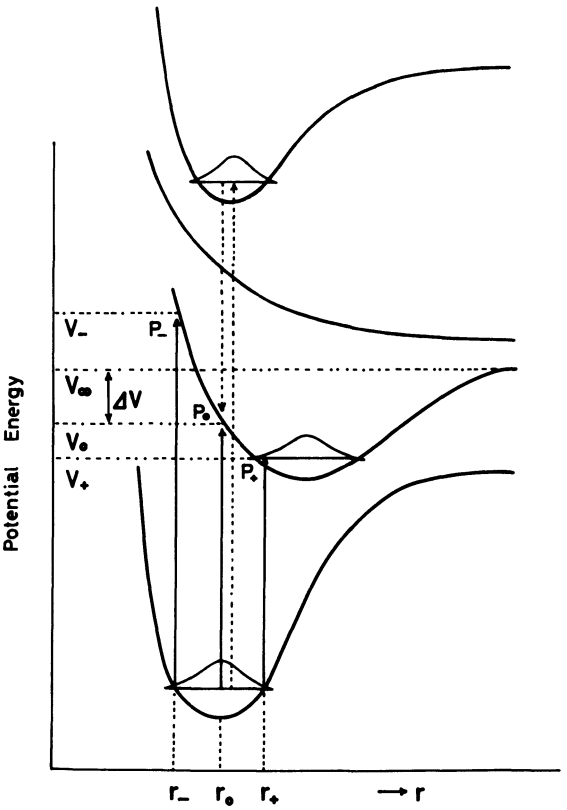

Fig. 1. The Franck-Condon principle of vertical ionization of molecule.

direct fragmentation can not take place. However, the latter case does not always mean that direct fragmentation never occurs. Although it is a small possibility, there is a chance that a molecule can be ionized at a shorter distance. If the potential energy at $p-$ ($V-$) is higher than V_∞, direct fragmentation can occur.

Figure 2 shows the results for hydrogen fluoride. The equilibrium distance of the ground-state ion is increased by about 0.1 Å from that of the molecular state. The vertical ionization at the equilibrium distance reaches a PE of −99.610387 au; this is lower than the energy after dissociation (−99.487271 au). Therefore, it may be concluded that ground-state direct fragmentation does not take place.

Figure 3 shows the case for methane. The PE curve for the ion is that of a C_{3v} adiabatic fragmentation, the lowest for a CH cleavage. It has a potential minimum at a very long distance (1.3280 Å).[7] Ionization at the equilibrium distance of the molecule gives a PE (−39.816667 au) which is higher than that after dissociation (−39.823607 au). Therefore, direct fragmentation is possible by ionization. It should be, however, stressed that this does not always mean that

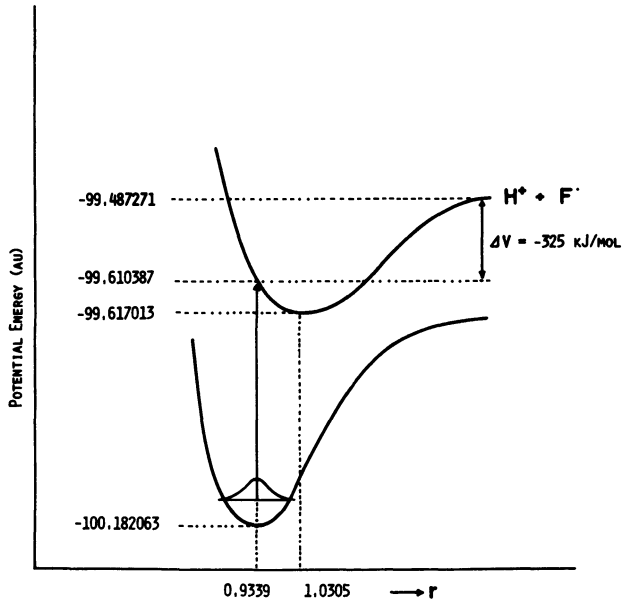

Fig. 2. Potential energy curves of the hydrogen fluoride ion and molecule by MP2/6-31G*.

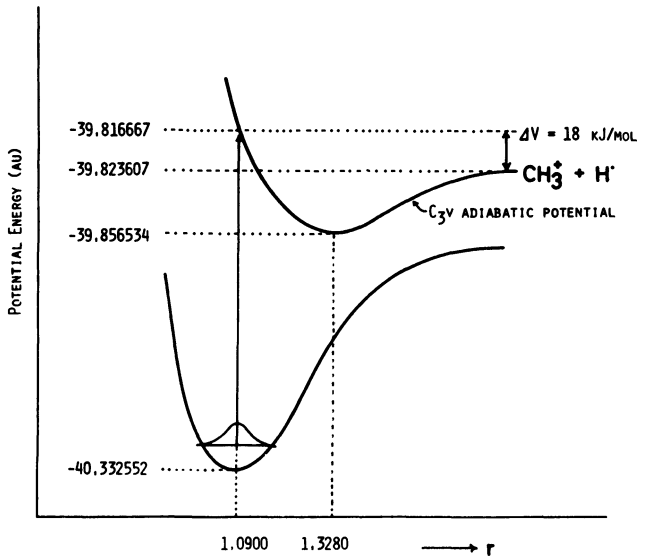

Fig. 3. Potential energy curves of the methane ion and molecule by MP2/6-31G*.

the appearance potential of a methyl cation is lower than that of a methane ion.[8]

Table 1. The ΔV Values and Appearance Potentials by MP2/6-31G*

Compound	ΔV	$Ap^{calcd\ a)}$	$Ap^{expl\ b)}$
	kJ/mol	(eV)	(eV)
$H\text{-}C_2H_5$	73	12.1	12.7
$CH_3\text{-}CH_3$	−76	13.6	13.5
$H\text{-}CH_2OH$	−15	11.0	11.7
$H\text{-}CH_2NH_2$	−13	9.5	10.3
$C_2H_5\text{-}NH_2$	−254	11.7	13.5
$CH_3\text{-}CH_2NH_2$	−30	9.4	9.7

a)Zero-point energies are not corrected. b)Appearance potentials are taken from Ref. 9.

In a similar way, we obtained results for some other compounds (summarized in Table 1). As references, the calculated and experimental[9] appearance potentials are listed in addition to the ΔV values. The positive ΔV values suggest a possible direct fragmentation. It is well known that the C–C bond in an ethylamine ion is easily broken under the EI condition; however, the present results show that such a cleavage is not a direct fragmentation. Consequently, it can be said that a direct fragmentation in the ground electronic state is possible in the CH bonds of hydrocarbons.

Synthesis and Properties of Manganese(III) Complex of Salen-Analog Containing Phenolic Pendant Group

Wakako KANDA
Laboratory of Chemistry, Kyushu Institute of Design, 4-9-1 Shiobaru, Minami-ku, Fukuoka 815
(Received October 8, 1985)

Synopsis. A manganese(III) complex, [Mn(sal-pen)], with *N,N'*-disalicylidene-2-methyl-4-(2-hydroxy-5-methylphenyl)-1,2-butanediaminate trianion (sal-pen^{3-}) has been synthesized and characterized. The complex was shown to have a square-pyramidal structure with a pendant phenolate group at the apex. The electronic spectral and electrochemical properties of the complex are discussed in terms of an axial coordination of the phenolate group.

The salen-analog, composed of a planar N_2O_2-donating system and a pendant phenolic group, *N,N'*-disalicylidene-2-methyl-4-(2-hydroxy-5-methylphenyl)-1,2-butanediamine (H_2(sal-Hpen), Fig. 1), functions as a pentadentate ligand to yield iron(III) and cobalt(III) complexes, [M(sal-pen)], with a deprotonated pendant phenolic oxygen at the apical position.[1] In general, iron(III) and cobalt(III) complexes with unidentate phenolic ligands readily undergo dissociations of the phenolate groups. On the other hand, it has been shown that [Co(sal-pen)] is very stable in nondonating solvents[2] and [Fe(sal-pen)] is stable even in alcohols.[3] The stabilities of these complexes in solutions are probably due to a chelating effect of the pendant phenolate group combined at the ethylene backbone of the salen skelton.

In this study, a manganese(III) complex of H_2(sal-Hpen) was prepared and its chemical properties were examined in view of the axial coordination of the pendant phenolic group.

The synthesis of [Mn(sal-pen)] was as follows: an ethanolic solution (10 cm^3) of manganese(II) acetate tetrahydrate (0.3 g) was added to an ethanolic solution (10 cm^3) of H_2(sal-Hpen)[1] (0.5 g) and sodium hydroxide (0.1 g) under a nitrogen atmosphere. The resulting pale-orange solution was then stirred for 3 h in the open air. The color of the solution immediately changed from orange to brown. Then, the solvent was evaporated at room temperature to give brown prisms, which were recrystallized from dichloromethane. The yeild was ca. 0.2 g.

Found: C, 62.35; H, 5.52; N, 5.09%. Calcd for $C_{26}H_{25}N_2O_3Mn \cdot 2H_2O$: C, 61.90; H, 5.79; N, 5.55%.

[Mn(salen)Cl] and [Mn(salen)OAc] were prepared by methods described in the literature.[4,5]

The effective magnetic moment of [Mn(sal-pen)] is 4.7 BM at room temperature; this corresponds to the value of high-spin manganese(III) complexes (4.7—5.0 BM).[6] A small temperature dependance of the moment in the range 80—300 K suggests a monomeric structure for the complex.

[Mn(sal-pen)] exhibits no IR band which can be attributed to an O–H vibration around 3200—3300 cm^{-1}. However, H_2(sal-Hpen), [Cu(sal-Hpen)], and [Ni(sal-Hpen)] show an O–H vibration in this region.[1] This suggests that the phenolic O–H in the pendant

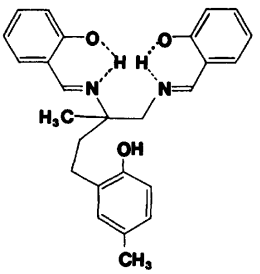

Fig. 1. The chemical structure of H_2(sal-Hpen).

group becomes deprotonated and coordinated to the metal. By an analogy of the IR spectrum with those of [Fe(sal-pen)] and [Co(sal-pen)], which possess a pentacoordinate structure with an N_2O_2-donating system at the equatorial plane and a phenolic oxygen at the apical site, [Mn(sal-pen)] is presumed to have a square-pyramidal structure with a phenolic oxygen at the apex.

The electronic spectrum of [Mn(sal-pen)] in dichloromethane (1×10^{-3} mol dm^{-3}) exhibits absorption bands at 20.6×10^3 (ε 1450), 25.0×10^3 (3850), 32.3×10^3 (16400), 35.7×10^3 (19200), and 43.5×10^3 (40300) cm^{-1}. The spectrum resembles those of pentacoordinate [Mn(salen)Cl] and [Mn(salen)OAc] with a chloride ion or an acetate ion at the apical site.[7] Molar conductivity measurements revealed these Mn complexes to be nonelectrolyte in dichloromethane. Thus, [Mn(sal-pen)] is presumed to have a square-pyramid geometry with a pendant phenolic group at the apex. According to these results, the lowest energy band (20.6×10^3 cm^{-1}) of [Mn(sal-pen)] can be assigned to the d-d band and the absorption at 25.0×10^3 cm^{-1} to the charge-transfer band.[7,8] The electronic spectrum of [Mn(sal-pen)] in methanol differs markedly from that in dichloromethane. This suggests a dissociation of the pendant group in polar methanol.[4]

The electrochemical properties of [Mn(sal-pen)] were investigated in comparison with those of [Mn(salen)Cl] and [Mn(salen)OAc] by means of polarography and cyclic voltammetry in dichloromethane. A three-electrode cell with a glassy carbon electrode as the working electrode, a platinum coil as the auxiliary electrode, and a saturated calomel electrode as the reference electrode was used for measurements. Tetrabutylammonium perchlorate was used as the supporting electrolyte. All the potentials were normalized using ferrocene as the internal standard (V vs. F_c/F_c^+).[9] The electrochemical results are shown in Fig. 2.

[Mn(sal-pen)] exhibits an irreversible wave at +0.32 V and a quasi-reversible wave at −0.76 V. Similar results were obtained for [Mn(salen)Cl] and [Mn(salen)OAc] in this study.[10] The redox wave around

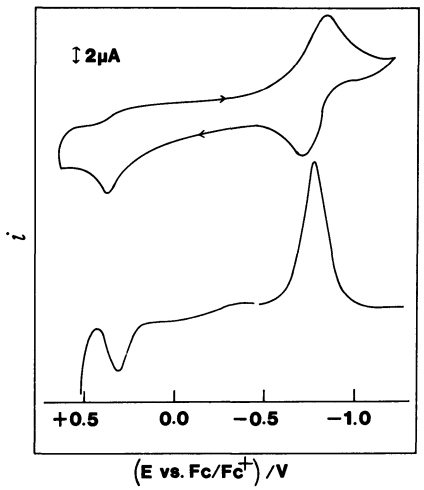

Fig. 2. Cyclic voltammogram (above) and differential pulse polarogram (below) of Mn(sal-pen) in dichloromethane.

−0.7 V was assigned to the Mn(II)/Mn(III) process while the irreversible oxidation at a positive potential was assigned to the Mn(III)/Mn(IV) process.[11–13] There was a slight difference in the Mn(III)/Mn(II) reduction potential among these complexes. The reduction potentials seem to be independant of the axial ligand. This is probably due to the fact that this process is associated with an electron acceptance on the $d_{x^2-y^2}$ orbital and, thus, not substantially influenced by a change in the axial ligand. On the contrary, the Mn(III)/Mn(IV) oxidation potentials are highly dependant upon the axial ligand. This is reasonable since the process involves the release of an electron from the d_{z^2} orbital. This must be much influenced by the charge of the axial ligand. The oxidation of [Mn(sal-pen)] occurred at a considerably lower potential relative to those of [Mn(salen)Cl] and [Mn(salen)OAc]. This suggests that the axial phenolate ligand in [Mn(sal-pen)] donates more strongly than a chloride ion or an acetate ion does.

Manganese(III) complexes with a unidentate phenolate ligand are generally difficult to synthesize because of the high lability of phenolate ligands. The present study reveals that a phenolatomanganese(III) complex can be readily isolated by incorporating a phenolate group into the tetradentate salen moiety.

The author wishes to express her thanks to Associate Professor Hisashi Ōkawa and Professor Shigeo Kida of the University of Kyushu for the magnetic measurement and the helpful discussions.

(Received October 21, 1985)

Synopsis. The crystal and molecular structure of the title complex was determined using the single-crystal X-ray diffraction method. A crystal of $CoHgC_{14}H_{22}N_6O_4S_4$, F.W. 726.15, is tetragonal with a space group $P\bar{4}$, a=12.082(3), c=8.097(2) Å, U=1182.0(5) Å^3, Z=2, D_x=2.04 Mg m^{-3}, and μ(Mo $K\alpha$)=7.72 mm^{-1}. Tetrahedral mercury(II) coordinated with four sulfur atoms and octahedral cobalt(II) coordinated with four nitrogen atoms of SCN^- (equatorially) and two oxygen atoms of H_2O (axially) are linked by thiocyanate bridges to form planar networks parallel to (001). The planes are connected by *N*-methyl-2-pyrrolidone (mpd) molecules through the hydrogen bonds with two coordinated water molecules at both side networks. The structure resembles that of the *N*,*N*-dimethylacetamide (dma) adduct, $CoHg(SCN)_4(H_2O)_2 \cdot 2$dma. These are new types of inclusion compounds.

Cobalt(II), mercury(II), thiocyanate (**1**),[1] and its Lewis-base adducts[2–5] are known to exist in a variety of polymeric structures. Among them, the previously reported *N*,*N*-dimethylacetamide (dma) adduct, $CoHg(SCN)_4(H_2O)_2 \cdot 2$dma (**2**),[5] was regarded as a kind of inclusion compound because dma molecules are maintained between the metal–thiocyanate networks by only the hydrogen bonds to the two ligating water molecules of both planes. The dma molecules are not easily removed, even when they are left standing for a long time in the air.

During the course of our further investigation we synthesized the *N*-methyl-2-pyrrolidone (mpd) adduct shown in the title (**3**). The structure has been determined by an X-ray diffraction analysis using its single crystal.

Experimental

Single-Crystal X-Ray Analysis. Crystals of **3** were obtained as follows: **1** (1.0 g, 2.0 mmol) was dissolved into 20 cm^3 of mpd. To the blue solution, an equal volume of water was added; the color of the solution turned red. After the solution was left standing overnight, precipitated **3** (red-brown in color) was separated. The yield was 1.1 g (74%). Anal. ($CoHgC_{14}H_{22}N_6O_4S_4$) Co, C, H, N.

The crystal was shaped into a sphere (ϕ=0.22 mm). Reflections within the range $3° < 2\theta < 70°$ were studied with a Rigaku AFC-6A automated four-cirle diffractometer using graphite-monochromated Mo $K\alpha$ radiation and the ω—2θ scan technique (scan speed 4° min^{-1}, scan width, 1.35+0.5 tanθ°). The intensities were corrected for Lorentz and polarization factors as well as for absorption. Of the 3082 independent reflections collected, 1751 reflections with $|F_o| > 3\sigma(|F_o|)$ were used for a structure determination. All the calculations were carried out on a HITAC M-280H computer at the Computer Center of the University of Tokyo using the local version of UNICS.[6] The scattering factors were taken from Ref. 7. The final R value[8] for all non-hydrogen atoms (applying the anisotropic temperature parameters) was 0.052. (The R value was 0.053 for the structure with an inverse chirality.)

Results and Discussion

Figures 1 and 2 show projections of the structures of **3** and **2**[5,a] (along the c axis) together with the numbering scheme of the atoms. Perspective drawings around the mpd bridge are given in Fig. 3. The select-

N(2)-Co-N(2^{v})	177.4(4)	Co-N(1^{vi})-C(1^{vi})	170.8(9)	O(11)···O(W2^{i})···O(11^{v})	87.9(4)

Key to the symmetry operations: i, x, y, 1+z; ii, $-x$, $-y$, z,; iii, y, 1$-x$, $-z$; iv, 1$-x$, 1$-y$, z; v, $-x$, 1$-y$, z; vi, $-y$, x, $-z$

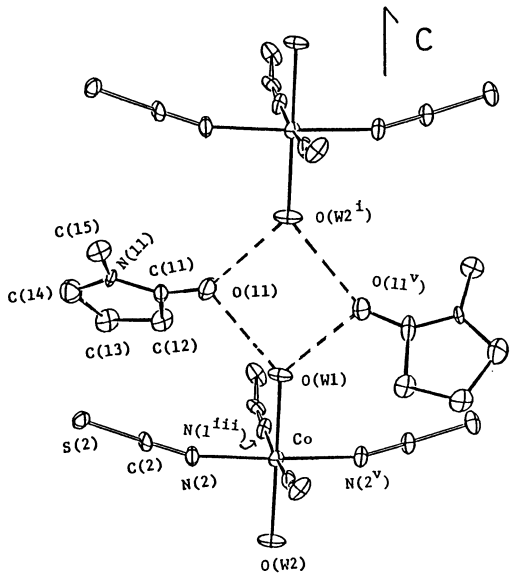

Fig. 3. A perspective drawing of the complex around a cobalt atom and the hydrogen bridging.

ed interatomic distances and bond angles are shown in Table 1.[9] The general feature of the thiocyanate network, as well as the hydrogen-bond bridging, is quite similar to that of **2**. The Hg(1) and Hg(2) atoms are tetrahedrally coordinated by four thiocyanate sulfur atoms, while the cobalt(II) atom is coordinated octahedrally with four thiocyanate nitrogen atoms (equatorially) and two water oxygen atoms (axially). The mpd molecules of **3** are maintained between two thiocyanate networks by only the hydrogen bonds. Thus, we can add **3** as the second member of the **2**-type inclusion compound. The interatomic distances and bond angles of the thiocyanate network, as well as those of the hydrogen-bridging part, are about the same as the corresponding values in **2**, respectively.

The volume of a unit cell of **3** is larger than that of **2** by 13 Å^3.[5] This is because an mpd molecule is larger than a dma molecule. Comparing Figs. 1 and 2, the corresponding position of the carbonyl oxygen atoms of dma and mpd in **2** and **3** are about the same; however, the positions of the other atoms are different, probably to pack dma or mpd molecules into the spaces most effectively. The angles around O(11), the carbonyl oxygen atom, in **2** and **3** are different from each other: O(W1)···O(11)-C(11), O(W1)···O(11)···O(W2^{i}), and O(W2^{i})···O(11)-C(11) are 122.2(9), 89,9(4), and 147.3(10) in **3**, and are 138.9(9), 86.1(4), and 127.7(7)° in **2**,[5] respectively. (The key to the symmetry operation; i,x,y, 1+z.) The Lewis base molecules in **2** or **3** are considered to occupy this space in order to pack the cage of the thiocyanate network well.

Our attempts to obtain the same type of complexes using *N*,*N*-diethylacetamide, *N*,*N*-dimethylpropionamide, *N*-ethyl-2-pyrrolidone, *N*,*N*-dimethylformamide, and *N*-methylformamide as the guests have not yet been successful. To be a guest of this type complex, of course, the formation of the effective hydrogen bonds to bridge it to the network-oxygen atoms is indispensable. Also, there may be some restrictions regarding the shape and the size of the guest molecule to be included into the vacancy of a host.

Acid Dissociation Constants of Dialkyldithiocarbamic Acids and *O,O'*-Dialkyl *S*-Hydrogen Dithiophosphates and Formation Constants of Their Complexes with Cadmium(II), Zinc(II), and Lead(II) in 1:1 v/v Water-DMF Medium

Kenjiro HAYASHI,* Yoshiaki SASAKI, Shoji TAGASHIRA, and Takagimi YANAGIDANI
Department of Chemistry, Faculty of Science, Yamaguchi University, Yoshida, Yamaguchi 753
(Received October 23, 1985)

Synopsis. The log values of β_3, the formation constants of metal complexes with dialkyldithiocarbamates and *O,O'*-dialkyl dithiophosphates, were determined by polarography. The pK_a values, the acid-dissociation constants of these ligands, were also determined kinetically. A linear relationship exists between these two variables for each metal and straight parallel lines were obtained.

Dithio-acids such as alkylxanthic acids (*O*-alkyl hydrogen dithiocarbonates, HRxan), dialkyldithiocarbamic acids (HR_2dtc), and *O,O'*-dialkyl *S*-hydrogen dithiophosphates (HR_2dtp) are chelating reagents which coordinate to metal ions through two sulfur atoms and have been used for the solvent extraction of metal ions.[1-3]

The present authors have been studying the thermodynamical stability of metal dithioato complexes using a solvent-extraction method.[4,5] Furthermore, in a preceding paper[6] the formation constants of metal-Rxan complexes in a 1:1 v/v water-*N,N*-dimethylformamide (DMF) medium were determined by polarography.

Following the previous research, the formation constants of metal-R_2dtc and -R_2dtp complexes in a water-DMF medium were determined. The stabilities of these complexes are discussed on the basis of the basicity of the ligands.

Experimental

Reagents. KR_2dtp and NaR_2dtc were synthesized and purified according to methods described in the literature.[7,8] Aqueous solutions of KR_2dtp were freshly prepared and those of NaR_2dtc were prepared immediately before use due to the instability of their solutions.

Stock solutions of cadmium(II), zinc(II), and lead(II) were prepared by dissolving each nitrate salt in 0.1 mol dm^{-3} of nitric acid, respectively. These solutions were volumetrically standardized with EDTA.

Apparatus and Procedures. The decomposition rate of R_2dtc^- was spectrophotometrically measured at 285 nm according to a previously described procedure.[6]

Direct-current polarographic waves were recorded with the same apparatus and under the same conditions as previously described.[6]

Results and Discussion

Acid Dissociation Constant of HR_2dtc. The decomposition rate of R_2dtc^- depended on the pH of the test solution. Hence, the decomposition rate (k_3) and the acid-dissociation (K_a) constants of HR_2dtc were determined using similar equations to those of the preceding paper:[6]

$$-\frac{d\ln([R_2dtc^-]+[HR_2dtc])}{dt} = \frac{k_3}{1+K_a[H^+]} \equiv \kappa$$

$$\log\frac{Abs_1}{Abs_2} = \frac{\kappa}{2.303}(t_2-t_1)$$

where Abs_1 and Abs_2 denote the absorbances at time t_1 and t_2, respectively. The obtained constants are given in Table 1.

On the other hand, HR_2dtp were too stable for determining the constants by a method based on the decomposition rate.

Figure 1 shows plots of the pK_a value in an aqueous medium vs. that in a water-DMF medium. The data used in Fig. 1, except that determined in this paper, are quoted from the preceding paper[6] and others.[9-11] Obviously, a linear relationship exists between the

Table 1. Acid Dissociation (K_a) and Decomposition Rate (k_3) Constants of HR_2dtc

	R			
	Methyl	Ethyl	Propyl	Butyl
pK_a	4.25	4.62	4.72	4.80
k_3/min^{-1}	11.2	21.4	15.6	15.9

two variables. Therefore, the unknown pK_a values of HEt_2dtp and HBu_2dtp in the water–DMF medium can be estimated from the values for the aqueous medium[12] by means of a straight-line relationship. Thus, their values were obtained as 0.18 and 0.58, respectively.

Formation Constants of Metal–R_2dtc and –R_2dtp Complexes. The direct-current polarographic waves, which were all cathodic and quasi-reversible waves for the two-electrons reduction of metal ions, were analyzed in the same manner as described previously[6]

Table 2. Formation constants (β_j) of Metal-R_2dtc and -R_2dtp Complexes

			R			
			Methyl	Ethyl	Propyl	Butyl
R_2dtc	Cd	log β_3	19.12	19.83	20.03	20.30
		log β_2	4.70	5.96	5.92	—
	Cd	log β_3	6.33	7.82	7.82	8.83
		log β_4	7.01	8.76	8.76	9.95
R_2dtp	Zn	log β_3	—	2.47	2.57	—
		log β_2	5.85	7.38	—	—
	Pb	log β_3	8.02	9.64	9.71	10.66
		log β_4	8.76	10.44	10.86	11.84

△: lead(II) complex, ●: cadmium(II) complex, ○: zinc(II) complex.

and the overall formation constants, β_j, of the complexes were obtained (Table 2).

It was observed that the β_j value for each metal increased upon increasing the pK_a value, i.e., the basicity of the ligand. This tendency was confirmed for β_3, including the results for metal–Rxan complexes[6] (Fig. 2). The individually observed points for each metal lie well along straight parallel lines. This is one instance of a "linear free-energy relationship",[13] indicating that R_2dtc^-, R_2dtp^-, and $Rxan^-$ have similar charactaristics regarding the formation of a metal complex. The difference in the complex-forming abilities of these ligands might be due to a difference in the electron density on the sulfur atoms in the ligand molecules.[14]

The β_3 values of the lead- and zinc–R_2dtc complexes could not be determined because of the difficulty in finding the pH region in which neither the hydrolysis of the metal ion nor the acid decomposition of the ligand occurred. However, these values can be estimated, respectively, by reading off a point on the line in Fig. 2.

The Differential Scanning Calorimetry of 1,3,5,7,2,4,6,8-Tetrathiatetrazocine

Yoshiyuki KUDO and Shuichi HAMADA*
Department of Applied Chemistry, Faculty of Science,
Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received November 18, 1985)

Synopsis. The molar heat of the decomposition of $S_4(NH)_4$ was obtained as 360±7 kJ mol^{-1} by means of differential scanning calorimetry. This value gave the standard enthalpy of the formation, $\Delta H_f(S_4(NH)_4, s, 298.15\,K)$, as 318±7 kJ mol^{-1}, which was comparable with that calculated (311 kJ mol^{-1}).

1,3,5,7,2,4,6,8-Tetrathiatetrazocine (tetrasulfur tetraimide, $S_4(NH)_4$) is finally pyrolyzed into sulfur, ammonia, and nitrogen in an argon atmosphere through step-by-step degradation.[1] However, little information on the thermodynamic properties is available, in contrast to those of tetrasulfur tetranitride (S_4N_4)[2,3] and tetrasulfur dinitride (S_4N_2).[2] In this work, the pyrolysis of this compound was studied by means of differential scanning calorimetry (DSC).

Experimental

The $S_4(NH)_4$ was prepared and purified by the method described in a previous paper.[1]

The heat of the decomposition of $S_4(NH)_4$ was measured at the heating rates of 16 and 32 K min^{-1} with a Perkin-Elmer, model DSC-1B, differential scanning calorimeter. The sample was carefully weighed with a microbalance and then tightly sealed in an aluminium container in an argon atmosphere. The DSC equipment was calibrated with an indium of 99.999% purity.

The molar heat capacity, C_p, of this compound was measured at the fixed heating rate of 8 K min^{-1} with the same equipment, using quartz as a reference. The sufficient reliability of this method was indicated by the agreement between the observed and the reported molar heat capacities of α-sulfur[4] (±1.4%) over the tempetarure range from 328 to 368 K.

Results and Discussion

Measurement of Heat of Decomposition of $S_4(NH)_4$. Figure 1 shows the DSC curve of $S_4(NH)_4$ taken at the heating rate of 16 K min^{-1} in the argon atmosphere. The DSC pattern consisted of sharp and broad exothermic peaks, in addition to an endothermic peak caused by its fusion. The former two peaks were attributable to the step-by-step degradation.[1] The dotted line in Fig. 1 was taken as the base line for estimating the heat of decomposition. The degradation immediately occurred after its fusion at the heating rates applied, though it took place even before fusion at such slow heating rates as 3 K min^{-1}.[1] Thus, the overall heat of decomposition was defined as the corresponding area by subtracting the endothermic peak area from the exothermic one in Fig. 1.

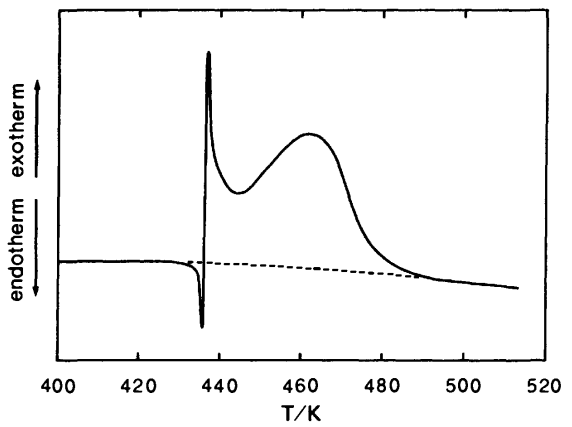

Fig. 1. DSC pattern of $S_4(NH)_4$ at heating rate of 16 K min^{-1}.

The molar heat of decomposition, Q, was obtained as 360±7 kJ mol^{-1} as the average for nine runs; the uncertainty value was defined as $\pm 3.0\sigma/\sqrt{n}$, where σ and n are the standard deviation and the number of data respectively. The value of Q was scarcely changed at either heating rate, i.e., 16 or 32 K min^{-1}, within the limits of experimental error shown above.

The molar heat capacity, C_p, of $S_4(NH)_4$ was measured over the temperatures from 328 to 363 K at the heating rate of 8 K min^{-1}. No chemical change in the sample was confirmed by thin-layer chromatography for 20 min after each run. Measurements below 323 K did not give reproducible results because of unstable base lines. The linear temperature dependence ($C_p = 0.153 + 1.26\times10^{-4}T$) gave the value of C_p as 0.191 kJ mol^{-1} K^{-1} at 298.15 K.

On the basis of stoichiometric correlation,[1] the overall pyrolytic reaction can be expressed as:[5]

$$S_4(NH)_4 = 1/2S_8 + 4/3N_2 + 4/3NH_3 \quad (1)$$

According to Eq. 1, the following equation yields the standard enthalpy of the formation of $S_4(NH)_4$:

$$\Delta H_f(S_4(NH)_4, s, 298.15\,K) = Q + 8/3RT + 1/2(\Delta H_t(\alpha,\beta) + \Delta H_m(\beta,\lambda) + X\Delta H_p) + 4/3\Delta H_f(NH_3, g, 298.15\,K) - \int_{298.15}^{T}\Delta C_p dT \quad (2)$$

where $\Delta H_t(\alpha,\beta)$ and $\Delta H_m(\beta,\lambda)$ are the enthalpy changes of transition from S_α to S_β (3.2 kJ mol^{-1})[6,7] and of the fusion of S_β (13.8 kJ mol^{-1});[6,7] ΔH_p, the enthalpy change of polymerization from S_λ to S_μ (13.3 kJ mol^{-1});[6,7] X, the fraction of S_μ (0.228 at 464 K);[8] $\Delta H_f(NH_3, g, 298.15\,K)$, the standard enthalpy of the formation of ammonia (−45.9 kJ mol^{-1}),[6] and ΔC_p, the difference in the molar heat capacities between the initial and final states.[6] The reaction temperature, T, was taken as 464 K at the maximum of the broad exothermic peak (Fig. 1), and the integral term was calculated as −1.5 kJ mol^{-1}.

According to Eq. 2, the standard enthalpy of the

formation of $S_4(NH)_4$, $\Delta H_f(S_4(NH)_4, s, 298.15\,K)$, was obtained as 318 ± 7 kJ mol^{-1}.

Calculation of Standard Enthalpy of the Formation of $S_4(NH)_4$. Sanderson's method[9] gave the S–N and N–H bond energies in $S_4(NH)_4$ as 247.7 and 363.8 kJ mol^{-1}, based on their respective bond lengths of 167.4[10] and 108 pm.[11] By combining these values with the standard enthalpies of the formation of atomic sulfur, nitrogen, and hydrogen,[12] the enthalpy of the formation of gaseous $S_4(NH)_4$, $\Delta H_f(S_4(NH)_4, g, 298.15\,K)$, was calculated as 426 kJ mol^{-1}.

The enthalpy of sublimation, ΔH_{sub}, is given as:[13]

$$\Delta H_{sub} = L^0 + RT \quad (3)$$

where L^0 is the lattice energy at 0 K. The lattice energy of the $S_4(NH)_4$ crystal was estimated by means of the Slater–Kirkwood equation,[14] assuming that the lattice energy is nearly equal to the London dispersion force, E, ($L^0=-E$),[13] and that the effect of hydrogen bonds in the crystal is negligible.[11] To calculate the value of E, the polarizabilities, α, of sulfur, nitrogen, and hydrogen atoms were taken as 2.836×10^{-24}, 9.437×10^{-25}, and 4.152×10^{-25} cm^3 respectively, which were deduced by the use of the Clausius-Mossotti relationship using corresponding atomic refractions.[15] Taking the 306 pairs of interatomic distances (less than 500 pm) which were given by the atomic coordinates,[10,11] the value of the ΔH_{sub} of $S_4(NH)_4$ was estimated as 115.0 kJ mol^{-1} ($E=-112.5$ kJ mol^{-1}).

For checking the reliability of this calculation, the enthalpies of the sublimation of tetrasulfur tetranitride and α-sulfur were also estimated in the same way.[16–18] The values thus calculated were 88.0 and 106.4 kJ mol^{-1} respectively; these values agreed closely with those observed (88.7[19] and 105.9 kJ mol^{-1} [12]).

The standard enthalpy of the formation, $\Delta H_f(S_4(NH)_4, s, 298.15\,K)$, was given as 311 kJ mol^{-1}, combined with the enthalpies of the formation at the gaseous state and of the sublimation. Consequently, the calculated value was in fair agreement with that obtained in this work (318 ± 7 kJ mol^{-1}).

Metal Complexes of Octabutyl- and Octaoctylporphyrins Preparation and Properties

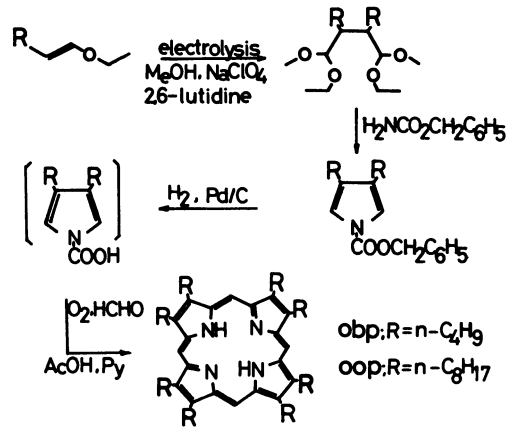
Chang Quing YE,† Haruki TSURUTA,* and Sei OTSUKA††
Research Laboratory, Takasago Perfumery Co., Ltd. 5-36-31, Kamata, Ohta-ku, Tokyo 144
††Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka 560
(Received July 3, 1985)

Synopsis. Octabutyl- and octaoctylporphyrin complexes of Fe^{II}, Co^{II}, Ni^{II}, and Cu^{II} ions were prepared as a family of highly lipophilic metalloporphyrins.

In one phase of our investigations on metalloporphyrins, those which are highly soluble in non-polar organic solvents were required. Potential candidates were metal complexes of porphyrins having long alkyl chains.[1] Thus, 2,3,7,8,12,13,17,18-octabutyl- and octaoctylporphyrin complexes of several metal ions such as Fe^{II}, Co^{II}, Ni^{II}, and Cu^{II} were prepared. Since, no report, to our best knowledge, on these metal complexes has been made so far, we wish to report here briefly the preparation and some chemical properties of these complexes.

Results and Discussion

Preparations. The ligands, octabutyl- (H_2obp) and octaoctylporphyrin (H_2oop), were prepared by a slight modification of Callot's method[2,3] as shown in the Scheme.



Scheme

Following essentially the literature methods[4—7] metal complexes of these porphyrins could be prepared. Thus, the reaction of acetates of Co(II), Ni(II), and Cu(II) with H_2obp or H_2oop gave the corresponding neutral metal complexes in a good to fair yield with a relative rate of formation, Co(II)<Ni(II)<Cu(II) complex. [FeCl(obp)] and [FeCl(oop)] were also prepared according to the literature procedures.[4]

As expected, they exhibited enhanced solubility in many organic solvents. Remarkably even hexane dissolves these complexes. On the other hand, they are practically insoluble in methanol, acetonitrile and dimethyl sulfoxide. The solubility trends are rather similar for the metal ions described above. The solubility differences between the two porphyrins obp and oop are also very small. However, their solubility in dioxane shows a salient feature. Namely, three neutral Co(II) complexes, [Co(oep)], [Co(obp)], and [Co(oop)] are moderately soluble in dioxane, whereas in the series of Cu(II) and Ni(II) porphyrins, only [Cu(oep)] and [Ni(oep)] are soluble in dioxane, all the other porphyrin complexes being sparingly soluble.

The UV-visible spectra of [M(oep)], [M(obp)], and [M(oop)] (M=Co, Ni, and Cu) were measured in $CHCl_3$ without adding axial ligands. As shown in Table 1 their α,β and Soret bands are very similar and in agreement with the spectra of oep complexes reported by Ogoshi.[8]

Table 1. UV-Visible Spectra of [M(obp)] and [M(oop)] (M=Co, Ni, and Cu) in $CHCl_3$

Experimental

Octaoctylporphyrin. A literature procedure[2] was employed with some modification. 1-Decenyl ethyl ether[9] (51.6 g) was electrolyzed in a cell with two 5 cm×15 cm graphite electrodes, to afford the acetal (15.1 g) (Scheme) in 25% yield. The acetal (14.4 g) was treated with benzyl carbamate (13.7 g) to give crude 1-benzyloxycarbonyl-3,4-dioctyl pyrrole, which was chromatographed on silica gel. A mixture of hexane and benzene (4:1) elution gave a yellow liquid (7.2 g) in 51% yield. ^{1}H NMR ($CDCl_3$) δ=0.89 [triplet, 6H, $-CH_2(CH_2)_6\underline{CH_3}$], 1.27 [singlet, 24H, $-CH_2(\underline{CH_2})_6CH_3$], 2.33 [triplet, 4H, $-\underline{CH_2}(CH_2)_6CH_3$], 5.33 [singlet, 2H, benzyl], 7.00 [singlet, 2H, pyrrole], 7.40 [singlet, 5H, benzyl]. MS $[M]^+$: 425. The *N*-benzyloxycarbonyl 3,4-dioctyl pyrrole (9.1 g) was submitted to hydrogenolysis at room temperature using Pd/C (5%, 700 mg) in a mixture of methanol and hexane (5:1) (100 ml). The resulting compounds were immediately treated with formaldehyde (35% aqueous solution, 2.2 ml), pyridine (76 ml), acetic acid (154 ml), and oxygen to afford octaoctylporphyrin (1.87 g) in 29% yield, mp 144—145 °C (lit, [10] 145.5 °C). The overall yield is 3.7% based on 1-decenyl ethyl ether. Octabutylporphyrin

†Study leave from Shanghai Institute of Organic Chemistry; A 1983 Takasago fellowship recipient.

mp 265—266 °C (lit, [10] 266—267 °C) was prepared in a similar manner in 6.8% from 1-hexenyl ethyl ether.

Chloro[octabutylporphyrianato(2)-]iron(III). Chloro[octabutylporphyrinato(2)-]iron(III) was prepared by the method described by Osa[5] in 89% yield, mp 202—203 °C. UV_{max} ($CHCl_3$): 382 (log ε, 5.01), 509 (3.98), 538 (3.99), 639 nm (3.68). MS $[M]^+$: 847 and 849 (Calcd, 846.9 and 848.9). Chloro-[octaoctylporphyrinato(2)-]iron(III) was prepared in the same way in 65%, mp 76—78 °C. UV_{max} ($CHCl_3$): 383 (log ε 5.02), 509 (3.99), 538 (4.00), 639 nm (3.68). MS $[M]^+$: 1295 and 1297 (Calcd, 1294.9 and 1296.9).

[Octaoctylporphyrinato(2)-]copper(II).[5-7] A mixture of octaoctylporphyrin (100 mg) dissolved in chloroform (50 ml) and a methanol solution (10 ml) saturated with copper acetate was reacted for 1 h at room temperature. Then methanol (100 ml) was added to precipitate a red solid, which was redissolved in chloroform. Methanol was added to give [octaoctylporphyrinato(2)-]copper(II) in 86% (90 mg) yield as red crystals, mp 185—187 °C. MS $[M]^+$: 1267 (Calcd, 1267.5). [Octabutylporphyrinato(2)-]copper(II) was prepared in a similar manner in 92% yield, mp>300 °C. MS $[M]^+$: 820 (Calcd, 819.5).

[Octabutylporphyrinato(2)-]cobalt(II). A methanol solution (10 ml) saturated with cobalt acetate was added to octabutylporphyrin (100 mg) disolved in chloroform (50 ml). The mixture was heated for 1 h. Methanol was added to the filtrate yielding a red solid. The solid was dissolved in dichloromethane and filtration was followed by concentration to a small volume. Methanol was then added to give [octabutylporphyrinato(2)-]cobalt(II) in 56% (60 mg) yield, mp>300 °C. MS $[M]^+$: 816 (Calcd, 815.9). [Octaoctylporphyrinato(2)-]cobalt(II) was obtained in the similar manner in 66% yield, mp 193—195 °C. MS $[M]^+$: 1263 (Calcd, 1262.9).

[Octabutylporphyrinato(2)-]nickel(II). A methanol solution (10 ml) saturated with nickel acetate was added to octabutylporphyrin (100 mg) dissolved in chloroform (50 ml) and heated under reflux for 5 h. Evaporation of chloroform and trituration with methanol afforded a crystalline product. [Octabutylporphyrinato(2)-]nickel(II) was obtained in 84% yield, mp 273—274 °C. ^1H NMR ($CDCl_3$) δ=1.14 (24H, $-CH_2CH_2CH_2C\underline{H}_3$), 1.77 (16H, $-CH_2CH_2C\underline{H}_2CH_3$), 2.21 (16H, $-CH_2C\underline{H}_2CH_2CH_3$), 3.87 (16H, $-C\underline{H}_2CH_2CH_2CH_3$), 9.75 (4H, $-C\underline{H}=$). MS $[M]^+$: 815 (Calcd, 814.7). [Octaoctylporphyrinato(2)-]nickel(II) was prepared in a similar manner in 58% yield, mp 150—151 °C. ^1H NMR ($CDCl_3$) δ=0.86 (24H, $-CH_2CH_2(CH_2)_5C\underline{H}_3$), 1.04—2.00 (80H, $-CH_2CH_2(C\underline{H}_2)_5CH_3$), 2.24 (16H, $-CH_2C\underline{H}_2(CH_2)_5CH_3$), 3.88 (16H, $-C\underline{H}_2CH_2(CH_2)_5CH_3$), 9.76 (4H, $-C\underline{H}=$). MS $[M]^+$: 1263 (Calcd, 1262.7).

One of the authors, Chang Qing Ye is grateful to Takasago Perfumery Co., Ltd. for the 1983 fellowship to carry out research work.

Pseudo-Sugars. XV. A Facile Synthesis of Pseudo-β-DL-fructopyranose

Tetsuo SUAMI,* Seiichiro OGAWA, Yasushi UEMATSU, and Atsuo SUGA
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Yokohama 223
(Received November 8, 1985)

Synopsis. Pseudo-β-DL-fructopyranose, DL-(1,2/3,4)-1-*C*-hydroxymethyl-1,2,3,4-cyclohexanetetrol, has been synthesized from DL-1,2-di-*O*-acetyl-(1,3/2)-3-bromomethyl-5-cyclohexene-1,2-diol by the seven-steps sequence in 21% overall yield.

In recent years, biochemical properties of pseudo-sugars have stimulated considerable synthetic effort toward their stereoisomers. In continuation to the preceding paper,[1] since we required large quantities of pseudo-β-DL-fructopyranose (**1**) in order not only to carry out biological test in detail, but also to use as an intermediate for derivatization, the improved stereospecific route to **1** has been worked out. The present synthesis should be applied for preparation of an optically active **1**,[2] which would give an interesting knowledge on a sweet tasting property of sugars in terms of the molecular chirality.

O-Deacetylation of DL-1,2-di-*O*-acetyl-(1,3/2)-3-bromomethyl-5-cyclohexene-1,2-diol (**3**)[3] with hydrochloric acid in ethanol gave the dihydroxy compound (**4**) in 83% yield. Epoxidation of **4** with *m*-chloroperbenzoic acid (MCPBA) in dichloromethane, followed by acetylation, gave 80% yield of single epoxide (**5**) preferentially. The stereospecificity may be attributed to the *cis*-directing effect of the adjacent C-1 hydroxyl group.[4] Dehydrobromination of **5** with silver fluoride in pyridine at room temperature afforded the *exo*-methylene compound (**6**) in a quantitative yield. Reductive cleavage of the epoxide ring of **6** was carried out with lithium aluminum hydride (LAH) in tetrahydrofuran (THF), followed by acetylation with acetic anhydride in pyridine, gave the triacetate (**7**) in 52% yield. Epoxidation of the *exo*-methylene group of **7** with MCPBA gave 90% yield of a single spiro epoxide (**8**). Treatment of **8** with sodium acetate in refluxing aqueous 2-methoxyethanol, followed by acetylation in the presence of 4-dimethylaminopyridine, afforded the pentaacetyl derivative (**2**) of **1** in 66% yield.[5] This compound was identical with an authentic sample[1] in all respects. These results also supported the assigned structures of **5** and **8**. Compound **2** could readily be converted into the free pseudo-sugar **1** quantitatively.[1] Therefore, the overall yield of **1** from **3** was 21%.

Experimental

General. The same method was used as described in the preceding paper.[1]

DL-(1,3/2)-3-Bromomethyl-5-cyclohexene-1,2-diol (4). A mixture of DL-1,2-di-*O*-acetyl-(1,3/2)-3-bromomethyl-5-cyclohexene-1,2-diol (**3**)[3] (10.0 g, 34 mmol) and ethanol (150 ml), and concd hydrochloric acid (50 ml) was stirred at room temperature for 13 h. The reaction mixture was treated with sodium hydrogencarbonate and then concentrated. The residue was extracted with ethanol several times and the extracts were concentrated to give a solid, which was purified by a silica-gel column (200 g) with ethyl acetate–hexane (1:3) as an eluant, giving 5.88 g (83%) of **4** as crystals: mp 80—80.5 °C; ^{1}H NMR ($CDCl_3$, 90 MHz) δ=1.74—2.35 (2H, m, H-3, 4), 3.36—3.85 (3H, m, H-2, 7, and 7′), 3.94—4.29 (1H, m, H-1), 5.37—5.87 (2H, m, H-5, 6).

Found: C, 40.43; H, 5.26; Br, 38.38%. Calcd for $C_7H_{11}BrO_2$: C, 40.60; H, 5.35; Br, 38.59%.

DL-3,4-Di-*O*-acetyl-1,2-anhydro-(1,2,3,5/4)-5-bromomethyl-1,2,3,4-cyclohexanetetrol (5). A mixture of **4** (0.10 g, 0.48 mmol) and MCPBA (0.16 g, 0.90 mmol) in dichloromethane (2 ml) was stirred at room temperature for 2 h. The reaction mixture was concentrated and the residue was treated with acetic anhydride (1 ml) and pyridine (2 ml) at room temperature overnight. The mixture was concentrated and the residue was taken up in ethyl acetate and the solution was washed with saturated sodium hydrogencarbonate and water thoroughly. Evaporation of the solvent gave a solid, which was purified by a silica-gel column to give 0.12 g (80%) of **5** as crystals: mp 110—110.5 °C. ^{1}H NMR ($CDCl_3$, 90 MHz) δ=2.05 (3H, s) and 2.10 (3H, s) (OAc), 1.58—2.54 (3H, m, H-5, 6, and 6′), 3.07—3.45 (4H, m, H-1, 2, 7, and 7′), 5.04 (1H, dd, *J*=8.1 and 9.2 Hz, H-4), 5.26 (1H, dd, *J*=8.1 and 2 Hz, H-3).

Found: C, 42.91; H, 4.92; Br, 25.76%. Calcd for $C_{11}H_{15}BrO_5$: C, 43.02; H, 4.92; Br, 26.02%.

DL-3,4-Di-*O*-acetyl-1,2-anhydro-(1,2,3/4)-5-methylene-1,2,3,4-cyclohexanetetrol (6). A suspension of **5** (0.20 g, 0.65 mmol), silver fluoride (0.20 g, 2 molar equiv), in pyridine (5 ml) was stirred at room temperature for 1 h. An insoluble material was removed by filtration and the filtrate was concentrated. The residue was purified by a silica-gel column (8 g) with ethyl acetate, giving 0.15 g (100%) of **6** as a syrup: ^{1}H NMR ($CDCl_3$, 90 MHz) δ=2.10 (3H, s) and 2.13 (3H, s) (OAc), 2.75—2.90 (2H, m, H-6 and 6′), 3.30—3.49 (2H, m, H-1 and 2), 4.87—5.03 (2H,

m, H-7 and 7'), 5.13 (1H, dd, J=8.3 and 2 Hz, H-3), 5.43 (1H, br d, J=8.3 Hz, H-4).

Found: C, 58.17; H, 6.36%. Calcd for $C_{11}H_{14}O_5$: C, 58.40; H, 6.24%.

DL-1,2,3-Tri-*O*-acetyl-(1,2/3)-4-methylene-1,2,3-cyclohexanetriol (7). To a solution of **6** (0.50 g, 2.2 mmol) in THF (24 ml) was added $LiAlH_4$ (0.42 g, 11 mmol) gradually, and the mixture was stirred at room temperature for 3 h. Then the mixture was filtered through a celite bed and the filtrate was concentrated and the residue was acetylated in the usual way. The product was purified by a silica-gel column (20 g) with ethyl acetate–hexane (1:5) as an eluant, giving 0.31 g (52%) of **7** as crystals: mp 60—61 °C; ^{1}H NMR ($CDCl_3$, 90 MHz) δ=2.01 (3H, s) and 2.13 (6H, s) (OAc), 1.45—2.56 (4H, m, H-5, 5', 6, and 6'), 4.85—5.08 (3H, m, H-1, 7, and 7'), 5.34—5.66 (2H, m, H-2 and 3).

Found: C, 57.60; H, 6.66%. Calcd for $C_{13}H_{18}O_6$: C, 57.77; H, 6.71%.

DL-2,3,4-Tri-*O*-acetyl-1,7-anhydro-(1,2/3,4)-1-*C*-hydroxymethyl-1,2,3,4-cyclohexanetetrol (8). A mixture of **7** (95 mg, 0.35 mmol), MCPBA (217 mg, 2.5 molar equiv), and dichloromethane (3 ml) was stirred at room temperature for 4 h. Excess peroxy acid was destroyed by sodium thiosulfate and the mixture was concentrated. The residue was processed as described in the preparation of **5** and the product was purified by a silica-gel column to give 90 mg (90%) of **8** as a syrup: ^{1}H NMR ($CDCl_3$, 90 MHz) δ=2.00 (3H, s), 2.06 (3H, s), and 2.10 (3H, s) (OAc), 2.68 (2H, s, H-7 and 7'), 1.35—2.93 (4H, m, H-5, 5', 6, and 6'), 4.89—5.53 (3H, m, H-2, 3, and 4).

Found: C, 54.51; H, 6.37%. Calcd for $C_{13}H_{18}O_7$: C, 54.54; H, 6.34%.

DL-2,3,4-Tri-*O*-acetyl-(1,2/3,4)-1-*C*-acetoxymethyl-1,2,3,4-cyclohexanetetrol (9). A mixture of **8** (0.47 g, 1.7 mmol), anhydrous sodium acetate (0.68 g, 8.3 mmol), and 90% aqueous 2-methoxyethanol (10 ml) was stirred at 80 °C for 6 h. The mixture was concentrated and the residue was acetylated in the usual way. The product was purified on a silica-gel column (40 g) with ethyl acetate–hexane (5:9) to give 0.45 g (78%) of **9** as crystals: mp 108—109 °C. ^{1}H NMR ($CDCl_3$, 90 MHz) δ=1.96 (3H, s), 2.08 (6H, s), and 2.10 (3H, s) (4 OAc), 3.90 and 4.00 (1H, d, J=11.4 Hz, $C\underline{H}_2OAc$), 5.25—5.50 (3H, m, H-2, 3, and 4).

Found: C, 52.17; H, 6.35%. Calcd for $C_{15}H_{22}O_9$: C, 52.02; H, 6.40%.

DL-1,2,3,4-Tetra-*O*-acetyl-(1,2/3,4)-1-*C*-acetoxymethyl-1,2,3,4-cyclohexanetetrol (2). A mixture of **8** (67 mg, 0.23 mmol), anhydrous sodium acetate (95 mg, 1.1 mmol), and 90% aqueous 2-methoxyethanol (2 ml) was heated at 80 °C for 6 h. The product was acetylated with acetic anhydride (1.5 ml) and pyridine (1.5 ml) in the presence of 4-dimethylaminopyridine (30 mg) at 60 °C for 14 h, and then at 90 °C for 4 h. The mixture was processed in the usual way and the product was purified by a silica-gel column with ethyl acetate–hexane (3:8) as an eluant, giving 60 mg (66%) of **2** as crystals: mp 147.5—148 °C. This compound was identical with an authentic sample[1] in all respects.

The authors express their sincere thanks to Mr. Saburo Nakada for the elementary analyses.

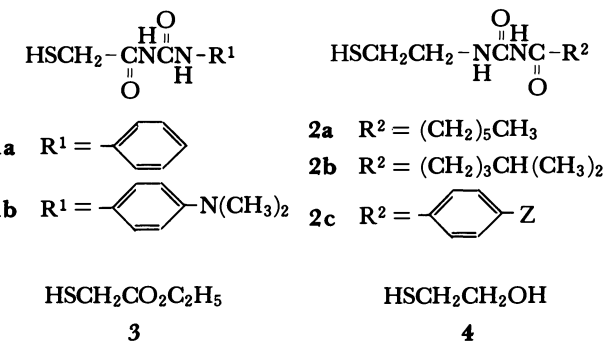
The Effect of Intermolecular Association on Kinetic Behavior. Rate Acceleration with Time in Oxidation of a Pair of Thiols

Masato M. Ito, Toshikazu Ogikubo, Hideki Ueda, Kazuomi Hagino, and Tadashi Endo*
College of Science and Engineering, Aoyama Gakuin University, Chitosedai, Setagaya-ku, Tokyo 157
(Received December 17, 1985)

Synopsis. In base-catalyzed oxidation of a pair of associating thiols [$HSCH_2$-CONHCONH-Ph and $HSCH_2CH_2$-NHCONHCO-C_6H_{13}], rate enhancement with time occurred in protic media, whereas the rate was reduced with time in aprotic solvents. For a pair of nonassociating thiols [$HSCH_2$-$CO_2C_2H_5$ and $HSCH_2CH_2OH$], the rate enhancement was neither observed in a protic solvent nor in an aprotic one.

Recently it has been shown that intermolecular association plays a significant role in chemical reactions.[1] In order to elucidate the effect of intermolecular association on kinetic behavior, we examined the rate of oxidation for pairs of associating (**1** and **2**, system A) and nonassociating thiols (**3** and **4**, system N) in various solvents, and report that the rate acceleration with time in the oxidation is only observed for the associating system.



$HSCH_2CO_2C_2H_5$ **3**

$HSCH_2CH_2OH$ **4**

The ln([RSH]/[RSH]$_0$) was plotted against time for oxidation of a pair of associating thiols **1a** and **2a,b** (systems A_{aa} and A_{ab}) in oxygen-saturated acetonitrile (MeCN) and H_2O–MeCN [mole fraction of water (x_w)=0.42], at 35.0°C in the presence of triethylamine (Et_3N) as a catalyst (Fig. 1). In MeCN the oxidation follows pseudo first-order kinetics, as in the case of the oxidation in the presence of a large excess of a base.[2,3] On the other hand, sharp downward curvature is observed in aqueous MeCN,[4] suggesting that rate acceleration occurs with time. This has been confirmed by a plot of [RSH]/[RSH]$_0$ against time showing downward curvature (Fig. 2).

The [RSH]/[RSH]$_0$–time profiles were further investigated in various solvents for oxidation of system A_{aa} (Fig. 2). Also in H_2O–EtOH (x_w=0.20), the reaction has proved to be accelerated with time. This holds for the oxidation in nonaqueous protic solvents, EtOH and EtOH–MeCN (x_{EtOH}=0.42), but not in 1,4-dioxane even after 100 h. These observations suggest that rate acceleration with time in oxidation of system A occurs in protic media.[5]

Thiols **1** and **2** have been shown to associate strongly with each other in $CDCl_3$ via two NH···O intermolecular hydrogen bonds between the inner -NHCO-

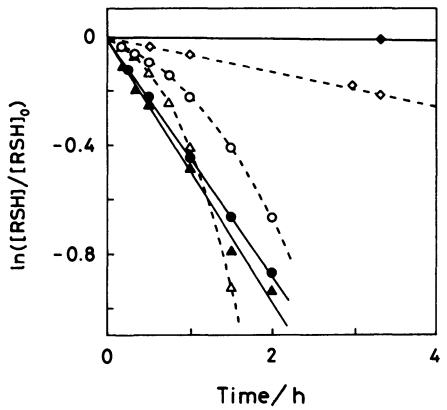


Fig. 1. First-order kinetic plots for oxidation of **1a** and **2a** (system A_{aa}), of **1a** and **2b** (system A_{ab}), and of **3** and **4** (system N) at 35.0°C. [RSH]$_0$=2.00×10^{-2} M, [Et_3N]=2.0×10^{-3} M. ●, System A_{aa} in MeCN; ○, system A_{aa} in H_2O–MeCN (x_w=0.42); ▲, system A_{ab} in MeCN; △, system A_{ab} in H_2O–MeCN (x_w=0.42); ◆, system N in MeCN; ◇, system N in H_2O–MeCN (x_w=0.42). Linear relationship for system N in aqueous MeCN is shown only until ca. 20% conversion in this figure.

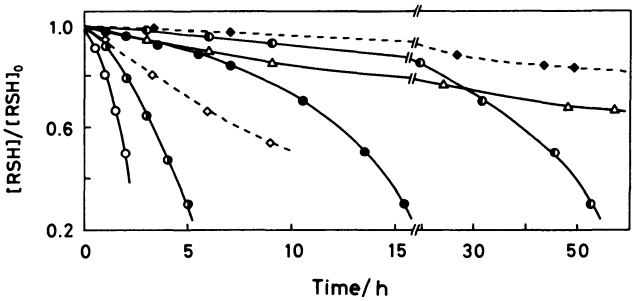

Fig. 2. Kinetic plots for oxidation of **1a** and **2a** (system A_{aa}) and **3** and **4** (system N) at 35.0°C. [RSH]$_0$=2.00×10^{-2} M, [Et_3N]=2.0×10^{-3} M. ○, System A_{aa} in H_2O–MeCN (x_w=0.42); ◑, system A_{aa} in MeCN–EtOH (x_{EtOH}=0.42); ●, system A_{aa} in H_2O–EtOH (x_{EtOH}=0.80); ◐, system A_{aa} in EtOH; △, system A_{aa} in 1,4-dioxane; ◇, system N in H_2O–MeCN (x_w=0.42); ◆, system N in MeCN.

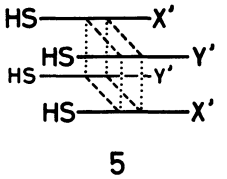

5

Fig. 3. Association scheme in a typical tetramer **5**. -----, Hydrogen bonds in dimers; ·····, noncovalent weak interactions responsible for stabilization of tetramers. The symbols X′ and Y′ represent R^1 and R^2, respectively.

units in the -CONHCONH- group to form tetramers (reaction intermediates) such as **5** (Fig. 3).[6]

Control experiments were performed using a pair of nonassociating thiols (**3** and **4**, system N) (Figs. 1 and 2). In H_2O–MeCN (x_w=0.42), the reaction follows pseudo first-order kinetics until at least 50% conversion (Fig. 1). In MeCN, the rate appears to follow second-order kinetics. These findings indicate that no rate enhancement occurs for system N regardless of the solvents employed.

From the results presented here, it seems reasonable to conclude that intermolecular association is responsible for the rate acceleration with time in the oxidation. Our work suggests the possibility that intermolecular association affects another aspect of kinetic behavior in chemical reactions.

Experimental

Materials. Thiols **1a** and **2a,b** were prepared as described previously.[3] Other thiols and Et_3N were purified by distillation through a fractionating column. Organic solvents were dried by proper procedures,[7] and purified by distillation. Water was purified through Millipore Milli-Q water purification system followed by distillation. The iodine solution (0.001 M (1 M=1 mol dm^{-3})) containing potassium iodide (0.005 M) was titrated with 1.00×10^{-3} M aqueous sodium arsenite standard solution before use.

Kinetics. The two thiols (**1** and **2** or **3** and **4**, 1.00×10^{-4} mol each) were weighed into a two-necked flask, and dissolved in 10.00 ml of the reaction solvent. The solution was stirred under an oxygen atmosphere for at least 4 h in a well-stirred water bath thermostated to ±0.1 °C. Oxidation of thiols was negligible in the absence of Et_3N. At time zero, 2.0×10^{-5} mol of Et_3N was added to the solution with a microsyringe, and time measurement was begun. At appropriate time intervals, a 0.50 ml portion of the reaction mixture was pipetted out, and quenched in 5 ml of a 1:9 mixture of 3 M hydrochloric acid with MeCN. The amount of remaining thiols in the quenched solution was then determined by titration with the 0.001 M iodine solution. Each plot in Figs. 1 and 2 represents the average of at least three, generally five, or more runs.

3) T. Endo, M. Hashimoto, T. Orii, and M. M. Ito, *Bull. Chem. Soc. Jpn.*, **57**, 1562 (1984) and the references cited therein.

4) Similar rate profiles were observed for oxidation of **1b** and **2c** (Z=H, Me, and Et) in H_2O–MeCN (x_w=0.42) at 35.0 °C.[3]

5) The rate-determining step is generally regarded as that given by Eq. 1 or 2 [G. Capozzi and G. Modena, "Oxidation of Thiols," in "The Chemistry of the Thiol Group," ed by S. Patai, Wiley, London (1974), Part 2, Chap. 17]. One

$$RSH + Et_3N \overset{K}{\rightleftharpoons} RS^- + Et_3NH^+ \quad (1)$$

$$RS^- + O_2 \longrightarrow RS\cdot + O_2^{\cdot-} \qquad k_2 \quad (2)$$

possible explanation for the rate profiles in Figs. 1 and 2 is associated with the behavior of superoxide anion ($O_2^{\cdot-}$) in solvents.

First, in aprotic solvents such as MeCN, the steady state assumption can be applied to $O_2^{\cdot-}$, since the $O_2^{\cdot-}$ (the other oxidant) formed in situ is known to oxidize thiols readily

$$RSH + O_2^{\cdot-} \longrightarrow RS\cdot + O_2H^- \quad (3)$$

(Eq. 3) to disulfides [S. Oae, T. Takata, and Y. H. Kim, *Bull. Chem. Soc. Jpn.*, **54**, 2712 (1981)]. If the step shown by Eq. 2 is rate-determining, the rate for the oxidation may be expressed as

$$-d[RSH]/dt = 2k_2'[RSH] \quad (4)$$

where $k_2'=k_2[O_2]K[Et_3N]/[Et_3NH^+]$. Thus, the oxidation will follow pseudo first-order kinetics (Fig. 1).[2]

Second, in protic solvents, the $O_2^{\cdot-}$ reacts with solvent molecules to give the other oxidants (Ox·), such as $HO_2\cdot$ [J. Rabani and S. O. Nielsen, *J. Phys. Chem.*, **73**, 3736 (1969)], which may also oxidize thiols (Eq. 5) to disulfides. If the

$$RSH + Ox\cdot \longrightarrow RS\cdot + OxH \qquad k_5 \quad (5)$$

step shown by Eq. 2 is rate-determining, the rate for the oxidation may follow the expression

$$-d[RSH]/dt = k_2'[RSH] + k_5[RSH][Ox\cdot] \quad (6)$$

Rate acceleration will occur at least when $k_2'<k_5[RSH]_0$.

Similar results are obtained, even if the rate-determining step is given by Eq. 1.

Synthesis and Absolute Configuration of an Optically Active Bisnoradamantane Derivative, (−)-6-Oxotricyclo-[3.3.0.0^{3,7}]octane-2-carboxylic Acid

Koichiro NAEMURA,* Masanori KOMATSU, and Hiroaki CHIKAMATSU
Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received November 12, 1985)

Synopsis. 6-Isopropylidenetricyclo[3.3.0.0^{3,7}]octane-2-carboxylic acid (**11**) was prepared from the dimethylfulvene–ethyl acrylate adduct **5**. Optical resolution of **11** was carried out via the (+)-1-(2-naphthyl)ethylamine salt, and (−)-**11** was transformed into (−)-6-oxotricyclo[3.3.0.0^{3,7}]octane-2-carboxylic acid (**14**) whose absolute configuration and absolute rotation were established.

The smallest rings in the tricyclo[3.3.0.0^{3,7}]octane (bisnoradamantane)[1] ring system are all five membered. Because of the highly symmetrical arrangement of the fused cyclopentane rings within this system, the hydrocarbon **1** is achiral ($3C_2$, $2\sigma_v$; D_{2d} symmetry) and four CH_2 groups in **1** are a pair of enantiotopic molecular subunits. Conversion of two of these CH_2 groups oriented coaxially along one of C_2 axes into π-systems desymmetrizes the D_{2d} symmetry inherent to **1**, leading to formation of chiral molecules, e.g. **2**, **3**, and **4**. Among these molecules, 6-methylenebisnoradamantan-2-one (**2**) (C_2 symmetry) and bisnoradamantane-2,6-dione (**3**) (D_2 symmetry) were prepared in racemic forms in our laboratory.[2] Gleiter and Kissler[3] reported the synthesis of (±)-2,6-dimethylenebisnoradamantane (**4**) (D_2 symmetry) and mentioned that this molecule is an interesting model for studying the intramolecular interaction of two π-fragments via a six membered ring. Our continuing interests in high-symmetry chiral cage-shaped molecules prompted us to prepare the bisnoradamantane derivative having two coaxially oriented unsaturated centers in an optically active modification.

In the preceding paper,[2] we reported that the eleven-step conversion of the maleic anhydride–cyclopentadiene adduct to 6-methylenebisnoradamantane-2-carboxylic acid (**17**) proceeded in 3% overall yield. The carboxylic acid **17** was the key intermediate for the preparation of **2**, **3**, and **4**.[2,3] We now chose 5-*endo*-ethoxycarbonyl-7-isopropylidenebicyclo[2.2.1]hept-2-ene (**5**) as the starting material for the preparation of bisnoradamantane derivative possessing two substituents. The Diels–Alder reaction of dimethylfulvene with ethyl acrylate yielded a 28% yield of **5**, which was transformed into **11** in 6% overall yield in seven steps.

The adduct **5**, without removing its *exo*-isomer, was reduced with $LiAlH_4$ to give **6** which was converted into **7** by tosylation followed by treatment with sodium cyanide. Alkaline hydrolysis of **7** yielded **8** in 42% overall yield from **5**. By use of Sauers' procedure,[4] **8** was converted into **10** via **9** in 27% overall yield. The cleavage reaction of **10** was accomplished with potassium *t*-butoxide and water. Contrary to our expectation that the ring opening of the cyclobutanone moiety in **10** should yield a mixture of two isomeric carboxylic acids depending upon the direction of bond cleavage, 6-isopropylidenebisnoradamantane-2-carboxylic acid (**11**) was the sole product isolated from the reaction mixture. Confirmation of structure **11** was obtained by its conversion into methyl 6-oxobisnoradamantane-2-carboxylate (**13**) which has been prepared in a racemic form.[2] Optical resolution of **11** was accomplished using (+)-1-(2-naphthyl)-ethylamine as the resolving agent. The resolved carboxylic acids, (−)-**11** ($[\alpha]_D$ −74.1°) and (+)-**11** ($[\alpha]_D$ +67.7°) were obtained respectively from the sparingly soluble and the soluble salts. Esterification of (+)-**11**, $[\alpha]_D$ +67.7°, with CH_2N_2 gave (+)-**12**, $[\alpha]_D$ +72.5°, which exhibited a singlet signal at δ 3.53 ppm due to CO_2CH_3 protons in its ^{1}H NMR spectrum. Addition of Eu(tfc)$_3$ [(+)-**12**/shift reagent=1.0/0.45 molar ratio] split the signal into two singlets at δ 5.90 and 5.98 ppm, and their integrated intensities indicated an enantiomer ratio of 90.5:9.5 corresponding to 81% optical purity.

Our next task is the determination of absolute configuration of these new compounds. Ozonization of (−)-**12**, $[\alpha]_D$ −77.5° (86.6% e.e.), followed by reductive work-up provided **13**. Its ^{1}H NMR spectrum and GLC behavior were identical with those of (±)-**13**.[2] Alkaline hydrolysis of **13** yielded (−)-**14**, $[\alpha]_D$ −60.8°. Calculation based on the optical purity of (−)-**12** assigns absolute rotation $[\alpha]_D$ −7.2° to (−)-**14**. The Wolff-Kishner reduction of (−)-**14** followed by esterification with CH_2N_2 furnished methyl (−)-(1*R*,3*R*,5*R*,7*R*)-bisnoradamantane-2-carboxylate (**16**) whose absolute configuration has been reported in our preceding paper.[5] The result eventually assigns the (1*R*,3*R*,5*R*,7*R*) configuration to (−)-**14**.

The optically active compounds **11** and **14** may serve as precursors for preparing bisnoradamantane derivatives having two coaxially oriented π-systems in an optically active form.

Experimental

Preparative GLC were done on a JGC-20K equipped with a TCD and using a 2 m×3 mm column of 10% PEG 20 M on

Chromosorb W.

5-Ethoxycarbonyl-7-isopropylidenebicyclo[2.2.1]hept-2-ene (5). A mixture of dimethylfulvene[6] (142 g, 1.34 mol) and ethyl acrylate (134 g, 1.34 mol) was heated at 100 °C for 44 h. Distillation of the product provided 78.5 g of **5** (28% yield); bp 78—82 °C (4 mmHg**). IR (neat film) 3060, 1735, 1180, 730 cm^{-1}.

Found: C, 75.72; H, 8.81%. Calcd for $C_{13}H_{18}O_2$: C, 75.69; H, 8.80%.

5-Hydroxymethyl-7-isopropylidenebicyclo[2.2.1]hept-2-ene (6). A solution of **5** (15.8 g, 0.0814 mol) in dry ether (200 mL) was added to a suspension of $LiAlH_4$ (2.50 g, 0.0658 mol) in dry ether (200 mL) and then the mixture was refluxed for 4.5 h. After a usual workup, the product was distilled to give 9.20 g of **6** (74% yield); bp 98—100 °C (4 mmHg). IR (neat film) 3450, 3060, 1030, 730, 710, 700 cm^{-1}.

Found: C, 80.31; H, 9.79%. Calcd for $C_{11}H_{16}O$: C, 80.44; H, 9.83%.

5-Cyanomethyl-7-isopropylidenebicyclo[2.2.1]hept-2-ene (7). Tosylation of **6** (9.20 g, 0.0605 mol) with tosyl chloride (13.9 g, 0.0728 mol) in pyridine (55 mL) gave 16.7 g of the tosylate as a viscous oil, which was mixed with NaCN (45.0 g, 0.918 mol) and *N,N*-dimethylformamide (520 mL). The mixture was heated at 110 °C for 20 h and a workup followed by distillation provided 7.22 g of **7** (80% yield); bp 114—118 °C (4 mmHg). IR (neat film) 3060, 2240, 730, 710, 700 cm^{-1}.

Found: C, 83.01; H, 8.70; N, 8.05%. Calcd for $C_{12}H_{15}N$: C, 83.19; H, 8.73; N, 8.09%.

5-Carboxymethyl-7-isopropylidenebicyclo[2.2.1]hept-2-ene (8). A mixture of **7** (36.7 g, 0.212 mol), KOH (35.7 g, 0.635 mol), and ethylene glycol (420 mL) was stirred at 140—150 °C for 8 h. A usual workup followed by distillation gave 31.2 g of **8** (77% yield); bp 142—146 °C (1 mmHg). IR (neat film) 1710, 720, 710 cm^{-1}.

Found: C, 74.88; H, 8.22%. Calcd for $C_{12}H_{16}O_2$: C, 74.97; H, 8.39%.

3-Isopropylidenetetracyclo[5.1.1.0^{2,6}.0^{4,8}]nonan-9-one (10). By use of a procedure similar to that reported by Sauers,[4] **8** (27.8 g, 0.145 mol) was converted into 6.80 g of **10** (32% yield) after alumina chromatography (pentane eluent) as a colorless oil; ^1H NMR (CCl_4) δ=1.60 (s, 3H), 1.63 (s, 3H), 1.4—1.6 (m, 2H), 2.2—3.0 (m, 6H). IR (neat film) 1780 cm^{-1}. The oily material was without further purification used in the next reaction.

6-Isopropylidenetricyclo[3.3.0.0^{3,7}]octane-2-carboxylic Acid (11). By use of a procedure similar to that reported by Sauers,[4] **10** (11.2 g, 0.0644 mol) was converted into **11** (3.84 g, 31% yield) after crystallization from pentane; mp 98—101 °C (in a sealed tube). IR (KBr) 1700 cm^{-1}.

Found: C, 75.13; H, 8.48%. Calcd for $C_{12}H_{16}O_2$: C, 74.97; H, 8.39%.

Optical Resolution of 11. To a solution of **11** (7.00 g, 0.0364 mol) in ethanol (70 mL) was added (+)-1-(2-naphthyl)ethylamine (6.23 g, 0.0364 mol). The deposited salt (6.26 g), $[\alpha]_D^{30}$ −8.71° (*c* 0.875, $CHCl_3$), was freed from the mother liquor which was reserved for isolation of the enantiomer (+)-**11**. Several times recrystallization of the salt from ethanol gave 3.49 g of the salt, $[\alpha]_D^{28}$ −32.6° (*c* 0.730, $CHCl_3$), which was stirred for 6 h with 10% HCl at room temperature. A usual workup provided 1.40 g of (−)-**11**, $[\alpha]_D^{28}$ −74.1° (*c* 0.805, $CHCl_3$). The carboxylic acid (−)-**11** (200 mg, 1.04 mmol) was treated with excess of a solution of diazomethane in ether with ice-cooling. A usual workup followed by prep. GLC separation (at 160 °C) gave 140 mg of (−)-**12** (65% yield); $[\alpha]_D^{27}$ −79.4° (*c* 0.903, $CHCl_3$). ^1H NMR (CCl_4) δ=1.7—1.9 (m, 4H), 1.51 (s, 6H), 2.4—2.8 (m, 5H), 3.53 (s, 3H). IR (neat film) 1730 cm^{-1}.

Found: C, 75.52; H, 8.75%. Calcd for $C_{13}H_{18}O_2$: C, 75.69; H, 8.80%.

From the dextrorotatory salt (1.44 g), $[\alpha]_D^{28}$ +53.3° (*c* 0.110, $CHCl_3$), isolated from the mother liquor, 550 mg of (−)-**11**, $[\alpha]_D^{28}$ +67.7° (*c* 0.950, $CHCl_3$), was obtained. Esterification of (+)-**11** (530 mg) gave 395 mg of (+)-**12**, $[\alpha]_D^{27}$ +72.5° (*c* 0.890, $CHCl_3$), after prep. GLC separation.

6-Oxotricyclo[3.3.0.0^{3,7}]octane-2-carboxylic Acid (14). Ozonization of (−)-**12**, $[\alpha]_D^{27}$ −77.5°, (900 mg, 4.37 mmol) followed by treatment with zinc powder and acetic acid was carried out by the similar procedure reported in our preceding paper[2] to give 235 mg of **13** (30% yield) after alumina chromatography (pentane–ether 1:1) followed by sublimation (75 °C at 30 mmHg); mp 63—65 °C (in a sealed tube) (lit,[2] (±)-**13**; mp 64—64.5 °C).

Found °C, 66.62; H, 6.78%. Calcd for $C_{10}H_{12}O_3$: C, 66.65; H, 6.71%.

The ester **13** (210 mg, 1.17 mmol) was stirred under reflux for 3 h in 4 mL of 50% aqueous methanol with KOH (205 mg) to give 158 mg of **14** (81% yield) after sublimation (110 °C at 10 mmHg); mp 120—121 °C (lit,[2] (±)-**14**; mp 125—126 °C). $[\alpha]_D^{25}$ −60.8° (*c* 0.875, MeOH). IR (KBr) 1760, 1710 cm^{-1}.

Found: C, 64.99; H, 6.09%. Calcd for $C_9H_{10}O_3$: C, 65.05; H, 6.07%.

Methyl (−)-Tricyclo[3.3.0.0^{3,7}]octane-2-carboxylate (16). By use of a procedure similar to that reported in our preceding paper,[2] the Wolff-Kishner reduction of (−)-**14** (130 mg, 0.783 mmol), $[\alpha]_D^{25}$ −60.8°, was carried out with KOH (282 mg) and hydrazine hydrate (310 mg, 6.20 mmol) in triethylene glycol (3 mL) to give 105 mg of **15**. Esterification of **15** with diazomethane yielded (−)-**16** (80 mg, 62% overall yield) after alumina chromatography followed by prep. GLC (at 120 °C); $[\alpha]_D^{26}$ −13.1° (*c* 0.655, $CHCl_3$) [lit,[5] bp 83—84 °C at 4 mmHg; $[\alpha]_D^{17}$ +14.5° ($CHCl_3$)].

Found: C, 72.34; H, 8.62%. Calcd for $C_{10}H_{14}O_2$: C, 72.26; H, 8.49%.

A New Synthesis of α-Phenylhomoallylnitriles from β-Nitrostyrene and Allylic Silanes

Hidemitsu UNO,* Satomi FUJIKI, and Hitomi SUZUKI*
Advanced Instrumentation Center for Chemical Analysis, Ehime University, Bunkyo-cho 2-5, Matsuyama 790
(Received October 18, 1985)

Synopsis. $TiCl_4$-catalyzed addition of allylic silanes to β-nitrostyrene affords γ,δ-unsaturated nitronates which, on treatment with low valent titanium in situ generated from Ti(IV) and zinc, are smoothly converted to γ,δ-unsaturated nitriles in moderate yields.

Michael-type additions of enol silyl ethers[1] and allylic silanes[2] to nitroalkenes have been used for the synthesis of 1,4-dicarbonyl compounds. In these reactions, an appropriate Lewis acid ($TiCl_4$, $SnCl_4$, or $AlCl_3$) is used as activator of nitroalkenes. Among the Lewis acids employed, $TiCl_4$ may be regarded as a potential reductant since, on treatment with zinc, it generates low valent titanium compound which can reduce carbonyl compounds to pinacols or olefins.[3] Based on this dual role of titanium compound, we have developed a new method of preparing α-phenylhomoallylnitriles **4**[4] from allylic silanes **1** and β-nitrostyrene (**2**).

In the presence of $TiCl_4$, allylic silanes **1** react smoothly with β-nitrostyrene (**2**) to give γ,δ-unsaturated silyl nitronates **3**. Subsequent addition of zinc dust to the reaction mixture produces low valent titanium from $TiCl_4$, which then converts nitronates **3** to γ,δ-unsaturated nitriles **4**.[5] Although the reaction is subject to extensive formation of phenylacetonitrile (**5**) as by-product, the yields of nitriles **4** are in most cases acceptable as shown in Table 1. In the absence of an allylic silane, β-nitrostyrene remained almost unaffected at low temperature, while by adding chlorodimethylphenylsilane or chlorotrimethylsilane instead of an allylic silane to the reaction system nitroolefin **2** was readily converted to nitrile **5** in good yield. Therefore, the formation of **5** as a common by-product would reasonably be attributed to the concurrent chlorinolysis of allylic silanes by $TiCl_4$.

Allylic groups usually entered into β-nitrostyrene (**2**) with allylic transposition (Entries 4—7).[6] However, buten-3-ylsilane **1h** afforded a mixture of two regioisomers (**4h**:**4d**=32:13) (Entry 8), while 2-methyl-2-propenylsilane **1i** suffered hydrochlorination of double bond of the final product (Entry 9).

The present reaction not only offers a new synthetic route to γ,δ-unsaturated nitriles, but also demonstrates a successful use of titanium compound as Lewis acid and reductant in a simple one-pot procedure.[7]

Experimental

Materials. Allylic silanes **1b** (bp 93 °C/2.27 kPa), **1h**[8] (bp 106 °C/2.67 kPa), and **1i** (110 °C/3.07 kPa) were prepared from chlorodimethylphenylsilane and the Grignard reagents. Crotylsilane **1d** (bp 106 °C/2.67 kPa) and prenylsilane **1e** (bp 115—118 °C/2.00 kPa) were prepared from silyllithium and allylic halides according to the literature.[9] Cinnamylsilane **1f** (bp 123 °C/27 Pa) was obtained by the reaction of a lithio derivative of allylbenzene with chlorodimethylphenylsilane. Allylic silane **1g** was prepared by our method.[10] Titanium tetrachloride was used after distillation. Products were identified by mass, IR, and ^1H NMR spectra as well as by direct comparison with authentic specimens. Purification of the products was performed by a silica-gel column chromatography (Wakogel C-200; hexane-CH_2Cl_2

as eluent) and/or preparative GPC (Japan Analytical Industry, LC-08; JAI-1H (20 mmID×60 cm)+JAI-2H (20 mmID×60 cm)).

General Procedure. To a stirred solution of β-nitrostyrene (**2**, 164 mg, 1.1 mmol) and an allylic silane (**1**, 1 mmol) in CH_2Cl_2 (10 ml) was added $TiCl_4$ (1 M** CH_2Cl_2 solution, 1.5 ml) at −15 °C under argon. After disappearance of **2** (ca. 2 h), dry THF and zinc dust (200 mg, 3 mmol) were added successively and the resulting dark purple mixture was stirred for another hour. The reaction was quenched by adding aqueous $NaHCO_3$ and ether. The suspension was then filtered through a Celite pad. The filtrate was separated and the aqueous layer was extracted twice with ether. The combined extracts were washed with brine and dried over Na_2SO_4. Evaporation of the solvent gave an oily material which was chromatographed on silica gel.

2-Phenyl-4-pentenenitrile 4a. 60 MHz ^{1}H NMR (CCl_4) δ= 2.58 (2H, t, J=7 Hz), 3.78 (1H, t, J=7 Hz), 5.12 (2H, m), 5.68 (1H, ddt, J=16, 10, and 7 Hz), and 7.30 (5H,m); IR (NaCl) 3047 (m), 3010 (m), 2975 (m), 2960 (m), 2900 (m), 2225 (m), 1635 (s), 1450 (s), 990 (m), 920 (s), 750 (vs), and 690 cm^{-1} (vs); MS m/z (rel intensity) 157 (M^+, 63), 117 (37), 116 (100), and 90 (98).

3-Methyl-2-phenyl-4-pentenenitrile 4d. 400 MHz ^{1}H NMR ($CDCl_3$) (major isomer) δ=1.12 (3H, d, J=6.7 Hz), 2.66 (1H, m), 3.82 (1H, d, J=11.6 Hz), 5.15 (2H, m), 5.75 (1H, m), and 7.30 (5H, m); (minor isomer) δ=1.14 (3H, d, J=7.6 Hz), 2.66 (1H, m), 3.73 (1H, d, J=6.4 Hz), 5.05 (2H, m), 5.75 (1H, m), and 7.30 (5H, m); IR (NaCl) 3080 (m), 3055 (m), 2960 (vs), 2925 (m), 2230 (m), 1640 (m), 1490 (s), 1455 (vs), 995 (s), 925 (vs), 750 (s), and 700 cm^{-1} (vs); MS m/z (rel intensity) 171 (M^+, 24), 117 (59), 116 (100), 115 (100), and 90 (21).

3,3-Dimethyl-2-phenyl-4-pentenenitrile 4e. 60 MHz ^{1}H NMR (CCl_4) δ=1.16 (6H, s), 3.50 (1H, s), 5.02 (2H, m), 5.80 (1H, dd, J=16 and 10 Hz), and 7.20 (5H, m); IR (NaCl) 2955 (vs), 2920 (m), 2235 (w), 1490 (s), 1450 (s), 1000 (m), 730 (vs), and 700 cm^{-1} (vs); MS m/z (rel intensity) 185 (M^+, 15), 117 (100), 116 (80), 115 (22), and 90 (16).

2,3-Diphenyl-4-pentenenitrile 4f. Colorless solids; mp 116—117 °C; 400 MHz ^{1}H NMR ($CDCl_3$) (major isomer) δ=3.72 (1H, t, J=7 Hz), 4.07 (1H, d, J=7 Hz), 5.17 (2H, m), 6.05 (1H, ddd, J=16, 10, and 7 Hz), and 7.20 (10H, m); (minor isomer) δ=3.68 (1H, t, J=7 Hz), 4.15 (1H, d, J=7 Hz), 5.17 (2H, m), 6.23 (1H, ddd, J=16, 10, and 7 Hz), and 7.20 (10H, m); IR (NaCl) 3050 (m), 3000 (m), 2945 (s), 2910 (s), 2195 (vw), 1450 (m), 1110(vs), 790 (vs), 745 (m), and 695 cm^{-1} (vs); MS m/z (rel intensity) 234 (M^+, 4), 207 (3), 119 (84), 118 (100), and 117 (100); Anal. Found: C, 87.25; H, 6.53; N, 5.85%. Calcd for $C_{17}H_{15}N$: C, 87.51; H, 6.48; N, 6.00%.

Methyl 5-Cyano-2-methyl-5-phenyl-2-pentenoate 4g. 60 MHz ^{1}H NMR ($CDCl_3$) δ=1.76 (3H, broad s), 2.72 (2H, t, J=7 Hz), 3.70 (3H, s), 3.86 (1H, t, J=7 Hz), 6.64 (1H, m), and 7.29 (5H, m); IR (NaCl) 2930 (m), 2910 (m), 2225 (m), 1710 (vs), 1450 (s), 1120 (vs), 740 (s), and 690 cm^{-1} (vs); MS m/z (rel intensity) 229 (M^+, 26), 143 (14), 128 (15), and 117 (100).

2-Phenyl-4-hexenenitrile 4h. 400 MHz ^{1}H NMR ($CDCl_3$) (cis isomer) δ=1.55 (3H, d, J=7.0 Hz), 2.67 (2H, m), 3.80 (1H, m), 5.43 (1H, m), 5.65 (1H, dq, J=10.1 and 7.0 Hz), and 7.32 (5H, m); (trans isomer) δ=1.70 (3H, d, J=6.1 Hz), 2.56 (2H, m), 3.80 (1H, m), 5.43 (1H, m), 6.59 (1H, dq, J=15.6 and 6.1 Hz), and 7.32 (5H, m); IR (NaCl) 3020 (m), 2960 (m), 2910 (m), 2245 (m), 1600 (m), 1495 (s), 1455 (vs), 970 (s), 760 (s), and 700 cm^{-1} (vs); MS m/z (rel intensity) 171 (M^+, 39), 117 (100), 116 (96), and 90 (49).

4-Chloro-4-methyl-2-phenylpentanenitrile. 400 MHz ^{1}H NMR ($CDCl_3$) δ=1.63 (3H, s), 1.78 (3H, s), 2.22 (1H, dd, J=15.0 and 3.1 Hz), 2.47 (1H, dd, J=15.0 and 9.8 Hz), 4.18 (1H, dd, J=9.8 and 3.1 Hz), and 7.40 (5H, m); IR (NaCl) 3010 (m), 2230 (m), 1600 (m), 1490 (s), 1450 (s), 1115 (s), 750 (s), and 700 cm^{-1} (vs); MS m/z (rel intensity) 209 (M^++2, 4), 207 (M^+, 9), 172 (18), 157 (7), 131 (100), 130 (13), 129 (40), 128 (14), 117 (57), and 116 (81).

The authors express their appreciation for the measurement of 400 MHz ^{1}H NMR spectra to Mr. Hiroyuki Furuta (Kyoto Univ.) and also for gifts chlorosilanes from Shin-etsu Chem. Co. Ltd.

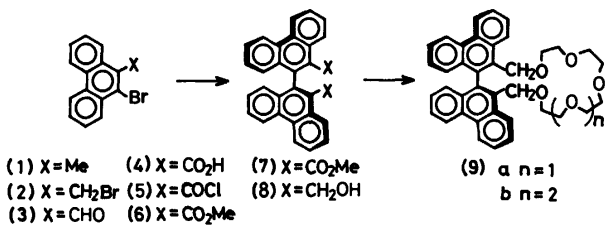
Synthesis and Chiral Recognition of Optically Active Crown Ethers Incorporating a 9,9′-Biphenanthryl Moiety as the Chiral Center

Koji YAMAMOTO,* Tomohito KITSUKI, and Yoshio OKAMOTO
Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received September 14, 1985)

Synopsis. Two chiral crown ethers incorporating a 9,9′-biphenanthryl moiety as the chiral center have been prepared, and their chiral recognition properties in transport of methyl (±)-phenylglycinate hydrochloride, (±)-1-phenylethylamine hydrochloride, and (±)-1,2-diphenylethylamine hydrochloride were examined.

As an extension of our recent synthetic studies on optically active crown ethers incorporating axially dissymmetric molecules,[1] we report here the preparation and chiral recognition properties of optically active crown ethers (**9**) having a 9,9′-biphenanthryl moiety as the chiral center.

Preparation of **9** was carried out according to the sequence of reactions illustrated in Scheme 1. In the



Scheme 1.

initial step 9-bromo-10-methylphenanthrene (**1**)[2] was converted into the corresponding bromomethyl derivative (**2**) by a side chain bromination, followed by a Sommelet reaction[3] and an oxidation to give the acid (**4**) (30% yield from 1). The latter was transformed into the corresponding acid chloride (**5**) and esterified to produce **6** (86.8% yield from **4**). The coupling of the bromo ester (**6**) to give the biphenanthryl diester (**7**) was effected under Ullmann conditions,[4] and the lithium aluminium hydride reduction of this ester gave the alcohol (**8**) (64.4% yield from **6**). Optical resolution of (±)-(**8**) was achived by HPLC with a column packed with (+)-poly(triphenylmethyl methacrylate);[5] elution with methanol gave optically pure (−)-(*S*)-(**8**)[6] and (+)- (*R*)-(**8**) with $[\alpha]_D$ (acetone) −70.0° and +69.7°, respectively. Condensation of (−)-(**8**) with tetraethylene glycol ditosylate (NaH–THF) afforded the (−)-(*S*)-9,9′-biphenanthryl-crown-5 (**9a**), mp 223—225 °C (55% yield). The (+)-(*R*)-biphenanthryl-crown-6 (**9b**) was prepared in the same way from (+)-(**8**). The (+)-alcohol (**8**) was condensed with pentaethylene glycol ditosylate to afford (+)-(*R*)-(**9b**), mp 201—203 °C (47% yield).

Table 1. Differential Transport of Enantiomeric Molecules

Host	Guest	Transport %	Configuration of dominant entiomer	Optical purity %
(−)-(*S*)-(**9a**)	a	1.4	*R*	21
	b	3.1	*S*	88
	c	3.5	*S*	49
(+)-(*R*)-(**9b**)	a	1.8	*S*	15
	b	4.1	*R*	20
	c	3.9	*R*	19

a) Methyl (±)-phenylglycinate hydrochloride. b) (±)-1,2-Diphenylethylamine hydrochloride. c) (±)-1-Phenylethylamine hydrochloride.

Table 1 gives the chiral recognition behavior of (−)-(*S*)-(**9a**) and (+)-(*R*)-(**9b**) with methyl (±)-phenylglycinate hydrochloride, (±)-1-phenylethylamine hydrochloride, and (±)-1,2-diphenylethylamine hydrochloride.

A few of the typical enantiomer selective crown ethers (**10**) prepared by Cram et al.[8] are shown in

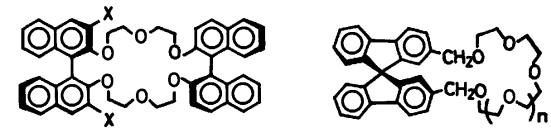


Figure. One of the most enantiomer selective of these compounds is the dimethyl derivative of the bis-(α,α′-binaphthyl)-22-crown-6 (**10**). With methyl (±)-phenylglycinate at 0 °C, a 90% optical purity was found for this crown by differential transport. Our results (Table 1) show that **9a** containing five oxygens has a higher enantiomer selectivity than **9b** containing six oxygens towards all substrates, and 1,2-diphenylethylamine of as high as 88% optical purity was 3.1% transported by (−)-(*S*)-(**9a**). These results are compatible with Prelog's experiment[9] which reveal that 9,9′-spiro-bifluorene-22-crown-5 (**11**) (n=1) possesses the highest enantiomer selectivity for several ammonium cations with a chiral substituent in a 9,9′-spiro-bifluorenocrown series (**11**).

Experimental

Melting points are uncorrected. IR and NMR spectra were recorded on a Hitachi 260-10 and a JNM-MH-100 spectrometer, respectively.

9-Bromo-10-(bromomethyl)phenanthrene (2). A stirred and refluxed solution of **1** (21.7 g, 80 mmol), *N*-bromosuccinimide (15.8 g, 80 mmol), and benzoyl peroxide (0.1 g) in CCl_4 (150 mL) was irradiated with a tungsten lamp (100 W) for 4 h. After a usual workup, the resulting solid was recrystallized from hexane to give **2** (19.6 g, 70% yield), mp 141—142 °C; ^{1}H-NMR (CCl_4) δ=5.13 (s, 2H), 7.48—8.60 (m, 8H) (Found: C, 51.42; H, 2.86%).

9-Bromo-10-formylphenanthrene (3). The aldehyde (**3**)

(4 g, 11.4 mmol) was synthesized from **2** under Sommelet conditions as described.[3] The crude product was recrystallized from benzene to yield **3** (2.4 g, 95%), mp 160—161 °C; IR (KBr) 1700 cm^{-1} (C=O); ^{1}H-NMR ($CDCl_3$) δ=7.54—9.05 (m, 8H), 10.92 (s, 1H) (Found: C, 63.26; H, 3.13; Br, 28.10%).

9-Bromo-10-phenanthrenecarboxylic Acid (4). The oxidation of **3** (8 g, 28 mmol) was carried out according to literature[10] using potassium permanganate (12 g). The resulting product was recrystallized from toluene to afford **4** (4.8 g, 56.8%), mp 221—223 °C; IR (KBr) 1710 cm^{-1} (C=O) (Found: C, 59.68; H, 2.96; Br, 26.66%).

Methyl 9-Bromophenanthrene-10-carboxylate (6). A mixture of **4** (5 g, 16.6 mmol), thionyl chloride (8.3 ml, 114 mmol), and toluene (20 ml) was gradually heated to boiling, whereupon the acid chloride dissolved. After refluxing for 3 h, the solvent was removed by vacuum distillation. The solid residue was recrystallized from benzene-hexane to give **5** (4.7 g, 88.6%), mp 73—74 °C; IR (KBr) 1780 cm^{-1} (C=O). A suspension of **5** (4.5 g, 14 mmol) in absolute methanol (20 ml) was stirred at room temperature untill dissolution had occured. The solution was then heated to reflux for 5 h, followed by evaporation under reduced pressure to give a crystalline solid. Recrystallization from benzene-hexane afforded **6** (4.2 g, 98%), mp 228—229 °C; IR (KBr) 1725 cm^{-1} (C=O); ^{1}H-NMR ($CDCl_3$) δ=4.07 (s, 3H), 7.54—8.68 (m, 8H) (Found: C, 60.95; H, 3.54; Br, 25.31%).

Dimethyl 9,9′-Biphenathryl-10,10′-dicarboxylate (7). The Ullmann coupling of **6** (1.0 g, 3.17 mmol) was carried out according to literature[11] using activated copper bronze (1.6 g), and dry DMF (15 ml). The resulting product was recrystallized from methanol to yield **7** (0.52 g, 69.7%), mp 226—227 °C; IR (KBr) 1725 cm^{-1} (C=O); ^{1}H-NMR ($CDCl_3$) δ=3.35 (s, 6H), 7.20—8.95 (m, 16H) (Found: C, 81.65; H, 4.71%).

10,10′-Bis(hydroxymethyl)-9,9′-biphenanthryl (8). A solution of **7** (3.3 g, 7 mmol) in dry THF (50 ml) was added to a suspension of $LiAlH_4$ (0.6 g, 15.8 mmol) in dry THF (90 ml). The mixture was refluxed for 0.5 h with stirring and cooled in an ice-bath. After a usual workup, the product was recrystallized from chloroform to give **8** (2.9 g, 92.4%), mp 292—294 °C; IR (KBr) 3450 cm^{-1} (OH); ^{1}H-NMR ($CDCl_3$) δ=1.57 (s, 2H), 4.72 (q, J=12 Hz, 4H), 7.16—8.90 (m, 16H) (Found: C, 81.75; H, 4.71%).

Optical Resolution of (±)-(8). Optical resolution of (±)-(**8**) was achieved by HPLC with a column packed with (+)-poly(triphenylmethyl methacrylate) as descrived.[12] A solution of (±)-(**8**) (15 mg) in methanol (15 ml) was injected on the column and eluted with methancl to give the first eluted (−)-isomer followed by (+)-isomer. The procedure was repeated to process a total of 1 g of **8**, and recrystallization of the resolved enantiomeric compounds from chloroform afforded optically pure (*S*)-(−)-(**8**) and (*R*)-(+)-(**8**) respectively. (*S*)-(−)-(**8**): 0.45 g (45%), mp 280—281 °C, $[\alpha]_D^{25}$ −70.0° (acetone); (*R*)-(+)-(**8**): 0.46 g (46%), mp 281—282 °C, $[\alpha]_D^{26}$ +69.7° (acetone).

(−)-(*S*)-Decahydrodiphenanthro[9,10-*o*:9′,10′-*q*][1,4,7,10,13]-pentaoxacyclononadecin (9a). To a boiling suspension of NaH (36 mg, 1.5 mmol) in dry THF (15 ml) was added a solution of (−)-(**8**) (170 mg, 0.41 mmol) and tetraethylene glycol ditosylate (180 mg, 0.41 mmol) in dry THF (30 ml) dropwise over 8 h period under N_2. The reaction mixture was refluxed for further 12 h, cooled in an ice-bath, and quenched with water (12 ml). After a usual workup, the crude product was chromatographed on alumina (benzene eluent) to give a solid which was recrystallized from benzene-hexane to furnish (−)-(**9a**) (130 mg, 55%), mp 223—225 °C, $[\alpha]_D^{23}$ −143.9° ($CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=3.05—3.78 (m, 16H), 4.70 (s, 4H), 7.15—9.10 (m, 16H); Found: C, 79.48; H, 6.35%. Calcd for $C_{38}H_{36}O_5$: C, 79.69; H, 6.34%.

(+)-(*R*)-Dodecahydrodiphenanthro[9,10-*r*:9′,10′-*t*][1,4,7,10,13,16]hexaoxacyclodocosin (9b). Condensation of (+)-(**8**) (400 mg, 0.965 mmol) with pentaethylene glycol ditosylate (480 mg, 0.965 mmol) was carried out by the same procedure as described for **9a**. The product was chromatographed on alumina (benzene eluent) followed by recrystallization from benzene-hexane to give (+)-(**9b**) (280 g, 47%), mp 201—203 °C, $[\alpha]_D^{25}$ +166° ($CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=3.10—3.75 (m, 20H), 4.69 (s, 4H), 7.20—8.97 (m, 16H); Found: C, 77.76; H, 6.48%. Calcd for $C_{40}H_{40}O_6$: C, 77.90; H, 6.54%.

Enantiomer Differential Transport. Differential transport was carried out in a conventional apparatus which consisted of an outer cylindrical gass vessel (24.5 mm inner diameter) and a central glass tube (15.5 mm inner diameter). The 0.01 M (1 M=1 mol dm^{-3}) $CHCl_3$ solution of the host separated the inner aqueous phase (0.1 M HCl) and the outer aqueous phase (0.08 M HCl) which contained $LiPF_6$ (0.4 M) and the racemic guest (0.08 M). The organic layer was stirred at 20 °C for 1 h, and transport was followed by monitoring the absorbance at 262 nm and $[\theta]_{262}$ of the inner aqueous phase.

Mössbauer Study of Tin in γ-AgI

Kazuhiro HIRAGA and Sumio ICHIBA*
Department of Chemistry, Faculty of Science, Hiroshima University,
Higashisenda-machi, Naka-ku, Hiroshima 730
(Received November 9, 1985)

Synopsis. Tin was deposited onto the surface of powdered γ-AgI and introduced into the matrix by solid-state diffusion at 300 °C. The ^{119}Sn Mössbauer spectra show that the deposit before heat treatment was epitaxially grown α-Sn and that the diffused tin was in the state of valency 4, occupying both the octahedral and tetrahedral interstices.

The state of tin in silver halides has been studied by means of Mössbauer spectroscopy. Meisel et al.[1] doped the AgCl polycrystals with 0.05 mol% ^{119}Sn and reported that tin atom existed as Sn^{4+}, occupying an interstice surrounded by four cation vacancies. Efimov et al.[2] also reported the presence of only Sn^{4+} in AgCl and AgI after study by means of emission Mössbauer spectroscopy. They introduced ^{119m}Sn into AgCl and AgI by fusing the corresponding salts with metallic ^{118}Sn and by then irradiating them with thermal neutrons. On the other hand, Lagunov and Polozenko[3] prepared alloys of AgCl and tin enriched with ^{119}Sn and reported that the spectrum of the state of Sn^{4+} in AgCl was due to SnO_2 particles in AgCl. As we have found a sophisticated method by which a small amount of tin can be introduced into the crystalline powder,[4] about 2.8 mol% of natural tin was introduced into the matrix of powdered AgI by the method; the Mössbauer spectra were then measured in order to elucidate the state of tin in AgI, which has not been clear hitherto.

Experimental

Freshly-prepared tin(II) chloride (8.4×10^{-5} mol) was dissolved in dry ethanol (20 cm^3), after which 3×10^{-3} mol of silver iodide (GR, Katayama Kagaku Kogyo Co., Ltd.), which has been sieved to 150—200 mesh, was added to the solution. The powder was suspended in the solution by means of supersonic waves and manual shaking. Sodium borohydride (5×10^{-4} mol) was then added to the solution at 3 °C. After the reduced tin has been deposited on the surface of the powder of AgI, the sediment was filtered out of the solution and washed thoroughly with oxygen-free water, dry ethanol, and finally dry ether under a nitrogen atmosphere in order to remove the reaction by-products. The sample powder was enveloped in an evacuated Pyrex glass ampoule, heated at 300 °C for 10 h, and then cooled to room temperature. The sample was identified as γ-AgI by the X-ray powder diffraction method before and after the heat treatment.

The Mössbauer spectra were recorded by the use of a constant-acceleration-type spectrometer with an accuracy of within 0.05 mm s^{-1}. The Mössbauer source of calcium stannate was used at room temperature, and the absorber was cooled at 93 K in a liquid nitrogen cryostat. The Mössbauer parameters were obtained from computer-fitted Lorentzian curves by the least-squares method.

