The viscosities were measured at 25 and 35 °C using an automatic viscometer of the Shibayama Scientific Co., Ltd. The densities were measured using a vibrating-tube densimeter, twin-type SS-D-200, of the Shibayama Scientific Co., Ltd. The details of the procedure were described in a previous paper.[9] The electric conductivities were measured with an LCR meter, AG-4301B, of the Ando Electric Co., Ltd., using a frequency of 1000 Hz.

Results and Discussion

Heats of Solution. Heat-of-solution measurements were carried out in the concentration range of $(1.5—2.8)\times10^{-3}$ mol dm^{-3}. In this concentration range, any dependence of the heat of solution on the concentration is within the limit of experimental error, so the average of three or more measurements has been taken as the heat of solution at infinite dilution, ΔH_s^0. The ΔH_s^0 values of NC_n and NC_nC_2N in water are listed in Table 2. The ΔH_s^0 values were all endothermic, and the results from the ΔH_s^0 values were used to calculate the change in the heat capacity for dissolution at infinite dilution, ΔC_p^0:

$$\Delta C_p^0 = d\Delta H_s^0/dT, \quad (1)$$

where T is the temperature. The ΔC_p^0 values obtained at 25 °C are also listed in Table 2.

The sign and magnitude of ΔC_p^0 can be taken as a relative measure of the structural effect upon the solvent water.[10,11] The ΔC_p^0 values of common salts

Table 2. Heats of Solution and Heat-Capacity Changes

n		ΔH_s^0/kJ mol^{-1}		ΔC_p^0/J K^{-1} mol^{-1}
	T/°C 15	25	35	25
		NC_n		
4	17.79±0.08	17.61±0.04	17.73±0.08	−3±6
5	18.80±0.09	19.03±0.03	19.20±0.10	20±7
6	14.92±0.10	15.47±0.05	16.18±0.07	63±6
		NC_nC_2N		
1	32.60±0.15	29.19±0.07	26.52±0.08	−304±9
2	52.42±0.21	49.52±0.25	47.10±0.28	−266±18
3	37.04±0.07	34.86±0.11	32.41±0.10	−231±6

indicate negative values, whereas the ΔC_p^0 values of hydrophobic solutes indicate positive values.

As may be seen in Table 2, the values of ΔH_s^0 of NC_4 are insensitive to the temperature, this means that ionic and hydrophobic hydration balance each other. In the case of NC_5 and NC_6, the ΔC_p^0 values become positive, and they are hydrophobic structure-makers. With the NC_nC_2N series, three salts showed the negative ΔC_p^0 values, though the magnitude of ΔC_p^0 become less negative as the number of carbon atoms in the methylene groups increases; they are water-structure-breakers. On comparing of the ΔC_p^0 values of NC_n and NC_nC_2N in Table 2 with those of alkyltrimethylammonium bromides and *N,N'*-polymethylenebis(trimethylammonium) dibromides reported in a previous paper,[1] it is found that, for the same number of carbon atoms, the hydrophobicity of the cyclic mono- and bis(quaternary ammonium) salts is weaker than that of the linear mono- and bis(quaternary ammonium) salts respectively.

The Viscosity *B* Coefficients. The viscosity of an aqueous solution of an electrolyte, η, for concentrations up to about 0.1 mol dm^{-3} can be represented by the Jones-Dole equation:[12]

$$\eta/\eta_0 = 1 + Ac^{1/2} + Bc, \quad (2)$$

where η_0 is the viscosity of water, and A and B, the characteristic constants of the solutes. The A coefficient was interpreted theoretically by Falkenhagen and Vernon;[13] it can be calculated using the data of the limiting equivalent conductivities of the salt, the cation, and the anion. The B coefficient is related to the ion-solvent interaction and to the size and shape of the ion, and it is highly specific for the electrolyte and the temperature. Equation 2 may be converted to:

$$\eta/\eta_0 - 1 - Ac^{1/2} = Bc. \quad (3)$$

When the left-hand side of Eq. 3, using the calculated values of A, is plotted against c, the viscosity B coefficient is obtained as the slope of a straight line. Figures 1 and 2 show the results of plotting Eq. 3. The values of A and B are listed in Table 3. It is noted that the B values of cyclic mono- and bis(quaternary ammonium) salts studied in this work are smaller than those of respective mono- and bis(quaternary ammonium) salts with the same number of carbon atoms reported in a previous paper.[2] Previous experimental results of viscosity B coefficients at 25 °C

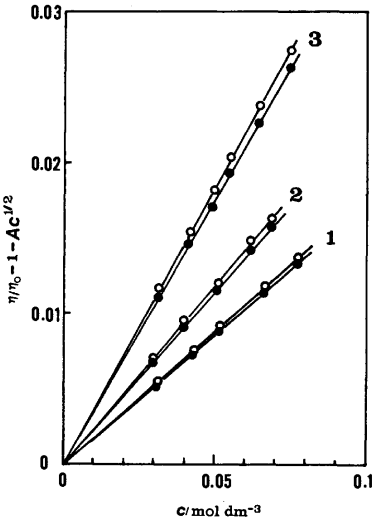

Fig. 1. Plots of $\eta/\eta_0-1-Ac^{1/2}$ against c for NC_n. 1, NC_4, 2, NC_5; 3, NC_6. O, 25 °C; ●, 35 °C.

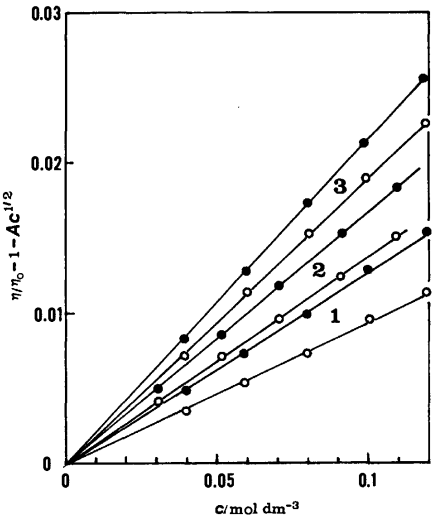

Fig. 2. Plots of $\eta/\eta_0-1-Ac^{1/2}$ against c for NC_nC_2N. 1, NC_1C_2N; 2, NC_2C_2N; 3, NC_3C_2N. O, 25 °C; ●, 35 °C

are available for iodide salts of NC_4 (0.142 dm^3 mol^{-1})[14] and NC_5 (0.208 dm^3 mol^{-1}).[14]

The temperature dependence of the B values may be regarded as an index of the solute-solvent interaction;

Table 3. The Values of A, B, and B_{ion}

n	T/°C	A/dm$^{3/2}$ mol$^{-1/2}$ 25	35	B/dm^3 mol^{-1} 25	35	B_{ion}/dm^3 mol^{-1} 25	35
				NC_n			
4		0.0066	0.0068	0.177	0.175	0.217	0.201
5		0.0067	0.0070	0.238	0.230	0.278	0.256
6		0.0069	0.0071	0.368	0.354	0.408	0.380
				NC_nC_2N			
1		0.0131	0.0136	0.094	0.128	0.174	0.180
2		0.0132	0.0137	0.137	0.168	0.217	0.220
3		0.0135	0.0140	0.189	0.216	0.269	0.268

the B values increase with the temperature for a solvent-structure-breaking salt, while they decrease with temperature for a solvent-structure-making solute.[15] For the NC_n series, it may be seen in Table 3 that the B values decrease as the temperature is raised from 25 to 35 °C; these salts may be considered to behave as structure-making salts in the water phase. However, as the difference in the B values of NC_4 between 25 and 35 °C is small, NC_4 may therefore be considered to behave as a borderline salt. For all the salts of NC_nC_2N used, the B values increase as the temperature is raised from 25 to 35 °C; these salts may be classified as structure-breaking salts in the water phase.

The B values of electrolytes are determined by adding the individual contributions of the ions. Out and Los[16] reported the ionic B values, B_{ion}, of the Br^- ion as a function of temperature according to the convention of Gurney[17] that the B_{ion} values for K^+ and Cl^- ion are equal. The B_{ion} values of Br^- ion[16] are -0.040 and -0.026 dm^3 mol^{-1} at 25 and 35 °C, respectively. The B_{ion} values of organic ions obtained are included in Table 3. With the NC_n^+ series, the B_{ion} values decrease with the temperature, so they are classified as structure-making ions. With the $NC_nC_2N^{2+}$ series, the B_{ion} values vary little with temperature. In this case the ionic hydration due to the two charge-bearing $>N(CH_3)_2^+$-groups may interfere with the interaction of hydrophobic-$(CH_2)_n$-groups with water. For both series of NC_n^+ and $NC_nC_2N^{2+}$ ions, the changes in the B_{ion} values, which occur as the temperature is raised from 25 to 35 °C, decrease with n; this indicates that hydrophobic hydration gradually increases with the number of methylene groups.

Synopsis. An interaction between aluminate and silicate ions in highly alkaline solution was investigated by a high-resolution ^{27}Al NMR study. The interaction greatly varied with alkali concentration, and did not occur at 1.0 mol dm^{-3} NaOH. At 0.10 mol dm^{-3} NaOH, the formation of a monomeric species with an ≡Al-O-Si≡ bond (Si/Al=1) was suggested and the formation constant was estimated to be 22.8 dm^3 mol^{-1}. At 0.015 mol dm^{-3} NaOH, polynuclear species with ≡Al-O-Si≡ bond was expected to be formed.

An important advantage of ^{27}Al is its 100% isotopic abundance, which makes ^{27}Al NMR a very sensitive probe. Much work has been reported on the environment of Al atoms in solid aluminosilicates, while little has been published on the characterization of solutions containing aluminosilicates or aluminate and silicate ions by the ^{27}Al NMR technique. Mueller et al.[1] observed four resonance lines of ^{27}Al NMR for tetramethylammonium aluminosilicate solutions of different molar ratios of Si and Al and assigned their lines to four kinds of monomeric AlO_4 tetrahedrons bonded to zero, one, two, and three silicon atoms, respectively. Glasser and Harvey[2] reported that for a given alkali-silicate-aluminate composition, the distribution of aluminium between uncomplexed aluminate and aluminosilicate complexes may vary with the cation present.

In this work an interaction between aluminate and silicate ions in strongly alkaline solutions was studied by a high-resolution ^{27}Al NMR.

Experimental

Sample and Reagents. All the reagents used were of analytical reagent grade. The sodium silicate solution (10^{-2} mol dm^{-3} Si) was prepared by dissolving silica gel in sodium hydroxide solution. The silicon concentration in the solution was determined spectrophotometrically. The sodium aluminate solution (10^{-2} mol dm^{-3} Al) was prepared by dissolving $AlCl_3 \cdot 6H_2O$ in sodium hydroxide solution. The aluminium concentration was standardized by EDTA titration.

Sample solutions with various molar ratios of Si and Al (Si/Al) up to 5 were prepared by mixing aluminate and silicate solutions. The aluminium concentration was fixed at 10^{-3} mol dm^{-3} and the sodium hydroxide concentration was adjusted to (a) 1.0, (b) 0.10, and (c) 0.015 mol dm^{-3}, respectively.

^{27}Al NMR Measurement. The ^{27}Al NMR spectra were recorded at 52 MHz on a JEOL FX-200 spectrometer. The sample solution was placed in a glass tube of 15 mm diameter. An aqueous $AlCl_3$ solution enclosed in a glass tube of 1 mm diameter was used as an external standard. The $AlCl_3$ solution (10^{-1} mol dm^{-3} Al) was prepared by dissolving $AlCl_3 \cdot 6H_2O$ in 1 mol dm^{-3} hydrochloric acid. The D_2O concentration in the standard and sample solutions was ca. 40% to operate the field frequency lock. NMR measurements were carried out at room temperature after allowing the sample solution to stand more than 24 h.

Results and Discussion

System (a) (1.0 mol dm^{-3} NaOH). The ^{27}Al NMR allows a clear distinction between AlO_6 octahedral and AlO_4 tetrahedral sites in aluminium-oxygen compounds. An ^{27}Al NMR spectrum of the sample solution (Si/Al=0) is shown in Fig. 1. The peak on the right is due to standard $[Al(H_2O)_6]^{3+}$ (Octahedral) and peak on the left (denotes as peak X) is due to the sample solution. The chemical shift (ppm) and the intensity of peak X were determined relative to the peak of standard $[Al(H_2O)_6]^{3+}$. The positive sign of the chemical shift denotes a downfield shift. The chemical shift of the peak X is 80.2 ppm and the signal is typical of monomeric $[Al(OH)_4]^-$ anions.[3]

In the spectra of the sample solutions of different Si/Al ratios, the peak X always appeared at 80.2 ppm. Moreover, the relative intensity of peak X, defined as follows, was unity independent of the Si/Al ratio:

$$RI = (A_X/A_s)/(A_0/A_s)$$

where A_x is the area of peak X, A_0 is the peak area for $[Al(OH)_4]^-$ (Si/Al=0), and A_s is the peak area for $[Al(H_2O)_6]^{3+}$. These facts indicate that no interaction between aluminate and silicate ions occurs, because of the high alkali concentration.

System (b) (0.10 mol dm^{-3} NaOH). The ^{27}Al NMR spectra did not change for several days after preparation of the sample solutions, indicating that an equilibrium was rapidly achieved in the system (b). Peak X of the sample solution (Si/Al>0) shifted

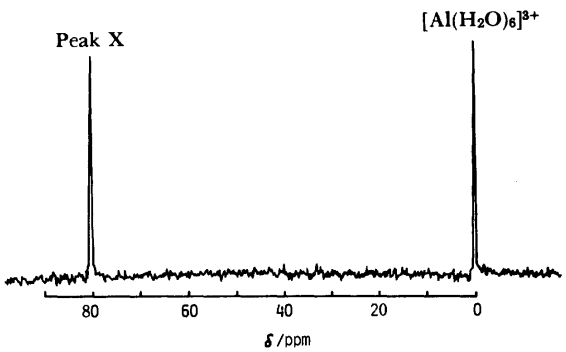

Fig. 1. ^{27}Al NMR spectra of sample solution (peak X) and external standard solution ($[Al(H_2O)_6]^{3+}$). NaOH concentration: 0.10 mol dm^{-3}. Si/Al=0.

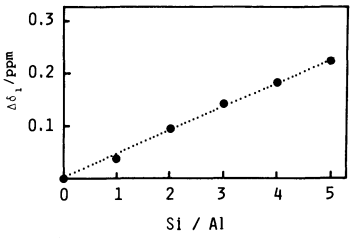

Fig. 2. Variation of chemical shift ($\Delta\delta_1$) with Si/Al ratio.
NaOH concentration: 0.10 mol dm^{-3}.

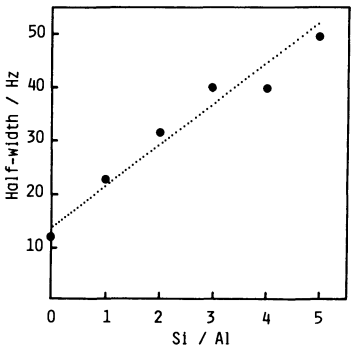

Fig. 3. Variation of half-width of peak X with Si/Al ratio.
NaOH concentration: 0.1 mol dm^{-3}.

slightly toward higher field from the peak of $[Al(OH)_4]^-$. The chemical shift difference between the peak X and the peak of $[Al(OH)_4]^-$, $\Delta\delta_1$, increased with increasing Si/Al ratio. Figure 2 shows the variation of $\Delta\delta_1$ with the Si/Al ratio. The half-width for peak X also increased with increasing Si/Al ratio, as shown in Fig. 3.

The electron donating property of the substituent to aluminium is a major factor in determining the chemical shift. The ^{27}Al upfield shift is due to the increased overall electron density of aluminium. The increase in the half-width of the peak X with increasing Si/Al ratio resulted from an increment of tetrahedrally coordinated aluminium atoms with low symmetry compared with the $[Al(OH)_4]^-$ tetrahedron. Consequently, the formation of species with an ≡Al–O–Si≡ bond was suggested. The relative intensity of peak X was unity regardless of the difference in the Si/Al ratio, indicating that all the aluminium was detected.

It seems reasonable that the species formed is assumed to be a 1:1 complex of aluminium and silicate (Si/Al=1) since the alkali concentration is high, the Al and Si concentrations are relatively low, and the $\Delta\delta_1$ values are small. Considering only a 1:1 complex formation, the reaction can be written as follows:

$$A + L \rightleftarrows AL \quad (1)$$

where A is aluminate ion, L is silicate ion, and AL is a 1:1 complex. The formation constant of AL, K, is

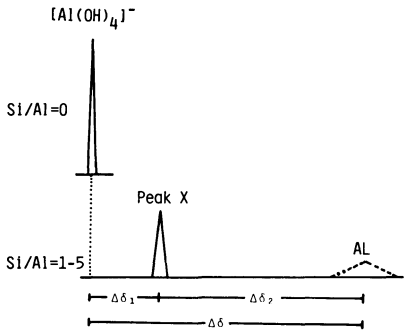

Fig. 4. Chemical shift profile in the system (b).
Peak A and Peak X can be observed, while peak AL is hypothetical one.

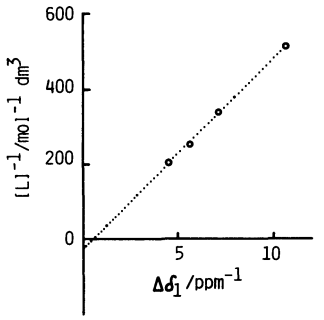

Fig. 5. Plot of $1/[L]$ against $1/\Delta\delta_1$.

represented by Eq. 2.

$$K = [AL]/[A]\cdot[L] \quad (2)$$

When an exchange rate between A and AL is rapid on the NMR time scale, the following relations can be valid.

$$\Delta\delta_1 : \Delta\delta_2 = [AL] : [A] \quad (3)$$

$$\Delta\delta = \Delta\delta_1 + \Delta\delta_2 \quad (4)$$

$\Delta\delta_2$ and $\Delta\delta$ are the chemical shift difference between peak X and peak AL and between peak A and peak AL, respectively (Fig. 4). From these equations, a following equation can be derived.

$$1/[L] = K\cdot\Delta\delta/\Delta\delta_1 - K \quad (5)$$

Since $\Delta\delta_1$ values were small, it can be considered that K is small and $[L]\simeq[L^*]$, ([L]: the concentration of free Si at equilibrium, [L*]: total concentration of Si). K and $\Delta\delta$ values were determined by a succesive approximation method. A plot of $1/[L]$ against $1/\Delta\delta_1$ is shown in Fig. 5. The plot gave a straight line and the correlation coefficient was 0.999. From the intersection and the slope of this line, K and $\Delta\delta$ values were calculated to be 22.8 (dm^3 mol^{-1}) and 2.2 (ppm), respectively.

On the other hand, the half-width for peak X, W_X, can be represented by Eq. 6, where W_A and W_{AL} denote the half-width for peak A and peak AL, respectively.

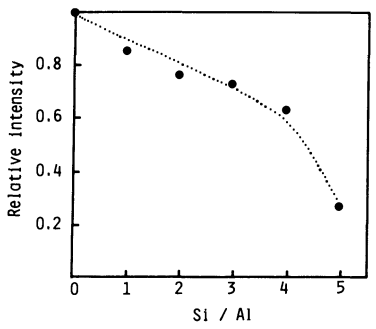

Fig. 6. Variation of the relative intensity for peak X with Si/Al ratio.
NaOH concentration: 0.015 mol dm^{-3}.

$$W_X = W_A \cdot [A]/([A] + [AL]) + W_{AL} \cdot [AL]/([A] + [AL]) \quad (6)$$

From Eqs. 2 and 6

$$W_{AL} = (W_X - W_A)/(K[L]) + W_X \quad (7)$$

The half-width of peak AL was calculated to be about 400 Hz, putting W_A, K, W_X, and [L] values in Eq. 7.

When the sample solution of Si/Al=4 was heated at 42 °C and 55 °C, the $\Delta\delta_1$ value and the half-width were found to approach those of the Si/Al=0 solution with increasing temperature, though the relative intensities were almost constant. The interaction between aluminate and silicate ions may not be allowed at higher temperature.

System (c) (0.015 mol dm^{-3} NaOH). Peak X appeared at 80.2 ppm independent of Si/Al ratio, while the relative intensity of peak X decreased with increasing Si/Al ratio (Fig. 6), indicating that the $[Al(OH)_4]^-$ species left in the solution decreases with increasing Si/Al ratio. Part of the aluminate ions in the solution is supposed to be irreversibly changed to a polynuclear species with an ≡Al–O–Si≡ bond. The relative intensity of the peak X decreased gradually over several days. The ^{27}Al NMR signal of the polynuclear species is considered to be too broad to be observed because of its lower symmetry.

The interaction between aluminate and silicate ions is greatly influenced by the alkali concentration.

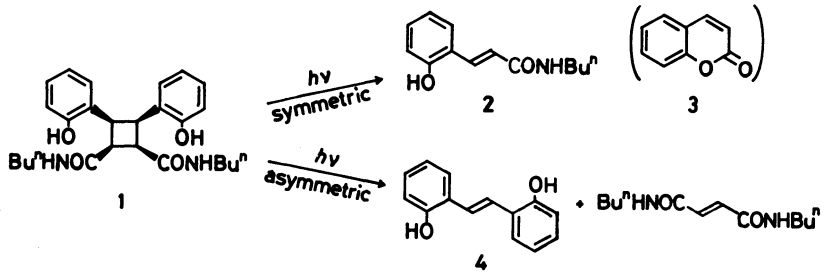
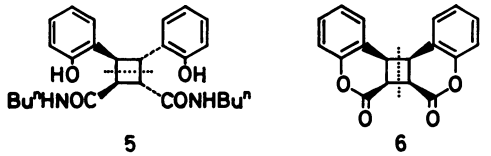
Solvent- and Wavelength-Dependence of the Photocleavage of the Cyclobutane Ring in *N,N'*-Dibutyl-*c*-3,*c*-4-bis-(2-hydroxyphenyl)-*r*-1,*c*-2-cyclobutanedicarboxamide

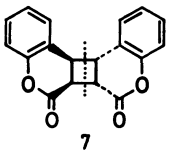
Noriyuki YONEZAWA,† Masataka KUBO,†† Kazuhiko SAIGO, and Masaki HASEGAWA*
Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received March 31, 1987)

Synopsis. The ratio between two photocleavage directions of the cyclobutane ring in the title compound varies with the solvent polarity and the irradiation wavelength, and the effect of the solvent polarity appears much larger in protic solvents than aprotic ones.

Head-to-head type cyclobutane compounds have two possible cleavage modes, namely, symmetric and asymmetric cleavages.[1] Most of the lactone-opened derivatives of head-to-head coumarin dimers have only one photocleavage direction, but the derivatives, of which all the substituents are situated in the cis positions to each other on the cyclobutane ring such as *N,N'*-dibutyl-*c*-3,*c*-4-bis(2-hydroxyphenyl)-*r*-1,*c*-2-cyclobutanedicarboxamide (**1**), were confirmed to undergo symmetric and asymmetric photocleavages competitively.[2-4] To clarify the factors which govern the photocleavage mode of these compounds, the photoscission reaction of **1** was investigated under various conditions by comparing with those of *N,N'*-dibutyl-*t*-3,*c*-4-bis(2-hydroxyphenyl)-*r*-1,*t*-2-cyclobutanedicarboxamide (**5**) and syn and anti head-to-head coumarin dimers **6** and **7**.







Results and Discussion

Irradiation of **1** was carried out in alcohols (protic) and MeCN (ε 37.5)/dioxane (ε 2.2) mixed solvents (aprotic). The products of photolysis were confirmed by comparing their retention times of HPLC analysis with those of the authentic samples. The conversions and the ratios between photocleavage modes were estimated by the area of elution bands and the molar absorptivities of the starting material, the products, and the standard sample as shown in the Eqs. 1 and 2, respectively:

conversion

$$= [S_h/\varepsilon_h + (S_c/\varepsilon_c + S_{cis}/\varepsilon_{cis} + S_{trans}/\varepsilon_{trans})/2]/(aS_s/\varepsilon_s) \quad (1)$$

symmetric fission/asymmetric fission

$$= (S_c/\varepsilon_c + S_{cis}/\varepsilon_{cis} + S_{trans}/\varepsilon_{trans})/(2S_h/\varepsilon_h) \quad (2)$$

where S is the area of the elution band recorded by the UV detector at 320 nm and ε is the molar absorptivity at 320 nm; h, c, cis, trans, s, and a denote **4**, **3**, *cis-N*-butylcoumaramide, **2**, standard meterial, and the ratio of the starting material to the standard material, respectively.

The molar absorptivity of *cis-N*-butylcoumaramide was determined by HPLC analysis of the solution of **2** after irradiation using Eq. 1. The isolation of *cis-N*-butylcoumaramide was unsuccessful because of its spontaneous relactonization to coumarin at room temperature, and the isomerization of **4** was not observed in our experiments.

The ratio between the two photocleavage modes of **1** varied with the solvent polarity and the wavelength of light as shown in Fig. 1. Though the symmetric cleavage mode was predominant in every case, asymmetric one gradually increased with shortening the wavelength, and protic solvents were favorable for asymmetric cleavage as compared to aprotic solvents.

† Present address: Nippon Kokan K. K., Kawasaki-ku, Kawasaki 210.

†† Present address: Mie University, Tsu, Mie 514.

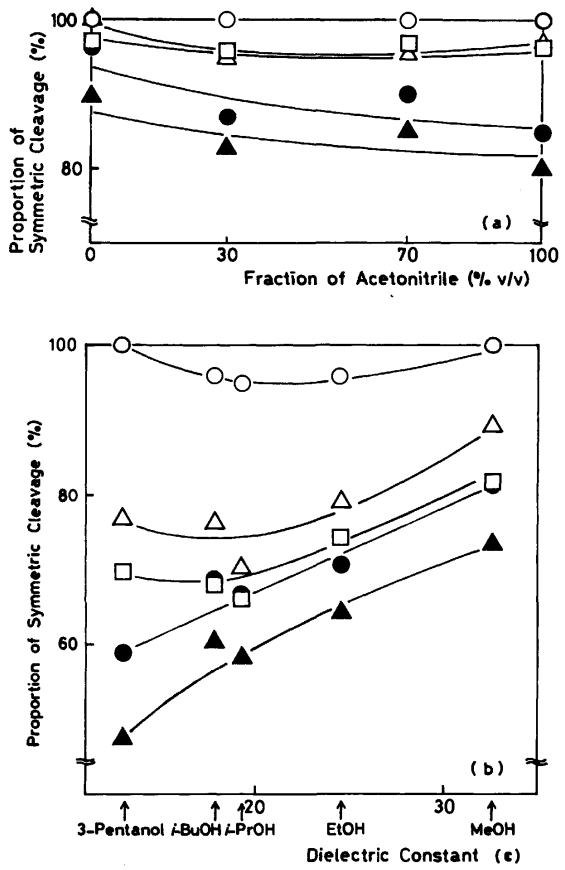


Fig. 1. The ratio between symmetric and asymmetric modes of the cyclocleavage reaction of **1** in (a) MeCN–dioxane and (b) alcohols (○: 330 nm, △: 304 nm, □: 277 nm, ●: 251 nm, and ▲: 224 nm).

The effects of solvent polarity appeared more remarkably at the range of shorter wavelength in both protic and aprotic solvents.

In protic solvents symmetric cleavage became more advantageous as the polarity of the solvent increased. In addition, the quantum yields for the formation of olefins in MeOH, calculated on the basis of Eq. 1, had also distinct dependence on the irradiation wavelength, i.e., $\phi_{224}=0.27$, $\phi_{251}=0.06$, $\phi_{277}=0.33$, and $\phi_{304}=0.05$. These results indicate that there exist at least two routes for this cyclocleavage reaction. On the other hand, the proportion of asymmetric photocleavage was almost constant in aprotic solvents.

In contrast, the exclusively asymmetric cleavage of the cyclobutane ring in **5** did not change by the wavelength nor by the solvent (dioxane, MeCN, or MeOH). And the irradiation of **6** or **7** in MeCN or dioxane solution always gave coumarin (**3**) as a sole product of the exclusively symmetric cleavage.

When the irradiation was carried out with the light of 251±10 nm wavelength using benzene as a sensitizer, the photocleavage reaction of **5**—**7** was accelerated by 3.2—3.5 times. But, the photocleavage reaction of **1** was sensitized by only 1.4 times. From the phosphorescence spectra of **1** and **5**, the triplet excited energies in MeOH were estimated to be 70 and 66 kcal mol^{-1}, respectively. Furthermore, the photocleavage reaction of **1** was not quenched by biacetyl and hardly sensitized by acetone or acetophenone. These results suggest that the cyclocleavage reaction of **1** proceeds predominantly via singlet excited state although the sensitization of the reaction with benzene indicates the existence of the reaction route via triplet excited state.

The dependence of the quantum yields on the irradiation wavelength and the different wavelength dependence between aprotic and protic solvents are considered to be attributed to the abilities of the solvents to stabilize **1** in both ground state and/or excitation process and the intermediates in the cyclocleavage reaction, presumably through hydrogen bonding interaction. In the ground state and the early stage of excitation, 2-hydroxyphenyl chromophore should interact with butylcarbamoyl group in several manners causing at least two excitation states in the ratio determined in accordance with the property of the medium. Moreover, one possible intermediate in the photocleavage reaction of **1** is an intramolecular excimer as observed in the cycloaddition of coumarin in ethanol to yield **6**.[5] But the evidence for the formation of the intramolecular excimer could not be obtained by the emission spectra. These phenomena show that in both protic and aprotic solvents at least two intermediates should exist and indicates that particularly in protic solvents the minor reaction routes was probably accelerated. The competitive photocleavage of **1** is distinctly different from exclusively one-directioned photocleavages of other lactone-opened derivatives of **6** and **7**.[2,4] This characteristic photochemical behavior of **1** was clearly brought in by the largely hindered cis-syn-cis configuration on the cyclobutane ring of **1**, which might make **1** to have peculiar conformations enabling the formation of intramolecular excimer and highly reactive intermediate by interaction of 2-hydroxyphenyl and carbamoyl groups, reflecting the hydrogen bonding and electrostatic effects of solvents.

Experimental

Irradiation was carried out with a JASCO CRM-FA spectroirradiator at room temperature. UV spectra were recorded on a Hitachi Model 100-60 spectrophotometer. Emission and phosphorescence spectra were recorded on a Hitachi MPF-4 fluorescence spectrophotometer. HPLC analysis was performed on a steel column (4 mm×250 mm) packed with LiChrosorb SI60 (5 μm, Merck and Co.) and the absorbance at 320 nm was monitored on a TOYO SODA UV8 Model II spectrophotometer at a flow rate of 0.4 ml min^{-1} using benzene–ethyl acetate (70:30 v/v) as an eluent.

Spectrograde solvents were used for reaction and UV measurement without further purification. **1** and **5**—**7** were prepared according to the literatures.[6,7] Standard and authentic samples for HPLC analysis, 4-ethoxycarbonyl-, and 4-phenoxycarbonylchalcones,[8] *trans*-*N*-butylcoumaramide (**2**),[9,10] and 2,2′-dihydroxystilbene (**4**),[2] were prepared according to the methods in the literatures. Other reagents were purified by the ordinary methods.[11]

Photolysis of 1 and 5—7. Through a solution of **1**, **5—7** (ca. 5×10^{-5} mol dm^{-3}) in a quartz cell, anhydrous nitrogen was bubbled for ca. 1 min. The photocleavage reaction was monitored by the UV spectrophotometer during the irradiation. Before the new absorption reached a maximum, the irradiation was stopped, and the solution was concentrated under reduced pressure. Then the residue was dissolved in benzene–ethyl acetate (70:30 v/v) containing a constant amount of a standard material (4-ethoxycarbonylchalcone, or 4-phenoxycarbonylchalcone) and analyzed by HPLC.

Quantum Yield. The quantity of the light absorbed was measured by the chemical actinometry.[12] The quantum yields for the formation of olefins in the photocleavage of MeOH solution **1** was determined as follows: Two quartz cells were set in series along the line of the irradiation light, where the former cell was for the photoreaction or blank, and the second for chemical actinometry. The photoirradiation of MeOH solution of **1** and MeOH alone performed under exactly same conditions. The quantum of the light absorbed by **1** was calculated on the basis of the difference of the quantities of the light absorbed by the solution in the second cell. The amount of total olefins calculated by Eq. 1 and the quantity of light absorbed by **1** afforded the quantum yield.

The relative rates of the photocleavage were determined as follows: Two quartz cells were set in the same manner as the quantum yield measurement described above. First, only the solvent was placed in the former cell and the solution of the cyclobutane compounds containing sensitizer or quencher in the second cell, then the photoirradiation was undertaken. Then, solvent containing same amount of sensitizer or quencher was placed in the former cell and the solution of substrate in the second cell, and photoirradiation was undertaken under the exactly same conditions. Relative rate was calculated by the ratio of conversion between above two photoirradiation.

Aldol Condensation Reaction between Formaldehyde and Acetone over Heat-Treated Synthetic Hydrotalcite and Hydrotalcite-Like Compounds

Eiichi Suzuki* and Yoshio Ono
Department of Chemical Engineering, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152
(Received July 30, 1987)

Synopsis. Synthetic hydrotalcite, $Mg_6Al_2(OH)_{16}CO_3 \cdot 4H_2O$, and its analogues were synthesized, heat-treated at 773 K, and used as catalysts for the title reaction to form methyl vinyl ketone (MVK) at 673 K. MVK was formed over all the catalysts examined, the highest MVK yield (20% on acetone basis) being found over the heat-treated hydrotalcite.

Hydrotalcite is one of the naturally occurring anionic clay minerals and is represented by the formula: $Mg_6Al_2(OH)_{16}CO_3 \cdot 4H_2O$.[1,2] Thus, magnesium-aluminium hydroxide octahedra form positively-charged layers, which are stacked on top of each other. Carbonate ions are located between the layers as interlayer anions. Hydrotalcite-like minerals, i.e. cation-substituted and/or anion-exchanged hydrotalcites, can be obtained by isomorphous substitution of the cations in the layer and/or of the anions in the interlayer of hydrotalcite.[3-7] It has been reported that these minerals can be synthesized[8] and have basicity upon heat treatment.[9] Several base-catalyzed reactions have been demonstrated: polymerizations of β-propiolactone[10] and of propylene oxide,[11] and self-aldol condensation of acetone.[12,13]

The present work was concerned with testing heat-treated hydrotalcite and hydrotalcite-like compounds as catalysts for a cross-aldol condensation reaction which is known to be catalyzed by acids or bases.[14] Here, a reaction between formaldehyde and acetone is examined, where methyl vinyl ketone (MVK) is the condensation product.

Experimental

Synthesis of Hydrotalcite and Hydrotalcite-Like Compounds. Hydrotalcite was synthesized by the procedures described by Reichle,[13] using $Mg(NO_3)_2 \cdot 6H_2O$, $Al(NO_3)_3 \cdot 9H_2O$, NaOH, and Na_2CO_3. According to the method reported by Miyata et al.,[6,8] was prepared isomorphous-substituted hydrotalcite with NO_3^{2-}, SO_4^{2-}, or CrO_4^{2-} anions. Isomorphous-substituted hydrotalcite, containing Co^{2+}-Al^{3+},[13] Ni^{2+}-Al^{3+},[13] Zn^{2+}-Cr^{3+},[13] or Li^{+}-Al^{3+} [15,16] ions in place of Mg^{2+}-Al^{3+} ions in hydrotalcite, was also prepared. The X-ray diffraction (XRD) patterns of the materials, thus synthesized, were identical to those previously reported.[3,6,16,17]

Cross-Aldol Condensation Reactions. The reactions were performed with a continuous-flow reactor operating at atmospheric pressure. The synthetic minerals were heated under a helium stream at a given temperature for 2 h before starting the reactions. A mixture of acetone and formalin, containing 36.8wt% of HCHO and 6.6wt% of methanol with a given HCHO/acetone molar ratio, was delivered to the reactor. The products from the outlet of the reactor were periodically analyzed by gas chromatograph.

Results and Discussion

Reactions over Anion-Exchanged Hydrotalcites. In Table 1, are summarized the results of reactions at 623 K with W/F of 7.9 g h mol^{-1} over the anion-exchanged hydrotalcites treated at 623 K, where W and F stand for the weight (g) of the catalyst used and the flow rate (mol h^{-1}) of the feed (formaldehyde+acetone +nitrogen+water), respectively. The heating of hydrotalcite samples at 623 K to obtain catalysts gave rise to changes in the XRD patterns of the samples:

Table 1. Reactions between Formaldehyde and Acetone over Anion-Exchanged Hydrotalcites, Containing Mg^{2+}-Al^{3+}-X^{n-} Ions[a]

Interlayer anion (X^{n-})	Acetone conversion/%	Selectivity to MVK[b]/%
CO_3^{2-}	20	93
NO_3^{-}	12	97
SO_4^{2-}	6.0	98
CrO_4^{2-}	3.7	100

a) Reaction conditions: pretreatment temperature= 623 K, reaction temperature=623 K, HCHO=10.1 kPa, Acetone=9.1 kPa and W/F=7.9 g h mol^{-1}. b) On acetone basis.

Table 2. Reactions between Formaldehyde and Acetone over Heated Cation-Substituted Hydrotalcites, Containing M_1^{2+}- or M_1^{+}-M_2^{3+}-CO_3^{2-} Ions[a]

Cations in layer M_1^{2+}- or M_1^{+}-M_2^{3+}	Acetone conversion/%	Selectivity to MVK/%	
		(Acetone)[b]	(HCHO)[c]
Mg^{2+}-Al^{3+}	21	96	64
Li^{+}-Al^{3+}	12	100	37
Co^{2+}-Al^{3+}	9.5	98	28
Ni^{2+}-Al^{3+}	11	69	21
Zn^{2+}-Cr^{3+}	2.7	73	5.4

a) Reaction conditions: pretreatment temperature=773 K, reaction temperature=673 K, HCHO=3.0 kPa, acetone=9.1 kPa and W/F=2.7 g h mol^{-1}. b) On acetone basis. c) On formaldehyde basis.

The pattern consisted of diffractions for both hydrotalcite and MgO for CO_3^{2-}- or NO_3^--exchanged hydrotalcite,[18,19] whereas the only pattern observed was that of hydrotalcite for SO_4^{2-}- or CrO_4^{2-}-exchanged one. The formation of MVK was observed for all the catalyst samples examined: Acetone conversion ranged from 3.7 to 20% and the selectivity to MVK on an acetone basis fell within the range 93—100%. The highest yield of MVK (19%) was obtained with heat-treated hydrotalcite containing CO_3^{2-} anions, with which further experiments were conducted.

Reactions over Cation-Substituted Hydrotalcites. In Table 2, are summarized the results of reactions over cation-substituted hydrotalcites. The heat-treated (at 773 K) hydrotalcite containing Li^+-Al^{3+} cations showed a diffuse XRD pattern for hydrotalcite, together with broad and indefinable diffractions. For all the other heated (at 773 K) hydrotalcites examined, no XRD pattern for hydrotalcite could be observed; the MgO phase for a hydrotalcite containing Mg^{2+}-Al^{3+} cations, a Co_3O_4 phase for Co^{2+}-Al^{3+}, a NiO phase for Ni^{2+}-Al^{3+}, and a ZnO phase for Zn^{2+}-Cr^{3+} were observed. Acetone conversion fell within the range 2.7—21%, the selectivity to MVK on an acetone basis being in the range of 69—100%. The selectivity to MVK on a formaldehyde basis decreased to 37% upon substituting Li^+ for Mg^{2+}, the major product being CH_3OH. The substitution of transition metal cations for Mg^{2+} or Al^{3+} also resulted in a decrease in the selectivity to MVK on a formaldehyde basis: Carbon dioxide was detected as the major product, together with CO and CH_3OH. Hydrotalcite, containing Mg^{2+}-Al^{3+}-CO_3^{2-} ions, was found to be the most effective precursor for a catalyst among the hydrotalcites examined.

Effect of Reaction Temperature. With an increasing reaction temperature, acetone conversion increased and reached 21—22% at 673—723 K over heat-treated hydrotalcite containing Mg^{2+}-Al^{3+}-CO_3^{2-} ions (Fig. 1). The selectivity to MVK on an acetone basis was constant (95%) throughout the whole reaction temperature range examined. The selectivity to MVK on a formaldehyde basis slightly depended on the reaction temperature (Fig. 1) and was 25% at 673—723 K.

Effect of Partial Pressure of Formaldehyde. The formation of CH_3OH can be attributed to a bimolecular reaction of formaldehyde, through a Cannizzaro reaction.[14] The Cannizzaro reaction may be suppressed by lowering the partial pressure of formaldehyde. In Fig. 2 the selectivities to MVK are shown both on an acetone and on a formaldehyde basis as a function of the partial pressure of formaldehyde. The selectivity to MVK on an acetone basis is in the range of 94—99%, while that on a formaldehyde basis is 25% at 10 kPa and 87% at 1.2 kPa. The acetone conversion is also given in Fig. 2 and is almost constant (20%) above 3.0 kPa of formaldehyde pressure; it decreases to 5% at 1.2 kPa. Thus, as expected, a higher selectivity to MVK on a formaldehyde basis was obtained at a low formaldehyde pressure, though the acetone conversion decreased drastically.

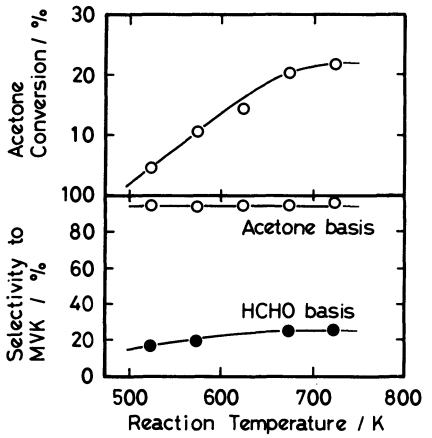

Fig. 1. Temperature dependence of acetone conversion and of selectivity to MVK.
Reaction conditions: pretreatment temperature=773 K, acetone=9.1 kPa, HCHO=10 kPa, and W/F=2.7 g h mol^{-1}.

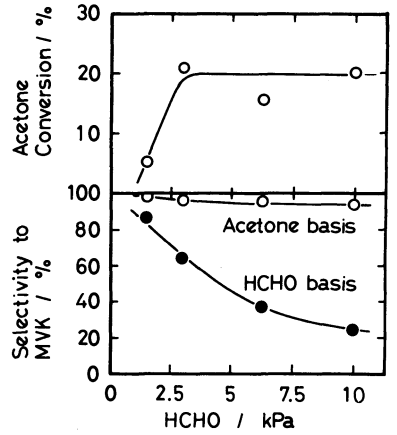

Fig. 2. Dependence of acetone conversion and of selectivity to MVK on partial pressure of formaldehyde.
Reaction conditions: pretreatment temperature=773 K, reaction temperature=673 K, acetone=9.1 kPa, and W/F=2.7 g h mol^{-1}.

Comparison of Results with Literature Data. Several catalytic cross-aldol condensation reactions between formaldehyde and acetone on solid catalysts have been reported. Malinowski et al.[20] obtained a 1% acetone conversion over a Na/SiO_2 catalyst. Tanaka et al.[21] examined the reaction at 573 K, W/F=27 g h mol^{-1} and acetone/HCHO molar ratio=1 over calcium hydroxyapatite ($Ca_5(OH)(PO_4)_3$) calcined at 773 K and obtained a 24% yield of MVK together with mesityl oxide of 2%. Igarashi et al.[22] examined the reaction over a ZrO_2-SiO_2 catalyst at an acetone/HCHO molar ratio ranging from 1 to 4 and obtained an 18—13% MVK yield on an acetone basis and 18—54% on a formaldehyde basis at 573 K and W/F=5 g h mol^{-1}. In the present work, over heat-treated

hydrotalcite, a 20% MVK yield on an acetone basis and a 62% on a formaldehyde basis were obtained at W/F=5 g h mol^{-1}. It therefore follows that the MVK yield on an acetone basis obtained in this study falls in the range of those reported earlier. The most predominant effect of using heat-treated hydrotalcite as a catalyst can be found in a slightly enhanced MVK yield on a formaldehyde basis.

In conclusion, heat-treated hydrotalcite and hydrotalcite-like minerals can catalyze the cross-aldol condensation reaction between formaldehyde and acetone. Among these, heat-treated hydrotalcite gave the highest MVK yield.

The ^{127}I Nuclear Quadrupole Resonance of an Iodine Complex with 1,3-Dithiane, $C_4H_8S_2 \cdot 2I_2$

Hiromitsu TERAO* and Hiroshi SAKAI†
Faculty of Integrated Arts and Sciences, Tokushima University,
Minamijosanjima-cho, Tokushima 770
†Research Reactor Institute, Kyoto University, Kumatori-cho, Sennan-gun, Osaka 590-04
(Received August 29, 1987)

Synopsis. The ^{127}I nuclear quadrupole resonance spectrum of 1,3-dithiane-$2I_2$ is reported. Two distinct S···I-I arrangements are present in the crystal. The charge on each iodine atom is obtained; the bonding in the complex is discussed in connection with analogous thioether-iodine complexes. The resonance lines for terminal iodine atoms indicate positive temperature coefficients.

It is well-known that halogen (or interhalogen) molecules act as electron acceptors toward electron-pair donor molecules (such as amines, ethers, and thioeters) and form n-σ-type charge-transfer (CT) complexes with them. In addition, the empirical results obtained from structural investigations show that if CT-bonds in the complexes are comparatively strong, isolated units of complex molecules involving almost linear arrangements of donor atom···halogen-halogen are found in the solid state. In this case, the CT-interaction between donor and acceptor appears to be simple and archetypal. It is, therefore, of great interest to evaluate the charge distributions on the halogen atoms in such complex molecules in order to clarify the nature of the CT-interation.

Many amine-halogen complexes belonging to this class have been investigated for this purpose by means of the halogen[1-3] (and also the nitrogen[4,5]) nuclear quadrupole resonance (NQR) and the ^{129}I Mössbauer effect.[6-8] However, complete results have been obtained for only a small number of complexes, since the NQR signals of the terminal halogen atoms were not detected in many cases and since the ^{129}I Mössbauer effect has been applied to only a few iodine complexes of this class.

Recently we ourselves have applied the ^{127}I NQR[9] and the ^{129}I Mössbauer effect[10] to a series of thioether-iodine complexes (involving a S···I_A-I_B arrangement), such as tetrahydrothiopyran (thiane)-iodine (1:1), 1,4-dithiane-iodine (1:2), and 1,4-thioxane-iodine (1:1), and have estimated the charges on both bridging iodine (I_A) and terminal iodine (I_B) atoms. In the present communication, we with to report the ^{127}I NQR results of 1,3-dithiane-$2I_2$, which has been selected in order to confirm the conclusion deduced in a previous investigation[9] of thioether-iodine complexes.

Experimental

Stoichiometric amounts of iodine and 1,3-dithiane were treated in a carbon tetrachloride solution at room temperature, because the complex had a tendency to decompose in a hot solution. After concentrating the solution under reduced pressure, we filtered the resulting purplish-black crystalline product. The product was extracted in a Soxhlet extractor with dichloromethane to obtain a well-crystallized sample suitable for the NQR measurements. Found: C, 7.72; H, 1.30; I, 81.06%. Calcd for $C_4H_8S_2$-$2I_2$: C, 7.65; H, 1.28; I, 80.85%.

The NQR measurements were carried out using an externally quenched super-regenerative Lecher-line oscillator, as has been described previously.[9]

Results and Discussion

Four resonance lines of the $m=\pm1/2\leftrightarrow\pm3/2$ transitions by the ^{127}I nuclei were observed for the 1,3-dithiane-$2I_2$ complex between 77 K and room temperature; the frequency values at 77 and 298 K are listed in Table 1, together with the corresponding frequencies for 1,4-dithiane-$2I_2$.[9] The assignment of the resonance lines to the $m=\pm1/2\leftrightarrow\pm3/2$ transitions was done on the basis of the ^{127}I NQR spectra[9] and the ^{129}I Mössbauer spectra[10] of analogous thioether-iodine complexes.

In the crystal structure of 1,4-dithiane-$2I_2$,[11] each sulfur atom is linked to one iodine moiety, and all the

Table 1. $^{127}I(m=\pm1/2\leftrightarrow\pm3/2)$ NQR Frequencies in 1,3-Dithiane-$2I_2$[a]

Compound	Frequency/MHz		$(d\nu/dT)_{T=273K}$	Assignment[b]
	77 K	298 K	kHz/K	
1,3-Dithiane-$2I_2$	377.34(7)[c]	372.24(2.5)	−28.9	$I_A(1)$
	371.56(13)	367.20(4.5)	−23.9	$I_A(2)$
	247.07(4.5)	252.04(2)	26.1	$I_B(1)$
	243.95(8)	248.67(3.5)	25.0	$I_B(2)$
1,4-Dithiane-$2I_2$[d]	377.81(6)	374.83(3)	−16.5	I_A
	233.37(2.5)	238.02(2)	25.4	I_B

a) The accuracy of the measurements was estimated to be within ±0.01 MHz in frequency and ±1 K in temperature. b) I_A and I_B denote the bridging and the terminal iodine atoms respectively. c) The numbers in parentheses are the signal-to-noise ratios as measured on an oscilloscope. d) Ref. 9.

S···I_A–I_B arrangements are identical. In accordance with this, only two resonance lines, corresponding to the bridging iodine (I_A) and the terminal iodine (I_B) atoms, have been observed. However, the observation of four resonance lines, though no crystallographic data is known, indicates that two distinct S···I_A–I_B arrangements are present in the 1,3-dithiane–$2I_2$ crystal. Presumably the respective S atoms at the 1- and 3-positions of the C_4S_2 ring are linked to one iodine moiety in such a way that these atoms are no longer equivalent to each other in the crystal.

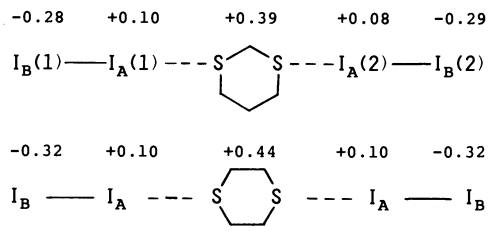
The assignment of the resonance lines to the I_A or the I_B atoms can be done unambiguously, since it is well-established that the lines for the I_B atoms have lower frequency values than those for the I_A atoms and that the frequency difference between them is very large. Further, considering that the signal-to-noise ratios of each two lines for the I_A and the I_B atoms are evidently different (ca. 1:1.8), we have tentatively made pairs of the weaker I_A line and the weaker I_B line and of the stronger I_A line and the stronger I_B line (Table 1).

A simple three-center four-electron bonding theory,[1,3,10] using only the valence p-orbitals of halogens, has been successfully applied to the donor atom···halogen–halogen systems. The charges on the halogen atoms can be well-explained with the theory.[12] By considering only the p-orbitals for the bondings of iodine atoms, therefore, we estimate the charges on both I_A and I_B atoms according to the Townes-Dailey approximation (in the previous paper[9] we reported this equation incorrectly):

$$\rho = (e^2q_{zz}Q/h)/(e^2q_{at}Q/h) - 1, \qquad (1)$$

where ρ is the charge on the iodine atom, where $e^2q_{zz}Q/h$ is the observed quadrupole coupling constant, and where $e^2q_{at}Q/h$ is the atomic quadrupole coupling constant (2292.7 MHz for ^{127}I).

As the arrangement of S···I_A–I_B is considered to be almost linear, the asymmetry parameters (η) are expected to be small for both I_A and I_B atoms. In fact, practically zero values of η were observed from the ^{127}I NQR measurements for the I_A atoms of several amine–I_2 complexes[3] and for the I_B atom of the thiane–I_2 complex.[9] By neglecting the expected small η value, the relation between the $e^2q_{zz}Q/h$ and the frequency (ν) are simplified to $e^2q_{zz}Q/h=20/3\cdot\nu$ for the ^{127}I ($m=\pm1/2\leftrightarrow\pm3/2$) transitions. Then, the ρ on the iodine atoms (and also the charges on the donors) are obtained from Eq. 1, by using the ν values at 77 K, as follows:



The charge transferred from the donor to the iodine moiety is slightly less in 1,3-dithiane–$2I_2$ than in 1,4-dithiane–$2I_2$. This is consistent with the observation that the former complex is more labile than the latter.

For comparison, in Fig. 1 the present data for the charge distributions in 1,3-dithiane–$2I_2$ are added to a previous figure[9] representing the relation of the charges on the I_A and the I_B atoms to the charges (per donor atom) on the donors. In the figure, the average values were used as the respective charges on the I_A

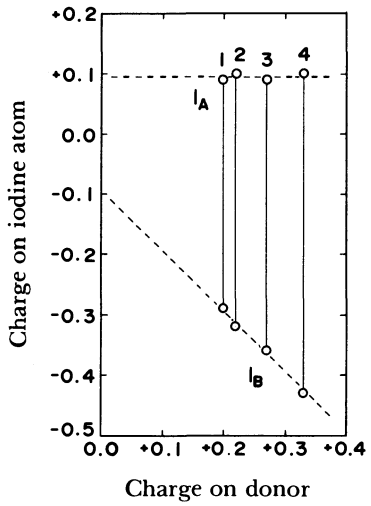


Fig. 1. Plot of the charges on I atoms vs. the charges on donors. (1) 1,3-Dithiane–$2I_2$, (2) 1,4-dithiane–$2I_2$,[9] (3) 1,4-thioxane–I_2,[9] (4) thiane–I_2.[9]

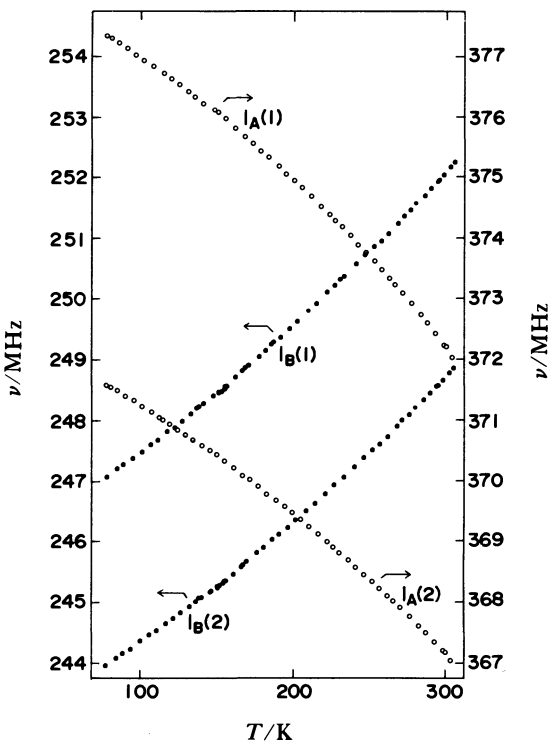

Fig. 2. Temperature dependence of the ^{127}I ($m=\pm1/2\leftrightarrow\pm3/2$) NQR frequencies in 1,3-dithiane–$2I_2$.

and the I_B atoms in 1,3-dithiane-$2I_2$.

Obviously, our previous finding is confirmed in Fig. 1:[9] The charges on the I_A atoms are almost independent of the charges on the donors, and hence the negative charges on the I_B atoms increase linearly with the increase in the charges on the donors. This observation suggests that the formation of the complex is followed by two effects: One is the polarization[2] of the iodine moiety by the donor, $I^{\delta+}$ $I^{\delta-}$ (represented as a no-bond ionic structure[1,9] in the valence-bond expression), and the other is the CT from the donor to the iodine moiety. Further, Fig. 1 shows that (1) the polarization effects are maintained at an almost constant value for the same donor atom[9] (ca. ± 0.1 *e* charges are polarized on the respective I_A and I_B atoms of an iodine moiety in the case of the S donors) and (2) the charges (ca. 0.2—0.3 *e*) transferred from the donors to the iodine moieties are mostly piled up on the I_B atoms.

The temperature dependence of the resonance frequencies measured between 77 K and room temperature is shown in Fig. 2. In accordance with the previous observations[1,2,4,9] the resonance lines of terminal iodine atoms have positive temperature coefficients (Table 1). This trend is qualitatively realized by considering the weakening of the CT-bond with the increasing temperature.[9]

12) Recently, Sakai et al.[8,10] found, in their ^{129}I Mössbauer investigations, that the quadrupole coupling constants ($e^2q_{zz}Q/h$) obtained from the quadrupole splittings are always smaller than the values to be expected from the isomer shifts (δ) in the case of the I_A atoms, whereas the two values were in fair agreement in the case of the I_B atoms. Those facts may indicate that the model using only the valence p-orbitals is oversimplified for the I_A atoms apart from the I_B atoms.

Ab Initio Calculation for Interaction Potential of He-He

Akira ICHIHARA, Kohtoku SASAGANE, Tohru IZAKI,* Tomoo MIYAZAKI, and Reikichi ITOH

(Received September 19, 1987)

Synopsis. Using the help of an ab initio calculation with a configuration interaction (CI) treatment, the potential energy of a He dimer system could be calculated in due consideration of a correction for the basis set superposition error. In evaluating CI matrix elements, the graphical unitary group approach was adopted.

There have been several reports in which the interaction potential of a He dimer system was calculated by the use of an ab initio MO method with a limited CI treatment.[1-6] In this paper, our results concerning SD and full CI calculations for the potential energy of the He dimer, comprising a small basis set, are compared with the results of calculations for the same system with a large basis set by Dacre[5] and Tatewaki.[6]

In an LCAO-MO-SCF-CI calculation, the introduction of a large basis set in order to increase the level of the approximation results in a rapid increase of CI matrix elements and computer time. Consequently, a limited CI treatment is generally adopted. It appears to be of interest to investigate the description of the interaction potential for a system with a small basis set. On the other hand, it is possible to adopt a treatment in which many electron excited configurations are introduced instead of employing a large basis set. It is, therefore, possible to further investigate the effect of many excited electron configurations on the CI treatment of the interaction potential for a system with a small basis set.

By using a graphical unitary group approach (GUGA)[7-11] to evaluate the CI matrix elements, it can be expected to facilitate a CI calculation while considering many electron excited configurations. As a first step, we provided our own computer program for the application of GUGA to the many electron excited correlation problem according to a treatment introduced by Shavitt.[10]

In this CI calculation, three different Gaussian basis sets [4S1P], [4S4P], and [4S1P1D] for a He atom were employed. These Gaussian basis sets comprised Schmidt (16s) primitive functions[12] augmented by Wells (4p) primitives.[13-14] The [4S] contraction was performed so that the atomic energy with the contracted set came close to that with an uncontracted set. In practice, the Schmidt (16s) primitives were contracted to the (6;5;4;1). The [1P] contraction was performed in the He dimer system at an internuclear distance of 5.6 Bohr after an SCF calculation with an uncontracted (4p) set placed on the [4S] contracted set. The [4S1P1D] basis set comprised the [4S1P] set augmented with an optimized single Gaussian d-type function.

It has already been pointed out that the result of CI calculations for the interaction energy of the supermolecule system must be corrected in order to eliminate the type error called a "basis set superposition error".[15-17] Boys first introduced the function counterpoise method[15] in order to overcome this error. In this method, the He dimer interaction energy (E_{int}) is calculated using the difference between the CI energy of the He dimer (E_{He_2}) and an appropriate reference energy (E_{ref}):

$$E_{int}(R) = E_{He_2}(R) - E_{ref}(R), \quad (1)$$

where R is the internuclear distance of the He dimer. The reference energy E_{ref} is defined as twice the CI energy of the He atom, with "ghost" orbitals at the expected location of the other He atom. The term "ghost" represents an atom with a nuclear charge zero and without any electrons. We employed this method in the case of a full CI calculation. Also, the counterpoise method introduced by Price[16] was used in for a SD CI calculation. Here, E_{ref} in Eq. 1 is defined as

$$E_{ref}(R) = \{2E_{ref}^{T}(R) - 2(1 - a_0^2)[E_{ref}^{CORR}(R) + (1 - a_0^2)E_{ref}^{SCF}(R)]\}/[a_0^2(2 - a_0^2)] + \varepsilon, \quad (2)$$

where E_{ref}^{SCF}, E_{ref}^{CORR}, E_{ref}^{T}, and a_0 represent the SCF, SD CI correlation, total (SCF and SD CI correlation) energy and the SCF ground-state coefficient of the He atom with ghost orbitals at an internuclear distance R. The constant ε was determined so that the interaction energy becomes zero at $R=\infty$.

In the present work, the spatial symmetry considered in the calculation of the He dimer system is $D_{\infty h}$. The MO calculation was performed by using the Gaussian 82 program provided by Pople and HITAC M680H system of the Computer Center of the University of Tokyo.

Results and Discussion

Tables 1 and 2 indicate the interaction potentials for the [4S1P] and [4S4P] basis sets by the SD CI calculation. It can be seen from Tables 1 and 2 that the SCF energy contributes to the repulsion between the He atoms, and that the correlation energy contributes to the attraction.[1-6] Each interaction potential predicts a minimum of 7.0 K at 5.8—6.0 Bohr. Reliable experimental values are 10.57—11.01 K at 5.6—5.63 Bohr.[5,18-21] From these results, it can be seen that the SD CI treatment for the [4S1P] and [4S4P] basis set is insufficient for describing a reliable interaction potential of the He dimer. On the other hand, it is obvious that the interaction potential curve is little affected by the [1P] contraction of Wells (4p)

primitive functions. We then investigated the effect of triple and higher excitation configurations on the CI treatment for the [4S1P] basis set.

Table 3 indicates the interaction potential for the [4S1P] basis set through a full CI calculation. There are 857 configurations which can contribute to the full CI calculation. The results of the limited CI calculation by Dacre[5] and Tatewaki[6] are also indicated in Table 3. In Dacre's work, a large Gaussian-type basis set including polarization functions was employed. He removed the triple and higher excitation effect from the reference energy. On the other hand, a Slater-type basis set was employed in Tatewaki's calculation. He performed first-order CI in which the triple and higher excitation configurations were effectively included. The basis set superposition error was considered to be almost negligible for his interaction potential.

The interaction potential given in Table 3 predicts a minimum of 7.8 K at 5.9 Bohr. These data are in good agreement with those results (8.4 K at 5.7 Bohr) by Dacre. In comparison with the results of our SD CI calculation, the full CI calculation lowers the potential depth by about 0.8 K. However, these calculated potential well depths are shallower than the experimental results. Tatewaki's results (9.8 K at 5.61 Bohr) reproduce the experimental values well.

Table 4 indicates the results of the interaction potential for the [4S1P1D] basis set by the SD CI calculation. This [4S1P1D] basis set for the He atom is composed of the [4S1P] basis and the single Gaussian d function. The exponent of the d function was optimized in order to describe the reliable interaction potential in the range 5 to 10 Bohr. The

optimum exponent was found to be 0.20. The potential minimum of this calculation is 10.8 K at 5.71 Bohr; this potential is in good agreement with the experimental results[21] of this range. From these results, it is obvious that the d-type function makes an important contribution to the interaction potential of the He dimer.

Finally, we investigated the interaction potential for the [4S1P1D] basis set by a full CI calculation in order to confirm the effect of triple and higher excitation configurations. There are 5944 configurations which can contribute to a full CI calculation. The new interaction potential appeared lower than the experimental results. This result may have been caused by using a d function which is not optimum for a full CI calculation.

It may be concluded from the results of this investigation that a small basis set [4S1P1D] can give the interaction potential of the He dimer by the aid of the CI calculation and the function counterpoise method.

We would like to thank Dr. Kazunari Suzuki for suggesting this problem and for stimulating our interest in it.

Photoacoustic in Situ Measurement of Quantum Efficiencies for Photoanodic Reactions at n-Type Semiconductor Electrodes

Sachio YOSHIHARA,* Ayyasamy ARUCHAMY, and Akira FUJISHIMA
Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received September 19, 1987)

Synopsis. The time required for the in situ measurement of quantum efficiencies during photoelectrochemical reactions is qreatly reduced by the photoacoustic spectroscopy (PAS) employing a piezoelectric transducer (PZT). PAS has been successfully applied for several reactions at TiO_2, ZnO, and CdS photoelectrodes and compared with previous studies by the photothermal spectroscopy (PTS).

In recent papers, we have reported on the measurement of quantum efficiencies during photoelectrochemical reactions by the photothermal spectroscopy (PTS).[1-4] In PTS, the heat produced during the relaxation of the excited carriers is detected as the change in the temperature of the semiconductor electrode. The advantage of this method is that the quantum efficiency determination does not require the calibration of the light source. But, PTS requires a longer measurement time because the time constant of the thermistor used as the sensor is quite large (ca. ls). So, we had to measure the PT signal for various potentials fixing the electrode potential at each value. The slope of the straight line plot of PT signal vs. electrode potential gave the quantum efficiency. Therefore, it is of interest to utilize sensors having faster response.

In the present work, we have been able to measure quantum efficiencies within a very short time by the photoacoustic spectroscopy (PAS) employing a piezoelectric transducer (PZT). Since the time constant of the PZT employed is very small (approximately 0.1 μs), we considered that the experiment time may be significantly reduced. This method may also be developed for the investigation of certain relaxation processes during the photoelectrochemical reactions.

Experimental

Instrumental. The complete setup for this experiment is shown in Fig. 1. Either He-Cd laser (325 nm; CDR 80 SG. Kimmon Electric Company Limited) or Ar-ion laser (488 nm; Spectra Physics 164) was employed as the light source. The laser beam was chopped by a light chopper (8—800 Hz; CH-353. NF Circuit Design Block).

The cell was equipped with a platinum counter electrode and a saturated calomel reference electrode (SCE). The laser beam was transmitted into the cell through an optically flat window of the cell. A nitrogen bubbler was employed for deoxygenating the solutions.

The working electrodes were cadmium sulfide single crystal [(001) surface, Teikoku Tsushin Company Limited] which had dimensions 10×10×1 mm^3 and a carrier density of 4.8×10^{16} cm^{-3}, titanium dioxide prepared by firing Ti plate, and zinc oxide polycrystals [ZnO powder, ca. lg (Wako Pure Chemical Industries) pressed at 150 kg cm^{-2} and sintered at 1300 °C for 3 h] which had dimensions 15φ×1.5 mm^3. The ohmic contact was made by In-Ga alloy on one side of each crystal and then a copper wire was attached to the contact with silver paste. A piezoelectric transducer (NEPEC NPM, N 21 or N 6; 10φ×1 mm^3, Tohoku Metal Industries) was attached to the same side where the contact has been given after interposing thin epoxy resin layer. Finally, the whole of the electrode except the front surface was covered with epoxy resin. The structure of the semiconductor electrode (with a PZT in place) is shown in Fig. 2. The semiconductor surface was etched just before use in concentrated hydrochloric acid for 10 s.

The signal from the piezoelectric transducer was detected by a lock-in amplifier (LI-574, NF Circuit Design Block) and the current-potential curve was measured under potentiostatic conditions using a potentiostat (HF 301, Hokuto Denko Company Limited) and a potential programmer (NPS-2, Nikko Keisoku Company Limited). The cyclic voltammogram was displayed on an X-Y recorder (Type 3033, Yokogawa Electric Works).

All chemicals were of reagent grade and were used without further purification.

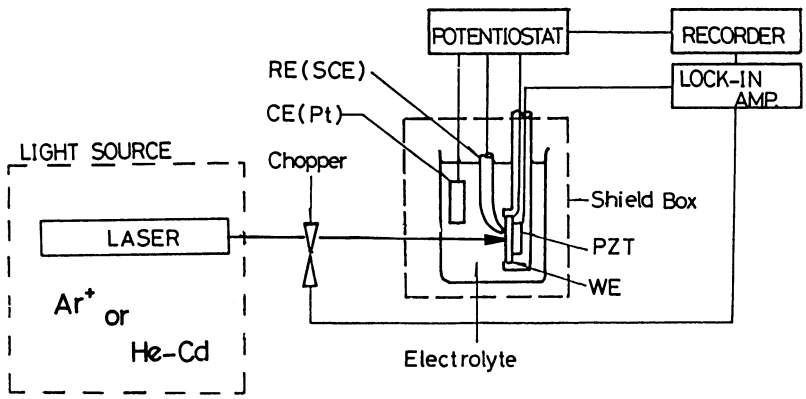

Fig. 1. Schematic diagram of the experimental setup for PAS.

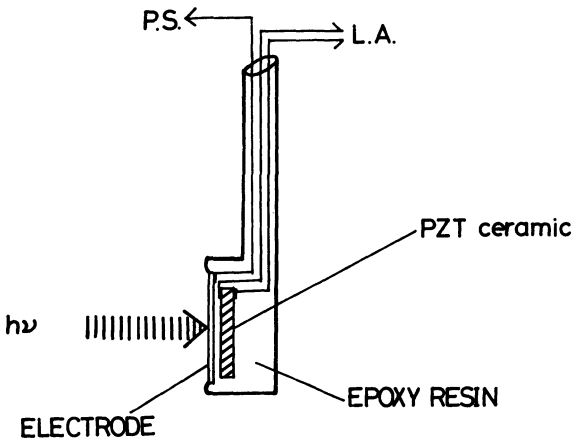

Fig. 2. Structure of the photoelectrode for PAS measurement.

Results and Discussion

The equation developed for the PTS[1] can be applied to the PAS also, since both mothods involve essentially the measurement of heat signals and the theoretical considerations are the same. For PAS the equation becomes

$$E(\Delta P/\Delta P_o) = (Q_{sc} + T\Delta S)/(It) + e\eta_q(V - V_{fb})$$

where E is the energy of the incident monochromatic light (eV/photon), I is the average absorbed intensity of light (photons/s), t is the illumination time (s), Q_{sc} is the heat evolved in the semiconductor via recombination and other radiationless processes, $T\Delta S$ is the heat evolved in term of an entropy change for the whole cell reaction (Electrochemical Peltier heat), e is elementary electric charge. η_q is the quantum efficiency of the photooxidation, ΔP and ΔP_0 are the PA signal amplitudes from the PZT at applied potential V and in the open circuit respectively, V_{fb} is the flatband potential.

Therefore, under constant illumination conditions (i.e. EIt held constant), a plot of $E(\Delta P/\Delta P_0)$ against $(V-V_{fb})$ yields the quantum efficiency, η_q, from the slope of the straight line.

The following semiconductor/electrolyte systems were investigated.

(1) n-TiO_2/Na_2SO_4, aq. ($4OH^- \rightarrow O_2+2H_2O+4e^-$)

(2) n-CdS/Na_2SO_4, Na_2SO_3aq. ($2SO_3^{2-}+2p^+ \rightarrow S_2O_6^{2-}$)[5-7]

(3) n-ZnO/Na_2SO_4 aq. ($2ZnO+4p^+ \rightarrow 2Zn^{2+}+O_2$)[8]

(4) n-TiO_2/Na_2SO_4, HCOONa aq. ($p^++HCOO^- \rightarrow CO_2+H^++e^-$; Current doubling)[9,10]

(5) n-CdS/Na_2SO_4, HCOONa aq. ($p^++HCOO^- \rightarrow CO_2+H^++e^-$; Current doubling)[11]

(6) n-ZnO/Na_2SO_4, HCOOH aq. ($ZnO+2p^++2HCOO^- \rightarrow Zn^{2+}+H_2O+2CO_2+2e^-$; Current doubling)[12-14]

Figure 3 shows the dependence of the photocurrent and the relative change in the PA signal ($\Delta P/\Delta P_0$) multiplied by the photon energy (E) on the electrode potential (V) for the CdS/Na_2SO_4, Na_2SO_3 aq. system. It is seen that the PA signal amplitude is proportional

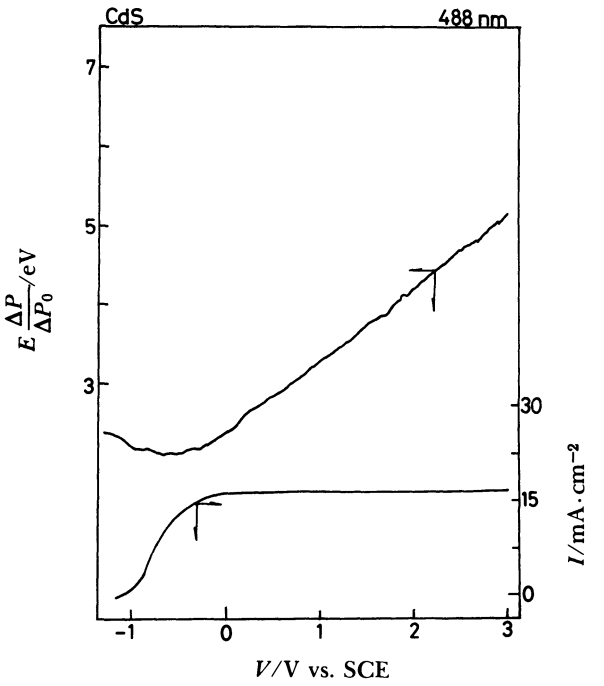

Fig. 3. Dependence of I (Photocurrent) and $E(\Delta P/\Delta P_0)$ on V (Applied potential) n-CdS Photoelectrode in 0.2 mol dm^{-3} Na_2SO_4, 1 mol dm^{-3} Na_2SO_3 aq. (Chopping frequency: 10 Hz).

to the electrode potential in the saturated photocurrent region. Taking the slope equal to the quantum efficiency, we found that the η values measured by PAS in this study are in good agreement with those obtained by PTS.[1-4] (See Tables 1 and 2) We have already reported that the quantum efficiency obtained by PTS coincides with the one obtained by actinometry. The apparently large difference in the η values of TiO_2 in Tables 1 and 2 is due to the fact that a single crystal was used for the earlier PTS study whereas we used a polycrystalline TiO_2 prepared by thermal oxidation of Ti in the present study. It is also known that the thermally formed TiO_2 gives a higher quantum efficiency.[15,16]

The dependence of ΔP_0 and the quantum efficiency on the chopping frequency have also been measured in order to find out the optimum conditions for measurement. Since the signal is detected by the lock-in method, the magnitude of the PAS signal is expected to decrease exponentially and Fig. 4 shows such behavior. On the other hand, the quantum efficiency is almost independent of the frequency. However, η shows a larger scatter at high frequencies while the value appears to be precise at lower frequencies. This is because the quantum efficiency is determined from ΔP_0 and ΔP and the precision is greater when ΔP and ΔP_0 become larger. The signals are large in the lower frequency region. However at too low frequencies (<1 Hz), sensitivity of the PZT used decreases. Therefore, a moderate chopping frequency must be chosen for this experiment.

Table 1. Measured Quantum Efficiencies for n-TiO_2, n-CdS, and n-ZnO by Photoacoustic Spectroscopy, ( ) Stands for the Value in the Case of Current Doubling Reaction

	Saturation current[a]	Quantum efficiency
	mA cm^{-2}	η
n-TiO_2[b]	5.44 (6.24)	0.8±0.05 (1.0±0.05)
n-CdS	16.4 (28.0)	0.9±0.01 (1.5±0.01)
n-ZnO	2.72 (5.36)	0.8±0.1 (1.5±0.1)

a) For TiO_2 and ZnO relatively low powder He-Cd laser (325 nm) and for CdS high power Ar-ion laser (488 nm) were used. b) TiO_2 electrode was prepared by thermal oxidation of Ti metal plate.

Table 2. Measured Quantum Efficiencies for n-TiO_2, n-CdS, and n-ZnO by Photothermal Spectroscopy,[1-4] ( ) Stands for the Value in the Case of Current Doubling Reaction

	Saturation current	Quantum efficiency
	mA cm^{-2}	η
n-TiO_2[a]	1.63 (2.15)	0.6 (0.7)
n-CdS	0.85 (1.43)	1.0 (1.7)
n-ZnO	1.23 (2.25)	0.9 (1.8)

a) Single crystal TiO_2.

Conclusion

In the PAS technique the Joule heat or the heat generated by the recombination of the excited carriers is detected as the distortion of the material or the acoustic wave from the material. This method requires much shorter time than the PTS for evaluating the quantum efficiency because of the very short time constant of the PZT. The efficiency values determined by PAS are in good agreement with PTS measurements. In future PAS utilizing PZT may be developed to obtain information concerning the recombination rates of photogenerated carriers by measuring the dependence of PA signal on the chopping frequency or the phase difference between PA signal and the reference signal. The recombination rates between CB and VB, the trapping rates of the photogenerated minority carriers at the surface recombination centers and the tunneling rates of electrons are some of the most important parameters in the semiconductor/electrolyte system. Work in this laboratory is under way to estimate above factors in the case of p-InP photoelectrodes.

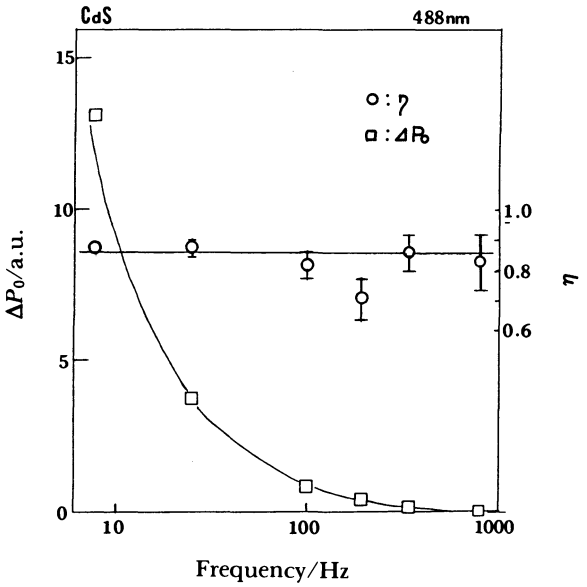

Fig. 4. Dependences of η (Quantum efficiency) and ΔP_0 (Photoacoustic signal amplitude at open circuit) on Chopping frequency, n-CdS Photoelectrode on 0.2 mol dm^{-3} Na_2SO_4, 1 mol dm^{-3} Na_2SO_3 aq.

The Complexing of the Magnesium and Barium Ions in Acetonitrile with Other Solvents. Investigation by the Use of a Polyacrylamide-Tetraethylene Glycol Monododecyl Ether Membrane Ion-Selective Electrode

Toshio NAKAMURA,* Hisakazu HIGUCHI, and Kosuke IZUTSU
Department of Chemistry, Faculty of Science, Shinshu University, Asahi, Matsumoto 390
(Received July 1, 1987)

Synopsis. The complexations of magnesium and barium ions in acetonitrile with DMF, DMSO, and HMPA were studied potentiometrically by the use of an organic polymer membrane electrode. The formation constants for 1:1 complexes of magnesium and barium ions, respectively, were 2.1×10^2 and 19 with DMF, 4.5×10^2 and 41 with DMSO, and (5.5×10^3) and 1.6×10^3 with HMPA. The roles of the basicity of the complexing solvent, crystallographic radius, and charge of the cations are discussed briefly.

Some types of ion-selective electrodes have been successfully used in physicochemical as well as in analytical studies of nonaqueous solutions.[1] Univalent cation-sensitive glass electrodes have been used in the studies of the complex formations of alkali metal ions in acetonitrile(AN)[2] and propylene carbonate[3] with other donor solvents and macrocyclic polyethers as well as in solvation studies of alkali metal ions in mixed nonaqueous solvents. The solid state copper sulfide electrode for copper(II)[4] and lanthanum fluoride electrode for fluoride ion[5] have also been used in solvation studies.

Recently, we have developed alkaline earth metal ion-sensitive electrodes for use in dipolar aprotic solvents. One was constructed by coating a platinum disk with polyacrylamide(PAA) coupled to a crown ether[6] and the other with PAA polymer coupled to acyclic polyether neutral carriers.[7] In the present report, the latter was used for a study of the complexing of magnesium and barium ions in AN with such solvent molecules as *N,N*-dimethylformamide(DMF), dimethyl sulfoxide(DMSO), and hexamethylphosphoric triamide(HMPA).

The emf of the following cell was measured: Ag/0.01 M $AgNO_3$+0.01 M Et_4NClO_4(AN)//0.05 M Et_4NClO_4(AN)//10^{-4} M $M^{2+}(ClO_4^-)_2$+0.01 M Et_4NClO_4 (AN+D)/PAA-POE4/Pt···Cell I where D denotes DMF, DMSO, or HMPA, M^{2+} the magnesium or barium ion to be investigated, and M is in mol dm^{-3}. POE4 is an abbreviation for tetraethylene glycol monododecyl ether. From the emf measurements of Cell I, the complex formation constants for the reaction of Eq. 1 were obtained by using Eqs. 2 to 4.

$$M_s^{2+} + xD = M_{xD}^{2+} \quad (1)$$

$$\beta_x = a(M_{xD}^{2+})/a(M_s^{2+})[D]^x \quad (2)$$

$$R_1 \equiv \{10^{(E_{AN}-E_{AN-D})/29.6} - 1\}/[D] = \sum_{i=1} \beta_i[D]^{i-1} \quad (3)$$

$$R_j \equiv (R_{j-1} - \beta_{j-1})/[D] = \sum_{i=j} \beta_i[D]^{i-j}, \quad (4)$$

where M_s^{2+} is M^{2+} solvated only by AN and M_{xD}^{2+} is M^{2+} cosolvated by x molecules of D; $a(M_s^{2+})$ and $a(M_{xD}^{2+})$ represent the activities of the respective species. [D] is the molar concentration of D. E_{AN} and E_{AN-D} represent the emfs of Cell I(in mV) in pure AN and AN-D, respectively.

Experimental

Apparatus. The construction of the electrodes, the cell assembly, and the potentiometric measurements were the same as those in a previous report.[7] A complexing solvent D was added to the cell with a microburette(Gilmont instruments, Inc. S1100A or S1200A), 5 μl in each step until its volume percent became 1%. In each step, the steady state potential was digitally read to ±0.1 mV. Analyses of the potentiometric data were carried out with a personal computer, NEC PC-9801 or Hewlett-Packard 86.

Reagents. Reagent grade magnesium and barium perchlorates were obtained from Wako Pure Chemical Industries, Ltd. Barium metal was the product of Kanto Chemical Co., Inc. Other reagents and solvents used in this experiment were the same as those in the previous report.[7]

Results

As shown by the typical potential-time curves in Fig. 1, a steady potential was quickly established after each addition of D to Cell I. Figure 2 shows an example of the relation between R_1, defined by Eq. 3, and [D] for the case in which D and M^{2+} were DMF and the magnesium ion, respectively. From the intercept and the slope of the straight line, $\beta_1=1.9\times10^2$ and $\beta_2=2.2\times10^3$ were obtained. For Mg^{2+}–DMSO and Ba^{2+}–DMF the formation constants, β_1 and β_2, were obtained in the same way. For Ba^{2+}–DMSO and Ba^{2+}–HMPA the relations between R_1 and [D] were not linear and a R_2–[D] relation defined by Eq. 4 was also used to determine the formation constants, β_2 and

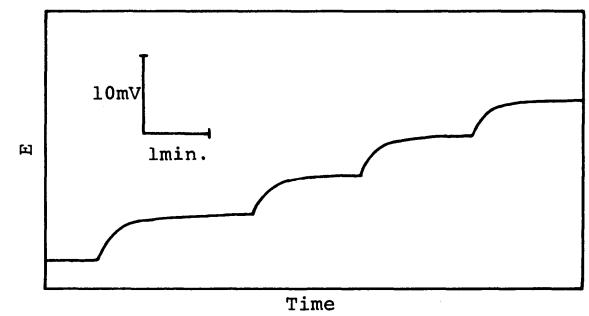

Fig. 1. Typical time vs. potential curve for titration of the barium ion(1×10^{-4}) M) in AN with DMSO. Ten μl DMSO was added to 10 ml of 0.01 M Et_4NClO_4–AN solution at each step.

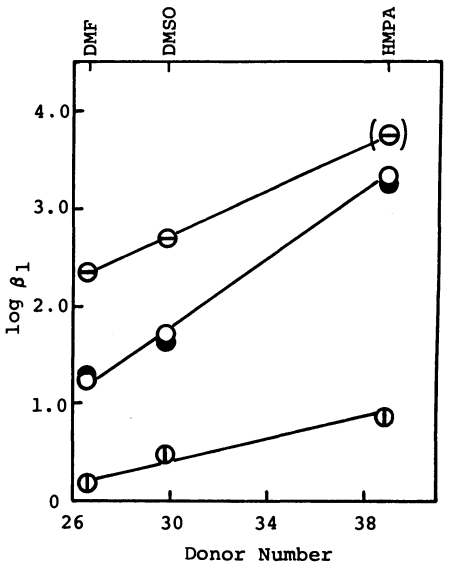

Fig. 3. The relation between log β_1 and donor numbers of solvents: (⊖) Mg^{2+}, (●) Ba^{2+}, (○) Li^+, (Φ) K^+.

β_3. In Table 1, however, only β_1 and β_2 are listed, since the reliability of β_3 was not sufficient in this experiment. A small amount of D was added to the solution in order to suppress any change of the organic membrane phase by the solvent effect. For D of DMF, DMSO, and HMPA, the maximum molar fraction of D added to Cell I was about 0.005, except if otherwise mentioned. The results are summarized in Table 1. The value of β_1 for the Ba^{2+}–DMF complex was also obtained by using a barium amalgam electrode instead of the PAA-POE4 electrode in Cell I. The barium metal was dissolved in mercury in order to construct the electrode; its concentration was about 0.33M for 1×10^{-3} M of the barium ion in Cell I. The experiment was carried out under oxygen-free conditions. The obtained β_1-value agreed with the value in Table 1 within the reliability of the experiment. The formation constants for the Mg^{2+}–HMPA complex in Table 1 were obtained in a somewhat different way since the potential after the addition of HMPA to the Mg^{2+}–AN solution gradually became ill-defined. The interaction of the magnesium ion with HMPA was so strong that the magnesium ion trapped by POE4 in the organic membrane phase seemed to become unstable; the electrode potential may be irreproducible. The method was as follows: To a 1×10^{-3} M solution of magnesium ion in Cell I was added twice equivalent of HMPA to the magnesium ion (the potentials before and after the addition were measured). The values of β_1 and β_2 were obtained from the potential jump by assuming that K_1/K_2(ratio of the stepwise formation constants) was the same as that for the Li^+–HMPA complexes in AN(i.e., $K_1:K_2=14:1$).

Discussion

From Table 1 the stabilities of the complexes of both the magnesium and barium ions in AN with DMF, DMSO, and HMPA increase in the order: DMF(26.6)<DMSO(29.8)≪HMPA(38.8). The figures in the parentheses show the Gutmann's donor number.[8] These orders are the same as those for the lithium and potassium ions. When the formation constants for the magnesium ion with DMF and DMSO are compared with those for the lithium ion, which has a crystallographic ionic radius very close to the magnesium ion, the former has β_1 and β_2 that are about one order larger than those of the latter. The situation is approximately the same for the case in which the ions are potassium and barium ions, although the stability of the HMPA complex with the barium ion is much larger than expected. These results may be attributed to the difference in the ionic charge. On the other hand, the larger complex formation abilities of the magnesium ion compared with those of the barium ion may be reasonably explained if we considered that the crystallographic radius of the magnesium ion is smaller than that of

the barium ion. Except for the complex of Mg^{2+}–HMPA, the values of β_1 in Table 1 seem to be reliable within ±10%, while those of β_2 within ±20%. The relations between the donor numbers of the complexing solvents and log β_1 are plotted in Fig. 3. It is interesting that in each case a linear relation was obtained. Complex formations of the barium ion occur with almost the same stability as those of the lithium ion.

Recently, we have plenty of thermodynamic and kinetic data concerning cation-macrocyclic ligand interactions in nonaqueous solvents.[9] However data concerning relatively weaker metal–ligand interactions, such as ion-solvent molecule interactions in the present study, are very scarce. The information obtained using the present electrode may effectively be used for a comparison of the relative strength of the solvation phenomena and specific interactions[8] between metal cations and dipolar aprotic solvent molecules.

This work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

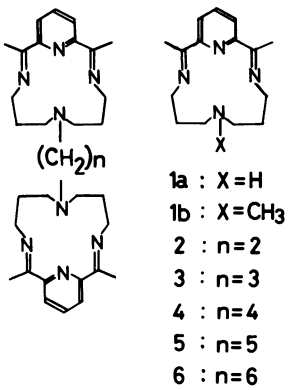
Electrochemical Studies on Metal-Metal Interactions in Bismacrocyclic Ni(II) Complexes

Katsura MOCHIZUKI
Department of Chemistry, Yokohama City University, Yokohama 236
(Received July 15, 1987)

Synopsis. Studies on five Ni(II) complexes, i.e., 7,7′-*polymethylene*bis[2,12-dimethyl-3,7,11,17-tetraazabicyclo-[11.3.1]heptadeca-1(17),2,11,13,15-pentaene]dinickel(II) perchlorates with *polymethylene* bridges of 2—6-C length, by cyclic voltammetry and differential pulse polarography, have revealed that the half-wave potentials of the $[Ni^{II}Ni^{II}]/[Ni^{II}Ni^{III}]$ and $[Ni^{II}Ni^{III}]/[Ni^{III}Ni^{III}]$ couples are not changed among the hexa- to tetramethylene derivatives but shifted toward the positive side in the following order: tetramethylene<trimethylene<ethylene derivative. These results are explainable in terms of the electrostatic repulsion due to these two metal ions.

Binuclear metal complexes with bis(tetraazamacrocycle) linked by a polymethylene or a carbon-carbon bridge have been used for studies on metal-metal interactions.[1-10] For example, Murase et al.[4] investigated bismacrocyclic Cu(II) complexes with **2**—**6**[11] by ESR spectroscopy and found effects of polymethylene length on antiferromagnetic interaction. Metal-metal interactions of Ni(II) complexes with ligands bis(cyclam)[1,10] and bis(isocyclam)[8] were studied by electrochemical methods and attributed to an electrostatic repulsion between two cations located close to each other. A limited number of Ni(II) complexes bridged by a carbon-carbon bond,[1,10] ethylene,[8] or *p*-xylylene[8], have been investigated. Ligands **2**—**6** seem to have the following advantages: 1) the length of the polymethylene bridge can be varied without causing any structural change in the tetraaza moieties; 2) observed metal-metal interactions are free from the delocalization of the two macrocycles. The author, therefore, has performed electrochemical studies on the series of Ni(II) complexes with **1a**, **1b**, and **2**—**6**.



The oxidation of the Ni(II) complexes with **1a**, **1b**, and **2**—**6** in acetonitrile was studied. Figure 1 shows cyclic voltammograms (CVs) and differential pulse polarograms (DPs). Both the electrochemical measurements apparently reveal that the facility of the oxidation is affected by the bridge length of ligand. All the Ni(II) complexes with **4**, **5**, and **6** show CVs in which one anodic and one cathodic peak appear with a ratio i_{pa}/i_{pc} of almost unity. Their respective DPs show one nearly symmetrical peak. Similar results were obtained in the case of monomacrocyclic Ni(II) complexes with **1a** and **1b**. The Ni(II) complexes with **2** and **3** give quite different CVs and DPs. The CV of $[Ni^{II}_2(\mathbf{3})]^{4+}$ has two shoulders each near the anodic and near the cathodic peak. The CV of $[Ni^{II}_2(\mathbf{2})]^{4+}$ has two anodic peaks at 1.25 and 1.35 V and two cathodic ones at 1.22 and 1.32 V. In the DP of $[Ni^{II}_2(\mathbf{3})]^{4+}$ one broad peak is observed; its half-width is larger than those of the Ni(II) complexes with **1a**, **1b**, and **4**—**6** (See Table 1). The DP of $[Ni^{II}_2(\mathbf{2})]^{4+}$ has two distinct peaks (1.30_0 and 1.23_5 V) with nearly equal intensities. These results indicate that the Ni(II) complexes having short bridges are oxidized stepwise at distinctly different potentials according to the consecutive reaction

$$[Ni^{II}Ni^{II}]^{4+} \overset{-e}{\rightleftharpoons} [Ni^{II}Ni^{III}]^{5+} \overset{-e}{\rightleftharpoons} [Ni^{III}Ni^{III}]^{6+}. \quad (1)$$

Table 1 lists electrochemical data evaluated from the DPs. The values of $E_{1/2}{}^{1}$ ($[Ni^{II}Ni^{II}]/[Ni^{II}Ni^{III}]$) of

				1.28_0
$[Ni^{II}{}_2(\mathbf{2})]^{4+}$	1.23_5	17_2	$8_9(8_7)$	1.22_9
	1.30_0			1.31_7

a) In acetonitrile, vs. $Ag\text{-}Ag^+$ (0.01 mol dm^{-3} $AgNO_3$), T=25 °C, and I=0.1 (Et_4NClO_4). b) Evaluated from half-width data by the method of Ref. 14. The value in parentheses was evaluated from E_p data.

the Ni(II) complexes with **4**—**6**, independent of bridge length, are very close to that of $[Ni^{II}(\mathbf{1b})]^{2+}$.[12] The $E_{1/2}{}^1$ values shift toward the positive side in the sequence of ligands: **2**>**3**>**4**. A similar but more pronounced trend is observed with the second oxidation step, $E_{1/2}{}^2$ ($[Ni^{II}Ni^{III}]/[Ni^{III}Ni^{III}]$). On a theoretical ground, consecutive oxidation of two equivalent and independent metal centers involves a potential separation, $\Delta E_{1/2}=E_{1/2}{}^2-E_{1/2}{}^1$, of 36 mV.[13,14] Thus, the larger value (49 mV) is observed with the Ni(II) complexes with **4**—**6**. More remarkable differences are found with $[Ni^{II}{}_2(\mathbf{2})]^{4+}$ (89 mV) and $[Ni^{II}{}_2(\mathbf{3})]^{4+}$ (75 mV). These results are reasonable because the electrostatic repulsion due to two metal ions undoubtedly increases with decrease in their distance.[15] Furthermore, the more pronounced effects observed for the second oxidation step as well as $\Delta E_{1/2}$ are acceptable, since the electrostatic repulsion due to two Ni(III) ions should be larger than that due to Ni(II) and Ni(III), which is in turn larger than that due to two Ni(II) ions.

Thus, all the data obtained show that the metal-metal interaction of the bismacrocyclic Ni(II) complexes is affected by the bridge length; the interaction is increased in the following sequence of ligands **2**>**3**>**4**=**5**=**6**. The crucial bridge length for the interaction lies between tri- and tetramethylene; to our best knowledge, such a finding is unprecedented in the literature.

Experimental

Materials. Monomacrocyclic Ni(II) complexes **1a** and **1b** were prepared according to the method described by Karn and Busch.[16] Bismacrocyclic Ni(II) complexes were synthesized by a method similar to that reported by Murase et al.[4]

Physical data of new compounds are given below together with some comments.

$[Ni^{II}{}_2(\mathbf{2})](ClO_4)_4$: A crude product was purified by column chromatography with ion-exchange resin (SP-Sephadex C-25) and 0.6 mol dm^{-3} NaCl as the eluant. The counter ion of the complex thus purified was replaced with perchlorate by the conventional method. Found: C, 36.28; H, 4.30; N, 10.27; Ni, 10.44%. Calcd for $C_{32}H_{46}N_8Ni_2Cl_4O_{16}$: C, 36.33; H, 4.38; N, 10.59; Ni, 11.09%. IR (Nujol): 1630 (C=N) and 1580 cm^{-1} (py); ^{13}C NMR (CF_3COOD, TMS) δ=17.8 (q), 25.2 (t), 41.9 (t), 51.7 (t), 55.6 (t), 127.8 (d), 145.1 (d), 156.7 (s), and 181.0 (s).

$[Ni^{II}{}_2(\mathbf{2})]Cl_4$: MS (FAB) m/z 764 ($[M-Cl+H]^+$), 729 ($[M-2Cl+H]^+$) and 693 ($[M-3Cl+H]^+$).

$[Ni^{II}{}_2(\mathbf{5})](ClO_4)_4\cdot 2H_2O$: Found: C, 36.86; H, 4.60; N, 9.68%. Calcd for $C_{35}H_{52}N_8Ni_2Cl_4O_{16}\cdot 2H_2O$: C, 37.00; H, 4.97; N, 9.86%. IR (Nujol): 1628 (C=N) and 1583 cm^{-1} (py); ^{13}C NMR (CF_3COOD, TMS) δ=17.5 (q), 20.1 (t), 24.2 (t), 25.8 (t), 51.6 (t), 52.3 (t), 55.2 (t), 127.7 (d), 146.1 (d), 156.2 (s), and 181.2 (s).

$[Ni^{II}{}_2(\mathbf{6})](ClO_4)_4\cdot H_2O$: Found: C, 38.04; H, 4.83; N, 9.94%. Calcd for $C_{36}H_{54}N_8Ni_2Cl_4O_{16}\cdot H_2O$: C, 38.19; H, 4.99; N, 9.90%. IR (Nujol): 1635 (C=N) and 1580 cm^{-1} (py); ^{13}C NMR (CF_3COOD, TMS) δ=17.3 (q), 19.7 (t), 24.0 (t), 27.6 (t), 51.3 (2t), 54.9 (t), 127.8 (d), 145.8 (d), 156.4 (s), and 181.2 (s).

The isolation of the Ni(II) complex perchlorates with **3** and **4** was also confirmed by elemental analysis, IR, and ^{13}C NMR.

Measurements: Electrochemical measurements were performed according to the same method as described in our previous paper.[17] The concentration of the Ni(II) complexes was ca. 1×10^{-3} mol dm^{-3}. Tetraethylammonium perchlorate (0.1 mol dm^{-3}) was used as the supporting electrolyte.

The author wishes to thank Dr. Eiji Nakamura of Institute for Life Science of Mitsubishi Kasei for the measurement of FAB-mass spectra.

Synopsis. The crystal structure of phenanthrene:picric acid molecular complex was determined by X-ray crystal analysis. Phenanthrene and picric acid molecules are stacked alternately along the c-axis, making their molecular planes parallel to each other. The intramolecular hydrogen bonding exists in a picric acid.

Phenanthrene:picric acid is one of the π-molecular complexes. Three polymorphs at least have been known.[1] Herbstein and Kaftory reported cell dimensions,[2] but crystal structures have not been described. We have tried to elucidate the crystal structure and will report here the results obtained.

Experimental

The components in equimolar ratio were solved in an excess of methanol. Yellow needles were precipitated by evaporation of the solution at room temperature. The diffraction intensities were measured on a Rigaku AFC-5 four-circle diffractometer with graphite-monochromated Cu $K\alpha$ radiation at 23 °C. Crystallographic and other information is summarized in Table 1.

The ω–2θ scan mode with a scan rate of 8° min^{-1} was employed with the ω scan range $(1.1+0.5\tan\theta)°$. A total of 2807 reflections with $|F_o|>3\sigma(|F_o|)$ was collected up to 2θ of 140°. No absorption correction was applied [μ(Cu $K\alpha$)= 10.99 cm^{-1}]. The structure was solved by a direct method using the program MULTAN[3] and refined by the block-diagonal least-squares method using initially B_{iso} and finally B_{ij} for non-hydrogen atoms. The difference Fourier synthesis showed two H atoms of phenanthrene and picric acid, and H atom of picric acid OH. The positions of other ten H atoms were calculated and refined. Final R was 0.076 (R_w= 0.083, S=1.045). The function minimized was $\Sigma w(|F_o|-|F_c|)^2$, where w of 1.0 was used. Atomic scattering factors were quoted from International Tables for X-Ray Crystallography (1974).[4]

Table 1. Crystallographic and Other Information for Phenanthrene:Picric Acid Complex

Molecular formula	$C_{14}H_{10}:C_6H_3N_3O_7$

μ(Cu $K\alpha$)/cm^{-1}	10.99

Results and Discussion

Cell dimensions are significantly different from those reported by Herbstein and Kaftory (a=8.99, b=14.81, c=7.12 Å, α=101.5, β=99.2, and γ=102.1°). The crystal used in this study is different from that used by Herbstein in morphology. The final atomic

parameters are listed in Table 2.[††]

Bond lengths and interbond angles are given in Table 3. The atomic numbering is shown in Fig. 1.[5]

The arrangement of the molecules in a unit cell is shown in Fig. 2. Phenanthrene and picric acid molecules are stacked along the c-axis, making their molecular planes parallel to each other. The distance between them is 3.4 Å. Those in opposite directions in a stack are also 3.4 Å. Thus there is no indication of 'pairing' of molecules within a stack.

The nitro group O2–N1–O3 (dihedral angle 11.8° to a plane of benzene ring) protrudes from the stacked column. Other two nitro groups are sandwiched in between two phenanthrene molecules (dihedral angles 0.53° for the nitro group O4–N2–O5 and 2.55° for O6–N3–O7).

In the crystal of picric acid the possibility of an intermolecular hydrogen bonding have been envisaged by Srikrishnan et al.[6] In the crystal of phenanthrene:picric acid complex, however, a difference Fourier map showed no clear evidence of an intermolecular hydrogen bonding. The H atom (H(O1)) of phenol OH is located at a reasonable position for intramolecular hydrogen bonding bet-

[††] The complete tables of observed and calculated structure factors, isotropic thermal parameters and the atomic coordinates of hydrogen atoms, and anisotropic thermal parameters of non-hydrogen atoms are kept as Document No. 8779 at the Office of the Editor of the Bulletin of the Chemical Society of Japan.

ween O(1) and O(7), the distances from which are 1.13 and 1.67 Å respectively. Such an intramolecular hydrogen bonding may cause the difference between the two N–O distances of the nitro group O6–N3–O7.

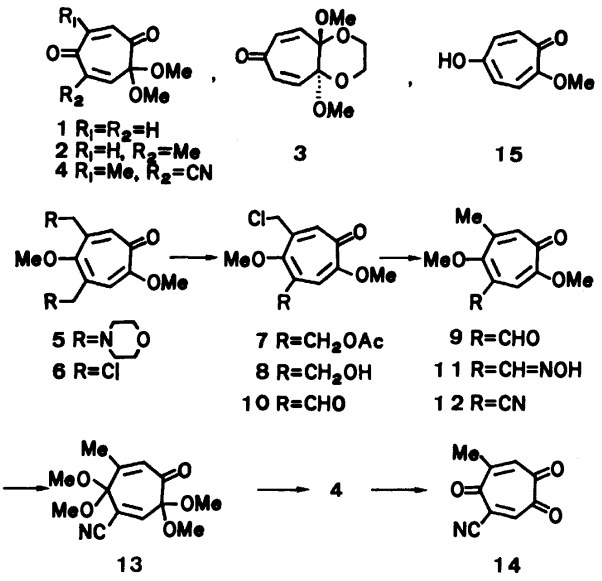
The Cyclic Voltammetry of *p*-Tropoquinone Acetals

Akira MORI,* Shun-ichi HIRAYAMA,† Yasutomo GOTO,† and Hitoshi TAKESHITA*
Institute of Advanced Material Study, 86, Kyushu University, Kasuga-koen, Kasuga, Fukuoka 816
†Graduate School of Engineering Sciences, 39, Kyushu University, Kasuga-koen, Kasuga, Fukuoka 816
(Received August 5, 1987)

Synopsis. The cyclic voltammetry of *p*-tropoquinone mono- and bisacetals was analyzed. Monoacetals showed an irreversible redox couple and an oxidation wave around +0.16 to −0.1 V vs. Ag/AgCl, the latter of which was due to a dianion species.

Recently, we have shown that, according to a cyclic voltammetry (CV) analysis, the redox process of tropoquinones generally occurs via two one-electron paths; however, the intensity of the second oxidation wave was sometimes diminished by subsequent chemical reactions of the anion radical species.[1,2] Here, we show the electrochemical behaviors of *p*-tropoquinone acetals, masked tropoquinone derivatives, which are suitable for CV studies when tropoquinones are unstable under the experimental conditions.

p-Tropoquinone acetals **1**—**3** were prepared as previously described,[3] except for 5-cyano-3-methyl-7,7-dimethoxy-2,5-cycloheptadiene-1,4-dione (**4**), which was prepared as shown in Scheme 1; 2,5-dimethoxy-4,6-bis(morpholinomethyl)tropone (**5**)[4] was treated with ethyl chloroformate[5] to give bis(chloromethyl) derivative (**6**) in 78% yield.



Next, an acetic acid solution of **6** with silver acetate at 80 °C quantitatively gave 4-acetoxymethyl-6-chloromethyl-2,5-dimethoxytropone (**7**), the saponification of which afforded air-sensitive 6-chloromethyl-4-hydroxymethyl-2,5-dimethoxytropone (**8**). The manganese(IV) oxide oxidation of **8** gave aldehydes **9** and **10**.

An oxime **11**, prepared from **9**, was a syn/anti-mixture (2:3) and dehydrated to a cyano derivative **12** in 28% yield. A subsequent cerium(IV) ammonium nitrate (CAN)-oxidation[6] of **12** gave a bisacetal **13** in 31% yield; upon an acid hydrolysis at 40 °C for 1.5 h, **13** gave a monoacetal **4** in 94% yield; however, the same treatment at 50 °C for 4.5 h gave 4-cyano-6-methyl-*p*-tropoquinone (**14**) in 1% yield.

The redox potentials of acetals, determined by CV, are summarized in Table 1. Among them, the second redox couple of **4** was hardly recognizable and the peak height of the second oxidation peak of **1** and **2** decreased.

The first and second reduction peak potentials ($E_{pr}1$ and $E_{pr}2$) of **1** were ca. 0.6 V more negative than those

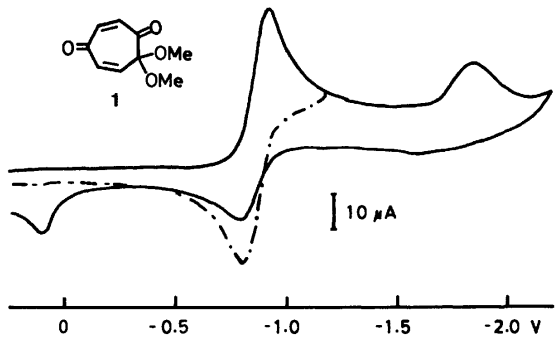


Fig. 1. The CV curves of **1**.

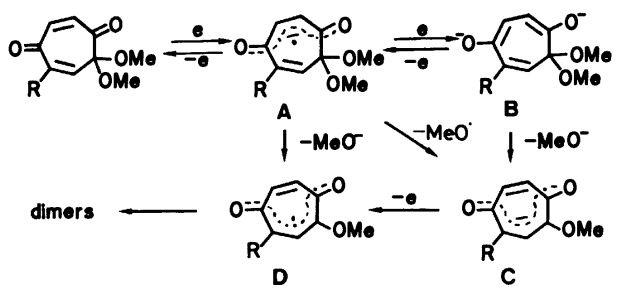
Table 1. Reduction and Oxidation Peak Potentials of Acetals and the Related Compounds[a]

	$E_{pr}1/E_{po}1$	$E_{pr}2/E_{po}2$
1[b]	−0.87/−0.74 (−0.81)[c]	−1.68/−1.46 (−1.65)
2[b]	−0.93/−0.77 (−0.85)	−1.88/— (−1.70)
3	−1.54/−1.38 (−1.48)	
4[b]	−0.56/−0.48 (−0.49)	−1.43/—
p-Tropoquinone	(−0.21)	(−1.10)
4-Methyl-*p*-tropoquinone	(−0.28)	(−1.15)

a) The CV were measured in anhydrous DMF with 0.1 M TBAF using Pyrex-glass sealed Pt wire as working and counter electrodes and standard Ag/AgCl as a reference electrode at 22—23 °C under N_2 atmosphere with a scan rate of 100 mV/s. b) Additional oxidation peaks were observed at +0.16, +0.09, and −0.11 V for **1**, **2**, and **4**, respectively. c) The values in parentheses showed the half-wave potentials.

of *p*-tropoquinone. The substituent effect (0.04 V) of a methyl group in *p*-tropoquinone acetal series was nearly the same as that (0.07 V) of the *p*-tropoquinone series.[1] In the case of **4**, the first reduction peak potential became more positive (by 0.36 V) due to a cyano group, a strong electron-attractive group. In the CV of monoacetals **1** and **2**, an oxidation wave was observed around +0.16 to −0.1 V vs. Ag/AgCl. These waves in **1** and **2** disappeared and their CV showed a reversible redox couple when the scanning was returned around −1.2 V. While the CV of 5-hydroxy-2-methoxytropone (**15**) showed an oxidation peak at +0.16 V, together with E_{pr}=−1.34 and E_{po}=−0.57 V, it is conceivable that the anion **C** was formed by the eliminations of a methoxide anion from dianion **B** and/or the methoxide radical from **A**, and that **C** was oxidized to the radical **D** at +0.16 V. Furthermore, since it has been established[6] that the one-electron oxidation of **15** gave dimers together with **1**, the irreversible redox couples of monoacetals must be due to a formation of dimeric products under CV conditions. The low intensity of the second peak could, thus, be explained by the involvement of alternative routes to **D** via eliminations of a methoxide ion and/or radical. In the case of **4**, routes **A** to **D** might become easier since the cyano group at C-5 should stabilize the radical intermediate **D**. Therefore, the process from **A** to **B** might be diminished.



Furthermore, the CV of **3** showed a quasi-reversible couple at E_{pr}=−1.54 and E_{po}=−1.38 V, and the substituents varied with the electrochemical behaviors of tropoquinone acetals.

Since an introduction of each cyano group was estimated to enhance the redox potentials by 0.36 V, the enhanced redox potentials of the fully substituted *p*-tropoquinones, such as dicyanodihalogeno-*p*-tropoquinones, could be estimated as +0.65 V vs. Ag/AgCl,[1] which may overcome the potential of 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ), the strongest oxidizing aromatic quinone presently available.

Experimental

Preparation of 6. To an anhydrous benzene solution (10 cm³) of ethyl chloroformate (1 g) was added an anhydrous benzene solution (20 cm³) of **5**[4] (814 mg) at 0—5 °C. After stirring at 40 °C for 10 h, the precipitates were filtered off and the filtrate was chromatographed on a silica-gel column to give **6** [yellow needles, mp 71—73 °C, 460 mg; 78%. Found: C, 50.35; H, 4.65%; *m/z*, 262.0180, 264.0147, 266.0137 (M⁺).[7] Calcd for $C_{11}H_{12}O_3Cl_2$: C, 50.21; H, 4.60%; *m/z*, 262.0164, 264.0135, 266.0104. ^{1}H NMR δ[8]=3.87 (3H, s), 3.94 (3H, s), 4.50 (2H, s), 4.63 (2H, s), 6.68 (1H, s), and 7.40 (1H, s). ^{13}C NMR δ=44.4, 45.0, 56.4, 63.5, 114.0, 132.5, 138.4, 143.2, 154.9, 161.7, and 178.5. IR *ν*: 1620, 1595, and 1570 cm⁻¹].

Reaction of 6 with AgOAc. An AcOH solution (10 cm³) of **6** (55 mg) and AgOAc (370 mg) was heated at 80 °C for 2 h. The resultant precipitates were filtered off, and the filtrate was chromatographed on a silica-gel column to give **7** [yellow needles, mp 96—98 °C (decomp), 60 mg; 100%. Found: *m/z*, 286.0580, 288.0564 (M⁺). Calcd for $C_{13}H_{15}O_5Cl$: 286.0605, 288.0576. ^{1}H NMR δ=2.14 (3H, s), 3.83 (3H, s), 3.90 (3H, s), 4.52 (2H, s), 5.16 (2H, s), 6.77 (1H, s), and 7.42 (1H, s). ^{13}C NMR δ=20.6, 44.8, 55.9, 63.2, 63.5, 113.2, 131.4, 138.3, 143.3, 155.4, 161.7, 170.5, and 178.4. IR *ν*: 1750, 1625, and 1600 cm⁻¹].

Saponification of 7 to 8 and Subsequent MnO_2-Oxidation to 9 and 10. To an MeOH solution (10 cm³) of **7** (555 mg) was added aqueous NaOH (1 M, 2 cm³ (1 M=1 mol dm⁻³)). After stirring for 5 min, the resultant brown solution was heated in vacuo in order to remove the solvent; the residue was diluted with water, acidified with dil HCl, and extracted with $CHCl_3$. The organic layer was dried over $MgSO_4$ and evaporated in vacuo to give **8** [a brown oil, 468 mg; 99%. ^{1}H NMR δ=3.78 (3H, s), 3.90 (3H, s), 4.50 (2H, s), 4.76 (2H, s), 7.21 (1H, s), and 7.35 (1H, s). ^{13}C NMR δ=45.1, 58.4, 61.9, 62.9, 113.5, 137.5, 138.3, 144.1, 154.4, 162.5, and 178.7]. Subsequently, to an anhydrous benzene solution (10 cm³) of **8** (474 mg) was added MnO_2 (113 mg). After refluxing for 4 h, the mixture was passed through a Celite column. The combined eluent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **9** [pale yellow needles, mp 121—122 °C, 396 mg; 98%. Found: *m/z*, 208.0732 (M⁺). Calcd for $C_{11}H_{12}O_4$: 208.0733. ^{1}H NMR δ=2.38 (3H, d, *J*=1 Hz), 3.84 (3H, s), 3.94 (3H, s) 7.16 (1H, s), 7.38 (1H, q, *J*=1 Hz), and 10.36 (1H, s). ^{13}C NMR δ=21.6, 56.4, 64.5, 106.6, 128.2, 141.5, 145.5, 161.2, 165.4, 179.1, and 190.7. IR *ν*: 1680, 1620, 1600, and 1575 cm⁻¹] and **10** [yellow needles, mp 158—159 °C, 1.6 mg; 0.3%. Found: *m/z*, 242.0308, 244.0297 (M⁺). Calcd for $C_{11}H_{11}O_4Cl$: 242.0343, 244.0304. ^{1}H NMR δ=3.97 (3H, s), 4.00 (3H, s), 4.55 (2H, s), 7.21 (1H, s), 7.54 (1H, s), and 10.34 (1H, s)].

Preparation of 11. An MeOH solution (10 cm³) of **9** (396 mg) and NH_2OH (100 mg) was refluxed for 1.5 h. After evaporating the solvent, the residue was diluted with water, and extracted with $CHCl_3$. The organic layer was dried over $MgSO_4$ and evaporated in vacuo, leaving **11** [pale yellow crystals, mp 171—172 °C, 386 mg; 91%. Found: *m/z*, 223.0841 (M⁺). Calcd for $C_{11}H_{13}O_4N$: 223.0842. ^{1}H NMR δ=2.33 (3H, d, *J*=1 Hz), 3.67 (3H, s), 3.90 (3H, s), 7.18 (1H, q, *J*=1 Hz), 7.36 (1H, s), and 8.44 (1H, s) for a major anti-isomer; 2.58 (3H, s), 3.47 (3H, s), 3.92 (3H, s), 6.78 (1H, s), 7.2 (1H, overlapped with solvent signal) and 8.55 (1H, s) for a minor syn-isomer. ^{13}C NMR δ=22.8, 56.7, 62.8, 111.1, 129.9, 137.8, 147.7, 148.9, 159.1, 162.0, and 180.7 for anti-isomer; 20.2, 57.0, 62.8, 106.1, 129.9, 137.0, 147.7, 148.9, 161.2, 163.1, and 180.7 for syn-isomer. IR *ν*: 3140, 3010, 2860, 1740, 1615, 1590, and 1545 cm⁻¹].

Preparation of 12. An Ac_2O solution (5 cm³) of **11** (29.3 mg) was heated at 120 °C for 4 h. After removing the solvent, the residue was chromatographed on a silica-gel column to give **12** [pale yellow crystals, mp 157—158 °C, 4.8 mg; 28%. Found: *m/z*, 205.0721 (M⁺). Calcd for $C_{11}H_{11}O_3N$: 205.0737. ^{1}H NMR δ=2.33 (3H, d, *J*=1 Hz), 3.90 (3H, s), 3.95 (3H, s), 6.48 (1H, s), and 7.30 (1H, q, *J*=1 Hz). ^{13}C NMR δ=22.1, 56.7, 62.3, 107.5, 109.8, 117.7, 140.7, 143.9, 161.6, 164.2, and 178.5. IR *ν*: 2220, 1620, 1595, and 1575 cm⁻¹] and **11** (10.9 mg).

The CAN-Oxidation of 12. A mixture of **12** (72.7 mg) and CAN (798 mg) was stirred at room temperature for 4 h.

The resultant mixture was extracted with $CHCl_3$ and the organic layer was washed with aq $NaHCO_3$ and dried over $MgSO_4$. The solvent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **13** [a pale yellow oil, 29.3 mg; 31%. Found: *m/z*, 267.1104 (M^+). Calcd for $C_{13}H_{17}O_5N$: 267.1104. ^1H NMR δ=1.93 (3H, d, J=1.3 Hz), 3.24 (6H, s), 3.29 (6H, s), 5.80 (1H, q, J=1.3 Hz), and 6.61 (1H, s). ^{13}C NMR δ=18.8, 50.7 (4C), 97.3, 100.7, 115.9, 124.2, 125.3, 147.6, 152.8, and 190.7. IR ν: 2230, 1745, 1710, and 1605 cm^{-1}].

Hydrolysis of 13 to 4. A mixture of acetone (5 cm^3), $HClO_4$ (2 M, 5 cm^3), and **13** (27 mg) was stirred at 40 °C for 1.5 h. The mixture was then diluted with water and extracted with $CHCl_3$. The extract was dried on $MgSO_4$ and evaporated in vacuo, leaving **4** [a yellow oil, 21 mg; 94%. Found: *m/z*, 221.0700 (M^+). Calcd for $C_{11}H_{11}O_4N$: 221.0689. ^1H NMR δ=2.10 (3H, d, J=1.3 Hz), 3.31 (6H, s), 6.06 (1H, q, J=1.3 Hz), and 6.78 (1H, s)].

Preparation of 14. To an acetone solution (1 cm^3) of **4** (12.9 mg) was added aq $HClO_4$ (1 M, 1 cm^3) and heated at 50 °C for 4.5 h. The mixture was diluted with water and extracted with $CHCl_3$. The extract was dried on $MgSO_4$ and evaporated in vacuo. The residue was chromatographed on a silica-gel column to give **14** [1 mg; 1%. Found: *m/z*, 175.0289 (M^+). Calcd for $C_9H_5O_3N$: 175.0269. ^1H NMR δ=2.44 (3H, d, J=1 Hz), 7.17 (1H, s), and 7.47 (1H, q, J=1 Hz)].

The authors wish to thank The Ministry of Education, Science, and Culture for a financial assistance to A. M. through a Grant-in-Aid for Scientific Research (No. 60470025).

7) Three separated peaks, due to $^{35}Cl_2$-, $^{35}Cl^{37}Cl$-, and $^{37}Cl_2$-isotope compositions, revealed a reasonable relative ratio of intensities, 9:3:1. Mass-spectral behaviors of other chloro derivatives were similar.

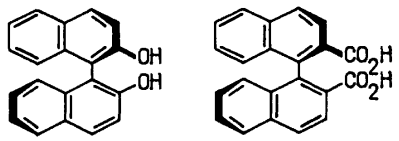
8) All the NMR spectra were measured in $CDCl_3$ solutions.

Convenient Optical Resolution of Axially Chiral 1,1'-Binaphthyl-2,2'-dicarboxylic Acid

Shigeyoshi KANOH, Yukihiko HONGOH, Masatoshi MOTOI, and Hiroshi SUDA*
Department of Chemistry and Chemical Engineering, Faculty of Technology, Kanazawa University, 2-40-20 Kodatsuno, Kanazawa 920
(Received September 8, 1987)

Synopsis. Axially chiral 1,1'-binaphthyl-2,2'-dicarboxylic acid was conveniently resolved through its brucine salts in satisfactory yields. The resolved diacids were confirmed to be optically pure from high-performance liquid chromatographic analyses of the dimethyl esters derived from them on an optically active poly(diphenyl-2-pyridylmethyl methacrylate) column.

In the last decade, much attention has been drawn to a variety of asymmetric reactions assisted by chirally hinged biaryl compounds.[1] For example, 2,2'-dihydroxy-1,1'-binaphthyl (**1**) has been well-known to bring about great success in complexation with chiral crown ethers[2] and asymmetric reductions of carbonyl compounds.[3] Besides the diol **1**, 1,1'-binaphthyl-2,2'-dicarboxylic acid (**2**) has been successfully utilized to the construction of chirality-recognizing units, as well.[4] Concerning the design of such chiral auxiliaries, the carboxylic substituents are advantageous for easy transformations into various functionalities.[5]



(R)-1 (R)-2

Regardless of the above excellent results, the enantiomers of **2** have been prepared by means of a conventional resolution through its quinine salt.[5b] The procedure seemed to be quite tedious, and the efficiency of resolution was rather low. As pointed out by Hall and Turner,[5b] the salt, which gave a higher optical rotation, was not always composed of optically pure **2**.[6] Moreover, the chiroptical property of the resolved salt was complicated by the fact that the salt formed clathrates with solvents used for recrystallization.[5b]

On the other hand, there is a direct synthetic route to homochiral **2** by Miyano et al.[7] via an intramolecular Ullmann coupling of the bis(bromonaphthoic) ester derived from optically active **1**. However, this route required a stoichiometric amount of axially chiral **1**, and the yield of the cyclic diester was not so high.[7]

Herein we wish to describe the improved optical resolution of (*RS*)-**2**. We found that brucine formed a nicely crystallizable salt with an equimolar amount of **2**. In order to effectively separate a mixture of the diastereomeric salts by recrystallization, solvents and the requisite quantities of solvent were screened. Consequently, it was found that a dextrorotatory salt with a relatively high optical purity was obtained under rather high dilution conditions in acetone. Recrystallization of the less soluble salt from acetone/methanol and work-up of the mother liquor led to pure (+)-brucine salt of (*R*)-**2** in a total 41% yield based on racemic **2**. This salt was identified as an acetone clathrate in a 1:1:1 (**2**:brucine:acetone) stoichiometry. In contrast to the case of the previous quinine salt, both the stoichiometric composition of the clathrate and its stability toward vacuum drying under ambient temperature facilitated the unambiguous estimation of the optical purity of each crop. Decomposition of the (+)-salt with diluted hydrochloric acid gave (*R*)-**2** in a 40% yield; the absolute configuration of the diacid was known.[8]

Similar decomposition of the salt in the mother liquor after removal of the (+)-salt gave (*S*)-enriched **2**. A small amount of the opposite (*R*)-**2** could be removed by a simple filtration, because the minor enantiomer formed a *racemic compound* which was sparingly soluble in diethyl ether. Thus, optically active (*S*)-**2** was obtained in a 45% yield. Any recrystallization process of the more soluble (−)-salt[9] was not needed for the acquisition of optically pure (*S*)-**2**; this is another merit of our method.

The diacids resolved thus may be recrystallized from diethyl ether. The rotation values of the purified enantiomers compare favorably with the earlier records.[5b,8] Of course, most of the resolving agent was reusable.