Results and Discussion

The Mössbauer absorption spectra of the sample before and after heat treatment are shown in Fig. 1. The Mössbauer parameters obtained from the spectra are listed in Table 1. The isomer shift of tin deposited on the γ-AgI substrate was 2.12 mm s^{-1}, a value which agreed roughly with the value of α-Sn, 2.03 mm s^{-1}, but not with that of β-Sn, 2.56 mm s^{-1}. The α-form of tin was found for the first time, whereas the β-form of tin was found previously in our studies of colloidal tin suspension,[5] tin deposit on the surface of α-Fe_2O_3 particles,[4] and tin on NaCl and KCl particles.[6] The α-form of tin may be formed by epitaxial growth. The γ-AgI substrate has a cubic structure of the zincblende type, while the deposited α-Sn, in contrast to β-Sn, has its corresponding cubic structure of the diamond type. Their structures are similar not only topologically but also metrically, so that the lattice constants are 6.489 Å and 6.473 Å respectively. Thus, one element of group 4B, Sn, fits into the 1B–7B compound, γ-AgI, neatly. It should also be noted that the isomer shifts of tin deposited on the surface of the particles of AgBr and AgCl were 2.33 and 2.40 mm s^{-1} respectively.[7]

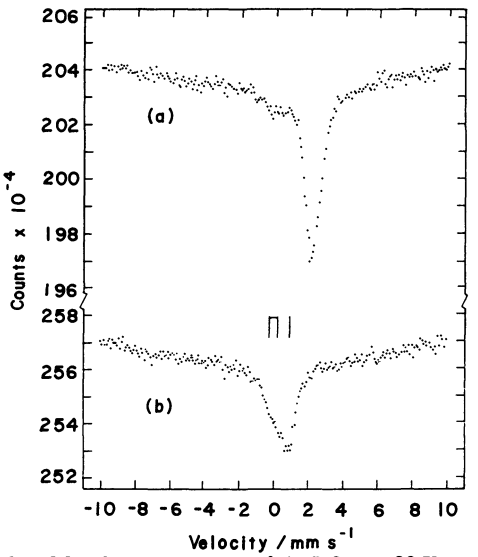

Fig. 1. Mössbauer spectra of AgI:Sn at 93 K.
(a) Before heating; (b) After heating at 300 °C for 10 h.

Table 1. ^{119}Sn Mössbauer Parameters for AgI : Sn at 93 K

	δ / mm s^{-1}	Δ / mm s^{-1}	Γ / mm s^{-1}	Relative area
(a)	2.12	—	1.05	1.00
(b)	0.86	—	0.91	0.47
	0.07	0.30	1.05	0.53

(a) Before heating. (b) After heating.

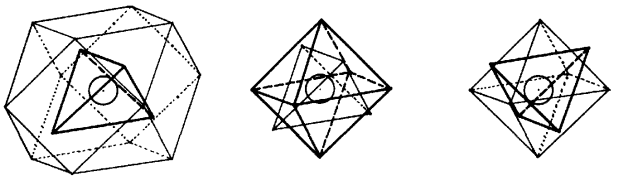

Fig. 2. Three models of the site for a tin atom in γ-AgI. (a) A site for the substitution; (b) and (c) Interstitial site. The circle shows the site for a tin atom. The polyhedra drawn in the thick line are the coordination polyhedra of iodine atoms and drawn in the thin line are the coordination polyhedra of silver atoms.

The absorption line of the tin in γ-AgI was near 0 mm s^{-1}, which corresponds to the Sn^{4+} oxidation state. The line shape was too complex to be attributed to a singlet peak, as in the results obtained by Efimov et al.[2] The parameters in Table 1(b) were derived on the assumption that the absorption line is a composite of a singlet component and a doublet component. The state of tin in γ-AgI will be inferred from the data thus obtained. Three models for the site of the foreign atom, Sn, are shown in Fig. 2. Figure 2(a) shows the silver atom site to be substituted, which is surrounded tetrahedrally by the first neighbors of four iodine atoms and cuboctahedrally by the second neighbors of twelve silver atoms. Two types of interstitial sites are examined; a wider one (Fig. 2(b)) and a narrower one which generates two subtypes in the vacancy distribution (Fig. 2(c)). The number of each site per unit cell is four. If it is assumed that the effective charge on a tin atom is four times as large as that on a silver atom, and that silver atoms nearest to the tin atom are removed to produce cation vacancies, only the tin atom at the interstitial site of Type b will give a singlet line due to the cubic symmetry, while any other sites, Type a or Type c, will give a doublet line. The data in Table 1(b) can be explained by the concurrent occupation of the sites of model b and c or a.

The plausibility of which models are occupied was examined by the use of the theories of the crystal potential and chemical bond.[8,9] Considering the electrostatic crystal potential of the doped crystal, the bond character of Ag–I, and the covalent or ionic radii of the three elements, we concluded that the occupation of the interstices is far more likely to occur than the substitution of a silver atom, and if the covalency (ca. 45%) acts predominantly, the Type c will be preferred to Type b.

Synthesis and Characterization of Lanthanoid Complexes with 1,3-Bis(2-pyridylmethyleneamino)-2-propanol

Masatomi SAKAMOTO
Department of Industrial Chemistry, Faculty of Engineering, Ehime University, Bunkyo-cho, Matsuyama 790
(Received December 2, 1985)

Synopsis. Lanthanoid complexes of a general formula $[Ln(appy)(NO_3)_2]H_2O$ (Ln=La, Pr, Nd, Eu, or Gd) have been synthesized with 1,3-bis(2-pyridylmethyleneamino)-2-propanol (Happy). The complexes were characterized to be mononuclear and of nine-coordination in solid state with quinquedentate $appy^-$ and two bidentate NO_3^- ions. On dissolution in dimethyl sulfoxide, the complexes were shown to dissociate into $[Ln(appy)(dmso)_n]^{2+}$ based on ^{13}C-NMR spectra and molar conductance measurements.

Many mononuclear lanthanoid complexes have been obtained and structurally characterized.[1] On the other hand, less attention has been paid to binuclear lanthanoid complexes, in spite of much interest in physicochemical properties such as spin-exchange interaction and quantum efficiency of luminescence in condensed systems of f-block elements.[2]

Recently, Schiff base derived from 1,3-diamino-2-propanol and a carbonyl compound such as salicylaldehyde or 2,4-pentanedione was shown to form binuclear copper(II) complexes bridged by the deprotonated alcoholic oxygen of the Schiff base.[3] X-Ray crystallographic analyses for the complexes revealed the Cu-Cu distance to be considerably long (≈3.5 Å), suggesting that the Schiff bases can also function as binucleating ligands toward lanthanoid(III) ions of a large ionic radius.

In this study, lanthanoid complexes (Ln=La, Pr, Nd, Eu, or Gd) of 1,3-bis(2-pyridylmethyleneamino)-2-propanol (the 1:2 condensation product of 1,3-diamino-2-propanol and 2-pyridinecarbaldehyde, abbreviated as Happy hereafter) have been synthesized and characterized, to see the complexing behavior of Happy toward lanthanoid(III) ions.

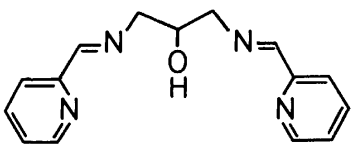

Fig. 1. Chemical structure of Happy.

Experimental

Preparation of Complexes. The metal nitrate (2 mmol) and 2-pyridinecarbaldehyde (2 mmol) were dissolved in methanol (20 cm^3). To this solution was added dropwise a methanolic solution (10 cm^3) of 1,3-diamino-2-propanol (1 mmol) under stirring at room temperature. The precipitate thus formed was filtered, washed with methanol and then with diethyl ether, and dried in vacuo. The yield based on the diamino alcohol was 30—50%.

Elemental analyses for the complexes are given in Table 1.

Measurements. Infrared spectra were measured with a JASCO IR-G spectrometer on KBr disks or nujol mulls. Electric conductivity measurements were carried out with a YOKOGAWA HEWLETT·PACKARD LCZ meter Model 4276A in dimethyl sulfoxide (DMSO) at 25 °C. Magnetic measurements were carried out by the Gouy method at room temperature. The apparatus was calibrated by the use of $Hg[Co(NCS)_4]$. ^{13}C-NMR spectra were recorded on a JEOL FX-100 spectrometer in DMSO-d_6 at 30 °C.

Results and Discussion

Analytical results demonstrated the stoichiometry of the complexes obtained to be $Ln(appy)(NO_3)_2H_2O$ (Table 1). It is presumed that the alcoholic group of the ligand is deprotonated and coordinated to the metal.

Infrared spectra of the complexes are essentially similar to each other. The coordination of the pyridine nitrogen to the metal is inferred from its in-plane deformation band located at 630 cm^{-1}.[4,5] The intense vibration at 1655 cm^{-1} is attributed to the C=N stretching mode. The azomethine nitrogen is probably coordinated to the metal, since Schiff bases are generally stabilized thermally when coordinated to a metal at the azomethine nitrogen.[6] In fact, it was impossible to isolate Happy in the metal-free state.

Table 1. Analytical, Magnetic, and Molar Conductance Data of Complexes

Complex	Found(%)(Calcd (%)[a])				μ_{eff} (B.M.)	Λ_M[b] (S cm^2mol^{-1})
	Ln	C	H	N		
La	24.67 (25.34)	32.64 (32.86)	2.85 (3.13)	15.71 (15.32)	dia.	78
Pr	25.93 (25.61)	32.06 (32.74)	2.79 (3.11)	15.22 (15.27)	3.34	77
Nd	26.29 (26.06)	32.32 (32.55)	2.95 (3.10)	15.06 (15.18)	3.31	77
Eu	27.92 (27.07)	31.73 (32.10)	2.79 (3.05)	14.99 (14.97)	3.31	77
Gd	28.43 (27.75)	31.82 (31.80)	2.76 (3.02)	14.86 (14.83)	7.95	76

a) Values for $Ln(appy)(NO_3)_2H_2O$. b) For 10^{-3} mol dm^{-3}.

The bands due to the nitrate ion appeared at 1450, 1300, 1035, and 815 cm^{-1}. This fact implies that the nitrate ion coordinates to the metal as a bidentate ligand.[7] The nitrate coordination is also supported by the splitting of the combination band in the 1700—1800 cm^{-1} region into two components;[8] the separation of the components for the La, Pr, Nd, Eu, and Gd complexes being 25, 27, 29, 32, and 34 cm^{-1}, respectively. The spectra on nujol mulls showed a broad band at 3500 cm^{-1}, suggesting that the H_2O molecule is not coordinated to the metal in each complex. Room-temperature magnetic moments for the complexes given in Table 1 are quite common for tervalent lanthanoid ions, respectively. Judging from these facts, the $[Ln(appy)(NO_3)_2]H_2O$ complexes are presumably mononuclear and of nine coordination with quinquedentate $appy^-$ and two bidentate NO_3^- ions, though the detailed structure for the complexes is unclear at present.

^{13}C-NMR spectrum of the La complex in DMSO-d_6 exhibited eight singlets at 163.62, 153.76, 149.71, 137.67, 125.76, 122.06, 70.04, and 64.41 ppm. The spectrum of 2-pyridinecarbaldehyde showed the carbonyl carbon signal at more lower field (193.33 ppm). Therefore, any indication of the cleavage of $appy^-$ into its components was not recognized from the spectrum of the La complex. It is likely that the coordination of $appy^-$ to the metal is maintained even in DMSO. The assignments of the signals for the La complex are as follows: 163.62 (azomethine carbon);[9] 153.76—122.06 (pyridine carbons);[9] 70.04 (methine carbon); 64.41 ppm (methylene carbon).

Electrical conductance measurements, on the other hand, revealed the complexes to become electrolytes in DMSO (Table 1). For 1:1 and 1:3 electrolytes, the molar conductances in DMSO are reported to be 37—43[10] and 110 Scm^2mol^{-1},[11] respectively. Molar conductances for $[Ln(appy)(NO_3)_2]H_2O$ (76—78 Scm^2mol^{-1}) clearly indicate that they behave as 1:2 electrolytes in DMSO. Evidently the nitrate ions are displaced with the solvent molecules to form $[Ln(appy)(dmso)_n]^{2+}$ species, though the number (n) of the coordinated solvent molecules is unknown.

From the above discussion, it is evident that Happy acts as a quinquedentate ligand toward lanthanoid ions to form 1:1 complexes with these ions. It should be mentioned that the complexing behavior of Happy differs from that of the macrocyclic Schiff base H_2apdapy (Fig. 2) bearing a structural relation to Happy. Recently, this macrocyclic Schiff base was shown to form 1:2 complexes with lanthanoid ions.[12]

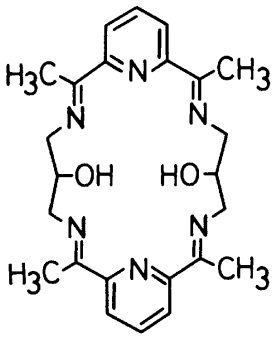

Fig. 2. Chemical structure of H_2apdapy.

The author is greatly thankful to Prof. Dr. Tomitaro Ishimori of Ehime University for his helpful discussion and encouragement throughout this work.

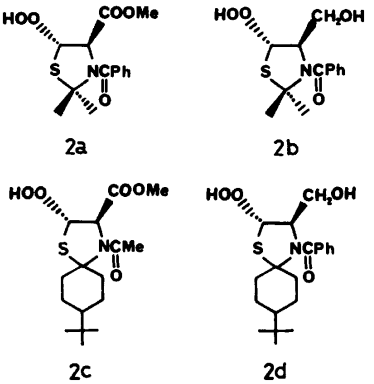
Asymmetric Oxidation of Sulfides with Optically Active Hydroperoxides Prepared by Singlet Oxygenation of Thiazolidine Derivatives

Toshikazu TAKATA and Wataru ANDO*
Department of Chemistry, The University of Tsukuba, Sakura, Ibaraki 305
(Received September 20, 1985)

Synopsis. Asymmetric oxidation of prochiral sulfides with optically active hydroperoxides prepared in situ by photo-sensitized oxygenation, gives chiral sulfoxides with moderate optical yields which are enhanced by addition of $Ti(OPr^i)_4$.

Asymmetric oxidation of sulfides is an essential and universal entry for synthesizing optically active sulfoxides with easy performance and less limitation, among several preparative methods with a variety of cptical yields.[1-7] However, the simplest oxidation with optically active peroxy acids resulted in low optical yields (0—5% e.e.),[1] in contrast to those with mixed oxidation systems, especially with modified Sharpless oxidation system (91% e.e.),[5,6] and electrochemical method (≈85% e.e.),[4] which were reported recently. The main reason is considered to be due not only to the distance between the chiral and reaction centers, but also to the lack of close interaction in the transition state. There has hitherto been no appropriate experimental verification for such a hypothesis, but the use of chiral hydroperoxide shortens the distance and therefore it would be expected to enhance the optical yield.

Although organic hydroperoxide is a relatively weak but useful oxidant for many organic substaces such as sulfides, to our knowledge it has not previously been used as a chiral oxidant for asymmentric oxidation of sulfides. In this paper, the optically active hydroperoxides that we have recently prepared by singlet oxygenation of thiazolidine derivatives,[8] are examined in the asymmetric oxidation of prochiral sulfides (Eq. 1).



The asymmetric oxidation was carried out in a single reaction adding a prochiral sulfide to a solution of a hydroperoxide freshly prepared in situ by photosensitized oxidation of thiazolidine derivative **1**. The results obtained for a few sulfides with four hydroperoxdes, are summarized in Table 1.

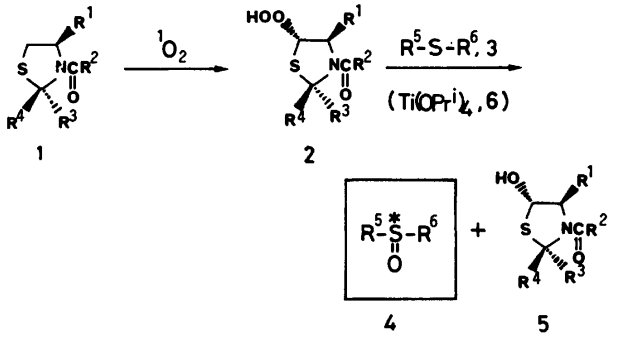


Fig. 1.

Table 1. Asymmetric Oxidation of Prochiral Sulfides with Optically Active Hydroperoxides

Run	Oxidant	Sulfide	Sulfoxide yield/%	Abs. confgn.	Optical purity/%[a]
1	**2a**	p-TolSMe(**4a**)	84	(+)-R	10.0(11)

11	**2c**+**6**	**4d**	81	(−)-S	21.3

a) Optical purity determined from specific optical rotation of purified sulfoxide (as for max. rotation, see Ref. 7. Parenthesis indicates enantiomer excess calculated from ^1H NMR integration using shift reagent Eu(hfc)3(tris[3-(heptafluoropropylhydroxymethylene)-*d*-camphorato], europium derivative) (error: ±ca. 5%). b) Not determined.

Table 1 indicates that some asymmetric induction on the sulfur atoms of the sulfides took place. The chemical yields of the sulfoxide product were satisfactory, while the optical purities were not high. However, these values are higher than those obtained in asymmetric oxidation with peroxy acids.[1] Direct comparison may be difficult because of the structural differences of the parent skeleton between these two oxidants. Among the hydroperoxieds used,[9] **2c** afforded good results with higher optical yields. As shown in Table 1 the absolute configuration of the excess enantiomer is variable depending on the structure not only of the hydroperoxides but also of the substrate sulfides. We believe that Mislow's suggestion is always operative where a small energy difference in the transition state would change the reaction course so as to give different results.[1]

The effect of the addition of $Ti(OPr^i)_4$ was examined, in expectation of a closer interaction in the transition state in the light of both the Sharpless[6,10] and the modified Sharpless[5] systems for asymmetric oxidations. In fact, enhancement of the optical purity was observed in the case of sulfides **4a** and **4b** (Runs 3 and 7, and 6 and 11). The absolute configuration, however, was changed by addition of **6** from *dextro* to *levo* rotatory for sulfide **4a** (Runs 1 and 7).

In this paper the first asymmetric oxidation of prochiral sulfides with optically active hydroperoxides is described. Since the increasing bulkiness of the oxidant peroxy acids does not always give rise to higher asymmetric induction,[1] the short distance between the reaction and chiral centers is important as well as the close interaction in the transition state during the oxidation. Therefore, the hypothesis that the low asymmetric induction in the peroxy acid oxidation is carried by two factors, is then justified by the results obtained here. Rough calculations[11] indicate the distances for peroxy acids are 361 pm and for hydroperoxide 225 pm. Such clear shortening of the distance in the hydroperoxide unambiguously causes the higher asymmetric induction. Addition of $Ti(OPr^i)_4$ (**6**) seems to affect the closeness in the transition state to some extent, although the exact structure of the transition state is still uncertain.[10]

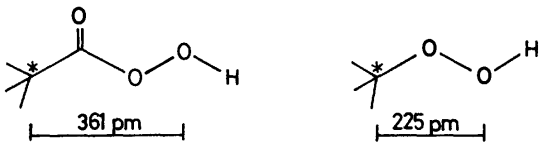

Fig. 2.

Experimental

Thiazolidines (1) were prepared from L-cysteine as described in the previous paper.[8] Sulfoxides (**4**) as products and alcohols (**5**)[12] as by-products were identified by reported physical and spectral data.

General Procedure. a) Without $Ti(OPr^i)_4$. A mixture of a thiazolidine derivative (1, 1—5 mmol) and TPP (5,10,15,20-tetraphenylporphyrin, 15 mg mmol^{-1} of 1) in dry THF ([C]=0.05—0.15 M (1 M=1 mol dm^{-3})) was photo-irradiated with a 500 W halogen lamp with bubbling dry oxygen at −30 °C. The reacton took 2 to 10 hs depending on the substrate (1) used.[8,12] To the resulting solution containing **2**, aprochiral sulfide (**3**, 2—10 mmol) was added and mixed well at −30 °C. The mixture was allowed to stand at −30 °C for 3 h and then at room temperature for a few hours in the dark to avoid further photo-oxidation of **3**. The resulting mixture was concentrated under reduced pressure and the residue was subjected to silica-gel chromatography (eluent: benzene-ethyl acetate-methanol=20:4:1). The products were eluted in the following order: TPP, sulfide **3**, sulfoxide **4**, and alcohol **5**. When further purification was necessary, the sulfoxide was purified by preparative high pressure liquid chromatography of sufficient sample for measurement of the optical rotation.

b) With $Ti(OPr^i)_4$. To the hydroperoxide (**2**) solution, $Ti(OPr^i)_4$ (1—5 mmol, equimolar of 1) and then sulfide **3** (2—10 mmol) were added subsequently at −30 °C. After the same treatment as above, to the reaction mixture concentrated, water (1—5 cm^3) and alumina (5—30 cm^3) were added. After allowing to stand for a few hours at room temperature and then drying with evaporator and vacuum pump, the resulting powder was poured onto the top of the column and chromatographed.

Hydrogenation and Dimerization of Bicyclo[2.2.1]hepta-2,5-diene Catalyzed by Cobalt(I) Complexes

Hiroyoshi KANAI,* Yoshiyuki WATABE, and Taisei NAKAYAMA
Department of Hydrocarbon Chemistry and Division of Molecular Engineering, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received October 9, 1985)

Synopsis. Bicyclo[2.2.1]hepta-2,5-diene **1** was hydrogenated to bicyclo[2.2.1]hept-2-ene **2** and tricyclo[2.2.1.$0^{2,6}$]heptane **3** in a 70:30 ratio and dimerized to Binor-S **4** by [CoX-(PPh_3)$_3$]-BF_3·Et_2O catalysts (X=halogen). **1** was dimerized to **4**—**7** having tricyclo[2.2.1.$0^{2,6}$]heptane skeletons by a [Co(SCN)(PPh_3)$_3$]-$ZnBr_2$-Zn system in THF.

Conjugated dienes were selectively hydrogenated to terminal olefins by [CoX(PPh_3)$_3$]-BF_3·Et_2O systems (X=halogen),[1] but to *cis*-olefins by [Co(SCN)(PPh_3)$_3$]-$ZnBr_2$-Zn systems.[2] Although bicyclo[2.2.1]hepta-2,5-diene **1** is a nonconjugated diene, π-electron systems are supposed to interact through the through-space overlap.[3] When **1** was treated with the [Co(SCN)-(PPh_3)$_3$]-$ZnBr_2$-Zn catalyst in the presence of hydrogen in 1,2-dimethoxyethane, bicyclo[2.2.1]hept-2-ene **2** (37%) and tricyclo[2.2.1.$0^{2,6}$]heptane **3** (31%) were formed with dimers (32%).[2]

The hydrogenation of **1** with a [CoBr(PPh_3)$_3$]-BF_3·Et_2O catalyst was attempted to give small amounts of **2** and **3** and large amounts of dimers (Table 1). The yield of hydrogenation increased slightly when **1** and BF_3·Et_2O were dropwise added to the cobalt complex solution. The ratio of **3**/**2** is lower than that (45/55) in the [Co(SCN)(PPh_3)$_3$]-$ZnBr_2$-Zn system.

Table 1. Hydrogenation and Dimerization of **1** with [CoX(PPh_3)$_3$]-BF_3·Et_2O Catalysts

X	Time min	Yield/%	
		Hydrogenated products (**2**:**3**)	Dimers (**4**)[a]
Cl	60	5.5 (72:28)	84 (94)
Br[b]	90	19 (68:32)	81 (99)

a) Selectivity of **4** in dimers. b) **1** (2.0 mmol) and BF_3 Et_2O (0.4 mmol) in C_6H_5Cl (5 ml) was added dropwise over 55 min.

Table 2. Dimerization of **1** with [CoX(PPh_3)$_3$]-Lewis Acid Systems

X	Lewis acid[a]	Solvent	Time	Conv.	Yield[b]/%	
			h	%	**4**	Other dimers
Br	BF_3Et_2O (0.14)	C_6H_5Br	2	100	98	0
	(4.1)			100	100	0
	(2.0)	C_6H_5Cl	0.17	—	75	0
		C_6H_5Br		—	85	0
		o-$CH_3C_6H_4Cl$		—	72	0
Cl	BF_3Et_2O (2.0)[c]	C_6H_5Br	10	99	95	0
	$ZnBr_2$ (1.0)		2	46	32	1.6
	(2.0)		14	50	35	1.4
	$AlCl_3$ (1.0)		2	18	2.2	0.5
	$AgClO_4$ (2.0)		14	55	53	0

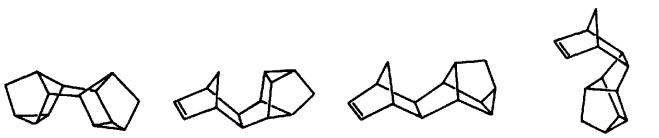
a) The number in parentheses is the ratio of Lewis acid to the cobalt complex. b) Based on **1** added. c) **1** (21.8 mmol, **1**/Co=218) was reacted at 0 °C.

The dimers exclusively consist of endo-*cis*-endo-heptacyclo[5.3.1.$1^{2,6}$.$1^{4,12}$.$1^{9,11}$.$0^{3,5}$.$0^{8,10}$]tetradecane, **4**, usually designated as "Binor-S."[4] [CoX(PPh_3)$_3$] alone has no activity toward the reaction of **1**. When **1** was treated with [CoX(PPh_3)$_3$] and BF_3 in bromobenzene under a nitrogen atmosphere, **4** was selectively produced in a short time. BF_3·Et_2O is superior to $ZnBr_2$ and $AlCl_3$ as the cocatalyst (Table 2). Silver perchlorate reacted with [CoCl(PPh_3)$_3$] to give a cationic complex, [Co(PPh_3)$_3$]$^+$,[1] which was highly selective for the formation of **4** although the yield was low. Lewis acids serve as the production of cationic cobalt complexes. Only slight differences were observed on the reactivity and product composition between halogens in [CoX(PPh_3)$_3$].

Schrauzer et al. have stressed that the formation of **4** with [Zn[Co(CO)$_4$]$_2$] proceeds via a π-complex multicenter process which involves an intermediate containing one molecule of **1** coordinated to each of two cobalt atoms.[4] However, dimerization of **1** to **4** has occurred over mononuclear cationic complexes, binuclear catalysts not being uniquely active for its formation.[5] It is now recognized that monomeric cationic d^8 phosphine complexes including Co, Rh, and Ir are active for the selective formation of **4**.[6]

Haloarenes and arenes are suitable solvents for the reaction, but ethers (tetrahydrofuran and anisole) and dichloromethane are ineffective. Excess of **1** had no effect on the composition of dimers unlike the case with [Zn[Co(CO)$_4$]$_2$] that **4** was obtained exclusively using only a high catalyst to **1** ratio.[4a]

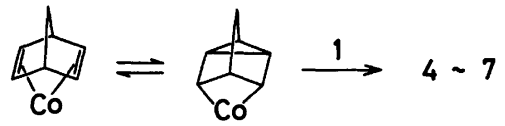
The dimerization of **1** with the [Co(SCN)(PPh_3)$_3$]-$ZnBr_2$-Zn system in THF gave dimers, **4**—**7** and an unidentified dimer(4%):



4 (36%) **5** (40%) **6** (9%) **7** (18%)

The dimers, **4**—**7**, consist at least of one tricyclo-[2.2.1.$0^{2,6}$]heptane skeleton. The catalytic activity and selectivity of the [Co(SCN)(PPh_3)$_3$]-$ZnBr_2$-Zn system are lower than those of [CoX(PPh_3)$_3$]-BF_3·Et_2O.

Deuteration of **1** by the [Co(SCN)(PPh_3)$_3$]-$ZnBr_2$-Zn system occurs specifically via the endo-addition of deuterium.[2] The tricyclo[2.2.1.$0^{2,6}$]heptane skeleton of dimers by both Co(I) complex systems suggests the following likely intermediates:



Tetracyclo[3.2.0.0^{2,7}.0^{4,6}]heptane (quadricyclane) **8** was treated with [CoBr(PPh$_3$)$_3$]–BF$_3$·Et$_2$O to give **4** exclusively. **1** was detected during the formation of **4**—**7** by the reaction of **8** with the [Co(SCN)(PPh$_3$)$_3$]–ZnBr$_2$–Zn system.

Experimental

Chlorobenzene, bromobenzene and *o*-chlorotoluene were commercially purified materials and used without further purification. Tetrahydrofuran was heated over lithium aluminium hydride and distilled just before use. Boron trifluoride–diethyl ether complex, zinc bromide, aluminium chloride and silver perchlorate were used without further purification. [CoX(PPh$_3$)$_3$] (X=Cl, Br) was prepared according to the method described earlier.[7] ^{1}H and ^{13}C NMR spectra were recorded on a Nicolet NT-300 and a JEOL FX-100 spectrometer, respectively.

Hydrogenation and Dimerization of 1 with [CoX(PPh$_3$)$_3$]–BF$_3$·Et$_2$O Catalysts. In a three-necked 100-ml flask [CoX(PPh$_3$)$_3$] (0.1 mmol) was placed. Chlorobenzene (10 ml) was added and the flask was dipped in an ice-water bath after several freeze-thaw operations. The flask was filled with atmospheric pressure of hydrogen and BF$_3$·Et$_2$O (0.2 mmol) and **1** (2.0 mmol) were added successively. After 60 min the products were analyzed by a Shimadzu 6A gas chromatograph (column for hydrogenated products: 30% Apiezon grease L 2 m, 80 °C; column for dimers: 20% SE-30, 2 m, 160 °C, and 20% PEG-20M 2 m, 175 °C). Hydrogenated products were identified as **2** and **3**.[8] **4** was identified by comparing its ^{1}H NMR spectrum with that of an authentic sample.[4]

Dimerization of 1 with [CoX(PPh$_3$)$_3$]–Lewis Acid. To a solution of [CoX(PPh$_3$)$_3$] (0.1 mmol) and Lewis acid in a solvent (10 ml) under nitrogen was added **1** (5.45 mmol) at r.t. and the mixture was stirred for an appropriate period. Dimers were analyzed by GLC.

Dimerization of 1 with [Co(SCN)(PPh$_3$)$_3$]–ZnBr$_2$–Zn System. The catalyst was prepared in situ from the reduction of [Co(SCN)$_2$(PPh$_3$)$_2$] (0.3 mmol) with Zn (3.0 mmol) and ZnBr$_2$ (1.0 mmol) in THF (10 ml) under nitrogen at 17 °C.[2] After the color of the solution changed from purple to brown (2—3 h), **1** (2.0 mmol) was added and the mixture was stirred at 17 °C for 20 h. Dimers were separated by a preparative gas chromatograph (20% SE-30, 2 m, 175 °C) and identified by comparing their ^{1}H and ^{13}C NMR spectra with those of authentic samples.[9]

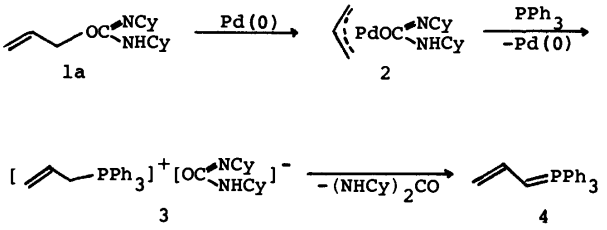
2-Allylisourea as a Starting Material for Palladium-Catalyzed Wittig-Type Allylidenation of Aldehydes

Yoshio INOUE,* Masanori TOYOFUKU, and Harukichi HASHIMOTO
Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Aoba, Aramaki, Sendai 980
(Received November 21, 1985)

Synopsis. 2-Allylic-substituted isoureas underwent Wittig-type allylidenation of aldehydes in the presence of triphenylphosphine and 2 mol% of [Pd(PPh$_3$)$_3$] to give the corresponding conjugated olefins in tolerable to good yields.

π-Allylpalladium chloride complex reacts with several nucleophiles such as stabilized carbanions (pK_a 10—20), enamines, and amines.[1a] The reaction is a well-established and useful synthetic method.[1b] Phosphines are also good nucleophiles, and an excess of triphenylphosphine has actually been shown to react with π-allylpalladium chloride in aqueous acetone to give [Pd(PPh$_3$)$_4$] and an allylic phosphonium salt.[2a] However this finding has not been fully utilized in organic syntheses.[2b,c] For example, the reaction of several aldehydes with allylic alcohols and triphenylphosphine under palladium catalysis has been reported.[2b]

Previously we reported that 2-allyl-1,3-dicyclohexylisourea (**1a**) was an efficient allylating agent for ketones,[3a] imides,[3b] and amides[3c] in the presence of a palladium (0) complex. The suggested reaction pathway involves the π-allyl intermediate **2** which is formed by the oxidative addition of **1a** to a palladium (0) complex. If triphenylphosphine reacts with **2** as a nucleophile, the phosphonium salt **3** may be formed. The isourea anion in **3** is a strong base and is expected to abstract an α-proton to afford allylidenetriphenylphosphorane (**4**). On this consideration we attempted Wittig-type allylidenation of aldehydes catalyzed by palladium (0) employing 2-allylisourea **1a** as the starting material.



A DMF solution of **1a** (1.0 equiv), triphenylphosphine (1.0 equiv), and benzaldehyde (1.0 equiv) was stirred at 50 °C for 3 h in the presence of 2 mol% of [Pd(PPh$_3$)$_3$]. 1-Phenyl-1,3-butadiene (**5a**) was obtained in 86% yield (*E*:*Z*=33:67) after chromatographic work-up. Ketones such as acetone, acetophenone, and benzophenone did not participate in the reaction. Tributylphosphine gave significantly lower yields of the products. Benzene could be used as a solvent in place of DMF without altering appreciably the product composition. Various conjugated olefins could be prepared from aldehydes and allylic-substituted isoureas **1** in tolerable to good yields. The results are shown in Table 1. Employment of an excess **1** increased the yields of the products. Linear dienes were obtained predominantly even though starting from an α-branched isourea, i.e., 2-(1-methyl-2-propenyl)isourea **1b′**. The same mixture as above was also obtained starting from 2-(2-butenyl)isourea **1b** indicating that the intermediate for each should be

same and that triphenylphosphine attacked preferencially the less hindered end of the π-allylic group. The initial *E*-geometry in the isoureas was almost preserved during the course of the reaction, but the stereoselectivity about a newly-formed double bond was not observed.[4]

The present reaction generally provides higher yields of dienes 5 under milder reaction conditions compared to the similar palladium-catalyzed Wittig-type olefinization involving allylic alcohols.[2b] It should be noted that this reaction proceeds under neutal conditions in contrast to the normal Wittig reaction in which basic conditions are adopted for the generation of phosphoranes from phosphonium salts.

Experimental

Materials. Allylic-substituted isoureas 1 were prepared from allylic alcohols and dicyclohexylcarbodiimide in the presence of a catalytic amount of copper(I) chloride according to the reported method.[5] [$Pd(PPh_3)_3$] was synthesized according to the known procedure.[6]

General Procedure for the Olefinization of Aldehydes with 1 (Table 1). A DMF solution (5 cm^3) of an allylic-substituted isourea **1** (2 mmol), triphenylphosphine (524 mg, 2 mmol), and an aldehyde (2 mmol) was stirred at 80 °C under nitrogen in the presence of [$Pd(PPh_3)_3$] (36 mg, 0.04 mmol). After 3 h, the reaction mixture was diluted with diethyl ether and the *N,N'*-dicyclohexylurea formed was filtered off. The filtrate was washed with saturated NaCl solution. The organic layer was dried over $MgSO_4$ and concentrated. The products were isolated by column chromatography on silica gel eluting with hexane. The isomer ratio was determined by GLC (Silicone GE SE-52, 20%, 2 m, for **5a—c**, **5e**, **5f**, or OV-1, 3%, 2 m, for **5d**). Individual isomer was separated by GLC (for **5a—c**, **5e**, **5f**) or TLC (for **5d**; silica gel, hexane/ethyl acetate=20/1).

On the Synthesis of Crystalline and Semicrystalline Tin(IV) Selenophosphate

Syed Ashfaq NABI and Zia Mahmood SIDDIQI*,†
Chemistry Department, Faculty of Education, University of Sebha, Sebha, Libya
†Department of Chemistry, Aligarh Muslim University, Aligarh, U.P., India
(Received October 24, 1984)

Synopsis. Samples of tin(IV) selenophosphate have been synthesized by mixing 0.05 M (1 M=1 mol dm^{-3}) aqueous solutions of tin(IV) chloride, sodium selenite, and sodium dihydrogenphoshate in different volume ratios and at different pH. A crystalline and a semicrystalline products are obtained when the precipitates are refluxed. Ion-exchange behavior of refluxed product is compared with the unrefluxed one.

Despite a large amount of work done on synthetic inorganic ion-exchangers only a little effort has been made to develop crystalline materials. In order to understand the mechanism of ion-exchange phenomenon in a systematic manner the crystallinity of the product is very important.[1] It is with this view in mind we have made an effort to synthesize tin(IV) selenophosphate in different sets of conditions. This report summarizes our findings in this direction.

Experimental

Reagents. Tin(IV) chloride (Baker Analyzed; U. S. A.), sodium selenite (BDH, England), and sodium dihydrogenphosphate (BDH, India) were used for the synthesis of tin(IV) selenophosphate. All other chemicals were of AnalarR grade.

Apparatus. The X-ray diffractometer PW 1140/90 was used for X-ray study.

Synthesis. Samples of tin(IV) selenophosphate were prepared by mixing 0.05M sodium dihydrogenphosphate and 0.05M sodium selenite solutions to 0.05M solution of tin(IV) chloride as described earlier.[2] The pH of mixture was adjusted by adding dilute sodium hydroxide or dilute hydrochloric acid solutions. The precipitate so formed was allowed to settle down for 24 h with mother liquor and then filtered, washed several times with distilled water, and then dried at 40 °C. The precipitate as obtained above was also refluxed for 6 h in various solutions. The refluxed precipitates (R_1, R_2, R_3, and R_4) were then filtered, washed with distilled water, dried at 40 °C, and converted into H^+ form by earlier method.[2] Conditions of synthesis, ion-exchange capacities and appearance of samples of tin(IV) selenophosphate are summarized in Table 1.

Ion-Exchange Capacity. The hydrogen-ion-liberation capacities of samples P_2 and R_3 with different metal ions were determined by column operations as reported earlier.[3] The results are given in Table 2.

X-Ray Diffraction Analysis. Manganese filtered Fe $K\alpha$ radiation was used for X-ray diffraction analyses of all samples. The results are reported in Table 3 and Fig. 1.

Discussion

It is clear from Table 1 that in general the ion-exchange capacity decreases by increasing the pH of solution at constant mixing ratio. It is also observed that there is no significant change in ion-exchange capacity of the material when the precipitate is refluxed for 6 h either in 2M nitric acid or in 2M phosphoric acid. The exchange capacity of tin(IV) selenophosphate (sample R_3) increases when the precipitate of sample P_2 is refluxed in a mixture of selenious acid and phosphoric acid. However, the product (sample R_4) becomes unstable when the precipitate is refluxed with selenious acid alone.

On comparing ion-exchange properties of refluxed product with unrefluxed material it is noted that the former has higher capacities with different metal ions (Table 2). The X-ray analysis of tin(IV) selenophosphate samples indicates that all samples are amorphous except samples R_4 and R_3 which appear to crystalline and semicrystalline. The diffraction pattern of R_4 is more pronounced and well defined (Fig. 1). It is interesting to note that amorphous tin(IV) selenophosphate (sample P_2) becomes crystalline when the precipitate is refluxed in 2M selenious acid for 6 h. The d-values of crystalline product of tin(IV) selenophosphate were calculated by Bragg's equation and are given in Table 3.

The authors are thankful to Professor M. S. Ahmad, Chairman, Department of Chemistry for research facilities and Council of Scientific and Industrial Research, New Delhi for financial assistance.

Hydrogen Bonding in Polyfluoride Ions

Tapas KAR and Abani Bhusan SANNIGRAHI*
Department of Chemistry, Indian Institute of Technology, Kharagpur 721302, India
(Received March 22, 1985)

Synopsis. Hydrogen bonding in the polyfluoride ions ($H_nF_{n+1}^-$, n=1 to 4) has been discussed in the light of atomic charges, bond ionicities, valencies and bond indices calculated from CNDO/2 wave functions. The hydrogen-bond energy in these ions is found to bear a qualitative relation with the bond index of the hydrogen bond.

The polyfluoride ions, in $H_nF_{n+1}^-$, wther n=1 to 4 have been experimentally characterized[1] as strong hydrogen-bonded systems. They are formed by the interaction of F^- with HF molecules. The experimentally determined structures of the polyfluorides show that the HF molecules are all hydrogen bonded to the central fluoride ion. Clark et al.[2] carried out ab initio SCF calculations and determined the electronic structure and hydrogen-bond energy of these systems. They found that HF_2^- possesses a symmetric linear structure, $H_2F_3^-$ a C_{2v} structure, $H_3F_4^-$ a D_{3h} structure and $H_4F_5^-$ a tetrahedral structure. All these ions contain adjacent strong hydrogen bonds and the average hydrogen-bond energy decreases with increasing n. We have in the present note discussed the hydrogen bonding in the polyfluoride ions in the light of atomic charges, bond ionicities, valencies and bond indices. All these quantities were obtained using CNDO/2 wave function.[3]

Method of Calculation. The experimental geometry being not available for all the species, calculations were performed at their ab initio SCF geometry.[2] Valencies (V_A) and bond indices (B_{AB}) where calculated using the following expressions: [4]

$$V_A = 2P_{AA} - \sum_{\lambda}^{A}\sum_{\sigma}^{A}(P_{\lambda\sigma})^2,$$

$$B_{AB} = \sum_{\lambda}^{A}\sum_{\sigma}^{B}(P_{\lambda\sigma})^2,$$

where, P_{AA} is the charge density on atom A and $P_{\lambda\sigma}$ is an element of the density matrix defined over the atomic orbitals. The percentage of ionic character or the ionicity of the bond A–B was calculated from the relation,

$$\%\ \text{Ionic character} = \frac{n_A - n_B}{n_A + n_B} \times 100,$$

where, n_A and n_B are the populations of atom A and B respectively. In order to calculate the atomic populations associated with a given bond, energy localized molecular orbitals (LMO) were obtained for each molecule using the criterion of Edmiston and Ruedenberg.[5]

Results and Discussion

All the LMO's were obtained with a high degree of localization. The nature of the LMO's indicates that the electronic structure of the polyfluoride ions can be described in a classical manner with an adequate numbers of HF bonds and lone pairs on the fluorine atoms. The hydrogen atom was found to be fractionally bonded in all the molecules.

Table 1. Bond Ionicities of the HF Bonds in Polyfluorides

Molecule	Bond	Population		% Ionic character
	X Y	X	Y	
HF	F-H	1.23	0.77	23.00
HF_2^-	F-H	1.63	0.35	63.78
$H_2F_3^-$	F-H	1.46	0.53	46.73
	F···H	1.82	0.14	85.71
$H_3F_4^-$	F-H	1.38	0.62	38.24
	F···H	1.90	0.08	91.92
$H_4F_5^-$	F-H	1.35	0.65	35.06
	F···H	1.93	0.06	93.46

Table 2. Atomic Charges, Valencies, and Bond Indices of Polyfluorides

Molecule	Atom	Atomic charge	Valency	Bond	Bond index
HF	F	−0.23	0.95	F-H	0.95
	H	+0.23	0.95		
HF_2^-	F	−0.65	0.58	F-H	0.46
	H	+0.30	0.92		
$H_2F_3^-$	F^t	−0.48	0.77	F^t-H	0.68
	H	+0.31	0.90	F^c···H	0.22
	F^c	−0.66	0.61		
$H_3F_4^-$	F^t	−0.40	0.84	F^t-H	0.78
	H	+0.30	0.91	F^c···H	0.13
	F^c	−0.70	0.56		
$H_4F_5^-$	F^t	−0.36	0.87	F^t-H	0.82
	H	0.29	0.91	F^c···H	0.09
	F^c	−0.72	0.55		

The percentage of ionic character of the HF bonds is given in Table 1. Of the four hydrogen-bonded species the HF_2^- ion is unique in the sense that it contains two equivalent bonds each of which can be described either by a normal H–F bond as in the HF molecule or by a dotted bond H···F as it is used to describe a hydrogen bond. The other species contain both types of bonds. The HF bond in HF_2^- is found to be more ionic compared to that in the isolated HF molecule, which indicates that the hydrogen-bond formation is accompanied by the weakening of the HF bond. In the other species the ionic character of the F–H bonds decreases and that of the F···H bonds increases as n increases. This implies that the strength of the hydrogen bond in polyfluorides should decrease with increasing n. Ab initio calculations of Clark et al.[2] support this prediction.

Atomic charges, valencies and bond indices of the

polyfluoride ions are given in Table 2. The atomic charge of the central fluorine increases as we go from HF_2^- to $H_4F_5^-$, which indicates that the magnitude of charge transferred from F^- (central fluorine) to HF molecules decreases with increasing n. Since charge transfer plays a very important role in the formation of the hydrogen bond, one may conclude that the strength of the hydrogen bond progressively decreases with the increasing number of HF molecules interacting with F^- ion to form polyfluorides.

Compared to that in the isolated HF molecule, the hydrogen valency decreases slightly upon hydrogen-bond formation. In HF_2^-, the status of the two H–F bonds and consequently that of the two fluorine atoms are identical. The valency of the terminal F atom increases and that of the central fluorine atom decreases with the increasing size of the polyfluoride ion.

The bond index of the F···H bonds gradually decreases and that of the F–H bond increases with increasing n. Since the bond index represents half the number of electrons engaged in covalent bonding, the above trend in bond index indicates that the strength of the hydrogen bond decreases gradually as we pass from HF_2^- to $H_4F_5^-$. Thus we find that the hydrogen-bond energy in the polyfluorides bears a qualitative relation with the bond index of the F···H bond. This can be understood from the fact that the diatomic contribution to the total CNDO/2 energy contains the term $-B_{AB}\gamma_{AB}/2$ which represents the exchange repulsion contribution to the binding energy. In order to verify whether the qualitative relation between bond index and hydrogen-bond energy holds good for other systems, we calculated the hydrogen-bond indices of the dimers and mixed dimers of NH_3, H_2O, and HF. The results are as follows: $(NH_3)_2$ (0.0026), $(H_2O)_2$ (0.0073), NH_3–H_2O (0.0106), $(HF)_2$ (0.0142), H_2O–HF (0.0199), and NH_3–HF (0.0302), where the figures in the parentheses indicate bond index. The experimental hydrogen-bond energy[6] in the above dimers follows the same order. It may be noted that the hydrogen-bond indices in these dimers are considerably less than those in the polyfluorides. It is consistent with the fact that the above dimers are weak hydrogen-bonded systems, while the polyfluorides are very strong hydrogen-bonded systems.

In Situ Trapping of NO. A Generalized Method for the Synthesis of Metal Nitrosyls

Mohammad Ishaque KHAN and Umesh Chandra AGARWALA*
Department of Chemistry, Indian Institute of Technology, Kanpur 208016, India
(Received February 4, 1985)

Synopsis. Several known nitrosyl complexes of Ru, Rh, Ir, Os, Co, and Mo have been synthesized using a more generalized method, using organic *N*-nitroso compounds. Physical methods such as IR, magnetic measurements, conductance measurements, melting points, and elemental analyses were used for the identification of the products of the reactions.

Although the coupling of gaseous NO with transition metal complexes to yield co-ordinated nitrosyls is a well documented process.[1] Its thermodynamic instability has surged interest in developing new synthetic routes for their synthesis. Our continuing interest in devising a new generalized procedure for introducing NO in metal complexes has suggested to us that the susceptibility of N-N bond cleavage in organic *N*-nitroso amino compounds resulting in the generation of NO in situ under mild experimental conditions could possibly provide a basis for such an attempt. This report suggests that such a goal is indeed realizable for incorporating NO in metal complexes.

Experimental

All the reagents used were of chemically pure grade. Carbon, hydrogen, and nitrogen analyses in the complexes were carried out by the microanalytical laboratory of Indian Institute of Technology.

Halide, cobalt, and rhodium in the complexes were analysed by standard methods. For the phosphorus estimation a weighed amount of the sample was decomposed by heating it for about 15 min with a mixture of sodium peroxide, sugar, and sodium nitrate in the ratio 20:1:3 in a Parr-Bomb crucible. The melt was extracted with water and filtered. After adding a few cm^3 of concentrated sulfuric acid to the filtrate it was evaporated to sulfur trioxide fumes. The resulting mixture was cooled, diluted with water, and filtered, if necessary. Phosphorus was estimated in the filtrate as ammonium molybdophosphate by standard procedure.

The IR spectra were recorded on Shimadzu IR-420 spectrophotometer in the region 4000—400 cm^{-1}. Conductivity measurements were carried out on an Elico Conductivity Bridge type-CM82T. Magnetic measurements were made with a Gouy balance at room temperature (25 °C).

In a typical run 10 cm^3 of a solution containing 0.5 mmol of the metal trihalide in methanol, ethanol, 2-methoxyethanol or benzene (as the ease may be, see Table 1) and 1 mmol of the desired *N*-nitroso amines were added successively to a well stirred, argon purged refluxing solution of about 2 mmol of coligand in the same solvent 15 cm^3. A slow stream of hydrogen chloride gas was also allowed to pass simultaneously through the reaction mixture while using *N*-nitroso alkyl amines, *N*-nitroso diethyl amine as nitrosylating agent (whereas dry chlorine gas was passed during the preparation of the dinitrosyl complex of molybdenum). The resulting reaction mixture was allowed to heat under reflux for about 15 to 20 min, where upon shining crystals of the corresponding nitrosyl in about 60% yield separated in most cases. In the case of molybdenum, a greenish yellow solution was obtained which on concentration to a small volume (5 cm^3), followed by addition of ethanol, gave greenish yellow crystals of the dinitrosyl. These crystals were collected by filtration, washed successively with ethanol, water, ethanol, and ether and dried in vacuo.

Results and Discussion

Table 1 illustrated the application of our procedure to the synthesis of various metal-nitrosyls. Since most of these nitrosyls are known, they have been identified by chemical analyses, and by comparing color, melting point, IR spectra, conductance, and magnetic susceptibility data with those reported.

The analytical data of the diamagnetic, non-conducting, greenish brown complex (mp 168 °C) obtained by the reaction of *N*-nitrosodiethylamine with $RuCl_3 \cdot xH_2O$ and PPh_3 in ethanol medium were in perfect agreement with empirical formula $[Ru\{(C_2H_5)_2N(NO)\}Cl_2(PPh_3)_2]$. Its IR spectrum exhibited bands at 1750(s) and 880(mw) cm^{-1}, assigned to ν(NO) and ν(C-N), respectively, in addition to all the characteristic bands of PPh_3 and the ligand.

In order to facilitate the release of NO by protonating the nitrogen atom N-NO, hydrogen chloride gas was passed through the reaction mixture while using *N*-nitrosodiethylamine as nitrosylating agent. The latter failed to nitrosylate without hydrogen chloride, probably because of its inability to acquire hydrogen ion from the reaction medium.

The purpose of passing dry chlorine gas in the reaction medium while preparing $[Mo(NO)_2Cl_2(PPh_3)_2]$, was two fold: (a) to oxidize molybdenum from zero to a higher oxidation state, and (b) to provide a source of chloride ions in the reaction after reduction.

Rapid perusal of Table 1 shows that the *N*-nitroso amino compounds having electron attracting substituents (R), ($\begin{matrix}R\\R\end{matrix}$>N-NO) effect the formation of nitrosyls with ease while the ones with electron-donating groups do not, but for the ruthenium case. The variations in the nitrosylating properties of *N*-nitroso amines may presumably be caused by the variation of electron density on nitrogen which will effect the N-N bond strength. The negative inductive effect (−I) resulting in the decrease of electron density at nitrogen might facilitate the scission of the N-N bond and vice versa. Thus, we expect that the presence of even one of the two substituents like C_6H_5, CN, CO, C_5H_5N, etc., on the nitrogen atom NO substituted will lead to nitrosylating reaction while the *N*-nitroso amines with both electron-donating groups like CH_3, C_2H_5,

Table 1. Preparation of Metal Nitrosyls

etc., on nitrogen atom, will not be effective nitrosylating agents but for ruthenium case. In the latter case the increased basicity of nitrogen (attached to NO group) because of the presence of alkyl groups, may cause *N*-nitroso amines preferentially coordinated to Ru through N atom attached to NO (i. e. $-Ru-N\langle^{R^1}_{R}$). Ruthenium being acid may withdraw electron density from nitrogen effecting the release of NO from the nitroso amines which subsequently attack on ruthenium with the formation of its nitrosyl. Thus, in case the metal ion is of low σ acidity (low oxidation states), the nitrosylation reaction may not take place.

Although the application of this new procedure has not yet been extensively extended, our present evidence indicates that the nitrosylation reactions will take place with *N*-nitroso amino compounds having at least one electron withdrawing group linked to NO substituted nitrogen atom. We believe that extension of the in situ, trapping of NO has an enormous potential for the effecient synthesis of metal nitrosyls which are rather difficult to synthesize under normal reaction conditions.

A New Aspect of the Pressure Effect in Syngas Conversion to Ethylene Glycol

Takashi MASUDA, Kazuhisa MURATA, and Akio MATSUDA*
National Chemical Laboratory for Industry, Tsukuba Research Center, Yatabe, Tsukuba, Ibaraki 305
(Received October 18, 1985)

Synopsis. Pressure effect in syngas conversion to ethylene glycol (EG) is understood in terms of respective partial pressures of hydrogen (P_{H_2}) and carbon monoxide (P_{CO}). A new mechanism is proposed to explain an extraordinary effect of P_{H_2} on the selectivity to EG.

There has been observed a remarkable pressure effect on the rate and the selectivity of syngas conversion to ethylene glycol (EG) in the case of both cobalt,[1,2] and rhodium catalysis.[2,3] Although it has been presumed that both P_{H_2} and P_{CO} are responsible for this pressure effect, its dependency on each of them has never been fully established.[4] We have, therefore, undertaken to clarify the reason for this pressure effect by doing a series of experiments, varrying P_{H_2} at a fixed P_{CO}, and vice versa.

Results and Discussion

Cobalt-catalyzed reactions were performed in a mixed solvent consisting of phenol and *m*-cresol in a weight ratio of 5 to 1, since it is a good solvent for cobalt catalysis according to our previous exploration. While *N*-methyl-2-pyrrolidone (NMP) was used as a solvent for rhodium catalysis, since Rh–NMP is one of the well known system for the EG synthesis.[1] The results of experiments carried out with $Co_2(CO)_8$ 0.855 g (5 mg-atom as Co), phenol 25 g, *m*-cresol 5 g, under various P_{H_2} at 210 °C for 2 h, where P_{CO} was fixed at a constant, 150 kg cm^{-2}, are shown in Fig. 1. The dependency of the rate of EG formation on P_{H_2} is remarkable, the order of EG formation with respect to P_{H_2} being in the range of 2—3. On the other hand, almost linear relation is observed between the rate of methanol formation and P_{H_2}. As a result, the selectivity to EG increases and that to methanol decreases dramatically, as P_{H_2} is increased. The selectivity to methyl formate is almost independent of P_{H_2}.

The results of experiments carried out with Rh(acac)$_3$ 0.08 g (0.2 mg-atom as Rh), NMP 20 g, under various P_{H_2} at 260 °C for 2 h, where P_{CO} was fixed at a constant, 400 kg cm^{-2}, are shown in Fig. 2. As in the case of cobalt catalysis, the dependency of EG formation on P_{H_2} is fairly larger than that of methanol. The order of EG formation with respect to P_{H_2} is about 2, while the rate of methanol formation increases almost linearly with P_{H_2}. Consequently, the selectivity to EG increases and

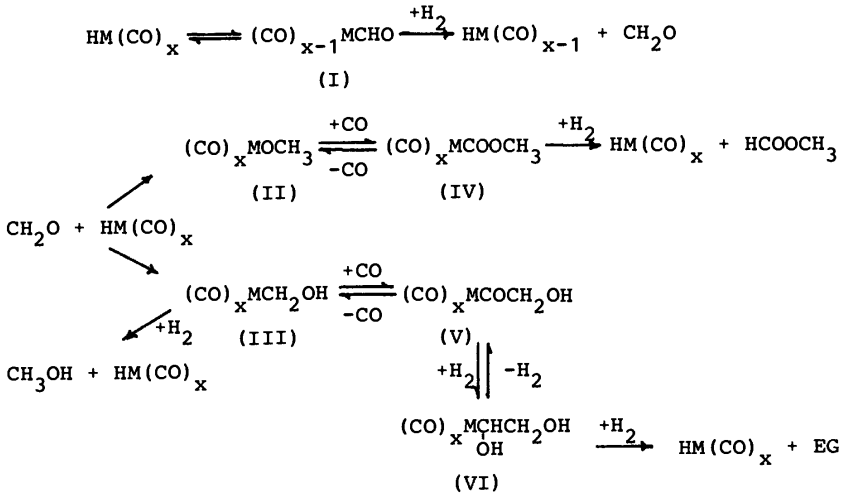
that to methanol decreases as P_{H_2} is increased. The selectivity to glycerol is almost independent of P_{H_2}.

The results of experiments carried out in the same manner as those shown in Fig. 1, except that P_{CO} was varied at a fixed P_{H_2}, 700 kg cm^{-2}, are shown in Fig. 3. The rate of EG formation is almost independent of P_{CO} in the range of 150—200 kg cm^{-2}, but it slightly declines as P_{CO} is increased above that range. On the other hand, the rate of methanol formation is independent of P_{CO} in the range of 200—300 kg cm^{-2}, whereas it sharply increases as P_{CO} is decreased below that range. As a result of these effects, the selectivity to EG showed a maximum and that to methanol a minimum, at the P_{CO} of about 200 kg cm^{-2}. The selectivity to methyl formate slightly increased with increasing P_{CO}. If value *A* (see caption of Fig. 1) is considered as representing the total CO hydrogenation activity, it is clear that the total rate of CO hydrogenation decreases as P_{CO} is increased.

The results of experiments carried out in the same manner as those shown in Fig. 2, except that P_{CO} was varied at a fixed P_{H_2}, 400 kg cm^{-2}, are shown in Fig. 4. Clearly, the rate of EG formation is almost independent of the P_{CO} in the range of 400—600 kg cm^{-2}, but the rate of methanol formation tends to decrease as P_{CO} is increased. As a consequence, the selectivity to EG slightly increases, and that to methanol declines as P_{CO} is increased. It is clear on calculating value *B* (see caption of Fig. 2), that the total rate of CO hydrogenation, in this case, is almost independent of P_{CO}.

In the course of our study of the cobalt catalyzed syngas reaction in the presence of formaldehyde, it was found that phenol-toluene mixture is a suitable solvent for EG formation,[5] and that the formation of unidentified products other than EG and methanol is dramatically suppressed by the presence of a small amount of ruthenium in addition to cobalt. Making use of these previous findings, the effect of P_{H_2} on the selectivity of syngas reaction with formaldehyde, where EG and methanol are the main products, was studied. The reactions were performed in an above mentioned solvent in the presence of $Co_2(CO)_8$ and $Ru_3(CO)_{12}$ in an atomic ratio of 10 to 1, where formaldehyde solution was fed, by means of a pump, to the reactor after the desired reaction temperature and pressure are reached in order to avoid the complexity arising from the reaction of formaldehyde occuring at a lower temper-



Scheme 1.

ature. The results are summarized in Fig. 5. A strikingly similar trend is observed as in the case of direct syngas conversion (cf. Figs. 1 and 2), i.e., the selectivity to EG increases and that to methanol decreases with increase in P_{H_2}.

Since a similar trend is observed in the P_{H_2} dependency of both cobalt- and rhodium-catalyzed reactions, the reactions in both cases are presumed to proceed by a generalized mechanism as shown in Scheme 1, where metal carbonyl hydride species is represented by $HM(CO)_x$ (M is Co or Rh). Formaldehyde intermediate, which is supposed to be produced by the hydrogenolysis of a formyl complex,[2] reacts with $HM(CO)_x$ to produce methoxy intermediate (II) and hydroxymethyl intermediate (III). EG and methanol is considered to be derived from a common intermediate (III), since there is always observed an opposite correlation between the selectivities of EG and methanol (cf. Figs. 1—4). On the other hand, methyl formate, the selectivity to which has any direct relation to neither EG nor methanol (cf. Figs. 1 and 3), is supposed to be derived from another intermediate (II). The hydroxyacetyl intermediate (V) is produced by the reversible addition of CO to intermediate (III), 1,2-dihydroxyethyl intermediate (VI) is produced by the reversible addition of H_2 to intermediate (V). Methanol is produced by the hydrogenolysis of intermediate (III), whereas EG is produced by the hydrogenolysis of intermediate (VI). Therefore, the order of EG formation with respect to P_{H_2} should be distinctively higher than that of methanol according to this scheme. Thus the reason for the effectiveness of hydrogen partial pressure on the EG selectivity is well understood by this mechanism.

Experimental

Apparatus. 100 ml Hastelloy C autoclave fitted with a stirrer; the autoclave is connected at the bottom through a valve to a gas-liquid separator, so that the reaction can be terminated at any desired time by opening the valve. The autoclave is brought to a desired temperature by heating under the pressure of CO or a mixed gas ($H_2/CO=1$), and pressure is readjusted to attain a desired P_{CO}. Then it is compressed with hydrogen to attain a desired P_{H_2}. Total pressure is kept constant (± 20 kg cm^{-2}) by supplying a mixed gas ($H_2/CO=2$) during the reaction.

A Reinterpretation for Ion Association at Micellar Surfaces Due to an Electrostatic Model

Tetsuo KANEKO*
Consulting Services Division, Electric Power Engineering Group, Japan NUS CO., Ltd.,
7-1 Nishi-Shinjuku 2 Chome, Shinjuku-ku, Tokyo 160
(Received September 26, 1985)

Synopsis. Ion association at the surface of a micelle is reinterpreted by considering that counter ions are bound by an electrostatic attraction with a spherical shell which is formed by the aggregation of the polar heads of amphiphilic molecules. It was found that the degree of ion association increased slightly with the increase in the aggregation number of amphiphilic molecules.

The association of counter ions with ionic micelles[1] has been suggested in experimental investigations, and an interpretation regarding it as an electrostatic interaction has been given to this association.[2,3] The investigations instigated by this interpretation have been performed on a basis of a micelle model with a uniform surface-charge density and the thermodynamics of micelle formation. Instead of the surface-charge density, the total charges, which are obtained by summing up the charges of the polar heads of the amphiphilic molecules and counter ions near a micellar surface, are introduced in this paper. As a result, the association of counter ions with an ionic micelle can be estimated according to electrostatics.

In this paper, the distribution of the counter ions which surround an ionic micelle is represented as forming a three-layered geometrical configuration as a result of electrostatic interaction. A reinterpretaton, for which the surface-charge density of a micelle is not introduced, is given to the characteristic of ion association on the basis of this distribution of the counter ions. The three-layered geometrical configuration is formed from a spherical shell composed of the polar head group of amphiphilic molecules, a layer composed of counter ions bound to the spherical shell, and an outermost layer where the movements of ions are not restricted strongly by the electrostatic field. In this investigation, it is assumed that the force which binds the counter ions within the spherical shell composed of the polar head group is electrostatic attraction. A micellar structure which includes counter ions within such a shell has been considered.[4] This micellar structure is taken into account when Gauss' law is applied to the first integration of the Poisson equation in order to obtain an approximate solution for the nonlinear Poisson-Boltzmann equation. An analytical approximate solution for the nonlinear Poisson-Boltzmann equation for a spherical micelle was given by Evans and Ninham.[3] In this paper, the surface potential for an ionized micelle is obtained on the basis of this analytical approximate solution and Gauss' law.

The association of counter ions with a micelle is estimated on the basis of this surface potential. This result gives an ion association independent of the counter-ion concentration if the aggregation number of amphiphilic molecules is constant with the change in the counter-ion concentration. It is interesting that the property independent of the counter-ion concentration is similar to that of a polyion solution. In addition, it was found that the degree of ion association increases slightly with the increase in the aggregation number of amphiphilic molecules. Thus, the dissociation of ionic micelle decreases slightly with an increase in the counter-ion concentration.

Model

In order to examine the association of counter ions with a micelle due to electrostatic attraction, the structure of the micellar surface should be taken into account.

It is assumed that the structure of the micellar surface is like that shown in Fig. 1. The polar heads of amphiphilic molecules in the assumed micellar model exist within a spherical surface ***D*** with a certain radius R, and the counter ions bound within ***D*** remain outside a spherical surface with the radius of $R-\delta R$, i.e., in a shell which has a thickness of δR. The surface potential on ***D*** is obtained by considering the micellar structure to be as is shown in Fig. 1.

The potential ψ around a spherical micelle is represented for a 1-1 electrolyte by this nonlinear Poisson-Boltzmann equation:

$$\frac{d^2\psi}{dr^2} + \frac{2}{r}\cdot\frac{d\psi}{dr} = \frac{8\pi n_0 e}{\varepsilon}\sinh\left(\frac{e\psi}{kT}\right), \tag{1}$$

where n_0 is the bulk electrolyte concentration, ε is the dielectric constant of the solvent, e is the unit charge, k is Boltzmann's constant, and T is the absolute temperature. The approximate solution[3] for the

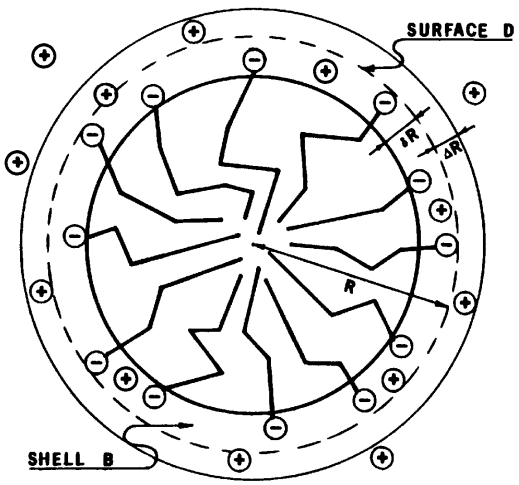

Fig. 1. Model of micelle. Polar head and counter ion are represented as (−) and (+) respectively.

surface potential ψ_0 on **D** which was obtained by Evans and Ninham from Eq. 1 is:

$$S^2 = 4\sinh^2\left(\frac{e\psi_0}{2kT}\right)\cdot\left\{1+\frac{4}{\kappa R}\cdot\frac{1}{\cosh(e\psi_0/2kT)+1}\right\}, \quad (2)$$

where $S \equiv -\frac{e}{\kappa kT}\cdot\left.\frac{d\psi}{dr}\right|_{r=R}$ and $\kappa^2 = 8\pi n_0 e^2/\varepsilon kT$.

In addition, the relation between the first and second terms on the left side of Eq. 1 for a larger r is:

$$\left|\frac{d^2\psi}{dr^2}\right| \gg \left|\frac{2}{r}\cdot\frac{d\psi}{dr}\right|,$$

as may be evaluated easily by the approximate solution of Debye-Hückel. Equation 2 is obtained by considering this relation and by integrating Eq. 1.

On the other hand, the first integration of Eq. 1 and Gauss' law lead to:

$$-\left.\frac{d\psi}{dr}\right|_{r=R} = \frac{Q}{\varepsilon R^2}, \quad (3)$$

where the charge Q has been in this investigation to consist of two terms. One term is caused by the charge of the polar head group; the other one is caused by the charge of the counter ions, which is bound by the potential within the spherical surface **D**. The charge Q which consists of these two terms is represented as:

$$Q = -eN + \int_{R-\delta R}^{R} en_0(\exp[-e\psi/kT] - \exp[e\psi/kT])\cdot 4\pi r^2 dr, \quad (4)$$

where N is the aggregation number of the amphiphilic molecules, assuming that the amphiphilic molecules are negatively ionized. Now, by substituting Eqs. 3 and 4 into Eq. 2, Eq. 2 is modified to the following equation:

$$\frac{e}{\varepsilon\kappa kT}\cdot\frac{1}{R^2}\cdot\{-eN + en_0\exp[-e\psi_0/kT]\cdot 4\pi R^2\cdot\delta R\}$$
$$\approx -\exp[-e\psi_0/2kT] - \frac{4}{\kappa R}, \quad (5)$$

where $e\psi_0/kT<0$ and $\exp[e\psi_0/kT] \ll 1 \ll \exp[-e\psi_0/kT]$ are taken into account, and where the integration in Eq. 4 is approximated by assuming that δR is small. Thus, from Eq. 5 we obtain for the surface potential ψ_0 the following equation:

$$\exp[-e\psi_0/kT] = \left(\frac{\varepsilon\kappa kT}{8\pi e^2 n_0\delta R}\right)^2\cdot$$
$$\left[-1+\sqrt{1+\frac{16\pi e^2 n_0\delta R}{\varepsilon\kappa kT}\left(\frac{e}{\varepsilon\kappa kT}\cdot\frac{eN}{R^2}-\frac{4}{\kappa R}\right)}\right]^2. \quad (6)$$

By using Eq. 6, the association of counter ions with an ionic micelle can be estimated and the behavior of ions known.

Results and Discussion

The number, N_c, of counter ions which are bound by electrostatic attraction within a spherical shell **B** is given by:

$$N_c = \int_{R-\delta R}^{R} n_0\exp[-e\psi/kT]\cdot 4\pi r^2 dr$$
$$\approx 4\pi R^2\delta R\cdot n_0\exp[-e\psi_0/kT].$$

Now, the degree of ion association β for counter ions bound in **B** is represented by the ratio of N_c to N, and, by using Eq. 6, β is represented as:

$$\beta = \frac{\chi_0 TR}{N}\cdot\frac{R}{2\delta R}\cdot\left[-1+\sqrt{1+2\cdot\frac{\delta R}{R}\left(\frac{N}{\chi_0 TR}-4\right)}\right]^2, \quad (7)$$

where $\chi_0=\varepsilon k/e^2$. It should be noted that n_0 does not appear in Eq. 7. This degree of ion association β, which does not include n_0, suggests that if an ionic micelle is associated with more counter ions, $|\psi_0|$ will decrease more and that, as a result, the thermal dissociation of counter ions will occur more easily. On the level of approximation used to obtain Eq. 7, the number of counter ions bound within the shell **B** is entirely independent of the counter-ion concentration if the change of N cannot be induced by the change in the counter-ion concentration. This result is similar to the result that Engström and Wennerström indicate for charged plates.[5] In addition, the characteristic of β shows that the degree of ion association decreases slightly with the increase in T and that it increases slightly with the increase in N.

Now, in order to estimate β, the radius R is determined from these relations:

$$R = (\text{hydrocarbon core radius } R') + (\text{thickness of shell } \delta R)$$

and:

$$(4\pi/3)R'^3 = Nv,$$

and thus:

$$R = (3Nv/4\pi)^{1/3} + \delta R. \quad (8)$$

For v, we use the volume of the hydrocarbon core given by:

$$v = 27.4 + 26.9\nu\ [\text{Å}^3],$$

where ν is close to the number of carbon atoms per chain.[6] In this paper, ν is regarded as the number of carbon atoms per chain. The values of β are shown in table 1, in which we use δR as 3 Å[2] and the R value given by Eq. 8 for lithium dodecyl sulfate (LDS) in order to calculate β.

Furthermore, another degree of ion association, β', for counter ions bond within the spherical surface with radius $R+\Delta R$ shown in Fig. 1 is defined as:

$$\beta' = \frac{1}{N}\cdot\int_{R-\delta R}^{R} n_0\exp[-e\psi/kT]\cdot 4\pi r^2 dr$$
$$+\frac{1}{N}\cdot\int_{R}^{R+\Delta R} n_0\exp[-e\psi/kT]\cdot 4\pi r^2 dr$$
$$\approx \beta + \frac{n_0}{N}\exp[-e\psi_1/kT]\cdot 4\pi(R+\Delta R)^2\Delta R, \quad (9)$$

where $\psi_1=\psi(R+\Delta R)$ and where it is assumed that ΔR is small. In order to estimate ψ_1, by using Gauss' law for the spherical surface with a radius of $R+\Delta R$ on the basis of the treatment introduced in the Model, we obtain:

$$-\left.\frac{d\psi}{dr}\right|_{r=R+\Delta R} = \frac{-eN}{\varepsilon(R+\Delta R)^2}$$
$$\cdot\left\{(1-\beta)-4\pi\Delta R(R+\Delta R)^2\frac{n_0}{N}\exp[-e\psi_1/kT]\right\},$$

Table 1. Values of β and β' Calculated for LDS

T	LDS	LiCl[a]	N[b]	β	β'
K	mol dm^{-3}	mol dm^{-3}			
308	0.074	0.0	57	0.32	0.43
308	0.074	0.2	81	0.37	0.50
308	0.074	0.4	92	0.39	0.52

310	0.294	0.0	71	0.36	0.47

a) Salt concentration in the solution of LDS. b) Data resulting from small-angle neutron-scattering data analysis for an LDS micellar system.[7]

and by substituting this equation into Eq. 2 for $r = R+\Delta R$, we obtain:

$$\exp[-e\phi_1/kT] = \frac{x_0 T}{8\pi n_0 \Delta R^2} \cdot \left[-1+\sqrt{1+\frac{2\Delta R}{R+\Delta R}\cdot\left\{\frac{N(1-\beta)}{x_0 T(R+\Delta R)}-4\right\}}\right]^2. \quad (10)$$

Therefore, by substituting Eq. 10 into Eq. 9, the following formula for β' is obtained:

$$\beta' = \beta + \frac{x_0 T(R+\Delta R)}{N}\cdot\frac{R+\Delta R}{2\Delta R}\cdot \left[-1+\sqrt{1+\frac{2\Delta R}{R+\Delta R}\left\{\frac{N(1-\beta)}{x_0 T(R+\Delta R)}-4\right\}}\right]^2. \quad (11)$$

The thickness of the shell ΔR included in Eq. 11 is:

$$\Delta R = 5.56 - \delta R\,[\text{Å}],$$

where 5.56Å is the mean diameter of a spherical polar head of dodecyl sulfate obtained by neutron scattering for an LDS solution.[7] It has been assumed here that the value of 5.56Å corresponds to $\delta R+\Delta R$ in the micellar model shown in Fig. 1. Thus, the values of β' obtained by Eq. 11 are shown in Table 1. These values of β' nearly all fall in the range of 0.5—0.8, indicating generally the degree of ion association. The change in β' with the change in the LDS concentration corresponds to the behavior of the degree of ion association obtained experimentally.[7] The values of β' in Table 1 indicate that the degree of ionic dissociation for an ionic micelle decreases slightly with the increase in the counter-ion concentration. Also, it is found that the micelles of smaller aggregation numbers have a higher degree of ionic dissociation; this is because of the characteristic of β' depending on the change in N.

If dissociation occurs in a micelle, the micelle becomes less stable due to an electrostatic repulsion between the polar heads of the amphiphilic molecules. The micelles of smaller aggregation numbers are less stable because of this electrostatic repulsion. On the contrary, instability due to the electrostatic repulsion decreases with the increase in N, because β values are larger for larger N values. As a result, we infer that the balance point between the hydrophobic effect for aiding micellar formation and an electrostatic repulsion disturbing micellar formation exists if N is larger than a certain value, although we can not discuss this balance point without the thermal influence factor.

We conclude that the characteristic of β' agrees well with the general property of ion association with an ionic micelle, although the value of δR has not yet been determined well enough.

Conclusions

Pictures of a micelle with wetted outer layers surrounded by spherical polar head groups with an average diameter equal to 5.56Å, pictures taken on the basis of neutron scattering, have been presented by Bendedouch, Chen, and Koehler.[7] We have divided such a wetted outer layer into two layers consisting of two spherical shells, as is shown in Fig. 1. The values of β' calculated by considering the two spherical shells nearly all fall in the range of 0.5—0.8, indicating generally the degree of ion association, although the value of δR used for calculating may have some uncertainty.

In addition, it has been found that the value of β' is independent of the counter-ion concentration, although the constancy of N is required as a condition. It is also noticed that this characteristic of β' may represent the property of a polyion solution.

The author wishes to express his thanks to Professor Tetsurou Ishiguro, Faculty of Science and Engineering, Chuo University, for valuable advice, and to Kazumi Kogure for reading and criticizing the manuscript.

Synopsis. Four new mixed-ligand chromium(III) complexes, $[Cr(acac)(bpy)(L)]^{2+}$ and $[Cr(bpy)(phen)(L)]^{3+}$, where L denotes a seven-membered chelate ligand, 2,2′-bipyridine *N,N′*-dioxide (bpdo) or its 3,3′-dimethyl derivative (mbdo), were prepared and resolved. All of the complexes formed only one of two possible racemic pairs of diastereomers. The pair was assigned to have an *ob*($\Delta(\delta)$, $\Lambda(\lambda)$) structure on the basis of the circular dichroism spectra and the absolute configuration of optically active mbdo recovered from the resolved complex.

2,2′-Bipyridine *N,N′*-dioxide (bpdo)[1] and 3,3′-dimethyl-2,2′-bipyridine *N,N′*-dioxide (mbdo)[2] form a skew seven-membered chelate ring, δ and λ, upon coordination (Fig. 1). Recently, we found that the conformations of these dioxide ligands (L) in mixed-ligand chromium(III) complexes are greatly influenced by the other ligands in the complex. Thus, $[Cr(en)_2(bpdo)]^{3+}$ [3] and $[Cr(acac)_2(L)]^{+}$ [4] formed only a *lel*($\Delta(\lambda)$, $\Lambda(\delta)$) isomer, whereas $[Cr(bpy\text{ or }phen)_2(L)]^{3+}$ [5] formed an *ob*($\Delta(\delta)$, $\Lambda(\lambda)$) isomer of two possible ones, *lel* and *ob*. Here, en, acac, bpy, and phen denote ethylenediamine, acetylacetonate(−1), 2,2′-bipyridine, and 1,10-phenanthroline, respectively. An examination using molecular models indicated that such a difference in selectivity comes from steric interactions among the ligands in the complex.

In this paper, we report on the preparation and stereochemistry of chromium(III) complexes which consist of three different bidentate ligands, $[Cr(acac)(bpy)(L)]^{2+}$ and $[Cr(bpy)(phen)(L)]^{3+}$. Since acac, bpy, and phen form planar chelate rings in a complex, these complexes can have two racemic pairs of diastereomers, *lel* and *ob*.

Experimental

Since the new complexes are photosensitive causing hydrolysis, the following experiments were carried out in the dark.

Preparation of $[Cr(acac)_2(bpy)]Cl\cdot 2.5H_2O$. The complex was prepared according to a method similar to that for $[Cr(acac)_2(phen)]ClO_4$.[6] An aqueous ethanol solution (90%, 300 cm³) containing $[Cr(acac)_3]$ (3.0 g, 8.6 mmol), bpy (4.0 g, 25.6 mmol), and concd HCl (3 cm³) was kept at 80 °C for 2 d with stirring. The resulting solution was evaporated under reduced pressure to give pink crystals. They were collected by filtration, washed with 2 mol dm⁻³ HCl and acetone, and recrystallized from hot water. Yield: 1.9 g (45%). Found: C, 49.19; H, 5.30; N, 5.68%. Calcd for $C_{20}H_{22}N_2O_4ClCr\cdot 2.5H_2O$: C, 49.34; H, 5.59; N, 5.75%.

Preparation and Resolution of [Cr(acac)(bpy)(bpdo or mbdo)]$(ClO_4)_2$. An aqueous 0.2 mol dm⁻³ HCl solution (50 cm³) containing $[Cr(acac)_2(bpy)]Cl\cdot 2.5H_2O$ (2.0 g, 4.1 mmol) was kept at 60 °C for 2 d with stirring. To the resulting solution, $NaClO_4$ (2.5 g) and bpdo·H_2O[7] (1.2 g, 5.8 mmol) or racemic mbdo[2] (1.3 g, 6.0 mmol) were added. The solution was again kept at 60 °C for 8 h with stirring to give reddish-brown crystals. They were collected by filtration, washed with cold water, and recrystallized from hot water. Yield: the bpdo complex, 1.1 g (41%); the mbdo complex, 1.3 g (43%). Found for the bpdo complex: C, 42.99; H, 3.31; N, 7.99%. Calcd for $C_{25}H_{23}N_4O_{12}Cl_2Cr$: C, 43.24; H, 3.34; N, 8.07%. Found for the mbdo complex: C, 44.78; H, 3.76; N, 7.68%. Calcd for $C_{27}H_{27}N_4O_{12}Cl_2Cr$: C, 44.89; H, 3.77; N, 7.76%. Each complex gave only one racemic pair of diastereomers, no indication for the formation of another isomer being detected on column chromatograms.

The complexes were resolved by SP-Sephadex C-25 column chromatography. The perchlorate of each complex (0.08 g) was loaded on a column (ϕ2.2×130 cm) of SP-Sephadex and eluted with a 0.15 mol dm⁻³ Na_2SO_4 solution. Although only one band was observed on the column, the front and rear fractions of the band showed positive and negative rotations at 546 nm, respectively. The fractions which showed a constant specific rotation were combined, diluted with water, and poured again on a small column (ϕ2.2×3 cm) of SP-Sephadex. The adsorbed complex was eluted with a 2 mol dm⁻³ NaCl solution. The eluate was mixed with $NaClO_4$ to give reddish-brown crystals. They were collected by filtration, washed with a small amount of cold water, and recrystallized from hot water. Found for the $(+)_{546}$-isomer of the bpdo complex: C, 43.14; H, 3.33; N, 8.03%. Calcd for $C_{25}H_{23}N_4O_{12}Cl_2Cr$: C, 43.24; H, 3.34; N, 8.07%. Found for the $(+)_{546}$-isomer of the mbdo complex: C, 44.66; H, 3.73; N, 7.68%. Calcd for $C_{27}H_{27}N_4O_{12}Cl_2Cr$: C, 44.89; H, 3.77; N, 7.76%.

Preparation and Resolution of [Cr(bpy)(phen)(bpdo or mbdo)]$(ClO_4)_3\cdot H_2O$. The complexes were prepared by a method similar to that for $[Cr(phen)_2(bpdo)](ClO_4)_3$[5] using $[Cr_2(OH)_2(bpy)_2(phen)_2](NO_3)_4\cdot 6H_2O$[8] and the dioxide ligand. The complexes were obtained as orange crystals. Yield: the bpdo complex, 34%; the mbdo complex, 27%. Found for the bpdo complex: C, 42.98; H, 2.69; N, 9.48%. Calcd for $C_{32}H_{24}N_6O_{14}Cl_3Cr\cdot H_2O$: C, 43.04; H, 2.93; N, 9.41%. Found for the mbdo complex: C, 44.10; H, 2.98; N, 9.00%. Calcd for $C_{34}H_{28}N_6O_{14}Cl_3Cr\cdot H_2O$: C, 44.34; H, 3.28; N, 9.12%. Each complex gave only one racemic pair of diastereomers, no indication for the formation of another isomer being detected on column chromatograms.

The complexes were completely resolved by SP-Sephadex column chromatography using a 0.15 mol dm⁻³ $Na_2[Sb_2((+)_{589}\text{-tart})_2]$ solution as an eluent. The $(+)_{589}$-isomer was eluted faster from the column. The optically

active complex was isolated as the perchlorate by the same method as that for $(-)_{589}$-$[Cr(phen)_2(bpdo)]^{3+}$.[5] Found for the $(-)_{589}$-isomer of the bpdo complex: C, 43.15; H, 2.74; N, 9.41%. Calcd for $C_{32}H_{24}N_6O_{14}Cl_3Cr \cdot H_2O$: C, 43.04; H, 2.93; N, 9.41%. Found for the $(-)_{589}$-isomer of the mbdo complex: C, 44.13; H, 2.98; N, 9.10%. Calcd for $C_{34}H_{28}N_6O_{14}Cl_3Cr \cdot H_2O$: C, 44.34; H, 3.28; N, 9.12%.

Recovery of mbdo from the Complexes. The optically active mbdo was recovered from $(+)_{546}$-$[Cr(acac)(bpy)(mbdo)]^{2+}$ and $(-)_{589}$-$[Cr(bpy)(phen)(mbdo)]^{3+}$ by the same method as that for $[Cr(mbdo)_3]^{3+}$.[2] Both recovered mbdo showed positive rotations at 589 nm.

Measurements. Absorption and circular dichroism (CD) spectra were recorded on a Shimadzu MPS-50L spectrophotometer and a Jasco J-40 spectropolarimeter, respectively. Optical rotations were measured with a Union PM-101 polarimeter.

Results and Discussion

Each of the complexes, $[Cr(acac)(bpy)(L)]^{2+}$ and $[Cr(bpy)(phen)(L)]^{3+}$ (L=bpdo, mbdo), formed only one of two possible racemic pairs, *lel*($\Delta(\lambda)$, $\Lambda(\delta)$) and *ob*($\Delta(\delta)$, $\Lambda(\lambda)$). The bpy·phen complexes were completely resolved by SP-Sephadex column chromatography using $Na_2[Sb_2((+)_{589}\text{-tart})_2]$ as an eluent, but the acac·bpy complexes were not under the same chromatographic conditions. Their resolutions were achieved by SP-Sephadex column chromatography using an achiral eluting agent Na_2SO_4, although the columns showed only one band. All the active complexes in aqueous solutions were optically stable in the dark, but gradually hydrolyzed in the light.

The absorption and CD spectra of $(+)_{546}$-$[Cr(acac)(bpy)(L)]^{2+}$ and $(-)_{589}$-$[Cr(bpy)(phen)(L)]^{3+}$ are shown in Fig. 2. The spectral data in the region of the first absorption band are listed in the Table. The

	20.70(1.76)	21.32(+2.05)
$(-)_{589}$-[Cr(bpy)-(phen)(bpdo)]$^{3+}$	18.7 (1.5)[b]	18.25(−2.13)
	20.88(1.78)	21.28(+1.24)

a) Values of ε and Δε are given in $mol^{-1}\,dm^3\,cm^{-1}$. b) Shoulder.

absorption spectra of the bpdo and mbdo complexes are nearly the same over the whole region. The bands at ca. 19000 cm^{-1} with a shoulder (ca. 17000 cm^{-1}) for the acac·bpy complexes and at ca. 21000 cm^{-1} with a shoulder (18700 cm^{-1}) for the bpy·phen complexes can be assigned to the first absorption band ($^4T_{2g} \leftarrow {}^4A_{2g}$). In the higher energy region, the complexes show complicated spectra due to absorptions of the three kinds of ligands. In this region, however, the spectra of the bpy·phen and acac·bpy complexes are very similar to the average of those of the corresponding bis-bpy and bis-phen complexes,[5] and bis-acac,[4] and bis-bpy complexes, respectively.

The CD spectra of the complexes are similar in pattern over the whole region. This suggests that all the isomers have the same absolute configuration, including the chirality of the skew dioxide chelate ring. The spectra are very similar to those of $\Delta(\delta)$-$[Cr(bpy\text{ or }phen)_2(L)]^{3+}$,[5] but quite different from those of $\Delta(\lambda)$-$[Cr(acac)_2(L)]^+$.[4] Thus, all the isomers have the $\Delta(\delta)$ structure.

The free mbdo ligand is optically stable and can be recovered from the complex.[2] Both mbdo recovered from $(+)_{546}$-$[Cr(acac)(bpy)(mbdo)]^{2+}$ and $(-)_{589}$-$[Cr(bpy)(phen)(mbdo)]^{3+}$ showed positive rotations at 589 nm. The $(+)_{589}$-mbdo ligand was assigned to the *S* configuration and forms a δ skew chelate ring in a complex.[2] This is consistent with the structure ($\Delta(\delta)$) of the complexes assigned on the basis of the CD spectra. Since the bpdo complexes give CD spectra similar to those of the corresponding mbdo complexes over the whole region, it is concluded that the bpdo complexes also form an *ob*($\Delta(\delta)$, $\Lambda(\lambda)$) isomer stereoselectively. While it is expected that $[Cr(bpy)(phen)(L)]^{3+}$ forms the same *ob* isomer as $[Cr(bpy\text{ or }phen)_2(L)]^{3+}$, the selectivity of $[Cr(acac)(bpy)(L)]^{2+}$ differs from that of $[Cr(acac)_2(L)]^+$ which gives only a *lel* isomer.[4] Molecular models indicate that in *lel*-$[Cr(acac)(bpy)(L)]^{2+}$ the 6(6′)-hydrogen atom of bpy comes very close to the 6(6′)-carbon (and hydrogen) atom of the dioxide. There is no such extreme proximity between the acac and dioxide ligands in both *lel* and *ob* forms. In the *ob* form, one of the pyridine rings of the dioxide is nearly parallel to the diimine ligand to form a stable structure. The selective formation of *ob*-$[Cr(acac)(bpy)(L)]^{2+}$ is attributable to such steric conditions.

This work was partially supported by a Grant-in-Aid for Scientific Research No. 60740330 from the Ministry of Education, Science and Culture.

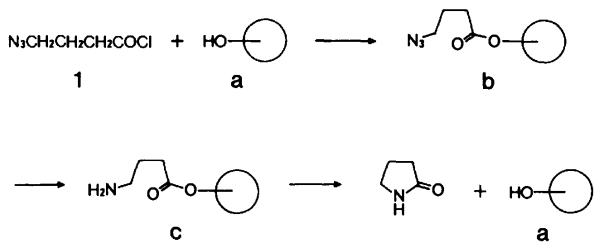
4-Azidobutyryl Group for Temporary Protection of Hydroxyl Functions

Shoichi KUSUMOTO,* Keiichiro SAKAI, and Tetsuo SHIBA
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received September 24, 1985)

Synopsis. 4-Azidobutyryl esters formed from hydroxyl compounds and 4-azidobutyryl chloride were shown to be cleaved via reduction to 4-aminobutyrate followed by intramolecular O→N-acyl migrations to regenerate the free hydroxyl groups. High susceptibility of azide group to reduction enables the selective removal of this acyl group leaving many other functional groups unchanged.

In the synthetic studies on complex carbohydrates and other polyhydroxylated natural products, selective protection of particular hydroxyl groups is always required. For this purpose, various protecting groups have been proposed. However, during our recent synthetic studies on complex glycolipids, we realized that new types of protecting groups other than known ones are still required to facilitate the synthesis. We thus examined the use of 4-azidobutyryl group and found that this acyl group is versatile for temporary protection of hydroxyl functions.



As the reagent for the introduction of 4-azidobutyryl group, the corresponding 4-azidobutyryl chloride (**1**) was prepared from γ-butyrolactone in four steps. Thus, opening of the γ-lactone[1] afforded ethyl 4-chlorobutyrate (**2**), which was then converted to ethyl 4-azidobutyrate (**3**).[2] Alkaline hydrolysis of **3** followed by reaction with thionyl chloride gave the desired chloride **1** as a colorless oil.[3]

Acylation of hydroxyl groups with this chloride (**1**) proceeded readily. The yields of the reaction with several substrates are summarized in Table 1.

We anticipated that the 4-aminobutyryl function which is formed on reduction of 4-azidobutyryl group would cause facile intramolecular O→N-acyl migration to regenerate the free hydroxyl group as shown in the scheme.[4] The only by-product formed thereby would be 2-pyrrolidinone which could be removed readily. Paulsen et al. described acylation of a trisaccharide with the chloride **1** and reduction of the resulting 4-azidobutyrate. However, they did not attempted the cleavage of the amino acyl group formed.[5]

One of the 4-azidobutyryl derivatives (**4b**) listed in Table 1 was then subjected to hydrogenolysis with palladium catalyst. TLC analysis revealed the presence of a small amount of the deacylated product (**4a**) in the reaction mixture together with the 4-aminobutyrate which gave a ninhydrin-positive spot. This indicated that the spontaneous deacylation certainly occurred even at room temperature, though the reaction rate was slow. The reaction was accelerated in boiling ethanol and completed within 1.5 h. The yield of deacylation step was 91% from **4b** as determined by HPLC analysis.

Owing to the high susceptibility of azide to catalytic hydrogenolysis, 4-azidobutyryl group can be selectively reduced and thus removed without affecting *O*-benzyl function in the same molecule as demonstrated in the deprotection of compound **5b**. Since benzyl ether is frequently employed as a persistent protecting group in many synthetic works, use of 4-azidobutyryl group would provide much flexibil-

ity to the synthetic plan for complex target compounds.

Selective cleavage of 4-azidobutyryl group was next attempted in the presence of olefinic double bond. Though the hydrogenolysis of the azide group was faster than saturation of the allyl group in compound **6b**, fully selective reduction of the former was not possible with palladium-black.[6] Several other catalyst such as Raney nickel with absorbed hydrogen or palladium on calcium sulfate were examined but shown to give similar results. Selective reduction was effected chemically as follows. By use of triphenylphosphine, reduction to aminobutyryl group and its cleavage proceeded in boiling dioxane in rather short time in one step. In THF or ethanol, the reaction was slow even at reflux temperature and the yield of the deacylated product decreased due to the formation of an unidentified by-product. Use of hydrogen sulfide gave more satisfactory results. Thus, reduction of **6b** in a mixture of pyridine–water with hydrogen sulfide at room temperature[7] followed by cleavage by heating in ethanol as above gave **6a** in a high yield (Table 1). At higher temperature than 60 °C in the same solvent mixture,[7] reduction and cleavage took place successively but at such temperature the solution colored deeply and the yield of the product was very low.

In addition, the azidobutyryl group proved to survive under reaction conditions employed for cleavage of some other temporary protecting groups. For example, compound **6b** did not changed at all by heating in acetic acid–water (9:1) for 1 h. Thus, isopropylidene and benzylidene groups can be removed without affecting the azidobutyryl group. Furthermore, the allyl group in **6b** was removed through isomerization with an iridium complex,[8] followed by cleavage with iodine[9] to give **7b**, the azidobutyryl group being thereby unaffected.

In conclusion, 4-azidobutyryl group can be used as a new versatile acyl-type protecting group for hydroxyl functions. It can be easily introduced and has sufficient stability as well as a prominent feature to be cleaved preferentially to most of the other known protecting groups.

Experimental

All melting points and boiling points are not corrected. HPLC was performed with Shimadzu LC-5A liquid chromatograph apparatus equipped with a Cosmosil $5C_{18}$ column (4×125 mm); solvent: CH_3CN–H_2O (45:55); detection: absorbance at 254 nm. For quantitative determination of a deprotection product, a known amount of benzophenone was added to the reaction mixture as an internal standard, the peak area determined by use of an integrator (Shimadzu Chromatopac C-R1A) and amount of the product calculated.

Ethyl 4-Azidobutyrate (3). Sodium azide (34.4 g, 0.531 mol) and 15-crown-5 (5.8 g, 0.027 mol) were added to a solution of ethyl 4-chlorobutyrate (**2**)[1] (40 g, 0.266 mol) in CH_3CN (160 ml). The mixture was heated under reflux for 12 h. The completion of the reaction was confirmed with GLC (polyethylene glycol HT, 120 °C), After usual work-up, the product was distilled in vacuo; yield 39.6 g (95%), bp 96.5—98.5 °C/16 mmHg (1 mmHg=133.322 Pa). ^{1}H-NMR and IR spectra of this product were identical to the data given by Keschmann and Zbiral.[2]

4-Azidobutyryl Chloride (1). Azido ester **3** (13.0 g, 82.7 mmol) was heated in a solution of KOH (5.6 g, 100 mmol) in EtOH (270 ml) under reflux for 2 h. After evaporation of the solvent and acidification (HCl), the product was extracted with ether, and worked up as usual. Thionyl chloride (9.0 ml, 123 mmol) was added to a solution of the oily product in benzene. The mixture was stirred at room temperature for 30 min and then heated under reflux for 1.5 h. Evaporation in vacuo followed by vacuum distillation afforded the chloride 1; yield 9.66 g (79%), bp 90—91 °C/16 mmHg. EI-MS: *m/z* 147 (M^+). ^{1}H-NMR ($CDCl_3$) δ=1.94 (2H, quintet), 3.02 (2H, t, J=7.1 Hz), and 3.38 (2H, t, J=6.5 Hz).

Propyl 2-Acetamido-3,6-di-*O*-benzoyl-2-deoxy-β-D-glucopyranoside (4a). Allyl 2-acetamido-3,6-di-*O*-benzoyl-2-deoxy-β-D-glucopyranoside (**6a**)[10] (300 g, 6.39 mmol) was hydrogenated with Pd-black in EtOH (150 ml) at room temperature and recrystallized from EtOAc; yield 2.35 g (78%), mp 180—182 °C. Found: C, 63.42; H, 6.18; N, 2.95%. Calcd for $C_{25}H_{29}NO_8$: C, 63.88; H, 6.20; N, 2.95%.

Propyl 2-Acetamido-4-*O*-(4-azidobutyryl)-3,6-di-*O*-benzoyl-2-deoxy-β-D-glucopyranoside (4b). To an ice-cooled solution of **4a** (500 mg, 1.06 mmol) and pyridine (0.17 ml, 2.1 mmol) in CH_2Cl_2 (25 ml) was added the chloride **1** (235 mg, 1.59 mmol). The mixture was stirred at room temperature for 4.5 h. The mixture was worked up as usual and the product recrystallized from EtOAc–hexane; yield 590 mg (95%); mp 142—144 °C, IR (nujol) 2100 cm^{-1} (N_3); $[\alpha]_D^{15}$ +0.40° (*c* 1.00, $CHCl_3$). Found: C, 59.66; H, 5.83; N, 9.52%. Calcd for $C_{29}H_{34}N_4O_9$: C, 59.79; H, 5.88; N, 9.62%.

Propyl 2-Acetamido-3-*O*-benzoyl-4-*O*-benzyl-2-deoxy-β-D-glucopyranoside (5a). Allyl 2-acetamido-3-*O*-benzoyl-4-*O*-benzyl-2-deoxy-β-D-glucopyranoside[10] (494 mg, 1.08 mmol) was hydrogenated as described for **4a**. The completion of the reaction was checked by HPLC. After usual work-up the product was recrystallized from EtOAc; yield 437 mg (88%); mp 171—172 °C; $[\alpha]_D^{24}$ −46.9° (*c* 1.00, $CHCl_3$). Found: C, 65.53; H, 6.85; N, 3.08%. Calcd for $C_{25}H_{31}NO_7$: C, 65.63; H, 6.83; N, 3.06%.

Propyl 2-Acetamido-6-*O*-(4-azidobutyryl)-3-*O*-benzoyl-4-*O*-benzyl-2-deoxy-β-D-glucopyranoside (5b). Compound **5a** was acylated with 4-azidobutyryl chloride (1) and pyridine in CH_2Cl_2 as described above for the preparation of **4b**. The product was recrystallized from EtOAc–hexane; yield 1.19 g (96%); mp 110 °C; IR (nujol) 2100 cm^{-1} (N_3); $[\alpha]_D^{24}$ −15.3° (*c* 1.00, $CHCl_3$). Found: C, 61.26; H, 6.35; N, 9.80%. Calcd for $C_{29}H_{36}N_4O_8$: C, 61.26; H, 6.38; N, 9.85%.

Allyl 2-Acetamido-4-*O*-(4-azidobutyryl)-3,6-di-*O*-benzoyl-2-deoxy-β-D-glucopyranoside (6b). Compound **6a**[10] was acylated with the chloride **1** as described above. The product was recrystallized from EtOAc–hexane; yield 739 mg (85%); mp 127—128 °C; $[\alpha]_D^{24}$ −1.20° (*c* 1.00, $CHCl_3$). Found: C, 60.05; H, 5.52; N, 9.62%. Calcd for $C_{29}H_{39}N_4O_9$: C, 59.99; H, 5.56; N, 9.65%.

Removal of 4-Azidobutyryl Group of 4b and 5b via Catalytic Hydrogenolysis. a) Compound **4b** (290 mg, 0.500 mmol) was dissolved in EtOH (10 ml) and hydrogenolyzed in the presence of Pd-black (50 mg) at room temperature under atmospheric pressure of H_2. After 3 h disappearance of the starting material was confirmed by TLC. The catalyst was filtered off, and the filtrate was heated under reflux for 1.5 h. Yield of **4a** was 91% as determined by HPLC (see above). Isolation yield after recrystallization from EtOAc–hexane was 195 mg (83%); mp 178—180 °C. The product was identified with an authentic specimen of **4a** by means of TLC and ^{1}H-NMR.

b) Compound **5b** (569 mg, 1.00 mmol) was hydrogenolyzed and heated in ethanol as described above for **4b**.

Recrystallization from EtOAc gave a product which was identical with an authentic specimen of **5a**; yield 428 mg (93%); mp 169—171 °C.

Removal of 4-Azidobutyryl Group of 6b. a) With Triphenylphosphine: Triphenylphosphine (24.3 mg, 0.12 mmol) was added to a solution of **6b** (58.0 mg, 0.10 mmol) in dioxane (10 ml) heated under reflux. Heating was continued for 2.5 h.[11] The mixture was then kept at 80 °C for additional 1.5 h. The yield of **6a** was 78% (HPLC, see above). The product was isolated by silica-gel column chromatography (silica gel, 10 g; $CHCl_3$–MeOH 15:1) and recrystallized from EtOAc–hexane. It was identified with an authentic sample of **6a** by means of TLC, HPLC and ^{1}H-NMR.

b) With Hydrogen Sulfide: Hydrogen sulfide was bubbled through a solution of **6b** (21.0 mg, 36.2 mmol) in a mixture of pyridine–H_2O (2:1) (4 ml) at room temperature for 2 h. The mixture was then kept in a stoppered bottle at room temperature for 2 d. After the solvent had been removed in vacuo, EtOH was added to the residue and insoluble materials were filtered off. The filtrate was heated under reflux for 2 h. The yield of **6a** was 95% (HPLC, see above). The isolated product was identified with **6a** as above.

2-Acetamido-4-*O*-(4-azidobutyryl)-3,6-di-*O*-benzoyl-2-deoxy-D-glucose (7b). Compound **6b** (300 mg, 0.517 mmol) and $Ir(COD)[PCH_3(C_6H_5)_2]_2PF_6$[8] (15 mg) was dissolved in degassed THF (5 ml). The catalyst was activated as described in the literature.[8] The solution was then stirred at 50 °C for 1.5 h. After cooling, H_2O and I_2 (260 mg, 1.00 mmol) were added and the mixture was stirred at room temperature for 30 min. A 5% aqueous solution of $NaHSO_3$ was added to the mixture until the color of I_2 disappeared. The mixture was extracted with $CHCl_3$, the organic layer washed successively with aqueous $NaHSO_3$ solution and water. The product was purified with a silica-gel column (10 g, $CHCl_3$–acetone 5:1) and recrystallized from EtOAc–hexane; yield 230 mg (86%); mp 148—150 °C; IR (nujol) 2100 cm^{-1} (N_3); $[\alpha]_D^{24}$ +45.9° (*c* 1.00, $CHCl_3$). Found: C, 57.87; H, 5.27; N, 10.17%. Calcd for $C_{26}H_{28}N_4O_9$: C, 57.77; H, 5.22; N, 10.37%.

Linear Furano Compounds: Synthesis of 7*H*-Furo[3,2-g][1]benzopyran-7-ones

Y. GEETANJALI, B. RAJITHA, and M. Kanakalingeswara RAO*
Department of Chemistry, Regional Engineering College, Warangal-506 004 A. P., India
(Received March 18, 1985)

Synopsis. A novel synthesis of 2-aroyl-7*H*-furo[3,2-*g*]-[1]benzopyran-7-ones, viz., **IIIa** and **b** was reported by condensing 2-benzoyl- and 2-(*p*-methoxybenzoyl)-3-methyl-5-acetyl-6-hydroxybenzofuran (**Ia** and **b**) with $C_6H_5CH_2$-COONa-Ac_2O. **VI** was synthesised by condensing 7-hydroxy-6-benzoyl-4,8-dimethylcoumarin (**IV**) with **V**. The basic ethers (**IIId—j**) were synthesised by demethylating **IIIb** with pyridinehydrochloride and resultant **IIIc** was condensed with *N,N*-dialkyl-2-haloalkanamine hydrochlorides. UV, IR, ^{1}H NMR, and Mass spectral data are also given.

2-(*p*-Hydroxybenzoyl)benzofuran,[1] 2-(*p*-hydroxybenzoyl)-3-ethylbenzofuran,[1] unsubstituted -7*H*-furo-[3,2-*g*][1]benzopyran-7-one, psoralene[2] and substituted -7*H*-furo[3,2-*g*][1]benzopyran-7-ones,[3] viz., 3-[*p*-(2-dimethylamino-1-methylethoxy)phenyl]-, 3-[*p*-[2-(diethylamino)ethoxy]phenyl]-, and 3-[*p*-(3-piperidinopropoxy)-phenyl]-substituted 2-phenyl-9-methyl-7*H*-furo-[3,2-*g*][1]benzopyran-7-ones have shown antifertility activity. The antifertility activity of these compounds is attributed to the presence of *p*-hydroxybenzoyl group and *p*-[2-(dialkylamino)alkoxy]-benzoyl and *p*-[2-(dialkylamino)alkoxy]phenyl groups.

Results and Discussion

Based on the above reports, 2-[*p*-[2-(dialkylamino)-alkoxy]-benzoyl]-7*H*-furo[3,2-*g*][1]benzopyran-7-ones-(**IIId—j**) were synthesised by developing the 2-pyrone ring on 2-benzoyl-and 2-(*p*-methoxybenzoyl)-3-methyl-5-acetyl-6-hydroxybenzofuran(**Ia** and **b**). 2-Benzoyl- and 2-(*p*-methoxybenzoyl)- 3,5-dimethyl-6-phenyl-7*H*-furo-[3,2-*g*][1]benzopyran-7-ones(**IIIa** and **b**) were synthesised to study structure and antifertility activity relationships.† **IIIa** and **b** were synthesised by refluxing a mixture of **Ia** and **b**, $C_6H_5CH_2COONa$ and Ac_2O at 180°C for 20—22 h in 70 and 80% yields. This method provides a convenient synthetic route for the synthesis of -7*H*-furo[3,2-*g*] [1]benzopyran-7-ones **IIIa** and **b** (Scheme 1). **IIIa** was also synthesised in 50% yield by refluxing a mixture of **Ia** with phenylacetyl chloride and freshly baked K_2CO_3 in dry acetone. **IIIb** was demethylated with pyridine hydrochloride to give 2-(*p*-hydroxybenzoyl)-3,5-dimethyl-6-phenyl-7*H*-furo[3,2-*g*][1]benzopyran-7-one(**IIIc**). **IIIc** was then, condensed with a number of *N,N*-dialkyl-2-haloalkanamine hydrochlorides in 1:1 mol ratio, and freshly baked K_2CO_3 in dry acetone for 20—22 h to give **IIId—j** (Scheme 1) in 60 to 70% yield.

2-Benzoyl-3-phenyl-5, 9-dimethyl-7*H*-furo[3, 2-*g*][1]-benzopyran-7-one(**VI**) (Scheme 2) was synthesised by condensing 7-hydroxy-6-benzoyl-4,8-dimethylcoumarin-(**IV**) with ω-bromoacetophenone (**V**) in 1:1 mol ratio freshly baked K_2CO_3 in dry acetone for 12 h (Scheme 2). The spectral data is summarized in Table 1. All the

†Antifertility activity is reported elsewhere.

mass spectra of compounds **IIIa, b,** and **VI** showed molecular ions M$^+$394(8.1%), M$^+$424(100%), and M$^+$394(1.5%) respectively.

Experimental

Melting points of all the compounds **IIIa—j** and **VI** were taken in open capillaries and are uncorrected. UV absorption spectra were taken on Shimadzu UV 240 Ultraviolet Visible spectrophotometer, IR spectra were recorded on Perkin-Elemer spectrophotometer, and ^{1}H NMR spectra on a Varian EM 390-90 MHz NMR spectrophotometer with TMS as an internal standard.

The procedures given below are typical of the general procedure employed.

2-(*p*-Methoxybenzoyl)-3,5-dimethyl-6-phenyl-7*H*-furo[3,2-*g*]-[1]benzopyran-7-one (IIIb). Five ml of Ac_2O was added to an intimate mixture of **Ib** (16.20 g; 0.05 mol) and sodium phenylacetate (15.8 g; 0.1 mol), and the mixture was refluxed in an oil bath at 180° for 24 h. The reaction mixture was cooled and poured onto a crushed ice (5g). The solid obtained was recrystallized from dioxane. Yield: 14 g (70%), Found: C, 76.37; H, 4.65%. Calcd for $C_{27}H_{20}O_5$: C, 76.41; H, 4.71%

2-(*p*-Hydroxybenzoyl)-3,5-dimethyl-6-phenyl-7*H*-furo[3,2-*g*]-[1]benzopyran-7-one (IIIc). **IIIb** (12.72 g; 0.03 mol) was added to the freshly distilled pyridine hydrochloride (34.5 g;

0.3 mol), and the mixture was refluxed for 30 min. The cooled reaction mixture was poured into water, and the solid filtered off, washed with water, dried, and crystallized from dioxane. Yield: 10.8 g(90%). Found: C, 76.02; H, 4.31%. Calcd for $C_{26}H_{18}O_5$: C, 76.09; H, 4.39%.

2-[*p*-(2-Pyrrolidinylethoxy)benzoyl]-3,5-dimethyl-6-phenyl-7*H*-furo[3,2-*g*][1]benzopyran-7-one (IIIg). IIIc (1.23 g; 0.003 mol) was dissolved in acetone (400 ml) and to this 1-(2-chloroethyl)pyrrolidine hydrochloride (0.510 g; 0.003 mol) and freshly baked K_2CO_3 (3g) were added, and the mixture was refluxed for 22 h. The inorganic impurities were filtered off and the residue was poured into ice cold water, filtered, washed with water, and crystallized from aqueous dioxane as colorless flakes. Yield: 0.950 g(65%). Found: C, 75.69; H, 5.65; N, 2.69%. Calcd for $C_{32}H_{29}NO_5$: C, 75.73; H, 5.71; N, 2.76%

2-Benzoyl-3-phenyl-5,9-dimethyl-7*H*-furo[3,2-*g*][1]benzopyran-7-one(VI). A mixture of **IV** (0.294 g; 0.001 mol) and ω-bromoacetophenone (0.199 g; 0.001 mol) in acetone (300 ml) was refluxed for 12 h cooled, and the inorganic impurities were filtered off. Acetone was recovered by distillation and the residue was poured into ice cold water. The solid obtained was recrystallized from dioxane as shining needles. Yield: 0.908 g(50%). Found: C, 79.10, H, 4.49%. Calcd for $C_{26}H_{18}O_4$: C, 79.18; H, 4.56%.

We are grateful to Prof. K. Koteswara Rao, Principal, REC, Warangal for providing facilities and to the CSIR, New Delhi, for the award of a Senior research fellowship to YG.

Prediction of IR Intensities of Bending Fundamentals in 2,4-Pentadiynenitrile by the Combination of ab Initio Calculation and Experimental Parameters

Masakatsu UYEMURA
Department of Industrial Chemistry, Faculty of Engineering,
Tokyo Institute of Polytechnics, Atsugi, Kanagawa 243-02
(Received September 24, 1985)

2,4-Pentadiynenitrile is a H(C≡C)$_n$C≡N-type molecule. Molecules with n=0 to n=5 are known as interstellar molecules. Infrared spectra have not been observed yet, because the synthesis of a molecule of this type becomes more difficult as the molecular size increases. In the present study, the frequencies and infrared intensities of bending fundamentals in 2,4-pentadiynenitrile were predicted from an ab initio calculation coupled with empirical corrections. Calculation errors have been estimated by comparing calculated and experimental values in small reference molecules which have local structures similar to those of 2,4-pentadiynenitrile. The errors in 2,4-pentadiynenitrile have also been estimated.

Molecules designated as H(C≡C)$_n$C≡N are known as interstellar molecules and the microwave spectra for those with n=1 to 5 have been identified by radio-telescope observations.[1-5] The spectroscopic parameters of these molecules, especially those for the bending vibrations, are essential for an analysis of the radio-telescope data,[6] but laboratory infrared spectra are available only for hydrogen cyanide (n=0) and 2-propynenitrile (n=1). In the present work, the frequencies and the infrared intensities for the bending fundamentals of 2,4-pentadiynenitrile (n=2) were predicted based on an ab initio calculation. It is widely accepted that semiempirical MO theory, such as CNDO, is a powerful means for resolving sign ambiguities in dp/dQ. These are indeterminable from experiments alone.[7] However, the accuracy of semiempirical MO theory is still insufficient to predict infrared intensities with practical accuracy. Nowadays, ab initio MO theory has been applied to molecules of moderate size and it has become accepted that their accuracies are generally much superiror to those of semiempirical ones. In some cases, however, large discrepancies still remain between the calculated and experimental dipole-moment derivatives.[8] The major reason for these discrepancies is the fact that the electron repulsion is not properly taken into account in the Hartree–Fock MO theory. In fact, when elaborated CI calculations are performed, the above-mentioned discrepancies are significantly reduced.[9,10] Then, highly correlated wave functions are necessary for the accurate prediction of frequencies and infrared intensities. The ab initio calculation at this level, however, can be carried out at the present time only for small molecules (for example hydrogen cyanide) and can not be extended easily to larger molecules. Therefore, some alternate approaches must be explored. One of them may be an empirical correction of Hartree-Fock calculations, where the differences between calculated and experimental quantities are assessed. These are then used to obtain an empirical correction to the ab initio results. Essentially the same approaches have been employed in the determination of force fields, where the force constants from ab initio calculations were multiplied by empirical scale factors to obtain a more accurate prediction than the ab initio results themselves.[11,12] In the present study, the ab initio calculations were carried out to obtain the force fields and dipole-moment derivatives for bending vibrations of three H(C≡C)$_n$C≡N type molecules, i.e., HC≡N (n=0), HC≡CC≡N (n=1), and HC≡CC≡CC≡N (n=2), and two related molecules, i.e., HC≡CH and N≡CC≡N. First, the calculated values were compared with the experimental ones in cyanogen, acetylene, and hydrogen cyanide (hereafter, called reference molecules), in order to obtain the empirical correction parameters. Then, the frequencies and the infrared intensities in 2-propynenitrile were predicted and compared with the experimental values so as to estimate the error in the prediction employed here. Finally, the frequencies and the infrared intensities of the bending fundamentals in HC≡CC≡CC≡N and DC≡CC≡CC≡N were predicted in the same way by the use of empirical correction terms.

The same procedure can be applied, in principle, to other larger molecules. However, the CPU time available for each project is limited. Thus, the calculation of a large molecule can be performed at the sacrifice of the quality of the results. On the other hand, as described later, the error of an MO calculation is fairly large for the molecules treated in this work. Therefore, it is necessary to maintain a moderate calculation level for the purpose of this work. After all, the maximum-size molecule must be determined to take these conditions into account. Under the present computational condition, 2,4-pentadiynenitrile (n=2) is the largest member in this series of molecules that can be treated at the same calculation level as 2-propynenitrile (n=1) and other small reference molecules.

Calculation

The ab initio MO calculations were carried out after Hartree-Fock approximations using Pople's 4-31G** split valence plus polarization basis set. The alpha parameters for the polarization functions in H, C, and N were taken to be 1.0, 0.70, and 0.75 respectively.[13-15] The programs used are library programs IMSPAK and HONDOG at Computer Center of Institute for Molecular Science.

Force Fields. First, the theoretical equilibrium geometry was sought for each molecule; then, each atom was displaced 0.01 a.u. along a Cartesian coordinate perpendicular to the molecular axis. The energy gradients were calculated at every configuration; then these energy gradients were differentiated numerically with respect to atomic displacement to obtain $\boldsymbol{F}_x$ matrices. These calculations were performed using the program IMSPAK.

Internal coordinates $\boldsymbol{R}$ and laboratory fixed coordinates $\boldsymbol{X}$ are related by the following expression:[17]

$$\boldsymbol{X} = (\boldsymbol{A} \vdots \boldsymbol{a})\begin{pmatrix}\boldsymbol{R}\\ \boldsymbol{\rho}\end{pmatrix} \tag{1}$$

where $\boldsymbol{\rho}$ corresponds to the Eckart condition which must be fulfilled by molecular fixed coordinates $\boldsymbol{R}$. The inverse transformation of Eq. 1 is expressed as

$$\begin{pmatrix}\boldsymbol{R}\\ \boldsymbol{\rho}\end{pmatrix} = \begin{pmatrix}\boldsymbol{B}\\ \boldsymbol{\beta}\end{pmatrix}\boldsymbol{X}, \tag{2}$$

where $\boldsymbol{B}$ matrices are defined by Wilson[18] and an explicit expression of the $\boldsymbol{\beta}$ matrices is shown in Ref. 17. The $\boldsymbol{F}$ matrices for each molecule were obtained from $\boldsymbol{F}_x$ matrices by

$$\boldsymbol{F} = \tilde{\boldsymbol{A}}\,\boldsymbol{F}_x\,\boldsymbol{A}, \tag{3}$$

where $\tilde{A}$ stands for the transpose of $\boldsymbol{A}$.

Atomic Polar Tensors (APTs). Atomic coordinates were displaced 0.01 a.u. along the Cartesian coordinate around the equilibrium geometry and the dipole moments were calculated at these geometries; then the dipole moments were differentiated numerically to obtain $\boldsymbol{P}_x$ matrices (APTs).[16,17]

Fundamental Frequencies ν_i, and Infrared Intensities A_i. The $\boldsymbol{F}$ matrices obtained from Eq. 3 and the $\boldsymbol{G}$ matrices were used to determine the fundamental frequencies ν_i and $\boldsymbol{L}$ matrices. $\boldsymbol{P}_x$ matrices are related to the dipole-moment derivatives with respect to the internal coordinates $\boldsymbol{P}_R$ by the following Eq.,

$$\boldsymbol{P}_R = \boldsymbol{P}_x\,\boldsymbol{A}, \tag{4}$$

and $\boldsymbol{P}_R$ are related to $\boldsymbol{P}_Q$, i.e., the dipole-moment derivatives with respect to the normal coordiate, by

$$\boldsymbol{P}_Q = \boldsymbol{P}_R\,\boldsymbol{L}. \tag{5}$$

Then, the integrated molar absorption coefficients A_i are expressed as;[19]

$$A_i = \frac{N g_i P_{Q_i}^2}{3c^2(4\varepsilon_0)} \tag{6}$$

where N is Avogadro's constant and g_i is the degree of degeneracy.

Results and Discussion

Force Fields. Calculated and experimental force constants for N≡CC≡N, HC≡CH, and HC≡N are shown in Table 1. The force fields of these molecules have been thoroughly studied and the experimental values in Table 1 were obtained from harmonic frequencies.[20-22] The relative errors found in the calculated values in these molecules are generally larger than those obtained in other molecules at a similar calculation level (Hartree-Fock approximation using split valence basis set).[12] At the same time, it may be noted that the errors depend to some extent on the local structure of the molecules where the internal coordinate is defined; for example, the ratios of experimental diagonal force constants to calculated ones are 0.67—0.64 for H-C≡C and H-C≡N bending coordinates, and 0.58 for C-C≡N bending respectvely, which seems to reflect the extent of the electron correlation in a triple bond. As for the

off-diagonal force constants, the ratios of experimental to calculated values vary to a large extent. In one case, the ratio of experimental to calculated values is close to unity, and far from unity in the other case. However, it must be noted that the absolute values of the off-diagonal force constants are much smaller than the diagonal ones, so that in the off-diagonal force constants a small absolute error gives a large relative one.

The bending force constants for HC≡CC≡N and HC≡CC≡CC≡N were obtained at the same calculation level. Then, the correction factors were multiplied by the calculated force constants to give the most accurate prediction for the force fields. These correction factors were taken from the ratios of the experimental to the theoretical force constants obtained for similar or same bending coordinates in the reference molecules, i.e., the correction factor for H-C≡C was taken from the mean value (0.657) of ratios both in H-C≡N of HC≡N and in H-C≡C of HC≡CH. As for the C-C≡C bending force constant, there is no corresponding value among the reference molecules. Therefore, the correction factor for this constant was assumed to be equal to that for C-C≡N in N≡CC≡N (0.586). These two force constants are similar in that they are bending coordinates around a carbon atom which is involved in a conjugated triple bond. As for the off-diagonal force constants in 2,4-pentadiynenitrile, only those which are related to adjacent bending coordinates were considered here, since others are less important for the calculation of vibrational frequencies. These constants are further classified into two groups. The first group (group A) is composed of those between C-C≡C and C≡C-C bending coordinates; both of which have common C≡C bond. Group B is composed of those between C≡C-C and C-C≡C or C-C≡N bending coordinates; both of which have common C-C bond. Experimental values of the force constants in group A are positive, and fairly correctly predicted by the ab initio method in the reference molecules (for example, the ratio of the experimental value to the calculated one is 0.86 in HC≡CH), whereas those in group B are negative and the predicted magnitudes are too large (the above-mentioned ratio is 0.33 in N≡CC≡N). These ratios were used as correction factors for the force constants in the two groups. The force constants of HC≡CC≡N predicted in this way are compared with the experimental ones in Table 2(a) and the experimental and predicted frequencies of 2-propynenitrile are summarized in Table 2(b). The predicted freqencies are in the range of 0.95—1.04 of the experimental ones. Here, it may be noted that the predicted force constants in Table 2(a) are based on empirical correction factors and these were derived from harmonic frequencies of reference molecules, whereas the experimental force constants of 2-propynenitrile are based on the observed experimental frequencies. It is well known that the observed frequencies are generally lower than the harmonic ones because of the anharmonicities in potential functions. On account of the above effect, it might be reasonable that the predicted force constant of H-C≡C bending is 5% larger than the experimental one. On the contrary, the predicted values for the C≡C-C and C-C≡N bending force constants are about 2 to 6% less than the experimental ones. These discrepancies will be explained from the following two reasons. First, the frequencies of ν_6 and ν_7 are fairly near so that relatively large correlations exist between these force constants (diagonal constants for C≡C-C and C-C≡N bending coordinates) and the experimental uncertainties are relatively large in these force constants. Second, there is no C≡C-C bending force constant in the reference molecules, so that the correction factor for this bending force constant was assumed to be equal to that for C-C≡N. The force constants of 2,4-pentadiynenitrile which were pre-

dicted in the same way are shown in Table 3.

Atomic Polar Tensors (APTs). Calculated and experimental atomic polar tensors (APTs) for N≡CC≡N, HC≡CH, and HC≡N are shown in Table 4.[24-26] In acetylene, good agreements were obtained between the calculated and the experimental APTs. On the other hand, fairly large errors were found in H and N of hydrogen cyanide. These errors are due to an overestimation of H–C and C≡N bond moments. This trend is also found in cyanogen in a more exaggerated way, where the calculated APT for N is 0.099*e* larger than the experimental one. This error is about 6-times larger than that in hydrogen cyanide. This error difference regarding the APTs for the N which participate in the C≡N bonds reflects a difference in the bonding characteristics in these C≡N bonds. This might be caused by a conjugation difference in these molecules. Therefore, when these APTs are used to predict those for 2-propynenitrile and 2,4-pentadiynenitrile, it becomes necessary to decide which of the reference molecules they are similar to. In the following calculation, the bonding characters of C≡N in 2-propynenitrile and 2,4-pentadiynenitrile were assumed to be the same as that in cyanogen. This is because these C≡N bonds participate in the conjugation. In this respect, hydrogen cyanide must be classified in a different category. The differences between the calculated and experimental APTs in the reference molecules are largest in C and N in cyanogen (0.099*e*) and the other differences are much smaller. Therefore, as a first approximation, it may be reasonable to correct errors only for C and N in a C≡N bond which participates in conjugation. In the following prediction of the APTs for C and N in a C≡N bond, 0.099*e* was subtracted from APTs for C and was added to those for N in 2-propynenitrile and 2,4-pentadiynenitrile to compensate the overestimation of the C≡N bond polarity. The other APTs were not subject to corrections and the ab initio results were used as the predicted values for the APTs. The predicted APTs of 2-propynenitrile and 2,4-pentadiynenitrile are shown in Table 5(a) and Table 6 respectively.

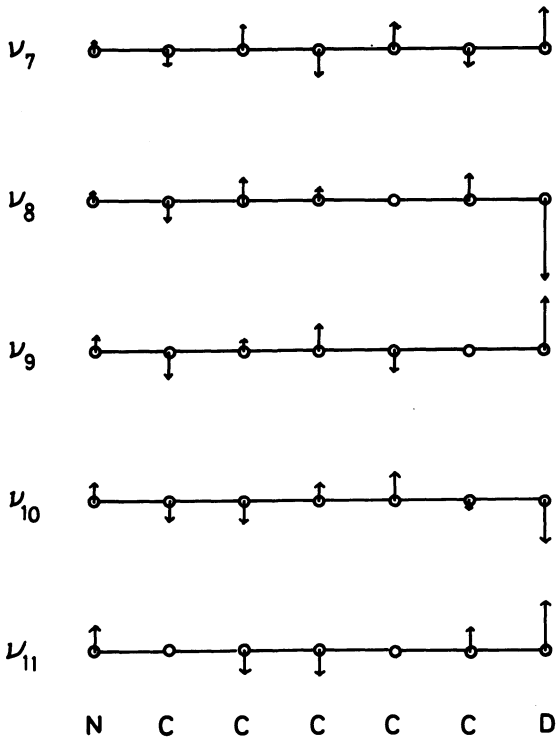

Fig. 1 (b). Normal modes of vibration in DCCCCCN.

experimental intensities lie between from 1.50 to 0.33. The value of this ratio for ν_5 in HCCCN is 1.17; this vibration results mainly from H–C≡C bending. The overestimated H–C polarity may be responsible for this overestimation. The errors in ν_7 intensities of HCCCN and DCCCN are much larger than those expected solely from the errors in APTs. In this mode, the molecules are bent mainly at the C–C≡N bending coordinate and the resultant changes of H–C and C≡N bond moments cancel each other. The net dipole-moment change becomes so small that a large relative error arises. Cancellations of this type occur more or less in ν_6 and ν_7 of HCCCN and DCCCN.

The sources of error in the predicted infrared intensities can be classified into two categories; one is the error in the APTs and the other is that in $\boldsymbol{L}$ matrices, which is mainly caused by the error in force fields. The $\boldsymbol{L}$ matrices determine the deformations of molecules, so that they determine the degree of cancellation or reinforcement of bond moments during the deformation. When this situation is taken into account, the general trend is well understood that the weak bands have large relative errors. To examine the influence of the error in the $\boldsymbol{L}$ matrix to the intensity A, another calculation was made for HCCCN and DCCCN, (Pred. (2) in Table 5(b)), where $\boldsymbol{L}$ matrices were determined from experimental force fields and the APTs were predicted as above. Here, it can be seen that the agreement between the experimental and predicted intensities of ν_6 and ν_7 in HCCCN and DCCCN have changed. This result seems to suggest that the errors in the predicted force fields are responsible to some extent for the errors in the predicted intensities, especially for low-intesity

bands.

Fundamental frequencies ν_i and infrared intensities A_i of bending vibrations in HCCCCCN and DCCCCCN were calculated using the predicted force fields (Table 3), and APTs (Table 6). Normal modes of vibrations for HCCCCCN and DCCCCCN are shown in Fig. 1. It can be seen that the ν_7 in the HCCCCCN is mainly localized at the H–C≡C bending coordinate. In the other vibrations, however, the vibrations delocalize more or less over the molecule. In the lowest vibrations (ν_{11} of HCCCCCN and DCCCCCN), the molecules are bent; thus the large bond moments of H–C (or D–C) and C≡N are inclined in the opposite direction and their moments cancel each other to give very low intensities. This situation is similar to that in ν_7 in 2-propynenitrile. As the vibrational frequency increases from ν_{11} to ν_8, the number of nodes in normal modes also increases, so that bond moments of H–C (or D–C) and C≡N cancel or reinforce each other, depending on the number of nodes. The resultant infrared intensities give rise to a intensity alternation.

As for the accuracy of the predicted force fields in 2-propynenitrile and 2,4-pentadiynenitrile, there may be no essential difference between them. Therefore, the predicted fundamental frequencies of 2,4-pentadiynenitrile are expected to have a comparable accuracy with that of 2-propynenitrile. The predicted frequency of ν_7 (mainly comprised from H–C≡C bending) in HCCCCCN may be about 4% too large as in HCCCN, since the correction factors for the H–C≡C diagonal force constants for these molecules were assumed to be equal. The other vibrations mainly consist of C≡C–C and C–C≡N bendings. Thus, their vibrational frequencies may be predicted too small, since the diagonal force constants for the C≡C–C and C–C≡N bendings have been predicted to be smaller than the experimental ones in 2-propynenitrile. These same correction factors were used for the prediction in 2,4-pentadiynenitrile.

It is more difficult to estimate the errors involved in the infrared intensities than those related to frequencies. This is because the former include errors from both the force fields and the APTs. However, it may be noted that the APTs for H, C, and N in H–C and C≡N bonds in these molecules are 2- to 7-times larger than those for other atoms. Thus, the $\boldsymbol{P}_R$ are dominated by APTs for these atoms and fairly good agreement were obtained between experimental and predicted APTs for H, C, and N in H–C and C≡N bonds in 2-propynenitrile. Therefore, the predicted APTs in 2,4-pentadiynenitrile are expected to have almost the same accuracy as those in 2-propynenitrile. The highest bending vibration (ν_7 in HCCCCCN) is mainly localized at H–C≡C bending. Thus, the infrared intensity is mainly donimated by the APTs of the H and C in H–C bond. At this point, it might be remembered that the APTs of H and C in the H–C bond in 2-propynenitrile were calculated to give an overestimated polarity with the direction (+)H–C(−), i.e, the magnitudes of APTs of H and C have been calculated too large by 6 to 17 percent. The calculated APT values for H and C in H–C≡C of 2,4-pentadiynenitrile are close to those in 2-propynenitrile. From this similarity in the APTs, it is inferred that the intensities of ν_7 in HCCCCCN and ν_5 in HCCCN may be predicted about 15 to 20% larger. In the other bending vibrations, it is difficult to estimate the errors in the predicted intensities since these vibrations delocalize over a molecule. Therefore, cancellations of bond moments occur to a larger extent. In such cases, some correlation may exist between the relative errors and the predicted intensities. In moderately strong bands (ν_7 and ν_{10} in HCCCCCN), their relative errors are expected to be 50% at most. In the weaker bands (ν_9 and ν_{11}), the predicted values may be regarded as order estimations.

Table 7. Predicted Frequencies (ν/cm^{-1}) and IR Intensities (A/km mol^{-1}) of Bending Fundamentals in HCCCCCN and DCCCCCN

HCCCCCN	ν_i	A_i	DCCCCCN	ν_i	A_i
ν_7	691	77.2	ν_7	580	2.33
ν_8	565	13.4	ν_8	537	41.1
ν_9	457	0.19	ν_9	444	2.9
ν_{10}	249	10.5	ν_{10}	242	11.1
ν_{11}	101	0.087	ν_{11}	98	0.098

The preliminary results of this work have been published previously,[27] and we should note that the intensity of the ν_8 fundamental in Table 1 in Ref. 27 was unfortunately misprinted and that the radiative transition rate through the ν_8 band was overestimated in the calculation. However, the total pump rate through the ν_8 and ν_7 bands decreases only by 15% due to this mistake and the main conclusion of the paper does not change.

The author wishes to express his thanks to Professor Keiji Morokuma and to Dr. Shigeki Kato of Institute for Molecular Science, for helpful discussions and kind advices. He also thanks to Professor Shuji Deguchi of the University of Illinois at Urbana-Champaign, for his encouragements throughout this work. The ab initio calculations were carried out at Computer Center, Institute for Molecular Science, using library programs IMSPAK and HONDOG. Normal coordinate calculations were carried out at Computer Center, The University of Tokyo.

^{129}I Mössbauer Spectroscopic Studies on the Iodine Complexes of *N,N'*-Diphenyl-*p*-phenylenediamine and *N,N'*-Diphenylbenzidine

Hiroshi SAKAI* and Yutaka MAEDA
Research Reactor Institute, Kyoto University, Kumatori-cho, Sennan-gun, Osaka 590-04
(Received November 11, 1985)

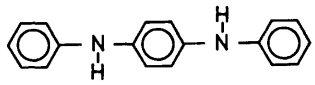
^{129}I Mössbauer and resonance Raman spectroscopy have been applied to the iodine complexes of *N,N'*-diphenyl-*p*-phenylenediamine (DPPD-$I_{2.4}$) and *N,N'*-diphenylbenzidine (DPB-$I_{2.7}$), which exhibit relatively high electrical conductivities. The Mössbauer spectra of these complexes indicate the existence of two unequivalent iodine sites, corresponding to the central and terminal iodine atoms of a linear I_3^- unit. The resonance Raman spectra suggest that the I_3^- unit exists as a successive chain in these complexes. This is consistent with the crystallographic data of the DPPD-$I_{2.4}$ complex. The charge density of the I_3^- unit is slightly different from that of the isolated I_3^- ion because of a weak covalent bond between I_3^- units. It is confirmed that both complexes are partially oxidized mixed-valence compounds, formulated as $(DPPD)^{+0.8}(I_3^-)_{0.8}$ and $(DPB)^{+0.9}(I_3^-)_{0.9}$.

Some iodine complexes of oligoanilinic derivatives show interesting electrical and magnetic properties.[1] One of these complexes, *N,N'*-diphenyl-*p*-phenylenediamine-iodine (DPPD-I_x, x=1.8—2.4), exhibits relatively high electrical conductivity ($\approx$0.3 S cm^{-1}) at room temperature with a low activation energy (0.07 eV).[2,3] It is found from measurements of the thermoelectric power that in this complex (x=2.0—2.4) the electron conductivity is slightly more predominant than the hole conductivity near room temperature.[2,4] The complex is paramagnetic and shows a strong electron-spin resonance signal.[2] Crystallographic data of the complex (x=2.4) suggest that the iodine atoms are arranged in successive chains consisting of I_3^- units perpendicular to the layer of the planar DPPD molecule.[5] The iodine chain is coordinated to NH groups of the DPPD molecule. The interatomic distance in the I_3^- unit is approximately 2.99 Å, slightly longer than that of usual triiodide ions (2.92 Å).[6] The distance of 3.44 Å between I_3^- units along the chain is shorter than twice the van der Waals radius of iodine.

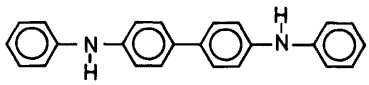
It is interesting to estimate the charge density of each iodine atom in order to understand the electrical and magnetic properties of the complex. The Mössbauer spectroscopy of ^{129}I is a powerful method for this purpose, since the electronic structure of iodine is directly derived from such Mössbauer parameters as the quadrupole coupling constant (e^2Qq) and its sign, the asymmetry parameter (η), and the isomer shift (δ). In this paper we report results of ^{129}I Mössbauer spectroscopy for the *N,N'*-diphenyl-*p*-phenylenediamine-$I_{2.4}$ (DPPD-$I_{2.4}$) and *N,N'*-diphenylbenzidine-$I_{2.7}$ (DPB-$I_{2.7}$) complexes. Furthermore, laser Raman spectra were measured for these complexes in order to clarify the configuration of iodine.

Experimental

Materials. The commercially available donor molecules, DPPD and DPB, were recrystallized from benzene. The ^{129}I labeled complexes used for measurements of the Mössbauer spectra were prepared from Na ^{129}I in an Na_2SO_3 solution. After oxidizing the iodide with 3 mol dm^{-3} H_2SO_4 and 10% H_2O_2, the resulting molecular iodine ($^{129}I_2$) was extracted with benzene. A dark-green DPPD-I_x complex with metallic luster was obtained upon adding a hot benzene solution of DPPD to the hot benzene solution of iodine. Lustrous, reddish-black crystals of DPB-I_x were obtained by mixing hot benzene solutions of DPB and excess iodine. The samples for measurements of resonance Raman spectra were prepared by using natural iodine in the same manner as the above procedures. The ratio of each component for these complexes was determined to be x=2.4 for DPPD-I_x and x=2.7 for DPB-I_x by iodometry.



N,N'-diphenyl-p-phenylenediamine
(DPPD)



N,N'-diphenylbenzidine
(DPB)

Measuremens. A single-line $^{66}Zn^{129}Te$ Mössbauer source was prepared by irradiating 140 mg $^{66}Zn^{128}Te$ at a thermal neutron fluence rate of 2×10^{13} n cm$^{-2}\cdot$s^{-1} for 1 h in the Kyoto University Reactor (KUR). The source activity produced by the ^{128}Te (n,γ) ^{129}Te reaction was initially about 10 mCi, sufficient to obtain a reasonable spectrum in 3—4 h of data collection. The Mössbauer spectra were measured in a transmission geometry by cooling the source and the absorber to 16 K with a closed cycle helium refrigerator. The 27.8 keV Mössbauer γ-rays were detected with a 1 mm-thick NaI(Tl) scintillation counter. The Mössbauer spectrometer was calibrated with a six-line spectrum of an Fe foil.

Laser Raman spectra were recorded with Ar^+ (514.5 nm)

excitation usig a JEOL-JRS-400T triple monochromator and photon-counting detection. The data were obtained with compressed pellets of powdered samples by the front-surface reflection method using 60 mW laser power and a spinning cell. No decomposition was observed with this laser power.

Results and Discussion

Mössbauer Spectra. ^{129}I Mössbauer spectra of the DPPD-$I_{2.4}$ and DPB-$I_{2.7}$ complexes at 16 K are shown in Fig. 1(a) and (b). The spectra, consisting of two different quadrupole octets, were analyzed by the least-squares method using a double set of fitting parameters such as the quadrupole coupling constant (e^2Qq), the asymmetry parameter (η), the isomer shift (δ), the full-width at half-maximum (2Γ), and the intensity of each peak. The dashed curves in the figure represent the best fitted quadrupole-split octets, and the solid lines indicate the superimposed curves of the two octets. The obtained Mössbauer parameters are summarized in Table 1, together with results of the isolated I_3^- ions in the [Ru(η-C_5H_5)$_2$I]I_3[7] and β-carotene-I_3[8] complexes. The e^2Qq values are converted to that of the ^{127}I nucleus.

The existence of two unequivalent iodine atoms observed in the Mössbauer spectrum of the DPPD-$I_{2.4}$ complex is consistent with the results of the crystallographic analysis, in which the iodine atoms are arranged in chains of linear I_3^- units.[5] The similarity of the spectrum of the DPB-$I_{2.7}$ complex to that of DPPD-$I_{2.4}$ suggested that the iodine atoms build up an I_3^- unit. Later, this speculation was confirmed by the resonance Raman spectrum of the DPB-$I_{2.7}$ complex. It is now appropriate to assign the iodine with the larger quadrupole splitting to the central iodine atom (I_c) of the linear I_3^- unit, whereas the other to the two terminal iodine atoms (I_t). No broadening of the line width has been observed for I_t of the DPPD-$I_{2.4}$ complex, suggesting that the I_3^- unit is symmetric. On the other hand, the line width of I_t is broadened considerably in the DPB-$I_{2.7}$ complex compared with that of I_c and the broadening is enhanced in the region of higher velocity. This implies that the charge densities on the two I_t atoms are slightly different; i.e., the I_3^- unit is slightly asymmetric. Attempts to fit the spectrum with three unequivalent iodine sites were unsuccessful. Therefore, the values of e^2Qq, η, and δ given in Table 1 are

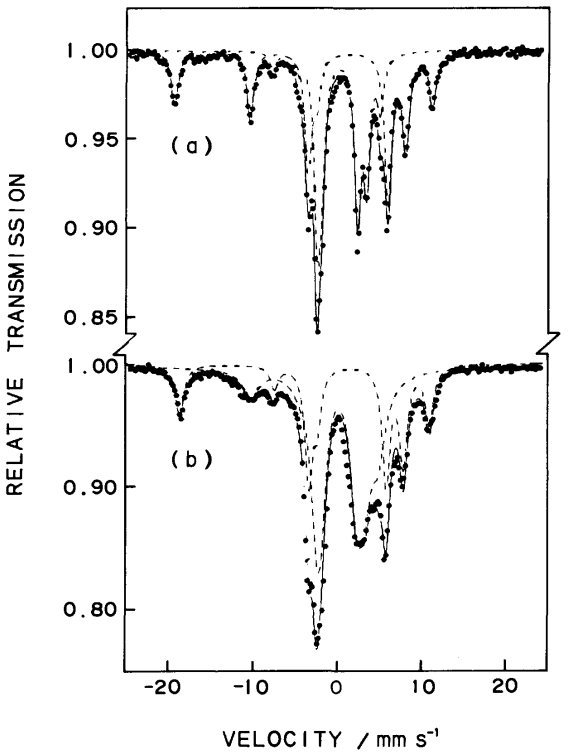


Fig. 1. ^{129}I Mössbauer spectra at 16 K of (a) *N,N'*-diphenyl-*p*-phenylenediamine-$I_{2.4}$ and (b) *N,N'*-diphenylbenzidine-$I_{2.7}$ complexes.

the means of those for the two I_t atoms. The ratios of the absorption areas of I_t and I_c were found to be 1.6:1 and 1.7:1 for the DPPD–$I_{2.4}$ and DPB–$I_{2.7}$ complexes, respectively, as shown in Table 1. The same tendency is found in the I_3^- ions of [Ru(η-C_5H_5)$_2$I]I_3[7] and β-carotene–I_3[8] complexes. The deviation from the composition ratio of 2:1 in I_3^- is explained in terms of the recoilless fraction and the saturation effect. The I_t atom is bonded to one adjacent I_c atom, whereas the I_c atom is bonded to two I_t atoms with the same bond strength. Therefore, the I_t atom is expected to have a lower recoilless fraction than the I_c atom. Since the effective absorber thickness for the I_t atom is twice that for the I_c atom, the saturation for I_t is more dominant than for I_c. These effects result in the decrease in the absorption area of I_t.

The values of e^2Qq, η, and δ are closely related to the charge distribution and the charge density of 5p-electrons localized on the iodine atom as follows:[9,10]

$$U_p = -e^2Qq_{obsd}/e^2Qq_{atom} = -N_z + (N_x + N_y)/2, \quad (1)$$

$$\eta = 3(N_x - N_y)/2U_p, \quad (2)$$

$$\delta = 1.5\,h_p - 0.54 \text{ (mm s}^{-1}\text{, for ZnTe source)}, \quad (3)$$

$$h_p = 6 - (N_x + N_y + N_z), \quad (4)$$

where U_p is the number of unbalanced p-electrons, e^2Qq_{atom}, the atomic iodine quadrupole coupling constant, is equal to 2292.7 MHz for ^{127}I, and h_p is the number of 5p-electrons removed from the $5s^25p^6$ (I^-) configuration. N_x, N_y, and N_z are the populations of 5p-electrons in the x, y, and z directions, respectively. When the bonding of iodine is formed by only $5p_\sigma$-electrons, one expects the relationship $U_p=h_p=1\pm i$ to be valid; i is the ionic character. When 5s-electrons take part in bond formation (sp hybridization), the relationship $U_p>h_p$ is generally observed because of the decrease in the s-electron density at the nucleus. On the contrary, the participation of the $5p_\pi$-electrons (double bond character or intermolecular bonding in the x or y direction) leads to the relationship $U_p<h_p$. The values of U_p and h_p obtained for each iodine atom are given in Table 1, together with those for the isolated I_3^- ions in the [Ru(η-C_5H_5)$_2$I]I_3 and β-carotene-I_3 complexes.

DPPD-$I_{2.4}$ Complex: The U_p value is very close to the h_p value for the I_t atom in the DPPD–$I_{2.4}$ complex, suggesting that the bonding of I_t is mainly due to $5p_\sigma$-electrons. This result is consistent with the small η value of the atom, which implies that the bonding of the I_t atom is almost axially symmetric. Therefore, the I_t atom might not be interacting with the NH group of the DPPD molecule. Even if it should interact, the hydrogen bond with the NH group may be extremely weak. The I_t atom of the complex is found to be negatively charged by 0.48 e^- due to the values of U_p and h_p. It is generally observed that the terminal iodine is negatively charged by 0.50 e^- in the isolated I_3^- ion. The small deviation may be attributable to the weak covalent bond between I_3^- units. That is, the charge on the I_t atom is slightly delocalized along the chain of I_3^- units. This would lead to an increae in the charge density on the I_c atom. Actually, the values of U_p and h_p for I_c in this complex are smaller than those for I_c in the isolated I_3^- ions.

For the I_c atom in the DPPD–$I_{2.4}$ complex, the h_P value is larger than the U_P value. The same tendency is observed for the I_c atoms in the isolated I_3^- ions. This has been generally explained in terms of the presence of π-bonding in which the iodine donates $5p_\pi$-electrons to the neighbor atoms. However, it is quite difficult to consider the presence of a double bond or an intermolecular bond in the isolated I_3^- ion from the crystallographic data of [Ru(η-C_5H_5)$_2$I]I_3.[7] Furthermore, if the discrepancy is due to the π-bonding, the charge density on the I_c atom is estimated to be +0.24 e^- from the h_p value. This value is unreasonably high compared with the charge density calculated from the molecular orbital treatment of a delocalized three-center four-electron bonding. Lucken[11] has pointed out the contribution of $3d_\sigma$-electrons, on the central atom, to the linear Br_3^- bond formation. In his treatment the electronic structure of trihalide ions are descrided as a mixture of two extreme configurations, i.e., a delocalized three-center four-electron bond using only the valence p-electrons and covalent σ bonds between two $d_\sigma p_\sigma$ hybrid orbitals of the central atom and p_σ orbitals of two terminal atoms. This treatment is applicable to the interpretation of Mössbauer data for the triiodide ion. The contribution of the $4d_\sigma$ hybridization may lead to an increase in the effective s-electron density at the nucleus. This would markedly increase the δ value, but would hardly increase e^2Qq. In our previous paper[12] his treatment on the triiodide ion was concluded to be valid. It is interesting to apply $4d_\sigma$ hybridization to the central iodine atom of the bridging I_3^- unit in the complex, assuming no interaction with the NH group of the donor molecule. Using Eqs 4 and 5 in Ref. 12, the number of $4d_\sigma$ electrons promoted to the $5p_\sigma$-orbital can be easily estimated from the δ and e^2Qq. The h_p and h_d (the number of $4d_\sigma$-electron defect) obtained for the I_c atom are evaluated to be 0.84 and 0.17, respectively. That is, 0.17 e^- of the $4d_\sigma$-electron is promoted to the $5p_\sigma$-orbital. Consequently, the charge localized on the I_c atom is about +0.01 e^-. Thus, the I_c atom has a slight positive charge. If the hydrogen bond exists between the I_c atom and the NH group, the contribution of the $4d_\sigma$ hybridization

would decrease and, therefore, the charge density localized on the I_c atom would also decrease slightly. Judging from the small η value of the I_c atom, the hydrogen bond may be considerably weak. In the isolated I_3^- ion of $[Ru(\eta\text{-}C_5H_5)_2I]I_3$ the I_c atom is positively charged by $0.05\,e^-$ (evaluated in Ref. 12). This value is obviously larger than that of the bridging I_3^- unit.

It is concluded from the charge densities of the I_t and I_c atoms that in the bridging I_3^- unit a slight amount of charge is delocalized along the chain, ascribed to a weak covalent bond between the I_3^- units. It is likely that the delocalization of a small amount of charge is responsible for the electron conduction observed for the investigated complex. Furthermore, this complex is concluded to be a partially oxidized mixed-valence compound from the ratio of the iodine atom to the DPPD molecule, and the charge distribution of which is formulated as $(DPPD)^{+0.8}$ $(I_3^-)_{0.8}$. A stacking column consisting of the partially oxidized DPPD molecules may govern hole conductivity.

DPB-$I_{2.7}$ Complex: The agreement between the U_P and h_P values is good for the I_t atom of the DPB-$I_{2.7}$ complex, although these values represent the mean for the two I_t atoms. Furthermore, the η value is small. These results suggest that the bonding of the I_t atoms is mainly due to the valence $5p_\sigma$-electrons in a similar manner as the I_t atom of the DPPD-$I_{2.4}$ complex. The average charge density for the two I_t atoms was evaluated to be $-0.49\,e^-$. On the other hand, it has been found for the I_c atom of the complex that e^2Qq , i.e, U_p, is smaller and the η is larger than those for the I_c atom of DPPD-$I_{2.4}$. These facts anticipate that an intermolecular bond (a hydrogen bond) exists between the I_c atom and the NH group of DPB in the perpendicular to the linear I_3^- bond. However, since the δ value, i.e., h_p, for the I_c atom of the complex is nearly equal to that of DPPD-$I_{2.4}$ (within experimental error), the charge density localized on the I_c atom might be almost the same as that of the DPPD-$I_{2.4}$ complex. That is, the charge on the I_c atom of the I_3^- unit is slightly positive in the DPB-$I_{2.7}$ complex, but less than that for the isolated I_3^- ion. From the ratio of each composition the present complex is shown to also be a partially oxidized, mixed-valence compound, the charge distribution of which is formulated as $(DPB)^{+0.9}(I_3^-)_{0.9}$ (similar to the DPPD-$I_{2.4}$ complex). If the donor molecule is arranged in a stacking column, whose structure has not been revealed yet, a large electrical conductivity would be expected for the complex. It is not clear from only the Mössbauer data whether the I_3^- unit exists as a successive chain or as an isolated form, although the Mössbauer data of the complex are close to those for the bridging I_3^- unit of the DPPD-$I_{2.4}$ complex rather than the isolated I_3^- ion. This question may be solved by the resonance Raman spectrum of the complex.

Resonance Raman Spectra. In Fig. 2 (a) and (b) are presented resonance Raman spectra of the DPPD-$I_{2.4}$ and DPB-$I_{2.7}$ complexes excited by the Ar^+ 514.5 nm line. Both spectra are very similar to each other, suggesting that the iodine species of these complexes exist in a similar chemical form. This is consistent with the Mössbauer spectra. The Raman bands at 107 and 213 cm^{-1} can be assigned to the symmetric stretching vibration of a linear I_3^- unit and its first overtone, respectively. Teitelbaum et al.[13,14] have reported that the isolated I_3^- ion in $(C_6H_5)_4As^+I_3^-$ shows a Raman band of the symmetric stretching vibration at 113 cm^{-1}, whereas the corresponding band is observed at 108 cm^{-1} for the bridging I_3^- unit in $(benzamide)_2H^+I_3^-$. The spectral pattern of the latter compound is similar to those observed for the present complexes. It is, therefore, concluded that the iodine species in the DPPD-$I_{2.4}$ and DPB-$I_{2.7}$ complexes exist as a successive chain of I_3^- units. This is consistent with the crystallographic data of the former.

We would like to express our grateful acknowledgement to Prof. Takenobu Higashimura (Research Reactor Institute, Kyoto University) for his helpful discussions and encouragement. We wish to thank

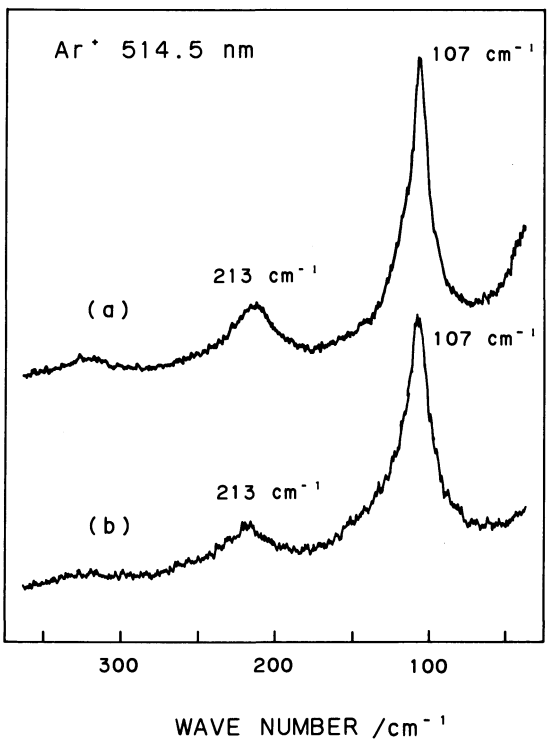

Fig. 2. Resonance Raman spectra excited by the Ar^+ 514.5 nm line of (a) *N,N'*-diphenyl-*p*-phenylenediamine-$I_{2.4}$ and (b) *N,N'*-diphenylbenzidine-$I_{2.7}$ complexes.

Mr. Shuichi Muraishi (JEOL Ltd.) for the measurements of the Raman spectra. This work was supported by the grant in aids of special research project on properties of molecular assemblies (No. 60104002) from the Ministy of Education, Science and Culture,.

A Novel Development for the Simulater of Intermolecular Potentials

Tatsuya TAKAGI,* Akito TANAKA, Shigeo MAEDA, Sanshiro MATSUO, Hideaki FUJIWARA, and Yoshio SASAKI
Faculty of Pharmaceutical Sciences, Osaka University, 1-6 Yamada-Oka, Suita, Osaka 565
(Received December 17, 1985)

A novel treatment for the estimation of intermolecular interactions is proposed, incorporating intermolecular parameters into the semiempirical MNDO MO method. These parameters vary depending on the atomic species, but are constants to be reduced to the original MNDO formalism when the atomic pair belongs to a same molecule. The core–core repulsion and the two electron integral terms were modified using these parameters. The parameters introduced have been determined so as to reproduce well the interaction energies of the different model systems of molecular interaction. The resulting parameters permit calculations of large systems with sufficient accuracy within reasonably short CPU time.

Intermolecular interactions play an important role in various fields of chemistry such as solution chemistry,[1] quantum pharmacology,[2] and organic chemistry.[3] Although recently quantum-mechanical treatment has become accurate to be comparable to the experimental value in different systems, CPU time is still a limiting factor for the calculation of especially interaction energies in many-body systems. Semiempirical MO methods are expected to benefit short CPU time with reasonable accuracy of calculation. To this purpose, several investigators have made calculations.[4]

A total reparameterization of a semiempirical MO method would be necessary including the intermolecular potentials besides the molecular properties such as heat of formation which are reproduced in the MNDO[5] and MINDO/3[6] MO methods. But such reparameterization is likely to disturb the results hitherto attained satisfactorily. Quite recently, Dewar et al.[7] proposed a new semiempirical MO formula, AM1, which is the improved version of the MNDO MO method. This method is reported to have better reproducibilities in single molecular property as well as in energies of intermolecular interactions, whose results are compared with our calculations below.

Another method may be pointed out for the treatment of intermolecular potentials. That is, a partial reparameterization of a semiempirical MO formalism. Burstein and Isaev[8] proposed the MNDO/H method using a new function for the core–core repulsion term, while Mohammad and Hopfinger[9] proposed the CNDO/2H and the MINDO/3H methods using new treatments of the resonance integral and the core–core repulsion terms. These methods enabled us to calculate the hydrogen bonding systems of the intermolecular as well as intramolecular origin. However, there are some shortcomings of them. The user has to determine in advance which atoms are hydrogen-bonded or not, and the applications are limited to those systems where intermolecular forces other than the hydrogen bond of interest are exactly calculable by the semiempirical MO methods.

We propose here a new method of treating intermolecular potentials, i.e., introduction of new parameters, intermolecular parameters, which contribute only to the intermolecular potentials.

Calculation

We selected the MNDO MO formalism for the basis of new method which can be used to study with a number of properties of molecular systems large enough to be interesting to the organic chemists and biochemists. The CNDO/2 MO formalism[10] might also be useful for the basis. In fact, CNDO/2H method is reported to be more reliable than MINDO/3H method.[9] However, the CNDO/2 MO method sometimes fails to predict correctly the heat of formation, molecular geometries, etc., and hence it is not adopted in the present paper.

A *QCPE*[11] program was improved in great deal[12] and modified to include corrections stated below and the program NICER[13] was used as a diagonalization routine. The program SIMPLX[14] was used to optimize the intermolecular parameters. Ab initio MO calculations were carried out according to the IMSPAK program system[15] and its Osaka University version.[16] The 4-31G basis set[17] was adopted throughout. All molecular geometries were optimized using MNDO MO method. Numerical calculations were performed on an NEAC S1000 computer plus HFP system at the Computer Center, Osaka University and HITAC M-200H computer at the Computer Center, Institute for Molecular Science.

Formalism

There are some papers[18] which indicate that the MNDO MO method underestimates energies of intermolecular interactions, especially for hydrogen bonding systems. Energy decomposition analyses proposed by Kitaura and Morokuma[19] show that the unstabilization of the ES (electrostatic) term at longer distances is responsible for this underestimation (Fig. 1). Since the EX (exchange repulsion) term always

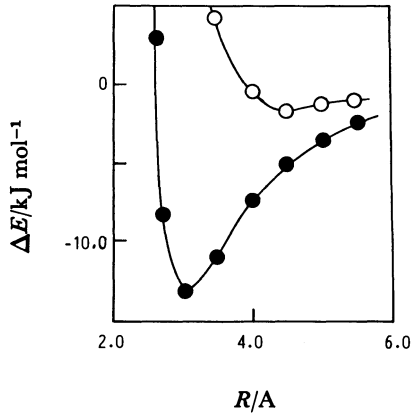

Fig. 1. Distance dependencies of the ES plus EX term for the $(H_2O)_2$ system. MNDO (●); ab initio (○).

vanishes in MNDO approximation, ES term in MNDO MO method is thought to correspond to the ES+EX term in ab initio MO method. The simplest way to correct for the ES term is to modify the core-core repulsion term. We tried to correct this as follows:

$$E_{ij}^{core}(SIMP) = E_{ij}^{core}(MNDO) - (A_i+A_j)[\exp\{-B_i(R_{ij}+\alpha)\} + \exp\{-B_j(R_{ij}+\alpha)\}]. \quad (1)$$

For atomic pairs of N-H and O-H a slightly different expression is used basing on the MNDO approximation:

$$E_{ij}^{core}(SIMP) = E_{ij}^{core}(MNDO) - (A_i+A_j)(R_{ij}+\alpha)[\exp\{-B_i(R_{ij}+\alpha)\} + \exp\{-B_i(R_{ij}+\alpha)\}], \quad (2)$$

where A_i, B_i, and α are intermolecular parameters. A's and B's vary depending on the atomic species, but A_i plus A_j is set to zero when i and j belong to a same molecule. A's and B's are determined empirically to fit to 110% of the most stable intermolecular distances and to 70% of the ES+EX calculated from 4-31G basis set. α is equal to 1.20 A in all cases. Although it would be better to fit to the experimental data, our attempt was interrupted by the insufficient data of intermolecular interactions in gas phase. The percentages, 110 and 70%, were taken by considering the characteristics of the relevant basis set, that is, the overestimation of electrostatic interaction energies and the underestimation of intermolecular distances.[20] The fifteen different systems which are illustrated in Fig. 2 were used for this parameterization. By these modifications, interaction energies from MNDO method were found to be improved in great deal except for the strongly hydrogen bonding systems. To take into account the latter systems, correction was made with the two

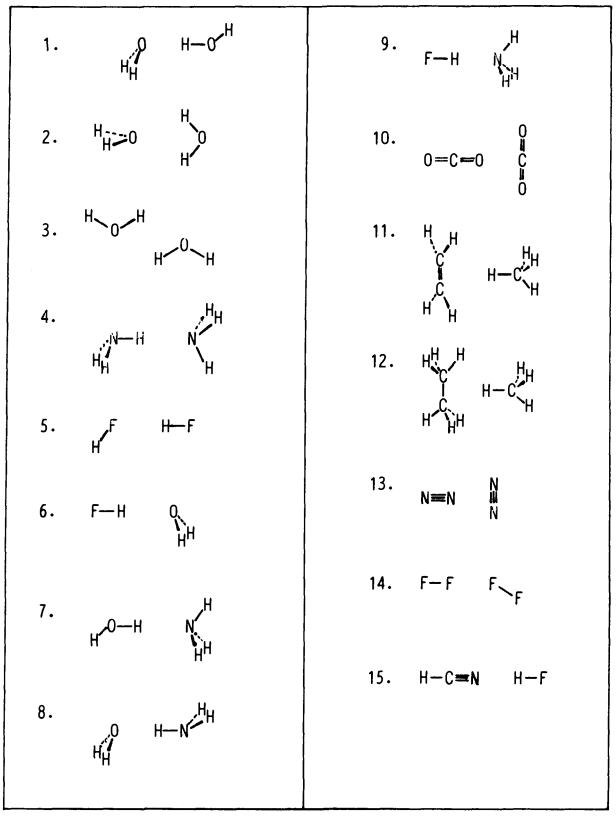

Fig. 2. Standard systems adopted for the SIMP parameterization.

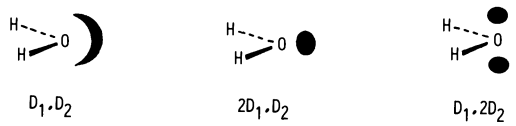

Fig. 3. Changes of the minimum point in molecular electrostatic potentials as a function of D_1 and D_2.

center repulsion integrals.

The two-center repulsion integrals are expanded in terms of multipole-multipole interactions [M^A_{lm}, M^B_{km}] in MNDO approximations. The formula for the integrals is expressed as follows:

$$\langle rs|tu\rangle = \sum_l \sum_k \sum_{m=-l\,\min}^{l\,\min} (e^2/2)^{l+k} \sum_{i=1}^{2^l} \sum_{j=1}^{2^k} [R_{ij}^2 + (\rho_i^A+\rho_k^B)^2]^{-1/2}, \quad (3)$$

where R_{ij} is the distance between the point charges i and j in the interacting configurations at atom A and B. For example, $\langle ss|sp_z\rangle$ is given by:

$$\langle ss|sp_z\rangle = [q^A, \mu_z^B] = -(e^2/2)[\{(R_{AB}-D_1^B)^2 + (\rho_0^A+\rho_1^B)^2\}^{-1/2}], \quad (4)$$

where D_1 and D_2 are the charge separations of the

multipole moments. Since D_1 and D_2 have been determined in MNDO approximation so as to reproduce well the molecular constants of each isolated molecule, it may be changed slightly in the interacting systems. In fact, the minimum point of molecular electrostatic potentials around H_2O molecule using MNDO formula[21] varies with the values of D_1 and D_2 (Fig. 3), and the molecular electrostatic potential map is different from the one using ab initio MO formula[22] when original values of D_1 and D_2 are used. This indicates that the changes in D_1 and D_2 may result in the correct map and the correct direction of the intermolecular interactions. Therefore, D_1 and D_2 are modified as follows:

$$D_l^{\mathrm{SIMP}} = f_l D_l \quad (l=1 \text{ or } 2). \tag{5}$$

f_l is the intermolecular parameters and set equal to 1.0 when atoms A and B belong to a same molecule but not when they belong to different molecules. Such definition of f_l, together with that of A_i in Eqs. 1 and 2, makes SIMP equivalent to MNDO for an isolated molecule. Equation 5 is applied only to the case of linear quadrupole, Q_{aa} and between hydrogen and heavy atoms when $l=2$. These parameters have been determined so as to reproduce well the interaction energies calculated from ab initio MO method for the different systems of molecular interaction illustrated in Fig. 2.

Results and Discussion

Table 1 lists the optimized values of the SIMP parameters for elements of H, C, N, O, and F. f_l values are approximately equal in the three atoms of N, O, and F, which indicates that the original MNDO MO method has made a similar error in the directions of the lone pairs of these atoms.

Tables 2 and 3 list the interaction energies and the most stable intermolecular distances calculated by SIMP, MNDO MO, AM1 MO, and ab initio (4-31G) MO method. It is clear that the results of SIMP reproduce well the one of ab initio MO method considering the aforementioned characteristics of 4-31G basis set. The regression analyses according to a relation $y=ax$ resulted in:

$$\Delta E(\mathrm{SIMP}) = 0.713\Delta E(4\text{—}31\ \mathrm{G}), \tag{6}$$
$$n = 15,\ R = 0.938,\ s = 4.85\ \mathrm{kJ\ mol^{-1}},$$

$$Re(\mathrm{SIMP}) = 1.033Re(4\text{—}31\ \mathrm{G}), \tag{7}$$
$$n = 15,\ R = 0.822,\ s = 0.37\ \mathrm{A}.$$

a) Except for H_2O plus F^- system. b) In parentheses listed are the results of ab initio MO method. c) Taken from Ref. 23. d) Taken from Ref. 24 e) Taken from Ref. 25. f) Near HF calculation. Taken from Ref. 26.

The regression coefficients are consistent with the initial purpose of fitting the results of the SIMP method to 110% of the *Re* values and to 70% of the ΔE values calculated from 4-31G basis set. The correlation coefficient is somewhat low in Eq. 7, but this is due to a small change in *Re* values.

We tested the SIMP method in the different 7 systems which were not used for the parametrization (Table 4). The reproducibility is satisfactory, considering the relations in Eqs. 6 and 7. SIMP also gives the correct molecular configurations in interacting systems. For example, although MNDO MO method gives 180 degree for the most stable values of θ in H_2CO plus HF system (Fig. 4), it gives 131 degree, which are approximately equal to that calculated from ab initio MO method.[22]

We expect that the SIMP method can be applied to various fields of chemistry–solvent effects on molecular structure, charge distribution, orbital energies, etc. These applications are currently under way in our laboratories.

The authours thank the Institute for Molecular Science for allotment of CPU time of the HITAC M-200H computer. Thanks are also due to Dr. Kizashi Yamaguchi for permitting us to use the IMSPAK program (Osaka University version) and to Dr. Yoshitaka Beppu for his advice in the development of SIMP program.

Solvent Extraction of Palladium(II) from Aqueous Chloride Media with 1,2-Bis(*tert*-hexylthio)ethane

Yoshinari BABA,* Toshiya EGUCHI, and Katsutoshi INOUE
Department of Industrial Chemistry, Faculty of Science and Engineering, Saga University, Honjo-machi, Saga 840
(Received July 22, 1985)

The extraction equilibrium and kinetics of palladium(II) extraction from an aqueous chloride media with 1,2-bis(*tert*-hexylthio)ethane (mixture), abbreviated as *t*-BHTE and denoted by B, in toluene were studied at 303 K. Palladium(II) was extracted as a 1:1 Pd:extractant complex, $[PdCl_2B]$. The partition coefficient of this extractant was evaluated as $K_d=5.5\times10^4$ for hydrochloric acid and $K_d=2.5\times10^4$ for an aqueous ammonium chloride solution. The results of kinetic experiments were quantitatively explained in terms of a reaction scheme in which parallel reactions of *t*-BHTE with $[PdCl_3]^-$ and $[PdCl_4]^{2-}$ in an aqueous phase were the rate-determining steps:

$$[PdCl_3]^-_{aq.} + B_{aq.} \xrightarrow{k_1} [PdCl_2B]_{aq.} + Cl^-_{aq.}$$

$$[PdCl_4]^{2-}_{aq.} + B_{aq.} \xrightarrow{k_2} [PdCl_2B]_{aq.} + 2Cl^-_{aq.}$$

The reaction rate constants for the above were evaluated as $k_1=6.4\times10^4$ dm^3 mol^{-1} s^{-1} and $k_2=2.6\times10^2$ dm^3 mol^{-1} s^{-1} for extraction from an aqueous ammonium chloride solution, and $k_1=6.7\times10^4$ dm^3 mol^{-1} s^{-1} and $k_2=3.2\times10^2$ dm^3 mol^{-1} s^{-1} from a hydrochloric acid solution.

Precious metals such as gold, silver, and platinum group metals are the most important rare metals indispensable in the high-technology industries as raw materials of catalysts, electronic materials and so on. Therefore, it is very important to develop effective techniques to recover these metals from spent catalysts or various kinds of scrap. However, the current refining processes involving these metals are based on highly complicated selective-precipitation techniques which consume great amounts of energy and labour. Also, these are often insufficient in terms of the achieved separation efficiency.

A solvent-extraction process is a potential alternative refining technology as well as an ion-exchange process. The most important factor in the solvent extraction of metals is extractant selectivity to the specified metal ions to be recovered. Precious metals such as gold, silver, platinum, and palladium belong to the soft metals which possess a strong affinity to ligands containing donating-type sulfur atoms which act as soft bases.[1] Consequently, neutral organic compounds containing sulfur atoms are very selective and effective extractants for precious metals.[2-6]

In a previous paper,[7] the authors discussed the extraction equilibrium of mercury(II) from hydrochloric acids with 1,2-bis(hexylthio)ethane in 1,2-dichloroethane and found that it is extracted as a 1:1 metal:extractant complex. In the present study, the extraction of palladium(II) with 1,2-bis(*tert*-hexylthio)ethane† was investigated from a chloride media while stressing its kinetic aspect since the extraction rate of palladium(II) is very slow compared to that of mercury(II). Toluene was used instead of 1,2-dichloroethane as a diluent from the standpoint of practical application.

† It was impossible to carry out the experiment of the extraction of palladium(II) with 1,2-bis(hexylthio)ethane in toluene because of the formation of a precipitate at the interface during extraction.

Experimental

Reagents. 1,2-Bis(*tert*-hexylthio)ethane(mixture), abbreviated as *t*-BHTE and denoted by B hereafter, was synthesized by a method similar to that of 1,2-bis(hexylthio)ethane described in a previous paper.[7] The product was purified by vacuum distillation(156—159 °C/6 mmHg(1 mmHg=133.322 Pa)) and identified using IR and NMR spectra and element analysis. The results of element analyses are as follows. Found: C, 63.9; H, 11.3%. Calcd for $C_{14}H_{30}S_2$: C, 64.1; H, 11.5%. The product was a transparent liquid with a confirmed purity of about 97% by gas chromatography. Analytical-grade toluene was used without further purification. Organic solutions of *t*-BHTE were prepared on a gravimetric basis by diluting *t*-BHTE with toluene. Aqueous solutions of palladium(II) were prepared by dissolving palladium(II) chloride in hydrochloric acid or aqueous ammonium chloride solutions containing a small amount of hydrochloric acid(0.01 mol dm^{-3}).

Procedure for the Measurement of Extraction Equilibrium. Under an excess concentration of *t*-BHTE over the palladium(II) concentration in the aqueous phase, palladium(II) was almost completely extracted over the whole concentration region of hydrochloric acid. The remaining amount of palladium(II) was too small to make a precise quantitative analysis. Therefore, only a loading test was carried out to determine the molar ratio of palladium(II) extracted into the organic phase to *t*-BHTE by varying the concentration ratio of *t*-BHTE in the organic phase to that of palladium(II) in the aqueous phase under the conditions

of a large excess of the palladium(II) concentration.

Equal volumes (0.02 dm^3) of the organic and aqueous phases taken in a 0.1 dm^3 stoppered glass flask were shaken for 5 d in a water bath maintained at 303 K. The concentration of *t*-BHTE in the organic phase was varied from 1×10^{-3} to 1×10^{-2} mol dm^{-3} and that of palladium(II) was varied about from 1.5 to 10 times of the *t*-BHTE concentration. After separating the two phases, the palladium(II) concentration in the aqueous phase was determined using a Nippon Jarrell-Ash model AA-782 atomic absorption spectrophotometer and that in the organic phase was calculated from the mass balance of the palladium(II) concentration in the aqueous phase before and after equilibration.

Procedure for the Measurement of Aqueous Solubility of *t*-BHTE. The aqueous solubility of *t*-BHTE was measured spectrophotometrically at 303 K according to the following method. A toluene solution of *t*-BHTE and hydrochloric acid or an aqueous ammonium chloride solution of known concentrations was shaken vigorously for 24 h with a volume ratio of aqueous phase to organic phase 10:1 using Iwaki's mechanical shaker type V-VD. After phase separation, a sample of aqueous phase (0.19 dm^3) was transferred to a separatory funnel, to which 0.05 dm^3 of 2×10^{-3} mol dm^{-3} aqueous palladium(II) solution containing 0.01 mol dm^{-3} hydrochloric acid was added and shaken for 24 h by a mechanical shaker in order to completely convert any *t*-BHTE dissolved in the aqueous phase to its palladium(II) complex. A small amount of toluene (0.005 dm^3) was added and shaken vigorously for 24 h to transfer the palladium(II) complex into toluene. The absorbance of the palladium(II) complex was measured at 403 nm against a toluene blank using a Shimadzu UV 140 spectrophotometer. Then, the extractant concentration dissolved in the aqueous phase was calculated from the molar absorptivity and volume ratios.

Procedure for the Measurement of Extraction Rate. The experimental apparatus used was a batch-type stirred glass cell with a 10-cm inner diameter and a 15-cm depth as shown in Fig.1. The vessel was fitted with four baffles, each of which was 1-cm wide and 14-cm long. Stirring was carried out using a impeller with six flat blades connected to a speed controller. The baffles and impellers made of stainless steel or Teflon were used in the extraction from aqueous ammonium chloride solution and hydrochloric acid, respectively.

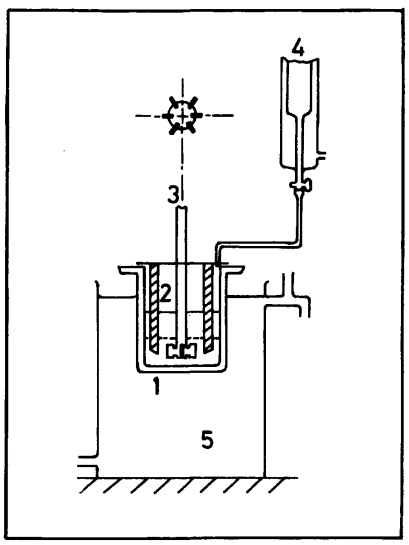

Fig. 1. Experimental apparatus.
1: Stirred glass cell, 2: baffle, 3: impeller, 4: reservoir with jacket, 5: thermostated bath.

Equal volumes (0.3 dm^3) of aqueous ammonium chloride solution or hydrochloric acid solution containing palladium(II) and *t*-BHTE solution of toluene were carefully introduced into the vessel. After that, stirring was initiated at a constant speed and samples were taken at definite time intervals. After phase separation, the palladium(II) concentration in the aqueous phase was determined using the atomic absorption spectrophotometer. The initial palladium(II) concentration was 5×10^{-4} mol dm^{-3} in all kinetic runs. The concentrations of the extractant and chloride ions were varied in the range of 5×10^{-3} to 0.1 mol dm^{-3} and of 0.1 to 6 mol dm^{-3}, respectively. Since the extraction rate was found to be independent of the stirring speed in a range greater than 1500 rpm, subsequent experiments were carried out at a constant stirring speed of 1500 rpm.

Results and Discussion

Equilibrium. The result of the loading test is shown in Fig.2. It indicates that the molar ratio of *t*-BHTE to palladium(II) in the organic phase asymptotically approaches unity. From this, the stoichiometric relation of this extraction reaction is considered to be generally expressed by

$$[PdCl_4]^{(i-2)-}_{aq.} + B_{org.} \rightleftharpoons [PdCl_2B]_{org.} + (i-2)Cl^-.$$

Aqueous Solubility of *t*-BHTE. The equilibrium distribution of *t*-BHTE between the aqueous phase and the organic phase is expressed by its physical partition to the aqueous phase as

$$B_{aq.} \rightleftharpoons B_{org.} \quad K_d' \qquad (1)$$

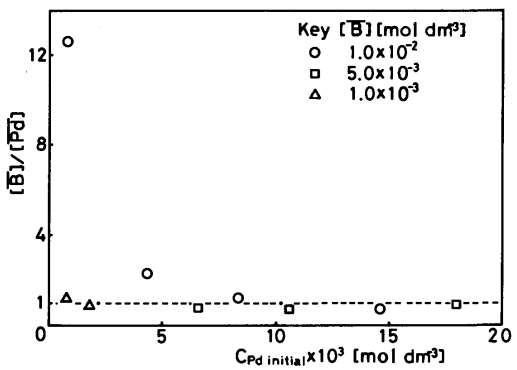

Fig. 2. Experimental results of the loading test at constant HCl concentration (1.0 mol dm^{-3}).

where K_d is the partition coefficient of *t*-BHTE and is expressed as

$$K_d = \frac{[\overline{B}]}{[B]}. \quad (2)$$

Here, the concentration of *t*-BHTE in the organic phase, $[\overline{B}]$, is nearly equal to its initial concentration since the partition coefficient is very large. The logarithm of Eq. 2 gives

$$\log [B] = \log [\overline{B}] - \log K_d. \quad (3)$$

Figure 3 shows the relation between the concentration of *t*-BHTE in the aqueous and organic phases based on Eq.3. The plotted points in this figure lie on a straight line with a slope of 1, regardless of the chloride ion concentration. There is, though, some scattering. From the intercept of the straight line with the ordinate, the partition coefficients, K_d, were evaluated as $K_d=5.5\times10^4$ and $K_d=2.5\times10^4$ for hydrochloric acid and aqueous ammonium chloride solution, respectively.

Kinetics. If it is assumed that the reaction rates in the forward and reverse directions are of pseudo-first-order with respect to the palladium(II) concentrations in the aqueous and organic phases, respectively. The relation between the palladium(II) concentration(a) in the aqueous phase and the contact time(t) is described as

$$\frac{a_i-a_e}{a_i}\ln\frac{a_i-a_e}{a_t-a_e} = k_f t, \quad (4)$$

where k_f denotes the observed reaction rate constant for the forward reaction and the subscripts i and e represent the initial and equilibrium states, respectively.

A typical experimental result is shown in Fig. 4. Here, the straight lines pass through the origin. The reaction-rate constants were obtained from the slopes of these straight lines.

Figure 5 shows the effect of the *t*-BHTE concentration on the observed extraction rate constant. In Fig. 5, the plots cluster along straight lines with slopes of 1; consequently, it can be concluded that the extraction rate is first order with respect to *t*-BHTE under these concentration regions.

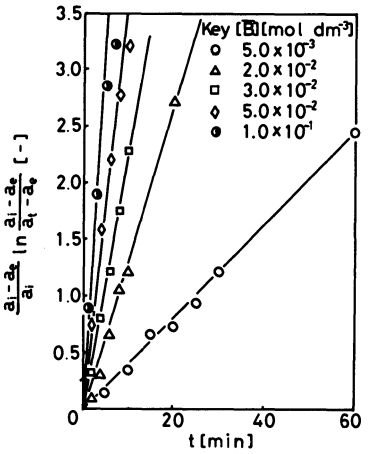

Fig. 4. Typical plot of the experimental results based on the pseudo-first-order rate expression at constant NH_4Cl concentration (0.5 mol dm^{-3}).

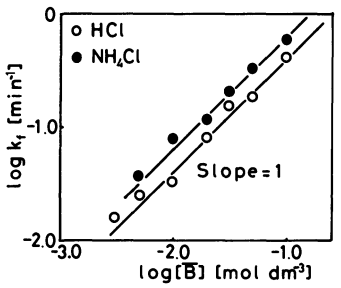

Fig. 5. Effect of *t*-BHTE concentration, at constant chloride ion concentration (0.5 mol dm^{-3}), on the observed extraction rate constant.

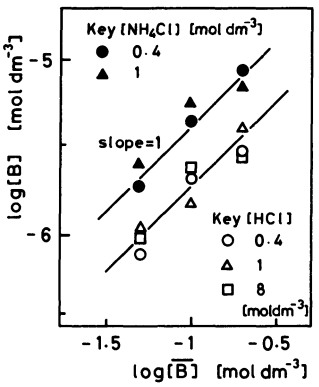

Fig. 3. Aqueous solubility of *t*-BHTE.

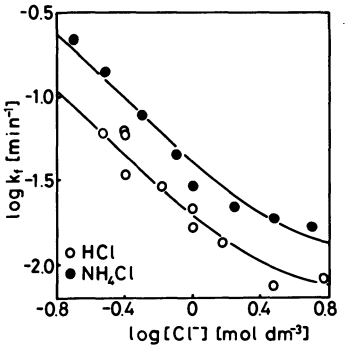

Fig. 6. Effect of chloride ion concentration, at constant *t*-BHTE concentration (1.0×10^{-2} mol dm^{-3}), on the observed extraction rate constant.

Similarly, the effect of chloride-ion concentration on the observed rate constants is shown in Fig. 6. For both aqueous media of hydrochloric acid and ammonium chloride, the plotted points lie on straight lines with slopes of −1 in the low-concentration range of chloride ions and approach constant values in the high-concentration range. Hence, it can be concluded that the extraction rate is inverse first order with respect to chloride ions in its low-concentration range and of zeroth order in its higher-concentration range.

In the concentration region of the chloride ions of the present study, the majority of palladium(II) exists as, tetrachloro complex, $[PdCl_4]^{2-}$, and a small amount of aquatrichloro complex, $[PdCl_3(H_2O)]^-$, coexists while the concentrations of the species, Pd^{2+}, $[PdCl(H_2O)_3]^+$, $[PdCl_2(H_2O)_2]$ can be negligible compared with those of the species, $[PdCl_3(H_2O)]^-$ or $[PdCl_4]^{2-}$. Among these, chloro complexes of palladium(II), the aquatrichloro complex, $[PdCl_3(H_2O)]^-$, is considered to be much more labile than other complexes as Rund[8] pointed out in their studies on the mechanism of substitution reactions of chloro complexes of palladium(II) with 1,10-phenanthroline and 2,2′-bipyridyl. Further, since *t*-BHTE has no interfacial activity, complexation with palladium(II) is not considered to take place at the interface between two phases but in the aqueous phase. Taking account of these facts, the following reaction scheme was put forward in order to explain the results of the extraction kinetics of palladium(II) mentioned above.

$$B_{org.} \rightleftharpoons B_{aq.} \qquad K_d^{-1} \tag{5}$$

$$[PdCl_3(H_2O)]^-_{aq.} + B_{aq.} \xrightarrow{k_1} [PdCl_2B]_{aq.} + Cl^-_{aq.} + H_2O \tag{6}$$

$$[PdCl_4]^{2-}_{aq.} + B_{aq.} \xrightarrow{k_2} [PdCl_2B]_{aq.} + 2Cl^-_{aq.} \tag{7}$$

$$[PdCl_2B]_{aq.} \rightleftharpoons [PdCl_2B]_{org.} \tag{8}$$

Assuming that the parallel reactions of $[PdCl_3(H_2O)]^-$ and $[PdCl_4]^{2-}$ with *t*-BHTE are the rate-determining steps, the rate expression can be described as follows:

$$-\frac{dC_{Pd}}{dt} = k_1[[PdCl_3(H_2O)]^-][B] + k_2[[PdCl_4]^{2-}][B] = (k_1\beta_3[Cl^-]^3/\alpha + k_2\beta_4[Cl^-]^4/\alpha)C_{Pd}[B]. \tag{9}$$

In the above equation, β_i is the stability constant of the *i*-th chloro complex of palladium(II) defined as follows.

$$Pd^{2+} + iCl^- \rightleftharpoons [PdCl_i]^{(i-2)-} \qquad \beta_i$$

$$\beta_i = [[PdCl_i]^{(i-2)-}]/[Pd^{2+}][Cl^-]^i. \tag{10}$$

In the present study, the following values[9] were used as the stability constants of the chloro complex of palladium(II): $\beta_1=10^{4.7}$, $\beta_2=10^{7.7}$, $\beta_3=10^{10.3}$, $\beta_4=10^{11.9}$. In Eq. 9, α is defined by

$$\alpha = 1 + \sum_{i=1}^{4} \beta_i[Cl^-]^i. \tag{11}$$

Under the present experimental conditions, Eq. 11 may be approximated by Eq. 12:

$$\alpha \simeq \beta_3[Cl^-]^3 + \beta_4[Cl^-]^4. \tag{12}$$

Eq. 9 is consequently approximated as

$$-\frac{dC_{Pd}}{dt} = \left\{\frac{k_1\beta_3[Cl^-]^3 + k_2\beta_4[Cl^-]^4}{\beta_3[Cl^-]^3 + \beta_4[Cl^-]^4}\right\} K_d^{-1}C_{Pd}[\overline{B}]. \tag{13}$$

In an even higher concentration range of chloride ions, it is further approximated by

$$-\frac{dC_{Pd}}{dt} = \{k_1(\beta_3/\beta_4)[Cl^-]^{-1} + k_2\}K_d^{-1}C_{Pd}[\overline{B}]. \tag{14}$$

C_{Pd} and $[\overline{B}]$ denote the total concentration of palladium(II) in the aqueous phase and that of *t*-BHTE in the organic phase, respectively.

Consequently, the proposed rate expression, Eq. 14, suggests that the extraction rate is first order with respect to *t*-BHTE in the organic phase and palladium(II) in the aqueous phase, respectively, and that it is of the inverse first order with respect to chloride ion in its low concentration region and of zeroth order in its high concentration region.

From the experimental results shown in Fig. 6, the reaction rate constants, k_1 and k_2, were evaluated by the least-square method according to Eq. 13 as $k_1=6.4\times10^4$ dm^3 mol^{-1}s^{-1} and $k_2=2.6\times10^2$ dm^3 mol^{-1}s^{-1} for the extraction from aqueous ammonium chloride solution, and as $k_1=6.7\times10^4$ dm^{3}mol^{-1}s^{-1} and $k_2=3.2\times10^2$ dm^3 mol^{-1} s^{-1} for that from hydrochloric acid using the distribution constants evaluated earlier. The values evaluated from two aqueous chloride media are in good agreement either for k_1 or for k_2. The large difference between k_1 and k_2 indicates that the aquatrichloro complex, $[PdCl_3(H_2O)]^-$, is much more labile than the tetrachloro complex, $[PdCl_4]^{2-}$, as mentioned earlier. However, these values are about two or three orders in magnitude greater than those obtained by Rund[8] in the complexation with 1,10-phenanthroline ($k_1=7.1\times10$ dm^3 mol^{-1}s^{-1} and $k_2=2.2$ dm^3 mol^{-1}s^{-1}). This might suggest the possibility of an interfacial reaction mechanism between two phases rather than the homogeneous reaction mechanism discussed above. More information regarding this system seems to be required.

The solid lines in Fig. 6 are the calculated results

from Eq. 13 using the evaluated values of k_1 and k_2, and the stability constants of the chloro complexes of palladium(II) and the partition coefficient of *t*-BHTE evaluated earlier. These lines are in fairly good agreement with the experimental results for both media. The difference between the rate of extraction from hydrochloric acid and that from aqueous ammonium chloride solution is attributable to that of the solubility of *t*-BHTE to both media.

The authors are indebted to Professor M. Takagi of Kyushu University for his instruction in the synthesis of 1,2-bis(*tert*-hexylthio)ethane.

Ylide-Metal Complexes. X.[1] An X-Ray Photoelectron Spectroscopic Study of Triphenylmethylenephosphorane and Gold- and Copper-Phosphorane Complexes

Yoshihisa YAMAMOTO* and Hidetaka KONNO†
Faculty of Pharmaceutical Sciences, Higashi Nippon Gakuen University, Ishikari-Tobetsu, Hokkaido 061-02
†Faculty of Engineering, Hokkaido University, Sapporo 060
(Received October 8, 1985)

Triphenylmethylenephosphorane, the bis(triphenylmethylenephosphorane)gold chloride and the corresponding copper chloride have been studied by X-ray photoelectron spectroscopy. For the phosphorane, the binding energies, E_B, for P 2s and P 2p peaks were observed at 190.1 and 132.6 eV, respectively. The E_B value for the P 2p peak agrees with that (132.6 eV) for the phosphonium ion in triphenylmethylphosphonium bromide. The C 1s spectrum was separated into two peaks at E_B=285.0 and 283.9 eV, assuming a ratio of 18:1. The peak at 285.0 eV corresponds to the phenyl carbons, and that at 283.9 eV can be assigned to the electron-rich methylene carbon. Thus, the structure of the phosphorane is considered to be an ylide formula, $(C_6H_5)_3\overset{+}{P}\text{-}\overset{-}{\ddot{C}}H_2$. In gold phosphorane complexes, E_B of the C 1s, P 2s, and P 2p peaks were close to those for the phosphorane. The E_B of the Cl $2p_{3/2}$, Au $4f_{7/2}$, and Au $4f_{5/2}$ peaks coincided with those for bis(triphenylphosphine)gold chloride. These results indicate the structure of the gold complex to be $(C_6H_5)_3\overset{+}{P}\text{-}\overset{-}{\ddot{C}}H_2$ / $(C_6H_5)_3\overset{+}{P}\text{-}\overset{-}{\ddot{C}}H_2$ $\diagdown\!\!\diagup\ \overset{+}{Au}$ ← Cl^-. The XPS results also indicate that the structure of the copper complex is similar to that of the gold complex.

Previously, we have been concerned with the preparation and properties of metal complexes with unstable triphenylmethylenephosphorane,[2] $(C_6H_5)_3P=CH_2$, and unstable triphenylmethylenearsorane[3] $(C_6H_5)_3As=CH_2$.

Many investigations regarding the XPS of metal complexes have been reported, especially, halogen complexes,[4] e.g., K_2MCl_6 (M: W, Re, Os, Ir, Pt); coordinated nitrogen-type complexes,[5] e.g., $[Co(NH_3)_5(NO_2)]Cl_2$; phosphine complexes,[6] e.g., $[(C_6H_5)_3P]_2CdCl_2$; olefine complexes,[7] e.g., $[(C_6H_5)_3P]_2Pt(CH_2=CH_2)$; metallocene,[8] e.g., $(\pi\text{-}C_5H_5)_2M$ (M: V, Cr, Mn, Fe, Co, Ni); carben complexes,[9] e.g., $(CO)_5CrC(OCH_3)CH_3$; and metal-carbonyl complexes,[10] e.g., $Fe(CO)_5$. However, the XPS study of ylide-metal complexes has not been reported so far, since preparation of complexes with unstable ylide was difficult.

The present paper deals with XPS measurements and the structure of triphenylmethylenephosphorane and its gold and copper complexes.

Experimental

XPS Measurements. Sample handling was always carried out in a 99.9995% pure nitrogen atmosphere to prevent possible decomposition. Samples were placed on a gold or nickel mesh holder and introduced into a spectrometer with a 99.9995% pure nitrogen atmosphere. After evacuating to better than 7×10^{-7} Pa (5×10^{-9}Torr†), the sample was cooled to 200 K, and irradiated with Mg $K\alpha$ X-ray (120 W). The instrument used was a VG ESCA 3 electron spectrometer. Analyzer energy was set to give a half width at half maximum [FWHM] of Au $4f_{7/2}$ peak of 1.18 eV. Peak separation of the spectra was made by the Gauss-Newton least-squares method, where a mixed Gaussian-Lorentzian curve shape having a fixed FWHM was utilized. The electron binding energies were calibrated by assigning 285.0 eV to the C 1s peak of the normal phenyl carbon.

Preparation of Phosphorane and Metal-Phosphorane Complexes. Triphenylmethylenephosphorane (**1**) was prepared from the triphenylmethylphosphonium bromide by the sodium amide method.[11] Bis(triphenylmethylenephosphorane)gold chloride (**6**), (triphenylmethylenephosphorane)(triphenylphosphine)gold chloride (**7**), and bis(triphenylmethylenephosphorane)copper chloride (**9**) were prepared by the method of the previous paper.[3b,11] Bis(triphenylphosphine)gold chloride (**8**) was prepared by the method of Baenziger.[12]

Results and Discussion

XPS of Triphenylmethylenephosphorane (1): The structure of phosphorane has been given in two formulae,[13] the ylide formula and the ylene formula as Scheme 1. The ylide formula shows a dipolar zwitterionic nature involving a carbanionic function and an onium center at the phosphorus element. In

$$\underset{\text{Ylide}}{R_3\overset{+}{P}-\overset{-}{\ddot{C}}H_2} \longleftrightarrow \underset{\text{Ylene}}{R_3P=CH_2}$$

Scheme 1.

† 1 Torr=133.322 Pa.

the ylene formula, a true double bond is postulated between the onium center and the phosphorane carbon. Although the P-C bond length of **1** was determined to be 1.66 Å by X-ray analysis[14](suggesting a double-bond character), the assignment of ylide or ylene formula for the phosphorane (**1**) remains unsolved so far.

The results by the XPS measurements of phosphorane (**1**) and the corresponding phosphonium salts are summarized in Table 1 with some reference values. The binding energy, E_B, value (132.6 eV) of the P 2p peak for triphenylmethylphosphonium bromide, $[(C_6H_5)_3\overset{+}{P}CH_3]Br^-$ (**2**), is in good agreement with that (132.5 eV) for phosphonium ion in benzyltriphenylphosphonium chloride,[15] $[(C_6H_5)_3\overset{+}{P}CH_2(C_6H_5)]Cl^-$ (**3**). In reference 16, the E_B of P 2p peak for **3** and methyltriphenylphosphonium chloride, $[(C_6H_5)_3\overset{+}{P}CH_3]Cl^-$ (**4**), are reported. However, those values are different from our results and also from those in reference 15. The E_B in reference 16, however, are somewhat ambiguous, because only E_B of the P 2p peak are given and there is no description of a calibration method. Therefore, the measured E_B for **2** is regarded as reasonable. Other reference values for **2** or **4** were not found by our literature survey. The E_B of the P 2p peak of **2** is different from that[6,15,17] for triphenylphosphine, $(C_6H_5)_3P$ (**5**), as is shown in Table 1. The E_B of **5** measured by different investigators show fairly large scattering, but the highest value is still lower than 132.6 eV of **2**.

In the XPS for phosphorane (**1**), the E_B of the P 2p peak was observed at 132.6 eV; i.e., phosphorus element in **1** can be assigned to the phosphonium ion. This suggests the ylide formula, $(C_6H_5)_3\overset{+}{P}-\overset{-}{C}H_2$. The C 1s spectrum for **1** showed a slightly distorted shape, a tailing at the lower binding-energy side and with a separate very weak satellite peak at the higher binding-energy side. The peak binding energy, E_B, was set at 285.0 eV as due to phenyl carbons. Assuming an 18:1 intensity ratio between phenyl carbons and a methylene carbon, the C 1s peak can be separated to two peaks at 285.0 eV and 283.9 eV. The E_B of the latter peak indicates an electron-rich carbon and is favorable to the ylide formula, but the results must be evaluated with caution since a few arbitrary factors are involved in the peak separation.

XPS of Bis(triphenylmethylenephosphorane)gold Chloride, $[(C_6H_5)_3PCH_2]_2AuCl$ (6), (Triphenylmethylenephosphorane)(triphenylphosphine)gold Chloride, $[(C_6H_5)_3PCH_2][(C_6H_5)_3P]AuCl$ (7), Bis(triphenylphosphine)gold Chloride (8) and Bis(triphenylmethylenephosphorane)copper Chloride, $[(C_6H_5)_3PCH_2]_2CuCl$ (9): The results of XPS for metal phosphorane and metal phosphine complexes are summarized in Table 2. The E_B of Au 4f and Cl $2p_{3/2}$ peaks for both gold complexes **6** and **7** are in good agreement with those for **8**. The E_B values for **8** coincide with those reported by others[18]: E_B[C 1s]=284.9 eV, E_B[P 2p]=131.8 eV, E_B[Cl $2p_{3/2}$]=197.5 eV, and E_B[Au $4f_{7/2}$]=85.2 eV, where oxidation number of gold has been assigned to +1. In addition, the structure of **8** has been found to be essentially trigonal planar by X-ray diffraction.[12] Therefore, the structure of **6** and **7** can be analogous to **8**, and the chloride in **6** and **7** can bond to Au(I). The E_B of C 1s, P 2s, and P 2p peaks for bonded phosphorane in **6** and **7** are very close to those for **1**, but are different from those for the coordinated phosphine. This suggests that the phosphorane in gold complexes can be the ylide formula; i.e., phosphorane-gold bonds are formed from the electron-pair in the carbanion and empty orbitals (sp^2) of gold. Then, the structure of **6** can be expressed as Scheme 2.

For copper complex **9**, the Cu 2p spectra showed no satellite peaks; thus the copper is monovalent

Table 1. Binding Energies Observed in the XPS of Phosphorane and Phosphonium Bromide, and Some Reference Values

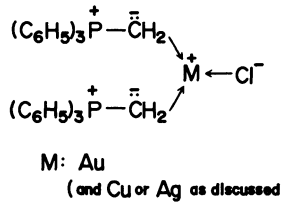

Scheme 2.

($3d^{10}$) or metallic.[19] The E_B of the Cu 2p peaks are much higher than those for commonly known complexes of Cu(I) or Cu(0),[19] but are in good agreement with those for triphenylphosphinecopper(I) chloride,[19a] $(C_6H_5)_3PCuCl$ (**10**), and tris(triphenylphosphine)copper(I) chloride, $[(C_6H_5)_3P]_3CuCl$ (**11**): E_B[Cu $2p_{3/2}$]=933.5 eV, and E_B[Cu $2p_{1/2}$]=953.2 eV assuming E_B[C 1s]=285.0 eV for phenyl carbons. The values for bis(triphenylphosphine)copper chloride, $[(C_6H_5)_3P]_2CuCl$ (**12**), were not found. Further, to distinguish the Cu(I) and Cu(0) Auger parameter, α, is known to be useful. It is defined as the kinetic energy of an intense Auger line minus that of an intense photoelectron line.[20] The measured $E_K[Cu_{LMM}] - E_K$[Cu $2p_{3/2}$] for copper in **9** was 361.3 eV. This value is very close to α=361.0 eV for CuCl and CuCN, but different from α=364.6 eV for metallic Cu.[20] Thus, the oxidation number of copper in **9** is one (or +1). Since other E_B values for **9** coincide with gold complex **6**, and the structure of **12**[21] is confirmed to be similar to that of **8**, the structure of **9** is as in Scheme 2. The XPS results strongly suggest that gold and copper complexes have the structure of Scheme 2. However, as a matter of course, X-ray diffraction may provide indisputable conclusions. So far, the diffraction is not conducted due to the difficulties of sample preparation, handling, and facilities.

The similarity of copper and gold complexes leads to a conclusion that the corresponding silver complex $[(C_6H_5)_3PCH_2]_2AgCl$ (**13**)[11] may have the same structure as is shown in Scheme 2.

Proton-Catalyzed Formation of Methyl Carbamate in the Reaction of Isocyanic Acid in Methanol

Hitoshi YASHIRO,† Jun-ichi TAKESHITA,†† Akitsugu OKUWAKI,* and Taijiro OKABE
Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Sendai 980
(Received August 14, 1985)

The rate of formation of methyl carbamate has been measured by a determination of the HNCO concentration. It can be expressed as follows: $r_c=k_c[HNCO][H^+]$. This rate equation was confirmed in the concentration range of HCl(0.76—1.53×10^{-3} mol dm^{-3}). Consequently, this reaction was subjected to a proton catalysis. However, at a H^+ concentration lower than 4×10^{-4} mol dm^{-3}, the observed rate was lower than that calculated by the rate equation, especially at a high HNCO concentration. This was explained by a reduction of the free HNCO concentration due to an association of HNCO with the formed carbamate.

Isocyanic acid reacts with alchohols to afford carbamates and allophanates.[1-2] The mechanism of the formation of carbamates via a rearrangement of the adduct without any consideration of catalysis was postulated by Blohm and Becker.[3] A detailed kinetic study of the HNCO-alcohol reaction, however, has been difficult since HNCO is produced in situ[4-6] because of its instability. Also a suitable method for determining HNCO or carbamates has not been developed.[7-8] The present authors have developed a method for a rapid determination of HNCO.[9] In this paper, the effects of HCl and triethylamine on the rate of formation of methyl carbamate are examined using the rapid method in a low-concentration range of HNCO(< 1.3 M) where the formation of methyl allophanate was negligible. Kinetic analyses show a proton-catalyzed mechanism for the reaction between MeOH and HNCO and a reduction mechanism regarding the rate by the formation of a complex.

Experimental

Reagents: Isocyanic acid was prepared and purified by Linhard's method.[10] The purity attained was 99.4% or greater. Methanol was purified by the usual method using magnesium activated by iodine. Methanolic hydrogen chloride solutions were prepared by bubbling HCl gas into MeOH. Sodium methoxide solution, 0.5 mol dm^{-3}, was prepared by addition of metallic Na pieces into MeOH.

Determination of HNCO: Excess MeONa was titrated with a standard HCl solution after adding a known amount of MeONa into a sample solution containing HNCO and filtering precipitated NaNCO.

Procedure: Methanol(20—30 cm^3) was placed in a 100-cm^3 round-bottomed flask with a ground-glass stopper and immersed in a thermostated bath. Isocyanic acid (0.7 g) was withdrawn with a pipet under a N_2 stream from a storage tube immersed in a Dry Ice-MeOH bath and added into the flask. After rapid agitation, a 2-cm^3 sample was quickly removed and the initial HNCO concentration was determined. Samples were then taken at certain intervals. The reaction mixture was not stirred during the reaction because no precipitate formed and the rate of formation of the carbamate was not altered by agitation.

Results

Effect of Isocyanic Acid, Triethylamine, and Hydrogen Chloride Concentrations. Isocyanic Acid Concentration: Figure 1 shows the effect of the initial HNCO concentration on the decrease in the HNCO concentration at 293 K. The rate of formation of methyl carbamate in MeOH, r_c, can be written as follows:

$$r_c = d[CH_3OCONH_2]_T/dt = -d[HNCO]_T/dt = k[HNCO]_T^{\alpha}, \quad (1)$$

where α is the order of the reaction, k the rate

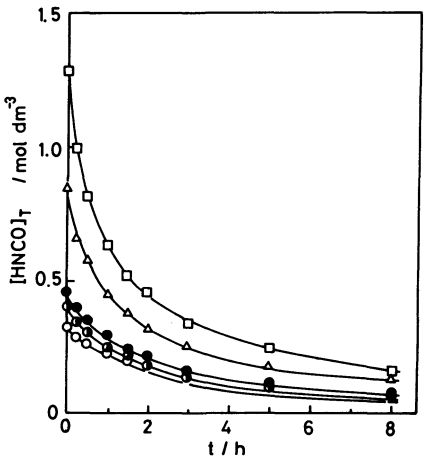

Fig. 1. Decreasing curves of concentration of HNCO at 293 K. $[HNCO]_0$(mol dm^{-3}): (□) 1.285, (△) 0.830, (●) 0.452, (◑) 0.406, (○) 0.319. Curves are calculated ones.

† Present address: Department of Applied Chemistry, Faculty of Engineering, Iwate University, Morioka 020.

†† Research Division, Japan Chemical Industrial Co. Ltd., Koto-ku, Tokyo 136.

constant for the formation of the carbamate, $[HNCO]_T$ the total HNCO concentration determined and $[CH_3OCONH_2]_T$ the total carbamate concentration. Then,

$$\log \tau_{1/m} = (1-\alpha)\log[HNCO]_0 + \log(m^{\alpha-1}-1)/k(\alpha-1), \quad (2)$$

where $\tau_{1/m}$ is the time required for decreasing the initial HNCO concentration to $1/m$ and $[HNCO]_0$ the initial HNCO concentration. Figure 2 shows plots of $\tau_{1/5}$ vs. $\log[HNCO]_0$. The order of the reaction, α, is 1.5 since the slope of the straight line is -0.5. From this data, we can write

$$2([HNCO]_T^{-1/2} - [HNCO]_0^{-1/2}) = kt. \quad (3)$$

This relationship is shown in Fig. 3. At an early stage, the relationship could be expressed by a dotted straight line. However the plots became lower than the straight line upon increasing the HNCO concentration and for a longer reaction time.

Triethylamine Concentration: In Fig. 4, 3/2 order rate plots are shown in the presence of triethylamine and methyl carbamate. The rate of formation was appreciably suppressed by triethylamine at about 10^{-4} mol dm^{-3}. The tendency is just reversed to the effect of bases on the reaction of phenyl isocyanate with MeOH in which the bases accelerated the formation of carbamates.[11] This discrepancy can be explained by the fact that triethylamine can not act as a base in the presence of a large excess of HNCO. Methyl carbamate also significantly reduced the rate.

Hydrogen Chloride Concentration: The rate of formation of methyl carbamate at 293 K was accelerated upon increasing the HCl concentration and became almost proportional to the first-order of the HNCO concentration at 4×10^{-3} mol dm^{-3}.

Discussion

Mechanism of the Formation of Methyl Carbamate. Rate Equation. The reactions ionvolved in the system can be considered as follows:

$$HNCO \overset{K_1}{\rightleftharpoons} H^+ + NCO^- \quad (4)$$

$$CH_3OH + HNCO \xrightarrow[k_c]{H^+} CH_3OCONH_2 \quad (5)$$

$$CH_3OCONH_2 + HNCO \overset{K_2}{\rightleftharpoons} CH_3CONH_2\cdot HNCO \quad (6)$$

$$HCl \longrightarrow H^+ + Cl^- \quad (7)$$

$$(C_2H_5)_3N + H^+ \longrightarrow (C_2H_5)_3NH^+, \quad (8)$$

where k_c is the rate constant. K_1 and K_2 are the equilibrium constants for Eqs.4 and 6, respectively.

Figure 5 shows the relationship between the HCl concentration and the slopes of the straight lines ($k_c[H^+]$) obtained from the first-order plots for the

HNCO concentration at 0.76—1.53×10^{-3} mol dm^{-3} of HCl and 273 K. This result supports the calculation that the rate of formation of the carbamate can be expressed by Eq. 9.

$$r_c = k_c[HNCO][H^+] \quad (9)$$

Rate-Determining Step. Blohm et al.[3] infered from an analogy to the mechanism of conversion of NH_4NCO to urea that carbamates are produced via a zwitterionic intermediate shown by Eq. 10(**a**). However, HNCO can hardly form such stable

$$CH_3OH + HNCO \overset{K_3}{\rightleftharpoons} CH_3\overset{+}{O}H\overset{-}{C}ONH \quad (10)$$

intermediate with MeOH since it is not a base such as NH_3. We considered simply that methyl carbamate was produced by a general acid-catalyzed reaction as shown by Eq. 9(**b**), since there were not enough data to discuss the proton-transfer process in the formation of methyl carbamate.

Mechanism of the Reduction of Rate by Methyl Carbamate. The plots in Fig. 3 became lower than the dotted line as the reaction proceeded. The tendency was enhanced at higher HNCO concentrations and for a longer reaction time. This may indicate that the formed methyl carbamate inhibited the reaction. This was confirmed by the result that the rate of formation decreased in the presence of 0.48 mol dm^{-3} methyl carbamate as shown in Fig. 4. From the rate Eq., there are the following three mechanisms by which the carbamate reduces its rate of formation: **A**) Reduction of the H$^+$ concentration, **B**) Reduction of the free HNCO concentration, **C**) Reduction of both concentrations. Each mechanism is discussed below.

In the case of **A**, the simplest mechanism is the formation of $CH_3OCO\overset{+}{H}NH_2$ as

$$CH_3OCONH_2 + H^+ \overset{K_4}{\rightleftharpoons} CH_3OCO\overset{+}{H}NH_2 \quad (11)$$

However, the decreasing curves of the HNCO concentration calculated by this mechanism could not be fitted with experimental data. The H$^+$ concentration was reduced remarkably by this mechanism; hence, the first-order linear relationship in Fig. 5 can not be obtained in such a low HCl concentration. Consequently, we did not consider any model composed of only case **A** as the mechanism of the reduction of rate. In the case of **B**, the simplest mechanism is the formation of a 1:1 complex as shown in Eq. 6. In this case, the H$^+$ concentration also slightly decreases through Eq. 4. In the case of **C**, the simplest mechanism is a combination of **A** and **B**.

Mechanism of the Formation of Methyl Carbamate. Four models can be made from the combination of the rate-determining step(**a** or **b**) and the mechanism of the reduction of rate(**B** or **C**) as follows: I **b-B**, II **b-C**, III **a-B**, IV **a-C**. In order to determine the optimum model, the decreasing curves of HNCO concentration as a function of time were simulated with these models.

In models III and IV, the decreasing curves could be fitted with the experimental ones only by model III. However, the formation constant (K_3) for the zwitterionic intermediate obtained was too great (1.0×10^{-2} mol^{-1} dm^3). Thus, model III is not reasonable since this value brings about a high concentration of the unstable intermediate.

In models I and II, the decreasing curves could be fitted with the experimental ones only by model I. The agreement could be obtained even in the presence of triethylamine, methyl carbamate, or HCl. In this model there is the problem that the formation of the 1:1 complex has not been confirmed by any other experiment. However, it is considered from the following facts that a weak interaction between an acid and base acts between methyl carbamate and HNCO to form the complex.

Isocyanic acid reacts quantitatively with strong bases such as MeONa or NaOH to precipitate the NaNCO[9] used in this study. An ion pair, $NH_4^+NCO^-$ is formed in DMSO between HNCO and NH_3 which is a weak base, and the formation constant is 79.6 at μ=0.0142.[12] It is known that carbamates promote the formation of those carbamates as base-catalyst.[11] In Fig. 4, it is shown that methyl carbamate is a very weak base.

Simulation. Theoretical Rate Equation. In order to calculate the rate of formation of methyl carbamate by Eq. 9, the concentrations of free HNCO and H$^+$ based on the model I shown by Eqs. 4—8 are derived as a function of initial and total concentrations of HNCO as follows. It will be shown that the first and 3/2 order rate equations can be derived by this model.

$$[HNCO] = [HNCO]_T - [NCO^-] - [CH_3OCONH_2 \cdot HNCO] \quad (12)$$

$$= [HNCO]_T/(1+K_2[CH_3OCONH_2]) \quad K_1/[H^+] \ll 1 \quad (13)$$

The concentration of free carbamate, $[CH_3OCONH_2]$, in Eq. 13 can be expressed as follows.

$$[CH_3OCONH_2] = [CH_3OCONH_2]_T - [CH_3OCONH_2 \cdot HNCO] \quad (14)$$

$[CH_3OCONH_2]_T$: total concentration; $[HNCO]_0 - [HNCO]_T$ (or $[CH_3OCONH_2]_0 + [HNCO]_0 - [HNCO]_T$)

$$[CH_3OCONH_2] = [CH_3OCONH_2]_T/(1+K_2[HNCO]) \quad (15)$$

This relationship is substituted in Eq. 13 and the expression is arranged.

$$K_2[HNCO]^2 + (1+K_2[HNCO]_0 - 2K_2[HNCO]_T)[HNCO] - [HNCO]_T = 0 \quad (16)$$

Thus, the HNCO concentration is expressed by Eq. 17 as the reasonable solution for Eq. 16.

$$[HNCO] = [-(1+K_2[HNCO]_0 - 2K_2[HNCO]_T) + \{(1+K_2[HNCO]_0 - 2K_2[HNCO]_T)^2 + 4K_2[HNCO]_T\}^{1/2}]/2K_2 \quad (17)$$

On the other hand, the concentration of H^+ can be expressed in the presence of HCl or triethylamine as follows.

In the Presence of HCl:

$$[H^+] = [HCl] + [NCO^-] \quad (18)$$

Consequently, the concentration of H^+ can be expressed by Eq. 19.

$$[H^+] = \{[HCl] + ([HCl]^2 + 4K_1[HNCO])^{1/2}\}/2 \quad (19)$$

In the Presence of Triethylamine:

$$[H^+] = [NCO^-] - [(C_2H_5)_3NH^+] \quad (20)$$

This can be solved similarly in the case of HCl, and the concentration of H^+ is expressed by Eq. 21.

$$[H^+] = \{-[(C_2H_5)_3N]_T + ([(C_2H_5)_3N]_T^2 + 4K_1[HNCO])^{1/2}\}/2 \quad (21)$$

Only HNCO: Hydrogen ion concentration can easily be derived from Eq. 19 or Eq. 21 as follows:

$$[H^+] = K_1^{1/2}[HNCO]^{1/2} \quad (22)$$

Thus, r_c can be expressed as Eq. 23.

$$r_c = k_c K_1^{1/2}[HNCO]^{3/2} \quad (23)$$

This Eq. is the differential form of Eq. 3 and k is equal to $k_c K_1^{1/2}$. Blohm and Becker[3] pointed out that if H^+ catalyzed the formation of carbamates, HNCO itself behaved as a catalyst. This was confirmed by the present work. In the presence of 10^{-3} mol dm^{-3} of HCl, the H^+ concentration is nearly equal to that of HCl since K_1 is very small and the free HNCO concentration can be replaced by that of the total HNCO at an early stage. Consequently, a first-order rate equation can be obtained. Thus, the two experimental rate equations could be derived from this mechanism.