The optical purity of the resolved **2** was determined

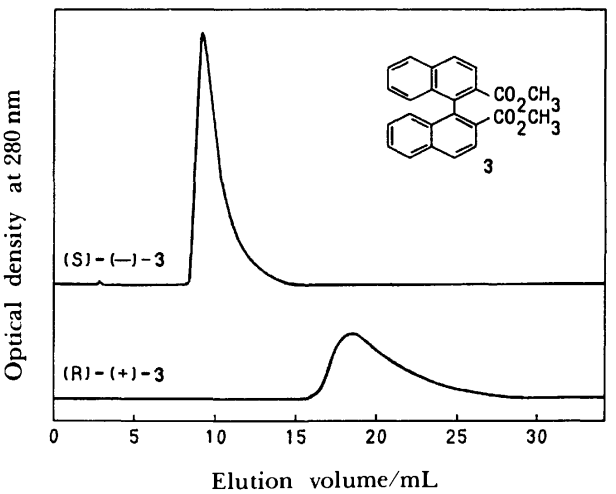


Fig. 1. Chromatograms of the dimethyl ester (**3**) derived from optically resolved **2**. Column: (−)-poly(D2PyMA), 25×0.46 (i.d.) cm; eluent: methanol; flow rate: 1.0 cm^3 min^{-1}; temperature, 25 °C.

from an HPLC analysis of the dimethyl ester (**3**) derived from the diacid. The packing material used for the optically active column was (−)-poly(diphenyl-2-pyridylmethyl methacrylate) [poly(D2PyMA)][10] coated on macroporous silica gel.[11] Base-line resolved separation was accomplished for racemic **3** on this column, using methanol as an eluent.[12] Figure 1 shows chromatograms of (+)- and (−)-**3** under the same conditions as those operated for the racemic material. The enantiomers were eluted at a different retention time to each other, which was in near agreement with that of either of two peaks observed for racemic **3**, and both chromatograms showed the absence of the opposite enantiomer. These results indicate that the diacids resolved in the present method are almost optically pure.

Although the present resolution method relies on a classical recrystallization of the diastereomeric salts, the operational simplicity and high efficiency will help chemists wishing to use the optically pure diacid **2**.

Experimental

General. Melting points are uncorrected. A thermal analysis was carried out with a DAINI SEIKOSHA differential scanning calorimeter SSC/560S, at a heating rate of 5 °C min^{-1}, using an aluminum open sample pan. IR and ^{1}H NMR spectra were recorded on a JASCO A-202 and a JEOL JNM-FX-100S (100 MHz) spectrometer, respectively. Optical rotations were determined on a JASCO DIP-360 digital polarimeter. High-performance liquid chromatograms (HPLC) were run on a 25×0.46 (i.d.)-cm stainless column of (−)-poly(D2PyMA), using a JASCO 880-PU pump equipped with a JASCO UVIDEC-100-II UV detector at 280 nm. Resolution was carried out with methanol at a flow rate of 1.0 cm^3 min^{-1} at 25 °C.

(*RS*)-1,1′-Binaphthyl-2,2′-dicarboxylic Acid (2). The titled compound was prepared by the method reported in the literature.[5b] The racemic diacid (**2**) was recrystallized from acetone to give a 2:1 stoichiometric clathrate of acetone to **2** as transparent prisms, the de-solvation of which converted them gradually into a nontransparent material during storage in an open vessel under ordinary conditions. The clathrate released the acetone molecules at 68 °C, and then melted at 276 °C under atmospheric pressure (from a differential scanning calorimetric analysis). Acetone clathrate of **2**; IR (KBr) 3500—2500, 1725, 1690, 1615, 1595, 1240, 1210, 1195, 1150, 1140 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=2.09 (s, acetone, 12H), 6.8—8.2 (m, ArH, 12H), 12.2 (br s, -COOH). Found: C, 73.34; H, 5.46%. Calcd for $C_{22}H_{14}O_4 \cdot 2C_3H_6O$: C, 73.35; H, 5.72%. A sample was dried at 90 °C under vacuum to give the de-solvated diacid; mp 272—274 °C (lit,[5b] mp 272—274 °C); IR (KBr) 3500—2500, 1680, 1615, 1595, 1280, 1250, 1165, 1140 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=3.3 (br s, -COOH, 2H), 6.8—8.2 (m, ArH, 12H).

Optical Resolution of (*RS*)-1,1′-Binaphthyl-2,2′-dicarboxylic Acid (2). All yields were based on (*RS*)-**2** used. A solution of 30.0 g (87.6 mmol) of de-solvated (*RS*)-**2** in 450 cm^3 of acetone was added to a refluxing solution of 34.6 g (87.7 mmol) of anhydrous brucine (*caution: highly poisonous*[13]) in 1.0 dm^3 of acetone. Colorless needles soon began to deposit from the resulting solution and the mixture was cooled in a refrigerator overnight. The separated crystals were filtered and washed with acetone to give 38.7 g of the less soluble salt after air-drying: $[\alpha]_D^{25}$ +125° (*c* 0.5, chloroform). The crude (+)-salt was dissolved in 1 dm^3 of methanol under refluxing, and then the hot solution was diluted with 500 cm^3 of hot acetone. Cooling the solution gave colorless needles, drying of which for 3 h at room temperature under vacuum gave 24.9 g (36%) of brucine salt of (*R*)-**2** as a 1:1 stoichiometric acetone clathrate: mp 211—214 °C; $[\alpha]_D^{25}$ +200° (*c* 0.5, chloroform). The filtrate was concentrated to about 150 cm^3 to give an additional (+)-salt. This work-up was repeated until (−)-brucine salt crystallized, and a small amount of a nearly inactive salt was discarded. The total yield of the pure (+)-salt was 41% (28.8 g). Found: C, 72.48; H, 5.71; N, 3.62%. Calcd for $C_{45}H_{40}N_2O_8 \cdot C_3H_6O$: C, 72.53; H, 5.83; N, 3.52%.

The (+)-salt was shaken with diethyl ether (200 cm^3) and 6 mol dm^{-3} hydrochloric acid, and the aqueous layer was extracted with ether (50 cm^3×2). The combined ethereal extracts were washed with 1 mol dm^{-3} hydrochloric acid and then brine, dried over Na_2SO_4, and evaporated to dryness. Drying of the amorphous powder at 90 °C under vacuum over P_2O_5 gave 12.1 g (40%) of (*R*)-**2**: $[\alpha]_{546}^{25}$ +123° (*c* 1.0, 0.1 mol dm^{-3} NaOH). An analytical sample was recrystallized from ether to give colorless platelets, that were dried under the same conditions as above: mp 197—199 °C (decomp), reported[5b] decomposition at ca. 120 °C for a 0.5 hydrate; $[\alpha]_{546}^{25}$ +127° (*c* 1.0, 0.1 mol dm^{-3} NaOH) (lit[5b] $[\alpha]_{546}^{20}$ +124.2° (*c* 1.115)). Found: C, 76.90, H, 3.95%. Calcd for $C_{22}H_{14}O_4$: C, 77.18, H, 4.12%.

The mother liquor from the initial salt formation was combined with the (−)-salt and the final filtrate, which were obtained in the above purification of the (+)-salt. The mixture was evaporated to dryness. The residual salt was similarly converted into **2**. The solids of (−)-enriched **2** were mixed with 100 cm^3 of ether, and the suspension was warmed to boiling and then cooled. Insoluble materials were filtered off, and the filtrate was reworked. The final filtrate was evaporated under reduced pressure, and the residue was dried at 90 °C under vacuum over P_2O_5 to give 13.5 g (45%) of (*S*)-**2** as an amorphous powder: $[\alpha]_{546}^{25}$ −125° (*c* 1.0, 0.1 mol dm^{-3} NaOH). Pure (*S*)-**2** was obtained by recrystallization from ether as colorless platelets: mp 199—200 °C (decomp), reported[5b] decomposition at ca. 120 °C for a 0.5 hydrate; $[\alpha]_{546}^{25}$ −127° (*c* 1.0, 0.1 mol dm^{-3} NaOH) (lit,[5b] $[\alpha]_{546}^{22}$ −125.2° (*c* 1.023)). Found: C, 77.17, H. 3.85%. Calcd for $C_{22}H_{14}O_4$: C, 77.18, H, 4.12%.

The acidic layers from the decomposition of the salts were combined, and basified by the addition of aqueous ammonia, and the precipitate was collected. Most of the used brucine was recovered by recrystallization from ethanol.

(*S*)-Methyl 1,1′-Binaphthyl-2,2′-dicarboxylate, (*S*)-3, and (*R*)-3. The resolved diacid (*S*)-**2** was treated with diazomethane, and the evaporated residue was chromatographed with benzene on silica gel to give the diester **3** (96%) as a white powder, which gave $[\alpha]_D^{25}$ −20.5° (*c* 1.0, methanol). A part of the solid was used as an HPLC sample without further purification. The remainder was recrystallized from methanol to give crystalline (*S*)-**3**:[14] mp 157—158 °C (lit,[8] mp 154—155 °C); $[\alpha]_D^{25}$ −21.7° (*c* 1.0, methanol), reported[8] ($[\alpha]_D^{25}$ −18° (*c* 1.2); IR (KBr) 1730, 1240, 1135, 765 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.49 (*s*, -OCH_3, 6H), 7.0—8.2 (m, ArH, 12H).

Similarly (*R*)-**2** was converted into (*R*)-**3**; mp 156.5—157.5 °C; $[\alpha]_D^{25}$ +22.4° (*c* 1.0, methanol).

The authors are indebted to Dr. Akito Ichida of Daicel Chemical Industries, Ltd. for packing the

poly(D2PyMA) column for HPLC. This work was supported in part by a Grant-in-Aid for Scientific Research No. 61470105 from the Ministry of Education, Science and Culture.

(Received August 10, 1987)

Synopsis. The selective liquid-phase oxidation of 3,4,5-trimethoxytoluene to 3,4,5-trimethoxybenzaldehyde, an important chemical intermediate for medicine production, was developed; when 2.0 mmol of the reactant was heated at 110 °C for 2 h in an autoclave under 3 atm O_2 with 10 ml of acetic acid in the presence of 0.75 mmol of $Co(OAc)_2$–$Mn(OAc)_2$ (3:1 mole ratio), a 92% yield of the aldehyde was obtained.

3,4,5-Trimethoxybenzaldehyde, an important chemical intermediate for medicine production, is produced by a stoichiometric synthesis from vanillin or an electrochemical oxidation of 3,4,5-trimethoxytoluene in the current manufacturing processes.[1] These procedures, however, still have several disadvantages which need to be improved. For example, a recent improvement in the electrochemical process has resulted in excessive electricity consumption. The liquid-phase oxidation of 3,4,5-trimethoxytoluene to 3,4,5-trimethoxybenzaldehyde is another attractive procedure from an industrial point of view. In a previous paper,[2] we demonstrated the potential effectiveness of the liquid-phase oxidation of substituted toluenes to the corresponding aldehydes; *p*-anisaldehyde could be obtained in a relatively high yield from *p*-methoxytoluene using multi-component metal salts. Through continuous efforts, we have developed a very selective method for the liquid-phase oxidation of 3,4,5-trimethoxytoluene to the aldehyde using a $Co(OAc)_2$–$Mn(OAc)_2$ mixture as the catalyst.

Experimental

Materials. The acetic acid, $Co(OAc)_2 \cdot 4H_2O$ (purchased from Wako), $Mn(OAc)_2 \cdot 4H_2O$ and all other reagents were used without further purification. 3,4,5-Trimethoxytoluene was obtained from Otsuka Chem. Co Ltd. 3,4,5-Trimethoxybenzyl alcohol and 3,4,5-trimethoxybenzyl acetate used as authentic standards for GC analysis were synthesized by an LAH reduction of 3,4,5-trimethoxybenzaldehyde and an esterification of 3,4,5-trimethoxybenzyl alcohol with acetic acid.

Procedure and Analysis. In a 50-ml autoclave, the substrate, catalysts, acetic acid, and the additives were mixed with a magnetic stirring bar. The autoclave was pressurized under 3.0 atm of O_2 and placed in an oil bath pre-warmed to the reaction temperature. After vigorous stirring for the prescribed time, the reaction was quenched by immersing the autoclave in an ice bath. After the reaction, naphthalene was added into the reaction mixture as an internal standard; the products were analyzed by GC on a Thermon 3000 on Chromosorb W.

Results and Discussion

Oxidation with $Co(OAc)_2$. The catalytic activities of various metal salts for the liquid-phase oxidation of 3,4,5-trimethoxytoluene were investigated. The results are summarized in Table 1. The reaction was carried out at 110 °C under 3 atm of O_2 in AcOH. With most of the metal salts, the reaction did not proceed. However, several cobalt salts, CoO, $Co(OAc)_2 \cdot 4H_2O$, and $Co_3(PO_4)_2 \cdot 8H_2O$, were found to be effective for the production of 3,4,5-trimethoxybenzaldehyde. The other products include 3,4,5-trimethoxybenzyl acetate and 3,4,5-trimethoxybenzyl alcohol. No detectable amount of 3,4,5-trimethoxybenzoic acid was yielded. The time course of the reaction of the oxidation of 3,4,5-trimethoxytoluene

catalyzed by $Co(OAc)_2 \cdot 4H_2O$ was examined under the same reaction conditions employed for the experiments outlined in Table 1. The conversion of 3,4,5-trimethoxytoluene initially increased with the reaction time and reached 100% at 1.5 h, when a 70% yield of 3,4,5-trimethoxybenzaldehyde was obtained. A further reaction did not increase the yield of 3,4,5-trimethoxybenzaldehyde (the yields were almost constant). The by-products, mainly 3,4,5-trimethoxybenzyl acetate, were formed during the initial 1.5 h; however, they were only detectable in trace amounts for longer reaction times. The total material balance decreased significantly, implying the formation of undetermined polymeric products. The effects of the reaction temperature and O_2 pressure were investigated in order to optimize the reaction conditions to obtain higher yields of the aldehyde; however, with $Co(OAc)_2 \cdot 4H_2O$, the maximum yield did not exceed 70%.

Synergism of $Co(OAc)_2$ and $Mn(OAc)_2$. The effects of several additives for the present reaction were examined (summarized in Table 2). The addition of metal bromides[3] critically lowered the catalytic activity; the yield of 3,4,5-trimethoxybenzaldehyde was very low. The addition of water[4] also retarded the catalytic activity. Ac_2O addition evidently enhances the activity; however, it causes an unpreferable further oxidation of the aldehyde.

The addition of several metal acetate salts were also attempted. Neither $Cr(OAc)_3$, $Ni(OAc)_2$ nor $Cu(OAc)_2$ resulted in a favorable improvement of the 3,4,5-trimethoxybenzaldehyde yield. However, upon the addition of $Ce(OAc)_3$ or $Mn(OAc)_2$ a considerable improvement was found. Especially, a $Co(OAc)_2$–$Mn(OAc)_2$ (3:1) mixture gave a very high yield of the aldehyde (91%). The synergistic effect of $Co(OAc)_2$ and $Mn(OAc)_2$ is evident from Fig. 1, in which the yield of 3,4,5-trimethoxybenzaldehyde is plotted against the ratio of $Mn(OAc)_2$ to $Mn(OA)_2$+$Co(OAc)_2$. $Mn(OAc)_2$, itself, shows only a low activity regarding oxidation. However, when it was combined with $Co(OAc)_2$, the mixture showed a higher activity for the production of 3,4,5-trimethoxybenzaldehyde than $Co(OAc)_2$ alone. The yield of the aldehyde strongly depends on the mixing ratio; the highest yield was obtained for a Co:Mn ratio of 3:1. The yield of the aldehyde also depended upon the total amount of the catalyst. In the range of the catalyst amount up to 0.75 mmol (with the fixed Co:Mn ratio, 3:1), the yield was almost proportional to the amount of catalyst, and reached the highest yield. The use of more catalyst, however, did not affect the yield very much.

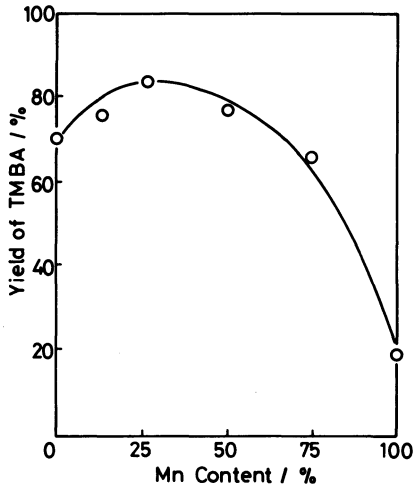

Fig. 1. The dependence of 3,4,5-trimethoxybenzaldehyde (TMBA) yield on Mn content in the oxidation of 3,4,5-trimethoxytoluene with $Co(OAc)_2$–$Mn(OAc)_2$ catalyst. O_2, 3 atm; 3,4,5-trimethoxytoluene, 2.0 mmol; solvent(AcOH), 10 ml; $Co(OAc)_2 \cdot 4H_2O$+$Mn(OAc)_2 \cdot 4H_2O$ 0.5 mmol; at 110 °C for 2 h.

Since a relatively high concentration of the catalyst was required to obtain a high yield of 3,4,5-trimethoxybenzaldehyde, recycling uses of the catalyst are desirable for industrial applications. Hence, the repeated oxidations of 3,4,5-trimethoxytoluene with the recovered catalyst from the resulting reaction mixture by extraction were attempted. Almost no decline in the catalytic activity and selectivity was observed, even after repeating 25 times. These results indicate the high utility of the present catalytic system for industrial use.

Infrared Spectra of Nitrogen Adsorbed on Ion-Exchanged ZSM-5 Zeolite

Tatsuya YAMAZAKI,* Isao WATANUKI, Sentaro OZAWA, and Yoshisada OGINO
Department of Chemical Engineering, Faculty of Engineering, Tohoku University, Aramaki-Aoba, Sendai 980
(Received August 11, 1987)

Amounts of nitrogen adsorbed by ion-exchanged ZSM-5 zeolites (H^+, Li^+, Na^+, K^+, Rb^+, and Cs^+) and silicalite have been measured under various conditions; pressure=6.7×10^2—6.7×10^4 Pa, temperature=196—273 K. IR spectra of adsorbed nitrogen have also been measured at 226 K under various nitrogen pressures (1.3×10^2—4.0×10^4 Pa). The adsorption capacity, the specific surface area, and the heat of adsorption have been evaluated from the adsorption data. These quantities coupled with the IR peak shifts observed have revealed that the nitrogen molecule adsorbed on a small and strong cationic site (Li^+, Na^+) has an orientation in which the longer molecular axis lies in parallel with the direction of the electric field of the cation site. It has also been revealed that the nitrogen molecule adsorbed on a large (K^+, Rb^+, Cs^+) or weak (H^+) cationic site takes on no special orientation. The electric field evaluated by analyzing the IR intensity is consistent with the adsorption model obtained.

ZSM-5 type zeolites have been studied extensively[1] as molecular shape selective catalysts and catalyst carriers. The adsorptive properties of the zeolites have also been studied by many researchers.[2-5] Nevertheless details of the molecular behavior of adsorbates in the zeolite pore still remain to be discovered. The present authors[6-8] have attempted to clarify the nature of the adsorption site over the ZSM-5 zeolite surface using an infrared spectroscopic technique developed by Cohen de Lara et al.[9-12] As reported in earlier papers,[6-8] this technique has yielded valuable information about the behavior of methane adsorbed on ZSM-5 zeolites. Nitrogen adsorption has been studied by the same technique in the present work, in order to accumulate further information about the adsorptive properties of the zeolites. Interesting results concerning interaction between the nitrogen molecule and the cationic adsorption site have been obtained. The purpose of this paper is to describe the experimental results and discuss the adsorption model.

Experimental

Materials. The zeolites used as adsorbents are listed in Table 1, which also summarizes adsorptive properties of these zeolites. The zeolites other than silicalite and NaZSM-5 were prepared by a conventional ion exchange method using 0.3—1.0 mol dm^{-3} solution containing a desired cation. A chemical analysis of the sample prepared proved that the ion exchange had been completed.

Commercial high purity nitrogen was used as an adsorbate gas after passage through a cold trap immersed in liquid nitrogen.

Methods. Details of the experimental methods have already been reported[6] and only important points are described below.

The amount of adsorption was measured using a conventional constant pressure type adsorption apparatus. The adsorbent was degassed at 573 K for 12 h at 1.3×10^{-3} Pa. The temperature range of the adsorption measurement was 196—273 K and the pressure range was 6.7×10^2—6.7×10^4 Pa. Part of the adsorption data was obtained at 77 K and used for the surface area (A_s) calculation; a finite layer BET theory (1.2—1.6 layers depending on the sample) was applied.

A cell reported in the previous paper[6] was used in the infrared (IR) spectroscopic study. A sample disk with a thickness of ca. 100 μm was degassed in the cell at 573 K for 12 h at 1.3×10^{-3} Pa. The IR spectra were recorded on a JEOL-JIR-100 FTIR spectrometer at a resolution of 2 cm^{-1} by averaging 200 scans. The temperature of the IR

measurement was 226 K and the pressure range was 1.3×10^{2}—4.0×10^{4} Pa.

Results and Discussion

Amount of Adsorption. Adsorption isotherms obtained are shown in Fig. 1 (a—g). The shapes of all the isotherms are analogous. It must be pointed out, however, that even silicalite, which contains few cationic adsorption sites, adsorbs a significant amount of nitrogen. This suggests that the pore wall itself provides nitrogen with adsorption sites and the ZSM-5 zeolite would have two kinds of adsorption sites, i.e. cationic sites and silicalite-like sites.

Although the full range of the adsorption isotherm could not be expressed by a Langmuir adsorption equation, part of the isotherm ranging from 1.3×10^{4} to 6.7×10^{4} Pa could be approximated by this adsorption equation and enabled us to estimate the maximum adsorption capacity V_m of the adsorbent. The V_m values thus obtained and the specific surface area A_s are shown in Fig. 2(a,b) as a function of the ionic radius (r_0)[13] of the cation incorporated into the zeolite. It is interesting that, both for RbZSM-5 and for CsZSM-5, the V_m value as well as the A_s value are remarkably small compared with the values for other zeolites.

The above mentioned relationships between V_m (or A_s) and r_0 have led the authors to draw the adsorption model illustrated in Fig. 3(a,b). The model assumes that pentagonal oxide ion rings[14] constitute the pore wall and the oxide ion has an ionic radius of 1.4 Å.[13] As shown in Fig. 3a, the void surrounded by five oxide ions can accept the whole body of a cation with a small radius; H^+, Li^+, and Na^+. On the other hand, as shown in Fig. 3b, the void can accept only part of the body of a large cation and a considerable part of the pore space over the pentagonal site is occupied by the cation itself; Rb^+ and Cs^+. The situation of K^+ is somewhat similar to that shown in Fig. 3b, though the extent of occupation of the pore space by the cation is small. It is thus obvious that an incorporation of such a small cation as H^+, Li^+, or Na^+ has little effect on the adsorption capacity as well as the specific surface area of the zeolite. The same situation is expected for K^+. On the other hand, the incorporation of Rb^+ or Cs^+ is expected to reduce V_m and A_s.

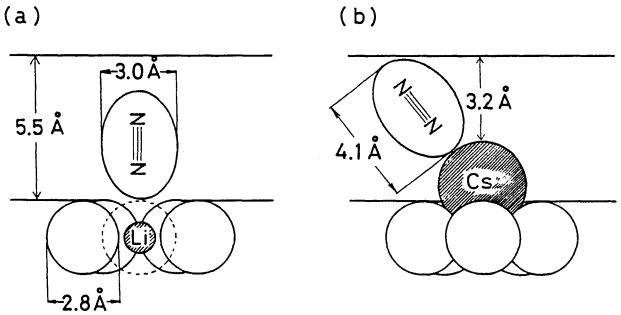

Fig. 3. Model for nitrogen adsorption on the cationic site. a: N_2 on Li^+ site, b: N_2 on Cs^+ site. (molecular size of nitrogen was taken from Ref. 15; pore size was taken from Ref. 14; O^{2-} size was taken from Ref. 13).

The model shown in Fig. 3 induces a discussion on the orientation of the nitrogen molecule adsorbed on the cationic site. As shown in Fig. 3a, the nitrogen molecule adsorbed on a small cationic site can take an orientation wherein the longer molecular axis is parallel with the direction of the electric field of the cation (perpendicular to the pore surface). On the other hand, as shown in Fig. 3b, the nitrogen molecule adsorbed on a large cation would find it difficult to assume such an orientation. Here, the discussion is rather speculative but its importance becomes clear in the later section of this discussion.

Heat of Adsorption. The adsorption isotherms shown in Fig. 1 enabled us to evaluated the isosteric heat of adsorption q_{st} using the Clausius-Clapeyron equation. An extrapolation of the q_{st} values obtained at different coverages to zero-coverage was carried out, in order to evaluate the heat of adsorption q°_{st} at zero coverage. The q°_{st} values thus obtained are also listed in Table 1. The decreasing order of the q°_{st} value is $Li^+ > Na^+ > K^+ > Rb^+ > Cs^+ > H^+ >$ silicalite. The larger q°_{st} value for ion-exchanged zeolites than that for silicalite strongly suggests that the adsorptive forces of all the cations are stronger than that of the pore wall (silicalite-like site). The adsorptive force of a cation consists of a dispersion force, an attractive force exerted upon the induced dipole on the adsorbed nitrogen, and an attractive force exerted upon the quadrupole of the adsorbed nitrogen molecule,[15] except for the repulsive force. The attractive forces mostly increase when the ionic radius of the cation becomes small. Thus the above sequence of q°_{st} values is reasonable, except for the small q°_{st} value for HZSM-5. Since the size of H^+ is very small (−0.04 Å),[16] oxide ions surrounding it would hinder the adsorbed nitrogen molecule from contacting with H^+. Namely, the steric hindrance of the oxide ions would separete the admolecule far from H^+, resulting in a weak adsorptive force and hence a small q°_{st}. A small ionic character[17] of H^+ might also be the cause of the small q°_{st} value of the HZSM-5 zeolite.

IR Spectra of Adsorbed Nitrogen. IR spectra of nitrogen-ion-exchanged zeolite adsorption systems are shown in Fig. 4(a—f). The observed spectra (dotted line) were found to be well simulated by a Lorentzian function as shown in the figure (solid line). According to the literature,[18] the IR band observed is assigned to the nitrogen stretching vibration $\nu_{N\text{-}N}$ which is usually IR inactive. An electric field of the cationic site probably has induced an IR active state of the adsorbed nitrogen.[18] This view has been supported by the fact that no absorption band has been observed for the silicalite-N_2 system. It is thus expected that the IR spectra shown in Fig. 4 would contain much informa-

tion about the interaction between the adsorbed nitrogen molecule and the cationic site. On account of the IR data, the adsorption characteristics suggested by the preceding discussion are expected to be further clarified.

IR Peak Position. IR peak positions for all the ZSM-5-N_2 adsorption systems are shown in Fig. 5 as a function of the amount of adsorption. The peak position varied little with the change in the amount of adsorption. The peak for the LiZSM-5-N_2 system was found at the highest wavenumber position and was followed by those for the other adsorption systems. The descending order of the peak position was $Li^+ > Na^+ > K^+ \simeq H^+ > Rb^+ \simeq Cs^+$. It must be pointed out, in addition, that the peak positions both for the LiZSM-5-N_2 system and for the NaZSM-5-N_2 system are located at considerably higher wavenumber than the gaseous nitrogen peak expressed by a dotted line (2330.7 cm^{-1}; Raman spectral value).[19]

The high frequency shifts observed (LiZSM-5-N_2, NaZSM-5-N_2) suggest that the adsorbed nitrogen molecule takes on an orientation as exemplified in Fig. 3a. According to the theoretical calculation of Cohen de Lara et al.,[10] a high frequency shift of the nitrogen IR band results from the orientation of the nitrogen molecule toward the direction of the electric field of the cationic site. The ionic radii of Li^+ and Na^+ are small and hence there are little geometrical restriction for the molecule to take such an orientation as mentioned above and illustrated in Fig. 3a. In addition, the strong attractive forces of these cations would be favorable to maintaining this orientation. On the other hand, a weak adsorptive force at the H^+ site probable can not maintain the orientation, though there is little geometrical restriction. The adsorptive force of the K^+ site is not so strong and, in addition, a small geometrical restriction due to the somewhat large ionic radius of this cation may exist. Thus the molecular orientation mentioned above would not persist on the K^+ site, though it might momentarily be induced. Both for the Rb^+-N_2 system and for the Cs^+-N_2 system, the adsorptive forces are weak and the Li^+-N_2 like orientation of adsorbed nitrogen is geometrically hindered as shown in Fig. 3b. Approximately speaking, therefore, nitrogen molecules on H^+, K^+, Rb^+, Cs^+ cationic sites would be in a random orientation state. This view is supported by the experimental observation that the IR peak positions for these systems are located close to that of the gaseous nitrogen (Fig. 5).

IR Peak Intensity. The integral molar extinction coefficient A needed to discribe the intensity of IR spectra of an adsorbed species is defined by[9]

$$A = (1/n \cdot l) \int \log (I_0/I)\, d\tilde{\nu}, \quad (1)$$

where I_0 is the intensity of incident light, I is the intensity of transmitted light, $\tilde{\nu}$ is the wavenumber, n is the number of moles of the vibrator in unit volume of the sample, and l is the thickness of the sample.

If we express the sample weight, the total amount of admolecules on the cationic sites of the sample, and the cross-sectional area of the sample by W (g), m_c (mol), and a (cm^2), respectively, Eq. 1 can be rewritten

as follows;

$$A=[1/(m_c/W)(W/a)]\int \log(I_0/I)\,d\tilde{\nu}, \quad (2)$$

or more concisely

$$AM_c=S, \quad (3)$$

where $M_c=m_c/W$, and $S=[1/(W/a)]\int \log(I_0/I)d\tilde{\nu}$. Since the right hand side of Eq. 3 can be evaluated from the experimental data, the molar extinction coefficient A is obtainable if we know the value of M_c. It must be pointed out here that the experimentally measured amount of adsorption M involves the amount of adsorption onto the pore wall (silicalite-like adsorption; M_s). Thus we can not use the adsorption isotherms shown in Fig. 1 to obtain the M_c value.

The evaluation of A can, however, be carried out in the following manner. Namely, if we assume that a Langmuir type adsorption equation is applicable to the nitrogen adsorption onto the cationic sites, the following relation should hold;

$$S=AM_c=AK_cb_cP/(1+K_cP), \quad (4)$$

where K_c, b_c, and P denote the adsorption equilibrium constant, the number of moles of the cation sites in unit weight of the zeolite sample, and the equilibrium nitrogen pressure, respectively. This equation (Eq. 4) enables us to evaluate A from the IR peak areas obtained under varying pressures.

According to Eq. 4, plots of P/S against P should be linear because

$$P/S=1/(AK_cb_c)+P/Ab_c. \quad (5)$$

Indeed, as we can see in Fig. 6, the straight line relationship between P/S and P has been found for all the adsorption systems. Since the value of b_c is known (Table 1), we can obtain A from the slope of the straight line. Values of A obtained in the present study are listed in Table 2. The decreasing order of the A value is $A_{Li^+}>A_{Na^+}>A_{K^+}>A_{Rb^+}>A_{Cs^+}>A_{H^+}$. This is parallel with the decreasing order of the heat of adsorption q°_{st} and very reasonable.

Electric Field of the Cationic Site. The electric field E of the cationic site in the ZSM-5 zeolite has already been determined[8] using methane as a probing molecule. Since the average size of the nitrogen molecule is almost the same as that of methane, the electric field determined by nitrogen should be identical with that obtained by methane. Thus we can examine the validity of the preceding discussion by comparing the E value obtained for nitrogen with that obtained for methane.

The relation between the electric field E and the IR extinction coefficient A varies, depending on the orientation of the probe molecule at the adsorption site. According to the preceding discussion, nitrogen molecules adsorbed on any of H^+, K^+, Rb^+, and Cs^+ site are considered to be almost randomly oriented. Thus the following relation[9] would be applicable;

$$A=(\pi/3c^2)E^2[(\partial\bar{\alpha}/\partial q)^2+(2/9)(\partial\gamma/\partial q)^2], \quad (6)$$

where c is the velocity of light, $\bar{\alpha}$ is the average polarizability defined from the polarizability ($\alpha_{||}$) along the direction of the electric field and that ($\alpha_\perp$) perpendicular to the direction of the electric field by $(1/3)(\alpha_{||}+2\alpha_\perp)$, γ is defined by $(\alpha_{||}-\alpha_\perp)$ to express an anisotropy in the polarizability, and q is the normal coordinate of vibration.

On the other hand, the following relation[9] would be applicable in evaluating the electric fields of the Li^+ site and the Na^+ site, because the nitrogen molecules on these sites are expected to take an orientation such

Zeolite	Peak position[a]	Extinction coefficient, A	Electric field of cation, E[b,c]
	cm^{-1}	m mol^{-1}	10^5 esu
HZSM-5	2330	351	1.19 (0.80)
LiZSM-5	2338	2457	2.00 (1.58)
NaZSM-5	2334	1602	1.62 (1.55)
KZSM-5	2330	897	1.91 (1.47)
RbZSM-5	2328	552	1.50 (1.36)
CsZSM-5	2328	297	1.10 (1.21)

a) Values at $M=10\times10^{-6}$ m^3-NTP/g are listed; M denotes the amount of adsorption. b) Values in parenthesis are the electric fields measured with methane. c) 1 esu=3×10^4 V m^{-1}.

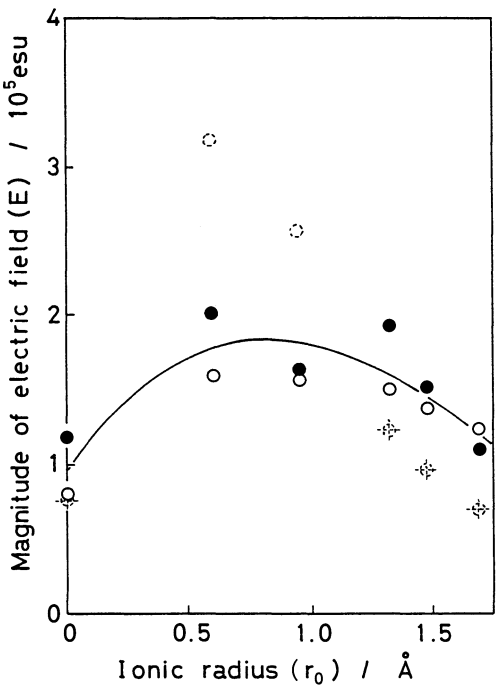

Fig. 7. Electric fields of cationic sites. ●: obtained from nitrogen IR data, O: obtained from methane IR data, ◌: values for random orientation (N_2–Li^+, and N_2–Na^+), ⊕: values with orientation (N_2–H^+, N_2–K^+, N_2–Rb^+, and N_2–Cs^+).

as is exemplified in Fig. 3a;

$$A=(\pi/3c^2)E^2[(\partial\bar{\alpha}/\partial q)+(2/3)(\partial\gamma/\partial q)]^2. \quad (7)$$

The results of the calculation are shown in Fig. 7. A close agreement between the E values obtained from the nitrogen IR data and those obtained from the methane IR data (Table 2) proves the validity of the adsorption model hitherto discussed. It must finally be noted that the following literature values[9] have been used in the above mentioned calculation of E;

$$|\partial\bar{\alpha}/\partial q| = 0.66\, N^{1/2}\, 10^{-16}\ \mathrm{cm^2\, g^{-1/2}},$$
$$|\partial\bar{\gamma}/\partial q| = 0.82\, N^{1/2}\, 10^{-16}\ \mathrm{cm^2\, g^{-1/2}},$$

where N is the Avogadro number.

Both derivatives have been assumed to be positive, in the present study. It is reported in the literature[9] that the positive value for $\partial\bar{\alpha}/\partial q$ appears pertinent. The use of negative value for $\partial\gamma/\partial q$ with positive value of $\partial\bar{\alpha}/\partial q$ in the calculation of Eq. 7 results in anomalously large values of E for every cation examined in the present study.

(Received August 21, 1987)

Micellar catalytic effects on the base dissociation of methylamine have been studied by ultrasonic absorption method. The dissociation constant, the rate constants, and the volume change of the reaction were obtained in the absence and in the presence of SDS. The micellar catalytic effects observed for methylamine was smaller than those for amines of long alkyl chain, which was ascribed to the facts that the former is incorporated into the micellar ionic atmosphere in the concentrated micellar solution while the latters are solubilized into micelles.

In a series of investigations by the ultrasonic absorption method, we have studied the micellar catalytic effects on the acid dissociation of aromatic carboxylic acids[1,2] and the base dissociation of amines.[3-6] In most of these micellar catalyzed reactions, the reactants have been solubilized in the micelles.[1-9] If the solubilization is a prerequisite for the micellar catalysis, one cannot expect micellar catalytic effects for carboxylic acids and alkylamines of short alkyl chain. The present work was intended to examine this problem. Static and kinetic studies were carried out for the base dissociation of methylamine, which has the shortest alkyl group of the alkylamines, in the presence of the SDS micelles. Comparing the results with those for the homologous alkylamines, the dependence of the micellar catalytic effects on the alkyl-chain length of the amines is discussed.

Experimental

Methylamine (MA), in the form of 30% aqueous solution, and propylamine were purchased from Tokyo Kasei and used without further purification. The concentration of MA was determined by pH titration. SDS purchased from Pierce was recrystallized twice in methanol. The critical micelle concentration (cmc) determined by conductivity measurements was found to be 8.0×10^{-3} M§ at 30 °C. All other chemicals were of reagent grade.

pH measurements were carried out with a pH meter (HM-20) using an electrode (GS-135C) of TOA Electronics Ltd. Ultrasonic absorption measurements were carried out by the pulse method in the frequency range of 7.5 to 95 MHz. Details of the apparatus have been described elsewhere.[10] All the absorption data fitted the single relaxation equation[11,12]

$$\frac{\alpha}{f^2} = \frac{A}{1+(f/f_r)^2} + B, \qquad (1)$$

where α is the absorption coefficient, f the frequency, f_r the relaxation frequency, and A and B are the relaxation and non-relaxation absorptions, respectively. The three parameters, f_r, A, and B, were determined by computer simulation. Experimental errors were within 8%, 5%, and 5% of the corresponding values, respectively. The velocity of sound was measured by the sing-around method at 1.92 MHz.[13] All the measurements were performed under nitrogen atmosphere and thermostated conditions. In the case of MA aqueous solution, the ionic strength, μ, was kept constant at 0.3 by the addition of NaCl.

§ 1 M=1 mol dm^{-3}.

Results and Discussion

Static and Kinetic Studies of the Base Dissociation of MA in Aqueous Solution. The base dissociation of MA in the absence of SDS was studied first in order to obtain referential data for the MA-SDS system.

For the reaction;

$$CH_3NH_3^+ + OH^- \underset{k_b}{\overset{k_f}{\longleftrightarrow}} CH_3NH_2 + H_2O\ , \qquad (2)$$

the base dissociation constant, K_b^0, is defined as,

$$K_b^0 = \frac{k_b}{k_f} = \frac{\gamma^2[CH_3NH_3^+][OH^-]}{[CH_3NH_2]} = \frac{\gamma^2\sigma^2C_0}{1-\sigma}\ , \qquad (3)$$

where γ is the mean activity coefficient, σ the degree of ionization, and C_0 the total concentration of MA. From the pH values in Table 1 and the activity coefficients calculated by the Davies equation,[14] pK_b^0 was obtained to be 3.44 (±0.02). This is in agreement with the literature value.[15]

Ultrasonic relaxation absorption was observed in the aqueous solution of MA in the MHz frequency range as shown in Fig. 1. The experimental condi-

Table 1. pH and Ultrasonic Absorption Parameters for the Methylamine Aqueous Solution at μ=0.3 and 30 °C

C_0 / M	pH	f_r / MHz	A (10^{-17})	B (10^{-17})

tions and the relaxation parameters obtained are listed in Table 1. As has been clarified by previous studies on a series of alkylamines,[16,17] the dependence of the relaxation parameters for the concentration and the pH indicates that the relaxation absorption is due to the base dissociation of MA. For Reaction 2, the relaxation parameters are related to the kinetic parameters by the following equations:[11,12]

$$(2\pi f_r)^2 = 4\gamma^2 k_f k_b C_0 + k_b^2, \quad (4)$$

$$(\alpha'\lambda)_{max} = \frac{\rho u^2 \pi}{2RT} \cdot (\Delta V)^2 \cdot \Gamma^{-1} \quad (5a)$$

with

$$\Gamma = [CH_3NH_3^+]^{-1} + [OH^-]^{-1} + [CH_3NH_2]^{-1}, \quad (5b)$$

where α' is the excess absorption coefficient, λ the wavelength, ρ the density, u the sound velocity, ΔV the volume change of the reaction, and the subscript max indicates maximum value. Plots of $(2\pi f_r)^2$ and $(\alpha'\lambda)_{max}$ against the concentration terms are shown in Figs. 2a and 2b, respectively. The kinetic parameters were obtained to be $\gamma^2 k_f$=2.7 (±0.4)×10^{10} M^{-1}s^{-1}, k_b=2.2 (±0.4)×10^7 s^{-1}, and ΔV=25.8 (±0.8) cm^3 mol^{-1}. The apparent base dissociation constant, K_b ($=k_b/\gamma^2 k_f$), was obtained from the pH data as pK_b=3.09 (±0.02).

Base Dissociation of MA in Micellar Solutions of SDS. The addition of SDS to a MA solution induces an increase of pH as shown in Fig. 3. As seen in this figure, pH changes very little in the region below the cmc, but increases rapidly above the cmc. This result implies that the base dissociation of MA is accerelated by its incorporation into the SDS micelles, and at rather high SDS concentration, the micellar effect, i.e., the incorporation saturates. Similar experiments were carried out also on propylamine. As shown in Fig. 3, the value of pH saturates at a somewhat lower concentration of SDS compared to that in the case of the MA-SDS system, and the change of pH induced by the addition of SDS is larger. These differences in the micellar effects on the two amines are discussed later.

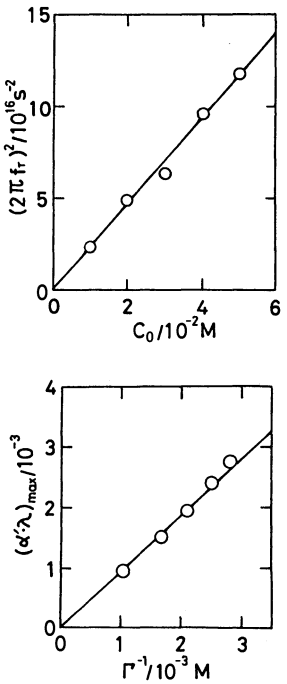

Fig. 2. Plots of (a) $(2\pi f_r)^2$ vs. MA concentration and (b) $(\alpha'\lambda)_{max}$ vs. Γ^{-1} for MA aqueous solution at μ= 0.3 and 30°C.

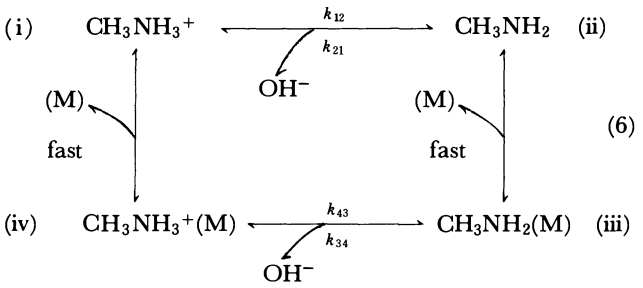
Table 2. pH and Ultrasonic Absorption Parameters for the Methylamine-SDS (0.30 M) System at 30 °C

[MA] / M	pH	f_r / MHz	A (10^{-17})	B (10^{-17})
0.01	11.41	9.9	159	26
0.02	11.60	12.9	237	27
0.03	11.70	16.3	254	27
0.04	11.78	18.4	240	26
0.05	11.83	20.3	272	27

Quantitative measurements of pH and ultrasonic absorption were performed on solutions of various concentrations of MA containing a constant concentration (0.30 M) of SDS. The experimental conditions and the obtained data are summarized in Table 2.

Taking into account small hydrophobicity of MA, it is probable that the base dissociation of MA occurs both in bulk and on the micellar surface, and the following coupled reaction mechanism is proposed:



where (M) indicates an adsorption site on the micelle and (i)—(iv) mean different states of MA. The apparent dissociation constant of MA in the 0.30 M SDS micellar solution, $\bar{K}_b$ (M), defined as,

$$\bar{K}_b(M) = \frac{\{[CH_3NH_3^+(M)] + [CH_3NH_3^+]\} \cdot [OH^-]}{\{[CH_3NH_2(M)] + [CH_3NH_2]\}}, \quad (7)$$

was obtained from the pH data as $p\bar{K}_b$ (M)=2.18 (±0.01).

Ultrasonic relaxation absorption of the MA-SDS system takes place in a lower frequency range and the relaxation amplitude is larger than those of the pure MA in aqueous solution (Fig. 1). Since the association and dissociation of MA to and from the micelles are very fast,[18] the relaxation time, τ, for the slowest process in Reaction 6 is given by the following equation:[19]

$$\tau^{-1} (= 2\pi f_r) =$$
$$\gamma^2 k_{12}\left\{2[CH_3NH_3^+] + \frac{[CH_3NH_2]}{[CH_3NH_2(M)]+[CH_3NH_2]} \cdot K_{12}\right\} +$$
$$\gamma^2 k_{43}\left\{2[CH_3NH_3^+(M)] + \frac{[CH_3NH_2(M)]}{[CH_3NH_2(M)]+[CH_3NH_2]} \cdot K_{43}\right\}, \quad (8)$$

with

$$K_{12} = \frac{k_{21}}{\gamma^2 k_{12}} = \frac{[CH_3NH_3^+] \cdot [OH^-]}{[CH_3NH_2]} = K_b(W), \quad (9)$$

$$K_{43} = \frac{k_{34}}{\gamma^2 k_{43}} = \frac{[CH_3NH_3^+(M)] \cdot [OH^-]}{[CH_3NH_2(M)]} = K_b(M), \quad (10)$$

where K_b (W) and K_b (M) are the apparent base dissociation constants of MA in the bulk and on the micelle, respectively. If the value of K_b (M) is given, we can calculate the concentrations of MA of the different states with use of Eqs. 7,9, and 10. Then the first term of the right hand side of Eq. 8 was calculated by introducing the kinetic value obtained above for the base dissociation of MA in aqueous solution, and τ^{-1} ($=2\pi f_r$) was plotted against the value in the parenthesis of the second term. When K_b (M) is properly assumed, this plot gives a straight line. Then the plot was examined by changing the K_b (M) values in the range of K_b (W) to $\bar{K}_b$ (M). A good linear relationship was obtained only for the K_b (M) values very close to $\bar{K}_b$ (M). The result indicates that Reaction 6 can be approximated by the equilibrium (iv)$\rightleftarrows$(iii), or in other words, all the MA is incorporated into the SDS micelles. The same result was suggested also from the pH saturation behavior at concentrated SDS solution as mentioned above. Consequently, the base dissociation of MA in the 0.30 M SDS solution can be approximated by the reaction,

$$CH_3NH_3^+(M) + OH^- \underset{k_b}{\overset{k_f}{\rightleftarrows}} CH_3NH_2(M) + H_2O. \quad (11)$$

Since this reaction is quite similar to Reaction 2, we can apply Eqs. 4 and 5 for the analysis of the relaxation parameters. Each plot of the relaxation parameters is shown in Figs. 4a and 4b. From these plots, the kinetic parameters for Reaction 11 were obtained to be: $\gamma^2 k_f$=3.5 (±0.6)×10^9 M^{-1}s^{-1}, k_b=2.3 (±0.4)×10^7 s^{-1}, and ΔV=22.4 (±0.7) cm^3 mol^{-1} at 30 °C.

Ultrasonic absorption was measured also in the MA-SDS system with changing pH. Experimental conditions and the results are listed in Table 3. For Reaction 11, f_r is related to the rate constants as follows:[11,12,19]

$$2\pi f_r = \gamma^2 k_f\{[CH_3NH_3^+(M)] + [OH^-]\} + k_b. \quad (12)$$

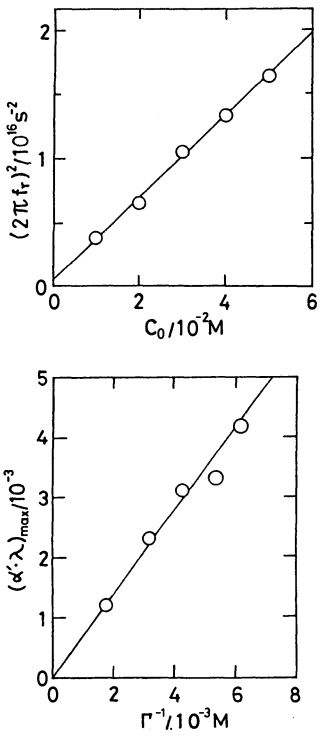


Fig. 4. Plots of (a) $(2\pi f_r)^2$ vs. MA concentration and (b) $(\alpha' \lambda)_{max}$ vs. Γ^{-1} for MA-SDS(0.30 M) system at 30 °C.

Table 3. Ultrasonic Absorption Parameters for the Methylamine (0.03 M)-SDS (0.30 M) System at Various pH and 30 °C

pH	f_r	A	B
	MHz	(10^{-17})	
10.80	18.0	36	30
11.14	16.8	88	28
11.43	13.4	152	30
11.73	16.5	195	28
12.18	26.2	98	26

The concentrations of the MA cation and OH^- were calculated from the pH, C_0, and K_b (M). Then, the value of $(2\pi f_r)$ was plotted against the concentration term of Eq. 12, and the rate constants were obtained to be; $\gamma\,{}^2k_f=3.6\,(\pm0.6)\times10^9\,M^{-1}s^{-1}$ and $k_b=2.4\,(\pm0.4)\times10^7\,s^{-1}$. For the relaxation absorption amplitude analysis, Eq. 5 can be applied. From the plot of $(\alpha'\lambda)_{max}$ vs. the concentration term, the value of ΔV was given to be 20.0 ($\pm$0.6) $cm^3\,mol^{-1}$. The fact that the absorption parameters can be satisfactorily analyzed by Eqs. 12 and 5 supports the assignment of the relaxation absorption to Reaction 11. Furthermore, the kinetic values were in reasonable agreement with the corresponding value obtained in the above experiments of MA concentration change.

Dependence of the Micellar Catalytic Effects on the Alkyl-Chain Length of the Amines. Magnitude of the micellar catalytic effects on the base dissociation of amines depends on their alkyl-chain length, e.g., as seen above, the pH change induced by the addition of SDS is larger for propylamine than for MA. Further examinations are performed in the following way.

Comparison of the values of pK_b^0 and pK_b (M) obtained above shows that the dissociation of MA is promoted by 1.26 pK_b unit in the micellar solution. Since the micellar effect has been about 1.5 pK_b unit for a series of amines of long alkyl chain in a 0.30 M detergent solution,[3-6] the micellar effect is smaller for MA.

Ultrasonic relaxation absorption spectrum reflects the difference of the alkyl-chain length of the amines in micellar solution. As shown in Fig. 5, f_r shifts to the lower frequency region and the absorption amplitude increases with increase of the alkyl-chain length of the amine. However, these dependences on the alkyl-chain length saturate rapidly and the absorption spectra for the systems of amines of C_{4-10}-SDS are almost indistinguishable from each other.[3-6]

For the base dissociation of alkylamines in a micellar solution, we have found that $\gamma\,{}^2k_f$ and k_b are both dependent on the base dissociation constant.[1-6] These situations are shown in Fig. 6 where the rate constants for MA obtained in this work are also plotted. Looking into this figure, we can discover the following features. (i) The rate constants for MA in an aqueous solution fall on the line expected from the corresponding literature values for the homologous amines.[16,17] (ii) The rate constants for MA in the micellar solution are much smaller than the corresponding values in aqueous solution at the same pK_b but larger than those for the amines of long alkyl chain in the micellar solution.[3,4] These results indicate that the base dissociation of MA is catalyzed by the SDS micelles but the catalytic effects are smaller than those for the amines of long alkyl chain.

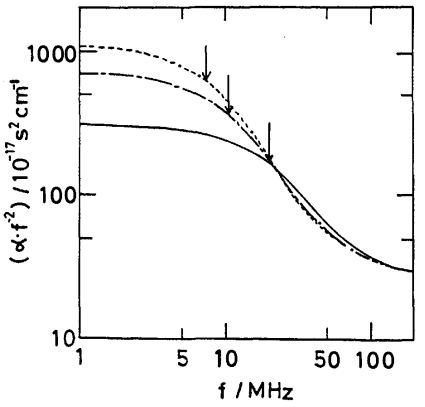

Fig. 5. Representative ultrasonic absorption spectra of the alkylamine(0.05 M)-SDS(0.30 M) solutions at 30°C: (——), MA; (-·-·-), propylamine; (----), amines of alkyl chain of C_{4-10}.

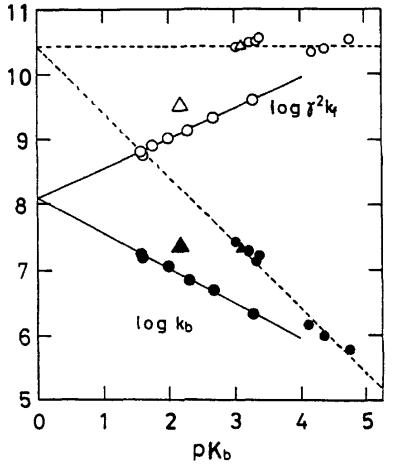

Fig. 6. pK_b dependencies of the rate constants for the base dissociation of the amines in the presence of 0.30 M SDS (large signs, data from Refs. 3—6) and in the absence of the micelles (small signs, data from Refs. 16 and 17): triangle indicates MA. The amines cited for the two conditions are not corresponding to each other.

Taking into consideration the fact that the pK_b values of alkylamines are almost the same in aqueous solution,[15] dependence of the micellar catalytic effects on the alkyl-chain length of amines should be ascribed to the position of the amino group in the micellar atmosphere. Judging from the behavior of saturation of the effects with the alkyl-chain length, the amino group of the amines of alkyl chains longer than C_4 is

in the Stern layer due to the solubilization of the alkyl chain into the micellar core. For the amines of alkyl chain shorter than C_4, the solubilization is inadequate, and the amino group may be outside of the Stern layer. Especially in the case of MA, ordinary solubilization is not conceivable. Then, the smaller micellar catalytic effects for MA are interpreted as follows.

The MA cation can be incorporated into the micellar atmosphere as a counter ion because of its small predominance in the hydrophobicity compared to Na^+.[20] On the other hand, undissociated MA may not be solubilized preferentially into the micelle. In a rather concentrated detergent solution, however, the micelle-micelle interaction becomes predominant because of the high cocentration of micellar aggregates,[21,22] and the free bulk will essentially disappear. Therefore, both dissociated and undissociated MA, which were in the bulk at lower detergent concentration are now incorporated into the micellar ionic atmosphere, i.e., Gouy-Chapman double layer. In fact, in recent investigations, we have found that noncharged amphiphilic molecules of short alkyl chain, e.g., methyl or ethyl group, can be incorporated into micelles at high detergent concentration.[23] As a consequence, we conclude that, in a concentrated SDS solution as in the present case, all the MA are incorporated into the micellar ionic atmosphere and the base dissociation is catalyzed moderately.

The authors wish to thank Professor Z. A. Schelly of University of Texas at Arlington and Mr. S. Nishioka of Hiroshima University for helps in this experiment.

Shape Selectivity of ZSM-5 Type Zeolite for Alkylation of Ethylbenzene with Ethanol

Jong-Ho KIM, Seitaro NAMBA,* and Tatsuaki YASHIMA
Department of Chemistry, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152
(Received August 22, 1987)

The alkylation of ethylbenzene with ethanol on ZSM-5 zeolites was studied at 673 K. The primary product in this alkylation on HZSM-5 catalyst was only *p*-diethylbenzene because of the transition-state selectivity. Therefore, the isomerization of *p*-diethylbenzene has to be restrained for the selective formation of *p*-diethylbenzene. The modified HZSM-5 catalysts with oxide of magnesium, phosphorus or boron showed much higher para-selectivity than the parent HZSM-5. The modification reduced not only the effective pore dimension of HZSM-5 but also the amount of strong acid sites. We claim that the absence of strong acid sites is necessary rather than the narrowness of pores for the suppression of the isomerization of *p*-diethylbenzene produced as a primary product.

The main channel of ZSM-5 type zeolite is cylindrical and its window is composed of a 10-membered oxygen ring, whose dimension is smaller than that of Y type zeolite.[1] In fact, *p*-xylene can be adsorbed selectively in the pores of HZSM-5 in the liquid phase competitive adsorption of the three xylene isomers at a low temperture as 273 K.[2] Therefore, it was expected that *p*-xylene could be selectively produced in the alkylation of toluene with methanol on HZSM-5 type zeolite catalysts. However, Yashima et al.[3] and Kaeding et al.[4] have reported that the equilibrium composition of xylene isomers is obtained in the alkylation of toluene with methanol on HZSM-5 at a high yield of xylene. When oxide of magnesium,[3,4] phosphorus,[4] or boron[4] is incorporated into HZSM-5 catalyst, a dramatic increase in para-selectivity is observed. That is, the fraction of the para-isomer in xylenes produced is above 90%. It has been also reported that in the ethylation of toluene[5] and ethylbenzene[6] on modified ZSM-5 zeolites a high para-selectivity is observed.

Many researchers suggest that the high para-selectivity for the alkylations mentioned above is caused by the shape selectivity of the modified ZSM-5 zeolites.[3-6] Kaeding et al. have proposed that the high para-selectivity of modified ZSM-5 zeolites is due to product selectivity (a kind of shape selectivity), namely the much higher intracrystalline diffusivity of the para-isomer in relation to the other two isomers.[4,6] Wei has presented a theoretical explanation for the experimental data, assuming product selectivity, and has concluded that the enhancement of para-selectivity happens under decreasing in conversion of alkylation and under increasing in catalytic activity for isomerization.[7]

On the other hand, Yashima et al. have reported the results of the alkylation of toluene with methanol on HY and HZSM-5 catalysts.[3] In the case of HY, *o*- and *p*-xylenes are primary products, while on HZSM-5, only *p*-xylene is a primary product. This is because of transition-state selectivity (a kind of shape selectivity) of HZSM-5. Accordingly, the alkylation to form any xylene other than the para-isomer is prevented as the transition state necessary for the alkylation to proceed is not reached due to steric and space restriction. When HZSM-5 is modified with oxide of magnesium, an enhancement in para-selectivity is observed. They suggested that the amount of strong acid sites must be reduced for the suppression of the isomerization of *p*-xylene produced preferentially in order to produce *p*-xylene selectively.

In this paper, we aim to clarify a role of oxide compounds, whose incorporation results in the improvement of para-selectivity of ZSM-5 zeolites. We choose the alkylation of ethylbenzene with ethanol as a para-selective reaction, because the larger alkyl groups in diethylbenzene are expected to provide clearer results compared with the case of the alkylation of toluene with methanol.

Experimental

Materials. ZSM-5 type zeolite was synthesized by a similar method to that described in Mobil's patent[8] using tetrapropylammonium bromide, sodium silicate, aluminium sulfate, sulfuric acid and sodium chloride. The synthesized zeolite was calcined at 773 K for 3 h in air. Its sodium cation was exchanged for a proton by using 1 mol dm^{-3} hydrochloric acid at 333 K. The HZSM-5 (Si/Al=96) modified with magnesium oxide, designated as Mg-HZSM-5, was prepared by impregnation of HZSM-5 with aqueous magnesium acetate solution followed by drying at 373 K and calcined at 823 K for 18 h in an air stream. P-HZSM-5, B-HZSM-5 were prepared by impregnation of HZSM-5 with aqueous phosphoric acid solution and aqueous boric acid solution, respectively, followed by a method similar to that for Mg-HZSM-5. The weighed catalyst was set in a quartz reactor and dehydrated at 823 K for 1 h in a helium stream before use.

Apparatus and Procedure. The reaction was carried out in a fixed bed type apparatus with a continuous flow system at atmospheric pressure. The reactant (ethylbenzene/ethanol=1/1 mol/mol) was fed with a microfeeder. Helium was used as a carrier gas. The conditions of the alkylation of ethylbenzene with ethanol on HZSM-5 were: activation

temperature=823 K; reaction temperature=673 K; (carrier gas)/(reactants)=(3 mol)/(2 mol); W/F=7.14 g h mol^{-1}. The effluent gas was cooled with an ice trap, and samples for analysis were collected periodically and were analyzed by gas chromatography.

The measurements of temperature programmed ammonia desorption (NH_3-TPD) from the catalysts were carried out as follows. After the catalyst was evacuated at 823 K for 1 h and exposed 80 Pa of ammonia gas at room temperature for 15 min, the catalyst was evacuated at room temperature for 15 min and then the temperature was brought to 773 K at a constant rate of 10 K min^{-1} under evacuation through the capillary. The relative amount of ammonia desorbed from the catalyst was determined by measuring the pressure in the system.

The competitive adsorption of three cresol isomers was carried out at 313 K using 1,3,5-triisopropylbenzene as solvent the molecular dimension of which was too large to enter the pores of the adsorbents. The competitive adsorption was initiated by adding 2 ml of 2 wt% adsorbate solution to 0.5 g of adsorbent. The amount of each isomer adsorbed was obtained from the change of concentration of each isomer in liquid phase. The concentration was determined by gas chromatographic analysis.

Results and Discussion

In the alkylation of ethylbenzene with ethanol on the HZSM-5 zeolite, *p*- and *m*-diethylbenzenes, benzene, ethylmethylbenzenes, and xylenes were observed as aromatic products and unreacted ethanol was not observed. Figure 1 shows the results of the alkylation. The activity and the selectivity for the catalyst did not change with process time. The conversion of ethylbenzene was 44% and the yield of diethylbenzene was 26%. The main product was diethylbenzene. The fraction of para-isomer in the diethylbenzenes produced was 39% and little *o*-diethylbenzene was produced. Therefore, it seems that HZSM-5 zeolites do not exhibit the para-selectivity.

In order to clarify the primary product in the alkylation of ethylbenzene with ethanol on HY or HZSM-5, the change in the distribution of diethylbenzene isomers with decreasing W/F was determined. The results on HY (Toyo Soda Ind. Co., Lot Y-30) at 548 K in the diethylbenzenes yield range of 41 to about 4% are shown in Fig. 2. The fraction of *m*-diethylbenzene decreased but those of *p*- and *o*-diethylbenzenes increased with decreasing W/F. In the case of HY catalyst, the primary product is not clear, but may be *p*- and *o*-diethylbenzenes. HY is not thought to exhibit the shape selectivity for this alkylation and the para/ortho orientation for this alkylation generally predominates.

The results on HZSM-5 at 673 K in the diethylben-

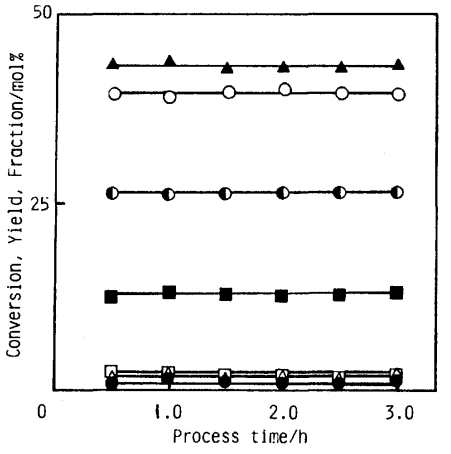

Fig. 1. Alkylation of ethylbenzene with ethanol on HZSM-5 at 673 K and W/F=7.14 g h mol^{-1}. Fig. 2. Change in fraction of each diethylbenzene isomer with W/F in alkylation of ethylbenzene with ethanol on HY at 548 K. Fractions of para-isomer (●), meta-isomer (▲) and ortho-isomer (■) in diethylbenzene produced.

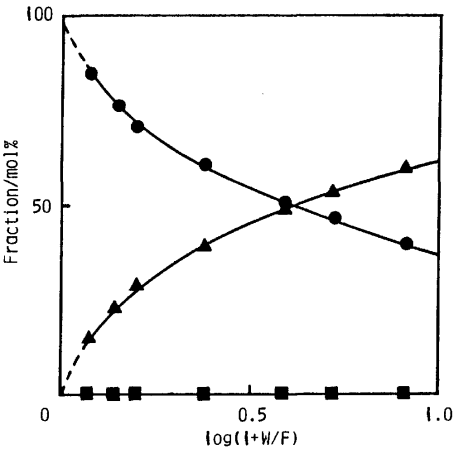

Fig. 3. Change in fraction of each diethylbenzene isomer with W/F in alkylation of ethylbenzene with ethanol on HZSM-5 at 673 K. Fraction of para-isomer (●), meta-isomer (▲), and ortho-isomer (■) in diethylbenzene produced.

zene yield range of 26 to about 3% are shown in Fig. 3. Although the molecular dimension of *o*-diethylbenzene was almost the same as that of *m*-diethylbenzene, little *o*-diethylbenzene was observed in these experiments. This indicates that HZSM-5 catalysts do not exhibit the product selectivity due to configurational diffusion effects. Instead they exhibit transition-state selectivity due to transition state restrictions. The formation of *o*-diethylbenzene through the alkylation of ethylbenzene with ethanol and through the isomerization of diethylbenzene produced is accordingly suppressed. The fraction of *p*-diethylbenzene increased to 100%, and the fraction of *m*-diethylbenzene decreased to 0% with decreasing W/F to 0. These results clearly indicate that the primary product of this alkylation on HZSM-5 catalyst is only *p*-diethylbenzene. The primary product on HZSM-5 is different from that of HY because of the transition-state selectivity of HZSM-5.

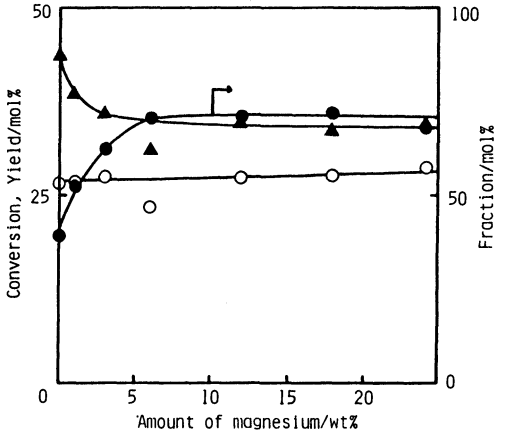

Fig. 4. Effect of amount of magnesium added to HZSM-5 on conversion of ethylbenzene (▲), yield of diethylbenzene (○), and fraction of para-isomer in diethylbenzene produced (●) at 673 K and W/F=7.14 g h mol^{-1}.

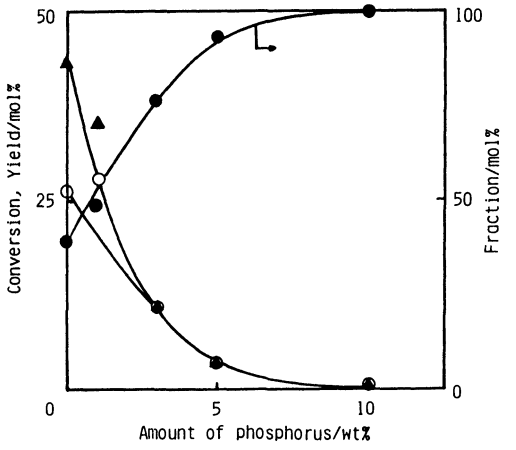

Fig. 5. Effect of amount of phosphorus added to HZSM-5 on conversion of ethylbenzene (▲), yield of diethylbenzene (○), and fraction of para-isomer in diethylbenzene produced (●) at 673 K and W/F=7.14 g h mol^{-1}.

Therefore, we believe that for the selective formation of *p*-diethylbenzene, the isomerization of *p*-diethylbenzene produced as a primary product must be suppressed.

The HZSM-5 loaded with oxide of magnesium, phosphorus or boron showed much higher selectivity for *p*-diethylbenzene formation than the parent HZSM-5 catalyst as observed in the alkylation of toluene with methanol.[3,4] Figures 4, 5, and 6 show the effect of the amount of magnesium, phosphorus or boron added to HZSM-5 zeolite on the fraction of *p*-diethylbenzene in diethylbenzenes produced, on the conversion of ethylbenzene and on the yield of diethylbenzenes. On the Mg-HZSM-5 (Fig. 4), the fraction of *p*-diethylbenzene increased and the conversion of ethylbenzene decreased with increasing amounts of magnesium added. It reached a maximum around 6 wt% of magnesium. In this case, the fraction of para-isomer in diethylbenzenes produced was 73%, and the conversion of ethylbenzene was 34%. The yield of diethylbenzene increased slightly with increasing amounts of magnesium (26—28%).

On the P-HZSM-5 (Fig. 5), the fraction of *p*-diethylbenzene increased to 100% with increasing amounts of phosphorus up to 10 wt%. However, the conversion of ethylbenzene and the yield of diethylbenzene decreased notably with increasing amounts of phosphorus, suggesting that the zeolite channels were rigorously blocked with phosphorus oxide and/or that the acid sites on the zeolite disappeared on the addition of phosphorus oxide.

On the B-HZSM-5 (Fig. 6), the fraction of *p*-diethylbenzene increased with increasing amounts of boron added, as well as magnesium and phosphorus. However, on B(10)HZSM-5 (Number in parentheses indicates the amount of boron added in wt%) the fraction of *p*-diethylbenzene was 100% at a conversion of ethylbenzene and a yield of diethylbenzene of 17, 14%,

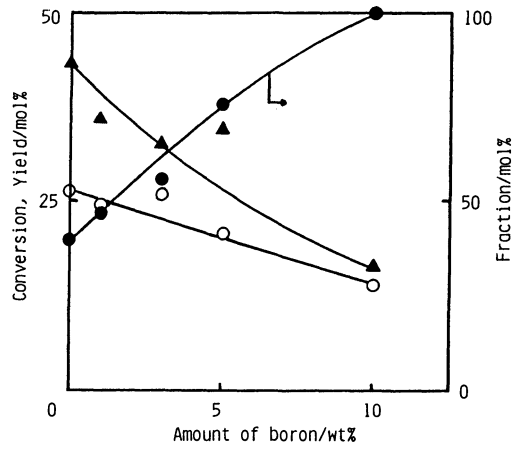

Fig. 6. Effect of amount of boron added to HZSM-5 on conversion of ethylbenzene (▲), yield of diethylbenzene (○), and fraction of para-isomer in diethylbenzene produced (●) at 673 K and W/F=7.14 g h mol^{-1}.

respectively. Although the B(10)HZSM-5 catalyst exhibited a relatively high activity, it showed an extremely high para-selectivity compared with P-HZSM-5 and Mg-HZSM-5 catalysts. The activity and the para-selectivity of Mg-HZSM-5 or P-HZSM-5 catalyst did not change with process time. However, in the case of B-HZSM-5, the conversion of ethylbenzene and the yield of diethylbenzene increased with process time, while the fraction of para-isomer in the diethylbenzene produced slightly decreased. This suggests that boron emerged from the catalyst system during the process time. The modified HZSM-5 type catalysts showed much higher selectivity for *p*-diethylbenzene formation than the parent HZSM-5.

As suggested before, modified HZSM-5 zeolites with the higher para-selectivity must exhibit the lower catalytic activity for the isomerization of *p*-diethylbenzene. In order to clarify the isomerization activity of the modified HZSM-5 catalysts, the reaction of *p*-diethylbenzene on HZSM-5, Mg(18)HZSM-5, P(5)HZSM-5, and B(10)HZSM-5 was carried out at 673 K. The results are shown in Table 1. In the reaction of *p*-diethylbenzene, the isomerization of *p*-diethylbenzene occurred simultaneously with the dealkylation, which was the reverse reaction of the alkylation. In the isomerization of *p*-diethylbenzene, *m*-diethylbenzene was produced, but *o*-diethylbenzene was not. This indicates the transition-state selectivity of HZSM-5. The order of the activities of the various catalysts examined here for the dealkylation of *p*-diethylbenzene agrees with that for the alkylation of ethylbenzene with ethanol. Namely, the order is HZSM-5 > Mg(18)-HZSM-5 > P(5)HZSM-5 > B(10)HZSM-5.

The order of the activities for isomerization of *p*-diethylbenzene is HZSM-5 > Mg(18)HZSM-5 > P(5)-HZSM-5 > B(10)HZSM-5. This order is exactly in reverse order of para-selectivities. From these results, it is concluded that the isomerization of *p*-diethylbenzene, which is the primary product in the alkylation of ethylbenzene with ethanol on the HZSM-5 catalyst, has to be suppressed for the selective formation of *p*-diethylbenzene.

In order to clarify that the modified catalyst, which shows the higher para-selectivity, exhibits the lower activity for *p*-diethylbenzene isomerization than the parent HZSM-5, the competitive adsorption of three cresol isomers and NH_3-TPD were examined. The results of the competitive adsorption and of NH_3-TPD give us the informations on the effective pore dimension of ZSM-5 zeolites[2] and on the acidic properties of the catalysts, respectively. The results of competitive adsorption of three cresol isomers are summarized in Table 2. The adsorption equilibrium was attained within 24 h. Therefore, the total amount of cresol isomers adsorbed and the para-selectivity were determined from the results at 24 h of adsorption time. The total amount of cresol isomers adsorbed decreased by the modification, suggesting that the oxide of magnesium, phosphorus or boron added reduces the effective pore dimension of HZSM-5 and/or blocks the zeolite channels. On the other hand, the para-selectivity for the competitive adsorption (see fraction of *p*-isomer in Table 2.) increased by the modification. This indicates that the effective pore dimension is reduced by the modification. The order of para-selectivities for the competitive adsorption of three cresol isomers are B(10)HZSM-5 > Mg(18)HZSM-5 > P(5)HZSM-5 > HZSM-5. This order is thought to correspond to that of the effective pore dimensions.[2] However it disagrees with that of para-selectivity for the alkylation of ethylbenzene with ethanol, that is, B(10)HZSM-5 > P(5)HZSM-5 > Mg(18)HZSM-5 > HZSM-5. This disagreement may suggest that the narrowness of the effective pore dimension is not so important to improve the para-selectivity in this alkylation on ZSM-5 zeolites.

Figure 7 shows the profiles of NH_3-TPD for HZSM-5 and modified HZSM-5 catalyts. The desorbed gas was only ammonia through the run. The HZSM-5 catalyst exhibited two peaks. One at 373 K corresponds to weak acid sites and the other at 603 K corresponds to strong acid sites. The amount of strong acid sites was remarkably reduced by the modification of HZSM-5 with oxide of magnesium, phosphorus or boron. The Mg(18)HZSM-5 catalyst still has a small amount of strong acid sites, while the P(5)HZSM-5 and B(10)HZSM-5 catalysts have few strong acid sites. The order of the amounts of the strong acid sites are HZSM-5 > Mg(18)HZSM-5 > P(5)HZSM-5 > B(10)HZSM-5. This order exactly coincides not only with the order of para-selectivities but also with that of activities for *p*-diethylbenzene isomerization shown in Table 1. These

facts suggest that the isomerization of *p*-diethylbenzene is more accelerated by the strong acid sites than the alkylation. Moreover, the intrinsic alkylation activities of the catalyst examined here except P-HZSM-5 are high enough, because ethanol is completely converted under our reaction conditions. Therefore, it is concluded that the strong acid sites on the catalyst have to be reduced for the selective formation of *p*-diethylbenzene by the alkylation of ethylbenzene with ethanol.

There is a large difference in yield of ethylbenzene in the alkylation of ethylbenzene with ethanol between P(5)HZSM-5 and B(10)HZSM-5. The difference in the acid properties between P(5)HZSM-5 and B(10)HZSM-5 is in the amount and strength of the weak acid sites. The B(10)HZSM-5 catalyst has more weak acid sites and exhibits a wider distribution in the weak acid site region (up to about 523 K in NH_3-TPD profile) compared with the P(5)HZSM-5 catalyst. Therefore, it is suggested that the activity for the alkylation of ethylbenzene with ethanol is related not only to the strong acid sites but also to the weak acid sites. However, the activity for the isomerization of diethylbenzene is related solely to the strong acid sites.

From these results, we conclude as follows. The isomerization of *p*-diethylbenzene, which is the primary poduct in the alkylation of ethylbenzene with ethanol on the HZSM-5 catalyst, has to be suppressed for the selective formation of *p*-diethylbenzene. The suppression of the isomerization of *p*-diethylbenzene is achieved by reducing the amount of strong acid sites rather than by reducing the effective pore dimension of the HZSM-5 zeolites.

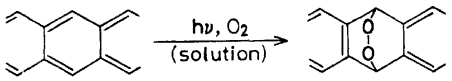
Photooxidation of the Evaporated Films of Polycyclic Aromatic Hydrocarbons Studied by X-Ray Photoelectron Spectroscopy

Masamichi YAMADA,† Isao IKEMOTO,†† and Haruo KURODA*
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received August 29, 1987)

Photooxidations of the evaporated films of rubrene, naphthacene, and pentacene were investigated by means of X-ray photoelectron spectroscopy. A rubrene film was found to be photooxidized far more easily than a naphthacene film although the molecules of rubrene and naphthacene in solution are known to be almost equally reactive for photooxidation. Although pentacene is photooxidized very easily in solution, the oxidation rate of a pentacene film was little enhanced by the light irradiation. Discussion is given on these behaviors of the evaporated films by considering the molecular packing in the solid state and the mechanism of photooxidation.

Photoconductivities of polycyclic aromatic hydrocarbons are known to be influenced more or less by the presence of oxygen in the ambient atmosphere.[1] Frankevich and his collaborators investigated the magnetic field effect on the photoconductive behaviors of evaporated films of rubrene (5,6,11,12-tetraphenylnaphthacene)[2] and naphthacene[3] in the oxygen atmosphere.

On the other hand, the photochemical reactions of polycyclic aromatic hydrocarbons with oxygen in solution have been extensively studied.[4,5] Polyacenes such as naphthacene and pentacene are rapidly converted to their transannular peroxides when their aerated solutions are irradiated with light.[4-6] Therefore one could expect that photooxidation will take place more or less when the photoconduction experiments are done on the solids of these hydrocarbons in the atmosphere containing oxygen.



However, little is known so far about the solid-state photooxidation of above-mentioned hydrocarbons except for rubrene.[7] This lack of information is largely due to the situation that, even if the photooxidation occurs in the solid state, it proceeds very slowly from the surface to the bulk in most organic solids, hence it is hard to follow the progress of oxidation by means of conventional experimental methods.

A variety of surface-sensitive techniques such as electron spectroscopies have developed since 1970's. However, they have scarcely been utilized in the studies of the reactions at the surfaces of organic molecular solids. Harada, Ohno and their collaborators examined the photooxidation of evaporated films of rubrene and naphthacene by ultraviolet photoelectron spectroscopy (UPS) and by Penning ionization electron spectroscopy (PIES).[8,9] They observed spectral changes due to photooxidation, and reported that a rubrene film is more easily photooxidized than a naphthacene film.

X-Ray photoelectron spectroscopy (XPS) is one of the most suitable techniques in such studies, because it can reveal non-destructively the elemental composition near the surface of molecular solids. We have previously studied the oxidation which proceeds in the dark, on the surfaces of the evaporated films of polycyclic aromatic hydrocarbons, by means of XPS.[10] In the present paper, we will report the results obtained on the photooxidation of the evaporated films of rubrene (**1**), naphthacene (**2**), and pentacene (**3**).

Experimental

Rubrene and naphthacene were commercially obtained and purified by sublimation in vacuo. Pentacene which had already been purified, was kindly supplied by Professor H. Inokuchi, Institute for Molecular Science.

X-Ray photoelectron spectra were measured with a McPherson ESCA 36 photoelectron spectrometer by using Mg $K\alpha$ (1253.6 eV) as the stimulating radiation. The sample chamber of the spectrometer was a little modified for the purpose of the present study. The layout of the modified sample chamber is illustrated in Fig. 1(a).

On each hydrocarbon, we carried out experiments with the following sequence. With the setup shown in Fig. 1(a), the

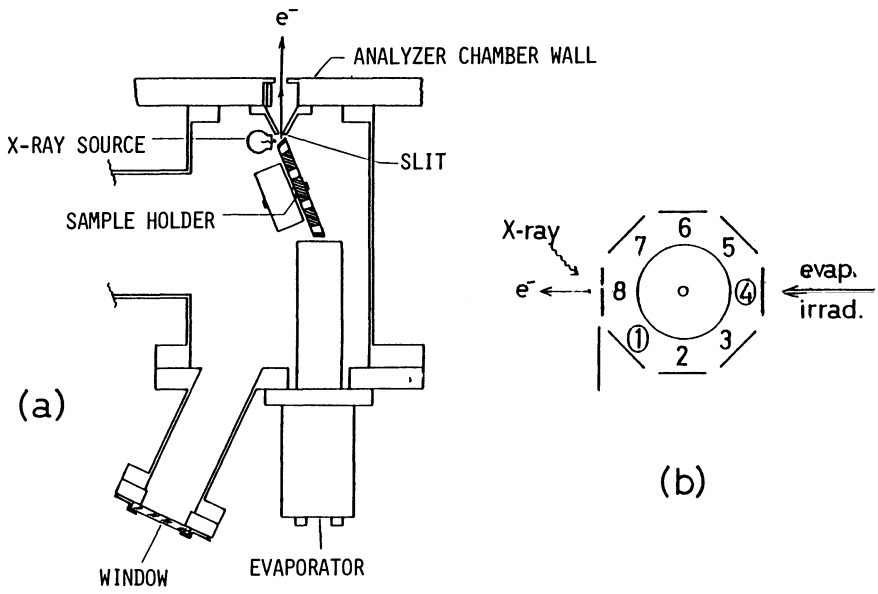

Fig. 1. (a) Layout of the sample chamber arranged for a photooxidation experiment, and (b) the side view of the 8-position sample holder. Sample films are prepared at the positions No. 1 and No. 4.

sample was deposited by sublimation in vacuo onto the substrates (aluminum or quartz plates) at the two different positions (No. 1 and No. 4 in Fig. 1(b)) of the 8-position rotatable sample holder, successively, and the first XPS measurement was done immediately. Then, the sample evaporator was quickly replaced with a Pyrex glass window while purging the sample chamber continuously with nitrogen. Since the oxidation of the sample film proceeds very slowly in the dark,[10] the above-mentioned procedure is allowable for the purpose of the present study even though we cannot completely avoid the contact of the sample film with oxygen. After the replacement of the evaporator with the window, the sample chamber was evacuated and the second XPS measurement was carried out. Next, we introduced oxygen to a desired pressure into the sample chamber, and one of the two sample films was irradiated with the light from a 500 W incandescent lamp through the window. During this procedure, the other sample film was sheltered from the light behind the sample holder. After the sample films were kept under the above-mentioned conditios for an appropriate period, the sample chamber was evacuated to carry out XPS measurement. Thereafter a similar procedure was repeated with different oxygen pressure and with different light irradiation time. The light irradiation was given to the two sample films alternately.

For each film, the binding energies, E_B's, were referenced to the Cls line (284.3 eV).[11]

Results

In the XPS spectra which were measured immediately after the preparation of the sample films under a high vacuum, all three hydrocarbons exhibited only a strong and sharp Cls peak, with the FWHM (full width at half maximum) of 1.5—1.7 eV.

Figure 2 illustrates the growth of the Ols peak in the spectrum of rubrene films at successive experimental stages. After the replacement of the evaporator with the window, both of rubrene films gave a weak Ols peak (see Fig. 2(b)). Figure 2(c) shows the Ols peaks measured after the films were kept in the oxygen of 1.5 kPa for 17 min, during which one film (at position

(b) After replacement of the evaporator with the window. (c) After exposure to 1.5 kPa oxygen for 17 min, No. 4 irradiated for 10 min. (d) After exposure to 1.6 kPa oxygen for 19 min, No. 1 irradiated for 11 min. (e) After exposure to 5.7 kPa oxygen for 69 min, No. 4 irradiated for 60 min.

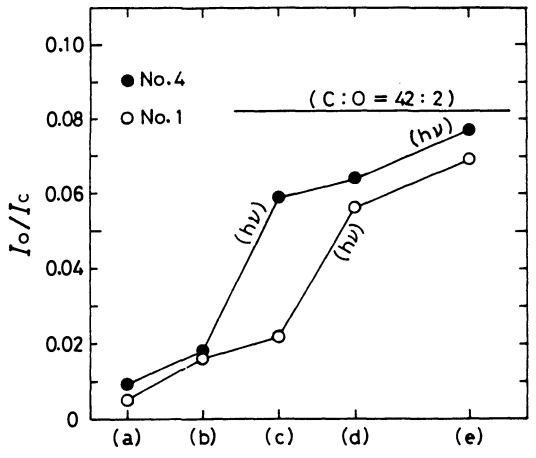

Fig. 3. Variation of the intensity ratios, Io/Ic, for two evaporated films of rubrene. "$(h\nu)$" indicates the irradiated film at each stage. The line designated by "C:O=42:2" indicates the ratio expected for the transannular peroxide of rubrene. Note that the ordinate is expanded twice as compared to those in Figs. 4 and 5. (a)—(e) on the abscissa correspond to (a)—(e) in Fig. 2.

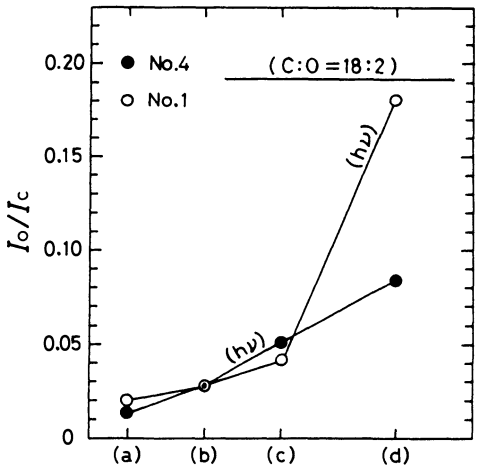

Fig. 4. Variation of the intensity ratios, Io/Ic, for two evaporated films of naphthacene. (a) Freshly evaporated films. (b) After replacement of the evaporator with the window. (c) After exposure to 5.1 kPa oxygen for 67 min, No. 4 irradiated for 61 min. (d) After exposure to 12.9 kPa oxygen for 620 min, No. 1 irradiated for 605 min.

No. 4 of the sample holder) was irradiated with light for 10 min. Note that a pronounced intensity increase occurred in the case of the irradiated film, while the Ols peak of the nonirradiated film increased little. In the next stage, the films were kept in the oxygen of 1.6 kPa for 19 min, and the film (at position No. 1) which had not been irradiated in the previous oxygen exposure, was irradiated with light for 11 min. Then the Ols peak of the irradiated film appreciably increased its intensity, and the intensity of Ols peak became almost equal between the two sample films as shown in Fig. 2(d). These results clearly demonstrate that the oxidation of a rubrene film is markedly enhanced by the light irradiation. Figure 2(e) shows the spectra measured after an exposure to the oxygen of 5.7 kPa for 69 min, during which one film (at position No. 4) was irradiated with light for 60 min. As compared with Fig. 2(d), the change of Ols spectrum is very little both with and without the light irradiation. Seemingly the intensity of Ols peak had nearly saturated already in the preceding stage.

The ratio of the integrated intensity of the Ols peak to that of the Cls peak, Io/Ic, was determined from the spectrum measured at each experimental stage. The results are plotted in Fig. 3, where the horizontal line designated by "C:O=42:2" represents the value expected for the transannular peroxide of rubrene under the assumption that the relative sensitivity of detection for carbon and oxygen is 0.58 : 1.00.[12] Note that the ratio obtained in the final stage is close to the value mentioned above.

The corresponding data for naphthacene and pentacene films are shown in Figs. 4 and 5, respectively.

In the case of a naphthacene film, the Io/Ic ratio was far below the value for the transannular peroxide even after the 61 min light irradiation in the oxygen of 5.1 kPa. It approached to the latter ratio when a film was irradiated for about 10 hours in the oxygen of 12.9 kPa. Thus markedly severer conditions seem to be necessary to photooxidize a naphthacene film as compared with a rubrene film.

The behavior of a pentacene film is very different from those of naphthacene and rubrene films. As can be seen from Fig. 5, the oxidation of a pentacene film is enhanced only little by the light irradiation, and the Io/Ic ratio was still about half of the value expected for the transannular peroxide even if the film had been irradiated with light for 9 hours in the oxygen of 14.4 kPa. It is hard to make a quantitative comparison of

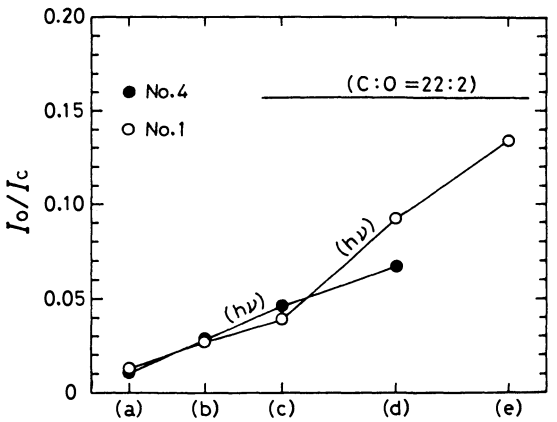

Fig. 5. Variation of the intensity ratios, Io/Ic, for two evaporated films of pentacene. (a) Freshly evaporated films. (b) After replacement of the evaporator with the window. (c) After exposure to 4.4 kPa oxygen for 146 min, No. 4 irradiated for 135 min. (d) After exposure to 14.4 kPa oxygen for 555 min, No. 1 irradiated for 540 min. (e) After kept in the air (dark) for 12 days.

photooxidation activities of three hydrocarbons from the results of the present study. But we may safely conclude that a pentacene film is far less reactive for photooxidation than rubrene and naphthacene films.

For the three hydrocarbons studied here, the binding energies of their Cls peaks are expected to be almost the same.[11] Furthermore, they will change little under our experimental conditions since, as seen in Figs. 3—5, less than two atoms among 18—42 carbon atoms in a molecule may be directly bound to oxygen atom in their oxidation products. Therefore, we utilized the Cls peak (284.3 eV) as the reference for the binding energy scale.

The observed binding energies, E_B's, and FWHM's of Ols peaks from oxidized hydrocarbon films are summarized in Table 1 together with the corresponding values of polycyclic carbonyl compounds. Note that the Ols binding energy is 532.5—532.7 eV in the case of the photooxidation products while it is 530.6—530.9 eV in the case of carbonyl compounds. This fact shows that carbonyl compounds are not the predominant products of photooxidation. In effect, the photooxidation product of rubrene in the solid state is considered to be the transannular peroxide[2,7-9] as is the case with photooxidation in solution.

The main photooxidation product is likely to be the transannular peroxide also in the case of a naphthacene film since the observed Ols binding energy is equal to the one observed of a rubrene film. But it is conceivable that some other oxidized species coexist in the case of a naphthacene film because the observed Ols peak is appreciably broader than that of a rubrene film. Probably, a part of the transannular peroxide is further transformed to more stable species. The Ols peak from an oxidized pentacene film is similar in position and width to that from a photooxidized naphthacene film. Some oxygen-containing species (including the transannular peroxide) may coexist on the surface of a pentacene film.

Table 1. Binding Energies and FWHM's of the Ols Peaks from Photooxidized Hydrocarbons and Polycyclic Carbonyl Compounds[a]

Compound	E_B/eV	FWHM/eV
Rubrene	532.7	2.3
Naphthacene	532.6	2.7
Pentacene	532.5	2.7
Anthraquinone	530.9[b]	1.7
Anthrone	530.9[b]	1.8
Mesonaphthodianthrone[c]	530.6[b]	1.7

a) Mg$K\alpha$ spectra of carbonyl compounds were obtained from the films freshly deposited in the sample chamber. b) The binding energy was referenced to the main Cls line, whose binding energy was assumed to be 284.3 eV. c) Phenanthro[1,10,9,8-*opqra*]-perylene-7,14-dione.

Discussion

As we have already mentioned, the three hydrocarbons studied here form the transannular peroxides by the photooxidation in solution. The following scheme has been proposed for the self-sensitized photoperoxidation of aromatic hydrocarbons.[13,14]

$$M(S_0) + h\nu \rightarrow M^*(S_1) \quad (1)$$
$$M^*(S_1) \rightarrow M^*(T_1) \quad (2)$$
$$M^*(S_1) + O_2(^3\Sigma) \rightarrow M^*(T_1) + O_2(^3\Sigma) \quad (3)$$
$$M^*(T_1) + O_2(^3\Sigma) \rightarrow M(S_0) + O_2^*(^1\Delta) \quad (4)$$
$$M(S_0) + O_2^*(^1\Delta) \rightarrow MO_2[\text{peroxide}] \quad (5)$$

where $M(S_0)$, $M^*(S_1)$, and $M^*(T_1)$ are the hydrocarbon molecules in the ground, singlet excited and triplet excited state, respectively, and $O_2(^3\Sigma)$ and $O_2^*(^1\Delta)$ are the oxygen molecules in the ground and singlet excited state (0.98 eV above the ground state),[15] respectively. Recently, it was established that $O_2^*(^1\Delta)$ can be generated also by the following process.[16]

$$M^*(S_1) + O_2(^3\Sigma) \rightarrow M^*(T_1) + O_2^*(^1\Delta) \quad (6)$$

In an aerated solution, $M^*(S_1)$ is quenched by oxygen via the process (3) or (6) with a diffusion controlled rate,[13] the rate constant being of the order of 10^{10} dm^3 mol^{-1} s^{-1}. The process (4) which produces the singlet oxygen $O_2^*(^1\Delta)$ by the energy transfer from $M^*(T_1)$, is also known to proceed rapidly with a rate constant of about one-ninth of the diffusion controlled value provided that the triplet state of the hydrocarbon, $M^*(T_1)$, has an energy in the range of 1.2—1.9 eV (e.g., naphthacene and anthracene).[13,17] Thus once $M^*(T_1)$ is formed, $O_2^*(^1\Delta)$ is produced with a yield of about unity via the process (4) in an air-saturated solution. On the other hand, the rate constant of the process (5) which gives the transannular peroxide by the reaction between $M(S_0)$ and $O_2^*(^1\Delta)$ is significantly lower than the diffusion controlled value except for extremely reactive hydrocarbons such as pentacene: It has been reported to be 4.2×10^7, 1.2×10^7, and 4.2×10^9 dm^3 mol^{-1} s^{-1} for rubrene, naphthacene and pentacene, respectively.[18] Therefore, the overall photooxidation rate will be primarily determined by the rate constant of the process (5), and consequently, pentacene will be the most reactive, and the reaction rate will be comparable between naphthacene and rubrene.

However, the results described in the preceding section, show that the situation is quite different in the solid state: the photooxidation takes place most easily in a rubrene film, and least in a pentacene film.

If we take an analogy to the above-mentioned scheme of the photooxidation in solution, we can consider that the solid-state photooxidation proceeds by the interaction of a hydrocarbon molecule with a singlet oxygen, $O_2^*(^1\Delta)$, which is formed by the energy transfer to an oxygen molecule either from a triplet exciton or from a singlet exciton of the hydrocarbon solid.

It is known that triplet excitons are produced with high efficiency in a naphthacene crystal via the fission

of a singlet exciton into two triplet excitons.[19] The same process takes place also in a rubrene crystal.[20] In the case of a naphthacene crystal, the interaction of a triplet exciton with oxygen[21] will occur only on the crystal surface, because naphthacene molecules are closely packed in the crystal,[22] so that it is difficult for oxygen molecules to diffuse into the bulk. It is well known that a transannular peroxide has a folded configuration whereas its parent hydrocarbon is planar. Close packing of molecules will hinder such large change of molecular shape, and consequently, retard the photooxidation. Therefore the oxidation will proceed only very slowly from the surface to the bulk. On the other hand, rubrene molecules are loosely packed in the crystal because of the four bulky, noncoplanar, substituents.[23] Thus oxygen molecules can easily diffuse into the bulk, and the formation of $O_2^*(^1\Delta)$[21] as well as that of the peroxide can occur not only on the crystal surface but also in the bulk. Furthermore, the distortion of the crystal lattice accompanying the formation of the transannular peroxide will easily take place in the bulk. Seemingly, these differences arising from the molecular packing in the crystal, are the origin of the significant difference in photooxidation reactivity between a naphthacene film and a rubrene film.

The fission of a singlet exciton to two triplet excitons can also take place in a pentacene crystal.[24] But, the energy of the triplet exciton[24] is lower than 0.98 eV and insufficient to produce a singlet oxygen by the energy transfer. Under this situation, a singlet oxygen $O_2^*(^1\Delta)$ is probably formed via the energy transfer from a singlet exciton to oxygen. This will primarily occur on the crystal surface since pentacene molecules are closely packed in the crystal to prevent the diffusion of oxygen into the bulk.[25] However, there will not be much probability that a singlet exciton reaches the crystal surface since the fission of the singlet exciton efficiently takes place in the bulk. Seemingly this explains why the oxidation of a pentacene film is little enhanced by the light irradiation though, in solution,[26] pentacene is photooxidized rapidly.

The authors wish to express their thanks to Professor Yoshiya Harada, the University of Tokyo, for helpful discussions, and to Professor Hirochika Sakuragi, the University of Tsukuba, for helpful information on singlet oxygen chemistry. We also would like to thank Professor Hiroo Inokuchi, Institute for Molecular Science, for kindly supplying pentacene.

11) In our preceding work (Ref. 10), we determined the binding energies of core peaks from polycyclic aromatic hydrocarbons by reference to $Au4f_{7/2}$ line (84.0 eV) from gold deposited on samples. The Cls binding energies thus obtained for four hydrocarbons were 284.3—284.6 eV (the average: 284.5 eV). However, according to Johansson et al. (G. Johansson, J. Hedman, A. Berndtsson, M. Klasson, and R. Nilsson, *J. Electron Spectrosc. Relat. Phenom.*, **2**, 295 (1973)), the binding energy of $Au4f_{7/2}$ line should be set at 83.8 eV (i.e., smaller by 0.2 eV than the previous value). Therefore, we adopted the value 284.3 eV for the Cls line in the present study.

12) The sensitivity ratio between Cls and Ols peaks used in this study (0.58 : 1.00) was derived from Mg $K\alpha$ spectra of the three carbonyl compounds listed in Table 1.

A Through Space/Bond Interaction Analysis of the Shape of the Band Structure of Polyacetylene

Yuriko Aoki, Akira Imamura,* and Takae Sasaki
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Hiroshima 730
(Received September 14, 1987)

The band structure of all-*trans*-polyacetylene is examined by using through space/bond interaction analysis. It is found that the cross-term in the perturbation expansion between two kinds of interactions governs the band shape near the gap: One kind is the interaction within the backbone, and the other is that between the backbone and the side chain. The relationship between the band structure and the symmetry of the interacting orbitals is also discussed.

The relationship between the structure of a polymer and its electronic states has attracted considerable attention from the theoretical point of view. All-*trans*-polyacetylene is a simple linear conjugated π system and is an insulator with a degenerate ground state because of the alternation of the C-C bond length. The electronic properties of pure polyacetylene have been investigated by using the Hartree-Fock tight-binding approximation both within one-electron pictures[1-9] and including electron-correlation effects.[10,11] There are other methods, for example, using the X_α approach[12,13] and the GKS potential,[14] which give better agreements with the experimental data than do the RHF results. Many theoretical studies show that the conductivity of such a system is intimately related to the distortion of the symmetry attributable to the bond alternation, which gives rise to the formation of a gap between the HOMO π band and the LUMO π^* band.[15-19] This polymer has recently been the focus of enormous interest because of the discovery that the conductivity can be controlled by doping with electron donors and acceptors.[20-27]. Brédas et al. showed, at the level of the ab initio method, that there is a relationship between the structural change in the bond alternation and the magnitude of the charge-transfer interaction between the polyacetylene and dopants.[28,29] Kertész carried out three-dimensional energy band calculations on highly doped donor and acceptor compounds of polyacetylene based on the rigid-band model[30] and discussed the interaction of the polymer π orbital with the orbitals of the dopants.[31] These facts imply that the conductivity of a Peierls-distorted[32] linear chain is strongly dependent on the environment of polymers in connection with the gap between the top of the filled π-electron valence band and the bottom of the unfilled π^*-electron conduction band.

On the other hand, there have been few studies of the energy band of σ electron orbitals, which are considered to be hardly responsible at all for the conductivity. Hoffmann's group has developed a chemical and theoretical approach to the electronic structures of solids, which mainly have two-dimensional layers, at the level of the extended Hückel method. In their studies, the band structures including σ orbitals of many inorganic crystals have been predicted and interpreted successfully in terms of the symmetry of the crystal orbitals. In order to obtain some insight into the behavior of the σ orbitals near the gap, we ourselves have extended the concept of the interaction of orbitals through-space and through-bonds, a concept that has been presented by Hoffmann et al.,[33] to a polymer system. In our previous paper,[34] this method was applied to the lone-pair orbitals of polynitrilomethylidyne, and it was found that the relationship between the energy band and the interaction of atomic orbitals can be interpreted in terms of the symmetry of the crystal orbitals. In the present article, we use this method for characterizing the electronic properties of polyacetylene on the presumption that the band structure with a high conductivity must be reflected in the interaction between orbitals near the gap. We expect that this analysis will provide information useful for the prediction of various properties of the polymers.

Calculation of Band Structure

The crystal orbital method has been described in the literature.[8,35] The necessary equations will, therefore, merely be listed below in explanation of the through space/bond interaction analysis. The ab initio crystal orbital method used in this study is based on the general SCF tight-binding LCAO formalism,[36] which corresponds essentially to Roothaan's Hartree-Fock equation for molecules.[37] A delocalized wave function of a single electron in the periodic potential of a one-dimensional crystal is represented as a linear combination of Bloch basis orbitals, which are symmetry-adapted combinations of atomic orbitals, χ_r, in this form:

$$\phi_i^k(r_1) = (2N+1)^{-1/2} \sum_{m=-N}^{+N} \sum_{r}^{n_r} \exp(ikR_m) C_{ir}(k) \chi_r(r_1 - R_m) \quad (1)$$

where k denotes a wavenumber vector in the first Brillouin zone, and i, an energy band. The $\chi_r(r_1-R_m)$ term stands for an atomic orbital localized in the m-th cell at $R_m(m=0, 1, 2, \cdots, N)$, while $2N+1$ is the number of elementary cells. For a given atomic basis and in the restricted HF-Roothaan scheme, the optimal set of one-electron wave functions, $\phi_i^k(r_1)$, is obtained by

solving the following equations:

$$\sum_S C_{is}(k)[F_{rs}(k) - S_{rs}(k)E_i(k)] = 0 \qquad (2)$$
$$r = 1, 2, \cdots\cdots, n_r$$

where,

$$F_{rs}(k) = \sum_{m=-M}^{+M} \exp(ikR_m)F_{rs}^{Qm}(R_m), \qquad (3)$$

$$S_{rs}(k) = \sum_{m=-M}^{+M} \exp(ikR_m)S_{rs}^{Qm}(R_m), \qquad (4)$$

whose solutions at various k points in BZ provide the band structure of $E_i(k)$. F_{rs}^{Qm} is the Fock matrix element between the r-th atomic orbital χ_r in the central cell and the s-th atomic orbital χ_s^m in the m-th cell. S_{rs}^{Qm} is the overlap integral between these orbitals.

Based on this scheme, the polymer Gaussian 74 program has been extensively developed by Suhai et al.[8] Previous to the through space/bond interaction analysis, ab initio calculations were performed on all-*trans*-polyacetylene by using this program, with an STO-3G basis set. Ten k-points in half the Brillouin zone were used, and the convergence criterion of 10^{-6} for the difference in density-matrix elements was adopted. Twice the magnitude of the lattice vector was taken as a translational vector corresponding to the unit cell of polyacetylene shown in Fig. 1.

The truncation of lattice sums in the Fock matrix given by Eq. 3 is a serious problem in obtaining the convergent energy values. Delhalle et al. have previously reported in considerable detail on the convergence properties of the long-range Coulombic contributions, using the Fourier representation technique, etc;[38-41] they have recently reported also on the behavior of exchange-energy contributions, which is important in the metallic system.[42-44] Recent data for *trans*-polyacetylene show that the difference in the band gap is less than 3kcal/cell in the region of included neighbors 4-50 C2H2- units at the HF/STO-3G level.[45] We made sure in the previous work on polynitrilometylidyne[38] that the absolute values of orbital energies are changed by a cut-off after a finite interaction range, but that the shapes of the band structures are retained, even when up to 16 CHN units are included. Therefore, in employing the through space/bond interaction analysis we used the Fock matrix elements by taking into account the contribution up to the third neighbor interaction (6 units) in the core-resonance integrals and the two-electron integrals.

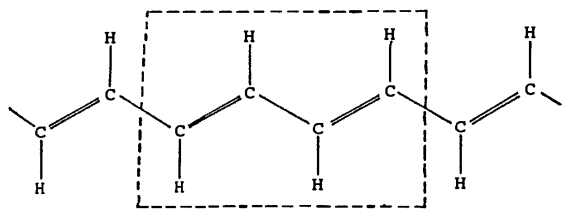

Fig. 1. Structure of all-trans polyacetylene. The unit cell is sorrounded with broken lines.

The geometries used here (Table 1) are the same as those described in Ref. 8. The band structures and the density of the states calculated indicate that the system is an insulator with a band gap of 8.12 eV, as is shown in Fig. 2. This value is, however, too large compared with the experimental value of ca. 2 eV.[46] Suhai has reported that the smaller bond alternation when correlation effects are included leads to a smaller gap (ΔE_g(HF/STO-3G)$\simeq$8.9 eV, ΔE_g (HF/6-31G**)$\simeq$5.1 eV, ΔE_g(HF+MP2/6-31G**)$\simeq$4.4 eV) at their optimal geometries) which should cover 70—75% of the valence-shell correlation energy.[11] This indicates that the correlation effects are essential for obtaining a good agreement with the experimental value in calculation including correlation effects. However, the purpose of our study is to obtain information with respect to the relationship between the orbital-energy dependence on the wavenumber vectors and the interactions of the crystal orbitals. If the nature of the material properties can be explained qualitatively from the point of view of orbital symmetry, without carrying out accurate calculations directly, it must be possible to provide easily a fundamental aspect for experimental investigation. As the first step in roughly predicting the electronic properties of polymers affected from the structural change or substitution effects, we have applied the through space/bond interaction analysis at the HF/STO-3G level to *trans*-polyacetylene.

Through Space/Bond Interaction Analysis

Method. For the analysis based on the through space/bond concept, all the Fock matrix elements and overlap integrals, which had been converged by ab initio SCF calculations, were classified into two kinds of interaction patterns. One type included those terms relating to the through-bond interactions, and the other type, the through-space interactions. The former type included the Fock matrices given by Eq. 3 and the overlap integrals given by Eq. 4 for diagonal elements and as well as off-diagonal elements between orbitals belonging to the same atom and between valence orbitals belonging only to the nearest neighboring atoms. For *trans*-polyacetylene, the valence orbitals indicate the 2s, $2p_x$, $2p_y$, and $2p_z$ orbitals on the C atom and the 1s orbitals on the H atoms. These elements were included for all cases of analyses. The latter type includes all the terms except those for the through-bond interaction, that is, those between particular valence orbitals belonging to remote atoms, between which there are no bonds. By investigating the influence of these through-space interactions on

Table 1. Geometries of $\{CH=CH\}_n$

r(C=C)	1.35Å	Angle (C=C-C)	120°
r(C-H)	1.09Å	Angle (C=C-H)	120°
r(C-C)	1.46Å		

the former through-bond interactions, the important through-space interaction for determining the band structure can be found. The technical details of the through space/bond method have been extensively described in a previous paper.[34] In this work, first, conspicuous through-space interactions governing the band shape are found by variational analysis, and next the concrete terms that contribute to the through-space interaction are analyzed by the perturbation method.

Variational Analysis. For performing the through-space/bond interaction variational analysis of the matrix elements, converged by the ab initio SCF calculations for Eq. 2, only the through-bond and some particular through-space components are reserved, the others are completely neglected. The eigenvalue problem for this new secular equation is solved only once, without further iterations for each wavenumber vector. By using the eigenvalue thus obtained, the effect of various through-space interactions on the band structure of the pure through-bond interaction can be investigated. The energy bands obtained by increasing the through-space components approach quantitatively to the results with full interaction, that is, the solution for Eq. 2 with full matrix elements. In this process, the most significant through-space interaction is found by comparing the changes in the band shapes. Furthermore, the relationship between band shapes and crystal orbitals for each through-space interaction can be investigated.

First, we calculated the energy bands of the pure through-bond interaction. The energy-band structure thus obtained is shown in Fig. 3. By comparing this band structure with the full interaction shown in Fig. 2, it is found that there is little difference in π and π^* bands between these two kinds of interactions. This is likely because the nature of the band structures for π-electron orbitals can be derived by a Hückel-type Hamiltonian, analogous to the pure through-bond interaction. On the other hand, it is noted that the LUMO σ^* band is greatly lowered by 0.7 au at $k=0°$, so that the gap between the valence and the conduction bands is extinguished. It is noteworthy that this band structure, calculated by including only the pure through-bond interactions, indicates a nearly metallic state. Therefore, we focused on this LUMO σ band and searched for the through-space interaction that elevates the LUMO σ^* energy to the insulator level.

We adopted the three kinds of through-space interactions shown in Fig 4., which exert significant effects on the band shapes of the pure through-bond interactions. The results of the analysis by various through-space interactions are shown in Figs. 5—7. Upon interaction between valence orbitals on the nonbonding C atoms (C-C interaction), no significant change in the LUMO σ^* band shape can be observed (Figs. 3 and 5). When the interaction between valence orbitals on C and the 1s orbital of H (C-H interaction) is added to the through-bond interaction, although the energy of the MO is unchanged at $k=0°$, it is raised by 0.5 au at $k=180°$ (Figs. 3 and 6). Moreover, by adding the C-C and C-H interactions, the LUMO σ^* energy level at $k=0°$ is raised and an energy gap between π and π^* bands appears (Figs. 3 and 7). The major part of the energetic destabilization at $k=0°$ originates from the coupling of the interaction within the backbone (C-C) with the interaction between the backbone and the side chain (C-H). This concurrent effect seems to be strong enough to give rise to the appearance of the

gap, although each interaction (C-C) or (C-H) makes no apparent contribution. This behavior near k=0° turns out to be especially different from that at k=180° which satisfies the additivity rule for individual through-space interactions.

Perturbational Analysis. In order to account for the anomalous behavior at k=0° indicated by the variational analysis, we investigated the band structure in more detail by means of a perturbative treatment. By using formula from the general perturbation theory

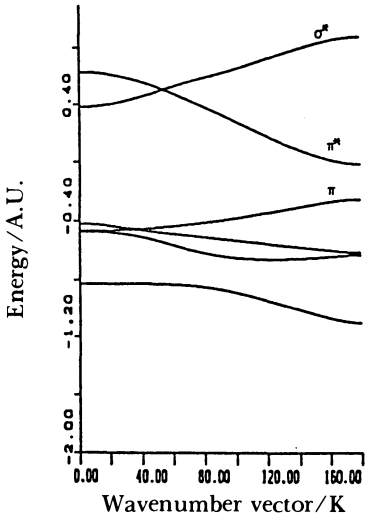

Fig. 7. The band structure for the pure through bond+(C-C+C-H) interaction.

for the extended Hückel method, which has been reported previously,[47] the first- and the second-order terms in the energy and coefficient are given as follows:

$$C_{ti}^{(1)} = -\sum_{\substack{j \\ (j\neq i)}}{}' C_{tj}^{(0)}/(E_j^{(0)} - E_i^{(0)}) \sum_r \sum_s (F_{rs}^{(1)} - S_{rs}^{(1)} E_i^{(0)}) C_{si}^{(0)} C_{rj}^{(0)*} - \frac{1}{2} C_{ti}^{(0)} \sum_r \sum_s C_{ri}^{(0)*} C_{si}^{(0)} S_{rs}^{(1)} \quad (5)$$

$$E_i^{(1)} = \sum_r \sum_s (F_{rs}^{(1)} - S_{rs}^{(1)} E_i^{(0)}) C_{ri}^{(0)*} C_{si}^{(0)} \quad (6)$$

$$C_{ti}^{(2)} = -\sum_{\substack{j \\ (j\neq i)}} C_{tj}^{(0)}/(E_j^{(0)} - E_i^{(0)}) [-\sum_r \sum_s S_{rs}^{(1)} E_i^{(1)} C_{si}^{(0)} C_{rj}^{(0)*} + \sum_r \sum_s \{F_{rs}^{(1)} - (S_{rs}^{(0)} E_i^{(1)} + S_{rs}^{(1)} E_i^{(0)})\} C_{si}^{(1)} C_{rj}^{(0)*}] - \frac{1}{2} C_{ti}^{(0)} \sum_r \sum_s [C_{ri}^{(1)*} C_{si}^{(1)} S_{rs}^{(0)} + (C_{ri}^{(1)*} C_{si}^{(0)} + C_{ri}^{(0)*} C_{si}^{(1)}) S_{rs}^{(1)} \quad (7)$$

$$E_i^{(2)} = -\sum_r \sum_s S_{rs}^{(1)} E_i^{(1)} C_{ri}^{(0)} C_{si}^{(0)*} + \sum_r \sum_s \{F_{rs}^{(1)} - (S_{rs}^{(0)} E_i^{(1)} + S_{rs}^{(1)} E_i^{(0)})\} C_{ri}^{(1)} C_{si}^{(0)*} \quad (8)$$

where i and j denote molecular orbitals, and r and s, atomic orbitals, and where $\sum_j'$ means that the summation covers all levels except i. In this study, the zero-order matrix elements $F_{rs}^{(0)}$ and $S_{rs}^{(0)}$ and the coresponding crystal orbital $C_{ti}^{(0)}$ and energy $E_i^{(0)}$ values, are the terms for the pure through-bond interaction. The first-order terms $F_{rs}^{(1)}$ and $S_{rs}^{(1)}$ are matrix elements for a selected pair of through-space components.

Equations 5 and 6 are calculated by taking a through-space interaction as a perturbation; then the concrete contribution included in the energy change obtained by solving Eq. 2 can be found. Figure 8 shows the energy bands of the LUMO σ^* orbital obtained by the first-order perturbation that is, $E^{(0)}(k)+E^{(1)}(k)$, for three kinds of through-space inter-

actions compared with the results obtained by the variation method. By C-C interaction the energy is raised at k=0° by 0.4 au; likewise C-H interaction raises it at k=180° by 0.5 au. The first-order energies by both C-C and C-H interactions, that is, the sum of the true interactions, change the energy band in the direction of the variational result.

The change in the band structure by the first-order perturbation should be predictable from the crystal orbitals for the pure through-bond interaction, the zero-th order wave function, and the perturbed matrix elements. The crystal orbitals at k=0° and 180° are shown schematically in Fig. 9. The crystal orbitals on C atoms at k=0° are directed to the z axis, which are out-of-phase between $2p_z$ orbitals on the C1 and C3. On the other hand, those at k=180° are directed to the hydrogen atoms, which are out-of-phase between C1 and H2 or C2 and H1. The positive overlap implies bonding, and the negative one, antibonding. Therefore, C-C interaction destabilizes the MO at k=0°, as does C-H interaction at k=180°. In this manner, this behavior can reasonably be interpreted in terms of the symmetry or the phase of crystal orbitals.

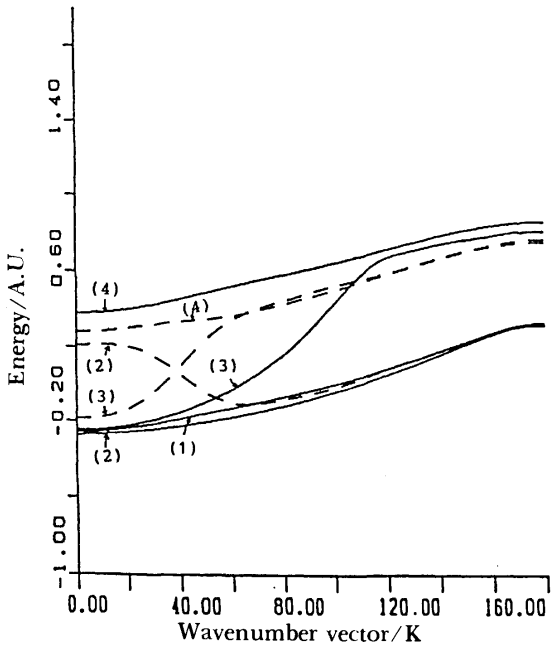

Fig. 8. The energy band of LUMO σ^* orbital by through space/bond interaction analysis. —— Variative analysis, ---- perturbative analysis (1) pure through bond interaction (2) C-C interaction (3) C-H interaction (4) (C-C+C-H) interaction.

It is noteworthy that the perturbation by the C-C interaction does not change the energy when the variational treatment is used, but it is raised at k=0° by the first-order perturbational treatment. This suggests that the terms more than first-order contribute greatly to the change in the energy band. It seems profitable to calculate the second-order energies in order to examine the concrete terms which elevate the LUMO σ band to the insulator level. The leading interaction term with the other levels in the second-order energy can be derived because, as can be seen from Eq. 8, the $E_i^{(2)}$ includes the term $C_{ii}^{(1)}$ that is given by the sum of the interactions with all the levels except i. Table 2 shows the first-order energies obtained by the three kinds of through-space interactions in comparison with the energy changes obtained by the variational treatment at k=0° and 180°.

At k=180°, the second-order energy obtained by the (C-C+C-H) interaction is almost equal to the sum of those obtained by both the C-C and C-H interactions; that is, the additivity rule holds for these interactions. The sum of the first-and the second-order energies gives values which are nearly equal to the energy changes obtained by the variational treatment. This shows that the substantial effect on the energy band of the through-space interactions may reasonably be interpreted by only the first-order term in the perturba-

Table 2. Gained Energies by Through-Space Interactions for the LUMO σ^* Orbitals (a.u.)

k=0°	Through space	C-C	C-H	C-C+C-H
	Perturbation			
	$E^{(1)}$	0.463	0.070	0.534

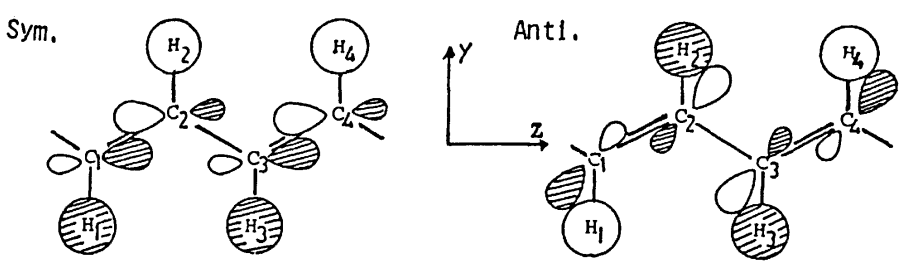

Fig. 9. Schematic representation of the magnitude of the coefficients of atomic orbitals in the crystal orbitals for the pure through bond interaction of all-*trans*-polyacetylene. Shaded areas represent positive lobes; unshaded negative. Sym. corresponds to k=0° and Anti. to k=180°.

tion expansion.

At k=0°, on the other hand, the second-order energy by the (C-C+C-H) interaction (0.205) is greatly different from the sum of those by both C-C and C-H interactions (−0.328, −0.402), even in sign. This behavior implies that the cross-terms included in the (C-C+C-H) interaction contribute positively to the second-order energy.

The cross-term is given by the following equation:

$$\begin{aligned} E_i^{(2)}(\text{cross}) &= -\sum_r\sum_s \{S^{(1)}_{rs(\text{C-C})} E^{(1)}_{i(\text{C-H})} + S^{(1)}_{rs(\text{C-H})} E^{(1)}_{i(\text{C-C})}\} C^{(0)}_{ri} C^{(0)*}_{si} \\ &+ \sum_r\sum_s (F^{(1)}_{rs(\text{C-C})} - S^{(1)}_{rs(\text{C-C})} E^{(0)}_i) C^{(1)}_{ri(\text{C-H})} C^{(0)*}_{si} \\ &+ \sum_r\sum_s (F^{(1)}_{rs(\text{C-H})} - S^{(1)}_{rs(\text{C-H})} E^{(0)}_i) C^{(1)}_{ri(\text{C-C})} C^{(0)*}_{si} \end{aligned} \quad (9)$$

where $S^{(1)}_{rs(\text{C-C})}$ and $F^{(1)}_{rs(\text{C-C})}$ represent the matrix elements for the through-space C-C interaction, and $S^{(1)}_{rs(\text{C-H})}$ and $F^{(1)}_{rs(\text{C-H})}$, those for the C-H interaction $E^{(1)}_{i(\text{C-H})}$ and $C^{(1)}_{rs(\text{C-H})}$ are the first-order perturbation energy and the corresponding coefficient obtained by only the C-H through-space interaction. $E^{(1)}_{i(\text{C-C})}$ and $C^{(1)}_{ri(\text{C-C})}$ have the same meaning. The cross-terms given by Eq. 9, which corresponds to the difference between $E^{(2)}_{i(\text{C-C+C-H})}$ and $E^{(2)}_{i(\text{C-C})}+E^{(2)}_{i(\text{C-H})}$, are 0.934 for k=0° and 0.001 for k=180°. The value of the cross-term is positive enough to elevate the LUMO σ^* band to the insulator level, in spite of the negative values caused by the C-C interaction (−0.328) and the C-H interaction (−0.402). Furthermore, the $C^{(1)}_{ri(\text{C-C})}$ and $C^{(1)}_{ri(\text{C-H})}$ terms, that include interaction with the other levels, result in a dominant factor in Eq. 9. From these results it seems reasonable to assume that the conspicuous results obtained by the variational treatment can essentially be interpreted by examining the second-order term. Therefore, the cross-term included in the second-order will be analyzed in order to investigate its explicit contribution.