Calculation of Rate and Equilibrium Constants. Generally, the rate equation is an ordinary differential equation

$$r_c = f([HNCO]_T, [HCl], [(C_2H_5)_3N], k_c, K_1, K_2). \quad (24)$$

These constants can be determined by solving Eq. 24 using the Runge-Kutta numerical-integration method to obtain the total concentration of HNCO at each reaction time by assuming these values.

The following values were obtained: k_c=131 mol^{-1} dm^3 min^{-1}, K_1=1.57×10^{-8} mol dm^{-3}, K_2=1.11 mol^{-1} dm^3 and σ=0.03622 mol^2 dm^{-6}. The value of $k_c K_1^{1/2}$ calculated from k_c and K_1 obtained is 1.01 h^{-1} and agreed with the observed value of 1.00+0.15 h^{-1} within experimental error. The solid lines in Fig. 1 are the decreasing curves of HNCO concentration calculated using these values. The calculated curves agreed well with the observed values.

Apparent Activation Energy and Dissociation Constant of HNCO. The relationships of Eq. 3 for 0.5 mol dm^{-3} HNCO solution at 273—303 K are shown in Fig. 6. In an early stage, linear relationships were observed. The apparent activation energy was 88 KJ mol^{-1} according to an Arrhenius plot of the slopes. The dissociation constant for HNCO at 273 K

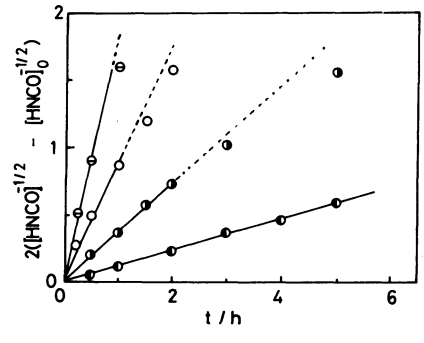

Fig. 6 Effect of temperature on the rate of formation. $[HNCO]_0$ (mol dm^{-3}): (⊖) 0.471, 303 K, (○) 0.406, 293 K (◑) 0.501, 283 K, (◐) 0.429, 273 K.

can be calculated from the values of $k_cK_1^{1/2}$ and k_c. These were 1.97×10^{-3} mol^{-1} dm$^{3/2}$min^{-1} and 40 mol^{-1} dm^3 min^{-1} from the slopes in Figs. 5 and 6, respectively. Thus, the dissociation constant of HNCO in MeOH is 2.40×10^{-9} mol dm^{-3} at 273 K and 1.57×10^{-8} mol dm^{-3} at 293 K.

Conclusion

In a kinetic study of the formation of methyl carbamate from HNCO in MeOH, we conclude that the rate-determining step is the reaction of MeOH and HNCO under the catalysis of proton and the product, methyl carbamate, reduces the apparent rate of its formation by association with HNCO to afford a complex.

Liquid Crystal Materials with Sulfur Atoms Incorporated in the Principal Structure. V. New Liquid Crystal Compounds; 2,5-Diaryl-1,3-Oxathianes

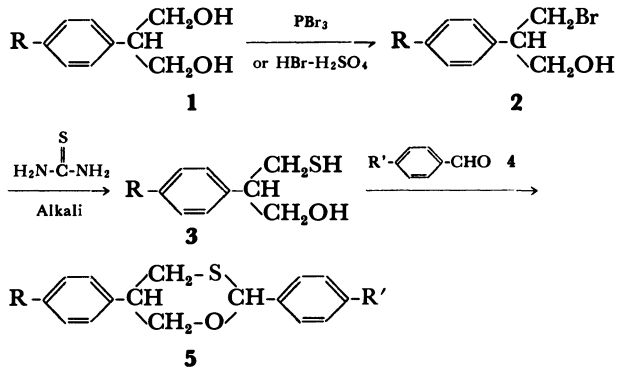
Yuichiro HARAMOTO,* Makoto SANO, and Hiroyoshi KAMOGAWA
Department of Applied Chemistry, Yamanashi University, Takeda 4, Kofu 400
(Received October 1, 1985)

2,5-Bis(*p*-substituted phenyl)-1,3-oxathianes (**5**), new liquid crystal compounds, and some corresponding 1,3-dioxanes were synthesized by the acetal formation reaction. The mesomorphic behaviors of compounds **5** were compared with those of the corresponding 1,3-dioxanes and 1,3-dithianes. Compounds **5** exhibited the lowest transition temperatures between nematic and isotropic phases. This seems to originate in the bend at the 1,3-oxathiane ring containing two heteroatoms, oxygen and sulfur, different in size. Compounds **5** also tend to exhibit supercooling states in nematic phase.

In recent years, 2,5-disubstituted 1,3-dithianes and 2,5-disubstituted 1,3-oxathianes, new types of liquid crystal compounds, have been reported.[1-8] The present study relates to the synthesis and mesomorphic behavior of 2,5-bis(*p*-substituted phenyl)-1,3-oxathianes (**5**). The mesomorphic behavior of **5** were also compared with those of the corresponding 1,3-dioxanes and 1,3-dithianes.

Results and Discussion

2,5-Bis(*p*-substituted phenyl)-1,3-oxathianes (**5**) were synthesized via the route shown in Scheme 1. In step **1—2**, PBr_3 must be used for *p*-ethoxy and *p*-methoxy compounds to prevent the cleavage of the ether bond, but in the case of *p*-methyl compounds, $HBr-H_2SO_4$ condition could be used under conventional conditions. The amounts of PBr_3 were controlled so as to effect mainly the monobromination of the diols. Compounds **5** were purified by means of recrystallizations from hexane. Those compounds which could not be purified by recrystallizations were purified first by column chromatography, then by recrystallizations from hexane until only a single spot in TLC was obtained. Compounds **5** thus synthesized were



R: OCH_3, OC_2H_5, CH_3.
R′: OC_2H_5, $OC_3H_7{}^n$, $OC_4H_9{}^n$, $OC_5H_{11}{}^n$, CH_3, CN.

Scheme 1.

all colorless and odorless powders which were soluble in common organic solvents.

Absorption of C2, C4, and C6 carbons of the 1,3-oxathiane ring in ^{13}C-NMR, as determined by ^1H-complete decoupling (COM), ^1H-off resonance decoupling (OFR), and ^1H-selective decoupling (SEL) procedures, are located at δ=84.09, 35.16, and 75.58, respectively (R=CH_3O, R′=OC_4H_9). These values are almost equal to those of trans isomers of 2-(*p*-substituted phenyl)-5-alkyl-1,3-oxathianes.[6] Therefore, the obtained compounds must be trans isomers. The presence of 1,3-dithianes and 1,3-dioxanes can be detected by the examination of C2 proton signals at δ=5.25 and 5.50, respectively. Measurements of mesomorphic ranges and assignments of mesophases were carried out by means of a micro melting point apparatus equipped with polarizers.

Mesomorphic ranges of the synthesized 2,5-bis(*p*-substituted phenyl)-1,3-oxathianes and the corresponding 1,3-dioxanes and 1,3-dithianes are given in Table 1.

Transition temperatures of isotropic to nematic (Tn-i) for compounds **5** are lower than those for the corresponding 1,3-dioxanes and 1,3-dithianes. It is known generally that the larger the molecular width, the lower Tn-i is.[9] The molecular widths of the heterorings increase in the order: 1,3-dioxane,<1,3-oxathiane<1,3-dithiane. But compounds **5** bent at the 1,3-oxathiane ring due to the difference of atomic size between sulfur and oxygen. Therefore, the actual molecular widths of these three compounds must increase in the order: 1,3-dioxane<1,3-dithiane<1,3-oxathiane. This fact may explain lower values of Tn-i for compounds **5** as compared with those of the corresponding dioxanes and dithianes. However, Tn-i of the dithianes are higher than those of the corresponding dioxanes. This seems to originate from the dispersion force of 1,3-dithiane ring having two sulfur atoms. It is said generally that the main factor affecting Tn-i is molecular width.[10] Concerning the dithianes, however, this rule dose not appear to hold. Namely, the effect of the molecular width

Table 1. Transition Temperature of Compounds **5** and the Corresponding 1,3-Dioxanes and 1,3-Dithianes

a) C=crystal; N=nematic; S=smectic; I=isotropic. b) Cited from Ref. 3.

may be smaller than that of the dispersion force of 1,3-dithiane ring having two sulfur atoms.

Compounds **5** having substituent R=CH_3 tend to become monotropic liquid crystal in contrast with those having substituent R=C_2H_5O or R=CH_3O. They also exhibited remarkable supercooling states in the nematic liquid crystal phase (R=CH_3C, R′=OC_4H_9:C–N 105 °C, N–C 68 °C).

Tn-i of a series of compounds **5** different only in substituent R decreased in the order: R=OC_2H_5>R=OCH_3>R=CH_3, and Tn-i of the compounds different only in substituent R′ exhibited somewhat higher values for those having alkoxyl groups of even carbon number (OC_2H_5, OC_4H_9).

Experimental

IR, ^{1}H-NMR, ^{13}C-NMR, and Mass spectra were obtained with a Hitachi 215 spectrophotometer, a JNM-PMX 60 spectrometer, a JNM-FX 90Q FT-NMR spectrometer, and a Hitachi RMU-6 MG spectrometer, respectively. Elemental analyses were carried out with a Perkin-Elmer 250 instrument. Transition temperatures and mesomorphic phases were determined by means of a Mitamura Riken micro melting point apparatus equipped with polarizers. The rates of heating and cooling were fixed to about 2 °C min^{-1}.

2-(*p*-Alkoxyphenyl)-3-bromo-1-propanols (2). To a solution of 2-(*p*-alkoxyphenyl)-1,3-propanediol (**1**; 0.08 mol),

anhyd benzene (150 ml), and pyridine (0.8 g) kept at 30 °C were added, dropwise, a solution of PBr_3 (0.027 mol), anhyd benzene (100 ml), and pyridine (0.3 g) (about 60 min). The solution was kept at 30 °C for 18 h. The reaction mixture was poured into ice water (400 ml) and extracted first with benzene (300 ml), then with ether (400 ml). The extract was washed with cold water (100 ml), dried over anhyd Na_2SO_4, and evaporated in vacuo at 30 °C.

3-Bromo-2-(*p*-methoxyphenyl)-1-propanol (2-1): Yield 50—60%. IR ($CHCl_3$) 3600 (OH), 2800—3000 (alkyl), 1600 (Ar), 1260 (ether) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=2.5—4.2 (m, 9H, CH, CH_2Br, CH_3O, CH_2OH), 6.6—7.3 (q, 4H, ArH).

3-Bromo-2-(*p*-ethoxyphenyl)-1-propanol (2-2): Yield 45—50%. IR ($CHCl_3$) 3600 (OH), 2800—3000 (alkyl), 1600 (Ar), 1260 (ether) cm^{-1}. ^1H-NHR ($CDCl_3$) δ=1.4 (t, 3H, CH_3), 2.5—4.3 (m, 9H, CH, CH_2Br, CH_2OH, CH_3CH_2O), 6.7—7.4 (q, 4H, ArH).

3-Bromo-2-(*p*-methylphenyl)-1-propanol (2-3): To a solution of 48% HBr (33 g) and concd H_2SO_4 (10 g) cooled in an ice bath were added successively 2-(*p*-methylphenyl)-1,3-propanediol (**1**; 0.065 mol) and concd H_2SO_4 (17 g). The solution was kept at 70—75 °C for 15 h. The reaction mixture was then poured into ice water (200 g). The mixture was stirred and extracted twice with ether (each 300 ml). The extract was washed with cold 10% aq $NaHCO_3$ (100 ml), dried over anhyd Na_2SO_4, and evaporated in vacuo at 30 °C. Yield 50—60%. IR ($CHCl_3$) 3600 (OH), 2800—3000 (alkyl), 1600 (Ar) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=2.3 (s, 3H, CH_3), 3.0—4.2 (m, 6H, CH, CH_2Br, CH_2OH), 7.2 (s, 4H, ArH).

2-(*p*-Substituted phenyl)-3-mercapto-1-propanols (3). To a solution of thiourea (0.064 mol) in triethylene glycol (10 ml) kept at 75 °C was added compound **2** (0.01 mol) in nitrogen atmosphere, followed by stirring at 75 °C for 18 h. Tetraethylenepentamine (0.01 mol) was then added, and the mixture was stirred at 75 °C for 2 h under a nitrogen atmosphere. The reaction mixture was poured into water (100 ml) and then extracted twice with ether (each 300 ml). The extract was washed with cold 5% aq HCl (100 ml), dried over anhyd Na_2SO_4, and evaporated in vacuo at 30 °C.

3-Mercapto-2-(*p*-methoxyphenyl)-1-propanol (3-1): Yield 60—65%. IR ($CHCl_3$) 3600 (OH), 2800—3000 (alkyl), 1600 (Ar), 1270 (ether) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=0.9—1.5 (b, 1H, SH), 2.3—4.3 (m, 6H, CH_2OH, CH_3O), 6.5—7.4 (q, 4H, ArH).

2-(*p*-Ethoxyphenyl)-3-mercapto-1-propanol (3-2): Yield 65—70%. IR ($CHCl_3$) 3600 (OH), 2800—3000 (alkyl), 1600 (Ar), 1270 (ether) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=0.9—1.5 (m, 4H, CH_3, SH), 2.4—3.0 (m, 3H, CH_2S, CH), 3.1—4.5 (m, 5H, CH_2O, CH_2OH), 6.5—7.4 (q, 4H, ArH).

3-Mercapto-2-(*p*-methylphenyl)-1-propanol (3-3): Yield 60—65%. IR ($CHCl_3$) 3600 (OH), 2800—3000 (alkyl), 1600 (Ar) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=1.0—1.4 (m, 1H, SH), 2.3 (s, 3H, CH_3), 2.5—4.0 (m, 6H, CH_2S, CH, CH_2OH), 7.1 (s, 4H, ArH).

2,5-Bis(*p*-substituted phenyl)-1,3-oxathianes (5). To a solution of compound **3** (0.004 mol) and *p*-substituted benzaldehyde **4** (0.004 mol) in anhyd $CHCl_3$ (300 ml) cooled in an ice bath were added BE_3-$(C_2H_5)_2O$ (0.5 g) and Molecular Sieve (3A, 1/15; 3 g). The mixture was stirred at 0—5 °C for 8 h and then at 20—25 °C for 18 h. The solution was washed with 10% aq $NaHCO_3$ (400 ml), dried over anhyd Na_2SO_4, and evaporated in vacuo at 40 °C. The crude product was purified by recrystallizations from hexane, if necessary, by column chromatography and recrystallizations.

The spectral properties and analytical data of the synthesized compounds are given below.

2-(*p*-Substituted phenyl)-5-(*p*-ethoxyphenyl)-1,3-oxathianes: IR ($CHCl_3$) 2800—3000 (alkyl), 1600 (Ar), 1280 (ether) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=0.8—2.3 (m, alkyl), 2.5—3.5 (m, 3H, CH, CH_2S), 3.7—4.5 (m, 6H, CH_2O), 5.8 (s, 1H, S-CH-O), 6.7—7.7 (m, 8H, ArH).

2-(*p*-Alkoxyphenyl)-5-(*p*-methylphenyl)-1,3-oxathianes: IR ($CHCl_3$) 2800—3000 (alkyl), 1600 (Ar), 1280 (ether) cm^{-1} ^1H-NMR ($CDCl_3$) δ=0.8—2.1 (m, alkyl), 2.3 (s, 3H, CH_3), 2.5—3.5 (m, 3H, CH, CH_3S), 3.7—4.5 (m, 4H, CH_2O), 5.8 (s, 1H, S-CH-O), 6.7—7.6 (m, 8H, ArH).

2-(*p*-Alkoxyphenyl)-5-(*p*-methoxyphenyl)-1,3-oxathianes: IR ($CHCl_3$) 2800—3000 (alkyl), 1600 (Ar), 1280 (ether) cm^{-1}. ^1H-NMR ($CDCl_3$) δ=0.9—2.1 (m, alkyl), 2.7—4.5 (m, 10H, CH_2S, CH, CH_2O, CH_3O), 5.8 (s, 1H, CH), 6.7—7.6 (m, 8H, ArH).

2,5-Bis(*p*-ethoxyphenyl)-1,3-oxathiane (5-1): Yield 43%. Found: C, 70.07; H, 6.99%. Calcd for $C_{20}H_{24}O_3S_1$: C, 69.73; H, 7.02%. MS (*m/z*) 344 (M^+).

5-(*p*-Ethoxyphenyl)-2-(*p*-propoxyphenyl)-1,3-oxathiane (5-2): Yield 35%. Found: C, 70.18; H, 7.17%. Calcd for $C_{21}H_{26}O_3S$: C, 70.36; H, 7.31%. MS (*m/z*) 358 (M^+).

2-(*p*-Butoxyphenyl)-5-(*p*-ethoxyphenyl)-1,3-oxathiane (5-3): Yield 47%. Found: C, 71.39; H, 7.54%. Calcd for $C_{22}H_{28}O_3S$: C, 71.02; H, 7.58%. MS (*m/z*) 372 (M^+).

5-(*p*-Ethoxyphenyl)-2-(*p*-pentyloxyphenyl)-1,3-oxathiane (5-4): Yield 39%. Found: C, 71.19; H, 7.68%. Calcd for $C_{23}H_{30}O_3S$: C, 71.46; H, 7.82%. MS (*m/z*) 386 (M^+).

5-(*p*-Ethoxyphenyl)-2-(*p*-methylphenyl)-1,3-oxathiane (5-5): Yield 32%. Found: C, 72.31; H, 6.93%. Calcd for $C_{19}H_{22}O_2S$: C, 72.57; H, 7.05%. MS (*m/z*) 314 (M^+).

2-(*p*-Ethoxyphenyl)-5-(*p*-methylphenyl)-1,3-oxathiane (5-6): Yield 40%. Found: C, 72.24; H, 7.08%. Calcd for $C_{19}H_{22}O_2S$: C, 72.57; H, 7.05%. MS (*m/z*) 314 (M^+).

5-(*p*-Methylphenyl)-2-(*p*-propoxyphenyl)-1,3-oxathiane (5-7): Yield 38%. Found: C, 73.46; H, 7.44%. Calcd for $C_{20}H_{24}O_2S$: C, 73.13; H, 7.37%. MS (*m/z*) 328 (M^+).

2-(*p*-Butoxyphenyl)-5-(*p*-methylphenyl)-1,3-oxathiane (5-8): Yield 44%. Found: C, 72.94; H, 7.72%. Calcd for $C_{21}H_{26}O_2S$: C, 73.64; H, 7.65%. MS (*m/z*) 342 (M^+).

2-(*p*-Ethoxyphenyl)-5-(*p*-methoxyphenyl)-1,3-oxathiane (5-9): Yield 23%. Found: C, 69.21; H, 6.83%. Calcd for $C_{19}H_{22}O_3S$: C, 69.06; H, 6.71%. MS (*m/z*) 330 (M^+).

5-(*p*-Methoxyphenyl)-2-(*p*-propoxyphenyl)-1,3-oxathiane (5-10): Yield 30%. Found: C, 69.65; H, 7.09%. Calcd for $C_{20}H_{24}O_3S$: C, 69.73; H, 7.02%. MS (*m/z*) 344 (M^+).

Versatile Synthesis of Cyclopropanecarboxylic Acid Derivatives by the $Ni(CO)_4$-Induced Reductive Carbonylation Reaction of *gem*-Dibromocyclopropanes

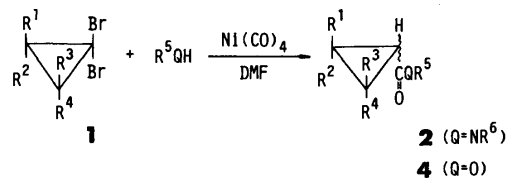
Toshikazu HIRAO,* Yoshiyuki HARANO, Yoshihiro YAMANA, Yuji HAMADA, Shinichiro NAGATA, and Toshio AGAWA
Department of Applied Chemistry, Faculty of Engineering, Osaka University, 2-1 Yamadaoka, Suita, Osaka 565
(Received October 22, 1985)

Reductive carbonylation of *gem*-dibromocyclopropanes was achieved by treatment with tetracarbonylnickel in the presence of alcohols, amines, thiols, or imidazole in DMF leading to the corresponding cyclopropanecarboxylic acid derivatives, respectively. Use of disulfides as an initial nucleophile resulted in carbonylation with sulfenylation at the geminal position. This method was applied to the intramolecular reductive carbonylation reaction of 2,2-dibromocyclopropanealkanols into bicyclic lactones. Nickel carbenoid and enolate complexes are assumed to be involved as key intermediates.

Cyclopropane derivatives are versatile synthetic intermediates since ring cleavage permits us to introduce three-carbon unit for selective carbon skeleton construction.[1] The methods for the cyclopropane ring formation have been advanced according to the development of carbene chemistry. On the other hand, the direct introduction of a functional group to a cyclopropane ring is fairly difficult although it diverses the utility of the cyclopropane ring transformation in organic syntheses. We already demonstrated[2] a versatile synthesis of cyclopropanecarboxylic acid derivatives by reductive carbonylation of *gem*-dibromocyclopropanes easily provided by the addition of dibromocarbene to olefinic compounds. The present paper describes a full account for this new method.

Results and Discussion

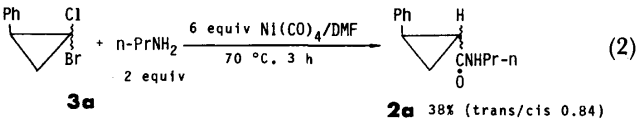
Treatment of the *gem*-dibromocyclopropane **1** with tetracarbonylnickel and amine in DMF gave a mixture of the *cis*- and *trans*-cyclopropanecarboxamides **2** (Eq. 1). This carbonylation reaction is



(1)

characterized by the simultaneous reduction of the geminal C–Br bond (reductive carbonylation). Our results are summarized in Table 1. A variety of *gem*-dibromocyclopropanes underwent reductive carbonylation with functional groups (e.g., methoxycarbonyl and cyano groups) inert under the conditions employed here. Aliphatic and aromatic amines reacted with almost equal ease. Use of excess tetracarbonylnickel increased the yields of **2**. The carbonylation reaction was suppressed substantially under CO flow and completely under 20 kg cm^{-2} of CO. This difference might be due to the occupation of coordination sites with CO.

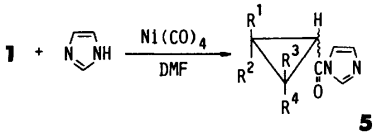
1-Bromo-1-chloro-2-phenylcyclopropane (**3a**) was also converted to the amide **2a** via reductive carbonylation (Eq. 2), this being in sharp contrast to



(2)

no reaction of 1,1-dichloro-2-phenylcyclopropane. The presence of one bromine atom is at least required for the success of the transformation.

Starting from 1-propanol or phenols, a stereoisomeric mixture of the cyclopropanecarboxylates **4** was produced. It is of interest that imidazole behaved as a nucleophile to give the 1-acylimidazoles **5** (Eq. 3). Since 1-acylimidazoles are known to be



(3)

susceptible to nucleophilic attack,[3] this method will permit a facile synthesis of cyclopropyl ketones.

Thiols did not work as a selective nucleophile for reductive carbonylation (Eq. 4). A substantial

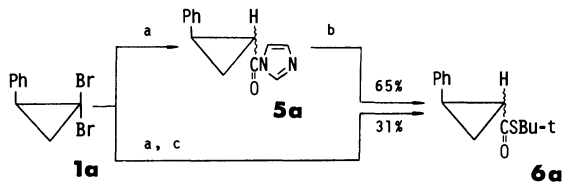
a) Reaction temperature, 70 °C. b) CO, flow. c) CO, 20 kg/cm². d) *S*-*t*-Butyl 1-*t*-butylthio-2-phenylcyclopropanecarbothioate (**7a**, 10%) and 1-bromo-2-phenylcyclopropane (33%) were obtained. e) 1-Phenyl-2-propylthiocyclopropane (**8n**, 5%) and 1-bromo-2-phenylcyclopropane (40%) were obtained. f) 1-Phenyl-2-phenylthiocyclopropane (**8o**, 32%) was obtained.

amount of *S*-*t*-butyl 1-*t*-butylthio-2-phenylcyclopropanecarbothioate (**7a**) or the cyclopropyl sulfide **8** was obtained as a by-product together with the desired cyclopropanecarbothioate **6** depending on thiols. For the selective preparation of **6**, the transformation from **5** was examined; 1-(2-phenylcyclopropylcarbonyl)imidazole (**5a**) was converted to **6a** in 65% yield on treatment with 2-methyl-2-propanethiol and a catalytic amount of $Mg(OEt)_2$.[3b] Furthermore, a one-pot transformation was performed only by the addition of 2-methyl-2-propanethiol to the crude resultant mixture of **5a** after removal of excess tetracarbonylnickel leading to **6a** selectively in 31% yield from 1,1-dibromo-2-phenylcyclopropane (**1a**) as shown in Scheme 1.

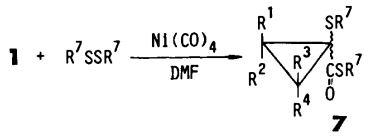
The formation of the 1-alkylthiocyclopropanecarbothioate **7a** is assumed to be explained by the



Reagents and conditions: (a) $Ni(CO)_4$ (6 equiv), Imidazole (2.5 equiv), DMF, 70 °C, 3 h; (b) *t*-BuSH (1.2 equiv), $Mg(OEt)_2$ (cat.), 25 °C, 14 h; (c) *t*-BuSH (1.2 equiv), 25 °C, 14 h.

Scheme 1.

intervention of the disulfide. Actually, the Ni(CO)$_4$-induced reaction of **1a** with dipropyl disulfide gave a mixture of *S*-propyl *cis*- and *trans*-2-phenyl-1-propylthiocyclopropanecarbothioates (**7n**) predominantly. Use of diphenyl or di-*t*-butyl disulfide resulted in the exclusive formation of **7** (Eq. 5, Table 2). This



(5)

Table 2. Preparation of **7**[a]

1	$R^7_2S_2$	Product, Yield/%			
	R^7	**7**		**6**

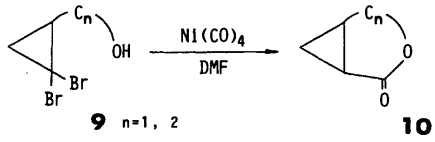
1a	Ph	**7o**	40	**6o**	0
1e	*n*-Pr	**7e**	40	**6e**	6

a) The reaction of **1** with Ni(CO)$_4$ (6 equiv) and $R^7_2S_2$ (2.5 equiv) was carried out at 70 °C for 20 h.

carbonylation accompanied by the simultaneous sulfenylation at the geminal position represents one of the scarcely investigated transition metal mediated reactions with disulfides.[4]

The *gem*-dibromocyclopropanes **9** bearing a hydroxyalkyl group (prepared by the addition of dibromocarbene to allylic or homoallylic alcohols[5]) were subjected to the intramolecular reductive carbonylation reaction giving the bicyclic *γ*- or *δ*-lactones **10**, respectively (Eq. 6, Table 3). It should be



(6)

noted that the intramolecular reaction of **9a** provides a facile preparative method for *cis*-chrysanthemic acid from prenyl alcohol because the bicyclic lactone **10a** has been reported to be its key synthetic intermediate.[6] In the case of *trans*-2,2-dibromo-3-

Table 3. Preparation of **10**

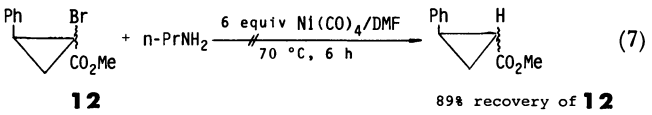
 **9e**	7	75	3	 **10e**	51

a) *cis*-2-Bromo-3,3-dimethylcyclopropanemethanol (**11a**) was produced as a by-product (10%). b) CO, flow. c) 1-Methyl-2-piperidone was used as a solvent. d) THF was used as a solvent. e) A mixture of *cis*- and *trans*-2-bromo-3,3-dimethylcyclopropanemethanols (18%) was produced as by-products and 72% of **9a** was recovered. f) 6-*endo*-Methyl-3-oxabicyclo[3.1.0]hexan-2-one was not formed and *cis*-2-bromo-*trans*-3-methylcyclopropanemethanol (**11c**, 24%) was produced as a by-product.

methylcyclopropanemethanol (**9c**), 6-*exo*-methyl-3-oxabicyclo[3.1.0]hexan-2-one (**10c**) was produced selectively. Lactonization of tertiary-alcohols (**9d** and **9e**) proceeded well. Decrease in the amount of tetracarbonylnickel led to a small amount of by-product, the *cis*-2-bromocyclopropanemethanol **11**, derived by reduction of the bromine atom *trans* to the hydroxymethyl group of **9**. As observed in the intermolecular reactions, 2,2-dichloro-3,3-dimethylcyclopropanemethanol did not react even at the high reaction temperature (75 °C, 5 h or 120 °C, 7 h).

It is likely that tetracarbonylnickel serves an important role in the reduction step. The carbonylation reaction of **1a** with 1-propanol-*d* gave the corresponding α-deuteriocyclopropanecarboxylate, indicating that the α-proton is derived from the one of the hydroxyl group. No carbonylation of monobromocyclopropanes under the conditions employed above rules out their intervention. Moreover, oxidative addition of **1** to tetracarbonylnickel seems unlikely because the reaction of **1a** with tetracarbonylnickel in the absence of 1-propanol at 70 °C for 3 h resulted in its recovery (94%). Our first proposal refers to the intermediacy of the α-bromocyclopropanecarboxylate which is reduced to **4**.[2] This reaction path was supported by the reduction of α-bromo-β-methyl-γ-butyrolactone to β-methyl-γ-butyrolactone with tetracarbonylnickel and a small amount of water.[7] However, the independently prepared methyl 1-bromo-2-phenylcyclopropanecarboxylate (**12**) was recovered without carbonylation on treatment with tetracarbonylnickel and propylamine (Eq. 7). This finding suggests that an alternative

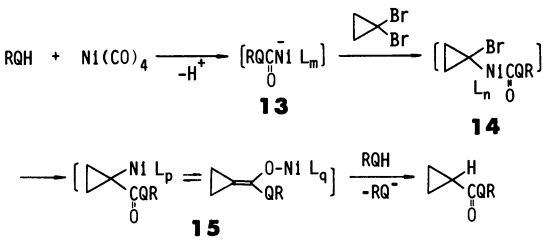


(7)

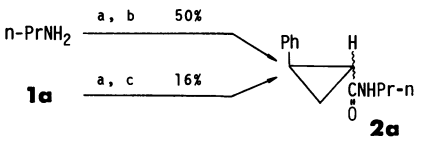
12 89% recovery of **12**

mechanism is operative.

A plausible reaction path is explained as depicted in Scheme 2. Tetracarbonylnickel is considered to contact with a nucleophile, e.g., alcohol to generate the complex **13**. A similar kind of intermediate has been reported to be present in carbonylation of vinyl halides.[8] This initial step is also ascertained by the following observations. Addition of **1a** to the DMF solution of tetracarbonylnickel pretreated with propylamine gave 50% yield of **2a**, but the reverse operation as shown in scheme 3 resulted in a poor yield of **2a** (16%). The interaction of amine with tetracarbonylnickel should be important to achieve the present transformation. The next step might be explained by invoking the attack of the complex **13** on **1** to form the nickel carbenoid complex **14**.[9] The migration of the alkoxycarbonyl group leads to the stable enolate complex **15**. Protonation with alcohol



Scheme 2.



Reagents and conditions: (a) $Ni(CO)_4$ (1 equiv), DMF, 70 °C, 3 h; (b) **1a** (1 equiv), 70 °C, 3 h; (c) *n*-$PrNH_2$ (1 equiv), 70 °C, 3 h.

Scheme 3.

completes the debromination process giving the reductive carbonylation product together with the generation of **13** from tetracarbonylnickel. Checking a crude mixture of the intermolecular reaction, a small amount of the reduced monobromocyclopropane was detected. The formation of this monobromocyclopropane and **11** is assumed to be derived by the degradation of the carbenoid complexes **14**. The present scheme also accounts for the reaction with disulfides which play both roles of a nucleophile and an electrophile. Reductive carbonylation of *gem*-dibromocyclopropanes is considered to depend on the intermediacy of the novel nickel carbenoid and enolate complexes.

Experimental

IR spectra were taken on a JASCO IRA-1 spectrometer. NMR spectra were obtained on JEOL JNM PMX-60 and JEOL JNM FX-90Q spectrometers in $CDCl_3$ solutions with tetramethylsilane as an internal standard. Mass spectrometry was performed with Hitachi RMU-6E and JEOL JMS-DX 300 (high resolution) spectrometers. The *gem*-dibromocyclopropanes **1**[10] and **9**,[5] 1-bromo-1-chloro-2-phenylcyclopropane (**3a**),[10] and methyl 1-bromo-2-phenylcyclopropanecarboxylate (**12**)[11] were prepared according to the reported methods.

General Procedure for the Preparation of Cyclopropanecarboxylic Acid Derivatives. To a stirred solution of the *gem*-dibromocyclopropane **1** (5.0 mmol) and a nucleophile (11 mmol) in freshly distilled DMF (12 mL) was added dry tetracarbonylnickel (30 mmol) at room temperature. The mixture was stirred at 70 °C for 3 h unless otherwise stated in Table 1. Excess of tetracarbonylnickel was removed under the reduced pressure. Ether (15 mL) and 5% aq HCl (15 mL) were added to the resultant mixture, which was

stirred at room temperature for 1 h and extracted with ether (3×10 mL). The combined organic layers were washed with brine, dried over Na_2SO_4, and concentrated. The residue was flash chromatographed to give a mixture of *cis*- and *trans*-cyclopropanecarboxylic acid derivatives. To purify **5**, chromatography on normal silica-gel column was done eluting with 20% EtOAc-hexane.

2a (*cis*): Mp 71—72 °C (uncorrected); IR (neat) 1620 cm^{-1}; ^{1}H NMR (90 MHz) δ=0.67 (t, 3H, J=5.0 Hz), 1.0—1.5 (m, 2H), 1.22 (ddd, 1H, J=9.5, 8.6, 7.0 Hz), 1.67 (ddd, 1H, J=9.5, 8.5, 5.8 Hz), 1.89 (ddd, 1H, J=7.0, 5.8, 5.0 Hz), 2.40 (ddd, 1H, J=8.6, 8.5, 5.0 Hz), 2.99 (q, 2H, J=5.1 Hz), 5.5—5.9 (m, 1H), 7.22 (broad s, 5H); MS m/z 203 (M$^+$). 5a: Mp 85—87 °C (uncorrected); IR (neat) 1710 cm^{-1}; ^{1}H NMR (90 MHz) δ=1.59 (ddd, 1H, J=8.7, 8.5, 5.3 Hz), 2.10 (ddd, 1H, J=7.6, 5.6, 5.3 Hz), 2.64 (ddd, 1H, J=8.8, 8.7, 5.6 Hz), 2.91 (ddd, 1H, J=8.8, 8.5, 7.6 Hz), 7.04 (broad s, 1H), 7.20 (broad s, 5H), 7.42 (broad s, 1H), 8.17 (broad s, 1H); MS m/z 212 (M$^+$). Found: C, 73.47; H, 5.81; N, 13.32%. Calcd for $C_{13}H_{12}N_2O$: C, 73.56; H, 5.70; N, 13.20%. The other isomer was obtained in a small amount.

5d: Oil; IR (neat) 1720 cm^{-1}; ^{1}H NMR (90 MHz) δ=0.04 (s, 9H), 0.1—2.0 (m, 6H), 7.12 (broad s, 1H), 7.53 (broad s, 1H), 8.28 (broad s, 1H); MS m/z 222 (M$^+$). **The Other**

Isomer: Oil; IR (neat) 1720 cm^{-1}; ^1H NMR (90 MHz) δ=−0.07 (s, 9H), 0.7—0.8 (m, 2H), 1.2—2.0 (m, 3H), 2.2—2.5 (m, 1H), 7.11 (broad s, 1H), 7.56 (broad s, 1H), 8.23 (broad s, 1H); MS *m/z* 222 (M^+). Found (mixture): C, 59.31; H, 7.99; N, 12.91%. Calcd for $C_{11}H_{18}N_2OSi$: C, 59.42; H, 8.16; N, 12.60%.

5h (*cis* and *trans*): IR (neat) 1720 cm^{-1}; ^1H NMR (60 MHz) δ=0.5—2.4 (m, 17H), 7.12 (broad s, 1H), 7.42 (broad s, 1H), 8.15 (broad s, 1H); MS *m/z* 220 (M^+). Found: C, 71.02; H, 9.17; N, 12.65%. Calcd for $C_{13}H_{20}N_2O$: C, 70.87; H, 9.15; N, 12.72%.

6a: Bp (Kugelrohr) 162—163 °C/0.45 mmHg; IR (neat) 1680 cm^{-1}; ^1H NMR (90 MHz) δ=1.26 (s, 9H), 1.1—1.5 (m, 1H), 1.7—2.0 (m, 1H), 2.2—2.8 (m, 2H), 7.21 (broad s, 5H); MS, Found 234.1075, Calcd for $C_{14}H_{18}OS$ 234.1078. The other isomer was obtained in a small amount.

6n (*cis*): IR (neat) 1680 cm^{-1}; ^1H NMR (90 MHz) δ=0.81 (t, 3H, *J*=7.0 Hz), 1.2—1.6 (m, 4H), 1.90 (ddd, 1H, *J*=7.3, 5.6, 5.1 Hz), 2.3—2.8 (m, 1H), 2.69 (t, 2H, *J*=7.0 Hz), 7.25 (broad s, 5H); MS, Found 220.0921, Calcd for $C_{13}H_{16}OS$ 220.0921. **(*trans*):** IR (neat) 1680 cm^{-1}; ^1H NMR (90 MHz) δ=0.98 (t, 3H, *J*=7.1 Hz); 1.48 (ddd, 1H, *J*=8.2, 6.5, 4.4 Hz), 1.4—1.8 (m, 2H), 1.75 (ddd, 1H, *J*=8.6, 4.7, 4.4 Hz), 2.27 (ddd, 1H, *J*=8.2, 4.7, 3.8 Hz), 2.67 (ddd, 1H, *J*=8.6, 6.5, 3.8 Hz), 2.90 (t, 2H, *J*=7.1 Hz), 7.0—7.4 (m, 5H); MS, Found 220.0920, Calcd for $C_{13}H_{16}OS$ 220.0921. Bp (mixture, Kugelrohr) 114—118 °C/0.2 mmHg.

6o (*cis* and *trans*): White solid; IR (neat) 1680 cm^{-1}; ^1H NMR (60 MHz) δ=1.1—1.6 (m, 1H), 1.7—2.1 (m, 1H), 2.4—3.0 (m, 2H), 7.24 (broad s, 10H); MS, Found 254.0765, Calcd for $C_{16}H_{14}OS$ 254.0765.

Conversion of 5a to 6a. According to the reported method,[3b] treatment of **5a** with 1.2 equiv of 2-methyl-2-propanethiol and a catalytic amount of $Mg(OEt)_2$ at 25 °C for 14 h gave **6a** in 65% yield.

One-Pot Synthesis of 6a. After treatment of **1a** with tetracarbonylnickel and imidazole, excess tetracarbonylnickel was removed under the reduced pressure. Then, 1.2 equiv of 2-methyl-2-propanethiol was added to the resultant mixture, which was stirred at 25 °C for 14 h. Workup was done in the similar manner as mentioned above to give **6a** in 31% yield.

Preparation of 7. The reaction of **1** with disulfides was carried out in the similar manner as mentioned above. The conditions are shown in footnotes of Table 2.

7a: IR (neat) 1660 cm^{-1}; ^1H NMR (90 MHz) δ=1.06 (s, 9H), 1.2—1.6 (m, 1H), 1.40 (s, 9H), 1.68 (dd, 1H, *J*=5.2, 2.7 Hz), 2.71 (dd, 1H, *J*=13.0, 5.2 Hz), 7.18 (broad s, 5H); MS *m/z* 322 (M^+). **The Other Isomer:** IR (neat) 1660 cm^{-1}; ^1H NMR (90 MHz) δ=1.19 (s, 9H), 1.50 (s, 9H), 1.71 (dd, 1H, *J*=9.4, 5.6 Hz), 2.27 (dd, 1H, *J*=8.1, 5.6 Hz), 3.23 (dd, 1H, *J*=9.4, 8.1 Hz), 7.17 (broad s, 5H); MS *m/z* 322 (M^+). Found (mixture): C, 66.98; H, 8.20; S, 20.01%. Calcd for $C_{18}H_{26}OS_2$: C, 67.03; H, 8.13; S, 19.88%.

7e (*cis* and *trans*): Oil; IR (neat) 2250, 1665 cm^{-1}; ^1H NMR (90 MHz) δ=1.00 (broad t, 6H), 1.2—2.6 (m, 9H), 2.6—3.1 (m,4H); MS *m/z* 257 (M^+). Found: C, 56.08; H, 7.69; N, 5.51; S, 24.60%. Calcd for $C_{12}H_{19}NOS_2$: C, 55.99; H, 7.44; N, 5.44; S, 24.91%.

7n (*cis* and *trans*): Oil; IR (neat) 1680 cm^{-1}; ^1H NMR (90 MHz) δ=0.7—1.1 (m, 6H), 1.2—1.8 (m, 6H), 2.1—2.8 (m, 5H), 7.1—7.5 (m, 5H); MS *m/z* 294 (M^+). Found: C, 65.41; H, 7.47; S, 21.65%. Calcd for $C_{16}H_{22}NOS_2$: C, 65.26; H, 7.53; S, 21.78%.

7o: Oil; IR (neat) 1690 cm^{-1}; ^1H NMR (90 MHz) δ=1.71 (dd, 1H, *J*=9.1, 8.0 Hz), 2.71 (dd, 1H, *J*=8.0, 5.1 Hz), 3.21 (dd, 1H, *J*=9.1, 5.1 Hz), 7.1—7.6 (m, 15H); MS *m/z* 362 (M^+). Found: C, 72.76; H, 5.05; S, 17.80%. Calcd for $C_{22}H_{18}OS_2$: C, 72.89; H, 5.01; S, 17.69%. The other isomer was not isolated.

6e (*cis* and *trans*): Oil; IR (neat) 2250, 1670 cm^{-1}; ^1H NMR (90 MHz) δ=1.00 (broad t, 3H), 1.2—2.7 (m, 8H), 2.7—3.1 (m, 2H); MS, Found 183.0717, Calcd for $C_9H_{13}NOS$ 183.0717.

Preparation of 10. The reaction was carried out in the similar manner as mentioned above by mixing **9** and tetracarbonylnickel in DMF. The conditions are shown in Table 3.

10a: Bp (Kugelrohr) 90—94 °C/2.8 mmHg; IR (neat) 1760 cm^{-1}; ^1H NMR (60 MHz) δ=1.16 (s, 6H), 1.8—2.3 (m, 2H), 4.0—4.6 (m, 2H); ^{13}C NMR δ=14.4 (q), 23.0 (s), 25.2 (q), 30.1 (d), 30.6 (d), 66.5 (t), 174.8 (s); MS *m/z* 126 (M^+). Found: C, 66.68; H, 8.21%. Calcd for $C_7H_{10}O_2$: C, 66.65; H, 7.99%.

10b: Bp (Kugelrohr) 107—110 °C/4.0 mmHg; IR (neat) 1765 cm^{-1}; ^1H NMR (90 MHz) δ=1.01 (dd, 1H, *J*=4.6, 3.2 Hz), 1.20 (dd, 1H, *J*=8.8, 4.6 Hz), 1.40 (s, 3H), 1.84 (dd, 1H, *J*=8.8, 3.2 Hz), 4.06 (d, 1H, *J*=9.0 Hz), 4.14 (d, 1H, *J*=9.0 Hz); ^{13}C NMR δ=16.9 (q), 19.0 (t), 23.7 (d), 25.4 (s), 73.5 (t), 176.7 (s); MS *m/z* 112 (M^+). Found: C, 64.04; H, 7.32%. Calcd for $C_6H_8O_2$: C, 64.27; H, 7.19%.

10c: Bp (Kugelrohr) 80—82 °C/0.9 mmHg; IR (neat) 1765 cm^{-1}; ^1H NMR (90 MHz) δ=1.19 (s, 3H), 1.0—1.4 (m, 1H), 1.79 (dd, 1H, *J*=5.9, 2.8 Hz), 1.9—2.1 (m, 1H), 4.1—4.4 (m, 2H); ^{13}C NMR δ=16.0 (q), 21.0 (d), 25.1 (d), 25.2 (d), 69.5 (t), 175.9 (s); MS *m/z* 112 (M^+). Found: C, 64.33; H, 7.08%. Calcd for $C_6H_8O_2$: C, 64.27; H, 7.19%.

10d: Bp (Kugelrohr) 69—70 °C/0.4 mmHg; IR (neat) 1765 cm^{-1}; ^1H NMR (90 MHz) δ=0.8—1.4 (m, 3H), 1.36 (s, 3H), 1.48 (s, 3H), 2.0—2.2 (m, 1H); ^{13}C NMR δ=11.1 (t), 19.2 (d), 24.1 (q), 27.6 (d), 29.1 (q), 82.7 (s), 175.7 (s); MS *m/z* 126 (M^+). Found: 66.55; H, 7.63%. Calcd for $C_7H_{10}O_2$: C, 66.64; H, 7.99%.

10e: Bp (Kugelrohr) 85—87 °C/0.5 mmHg; IR (neat) 1725 cm^{-1}; ^1H NMR (90 MHz) δ=0.7—0.9 (m, 1H), 1.1—2.3 (m, 5H), 1.34 (s, 3H), 1.47 (s, 3H); ^{13}C NMR δ=11.9 (d), 12.5 (d), 18.8 (t), 27.5 (q), 29.1 (q), 35.8 (t), 83.1 (s), 172.4 (s); MS *m/z* 140 (M^+). Found: C, 68.32; H, 8.51%. Calcd for $C_8H_{12}O_2$: C, 68.54; H, 8.63%.

11a: Oil; IR (neat) 3300, 1250 cm^{-1}; ^1H NMR (60 MHz) δ=1.08 (dt, 1H, *J*=7.5, 7.4 Hz), 1.17 (s, 6H), 1.56 (broad s, 1H), 3.00 (d, 1H, *J*=7.4 Hz), 3.75 (d, 2H, *J*=7.5 Hz); MS, Found 160.9966, Calcd for $C_6H_{11}OBr$–OH 160.9965.

11c: Oil; IR (neat) 3480, 1250 cm^{-1}; ^1H NMR (90 MHz) δ=0.92 (ddt, 1H, *J*=7.7, 6.1, 4.0 Hz), 1.17 (ddq, 1H, *J*=5.7, 4.0, 3.6 Hz), 1.27 (d, 3H, *J*=5.7 Hz), 1.62 (broad s, 1H), 2.97 (dd, 1H, *J*=7.7, 3.6 Hz), 3.59 (d, 2H, *J*=6.1 Hz); MS, Found 163.9835, Calcd for C_5H_9OBr 163.9837.

This work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science, and Culture.

Regioselectivity in the Catalytic Hydrogenolysis of 7-Fluoro-1-phenylbicyclo[4.1.0]heptanes

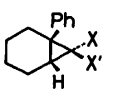
Koji Isogai,* Jun-ichi Sakai, and Katsuhiko Kosugi
Department of Applied Chemistry, Faculty of Engineering, Niigata University, Ikarashi, Niigata 950-21
(Received November 15, 1985)

The palladium-catalyzed hydrogenolysis of 7-chloro-7-fluoro-1-phenyl-, 7-fluoro-1-phenyl-, and 7,7-difluoro-1-phenylbicyclo[4.1.0]heptane was investigated. The hydrogenolysis of the cyclopropane ring occurs at the C_1–C_6 bond selectively, accompanied by the elimination of the *endo*-halogen. The hydrogenolysis of *endo*-7-fluoro-1-phenylbicyclo[4.1.0]heptane proceeded rapidly to give phenylcycloheptane as a sole product, whereas *exo*-7-fluoro-1-phenylbicyclo[4.1.0]heptane reacted slowly to give *trans*-1-fluoro-2-phenylcycloheptane, accompanied by a small amount of the C_1–C_7 bond-cleaved product. The different reactivity between the endo and exo derivatives became more considerably by the introduction of a methyl group at the 2-position. Thus, with the compounds having 2-methyl group the *endo*-fluoro derivative was cleaved at the C_1–C_6 bond accompanied by the C_1–C_7 bond cleavage, whereas the *exo*-fluoro derivative was cleaved at the C_1–C_7 bond exclusively.

Although many studies on the catalytic hydrogenolysis of vinyl, aryl, allyl, and benzyl fluorides have been reported,[1] little attention has been given to the catalytic hydrogenolysis of cyclopropyl fluorides. In the previous paper,[2] we reported the regioselective hydrogenolysis of 1,1-difluoro-3-methyl-2-phenylcyclopropane. The cyclopropane ring was cleaved at the C_2–C_3 bond exclusively using both palladium oxide (PdO) and Raney nickel (R-Ni), accompanied by a considerable extent of the carbon-fluorine bond hydrogenolysis. Mitsui et al.[3] reported that 1-phenylbicyclo[4.1.0]heptane and its 2-methyl derivative were hydrogenolyzed at the C_1–C_7 bond preferentially because of the difference of the catalyst hindrance between the C_1–C_6 bond and the C_1–C_7 bond on the catalyst surface. It seems to be interesting to investigate the behavior of the fluorine for the regioselectivity in the catalytic hydrogenolysis of the cyclopropane ring contained in such condensed ring systems. Here, we wish to report the palladium-catalzed hydrogenolysis of several 7-fluoro-substituted -phenylbicyclo[4.1.0]heptanes.

Results and Discussion

exo-7-Chloro-*endo*-7-fluoro-1-phenyl- (1-endo-F), *endo*-7-chloro-*exo*-7-fluoro-1-phenyl- (1-exo-F), *endo*-7-fluoro-1-phenyl- (2-endo-F), *exo*-7-fluoro-1-phenyl- (2-exo-F) and 7,7-difluoro-1-phenylbicyclo[4.1.0]heptane (**3**) were hydrogenated over PdO in ethanol solution at room temperature under atmospheric pressure. The results are shown in Table 1. The hydrogenolysis of the cyclopropane ring of these fluorocyclopropanes occurred at the C_1–C_6 bond selectively although only 2-exo-F was accompanied by a small amount of the C_1–C_7 bond cleaved product. Characteristic differences between the endo isomer and the exo isomer were observed in the reactivity and in the ratio of the products. The reaction of 1-endo-F proceeded very slowly and gave phenylcycloheptane (**5**) as a sole product, whereas the reaction of 1-exo-F proceeded rapidly than that of 1-endo-F to give **5** (37%) and *cis*-1-fluoro-2-phenylcycloheptane (**6**) (63%). On the other hand, 2-endo-F reacted very rapidly to give **5** as a sole product, whereas 2-exo-F reacted slowly to give mainly *trans*-1-



1-endo-F: X=F, X'=Cl
1-exo-F : X=Cl, X'=F
2-endo-F: X=F, X'=H
2-exo-F : X=H, X'=F
3 : X=F, X'=F

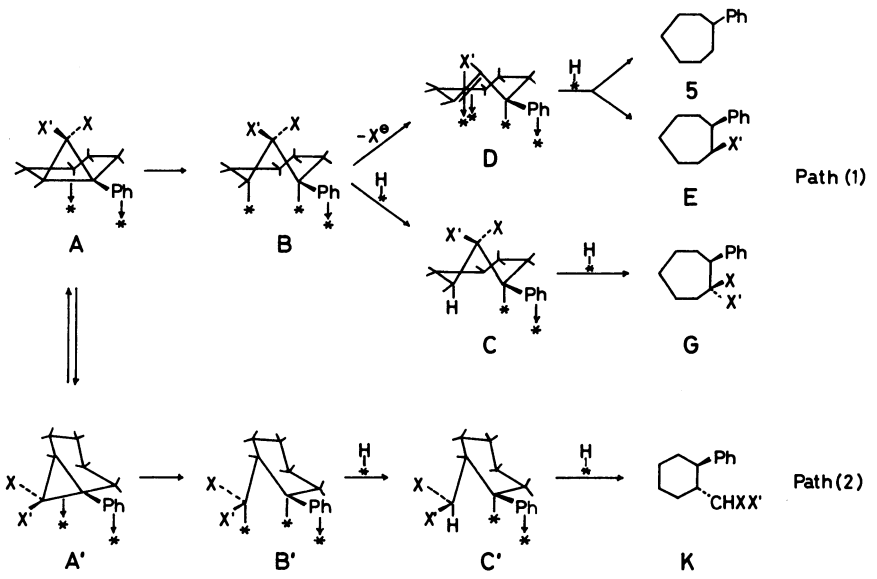
Table 1. Hydrogenolysis of 7-Fluoro-1-phenylbicyclo[4.1.0]heptanes

Substrate	Reaction time/h	Conversion %	Composition of products (%)				
			C_1–C_6 Fission				C_1–C_7 Fission
			5	**6**	**7**	**8**	**9**
1-endo-F	24	47	100	—	—	—	—
1-exo-F	4	95	37	63	—	—	—
2-endo-F	1	97	100	—	—	—	—
2-exo-F	24	96	10	—	78	—	12
3	0.5	100	20	27	—	53	—

Substrate: 20 mg, PdO: 20 mg.



Scheme 1.

fluoro-2-phenylcycloheptane (**7**) (78%) with **5** (10%), accompanying a small amount of *trans*-1-fluoromethyl-2-phenylcyclohexane (**9**) formed by the C_1–C_7 bond cleavage. The hydrogenolysis of **3** proceeded more easily and gave **5**, **6**, and 1,1-difluoro-2-phenylcycloheptane (**8**) of the C_1–C_6 bond cleaved products.

It has been known that the bond lengths of cyclopropane are changed markedly by the fluorine substitution. The available data of ring bond length (Å) for C_1–C_2 and C_2–C_3 bonds in cyclopropane,[4] 1,1-dichloro-,[5] chloro,[6] fluoro,[7] and 1,1-difluorocyclopropane[8] are reported, respectively, as follows; 1.514, 1.514; 1.532, 1.534; 1.513, 1.515; 1.494, 1.527; 1.464, 1.552. In the case of 7-fluoro derivatives of 1-phenylbicyclo[4.1.0]heptane, analogous lengthening of the C_1–C_6 bond and shortening of the C_1–C_7 and C_6–C_7 bonds are expected which may cause an additional strain in the condensed ring system. In this hydrogenation, these effects may overcome the steric effect which is a dominant factor in the case of the parent compound and the C_1–C_6 bond hydrogenolysis occurs preferentially.

Additionally, the ease of hydrogenolysis of the cyclopropane ring and the carbon–fluorine bond seems to depend markedly upon whether the fluorine binds to endo- or exo-side. A similar stereochemical behavior was reported in the case of the ring-enlargement of 7-chlorobicyclo[4.1.0]heptanes by means of a thermal[9] and a solvolysis[10] reaction. The *endo*-chloro isomer reacts more easily than the *exo*-chloro isomer with the elimination of the chlorine as chloride ion. This stereospecific reaction is explained by a "concerted disrotatory process."[11] Similar fast progress of the ring-enlargement was observed in the hydrogenolysis of 1-exo-F, 2-endo-F, and **3**. Therefore, the elimination of the *endo*-halogen seems to contribute as one of fators to make easy the C_1–C_6 bond hydrogenolysis.

A probable pathway is shown in Scheme 1. The substrate adsorbs on the catalyst by the C_1–C_6 bond (adsorbed species A) or the C_1–C_7 bond (adsorbed species A′). In the case of the parent compound 1-phenylbicyclo[4.1.0]heptane (X=H, X′=H in A and A′), A has a larger catalyst hindrance than A′. Therefore, the C_1–C_7 bond cleaves preferentially.[3] In the hydrogenolysis of the fluorocyclopropanes, however, the weakening effect of the C_1–C_6 bond seems to overcome the catalyst hindrance and the hydrogenolysis proceeds easily through Path (1). Releasing the strain of the condensed ring by the ring-enlargement makes easy the formation of the C_1,C_6-diadsorbed species B from A. Additionally, in the case of 1-exo-F (X=Cl, X′=F) and 2-endo-F (X=F, X′=H), the elimination of the *endo*-halogen accelerates the C_1–C_6 bond cleavage to give cycloolefin intermediate D. Subsequent cis addition of hydrogen forms **5** and **6** (X′=F in E) competitively.

In this hydrogenation, 1-endo-F was ring-enlarged and gave **5**. The hydrogenolysis of 1-endo-F, therefore, seems to proceed via A, B, and D similarly to that of 1-exo-F and 2-endo-F. However, the reaction of 1-endo-F proceeded more slowly than that of 2-endo-F. Although the cause of the difference in the reactivity between 1-endo-F and 2-endo-F is not clear, it appears that the chlorine probably plays a role in the adsorption step. The role may be explained as one of examples of self-poisoning effects.[12] Because of the affinity of the chlorine to the catalyst is relatively stronger than that of the fluorine, the contribution of A′ in the adsorption state of 1-endo-F seems to be expected to some extent.

Table 2. Hydrogenolysis of 7-Fluoro-2-methyl-1-phenylbicyclo[4.1.0]heptanes

Substrate	Reaction time/h	Conversion %	Composition of products/%	
			C_1–C_6 Fission **10**	C_1–C_7 Fission **11**
4-endo-F	2	100	83	17
4-exo-F	8	86	—	100

Substrate: 20 mg, PdO: 100 mg.

The adsorption of the chlorine in A′ causes the lowering of the activity of catalyst. This effect makes difficult the hydrogenolysis of 1-endo-F from A′ which hinders the adsorption of 1-endo-F by the C_1–C_6 bond. By these factors, the lowering the activity of catalyst and the hindrance of adsorption by the C_1–C_6 bond, the hydrogenolysis of 1-endo-F seems to be retarded considerably. Although this self-poisoning effect affects in the case of 1-exo-F, the reaction seems to proceed smoothly by the assistance of the ready elimination of the *endo*-chlorine.

On the other hand, 2-exo-F reacted slowly than 2-endo-F and gave **7** (X=H, X′=F in G). The formation of **7** is explained by an alternative pathway in Path (1). Because the elimination of the *exo*-fluorine from B is disadvantageous stereoelectronically,[11] the cleavage of the C_1–C_6 bond of 2-exo-F proceeds more slowly than that of 2-endo-F and forms the half-hydrogenated state C (X=H, X′=F) without the elimination of the *exo*-fluorine. The half-hydrogenated state C receives hydrogen from the catalyst to give **7**. Furthermore, 2-exo-F gave a small amount of the C_1–C_7 bond cleaved product 9 (X=H, X′=F in K). The pathway of the C_1–C_7 bond cleavage may be explained by Path (2). Because the cleavage of the C_1–C_6 bond from A is relatively slow, the sterically less-hindered adsorption species A′ participated to some extent in this hydrogenation and causes the contamination of the C_1–C_7 bond cleaved product formed via B′ and C′.

In the case of the hydrogenolysis of **3** (X=F, X′=F), it was expected that **3** reacted in analogy with 1-exo-F to give **5** and **6**. However, **8** (X=F, X′=F in G) was obtained in an about 50% yield with **5** and **6**. It seems to be that the 7,7-difluoro-substitution weakens the C_1–C_6 bond more strongly and the C_1–C_6 bond cleaves easily without the assistance of the elimination of the *endo*-fluoine followed by the competitive formation of D (X′=F) and C (X=F, X′=F).

The difference observed in the hydrogenolysis of 2-endo-F and 2-exo-F appeared more strongly in the case of 2-methyl derivatives of 2-endo-F and 2-exo-F. The results of the hydrogenolysis of *t*-7-fluoro-*c*-2-methyl-*r*-1-phenylbicyclo[4.1.0]heptane (4-endo-F) and *c*-7-fluoro-c-2-methyl-*r*-1-phenylbicyclo[4.1.0]heptane (4-exo-F) are shown in Table 2. Since the rate of

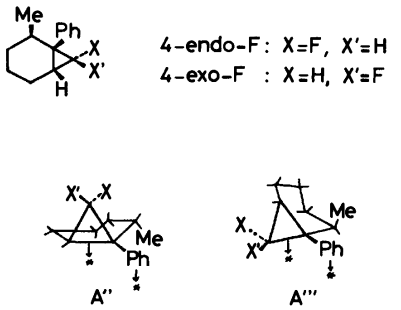


Fig. 2.

hydrogenolysis of 4-endo-F and 4-exo-F was considerably slower than that of 2-endo-F and 2-exo-F, PdO was used in the amount five times that for the other compounds. Although the hydrogenolysis of 4-endo-F proceeded more easily than 4-exo-F to give mainly *cis*-1-methyl-2-phenylcycloheptane (**10**), it was accompanied by *r*-1-fluoromethyl-*t*-3-methyl-*t*-2-phenylcyclohexane (**11**) which was arose by the C_1–C_7 bond cleavage. On the other hand, 4-exo-F was cleaved at the C_1–C_7 bond exclusively to give **11** as a sole product.

As can be seen from Fig. 2, the 2-methyl group increases the catalyst hindrance against the adsorption of the C_1–C_6 bond in the adsorbed species A.″ This steric effect seems to be large enough to retard the C_1–C_6 bond cleavage and 4-exo-F prefers the adsorbed species A‴ to give the C_1–C_7 bond cleaved product exclusively. This steric effect seems to affect even in the hydrogenolysis of 4-endo-F and causes the contamination of the C_1–C_7 bond cleaved product.

Experimental

^{1}H NMR spectra were recorded on a JNM-PMX 60 spectrometer with $Si(CH_3)_4$ as the internal standard. ^{19}F NMR spectra were recorded on a JNM-FX 90Q spectrometer with CF_3COOH as the external standard. Mass spectra were obtained with a HITACHI M-60 GC-MS spectrometer.

***exo*-7-Chloro-*endo*-7-fluoro-1-phenylbicyclo[4.1.0]heptane (1-endo-F) and *endo*-7-Chloro-*exo*-7-fluoro-1-phenylbicyclo-[4.1.0]heptane (1-exo-F).** According to the procedure of Ando et al.,[13] to a mixture of 1-phenylcyclohexene (20.5 g, 0.13 mol) and sodium hydride (3.1 g, 0.13 mol) was added

methyl dichlorofluoroacetate (30 g 0.13 mol) at 0—5 °C. After 2 h, methanol (4.2 ml) was added to the reaction mixture. A mixture of 1-endo-F and 1-exo-F (1:2) was obtained in a 24% yield; bp 110—113 °C/6 mmHg (1 mmHg=133.322 Pa). ^{19}F NMR ($CDCl_3$) δ=45.8 (d, J_{HFvic}= 19.5 Hz, cis), 68.8 (d, J_{HFvic}=3.0 Hz, trans). Found: C, 69.64; H, 6.33%. Calcd for $C_{13}H_{14}FCl$: C, 69.49; H,6.28%.

Isomers 1-endo-F and 1-exo-F were separated by preparative VPC. **1-endo-F:** MS *m/z* 224(M^+). ^{19}F NMR ($CDCl_3$): δ=68.8 (d, J_{HFvic}=3.0 Hz). **1-exo-F:** MS *m/z*: 224 (M^+). ^{19}F NMR ($CDCl_3$): δ=45.8 (d, J_{HFvic}=19.5 Hz). The value of ^{19}F NMR is comparable to that of each isomer of 7-chloro-7-fluorobicyclo[4.1.0]heptane.[9]

***endo*-7-Fluoro-1-phenylbicyclo[4.1.0]heptane (2-endo-F) and *exo*-7-Fluoro-1-phenylbicyclo[4.1.0]heptane (2-exo-F).** A mixture of 1-endo-F and 1-exo-F (0.5 g) was hydrogenated by use of Raney nickel (2 g) in ethanol in the presence of ethylenediamine (0.8 g) at room temperature under atmospheric pressure. The carbon-chlorine bond was hydrogenolyzed selectively with retention of configuration to give 2-endo-F and 2-exo-F, respectively, with a small amount of cyclopropane ring cleaved products. From the reaction mixture, the two isomers were separated by preparative VPC.

2-endo-F: MS *m/z* 190(M^+). ^{1}H NMR (CCl_4) δ=7.13 (5H, s, C_6H_5), 4.47 (1H, dd, J_{HFgem}=66.6 Hz, J_{HHvic}=7.0 Hz), 2.5—1.0 (9H, broad, ring). Found: C, 82.14; H, 8.09%. Calcd for $C_{13}H_{15}F$: C, 82.07; H, 7.95%.

2-exo-F: MS *m/z*: 190(M^+). ^{1}H NMR (CCl_4) δ=7.16 (5H, s, C_6H_5), 4.30 (1H, dd, J_{HFgem}=66.6 Hz, J_{HHvic}=2.5 Hz), 2.5—1.0 (9H, broad, ring). Found: C, 82.06; H, 8.16%. Calcd for $C_{13}H_{15}F$: C, 82.07; H, 7.95%. The values of ^{1}H NMR are comparable to those of each isomer of 7-fluoro-bicyclo[4.1.0]heptane.[9]

7,7-Difluoro-1-phenylbicyclo[4.1.0]heptane (3). A mixture of 1-phenylcyclohexene (9.0 g, 0.057 mol), chlorodifluoromethane (12 g, 0.4 mol), epichlorohydrin (28.3 g, 0.31 mol) and tetrabutylammonium chloride (1.1 g) was heated at 130 °C, 19 h, in an autoclave according to the procedure of Kamel.[14] The fraction, bp 93—96 °C/7 mmHg, 4.0 g, was purified by preparative VPC to give **3**. MS *m/z*: 208(M^+). ^{1}H NMR (CCl_4) δ=7.19 (5H, s, C_6H_5), 2.66—0.85 (9H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=49.2 (dd, J_{FF}=148.4 Hz, J_{HFvic}=15.6 Hz), 64.6 (dd, J_{FF}=148.4 Hz, J_{HFvic}=3.0 Hz). Found: C, 74.78; H, 6.83%. Calcd for $C_{13}H_{14}F_2$: C, 74.97; H, 6.78%.

***t*-7-Fluoro-*c*-2-methyl-*r*-1-phenylbicyclo[4.1.0]heptane (4-endo-F) and *c*-7-Fluoro-*c*-2-methyl-*r*-1-phenylbicyclo[4.1.0]-heptane (4-exo-F).** To a mixture of 3-methyl-2-phenylcyclohexene (22.5 g, 0.13 mol) and sodium hydride (3.1 g, 0.13 mol) was added methyl dichlorofluoroacetate (30 g, 0.13 mol) at 0—5 °C followed by addition of methanol (4 ml) as described above. A mixture of endo and exo isomers of 7-chloro-7-fluoro-*c*-2-methyl-*r*-1-phenylbicyclo-[4.1.0]heptane (endo-F/exo-F=3/7) was obtained in a 20% yield, bp 115—120 °C/4 mmHg. MS *m/z*: 238(M^+). ^{19}F NMR ($CDCl_3$) δ=71.7 (d, J_{HFvic}=3.0 Hz) 48.0 (d, J_{HFvic}=22.4 Hz). Found: C, 70.24; H, 6.99%. Calcd for $C_{14}H_{16}FCl$: C, 70.43; H, 6.76%.

The chlorofluorocyclopropane was hydrogenated over Raney nickel according to the preceding procedure to give a mixture of 4-endo-F and 4-exo-F and the isomers were separated by preparative VPC, respectively.

4-endo-F: MS *m/z*: 204(M^+). ^{1}H NMR (CCl_4) δ=7.13 (5H, s, C_6H_5), 4.50 (1H, dd, J_{HFgem}=66.6 Hz, J_{HHvic}=6.6 Hz) 2.4—0.9 (8H, broad, ring), 0.67 (3H, d, J=7.0 Hz, CH_3). Found: C, 82.55; H, 8.55%. Calcd for $C_{14}H_{17}F$: C, 82.31; H, 8.39%.

4-exo-F: MS *m/z*: 204(M^+). ^{1}H NMR (CCl_4) δ=7.16 (5H, s, C_6H_5), 4.35 (1H, dd, J_{HFgem}=66.6 Hz, J_{HHvic}=2.4 Hz), 2.2—0.8 (8H, broad, ring), 0.67 (3H, d, J=6.4 Hz, CH_3). Found: C, 82.47; H, 8.43%. Calcd for $C_{14}H_{17}F$: C, 82.31; H, 8.39%.

General Procedure of Hydrogenation. Substrates (20 mg) were hydrogenated over PdO (20 mg, Kawaken Fine Chemical Co.) in ethanol (2 ml) at room temperature under atmospheric pressure. The composition of the products was determined by VPC at appropriate time intervals.

Identification of Products. After the hydrogenolysis proceeded appropriately, the reaction mixture was subjected to measurement of GC-MS. For measurement of NMR and elementary analysis, each component of products was separated by preparative VPC.

Phenylcycloheptane (5): Ms *m/z*: 174(M^+), which was identical with that of an authentic sample, bp 113—114 °C/10 mmHg, lit,[15] bp 114.5 °C/10 mmHg, prepared by the hydrogenation of 1-phenylcycloheptene over Pd-C.

***cis*-1-Fluoro-2-phenylcycloheptane (6):** MS *m/z*: 192(M^+). ^{1}H NMR (CCl_4) δ=7.14 (5H, s, C_6H_5), 4.88 (1H, mm, J_{HFgem}=48.0 Hz), 2.6—1.0 (12H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=112.13 (m). Found: C, 81.37; H, 8.89%. Calcd for $C_{13}H_{17}F$: C, 81.21; H, 8.91%.

Compound **6** was identical with an authentic sample which was prepared as follows; hydrogenation of 1-phenyl-8-oxabicylo[5.1.0]octane (3.9 g) over Raney nickel (2 g) in hexane at room temperature under atmospheric pressure gave phenylcycloheptane (41%) and a mixture of *cis*- and *trans*-2-phenylcycloheptanol (51%, trans/cis=9/1). The fractional distillation of the reaction mixture gave *trans*-2-phenylcycloheptanol, 1.7 g, bp 130—137 °C/4 mmHg, lit,[16] bp 113—114 °C/0.5 mmHg, *p*-nitrobenzoate, mp 83—84 °C, lit,[16] mp 84—85 °C. To a methylene dichloride soluion (5 ml) of *trans*-2-phenylcycloheptanol (0.95 g, 5 mmol) was added a methylene chloride solution (5 ml) of hexafluoropropene-diethylamine (1.35 g, 6 mmol) at 0—5 °C and allowed to stand overnight. After removal of low boiling products, the residue was purified by a column chromatography to obtain **6** (70 mg). The values of NMR and elementary analysis were in agreement with those of **6** obtained by the hydrogenolysis of 1-exo-F and **3**. ^{1}H NMR (CCl_4) δ=7.14 (5H, s, C_6H_5), 4.85 (1H, mm, J_{HFgem}=48.0 Hz), 2.6—1.0 (12H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=112.13 (m). Found: C, 80.86; H, 8.87%. Calcd for $C_{13}H_{17}F$: C, 81.21; H, 8.91%.

***trans*-1-Fluoro-2-phenylcycloheptane (7):** MS *m/z*: 192(M^+). ^{1}H NMR (CCl_4) δ=7.15 (5H, s, C_6H_5), 4.54 (1H, mm, J_{HFgem}=46.0 Hz), 2.4—1.2 (12H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=86.38 (m). Found: C, 81.40; H, 9.05%. Calcd for $C_{13}H_{17}F$: C, 81.21; H, 8.91%.

Compound **7** was identical with an authentic sample which was prepared as follows; hydrogenation of 1-phenyl-8-oxabicyclo[5.1.0]octane (3.2 g) over Pd-C (0.36 g) in hexane solution in the presence of diethylamine (0.67 g) gave phenylcycloheptane (3%) and 2-phenylcycloheptanol (96%, cis/trans=95/5). The fractional distillation gave *cis*-2-phenylcycloheptanol, 2.5 g, bp 124—132 °C/3.5 mmHg,

lit,[16] bp 98.5—102.5 °C/0.25 mmHg, *p*-nitrobenzoate, mp 90—92 °C, lit,[16] mp 92—93 °C. Fluorination of the *cis*-alcohol (0.95 g) was carried out in a similar manner as described above to obtain **7** (0.45 g). The values of NMR and elementary analysis were in agreement with those of **7** obtained by the hydrogenolysis of 2-exo-F. ^{1}H NMR (CCl_4) δ=7.16 (5H, s, C_6H_5), 4.56 (1H, mm, J_{HFgem}=46.0 Hz), 2.4—1.2 (12H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=86.38 (m). Found: C, 80.89; H, 8.91%. Calcd for $C_{13}H_{17}F$: C, 81.21; H, 8.91%.

1,1-Difluoro-2-phenylcycloheptane (8): MS *m/z*: 210(M^+). ^{1}H NMR (CCl_4) δ=7.17 (5H, s, C_6H_5), 2.7—0.8 (11H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=4.80 (mm, J_{FFgem}=243.2 Hz), 23.27 (mm, J_{FFgem}=243.2 Hz). Found: C, 74.09; H, 7.80%. Calcd for $C_{13}H_{16}F_2$: C, 74.26; H, 7.67%.

***trans*-1-Fluoromethyl-2-phenylcyclohexane (9):** MS *m/z*: 192(M^+). ^{1}H NMR (CCl_4) δ=7.17 (5H, s, C_6H_5), 4.00 (2H, dd, J_{HFgem}=48.0 Hz, J_{HHvic}=3.0 Hz, CH_2F), 2.6—1.2 (10H, broad, ring). ^{19}F NMR ($CDCl_3$) δ=153.68 (m). Found: C, 80.92; H, 8.77%. Calcd for $C_{13}H_{17}F$: C, 81.21; H, 8.77%.

Compound **9** was identical with an authentic sample which was prepared as follows; to a methylene dichloride solution (5 ml) of *trans*-2-phenylhexahydrobenzyl alcohol (0.95g, 5 mmol), mp 46—48 °C, lit,[17] mp 46—48 °C, was added a methylene chloride solution (5 ml) of hexafluoropropene-diethylamine (1.35 g, 6 mmol) at 0—5 °C and the reaction mixture was allowed to stand overnight. The fraction, bp 107—110 °C/5 mmHg, 0.55 g, was purified by TLC and 0.17 g of **9** was obtained. The values of NMR and elementary analysis were in agreement with those of **9** obtained by the hydrogenolysis of 2-exo-F. ^{1}H NMR (CCl_4) δ=7.15 (5H, s, C_6H_5), 3.96 (2H, dd, J_{HFgem}=48.0 Hz, J_{HHvic}=2.8 Hz, CH_2F). ^{19}F NMR ($CDCl_3$) δ=153.68 (m). Found: C, 81.17; H, 8.97%. Calcd for $C_{13}H_{17}F$: C, 81.21; H, 8.91%.

***cis*-1-Methyl-2-phenylcycloheptane (10):** MS *m/z*: 188(M^+). ^{1}H NMR (CCl_4) δ=7.11 (5H, s, C_6H_5), 2.6—1.2 (12H, broad, ring), 0.73 (3H, d, *J*=6.0 Hz, CH_3). Found: C, 89.16; H, 10.73%. Calcd for $C_{14}H_{20}$: C, 89.29; H, 10.71%.

***r*-1-Fluoromethyl-*t*-3-methyl-*t*-2-phenylcyclohexane (11):** MS *m/z*: 206(M^+). ^{1}H NMR (CCl_4) δ=7.17 (5H, s, C_6H_5), 4.13 (2H, dd, J_{HFgem}=48.0 Hz, J_{HHvic}=3.0 Hz, CH_2F), 2.6—1.2 (9H, broad, ring), 0.78 (3H, d, *J*=7.0 Hz, CH_3). ^{19}F NMR ($CDCl_3$) δ=153.08 (m). Found: C, 81.74; H, 9.16%. Calcd for $C_{14}H_{19}F$: C, 81.51; H, 9.28%.

The authors are grateful to the Japan Association of Chemistry for financial support. We also thank Mr. Masakazu Okumiya, Osaka University, for elementary analysis and Mr. Takao Ohno, Analytical Instrument Laboratory of Niigata University, for ^{19}F NMR measurement.

Intramolecular "Diene-Regenerable" Diels-Alder Reaction of 2-Pyrone-6-carboxamides.[1] Preparation and Reaction of Fused 1,3-Cyclohexadiene Systems

Michihiko NOGUCHI,* Shinji KAKIMOTO, Hisao KAWAKAMI, and Shoji KAJIGAESHI
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
(Received November 25, 1985)

The 2-pyrone-6-carboxamides, prepared from 2-pyrone-6-carbonyl chloride and substituted allylamine, undergo an intramolecular Diels–Alder reaction spontaneously to give 3a,4,5,7a-tetrahydro-1-oxoisoindoline-5,7a-carbolactones, which regenerate the diene moieties by the decarboxylation to afford 3a,4-dihydro-1-oxoisoindolines. 3a,4,4a,5-Tetrahydro-1(2*H*)-isoquinolone and 2,3,4,5,5a,6-hexahydro-1*H*-2-benzazepin-1-one derivatives are obtained similarly from the corresponding amides. These fused 1,3-cyclohexadiene systems reveal to be versatile synthetic intermediates for polycyclic compounds by cycloaddition reaction and for benzo-fused heterocycles by dehydrogenation. The stereochemistries in the successive cycloaddition reactions are also discussed.

Previously, we reported that 2-pyrone-6-carboxylates bearing dienophiles at the ester moieties underwent "diene-regenerable" Diels–Alder reaction intramolecularly to give 3a,4-dihydrophthalide derivatives.[2] The 3a,4-dihydrophthalides behaved as novel functionalized 1,3-cyclohexadiene systems and provided a favorable method for the synthesis of 5,7a-ethanophthalides by the intermolecular Diels–Alder reaction with olefins[2] and of 4-substituted phthalides by oxidation.[3]

In this paper we wish to report that 2-pyrone-6-carboxamides, prepared from 2-pyrone-6-carbonyl chloride and substituted allylamines in situ, undergo an intramolecular Diels–Alder reaction to give tetracyclic adducts, which are smoothly converted to 3a,4-dihydro-1-oxoisoindolines by the extrusion of carbon dioxide. 1(2*H*)-Isoquinolone and 1*H*-2-benzazepin-1-one derivatives are obtained similarly by the intramolecular "diene-regenerable" Diels–Alder reaction of the corresponding 2-pyrone-6-carboxamides. The reaction of the fused 1,3-cyclohexadienes with *N*-phenylmaleimide and the oxidation of the 1,3-cyclohexadienes to benzo-fused heterocycles are also detailed.

Results and Discussion

Intramolecular Diels-Alder Reaction of 2-Pyrone-6-carboxamides. The reaction of 2-pyrone-6-carbonyl chloride (**1**) and *N*-allylaniline (**2a**) in the presence of triethylamine (Et_3N) at room temperature gave a crystalline product **4a** in 60% yield.

Unfortunately, **4a** did not provide satisfactory results on the elemental analysis, and the molecular ion peak on its mass spectrum was not observed because of its instability. Its IR spectrum, however, exhibited strong absorption bands at 1770 and 1700 cm^{-1} assignable to the lactone an lactam carbonyl streching vibrations, respectively. Also, its ^1H NMR spectrum (Table 2) showed two olefinic protons at δ=6.53 and 6.96 and the complicated signals over the region of δ=2 to 4 (total 6H) assigned to methylene and methine protons together with phenyl protons (5H). On the basis of these spectral data and the chemical conversions delineated later, **4a** was deduced to be not the expected *N*-allyl-2-pyrone-6-carboxanilide (**3a**) but 3a,4,5,7a-tetrahydro-1-oxo-2-phenylisoindoline-5,7a-carbolactone, an intramolecular Diels–Alder adduct of **3a**.

Similarly, the reaction of **1** with *N*-allylbenzylamine (**2b**), *N*-benzyl-*trans*-cinnamylamine (**2c**), *N*-(*trans*-2-butenyl)benzylamine (**2d**), and *N*-methyl-*trans*-cinnamylamine (**2e**) in the presence of Et_3N gave the corresponding Diels–Alder adducts **4b—e** in good yields. These results are summarized in Tables 1 and 2.

The stereochemistry at the 3-position of **4** could not be determined only on the basis of the coupling constants between 3-H and 3a-H or 3a-H and 4-H. However, its structure was deduced to be **4**-*endo* from the following inspections using the molecular models of **4**-*endo* and **4**-*exo* as well as the transition states. Firstly, the methylene protons at the 3-position of **4** were observed almost equivalently as shown in Table 2. The methylene protons at the 3-position of **4**-*endo* are possible to be equivalent and, on the other hand, those of **4**-*exo* are not so because of the anisotropic effect arising from the ether-

Fig. 1. Possible transition states for the intramolecular Diels–Alder reaction of **3**.

oxygen atom of the lactone moiety.

The configurations between 3a- and 4-positions of **4c**, **4d**, and **4e** were determined to be *trans* from those of the 3a,4-dihydro-1-oxoisoindoline derivatives, which were obtained by the decarboxylation of **4** as mentioned later.

The considerations using the molecular models of the possible transition states[4] in this reaction also indicate the predominant formation of **4**-*endo*, i.e., the orientation A leading to **4**-*endo* seems to be more favorable than B leading to **4**-*exo*, in which the sterical repulsion between one of the allylic methylene protons and the ether-oxygen atom of 2-pyrone part in **3** becomes serious along with the progress of the reaction (Fig. 1).

The Diels–Alder adducts from 2-pyrones and dienophiles are not so stable as well-known and only a few examples of the isolation have been reported.[5] To be emphasized is the isolation of the adducts **4**, because **4** possess further strained structures than the adducts reported previously.[5]

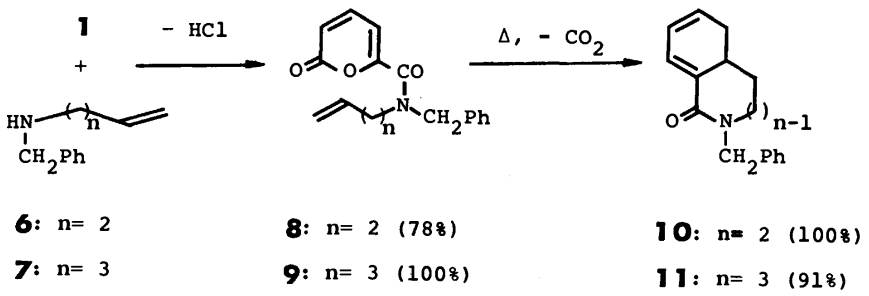
Predictively, the adducts **4** are thermodynamically and photochemically unstable and converted gradually to 3a,4-dihydro-1-oxoisoindoline derivatives by the decarboxylation during the storage in the crystalline or solution state under shield of light in a refrigerator.

For example, **4a** was heated in hexane under reflux for a few minites to give 3a,4-dihydro-1-oxo-4-phenylisoindoline (**5a**) quantitatively. 3a,4-Dihydro-1-oxoisoindolines **5b**—**e** were similarly obtained from the corresponding adducts **4b**—**e** in quantitative yields (Scheme 2).

The analytical and spectroscopic data of **5** were consistent with the proposed structures. Especially, their stereochemical confirmations at the 3a- and 4-positions were accomplished by the following ^{1}H NMR spectral data; for **5a** the vicinal coupling constants (5.9 and 2.2 Hz) between the olefin proton (5-H) and the methylene protons (4-H) were assigned to be $J_{5-4(a)}$ and $J_{5-4(b)}$, respectively. Nextly, the pronounced large coupling constants (17.2 and 9.7 Hz)[6] between 3a-H and 4-H were deduced to be *trans* and *cis*, respectively. These assignments were almost identical with those of 3a,4-dihydrophthalide.[2] Among **4c**, **4d**, and **4e**, the stereochemistry at the 3a- and 4-positions of **4c** was only determined to be *trans* on the basis of the vicinal coupling constants among the adjacent three protons at the 3a-, 4-, and 5-positions (J_{3a-4}=17.0 and J_{4-5}=0.8 Hz) (Table 3).

This means that the intramolecular Diels–Alder reaction of amide **3c** is carried out with the retention of the stereochemistry on the dienophile moiety. Taking the integrity of the stereocontrol in this reaction into consideration, the stereochemistries at the 3a- and 4-positions of **5d** and **5e** were suggested to be also *trans*.

The above findings revealed that the "diene-regenerable" Diels–Alder reaction of 2-pyrone-6-



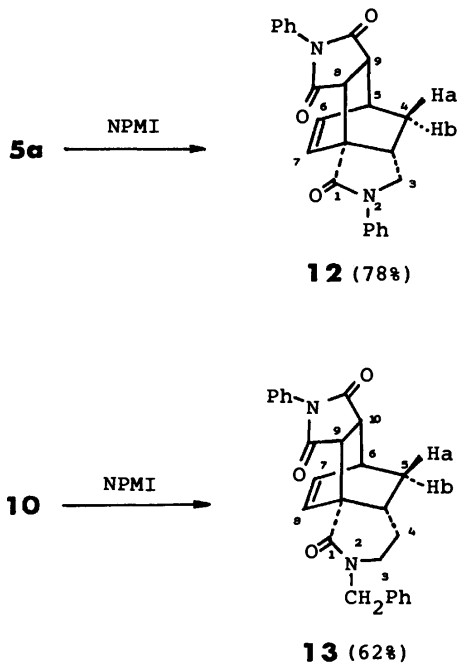
Scheme 3.

carboxamides **3** provided an attractive route to obtain 3a,4-dihydro-1-oxoisoindolines, so we attempted to apply this method to the preparation of the 1,3-cyclohexadiene systems fused by six- and seven-membered heterocycles containing nitrogen atom.

The reaction of **1** with *N*-(3-butenyl)benzylamine (**6**) and *N*-(4-pentenyl)benzylamine (**7**) in the presence of Et_3N at room temperature gave the 2-pyrone-6-carboxamides **8** and **9**. The successive intramolecular Diels–Alder reaction of **8** and **9** proceeded only under the severer conditions, i.e., under reflux in toluene for **8** and in *o*-dichlorobenzene for **9**, to give 2-benzyl-3,4,4a,5-tetrahydro-1(2*H*)-isoquinolone (**10**) and 2-benzyl-2,3,4,5,5a,6-hexahydro-1*H*-2-benzazepin-1-one (**11**), respectively (Scheme 3).

Cycloaddition Reaction of Fused 1,3-Cyclohexadienes 5a and 10 with *N*-Phenylmaleimide (NPMI). In order to obtain the stereochemical aspect on the Diels–Alder reaction of the fused 1,3-cyclohexadiene systems, the reaction of **5a** and **10** with NPMI was investigated.

The reaction of **5a** or **10** with an equimolar NPMI in xylene under reflux and the successive working-up gave the cycloadduct **12** or **13** as a sole product (Scheme 4).



Scheme 4.

The structure of **12** was deduced to be a 3a,4,5,7a-tetrahydro-5,7a-ethano-1-oxoisoindoline derivative on the basis of its spectral data. It was confirmed that the stereochemistry at the 3a- and 7a-junctions was *cis* and the configurations of the protons at the 8- and 9-positions were both *exo* from the analysis of its ^1H NMR spectrum compared with that of cycloadduct[2] from 3a,4-dihydrophthalide and NPMI or of the related similar ring systems.[7]

The structure of **13** was deduced to be a 3,4,4a,5,6,8a-hexahydro-6,8a-ethano-1(2*H*)isoquinolone derivative also from its spectral data. The sufficient assignment of the signals in its ^1H NMR spectrum was not accomplished, because some of the methylene and methine protons were superimposed one another. However, the signal patterns[8] of the olefin protons of **13** were almost identical with those of **12**; δ=6.24 (dd, 1H, J=6.8 and 8.5 Hz) and 6.77 (d, 1H, J=8.5 Hz) for **12** and δ=6.26 (dd, 1H, J=5.7 and 9.0 Hz) and 6.86 (d, 1H, J=9.0 Hz) for **13**, so the stereochemistry at the 4a- and 8a- junctions of **13** was concluded to be also *cis*. Although the configurations of the protons at the 9- and 10-positions were obscure, they were tentitatively assigned to be both *exo* similarly to those of **12** according to the reaction pathway.

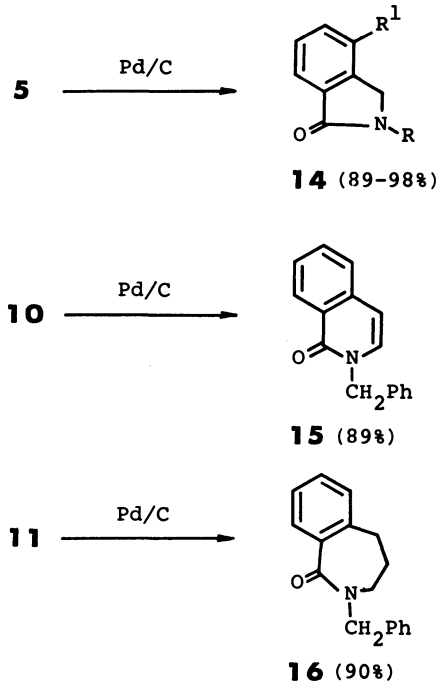
These findings indicate that the Diels–Alder reaction of **5a** and **10** with NPMI proceeds in a highly stereoselective manner. Therein, an only approarch of NPMI to 1,3-diene moiety of **5a** or **10** leading to *cis*-fused lactam ring seems to be possible owing to the less ring distorsion at the transition state in the reaction.

Dehydrogenation of Fused 1,3-Cyclohexadiene Systems 5, 10, and 11 to Benzo-Fused Heterocycles. As described above, 4-substituted phthalides were prepared by the facial oxidation of 3a,4-dihydrophthalides with palladium-charcoal (Pd/C), so we investigated the dehydrogenation of 3a,4-dihydro-1-oxoisoindolines **5** and their higher homologs, **10** and **11**, to the benzo-fused heterocycles.

The heating of **5** in refluxing xylene in the presence of Pd/C gave the expected 1-oxoisoindolines **14** almost quantitatively. While the similar treatment of **11** with Pd/C in refluxing *o*-dichlorobenzene yielded 2-benzyl-2,3,4,5-tetrahydro-1*H*-2-benzazepin-1-one (**16**)[9], **10** gave 2-benzyl-1(2*H*)-isoquinolone(**15**)[10] with the elimination of two equimolar hydrogen under similar dehydrogenating conditions (Scheme 5).

Finally, the possibility of the one-pot preparation of the benzlactams **15** and **16** from **8** and **9**, respectively, was surveyed. Heating of the amide **8** in refluxing toluene in the presence of Pd/C gave 2-benzyl-3,4-dihydro-1(2*H*)-isoquinolone (**17**;[9] 43%) and **14d** (47%). A similar reaction of **9** furnished 2-benzyl-3,4-dihydro-5-methyl-1(2*H*)-isoquinolone (**18**; 87%) as a sole product. In both cases, the terminal olefins of the dienophile moieties were isomerized by the Pd/C to the inner ones, which cycloadded to the 4π-components of 2-pyrones (Scheme 6). Interestingly, the dehydrogenation of the dihydro-1(2*H*)-isoquinolones **17** and **18** to 1(2*H*)-isoquinolone systems was suppressed under these reaction conditions.

In conclusion, the intramolecular "diene-regenerable" Diels–Alder reaction of 2-pyrone-6-carboxamides provided an attractive synthetic method for the 1,3-cyclohexadiene systems fused by pyrrole, pyridine, and azepine rings, which are versatile intermediates for polycyclic compounds and benzo-fused heterocycles. Among them, it should be emphasized that the stereochemistries of the final polycyclic compounds depend upon those of the successive intra- and intermolecular cycloaddition reactions.



Scheme 5.

Experimental

General. All melting points are uncorrected. The IR spectra were measured on a JASCO IRA-1 spectrometer. The ^{1}H NMR spectra were obtained on JEOL FX-200 and JMN-MH-100 spectrometers with tetramethylsilane as an internal standard. The mass spectra were determined with JEOL JMS-012G-2 and JMS-D mass spectrometers equipped with direct inlets and at an ionization energy of 75 eV. The elemental analyses were performed on a Hitachi 026 CHN analyzer. The thin-layer chromatography was accomplished on 0.2 mm precoated plates of silica gel 60F-254 (Merck) or on 0.2 mm precoated plates of aluminium oxide 60F-254 Type E (Merck). The visualization was made with ultraviolet light (254 and 365 nm). For the preparative column chromatography, Wakogel C-300 was used.

Preparation of 3a,4,5,7a-Tetrahydro-1-oxoisoindoline-5,7a-carbolactones 4 from 2-Pyrone-6-carbonyl Chloride (1)

and Allylamines 2. Typical Procedure: To a stirred and cooled at 0 °C solution of *N*-allylaniline (**2a**)(32 mmol) and Et_3N (35 mmol) in THF (40 mL), **1**[11] (32 mmol) in THF (10 mL) was added dropwise for 30 min and the reaction mixture was stirred for additional 12 h at room temperature. The resultant triethylamine hydrochloride was filtered off and the filtrate was evaporated in vacuo at room temperature. The crystallization and successive washing with ethanol gave 4.8 g (60%) of **4a**.

A similar reaction of **1** with **2e** gave **4e** also as a crystalline form. On the other hand, **4b**, **4c**, and **4d** were obtained as oily products, so their purification was accomplished with a column chromatography (silica gel-ether).

Some efforts to purify **4** enough to obtain the satisfactory elemental analyses, e.g., recrystalization or purification with a performance liquid chromatography, were made without success.

Heating of **4a** in a capillary at 45 °C showed some changes of its crystalline form and **4a** melted at 94—95 °C. The melting point was identical with that of the decarboxylated product **5a**. The mass spectrum of **4a** under the ordinarily-measured conditions was also identical with that of **5a**.

The results of these reactions and the spectral data of the products **5** are summarized in Tables 1 and 2, respectively.

Decarboxylation of 3a,4,5,7a-Tetrahydro-1-oxoisoindoline-5,7a-carbolactones 4. Typical Procedure: A solution of **4a** (500 mg, 1.96 mmol) in hexane (30 mL) was refluxed for a few minutes and cooled at −30 °C to give 410 mg (99%) of the crystalline **5a**.

5a: Colorless plates (hexane-ethanol); mp 94—95 °C; IR (KBr) 1675 cm^{-1} (CO); MS *m/z* (relative intensity) 211 (M^+, base peak), 107 (22), 106 (72), 105 (Ph-CH=NH$^+$, 92), 104 (27), 92 (M^+−PhNCO, 37), 91, 77.

From Penicillin to Penem and Carbapenem. VIII.[1] Introduction of an Allyl Group at the C-4 Position of the Azetidinone Molecule, and the Synthesis of Dethiathienamycin

Katsumi FUJIMOTO, Yuji IWANO, and Koichi HIRAI*
Chemical Research Laboratories, Sankyo Co., Ltd. 1-2-58, Hiromachi, Shinagawa-ku, Tokyo 140
(Received November 29, 1985)

A new C_3-unit introduction reaction at the *C*-4 position of 4-acetoxy-2-azetidinone derivatives using tetraallyltin in the presence of 1/10 equiv of boron trifluoride etherate in dichloromethane is described. Dethiathienamycin was synthesized from (3*S*,4*R*)-4-allyl-3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone via the ylide intermediate.

Thienamycin (**16**) and the majority of the carbapenems are extremely active antibiotics against a broad range of Gram-positive and Gram-negative bacteria and have natural stability against β-lactamases.

Naturally occurring carbapenems, however, are highly unstable compounds because of their ring strain and other factors.[2] They are sufficiently stable only in a limited pH range around neutrality. This and the fact that it has so far not been possible to increase fermentation yields by strain optimization have made their isolation in large quantities from culture filtrates difficult.

Therefore, considerable effort has been devoted to the synthesis of these compounds and the search for more stable derivatives.[2] In their syntheses a wide variety of compounds have been used as starting materials; in our case we used the azetidinone derivative **6**, which is easily obtainable from 6-APA (6-aminopenicillanic acid).

A fundamental problem for the synthesis of carbapenem derivatives from 2-azetidinone derivatives such as **6** is how to introduce a carbon substituent at the *C*-4 position of the 2-azetidinone molecule. As possible solutions several C–C bond formation methods at the *C*-4 position have been elaborated; they can be divided into the following five categories:

1. Utilization of active methylene compounds[3]
2. Utilization of organometallic reagents[4]
3. Utilization of silyl derivatives[5]
4. Utilization of carbene insertion to the C–S bond[6]
5. Utilization of potassium cyanide[7]

A common intermediate for the above reactions (excluding 4) is reasonably considered to be the azetinone (or 2-oxoazetidinium) one (**3** or its *N*-substituted one).

We took advantage of allyltin reagent for the introduction of the C_3-unit under the following working hypotheses. The properties of tin organyls are different from those of silicon and germanium in a greater tendency of Sn^{IV} to be able to coordinate in more than four centers and ionize more easily to give cationic species.[8] As shown in Chart 1 the coordination of Lewis acid would assist in the elimination of the acyloxy group to generate 2-oxoazetidinium intermediate **3**. Allyltin is apt to react with cationic derivative, and therefore under these conditions tetraallyltin should attack the acyliminium intermediate to give 4-allyl-2-azetidinone. The trialkyl(or triallyl)tin cation which is generated in this reaction process would react with the Lewis acid–acetoxy complex (e.g. $BF_3 \cdot OAc$) to generate the Lewis acid (e.g. BF_3). Under these hypotheses the reaction should proceed on inclusion of a catalytic amount of Lewis acid.

In this report we describe a mild and convenient method for the introduction of the allyl substituent at

Chart 2.

Table 1. Effects of Lewis Acids

Lewis Acids	Yield/%
$SnCl_4$	30
$TiCl_4$	45
BF_3OEt_2	85
$ZnCl_2$	0
ZnI_2	0

the *C*-4 position of the azetidinone molecule, and application of this to the synthesis of dethiathienamycin (**17**).

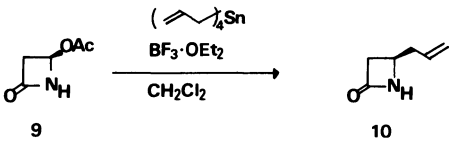
First, we investigated the reaction between 4-acetoxy-3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone (**6**) and tetraallyltin.

1) Effect of Lewis Acids. 4-Acetoxy-2-azetidinone derivative **6** was reacted with tetraallyltin in the presence of several kinds of Lewis acids. As shown in Table 1 zinc chloride and iodide failed to give the desired product. But tin tetrachloride and titanium tetrachloride gave **7** in moderate yields. Boron trifluoride etherate was the best of the five catalysts checked. 4-Acetoxy-2-azetidinone **6** was reacted with tetraallyltin in the presence of 0.1 equiv of boron trifluoride etherate in dichloromethane to give the 4-allyl-2-azetidinone (**7**) in 85% yield.

2) Effect of Amount of Tetraallyltin. Next we checked how many allyl groups in the tetraallyltin molecule could be used in this reaction. One, 0.5, and 0.25 mol of tetraallyltin was reacted with 1 mol of 4-acetoxy-2-azetidinone derivative **6** to give the desired product **7** in 85, 65, and 0% yield, respectively. These results suggest that two of the four allyl groups in the tetraallyltin molecule are effective enough in this allylation reaction. The same product **7** was also obtained using 1 equiv of allyltributyltin under the same conditions.

The 4-allyl-2-azetidinone produced was found to be identical with an authentic sample prepared from the corresponding 4-(phenylsulfonyl)-2-azetidinone derivative **8** and allylmagnesium bromide under the reported conditions.[9]

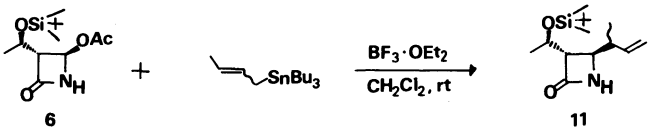
The simple 4-acetoxy-2-azetidinone (**9**) was also reacted with tetraallyltin in the presence of boron trifluoride etherate in dichloromethane to yield 4-allyl-2-azetidinone (**10**) in 74% yield.



9 10

Chart 3.

In the case of tributylcrotyltin,[10] the 4-(1-methylallyl)-2-azetidinone **11** was obtained as a 1:1 mixture (^{1}H NMR, δ=1.17, 1/2 CH_3, d, J=6 Hz and 1.21, 1/2 CH_3, d, J=6 Hz) in 80% yield.



6 11

Chart 4.

It is well known that boron trifuoride etherate in chloroform is one set of conditions for the desilylation of the silyl ether.[11] Therefore the *p*-nitrobenzyloxycarbonyl (PNZ) protected azetidinone derivatives **12—14**, which are stable to the above conditions, were subjected to the above and the progress of the reaction was monitored on silica-gel TLC (UV detected). As shown in Table 2, regardless of the configurations of the *C*-4 acyloxy groups, the reaction completed in 6 h and the same 4-allyl substituted azetidinone product **15** was obtained in 93% isolated yield.

At this stage, out of interest in antibacterial activity, we turned our attention to the synthesis of dethiathienamycin (**17**) in which the sulfur atom is

Chart 6′.

missing from the thienamycin molecule (**16**). Our strategy was as follows: i) The construction of the carbapenem skeleton was to be achieved by intramolecular Wittig reaction. ii) Compound **18** was to be synthesized from allylazetidinone **7** by the combination of 3 parts; *p*-nitrobenzyl glyoxylate, aminomethyl synthon, and the oxygen function at the 2-position of the allyl group.

We considered that the epoxidation of the double bond was useful for the introduction of the oxygen function, and the cyanide anion was taken advantage of for the aminomethyl synthon. Along these lines, the 4-allyl-2-azetidinone derivative **7** was oxidized with *m*-chloroperbenzoic acid in dichloromethane to the epoxide **19** as a mixture of two diastereomers, one of which crystallized: mp 83.5 °C $[\alpha]_D^{24}$ −18°(*c* 1, $CHCl_3$). The epoxide ring in **19** was opened regiospecifically to the cyano alcohol derivative **20**, one of the diastereomers of which also crystallized, mp 120—125 °C, on treatment with potassium cyanide in *N*,*N*-dimethylformamide–water (3:1) at room temperature for 15 h. The cyano group was then hydrogenated to the amino group using platinum oxide in acetic acid, and the succesive protection of the amino group by *p*-nitrobenzyloxycarbonyl chloride gave the compound **21** in 50% yield from **20**. The hydroxyl group in **21** was effectively oxidized to the ketone **22** with pyridinium chlorochromate in dichloromethane. Compound **22** was condensed with *p*-nitrobenzyl glyoxylate to afford the aminal derivative **23**, which was chlorinated by thionyl chloride and successively reacted with triphenylphosphine to give the ylide **24**. The intramolecular Wittig condensation reaction was easily performed by heating in benzene at 80 °C to afford the carbapenem **25**. The desilylation of this compound **25** could not be achieved under ordinary conditions (e.g. boron trifluoride etherate in acetonitrile, tetrabutylammonium fluoride and acetic acid, pyridine–acetic acid), presumably because of the instability of the carbapenem skeleton.

Therefore at the stage of **22** the silyl protective group was changed to the *p*-nitrobenzyloxycarbonyl group. The desilylation conditions, boron trifluoride

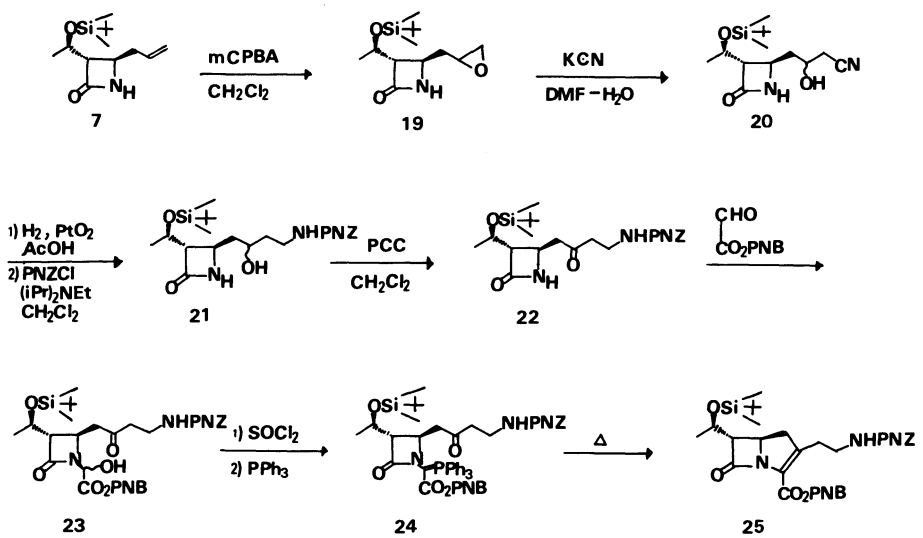

Chart 7.

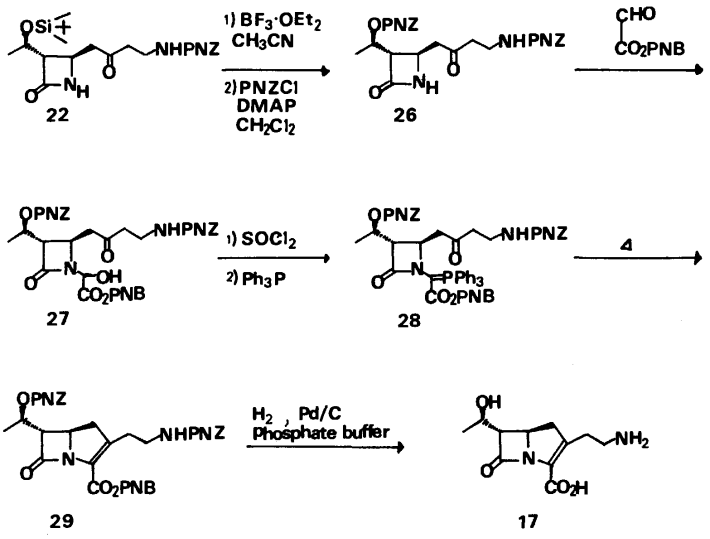

Chart 8.

etherate in acetonitrile were effectively applied to compound **22** to give the 1-hydroxyethyl compound, mp 115—116 °C. The hydroxyl group was reprotected with the *p*-nitrobenzyloxycarbonyl group using *p*-nitrobenzyloxycarbonyl chloride-4-(dimethylamino)-pyridine in dichloromethane to give the compound **26** in 50% isolated yield. The aminal formation reaction between **26** and *p*-nitrobenzyl glyoxylate (water was removed azeotropically before use) was smoothly performed in benzene in the presence of a catalytic amount of triethylamine at 40 °C for 5 min to afford the expected compound **27**. Chlorination and the ylide formation were performed under the standard conditions[12] to afford the ylide **28**. The intramolecular Wittig reaction was successfully applied to the ylide **28** by refluxing in benzene for 5 h to yield the desired carbapenem derivative **29**: IR(neat): 3400, 1775, 1745, 1720 cm^{-1}. The final stage of the synthesis; the deprotection of the *p*-nitrobenzyloxycarbonyl and *p*-nitrobenzyl group of the carbapenem derivative **29**, was achieved hydrogenetically by 10% palladium on carbon in phosphate buffer (pH 7.0), and the purification of the crude product was performed carefully on CHP 20P (75—150 μ) chromatography (water elution) to give the desired dethiathienamycin **17**. The antibacterial activity of dethiathienamycin (**17**) thus obtained is as follows: M.I.C. (μg/ml), Staphylococcus aureus FDA 209P JC 0.01, *Staphylococcus aureus* 56 (PCase+) 0.01, *Escherichia coli* NIHJ JC-2 0.2, *Escherichia coli* 609 (PCase+) 0.4, *Pseudmonas aeruginosa* 1001 12.5, *Klebsiela pneumoniae* 806 0.4. These activities are about one half of those of thienamycin (**16**).

Experimental

General. All melting points are uncorrected. Specific rotations were measured using a Perkin-Elmer 241 polarimater. IR spectra were recorded on JASCO A102 and A320 Infrared spectrometers. NMR spectra were taken using a Varian EM 360L spectrometer (60 MHz) and the chemical shifts are expressed in ppm units using TMS as internal standard: s, singlet; d, doublet; dd, doublet of doublet; ddd, doublet of doublet of doublet; t, triplet; q, quartet; dq, doublet of quartet; m, multiplet. Mass spectra (MS) were measured on JMS 01SG and JMS D300 mass spectrometers. (Preparative) TLC was carried out on Merck TLC-plates silica gel F_{254} Pre-coated, layer thickness: (2 mm) 0.25 mm and spots were made visible by ultraviolet irradiation.

(3*S*,4*R*)-4-Allyl-3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone (7) Reaction of 6 with Tetraallyltin. General Procedure: To a stirred solution of 1 g (3.484 mmol) of (3*R*,4*R*)-4-acetoxy-3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone (**6**) in 20 ml of anhydrous dichloromethane was added 1.46 g (5.166 mmol) of tetraallyltin and 49.5 mg (0.3484 mmol) of boron trifluoride etherate under a nitrogen atmosphere. The resulting yellow solution was stirred at room temperature (rt) for 15 h. Dichloromethane was added and the mixture was washed three times with water and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. Purification of the oil residue by flash column chromatography (cyclohexane-ethyl acetate, 2:1 v/v) afforded 800 mg (85%) of allylazetidinone (**7**):mp 70—77 °C; ^1H NMR ($CDCl_3$) δ=0.06 (6H, s), 0.87 (9H, s), 1.19 (3H, d, J=6 Hz), 2.2—2.5 (2H, m), 2.74 (1H, ddd, J=1.5, 3, and 5 Hz) 3.5—3.85 (1H, m), 3.95—4.35 (1H, m), 4.8—5.9 (3H, m).

Found: C, 62.47; H, 10.05; N, 5.20%. Calcd for $C_{14}H_{27}NO_2Si$: C, 62.40; H, 10.10; N, 5.20%.

Reaction of 6 with Allyltributyltin: To a solution of 60 mg (0.2091 mmol) of **6** in 6 ml of anhydrous dichloromethane was added 200 mg (0.6050 mmol) of allyltributyltin and 10 mg (0.0704 mmol) of boron trifluoride etherate under a nitrogen atmosphere. The resulting yellow solution was stirred at rt for 16 h. Dichloromethane was added and the mixture was washed three times with water and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. The residue was purified

by TLC (cyclohexane-ethyl acetate, 2:1 v/v) to give 40 mg (71%) of the desired product (**7**).

4-Allyl-2-azetidinone (9): To a solution of 550 mg (4.264 mmol) of 4-acetoxy-2-azetidinone in dichloromethane (10 ml) was added 1.4 g (4.95 mmol) of tetraallyltin and 60 mg (0.42 mmol) of boron trifluoride etherate under a nitrogen atmosphere. The resulting yellow solution was stirred at rt for 15 h. Dichloromethane was added and the mixture was washed with water and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. The residue was purified by TLC (cyclohexane-ethyl acetate, 2:1 v/v) to give 350 mg (74%) of the desired product **9**: mp 76—77 °C; ^{1}H NMR ($CDCl_3$) δ=2.2—2.5 (2H, t like), 2.4—2.75 (1H, m), 2.82—3.21 (1H, m), 3.45—3.8 (1H, m), 4.8—6.05 (3H, m), 6.9 (1H, br s).

(3*S*,4*R*)-3-[(*R*)-1-(*t*-Butyldimethylsilyloxy)ethyl]-4-(1-methyl-2-propenyl)-2-azetidinone (11): To a solution of 100 mg of **6** in 2 ml of dichloromethane was added 248 mg of 2-butenyltributyltin and 5 mg of boron trifluoride etherate. The mixture was stirred for 5 h and dichloromethane was added. The solution was washed with aqueous sodium hydrogencarbonate and water, dried over anhydrous magnesium sulfate, and evaporated. The residue was purified by flash column chromatography (cyclohexane-ethyl acetate, 2:1 v/v) to give 78.9 mg (80%) of the desired product **11**: ^{1}H NMR ($CDCl_3$) δ=0.08 (6H, s), 0.78 (9H, s), 1.05 (3H, d, J=6 Hz), 1.17 (3/2H, d, J=6 Hz), 1.21 (3/2H, d, J=6 Hz), 2.6—2.9 (1H, m), 3.2—3.6 (1H, m), 4.12 (1H, quintet, J=6 Hz), 4.8—5.3 (2H, m), 5.3—6.0 (1H, m), 6.0—6.7 (1H, m).

(3*S*,4*R*)-4-Allyl-3-[(*R*)-1-(*p*-nitrobenzyloxycarbonyloxy)ethyl]-2-azetidinone (15): To a solution of 115 mg (0.327 mmol) of (3*R*,4*S*)- or (3*R*,4*R*)-4-acetoxy-3-[(*R*)-1-(*p*-nitrobenzyloxycarbonyloxy)ethyl]-2-azetidinone (**12**, **13**) in 5 ml of anhydrous dichloromethane was added 115 mg (0.407 mmol) of tetraallyltin and 4.64 mg (0.0327 mmol) of boron trifluoride etherate under a nitrogen atmosphere. The resulting yellow solution was stirred at rt for 5 h. Dichloromethane was added and the mixture was washed 3 times with water, and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. The residue was purified by TLC (cyclohexane-ethyl acetate, 2:1 v/v) to give 101 mg (92.6%) of the desired product **15**: IR (neat): 3300 and 1740 cm^{-1} (lactam carbonyl); ^{1}H NMR ($CDCl_3$) δ=1.42 (3H, d, J=6.5 Hz), 2.36 (2H, t, J=6.5 Hz), 3.00 (1H, dd, J=2.5 and 7.5 Hz), 4.9—6.1 (4H, m), 5.20 (2H, s), 6.25 (1H, br s), 7.4—8.3 (4H, A_2B_2 type).

The same procedure with (3*R*,4*S*)-4-benzoyloxy-3-[(*R*)-(*p*-nitrobenzyloxycarbonyloxy)ethyl]-2-azetidinone (**14**) gave **15** in 93% yield.

(3*S*,4*R*)-4-(2,3-Epoxypropyl)-3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone (19): To a solution of 800 mg (2.97 mmol) of 4-allylazetidinone **7** in 20 ml of anhydrous dichloromethane was added 780 mg (4.52 mmol) of *m*-chloroperbenzoic acid in an ice bath. The mixture was stirred at rt for 15 h. The reaction mixture was washed with 5% aqueous sodium hydrogenecarbonate and water successively, and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure to give 650 mg of the desired product **19**. One of the diastereomers was recrystallized from petroleum ether: mp 83.5 °C;R_f= 0.45 (cyclohexane-ethyl acetate 1:2 v/v); IR (nujol) 3140, 3080, 1760, 1712 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.08 (6H, s), 0.89 (9H, s), 1.19 (3H, d, J=6 Hz), 1.5—2.1 (2H, m), 2.3—3.1 (5H, m), 3.6—4.4 (2H, m).

Found: C, 59.02; H, 9.45; N, 4.89%. Calcd for $C_{14}H_{27}NO_3Si$: C, 58.91; H, 9.53; N, 4.90%.

(3*S*,4*R*)-4-(3-Cyano-2-hydroxypropyl)-3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone (20): To a solution of 500 mg (1.75 mmol) of **19** in 3 ml of DMF and 1 ml of water was added 250 mg (3.85 mmol) of potassium cyanide. The mixture was stirred at rt for 15 h. Ethyl acetate was added and the reaction mixture was washed with water and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. Purification of an oily residue by flash column chromatography (cyclohexane-ethyl acetate, 1:2 v/v) afforded 420 mg (77%) of the desired product **20**. One of the diastereomers crystallized from petroleum ether and ethyl acetate: mp 120—125 °C; IR (nujol) 3330, 2240(CN), 1700 cm^{-1} (lactam C=O); ^{1}H NMR ($CDCl_3$) δ=0.08 (6H, s), 0.89 (9H, s), 1.21 (3H, d, J=6 Hz), 1.7—2.1 (2H, m), 2.45—3.0 (3H, m), 3.5—4.4 (3H, m), 6.6 (1H, br s).

Found: C, 57.87; H, 9.05; N, 8.92%. Calcd for $C_{15}H_{28}N_2O_3Si$: C, 57.66; H, 9.03; N, 8.96%.

(3*S*,4*R*)-3-[(*R*)-1-(*t*-Butyldimethylsilyloxy)ethyl]-4-[(*p*-nitrobenzyloxycarbonylamino)-2-hydroxybutyl]-2-azetidinone (21): A mixture of 821 mg (2.63 mmol) of **20** and 42 mg of platinum oxide in 8 ml of glacial acetic acid was stirred under a hydrogen atmosphere at 1 atm for 5 h. The mixture was filtered through Celite and evaporated to give the desired amino derivative.

To a solution of the amino derivative thus obtained in 5 ml of dichloromethane was added 850.7 mg (3.95 mmol) of *p*-nitrobenzyl chloroformate and 1.02 g (7.91 mmol) of *N*,*N*-diisopropylethylamine. The mixture was stirred at rt overnight. Ethyl acetate (50 ml) was added and the mixture was washed with water two times and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. Purification of a residue by flash column chromatography (cyclohexane-ethyl acetate, 1:10 v/v) afforded 612.7 mg (47%) of the desired product **21** as a 3:5 mixture of diastereomers. Diastereomer I: R_f=0.55 (ethyl acetate); ^{1}H NMR ($CDCl_3$) δ=0.12 (6H,s), 0.89 (9H, s), 1.25 (3H, d, J=6 Hz), 1.4—2.0 (4H, m), 2.7—3.1 (1H, m), 2.0—4.4 (6H, m), 5.13 (2H, s), 5.63 (1H, t, J=6 Hz), 6.69 (1H, s), 7.3—8.3 (4H, m). Diastereomer II: R_f=0.50 (ethyl acetate); ^{1}H NMR ($CDCl_3$) δ=0.08 (6H, s), 0.88 (9H, s), 1.22 (3H, d, J=6 Hz), 1.4—2.1 (4H, m), 2.6—3.0 (1H, m), 3.0—4.1 (5H, m), 3.9—4.3 (1H, m), 5.16 (2H, s), 5.66 (1H, t, J=6 Hz), 6.65 (1H, s), 7.3—8.2 (4H, m).

(3*S*,4*R*)-3-[(*R*)-1-(*t*-Butyldimethylsilyloxy)ethyl]-4-[4-(*p*-nitrobenzyloxycarbonylamino)-2-oxobutyl]-2-azetidinone (22): To a solution of 368.6 mg (0.754 mmol) of **21** in 25 ml of dichloromethane was added 1.12 g (5.20 mmol) of pyridinium chlorochromate. The mixture was stirred at rt for 3 h and filtered through Celite. Dichloromethane was added to the filtrate and the solution was washed with water two times and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. The residue was purified by TLC (cyclohexane-ethyl acetate, 1:2 v/v) to give 242.9 mg (66%) of the desired product **22**: R_f=0.6

(cyclohexane-ethyl acetate, 1:2 v/v); ^{1}H NMR ($CDCl_3$) δ= 0.07 (6H, s), 0.86 (9H, s), 1.19 (3H, d, J=5.4 Hz), 2.4—3.0 (4H, m), 3.42 (2H, q like, J=6 Hz), 3.7—4.1 (1H, m), 3.9—4.4 (1H, m), 5.13 (2H, s), 5.70 (1H, br t, J=6 Hz), 6.52 (1H, br s), 7.3—8.2 (4H, m).

***p*-Nitrobenzyl 2-[(3*S*,4*R*)-3-[(*R*)-1-(*t*-Butyldimethylsilyloxy)-ethyl]-4-[4-(*p*-nitrobenzyloxycarbonylamino)-2-oxobutyl]-2-oxo-1-azetidinyl]-2-hydroxyacetate (23):** A mixture of 242.9 mg (0.4297 mmol) of **22** and 250 mg (1.10 mmol) of *p*-nitrobenzyl glyoxylate monohydrate in 100 ml of benzene was refluxed overnight. Triethylamine was added to this solution and the mixture was refluxed for 6 h. The solvent was removed under reduced pressure. A residue was purified by TLC (hexane-ethyl acetate-acetone, 8:6:3 v/v) to give 258.1 mg (86%) of the desired product **23** as a mixture of two diastereomers: R_f=0.55, 0.50 (hexane-ethyl acetate-acetone, 8:6:3 v/v); ^{1}H NMR ($CDCl_3$) δ=0.02 (3H, s), 0.05 (3H, s), 0.84 (9H, s), 1.22 (3H, d, J=6.4 Hz), 1.7—2.1 (1H, m), 2.4—3.2 (4H, m), 3.2—4.5 (5H, m), 5.0—6.0 (6H, m), 7.2—7.8 (4H, m), 7.9—8.5 (4H, m).

***p*-Nitrobenzyl 2-[(3*S*,4*R*)-3-[(*R*)-1-(*t*-Butyldimethylsilyloxy)-ethyl]-4-[4-(*p*-nitrobenzyloxycarbonylamino)-2-oxobutyl]-2-oxo-1-azetidinyl]-2-triphenylphosphoranylideneacetate (24):** To a solution of 258.1 mg (0.3677 mmol) of **23** in 22 ml of THF was added 0.064 ml of 2,6-lutidine. The mixture was cooled to −30 °C and 0.04 ml of thionyl chloride was added. The reaction mixture was stirred for 1 h and the precipitate formed was filtered through Celite. The solvent was removed under reduced pressure to give a crude chloro derivative.

The chloro derivative was dissolved in 14 ml of dioxane and 192 mg (0.733 mmol) of triphenylphosphine and 0.09 ml of 2,6-lutidine was added to this solution. The mixture was stirred at rt overnight. Ethyl acetate was added and the solution was washed with water two times and dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure. A residue was purified by TLC (hexane-ethyl acetate-acetone, 10:6:3 v/v) to give 93.5 mg (27%) of the desired product **24** and 24.7 mg (8%) of the desilylated phosphorane.

***p*-Nitrobenzyl (5*R*,6*S*)-6-[(*R*)-1-(*t*-Butyldimethylsilyloxy)-ethyl]-3-[2-(*p*-nitrobenzyloxycarbonylamino)ethyl]-7-oxo-aza-bicyclo[3.2.0]hept-2-ene-2-carboxylate (25):** To a solution of 165.8 mg (0.175 mmol) of **24** in 80 ml of dry benzene was added catalytic amount of hydroquinone. The mixture was refluxed for 5 h. The solvent was removed under reduced pressure and a residue was purified by medium pressure liquid chromatography on silica gel (cyclohexane-ethyl acetate, 2:3 v/v) to give 85 mg (73%) of the desired product **25**: R_f=0.4 (cyclohexane-ethyl acetate, 2:3 v/v); ^{1}H NMR ($CDCl_3$) δ=0.09 (6H, s), 0.86 (9H, s), 1.23 (3H, d, J=6.6 Hz), 2.4—3.7 (7H, m), 3.8—4.5 (2H, m), 4.8—5.4 (1H, m), 5.08 (2H, s), 5.1—5.4 (2H, m), 7.2—7.8 (4H, m), 7.8—8.4 (4H, m); IR(neat) 3380, 1765 (lactam C=O), 1715(NHC=O) cm^{-1}.

A Revised Primary Structure of Neocarzinostatin Using the Combination of Endopeptidase, Carboxypeptidase Y and Fast Atom Bombardment Mass Spectrometry

Kazuo HIRAYAMA,* Toshihiko ANDO, Rei TAKAHASHI, and Asao MURAI
Central Research Laboratories, Ajinomoto Co., Inc., Kawasaki, Kanagawa 210
(Received July 26, 1985)

The amino acid sequence of antitumor protein neocarzinostatin was revised and confirmed on the basis of mass spectrometric studies. Fast atom bombardment mass spectrometric experiments on neocarzinostatin and its tryptic, chymotryptic, staphylococcal protease, and carboxypeptidase Y digested peptides gave the molecular weights of various peptides and, in some cases, partial sequence information. These experiments gave a revised sequence, Glu(105)-Pro(106) to Pro(105)-Glu(106) and Asp(60) to Asn(60). The peptide fragments produced by these endopeptidase cleavage completely covered the full sequence of neocarzinostatin. Thirty-five of the 113 amino acids were determined by the carboxypeptidase Y digestion.

Mass spectrometric techniques have been used a number of times in the determination of the primary structure of peptides and proteins. Fragmentation of the electron impact method has been used for a long time in this area. Over the last year, new ionization techniques, field desorption (FD) mass spectrometry and fast atom bombardment (FAB) mass spectrometry, have been developed. These are paticularly suitable for underivatized peptides producing rather abundant molecular ions (M^+) or protonated molecular ions (MH^+). It is difficult to determine the primary structure of peptides by mass spectrometry alone. Shimonishi et al. established the combination of FD or FAB mass spectrometry with Edman degradation or exopeptidase digestion.[1-10] These techniques are suitable for peptide mixtures and may prove to be a valuable approach technique for the sequence determination of peptides and proteins.

Neocarzinostatin is an antitumor antibiotic protein[11-15] isolated from culture filtrates of *Streptomyces carzinostaticus*.[11] It is a single-chain polypeptide constituted of 113 amino acids and exists as an apoprotein and an associated nonprotein chromophore. The amino acid sequence of neocarzinostatin was first reported in 1972 by Maeda et al. using the Edman degradation method.[16,17] The structure of neocarzinostatin was corrected in 1982 by Biemann by a combination of tryptic and chymotryptic digestion, FABMS and GCMS (Fig. 1).[18] Recently, we found that there were a number of peptides from staphylococcal protease digests with m/z that conformed to the published sequence (Fig. 1), indicating the correctness of these regions, and two (m/z 706.9 and 2753.3) that did not. This clearly shows that the sequence is in error. Therefore, we reinvestigated the previously proposed primary structure of neocarzinostatin by a combination of endopeptidase, carboxypeptidase Y and FABMS without the Edman degradation method. Consequently, we found that Glu(105)-Pro(106) must be corrected to Pro(105)-Glu(106) and Asp(60) must be replaced with Asn(60) in Fig. 1. Recently, Biemann and coworkers published the revised primary structure of neocarzinostatin, in which Glu(105)-Pro(106) was corrected to Pro(105)-Glu(106) by our indication and by their GCMS data.[19] In addition, the structure of the chromophore was determined in 1985.[20]

We report in this paper the revised primary structure of neocarzinostatin and the reason for the exchange of Glu(105)-Pro(106) for Pro(105)-Glu(106)

and the replacement Asp(60) with Asn(60) by the combination of the enzymatic cleavage (trypsin, chymotrypsin, staphylococcal protease), carboxypeptidase Y digestion and FABMS.

Experimental

Mass Spectrometry. Positive ion FAB mass spectra were recorded with a JMS HX-100 double focusing mass spectrometer fitted with a 23 kilogauss high field magnet, operating at accelerating voltages at 5 kV. The atom emission gun current of 20 mA was maintained at 6 kV for the generation of the xenon fast atom beam. Mass spectra were recorded with a JMA-3500 mass data system. A sample of the underivatized peptides was prepared by dissolving c. 5 μg samples in c. 1.5 μl of 1:1 glycerol–1 M† HCl. This solution was deposited on a stainless steel sample stage for introduction into the mass spectrometer ion source on the end of an axially mounted sample introduction probe.

Reagents and Enzymes. Dithiothreitol and iodoacetic acid were obtained from Wako Pure Chemical Industries Ltd., (Japan). Staphylococcal protease was purchased from Miles Laboratories Inc., (U.S.A.). Trypsin and chymotrypsin were from Sigma Chemical Co., (U.S.A.) and carboxypeptidase Y from Oriental Yeast Co., Ltd. (Japan).

Reduced and Carboxymethylated Neocarzinostatin. Commercially available neocarzinostatin (Yamanouchi Seiyaku Co., Inc.) was dialyzed against water and lyophilized. The crude neocarzinostatin was washed with methanol several times, dialyzed against water and lyophilized. Five μmol of neocarzinostatin was dissolved in 6 ml of Tris/HCl buffer (pH 8.0) containing 8 M urea and 0.2% EDTA. After addition of 300 μmol of dithiothreitol, the mixture was gassed with nitrogen for 10 min before heating for 3 h at 50 °C and was allowed to stand overnight in the dark at room temperature. To this mixture 100 mg of iodoacetic acid in 0.6 ml of 1 M NaOH were added. Alkylation was conducted at pH 8.0 or 8.5 by addition of 1 M NaOH. After 30 min the mixture was dialyzed against 0.2 M acetic acid and lyophilized.

Enzymatic Digestion (a) Trypsin: Under the standard conditions of 50:1 molar ratio of substrate to trypsin in 50 μl of 0.2 M ammonium acetate buffer (pH 8.0), 0.5 mg of the reduced and carboxymethylated neocarzinostatin was digested. The solution was incubated at 25 °C for 6 h. The hydrolysis was stopped by freezing and lyophilizing the solution.

(b) Chymotrypsin: The reduced and carboxymethylated neocarzinostatin (0.5 mg) or its endopeptidase digested peptides (0.5 mg) were treated under the conditions of 200:1 molar ratio of substrate to chymotrypsin in 50 μl of 0.2 M ammonium acetate buffer (pH 8.0). The solution was incubated at 25 °C for 30 min. The hydrolysis was stopped by freezing and lyophilising the solution.

(c) Staphylococcal Protease: The reduced and carboxymethylated neocarzinostatin (0.5 mg) was digested under the conditions of a 50:1 molar ratio of substrate to staphylococcal protease in 50 μl of 5 mM ammonium carbonate buffer (pH 8.8). The solution was incubated at 37 °C for 24 h. The hydrolysis was stopped by freezing and lyophilising the solution.

(d) Carboxypeptidase Y: After digestion by endopeptidase, the subpeptides were lyophilised and added to 100 μl of 0.05% pyridine–acetate buffer (pH 6.0) containing 20 μg of carboxypeptidase Y. The enzyme digestion was carried out at 37 °C, and aliquots were removed from the reaction mixture at different time intervals (1 min, 10 min, 1 h, 2 h) and isolated by freeze-drying.

Results and Discussion

(a) Chymotryptic Peptide: The positive ion FAB mass spectrum of the chymotryptic digest of the reduced and carboxymethylated neocarzinostatin indicated the presence of at least seven peptides shown in Fig. 2. Each peptide appears as the corresponding protonated molecular ions, MH^+. Five of the seven chymotryptic peptides (C1, C2, C5, C6, and C7) fit the published sequence on the basis of chymotrypsin specificity. The peptides C3 and C4 did not fit any fragment expected from the enzyme specificity (Table 1). If either Asp(57) or Asp(60) is replaced by Asn, C3 and C4 are matched to the position Ala(46)–Leu(67) and Ser(53)–Leu(67) in Fig. 1, respectively, on the basis of their m/z and chymotrypsin specificity.

(b) Tryptic Peptide: Only two of the four expected peptides could be found in the positive ion FAB mass spectrum of the tryptic peptides of the reduced and carboxymethylated neocarzinostatin; those with m/z=1859.0 (T1) and 1275.5 (T2) (data not shown). The other two peptides could not be found because they were too large to be observed by the spectrometer. The two tryptic peptides were matched with the sequence shown in Fig. 1 on the basis of

† 1 M=1 mol dm^{-3}.

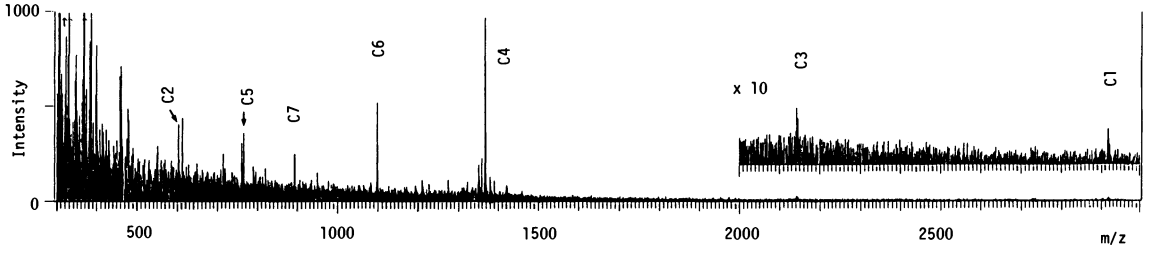

Fig. 2. The positive ion FAB mass spectrum of the chymotryptic digest of the reduced and carboxymethylated neocarzinostatin.

Table 1. Peptides Generated by Enzymatic Cleavage of the Reduced and Carboxymethylated Neocarzinostatin

Peptide	Observed mass value	Theoretical[a] mass value	Matching section (based on enzyme specificity) of:

a) Calculated from the revised sequence.

their trypsin specificity (Table 1).

In order to determine the amino acid sequence of the tryptic peptides, they were subjected to chymotryptic cleavage and carboxypeptidase Y digestion. Figure 3 shows the positive ion FAB mass spectra of the chymotryptic peptides and of the digest with carboxypeptidase Y. The chymotryptic subpeptides TC1, TC2, TC3, TC5, TC6, and TC7 fit the sequence on the basis of their trypsin and chymotrypsin specificity. The peptide TC4 did not conform to enzyme specificity. After treatment with carboxypeptidase Y, subpeptide TC1(m/z 1858.6) gave mass peaks at m/z 1631.7, m/z 1532.8, and m/z 1431.5, on the FAB mass spectra. The results indicated that the C-terminal sequence of TC1 was -Thr-Val-[Val, Lys] (see Table 2). Similarly, the mass peaks at m/z 915.5, m/z 844.2, m/z 743.2, m/z 686.2, and m/z 615.0 from the subpeptide TC2 (m/z 1078.1) indicated that the C-terminal sequence of TC2 was -Ala-Gly-Thr-Ala-Tyr. In the same way, the mass peaks at m/z 490.2 from the subpeptide TC3 (m/z 603.7) showed that the C-terminus of TC3 was -Leu (or Ile). In the same manner, the mass peaks at m/z 1254.3, m/z 1167.5, m/z 1066.3, m/z 979.3, m/z 908.3, m/z 821.1, m/z 650.1, and m/z 579.6 from the subpeptide TC4 (m/z 1367.2) indicated that the C-terminal sequence of TC4 was -Ala-[Asn, Gly]-Ser-Ala-Ser-Thr-Ser-Leu(or Ile). If 60th amino acid residue is Asp, these mass peaks must be m/z 1255, m/z 1168, m/z 1067, m/z 980, m/z 909, m/z 822, m/z 650, and m/z 579. Accordingly it was necessary to replace Asp(60) with Asn in Fig. 1. Furthermore, the mass peaks at m/z 2666.9, m/z 2496.0, m/z 2439.1, and m/z 2309.8 from the subpeptide TC7(m/z 3126.9) indicated that the C-terminal sequence of TC7 was -Glu-Gly-[Val, Ala]-[Ile(or Leu), Ser, Phe, Asn]. These results show that the 106th amino acid residue of the sequence must be Glu.

(c) Staphylococcal Protease Digested Peptides: Two FABMS experiments were carried out on the staphylococcal protease digested peptides. First, the staphylococcal protease digested peptides were hydro-

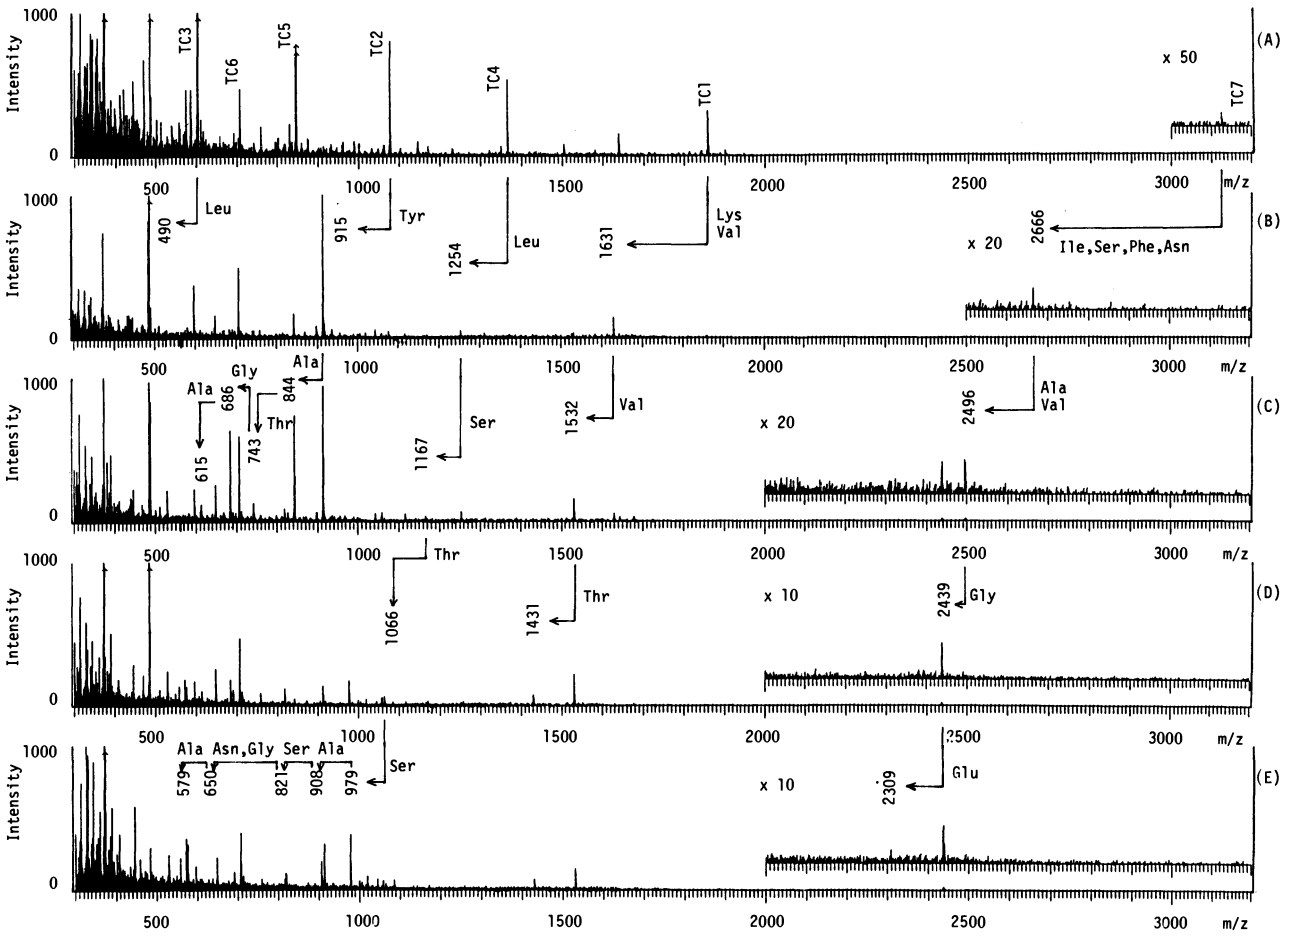

Fig. 3. The positive ion FAB mass spectra of the chymotryptic digest of the tryptic subpeptides (A) and of the digest with carboxypeptidase Y (B: 1 min, C: 10 min, D: 1 h, E: 2 h).

Table 2. Peptides Generated by Chymotryptic Cleavage of the Tryptic Peptides and of the Digest with Carboxypeptidase Y

Peptide	Observed mass value	Theoretical mass value	Matching section		C-terminal sequence
			Fig. 1.	Fig. 7.	
TC1	1858.6	1858.97	1—20	1—20	-Thr-Val-[Val, Lys]
TC2	1078.1	1078.55	21—32	21—32	-Ala-Gly-Thr-Ala-Tyr
TC3	603.7	603.33	40—45	40—45	-Leu(or Ile)
TC4	1367.2	1367.62	None	53—67	-Ala-[Asn,Gly]-Ser-Ala-Ser-Thr-Ser -Leu(or Ile)
TC5	846.9	846.40	72—78	72—78	
TC6	708.8	708.36	77—82	77—82	
TC7	3126.9	3127.35	None	83—113	-Glu-Gly-[Val, Ala]-[Ile(or Leu), Ser, Phe, Asn]

lyzed with trypsin or chymotrypsin, and the total hydrolysate was subjected to FABMS to give the molecular weights of the resulting peptides. Second, to determine the C-terminal sequence of staphylococcal protease digested peptides, they were subjected to carboxypeptidase Y digestion. The positive ion FAB mass spectrum of the tryptic peptides is shown in Fig. 4. Six tryptic peptides ST1, ST2, ST3, ST4, ST5, and ST7 fit the sequence shown in Fig. 1 on the basis of staphylococcal protease and trypsin specificity (Table 1). But the peptides ST6, ST8, and ST9 could not be matched with the published sequence on the basis of enzyme specificity.

If Asp(60) is replaced by Asn, ST6 fits the position Ala(59)-Arg(70) in Fig. 1 on the basis of its *m/z* and enzyme specificity. If Glu(105)-Pro(106) is Pro(105)-

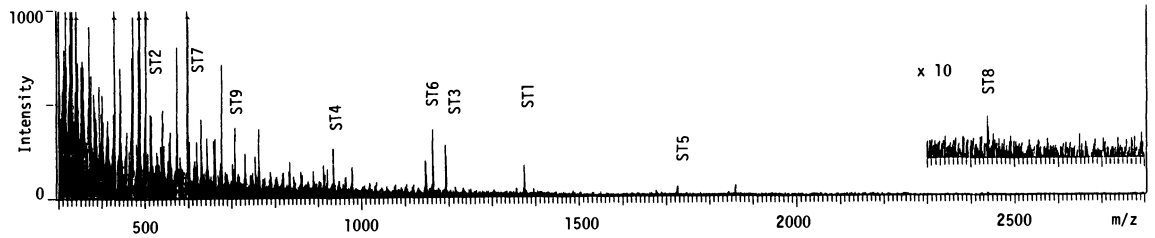

Fig. 4. The positive ion FAB mass spectrum of the tryptic digest of the staphyococcal protease digested subpeptides.

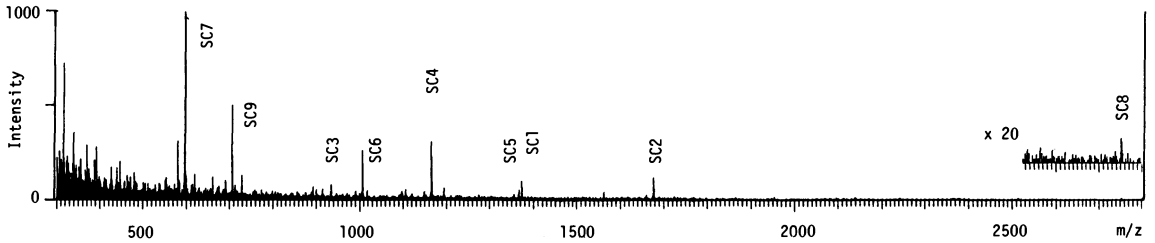

Fig. 5. The positive ion FAB mass spectrum of the chymotryptic digest of the staphylococcal protease digested subpeptides.

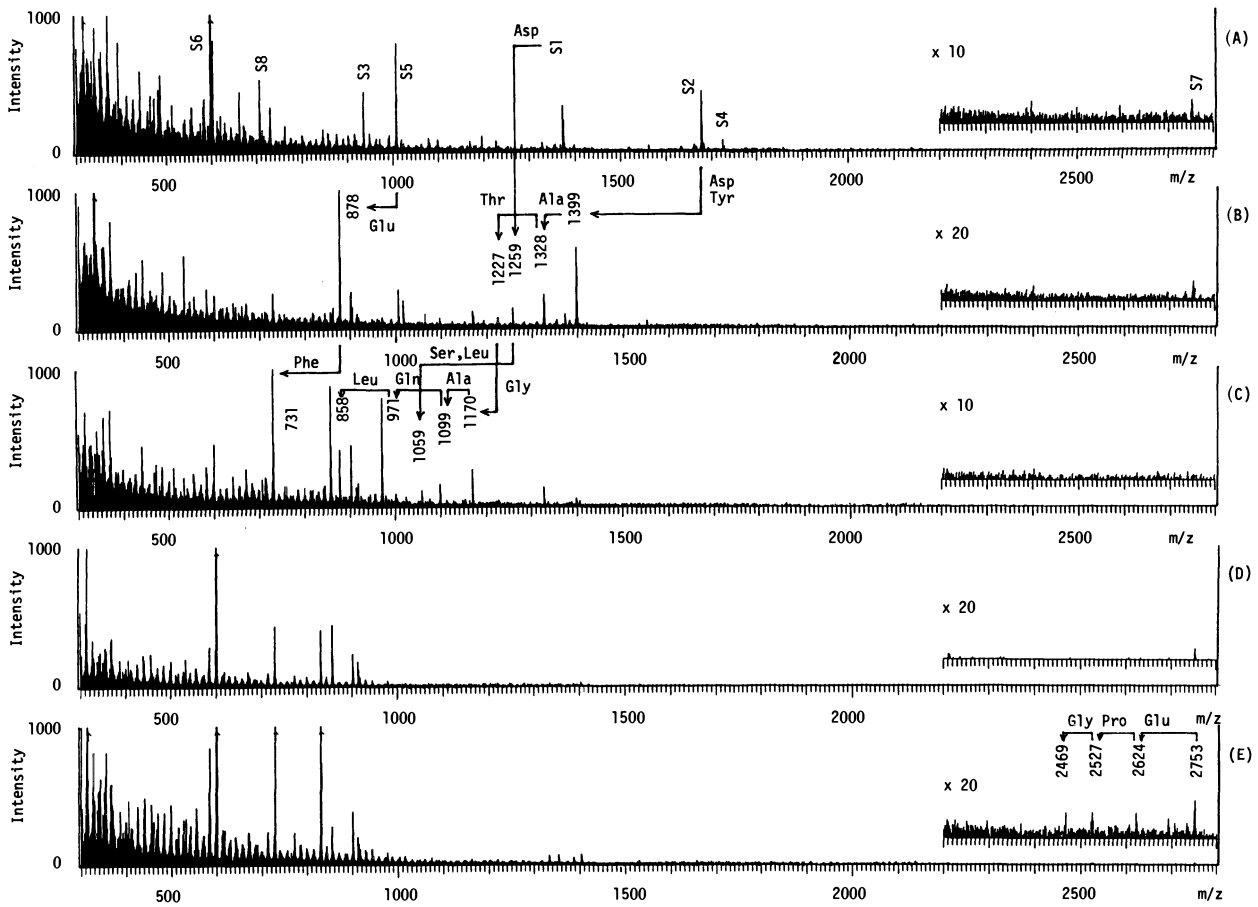

Fig. 6. The positive ion FAB mass spectra of the staphylococcal protease digested peptides of the reduced and carboxymethylated neocarzinostatin (A) and of the digest with carboxypeptidase Y (B: 1 min, C: 10 min, D: 1 h, E: 2 h).

Glu(106), ST8 and ST9 are matched to the position Trp(83)–Glu(106) and Gly(107)–Asn(113), respectively.

The positive ion FAB mass spectrum of the chymotryptic digest is shown in Fig. 5. Six chymotryptic peptides SC1, SC2, SC3, SC4, SC6, and SC7 fit the published sequence on the basis of staphylococcal protease and chymotrypsin specificity (see Table 1). The peptides SC5, SC8, and SC9 did not correspond to any fragment expected from the enzyme specificity.

If either Asp(57) or Asp(60) is replaced by Asn, SC5 corresponds to the position Ser(53)–Leu(67) in Fig. 1 on the basis of their *m/z* and enzyme specificity. If Glu(105)–Pro(106) is Pro(105)–Glu(106), SC8 and SC9 are matched to the position Gly(80)–Glu(106) and Gly(107)–Asn(113), respectively.

Figure 6 shows the positive ion FAB mass spectra of the staphylococcal protease digested peptides of the reduced and carboxymethylated neocarzinostatin and of their digest with carboxypeptidase Y. Six subpeptides S1, S2, S3, S4, S5, and S6 fit the published sequence on the basis of staphylococcal protease specificity. But the peptides S7 and S8 did not correspond to any fragment expected from the enzyme specificity (Table 3).

After treatment with carboxypeptidase Y, peptide S1 (*m/z* 1374.0) gave the mass peaks at *m/z* 1259.6

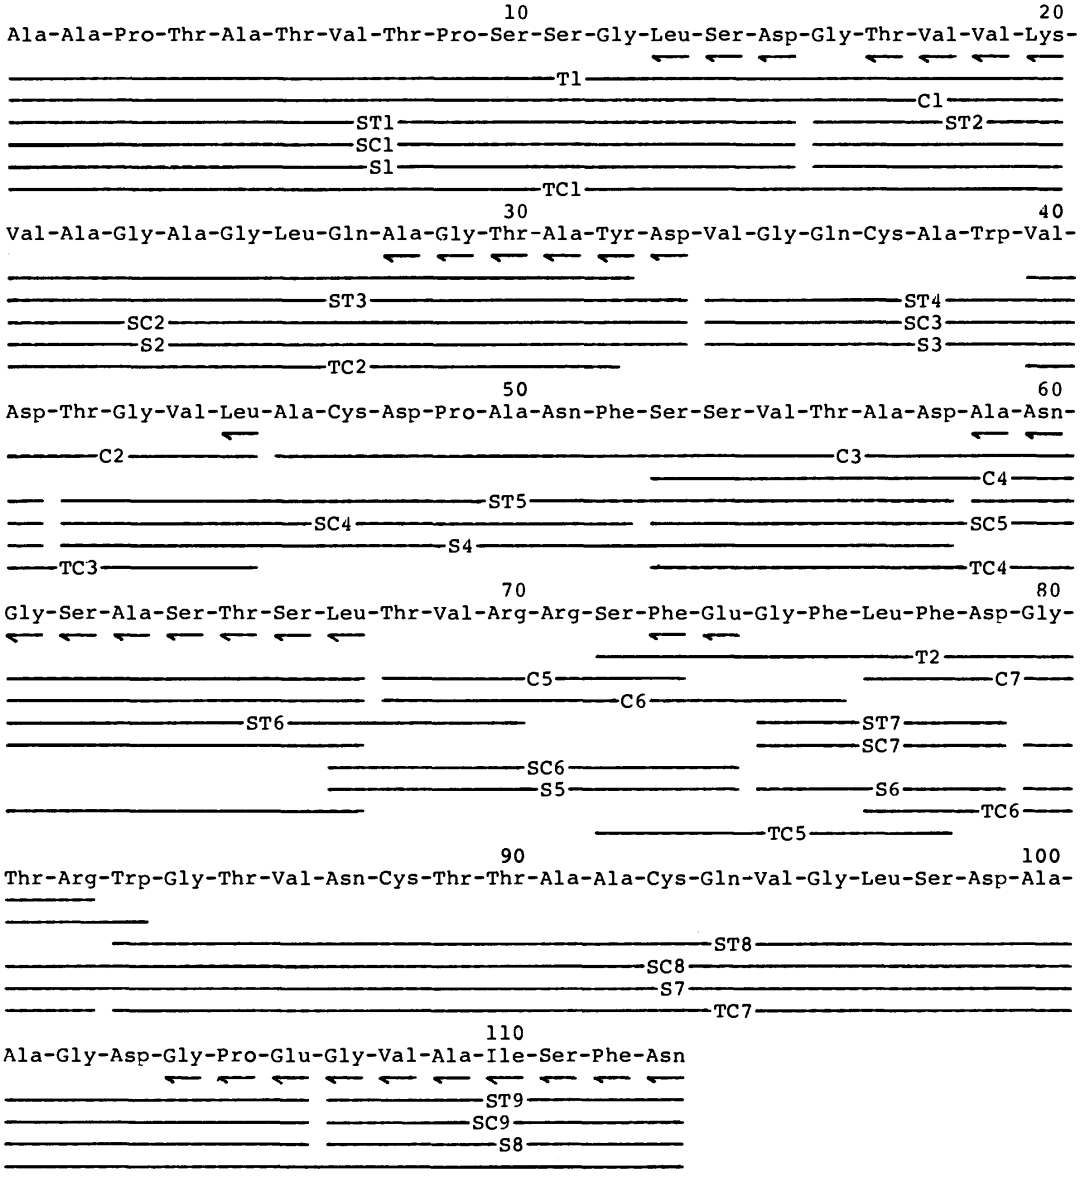

Fig. 7. The correct primary structure of neocarzinostatin and the sequence data with the results of endopeptidase and carboxypeptidase Y. ←—, Carboxypeptidase Y data; FABMS peptides produced by cleavage with trypsin (T), chymotrypsin (C), staphylococcal protease (S), staphylococcal protease and trypsin (ST), staphylococcal protease and chymotrypsin (SC), and trypsin and chymotrypsin (TC) are underlined.

Table 3. Peptides Generated by Staphylococcal Protease Cleavage of the Reduced and Carboxymethylated Neocarzinostatin and of the Digest with Carboxypeptidase Y

Peptide	Observed mass value	Theoretical mass value	Matching section		C-terminal sequence
			Fig. 1.	Fig. 7.	
S1	1374.0	1374.67	1—15	1—15	-[Leu(or Ile), Ser]-Asp
S2	1677.4	1677.87	16—33	16—33	-Leu-Gln(or Lys)-Ala-Gly-Thr-Ala-Tyr-Asp
S3	935.0	935.39	34—41	34—41	
S4	1725.3	1725.76	42—58	42—58	
S5	1007.1	1007.56	67—74	67—74	-Phe-Glu
S6	598.7	598.28	75—79	75—79	
S7	2753.3	2753.17	None	80—106	-Gly-Pro-Glu
S8	706.9	707.36	None	107—113	

and *m/z* 1059.5 on the FAB mass spectra. The results indicated that the C-terminal sequence of S1 was [Leu(or Ile), Ser] -Asp (see Table 3). Similarly, the mass peaks at *m/z* 1399.8, *m/z* 1328.8, *m/z* 1227.7, *m/z* 1170.6, *m/z* 1099.6, *m/z* 971.5 and *m/z* 858.3 from the peptide S2 (*m/z* 1677.4) indicated that the C-terminal sequence of S2 was -Leu-Gln(or Lys)-Ala-Gly-Thr-Ala-Tyr-Asp. In the same manner, the mass peaks at *m/z* 878.7 and *m/z* 731.2 from the peptide S5(*m/z* 1007.1) indicated that the C-terminal sequence of S5 was -Phe-Glu. Similarly, the mass peaks at *m/z* 2624.4, *m/z* 2527.1 and *m/z* 2469.8 from the peptide S7(*m/z* 2753.3) showed that the C-terminal sequence of S7 was -Gly-Pro-Glu. These results show that the position of Glu(105) and Pro(106) must be interchanged with each other.

The correct primary structure of neocarzinostatin and the sequence data are summarized in Fig. 7 with the results of carboxypeptidase Y digestion. This primary structure is the same as shown in Fig. 1 except Glu(105)-Pro(106) and Asp(60). Asp(60) would be caused by a variety of neocarzinostatin or by a mutation of *Streptomyces carzinostaticus* or by chemical change when it is isolated. Consequently, the subpeptides C3, C4, ST6, ST8, ST9, SC5, SC8, SC9, TC4, TC7, S7, and S8 correspond to the position 46—67, 53—67, 59—70, 83—106, 107—113, 53—67, 80—106, 107—113, 53—67, 83—113, 80—106, and 107—113 in Fig. 7. As shown in Fig. 7, the peptide fragments produced by the three kinds of enzymatic digestion completely covered the full sequence of neocarzinostatin. This implied the usefulness of the combination of enzymatic digestion and FAB mass spectrometry for the primary sequence studies of proteins.

We would like to thank Professors K. Biemann (Department of Chemistry, Massachusetts Institute of Technology), H. Matsuda and T. Matsuo (Institute of Physics, College of General Education, Osaka University) for much helpful discussion throughout this work and Mr. T. Higuchi of Jeol Ltd. for operating the FABMS system.

Nature of Substituent Effect of Nitro and Methoxyl Group on Photocycloaddition of Polymethylene Dicinnamates

Masayuki KUZUYA,* Naohisa YOKOTA, Akihiro NOGUCHI, and Takachiyo OKUDA
Gifu Pharmaceutical University, 6-1, Mitahora-higashi 5-Chome, Gifu 502
(Received October 8, 1985)

The nature of the nitro substituent effect and topotactic assistance by the polymethylene chain of polymethylene dicinnamates upon the rate of photocyclization and the stereochemistry of photoproducts have been explored, in comparison with the similar effect of a methoxyl substituent; a striking rate enhancement and stereospecificity of the photoproduct were observed on a trimethylene dicinnamate derivative. However, the detailed study of the stereochemical course of the photoproduct has revealed that the dependence of the topotactic assistance of nitro derivatives on the polymethylene chain length largely differs from that of methoxy derivatives. Based on the results of the CNDO/S-CI excited state calculation of the model compounds, it is concluded that the acceleration character of the nitro substituent is mainly due to the odd electron density at the reaction site, i.e. the olefinic double bond; it is not due to the facile exciplex formation on the excited singlet state, unlike that of a methoxyl substituent.

In a previous paper of this series,[1] we have reported the excited state multiplicity responsible for an intramolecular photocycloaddition of polymethylene dicinnamates bearing methoxyl substituent at the benzene ring as studied by quenching experiments. We have shown a striking parallelism between the acceleration character of a 3-methoxyl substituent and the involvement of the excited singlet state in the reaction.

It is also known that a 4-nitro substituent in the benzene ring of cinnamate derivatives accelerates the photocycloaddition, and the participation of the excited singlet state is nearly the same as that of an unsubstituted cinnamate.[2] This indicates that the nature of the substituent effect on the rate of the photocycloaddition should differ from that of a methoxyl substituent.

Accordingly, it is of interest to study how a strong electron-withdrawing nitro substituent exerts an influence upon the photocycloaddition of polymethylene dicinnamates in comparison with that of a methoxyl derivatives.

In the present paper, we report an accelerating action of a nitro substituent and a polymethylene chain effect based upon the electronic structure and the stereochemistry of the photoproducts.

Experimental

Melting points were determined on a Shibata melting point apparatus and are uncorrected. IR spectra on KBr disks were recorded on a JASCO A-102 spectrometer, ^{1}H NMR spectra in $CDCl_3$ with TMS as internal standard on a Hitachi R-20 (60 MHz) spectrometer, UV spectra in acetonitrile on a Hitachi 323 spectrophotometer, and MS on a JEOL JMS-D300 spectrometer at 70 eV. Elemental analyses were carried out by the Microanalytical Laboratory, Gifu Parmaceutical University.

Materials. Polymethylene bis(nitrocinnamate)s **4b—j** and **5b—j** were prepared in 60—80% yields from α,ω-dibromoalkanes (n=2—6 and 10) and sodium nitrocinnamates according to the reported procedure.[3] The physical and spectral data are shown in Table 1.

UV-Irradiation. Each of the acetonitrile solutions of the di-trans-cinnamate derivatives (1.7×10^{-5} mol dm^{-3}) was irradiated with a grating monochromator (JASCO Model CRM-FM) with 2 kW Xenon lamp and 3 nm bandwidth. The resulting solution was subjected to UV spectral measurement at appropriate intervals.

The quantum efficiencies were determined in a similar manner to that previously reported[4] by the relative efficiencies approximated with the following formula on the basis of ethylene dicinnamates (**1b**).

$$\Phi_{rel} = (p\times\varepsilon)^{-1}$$

Here p is the irradiated photon number for the one-half decrease in concentration of total dicinnamate, which is calculated by an integrator of the grating monochromator used in the UV-irradiation and ε is the molar absorptivity at the irradiating wavelength.

Stereochemical Analysis of Photoproducts. A nitrogen saturated acetonitrile solution containing ca. 2×10^{-5} mol of each dicinnamate derivative was irradiated on a 400 W high pressure mercury lamp (RIKO Model RH 400-10 W) through a Pyrex filter for 10—100 h until the reaction proceeded to 90%. After the solvent was removed, the ^{1}H NMR spectrum of the residue was measured and the stereochemistry of the products was determined as follows: It is known that in the ^{1}H NMR spectrum the protons of *cis*-1,2-benzene rings on cyclobutane ring are shifted upfield owing to mutual shielding.[5] In fact, the aromatic proton signals of β-truxinate produced by the photolysis of **1c** appeared up field by ca. δ 0.36 above that of **1c**. The photolysate of **1d** showed two aromatic signals shifted upfield by δ 0.36 and 0.13 compared with that of **1d** so that the latter can be attributed to δ-truxinate. Based on these facts, the structures of the photoproducts were assigned; several selected ^{1}H NMR spectral features of the aromatic region of trimethylene series are listed in Table 2. Furthermore, in the MS no intermolecular photo-adduct was detected.

Table 2. Aromatic Proton Signals of Photoproduct

Photo-product No.	β-Truxinate		δ-Truxinate	
	Δδ	δ	Δδ	δ
11c	−0.36,	6.70—7.12 (m)	−0.11,	7.23 (s)

15c	−0.65,	7.00 (d, J=8)	−0.39,	7.26 (d, J=8)
	−0.19,	7.93 (d, J=8)	−0.02,	8.10 (d, J=8)

Molecular Orbital Calculations. The electronic structures of substituted cinnamic acids as model compounds in excited states were calculated by the CNDO/S-CI method with standard parameters.[6] The planar structure (C_s symmetry) was assumed, and standard bond lengths and bond angles were employed for the geometric parameters.[7] Two-center two-electron repulsion integrals were evaluated according to the Mataga-Nishimoto formula.[8] In the CI procedure 20 singly excited configurations below 16 eV were used.

Results and Discussion

Nitro-Substituent Effect. The progressive spectral changes of trimethylene bis(3-nitrocinnamate)s (**4c**) and trimethylene bis(4-nitrocinnamate)s (**5c**) are

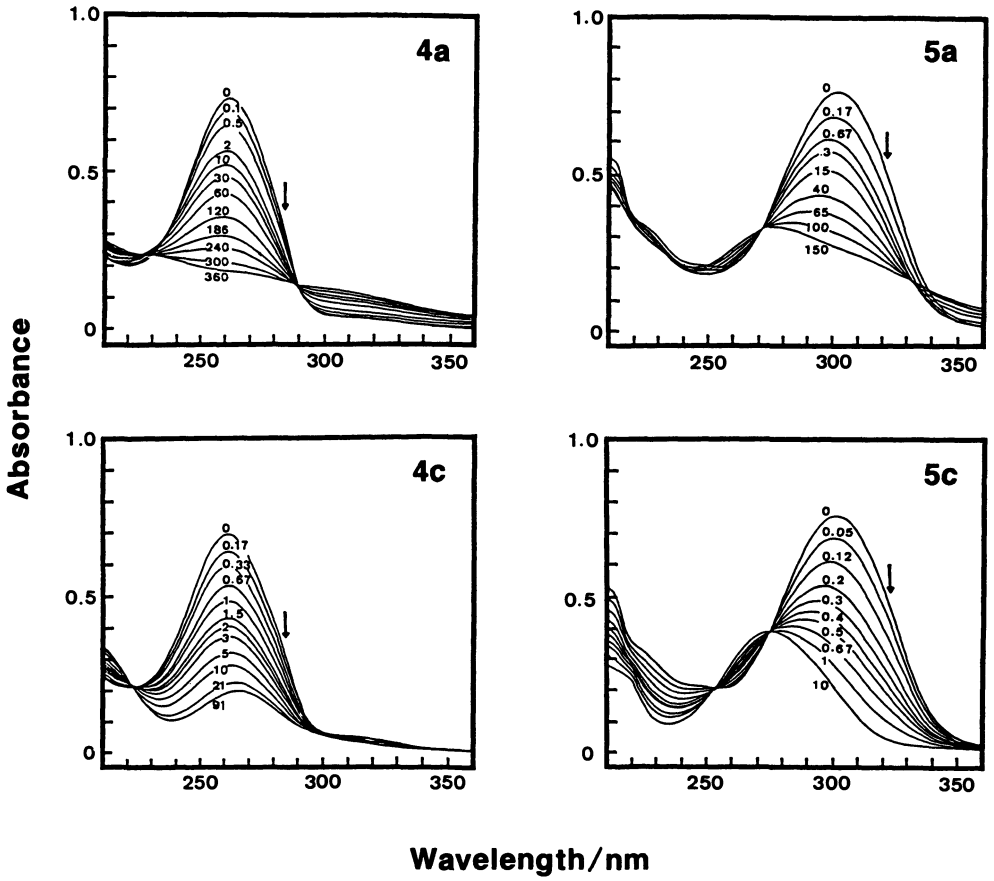

Fig. 1. Electronic spectral changes upon UV irradiation of methyl cinnamates and trimethylene dicinnamates. The arrows and numerical values in each spectrum indicate the irradiation wavelength and irradiation time (min), respectively.

shown in Fig. 1 together with those of methyl 3- and 4-nitrocinnamate (**4a** and **5a**) as unchained compound models for comparison.

It is seen from Fig. 1 that, on irradiation of methyl 3- and 4-nitrocinnamate (**4a** and **5a**), the absorption of the starting **4a** and **5a** decreased rapidly with isosbestic points at 235 and 272 nm, respectively. In the later stage of the reaction, such points disappeared or became faint. This result indicated that trans-cis photoisomerization proceeded until a photoequilibrium state was attained and then photocyclization occurred as an ensuing process in both cases. On the other hand, for trimethylene bis(3-nitrocinnamate)s (**4c**) and trimethylene bis(4-nitrocinnamate)s (**5c**), the decrease of the absorption of **4c** and **5c**, especially **5c**, was faster than that in the corresponding unchained compound **4a** and **5a**, and the isosbestic point was observed at 224 nm for **4c**, and 255 and 275 nm for **5c** throughout the reaction.

This result clearly indicated that the reaction of **4c** and **5c** involved a single photochemical process of photocyclization, and the rates of the photocyclization are far higher than those for the corresponding unchained cinnamates, due to the effect of the trimethylene chain.

The dependency of the relative quantum efficiencies for photocyclization on chain length were investigated and are shown in Fig. 2 together with those of the methoxy derivatives.

In fact, for the trimethylene compounds, the photocyclization of the 4-nitro derivative **5c** was three times as efficient as for 3-methoxy **2c** and 3-nitro **4c**. The quantum efficiencies diminished markedly with an increase or decrease in the number of methylene groups relative to those of the trimethylene compounds.

In order to compare the nature of the nitro substituent effect with that of methoxyl substituent on the photocylization, the electronic structure of the excited states of 3- and 4-nitrocinnamic acid (**4a'** and **5a'**) as model compounds were calculated by the

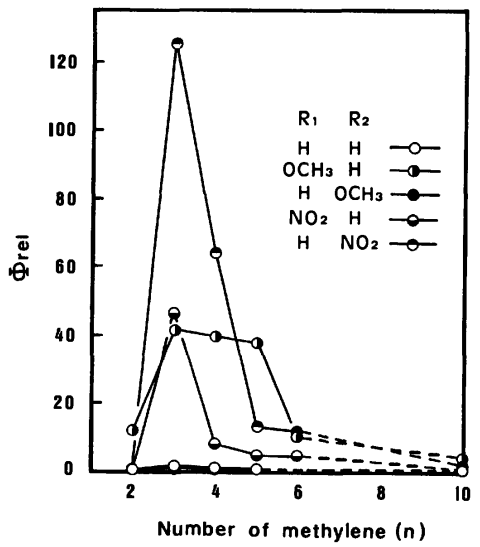

Fig. 2. Substituent effect on the photolability toward [2+2] cycloaddition on polymethylene dicinnamates.

CNDO/S-CI method. The reliability of this method for reproducing the experimental values of the lower transition energies of cinnamate derivatives has been proven in our previous paper.[4]

The calculated electronic structural features for **4a'** and **5a'** were summarized in Table 3.

The correlation between the experimental absorption wavelengths of **4a** and **5a** and the calculated transition energies of **4a'** and **5a'** was examined by a least square method. In fact, the lower transition energies of nitro derivatives were also found to be well reproduced and those thus corrected were shown in Fig. 3.

In general, the reactivity of a photochemical reaction can be discussed more reasonably on the basis of the partial atomic orbital population of the singly occupied orbital (SOMO) than of the total atomic orbital population. Thus the substituent effect on the reactivity for photocyclization can be estimated on the basis of the odd electron densities

Table 3. Computed Electronic Features for Excited States of Substituted Cinnamic Acids

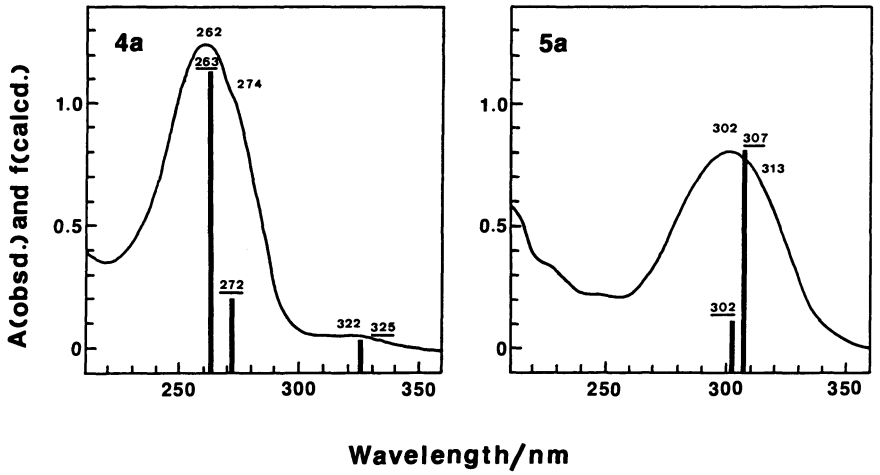

Fig. 3. Comparisons between the observed UV spectrum (solid curves) and the computed transition energy with correction (stick plot spectrum).
4a: Methyl 3-nitrocinnamate (ε=120000)
5a: Methyl 4-nitrocinnamate (ε=88000)

(Q_{odd}) of the lowest π-π^* excited state (S_3) calculated by the following formula, since S_3 state has a large value of Q_{odd} on C_α with the large oscillator strength.

$$Q_{odd} = \sum_i \alpha c_i^2, \quad \alpha = \sum_j C_i^2$$

c_i: The coefficient of i th MO (SOMO).
C_i: The CI coefficient of i th MO (SOMO) composed of each electronic configuration in S_3 state.
j: The number of electronic configuration involved i th MO (SOMO).

The correlation between the calculated Q_{odd} of the C_α at the lowest $S^{\pi-\pi^*}$ state (S_3) including those for methoxy derivatives of which detailed electronic structures were reported in a previous paper[4] and the relative quantum efficiencies (Φ_{rel}) for photocyclization of the trimethylene compounds was plotted, and is shown in Fig. 4.

It can be seen that the plots are linear demonstrating that the reactivity of the cinnamate derivatives was well correlated with the odd electron densities of the olefinic double bond at the lowest $S^{\pi-\pi^*}$ state. However, the plot of **5a** deviated considerably from the line. In the characteristics for the electronic structure of **4a'** and **5a'**, in the ground state the π-charge densities of the benzene ring are lower than that of cinnamic acid (=5.9664[4]) owing to a nitro group. In the S_3 state the further decrease in the π-charge density of the benzene ring was shown at the expense of the greater increase in that of the nitro group. These electronic features were considerably greater than those of the methoxy derivatives. This characteristic may cause electronic repulsion between the aromatic moiety in the excited state and that in the ground state. This repulsion would effect the transition state of the photocyclization reducing the exciplex formation. We believe this is one of the major reasons for the large deviation of 4-nitro derivatives shown in Fig. 4.

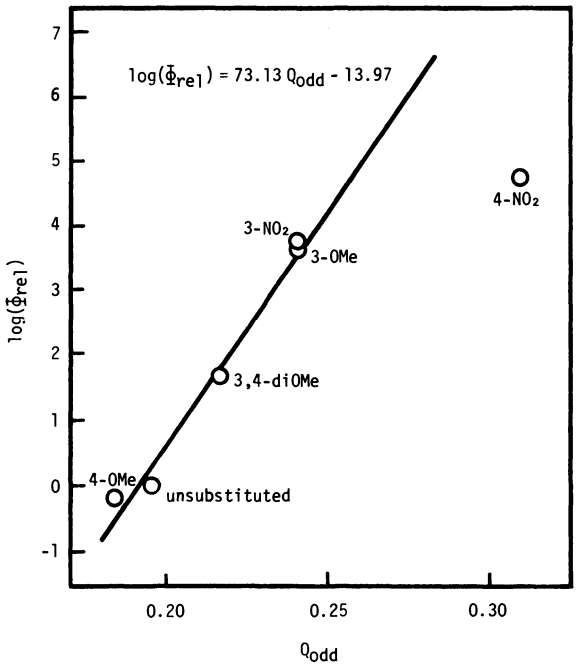

Fig. 4. Relationship between the calculated odd electron densities (Q_{odd}) of the C_α at the lowest $S^{\pi-\pi^*}$ state and the relative quantum efficiencies (Φ_{rel}) for photocyclization.

Stereochemistry of Photoproduct. The dependence of the stereochemistry of the photoproduct on the 4-nitro substituent and the number of methylene groups are shown in Fig. 5 together with those of other derivatives **1**—**3**.

As a general feature of Fig. 5, β-truxinate was exclusively formed for n=2, because of a difficulty in the production of δ-truxinate due to the geometrical

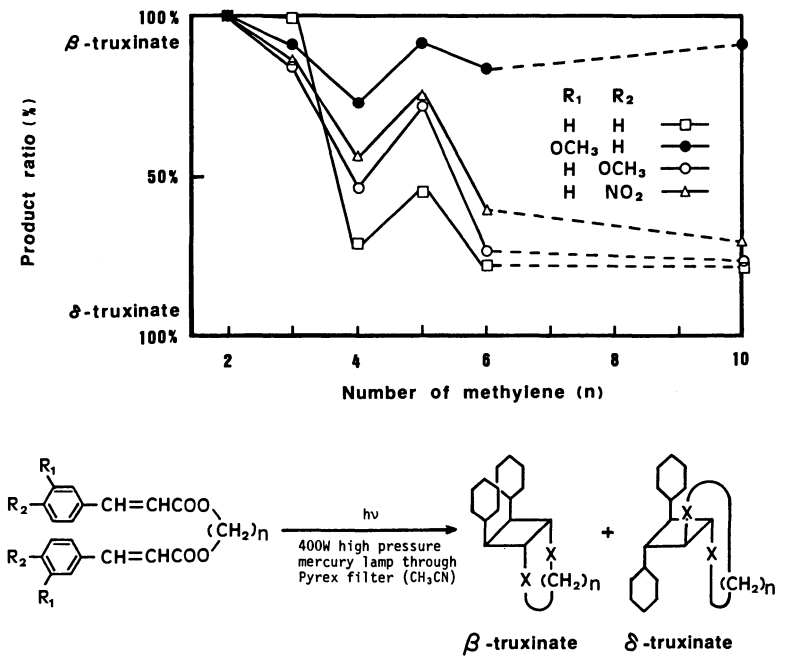

Fig. 5. Dependence of the stereochemistry of photoproduct upon alkane chain length and substituent.

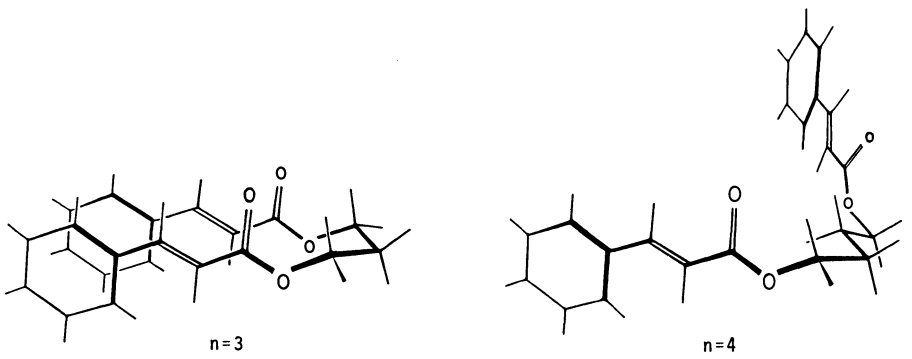

Fig. 6. The odd-even alternating effects of polymethylene chain on parallel arrangement of two cinnamoyl groups (Alkane chains are assumed to take an extended trans form).

restriction of ethylenic moiety. This tendency was shown also for n=3 and δ-truxinate was the main product. However, it was shown that the ratio of δ-truxinate in the total photoproduct markedly decreased for n=4 and that such a ratio increased again for n=5. These results indicated that the stereochemical course of the photoproduct are strongly depended on the odd or even number of the polymethylene chain. The most plausible geometrical situations of polymethylene dicinnamates are illustrated in Fig. 6 for n=3 and n=4 as representative examples.

Thus, an odd-even alternating effect of the methylene chain can be interpreted in terms of the vast difference in the geometric alignment between the two cinnamoyl moieties.[9,10] Another noteworthy feature in Fig. 5 is that only for 3-methoxy derivatives, was β-truxinate the main photoproduct irrespective of the number of methylene groups, unlike the case of the other derivatives.

From the above experimental results, it can be concluded that the high photocyclization efficiency of the trimethylene bis(4-nitrocinnamate)s (**5c**) is due to the high odd electron density in the olefinic moiety and the greater decrease of the efficiency and the less stereospecificity for the formation of β-truxinate product is due to the low efficiency for exciplex formation.

Conclusion

Pseudo-dimerization of the two cinnamoyl moie-

ties of polymethylene dicinnamates proceeds through both singlet and triplet pathways, but predominantly through the singlet pathway. The singlet pathway consists of two steps, i.e. the formation of an exciplex and its subsequent pseudo-dimerization. The topotactic assistance by the polymethylene chain mainly affects the formation of the exciplex and concomitantly the stereochemistry of the photocyclization; for n=3 the two cinnamoyl groups can assume the most preferable alignment for the formation of the exciplex resulting in the highest reactivity.[4,9] On the other hand, substituent perturbation could affect both steps. That is, the π-charge density of the benzene moiety and the odd electron density in the olefinic moiety affects the formation of the exciplex and the photodimerization, respectively. Thus, the observed rate enhancement of the pseudo-dimerization of 3-methoxy derivative can be concluded to be assisted by facile exciplex formation; accordingly the high stereoselectivity of the photoproducts was observed. That of the 4-nitro derivative can be ascribed to the high odd electron density of the olefinic double bond, not to the formation of the exciplex, demonstrated by the less stereoselectivity of the photoproduct of the derivatives linked with a longer polymethylene chain.

(Received November 16, 1985)

To improve the synthetic yield of bleomycin and its analogues, it is necessary to find the high yield procedure for condensation of sugar portion with the hydroxyl group of *erythro*-β-hydroxy-L-histidine moiety, preventing the *N*-glycosylation to imidazole. The present studies include the condensations of 4,6-di-*O*-acetyl-2,3-di-*O*-methyl-α-D-glucopyranosyl bromide (**10**) or 3,4,6-tri-*O*-acetyl-2-*O*-(2,4,6-tri-*O*-acetyl-3-*O*-carbamoyl-α-D-mannopyranosyl)-α-L-gulopyranosyl bromide (**3**) and 3,4,6-tri-*O*-acetyl-2-*O*-[2,4,6-tri-*O*-acetyl-3-*O*-(*N*-acetylcarbamoyl)-α-D-mannopyranosyl]-α-L-gulopyranosyl bromide (**28**) with a variety of protected derivatives of *erythro*-β-hydroxy-L-histidine. The results revealed that a) N^{im}-tosyl group is most effective to prevent the N^{im}-glycosylation, b) use of silver carbonate and silver perchlorate at low temperature (−55 °C) gave the desired α-glycosides in satisfactory yields, and c) among the esters (methyl and *p*-nitrobenzyl) and the *N*-protecting groups (Z, Boc, and pMZ) of *erythro*-β-hydroxy-L-histidine, methyl and Z were the best groups, respectively. Using the method thus improved, the desired *O*-α-L-guloside, that is, *erythro*-β-*O*-[3,4,6-tri-*O*-acetyl-2-*O*-(2,4,6-tri-*O*-acetyl-3-*O*-carbamoyl-α-D-mannopyranosyl)-α-L-gulopyranosyl]-N^{α}-benzyloxycarbonyl-$N^{im(\tau)}$-tosyl-L-histidine *p*-nitrobenzyl ester (**31**) was successfully prepared.

Bleomycin is an antitumor antibiotic clinically used in the treatment of squamous cell carcinoma, malignant lymphomas, and testis tumors.[1] The total synthesis of bleomycin A2 (**1**) had been accomplished by our group[2,3] and Hecht et al.[4] In our first total

Dnp: $C_6H_3(NO_2)_2$(*o*, *p*)

Chart 1.

synthesis, the key step was the coupling of a protected suger, 3,4,6-tri-*O*-acetyl-2-*O*-(2,4,6-tri-*O*-acetyl-3-*O*-carbamoyl-α-D-mannopyranosyl)-α-L-gulopyranosyl bromide (**3**), with protected pentapeptide **2**[5] at the hydroxyl group of *erythro*-β-hydroxy-L-histidine. We therefore intended to improve the yield of the desired coupling product. In this paper we describe the basic experiments for this purpose, that is, coupling reactions of protected glucosyl and 2-*O*-mannopyranosyl-α-L-gulopyranosyl bromides with several protected *erythro*-β-hydroxy-L-histidine.

Glycosylation of a Derivative (14) of β-Hydroxy-L-histidine Protected with a Dnp Group at Imidazole Moiety. As a model glycosyl bromide for bleomycin synthesis, we prepared 4,6-di-*O*-acetyl-2,3-di-*O*-methyl-α-D-glucopyranosyl bromide (**10**). Methyl 4,6-*O*-cyclohexylidene-α-D-glucopyranoside (**4**)[6] was methylated with methyl iodide in *N*,*N*-dimethylformamide (DMF) to give the 2,3-di-*O*-methyl ether **5**.

Chart 2.

Acidic hydrolysis of **5** followed by acetylation gave the 4,6-di-*O*-acetyl derivative **7**.[7] Acetolysis of **7** gave the corresponding 1-*O*-acetyl α- and β-D-glucoses **8** and **9** in 79 and 13% yield, respectively, with slightly accompanied methyl 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranoside (1.4%).[8] Treatment of the mixture of **8** and **9** with hydrogen bromide in acetic

acid gave the α-l-bromide **10**.

As a protected β-hydroxy-L-histidine for the condensation with **10**, we prepared a N^{im}-(2,4-dinitrophenyl) (=Dnp)-N^{α}-benzyloxycarbonyl(=Z) derivative[9] **14** of β-hydroxy-L-histidine. Since the low yield of our first condensation[2] was considered to be correlated to the presence of the bulky N^{α}-*t*-butoxycarbonyl (Boc) group near the hydroxyl group, the Boc group was replaced by a Z group. Treatment of **11** with *O*-benzyl *S*-(4,6-dimethyl-2-pyrimidinyl) thiocarbonate (Z–S reagent)[10] gave the N^{α}-Z-derivative **12** in high yield. Treatment of **12** with hydrogen chloride in methanol (to give **13**) followed by reaction with 2,4-dinitrofluorobenzene gave **14**.

Chart 3.

The position of the Dnp group, which remained ambiguous in the previous papers,[2,5] was determined by the procedure of Bell and Jones.[11] Treatment of **14** with benzyl chloroformate and sodium hydrogen-

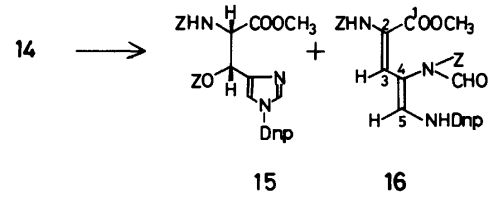

Chart 4.

carbonate in chloroform–water gave two main products. ^{1}H NMR spectroscopy provided evidences for their structural assignments: *O*-benzyloxycarbonyl derivative **15** of **14** and methyl 2,4-bis(benzyloxycarbonylamino)-4-*N*-formyl-5-(2,4-dinitroanilino)-2,4-pentadienoate (**16**). The ^{1}H NMR spectrum of **16** showed a doublet (J=12 Hz, NHDnp) at δ 10.64, which collapsed to a singlet on irradiation at δ 7.22 and disappeared on deuteration. The doublet at δ 7.22 (J=12 Hz, =C*H*–NHDnp) became a singlet on deuteration or irradiation at δ 10.64. Two singlets appeared at δ 7.49 (HC=) and 9.25 (*N*CHO), the latter being gradually disappeared on deuteration. These results indicate the hydrogen assignments to be described in the parentheses and, therefore, it was concluded that Dnp was attached to the nitrogen (*N*-5) bearing a hydrogen and a methine (C-5), not the nitrogen (*N*-4) bearing a formyl group. Thus, the structure of **16** was 2,4,5-tris(substituted amino)-2,4-diene, supporting the structure of **14**. The geometrical structure of **16** was not studied, however, from the expected reaction pathway and the NMR spectrum, a mixture of two isomers possibly composed of *E,Z* (major) and *Z,Z*-structures was presumed as follows. The compound **16** may be produced from **15** by a sequence of reactions including benzyloxycarbonylation of the $N^{im(\pi)}$ group, hydrolysis of the imidazole ring to give an *N*-formyl group,[12] and removal of a ZOH fragments (to give the 2,3-unsaturation).

According to the cross-ring coupling constant criterion suggested by Matthews and Rapoport,[13] the coupling constant between the two CH protons of imidazole ring is 0.9—1.0 Hz for the $N^{im(\pi)}$-substituted derivatives and 1.1—1.5 Hz for the $N^{im(\tau)}$-substituted derivatives. In the ^{1}H NMR spectrum of **14**, the broad singlet at δ 7.59 (H-2 of imidazole) measured at room temperature was resolved into a sharp doublet of 1.2 Hz at 55 °C, supporting the structure of **14** deduced from the structure of **16**.

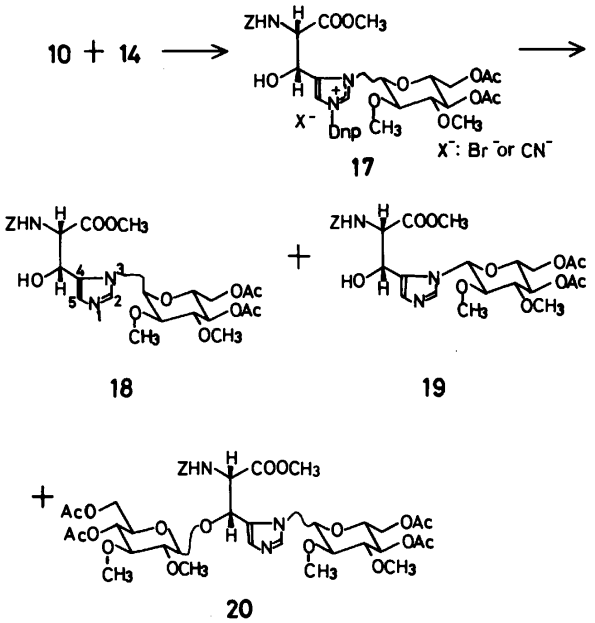

Chart 5.

Glycosylation of compound **14** with the bromide **10** according to the previous method[2] ($HgCN_2$ and molecular sieves in sulfolane, 40 °C, overnight) gave a complex mixture mainly comprised of two glucosides **17** having the Dnp groups. Since the mixture was unstable to light and cleavage of the Dnp group

occurred gradually during the purification, the Dnp group of **17** was removed beforehand by treatment with 2-mercaptoethanol to give the α- and β-$N^{im(3)}$-glucosides **18** and **19** in 34 and 26% yield (based on **14**) and a mixture of products (**20**, 6%) glucosylated both at $N^{im(3)}$ and OH-3. The positions of the glucosyl moieties in **18** and **19** were determined to be N^{im} from the low chemical shifts[14] of the anomeric protons (δ 6.30 and J=3.5 Hz, and δ 5.54 and J=9 Hz, respectively). The above results show that, glucosylation occurs at the $N^{im(3)}$ position in preference to the hydroxyl group in the presence of the $N^{im(1)}$-Dnp protecting group.

Preparation of the *O*-Glycosyl Derivatives of β-Hydroxy-L-histidine. As described previously in our communication,[3] N^{im}-tosyl group was revealed to be suitable for prevention of N^{im}-glycosylation. The *N*-tosyl compound **21** prepared from **13** showed a large

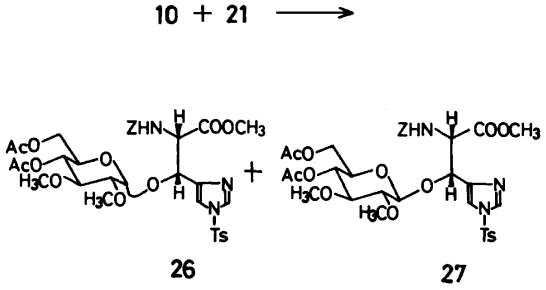

Chart 6.

cross-ring coupling constant ($J_{2,4}$=1.5 Hz) in its ^{1}H NMR spectrum, suggesting[13] the introduction of the tosyl group at $N^{im(\pi)}$. Condensation of **21** with the bromide **10** in the presence of mercury(II) cyanide and molecular sieves in dry dichloromethane at room temperature gave the desired α- and β-*O*-glucosides **26** and **27** in 21% yield in a ratio of 2:1, with the corresponding detosyl derivatives. Pure **26** and **27** were isolated by preparative high-performance liquid chromatography. The chemical shifts of the resonances of the anomeric protons of **26** and **27** in their ^{1}H NMR spectra (δ 4.89 and J=3.5 Hz for **26**, and δ 4.50 and J=7.5 Hz for **27**) supported the *O*-glucosides.

When the condensation was carried out in the presence of a mixture of silver carbonate and silver perchlorate as the catalysts at room temperature, the ratio of **26** and **27** was improved to 20:1 but without change of the yield (≈20%). Formation of the detosyl-di-N^{im},*O*-glucoside (≈25%) was also observed. However, the condensation yield was surprisingly improved to 67%, with the above ratio of **26** and **27** maintained, when the reaction was carried out at a low temperature (−55 °C). In this case, the yield of the detosyldiglucosyl derivative was lowered to 8%. It should be noted that sole lowering the reaction temperature remarkably suppressed the removal of the tosyl group and increased the yield of the desired *O*-α-glucoside. When mercury(II) cyanide was used as the catalyst, no reaction occurred at −55 °C, revealing the desirable effects of the silver catalysts.

The above reaction conditions were next applied to

	R^1	R^3	R^3

Chart 7.

the condensation of **21** and a protected 2-*O*-[3-*O*-(*N*-acetylcarbamoyl)-α-D-mannopyranosyl]-α-L-gulopyranosyl bromide (**28**) prepared from 1,3,4,6-tetra-*O*-acetyl-2-*O*-(2,4,6-tri-*O*-acetyl-3-*O*-carbamoyl-α-D-mannopyranosyl)-β-L-gulopyranose[2] by bromination with hydrogen bromide–acetic acid–acetic anhydride. When **28** was used in 1.4 molar equivalents for **21**, the best yield (95%) of **29** was obtained. Incidentally, when 1.1, 1.2, 1.3 molar equivalents of **28** for **21** were used, 69, 77, and 89% of **29** were obtained. The structure of **29** was confirmed by the ^{1}H NMR spectrum (Fig. 1).

N^{α}-Protecting groups were further studied. When N^{α}-Boc- (**22**) and N^{α}-(*p*-methoxybenzyloxycarbonyl)(=PMZ) derivatives (**23**) of N^{im}-tosyl-β-hydroxy-L-histidine methyl ester were condensed with **28**, the yields of the desired *O*-α-L-gulosides were lower than the case when Z-group was used. The inspection of the ^{1}H NMR spectra of the mixtures of products obtained by the both reactions revealed that considerable part of these protecting groups were removed during the coupling reaction.

Finally, in view of easy removal of protecting group, methyl ester group of **21** was replaced by a *p*-nitrobenzyl, and the *N*-acetyl of the carbamoyl group was omitted. Compound **12** was treated with tosyl chloride as described for **21** to give the N^{im}-tosyl derivative **24**, which was led to the *p*-nitrobenzyl ester **25** by treatment with *p*-nitrobenzyl bromide. Condensation of **25** and 3,4,6-tri-*O*-acetyl-2-*O*-(2,4,6-tri-*O*-acetyl-3-*O*-carbamoyl-α-D-mannopyranosyl)-α-L-gulopyranosyl bromide (**3**) by the same procedure as above described for **29** gave the desired *O*-α-L-guloside **31** (43% from **25**) with recoverd **25** (25%). The product **31** is useful for the synthesis of bleomycin and its analogues.

In conclusion, the present studies revealed that (a) $N^{im(\pi)}$-tosyl group successfully prevented the glycosylation at $N^{im(\pi)}$, (b) use of a mixture of silver carbonate

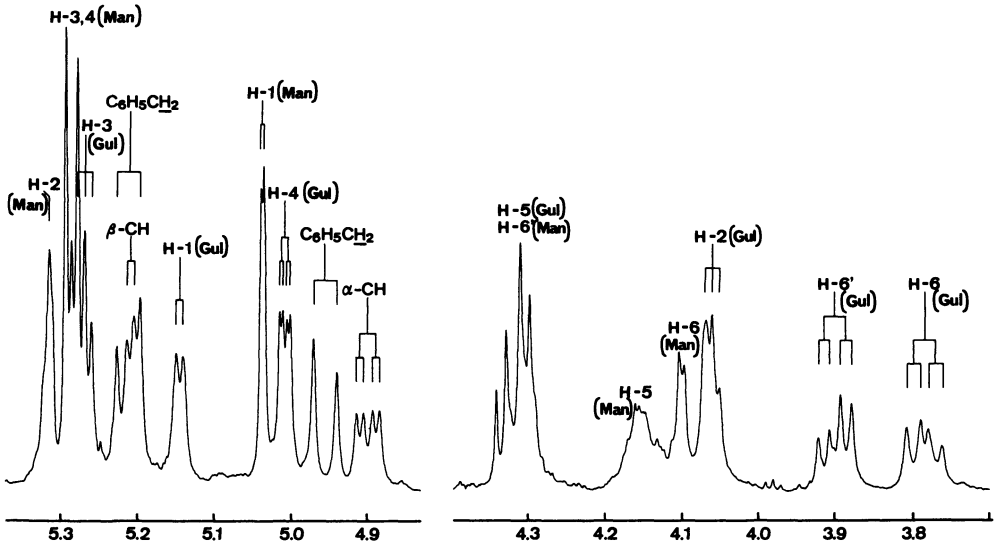

Fig. 1. Partial ^{1}H NMR spectrum of **29** (400 MHz, $CDCl_3$).

and silver perchlorate at low temperature (−55 °C) gave the desired *O*-α-glycosyl compounds almost selectively in satisfactory yields, and (c) among the protective groups of α-amino and carboxylic acid in the β-hydroxy-L-histidine portion, benzyloxycarbonyl and methyl groups, respectively, gave the best yield of the *O*-glycoside.

Experimental

IR spectra were determined in KBr disks on a Jasco A-202 infrared spectrophotometer. ^{1}H NMR spectra were recorded at 25 °C, unless otherwise stated, with Bruker WM-250 and WM-400 spectrometers (250 MHz and 400 MHz, respectively). Tetramethylsilane (δ=0.00) was used as an internal standard. Proton assignments of the products were confirmed by decoupling method if necessary. Secondary ion mass spectra (SIMS) and field desorption mass spectra (FDMS) were recorded on a Hitachi M-80 spectrometer. Optical rotations were measured in 0.1-dm cells of 0.5-ml capacity by using a Perkin-Elmer Model 241 polarimeter. Thin-layer chromatography (TLC) was carried out on E. Merck precoated TLC plates (silica gel 60 F-254). For column chromatography, silica gel (Wakogel C-200) was used, unless otherwise stated.

Methyl 4,6-*O*-Cyclohexylidene-2,3-di-*O*-methyl-α-D-glucopyranoside (5). To a solution of methyl 4,6-*O*-cyclohexylidene-α-D-glucopyranoside[6] (**4**, 505 mg) in dry *N*,*N*-dimethylformamide (DMF) (3 ml) were added silver oxide (2.15 g) and methyl iodide (0.6 ml), and the mixture was vigorously shaken at room temperature overnight. The resulting solution showed, on TLC with benzene–ethyl acetate (1:1), a single spot of **5** at R_f 0.64 (cf. **4**, R_f 0.16). The mixture was centrifuged and the residue was washed with DMF. The solutions combined were concentrated and the residue was extracted with chloroform. The organic solution was washed with water, dried ($MgSO_4$), and concentrated to give a pale yellow syrup (615 mg), that was purified by column chromatography with benzene–ethyl acetate (4:1) to give needles of **5**, 453 mg (81%), mp 82—83 °C; $[\alpha]_D^{23}$ +117° (*c* 1, $CHCl_3$); ^{1}H NMR (250 MHz, $CDCl_3$): δ=3.23 (1H, dd, H-2), 3.41, 3.53, 3.62 (each 3H, s, OCH_3), 4.80 (1H, d, H-1); $J_{1,2}$=3.5, $J_{2,3}$=8.5 Hz.

***erythro*-β-*O*-(4,6-Di-*O*-acetyl-2,3-di-*O*-methyl-α- and β-D-glucopyranosyl)-N^{α}-benzyloxycarbonyl-$N^{im(\tau)}$-tosyl-L-histidine Methyl Esters (26 and 27). A) Reaction Using Mercury(II) Cyanide as the Catalyst.** To a solution of **21** (20.8 mg) and the bromide **10** (26.0 mg, ≈1.5 mol equiv for **21**) in dry dichloromethane (0.5 ml) was added powdered molecular sieves 4A (50 mg) and the mixture was stirred in the dark at room temperature for 2 h. Mercury(II) cyanide (51 mg, 3 mol equiv for **10**) was added and the mixture was stirred at room temperature for 48 h (even after 24 h, **10** and **21** still remained). The resulting solution showed, on TLC with chloroform-methanol (20:1), several spots at R_f 0.48 (**26** and **27**), 0.30 (**21**), 0.22 (detosyldi-N^{im},*O*-glucosyl derivatives) and 0.12 (N^{im}-glucosyl derivatives) (cf. **10**: R_f 0.68). The mixture was centrifuged, and the supernatant solution and the dichloromethane washings of the residue combined were washed with water, dried ($MgSO_4$), and concentrated to give a pale yellow solid (42.6 mg), that was twice column-chromatographed with chloroform-methanol (50:1) to give a mixture of **26** and **27** (2:1, determined by the ^{1}H NMR spectrum), 5.8 mg (21% from **21**), a mixture of detosylglucosyl derivatives, 14.9 mg, and **21**, 3.2 mg (15%). Compounds **26** and **27** showed the same R_f value with several kinds of solvent systems tested but was separated by means of analytical high-pressure liquid chromatography (Waters Model 6000A, μ-porasil silica column) using chloroform as the developer. The physicochemical data of **26** and **27** described next were taken by the isolated products.

B) Reaction Using Silver Carbonate-Silver Perchlorate as the Catalyst. A mixture of **21** (43.6 mg), the bromide **10** (51 mg, ≈1.4 mol equiv for **21**) and powdered molecular sieves 4A (90 mg) in dry dichloromethane (1.8 ml) was stirred in the dark at room temperature for 2 h, then cooled to −55 °C. Silver carbonate (48.3 mg, 1.3 mol equiv for **10**) and silver perchlorate (43.1 mg, 1.4 mol equiv for **10**) were added and the mixture was stirred at −55 °C for 5.5 h. Work-up as described for A) gave a pale brown syrup (82 mg), that was thrice column-chromatographed with benzene-ethyl acetate (2:1), chloroform-methanol (50:1), and chloroform-acetone (10:1) to give a mixture of **26** and **27** (≈20:1, determined by the ^{1}H NMR spectrum), 45.9 mg (67% based on **21**), a mixture of detosyldiglucosyl derivatives, 6.0 mg (8%), and **21**, 3.0 mg (7%).

Synthesis of 6-Amino-6-deoxy-L-idopyranosides

Keiji MATSUDA, Tsutomu TSUCHIYA,* Takahiro TORII, and Sumio UMEZAWA
Institute of Bioorganic Chemistry, 1614 Ida, Nakahara-ku, Kawasaki 211
(Received November 21, 1985)

Methyl 6-amino-6-deoxy-α- and -β-L-idopyranosides have been prepared from 3-*O*-acetyl-1,2-*O*-isopropylidene-D-glucofuranose via 5,6-anhydro-1,2-*O*-isopropylidene-L-idofuranose and the azide product derived from it. Isopropyl 6-amino-6-deoxy-α- and -β-L-idopyranosides were prepared from 6-azido-2,3,4-tri-*O*-benzyl-6-deoxy-α-L-idopyranosyl chloride and 2-propanol. Nonprotected α- and β-L-idopyranosides were distinguished by their $J_{1,2}$ proton couplings.

In the course of our synthetic studies on the analogs of aminoglycoside antibiotics containing 2,6-diamino-2,6-dideoxy-L-idopyranose, such as neomycin B, lividomycins, and paromomycin I, we needed to know the characteristics of the most basic 6-amino-6-deoxy-L-idopyranosides. In this paper we describe the syntheses of methyl and isopropyl 6-amino-6-deoxy-α-and-β-L-idopyranosides.

Sorkin and Reichstein[1] prepared methyl α-and β-D-idopyranosides from methyl 4,6-*O*-benzylidene-D-galactopyranosides by alkaline hydrolysis of the corresponding 2,3-anhydro-D-gulo- and -talo derivatives. In the synthesis of 3,6-diamino-3,6-dideoxy-D-idose, Hanessian and Haskell[2] used this kind of procedure. To prepare 6-deoxy-L-idosides, 5,6-unsaturated D-*xylo* compounds such as methyl 2,3,4-tri-*O*-acetyl-6-deoxy-α-D-*xylo*-hex-5-enopyranoside[3] were usually reduced catalytically. In the synthesis of 3-*O*-acetyl-2,6-diazido-4-*O*-benzyl-2,6-dideoxy-L-idopyranosyl chloride,[4] a precursor for the 2,6-diamino-2,6-dideoxy-L-idoside portion of neomycin B, we applied a head-to-tail inversion technique for a D-glucose derivative. Meyer and Reichstein[5] prepared L-idopyranose from 1,2-*O*-isopropylidene-5-*O*-tosyl-D-glucofuranose derivatives through hydrolysis of the 5,6-anhydro-L-idofuranoses derived from the D-glucofuranose. Since then most investigators used 5,6-anhydro compounds or similar methods using 5,6-epimine[6] or oxazoline[7,8] to prepare L-ido derivatives. In our present synthesis, the 6-amino-6-deoxy-L-idopyranosides (**13** and **14**) were also prepared by way of a 5,6-anhydro compound.

3-*O*-Acetyl-1,2-*O*-isopropylidene-D-glucofuranose[9] (**1**) was treated with *p*-nitrobenzoyl chloride in pyridine at −40 °C, when crystalline 6-*O*-(*p*-nitrobenzoyl) derivative **2** was obtained in high yield. No acetyl migration suggested[5] was observed. After mesylation of **2** (to give the 5-*O*-mesyl derivative,**3**) two acyl groups were removed by methanolic ammonia to give the diol **4**. Attempts to selectively remove the 6-*O*-(*p*-nitrobenzoyl) group by controlled reaction conditions were unsuccessful giving a mixture including a migration product, 6-*O*-acetyl derivative. Treatment of **4** with 1,8-diazabicyclo-[5.4.0]undec-7-ene (DBU) in oxolane gave the 5,6-anhydro derivative **5** of L-ido structure in a moderate yield. If methanolic ammonia or methanolic sodium methoxide was used instead of DBU, no pure **5** was obtained possibly by contamination of a 3,5-oxetane derivative as suggested by Buchanan and Oakes.[10] The structure of **5** was proved by the acetyl derivative **6** of **5**. From the ^1H NMR spectrum, it was clarified that the acetyl group was introduced at C-3, not at C-6, precluding the oxetane structure of **5**. Opening the 5,6-anhydro ring with a mixture[11] of sodium azide-ammonium chloride gave the 6-azido-L-idofuranose **7**. Reaction without the use of ammonium chloride gave **7** in only poor yield. Structure of **7** was proved by inspection of the ^1H NMR spectrum of the di-*O*-acetyl derivative **8**. Refluxing **7** with methanolic hydrochloric acid gave

a mixture of several products. Separation of them by usual silica-gel or resin column chromatography was found difficult; however, the portion of the anomeric mixture of 6-azidoglycopyranosides **11** and **12** was successfully isolated by a borate-form resin column chromatography using a borate buffer as the eluent.

The anomeric mixture was then acetylated and the tri-*O*-acetyl-6-azido-6-deoxy-α- (**9**) and -β-L-idopyranosides (**10**) were separated by silica-gel column chromatography. Removal of the acetyl groups from **9** and **10** gave pure methyl 6-azido-6-deoxy-α- (**11**) and -β-L-idopyranosides (**12**). Catalytic reduction of **11** and **12** gave the corresponding 6-amino-6-deoxy-α- (**13**) and -β-L-idopyranosides (**14**).

Isopropyl 6-amino-6-deoxy-α-L-idopyranosides (**18** and **19**) were prepared from 6-azido-2,3,4-tri-*O*-benzyl-6-deoxy-L-idopyranosyl chloride[12] (**15**). Condensation of **15** with 2-propanol in the presence of mercury(II) cyanide in dichloromethane gave the isopropyl α- and -β-L-idopyranoside derivatives **16** and **17** in 1:4 ratio after chromatography. Reduction of the azido and removal of the benzyl groups of **16** and **17** with sodium in liquid ammonia gave the glycosides **18** and **19**. To confirm their structures, *N*-benzyloxycarbonyl derivatives **20** and **21** were prepared. Periodate oxidation of the both compounds gave one molar equivalent of formic acid, respectively, proving the presence of contiguous three hydroxyl groups.

One of the purposes of our syntheses was to examine the possibility to distinguish the anomers from their ^{1}H NMR spectra, especially from the $J_{1,2}$ values. Since hydrogens at C-1 and C-2 of both anomers (**9**, **10**, **11**, **12**, **13**, **14**, **18**, and **19**) are supposed to be situated in gauche relationship except for the $^4C_1$ conformation of the α-L-isomers, small $J_{1,2}$ proton coupling constants of all compounds are expected (see Fig. 1). Indeed, in the β-L-idosides **10**, **12**, **14**, and **19**, the $J_{1,2}$ proton coupling constants were all small (1—2 Hz) and, in **10**, **12**, and **19**, the $J_{2,3}$, $J_{3,4}$, and $J_{4,5}$ were so small (2—4 Hz) as those typical for the $^1C_4$(L) conformation of idopyranosides reported.[13,14] It should be stressed that both tri-*O*-acetyl-6-azido-6-deoxy-β-L-idoside (**10**) and the corresponding deacetylated idoside **12** had almost equal *J* values ($J_{1,2}$—$J_{4,5}$) suggesting that the presence of the *O*-acetyl groups of **10** did not necessarily contribute[15] the stability of the $^1C_4$(L) conformation. In the 6-amino-6-deoxy-β-L-idosides (**14** and **19**), although the *J* values of **14** except for $J_{1,2}$ could not be measured by overlapping with other signals, $^1C_4$ (L) conformations were presumed. Therefore it is concluded that all β-L-idosides described here take the $^1C_4$ (L) conformation exclusively. In the α-L-idosides **9**, **11**, **13**, and **18**, the $J_{1,2}$ values (3.5—6 Hz) of **11**, **13**, and **18** were larger than those (0.5—2 Hz) of the tri-*O*-acetyl-6-azido-6-deoxy-α-L-idoside (**9**), which, judging from the other *J* values (see Experimental), was suggested to take the ideal $^1C_4$ (L) conformation, stabilized[15] by the presence of the *O*-acetyl groups. Other nonprotected derivatives **11**, **18**, and possibly **13** will take a conformation equilibrated by two chair conformations ($^1C_4 \rightleftarrows {}^4C_1$), in NMR time-scale. It was further assumed that the isopropyl α-L-idopyranoside (**18**) took more $^4C_1$ (L) conformation than the methyl α-L-idosides **11**, **13**, the fact being ascribed to the tendency of the bulky isopropoxy group of **18** to take an equatrial position. Since $J_{2,3}$ and $J_{3,4}$ of **11** and **18** were almost equal,[16] respectively, contribution of a skew conformation will be negligible. In conclusion, α- and β-L-idopyranosides, so far described, can be distinguished by the $J_{1,2}$ values (α-L: 3.5—6 Hz, β-L: 1—2 Hz) if the protecting groups of the idopyranosides are absent. This affords a useful method for the discrimination of the anomers of nonprotected idopyranosides.

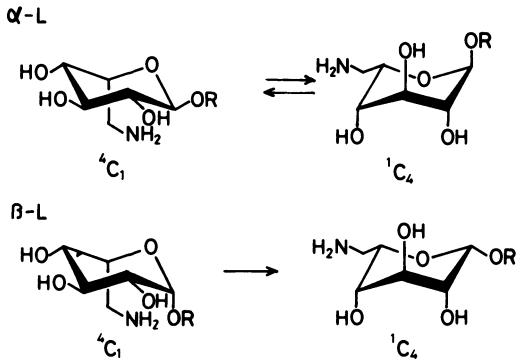

Fig. 1.

Experimental

General. ^{1}H NMR spectra were recorded at 90 MHz with a Varian EM-390 spectrometer unless otherwise stated.

The 250 MHz spectra were measured in the FT mode with a Bruker WM 250 spectrometer. IR spectra were recorded with a Hitachi 285 infrared spectrophotometer. Optical rotations were measured with a Perkin-Elmer 241 polarimeter. Thin-layer chromatography (TLC) was performed on precoated kieselgel 60, Merck. For column chromatography, silica gel (Wakogel C-200) was used.