We attempt to represent the second-order energy explicitly by the zero-order crystal orbitals instead of the first-order crystal orbitals. We define:

$$T^{(1)}_{rs,i} = F^{(1)}_{rs} - S^{(1)}_{rs} E^{(0)}_i , \quad (10)$$

and substitute Eqs. 5, 6, and 10 into Eq. 8; then the second-order energy is expressed as follows:

$$\begin{aligned} E_i^{(2)} &= -\sum_r\sum_s S^{(1)}_{rs} \sum_p\sum_q T^{(1)}_{pq,i} C^{(0)}_{pi} C^{(0)*}_{qi} C^{(0)}_{ri} C^{(0)*}_{si} \\ &- \sum_r\sum_s (T^{(1)}_{rs,i} - S^{(0)}_{rs} \sum_p\sum_q T^{(1)}_{pq,i} C^{(0)}_{pi} C^{(0)*}_{qi}) \\ &\times \{ \sum'_{j(\neq i)} C^{(0)}_{rj} \sum_t\sum_u T^{(1)}_{tu,i} C^{(0)}_{ti} C^{(0)*}_{uj} / (E^{(0)}_j - E^{(0)}_i) \\ &+ \frac{1}{2} C^{(0)}_{ri} \sum_t\sum_u C^{(0)}_{ti} C^{(0)*}_{ui} S^{(1)}_{tu} \} C^{(0)*}_{si} \end{aligned} \quad (11)$$

Neglecting the term $S^{(0)}_{rs} E^{(1)}_i$, that is, $S^{(0)}_{rs} \sum_p\sum_q T^{(1)}_{pq,i} C^{(0)}_{pi} C^{(0)*}_{qi}$ because of its small value, Eq. 11 becomes approximately:

$$\begin{aligned} E_i^{(2)} &= -\frac{3}{2} \sum_r\sum_s T^{(1)}_{rs,i} C^{(0)}_{ri} C^{(0)*}_{si} \sum_t\sum_u S^{(1)}_{tu} C^{(0)}_{ti} C^{(0)*}_{ui} \\ &- \sum_r\sum_s T^{(1)}_{rs,i} \sum'_{j(\neq i)} C^{(0)}_{rj} \sum_t\sum_u T^{(1)}_{tu,i} C^{(0)}_{ti} C^{(0)*}_{uj} C^{(0)*}_{si} / (E^{(0)}_j - E^{(0)}_i) . \end{aligned} \quad (12)$$

The first term relates only to the i-th crystal orbital, and the second term, to the other crystal orbitals belonging to all levels except i. The behavior of the energy band near k=0° suggests a great contribution of the second-order term in Eq. 12. Suppose that the focused i-th crystal orbital interacts strongly with the k-th crystal orbital and weakly with the other crystal orbitals: then Eq. 12 becomes approximately:

$$E^{(2)'}_{i(k)} = -\sum_r\sum_s T^{(1)}_{rs,i} C^{(0)*}_{si} C^{(0)}_{rk} \sum_t\sum_u T^{(1)}_{tu,i} C^{(0)}_{ti} C^{(0)*}_{uk} / (E^{(0)}_k - E^{(0)}_i) \quad (13)$$

where the interactions with all levels except k are completely neglected. We write:

$$\sum_r\sum_s T^{(1)}_{rs,i} C^{(0)*}_{si} C^{(0)}_{rk} = H^{(1)}_{ik} \quad (14)$$

and using the fact that $T^{(1)}_{rs,i}$ is Hermitian, Eq. 13 is reduced to:

$$E^{(2)'}_{i(k)} = -|H^{(1)}_{ik}|^2 / (E^{(0)}_k - E^{(0)}_i) \quad (15)$$

When the $H^{(1)}_{ik}$ includes two kinds of interactions, $H^{(1)}_{\text{A}}$ and $H^{(1)}_{\text{B}}$, Eq. 15 becomes:

$$E^{(2)'}_{i(k)} = -|H^{(1)}_{\text{A}} + H^{(1)}_{\text{B}}|^2 / (E^{(0)}_k - E^{(0)}_i) \quad (16)$$

where,

$$H^{(1)}_{\text{A}} = \sum_r\sum_s (F^{(1)}_{rs}(\text{A}) - S^{(1)}_{rs}(\text{A}) E^{(0)}_i) C^{(0)*}_{ri} C^{(0)}_{sk} \quad (17)$$

$$H^{(1)}_{\text{B}} = \sum_r\sum_s (F^{(1)}_{rs}(\text{B}) - S^{(1)}_{rs}(\text{B}) E^{(0)}_i) C^{(0)*}_{ri} C^{(0)}_{sk} \quad (18)$$

This means that the i-th orbital is stabilized in the second-order energy by the interaction with the upper levels of crystal orbitals, while it is destabilized with the lower ones. We have here evidence for the well-known conclusion that the energy levels with like symmetry crystal orbitals repel each other. As is implied by Eq. 16, $E^{(2)}_{i(k)}$ is destabilized only by the interaction with the energy levels in the proximity of the i-th level. The cross-term between the A and B interactions is expressed approximately as:

$$E^{(2)'}_i(\text{cross}) = -2Re(H^{(1)}_{\text{A}} H^{(1)*}_{\text{B}}) / (E^{(0)}_k - E^{(0)}_i), \quad (19)$$

provided that only the pair of the i-th and k-th crystal orbitals interacts strongly with each other. The terms relating only to the $H^{(1)}_{\text{A}}$ or $H^{(1)}_{\text{B}}$, that is $-|H^{(1)}_{\text{A}}|^2/(E^{(0)}_k - E^{(0)}_i)$ or $-|H^{(1)}_{\text{B}}|^2/(E^{(0)}_k - E^{(0)}_i)$, usually give negative values. The cross-term $E^{(2)'}_i$ (cross) given by Eq. 19 is a negative values if $H^{(1)}_{\text{A}}$ and $H^{(1)}_{\text{B}}$ have the same signs and a positive value if $H^{(1)}_{\text{A}}$ and $H^{(1)}_{\text{B}}$ have different signs. By means of the formulae thus described, we can proceed to an analysis of specific cases of energy-band structures.

As can be seen from the band structure for the pure through-bond interaction, shown in Fig. 3, the LUMO σ^* band and the upper σ^* band approach each other closely at $k=0°$. This shows that the LUMO σ^* band is referred especially to the influence of the upper σ^* band so as to avoid the crossing with it. Therefore, it seems reasonable to apply the above-mentioned approximation given by Eq. 16 to the case at $k=0°$. In the present case, the value of $H_A^{(1)}$ corresponding to the C-C interaction and that of $H_B^{(1)}$ corresponding to the C-H interaction are -0.185 and 0.171, respectively. The different signs of the two terms support the idea that the cross- term between these two kinds of interactions should be positive so as to destabilize the second-order energy of the LUMO σ^*.

Next, we will attempt to predict readily the contribution of the cross-term to the second-order energy in terms of the phase of the zero-order crystal orbitals without calculating the term $E_{i(k)}^{(2)}$ (cross). Equations 17 and 18 imply that whether or not the signs of the $H_{C\text{-}C}^{(1)}$ and the $H_{C\text{-}H}^{(1)}$ are the same can be elucidated by means of the i-th and the k-th zero-order crystal orbitals. The crystal orbitals for the pure through-bond interaction are shown schematically in Fig. 10 for the i-th LUMO σ^* orbital and the upper k-th σ^* orbital. The 2p orbital on Cl of the i-th orbital and that on C3 of the k-th orbital, for example, are in-phase along the direction of the z-axis, as are the 2p orbital on Cl of the k-th orbital and that on C3 of the i-th orbital, so that the $H_{C\text{-}C}^{(1)}$ become negative. The ls orbital on Hl of the i-th orbital and the 2p orbital on C2 of the k-th orbital are out-of-phase along the direction of the y-axis, as

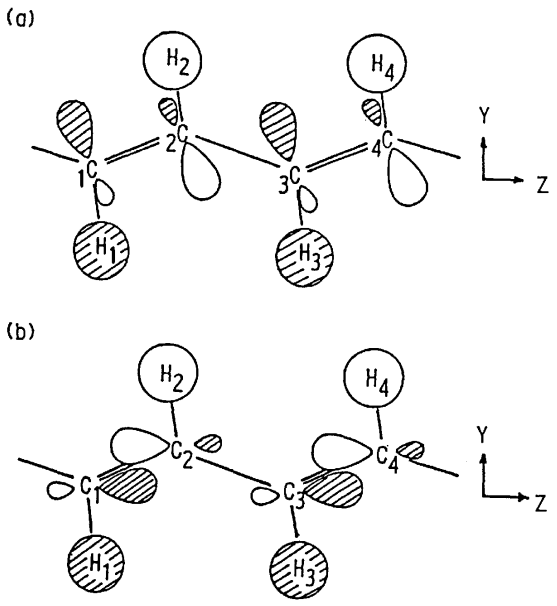

Fig. 10. Schematic representation of the magnitude of the coefficients of atomic orbitals in the crystal orbitals at $k=0°$ for the pure through bond interaction of all-*trans*-polyacetylene. Shaded areas represent positive lobes; unshaded negative. (a) k-th and (b) i-th levels in Eqs. 13—18.

are the 1s orbital on H1 of the k-th orbital and the 2p orbital on C2 of the i-th orbital, so that the $H_{C\text{-}H}^{(1)}$ is positive. This explication is consistent with the results obtained by calculating the $H_{C\text{-}C}^{(1)}$ and $H_{C\text{-}H}^{(1)}$ terms. This shows that the effect of the cross-term on the band shape should be predictable from the phase of the crystal orbitals with only the pure through-bond interaction. As a result of the perturbative analysis, it was found that the large positive cross term (0.934) between the $H_{C\text{-}C}^{(1)}$ and the $H_{C\text{-}H}^{(1)}$ terms governs the LUMO σ^*-band shape near $k=0°$ for the full interaction and is responsible for the appearance of the gap between the π and π^* bands. This method seems useful for investigating the relationship between the structural problem of a polymer and its band structure, which plays an important role in the conducting mechanism. Henceforth, we intend to apply this approach to the estimation of the structures of various polymers which are favorable for a high conductivity.

Conclusion

In this article we discuss the features of the band structure of all-*trans* polyacetylene as obtained by the use of through space/bond interaction analysis. The band structure for the pure through-bond interaction shows that the LUMO σ^* orbital is greatly lowered at $k=0°$ and extinguishes the gap between the π and π^* bands. The results obtained by the variational analysis for the LUMO σ^* orbital at $k=0°$ are different from those obtained at $k=180°$ with regard to the dependences of the band structure on through-space interactions. The most interesting feature is that there is a large coupling between two interactions; one is the interaction between C atoms belonging to the neighboring cells, and the other is that between the C atom and the H atom bonded to the neighboring C atom. It is this coupling term that is responsible for the band shape near $k=0°$. This fact suggests an important rule of the cross term between these two kinds of interactions. With the aid of the perturbation method, a simple formula for the cross-term is derived when two particular energy levels interact very strongly so as to avoid crossing. This formula enabled us to predict, though in a somewhat rough way, the behavior of the σ orbital near the gap in the band structure of all-*trans*-polyacetylene.

This work was supported by a Grant-in-Aid for Scientific Research from the Ministry of Education for which we express our gratitude. The computations were carried out on HITAC M-200H computers at the Information Processing Center of Hiroshima University and HITAC M-680H computers at the Institute for Molecular Science.

Studies of the Rate of the Formation of Talc under Hydrothermal Conditions at 400—460 °C

Haruto MURAISHI
Department of Chemistry, Fukuoka University of Education, Akama, Munakata, Fukuoka 811-41
(Received September 16, 1987)

The rate of the formation of talc from brucite powders with soluble silica under hydrothermal conditions was investigated in the temperature range of 400—460 °C, a range including the equilibrium temperature for the reaction: brucite+serpentine⇄2 forsterite+3H_2O. Serpentine appeared as an intermediate phase below 415 °C, while above 430 °C forsterite appeared in addition to serpentine. The apparent reaction can be represented as:

(below 415° C) brucite → serpentine → talc

(above 430° C) brucite → serpentine, brucite → forsterite, serpentine → talc, forsterite → talc

The reaction was apparently expressed as a pseudo-first-order reaction. The overall rate of the reaction did not increase with the increase in the temperature. Arrhenius plots of the rate constants for the overall reaction showed a curve with a maximum at about 415 °C and a minimum at about 445 °C which was caused by the alteration of the reaction by the appearance of forsterite at 430 °C.

The mechanism of the formation of silicates under hydrothermal conditions has been investigated from the standpoints of synthesis[1-3] and metamorphic reactions.[4-7] In spite of the many investigations into the synthesis of zeolite which have been done, however, the mechanism for the formation of zeolite has not yet been completely revealed. For the metamorphic reaction, though, the rates of hydration and dehydration (or forward and backward reactions) have been well investigated near the equilibrium temperature, and an effective rate constant has been obtained.

The kinetic study of solid-state reactions is generally attended with several problems. One of the problems with the reaction is that the observed overall rate of the reaction is usually controlled by the diffusion step (e.g., lattice diffusion) and is then influenced by the size and the shape of the starting materials. A physical process, such as diffusion, will not give useful information on surface reactions, nucleation, and intermediate formation. In order to obtain some information on these reactions of hydrothermal synthesis, it is necessary to simplify the reaction system and to set up a suitable reaction situation. From these points of view, we have now studied the hydrothermal synthesis of the MgO-SiO_2-H_2O system.

It has been found that the reaction of brucite ($Mg(OH)_2$) with SiO_2 involved the dissolution process of SiO_2 and that the dissolved silica was adsorbed on the surface of brucite in the initial step of the reaction. The adsorption was chemisorption, and the surface of the silica-adsorbed brucite consisted of an amorphous silicate layer at atmospheric pressure.[8,9] When the resulting amorphous silicate on the brucite was treated hydrothermally, it crystallized as serpentine ($Mg_3Si_2O_5(OH)_4$) at temperatures below 400 °C and was further transformed into forsterite (Mg_2SiO_4) above 420 °C.[10] In addition, it was found from the kinetic study that the difference in the particle size of brucite powder influenced not only the overall reaction rate but also the rate-determining step.[11]

In this study, the formation of talc ($Mg_3Si_4O_{10}(OH)_2$) was followed as a function of the time at various temperatures (400—460 °C) including the equilibrium temperature for the reaction: brucite+serpentine⇄2 forsterite+3 H_2O. The reaction was carried out under such conditions that the silica could react with the solid brucite in the state of soluble silica in an autoclave; the concentration was kept almost constant during the reaction by the use of a large excess of silica. This simplified reaction system led to a kinetic analysis of the formation of talc through intermediate products. The most reasonable process of the formation of talc around the equilibrium temperature will be discussed based on these results.

Experimental

Two-tenths of a gram of $Mg(OH)_2$ powder, packed naturally into a basket mounted on a holder, was placed above 2.0 g of silica gel powder situated at the bottom of a modified Mory-type autoclave with a capacity of about 30 cm^3. The filling ratio of water in the autoclave was 35%; this ratio corresponds to a pressure of about 300—500 bars at 400—460 °C. A solution in an autoclave was kept saturated with soluble silica at a concentration of 700—900 ppm throughout the reactions in the temperature range of 400—460 °C, since a large excess of silica was used as the silica source.

After a definite time of heating, the autoclave was rapidly quenched with water and the materials were taken out. The reactant and products were identified by the use of X-ray diffractometry and DTA. Their quantities could be determined with a gravimetric technique (TGA) and by means of their X-ray diffraction patterns. These methods have been fully described in a previous paper.[11,12]

Results and Discussion

Analysis of Experimental Conversion Curves. Figure

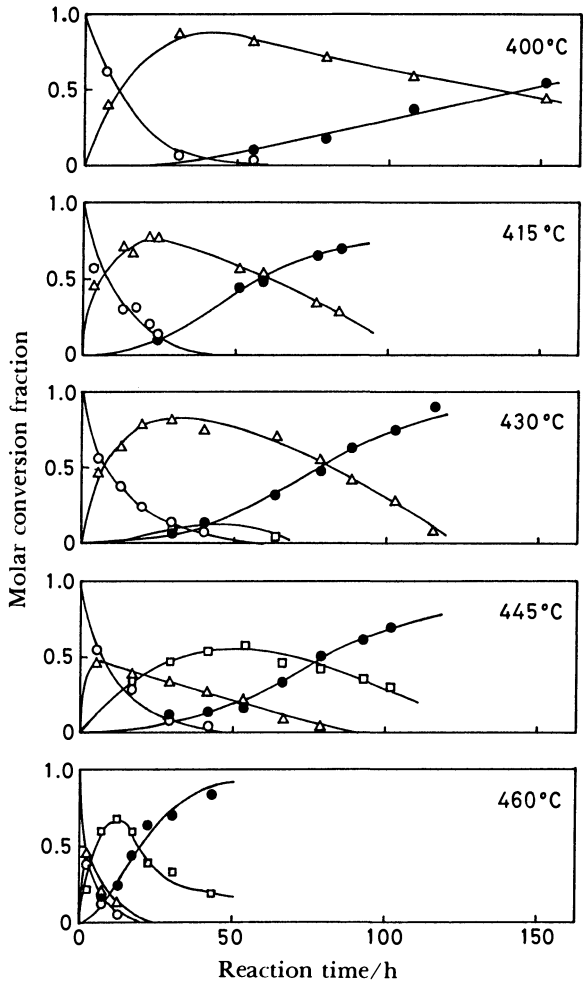

Fig. 1. Experimental conversion curves for the reaction of brucite with soluble silica at 400—460°C.
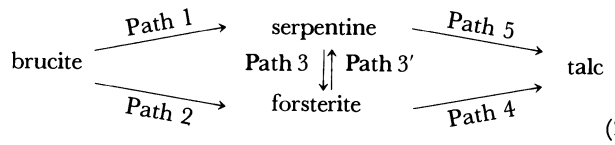
○: brucite, △: serpentine, □: forsterite, ●: talc.

1 shows the molar conversion curves for the reaction of solid brucite with soluble silica at 400—460 °C. Talc was formed through serpentine at 415 °C or below and through serpentine and forsterite as intermediates above 430 °C. It was noted that the temperature where forsterite appeared in the present kinetic study was higher than that in the equilibrium data obtained previously by Bowen and Tuttle.[13] When serpentine alone appeared as an intermediate substance, the reaction represented, as has been described previously,[11] a first-order consecutive irreversible reaction:

$$\text{brucite} \rightarrow (\text{serpentine}) \rightarrow \text{talc} \qquad (1)$$

When forsterite appeared in addition to serpentine, its overall reaction, brucite→(serpentine, forsterite)→talc, may be summarized in the following apparent process including Reaction 1:



(2)

Each reaction pathway can be expressed by the following reactions, which proceed in the direction of the most stable form under the present experimental conditions:

$$\text{Path 1} \quad 3Mg(OH)_2 + 2SiO_2 \rightarrow Mg_3Si_2O_5(OH)_4 + H_2O \qquad (3)$$

$$\text{Path 2} \quad 2Mg(OH)_2 + SiO_2 \rightarrow Mg_2SiO_4 + 2H_2O \qquad (4)$$

$$\text{Path 3} \quad 2Mg_3Si_2O_5(OH)_4 \rightarrow 3Mg_2SiO_4 + SiO_2 + 4H_2O \qquad (5)$$

$$\text{Path 3'} \quad 3Mg_2SiO_4 + SiO_2 + 4H_2O \rightarrow 2Mg_3Si_2O_5(OH)_4 \qquad (6)$$

$$\text{Path 4} \quad 3Mg_2SiO_4 + 5SiO_2 + 2H_2O \rightarrow 2Mg_3Si_4O_{10}(OH)_2 \qquad (7)$$

$$\text{Path 5} \quad Mg_3Si_2O_5(OH)_4 + 2SiO_2 \rightarrow Mg_3Si_4O_{10}(OH)_2 + H_2O \qquad (8)$$

These equations are all similar in form to the reactions of magnesium compounds with silica. When the plural reactants except silica take part in magnesium silicate formation, the reaction are summarized in the following equations.

$$\text{Path 2+3} \quad Mg(OH)_2 + Mg_3Si_2O_5(OH)_4 \rightarrow 2Mg_2SiO_4 + 3H_2O \qquad (9)$$

$$\text{Path 2+3'} \quad 4Mg(OH)_2 + Mg_2SiO_4 + 3SiO_2 \rightarrow 2Mg_3Si_2O_5(OH)_4 \qquad (10)$$

Unfortunately, Reactions 9 and 10 may be actually indistinguishable from the sums of Reactions 4 and 5, and Reactions 4 and 6, respectively.

In order to quantitatively determine some experimental observations on the formation of talc, we tried to analyze the experimental conversion curves. Some preliminary discussion will, however, be useful before an analysis of the rate of solid-state reaction is attempted.

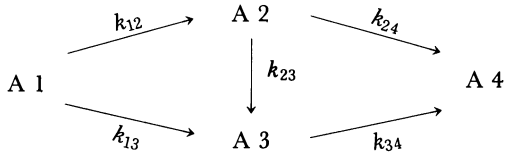
(a) The fraction reacted in a solid-state reaction is represented by a quantity of the reacting species, α_i, instead of the concentration, C_i, in a homogeneous reaction, since the concept of concentration in the reactivity of a solid is meaningless:

$$\text{Rate} = kf(\alpha_i)$$

(b) The silica concentration in hydrothermal solutions was almost constant during the reaction times, as has been described above. The silica concentration (C_{SiO_2}) can, therefore, be considered to be a constant factor of the rate constant, k:

$$k = k'C_{SiO_2}$$

We can picture a generalized reaction scheme based on the apparent reaction process 2 as follows:



where Al and A4 are brucite as a starting material and

talc as a final product respectively and where A2 and A3 are arbitrarily assigned to serpentine and forsterite as intermediate species in the reaction system. k_{12}, k_{13}, k_{23}, k_{24}, and K_{34} are the rate constants for the reaction paths. If the reaction is a first-order reaction similar to Reaction 1, described previously, the differential rate equations will be expressed as follows:

$$\frac{d\alpha_1}{dt} = -(k_{12} + k_{13})\alpha_1 \tag{11}$$

$$\frac{d\alpha_2}{dt} = k_{12}\alpha_1 - (k_{23} + k_{24})\alpha_2 \tag{12}$$

$$\frac{d\alpha_3}{dt} = k_{13}\alpha_1 + k_{23}\alpha_2 + k_{34}\alpha_3 \tag{13}$$

$$\frac{d\alpha_4}{dt} = k_{24}\alpha_2 + k_{34}\alpha_3 \tag{14}$$

where α_1, α_2, α_3, and α_4 indicate the numbers of moles of A1, A2, A3, and A4 respectively to one mole of the starting material, A1.

$$t = 0 \quad \begin{cases} \alpha_1 = 1 \\ \alpha_2 = \alpha_3 = \alpha_4 = 0 \end{cases}$$

$$t = \infty \quad \begin{cases} \alpha_1 = \alpha_2 = \alpha_3 = 0 \\ \alpha_4 = 1 \end{cases}$$

The solutions of Eqs. 11, 12, 13, and 14 are given as:

$$\alpha_1 = \exp\{-(k_{12} + k_{13})t\} \tag{15}$$

$$\alpha_2 = \frac{k_{12}}{k_{23}+k_{24}+k_{12}-k_{13}}[\exp\{-(k_{12}+k_{13})t\} - \exp\{-(k_{23}+k_{24})t\}] \tag{16}$$

$$\alpha_3 = \frac{1}{k_{34}-k_{12}-k_{13}}\left(k_{13} + \frac{k_{12}k_{23}}{k_{23}+k_{24}-k_{12}-k_{13}}\right) \times \exp\{-(k_{12}+k_{13})t\} - \frac{k_{12}k_{23}}{(k_{23}+k_{24}-k_{12}-k_{13})(k_{34}-k_{23}-k_{24})}\exp\{-(k_{23}+k_{24})t\} - \left\{\frac{1}{k_{34}-k_{12}-k_{13}}\left(k_{13} + \frac{k_{12}k_{23}}{k_{23}+k_{24}-k_{12}-k_{13}}\right) + \frac{k_{12}k_{23}}{(k_{23}+k_{24}-k_{12}-k_{13})(k_{34}-k_{23}-k_{24})}\right\}\exp(-k_{34}t) \tag{17}$$

$$\alpha_4 = 1 - \alpha_1 - \alpha_2 - \alpha_3 \tag{18}$$

These equations can be applied in any type of reaction which begins at A1 and terminates at A4 (e.g., A1→A2→A4, A1→A3→A4, A1→A2→A3→A4).

The experimental conversion curves shown in Fig. 1 were analyzed by a procedure which obtained a model curve fitted to the experimental data using a computer. These model curves are shown in Fig. 2 in comparison with the experimental data. It may be seen from this figure that the experimental observations are successfully represented by the theoretical equations except for the latter half-term of the formation of talc.

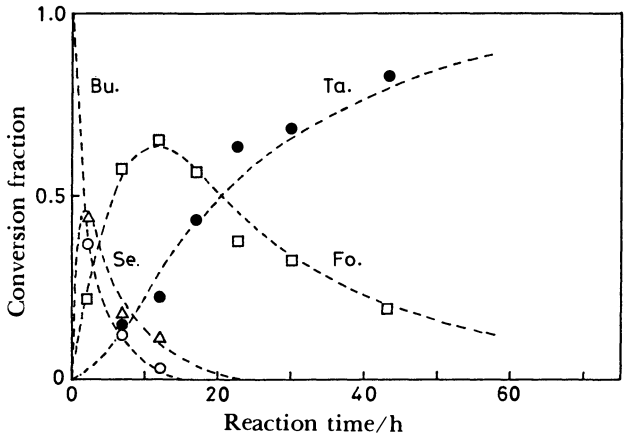


Fig. 2. Calculated conversion curves as compared to experimental conversion data at 460°C.
Bu.: brucite, Se.: serpentine, Fo.: forsterite, Ta.: talc.

The reason why the experimental rate data are represented by a first-order equation is as follows:

(a) In the present study, the concentration of silica was not a variable in the rate equation, but one of the constant factors that were contained in the rate-constant term, since the silica concentration was almost constant throughout the reaction, as has been described previously. The reaction may, therefore, be simplified to a pseudo-first-order reaction.

(b) The brucite used as a starting material was found, by electron microscopy and X-ray diffractometry, to consist of smaller disk like grains (or crystallites) a few hundred angstromes in size. Moreover, it has been observed that the amount of brucite was reduced with the reaction time, while the crystallite size of the residual brucite was changed very little by the reaction. The crystallinity of the intermediate product was also small in size (such as brucite) and did not grow during the reaction term. These results suggest that crystallites are units of the reaction and that the conversion process is controlled by a surface reaction and/or nuclei formation rather than by mass transfer. This reaction may be expressed by this equation:

$$\alpha = 1 - \exp(-kt^n) \tag{19}$$

which is universally applicable to nuclei formation and crystal growth.[14] When the rate-determining step is nuclei formation or a surface reaction, the value of n is 1. The rate of the reaction, therefore, is expressed by this equation:

$$\ln(1-\alpha) = kt \tag{20}$$

which is equal to the first-order reactions in homogeneous reactions.

The rate constants obtained are shown in Table 1.

Effect of the Equilibrium Temperature on the Overall Rate of the Reaction. Figure 3 shows the plot of log $(1/t_{0.5})$ vs. $1/T$, where $t_{0.5}$ is the time for a 50%

Table 1. Rate Constants for the Reaction of Brucite with Soluble Silica

Reaction temp	Rate constants $10^2k/h^{-1}$				
°C	k_{12}	k_{13}	k_{23}	k_{34}	k_{24}
400	6.8	—	—	—	0.63
415	11.0	—	—	—	1.4
430	8.5	0.22	0.05	0.11	1.1
445	8.0	2.7	3.5	1.3	0.42
460	28.0	8.1	19.0	4.0	3.1

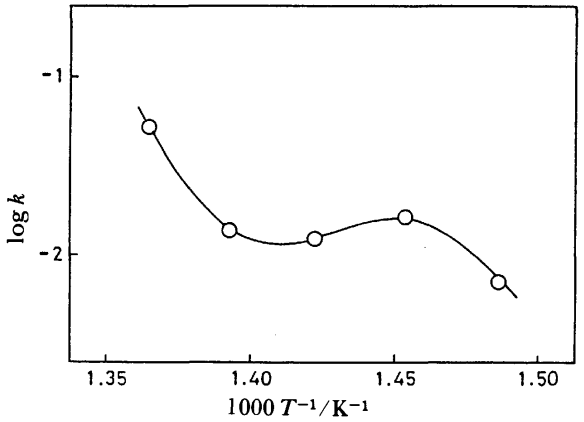

Fig. 3. Arrhenius plot of rate constant ($k=t_{0.5}^{-1}$) for the overall rate of talc formation.

formation of talc as the final product. The unit of the rate constant, $k=t_{0.5}^{-1}$, involves the h^{-1} unit. The characteristic plot obtained has a double hump; this plot is given by a lowering of the reaction rate to near the temperature at which forsterite appeared. The plots for the rate constants below 415 °C and above 445 °C may reflect the apparent activation energies for Reactions 1 and 2 respectively. In the temperature range of 415—445 °C, a plot with a slightly positive slope with a negative activation energy was obtained. This region may reflect intermediate values, behaving as a weighted means of two kinds of apparent activation energies of Reactions 1 and 2. If the rate-controlling step (or the reaction path) in such reactions as A→B→C and $A \begin{matrix} \nearrow B \\ \searrow C \end{matrix}$ changes at a particular temperature, typical plots in which two straight lines cross each other at that temperature will be obtained. In the present study, however, other factors further complicated the situation.

Arrhenius plots for the five rate constants given in Table 1 are shown in Fig. 4. The plots for k_{13}, k_{23}, and k_{34} are found to have a steep slope. These rate constants for the formation of forsterite are essentially zero at the equilibrium temperature for the brucite+serpentine⇆2 forsterite+3 H_2O reaction. Since the direction of departure from the equilibrium temperature is also equal to the direction of the rise in the temperature, the slopes of the plots for these rate constants are larger

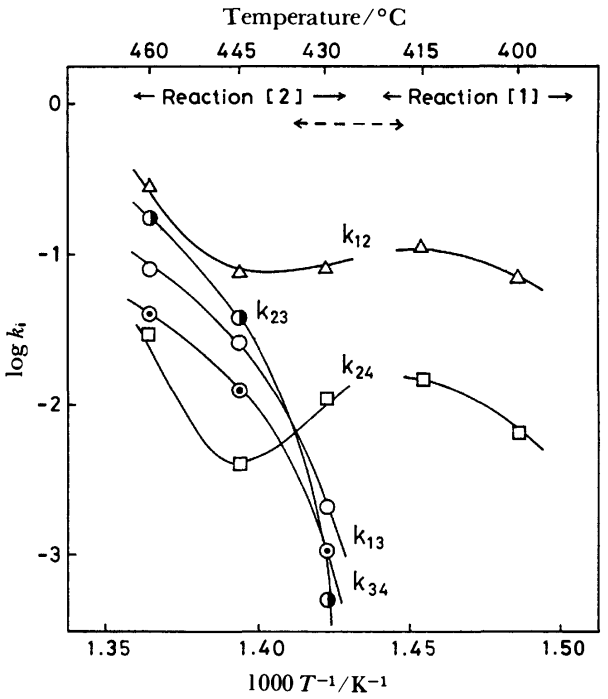

Fig. 4. Arrhenius plots of rate constants k_{12}, k_{13}, k_{23}, k_{24}, and k_{34} for each reaction path.

than the others. The plots for k_{12} and k_{24} are similar to that for the overall reaction shown in Fig. 3. These plots may be divided into three regions as has been described above. The rate of Reaction 1, which is represented by k_{12} and k_{24} at the temperature of 415 °C and below, may essentially tend to increase with an increase in the temperature, even at the temperature of 430 °C, since there are no other factors that influence the kinetics of Reaction 1 except for the appearance of forsterite. However, a part of the serpentine produced at 430 °C is transformed into forsterite, and then the apparent rate of the formation of serpentine may be lowered. The rate of talc formation may also be lowered as a result of some distortion of the nucleation. Above 445 °C, forsterite is directly formed on brucite (Path 2) rather than through serpentine (Paths 1 and 3); that is, the main path of the formation of talc consists of Paths 2 and 4. It may, then, be said that the reaction path for forsterite becomes the most important factors controlling the overall reaction with an increase in the temperature.

Some Considerations on the Formation of Intermediates. The intermediates in talc formation appeared in the order of serpentine→frosterite, as may be seen in the experimental conversion curves above 445 °C (see Fig. 1). It has also been observed that silica-adsorbed brucite, when treated hydrothermally above 420 °C, was transformed into forsterite through serpentine-like silicate,[10] although, at higher temperatures, serpentine was no longer detectable. On the other hand, the equilibrium data on the stable phases of magnesium silicate in hydrothermal solutions containing sil-

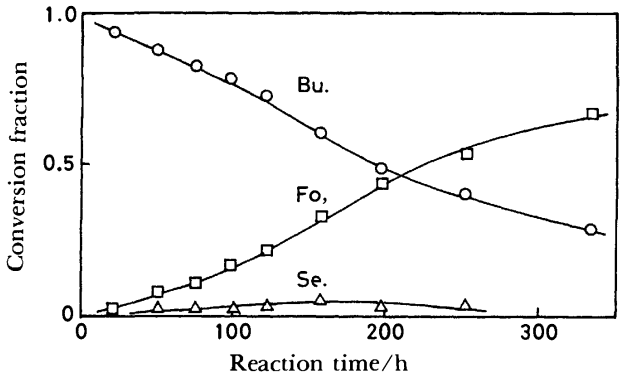

Fig. 5. Experimental conversion curve for the reaction of brucite with a low concentration solution of silica at 445°C.

ica reported by Hemley et al.[15] are different. They reported that magnesium silicates were transformed from brucite into forsterite→serpentine→talc with increases in the concentrations of silica and that the SiO_2/MgO ratios increase in that same order.

The reason why the kinetics of the formation of serpentine is much faster than that of forsterite is as follows: It may be presumed that the brucite surface is an excellent substrate for the nucleation of serpentine, since both brucite and serpentine are made of the same layered structure consisting of a Mg-O framework. The crystal nuclei of serpentine may, therefore, be generated with ease. In addition, since the formation of forsterite in accompanied by the severance of the Mg-O framework of brucite, it may require a large activation energy in the reconstructive reaction.

In order to obtain further information on the formation of serpentine and forsterite, a qualitative kinetic study was attempted under various conditions.

(a) Brucite was allowed to react under a low concentration of silica. A piece of quartz or serpentine, as a silica source, and same brucite were placed apart from each other in the same way. The reaction was very slow, and it produced a mere trace amount of serpentine. The conversion curves for the reaction of the brucite with the silica liberated from the serpentine are shown in Fig. 5.

(b) On the other hand, we employed a lod-like briquette consisting of the brucite powder as a starting material, with a smaller surface area, and examined it in the same manner as in the reaction of brucite with soluble silica. Its briquette was prepared by compressing the powder at a pressure of 50 $kg\,cm^{-2}$ by using a piston anvil. The reaction was very slow, similar to a diffusion-controlled bulk reaction in a solid. The reacted briquette was scrapped, step by step, from its surface and then evaluated. Talc, forsterite, and brucite were found to have been formed, in this order, from the surface toward the inner part. Only a small amount of serpentine was detected throughout the reaction.

In addition to the reaction rate, the differences in the reaction conditions influenced the appearance of intermediates. It can be seen from these results that the surface of the brucite powders contribute much to the nucleation of serpentine; when its surface is in contact with a higher concentration of silica solutions, they contribute still more. On the other hand, forsterite as a intermediate mainly appears when larger grains of brucite are used, when there is lower concentrated solution of silica, and at a temperature higher than the equilibrium temperature. Thus, in addition to the temperature, both the apparent (or net) grain size of the reactant and the silica concentration contribute to the appearance of an intermediate.

The author wishes to express his thanks to Dr. Shigeto Kitahara for his kind guidance and continuous encouragement throughout this work. The author also would like to thank Mr. Hideo Nagata for his assistance in the preparation of the silicate and in obtaining the X-ray diffraction data.

The Effects of the Sol-Gel Transition of Alginates on Effective Charge Densities

Masakatsu YONESE,* Kazuhiko BABA, and Hiroshi KISHIMOTO
Faculty of Pharmaceutical Sciences, Nagoya City University, Tanabe-dori, Mizuho-ku, Nagoya 467
(Received September 28, 1987)

The counterion binding properties of alginate (Alg) sol and gel were studied by using the membrane potential method, in which membranes were constructed of an Alg layer sandwiched between supporting films. The concentrations of Alg W_{Alg} ranged from 0.0025 to 0.0063 g cm^{-3}, and the membrane potentials were measured in NaCl, $MgCl_2$, and $CaCl_2$ solutions. The effective charge densities of Alg (θ^{*2}) were obtained by curve fittings with the theoretical values of the multimembrane potentials. The ratios of θ^{*2} to the concentration of uronate units θ_0 were found not to depend on W_{Alg}; their mean values were 0.45, 0.28, and 0.12 for Na-, Mg-, and CaAlg. The results of Na- and MgAlg in the sol state were bigger than Manning's theoretical values. The much smaller values of CaAlg in the gel state than MgAlg in the sol state showed that the Ca ion binding was enhanced by the gellation not only in the junction, but also in the networks.

Alginate (Alg) is a major structural polysaccharide found in intercelluar substances of brown algae, such as Laminaria hyperbória and Laminaria digitata, and is a linear block copolymer of β-D-mannuronate (M) and its C-5 epimer, α-L-guluronate (G). They link together in an alternative way (MG block) or in consecutive homopolymeric ways (G and M block). The ratio of M and G and the block compositions vary with the sources of brown algaes, and even with the same source, they vary by part and by age.[1] Alginates are gelled by the addition of divalent metal ions M^{++}, except for Mg^{++} ions. The crosslinks are formed by the stackings of the G blocks of alginate chains mediated by M^{++}.[2-4] Differing from thermotropic gels, such as carrageenan, Alg shows a sol-gel transition without any alteration in the temperature.[5] Therefore, it is a very valuable polysaccharide for basic studies of gel and for applications in the pharmaceutical field.[6,7]

The counterion-binding properties of Alg have been studied primarily by means of a dialysis-equilibrium method, and the divalent metal ions inducing its gellation have been reported to bind spcifically.[8-10] To elucidate the counterion-binding properties of Alg in sol and gel states, the membrane potential method[11] was used; in the method, membranes are constructed of an Alg sol and gel layer sandwiched between supporting films. The effective charge densities of Alg are studied. This method makes it possible to study the charge densities of both the sol and the gel, i.e., the effects of the sol-gel transition of Alg on counterion-bindings.

Experimental

Materials. Purified sodium alginate (NaAlg) was prepared from commercial NaAlg (Tokyo Kasei Kogyo Co., Ltd.) by dialyzing it against distilled water for 3 days, followed by filtration to remove any insoluble substances. The NaAlg thus purifed was stored under refrigeration after freeze-drying. The weight average molar mass of NaAlg was determined to be $M_w=1.32\cdot10^5$ g mol^{-1} by using a light scattering photometer LS-8 (Toyo Soda Manufacturing Co., Ltd., Japan). The compositions of NaAlg were analyzed by means of circular dichroism, CD,[12] and ^{1}H NMR.[13] The guluronate fraction F_G was found to be 0.33 or 0.37 by the two methods, while the fraction of the consecutive guluronate block F_{GG} and that of the alternative block composed of guluronate and mannuronate F_{MG} were determined to be 0.28 and 0.18 by ^{1}H NMR. All the other reagents were special grade. Distilled and deionized water was used for the preparation of aqueous solutions.

Measurement of Membrane Potential. In order to estimate the effective charge densities of polyelectrolyte solutions, the membrane potentials were studied by using the multimembrane, shown in Fig. 1 (a), constructed of a poly-

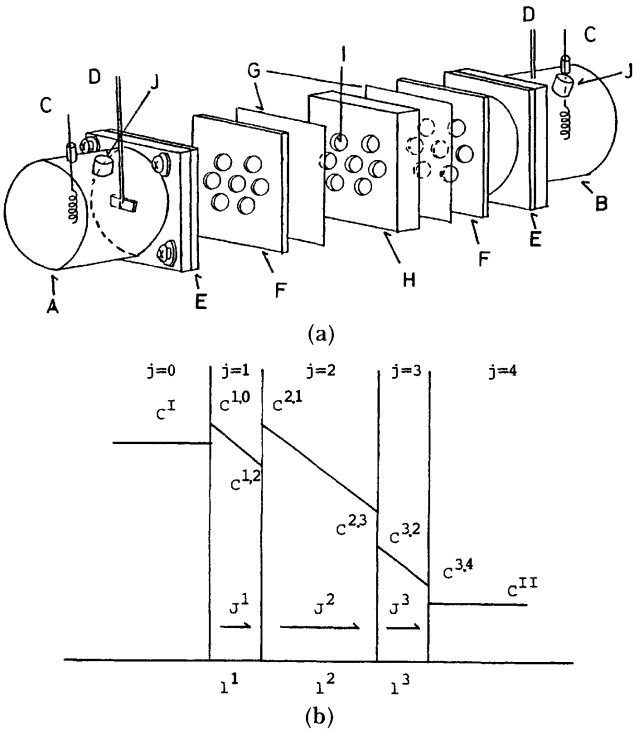

Fig. 1. Schemes of multimembrane. (a) Membrane potential measurement cell. A; compartment I, B; compartment II, C; Ag/AgCl electrode, D; stirring bar, E; silicone rubber, F; perforated stainless steel plate, G; support film (first and third layer), H; perforated polyacrylic resin plate, I; sample injection hole (second layer), J; inlet for solution injection. electrolyte solution layer (I) sandwiched between supporting films (G): Solution I |Film| Polyelectrolyte solution layer |Film| Solution II. Dialysis membranes, C.M., (0.0033 cm in thickness, Seamless Cellulose Tubing, Union Carbide Corp.) was used as supporting films. NaAlg solutions were put into holes (I) (0.25 cm in radius) in a perforated polyacrylic resin plate (H) (0.3 cm thick, with 7 holes in it), and the supporting films on both sides were fixed by means of perforated stainless steel plates (F). The concentrations of Alg W_{Alg} were in the range from 0.0025 to 0.00626 g cm^{-3}. The concentration ratios of electrolyte solutions in the Compartments I (A) and II (B), R ($=C^{I}/C^{II}$) were 10 and 2. Both solutions were stirred at 500 rpm by means of stirring bars (D) so as to attain a constant thickness of the stagnant layer (=40 μm), a value which was obtained by measuring the permeability coefficients of NaCl through the single and double dialysis membranes.[14] The membrane potentials E between Solution I and Solution II were measured by means of Ag/AgCl electrodes (C), whose electrode potentials had been obtained by using Kieland's individual activil coefficients.[15] To obtain the effective charge density of the supporting films, C.M., the membrane potentials were measured in the following systems: Solution I |Supporting film| Solution II. All the membrane potentials were measured at 25 °C.

Theory and Method

Membrane Potential of Supporting Film. When a charged membrane separates electrolyte solution I and II whose concentration ratio C^{I}/C^{II} is R, the membrane potentials E are obtained by the summation of the diffusion potential in the membrane phase E^* and the Donnan potentials E_B at both interfaces;[16-18] they are expressed by the following equation:

$$E=E^{II}-E^{I}=(RT/F)((1/z_A)\ln R+(1/z_A)\ln(C^{II}/C^{I}) +((1/z_M-1/z_A)T_A^*-1/z_M)\times \ln((\bar{C}^{I}-(1/z_A)(1-T_A^*)\theta^*)/(\bar{C}^{II}-(1/z_A)(1-T_A^*)\theta^*)) \quad (1)$$

where θ^* and T_A^* are effective charge density of the membrane and the transference number of the anion in it. $\bar{C}_A^{I}$ and $\bar{C}_A^{II}$ are the interfacial concentration of the anion, and z_A and z_M are algebraic valences of the anion and the cation. The interfacial concentrations can be obtained by using the Donnan equilibrium between ions in the membrane phase and in bulk solutions, expressed by Eq. 2, and the electro-neutrality condition expressed by Eq. 3:

$$(\bar{C}_A/C_A)^{1/z_A}=(\bar{C}_M/C_M)^{1/z_M} \quad (2)$$

$$z_M\bar{C}_M+z_A\bar{C}_A+\theta^*=0 \quad (3)$$

Membrane Potentials of Multimembranes. The multimembrane, consisting of the polyelectrolyte solution sandwiched between supporting films, is shown in Fig. 1. The membrane potential E is the summation of the interfacial potentials generated at each interface of the multimembrane and the diffusion potential in each layer. According to the notations in Fig. 1 (b), E is expressed by the following equation:

$$E=\sum_{j=0}^{3}E_B^{j,j+1}+\sum_{j=1}^{3}E^{*j} \quad (4)$$

where $E_B^{j,j+1}$ and E^{*j} are the donnan potential at each interface and the diffusion potential in each layer respectively; the superscripts j and $(j,j+1)$ denote the jth layer and the interface between j and the $(j+1)$th layer respectively. The superscripts 0 and 4 denote Solution I and II, the first and third layers are supporting films, and the second one is the polyelectrolyte-solution layer. Denoting the concentration of the jth layer at the interface j and $(j+1)$th one by $\bar{C}^{j,j+1}$, and the effective charge density of the jth layer by θ^{*j}, E can be expressed by:

$$E=\frac{RT}{F}\left[\sum_{j=0}^{3}\ln\frac{\bar{C}_A^{j+1,j}}{\bar{C}_A^{j,j+1}}+\left\{\left(\frac{1}{z_M}+\frac{1}{z_A}\right)T_A^{*j}-\frac{1}{z_M}\right\}\times \sum_{j=1}^{3}\frac{\bar{C}_A^{j,j-1}+\frac{1}{z_A}(1-T_A^{*j})\theta^{*j}}{\bar{C}_A^{j,j+1}+\frac{1}{z_A}(1-T_A^{*j})\theta^{*j}}\right] \quad (5)$$

where T_A^{*j} is the transference number of the anion A in the jth layer. The Donnan equilibrium and the electro-neutrality conditions at each interface are expressed by the following equations:

$$(\bar{C}_A^{j+1,j}/\bar{C}_A^{j,j+1})^{1/z_A}=(\bar{C}_M^{j+1,j}/\bar{C}_M^{j,j+1})^{1/z_M} \quad (6)$$

$$z_M\bar{C}_M^{j,j+1}+z_A\bar{C}_A^{j,j+1}+\theta^{*j}=0 \quad (7)$$

$$z_M\bar{C}_M^{j+1,j}+z_A\bar{C}_A^{j+1,j}+\theta^{*j+1}=0 \quad (8)$$

j=0, 1, 2, and 3

where θ^{*0} and θ^{*4}, denoting the values of Solution I and II, are equal to 0. When θ^{*1} and θ^{*3} are known, $\bar{C}_A^{1,0}$ $\bar{C}_M^{1,0}$, $\bar{C}_A^{3,4}$, and $\bar{C}_M^{3,4}$ can be obtained by means of Eqs. 6—8 and as functions of C^{I} or C^{II}. Under steady state conditions, the fluxes of the ions J_i^j are equal in each layer, according to the continuity law:

$$J_i^1=J_i^2=J_i^3 \quad (9)$$

Approximating that concentrations of ions in each layer vary linearly,[19-21] the fluxes of the anion A are expressed by:

$$J_A^j=-P_A^j\frac{\bar{C}_A^{j,j+1}-\bar{C}_A^{j,j-1}}{l^j}(1+X) \quad (10)$$

$$X=\frac{\frac{z_M}{z_M-z_A}\theta^{*j}(\frac{1}{z_M}-\frac{1}{z_A})T_A^{*j}}{\bar{C}_A^{j,j+1}-\bar{C}_A^{j,j-1}}\times \ln\frac{\frac{z_M-z_A}{z_M}\bar{C}_A^{j,j+1}-(\frac{1}{z_M}-\frac{1}{z_A})(1-T_A^{*j})\theta^{*j}}{\frac{z_M-z_A}{z_M}\bar{C}_A^{j,j-1}-(\frac{1}{z_M}-\frac{1}{z_A})(1-T_A^{*j})\theta^{*j}} \quad (11)$$

j=1, 2, and 3

where P_A^j is the permeabiity coefficient of the anion in the j layer and where l^j is the thickness of the j layer. So as to satisfy Eq. 9, $\bar{C}_A^{1,2}$, $\bar{C}_A^{2,1}$, $\bar{C}_A^{2,3}$, and $\bar{C}_A^{3,2}$ can be obtained from Eq. 10 by numerical analysis. Then, the

membrane potentials E can be obtained from Eq. 5.

The effects of the supporting films on the membrane potential of the multimembrane can be discussed theoretically. Figures 2 and 3 show some of the calculated membrane potentials. The effects of the effective charge densities of the supporting films ($\theta^{*1}=\theta^{*3}$) on the membrane potentials are shown in Fig. 2. The effective charge density of the second layer is $\theta^{*2}=-0.01$ mol dm^{-3}, while those of the supporting films (θ^{*1} and θ^{*3}) vary from 0 to -0.1. The effects of θ^{*2} on E are shown in Fig. 3. The effective charge densities of the supporting films are $\theta^{*1}=\theta^{*3}=-0.01$ mol dm^{-3}, while that of the second layer varies from 0 to -0.1. In the calculations, Solution I and II are assumed to be NaCl solutions, and their ratio R to be 10. The P^{*1} ($=P^{*3}$) value is $1.92\cdot10^{-6}$ cm^2 s^{-1} which was obtained experimentally, and P^{*2} is $1.60\cdot10^{-5}$ cm^2 s^{-1}, which is approximated to be equal to the diffusion coefficient in an aqueous solution. The transference numbers of ions in membranes have been reported to be almost equal to those in their solutions.[16-18] Then, as the T_A^* value, the transference number of Cl^- in an NaCl solution was cited from the literature.[22] The thickness of the supporting films and the second layer are 0.0033 cm ($=l^1=l^3$) and 0.3 cm respectively, which are the same dimensions as those in the cell shown in Fig. 1 (a). It should be noted that the membrane potentials are affected not only by the effective charge densities of these layers but also by the diffusivities of ions through them. As the effective charge density of a supporting film θ^{*1} ($=\theta^{*3}$) drcreases under a constant θ^{*2}, as is shown in Fig. 2, the membrane potentials E are found to decrease abruptly in the lower-concentration region. When the θ^{*1} values are smaller than -0.001, the E values are almost the same; i.e., if θ^{*1} is at least smaller than one tenth of θ^{*2}, E is almost equal to those of $\theta^{*1}=0$. As is shown in Fig. 3, even when the θ^{*2} values are smaller than θ^{*1} ($=-0.01$), such as $\theta^{*2}=-0.001$ and -0.005, the differences between their membrane potentials are found to be clear, and even in these cases the θ^{*2} values can be obtained by the curve-fitting method.

Results

Effective Charge Density of Support Film. The membrane potentials of the supporting films C.M. were measured for NaCl, $MgCl_2$, and $CaCl_2$ solutions; the results are shown as functions of log C^I in Fig. 4. Their concentration ratios R ($=C^I/C^{II}$) were 10. The E values showed a shift from Donnan potentials to diffusion potentials with the increase in C^I. By the curve-fitting method, the effective charge densities of the film C.M., θ^*, were determined. The solid curves show the theoretical values obtained from Eq. 1 by selecting their most suitable values θ^* so as to agree with the experimental results in the high-concentration regions. In the calculations of the theoretical values, as the T_A^* values the transference numbers of the anion in the solutions were cited from the literature.[22] The θ^* values of the supporting film were found to be -0.0028, -0.0025, and -0.0026 mol dm^{-3} for NaCl, $MgCl_2$ and $CaCl_2$ solutions.

Effective Charge Densities of Alginates. The membrane potentials of the multimembranes (|Film C.M. |Alg Solution|Film C.M.|) were measured for the NaCl and $MgCl_2$ solutions, whose concentration ratio R was 10. The Alg solutions in the membrane ranged from W_{Alg}=0.00250 to 0.00262 g cm^{-3}. As is shown in Fig. 5, the E values showed abrupt decreases in the higher-concentration regions with the increase of W_{Alg}. The solid curves show the theoretical values obtained by selecting the most suitable values for the effective charge densities of alginate solutions, θ^{*2}, so as to agree with the experimental results. The θ^{*2} values are shown in Table 1, in which the effective

a) CaAlg gelled by 1.0 mol dm^{-3}. b): $T_A^*=T_A^{*1}=T_A^{*2}=T_A^{*3}$. θ^{*1}: charge density of supporting film C.M.($=\theta^{*3}$). θ^{*2}: charge density of Alg. θ_0: concentration of Alg on the basis of uronate units.

charge densities of the supporting films C.M. θ^{*1} ($=\theta^{*3}$) and the transference numbers of the anion T_A^{*i} used in calculations are also shown. The absolute values θ^{*2} for the NaCl solution were bigger than those for $MgCl_2$, and they increased with the increase in W_{Alg}. Figure 6 shows the membrane potentials for the NaCl and $MgCl_2$ solutions, whose concentration ratio R was 2. The most suitable θ^{*2} values of Alg are shown in Table 1, also. They were in good agreement with the θ^{*2} values obtained when R=10.

In the cases of the NaCl and $MgCl_2$ solutions, the Alg were in sol states, but in the case of the $CaCl_2$ solutions they were in the gel state. The membrane potentials of the Alg in the gel state were measured as follows. The Alg sols (NaAlg) in the second layer were transited to gel by putting $CaCl_2$ solutions (1.0 mol dm^{-3}) into both compartments, I and II, and before the measurements of E, the free ions in the CaAlg gel layer were removed by dialysis against distilled water. Figure 7 shows the membrane potentials of the multimembranes containing CaAlg gels for NaCl and $CaCl_2$ solutions (R=10) and also the theoretical curves obtained by using the most suitable effective charge densities θ^{2*}, which are shown in Table 1. The absolute values of the effective charge density of CaAlg were found to be less than those of MgAlg. This is attributable to the capture of the Ca ion in the junctions. The absolute values of θ^{*2} of CaAlg for NaCl-solution systems were bigger than those for $CaCl_2$ solutions. This is considered to result from the partial ion-exchange of Ca with Na ions.

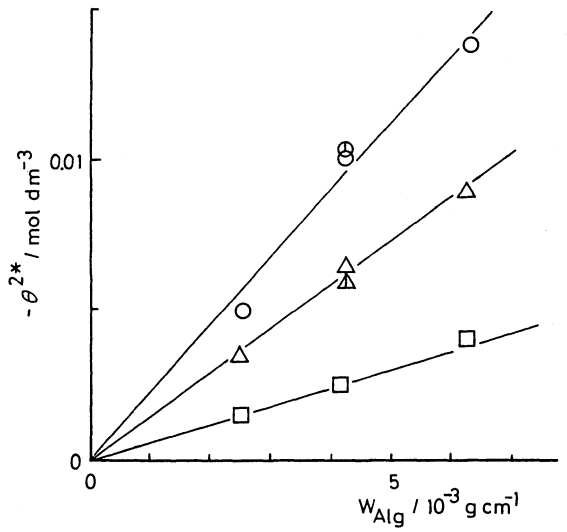

Fig. 8. Effective charge densities vs. concentrations of alginates. NaAlg: ○ (R=10), ⊕ (R=2). MgAlg: △ (R=10), ▲ (R=2). CaAlg: □ (R=10).

Figure 8 shows the effective charge densities of alginates as a function of the concentration of alginates W_{Alg}. As W_{Alg} increases, the absolute values increase almost linearly; their magnitudes were as follows; Na- > Mg- > Ca-Alg.

Discussion

Counterion-Binding Characteristics of Alginates. The concentration of Alg based on the uronate units, which corresponds to the concentration of carboxyl groups C_{car} mol dm^{-3}, is obtained by the use of Eq. 12. If all the carboxyl groups work as charged groups, the absolute value of the charge density of Alg is equal to C_{car}:

$$C_{car}=|\theta_0|=10^3\, W_{Alg}/M_u, \qquad (12)$$

where M_u is the molar mass of the uronates. The ratios of the effective charge density of Alg to θ_0, θ^{*2}/θ_0, show the fractions of the ionized carboxyl groups. The W_{Alg} in the second layer might decrease because of osmotic pressures. However, by the help of the perforated support plates (F) shown in Fig. 1 (a), we estimate that the decrease in W_{Alg} could be neglected. As is shown in Table 1, the θ^{*2}/θ_0 values were found not to depend remarkably on W_{Alg} in the experimental region. The mean θ^{*2}/θ_0 values for Na-, Mg-, and CaAlg were 0.45, 0.28, and 0.12 respectively. Na- and MgAlg were in sol states. The interactions of Na^+ and Mg^{2+} with Alg were dominantly electrostatical. Therefore, the differences in their values θ^{*2}/θ_0 can be surmised to result from their valence effects. Ca ions mediate the stackings of Alg molecules to form the junctions.[2-4] Then, the much smaller value of CaAlg than MgAlg results from the constraints of Ca ions in the junctions and in the networks.

Alg can be considered to behave as a rod like polyelectrolyte in diluted solutions, because of the electrostatical repulsive force between the charged groups and the rigidity of their saccharide structure. Manning's theory[23,24] is appropriate for discussing the thermodynamic quantities of rod like polyelectrolytes in diluted solutions.[25-30] By comparing our results with the

theoretical results, the effects of the polymer-polymer interactions and the network formations on counterion bindings can be discussed. In theory, the interaction of polyelectrolytes with counterions are considered to be of two modes: the Debye-Hückel ion atmosphere and the condensation on charged groups. The key parameter, ξ, for the counterion condensation in Manning's theory is defined by Eq. 13 and is proportional to the line charge density,[23,24] i.e., the reciprocal of the distance between the neighbouring charged groups b:

$$\xi = e^2/(4\pi\varepsilon kTb) \quad (13)$$

where e is the protonic charge and where ε is the permitivity of the solvent. The b value of NaAlg has been reported to be 0.497 nm, and the ξ value, 1.43.[31] The osmotic coefficients ϕ_M of salt-free polyelectrolytes are expressed by:

$$\phi_M = 1/(2z_i\xi) \quad (14)$$

The theoretical ϕ_M values of Alg with monovalent and divalent counterions are 0.35 and 0.17. The ϕ_M value can be considered approximately to be the degree of ionization of the charged groups in polymers.[32] By comparing the experimental θ^{*2}/θ_0 values shown in Table 1 with the ϕ_M values, we can see that both results for Na- and MgAlg were much larger than the ϕ_M values. Kobatake et al.[11] discussed precisely the thermodynamical and hydrodynamical effective charge densities of Poly (styrenesulfonate) (PSS) solutions by using the membrane-potential and Donnan-potential methods. Their θ^{*2}/θ_0 values of potassium salt of PSS (KPSS) obtained from the membrane potential were reported to be 0.4. As the theoretical value ϕ_M of KPSS is 0.18,[24] the effective charge density was also much greater than the ϕ_M value. It is a significant problem that the effective charge densities of polyelectrolyte solutions are much greater than the ϕ_M values. This might be the effect of the hydrodynamical effects described by Kobatake et al.[11]

Effects of Gellation on Ca-Ion Bindings. The electrostatical interactions of Mg and Ca ions with Alg are assumed to be equal. Then, the difference in θ^{*2}/θ_0 between Mg- and CaAlg, $|(\theta^{*2}(\text{MgAlg})-\theta^{*2}(\text{CaAlg}))/\theta_0|=0.16$, shows the ratio of the enhanced Ca-ion bindings due to the gellation of Alg. Whether this increase results primarily from the entrapping of Ca ions in the junctions should be discussed. When the fraction of the junctions in a Alg molecule is F_j, on the basis of the concentration of the uronate units, and when the Ca-ion binding ratio in the junctions and in the Alg chains between the junctions are $(\sigma_j)_{Ca}$ and $(\sigma_i)_{Ca}$, the fraction of ionized carboxyl groups in CaAlg gels $(\theta^{*2}/\theta_0)_{Ca}$ can be expressed by the following equation:

$$(\theta^{*2}/\theta_0)_{Ca} = F_j(1-(\sigma_j)_{Ca}) + (1-F_j)(1-(\sigma_i)_{Ca}). \quad (15)$$

The Ca ions entrapped in the junctions can be assumed to bind completely to Alg,[33] i.e., $(\sigma_j)_{Ca}=1$, and all GG blocks are assumed to contribute to the formation of the junctions, i.e., $F_j=F_{GG}=0.28$. Under these assumptions, the value $(\sigma_i)_{Ca}$ of CaAlg is calculated from the result $(\theta^{*2}/\theta_0)_{Ca}$ (=0.12); it is 0.83, which is bigger than the Mg-ion-binding ratio σ_{Mg} (=$(1-(\theta^{*2}/\theta_0)_{Mg}$=0.72). Actually, F_j is considered to be smaller than F_{GG}. Therefore, $(\sigma_i)_{Ca}$ should be bigger than 0.83. From these considerations, it can be concluded that the Ca-ion bindings are enhanced by the gellation not only in the junction, but even in the regions between the junctions, i.e., in the networks.

The Crystal and Molecular Structures of *N*-Phenyl-4-nitrobenzylamine, *N*-Phenyl-4-nitrophenethylamine, and *N*-Methyl-*N*-*p*-tolyl-4-nitrophenethylamine

Fujiko IWASAKI,* Yoshiaki MASUKO, Sachiko MONMA, Toshiya WATANABE, and Kiyoshi MUTAI†
Department of Materials Science, The University of Electro-Communications, Chofu-shi, Tokyo 182
†Department of Chemistry, College of General Education, University of Tokyo, Komaba, Meguro, Tokyo 153
(Received October 2, 1987)

The crystal and molecular structures of *N*-phenyl-4-nitrobenzylamine (**1**), *N*-phenyl-4-nitrophenethylamine (**2**), and *N*-methyl-*N*-*p*-tolyl-4-nitrophenethylamine (**3**) have been determined by the X-ray method. The crystals of **1** are monoclinic, $P2_1/n$, a=16.924(1), b=8.792(1), c=7.642(1) Å, β=91.59(1)°, V=1136.8(1) Å^3, Z=4, D_x=1.334 Mg m^{-3}. **2** is triclinic, $P\bar{1}$, a=15.106(1), b=9.573(1), c=9.427(1) Å, α=113.22(1), β=91.27(1), γ=83.61(1)°, V=1244.7(2) Å^3, Z=4, D_x=1.293 Mg m^{-3}. **3** is trigonal, $P3_1$, a=b=8.435(1), c=17.758(1) Å, α=β=90°, γ=120°, V=1094.2 Å^3, Z=3, D_x=1.231 Mg m^{-3}. The final R values are 0.064, 0.059, and 0.045 for 1625, 3606, and 1131 observed reflections of **1**, **2**, and **3**, respectively. About the amino-methylene N–C bond the phenyl group is trans to C for the molecules of **1** and **2**, while in **3** the phenyl group is gauche to C about the N–C bond. The nitrophenyl plane of **3** is stacked on the *p*-toluidino plane of the neighbouring molecule alternately with the mean distance of 3.40 Å. The presence of the intermolecular CT interaction of **3** has been confirmed by the electronic absorption spectra of these compounds in the solid state.

Intramolecular interactions, especially a charge-transfer interaction, are extensively studied for *N*-[ω-(4-nitrophenyl)alkyl]anilines in which electron donor (anilino) and acceptor (4-nitrophenyl) moieties are bound together by a polymethylene chain.[1] The study with UV-VIS spectroscopy revealed that the solutions of the lower homologs show the presence of an intramolecular charge-transfer interaction, which is also detectable by the pale yellow color of the dilute solutions (ca. 10^{-4} mol dm^{-3}). Since the color persists in solid, even in the higher homologs, we suspected the presence of another type of intramolecular donor-acceptor interaction in the solid state. The crystal structure analysis of *N*-phenyl-4-nitrobenzylamine (**1**), *N*-phenyl-4-nitrophenethylamine (**2**), and *N*-methyl-*N*-*p*-tolyl-4-nitrophenethylamine (**3**) was carried out by the X-ray method in order to determine their molecular conformations and intra- and/or intermo-

lecular interactions. The compounds **1** and **2** were chosen because they are the first two members of the homologous series of the most basic group studied so far. The compound **3** was chosen on account of its remarkable orange-red color in the crystals, while the other derivatives studied are all pale brown or yellow in the solid state.

Experimental

X-Ray Crystal Structure Determination. Crystal data and some experimental conditions are listed in Table 1. Intensities were collected on a Rigaku automatic diffractometer with graphite-monochromated Cu $K\alpha_1$ (λ=1.54051 Å) radiation, using the ω-2θ scan technique with a scanning rate of 4° min^{-1} in 2θ. At both ends of the scan range 10s background counts were taken for each reflection. Three reflections were monitored after every 50 reflections. Variations of intensities of the monitored reflections were within 1, 1.5, and 2% for **1**, **2**, and **3**, respectively. Reflections with $|F_o| \geqslant 3\sigma(F_o)$ were used for structure determination.

The structures were solved by the direct method with the program MULTAN 78.[2] All non-hydrogen atoms were refined by the block-diagonal least-squares with anisotropic temperature factors. Difference maps showed all the hydrogen atoms. During the final stage of the refinement 5, 11, and 1 strong reflections which were seriously affected by extinction were omitted from the reflection data of **1**, **2**, and **3**, respectively. Least-squares refinements with anisotropic temperature factors for the non-hydrogen atoms and iso-

$B_{eq}=4/3\sum_i\sum_j \beta_{ij}\boldsymbol{a}_i\cdot\boldsymbol{a}_j$.
The e.s.d.'s in parentheses refer to the last digits.

tropic ones for H gave the final R values of 0.060, 0.051, and 0.041 for 1620, 3595, and 1130 reflections of **1**, **2**, and **3**, respectively. The quantity minimized was $\sum w(|F_o|-k^{-1}|F_c|)^2$. For **1**, $w=1/(0.41515-0.0188|F_o|+0.0016|F_o|^2)$, for **2**, $w=1$ for all reflections, and for **3**, $w=1/(0.1936+0.0157|F_o|+0.0014|F_o|^2)$. The R values for 1625, 3606, and 1131 observed reflections of **1**, **2**, and **3** were 0.064, 0.059, and 0.045, respectively. Atomic scattering factors were taken from International Tables for X-Ray Crystallography.[3] All computations were performed on a HITAC M180 Computer of the Data Processing Center of the University of Electro-Communications with the programs UNICS III,[4] MULTAN 78,[2] and ORTEP II.[5] The final atomic parameters are given in Table 2.[6]

Electronic Spectra. A small amount of crystals of **1**—**3** was melted on a quartz plate (22×13×1 mm^3), covered with another quartz plate of nearly the same size, and left to crystallize. No attempt was made to control the thickness of the solid. The absorption spectrum of the plate was recorded on a Hitachi UV-3200 spectrophotometer.

Discussion

Molecular Structures. The molecular structures with the atomic numbering are shown in Fig. 1. Bond distances and angles are listed in Table 3. Some torsion angles are listed in Table 4. For **2**, there are two crystallographically independent molecules, **A** and **B**, in an asymmetric unit. These two molecules, however, have the same structures within the experimental errors. For **1** the phenyl group is trans to the 4-nitrophenyl group about the N(1)-C(7) bond. The

torsion angle of C(1)-N(1)-C(7)-C(9) is 175.2(2)°, while the corresponding angle of *N*-(2-bromophenyl)-2-bromobenzylamine is 88.5° because of the existence of large ortho substituents.[7] For **2** the phenyl group is trans to C(8) about the N(1)-C(7) bond and N(1) is trans to the 4-nitrophenyl group about the C(7)-C(8) bond. On the other hand in the case of **3** the phenyl group is gauche to C(8) about the N(1)-C(7) bond and N(1) is trans to 4-nitrophenyl group about the C(7)-C(8) bond. To analyze the planarity of molecular moieties, each molecule has been devided into three fragments: (1) C(1)—C(6) plane of the phenyl or *p*-tolyl groups; (2) C(9)—C(14) of the nitrophenyl groups; and (3) the central chain N(1)-C(7)-C(9) of **1** or N(1)-C(7)-C(8) of **2** and **3**. The dihedral angles of these planes are also listed in Table 4. The phenyl group of **1** and **2** is roughly parallel to the central chain and the 4-nitrophenyl group of **2** is perpendicular to the plane (3). For **3** both six membered rings are almost perpendicular to the central chain, and they are approximately parallel to each other. The nitro group of each compound is nearly coplanar to the phenyl ring. The dihedral angles beween the plane (2) and the nitro group are 3.6, 2.7, 2.6, and 0.4°, for **1**, **2A**, **2B**, and **3**, respectively.

Significant differences are observed about the dimensions of the amino groups between **1** and the other compounds, **2** and **3**. The N(1)-C(1) bond of **1** is longer than those of **2** and **3**, while the N(1)-C(7) bond of **1** is shorter than those of **2** and **3**. The bond angle of C(1)-N(1)-C(7) of **1** is slightly smaller than the corresponding angles of **2** and **3**. The N(1)-C(1) bonds of **2** and **3** show a larger double-bonded character compared with those of anilines. The corresponding length of *N*-benzylideneaniline is 1.460 Å.[8] These features correspond to the difference of the planarity of the amino plane C(1)-N(1)R-C(7) (R=H(1) or C(16)) between the benzyl and phenethyl compounds. The deviations of N(1) from the plane defined by C(1), C(7) and H(1)/C(16) are 0.259, 0.167, 0.125, and 0.145 Å for **1**, **2A**, **2B**, and **3**, respectively.

Crystal Stuctures and Interactions. Crystal structures are shown in Fig. 2 and some intermolecular contacts are listed in Table 5. The packing mode of the molecules in the crystal **2** is approximately $P2_1/c$. There are no special contacts suggesting an intermolecular CT interaction nor an NH ··· O hydrogen bond for **1** and **2**, in spite of the possibility of these interactions. On the other hand in the case of **3** the nitrophenyl plane is stacked on the *p*-tolyl plane of the neighbouring molecule alternately, as shown in Fig. 3.

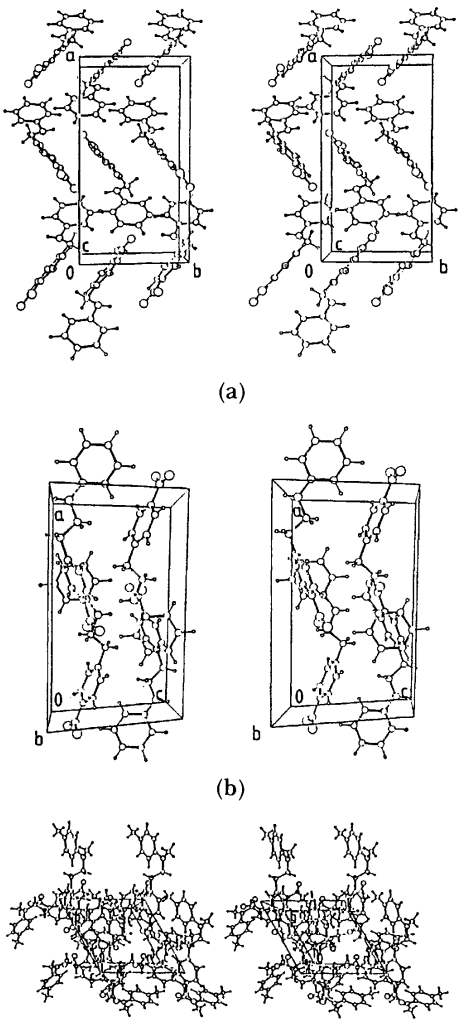

Fig. 2. Stereoscopic view of the crystal structures. (a) **1**, (b) **2**, and (c) **3**.

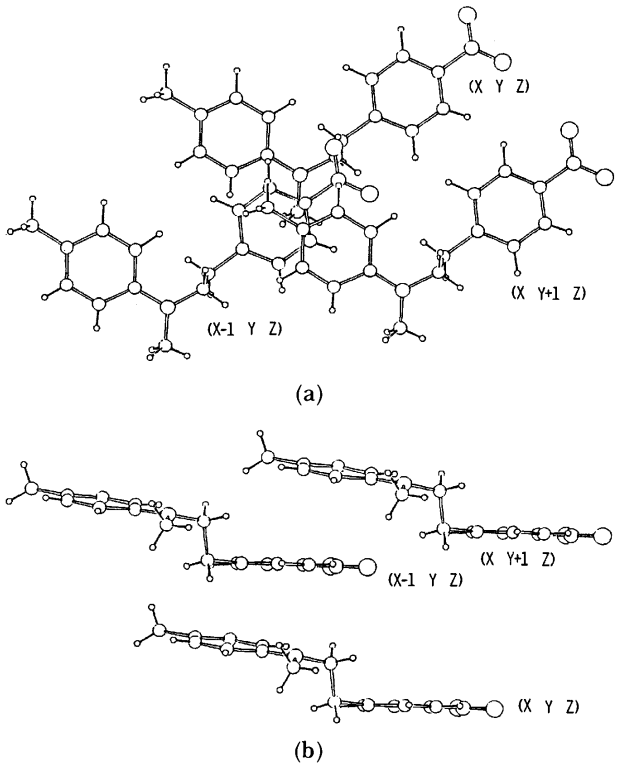

Fig. 3. Molecular stacking of **3**. (a) Projection to the nitrophenyl plane. (b) Side view of the stacking

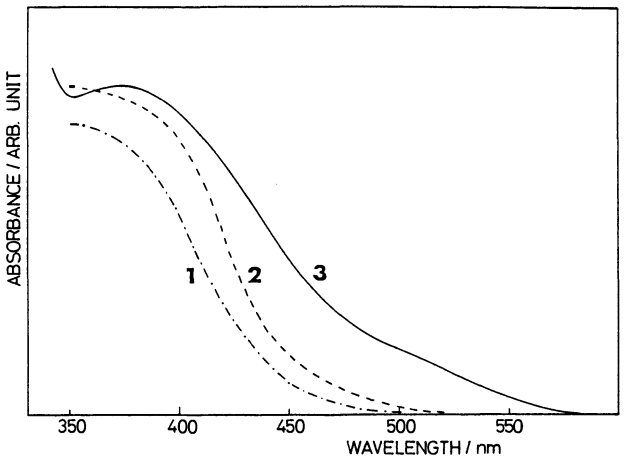

Fig. 4. Electronic spectra of **1**, **2**, and **3** in the solid state. Absorbance is in an arbitrary unit.

The mean distance between these planes is 3.40 Å, which is short enough for π-π overlap or CT interaction and this may relate to the orange-red color of the crystals of **3** compared to pale-brown of **1** and **2**. In order to confirm the presence of the interaction, the electronic absorption spectra of these compounds in the solid state were measured. As illustrated in Fig. 4, **1** and **2** show almost a similar spectral curve. On the other hand **3** has an extra absorption at 400—600 nm region, which is undoubtedly responsible for its orange-red color. Taking into account the molecular arrangement of **3** in the crystals, it is reasonable to conclude that there is an intermolecular CT interaction between 4-nitrophenyl and *p*-toluidino moieties.

This work was supported in part by a Grand-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

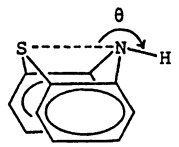
Solution Structure and Preferred Orientation of 3,7-Dichloro-10*H*-phenothiazine Dissolved in Nematic Liquid Crystal†

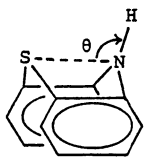
Hideaki FUJIWARA,* Masayuki WATANABE, and Yoshio SASAKI
Faculty of Pharmaceutical Sciences, Osaka University, 1-6 Yamadaoka, Suita, Osaka 565
(Received October 3, 1987)

^{1}H NMR spectrum of the title compound was measured in a nematic liquid crystal ZLI1167 and analyzed utilizing modified versions of the LAOCN program. Direct couplings obtained were interpreted on the basis of a folded structure of tricyclic framework. The results show that the dihedral angle between the two benzene rings is 153.1±2.0° and the angle of S ··· N-H is 170.9±6.7°. Hence a "H-intra" conformation is dominant in a mobile state dissolved in the nematic liquid crystal. The preferred orientation of this molecule in ZLI1167 is discussed by comparing the results with those of the dibromo analogue reported previously and by comparing the principal axes of the order tensor with those of the moment of inertia. The chlorine and bromine atoms are supposed to exert a special steric effect on the ordering of these molecules.

We have studied the solution structure and orientation of 3,7-dibromo-10*H*-phenothiazine dissolved in a thermotropic liquid crystal in a previous report of this series.[1] In that work the "H-intra" conformation was



"H-intra" form



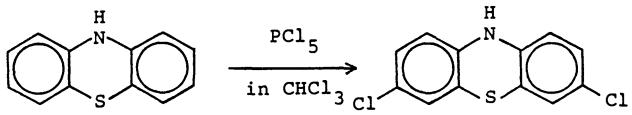
"H-extra" form

evidenced in a mobile state in conformity with a theoretical prediction[2] and crystal data[3] for 10*H*-phenothiazine. The dihedral angle between two benzene rings was observed to be smaller by ca. 10° than that reported for crystal of the unsubstituted compound. With regard to the orientation of solute in liquid crystal, bromine atoms were suggested to exert a steric effect in 3,7-dibromo-10*H*-phenothiazine.

Hitherto, several factors have been reported to be responsible for the orientation of molecules in liquid crystal, i.e., the dispersion force,[4-7] the electric dipole-dipole interaction,[4,5] and the Lewis acid-base interaction[8] between solute and solvent molecules, and further the molecular shape and the moment of inertia of solute.[9] The steric effect of substituent is also pointed out as one of these factors.[10] To investigate further the effect of substituent on the solution structure as well as on the preferred orientation, 3,7-dichloro-10*H*-phenothiazine is synthesized and analyzed in the present study. The results are discussed by comparison with those for the dibromo derivative.

Experimental

3,7-Dichloro-10*H*-phenothiazine was synthesized by the chlorination of 10*H*-phenothiazine.[11] The raw product was recrystallized from benzene after decolorizing by sodium dithionite $Na_2S_2O_4$. The final pale-green product melts at 227—229°C (lit., 227 °C[11]).



The liquid crystal ZLI1167 from Merck was used without further purification. The solute was dissolved in this solvent at a concentration of 6.7 wt%. ^{1}H NMR spectrum was measured on a Varian XL-200 NMR spectrometer operating at 200 MHz, and the prove temperature was 34.1 °C. 5000 fids were accumulated using a 40° pulse (4 μs). The acquisition time was 0.4 s over a spectral width of 8000 Hz. The data were Fourier transformed to obtain a convolution difference spectrum for 16k data points (CD=0.05 and CCD=1.0). The resulting line width was ca. 10 Hz in the center and ca. 20 Hz in the edges of the spectrum. A small amount of 1,10-phenanthlorine was added to suppress the extraordinary line broadening observed in preliminary measurements. Such broadening was probably induced by a trace amount of paramagnetic impurity. The normal spectrum in isotropic solution was measured on a Hitachi R-22 NMR spectrometer in the CW mode at 90 MHz and at 34.1 °C. Solvent used was a mixture of dimethyl sulfoxide and carbon tetrachloride (20/80 vol%), in which a better separation in chemical shift was obtained.

Analysis of the NMR spectrum observed in ZLI1167 was made by the use of programs LAO3D9 and LAO3D9D which are versions of LAOCN3 modified by the authors.[1] A program SHAPE[12] was used to calculate structural and order parameters from the experimental direct couplings. Only the diagonal terms (variances) were input for the error analysis in this program. The principal axes of moment of inertia were determined by utilizing a program XYZ.[13]

All the above calculations were done on NEAC S-1000 and SX-1 computers at the Computation Center in Osaka University.

Results and Discussion

The indirect couplings of 3,7-dichloro-10*H*-phenothiazine measured in the isotropic medium were J_{12}= 8.25 and J_{23}=2.25 Hz, other couplings being very small. The spectrum in ZLI1167 was simulated using direct couplings obtained previously for the dibromo deriv-

ative as an initial set of parameters.[1] Although the spectrum in the present case resembles to that in the previous report, simulation could not be accomplished straightforwardly. Therefore, some difference in orientation or in solution structure was expected between the two derivatives. NMR parameters reached at the completion of spectral analysis are given in Table 1. Sixty-one lines were assigned and the final rms error was 1.47 Hz in the LAOCN calculation. The

experimental and the simulated spectra are depicted in Fig. 1. We analyzed the experimental direct couplings to derive the solution structure and preferred orientation of solute in liquid crystal. The inversion rate of tricyclic framework was assumed to be slower than the rate of whole molecular reorientaion. In the previous study[1] we did not find any significant difference in the structural and ordering parameters for the two limiting models of a fast inversion and a slow one. The results of the present analysis are listed in Table 2. The weighted rms error between experimental and recalculated direct couplings was 0.202 Hz. This is a little larger than the error usually encountered in the NMR study using liquid crystal solvents. But such an error would be inevitable in the present case because experimental direct couplings contain larger errors coming from the line broadening in NMR spectrum observed especially in the edges. Such broadening may be due to a residual trace amount of paramagnetic impurity as stated above. In Table 2 structural parameters are also listed for the dibromo derivative[1] together with the crystal data of 10*H*-phenothiazine.[3] Dihedral angle (ϕ_0) and angle of S ··· N-H (θ) are both smaller in the dihalogeno derivatives as compared to those in unsubstituted 10*H*-phenothiazine. For further quantitative discussion of these angles, systematic work by the NMR spectroscopy would be necessary for other derivatives including 10*H*-phenothiazine itself.

The order parameters of S_{zz} and S_{yz} are larger for the dichloro derivative as compared to those for the

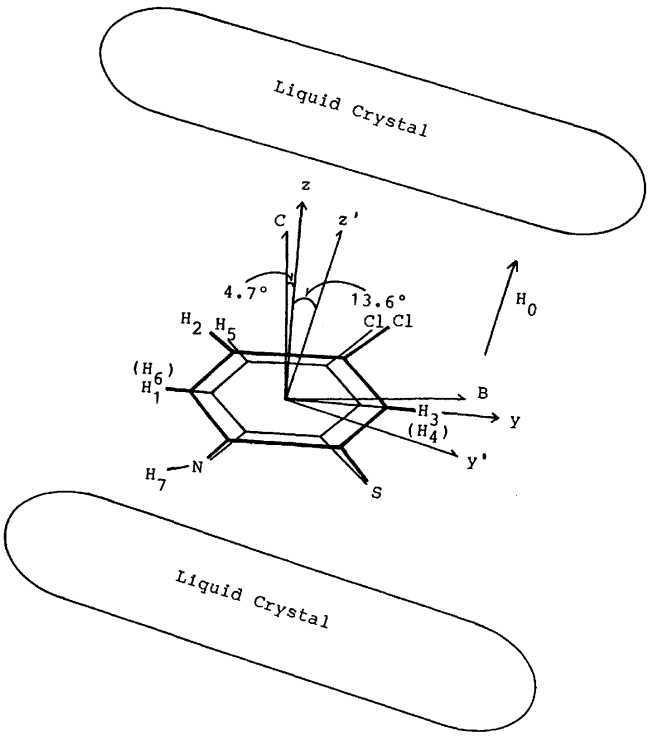

Fig. 2. Principal axis systems for the order tensor (x', y', z') and for the moment of inertia (A, B, C) in 3,7-dichloro-10*H*-phenothiazine (side view). The x' and A axes coincide with the x axis from the C_s symmetry, but these three axes are abbreviated for simplicity in the Figure. The x, y, and z axes are defined so as to place protons of H_1, H_3, H_4, and H_6 on the xy plane. The angles of rotation are −13.6° for y' and z' and 4.7° for B and C with respect to the y and z axes. H_0 denotes the direction of external magnetic field.

dibromo analogue. The absolute value of S_{xx} is, however, smaller for the dichloro derivative. This is a reason why the NMR spectrum of the dichloro derivative is not simply similar to that of the dibromo derivative. Such a decrease in S_{xx} means lowering of orientational order along x axis. This is in accordance with a shortening in diameter along the x direction for the chlorine derivative as compared to the bromine derivative. The positive large values of S_{zz} for both the dichloro and dibromo derivatives indicate that the molecule is most liable to orient with its z axis parallel to the external magnetic field. This leads to the most preferred orientaion of tricyclic plane perpendicular to the long axis of solvent which also orients perpendicular to the external magnetic field.[14] Such orientational behavior is better understood by considering the principal values of the order parameter. The principal axes of the order parameter(x', y', and z') can be obtained by rotating y and z axes anticlockwise around the x axis by an angle of ω which satisfies a relation: $\mathrm{TAN}(2\omega)=2S_{yz}/(S_{yy}-S_{zz})$.[1] From this equation $\omega=-13.6°$ is obtained, and the principal values turn out to be $S_{x'x'}=S_{xx}=-0.1162$ and $S_{z'z'}=\sin^2\omega S_{yy}+\cos^2\omega S_{zz}-\sin(2\omega)S_{yz}=0.2090$. Therefore, z' axis orients most preferrably perpendicular to the solvent molecule as shown in Fig. 2. The principal axes of the moment of inertia (A, B, and C) are also depicted in Fig. 2 (I_A=406.4, I_B=3068.6, and I_C=3371.1 amu Å^2). By comparing Fig. 2 with Fig. 2 in Ref. 1, following tendency is noticed: substitution of Cl atoms for Br atoms makes z' and C axes inclined much toward the Cl atoms in conformity with the smallness in size and weight of the Cl atoms, also it reduces slightly the discrepancy between the two principal axis systems determined for the order tensor and for the moment of inertia. Such a steric effect of substituent was already observed in cases of the stereoisomers of 1,2,3,4,5,6-hexachlorocyclohexane.[10] The absolute value of $S_{x'x'}/S_{z'z'}$ is equal to 0.56 for the dichloro derivative, which is smaller than the value of 0.61 for the dibromo derivative. This is in accordance with the trend in size of the substituents.

The author (H.F.) is grateful to Professor Kensuke Takahashi of Nagoya Institute of Technology for facilities for the NMR measurements.

Effects of Supporting Electrolyte and pH on Charge Transport within Electropolymerized Poly(*o*-phenylenediamine) Films Deposited on Graphite Electrodes

Noboru OYAMA,* Takeo OHSAKA, Kazuyuki CHIBA, and Katsuhiko TAKAHASHI
Department of Applied Chemistry for Resources, Tokyo University of Agriculture and Technology, Koganei, Tokyo 184
(Received October 3, 1987)

The homogeneous charge-transport process within electropolymerized electroactive poly(*o*-phenylenediamine) (PPD) films on graphite electrodes in various supporting electrolytic solutions (i.e., NaCl, $NaClO_4$, Na_2SO_4, LiCl, CF_3COONa, tetraethylammonium chloride (TEACl) and sodium *p*-toluenesulfonate (NaPTS)) at various pH's was examined by potential-step chronoamperometry and chronocoulometry. The overall charge-transport process was found to obey Fick's diffusion laws and thus the apparent diffusion coefficients (D_{app}) for the diffusion-like charge-transport process were estimated. The D_{app} values for the oxidation and reduction processes (i.e., D^a_{app} and D^c_{app}) were almost the same at pH 1.0 irrespective of the thickness of PPD films and were actually independent of the supporting electrolytes except for NaPTS. As pH was increased from 1 to 7, the D^a_{app} values decreased slightly from ca. 5.6×10^{-8} to 1.6×10^{-8} $cm^2\,s^{-1}$ and the D^c_{app} values did more largely from ca. 5.6×10^{-8} to 2.2×10^{-9} $cm^2\,s^{-1}$. This behavior was essentially common to all the supporting electrolytes examined. Such pH dependences of D^a_{app} and D^c_{app} are discussed on the basis of the fact that the charge-transport process within PPD films involves the intrinsic electron-transfer process between adjacent electroactive sites as well as the proton addition-elimination process, the charge-compensating counterion motion, the motion of solvent and the segmental motion of the polymeric chain. Especially, it is demonstrated that in this system the proton addition-elimination process must necessarily occur in order for the charge-transport process to proceed.

A large amount of work is devoted at present to a new class of organic polymers (in most cases obtained as films on electrode surfaces) produced by electropolymerization of various kinds of aromatic compounds (e.g., NH_2 and/or OH groups-containing aromatic compounds, heterocyclic aromatic compounds, polynuclear aromatic compounds and vinyl group-containing aromatic compounds), owing to the large field of potential applications of the resulting polymers themselves as well as the "composite" electrode materials composed of electrode substrates and the polymer films.[1] The property-dependent applications of electropolymerized film-coated electrodes have been suggested in various fields.[1]

On the other hand, some basic problems concerning electropolymerizations and the resulting films remain to be fully understood, e.g., the chemical composition and structure of films, the conductivity of films, the mechanism of electropolymerization and the rate of charge (ion and/or electron) transport through films. Especially in the case where polymer film-coated electrodes are used under a "wet" state (e.g., as electron-transfer catalysts (or mediators) for the redox reaction of a dissolved redox species) the rate of charge transport within films is one of the important factors which define the usefulness of film-coated electrodes as materials or devices with desired properties.

This paper deals with a potential-step chronoamperometric and chronocoulometric study of the charge transport within electroactive poly(*o*-phenylenediamine) (PPD) films which can be prepared by electropolymerization of *o*-phenylenediamine in an acidic solution.[2] There are relatively many papers concerning the functions of PPD films, e.g., protection against photo-corrosion of n-type semiconductor electrodes,[3] anticorrosion of metals,[4] pH response,[5-7] permselectivity,[8] and electrochemical diode property.[9] Such different properties of PPD films depend on the electrolytic conditions in their preparation. Recently, we[10] have examined the kinetics of the electrode reaction of PPD films deposited on graphite electrodes in an aqueous supporting electrolytic solution, and reported that the heterogeneous electron-transfer reaction obeys the conventional Butler-Volmer equation and the homogeneous charge-transport process within films can be treated as a Fickian diffusion process. Also, we have revealed that the PPD prepared from an acidic aqueous solution is a ladder polymer with phenazine rings.[2] The rates of the charge-transport within PPD films in aqueous solutions containing various supporting electrolytes at various pH's have been estimated as apparent diffusion coefficients (D_{app}) for the diffusion-like charge transport within the films. The results reveal that the proton addition-elimination process involved in the oxidation-reduction reaction of the PPD film as well as the motion of supporting electrolyte ions which is necessarily, for charge neutrality, coupled to electron transfer are closely related to the rate of the overall charge-transport process within the films.

Experimental

Materials. *o*-Phenylenediamine (Tokyo Kasei Co.) was purified three times by recrystallization from water and dried under reduced pressure. Sodium chloride (NaCl), sodium sulfate (Na_2SO_4), sodium perchlorate ($NaClO_4$) (Wako Chemical Co.), lithium chloride (LiCl), tetraethylammonium chloride (TEACl), sodium *p*-toluenesulfonate (PTSNa) (Kanto Chemical Co.), and sodium trifluoroacetate

(CF_3COONa) (Aldrich), which were reagent grade, were used as supporting electrolytes without further purification. In each supporting electrolytic solution, the concentration of supporting electrolyte was 0.2 M (1M=1 mol dm^{-3}). At pH<2, no buffer solutions were used and at pH 3—7, a citric acid-disodium hydrogenphosphate buffer (20 mM) was used. The basal plane pyrolytic graphite (BPG) (Union Carbide Co.) disk electrodes (area: 0.2 cm^2) were prepared and mounted into glass tube with heat-shrinkable polyolefin tube. Fresh electrode surfaces were produced by cleaving the disk with a scalpel. Aqueous solutions were prepared from doubly distilled water. All other chemicals were reagent grade and were used as received.

Preparation of Poly(*o*-phenylenediamine) (PPD) Films. The PPD films were prepared on BPG or In-Sn oxide conducting glass (ITO) electrodes by scanning (at 50 mV s^{-1}) the electrode potential between −0.8 and 1.2 V vs. SSCE in a 0.5 M Na_2SO_4-H_2SO_4 solution (pH 1.0) containing 50 mM *o*-phenylenediamine, as previously described.[2] The films prepared on BPG (or ITO) electrodes were rinsed with H_2SO_4 solution (pH 1.0) and then with distilled water, and used for further study without removing them from the electrode surfaces. The thicknesses of the films were controlled by the amount of charge passed during the electrochemical polymerization. The film thicknesses (ϕ) were measured with a Surfcom 550 A (Surface Texture Measuring Instrument, Tokyo Seimitsu Co.) as previously described.[2,9]

Apparatus and Procedures. A standard three-electrode electrochemical cell was used for all electrochemical experiments. The electrode assembly consisted of a bare or PPD-coated BPG (or ITO) as working electrode, a sodium chloride saturated calomel electrode (SSCE) as reference electrode and a spiral platinum electrode as counter electrode.

The surface concentration (Γ_p°) of the electroactive site in PPD films was estimated in mol cm^{-2} by measuring the area of cyclic voltammograms (for the oxidation-reduction reaction of PPD films themselves) obtained at scan rate of 2 mV s^{-1} in a 0.2 M $NaClO_4$-$HClO_4$ solution (pH 1.0). The molar concentration (C_p°) (in mol cm^{-3}) of the electroactive site was calculated from the Γ_p° thus obtained using the thicknesses (ϕ) of the films. It was found that there is a linear relationship between ϕ and Γ_p° at $\Gamma_p^\circ < 1.0\times10^{-7}$ mol cm^{-2} and that the C_p° values are $(7.8\pm0.8)\times10^{-4}$ mol cm^{-3} irrespective of ϕ at $\phi < 2\times10^{-4}$ cm.

For cyclic voltammetry, potential-step chronoamperometry and potential-step chronocoulometry, a home-made instrument was employed along with a Nicolet digital oscilloscope (model 3091) and X-Y recorder (Graphtec Co., Tokyo). Positive feedback circuitry was employed to compensate the resistances (these were typically ca. 20—50 Ω) associated with the polymer coatings as much as possible. All experiments were run under nitrogen atmosphere at laboratory temperature (25±1 °C). Potentials were measured and are quoted with respect to SSCE.

Results

Figure 1 shows a typical cyclic voltammogram representing the electrochemical response for the oxidation-reduction reaction of the PPD film deposited on BPG electrode in a 0.2 M $NaClO_4$-$HClO_4$ aqueous solution (pH 1.0). The wave shape resembles that for the ordinary electrode reaction of a solution-phase redox species at an uncoated electrode,[11] that is, the wave has "diffusion tails" and its shape is unsymmet-

ric, although in general electropolymerized electroactive polymer films display the complicated redox responses as being reported for the electropolymerized polyaniline film.[12,13] Based on our recent studies[2] concerning the structure of the PPD film, the electroactive sites in PPD films are considered to be phenazine rings.

In order to estimate the kinetic parameters characterizing the charge-transport process within the films, the potential-step chronoamperometric and chronocoulometric responses for the oxidation and reduction of the PPD films were examined. A typical example of such an examination is shown in Fig. 2. The Cottrell plots (i.e., i-$t^{-1/2}$ and Q-$t^{1/2}$ plots) are linear at short times. The deviation from the linearity indicates that currents in longer times become controlled by finite diffusion.[14,15] These facts indicate that the charge-transport process within the PPD films follows Fickian diffusion laws. Thus, the slopes of the linear plots shown in Fig. 2 yielded the apparent diffusion coefficients (D_{app}) for the diffusion-like charge-transport process within the films. The obtained D_{app}'s are summarized in Tables 1 and 2 and Fig. 3. The D_{app}

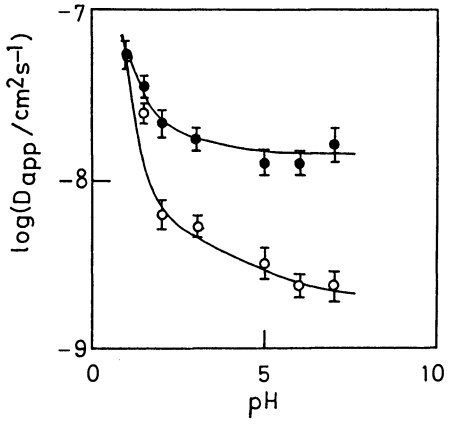

Fig. 3. pH dependences of D^{a}_{app} and D^{c}_{app}. (●): for the oxidation process (D^{a}_{app}); (○): for the reduction process (D^{c}_{app}). Supporting electrolyte: 0.2 M NaCl. values (i.e., D_{app}^{a} and D_{app}^{c}) for anodic and cathodic processes in an acidic solution are almost the same irrespective of the film thicknesses and supporting electrolytes examined.

Figure 4 shows typical cyclic voltammograms of the PPD film at different pH's. As reported previously,[2] the anodic and cathodic peak potentials (E_p^{a} and E_p^{c}) shifted to negative values with increasing pH and the slopes of the formal redox potential ($E^{o\prime}$), estimated as the average of E_p^{a} and E_p^{c} values, vs. pH plots were about −60 mV pH^{-1} in the examined range of pH 1 to 7. This suggests that the overall electrode reaction of the PPD film is a H^+/e^- (1/1) reaction. Then, the peak currents decreased slightly with an increase in pH. This was found to be not due to the decrease of the electroactive site number (N_{active}) in the PPD film, but due to the decrease in the apparent rate of the diffusion-like charge transport in the film. The concentrations (C_p^{o}) of the electroactive site were almost constant (7.8×10^{-4} mol cm^{-3}) within experimental error irrespective of pH in the examined range of pH 1 to 7. In this case, N_{active}, i.e., C_p^{o} values at various pH's were determined by the graphical integration of the cyclic voltammograms as described in Experimental section. Such a decrease of peak currents with increasing pH was found to be clearly reflected in the potential-step chronoamperometric (and chronocoulometric) behavior and as a result in the D_{app} values. The results are shown in Fig. 3. It is apparent that as pH increases both D_{app}^{a} and D_{app}^{c} decrease. Further, we can see that the difference between D_{app}^{a} and D_{app}^{c} values becomes larger with increasing pH. A typical example of the potential-step chronoamperometric data demonstrating the largely different D_{app} values for the oxidation and reduction processes at pH 5.0 is shown in Fig, 5. The slope of the i vs. $t^{-1/2}$ plot for the oxidation process is significantly larger than that for the reduction process, and thus in contrary to the D_{app}'s obtained in more acidic solutions (e.g., at pH 1.0) the D_{app}^{a} value is much larger than the D_{app}^{c} value. The related data are summarized in Table 3.

pH dependence of the swelling of PPD films was examined by measuring the wet thickness (ϕ_{wet}) of the films swollen in 0.2 M NaCl aqueous solutions of various pH's. The result is shown in Fig. 6. The ϕ_{wet}/ϕ_{dry} values (ϕ_{dry}: dry thickness) decreased largely with an increase in pH in the range of pH 1 to 3, and at higher pH's they decreased slightly with increasing pH. This behavior is associated with the protonation of PPD film, as mentioned below.

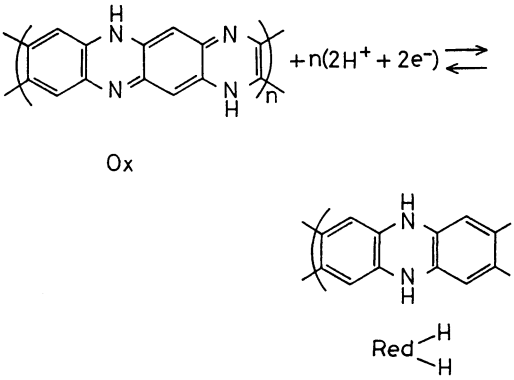
Discussion

From Table 1, it is apparent that Γ_p^o's are proportional to ϕ. This indicates that C_p^o values which are estimated as Γ_p^o/ϕ are constant irrespective of ϕ, that is, the distribution of the electroactive sites in the PPD films is homogeneous. Further, we can see that the values of D_{app}^a and D_{app}^c are actually independent of ϕ in the examined range of ϕ from 0.19 to 1.4 μm and the D_{app}^a and D_{app}^c values are almost the same ($(2.7\pm 1.1)\times10^{-8}$ $cm^2 s^{-1}$).

Table 2 shows the D_{app} values measured in different supporting electrolytic solutions at pH 1.0. The Γ_p^o values seem to slightly change with supporting electrolytes, probably suggesting the partially inhomogeneous distribution of the electroactive sites and the formation of electroinactive regions. Similar results have been also observed for other polymeric film-coated electrodes.[16,17] $D_{app}^a \approx D_{app}^c$ for a given supporting electrolyte. The D_{app} 's obtained in $NaClO_4$, NaCl, CF_3COONa, and Na_2SO_4 electrolytic solutions are almost the same and those in PTSNa solution seem to be a little smaller. This may reflect the different rates of the diffusional motion of electrolytic ions which is necessarily coupled to electron transfer, as can be expected from the Stokes radii (γ_s) of the electrolytic ions used: $\gamma_s(PTS^-) > \gamma_s(Na^+) \approx \gamma_s(CF_3COO^-) \approx \gamma_s(SO_4^{2-}) > 2\gamma_s(Cl^-) \approx 2\gamma_s(ClO_4^-)$.[18]

Table 3 shows the D_{app}'s obtained in various supporting electrolytes containing 20 mM CH_3COONa/CH_3COOH buffer solution (pH 5.0). For all the supporting electrolytes examined, D_{app}^a's are largely different from D_{app}^c's. For example, in the case of NaCl and TEACl electrolytes D_{app}^a's are about one order of magnitude larger than D_{app}^c's. This remarkable fact demonstrates the significantly different rates of the homogeneous charge transports within the films during the reduction and oxidation processes, and seems to be associated with the low concentration (i.e., 10^{-5} M) of hydrogen ion. The more detailed pH responses of D_{app}^a and D_{app}^c values are shown in Fig. 3. Both D_{app}^a's and D_{app}^c's decrease with increasing pH and the degree of the decrease is different each other: As pH was increased from 1 to 7, D_{app}^a's decreased from ca. 5.6×10^{-8} to 1.6×10^{-8} $cm^2 s^{-1}$ and D_{app}^c's from 5.6×10^{-8} to 2.2×10^{-9} $cm^2 s^{-1}$. Such essentially different pH dependences of D_{app}^a and D_{app}^c may be ascribable to the fact that a proton addition-elimination process is involved in the homogeneous charge-transport process in the PPD films which can be regarded as a homogeneous oxidation-reduction process between electroactive sites, as mentioned below.

On the basis of the fact that PPD is a ladder polymer with phenazine rings[2] and that the slope of the $E^{o\prime}$ .vs. pH plot is ca. -60 mV pH^{-1} in the range of pH 1—7, and with the assumption that the protonation constant (pK_a) of PPD is ca. 1 based on the pK_a values of phenazine ($pK_{a_1}=1.2$ and $pK_{a_2}=-4.3$),[19,20] the heterogeneous electron-transfer reaction of PPD in aqueous solutions of pH ca. 1—7 may be written as:



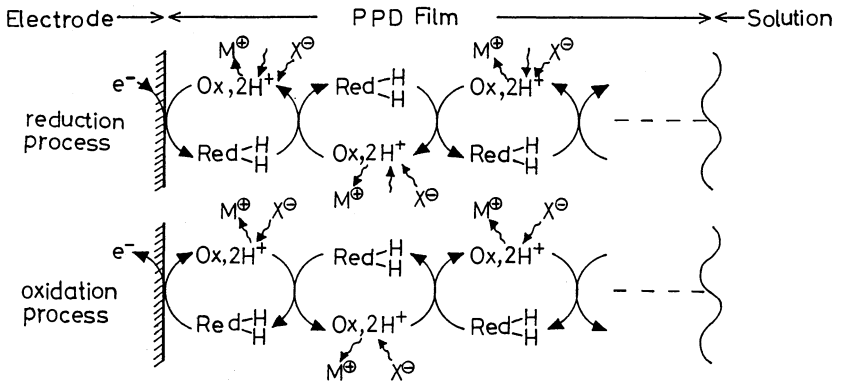


Fig. 7. Schematic depiction of homogeneous charge-transport process within PPD films on electrodes. The symbols Ox and Red represent the oxidized and reduced forms (see text), respectively, of the PPD, and $M^{\oplus}$ and $X^{\ominus}$ indicate supporting electrolytic cations and anions, respectively. H^+ is hydrogen ion. The symbol $\rightsquigarrow$ shows the diffusional motion of H^+, $M^{\oplus}$ and $X^{\ominus}$. The symbols $\curvearrowright$ and $\curvearrowleft$ show the homogeneous oxidation-reduction (electron self-exchange) reaction between adjacent electroactive sites.

From the analogy with the heterogeneous electron-transfer reaction (Eq. 1), the mechanism of the homogeneous charge (ion and electron)-transport process within solvent-swollen PPD films undergoing electrolysis (i.e., oxidation and reduction of the electroactive sites) can thus be schematically represented as in Fig. 7. The charge-transport process is considered to involve the intrinsic electron-transfer process between adjacent electroactive sites, the proton addition-elimination process, the charge-compensating counterion motion, the motion of solvent and the segmental motion of the polymeric chain. The charge-transport rate, which will be determined by only the slower of these various processes, is characterized by the D_{app}'s mentioned throughout the paper.

The D^{a}_{app}'s tend to decrease slightly with increasing pH, especially in the range of pH between 1 and ca. 2 and are almost constant at pH 2—7. This may be explained as follows: The pK_a of PPD may be assumed to be ca. 1 as mentioned above. Thus, the degree of the protonation of PPD is thought to change with pH in the pH range where the decreasing of D^{a}_{app} with an increase in pH was observed. Further, the swelling of the PPD film is associated with the protonation: The higher the degree of the protonation of PPD is, the larger is the swelling of its film (see Fig. 6). In a more swollen film, the motions of supporting electrolytic ions and solvents and/or the segmental motion of polymeric chains become easier and as a result larger D^{a}_{app} values are obtained at lower pH's.

The same explanation seems to be also applicable to the decreasing of D^{c}_{app}'s with increasing pH. However, in this case, another important factor should be taken into account. That is to say, in order for the charge-transport process during the reduction process to proceed more rapidly, hydrogen ions are necessary to be sufficiently present in the vicinity of the oxidized sites (symbolized by "Ox" in Fig. 7). The apparent rate of the charge transport during the reduction process should decrease with decreasing the concentration of hydrogen ion. Thus, the D^{c}_{app} values decrease with increasing pH.

Equations-of-Motion Method for the Electronic Transitions to Compound (1p-1h)+(2p-2h) States

Tai-ichi SHIBUYA,* Tadashi FUNADA,§ and Haruo GOTOH
Department of Chemistry, Faculty of Textile Science and Technology, Shinshu University, Ueda, Nagano-ken 386
(Received October 6, 1987)

The equations-of-motion (EOM) method proposed by Shibuya and McKoy (*Phys. Rev.*, **A2**, 2208 (1970); *J. Chem. Phys.* **58**, 500 (1973)) has been extended to include (2p-2h)-state creation and annihilation operators in the excitation operator $O_\lambda^\dagger$.

The equations-of-motion (EOM) method proposed by Shibuya and McKoy[1] has been successfully applied to ab initio calculations of the transition energies and oscillator strengths of small molecules like C_2H_4, CO, N_2, C_6H_6, H_2O, and CH_4.[2,3] The EOM method has the advantage that the equations are set up directly for the electronic transitions, i.e. for the difference between the ground and the excited states, while in the traditional CI method the equation is solved for each of the states separately.

The basic idea of the EOM method is to find an excitation operator $O_\lambda^\dagger$ which creates an excited state $|\lambda>$ by its action on the ground state $|0>$:

$$|\lambda>=O_\lambda^\dagger|0> \quad (\text{and } O_\lambda|0>=0). \tag{1}$$

As was shown by Sinanoğlu,[4] the major part of the closed-shell ground state correlation consists of doubly-excited configurations, i.e. 2p-2h states. Thus, it is natural to construct the $O_\lambda^\dagger$ as a linear combination of 1p-1h creation and annihilation operators. The coefficients of the linear combination are determined in such a way that the excitation operator $O_\lambda^\dagger$ satisfies the equation

$$[H,O_\lambda^\dagger]|0>=\omega_\lambda O_\lambda^\dagger|0>, \tag{2}$$

which takes the same form as the equation of motion for a boson creation operator. In this equation ω_λ is the energy difference between $|0>$ and $|\lambda>$.

The low-lying excited states of molecules are usually well described as the linear combinations of 1p-1h states. However, some of the important valence states of conjugated molecules are essentially of 2p-2h states. The well-known example is the 2^1Ag state of linear polyenes.[5] For these states, the perturbative treatment proposed earlier[1b] is not adequate and the whole EOM-Hamiltonian matrix including those elements of 2p-2h states must be diagonalized to give correct solutions of the excitation operator. In the present work, we provide all the matrix elements needed for this type of the EOM calculations. Recently Oddershede and coworkers[6] have developed the perturbative propagator methods which are essentially equivalent to our perturbative treatment.[1b] Many references in relation with the propagator methods and the EOM methods are found in a recent review by Oddershede.[7]

§ Present address: Yashiro High School, Koshoku, Nagano-ken 387.

The EOM for 1p-1h States

In this section, we begin with a summary of the previously developed EOM method for 1p-1h states.[1] Let us consider the excitation of an electron from the occupied orbital γ to the unoccupied orbital m. The excited electron may take the spin state of α or β. Thus, if the molecule is initially in the closed-shell ground state, its final state may be either singlet ($S=0$) or triplet ($S=1$). Therefore, the creation operators of the particle-hole pairs are written[1a]

$$\left.\begin{aligned} C_{m\gamma}^\dagger(00) &= (2^{-1/2})[c_{m\alpha}^+ c_{\gamma\alpha} + c_{m\beta}^+ c_{\gamma\beta}] \\ C_{m\gamma}^\dagger(1M) &= \begin{cases} -c_{m\alpha}^+ c_{\gamma\beta} & (M=+1) \\ (2^{-1/2})[c_{m\alpha}^+ c_{\gamma\alpha} - c_{m\beta}^+ c_{\gamma\beta}] & (M=0) \\ c_{m\beta}^+ c_{\gamma\alpha} & (M=-1) \end{cases} \end{aligned}\right\} \tag{3}$$

where $c_{i\alpha}^+$ and $c_{i\alpha}$ are the creation and the annihilation operators of an elcctron in the state of orbital i and spin α, respectively, and they satisfy the anticommutation relations of fermions. Inspecting the structure of the correlated ground state $|0>$ according to Sinanoğlu's many-electron theory,[4] we have proposed that the excited state $|\lambda>$ of spin-symmetry S, M may be obtained by the action of the excitation operator

$$O^\dagger(\lambda SM)=\sum_{m\gamma}\{Y_{m\gamma}(\lambda S)\,C_{m\gamma}^\dagger(SM)-Z_{m\gamma}(\lambda S)\,C_{m\gamma}(\overline{SM})\} \tag{4}$$

on the ground state $|0>$. In this expression,

$$C_{m\gamma}(\overline{SM})=(-)^{S+M}\,C_{m\gamma}(S,-M) \tag{5}$$

annihilates the (m, γ) pair and gives a state of spin-symmetry S, M. Note that $C_{m\gamma}(SM)$ is the adjoint operator of $C_{m\gamma}^\dagger(SM)$.

Solutions of Eq. 2 are readily found by solving the variational equation[8]

$$<0|[\delta O_\lambda, H, O_\lambda^\dagger]|0>=\omega_\lambda<0|[\delta O_\lambda, O_\lambda^\dagger]|0>, \tag{6}$$

where the double commutator is defined as

$$[a,H,b]=\frac{1}{2}([a,[H,b]]+[[a,H],b]). \tag{7}$$

The problem here is to find the eigenvector (Y,Z) in Eq. 4 and the eigenvalue ω_λ. We have shown[1] that the

substitution of Eq. 4 into 6 leads to the matrix equation

$$\begin{bmatrix} A & B \\ -B & -A \end{bmatrix} \begin{bmatrix} Y(\lambda) \\ Z(\lambda) \end{bmatrix} = \omega_\lambda \begin{bmatrix} D & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} Y(\lambda) \\ Z(\lambda) \end{bmatrix} \tag{8}$$

where

$$\left.\begin{aligned} A_{m\gamma,n\delta}(S) &= <0|[C_{m\gamma}(SM), H, C_{n\delta}^{\dagger}(SM)]|0> \\ B_{m\gamma,n\delta}(S) &= -<0|[C_{m\gamma}(SM), H, C_{n\delta}(\overline{SM})]|0> \\ D_{m\gamma,n\delta} &= <0|[C_{m\gamma}(SM), C_{n\delta}^{\dagger}(SM)]|0> \end{aligned}\right\} \tag{9}$$

Note that A and B are independent of M, and D is independent of S and M. We shall henceforth denote unoccupied orbitals (particle states) by m, n, p, or q, and occupied orbitals (hole states) by γ, δ, μ, or ν. In expanding these elements explicitly, we first let

$$<0|0>=1. \tag{10}$$

Then, in the level of the 2nd-order perturbation theory of the ground-state correlation, we obtain[1]

$$\left.\begin{aligned} A_{m\gamma,n\delta}(S) &= A^{\circ}_{m\gamma,n\delta}(S) \\ &\quad + \delta_{\gamma\delta}\left[T_{mn} - \frac{1}{2}(\varepsilon_m + \varepsilon_n - 2\varepsilon_\gamma)\rho_{mn}\right] \\ &\quad - \delta_{mn}\left[T_{\gamma\delta} - \frac{1}{2}(2\varepsilon_m - \varepsilon_\gamma - \varepsilon_\delta)\rho_{\gamma\delta}\right] \\ B_{m\gamma,n\delta}(S) &= B^{\circ}_{m\gamma,n\delta}(S) + (-1)^S S_{m\gamma,n\delta} \\ D_{m\gamma,n\delta} &= \delta_{mn}\,\delta_{\gamma\delta} + \delta_{mn}\,\rho_{\gamma\delta} - \delta_{\gamma\delta}\,\rho_{mn}, \end{aligned}\right\} \tag{11}$$

where A° and B° are the RPA matrices, i.e.

$$\left.\begin{aligned} A^{\circ}_{m\gamma,n\delta}(S) &= \delta_{mn}\,\delta_{\gamma\delta}(\varepsilon_m - \varepsilon_\gamma) - V_{m\delta n\gamma} + (\delta_{S0})\,2V_{m\delta\gamma n} \\ B^{\circ}_{m\gamma,n\delta}(S) &= -(-1)^S V_{mn\delta\gamma} + (\delta_{S0})\,2V_{mn\gamma\delta}. \end{aligned}\right\} \tag{12}$$

ε_k is the HF orbital energy and

$$V_{ijkl} \equiv <i(1)j(2)|(r_{12})^{-1}|k(1)l(2)>. \tag{13}$$

T and S are correction terms linear in the ground-state correlation coefficients. ρ is quadratic in the correlation coefficients. They are explicitly written as

$$\left.\begin{aligned} S_{m\gamma,n\delta} &= -\sum_{p\mu}[V_{m\mu\delta p}\,C_{p\mu,n\gamma}(0) + V_{n\mu\gamma p}\,C_{p\mu,m\delta}(0)] \\ T_{mn} &= -\frac{1}{2}\sum_{q\mu\nu}[V_{mq\mu\nu}\,C_{q\nu,n\mu}(0) + V_{\mu\nu nq}\,C_{m\mu,q\nu}(0)] \\ T_{\gamma\delta} &= \frac{1}{2}\sum_{pq\nu}[V_{pq\gamma\nu}\,C_{q\nu,p\delta}(0) + V_{\delta\nu pq}\,C_{p\gamma,q\nu}(0)] \end{aligned}\right\} \tag{14}$$

and

$$\left.\begin{aligned} \rho_{mn} &= \frac{1}{2}\sum_{p\mu\nu}\sum_{S=0,1} C'_{p\mu,m\nu}(S)\,C_{n\nu,p\mu}(S) \\ \rho_{\gamma\delta} &= -\frac{1}{2}\sum_{pq\mu}\sum_{S=0,1} C'_{p\mu,q\gamma}(S)\,C_{q\delta,p\mu}(S), \end{aligned}\right\} \tag{15}$$

where

$$C'(0) = \frac{1}{4}[3C(0) + C(1)];\quad C'(1) = \frac{1}{4}[C(0) + 3C(1)]. \tag{16}$$

To the first order in the Rayleigh-Schrödinger perturbation theory the ground-state correlation coefficients are given by

$$C_{m\gamma,n\delta}(S) \cong -B^{\circ}_{m\gamma,n\delta}(S)/(\varepsilon_m + \varepsilon_n - \varepsilon_\gamma - \varepsilon_\delta). \tag{17}$$

Finally, in the diagonalization approximation

$$D_{m\gamma,n\delta} \cong \delta_{mn}\delta_{\gamma\delta}(1 + \rho_{\gamma\gamma} - \rho_{mm}) \equiv \delta_{mn}\,\delta_{\gamma\delta}\,g_{m\gamma}^2, \tag{18}$$

Eq. 8 becomes

$$\begin{bmatrix} \mathscr{A} & \mathscr{B} \\ -\mathscr{B} & -\mathscr{A} \end{bmatrix} \begin{bmatrix} \mathscr{Y}(\lambda) \\ \mathscr{Z}(\lambda) \end{bmatrix} = \omega_\lambda \begin{bmatrix} \mathscr{Y}(\lambda) \\ \mathscr{Z}(\lambda) \end{bmatrix}, \tag{19}$$

where

$$\left.\begin{aligned} \mathscr{A}_{m\gamma,n\delta} &\equiv g_{m\gamma}^{-1}\,A_{m\gamma,n\delta}\,g_{n\delta}^{-1} \\ &= \delta_{mn}\,\delta_{\gamma\delta}(\varepsilon_m - \varepsilon_\gamma) \\ &\quad + \{-[V_{m\delta n\gamma} + \delta_{mn}\,T_{\gamma\delta} - \delta_{\gamma\delta}\,T_{mn}] \\ &\quad + (\delta_{S0})\,2V_{m\delta\gamma n}\}/g_{m\gamma}\,g_{n\delta}) \\ \mathscr{B}_{m\gamma,n\delta} &\equiv g_{m\gamma}^{-1}\,B_{m\gamma,n\delta}\,g_{n\delta}^{-1} \\ &= \{-(-1)^S[V_{mn\delta\gamma} - S_{m\gamma,n\delta}] \\ &\quad + (\delta_{S0})\,2V_{mn\gamma\delta}\}/(g_{m\gamma}\,g_{n\gamma}) \\ \mathscr{Y}_{m\gamma} &\equiv g_{m\gamma}\,Y_{m\gamma};\quad \mathscr{Z}_{m\gamma} \equiv g_{m\gamma}\,Z_{m\gamma}. \end{aligned}\right\} \tag{20}$$

The EOM for (1p-1h)+(2p-2h) States

The excitation operator in Eq. 4 is now extended to include 2p-2h creation and annihilation operators:

$$\begin{aligned} O^{\dagger}(\lambda SM) &= \sum_{m\gamma}\{Y_{m\gamma}(\lambda S)\,C_{m\gamma}^{\dagger}(SM) - Z_{m\gamma}(\lambda S)\,C_{m\gamma}(\overline{SM})\} \\ &\quad + \sum_{(m\gamma,n\delta)}\{Y^{(2)}_{(m\gamma,n\delta)}(\lambda S)\,\Gamma^{\dagger}_{(m\gamma,n\delta)}(SM) \\ &\qquad - Z^{(2)}_{(m\gamma,n\delta)}(\lambda S)\,\Gamma_{(m\gamma,n\delta)}(\overline{SM})\}, \end{aligned} \tag{21}$$

where $\Gamma^{\dagger}_{(m\gamma,n\delta)}(SM)$ are 2p-2h creation operators. The second summation in Eq. 21 runs over all the independent 2p-2h states, not over $m\gamma$ and $n\delta$ separately. In general, $\Gamma^{\dagger}_{(m\gamma,n\delta)}(SM)$ is a linear combination of $C_{m\gamma}^{\dagger}(SM)C_{n\delta}^{\dagger}(00)$, $C_{n\delta}^{\dagger}(SM)C_{m\gamma}^{\dagger}(00)$, $C_{m\delta}^{\dagger}(SM)C_{n\gamma}^{\dagger}(00)$, and $C_{n\gamma}^{\dagger}(SM)\,C_{m\delta}^{\dagger}(00)$.