3-*O*-Acetyl-1,2-*O*-isopropylidene-6-*O*-(*p*-nitrobenzoyl)-D-glucofuranose (2). A mixture of 3-*O*-acetyl-1,2-*O*-isopropylidene-D-glucofuranose[9] (**1**, 36.4 g) and *p*-nitrobenzoyl chloride (30.7 g) in pyridine (600 ml) was kept at −40 °C overnight. Addition of water (3 ml) followed by evaporation gave a residue, that was extracted with chloroform. The organic solution was washed with aqueous saturated potassium hydrogensulfate and aqueous saturated sodium hydrogencarbonate, dried (Na_2SO_4), and concentrated to give a solid. Recrystallization from chloroform–hexane gave pale-yellow crystals, 53.0 g (93%), mp 132—133 °C, $[\alpha]_D^{20}$ −14 ° (*c* 1, chloroform); IR (KBr): 1735 (ester); 1540 and 1350 cm^{-1}(nitro); ^1H NMR ($CDCl_3$): δ=1.37 and 1.54 (Me_2C), 2.20 (3H, s, Ac), 3.08 (1H, br m, OH), 3.98 (1H, dq, H-5), 4.32 (1H, dd, $J_{3,4}$=2.5, $J_{4,5}$=9 Hz, H-4), 4.48 (1H, dd, $J_{5,6}$=6, $J_{6,6'}$=12.5 Hz, H-6), 4.65 (1H, d, $J_{1,2}$=4, $J_{2,3}$=0 Hz, H-2), 4.80 [1H, dd, *J*=2.5 (=$J_{5,6'}$) and 12.5 Hz, H-6′], 5.33 (1H, d, *J*=2.5 Hz, H-3), 5.95 (1H, d, H-1), 8.32 (4H, s, phenyl).

Found: C, 52.43; H, 5.20; N, 3.36%. Calcd for $C_{18}H_{21}NO_{10}$: C, 52.56; H, 5.15; N, 3.40%.

3-*O*-Acetyl-1,2-*O*-isopropylidene-5-*O*-methylsulfonyl-6-*O*-(*p*-nitrobenzoyl)-D-glucofuranose (3). A solution of **2** (5.2 g) and methanesulfonyl chloride (2.94 ml) in pyridine (100 ml) was kept for 3 h at room temperature. Work-up as described above gave a solid of **3**, 5.8 g (94%), $[\alpha]_D^{20}$ −4 ° (*c* 1, chloroform); ^1H NMR ($CDCl_3$): δ=3.08 (3H, s, Ms), 5.32 (1H, dq, H-5), 5.42 (1H, d, H-3), 5.98 (1H, d, H-1).

Found: C, 46.35; H, 4.71; N, 2.63; S, 6.66%. Calcd for $C_{19}H_{23}NO_{12}S$: C, 46.63; H, 4.74; N, 2.86; S, 6.55%.

1,2-*O*-Isopropylidene-5-*O*-methylsulfonyl-D-glucofranose (4). A mixture of **3** (38 g) and 1 M† methanolic ammonia (680 ml) was stirred until the mixture became clear and the solution was kept at room temperature (totally 6 h). Neutralization with 1 M aqueous hydrochloric acid followed by evaporation gave a residue, that showed, on TLC with benzene–ethyl acetate (2:1), spots at R_f 0.38 (minor), 0.27 (**5**, minor) and 0.16 (**4**, major) (cf. **3**: R_f 0.63). The residue was extracted with chloroform and the soution washed with aqueous saturated sodium sulfate, dried (Na_2SO_4), and concentrated. Silica-gel (1 kg) column chromatography of the residue with benzene–ethyl acetate (1:2) gave an unknown product (R_f 0.38, 3.6 g), the 5,6-epoxy compound (**5**, 2.2 g) and a solid of **4**, 14.1 g (61%); **4**: $[\alpha]_D^{20}$ −3 ° (*c* 1, chloroform); ^1H NMR ($CDCl_3$; measured after shaking with slight D_2O): δ=1.34 and 1.55 (each s, Me_2C), 3.22 (3H, s, Ms), 3.85 (1H, dd, $J_{5,6}$=5.5, $J_{6,6'}$= 12.5 Hz, H-6), 4.10 (1H, dd, $J_{5,6'}$=3 Hz, H-6′), 4.15—4.4 (2H, H-3, 4), 4.58 (1H, d, $J_{1,2}$=4 Hz, H-2), 4.95 (1H, H-5), 5.96 (1H, d, H-1).

Found: C, 39.94; H, 6.35; S, 10.37%. Calcd for $C_{10}H_{18}O_8S$: C, 40.26; H, 6.08; S, 10.75.

5,6-Anhydro-1,2-*O*-isopropylidene-L-idofuranose (5). To a solution of **4** (14.0 g) in oxolane (300 ml) was added 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) (20 ml) and the solution was kept at room temperature overnight, then another DBU (8 ml) was added and kept likewise for further 24 h. TLC of the solution with benzene–ethyl acetate (1:2) showed spots at R_f 0.55 (**5**) and 0.45 (slight, **4**). After concentration to a small valume, chloroform was added and the organic solution was washed with 0.2 M phosphate buffer (pH 6) (a part of **5** was lost by dissolving in the solution), then aqueous saturated sodium sulfate, dried (Na_2SO_4), and concentrated. Silica-gel (250 g) column chromatography of the residue with benzene–ethyl acetate (1:2) gave **5** as crystals, 5.9 g (62%) and **4** recovered (0.9 g); mp 74—75 °C, $[\alpha]_D^{20}$ −26 ° (*c* 1, chloroform); ^1H NMR ($CDCl_3$): δ=1.35 and 1.52 (each s, Me_2C), 2.87 (2H, narrow m, H-6,6′), 3.02 (1H, d, *J*=5 Hz, OH-3; disappeared on deuteration), 3.35 (1H, q, $J_{5,6}$=$J_{5,6'}$=$J_{4,5}$=3.5 Hz, H-5), 4.22 [1H, dd, *J*=3 (=$J_{3,4}$) and 3.5 Hz, H-4], 4.38 (1H, dd, *J*= 3 and 5 Hz, H-3; on irradiation at δ 3.02 or on deuteration, the dd collapsed to a d), 4.56 (1H, d, $J_{1,2}$=3.5 Hz, H-2), 5.96 (1H, d, H-1).

Found: C, 53.18; H, 6.85%. Calcd for $C_9H_{14}O_5$: C, 53.46; H, 6.98%.

3-*O*-Acetyl-5,6-anhydro-1,2-*O*-isopropylidene-L-idofuranose (6). Compound **5** (490 mg) was treated with acetic anhydride (0.26 ml) in pyridine (15 ml) at 0 °C for 20 h. Usual work up gave amorphous powder of **6**, 496 mg (84%), $[\alpha]_D^{20}$ +15 ° (*c* 1, chloroform); ^1H NMR ($CDCl_3$): δ=1.36 and 1.55 (each s, Me_2C), 2.17 (3H, s, Ac), 5.38 (1H, d, *J*=3 Hz, H-3).

Found: C, 54.31; H, 6.58%. Calcd for $C_{11}H_{16}O_6$: C, 54.09; H, 6.60%.

6-Azido-6-deoxy-1,2-*O*-isopropylidene-L-idofuranose (7). A mixture of sodium azide (3.8 g) and ammonium chloride (3.6 g) in dry *N*, *N*-dimethylformamide (300 ml) was stirred at 100 °C for 1 h, then **5** (5.8 g) was added and further heated at the temperature for 1.2 h. TLC of the solution with chloroform–methanol (10:1) showed spots at R_f 0.5 (**5**, slight), 0.45 (**7**) and 0.4 (trace). After addition of chloroform (500 ml) the organic solution was washed with aqueous saturated sodium sulfate, dried (Na_2SO_4), and concentrated. Chromatography (silica gel, 260 g) of the residue with chloroform (300 ml), then chloroform–methanol (10:1) gave crystals of **7**, 4.7 g (68%) and **5** recovered (1.1 g, 19%); **7**: mp 97—99 °C, $[\alpha]_D^{20}$ −24 ° (*c* 1, chloroform); IR (KBr) 2100 cm^{-1} (N_3); ^1H NMR ($CDCl_3$; measured after shaking with slight D_2O): δ=1.36 and 1.50 (Me_2C), 3.53 (2H, double ABq, H-6,6′), 4.31 (1H, d, $J_{3,4}$=3 Hz; t before deuteration; H-3), 4.55 (1H, d, $J_{1,2}$=4 Hz, H-2), 6.01 (1H, d, H-1).

Found: C, 44.09; H, 5.99; N, 16.88%. Calcd for $C_9H_{15}N_3O_5$: C, 44.08; H, 6.16; N, 17.13%.

3,5-Di-*O*-acetyl-6-azido-6-deoxy-1,2-*O*-isopropylidene-L-idofuranose (8). Compound **7** (70 mg) was treated with acetic anhydride (0.08 ml) in pyridine (1.5 ml) in a usual manner to give a syrup, 80 mg (85%), $[\alpha]_D^{20}$ −26 ° (*c* 1, chloroform); *m/z* 330 $(M+1)^+$; ^1H NMR (benzene-d_6): δ=1.08 and 1.40 (Me_2C), 1.60 and 1.72 (each 3H, s, Ac), 5.28 (1H, d, H-3), 5.45 [1H, ddd, *J*=8 (=$J_{4,5}$), 4, and 5.5 Hz, H-5].

Methyl 6-Azido-6-deoxy-L-idopyranosides (11+12). A solution of **7** (100 mg) in 1.4 M methanolic hydrochloric acid (5 ml) was refluxed for 1.5 h. TLC of the solution

† 1M=1 mol dm^{-3}.

with chloroform–methanol (10:1) showed spots at R_f 0.38, 0.33, 0.27 (minor), and 0.15 (trace) (cf. **7**: R_f 0.52). The solution was neutralized with Dowex 1×2 resin (OH^- form), filtered, and concentrated. The residue was chromatographed on a column of Dowex 1×2 (borate form, 15 ml) with 0.0025 M aqueous $K_2B_4O_7$ solution (elution speed: 0.25 ml min^{-1}). The eluate (16—26 ml) containing the pyranosides (R_f 0.38 and 0.33) was passed through a column of Dowex 50W ×2 resin (H^+ form, 5ml) with water and concentrated. The residue was repeatedly concentrated with additions of methanol (until boric acid was undetected) to afford a syrup of a mixture of **11** and **12**, 55 mg (6%).

Methyl 2,3,4-Tri-*O*-acetyl-6-azido-6-deoxy-α- (9) and -β-L-idopyranosides (10). A solution of a mixture of **11** and **12** (54.8 mg) in pyridine (1.5 ml) was treated with acetic anhydride (0.2 ml) at room temperature overnight. TLC of the solution with benzene–ethyl acetate (3:1), showed spots of R_f 0.54 (**9**) and 0.48 (**10**). After addition of water (0.1 ml), the solution was concentrated. The chloroform solution of the residue was washed with water, dried (Na_2SO_4), and concentrated. The residue was chromatographed with benzene–ethyl acetate (5:1) to give a syrup (from the earlier fractions) of **9**, 43.4 mg (50%) and crystals of **10**, 30.8 mg (36%).

9: $[\alpha]_D^{20}$ −25° (*c* 1, chloroform); IR (KBr) 2100 cm^{-1} (N_3); *m/z* 346 $(M+1)^+$, 314 (M^+−MeO); ^1H NMR ($CDCl_3$): δ=2.15, 2.17 and 2.20 (each 3H, s, Ac), 3.25 (1H, dd, H-6), 3.50 (3H, s, OCH_3), 3.59 (1H, dd, H-6′), 4.37 (1H, ddd, H-5), 4.77 (1H, br s, half-height width was ≈3.5 Hz, H-1), 4.87 (2H, m, H-2,4), 5.02 (incomplete t with small splittings, H-3); $J_{1,2}$ ≈0.5, $J_{2,3}$ ≈3, $J_{3,4}$=3.5, $J_{4,5}$=2, $J_{5,6}$=4, $J_{5,6'}$=8.5 and $J_{6,6'}$=13 Hz.

In C_6D_6 at 250 MHz: δ=1.55, 1.60, and 1.65 (each s, Ac), 2.66 (1H, dd, H-6), 3.14 (3H, s, OCH_3), 3.20 (1H, dd, H-6′), 4.14 (1H, dt, H-5), 4.66 (1H, d, H-1), 4.85 (1H, t, H-4), 5.14 (1H, dd with small splittings, H-2), 5.26 (1H, t with small splittings, H-3); $J_{1,2}$=2, $J_{2,3}$=$J_{3,4}$=4, $J_{4,5}$ ≈3, $J_{5,6}$=8.5, $J_{5,6'}$= 3,5, $J_{1,3}$≈0.5, and $J_{2,4}$≈0.5 Hz.

10: Mp 107—108 °C, $[\alpha]_D^{20}$ +62° (*c* 1, chloroform); IR (KBr) 2100 cm^{-1} (N_3); ^1H NMR ($CDCl_3$) δ=2.18 (9H, s, Ac) (in pyridine-d_5: 2.08, 2.10 and 2.18, each 3H s), 3.30 (1H, dd, H-6), 3.62 (3H, s, OCH_3), 3.70 (1H, dd, H-6′), 4.16 (1H, ddd, H-5), 4.80 (1H, d, H-1), 4.88 [1H, dd with small splittings ($J_{2,4}$ ≈0.5 Hz), H-4], 4.98 [1H, dd with small splittings (≈0.5 Hz), H-2], 5.20 (1H, t, H-3); $J_{1,2}$=2, $J_{2,3}$= $J_{3,4}$=$J_{5,6}$=4, $J_{4,5}$=2.5, $J_{5,6'}$=8, and $J_{6,6'}$=13 Hz.

Found: C, 45.30; H, 5.59; N, 12.03%. Calcd for $C_{13}H_{19}N_3O_8$: C, 45.22; H, 5.55; N, 12.17%.

Methyl 6-Azido-6-deoxy-α- (11) and -β-L-Idopyranosides (12). To a solution of **9** (34.7 mg) in methanol (2 ml), barium hydroxide octahydrate (70 mg) was added and the mixture was stirred for 10 min at room temperature. After bubbling carbon dioxide, the mixture containing barium carbonate was concentrated and the residue was extracted with 1,4-dioxane. The extracted product was chromatographed on a short column of silica gel with chloroform–methanol (10:1) to give a syrup of **11**, 19.4 mg (88%), which crystallized on standing. In a similar manner a syrup of **12**, 15.1 mg (82%) was obtained from **10** (29.1 mg).

11: Mp 62—63 °C, $[\alpha]_D^{20}$ −74° (*c* 0.9, water); IR (KBr) 2100 cm^-; ^1H NMR (pyridine-d_5–D_2O=10:1): δ=3.58 (3H, s, OCH_3), 3.61 (1H, dd, H-6), 3.98 (1H, dd, H-6′), ≈4.13 (1H, H-4), 4.15 (1H, dd, H-2; on irradiation of H-1, the dd collapsed to a d), 4.46 [1H, dd with small splittings ($J_{1,3}$≦0.5 Hz), H-3], 4.62 (1H, ddd, H-5), 5.11 (1H, d with small splittings, H-1); $J_{1,2}$=3.5, $J_{2,3}$=5, $J_{3,4}$=$J_{5,6}$=4, $J_{4,5}$=2.5, $J_{5,6'}$=9, and $J_{6,6'}$=13 Hz.

Found: C, 38.53; H, 5.97; N, 18.85%. Calcd for $C_7H_{13}N_3O_5$: C, 38.36; H, 5.98; N, 19.17%.

12: $[\alpha]_D^{20}$ +54° (*c* 0.9, water): IR (KBr) 2100 cm^{-1}; ^1H NMR (pyridine-d_5–D_2O=10:1): δ=3.48 (1H, dd, H-6), 3.66 (3H, s, OCH_3), 4.00 (1H, narrow m, H-2), 4.01 (1H, dd, H-6′), 4.28 (1H, dd with small splittings, H-4), 4.53 (1H, ddd, H-5), 4.66 (1H, t, H-3), 5.14 (1H, d, H-1); $J_{1,2}$=1, $J_{2,3}$= $J_{3,4}$=$J_{5,6}$=4, $J_{4,5}$=2.5, $J_{5,6'}$=7.5, and $J_{6,6'}$=13 Hz.

Found: C, 38.27; H, 5.91; N, 18.88%. Calcd for $C_7H_{13}N_3O_5$: C, 38.36; H, 5.98; N, 19.17%.

Metyl 6-Amino-6-deoxy-α- (13) and -β-L-idopyranosides (14). An aqueous solution (1.5 ml) of **11** (16.5 mg) was hydrogenated (3 kg cm^{-2} of hydrogen) for 1 h in the presence of palladium black under shaking. Filtration followed by concentration gave a ninhydrin-positive solid of **13**, that was reprecipitated from methanol solution by addition of ethyl acetate, 13.0 mg (77% as hemicarbonate). In a similar manner **14** was obtained from **12** (12.9 mg) as a solid of hemicarbonate, 10.4 mg (79%).

13: $[\alpha]_D^{20}$ −88° (*c* 1, water): ^1H NMR (D_2O at 60 °C): δ=3.57 (3H, s, OCH_3), 4.75 (1H, d, $J_{1,2}$=4.5 Hz, H-1).

Found: C, 39.84; H, 7.02; N, 5.95%. Calcd for $C_7H_{15}NO_5 \cdot 1/2\ H_2CO_3$: C, 40.17; H, 7.19; N, 6.25%.

14: $[\alpha]_D^{20}$ +52° (*c* 0.9, water); ^1H NMR (D_2O at 60 °C): δ=3.65 (3H, s, OCH_3), 4.83 (1H, d, $J_{1,2}$=2 Hz, H-1).

Found: C, 40.32; H, 7.04; N, 6.08%. Calcd for $C_7H_{15}NO_5 \cdot 1/2H_2CO_3$: C, 40.17; H, 7.19; N, 6.25%.

Isopropyl 6-Azido-2,3,4-tri-*O*-benzyl-6-deoxy-α- (16) and -β-L-idopyranosides (17). A mixture of dry 2-propanol (0.8 ml), mercury(II) cyanide (680 mg) and Drierite ($CaSO_4$, 1.84 g activated at 235 °C for 3 h in vacuo) in dichloromethane (3 ml) was stirred for 1 h at room temperature. The 1-chloride[12] **15** (667 mg) dissolved in dichloromethane (3 ml) was added to the above suspension and the mixture was stirred overnight at room temperature. After addition of chloroform (50 ml), the mixture was filtered, and the solution was washed with aqueous sodium hydrogencarbonate, dried (Na_2SO_4), and concentrated. The residue was chromatographed on a silica-gel column with benzene–ethyl acetate (100:1) to give solids of **16**, 114 mg (16%), R_f 0.6 on TLC with benzene–ethyl acetate=30:1, and **17**, 425 mg (61%), R_f 0.48.

16: $[\alpha]_D^{26}$ −14.5° (*c* 1, chloroform). Found: C, 69.49; H, 6.77; N, 7.91%. Calcd for $C_{30}H_{35}N_3O_5$: C, 69.32; H, 6.77; N, 8.12%.

17: $[\alpha]_D^{26}$ +80° (*c* 1, chloroform). Found: C, 69.40; H, 6.79; N, 8.07%. Calcd for $C_{30}H_{35}N_3O_5$: C, 69.32; H, 6.77; N, 8.12%.

Isopropyl 6-Amino-6-deoxy-α-L-idopyranoside (18). A solution of **16** (76 mg) in oxolane (1.5 ml) was added to a solution of sodium metal (ca. 50 mg) in liquid ammonia (ca. 5 ml, −50 °C) and the deep-blue solution was kept at the temperature for 2 h. After addition of methanol to consume the residual sodium to give a colorless solution, ammonia was evaporated with gradual raise in temperature (finally under diminished pressure). The strongly alkaline

aqueous solution of the residue was passed through a column of Dowex 50 W×2 (NH_4^+ form) with water, and the ninhydrin-positive fractions combined were concentrated. The residue was chromatographed on a column of CM-Sephadex C-25 (10 ml) with water (30 ml), then 0.5 M aqueous ammonia to give a solid of **18**, 22 mg (65% as 1/6 carbonate), $[\alpha]_D^{24}$ −73° (*c* 1, water); ^{1}H NMR (in D_2O containing 20% ND_3 at 250 MHz): δ=1.19 and 1.24 (each 3H d, *J*=6 Hz, CH*Me*$_2$), ABq cendered at 2.85 (2H, H-6,6′), 3.35 (1H, dd, H-2), 3.72 (1H, dd, H-4), 3.96 (1H, m, H-5), 4.02 (1H, m, OC*H*Me$_2$), 4.72 (1H, d, H-1); $J_{1,2}$=6, $J_{2,3}$=8.5, $J_{3,4}$=7.5, $J_{4,5}$=4.5 Hz.

Found: C, 47.79; H, 8.22; N, 5.76%. Calcd for $C_9H_{19}NO_5 \cdot 1/6H_2CO_3$:C, 47.55; H, 8.36; N, 6.05%

Isopropyl 6-Amino-6-deoxy-β-L-idopyranoside (19). Compound **17** (160 mg) was treated smilarly as described for **18** to give a solid of **19**, 45 mg (63% as 1/6 carbonate), $[\alpha]_D^{24}$ +42° (*c* 1, water). ^{1}H NMR (in D_2O containing 20% ND_3 at 250 MHz): δ=1.19 and 1.24 (each 3H, d, *J*=6 Hz, CH*Me*$_2$), ABq centered at 2.86 (2H, H-6,6′), 3.58 (1H, dd, H-4), 3.62 (1H, ddd, H-2), 3.85 (1H, m, H-5), 3.99 (1H, t, H-3), 4.11 (1H, m, OC*H*Me$_2$), 4.91 (1H, d, H-1); $J_{1,2}$=1.5, $J_{2,3}$=$J_{3,4}$=4, $J_{4,5}$=2, $J_{2,4}$=1 Hz.

Found: C, 47.38; H, 8.23; N, 6.13%. Calcd for $C_9H_{19}NO_5 \cdot 1/6\ H_2CO_3$: C, 47.55; H, 8.36; N, 6.05%.

Isopropyl 6-Benzyloxycarbonylamino-6-deoxy-α-L-idopyranoside (20). To a solution of **18** (18 mg) in 50% aqueous methanol (2 ml) were added benzyl chloroformate (0.03 ml) and anhydrous sodium carbonate (50 mg), and the mixture was stirred for 2 h under ice-cooling. Concentration gave a residue, that was extracted with hot acetone. The isolated product was purified by silica-gel column chromatography with chloroform–methanol (20:1) to give a solid of **20**, 18 mg (65%). Recrystallization from chloroform–hexane gave needles, mp 157.5—159.5 °C, $[\alpha]_D^{25}$ −93° (*c* 1, chloroform). ^{1}H NMR ($CDCl_3$ containg slight D_2O): δ=1.20 and 1.25 (each 3H, d, CH*Me*$_2$), 5.02 (1H, d, *J*≈1 Hz, H-1), 5.19 (2H, s, PhC*H*$_2$CO$_2$).

Found: C, 57.20; H, 6.93; N, 3.82%. Calcd for $C_{17}H_{25}NO_7$: C, 57.46; H, 7.04; N, 3.94%.

Isopropyl 6-Benzyloxycarbonylamino-6-deoxy-β-L-idopyranoside (21). Compound **19** (55 mg) was treated similarly as described for **20** to give a solid of **21**, 67 mg (79%), $[\alpha]_D^{25}$ +10° (*c* 1, chloroform). ^{1}H NMR ($CDCl_3$ containing slight D_2O): δ=1.18 and 1.26 (each 3H, d, CH*Me*$_2$), 4.88 (1H, apparent s, H-1), 5.14 (2H, s, PhC*H*$_2$CO$_2$).

Found: C, 57.19; H, 7.06; N, 3.86%. Calcd for $C_{17}H_{25}NO_7$: C, 57.46; H, 7.04; N, 3.94%.

Periodate Oxidations of 20 and 21. A mixture of **20** or **21** (4.0 mg, each, 11.27 μM) and sodium periodate (12 mg, 56 μM) in water (1.2 ml) was stirred at 5 °C for 2 days. Analysis of the formic acid liberated by color detection method (at 450 mμ) by 5,5-diethyl-2-thiobarbituric acid[17] showed 14.20 and 14.75 μM (1.26 and 1.31 molar equiv for **20**), and 13.40 and 13.65 μM (1.19 and 1.21 molar equiv for **21**) formic acid.

New Synthesis and Some Reactions of Vinyl Arenecarbodithioates. Wittig Reaction of (Triphenylphosphonio)methyl Arenecarbodithioate Iodides

Masaru ISHIDA, Koh-ichi KAGA, Hiroyuki SATO, Masato YOKOI, and Shinzi KATO*
Department of Chemistry, Faculty of Engineering, Gifu University, Yanagido, Gifu 501-11
(Received November 29, 1985)

Wittig reaction of new phosphonium salts, (triphenylphosphonio)methyl arenecarbodithioate iodides, with variety of aldehydes gave the corresponding vinyl arenecarbodithioates in moderate to good yields. Reaction of the vinyl dithiocarboxylate with nucleophiles such as potassium alkoxide or alkanethiolate was investigated and found to give the thioacylated products in high yields. Ab initio molecular orbital calculations of the model compound, vinyl dithioformate, are also discussed.

During the investigation on dithiocarboxylic acid derivatives,[1] the dithiocarboxylic ester containing a double bond α to the sulfide sulfur has attracted our attention, because of the interest in the spectral and physical properties and the potential usefulness as synthetic intermediates. Recently, the following three methods have been reported for the synthesis of vinyl alkanedithioates, 1) base-catalysed rearrangement of allyl dithiocarboxylate;[2] 2) base-induced ring opening of 2-ylidene-1,3-dithiolanes;[3] and 3) addition reaction of dithiocarboxylic acid to acetylene derivatives.[4] However, for the synthesis of vinyl arenecarbodithioates **6**, no general method has been developed.

In our preliminary report,[5] we have described a convenient and general synthesis of the esters **6** via Wittig reaction of (triphenylphosphonio)methyl arenecarbodithioate iodides **3**[6,7] with various aldehydes. In the present paper, we report full details of our study on the preparation of vinyl arenecarbodithioates and their synthetic applications together with results of molecular orbital calculation of vinyl dithioformate, which provide the estimation of the reactivity and structure of **6**.

Results and Discussion

Synthesis of the Phosphonium Salts. The phosphonium salts **3** are easily prepared by addition of piperidinium arenecarbodithioates **1**[8] to a chloroform suspension of (iodomethyl)triphenylphosphonium iodide (**2**)[9] at room temperature (Table 1). The crude salts **3** dried in vacuo were pure enough to be subjected to the following reactions. The structures of **3** were confirmed on the basis of spectral data and elemental analyses. For example, the ^{1}H NMR spectrum of the phosphonium salt **3c** showed a doublet peak at δ 6.08 with a coupling constant of 8 Hz (J_{H-P}). The IR spectrum of **3c** showed an absorption at 1240 cm^{-1} due to thiocarbonyl stretching frequency. The UV spectrum exhibited an absorption band at 360 nm (log ε=4.36) due to $\pi\rightarrow\pi^*$ transitions. At visible region, an absorption band was observed at 483 nm (log ε=2.53) due to $n\rightarrow\pi^*$ transitions of thiocarbonyl moiety with the hypsochromic shift from that of methyl 4-methoxybenzenecarbodithioate.[10]

a) Isolated yield.

Synthesis of Vinyl Arenecarbodithioates. The Wittig reaction of the phosphonium salts **3** was carried out as follows. The salt **3** suspended in tetrahydrofuran (THF) was treated with an equimolar amount of potassium *t*-butoxide at −75 °C under argon atmosphere to give a deep purple solution of the ylide **4**.[11] Then, the aldehyde **5a, b, d,** or **e** was added to the solution and the mixture was gradually warmed to 0 °C (Method A). After workup, the corresponding vinyl arenecarbodithioates **6** were obtained in moderate to good yields. In the reaction with relatively inactive aldehydes **5c** and **f—i**, forcing conditions were required: The aldehyde **5** was added to the ylide solution at −30 °C and the reaction mixture was maintained at that temperature with stirring for 0.5—5 h (Method B). The cis/trans ratios of the products **6** seem to be dependent on the

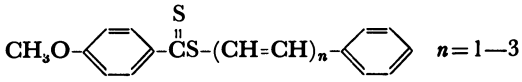
Scheme 2.

Spectra of Vinyl Arenecarbodithioates. The typical spectra are exemplified by the vinyl dithiocarboxylate **6i**. The ^{1}H NMR spectrum of the crude **6i** showed two doublet peaks at δ 6.17 (J=10.0 Hz) and 6.29 (J=16.0 Hz) with an integration ratio of 1:1. The former resonance is due to the olefinic proton of *cis*-**6i** and the latter is due to that of *trans*-**6i**.[4] The geometrically pure samples were obtained from fractional recrystallization from methanol. The IR spectra of *cis*-and *trans*-**6i** showed C=S stretching absorptions at 1245 and 1240 cm^{-1}, respectively. The UV spectra of *cis*- and *trans*-**6i** showed absorption maxima due to $\pi\rightarrow\pi^*$ transitions of thiocarbonyl moieties at 362 (log ε=4.33) and 361 nm (log ε=4.41), respectively. In the visible spectra, the absorptions due to n→π^* transition were observed at 505 nm (*cis*-**6i**; log ε=2.41) and at 502 nm (*trans*-**6i**; log ε=2.51). It is noted that the wavelengths of the absorption maxima due to thiocarbonyl moieties of the vinyl dithiocarboxylates **6d**, **f**, and **j** (4-$CH_3OC_6H_4$-CS_2-$(CH=CH)_n$-Ph, n=1—3) are clearly dependent on the number of conjugated double bonds of enethiolate moieties (Table 3).

Table 3. The Absorption Bands of Electron Spectra with High Molar Absorptivities (log ε>4) of a Series of Vinyl Dithiocarboxylates **6d**, **f**, and **j**



Compound No.	n	Absorption [nm] (log ε)[a]		
6d	1			356 (4.47)[b]
6f	2	296 (4.44)	350 (4.39)	400 (4.31)[c]
6j	3		334 (4.67)	418 (4.43)[c]

a) CH_2Cl_2 as a solvent. b) n→π^* transition band of thiocarbonyl moiety of **6d** was observed at 503 nm (log ε=2.53). c) Other absorption maxima were not observed at visible region.

Reaction of Vinyl Dithiocarboxylates with Nucleophiles. Since the enethiolate moiety of the ester **6** can be considered as a good leaving group, the reaction of **6** with some nucleophiles such as potassium alkoxides and alkanethiolates was investigated.

A solution of **6e** in THF was added to a solution of equimolar amount of potassium methoxide in

methanol at 0 °C under nitrogen atmosphere. The resulting deep purple solution[12] was stirred for 2 h at that temperature and then quenched with phenacyl bromide to give *O*-methyl 4-methoxybenzenecarbothioate (**7a**) in 80% yield.[13] The counter part, potassium ethenethiolate **8**, was isolated as a vinyl sulfide **10a** in 84% yield. High yield formation of **10a** may suggest that the vinyl dithiocarboxylate **6** can be considered as a useful precursor of enethiolate **8**. In a similar manner, potassium phenolate was converted into *O*-phenyl 4-methoxybenzenecarbothioate (**7d**) in 77% yield.

It is noteworthy that the reaction of **6e** with potassium 2-methyl-2-propanethiolate also gave *t*-butyl 4-methoxy-benzenecarbodithioate (**9c**) in 51% yield, which can not be prepared by esterification of piperidinium or alkali metal dithiocarboxylate with *t*-butyl bromide (Table 4).

The structural confirmation of the products **7**, **9**, and **10** were performed on the basis of the comparison of their spectra and physical properties with those of the authentic samples.[13–18]

Molecular Orbital Calculation. In order to estimate the reactivity and the structure of the vinyl dithiocarboxylates **6**, molecular orbital calculations were performed on the model compound, vinyl dithioformate (**11**). Two sets of the conformers, **11-I** and **11-II**, were optimized by the ab initio MO calculation with the minimal (STO-3G) basis set. The calculation of the total energy showed that the conformer **II** is more stable than the conformer **I** with the energy difference of 0.154 eV (14.9 kJ mol^{-1}) (Fig. 1).

The frontier orbitals of the conformers are illustrated in Fig. 2. The HOMO of the conformer I is a nonbonding orbital of thiocarbonyl sulfur. Whereas HOMO of the conformer **II** is a π-allyl type orbital at carbodithioate moiety. Thus, the [3+2] cycloaddition reactions[19] with dienophiles at dithiocarboxy moiety may be expected. The LUMO is π^* orbital of thiocarbonyl moiety and the coefficient is largest at thiocarbonyl carbons in both of the conformers. These calculation are well-compatible with experimental results.

In summary, the first general synthesis of vinyl arenecarbodithioate **6** via Wittig reaction of (triphenylphosphonio)methyl arenecarbodithioate iodide **3** have been developed. Some reactions of the vinyl

Experimental

Melting points were determined using a Yanagimoto melting point apparatus and are uncorrected. The IR spectra were measured on a JASCO grating IR spectrometer IR-G. The UV and Vis spectra were measured on a Hitachi 124 spectrophotometer. The ^{1}H NMR spectra were recorded on Hitachi R-24 (60 MHz), Hitachi R-22 (90 MHz), and JEOL-JNM-GX 270 (270 MHz) with tetramethylsilane as an internal standard. Mass spectra were recorded on Hitachi RMU-6M mass spectrometer at an ionizing voltage of 20 eV. Elemental analyses were performed by Elemental Analysis Center of Osaka Univer-

sity.

Preperation of [4-Methoxy(thiobenzoyl)thiomethyl]triphenylphosphonium Iodide (3c): Typical Procedure: To a solution of (iodomethyl)triphenylphosphonium iodide (**2**, 2.65 g, 5 mmol) in methanol/dichloromethane (1:3, 450 mL), piperidinium 4-methoxybenzenecarbodithioate (**1c** 1.34 g, 5 mmol) was added at room temperature. The mixture was stirred for an hour. After removal of the solvent in vacuo, the residue was poured into dichloromethane (100 mL), washed with water (3×50 mL), and dried over anhydrous sodium sulfate. Addition of ethyl acetate (50 mL) to the extracts followed by condensation in vacuo to ca. 50 mL gave the salt **3c** as orange precipitates (1.815 g, 62%). Recrystallization from dichloromethane/ethyl acetate (2:1) gave analytically pure **3c**: Mp 202—205 °C; IR (KBr) 1250 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 360 nm (log ε=4.36), 483 nm (log ε=2.53); ^1H NMR ($CDCl_3$) δ=3.76 (3H, s, CH_3), 6.08 (2H, d, J=8 Hz, CH_2), 6.7 (2H, d, aromatic), 7.40—8.15 (17H, m, aromatic). Found: C, 55.43; H, 4.08%. Calcd for $C_{27}H_{24}OS_2PI$: C, 55.29; H, 4.12%.

[(Thiobenzoyl)thiomethyl]triphenylphosphonium Iodide (3a): Similarly to the synthesis of **3c**, from the salt **2** (2.65 g, 5.0 mmol) and piperidinium benzenecarbodithioate (**1a**, 1.19 g, 5.0 mmol) was obtained 1.46 g (53%) of the salt **3a**. Pure **3a** was recrystallized from dichloromethane/ethyl acetate (1:1): Mp 174—178 °C; IR (KBr) 1230 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 308 nm (log ε=4.37), 483 nm (log ε=2.34); ^1H NMR ($CDCl_3$*) δ=5.90 (2H, d, J=9 Hz, CH_2), 7.20—8.20 (20H, m, aromatic). Found: C, 56.09; H, 4.03%. Calcd for $C_{26}H_{22}S_2PI$: C, 56.13; H, 3.99%. *Containing 5% of DMSO-d_6.

[4-Methyl(thiobenzoyl)thiomethyl]triphenylphosphonium Iodide (3b): Similarly to the synthesis of **3c** from the salt **2** (2.65 g, 5.0 mmol) and piperidinium 4-methylbenzenecarbodithioate (**1b**, 1.27 g, 5.0 mmol) was obtaind 2.20 g (77%) of the salt **3b**. Pure **3b** was recrystallized from dichloromethane/ethyl acetate (1:1): Mp 179—182 °C; IR (KBr) 1240 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 321 nm (log ε=4.38), 487 nm (log ε=2.44); ^1H NMR ($CDCl_3$*) δ=2.42 (3H, s, CH_3), 5.85 (2H, d, J=9 Hz, CH_2); 7.20—8.15 (19H, m, aromatic). Found: C, 56.89; H, 4.19%. Calcd for $C_{27}H_{24}S_2PI$: C, 56.85; H, 4.24%. *Containing 5% of DMSO-d_6.

2-Phenylvinyl 4-Methoxybenzenecarbonditioate (6d): Typical Procedures (Method A): To the salt **3c** (0.587 g, 1.0 mmol) suspended in dry THF (30 mL) was added potassium t-butoxide (0.112 g, 1.0 mmol) under argon atmosphere at −75 °C. The mixture was stirred for 30 min. Then benzaldehyde (**5a**, 0.11 g, 1.0 mmol) was added and the mixture was gradually warmed to 0 °C within 3 h. The mixture was poured into water (50 mL), extracted with ether (3×50 mL), and the extract was dried over anhydrous sodium sulfate. After removal of the solvent, the residue was chromatographed on silica gel (benzene/hexane=1:10 as eluant) to give a red oil. After addition of ethanol, the oil was cooled at −20 °C to give 0.112 g (39%) of red crystalls of **6d**: Mp 49—50 °C; IR (KBr) 1245 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 356 nm (log ε=4.47), 503 nm (log ε=2.53); ^1H NMR ($CDCl_3$) δ=3.85 (3H, s, CH_3), 6.90 (1H, d, J=11 Hz, vinyl), 6.75—8.20 (10H, m, aromatic and vinyl); MS m/z, 286 (M^+). Found: C, 66.98; H, 4.98; S, 22.41%. Calcd for $C_{16}H_{14}OS_2$: C, 67.00; H, 4.93; S, 22.36%.

2-(4-Nitrophenyl)vinyl Benzenecarbodithioate (6a): Similarly to the synthesis of **6d**, from the salt **3a** (0.556 g, 1.0 mmol) and 4-nitrobenzaldehyde (**5b**, 0.15 g, 1.0 mmol) was obtained 0.14 g (45%) of **6a** as red crystals. Recrystallization from ethanol gave pure **6a**: Mp 135—138 °C; IR (KBr) 1225 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 328 nm (log ε=4.42), 512 nm (log ε=2.38); ^1H NMR ($CDCl_3$) δ=7.0 (1H, d, J=12 Hz, vinyl), 7.3—8.4 (10H, m, aromatic and vinyl); MS m/z, 301 (M^+). Found: C, 59.43; H, 3.75; N, 4.53%. Calcd for $C_{15}H_{11}NO_2S_2$: C, 59.78; H, 3.68; N, 4.65%.

2-Phenylvinyl 4-Methylbenzenecarbodithioate (6b): Similarly to the synthesis of **6d**, from the salt **3b** (0.571 g, 1.0 mmol) and benzaldehyde (**5a**, 0.11 g, 1.0 mmol) was obtained 0.20 g (75%) of **6b** as red crystals: Mp 50—51 °C; IR (KBr) 1245 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 328 nm (log ε=4.32), 503 nm (log ε=2.40); ^1H NMR ($CDCl_3$) δ=2.35 (3H, s, CH_3), 6.95 (1H, d, J=11.3 Hz, vinyl), 7.10—8.20 (10H, m, aromatic and vinyl); MS m/z, 270 (M^+). Found: C, 70.82; H, 5.23; S, 23.51%. Calcd for $C_{16}H_{14}S_2$: C, 71.07; H, 5.22; S, 23.68%.

2-(4-Nitrophenyl)vinyl 4-Methylbenzenecarbodithioate (6c): Similarly to the synthesis of **6d**, from the salt **3b** (0.571 g, 1.0 mmol) and 4-nitrobenzaldehyde (**5b**, 0.15 g, 1.0 mmol) was obtained 0.28 g (89%) of **6c**. Recrystallization from ethanol gave pure **6c**: Mp 122—128 °C; IR (KBr) 1255 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 332 nm (log ε=4.43), 507 nm (log ε=2.34); ^1H NMR ($CDCl_3$) δ=2.35 (3H, s, CH_3), 6.92 (1H, d, J=11.3 Hz, vinyl), 7.05—8.40 (9H, m, aromatic and vinyl); MS m/z, 315 (M^+). Found: C, 61.12; H, 4.15%. Calcd for $C_{16}H_{13}NO_3S_2$: C, 60.93; H, 4.15%.

2-(4-Nitrophenyl)vinyl 4-Methoxybenzenecarbodithioate (6e): Similarly to the synthesis of **6d**, from the salt **3c** (0.586 g, 1.0 mmol) and 4-nitrobenzaldehyde (**5b**, 0.151 g, 1.0 mmol) was obtained 0.186 g (56%) of **6e**. Recrystallization from methanol gave pure **6e** as orange needles (cis/trans=5:1): Mp 166—168 °C; IR (KBr) 1225 (C=S) cm^{-1}. UV and Vis (CH_2Cl_2) 367 nm (log ε=4.58), 504 nm (log ε=2.57); ^1H NMR ($CDCl_3$) δ=3.89 (3H, s, CH_3), 6.98 (0.8H, d, J=11.0 Hz, vinyl), 7.06 (0.2H, d, J=16.5 Hz, vinyl), 6.80—7.20 (2H, m, aromatic), 7.77 (0.8H, d, J=11.0 Hz, vinyl), 8.03 (0.2H, d, J=16.5 Hz, vinyl), 7.20—8.40 (6H, m, aromatic); MS m/z, 331 (M^+). Found: C, 57.95; H, 4.00; N, 4.21; S, 19.19%. Calcd for $C_{16}H_{13}NO_3S_2$: C, 57.99; H, 3.95; N, 4.23; S, 19.32%.

4-(4-Nitrophenyl)-1,3-butadienyl 4-Methoxybenzenecarbodithioate (6g): Similarly to the synthesis of **6d**, from the salt **3c** (0.586 g, 1.0 mmol) and 4-nitrocinnamaldehyde (**5d**, 0.177 g, 1.0 mmol) was obtained 0.32 g (88%) of the dithiocarboxylate **6g**. Recrystallization from dichloromethane/ethanol (2:1), gave pure **6g** as red crystals: Mp 192—194 °C; IR (KBr) 1245 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 365 nm (log ε=4.55), 513 nm (log ε=2.96); ^1H NMR ($CDCl_3$) δ=3.90 (3H, s, CH_3), 6.65—8.20 (12H, m, aromatic and olefinic); MS m/z, 357 (M^+). Found: C, 60.24; H, 4.32; N, 3.67; S, 17.73%. Calcd for $C_{18}H_{15}NO_3S_2$: C, 60.48; H, 4.23; N, 3.92; S, 17.94%.

4-(2-Nitrophenyl)-1,3-butadienyl 4-Methoxybenzenecarbodithioate (6h): Similarly to the synthesis of **6d**, from the salt **3c** (0.586 g, 1.0 mmol) and 2-nitrocinnamaldehyde (**5e**, 0.177 g, 1.0 mmol) was obtained 0.33 g (94%) of the sulfide **6h** as red crystals. Recrystallization from dichoromethane/ethanol gave pure **6h**: Mp 96—100 °C; IR (KBr) 1250

(C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 361 nm (log ε=4.52), 491 nm (log ε=2.72); ^1H NMR ($CDCl_3$) δ=3.85 (3H, s, CH_3), 6.5—8.3 (12H, m, aromatic and olefinic); MS *m/z*, 357 (M^+). Found: C, 60.35; H, 4.22; N, 3.98; S, 17.65%. Calcd for $C_{18}H_{15}NO_3S_2$: C, 60.48; H, 4.23; N, 3.92; S, 17.94%.

2-(4-Nitrophenyl)vinyl 4-Methoxybenzenecarbodithioate (6e): Typical Procedure (Method B): To the salt **3c** (0.587 mg, 1 mmol) suspended in 40 mL of dry THF was added potassium *t*-butoxide (0.112 g, 1 mmol) at −30 °C [Dry Ice/carbontetrachloride-chloroform (50:1)]. The solution was stirred for 30 min. Then, 4-nitrobenzaldehyde (**5b**, 0.151 g, 1 mmol) was added to the resulting deep purple solution of the ylide. The reaction mixture was gradually warmed to 0 °C with stirring within 3 h. After usual workup, was obtained 0.228 g (69%) of vinyl dithiocarboxylate **6e** as a mixture of cis and trans isomers (1:1). The ratio of the isomers was determined on the basis of ^1H NMR.

4-Phenyl-1,3-butadienyl 4-Methoxybenzenecarbodithioate (6f): Similarly to the synthesis of **6e** (Method B), from the salt **3c** (0.587 g, 1.0 mmol) and cinnamaldehyde (**5c**, 0.132 g, 1.0 mmol) was obtained 0.145 g (46%) of **6f** as red crystals. Recrystallization from methanol gave pure **6f**: Mp 95—97 °C; IR (KBr) 1250 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 296 nm (log ε=4.44), 350 nm (log ε=4.39), 400 nm (log ε=4.31); ^1H NMR ($CDCl_3$) δ=3.90 (3H, s, CH_3), 6.70—8.20 (13H, m, aromatic and olefinic); MS *m/z*, 312 (M^+).

4-Phenyl-1-buten-3-ynyl 4-Methoxybenzenecarbodithioate (6i): Similarly to the synthesis of **6e** (Method B), from the salt **3c** (1.173 g, 2.0 mmol) and 3-phenyl-2-propynal (**5f**, 0.26 g 2.0 mmol) was obtained 0.39 g (63%) of red crystals of **6i** as a mixture of cis and trans isomers (1:1). Fractional recrystallization from dichloromethane/methanol gave geometrically pure samples: *cis*-**6i**: red crystals: Mp 69—73 °C; IR (KBr) 1240 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 294 nm (log ε=4.19), 362 nm (log ε=4.33), 505 nm (log ε=2.41); ^1H NMR ($CDCl_3$) δ=3.87 (3H, s, CH_3), 6.17 (1H, d, *J*=10 Hz, vinyl), 7.70 (1H, d, *J*=8Hz, vinyl), 6.8—8.2 (9H, m, aromatic); MS *m/z*, 310 (M^+). Found: C, 69.56; H, 4.38%. Calcd for $C_{18}H_{14}OS_2$: C, 69.65; H, 4.55%. *trans*-**6i**: orange crystals: Mp 125—127 °C; IR (KBr) 1240 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 293 nm (log ε=4.33), 361 nm (log ε=4.41), 502 nm (log ε=2.51); ^1H NMR ($CDCl_3$) δ=3.87 (3H, s, CH_3), 6.29 (1H, d, *J*=16 Hz, vinyl), 7.65 (1H, d, *J*=16 Hz, vinyl), 6.8—8.1 (9H, m, aromatic); MS *m/z*, 310 (M^+). Found: C, 69.68; H, 4.36%. Calcd for $C_{18}H_{14}OS_2$: C, 69.65; H, 4.55%.

6-Phenyl-1,3,5-hexatrienyl 4-Methoxybenzenecarbodithioate (6j): Similarly, from the salt **3c** (1.17 g, 2.0 mmol) and potassium *t*-butoxide (0.235 g, 2.0 mmol) was prepared 2.0 mmol of the ylide. Then, 5-phenyl-2,4-pentadienal (**5g**, 0.316 g, 2.0 mmol) was added at −30 °C and the reaction mixture was stirred at that temperature for 5 h. After usual workup, 0.369 g (55%) of **6j** was obtained as red crystals. Recrystallization from hot methanol gave pure **6j**: Mp 169—170 °C; IR (KBr) 1245 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 334 nm (log ε=4.67), 418 nm (log ε=4.43); ^1H NMR ($CDCl_3$) δ=3.83 (3H, s, CH_3), 6.33—8.13 (15H, m, aromatic and olefinic); MS *m/z*, 338 (M^+). Found: C, 70.80; H, 5.38%. Calcd for $C_{20}H_{18}OS_2$: C, 70.97; H, 5.36%.

1-Propenyl 4-Methoxybenzenecarbodithioate (6k): Similarly to the synthesis of **6j**, from the salt **3c** (0.587 g, 1.0 mmol) and acetaldehyde (**5h**, 0.04 g, 0.9 mmol) was obtained 0.132 g (65%) of **6k** as a red oil (cis/trans=3:2). Analytically pure sample was obtained by preparative TLC (R_f=0.6, dichloromethane/hexane=2:3): IR (neat) 1235 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 347 nm (log ε=3.72), 500 nm (log ε=1.71); ^1H NMR* ($CDCl_3$) δ=1.89 (1.8H, dd, *J*=1.5 and 7.0 Hz, CH_3), 1.97 (1.2H, dd, *J*=1.5 and 6.6 Hz, CH_3), 3.85 (3H, s, CH_3), 6.16 (0.4H, qd, *J*=6.6 and 15.6 Hz, vinyl), 6.16 (0.6H, qd, *J*=7.0 and 9.52 Hz, vinyl), 6.8—7.0 (2H, m, aromatic), 6.84 (0.4H, qd, *J*=1.2 and 15.6 Hz, vinyl), 7.02 (0.6H, qd, *J*=1.2 and 9.5 Hz, vinyl), 8.0—8.2 (2H, m, aromatic); MS *m/z*, 224 (M^+). Found: C, 58.68; H, 5.68%. Calcd for $C_{11}H_{12}OS_2$: C, 58.90; H, 5.39%. *270 MHz

1-Butenyl 4-Methoxybenzenecarbodithioate (6l): Similarly to the synthesis of **6j**, from the salt **3c** (0.587 g, 1.0 mmol) and propanal (**5i**, 0.06 g, 1.0 mmol) was obtained 0.066 g (28%) of **6l** as a red oil (cis/trans=1:1). Analytically pure sample was obtained by preparative TLC (R_f=0.8, dichloromethane/hexane=2:3): IR (neat) 1235 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 345 nm (log ε=4.13), 498 nm (log ε=2.14); ^1H NMR* ($CDCl_3$) δ=1.07 (1.5H, t, *J*=7.7 Hz, CH_3), 1.13 (1.5H, t, *J*=7.3 Hz, CH_3), 2.2—2.4 (2H, m, CH_2), 3.85 (3H, s, CH_3), 6.07 (0.5H, td, *J*=7.3 and 9.5 Hz, vinyl), 6.20 (0.5H, td, *J*=6.6 and 15.8 Hz, vinyl), 6.86 (0.5H, td, *J*=1.5 and 15.8 Hz, vinyl), 6.8—6.9 (2H, m, aromatic), 7.00 (0.5H, td, *J*=1.5 and 9.5 Hz, vinyl), 8.0—8.2 (2H, m, aromatic); MS *m/z*, 238 (M^+). Found: C, 60.42; H, 6.18%. Calcd for $C_{12}H_{14}OS_2$: C, 60.47; H, 5.92%. *270 MHz-NMR

***O*-Methyl 4-Methoxybenzenecarbothioate (7a): Typical Procedures:** A solution of the dithiocarboxylate **6e** (0.083 g, 0.25 mmol) in 50 mL of dry THF was added dropwise at −70 °C to a solution of potassium methoxide (0.028 g, 0.24 mmol) in methanol (10 mL). The reaction mixture was warmed to 0 °C and the resulting deep purple solution (Vis; λ_{max}=493 nm) was stirred at 0 °C for 20 min. Then, to the enethiolate generated phenacyl bromide (0.05 g, 0.25 mmol) in 10 mL of methanol was added and stirred for 10 min. The mixture was quenched by addition of 5 drops of concentrated hydrochloric acid. The color of the solution turned to pale red then to yellow. After removal of the solvent, the residue was diluted with 50 mL of dichloromethane and washed with water (3×30 mL) and dried over anhydrous sodium sulfate. After concentration, the residue was purified by preparative TLC (hexane/dichloromethane=2:1 as eluant) gave 0.036 g (80%, R_f=0.63) of **7a** as yellow crystals together with 0.063 g (84%, R_f=0.11) of phenacyl 2-(4-nitrophenyl) vinyl sulfide (**10a**)[6] as pale yellow crystals. **7a**: Mp 43.5—45 °C [lit, mp 47 °C,[13a] 45 °C,[13a]]; IR (KBr) 1250 (C=S) cm^{-1}; ^1H NMR (CD_3COCD_3) δ=3.87 (3H, s, CH_3), 4.24 (3H, s, CH_3), 6.9—8.15 (4H, m, aromatic) [lit,[13a] ^1H NMR (CD_3COCD_3) δ=3.89 (3H, s, CH_3), 4.27 (3H, s, CH_3), 7.0—8.22 (4H, m, aromatic)]; MS *m/z*, 182 (M^+).

***O*-Methyl 4-Methylbenzenecarbothioate (7b):** Similarly to the synthesis of **7a**, a solution of the dithiocarboxylate **6c** (0.079 g, 0.25 mmol) in 40 mL of THF was treated with potassium *t*-butoxide (0.028 g, 0.25 mmol) in methanol (10 mL). In this case, the enethiolate generated was quenched by 2,4-dinitrochlorobenzene (0.051 g, 0.25 mmol). After usual workup, the residue was purified by preparative TLC (hexane/dichloromethane=1:1 as eluant) to give 0.034 g (82%, R_f=0.75) of **7b** as yellow oil together with

0.043 g (43%, R_f=0.05) of **10b**. **7b**: IR (neat) 1230 (C=S) cm^{-1}; ^1H NMR (CD_3COCD_3) δ=2.38 (3H, s, CH_3), 4.24 (3H, s, CH_3), 7.20—8.02 (4H, m, aromatic) [lit,[13a] ^1H NMR (CD_3COCD_3) δ=2.34 (3H, s, CH_3), 4.27 (3H, s, CH_3), 7.24—8.12 (4H, m, aromatic)]; MS *m/z*, 166 (M^+). The IR spectrum was well consistent with that of the authentic sample.[15] **10b**: Mp 153—158 °C; IR (KBr) 1330, 1510 (NO_2) cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.73 (1H, d, *J*=10.5 Hz, vinyl), 7.20 (1H, d, *J*=10.5 Hz, vinyl), 7.6—7.9 (m, 3H, aromatic), 8.2—8.3 (m, 2H, aromatic), 8.43 (1H, dd, *J*=2.5 and 8.8 Hz, aromatic), 9.05 (1H, d, *J*=2.5 Hz, aromatic); MS *m/z*, 347 (M^+).

***O*-Ethyl 4-Methoxybenzenecarbothioate (7c):** Similarly to the synthesis of **7a**, the dithiocarboxylate **6e** (0.165 g, 0.5 mmol) was treated with potassium *t*-butoxide (0.056 g, 0.5 mmol) in ethanol (30 mL). After similar workup, the residue was purified by preparative TLC (ether/hexane=1:5 as eluant) to give 0.056 g (57%, R_f=0.45) of **7c** as yellow crystals together with 0.023 g (15%, R_f=0.1) of **10a**. **7c**: Mp 26—26.5 °C [lit,[16] mp 28—30 °C]; IR (KBr) 1220 (C=S) cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.49 (3H, t, *J*=7.2 Hz, CH_3), 3.87 (3H, s, CH_3), 4.69 (2H, q, *J*=7.2 Hz, CH_2), 6.9—8.2 (4H, m, aromatic); MS *m/z*, 196 (M^+).

***O*-Phenyl 4-Methoxybenzenecarbothioate (7d):** Similarly to the synthesis of **7b**, a solution of the dithiocarboxylate **6e** (0.083 g, 0.25 mmol) in 40 mL of THF was added dropwise at 20 °C to a solution of potassium phenoxide prepared from potassium *t*-butoxide (0.028 g, 0.25 mmol) and phenol (0.024 g, 0.25 mmol) in 10 mL of THF. The enethiolate generated was quenched by 2,4-dinitrochlorobenzene (0.05 g, 0.25 mmol) in 10 mL of THF. After similar workup, the residue was purified by preparative TLC (hexane/dichloromethane=1:1) to give 0.047 g (77%, R_f=0.47) of **7d** as pale yellow crystals together with 0.035 g (43%, R_f=0.04) of 2,4-dinitrophenyl 2-(4-nitrophenyl)vinyl sulfide (**10b**). **7d**: Mp 111—112 °C (recrystallized from methanol); IR (KBr) 1260 (C=S) cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.88 (3H, s, CH_3), 6.80—8.40 (9H, m, aromatic); MS *m/z*, 244 (M^+). Found: C, 68.35; H, 4.85%. Calcd for $C_{14}H_{12}O_2S$: C, 68.82; H, 4.95%.

Ethyl 4-Methoxybenzenecarbodithioate (9a): Typical Procedures: A solution of the dithiocarboxylate **6e** (0.083 g, 0.25 mmol) in THF (40 mL) was added dropwise to a solution of potassium ethanethiolate (0.25 mmol) prepared from potassium *t*-butoxide (0.028 g, 0.25 mmol) and ethanethiol (4 mL) in THF (10 mL) at −70 °C. The reaction mixture was stirred at that temperature for 1 h, then gradually warmed to −10 °C within 1 h. After standing for additional 1 h phenacyl bromide (0.05 g, 0.25 mmol) was added. After usual workup, the residue was purified by preparative TLC (hexane/dichloromethane=2:1 as eluant) to give 0.043 g (81%, R_f=0.48) of **9a** as reddish orange crystals, together with 0.056 g (75%, R_f=0.10) of **10a**. **9a**: Mp 20—21 °C [lit,[16] mp 22—25 °C]; IR (neat) 1235 (C=S) cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.40 (3H, t, *J*=7.5 Hz, CH_3), 3.45 (2H, q, *J*=7.5 Hz, CH_3), 3.80 (3H, s, CH_3), 6.75—8.10 (4H, m, aromatic); MS *m/z*, 212 (M^+).

Ethyl 4-Methylbenzenecarbodithioate (9b): Similarly to the synthesis of **9a**, the dithiocarboxylate **6c** (0.079 g, 0.25 mmol) was treated with potassium ethanethiolate (0.025 g, 0.25 mmol) in ethanol (10 mL). The enethiolate generated was quenched by 2.4-dinitrochlorobenzene (0.05 g, 0.25 mmol). After usual workup, the residue was purified by preparative TLC (hexane/dichloromethane=1:1) to give 0.030 g (67%; R_f=0.80) of **9b** as a red oil, together with 0.044 g (56%; R_f=0.05) of **10b**. **9b**: IR (neat) 1230 (C=S) cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (3H, t, *J*=7.5 Hz, CH_3), 2.30 (3H, s, CH_3), 3.32 (2H, q, *J*=7.5 Hz, CH_2), 7.13 (2H, m, aromatic), 7.90 (m, 2H, aromatic) [lit,[17] ^1H NMR ($CDCl_3$) δ=1.3 (3H, t), 2.3 (3H, s), 3.3 (2H, q), 7.2 (2H, m), 7.9 (2H, m)]; MS *m/z*, 196 (M^+).

***t*-Butyl 4-Methoxybenzenecarbodithioate (9c):** Similarly to the synthesis of **9a**, a solution of the dithiocarboxylate **6e** (0.083 g, 0.25 mmol) in THF (40 mL) was treated with potassium 2-methyl-2-propanethiolate (0.032 g, 0.25 mmol) in THF (10 mL). After usual workup, the residue was purified by preparative TLC (hexane/dichloromethane=2:1 as eluant) to give 0.031 g (51%, R_f=0.55) of **9c** as reddish orange crystals, together with 0.052 g (70%, R_f=0.12) of **10a**. **9c**: Mp 37.5—39.5 °C; IR (KBr) 1240 (C=S) cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.65 (9H, s, CH_3), 3.80 (3H, s, CH_3), 6.75—8.25 (4H, m, aromatic); MS *m/z*, 240 (M^+). All of the spectra were well consistent with those of authentic sample.[1c]

Phenyl 4-Methoxybenzenecarbodithioate (9d): Similarly to the synthesis of **9a**, the dithiocarboxylate **6e** (0.083 g, 0.25 mmol) was treated with potassium benzenethiolate (0.037 g, 0.25 mmol) in ethanol (10 mL). After usual workup, the residue was purified by preparative TLC (ether/hexane=2:1 as eluant) to give 0.03 g (46%; R_f=0.36) of **9d** as red crystals, together with 0.061 g (82%; R_f=0.07) of **10a**. **9d**: Mp 79.5—83.0 °C [lit,[18] mp 83 °C]; IR (KBr) 1240 (C=S) cm^{-1}; UV and Vis (CH_2Cl_2) 361 nm (log ε=4.23), 511 nm (log ε=2.27); ^1H NMR ($CDCl_3$) δ=3.80 (3H, s, CH_3), 6.75—8.25 (4H, m, aromatic), 7.4 (5H, s, aromatic); MS *m/z*, 260 (M^+).

We wish to acknowledge associate Prof. Dr. Satoshi Inagaki of Gifu University for his valuable advices on molecular orbital calculation. The calculation was carried out on a Hitachi computer of Institute for Molecular Science.

(Received January 14, 1986)

Two disaccharide dipeptides, i.e., *O*-(*N*-acetyl-β-D-glucosaminyl)-(1→4)-*N*-acetylmuramyl-L-alanyl-D-isoglutamine (**2**) and *O*-(*N*-acetyl-β-muramyl-L-alanyl-D-isoglutamine)-(1→4)-*N*-acetyl-D-glucosamine (**3**), which correspond to partial structures of cell wall peptidoglycan were synthesized via the same glucosamine disaccharide as a common intermediate. Thus, selective introduction of lactic acid moiety on either one of the sugar moieties of the intermediate gave two disaccharides respectively which contain muramic acid on either reducing or nonreducing side. Coupling of the peptide moiety followed by deprotection afforded **2** and **3**. The results of biological tests showed that both **2** and **3** have the same magnitude of immunostimulating activities as those of *N*-acetylmuramyl-L-alanyl-D-isoglutamine which is the minimum structure required for expression of the activities.

Bacterial peptidoglycan is an integral part of the cell walls and known to exhibit a potent activity to modulate the defense mechanism of higher animals. Its structure is composed of glycan chains interlinked with peptide bridges. The former is β(1—4)glycan of alternating *N*-acetylglucosamine and *N*-acetylmuramic acid whose carboxyl group is the point of linkage to the peptide. It was independently demonstrated by us and a French group that the minimum structure required for the immunostimulation is *N*-acetylmuramyl-L-alanyl-D-isoglutamine (**1**), which is a common building block of the above architecture.[1,2] After this initial work, we prepared many derivatives and structural analogs of the muramyl peptide **1** and studied the relationship between their chemical structures and immunological activities.[3] In the meantime, comparison of immunopharmacological activities of various enzymatic digests of cell wall peptidoglycans has revealed that digests prepared with endopeptidases are generally more active than the muramyl dipeptide **1** as well as than digests obtained by use of glycosidases.[4] The endopeptidases are capable of hydrolyzing the cross linkages between the neighboring glycan chains, while the glycosidases split the glycan chain itself. These results seem to indicate that the presence of long glycan chain rather than the peptide network is required for efficient manifestation of these biological activities.

In view of the above findings, as the first step of a synthetic approach to a peptidoglycan polysaccharide peptides with stronger biological activities than the muramyl dipeptide **1**, we synthesized two disaccharide dipeptides, i.e., *O*-(*N*-acetyl-β-D-glucosaminyl)-(1→4)-*N*-acetylmuramyl-L-alanyl-D-isoglutamine (**2**) and *O*-(*N*-acetyl-β-muramyl-L-alanyl-D-isoglutamine)-(1→4)-*N*-acetyl-D-glucosamine (**3**), which correspond to structures having an *N*-acetylglucosamine unit β(1—4)-linked on either side of **1**. In other words, **2** and **3** are larger fragments of cell wall than **1** by one glucosamine residue.

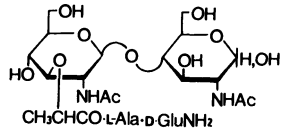
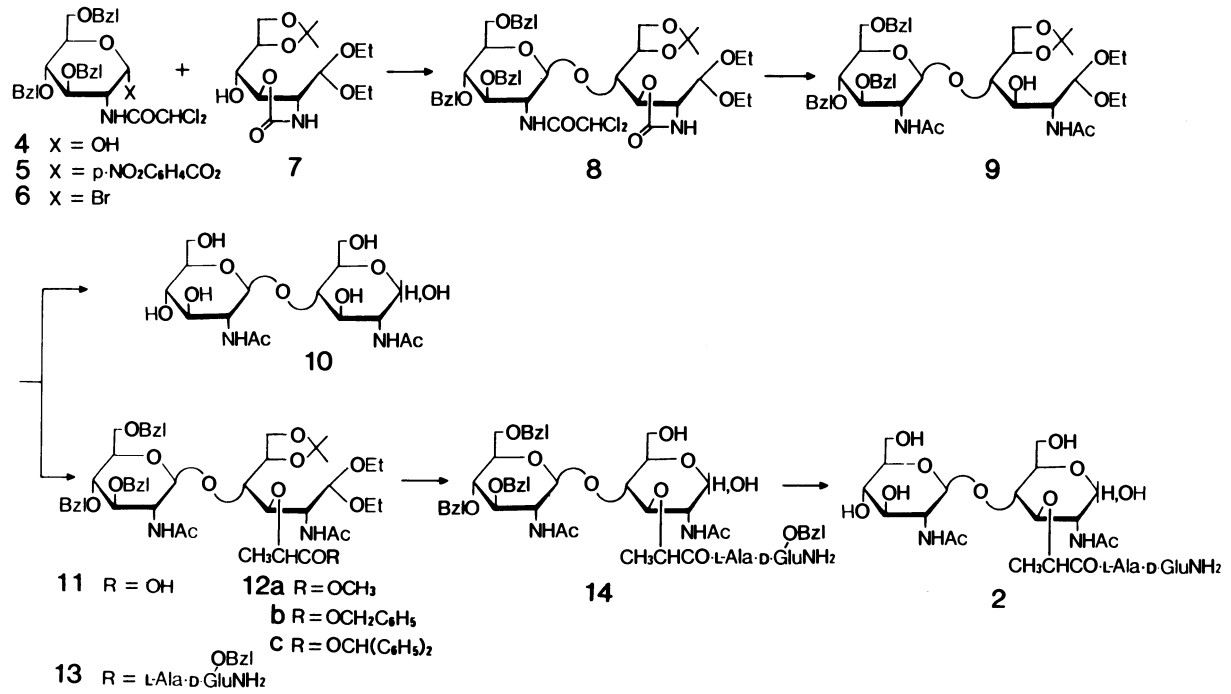
2



3

As reported in our preliminary communications,[5,6] the synthesis was performed via a common β(1—4)-linked disaccharide of glucosamine. One of its sugar residues was then selectively transformed into muramic acid to form the two alternative β(1—4)-linked disaccharides respectively. Coupling of the peptide moiety followed by deprotection afforded the desired products **2** and **3**. We describe in this paper the details of the synthesis. After our initial paper[5] on the synthesis of **2**, two other research groups also reported syntheses of both types of the disaccharide dipeptides via glucosamine disaccharides.[7,8] In the accompanying paper,[9] we also describe different approaches to form the corresponding disaccharide portions of **2** and **3** by means of a direct coupling of

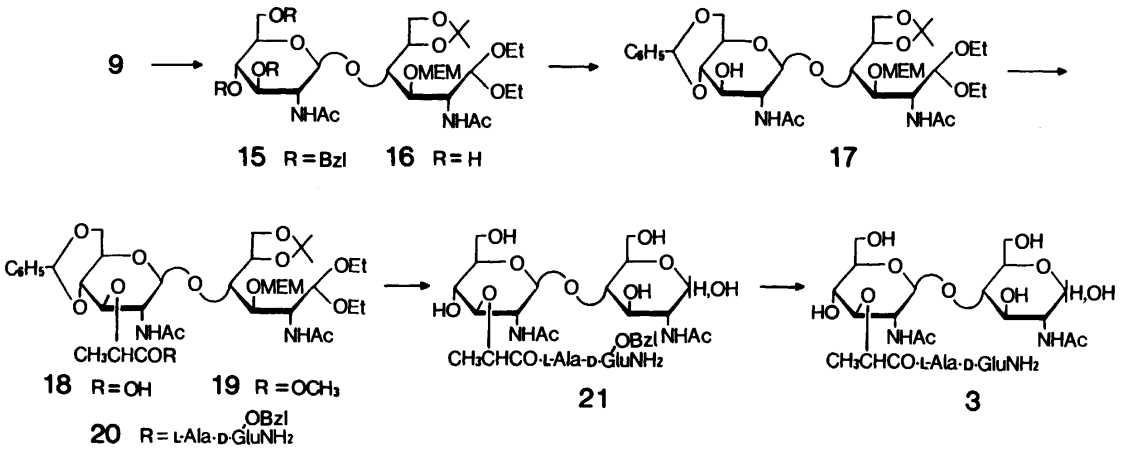


glucosamine and muramic acid residues.

In this investigation, an appropriate β(1—4)-linked glucosamine disaccharide which served as the common synthetic intermediate was prepared by coupling of the glycosyl bromide **6** with a known open-chain derivative of glucosamine, i.e., 2-amino-2-*N*: 3-*O*-carbonyl-2-deoxy-5,6-*O*-isopropylidene-D-glucose diethyl acetal (**7**).[10] The bromide **6** was prepared from 2-amino-3,4,6-tri-*O*-benzyl-2-deoxy-D-glucose.[11] After dichloroacetylation[12] of its amino group, the product **4** was converted into 1-*p*-nitrobenzoate **5** and then treated with dry hydrogen bromide in dichloromethane to give **6**.[13] The condensation of **6** with **7** in the presence of mercury(II) cyanide in benzene afforded the disaccharide **8** as the main product. The β-configuration of the newly formed glycosidic bond was ascertained chemically by converting **8** into *N,N'*-diacetylchitobiose. Thus, cleavage of the oxazolidone and dichloroacetyl protecting groups in **8** by alkaline hydrolysis gave **9**. *N*-Acetylation followed by further deprotection afforded the disaccharide **10** which was identified with an authentic sample of *N,N'*-diacetylchitobiose obtained from natural chitin.

For the preparation of the disaccharide which has the muramic acid residue on the reducing side, **9** obtained above was used as an intermediate. In this compound only one hydroxyl group remains free on C-3 where lactic acid moiety should be introduced to form muramic acid. The hydroxyl group of **9** was thus converted into the sodium alkoxide and treated with (*S*)-2-chloropropionic acid as described by Matsushima and Park.[14] However, when only dioxane was used as solvent as described,[14] the yield of the product **11** was quite variable. This seemed to be due to the difficulty in formation of alkoxide anion in that solvent in which **9** was only poorly soluble. Use of DMF as co-solvent improved the situation and the desired disaccharide derivative **11** could be obtained in a reproducible yield. The product was purified and isolated after esterification with diazomethane, phenyldiazomethane, or diphenyldiazomethane as methyl, benzyl, or diphenylmethyl ester (**12a**, **b**, **c**), respectively. Among these, only the diphenylmethyl derivative was crystalline. The structure of **12** was confirmed by converting **12a** into a known peracetylated derivative of *O*-β-D-glucosaminyl-(1→4)-muramic acid methyl ester.[15,16] The ester group of **12** was again hydrolyzed after purification and the resultant, free carboxyl group was coupled with L-alanyl-D-isoglutamine benzyl ester[1b] by means of the dicyclohexylcarbodiimide (DCC)–*N*-hydroxysuccinimide procedure to give the fully protected disaccharide dipeptide **13**. Deprotection of **13** was performed in two steps. Thus, the two acetal groups were first removed with hot aqueous acetic acid to give **14**, which in turn was subjected to hydrogenolysis. The final product **2** was isolated as a homogeneous hygroscopic powder.

Another disaccharide having the muramic acid residue on the nonreducing end was also synthesized from **9**. After the free hydroxyl group on position 3 had been protected with 2-methoxyethoxymethyl (MEM) group, the benzyl groups were hydrogenolyzed and the two hydroxyl groups on positions 4' and 6' again protected as benzylidene derivative to give a disaccharide **17** to be used for introduction of lactic acid moiety at position 3'. It was condensed with



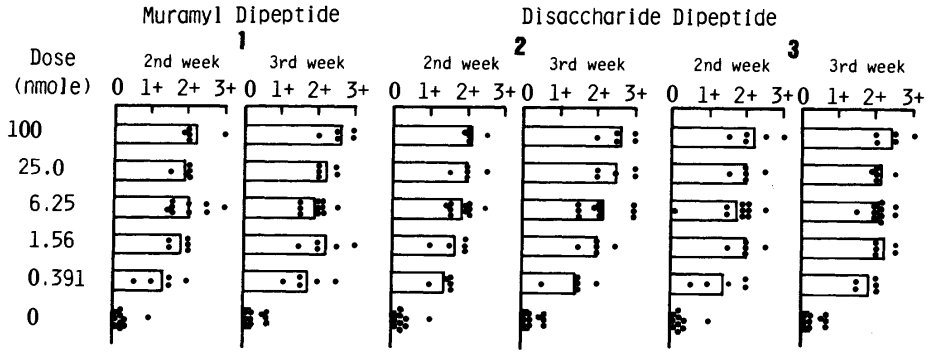


Fig. 1. Induction of delayed-type hypersensitivity against ovalbumin by **1**, **2**, and **3** in guinea pigs (corneal reaction). Each dot represents the score (arbitrarily graded with a maximum of 3+) for individual animal. Each column shows the mean score.

(*S*)-2-chloropropionic acid under similar conditions as above to afford the desired disaccharide **18** which was purified as the methyl ester **19** after esterification with diazomethane. Coupling of the dipeptide moiety as above gave a protected disaccharide dipeptide **20**, which was then subjected to deprotection reaction in two steps. In the first step when **20** was heated in aqueous acetic acid in order to remove all acetal-type protections, several by-products such as ethyl glycoside of the desired product were formed. However, by-products formation could be greatly suppressed by employing appropriate reaction conditions (see experimental section). The product **21** was isolated after purification with a column of porous polymer. It was then hydrogenolyzed to give the second disaccharide dipeptide **3**.

Immunoadjuvant activities of both disaccharide dipeptides prepared (**2** and **3**) were tested in guinea pigs by using ovalbumin as a test antigen. Their activities were compared with those of the muramyl dipeptide **1**. As shown in Figs. 1, 2, and 3, no significant differences were observed with the adjuvant activities among these compounds in terms of the induction of cellular immunity (as tested by corneal and tuberculin-type skin reactions) and the

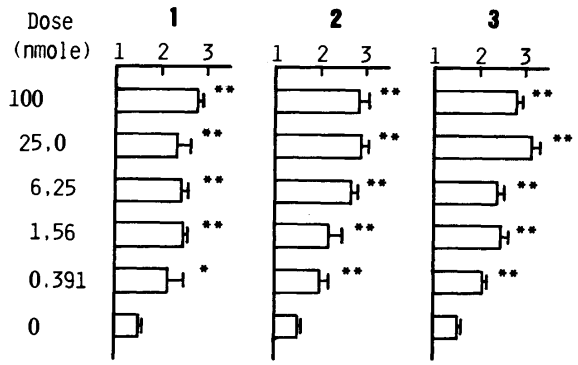

Fig. 2. Induction of delayed-type hypersensitivity against ovalbumin by **1**, **2**, and **3** in guinea pigs (tuberculin type of skin reaction). The extent of skin induration is expressed as ratios of the reading (48 h) at each test site to that at the control site. Significant difference from control group: $*P<0.05$, $**P<0.01$.

stimulation of humoral immunity (by determination of serum anti-ovalbumin level). We reported in a previous paper[17] that the glucosaminylmuramyl dipeptide **2** showed higher immunoadjuvant activities than **1**. Though discrepancy on this point might be due to the difference of antigen doses used for the

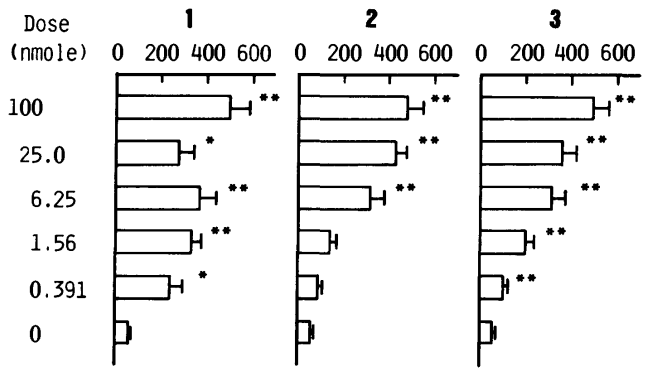

Fig. 3. Elevation of serum precipitating antibody levels against ovalbumin by **1**, **2**, and **3** in guinea pigs. Antibody level in serum is expressed as μg of antibody nitrogen per ml of serum. Significant difference from control group: $*P<0.05$, $**P<0.01$.

immunization (1 mg in the previous study and 0.1 mg in the present one), it should be concluded from the result obtained above that additional single glucosamine residue was not sufficient to induce a significant enhancement of the activities of **1**. Longer glycan chains might be required for effective potentiation. Synthesis of a peptidoglycan part structure with a longer saccharide is now being undertaken in our laboratory to confirm this assumption.

Experimental

All melting points are uncorrected. ^{1}H NMR spectra were measured for $CDCl_3$ solutions with tetramethylsilane as an internal standard (δ, ppm). FD-MS spectra were obtained with Si-emitter on JEOL OI-SG mass spectrometer. Optical rotations were measured with a Perkin-Elmer 141 polarimeter. Column chromatography and preparative thin-layer chromatography were carried out with Kieselgel 60 (0.063—0.2 mm) and with pre-coated Kieselgel F_{254} plates (0.5 mm thickness), E. Merck.

3,4,6-Tri-*O*-benzyl-2-deoxy-2-dichloroacetamido-D-glucopyranose (4). Pentachlorophenyl dichloroacetate (1.95 g, 5.16 mmol) and triethylamine (0.73 ml, 5.16 mmol) were added at room temperature to a stirred suspension of 2-amino-3,4,6-tri-*O*-benzyl-2-deoxy-D-glucose hydrochloride[11] (2.51 g, 5.16 mmol) in anhyd tetrahydrofuran (THF). After the mixture had been stirred at room temperature for 90 min, insoluble materials were filtered off, the filtrate evaporated in vacuo to give a gelatinous solid. It was purified by reprecipitation from dioxane–ether to give **4**; 2.38 g (82%); mp 217—219 °C(decomp). Found: C, 61.89; H, 5.56; N, 2.50; Cl, 12.50%. Calcd for $C_{29}H_{31}NO_6Cl_2$: C, 62.15; H, 5.58; N, 2.50; Cl, 12.56%.

3,4,6-Tri-*O*-benzyl-2-deoxy-2-dichloroacetamido-α-D-glucopyranosyl *p*-Nitrobenzoate (5). To an ice-cooled stirred solution of **4** (2.31 g, 4.12 mmol) in pyridine (50 ml) was added *p*-nitrobenzoyl chloride (2.30 g, 12.4 mmol) dissolved in a small amount of CH_2Cl_2. The mixture was stirred under ice-cooling for 2 h then at room temperature for 30 min. After usual work-up, the crude product was recrystallized from $CHCl_3$–ether; 2.50 g (86%); mp 173—174 °C; $[\alpha]_D^{20}$ +125° (*c* 1.00, $CHCl_3$). Found: C, 60.72; H, 4.82; N, 3.81; Cl, 9.89%. Calcd for $C_{36}H_{34}N_2O_9Cl_2$: C, 60.49; H, 4.83; N, 3.95; Cl, 9.99%.

3,4,6-Tri-*O*-benzyl-2-deoxy-2-dichloroacetamido-D-glucopyranosyl Bromide (6). A saturated solution of dry HBr in dry CH_2Cl_2 (5.5 ml) was added to a solution of **5** (2.00 g, 2.82 mmol) in dry CH_2Cl_2 (30 ml). The mixture was left stand at room temperature for 30 min. The precipitate of *p*-nitrobenzoic acid was removed by filtration. The residue obtained by evaporation of the solvent in vacuo at room temperature was dried over KOH and P_2O_5 in a desiccator overnight. It was used for the next coupling reaction without further purification.

2-Amino-4-*O*-(3,4,6-tri-*O*-benzyl-2-deoxy-2-dichloroacetamido-β-D-glucopyranosyl)-2-*N*: 3-*O*-carbonyl-2-deoxy-5,6-*O*-isopropylidene-D-glucose Diethyl Acetal (8). Dry benzene (30 ml) was added to 2-amino-2-*N*:3-*O*-carbonyl-2-deoxy-5,6-*O*-isopropylidene-D-glucose diethyl acetal (**7**) (0.90 g, 2.82 mmol) and powdered $Hg(CN)_2$ (2.14 g, 8.46 mmol). From this mixture, benzene (ca. 10 ml) was distilled off in order to remove the remaining trace of water. After cooling, a solution of the bromide **6** [obtained from **5** (2.00 g, 2.82 mmol)] in dry benzene (20 ml) was added and the mixture was stirred at room temperature for 24 h. The reaction mixture was diluted with $CHCl_3$, washed successively with 10% brine and H_2O, and dried ($MgSO_4$). The product was purified by chromatography on a silica-gel column ($CHCl_3$–acetone 6:1). Recrystallization from benzene–hexane gave **8**; 0.81 g (33%); mp 52—57 °C. $[\alpha]_D^{17}$ −11.0° (*c* 1.00, $CHCl_3$). Found: C, 59.74; H, 6.37; N, 3.23; Cl, 8.13%. Calcd for $C_{43}H_{54}N_2O_{11}Cl_2$: C, 59.92; H, 6.33; N, 3.25; Cl, 8.23%.

2-Acetamido-4-*O*-(2-acetamido-3,4,6-tri-*O*-benzyl-2-deoxy-β-D-glucopyranosyl)-2-deoxy-5,6-*O*-isopropylidene-D-glucose Diethyl Acetal (9). A mixture of **8** (4.25 g, 4.93 mmol) and $Ba(OH)_2 \cdot 8H_2O$ (18.6 g, 59.1 mmol) in dioxane (43 ml) and H_2O (43 ml) was heated at 100 °C with stirring for 16 h. The mixture was cooled, neutralized with CO_2 and filtered. The filtrate was concentrated in vacuo. The residue was dissolved in pyridine (50 ml), treated with acetic anhydride (13.9 ml), and worked up as usual. The crude acetylation product was dissolved in MeOH (80 ml), and 1M†† NaOMe in MeOH (8 ml) was added to it. The mixture was stirred at room temperature for 1 h and neutralized with Dowex 50 (H^+). Evaporation of the solvent in vacuo and purification with silica-gel column chromatography ($CHCl_3$–MeOH 15:1) afforded **9** as colorless syrup; 3.56 g (89%). ^{1}H NMR: 1.13 (6H, t, J=6.8 Hz $OCH_2C\underline{H}_3$), 1.28 and 1.40 (each 3H, s, isopropylidene CH_3), 1.90 (6H, s, $COCH_3$), 7.37 (15H, s, $OCH_2C_6\underline{H}_5$).

***N,N'*-Diacetylchitobiose (10).** Compound **9** (310 mg) was heated at 80 °C in 60% aq AcOH (10 ml) with stirring for 1 h. After evaporation of the solvent in vacuo, the residue was recrystallized from ethanol–hexane and then subjected to hydrogenolysis on Pd-black in 50% AcOH. The product was purified with preparative TLC (phenol–H_2O 3:1) to give a solid, 40 mg (27%), which was recrystallized from H_2O–acetone; mp 242—243 °C(decomp);

†† 1 M=1 mol dm^{-3}.

$[\alpha]_D^{22}$ +16.3° (*c* 0.40, H_2O; after equilibration). This product was identified with an authentic specimen of *N,N'*-diacetylchitobiose (mp 240—241 °C decomp, $[\alpha]_D^{22}$ +17.5°) by means of TLC and ^1H NMR.

2-Acetamido-4-*O*-(2-acetamido-3,4,6-tri-*O*-benzyl-2-deoxy-β-D-glucopyranosyl)-3-*O*-[(*R*)-1-(benzyloxycarbonyl)ethyl]-2-deoxy-5,6-*O*-isopropylidene-D-glucose Diethyl Acetal (12b). Sodium hydride (50% oil dispersion, 1.1 g, 23 mmol) was added to a solution of **9** (5.30 g, 6.56 mmol) in a mixture of dioxane (120 ml)–DMF(60 ml) at room temperature. After the mixture had been stirred at 60 °C for 20 min, (*S*)-2-chloropropionic acid (2.13 g, 20 mmol) and then NaH (1.3 g, 26 mmol) were added. The mixture was stirred at 60 °C for 8 h, cooled and the excess of NaH was decomposed by addition of ice. Acidification with 1 M HCl followed by extraction with $CHCl_3$ gave crude free acid **11**, which was treated with phenyldiazomethane in $CHCl_3$–hexane. The product was purified by silica-gel column chromatography (benzene–ethyl acetate 1:2) to give the benzyl ester **12b** as a pale yellow syrup; 3.0 g (47%); FD-MS: *m/z* 970 (M^+).

The corresponding methyl and diphenylmethyl esters **12a** and **c** were prepared in similar manners.

Compound 12a: Syrup; ^1H NMR: 1.12 (6H, t, *J*=7.0 Hz, $OCH_2C\underline{H}_3$), 1.25 and 1.38 (each 3H, s, isopropylidene CH_3), 1.25—1.38 (3H, $C\underline{H}_3CHCO_2$), 1.93 and 2.03 (each 3H, s, $COCH_3$), 3.73 (3H, s, CO_2CH_3), 7.33 (16H, C_6H_5 and $N\underline{H}COCH_3$).

Compound 12c: Mp 87—92 °C; $[\alpha]_D^{18}$ +21.0° (*c* 0.40, $CHCl_3$). Found: C, 68,99; H, 7.08; N, 2.56%. Calcd for $C_{60}H_{74}N_2O_{14}$: C, 69.05; H, 7.15; N, 2.68%.

2-Acetamido-4-*O*-(2-acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-1,4,6-tri-*O*-acetyl-2-deoxy-3-*O*-[(*R*)-1-(methoxycarbonyl)ethyl]-α-D-glucopyranose. Methyl ester (**12a**) (50 mg) was heated in 60% AcOH (1 ml) at 60 °C for 1 h then at 80 °C for 1 h. The main product was isolated by means of preparative TLC on silica gel ($CHCl_3$–MeOH 9:1). Hydrogenolysis followed by acetylation with acetic anhydride and pyridine afforded peracetate of methyl ester as a mixture of the α- and β-anomers. It was again dissolved in acetic anhydride and treated with $ZnCl_2$ at 40 °C for 14 h to enrich the α-acetate, which was isolated as needles through recrystallization from acetone-ether; mp 231—233 °C; $[\alpha]_D^{18.5}$ +42.9° (*c* 0.07, $CHCl_3$).

Reported values for the natural specimen isolated from bacterial cells: Mp 235—236 °C; $[\alpha]_D^{22}$ +40° (*c* 0.20, $CHCl_3$).[14] Those for a synthetic specimen: Mp 237—238 °C; $[\alpha]_D$ +38° (*c* 0.23, $CHCl_3$).[15]

Benzyl L-Alanyl-D-isoglutaminate *N*-Acylated with 2-Acetamido-4-*O*-(2-acetamido-3,4,6-tri-*O*-benzyl-2-deoxy-β-D-glucopyranosyl)-2-deoxy-5,6-*O*-isopropylidene-3-*O*-[(*R*)-1-carboxyethyl]-D-glucose Diethyl Acetal (13). A solution of methyl ester **12a** (0.63 g, 0.70 mmol) in 0.5 M KOH in MeOH (14 ml) was stirred at room temperature for 24 h. The mixture was acidified with 3M citric acid, diluted with water and extracted with CH_2Cl_2. The organic layer was washed with H_2O, dried ($MgSO_4$) and evaporated in vacuo to give **11** as a syrup. It was dried by coevaporation with benzene in vacuo and then dissolved in dry THF. Benzyl L-alanyl-D-isoglutaminate hydrochloride (0.36 g, 1.1 mmol) and triethylamine (0.15 ml, 1.1 mmol) was added to the solution and the mixture was stirred in an ice bath for 30 min. *N*-Hydroxysuccinimide (0.12 g, 1.1 mmol) and DCC (0.14 g, 0.70 mmol) were added. Stirring was continued under cooling overnight. After addition of DCC (0.03 g, 0.14 mmol), the mixture was stirred at room temperature for further 3 h. Usual work-up and purification by column chromatography on silica gel ($CHCl_3$–MeOH 9:1) followed by reprecipitation form benzene-hexane afforded **13** as amorphous solid; 0.48 g (59%); mp 55—65 °C; $[\alpha]_D^{18}$ +9.5° (*c* 0.21, $CHCl_3$). Found: C, 63.11; H, 7.33; N, 5.90%. Calcd for $C_{62}H_{83}N_5O_{17}\cdot 1/2H_2O$: C, 63.14; H, 7.18; N, 5.94%.

Benzyl L-Alanyl-D-isoglutaminate *N*-Acylated with 2-Acetamido-4-*O*-(2-acetamido-3,4,6-tri-*O*-benzyl-2-deoxy-β-D-glucopyranosyl)-2-deoxy-3-*O*-[(*R*)-1-carboxyethyl]-D-glucose (14). Compound **13** (0.35 g, 0.30 mmol) was heated in 60% AcOH at 60 °C for 70 min. The product was purified by preparative TLC on silica gel ($CHCl_3$–MeOH 9:1). Precipitation by addition of ethyl acetate–hexane to a $CHCl_3$–MeOH (2:1) solution afforded colorless solid; 0.18 g (57%); mp 187—194 °C(decomp); $[\alpha]_D^{18}$ +8.5° (*c* 0.13, pyridine). Found: C, 61.25; H, 6.55; N, 6.42%. Calcd for $C_{55}H_{69}N_5O_{16}\cdot H_2O$: C, 61.49; H, 6.66; N, 6.51%.

L-Alanyl-D-isoglutamine *N*-Acylated with 2-Acetamido-4-*O*-(2-acetamido-2-deoxy-β-D-glucopyranosyl)-2-deoxy-3-*O*-[(*R*)-1-carboxyethyl]-D-glucose (2). Compound **14** (135 mg, 0.13 mmol) was suspended in MeOH and hydrogenolyzed in the presence of Pd-black catalyst at room temperature. The product was precipitated from MeOH–acetone to give hygroscopic powder, 90 mg (quantitative); mp 170—178 °C (decomp); $[\alpha]_D^{24}$ +0.6° $[\alpha]_{365}^{24}$ −21.7° (*c* 1.0, H_2O after equilibration). Found: C, 45.36; H, 6.40; N, 9.66%. Calcd for $C_{27}H_{45}N_5O_{16}\cdot H_2O$: C, 45.44; H, 6.44, N, 9.81%.

4-*O*-(2-Acetamido-3,4,6-tri-*O*-benzyl-2-deoxy-β-D-glucopyranosyl)-2-acetamido-2-deoxy-5,6-*O*-isopropylidene-3-*O*-(2-methoxyethoxymethyl)-D-glucose Diethyl Acetal (15). To a solution of **9** (1.60 g, 1.97 mmol) in a mixture of dioxane (32 ml)–DMF (16 ml) was added NaH (50% oil dispersion, 95 mg, 2.37 mmol). The mixture was stirred under Ar atmosphere at 60 °C for 30 min. The mixture was then cooled in an ice bath. 2-Methoxyethoxymethyl chloride (295 mg, 2.37 mmol) was added with stirring. After 70 min, a saturated aq solution of $NaHCO_3$ was added to the mixture. The solvent was removed in vacuo, the residue worked up as usual and subjected to silica-gel column chromatography ($CHCl_3$–acetone 2:1) to give **15** as colorless syrup; 1.00 g (57%); ^1H NMR: 4.75 (2H, s, OCH_2O) 3.80 (3H, s, OCH_3); FD-MS: *m/z* 919 $(M+Na)^+$. Further elution of the column afforded unchanged starting material (**9**); 0.65 g (41%).

4-*O*-(2-Acetamido-4,6-*O*-benzylidene-2-deoxy-β-D-glucopyranosyl)-2-acetamido-2-deoxy-5,6-*O*-isopropylidene-3-*O*-(2-methoxyethoxymethyl)-D-glucose Diethyl Acetal (17). Compound **15** (1.38 g, 1.54 mmol) was dissolved in EtOH (15 ml) and hydrogenolyzed at room temperature in the presence of Pd-black catalyst. The solid product **16** obtained by evaporation of the solvent in vacuo was used for the following reaction after drying by co-evaporation with benzene.

To a solution of **16** in DMF (20 ml) were added benzaldehyde dimethyl acetal (1.00 g, 6.61 mmol) and *p*-toluenesulfonic acid monohydrate (30 mg, 0.16 mmol). The mixture was kept at 40 °C and rotated on a rotary

evaporator in vacuo for 30 min. After usual work-up and purification with a silica-gel column ($CHCl_3$–acetone 1:2) afforded **17** as a pale yellow solid; 0.59 g (54% from **15**); FD-MS: *m/z* 737 $(M+Na)^+$.

4-*O*-[2-Acetamido-4,6-*O*-benzylidene-2-deoxy-3-*O*-[(*R*)-1-(methoxycarbonyl)ethyl]-β-D-glucopyranosyl]-2-acetamido-2-deoxy-5,6-*O*-isopropylidene-3-*O*-(2-methoxyethoxymethyl)-D-glucose Diethyl Acetal (19). To a solution of **17** (370 mg, 0.52 mmol) in a mixture of dioxane (8 ml)–DMF (4 ml) was added NaH (50% oil dispersion, 41 mg, 1.0 mmol). The mixture was stirred under Ar atmosphere at 60 °C for 30 min. Then (*S*)-2-chloropropionic acid (224 mg, 2.06 mmol) and NaH (103 mg, 2.6 mmol) were added. The mixture was treated and worked up as described for the preparation of **12b**. The crude product was treated with CH_2N_2 and purified by silica-gel column chromatography ($CHCl_3$-acetone 2:3). Lyophilization of a dioxane solution afforded a colorless solid; 274 mg (66%) $[\alpha]_D^{20}$ +0.4°, $[\alpha]_{365}^{20}$ −11.8° (*c* 1.00, MeOH), ^1H NMR: 3.90 (3H, s, CO_2CH_3), 1.20 (3H, d, *J*=7 Hz, CH_3 of lactyl residue); FD-MS: *m/z* 801 $(M+H)^+$, 823 $(M+Na)^+$. Found: C, 55.64; H, 7.33; N, 3.45%. Calcd for $C_{38}H_{60}N_2O_{16}\cdot H_2O$: C, 55.73; H, 7.63, N, 3.42%.

Benzyl L-Alanyl-D-isoglutaminate *N*-Acylated with 4-*O*-[2-Acetamido-4,6-*O*-benzylidene-2-deoxy-3-*O*-[(*R*)-1-carboxyethyl]-β-D-glucopyranosyl]-2-acetamido-2-deoxy-5,6-*O*-isopropylidene-3-*O*-(2-methoxyethoxymethyl)-D-glucose Diethyl Acetal (20). To a solution of **19** (264 mg, 0.33 mmol) in MeOH (3.3 ml) was added 1 M KOH in MeOH (3.3 ml). The mixture was stirred at room temperature for 2 h, acidified with aq citric acid solution. After evaporation of the solvent, the residue was extracted with $CHCl_3$ and worked up as usual. The free acid obtained was dissolved in dry THF and cooled in an ice-bath. To this solution were added benzyl L-alanyl-D-isoglutaminate trifluoroacetate (209 mg, 0.50 mmol), triethylamine (51 mg, 0.50 mmol), *N*-hydroxysuccinimide (58 mg, 0.50 mmol), and DCC (82 mg, 0.40 mmol). The mixture was stirred at 0 °C for 30 min and then at room temperature for 4 h. Usual work-up and purification with a silica-gel column (acetone) followed by lyophilization from dioxane afforded colorless powder; 313 mg (88%); mp 78—85 °C (with sintering at 65 °C); $[\alpha]_D^{17}$ −1.5°, $[\alpha]_{365}^{17}$ −9.3° (*c* 1.00, MeOH); FD-MS: *m/z* 1076 $(M+H)^+$. Found: C, 56.63; H, 7.03; N, 6.38%. Calcd for $C_{52}H_{77}N_5O_{19}\cdot 1.5H_2O$: C, 56.61; H, 7.31; N, 6.35%.

Benzyl L-Alanyl-D-isoglutaminate *N*-Acylated with 2-Acetamido-4-*O*-[2-acetamido-2-deoxy-3-*O*-[(*R*)-1-carboxyethyl]-β-D-glucopyranosyl]-2-deoxy-D-glucose (21). A solution of **20** (145 mg, 0.13 mmol) in 90% AcOH (5 ml) was heated at 100 °C for 30 min. After cooling and evaporation of the solvent, the residue was subjected to column chromatography on DIAION HP-20 (linear gradient from H_2O to MeOH) and lyophilized from water to give colorless powder; 42 mg (40%): $[\alpha]_D^{11}$ +18.6° (*c* 1.00, H_2O); FD-MS: *m/z* 786 $(M+H)^+$. Found: C, 50.80; H, 6.58; N, 8.47%. Calcd for $C_{34}H_{51}N_5O_{16}\cdot H_2O$: C, 50.80; H, 6.65; N, 8.71%.

L-Alanyl-D-isoglutamine *N*-Acylated with 2-Acetamido-4-*O*-[2-acetamido-2-deoxy-3-*O*-[(*R*)-1-carboxyethyl]-β-D-glucopyranosyl]-2-deoxy-D-glucose (3). Compound **21** (38 mg, 0.048 mmol) was dissolved in H_2O (4 ml) and hydrogenolyzed in the presence of Pd-black catalyst at room temperature. The product was lyophilized from water; 33 mg (quantitative); $[\alpha]_D^{11}$ +18.8° (*c* 1.00, H_2O); FD-MS: *m/z* 718 $(M+Na)^+$. Found: C, 46.50; H, 6.57; N, 9.67%. Calcd for $C_{27}H_{45}N_5O_{16}\cdot 1/4H_2O$: C, 46.32; H, 6.55; N, 10.00%.

Immunoadjuvant Activities. Immunoadjuvant activities of two disaccharide dipeptides, **2** and **3**, were tested in comparison with the muramyl dipeptide **1** by the methods previously described.[18,19] In brief, group of five guinea pigs [weight 300 to 400 g (strain Yodo, Nihon Rabbit Co., Osaka)] were immunized by intrafoot-pad injection of graded amount of test synthetic specimens or the muramyl dipeptide **1** and with 100 μg of ovalbumin (Sigma) incorporated into Freund incomplete adjuvant (Difco). Two and three weeks later, induction of delayed-type hypersensitivity was evaluated by corneal test, in which ovalbumin solution was injected intracorneally. The induction of delayed-type hypersensitivity was also determined by measuring the extent of induration of the skin site which received intracutaneous injection of 0.1 ml of ovalbumin solution (1 mg/ml) on day 26. Anti-ovalbumin precipitating antibody levels in serum were estimated with serum specimen drawn 4 weeks after the immunization by the quantitative precipitin reaction. The results are summarized in Figs. 1, 2, and 3.

Synthesis of β(1—4)-Linked Disaccharides of *N*-Acetylglucosamine and *N*-Acetylmuramic Acid by Their Direct Condensation

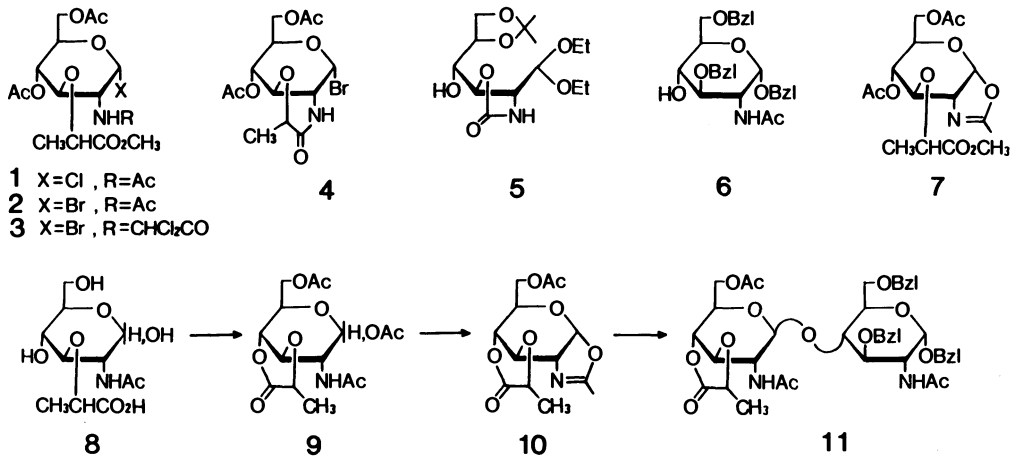
Shoichi KUSUMOTO, Masahiro IMOTO, Tsuyoshi OGIKU, and Tetsuo SHIBA*
Department of Chemistry, Faculty of Science, Osaka University,
Toyonaka, Osaka 560
(Received January 14, 1986)

As a basic study in the synthetic approach to immunoactive cell wall peptidoglycan whose backbone is a β(1—4)-linked saccharide of alternating glucosamine and muramic acid, methods for the direct condensation of these sugar components were studied and *O*-(*N*-acetyl-β-muramyl)-(1→4)-*N*-acetyl-D-glucosamine and *O*-(*N*-acetyl-β-D-glucosaminyl)-(1→4)-*N*-acetylmuramic acid were synthesized. In the synthesis of the latter disaccharide, previous formation of an ester bond between the carboxyl group of muramic acid and the 6-hydroxyl group of glucosamine proved to facilitate the glycoside bond fromation between these sugar moieties.

In the preceding paper, we reported syntheses of two disaccharide-dipeptides which correspond to partial structures of cell wall peptidoglycan, i.e., *O*-(*N*-acetyl-β-D-glucosaminyl)-(1→4)-*N*-acetylmuramyl-L-alanyl-D-isoglutamine and *O*-(*N*-acetyl-β-muramyl-L-alanyl-D-isoglutamine)-(1→4)-*N*-acetyl-D-glucosamine.[1] Both of these structures contain additional one D-glucosamine unit linked to either position 1 or 4 of the muramic acid residue of *N*-acetylmuramyl-L-alanyl-D-isoglutamine which is the minimum structure responsible for the immunostimulating activity of cell wall peptidoglycan. Since cell wall fragments which retain long glycan chains generally show higher activity than the muramyl dipeptide, we expected similar enhancement of the activity for these disaccharide dipeptides as well. However, the result of biological tests revealed that only one additional glucosamine unit is not sufficient and a longer glycan structure would be required for significant enhancement of the activity.[1]

In this respect, we were interested in the synthesis of a larger cell wall structure whose backbone consists of an alternating glycan of glucosamine and muramic acid. For construction of such a glycan structure, direct coupling of the component sugar seemed to be necessary.[2] However, no direct synthesis of saccharides of muramic acid has been reported yet. We thus examined this approach and describe in this paper a preparation of both sequences of β(1—4) disaccharide consisting of glucosamine and muramic acid by their direct condensation.

The synthesis of the disaccharide in which muramic acid is located on the non-reducing side, i.e., O-(*N*-acetyl-β-muramyl)-(1→4)-*N*-acetyl-D-glucosamine, was performed as follows. At first, several glycosyl halogenides **1**—**4** were prepared[3] and subjected to reaction with glucosamine derivatives (**5** or **6**) in the presence of mercury(II) cyanide. However, no disaccharide was obtained in any combination of reaction partners, halogenides being transformed quantitatively to the corresponding oxazolines.[4] Therefore, glycosidation with oxazoline derivatives was next attempted. The oxazoline **7** derived from peracetylated methyl ester of muramic acid was subjected to acid-catalyzed reaction[5] with the glycosyl acceptor **5** or **6** as above. Again in these cases, no disaccharide was obtained. After prolonged reaction period, **7** was either hydrolyzed or changed to the corresponding glycal. Such low ability of the muramic acid derivative **7** to act as glycosyl donor seemed to be attributed to the steric hindrance caused by the lactic acid moiety, which might cover the upper face of the molecules, hindering the access of



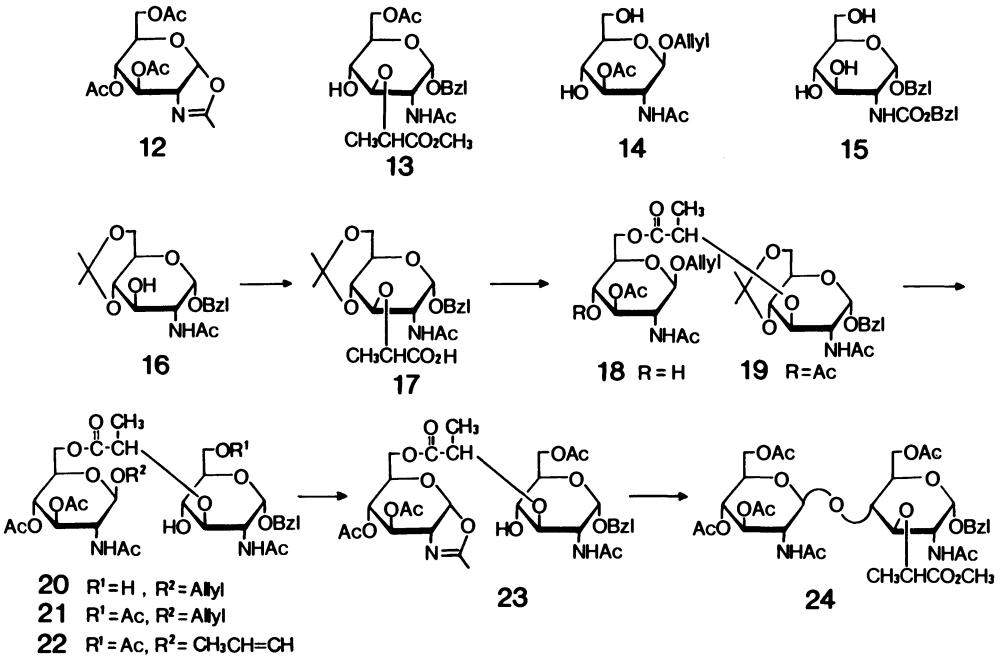
the glycosyl acceptor from the β-side.[6]

Relaxation of this steric hindrance could be expected in the oxazoline of an intramolecular ester form **10** where the lactic acid moiety is kept away from C-1. Formation of this ester also serves for the simultaneous protection of both carboxyl and 4-hydroxyl groups of the muramic acid moiety. In fact, by coupling of **10** with the glucosamine derivative **6** the desired β(1—4) disaccharide **11**[7] was obtained in 21% yield. The relatively low yield of **11** could be ascribed to the known very poor reactivity of the 4-hydroxyl group of glucosamine in the pyranoside form.

The next target of the synthesis was another disaccharide in which muramic acid is the reducing component. The first attempt to condense the simple peracetylated oxazoline **12** with the muramic acid derivative **13** failed to give a disaccharide. In addition to the known low reactivity of the 4-hydroxyl group described above, a steric hindrance due to the lactic acid moiety in **13** might be responsible in this case, too. Therefore, a novel device was required to facilitate the coupling. We thus tried to connect the two components prior to the glycosidation reaction with an ester linkage which can be formed more readily than a glycosidic bond. The muramic acid possesses a carboxyl function which can be used for this connection. The glycosidation reaction then becomes an intramolecular process and hence could be expected to proceed more easily. In the field of peptide chemistry, several examples of similar approaches had been described where two components to be coupled had been brought close together by auxiliary groups.[8,9]

Examination of molecular models indicated that an ester linkage between the carboxyl group of the muramic acid residue and the 6-hydroxyl groups of glucosamine is sterically most favorable for the formation of β(1—4) glycoside. According to this strategy, a synthetic precursor required for the glycosidation reaction, i.e., an oxazoline with an ester-linked muramic acid, was prepared as follows. The 6-hydroxyl group of the glucosamine derivative **14** was esterified with the protected muramic acid **17**.[10] Acetylation of the remaining free 4′-hydroxyl group in the product **18** followed by cleavage of the acetonide and 6-*O*-monoacetylation afforded **21**. All these transformations proceeded in satisfactory yields. When **21** was subjected to the standard conditions for allyl-propenyl isomerization described by Gent and Gigg[11] (in the presence of DABCO in ethanol-benzene-water), cleavage of the inter-sugar ester linkage occurred preferentially. This side reaction could be avoided by using dry benzene as solvent and eliminating DABCO. The propenyl glycoside **22** thus obtained was then treated with mercury (II) salt[12] to give the desired oxazoline **23** as syrup.

Glycosidation was effected in the presence of *p*-toluenesulfonic acid at 50 °C. The product was purified after cleavage of the ester linkage by methanolysis followed by re-*O*-acetylation.[13] The peracetylated methyl ester of *O*-(β-glucosaminyl)-(1→4)-muramic acid benzyl glycoside (**24**) was obtained in 20% yield from the oxazoline **23**. In contrast, no disaccharide was obtained at all under similar reaction conditions as described above in the reaction of the two corresponding monosaccharide units **12** and **13** which were not linked previously together with an ester bond. Consequently, the presence of the ester linkage which kept the two sugar moieties



in close proximity to each other certainly favored the formation of the desired glycoside bond in the above experiment. Thus, this is the first example of the so-called "entropic activation"[9] in glycosidation reaction.

Since both sequences of β(1—4) disaccharide were prepared by direct condensation of glucosamine and muramic acid as described in this work, the basic problem was solved in the synthesis of cell wall glycan which consists of the alternating these two sugar moieties. Furthermore, the receipt of "entropic activation" demonstrated in this work seems to have wide applicability. Its some application even for glycosides without muramic acid were already attempted[14] by linking sugar moieties with dicarboxylic acids and the result will be reported in details elsewhere.

Experimental

All melting points are uncorrected. ^{1}H NMR spectra were measured for $CDCl_3$ solutions with tetramethylsilane as an internal standard (δ, ppm). Optical rotations were measured with a Perkin-Elmer 141 polarimeter. FD-MS spectra were obtained with Si-emitter on JEOL O1-SG mass spectrometer. Column chromatography and preparative thin-layer chromatography were carried out with Kieselgel 60 (0.063—0.2 mm) and with pre-coated Kieselgel F_{254} plates (0.5 mm thickness), E. Merck.

2-Acetamido-1,6-di-*O*-acetyl-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-D-glucopyranose (Intramolecular Ester Form) (9). Acetic anhydride (10.0 ml, 106 mmol) was added to a suspension of *N*-acetylmuramic acid (**8**) (4.05 g, 15.3 mmol) in THF (130 ml). After the mixture had been stirred at 30 °C for 13 h and cooled to room temperature, pyridine (20 ml) was added to it. The mixture was stirred at room temperature for additional 8 h. The product isolated by usual work-up was recrystallized from $CHCl_3$–ether; 4.33 g (79%); mp 200—205 °C(decomp); $[\alpha]_D^{23}$ +151° (*c* 1.00, $CHCl_3$), ^{1}H NMR (100 MHz): 6.40 (1H, d, *J*=8 Hz, NH); 6.20 (1H, d, *J*=3 Hz, H-1), 2.15, 2.10, and 1.95 (each 3H, s, $COCH_3$), 1.50 (3H, d, *J*=7 Hz, lactyl CH_3). Found: C, 49.93; H, 5.87; N, 3.83%. Calcd for $C_{15}H_{21}NO_9$: C, 50.14; H, 5.89; N, 3.90%.

6-*O*-Acetyl-2-amino-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-1-α-*O*:2-*N*,*N*-ethylidyne-D-glucopyranose (Intramolecular Ester Form) (10). Compound **9** (4.25 g, 11.8 mmol) was dissolved in a saturated solution of dry HBr in CH_2Cl_2 (80 ml), and the mixture was left stand at room temperature for 13 h. After the solvent had been evaporated in vacuo. The residue was dried in vacuo over KOH, overnight, and dissolved again in dry CH_2Cl_2 (80 ml). Pyridine (20 ml) was added to the solution. The mixture was stirred at room temperature for 1 h, washed with H_2O, dried ($MgSO_4$) and evaporated in vacuo to give syrup. It was used for the next reaction without further purification after co-evaporation in vacuo three times with toluene. ^{1}H NMR (60 MHz): 6.0 (1H, d, *J*=7 Hz, H-1), 2.10 and 2.15 (each 3H, s, oxazoline CH_3 and CH_3CO), 1.60 (3H, d, *J*=7 Hz, lactyl CH_3).

Benzyl 4-*O*-[2-Acetamido-6-*O*-acetyl-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-β-D-glucopyranosyl]-2-acetamido-3,6-di-*O*-benzyl-α-D-glucopyranoside (Intramolecular Ester Form) (11). *p*-Toluenesulfonic acid monohydrate (80 mg, 0.42 mmol) was dehydrated by heating at 110 °C in vacuo. To this was added a solution of **10** (obtained from 4.25 g of **9** as described above) and benzyl 2-acetamido-3,6-di-*O*-benzyl-2-deoxy-α-D-glucopyranoside (**6**) (1.82 g, 3.70 mmol) in dry CH_2ClCH_2Cl (50 ml). The mixture was heated at 70 °C for 13 h. After evaporation of the solvent in vacuo, the product was purified by silica-gel column chromatography and recrystallized from $CHCl_3$–acetone; 604 mg (21% based on **6**); mp 262—265 °C (decomp); $[\alpha]_D^{20}$ +114° (*c* 1.01, $CHCl_3$). ^{1}H NMR (100 MHz): 7.40, 7.30, and 7.25 (each 5H, s, aromatic), 1.90, 1.85, and 1.70 (each 3H, s, CH_3CO), 1.45 (3H, d, *J*=7 Hz, lactyl CH_3). FD-MS: *m/z* 791 $(M+H)^+$, 813 $(M+Na)^+$. Found: C, 63.66; H, 6.34; N, 3.55%. Calcd for $C_{42}H_{50}N_2O_{13}$; C, 63.79; H, 6.37; N, 3.54%.

Benzyl 2-Benzyloxycarbonylamino-2-deoxy-α-D-glucopyranoside (15). To a suspension of 2-benzyloxycarbonylamino-2-deoxy-D-glucose[15] (120 g, 0.384 mol) in benzyl alcohol (900 ml) heated at 100 °C, a solution of dry HCl (29.9 g) in benzyl alcohol (180 ml) was added. The mixture was stirred at 100 °C till a homogeneous solution was obtained. After cooling, the mixture was poured into ether (1 l). The precipitate obtained on addition of hexane (2 l) was filtered and recrystallized form EtOH; 144 g (77%); mp 168—170 °C; $[\alpha]_D^{13}$ +123° (*c* 0.98, MeOH).[16]

Benzyl 2-Acetamido-2-deoxy-4,6-*O*-isopropylidene-α-D-glucopyranoside (16).[10] Compound **15** (20.0 g, 59.8 mmol) was hydrogenolyzed with Pd-black in a mixture of MeOH and THF (1:1, 400 ml). When the starting material disappeared as checked with TLC, the catalyst was filtered off, and acetic anhydride was (10.0 ml, 106 mmol) added to the filtrate. After 1 h at room temperature, the solvent was evaporated in vacuo. The residue was recrystallized from EtOH to give the acetamido derivative; 16.4 g (94%).

To a suspension of this product (10.0 g, 26.6 mmol) in dry acetone (150 ml), were added 2,2-dimethoxypropane (3.0 ml, 28 mmol) and *p*-toluenesulfonic acid monohydrate (0.25 g). The mixture was stirred at room temperature for 4 h and worked up as usual to give **16** as amorphous solid; 10.4 g (88% from **15**); $[\alpha]_D^{13}$ +98.3° (*c* 0.97, $CHCl_3$). ^{1}H NMR (60 MHz): 7.20 (5H, s, aromatic), 4.87 (1H, d, *J*=2.5 Hz, H-1), 1.67 and 1.47 (each 3H, s, isopropylidene CH_3).

Benzyl 2-Acetamido-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-4,6-*O*-isopropylidene-α-D-glucopyranoside (17).[10] Sodium hydride (60% oil dispersion; 1.65 g, 68.4 mmol) was added to a solution of **16** (12.0 g, 34.2 mmol) in dry dioxane (700 ml). The mixture was heated to 60 °C and (*S*)-2-chloropropionic acid (8.00 g, 68.4 mmol) was added to it. Stirring was then continued at 60 °C for 1 h. After the excess NaH had been decomposed with ice, the solvent was evaporated in vacuo and the residue extracted with $CHCl_3$ after acidification. Usual work-up afforded a syrup which was dissolved in AcOEt and treated with an ethereal solution of CH_2N_2. Complete evaporation of the volatile materials (bath 50 °C at 5 mmHg) afforded a crystalline residue, which was once washed with a mixture of ether–hexane (5:1) and then hydrolyzed with KOH (2.0 g, 36 mmol) in MeOH (120 ml) at room temperature. Removal of the solvent after neutralization with Amberlite IRC-CG50 (H^+) afforded amorphous solid; 11.9 g (82%); $[\alpha]_D^{16}$ +127.3° (*c* 0.92, $CHCl_3$). ^{1}H NMR (90 MHz): 9.05 (1H, broad s, COOH),

7.95 (1H, d, J=2 Hz, NHAc), 7.28 (5H, s, aromatic), 5.35 (1H, d, J=2.5 Hz, H-1), 4.35 (1H, q, $CH_3\underline{C}H(O)$-COOH), 2.05 (3H, s, CH_3CO), 1.51 and 1.40 (each 3H, s, isopropylidene CH_3), 1.42 (3H, d, J=6.8 Hz, $\underline{C}H_3CH(O)$-COOH).

Allyl 2-Acetamido-3-*O*-acetyl-2-deoxy-β-D-glucopyranoside 6-*O*-Esterified with Benzyl 2-Acetamido-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-4, 6-*O*-isopropylidene-α-D-glucopyranoside (18). Dicyclohexylcarbodiimide (3.80 g, 18.4 mmol) and 4-dimethylaminopyridine (0.02 g) were added to an ice-cooled solution of allyl 2-acetamido-3-*O*-acetyl-2-deoxy-β-D-glucopyranoside (**14**) (5.00 g 16.5 mmol) and **17** (7.70 g, 18.2 mmol) in a mixture of THF (20 ml) and dioxane (100 ml). After the mixture had been stirred at room temperature for 24 h, the product isolated by usual work-up and silica-gel column chromatography ($CHCl_3$–MeOH 30:1) was recrystallized from EtOAc–hexane; 10.0 g (86%); mp 107—111 °C; $[\alpha]_D^{16}$ +61.1° (c 1.11, $CHCl_3$). Found: C, 56.57; H, 6.99; N, 3.87%. Calcd for $C_{34}H_{48}N_2O_{14}\cdot 3/4H_2O$: C, 56.54; H, 6.91; N, 3.88%.

Allyl 2-Acetamido-3,4-di-*O*-acetyl-2-deoxy-β-D-glucopyranoside 6-*O*-Esterified with Benzyl 2-Acetamido-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-4, 6-*O*-isopropylidene-α-D-glucopyranoside (19). Compound **18** (2.36 g, 3.33 mmol) was acetylated with acetic anhydride in pyridine. After usual work-up, the product was recrystallized from EtOAc–hexane; 1.89 g (76%); mp 168—170 °C; $[\alpha]_D^{16}$ +75.6° (c 0.93, $CHCl_3$). FD-MS: m/z 750 (M^+). Found: C, 57.55; H, 6.73; N, 3.70%. Calcd for $C_{36}H_{50}N_2O_{15}$: C, 57.59; H, 6.71 N, 3.73%.

Allyl 2-Acetamido-3,4-di-*O*-acetyl-2-deoxy-β-D-glucopyranoside 6-*O*-Esterified with Benzyl 2-Acetamido-6-*O*-acetyl-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-α-D-glucopyranoside (21). Compound **19** (4.10 g, 5.47 mmol) was heated at 90 °C in 90% AcOH (100 ml) for 30 min. Evaporation of the solvent followed by co-evaporation with toluene in vacuo and trituration with ether afforded **20** as crystals, which were collected by filtration; 3.71 g (96%), mp 180—181 °C, $[\alpha]_D^{16}$ +58.4° (c 1.07, MeOH).

This compound (4.00 g, 5.6 mmol) was dissolved in pyridine (100 ml) and treated with acetic anhydride (2.3 ml, 23 mmol) under ice-cooling for 3 h. Usual work-up followed by purification with a silica-gel column ($CHCl_3$-MeOH, 30:1) gave an amorphous solid; 3.8 g (90%); $[\alpha]_D^{16}$ +98.4° (c 0.92, $CHCl_3$). Found: C, 55.52; H, 6.52; N, 3.67%. Calcd for $C_{35}H_{48}N_2O_{16}\cdot 1/4H_2O$: C, 55.51; H, 6.46; N, 3.70%.

1-Propenyl 2-Acetamido-3,4-di-*O*-acetyl-2-deoxy-β-D-glucopyranoside 6-*O*-Esterified with Benzyl 2-Acetamido-6-*O*-acetyl-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-α-D-glucopyranoside (22). Compound **21** (2.00 g, 2.66 mmol) was heated under reflux with chlorotris(triphenylphosphine)rhodium(I) (200 mg) in anhyd benzene under Ar atmosphere for 16 h. After evaporation of the solvent in vacuo, the product was isolated by silica-gel column chromatography ($CHCl_3$–MeOH, 30:1) as pale yellow solid; 1.34 g (67%); $[\alpha]_D^{16}$ +9.06° (c 1.02, $CHCl_3$). ^{1}H NMR (90 MHz): 6.30—5.88 (1H, m, $OC\underline{H}$=$CHCH_3$), 1.53 (3H, dd, OCH=$CHC\underline{H}_3$).

3,4-Di-*O*-acetyl-2-amino-2-deoxy-1-α-*O*: 2-*N*,*N*-ethylidyne-D-glucopyranose 6-*O*-Esterified with Benzyl 2-Acetamido-6-*O*-acetyl-3-*O*-[(*R*)-1-carboxyethyl]-2-deoxy-α-D-glucopyranoside (23). After a solution of **22** (800 mg, 1.1 mmol) in anhyd CH_3CN (15 ml) had been stirred with powdered $CaSO_4$ (300 mg) at room temperature, $HgCl_2$ (450 mg, 1.7 mmol) and HgO (450 mg, 2.1 mmol) were added to it and the whole mixture was stirred at 60 °C under Ar atmosphere for 2 h. Usual work-up and column chromatographic purification on silica gel ($CHCl_3$–MeOH, 50:1) afforded colorless syrup; 313 mg (41%). ^{1}H NMR (100 MHz): 5.99 (1H, d, J=7.8 Hz, H-1 of oxazoline form). FD-MS: m/z 694 (M^+).

Benzyl 4-*O*-(2-Acetamido-3,4,6-tri-*O*-acetyl-β-D-glucopyranosyl)-2-acetamido-6-*O*-acetyl-2-deoxy-3-*O*-[(*R*)-1-(methoxycarbonyl)ethyl]-α-D-glucopyranoside (24). Compound **23** (225 mg, 0.32 mmol) was heated in dry CH_2ClCH_2Cl (4.5 ml) in the presence of p-toluenesulfonic acid (2 mg) at 50 °C for 16 h. The mixture was cooled and then treated with ethereal solution of CH_2N_2. The solvent was evaporated in vacuo and the residue was treated with 0.1 M† NaOMe (20 ml). After 3 h, the mixture was neutralized with Dowex 50×8 (H^+) and evaporated in vacuo. The residue was dried by co-evaporation with benzene and then acetylated with acetic anhydride (0.4 ml) and pyridine (5 ml). The product obtained by usual work-up followed by silica-gel column chromatography ($CHCl_3$–MeOH, 50:1) was recrystallized from EtOAc–ether; 47.9 mg (20%); mp 192—194 °C; $[\alpha]_D^{11}$ +102° (c 1.04, $CHCl_3$). FD-MS: m/z 768 (M^+). Found: C, 54.63; H, 6.32; N, 3.68%. Calcd for $C_{35}H_{48}N_2O_{17}$: C, 54.68; H, 6.29; N, 3.64%.

Studies of Liquid Water by Computer Simulations. IV. Transport Properties of a 2-D Model

Yosuke KATAOKA
Department of Chemistry, Faculty of Science, Kyoto University, Kyoto 606
(Received September 5, 1985)

The constant-temperature constant-pressure molecular dynamics simulations of a water-like system are performed at many temperatures and pressures. A 2-dimensional model of water is used for the system with 576 molecules in a square cell. Thermodynamical quantities are anomalous as in liquid water. The temperature-dependences of the calculated self-diffusion coefficient and the shear viscosity are in agreement with the observed values at low pressures. The effects of compression on these transport coefficients are reproduced qualitatively. The bulk viscosity obtained is larger than the shear viscosity. The order of magnitude of the calculated thermal conductivity is in agreement with the experimental results. The contribution of the rotational motion to the thermal conductivity is calculated in order to discuss the anomalous temperature-dependence of this coefficient.

The behavior of the shear viscosity[1-6] and the self-diffusion coefficient[7-11] of liquid water at temperatures below about 300 K is unique. The initial application of pressure causes the viscosity to decrease, and the diffusion coefficient to increase. The Stokes-Einstein equation is valid even in supercooled water.[4-5] Although there are some molecular dynamics(MD) calculations of the self-diffusion coefficient,[12-14] it seems that a systematic study has not yet been performed on the viscosity nor on the thermal conductivity. The thermal conductivity of liquid water has a maximum as a function of temperature under constant pressure.[2,15,16] The thermal conductivity has considerable technical importance, but our understanding of the molecular behavior underlying the phenomenon is poorly developed.[2] Only a couple of phenomenological theories has been published concerning the anomaly of the thermal conductivity.[17,18] For this reason, we are planning to perform MD simulations at many temperatures and pressures to obtain the transport coefficients of liquid water.

Since the calculation of the transport coefficients is not easy,[19-22] we use the 2-D model of water,[23] as the first step. Despite theoretical predictions that transport coefficients in 2-D system diverge, a computer simulation of the small system can be used to study the transport properties.[24-27]

In the first paper of this series,[23] it was shown that a simple 2-D model of water can reproduce the main features of the thermodynamical behavior observed in real water. In the previous article,[28] dynamical properties of the 2-D water were studied by microcanonical MD simulation. The dipole direction relaxation time and the self-diffusion coefficient were calculated as functions of temperature and density. The effects of compression on these quantities are in good agreement with the experimental data.[28]

We use constant temperature and constant pressure MD(T-P-MD), because this method is more convenient to obtain the temperature dependence or pressure dependence of the system. Many methods are developed for the constant temperature MD.[29-34] Among them, Nosé's method[34] is used because this can conveniently be combined with Andersen's constant pressure MD.[31] By T-P-MD, the isothermal compressibility, the thermal expansion coefficient and the heat capacity at constant pressure are calculated from the fluctuations of the relevant quantities. Transport coefficients are calculated using the standard Kubo formula.[36]

As we have no experimental results on any 2-D water-like liquid, the absolute values obtained will be compared with those of the real water, where we shall use reduced units.[23] In the qualitative comparison of the temperature and pressure dependences, arbitrary scales will be used as follows.

The zero point of the thermal expansion coefficient and its maximum near the critical temperature are used to fix the temperature scale tentatively for the comparison of the calculated results with those of real water. By such a comparison, it is shown that the calculated transport coefficients are in agreement with those of real water. Although the maximum of the thermal conductivity as a function of temperature is not obtained, it is found that the contribution of the rotational motion to this coefficient has a maximum.

Molecular Dynamics Method

The 2-D model of water has been described in the first paper of this series.[23] The micro canonical molecular dynamics calculation was performed previously.[28] Therefore only the new aspects are described here.

The mass M of the molecule is 18 in units of atomic weight and the moment of inertia I is 3.34×10^{-44} gm^2. We use the following reduced units.[28] The energy E is measured in units of ε_0=24.68 kJ mol^{-1}($-\varepsilon_0$ is the absolute minimum of the

pair potential energy), the temperature in units of ε_0/k_B (k_B is the Boltzmann constant), the length in units of R_0=0.276 nm. The unit of time is

$$t_0 = (MR_0^2/\varepsilon_0)^{1/2} = 2.37\times 10^{-13}\ \text{s}. \quad (1)$$

The system consists of 576 molecules in a square unit cell with the periodic boundary condition. The dynamical equations are integrated with time increment

$$\Delta t = 0.435\times 10^{-15}\ \text{s} = 0.00184\, t_0 \quad (2)$$

by the predictor-corrector method.[37,38]

The constant temperature MD method of Nośe[34] is used in this paper. According to Nośe,[34] an additional degree of freedom s is introduced which acts as an external system on the system of N molecules. A constant Q appears in the kinetic energy part as $p_s^2/2Q$ in the total Hamiltonian, where p_s is the conjugate momentum of s. After some trial and error calculations, we have decided somewhat arbitrarily to choose 636 $\varepsilon_0 t_0^2$ for Q. The constant pressure MD method of Andersen is combined. In this method, the area A of the N molecular system is a variable. A constant W is introduced in the kinetic term as $p_A^2/2W$ where p_A is the conjugate momentum of A. We chose 1.92×10^{-3} $\varepsilon_0 t_0^2$ as the value of W after some preliminary simulations.

The total energy is conserved within 0.02% after 60000 steps, or 26 ps. In our standard run, 60000 steps are spent for the aging of the system. After this interval, the 60000-step run is performed at least twice, where the molecular dynamics statistical averages are obtained.

The shear viscosity, the bulk viscosity and the thermal conductivity are calculated by the standard Kubo type formula.[19,36] Averages of at least 6000 values are taken for the initial time in the standard 60000-step run. Some long runs are needed at low temperatures because of the long tail of the correlation function for the shear viscosity. In such cases, the MD run is as long as 120000 steps. The representative range of the time integration of the correlation function for the shear viscosity is $0\leq t\leq 3.6$ ps at T=0.194 ε_0/k_B, P=0.186 ε_0/R_0^2.

Thermodynamical Properties

The thermodynamic coefficients such as the thermal expansion coefficient, the isothermal compressibility and the heat capacity at constant pressure are easy to calculate because of the constant temperature and constant pressure MD method used in this paper. First the calculated thermodynamical quantities are compared with the experimental results. The temperature scale for the comparison is shown in this section. It will be used also in the comparison of the transport coefficients in the next section.

The thermal expansion coefficient at constant pressure, α, is calculated from the cross fluctuation of area A and enthapy H[35] (circle in Fig. 1)

$$\alpha = \frac{\langle AH\rangle - \langle A\rangle\langle H\rangle}{k_B T^2 \langle A\rangle}, \quad (3)$$

and also from the numerical differentiation of the area A of the N-molecule system (triangle in Fig. 1). The pressure P=0.186 ε_0/R_0^2 in Fig. 1 is the representative low pressure in 2-D water.[23] The results by these methods are in good agreement with the experimental values[1,2,39,40] if we use the temperature scale shown in Fig. 1. (The temperature scale for real water is shown in the upper part. The zero point and the scale of temperature for the real water are different from those for 2-D water. For this reason, the comparisons of the temperature dependences are only qualitative in the following figures.) In this figure, the experimental results are shown by the dotted line (normal pressure) and the dash-dotted line (P=100 MPa). As for the absolute value of the calculated expansion coefficient, the comparison is satisfactory at moderate temperatures. The coefficient obtained around the critical temperature T_c is small compared with the experimental results. This may result from the small number of molecules in the basic cell (N=576). The critical temperature of our 2-D water is about 0.263 ε_0/k_B and the critical pressure P_c is about 0.17 ε_0/R_0^2 which were estimated by the equation of state.[23]

The isothermal compressibility κ_T is calculated from the fluctuation[35] as shown below (triangle in

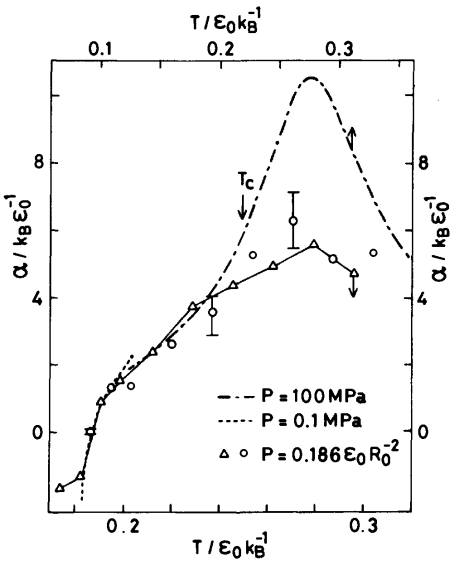

Fig. 1. Plot of the thermal expansion coefficient α vs. temperature T, at P=0.186 ε_0/R_0^2, ○ from the fluctuation, △ from the differentiation of the area. The dotted and the dash-dotted lines show the experimental results.[1,2,39,40]

Fig. 2):

$$\kappa_T = \frac{\langle A^2\rangle - \langle A\rangle^2}{k_B T \langle A\rangle}, \tag{4}$$

and by means of the radial distribution function $g(R)$[35] (circle in Fig. 2)

$$\kappa_T = \frac{\langle A\rangle}{k_B T N} + \frac{1}{k_B T}\int_0^\infty [g(R)-1]2\pi R dR. \tag{5}$$

The results are in agreement with the experimental ones.[1,2,40,41] We can see that the calculated compressibility has a reasonable value at moderate temperatures, and that the anomalies at low temperatures and at high temperatures are reproduced at least qualitatively.

The calculated heat capacity at constant pressure, C_p, is shown in Fig. 3, where the circles are the values

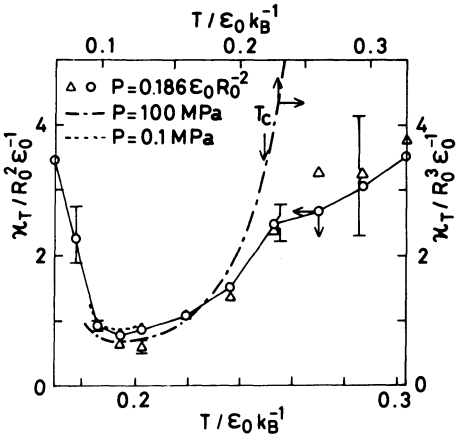

Fig. 2. Plot of the isothermal compressibility κ_T vs. temperature T, at $P=0.186\ \varepsilon_0/R_0^2$, △ from the fluctuation, ○ from the radial distribution function. The dotted and the dash-dotted lines show the experimental results.[1,2,40,41]

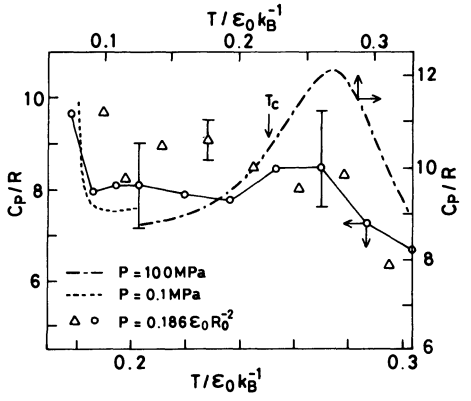

Fig. 3. Plot of the heat capacity at constant pressure C_p vs. temperature T, at $P=0.186\ \varepsilon_0/R_0^2$, ○ from the fluctuation, △ from the differentiation of H. The dotted and the dash-dotted lines show the experimental results.[1,2,40,42]

obtained from the fluctuation of the enthalpy H

$$C_p = \frac{\langle H^2\rangle - \langle H\rangle^2}{k_B T^2}, \tag{6}$$

and the triangles mean the result of the numerical differentiation of the enthalpy with respect to temperature. Unfortunately the calculated results scatter. We see however that the absolute values are in agreement with the experimental results. The temperature dependence is not inconsistent with that of the experimental values.[1,2,40,42]

Transport Coefficients

In this section, the calculated transport coefficients are compared with the experimental results and the time correlation functions are discussed.

The self-diffusion coefficient D is calculated from the mean square displacement $\langle \Delta r^2\rangle$ and from the velocity auto-correlation function.[38]

$$D = \lim_{t\to\infty} \frac{\langle \Delta r^2\rangle}{4t}, \tag{7}$$

$$D = \frac{1}{2}\int_0^\infty \langle v(t)\cdot v(0)\rangle dt. \tag{8}$$

The calculated coefficient D is plotted against pressure in Fig. 4 for several temperatures. The experimental results are shown by the dotted lines.[7-11] The anomaly of the self-diffusion coefficient is qualitatively reproduced as shown in Fig. 4 if we tentatively use the pressure scale for comparison with real water. The pressure scales and zero points are arbitrary for the purpose of qualitative comparison in Figs. 4 and 7.

The shear viscosity η and the bulk viscosity η_B are calculated from the relevant time correlation functions:[19,36]

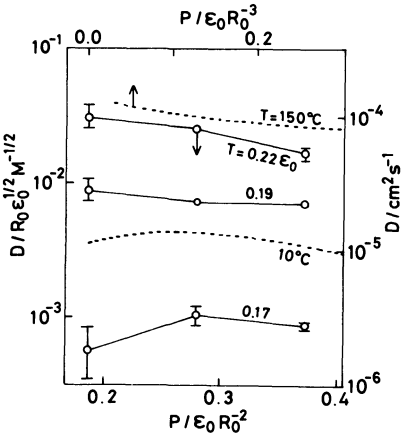

Fig. 4. Plot of the self-diffusion coefficient D vs. pressure P. Values of the temperature are indicated next to each curve.
The dotted lines are the experimental results.[7-11]

$$\eta = \frac{1}{k_B T\langle A\rangle}\int_0^\infty \langle J^{xy}(t)\cdot J^{xy}(0)\rangle \mathrm{d}t, \tag{9}$$

$$\eta_B = \frac{1}{4k_B T\langle A\rangle} \times \sum_{\alpha,\beta=x,y}\int_0^\infty \langle [J^{\alpha\alpha}(t)-\langle J^{\alpha\alpha}\rangle]\cdot[J^{\beta\beta}(0)-\langle J^{\beta\beta}\rangle]\mathrm{d}t, \tag{10}$$

$$J^{\alpha\beta} \equiv M\sum_i v_{i\alpha}v_{i\beta} + \sum_i r_{i\alpha}f_{i\beta}, \tag{11}$$

where M is the mass of the molecule and $v_{i\alpha}$ the α component of the velocity of i-th molecule. And r_i means the position of the i-th molecule and f_i is the force that the i-th molecule feels.

The viscosities obtained are shown in Fig. 5, where the results by several MD methods are compared. In this figure each circle (shear viscosity) and triangle (bulk vicosity) means the value obtained from each 60000-step run. The bar shows the average. Although the calculated values scatter, the shear viscosity can be obtained by the constant temperature and constant pressure MD (T-P-MD) as shown in this figure. Contrary to this, the orders of magnitude of the bulk viscosity by P-MD and T-P-MD were different from that of bulk viscosity by the micro canonical MD. This may arise from the fact that the bulk viscosity is related to the fluctuation of pressure P (see Eq. 10) and the area A is controlled in P-MD so the time dependence of P is artificial in this special MD.

Figure 5 shows that the bulk viscosity η_B is larger than the shear viscosity (at T=0.194 ε_0/k_B, P=0.186 ε_0/R_0^2):

$$\frac{\eta_B}{\eta} = 1.4 \tag{12}$$

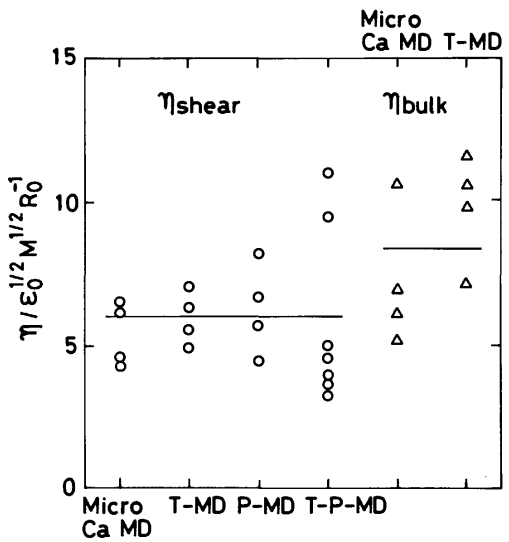

Fig. 5. Shear viscosity (○) and bulk viscosity (△) by several MD methods at T=0.194 ε_0/k_B, P=0.186 ε_0/R_0^2.

in accordance with the experimental results.[2,43] This feature is confirmed at another state (T=0.186 ε_0/k_B, P=0.216 ε_0/R_0^2), where the value of the ratio is also η_B/η=1.4.

The temperature dependence of the shear viscosity η at P=0.186 ε_0/R_0^2 is shown in Fig. 6, where the temperature scale is the same as that in Fig. 1. We see that the shear viscosity in the reduced units has a reasonable value as a function of temperature in Fig. 6. The calculated shear viscosity η is plotted against pressure P at several temperatures in Fig. 7. The experimental results are shown in the dotted lines.[1,6] The main anomalous feature in the shear viscosity of liquid water is seen in Fig. 7.

The shear viscosity η and the self-diffusion co-

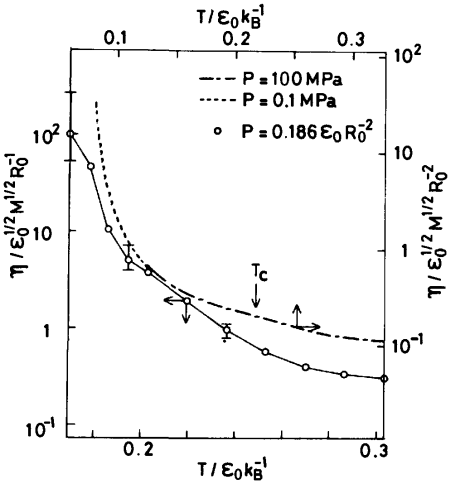

Fig. 6. Plot of the shear viscosity η vs. temperature T, at P=0.186 ε_0/R_0^2.

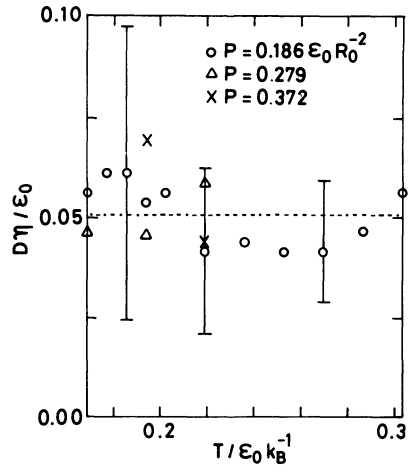

Fig. 9. Plot of the product ηD vs. T.

efficent D are plotted against $1/T$ in Fig. 8. As shown in this figture these quantities have about the same activation energy, so the product of these ηD is almost constant as a function of temperature as shown Fig. 9.

The thermal conductivity λ is calculated by the correlation function of the heat current $\boldsymbol{S}$(t):

$$\lambda = \frac{1}{2k_B T^2 \langle A \rangle} \int_0^\infty \langle \boldsymbol{S}(t) \cdot \boldsymbol{S}(0) \rangle \mathrm{d}t, \tag{13}$$

$$\boldsymbol{S}(t) \equiv \frac{\mathrm{d}}{\mathrm{d}t} \sum_i H_i \mathbf{r}_i, \tag{14}$$

were H_i is the contribution of the i-th molecule to the total Hamiltonian of the system $\mathscr{H}$:

$$\mathscr{H} = \sum_i H_i. \tag{15}$$

The calculated thermal conductivity λ is shown in Fig. 10 (open circle). The dotted line corresponds to the observed value at normal pressure.[2,15,16] The dash-dotted line means the experimental conductivity

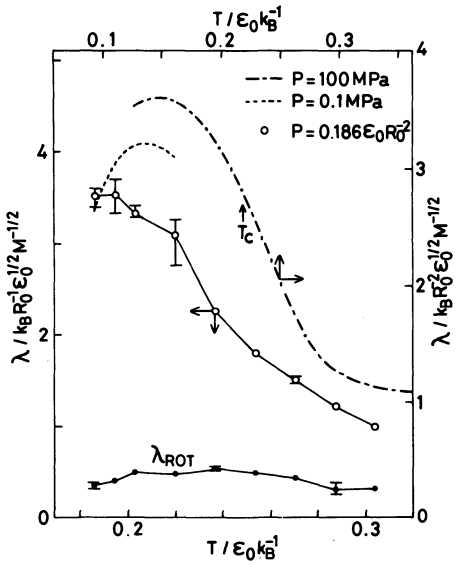

Fig. 10. Plot of the thermal conductivity λ vs. temperature T at $P=0.186\ \varepsilon_0/R_0^2$ (○).
The contribution from the rotational motion is also shown (●). The dotted and the dash-dotted lines show the experimental results.[2,15,16,44]

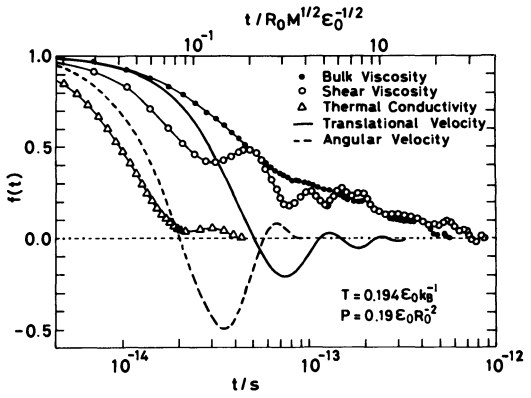

Fig. 11. The normalized correlation functions for the transport coefficients f(t) vs. time t, at $T=0.194\ \varepsilon_0/k_B$, $P=0.186\ \varepsilon_0/R_0^2$.

under pressure (P=100 MPa)[44] in this figure.

The order of magnitude of the calculated thermal conductivity is in agreement with those of the experimental results if we use the reduced quantities. The conductivity obtained has a tendency to saturate when the temperature is decreased. However, the maximum is not seen in the calculated temperature dependence of the conductivity. The contribution of the rotational motion is also shown in this figure (closed circle). This part has a maximum as a function of temperature. This contribution comes from the differentiation of the molecular Hamiltonian H_i with respect to the angle of the molecule φ:

$$\frac{\mathrm{d}H_i}{\mathrm{d}t} = \sum_j \left[\frac{\partial H_i}{\partial x_j}\dot{x}_j + \frac{\partial H_i}{\partial y_j}\dot{y}_j + \frac{\partial H_i}{\partial \varphi_j}\dot{\varphi}_j \right]. \tag{16}$$

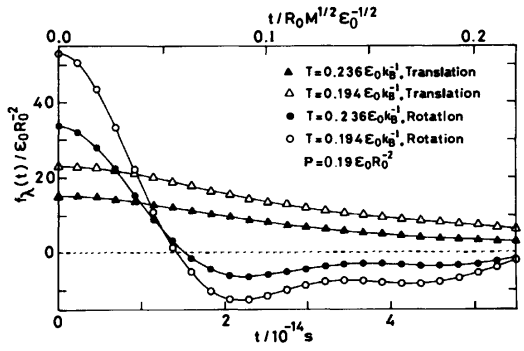

Fig. 12. The unnormalized correlation functions for the thermal conductivity $f_\lambda(t)$ vs. time t, at $P=0.186$ ε_0/R_0^2.

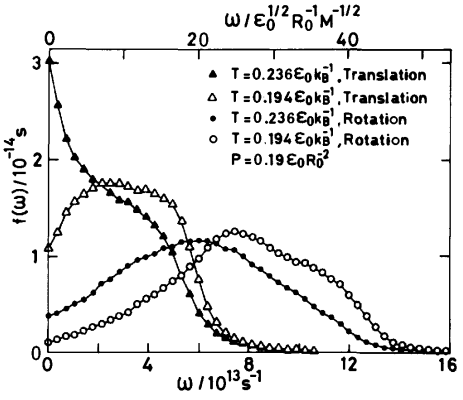

Fig. 13. The Fourier transforms of the correlation functions of velocity at $P=0.186$ ε_0/R_0^2.

We expect such a contribution is more important in real water than in 2-D water which has only one rotational degree of freedom.

The normalized correlation functions are shown in Fig. 11 in order to see the microscopic aspects of the transport coefficients (cf Ref. 19). The long tails are seen in the correlation functions for the shear viscosity (open circle) and bulk viscosity (closed circle). In contrast to these, the correlation function for the thermal conductivity has a short tail at this state ($T=0.194$ ε_0/k_B, $P=0.186$ ε_0/R_0^2). Its correlation time is about the same with as that of the correlation function of the rotational velocity.

The non-normalized correlation functions for the thermal conducvity $f_\lambda(t)$, defined as

$$\lambda = \int_0^\infty f_\lambda(t)\mathrm{d}t \tag{17}$$

are plotted in Fig. 12. In this figure, the contribution from the translational motion and that from the rotational one are compared and their temperature dependences are also compared. From this figure we can see the cancellation in the rotational part in the integration of the correlation function. This cancellation is more complete at $T=0.194$ ε_0/k_B than at $T=0.236$ ε_0/k_B. This is the reason for the increase of the rotational contribution when the temperature is increased from $T=0.194$ ε_0/k_B to $T=0.236$ ε_0/k_B. Such cancellation is due to the oscillatory feature of the rotational motion at these temperatures a shon in Fig. 13. In this figure, the auto-correlation functions of the velocity are compared. The oscillatory motion converts to diffusive motion in the translational motion when the temperature is raised from 0.194 ε_0/k_B to 0.236 ε_0/k_B. However, the oscillatory character persists in the rotational motion.

We summarize the above discussion as follows: The contribution from the rotational motion is important in order to understand the origin of the anomalous temperature dependence of the thermal conductivity of liquid water. This conclusion is different from the result of the previous theory,[18] where the anomaly is attributed to the translational motion of the cavity molecule. The estimated relaxation time of the cavity molecule[18] seems too long compared with the result of the MD calculation.[28] We plan to perform more MD calculations using a more realistic model for water.

Finally, we mention the effect of low dimensionality on the dynamical properties. It is difficult to see the long time tail in the velocity autocorrelation function in our system because of the oscillatoty behaviour (see Fig. 11). The values obtained for the transport coefficients are finite. This may come from the small number of molecules in the system and also from the short time range examined.

The author would like to thank Dr. Shuichi Nosé for letting us know his work on the constant temperature MD method prior to publication. The computation was done at the Computer Center of the Institute for Molecular Science and at the Kyoto University Data Procesing Center. The present work was partially supported by a Grand-in-Aid for Scientific Research No. 60129031 from the Ministry of Education, Science and Culture and by the Kyoto University Data Processing Center.

Formation of New Paramagnetic Complexes between Quinones and Their Semiquinone Anions in the Presence of a Cryptand or a Crown Ether

Kosaku SUGA,* Tsuyoshi TAKIGUCHI,† and Shigeru AOYAGUI
Department of Chemical Engineering, Tokyo Institute of Technology,
Ohokayama, Meguro-ku, Tokyo 152
(Received November 5, 1985)

The formation of new paramagnetic complexes is evidenced by the ESR spectra of anion radicals of duroquinone, *p*-benzoquinone, and 2,5-di-*t*-butyl-*p*-benzoquinone in tetrahydrofuran, which are recorded in the presence of their parent molecules and cryptand 222 or 18-crown-6. The numerical values for the equilibrium constant, standard enthalpy and standard entropy of the complex formation are also determined.

There are several reports about the formation of dimer cations between polyaromatic hydrocarbons and their cation radicals.[1,2] However, the formation of such dimer anions have scarcely been reported. In this paper, we report the formation of new paramagnetic complexes between several derivatives of *p*-benzoquinone and their semiquinone anions in the presence of a cryptand or a crown-ether in tetrahydrofuran at low temperature.

Experimental

p-Benzoquinone (BQ) was purified by sublimation. Other reagents; commercial duroquinone (DQ), 2,5-di-*t*-butyl-*p*-benzoquinone (DBQ), cryptand 222 (CRP) and 18-crown-6(CW) were used without further purification. The solvent, tetrahydrofuran (THF) was purified as described previously.[3] The method of deuteration followed the literature.[4] Semiquinone anion radicals (Q^-) were prepared in vacuo by reducing their parent molecules (Q) with anthracene anion radical, which was prepared by sodium or potassium reduction of anthracene. The respective test solutions used contained 0.5—1 mM (1 M=1 mol dm^{-3}) of Q^- ion-paired with an equivalent amount of Na^+ or K^+. When required, known amounts of Q, CRP, and CW were added. Simulated ESR spectra were calculated with a NEC PC-9801F2 personal computer.

Results and Discussion

The ESR spectra of Na^+DQ^- and K^+DQ^- recorded at −50 °C could be analyzed in terms of two sets of six equivalent hydrogens and one alkali metal atom, whose hyperfine splitting (hfs) constants (a) agree with the literature values.[5] An addition of DQ to these solutions caused electron-exchange broadening, but no new signals.

Figure 1 (a) shows an ESR spectrum of K^+DQ^- at −50 °C in the presence of CRP. Na^+DQ^- gave a similar spectrum under the same experimental conditions. These spectra, having no metal hfs, could be analyzed in terms of twelve equivalent hydrogens with a=1.9 G. This finding suggests that DQ^- should exist in the form of a free ion or an ion

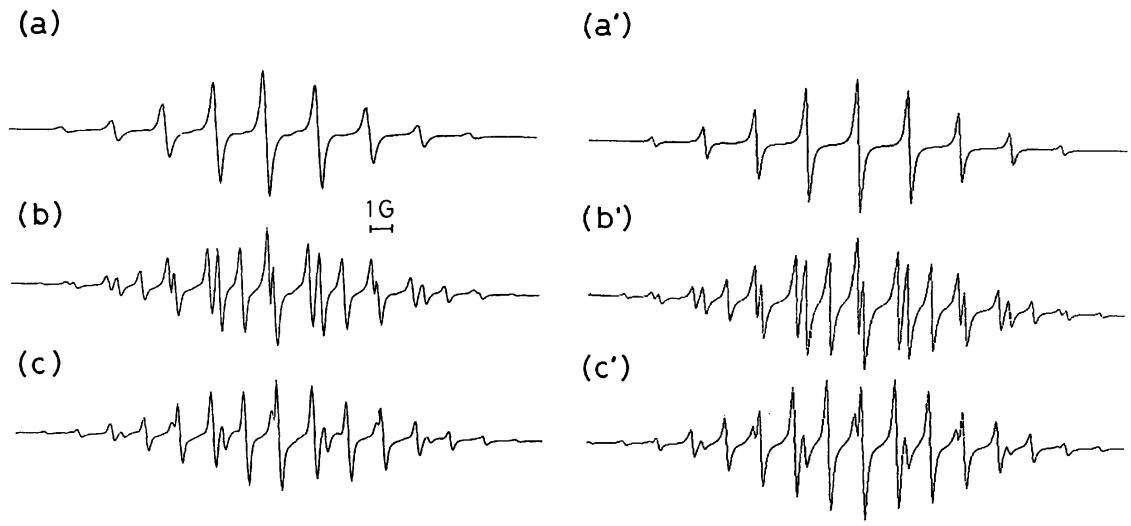

Fig. 1. ESR spectra of K^+DQ^- in THF containing 3.3 mM cryptand and (a) 0, (b) 6.4, (c) 12.8 mM DQ at −50 °C, and the corresponding computer simulated spectra; (a')—(c').

† Present address: Department of Electronic Chemistry, Graduate School at Nagatuta, Tokyo Institute of Technology, Nagatuta, Midori-ku, Yokohama 227.

pair whose cation is migrating rapidly between two oxygen sites.

Figure 1 (b) and (c) show that an increasing addition of DQ to the test solution gives rise to a new signal of increasing intensity, and the original signals of decreasing intensity. The new signal decreased in intensity with raising temperature, and became unobservable at 25 °C. This spectral change with temperature was reversible.

Figure 2 (a)—(c) show that a similar ESR pattern can be found for Na^+BQ^-, except that the hf structure is due to four equivalent hydrogens of a=2.38 G.

The ESR spectra of Na^+DBQ^- recorded at room temperature in the presence and absence of CRP exhibited hf structures due to two equivalent hydrogens and two nonequivalent hydrogens, respectively. The a value for the former hydrogens was 2.38 G, and the values for the latter agreed with the literature values.[6]

According to Fig. 3 (a)—(c), the effect of DBQ addition to the solution containing Na^+DBQ^- and CRP is the same as in Fig. 1 (a)—(c) and Fig. 2 (a)—

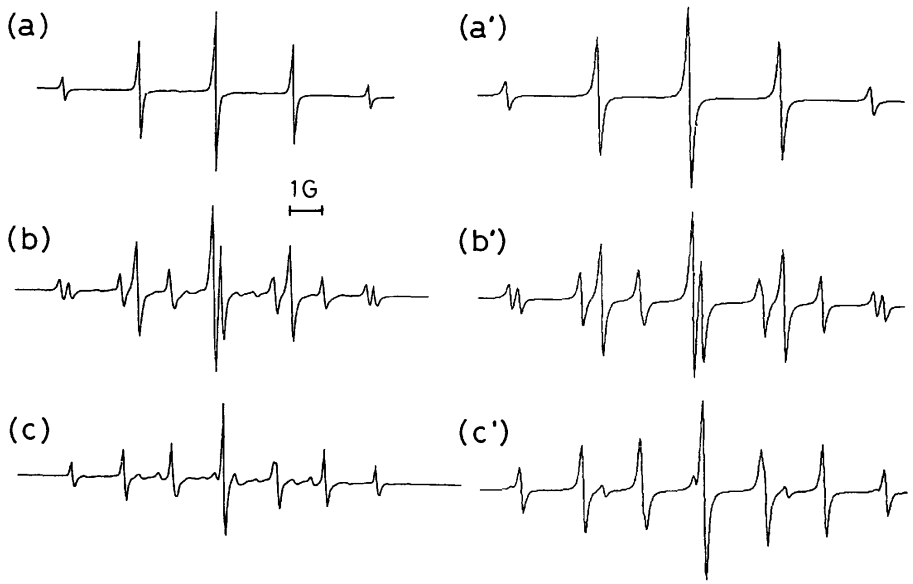

Fig. 2. ESR spectra of Na^+BQ^- in THF containing 3.1 mM cryptand and (a) 0, (b) 1.97 and (c) 4.12 mM BQ at −75 °C, and the corresponding computer simulated spectra; (a')—(c').

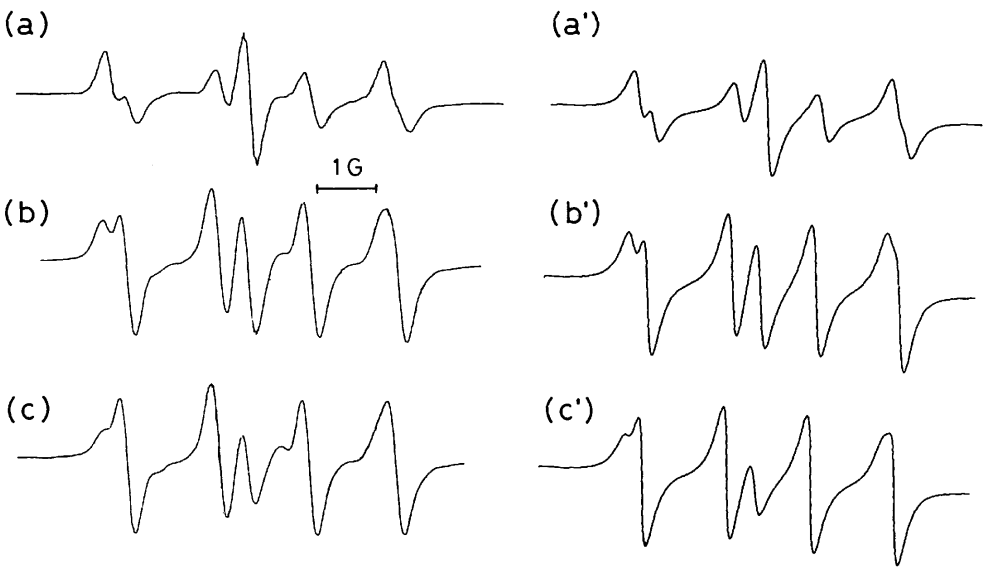

Fig. 3. ESR spectra of Na^+DBQ^- in THF containing 3.1 mM cryptand and (a) 0.3, (b) 17.1 and (c) 32.7 mM DBQ at −50 °C, and the corresponding computer simulated spectra; (a')—(c').

(c). Four new hf lines caused by DBQ addition, having equal intensities, can be attributed to two nonequivalent hydrogens of a=3.12 G and 1.56 G, respectively.

All features of the ESR spectra of Na^+DBQ^- with and without DBQ were not changed by substituting CW for CRP, except for the broadening of two inner peaks of the original four lines.

Figure 1 (a′)—(c′) show computer simulated ESR spectra assuming the following situations; (A) The new paramagnetic species have two nonequivalent groups of hydrogens including 6 members respectively. (B) The hf constants for these two hydrogen groups of the new species are 2.54 and 1.27 G, and the hf constant for the equivalent 12 hydrogens of the original species is 1.90 G. (C) The observed ESR spectrum is the superposition of the original spectrum and the new spectrum having intensities corresponding to their concentrations. (D) The difference of the center field of each spectrum due to the difference of g values is 0.25 G. These simulated spectra agreed well with the observed spectra.

Figure 2 (a′)—(c′) show the similarly simulated spectra assuming that the hf constants of the two groups of hydrogens (2 members) for the new species are 3.38 and 1.74 G respectively; the hf constant for the 4 hydrogens of the original species is 2.56 G; and the difference of the center field is 0.25 G. Figure 3 (a′)—(c′) show the simulated spectra assuming that the hf constants of the two nonequivalent hydrogens for the new species are 3.12 and 1.56 G; the hf constant for the 2 equivalent hydrogens of the original species is 2.38 G; and the differnce of the center field is 0.25 G. These simulated spectra also agreed well with the observed spectra.

The finding that these new signals can be found only in the presence of Q and increase in intensity with increasing Q concentration strongly suggests that they should be attributed to certain aggregates of Q and Q^-. Table 1 shows the equilibrium constants (K) for this association which were calculated from the relative intensities of the original and the new signals at different Q concentrations by assuming that the association occurred between one Q and one Q^-. The validity of this assumption may be supported by the K values which are nearly independent of the Q concentration.

Furthermore, the K values were little affected by the variations of the concentrations of CRP and CW, and of the kinds of alkali metal cations and crown compounds.

Figure 4 shows $\log K$ vs. T^{-1} plots for DBQ and BQ, and Table 2, the resultant values for the standard enthalpy ($\Delta H°$) and entropy ($\Delta S°$) of the association reaction. Both the $\Delta H°$ and $\Delta S°$ values are smaller for quinones of greater molecular size.

The results described above strongly suggests that

associations between quinones and their anion radicals occur in THF containing CRP and CW. If the associates are charge-transfer complexes like dimer cations,[1] the unpaired electron should be delocalized over two quinone molecules. Such a situation, however, is not in accord with the observed ESR pattern. On the contrary, if the unpaired electron is localized on one quinone molecule, the numbers of observed hf lines are reasonable. ESR

spectrum of the deuterated BQ (BQ-d_1) anion in THF containing CRP and BQ-d_1 supported this situation.

In this case, however, no simple structural model can explain the formation of such aggregates containing two Q molecules. A tentative model is given as follows: A quinone anion ion-paired with an alkali metal cation, which is captured by CRP and CW, can further associate with a quinone molecule, where an unpaired electron is localized on one quinone molecule and the migration of the cation is hindered. Then, the hf constants of the two sets of half number of equivalent hydrogens are not averaged, and the ratio of these happens to be about 2.0 as is seen in the case of the 2,5-DBQ anion ion pair: $a(H_3)$=1.50 G, $a(H_6)$=3.14 G at 0 °C.

We wish to thank Profs. Hiroshi Fukutomi and Hiroshi Tomiyasu for giving us facilities for the ESR measurements at The Research Laboratory for Nuclear Reactor in Tokyo Institute of Technology. We wish to thank Dr. Eiichi Ichikawa for his helpful suggestion to us about the method of deuteration of *p*-benzoquinone.

The Effect of the Substrate on the Epitaxial Growth of the Hexatriacontane Crystal

Michio ASHIDA, Yasukiyo UEDA, and Hisao YANAGI
Depertment of Industrial Chemistry, Faculty of Engineering, Kobe University, Rokko, Nada, Kobe 657
(Received November 5, 1985)

The epitaxial crystallization of hexatriacontane vacuum-evaporated onto a gold-covered KCl (001) surface was investigated as a function of the gold coverage. The hexatriacontane film on the KCl surface was composed of rod-like crystals taking the orientation of $(110)_H//(001)_{KCl}$ and $[001]_H//[110]_{KCl}$. The film on evaporated gold film was composed of lamellar crystals taking the orientation of $(001)_H$ parallel to the substrate and a random orientation in the azimuthal direction. The hexatriacontane film evaporated on the substrate which was partly covered with gold particles was composed of both rod-like and lamellar crystals. When the coverage ratio of the gold particles was low, the lamellar crystals in the hexatriacontane film took the orientation of $(001)_H//(001)_{KCl}$ and $[110]_H//[110]_{KCl}$. The numbers of lamellar crystals increased, and their orientation in the azimuth became more random, with and increase in the gold coverage.

In recent years thin films of organic compounds have attracted a good deal of attention because of their electronic and photoelectronic properties as semiconductors. The properties of ultrathin films are probably controlled by the molecular arrangement in the films. The main methods of preparing oriented thin films are the Langmuir-Blodgett (L-B) method and the vacuum-evaporation method. The former has been developed for preparing oriented organic thin films by mean of a wet process, and the properties of L-B films have been reported by many investigators.[1] In the case of vacuum-evaporation as a dry process, on the contrary, although there have been a number of reports on the structures of metals and inorganic compounds, there have been few reports on those of organic compounds.[2-5] We have investigated the orientation of vacuum-deposited films of organic compounds which consist of planar molecules, such as polycyclic aromatic compounds[6] and phthalocyanines.[7] The organic crystals composed of linear molecules, such as normal paraffins,[8] polyethylene[9] and polypropylene,[10] were also found to grow epitaxially in two modes on alkali halide, depending on the substrate temperature. When the substrate was preheated at 150 °C and kept at about 25 °C, the film was composed of rod-like crystals in which the linear molecules lay parallel to the substrate surface. On the substrate kept at temperatures in the vicinity of the respective melting points, the film was composed of disk-like crystals in which the molecules were oriented perpendicularly to the substrate. These two types of epitaxial crystallization have been reported for many polymers crystallizing on the surfaces of alkali halides and mica from organic solutions.[11-16] It has also been observed by X-ray diffraction that hexatriacontane film vacuum-evaporated on a copper block at room temperature is composed of crystals growing in such a way that the chain axes are oriented perpendicularly to the metal surface.[17] Those findings suggest that the orientation of vacuum-evaporated organic films depends on the substrate temperature and the substrate material. The interaction between the substrate surface and the linear molecules probably gives the nucleation of these two types of oriented crystals.

In the present work, in order to change the strength of the substrate-molecule interaction, a cleavage surface of a KCl single crystal was covered partly with either oriented gold particles or random ones and was then used as the substrate for vacuum-evaporated hexatriacontane film. The effect of the gold coverage and the substrate structure on the orientation of hexatriacontane crystal was investigated by using electron microscopy and electron diffraction.

Experimental

Gold was evaporated onto a cleavage surface of a KCl single crystal which had been maintained at room temperature (25 °C) or 400 °C in a vacuum of 10^{-5} Torr†. The amount of evaporated gold was controlled with a quartz-crystal microbalance. The coverage of gold particles on the KCl surface and the particle size were measured by means of electron micrographs by using a Laxer 450-particle analyzer. A clean KCl (001) surface and a gold-covered KCl surface were used as the substrates for preparing hexatriacontane films. The substrates were preheated at 150 °C for 1 h and were then kept at room temperature in a vacuum of 10^{-5} Torr, as has been described in a previous paper.[8] Hexatriacontane obtained from the Tokyo Chemical Industry Co., Ltd., was evaporated onto the substrate from a quartz crucible source heated with a tungsten coil. The deposition rate was about 2 nm min^{-1}. The thickness of the deposited films was controlled at about 100 nm by using a quartz-crystal microbalance. The specimens used for electron microscopy were prepared by dissolving the KCl crystal in water after the film had been backed with evaporated carbon film.

† 1 Torr=133.322 Pa.

The films were examined by means of a HU-11A Electron Microscope.

Results and Discussion

Figure 1 shows the stage of the growth of the gold evaporated onto a cleavage surface of KCl maintained at 400 °C. At the initial stage of deposition, fine particles were dispersed uniformly over the substrate surface, as is shown in Fig. 1(a), these gold particles grew larger (b, c), until they eventually joined to form isolated islands(d) and finally formed a continuous film, with an increase in the amount of the deposit. The electron-diffraction pattern from these films displayed the same single-crystal pattern as is shown in Fig. 2, indicating that the individual fine particles were single crystals with the same orientation of $(001)_{Au}//(001)_{KCl}$ and $[100]_{Au}//[100]_{KCl}$. The characteristics of the evaporated gold films shown in Fig. 1 are given in Table 1. In the case of gold evaporated on a cleavage surface of KCl at room temperature, gold particles were dispersed randomly over the surface in the initial stage and then accumulated to form a continuous film when the deposit increased. All films formed at room temperature gave a polycrystalline diffraction pattern, in contrast to the case at 400 °C.

As has been described in the previous paper,[8] hexatriacontane film on a cleavage surface of KCl without heat treatment was composed of small granules giving a ring-diffraction pattern. Epitaxial growth of hexatriacontane occurred on the cleavage surface of KCl which had been preheated at 150 °C for 1 h and then kept at about 25 °C. Therefore, the same heat treatment was carried out for all the substrates before the evaporation. The hexatriacontane film evaporated on a clean surface of KCl was composed of raft-like crystals crossing each other orthogonally, as is shown in Fig. 3(a). The electron-diffraction pattern from the film gave a superposition of two identical fiber diagrams rotated at 90° with respect to each other, as is shown in Fig. 3(b). The hexatriacontane crystal has an orthorhombic subcell with dimensions of a=7.42 Å, b=4.954 Å, and c=2.546 Å. It was found from the electron-diffraction pattern that the hexatriacontane crystal had its (110) plane parallel to the KCl (001) surface and its c-axis along the [110] direction of the KCl crystal; that is, the crystal took the parallel c-axis orientation.[8] When hexatriacontane was evaporated on the KCl surface 11% covered with gold particles, the film was composed of rod-rike crystals crossing each other

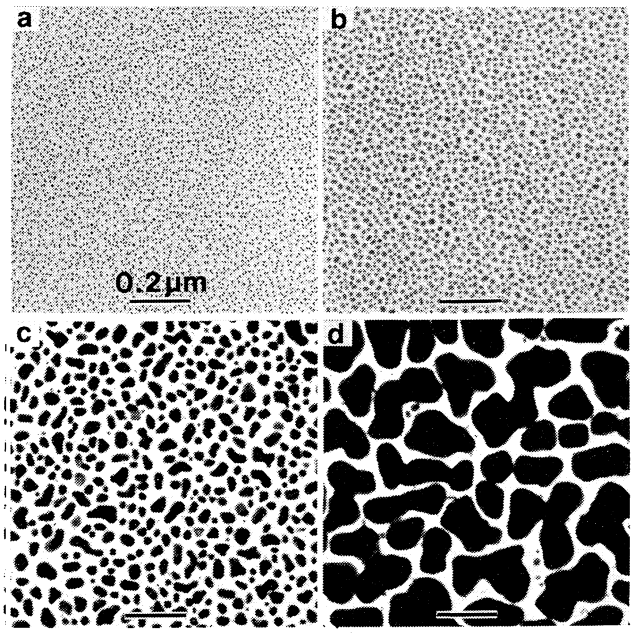

Fig. 1. A sequence of electron micrographs showing various stages of growth of gold films formed at 400 °C on KCl. The coverage of gold are (a) 11%, (b) 24%, (c) 54%, and (d) 74%.

orthogonally and lamellar crystals filling in the space among the former, as is shown in Fig. 4(a). The electron-diffraction pattern in Fig. 4(b) shows the net pattern overlapping with arc spots, which indicates that the film contains two kinds of crystals with different orientations. The reflection spots are indexed as is shown in Fig. 5. The net-reflection spots with strong intensity coincide with the diffraction pattern observed from the film in Fig. 3(a). The arc-reflection spots on the ring pattern have the indices of $hk0$ and show a C_{4v} symmetry, whose mirror planes correspond to the (110) planes of KCl. These reflection spots suggest that the crystals take their c-axes perpendicularly to the substrate surface. Therefore, the arc pattern is composed of four sets of a net pattern, one of which is given by open circles, with C_{4v} symmetry. It is noted that the series of 110 and its higher-order reflection spots in the ring pattern coincide with the [110] direction of KCl and that this oriented direction agrees with that of the c-axes of the crystals illustrated in Fig. 3(b). On the basis of these diffraction patterns, the relative orientation between deposited gold particles and

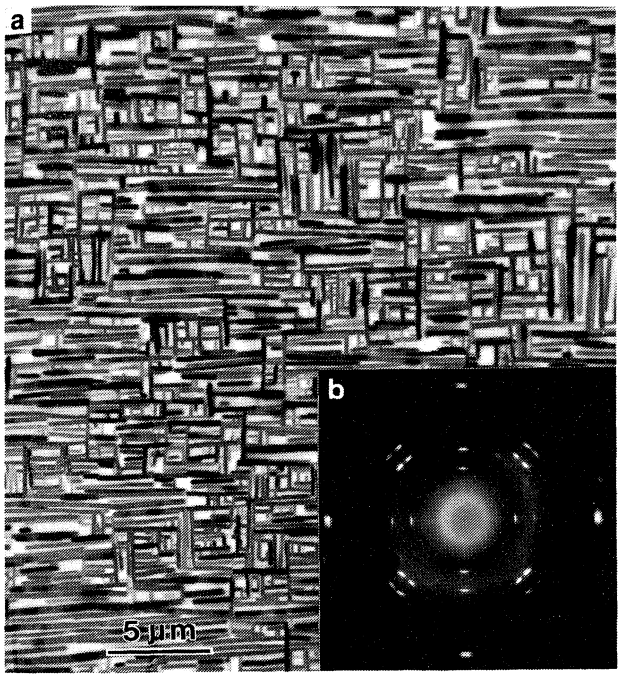

Fig. 3. Electron micrograph (a) and electron diffraction pattern (b) of hexatriacontane film evaporated on a clean cleavage surface of KCl.

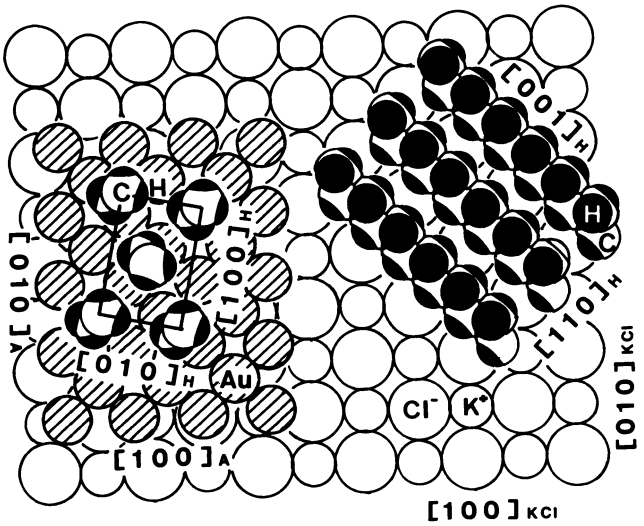

Fig. 6. Schematic diagram of the relative orientation of hexatriacontane crystals, gold and KCl (001) surface shown in Fig.4.

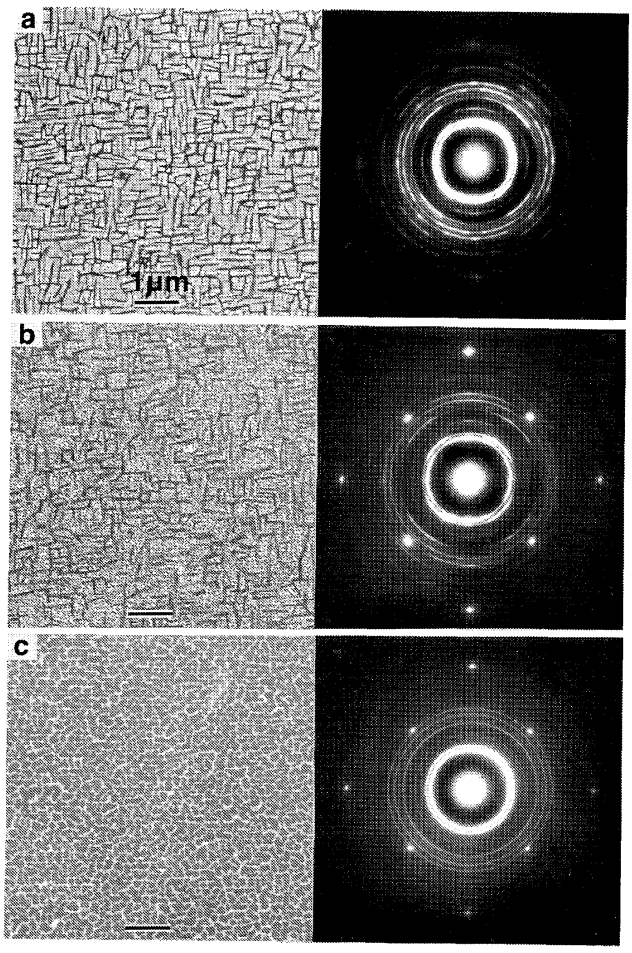

Fig. 7. Electron micrographs and electron diffraction patterns of hexatriacontane films evaporated on KCl surfaces covered with gold particles by(a) 24, (b) 54, and (c) 74%, respectively.

hexatriacontane crystals on the KCl surface can be explained in terms of a real lattice, as is shown schematically in Fig. 6. When the rod-like crystals take the orientation of $(110)_H//(001)_{KCl}$ and $[001]_H//[110]_{KCl}$, a closed-packing layer of the linear molecules lies adjacent to the KCl surface, with their long axes along the substrate [110] direction. On the other hand, it seems that the lamellar crystals nucleate on gold particles and grow over the surrounding KCl surface. The linear molecules in the lamellar crystal stand perpendicular to the substrate surface, and their closed-packing layers are arranged along the substrate [110] direction. Figures 7(a), (b), and (c) show electron micrographs and electron-diffraction patterns of the films deposited on the substrates covered about 24, 54, and 74% respectively with gold particles. The number of rod-like crystals decreased and the lamellar region increased with an increase in the coverage of the gold. Corresponding to these morphological variations, the more the substrate was covered with a gold deposit, the more predominancy

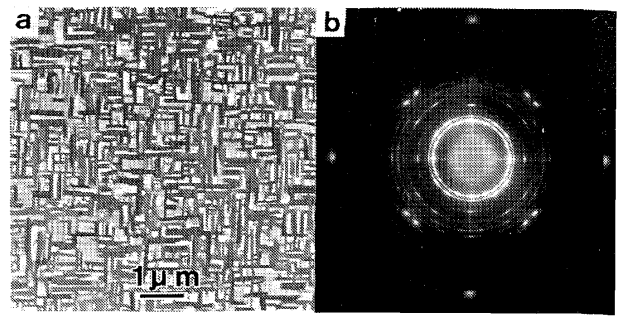

Fig. 8. Electron micrograph (a) and electron diffraction pattern (b) of hexatriacntane film evaporated on KCl surface covered by 12% with randomly-oriented gold particles.

of the ring pattern was observed in the electron-diffraction patterns. On the substrate with a gold coverage above 74%, the lamellar crystals covered the substrate uniformly, and the electron-diffraction pattern from the film showed a complete ring of ($hk0$) reflections of hexatriacontane crystals and net spots of gold crystals. These findings indicate that the film consists of polycrystals with their c-axes perpendicular to the substrate surface and with a random azimuthal orientation when the substrate surface is covered largely with a gold deposit. Figure 8 shows an electron micrograph and electron diffraction pattern of the hexatriacontane film evaporated on a substrate which is about 12% covered with gold particles taking a random orientation. The film was composed of rod-like and lamellar crystals as well as the film evaporated on the oriented gold. The ratio of the lamellar crystals to the rod-like crystals increased with an increase in the amount of gold deposited. This tendency was similar to the result for the films growing on the substrate surface covered with oriented gold. Consequently, it may be concluded that the orientation of hexatriacontane is dependent on the coverage of gold particles, but is independent of their orientation.

Alkali halide crystals have lines of unicharge ionic species which are aligned in the [110] direction of the (001) face, and the species exert a long-range dipole force which influences the orientation of long-chain molecules.[18] When hexatriacontane molecules are deposited on a clean surface of KCl, their long chains are arranged parallel to the [110] direction of KCl in the most closely packed way by means of an interaction between the KCl surface and the molecules, which causes the crystal to take the orientation of $(110)_H//(001)_{KCl}$ and $[001]_H//[110]_{KCl}$. On the other hand, the molecules deposited on gold particles yielded a nucleus of the oriented crystallite having $(001)_H//(001)_{Au}$. In the case of solution-grown polymers, two ways have been proposed for the nucleation of the crystals with their chain axes

perpendicular to the substrate surface; that is, nucleation in the solution[13] and nucleation at the side of the crystals already grown with their chain axes parallel to the substrate surface.[16] It has been concluded that a prerequisite condition for the formation of such oriented crystals is the presence of a weak interaction between the substrate surface and the polymer molecules.[15] It is well known that hexatriacontane crystals grow in lamellae, in which the long chains are arranged perpendicular to the flat face, from organic solutions.[19] This fact suggests that this crystal habit for hexatriacontane is the most stable form thermodynamically. Therefore, if there is little interaction between deposited molecules and a substrate, hexatriacontane molecules deposited on the substrate surface probably grow to a lamellar crystal on the surface. It seems that hexatriacontane molecules deposited on the gold surface form a nucleus of lamellar crystal, independently of the orientation of the deposited gold.

On the substrate surface covered partly with gold particles, some molecules deposited on the KCl surface grow to rod-like crystals, taking the parallel c-axis orientation, while the other molecules deposited on gold particles nucleate in lamellar crystals. Once nucleation and partial growth has occurred on fine gold particles, the reorientation of these "precrystals" to align with a preferential epitaxial growth direction on the KCl substrate would account for the regular crystalline orientation observed for epitaxy on KCl. Finally, the growth of these crystals directed by the epitaxial interaction with the KCl substrate may produce the unique azimuthal orientation of $[110]_H//[110]_{KCl}$. Alternatively, crystals growing on large gold particles and the gold substrate cannot experience these epitaxial interactions; thus, the hexatriacontane film may be composed of lamellar crystals with a random azimuthal orientation.

Phase Transition of Quaternary Alkyl Halide Salts of 1,4-Diazabicyclo[2.2.2]octane

Jun SHIMIZU, Kengo IMAMURA, Takashi NOGAMI,* and Hiroshi MIKAWA†
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-oka, Suita, Osaka 565
(Received November 12, 1985)

A series of quaternary alkyl halide salts of 1,4-diazabicyclo[2.2.2]octane (DABCO) exhibited first-order phase transitions in the temperature range of 62—100 °C. Abrupt changes of halide anion conductivities were observed by two to three orders of magnitude at the transition temperatures. The transition temperature and the heat of transition tend to increase with the increase of the alkyl chain length. The temperature dependence of an IR spectrum showed that the band progressions due to long alkyl chain disappeared above the phase transition. This fact suggests that the *trans*-zigzag conformation of alkyl chains in the low temperature phase is destroyed by the internal rotation of the alkyl chain above the transition temperature.

Long-chain alkanes and their derivatives have attracted much attention for more than 50 years since the work by Müller.[1] He discovered a solid-state phase transition at a few degrees below the melting point. It has now been established that the phase transition is to be attributed to the hindered rotation of the alkyl chains.[2] The solid-state phase transition between an ordered phase (low temperature phase) and a rotator phase (high temperature phase) is interesting in relation to the melting process of polymer crystals as well as to the similar phase transition of some membranes (phospholipids).[3] The theoretical work on this problem before 1965 was surveyed by McClure.[4] Phase transitions involving conformational change were also observed for some *n*-alkanes.[5] Knowledge of the various types of polymethylene motions has accumulated substantially in the past few years, since the problems have been tackled both theoretically[6] and experimentally[7] with various independent techniques.

Independent of the above subjects, we have been studying halide anion conductivities by using several organic materials such as crown ether complexes,[8] cryptand complexes,[9] quaternary alkylammonium halides,[10] and quaternary alkylphosphonium halides.[11] As an extention of these studies, we have investigated the halide anion conductivities of a series of quaternary alkyl halide salts of 1,4-diazabicyclo[2.2.2]octane (DABCO), and found a first-order phase transition with concomitant and abrupt changes of the halide anion conductivities and crystal structures.[12] It has now been clarified that the phase transition in the present systems is to be attributed to the internal rotation of the C–C bonds of the alkyl chains in the solid state. Unlike alkanes and their derivatives, the phase transition temperature of the DABCO salts are more than one hundred degrees below their melting points (or decomposition points). This paper describes more details of the phase transition of the DABCO salts from the viewpoints of halide anion conductivities, thermal analyses, infrared absorption spectroscopy, and observations with a polarization microscope. The names of the quaternary alkyl halide salts of DABCO in the present study are abbreviated by the numbers of carbons of alkyl chains and the kinds of anions. For example, *N,N'*-didodecyl-1,4-diazoniabicyclo[2.2.2]octane dibromide is abbreviated as C_{12}-DABCO-Br. The materials studied are shown in Fig. 1.

Experimental

Materials. Methyl alcohol was distilled without any drying procedures. Acetonitrile was passed through a column composed of several layers of basic, neutral, and acidic aluminas, refluxed over calcium hydride overnight, and then distilled. DABCO and all of alkyl halides were used without purifications.

Syntheses of Quaternary Alkyl Halide Salts of DABCO.

† Present address: Department of Environment and Safety Engineering, Faculty of Engineering, Fukui Institute of Technology, Gakuen-cho, Fukui 910.

Synthesis of quaternary alkyl halide salt of DABCO is described for C_{12}-DABCO-Br as a typical example. A methanol solution (30 ml) of DABCO (1.68 g, 15 mmol) and dodecyl bromide (7.48 g, 30 mmol) was refluxed for 36 h, and then allowed to cool to room temperature. It was then poured into benzene (500 ml) to obtain a white precipitate. It was filtered, dried, and then recrystallized three times from acetonitrile to obtain crystals of thin rectangular plates. For the chloride salts, acetonitrile was used as a reaction medium, and the reaction was conducted for 96 h. For the iodide salts, the same reaction conditions as described in the above example were adopted. In some cases, powders precipitate when the solution was cooled to room temperature after the reaction. In this case, a hot homogeneous solution was poured into benzene to obtain a precipitate. The solvents of recrystallization are as follows: acetonitrile for bromide salts possessing alkyl chains of C_{10}–C_{14}, and all of the chloride salts; ethyl alcohol for C_{14}-DABCO-I, C_{16}-DABCO-I, and bromide salts possessing longer alkyl chains than C_{14}

Measurements. Ionic conductivities were measured by a vector impedance meter 4800A (Hewlett Packard) in the frequency range of 25 Hz—500 kHz. Since all of the samples were hygroscopic, they were handled in a glove box until they were transferred to a glass vessel. The sample was compressed to a pellet (13 mm of diameter and ca. 0.5 mm of thickness) by applying a pressure of 300 kg cm^{-2} and sandwiched between platinum plates. After setting it was transferred to a sample holder made of Teflon, it was mounted in a glass vessel, dried under dynamic vacuum at 80 °C overnight, cooled to room temperature, and then subjected to measurement. After the drying procedure, the contribution of the proton conduction due to moisture seems to be negligible. Differential scanning calorimetry measurements of the samples were made on a SSC-560S (Daini Seikousha Co. Ltd) calorimeter with a scanning speed of 5 °C min^{-1}. The temperature dependence of the infrared spectra was measured by an A-102 (Japan Spectroscopic Co. Ltd.) for a KBr disk sample. The sample holder was surrounded by a ribbon heater.

Results and Discussion

Halide Anion Conductivities. All of the samples have already been confirmed as halide anion conductors.[12,13] Ionic conductivities were measured by an AC method. The impedance and a phase shift were measured, and the real and imaginary parts of the impedance were plotted for various frequencies (25 Hz—500 kHz). The impedance plot for C_{12}-DABCO-Br thus obtained at 78 °C is shown in Fig. 2 as a typical example. A semicircular arc was obtained in the high frequency range, which indicates that the equivalent circuit of the impedance is approximated by a parallel connection of a resistance and a capacitance. The linear relation with a 45° slope in the low frequency range might be due to a Warburg impedance. The resistance of the sample was estimated from the extrapolation of the semicircular arc to an abscissa. Temperature

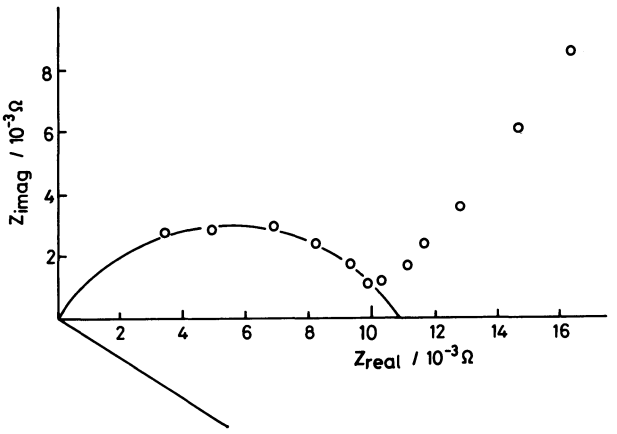

Fig. 2. The plots of the real and imaginary parts of impedance of C_{12}-DABCO-Br (a compressed pellet sample with an electrode area of 1.33 cm^2 and a thickness of 0.346 mm) at 78 °C in the frequency range of 25 Hz—500 kHz.

dependences of halide anion conductivities were measured with raising the temperature of the sample slowly from a room temperature; they are shown in Fig. 3 ((a) for chlorides, (b) for bromides, and (c) for iodides). Conductivities less than 10^{-9} S cm^{-1} are below the limit of our measurements. The following facts are noteworthy from this figure. (1) All of the samples show abrupt increases of the ionic conductivities by two to three orders of magnitude within narrow temperature ranges; this is attributed to a first-order phase transition as described later. (2) The order of the transition temperatures (T_c) of chlorides, bromides, and iodides is $Cl^- < Br^- < I^-$, when the carbon numbers of alkyl groups are fixed. (3) The longer the alkyl chains, the higher are the T_c, although a few exceptions are found.[14] (4) The order of the ionic conductivities of chlorides, bromides, and iodides is $Cl^- > Br^- > I^-$. (5) The longer the alkyl chain, the lower is the halide anion conductivity below T_c. However, the halide anion conductivities are close to each other above T_c; these points will be discussed later.

The close correspondence between T_c's and the lengths of the alkyl chains suggests that the phase transition is closely related to the structure of the alkyl group. The order of the ionic conductivities among three halides are due to the anionic size; the bigger the anionic size, the lower is its conductivity. Part of Table 1 shows materials, and the ratios of halide anion conductivities before (σ_l) and after (σ_h) the phase transition, i.e., σ_h/σ_l. The changes of the conductivities at T_c were found to be in the range of 150—180 for chloride salts, 630—3600 for bromide salts, and 140—350 for iodide salts. The abrupt change of the ionic conductivity showed hysteresis phenomena. Figure 4 shows the experimental results

of C_{12}-DABCO-Br as an example, when the temperature was elevated above T_c and then cooled down again.

Differential Scanning Calorimetries. DSC measurements of the salts showed an endothermic transition at T_c when the temperature was elevated from room temperature across the T_c. An exothermic transition was observed at T_c when the temperature was lowered after it had been raised above T_c. Table 1 also shows T_c's and the endothermic (Q_{en}) and the exothermic (Q_{ex}) heats of transition. Owing to the hysteresis phenomenon, two T_c's are shown for each material. They were obtained by the onset of DSC peaks. The transition temperatures observed by heating the sample were, in general, higher than those observed by cooling the sample. The differences of the two T_c's were found to be in the range of 8—11 °C for chloride salts, 2—10 °C for bromide salts, and 2 °C for iodide salts. Figure 5 shows plots of the transition temperatures against the

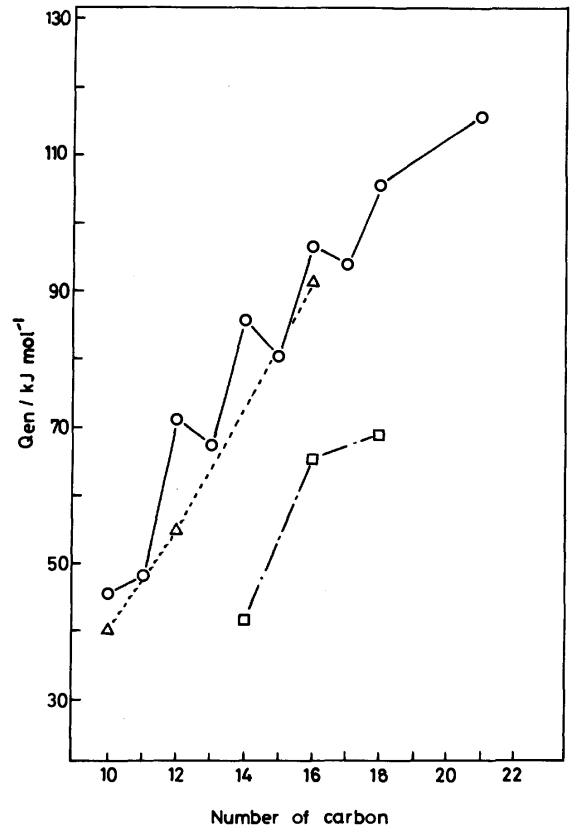

Fig. 6. Plots of endothermic heats of transition against the number of carbons of alkyl group. □: chloride, ○: bromide, △: iodide.

number of carbon atoms of the alkyl group attached to the DABCO nitrogen. This figure shows two T_c's for each material, corresponding to that observed by heating the sample and that observed by cooling. It is noteworthy that an even-odd number effect of carbons on the transition temperature was found for bromide salts in Fig. 5. The same type of effect on the phase transition temperature was also observed for a series of long chain alkanes and alcohols.[15] In most materials, the endothermic heats of transition were slightly larger than the exothermic heats of transition; this point will be discussed later. Figure 6 shows the plots of the endothermic heats of transition against the carbon numbers of the alkyl groups. This figure shows only the endothermic heats of transition, because they seem to represent the latent heats between the two phases more correctly than the exothermic heats of transition as described later. The heats of transition tend to increase as the alkyl group chains become longer. This suggests that the main factor controlling the transition is the change of the conformation of the alkyl chain. The order of the heats of transition of chlorides, bromides, and iodides is $Br^- > I^- > Cl^-$, if the number of carbon atoms in the alkyl group is fixed. It is noteworthy that an excellent even-odd number effect is observed for bromide salts as shown in Fig. 6.[15]

Infrared Absorption Spectroscopy. The temperature dependence of the infrared absorption spectra was measured to obtain more information on the phase transition. Figure 7 shows the temperature dependence of the IR spectra of C_{14}-DABCO-Br measured for a KBr disk sample at 30 and 100 °C as an example. The absorptions shown by the solid and dotted arrows at 30 °C are assumed to be due to band progressions,[16] which are well-known for long alkanes.[18] Many band progressions were smeared out at 100 °C. Detailed measurements revealed that this change of the absorption occurred exactly at the transition temperature. The disappearance of several band progressions in the high temperature range indicates that the *trans*-zigzag conformation of the alkyl chain in the low temperature phase is destroyed by the internal rotation of the C–C bonds of alkyl chain above the transition temperature.[19] Thus, the phase transition observed for DABCO salts is an order-disorder type.

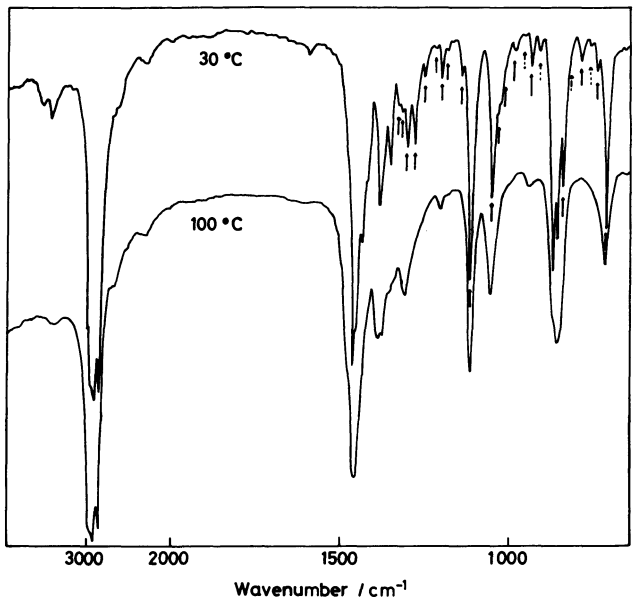

Fig. 7. Infrared absorption spectra of C_{14}-DABCO-Br for the KBr disk sample at 30 °C and 100 °C. The absorptions shown by the solid and dotted arrows at 30 °C are assigned to band progressions of the CH_2 vibrational mode.

Observation by Polarization Microscope. The above conclusion was also supported by observing the sample crystal in a polarization microscope under crossed Nicols condition. The bright transmitted light in the low temperature phase disappeared almost completely at the transition temperature, and the situation was unchanged even if the crystal were rotated above T_c. The abrupt decrease of the transmitted light above T_c reflects the lack of anisotropy of the crystal[20] due to the internal rotation of the C–C bonds of the alkyl chain.

Miscellaneous Discussions. The fact that the ionic conductivities become lower with the increase of the alkyl chain length below T_c is explained as follows. Judging from the crystal shapes of DABCO salts (very thin and rectangular) and from the crystal structures of related compounds,[21] the DABCO salts seem to possess layered structures, in which the long axes of the molecules are parallel with each other. The ion transport perpendicular to the long axis of a molecule seems not to be influenced so much by the length of the alkyl chain. On the other hand, the ion transport parallel to the long axis of the molecule will be retarded by the increase of the alkyl chain length, because the ion hopping length between anionic sites becomes longer. Thus, the latter effect accounts for the experimental observations. The reason why the ionic conductivities above T_c were similar to each other is as yet not clear. However, the following factors may be operative. The channel of the halide anion transport is greatly influenced by the packing of the individual molecule in the crystal. Since the material converts to the disordered phase above T_c, the peculiar pathway in the low temperature phase, which is closely related to the length of the molecule, and/or to the packing of molecules in the solid, would be destroyed or averaged by the movement of the alkyl group to give a structure-insensitive situation for anion transport.

The facts that the endothermic heats of transition are slightly larger than the exothermic heats of transition in most materials would be explained as follows. The former is caused by the transition from the ordered phase to the disordered phase. On the other hand, the latter is caused by the reverse transition. However, the disorder of the alkyl chain remains to some extent in the latter case, which gives rise to smaller exothermic heats of transition. This is consistent with the microscope observation that the surface of the crystal was wrinkled when the temperature was raised and lowered several times across T_c. Thus, the endothermic heat of transition seems to correspond to the latent heat between the ordered phase and the disordered phase more correctly than the exothermic heat of transition.

Summary. In conclusion, we have found that a series of quaternary alkyl halide salts of DABCO show first-order phase transitions, with concomitant and abrupt changes of halide anion conductivities, and infrared absorption spectra. The transition is caused by the change of the conformation of the alkyl group, possibly by the internal rotation of the C–C bonds of the alkyl chains. Therefore, the phase transition in the present study is closely related to the phase transitions of alkanes and their derivatives. The most distinct difference of the DABCO salts from others is that the transition temperatures are more than 100 degrees lower than the melting points (or decomposition points), because the latter are usually above 200 °C. The reason is that the present DABCO salts are ionic materials, and the lattice is more rigid than that of long alkanes and their derivatives which are covalent materials. The abrupt changes of the halide anion conductivities and the absence of birefringence above the transition temperature may be applicable to thermal switching devices. In this case, an output signal can be obtained both by electrical and optical techniques. The large differences between the transition temperatures and the melting points (or decomposition points) are favorable for such a device, because it ensures stability.

The authors are grateful to Professor Masamichi Kobayashi, Department of Macromolecular Science, Faculty of Science, Osaka University, for his discussions on the phase transitions of alkanes and on the assignment of the infrared absorption spectra of the present study. We are also grateful to Professor

Shigekazu Kusabayashi and Dr. Shunsuke Takenaka for the use of the DSC and the polarization microscope.

13) A charge carrier was determined as a bromide or an iodide anion by a DC technique, using a graphite pellet electrode containing tetrabutylammonium tribromide or tetrabutylammonium triiodide (see Ref 12). In the case of the quaternary alkyl chloride salts of DABCO, we could not use the same technique, because of the instability of tetrabutylammonium trichloride. Judging from the similarity of the materials, however, the charge carrier of the chloride salts would be a chloride anion.

16) The peak positions of the solid arrows are in fairly good accordance with the band progressions of n-$C_{15}H_{32}$, which have the same numbers of CH_2 units as the alkyl group of C_{14}-DABCO-Br. For the detailed assignments of the band progressions, see Ref. 17. The absorptions shown by the dotted arrows are due to the band progressions possessing the phase difference (ϕ_k) between adjacent CH_2 units given by $\phi_k=k\pi/14$, where k is an even number. These bands become IR-active because of the lower symmetry of the alkyl group of C_{14}-DABCO-Br than n-$C_{15}H_{32}$. The assignments of the band progressions in Fig. 7 have some ambiguities in the range of 1170—1310 cm^{-1}, because both the CH_2 wagging and CH_2 twisting-rocking modes have absorptions in this range. Since single absorption was observed at 720 cm^{-1} (CH_2-rocking mode) in Fig. 7, C_{14}-DABCO-Br seems to possess a parallel-packed molecular structure in the crystal. In this case, crystal field splitting does not appear. The separations of the absorptions shown by the arrows are too large to be the crystal field splittings, because these are usually less than 10 cm^{-1}.

(Received November 21, 1985)

The decay rates of ground-state atomic nitrogen in the presence of C_2H_4(ethene), $\Delta^{1,3}$-C_4H_6(1,3-butadiene), and C_2H_2(ethyne) were measured by using a pulse radiolysis-resonance absorption technique. It was found that the decay rates decrease drastically upon the addition of a small amount of I_2, an efficient radical scavenger. This suggests that the decay of N(^4S) in the absence of I_2 is due to the reactions between the N(^4S) and the free radicals. The rate constants for the reactions of N(^4S)+C_2H_4, $\Delta^{1,3}$-C_4H_6, and C_2H_2 were estimated to be much less than 10^3 m^3 mol^{-1} s^{-1}. The rate constant for the N+I_2→NI+I reaction was measured to be 2.4×10^4 m^3 mol^{-1} s^{-1}.

The reactions of active nitrogen with unsaturated hydrocarbons, especially with C_2H_4(ethene), have been studied very extensively. Two valuable reviews by Winkler and his co-workers appeared in 1968 and 1970 in which the studies on this subject prior to 1970 were summarized.[1,2] In 1949, Greenblatt and Winkler found that the major product of the reaction of active nitrogen with C_2H_4 is HCN; they proposed the following reaction mechanism:[3]

$$N(^4S) + C_2H_4 \longrightarrow C_2H_4N, \quad (1)$$
$$C_2H_4N \longrightarrow HCN + CH_3, \quad (2)$$
$$N(^4S) + CH_3 \longrightarrow HCN + 2H, \quad (3)$$

followed by the normal atom- and radical-recombination processes. This simple mechanism has been modified by many investigators, including Winkler and his co-workers.[4-6] In 1965, Herron proposed the following modified mechanism,[5] taking into account the observation that the concentration of N atoms determined by the NO titration technique, $[N]_{NO}$, is larger than that estimated from the amount of HCN produced in the presence of an excess amount of C_2H_4, $[N]_{HCN}$:[7]

$$N + C_2H_4 \longrightarrow HCN + CH_3, \quad (4)$$
$$N + CH_3 \longrightarrow HCN + 2H, \quad (3)$$
$$H + C_2H_4 \longrightarrow C_2H_5, \quad (5)$$
$$H + C_2H_5 \longrightarrow 2CH_3, \quad (6)$$
$$N + C_2H_5 \longrightarrow NH + C_2H_3, \quad (7)$$
$$N + NH \longrightarrow N_2 + H. \quad (8)$$

Here, Reactions 6—8 are important to explain the finding that the value of $[N]_{NO}$ approaches $[N]_{HCN}$ upon the addition of atomic hydrogen. Herron, in his later work, estimated the rate constant for Reaction 4 to be 8×10^3 m^3 mol^{-1} s^{-1} at 320 K.[8] Although the above mechanism could explain most features of the reaction of active nitrogen with C_2H_4, Safrany and Jaster questioned Reaction 4, the spin-forbidden internal rearrangement step.[9] They considered that the initial step must be the formation of free radicals. If active nitrogen contains atomic hydrogen as an impurity, even only a small amount, alkyl radicals can easily be produced by Reaction 5 and its succeeding chain processes. They also proposed the following reactions for the radical soures:

$$N + N + C_2H_4 \longrightarrow N_2 + C_2H_3 + H, \quad (9)$$

and:

$$N + N + M \longrightarrow N_2^* + M, \quad (10)$$
$$N_2^* + C_2H_4 \longrightarrow N_2 + C_2H_3 + H, \quad (11)$$

where N_2^* stands for electronically excited nitrogen molecules. Safrany's proposal was supported by Michael and his co-workers, who measured the reaction rates of N(^4S)+C_2H_4 at very low concentrations of N atoms ($\simeq10^{-6}$ mol m^{-3}) and found that the rate constant is less than 1×10^2 m^3 mol^{-1} s^{-1}.[10-12] In an earlier article from this laboratory, Sato et al. obtained the rate constant for the addition of N(^4S) to some unsaturated hydrocarbons by employing a pulse radiolysis-resonance absorption technique.[13] Their reported value for N+C_2H_4 was 4×10^4 m^3 mol^{-1} s^{-1}, the same order as that reported by Herron,[8] but more than two orders of magnitude larger than that reported by Michael.[12] Michael has insisted that, in the system of Sato et al., an intense electron beam must have produced a large amount of $N_2(A^3\Sigma_u^+)$, which must then have disturbed the measurement by producing free radicals.

There is no doubt that unsaturated hydrocarbons react with active nitrogen fairly rapidly, and that the reaction mechanisms are not simple. It is not certain, though, whether the initial step of the sequence is the addition of N atoms to the C=C double bonds or the formation of free radicals. Therefore, we re-measured the reaction rates for N+C_2H_4, $\Delta^{1,3}$-C_4H_6(1,3-butadiene), C_2H_2(ethyne), and C_2HCl_3(trichloroethene) in the presence of I_2, which scavenges free radicals as

well as quenches electronically excited molecular and atomic nitrogen.

Experimental

The experimental apparatus and the procedure were similar to those described elsewhere.[13,14] Briefly, a mixture of N_2 (typically 93±2 kPa), I_2 (0—4 Pa), and unsaturated hydrocarbons (0—7 Pa) was irradiated with a pulsed electron beam from a Febetron 706 apparatus (Hewlett Packard Co.). The change in the concentration of N(^{4}S) was measured by means of the absorption of the resonance lines ($3^4P_J \leftarrow 2^4S$) around 120 nm. The linear relationship between the optical density and the atomic concentration has been confirmed in a previous work.[13] The output of the photomultiplier tube (Hamamatsu R976) was amplified and processed with a wave memory (NF Circuit Design Block Co. WM-852) and a computer (NEC PC-9801F). All experiments were performed at 302±4 K.

Research-grade N_2 (Toyo Sanso) was used after having been passed through a furnace of copper chips at 590 K and a trap filled with a molecular sieve 4A at 77 K. Products of Takachiho Kako were used for $\Delta^{1,3}$-C_4H_6 and C_2H_2. The C_2H_4 was a product of Yokohama Chemical Co., while the C_2HCl_3 and I_2 were those of Koso Chemical Co.

Results

In the system of pure N_2, N(^{4}S) decayed very slowly; the decay rate was 3.2 s^{-1} (average of 13 runs). In the presence of a small amount of unsaturated hydrocarbons, however, N(^{4}S) decayed much more rapidly and the temporal profiles of the concentration were not single-exponential. These features were the same as those observed in a previous work.[13]

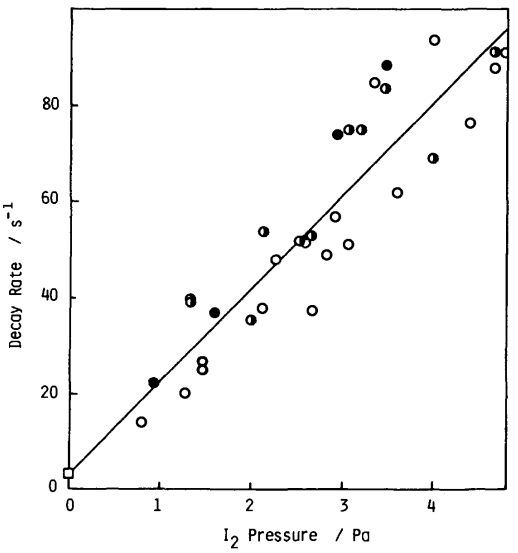

Fig. 1. The decay rate of N(^{4}S) as a function of the I_2 pressure. Total pressures are 53 kPa(◑), 93 kPa (○), and 133 kPa(●). The symbol □ stands for the average of 13 runs measured in the pure N_2 system.

In the system of N_2+I_2, the N(^{4}S) concentration decreased exponentially with the time, and the decay rate showed a linear dependence on the I_2 pressure, as is shown in Fig. 1. It was also found that the decay rate is independent of the total pressure between 53 kPa and 133 kPa.

In the system of the mixture of the three components, N_2, I_2, and unsaturated hydrocarbons, the decay of the N(^{4}S) concentration was again exponential, and the decay rates were much smaller than that observed in the system of the mixture of N_2 and the same amount of the hydrocarbon. Except in the case of C_2HCl_3, they were even smaller than that of the N_2+I_2 system. In other words, the decay rates of N(^{4}S) decreased in the following order, except for C_2HCl_3:

N_2 + unsaturated hydrocarbon $\gg$ N_2 + I_2

$>$ N_2 + I_2 + unsaturated hydrocarbon $>$ N_2 only.