The substitution of Eq. 21 into Eq. 6 gives

$$\begin{bmatrix} A & B & A^{(1,2)} & B^{(1,2)} \\ -B & -A & -B^{(1,2)} & -A^{(1,2)} \\ A^{(2,1)} & B^{(2,1)} & A^{(2,2)} & B^{(2,2)} \\ -B^{(2,1)} & -A^{(2,1)} & -B^{(2,2)} & -A^{(2,2)} \end{bmatrix} \begin{bmatrix} Y(\lambda) \\ Z(\lambda) \\ Y^{(2)}(\lambda) \\ Z^{(2)}(\lambda) \end{bmatrix} = \omega_\lambda \begin{bmatrix} D & 0 & 0 & 0 \\ 0 & D & 0 & 0 \\ 0 & 0 & D^{(2,2)} & 0 \\ 0 & 0 & 0 & D^{(2,2)} \end{bmatrix} \begin{bmatrix} Y(\lambda) \\ Z(\lambda) \\ Y^{(2)}(\lambda) \\ Z^{(2)}(\lambda) \end{bmatrix}, \tag{22}$$

where the matrix elements of A, B, and D are already given above, and the matrix elements of $A^{(1,2)}$, $B^{(1,2)}$, $A^{(2,2)}$, $B^{(2,2)}$, and $D^{(2,2)}$ are defined by

Table 1. The Orthonormal 2p-2h Creation Operators $\Gamma^{\dagger}_{(m\gamma,n\delta)}$

$S=M=0$	
$\Gamma^{\dagger}_{(m\gamma,m\gamma)}=c_{m\alpha}{}^{+}c_{m\beta}{}^{+}c_{\gamma\beta}c_{\gamma\alpha}=C_{m\gamma}{}^{\dagger}(00)C_{m\gamma}{}^{\dagger}(00)$	
$\Gamma^{\dagger}_{(m\gamma,n\gamma)}=(1/\sqrt{2})(c_{m\alpha}{}^{+}c_{n\beta}{}^{+}+c_{n\alpha}{}^{+}c_{m\beta}{}^{+})c_{\gamma\beta}c_{\gamma\alpha}=\sqrt{2}C_{m\gamma}{}^{\dagger}(00)C_{n\gamma}{}^{\dagger}(00)$	$(m\neq n)$
$\Gamma^{\dagger}_{(m\gamma,m\delta)}=(1/\sqrt{2})c_{m\alpha}{}^{+}c_{m\beta}{}^{+}(c_{\delta\beta}c_{\gamma\alpha}+c_{\gamma\beta}c_{\delta\alpha})=\sqrt{2}C_{m\gamma}{}^{\dagger}(00)C_{m\delta}{}^{\dagger}(00)$	$(\gamma\neq\delta)$
$\Gamma^{\dagger}_{(m\gamma,n\delta)_1}=1/2(c_{m\alpha}{}^{+}c_{n\beta}{}^{+}+c_{n\alpha}{}^{+}c_{m\beta}{}^{+})(c_{\delta\beta}c_{\gamma\alpha}+c_{\gamma\beta}c_{\delta\alpha})=C_{m\gamma}{}^{\dagger}(00)C_{n\delta}{}^{\dagger}(00)+C_{m\delta}{}^{\dagger}(00)C_{n\gamma}{}^{\dagger}(00)$	$(m\neq n,\gamma\neq\delta)$
$\Gamma^{\dagger}_{(m\gamma,n\delta)_2}=(1/\sqrt{3})\{(c_{m\alpha}{}^{+}c_{n\alpha}{}^{+}c_{\delta\alpha}c_{\gamma\alpha}+c_{m\beta}{}^{+}c_{n\beta}{}^{+}c_{\delta\beta}c_{\gamma\beta})$ $+1/2(c_{m\alpha}{}^{+}c_{n\beta}{}^{+}-c_{n\alpha}{}^{+}c_{m\beta}{}^{+})(c_{\delta\beta}c_{\gamma\alpha}-c_{\gamma\beta}c_{\delta\alpha})\}=(1/\sqrt{3})(C_{m\gamma}{}^{\dagger}(00)C_{n\delta}{}^{\dagger}(00)-C_{m\delta}{}^{\dagger}(00)C_{n\gamma}{}^{\dagger}(00))$	$(m\neq n,\gamma\neq\delta)$
$S=1,\ M=0$	
$\Gamma^{\dagger}_{(m\gamma,n\gamma)}=(1/\sqrt{2})(c_{m\alpha}{}^{+}c_{n\beta}{}^{+}-c_{n\alpha}{}^{+}c_{m\beta}{}^{+})c_{\gamma\beta}c_{\gamma\alpha}=(1/\sqrt{2})(C_{m\gamma}{}^{\dagger}(10)C_{n\gamma}{}^{\dagger}(00)-C_{n\gamma}{}^{\dagger}(10)C_{m\gamma}{}^{\dagger}(00))$	$(m\neq n)$
$\Gamma^{\dagger}_{(m\gamma,m\delta)}=(1/\sqrt{2})c_{m\alpha}{}^{+}c_{m\beta}{}^{+}(c_{\delta\beta}c_{\gamma\alpha}-c_{\gamma\beta}c_{\delta\alpha})=(1/\sqrt{2})(C_{m\gamma}{}^{\dagger}(00)C_{m\delta}{}^{\dagger}(10)-C_{m\delta}{}^{\dagger}(10)C_{m\gamma}{}^{\dagger}(00))$	$(\gamma\neq\delta)$
$\Gamma^{\dagger}_{(m\gamma,n\delta)_1}=1/2(c_{m\alpha}{}^{+}c_{n\beta}{}^{+}-c_{n\alpha}{}^{+}c_{m\beta}{}^{+})(c_{\delta\beta}c_{\gamma\alpha}+c_{\gamma\beta}c_{\delta\alpha})$ $=1/2(C_{m\gamma}{}^{\dagger}(10)C_{n\delta}{}^{\dagger}(00)-C_{n\delta}{}^{\dagger}(10)C_{m\gamma}{}^{\dagger}(00)+C_{m\delta}{}^{\dagger}(10)C_{n\gamma}{}^{\dagger}(00)-C_{n\gamma}{}^{\dagger}(10)C_{m\delta}{}^{\dagger}(00))$	$(m\neq n,\gamma\neq\delta)$
$\Gamma^{\dagger}_{(m\gamma,n\delta)_2}=1/2(c_{m\alpha}{}^{+}c_{n\beta}{}^{+}+c_{n\alpha}{}^{+}c_{m\beta}{}^{+})(c_{\delta\beta}c_{\gamma\alpha}-c_{\gamma\beta}c_{\delta\alpha})$ $=1/2(C_{m\gamma}{}^{\dagger}(10)C_{n\delta}{}^{\dagger}(00)-C_{n\delta}{}^{\dagger}(10)C_{m\gamma}{}^{\dagger}(00)-C_{m\delta}{}^{\dagger}(10)C_{n\gamma}{}^{\dagger}(00)+C_{n\gamma}{}^{\dagger}(10)C_{m\delta}{}^{\dagger}(00))$	$(m\neq n,\gamma\neq\delta)$
$\Gamma^{\dagger}_{(m\gamma,n\delta)_3}=(1/\sqrt{2})(c_{m\alpha}{}^{+}c_{n\alpha}{}^{+}c_{\delta\alpha}c_{\gamma\alpha}-c_{m\beta}{}^{+}c_{n\beta}{}^{+}c_{\delta\beta}c_{\gamma\beta})=(1/\sqrt{2})(C_{m\gamma}{}^{\dagger}(10)C_{n\delta}{}^{\dagger}(00)+C_{n\delta}{}^{\dagger}(10)C_{m\gamma}{}^{\dagger}(00))$	$(m\neq n,\gamma\neq\delta)$

$$
\left.\begin{aligned}
&A^{(1,2)}{}_{m'\gamma';(m\gamma,n\delta)}(S)\\
&\quad=\langle 0|[C_{m'\gamma'}(SM),\ H,\Gamma^{\dagger}_{(m\gamma,n\delta)}(SM)]|0\rangle\\
&B^{(1,2)}{}_{m'\gamma';(m\gamma,n\delta)}(S)\\
&\quad=-\langle 0|[C_{m'\gamma'}(SM),\ H,\Gamma_{(m\gamma,n\delta)}(\overline{SM})]|0\rangle\\
&A^{(2,2)}{}_{(m'\gamma',n'\delta');(m\gamma,n\delta)}(S)\\
&\quad=\langle 0|[\Gamma_{(m'\gamma',\,n'\delta')}(SM),\ H,\Gamma^{\dagger}_{(m\gamma,n\delta)}(SM)]|0\rangle\\
&B^{(2,2)}{}_{(m'\gamma',n'\delta');(m\gamma,n\delta)}(S)\\
&\quad=-\langle 0|[\Gamma_{(m'\gamma',\,n'\delta')}(SM),\ H,\Gamma_{(m\gamma,n\delta)}(\overline{SM})]|0\rangle\\
&D^{(2,2)}{}_{(m'\gamma',n'\delta');(m\gamma,n\delta)}\\
&\quad=\langle 0|[\Gamma_{(m'\gamma',\,n'\delta')}(SM),\ \Gamma^{\dagger}_{(m\gamma,n\delta)}(SM)]|0\rangle
\end{aligned}\right\}\qquad (23)
$$

Note that

$$A^{(2,1)}=\tilde{A}^{(1,2)};\ B^{(2,1)}=\tilde{B}^{(1,2)}. \qquad (24)$$

Also note that $A^{(1,2)}$, $B^{(1,2)}$, $A^{(2,2)}$, and $B^{(2,2)}$ are independent of M, and that $D^{(2,2)}$ is independent of S and M.

In the present work, we shall replace the correlated ground state $|0\rangle$ in Eq. 23 by the Hartree-Fock ground state $|HF\rangle$, obtaining $A^{\circ(1,2)}$, $B^{\circ(1,2)}$, $A^{\circ(2,2)}$, $B^{\circ(2,2)}$, and $D^{\circ(2,2)}$, respectively. It is clear that $B^{\circ(1,2)}$ and $B^{\circ(2,2)}$ vanish, for the Hamiltonian H consists of only the pair creation operators $C_{ij}{}^{\dagger}(00)$ and their products $C_{ij}{}^{\dagger}(00)C_{kl}{}^{\dagger}(00)$. The matrix elements of $A^{\circ(1,2)}$ and $A^{\circ(2,2)}$ are obtained from their primitive elements given in the Appendix. The matrix $D^{\circ(2,2)}$ becomes an identity matrix when the basis set of $\Gamma^{\dagger}_{(m\gamma,n\delta)}$ is chosen such as given in Table 1. These 2p-2h creation operators were given earlier in Ref. 1b. They are reproduced here for convenience and some typographic errors involved there have been corrected. In this basis set of 2p-2h creation operators, we now have, instead of Eq. 22,

$$
\begin{bmatrix}
\mathscr{A} & \mathscr{B} & \mathscr{A}^{\circ(1,2)} & 0\\
-\mathscr{B} & -\mathscr{A} & 0 & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & 0 & A^{\circ(2,2)} & 0\\
0 & -\mathscr{A}^{\circ(2,1)} & 0 & -A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}\mathscr{Y}\\ \mathscr{Z}\\ Y^{(2)}\\ Z^{(2)}\end{bmatrix}
=\omega
\begin{bmatrix}\mathscr{Y}\\ \mathscr{Z}\\ Y^{(2)}\\ Z^{(2)}\end{bmatrix}, \qquad (25)
$$

where $\mathscr{A}$, $\mathscr{B}$, $\mathscr{Y}$, and $\mathscr{Z}$ are already given in the preceding section, and

$$\mathscr{A}^{\circ(1,2)}{}_{m'\gamma';\,(m\gamma,n\delta)}=A^{\circ(1,2)}{}_{m'\gamma';\,(m\gamma,\,n\delta)}/g_{m'\gamma'}. \qquad (26)$$

In order to reduce the matrix size of Eq. 25, we first write it as

$$
\begin{bmatrix}
\mathscr{A}-\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}\mathscr{Y}-\mathscr{Z}\\ Y^{(2)}-Z^{(2)}\end{bmatrix}
=\omega
\begin{bmatrix}\mathscr{Y}+\mathscr{Z}\\ Y^{(2)}+Z^{(2)}\end{bmatrix}, \qquad (27a)
$$

$$
\begin{bmatrix}
\mathscr{A}+\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}\mathscr{Y}+\mathscr{Z}\\ Y^{(2)}+Z^{(2)}\end{bmatrix}
=\omega
\begin{bmatrix}\mathscr{Y}-\mathscr{Z}\\ Y^{(2)}-Z^{(2)}\end{bmatrix}. \qquad (27b)
$$

Multiplication of the matrix

$$
\begin{bmatrix}
\mathscr{A}-\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
$$

from the left on both sides of Eq. 27b gives

$$
\begin{bmatrix}
\mathscr{A}-\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}
\mathscr{A}+\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}\mathscr{Y}+\mathscr{Z}\\ Y^{(2)}+Z^{(2)}\end{bmatrix}
=\omega^2
\begin{bmatrix}\mathscr{Y}+\mathscr{Z}\\ Y^{(2)}+Z^{(2)}\end{bmatrix}. \qquad (28)
$$

Similarly we also have

$$
\begin{bmatrix}
\mathscr{A}+\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}
\mathscr{A}-\mathscr{B} & \mathscr{A}^{\circ(1,2)}\\
\mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)}
\end{bmatrix}
\begin{bmatrix}\mathscr{Y}-\mathscr{Z}\\ Y^{(2)}-Z^{(2)}\end{bmatrix}
=\omega^2
\begin{bmatrix}\mathscr{Y}-\mathscr{Z}\\ Y^{(2)}-Z^{(2)}\end{bmatrix}. \qquad (29)
$$

Solving either Eq. 28 or 29 may suffices if one is only interested in finding the transition energy ω. For the evaluation of the transition moments, however, both eigenvectors of Eqs. 28 and 29 are needed. In any case, the order of the matrix to be diagonalyzed has been reduced to the half.

The Transition Moment

In deriving the explicit expressions of the matrix elements, we have assumed the normalization condition of Eq. 10 for the $|0>$. For excited states, we let

$$<\lambda|\lambda>=1. \tag{30}$$

Then, the transition dipole moment is written

$$\begin{aligned}\boldsymbol{D}_\lambda &=<0|(\boldsymbol{r})_{op}|\lambda> \\ &=-\sqrt{2}\sum_{ij}\boldsymbol{d}^\circ_{ij}<0|[C_{ij}{}^\dagger(00),\ O^\dagger{}_\lambda]|0>,\end{aligned} \tag{31}$$

where

$$\boldsymbol{d}^\circ_{ij}\equiv\int i(\boldsymbol{r})\,\boldsymbol{r}\,j(\boldsymbol{r})\,\mathrm{d}^3r. \tag{32}$$

The oscillator strength is given by

$$f_\lambda\equiv(2/3)\,\omega_\lambda|\boldsymbol{D}_\lambda|^2. \tag{33}$$

Employing the diagonalization approximations used in the treatment of D and $D^{(2,2)}$, we can rewrite the normalization condition Eq. 30 as

$$\begin{aligned}&\sum_{m\gamma}\{|\mathcal{Y}_{m\gamma}(\lambda S)|^2-|\mathcal{Z}_{m\gamma}(\lambda S)|^2\} \\ &\quad+\sum_{(m\gamma.n\delta)}\{|Y^{(2)}_{(m\gamma.n\delta)}(\lambda S)|^2-|Z^{(2)}_{(m\gamma.n\delta)}(\lambda S)|^2\}=1\end{aligned} \tag{34}$$

Note that the first and the second terms on the left-hand side of this equation are the scalar products of $(\mathcal{Y}+\mathcal{Z},\mathcal{Y}-\mathcal{Z})$ and $(Y^{(2)}+Z^{(2)},\ Y^{(2)}+Z^{(2)})$. These are evaluated by using eigenvectors of Eqs. 28 and 29. With the diagonalization approximation in Eq. 18, Eq. 31 leads to

$$\boldsymbol{D}_\lambda=\delta_{S0}\sqrt{2}\sum_{m\gamma}\{\mathcal{Y}_{m\gamma}(\lambda 0)+\mathcal{Z}_{m\gamma}(\lambda 0)\}\,(g_{m\gamma}\boldsymbol{d}^\circ{}_{m\gamma}). \tag{35}$$

Note that terms of $Y^{(2)}$ and $Z^{(2)}$ vanish in deriving the last expression, for in our approximation,

$$<0|[C_{ij}{}^\dagger(00),\ \Gamma^\dagger{}_{(m\gamma.n\delta)}(00)]|>=0. \tag{36}$$

Thus, $\boldsymbol{D}_\lambda$ is only indirectly affected by $Y^{(2)}$ and $Z^{(2)}$ through the normalization condition Eq. 34. When the second term bccomes large on the left-hand side of Eq. 34, $\boldsymbol{D}_\lambda$ may drastically reduce in comparison with that obtained from the (1p-1h) EOM.

Discussion

With the results obtained above, we are now able to make computations of the EOM at the level of (1p-1h)+(2p-2h). Previously we[9] analyzed the dynamical screening due to sigma-electrons in the $\pi\rightarrow\pi^*$ transition of the ethylene molecule. We showed that the N→T (triplet) transition is almost free from this kind of screenings but the N→V (singlet) transition is significantly affected. More recently we[10] have shown that in the zero-differential overlap (ZDO) approximation between sigma- and pi-orbitals, the triplet $\pi\rightarrow\pi^*$ transitions are generally unaffected by the dynamical screening. Such observations have led us[11] to propose a scheme to parametrize the EOM for $\pi\rightarrow\pi^*$ transitions. In the forthcoming papers, we propose a semi-empirical scheme of the (1p-1h)+(2p-2h) EOM for $\pi\rightarrow\pi^*$ transitions and present numerical results of its application to linear polyenes.

Appendix: The Matrix Elements of $A^{\circ(1,2)}$ and $A^{\circ(2,2)}$

The matrix elements of $A^{\circ(1,2)}$ and $A^{\circ(2,2)}$ appearing in Eqs. 25—29 are constructed on the orthonormal basis set of $\Gamma^\dagger{}_{(m\gamma.n\delta)}$ in Table 1. These elements are readily obtained from the primitive elements

$$\begin{aligned}&A^{\circ(1,2)}{}_{m'\gamma';\,m\gamma.\,n\delta}(S) \\ &\quad\equiv<HF|[C_{m'\gamma'}(SM),\ H,C_{m\gamma}{}^\dagger(SM)C_{n\delta}{}^\dagger(00)]|HF>\end{aligned} \tag{A. 1}$$

$$\begin{aligned}&A^{\circ(2,2)}{}_{m'\gamma',\,n'\delta';\,m\gamma.\,n\delta}(S) \\ &\quad\equiv<HF|[(C_{m'\gamma'}{}^\dagger(SM)\,C_{n'\delta'}{}^\dagger(00))^\dagger, \\ &\qquad H,C_{m\gamma}{}^\dagger(SM)C_{n\delta}{}^\dagger(00)]|HF>\end{aligned} \tag{A. 2}$$

To expand these primitive elements, it is convenient to have the Hamiltonian in the following form:[1a]

$$\left.\begin{aligned}&H=H(1)+H(2)+H(3); \\ &H(1)=\sum_i\varepsilon_i\sqrt{2}\,C_{ii}{}^\dagger(00), \\ &H(2)=\sum_{ij}[-\frac{1}{2}\sum_k V_{ikkj}+\sum_\gamma(V_{i\gamma\gamma j}-2V_{i\gamma j\gamma})]\,\sqrt{2}\,C_{ij}{}^\dagger(00), \\ &H(3)=\sum_{ijkl}V_{ijkl}\,C_{ik}{}^\dagger(00)\,C_{jl}{}^\dagger(00),\end{aligned}\right\} \tag{A. 3}$$

where

$$V_{ijkl}=<i(1)j(2)|(r_{12})^{-1}|k(1)l(2)>. \tag{A. 4}$$

In Eq. A. 3, γ refers to a hole orbital and i, j, k, l to any orbital, i.e., hole or particle. Cf. Ref. 1a for various relations useful in expanding the right-hand side of Eqs. A. 1 and A. 2.

First note that Eqs. A. 1 and A. 2 can be also written as

$$\begin{aligned}&A^{\circ(1,2)}{}_{m'\gamma';\,m\gamma.\,n\delta}(S) \\ &\quad=<HF|[C_{m'\gamma'}(S0),\ H]C_{m\gamma}{}^\dagger(S0)C_{n\delta}{}^\dagger(00)|HF> \\ &\quad+\frac{1}{2}<HF|HC_{m'\gamma'}(S0)C_{m\gamma}{}^\dagger(S0)\,C_{n\delta}{}^\dagger(00)|HF>\end{aligned} \tag{A. 5}$$

$$\begin{aligned}&A^{\circ(2,2)}{}_{m'\gamma',\,n'\delta';\,m\gamma.n\delta}(S) \\ &\quad=<HF|[C_{n'\delta'}(00)\,C_{m'\gamma'}(S0)[H,\ C_{m\gamma}{}^\dagger(S0)\,C_{n\delta}{}^\dagger(00)]|HF> \\ &\quad+\frac{1}{2}<HF|[C_{n'\delta'}(00)C_{m'\gamma'}(S0)C_{m\gamma}{}^\dagger(S0)\,C_{n\delta}{}^\dagger(00),\ H]|HF>.\end{aligned} \tag{A. 6}$$

In the second term of Eq. A. 5, we have

$$<HF|H(1)C_{m'\gamma'}(S0)C_{m\gamma}{}^\dagger(S0)C_{n\delta}{}^\dagger(00)|HF>=0 \tag{A. 7}$$

and

$$\begin{aligned}&<HF|H(2)C_{m'\gamma'}(S0)C_{m\gamma}{}^\dagger(S0)C_{n\delta}{}^\dagger(00)|HF> \\ &\quad=-<HF|H(3)C_{m'\gamma'}(S0)C_{m\gamma}{}^\dagger(S0)C_{n\delta}{}^\dagger(00)|HF> \\ &\quad=\sqrt{2}\sum_{p\mu}\{\frac{1}{2}(\sum_\nu V_{\mu\nu\nu p}-\sum_q V_{\mu qqp})-2\sum_\nu V_{\mu\nu p\nu}\}\times \\ &\quad<HF|C_{p\mu}(00)C_{m'\gamma'}(S0)C_{m\gamma}{}^\dagger(S0)C_{n\delta}{}^\dagger(00)|HF>.\end{aligned} \tag{A. 8}$$

In the second term of Eq. A. 6, we have

$$C_{n'\delta'}(00)C_{m'\gamma'}(S0)C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)|HF\rangle$$
$$=\{\delta_{m'm}\delta_{n'n}(\delta_{\gamma'\gamma}\delta_{\delta'\delta}-\frac{1}{2}\delta_{\gamma'\delta}\delta_{\delta'\gamma})$$
$$+\delta_{m'n}\delta_{n'm}(\delta_{S0}\delta_{\gamma'\delta}\delta_{\delta'\gamma}-\frac{1}{2}\delta_{\gamma'\gamma}\delta_{\delta'\delta})\}|HF\rangle \quad \text{(A. 9)}$$

and a similar expression for $\langle HF|C_{n'\delta'}(00)C_{m'\gamma'}(S0)C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$. Hence, the second terms of Eqs. A. 5 and A. 6 vanish, and we have

$$A^{\circ(1,2)}{}_{m'\gamma';\,m\gamma,n\delta}(S)$$
$$=\langle HF|[C_{m'\gamma'}(S0),H]C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)|HF\rangle \quad \text{(A. 10)}$$

$$A^{\circ(2,2)}{}_{m'\gamma',\,n'\delta';\,m\gamma,\,n\delta}(S)$$
$$=\langle HF|[C_{n'\delta'}(00)C_{m'\gamma'}(S0)[H,C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)]|HF\rangle \quad \text{(A. 11)}$$

Now, it is useful to note the following equations:

$$[H(1),C_{m\gamma}{}^{\dagger}(S0)]=(\varepsilon_m-\varepsilon_\gamma)C_{m\gamma}{}^{\dagger}(S0) \quad \text{(A. 12)}$$

$$[H(2),C_{m\gamma}{}^{\dagger}(S0)]$$
$$=\sum_i\{-\frac{1}{2}\sum_k V_{ikkm}+\sum_{\gamma''}(V_{i\gamma''\gamma''m}-2V_{i\gamma''m\gamma''})\}C_{i\gamma}{}^{\dagger}(S0)$$
$$-\sum_j\{-\frac{1}{2}\sum_k V_{\gamma kkj}+\sum_{\gamma''}(V_{\gamma\gamma''\gamma''j}-2V_{\gamma\gamma''j\gamma''})\}C_{mj}{}^{\dagger}(S0) \quad \text{(A. 13)}$$

$$[H(3),C_{m\gamma}{}^{\dagger}(S0)]$$
$$=-\frac{1}{2}\sum_{ik}V_{ikkm}C_{i\gamma}{}^{\dagger}(S0)-\frac{1}{2}\sum_{jk}V_{\gamma kkj}C_{mj}{}^{\dagger}(S0)$$
$$+\sum_{ij}V_{\gamma ijm}C_{ij}{}^{\dagger}(S0)$$
$$+\sqrt{2}\sum_{kl}\{\sum_i V_{ikml}C_{kl}{}^{\dagger}(00)C_{i\gamma}{}^{\dagger}(S0)$$
$$-\sum_j V_{\gamma kjl}C_{kl}{}^{\dagger}(00)C_{mj}{}^{\dagger}(S0)\} \quad \text{(A. 14)}$$

which amounts to

$$[H,C_{m\gamma}{}^{\dagger}(S0)]$$
$$=(\varepsilon_m-\varepsilon_\gamma)C_{m\gamma}{}^{\dagger}(S0)+\sum_{ij}V_{\gamma ijm}C_{ij}{}^{\dagger}(S0)$$
$$-\sum_i(\sum_{m''}V_{im''m''m}+\sum_{\gamma''}2V_{i\gamma''m\gamma''})C_{i\gamma}{}^{\dagger}(S0)$$
$$-\sum_{j\gamma''}(V_{\gamma\gamma''\gamma''j}-2V_{\gamma\gamma''j\gamma''})C_{mj}{}^{\dagger}(S0)$$
$$+\sqrt{2}\sum_{kl}\{\sum_i V_{ikml}C_{kl}{}^{\dagger}(00)C_{i\gamma}{}^{\dagger}(S0)$$
$$-\sum_j V_{\gamma kjl}C_{kl}{}^{\dagger}(00)C_{mj}{}^{\dagger}(S0)\} \quad \text{(A. 15)}$$

Also note that

$$[H,C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)]$$
$$=(\varepsilon_m+\varepsilon_n-\varepsilon_\gamma-\varepsilon_\delta)C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+\sum_{ij}\{V_{\gamma ijm}C_{ij}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)+V_{\delta ijn}C_{m\gamma}{}^{\dagger}(S0)C_{ij}{}^{\dagger}(00)\}$$
$$-\sum_i\{(\sum_p V_{ippm}+2\sum_\mu V_{i\mu m\mu})C_{i\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+(\sum_p V_{ippn}+2\sum_\mu V_{i\mu n\mu})C_{m\gamma}{}^{\dagger}(S0)C_{i\delta}{}^{\dagger}(00)$$
$$-\sum_{p\mu}\{(V_{\gamma\mu\mu j}-2V_{\gamma\mu j\mu})C_{mj}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+(V_{\delta\mu\mu j}-2V_{\delta\mu j\mu})C_{m\gamma}{}^{\dagger}(S0)C_{nj}{}^{\dagger}(00)\}$$
$$+\sqrt{2}\sum_{kl}[\{\sum_i V_{ikml}C_{kl}{}^{\dagger}(00)C_{i\gamma}{}^{\dagger}(S0)$$
$$-\sum_j V_{\gamma kjl}C_{kl}{}^{\dagger}(00)C_{mj}{}^{\dagger}(S0)\}C_{n\delta}{}^{\dagger}(00)$$
$$+C_{m\gamma}{}^{\dagger}(S0)\{\sum_i V_{iknl}C_{kl}{}^{\dagger}(00)C_{i\delta}{}^{\dagger}(00)$$
$$-\sum_j V_{\delta kjl}C_{kl}{}^{\dagger}(00)C_{nj}{}^{\dagger}(00)\}]. \quad \text{(A. 16)}$$

Now, from Eq. A. 15, we have

$$[C_{m'\gamma'}(S0),H]$$
$$=(\varepsilon_{m'}-\varepsilon_{\gamma'})C_{m'\gamma'}(S0)+\sum_{ij}V_{jm'\gamma'i}C_{ij}(S0)$$
$$-\sum_i(\sum_p V_{pm'ip}+2\sum_\mu V_{m'\mu i\mu})C_{i\gamma'}(S0)$$
$$-\sum_{j\mu}(V_{\mu j\gamma'\mu}-2V_{j\mu\gamma'\mu})C_{m'j}(S0)$$
$$+\sqrt{2}\sum_{kl}\{\sum_i V_{m'lik}C_{i\gamma'}(S0)C_{kl}(00)$$
$$-\sum_j V_{jl\gamma'k}C_{m'j}(S0)C_{kl}(00)\}. \quad \text{(A. 17)}$$

The substitution of this expression into Eq. A. 10 gives

$$A^{\circ(1,2)}{}_{m'\gamma';m\gamma,n\delta}(S)$$
$$=\langle HF|\sqrt{2}\sum_{kl}\{\sum_i V_{m'lik}C_{i\gamma'}(S0)C_{kl}(00)$$
$$-\sum_j V_{jl\gamma'k}C_{m'j}(S0)C_{kl}(00)\}C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)|HF\rangle$$
$$=\langle HF|\sqrt{2}\sum_{q\nu}\{\sum_p V_{m'\nu pq}C_{p\gamma'}(S0)C_{q\nu}(00)$$
$$-\sum_\mu V_{\mu\nu\gamma'q}C_{m'\mu}(S0)C_{q\nu}(00)\}C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)|HF\rangle$$
$$=\sqrt{2}\{\delta_{\gamma'\gamma}(V_{m'\delta mn}-\frac{1}{2}V_{m'\delta nm})$$
$$+\delta_{\gamma'\delta}(\delta_{S0}V_{m'\gamma nm}-\frac{1}{2}V_{m'\gamma mn})$$
$$-\delta_{m'm}(V_{\gamma\delta\gamma'n}-\frac{1}{2}V_{\delta\gamma\gamma'n})-\delta_{m'n}(\delta_{S0}V_{\delta\gamma\gamma'm}-\frac{1}{2}V_{\gamma\delta\gamma'm})\}. \quad \text{(A. 18)}$$

On the other hand, the substitution of Eq. A. 16 into Eq. A. 11 gives

$$A^{\circ(2,2)}{}_{m'\gamma',n'\delta';\,m\gamma,n\delta}(S)$$
$$=\langle HF|C_{n'\delta'}(00)C_{m'\gamma'}(S0)$$
$$\times[(\varepsilon_m+\varepsilon_n-\varepsilon_\gamma-\varepsilon_\delta)C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+\sum_{p\mu}\{V_{\gamma p\mu m}C_{p\mu}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+V_{\delta p\mu n}C_{m\gamma}{}^{\dagger}(S0)C_{p\mu}{}^{\dagger}(00)\}$$
$$-\sum_q\{(\sum_p V_{qppm}+2\sum_\mu V_{q\mu m\mu})C_{q\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+(\sum_p V_{qppn}+2\sum_\mu V_{q\mu n\mu})C_{m\gamma}{}^{\dagger}(S0)C_{q\delta}{}^{\dagger}(00)\}$$
$$-\sum_{p\mu}\{(V_{\gamma\mu\mu\nu}-2V_{\gamma\mu\nu\mu})C_{m\nu}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)$$
$$+(V_{\delta\mu\mu\nu}-2V_{\delta\mu\nu\mu})C_{m\gamma}{}^{\dagger}(S0)C_{n\nu}{}^{\dagger}(00)\}]|HF\rangle$$
$$+\langle HF|C_{n'\delta'}(00)C_{m'\gamma'}(S0)$$
$$\times\sqrt{2}\sum_{kl}[\{\sum_i V_{ikml}C_{kl}{}^{\dagger}(00)C_{i\gamma}{}^{\dagger}(S0)$$
$$-\sum_j V_{\gamma kjl}C_{kl}{}^{\dagger}(00)C_{mj}{}^{\dagger}(S0)\}C_{n\delta}{}^{\dagger}(00)$$
$$+C_{m\gamma}{}^{\dagger}(S0)\{\sum_i V_{iknl}C_{kl}{}^{\dagger}(00)C_{i\delta}{}^{\dagger}(00)$$
$$-\sum_\nu V_{\delta kvl}C_{kl}{}^{\dagger}(00)C_{n\nu}{}^{\dagger}(00)\}]|HF\rangle. \quad \text{(A. 19)}$$

The last term of this expression can be reduced as follows: (the lasst term)

$$
\begin{aligned}
&=\langle HF|C_{n'\delta'}(00)C_{m'\gamma'}(S0)\times\\
&[-\sum_{q\nu}\{V_{\delta qm\nu}C_{n\gamma}{}^{\dagger}(S0)+V_{\gamma qn\nu}C_{m\delta}{}^{\dagger}(S0)\}C_{q\nu}(00)\\
&+\sum_{q}\{\sum_{p}V_{pqmn}C_{p\gamma}{}^{\dagger}(S0)-\sum_{\nu}V_{\gamma qn\nu}C_{m\nu}{}^{\dagger}(S0)\}C_{q\delta}{}^{\dagger}(00)\\
&+\sum_{\nu}\{\sum_{\mu}V_{\gamma\delta\mu\nu}C_{m\mu}{}^{\dagger}(S0)-\sum_{q}V_{q\delta m\nu}C_{q\gamma}{}^{\dagger}(S0)\}C_{n\nu}{}^{\dagger}(00)\\
&+\{\sum_{q}(\sum_{p}V_{pqmn}+2\sum_{\nu}V_{q\nu m\nu})C_{q\gamma}{}^{\dagger}(S0)\\
&+\sum_{\mu\nu}(V_{\gamma\mu\mu\nu}-2V_{\gamma\mu\nu\mu})C_{m\nu}{}^{\dagger}(S0)\\
&+2\sum_{q\nu}(\delta_{S0}V_{\gamma qm\nu}-V_{q\gamma m\nu})C_{q\nu}{}^{\dagger}(S0)\}C_{n\delta}{}^{\dagger}(00)\\
&+C_{m\gamma}{}^{\dagger}(S0)\{\sum_{q}(\sum_{p}V_{pqnp}+2\sum_{\nu}V_{q\nu n\nu})C_{q\delta}{}^{\dagger}(00)\\
&+\sum_{\mu\nu}(V_{\delta\mu\mu\nu}-2V_{\delta\mu\nu\mu})C_{n\nu}{}^{\dagger}(00)\\
&+2\sum_{q\nu}(V_{\delta qn\nu}-V_{\delta q\nu n})C_{q\nu}{}^{\dagger}(00)\}]|HF\rangle. \qquad \text{(A. 20)}
\end{aligned}
$$

Thus, Eq. A. 19 becomes

$$
\begin{aligned}
&A^{\circ(2,2)}{}_{m'\gamma',n'\delta';\,m\gamma,n\delta}(S)\\
&=\langle HF|C_{n'\delta'}(00)C_{m'\gamma'}(S0)\times\\
&[(\varepsilon_m+\varepsilon_n-\varepsilon_\gamma-\varepsilon_\delta)C_{m\gamma}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)\\
&+\sum_{q\nu}\{(2V_{\delta qn\nu}-V_{\delta q\nu n})C_{m\gamma}{}^{\dagger}(S0)C_{q\nu}{}^{\dagger}(00)\\
&+(\delta_{S0}2V_{\gamma qm\nu}-V_{q\gamma m\nu})C_{q\nu}{}^{\dagger}(S0)C_{n\delta}{}^{\dagger}(00)\\
&-\sum_{q\nu}\{V_{\delta qm\nu}C_{n\gamma}{}^{\dagger}(S0)+V_{\gamma qn\nu}C_{m\delta}{}^{\dagger}(S0)\}C_{q\nu}{}^{\dagger}(00)\\
&+\sum_{q}\{\sum_{p}V_{pqmn}C_{p\gamma}{}^{\dagger}(S0)-\sum_{\nu}V_{\gamma qn\nu}C_{m\nu}{}^{\dagger}(S0)\}C_{q\delta}{}^{\dagger}(00)\\
&+\sum_{\nu}\{\sum_{\mu}V_{\gamma\delta\mu\nu}C_{m\mu}{}^{\dagger}(S0)\\
&-\sum_{q}V_{q\delta m\nu}C_{q\gamma}{}^{\dagger}(S0)\}C_{n\nu}{}^{\dagger}(00)]|HF\rangle. \qquad \text{(A. 21)}
\end{aligned}
$$

After some tedious calculations using Eq. A. 9 in the last expression, we finally obtain

$$
\begin{aligned}
&A^{\circ(2,2)}{}_{m'\gamma',n'\delta';\,m\gamma,n\delta}(S)\\
&=\{(\varepsilon_m+\varepsilon_n-\varepsilon_\gamma-\varepsilon_\delta)\times\\
&[(\delta_{m'm}\delta_{n'n}\delta_{\gamma'\gamma}\delta_{\delta'\delta}-\frac{1}{2}\delta_{m'm}\delta_{n'n}\delta_{\gamma'\delta}\delta_{\delta'\gamma}\\
&-\frac{1}{2}\delta_{m'n}\delta_{n'm}\delta_{\gamma'\gamma}\delta_{\delta'\delta})+(\delta_{S0})\delta_{m'n}\delta_{n'm}\delta_{\gamma'\delta}\delta_{\delta'\gamma}]\\
&+(\delta_{m'm}\delta_{n'n}-\frac{1}{2}\delta_{m'n}\delta_{n'm})V_{\gamma\delta\gamma'\delta'}\\
&+((\delta_{S0})\delta_{m'n}\delta_{n'm}-\frac{1}{2}\delta_{m'n}\delta_{n'n})V_{\gamma\delta\delta'\gamma'}\\
&+(\delta_{\gamma'\gamma}\delta_{\delta'\delta}-\frac{1}{2}\delta_{\gamma'\delta}\delta_{\delta'\gamma})V_{m'n'mn}\\
&+((\delta_{S0})\delta_{\gamma'\delta}\delta_{\delta'\gamma}-\frac{1}{2}\delta_{\gamma'\gamma}\delta_{\delta'\delta})V_{n'm'mn}\}\\
&+\{[\delta_{m'm}\delta_{\gamma'\gamma}(2V_{\delta n'n\delta'})-(\delta_{m'm}\delta_{\delta'\gamma}V_{\delta n'n\gamma'}+\delta_{n'm}\delta_{\gamma'\gamma}V_{\delta m'n\delta'}\\
&+\delta_{m'n}\delta_{\gamma'\gamma}V_{\delta n'm\delta'}+\delta_{m'm}\delta_{\gamma'\delta}V_{\gamma n'n\delta'})\\
&+\frac{1}{2}(\delta_{m'm}\delta_{\delta'\delta}V_{\gamma n'n\gamma'}+\delta_{n'n}\delta_{\gamma'\gamma}V_{\delta m'm\delta'}\\
&+\delta_{m'n}\delta_{\delta'\gamma}V_{\delta n'm\gamma'}+\delta_{n'm}\delta_{\gamma'\delta}V_{\gamma m'n\delta'})]\\
&+(\delta_{S0})[2(\delta_{m'n}\delta_{\gamma'\delta}V_{\gamma n'm\delta'}\\
&+\delta_{n'm}\delta_{\delta'\gamma}V_{\delta m'n\gamma'}+\delta_{n'n}\delta_{\delta'\delta}V_{\gamma m'm\gamma'})\\
&-(\delta_{n'n}\delta_{\gamma'\delta}V_{\gamma m'm\delta'}+\delta_{m'n}\delta_{\delta'\delta}V_{\gamma n'm\gamma'})]\\
&+(\delta_{n'm}\delta_{\delta'\delta}V_{\gamma m'n\gamma'}+\delta_{n'n}\delta_{\delta'\gamma}V_{\delta m'm\gamma'})]\}\\
&+\{[-\delta_{m'm}\delta_{\delta'\delta}V_{\gamma n'\gamma'n}+\delta_{n'n}\delta_{\gamma'\gamma}V_{\delta m'\delta'm}\\
&+\delta_{m'm}\delta_{\gamma'\gamma}V_{\delta n'\delta'n}+\delta_{n'n}\delta_{\delta'\delta}V_{\gamma m'\gamma'm})\\
&+\frac{1}{2}(\delta_{m'm}\delta_{\delta'\gamma}V_{\delta n'\gamma'n}+\delta_{n'm}\delta_{\gamma'\gamma}V_{\delta m'\delta'n}+\delta_{m'n}\delta_{\gamma'\gamma}V_{\delta n'\delta'm}\\
&+\delta_{m'm}\delta_{\gamma'\delta}V_{\gamma n'\delta'n}+\delta_{n'n}\delta_{\gamma'\delta}V_{\gamma m'\delta'm}+\delta_{m'n}\delta_{\delta'\delta}V_{\gamma n'\gamma'm}\\
&+\delta_{n'm}\delta_{\delta'\delta}V_{\gamma m'\gamma'n}+\delta_{n'n}\delta_{\delta'\gamma}V_{\delta m'\gamma'm})]\\
&+(\delta_{S0})[-(\delta_{m'n}\delta_{\delta'\gamma}V_{\delta n'\gamma'm}+\delta_{n'm}\delta_{\gamma'\delta}V_{\gamma m'\delta'n}\\
&+\delta_{m'n}\delta_{\gamma'\delta}V_{\gamma n'\delta'm}+\delta_{n'm}\delta_{\delta'\gamma}V_{\delta m'\gamma'n})]\}. \qquad \text{(A. 22)}
\end{aligned}
$$

Note that all the terms in the second braces are of particle-hole "exchange integral" type and those in the third braces are of particle-hole "Coulomb integral" type.

Dielectric Loss of Dehydrated Rb_3Na_8-ZK4 Zeolite

Tatsuo OHGUSHI
Department of Materials Science, Toyohashi University of Technology, Toyohashi 440
(Received October 12, 1987)

The dielectric properties of completely dehydrated Rb_3Na_8-ZK4 zeolite were studied in the range 12—2.2×10^6 Hz and 211—705 K. Two kinds of losses, relaxation and conduction, were observed. The relaxation loss in the higher-frequency region had an activation energy of 99±2 kJ mol^{-1} and was tentatively assigned to a jump of the Rb^+ ion from an 8-ring site to a vacant 4-ring site. The loss at the lower-frequency region had an activation energy of 95±3 kJ mol^{-1} and was attributed to a movement of the Rb^+ ion on the 8-ring site beyond the unit-cell dimension.

In a recent study on the ^{18}O-exchange between CO_2 and zeolite A, it was confirmed that exchangeable cations migrate out from their normal sites and take part in the formation of an activated complex.[1] Movements of exchangeable cations in a zeolite play a decisive role in the thermal deterioration of its crystallinity and may also play an important role in catalytic processes at higher temperatures. Dielectric measurements are most appropriate for studying cation movement in zeolites, since the jump of cation produces a dielectric loss peak.

Dielectric studies of hydrated zeolites have been carried out by many workers, and various properties have been elucidated. Water in a zeolite increases its electrical conductivity.[2-5] The activation energy in a dielectric relaxation process is seriously influenced by adsorbed water.[3,6-9] However, as pointed out by Jonscher et al.,[10] the dielectric properties of completely dehydrated zeolites have been little known and, thus, the dielectric effect of cationic movements in the completely dehydrated zeolites have not been well understood.

Zeolite A is a leading zeolite for studying the physical and chemical properties of zeolites, and its nature is well-understood. In zeolite A, there exist three structurally distinct cations: those located on the sites of 8-, 6-, and 4-membered oxygen rings, respectively. These cations are abbreviated as an 8-, 6-, and 4-ring cation, respectively, in the following. The distribution of these cations had been studied in detail.[11-20] The presence of three structurally distinct cations makes it too complicate to determine which cation is responsible for a dielectric loss. On the other hand, zeolite ZK4 is isostructural with zeolite A and has two structurally distinct cations, 8- and 6-ring cations,[21] and is appropriate for determining to which cation an observed dielectric loss is to be assigned.

Experimental

Apparatus. The measurement system is shown in Fig. 1. In order to ensure a clean vacuum, parts for an ultrahigh vacuum and a turbo molecular pump were used. Methane is usually evolved, even though in small amounts, from the stainless-steel wall; therefore oxygen was continuously flowed into the system at a pressure level of 5×10^{-4} Pa in order to oxidize methane. At temperatures lower than 470 K, at which the decomposition of methane may not occure, oxygen was not introduced. At temperatures lower than room temperature, helium gas was introduced as a heat conductor, through a helium leaker of quartz kept above 670 K. Dielectric measurements were made with a Cole-Gross-type bridge.[22] A guard electrode is useful for determining the absolute value of the dielectric constant and to reduce the surface leakage current. In the present work, however, we did not require the absolute value of the dielectric constant but, rather, its frequency and temperature dependence; further, the surface leakage current was minimized by vacuum techniques, so that it was not necessary to use the guard electrode, thus avoiding unnecessary complications in the cell system.

Sample. Zeolite ZK4, supplied by Vaughan,[23] had a composition of $Na_{11.0}(AlO_2)_{11.0}(SiO_2)_{13.0}\cdot nH_2O$ (abbreviated as $Na_{11.0}$-ZK4), and was used as a starting material. The zeolite was ion-exchanged with a 0.2 mol dm^{-3} solution of CH_3COORb; its composition was determined by atomic absorption spectrometry to be $Rb_{3.0}Na_{8.0}$-ZK4. Powdery zeo-

lite was pressed at a pressure of 900 kg cm^{-2} (8.8×10^7 Pa) at room temperature; the obtained disk had a density of 62% of the single crystal value. The sample did not show any sign of structural damage in its X-ray diffraction pattern and in the water sorption capacity. Thin gold films were evaporated on both sides of the disk for electric contact with gold electrodes. A sample placed in the vacuum system was gently heated under pumping, the temperature being raised by a step of 50 K at an interval of 10 h and finally baked out at 670 K for one day. The back-ground pressure reached was less than 4×10^{-5} Pa. This pressure did not change upon baking out at 670 K for one more day, and was close to the back-ground pressure of the vacuum system without a sample at 670 K, ca. 3×10^{-5} Pa; thus, we judged the sample to be completely dehydrated.

Results

Complex dielectric constants ($\varepsilon^*=\varepsilon'-i\varepsilon''$) were measured as a function of the frequency, f, in the range 12—2.2×10^6 Hz and 211—705 K. Their values measured were not corrected for the packing factor, since we do not need the absolute values (as mentioned above). The sample temperature, T, was controlled, at least, within ±0.5 K of a preset temperature. Data were reproducible in a range of ±1%.

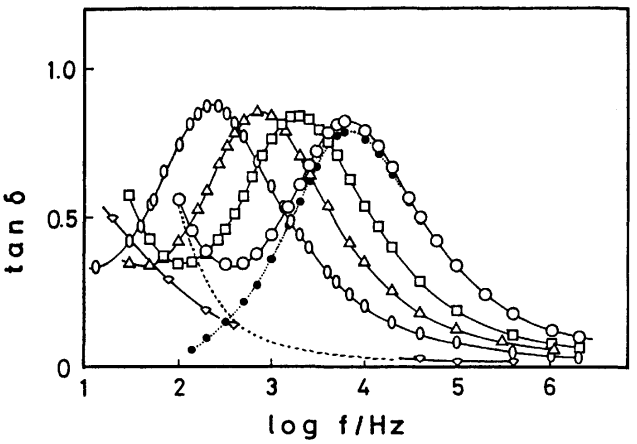

Fig. 2. Spectra of loss tangent. ○: 705.2 K, □: 656.6 K, △: 624.0 K, 0: 588.3 K, ◇: 500.3 K, broken line: loss tangent of conduction ($\tan\delta_c=\varepsilon''_c/\varepsilon'_{obs}$) at 705.2 K, calculated by using relation of $\varepsilon''_c=\sigma/2\pi f\varepsilon_o$ with σ=1.93×10^{-7} S m^{-1}, ●: loss tangent of relaxation ($\tan\delta_r$) at 705.2 K, obtained from relation of $\tan\delta_r=\tan\delta_{obs}-\tan\delta_c$. Subscript obs denotes observed value.

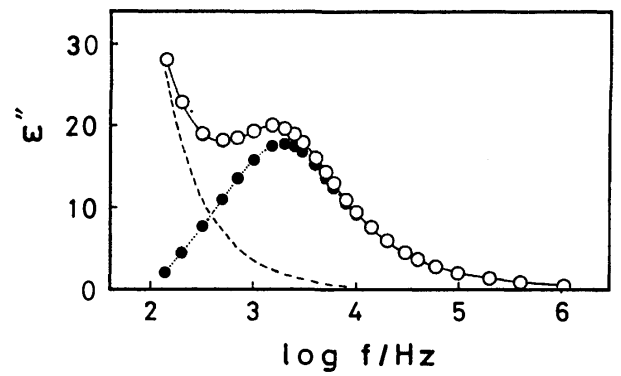

Fig. 3. Spectrum of dielectric loss. ○: observed value at 705.2 K (ε''_{obs}), broken line: conduction loss, ε''_c, calculated from $\varepsilon''_c=\sigma/2\pi f\varepsilon_o$ with σ=1.93×10^{-7} S m^{-1}, ●: relaxation loss ε''_r ($=\varepsilon''_{obs}-\varepsilon''_c$).

The spectra of the loss tangent ($\tan\delta$) and ε'' contain two kinds of losses: one a relaxation loss peak in the higher-frequency region and the other a loss in the lower-frequency region (abbreviated as the low-frequency loss), as shown in Figs. 2 and 3. Let f_{tan} be the applied frequency giving a maximum peak of the loss tangent; we can then approximately determine the activation energy in the relaxation process, E_{tan}, from Arrhenius plots of ln f_{tan} vs. $1/T$. The value obtained is given in Table 1. In the spectra of ε'' (Fig. 3), the low-frequency loss is described by the conductivity loss expressed as $\varepsilon''_c=\sigma/2\pi f\varepsilon_o$, where σ is the apparent specific d.c. conductivity and ε_o the permittivity of vacuum. The low-frequency loss gives a steep rise at higher ε' in the Cole-Cole plots (Fig. 4); this rise is a characteristic of the conduction loss.[24] The low-frequency loss has been frequently observed in zeolite systems and is attributed to the conduction loss.[2,7,25,26] Thus, the low-frequency loss in the present system is assigned to the conduction loss. The most appropriate value of σ was determined by the method described in the Appendix; contributions of the conductivity loss and the conductivity loss tangent were calculated as shown in Figs. 2 and 3. From plots of ln σ vs. $1/T$, the activation energy in the conduction process, E_c, was determined, as listed in Table 1. A relaxation loss part, ε''_r, is obtained from the relation

$$\varepsilon''_r=\varepsilon''_{obs}-\varepsilon''_c=\varepsilon''_{obs}-\sigma/2\pi f\varepsilon_o.$$

Cole-Cole plots, ε''_r vs. ε'_{obs}, are well described by a single circular arc, as shown in Fig. 4; this shows that the loss part, ε''_r, contains a single relaxation process. The

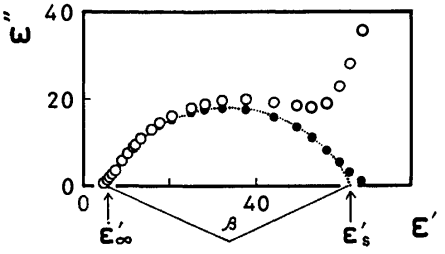

Fig. 4. Cole-Cole plots. ○: observed value at 705.2 K (ε''_{obs} vs. ε'_{obs}), ●: value corrected for conduction loss ($\varepsilon''_{obs}-\varepsilon''_c$ vs. ε'_{obs}, $\varepsilon''_c=\sigma/2\pi f\varepsilon_o$ wth σ=1.93×10^{-7} S m^{-1}) ε'_s=61.2, ε'_∞=5.6, β=108°. Subscript obs denotes observed value.

Table 2. Factors of Cole-Cole Circular Arc at Various Temperatures

T/K	ε'_s	ε'_∞	$\varepsilon'_s/\varepsilon'_\infty$	β/deg
705.2	61.2	5.6	11	108
673.9	60.7	5.3	11	109
656.6	61.9	5.6	11	107
624.0	64.0	5.7	11	106
588.3	63.3	5.8	11	102

values of ε'_s, ε'_∞, and β can be determined on the Cole-Cole plots, as shown in Fig. 4 and listed in Table 2, where ε'_s, ε'_∞, and β denote the permittivities at $f\to 0$ and $f\to\infty$, respectively, and the central angle subtended by the circular arc. The frequency, $f_{\varepsilon''}$, giving the maximum value of ε''_r was determined on the spectrum of ε''_r. From Arrhenius plots of $\ln f_{\varepsilon''}$ vs. $1/T$, the activation energy of the relaxation loss, $E_{\varepsilon''}$, and the frequency factor of the jumping cation, ω_0, were obtained as given in Table 1, where ω_0 is defined as $\ln f_{\varepsilon''} = \ln \omega_0/2\pi - E_{\varepsilon''}/RT$.

Discussion

The observed values of $E_{\tan}$ and $E_{\varepsilon''}$ agree well with each other, as shown in Table 1; this shows that $\varepsilon'_s/\varepsilon'_\infty$ and β are independent of the temperature, since their activation energies are given as[27]

$$E_{\tan} = -R\left[\frac{\mathrm{d}}{\mathrm{d}(1/T)}\ln f_{\tan}\right] = -R\left[\frac{\mathrm{d}}{\mathrm{d}(1/T)}\ln f_{\varepsilon''} + \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}(1/T)}\frac{1}{\beta}\ln\left(\frac{\varepsilon'_s}{\varepsilon'_\infty}\right)\right]$$

and

$$E_{\varepsilon''} = -R\frac{\mathrm{d}}{\mathrm{d}(1/T)}\ln f_{\varepsilon''}.$$

As can be seen from Table 2, $\varepsilon'_s/\varepsilon'_\infty$ and β are virtually independent of the temperature. Therefore, one may determine, in the present system, the activation energy of the cation jump in the relaxation process from Arrhenius plots of either $\ln f_{\varepsilon''}$ or $\ln f_{\tan}$.

The values of $E_{\varepsilon''}$ and E_c are close to each other. This suggests, as pointed out by Barrer et al.[24] and Rosseinsky et al.,[28] that the relaxation process involves the same cation jump as that in the conduction process. If a charge carrier has a same mechanism in the relaxation process and the conduction process, the dielectric relaxation frequency is related to the specific d.c. conductivity as[29,30]

$$\sigma = \frac{\pi n e^2 d^2 f_{\varepsilon''}}{3kT},$$

where n is the number density of the charge carrier per unit volume, e the elementary charge and d the jump distance. From the equation, one has

$$E_{\varepsilon''} - E_c = RT.$$

In the present experimental conditions, RT is 5—6 kJ mol^{-1} (T is 588—705 K) and the above relation is satisfied within the experimental error.

Let us consider the allowed cation jumps in the zeolite used. There is no data concerning X-ray structural analyses of the Rb_3Na_8-ZK4 zeolite. From X-ray structural analyses of zeolite A, it was found that the Na^+ ion had a stronger affinity for the 6-ring than the Rb^+ ion, and that the Rb^+ ion occupied the center of the 8-ring.[18] It is highly probable that the cations have the same site-affinities in both zeolite A and ZK4. We therefore conclude that $8Na^+$ ions occupy the 6-rings and $3Rb^+$ ions at the centers of the 8-ring in Rb_3Na_8-ZK4 (all 4-ring sites are vacant in zeolite ZK4[21]). A vacant site is necessary for a cation to move. In the above cation distribution, therefore, only three kinds of jumps are allowed. The first is a jump of the Rb^+ ion on the 8-ring to the 4-ring, called Jump I. The 6-ring has two kinds of sites near it, SI and SI', and can accommodate one cation on either site,[16,17] where SI and SI' denote the sites of the large cage side and the sodalite cage side of the 6-ring plane, respectively. The free diameter of the 6-ring is sufficiently large for a Na^+ ion to pass through the ring;[14,15,31] therefore the Na^+ ion can jump between SI and SI', called Jump II. The third is a jump of the Na^+ ion on SI to the 4-ring, called Jump III. In Jumps I—III, only Jump I can contribute to the ionic conduction, since the Rb^+ ion can go away from the unit cell dimension through the route 8-ring→4-ring→another 8-ring. The Na^+ ion has no route to escape from the cell. Consequently, we can assign Jump I to the observed low-frequency loss. This assignment is supported by the results of Haidar et al.[10] They studied the dielectric behaviors of a Ca-A zeolite which was not completely dehydrated, and observed the low-frequency loss. They assigned the loss to a movement beyond the unit-cell dimension of Ca^{2+} ion or ionic species arising from the presence of humidity. In the present zeolite, there is no humidity and, thus, humidity does not become the cause of the low-frequency loss.

If the mechanism of the relaxation loss observed in the present zeolite is same as that of the conduction loss, as suggested above, Jump I is also responsible for the relaxation loss. However, it may be necessary to confirm this assignment by other experiments.

Recently, there has been a discussion concerning the mechanism of the low-frequency loss:[10,32] two kinds, true d.c. and quasi d.c., conduction mechanisms exist. In the present system, measurements could not be made at a sufficiently low frequency range to judge which conduction mechanism was the origin of the low-frequency loss. Whether the low-frequency loss is raised by the true or the quasi d.c. conduction, the charge carrier moves beyond the unit cell dimension and, hence, the assignment of Jump I to the observed low-frequency loss is valid.

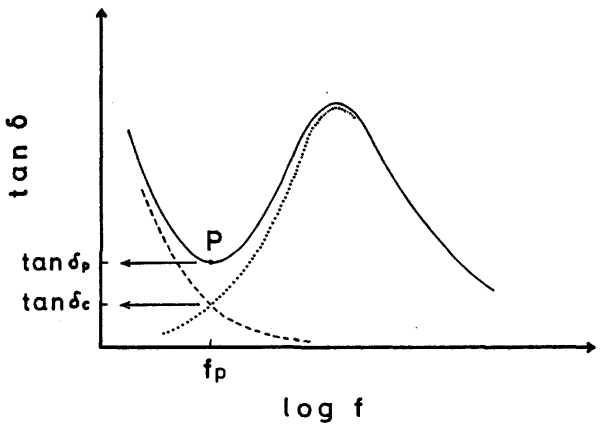

Fig. A-1. Spectrum of loss tangent. Solid line: observed loss tangent, broken line: loss tangent of conduction, dotted line: loss tangent of relaxation, P: saddle point, f_p: frequency at P, $\tan\delta_p$: observed loss tangent at f_p, $\tan\delta_c$: loss tangent of conduction at f_p.

Appendix

In the present system, the low-frequency loss overlaps the relaxation loss. It is desirable to resolve such a composite loss into individual losses in order to study the characteristics of the each loss. The low-frequency loss can be described by $\varepsilon''_c=\sigma/2\pi f\varepsilon_o$. However, there are some arbitrary choices in a determination of the σ-value. Hence, some devices may be necessary in order to determine the σ-value without any arbitrariness. In this Appendix, an approximate determining method is described.

The shape of a loss band and a saddle point clearly manifest themselves in the spectrum of tan δ more than ε''. Hence, the present method can be applied to the spectrum of tan δ. Let tan δ_p and f_p be the values of loss tangent and the frequency at the saddle point P, respectively, as shown in Fig. A-1. At the saddle point, the loss tangent of the conduction, tan δ_c, is approximately equal to the loss tangent of the relaxation, tan δ_r. Then, one has

$$\begin{aligned}\tan\delta_p &= \tan\delta_c + \tan\delta_r \\ &= 2\tan\delta_c. \end{aligned} \quad \text{(A-1)}$$

From the definition of loss tangent, tan δ_p and tan δ_c are written as

$$\tan\delta_p = \frac{\varepsilon''_p}{\varepsilon'_p} \quad \text{(A-2)}$$

and

$$\tan\delta_c = \frac{\varepsilon''_{cp}}{\varepsilon'_p}, \quad \text{(A-3)}$$

where ε'_p and ε''_p denote the observed values of the permittivity and the loss at f_p, respectively, and ε''_{cp} the conduction loss at f_p. The value of ε''_{cp} is expressed as

$$\varepsilon''_{cp} = \frac{\sigma_m}{2\pi f_p\varepsilon_o}, \quad \text{(A-4)}$$

where σ_m denotes the most appropriate value of σ. From the Eqs. A-1—A-4, one obtaines

$$\sigma_m=\pi\varepsilon_o f_p\varepsilon'_p\tan\delta_p$$

or

$$\pi\varepsilon_o f_p\varepsilon''_p.$$

The present author sincerely thanks Prof. Tetsuo Takaishi of Toyohashi University of Technology, for useful discussions, and Dr D. E. W. Vaughan of Exxon Research and Engineerring Co., who supplied ZK4 zeolite. The present work was partially supported by Grant-in-Aid for Encouragement of Young Scientists of the Ministry of Education of the Japanese Government, contract no. 60740232.

(Received November 5, 1987)

Polarized reflectance spectra were measured on the single crystals of (BMDT-TTF)AsF_6 and (BMDT-TTF)SbF_6. The charge-transfer band was observed along the stacking direction in the crystals of (BMDT-TTF)AsF_6, while in the crystal of (BMDT-TTF)SbF_6 the charge-transfer band was found not only along the stacking direction but also along the S ··· S direction nearly parallel to the short axis of the BMDT-TTF molecule. The effective on-site Coulomb energies and the transfer integrals of these salts were estimated by analyzing the charge-transfer bands.

Recently organic conductors based on BEDT-TTF (bis(ethylenedithio)tetrathiafulvalene) have been extensively studied, and many metallic salts have been found one after another.[1-3] BMDT-TTF (bis(methylenedithio)tetrathiafulvalene)) is one of the derivatives of BEDT-TTF, and involves the same conjugated moiety as that of BEDT-TTF. In contrast to BEDT-TTF salts, the positive charge in BMDT-TTF radical salts tends to be localized despite two-dimensional S ··· S network is formed in these crystals like the crystals of BEDT-TTF salts.[4,5] The characteristics of such an electronic structure is probably related to the magnitude of the electron-electron Coulomb energy and the transfer integrals. In this paper, we studied the optical spectra of the (1 : 1) salts of BMDT-TTF, (BMDT-TTF)AsF_6, and (BMDT-TTF)SbF_6, for the purpose to characterize the dimensionality of the intermolecular interaction and of the electron-electron Coulomb interaction.

Experimental

BMDT-TTF was synthesized by the method described elsewhere.[4] Single crystals of (BMDT-TTF)AsF_6 and (BMDT-TTF)SbF_6 were prepared by the method of electrochemical crystallization in the 1,1,2-trichloroethane solutions of BMDT-TTF, $(n\text{-Bu})_4NAsF_6$, and $(n\text{-Bu})_4NSbF_6$ being used as electrolytes. (BMDT-TTF)AsF_6 crystallized into thin needle-like crystals elongated along the c-axis, the typical length being 1.3 mm. The single crystal of (BMDT-TTF)SbF_6 was a thin platelet developping the (100) crystal face. The crystal axes and faces were determined by the oscillation and Weissenberg photographs. The polarized reflectance spectra were measured by the use of a microspectrophotometric technique. The reflectance spectrum was measured in the spectral region from 4.2×10^3 cm^{-1} to 25×10^3 cm^{-1}.

Results and Discussion

The crystal of (BMDT-TTF)AsF_6 belongs to the triclinic system with the space group, $P\bar{1}$,[6] the unit cell containing one molecule. BMDT-TTF is stacking along the c-axis with their molecular planes parallel to each other. The neighboring molecule is shifted along the long axis of molecule, and the long axis is inclined by 34° to the c-axis. Since these molecular column is surround by AsF_6 anions, the intermolecular interaction is expected to be strongest along the c-axis. Figure 1 shows the crystal structure projected onto the (100) plane and the reflectance spectra of (BMDT-TTF)AsF_6 measured on the (100) crystal face. The dispersions of the reflectance were observed at 5×10^3 cm^{-1}, 11×10^3 cm^{-1}, and 21×10^3 cm^{-1} in the //c spectrum. Since BMDT-TTF salt is not soluble in organic solvents, we assinged these electronic transitions by comparing with the electronic spectrum of BPDT-TTF (bis(propylenedithio)tetrathiafulvalene) salts, the cation of which involves the same conjugated moiety as BMDT-TTF. The electronic transitions of the cation radical of BPDT-TTF in the 1,1,2-trichloroethane was found at 13.5×10^3 cm^{-1} (A), 18.4×10^3 cm^{-1} (B), and 22.4×10^3 cm^{-1} (C) in the visible region of the absorption spectrum.[7] Since the transition, B. is much weaker than the other transitions, the dispersion at 11×10^3 cm^{-1} and 21×10^3 cm^{-1} were assigned to these

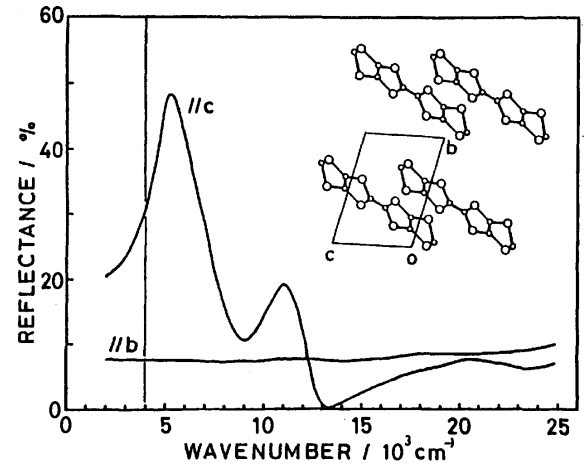

Fig. 1. Polarized reflectance spectrum of (BMDT-TTF)AsF_6 on the (100) crystal face. The reflectance curves in the region lower than 4×10^3 cm^{-1} are the extrapolated curves by the curve fittings based on the Lorentz model. The inset shows the crystal structure projected onto the (100) plane.

intramolecular transitions, A and C, respectively. Thus, the lowest excitation at 5×10^3 cm^{-1} was safely assigned to the charge-transfer (CT) transition between BMDT-TTF$^+$'s. This assignment is supported by the polarization direction which is parallel to the stacking axis of BMDT-TTF. Incidentally, the intramolecular transitions in this spectral region were found to be polarized parallel to the long axis of molecule, since the short axis of the molecule is nearly perpendicular (93°) to the c-axis.

The crystal of (BMDT-TTF)SbF_6 belongs to the triclinic system with the space group $P\bar{1}$, and $Z=1$.[8] BMDT-TTF is stacking along the b-axis such a manner as the long axis is inclined by 35° to the stacking axis. The adjacent molecule is mutually shifted to the long and short axes of molecule, so that one of the 1,3-dithiole moiety of BMDT-TTF is overlapping the same portion of the adjacent molecule. In this sense the intermolecular interaction along this stacking direction seems to be relatively weak. In contrast to the structure of (BMDT-TTF)AsF_6 the molecular columns linked by the S ··· S interaction make a sheet parallel to the (100) plane, and several short S ··· S contacts are reported between the neighboring molecules in this sheet.[8] Figure 2 shows the crystal structures and the polarized reflectance spectra measured on the (100) and (010) crystal faces. According to the spectrum of (BMDT-TTF)AsF_6 the intramolecular transitions at 11×10^3 cm^{-1} and 21×10^3 cm^{-1} are polarized parallel to the long axis of molecule. Therefore, the dispersion at 11.5×10^3 cm^{-1} in the //a spectrum and that at 20×10^3 cm^{-1} in the //b spectrum are respectively assignable to these intramolecular transitions, A and C. The assignment of the 20×10^3 cm^{-1} transition is consistent with the observed polarization dependence, since the long axis of molecule is least inclined (35°) to the b-axis among the three crystallographic axes as shown in Fig. 2. The shoulder at 17×10^3 cm^{-1} in the //b spectrum probably corresponds to the weak absroption band, B, found at 18.4×10^3 cm^{-1} in the solution spectrum of the BPDT-TTF cation radical. From the polarization direction the strongest dispersion at 5×10^3 cm^{-1} in the //c spectrum is safely assigned to the CT transition between BMDT-TTF$^+$'s through the S ··· S interaction. The dispersion at 9×10^3 cm^{-1} in the //b spectrum looks like the intramolecular transition, A, but the excitation energy does not agree with the a-component of the transition, A. Furthermore, the width of this dispersion is slightly broader than that of the CT band in the //c spectrum. Thus we assinged this 9×10^3 cm^{-1} dispersion to the superposition of the CT transition along the stacking direction parallel to the b-axis and the b-component of the intramolecular transition, A, since both transitions take place most strongly along the b-axis. This assignment was confirmed by the low-temperature spectrum, because a small shoulder was found at 11×10^3 cm^{-1} in the //b spectrum at 42 K as shown in Fig. 3. Therefore, we arrived at the most important result in this experiment that two kinds of charge-transfer transitions were observed along the S ··· S direction as well as the stacking direction in the crystal of (BMDT-TTF)SbF_6. Such a two-dimensional intermolecular interaction has been observed in many BEDT-TTF salts.[9,10] This is the first optical evidence of the two dimensionality of

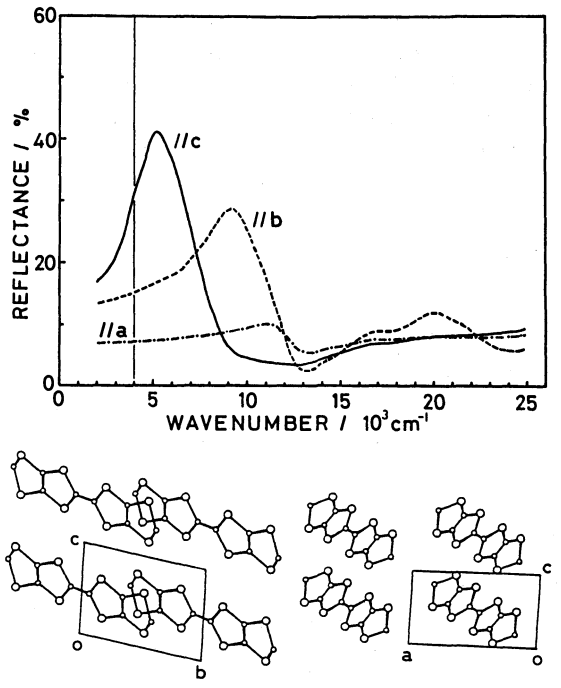

Fig. 2. Polarized reflectance spectrum and crystal structure of (BMDT-TTF)SbF_6. The //c and //b spectra were measured on the (100) crystal face, and the //a spectrum was measured on the (010) face. The reflectance curves in the region lower than 4×10^3 cm^{-1} are the extrapolated curves by the curve fittings based on the Lorentz model.

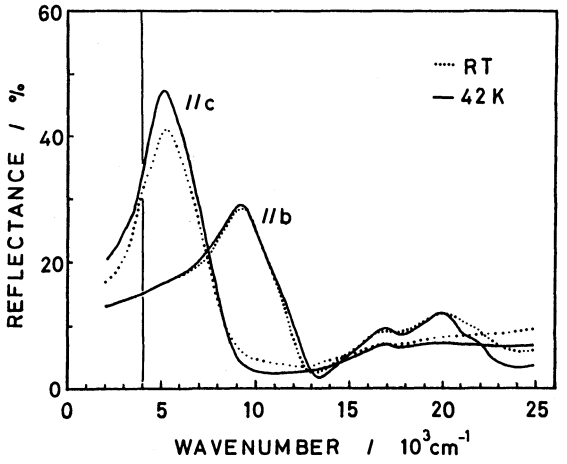

Fig. 3. Low-temperature reflectance spectrum of (BMDT-TTF)SbF_6. The room-temperature spectrum is also illustrated by a dotted line for comparison. The reflectance curves in the region lower than 4×10^3 cm^{-1} are the extrapolated curves by the curve fittings based on the Lorentz model.

BMDT-TTF salts.

Figures 4a and 4b show the optical conductivity spectra of (BMDT-TTF)AsF_6 and (BMDT-TTF)SbF_6 obtained from the Kramers-Kronig transformation of the reflectance spectra. These salts have half-filled metallic band structures, if the electron-electron correlation is fully screened. However, the appearance of the CT band shown in Fig. 4 indicates the existence of a band gap. In addition, both of these salts exhibit semiconductive behavior as regards the temperature dependence of the electrical resistivity.[6,8] These results clearly show that the strong Coulomb interaction plays an important role in these materials. As shown in the conductivity spectrum of (BMDT-TTF)SbF_6, the CT absorption bands of the //c and //b spectra show up at different wavenumbers separating about 4×10^3 cm^{-1}. The excitation energy of the CT band in the limit of a strongly correlated half-filled band is given by $U-V_i$, where U is the on-site Coulomb energy, V_i, the Coulomb energy between the neighboring sites along the i-th direction. The distance between the centers of adjacent molecules is 5.63 Å along the c-axis, whereas that is 7.50 Å along the b-axis. Therefore, the difference of the excitation energies between the CT transitions polarized along the c-and b- axes is attributed to the nearest-neighbor Coulomb interaction which depends on the distance between the adjacent molecules. The similar phenomenon was found in the single-crystal absorption spectrum of $(TTF)ClO_4$, in which two charge-transfer bands separated by 3×10^3 cm^{-1} were interpreted to be the intra-dimer and inter-dimer CT transitions.[11] This interpretation to the spectrum of (BMDT-TTF)SbF_6 means that the magnitude of the long range Coulomb energy is comparable to that of the on-site Coulomb energy, and thus the excited state is not the free-electron and free-hole state but the bound electron-hole state. In this situation charge-transfer process takes place predominantly between the adjacent molecules, so that the CT transition can be approximately analyzed by a dimer model. In the dimer model, the excitation energy and the oscillator strength of a CT band is represented by the Eqs. 1 and 2,[12]

$$E_{CT}=U_{eff}/2+(U_{eff}^2/4+4t^2)^{1/2} \quad (1)$$

$$f=(2d^2m_eN_d/N\hbar^2)(2t^2/(U_{eff}^2/4+4t^2)^{1/2}) \quad (2)$$

where E_{CT}, U_{eff}, t, f, d, m_e, N_d, and N denote the CT excitation energy, the effective on-site Coulomb energy, the transfer integral, the oscillator strength, the distance between the centers of molecules, the electron mass, the number density of a dimer, and the number density of BMDT-TTF, respectively. We set N_d/N equal to 1, since the CT interaction equivalently occurs to both side of a molecule in a regular chain. The oscillator strength, f, of the CT band was calculated by using the following equation,

$$f=(2m_e/\pi e^2N)\int\sigma(\omega)d\omega \quad (3)$$

where e and $\sigma(\omega)$ are the charge of an electron and the conductivity spectrum, respectively. Table 1 shows the effective on-site Coulomb energy, $U_{eff}=U-V$, and the transfer integral, t, which were calculated by the use of the Eqs. 1 and 2. The oscillator strength and thus the transfer integral in the //b spectrum of (BMDT-TTF)SbF_6 is the upper limit because the b-component of the intramolecular transition is involved in the 9.0×10^3 cm^{-1} band. Keeping this point in mind, the relation between the transfer integral and the overlap integral is qualitatively good in BMDT-TTF salts.

Bondeson and Soos numerically examined the systematic deviation of the excitation energy and the transition probability of a CT transition in going from a dimer to a finite chain by the aid of a diagrammatic valence bond method.[13] According to their calculation, a dimer model is a good approximation to the infinite chain only for $U_{eff}/4t>3.5$, otherwise the excitation energy predicted from a dimer model is considerably larger than that of an infinite chain. Unfortunately, the parameters, $U_{eff}/4t$, of these BMDT-TTF salt is not in the former regime, so that the actual effective on-site Coulomb energies in Table 1 is considered to be significantly larger than the values listed in Table 1. Therefore, we analyzed the CT spectrum of the one-dimensional (BMDT-TTF)AsF_6 salt by a Hubbard model, in which the long range Coulomb

energy is completely neglected. In the one-dimensional chain, the exact solutions were reported on the optical excitation energy[14] and the oscillator strength[15] as shown in the following equations.

$$E_{opt}/4t = u - 1 + 2\int_0^\infty (J_1(x)/x)(1+\exp(2ux))^{-1}\,dx \quad (4)$$

$$(f/4t)(\hbar^2/md^2) = \int_0^\infty (J_0(x)J_1(x))[x^{-1}(1+\exp(2ux))^{-1} + u(1+\cosh(2ux))^{-1}]\,dx \quad (5)$$

where E_{opt} is the absorption edge of the optical transition across the Hubbard gap, u is defined to be $U_{eff}/4t$, and $J_0(x)$ and $J_1(x)$ are the Bessel functions. The values of $E_{opt}/4t$ and $(f/4t)(\hbar^2/md^2)$, which were obtained by numerical calculation, were plotted against u in Fig. 5 together with the quantity of $(E_{opt}/f)(md^2/\hbar^2)$ which is experimentally obtainable. We defined the absorption edge, E_{opt}, as the wavenumber at which the conductivity curve takes half of the maximum value of the CT absorption band. The parameter, $u=U_{eff}/4t$, was calculated to be 1.80 from the u-dependent curve of $(E_{opt}/f)(md^2/\hbar^2)$ by the use of the experimental values, E_{opt}=0.56 eV, f=0.43, and d=5.84 Å. The parameters, t and U_{eff}, were determined to be 0.14 eV and 1.0 eV from the u-dependent curves of $(E_{opt}/4t)$ and $(f/4t)(\hbar^2/md^2)$. This is the first attempt to analyze the CT band of the regular-stack one-dimensional chain with a half-filled band on the basis of the exact solution of the Hubbard model. However, the analysis is not complete, because the appearance of the two CT bands at different wavenumbers in the polarized spectrum of (BMDT-TTF)SbF_6 indicates that the nearest-neighbor Coulomb interaction should be included in the analysis. However, the theoretical study on the optical transition of the extended Hubbard model has not been conducted in the case $u\simeq1$. Bondeson and Soos numerically examined the difference of the optical

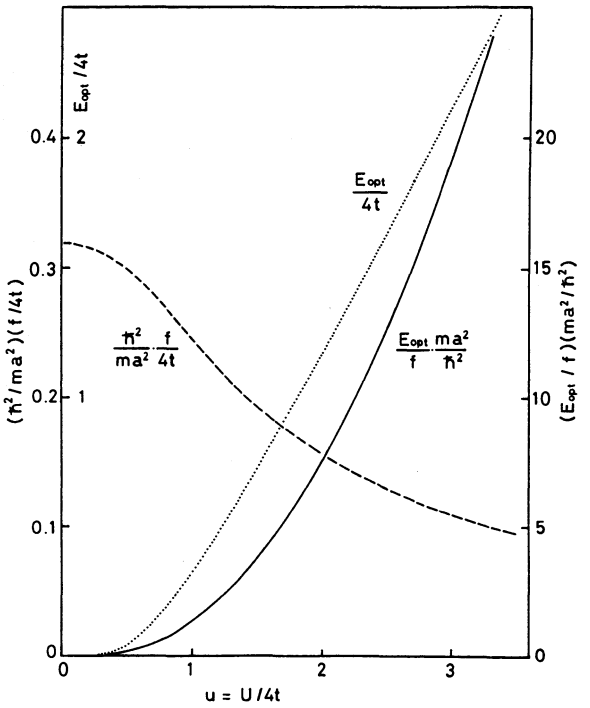

Fig. 5. Numerical calculation of the excitation energy, the oscillator strength, and their ratio which is predicted from the exact solution of the one-dimensional Hubbard model.

transition across the Hubbard gap between the extended Hubbard model and the Hubbard model. According to their calculation the excitation energy of the CT band based on the extended Hubbard model in the case $U-V_1\simeq4t$ is significantly higher than that based on the Hubbard model in the case $U_{eff}\simeq4t$ and much lower than that of the dimer model. Therefore, we consider that the effective on-site Coulomb energy, U_{eff}, is in the range between 0.6 eV and 1.0 eV. The numerical calculation by Bondeson and Soos also indicated that the transition probability of the CT band did not change significantly among the dimer model, the Hubbard model and the extended Hubbard model, so that the transfer integral, t, was estimated to be about 0.1—0.15 eV. Torrance et al. examined the band parameters of TTF salts, (TTF)X (X=$Cl_{0.80}$, $Br_{0.79}$, and $I_{0.71}$).[16] They estimated the parameters, U_{eff} and t, to be 1.25 eV and 0.28 eV, respectively. Because they used the dimer model to obtain these parameters. U_{eff} must be larger than 1.25 eV. Therefore, we conclude that the on-site Coulomb energy of BMDT-TTF salt is significantly smaller than that of TTF salts. This is in accord with the extended molecular structure of BMDT-TTF in comparison with TTF.

Photoreduction of Anthraquinone by Triethylamine in Ethanol and Toluene Studied by Steady-State Photolysis and Laser Photolysis

Kumao HAMANOUE,* Toshihiro NAKAYAMA, Yoshiaki YAMAMOTO, Kazuhide SAWADA, Yoshihito YUHARA, and Hiroshi TERANISHI
Department of Chemistry, Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto 606
(Received November 14, 1987)

Photoreduction of anthraquinone (AQ) by triethylamine (TEA) in toluene and ethanol was studied by means of steady-state photolysis and laser photolysis. In toluene, addition of TEA enhanced the quantum yield of photoreduction of AQ, and the reaction was found to originate via the formation of an exciplex between ground-state TEA and the lowest triplet state of AQ: This exciplex changed to a contact ion pair followed by proton transfer, generating anthrasemiquinone radical and triethylamine radical, and 9,10-anthracenediol was obtained as the final photoproduct. Although the mechanism of the photoreduction of AQ in ethanol/TEA was essentially the same as that in toluene/TEA and the final products in ethanol/TEA were 9,10-anthracenediol and its anion, the quantum yield of photoreduction decreased with increase in TEA concentration. It was proposed that the exciplex in ethanol was quenched by ground-state TEA via the formation of a triplex of a radical anion of AQ and a radical cation of TEA dimer bonded by the three σ-electrons on two nitrogen atoms, based on the suggestion made by Hub et al. (*J. Am. Chem. Soc.*, **106**, 701 (1984); **106**, 708 (1984)).

Photoinduced electron transfer is one of the most important primary processes in a number of photochemical reactions, and the photoreductions of aromatic carbonyls in amine solutions have been investigated extensively.[1-6] Although intermediacy of a radical anion of ketones or a complex (an exciplex, a charge-transfer complex or an ion pair) of triplet ketones with ground-state amines has been proposed, the mechanism for the formation of these ionic species and the interconversion among them are generally dependent on the combination of the donor and the acceptor as well as the nature of the solvent. Moreover, the absorption spectra of these various species are generally very similar to each other. Therefore, it is very important to know the difference in the absorption spectra of the ionic species for full understanding of their formation.

Since we have observed that the quantum yields of photoreduction of anthraquinone (AQ) and haloanthraquinones (the chloro and bromo compounds) are increased by the addition of triethylamine (TEA), it is expected that ionic species mentioned above are also produced upon photolysis of anthraquinones/TEA in solution. As an extension of our study on the photophysics and photochemistry of anthraquinones,[7-12] this paper deals with the details of the photoreduction of AQ by TEA in ethanol and toluene, studied by means of steady-state photolysis and laser photolysis. Preliminary results have already been published elsewhere.[13]

Experimental

Chemicals. The details of the methods of preparation of AQ have been given in our previous paper.[7] GR-grade TEA (Wako) was refluxed over calcium hydride and distilled under nitrogen. Spectral-grade ethanol (Nakarai), and scintillation-grade benzene (Dojin) and toluene (Dojin) as the solvents were used without further purification. Unless otherwise stated, the sample solutions were degassed by several freeze-pump-thaw cycles.

Steady-State Photolysis. Photolysis of AQ/TEA in solution was carried out at room temperature using an USH-500D super-high pressure mercury lamp. Light of 313-nm monochromatic wavelength was selected by the combination of two Toshiba color glass filters (UV-29 and UV-D33S) and a filter solution ($Ni_2SO_4 \cdot 6H_2O$, 50 g dm^{-3}, path length 2 cm). Absorption spectra were taken on a Hitachi 200-20 spectrophotometer. The quantum yields of photoreduction were determined by the Hatchard-Parker's tris(oxalato)ferrate(III) actinometry method.[14]

For the identification of absorption spectra of a radical anion ($AQ^{\cdot-}$) of AQ and monoanion (AQH^-) of 9,10-anthracenediol (AQH_2), photolyses of AQ and AQH_2 in alkaline ethanol were performed using 366- and 404-nm lights, respectively, where light of 366-nm monochromatic wavelength was selected by the combination of two Toshiba color glass filters (UV-35, UV-D35) and a filter solution ($CuSO_4 \cdot 5H_2O$, 100 g dm^{-3}, path length 3 cm) and 404-nm light was selected by the combination of a Toshiba color glass filter (UV-39) and a filter solution (loc. cit.).

Laser Flash Photolysis. All transient absorption spectra were taken at room temperature. Unless otherwise stated, picosecond laser photolysis was performed using the second harmonic (347.2 nm) of a picosecond mode-locked ruby laser. The details of this laser photolysis system with a 30 ps instrumental time constant have been given elsewhere.[15] A double-beam optical arrangement was adopted and an absorption spectrum over a range of 200-nm wavelengths was obtained by two measurements: First, reference and probe light intensities without firing the exciting laser pulse, i.e., $I_O^A(\lambda)$ and $I_O^B(\lambda)$, respectively, were measured. Next, reference and probe light intensities with firing the exciting laser pulse, i.e., $I_E^A(\lambda)$ and $I_E^B(\lambda)$, respectively, were measured. Then, the absorbance $D(\lambda)$ at a given delay time was calculated by a microcomputer using the following equation;

$$D(\lambda) = \log[I_E^A(\lambda)/I_E^B(\lambda)] - \log[I_O^A(\lambda)/I_O^B(\lambda)] \quad (1)$$

where λ is the wavelength. The sample solutions in a cell of 2-mm path length were not deaerated.

To confirm a weak triplet-triplet ($T'\leftarrow T_1$) absorption of AQ at 500—600 nm, picosecond laser photolysis was also performed using the third harmonic (355 nm), with a pulse width of ≈25 ps, from a mode-locked Nd^{3+}: YAG laser of Osaka University, where the sample solutions in a cell of 10-mm path length were deaerated. The details of this laser photolysis system have been given elsewhere by Miyasaka et al.[16] The time-resolved absorption spectrum over a range of 400-nm wavelengths was calculated by

$$D(\lambda)=\log[\sum I_E^A(\lambda)/\sum I_E^B(\lambda)]-\log[\sum I_O^A(\lambda)/\sum I_O^B(\lambda)] \quad (2)$$

where spectral averaging was made five times.

The details of the Q-switched ruby laser photolysis system have also been given elsewhere.[10,17] The half-peak duration of the second harmonic (347.2 nm) was 20 ns, and the decay of the transient absorption was recorded by a combination of an HTV R666 photomultiplier with an Iwatsu TS-8123 storage oscilloscope: Time-resolved absorption spectra at delay times longer than 2 μs were recorded by the "ISD" system,[18] that is, a combination of a nanosecond ruby laser with an image sensor detector and a microcomputer, where a pulsed xenon flash lamp with a 1.7-μs full width at half-maximum intensity was used as a probe-light source. The time-resolved absorption spectrum over a range of 400-nm wavelengths was calculated by

$$D(\lambda)=\log[\sum I_O(\lambda)-\sum I_b(\lambda)]-\log[\sum I_E(\lambda)-\sum I_d(\lambda)] \quad (3)$$

where $I_b(\lambda)$ is the dark current spectrum of the detector system, and $I_d(\lambda)$ is the emission intensity due to the excited species, as measured without the probe light upon firing of the laser pulse. (Also, spectral averaging was made five times.) The sample solutions in a cell of 10-mm path length were deaerated.

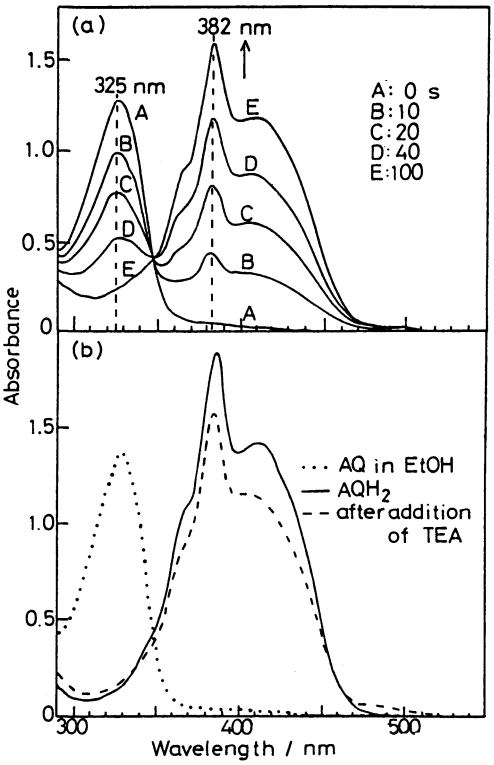

Fig. 1. Absorption spectral change of AQ/TEA (0.2 M) in ethanol upon irradiation with 313-nm light at room temperature (a), and change of the absorption spectrum of AQH_2 upon addition of TEA (b).

Results

Steady-State Photolysis. The absorption spectral change of AQ/TEA (0.2 M; 1 M=1 mol dm^{-3}) in ethanol at room temperature is shown in Fig. 1a: Upon irradiation with 313-nm light, the absorption band of AQ with λ_{max}=325 nm decreased and a new band of the photoproduct with λ_{max}=382 nm built up, accompanied by an isosbestic point at 346 nm. This reaction is essentially the same as that of AQ in the absence of TEA.[8] Thus, one can safely conclude that the absorption band with λ_{max}=382 nm is due to AQH_2. In Fig. 1a, however, one can observe a weak tail at 470—530 nm. Such an absorption was not observed in the absence of TEA. We interpret this weak tail as the absorption due to AQH^-, based on the following reasons: (1) We have already reported that the forms of 10-cyano-9-anthrol (or its anion) and 10-benzoyl-9-anthrol (or its anion) in a solution containing TEA was dependent on the basicity, polarity and rigidity of medium as well as temperature.[19] The absorption bands of the base forms were observed at longer wavelengths than those of the acid forms. (2) As shown in Fig. 1b, 313-nm photolysis of AQ in ethanol without TEA yielded AQH_2. Subsequent addition of TEA in vacuo gave rise to the same absorption spectrum as that observed in Fig. 1a. (3) Upon addition of 0.2-ml aqueous solution of NaOH (0.01 M) to 4-ml ethanol solution of AQH_2 in vacuo, spectrum A of AQH_2 changed to spectrum B as shown in Fig. 2a; the concentration of NaOH in this alkaline ethanol is 4.8×10^{-4} M. (Inserted spectrum is the absorption spectrum of AQH^- reported by Carlson and Hercules.[20]) Upon photolysis with 404-nm light, the absorption bands at 393, ca. 484, ca. 773 and ca. 860 nm increased (cf. spectra C, D, and E).

AQ in alkaline ethanol is known to be photoreduced readily to form $AQ^{\cdot-}$. Figure 2b shows the absorption spectrum of $AQ^{\cdot-}$, prepared by 366-nm photolysis of AQ in alkaline ethanol (loc. cit.). The spectrum thus obtained is essentially identical with that reported by Carlson and Hercules[20] (cf. Inserted spectrum). Comparison of the absorption spectra in Fig. 2a with those in Fig. 2b suggests that photolyses of AQH_2, AQH^-, and AQ in alkaline ethanol give rise to the formation of $AQ^{\cdot-}$ as a final product. These results differ somewhat from that of Carlson and Hercules;[20] they reported that photolysis of $AQ^{\cdot-}$ in alkaline ethanol with 350-nm light gave rise to quantitative formation of AQH^-.

Anyway, it is reasonable to conclude that AQH_2 ionizes partly to the base form in TEA/ethanol solution. Thus, the quantum yields (Φ) of photoreduction of AQ in several TEA/ethanol solutions were deter-

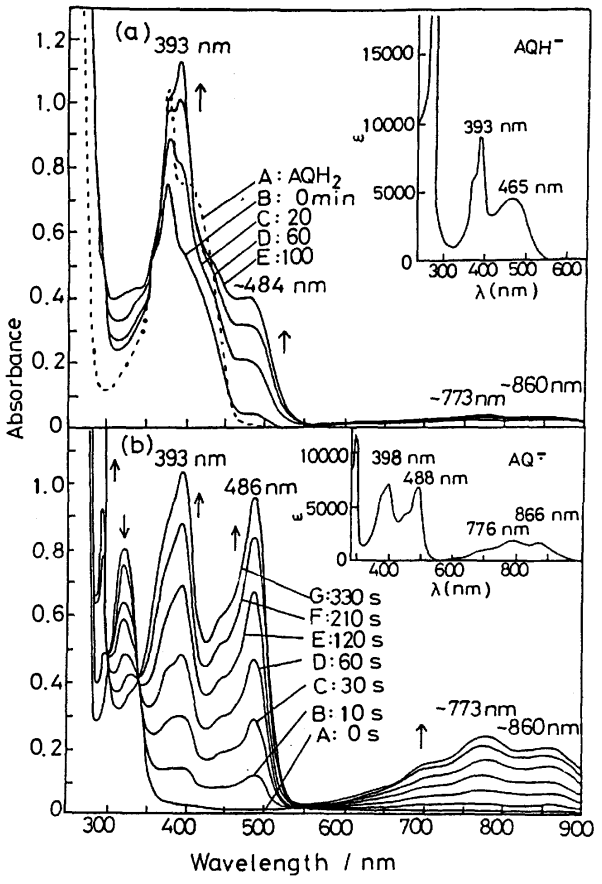

Fig. 2. Absorption spectral change of AQH_2 in alkaline ethanol ($NaOH=4.8\times10^{-4}$ M) upon irradiation with 404-nm light at room temperature (a), and absorption spectrum of $AQ^{\cdot-}$ prepared by 366-nm photolysis of AQ in alkaline ethanol at room temperature (b). Inserted spectra in (a) and (b) are the absorption spectra of AQH^- and $AQ^{\cdot-}$, respectively, reported by Carlson and Hercules.[20]

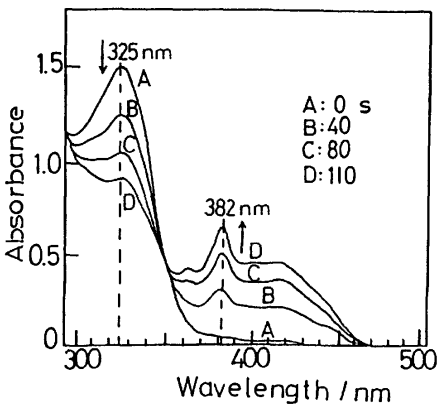

Fig. 3. Absorption spectral change of AQ/TEA (0.2 M) in toluene upon irradiation with 313-nm light at room temperature.

mined by measuring the decrease in the absorbance of AQ, and the results obtained are listed in Table 1. For comparison, we also show the value of Φ obtained in ethanol without TEA.

Photolysis of AQ/TEA (0.2 M) in toluene gave the same result as that in toluene without TEA and the final photoproduct was AQH_2 (cf. Fig. 3). No formation of AQH^- was observed. This is consistent with our previous observation[19] that the acid-base equilibrium of 10-cyano-9-anthrol and its base form (and 10-benzoyl-9-anthrol and its base form) depends on the dielectric constant of the solvent even in the presence of TEA. Thus, the values of Φ in several TEA/toluene solutions were determined by measuring the increase in the absorbance due to AQH_2, and the values obtained are also listed in Table 1 together with that in toluene without TEA.[21]

Laser Flash Photolysis. Figure 4 shows the transient absorption spectra obtained at room temperature upon picosecond laser photolyses of AQ/TEA (1 M) in ethanol (a) and toluene (b), respectively. The absorption spectra at a delay time of 40 ps in both solvents are nearly identical with the $T'\leftarrow T_1$ absorption spectrum of the lowest triplet state (T_1) of AQ, recorded at 77 K in EPA (ether/isopentane/ethanol=5:5:2 in volume ratio) without TEA (cf. Fig. 4c).[7,18]

Although the $T'\leftarrow T_1$ absorption spectra at room temperature are very weak, Manring and Peters[22] observed a strong $T'\leftarrow T_1$ absorption spectrum with a maximum absorbances at λ_{max}=623 and 677 nm, and a shoulder at 582 nm in deaerated benzene (cf. dotted line in Fig. 5b). Since this spectrum is obtained from the accumulation of at least 200 laser shots and the hydrogen-atom abstraction of triplet AQ from the solvent molecule gives rise to the formation of anthrasemiquinone radical ($AQH\cdot$),[10,11,20] the transient absorption spectrum observed by Manring and Peters might contain absorption due to $AQH\cdot$. In fact, Carlson and Hercules[20] have reported that $AQH\cdot$ has

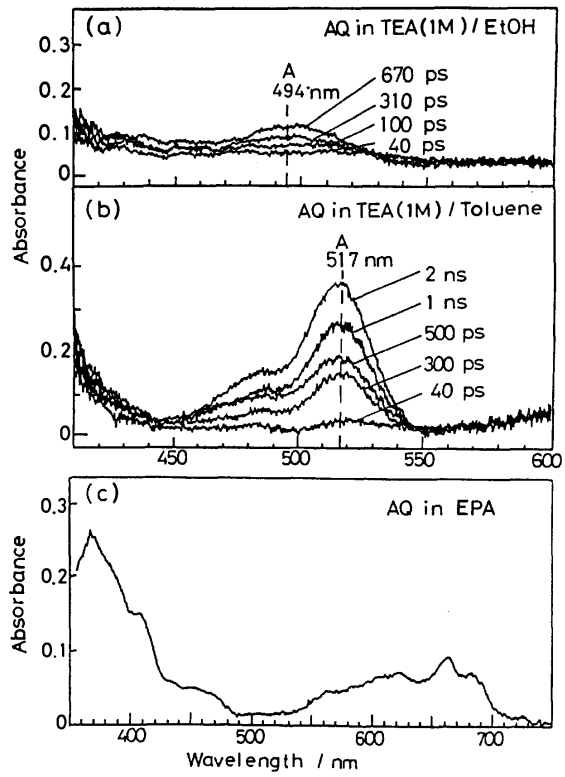

Fig. 4. Transient absorption spectra of AQ/TEA (1 M) in ethanol (a) and toluene (b) obtained by picosecond ruby laser photolysis at room temperature. The spectrum in (c) is the $T' \leftarrow T_1$ absorption spectrum of AQ at 77 K in EPA, obtained by nanosecond ruby laser photolysis.

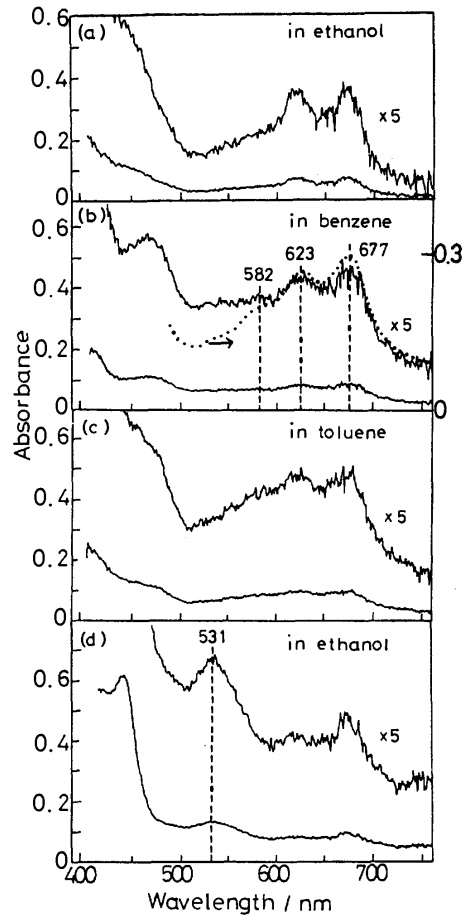

Fig. 5. The $T' \leftarrow T_1$ absorption spectra of AQ at room temperature in ethanol (a), benzene (b), and toluene (c), obtained by picosecond Nd^{3+}:YAG laser photolysis at a delay time of 100 ps. The spectra in (d) were obtained for the sample which was illuminated by 175 laser shots before the spectral measurement, and the $T' \leftarrow T_1$ absorption spectrum reported by Manring and Peters[22] is shown by a dotted line in (b).

three absorption bands at 678, 631, and 575 nm in ethanol. Thus, we have also performed picosecond laser photolyses of AQ in deaerated ethanol, benzene, and toluene using a picosecond Nd^{3+}: YAG laser of Osaka University.[16] Obviously, the spectra obtained by us (cf. Figs. 5a—c) are very weak compared with that obtained by Manring and Peters, being due to the fact that our transient spectra are not essentially accumulated as can be seen in Eq. 2. However, five times expansion of the transient spectra clearly indicates that they are identical with that obtained by Manring and Peters, even in ethanol solution in which the quantum yield of photoreduction is unity. We have also measured the transient spectra of the sample solutions which were illuminated by 175 laser shots before the spectral measurements. The spectra obtained in benzene and toluene were identical with those shown in Figs. 5b and c, although that in ethanol had an additional band at 531 nm (cf. Fig. 5d). This band is different from those of AQH· and AQH_2. (At present, we cannot assign this band.) All the results obtained so far indicate that the weak absorptions at 500—700 nm are not due to AQH· but due to triplet AQ, based on the following reasons: (1) The dominant feature of the absorption spectrum of AQH· is the existence of peaks of nearly equal intensity at 631 and 678 nm in ethanol.[20] (2) The absorption spectrum of AQH· is observed on a microsecond time scale after the excitation of AQ.[10,11,20] (3) The value of Φ is unity in ethanol, while that in toluene is smaller than 0.5 as can be seen in Table 1. However, the spectral intensities in Figs. 5a—c are almost identical.

In Fig. 4, a comparison of the $T' \leftarrow T_1$ absorption spectrum at 40 ps delay with those at delay times longer than 100 ps suggests that a new intermediate (Band A) is produced after the buildup of the T_1 state of AQ, because the time constant for the buildup of the $T' \leftarrow T_1$ absorption of AQ is less than 70 ps.[23] Upon picosecond laser photolyses of 1,8-dichloroanthraquinone (DCAQ)/TEA (1 M) in ethanol and toluene,[24] we observed that the transient absorption spectra at delay times shorter than 100 ps were identical with those observed in the absence of TEA.[12] A new intermediate (λ_{max}=540 nm in TEA/ethanol and 566 nm in TEA/toluene) similar to those in Fig. 4 built up

at the expense of the T_1 state:[24] Recently, we have confirmed that addition of 2 M TEA in toluene quenches both the second triplet (T_2) and T_1 states of DCAQ.[25]

Figure 6a shows the results of nanosecond laser photolysis of AQ/TEA (0.2 M) in ethanol: The transient absorption at 490 nm appeared within the duration of the nanosecond laser pulse and increased up to 4 μs delay, and the maximum absorbance persisted beyond 200 μs with no measurable decay. In accordance with this, the transient absorption spectrum taken immediately after the nanosecond laser pulse is identical with that observed upon picosecond laser photolysis, while those (Band B) taken at delay times longer than 2 μs are shifted to the blue by ca. 8 nm as can be seen in Fig. 6b. (The spectrum shown by open circles was obtained by separate measurements of the absorbances at a number of desired wavelengths,[13] each following a single laser shot, that is, by point-to-point observation.) On a much longer time scale, Band B decayed accompanied by the appearance of a new absorption (Band E) as shown in Fig. 6c. Band E is identical with the absorption band of AQH_2 (cf. Fig. 1a). Moreover, the rise and decay of Band B could be fitted by first-order reaction kinetics as shown in Fig. 7. In ethanol, the rate constants for the buildup of Band B increased with increasing concentration of TEA (cf. closed circles in Fig. 8). On the other hand, no concentration effect of TEA on the decay of Band B was observed. (For comparison, we also show the variation of $1/\Phi$ with the concentration of TEA by open circles.)

Similar results were also obtained in toluene as shown in Fig. 9. The transient absorption of Band A (λ_{max}=517 nm) observed upon picosecond laser photolysis also appeared within the duration of the nanosecond laser pulse (cf. dotted line in Fig. 9a). And the

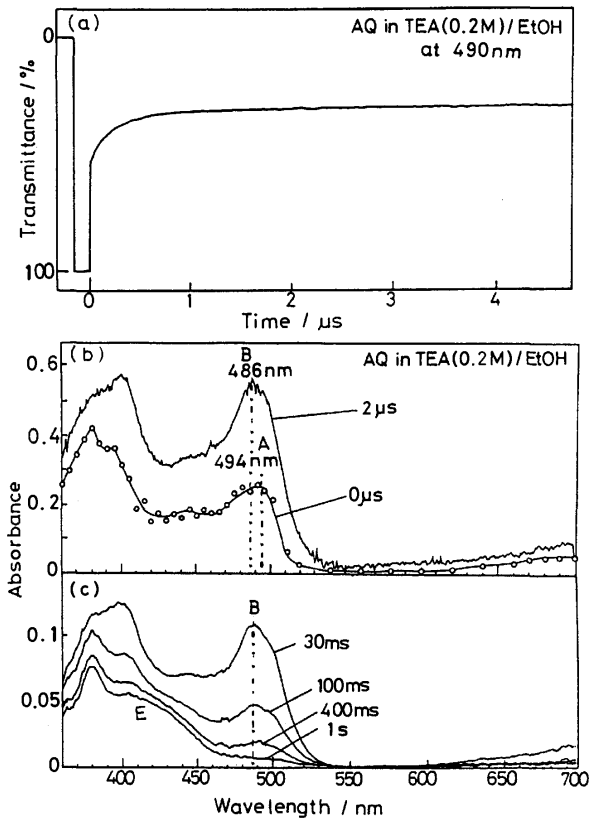

Fig. 6. Time-variation of the transient absorption at 490 nm (a) and change of the transient absorption spectra (b, c) of AQ/TEA (0.2 M) in ethanol, obtained by nanosecond ruby laser photolysis at room temperature.

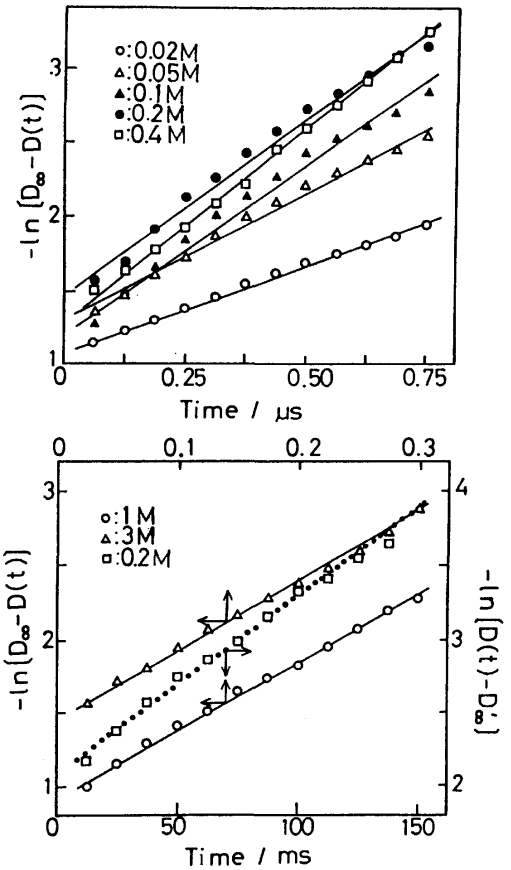

Fig. 7. First-order plots for the rise (full lines) and the decay (dotted line) of Band B in ethanol. Numbers in figures are the concentrations of TEA.

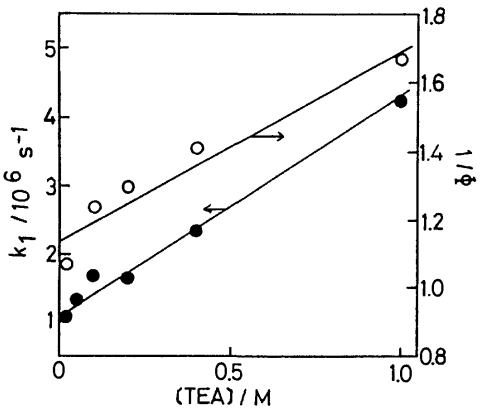

Fig. 8. Plots of k_1 (closed circles) and $1/\Phi$ (open circles) against the concentration of TEA in ethanol.

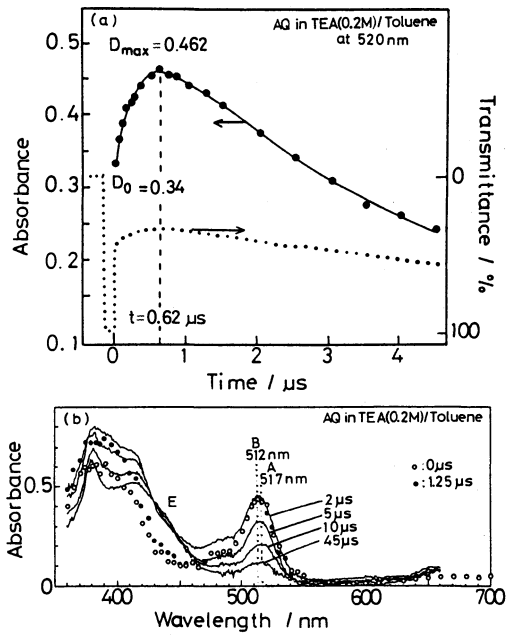

Fig. 9. Time-variation of the transient absorption at 520 nm (a, dotted line) and change of the transient absorption spectra (b) of AQ/TEA (0.2 M) in toluene, obtained by nanosecond ruby laser photolysis at room temperature. Closed circles and a full line in (a) are the absorbances and the best-fit theoretical curve, respectively.

transient absorption increased initially, followed by the spectral shift by ca. 5 nm to Band B (cf. Fig. 9b). (The spectra shown by open and closed circles were recorded by point-to-point measurement.[13]) Thus, one may say that the small spectral shift of ca. 5 nm is within the experimental error. However, the spectra recorded by the ISD system (full lines) are essentially identical with those obtained by point-to-point method. The decay of Band B was accompanied by the buildup of the new absorption due to AQH_2 (Band E at ca. 440 nm), and one can clearly observe the existence of two isosbestic points at 430 and 450 nm. The effects of the concentration of TEA on the buildup and decay of Band B were negligible.

Discussion

The results of steady-state photolysis of AQ/TEA with 313-nm light indicate the existence of a clear isosbestic point which support quantitative conversion of AQ to AQH_2 (and its anion). Exposure to oxygen caused quantitative oxidation of AQH_2 back to AQ. These results are just the same as the photoreductions of AQ and haloanthraquinones in the absence of TEA.[8,9]

Table 1 shows that the values of Φ in TEA/toluene solutions are clearly greater than 0.5, while that in toluene without TEA is 0.3. This enhancement of the photoreduction of AQ by TEA is very similar to that of benzophenone (BP) by several amines,[1-6] and the generally accepted mechanism is that an electron is transferred from amines to triplet BP, forming a radical anion of BP or a complex (an exciplex, a charge-transfer complex or an ion pair) of triplet BP with ground-state amines. It is also thought that the complex is quenched either by proton transfer, generating a benzhydrol radical and an amine radical, or by spin inversion followed by back electron transfer, yielding ground-state BP and amine. In ethanol, the quantum yields of photoreduction of AQ decreased with increase in TEA concentration. This problem will be discussed later.

Except for Band E, the transient absorption spectra in Figs. 4b, 6b—c, and 9b are very similar to those of $AQ^{\cdot-}$ which were produced upon photolysis of AQ in alkaline ethanol (cf. Fig. 2b) or γ-radiolysis of AQ in 2-methyltetrahydrofuran at 77 K.[26] Although no transient photocurrent was detected in toluene, it was observed in ethanol. However, the rise and decay of this photocurrent were different from those of Bands A and B. Moreover, the intensity of the initial photocurrent increased after repeated measurements, indicating that the photocurrent is due to some ionic species produced electrochemically.

We conclude that Bands A and B are different from the $T'\leftarrow T_1$ absorption of AQ observed by us (cf. Fig. 5) and Manring and Peters,[22] based on the following reasons: The $T'\leftarrow T_1$ absorptions in Fig. 4 are very weak compared with Bands A and B. Moreover, their spectral profile and the positions of the absorption maxima are essentially different from those of the $T'\leftarrow T_1$ absorptions.

Based on the above discussion and those for the absorption spectra of the radical anions,[27] it is reasonable to make the following conclusions: (1) The intermediate (Band A) observed by picosecond laser photolysis is identical with that produced within the duration of the nanosecond laser pulse. This intermediate may be assigned to a triplet exciplex between ground-state TEA and the T_1 state of AQ. (2) In ethanol, the exciplex generates a contact ion pair (Band B) between $AQ^{\cdot-}$ and the radical cation ($TEA^{\cdot+}$) of TEA. The contact ion pair may be relatively stable in a polar solvent such as ethanol, because no decay of the contact ion pair was observed up to 200 μs delay. Since AQH_2 was produced upon steady-state photolysis of AQ/TEA in ethanol as shown in Fig. 1a, the contact ion pair may finally disappear by proton transfer from $TEA^{\cdot+}$ to $AQ^{\cdot-}$, generating neutral $AQH\cdot$ and triethylamine radical ($TEA\cdot$). Actually the decay of Band B was accompanied by the appearance of the absorption due to AQH_2 (cf. Fig. 6c). (3) In toluene, the exciplex also generates the contact ion pair, however, it is subsequently quenched by proton transfer on a microsecond time scale.

If the mechanism mentioned above is correct, the photoreduction of AQ by TEA in ethanol and toluene may be interpreted in terms of the following consecutive reactions based on the results of photoreduction of

several anthraquinones without TEA[8-11] and BP/amines;[1-6] Triplet AQ+TEA→Exciplex→Contact ion pair→AQH·+TEA·; TEA·+AQ→AQH·; 2AQH·→AQ+AQH_2 (and its base form). AQH· may also be produced via the hydrogen-atom abstraction by ground-state AQ from TEA·, because the value of Φ in the presence of TEA are greater than 0.5 as shown in Table 1. In toluene without TEA, the value of Φ is smaller than 0.5, indicating that no AQH· is produced via the hydrogen-atom abstraction by ground-state AQ from a benzyl radical. In ethanol without TEA, the value of Φ was unity, while in TEA/ethanol solutions, Φ's were between 0.93 ([TEA]=0.02 M) and 0.60 ([TEA]=1 M). This may be due to the back electron transfer in the exciplex or ion pair. Also, quenching of the exciplex by ground-state TEA is expected to occur as will be discussed later.

From the buildup time of the exciplex of AQ/TEA, the rate constant for electron transfer from ground-state TEA to triplet AQ was estimated to be $\approx 2.5\times10^9$ M^{-1} s^{-1} in ethanol. This value is nearly equal to those for BP/TEA in benzene (3×10^9 M^{-1} s^{-1})[2] and BP/1,4-diazabicyclo[2.2.2]octane (DABCO) in ethanol (2.3×10^9 M^{-1} s^{-1}).[5] Since the transient absorption at 490 nm did not decay up to 200 μs in ethanol, the buildup of the absorbance $D(t)$ at time t can be given by

$$D(t)=D_0(1-\alpha\beta)\exp(-k_1t)+D_0\alpha\beta \quad (4)$$

where D_0 is the absorbance of the exciplex at $t=0$, α is the ratio of the extinction coefficient of the contact ion pair (Band B) to that of the exciplex (Band A), β is the efficiency of formation of the contact ion pair from the exciplex and k_1 is the decay constant of the exciplex. We determined $D_\infty=D_0\alpha\beta$ from the absorbance at 4 μs delay in Fig. 6a, and the plots of $-\ln[D_\infty-D(t)]$ against time gave the straight lines as shown by full lines in Fig. 7. Band B decayed on a much longer time scale and the decay constant (k_2) could be obtained by the first-order plot of $-\ln[D(t)-D'_\infty]$ vs. t, where D'_∞ is the absorbance due to the final product (cf. dotted line in Fig. 7). In Table 1, the decay constants of the exciplex and ion pair obtained so far are also listed.

In toluene, $D(t)$ may be expressed by

$$D(t)=D_0\left(1-\frac{\alpha\beta k_1}{k_1-k_2}\right)\exp(-k_1t)+\frac{D_0\alpha\beta k_1}{k_1-k_2}\exp(-k_2t). \quad (5)$$

We determined $\alpha\beta$ from the value of D_{max} as a function of k_1 and k_2 (cf. Fig. 9a), and the rate constants can be determined by a best fit of the theoretical curve of $D(t)$ to the experimental values. A typical curve of $D(t)$ is also shown in Fig. 9a (full line), and the best-fit values obtained so far are also listed in Table 1. (The value of $\alpha\beta$ was nearly constant, i.e., 1.53.)

Although we have proposed that triplet AQ produces exciplexes with ground-state TEA both in ethanol and toluene and there are many papers to infer the existence of triplet exciplexes,[28] direct observation of their phosphorescences is extremely rare. This may be due to the fact that the phosphorescences are generally observable only in rigid media at low temperature where diffusion is extremely slow. Since the phosphorescences can be studied only with the complexes which are present in the ground state already, and since the exciplexes mean the nonexistence of the ground-state complexes, observation of the exciplex phosphorescences may be difficult even at 77 K.

It is well known that the lifetimes of the singlet exciplexs or ion pairs are in general of the order of a few nanoseconds.[29] However, we believe that our data in Table 1 are reasonable based on the following considerations: (1) Decay constants even for singlet exciplexes are sometimes small:[29] benzene/tetracyanobenzene (TCNB), $k_1=6.8\times10^6$ s^{-1}; toluene/TCNB, $k_1=8.2\times10^6$ s^{-1}; pyrene/*N*,*N*-dimethylaniline, $k_1=5.3\times10^6$ s^{-1}. (2) The phosphorescence lifetimes (τ_p) of exciplexes at 77 K are shorter than those of the electron donors or electron acceptors.[29] For example, τ_p of TCNB complexes with benzene, toluene, mesitylene, durene, and hexamethylbenzene are 3.0, 2.4, 2.3, 1.7, and 0.76 s, respectively, and all shorter than that of TCNB itself, 3.2 s. This is consistent with our result at room temperature; the lifetime of triplet AQ in toluene is 15.3 μs, while that of AQ/TEA exciplex can be calculated from Table 1 to be ca. 0.29 μs. (3) In liquid solutions at room temperature, the triplet exciplexes with decay constants of 10^4—10^6 s^{-1} are also known.[2,30,31]

Hub et al.[32] observed that an exciplex of singlet *trans*-stilbene (TS) with several amines was quenched by ground-state amines at their higher concentrations: They interpreted this quenching in terms of the interaction of amine radical cation with neutral amine, forming a triplex of a radical anion of TS and a radical cation of amine dimer bonded by the three σ-electrons on two nitrogen atoms. Thus, it is expected that the triplet exciplex of AQ/TEA may also be quenched by the formation of a triplet triplex of $AQ^{\cdot-}/TEA_2^{+}$. In fact, the values of Φ in ethanol decreased with increase in the concentration of TEA, indicating exciplex quenching by ground-state TEA (cf. Table 1). If exciplex formation is assumed to occur irreversibly, one can give the following approximate kinetic scheme (Scheme 1).

$$\begin{array}{ccc} AQ & \xrightarrow{h\nu} & AQ(T_1) \\ & & AQ(T_1)+TEA \\ & & \downarrow \\ AQ+TEA & \xleftarrow{k_d^0} & (AQ^{\cdot-}\cdots TEA^{+})^* \xrightarrow{k_q[TEA]} Triplex \\ & & \downarrow k_{ion} \\ & & (AQ^{\cdot-}\cdots TEA^{+}) \\ & & \downarrow k_2 \end{array}$$

Scheme 1.

Under these conditions, the decay constant of the exciplex can be given by

$$k_1 = k_d^0 + k_{ion} + k_q[\mathrm{TEA}]. \quad (6)$$

A plot of k_1 against the concentration of TEA ([TEA]) gave a straight line with the quenching rate constant of 3.1×10^6 M^{-1} s^{-1} in ethanol (cf. Fig. 8). This value is about two orders of magnitude smaller than that obtained for the singlet exciplex of TS/TEA, i.e., 3×10^8 $M^{-1}s^{-1}$, but may be nearly equal to that obtained for TS/diisopropylamine, i.e., $\ll1.0\times10^7$ M^{-1} s^{-1} by Hub et al.[32] (In toluene, the value of k_q was negligibly small compared with that in ethanol.)

The approximate values of k_d^0 and k_{ion} for the exciplex of AQ/TEA in ethanol can be obtained from the dependence of $1/\Phi$ on [TEA] using the following equation;

$$\frac{1}{\Phi} = \left(\frac{k_d^0 + k_{ion}}{k_{ion}} + \frac{k_q[\mathrm{TEA}]}{k_{ion}}\right)\cdot\frac{1}{\gamma} \quad (7)$$

where γ is the efficiency of formation of AQH· from the contact ion pair. Since a plot of $1/\Phi$ against [TEA] gave a straight line (cf. open circles in Fig. 8), the values of k_d^0 and k_{ion} were determined to be 8.4×10^5 s^{-1} and 5.6×10^6 s^{-1}, respectively, on the assumption that γ is unity. In toluene, the value of Φ is independent of [TEA] as can be seen in Table 1, indicating that the value of $k_d^0+k_{ion}$ is much greater than that of k_q[TEA].

The formation of exciplexes with ground-state TEA was also observed for triplet α-haloanthraquinones both in ethanol and toluene.[13,24,26] However, our results are a little different from those of BP/amine (amine=TEA, *N*,*N*-diethylaniline, *N*,*N*-dimethylaniline, DABCO), reported by Peters et al.: In their first two papers,[4,5] they proposed that an electron was transferred from amine to triplet BP forming an exciplex. Later they changed the assignment of the exciplex to that of a solvent-separated ion pair,[6] but no explanation has been given. Presumably their assignment to the solvent-separated ion pair may be based on their finding that picosecond laser photolysis of BP/amine in acetonitrile gave rise to a new intermediate with λ_{max} of 715 nm. Since this intermediate changed to another intermediate with λ_{max} of 690 nm on a picosecond time scale, they concluded that the photoreduction proceeded via rapid electron transfer from amine to triplet BP forming the solvent-separated ion pair followed by the formation of a contact ion pair. In ethanol, the absorption maximum shifted to blue from 690 to 625 nm, and this spectral shift was attributed to the formation of a hydrogen-bonded solvent-separated ion pair from an initially formed contact ion pair.

In our present study both in ethanol and toluene, however, no spectral shift was observed on a picosecond time scale, nor in 2-methyltetrahydrofuran, acetone and dimethylsulfoxide. On a few microsecond time scale, the transient absorption shifted to blue by ca. 8 nm in ethanol and ca. 5 nm in toluene, and the shifted bands decayed following a single exponential function. Thus, we suggest that the exciplex is produced initially in both ethanol and toluene.

The spectral shifts observed by Peters et al. might be due to a special solvent effect of acetonitrile. This explanation is based on the following facts:[33] (1) Picosecond laser photolysis of AQ/TEA (1 M) in acetonitrile gave rise to the spectral change similar to those observed by Peters et al. Namely, an absorption band (Band X) with λ_{max}=540 nm built up during the first 500 ps delay and this band did not decay up to 2 ns. On the other hand, an absorption band (Band Y) with λ_{max}=515 nm increased up to 2 ns and the overall spectral profile at 2 ns delay looked like a superposition of Bands X and Y. (2) Nanosecond laser photolysis of AQ/TEA (0.2 M) in acetonitrile revealed that the absorption spectrum taken immediately after the laser pulse was similar to that observed upon picosecond laser photolysis at 2 ns delay, while those taken at delay times longer than 0.05 μs had no absorption due to Band Y. This indicates that Band Y shifted to red by ca. 25 nm: The transient absorption at 540 nm appeared within the duration of the nanosecond laser pulse, and it increased up to 1 μs delay. The maximum absorbance persisted beyond 50 μs and decayed on a much longer time scale, following second order reaction kinetics. (3) A transient photocurrent was detected in acetonitrile, and its buildup curve was identical with that of the transient absorption. (4) Nanosecond pulse radiolysis of AQ in acetonitrile without TEA gave rise to the appearance of a new absorption band similar to Band X: The rate constant for the buildup of this new absorption band was equal to that for the decay of the absorptions due to anionic species such as a solvated electron, monomeric and/or dimeric radical anion of acetonitrile.[34]

Thus, we proposed that Bands X and Y were due to a free $AQ^{\cdot-}$ and an exciplex, respectively. Since the transient absorption spectrum obtained by picosecond laser photolysis exhibited the time-dependent spectral change, the free $AQ^{\cdot-}$ and the exciplex may be produced independently from the different encounter collisional complexes between ground-state TEA and triplet AQ.[3,30] We suggested that the free $AQ^{\cdot-}$ and the exciplex in acetonitrile were produced via the T_2 and T_1 states of AQ, respectively, based on the following facts: The time constants for the internal conversion from the T_2 to T_1 states were estimated to be less than 70 ps for AQ and 1-chloroanthraquinone (1-CAQ),[23] while that for DCAQ was 0.70—0.75 ns.[12] In accordance with this, the ratio of the intensity of Band Y to that of Band X for DCAQ[35] was smaller than those for AQ[33] and 1-CAQ.[35]

We wish to express our sincere thanks to Professor Noboru Mataga and Dr. Hiroshi Miyasaka of Osaka University for the help in the measurements of the

transient absorptions using a picosecond Nd^{3+}:YAG laser. Thanks are also due to Dr. Yoshinori Hirata of Osaka University for his help in the measurements of transient photocurrents.

21) We confirmed that the values of Φ determined from the decrease of AQ absorptions matched those from the increase of AQH_2 absorptions. Since the prolonged photolysis of AQ in toluene without TEA gave rise to complicated reactions, the extinction coefficient of AQH_2 in TEA/toluene solution was determined as follows: First, AQH_2 was produced upon photolysis of AQ in ethanol without TEA, and the yield of AQH_2 was determined. Next, ethanol was removed in vacuo, and then TEA/toluene was added. Thus, one could determine the extinction coefficient of AQH_2 in TEA/toluene solution.

Rate of Solvent Extraction of Chromium(III) with Acetylacetone into Carbon Tetrachloride

Tatsuya SEKINE,* Kazuho INABA,† Tatsumu MORIMOTO, and Hidehiko AIKAWA
Department of Chemistry, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
†Water and Soil Environment Division, National Institute for Environmental Studies, Onogawa, Tsukuba-shi, Ibaraki 305
(Received May 2, 1987)

The rate of solvent extraction of chromium(III) in aqueous perchlorate solutions into carbon tetrachloride as the tris(acetylacetonato) complex has been determined. The rate was first order with respect to the acetylacetone concentration and inverse first order with respect to the hydrogen-ion concentration. From this information, the rate-controlling reaction is concluded to be the formation of the first complex in the aqueous phase by a reaction between $[Cr(OH)]^{2+}$ and HA.

Since the rate of solvent extraction of chromium(III) in aqueous solutions with chelating extractants is very low, this experimental method can be used only when it is enhanced, for example, by heating the aqueous solutions containing hydrated Cr^{3+} ions in the presence of the extractant[1] or by the complex formation of metal ions with a second ligand, such as fluoride ions.[2]

In the course of a series of kinetic studies on the solvent extraction of chromium(III) with β-diketones, it has been found that the rate of extraction with acetylacetone (2,4-pentanedione, HA) was much higher when the diluent was 4-methyl-2-pentanone (MIBK) than when it was carbon tetrachloride; the extraction into the latter solvent was negligible, even after two-phase agitation for 24 h, while it was measurable into the former solvent under identical conditions, except for the diluent.[3]

In the present study, the rate of extraction of Cr^{3+} in aqueous sodium perchlorate solutions into this non-polar solvent with β-diketone was measured at a much higher ligand concentration than in the previous work and the mechanism of the extraction process as well as the rate-controlling reaction was considered.

Experimental

All the experiments were carried out at 298 K. The solvent and reagents were of reagent grade. The tris(acetylacetonato)chromium(III) was obtained from Dojindo Laboratories. Sodium perchlorate was recrystallized three times from water. Carbon tetrachloride was washed twice with water before use. The aqueous solutions were 4 mol dm^{-3} sodium perchlorate constant ionic media containing 1×10^{-3} mol dm^{-3} of Cr^{3+} and 5×10^{-3} mol dm^{-3} of sulfanilic acid-sulfanilate buffer which kept the hydrogen-ion concentration from 10^{-3} to $10^{-4.5}$ mol dm^{-3}. Experiments were carried as follows: A portion of the aqueous solution and the same volume of an organic solution of acetylacetone was placed in a stoppered glass vessel. The two phases were agitated at such a speed that no increase in the rate was found upon further increasing the agitation speed for a certain time; they were then centrifuged. The content of the tris(acetylacetonato)chromium(III), CrA_3, in the organic phase was determined from the optical density at 380 nm and the chromium(III) concentration in the aqueous phase was determined by an atomic absorption method.

The distribution constant of the CrA_3 complex was determined as follows. A carbon tetrachloride solution containing 1×10^{-3} mol dm^{-3} of the complex and 1×10^{-1} mol dm^{-3} of acetylacetone was agitated with the same volume of an aqueous perchlorate solution for 3 min; then the two phases were centrifuged off. The chromium(III) content in the aqueous phase was determined by the atomic absorption method.

Results and Discussion

In the present paper, all species in the organic phase are denoted by "org" and that in the aqueous phase by using no subscript. The volumes of the two phases were the same. The hydrogen-ion concentration was always higher than 1×10^{-5} mol dm^{-3}. The pK_a of the reagent was about 10.1[4] and was in large excess to the metal ions. Under these conditions, the following equation may be written for the extractant in the aqueous phase:

$$[HA]_{total}=[HA]+[A^-]+\sum a[CrA_a^{3-a}]. \quad (1)$$

The value of distribution constant of the CrA_3 complex, $K_{dm}=[CrA_3]_{org}/[CrA_3]$, was obtained to be $10^{2.24}$.

It was found that the rate of solvent extraction was not affected by the speed of the two-phase agitation. There was no difference in the rate of solvent extraction when the two phases in the vessel were continuously agitated using a mechanical shaker and when they were agitated by hand for a few minutes after they were left standing in the dark after an initial agitation of the two phases. Furthermore, when an aqueous solution which contained the metal ions, acetylacetone, and the buffer was left standing in the dark for a certain time and agitated with a carbon tetrachloride solution of acetylacetone for 30 min, the amount extracted was similar to that when the two phases were continuously agitated. These results indicate that the rate controlling reaction is the complex formation in the aqueous phase and that it is neither a reaction on the interface nor in the organic phase.

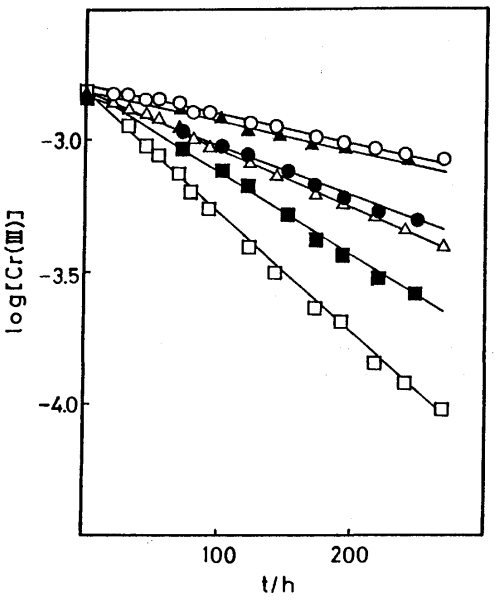

Fig. 1. Amount of extracted Cr(III) as tris(acetylacetonato) complex into carbon tetrachloride as a function of standing time of the system. The pH of solution is; 3.42 (○), 3.93 (△), 4.46 (□), 3.89 (●), 3.45 (▲), and 4.32 (■).

Figure 1 shows the decrease in the chromium(III) concentration in the aqueous phase upon solvent extraction as a function of time. As can be seen from Fig. 1, each set of data can be represented by a straight line and, thus, the rate of extraction should be first order with respect to the total chromium(III) concentration in the aqueous phase. The rate of solvent extraction, V_{se}, can be given by the decrease in the chromium(III) concentration in the aqueous phase, [Cr(III)], and can be written

$$V_{se} = -\mathrm{d}[\mathrm{Cr(III)}]/\mathrm{d}t = k_{obsd}[\mathrm{Cr(III)}]. \quad (2)$$

Figure 2 gives a log k_{obsd} vs. log [HA] plot for a $-\log[H^+]$ of 3.6. As can be seen from Fig. 2, the values of k_{obsd} are first order with respect to [HA] and, thus, the formation of the first complex should be the rate-determining step.

Figure 3 gives the dependence of k_{obsd} on the hydrogen-ion concentration. In this figure, the value of $k_{obsd}/[HA]$ is given on the basis of the results in Fig. 2 in order to compare the data at different extractant concentrations. The plot in Fig. 3 is not a straight line but a curve. After trials, the following equation was found to fit well with the experimental data when $C_1=10^{-8.9}$ and $C_2=10^{-4.3}$:

$$\log(k_{obsd}/[HA]) = \log(C_1/(C_2+[H^+])). \quad (3)$$

The above values of C_1 and C_2 are introduced into Eq. 3. The broken line in Fig. 3 is calculated by using this data. Thus, Eq. 2 can be rewritten as

$$V_{se} = C_1[\mathrm{Cr(III)}][HA]/([H^+]+C_2). \quad (4)$$

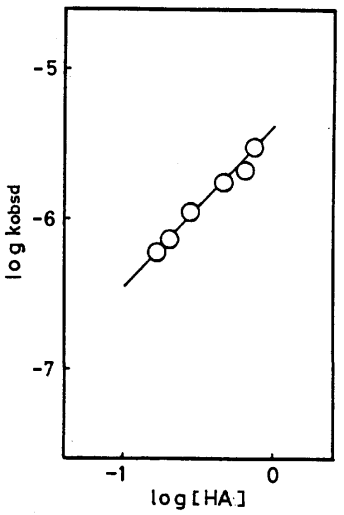

Fig. 2. Rate of complex formation as a function of concentration of acetylacetone in undissociated form in aqueous phase. The slope of the line is +1.

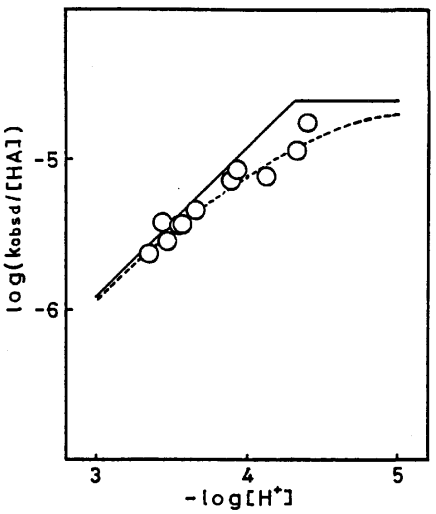

Fig. 3. Rate of solvent extraction of Cr(III) into carbon tetrachloride as a function of hydrogen ion concentration. Aqueous phase: 4 mol dm^{-3} $NaClO_4$. The broken line is the calculated curve by using Eq. 3 with $C_1=10^{-8.9}$ and $C_2=10^{-4.3}$. Each asymptote give the value when $[H^+]\to\infty$ and $[H^+]\to 0$.

When the rate-controlling reaction is the formation of the first complex in the aqueous phase, it can be given by one or both of the following equations:

$$[\mathrm{Cr(OH)}]^{2+} + \mathrm{HA} \quad (5)$$

and/or

$$\mathrm{Cr}^{3+} + \mathrm{A}^-. \quad (6)$$

The rate of complex formation, V_{cf}, may be given by

$$V_{cf} = k_1[\mathrm{Cr(OH)}^{2+}][HA] + k_2[\mathrm{Cr}^{3+}][\mathrm{A}^-]. \quad (7)$$

When only the following hydrolysis is taken into the account,

$$[\mathrm{Cr(H_2O)_6}]^{3+} \rightleftarrows [\mathrm{Cr(OH)(H_2O)_5}]^{2+} + \mathrm{H}^+$$

and

$$K_h=[Cr(OH)^{2+}][H^+]/[Cr^{3+}], \quad (8)$$

the total amount of uncomplexed chromium(III) can be given as

$$[Cr(III)]_{uncomp} = [Cr^{3+}]+[Cr(OH)^{2+}] = [Cr^{3+}](1+K_h/[H^+]). \quad (9)$$

The formation of polymerized species such as $[Cr_2(OH)_2]^{4+}$, $[Cr_2(OH)_3]^{3+}$, and $[Cr_2(OH)_4]^{2+}$ by the hydrolysis of chromium(III) has been pointed out.[5] For example, when $-\log[H^+]$ is 4 and the total chromium(III) concentration is 1×10^{-3} mol dm^{-3}, the formation of polymerized species after 10 days can be calculated by using the constants;[5] this value was found to be about 10%. Thus, effects due to the polymerized species could be neglected in the considerations of the rate in the early stage of the reaction. By using Eq. 8, Eq. 7 can be written as

$$V_{cf}=(k_1K_h+k_2K_a)[Cr^{3+}][HA]/[H^+], \quad (10)$$

where K_a is the acid dissociation constant, $K_a=[H^+][A^-]/[HA]$, and K_h is the hydrolysis constant in Eq. 8. The value of the constant in the literature is[4] $K_a=10^{-10.1}$. The value of K_h in the literature ranges[6] from $10^{-3.5}$ to $10^{-4.2}$; a value of $10^{-4.3}$ was reported in a recent paper.[5]

On the basis of Eq. 9, Eq. 10 can be rewritten as

$$V_{cf}=(k_1K_h+k_2K_a)[Cr(III)]_{uncomp}[HA]/([H^+]+K_h). \quad (11)$$

When $[Cr(III)]_{uncomp}$ is almost the same as [Cr(III)], it should be regarded from Eqs. 4 and 11 that $C_1=(k_1K_h+k_2K_a)$ and $C_2=K_h$.

In this data analysis, it was assumed that $[Cr(III)]_{uncomp}$ is equal to [Cr(III)]; that is, the total concentration of the acetylacetonato complex species, $[CrA^{2+}]+[CrA_2^+]+[CrA_3]$, is negligible compared to $[Cr(III)]_{uncomp}$. Separate experiments were made in order to examine this as follows. A portion of the aqueous phase was separated from the organic phase after two-phase agitation for a certain time. This was again agitated for a certain time with the same volume of carbon tetrachloride containing the same concentration of the extractant, but with no chromium(III). It was found that no chromium(III) in the aqueous phase was extracted by this second extraction. When the $[CrA]^{2+}$ and/or $[CrA_2]^+$ species are present in appreciable amounts in this separated aqueous phase, each should react with the ligand at a higher rate than of the rate-controlling reaction to form the CrA_3 species, which is extracted well as the K_{dm} value indicates. For this reason, the amounts of these species and of the CrA_3 species is, for all practical purposes, negligible compared to the amount of Cr^{3+} or $[Cr(OH)]^{2+}$ in this aqueous solution.

Due to a proton ambiguity, it is generally impossible to conclude whether Eq. 5 or 6 is the rate-controlling reaction. However, the former seems to control the whole process; if the former was the controlling reaction, the value of k_1K_h would be calculated to be $10^{-8.9}$ (s^{-1}) and, consequently, the value of k_1 would be obtained as $10^{-4.6}$ ($mol^{-1}\,dm^3\,s^{-1}$). The keto-enol equilibrium of the β-diketone should be taken into account. Since the enol form of acetylacetone is only 20% of the undissociated form,[7] ($K_e=[HA]_{enol}/[HA]_{keto}=10^{-0.63}$), the rate constant should be about 5-times higher if only the enol form of the β-diketone reacts in the way given by Eq. 5. However, it still is seen that the rate constant, k_1, is about 10^{-4} ($mol^{-1}\,dm^3\,s^{-1}$). If the latter would control the extraction, the value of k_2K_a should be equal to $10^{-8.9}$ (s^{-1}). As pointed out, K_a in these ionic media is $10^{-10.1}$ (mol dm^{-3}) and, consequently, k_2 is calculated to be $10^{1.2}$ ($mol^{-1}\,dm^3\,s^{-1}$).

In the literature,[8,9] the rate constant for the complex formation of hydrated Cr^{3+} with various ligands is in the range 10^{-5} to 10^{-7} ($mol^{-1}\,dm^3\,s^{-1}$), while that of $[Cr(OH)]^{2+}$ is in a range 10^{-3} to 10^{-5} ($mol^{-1}\,dm^3\,s^{-1}$). The present results, $k_1\simeq10^{-4}$ ($mol^{-1}\,dm^3\,s^{-1}$), suggest that the complex formation in the system studied proceeds through a reaction of the $[Cr(OH)]^{2+}$ species with the undissociated form of acetylacetone, HA.

The mechanism of water exchange of hydrated Cr^{3+} and $[Cr(OH)]^{2+}$ was considered from the viewpoint of the activation volume of the reaction.[8] It was concluded that the water exchange from the Cr^{3+} species proceeded through an I_a mechanism while the reaction for that from the $[Cr(OH)]^{2+}$ species had a dissociative character. The difference of the rate constant for the complex formation of the hydrated Cr^{3+} and $[Cr(OH)]^{2+}$ species may possibly be explained by the difference in the reaction mechanism. However, the conclusion does not seem to be definite.

The ratio of the total amount of the complexes formed in the system and the amount extracted is given as

$$R = [CrA_3]_{org}/([CrA^{2+}]+[CrA_2^+]+[CrA_3]+[CrA_3]_{org}) = K_{dm}\beta_3[A^-]^3/(\beta_1[A^-]+\beta_2[A^-]^2+\beta_3[A^-]^3+K_{dm}\beta_3[A^-]^3), \quad (12)$$

where β_n is the stability constant of the "n-th" complex. Since the value of K_{dm} is $10^{2.24}$, it can be concluded that nearly all of the complexes formed are extracted as the CrA_3 species into the organic phase when this ratio is approximately unity; however, if R is to some extent smaller than unity, the complexed chromium(III) which remains in the aqueous phase cannot be neglected.[10]

It was reported that the rate constant for the complex formation with the same ligand obtained by the data of solvent extraction into MIBK is several orders higher than the present value.[4] This problem will be considered in another paper.

The authors are grateful to Mr. Takashi Kurihara for his valuable discussion and experimental aids.

(Received May 30, 1987)

Changes in the chemical compositions of Tamagawa Hot Spring waters and Pb-bearing barite (hokutolite) were examined. Samples were obtained from various locations and various time in Tamagawa Hot Spring. The relationships between the hot spring waters and the minerals were expressed as partition equations and phenomenological equations; then, the partition coefficients and phenomenological coefficients were calculated. The apparent partition coefficients of Pb^{2+} and of Sr^{2+} between the two phases were found to have increased, from 0.14 to 0.30(0.31) and from 0.023 to 0.035(0.042) respectively, with the decrease in the hokutolite growth rate since 1973. The reaction rate of hokutolite as calculated from the phenomenological equations was, however, about 2 times higher in 1983 than in 1965. These results were ascribed to the rise in the degree of the supersaturation of barium sulfate and also to the increase in the nucleation rate in the hot spring water.

The partition formula of a chemical element between an aqueous solution and a solid solution is often useful in expressing the relationship between these two phases. There are, however, some problems with this manner. One is the remarkable dispersion of partition coefficients[1] caused by the effect of the chemical nonequilibrium of each ion between the two phases, and the other is the difficulty of expressing the partition of the multicomponent system.[2] For the measurement of the partition coefficient of trace elements between an aqueous solution and an insoluble salt like barium sulfate, it needs a long time to reach a chemical equilibrium, so it is sometimes convenient for getting an equilibrium value to use the data of the chemical compositions of natural minerals and hot spring waters instead of the data from synthetic solids and solutions in a laboratory.[3]

As to the partition of a multicomponent system, Takano[2] proposed a formulation of a three-component system on the basis of an ion-exchange reaction, but there have been very few actual applications to experimental and natural data.

Sasaki[4] proposed a formulation of partition by utilizing phenomenological equations and applied it to the data of Tamagawa Hot Spring. To solve these phenomenological equations, however, several sets of data obtained under different conditions are needed.

In recent years conspicuous changes in chemical composition have been observed in several hot springs, including Tamagawa Hot Spring[5-7] and Kusatsu Hot Spring,[8,9] in Japan. Tamagawa Hot Spring showed remarkable increases in the SO_4^{2-} and Fe^{2-} concentrations from 1973 to 1978, from about 1200 ppm to 2600 ppm, and from about 90 ppm to 170 ppm, respectively. Sasaki[4,10] reported that these increases caused the changes in the Ba^{2+}, Pb^{2+}, and Sr^{2+} concns, of the hot spring waters. These cations are the main components of the Pb-bearing barite (hokutolite) precipitated from the hot spring waters in this district.[11] Hokutolite is a famous radioactive mineral and has been designated as a special natural monument in Japan since 1952.

The present authors[12] observed and examined the hokutolite which had been growing at Yubana fall (the end of the Yubana conduits in Tamagawa Hot Spring; shown in Fig. 1) after 1953; they also observed increases in the Pb, Sr, and Fe[a] contents (Table 1) with the decrease in the crystal growth rate (0.10 mm y^{-1} to 0.05 mm y^{-1}) after 1973. They supposed that the changes in the mineral were attributable to the decrease in the Ba^{2+} concn in the hot spring water, which might have been caused by the increase in the SO_4^{2-} concn, judging from the ionic equilibria.

The aims of present work are to ascertain the truth of this supposition formerly proposed by the present authors[12] and to clarify the relationship between the

changes in the chemical composition of the hot spring waters and those in the chemical composition and the crystal growth rate of mineral (hokutolite) occurring in this area.

Experimental

The hot spring water samples were collected in October, 1983, in August, 1985, and in August, 1986, at four sites, Obuki Spring and Kobuki Spring (1983, 1985, 1986), Yubana fall (1985, 1986), and the so-called poisonous water tunnel (1986) (Fig. 1).

Analytical Procedures. 1) Barium and Lead: After sampling, the Ba^{2+} and Pb^{2+} were separated immediately in situ from the other elements by coprecipitation with strontium sulfate.[14] The precipitate was brought to the laboratory, decomposed by means of hydriodic acid,[15] and analyzed. The Ba^{2+} and Pb^{2+} were determined by flame photometry and atomic-absorption spectroscopy (AAS) respectively.

2) Strontium: The Sr^{2+} was preconcentrated using Pb^{2+} and fuming nitric acid, and was determined by the use of AAS.[11]

3) Sulfate and Chloride: The SO_4^{2-} concentration was determined by the use of the gravimetric method.[16] The Cl^- concentration was measured by means of chloride-ion electrode using an ion meter (DKK, IOC-10).

Results and Discussion

The analytical results of the hot spring water are shown in Table 2. The analytical data given by Takano[14] and by Takano and Watanuki[11] for the waters sampled in 1965 are also listed in Table 2. It may be seen that the SO_4^{2-} concns in the Obuki vent were about 2100—2300 ppm in 1983, about 1600 ppm in 1985, and 1200 ppm in 1986, indicating a decrease in the SO_4^{2-} from the maximum value (ca. 2600 ppm)[6,17] in 1978.

The Ba^{2+} concentrations in 1983 and in 1985 are at levels similar to or a little higher than those in 1965. This result is contrary to our estimation[12] previously mentioned. On the other hand, the Pb^{2+} concentrations have decreased, and the Sr^{2+} concns have increased, in both spring waters. The Cl^- concns are nearly invariable during the 1965—1986 period,

D_{Sr}	0.023	0.035	0.042

though the 1978 value (ca. 3300 ppm)[6] was a little high.

As compared with the Obuki Spring, the Kobuki Spring shows a slightly low pH value, slightly high Ba^{2+}, Pb^{2+}, and Sr^{2+} values (1983, 1985), and or Cl^- and SO_4^{2-} concns, very similar Sr^{2+}, Pb^{2+}, and Ba^{2+} (1986) concns.

The relationship between the chemical composition of a Pb-bearing barite crystal and that of Tamagawa Hot Spring water can be expressed by the following equation:

$$(M/Ba)_{crystal} = D_M\,(M/Ba)_{solution}, \quad (1)$$

where D_M denotes an apparent partition coefficient of M between the $BaSO_4$ crystal and the thermal solution on the basis of the surface equilibrium and where M refers to Pb, Sr or other minor elements. (M/Ba) indicates the weight ratio or mole ratio of two elements in each phase.

The partition of an element between the binary solid phase and the aqueous phase was formulated by Takano[2] on the basis of the ion exchange equilibrium as an example of treating a multicomponent chemical equilibrium system, but farther experimental study has not been carried out.

In this paper Eq. 1 is used.

If D_M is constant for the Tamagawa water, the chemical composition of hokutolite, (Ba, Pb, Sr)SO_4, can be calculated from the (Pb^{2+}/Ba^{2+}) and (Sr^{2+}/Ba^{2+}) ratios of the thermal solution (Obuki Spring water). Both ratios are shown in Table 3. It can clearly be seen that the (Pb^{2+}/Ba^{2+}) ratios of I in 1983 are lower than in 1965, while the (Sr^{2+}/Ba^{2+}) ratios are at similar levels between I in 1983 and in 1965 in both springs. Actually, however, the Pb/Ba and Sr/Ba ratios in hokutolite clearly increased[12] (see Table 1(b)). The apparent partition coefficients were calculated from the data in Tables 1 and 2; they are shown in Table 4. In this case, the solutions in 1965 and in 1983 were assumed to be the solutions from which the Pb-bearing barite crystals of 1953—1972 and of 1973—1981 were formed. It was found that the apparent partition coefficients of Pb and Sr both nearly doubled.

The reasons for these rises in the apparent partition coefficients seem to be profoundly interesting.

Takano[14] interpreted the variation in the Pb content of barite in terms of Pb-chloro complex formation. However, the chloro complex effect is a nondecisive factor in this case because the Cl^- concns in 1965 and in 1983 are nearly equal.

Ichikuni[18] noted that the major portion of the barium in the spring water might have been precipitated as barium sulfate within 100 m of the vent of the Obuki Spring; he also explained the increase in the Pb content in Pb-bearing barite collected at various points of the stream of Tamagawa Hot Spring. He used the homogeneous partition coefficient of Kolthoff and Noponen,[19] which is based on the solid-liquid equilibrium, as a first approximation. He calculated the crystal growth rate as 0.86 mm y^{-1}, which was considerably higher than the results of crystal growth rate obtained by Saito et al.[20] (0.09—0.25 mm y^{-1}) and by the present authors[12] (0.05—0.10 mm y^{-1}). He considered that the barium sulfate (barite) precipitates mainly in the form of minute crystals and that part of them are buried in sulfurous sinter, as was also observed by Saito et al.[20]

Takano (private communication) thought that nearly pure $BaSO_4$ is already formed as fine particles (clusters) in the upper part of the vents. To examine these ideas, the ion-activity products (IAP) of barium sulfate at several points were calculated as follows:

$$IAP = a_{Ba^{2+}} \cdot a_{SO_4^{2-}} = \frac{a_{Ba^{2+}} \cdot a_{HSO_4^-}}{a_{H^+}} K_2, \quad (2)$$

Obuki vent (100 °C) $IAP(1965) = 2.70\times10^{-10}$,
$IAP(1983) = 4.70\times10^{-10}$, (3)

Yubana fall (70 °C) $IAP(1965) = 6.15\times10^{-10}$,
$IAP(1983) = 10.8\times10^{-10}$, (4)

Yudaki fall (25 °C) $IAP(1965) = 6.35\times10^{-10}$, (5)

where K_2 is the second dissociation constant of sulfuric acid, K_2: $10^{-3.0}$ at 100 °C, $10^{-2.6}$ at 70 °C, and $10^{-2.0}$ at 25 °C.[21]

These IAP values show that Obuki Spring water is nearly saturated, or even a little supersaturated, while

Yubana fall and Yudaki fall are supersaturated with $BaSO_4$, whose solubility product, K_{sp}, is 2.82×10^{-10} (100 °C), 2.56×10^{-10} (70 °C), or 1.12×10^{-10} (25 °C).[22]

Liu et al.[23] and Sasaki and Minato[24] have shown that the rise in the degree of supersaturation, shown by the value of $IAP/K_{sp}-1$, causes the formation of many fine nuclei in the cases of $BaSO_4$ and (Ba, Pb)SO_4 crystallization. Now we can postulate that numerous barite microcrystals, which are hardly visible, are formed from three-dimensional nuclei, that they flow, drifting downstream from the upper stream, and that a large part of them no longer adhere to the crustal hokutolite crystals. This image suggests the decrease in the dissolved free Ba^{2+} concn and, therefore, the increase in Pb^{2+}/Ba^{2+} and Sr^{2+}/Ba^{2+} in the solution and the resulting increase in Pb/Ba and Sr/Ba in hokutolite crystals; at the same time, it explains the reduction of the hokutolite growth rate.

To verify this idea, the following experiments were carried out. The hot spring waters collected at Obuki and Kobuki Springs (1985) and at Yubana fall (1986) were immediately filtered with 0.1 μm membrane filters before the coprecipitation of Ba^{2+} and Pb^{2+} with strontium sulfate; then, the Ba^{2+} and Pb^{2+} concentrations were determined. The results are shown in Table 5. It was found that the Ba^{2+} and Pb^{2+} concns were nearly invariable by filtration for Obuki hot spring water, but were reduced in the Yubana fall water. These results obviate the possibility of barite microcrystals or, at least, obviate the possibility of crystals over 0.1 μm in diameter around the Obuki vent. At the Yubana fall, however, at least 20% of the Ba^{2+} had already become barite particles over 0.1 μm in diameter, although the SO_4^{2-} concn in 1986 had returned to nearly the same value as in 1965.

According to the crystal-growth (precipitation) theory, an increase in the degree of supersaturation brings about an acceleration of the crystal growth.[25] It is known that the rise in the growth rate brings about an increase in the apparent partition coefficient of a minor element in a depletion system:[26,27]

$$\lambda = \frac{I/M - k_1}{I/M - k_2}. \tag{6}$$

Table 5. Barium and Lead Concentrations of Filtered Tamagawa Hot Spring Water Compared with Non-Filtered Water (mg·dm^{-3})

Locality	Treatment	Ba^{2+}	Pb^{2+}

Sasaki,[4] treated the partition of a multicomponent-system using the matrix formula of phenomenological equations[28,29] and assuming that the precipitation reaction proceeds under conditions close to those of chemical equilibrium. The case of a three-component system may be formulated as follows:

$$\begin{pmatrix} v_{r1} \\ v_{r2} \\ v_3 \end{pmatrix} = k_r \begin{pmatrix} x_{r1} \\ x_{r2} \\ x_{r3} \end{pmatrix} = \begin{pmatrix} L_{11} & L_{12} & L_{13} \\ L_{21} & L_{22} & L_{23} \\ L_{31} & L_{32} & L_{33} \end{pmatrix} \begin{pmatrix} A_{r1} \\ A_{r2} \\ A_{r3} \end{pmatrix} (r=1, 2, 3), \tag{7}$$

$k_r x_{ri}$ (i=1, 2, 3) is the precipitation rate of each end member, where x_{ri} (i=1, 2, 3) expresses the chemical composition (mol%) and where k_r is the reaction-rate parameter of the r'th solid phase (k_1=1 is the standard value). L_{ij} (i=1, 2, 3; j=1, 2, 3) is the phenomenological coefficient, and A_{ri} (i=1, 2, 3) is the chemical affinity of each end-member component of the r'th solid solution in the precipitation reaction.[30]

For example, A_{BaSO_4} is calculated by means of:

$$A_{BaSO_4} = RT \ln S_{BaSO_4}, \tag{8}$$

where S_{BaSO_4} is the supersaturation ratio: S_{BaSO_4}=IAP($BaSO_4$)/K_{sp}($BaSO_4$), where IAP($BaSO_4$) is an ion-activity product of Ba^{2+} and SO_4^{2-} in the spring water and where K_{sp}($BaSO_4$) is the solubility product of $BaSO_4$ at each temperature.

Using the data in Tables 1 and 2 and other sources,[11,14] following reaction-rate equations are obtained:

Yubana fall:

1965
$$k_1 \begin{pmatrix} 83.67 \\ 14.58 \\ 1.06 \end{pmatrix} = \begin{pmatrix} L_{11} & L_{12} & L_{13} \\ L_{21} & L_{22} & L_{23} \\ L_{31} & L_{32} & L_{33} \end{pmatrix} \begin{pmatrix} 0.615 \\ -2.298 \\ -5.150 \end{pmatrix}, \tag{9}$$

1983
$$k_2 \begin{pmatrix} 83.02 \\ 14.73 \\ 1.58 \end{pmatrix} = \begin{pmatrix} L_{11} & L_{12} & L_{13} \\ L_{21} & L_{22} & L_{23} \\ L_{31} & L_{32} & L_{33} \end{pmatrix} \begin{pmatrix} 0.724 \\ -2.425 \\ -4.762 \end{pmatrix}, \tag{10}$$

Yudaki fall:

1965
$$k_3 \begin{pmatrix} 81.41 \\ \\ 16.55 \end{pmatrix} = \begin{pmatrix} L_{11} & L_{12} & L_{13} \\ \\ L_{21} & L_{22} & L_{23} \end{pmatrix} \begin{pmatrix} 1.027 \\ -1.886 \\ -4.399 \end{pmatrix}. \tag{11}$$

The solution is given as follows:

L_{11}=1078.4, L_{12}=L_{21}=200.7, L_{13}=L_{31}=23.0, L_{22}=39.7, L_{23}=L_{32}=3.4, L_{33}=1.0, k_2=2.2, k_3=7.5.

These calculations indicate that the precipitation rate of hokutolite was higher in 1983 (k_2=2.2) than in 1965 (k_1=1.0), and that it was higher in the Yudaki fall (k_3=7.5) than in the Yubana fall (k_1=1.0) in 1965 with an increase in the chemical affinity of the $BaSO_4$-formation reaction. However, the actual growth rate of hokutolite was lower in 1983 (0.05 mm y^{-1}) than in 1965 (0.10 mm y^{-1}).[12] Also the growth rate in the

Yudaki fall was lower (0.09 mm y^{-1}) than in the Yubana fall (0.25 mm y^{-1}).[20]

This discrepancy seems to be explicable by taking account of the nucleation rate of lead-bearing barite, as has already been mentioned. That is, at the Yubana fall or the Yudaki fall, numerous fine (three-dimensional) nuclei of hokutolite are formed because of the high supersaturation with regard to $BaSO_4$, but a large part of them cannot adhere to the crustal hokutolite crystals in an open-flow system like Tamagawa, so the actual crystal-growth rate decreases in spite of the increase in the total precipitation rate. These relations may be roughly formulated as following:

$$v = m_1 A - m_2 \exp(-\Delta G^*/RT), \quad (12)$$

$$\Delta G^* = \frac{16\pi\gamma^3 V^2}{3A^2}, \quad (13)$$

where v: apparent growth rate, A: chemical affinity of the $BaSO_4$ formation reaction, γ: surface energy of $BaSO_4$, V: mole volume of $BaSO_4$, ΔG^*: critical free enegy of nucleus formation, m_1, m_2: constants.

The first term in Eq. 12 indicates the total precipitation rate, while the second term expresses the elimination rate of small nucleus crystals of hokutolite. It is, however, questionable whether or not nucleation formation rate of $BaSO_4$ is expressed as the second term in Eq. 12.[30] More quantitative and precise analyses will be needed to confirm this inference.

Finally, we must consider the reason for the recent changes in the Tamagawa hot spring waters mentioned above. Considering the changes in the pH, and in the Fe^{2+} and SO_4^{2-} concentrations, we can guess that a reaction like the following one might have occurred in the deep places under the Obuki vent:

$$FeS_2 + 10H_2O + 15SO_2 \rightarrow Fe^{2+} + 10H^+ + 10HSO_4^- + 6S + S^{2-}. \quad (14)$$

This reaction proceeds toward the right side with an increase in the SO_2, indicating an increase in volcanic activity.[8,31] Moreover, with the rise in the S^{2-} concn in Eq. 14, the decrease in the Pb^{2+} concn can be explained as the next reaction of PbS (galena) formation:

$$Pb^{2+} + S^{2-} \rightarrow PbS. \quad (15)$$

These reactions explain the rise in the HSO_4^- and Fe^{2+} concns and also the fall in the pH and the Pb^{2+} concn nearly quantitatively. Of course, this is only one possible reaction process to explain the compositional changes in Tamagawa hot spring waters in recent years. The presence of FeS_2 and PbS and the reaction temperature and the reaction depth have, in fact, not yet been established. Further experimental research and discussion are needed.

The authors wish to thank Dr. Bokuichiro Takano, Tokyo University, for his valuable advice and continuous encouragement.

Circular Dichroism Spectra of the Dicobalt(III) Complexes Containing Two Bridging μ-Hydroxo Ligands

Tomoharu AMA,* Hiroshi KAWAGUCHI, and Takaji YASUI
Department of Chemistry, Faculty of Science, Kochi University, Akebono-cho, Kochi 780
(Received August 1, 1987)

Five cobalt(III) complexes, $[(gly)_2Co(\mu\text{-}OH)_2Co(en)_2]^{2+}$ (two geometrical isomers), $[(edda)Co(\mu\text{-}OH)_2Co(en)_2]^{2+}$ (two geometrical isomers), and $[(nta)Co(\mu\text{-}OH)_2Co(en)_2]Cl$, were newly prepared and optically resolved. Their structures were assigned on the basis of visible and UV absorption, ^1H NMR, and circular dichroism (CD) spectral data. It was found that the CD contributions of the two different cobalt(III) chromophores are additive in the present complex systems. The vicinal CD which is induced on one of the two cobalt chromophores by the other chiral cobalt chromophore was strong ($|\Delta\varepsilon|$: ca. 2). These complexes are stable for several days in aqueous solution.

Although many reports on the preparation and characterization of dicobalt(III) complexes containing two bridging hydroxo ligands have been published, only a few reports have dealt with the complexes containing two different cobalt(III) chromophores bridged with the two hydroxo groups.[2-5] However, the complexes of this type are the fundamental polynuclear ones and are suitable for the investigation of the interaction between the two cobalt atoms. Accordingly, a reliable method to prepare many complexes of this type is required. In the pevious paper,[2] the preparation of ammine complexes such as $[(L)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$ (L=$(gly)_2$, edda, or nta)[1] was reported and the following suggestion was given: the dicobalt(III) complexes with two μ-hydroxo, in which two hydrogen-bonds are formed between the amino groups on one of the two cobalt atoms and the carboxyl groups on the other cobalt atom, are preferentially produced. In order to confirm the suggestion, we tried to prepare the complexes with two ethylenediamine ligands instead of four ammine ligands (Fig. 1). In the present paper, the interaction between the cobalt(III) chromophores and the additivity rule in the CD spectra of the polynuclear complexes will be described in detail on the basis of the CD spectral data of these optically active isomers of ethylenediamine complexes. The preparation and stability of the complexes will also be described.

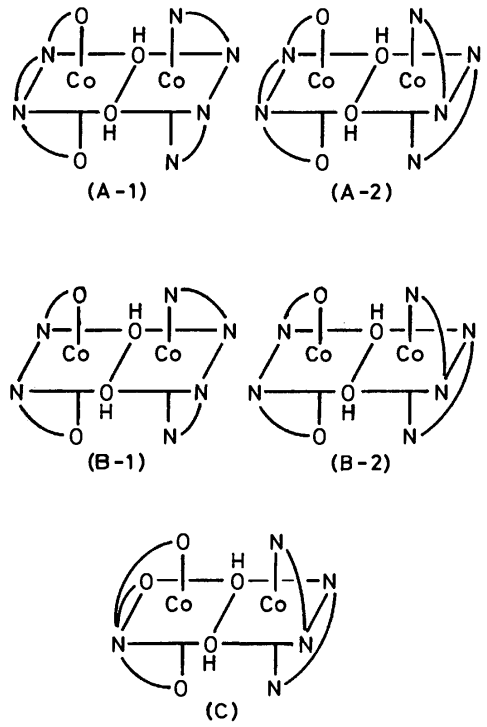

Fig. 1. Structures of the prepared complexes:
(A-1) (*Λ*, *Λ*)-$[(edda)Co(\mu\text{-}OH)_2Co(en)_2]^{2+}$ ($(+)^{CD}_{565}$**E-1**);
(A-2) (*Λ*, *Λ*)-$[(edda)Co(\mu\text{-}OH)_2Co(en)_2]^{2+}$ ($(+)^{CD}_{580}$**E-2**);
(B-1) (*Λ*, *Λ*)-$[(gly)_2Co(\mu\text{-}OH)_2Co(en)_2]^{2+}$ ($(+)^{CD}_{560}$**G-1**);
(B-2) (*Λ*, *Λ*)-$[(gly)_2Co(\mu\text{-}OH)_2Co(en)_2]^{2+}$ ($(+)^{CD}_{580}$**G-2**);
and (c) (*Λ*)-$[(nta)Co(\mu\text{-}OH)_2Co(en)_2]^{+}$ ($(-)^{CD}_{625}$**N-1**).

Experimental

Preparation of the Complexes. $[(edda)Co(\mu\text{-}OH)_2Co(en)_2]Cl_2$: In 5 cm^3 of water, $K[Co(edda)(CO_3)]\cdot H_2O$ (2.0 g)[6] was suspended and then acidified with 60% $HClO_4$ (2 cm^3). Separately, $[Co(en)_2(CO_3)]ClO_4$ (2.0 g) was suspended in 5 cm^3 of water and acidified with 60% $HClO_4$ (2 cm^3). The two solutions were mixed. The pH of the mixed solution was adjusted to 8.5 with 2 mol dm^{-3} KOH and then stirred for 60 min in a water bath at 50 °C. The reacted solution was cooled to room temperature, neutralized using 2 mol dm^{-3} $HClO_4$ and filtered. The filtrate was loaded on a column (4.7 cm×50 cm) of SP-Sephadex (K^+ form), and the adsorbed band was developed with 0.4 mol dm^{-3} KCl. The eluate from the third band (dark-violet) was transferred to another SP-Sephadex column (K^+ form) and repeatedly developed on the column using a micropump until the adsorbed band completely separated into two bands [**E-1** (earlier band) and **E-2** (later band)]. The eluate from **E-1** was evaporated to about 10 cm^3 and the KCl which deposited was filtered off. Methanol was added to the filtrate and the KCl which deposited was again filtered off. After the filtrate was evaporated almost to dryness, the residue was dissolved in 50 cm^3 of water. The solution was poured onto a column (4.7 cm×50 cm) of SP-Sephadex (K^+ form) once more. The adsorbed band was developed with 0.1 mol dm^{-3} K_2Sb_2 (*d*-tart)$_2$. This development was repeated on the column using a micropump until the adsorbed band completely separated into

two dark-violet bands. The earlier- and later-eluted bands exhibited (−) and (+) CD signs at 565 nm, respectively. Each band was eluted with 0.1 mol dm^{-3} of K_2Sb_2(*d*-tart)$_2$, and the eluted solution was concentrated to small volume under reduced pressure. To the concentrated solution, methanol was added to deposit K_2Sb_2(*d*-tart)$_2$. After the deposited K_2Sb_2(*d*-tart)$_2$ was filtered off, the filtrate was evaporated almost to dryness to exclude methanol and was diluted with a little water. The solution was reloaded on a short column (3 cm×5 cm) of QAE-Sephadex (Cl^- form) and eluted with water. The eluted solution was concentrated to small volume. Crude complex of the optically active isomer was obtained by adding methanol and acetone to the concentrated solution, which was recrystallized from water by adding methanol and acetone.

The eluate from **E-2** was optically resolved by a method similar to that employed for **E-1**. The earlier and later eluates on the development with K_2Sb_2 (*d*-tart)$_2$ were $(+)^{CD}_{580}$ and $(-)^{CD}_{580}$ forms, respectively. Found for the $(+)^{CD}_{565}$ **E-1** isomer: C, 22.14; H, 5.68; N, 15.52%. Calcd for [(edda)Co(μ-OH)$_2$-Co(en)$_2$]Cl$_2$·1.5H$_2$O=$C_{10}H_{31}N_6O_{7.5}Cl_2Co_2$: C, 22.07; H, 5.74; N, 15.44%. Found for the $(+)^{CD}_{580}$ **E-2** isomer: 21.08; H, 6.06; N, 14.82%. Calcd for [(edda)Co(μ-OH)$_2$Co(en)$_2$]Cl$_2$·3H$_2$O= $C_{10}H_{34}N_6O_9Cl_2Co_2$: C, 21.03; H, 6.00; N, 14.71%.

[(gly)$_2$Co(μ-OH)$_2$Co(en)$_2$]Br$_2$: By a method similar to that described above, this complex was prepared from K[Co-(gly)$_2$(CO$_3$)] (2.0 g)[6] and [Co(en)$_2$(CO$_3$)]ClO$_4$ (2.0 g) (reaction conditions: pH 8.0, 50 °C, 45 min). The reacted solution was cooled to room temperature, neutralized using 2 mol dm^{-3} HClO$_4$ and filtered. The filtrate was loaded on a column (4.7 cm×50 cm) of SP-Sephadex C-25 (NH_4^+ form), and the adsorbed band was developed with 0.2 mol dm^{-3} $(NH_4)_2SO_4$. The eluate from the third band (dark-violet) was transferred to another SP-Sephadex column (NH_4^+ form) and repeatedly developed on the column using a micropump until the adsorbed band separated completely into two bands [**G-1** (earlier band) and **G-2** (later band)]. An eluate from **G-1** was evaporated to about 10 cm^3 and methanol was added to the concentrated solution. After the $(NH_4)_2SO_4$ which deposited was filtered off, the filtrate was evaporated almost to dryness. The crude complex was dissolved in 50 cm^3 of water and optically resolved on the column by the same method as that described for **E-1**. The earlier- and later-eluted bands on the development with K_2Sb_2(*d*-tart)$_2$ showed (−) and (+) CD signs at 560 nm, respectively. Finally, each of the resolved **G-1** was converted to the Br^- salt using a QAE-Sephadex column (Br^- form).

The eluate from **G-2** was optically resolved by the same method as that employed for **G-1**. The earlier and later eluates on the development with K_2Sb_2(*d*-tart)$_2$ were $(+)^{CD}_{580}$ and $(-)^{CD}_{580}$ isomers, respectively. Found for the $(+)^{CD}_{560}$ **G-1** isomer: C, 15.78; H, 4.88; N, 13.82%. Calcd for [(gly)$_2$Co(μ-OH)$_2$Co(en)$_2$]Br$_2$·1.5H$_2$O=$C_8H_{29}N_6O_{7.5}Br_2Co_2$: C, 15.83; H, 4.82; N, 13.84%. Found for the $(+)^{CD}_{580}$ **G-2** isomer: C, 15.95; H, 4.67; N, 14.05%. Calcd for [(gly)$_2$Co(μ-OH)$_2$Co(en)$_2$]Br$_2$·H$_2$O=$C_8H_{28}N_6O_7Br_2Co_2$: C, 16.07; H, 4.72; N, 14.05%.

[(nta)Co(μ-OH)$_2$Co(en)$_2$]Cl: By a method similar to that described for [(edda)Co(μ-OH)$_2$Co(en)$_2$]Cl$_2$, [(nta)Co(μ-OH)$_2$-Co(en)$_2$]$^+$ (**N-1**) was prepared from K$_2$[Co(nta)(CO$_3$)] and [Co(en)$_2$(CO$_3$)]ClO$_4$ (reaction conditions: pH 8.5, 50 °C, 40 min). The reacted solution was cooled to room temperature, neutralized using 2 mol dm^{-3} HClO$_4$ and filtered. The filtrate was loaded on a column (4.7 cm×50 cm) of SP-Sephadex (K^+ form), and the adsorbed band developed with 0.2 mol dm^{-3} KCl. The eluate from the second band (dark-violet) was evaporated to about 10 cm^3 and methanol was then added to the concentrated solution. The KCl which deposited was filtered off and the filtrate was evaporated almost to dryness. The crude complex was dissolved in 50 cm^3 of water and optically resolved by the same method as that employed for **E-1**. The earlier and later eluates on the development with K_2Sb_2(*d*-tart)$_2$ were $(-)^{CD}_{625}$ and $(+)^{CD}_{625}$ isomers, respectively. Calcd for the $(+)^{CD}_{625}$ isomer: C, 22.47; H, 5.33; N, 13.06%. Calcd for [(nta)Co(μ-OH)$_2$Co(en)$_2$]Cl·2H$_2$O=C_{10}-$H_{28}N_5O_{10}ClCo_2$: C, 22.59; H, 5.30; N, 13.17%.

Spectral Measurements. The visible and UV absorption and the CD spectra were recorded on a Hitachi 557 spectrophotometer and a JASCO J-22 spectropolarimeter in aqueous soiution, respectively. ^{1}H NMR spectra were recorded on a JEOL MH-100 spectrometer using DSS as an internal standard in D$_2$O solution.

Results and Discussion

Structural Assignments and Absorption Spectra. The Complexes Containing edda: The first absorption band of the edda complex **E-1** (or **E-2**) is very broad (Fig. 2), suggesting that **E-1** (or **E-2**) contains two chromophores of different types in the complex

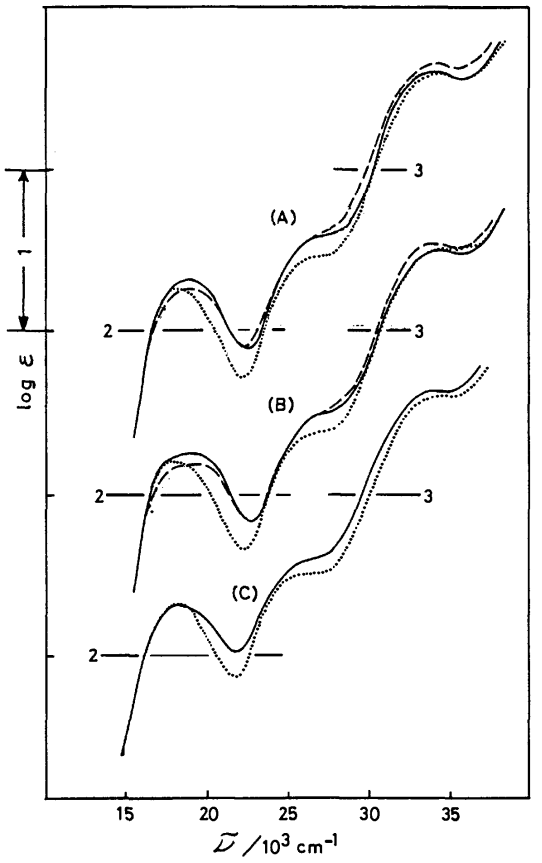

Fig. 2. Absorption spectra of the complexes: (A) **E-1** (——), **E-2** (----), and [(edda)Co(μ-OH)$_2$Co(NH$_3$)$_4$]$^{2+}$ (……); (B) **G-1** (——), **G-2** (----), and [(gly)$_2$Co(μ-OH)$_2$Co(NH$_3$)$_4$]$^{2+}$ (……); and (C) **N-1** (——) and [(nta)Co(μ-OH)$_2$(NH$_3$)$_4$]$^+$ (……). The ε values are given in mol^{-1} dm^3 cm^{-1}.

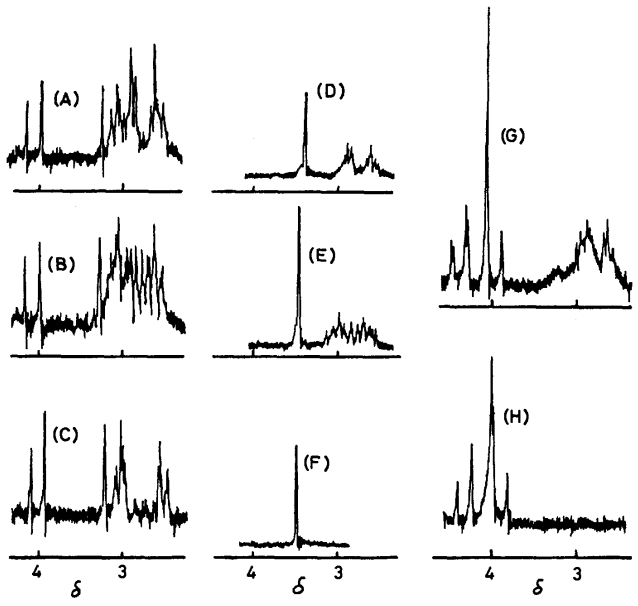

Fig. 3. ^{1}H NMR spectra of the complexes: (A) **E-1**, (B) **E-2**, (C) $[(edda)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$, (D) **G-1**, (E) **G-2**, (F) $[(gly)_2Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$, (G) **N-1**, and (H) $[(nta)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{+}$.

ion. However, the chromatographic development on an SP-Sephadex column gave only a single band, showing that the complex is cationic and not a mixture of cationic and anionic complexes. Accordingly, it is reasonable to propose that the two chromophores are bridged in the cationic complex ion.

The ^{1}H NMR spectral pattern of the glycinate protons of the coordinated edda in **E-1** (or **E-2**) resembles that in $[(edda)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$ [2] (Fig. 3). That is, the glycinate methylene protons of edda in **E-1** (or **E-2**) appeared as an AB quartet signal (δ: ca 3.1 and ca. 4.0), suggesting that the two glycinate methylenes in edda are equivalent in their chemical environment; the edda takes α-cis chelation form.[9] In addition, the ethylenediamine backbones of edda appeared as multiplet signals (δ: ca. 2.7) in both the ammine and the ethylenediamine complexes. These similarities show that the present edda complexes have the same di-μ-hydroxo structure as that of $[(edda)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$. The signals arising from ethylenediamine also appeared at ca. 2.7 ppm in **E-1** (or **E-2**) as a multiplet, overlapping with those arising from the backbone of edda. The intensity ratio of (quartet (δ: ca. 3.1 and 4.0))/(multiplets (δ: ca. 2.7)) was 4/12, indicating that the ratio of edda/en is 1/2. Moreover, the elemental analysis data suggest that the edda/en ratio in each complex is 1/2. Accordingly, both **E-1** and **E-2** contain (edda) and $(en)_2$ moieties.

A characteristic UV absorption band arising from the $Co(\mu\text{-}OH)_2Co$ moiety,[14] such as $[Co_2(NH_3)_8(\mu\text{-}OH)_2]^{4+}$ and $[Co_2(en)_4(\mu\text{-}OH)_2]^{4+}$,[10-12] was also observed in the present edda complexes at ca. 34000 cm^{-1} (Fig. 3). The band intensities of **E-1** and **E-2** are nearly equal to those of the complexes containing two bridging OH's. These results also suggest that **E-1** and **E-2** have the $Co(\mu\text{-}OH)_2Co$ moiety (Fig. 1).

Although the UV and visible spectral pattern of either **E-1** or **E-2** was similar to that of $[(edda)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$, some minor differences were observed. The first absorption band (the d-d absorption band which appears at ca. 18000 cm^{-1}) of each ethylenediamine complex was broader than that of the ammine complex and the band maximum of the former was observed at higher energy than the latter. These observations can be explained as follows. The first absorption band maximum of the $Co(en)_2(\mu\text{-}OH)_2$ moiety can be assigned to the higher energy side with higher intensity than that of $Co(NH_3)_4(\mu\text{-}OH)_2$ moiety, since the first absorption band of $[Co(en)_2(O\text{-}O)]^+$ (O-O: $C_2O_4^{2-}$ or CO_3^{2-}) shifts to the higher energy side with higher intensity than that of $[Co(NH_3)_4(O\text{-}O)]^+$.[10,13] On the other hand, the first absorption band maximum of the $Co(edda)(\mu\text{-}OH)_2$ moiety can be assigned to the lower energy side with higher intensity than that of the $Co(en)_2(\mu\text{-}OH)_2$ or $Co(NH_3)_4(\mu\text{-}OH)_2$ moiety. Accordingly, the overlapping band due to the $Co(en)_2(\mu\text{-}OH)_2$ and $Co(edda)(\mu\text{-}OH)_2$ moieties gives a broader first absorption band in $[(edda)Co(\mu\text{-}OH)_2\text{-}Co(en)_2]^{2+}$ than the overlapping band due to the $Co(NH_3)_4(\mu\text{-}OH)_2$ and $Co(edda)(\mu\text{-}OH)_2$ moieties in $[(edda)Co(\mu\text{-}OH)_2(Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$.[2] The second absorption band (the d-d transition observed at ca. 25000 cm^{-1}) of these complexes appeared as a shoulder beside the strong charge-transfer band (at ca. 34000 cm^{-1}) arising from the bridging OH's.[14] The intensity of the second band of **E-1** (or **E-2**) is slightly stronger than that of $[(edda)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$.

The Complexes Containing gly: The structural assignments of the glycinato complexes **G-1** and **G-2** also are made on the basis of the absorption and ^{1}H NMR spectral data. The possiblity that the $Co(gly)_2(\mu\text{-}OH)_2$ moiety in each complex has trans(N) structure can be ruled out. The shape of the absorption band of **G-1** (or **G-2**) is similar to those of **E-1** and **E-2** having C_2-*cis*(*N*)-$[Co(N)_2(O)_4]$ structure. Furthermore, the complexes do not exhibit such a shoulder band at ca. 16000 cm^{-1} as is characteristic to the *trans*-(*N*)-$[Co(N)_2(O)_4]$ type chromophore.[15,16] The possibility that the $Co(gly)_2(\mu\text{-}OH)_2$ moiety of each complex has the C_1-*cis*(*N*)-$[Co(N)_2(O)_4]$ structure is also ruled out, because the two glycinate methylene protons in the moiety appeared as a singlet signal in ^{1}H NMR (Fig. 3); this suggests that the moiety has a C_2 axis which makes the two methylenes equivalent. The two possible geometrical isomers based on the above discussion are shown in Fig. 1. The ^{1}H NMR and visible absorption spectra of **G-1** and **G-2** are similar to those of $[(gly)_2Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$ as those of **E-1** and **E-2** are to those of $[(edda)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{2+}$.

The Complexes Containing nta: This complex **N-1** also showed the characteristic band arising from the

$Co(\mu\text{-}OH)_2Co$ moiety[14] at 34000 cm^{-1} with nearly the same intensity as that of **E-1** or **E-2**. The elemental analysis data showed that the nta/en ratio in the complex is 1/2. Accordingly, the structure $[(nta)Co(\mu\text{-}OH)_2Co(en)_2]^+$ is assigned. Only one geometrical isomer (chiral) is possible for this complex ion.

The ^1H NMR spectra of **E-1**, **E-2**, **G-1**, and **G-2** (these are ethylenediamine Complexes) resemble those of the corresponding ammine complexes respectively, while the ^1H NMR spectrum of **N-1** is slightly different from the corresponding ammine complex, $[(nta)Co(\mu\text{-}OH)_2Co(NH_3)_4]^+$. That is, the glycinate protons in nta appeared as two AB quartets and one singlet in **N-1**, while they appeared as one AB quartet (for four protons) and one singlet (for two protons) in the corresponding ammine complex (Fig. 3). This result is interpreted as follows. In the ammine complex, the two glyinate rings in nta are equivalent in chemical environment because the OH-Co-OH plane is a mirror plane. On the other hand, in **N-1**, the mirror plane is broken by the two coordinated ethylenediamines on the neighboring cobalt atom.

CD Spectra. The CD spectra of the optically active complexes are illustrated in Fig. 4. The $(+)^{CD}_{565}$ **E-1** and $(+)^{CD}_{560}$ **G-1** isomers (Fig. 4 shows the CD curve for $(-)^{CD}_{560}$ **G-1** isomer) show two intense CD bands with opposite signs in the first absorption band region. As their main CD bands in the lower energy side corresponding to the *cis*-$[Co(N)_2(O)_4]$ type chromophore are (+) sign, the configuration around the *cis*-$[Co(N)_2(O)_4]$ type chromophore is assigned to Λ.[17] On the other hand, these complexes show (−) CD in the first absorption band region of the *cis*-$[Co(N)_4(O)_2]$ type chromophore, suggesting that these complexes have Δ configurations[17] around the $Co(en)_2(\mu\text{-}OH)_2$ moieties which belong to the *cis*-$[Co(N)_4(O)_2]$ type chromophore. The deduced structures are illustrated in Fig. 1 (A-1 and B-1).

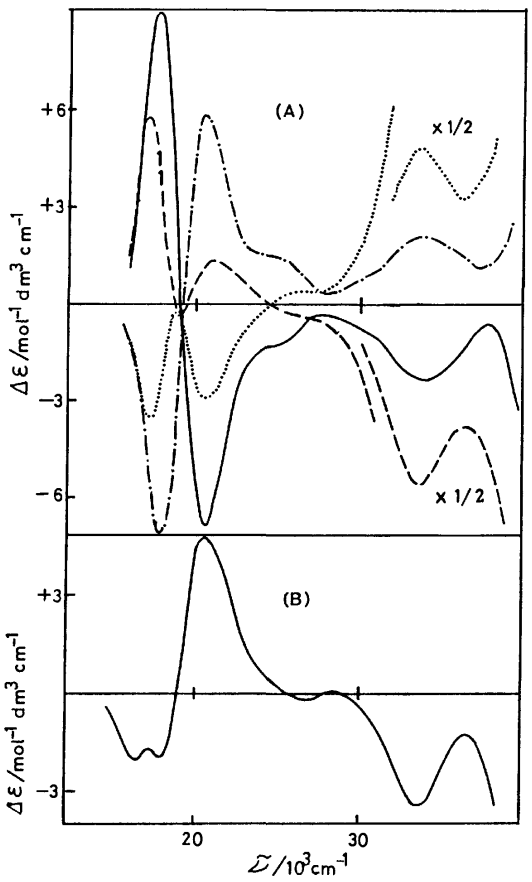

Fig. 4. CD spectra of the complexes: (A) $(+)^{CD}_{565}$**E-1** (——), $(+)^{CD}_{580}$**E-2** (----), $(-)^{CD}_{560}$**G-1** (-·-·-), and $(-)^{CD}_{580}$**G-2** (·····); and (B) $(-)^{CD}_{625}$**N-1** (——).

In contrast to these complexes, $(+)^{CD}_{580}$ **E-2** and $(+)^{CD}_{580}$ **G-2** showed two (+) CD components in the first absorption band region. Therefore, either **E-2** or **G-2** has Λ configurations in both *cis*-$[Co(N)_2(O)_4]$ and *cis*-$[Co(N)_4(O)_2]$ moieties (Fig. 1 (A-2 and B-2)).

The CD pattern of **G-1** resembles that of **E-1** in the region of 15000—38000 cm^{-1}. This result suggests that the geometrical structure of the $Co(gly)_2(\mu\text{-}OH)_2$ moiety in **G-1** is similar to that of $Co(edda)(\mu\text{-}OH)_2$ in **E-1** (*cis*(*N*)-$[Co(N)_2(O)_4]$ type), as described above. The CD spectrum of **G-2** resembles that of **E-2**.

The $(-)^{CD}_{625}$ **N-1** isomer shows three CD components in the first absorption band region (Fig. 4(B)). The small (−) CD (at 18000 cm^{-1}) and large (+) CD (at 20600 cm^{-1}) components are presumed to arise from the Λ-$Co(en)_2(\mu\text{-}OH)_2$ moiety, because the CD components of this moiety is expected to appear in a higher energy region than that of the $Co(nta)(\mu\text{-}OH)_2$ moiety. Since the $Co(nta)(\mu\text{-}OH)_2$ moiety is achiral, it is supposed that no CD is observed in the first absorption band region corresponding to the $Co(nta)(\mu\text{-}OH)_2$ moiety (near 16000 cm^{-1}). In spite of this supposition, CD was observed at 16200 cm^{-1}. This CD is the vicinal CD induced by the neighboring $Co(en)_2(\mu\text{-}OH)_2$ moiety which is chiral. It is noteworthy that the sign of this CD component is opposite from that of the main CD in the first absorption band region of $Co(en)_2(\mu\text{-}OH)_2$ moiety.

CD Additivity of the Two Neighboring Co(III) Chromophores: It has been clarified that the configurational CD of the Co(III) chromophore and the vicinal CD of the asymmetric carbon or nitrogen are additive in the d-d transition band region.[17] However, for the polynuclear complexes, there are few reports about the CD additivity of the Co(III) chromophores neighboring to one another.[18] In this work, assuming that the CD of one of the Co(III) chromophores in each di-μ-hydroxo complex is separable from that of the other Co(III) chromophore, the CD of the prepared complex is assigned to the CD contributions of the two Co(III) chromophores. The additivity is then confirmed by comparison of the analyzed data with other CD data, as described below.

The CD spectra arising from the $Co(edda)(\mu\text{-}OH)_2$ and $Co(en)_2(\mu\text{-}OH)_2$ moieties in **E-1** and **E-2** were separated by the following equations, where Δ_{en} and

Λ_{en} mean the CD contributions arising from the Δ- and Λ-Co(en)$_2$(μ-OH)$_2$ moieties, and Δ_{edda} and Λ_{edda} mean those from the Δ- and Λ-Co(edda)(μ-OH)$_2$ moieties, respectively.

$$\Lambda_{en} = \frac{1}{2}\{(\Lambda_{edda}, \Lambda_{en}) - (\Lambda_{edda}, \Delta_{en})\}$$

$$= \frac{1}{2}\{((+)^{CD}_{580}\ \textbf{E-2}) - (+)^{CD}_{565}\ \textbf{E-1})\} \quad (1)$$

$$\Delta_{en} = -\Lambda_{en} \quad (2)$$

$$\Lambda_{edda} = \frac{1}{2}\{(\Lambda_{edda}, \Lambda_{en}) + (\Lambda_{edda}, \Delta_{en})\}$$

$$= \frac{1}{2}\{((+)^{CD}_{580}\ \textbf{E-2}) + ((+)^{CD}_{565}\ \textbf{E-1})\} \quad (3)$$

$$\Delta_{edda} = -\Lambda_{edda} \quad (4)$$

The CD curves for the calculated Λ_{edda} coincide well with the observed CD curve of Λ-[(edda)Co(μ-OH)$_2$-Co(NH$_3$)$_4$]$^{2+}$. This result suggests that the CD contributions arising from the Co(edda)(μ-OH)$_2$ moieties are similar to each other in the complexes having the same type chromophore ([Co(N)$_4$(O)$_2$] type) in the vicinity of Co(edda)(μ-OH)$_2$ moiety, showing the CD additivity of the two Co(III) chromophores. Similar additivity of the CD contributions of the cobalt chromophores were reported for *cis*-[Co(CN)$_2${(μ-OH)$_2$Co(en)$_2$}$_2$]$^{3+}$.[18,19]

The same discussion as described above can be applied to the glycinato complexes, **G-1** and **G-2**, based on the following equations.

$$\Lambda_{en} = \frac{1}{2}\{(\Lambda_{gly}, \Lambda_{en}) - (\Lambda_{gly}, \Delta_{en})\}$$

$$= \frac{1}{2}\{((+)^{CD}_{580}\ \textbf{G-2}) - (+)^{CD}_{560}\ \textbf{G-1})\} \quad (5)$$

$$\Delta_{en} = -\Lambda_{en} \quad (6)$$

$$\Lambda_{gly} = -\Delta_{gly} \quad (7)$$

$$\Delta_{gly} = -\frac{1}{2}\{(\Lambda_{gly}, \Lambda_{en}) + (\Lambda_{gly}, \Delta_{en})\}$$

$$= -\frac{1}{2}\{((+)^{CD}_{580}\ \textbf{G-2}) + (+)^{CD}_{560}\ \textbf{G-1})\} \quad (8)$$

In these equations, Δ_{gly} and Λ_{gly} mean the CD contributions from the Δ- and Λ-Co(gly)$_2$(μ-OH)$_2$ moieties and the Δ_{en} and Λ_{en} mean the CD contributions of Δ- and Λ-Co(en)$_2$(μ-OH)$_2$ moieties in **G-1** and **G-2**. The calculated Δ_{gly} CD curve coincides with the observed curve of Δ-[(gly)$_2$Co(μ-OH)$_2$Co(NH$_3$)$_4$]$^{2+}$ as for the edda complexes.

The CD curve for the Λ_{en} obtained from **E-1** and **E-2** is similar to that obtained from **G-1** and **G-2** in the range 15000—38000 cm^{-1} (Fig. 5). This can be interpreted in a similar manner to that described above. The cobalt(III) chromophores existing in the vicinity of the Co(en)$_2$(μ-OH)$_2$ moieties are equally *cis*-[Co(N)$_2$(O)$_4$] type in each of **E-1** and **E-2** pair or **G-1** and **G-2** pair, the CD spectra arising from the Co(en)$_2$(μ-OH)$_2$ are similar to each other. However, the CD pattern of Λ_{en} is different from that of Λ-**N-1**. This result suggests that the CD pattern of Co(en)$_2$(μ-OH)$_2$ is affected by the neighboring chromophores, that is, the chromophore exisiting in the vicinity of Co(en)$_2$(μ-OH)$_2$ belongs to the [Co(N)(O)$_5$] type in **N-1** and differs from the *cis*-[Co(N)$_2$(O)$_4$] type which is found in **E-1**, **E-2**, **G-1**, and **G-2**.

The Λ_{en} CD curve has a relatively strong (−) CD component at ca. 18500 cm^{-1} compared to the vicinal CD of the mononuclear tris(bidentate) complexes (Fig. 5).[17] It is expected that this CD component may contain the vicinal (−) CD on the [Co(N)$_2$(O)$_4$] type chromophore induced by the Λ-Co(en)$_2$(μ-OH)$_2$ moiety, since the Λ-[(nta)Co(μ-OH)$_2$Co(en)$_2$]$^+$ shows a (−) vicinal CD on the first absorption band region of the Co(nta)(μ-OH)$_2$ moiety ($\Delta\varepsilon$: ca. −2) which is induced by the chiral Co(en)$_2$(μ-OH)$_2$ moiety. In addition, it is expected that the Λ-Co(en)$_2$(μ-OH)$_2$ moiety has another (−) CD component at ca. 18000 cm^{-1} similarly to Λ-**N-1** (at 18000 cm^{-1}). Accordingly, the overlapping of the induced (−) CD and this CD may give a relatively strong CD at 18500 cm^{-1}.

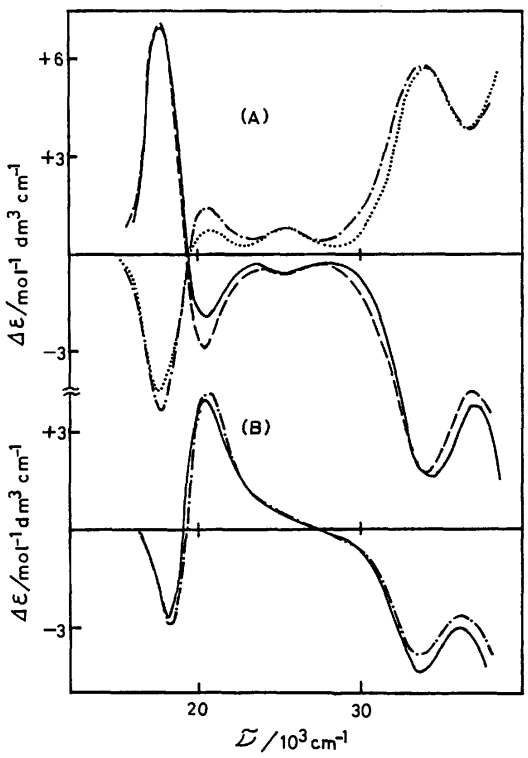

Fig. 5. Calculated and observed CD curves of the complexes: (A) Λ_{edda} in Eq. 3 (——), Λ-[(edda)Co(μ-OH)$_2$Co(NH$_3$)$_4$]$^{2+}$ (– – –), Δ_{gly} in Eq. 8 (–·–·–), and Δ-[(gly)$_2$Co(μ-OH)$_2$Co(NH$_3$)$_4$]$^{2+}$ (·····); and (B) Λ_{en} in Eq. 1 (——) and Λ_{en} in Eq. 5 (–·–·–).

In the charge transfer band region of μ-OH (ca. 34000 cm^{-1}),[14] strong CD bands are observed for the calculated CD curves. The averaged CD intensities calculated for the chiral Co(L)(μ-OH)$_2$ moieties are as follows: Λ-Co(en)$_2$(μ-OH)$_2$ (ca. -4), Λ-Co(gly)$_2$(μ-OH)$_2$ (ca. -6), Λ-Co(edda)(μ-OH)$_2$ (ca. -7), and Λ-*fac*(*O*)-Co(en)(gly)(μ-OH)$_2$ (ca. -5).[5] These values are significantly different from each other, showing that the CD intensity is affected by the ligands except for μ-OH. However, the follwing rough prediction is possible for the chiral di(μ-hydroxo)dicobalt(III) complexes: the complexes which have (Δ-Δ) or (Λ-Λ) pairs show larger CD intensities (absolute values) than those which have (Δ-Λ) or (Λ-Δ) pairs.

Stability of the Complexes. Absorption spectral changes with time were measured in the aqueous solutions of some of the di-μ-hydroxo complexes at 20 °C. Solutions of these complexes showed no spectal change for several days, while that of $[Co_2(\mu\text{-}OH)_2(NH_3)_8]Br_4$ showed an obvious change after one day. This means that these complexes are more stable than $[Co_2(\mu\text{-}OH)_2(NH_3)_8]^{4+}$, suggesting that some stabilizing factors exist in the present complexes. On the X-ray study of $[Cr_2(L\text{-}pro)_4(\mu\text{-}OH)_2]$, Oki and Yoneda[20] pointed out that the two intramolecular N-H···O hydrogen bonds (bridging two chromophores) stabilize the di-μ-hydroxo structure. Moreover, in the X-ray study of $[(en)(gly)Co(\mu\text{-}OH)_2Co(en)(gly)]^{2+}$, it was confirmed that the two hydrogen bonds which bind amino and carboxylate groups stabilize the dinuclear structure.[21] Accordingly, it is reasonable to propose two hydrogen bonds as the stabilizing factor of the present complexes. It was not easy to prepare the isomers having one or no hydrogen bonds, but it was easy to prepare those having two hydrogen bonds. This result agrees with that obtained for the isomers of $[(en)(gly)Co(\mu\text{-}OH)_2Co(en)(gly)]^{2+}$ [5] and $[(L)Co(\mu\text{-}OH)_2Co(NH_3)_4]^{n+}$ (L=(gly)$_2$, (edda), and (nta)),[2] suggesting that the hydrogen bond is important as a stabilizing factor.

Studies of the Hydrous Niobium(V) Oxide Ion Exchanger. IV. The Rate of the Isotopic Exchange of Sodium Ions between the Exchanger in the Na^+ Form and Aqueous Solutions

Yasushi INOUE,* Hiromichi YAMAZAKI, and Mitsuji IKEDA
Department of Nuclear Engineering, Faculty of Engineering, Tohoku University, Aramaki, Sendai 980
(Received August 3, 1987)

The rate of the isotopic exchange of sodium ions between the hydrous niobium(V) oxide ion exchanger in the Na^+ form and aqueous solutions was determined radiochemically. Since the fractional attainment of equilibrium was independent of the sodium-ion concentration in the solutions ($\geqq$0.1 mol dm^{-3}), and inversely proportional to the square of the particle radius, the isotopic exchange rate on the hydrous niobium(V) oxide is controlled by the diffusion of the sodium ions in exchanger particles. The self-diffusion coefficients of sodium ions (D=3.1×10^{-7} cm^2 s^{-1} at 25 °C) and their activation energy (E_a=27±4 kJ mol^{-1}) were also determined.

An investigation of ion-exchange kinetics is very important for understanding the ion-exchange mechanism of hydrous metal oxides. A measurement of the rate of the isotopic exchange of cations between ion exchangers and aqueous solutions provides fundamental data which are useful for elucidating ion-exchange kinetics. As a part of the study in our series, radiochemical experiments were previously undertaken to measure the rate of the isotopic exchange of sodium ions between hydrous tin(IV) oxide in the Na^+ form and the aqueous solutions of sodium salts. The rate-controlling step of the reaction was concluded to be the diffusion of ions in the primary particles, which were formed at the initial stage of precipitation and aggregated to form the oxide gel.[1] It is especially interesting to know whether we can generalize this view regarding the isotopic-exchange rate for a variety of hydrous metal oxides.

This paper deals with the rate of the isotopic exchange of sodium ions between hydrous niobium(V) oxide in the Na^+ form and aqueous solutions and with the comparison between this and the hydrous tin(IV) oxide cases.

Experimental

Preparation of the Exchanger in the Na^+ Form Spiked with ^{22}Na. The hydrous niobium(V) oxide was prepared by a previously recommended method. The sample was classified into four particle sizes by using Japan Industrial Standerd sieves; it was then converted to the H^+ form by treating it with a 0.1 mol dm^{-3} HCl solution. After being washed with water, the exchanger was air-dried and stored in a desiccator containing a saturated NH_4Cl solution (relative humidity, 79%).[2] Table 1 shows the particle size and some properties of each sample. The average particle radius was estimated by approximating the particle shape by a sphere, from the particle-size distribution measured in a 83 wt% glycerol solution by using a Seishin Enterprise Micron-Photo-Sizer, Model SKC-2000S. The specific surface area of the sample, after being heated at 110 °C to constant weight, was determined by the BET method (N_2 adsorption at −196 °C) using a Yanagimoto Surface Area Measuring Apparatus, Model GSA-10.

The exchanger in the H^+ form was converted to the Na^+ form by treating it on a column with a Na^+ solution, followed by labeling with ^{22}Na by equilibrating with the ^{22}Na solution for 2 d at room temperature. After having been washed with a solution free from ^{22}Na, the exchanger was used for the rate measurements. The Na^+ solutions having the same chemical composition were used throughout these three procedures; the solutions prepared by the desired combinations of NaCl and NaOH were used when the rate was measured at pH 11.0, and buffer solutions, 0.1 mol dm^{-3} NaH_2PO_4 (72.2 vol%)-0.05 mol dm^{-3} $Na_2B_4O_7$ (27.8 vol%) solution and 0.1 mol dm^{-3} NaH_2PO_4 (46.5 vol%)-0.05 mol dm^{-3} $Na_2B_4O_7$ (53.5 vol%), respectively, were used when the rate was measured at pH 6.0 and 8.0.

Measurement of the Isotopic Exchange Rate. All the rate measurements were performed in a nitrogen atmosphere by using the same apparatus as descrived earlier.[3] The rate was measured in solutions with the same compositions as those

Table 1. Particle Size and Some Properties of Samples

Particle size	Average radius	Density	Ion-exchange capacity[b]	Composition[c]	Specific surface area
mesh[a]	μm	g cm^{-1}	mmol g^{-1}	molH_2O (molNb_2O_5)$^{-1}$	m^2 g^{-1}
−48+60	145±4	2.38±0.05	2.34±0.02	—	321±5
−70+80	107±3	—	—	—	314±5
−100+120	74±2	—	—	6.45±0.06	—
−145+200	52±2	2.39±0.05	2.36±0.02	—	317±5

a) Japan Industrial Standard mesh. b) Exchange capacity for Na^+ at pH 11.0 (ionic strength=0.1). c) The water content was determined from the weight loss at 850 °C.

used for converting the exchanger to the Na^+ form; otherwise, the ion-exchange reaction would occur between H^+ and Na^+ ions, since the ion-exchange capacity for Na^+ strongly depends on the pH and on the concentration of the solution. A 0.05-gram to 0.17-gram portion of the sample was placed in a cage and immersed in 200 cm^3 of a solution of the desired composition while the cage was being rotated. The frequency of the revolution was measured with a Yokogawa, Model 2607, photo tachometer. The solution had been adjusted in advance to a constant temperature within ±0.1 °C. Aliquots of the solution (0.2 cm^3) were taken out at appropriate time intervals in order to measure the radioactivity with a well-type NaI(Tl)-scintillation counter(Aroka Model ARC-361). The time of the contact of the exchanger with the solution was taken as the time elapsing between the immersion of the cage and the withdrawal of an aliquot of the solution. The fractional attainment of equilibrium, $F(t)=C_t/C_\infty$, was calculated from these results; here, C_t is the total radioactivity of the solution at time t and C_∞ at $t=\infty$. C_∞ was calculated using $C_\infty=C_iM/(M+m)$, where C_i is the initial total radioactivity of the exchanger, and m and M, the total amounts of Na^+ in the exchanger and in the solution, respectively. Although the rate was measured by a batch method, the infinite solution-volume approximation is closely obeyed under the present experimental conditions: less than 0.17 g of the exchanger per 200 cm^3 of the solution.

Results and Discussion

In order to ascertain the efficiency of agitation, the effect of the stirring rate on the half-exchange time was examined for pH-11 solutions of different NaCl concentrations. The time required for half-exchange became shorter as the revolution rate increased, and reached a constant value at 1050 min^{-1}. Furthermore, it was confirmed that no particles were broken down during the agitation of the revolution rate up to 1500 min^{-1}. On the basis of these results, a revolution rate of 1300 min^{-1} was adopted throughout the experiment.

The comparison of the isotopic exchange rates in up to 1 mol dm^{-3} solutions of different sodium salts indicated that no difference was observed in the rates between anions in the solutions (Cl^-, ClO_4^-, and SO_4^{2-}).

Figure 1 shows the results of the method called "interruption test" in 0.1 mol dm^{-3} sodium concentration; the exchangers were removed from the solution for 1 h and then reimmersed. The rate immediately after reimmersion was greater than that prior to the interruption, suggesting that the rate is controlled by particle diffusion.

When the isotopic exchange rate is controlled by the diffusion of the ions in spherical exchangers immersed in a well-stirred solution of approximately an infinite volume, the fractional attainment of equilibrium, $F(t)$, can be obtained by solving the following equation:[4]

$$F(t) = 1 - \frac{6}{\pi^2}\sum_{n=1}^{\infty}\frac{1}{n^2}\exp(-Bn^2t), \quad (1)$$

$$B=\pi^2D/r^2, \quad (2)$$

D is the self-diffusion coefficient of the ions in the exchanger and r refers to the radius of the particles. When $F(t)$ is less than about 0.4, Eq. 1 can be approximated by a simpler form:[5]

$$F(t) = \frac{6}{r}\left(\frac{Dt}{\pi}\right)^{1/2}, \quad (3)$$

which holds to a fairly good approximation. Therefore, a plot of $F(t)$ against the square root of the contact

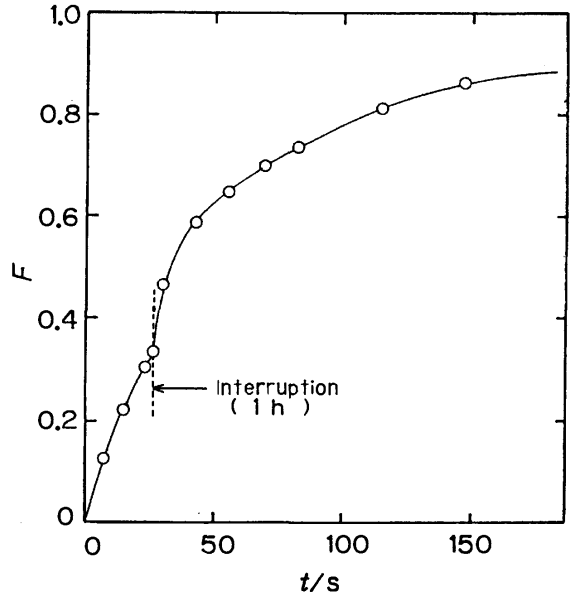

Fig. 1. Interruption test. Sample, −70+80 mesh; temperature, 5.0°C; 0.10 mol dm^{-3} Na(Cl,OH); pH, 11.0.

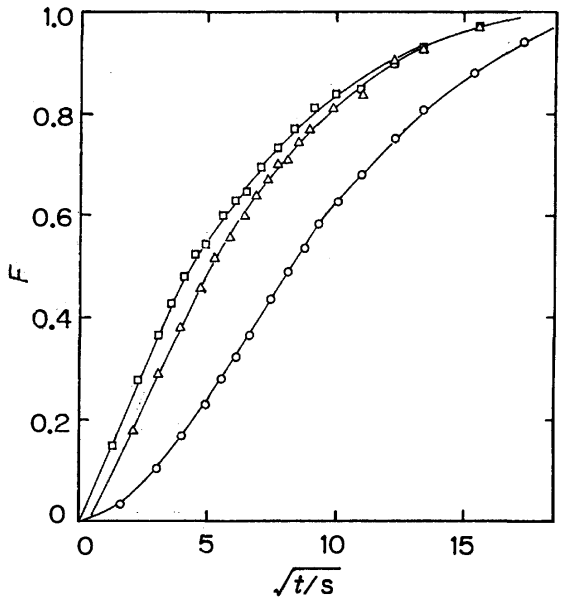

Fig. 2. Effect of Na^+ concentration on the isotopic exchange rates. Sample, −70+80 mesh; temperature, 5.2°C; pH, 11.0; Na(Cl,OH) concn/ mol dm^{-3}, ○: 0.01, △: 0.10, □: 1.0.

time must give a straight line passing through the point of origin in the region in which $F(t)$ is less than 0.4.

Figure 2 shows the influence of the sodium ion concentration on the rate. When the concentration was higher than or equal to 0.1 mol dm^{-3}, although there was very small induction period of the exchange reaction in 0.1 mol dm^{-3} solution, the rate of the exchange reaction was independent of the concentration of the solutions; the straight lines between $F(t)$ and $t^{1/2}$ had the same slope within the experimental errors. In the case of a 0.01 mol dm^{-3} solution, a linear relation did not hold between $F(t)$ and $t^{1/2}$. This cannot be understood by the film diffusion control, since a plot of $-\log(1-F(t))$ against t was sigmoid. This observation can be understood by considering that the equilibrium of sodium ion concentrations between the surface of the exchanger and in the solution was temporarily disturbed by the rinsing of the particles after the labeling, and that the surface concentration of sodium ions approaches equilibrium at a rate proportional to the concentration in the solutions when the exchanger was again immersed in the solution for the rate measurement. The result in a 0.01 mol dm^{-3} solution is ascribed to an overlapping of the rate of the reestablishment of the equilibrium surface-concentration of sodium ions and the isotopic exchange rate.

As has been previously described, this material is considered to have at least two kinds of dissociable ion-exchange sites owing to the presence of an inflection point at pH 7.3 in the cation-uptake curve.[2,6,7] This means that the sites contributing to the exchange reaction have different acidities in each side of the inflection point; only sites having high acidity effect the exchange reaction in a solution of pH lower than 7.3, and, at a higher pH, less acidic sites also participate in the exchange reaction. The exchange rate, however, was independent of pH, as is shown in Fig. 3. Consequently, the change of the electronic density on the exchange sites, which results in the difference in the acidity among the sites, has no influence on the exchange rate.

Figure 4 shows the effect of the particle size on the rate for a 0.1 mol dm^{-3} sodium ion concentration. Here, Bt values were calculated from the measured values of $F(t)$ by using the equation derived by D. Reichenberg:

$$Bt=2\pi-\frac{\pi^2}{3}F(t)-2\pi\left(1-\frac{\pi}{3}F(t)\right)^{1/2}. \quad (4)$$

This equation gives a fairly good approximation in the region where $F(t)$ is less than 0.85.[8] The reason why the Bt-t plots were used instead of Eq. 3 is because the fast rate of the exchange reaction causes a decrease in the number of experimental points falling within the limit of the validity of the equation ($F(t)<0.4$), due to a technical difficulty. When the rate is controlled by the particle diffusion, the plot of Bt against t must give a straight line passing through the point of origin, and the slope of this straight line, i.e., B, is inversely proportional to the square of the particle radius. This figure shows that the plot agrees well with this expectation, irrespective of the particle sizes. In a solution of 1.0 mol dm^{-3} sodium ion concentration, the same dependency was also obtained. Table 2 shows the relation between the particle radii(r) and B, as well as the D calculated from these values. Since D is independent

of the particle size, B is inversely proportional to $1/r^2$. Furthermore, since the self-diffusion coefficients of sodium ions are independent of the concentration in solutions, the mechanism of the diffusion of sodium ions in the exchanger is considered to be unchanged by the composition of the material.

When these results are combined with the preceding discussion, the isotopic exchange rate on the hydrous niobium(V) oxide in a Na^+ solution higher than 0.1 mol dm^{-3} is controlled by the diffusion of the sodium ions in the exchanger particles.

The effect of temperature on the isotopic exchange rates was studied in a 0.1 mol dm^{-3} sodium ion solution, as is shown in Fig. 5. This figure indicates that the rates of the exchange increased with temperature. The self-diffusion coefficients of sodium ions were then evaluated from the slopes of these lines by using Eq. 2. These values are summarized in Table 3. When

log D was plotted against $1/T$, a good linearity was obtained (Fig. 6). From the Arrhenius equation, $D=D_0 \exp(-E_a/RT)$, the activation energy, E_a, and the constant, D_0, were determined. The self-diffusion coeffient of sodium ions at 25 °C ($D=3.1\times10^{-7}$ cm^2 s^{-1}) and its activation energy ($E_a=27\pm4$ kJ mol^{-1}) in the hydrous niobium(V) oxide are similar to those reported for sodium ion diffusion in a sulfonated polystyrene type cation-exchange resin of 16% divinylbenzene ($D=2.7\times10^{-7}$ cm^2 s^{-1} at 25 °C, and $E_a=35$ kJ mol^{-1}).[9]

These findings shows that in the hydrous niobium(V) oxide the diffusion of the counter ions in the exchanger particles is the rate-determining step of the exchange reaction in a Na^+ solution higher than 0.1 mol dm^{-3}. This differs from the case of the hydrous tin(IV) oxide; the rate-controlling step is the diffusion of the counter ions in the primary particles, which are formed during the initial stage of precipitation and aggregate to form the hydrous tin(IV) oxide gel. We can, therefore, conclude that the rate of the ion-exchange reaction of hydrous metal oxides cannot be generally interpreted in terms of the same rate-controlling step. Hence, in the analysis of the ion-exchange rates of these materials, the rate-controlling step should be clarified for each.

Precise Measurement of Helium Isotopes in Terrestrial Gases

Yuji SANO* and Hiroshi WAKITA
Laboratory for Earthquake Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received August 7, 1987)

Helium isotope ratios of terrestrial natural gas samples were measured using a high-precision mass spectrometer and an ultrahigh-vacuum purification line. The line is equipped with a charcoal trap held at 40 K using a helium expansion refrigerating machine. To avoid interference, Ne was completely separated from He by the trap before the gas was admitted to the mass spectrometer. Ion beams of ^{3}He and ^{4}He were measured at the same time by a double collector system. A resolving power of about 550 at the 5% level of the peak height was attained for the complete separation of ^{3}He ions from those of HD and H_3. Precision and reproducibility of the helium isotope ratio were less than 1%, examined by repeated measurements of an air standard. Accuracy of the ratio was checked by comparing observed data with reports in the literature.

Helium has two stable isotopes, of mass number 3 and 4. Most ^{3}He in terrestrial samples is considered to be a trapped component of solar nebulae at the time of the Earth's accretion (primordial He). In contrast ^{4}He is produced by radioactive decay of U and Th in crustal rocks (radiogenic He). The ^{3}He/^{4}He ratio provides useful information on the origin of He[1,2] (primordial or radiogenic). It is well-established that heliums with ^{3}He/^{4}He ratios higher than that of the air (1.40×10^{-6}) are found in gas and rock samples from volcanic and geothermal areas.[3] The helium is thought to be an emanation of the primordial He which still remains deep in the earth. On the other hand, heliums with lower ^{3}He/^{4}He ratios than the air He ratio are reported for non-volcanic regions.[4] This suggests that degassing of the primordial helium has a close relation to geotectonic activity in the region, and particularly to magmatic activity. Thus, the ^{3}He/^{4}He ratio is an important key to the study of magmatic volatiles.[5]

Precise measurements of the ^{3}He/^{4}He ratio can also provide a powerful and convenient method for analysis of environmental tritium. Using a mass spectrometer with extremely high sensitivity, it is possible to detect excess ^{3}He which has accumulated for a sufficient amount of time by in situ decay of tritium in groundwater. The method has been developed by Clarke et al.[6] and is applied to environmental and limnological studies.[7,8] In addition helium isotope ratios can be used in research on the origin of natural gases,[9] on marine ferromanganese nodules,[10] and on the problem of the atmospheric helium budget.[11,12]

In this paper we report precise measurements of ^{3}He/^{4}He and ^{20}Ne/^{4}He ratios in terrestrial natural gas samples. Since ^{20}Ne/^{4}He ratios of mantle-derived and crustal gases are significantly lower than that of air, the ^{20}Ne/^{4}He ratio of the sample can be used as an indicator of air contamination. The analytical system used included a high-precision mass spectrometer, a quadrupole mass spectrometer, a purification and separation vacuum line, and a charcoal trap equipped with a He expansion refrigerator. Performance data are also given. With its high precision and accuracy, the present ^{3}He/^{4}He measurement system is applicable to various fields of geochemistry and environmental sciences.

Experimental

Helium Purification Vacuum Line and Purification Procedure. In order to purify He and Ne from original gas samples and to separate He from Ne, an ultrahigh-vacuum line was constructed (Fig. 1). Since He permeates normal glass quickly, stainless steel was used for all parts of the line. The line consists of three purification and separation parts divided by all-metal bakable valves (V1, V3, and V4). The system in principle resembles that reported by Sano et al.,[13] but several improvements were made. A turbo molecular pump (TMP) is used for creating a rough vacuum instead of an oil diffusion pump. A quadrupole mass spectrometer (QMG112, Balzers) is used in the third part of the line to measure the ^{20}Ne/^{4}He ratio in a gas sample and to ensure adsorption of Ne in a cryogenic charcoal trap (CT3) held at 40 K. A Pirani gauge (PG) is attached to the first part to examine the vacuum when an original gas sample is being introduced.

Hot spring and natural gas samples were collected via the water displacement method in the field using a 50-cm^3 lead glass container with vacuum valves at both ends. After the container was brought back to the laboratory, it was connected directly to the inlet part of the line using an O-ring high-vacuum connector or Tygon tube. A sample of about 1 cm^3 STP was admitted to the first part, and major components such as N_2, O_2, Ar, CH_4, H_2O, and CO_2 were removed by a charcoal trap (CT1) kept at liquid nitrogen temperature (77 K). Unadsorbed components including He and Ne were expanded to the second part. Using a titanium–zirconium getter furnace (TZ1) held at 550 °C and a charcoal trap (CT2) kept at 77 K, He and Ne were purified. When the TZ1 reached room temperature, the purified fraction was introduced into the third part.

The ^{20}Ne/^{4}He ratio of the purified sample was measured by a quadrupole mass spectrometer (QMS) in the third part. No other chemical species except He and Ne were detected by QMS. Interference from doubly charged ions of ^{40}Ar with ^{20}Ne was reduced by a charcoal trap (CT2) held at 77 K and was checked by measurements of the ^{20}Ne/^{22}Ne ratio. Even in the case of a small Ne content, the ^{20}Ne/^{22}Ne ratio showed an atmospheric value of about 10, suggesting negligible contribution of the doubly-charged ^{40}Ar ions. Since the ^{20}Ne/^{4}He ratio was determined by a peak height method, uncer-

tainty was about 10% at maximum.

Separation of Helium from Neon. According to Rison and Craig,[14] varying He/Ne ratios in a mass spectrometer affected the measured $^3He/^4He$ ratio by up to 10%. If atmospheric He is used as a working standard without separating the Ne, measured values on samples whose He/Ne ratios are quite different from that of air would be significantly erroneous and require major correction. Similar results were suggested by several groups[15] using special $^3He/^4He$ mass spectrometers originally designed by Clarke et al.[6] Thus, it is necessary to separate He from Ne when a precise $^3He/^4He$ ratio is required.

A cryogenic charcoal trap (CT3) was attached to the third part of the purification line (Fig. 1) in order to adsorb Ne completely. The mechanism is in principle similar to that of the improved charcoal trap reported by Reynolds et al.[16] Cooling was done by a commercial He expansion refrigerating machine (Cryomini-S, Osaka-sanso Co.), which was constantly operated at full cooling level. Temperature can be readily controlled by a feedback system (PID) composed of a variable heater and a thermometer. Since the working He in the compressor and the expansion head is sealed by a metal wall, no He leak to the laboratory air is possible.

About 2000 cm^3 STP air was introduced into the vacuum line and was purified by charcoal traps (CT1 and CT2) and a titanium zirconium getter (TZ1). The purified He and Ne were stored in a 2000 cm^3 stainless steel vessel (SD in Fig. 1) and used as a running standard gas. About 0.5 cm^3 STP of standard gas, the volume in the space between the valves (V9 and V10), was expanded into the line and the separation of He from Ne was examined. Figure 2 shows equilibrium ion currents by QMS (normalized to 100% release) versus trap

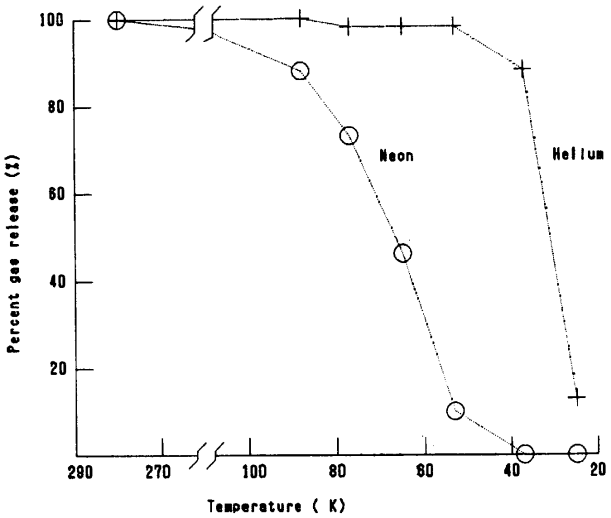

Fig. 2. Equilibrium ion currents for ^4He and ^{20}Ne versus charcoal temperature.

temperature at CT3. The sorption curves agree well with those reported by Reynolds et al.[16] An excellent separation of He from Ne is attained at approximately 40 K in our system.

Mass Spectrometer and Helium Isotope Ratio Measurement. The $^3He/^4He$ ratio was measured with a 27 cm radius extended geometry static gas mass spectrometer. Our instrument was a catalogue model, VG5400 (VG Isotopes, Winsford), modified somewhat in order to detect ^3He and ^4He ion beams simultaneously. The ^3He beam was mea-

sured by a Daly multiplier collector and the ^{4}He beam by a conventional Faraday cup. The resolving power of the Daly collector was higher than 510; that of the Faraday cup, about 200. In order to obtain coincidence of ^{3}He and ^{4}He beams—that is, simultaneous collection of the two beams—the position of the Faraday cup is adjustable by a manipulator. If the coincidence of ^{3}He and ^{4}He beams is sufficient, it is not necessary to perform the peak jumping procedure. These modifications lead to a highly precise ^{3}He/^{4}He ratio measurement. Peak heights of ^{3}He and ^{4}He ion currents were obtained simultaneously by dual-digital electrometers, and the ratio was calculated by a computer. Twenty-five measurements of the ratio were conducted in an individual run, and the ratios were extrapolated to the initial time when the sample was introduced into the mass spectrometer.

Results and Discussion

Neon Interference and Pressure Dependence of the Helium Isotope Ratio. As stated above, varying He/Ne ratios in samples may affect the measured ^{3}He/^{4}He ratio. The relation between the ^{3}He/^{4}He ratio of an air standard and co-existing Ne content, here expressed as ^{20}Ne/^{4}He ratio, is examined (Fig. 3). There is a negative correlation between the ^{3}He/^{4}He and ^{20}Ne/^{4}He ratios: the higher the ^{20}Ne/^{4}He ratio, the lower the observed ^{3}He/^{4}He ratio. The measured ^{3}He/^{4}He ratio of air He containing Ne with the ^{20}Ne/^{4}He ratio of 3.14 (which is air composition) shows a value about 11% lower than the ^{3}He/^{4}He ratio of air He without Ne. If we compare the peak heights of the ^{3}He and ^{4}He, ion currents of ^{4}He are almost constant against varying ^{20}Ne/^{4}He ratios, whereas those of ^{3}He decrease with the ^{20}Ne/^{4}He ratios. This may be attributed either to suppression of the ion beam of ^{3}He in the presence of Ne or to depression of the efficiency of the Daly multiplier by Ne.

The relation between the ^{3}He/^{4}He ratio of air He and total pressure in a mass spectrometer (6-60-SGA, Nuclide Co.) was reported by Sano et al.[13] The higher the total pressure in the mass spectrometer, the higher was the ^{3}He/^{4}He ratio. A similar relation is examined in this work in the range from about 2.0×10^{-5} to 2.5×10^{-4} Pa (Fig. 4). There is a negative correlation between the ^{3}He/^{4}He ratio and the pressure, in contrast to the previous results.[13] In the pressure range below 9×10^{-5} Pa, the ^{3}He/^{4}He ratio is almost constant within an experimental error margin. In contrast, a remarkable decrease in the ^{3}He/^{4}He ratio is observed in the pressure range of about 2×10^{-4} Pa. The discrimination is up to about 6% of the ratio. Taking into account this effect, the total pressure of He was kept lower than 9×10^{-5} Pa in the actual measurements of natural gas samples.

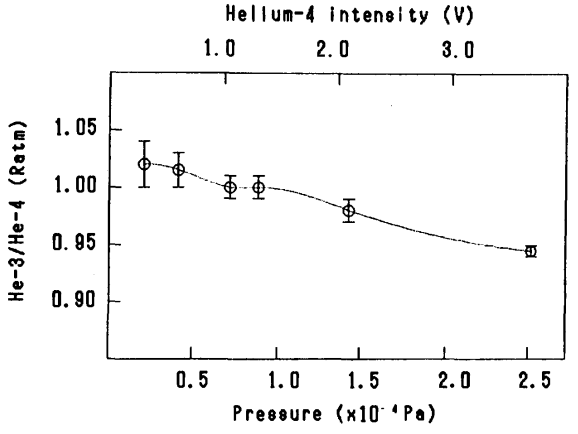

Fig. 4. Pressure dependence of the atmospheric ^{3}He/^{4}He ratios in the mass spectrometer.

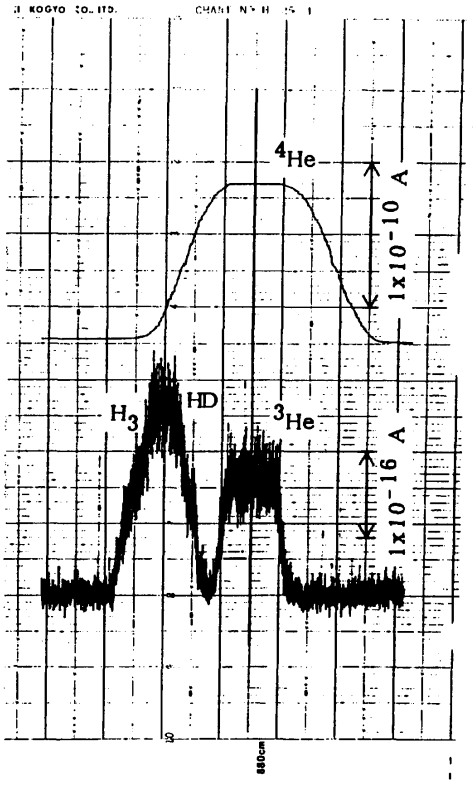

Fig. 5. A typical mass spectrum of purified He from the atmosphere of about 0.3 cm^3 STP.

Reproducibility of the Helium Isotope Ratio Measurements. Since the atmospheric $^3He/^4He$ ratio shows a constant value of $(1.40\pm0.03)\times10^{-6}$, irrespective of latitude, longitude and elevation,[17] air He is regarded as an ideal standard gas. Generally the observed $^3He/^4He$ ratio was represented as a form of the ratio to the air He.[3] The unit of R/R_{atm} is defined here to indicate the $^3He/^4He$ ratio relative to the air value of 1.40×10^{-6}. In this work accuracy and reproducibility of the $^3He/^4He$ ratio were examined by repeated measurements of air He in a standard vessel. In the process He of about 1.8×10^{-6} cm^3 STP was admitted to the mass spectrometer and the $^3He/^4He$ ratio was measured. A typical mass spectrum of ^3He and ^4He in the air standard is shown in Fig. 5. An excellent separation of ^3He from HD plus H_3 beams was observed on the Daly collector with a flat peak shape. A resolving power of about 550 at the 5% level of the peak height was attained. The sensitivity of the Faraday cup was estimated to be about 5×10^{-5} A cm^{-3} STP ^4He and that of the Daly collector to be 3×10^{-3} A cm^{-3} STP ^3He. Taking into account the noise level of the Daly collector of 2×10^{-18} A, the detection limit of ^3He is calculated to be 3×10^{-14} cm^3 STP, which is equivalent to 8×10^5 atoms and about 25 times lower than the previous system.[13]

	av.	1.510±0.011	1.11±0.03	0.671±0.014

Results of repeated measurements of the $^3He/^4He$ ratio in air are summarized in Table 1 together with the $^{20}Ne/^4He$ data obtained by QMS. The $^3He/^4He$ ratios were calculated by the observed ratio of the Daly collector's output to the Faraday's output and by the gain of the Daly over the Faraday. The gain was independently determined using different amounts of ^4He. The mass discrimination factor of the measuring system was examined by comparing the mean value of $(1.510\pm0.010)\times10^{-6}$ with the critical ratio of $(1.399\pm0.013)\times10^{-6}$. The discrimination factor of about 7.9% is smaller than that of the previous system.[13] The reproducibility of the $^3He/^4He$ ratio is 0.69% within three weeks, and the value is comparable to the precision of each individual run. The value of 0.69% is the lowest one so far reported.[13,18,19] The $^{20}Ne/^4He$ ratios were calculated using ion current ratios of ^4He to ^{20}Ne in QMS, which show almost constant values of (0.671±0.014) during this period.

Accuracy of the Helium Isotope Ratio Measurements. The $^3He/^4He$ ratios of eight volcanic and hot spring gases collected at representative sites were measured. At the time of measurement, the pressure dependency of the $^3He/^4He$ ratio was taken into account. The observed $^3He/^4He$ ratios were calibrated against that of the air standard obtained on the same day. The results are listed in Table 2 together with reference data including the institutions where the ratios were measured. The error assigned to the observed $^3He/^4He$ ratios is one standard deviation, including a statistical error of an individual run and an error of the air standard to which the $^3He/^4He$ ratio is calibrated. Thus calculated, the net uncertainty of the measurement in this study is less than 1% of the $^3He/^4He$ ratio.

The observed $^3He/^4He$ ratios range from 0.331 R/R_{atm} to 16.23 R/R_{atm}. These agree well with the reference data except for the Kakehashi sample (No. 6).

Table 2. $^3He/^4He$ Ratios of Terrestrial Gases

SIO: Scripps Institution of Oceanography, University of California. UCB: Berkeley, University of California. OU: Osaka University. UT: University of Tokyo.

The discrepancy observed in No. 6 is about 7% of the ratio. Excluding this sample, differences are about 4% at maximum and equivalent to the experimental errors of the reference data. This suggests that the present system gives sufficiently accurate $^3He/^4He$ ratio measurements, assuming the reliability of the reference data.

The $^3He/^4He$ ratio of the Yellowstone sample (No. 1), 16.23 R/R_{atm}, is significantly higher than the $^3He/^4He$ ratios of 8—9 R/R_{atm} in mid-ocean ridge basalt (MORB).[3] Since the composition of the MORB is considered to be representative of the Earth's upper mantle, the source region of the Yellowstone sample is more primitive than that of the upper mantle. Gas samples from the Hakone volcano (No. 2) and the Nigorigo hot spring near the Ontake volcano (No. 3) show $^3He/^4He$ ratios of about 6 R/R_{atm}, identical to those in the circum Pacific volcanic region and slightly lower than the MORB. The $^3He/^4He$ ratio of bubbling gas in a Kashima well (No. 9), situated on the forearc region of Northeast Japan, is lower than the air ratio. Radiogenic He produced in crustal rock and sediment may be dominant in the sample.

Conclusion

The present analytical system has a high sensitivity of 5×10^{-5} A cm^{-3} STP of ^4He measured with a Faraday cup, an extreme precision of less than 1%, and sufficient accuracy of $^3He/^4He$ ratio measurement. The system can be applied to various fields of geoscience research, such as mantle geology, volcanology, marine chemistry, and environmental and limnological studies.

Interfacial Adsorption of 1,10-Phenanthroline Complexes in Solvent Extraction Systems

Hitoshi WATARAI,* Yoko HORII, and Mitsuaki FUJISHIMA
Department of Chemistry, Faculty of Education, Akita University, Akita 010
(Received August 8, 1987)

A significant adsorptivity of tris(1,10-phenanthroline)iron(II), $[Fe(phen)_3]^{2+}$, at the interface of chloroform or carbon tetrachloride/0.1M aqueous sodium chloride systems was determined by means of interfacial tension measurements at 25 °C. In the distribution systems of phen containing Zn(II) or Cu(II), a characteristic interfacial tension lowering was observed and interpreted in terms of an interfacial adsorption of metal-phen complexes.

Ion-association extraction of Fe(II) with 1,10-phenanthroline, phen, has been extensively studied not only for a colorimetric determination of iron itself, but also for an indirect determination of a variety of organic and inorganic anions which are extractable with $[Fe(phen)_3]^{2+}$.[1,2] Although the stoichiometry of the overall extraction equilibrium between bulk phases has been established, there is no available information concerning the role of the interface in an extraction with phen and its derivatives, except those which we reported recently. In this case the interfacial adsorption of protonated phen derivatives in the chloroform/acidic aqueous phase[3] and of Cu(II) and Zn(II) 4,7-diphenyl-1,10-phenanthroline complexes in the chloroform/aqueous phase systems[4] were determined by means of a high-speed stirring method. Also, a significant role of the interface was demonstrated. For the elucidation of a realistic mechanism of ion-association extraction, which should include a rational assessment on interfacial reactions, further extensive studies concerning interfacial phenomena are required.

In the present study, first the interfacial adsorptivity of $[Fe(phen)_3]^{2+}$, a very stable tris(phen) complex, was examined by means of interfacial tension measurements. Secondly, the interfacial tension in the systems containing both phen and Zn(II) or Cu(II), which include mono, bis, and tris(phen) complexes, was measured; the adsorptivity of each complex, especially of the tris(phen) complexes, is discussed based on the results of $[Fe(phen)_3]^{2+}$ system.

Experimental

Chemicals. phen, wako G.R., was used as purchased. $[Fe(phen)_3]Cl_2$ and $[Fe(phen)_3](ClO_4)_2$ were synthesized by the conventional methods and purified by recrystallization from an aqueous solution. Chloroform, Wako G.R., was washed with an equal amount of water three times prior to use. Carbon tetrachloride, Nakarai G.R., was shaken with sulfuric acid, washed with water and then fractionally distilled. Other chemicals used were of all G.R. grade. Stock solutions of Zn(II) and Cu(II) were prepared by dissolving pure zinc powder and $CuCl_2 \cdot 2H_2O$ in hydrochloric acid solution, respectively. The ionic strength of the aqueous solution was adjusted to 0.1 by sodium chloride, and the pH was controlled by hydrochloric acid and sodium acetate (0.002 M, 1 M=1 mol dm^{-3}). The use of sodium chloride completely depressed the ion-association extraction of metal-phen complexes and made conspicuous the interfacial adsorption of the complexes.

Interfacial Tension Measurements. Measurements of the interfacial tension, γ, were carried out by means of a drop-volume method at 25±1 °C. The apparatus used is schematically shown in Fig. 1. The organic and aqueous phases, 10 ml each, were shaken for 30 min and equilibrated prior to the measurements. The aqueous drop produced on the end of a glass capillary (6 mm o.d.) was slowly released after 5 min equilibration, and the volume of a detached drop was measured using a Gilmont micrometer pipet s1200 (2 μl smallest division) or s4200 (0.1 μl smallest division). The volume of one drop was determined as an average of at least 5 drops. The interfacial tension was then calculated by using the interfacial tension values of 31.5 dyn cm^{-1} and 44.55 dyn cm^{-1} for $CHCl_3$/water and CCl_4/water systems, respectively, and by applying the Lando-Oakley's equation.[5]

Distribution of phen. Distribution constants of phen in

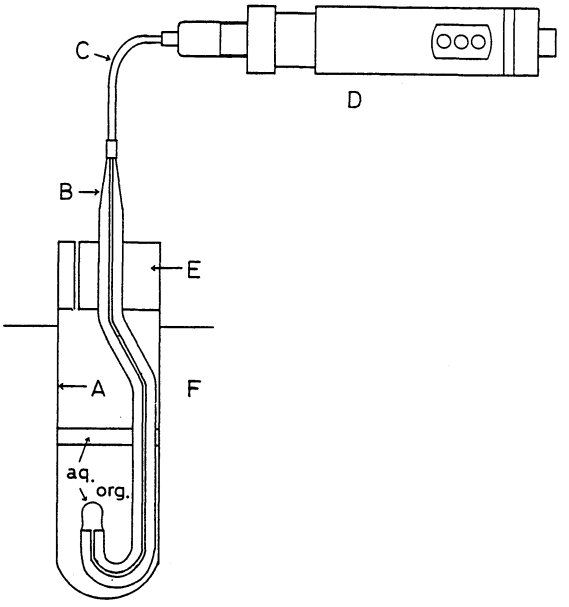

Fig. 1. Apparatus for interfacial tension measurements by drop-volume method in halomethane/water system: A, glass vessel; B, glass capillary; C, teflon tube; D, digital micrometer pipet; E, stopper with a hole; F, thermostated water bath.

$CHCl_3$/0.1 M NaCl and CCl_4/0.1 M NaCl systems were determined by a batch method. An aqueous solution of phen, 5 ml or 10 ml, was shaken with 5 ml organic solvent for 30 min by means of a mechanical shaker. The pH of the aqueous phase was controlled to higher than 6.2. From the absorbances at 265 nm of the aqueous phases before and after distribution, the distribution constant, K_D, was calculated, as listed in Table 1. Absorbance measurements were carried out by means of a Hitachi 200-20 or UVIDEC 430 spectrophotometer. The value of K_D was employed for the calculation of the concentrations of mono, bis, and tris(phen) complexes in the aqueous phases of $CHCl_3$/aqueous systems containing phen, and Zn(II) or Cu(II). An NEC PC-microcomputer was used for both calculations of the concentrations and the interfacial tensions.

Results and Discussion

Interfacial Adsorption of $[Fe(phen)_3]^{2+}$. The interfacial tension in an $CHCl_3$/0.1 M NaCl solution decreased upon the addition of $[Fe(phen)_3]^{2+}$ above a concentration of 10^{-6} M, as shown in Fig. 2. The substitution of $[Fe(phen)_3]Cl_2$ by $[Fe(phen)_3](ClO_4)_2$ did not seriously affect γ under the present conditions. When the organic solvent was changed from $CHCl_3$ to CCl_4, the concentration at which γ began to decrease was shifted to a value about 100-times higher than that in the $CHCl_3$ system (see Fig. 2).

The observed lowering in γ is attributable to an interfacial adsorption of $[Fe(phen)_3]^{2+}$, which is usually analysed according to the Gibbs equation or the Langmuir isotherm. The interfacial excess Γ of a solute is defined by the Gibbs equation:

$$\Gamma = -\frac{1}{RT}\frac{\partial\gamma}{\partial \ln C}, \quad (1)$$

where C refers to the solute concentration in aqueous phase. However, according to the Langmuir isotherm, the interfacial concentration of the solute, C_i, can be represented by

$$C_i = \frac{aK'C}{a+K'C}, \quad (2)$$

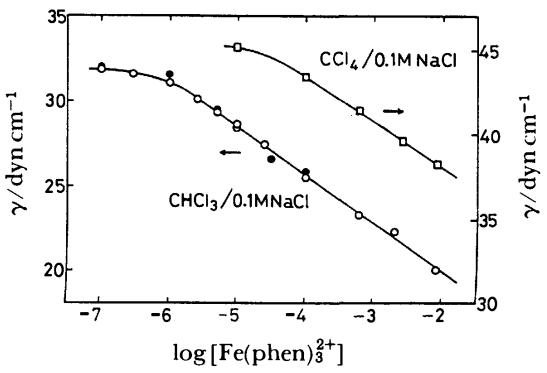

Fig. 2. Interfacial tension lowering by addition of $[Fe(phen)_3]Cl_2$ (○) or $[Fe(phen)_3](ClO_4)_2$ (●) in $CHCl_3$/0.1 M NaCl (pH=6.2) and CCl_4/0.1 M NaCl (pH=6.2).

where a refers to the interfacial concentration at saturation and K' to the equilibrium constant for adsorption of the solute from aqueous phase to interface at infinite dilution. By combining Eqs. 1 and 2 by approximating $\Gamma \fallingdotseq C_i$, and integrating the combined equation over a concentration range from zero to C, corresponding to the interfacial tension from γ_0 to γ, one obtains

$$\gamma = \gamma_0 - aRT \ln\left(1+\frac{K'C}{a}\right). \quad (3)$$

When $C \gg a/K'$, Eq. 3 becomes,

$$\gamma = \gamma_0 - aRT \ln\frac{K'}{a} - aRT \ln C. \quad (4)$$

Equation 4 represents a linear relationship between γ and log C, as observed in a higher-concentration region in Fig. 2; the slope of the straight line refers to $-2.303aRT$. In addition, the concentration C^*, at which the straight line of Eq. 4 and another straight line of $\gamma=\gamma_0$ crosses, is found to be equal to a/K'. The application of these analyses to $[Fe(phen)_3]^{2+}$ systems yields parameters a and K' for the two-solvent systems listed in Table 1. The values of the interfacial concentration at the saturation or interfacial area occupied by a single complex ion does not differ very much in two-solvent systems (see Table 1). As for the values of C^*, however, as well as those of K', there is a strong solvent dependence: K' in $CHCl_3$ system is 86-times larger than that in the CCl_4 system; this means that the $[Fe(phen)_3]^{2+}$ ion is much more adsorbable to the $CHCl_3$/water interface than the CCl_4/water interface. Ozeki et al. recently reported that $[Fe(phen)_3]^{2+}$ is never surface-active from the fact that the surface tension of a 5.0×10^{-4} M $[Fe(phen)_3](ClO_4)_2$ solution was 71.93 ± 0.1 dyn cm^{-1}, agreeing with that of pure water.[6] Consequently, the interfacial adsorptivity of $[Fe(phen)_3]^{2+}$ observed in the present systems should be ascribable to a lipophilic interaction between phen molecules coordinated to Fe(II) and the organic solvent at the interface. This idea is supported by the fact that the distribution constant of phen, which is a measure of the lipophilic interaction, is much larger in the $CHCl_3$ system (see Table 1). From the above discussion, it is concluded that tris(phen) complexes are strongly

Table 1. Parameters in the Interfacial Adsorption of $[Fe(phen)_3]^{2+}$ at 25 °C

Parameter	Organic solvent	
	CCl_4	$CHCl_3$
a/mol cm^{-2}	4.80×10^{-11} (346)[a]	4.98×10^{-11} (333)
C^*/mol l^{-1}	4.50×10^{-5}	5.40×10^{-7}
K'/l cm^{-2}	1.07×10^{-6}	9.23×10^{-5}
K_D(phen)	1.14 ± 0.07	723 ± 18

a) Values in parentheses refer to an area (Å^2) per molecule.

Effects of zinc(II) and copper(II) on the interfacial tension of phen-$CHCl_3$/0.1 M NaCl systems: no metal ion (----); $[Zn^{2+}]_T=1.0\times10^{-4}$ M, pH=6.06 (○), 1.0×10^{-3} M, pH=5.33 (●), 5.0×10^{-3} M. pH=3.44 (□), 1.0×10^{-2} M, pH=2.68 (■); $[Cu^{2+}]_T=1.0\times10^{-4}$ M, pH=6.28 (○), 1.0×10^{-3} M. pH=6.03 (●).

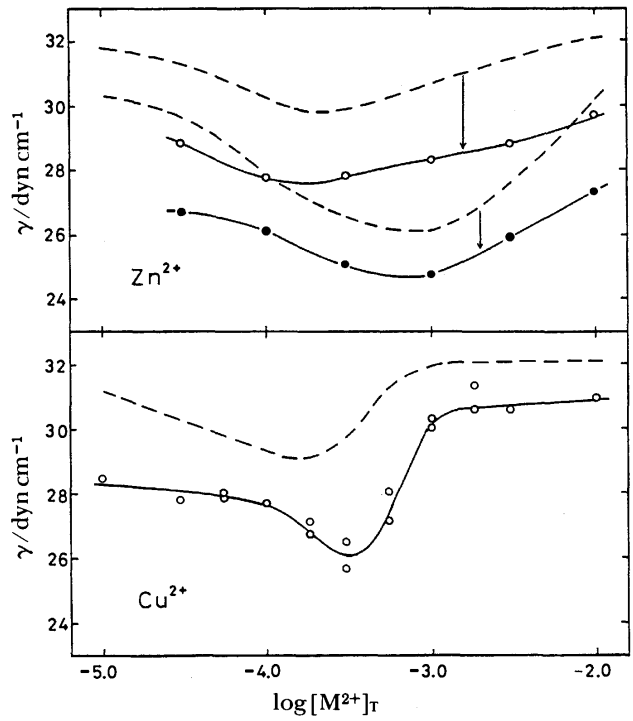

Fig. 4. Dependence of interfacial tension in $CHCl_3$ system on the zinc(II) and copper(II) concentrations at a constant phen concentration: $[phen]_T=6.21\times10^{-4}$ (○), 2.49×10^{-3} M (●), pH=6.1 in Zn(II) systems; $[phen]_T=6.24\times10^{-4}$ M (○), pH=3.91—6.02 in Cu(II) systems.

adsorbable at the $CHCl_3$/water interface.

Interfacial Adsorption of Zn(II)-phen and Cu(II)-phen Complexes. The interfacial tension in phen-$CHCl_3$/0.1 M NaCl systems containing Zn(II) or Cu(II) ions depended on both the concentrations of phen and the metal ion. In Fig. 3, the effect of the metal ions on plots of γ vs. the logarithm of the total phen concentration, log $[phen]_T$, is shown. In both systems, the following tendencies are observed: in a lower phen concentration, the lowering of γ is larger in a lower metal concentration than that in a higher metal concentration, while in a higher phen concentration the situation is reversed, more obviously in Cu(II) systems. In the region $[phen]_T=10^{-4}$—10^{-3} M, the values of γ in $[Cu^{2+}]_T=10^{-4}$ M are lower than those in $[Cu^{2+}]_T=10^{-3}$ M. This means that the species formed under the condition $[phen]_T>[Cu^{2+}]_T$ is more adsorbable than those formed under $[phen]_T<[Cu^{2+}]_T$, suggesting a preferencial adsorptivity of a bis or tris-(phen) complex than a mono(phen) complex. When the total phen concentration was fixed, the plots of γ vs. log $[M^{2+}]_T$ showed a minimum that depended on the phen concentration, as shown in Fig. 4. It is noted in Fig. 4 that the Zn(II) concentration, showing a minimum in γ, shifted toward a higher region when $[phen]_T$ was increased. These interfacial tension lowering characteristics are thought to be ascribable to the adsorption of Zn(II) or Cu(II)-phen complexes, since the adsorptivity of phen is very low.[3] In order to discuss which type of the complex is most responsible for the lowering of γ, the concentrations of mono-, bis-, and tris(phen) complexes in the aqueous phase under the given total concentrations of metal ion and phen were calculated using

$$[M^{2+}]_T = [M^{2+}](1+\beta_1[L]+\beta_2[L]^2+\beta_3[L]^3) \quad (5)$$

and

$$[L]_T = (1+\frac{[H^+]}{K_a}+K_D)[L] + [M^{2+}](\beta_1[L]+2\beta_2[L]^2+3\beta_3[L]^3), \quad (6)$$

where $[M^{2+}]$ and [L] refer to the concentrations of the free metal ion and the free ligand phen, respectively; the subscript T denotes the total concentration of the metal ion or phen. The value of the formation constants used for the calculation are log $\beta_1=6.30$, log $\beta_2=11.95$, and log $\beta_3=17.05$ for Zn(II)-phen system and log $\beta_1=8.82$, log $\beta_2=15.39$, and log $\beta_3=20.41$ for Cu(II)-phen system.[7] A calculation of $[M^{2+}]$, $[ML^{2+}]$

$[ML_2^{2+}]$, and $[ML_3^{2+}]$ was carried out by determining the best value of [L] so that the $[M^{2+}]_T$ and $[L]_T$ calculated by Eqs. 5 and 6 would agree with the experimental concentrations. The contribution of $[LH^+]$ in Eq. 6 was not serious in almost systems studied here, since pK_a=4.98 for phen.[7] Because a preliminary comparison between the calculated results and Figs. 3 and 4 suggested a significant contribution of ML_3^{2+}, a semi-quantitative comparison was attempted between the observed γ values and the estimated values using

$$\gamma = 32.1 - 1.24 \ln\left(1 + \frac{[ML_3^{2+}]}{5.40 \times 10^{-7}}\right), \quad (7)$$

which is determined for the $[Fe(phen)_3]^{2+}$ system, assuming that the adsorptivity of ML_3^{2+} is the same as that of $[Fe(phen)_3]^{2+}$. The broken lines in Fig. 4 show the γ estimated using the calculated $[ML_3^{2+}]$ and Eq. 7. Although a quantitative agreement between the calculated and observed γ's is not satisfactory, the features of the γ vs. log $[M^{2+}]_T$ profile are well-reproduced, especially in Zn(II) systems. The observed minima in Zn(II) systems correspond to the situation where $[M^{2+}]_T$: $[L]_T$=1 : 3. These results confirm that a predominant species at the interface in Zn(II) systems is $[Zn(phen)_3]^{2+}$. In Cu(II) systems, the minimum point in Fig. 4 is close to $[M^{2+}]_T$: $[L]_T$=1 : 2. Hence, the adsorption of $[Cu(phen)_2]^{2+}$ as well as $[Cu(phen)_3]^{2+}$ may take place in higher Cu(II) concentration.