Figures 2 and 3 illustrate the relationships between the decay rates of N(^{4}S) and the I_2 pressures in the presence of 3.3 and 6.7 Pa of C_2H_4 and $\Delta^{1,3}$-C_4H_6 respectively. The values in the absence of I_2 are rough and less reliable, since the decay was not single exponential. In the cases of $\Delta^{1,3}$-C_4H_6 and C_2H_2, the decay rates increased linearly with the I_2 pressure, and the apparent decay-rate constants were about half of that in the N_2+I_2 system, regardless of the hydrocarbon pressures. In the case of C_2H_4, a slight

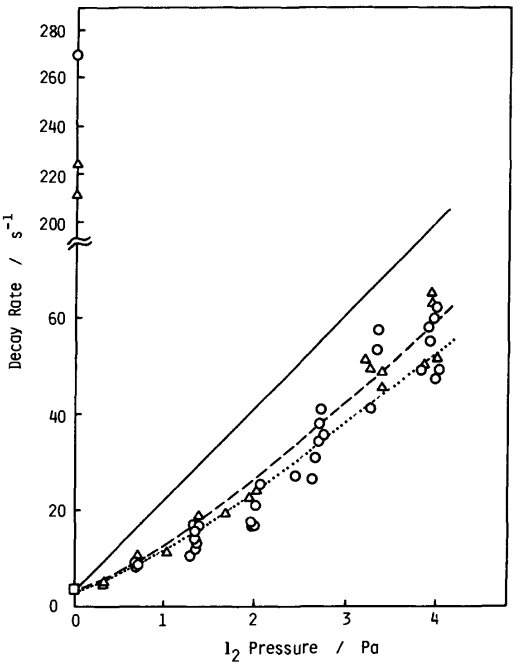

Fig. 2. The decay rate of N(^{4}S) as a function of the I_2 pressure in the presence of 3.3 Pa (△) and 6.7 Pa (○) of C_2H_4. The solid, broken, and dotted lines are results of the simulation in the absence and in the presence(3.3 Pa and 6.7 Pa) of C_2H_4, respectively.

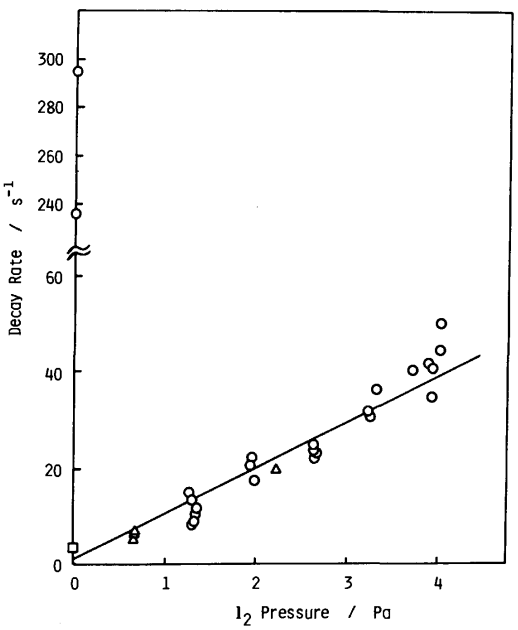

Fig. 3. The decay rate of N(⁴S) as a function of the I_2 pressure in the presence of 3.3 Pa (△) and 6.7 Pa (○) of $\Delta^{1,3}$-C_4H_6.

nonlinearity between the decay rate and the I_2 concentration could be observed, although the result was very similar to those for $\Delta^{1,3}$-C_4H_6 and C_2H_2 when the I_2 pressure was lower than 2.6 Pa. As for C_2HCl_3, the decay rate of N(⁴S) did not decrease so drastically as in the other cases upon the addition of I_2. In the absence of I_2, when the C_2HCl_3 pressure was around 7 Pa, the decay rate was in the order of 200 s^{-1}. In the presence of 1—4 Pa of I_2, the decay rate did not show any marked dependence on the I_2 pressure, and the average value was 58±11 s^{-1}.

Discussion

N_2+I_2 System. Phillips and his co-workers have studied this system by employing a discharge-flow technique. They proposed that the essential steps in this system are:[15-18]

$$N(^4S) + I_2 \longrightarrow NI(^3\Sigma^-) + I, \quad (12)$$
$$N(^4S) + NI(^3\Sigma^-) \longrightarrow N_2^* + I, \quad (13)$$
$$N_2^* + I_2 \longrightarrow N_2 + I_2^*, \quad (14)$$
$$N_2^* + I \longrightarrow N_2 + I^*, \quad (15)$$
$$NI + \text{wall} \longrightarrow (1/2)N_2 + (1/2)I_2, \quad (16)$$

where N_2^* is considered to be $N_2(W^3\Delta_u)$.[18] Since they have mentioned nothing about the quantum yield for the production of $N_2(W^3\Delta_u)$ in Reaction 13, some part of the product may be $N_2(A^3\Sigma_u^+)$ or vibrationally excited $N_2(X^1\Sigma_g^+)$. In the present system, since the total pressure was very high, it seems unlikely that Reaction 16 plays an important role. Termolecular processes, such as N+I+M→NI+M, may also be unimportant, because no total pressure dependence of the decay rate could be observed. If Reaction 13 is fast, and if it can be assumed that the concentration of NI is almost constant during the decay of N(⁴S), then the observed decay-rate constant must be twice the rate constant for Reaction 12, which has been calculated to be $(2.4\pm0.2)\times10^4$ m^3 mol^{-1} s^{-1}. This value is in fair agreement with that of Phillips, 1.4×10^4 m^3 mol^{-1} s^{-1}.[16] The assumption that the reaction rate for Reaction 13 is fast in this system is supported by the observation that the addition of unsaturated hydrocarbons decreases the apparent decay rates. This will be discussed in the next section.

N_2+I_2+C_2H_4 System. The addition of I_2 to the N_2+C_2H_4 system, even in only a tiny amount, drastically decreases the decay rate of N(⁴S). This strongly suggests that the rate for N+C_2H_4 is slow and that the apparent decay observed in the absence of I_2 is due to the reactions between the N(⁴S) and the free radicals. The finding that the decay rate in the three component system is even smaller than that in the N_2+I_2 system can be explained by assuming that NI is reactive to C_2H_4. However, it is impossible to account for the nonlinear relationship between the decay rate and the I_2 pressure shown in Fig. 2 by assuming the mechanism presented by Phillips. In order to explain this nonlinearity, we assumed the following reaction sequence:

$$N + I_2 \longrightarrow NI(^3\Sigma^-) + I, \quad (12)$$
$$N + NI \longrightarrow N_2(\text{or } N_2^*) + I, \quad (13)$$
$$NI + I_2 \longrightarrow NI_2 + I, \quad (17)$$
$$N + NI_2 \longrightarrow \text{Products}, \quad (18)$$
$$NI + C_2H_4 \longrightarrow \text{Products}. \quad (19)$$

In the absence of C_2H_4, this mechanism cannot, however, be distinguished from that proposed by Phillips if Reactions 13, 17, and 18 are much faster than Reaction 12. In the presence of C_2H_4, on the other hand, Reaction 19 competes with Reaction 17. When the I_2 pressure is high, Reaction 17 should be dominant and the result should agree with that in the absence of C_2H_4. When the I_2 pressure is low, however, Reaction 19 should be dominant and the apparent decay rate constant should be half of that in the absence of C_2H_4. Electronically excited molecular nitrogen is considered to be quenched by I_2 and C_2H_4 very rapidly. The alkyl and vinyl radicals produced from excited molecular nitrogen are considered to be scavenged by I_2 at an early stage. Atomic iodine may not disturb the system, either. The quenching of the first excited state of atomic iodine, $I(^2P_{1/2})$, by C_2H_4 is physical and slow. The rate constant has been measured as 4×10^4 m^3 mol^{-1} s^{-1}.[19] The reaction rate for $I(^2P_{3/2})$ should be even slower. If we assume that

the reaction rates for Reactions 13, 17—19 are much larger than that for Reaction 12, and that the rates for Reactions 17 and 19 are comparable, the nonlinear relationship can be deduced. The solid, broken, and dotted lines in Fig. 2 are the results of a simulation using the following rate constants (in units of $m^3\,mol^{-1}\,s^1$); $k_{12}=2.4\times10^4$, $k_{13}=6.0\times10^6$, $k_{17}=1.9\times10^6$, $k_{18}=6.0\times10^7$, $k_{19}=2.4\times10^6$. In the simulation, the inclusion of the NI+NI reaction had no effect on the results; the NI concentration must be very small compared with that of $N(^4S)$. It seems unlikely that $N(^4S)$ is reactive to C_2H_4, because the slope of the line in Fig. 2 at low pressures of I_2 (below 2.6 Pa), which is almost linear, is half of that in Fig. 1. By comparing these slopes, the rate constant for $N(^4S)+C_2H_4$ is calculated to be much less than $10^3\,m^3\,mol^{-1}\,s^{-1}$, which agrees with the result of Michael.[12]

In the absence of I_2, the reaction mechanism must be very complex. Safrany has presented the following mechanism, assuming that reactions which require drastic internal rearrangements, the rupture of double bonds, or a simultaneous rupture of more than one bond are unimportant:[20]

$$H + C_2H_4 \longrightarrow C_2H_5, \quad (5)$$
$$H + C_2H_5 \longrightarrow 2CH_3, \quad (6)$$
$$N + C_2H_5 \longrightarrow NH + C_2H_4, \quad (7)$$
$$N + C_2H_5 \longrightarrow CH_3 + H_2CN, \quad (20)$$
$$N + CH_3 \longrightarrow H + H_2CN, \quad (21)$$
$$N + C_2H_3 \longrightarrow NH + C_2H_2 \quad (22)$$
$$N + H_2CN \longrightarrow NH + HCN, \quad (23)$$
$$H + H_2CN \longrightarrow H_2 + HCN, \quad (24)$$
$$N + NH \longrightarrow N_2 + H, \quad (8)$$

and other atom- and radical-recombination reactions. Here, H atoms are considered to be formed by either Reaction 9 or Reactions 10 and 11. Although we do not think Safrany's assumptions are beyond question, the above mechanism is consistent with the present finding that $N(^4S)$ atoms do not react with C_2H_4 directly, and so this is probably the best starting point to an understanding of this complicated system. Safrany also considered that the H_2CN radical, which is isoelectronic to CHO and CH_3, must play an important role. The production of H_2CN in the active nitrogen/alkene system has also been confirmed by Takahashi and Miyazaki[6] and by Brooke and Mile.[21] Takahashi and Miyazaki detected D_2CN mass-spectrometrically in the system of active nitrogen and C_2D_4. They also detected CH_2 (CD_2) as an intermediate. As a source of CH_2 (CD_2), they proposed the following reactions:

$$N + C_2H_4 \longrightarrow CH_2 + H_2CN, \quad (25)$$
$$N + H_2CN \longrightarrow N_2 + CH_2. \quad (26)$$

As we have shown, however, the $N+C_2H_4$ reaction, including Reaction 25, is extremely slow. According to Safrany's suggestion, Reaction 26 can not occur, because it would require a rupture of the C=N double bond. Reactions such as:

$$N + C_2H_3 \longrightarrow HCN + CH_2, \quad (27)$$

can be excluded from the same reason. The abstraction of atomic hydrogen from CH_3 by H atoms or CH_3 radicals is 24 kJ mol^{-1} endothermic and must be very slow. On the other hand, abstraction by CN:

$$CH_3 + CN \longrightarrow CH_2 + HCN, \quad (28)$$

is exothermic. In spite of many efforts,[1,2,22,23] it is not yet clear how CN radicals are formed in active nitrogen/organic compound systems, but there is no doubt that CN is produced, since intense CN emission, in both red and violet systems, has been observed. Therefore, we would like to propose that CN is the precursor of CH_2. One possible source of CN is:[20]

$$N + N + HCN \longrightarrow N_2 + H + CN. \quad (29)$$

$N_2+I_2+\Delta^{1,3}$-C_4H_6 System. In this system, the decay rate of $N(^4S)$ showed a linear dependence on the I_2 pressure, and the slope of the linear plots was almost half of that of the N_2+I_2 system. These results can be explained by a reaction mechanism similar to that for C_2H_4 if the reaction rate for $NI+\Delta^{1,3}$-C_4H_6 is much faster than that for Reaction 17. The rate constant for $N+\Delta^{1,3}$-C_4H_6 is less than $10^3\,m^3\,mol^{-1}\,s^{-1}$.

$N_2+I_2+C_2H_2$ System. The situation in this system is analogous to that in the $N_2+I_2+\Delta^{1,3}$-C_4H_6 system. The rate constant for $N+C_2H_2$ is, again, less than $10^3\,m^3mol^{-1}s^{-1}$, which agrees with the result of Michael.[12] Safrany and Jaster have found that the reaction of C_2H_2 with active nitrogen is very different from those of alkenes or alkanes, and that it is rather similar to those of C_2N_2 and HCN.[20,24] One of the most characteristic features is that the fraction of N atoms initially present and converted to HCN is low, even in the presence of H atoms. It was also observed that the specific rate is strongly dependent on the C_2H_2 pressure. In order to explain these features, Safrany and Jaster considered that C_2N_2 is produced at the first stage of the sequence. They assumed the following replacement reaction:

$$N + C_2H_2 \longrightarrow CHCN + H, \quad (30)$$

follwed by:

$$N + CHCN \longrightarrow C_2N_2 + H. \quad (31)$$

From the length of the reaction flames, they estimaed the lower limit of the rate constant for Reaction 30 to be 4×10^3 m^3 mol^{-1} s^{-1}.[20,24] However, this value seems too large compared to the present upper limit, 10^3 m^3 mol^{-1} s^{-1}; we think Reaction 30 should be replaced by the following two reactions:

$$N_2^*(\text{or } N+N) + C_2H_2 \longrightarrow N_2 + C_2H + H, \quad (32)$$

$$N + C_2H \longrightarrow CHCN. \quad (33)$$

After the formation of CHCN and C_2N_2, the reaction sequence proposed by Safrany and Jaster seems to be enough to explain the experimental results.

N_2+I_2+C_2HCl_3 System. As has been mentioned, the decay rate of N(⁴S) showed no marked dependence on the I_2 pressure between 1—4 Pa. This suggests that 4 Pa of I_2 is not sufficient to scavenge free radicals completely in this system. Since I_2 is a very efficient scavenger for monoradicals, it may be supposed that biradicals, such as CCl_2, are produced and that they are less reactive to I_2. The C=C double bond is weakened by halogen substitution; this may be the cause for the production of biradicals. The upper limit of the rate constant for the N(⁴S)+C_2HCl_3 reaction is estimated to be 10^4 m^3 mol^{-1} s^{-1}.

Recently, Choo and Kim reported the bimolecular rate constant for N(⁴S)+C_2HCl_3 to be 1.6×10^4 m^3 mol^{-1} s^{-1}.[25] This value is a little larger than the present upper limit, and it is much larger than that for N(⁴S)+C_2H_4. The reaction path for N+C_2HCl_3 may be different from that for N+C_2H_4, but we are afraid they have not eliminated the contribution of the reactions of N(⁴S) with free radicals completely. In the systems of active nitrogen and fluoroethenes, Jones and Ahmed have shown that the hydrogen and fluorine atoms eventually formed play significant roles and that they must be the species initiating the reactions.[26]

Thermodynamical Considerations. Finally, it should be mentioned why N(⁴S) is so unreactive to hydrocarbons. Michael has discussed that intermediate quartet states are not crossed by potential surfaces which correlate with product states.[11,12] The following thermodynamical consideration suggests that the quartet states are physically unstable and that they decompose back into their initial components. The addition reaction of H(²S) to C_2H_4 to produce C_2H_5 is 160 kJ mol^{-1} exothermic. In the case of the O(³P)+C_2H_4 reaction to produce triplet biradicals, the exothermicity is much less. According to the ab initio Hartree-Fock calculation, it is 18 kJ mol^{-1}.[27] This small exothermicity may correspond to the weakness of the C-O single-bond strength compared to the C-H bond in most organic compounds.[28] Since the C-N single-bond strength is weaker still,[28] it is not surprising if the formation of quartet C_2H_4N triradicals is endothermic.

The next question is why NI($^3\Sigma^-$) is reactive. In order to explain the present experimental results, it is necessary to assume that the rate constant for Reaction 19, NI($^3\Sigma^-$)+C_2H_4, is larger than 10^5 m^3 mol^{-1} s^{-1}, while the order of the rate constant for NH($^3\Sigma^-$)+C_2H_4 has been estimated to be only 10^4 m^3 mol^{-1} s^{-1}.[29] The formation of triplet C_2H_4NI biradicals may not necessarily be endothermic, even if the formation of triplet C_2H_4NH biradicals is endothermic, but this seems less likely. One possibility is the production of stable ring compounds, such as cyclic C_2H_4NI. This process is spin-forbidden, but it may proceed fairly rapidly because of the heavy-atom effect of iodine atoms. For further discussion, accurate measurements of the rate constants for the NI reactions as well as those for NH are desired.

Spectrophotometric and Analogue Derivative Spectrophotometric Determination of Chromium(III) with 2-(5-Bromo-2-pyridylazo)-5-(*N*-propyl-*N*-sulfopropylamino)phenol

Yoshio SHIJO* and Kaoru SAKAI
Department of Environmental Chemistry, Faculty of Engineering, Utsunomiya University, 2753, Ishii-cho, Utsunomiya 321
(Received August 26, 1985)

A sensitive method for the spectrophotometric determination of chromium(III) with 2-(5-bromo-2-pyridylazo)-5-(*N*-propyl-*N*-sulfopropylamino)phenol (5-Br-PAPS) is described. 5-Br-PAPS reacts with chromium(III) to form a 1:2 (metal:ligand) complex in weakly acidic media upon heating at 95 °C. The complex has an absorption maxima at 592 nm and gives a constant absorbance in the pH range of 3.4—6.2. The molar absorptivity and sensitivity for an absorbance of 0.001 are 8.94×10^4 dm^3 mol^{-1} cm^{-1} and 0.58 ng cm^{-2} respectively. The complex, once formed, is not decomposed by the addition of *trans*-1,2-cyclohexanediamine-*N*,*N*,*N*′*N*′-tetraacetic acid (CDTA). Thus, the selectivity of the method can be increased by the use of CDTA as a masking agent. The sensitivity of the method can be increased by employing analogue-derivative spectrophotometry, chromium(III) determination at parts-per-billion levels being feasible.

2-(5-Bromo-2-pyridylazo)-5-(*N*-propyl-*N*-sulfopropylamino)phenol (5-Br-PAPS) is a relatively new type of spectrophotometric reagent[1]. It is a water-soluble pyridylazo compound which has been developed by introducing a sulfoalkyl group into the amino group of the mother compound without sacrificing the oridinal spectrophotometric sensitivity. The reagent has the same chelating system as 4-(2-pyridylazo)-resorcinol (PAR), but is more sensitive than PAR for the determination of most metals, having molar absorptivities in the region of 1×10^5 dm^3 mol^{-1} cm^{-1} for several transition-metal complexes. 5-Br-PAPS has been reported to be a spectrophotometric reagent for the determination of zinc(II)[1] and vanadium(V).[2]

In the present work, a sensitive spectrophotometric method for the determination of chromium(III) with 5-Br-PAPS is descrived. The reagent reacts with chromium(III) to form a stable blue complex upon heating at 95 °C. The complex, once formed, is not decomposed by the addition of CDTA, whereas most other metal complexes are readily decomposed by CDTA. The conditions for the color development, the composition of the complex, and the influence of other metal ions are reported. The proposed method is very sensitive and selective for the determination of chromium(III). The sensitivity of the method is comparable to that of the 2-(5-bromo-2-pyridylazo)-5-diethylamino phenol (5-Br-PADAP) method (log ε=5.08)[3],but the former is better in selectivity than the latter because CDTA can be used as the masking agent. The method developed can be made even more sensitive by the use of an analogue derivative spectrophotometric technique.

Experimental

Reagents and Apparatus. The 5-Br-PAPS solution (5×10^{-3} M) was prepared by dissolving 0.120 g of 5-Br-PAPS (Dojindo Co., Ltd., Japan) in 50 cm^3 of water. The solution was stable for one week. The chromium(III) solution (1000 μg cm^{-3}) was prepared by dissolbing 0.500 g of metallic chromium (99.99% pure) in 45 cm^3 of hydrochloric acid by heating on a hotplate, and then by diluting the solution to 500 cm^3 with water. The solution was stable for at least six months. Working solutions were prepared by the dilution of this solution with 0.1 M† hydrochloric acid. All reagents were of an analytical-reagent grade, and all solutions were prepared with distilled, deionized water.

A Hitachi 100-10 spectrophotometer and a Hitachi 200-20 recording spectrophotometer were used. To obtain the derivative spectrum, a modified Hitachi 200-0576 derivative unit composed of two analogue-differentiation circuits (each having six different time-constants[4,5]) was connected in series between a Hitachi 200-20 recording spectrophotometer's output and a Hitachi 200 recorder's input. Cells with a 10-mm optical-path length were used throughout all the measurements unless stated otherwise.

Procedure. Ordinary spectrophotometry: To an aliquot containing less than 5 μg of chromium(III) in a 10-cm^3 test tube, 1 cm^3 of a 5×10^{-3} M 5-Br-PAPS solution and 1 cm^3 of a 2 M acetate buffer (pH 5) were added. The solution was diluted with water to 7 cm^3, and then heated 95 °C in a water bath for 20 min in order to complete the complexation. After cooling, the solution was transferred into a 10-cm^3 volumetric flask and diluted to the mark with water. The absorbance of the resultant solution was measured at 592 nm against a reagent blank prepared under the same conditions using 1-cm cells. Second-derivative spectrophotometry: When the chromium(III) content of the colored solution obtained by the procedure described above was too low to give a measurable absorbance, the procedure was carried out as follows. The second-derivative spectrum (from 700 to 500 nm) was recorded against a reagent blank by using a combination of both first-and second-order differentiation circuits of No. 6 and a scan speed of 120 nm min^{-1}, and the second-derivative value (the vertical

† 1 M=1 mol dm^{-3}.

distance from a peak to a trough) was measured.

Results and Discussion

Absorption Spectra. The absorption spectra of the chromium(III)-5-Br-PAPS complex at pH 5 is shown in Fig. 1, together with its second-derivative spectrum. The absorption spectra have an absorption peak at 592 nm and a shoulder on the shorter-wavelength side of the main absorption band. The absorption spectra of the complex was little affected by the addition of such cationic or anionic surfactants as tetradecyldimethylbenzylammonium chloride or dodecylbenzenesulfonic acid.

Effect of Experimental Variables. The pH dependence of the chromium(III) complex formation with 5-Br-PAPS by heating at 95 °C for 20 min is illustrated in Fig. 2. It was found that a constant absorbance at 592 nm was obtained in the pH range of 3.4—6.2. The absorbance of 5-Br-PAPS increases abruptly below pH 4 by increasing the protonated form of the amino group.

The reaction between chromium(III) with 5-Br-PAPS at room temperature is very slow. Therefore, the formation of the complex should be accelerated by heating. The effect of the heating time at 95 °C on the formation of the complex was examined. It was found that a constant absorbance was obtained by heating for more than 15 min at 95 °C. The complex, once formed at pH 5, was stable and gave a constant absorbance after 2 h.

The effect of the 5-Br-PAPS concentration on the absorbance of the complex was also examined. A concentration of more than 4×10^{-4} M was required to obtain a constant absorbance.

Composition of the Complex. The molar composition of the complex formed under the conditions described in the foregoing procedure was examined by Job's method of continuous variation. The results are shown in Fig. 3. The method indicated that the metal/ligand ratio of the complex was 1:2.

Calibration Graph. A straight-line calibration graph passing through the point of origin was obtained for chromium(III) concentrations of 0.04—0.6 $\mu g\,cm^{-3}$ using the foregoing procedure. The equation for the graph was Cr ($\mu g\,cm^{-3}$)=0.58 A (1), where A is the absorbance. The sensitivity for an absorbance of 0.001 and the molar absorptivity calculated from Equation (1) were 0.58 ng cm^{-2} and 8.94×10^4 $dm^3\,mol^{-1}\,cm^{-1}$ respectively.

Effect of Diverse Ions. The use of masking agents is required for the determination of chromium(III) with 5-Br-PAPS because many metal ions interfere with the formation of the colored complex. As masking agents, 0.2 cm^3 of 0.1 M tartaric acid was added before the addition of 5-Br-PAPS and 0.2 cm^3

Table 1. Tolerance Limits for Various Metal Ions in the Determination of 2 μg of Chromium(III). Tolerable Error: ±3%

Ions	Tolerance limit
Bi(III), La(III), Sc(III)	200 μg
Th(IV)	120 μg
Pb(II), Zr(IV)	40 μg
Fe(III), In(III), Mn(II), Mo(VI), Zn(II)	20 μg
V(V)[a]	4 μg
U(VI)[a]	2 μg
Ni(II)	400 ng
Co(II)	40 ng

a) Two hundred μl of 10% hydroxylamine hydrochloride was added after the formation of the chromium(III) complex.

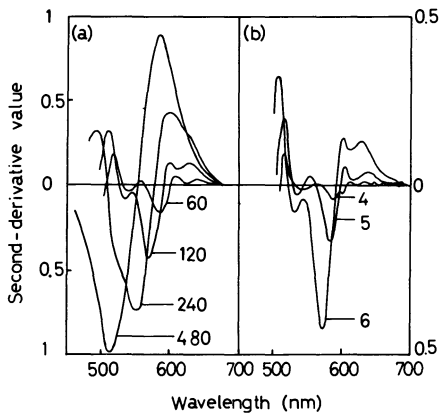

Fig. 4. Influence of (a) scan speed (with circuits all No.6) and (b) circuit number (with scan speed 120 nm min^{-1}) on second-derivative spectra of chromium–5-Br-PAPS complex. chromium(III), 60 ng ml^{-1}; 5-Br-PAPS, 5×10^{-4} M; pH, 5.

of 0.05 M CDTA after the formation of the chromium(III)–5-Br-PAPS complex in the foregoing procedure, then the mixture was heated at 95 °C for 5 min. Many metal complexes of 5-Br-PAPS decomposed upon the addition of CDTA. The absorbance of the chromium(III) complex, however, decreased only 5% compared with that in the absence of masking agents, because ligand exchange between CDTA with 5-Br-PAPS of the chromium(III) complex is very slow. The effects of foreign ions on the determination of chromium(III) when masking agents are used as has been described above are summarised in Table 1. The amounts of bismuth(III), lanthanum(III), scandium(III), thorium(IV), lead(II), zirconium(IV), iron(III), indium(III), manganese(II), molybdenum(VI), and zinc(II) tolerated are 200—20 μg. The masking of vanadium(V) and uranium(VI) with hydroxylamine hydrochloride are incomplete. Cobalt(II) and nickel(II) interfere seriously because these complexes with 5-Br-PAPS, once formed, are very stable and are little decomposed by the addition of CDTA.

Selection of Conditions for Measurement of the Second-Derivative Spectrum. Ishii and his coworkers have previously reported that derivative spectrophotometry using an analogue differentiation circuit is extremely effective in the sensitisation of ordinary spectrophotometry.[4,5] In this work, a derivative unit which is analogous to their apparatus was used. The second-derivative spectrum of the analyte is recorded, and the vertical distance from a peak to a trough, or from the base line to a trough of the spectrum, is measured. Since this distance(D) depends on both the time constant of the analogue differentiation circuits and the scanning speeds used, these need to be selected so as to give a large, well-resolved peak. The second-derivative spectra of the chromium(III)–5-Br-PAPS complex measured with varying circuit numbers and scan speeds are shown in Fig. 4. The largest peaks, but a poor linearity of the calibration graph, were obtained in the conditions of circuit No. 6 and a scan speed of 480 nm min^{-1}. The conditions of circuit No. 6 and a scan speed of 120 nm min^{-1} are found to be preferred for the determination of chromium(III) because reproducible data and a linear relationship for the chromium(III) concentration are obtained under these conditions.

Calibration Graph. The calibration graph, prepared by plotting the second-derivative value versus the chromium(III) concentration, was a straight line passing through the point of origin when either the peak-to-trough values or the base line-to-trough values were plotted. The equations for each graph, measured by employing a combination of circuit No.6 and a scan speed of 120 nm min^{-1}, are as follows; Cr(ng cm^{-3})=106 D (2) for the peak-to-trough measurements and Cr(ng cm^{-3})=134 D (3) for the base line-to-trough measurements, where D is the second-derivative value represented by the conversion of the value into the absorbance. From Eqs. 2 or 3, it can be seen that chromium(III) down to the 5 ng cm^{-3} level can be easily determined by the proposed method.

Comparison with Other Methods. Sensitive chromogenic reagents for the determination of chromium(III) include 5-Br-PADAP,[3] 2-(5-bromo-2-pyridylazo)-5-diethylaminophenol,[6] chromazurol S–hexadecyltrimethylammonium bromide,[7] phenylarsenazo,[8] PAR,[9] and diphenylcarbazide.[10] The first three are sensitive enough ($\log\varepsilon\fallingdotseq5$), but have a poor selectivity. The last three have a higher selectivity, but are they less sensitivity than the first two. In comparison with the methods using these reagents, the proposed method is sensitive ($\log\varepsilon=4.95$), selective, and stable. Further, the method can be applied

to more dilute samples by employing analogue-derivative spectrophotometry.

A New Method for Measuring 1:1 Association Constants Based on Releasing Rate of Free Ligand from Aqueous into Gaseous Phase, Applied to Determining Formation Constants of Metal Acetylacetonate Complexes

Isao SANEMASA,* Yuko NISHIMOTO, Akira TANAKA, and Toshio DEGUCHI
Department of Chemistry, Faculty of Science, Kumamoto University,
Kurokami 2-39-1, Kumamoto 860
(Received September 11, 1985)

A simple method is presented that allows estimation of 1:1 association constants between volatile and nonvolatile solutes in aqueous medium. On introducing an inert gas at a constant flow rate into the aqueous phase, the volatile solute is expelled from the solution, and the amount of the released solute is measured as a function of aeration time. Measurements are made in two separate runs at the same inert gas flow rate, one in the absence and the other in the presence of nonvolatile solutes. The releasing rate of the volatile solute is reduced with increasing association between both the solutes in the aqueous medium. The method was used to estimate formation constants of 1:1 acetylacetone complexes with metal ions, Cu(II), Ni(II), Co(II), Mg(II), Fe(II), Fe(III), and Al(III), at 25.0 °C and I=0.1 ($NaClO_4$), results being compared with literature values.

It has been shown that the disproportionation constant of mercury(I) in aqueous medium, i.e., the equilibrium constant for $Hg_2^{2+} \rightleftharpoons Hg^{2+}+Hg$, can be determined by combining two rate constants obtained from two independent experiments: one is concerned with measurement of the disproportionation rate while the equilibrium is caused to shift to the right by introducing nitrogen gas at a constant flow rate into the solution containing Hg(I) to expel Hg, and the other is concerned with measurement of the releasing rate of metallic mercury in the absence of Hg(II) at the same N_2 gas flow rate.[1] The present work was undertaken to demonstrate that the method might be applicable widely to systems where association occurs in aqueous medium between volatile and nonvolatile solutes.

In this work we are concerned with measurement of 1:1 formation constants of metal complexes. Acetylacetone was selected because this ligand is volatile[2] and because formation constants for a wide variety of metal ions are available from published compilations.[3] Various methods such as spectrophotometry, potentiometry, polarography, calorimetry, and solvent extraction have so far been used to determine formation constants for metal acetylacetonates.[3-8] Compared with these techniques, the present method is simple and not specific for the metal ions to be studied.

Experimental

Reagents and Materials. Distilled deionized water was used throuhout. Acetylacetone was of analytical reagent grade from Wako Pure Chemical. Stock solutions of 0.1 or 0.2 M (1 M=1 mol dm^{-3}) metal ions were prepared by dissolving their salts (ammonium iron(III) sulfate, aluminium potassium sulfate, sulfate and chloride for Cu(II), and chlorides for the other metals) in 0.01 M $HClO_4$, and standardizing gravimetrically (Fe: Fe_2O_3 converted to hydroxide; Al: 8-quinolinolate; Ni: dimethylglyoximate; Co: Co_3O_4 converted to α-nitroso-β-naphtholate) or titrimetrically (Mg: EDTA; Cu: iodometry). Amberlite XAD-2 resin, 20—50 mesh (Rohm and Hass), was ground in an agate mortar, a 50—80 mesh portion was collected and washed with ethanol by decantation until the supernatant became clear.

Preparation of Sample Solutions. A known amount of acetylacetone (5 to 50 μL) was added with a 25 or 100 μL micropipet to ca. 50 cm^3 of 0.1 M $NaClO_4$, a known volume of a metal ion stock solution was added, the pH was adjusted with a suitable buffer solution, and finally the solution was diluted to 100 cm^3 with 0.1 M $NaClO_4$ (the acetylacetone concentration was in the range of 4.87×10^{-4} to 4.87×10^{-3} M and the metal ion concentration was in the range indicated in Tables 1—3). The buffer solutions used are as follows: 0.2 M acetic acid-0.2 M sodium acetate (pH=3—6), 0.1 M sodium dihydrogenphosphate-0.1 M sodium hydroxide (pH=6—7.5), and 0.2 M boric acid-0.2 M potassium chloride-0.2 M sodium hydroxide (pH=7.5—10). For pHs lower than 3, perchloric acid (0.1 M) was used. The amount of the buffer or $HClO_4$ solution added to an aqueous solution containing both acetylacetone and metal ion was moderated so that the contribution of buffer salts to the increase in ionic strength was less than 0.01. The pH was measured with a Horiba Type F-7 pH meter to 0.01 pH unit.

Apparatus and Procedures. A 25 cm^3 portion of sample solution was transferred into a 100 cm^3 Erlenmeyer flask with a ground glass joint, the flask being immersed in a thermostated bath at 25.0±0.1 °C. A gas-inlet-type adaptor was mounted on the flask and nitrogen gas was dispersed through the solution via a sintered glass ball at a constant flow rate of 895 $cm^3\,min^{-1}$. The N_2 gas flow rate was adjusted by means of a needle valve and monitored during the aeration by a flow meter (Ueshima Brooks Rotameter); a deviation within 2% was observed around the adopted flow rate. The N_2 gas leaving the sample solution was

passed through a 5 mm×5 cm glass column which contained XAD-2 resin beads 3.5 cm in length and had its exit end plugged with glass wool. After a fixed time, the N_2 gas stream was interruted, the XAD column was replaced by another one, and the introduction of N_2 gas was resumed. This operation was repeated at regular time intervals. The acetylacetone adsorbed on the resin was completely eluted out with a 5 cm^3 ethanol, and the amount expelled from the solution during the fixed time was determined spectrophotometrically at 272 nm by reference to a calibration curve prepared in advance with acetylacetone-ethanol solutions of known concentrations. The XAD column, after subjected to elution with ethanol and air-dried, could be used repeatedly.

After completion of each aeration run, the pH of the sample solution was checked; no appreciable change in pH was found before and after aeration.

Results

Derivation of an Equation That Allows Estimation of 1:1 Metal Acetylacetonate Complex Formation Constants. The equilibria among the species that should be taken into account are

$$\text{acac}^- + \text{M}^{n+} \rightleftharpoons \text{M(acac)}^{n-1}, \ K_1, \quad (1)$$

$$\text{Hacac} \rightleftharpoons \text{H}^+ + \text{acac}^-, \ K_a, \quad (2)$$

$$\text{Hacac(aq)} \longrightarrow \text{Hacac(gas)}, \ k, \quad (3)$$

where K_1, is the formation constant of 1:1 metal acetylacetonate complex, K_a is the acid dissociation constant of acetylacetone (Hacac), and k is the rate constant for the expulsion of Hacac molecules from the aqueous into the gaseous phase. For convenience, symbol L^- will hereafter be used to denote species $acac^-$.

The solute HL expelled into the gaseous phase is to be trapped successively by XAD-2 columns, and the amount, Q_{HL}, trapped during a fixed time is measured as a function of aeration time, t. Here, we assume that the releasing rate of HL at a constant N_2 gas flow rate is of first-order dependence on the concentration of this species present in the solution, and thus

$$dQ_{HL}V^{-1}/dt = k[HL], \quad (4)$$

where V is the volume of the aqueous phase. We have mass-balance equations

$$C_M = [M^{n+}] + [ML^{n-1}], \quad (5)$$

$$\begin{aligned} C_{HL} &= [HL] + Q_{HL}V^{-1} + [ML^{n-1}] + [L^-] \\ &= [HL] + Q_{HL}V^{-1} + K_1[L^-][M^{n+}] + [L^-] \\ &= [HL] + Q_{HL}V^{-1} + (K_1[M^{n+}] + 1)K_a[HL][H^+]^{-1}, \end{aligned} \quad (6)$$

where C_M and C_{HL} indicate the total concentration of metal ions and that of acetylacetone, respectively. Substitution of Eq. 6 into Eq. 4 yields

$$dQ_{HL}V^{-1}/dt = k(C_{HL} - Q_{HL}V^{-1})/(1 + K_a[H^+]^{-1} + K_1K_a[M^{n+}][H^+]^{-1}), \quad (7)$$

which becomes, on integration and with $Q_{HL}=0$ at $t=0$,

$$\ln (C_{HL} - Q_{HL}V^{-1}) = -kt/(1 + K_a[H^+]^{-1} + K_1K_a[M^{n+}][H^+]^{-1}) + \ln C_{HL}. \quad (8)$$

Plots of $\ln(C_{HL}-Q_{HL}V^{-1})$ vs. t will give a straight line with a slope which corresponds to $-k/(1+K_a[H^+]^{-1}+K_1K_a[M^{n+}][H^+]^{-1})$ or to $-k/(1+K_a[H^+]^{-1})$ in the absence of metal ions. Under the condition that the total concentration of metal ions is sufficiently large compared to the concentration of the metal complex formed, that is, $C_M \gg [ML^{n-1}]$, we can set $[M^{n+}]$ in Eq. 8 equal to C_M.

Estimation of k and K_a. The constants k and K_a were determined from runs in the absence of metal ions. Figure 1 shows some plots constructed with the aid of Eq. 8. It is found that these plots give straight lines up to ca. 70% release of the acetylacetone initially present in the solution. This linearity verifies the validity of the assumption that the releasing rate of HL is first order in this species at a constant aeration rate. It can be seen from Fig. 1 that when the total concentration of HL is the same, the

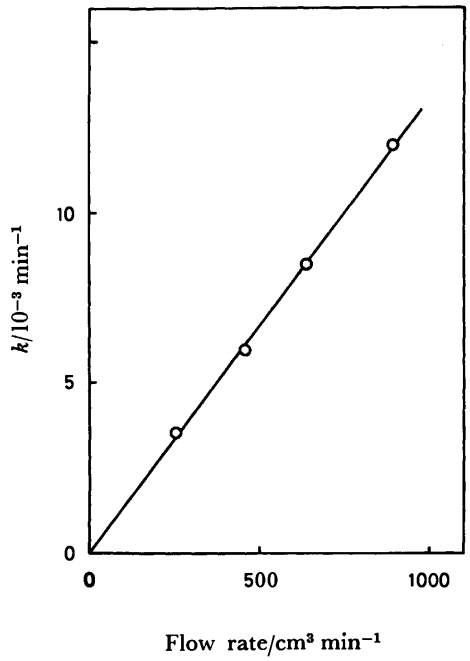

Fig. 3. k as a function of N_2 gas flow rate in the absence of metal ions. pH 2.30; C_{HL} 5.87×10^{-4} mol dm^{-3}.

slopes coincide with one another at the same aeration rate. This also supports the validity of Eq. 4.

At a constant N_2 gas flow rate, the slope of the straight line is almost constant in the acidic region, but steeply decreases in higher pH solutions, as seen from the plots of $k/(1+K_a[H^+]^{-1})$ vs. pH shown in Fig. 2. A least-squares calculation has revealed that k is 1.20×10^{-2} min^{-1} at an aeration rate of 895 cm^3 min^{-1} and that pK_a is 9.17. The K_a value thus determined is about half the reference one, 8.82 as pK_a,[9] reported at 25 °C and I=0.1(Na$^+$, H$^+$)ClO$_4$. The rate

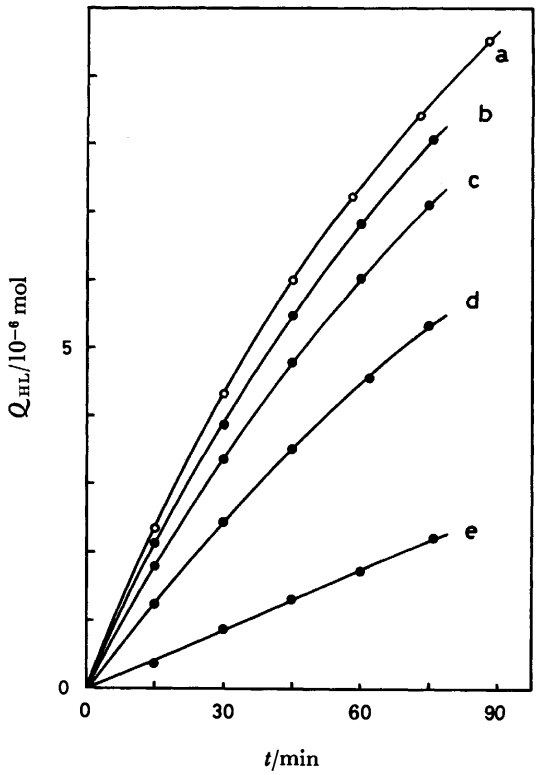

Fig. 4. The plots of Q_{HL} vs. t in the absence and presence of metal ions. N_2 gas flow rate 895 cm^3 min^{-1}; C_{HL} 5.85×10^{-4} mol dm^{-3}; (a): C_M=0, pH=2.30, (b): $C_{Mg}=2.05\times10^{-3}$ mol dm^{-3}, pH=7.37, (c): $C_{Ni}=9.85\times10^{-3}$ mol dm^{-3}, pH=4.76, (d): C_{Cu}(sulfate)$=1.98\times10^{-3}$ mol dm^{-3}, pH=3.68, (e): $C_{Fe(III)}=4.02\times10^{-3}$ mol dm^{-3}, pH=1.82.

constant, k is proportional directly to the N_2 gas flow rate in the range of 250 to 895 cm^3 min^{-1} studied, as shown in Fig. 3. In the subsequent runs, the flow rate was fixed at 895 cm^3 min^{-1} to reduce the time required for completing a single run.

Estimation of K_1. The amount of acetylacetone released into the gaseous phase was plotted against aeration time to give a parabolalike curve. Results for some metals are shown in Fig. 4, in which the result obtained in the absence of metal is included for comparison. Plots constructed with the aid of Eq. 8 gave straight lines for each run over the aeration time range investigated. Insofar as sample solutions are sufficiently acidic that the term $K_a[H^+]^{-1}$ can be neglected compared to unity, and provided also that the total concentration of metal ions is sufficiently large compared with the ligand concentration, the slope of the straight line can be taken as $-k/(1+K_1K_aC_M[H^+]^{-1})$. The effect of C_M and pH on the slope was examined for Cu and Ni. The results are shown in Fig. 5 ($C_{Ni}=1.97\times10^{-3}$—4.93×10^{-2} M, $C_{HL}=5.85\times10^{-4}$ M, and pH almost constant around 4.8) and in Fig. 6 ($C_{Cu}=1.98\times10^{-3}$ M, $C_{HL}=5.85\times10^{-4}$ M, and pH=1.02—4.89). As expected, the gradient of the straight line decreases as either C_M or pH increases.

The k and K_a values being known from the runs undertaken in the absence of metal, we can evaluate K_1 for each metal from the slope of the straight line. The K_1 values thus determined for Cu and Ni under various C_M and pH conditions are given in Table 1, and those for the other seven metals studied are summarized in Table 2, in which the K_1 values evaluated by using the reference pK_a(=8.82) are also listed together with those reported in the literature.[4-8] The K_1 values obtained by the present method are in reasonable agreement within 0.1 to 0.2 in the log unit with the literature values except for Al(III), which case differs by ca. 0.4 log unit.

Discussion

There are various factors which affect the precision and accuracy of the method proposed here for evaluating association constants between volatile and nonvolatile solutes. As was noted in a previous paper,[1] it is a requirement to carry out two separate runs, one in the absence and the other in the presence of nonvolatile solutes, under the same aeration conditions. To meet this requirement, the same sintered glass ball should be used in common, and the N_2 gas flow rate should be controlled to be as identical with each other as possible. Indeed, the rate constant, k, the absolute value of which is of no significance, is a function of the aeration rate (Fig. 3). In addition, the ionic strength and the kind of the electrolyte used to adjust it should be the same for the two runs, because the so-called salting-out effect may influence the volatility of the solute of interest, and hence the k value.

Particular attention should be paid to the presence of such electrolytes as may cause association with the nonvolatile solute to be studied, since this also affects the accuracy of the present method. For instance, the K_1 value for Cu decreases step by step as C_M increases, as can be seen from Table 1, when the sulfate salt is used; we first thought this arose from the salting-out of SO_4^{2-} ions, but it now seems more reasonable to consider ion-pair formation between Cu^{2+} and SO_4^{2-}.[10] The K_1 value of Cu(II) for the chloride salt is employed for this reason. Incidentally, the ion-pair formation constant has been reported to be ca. 200 at 25 °C and at ionic strengths corrected to zero.[3] The K_1 value of Cu(II) for the sulfate salt is to be underestimated unless the free metal ion concentration, $[M^{n+}]$, in the experimentally determined slope, $-k/(1+K_1K_a[M^{n+}][H^+]^{-1})$, is corrected for the

ion-pair formation, that is, $[Cu^{2+}]=C_{Cu}-[Cu^{2+}SO_4^{2-}]$.

The choice of proper pK_a value is essential in estimating K_1. We have listed the two K_1 values in Table 2, one being evaluated based on pK_a=9.17 and the other on pK_a=8.82 reported in the literature. Although the K_a value determined in this work is appreciably lower, we are of the opinion that the use of this value leads to a better K_1 value since the same procedure employed to evaluate both pK_a and K_1 tends to compensate for systematic errors inherent in the present method.

An important point to keep in mind is the magnitude of the product, $K_1K_aC_M[H^+]^{-1}$. The value of K_1, cannot be evaluated accurately or at all when the term is too small compared with unity. This may be responsible for the unusual values observed for Cu at pH=1.02 and for Ni at pH=3.80 (Table 1). To get more reliable K_1, the solution pH and/or C_M should desirably be high for metals with relatively small stability constants. The choice of the solution pH, however, may be limited for metals subject to hydrolysis. For metals with large stability constants, on the other hand, these conditions are not necessarily desirable, because it takes a prolonged time to expel the free ligand from the aqueous phase.

When it is necessary to consider hydrolysis of metal ions, the concentration of M^{n+} should be modified by using $\alpha_{M(OH)}$, a side reaction coefficient, into $[M^{n+}]=C_M/\alpha_{M(OH)}$; with correction for the hydrolysis reaction, $M^{n+}+H_2O \rightleftarrows M(OH)^{n-1}+H^+$, the complex formation constant, $K_{1,correct}$, can be written as

$$\log K_{1,correct} = \log K_1 + \log \alpha_{M(OH)},$$

including the second term of the right hand side of the equation as a correction term. This correction term, however, is negligibly small at the solution pH adopted here except for Fe(III). The K_1 value of Fe(III) listed in Table 2 has been corrected by 0.1 in the logarithmic unit; for Fe(III) the literature value of −2.55 was used as $\log K_{hydrol}$, where K_{hydrol} is the hydrolysis constant and can be converted into the side reaction coefficient by the relationship, $\alpha_{M(OH)}=1+K_{hydrol}[H^+]^{-1}$.

An attempt was made to evaluate 1:2 formation constants for some metal acetylacetonato complexes on the basis of the equilibration

$$acac^- + M(acac)^{n-1} \rightleftharpoons M(acac)_2^{n-2},\ K_2 \qquad (9)$$

It is difficult in this case to derive a rate equation like Eq. 7 under the experimental condition $C_{HL}>C_M$ or $C_{HL}\approx C_M$. We therefore tried to estimate K_2 through the following three successive steps. The first step: $\log(Q_{HL}/V)$ is plotted vs. $\log t$ to give a straight line for each run, and the intercept, $\log a$, and the slope, b, are derived. The second step: on the assumption $Q_{HL}/V=a\ t^b$, $dQ_{HL}V^{-1}/dt$ is calculated at a selected aeration time, t, and then, the concentration of free

HL present in the solution at t is obtained based on the rate equation, Eq. 4. The third step: from the mass-balance equations

$$C_{HL} = [HL] + Q_{HL}/V + [L^-] + [ML^{n-1}] + 2[ML_2^{n-2}],$$
$$C_M = [M^{n+}] + [ML^{n-1}] + [ML_2^{n-2}],$$

a) As the chloride salt, $C_{Cu}=9.80\times10^{-4}$ mol dm^{-3}, $C_{HL}=2.14\times10^{-3}$ mol dm^{-3}, pH=4.89, and the data used are pK_a=9.17 and log K_1=8.3. b) Ref. 7. c) $C_{Ni}=9.85\times10^{-4}$ mol dm^{-3}, $C_{HL}=2.14\times10^{-3}$ mol dm^{-3}, pH=6.86, and the data used are pK_a=9.17 and log K_1=5.9. d) Ref. 5. e) $C_{Fe}=4.02\times10^{-3}$ mol dm^{-3}, $C_{HL}=4.87\times10^{-3}$ mol dm^{-3}, pH=2.12, and the data used are pK_a=9.17 and log K_1=10.5. f) $C_{Al}=9.96\times10^{-4}$ mol dm^{-3}, $C_{HL}=2.14\times10^{-3}$ mol dm^{-3}, pH=3.58, and the data used are pK_a=9.17 and log K_1=9.7.

we can derive

$$C_{HL} = [HL] + Q_{HL}/V + K_a[HL][H^+]^{-1} + 2C_M - [M^{n+}](2+K_1K_a[HL][H^+]^{-1}),$$

which allows us to estimate $[M^{n+}]$ by using the K_a and K_1 values evaluated by the present method, and in turn, $[ML^{n-1}]$ and $[ML_2^{n-2}]$ can be determined from the mass-balance relationships, from which K_2 is to be derived. The values thus determined are given in Table 3. Again, if it is necessary to make correction for the hydrolysis of metal ions, the product $[M^{n+}]\alpha_{M(OH)}$ must be employed instead of the simple $[M^{n+}]$; this correction was applied only to Fe(III).

It is informative to follow the change in concentration of such species as M^{n+}, ML^{n-1}, and ML_2^{n-2} as a function of aeration time. As aeration proceeds, $[ML_2^{n-2}]$ decreases with an accompanying increase in $[M^{n+}]$ (and also in $[ML^{n-1}]$ when C_{HL} is sufficiently large compared to C_M). In the case of Fe(III) given in Table 3, there was observed a steady state with respect to the ML^{n-1} species, which may result from C_{HL} being nearly equal to C_M. It appears that the K_2 value thus derived for each metal falls gradually as aeration proceeds. This is quite unreasonable and is probably caused by the assumption made in the second step, that is, the Q_{HL}/V vs. t plot follows a parabolic curve. In reality, the log(Q_{HL}/V) vs. log t plots show a slight deviation from the linearity and this trend is pronounced with prolonging aeration time. Therefore, the differential treatment of experimental results employed here to estimate K_2 led to erroneous evaluation of 1:2 association constants.

If it is convenient to follow the rate of decrease in the concentration of the associated species instead of measuring the releasing rate of the volatile solute expelled from the aqueous into the gaseous phase, the rate equation can be expressed as

$$-d[A\cdot B]/dt = kK^{-1}[A\cdot B][B]^{-1} = kK^{-1}[A\cdot B](C_M-[A\cdot B])^{-1},$$

which becomes, on integration and with $[A\cdot B]=[A\cdot B]_o$, the initial (t=0) concentration

$$C_B \ln [A\cdot B] - [A\cdot B] = -kK^{-1}t + C_B \ln [A\cdot B]_o - [A\cdot B]_o,$$

where A, B, and A·B denote the volatile, nonvolatile, and associated species, respectively, K is an association constant, and k is a rate constant of the expulsion of A from the aqueous phase in the absence of B. This is essentially the same form as that previously used to determine the disproportionation constant of mercury(I).[1] Implicit in this rate equation and also in Eq. 4 (and Eq. 7) is the assumption that the transfer of volatile solute from

the aqueous into the gaseous phase is the rate-determining step. If, on the other hand, an association equilibrium is the rate-determining step. the association constant cannot be estimated. This is a limitation on the applicability of the present method.

In general, it is somewhat difficult to measure association constants between nonvolatile and highly volatile solutes, because it is hard to maintain constant the concentration of the latter in the aqueous medium. The present method is applicable only to very volatile solutes, and in this respect seems complementary. The present technique need not maintain the volatile solute concentration constant, and its total concentration in the aqueous medium can easily be determined by aerating the medium with an inert gas for a prolonged period and by trapping the released solute during the aeration

An important application of the method proposed here will be encountered when hydrophobic interaction is to be studied in the aqueous environment between nonvolatile and volatile solutes.

Department of Chemistry, Faculty of Science, Shimane University, Matsue 690

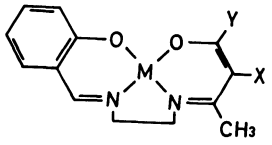
(Received September 24, 1985)

The nucleophilic replacement of halogen on the methine carbon of a Schiff base complex of nickel(II) or copper(II) by ethyl mercaptoacetate in dichloromethane proceeds via a four-centered intermediate, in which two polarizable atoms, such as bromine and sulfur, may stabilize strained bond angles. In the case of a free Schiff base ligand, a relatively stable adduct was spectrophotometrically confirmed. The adduct is thought to have a configuration analogous to that of a spiro compound containing a five-membered ring. Free ligands show no absorption bands in the wavelength region longer than 340 nm, while the adduct shows band at 375 nm assignable to a n-π* transition.

Many electrophilic substitutions of coordinated ligands have been reported; e.g. the methine protons of β-diketonato metal complexes have been replaced by such electrophiles as bromine, iodine, acyl derivatives, and sulfur.[1] The substitutions have also been reported on a quadridentate Schiff base complex of nickel(II) or copper(II), and those kinetics have been investigated.[2-4] On the other hand, only a few nucleophilic substitutions have been reported; the further conversion of the halogeno-substituted methine carbon of the β-diketone or a quadridentate Schiff base complex was been carried out with such nucleophiles as benzenethiol, its derivatives, and ethyl mercaptoacetate.[5-7] In this paper, we wish to report further studies of the nucleophilic substitution mechanism of the unsymmetrical quadridentate Schiff base and its complex of nickel(II) or copper(II) with ethyl mercaptoacetate, $HSCH_2CO_2C_2H_5$. The complexes used in this study are shown in Fig. 1.

Results and Discussion

The Substitution Reaction of the Nickel(II) or Copper(II) Complex. By the addition of ethyl mercaptoacetate, the spectrum of Ni(L-Br, CH_3) in dichloromethane changed to that of Ni(L-$SCH_2CO_2C_2H_5$, CH_3), with an isosbestic point at 288 nm (Fig. 2). The rate of reaction (1) was determined by means of the absorbance change at 385 nm by the use of a pseudo- first-order method:



M(L-X,Y)

Fig. 1. Abbreviation of the Schiff base metal complexes.

$$Ni(L\text{-}Br,\ CH_3) + HSCH_2CO_2C_2H_5 \longrightarrow Ni(L\text{-}SCH_2CO_2C_2H_5,\ CH_3) + HBr \quad (1)$$

The plot of $-\ln(A_\infty - A_t)$ vs. the time was linear to at least 80% completion, where A_t and A_∞ represent the absorbances at time t and infinity respectively. The pseudo- first-order rate constant (k_{obsd}) was estimated from its slope. The rate was also measured at

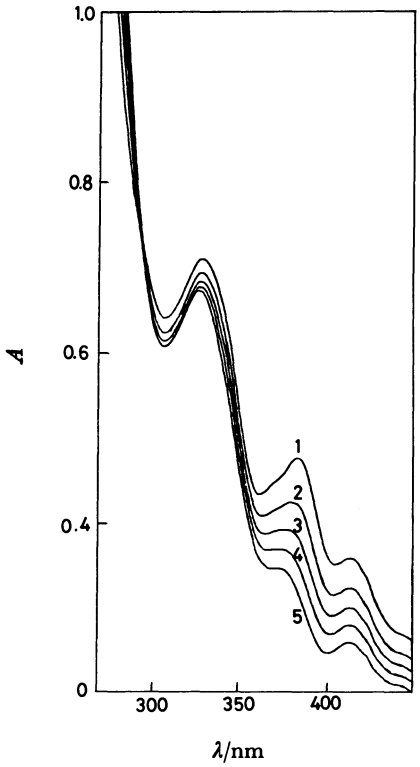


Fig. 2. Spectral change during the reaction of Ni(L-Br, CH_3) with ethyl mercaptoactate in dichloromethane at 20 °C: $[Ni(L\text{-}Br,CH_3)]_0 = 1.50 \times 10^{-4}$ mol dm^{-3}, $[HSCH_2CO_2C_2H_5]_0 = 3.00 \times 10^{-3}$ mol dm^{-3}. 1: 30 s, 2: 10 min, 3: 30 min, 4: 45 min, and 5: 80 min after the reaction.

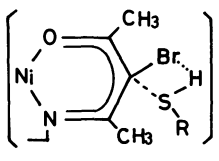
Table 1. The Rate Constants for the Reactions of the Nickel(II) and Copper(II) Complexes with Ethyl Mercaptoacetate in Dichloromethane

Run	$k^{a)}_{obsd}/10^{-3}$ s^{-1}	Conditions
1	2.45±0.35	Ni(L-Br, CH_3) + $HSCH_2CO_2C_2H_5$ (2.25×10^{-3} mol dm^{-3})
2	2.71±0.55	(3.30×10^{-3} mol dm^{-3})
3	3.12±0.52	(3.75×10^{-3} mol dm^{-3})
4	4.44±0.63	(4.50×10^{-3} mol dm^{-3})
5	4.76±0.41	(5.25×10^{-3} mol dm^{-3})
	$k^{b)}$/mol^{-1} dm^3 s^{-1}	
6	$(9.20\pm0.98)\times10^{-1}$	Ni(L-Br, CH_3) + $HSCH_2CO_2C_2H_5$
7	$(1.12\pm0.15)\times10^{-3}$	Ni(L-Cl, CH_3) + $HSCH_2CO_2C_2H_5$
8	4.40±0.51	Ni(L-Br, C_6H_5) + $HSCH_2CO_2C_2H_5$
9	$(5.30\pm1.20)\times10$	Cu(L-Br, CH_3) + $HSCH_2CO_2C_2H_5$
	$k^{a,c)}_{obsd}/10^{-2}$ s^{-1}	Ni(L-Br, CH_3) + $HSCH_2CO_2C_2H_5$
10	0.53±0.11	$[EtOH]_0$ = 0.2%(v/v)
11	0.91±0.14	0.4%
12	1.25±0.18	0.6%
13	1.63±0.13	0.8%
14	1.94±0.21	1.0%
15	3.57±0.24	1.5%
16	4.33±0.28	2.0%

a) The first-order rate constants. b) The second-order rate constants. c) $[HSCH_2CO_2C_2H_5]_0 = 3.00\times10^{-3}$ mol dm^{-3}. $[complex]_0 = 1.50\times10^{-4}$ mol dm^{-3}.

327 nm. Both values were the same (within the limit of experimental error), showing no wavelength-dependence of the rate. The value of k_{obsd} was proportional to the concentration of ethyl mercaptoacetate, indicating that the reaction order is first in the concentration of the nucleophile (Runs 1—5 in Table 1).

Ni(L-Br, CH_3) did not react with ethyl hydroxyacetate under the same conditions as those used for ethyl mercaptoacetate. This corresponds to the finding that acetylacetone complexes of aluminum(III), chromium(III), iron(III), and cobalt(III) react with benzenethiols, but not with phenols.[5] The rate constant of the reaction for Ni(L-Cl, CH_3) was very small compared with that for Ni(L-Br, CH_3)(Runs 6 and 7). It has also been reported that the substitution for Ni(L-Br, C_6H_5) is performed with *N*-bromosuccinimide, but not with *N*-chlorosuccinimide.[8] That is, at least two polarizable atoms, such as sulfur and bromine, are required to promote the reaction facilely. The following four-centered intermediate might be proposed in view of the results concerning a solvent effect to be discussed later:



Scheme 1.

where R is $CH_2CO_2C_2H_5$.

A sulfur atom of the nucleophile is more polarizable than an oxygen atom; thus, the clouds of valence electrons about the sulfur atom are more easily distorted by methine carbon than those about the oxygen atom. A bromine atom might play the same role in the intermediate. Then, the polarizable sulfur and bromine atoms must stabilize the strained intermediate. By the addition of ethanol (>2% v/v) to the dichloromethane solution of Ni(L-Br, CH_3) and ethyl mercaptoacetate, the reaction was strongly depressed. Ethanol destabilizes the intermediate, with the formation of a hydrogen bond. However, the rate was increased up to 2% of ethanol (Runs 10—16). Probably, ethyl mercaptoacetate forms a dimer in a nonpolar solvent such as dichloromethane; thus, the concentrations of the monomer species which is active for the reaction might be increased by the addition of adequate amounts of ethanol.

A similar intermediate has been proposed for the nucleophilic substitution of the bromo-substituted methine carbon of the β-diketonato metal complexes for thiophenols; the reaction occurred in dichloromethane, but was depressed in a polar solvent, such as ethanol, acetone or ethyl ether. The reaction was also inhibited by the addition of small amounts of pyridine or piperidine.[5]

The rate constant for Ni(L-Br, C_6H_5) was about six times that for Ni(L-Br, CH_3) (Runs 6 and 8). A phenyl group attracts an electron from the chelate ring, promoting the nucleophilic substitution on the methine carbon. The rate constant for Cu(L-Br, CH_3)

is about fifty times that for Ni(L-Br, CH_3) (Runs 6 and 9). The electronegativities of the nickel(II) and copper(II) ions are almost the same,[9] which might exclude the inductive effect of the central metal ion on the reaction rate. The same tendency has been reported for the case of the electrophilic substitution reactions of M(L-H, CH_3), where M is H_2, Cu(II), or Ni(II), for *N*-chlorosuccinimide; e.g., the copper(II) complex shows an extremely large rate constant as compared with the nickel(II) complex and the free ligand.[4] As has been proposed for the electrophilic substitution, the copper(II) ion may catalyze the reaction via the formation of an ethyl mercaptoacetate adduct. However, the details are not known at present.

The Substitution Reaction of the Free Ligand. The spectral change of the free ligand, H_2(L-Br, CH_3) with ethyl mercaptoacetate is shown in Fig. 3. At first, the absorption band of H_2(L-Br, CH_3) at 328 nm was decreased, and then new peaks appeared at 284 and 375 nm; isosbestic points were found at 242, 263, 311, and 352 nm. Subsequently, both bands were gradually decreased, followed by the appearance of the band at 316 nm, where isosbestic points were not observed, probably because of the presence of side reactions. However, the final spectrum is consistent with that of hydrobromide of H_2(L-$SCH_2CO_2C_2H_5$, CH_3), the preparation of which will be discussed later. That is, a relatively stable adduct might be formed in the reaction of the free ligand and ethyl mercaptoacetate.

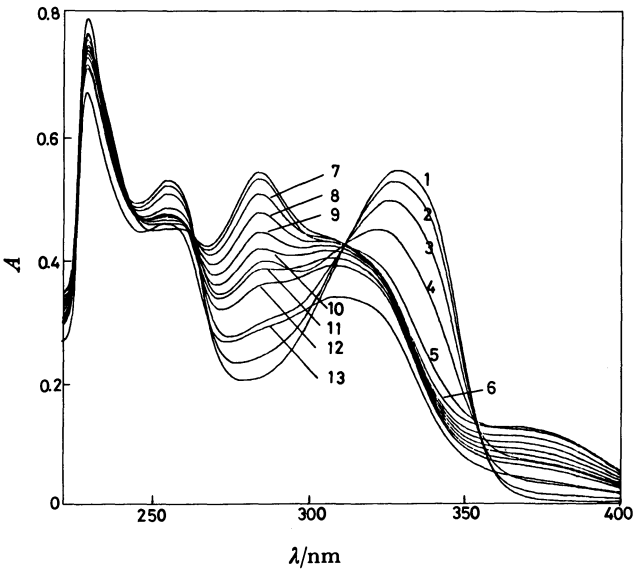


Fig. 3. Spectral change during the reaction of H_2(L-Br,CH_3) with ethyl mercaptoacetate in dichloromethane at 20 °C; $[H_2(L\text{-}Br,CH_3)]_0 = 1.00 \times 10^{-4}$ mol dm^{-3}, $[HSCH_2CO_2C_2H_5]_0 = 2.50 \times 10^{-4}$ mol dm^{-3}. 1: 1 min, 2: 30 min, 3: 1 h, 4: 1 h 30 min, 5: 2 h, 6: 2 h 30 min, 7: 3 h 30 min, 8: 4 h 30 min, 9: 5 h 50 min, 10: 7 h 10 min, 11: 10 h 20 min, 12: 11 h 20 min, and 13: 19 h 40 min after the reaction. The intensiry of absorption at 284 nm was increased in time courses from 1 to 6, whereas it was decreased from 7 to 13.

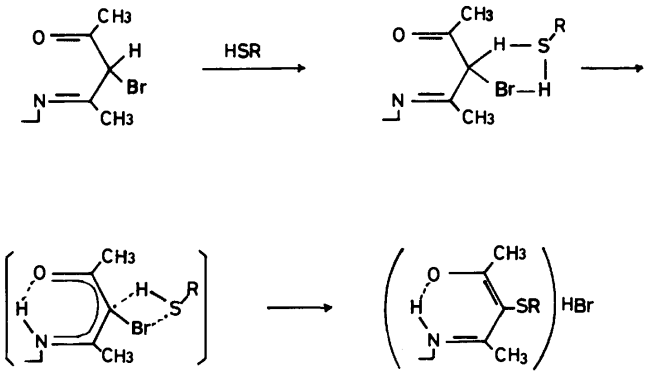
To elucidate the reaction mechanism, a few further experiments were carried out. The formation rate of the adduct in benzene was faster than that in dichloromethane, but the spectrum of H_2(L-Br, CH_3) did not change upon the addition of the nucleophile in ethanol. The spectrum of the free ligand also did not change with ethyl hydroxyacetate. In addition, the spectrum of H_2(L-H, CH_3) and H_2(L-Cl, CH_3) showed no change with ethyl mercaptoacetate. Thus, two polarizable atoms must be required to form the adduct. Attempts to isolate the adduct were unsuccessful because of decomposition during purification. As *p*-toluenethiol has been reported to act as a nucleophile toward a Schiff base nickel(II) complex,[7] it was added to the dichloromethane solution of the free ligand. The spectral change was similar to that of ethyl mercaptoacetate; e.g., at first, a band appeared around 375 nm, but subsequently its intensity was decreased. By the addition of 1-butanethiol, similar spectral change was also observed. That is, only the SH group of the nucleophile must play an important role in the formation of the adduct. The band at 375 nm disappeared in polar solvents, such as methanol, ethanol, and acetone. The free ligands, such as H_2(L-H, CH_3), H_2(L-Cl, CH_3), H_2(L-Br, CH_3), and H_2(L-$SCH_2CO_2C_2H_5$, CH_3), exhibit no band at wavelengths longer than 340 nm. Therefore, the new band may be ascribed to a n-π^* transition in the adduct.

It is known that the free Schiff base ligand has three tautomeric forms: The Schiff base, the keto enamine, and the imino enol.[10] Although the keto-enamine form exists predominantly in solution,[10] with the nucleophile, the Schiff base type might form an adduct with a five-membered ring system (see the following reaction Scheme). Because the strains of the bond angles must be less than those in the four-centered system, the free Schiff base ligand at first forms a relatively stable spiro-type adduct with the nucleophiles. On the other hand, the metal complex can not form the adduct because of the lack of the enol hydrogen atom.

The nucleophilic-substituted ligand was also prepared; pale yellow precipitates were immediately obtained by the reaction of H_2(L-Br, CH_3) and ethyl mercaptoacetate in a benzene solution, but could not be characterized because of their decomposition to a brownish, tarry material. A test of silver nitrate was positive for the precipitates, showing the presence of bromide. To characterize the precipitates, nickel(II) acetate was added to their methanol solution; the orange nickel(II) complex was thus obtained and identified as Ni(L-$SCH_2CO_2C_2H_5$, CH_3) by means of an elemental analysis and ^1H NMR measurements. Thus, the precipitates might be confirmed to be

hydrobromide of H_2(L-$SCH_2CO_2C_2H_5$, CH_3). In the ^1H NMR spectrum of the salt, an additional proton signal appeared in the low magnetic field (δ=11.02), probably arising from a -CH=N$\underline{H}^+$- proton. By the addition of an adequate amount of triethylamine to the salt, hydrogen bromide was liberated, resulting in an oily H_2(L-$SCH_2CO_2C_2H_5$, CH_3) compound which showed no band at 375 nm in dichloromethane. That is, the reaction might proceed as follows:



Scheme 2.

Consequently, the reaction of the Schiff base metal complex with ethyl mercaptoacetate proceeds via the four-centered intermediate, in which two polarizable atoms are required to stabilize the strained bond angles. On the other hand, the free Schiff base ligand at first forms the adduct with the five-membered ring system which shows the characteristic absorption band at 375 nm. Subsequently, the adduct slowly changes to the final product via the above intermediate.

Experimental

The Cu(L-Br, C_6H_5), Cu(L-Cl, C_6H_5), Ni(L-$SCH_2CO_2C_2H_5$, CH_3), and Ni(L-$SCH_2CO_2C_2H_5$, CH_3) complexes were prepared by the method described before.[4]

The Preparation of Cu(L-$SCH_2CO_2C_2H_5$, CH_3). A complex was prepared in a manner similar to those used for the nickel(II) complexes and was recrystallized with a mixture of methanol and water. Found: C, 50.37; H, 5.39; N, 6.61%. Calcd for $C_{18}H_{22}O_4SCu$: C, 50.75; H, 5.22; N, 6.57%. UV(CH_2Cl_2)λ_{max}(log ε) 268 (4.26), 328 (4.04), 384 (3.66), and 554 (2.65) nm. IR (ν CO) 1730 cm^{-1}.

The Preparation of Hydrobromide of H_2(L-$SCH_2CO_2C_2H_5$, CH_3). A benzene solution (20 cm^3) of 0.21 cm^3 (2.0 mmol) $HSCH_2CO_2C_2H_5$ was added to 50 cm^3 of a benzene solution containing 0.67 g (2.0 mmol) H_2(L-Br, CH_3); the mixture was then stirred at room temperature for 20 min. The pale yellow precipitates were filtered off and dried in a nitrogen atmosphere. The compound was sealed in a sample tube which had been purged with a nitrogen gas to prevent its decomposition into the brownish tarry material in air. ^1H NMR (DMSO-d_6) δ=1.39 (3H, t, CH_3), 2.67 (6H, s, CH_3), 3.43 (2H, s, SCH_2), 3.96—4.62 (6H, m, CH_2CH_2, $C\underline{H}_2CH_3$), 7.59—8.48 (4H, m, C_6H_4), 9.34 (H, s, -C$\underline{H}$=NH^+-), and 11.02 (H, s, -CH=N$\underline{H}^+$-) ppm.

The Preparation of H_2(L-$SCH_2CO_2C_2H_5$, CH_3). Adequate amounts of triethylamine were added to a dichloromethane suspension of the tarry hydrobromide salt, which then immediately dissolved. The hydrobromide of triethylamine was extracted with water for a few times, and the remaining dichloromethane solution was dehydrated on anhydrous sodium carbonate. When the solution was then concentrated under a reduced pressure, an oily material was obtained. ^1H NMR ($CDCl_3$) δ=1.25 (3H, t, CH_3), 2.34 (6H, d, CH_3), 3.33 (2H, s, SCH_2), 3.94 (4H, m, CH_2CH_2), 4.16—4.46 (2H, q, $C\underline{H}_2CH_3$), 7.44—8.09 (4H, m, C_6H_4), and 9.17 (H, s, CH=N) ppm. The orange nickel(II) complex was derived by adding an aqueous solution of nickel(II) acetate to the methanol solution of the oily material; it was then recrystallized with methanol. Found: C, 51.12; H, 4.95; N, 6.34%. Calcd for $C_{18}H_{22}N_2O_4SNi$: C, 51.33; H, 5.28; N, 6.65%. ^1H NMR ($CDCl_3$) δ=1.42 (3H, t, CH_3), 2.54 (3H, s, CH_3), 2.57 (3H, s, CH_3), 3.33—3.70 (6H, m, SCH_2, CH_2CH_2), 4.36—4.52 (2H, m, $C\underline{H}_2CH_3$), 7.16—7.99 (4H, m, C_6H_4), and 8.51 (H, s, CH=N) ppm. IR (ν CO) 1739 cm^{-1}.

Measurements. The ^1H NMR spectra were recorded with a JEOL-MH 100 spectrophotometer at a frequency of 100 MHz. The chemical shifts were determined in ppm, using TMS as the internal standard. The electronic spectra in solution and the infrared spectra using KBr pellets were measured on a Hitachi 124 spectrophotometer and a Hitachi 215 spectrophotometer respectively.

The authors wish to thank Mr. S. Kiyota for his preparation of some samples for kinetic measurements.

^{13}C NMR Study of the Cobalt(III) Complexes Containing Ethylenediamine-*N*-acetate (edma): $[Co(edma)_2]^+$ and [Co(ida)(edma)]

Tomoharu AMA,* Hiroshi KAWAGUCHI, and Takaji YASUI
Department of Chemistry, Faculty of Science, Kochi University,
Akebono-cho, Kochi 780
(Received November 13, 1985)

The ^{13}C NMR chemical shifts of the glycinate ring (G-ring) carbons of edma's in the six geometrical isomers of $[Co(edma)_2]^+$ were measured. It was shown that the trans ligands and chelation form (meridional or facial form) influence the ^{13}C NMR chemical shifts of the G-ring carbons in the same way as the magnetic anisotropy generated on the cobalt(III) center does. The chemical shifts of the ethylenediamine ring (E-ring) carbons of coordinating edma's were also influenced by the trans ligands and the chelation form, similarly to those of the G-ring carbons. Four geometrical isomers of [Co(ida)(edma)] were newly prepared and their structural assignments were made according to their ^{13}C NMR behavior.

It is known that the ^{13}C NMR chemical shifts of a ligand in the cobalt(III) complexes are influenced by the magnetic anisotropy of the cobalt center,[1] the chelation forms[2,3] (e. g. mer- and fac- forms), and the nature of the ligating atom in the trans position to the ligand. The latter influence has been studied for the glycinate ligand in the $[Co(ox)_x(gly)_y(en)_z]$ ($x+y+z=3$) series by Juranic et al.[4] However, their results have not yet been applied to the complexes of polydentate ligands having glycinate rings (G-ring).

In previous papers,[5,6] the structural assignments of the geometrical isomers of $[Co(edma)_2]^+$ (edma: $NH_2CH_2CH_2NHCH_2COO^-$) were reported. In this work we expand the results of Juranic et al. to the G-ring and to the ethylenediamine ring (E-ring) of edma in the six isomers of $[Co(edma)_2]^+$ and clarify which factor is the most important one to evaluate the ^{13}C chemical shifts of the coordinating edma's, comparing the three influences mentioned above. The result obtained for the $[Co(edma)_2]^+$ complex are applied to the newly prepared isomers of [Co(ida)(edma)] (ida: $NH(CH_2COO^-)_2$). The geometrical structures of the latter are discussed on the basis of absorption and ^{13}C NMR spectral data.

Experimental

Preparation of the Complexes. Four Isomers of the [Co(ida)(edma)] Complex: A solution containing 2.4 g of $CoCl_2 \cdot 6H_2O$, 1.3 g of iminodiacetic acid (H_2ida) and 2.3 g of ethylenediamine-*N*-acetic acid dihydrochloride dihydrate ($Hedma \cdot 2HCl \cdot 2H_2O$) in 100 cm^3 of water was adjusted to pH 5 with a 2 mol dm^{-3} NaOH solution. The pH being kept constant at 5, 24 g of PbO_2 was stirred into the solution in small portions at 30 °C. After 1 h, insoluble materials were removed by filtration. A solution containing neutral complexes was obtained by passing the filtrate through an SP-Sephadex (K^+ form) column and a QAE-Sephadex (SO_4^{2-} form) column (eluent: water). This solution was evaporated to about 10 cm^3 and poured onto a QAE-Sephadex (Cl^- form) column. A band adsorbed on the column was separated into three parts by recyclic developement with water: The first, a brown band; the second, two overlapped bands (violet and red-brown); and the third, a pink band. The second part was repeatedly developed on a QAE-Sephadex column (SO_4^{2-} form), by which means the violet (earlier eluate) and the red-brown (later eluate) bands were separated. Each solution eluted from the four bands was concentrated under reduced pressure, after which methanol was added to the concentrated solution to obtain crystals. Recrystallization was carried out from water by adding methanol except for the pink isomer which was recrystallized from warm water. Yields: The brown, 320 mg; the violet, 570 mg; the red-brown, 10 mg; and the pink isomer, 300 mg. Found for the brown isomer: C, 30.86; H, 4.76; N, 13.53%. Calcd for $[Co(ida)(edma)]=C_8H_{14}N_3O_6Co$: C, 31.28; H, 4.59; N, 13.68%. Found for the violet isomer: C, 29.24; H, 5.14; N, 12.74%. Found for the red-brown isomer: C, 29.54; H, 5.01; N, 12.96%. Found for the pink isomer: C, 29.51; H, 5.06; N, 12.90%. Calcd for $[Co(ida)(edma)] \cdot H_2O=C_8H_{16}N_3O_7Co$: C, 29.55; H, 4.96; N. 12.92%.

Six Isomers of the $[Co(edma)_2]X$ Complex: The preparation and separation were described in our previous paper.[5,6]

Spectral Measurements. The ^{13}C NMR spectra of the isomers were recorded on a JEOL FX-100 spectrometer, in the pulsed Fourier transform/proton noise decoupled mode. The field frequency ratio was stabilized by locking to internal D_2O. The peak positions were measured relative to internal dioxane (δ=67.40). No ^{13}C NMR spectra were obtained for the pink isomer of [Co(ida)(edma)] because of its low solubility in D_2O.

The two $-\underline{C}H_2-$ carbons neighboring to -NH- in coordinating edma ($-\underline{C}H_2NH\underline{C}H_2-$) were distinguished from one another by means of the ^1H selective decoupling method as the carbons were observed in the close magnetic fields in each isomer of $[Co(edma)_2]^+$; the methylene carbon of the G-ring appeared as a singlet peak when the glycinate $-CH_2-$ protons were decoupled. The signals which appeared near δ=180 and 40 were assigned to $-\underline{C}OO^-$ and $-\underline{C}H_2NH_2$ carbons, respectively.

The visible and UV absorption spectra were recorded on a HITACHI 557 spectrophotometer in aqueous solutions.

Results and Discussion

The numbering of the carbons in an edma ligand is as follows.

NH_2-CH_2-CH_2-NH-CH_2-COO^-
C-4 C-3 C-2 C-1

The $[Co(edma)_2]^+$ complex provides six geometrical isomers as shown in Fig. 1. The structural assignments of the geometrical isomers have been reported in the previous papers.[5,6] The ^{13}C NMR data of these isomers are listed in Table 1.

It is known that the chemical shifts of the ligands are influenced by the magnetic anisotropic effect of the cobalt(III) ion. The method of estimating this effect has been studied by Yoneda et al.[1] The anisotropy values (σ_{Co}) calculated for the coordinating edma's in $[Co(edma)_2]^+$ are presented in Table 1, together with the observed (δ^{obsd}) and corrected ($\delta^{cor}=\delta^{obsd}+\sigma_{Co}$) chemical shift values.

The ^{13}C NMR Chemical Shifts of the Complex Containing Facially Coordinating edma (*fac*-edma). The corrected chemical shift (δ^{cor}) of the C-1 carbons in coordinating edma's are classified into three types from the difference of two ligating atoms in the trans positions to two ligating atoms (N and O) of the G-ring of edma, as shown in Fig. 2(a); Types A, B, and C exhibit ^{13}C signals at lower, higher, and middle fields, respectively. Similarly to the C-1 carbons, the δ^{cor} values of the C-2 carbons can also be classified into three types as shown in Fig. 2(b). These results are in agreement with that obtained for the glycine ligand in the $[Co(ox)_x(gly)_y(en)_z]$ series by Juranic et al.[4] However, they do not describe the possibility of the classification for ethylenediamine (en) carbons. In the case of this series of the complex it is difficult to assign accurately each NMR signal to each carbon of

the en ligand because the chemical shifts of the en carbons are almost the same. On the contrary, as the chemical shift of C-3 is separated from that of C-4 in edma, it is to be easy to remove their erroneous signal assignments. In fact, our present data show that classifications similar to the C-1 and C-2 carbons are possible for the C-3 and C-4 carbons of the E-ring in edma (Table 1).

In both of the E- and G-rings, the difference in the chemical shifts between the Type A and Type B carbons (2—3 ppm) is larger than that caused by the magnetic anisotropy of a cobalt center (<1 ppm). However, the difference between the Types A and C or between the Types B and C is comparable to that caused by the anisotropy.

When a ligating N in the trans position to the ligating O of the G-ring is replaced by O, the C-1 carbon resonance is shifted to a lower field, while the C-2 carbon resonance is shifted to a higher field (alternation effect).[7] (On the contrary, when a ligating N in the trans position to -NH- nitrogen of the G-ring is replaced by O, the C-1 carbon resonance is shifted to a higher field and the C-2 carbon resonance to a lower field.) That is, an influence from the trans position works alternately on the chemical shifts of the C-1 and C-2 carbons in the G-ring. A similar alternation effect is also observed for two neighboring carbons in the E-ring. This effect has been observed for the substituted alkenes and for the protonation shifts of alkylamines.[8,9]

^{13}C NMR Chemical Shifts of the Complex Containing Meridionally Coordinating edma (*mer*-edma).

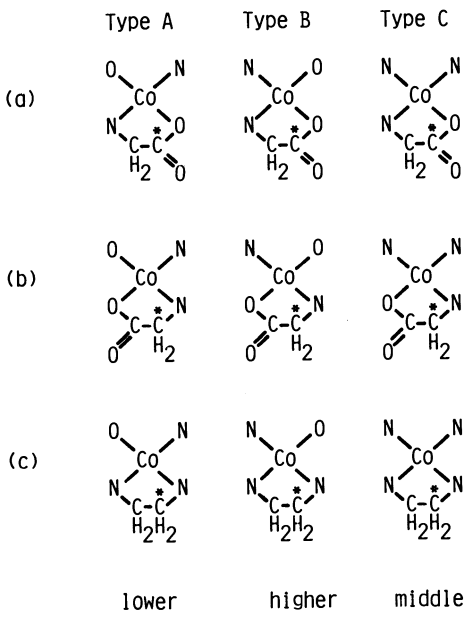

Fig. 2. Classification of the carbons in the coordinating edma: (a) for the C-1 carbon in the G-ring, (b) for the C-2 carbon in the G-ring, and (c) for the C-3 and C-4 carbons in the E-ring.

The chemical shifts of *mer*-edma are different from those of *fac*-edma, that is, the C-2 and C-3 carbons of *mer*-edma exhibit their chemical shifts in a higher field than those of *fac*-edma. This behavior is consistent with that of the $-CH_2NHCH_2-$ carbons of dien (dien: $NH(CH_2CH_2NH_2)_2$) and ida (The carbons in the mer-form resonate in a higher field than those in the fac-form.)[5,6] On the contrary, the C-4 carbon signal of *mer*-edma appears at a lower field than that of *fac*-edma.

The chemical shift difference of C-2 between *mer*- and *fac*-edma's is about 2.5 ppm, and those of C-3 and C-4 are about 3 and 3.5 ppm respectively. These values are much larger than the chemical shift difference caused by the magnetic anisotropy effect of the cobalt center.

Structural Assignments of the Isomers of [Co(ida)(edma)]. Figure 3 shows the geometrical structures of four possible isomers of [Co(ida)(edma)], and Fig. 4 shows their electronic absorption spectra. The pink isomer shows a sharp band in the first absorption band region, while the violet, brown and red-brown isomers show only a broad band or a shoulder band. This behavior makes it possible to assign the pink isomer to *fac*(O) and other three isomers to *mer*(O).[10] The red-brown isomer can be assigned to *mer*(O)*mer*(ch), because its first absorption band has the strongest intensity among the four geometrical isomers.[11] Although the geometrical structure (*mer*(O)*cis*(NH) or *mer*(O)*trans*(NH)) of the other two isomers (violet and brown) can not be assigned solely by the visible absorption spectra, it is possible to assign them from their ^{13}C NMR data.

The chemical shift of the C-4 carbon in *mer*(O)-*mer*(ch) [Co(ida)(edma)] (containing *mer* A Type C-4 carbon) can be calculated, assuming that its δ^{cor}(C-4) value is nearly equal to that of the mer isomer of $[Co(edma)_2]^+$ (which contains *mer* A Type C-4

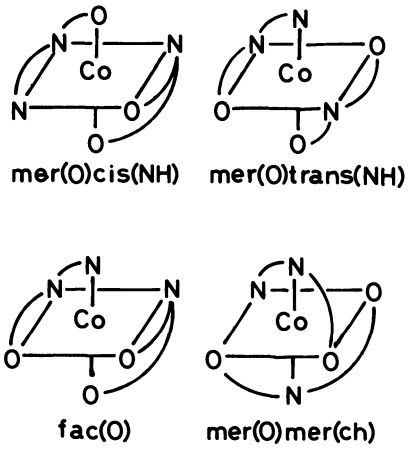

Fig. 3. The four geometrical isomers of [Co(ida)-(edma)].

Table 2. The Calculated and Observed Chemical Shifts of C-4 Carbons of edma in the Isomers of [Co(ida)(edma)]

	σ_{Co}	Type	Estimated δ^{cor} b)	δ^{cal} a)	Color of the isomer	δ^{obsd}
mer(O)*cis*(NH)	−0.5	*fac* B	40.4	40.9	Violet	41.08
mer(O)*trans*(NH)	−0.2	*fac* A	43.5	43.7	Brown	43.86
mer(O)*mer*(ch)	−0.2	*mer* A	47.2	47.4	Red-brown	47.22

a) $\delta^{cal}=\delta^{cor}-\sigma_{Co}$. b) The δ^{cor} values which appeared in Table 1 were averaged.

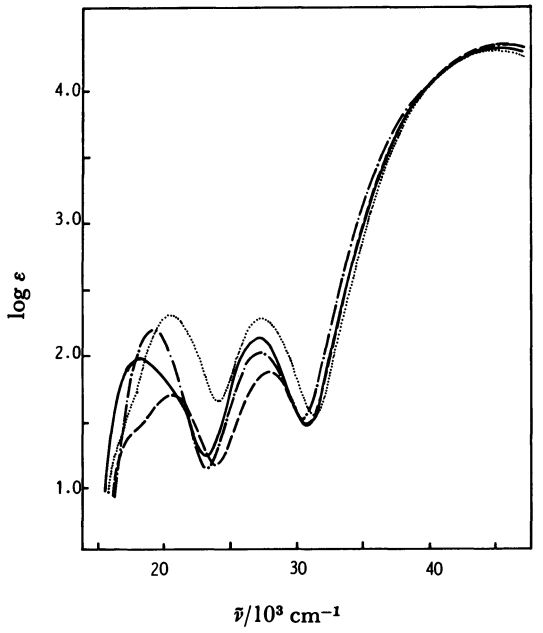

Fig. 4. Absorption spectra of the four isomers of [Co(ida)(edma)]; violet (——), brown (— —), red-brown (·····), and pink (—·—).

carbon, too; δ^{cor}(C-4)=47.2) and that the equation, $\delta^{cal}(=\delta^{obsd})=\delta^{cor}-\sigma_{Co}$, is applicable to the isomer of *mer*(O)*mer*(ch) [Co(ida)(edma)] (the σ_{Co} value (−0.2 ppm) of this isomer is calculated by the method described in Ref. 1.). The δ^{cal}(C-4) value (δ=47.4) of the *mer*(O)*mer*(ch) isomer is nealy equal to the δ^{obsd}(C-4) value of the red-brown isomer (δ=47.22), but not to that of either the violet (δ=41.08) or the brown (δ=43.86) isomer (Table 2). On the basis of these results, the red-brown isomer is assigned to the *mer*(O)*mer*(ch). In the similar manner, comparing the δ^{cal}(C-4) value of the *mer*(O)*cis*(NH) (δ=40.9) or *mer*(O)*trans*(NH) (δ=43.7) [Co(ida)(edma)] with the δ^{obsd}(C-4) values of the obtained *mer*(O)-form isomers of [Co(ida)(edma)], the violet isomer is assigned to *mer*(O)*cis*(NH) and the brown isomer to *mer*(O)-*trans*(NH).

(Received December 9, 1985)

Alkali and alkaline earth metal cations were chromatographed over silica gels and polymer matrices which had been modified by the addition of benzo-15-crown-5, benzo-18-crown-6, and benzo-21-crown-7, using water as the mobile phase. The retention sequences of the cations agreed closely with the stability sequences of the corresponding crown-ether complexes. The best separation was attained on the silica gels modified by the use of benzo-18-crown-6. The retention times increased in this sequence: $Li^+ < Na^+ < Rb^+ < Cs^+ < K^+$; $Mg^{2+} < Ca^{2+} < Sr^{2+} < Ba^{2+}$. The retention sequences on the benzo-15-crown-5 and benzo-21-crown-7 columns were $Li^+ < Na^+ \approx Cs^+ < Rb^+ < K^+$ and $Li^+ \approx Na^+ < K^+ < Rb^+ \approx Cs^+$ respectively. The resin-based columns showed similar retention sequences, but were inferior in their separation ability to the silica-based ones. The retention times were affected by many factors, such as the cation concentration, the species of the counter anions, the kind and composition of the second solvents in the mixed mobile phase, and the column temperature.

Crown ethers are attractive to analytical chemists because of their selective cation-binding ability. In the field of chromatography, these substances have frequently been used as stationary phases. Four types of stationary phases have so far been developed depending on the method of crown-ether immobilization and on the kind of supporting material. Kimura et al.[1] chromatographed alkali metal cations over ODS-silica gels coated with dodecyl-18-crown-6 or decyl-cryptand 221. Igawa et al.[2-4] showed that silica gels coated with polyamide crown resins were useful for separating anions rather than cations. The stationary phases of this type are easy to prepare, but the loss of the crown ethers by elution is inevitable. The loss can be avoided by bonding them onto a certain supporting material. Blasius et al.[5,6] investigated extensively the chromatographic separation of many cations on crown ether- or cryptand-containing polymer matrices. Nakajima et al.[7-9] also studied the separation of alkali metal cations on crown-modified silica gels.

This paper will describe the immobilization of different crown ethers on silica gels and polymer matrices and the chromatographic separation behavior of the alkali and alkaline earth metal cations on these columns. Factors affecting the retention behavior were also investigated.

Experimental

Syntheses of Amino Crown Ethers. Benzo-15-crown-5 (B15C5), benzo-18-crown-6 (B18C6), and benzo-21-crown-7 (B21C7) were synthesized from catechol and 1,11-dichloro-3,6,9-trioxaundecane, 1,14-dichloro-3,6,9,12-tetraoxatetradecane, and 1,17-dichloro-3,6,9,12,15-pentaoxaheptadecane respectively by the method of Pedersen.[10] The dichloro compounds were prepared as follows: Polyethylene glycol (average mol. wt.=400) was treated with thionyl chloride in the presence of a small quantity of pyridine, and the product was fractionated by vacuum distillation. The crown ethers thus obtained were nitrated and then reduced to their respective amino compounds according to the method of Ungaro et al.[11]

Preparation of Crown-Modified Packings. Wakogel LC-5H (particle size: 5 μm, pore size: 60 nm) of an irregular type (Wako Chemical Industries, Ltd.) and LiChrosorb Si-100 (particle size: 5 μm, pore size: 100 nm) of a spherical type (Merck) were used as the supporting materials. The silica gels were activated by 6 M hydrochloric acid (1 M=1 mol dm^{-3}) under reflux with stirring for 8 h, washed thoroughly with water, and finally dried under a vacuum. A mixture of 5 g of the silica gels, 2 g of 6,7-epoxy-4-oxohexyltrimethoxysilane, and 100 cm^3 of dry toluene was heated under reflux with stirring for 10 h. After being separated from the mixture, the epoxy-modified silica gels were suspended in 100 cm^3 of dry toluene and then heated in the same manner in the presence of 3 g of the amino derivatives. The amount of crown ether moiety immobilized on the silica gels was determined to be 0.1—0.3 mmol per g of the dried crown-modified silica gels, judging from the weight loss on heating at 800 °C. Finally, the silica gels were treated with trimethylchlorosilane in order to endcap the residual silanol group. The estimated silica surface is shown in Fig. 1 (above).

Hitachi COOH type gels (No. 3011-C, 10—15 μm) were used as the polymer matrices. The crown ether moieties were introduced as follows: 2.6 g of the dry resins were dispersed in 40 cm^3 of toluene and treated with 4 cm^3 of thionyl chloride under reflux for 6 h. The resulting resins were washed well with dry toluene and then treated with 25 cm^3 of a pyridine solution containing 2.1 g of 4′-aminobenzo-18-crown-6 by occasional gentle swirling for two days at room temperature. The amount of the crown moiety immobilized was estimated to be 0.6 mmol per g of the crown-modified resin by measuring the amount of potassium picrate adsorbed on it. The estimated structure

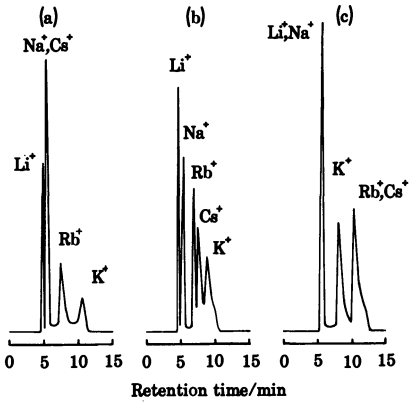

Fig. 2. Chromatograms of equimolar mixtures of alkali metal chlorides over the silica-based crown columns. (a): B15C5 ($n=1$), (b): B18C6 ($n=2$), (c): B21C7 ($n=3$).
Sample size: (a) 0.5 M, 3 μl (1l=1000 cm³); (b) 0.05 M, 5 μl; (c) 0.01 M, 5 μl.
Mobile phase: water, Flow rate: 0.5 ml min^{-1}.

is also shown in Fig. 1 (below).

Packing to Columns. The crown-modified silica-based packings were made balanced-density slurries by ultrasonic mixing with a Chemco C-type slurry solvent (Chemco Scientific Co., Ltd.) and pumped into stainless-steel columns (4 mm i.d., 250 mm length) with methanol according to a given pressure program by using a Model 124 Chemco Slurry-Packing Apparatus. The crown-modified resin-based packings were packed in a similar manner by using a methanol-chloroform mixture as the slurry solvent. The columns thus obtained were conditioned by elution with methanol and then a large quantity of water.

Materials. The alkali and alkaline earth metal salts were of an analytical grade. The water was purified by the use of an Auto Still (Model WAG-28, Yamato Scientific Co., Ltd.) equipped with ion-exchange resins and a glass-made distilling apparatus. The resulting water was distilled again with an all-quartz-made, non-boiling type distilling apparatus (HF-200, Fujiwara Seisakusho Co., Ltd.), preventing contamination of the water with CO_2 in the air.

Chromatographic Measurements. An assembly consisting of a pump (Shimadzu LC-5A), a sample injector (Rheodyne 7125), a conductometric detector (LDC conducto Monitor), and a recorder (YHP Reporting Integrator 3390A) was used for high-performance liquid chromatography. Freshly distilled water was used as the mobile phase. For the silica-based columns, the pressure drops were about 50 kg cm^{-2} at a flow rate of 0.5 cm^3 min^{-1} and for the resin-based ones, less than 20 kg cm^{-2} at a flow rate of 1.0 cm^3 min^{-1}. Chromatography was performed at 25 °C unless otherwise stated.

Results and Discussion

Separation of Alkali and Alkaline Earth Metal Cations. Typical chromatograms of the alkali metal cations on the crown-modified silica-gel columns are shown in Fig. 2. Li^+, Na^+, K^+, Rb^+, and Cs^+ were separated satisfactorily from each other on the B18C6-modified silica-gel (B18C6–Si) column. Na^+ was not separated from Cs^+ on the B15C5-Si column. Two pairs of ions, Li^+/Na^+ and Rb^+/Cs^+, were not separated on the B21C7–Si column. Figure 2 also shows that the retention sequences vary greatly according to the ring size of the crown ether moieties; the retention times on the B15C5–Si, B18C6–Si, and B21C7–Si columns increased in this sequence: $Li^+ < Na^+ \approx Cs^+ < Rb^+ < K^+$; $Li^+ < Na^+ < Rb^+ < Cs^+ < K^+$; and $Li^+ \approx Na^+ < K^+ < Rb^+ \approx Cs^+$ respectively.

Crown ethers are known to form 'metal-in-the-hole'-type complexes with many cations. Cations which fit into the hole of the crown ether form stable complexes of 1:1 stoichiometry. On the other hand, cations which are too large to fit into the molecular hole tend to form 1:2 (cation:crown) complexes, which are, in most cases, more stable than the 1:1 complexes. It is natural to consider that cations which can form more stable complexes are retained more strongly. The retention sequence on the B15C5-Si column can be elucidated on the basis of the stability sequence by assuming the 1:2 interactions for K^+ and Rb^+ (Table 1). The retention sequence on the B21C7–Si column was consistent with the stability sequence. For the B18C6–Si columns, both sequences agreed well; however, it was found that, in certain columns, Cs^+ appeared in the eluents before Rb^+, whereas, in other columns, it appeared as late as K^+. Nakajima et al.[8] indicated that poly(benzo-18-crown-6)- and bis(benzo-18-crown-6)-modified silica-gel columns possessing neighboring crown ether moieties were favorable for forming 1:2 complexes with Cs^+ and retained it most strongly among the alkali metal cations. Taking into account the fact that the densities of the crown ether moieties

Table 1. Stability Constants (logarithmic unit) of Crown Ether Complexes with Alkali and Alkaline Earth Metal Cations

Cation	r/nm[a]	B15C5[b] in 70% MeOH	18C6[c] in H_2O	21C7[d] in MeOH
Li^+	0.068			
Na^+	0.097	1.99	0.8	
K^+	0.133	1.5, 4.15[e]	2.03	4.41

Cs^+	0.167	1.7	0.99	5.02
Ca^{2+}	0.099		<0.5[f]	
Sr^{2+}	0.112		2.72	
Ba^{2+}	0.134		3.87	

a) Ionic radii, Ref. 12. b) Benzo-15-crown-5, Ref. 13. c) 18-Crown-6, Ref. 14. d) 21-Crown-7, Ref. 15. e) 1:2 (Cation : crown) complex. f) Ref. 15.

of the present columns are as high as those of their columns (0.3 mm g^{-1}), it is probable that, even in the present columns, Cs^+ forms the 1:2 complexes to an appreciable extent, though the spatial arrangement of the crown ether moieties is less favorable than that of their columns. It seems, therefore, natural to consider that the columns with a high crown density retain Cs^+ longer.

The pore size of the silica gels showed no appreciable effect on the elution behavior of the cations.

Separation of Alkaline Earth Metal Cations. Chromatograms of the alkaline earth metal cations on the B15C5- and B18C6-Si columns are shown in Fig. 3((a) and (b)). The retention sequence on the former column was $Mg^{2+} \approx Ca^{2+} < Sr^{2+} < Ba^{2+}$; Mg^{2+} was not separated from Ca^{2+}. On the other hand, the retention sequence on the latter column was $Mg^{2+} < Ca^{2+} < Sr^{2+} < Ba^{2+}$; the separation of Mg^{2+} from Ca^{2+} was still unsatisfactory.

A mixture of the alkali and alkaline earth metal cations was chromatographed over the B18C6-Si column (Fig. 3(c)). Na^+, Sr^{2+}, and Rb^+ were separated from each other almost satisfactorily. The separation of Ca^{2+} from Li^+ was not achieved. The retention sequence agreed with the stability sequence. Sr^{2+}, however, was retained more weakly than had been expected from its stability constant.

A few univalent cations other than the alkali metal cations were chromatographed over the B18C6-Si column. Tl^+ was retained longer than K^+. Ag^+ was not detected as a peak. Quarternary ammonium salts were all eluted so rapidly that they were only poorly separated, the retention sequence being: benzyltrimethylammonium<trimethylammonium≈ammonium ions.

Counter Anions. Many investigators[3-8] have pointed out that the retention times of cations on crown-modified columns were affected markedly by

a) Mobile phase: water, Flow rate: 0.4 cm^3 min^{-1}, Sample size: 0.1 mol dm^{-3}, 5 μl (1 l=1000 cm^3), Temp: 20 °C. b) Ref. 12. c) Ref. 16. d) 0.05 mol dm^{-3} picrate.

the anion species also present. In the present work, the effect of anions was investigated by using the B18C6- and B21C7-Si columns. The retention times obtained are summarized in Table 2, together with the anionic radii. From Table 2, it is clear that the retention times increase with an increase in the ionic size: $Cl^- < Br^- < NO_3^- < I^- < SCN^-$. This sequence

agreed with that reported by Igawa et al.[3] In the present experiment, however, SO_4^{2-} was not eluted so fast as they reported. The retention sequence for some oxyacid anions was $IO_3^-<BrO_3^-<ClO_3^-$, the sequence being difficult to explain from the size effect alone. In Fig. 4, the retention time is plotted against the lyotropic number,[17] which reflects the hydrophobic nature of anions. The higher the hydrophobicity, the longer the retention time becomes. It should be noted that ClO_4^- is retained much longer on the stationary phase. In Fig. 5, the retention time is plotted against the *A* value introduced by Motomizu.[18] He indicated that the extraction constants, K_{ex}, for the chloroform extraction of ion pairs could be divided into two terms: $\log K_{ex}=C+A$, where *C* and *A* represent the extractabilities of the cation and anion species respectively. The *A* value further reflects the hydrophobicity and the ion-pair formation ability of the anion. Figure 5 shows that, for many anions, the retention times are closely related to the *A* values. It is of interest to note that, in Fig. 5, the plot of ClO_4^- falls on a curve, unlike as in Fig. 4. It can be concluded that so-called soft anions are retained strongly on the crown-modified silica-gel columns. Table 2 shows that $[Fe(CN)_6]^{3-}$ and $[Fe(CN)_6]^{4-}$ are retained very weakly on the B18C6-Si column, whereas they are retained very strongly on the B21C7-Si column. The reason for this is not clear.

Cation Concentration. The alkali metal cations were chromatographed separately over the B18C6-Si column by varying their concentrations (Fig. 6). The peak area yielded a straight line when plotted against the concentration, the linear range being from about 0.005 to 0.06 mol dm^{-3}. The lower concentration limit differed slightly with different cations; the limit appeared at somewhat higher concentrations for strongly retained cations (K^+, Cs^+, and Rb^+). Just outside the lower limit, the peak heights decreased rapidly with a decrease in the concentration, until finally the peak disappeared below the very broad, irregularly shaped background peak. The background peaks of this type were observed for all the cations tested, regardless of the species of the crown ether moieties. Therefore, the base-line separation among the strongly retained cations was not achieved (Figs. 2 and 3). Figure 7 shows that the retention time increases with a decrease in the cation concentration, the rate of increase being greater at lower concentrations. The peak assignment of the chromatograms must be made carefully because the

retention time depends not only on the species of the counter anion, but also on the cation concentration.

Water-Methanol as the Mobile Phase. The stability constants of crown ether complexes are known to be three to four decades higher in methanol than in water.[19] Izatt et al.[13] showed clearly that the stability constants of benzo-15-crown-5 complexes increased regularly as the methanol portion of water–methanol mixtures was increased. Figure 8 shows that the retention times of the alkali metal cations increase with an increase in the methanol fraction, in accordance with the observation of Izatt et al. This figure also shows that the retention-time differences between any two cations become greater as the methanol portion increases; this finding implies that the addition of methanol improves the separation of the cations. With this in mind, the alkali metal cations were chromatographed over the B18C6–Si column by using a water–methanol (20% v/v) mixture as the mobile phase. However, little improvement was observed because of the broadening of the peaks. Pure water, therefore, is recommended as the mobile phase from the practical point of view.

Crown-Modified Resin Columns. The chromatographic behavior of the alkali metal cations was investigated on the resin-based B15C5 and B18C6 columns. Some typical chromatograms are shown in Fig. 9. The retention sequences of the cations on the B15C5- and B18C6–resin columns were $Li^+<Na^+\approx Cs^+<Rb^+<K^+$ and $Li^+<Na^+<Cs^+\approx Rb^+<K^+$ respectively. The retention behavior was very similar to that observed on the corresponding silica-based column (cf. Fig. 2 (a) and (b)). The separation patterns, however, were not so good as the silica-based columns. Na^+ was also not separated from Cs^+ on the B15C5–resin column. A linear relation between the peak area and the cation concentration was also observed with the resin-based columns in the range from about 0.01 to 0.1 M; the lower limit of the linear range was slightly higher than that of the silica-based column. It was noted that the retention time on the resin-based columns increased with an increase in the cation concentration, unlike the case with the silica-based columns.

Figure 10 shows that the retention time of the alkali metal cations depends to a considerable extent on the second solvent species. The addition of methanol increased the retention times, as has been mentioned above. On the other hand, the addition of