The authors wish to thank the Ministry of Education, Science and Culture for a financial support, a Grant-in-Aid for Scientific Research to H.W. (No. 61470034).

Association of Naphthalene and Its Methyl Derivatives with Cyclodextrins in Aqueous Medium

Motohisa FUJIKI, Toshio DEGUCHI, and Isao SANEMASA*
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received September 5, 1987)

Formation constants of naphthalene and its (1- and 2-)methyl and (1,4-, 1,5-, and 1,8-)dimethyl derivatives with α-, β-, and γ-cyclodextrins (CyD) were determined in the aqueous medium in the presence of excess CyD. The technique used to study associations between host (CyD) and guest(hydrocarbon) is based on the facts that the guest molecules can be driven out to gaseous phase by introducing an inert gas at a constant flow rate into the aqueous solution and that the volatilization rate of guest decreases with increasing association with the host in aqueous solution. The 1:1 and 2:1 (host:guest) formation constants were evaluated at 25 °C. From the formation constant estimated, a host-guest spatial-fitting model for each association complex is presented.

We have recently reported a method useful for estimating association constants between volatile and nonvolatile solutes in aqueous medium.[1-2] The method is based on volatility of nonelectrolyte solute in water. Volatile molecules are driven out to gaseous phase by introducing an inert gas at a constant flow rate into the aqueous solution. The volatilization rate was measured with and without addition of nonvolatile solute which associates with the volatile solute and decreased with the degree of association between the solutes. The method is applicable to such systems where (a) one of the solute is volatile, (b) the concentration of nonvolatile solute is sufficiently high in comparison with that of volatile solute, and (c) the rate of association is rapid compared with the volatilization rate.

The method was applied to association of benzene and alkylbenzenes as guests with cyclodextrins (CyD) as hosts and 1:1 and 2:1 (host:guest) formation constants were evaluated.[3] The present work is concerned with an application of the method to association of naphthalene and its methyl derivetives with α-, β-, and γ-CyDs.

There have been reported several data concerning the naphthalene-CyD formation constant.[4-7] The data are, however, only on the β-CyD complex and little is known concerning naphthalene derivatives. The present study was undertaken to see whether or not the volatilization method is successfully applicable to naphthalene and its derivatives and to elucidate the effects of the cavity size of host and the steric hindrance of guest on the host-guest inclusion complex formation.

Experimental

Materials and Preparation of Sample Solutions. Distilled deionized water was used throughout the experiments. Aromatic hydrocarbons used as guest were of analytical reagent grade (the purity is listed in Table 1). Cyclodextrins (α-, β-, and γ-CyD) used as host were of guaranteed grade from Nakarai Chemical Co. Both guest and host reagents were used without further purification. An aqueous solution of each guest was prepared by adding an excess solid or liquid hydrocarbons to water and stirring for at least 24 h. After standing the mixture for at least 24 h, a portion of the saturated guest solution was transferred into a separatory funnel and the UV absorption of its chloroform extract was measured to determine the guest concentration, and another portion was transferred into a 2.5ϕ×25 cm cylindrical glass tube. A suitable amount of CyD, which had been dried over phosphorus pentaoxide under vacuum, was weighed and dissolved into the guest solution. The solution was then diluted to 100 cm^3 with water. Ranges of concentration of guest and host are given in Table 3.

Amberlite XAD-2 resin (Rohm and Hass) of 100—150 mesh size was used as an adsorbent of guest vapor.

Apparatus and Procedures. The apparatus and the experimental procedure were the same as those described in the previous paper with minor modifications.[3] Because the volatility of guest substances examined in this study is considerably lower than that of benzene and alkylbenzenes, a sintered glass ball was used as an N_2 bubbler to drive guest molecules effectively out of the aqueous solution at higher N_2 flow rates (Table 1). The N_2 gas leaving the sample solution was passed through an XAD resin column of 0.5ϕ×10 cm and the guest hydrocarbon adsorbed on the resin for a fixed time was eluted out with $CHCl_3$ of 6 cm^3. The amount of guest collected in an XAD column, ΔQ_ϕ, was determined by UV spectroscopy at the optimum wavelength for each guest hydrocarbon (Table 1).

Table 1. Experimental Conditions

Guest substance	Purity	λ[a]	N_2 gas flow rate
	%	nm	$cm^3 min^{-1}$
Naphthalene	G.R.[b]	276.6	50, 150, 250
1-Methyl-naphthalene	97	283.0	350
2-Methyl-naphthalene	G.R.	277.2	350
1,4-Dimethyl-naphthalene	95	243.0	700
1,5-Dimethyl-naphthalene	98.0	289.0	700
1,8-Dimethyl-naphthalene	95.0	287.6	700

a) The wavelength for determining the concentration of guest molecules after $CHCl_3$ extraction. b) Guaranteed grade reagent (the purity is not specified).

Results and Discussion

Estimation of 1 : 1 and 2 : 1 (Host : Guest) Formation Constants. Under the present experimental conditions that host molecules are always excess over guest molecules, the possible host : guest stoichiometric ratios are 1 : 1 and 2 : 1. Then, the reactions that should be taken into account are:

$$\mathrm{CyD}+\phi \rightleftarrows \mathrm{CyD}\cdot\phi,\ (K_1), \tag{1}$$

$$\mathrm{CyD}\cdot\phi+\mathrm{CyD} \rightleftarrows \mathrm{CyD_2}\cdot\phi,\ (K_2), \tag{2}$$

and

$$\phi(\mathrm{aq}) \rightarrow \phi(\mathrm{gas}),\ (k), \tag{3}$$

where ϕ refers to a guest hydrocarbon molecule, K_1 and K_2 are the corresponding stepwise formation constants, and k is the rate constant for transfer of guest molecules from aqueous to gaseous phase.

We assume that the release of guest molecules at a constant N_2 flow rate is of first-order with respect to the concentration of free species in the solution as follows:

$$dQ_\phi V^{-1}/dt = k[\phi], \tag{4}$$

where V is the volume of aqueous solution.

An equation to estimate K_1 and K_2 can be derived using the total concentrations of host (C_{CyD}) and guest (C_ϕ) and the amount of guest released from aqueous solution during the aeration time (Q_ϕ, the sum of ΔQ_ϕ from time 0 to t), in the same way as described in the previous paper as follows:[3]

$$\ln(C_\phi - Q_\phi V^{-1}) = -kt/(1+K_1C_{CyD}+K_1K_2C_{CyD}^2) + \ln C_\phi = -k't + \ln C_\phi, \tag{5}$$

where

$$k' = k/(1+K_1C_{CyD}+K_1K_2C_{CyD}^2). \tag{6}$$

Rearrangement of Eq. 6 yields:

$$1/k' = K_1K_2C_{CyD}^2/k + K_1C_{CyD}/k + 1/k. \tag{7}$$

Plots according to Eq. 5 for naphthalene-β-CyD are shown in Fig. 1. The plots give straight lines up to ca. 70% release of the guest hydrocarbon initially present in the solution. This linearity verifies the assumption that the volatilization of guest molecules follows a first-order reaction at a constant N_2 flow rate. The slopes of resulting straight lines, k' (and k), were evaluated using the least-squares method; the results for naphthalene are given in Table 2. Both k and k' values change with the N_2 flow rate, but their values

a) $k'=k/(1+K_1C_{CyD}+K_1K_2C_{CyD}^2)$, where C_{CyD} is the total concentration of cyclodextrin. b) The initial concentration of naphthalene. c) The average of four determinations.

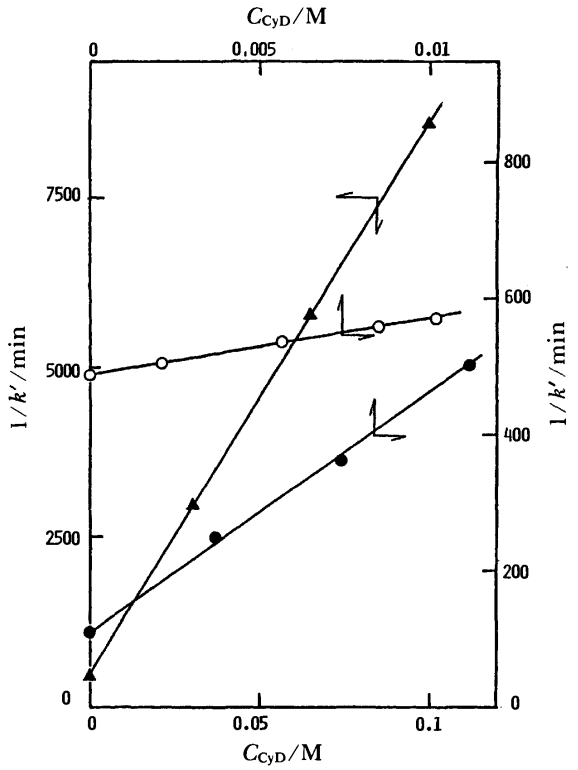

Fig. 2. The plots of $1/k'$ vs. C_{CyD}. Examples of straight line. 1-Methylnaphthalene-β-CyD (●), 1,8-dimethylnaphthalene-β-CyD (○), 1,8-dimethylnaphthalene-γ-CyD (▲).

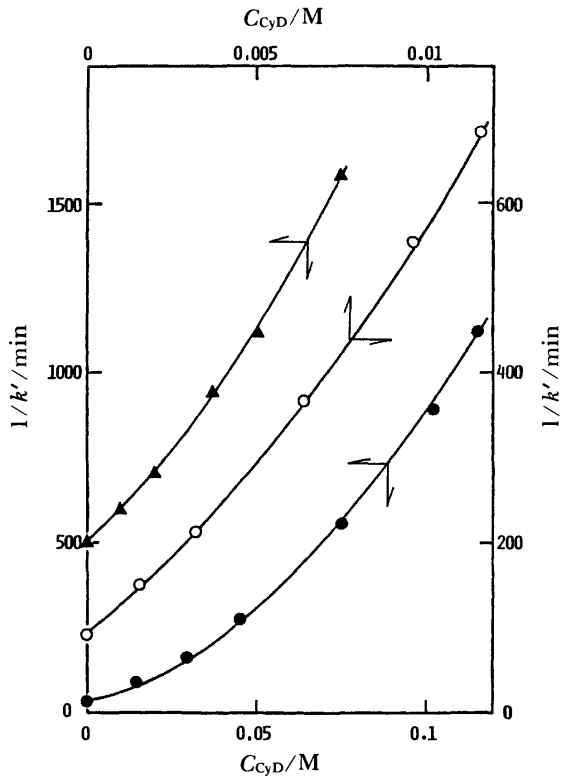

Fig. 3. The plots of $1/k'$ vs. C_{CyD}. Examples of parabolic curve. Naphthalene-α-CyD (●), 1,4-dimethylnaphthalene-β-CyD (○), 1,8-dimethylnaphthalene-α-CyD (▲).

are not significant when the N_2 flow is set at the same rate for two runs in the presence and absence of CyD. The K values determined for naphthalene-β-CyD at three different N_2 flow rates of 50, 150, and 250 cm^3 min^{-1} are found to be (6.6, 6.2, and 6.3)$\times 10^2$ M^{-1} (M≡mol dm^{-3}), respectively. Relatively large deviation inherent in the present method being considered, these K values for naphthalene-β-CyD seem to be in a reasonable agreement. This suggests that the rate of association is rapid compared with the volatilization rate; the essential requirement of the present method is fulfilled.

Figures 2 and 3 show some typical results plotted by a curve-fitting method with the aid of Eq. 7. The $1/k'$ vs. C_{CyD} plots appear to be linear (Fig. 2) or parabolic (Fig. 3) depending on the host-guest combination. The K_1 and K_2 values determined in this work are summarized in Table 3. As was pointed out in our previous paper,[3] the deviation of formation constant is relatively large, which arises from uncertainty in determining the amount of released guest; the overall error in Q_ϕ becomes large due to the accumulation of errors in ΔQ_ϕ.

The K value estimated here for naphthalene-β-CyD of 6.3$\times 10^2$ M^{-1} is consistent with the literature values,

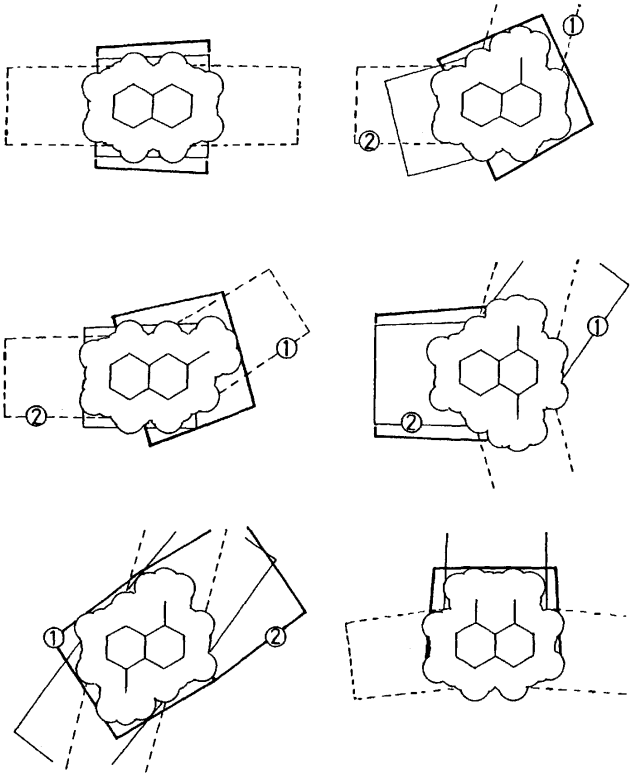

Fig. 4. Host-guest inclusion model. α-, β-, and γ-cyclodextrin cavities are drawn by dotted, thin solid, and thick solid lines, respectively. In the case of 2:1 (host:guest) complex being formed, the binding sites corresponding to K_1 and K_2 are, when necessary, are indicated respectively by the numbers, 1 and 2, in the circle.

a) The confidence level is set at 95%. b) The initial concentration of guest substance. c) The total concentration of cyclodextrin. d) The dash-sign indicates that K_2 was not evaluated, because $1/k'$ vs. C_{CyD} plots by Eq. 7 gave nearly straight line only.

685,[4] 730,[4] and 850 M^{-1},[6] determined by fluorescent method (the enhancement of guest fluorescence intensity in the presence of host). The UV absorption measurement, on the other hand, seems to give a lower value, 186 M^{-1}.[7]

For the naphthalene-β-CyD system, Hamai proposed 2 :2 complex formation:[4]

$$\beta\text{-CyD}\cdot\phi + \beta\text{-CyD}\cdot\phi \rightleftarrows (\beta\text{-CyD}\cdot\phi)_2. \quad (8)$$

The equilibrium constant is reported to be 4000 M^{-1}. If the 2 :2 complex exists, a 5% of the 1 : 1 complex is to be converted into the 2 : 2 form, when the initial concentration of naphthalene is 10^{-5} M and that of β-CyD is 10^{-2} M. Under the present experimental conditions, where the contribution of Reaction 8 is small, we have ignored the equilibrium of 2 : 2 complex formation in determining K.

Host-Guest Spatial-Fitting Model. The following data in Å unit were used for guests; bond length: 1.40 for the average C-C in naphthalen,[8]1.54 for C-C in alkyl group, 1.08 for C-H in naphthalene and alkyl group, van der Waals radius:[9] 1.0 for H and 1.7 for C. Concerned with hosts, we used the values; the inner diameter of cavity:[10] 4.7—5.2 for α-CyD, 6.0—6.4 for β-CyD, and 7.5—8.3 for γ-CyD (the smaller value is for the primary hydroxyl group and the larger is for the secondary hydroxyl group), the cavity depth:[11] 6.7 for α-CyD and ca. 7 for β- and γ-CyD.

By taking into account the magnitude of K_1 and K_2, inclusion models for all the host-guest combinations studied in this work are depicted in Fig. 4. When two hosts share a single guest, unambiguous assignment of K_1 and K_2 to the corresponding binding site is difficult. Then, we assumed that alkyl group is included in CyD cavity preferentially to naphthalene ring if the cavity entrance radius admits. Another assumption was made that a guest enters into CyD through wider secondary hydroxyl side.

It has been suggested that, if K_2 is large or nearly equal to K_1, the cross-section of secondary hydroxyl group sides of two CyDs are situated in parallel to each other in a suitable distance to form hydrogen bond.[12] In view of the K_2 values for the present 2 : 1 complexes being smaller than the corresponding K_1, we speculate that the distance along a naphthalene molecule is too long for two α-CyDs to cooperate with each other to form hydrogen bonds, while the distance is suitable for the second α-CyD to act to stabilize the 1 : 1 complex for benzene and also for *p*-xylene.

The cavity size of γ-CyD is sufficiently large to

include naphthalene ring, while the diameter of β-CyD cavity seems small to include a whole naphthalene molecule.[13] The cavity of β-CyD is, however, considered to suitably fit the naphthalene molecule, because K of β-CyD is larger than that of γ-CyD. The inner diameter of β-CyD we employed should be larger by 10%. According to this modification, 2-methylnaphthalene can enter the β-CyD cavity from methyl substituent. It seems, however, that 1-methyl derivative cannot be included from this substituent side due to the steric hindrance. The bulky 1,8-dimethyl groups obviously hinder the guest from entering deeply into β-CyD, but seem to exert no hindrance effect on γ-CyD. The 1,4-dimethyl groups, on the other hand, have a hindrance effect on γ-CyD. The size of γ-CyD fits most suitably 1.5-dimethylnaphthalene, and a large van der Waals stabilization works.

For benzene, alkylbenzenes, naphthalene, and its methyl derivatives, the largest formation constants observed are as follows; propylbenzene for α-CyD ($5.9\times10^2\,M^{-1}$), isopropylbenzene for β-CyD ($1.2\times10^3\,M^{-1}$), and 1,5-dimethylnaphthalene for γ-CyD ($1.00\times10^3\,M^{-1}$). From these observations, the alkyl chain seems to contribute to form more stable complexes with CyDs than an additional condensed ring does. This implies that the hydrophobic nature of guest is an important factor when the host-guest spatial-fitting requirement meets.

It should be emphasized that the inclusion models presented here are highly speculative because they are made based only on the magnitude of K_1 and K_2. Other information such as NMR, CD, and X-ray crystallographic data and thermodynamic and kinetic studies are necessary to confirm the inclusion model.

Crystal and Molecular Structure of Cobalt(II)mercury(II) Thiocyanate Adducts Having a New Layer Structure

Hisashi KINOSHITA* and Akira OUCHI†

Department of Chemistry, Faculty of Liberal Arts, Shizuoka University, Ohya, Shizuoka 422

†Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153

(Received September 29, 1987)

N-Methyl-2-piperidone adduct and dimethyl sulfoxide adduct of cobalt(II)mercury(II) thiocyanate were synthesized and their crystal and molecular structures were determined by the single-crystal X-ray diffraction technique. The former adduct is triclinic with a space group $P\bar{1}$, a=8.488(3), b=17.206(7), c=8.466(3) Å, α=103.72(1)°, β=90.00(1)°, γ=100.85(1)°, Z=2, while the latter adduct is orthorhombic with a space group $P2_12_12_1$, a=8.418(3), b=27.389(10), c=8.407(3) Å, Z=4, and the final R values obtained were 0.059 and 0.066, respectively. In these adducts each mercury atom is in the tetrahedral geometry, coordinated with four sulfur atoms of the thiocyanate (SCN) ions, and each cobalt atom is in the octahedral geometry, coordinated with four nitrogen atoms of SCN ions and two oxygen atoms of the Lewis-base molecules which occupy the trans-positions. Each pair of different kinds of metal atoms are bridged by an SCN ion forming a 16-membered ring of $Co_2Hg_2(SCN)_4$; these are linked, forming a two-dimensional network. The Lewis-base ligands are extended perpendicular to the plane on both sides. The complex layers are piled up in parallel, and there are no chemical or hydrogen bondings between the layers. This is a new type of the structure for $CoHg(SCN)_4L_2$ (L=Lewis base) type adducts.

The cobalt(II)mercury(II) thiocyanate (**1**) was found to have a diamond-like three-dimensional polymeric structure,[1] in which both kinds of the metal atoms are in the tetrahedral geometry. Each metal atom is linked with four metal atoms of another kind by one thiocyanate ion (SCN), respectively.

Previously, the present authors studied and determined the crystal and molecular structures of various Lewis base adducts of **1**.[2-6] According to our results, as well as other references, adducts with formula $CoHg(SCN)_4L_2$ (L=*N*,*N*-dimethylformamide (dmf),[7] *N*-methylformamide (mfa),[3] and pyridine (py)[8]) always have three-dimensional polymeric structures. On the other hand, complexes with formula $CoHg(SCN)_4(H_2O)_2\cdot 2L$ (L=*N*,*N*-dimethylacetamide (dma),[4] *N*-methyl-2-pyrrolidone (mpd)[5] and 2-pyrrolidone (pd)[6]) have a layer-type network structure of $[CoHg(SCN)_4(H_2O)_2]_n$: the Lewis-base molecules are not directly coordinated to any metal atoms, but are only hydrogen-bonded to the coordinated water, taking positions between the layers.

Along this line of research, we have continued to search for adducts with other linkage structures; we found two adducts of the type $CoHg(SCN)_4L_2$ in their crystalline states (L=*N*-methyl-2-piperidone (mpp) and dimethyl sulfoxide (dmso)). The former is a new compound, while the latter had already been reported by Makhija,[9] However, neither of their structures had been reported. Consequently, their crystal and molecular structures were determined by the X-ray diffraction method using their single crystals.

Experimental

Synthesis of the Adducts. (1) Bis(*N*-methyl-2-piperidone)-tetrakis(thiocyanato)cobalt(II)mercury(II) (**2**). A crystalline powder of **1** (1.0 g, 2.0 mmol) was dissolved into mpp (10 cm³), and 20 cm³ of water was added to the solution. It was left standing for several days and crystals of **2** were deposited. The pink crystals were filtered off and dried over silica gel. Yield: 0.5 g, 36%. Found: Co, 8.30; C, 26.24; H, 3.21; N, 11.55%. Calcd for $CoHgC_{16}H_{22}N_6O_2S_4$: Co, 8.21; C, 26.76; H, 3.09; N, 11.70%.

(2) Bis(dimethyl sulfoxide)tetrakis(thiocyanato)cobalt(II)-mercury(II) (**3**). Although this adduct had already been synthesized by Makhija from the tetrahydrofuran adduct of **1**,[9] we could obtain **3** more easily by the following method. A crystalline powder of **1** (1.0 g, 2.0 mmol) was dissolved into dmso(10 cm³), and 12 cm³ of water was added to the solution. It was left standing overnight and crystals of **3** were deposited. The pink-red crystals were filtered off and dried over silica gel. Yield: 0.8 g, 62%. Found: Co, 9.10; C, 14.66; H, 1.84; N, 8.61%. Calcd for $CoHgC_8H_{12}N_4O_2S_6$: Co, 9.09; C, 14.83; H, 1.87; N, 8.64%.

Intensity Data Collection. Crystals of **2** (dimensions 0.2×0.2×0.2 mm³), and of **3** (spherical, with ϕ=0.21 mm) were used for intensity data measurements.

Crystallographic data are as follows: **2**, $CoHgC_{16}H_{22}N_6O_2S_4$, *F.W.*=718.17, triclinic, with the space group of $P\bar{1}$, a=8.488(3), b=17.206(7), c=8.466(3) Å, α=103.72(1)°, β=90.00(1)°, γ=100.85(1)°, U=1178.4(6) Å³, Z=2, D_m=2.03(3) g cm⁻³, D_c=2.03 g cm⁻³, μ(Mo$K\alpha$)=7.74 mm⁻¹.

3, $CoHgC_8H_{12}N_4O_2S_6$, *F.W.*=648.12, orthorhombic with the space group of $P2_12_12_1$, a=8.418(3), b=27.389(7), c=8.407(3) Å, U=1938.3(10) Å³, Z=4, D_m=2.22(3) g cm⁻³, D_c=2.22 g cm⁻³, μ(Mo$K\alpha$)=9.57 mm⁻¹.

Reflections within the ranges of $3°<2\theta<55°$ for **2** and $3°<2\theta<60°$ for **3** were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer with graphite-monochromated Mo$K\alpha$ radiation (λ=0.71073 Å). The ω-2θ scan technique was employed (scan speed, 4° min⁻¹; scan width, 1.21+0.5tanθ° for **2** and 1.25+0.5tanθ° for **3**).

For **2**, of the 5435 independent reflections measured, 4051 $|F_o|>3\sigma(|F_o|)$ reflections were used for a structure determinaion; for **3**, of the 3271 independent reflections measured, 1953 $|F_o|>3\sigma(|F_o|)$ reflections were used. The intensities were corrected for Lorentz and polarization factors, as well as for absorption using numerical Gaussian integration.[10]

Structure Determination. The structures were solved by the heavy-atom method. The positions of the mercury and

cobalt atoms were deduced from a three-dimensional Patterson map, while the other non-hydrogen atoms were located by means of succesive Fourier syntheses. Their positional and thermal parameters (first isotropic and finally anisotropic) were refined by a block-diagonal least-squares method. The final R values obtained, applyng their anisotropic temperature parameters, were 0.059 for **2** and 0.066 for **3**.[11] (In the case of **3**, since it does not have a center of symmetry, the structure of the reversed chirality was also examined. However, since its R value was 0.069, the structure was not adopted.)

All calculations were carried out on a HITAC M-680H computer apparatus at the Computer Center of the University of Tokyo using a local version of the UNICS program system.[12] The atomic scattering factors were taken from Ref. 13.

Other Measurements. The magnetic moments of their solid samples were measured at 20 °C using a Gouy balance. The infrared absorption spectra were obtained by means of a JASCO IR810 grating infrared spectrophotometer using mineral oil and hexachloro-1,3-butadiene mull.

Results and Discussion

The final atomic parameters of the non-hydrogen atoms are listed in Tables 1 and 2, while the selected bond lengths and bond angles are shown in Tables 3 and 4, respectively.[14] Perspective drawings of both complexes around the mercury and the cobalt atoms are given in Figs. 1 and 2, together with the numbering scheme of the atoms.

Although the crystal systems as well as the space groups of **2** and **3** are different from each other (triclinic, $P\bar{1}$ for **2**, and orthorhombic, $P2_12_12_1$ for **3**), their molecular structures resemble each other. In both adducts each mercury atom is coordinated with four SCN sulfur atoms and is in a tetrahedral geometry.

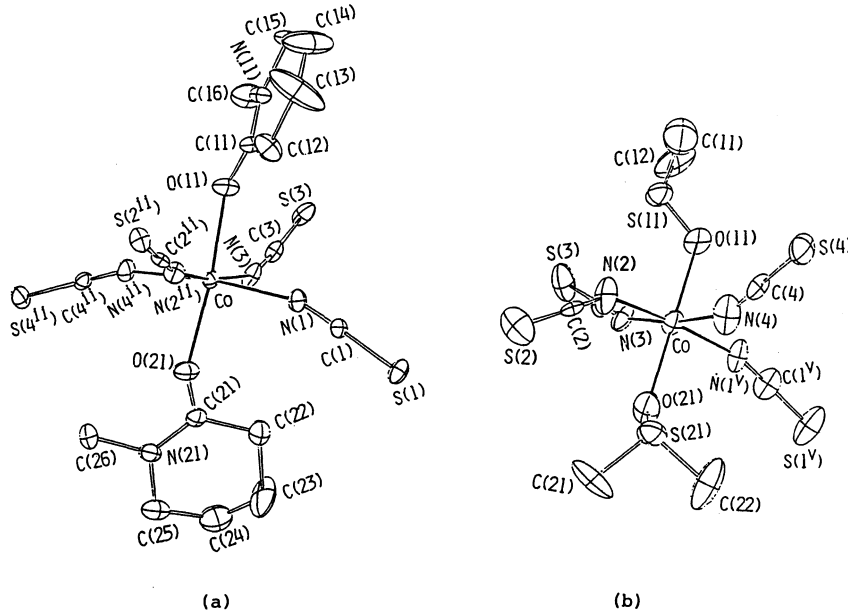

Fig. 2. The perspective drawing of the complex around a cobalt atom and the included Lewis bases. (a) $CoHg(SCN)_4(mpp)_2$: (b) $CoHg(SCN)_4(dmso)_2$. Key to the symmetry operations, see Ref. 15.

The average Hg-S lengths are 2.542 Å (maximum 2.554 and minimum 2.533 Å) for **2** and 2.537 Å (maximum 2.554 and minimum 2.525 Å) for **3**. The average bond angles around the mercury atoms of these complexes are not much different from the typical tetrahedral angles: the deviations are in the same grade as the other several mercury thiocyanates already reported.[1,16-18]

In **2** and **3**, the cobalt atom is hexa-coordinated and is in an octahedral geometry; both of the oxygen atoms of the Lewis base molecules are coordinated axially, while four SCN nitrogen atoms are coordinated equa-

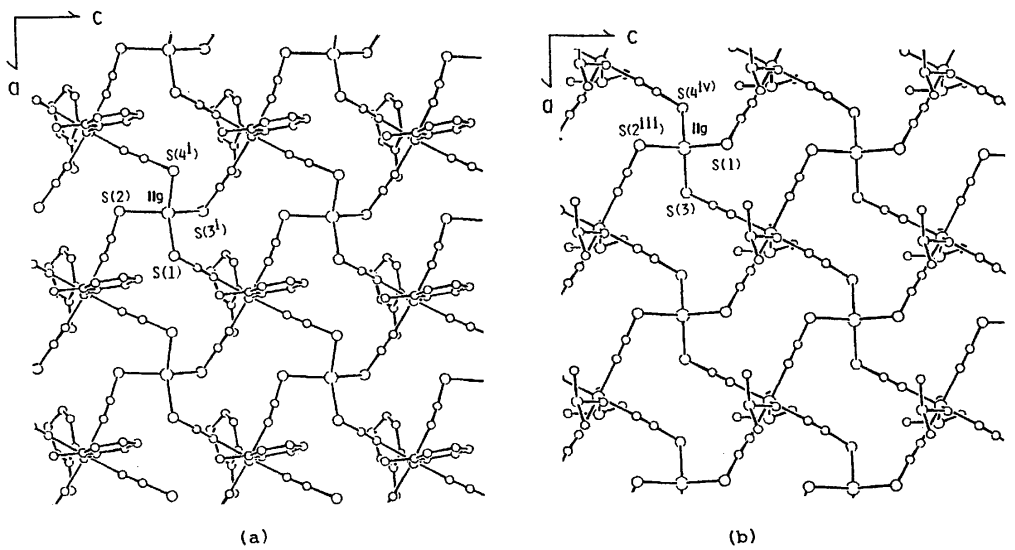

Fig. 3. The perspective drawing of the complex layer parallel to the (0 1 0) plane. (a) $CoHg(SCN)_4(mpp)_2$: (b) $CoHg(SCN)_4(dmso)_2$. Key to the symmetry operations, see Ref. 15.

torially. The average Co-N and Co-O bond lengths are 2.117 and 2.090 Å for **2** and 2.131 and 2.095 Å for **3**, respectively. They are about the same as the Co-N[19-21] and Co-O[22-24] lengths of the common octahedral cobalt(II) complexes. The average bond angles, N-Co-O and N-Co-N (between vicinal nitrogen atoms), are 90.0° and 90.2° for **2** and 90.1° and 90.2° for **3**, respectively. The angles O-Co-O are a little distorted from 180°, i.e. 173.5(3)° for **2** and 172.1(6)° for **3**, respectively. In total, the octahedral geometry of the cobalt core is not much deformed from the ideal form. The bond angles of Co-N-C, on the average, are 160.5° for **2** and 156.0° for **3**, respectively, being much deviated from 180°. Such large distortions of the angles are probably due to a steric hindrance to form the planar complex networks in the crystal.

Each pair of mercury and cobalt atoms is bridged by one SCN ion (where the sulfur atom is ligated to the mercury and the nitrogen atom to the cobalt atom). As is shown in Fig. 3, in both adducts, two mercury(II), two cobalt(II), and four SCN ions make a sixteen-membered ring which organizes the unit of a two-dimensional network. They resemble the $[CoHg(SCN)_4(H_2O)_2]_n$ network found in the $CoHg(SCN)_4(H_2O)_2 \cdot 2L$ type inclusion compounds previously reported,[4-6] although in these new complexes, Lewis base molecules are coordinated directly to the cobalt(II) atoms in place of the water molecules. As shown in Fig. 4, the complex network layers are piled up in the b-axis direction, and no chemical or hydrogen-bond bridgings exist between the layers: the interlayer space is occupied by the Lewis base molecules (mpp in **2**, dmso in **3**), which are coordinated to the cobalt(II) atoms of both side layers, respectively.

The respective complex layers found in **2** and **3** are almost in the same type structure. The y-coordinates

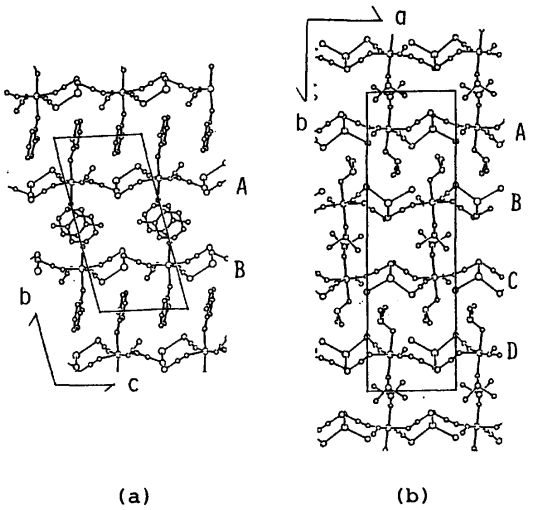

Fig. 4. The projection of the unit cell of the complex to the (1 0 0) plane (a) and to the (0 0 1) plane (b). (a) $CoHg(SCN)_4(mpp)_2$: (b) $CoHg(SCN)_4(dmso)_2$.

of all the (Co and Hg) metal atoms of one unit, sixteen-membered ring is approximately the same; the ring is regarded as being nearly in a plane, although four SCN sulfur atoms (and to a less extent the SCN carbon atoms) are located above or below the plane of the four metal atoms. The side-by-side SCN ions coordinated to one cobalt atom are extended above and beneath the respective positions of their sulfur atoms, which are above or beneath the complex plane, making a tetrahedral geometry around the mercury atom which is on the plane.

On the other hand, in $[CoHg(SCN)_4(H_2O)_2] \cdot 2L$ type complexes, cobalt atoms exist in positions slightly above and below the mercury network plane, alternately, since all four SCN ions coordinated to one

447(s)		440(s)		440(s)	δ(SCN)

1, $CoHg(SCN)_4$; **2**, $CoHg(SCN)_4(mpp)_2$; **3**, $CoHg(SCN)_4(dmso)_2$.

cobalt atom are extended upward or downward. The stress around the cobalt atom may be less than that of the title complexes. (The angles of Co-C-N of the $[CoHg(SCN)_4(H_2O)_2]\cdot 2L$ type complexes are about 165—170°:[4-6] the distortions from 180° are less than the title complexes.)

The unit rings are linked two-dimensionally. In each network plane, there are two types of unit rings, I and II, which are alternately laid side by side along the [1, 0, 1] and [1, 0, −1] axes. Rings I and II are about the same in form: the latter has an arrangement of atoms which rotates unit I by 90° around an axis perpendicular to the ring plane.

In **2**, since the unit cell has a center of symmetry and Z=2, two kinds of layers, A and the reversed one B, are in a unit cell, they appear alternately along the b-axis in the crystal. As shown in Table 1, since the *y*-coordinates of the cobalt and mercury atoms are approximately the same, 0.25, all the interlayer separations (b-axis length ×0.5 $\sin\alpha$ $\sin\gamma$) are about the same, 8.21 Å. In the crystal, the same kind of metal atoms of all layers are laid in a zigzag pattern along the b-axis. As shown in Fig. 4, the respective planes of the mpp rings coordinated to the cobalt atoms of the layers above and below line up, one after another, and are arranged in the a- or c-axis direction.

Although the structure of the layers in **3** is not much different from that of **2**, some of their detailed bond lengths and bond angles are a little different from each other. Since the space group of **3** is $P2_12_12_1$, (Fig. 4), there are four such parallel complex layers in one unit cell along the b-axis; however, only one layer is crystallographically independent. As shown in Table 2, since the *y*-coordinates of the cobalt(II) and mercury(II) atoms of **3** are approximately the same, 0.62, the metal atomic *y*-coordinates of the four layers, A—D, are about, 0.12(A), 0.38(B), 0.62(C), and 0.88(D), respectively. Therefore, all interlayer separations are about the same in distances, about one-fourth of the b-axis length, 6.847 Å; they are piled up in the order D′, A, B, C, D, A″,⋯. Since the *x*- and *z*-coordinates of the cobalt and mercury atoms are approximately 0.25, 0 and 0.75, 0.50 (exactly, 0.26126, 0.00620 and 0.7633, 0.4984), the mercury and cobalt atoms of the A-layer have approximately the same *x*- and -coordinates as the cobalt and mercury atoms of the C-layer, respectively; the same relation for the metal coordinates are also found between those in the B and D layers. The positions of the metal atoms, together with the bridging SCN ions of the respective layers of **3**, are schematically shown in Fig. 5 by the projections to the ac-plane. The dmso ligands coordinated to the cobalt atoms are extended approximately perpendicular to the complex layer. The positions above and below the cobalt atom of one layer are approximately at the center of the sixteen-membered rings of the next complex layers on both sides. Therefore, no other atoms take positions very near the dmso molecules.

The positions of half of the SCN sulfur atoms overlap with the sulfur atom positions of one-side next complex layer respectively; the other half overlap with those of the other side next layer. Each pair of over-

lapping sulfur atoms of the side-by-side planes deviate above or below the network in order to decrease their interatomic distances to a value smaller than the separation of the complex layers.

Thus, these $CoHg(SCN)_4L_2$ type mixed complexes have a new characteristic layer structure, which is reported here for the first time.

Some infrared spectral data are shown in Table 5. When the wavenumbers of the peaks of **2** and **3** are compared with those of the free-ligand molecules, mpp[25] and dmso,[26] its ν(C=O) peak in **2** and ν(S=O) peak in **3** are found to be red-shifted by 60—70 cm^{-1}. Such red shifts are larger than those which have also been observed in the spectra of some amide adducts of previously reported $[CoHg(SCN)_4(H_2O)_2]\cdot 2L$ types.[4-6] This fact is due to the direct coordinate bonds of the Lewis base molecule to the cobalt atom. The wave numbers of the bands caused by the SCN ions of **1**, **2** and **3** are not very different from one another.

The magnetic moment of **2** is about 5.10 BM, and that of **3**, about 4.99 BM at 20 °C (1 BM=9.274078(36)$\times 10^{-24}$ JT^{-1}). These values are typical for the cobalt(II) ion in the octahedral geometry.

Depletion-Mode Field Effect Semiconductor Sensor with Cation-Sensitive Polymer Membranes

Yusuke Okawa,* Mitsunori Sukigara, Shoichiro Yoshida, and Tadashi Watanabe*
Institute of Industrial Science, The University of Tokyo, 7-22-1 Roppongi, Minato-ku, Tokyo 106
(Received September 29, 1987)

Semiconductor ion sensors based on the surface conductance change due to a variation in the depletion layer thickness have been constructed. An n-SnO_2 electrode was coupled with four kinds of cation-sensitive polymer membranes (Fe^{3+}- and Cu^{2+}-exchanged Nafion membranes and poly(vinyl chloride)-supported dioctyl phthalate membranes containing a neutral carrier, valinomycin or nonactin), and its surface conductance was measured under depletion conditions as a function of the cation concentration. The sensor exhibited sensitivity to Fe^{3+}, Cu^{2+}, K^+, or NH_4^+ at levels higher than 10^{-4} mol dm^{-3} within 10 s. The sensor response was analyzed in terms of (1) the dependence of the surface conductance on the surface band bending and (2) the potential difference at solution/membrane interfaces. From the analysis, it is confirmed that the membranes show nearly Nernstian behavior and that the semiconductor acts as a potentiometric transducer. The applicability of the depletion-mode semiconductor sensor is discussed.

Semiconductor devices with low output impedance have been extensively studied recently in view of micro and multifunctional sensor fabrication. Many of such devices are of the ISFET (ion-sensitive field effect transistor) type, introduced by Bergveld,[1,2] with an insulator/semiconductor structure. The device is a modification of the MISFET (metal-insulator-semiconductor FET) and is based on the variable thickness of the inversion layer (channel) of a semiconductor substrate.[3,4] A variety of chemically sensitive membranes has been coupled with this device to develop effective sensors.[4]

There are another type of field effect devices, namely, the metal-semiconductor FET (MESFET) and junction FET (JFET), in which a change in the depletion layer thickness is utilized.[5] However, application of these devices for chemical sensor construction has scarcely been studied.

A field effect chemical sensor can be constructed also by use of semiconductor/electrolyte interfaces as follows. When an anodic bias is applied to an n-type semiconductor in contact with an electrolyte solution, a depletion layer is formed in the semiconductor. The conduction electrons are driven away from the surface region of the semiconductor. A change in the depletion layer thickness, caused for instance by ionic adsorption, alters the surface conductance of the semiconductor. Since the depletion layer acts as an insulating layer, no insulator needs to be placed on the semiconductor surface, and the device has no p-n junction in the semiconductor substrate. Thus, the structure of the sensor based upon the above principle is much simpler than that of the conventional ISFET.

In a previous paper,[6] we used n-type SnO_2 as a semiconductor and a perfluorinated sulfonate cation-exchange polymer, Nafion, as an ion-sensitive layer, to fabricate the first example of a "depletion-mode field effect sensor." The present work has been conducted to explore further the applicability of the depletion-mode sensor. By combining an SnO_2 electrode with four kinds of cation-sensitive polymer membranes, sensors for Fe^{3+}, Cu^{2+}, K^+, and NH_4^+ have been developed.

Experimental

Materials. Nafion (a 5% alcoholic solution, equivalent weight 1100), valinomycin, and nonactin were obtained from Aldrich Chemical Co., Sigma Chemical Co., and Boehringer Mannheim GmbH, respectively. Poly(vinyl chloride) (PVC, degree of polymerization 1100), dioctyl phthalate (DOP) as a plasticizer, and spectro-grade tetrahydrofuran (THF) were from Wako Pure Chemicals. $FeCl_3 \cdot 6H_2O$, $CuCl_2 \cdot 2H_2O$, KCl, NH_4Cl, LiCl, NaOH, and HCl were of reagent grade. All these chemicals were used without further purification. Distilled water, or deionized water purified with Milli Q-II (Millipore Ltd.) was used.

Preparation of Sensors. SnO_2-coated glass plates were used as semiconductor substrates. The SnO_2 layer had a thickness of about 50 nm and a donor density of 10^{21} cm^{-3}. Two terminals, W and D, were placed on the SnO_2 layer with the ohmic contacts of indium metal, which were insulated with an epoxy resin. The effective surface area of the sensor was 1×1 cm^2.

The Nafion membrane was prepared as follows.[6] A Nafion solution was spread on the SnO_2 surface and dried; the thickness of the membrane was estimated to be 1—2 μm from the weight gain. The Nafion-coated semiconductor was then immersed in a 0.2 M (1 M=1 mol dm^{-3}) $FeCl_3$ or $CuCl_2$ aqueous solution for at least 16 h to obtain ion-exchanged Nafion.

The neutral carrier-PVC membranes were cast from a THF solution containing 12 mg of PVC, 2.5 mg of a neutral carrier, and 35 μl of DOP.[7] The membrane formed on the semiconductor was air-dried overnight, then placed in a vacuum desiccator for 1 h. The thickness of the membranes was roughly 0.1 mm. The membranes were conditioned by immersing them in 0.2 M KCl and NH_4Cl aqueous solutions for valinomycin and nonactin, respectively.

The sensor construction is illustrated in Fig. 1.

Operation of Sensors. The electrical conductance of the sensor at a constant electrode potential, V_W, was measured as reported in the previous paper.[6] The electrode potential was

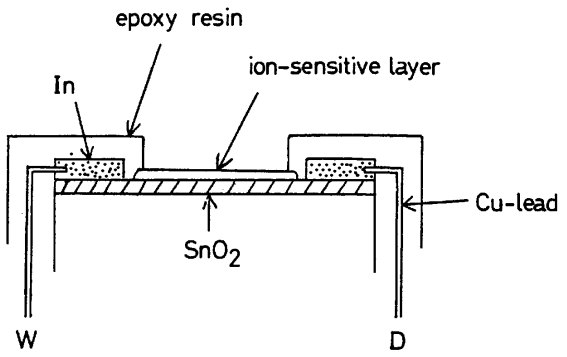

Fig. 1. Schematic representation of sensor construction.

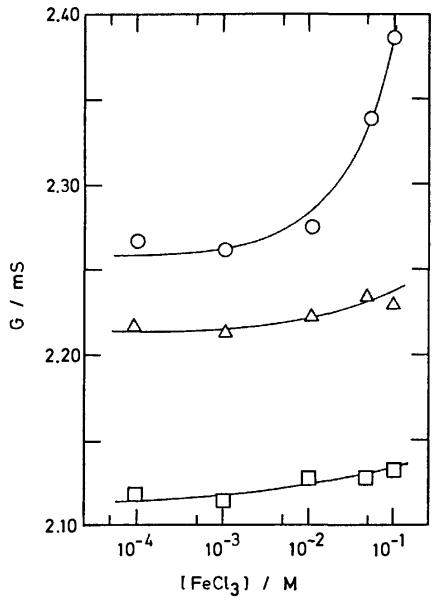

Fig. 2. Response of the Fe^{3+}-sensor (Fe^{3+}-Nafion/SnO_2). V_W=+400 (○), +500 (△), +1000 mV (□) vs. Ag/AgCl.

controlled by a Toho Technical Research potentiostat Model 2000 against an Ag/AgCl (KCl saturated) reference electrode. A small voltage (1—5 mV), V_D, was applied with a Yokogawa voltage supply Model 2553 between the two terminals, W and D, and the current, I_D, was measured by a Takeda Riken electrometer Model TR 8651. The electrical conductance, G, was calculated from the relation;

$$G = \partial I_D / \partial V_D.$$

For measurements of the time response to a concentration step, the voltage supply and the electrometer were replaced with a Yokogawa-Hewlett-Packard low frequency impedance analyzer Model 4192A operated at 1 kHz and 5 mV.

All the measurements were carried out at room temperature and in solutions flushed with nitrogen.

Results

Nafion-Based Fe^{3+}- and Cu^{2+}-Sensors. Figure 2 shows a typical response of the Fe^{3+}-sensor carrying an Fe^{3+}-exchanged Nafion membrane in the aqueous solutions containing $FeCl_3$ in the concentration range

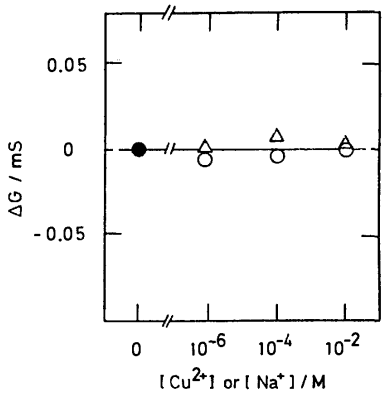

Fig. 3. Effect of coexisting Cu^{2+} (○) and Na^+ (△) on the Fe^{3+}-sensor. [$FeCl_3$]=1×10^{-3} M (pH 1.5); V_W=+400 mV vs. Ag/AgCl.

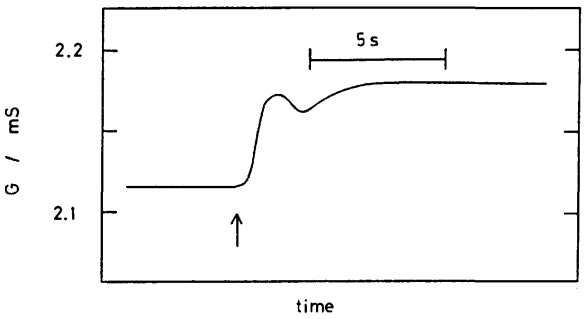

Fig. 4. Time response of the Fe^{3+}-sensor to a Fe^{3+} concentration step (0→0.1 M). V_W=+400 mV vs. Ag/AgCl.

from 10^{-4} to 10^{-1} M at pH 1.5. The conductance of the sensor changed with a change in the $FeCl_3$ concentration. The sensitivity is higher at more negative electrode potentials. At an appropriate electrode potential, the Fe^{3+}-sensor can detect Fe^{3+} ions at levels higher than 10^{-4} M.

The Fe^{3+}-sensor shows no pH dependence.[6] Addition of Na^+ or Cu^{2+} to a 10^{-3} M $FeCl_3$ test solution did not alter the sensor response, as depicted in Fig. 3, where a change in surface conductance, ΔG, upon addition of these interfering ions is plotted against their concentration. This result ensures a good selectivity of the Fe^{3+}-sensor.

Figure 4 shows a time response of the Fe^{3+}-sensor to a stepped change in Fe^{3+} concentration from 0 to 0.1 M under vigorous stirring. Though the trace is perturbed in the initial phase probably due to non-uniform mixing of the solution, the response of the sensor is completed within 10 s, which is short enough for practical use.

Use of the Cu^{2+}-exchanged Nafion membranes gave electrodes sensitive to Cu^{2+}. A typical response of the Cu^{2+}-sensor in the aqueous solutions containing $CuCl_2$ at pH 1.5 is given in Fig. 5. Similar to the Fe^{3+}-sensor, the sensitivity is higher at more negative electrode potentials. The effective potential range for

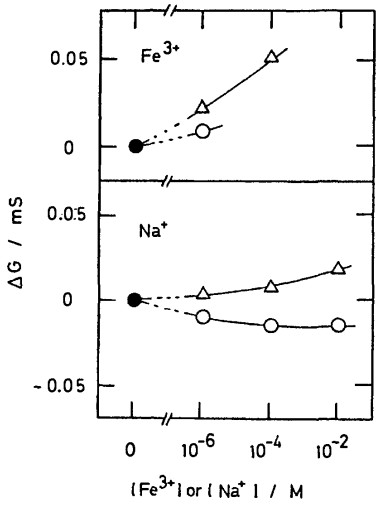

Fig. 6. Effect of coexisting Fe^{3+} and Na^+ on the Cu^{2+}-sensor. [$CuCl_2$]=1×10^{-3} M (pH 1.5); V_W=+150 (○), +300 mV (△) vs. Ag/AgCl.

the Cu^{2+}-sensor is negative of that for the Fe^{3+}-sensor.

Figure 6 shows the effect of interfering ions (Na^+ and Fe^{3+}) to the response of a Cu^{2+}-sensor (in 10^{-3} M $CuCl_2$, pH 1.5). The conductance of the sensor was affected by the addition of these ions, and hence the selectivity of the Cu^{2+}-sensor is not sufficient.

Since the semiconductor used in this work is highly doped, the depletion layer is correspondingly thin; for example, about 1.0 and 1.4 nm at electrode potentials 0.4 and 1.0 V vs. Ag/AgCl, respectively, for the case of the SnO_2 in direct contact with a pH 1.5 electrolyte solution. The conduction electrons may tunnel to the solution through the depletion layer,[8] giving rise to a

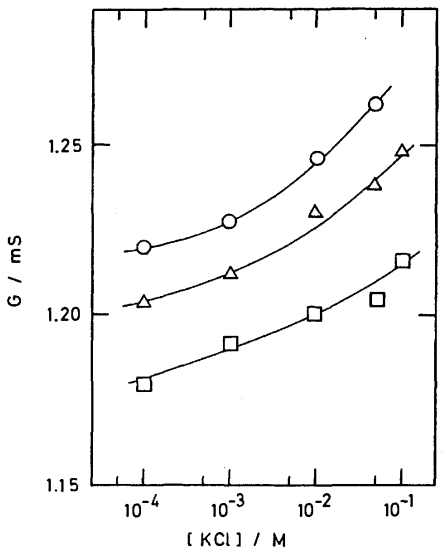

Fig. 7. Response of the K^+-sensor (valinomycin-DOP-PVC/SnO_2). V_W=−200 (○), −100 (△), +100 mV (□) vs. Ag/AgCl.

cathodic current reducing Fe^{3+} or Cu^{2+}.[9] The utilization of this current for the sensor signal was discussed in the previous work.[6] In the case of the Cu^{2+}-sensor, the current reducing Fe^{3+} was too large to carry out a stable conductance measurement, because the effective operational range for the Cu^{2+}-sensor is negative enough to reduce Fe^{3+}.[9]

Neutral Carrier-Based K^+- and NH_4^+-Sensors. Several macrolide antibiotics are known to exhibit highly selective complexing ability to certain cations.[10] Valinomycin for K^+ [11] and nonactin for NH_4^+ [12] are typical examples, and have been used as cation carriers in liquid membrane systems.[10,13] Combination of a polymer-supported liquid membrane containing a carrier and a semiconductor transducer gives an ion sensor.[14] In view of this, we have attempted to construct K^+- and NH_4^+-sensors by use of PVC-supported DOP membranes.[15]

The valinomycin-based sensor showed K^+-sensitivity, as illustrated in Fig. 7. The solution was a KCl aqueous solution containing 0.1 M NaCl (pH 6.2). The K^+-sensor did not respond to Na^+ and Li^+ at concentrations below 10^{-2} M, and to H^+ for pH value ranging from 4 to 10.

The response of a nonactin-based NH_4^+-sensor is shown in Fig. 8. Here an NH_4Cl aqueous solution containing 0.1 M NaCl was used. The sensor did not respond to Na^+ and K^+ at concentrations below 10^{-2} M.

Discussion

Under depletion conditions, the surface conductance of a semiconductor depends on the space charge layer thickness, which in turn is related to the surface band bending. This situation is described by the following equation for n-type semiconductors;[6]

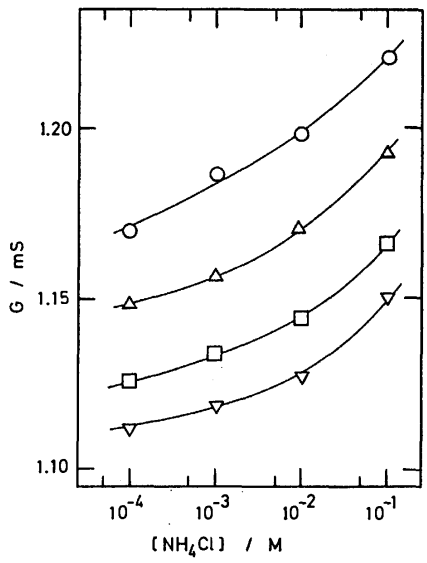

Fig. 8. Response of the NH_4^+-sensor (nonactin-DOP-PVC/SnO_2). V_W=−100 (○), +0 (△), +100 (□), +200 mV (▽) vs. Ag/AgCl.

$$\Delta\sigma_S = -(2\varepsilon e N_D \mu_e^2)^{1/2}(-V_S)^{1/2}. \quad (1)$$

Here V_S is the band bending at surface ($V_S=V_{fb}-V_W$; V_{fb} is the flatband potential), $\Delta\sigma_S$ the difference between the surface conductivity under a depletion condition ($V_S<0$) and that at the flatband state ($V_S=0$), ε the dielectric constant of the semiconductor, μ_e the mobility of the conduction electrons, N_D the donor density, and e the elementary charge.

As the potential drop in the Helmholtz layer of an oxide semiconductor surface changes in general with pH of the solution,[16] V_{fb}, and hence V_S and the surface conductance, of the semiconductor in direct contact with an electrolyte solution depend on pH of the solution under potentiostatic conditions. For the sensors developed in this work, however, the semiconductor surface is covered with an ion-sensitive polymer membrane. In such a case a change in V_S via the cation concentration change in solution should be caused by the potential difference at the membrane/solution interface. This has been confirmed previously by flatband potential measurements for the Nafion/SnO_2 system.[6] The flatband potential is generally estimated from the Mott-Schottky plot of the depletion capacitance. However, this procedure is difficult to apply to the high-resistance and low-capacitance membrane/semiconductor system as in the present study.

If the potential difference at the membrane/solution interface exhibits the Nernstian behavior, a plot of G against $[V_W-(RT/nF)\ln a]$, where n is the valency of the cation and a is its activity, should give a single curve for a variety of V_W-a combinations. The term $(RT/nF)\ln a$ is approximated by $(0.059/n)\log c$ (V) at T=300 K, where c is the cation molarity. Figures 9 and 10 show the G vs. $[V_W-(0.059/n)\log c]$ plots for the Fe^{3+}- and NH_4^+-sensors, respectively. Each plot gives a single curve, and the above-mentioned point is thus

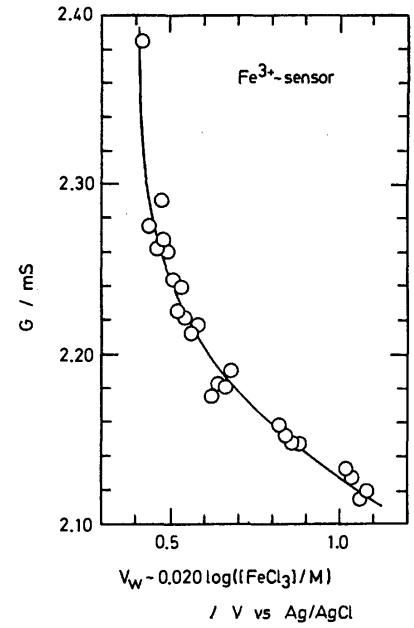

Fig. 9. Plot of the surface conductance against $V_W-(0.059/n)\log c$ for the Fe^{3+}-sensor (n=3).

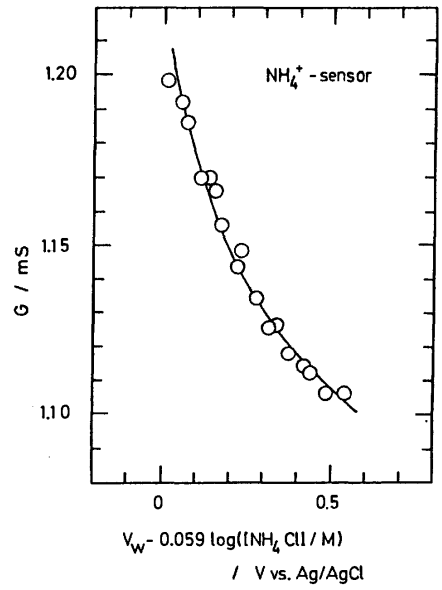

Fig. 10. Plot of the surface conductance against $V_W-(0.059/n)\log c$ for the NH_4^+-sensor (n=1).

verified. Similar results were also obtained both for Cu^{2+}- and K^+-sensors.

The dependence of the sensitivity on the electrode potential is explained with reference to Eq. 1. A more negative electrode potential gives a smaller band bending for a given cation concentration (the band edge is fixed to the solution at the given cation concentration). At a more negative potential, therefore, the change in the surface conductance is greater for a change in the cation concentration, thus resulting in higher sensitivity.

Our measurements have shown that the selectivity of the Cu^{2+}-sensor is poorer than that of the Fe^{3+}-sensor.

This could be accounted for by invoking a higher affinity of the sulfonato groups in Nafion to Fe^{3+} than to Cu^{2+}, as has been suggested also for Nafion-based ion-selective electrodes.[17] In contrast, valinomycin and nonactin are ionophores highly selective to K^+ and NH_4^+, respectively.[11,12] This is corroborated by the excellent selectivities of the K^+- and NH_4^+-sensors developed in this work.

The Nafion-based Cu^{2+}-sensor required application of a more negative electrode potential than the Fe^{3+}-sensor for the sufficient sensitivity. This observation is explained qualitatively as follows. As the affinity of the sulfonato groups is higher to Fe^{3+} than to Cu^{2+}, the difference in the chemical potential of Fe^{3+} between in Nafion and in the solution is larger than in the case of Cu^{2+}. The electrochemical potentials of the cation in Nafion and in the solution are equal at equilibrium. On a reasonable assumption that the electrical potential drop in the solution is zero, the electrical potential in Nafion is more positive for Fe^{3+} than for Cu^{2+}. Hence the band edge of the semiconductor contacting Nafion is more lowered, or V_{fb} is more positive for Fe^{3+} than for Cu^{2+}. Thus the Cu^{2+}-sensor required application of a more negative electrode potential for the sufficient sensitivity.

The performance of the sensors constructed in this work is based mainly on the properties of the membrane used, and the semiconductor is acting as a potentiometric transducer under depletion conditions. Incorporation of other chemically sensitive layers into this simple yet effective transducer may introduce new useful chemical sensors.

Further, the present system could find potential application for the electrochemical characterization of thin layers on solid substrates, including Langmuir-Blodgett films.

This work has been supported in part by Grants-in-Aid from the Ministry of Education, Science and Culture (Nos. 61103007 and 61227005).

Dynamic NMR as a Nondestructive Method for the Determination of Rates of Dissociation. XIII. Sulfur Inversion in 9,9-Dialkyl-10-mesitylthioxanthenium Salts[1)]

Michinori Ōki*,† and Yasuhisa Yamada
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received July 31, 1987)

The sulfur-inversion in the title compound (alkyl=ethyl) was found to take place with the following activation parameters by dynamic NMR spectroscopy: ΔH^{*}=23.8±0.2 kcal mol^{-1}, ΔS^{*}=2.6±0.4 cal mol^{-1} K^{-1}. The significance of the near zero entropy of activation is discussed. The mesityl group in the title compounds also showed restricted rotation of which barrier to rotation was estimated to be 14 kcal mol^{-1} at 318 K for the compound where the alkyl is a methyl.

During the course of investigation by the dynamic NMR spectroscopy on the dissociation of a chemical bond, it has become clear that the entropy of activation is large positive if the ground state is ionic and the transition state is losing the electric charge, whereas it is large negative if the ground state is covalent and the transition state is of ionic character.[2)] Thus this technique may be used as a diagnostic means for the mechanism of a dynamic process of a molecule.

Sulfur-inversion in sulfonium ions is known to take place with a free energy of activation of ca. 25—30 kcal mol^{-1} (1 cal=4.184 J).[3)] In contrast to this fact, the sulfur ligand in platinum complexes inverts with much less free energy of activation,[4)] which might be an implication that the mechanism of the sulfur-inversion in the complexes is different from the true inversion: inversion after dissociation is one of the alternative possibilities.

In tackling this problem, we expected that the dynamic NMR technique would give valuable information. However, literature search indicated that the number of literatures that treated with this problem by dynamic NMR is very limited: to our knowledge, there is only one paper that reports the kinetic parameters of sulfur-inversion in sulfonium ions, this paper giving only free energy of activation.[5)] Therefore, some basic data should be accumulated in order to prove that the dynamic NMR technique is useful in discussing the mechanism of inversion of sulfur. As one of the contributions to this end, we have reported that the sulfur-inversion in a sulfonium ion, in which the C-S bond dissociation is unlikely to occur, exhibits near-zero entropy of activation by a classical method.[6)] A next problem is to prove that the dynamic NMR technique affords in fact a near-zero entropy of activation, if the mechanism of the sulfur-inversion does not involve the C-S bond dissociation followed by inversion.

The only one literature we found reported that the sulfur-inversion in 9,9-dimethyl-10-phenylthioxanthenium perchlorate takes place to show coalescence of the two methyl signals at ca. 200 °C at 60 MHz.[5)] In this compound, the C-S bonds involved are aromatic carbon-to-sulfur ones only: the involvement of the bond dissociation is unlikely in the sulfur-inversion. Since the coalescence temperature of the key signals of the reported compound would be too high for the instrument we possess (270 MHz), we decided to modify the molecule to lower the coalescence temperature.

There are two techniques to lower the coalescence temperature: one is to reduce the difference in chemical shifts of the exchanging nuclei, and the other is to raise the ground state energy so that the energy gap between the ground state and the transition state for inversion becomes small. We chose the latter method firstly. The former will be accomplished by selecting the chain length of the alkyl groups at the 9-position.

The syntheses of the compounds used in this study were carried out by the known methods. 9,9-Dialkylthioxanthene (**1**) was oxidized to the corresponding sulfoxide **2** which was treated with sulfuric acid after dissolving in mesitylene.[5)] For the synthesis of 9,9-dibenzyl compound, this method failed probably because of the presence of the phenyl ring in the benzyl group. Therefore, only the 10-phenyl derivative **5** was prepared by phenylation[7)] of 9,9-dibenzylthioxanthene (**4**).

Although it was hoped that the introduction of a mesityl group into the 10-position of the thioxanthenium ion would lower the barrier to inversion, the change in the observed line shapes of 10-mesityl-9,9-dimethylthioxanthenium perchlorate (**3**: R=CH_3, X=ClO_4) at high temperatures was not good enough for the total line shape analysis. Introduction of two benzyl groups in the 9-position of thioxanthenium ion was not satisfactory either: 9,9-dibenzyl-10-phenylthioxanthenium perchlorate (**5**) possessed a too high barrier to inversion for the measurement with our instrument, although we hoped that the steric effects of the benzyl groups would lower the barrier.

Finally we synthesized 9,9-diethyl-10-mesitylthioxanthenium tetrafluoroborate (**3**: R=C_2H_5, X=BF_4) and found the compound to be suitable for the

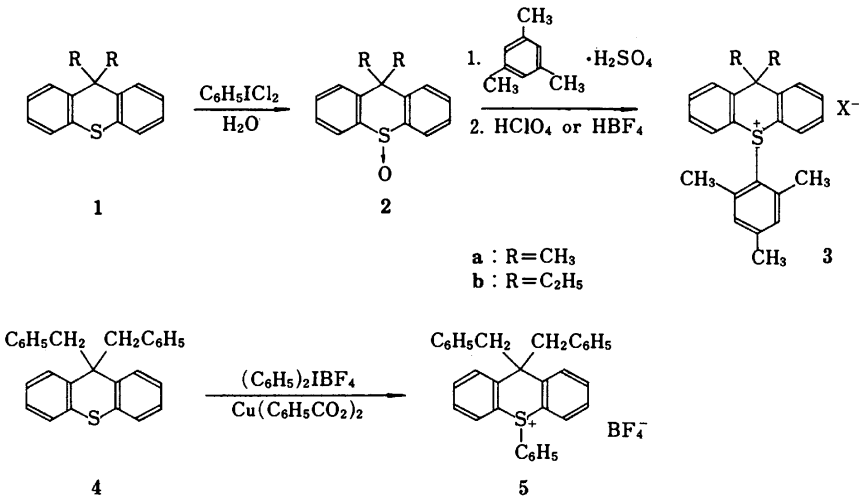

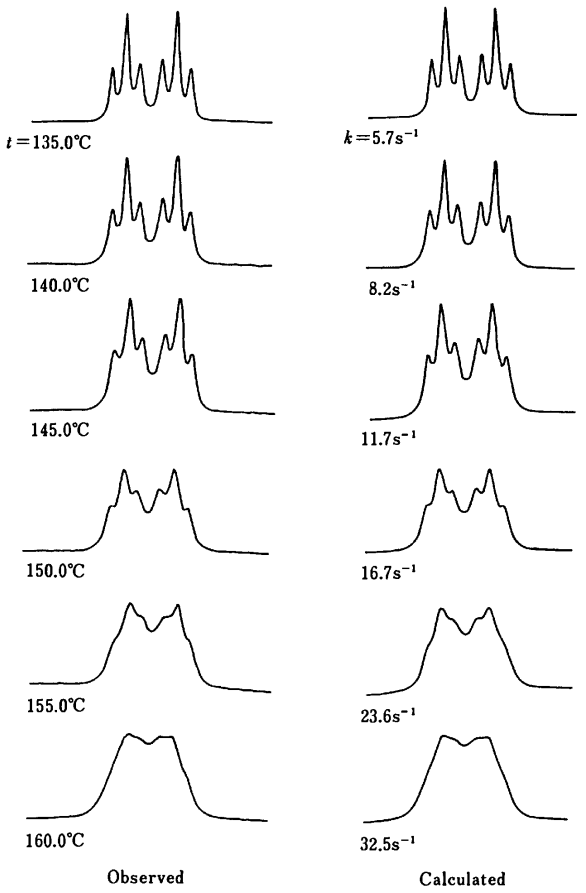

Fig. 1. Observed and calculated line shapes of the methyl protons of 9,9-diethyl-10-mesitylthioxanthenium tetrafluoroborate.

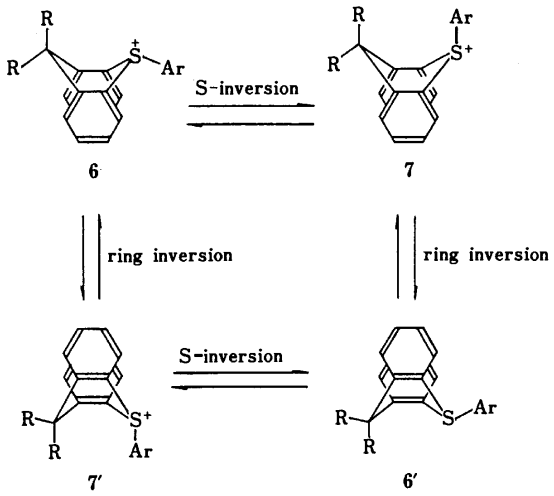

Fig. 2. Isomerization circuit.

dynamic NMR work, thanks to the steric effects given by the mesityl group and probably by the ethyl groups, in addition to the small chemical shift differences of the methyl protons in the ethyl groups. The kinetic data obtained by the total line shape analysis are given in Fig. 1, taking typical examples, together with observed and calculated line shapes for the methyl protons of the ethyl groups. The enthalpy of activation, 23.8±0.2 kcal mol^{-1}, and entropy of activation, 2.6±0.4 cal mol^{-1} K^{-1}, were obtained by putting these results into the Eyring equation. The correlation coefficient was excellent.

The feature of the kinetic parameters is the near-zero entropy of activation. Since the C-S bonds in this compound can be assumed to not dissociate under the conditions of the investigation, the sulfur-inversion must be a single step process. In such processes, the entropy of activation is near-zero in agreement with the results obtained by a classical method applied to other sulfonium compounds that do not easily dissociate at the C-S bonds. We may conclude that in those cases the dynamic NMR technique gives reliable data as was the case of internal rotation in molecules.[8]

It may be argued that, since the 9,10-dihydroanthracene and its analogs take a boat conformation in the ground state,[9] the process we observe here may not be the sulfur-inversion. We believe, however, that the process observed here is indeed the sulfur-inversion for the following reasons. The isomerization circuit is shown in Fig. 2. Firstly, the rates of ring inversion in

this type of compounds are known to be very large at room temperature.[10] Therefore, the ring inversion cannot be the rate-determining step of the observed process. Secondly, if the mesityl group is axial **7** or **7'**, then the steric interaction of the mesityl group with the alkyl group in the 9-position that opposes the mesityl group is great: the mesityl-axial conformation **7** or **7'** will be too unstable to be observed. Therefore, the ground state for the compounds in question must be the mesityl-equatorial conformation **6** and **6'**. When sulfur-inversion takes place from the stable conformation, the mesityl-axial conformation is assumed transiently but the ring inversion follows very rapidly. It also means that, if the ring inversion takes place to form the mesityl-axial conformation, the reverse process follows rapidly.

The molecular ion of 9,9-dialkyl-10-mesitylthioxanthenium showed broad peaks for the methyl protons of the mesityl group as well as the aromatic protons which are directly bonded to the mesityl-phenyl group at room temperature to indicate that the rotation of the mesityl group is fairly slow. By lowering the temperature of the solution of 9,9-dimethyl-10-mesitylthioxanthenium perchlorate (**3**: R=CH_3, X=ClO_4), we found the two methyl signals were separated (1.14 and 2.96) as well as the meta protons of the mesityl group (7.14 and 7.38). The coalescence of the methyl proton signals took place at 318 K. Because of the presence of other proton signals in the region where the coalescence of the signals took place, we abandoned the total line shape analysis and the free energy of activation for rotation was obtained as 14 kcal mol^{-1} at the coalescence temperature by assuming that the chemical shift difference is constant throughout the temperature range examined.

This barrier to rotation may be compared with that for the mesityl or 2,6-dimethylphenyl group in 9,9-dimethyl-10-(2,6-dimethylphenyl)-9,10-dihydroanthracene, 19.6 kcal mol^{-1} at 399 K,[11] and 9,9-dimethyl-10-mesitylxanthene , 17.6 kcal mol^{-1} at 298 K.[12] The lowering of the barrier to rotation in the sulfur compound (**3**: RCH$_3$, X=ClO_4) is undoubtedly caused by the large bond-lengths of the C-S bonds relative to the C-C bonds.

Experimental

NMR Measurement. The NMR data including the dynamic NMR were collected with the use of a JEOL GX-270 spectrometer unless otherwise mentioned. The temperature was calibrated by a thermometer. For the dynamic NMR measurements, a solution of ca. 40 mmol L^{-1} was used. Dimethyl-d_6 sulfoxide and chloroform-*d* were used for high and low temperature measurements, respectively.

Calculation of Rate Constants. The exchange of spins observed here is in principle $A_3X_2B_3Y_2 \rightleftarrows B_3Y_2A_3X_2$. We approximated the process to be $AX_2 \rightleftarrows BY_2$ for the convenience of calculation which was carried out by the use of DNMR3 program.[13] The coupling constants were found to be constant at several temperatures, where the exchange was negligibly slow. Thus we assumed $J_{AX}=J_{BY}=7.3$ Hz at the temperature range examined. Since the transverse relaxation time (T_2) could not be obtained from a signal within the molecule, the relaxation time was obtained by calculation that gave the best fit with the observed signals at temperatures in the slow exchange limit. T_2 was thus obtained as 0.12 s and this value was used throughout the calculation of the line shapes at various temperatures. The chemical shifts drifted as the temperature was changed. At the slow exchange limit, we observed the chemical shifts of the A, B, X, and Y protons at various temperatures to obtain the correlations between the temperature and the chemical shift. The results are shown in Table 1. These relations were extrapolated to the temperatures where the line shapes changed. The agreement between the observed and the calculated spectra was excellent, as is seen in Fig. 1. The following rate constants (s^{-1}) were obtained (temperature in °C given in parentheses): 5.7 (135.0), 6.8 (137.5), 8.2 (140.0), 9.7 (142.5), 11.7 (145.0), 13.9 (147.5), 16.7 (150.0), 19.6 (152.0), 23.6 (155.0), 28.0 (157.5), 32.5 (160.0), 38.5 (162.5). These data were put into the Eyring equation to obtain the enthalpy of activation, 23.8±0.2 kcal mol^{-1}, and entropy of activation, 2.6±0.4 cal mol^{-1} K^{-1}. The correlation coefficient was 0.999.

Table 1. Correlation between Temperature and Chemical Shifts of the Protons Involved in the Exchange

Nuclei[a]	$f(t)$[b]
A	$0.179t$ +151.41
B	$0.234t$ +170.22
X	$0.144t$ +489.97
Y	$0.0510t$+735.89

a) For A, B, X, and Y, see the text. b) $\nu=f(t)$, t being temperature in °C.

For the calculation of the free energy of activation for rotation of the mesityl group, the equation

$$k_c = \frac{\pi\Delta\nu}{\sqrt{2}}$$ [14]

was used, where $\Delta\nu$ is the chemical shift difference of the exchanging proton signals and k_c the rate constant at the coalescence temperature. The value of the rate constant was put into the Eyring equation.

9,9-Dibenzylthioxanthene (4). To a solution of 5.32 g (17.5 mmol) of 9-benzylthioxanthen-9-ol[15] in 100 mL of ether was added 30 mL of 70% perchloric acid at −78 °C with stirring. The mixture was allowed to warm up to the room temperature and the red precipitates were collected. Recrystallization from hot acetic acid gave 4.91 g of 9-benzylthioxanthylium perchlorate. To a Grignard solution prepared from 4.8 g (38 mmol) of benzyl chloride, 0.92 g (38 mmol) of magnesium and 100 mL of ether, was added 4.90 g (12.7 mmol) of the perchlorate and the mixture was refluxed for 2 h. The mixture was decomposed with aqueous ammonium chloride and the ether layer was separated. After drying over sodium sulfate, ether was removed and the residue was submitted to chromatography on silica gel with hexane as an eluent to afford 2.44 g (50.8%) of the desired product and 1.00 g of 9-benzylidenethioxanthene, identified by its melting

point, 119.0—120.0 °C (lit,[15] mp 121—122 °C), and its ^{1}H NMR spectra ($CDCl_3$, δ): 6.87 (1H, s), 6.9—7.8 (13H, m). The desired product was purified by recrystallization from dichloromethane-hexane, mp 160.0—161.0 °C. Found: C, 85.39; H, 5.80; S, 8.27%. Calcd for $C_{27}H_{22}S$: C, 85.67; H, 5.86; S, 8.47%. ^{1}H NMR ($CDCl_3$) δ=3.52 (4H, s), 6.6—7.4 (18H, m).

9,9-Dibenzyl-10-phenylthioxanthenium Tetrafluoroborate (5). A mixture of 0.55 g (1.5 mmol) of 9,9-dibenzylthioxanthene in 15 mL of chlorobenzene, 0.55 g (1.5 mmol) of diphenyliodonium tetrafluoroborate[7] and 10 mg of copper(II) benzoate was heated at 120—125 °C under a nitrogen atmosphere for 3 h. The mixture was cooled and ether was added to induce precipitation. Recrystallization of the precipitate from ethanol afforded 0.33 g (42%) of the desired product, mp 296—297 °C (decomp). Found: C, 72.79; H, 4.75; S, 6.16%. Calcd for $C_{33}H_{27}BF_4S$: C, 73.07; H, 5.02; S, 5.91%. ^{1}H NMR ($CDCl_3$) δ=3.60 (2H, s), 4.08 (2H, s), 6.02 (2H, d, J=7.2 Hz), 6.6—7.6 (17H, m), 7.96 (2H, t, J=7.2 Hz), 8.42 (2H, d, J=7.2 Hz).

10-Mesityl-9,9-dimethylthioxanthenium Perchlorate (3a: X=ClO$_4$). To a solution of 0.44 g (1.8 mmol) of 9,9-dimethylthioxanthene 10-oxide (**2a**)[5] in 5 mL of mesitylene, was added 1 mL of concentrated sulfuric acid at 0 °C with stirring. The stirring was continued for 10 d. The mixture was poured into water and shaken with ether. To the aqueous layer cooled at 0 °C, was added 2 mL of 70% perchloric acid. After stirring for 1h, the precipitates were collected and washed with water and then with ether. Recrystallization from acetone-ether afforded 0.60 g of the desired product, mp 262.0—263.5 °C. Found: C, 64.56; H, 5.90; S, 7.56; Cl, 8.08%. Calcd for $C_{24}H_{25}ClO_4S$: C, 64.78; H, 5.66; S, 7.20; Cl, 7.97%. ^{1}H NMR ($CDCl_3$, −50 °C) δ=1.14 (3H, s), 1.52 (3H, s), 2.18 (3H, s), 2.46 (3H, s), 2.96 (3H, s), 7.14 (1H, s), 7.25 (2H, d, J=7.5 Hz), 7.38 (1H, s), 7.51 (2H, d, J=7.5 Hz), 7.78 (2H, t, J=7.5 Hz), 7.91 (2H, d, J=7.5 Hz).

9,9-Diethylthioxanthene 10-Oxide (2b). To a solution of ethylmagnesium iodide prepared from 1.0 mL (13 mmol) of ethyl iodide, 0.3 g (13 mmol) of magnesium and 50 mL of ether, was added 1.85 g (5.70 mmol) of 9-ethylthioxanthylium perchlorate[16] and the mixture was heated for 2 h. The mixture was decomposed with aqueous ammonium chloride and the ether layer was separated. The ether solution was washed with water and dried over magnesium sulfate. Evaporation of the solvent afforded practically pure 9,9-diethylthioxanthene (**1b**) in 99% yield. ^{1}H NMR ($CDCl_3$) δ=0.68 (6H, t, J=7.3 Hz), 2.07 (4H, q, J=7.3 Hz), 7.1—7.5 (8H, m).

The practically pure thioxanthene **1b** was dissolved in 10 mL of pyridine and 1 mL of water. To the solution was added 1.70 g (6.18 mmol) of phenyliodonium dichloride in 7 mL of pyridine in 10 min at −40 °C and the mixture was stirred overnight. Dilute sulfuric acid was added with cooling to neutralize and the mixture was extracted with chloroform. The chloroform layer was washed with water and dried over sodium sulfate. Evaporation of the solvent and addition of hexane afforded crystals in 87.5% yield. Recrystallization of the product from hexane gave the pure sample, mp 125.0—125.5 °C. Found: C, 75.46; H, 6.84; S, 11.84%. Calcd for $C_{17}H_{18}OS$: C, 75.52; H, 6.71; S, 11.86%. ^{1}H NMR ($CDCl_3$) δ=0.61 (3H, t, J=7.5 Hz), 0.84 (3H, t, J=7.5 Hz), 1.62 (2H, q, J=7.5 Hz), 2.47 (2H, q, J=7.5 Hz), 7.4—7.6 (6H, m), 8.0—8.2 (2H, m).

9,9-Diethyl-10-mesitylthioxanthenium Tetrafluoroborate (3b: X=BF$_4$). A mixture of 0.38 g of the sulfoxide **2b**, 5 mL of mesitylene and 1 mL of concentrated sulfuric acid was stirred at room temperature for 4 d. The mixture was poured into ice-water and ether-soluble materials were removed by shaking with ether. To the aqueous layer was added 2 mL of 40% tetrafluoroboric acid with cooling and the mixture was stirred for 1 h at 0 °C. The precipitate was collected by filtration, washed with water and then with ether, and recrystallized from ethanol to afford 0.17 g of the desired product, mp 202.0—203.0 °C. Found: C, 67.83; H, 6.53; S, 6.96%. Calcd for $C_{26}H_{29}BF_4S$: C, 67.53; H, 6.40; S, 7.16%. ^{1}H NMR (DMSO-d_6) δ=0.57 (3H, t, J=7.3 Hz), 0.64 (3H, t, J=7.3 Hz), 1.38 (3H, br s), 1.86 (2H, q, J=7.3 Hz), 2.40 (3H, s), 2.73 (2H, q, J=7.3 Hz), 2.94 (3H, br s), 7.21 (1H, br s), 7.38 (2H, d, J=7.8 Hz), 7.49 (1H, br s), 7.60 (2H, t, J=7.8 Hz), 7.86 (2H, t, J=7.8 Hz), 8.09 (2H, d, J=7.8 Hz).

Dynamic NMR as a Nondestructive Method for the Determination of Rates of Dissociation. XIV. Examination of Rates of Proton-Detachment from Ammonium Ions with Multiple Probes[1)]

Toshiari Morita and Michinori Ōki*,†
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received November 5, 1987)

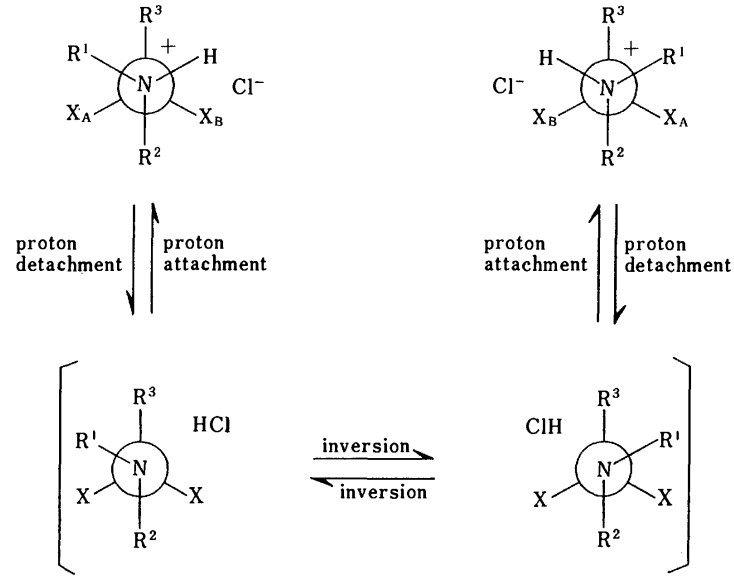
The rates of proton-detachment and those of topomerization in ammonium ions of benzyldiethylammonium chloride and benzylisopropylmethylammonium chloride were determined by dynamic NMR spectroscopy, by taking advantage of loss of coupling of the benzylic methylene or the methyl protons for the former process and site-exchange of the diastereotopic protons at the ethyl-methylene, isopropyl-methyl, or benzylic methylene positions for the latter in ^{1}H NMR spectroscopy. The rates of the both processes were in good agreement with each other to indicate that the rate-limiting process in the observed topomerization is the proton-detachment. Thus it is shown that any available probes may be used for the proton-detachment or for the ivestigation of the proton affinity of amines by the dynamic NMR spectroscopy in aprotic solvents. The preference of the probes was discussed.

The knowledge on basicity of amines in aprotic solvents is important in understanding organic reactions, because most of them are carried out in organic solvents and bases are important catalysts in many cases. Although basicity of amines in aqueous solvents has well been documented[2)] and proton affinity of amines in the gas-phase has recently been discussed,[3)] the determination of basicity or proton affinity of amines in organic solvents is not straightforward and lacks general reliability.

In the series of investigation of proton affinity of amines in aprotic solvents by dynamic NMR spectroscopy, we have demonstrated that the dynamic NMR technique is a potentially very useful method in the field of determination of proton affinity of amines in aprotic solvents. In addition to the fact that the proton affinity of the series of *p*-substituted *N*,*N*-dibenzylanilines in chloroform-*d* parallels those of the series of *p*-substituted *N*,*N*-dimethylanilines in water and *p*-substituted anilines in the gas phase,[4)] we have been able to demonstrate that examination of proton affinity of anions derived from strong acids in aprotic solvents is possible by applying the same technique that utilizes a constant amine and a series of acid salts derived therefrom.[5)]

Although this technique is potentially widely applicable, there have remained two points to be clarified before claiming the general applicability. The origin of the problems is that we have used benzylic methylene proton signals, which simultaneously lose coupling and exchange sites on detachment of the proton from the anilinium ion, as a probe in ^{1}H NMR spectroscopy.

The topomerization processes involve three steps, as



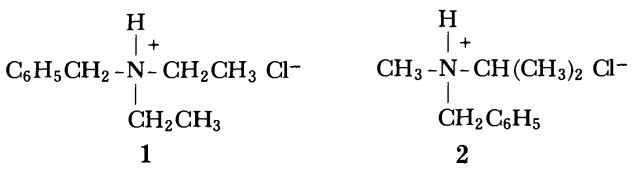
Scheme 1. Topomerization processes

† Present address: Department of Chemistry, Faculty of Science, Okayama University of Science, Ridaicho, Okayama 700.

are shown in Scheme 1: proton detachment, inversion of amine, and proton attachment. In the previous work, it was assumed that the rate-limiting step is the proton detachment because the inversion of amine is a rapid process[6] and proton atachment to amine should also be fast. However, this assumption should be confirmed.

The second problem is that, in the line shape analyses, we have assumed that the coupling constant between the ammonium proton and the benzylic methylene protons in the *N,N*-dibenzylanilinium ions is inversely proportional to the rate of proton detachment at a certain range where the rate is reasonably large, since DNMR3 program[7] does not accommodate the two processes involved. This again remains to be confirmed.

To overcome these problems, it is necessary to compare the rates of true proton-detachment with the rates of topomerization which are not affected by the coupling with the detaching proton. After establishing these rates, we may compare the rates of topomerization that are obtained by observing topomerization with concomitant loss of coupling. Thus we designed molecules that conform with these requirements. They are benzyldiethylammonium chloride (**1**) and benzylisopropylmethylammonium chloride (**2**).



1 **2**

Compound **1** is an example of aliphatic amines that carry two probes. The benzylic methylene protons should show coupling with the ammonium proton as far as the proton sticks to the amino-nitrogen. This probe should provide the rates of proton-detachment, as has been shown by the case of *N,N*-dimethylcyclohexylamine hydrochloride.[8,9] The ethyl-methylene protons are diastereotopic when the proton-detachment is slow and show both site-exchange and loss of coupling with the ammonium proton when the process becomes fast.

Compound **2** provides three probes for the determination of the rates of the observable processes. The coupling of the *N*-methyl protons with the ammonium proton should be lost in the fast exchange limit. The isopropyl-methyls are the probe that should give information of the topomerization but has negligibly small coupling constant with the detaching ammonium proton. Compound **2** also carries benzylic methylene protons that are diastereotopic if the proton detachment is slow, exchange their site on topomerization, and show coupling, that disappears at the fast exchange limit of the ammonium proton, with the ammonium proton at the slow exchange limit. Thus this compound possesses all the necessary probes for comparison of the rate constants.

Syntheses of the compounds in question are straightforward. The hydrochlorides were purified by recrystallization to avoid any complexity arising from the excess of acid or base,[9] and dissolved in 1,1,2,2-tetrachloroethane-d_2. The observed and calculated spectra are shown in Figs. 1 and 2, where the line shapes at the same temperature are arranged along the abscissa for the convenience of comparison. The rate constants thus obtained and temperatures were put into the Eyring equation to afford activation parameters which are compiled in Table 1.

As are clear from both figures, the rate constants obtained with the two probes in **1** and those obtained from the three probes in **2** show satisfactory agreement, the disagreement in the rate constants being generally within 10%. The results confirm that the nitrogen-

inversion in these compounds is indeed fast and the rate-limiting step in the topomerization is the proton-detachment, because the proton-attachment to an amine is believed to be diffusion-controlled and is very fast.[10] They also confirm that the probe which shows both site-exchange and the loss of coupling also gives satisfactory results, although the method involves an assumption about the dependence of the coupling constants on the rate of detachment.

The results also suggest that any of the probes available in these amine hydrochlorides may be used in determining the rates of proton-detachment. This finding is quite useful and extends the scope of application of this technique, because an overlap of the line shapes of the exchanging nuclei with other signals often obscures the calculation results, some of the signals due to the exchanging nuclei may be hidden by other signals, or only one type of probes is available in a given molecule. It is now possible to use any of the probes, the loss of coupling, the site-exchange, and the combination of the both phenomena, in determining the proton affinity of amines in aprotic solvents.

A remaining problem is which probe is prefered when multiple of them are available in a given compound. Our choice is the protons of the isopropyl-methyls like in compound **2**. As is clear from Fig. 2, the change in line shapes is observable at the largest range of temperature if the isopropyl-methyl protons are used as probes. The loss of coupling of the methyl protons in **2** is treated as if the chemical shift difference corresponds to the coupling constant.[11] Since usually the coupling constant is small, i.e. ca. 5 Hz for the

CH-NH^+ protons, coalescence of the signals takes place in a rather small temperature range. In addition, the determination of the transverse relaxation times (T_2) can be problematic in this case because of the simple line shapes as is discussed later. For the diastereotopic proton pair which shows the coupling with the ammonium proton, our approximation forces us to use rather a small temperature range as well. In principle, it is possible to treat the line shapes of this kind of probes by analyzing the loss of coupling first and applying the extrapolated coupling constants to the calculation of the site exchange of the diastereotopic protons, but this procedure is tedious and does not guarantee the reliable data. The discussion presented here favors the use of isopropyl-methyl protons due to the fact that the more rate constants are available than the coupling and coupling-site-exchange cases to make the Eyring plot more reliable.

There is still another point for the preference of the isopropyl-methyl probe. That is, the more complex signals give the more reliable data in the line shape analysis owing to the multitude of checking points in the simulation.[12,13] The simpler line shapes are known to tend to produce large errors especially in entropy of activation. Since coupling with the ammonium proton gives a simple two-singlet pattern, the reliability of the line shape analysis must be considered carefully. The small errors in the activation parameters obtained from the methyl signals in **2** is rather fortuitous, The benzylic methylene signals in **2** should be better than those due to the methyl protons, but the assumption we made seems to deteriorate the quality of the data to some extent.

As the results of these factors, the kinetic parameters obtained from the isopropyl-methyl probes in **2** contain the smallest errors among those obtained here (see Table 1). The errors in the kinetic parameters obtained from the benzylic methylene probe are rather large owing to the approximation we employed. The method cannot avoid the ambiguity in determining the coupling constants and the rate constants (see Experimental part).

Compound **1** casts an additional problem to us. That is, the exchange of the sites of the methylene protons in the ethyl groups is in principle that of $ABL_3X \rightleftarrows BAL_3X$, in addition to the loss of coupling on proton-detachment. This exchange is too complicated for our program. Therefore, we irradiated the the ammonium proton to simplify the exchange to $ABX_3 \rightleftarrows BAX_3$. This operation might cause some error in the line shapes. Since this kind of operation has not been carried out, to our knowledge, in the dynamic NMR study, it was desired to confirm its reliability. If the technique does not involve problems, it will be both convenient and reliable, because the complexity of the signals will guarantee good quality of data.

In order to check the influence on the kinetic parameters given by decoupling operations, we carried out the measurement of the line shapes due to benzylic methylene protons in **2** with irradiation at the ammonium proton frequency. The rate constants were obtained as follows as the results of line shape analysis (rate constants in s^{-1} and temperatures in °C in parentheses are given): 10.0 (82.8), 15.6 (85,3), 20.6 (87.7), 28.8 (90.2), 55.0 (95.1), 76.4 (97.6). Activation parameters derived from these data are given in Table 1 as well. The agreement is excellent with those derived by using other probes and the correlation coefficient satisfactory. The results confirm that the line shape analysis using those produced by decoupling is a satisfactory method.

The feature of the kinetic parameters in Table 1 is very large, positive entropies of activation. The similar values have been obtained for *p*-substituted *N,N*-dibenzylanilinium halides[4,5] and for [*o*-(diethylaminomethyl)phenyl]halodimethylstannanes.[14] Large, positive entropies of activation seem to be general in the process when one goes from the ionic ground state to the less ionic transition state, The freedom of motion of solvent molecules must increase in the transition state in these cases.

Close examination of the data in Table 1 reveals that compond **2** gives a larger entropy of activation than **1** which in turn gives a larger entropy of activation than the *N,N*-dibenzylanilinium chloride (18—24 cal mol^{-1} K^{-1}).[4] This will probably mean that the transition state for the proton-detachment in an ammonium ion derived from a strong base is later than in that derived from a weak base. The apparent trend we have seen in the series of *N,N*-dibenzylanilinium chlorides, namely the trend that a weak base gives a larger entropy of activation for the proton-detachment than a strong,[4] is now concluded not significant. The fortuitous trend was caused by the errors involved in the line shape analysis of the benzylic methylene proton signals which simultaneously lose coupling and exchange sites on proton-detachment.

Experimental

Materials. *N,N*-Diethylbenzylamine, bp 60—62 °C/3.5 mmHg (1 mmHg=133.322 Pa) (lit,[15] bp 211—212 °C), was prepared by a standard method starting from benzyl chloride and diethylamine. ^{1}H NMR ($CDCl_3$) δ=1.01 (6H, t, J=7.0 Hz), 2.49 (4H, q, J=7.0 Hz), 7.1—7.4 (5H, m). *N*-Isopropyl-*N*-methylbenzylamine, bp 60—62 °C/3.5 mmHg, was prepared by formylation of *N*-isopropylbenzylamine by a standard method and by reduction of the resulting formyl compound with lithium tetrahydridoaluminate. ^{1}H NMR ($CDCl_3$) δ=1.07 (6H, d, J=7.0 Hz), 2.13 (3H, s), 2.86 (1H, sept, J=7.0 Hz), 3.84 (2H, s), 7.2—7.4 (5H, m).

The hydrochlorides of the amines were prepared by dissolving them in hexane and introducing hydrogen chloride gas into the solution. The precipitates thus obtained were recrystallized from tetrahydrofuran.

Benzyldiethylammonium Chloride (1), mp 182—183 °C. Found: C, 66.22; H, 8.97; N, 7.05; Cl, 17.80%, Calcd for

$C_{11}H_{18}ClN$: C, 66.15; H, 9.08; N, 7.01; Cl, 17.75%. ^1H NMR ($CDCl_3$) δ=1.46 (6H, t, J=7.3 Hz), 3.07 (4H, m), 4.16 (2H, d, J=5.3 Hz), 7.4—7.7 (5H, m), 12.43 (1H, br s).

Benzylisopropylmethylammonium Chloride (2), mp 126—127 °C. Found: C, 66.01; H, 9.02; N, 7.10; Cl, 17.65%. Calcd for $C_{11}H_{18}ClN$: C, 66.15; H, 9.08; N, 7.01; Cl, 17.75%. ^1H NMR ($CDCl_3$) δ=1.36 (3H, d, J=6.4 Hz), 1.52 (3H, d, J=6.4 Hz), 2.63 (3H, d, J=4.8 Hz), 3.49 (1H, m), 4.15 (2H, m), 7.4—7.8 (5H, m), 12.27 (1H, br s).

Dynamic NMR Spectral Study. The spectral measurement was carried out with either a JEOL FX-200 or JEOL GX-270 spectrometer. Since we used a spectrometer that operated at 60 MHz for the determination of rates of proton-detachment in *N,N*-dibenzylanilinium halides,[4,5] the 200 MHz machine was more convenient for comparison due to the fact that the 270 MHz machine gave apparently different line shapes because of the larger chemical shift differences. Samples were dissolved in 1,1,2,2-tetrachloroethane-d_2, which was dried over Molecular Sieves 4A, to make up ca. 50 mmol L^{-1} solutions.

Temperature was determined by a thermocouple. The chemical shift differences of the exchanging nuclei and coupling constants were checked at the slow exchange limits. All the coupling constants were found to be temperature-independent, whereas the chemical shift differences changed linearly with the temperature. The chemical shift differences were at least checked at four temperatures to find that they were linearly correlated with temperature, except for the isopropyl-methyl proton signals, of which chemical shift differences were temperature-independent. The results are shown in Table 2. These straight lines were extrapolated to the temperatures where the change in line shapes was observed. The simulation was carried out with the use of DNMR3 program.[7] T_2 was estimated from the line width due to the undeuterated solvent molecules and was adjusted to give the best fit in simulation for the line shapes involved in the site-exchange. Thanks to the complexity of the signals, changes in T_2 and rate constant k gave different effects on the line shapes in these cases, as were observed in other complex signals,[16] thus enabling us to determine T_2 and k uniquely.

For the simulation of the exchanging benzylic methylene proton signals, ABX⇄BAX, that lose coupling on dissociation of the ammonium proton was performed in the following way. At the coalescence temperature where the quadruplet-doublet became a broad quadruplet, the rate constant of the proton-detachment and the J_{AX} and J_{BX} values, the rough values of which were estimated from those at low temperatures, were used as variants and the T_2 and the chemical shift differences between A and B, which could be derived as above, were taken as given. The best fit values of the rate constant and the coupling constants were sought in the simulation of the line shapes. After determining the rate constant at the temperature, then the coupling constants, J_{AX} and J_{BX}, were treated as inversely proportional to the rate constant of proton-detachment. The obtained rate constants were doubled for comparison with the data obtained from the loss of coupling because the topomerization takes place only when the proton attaches to the amine after inversion of the amine and the attachment at the same configuration is not counted in the topomerization.

Table 2. Equations Correlating the Chemical Shift Differences and Temperature in Given Probes in **1** and **2**

Compound	Probe	$f(T)$[a]	External magnetic field
			MHz
1	$CH_3\underline{CH_2}$	42.9−0.040T	270
2	$(\underline{CH_3})_2CH$	26.5±0.000T	200
	$C_6H_5\underline{CH_2}$	−63.8+0.235T	200
	$C_6H_5\underline{CH_2}$[b]	−85.2+0.313T	270

a) $f(T)$ for $\Delta\nu$/Hz=$f(T)$/K. b) Decoupled with the ammonium proton.

For the simulation of the line shapes which change owing to the detachment of the ammonium proton, the principle established for methylamine in dilute hydrochloric acid[11] was used. The spin-spin coupling constants were invariant within the slow exchange limit. T_2 was estimated from the line width of the undeuterated solvent peak and this value was used throughout the simulations of the spectra at various temperatures. Since the changes in k and T_2 gave similar trends in the modification of the line shapes, there remains ambiguity in the rate constants thus obtained to some extent.

For the decoupled measurements, care was exercised for not affecting the line shapes in the slow exchange limit. The irradiation of the ammonium proton was carried out at the center of the broad signal. The irradiation power was IRATN 130.

The measurement of the ^1H NMR spectra at 200 MHz was carried out at Showa Denko Company, Ltd. We wish to thank for the permission of the use of the instrument. The work was supported by a Grant-in-Aid (No. 61134043) for Fundamental Scientific Research of the Ministry of Education, Science and Culture.

Dynamic NMR as a Nondestructive Method for Determination of Rates of Dissociation. XV. Dissociation of Thioether and Ether Ligands in Tin(IV) and Boron Complexes and Significance of Entropy of Activation Therein[1)]

Michinori Ōki*,† and Yasuhisa Yamada

(Received November 5, 1987)

The rates of dissociation of thioether ligands which are imbedded in organotin(IV) compounds, such as trichloro[*o*-(ethylthiomethyl)phenyl]stannane, were determined by the dynamic NMR method. The dynamic processes of the corresponding ether ligands was too fast to detect as the change in line shapes in ^{1}H NMR spectra. All the boron compounds examined, which possessed similar structures to the stannane and were of the boronate type, failed to show dissociation of a thioether or ether ligand due to their large rates of dissociation. The rates of dissociation of a thioether-tribromoboron complex were determined by the same technique. The feature of the activation parameters was that the compounds examined exhibited fairly large positive entropy of activation in accordance with other results that involve dissociation of ionic species into covalent species.

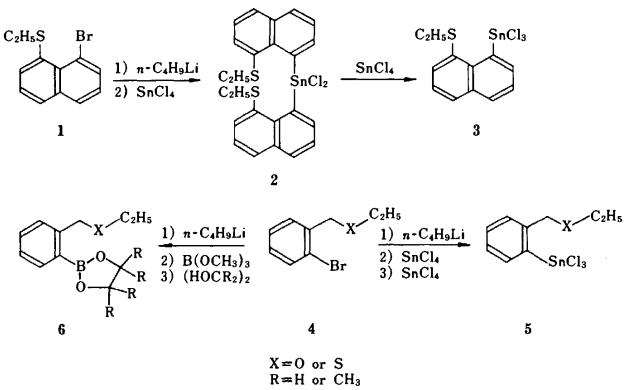
The mechanism of sulfur inversion in sulfur-ligands in platinum(II) complexes attracted interests of some investigators. It seemed generally accepted that the inversion took place without breaking the Pt-S bond.[2)] However, it was shown recently that sulfur-ligands in platinum complexes could dissociate under certain circumstances.[3)] We felt therefore that it would be worthwhile to provide a methodology of diagnosing the mechanism of sulfur-inversion in coordination compounds.

Our experience shows that, if dissociation takes place from an ionic ground state via more or less covalent transition state, the entropy of activation should be large positive, and, if the ground state is covalent and the transition state is ionic, the entropy of activation is large negative.[4)] Since thioether-platinum(II) complexes can be considered to possess an ionic ground state and the transition state for dissociation of the ligand is of covalent character, it is expected that, if the dissociation is the rate determining step in the sulfur-inversion, the entropy of activation is large positive whereas it will be near-zero, if a simple sulfur-inversion takes place.

Indeed, there is a literature that reports the entropy of activation is very small in sulfur-inversion in a platinum(II)-thioether complex.[5)] This result might be taken as evidence for the sulfur-inversion without breaking of the Pt-S bond, but there are several points to be considered before concluding in that way. Firstly, the examples that show nearly-zero entropy of activation in the sulfur-inversion in platinum-sulfur complexes are too few in literature. Secondly, the compound examined in the literature contained two thioether ligands that might affect observation of the sulfur-inversion processes. Thirdly, for not only the cases of platinum complexes, examples of reported entropy of activation are too few. Dissociation of boron-ether[6)] or boron-ketone[7)] complexes as investigated by the dynamic NMR technique has been reported, but the free energy of activation was obtained at only one point of temperature. There is also a literature that reports sulfur-inversion in a thioether-trichloroboron complex,[8)] but the results are again obtained at one temperature.

We felt on the above backgrounds that at least some examples should be provided before concluding the relationship between the entropy of activation and the mechanism of sulfur (or oxygen) inversion that is simple and causes no ambiguity about the conclusion. Thus we have examined a case that is purely sulfur-inversion that gives near-zero entropy of activation both by classical[9)] and dynamic NMR[10)] methods. In this paper we wish to report that the entropy of activation for the sulfur-inversion of which mechanism is supposed to be dissociative indeed is large, positive.

The compounds of which rates of sulfur-inversion were examined by the dynamic NMR technique were prepared in the following way. 1-Bromo-8-ethylthionaphthalene (**1**) which was prepared by a standard diazotization and substitution reaction of 8-bromo-1-naphthalenamine was lithiated with butyllithium and was then treated with tin(IV) chloride. This operation afforded dichlorobis(8-ethylthio-1-naphthyl)stannane (**2**), as are observed in other similar reactions. Com-

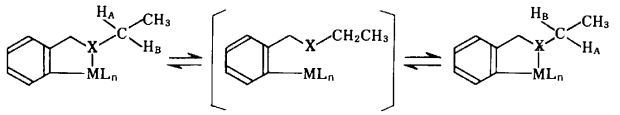


† Present address: Department of Chemistry, Faculty of Science, Okayama University of Science, Ridaicho, Okayama 700.

pound **2** was treated with excess of tin(IV) chloride to give trichloro(8-ethylthio-1-naphthyl)stannane (**3**).[11]

The syntheses of trichloro[(*o*-ethoxymethyl)phenyl]-stannane (**5**: X=O) and the thio analog (**5**: X=S) were performed similarly from *o*-bromo[ethoxy(or ethylthio)methyl]benzene (**4**). Treatment of **4** with butyllithium followed by methyl borate and then a 1,2-diol afforded 2-[*o*-ethoxy(or ethylthio)methylphenyl]-1,3,2-dioxaborolane (**6**: X=O or S, R=H or CH_3).

The selection of the compounds bases on our principle that a diastereotopic pair of protons exchange their sites on dissociation followed by racemization and recombination.[12] The methylene or gem-dimethyl protons act as probes because they are diastereotopic as far as the ligand sticks to the metalloid center. It is possible that the sulfur-inversion takes place without breaking the sulfur-metalloid bond. But if it were the case, the entropy of activation would be close to zero as were the cases of pure sulfur-inversion.[9,10,13]



Scheme 1. A typical site-exchange process for the diastereotopic methylene protons by dissociation.

The methylene protons of the ethyl group in compound **3** showed a typical A_2 pattern of an A_2X_3 system. When the temperature was lowered to −90 °C, the signal began to broaden at 270 MHz, but the complete decoalescence of the signal was not observed. Although it is difficult to mention the exact free energy of activation for the process without knowing the chemical shift difference of the A and B protons, the rough estimate of the free energy of activation for the process is 8—10 kcal mol^{-1} (1 cal=4.184 J) at −90 °C. In contrast, compound **5** (X=S) showed the change in line shapes at and below −65 °C and the line shapes at −90 °C and below indicated that it was in the slow exchange limit. The total line shape analysis of the spectra afforded the rate constants shown in Table 1 and putting these rate constants and temperatures into the Eyring equation afforded the following kinetic parameters: $\Delta H^{\ddagger}$=12.7±0.2 kcal mol^{-1}, $\Delta S^{\ddagger}$= 13.3±1.0 cal mol^{-1} K^{-1}, $\Delta G^{\ddagger}_{273}$=9.1 kcal mol^{-1}. The low energy barrier to the process observed for **3** relative to **5** can be ascribed to the strain in the coordinated form of **3** relative to **5**, because the skeleton of the molecule is more rigid because of the presence of the naphthalene nucleus than in **5**.

The oxygen compound (**5**: X=O) failed to show any line broadening even at −50 °C where compound **5** (X=S) showed the line-broadening. We judge that the dynamic process for the oxygen-tin complex is much faster than that in the sulfur compound. This is in accordance with the fact that the $(CH_3)_2O$-$TiCl_4$ complex is less stable than the $(CH_3)_2S$-$TiCl_4$.[14]

All the boron compounds (**6**: X=O or S, R=H or CH_3) failed to show line broadening at −90 °C at 270 MHz. Therefore the barrier to the dynamic process that we expected to observe was apparently very low. We believe this observation owes to two factors. The first is that the formation of 5-membered ring will cost some energy because of the short bond distances involving the boron atom and the second is that boron acidity in boronates is lower than that of boron trihalide or trialkylborane due to the 2p-2p conjugation between the oxygen and the boron atoms.[15] The latter factor may be more effective than the former in lowering the barrier to the process, because dissociation of amine ligands in the similar compounds has been reported.[16,17]

Thus for the boron compound, we chose an intermolecular complex for the investigation, where boron which carries electronegative substituents can be easily used. As a sulfide, we used 3,3,4,4-tetramethylthiolane that had been made by us.[9] Tribromoboron was our choice because of easy handling. Thus compound **7**, 3,3,4,4-tetramethylthiolane-tribromoboron complex, was made. The reason for the selection of compound **7** is that the two pairs of the gem-dimethyl protons can be used as probes for the dissociation: although the gem-protons alpha to the sulfur atom in a sulfide can be diastereotopic on ligation of the sulfide to a boron compound, they show very complex signals because of coupling with ^{10}B and ^{11}B.

Table 1. Rate Constants (Temperature in °C) of M-S Bond Dissociation as Determined by Dynamic NMR Spectroscopy

Compound	k/s^{-1} (Temp/°C)
5	12.0 (−80.9), 18.0 (−78.4), 28.0 (−75.9), 43.0 (−73.4), 65.0 (−70.9), 98.0 (−68.3), 142.0 (−65.8)
7[a]	3.0 (4.8), 4.3 (7.3), 6.1 (9.9), 8.7 (12.4), 12.4 (14.8), 17.1 (17.4), 23.0 (19.9), 32.4 (22.4)
7[b]	3.0 (4.8), 4.3 (7.2), 6.1 (9.8), 8.7 (12.3), 12.3 (14.8), 17.1 (17.4), 23.0 (19.8), 32.4 (22.4)

a) 20% excess of BBr_3 added. b) 10 molar excess of BBr_3 added.

Compound **7** dissociated to ca. 5% into the sulfide and tribromoboron in chloroform-*d* at −50 °C, as found by ^{1}H NMR spectrum at 270 MHz. Since excessive sulfide can cause S_N2 type substitution in addition to dissociative mechanisms, as was the case of ether-borane complexes,[6] we added excess of tribromoboron to the solution: if the excess of the boron compound affects the dissociation rates, extrapolation to the zero excess of the Lewis acid should give intrinsic rates of dissociation of the sulfur-boron complex. The results are given in Table 1, where only two extreme values are shown. At other points of excess of the boron compound, the rate constants were the same with those listed in the table. Putting these parameters to the Eyring equation, we obtain the following activation parameters: $\Delta H^{\ddagger}$=21.5±0.4 kcal mol^{-1}, $\Delta S^{\ddagger}$=21.0±1.4 cal mol^{-1} K^{-1}.

The feature of the kinetic parameters for both compounds **5** (X=S) and **7** is that the entropy of activation is both large positive, although the enthalpy of activation is different. This makes a sharp contrast to the case of pure sulfur-inversion that gives near-zero entropy of activation. The results are in agreement with others in that the entropy of activation is positive when the ground state is of ionic character and the transition state for dissociation reduces the ionic character. The generality of the rule thus encompasses the coordination complexes that contain sulfur ligands.

Experimental

Dynamic NMR Spectroscopy. All the ^{1}H NMR spectra were recorded on a JEOL GX-270 NMR spectrometer operating at 270 MHz. The temperature indicated on the temperature setting of the machine was calibrated by a thermocouple. A sample was dissolved in an appropriate solvent to make up ca. 50 mmol L^{-1} solutions. The solvent was dichloromethane-d_2 in the case of intramolecularly ligating stannane and borane compounds and it was chloroform-*d* for compound **7**. When 20% excess of tribromoboron was added to the chloroform-*d* solution of **7**, no signal attributable to the free sulfide was observed. The spin exchange was treated as AB $\rightleftarrows$ BA with no coupling for compound **7** and $ABX_3 \rightleftarrows BAX_3$ for compound **5** and the line shapes were simulated with the use of DNMR3 program.[18] The chemical shift differences of the methyl signals (A and B) in compound **7** drifted a little according to temperatures of observation and the linear relation was obtained between the former and the latter in the slow exchange limit: $\Delta\nu$/Hz=0.016t/°C+12.5 for the cases of small excess of tribromoboron and $\Delta\nu$/Hz=0.016t/°C+12.3 for the case where tribromoboron was of 10 molar excess. In the case of compound **5**, the chemical shift differences between A and B protons and between A and X protons were constant in the slow exchange limit at 99.6 and 364 Hz, respectively. The coupling constants, J_{AB} and J_{AX}=J_{BX}, for compound **5** were constant at −13.6 and 7.3 Hz, respectively, throughout the temperature range examined. These results were extended to the temperature range, where line broadening and coalescence took place, in calculation of the spectra. T_2 was estimated to be 0.10 s for compound **5** and 0.16 s for **7** and these values were used throughout the simulation of the line shapes. The best fit between the observed and the calculated spectra were obtained by visual fitting. The agreement between them was satisfactory. The rate constants thus obtained were put into the Eyring equation to produce the activation parameters.

1-Bromo-8-ethylthionaphthalene (1). 1-Amino-8-bromonaphthalene[19] (5.00 g or 22.5 mmol) was dissolved in 50 mL of water and 6 mL of concentrated hydrochloric acid by heating. To the cooled mixture, was added a solution of 1.6 g (23 mmol) of sodium nitrite in 10 mL of water with shaking. The diazotized solution was neutralized by adding aqueous sodium acetate with cooling and filtered. The solution was added at 40 °C to an aqueous solution of sodium ethanethiolate prepared from 1.0 g (25 mmol) of sodium hydroxide, 50 mL of water and 1.6 mL (22 mmol) of ethanethiol. The mixture was heated to 90 °C and stirred at that temperature for 2 h. The cooled mixture was extracted with benzene, and the extract was washed with water. After drying over magnesium sulfate, the solvent was evaporated and the residue was submitted to chromatography on silica gel with hexane as an eluent. The desired product was obtained in 46.7% yield after recrystallization from hexane, mp 47.0—48.0 °C. Found: C, 53.75; H, 4.08%. Calcd for $C_{12}H_{11}BrS$: C, 53.95; H, 4.08%. ^{1}H NMR ($CDCl_3$) δ=1.36 (3H, t, J=7.6 Hz), 2.93 (2H, q, J=7.6 Hz), 7.1—7.9 (6H, m).

Dichlorobis(8-ethylthio-1-naphthyl)stannane (2). To a solution of 2.40 g (8.98 mmol) of the bromo compound **1** in 80 mL of ether was added 7.5 mL (11 mmol) of a ca. 1.5 mol L^{-1} hexane solution of butyllithium at −30 °C under a nitrogen atmosphere. The mixture was allowed to stand so that the temperature slowly rose until the temperature became ambient. The solution was transfered to a dropping funnel through a Teflon tube and added to a solution of 2 mL (17 mmol) of tin(IV) chloride in 100 mL of benzene at room temperature. After the reaction was continued for an additional hour at the temperature, the solvent was evaporated. Recrystallization of the residue from dichloromethane-hexane afforded the desired compound, mp 225.5—226.5 °C, in 67% yield. Found: C, 50.83; H, 3.66; Cl, 12.57; S, 11.47%. Calcd for $C_{24}H_{22}Cl_2S_2Sn$: C, 51.10; H, 3.93; Cl, 12.57; S, 11.37%. ^{1}H NMR ($CDCl_3$) δ=0.89 (6H, t, J=7,7 Hz), 2.70 and 3.00 (4H, AB part of ABX_3, J_{AB}=12.0 Hz, J_{AX}=J_{BX}=7.7 Hz), 7.4—8.1 (10 H, m), 8.86 (2H, dd, J=6.9 and 1.3 Hz).

Trichloro(8-ethylthio-1-naphthyl)stannane (3). A solution of 1.70 g (3.01 mmol) of the diaryldichlorostannane (**2**) and 1 mL (9 mmol) of tin(IV) chloride in 80 mL of toluene was heated under reflux for 12 h under a nitrogen atmosphere. The solvent was evaporated and the residue was extracted with hot hexane. Cooling the hexane extract afforded crystals. Recrystallization of the product from dichloromethane-hexane gave a pure sample, mp 108.5—109.5 °C. Found: C, 34.89; H, 2.76; Cl, 25.99; S, 7.85%. Calcd for $C_{12}H_{11}Cl_3SSn$: C, 34.96; H, 2.69; Cl, 25.79; S, 7.78%. ^{1}H NMR ($CDCl_3$) δ=1.23 (3H, t, J=7.4 Hz), 2.96 (2H, q, J=7.4 Hz), 7.5—8.2 (5H, m), 8.58 (lH, d, J=7.2 Hz).

Dichlorobis[2-(ethylthiomethyl)phenyl]stannane, mp 174.5—175.5 °C, was obtained by similar treatment of 1-bromo-2-(ethylthiomethyl)benzene[20] as described in the preparation of **2** in 45% yield. Found: C, 43.44; H, 4.50; Cl, 15.42%. Calcd for $C_{18}H_{22}Cl_2S_2Sn$: C, 43.93; H, 4.51; Cl, 14.41%. ^{1}H NMR ($CDCl_3$) δ=0.99 (6H, t, J=7.5 Hz), 2.37 (4H, q, J=7.5 Hz), 4.11 (4H, s), 7.2—7.5 (6H, m), 8.2—8.3 (2H, m).

Trichloro[2-(ethylthiomethyl)phenyl]stannane (**5**: X=S), mp 108.5—109.5 °C, was similarly obtained by treating the diaryldichlorostannane with $SnCl_4$ in 79% yield. Found: C, 28.49; H, 2.95; Cl, 27.92%. Calcd for $C_9H_{11}Cl_3SSn$: C, 28.73; H, 2.95; Cl, 28.26%. ^1H NMR ($CDCl_3$) δ=1.28 (3H, t, J=7.4 Hz), 2.40 (2H, q, J=7.4 Hz), 4.10 (2H, s), 7.4—7.7 (3H, m), 8.1—8.2 (1H, m).

Dichlorobis[2-(ethoxymethyl)phenyl]stannane was similarly prepared from 1-bromo-2-(ethoxymethyl)benzene.[21] The product was recrystallized from dichloromethane-hexane to give 46% of the desired product, mp 194.0—195.0 °C. Found: C, 46.78; H, 4.92; Cl, 15.45%, Calcd for $C_{18}H_{22}Cl_2O_2Sn$: C, 47.00; H, 4.82; Cl, 15.42%. ^1H NMR ($CDCl_3$) δ=0.92 (6H, t, J=6.9 Hz), 3.37 (4H, q, J=6.9 Hz), 4.70 (4H, s), 7.1—7.5 (6H, m), 8.3 (2H, m).

Trichloro[2-(ethoxymethyl)phenyl]stannane (**5**: X=O), mp 130.5—132.0 °C, was similarly prepared as for the preparation of **3** in 67% yield. The analytical sample was obtained by recrystallization from hexane. Found: C, 29.73; H, 3.21; Cl, 29.44%. Calcd for $C_9H_{11}Cl_3OSn$: C, 30.01; H, 3.08; Cl, 29.52%. ^1H NMR ($CDCl_3$) δ=1.44 (3H, t, J=7.0 Hz), 4.15 (2H, q, J=7.0 Hz), 4.81 (2H, s), 7.4 (1H, m), 7.5—7.6 (2H, m), 8.0—8.1 (1H, m).

2-[2-(Ethylthiomethyl)phenyl]-4,4,5,5-tetramethyl-1,3,2-dioxaborolane (**6**: X=S, R=CH_3). To a solution of 4.03 g (17.4 mmol) of 1-bromo-2-(ethylthiomethyl)benzene[21] in 50 mL of ether was added 12.2 mL (18.3 mmol) of a ca. 1.5 mol L^{-1} hexane solution of butyllithium at −78 °C under a nitrogen atmosphere. The mixture was allowed to warm slowly up to room temperature and then transferred to a dropping funnel through a Teflon tube. The mixture was added to 3.4 mL (30 mmol) of trimethyl borate in 50 mL of ether at −78 °C and allowed to warm slowly up to the room temperature. Water (10 mL) and then 10 mL of dilute sulfuric acid were added to the mixture and the ether layer was separated. The aqueous layer was extracted with ether and the combined ether layers were washed with water. The solvent was evaporated and the residue was mixed with 2.0 g (17 mmol) of 2,3-dimethyl-2,3-butanediol and 150 mL of toluene. The mixture was heated with a Dean-Stark apparatus for 2 h. The mixture was then fractionally distilled to give the desired product, bp 128.0—130.0 °C/3 mmHg (1 mmHg=133.322 Pa). The yield was 1.8 g (37%). Found: C, 64.85; H, 8.51; S, 11.66%. Calcd for $C_{15}H_{23}BO_2S$: C, 64.76; H, 8.33; S, 11.52%. ^1H NMR ($CDCl_3$) δ=1.17 (3H, t, J=7.5 Hz), 2.38 (2H, q, J=7.5 Hz), 1.40 (12H, s), 4.01 (2H, s), 7.2—7.3 (3H, m), 7.7—7.8 (1H, m).

2-[2-(Ethylthiomethyl)phenyl]-1,3,2-dioxaborolane (**6**: X=S, R=H), bp 114—115 °C/3 mmHg, was similarly prepared by treating 2-(ethylthiomethyl)phenyllithium with trimethyl borate and then with acidic water followed by ethylene glycol in 55% yield. Found: C, 59.45; H, 6.94; S, 14.09%. Calcd for $C_{11}H_{15}BO_2S$: C, 59.48; H, 6.81; S, 14.09%. ^1H NMR ($CDCl_3$) δ=1.19 (3H, t, J=7.4 Hz), 2.40 (2H, q, J=7.4 Hz), 4.00 (2H, s), 4.37 (4H, s), 7.1—7.3 (3H, m), 7.7—7.8 (1H, m).

2-[2-(Ethoxymethyl)phenyl]-1,3,2-dioxaborolane (**6**: X=O, R=H), bp 95—105 °C/4 mmHg, was similarly prepared from 1-bromo-2-(ethoxymethyl)benzene[21] as for the preparation of **6** (X=S, R=CH_3) in 46% yield. The distillate solidified and was recrystallized from dichloromethane-hexane to afford a pure sample, mp 50.0—51.0 °C. Found: C, 64.23; H, 7.06%. Calcd for $C_{11}H_{15}BO_3$: C, 64.12; H, 7.34%. ^1H NMR ($CDCl_3$) δ=1.24 (3H, t, J=6.9 Hz), 4.56 (2H, q, J=6.9 Hz), 4.38 (4H, s), 4.74 (2H, s), 7.2—7.5 (3H, m), 7.8 (1H, m).

3,3,4,4-Tetramethylthiolane-Tribromoboron Complex (7). To a solution of 0.20 g (0.14 mmol) of the thiolane[9] in 1 mL of dichloromethane was added 0.15 mL (0.16 mmol) of tribromoboron at −78 °C and then dry hexane to give precipitates. The supernatant liquid was removed by a syringe and the residue was recrystallized from dichloromethane-hexane. This compound began to decompose at 118 °C, as indicated by the sublimed crystals of the thiolane, and then the decomposition was complete at 170—192 °C. Found: S, 7.76%. Calcd for $C_8H_{16}BBr_3S$: S, 8.12%. ^1H NMR ($CDCl_3$, −50 °C) δ=1.10 (6H, s), 1.14 (6H, s), 3.1—3.6 (4H, m). An additional peak attributable to free thiolane at δ 0.96 (ca. 5%) was observed under the conditions.

(Received June 6, 1987)

Several 9-substituted 9-(2-methylthiophenyl)fluorene derivatives and their oxidation products, 9-substituted 9-(2-methylsulfinylphenyl)fluorene derivatives were prepared. Each equilibrium constant was investigated and the conformational equilibria *ap* ⇄ *sp* of these compounds were discussed on the basis of nonbonding intramolecular interactions (attraction or repulsion) between 2-substituents in phenyl moieties (methylthio or methylsulfinyl) and fluorene ring or 9-substituents. It was found that the conformational equilibria were effected by the electronic properties of methylthio and methylsulfinyl groups. Kinetic data for internal rotation of a few compounds were shown.

9-(2-Substituted phenyl)fluorene derivatives have been the subject of recent interest because of their high barriers to rotation about the C(9)-C(Ar) bond; many important stereochemical effects have been found in these systems.[2,3] We have also investigated the restricted rotation about the C(9)-C(Ar) bonds in 9-substituted 9-(2-methylphenyl)fluorene derivatives[4] and 9-(2-methoxyphenyl)fluorene derivatives.[5] In the present paper, we wish to report on the syntheses of some 9-substituted 9-(2-methylthiophenyl)fluorene derivatives and their oxidation products, 9-substituted 9-(2-methylsulfinylphenyl)fluorene derivatives, and to discuss the conformational equilibria of these compounds on the basis of nonbonding intramolecular interactions between 9-substituents and the 2-methylthio or 2-methylsulfinyl group.

Results and Discussion

Preparation of 9-Substituted 9-(2-Methylthiophenyl)-fluorene Derivatives. The treatment of fluorenone with 2-methylthiophenyllithium, which was prepared by the reaction of 2-methylthiobromobenzene[6] and butyllithium in ether, followed by hydrolysis, afforded 9-(2-methylthiophenyl)-9-fluorenol (**1**). Bubbling hydrogen bromide into a solution of **1** in acetic acid gave 9-bromo-9-(2-methylthiophenyl)fluorene (**2**); then, **2** was refluxed in methanol or ethanol to give 9-methoxy- (**3a**) or 9-ethoxy-9-(2-methylthiophenyl)-fluorene (**3b**), respectively. The reduction of **1** with hydriodic acid gave 9-(2-methylthiophenyl)fluorene (**4**). 9-Lithio compound **5** was obtained from **4** and butyllithium, and then converted directly to 9-methyl- (**6a**) or 9-ethyl-9-(2-methylthiophenyl)fluorene (**6b**) by treating with methyl iodide or ethyl iodide, respectively. 9-(2-Methylthiophenyl)-9-fluorenecarboxylic acid (**7**) was prepared by the treatment of **5** with Dry Ice in ether. After heating **7** with thionyl chloride at 50 °C, methanol was added to afford 9-methoxycarbonyl-9-(2-methylthiophenyl)fluorene (**8**). Upon continuous heating of **7** with thionyl chloride at 80 °C, a ring compound, spiro[benzo[*b*]thiophene-3(2*H*),9′-fluoren]- 2-one (**10**) was obtained. 9-Acetyl- (**9a**) and 9-benzoyl-9-(2-methylthiophenyl)fluorene (**9b**) were obtained by the treatment of **5** with acetic anhydride and benzoyl chloride in ether, respectively. 9-Substituted 9-(2-methylthiophenyl)fluorene derivatives **1**—**9** are shown in Scheme 1.

Scheme. 1.

Preparation of 9-Substituted 9-(2-Methylsulfinylphenyl)fluorene Derivatives. Some of the 9-substituted 9-(2-methylthiophenyl)fluorene derivatives were converted to 9-substituted 9-(2-methylsulfinylphenyl)-fluorene derivatives by oxidation with nitric acid (d=1.38). That is, 9-(2-methylsulfinylphenyl)-9-fluorenol (**11**) was prepared by the reaction of **1** with nitric acid in acetic acid at 10—20 °C. In this case, when the reaction temperature was raised to 50 °C, a ring closed compound, spiro[3*H*-2,1-benzoxathiole-3,9′-fluorene] 1-oxide (**16**), was obtained. The reactions of **3a** and **3b** with nitric acid in acetic acid at 10—20 °C afforded 9-methoxy- (**12a**) and 9-ethoxy-9-(2-methylsulfinylphenyl)fluorene (**12b**), respectively. Then, **4** was treated with nitric acid under the same reaction conditions to give 9-(2-methylsulfinylphenyl)fluorene (**13**). Furthermore, the oxidation of **6a** by nitric acid was

carried out at 35—45 °C in acetic acid to afford 9-methyl-9-(2-methylsulfinylphenyl)fluorene (**14**). Reactions of **9a** and **9b** with nitric acid in acetic acid were carried out at 35—45 °C to give 9-acetyl-(**15a**) and 9-benzoyl-9-(2-methylsulfinylphenyl)fluorene (**15b**), respectively. These results are shown in Table 1.

Conformational Equilibria of 9-Substituted 9-(2-Methylthiophenyl)fluorene Derivatives. Previously, we discussed the conformations of 9-substituted 9-(2-methylphenyl)- and 9-substituted 9-(2-methoxyphenyl)fluorene derivatives on the basis of their 2-methyl and 2-methoxyl signals in ^1H NMR at low or room temperature.

In this case, the conformations of 9-(2-methylthiophenyl)fluorene derivatives were investigated on the basis of 2-methylthio signals in ^1H NMR at 50—40 °C. The NMR data for these signals are illustrated in Fig. 1. These compounds can be clearly classified into three groups: The first group includes compounds **2**, **6a**, and **6b** in which the signals for methylthio groups appear at a high field; the second includes compounds, **4**, **7**, **8**, **9a**, and **9b** in which the signals for methylthio groups are observed in a low field; the third contains the compounds, **1**, **3a**, and **3b** in which the signals for methylthio groups are found in a middle field.

The compounds that belong to the third group (9-substituents: OH, OCH_3, OC_2H_5) showed a broad singlet for methylthio protons at room temperature. As

ap-form *sp*-form

Y: OH, OCH_3, OC_2H_5

Fig. 2. Isomerization processes between *sp* and *ap* forms in **1**, **3a**, and **3b**.

the temperature was lowered, these signals gradually changed to broad two singlets; then, the signal of **1** showed two sharp singlets at δ 1.88 and 2.55 (2.0 : 1) at −30 °C, whereas that of **3a** showed two sharp singlets at δ 1.89 and 2.51 ppm (2.3 : 1) at −30 °C. The methylthio signal at the higher field corresponds to a conformation of the *ap*-form and the other at a lower field to that of the *sp*-form. It is known that the 2-substituent of the *ap* conformation is located in a shielding zone of the fluorene ring. Thus, the substituent gives an ^1H NMR signal at a higher field than that of the *sp* conformation, which is located in a deshielding zone of the fluorene ring. We have already reported that in 9-(2-methoxyphenyl)-9-fluorenol the *sp*-form was only observed because of its high stabilization, which was caused by an intramolecular hydrogen bond between the oxygen atom of the 2-methoxyl group and the hydrogen atom of the 9-hydroxyl group. However, in compound **1**, the hydrogen bond between the sulfur atom of the 2-methylthio group and the hydrogen atom of the 9-hydroxyl group could not be recognized by its IR spectra in several solvents. This may be due to the weakness of the electronegativity of the sulfur atom compared with that of the oxygen atom. The steric repulsion between the methylthio group and the hydroxyl group may unstabilize the *sp*-form of **1**. After all, third-group compounds predominantly existed as the *ap*-form (Fig. 2).

Furthermore, the rotational barriers about the C(9)–C(Ar) bonds in **1** and **3a** were obtained by line-shape analyses of methylthio signals in their DNMR spec-

tra.[7] The results are tabulated together with those of compounds in which the equilibria were onesided, in Table 2.

In first-group compounds (Y: Br, CH_3, C_2H_5), the chemical shifts for these methylthio protons appeared at δ 1.72—1.80. These chemical shifts have been approximated to those for the *ap*-methylthio proton (roughly δ=1.9) in third-group compounds; these methylthio signals do not split, even at −50 °C. These results indicate that a steric repulsion between the 9-substituents and the 2-methylthio group in first-group compounds makes the equilibria *ap*⇄*sp* incline to the *ap*-form, exclusively.

The chemical shifts (δ 2.28—2.53) for methylthio protons in the compounds (Y: H, CO_2CH_3, $COCH_3$, COPh, and CO_2H) that belong to the second group, have been approximated to those for *sp*-methylthio group in third-group compounds (roughly δ=2.5); no split of these signals occured until −50 °C. It is then shown that the equilibria *ap*⇄*sp* lies very far to the *sp* side, contrary to the case of the first group.

We have described that in the 9-substituted 9-(2-methoxyphenyl)- and 9-substituted 9-(2-methylphenyl)fluorene derivatives, the compounds in which 9-substituents bear carbonyl groups have an intramolecular attractive interaction between the carbonyl group and the methoxyl or methyl group. Furthermore, Ōki and his coworkers have proposed that the same interaction existed in several 1,4-dimethyl-9-(carbonylmethyl)triptycene.[8] It is reasonable that in compounds **7**—**9** a dipole-electric charge interaction between the carbonyl and methylthio group makes the *sp*-conformation more predominant (Fig. 3).

ap-form *sp*-form

Fig. 3. Isomerization processes between *sp* and *ap* forms in 9-carbonyl compounds **7**—**9**.

Conformational Equilibria of 9-Substituted 9-(2-Methylsulfinylphenyl)fluorene Derivatives. Regarding 9-(2-methylsulfinylphenyl)fluorene derivatives, their conformations are discussed in terms of the chemical shifts for the 2-methylsulfinyl proton in their ^{1}H NMR.

These NMR data are listed in Table 3. The equilibrium constants, or predominant conformers, are tabulated in Table 2. Regarding compound **13**, two signals (δ 1.72 and 3.00) appeared at room temperature, the former being assigned to methylsulfinyl protons of the *ap*-form; the latter was assigned to those of the *sp*-form (*ap*/*sp*=1/1.5). On the contrary, only the *sp*-form was observed in **4**. The *sp*-form was fairly unstabilized by means of a steric repulsion between the 9-

hydrogen and methylsulfinyl group; then, two conformers existed in equilibria. Table 3 also shows that the signals for methylsulfinyl protons in most compounds, except **14**, can be approximated to that for methylsulfinyl protons in the *sp*-form of **13** (δ 3.0). It is suggested that the *sp*-form exists predominantly in these compounds.

When **11** was measured in the NMR spectra at low temperatures, the signal of methylsulfinyl protons split into two singlets at δ 1.24 (*ap*-form) and 2.64 (*sp*-form), and its ratio was 1/4. The conformational equilibria of **11** was different from that of **1**. The *sp*-form was predominant due to a dipole-electric charge interaction between the methylsulfinyl and hydroxyl groups rather than hydrogen bond. An attempt to measure the FT-IR spectra of **11** in CCl_4 failed because of the insolubility of **11** in the solvent.

In compound **12a**, with a methoxyl group at the 9-position, the signal for the methylsulfinyl proton appeared as a broad singlet at room temperature, and split into two singlets at δ 1.66 and 3.18 (*ap*/*sp*=1/15) at −33 °C. Accordingly, the *sp*-form must be exclusively predominant. The favorable conformation has also been reversed compared with the case of sulfides, **3a** and **3b**. It can be considered that an attractive (dipole-electric charge) interaction operates between the methylsulfinyl and alkoxyl groups.

The chemical shifts for the methylsulfinyl proton in **15a** and **15b** have approximated to that for the methylsulfinyl proton of the *sp*-form in **13**. The signal in **15a** appeared as a sharp singlet in the temperature range −50 to 30 °C. The predominance of the *sp*-conformation stemmed from an attractive interaction between the methylsulfinyl and carbonyl group.

The signal for the methylsulfinyl group in **14** was observed as a sharp singlet at δ 1.56 near to the value of the *ap*-form of **13**. The steric strain between the methylsulfinyl and methyl groups results in a predominance of the *ap*-from.

The activation free energies of the internal rotation (*ap*⇄*sp*) of **11**, **12a**, and **13** are shown in Table 2. The higher barrier of **13**, compared to that of **11**, may be attributed to a lowering of the ground state of **13**.

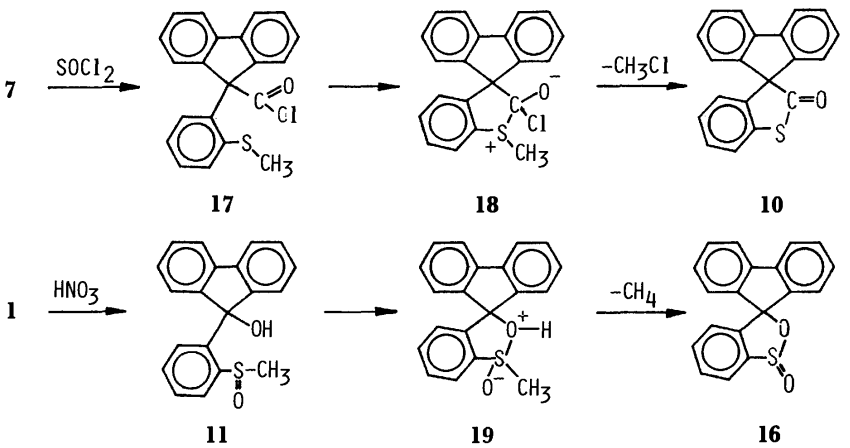
Formation of Ring-Closed Compounds 10 and 16. As described above, an attempted esterification of **7** and an oxidation of **1** under severe conditions gave ring closed compounds **10** and **16**, respectively. These mechanisms are considered to be as follows. Acid chloride **17** was obtained by the reaction of **7** with thionyl chloride and converted to cyclic sulfonium salt **18** at a higher temperature (80 °C); then **10** should have been obtained by the elimination of methyl chloride from this unstable intermediate **18**. The oxidation of **1** by nitric acid afforded **11**, which is ring closed to intermediate **19**; then **19** eliminates methane to give **16**. These reactions are shown in Scheme 2.

Experimental

All melting points are uncorrected. The ^1H NMR spectra were recorded on a JEOL-MH-100 spectrometer with a JEOL model JES-VT-3 variable temperature controller. The chemical shifts are expressed in ppm, with tetramethylsilane as an internal standard. Dynamic NMR spectra were analyzed by using a modified version of the computer program DNMR3. The IR spectra were measured on a IRA-1 spectrometer as potassium bromide pellets.

9-(2-Methylthiophenyl)-9-fluorenol (1). To a solution of *o*-bromophenyl methyl sulfide (27.4 g, 0.14 mol) in dry ether (80 ml) was added a solution of commercial butyllithium in hexane (82.2 ml) at −40 °C. After the reaction mixture was stirred for 1.5 h, a solution of fluorenone (24.3 g, 0.14 mol) in dry benzene was added dropwise. The reaction mixture was stirred for 15 min and allowed to warm at room temperature. The mixture was hydrolyzed by dil. hydrochloric acid, extracted with benzene, washed with water, dried ($MgSO_4$) and concentrated in vacuo to give a solid which was recrystallized first from benzene and then ethanol to give **1** as colorless needles; yield: 25.2 g (61%); mp 141 °C. ^1H NMR ($CDCl_3$) δ=1.95 (3H, br. s, SCH_3), 2.52 (1H, br.s, OH), and 6.92—8.36 (12H, m, H_{arom}). Found: C, 79.05; H, 5.26%. Calcd for $C_{20}H_{16}OS$: C, 78.91; H, 5.30%.

9-Bromo-9-(2-methylthiophenyl)fluorene (2). Into a solution of **1** (1.83 g, 6 mmol) in acetic acid (20 ml) was



Scheme 2.

bubbled hydrogen bromide gas generated from tetralin and bromine for 30 min. After being stirred for 1 h, the precipitated solid was filtered and washed with water. The crude product was recrystallized from hexane–benzene (1 : 4) to give **2** as slight yellow prisms; yield: 2.03 g (92%); mp 167 °C (decomp). ^{1}H NMR ($CDCl_3$) δ=1.80 (3H, s, SCH_3), 6.92—7.69 (11H, m, H_{arom}), and 8.46—8.62 (1H, m, 6′-H). Found: C, 65.58; H, 4.10%. Calcd for $C_{20}H_{15}BrS$: C, 65.40; H, 4.12%.

2-Methoxy-9-(2-methylthiophenyl)fluorene (3a). A solution of **2** (0.55 g, 1.5 mmol) in methanol (5 ml) was refluxed for 1.5 h. After cooled, the product **3a** was filtered and pure enough for analysis; colorless prisms; yield: 0.46 g (97%; mp 96—97 °C. ^{1}H NMR ($CDCl_3$) δ=1.96 (3H, br. s, SCH_3), 2.78 (3H, s, OCH_3), and 7.00—8.12 (12H, m, H_{arom}). Found: C, 78.86; H, 5.68%. Calcd for $C_{21}H_{18}OS$: C, 79.21; H, 5.70%.

2-Ethoxy-9-(2-methylthiophenyl)fluorene (3b). Compound **2** (0.55 g, 1.5 mmol) was treated with ethanol instead of methanol and the reaction mixture was worked up as described for the preparation of **3a** to give **3b** as colorless crystals; yield: 0.38 g (76%); mp 127—128 °C. ^{1}H NMR ($CDCl_3$) δ=1.04 (3H, t, $CH_2C\underline{H}_3$), 1.99 (3H, br.s, SCH_3), 2.89 (2H, q, CH_2), and 7.0—8.0 (12H, m, H_{arom}). Found: C, 79.44; H, 6.08%. Calcd for $C_{22}H_{20}OS$: C, 79.48; H, 6.06%.

9-(2-Methylthiophenyl)fluorene (4). Hydriodic acid (57%, 15 g, 70 mmol) was added dropwise to a solution of **1** (6.08 g, 20 mmol) in acetic acid (150 ml), and refluxed for 1.5 h. The reaction mixture was poured into water and $NaHSO_3$ powder was added to the above mixture. The solution was extracted with benzene. The benzene solution was washed with Na_2CO_3 solution and water, and then dried with $MgSO_4$. The solution was evaporated in vacuo, leaving a residue which was recrystallized from benzene–acetone (1 : 2) to give **4** as colorless needles; yield: 4.54 g (79%); mp 118—119 °C. ^{1}H NMR ($CDCl_3$) δ=2.53 (3H, s, SCH_3), 5.74 (1H, s, 9-H), 6.32 (1H, d, 6′-H), and 6.64—7.78 (11H, m, H_{arom}). Found: C, 83.40; H, 5.61%. Calcd for $C_{20}H_{16}S$: C, 83.29; H, 5.59%.

9-Methyl-9-(2-methylthiophenyl)fluorene (6a). 9-Lithio-(2-methylthiophenyl)fluorene (**5**) was prepared from the reaction of **4** (0.5 g, 1.73 mmol) in dry ether (50 ml) and a solution of commercial butyllithium in hexane (1.7 ml) under a N_2 atmosphere.

To the above solution was added methyl iodide (0.22 ml, 3.46 mmol) dropwise, stirred for 30 min. The reaction mixture was poured into water, extracted with benzene, and dried with $MgSO_4$. The solution was evaporated in vacuo, leaving a residue which was column-chromatograhed on alumina using benzene as an eluent to give **6a**; yield: 0.38 g (73%); colorless needles; mp 149—151 °C (from hexane). ^{1}H NMR ($CDCl_3$) δ=1.72 (3H, s, SCH_3), 1.76 (3H, s, CH_3), and 6.87—7.84 (12H, m, H_{arom}). Found: C, 83.66; H, 5.99%. Calcd for $C_{21}H_{18}S$: C, 83.40; H, 6.00%.

9-Ethyl-9-(2-methylthiophenyl)fluorene (6b). Compound **5** prepared for **1** (0.5 g, 1.7 mmol) was treated with ethyl iodide (1.0 ml, 12.5 mmol) instead of methyl iodide and the reaction mixture was worked up as described for the preparation of **6a**, to give **6b** as colorless crystals; yield: 0.38 g (76%); mp 69—73 °C. ^{1}H NMR $CDCl_3$) δ=0.30 (3H, t, $CH_2C\underline{H}_3$), 1.76 (3H, s, SCH_3), 2.32 (2H, q, CH_2), and 6.80—7.86 (12H, m, H_{arom}). Found: C, 83.35; H, 6.35%. Calcd for $C_{22}H_{20}S$: C, 83.50; H, 6.37%.

9-(2-Methylthiophenyl)-9-fluorenecarboxylic Acid (7). A solution of compound **5** from **1** (2.6 g, 9 mmol) in ether was poured into crushed Dry Ice and stirred for 30 min. The reaction mixture was poured into a ice-water. The precipitated solid was filtered and recrystallized from ethyl acetate to give **7** as colorless crystals; yield: 1.93 g (64%); mp 180 °C (decomp). IR (KBr): 1680 cm^{-1} (CO), 3070 (OH); ^{1}H NMR ($CDCl_3$) δ=2.38 (3H, s, SCH_3), and 6.43—7.81 (12H, m, H_{arom}). Found: C, 75.54; H, 4.91%. Calcd for $C_{21}H_{16}O_2S$: C, 75.87; H, 4.85%.

9-Carboxymethyl-9-(2-methylthiophenyl)fluorene (8). A mixture of **7** (0.2 g, 0.6 mmol), thionyl chloride (5 ml), and *N,N*-dimethylformamide (3 drops) were heated at 50—60 °C for 1 h. To the reaction mixture was added methanol (10 ml); the precipitated solid was then extracted with benzene. The benzene solution was washed with $NaHCO_3$ solution, dried with $MgSO_4$, and concentrated in vacuo. The crude product was recrystallized from acetone to give **8** as colorless prisms; yield: 0.05 g (24%); mp 132—135 °C. IR (KBr): 1700 cm^{-1} (CO); ^{1}H NMR ($CDCl_3$) δ=2.47 (3H, s, SCH_3), 3.59 (3H, s, $COOCH_3$), 6.42 (1H, d, 6′-H), and 6.53—7.75 (11H, m, H_{arom}). Found: C, 75.98; H, 5.33%. Calcd for $C_{22}H_{18}O_2S$: C, 76.27; H, 5.24%.

9-Acetyl-9-(2-methylthiophenyl)fluorene (9a). To a solution of **5** prepared from **1** (0.6 g, 2 mmol) in ether was added a solution of acetic acid anhydride (0.3 ml) in ether (1 ml) dropwise at room temperature. After being stirred for 1 h, the reaction mixture was poured into water, extracted with benzene, washed with water, and dried with $MgSO_4$. The solvent was distilled off in vacuo, leaving a residue which was recrystallized from benzene to give **9a** as colorless plates; yield: 0.25 g (36%); mp 174—175 °C. IR (KBr): 1680 cm^{-1} (CO); ^{1}H NMR ($CDCl_3$) δ=1.88 (3H, s, $COCH_3$), 2.44 (3H, s, SCH_3), 6.55 (1H, d, 6′-H), and 6.72—7.85 (11H, m, H_{arom}). Found: C, 80.04; H, 5.51%. Calcd for $C_{22}H_{18}OS$: C, 79.96; H, 5.49%.

9-Benzoyl-9-(2-methylthiophenyl)fluorene (9b). Compound **5** prepared from **1** (1.0 g, 3.5 mmol) was reacted with benzoyl chloride (0.74 g, 5 mmol) instead of acetic anhydride; the reaction mixture was worked up as described for the preparation of **9a**, to give **9b** as colorless prisms; yield: 1.27 g (92%); mp 181—182 °C (from acetone). IR (KBr): 1645 cm^{-1} (CO); ^{1}H NMR ($CDCl_3$) δ=2.39 (3H, s, SCH_3), 6.51 (1H, d, 6′-H), and 6.63—7.86 (16H, m, H_{arom}). Found: C, 82.25; H, 5.09%. Calcd for $C_{27}H_{20}OS$: C, 82.62; H, 5.14%.

Spiro[benzo[*b*]thiophene-3(2*H*),9′-fluorene]-2-one (10). A mixture of **7** (0.5 g, 1.5 mmol), thionyl chloride (3 ml), and *N,N*-dimethylformamide (3 drops) was refluxed for 2 h. Thionyl chloride was distilled off in vacuo and methanol (15 ml) was added to the above residue. The mixture was refluxed for another 1 h. The solution was concentrated in vacuo, leaving a crude product which was recrystallized from benzene to give **10** as colorless crystals; yield: 0.1 g (20%); mp 139—140 °C. IR (KBr): 1710 cm^{-1} (CO); ^{1}H NMR ($CDCl_3$) δ=6.31—7.79 (12H, m, H_{arom}). Found: C, 80.26; H, 4.12%. Calcd for $C_{20}H_{12}OS$: C, 79.97; H, 4.03%.

9-Substituted 9-(2-Methylsulfinylphenyl)fluorenes (11—15). General Procedure: To a solution of **1** (0.61 g, 2.0 mmol) in acetic acid (10 ml) was added nitric acid (d=1.38, 1 ml) dropwise at 18 °C with stirring. After being stirred at 10—20 °C for 3 h, the reaction mixture was poured into water. The precipitated solid was extracted with benzene. The benzene solution was washed with a $NaHCO_3$ solution and water, and then dried with $MgSO_4$. The solvent was distilled off to obtain a residue which recrystallized from benzene and

then ethanol to give **11** as colorless needles; yield; 0.48 g (75%); mp 214—216 °C (decomp). IR (KBr): 1020 cm^{-1} (SO), 3080 (OH); ^1H NMR ($CDCl_3$) δ=2.52 (3H, br.s, $SOCH_3$), 4.10 (1H, br.s, OH), and 6.22—8.18 (12H, m, H_{arom}). Found: C, 74.82; H, 5.05%. Calcd for $C_{20}H_{16}O_2S$: C, 74.97; H, 5.03%.

9-Methoxy-9-(2-methylsulfinylphenyl)fluorene (12a). This compound was obtained as colorless crystals; yield: 93%; mp 222—223 °C (from methanol). IR (KBr): 1050 cm^{-1} (SO). Found: C, 75.49; H, 5.45%. Calcd for $C_{21}H_{18}O_2S$: C, 75.42; H, 5.43%.

9-Ethoxy-9-(2-methylsulfinylphenyl)fluorene (12b). This compound was obtained as colorless prisms; yield: 32%; mp 201—203 °C (from ethanol). IR (KBr): 1050 cm^{-1} (SO). Found: C, 76.08; H, 5.79%. Calcd for $C_{22}H_{20}O_2S$: C, 75.83; H, 5.79%.

9-(2-Methylsulfinylphenyl)fluorene (13). This compound was obtained as colorless needles; yield: 82%; mp 233—235 °C (from benzene). IR (KBr): 1050 cm^{-1} (SO). Found: C, 79.25; H, 5.46%. Calcd for $C_{20}H_{16}OS$: C, 78.91; H, 5.30%.

9-Methyl-9-(2-methylsulfinylphenyl)fluorene (14). This compound was obtained as colorless crystals (from benzene-hexane); yield: 78%; mp 177—178 °C. IR (KBr): 1050 cm^{-1} (SO). Found: C, 78.95; H, 6.03%. Calcd for $C_{21}H_{18}OS$: C, 79.21; H, 5.70%.

9-Acetyl-9-(2-methylsulfinylphenyl)fluorene (15a). This compound was obtained as slight yellow prisms (from benzene-hexane); yield: 41%; mp 184—186 °C. IR (KBr): 1055 cm^{-1} (SO). Found: C, 76.32; H, 5.29%. Calcd for $C_{22}H_{18}O_2S$: C, 76.27; H, 5.24%.

9-Benzoyl-9-(2-methylsulfinylphenyl)fluorene (15b). This compound was obtained as colorless crystals; yield: 12%; mp 186—189 °C (from benzene). IR (KBr): 1055 cm^{-1} (SO). Found: C, 79.15; H, 5.03%. Calcd for $C_{27}H_{20}O_2S$: C, 79.38; H, 4.94%.

Spiro[3*H*-2,1-benzoxathiole-3,9′-fluorene] 1-Oxide (16). To a solution of **1** (0.6 g, 2 mmol) in acetic acid (10 ml) was added nitric acid (d=1.38, 2 ml) dropwise. After being stirred at 50—60 °C for 30 min, the reaction mixture was poured into water. The mixture was extracted with benzene, and worked up as described for the preparation of **11** to give **16** as colorless prisms; yield: 0.23 g (38%); mp 161—162 °C (from acetone and then ethanol). IR (KBr): 1120 cm^{-1} (SO); ^1H NMR ($CDCl_3$) δ=6.38—8.10 (12H, m, H_{arom}). Found: C, 74.99; H, 4.12%. Calcd for $C_{19}H_{12}O_2S$: C, 74.98; H, 3.97%.

The authers wish to thank Professor Masashi Tashiro, Institute of Advances Material Study, Kyushu University, for the elemental analyses, and are grateful for the financial support of this work by Research Grant-in-Aid from the Ministry of Education, Science and Culture (No. 60470023).

Infrared Spectroscopic Conformational Analysis of Polystyrene Resin-Bound Human Proinsulin C-Peptide Fragments.[1] β-Sheet Aggregation of Peptide Chains during Solid-Phase Peptide Synthesis

Mitsuaki NARITA,* Shinya HONDA, Hiroshi UMEYAMA, and Toshihiko OGURA
Department of Industrial Chemistry, Faculty of Technology, Tokyo University of Agriculture and Technology, Koganei 184
(Received August 1, 1987)

Conformational analysis of human proinsulin C-peptide fragments bound to cross-linked and soluble polystyrene resin matrices was performed using IR absorption spectroscopy. The conformational analysis of octa- and tridecapeptides in the swollen and solid states revealed that both peptides easily interacted with each other through intermolecular hydrogen bonding to form a β-sheet aggregation even at a low loading of peptide chains on the matrices. The high potential of the resin-bound peptides for the β-sheet formation was compatible with that of the corresponding peptides free from macromolecular protecting groups and was predicted using the average coil conformational value, $\langle P_c \rangle$, of each peptide. The significance of the results is discussed in connection with solid-phase peptide synthesis. Effects of shear stress on conformational transformations of resin-bound peptides was also examined in the solid state.

Peptide synthesis by fragment condensation on cross-linked and soluble polymer supports has been expected to be one of the most promising methods for syntheses of large peptides and proteins.[2,3] However, a serious problem in the method is the low yields in some fragment condensation reactions on resin supports.[4] In previous papers,[5-7] we demonstrated that decrease in coupling yields occurred on a copoly(styrene-2% divinylbenzene) support due to the restricted permeability of carboxyl-component peptides into resin matrices. We also verified that the permeability was further restricted by additional cross-linking caused by a β-sheet formation of amino-component peptides on resin matrices. Thus, the conformational analysis of cross-linked polystyrene resin-bound oligopeptides is of utmost importance in connection with solid-phase peptide synthesis. However, very few investigations have been reported of the conformational analysis of cross-linked polystyrene resin-bound oligopeptides.[8-10] In order to elucidate the hydrogen-bonding behavior of resin-bound oligopeptides, we studied the conformational properties of cross-linked polystyrene resin-bound oligo(Leu)s and showed that the peptide chains had various conformations depending on the peptide chain length.[8,9]

In this paper, we report IR absorption spectroscopic analysis of cross-linked and soluble polystyrene resin-bound human proinsulin C-peptide fragments and demonstrate that a β-sheet aggregation through intermolecular hydrogen bonds is commonly achieved in solid-phase peptide synthesis. The resin-bound oligopeptides used in this study are illustrated in Fig. 1. Cross-linked and soluble resin-bound peptides **1a** and **1b**, **2a** and **2b**, and **3a** and **3b** correspond to human proinsulin C-peptide (9-13), (6-13), and (1-13), respectively. The numbers in parentheses in the following C-peptide represent the positions of the first and last amino acids from the N-terminal in human proinsulin C-peptide.[11]

Experimental

Materials. Copoly(styrene-1% divinylbenzene) beads of 200—400 mesh, Bio-Beads S-X1, were purchased from Bio-

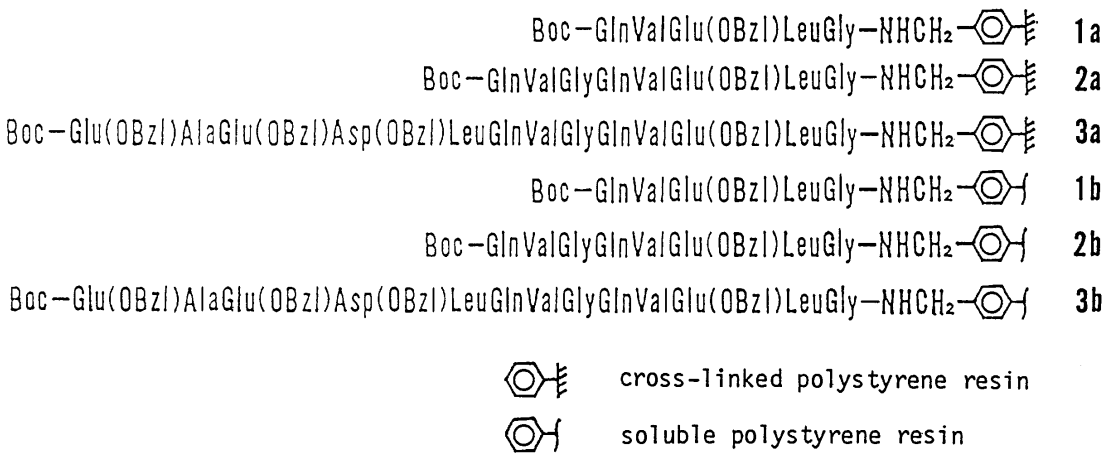

Fig. 1. The cross-linked and soluble polystyrene resin-bound peptides **1a**—**3a** and **1b**—**3b**.

Rad Laboratories. The aminomethylation was performed according to the method described previously.[12] Soluble aminomethylated polystyrene was prepared by the copolymerization of styrene and a mixture of *m*- and *p*-(phthalimidomethyl)styrene, followed by hydrazinolysis.[13] Human proinsulin C-peptide fragments, Boc-Gln-Val-Glu(OBzl)-Leu-Gly-OH, Boc-Gln-Val-Gly-OH, and Boc-Glu(OBzl)-Ala-Glu(OBzl)-Asp(OBzl)-Leu-OH, were those prepared before.[14] These peptide fragments were successively coupled with aminomethylated polystyrene resins in a mixture of dichloromethane and *N*-methylpyrrolidone (1/1, v/v) using DCC as a coupling reagent in the presence of HOBt.[2,8] The reaction using DCC and HOBt as coupling reagents is well-known to be nearly free from racemization.[15] Amino acid analyses of acid hydrolysates of the resin-bound peptides showed that the mole ratios of the component amino acid are close to the values calculated (Table 1).

IR Measurements. The IR absorption spectra of resin-bound peptides were recorded at room temperature with a JEOL Model JIR-100 FT-IR spectrometer. IR measurements in the swollen state were performed by holding the samples between potassium bromide windows after resin-bound peptides were swollen in each solvent overnight. IR measurements in solution were recorded by employing 0.1 mm path length cells with potassium bromide windows. The concentration of the solution was kept near 50 mg ml^{-1}. Only the soluble resin-bound peptide **1b** was soluble in dichloromethane and tetrahydrofuran, and the soluble resin-bound peptides **2b** and **3b** were insoluble in both solvents. The peptides **1b—3b** were insoluble in carbon tetrachloride, and the IR absorption spectra of these insoluble peptides were obtained in the swollen state. IR measurements in the solid state for the soluble resin-bound peptides **1b—3b** were carried out on films cast from their dichloromethane solution or gel in dichloromethane. IR absorption spectra without influence of shear stress (Fig. 6) were obtained using these samples. IR absorption spectra of the cross-linked resin-bound peptides **1a—3a** in the solid state under slight shear stress (Fig. 6) were obtained in a Nujol mull after the solid samples were weakly pulverized with Nujol by hand using an agate mortar.[8,16] The IR absorption spectra of the peptides **1a—3a** and **1b—3b** after application of shear stress (Fig. 7) were also obtained in a Nujol mull after the solid samples were strongly pulverized without Nujol by hand using an agate mortar.[8,16]

Amino Acid Analyses. The amino acid composition of acid hydrolysate was determined using Shimadzu HPLC LC-3A all amino acid analysis system. The conditions of acid hydrolyses of resin-bound peptides were the same to those described before.[14]

Results and Discussion

Oligopeptides Bound to Cross-Linked and Soluble Polystyrene-Resin Matrices. The copoly(styrene-1% divinylbenzene) resin support (Bio-beads S-X1), used as a starting resin bead, has commonly been used for solid-phase peptide synthesis, and the aminomethylated form is expected to have a uniform distribution of aminomethyl groups, based on the reaction mechanism of aminomethylation.[12] Soluble aminomethylated polystyrene was prepared by the copolymerization of styrene and a mixture of *m*- and *p*-(phthalimidomethyl)styrene, followed by hydrazinolysis.[13] The aminomethyl groups are also thought to be randomly distributed on the basis of the copolymerization curve. The first peptide, Boc-Gln-Val-Glu(OBzl)-Leu-Gly-OH, was directly coupled with aminomethyl groups using DCC and HOBt as coupling reagents. The peptide contents were 106 $\mu mol\,g^{-1}$ of resin (ca. 1.1 mol-% per styrene unit) for the cross-linked resin-bound peptide **1a** and 104 $\mu mol\,g^{-1}$ of resin for the soluble resin-bound peptide **1b**, respectively. These initial peptide contents were selected in order to get rational information for peptide chain interactions in the conventional solid-phase method.

Conformational Analysis of the Cross-Linked and Soluble Resin-Bound Peptides Swollen or Soluble in Dichloromethane. The IR absorption spectra of the cross-linked resin-bound peptides **1a—3a** swollen in dichloromethane are presented in Fig. 2 in the most significant spectral regions for conformational assignments (3500—3100 cm^{-1}, amide A; 1800—1600 cm^{-1}, amide I). Figure 3 illustrates those of the soluble resin-bound peptides **1b—3b** soluble or swollen in dichloromethane. The peptide **1b** dissolved in dichloromethane, while the peptides **2b** and **3b** were in a gel. Except for the soluble resin-bound peptide **1b**, the resin-bound peptides **1a—3a**, **2b**, and **3b** show strong bands around 3280 cm^{-1} in the amide A region and 1630 cm^{-1} in the amide I region, assigned to a β-sheet structure.[8,9,17-19] The results of the cross-linked resin-bound peptides **1a—3a** indicate that cross-linked resin-bound peptides swollen in dichloromethane, a most common solvent in conventional solid-phase peptide synthesis, can easily interact with each other through

Table 1. Amino Acid Analyses of the Resin-Bound Peptides **1a—3a** and **1b—3b**[a]

Resin-bound peptide	Asp	Glu(Gln)[b]	Gly	Ala	Val	Leu
1a	—	1.79 (2)	1.08 (1)	—	0.98 (1)	1.00 (1)
2a	—	2.96 (3)	1.90 (2)	—	2.03 (2)	1.00 (1)
3a	0.97 (1)	4.84 (5)	2.12 (2)	0.92 (1)	2.28 (2)	2.00 (2)
1b	—	1.88 (2)	1.08 (1)	—	1.00 (1)	1.06 (1)
2b	—	2.75 (3)	1.86 (2)	—	2.00 (2)	1.15 (1)
3b	0.93 (1)	4.74 (5)	2.06 (2)	0.90 (1)	2.17 (2)	2.00 (2)

a) The values in parentheses are the calculated ones. b) The values are the total ones of Glu and Gln residues.

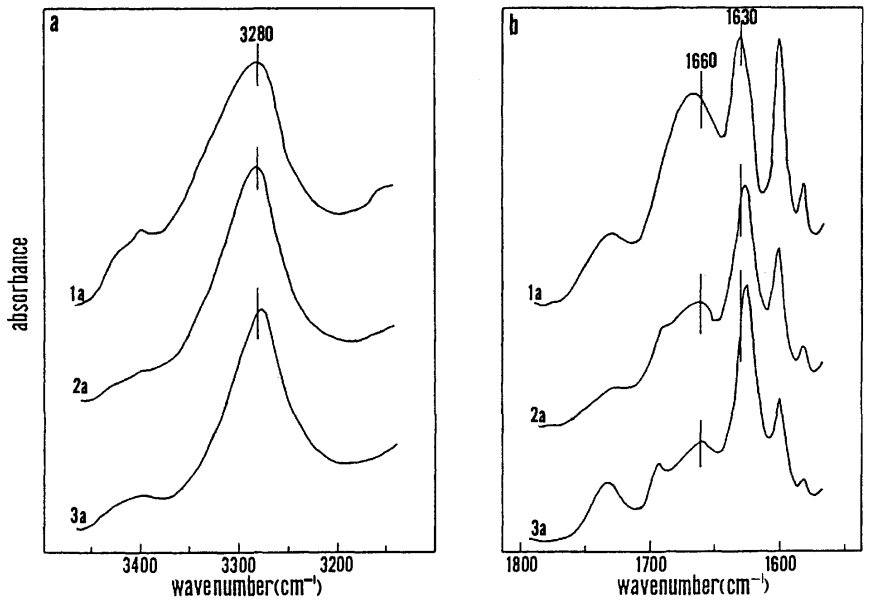

Fig. 2. IR absorption spectra in the amide A (a) and amide I (b) regions of the cross-linked resin-bound peptides **1a**—**3a** swollen in dichloromethane. The absorption band at 1603 cm^{-1} is due to aromatic rings of the polystyrene supports.

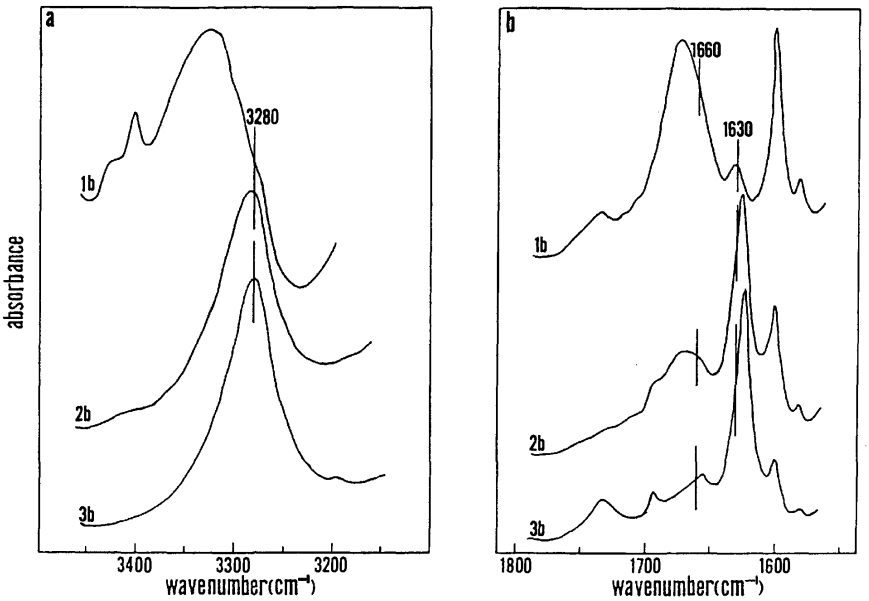

Fig. 3. IR absorption spectra in the amide A (a) and amide I (b) regions of the soluble resin-bound peptides **1b**—**3b** soluble or swollen in dichloromethane. For assignment of the absorption band at 1603 cm^{-1}, see Fig. 2.

peptide main chains to form intermolecular hydrogen bonds even at a low loading of peptide chains on the matrices. Especially, the result of the peptide **1a** clearly shows that the intraresin site separation of the peptide chains is not achieved even at a pentapeptide level. The conformational behavior of the soluble resin-bound peptides **2b** and **3b** is essentially the same as that of the cross-linked resin-bound peptides **2a** and **3a**. On the other hand, the soluble resin-bound peptide **1b** shows a weak band at 1630 cm^{-1} and a strong band at 1675 cm^{-1}in the amide I region, indicating that the resin-bound peptide **1b** is nearly free from intermolecular hydrogen bonds. As pointed out before,[8,9] the high potential for the β-sheet formation of the cross-linked resin-bound peptide **1a** swollen in dichloromethane is attributed to cross-linking by divinylbenzene, that is, the cross-linking has a concentrating effect. The conformational behavior of the cross-

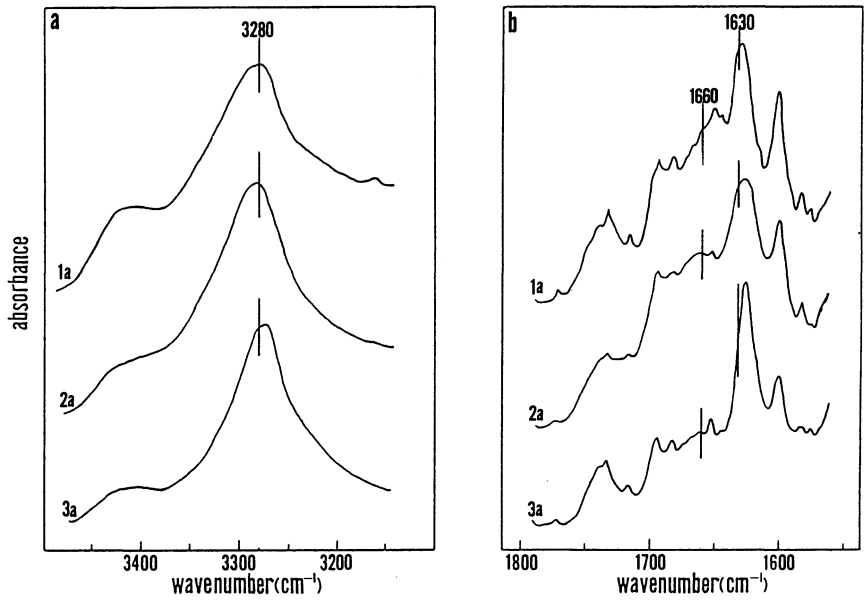

Fig. 4. IR absorption spectra in the amide A (a) and amide I (b) regions of the cross-linked resin-bound peptides **1a—3a** swollen in carbon tetrachloride. For assignment of the absorption band at 1603 cm^{-1}, see Fig. 2.

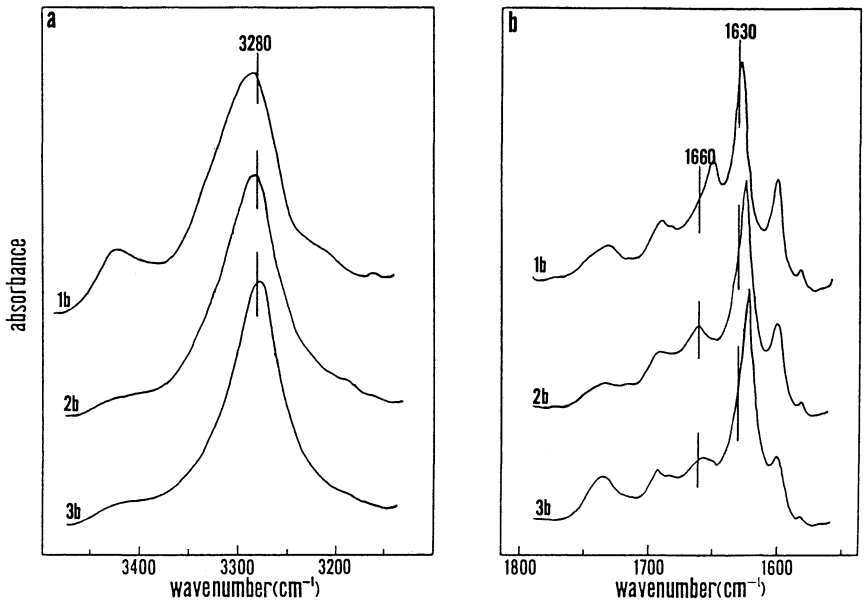

Fig. 5. IR absorption spectra in the amide A (a) and amide I (b) regions of the soluble resin-bound peptides **1b—3b** swollen in carbon tetrachloride. For assignment of the absorption band at 1603 cm^{-1}, see Fig. 2.

linked and soluble resin-bound peptides **1a—3a** and **1b—3b** in tetrahydrofuran (not shown) is essentially the same as that in dichloromethane, and the β-sheet aggregation in tetrahydrofuran is also easily achieved at a pentapeptide level in a cross-linked resin-bound peptide. Although it had been assumed that the cross-linked resin matrix isolated the growing peptide chains at a low loading, these results show that site-site reactions between pendant peptide chains do occur even at a pentapeptide level in solid-phase peptide synthesis.

The results obtained for the human proinsulin C-peptide fragments bound to resin matrices are essentially the same as those obtained for resin-bound oligo (Leu)s[9] and the corresponding human proinsulin C-peptide fragments free from macromolecular protecting groups,[18] indicating that polar side chains can not disturb the formation of the β-sheet structure in solid-

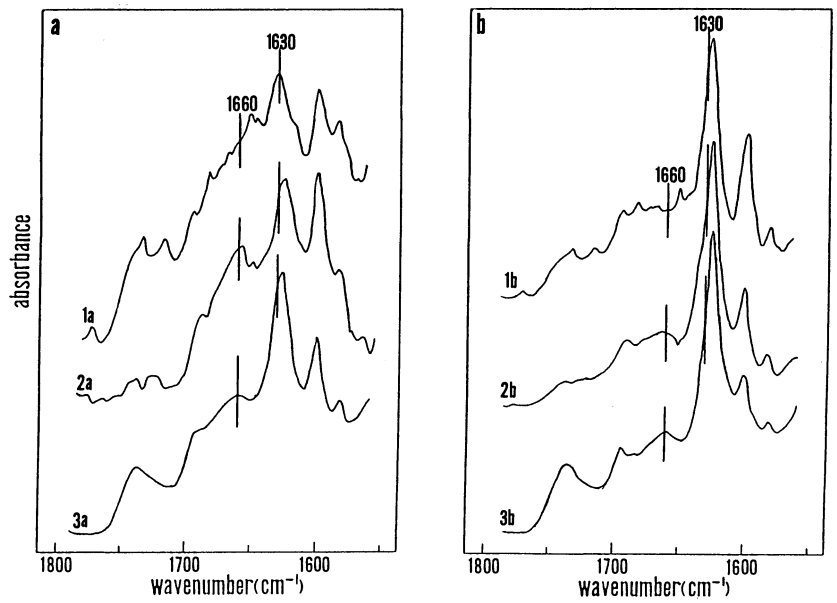

Fig. 6. IR absorption spectra in the amide I regions of the cross-linked resin-bound peptides **1a—3a** (a) and the soluble resin-bound peptides **1b—3b** (b) in the solid state. For assignment of the absorption band at 1603 cm^{-1}, see Fig. 2.

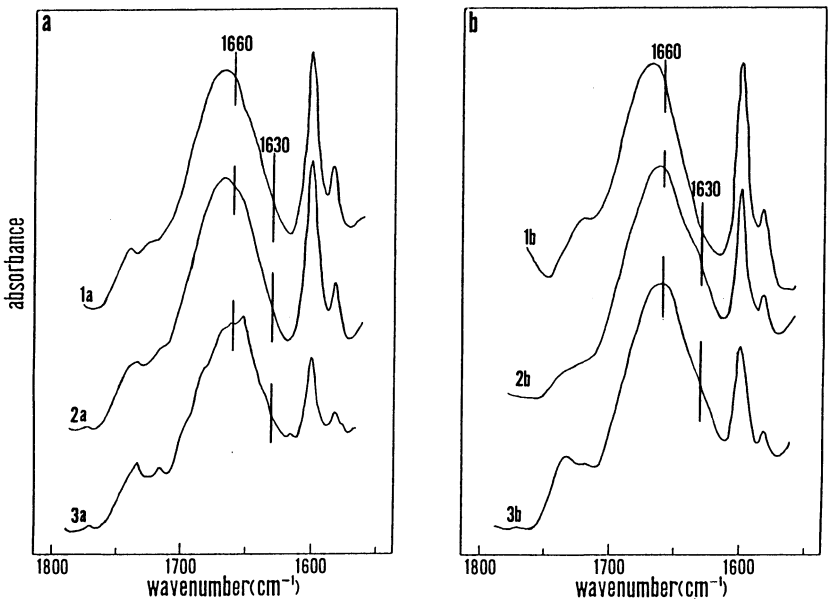

Fig. 7. IR absorption spectra in the amide I regions of the cross-linked resin-bound peptides **1a—3a** (a) and the soluble resin-bound peptides **1b—3b** (b) in the solid state after application of strong shear stress. For assignment of the absorption band at 1603 cm^{-1}, see Fig. 2.

phase peptide synthesis. Since the potential for a β-sheet formation of peptide fragments has successfully been predicted using an average coil conformational value, $\langle P_c \rangle$, calculated from the coil conformation parameter, P_c, for each amino acid,[18,20,21] the potential for a β-sheet formation of resin-bound peptides can be predicted by this method.

Conformational Analysis of the Cross-Linked and Soluble Resin-Bound Peptides Swollen or Soluble in Carbon Tetrachloride. Figures 4 and 5 illustrate the IR absorption spectra in the amide A and amide I regions of the peptide resins **1a—3a** and **1b—3b**, respectively. All of the peptides show strong bands around 3280 and 1630 cm^{-1}, assigned to a β-sheet structure.[8,9,16-18] The conformational behavior of the soluble resin-bound pentapeptide **1b** swollen in carbon tetrachloride is different from that in dichloromethane and tetrahydrofuran. It is attributed to the high poten-

tial of carbon tetrachloride for promoting a β-sheet formation of peptides. The β-sheet formation of the resin-bound peptides **1a—3a** and **1b—3b** in carbon tetrachloride indicates that the peptide phase aggregated through intermolecular hydrogen bonding behaves like a suspended crystalline, while the polystyrene part swells well in carbon tetrachloride. The conformational behavior of the resin-bound peptides **1a—3a**, **2b**, and **3b** in dichloromethane and tetrahydrofuran also indicates that a microphase separation occurs in the solvents. These results indicate that the insolubility of the peptide part in these solvents, causing the restricted permeability of carboxyl components and incomplete coupling reactions, becomes a serious problem in solid-phase peptide syntheses as well as in the classical solution method, although the insolubility of the peptide phase has been out of consideration in solid-phase peptide synthesis.

Conformational Analysis of Cross-Linked and Soluble Resin-Bound Oligopeptides in the Solid State. Figure 6 shows the IR absorption spectra of the peptide resins **1a—3a** and **1b—3b** in the amide I region. The spectra of the soluble resin-bound peptides **1b—3b** show a strong band at 1630 cm^{-1} characteristic of a β-sheet structure.[8,9,17—19] They are accompanied by weak shoulder bands around 1660 cm^{-1}, assigned to other conformations or amide carbonyl groups of Gln residues: those of the cross-linked resin-bound peptides **1a—3a** are accompanied by stronger shoulder bands around 1660 cm^{-1}. The latter spectra are resemble those of the corresponding oligopeptides free from macromolecular protecting groups.[17] The difference in the conformational behavior between the peptides **1a—3a** and **1b—3b** may be caused by added shear-stress in preparing IR samples. In fact, the β-sheet structures of the cross-linked and soluble resin-bound peptides **1a—3a** and **1b—3b** are easily disrupted by application of strong shear stress as shown in Fig. 7. The easy disruption of the β-sheet structure for the resin-bound peptides **1a—3a** and **1b—3b** reflects the potential of the peptide parts for the formation of an α-helical structure.[16]

The conformational behavior of the peptide resins **1a—3a** and **1b—3b** in the solid state resembles that of resin-bound oligo (Leu)s.[8] The easy formation of the β-sheet structure for the resin-bound peptides **1a—3a** and **1b—3b** in the solid state also indicates that resin-bound peptide chains having polar side chains can easily interact with each other through peptide main chains to form intermolecular hydrogen bonds even in polymer networks as well as in resin-bound hydrophobic peptide chains.

The authors are indebted to the financial support of the Asahi Glass Foundation for Industrial Technology. We also wish to thank Ajinomoto Co., Ltd., for the generous gift of various amino acids.

Synthetic Studies on Germacranolides: Synthesis of Optically Active 3-Benzoyloxy-6-oxo-13-nor-12,8-heliangolide

Akiko UTAGAWA,† Hiroshi HIROTA,* Shigeru OHNO, and Takeyoshi TAKAHASHI††
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received August 6, 1987)

Optically active (3*R*,7*R*,8*R*,1(10)*E*,4*Z*)-3-benzoyloxy-6-oxo-13-nor-1(10),4-germacradieno-12,8-lactone, a key synthetic intermediate for naturally occurring hiyodorilactone A, was prepared from (−)-carvone.

A group of sesquiterpene lactones with germacrane skeleton, named generically as "germacranolides," have been isolated from various plants.[1] Among them, 1(10)-*trans*-4-*cis*-germacranolides are called as "heliangolide." We have already reported several synthetic studies on 3-oxygenated heliangolides,[2] such as (−)-4,5-*cis*-3β-hydroxygermacranolide (**1**)[2c] isolated from *Tanacetum tanacetioides*, starting from optically active carvone using oxy-Cope rearrangement to construct the ten-membered ring. Since most of naturally occurring heliangolides possess acyloxyl group at C-8 position, which may enhance biological activities, we planned to synthesize 3,8-dihydroxylated heliangolide derivatives, such as hiyodorilactone A (**2**) which was isolated from *Eupatorium sachalinense* Makino by our group and showed a strong inhibitory activity in vivo against Ehrlich ascites carcinoma.[3] This compound **2** has already been synthesized by Still et al., who introduced the oxygen functional group at C-8 position by Baeyer-Villiger oxidation of a cyclobutanone ring under drastic conditions (anhydrous H_2O_2).[4]

In this paper, we would like to report another method to introduce oxygen functional group at C-8 position of the germacrane skeleton and the preparation of (3*R*, 7*R*, 8*R*, 1(10)*E*, 4*Z*)-3-benzoyloxy-6-oxo-13-nor-1(10),4-germacradieno-12,8-lactone (**3**) from (−)-carvone (**4**). The compound **3** is the antipode of **5**, which was a key intermediate on the total synthesis of hiyodorilactone A (**2**) by Still's group, except for the difference in the protecting group of the alcohol at C-3 position. If (+)-carvone, which is also commercially available at a higher price, is used as the starting material, the antipodal compound of **3** could be obtained. To construct the ten-membered ring, both we and Still's group had applied oxy-Cope rearrangemet to compounds **6** and **7**, respectively.

In order to introduce an oxygen functional group at C-8 position, we must use a compound which possesses a substituent (X) on the terminus of vinyl group of **6** as a substrate for oxy-Cope rearrangement to be able to transform into oxygen functional group at later stages. As a model compound, we first tried to prepare a compound **8** having ethoxyl group as X from isopiperitenone (**9**) and 2-ethoxyvinyllithium,[5] but it became clear that **8** decomposed via deethanolization upon purification and/or under the reaction conditions of oxy-Cope rearrangement. Then we decided to use 1-methylethylidene group, which could be transfered into oxygen by ozonolysis as X group of **6**. To determine the reaction conditions of oxy-Cope rearrangement, allenyl alcohol **10a** was prepared from isopiperitenone (**9**) and 3,3-dimethylallenyllithium (generated from 1,1-dimethylallene and methyllithium)[6] in 79% yield. When **10a** was refluxed with potassium hydride and 18-crown-6 in THF for 30 min (anionic oxy-Cope rearrangement),[2,4,7] piperitenone (**11**), which would be produced by the removal of dimethylallene followed by double bond isomerization, was obtained as a major product. When trimethylsilyl ether derivative of **10a** was heated at 150 °C without solvent under nitrogen atmosphere (siloxy-Cope rearrangement),[8] no reaction took place after 1 h. When **10a** was heated with almost ten equivalent moles of 1-methyl-2-pyrrolidinone at 120—130 °C for about 10 h (solvent-assisted oxy-Cope rearrangement),[9] the desired compound **12a** was produced (isolation yield: 25%) together with approximately the same amounts of the starting material **10a** and a bicyclic compound **13a**. The structure of **13a** was deduced from ^{1}H NMR spectrum, and **13** would be formed via ene reaction.

Since the ten-membered-ring compound **12a** could be obtained in considerable yield, solvent-assisted oxy-Cope rearrangement reaction was applied to the compound **10b** having an additional hydroxyl group of a benzoylated form. The benzoyloxyl group was considered to be stable under the transformation reactions of **12b** into **3**.

The benzoyloxy ketone **14**, which was obtained from (−)-carvone (**4**) via carveol and carvyl benzoate, was treated with 3,3-dimethylallenyllithium[6] to afford **10b** in 29% yield. The alcohol **10b** was rearranged into the ten-membered-ring compound **12b** in 32% yield on heating with 1-methyl-2-pyrrolidinone at about 100 °C for 22 h. Other products, such as the bicyclic compound **13b**, were also formed, but these were not fully characterized. Ozonolysis of **12b** at −30 °C, adjusting the amount of ozone as less than 1 equivalent mole by pre-adsorption on a proper amount of silica gel, gave the desired diketone **15** in 21% yield. The diketone **15**

† Present name and address: Akiko KAKIZAKI; Tokyo Metropolitan Hino High School, Ishida 190, Hino, Tokyo 191.

was accompanied by almost the same amount of a compound, which would have structure **16**, formed by cleavage of the non-conjugated trisubstituted double bond of **12b**. Signals of ^{1}H NMR showed that diketone **15** existed as approximately 1 : 1 mixture of two conformational isomers at room temperature.

Table 1. Main Proton Signals of **3** and **5** at 270 MHz ^{1}H NMR

Position	3			5[a]		
	δ		J/Hz	δ		J/Hz
1-H	5.1	m[b]		4.94	dd	12 and 5
3-H	6.48	dd	11.6 and 4.2	5.31	dd	12 and 4
5-H	6.14	br s		6.09	br s	
7-H	3.63	td	12.6 and 8.1	3.56	td	13 and 8
8-H	5.11	m[b]		5.04	ddd	13, 8, and 3
11-H	2.41	dd	18.1 and 8.1	2.36	dd	18 and 8

a) Analyzed a copy of spectral chart sent from Prof. Still. b) Overlapped each other.

Diketone **15** was treated with sodium hydride followed by ethyl bromoacetate to give a diketo ester **17** in 44% yield. This compound **17** was also observed as a 1 : 2 mixture of two conformers by ^{1}H NMR at room temperature. When temperature was raised up to 45 °C, a set of olefinic methyl signals (δ ca. 1.95) having smaller chemical shift differences at room temperature coalesced into a singlet in the 270 MHz ^{1}H NMR spectrum. Stereochemistry at C-7 of **17** was assumed as 7α-H by considering the reaction pathway. That is, the enolate ion generated with sodium hydride would have a more stable 6Z-double bond, and the electrophile would attack from the peripheral side of the ten-membered ring to give 7α-H configuration compound. Similar argument has also been made in previous papers.[2] This stereochemical assignment was confirmed by subsequent transformation into γ-lactone **3**.

Treatment of **17** with sodium borohydride in ethanol gave a γ-lactone (**3**; $\nu_{C=O}$ 1780 cm^{-1}) as a major product (45% yield). The stereostructure of **3** was deduced to 8*R* or *cis*-lactone from Dreiding model consideration. It was very difficult to construct *trans*-lactone by Dreiding model, while it was fairly easy to make *cis*-lactone. This stereochemical assignment was confirmed by direct comparison of 270 MHz ^1H NMR spectra of **3** and **5**. In Table 1 were listed assignments, chemical shifts, and coupling constants of the main proton signals of **3** and **5** for comparison.

Thus the structure of **3** was shown to be (3*R*, 7*R*, 8*R*,1(10)*E*,4*Z*)-3-benzoyloxy-6-oxo-13-nor-1(10),4-germacradieno-12,8-lactone.

Experimental

General Procedures. All melting points were measured on a Mel-temp capillary melting point apparatus (Laboratory Devices) and uncorrected. Optical rotation was determined on a JASCO polarimeter DIP-181. Ultraviolet absorption (UV) and infrared (IR) spectra were measured on a Hitachi 340 and a Hitachi 260-30 spectrometer, respectively. Proton nuclear magnetic resonance (^1H NMR) spectra were taken using a Varian EM390 (90 MHz) and a JEOL GX270 (270 MHz) at ambient temperature, unless otherwise noted. Chemical shifts were expressed in δ (ppm) downfield from tetramethylsilane as an internal standard and coupling constants in Hz. Mass spectra (MS) were run on a JEOL JMS-D300 mass spectrometer operating at 70 eV. Thin-layer chromatography (TLC) including preparative one was carried out on Kieselgel 60 GF_{254} coated in 0.25 mm-thickness. Wakogel C-200 (Wako) was used for silica-gel column chromatography.

(+)-3-Methyl-1α-(3-methyl-1,2-butadienyl)-6β-(1-methylethenyl)-2-cyclohexen-1β-ol (10a). To an ether solution of methyllithium (0.58 M (1M=1mol dm^{-3}); 23.5 mL) was added diisopropylamine (0.05 mL) followed by 4.2 mL of a mixture (4:7) of 3-methyl-1,2-butadiene and tetrahydrofuran (THF), dropwisely at room temperature under nitrogen atmosphere, and the mixture was stirred for 4 h. At −78 °C, (±)-isopiperitenone (1.25 g) in ether (5 mL) was added dropwise. After stirring for about 2 h at room temperature and addition of saturated brine, the reaction mixture was extracted with ether. Usual work-up afforded 1.77 g of oily residue. Pure **10a** (1.426 g) was obtained by Kugel-Rohr distillation (80 °C/0.05 mmHg; 1 mmHg=133.322 Pa): an oil, IR (neat) 3460, 1670, 1635, 965, and 890 cm^{-1}; ^1H NMR (CCl_4; 90 MHz) δ=1.70 (9H, br s), 1.80 (3H, br s), 4.72 (1H, br s), 4.84 (1H, br s), 4.97 (1H, sept), and 5.28 (1H, br s); MS *m/z* (%) 218 (M^+, 6), 203 (5), 200 (100), 185 (55), 157 (57), and 143 (72); Found: *m/z* 218.1659. Calcd for $C_{15}H_{22}O$: M, 218.1669.

(2*Z*,6*E*)-3,7-Dimethyl-9-(1-methylethylidenyl)-2,6-cyclodecadien-1-one (12a). A solution of allenyl derivative (**10a**; 544 mg) in 6 mL of 1-methyl-2-pyrrolidinone was heated at 120—130 °C (bath temperature) for about 10 h under argon atmosphere. After cooling and addition of ether, the mixture was poured into water, and was extracted with ether as usual. ^1H NMR showed that the residue was consisted from three compounds, that is, the starting material **10a**, the objective ten-membered ketone **12a**, and a bicyclic compound **13a**, the ratio of which was almost 3:2:2, respectively. The residue was separated by column and preparative thin-layer chromatographies (solvent: hexane-ethyl acetate). **12a** (139 mg): white amorphous solid; IR (nujol) 1680, 1633, 1210, 1085, and 992 cm^{-1}; ^1H NMR (CCl_4; 90 MHz) δ=1.35 (3H, br s), 1.77 (9H, br s), 4.94 (1H, br t, *J*=8 Hz), and 5.77 (1H, br s); MS *m/z* (%) 218 (M^+, 100), 200 (71), and 185 (49); Found: *m/z* 218.1666. Calcd for $C_{15}H_{22}O$: M, 218.1669. **13a**: an oil; IR (neat) 3350, 1660, 1640, 1255, 1090, and 965 cm^{-1}; ^1H NMR (CCl_4; 90 MHz) δ=1.70 (9H, br s), 2.68 (1H, dd, *J*=14 and 3 Hz), 3.28 (1H, dd, *J*=14 and 3 Hz), 4.51 (1H, br s), 4.77 (1H, br s), and 5.27 (1H, br s); MS *m/z* (%) 218 (M^+, 20), 200 (61), 185 (35), 175 (100), and 157 (50); Found: *m/z* 218.1662. Calcd for $C_{15}H_{22}O$: M, 218.1669.

(−)-*cis*-Carvyl Benzoate ((3*R*, 5*R*)-3-Benzoyloxy-2-methyl-5-(1-methylethenyl)cyclohexene) and (4*R*, 6*R*)-4-Benzoyloxy-3-methyl-6-(1-methylethenyl)-2-cyclohexen-1-one (14). A solution of (−)-carvone (**4**; 50 g) in dry ether (150 mL) was added dropwise over 30 min to a stirring suspension of lithium aluminium hydride (6.5 g) in dry ether (300 mL) at about 0 °C. After additional 30 min stirring at room temperature, water and 2 M hydrochloric acid were added, successively. Ether extraction followed by removal of the solvent was performed as usual to afford carveol.[10] Benzoyl chloride (60 mL) was added to a solution of carveol in pyridine (300 mL) at about 0 °C, and the mixture was stirred at room temperature for 8 h. After addition of methanol (100 mL) followed by saturated brine, organic solvents were removed in vacuo, and the reaction mixture was extracted with ether as usual to afford crude carvyl benzoate. Kugel-Rohr distillation (170 °C, 0.5 mmHg) of a part of this crude material afforded the analytical sample of carvyl benzoate: $[\alpha]_D^{22}$ +13.3° (*c* 1.25, EtOH); UV (EtOH) 229.5 nm (ε 14280); IR (neat) 1725, 1645, 1270, and 1115 cm^{-1}; ^1H NMR ($CDCl_3$; 270 MHz) δ=1.71 (3H, br s), 1.74 (3H, s), 4.74 (2H, s), 5.6—5.8 (2H, m), 7.4—7.6 (3H, m), and 8.0—8.1 (2H, m); MS *m/z* (%) 256 (M^+, 5), 213 (15), 134 (14), 119 (19), and 105 (100); Found: C, 79.48%; H, 7.72%; and *m/z* 256.1466. Calcd for $C_{17}H_{20}O_2$: C, 79.65%; H, 7.86%; and M, 256.1464.

A solution of the crude carvyl benzoate in carbon tetrachloride (50 mL) was added to a carbon tetrachloride solution (700 mL) of *t*-butyl chromate (prepared from 130 g of chromium(VI) oxide). Acetic anhydride (200 mL) and acetic acid (70 mL) was added, and the whole was refluxed for 16 h. After filtration and addition of a solution of oxalic acid (160 g) in 1.2 L of water and then solid oxalic acid (50 g), the reaction mixture was extracted with ether. The ether layer was washed with aqueous sodium hydrogensulfite, saturated sodium hydrogencarbonate aqueous solution, and saturated brine, successively, and dried over anhydrous sodium sulfate. After evaporation of solvent, the residue was chromatographed on a column of silica gel (800 g). Elution with hexane-ethyl acetate (8:1) afforded 28 g of the unreacted carvyl benzoate and 21 g of the objective allyl-oxidation product **14**: an oil, $[\alpha]_D^{22}$ +27.9° (*c* 0.143, EtOH); UV (EtOH) 232.5 nm (ε 27600); IR (neat) 1725, 1680, 1645 (sh), 1265, and 1115 cm^{-1}; ^1H NMR ($CDCl_3$; 270 MHz) δ=1.75 (3H, s), 2.02 (3H, br s), 4.85 (1H, br s), 5.00 (1H, br s), 5.95—6.05 (2H, m), 7.4—7.7 (3H, m), and 8.05—8.15 (2H, m); MS *m/z* (%) 270 (M^+, 1.5), 202 (3), 148 (7), 105 (100), and 77 (25); Found: C, 75.31; H, 6.87, and *m/z* 270.1262. Calcd for $C_{17}H_{18}O_3$: C, 75.53; H, 6.71, and M, 270.1256.

(1*R*,4*R*,6*R*)-4-Benzoyloxy-3-methyl-1-(3-methyl-1,2-butadienyl)-6-(1-methylethenyl)-2-cyclohexen-1-ol (10b). To a

mixture of butyllithium (1.2 mL; 1.8 M hexane solution), THF (3 mL), and several drops of diisopropylamine was added a mixture (3 : 1) of 3-methyl-1,2-butadiene and THF, dropwise at room temperature. After stirring for 1 h, the mixture was added dropwise into a solution of **14** (280 mg) in THF (5 mL) at −78 °C, and was stirred for 1 h at −60 °C and then 10 min at 0 °C. Saturated ammonium chloride aqueous solution was added, and the reaction mixture was exracted with ether as usual. After evaporation, the residue was separated by column chromatography (SiO_2 16 g). Elution with hexane-ether (20 : 1) afforded the objective compound **10b** (100 mg): an oil, $[\alpha]_D^{19}$ +83.0° (*c* 1.73, EtOH), IR (neat) 3530, 1715, 1640, and 1275 cm^{-1}; ^1H NMR ($CDCl_3$; 270 MHz) δ=1.71 (3H, d, *J*=3 Hz), 1.74 (3H, d, *J*=3 Hz), 1.76 (3H, br s), 1.86 (3H, br s), 4.82 (1H, br s), 5.00 (1H, br s), 5.09 (1H, sept, *J*=3 Hz), 5.58 (1H, br s), 5.62 (1H, dd, *J*=10 and 7 Hz), 7.4—7.65 (3H, m), and 7.95—8.1 (2H, m); MS *m/z* (%) 338 (M^+, 0.6), 320 (0.8), 271 (5), 216 (5), 122 (7), and 105 (100); Found: *m/z* 338.1852. Calcd for $C_{22}H_{26}O_3$: M, 338.1880.

(4*R*, 2*Z*, 6*E*)-4-Benzoyloxy-3,7-dimethyl-9-(1-methylethylidenyl)-2,6-cyclodecadien-1-one (12b). A solution of **10b** (277 mg) in 2.8 mL of 1-methyl-2-pyrrolidinone was heated at 105 °C (bath temperature) for 22 h under argon atmosphere. After cooling to room temperature and the addition of ether, the whole was poured into water and was extracted as usual. After evaporation, the residue was separated by silica gel (15 g) column chromatography. Elution with hexane-ether (20 : 1) afforded 153 mg of recovered starting material **10b** and 40 mg of the objective ketone **12b**. **12b**: white crystals, mp 153—155.5 °C (recrystallized from ether); $[\alpha]_D^{19}$ −150° (*c* 0.44, $CHCl_3$); UV (EtOH) 230 nm (ε 21100); IR (KBr) 1720, 1690, 1645, and 1280 cm^{-1}; ^1H NMR ($CDCl_3$; 270 MHz) δ=1.61 (3H, br s), 1.79 (3H, br s), 1.86 (3H, s), 1.93 (3H, br s), 5.15 (1H, br t, *J*=8 Hz), 6.11 (1H, dd, *J*=11 and 6 Hz), 6.13 (1H, br s), 7.35—7.6 (3H, m), and 8.0—8.1 (2H, m); MS *m/z* 338 (M^+, 10), 320 (3), 295 (2), 233 (2), 216 (23), 198 (25), 173 (22), 122 (17), and 105 (100); Found: C, 78.03; H, 7.52; and *m/z* 338.1875. Calcd for $C_{22}H_{26}O_3$: C, 78.07; H, 7.74; and M, 338.1880.

Quantification of an Amount of Ozone. Some known amount of silica gel, which had been activated for several hours at 110 °C, was packed into a U-shaped glass tube, one end of which was connected with an ozonator and the other end was introduced into potassium iodide aqueous solution. At −78 °C, ozone was passed through the tube to be adsorbed on the silica-gel surface. When the potassium iodide solution was colored, the silica gel was judged to be saturated with ozone. Nitrogen stream was passed through the tube at room temperature to liberate the adsorbed ozone, which was then introduced into 2% aqueous solution of potassium iodide for titration. The potassium iodide solution containing iodide was acidified with sulfuric acid, and was titrated with standard sodium thiosulfate aqueous solution. As the result, it was turned out that 1.16% (w/w) ozone was adsorbed on the silica gel.[11]

(3*R*, 1(10)*E*, 4*Z*)-3-Benzoyloxy-11,12,13-trinor-1(10),4-germacradiene-6,8-dione (15). A solution of ketone **12b** (64 mg) in methanol (2 mL) and dichloromethane (1 mL) was stirred at −30 °C with introduction of ozone which was liberated from the saturated surface of 510 mg of the silica gel by nitrogen stream. (Calculated amount of ozone was 6.1 mg; 0.68 equivalent mole.) Acetic acid (0.2 mL) and zinc powder (ca. 50 mg) were added, and the mixture was stirred at 0 °C to room temperature for 15 min. After removal of excess zinc powder by filtration, the reaction mixture was diluted with ether, poured into water, and then was exracted with ether as usual. After evaporation, the residue was separated by preparative TLC (benzene-ether (5 : 1)). Together with the unreacted material **12b** (8.7 mg; R_f 0.7) and a compound (probably **16**; 8 mg; R_f 0.2), 10.8 mg of diketone (**15**; R_f 0.3) was obtained. **15**: an oil, $[\alpha]_D^{18}$ −130° (*c* 0.27, $CHCl_3$); UV (EtOH) 230 nm (ε 18100); IR (neat) 1730, 1720, 1680, 1640, and 1280 cm^{-1}; ^1H NMR (CCl_4; 90 MHz) δ=1.48 (1.5H, br s), 1.74 (1.5H, br s), 1.90 (1.5H, br s), 1.98 (1.5H, br s), ca. 5.3 (1H, m), 6.02 (1H, br s), 6.22 (0.5H, dd, *J*=11 and 5 Hz), 6.41 (0.5H, dd, *J*=11 and 4 Hz), ca. 7.4 (3H, m), and ca. 8.0 (2H, m); MS *m/z* (%) 312 (M^+, 4.5), 190 (7), 172 (11), 122 (7), and 105 (100); Found: *m/z* 312.1356. Calcd for $C_{19}H_{20}O_4$: M, 312.1350.

Ethyl (3*R*, 7*R*, 1(10)*E*, 4*Z*)-3-Benzoyloxy-6,8-dioxo-13-nor-1(10),4-germacradien-12-oate (17). To a mixture of 5 mg of 50% sodium hydride in oil dispersion and 1 mL of THF was added a solution of diketone **15** (19.6 mg) in THF (1 mL) at 0 °C. After stirring for 30 min at room temperature, large excess amount of ethyl bromoacetate (0.03 mL) was added at 0 °C, and the mixture was stirred for 1.5 h at room temperature. Saturated brine was added, and the reaction mixture was extracted with ether as usual. After evaporation, the residue was separated by preparative TLC (hexane-ether (1 : 2)). Together with the starting material **15** (3.3 mg, R_f 0.4), 9.2 mg of diketo ester **17** (R_f 0.6) was obtained. **17**: white crystals, mp 148—149.5 °C (recrystallized from ether); $[\alpha]_D^{14}$ −160° (*c* 0.18, $CHCl_3$); UV (EtOH) 230 nm (ε 21300); IR (KBr) 1725, 1680, 1635, and 1280 cm^{-1}; ^1H NMR ($CDCl_3$; 270 MHz) δ=1.25 (3H, t, *J*=7 Hz), 6.29 (1H, br s), ca. 7.5 (3H, m), and ca. 8.0 (2H, m). Other signals could be assigned to one of two conformational isomers, the ratio of which was almost 2 : 1. The major isomer: δ=1.72 (3H, br s), 1.96 (3H, br s), 2.45 (1H, q, *J*=11.7 Hz), 2.90, 2.95, 3.44, and 3.49 (2H, ABq, *J*=13.7 Hz), 4.02 (1H, t, *J*=7.1 Hz), 4.12 (2H, q, *J*=7.1 Hz), 5.11 (1H, br dd, *J*=12 and 5 Hz), and 6.35 (1H, dd, *J*=11.7 and 3.8 Hz). The minor isomer: δ=1.65 (3H, br s), 1.98 (3H, br s), 2.17 (1H, ddd, *J*=12, 12, and 7.8 Hz), 3.00, 3.04, 3.21, and 3.26 (2H, ABq, *J*=11.5 Hz), 4.24 (1H, dd, *J*=8.5 and 5.9 Hz), 4.13 (2H, q, *J*=7.1 Hz), 5.50 (1H, br t, *J*=8 Hz), and 6.25 (1H, dd, *J*=12 and 5.7 Hz). MS *m/z* (%) 398 (M^+, 8), 276 (11), 212 (25), 122 (28), and 105 (100); Found: *m/z* 398.1723. Calcd for $C_{23}H_{26}O_6$: M, 398.1729.

(3*R*, 7*R*, 8*R*, 1(10)*E*, 4*Z*)-3-Benzoyloxy-6-oxo-13-nor-1(10),4-germacradieno-12,8-lactone (3). To a solution of diketo ester **17** (4.4 mg) in ethanol (2 mL) and dichloromethane (0.1 mL) was added sodium borohydride (1 mg) at 0 °C, and the mixture was stirred for 1 h. After addition of acetone to destroy the excess hydride reagent, the reaction mixture was acidified by addition of dil. HCl. After concentration of the solution in vacuo, ether extraction as the usual work-up, and evaporation, the residue was separated by preparative TLC (hexane-ethyl acetate (2 : 1)). Togethr with the unreacted material **17** (0.9 mg, R_f 0.6), lactone **3** (1.4 mg, R_f 0.3) was obtained. **3**: white crystals, mp 149—150.5 °C (recrystallized from $CHCl_3$); $[\alpha]_D^{19}$ −190° (*c* 0.14, $CHCl_3$); UV (EtOH) 232 nm (ε 18100); IR (Nujol) 1780, 1730, 1710, 1680, 1620, 1275, and 1170 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.57 (3H, br s), 1.94 (3H, br s), ca. 2.4 (2H, m), 2.41 (1H, dd, *J*=18.1 and 8.1 Hz), ca. 2.6 (2H, m), 3.25 (1H, dd, *J*=18.1 and 12.6 Hz), 3.63 (1H, td, *J*=12.6 and 8.1 Hz), 5.1 (2H, m), 6.14 (1H, br s), 6.48 (1H, dd, *J*=11.6 and 4.2 Hz), 7.4—7.7 (3H, m), and 8.0—8.15

Metal(II) *d*-Tartrates Catalyzed Asymmetric Ring Opening of Oxiranes with Various Nucleophiles

Hiroyuki YAMASHITA
Central Research Institute, Mitsui Toatsu Chemicals, INC., Kasama-cho, Sakae-ku, Yokohama 247
(Received August 13, 1987)

The asymmetric ring opening of *meso*-2,3-disubstituted oxiranes with thiols, aniline, and trimethylsilyl azide was studied by the use of metal(II) *d*-tartrates as heterogeneous chiral Lewis acid catalysts. The enantioselectivity varied widely with the combination of oxirane, nucleophile, and metal(II) *d*-tartrate, and Zn(II) *d*-tartrate gave the best enantioselectivity in the respective reactions of 1,2-epoxycyclohexane with 1-butanethiol, aniline, and trimethylsilyl azide to afford the corresponding adducts in 85, 58, and 42% ee, respectively. Furthermore, the kinetic resolution of racemic oxiranes with thiols catalyzed by Zn(II) *d*-tartrate was studied.

Catalytic asymmetric synthesis has attracted much attention because a large quantity of optically active compound can be effectively produced by using a small quantity of chiral source.

Although various types of catalytic asymmetric synthesis have been reported, only a little have been known about catalytic enantiotopos differentiating reaction, namely, the differentiation between two equivalent moieties in a symmetrical molecule by a chiral catalyst. To our knowledge, the asymmetric reduction of cyclic anhydride to lactone[1] and the asymmetric oxidation of *cis*-1,2-bis(hydroxymethyl)-cycloalkane to lactone[2] by a chiral ruthenium complex have been reported in this category, but their enantioselectivities were not satisfactory.

Only a few chiral Lewis acid catalysts have been known, for example, alkoxydichloroaluminium[3] and dialkoxydichlorotitanium[4] in the Diels-Alder reaction, and diphenoxyzinc[5] in the cyclization of unsaturated aldehyde. Optically active alkoxyl or phenoxyl group is involved in these catalysts as a chiral source and they were used by in situ preparation because of their instabilities.

In the course of our studies on the preparation of optically active polyfunctionalized synthetic building blocks by asymmetric synthesis starting from symmetrical compounds,[6] we recently communicated the asymmetric ring opening reaction of *meso*-2,3-disubstituted oxiranes with some nucleophiles catalyzed by Zn(II) *d*-tartrate or Cu(II) *d*-tartrate.[7] This reaction is classified as a catalytic enantiotopos differentiating reaction. These metal(II) *d*-tartrates act as heterogeneous chiral Lewis acid catalysts which have the advantages of the stability to air, moisture, and heat, and the easy recovery from reaction mixture simply by filtration.

Results and Discussion

Various metal(II) *d*-tartrates such as BeT·H_2O,[8] MgT·H_2O,[9] CaT·H_2O,[10] SrT·H_2O,[10] BaT,[10,11] MnT,[12] FeT,[12] CoT,[12,13] NiT·H_2O,[12,14] CuT,[15] ZnT,[12,16] CdT,[12,17] HgT,[12,18] SnT, and PbT[12] (T=*d*-tartrate) were examined as chiral catalysts by the use of 10 mol% of metal(II) *d*-tartrate in dichloromethane at room temperature in the reactions of 1,2-epoxycyclohexane with thiols such as *p*-toluenethiol, phenylmethanethiol, and 1-butanethiol to give the corresponding optically active *trans*-2-substituted cyclohexanols. In these reactions, active metal ions were Zn^{2+} and Mn^{2+} which have almost same electronegativities,[19] 8.0 and 7.5, respectivery. Other metal ions with lower or higher electronegativities exhibited no catalytic activities.

Next, instead of thiols, we tried various nucleophiles in the presence of 15 metal(II) *d*-tartrates described above, and found that aniline and trimethylsilyl azide gave optically active *trans*-2-anilinocyclohexanol and *trans*-1-azido-2-(trimethylsilyloxy)cyclohexane, respectively. In the reaction with aniline, MnT, FeT, ZnT, CoT, SnT, and CuT were active, and the electronegativities of these metal ions ranged from 7.5 to 9.5. When trimethysilyl azide was employed as a nucleophile, ZnT, CuT, MnT, SnT, CdT, FeT, and MgT·H_2O were active, and the electronegativities of these metal ions ranged widely from 6.0 to 9.5. Other nucleophiles such as benzylamine, ammonia, phenol, benzyl alcohol, methanol, benzoic acid, phenylacetic acid, and acetic acid resulted in no reactions by the use of metal(II) *d*-tartrates screened.

Reaction of *meso*-Oxiranes with Thiols. The results of the asymmetric ring opening of 1,2-epoxycyclohexane, 1,2-epoxycyclopentane, and *cis*-2,3-dimethyloxirane catalyzed by ZnT or MnT are summerized in Table 1. Comparing the chemical yields in the reactions for 5 d, the reactivity of oxiranes decreased in the order of 1,2-epoxycyclohexane > *cis*-2,3-dimethyloxirane > 1,2-epoxyclopentane with each thiol. No reaction took place in the cases of 1,2-epoxycyclooctane and *exo*-2,3-epoxynorbornane probably because of their steric hindrance around their oxirane rings. The same steric effects had been noticed in the reduction of oxiranes with lithium aluminium hydride[20] or sodium borohydride.[21]

The reactivity of thiols decreased in the order of *p*-toluenethiol > phenylmethanethiol > 1-butanethiol

a) The mixture of oxirane (2 mmol), thiol (2 mmol), and catalyst (0.2 mmol) in CH_2Cl_2(5 cm^3) was stirred at room temperature for 5 d. b) (*c* 5.0, CH_2Cl_2). c) Absolute configuration.

with each oxirane. This order can be ascribed to the reverse order of the electron densities on their sulfur atoms.

When MnT was used as a catalyst, these orders were clearly observed. While 1,2-epoxycyclohexane reacted with *p*-toluenethiol to give the corresponding product in an excellent yield, the combination of less reactive oxiranes such as 1,2-epoxycyclopentane and *cis*-2,3-dimethyloxirane and less reactive thiols such as phenylmethanethiol and 1-butanethiol resulted in almost no reactions.

Compared with ZnT, MnT showed less catalytic activity and enantioselectivity, but exibited the following interesting feature, that is, MnT varied the stereoselectivity according to the combination of oxiranes and thiols to give (1*S*,2*S*)-**1**,**3**, (1*R*,2*R*)-**2**, and (2*R*,3*R*)-**7**, while ZnT gave (1*R*,2*R*) or (2*R*,3*R*)-product in all cases.

In the reaction of 1,2-epoxycyclohexane with *p*-toluenethiol, the salts such as Zn(II) (2*R*,3*R*)-2,3-dimethoxysuccinate (ZnDMS),[22)] Zn(II) (2*R*,3*R*)-2-hydroxy-3-methoxysuccinate (ZnHMS),[23)] Zn(II) (*S*)-2-hydroxysuccinate (ZnHS), and Zn(II) (*S*)-2-methoxysuccinate (ZnMS)[24)] were catalytically active but scarcely selective.

a) The mixture of 1,2-epoxycyclohexane (2 mmol), aniline (2 mmol), and catalyst (0.2 mmol) in CH_2Cl_2 (5 cm^3) was stirred at room temperature for 7 d. b) (*c* 2.0, CH_2Cl_2). c) Absolute configuration.

In order to confirm the absolute configurations of ring opening products, *trans*-2-(arylthio or alkylthio)-cyclohexanols **1**—**3**, -cyclopentanols **4**—**6**, and *threo*-3-(arylthio or alkylthio)-2-butanols **7**—**9** were converted into optically active 2-cyclohexen-1-ol,[25)] 2-cyclopenten-1-ol,[26)] and 3-buten-2-ol,[27)] respectively, by oxidation with *m*-chloroperbenzoic acid and successive thermal decomposition of the resulting *S*-oxides with-

out the formation of ketones. The enantiomeric exesses (ee) of **1—9** were determined by ^{19}F NMR measurements of their esters of (+)-α-methoxy-α-(trifluoromethyl)phenylacetic acid (MTPA).[28]

Reaction of *meso*-Oxiranes with Aniline. The results of the asymmetric ring opening of 1,2-epoxycyclohexane with aniline are summerized in Table 2. The salts such as ZnT, MnT, CoT, and SnT gave (1*R*,2*R*)-2-anilinocyclohexanol (**10**), while CuT and FeT gave (1*S*,2*S*)-**10**.

The enantiomeric excess of **10** was determined by ^{19}F NMR measurement of the MTPA ester of 2-(*N*-methylanilino)cyclohexanol (**11**) derived from **10** by *N*-methylation with Me_2SO_4. In order to confirm the absolute configuration, **11** was oxidized with *m*-chloroperbenzoic acid and the resulting *N*-oxide was transformed into optically acitve 2-cyclohexen-1-ol by thermal decomposition.

Compared with the reaction of 1,2-epoxycyclohexane with thiols, the chemical and optical yields were rather low in the reaction with aniline. One of the reasons could be considered that the amino alcohol **10** thus formed tightly coordinated to metal ion as a basic bidentate to decrease both catalytic activity and enantioselectivity of the salt. This possibility was clarified by the examination of the relationship between chemical yield and optical yield. As shown in Table 3, when 10 mol% of ZnT was used, the ee values were almost constant throughout the reaction in the case of *p*-toluenethiol. On the other hand, in the case of aniline, the ee values were gradually decreased and the reaction stopped completely after 28 d. When 50 mol% of ZnT was used, the reaction completed (95% yield) within 7 d, however, the enantioselectivity was not improved (37% ee).

Reaction of *meso*-Oxiranes with Trialkylsilyl Azide. The results of the reactions of 1,2-epoxycyclohexane, 1,2-epoxycyclopentane, and *cis*-2,3-dimethyloxirane with trimethylsilyl azide are summerized in Table 4. Throughout the experiments, (1*R*,2*R*)-products were produced in almost all cases except in the combination of 1,2-epoxycyclohexane and MnT resulting in the formation of (1*S*,2*S*)-product. The chemical yield was satisfactory, however, the optical yield was only 42% ee at best.

We screened several trialkylsilyl azides in place of trimethylsilyl azide to improve the enantioselectivity. When *t*-butyldimethylsilyl azide and triethylsilyl azide were employed, almost no products were obtained due to their severe steric hindrance, while ethyldimethylsilyl azide and isopropyldimethylsilyl azide gave the corresponding ring opening products **15—20** though in poor optical yields. These results are summerized in Table 5.

a) The mixture of oxirane (4 mmol), thiol (2 mmol), and ZnT (0.2 mmol) in CH_2Cl_2 (10 cm^3) was stirred at room temperature. b) 0.4 mmol. c) Complete consumption time of thiol checked by thin-layer chromatography. d) Based on oxirane. e) Ring opening product **21**. f) Absolute configuration.

These *O*-silylated β-azido alcohols **12—20** were desilylated by refluxing with methanol in the presence of a catalytic amount of concd HCl, and successive catalytic hydrogenolysis with 10% Pd-C resulted in the formation of corresponding *trans*-β-amino alcohols whose absolute configurations and maximum optical rotations have been known.

Kinetic Resolution of Racemic Oxiranes. As a model study, we examined the kinetic resolution of racemic oxiranes with thiols catalyzed by ZnT. At first, the reaction of 2-phenyloxirane with half molar equivalents of various thiols were carried out until thiols were completely consumed. When bulky 2-methyl-2-propanethiol was used as a nucleophile, (*R*)-2-phenyloxirane[29] was recovered in 15% ee. In the same reaction of 1-benzyloxy-2,3-epoxypropane, (*R*)-oxirane[30] was recovered in 27% ee. When *trans*-2,3-dimethyloxirane was treated with half molar equivalents of *p*-toluenethiol, (2*S*,3*R*)-3-(*p*-tolylthio)-2-butanol (**21**) was obtained in 43% ee, and in the case of 10 mol% of *p*-toluenethiol, the product **21** showed 72% ee. The recovery of unreacted *trans*-2,3-dimethyloxirane was failed because the separation from solvent (CH_2Cl_2) by distillation was difficult, however, (2*R*, 3*R*)-2,3-dimethyloxirane might be remained judging from the configuration of the ring opening product **21**.

The combination of *trans*-2,3-dimethyloxirane and less reactive thiols such as phenylmethanethiol, 1-butanethiol, and 2-methyl-2-propanethiol resulted in no reactions. These results are summerized in Table 6.

In all these reactions catalyzed by ZnT, thiols attacked the back side of the asymmetric carbon having *S*-configuration faster than that of *R*-configuration. These results were in good accordance with the intramolecular enantioselectivity in the reaction of *meso*-oxiranes with thiols catalyzed by ZnT, that is, thiols attacked the side of *S*-configuration and (1*R*,2*R*)-β-substituted alcohols were obtained.

Structure of Metal (II) *d*-Tartrate. The salts such as $CaT \cdot 4H_2O$,[31,32] $SrT \cdot 3H_2O$,[31] $CuT \cdot 3H_2O$,[33] and $Ni_2T_2 \cdot 5H_2O$[34] are known to have common polymeric structures stabilized by three dimensional networks of hydrogen bonds, but their detailed coordination structures are different in every salts. Furthermore, the structure of anhydrous ZnT has been reported to be X-ray crystallographycally amorphous.[35] Considering these structural variations, it is difficult to simply presume the structures of the other metal(II) *d*-tartrates employed in the present experiments.

The catalytically active metal ions existed in a certain range of electronegativity in accordance with thiols, aniline, and trialkylsilyl azide, and highly basic nucleophiles such as benzylamine and ammonia resulted in no reactions. The enantioselectivity was varied according to the combination of oxirane, nucleophile, and metal(II) *d*-tartrate. Based on these results, it may be possible to consider that both oxirane and nucleophile coordinate simultaneously to metal (II) *d*-tartrate which acts as a heterogeneous Lewis acid catalyst to activate the oxirane, and the entropically advantageous state enables the enantioselective ring opening reaction to proceed smoothly. The detailed mechanism of the enantiotopos differentiation is remained unknown at present.

Experimental

All the boiling points and the melting points were uncorrected. The IR spectra were recorded with a JASCO IRA-2 spectrometer. The ^1H NMR spectra were measured with a JEOL JNM-3H-60 spectrometer or a JEOL JNM-PMX-60SI spectrometer with tetramethylsilane as an internal standard, and ^{19}F NMR spectra were taken with a Varian EM-390 spectrometer. The optical rotations were measured with a Union Giken PM-101 polarimeter or a JASCO DIP-181 polarimeter. Kugelrohr distillation was carried out with a Sibata GTO-250RS distilling apparatus. Column chromatography was performed on silica gel (Wakogel C-200). Dichloromethane and benzene were stored over Molecular Sieves 4A.

Preparation of Metal(II) Dicarboxylates. Typical Procedures for the Preparation of ZnT. Method A. To an aqueous solution (100 cm^3) of $ZnCl_2$ (13.6 g, 0.10 mol) was added an aqueous solution (100 cm^3) of potassium sodium *d*-tartrate tetrahydrate (28.2 g, 0.10 mol). The mixture was stirred at room temperature for 1 h and was left overnight. The precipitated white powder was collected by filtration, washed with water (100 cm^3) and methanol (50 cm^3), and dried at 150 °C/1 Torr (1 Torr≈133.322 Pa) for 5 h to afford ZnT (21 g, 98%). Found: C, 22.49; H, 1.93; Zn, 30.27%. Calcd for $C_4H_4O_6Zn$: C, 22.51; H, 1.89; Zn, 30.63%.

Method B. An aqueous solution (100 cm^3) of Zn $(OAc)_2 \cdot 2H_2O$ (27.9 g, 0.10 mol) was added to an aqueous solution (100 cm^3) of *d*-tartaric acid (15.0 g, 0.10 mol). The mixture was stirred for 1 h, and was left over night followed by the same work-up as Method A to give ZnT (21 g, 98%). Found: C, 22.53; H, 1.92; Zn, 30.32%. Calcd for $C_4H_4O_6Zn$: C, 22.51; H, 1.89; Zn, 30.63%.

The other salts such as $BeT \cdot H_2O$, $CaT \cdot H_2O$, $SrT \cdot H_2O$, BaT, MnT, FeT, and CuT were prepared from the corresponding metal(II) chlorides and potassium sodium *d*-tartrate by method A, and $MgT \cdot H_2O$, CoT, $NiT \cdot H_2O$, CdT, HgT, and PbT were prepared from the corresponding metal(II) diacetates and *d*-tartaric acid by method B.

The salts such as ZnDMS, ZnHMS, ZnHS, and ZnMS were prepared from $Zn(OAc)_2 \cdot 2H_2O$ and the corresponding dicarboxylic acids by method B with a slight modification. These salts were very soluble in water. The aqueous reaction mixture was evaporated in vacuo, and the residual salt was washed with methanol and dried.

The yields and analytical data for metal(II) dicarboxylates: $BeT \cdot H_2O$ (54%), Found: C, 27.05; H, 3.62%. Calcd for $C_4H_6O_7Be$: C, 27.44; H, 3.45%. $MgT \cdot H_2O$ (37%), Found: C. 24.98; H. 3.42%. Calcd for $C_4H_6O_7Mg$: C, 25.23; H, 3.18%. $CaT \cdot H_2O$ (94%), Found: C, 23.14; H, 3.11%. Calcd for $C_4H_6O_7Ca$: C, 23.30, H, 2.93%. $SrT \cdot H_2O$ (82%), Found: C,19.01; H, 2.22%. Calcd for $C_4H_6O_7Sr$: C, 18.94; H, 2.38%. BaT (98%), Found: C, 16.18; H, 1.58%. Calcd for $C_4H_4O_6Ba$: C, 16.83; H, 1.41%. MnT (94%), Found: C, 23.28; H, 2.09%. Calcd for $C_4H_4O_6Mn$: C, 23.43; H, 1.97%. FeT (86%), Found: C, 23.52; H, 2.06%. Calcd for $C_4H_4O_6Fe$: C, 23.56; H, 1.98%. CoT (71%), Found: C, 23.54; H, 2.06%. Calcd for $C_4H_4O_6Co$: C, 23.21; H, 1.95%. $NiT \cdot H_2O$ (77%), Found: C, 21.11; H, 2.82%. Calcd for $C_4H_6O_7Ni$: C, 21.37; H, 2.69%. CuT (99%), Found: C,22.69; H, 2.01%. Calcd for $C_4H_4O_6Cu$: C, 22.70; H, 1.91%. CdT (88%), Found: C,18.43; H, 1.50%. Calcd for $C_4H_4O_6Cd$: C, 18.44; H, 1.55%. HgT (92%), Found: C, 13.77; H,1.11%. Calcd for $C_4H_4O_6Hg$: C, 13.78; H, 1.16%. PbT (96%), Found: C, 13.29; H, 1.04%. Calcd for $C_4H_4O_6Pb$: C, 13.52; H, 1.13%. SnT (90%), Found: C, 17.94; H, 1.60%. Calcd for $C_4H_4O_6Sn$: C, 18.01; H, 1.51%. ZnDMS (96%), Found: C, 29.75; H, 3.46%. Calcd for $C_6H_8O_6Zn$: C, 29.84; H, 3.34%. ZnHMS (92%), Found: C, 26.43; H, 2.81%. Calcd for $C_5H_6O_6Zn$: C, 26.40; H, 2.66%. ZnHS (85%), Found: C, 24.14; H, 2.19%. Calcd for $C_4H_4O_5Zn$: C, 24.33; H, 2.04%. ZnMS (95%), Found: C, 28.35; H, 2.93%. Calcd for $C_5H_6O_5Zn$: C, 28.40; H, 2.86%.

General Procedure for the Reaction of *meso*-Oxiranes with Thiols. To a dichloromethane (5 cm^3) solution of oxirane (2 mmol) and thiol (2 mmol) was suspended metal(II) *d*-tartrate (0.2 mmol). The heterogeneous mixture was stirred at room temperature for 5 d. After filtration of metal(II) *d*-tartrate, the filtrate was concentrated and purified by column chromatography on silica gel (hexane:ethyl acetate=10:1) to give *trans*-β-(alkylthio or arylthio) alcohol. The isolated yields, optical rotations, and enantiomeric excesses of the adducts **1—9** in the various combination of oxiranes thiols, and metal(II) *d*-tartrates are listed in Table 1. Spectral and analytical data for **1—9** are as follows.

(1*R*,2*R*)-2-(*p*-Tolylthio)cyclohexanol (1): IR (neat) 3450, 800 cm^{-1}; ^1H NMR (CCl_4) δ=1.02—1.48 (4H, m), 1.52—1.83

(2H, m), 1.83—2.12 (2H, m), 2.32 (3H, s), 2.43—2.78 (1H, m), 2.90 (1H, s), 2.98—3.39 (1H, m), 7.04 (2H, d, J=8 Hz), 7.32 (2H, d, J=8 Hz). Found: C, 70.03; H, 8.27; S, 14.37%. Calcd for $C_{13}H_{18}OS$: C, 70.22; H, 8.16; S, 14.42%.

(1*R*,2*R*)-2-(Benzylthio)cyclohexanol (2): IR (neat) 3450, 690 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.02—1.48 (4H, m), 1.50—1.82 (2H, m), 1.72—2.12 (2H, m), 2.15—2.42 (1H, m), 2.83 (1H, s), 3.08—3.36 (1H, m), 3.62 (2H, s), 7.18 (5H, s). Found: C, 69.93; H, 8.10; S, 14.38%. Calcd for $C_{13}H_{18}OS$: C, 70.22; H, 8.16; S, 14.42%.

(1*R*,2*R*)-2-(Butylthio)cyclohexanol (3): IR (neat) 3450, 730 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.93 (3H, t, J=8 Hz), 1.00—2.25 (12H, m), 2.52 (2H, t, J=7 Hz), 2.25—2.50 (1H, m), 2.80 (1H, s), 3.08—3.45 (1H, m). Found: C, 63.50; H, 10.59; S, 16.95%. Calcd for $C_{10}H_{20}OS$; C, 63.77; H, 10.70; S, 17.03%.

(1*R*,2*R*)-2-(*p*-Tolylthio)cyclopentanol (4): IR (neat) 3410, 780 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.10—2.38 (6H, m), 2.27 (3H, s), 3.16—3.37 (1H, m), 3.45 (1H. s), 3.80—4.18 (1H, m), 7.00 (2H, d, J=8 Hz), 7.25 (2H, d, J=8 Hz). Found: C, 68.93; H, 8.03; S. 15.05%. Calcd for $C_{12}H_{16}OS$: C, 69.19; H, 7.74; S, 15.39%.

(1*R*,2*R*)-2-(Benzylthio)cyclopentanol (5): IR (neat) 3410, 690 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.10—2.30 (6H, m), 2.60—2.84 (1H, m), 3.19 (1H, s), 3.66 (2H, s), 3.78—4.04 (1H, m), 7.26 (5H, s). Found: C, 69.25; H, 8.03; S, 15.10%. Calcd for $C_{12}H_{16}OS$: C, 69.19; H, 7.74; S. 15.39%.

(1*R*,2*R*)-2-(Butylthio)cyclopentanol (6): IR (neat) 3410 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.96 (3H, t, J=6 Hz), 1.05—2.38 (10H, m), 2.17 (1H, s), 2.53 (2H, t, J=7 Hz), 2.65—2.96 (1H, m), 3.87—4.18 (1H. m). Found: C, 62.28; H, 10.26; S, 18.21%. Calcd for $C_9H_{18}OS$: C. 62.02, H, 10.41; S, 18.39%.

(2*R*,3*R*)-3-(*p*-Tolylthio)-2-butanol (7): IR (neat) 3430, 810 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.87 (3H, d, J=7 Hz), 1.24 (3H, d, J=7 Hz),2.35 (3H, s), 2.43 (1H, s). 2.67—3.08 (1H, m), 3.32—3.75 (1H, m), 7.07 (2H, d, J=8 Hz), 7.32 (2H, d, J=8 Hz). Found: C, 67.14; H, 7.99; S, 16.43%. Calcd for $C_{11}H_{16}OS$: C, 67.30; H, 8.22; S, 16.33%.

(2*R*,3*R*)-3-(Benzylthio)-2-butanol (8): IR (neat) 3430, 690 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.15 (3H, d, 7 Hz), 1.21 (3H, d, J=7 Hz), 2.29 (1H, s), 2.37—2.65 (1H, m), 3.40—3.66 (1H, m), 3.74 (2H, s), 7.34 (5H, s). Found: C. 67.56; H, 8.38; S, 16.21%. Calcd for $C_{11}H_{16}OS$: C, 67.30; H, 8.22; S, 16.33%.

(2*R*,3*R*)-3-(Butylthio)-2-butanol (9): IR (neat) 3430 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.94 (3H, t, J=7 Hz), 1.09 (3H, d, J=6 Hz), 1.33 (3H, d, J=7 Hz), 1.34—1.82 (4H, m), 2.03 (1H, s), 2.38—2.69 (1H, m), 2.35 (2H, t, J=7 Hz), 3.32—3.58 (1H, m). Found C, 59.43; H, 10.97; S, 19.58%. Calcd for $C_8H_{18}OS$: C, 59.21; H, 11.18; S, 19.75%.

Reaction of 1,2-Epoxycyclohexane with Aniline Catalyzed by ZnT. To a dichloromethane (5 cm^3) solution of 1,2-epoxycyclohexane (196 mg, 2 mmol) and aniline (186 mg, 2 mmol) was suspended ZnT (43 mg, 0.2 mmol). The heterogeneous mixture was stirred at room temperature for 7 d. After filtration of ZnT, the filtrate was concentrated and purified by column chromatography on silica gel ($CHCl_3$) to afford 108 mg (28% yield) of (1*R*,2*R*)-2-anilinocyclohexanol (**10**): $[\alpha]_D^{23}$ −52.6° (*c* 2.0, CH_2Cl_2); mp 78—81 °C; IR (KBr) 3370, 3450, 1590, 1280 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.00—1.52 (4H, m), 1.55—1.88 (2H, m), 1.88—2.24 (2H, m), 2.86—3.45 (2H, m), 3.34 (2H, s), 6.48—6.51 (3H, m), 6.96—7.23 (2H, m). Found: C, 75.12; H, 8.86; N, 7.48%. Calcd for $C_{12}H_{17}NO$: C, 75.36, H, 8.96, N, 7.32%. The isolated yields, optical rotations, and enantiomeric excesses of **10** in the use of various metal(II) *d*-tartrates are listed in Table 2.

Preparation of Trialkylsilyl Azide. Trimethylsilyl azide was commercially available (Tokyo Kasei) and was used without further purification. The following trialkylsilyl azides were prepared from the corresponding trialkylsilyl chlorides and sodium azide according to the literature for the preparation of trimethylsilyl azide.[36]

Ethyldimethylsilyl Azide: Yield 56%; bp 72 °C/150 Torr; IR (neat) 2160 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.14 (6H, s), 0.72 (2H, q, J=8 Hz), 1.04 (3H, t, J=8 Hz). Found: C, 37.29; H, 8.51, N, 32.40%. Calcd for $C_4H_{11}N_3Si$: C, 37.18; H, 8.58; N, 32.51%.

Isopropyldimethylsilyl Azide: Yield 72%; bp 75 °C/90 Torr; IR (neat) 2140 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.23 (6H, s), 1.04 (6H, d, J=5 Hz), 1.03 (1H, q, J=5 Hz). Found: C, 41.73; H, 9.04; N, 29.45%. Calcd for $C_5H_{13}N_3Si$: C, 41.91; H, 9.15; N, 29.33%.

***t*-Butyldimethylsilyl Azide:** Yield 84%; bp 78 °C/67 Torr; IR (neat) 2140 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.22 (6H, s), 0.97 (9H, s). Found: C, 45.90; H, 9.75; N, 26.47%. Calcd for $C_6H_{15}N_3Si$: C, 45.81; H, 9.61; N, 26.72%.

Triethylsilyl Azide: Yield 80%; bp 82 °C/35 Torr; IR (neat) 2130 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.79 (6H, q, J=9 Hz), 1.05 (9H, t, J=9 Hz). Found: C, 45.82; H, 9.75; N, 26.51%. Calcd for $C_6H_{15}N_3Si$: C, 45.81; H, 9.61; N, 26.72%.

General Procedure for the Reaction of *meso*-Oxiranes with Trialkylsilyl Azides. To a benzene (5 cm^3) solution of oxirane (10 mmol) and trialkylsilyl azide (12 mmol) was suspended metal(II) *d*-tartrate (1 mmol). The heterogeneous mixture was stirred at room temperature for 14 d. After filtration of metal(II) *d*-tartrate, the filtrate was concentrated and purified by Kugelrohr distillation to afford *trans*-*O*-trialkylsilyl β-azido alcohol. The isolated yields, optical rotations, and enantiomeric excesses of the adducts in the various combination of oxiranes, trialkylsilyl azides, and metal(II) *d*-tartrates are listed in Tables 4 and 5. Spectral and analytical data of the adducts **12—20** are as follows.

(1*R*,2*R*)-1-Azido-2-(trimethylsilyloxy)cyclohexane (12): Bp 110 °C/5 Torr; IR (neat) 2110 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.16 (9H, s), 1.02—1.05 (4H, m), 1.55—2.20 (4H, m), 3.00—3.60 (2H, m). Found: C, 50.58: H, 8.93; N, 19.83%. Calcd for $C_9H_{19}N_3OSi$: C, 50.65; H, 8.98; N, 19.70%.

(1*R*,2*R*)-1-Azido-2-(trimethylsilyloxy)cyclopentane (13): Bp 105 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.12 (9H, s), 1.23—2.25 (6H, m), 3.40—3.76 (1H, m), 3.78—4.10 (1H, m). Found: C, 48.01, H, 8.47; N, 21.32%. Calcd for $C_8H_{17}N_3OSi$: C, 48.20: H, 8.60, N. 21.08%.

(2*R*,3*R*)-2-Azido-3-(trimethylsilyloxy)butane (14): Bp 100 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.13 (9H, s), 1.15 (3H, d, J=10 Hz), 1.16 (3H, d, J=10 Hz), 2.98—3.40 (1H, m), 3.50—3.89 (1H, m). Found: C, 44.72; H, 8.98; N, 22.51%. Calcd for $C_7H_{17}N_3OSi$: C, 44.88; H, 9.15; N, 22.43%.

(1*R*,2*R*)-1-Azido-2-(ethyldimethylsilyloxy)cyclohexane (15): Bp 120 °C/6 Torr; IR (neat) 2100 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.10 (6H, s), 0.58 (2H, q, J=8 Hz), 0.96 (3H, t, J=8 Hz), 1.02—2.35 (8H, m), 2.70—3.63 (2H, m). Found: C,52.69; H, 9.13; N, 18.40%. Calcd for $C_{10}H_{21}N_3OSi$: C, 52.82; H, 9.31; N, 18.48%.

(1*R*,2*R*)-1-Azido-2-(ethyldimethylsilyloxy)cyclopentane (17): Bp 105 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.10 (6H, s), 0.58 (2H, q, J=8 Hz), 0.96 (3H, t, J=8 Hz); 1.16—2.24 (6H, m), 3.48—3.82 (1H, m), 3.84—4.19 (1H,

m). Found: C, 50.51; H, 8.79%; N, 19.79%. Calcd for $C_9H_{19}N_3OSi$: C, 50.65; H, 8.98; N, 19.70%.

(2*R*,3*R*)-2-Azido-3-(ethyldimethylsilyloxy)butane (19): Bp 100 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^1H NMR (CCl_4) δ=0.09 (6H, s), 0.58 (2H, q, J=8 Hz), 0.97 (3H, t, J=8 Hz), 1.13 (3H, d, J=6 Hz), 1.15 (3H, d, J=6 Hz), 3.02—3.42 (1H, m), 3.44—3.86 (1H, m). Found: C, 47.76; H, 9.38; N, 20.98%. Calcd for $C_8H_{19}N_3OSi$: C, 47.72; H, 9.51; N, 20.87%.

(1*R*,2*R*)-1-Azido-2-(isopropyldimethylsilyloxy)cyclohexane (16): Bp 135 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^1H NMR (CCl_4) δ=0.09 (6H, s), 0.92 (1H, q, J=5 Hz), 0.97 (6H, d, J=5 Hz), 1.00—2.32 (8H, m), 2.83—3.85 (2H, m). Found: C, 54.71; H, 9.48; N, 17.46%. Calcd for $C_{11}H_{23}N_3OSi$: C, 54.72; H, 9.60; N, 17.41%.

(1*R*,2*R*)-1-Azido-2-(isopropyldimethylsilyloxy)cyclopentane (18): Bp 120 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^1H NMR (CCl_4) δ=0.07 (6H, s), 0.92 (1H, q. J=5 Hz), 0.97 (6H, d, J=5 Hz), 1.35—2.32 (6H, m), 3.40—3.83 (1H, m), 3.84—4.17 (1H, m). Found: C, 52.91; H, 9.57; N, 18.47%. Calcd for $C_{10}H_{21}N_3OSi$: C, 52.82; H, 9.31; N, 18.48%.

(2*R*,3*R*)-2-Azido-3-(isopropyldimethylsilyloxy)butane (20): Bp 110 °C/5 Torr; IR (neat) 2100 cm^{-1}; ^1H NMR (CCl_4) δ=0.08 (6H, s), 0.92 (1H, q, J=5 Hz), 0.97 (6H, d, J=5 Hz), 1.17 (3H, d, J=9 Hz), 1.26 (3H, d, J=9 Hz); 3.02—3.83 (2H, m). Found: C, 50.46; H, 9.63; N, 19.47%. Calcd for $C_9H_{21}N_3OSi$: C, 50.19: H, 9.83; N, 19.51%.

Kinetic Resolution of *trans*-2,3-Dimethyloxirane. To a dichloromethane (100 cm^3) solution of *trans*-2,3-dimethyloxirane (2.88 g, 40 mmol) and *p*-toluenethiol (2.48 g, 20 mmol) was suspended ZnT (0.43 g, 2 mmol). This heterogeneous mixture was stirred at room temperature for 14 d. After filtration of ZnT, the filtrate was concentrated and purified by column chromatography on silica gel (hexane : ethyl acetate=10 : 1) to afford (2*S*,3*R*)-3-(*p*-tolylthio)-2-butanol (**21**) (3.70 g, 47%). $[\alpha]_D^{23}$ +2.16° (*c* 5.00, CH_2Cl_2). IR (neat) 3440, 800 cm^{-1}. ^1H NMR (CCl_4) δ=1.16 (3H, d, J=8 Hz), 1.27 (3H, d, J=8 Hz), 2.08 (1H, s), 2.37 (3H, s), 2.96—3.27 (1H, m), 3.50—3.86 (1H, m), 7.07 (2H, d, J=8 Hz), 7.30 (2H, d, J=8 Hz). Found: C, 67.07; H, 8.26; S, 16.39%. Calcd for $C_{11}H_{16}OS$: C, 67.30; H, 8.22; S, 16.33%.

Typical Procedures for the Conversion of (1*R*,2*R*)-1 into (*R*)-2-Cyclohexen-1-ol. Oxidation of 1. To a $CHCl_3$ (50 cm^3) solution of **1** (4.04 g, 20 mmol, $[\alpha]_D^{23}$ −45.0°, (*c* 5.00, CH_2Cl_2)) was added *m*-chloroperbenzoic acid (5.2 g, 30 mmol) little by little on ice cooling with stirring. Afer stirring for 30 min at room temperature, the reaction mixture was washed with 20 cm^3 of 5% aqueous $KHCO_3$ three times, dried over Na_2SO_4, concentrated, and purified by column chromatography on silica gel ($CHCl_3$: MeOH=50 : 1) to afford the corresponding S-oxide (4.4 g, 92%). Mp 135—139 °C. IR (KBr) 3380, 1020 cm^{-1}.

Thermal Decomposition of *S*-Oxide of 1. The mixture of *S*-oxide of **1** (3.2 g, 13 mmol) and $CaCO_3$ (1.3 g, 13 mmol) was heated at 150 °C/10 Torr for 3 h. During the thermal decomposition, the distillate was collected in a reciever with Dry Ice-acetone cooling, and was purified by Kugelrohr distillation (100 °C/15 Torr) to give (*R*)-2-cyclohexen-1-ol (0.90 g, 69%, $[\alpha]_D^{23}$ +92.4° (*c* 0.60, $CHCl_3$)).

By the same way, (1*R*,2*R*)-**2** ($[\alpha]_D^{23}$ −34.4°) and (1*R*,2*R*)-**3** ($[\alpha]_D^{23}$ −44.7°) were transformed into (*R*)-2-cyclohexen-1-ol ($[\alpha]_D^{23}$ +102.7 and +110.8°) in 41 and 58% yields, respectively.

The 2-substituted cyclopentanols such as (1*R*,2*R*)-**4** ($[\alpha]_D^{23}$ −7.97°), (1*R*,2*R*)-**5** ($[\alpha]_D^{23}$ −7.80°), and (1*R*,2*R*)-**6** ($[\alpha]_D^{23}$ −15.1°) were converted into (*R*)-2-cyclopenten-1-ol ($[\alpha]_D^{23}$ +46.8, +52.3, and +81.9° (*c* 1.0, $CHCl_3$)) in 80, 62, and 48% yields, respectively.

The 3-substituted 2-butanols such as (2*R*,3*R*)-**7** ($[\alpha]_D^{23}$ −25.8°), (2*R*,3*R*)-**8** ($[\alpha]_D^{23}$ −18.5°), and (2*R*,3*R*)-**9** ($[\alpha]_D^{23}$ −29.0°) were converted into (*R*)-3-buten-2-ol ($[\alpha]_D^{23}$ −16.9, −23.1, and −21.8° (neat)) in 57, 41, and 53% yields, respectively. Furthermore, (2*S*,3*R*)-**21** ($[\alpha]_D^{23}$ +2.16°) was also converted into (*S*)-3-buten-2-ol ($[\alpha]_D^{23}$ −14.1° (neat)) in 51% yield.

Conversion of (1*R*,2*R*)-10 into (*R*)-2-Cyclohexen-1-ol. *N*-Methylation of 10. To a methanol (50 cm^3) solution of (1*R*,2*R*)-**10** (4.2 g, 22 mmol, $[\alpha]_D^{23}$ −52.6° (*c* 5.0, CH_2Cl_2)) was added 50 cm^3 of 25% aqueous K_2CO_3, and Me_2SO_4 (12.6 g, 100 mmol) during 2 h with vigorous stirring. After adding 10 cm^3 of 5% aqueous NaOH, the reaction mixture was extracted with 50 cm^3 of ethyl acetate, dried over Na_2SO_4, cocentrated, and purified by column chromatography on silica gel (hexane : ethyl acetate=6 : 1) to yield (1*R*,2*R*)-**11** (4.2 g, 94%,). $[\alpha]_D^{23}$ +46.4° (*c* 5.0, CH_2Cl_2). IR (neat) 3450 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.10—1.85 (8H, m), 2.18 (1H, s), 2.76 (3H, s), 3.20—3.85 (2H, m), 6.60—7.38 (5H, m). Found: C, 76.18; H, 9.28; N, 6.86%. Calcd for $C_{13}H_{19}NO$: C, 76.06; H, 9.33; N, 6.82%.

Oxidation of (1*R*,2*R*)-11. To a dichloromethane (50 cm^3) solution of **11** (4.2 g, 20 mmol) was added *m*-chloroperbenzoic acid (4.0 g, 23 mmol) little by little. After being stirred for 1 h at room temperature, the mixture was washed with 50 cm^3 of 10% aqueous K_2CO_3 three times, dried over Na_2SO_4, concentrated, and purified by column chromatography on silica gel ($CHCl_3$: MeOH=20 : 1) to afford the corresponding *N*-oxide (3.7 g, 82%). Mp 123—125 °C. IR (KBr) 3420, 1450, 1110 cm^{-1}.

Thermal Decomposition of *N*-Oxide. The *N*-oxide of **11** (1.0 g, 4.5 mmol) was heated at 140 °C/20 Torr for 3 h. The distillate was collected in a reciever with Dry Ice-acetone cooling, and was purified by Kugelrohr distillation to yield (*R*)-2-cyclohexen-1-ol (0.30 g, 67%, $[\alpha]_D^{23}$ +69.3° (*c* 0.60, $CHCl_3$).

Desilylation of *O*-Trialkylsilyl β-Azido Alcohols 12—20. Typical Procedure for the Desilylation of (1*R*,2*R*)-12 into (1*R*,2*R*)-2-Azidocyclohexanol. A methanol solution (8 cm^3) of (1*R*,2*R*)-**12** (2.13 g, 10 mmol, $[\alpha]_D^{23}$ +10.9° (*c* 2.0, CH_2Cl_2)) and 0.05 cm^3 of concd HCl was refluxed for 2 h. After being concentrated in vacuo, the residue was purified by Kugelrohr distilation (105 °C/4.5 Torr) to give (1*R*,2*R*)-2-azidocyclohexanol (1.4 g, 92%). $[\alpha]_D^{23}$ −30.8° (*c* 2.0, CH_2Cl_2). IR (neat) 3320, 2100 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.00—2.28 (8H, m), 2.26 (1H, s), 3.00—3.70 (2H, m). Found: C, 50.89; H, 7.64; N, 29.71%. Calcd for $C_6H_{11}N_3O$: C, 51.05; H, 7.85; N, 29.77%.

By the same way, (1*R*,2*R*)-**15** and **16** ($[\alpha]_D^{23}$ +2.40 and +0.38°) were transformed into (1*R*,2*R*)-2-azidocyclohexanol ($[\alpha]_D^{23}$ −10.5 and −11.1°) in 85 and 87%, respectively.

Desilylation of (1*R*,2*R*)-**13**, **17**, and **18** ($[\alpha]_D^{23}$ −10.1, −9.08, and −7.44° (*c* 2.0, CH_2Cl_2)) were similarly carried out to afford (1*R*,2*R*)-2-azidocyclopentanol ($[\alpha]_D^{23}$ −21.0, −16.5, and −14.3° (*c* 2.0, CH_2Cl_2)) in 91, 88, and 86%. Bp 105 °C/5 Torr (Kugelrohr distillation). IR (neat) 3290, 2120 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.30—2.56 (6H, m), 3.36 (1H, s), 3.40—3.78 (1H, m), 3.80—4.42 (1H, m). Found: C.47.30; H, 7.09; N, 33.12%. Calcd for $C_5H_9N_3O$: C, 47.22; H, 7.13, N, 33.05%.

Desilylation of (2*R*,3*R*)-**14**,**19**, and **20** ($[\alpha]_D^{23}$ −3.35, −3.56, and −9.45° (*c* 2.0, CH_2Cl_2)) yielded (2*R*,3*R*)-3-azido-2-butanol ($[\alpha]_D^{23}$ −37.8, −18.3, and −29.2° (*c* 2.0, CH_2Cl_2)) in

86, 86, 81%, respectively. Bp 100 °C/5 Torr (Kugelrohr distillation). IR (neat) 3370, 2100 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.12 (2H, d, J=12 Hz), 1.25 (2H, d, J=12 Hz), 2.30 (1H, s), 3.03—3.79 (2H, m). Found: C, 41.79; H, 7.67; N, 36.42%. Calcd for $C_4H_9N_3O$: C, 41.72; H, 7.88; N, 36.42%.

Hydrogenolysis of Azido Alcohols. Typical Procedure for the Hydrogenolysis of (1*R*,2*R*)-2-Azidocyclohexanol. The catalytic hydrogenolysis of (1*R*,2*R*)-2-azidocyclohexanol (1.3 g, 9.2 mmol, $[\alpha]_D^{23}$ −30.8° (*c* 2.0, CH_2Cl_2)) was carried out in methanol (12 cm^3) with 10% Pd-C (0.1 g) under atmospheric pressure at room temperature for 1 h. The catalyst was filtered off, and the filtrate was concentrated and purified by Kugelrohr distillation (165 °C/5 Torr) to afford (1*R*,2*R*)-2-aminocyclohexanol (1.2 g, 86%). $[\alpha]_D^{23}$ −15.9° (*c* 1.3, H_2O), (lit,[37] $[\alpha]_D^{22}$ −37.6°).

In a similar manner, the catalytic hydrogenolysis of (1*R*,2*R*)-2-azidocyclopentanol and (2*R*,3*R*)-3-azido-2-butanol ($[\alpha]_D^{23}$ −21.0 and −37.8° (*c* 2.0, CH_2Cl_2)) gave (1*R*,2*R*)-2-amonocyclopentanol (95% yield, $[\alpha]_D^{23}$ −10.2° (*c* 1.7, EtOH lit,[38] $[\alpha]_D^{20}$ −33.3°) and (2*R*,3*R*)-3-amino-2-butanol (95% yield, $[\alpha]_D^{23}$ −6.84° (neat); lit,[39] $[\alpha]_D^{25}$ −17.05°), respectively.

We wish to express our thanks to Professor Teruaki Mukaiyama of Tokyo Science University for correcting the manuscript and encouragement.

(Received August 20, 1987)

Hydroxylations of 2-(1-hydroxyalkyl)-1,4,5,8(or 1,4,5,6,8)-tetra(or penta)methoxynaphthalenes and 2-(1-hydroxyalkyl)-1,4-dimethoxybenzenes at the 3-position were accomplished by a one-pot procedure. The same procedure has been found to be applicable to 2-(1-hydroxyalkyl)naphthalenes and (1-hydroxyalkyl)benzenes having no methoxyl substituent.

Our synthetic route of Erythrostominone (**1**)[2)] requires a polymethoxynaphtol **2** which has a possibility of being converted into **1** by using our method.[3)] During synthetic studies involving naphthoquinone derivatives, we have found a new one-pot procedure that introduces a phenolic hydroxyl group into type-**3** compounds at the ortho position of the hydroxyalkyl to give type-**2** compounds in good yields.

Usually, the hydroxylations of aromatic rings by the oxidation of the corresponding Grignard or organolithium compounds required two steps,[4)] except for the synthesis of 2,2′-dimethoxy-3,3′-dihydroxybiphenyl from 2,2′-dimethoxybiphenyl by Gilman et al.[5)] That is to say, the first step should be a halogenation of the starting aromatic compounds and the second an oxidative hydroxylation of the Grignard or lithium compounds obtained from the halides.

The lithiation of aromatic rings having both methoxyl and hydroxymethyl groups at 1- and 3-positions has already been reported.[6)] Also, aromatics bearing either a methoxyl or hydroxymethyl group could be ortho lithiated.[7)] However, no information has been found in the literature concerning one-pot hydroxylation at the 2-position of aromatic rings having methoxyl and hydroxyalkyl groups at both the 1- and 3-positions, or about one-pot ortho hydroxylation of aromatics bearing only one hydroxyalkyl. In this paper, we report one-pot ortho hydroxylations of 2-(1-hydroxyalkyl)naphthalenes and (1-hydroxyalkyl)benzenes.

Results and Discussion

The substrates **3a—3f** in THF were first treated with butyllithium, then with butylmagnesium bromide and at last oxidized by dry oxygen. A decomposition of the system by an addition of dil HCl or aq NH_4Cl resulted in the formation of naphthols **2a—2f** (Table 1).

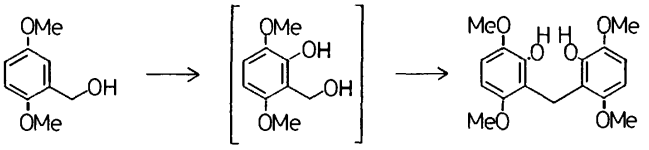
4a 5a

This hydroxylation procedure was applicable to syntheses of the 2-naphthols **5a** and **5b** from 2-(1-hydroxyalkyl)naphthalenes **4a** and **4b** having no methoxyl group (Table 2). The reactions were usually carried out in the presence of *N,N,N′,N′*-tetramethylethylenediamine in an ether solvent. Even if a large excess of *n*-BuLi was used for the reactions, a part of the starting materials was always recovered.

It was clearly proved by ^{13}C NMR that the newly introduced hydroxyl group had occupied the 3-position in the substrats **4a** and **4b**. It is well-known that the ^{13}C-chemical shift of the ortho positional carbon atom adjacent to the carbon atom bearing the hydroxyl group in an aromatic ring moves upfield to an appreciable extent.[8] The chemical shift of C_1 (δ 110.25) in product **5a** was observed more upfield than that of C_4 (δ 128.83) in 2-hydroxymethylnaphthalene (**4a**). Since this C_1 peak (δ 110.25) of the singlet changed into a doublet upon a proton off-resonace decoupling operation, this carbon atom must be a tertiary one of C_1. Therefore, the newly introduced



6a 7a

hydroxyl group occupied the 2-position in **5a**.

In the similar fashion, the benzenes **6a—6f** were also ortho-hydroxylated to give phenols **7a—7f** (Table 3).

A product from **6a** was concluded to have the structure **7a** and the formation process might be as shown in the following chart. This is one of the typical Bakelite formation reactions. Martin,[9] for example, has reported that the formation of his diphenylmethanes could be explained best by a loss of one mole of water and one mole of formaldehyde between two moles of hydroxymethylphenols; he confirmed a loss of formaldehyde in this experiment. These kinds of condensations were easily carried out in the presence of lithium hydroxide.[10] Dean et al.[11] also reported that a change of 1-hydroxymethyl-2-naphthol into 1,1′-methylenedi-2-naphthol occured at 25 °C in ethanol containing of HCl during 1 min, along with an elimination of formaldehyde.

Experimental

^{1}H and ^{13}C NMR spectra were taken on a JEOL JNM-60. MS was obtained with a JEOL DX-300, IR with a Hitachi 260-30. Column chromatography was carried out on silica gel (Wakogel C-200) or alumina gel (Sumitomo, KCG-30) with chloroform as eluent. Melting points were determined with a Yanagimoto micromelting point apparatus and uncorrected. High-performance liquid chromatography (HPLC) was performed with a EYELA PLC-10 using TC-ODS 1171.

Materials. The substrates **3a—3f** were prepared by reductions or by Grignard reactions of 2-formyl-1,4,5,8-tetramethoxynaphthalene (see Ref. 12) and of 2-formyl-1,4,5,6,8-pentamethoxynaphthalene (see Ref. 3).

3a: A cream-colored solid (99% yield); mp 104—105 °C (from hexane-benzene); IR (KBr) 3520 (OH) and 1060 cm^{-1} (OCH_3, OH); ^{1}H NMR ($CDCl_3$) δ=2.42 (s, 1H, OH), 3.76, 3.88, 3.90, 3.92 (each s, 3H, OCH_3), 4.84 (s, 2H, CH_2), 6.80 (s, 2H, ArH), and 6.91 (s, 1H, ArH); MS, *m/z* 278 (M^+), 263, and 245. Calcd for $C_{15}H_{18}O_5$: C, 64.74; H, 6.52%. Found: C, 64.39; H, 6.57%.

3b: It was prepared as shown in Ref. 12.

3c: Colorless viscous oil (99% yield); IR (neat) 3450 (OH), 1600, and 1070 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.89 (t, *J*=6.6 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.42 (broad, 1H, OH), 3.74, 3.88 (each s, 3H, OCH_3), 3.92 (s, 6H, OCH_3), 5.22 (t, *J*=6.0 Hz, 1H, CH), 6.80 (s, 2H, ArH), and 6.97 (s, 1H, ArH); MS, *m/z* 334 (M^+), 316 ($M^+ - H_2O$), 301, 270, 231, and 137; HRMS, Calcd for $C_{19}H_{26}O_5$: M, 334.1781. Found: *m/z* 334.1784.

3d: Colorless viscous oil (89% yield); IR (neat) 3450 (OH), 1600, 1360, 1070 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.90 (t, *J*=6.0 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.18 (broad, 1H, OH), 3.74, 3.81, 3.94 (each s, 3H, OCH_3), 3.97 (s, 6H, OCH_3), 5.22 (t, *J*=6.9 Hz, 1H, CH), 6.73 (s, 1H, ArH), and 6.92 (s, 1H, ArH);

MS, m/z 364 (M^+), 346 ($M^+ - H_2O$), 331, and 152; HRMS, Calcd for $C_{20}H_{28}O_6$: M, 364.1862. Found: m/z 364.1885.

3e: Colorless viscous oil (97% yield); IR (neat) 3470 (OH), 1640 (C=C), 1605, 1070, 995 (vinyl), and 915 cm^{-1} (vinyl); ^1H NMR ($CDCl_3$) δ=2.20 (broad, 1H, OH), 2.57 (t, J=6.9 Hz, 2H, CH_2), 3.75, 3.88 (each s, 3H, OCH_3), 3.92 (s, 6H, OCH_3), 4.9—5.4 (m, 3H, CH, $=CH_2$), 5.9 (m, 1H, -CH=), 6.81(s, 2H, ArH), and 7.00 (s, 1H, ArH); MS, m/z 318 (M^+), 300 ($M^+ - H_2O$), 285, 277, and 262; HRMS, Calcd for $C_{18}H_{22}O_5$: M, 318.1467. Found: m/z 318.1472.

3f: Cream-colored crystals (98% yield); mp 90—91 °C (from hexane); IR (KBr) 3460 (OH), 1640 (C=C), 1600, 1070, 995 (vinyl), and 915 cm^{-1} (vinyl); ^1H NMR ($CDCl_3$) δ=2.20 (broad, 1H, OH), 2.56 (t, J=6.8 Hz, 2H, CH_2), 3.75, 3.81, 3.95 (each s, 3H, OCH_3), 3.98 (s, 3H, OCH_3), 4.9—5.4 (m, 3H, CH, $=CH_2$), 5.9 (m, 1H, -CH=), 6.73, 6.95 (each s, 1H, ArH); MS, m/z 348 (M^+), 330 ($M^+ - H_2O$), 315, and 269. Calcd for $C_{19}H_{24}O_6$: C, 65.50; H, 6.94%. Found: C, 65.25; H, 7.01%.

Substrates **4a** and **4b** were obtained by a treatment of 2-formylnaphthalene with $NaBH_4$ or with butylmagnesium bromide.

4a: White crystals; mp 82—83 °C (lit,[13a] mp 81—82 °C); ^{13}C NMR ($CDCl_3$) δ=125.90 (C_3), 126.48, 126.68, 127.17, 128.98 (C_4, C_5, C_8), 134.06 (s, C_{10}), 134.80 (s, C_9), 141.34 (s, C_2).

4b: A white solid (96% yield); mp 50—51 °C; IR (KBr) 3300 (OH), 1600, 1050, and 1010 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, J=5.1 Hz, 3H, CH_3), 1.1—2.1 (m, 7H, OH, CH_2), 4.82 (t, J=7.1 Hz, 1H, CH), and 7.3—7.9 (m, 7H, ArH); ^{13}C NMR ($CDCl_3$) δ=124.19 (C_3), 124.63, 125.70, 126.05, 127.71, 127.95, 128.19 (C_4), 132.99 (s, C_{10}), 133.28 (s, C_9), 142.32 (s, C_2); MS, m/z 214 (M^+), 196 ($M^+ - H_2O$), 157, and 129. Calcd for $C_{15}H_{18}O$: C, 84.07; H, 8.47%. Found: C, 83.55; H, 8.54%.

Substrates **6a** and **6e** were commercially available, and **6b**, **6c**, **6d**, and **6f** were prepared by reductions of Grignard reactions of the corresponding aldehydes.

6b: White crystals (92% yield); mp 52—53 °C (from hexane); IR (KBr) 3360 (OH), 1600, 1220, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, J=5.3 Hz, 3H, CH_3), 1.1—1.9 (m, 7H, OH, CH_2), 2.57 (d, J=5.9 Hz, 1H, OH), 3.76, 3.80 (each s, 3H, OCH_3), 4.82 (q, J=5.9 Hz, 1H, CH), and 6.7—7.0 (m, 3H, ArH); MS, m/z 224 (M^+), 206 ($M^+ - H_2O$), 177, and 167. Calcd for $C_{13}H_{20}O_3$: C, 69.61; H, 8.99%. Found: C, 69.65; H, 9.06%.

6c: Colorless viscous oil (99% yield); IR (neat) 3300 (OH), 1600, 1260, and 1040 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.60 (t, J=5.2 Hz, 1H, OH), 3.76 (s, 3H, OCH_3), 4.59 (d, J=5.2 Hz, 2H, CH_2), and 6.6—7.3 (m, 4H, ArH); MS, m/z 138 (M^+), 109, and 77; HRMS, Calcd for $C_8H_{10}O_2$: M, 138.0682. Found: m/z 138.0696.

6d: Colorless viscous oil (98% yield); IR (neat) 3350 (OH), 1600, 1265, and 1040 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, J=5.3 Hz, 3H, CH_3), 1.0—2.0 (m, 7H, OH, CH_2), 3.80 (s, 3H, OCH_3), 4.62 (t, J=6.6 Hz, 1H, CH), and 6.7—7.3 (m, 4H, ArH); MS, m/z 194 (M^+), 176 ($M^+ - H_2O$), 137, and 109; HRMS, Calcd for $C_{12}H_{18}O_2$: M, 194.1306. Found: m/z 194.1301.

6f: Colorless viscous oil (93% yield); IR (neat) 3380 (OH), 1500, 1455, and 1040 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, J=5.1 Hz,3H, CH_3), 1.0—1.9 (m, 6H, CH_2), 2.11 (broad, 1H, OH), 4.62 (t, J=5.6 Hz, 1H, CH), and 7.30 (s, 5H, ArH); MS, m/z 164 (M^+), 163, 107, and 79; HRMS, Calcd for $C_{11}H_{16}O$: M, 164.1200. Found: m/z 164.1196.

General Procedure for Hydroxylations of the Substrates 3a—3f. A solution of a substrate (1 mmol) in THF (10 ml) was cooled to −15 °C in an ice bath, then allowed to react with n-BuLi (7 mmol, 10 w/v% in hexane), stirred at −15 °C for 2 h. To the system, a dark red solution, was added a solution of butylmagnesium bromide in THF (Mg: 8 mmol; BuBr: 8 mmol; THF: 10 ml) at −15 °C. After 1 h, dry oxygen was bubbled into the system for 1 h at such a rate as to keep the temperature below 0 °C. The reaction mixture was decomposed upon the addition of dil HCl or aq NH_4Cl, extracted with chloroform, washed with brine, dried over Na_2SO_4, and concentrated. Purification of the crude products by silica-gel chromatography with chloroform as eluent gave the hydroxylated products **2a—2f**. The purity of the oily products isolated by chromatography was determined by HPLC.

General Procedure for Hydroxylations of 4a, 4b, and 6a—6f. n-BuLi (7.5 mmol) was added under cooling to −15 °C to a solution of a substrate (3 mmol) and *N,N,N',N'*-tetramethylethylenediamine (7.5 mmol) in ether (15 ml) and stirred at room temperature for 3 h. To the system was added a solution of butylmagnesium bromide (9 mmol) in THF (15 ml) at −10 °C. Oxidation, decomposition, and purification procedures were carried out in the same manner as the above mentioned general procedure.

2a: Viscous oil (contained ca. 20% of **3a**); IR (neat) 3400 (OH), 1605, 1370, 1075, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.38 (broad, 2H, OH), 3.74, 3.77, 3.90, 3.92 (each s, 3H, OCH_3), 4.84 (s, 2H, CH_2), 6.68 (d, J=5.7 Hz, 1H, ArH), and 6.76 (d, J=5.7 Hz, 1H, ArH); MS, m/z 294 (M^+), 279, and 233; HRMS, Calcd for $C_{15}H_{18}O_6$: M, 294.1102. Found: m/z 294.1093.

2b: Viscous oil (a pure); IR (neat) 3400 (OH), 1600, 1355, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.21 (broad, 2H, OH), 3.79, 3.85, 3.86, 3.97, 4.06 (each s, 3H, OCH_3), 4.85 (s, 2H, CH_2), and 6.74 (s, 1H, ArH); MS, m/z 324 (M^+), 309, 291, 279, and 263; HRMS, Calcd for $C_{16}H_{20}O_7$: M, 324.1208. Found: m/z 324.1206.

2c: Viscous oil (contained ca. 20% of **3c**); IR (neat) 3400 (OH), 1603, 1365, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.90 (t, J=6.0 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.28 (broad, 2H, OH), 3.72, 3.76, 3.89, 3.93 (each s, 3H, OCH_3), 5.21 (t, J=6.0 Hz, 1H, CH), 6.69 (d, J=6.3 Hz, 1H, ArH), and 6.78 (d, J=6.3 Hz, 1H, ArH); MS, m/z 350 (M^+), 332 ($M^+ - H_2O$), 317, and 301; HRMS, Calcd for $C_{19}H_{26}O_6$: M, 350.1730. Found: m/z 350.1755.

2d: Viscous oil (a pure); IR (neat) 3400 (OH), 1600, 1355, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.91 (t, J=6.0 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.22 (broad, 1H, OH), 3.75, 3.83, 3.86, 3.97, 4.04 (each s, 3H, OCH_3), 5.23 (t, J=7.2 Hz, 1H, CH), 6.22 (broad, 1H, OH), and 6.77 (s, 1H, ArH); MS, m/z 380 (M^+), 362 ($M^+ - H_2O$), 347, and 309; HRMS, Calcd for $C_{20}H_{28}O_7$: M, 380.1835. Found: m/z 380.1847.

2e: Viscous oil (contained ca. 10% of **3e**); IR (neat) 3430 (OH), 1640 (C=C), 1605, 1370, 1050, 995 (C=C), and 920 cm^{-1} (C=C); ^1H NMR ($CDCl_3$) δ=2.22 (broad, 2H, OH), 2.58 (t, J=6.7 Hz, CH_2), 3.75, 3.76, 3.89, 3.93 (each s, 3H, OCH_3), 4.9—5.5 (m, 3H, CH, $=CH_2$), 5.9 (m, 1H,-CH=), 6.73 (d, J=11.0 Hz, 1H, ArH), and 6.91 (d, J=11.0 Hz, 1H, ArH); MS, m/z 334 (M^+), 316 ($M^+ - H_2O$), 300, and 277; HRMS, Calcd for $C_{18}H_{22}O_6$: 334.1417. Found: m/z 334.1429.

2f: Viscous oil (a pure); IR (neat) 3400 (OH), 1640 (C=C), 1600, 1355, 1050, 990 (C=C), 915 cm^{-1} (C=C); ^1H NMR

($CDCl_3$) δ=2.30 (broad, 1H, OH), 2.58 (t, J=6.8 Hz, 2H, CH_2), 3.76, 3.83, 3.86, 3.97, 4.04 (each s, 3H, OCH_3), 4.9—5.5 (m, 3H, CH, $=CH_2$), 5.9 (m, 1H, -CH=), 6.30 (broad, 1H, OH), and 6.81 (s, 1H, ArH); MS, m/z 364 (M^+), 346 ($M^+ -H_2O$), 331, and 323; HRMS, Calcd for $C_{19}H_{24}O_7$: M, 364.1523. Found: m/z 364.1538.

5a: Cream-colored crystals; mp 191—192 °C (from hexane-ethanol); IR (KBr) 3430 (OH), 3150 (OH), 1630, 1600, 1245, and 870 cm^{-1}; ^1H NMR ($(CD_3)_2CO$) δ=4.45 (q, J=4.9 Hz, 1H, OH), 4.89 (d, J=4.9 Hz, 2H, CH_2), 7.0—8.0 (m, 6H, ArH), and 8.75 (s, 1H, OH); ^{13}C NMR ($(CD_3)_2CO$) δ=62.24 (CH_2OH), 110.25 (d, C_1), 124.29 (C_6), 126.93 (C_8), 127.07 (C_5), 127.36 (C_7), 128.78 (C_4), 129.91 (s, C_{10}) 132.01 (s, C_9), 135.53 (C_3), and 155.03 (C_2); MS, m/z 174 (M^+), 156, and 128. Calcd for $C_{11}H_{10}O_2$: C, 75.84; H, 5.79%. Found: C, 75.41; H, 5.86%.

5b: Cream-colored crystals; mp 81—82 °C (from hexane); IR (KBr) 3450 (OH), 3100 (OH), 1630, 1600, 1230, 1170, 875, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, J=5.0 Hz, 3H, CH_3), 1.1—2.1 (m, 6H, CH_2), 2.72 (broad, 1H, OH), 4.96 (t, J=6.9 Hz, 1H, CH), 7.1—7.9 (m, 6H, ArH), and 7.98 (s, 1H, OH); ^{13}C NMR ($CDCl_3$) δ=14.08, 22.59, 28.11, 36.91, 76.42, 111.67 (d, C_1), 123.65 (C_6), 126.34 (C_5, C_7, C_8), 127.61 (C_4), 128.19 (s, C_{10}), 129.95 (s, C_9), 134.26 (C_3), and 153.66 (C_2); MS, m/z 230 (M^+), 212 ($M^+ -H_2O$), 183, and 157. Calcd for $C_{15}H_{18}O_2$: C, 78.23; H, 7.88%. Found: C, 77.69; H, 7.87%.

7a: White crystals; mp 209.5—210.5 °C (from hexane-ethanol); IR (KBr) 3370 (OH), 1600, 1230, and 1045 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.75, 3.76 (each s, 6H, OCH_3), 3.80 (s, 2H, CH_2), 5.49 (s, 2H, OH), 6.56, 6.61 (each s, 2H, ArH); ^{13}C NMR ($(CD_3)_2NCDO$) δ=29.04 (CH_2), 56.13 (C_3-OMe), 57.30 (C_6-OMe), 101.06 (C_5), 116.37 (C_4), 120.03 (C_1), 141.99 (C_3), 146.68 (C_2), and 152.64 (C_6); MS, m/z 320 (M^+), 305, 289, and 153. Calcd for $C_{17}H_{20}O_6$: C, 63.74; H, 6.29%. Found: C, 63.36; H, 6.45%.

7b: Viscous oil (contained ca. 16% of **6b**); IR (neat) 3550 (OH), 3430 (OH), 1610, 1200, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, J=5.4 Hz, 3H, CH_3), 1.1—2.0 (m, 7H, OH, CH_2), 3.74, 3.84 (each s, 3H, OCH_3), 4.62 (t, J=6.5 Hz, 1H, CH), 5.64 (s, 1H, ArOH), 6.53 and 6.92 (each s, 1H, ArH); MS, m/z 240 (M^+), 239, 222 ($M^+ -H_2O$), 193, and 161; HRMS, Calcd for $C_{13}H_{20}O_4$: 240.1362. Found: m/z 240.1396.

7c: White crystals; mp 115—116 °C (from hexane); IR (KBr) 3440 (OH), 3150 (OH), 1600, 1265, 1235, 1030, and 995 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.57 (s, 1H, OH), 3.90 (s, 3H, OCH_3), 4.61 (s, 2H, CH_2), 5.60 (s, 1H, ArOH), and 6.87 (m, 3H, ArH); MS, m/z 154 (M^+), 137, 93, and 65. Calcd for $C_8H_{10}O_3$: C, 62.33; H, 6.54%. Found: C, 62.37; H, 6.66%.

7d: A semisolid; IR (neat) 3400 (OH), 1600, 1270, and 1035 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, J=5.4 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.35 (broad, 1H, OH), 3.85 (s, 3H, OCH_3), 4.62 (t, J=4.4 Hz, 1H, CH), 5.80 (broad, 1H, ArOH), and 6.80 (m, 3H, ArH); MS, m/z 210 (M^+), 153, 125, and 93; HRMS, Calcd for $C_{12}H_{18}O_3$: M, 210.1257. Found: m/z 210.1278.

7e: White crystals, mp 82.5—83.5 °C (from hexane-ethanol) (lit, [13b] mp 80 °C).

7f: Viscous oil (a pure); IR (neat) 3300 (OH), 1590, 1240, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.90 (t, J=5.9 Hz, 3H, CH_3), 1.1—2.0 (m, 6H, CH_2), 2.53 (broad, 1H, OH), 4.82 (t, J=5.6 Hz, 1H, CH), 6.7—7.4 (m, 4H, ArH), and 7.93 (s, 1H, ArOH); MS, m/z 180 (M^+), 162 ($M^+ -H_2O$), 133, and 77; HRMS, Calcd for $C_{11}H_{16}O_2$: 180.1150. Found: 180.1119.

The reaction of 1-methyl-1-azaazulen-2(1*H*)-one (**1a**) with dimethyl acetylenedicarboxylate (DMAD) or dibenzoylacetylene (DBA) in refluxing acetonitrile gave 1,2-disubstituted azulene (**2**), 2-methylcyclopent[*de*]isoquinolin-3(2*H*)-ones, 1-methyl-1-azacyclopent[*cd*]azulen-2(1*H*)-ones, and 3-substituted 1-methyl-1-azaazulen-2(1*H*)-ones, whereas in refluxing *t*-butylbenzene, compound **2** and 6,8-etheno-1-methylcyclohepta[*b*]pyrrol-2(1*H*)-one were obtained as major products. The reactions proceeded periselectively depending on the temperature. 2-Hydroxy-1-azaazulene behaved as 1-azaazulen-2(1*H*)-one and the reaction with DMAD gave similar result as for **1a**. The reaction of 2-amino-1-azaazulene with DMAD gave methyl 2,4a-dihydro-2-oxo-1,4a-diazabenz[*a*]azulene-4-carboxylate and tetramethyl 4,5-dihydro-1*H*-1,11-diazacyclohept[*a*]azulene-2,3,4,5-tetracarboxylate. The reaction of 2-mercapto-1-azaazulene with DMAD gave tetramethyl 4,4a-dihydro-4a-azabenz[*a*]azulene-1,2,3,4-tetracarboxylate in moderate yield. The reaction mechanisms of these reactions are discussed.

We have studied the cycloadditions of 1-azaazulenes with reactive acetylenes and found that the acetylenes first attaked the N-1 position of 1-azaazulenes and give dipolar intermediates.[1,2] As a continuation of our work, we have advanced the reaction to 2-hydroxy-, 2-amino-, and 2-mercapto-1-azaazulenes. It is known that 2-hydroxy-1-azaazulene is a tautomer of 1-azaazulen-2(1*H*)-one and reacts toward electrophile at the C-3 position as well as the N-1 position.[3-9] Therefore, it is expected that 2-hydroxy-1-azaazulene with reactive acetylenes undergoes another type of cycloaddition reaction. Therefore, we first investigated the reaction of 1-methyl-1-azaazulen-2(1*H*)-one[9] in order to understand the reaction of the keto-form.[10] We then investigated the reaction of 2-hydroxy-, 2-amino-, and 2-mercapto-1-azaazulenes.

A treatment of **1a** with dimethyl acetylenedicarboxylate (DMAD) in refluxing acetonitrile for 120 h gave dimethyl 1,2-azulenedicarboxylate[11,12] (**2a**) (9%), dimethyl 2-methyl-2,3-dihydro-3-oxocyclopent[*de*]-

isoquinoline-4,5-dicarboxylate (**3a**) (11%), dimethyl 1-methyl-1,2,2a,3-tetrahydro-2-oxo-1-azacyclopent[*cd*]-azulene-3,4-dicarboxylate (**4a**) (11%), dimethyl 1-methyl-1,2-dihydro-2-oxo-1-azacyclopent[*cd*]azulene-3,4-dicarboxylate (**5a**) (7%), dimethyl 1-methyl-1,2-dihydro-2-oxo-1-azaazulene-3-maleate (**6a**) (17%), and dimethyl 1-methyl-1,2-dihydro-2-oxo-1-azaazulene-3-fumarate (**7a**) (21%). These structures were determined on the basis of the spectroscopic data as well as on elemental analyses. Compound **3a** was a stable fused 3(2*H*)-isoquinolinone derivative. In its ^{1}H NMR spectrum, a signal of the 1H singlet assignable to H-1 can be seen at δ 8.73 , which is a reasonable value as 3(2*H*)-isoquinolinone.[13] In the ^{1}H NMR spectrum of **4a**, AB doublets can be seen at δ 3.10 and 4.32 (J=9.2 Hz), and in the ^{13}C NMR spectrum, two methine signals at δ 43.14 and 50.09. The dehydrogenation of **4a** by tetrachloro-*o*-benzoquinone (TCQ) gave **5a** in 47% yield. The result assists with the structure.

When the above reaction was carried out in refluxing *t*-butylbenzene for 3 h, compounds **2a** (21%), **3a** (5%), **5a** (0.8%), and dimethyl 6,8a-etheno-1-methyl-1,2-dihydro-2-oxocyclohepta[*b*]pyrrole-7,8-dicarboxylate (**8a**) (49%) were isolated. In the ^{13}C NMR spectrum of **8a**, signals assignable to sp^3 carbons can be seen at δ 38.70 (d, C-6) and 71.55 (s, C-8a), and in its ^{1}H NMR spectrum, methine proton can be observed at δ 4.46 (ddd, J=8.5, 6.7, and 1.2 Hz, H-6). Further evidence supporting the structure of **8a** is provided by its mass spectrum which displays an intense peak at m/z 159 (98%) associated with the loss of DMAD.

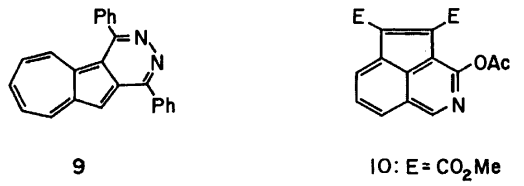
Ethyl 1-methyl-1,2-dihydro-2-oxo-1-azaazulene-3-carboxylate (**1b**) did not react with DMAD in refluxing benzene or acetonitrile, but gave **8b** (66%) in refluxing *t*-butylbenzene.

In a similar treatment, the reaction of **1a** with dibenzoylacetylene (DBA) in refluxing acetonitrile gave **2b** (9%), **3b** (3%), **4b** (50%), **5b** (6%), and **7b** (6%), and in refluxing *t*-butylbenzene **2b** (60%), **3b** (19%), and **8c** (15%). Dehydrogenation of **4b** with TCQ gave **5b** in a 70% yield.

The reaction of 1,2-dibenzoylazulene **2b** with hydrazine hydrate gave the corresponding pyridazino derivative **9**.

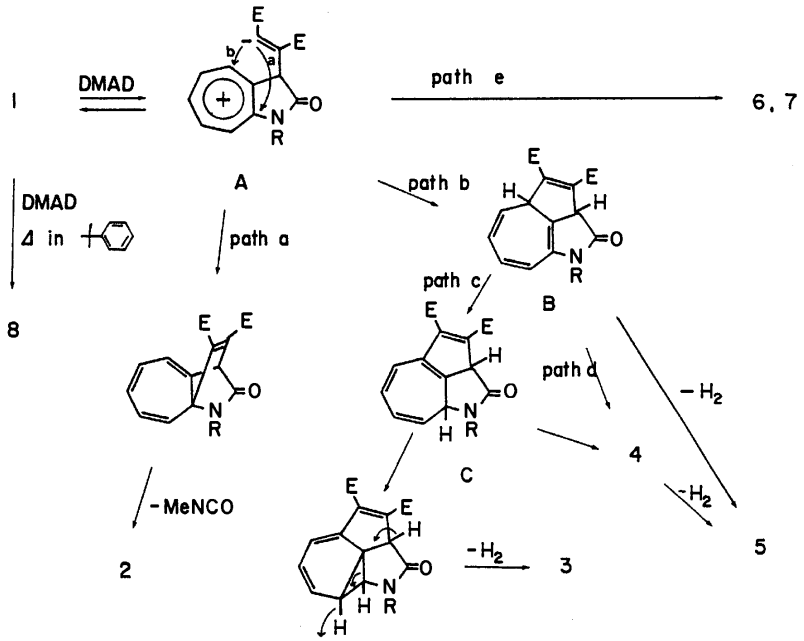
The reaction of 2-hydroxy-1-azaazulene with DMAD in refluxing acetonitrile gave **2a** (7%), **3c** (35%), **5c** (5%), **6c** (21%), and **7c** (30%). The result was similar to that of **1a**; it is therefore considered that 2-hydroxy-1-azaazulene behaved as 1-azaazulen-2(1*H*)-one (**1c**). The observation that compound **1b** exists in exactly the keto form in the ^{1}H NMR spectrum in $CDCl_3$ is in agreement with the above consideration. The structures obtained from the above reaction were assigned on the basis of spectroscopic data as well as on elemental analyses.

Compound **3c** was acetylated with acetic anhydride to give **10**. In the IR spectrum of **10**, three ester carbonyl signals were observed at 1756, 1730, and 1700 cm^{-1}, whereas the amide carbonyl signal was not. We therefore assigned **10** as an *O*-acetylated compound. In the ^{1}H NMR spectrum of **10**, an H-1 proton was observed at δ 8.92. The ^{1}H NMR spectrum of **3c** in DMSO-d_6 shows a signal of H-1 at δ 8.91, which is



9

10: E = CO_2Me



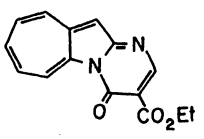
Scheme 1.

comparable with that of **10**. Therefore, we considered that compound **3c** would exist in an enol form in DMSO-d_6.

Previously, we reported that ethyl 1,2-dihydro-2-oxo-1-azaazulene-3-carboxylate (**1d**) reacted with DMAD to give **1e**.[2] Different from this, the corresponding fumarate was not obtained upon the reaction of **1c**. This result suggested that the C-3 position of **1c** is more reactive than the N-1 position.

A plausible mechanism is shown in Scheme 1. When DMAD attacks the C-3 position of **1**, which is a reactive site towards electrophile, a dipolar species **A** should be produced. A cyclization on the C-8a position of **A** and a successive elimination of MeNCO furnishes **2** (path a). A cyclization on the C-4 position of **A** gives **B** (path b), and several successive 1,5-hydrogen shifts of **B** produces **C** (path c) and **4** (path d). Dehydrogenation of **B** and/or **4** affords **5**. A tautomerization of **C** and a subsequent dehydrogenation leads to **3** (path c). A protonation and aromatization of **A** gave Michael adducts **6** and **7** (path e). Through a reaction at a higher temperature a Diels-Alder reaction occurs on a seven-membered ring and **8** is produced, in addition to the cycloaddition-cycloreversion product **2**. It is considered that the activation energy of the formation of **8** is higher than that of **A**. Consequently, compound **A** is favorably produced at lower temperatures. A similar periselectivity dependence on the temperature is known regarding the reaction of 5-azaazulene with reactive acetylenes.[14]

The treatment of 2-amino-1-azaazulene (**11**) with DMAD in refluxing acetonitrile for 5 h gave methyl 2,4a-dihydro-2-oxo-1,4a-diazabenz[*a*]azulene-4-carboxylate (**12**) and tetramethyl 4,5-dihydro-1*H*-1,11-diazacyclohept[*a*]azulene-2,3,4,5-tetracarboxylate (**13**) in 18.5% and 19% yield, respectively. These structures were assigned on the basis of the spectroscopic data as well as elemental analyses. The ^{1}H NMR spectrum of **12** shows protons at δ 4.04 (s, Me), 7.09 (s, H-10), 7.19 (s, H-3), 7.25—7.45 (m, H-6, 7, and 8), 7.94 (d, J=10.4 Hz, H-9), and 9.84—9.96 (H-5). In the ^{1}H NMR of 4-oxo compound **14**,[15] proton at C-5 was observed at δ 10.05—10.30. Different from the 4-oxo compound, deesterification of **12** gave no distinct compound. We therefore assigned **12** as being a 2-oxo compound. The ^{1}H NMR spectrum of **13** showed a pair of AB doublets (J=4.9 Hz) at δ 4.97 and 5.21. In its ^{13}C NMR spectrum, sp^3 carbon appeared at δ 43.47 (d) and 45.43 (d).

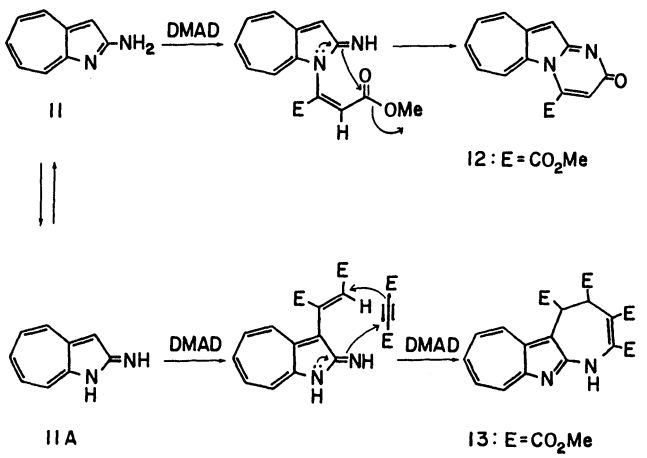


14

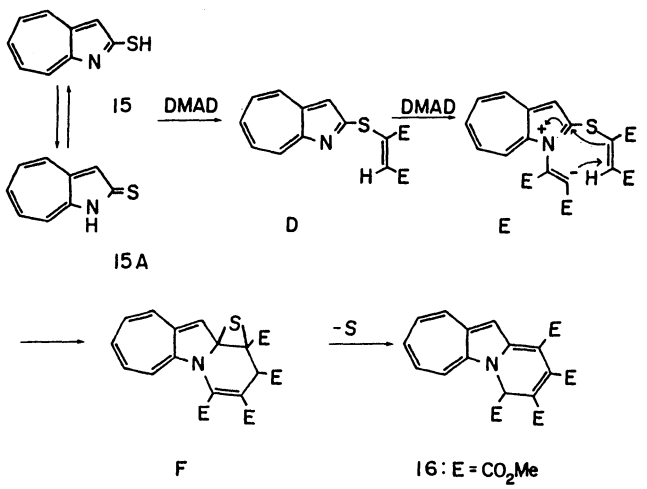
A plausible mechanism is shown in Scheme 2. When DMAD attacks the N-1 position of amino-form **11**, compound **12** should be produced. An attack of DMAD at the C-3 position of imino-form **11A** and a successive reaction of another molecule of DMAD furnishes **13**. In the ^{1}H NMR spectrum of **11** in $CDCl_3$, equilibrium (80% of **11**, 20% of **11A**) was observed.

The treatment of 2-mercapto-1-azaazulene (**15**) with DMAD in refluxing acetonitrile for 17 h gave a complex mixture and only **16** was isolated in 38% yield. Compound **16** was analyzed as $C_{21}H_{19}NO_8$ from HRMS and elemental analysis, and assigned as tetramethyl 4,4a-dihydro-4a-azabenz[*a*]azulene-1,2,3,4-tetracarboxylate. The ^{1}H NMR spectrum of **16** shows protons at δ 6.41 (s, H-4), 7.10—7.20 (m, H-6, 7, 8, and 9), 7.45 (s, H-10), and 7.63 (d, J=11.0 Hz, H-5), in addition of four methyl singlets. In its ^{13}C NMR spectrum, one sp^3 carbon was observed at δ 54.74 (d).

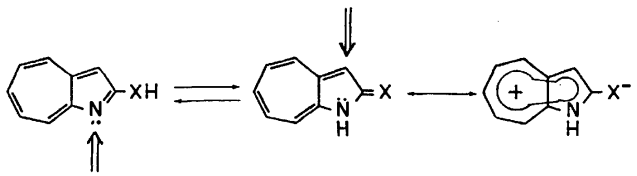
A plausible mechanism is shown in Scheme 3. In the ^{1}H NMR spectrum of **15** in $CDCl_3$, a predominant existance of the thione form **15A** (over 95%) was observed. This suggests that the reaction of **15A** with DMAD (considered as soft electrophile) would first occur on sulfur, which is a most soft atom, and gives 1-azaazulene **D**. A second molecule of DMAD attacks



Scheme 2.



Scheme 3.



G H I

the N-1 position of **D** and gives a dipolar intermediate **E**. A cyclization of **E** affords **F**, and a desulfurization of **F** furnishes **16**.

All these results show that DMAD first attacks the N-1 position of the 1-azaazulene form **G**, whereas DMAD first attacks the C-3 position or soft atom of 1,2-dihydro-1-azaazulen-2-ylidene form **H**. The reason for the difference in the reaction is considered to be as follows. In form **G**, the N-1 atom is most electron rich,[16] and a lone pair on nitrogen would have more nucleophilicity than C-3 carbon. On the other hand, in form **H**, the nucleophilicity of a lone pair on nitrogen would decrease owing to the contribution to the 10-π aromatic resonance as form **I**. The observation that the reaction occures on the N-1 position (**1d**) or not at all (**1b**) at lower temperatures, whereas the Diels-Alder reaction on seven membered ring is predominant at higher temperature (**1b**), when 3-position is blocked in form **H**, assists in the above consideration.

Experimental

Melting points are uncorrected. ^{1}H NMR sapctra (250 MHz) and ^{13}C NMR spectra (62.87 MHz) were recorded on a Hitachi R-250H spectrometer using deuteriochloroform as a solvent with tetramethylsilane as an internal standard, unless otherwise stated. IR spectra were recorded on a Hitachi 270-50 infrared spectrophotometer for Nujol mulls. Mass spectra were determined with a JEOL JMS-01SG-2 spectrometer (70 eV). Kieselgel 60 was used for column chromatography unless otherwise stated.

Reaction of 1 with DMAD. a) A solution of **1a** (0.510 g) and DMAD (1.367 g) in dry acetonitrile (30 ml) was refluxed for 120 h and evaporated. The residue was chromatographed. Elution with benzene gave **2a** (0.072 g, 9%), which was recrystallized from hexane to give violet needles, mp 53—54 °C (lit,[12] mp 45 °C, lit,[11] oil); ^{1}H NMR δ=3.96 (3H, s, OMe), 3.99 (3H, s, OMe), 7.48 (1H, s, H-3), 7.48 (1H, t, J=9.8 Hz, H-5), 7.57 (1H, t, J=9.8 Hz, H-7), 7.87 (1H, t, J=9.8 Hz, H-6), 8.50 (1H, d, J=9.8 Hz, H-4), and 9.44 (1H, d, J=9.8 Hz, H-8); IR 1732 and 1698 cm^{-1} (ester C=O); MS m/z (rel intensity) 244 (M$^+$; 81), 213 (100), 186 (11), 183 (14), 127 (14), and 126 (10); Anal. ($C_{14}H_{12}O_4$) C, H. Elution with benzene–chloroform (4 : 1) gave a 1 : 1-mixture (from the integration of the ^{1}H NMR) of **3a** and **4a** (0.216 g, 22%). Fractional recrystallization of the mixture from cyclohexane gave **3a** [0.055 g, yellow needles, mp 168—169 °C, ^{1}H NMR δ=3.40 (3H, s, NMe), 3.99 (3H, s, OMe), 4.11 (3H, s, OMe), 6.95 (1H, dd, J=6.1 and 1.2 Hz, H-6), 7.45—7.60 (2H, m, H-7 and 8), and 8.73 (1H, s, H-1); ^{13}C NMR δ=26.36 (q), 52.84 (q), 53.08 (q), 106.85 (d), 120.59 (d), 123.86 (s), 126.08 (s), 127.81 (s), 127.99 (s), 130.21 (d), 130.50 (s), 134.04 (d), 139.85 (s), 165.30 (s), 165.38 (s), and 166.64 (s); IR 1738, 1722, and 1700 (ester C=O), 1638 (amide C=O), and 795 cm^{-1} (1,2,3-trisubstituted benzene); MS m/z (rel intensity) 299 (M$^+$; 100), 268 (62), 196 (16), 183 (39), 182 (21), 181 (26), 127 (13); Anal. ($C_{16}H_{13}NO_5$) C, H, N.] and **4a** [0.030 g, yellow prisms, mp 151—152 °C, ^{1}H NMR δ=3.08 (3H, s, NMe), 3.10 (1H, d, J=9.2 Hz, H-2a), 3.86 (3H, s, OMe), 3.88 (3H, s, OMe), 4.32 (1H, d, J=9.2 Hz, H-3), 5.66 (1H, d, J=6.1 Hz, H-8), 6.40—6.50 (2H, m, H-5 and 6), and 6.65—6.75 (1H, m, H-7); ^{13}C NMR δ=27.14 (q), 43.14 (d), 50.09 (d), 52.33 (q), 52.55 (q), 98.33 (d), 122.19 (d), 124.69 (d), 124.75 (s), 130.83 (s), 131.29 (d), 134.43 (s), 134.68 (s), 162.86 (s), 164.40 (s), and 170.73 (s); MS m/z (rel intensity) 301 (M$^+$; 100), 241 (26), 210 (26), 200 (26), 154 (11), 140 (13), 127 (12), 115 (10), and 114 (11); IR 1720 and 1706 (ester C=O), and 1628 cm^{-1} (amide C=O); Anal. ($C_{16}H_{15}NO_5$) C, H, N.]. Elution with chloroform gave **5a** (0.065 g, 7%), which was recrystallized from cyclohexane-dichloromethane to give red needles, mp 190—191 °C, ^{1}H NMR δ=3.52 (3H, s, NMe), 3.94 (3H, s, OMe), 4.05 (3H, s, OMe), 7.48 (1H, d, J=9.8 Hz, H-8), 7.72 (1H, t, J=9.8 Hz, H-6), 8.15 (1H, t, J=9.8 Hz, H-7), and 9.16 (1H, d, J=9.8 Hz, H-5); ^{13}C NMR δ=26.55 (q), 51.67 (q), 52.72 (q), 113.74 (d), 114.03 (s), 115.22 (s), 128.29 (d), 135.17 (s), 137.11 (s), 138.93 (s), 140.87 (d), 141.40 (d), 149.96 (s), 162.79 (s), 164.23 (s), and 167.63 (s); IR 1734, 1708, and 1700 (ester C=O), and 1620 cm^{-1} (amide C=O); MS m/z (rel intensity) 299 (M$^+$; 35), 268 (76), 240 (22), 238 (22), 210 (36), 209 (39), 196 (47), 182 (40), 153 (51), 152 (50), 126 (100), 114 (75). Anal. ($C_{16}H_{13}NO_5$) C, H, N. Further elution gave **6a** (0.164 g, 17%), which was recrystallized from cyclohexane–dichloromethane to give red prisms, mp 123.5—124 °C, ^{1}H NMR δ=3.58 (3H, s, NMe), 3.79 (3H, s, OMe), 3.96 (3H, s, OMe), 7.00 (1H, s, H-vinyl), 7.05—7.40 (4H, m, H-5, 6, 7, and 8), and 7.76 (1H, d, J=11.0 Hz, H-4); IR 1715 and 1656 (ester C=O), and 1620 cm^{-1} (amide C=O); Anal. ($C_{16}H_{13}NO_5$) C, H, N. Elution with chloroform–ethyl acetate (1 : 1) gave **7a** (0.206 g, 21%), which was recrystallized from cyclohexane–dichloromethane to give red prisms, mp 150—151 °C, ^{1}H NMR δ=3.58 (3H, s, NMe), 3.68 (3H, s, OMe), 3.81 (3H, s, OMe), 6.90—7.30 (5H, m, H-4, 5, 6, 7, and 8), and 7.15 (1H, s, H-vinyl), IR 1728 and 1672 (ester C=O), and 1630 cm^{-1} (amide C=O); Anal. ($C_{16}H_{15}NO_5$) C, H, N.

b) A solution of **1a** (0.200 g), and DMAD (0.536 g) in t-butylbenzene (6 ml) was refluxed for 3 h and evaporated. The residue was chromatographed. Elution with benzene gave **2a** (0.064 g, 21%). Elution with benzene–chloroform (1 : 1) gave **3a** (0.019 g, 5%) and **5a** (0.003 g, 0.8%), successively. Elution with chloroform gave **8a** (0.185 g, 49%), which was recrystallized from cyclohexane to give colorless scales, mp 156—158 °C, ^{1}H NMR δ=3.05 (3H, s, NMe), 3.77 (3H, s, OMe), 3.78 (3H, s, OMe), 4.46 (1H, ddd, J=8.5, 6.7, and 1.2 Hz, H-6), 5.95 (1H, s, H-3), 6.06 (1H, d, J=10.4 Hz, H-4), 6.21 (1H, dd, J=7.9 and 1.2 Hz, H-9), 6.41 (1H, dd, J=10.4 and 8.5 Hz, H-5), and 6.66 (1H, dd, J=7.9 and 6.7 Hz, H-10); ^{13}C NMR δ=26.47 (q), 38.70 (d), 52.64 (q×2), 71.55 (s), 120.57 (d), 121.16 (d), 129.47 (d), 132.62 (d), 133.26 (d), 134.23 (s), 145.64 (s), 147.03 (s), 163.07 (s), 164.95 (s), and 171.28 (s); IR 1735, 1720, and 1688 (ester C=O), and 1622 (amide C=O); MS m/z (rel intensity) 301 (M$^+$; 100), 270 (19), 269 (13), 242 (88), 241 (35), 210 (45), 198 (16), 183 (47), 159 (98), 154 (26), 130 (16), and 127 (12); Anal. ($C_{16}H_{15}NO_5$) C, H, N.

c) A mixture of **1b** (0.075 g) and DMAD (0.1 g) in t-butylbenzene (5 ml) was refuxed for 7 h and evaporated. The

residue was chromatographed with chloroform to give **8b** (0.08 g, 66%), which was recrystallized from hexane to give colorless prisms, mp 99—101 °C, ^{1}H NMR δ=1.36 (3H, t, J=7.0 Hz, Me), 3.06 (3H, s, NMe), 3.77 (3H, s, OMe), 3.78 (3H, s, OMe), 4.34 (2H, q, J=7.0 Hz, OCH_2), 4.57 (1H, ddd, J=7.9, 6.7, and 1.2 Hz, H-6), 6.23 (1H, dd, J=7.9 and 1.2 Hz, H-9), 6.69 (1H, dd, J=11.0 and 7.9 Hz, H-5), 6.78 (1H, dd, J=7.9 and 6.7 Hz, H-10), and 6.84 (1H, d, J=11.0 HZ, H-4); IR 1748, 1720, and 1710 (ester C=O), and 1688 cm^{-1} (amide C=O); Anal. ($C_{19}H_{19}NO_7$) C, H, N.

d) A solution of **1c** (0.250 g) and DMAD (0.75 g) in dry acetonitrile (30 ml) was refluxed for 45 h and evaporated. The residue was chromatographed. Elution with benzene gave **2a** (0.029 g, 7%). Elution with chloroform gave **3c** (0.180 g, 35%), which was recrystallized from cyclohexane-dichloromethane to give orange prisms, mp 176—178 °C, ^{1}H NMR δ=4.00 (3H, s, OMe), 4.12 (3H, s, OMe), 7.11 (1H, d, J=6.7 Hz, H-6), 7.56 (1H, dd, J=7.9 and 6.7 Hz, H-7), 7.63 (1H, d, J=7.9 Hz, H-8), 8.59 (1H, bs, exch., OH), and 8.81 (1H, s, H-1). δ (DMSO-d_6)=3.93 (6H, s, OMe×2), 7.15 (1H, d, J=6.7 Hz, H-6), 7.64 (1H, dd, J=8.5 and 6.7 Hz, H-7), 7.79 (1H, d, J=8.5 Hz, H-8), 8.91 (1H, s, H-1), and 11.13 (1H, s, exch., OH); IR 3188 (OH), 1750, 1722, and 1702 (ester C=O), 1638 (amide C=O), and 795 cm^{-1} (1,2,3-trisubstituted benzene); Anal. ($C_{15}H_{11}NO_5$) C, H, N. Further elution gave **5c** (0.026 g, 5%), which was recrystallized from cyclohexane-dichloromethane to give orange needles, mp 250—251 °C, ^{1}H NMR δ (DMSO-d_6)=3.86 (3H, s, OMe), 3.90 (3H, s, OMe), 7.72 (1H, d, J=9.8 Hz, H-8), 7.90 (1H, t, J=9.8 Hz, H-6), 8.37 (1H, t, J=9.8 Hz, H-7), 9.08 (1H, d, J=9.8 HZ, H-5), and 11.48 (1H, s, exch., NH); IR 3284 (NH), 1730, 1704, and 1684 (ester C=O), and 1625 cm^{-1} (amide C=O); MS Found: m/z 285.0617. Calcd for $C_{15}H_{11}NO_5$: M, 285.0638. Elution with chloroform-ethyl acetate gave **6c** (0.106 g, 21%), which was recrystallized from cyclohexane-dichloromethane to give red micro needles, mp 248—249 °C, ^{1}H NMR δ=3.80 (3H, s, OMe), 3.98 (3H, s, OMe), 7.05 (1H, s, H-vinyl), 7.10 (1H, dd, J=11.5 and 9.5 Hz, H-5), 7.30—7.42 (3H, m, H-6, 7, and 8), 7.80 (1H, d, J=11.5 Hz, H-4), and 11.27 (1H, s, exch., NH), δ (DMSO-d_6)=3.70 (3H, s, OMe), 3.86 (3H, s, OMe), 7.03 (1H, s, H-vinyl), 7.22 (1H, dd, J=11.6 and 9.8 Hz, H-5), 7.30—7.50 (3H, m, H-6, 7, and 8), 7.60 (1H, d, J=11.6 Hz, H-4), and 12.20 (1H, s, exch., NH); IR 3100—2600 (broad, NH), 1736 and 1704 (ester C=O), and 1652 cm^{-1} (amide C=O); Anal. ($C_{15}H_{13}NO_5$) C, H, N. Elution with ethyl acetate gave **7c** (0.150 g, 30%), which was recrystallized from cyclohexane-dichloromethane to give orange needles, mp 165—167 °C, ^{1}H NMR δ=3.67 (3H, s, OMe), 3.82 (3H, s, OMe), 7.03 (1H, dd, J=9.16 and 9.14 Hz, H-5), 7.10—7.32 (3H, m, H-6, 7, and 8), 7.19 (1H, s, H-vinyl), 7.35 (1H, d, J=9.16 Hz, H-4), and 12.43 (1H, s, exch., NH); IR 3150—2600 (broad, NH), 1730 (ester C=O), and 1644 cm^{-1} (amide C=O); Anal. ($C_{15}H_{13}NO_5$) C, H, N.

Reaction of 1 with DBA. a) A solution of **1a** (0.461 g) and DBA (1.357 g) in dry acetonitrile (30 ml) was refluxed for 72 h and evaporated. The residue was chromatographed. Elution with benzene gave **2b** (0.083 g, 8.5%), which was recrystallized from hexane to give blue prisms, mp 133—134 °C, ^{1}H NMR δ=7.10—7.52 (11H, m, H-5 and phenyl×2), 7.54 (1H, dd, J=10.4 and 9.8 Hz, H-7), 7.63 (1H, s, H-3), 7.89 (1H, dd, J=10.4 and 9.8 Hz, H-6), 8.60 (1H, d, J=9.8 Hz, H-4), and 9.19 (1H, d, J=10.4 Hz, H-8); IR 1670 cm^{-1} (C=O); Anal. ($C_{24}H_{16}O_2$) C, H. Elution with benzene-chloroform (1 : 1) gave **3b** (0.037 g, 3%), which was recrystallized from cyclohexane-dichloromethane to give yellow prisms, mp 204—205 °C, ^{1}H NMR δ=3.67 (3H, s, NMe), 7.03 (1H, dd, J=5.5 and 2.5 Hz, H-6), 7.4—7.7 (8H, m, H-7, 8, and m,p-phenyl×2), 7.83 (2H, d, J=7.3 Hz, H-o-phenyl), 7.88 (2H, d, J=7.3 Hz, H-o-phenyl), and 8.30 (1H, s, H-1); IR 1700, 1672, and 1652 (C=O), and 1632 cm^{-1} (amide C=O); Anal ($C_{26}H_{17}NO_3$) C, H, N. Further elution gave **4b** (0.568 g, 50%), which was recrystallized from cyclohexane to give orange micro needles, mp 100—102 °C, ^{1}H NMR δ=3.13 (3H, s, NMe), 3.32 (1H, bd, J=9.2 Hz, H-2a), 4.92 (1H, d, J=9.2 Hz, H-3), 5.73 (1H, bd, J=6.1 Hz, H-8), 6.35—6.45 (2H, m, H-5 and 6), 6.72 (1H, dd, J=9.8 and 6.1 Hz, H-7), 7.05—7.52 (10 H, m, phenyl×2); IR 1716 and 1662 (C=O), and 1638 cm^{-1} (amide C=O); Anal. ($C_{26}H_{19}NO_3$) C, H, N. Elution with chloroform gave **5b** (0.063 g, 6%), which was recrystallized from cyclohexane-dichloromethane to give red needles, mp 246—247 °C, ^{1}H NMR δ=3.55 (3H, s, NMe), 7.05—7.52 (8H, m, phenyl), 7.53 (1H, d, J=9.8 Hz, H-8), 7.61 (2H, d, J=7.3 Hz, H-o-phenyl), 7.74 (1H, t, J=9.8 Hz, H-6), 8.20 (1H, t, J=9.8 Hz, H-7), and 8.96 (1H, d, J=9.8 Hz, H-5); IR 1718 and 1654 (C=O) and 1624 cm^{-1} (amide C=O); Anal. ($C_{26}H_{17}NO_3$) C, H, N. Further elution gave **7b** (0.064 g, 6%), which was recrystallized from cyclohexane-dichloromethane to give red prisms, mp 201—203 °C, ^{1}H NMR δ=3.66 (3H, s, NMe), 7.00—7.20 (3H, m, H-5, 6, and 7), 7.30—7.60 (7H, m, H-8 and m,p-phenyl ×2), 7.88 (1H, d, J=11.0 Hz, H-4), 8.04 (2H, d, J=6.7 Hz, H-o-phenyl), 8.07 (2H, d, J=6.7 Hz, H-o-phenyl), and 8.59 (1H, s, H-vinyl); IR 1664 (C=O) and 1638 cm^{-1} (amide C=O); Anal. ($C_{26}H_{19}NO_3$) C, H, N.

b) A solution of **1a** (0.200 g) and DBA (1.472 g) in t-butylbenzene (10 ml) was refluxed for 1 h and evaporated. The residue was chromatographed. Elution with benzene gave recovered DBA (0.884 g) and **2b** (0.638 g, 60%). Elution with benzene-chloroform (1 : 1) gave **3b** (0.231 g, 19%). Elution with chloroform gave **8c** (0.188 g, 15%), which recrystallized from cyclohexane to give colorless prisms, mp 174—174.5 °C, ^{1}H NMR δ=2.88 (3H, s, NMe), 4.42 (1H, ddd, J=8.5, 6.7, and 1.2 Hz, H-6), 6.02 (1H, s, H-3), 6.29 (1H, d, J=10.4 Hz, H-4), 6.36 (1H, dd, J=7.9 and 1.2 Hz, H-9), 6.48 (1H, dd, J=10.4 and 8.5 Hz, H-5), 6.86 (1H, dd, J=7.9 and 6.7 Hz, H-10), and 7.14—7.50 (10H, m, phenyl ×2); IR 1688 and 1662 (C=O), and 1646 cm^{-1} (amide C=O); Anal. ($C_{26}H_{19}NO_3$) C, H, N.

Dehydrogenation of 4. a) A mixture of **4a** (0.030 g) and TCQ (0.080 g) in dry benzene (20 ml) was refluxed for 2 h and evaporated. The residue was chromatographed on alumina. Elution with chloroform gave **5a** (0.014 g, 47%).

b) A mixture of **4b** (0.440 g) and TCQ (1.200 g) in dry benzene (50 ml) was refluxed for 1 h and evaporated. The residue was chromatographed on alumina with chloroform to give **5b** (0.308 g, 70%).

Synthesis of 9. A solution of **2b** (0.184 g) and 80% hydrazine hydrate (1 ml) in ethanol (20 ml) was refluxed for 30 min and evaporated. The residue was chromatographed with chloroform to give **9** (0.081 g, 45%), which was recrystallized from cyclohexane-dichloromethane to give blue prisms, mp >300 °C, ^{1}H NMR δ=7.14 (1H, dd, J=1.0 and 7.9 Hz, H-6), 7.31 (1H, dd, J=9.8 and 8.6 Hz, H-8), 7.55—7.70 (7H, m, H-7 and m,p-phenyl ×2), 7.74 (1H, s, H-10), 7.80—7.88 (2H, m, H-o-phenyl), 8.15—8.21 (2H, m, H-o-phenyl), 8.40 (1H, d, J=9.8 Hz, H-9), and 8.44 (1H, d, J=7.9 Hz, H-5); IR no carbonyl absorption; MS m/z (rel intensity) 332 (M^+; 100), 331 (64), 302 (91), 300 (50), 276 (52), 226 (52), 202 (24), 200

(25), 151 (57), 150 (50), 138 (41), 126 (28), and 77 (71); Anal. ($C_{24}H_{16}N_2$) C, H, N.

Acetylation of 3c. A mixture of **3c** (0.080 g), acetic anhydride (10 ml), and conc. sulfuric acid (1 drop) was refluxed for 1 h and poured into water (100 ml). The mixture was neutralized with sodium hydrogencarbonate, extracted with chloroform, washed with water, dried over sodium sulfate, and evaporated. The residue was recrystallized from cyclohexane to give **10** (0.035 g, 38%) as yellow prisms, mp 174—176 °C, ^{1}H NMR δ=2.80 (3H, s, Me), 4.01 (3H, s, OMe), 4.13 (3H, s, OMe), 7.71 (1H, dd, J=8.6 and 6.7 Hz, H-7), 7.83 (1H, d, J=8.6 Hz, H-8), 8.32 (1H, d, J=6.7 Hz, H-6), and 8.92 (1H, s, H-1); IR 1756, 1730, and 1700 cm^{-1} (ester C=O). HRMS Found: m/z 327.0750. Calcd for $C_{17}H_{13}NO_6$: M, 327.0744.

Reaction of 2-Amino-1-azaazulene with DMAD. A solution of **11** (0.577 g) and DMAD (0.85 g) in acetonitrile (50 ml) was refluxed for 5 h and evaporated. The residue was chromatographed. Elution with chloroform gave **12** (0.188 g, 18.5%), which was recrystallized from cyclohexane-dichloromethane to give violet needles, mp 223—225 °C, ^{1}H NMR δ=4.04 (3H, s, OMe), 7.09 (1H, s, H-10), 7.19 (1H, s, H-3), 7.25—7.45 (3H, m, H-6, 7, and 8), 7.94 (1H, d, J=10.4 Hz, H-9), and 9.84—9.96 (1H, m, H-5); Anal. ($C_{14}H_{10}N_2O_3$) C, H, N. Elution with chloroform-ethyl acetate (1 : 1) gave **13** (0.325 g, 19%), which was recrystallized from ethyl acetate to give orange prisms, mp 182—183 °C, ^{1}H NMR δ=3.45, 3.61, 3.63, and 3.79 (each 3H, s, OMe), 4.97 (1H, d, J=4.9 Hz, H-4), 5.21 (1H, d, J=4.9 Hz, H-5), 7.60—7.80 (3H, m, H-7, 8, and 9), 8.12 (1H, bs, NH, exch.), and 8.20—8.38 (2H, m, H-6 and 10); ^{13}C NMR δ=43.47 (d), 45.43 (d), 52.38 (q), 52.49 (q×2), 52.75 (q), 105.64 (s), 106.37 (s), 128.74 (d), 129.83 (d), 130.85 (d), 131.77 (d), 134.04 (d), 139.79 (s), 145.84 (s), 156.02 (s), 159.08 (s), 165.20 (s), 167.71 (s), 169.81 (s), and 170.84 (s); IR 3230 (NH), 1750, 1740, 1730, and 1704 cm^{-1} (ester C=O); Anal. ($C_{21}H_{20}N_2O_8$) C, H, N.

Reaction of 2-Mercapto-1-azaazulene with DMAD. A mixture of **15** (0.350 g), DMAD (0.82 g), and acetonitrile (50 ml) was refluxed for 5 h, then evaporated. The residue was chromatographed. Elution with chloroform gave **16** (0.347 g, 35%), which was recrystallized from cyclohexane to give violet needles, mp 188—189 °C, ^{1}H NMR δ=3.64, 3.81, 3.83, 3.96 (each 3H, s, OMe), 6.41 (1H, s, H-4), 7.10—7.20 (4H, m, H-6, 7, 8, and 9), 7.45 (1H, s, H-10), and 7.63 (1H, d, J=11.0 Hz, H-5); ^{13}C NMR δ=51.16 (q), 52.03 (q), 52.38 (q), 53.03 (q), 54.74 (d), 91.40 (s), 101.02 (s), 110.71 (d), 115.76 (d), 131.50 (d), 132.13 (d), 132.60 (d), 133.04 (d), 142.73 (s), 143.65 (s), 146.39 (s), 152.22 (s), 164.23 (s), 164.94 (s), 167.52 (s), and 168.53 (s); IR 1740, 1690, 1676, and 1665 cm^{-1} (ester C=O); MS m/z (rel intensity) 413 (M^+; 2), 412 (7), 382 (5), 354 (100), and 178 (6). Found: C, 60.53; H, 4.58; N, 3.16%. Calcd for $C_{21}H_{19}NO_8$: C, 61.02; H, 4.63; N, 3.39%. HRMS Found: m/z 413.1109. Calcd for $C_{21}H_{19}NO_8$: M, 413.1109.

We thank Dr. Masafumi Yasunami (Tohoku University) and Dr. Akira Mori (Kyushu University) for the measurements of the mass spectra and elemental analyses.

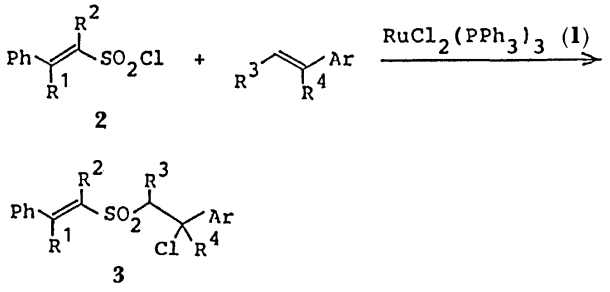
Synthesis of Substituted 1,3-Dienes by the Reaction of Alkenesulfonyl Chlorides with Olefins Catalyzed by a Ruthenium(II) Complex

Masayuki KAMEYAMA, Hiroshi SHIMEZAWA, Takeshi SATOH, and Nobumasa KAMIGATA*
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received August 31, 1987)

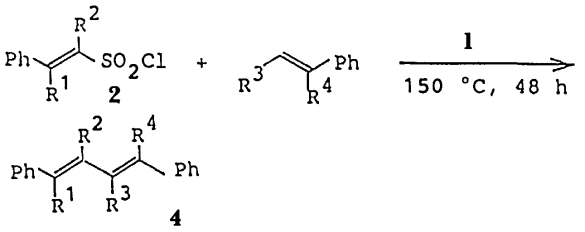
Alkenesulfonyl chlorides reacted with vinylarenes in the presence of a catalytic amount of dichlorotris(triphenylphosphine)ruthenium(II) to give substituted 1 : 1 adducts, which were dehydrochlorinated and desulfonylated successively to form substituted (*E,E*)-1,3-dienes in good yield.

We have previously reported that the reaction of alkane- and arenesulfonyl chlorides with olefins catalyzed by dichlorotris(triphenylphosphine)ruthenium(II) (**1**) under mild conditions affords 1 : 1 adducts in high yield.[1] We recently found that alkenesulfonyl chlorides reacted with olefins in the presence of the ruthenium(II) catalyst **1** to form 1 : 1 adducts, which were dehydrochlorinated and desulfonylated successively by raising the reaction temperature from 80 to 150 °C to give (*E,E*)-1,4-diaryl-1,3-butadienes in high yield.[2,3] However, these reactions were limited to the formation of 1,3-butadienes substituted with aryl groups at the 1- and 4-positions. Here, we report on the formation of substituted 1,3-dienes by the reaction of alkenesulfonyl chlorides with styrenes catalyzed by the ruthenium(II) complex **1**.

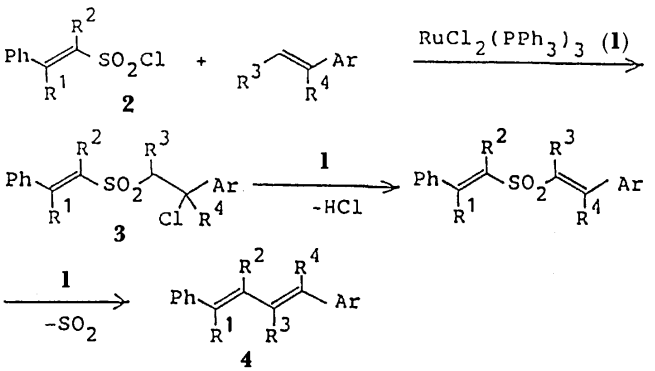
The reaction of (*E*)-2-phenyl-1-propene-1-sulfonyl chloride (**2b**) with styrene was carried out in benzene, in the presence of a catalytic amount of dichlorotris(triphenylphosphine)ruthenium(II) (**1**), by heating the reaction mixture at 80 °C under a nitrogen atmosphere to give 1 : 1 adduct **3d** in 89% yield. Similarly, (*E*)-2-phenylethene-, (*E*)-2-phenyl-1-propene-1-, and (*E*)-1-phenyl-1-propene-2-sulfonyl chloride (**2a—c**) were added to substituted vinylarenes using **1** as a catalyst at 80—100 °C to afford 1 : 1 adducts **3** in high yield. The results are summarized in Table 1. Thus, the ruthenium(II)-phosphine catalyzed addition reaction of styrenesulfonyl chlorides possessing methyl group at α- and β-position (**2b** and **2c**) to α- and β-methylstyrenes was found to give 1 : 1 adducts in good yield.



The reaction of (*E*)-2-phenyl-1-propene-1-sulfonyl-chloride with styrene catalyzed by **1** was also carried out in benzene upon raising the reaction temperature from 80 to 150 °C, to give unsymmetrical 1,4-diphenyl-1,3-pentadiene (**4b**) in 51% yield. Similarly, several alkenesulfonyl chlorides **2a—c** were reacted with substituted vinylarenes in order to study the scope and limitation of the formation of substituted 1,3-dienes. The results are summarized in Table 2.



We have previously reported that the reaction of (*E*)-2-phenylethenesulfonyl chloride with *p*-methylstyrene catalyzed by **1** proceeds successively via an addition, dehydrochlorination, and desulfonylation to give (*E*)-2-chloro(*p*-tolyl)ethyl styryl sulfone, (*E,E*)-*p*-methylstyryl sulfone, and (*E,E*)-1-phenyl-4-(*p*-tolyl)-1,3-butadiene, respectively, by studying the time course. Moreover, it was also found that a ruthenium(II) catalyst was effected in each of the three steps.[3] Therefore, the formation of substituted 1,3-diene **4** could be accounted for by the following path-way, as shown in Scheme 1. Alkenesulfonyl chlorides **2** react with the olefins catalyzed by the ruthenium(II) complex **1** to give 1 : 1 adducts **3** during the initial step. Dehydrochlorination and desulfonylation from adducts **3** take place, successively, in the presence of the ruthenium complex **1** to afford substituted 1,3-dienes **4**.



Scheme 1.

There are a number of methods for the preparation of 1,3-dienes;[4-6] however, some of them can prepare

Table 1. Reaction of Alkenesulfonyl Chloride with Olefin Catalyzed by $RuCl_2(PPh_3)_3$ (**1**)

Sulfonyl chloride	Olefin	Temp/°C	Time/h	Product	Yield/%
 **2a**		80	70	**3a**	88
		100	36	**3b**	46[21]
		100	24	**3c**	23
 **2b**		80	24	**3d**	89
		80	21	**3e**	81
		80	13	**3f**	95
		80	24	**3g**	70
		100	36	**3h**	80[21]
		100	24	**3i**	61
 **2c**		80	24	**3j**	84
		80	37	**3k**	74
		80	37	**3l**	76
		80	72	**3m**	70
		100	36	**3n**	80[21]
		100	24	**3o**	53

only symmetrical 1,3-dienes[7-12] and others require sophisticated organometallic reagents.[13-17] On the other hand, the present method can be used to prepare symmetrical and unsymmetrical 1,3-dienes in good yield by the reaction of easily available sulfonyl chlorides with olefin. The reaction of **2c** with 2-phenyl-1-propene afforded 2-methyl-1,4-diphenyl-1,3-pentadiene (**4e**) and (*E*)-2-chloro-2-phenylpropyl 1-methyl-2-phenylethenyl sulfone (**3n**) in 15% and 63% yields, respectively (Run 8 in Table 2). This indicates that the adduct **3n** was not readily dehydrochlorinated and desulfonylated to 1,3-diene **4e** when ethenesulfonyl chloride has a substituent at the β-position, probably by the steric effect of the methyl group.

A reaction of (*E*)-1-propene-1-sulfonyl chloride with styrene was carried out at 150 °C using the ruthenium(II) complex **1** while expecting the formation of 1-phenyl-1,3-pentadiene. Unfortunately, the expected 1,3-diene was not obtained, though various transition metal complexes, such as $NiCl_2(PPh_3)_2$, $Pd(PPh_3)_4$, $PdCl_2(PPh_3)_2$, $Pt(PPh_3)_4$, $RhCl(PPh_3)_3$, and $RuCl_2(PPh_3)_3$, were used as catalysts. The results show that

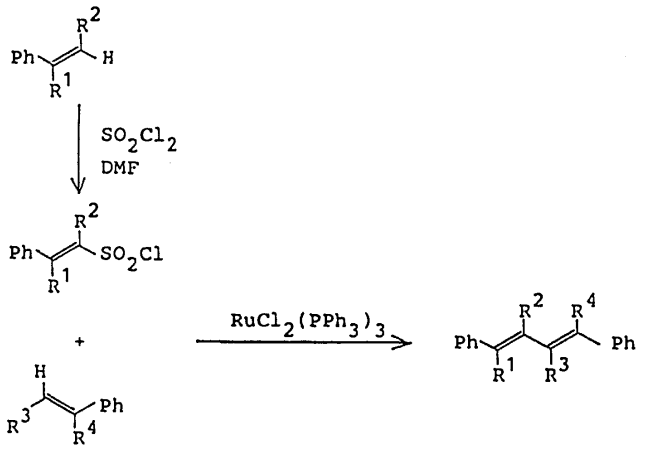
Table 2. Formation of (*E,E*)-1,3-Dienes by the Reaction of (*E*)-Alkenesulfonyl Chlorides with Olefin Catalyzed by the Ruthenium(II) Complex **1**

Run	Sulfonyl chloride	Olefin	Product	Yield/%
1	 **2a**		 **4a**	91
2			 **4b**	56
3			 **4c**	38
4	 **2b**		 **4b**	51
5			 **4d**	80
6			 **4e**	23[a]
7	 **2c**		 **4c**	21
8			 **4e**	15[b]
9			 **4f**	10[c]

a) Isomer of **4e** was isolated in 17% yield. b) Adduct **3n** was formed in 63% yield. c) Isomer of **4f** and adduct **3o** were isolated in 6% and 16% yield respectively.

the reaction of alkenesulfonyl chlorides without an aryl group with vinylarenes did not afford 1,3-dienes, although the reason has not yet been clarified.

In conclusion, symmetrically and unsymmetrically substituted 1,4-diaryl-1,3-dienes were formed by the reaction of alkenesulfonyl chlorides with olefins catalyzed by the ruthenium(II) complex. The present method involves a very excellent one-pot synthesis of symmetrical and unsymmetrical (*E,E*)-1,4-diaryl-1,3-dienes, since substituted ethenesulfonyl chloride can be prepared very easily by treating vinylarenes with sulfuryl chloride in *N,N*-dimethylformamide.[18] The present reaction can be regarded as an oxidative coupling reaction of each terminal carbon atom of two kinds of vinylarenes by using sulfuryl chloride and ruthenium(II) catalyst. Since a direct oxidative coupling of vinylarenes is impossible, the present reaction offers a novel and convenient synthetic method of symmetrical and unsymmetrical (*E,E*)-1,4-diaryl-1,3-dienes.



Experimental

Measurement. Melting points and boiling points were uncorrected. The infrared absorption spectra were determined on a Hitachi Model 260-10 spectrophotometer with samples as either neat liquids or KBr disks. The proton magnetic resonance spectra were recorded at 60 MHz by using a JMX-PMX 60 SI spectrometer with Me_4Si as an internal standard in $CDCl_3$. Mass spectra were determined with a JEOL JMX-DX 300 mass spectrometer with JEOL 5000 Mass Data System at an ionizing voltage of 20—70 eV. The gel-permeation chromatography was accomplished on a JAI LC-08 liquid chromatograph with a JAIGEL-1H column (20ϕ×600 mm×2) using chloroform as an eluent.

Materials. Dichlorotris(triphenylphosphine)ruthenium-(II) (**1**) was prepared according to a procedure described in the literature.[19] (*E*)-2-Phenylethenesulfonyl chloride (**2a**) was prepared from styrene by treatment with sulfuryl chloride in *N,N*-dimethylformamide by the method described in the literature:[18] yield 50%; mp 87—88 °C (from ethanol–hexane; lit, mp 89—90 °C). (*E*)-2-Phenyl-1-propene-1-sulfonyl chloride (**2b**) or (*E*)-1-phenyl-1-propene-2-sulfonyl chloride (**2c**) were prepared from 2-phenyl-1-propene or 1-phenyl-1-propene by treating with sulfuryl chloride in *N,N*-dimethylformamide–dichloromethane and then with triethylamine in ether: (**2b**) yield 29%; bp 96—98 °C/0.2 mmHg (1 mmHg=133.322 Pa); IR (neat) 1370 and 1170 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.65 (3H, s), 6.90 (1H, s), and 7.40 (10H, s); MS *m/z* 216 (M^+): (**2c**) yield 68%; bp 95—96 °C/0.2 mmHg; IR (neat) 1370, 1355, and 1170 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.45 (3H, s), 7.35 (5H, s), and 7.65 (1H, s); MS *m/z* 216 (M^+). (*E*)-1-Propene-1-sulfonyl chloride was prepared from propylene oxide by treatment with sodium hydrogensulfite, phosphorus pentachloride, and then triethylamine in ether according to the literature:[20] yield 68%; bp 88—89 °C/21 mmHg. Styrene, *p*-methylstyrene, *p*-chlorostyrene (Tokyo Kasei Chemicals), *m*-nitrostyrene (Aldrich Chemicals), 2-phenyl-1-propene, and 1-phenyl-1-propene (Wako Chemicals) were purified by distillation prior to use.

Formation of 1:1 Adducts by the Reaction of Alkenesulfonyl Chlorides with Olefins. To a solution of 1.0 mmol of alkenesulfonyl chloride and 1.5 mmol of olefin in 2.0 cm^3 of benzene or toluene was added 0.01 mmol of dichlorotris(triphenylphosphine)ruthenium(II) (**1**) and heated at 80—100 °C under a nitrogen atmosphere. The reaction mixture was chromatographed on florisil by using benzene as an eluent to separate polar substances. Nonpolar substances were purified by gel-permeation chromatography using chloroform as an eluent to isolate 1:1 adducts **3a—o**.

The physical and spectral data of compounds **3a—o** are as follows:

(*E*)-2-Chloro-2-phenylethyl Styryl Sulfone (3a): Mp 97—98 °C; IR (KBr) 1310 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.78 (1H, d, J=7.8 Hz), 3.82 (1H, d, J=7.8 Hz), 5.33 (1H, t, J=7.8 Hz), 6.33 (1H, d, J=15 Hz), 7.10—7.40 (10H, m), and 7.35 (1H, d, J=15 Hz); MS m/z 306 (M^+).

(*E*)-2-Chloro-2-phenylpropyl Styryl Sulfone (3b): IR (neat) 1310 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.20 (2H, s), 5.42 (1H, s), 5.60 (1H, s), 6.43 (1H, d, J=16 Hz), 7.00—7.30 (10H, m), and 7.32 (1H, d, J=16 Hz);[21] MS m/z 321 (M^+ +1);[22] HRMS, Found m/z 320.0743, Calcd for $C_{17}H_{17}O_2SCl$: M, 320.0637.

(*E*)-2-Chloro-1-methyl-2-phenylethyl Styryl Sulfone (3c): Mp 95—96 °C; IR (KBr) 1310 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.53 (3H, d, J=8.0 Hz), 3.22—3.63 (1H, m), 5.59 (1H, d, J=4.0 Hz), 6.38 (1H, d, J=15 Hz), 7.27 (10H, s), and 7.38 (1H, d, J=15 Hz); MS m/z 320 (M^+); HRMS, Found: m/z 319.0577, Calcd for $C_{17}H_{16}O_2SCl$: M, 319.0559.

(*E*)-2-Chloro-2-phenylethyl 2-Phenyl-1-propenyl Sulfone (3d): Mp 95—96 °C; IR (KBr) 1305 and 1120 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.40 (3H, s), 3.70—3.85 (2H, m), 5.36 (1H, t, J=6.0 Hz), 6.07 (1H, s), and 7.00—7.80 (10H, m); MS m/z 320 (M^+); HRMS, Found: m/z 320.0644, Calcd for $C_{17}H_{17}O_2SCl$: M, 320.0637.

(*E*)-2-Chloro-2-(*p*-tolyl)ethyl 2-Phenyl-1-propenyl Sulfone (3e): IR (neat) 1310 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.17 (3H, s), 2.37 (3H, s), 3.79 (2H, d, J=6.0 Hz), 5.33 (1H, t, J=6.0 Hz), 5.93 (1H, s), and 6.70—7.70 (9H, m); MS m/z 298 (M^+ −HCl); HRMS, Found: m/z 298.0993, Calcd for $C_{18}H_{17}O_2S$: M, 298.1027.

(*E*)-2-Chloro-2-(*p*-chlorophenyl)ethyl 2-Phenyl-1-propenyl Sulfone (3f): Mp 58—60 °C; IR (neat) 1310 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.43 (3H, s), 3.76—3.85 (2H, m), 5.36 (1H, t, J=6.0 Hz), 6.06 (1H, s), and 7.00—7.50 (9H, m); MS m/z 354 (M^+); HRMS, Found m/z 354.0222, Calcd for $C_{17}H_{16}O_2SCl_2$: M, 354.0248.

(*E*)-2-Chloro-2-(*m*-nitrophenyl)ethyl 2-Phenyl-1-propenyl Sulfone (3g): Mp 101—102 °C; IR (KBr) 1540, 1350, 1310, and 1120 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.48 (3H, s), 3.75—3.90 (2H, m), 5.47 (1H, t, J=6.0 Hz), 6.13 (1H, s), and 7.18—8.21 (9H, m); MS m/z 365 (M^+); HRMS, Found: m/z 365.0523, Calcd for $C_{17}H_{16}O_4NSCl$: M, 365.0488.

(*E*)-2-Chloro-2-phenylpropyl 2-Phenyl-1-propenyl Sulfone (3h): IR (neat) 1305 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.33 (3H, s), 4.13 (2H, s), 5.39 (1H, s), 5.57 (1H, s), 6.30 (1H, m), and 6.70—7.40 (10H, m);[16] MS m/z 335 (M^+ +1);[17] HRMS, Found: m/z 299.1125, Calcd for $C_{18}H_{19}O_2S$: M, 299.1105.

(*E*)-2-Chloro-1-methyl-2-phenylethyl 2-Phenyl-1-propenyl Sulfone (3i): IR (neat) 1300 and 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.36 (1H, d, J=7.0 Hz), 1.54 (2H, d, J=7.0 Hz), 2.48 (3H, s), 3.10—3.65 (1H, m), 5.40—5.64 (1H, m), 6.00—6.10 (1H, m), and 6.90—7.30 (10H, s); MS m/z 335 (M^+ +1);[17] HRMS, Found: m/z 299.1105, Calcd for $C_{18}H_{19}O_2S$: M, 299.1105.

(*E*)-2-Chloro-2-phenylethyl 1-Methyl-2-phenylethenyl Sulfone (3j): Mp 93—95 °C; IR (neat) 1300 and 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.20 (3H, d, J=1.2 Hz), 3.76 (2H, d, J=6.0 Hz), 5.26 (1H, t, J=6.0 Hz), and 7.00—7.40 (11H, m); MS m/z 320 (M^+); HRMS, Found: m/z 284.0831, Calcd for $C_{17}H_{16}O_2S$: M, 284.0871.

(*E*)-2-Chloro-2-(*p*-tolyl)ethyl 1-Methyl-2-phenylethenyl Sulfone (3k): Mp 91—92 °C; IR (neat) 1305 and 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.09—2.15 (6H, m), 3.77 (2H, d, J=6.0 Hz), 5.26 (1H, t, J=6.0 Hz), and 7.00—7.30 (10H, m); MS m/z 334 (M^+); HRMS, Found: m/z 298.1036, Calcd for $C_{18}H_{17}O_2S$: M, 298.1027.

(*E*)-2-Chloro-2-(*p*-chlorophenyl)ethyl 1-Methyl-2-phenylethenyl Sulfone (3l): Mp 91—92 °C; IR (KBr) 1310 and 1140 cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.14 (3H, s), 3.75 (2H, d, J=6.0 Hz), 5.28 (1H, t, J=6.0 Hz), and 7.10—7.40 (10H, m); MS m/z 354 (M^+); HRMS, Found: m/z 354.0267, Calcd for $C_{17}H_{16}O_2SCl_2$: M, 354.0248.

(*E*)-2-Chloro-2-(*m*-nitrophenyl)ethyl 1-Methyl-2-phenylethenyl Sulfone (3m): IR (neat) 1540, 1360, 1310, and 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.21 (3H, s), 3.73—3.88 (2H, m), 5.41 (1H, t, J=6.0 Hz), and 7.00—8.20 (10H, m); MS m/z 365 (M^+); HRMS, Found: m/z 365.0452, Calcd for $C_{17}H_{16}O_4NSCl$: M, 365.0488.

(*E*)-2-Chloro-2-phenylpropyl 1-Methyl-2-phenylethenyl Sulfone (3n): IR (neat) 1300 and 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.40 (3H, s), 4.13 (2H, s), 5.04 (1H, s), 5.20 (1H, s), and 6.90—7.30 (11H, m);[16] MS m/z 335 (M^+ +1);[17] HRMS, Found: m/z 299.1167, Calcd for $C_{18}H_{19}O_2S$: M, 299.1105.

(*E*)-2-Chloro-1-methyl-2-phenylethyl 1-Methyl-2-phenylethenyl Sulfone (3o): Mp 112—113 °C; IR (KBr) 1300 and 1140 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.25 (1H, d, J=7.0 Hz), 1.55 (2H, d, J=7.0 Hz), 2.10—2.30 (3H, m), 3.28—3.86 (1H, m), 5.14—5.53 (1H, m), and 7.00—7.60 (10H, m); MS m/z 335 (M^+ +1);[17] HRMS, Found: m/z 334.0762, Calcd for $C_{18}H_{19}O_2SCl$: M, 334.0794.

The Formation of 1,3-Dienes by the Reaction of Alkenesulfonyl Chlorides with Olefins. A solution containing of 1.0 mmol of alkenesulfonyl chloride, 1.5 mmol of olefin, and 0.01 mmol of the ruthenium(II) complex **1** in 2.0 cm^3 of benzene was degassed and heated in a sealed tube at 150 °C for 48 h. Gel-permeation chromatography using chloroform as an eluent was performed to isolate 1,3-dienes.

The physical and spectral data of the compounds **4a—f** are as follows:

(*E,E*)-1,4-Diphenyl-1,3-butadiene (4a): Mp 148—149 °C (lit,[23] mp 149.7 °C); IR (KBr) 3010, 1490, 1440, 990, 740, and 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.10—6.80 (4H, m) and 6.90—7.40 (10H, m); MS m/z 206 (M^+).

(*E,E*)-1,4-Diphenyl-1,3-pentadiene (4b): Mp 95—96 °C (lit,[24] mp 95.5—97 °C); IR (KBr) 3030, 1595, 1490, 1440, 970, 750, and 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.21 (3H, s), 6.36—6.89 (2H, m), and 7.00—7.50 (11H, m); MS m/z 220 (M^+).

(*E,E*)-2-Methyl-1,4-diphenyl-1,3-butadiene (4c): Mp 76—77 °C (lit,[5] mp 78—80 °C); IR (KBr) 3020, 1490, 1440, 960, 740, and 695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.08 (3H, s) and 6.17—7.40 (13H, m); MS m/z 220 (M^+).

(*E,E*)-2,5-Diphenyl-2,4-hexadiene (4d): Mp 130—132 °C (lit,[8] mp 136—137.5 °C); IR (KBr) 3030, 2960, 1495, 1445, 760, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.20 (6H, s), 6.70 (2H, s), and 7.03—7.50 (10H, m); MS m/z 234 (M^+).

(*E,E*)-2-Methyl-1,4-diphenyl-1,3-pentadiene (4e): IR (neat) 3030, 2850, 1600, 1490, 1440, 1380, 1025, 880, 750, and 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.27 (6H, s), 6.81 (2H, m), and 7.15—7.60 (10H, m); MS *m/z* 234 (M^+); HRMS, Found: *m/z* 234.1408, Calcd for $C_{18}H_{18}$: M, 234.1408.

(*E,E*)-2,3-Dimethyl-1,4-diphenyl-1,3-butadiene[13] (4f): IR (neat) 2900, 1490, 1450, 750, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.79 (6H, s) and 6.80—7.40 (12H, m); MS *m/z* 234 (M^+); HRMS, Found: *m/z* 234.1404, Calcd for $C_{18}H_{17}$: M, 234.1408.

New Application of Solid Acid to Carbon-Carbon Bond Formation Reactions: Clay Montmorillonite-Catalyzed Aldol Reactions of Silyl Enol Ethers with Aldehydes and Acetals

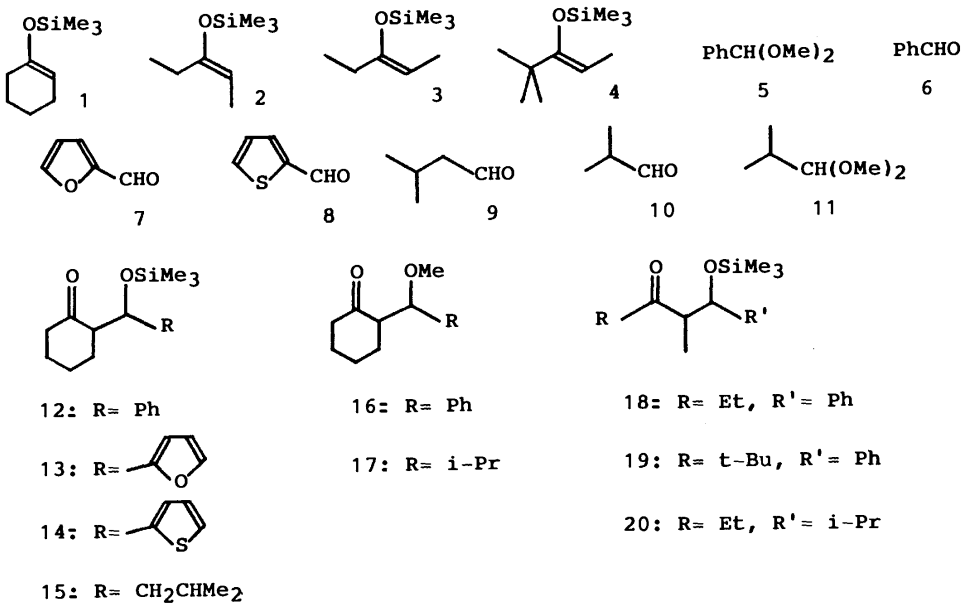
Motomitsu KAWAI, Makoto ONAKA,* and Yusuke IZUMI
Department of Synthetic Chemistry, Faculty of Engineering, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464
(Received September 16, 1987)

A new attempt of utilizing solid acid to the cross aldol reaction of silyl enol ethers with aldehydes or acetals has been investigated. Among solid acids employed, the reaction is promoted most effectively by a catalytic amount of aluminium ion-exchanged montmorillonite (Al-Mont). Simple diastereoselection is significantly sensitive to the nature of the reaction solvent used in the Al-Mont-catalyzed reaction. When the aluminium ions in Al-Mont were replaced by protons or titanium ions in order to investigate the cation effect, almost the same results were observed on simple diastereoselectivity and diastereofacial selectivity. This fact suggests that the metal cations in montmorillonite do not work as Lewis acid in the present aldol reaction. The acid catalysis of montmorillonite in the present aldol reaction is discussed in comparison with the catalytic behavior of some homogeneous acids.

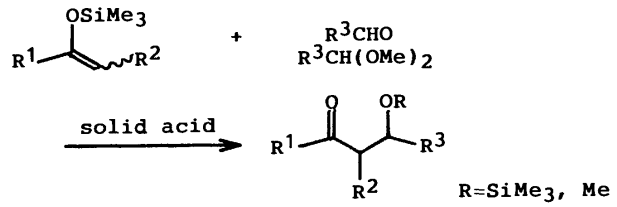
The use of a preformed metal enolate has become a general method for the directed cross aldol reactions.[1] Especially, silyl enol ethers are widely utilized as enolates owing to their isolable properties, and undergo directed aldol reactions with carbonyl compounds in the presence of acidic promoters or by treatment of fluoride ions. As acidic promoters, not only a stoichiometric amount of Lewis acid like $TiCl_4$[2a] but also a catalytic amount of $CF_3SO_3SiMe_3$,[2b] Ph_3CClO_4,[2c] or Me_2AlCl[2d] are used to activate aldehydes or acetals electrophilically. These promoters are soluble in the reaction media, but there is few reports on the aldol reaction using a solid acid as a promoter under heterogeneous conditions.[3]

Recently we demonstrated that the allylation of acetals and carbonyl compounds with allylic silanes was catalyzed by solid acids in a heterogeneous system.[4] Especially clay montmorillonite was found to be the most efficient catalyst among the solid acids of mica, zeolite, silica-alumina, and ion-exchange resin. This experiment is the first example of an inorganic solid acid-catalyzed carbon-carbon bond-formation reaction using organosilicon reagents.[5]

Clay montmorillonite is a layered silicate possessing ion-exchange ability.[6a] Acid property of montmorillonite can be easily altered by replacing interlayered cations in the montmorillonite without any change of the crystalline structure. Although several works using montmorillonite have been done for the acid-catalyzed organic reactions,[6] the application of montmorillonite to C-C bond-formation reactions under mild conditions is quite rare. For example, montmorillonite was reported to promote the Friedel-Crafts type alkylations,[7a] the Diels-Alder reactions,[7b] and the condensation of acetals with alkyl vinyl ethers.[7c]



Our objectives are to utilize inorganic solid acids instead of liquid acids to complete C-C bond-formation reactions and to compare catalysis between heterogeneous and homogeneous acids. A montmorillonite-catalyzed allylation reaction is one of them.[4] We have also showed that aluminium ion-exchanged montmorillonite (Al-Mont) is an effective catalyst for the aldol reactions of silyl enol ethers or silyl ketene acetals with carbonyl compounds or acetals.[8] Here we describe additional examples of the aldol reactions and clarify the catalysis of the montmorillonite.



Results and Discussion

Simple Diastereoselection. The reaction of silyl enol ether **1** with an acetal **5** was examined in the presence of various solid acids and the results are listed in Table 1. The reaction proceeded smoothly with the aid of solids even under heterogeneous conditions to afford the corresponding aldol adducts in good yield (Entries 1—5, 7). Among solid acids, aluminium ion-exchanged montmorillonite (Al-Mont) showed the highest catalytic activity (Entries 1, 2) and good diastereoselectivity for an erythro adduct especially in 1,2-dimethoxyethane (DME) (Entry 2).

Next, the reaction of **1** with an aldehyde **6** was examined with respect to catalytic activity and diastereoselectivity affected both by reaction solvents and by exchangeable cations in the montmorillonite (Table 2, Entries 1—6). Al-Mont showed slightly higher activity than proton- or titanium ion-exchanged montmorillonite (described as H-Mont and Ti-Mont, respectively) (Entries 1, 2, 5, 6). Al-Mont also showed higher diastereoselectivity since the reaction proceeded at lower temperature.

The use of solid acids in liquid-phase organic reactions provides an advantage of a much more simple work-up procedure compared with that of liquid acids. As work up, only filtering a reaction mixture through a Celite pad is required in order to separate a solid catalyst from organic products. Thus the aldol adduct **12** was obtained in the form of trimethylsilyl ether.

Table 1. The Aldol Reaction of **1** with **5**[a]

Entry	Catalyst	Condition Temp/°C (Time/h)	Yield/ %[b]	Threo: Erythro
1	Al-Mont	−78(1), −50(0.2)	84	45:55
2	Al-Mont[b]	−60(0.5), −50(1.5)	93	13:87
3	SiO_2-Al_2O_3	−50(0.3), −30(1)	73	30:70

a) Silyl enol ether (1 mmol), aldehyde (1 mmol), and Al-Mont (0.2 g) were used. b) Isolated yield. c) 2 mmol of aldehyde was used. d) E/Z=83/17. e) E/Z=10/90. f) Unidentified by-products were obtained. g) The major by-product was cyclohexanone. h) 1.3 mmol of aldehyde or acetal was used.

The diastereoselectivity in the montmorillonite-catalyzed aldol reaction of **1** and **6** was considerably dependent on the nature of solvent.[9)] A threo isomer was preferentially formed in toluene (Table 2, Entries 1, 2), while an erythro isomer was dominant in DME (Table 2, Entries 5, 6).

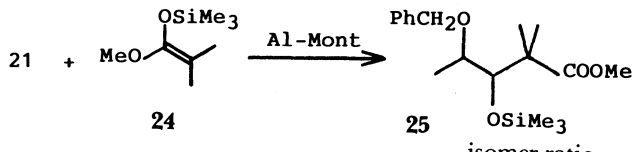
The solvent effect on the diastereoselectivity was also observed with other substrates in Table 3. Generally, when aromatic aldehydes (benzaldehyde, furfural,[10)] 2-thiophenecarbaldehyde) and benzaldehyde dimethyl acetal were used, the ratio of threo to erythro increased in the following order of the solvent except Entry 4: DME < CH_2Cl_2 < $PhCH_3$ (Entries 1—3, 5—20). In the case of an aliphatic aldehyde and its acetal (Entries 21—32), however, the orderly solvent effects were not observed.

The dependence of diastereoselection upon solvents was not specific to the montmorillonite-catalyzed aldol reactions, but also recognized in the reactions promoted by a solid acid of SiO_2-Al_2O_3 (Table 2, Entries 7—9) and a homogeneous liquid acid of $BF_3 \cdot OEt_2$ (Table 2, Entries 16—18) though to a lesser extent. However no common pattern for the solvent effect was observable.

Acid strength of Al-Mont was measured in various solvents by use of Hammett indicators, and the result is listed in Table 4. In CH_2Cl_2 or $PhCH_3$, strongly acidic sites ($H_0 \leqq -8.2$) were detected on Al-Mont.[11] On the other hand, the acid strength of Al-Mont was weakened to $-5.6 < H_0 \leqq -3.0$ in 1,2-dimethoxyethane (DME). DME is relatively basic and thus interacts with the acid sites on montmorillonite to reduce their acid strength. We assume that the diastereoselectivity of the aldol reaction catalyzed by Al-Mont relates with the acid strength of Al-Mont since the interaction between aldehydes (acetals) and acid sites on Al-Mont is depending on the acid strength of the acid sites, and influences the stabilities of transition states of the reaction.

Diastereofacial Selection. In addition to simple diastereoselection, we also investigated diastereofacial selection in Al-Mont-catalyzed aldol reactions.

Reetz and his co-workers found that good asymmetric induction was observed in the Lewis acid-mediated aldol reactions of α- and β-alkoxy aldehydes with silyl enol ethers.[12] The diastereofacial preferences were explained with a chelation model having coordination between the two oxygens of an alkoxy aldehyde and a metal of Lewis acid. We examined whether chelation control is possible for metal cations in montmorillonite. In contrast to $TiCl_4$ which induced exclusively a chelation-controlled product **23a**,[13] various metal ions-exchanged montmorillonites showed only a slight preference for **23a** over **23b** and almost the same ratio of **23a** to **23b** irrespective of a metal cation (Table 5). The reaction of **21** with silyl ketene acetal **24** was also examined, but the diastereoselectivity was low.



24 **25**

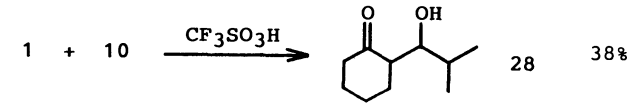
isomer ratio =54:46

These facts suggest that exchangeable ions in montmorillonite do not work as Lewis acid. Moreover, proton-exchanged montmorillonite (H-Mont) showed similar activity and diastereoselectivity to those of Al-Mont (Table 2, Entry 1,2; Table 5). Thus we assume that Brönsted acid sites (protons) generated by the dissociation of hydrated water in Al-Mont[14] actually play an important role in promoting the present aldol reaction.

$$M^{n+}(H_2O) \rightarrow (M\text{-}OH)^{(n-1)+} + H^+$$

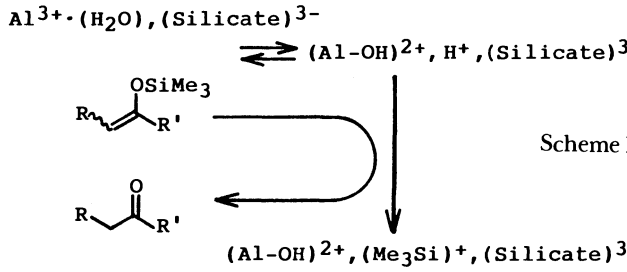
Secondly, we chose an aldehyde **26** to investigate whether Cram's rule is applicable. In analogy with $BF_3 \cdot OEt_2$-mediated reactions of *t*-butyldimethylsilyl enol ether,[15] Al-Mont showed high asymmetric induction in the reaction of **26** with **22** to afford **27a** (a Cram product) selectively (Table 6).

Comparison of Catalysis between Al-Mont and Trifluoromethanesulfonic Acid (CF_3SO_3H). As homogeneous acid catalysts, we chose CF_3SO_3H and its silylated form, trimethylsilyl trifluoromethanesulfonate ($CF_3SO_3SiMe_3$) so as to compare the acid catalysis between heterogeneous and homogeneous acids. $CF_3SO_3SiMe_3$ was reported to be ineffective for the aldol reactions of aldehydes with silyl enol ethers.[2b] In our hands, however, the reaction of **1** with **6** smoothly proceeded even at low temperature in the presence of $CF_3SO_3SiMe_3$ as well as CF_3SO_3H[16] (Table 2, Entries 12, 13, 15). CF_3SO_3H also promoted the reaction of **1** with an aliphatic aldehyde.



The catalytic behavior of $CF_3SO_3SiMe_3$ and CF_3SO_3H with respect to both the yield and the diastereoselectivity of **12** was found to be almost the same (Table 1, Entries 8, 10; Table 2, Entries 12, 15). CF_3SO_3H is known to be transformed to $CF_3SO_3SiMe_3$ on treatment with a silylating reagent.[17] On the basis of these facts, it seems likely that CF_3SO_3H is silylated by silyl enol ether to generate an active species of $CF_3SO_3SiMe_3$ which is in turn involved in an acid catalysis cycle[2b] of the aldol reaction.

Similarly, in the case of Al-Mont, we speculate that an active species is not a Brönsted acid site (proton) itself but a trimethylsilyl cation species derived from the reaction of Al-Mont and silyl enol ethers.[18]



Scheme 1.

Table 4. Acid Strength of Al-Mont in Various Solvents

Indicator (H_0)	AQ (−8.2)	BAP (−5.6)	DCA (−3.0)	Maximum acid strength

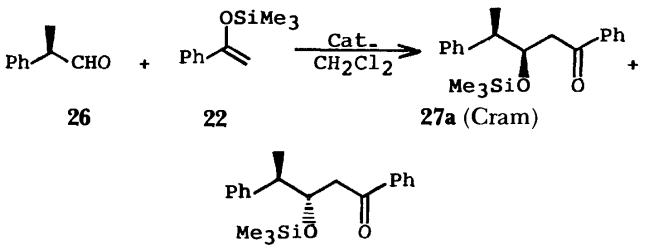
Reaction conditions: **21** (1 mmol), **22** (1 mmol), montmorillonite (0.2 g), solvent (CH_2Cl_2).

Table 6. The Aldol Reaction of **22** with **26**



26 **22** **27a** (Cram)

27b (anti Cram)

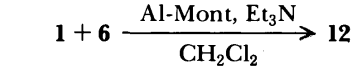
Catalyst	Temp/°C (Time/h)	Yield/%	**27a**:**27b**
Al-Mont	−65(1)	65	93:7
H-Mont	−50(1)	54	92:8

Reaction conditions: **22** (1 mmol), **26** (1 mmol), montmorillonite (0.2 g), solvent (CH_2Cl_2).

Consideration about Acid Strength of Al-Mont. Both Al-Mont and CF_3SO_3H (a super acid[19]) promote the aldol reaction of **1** and **5**, while CH_3SO_3H (a strong acid) is completely ineffective (Table 1, Entry 9; Table 2, Entry 14). Therefore the acid strength of Al-Mont is considered to be stronger than CH_3SO_3H. Moreover, Al-Mont promoted the allylation reaction of 4-*t*-butylcyclohexanone with allyltrimethylsilane (80% yield)[4] but CF_3SO_3H failed.[20] Thus Al-Mont has higher catalytic activity than CF_3SO_3H.

Although acid strength of montmorillonite (dried at 120—130 °C in air) has been estimated to be rather low ($-8.2 < H_0 \leqq -3.0$) by several groups,[14,21] we observed that the sample of Al-Mont which was dried at 25 °C/0.5 Torr (1 Torr=133.322 Pa) for 24 h showed maximum acid strength of $-8.2 < H_0 \leqq -5.6$ in CH_2Cl_2, and the sample which was dried at 120 °C/0.5 Torr for 3 h possessed very strong acid sites of $H_0 \leqq -8.2$ in CH_2Cl_2 (Table 4). Judging from our results concerning the allylation[4] and the aldol reactions, Al-Mont (dried at 120 °C/0.5 Torr for 3 h) is one of the strongest solid acids.

Table 7. Poisoning Experiments[a]



Entry	Et_3N (mol%)[b]	Yield of **12**/%	Threo: Erythro
1	0	93	61 : 39
2	0.05	95	62 : 38
3	0.15	58	64 : 36
4	0.5	1[c]	—
5	4.7	0[c]	—

a) **1** (1 mmol), **6** (1 mmol), Al-Mont (0.2 g), solvent (CH_2Cl_2), −78 °C, 0.5 h. b) Mol% of Et_3N based on **6**. c) Estimated by GC.

The Amount of Active Sites on Montmorillonite for Aldol Reactions. In order to confirm that Al-Mont acts catalytically in promoting the aldol reaction, the number of active site on Al-Mont was estimated by a poisoning experiment. After a part of acid sites on Al-Mont was deactivated by addition of triethylamine, the standard aldol reaction of **1** with **6** was performed, and judged from the change in the yield of **12**. The results are listed in Table 7. Surprisingly, only 0.5 mol% of the amine based on an aldehyde **6** is enough completely to prevent the reaction at −78 °C (Entry 4). It is concluded that a very small amount (less than 0.025 meq/g · Al-Mont) of acid sites on Al-Mont acts as an efficient catalyst in the aldol reaction.

Experimental

Measurement. ^1H NMR spectra were recorded in $CDCl_3$ with a Hitachi R-600 (60 MHz) spectrometer. ^{13}C NMR spectra were measured in $CDCl_3$ with a JEOL FX-60 spectrometer at 15 MHz or a JEOL JNM GX-400 spectrometer at 100 MHz. The chemical shifts (δ) are expressed in parts per million downfield from an internal standard of tetramethylsilane. Infrared spectra were recorded in CCl_4 on a JASCO IRA-2 spectrometer. Analytical gas-liquid chromatography (GC) was done with a Shimadzu GC-8A instrument with a flame ionization detector and nitrogen carrier gas. The following capillary columns were used: OV-1 Bonded, 25 m×0.25 mm; PEG-HT Bonded, 25 m×0.25 mm. The flow rate of carrier gas was 1—2 ml min^{-1} (0.5—1.0 kg cm^{-2}). Preparative thin-layer chromathography (TLC) was done on 20×20 cm glass plates coated with 1 mm thickness of Merck silica gel PF_{254}.

Solvents and Reagents. Dichloromethane was distilled from P_2O_5 and stored over Molecular Sieves 3A. Toluene was dried over Molecular Sieves 3A. 1,2-Dimethoxyethane (DME) and ether were distilled from $LiAlH_4$ prior to use. Triethylamine, $CF_3SO_3SiMe_3$, and pyridine were distilled from CaH_2. $BF_3 \cdot OEt_2$, 4-*t*-butylcyclohexanone, and Hammett indicators [anthraquinone (AQ), benzylideneacetophenone (BAP), and dicinnamylideneacetone (DCA)] were purchased and used without further purification. Silyl enol ethers, **1**,[22] **2** (*E*:*Z*=87:13),[23] **3** (*E*:*Z*=10:90),[24] **4** (*Z* isomer

only),[23] and **22**[22] were prepared according to the literature and the isomeric ratio of these substrates was determined by GC. Silyl ketene acetal **24** was prepared according to the literature.[25] Aldehydes **6**—**10**, **26** and CF_3SO_3H were commercially available and distilled before use. Aldehyde **21** was prepared according to the literature.[26] Acetals **5** and **11** were prepared by a conventional procedure.

Preparation of Ion-Exchanged Montmorillonites. The montmorillonite used in this study was purified Na^+ ion-exchanged montmorillonite, "Kunipia F" (cation-exchange capacity=1.19 meq. g^{-1}) supplied by Kunimine Industries Co. Aluminium ion exchange was effected by the addition of the powdered sodium ion-exchanged montmorillonite (Na-Mont, 100 g) to an aqueous solution (800 ml) of $Al(NO_3)_3 \cdot 9H_2O$ (150 g, 0.4 mol) with vigorous stirring at rt for 2 h. The resultant suspension was filtered on a Büchner funnel by suction. The clay was collected, suspended again in deionized water (500 ml) with stirring at rt for 1 h, filtered on a suction funnel, and washed with deionized water (200 ml). The clay collected was again suspended in a mixture of deionized water (200 ml) and methanol (200 ml) with stirring at rt for 1 h and filtered. This procedure was repeated twice. The washed clay was predried at 20 °C/1 Torr for 6 h, and the agglomerated clay was then ground and passed through a 60 mesh screen. The resultant powdery clay was dried at 20 °C/0.5 Torr for 24 h, and stored in a desiccator over anhydrous silica gel until use.

Similarly titanium ion exchange was conducted using 10 g of Na-Mont and aqueous $TiCl_3$ and the grinding of the Ti-excanged montmorillonite was performed under nitrogen atmosphere. Proton exchange was done using 5 g of Na-Mont and 100 ml of 1 mol dm^{-3} HCl.

Other Solid Acids. SiO_2–Al_2O_3 is a reference catalyst provided by Catalysis Society of Japan: JRC-SAL-2 (Al_2O_3 content: 13.75%). Zeolite CaY (the content of cations: Ca^{2+} 45%, Na^+ 55%) was prepared by treatment of NaY (Shokubai Kasei Co.: ZCP-50) with aqueous $CaCl_2$.[27] SiO_2–Al_2O_3 and CaY was predried at 400 °C in air for 3 h, stored in a desiccator, and then dried over flames at ca. 350 °C/0.5 Torr for 10 min or dried over an electric furnace at 400 °C/0.5 Torr for 3 h (Table 2, Entries 7—9) in a reaction vessel prior to use.

Nafion-117 [a perfluorinated resin of sulfonic acid (1 meq. g^{-1}, Du Pont)] was immersed in dry methanol overnight, washed with dry methanol, dried at 25 °C and 0.5 Torr for 30 min, and used for the reaction of **1** with **5**.

General Procedure for Clay Montmorillonite-Catalyzed Aldol Reactions of Silyl Enol Ethers with Aldehydes and Acetals. Montmorillonite (0.2 g) in a 20 ml round-bottomed flask was dried at 120 °C and 0.5 Torr for 3 h in an oil bath, and cooled under nitrogen. A solution of an aldehyde or an acetal (1 mmol) in a solvent (3 ml) was added. After the mixture being stirred for 1 min, a solution of silyl enol ether (1 mmol) in a solvent (1 ml) was added at −78 °C. The temperature was raised, the mixture was stirred under the conditions listed in tables. As work-up, cold ether (−50 °C, 5 ml) was added, the montmorillonite was filtered off through a Celite pad and washed with ether. The organic layer was evaporated and distilled on a Kugelrohr apparatus to yield aldol products.

General Procedure for Liquid Acid Promoter-Mediated Reactions (Table 1, Entries 8—11). To a stirred solution of **1** (1 mmol) and **5** (1 mmol) in CH_2Cl_2 (3 ml) was added an appropriate amount of an acid promoter in CH_2Cl_2 (1 ml) under a nitrogen atmosphere at −78 °C. After the mixture being stirred, aqueous $NaHCO_3$ was added, the resulting mixture was extracted with ether. An organic layer was dried over Na_2SO_4, and distilled on a Kugelrohr apparatus to yield **16**.

General Procedure for CF_3SO_3H and $CF_3SO_3SiMe_3$-Mediated Reactions of Aldehydes with Nucleophiles. To a stirred solution of an aldehyde (1 mmol) and a nucleophile (1 mmol) in CH_2Cl_2 (3 ml) was added an acid promoter (0.003 mmol) in CH_2Cl_2 (1 ml) under a nitrogen atmosphere at −78 °C. When the reaction was slow, the temperature was raised and/or the acid promoter was supplemented. The mixture was quenched with a few drops of pyridine, diluted with ether, and poured into an aqueous $NaHCO_3$ solution, and then the organic solvent was evaporated. Organic products were extracted with ether. The extract was washed with water and dried over Na_2SO_4, and products were purified by distillation or by TLC.

$BF_3 \cdot OEt_2$-Mediated Reaction of 1 and 6 (Table 2, Entries 16—18). To a stirred solution of **6** (1 mmol) in a solvent (2 ml) at −78 °C was added a solution (1 ml) of $BF_3 \cdot OEt_2$ (1 mmol) under a nitrogen atmosphere. Then **1** (1 mmol) in a solvent (1 ml) was added. After the mixture being stirred under conditions listed in Table 2, the reaction was quenched by injecting aqueous $NaHCO_3$. The mixture was warmed to room temperature and the mixture was extracted with ether. The organic layer was dried over Na_2SO_4 and the solvent was removed. The crude product was treated with *N*-(trimethylsilyl)imidazole (1 mmol) and one drop of chlorotrimethylsilane in ether for 0.5 h at room temperature. The reaction mixture was washed with water and the organic layer was dried over Na_2SO_4. The organic layer was evaporated and distilled on a Kugelrohr apparatus to yield **12**.

Poisoning Experiments of Al-Mont with Triethylamine. Al- Mont (0.2 g) in a 20 ml round-bottomed flask was dried at 120 °C and 0.5 Torr for 3 h in an oil bath, cooled to −78 °C under nitrogen, and dipped with CH_2Cl_2 (1 ml). Then a solution of triethylamine (0.0005—0.047 mmol) in CH_2Cl_2 (1 ml) was added. After the mixture was stirred for 10 min, a solution of **6** (1 mmol) in CH_2Cl_2 (1 ml) was added. After 5 min, a solution of **1** (1 mmol) in CH_2Cl_2 (1 ml) was added dropwise over 0.5 min and the mixture was stirred for 30 min at −78 °C and cold ether (5 ml) was added. Al-Mont was filtered off through a Celite pad and washed with ether. The organic layer was evaporated and distilled on a Kugelrohr apparatus to yield **12**.

Measurement of Acid Strength of Al-Mont.[21] Al-Mont (0.05 g) was dried at 120 °C and 0.5 Torr for 3 h. This sample was immersed in a solvent (1 ml). Then a few drops of a 0.1 wt% benzene solution of a Hammett indicator was added and the color of the indicator on the sample was judged with naked eyes.

Stereochemistry of Products. The assignment of relative configuration (threo or erythro) of the aldol products derived from **12**—**15** was made with ^1H NMR analysis of the $J_{threo} > J_{erythro}$ relationship[1b,28] and ^{13}C NMR analysis based on the upfield chemical shifts of the carbinol carbon and the methine carbon in the erythro isomer compared with those in the threo isomer.[29] Othe products were identified according to the literatures.[2a,2b,13,15,23,29,30] Diastereomer ratios were determined by GC except for **18**.

2-[Phenyl(trimethylsiloxy)methyl]cyclohexanone (12).[2a]

A mixture of diastereomers (threo : erythro=3 : 1): bp 140 °C (bath temp)/0.3 Torr; ^{1}H NMR ($CDCl_3$) δ=0.01 and 0.05 (two s, 3 : 1 ratio, 9H, CH_3Si), 1.3—2.6 (br, 9H, aliphatic CH), 5.10 (d, J=7.9 Hz, CHO, threo), 5.38 (d, J=3.9 Hz, CHO, erythro), and 7.28 (s, 5H, C_6H_5); IR (CCl_4) 1713 cm^{-1} (C=O); GC (OV-1, 25 m, 180 °C, 0.5 kg cm^{-2}) t_R 12.8 min (threo), 13.2 min (erythro).

2-(Phenylhydroxymethyl)cyclohexanone. A mixture of diastereomers obtained from **12** by hydrolysis: ^{1}H NMR ($CDCl_3$) δ=1.2—2.7 (br, 9H, aliphatic CH), 4.78 (d, J=8.7 Hz, CHO, threo), 5.37 (d, J=2.3 Hz, CHO, erythro), and 7.30 (s, 5H, C_6H_5), ^{13}C NMR ($CDCl_3$) δ=57.0 and 57.2 (1 : 3 ratio, O=C<u>C</u>H), 70.3 and 74.4 (1 : 3 ratio, CHO); IR (CCl_4) 1700 (C=O) and 3560 cm^{-1} (OH).

2-[(2-Furyl)trimethylsiloxymethyl]cyclohexanone (13). A mixture of diastereomers (threo : erythro=1 : 4): bp 140 °C (bath temp)/0.3 Torr; ^{1}H NMR ($CDCl_3$) δ=0.01 and 0.04 (two s, 1 : 4 ratio, 9H, CH_3Si), 1.4—3.1 (br, 9H, aliphatic CH), 5.14 (d, J=8.2 Hz, CHO, threo), 5.28 (d, J=6.0 Hz, CHO, erythro), 6.3 (m, 2H, CH=C), and 7.4 (m, 1H, C=CH-O); IR (CCl_4) 1714 cm^{-1} (C=O); GC (PEG-HT, 150 °C, 1.0 kg cm^{-2}; t_R 6.8 min (erythro), 7.4 min (threo).

2-[(2-Furyl)hydroxymethyl]cyclohexanone. Obtained from **13** by hydrolysis. ^{13}C NMR ($CDCl_3$) δ=54.5 and 54.9 (4 : 1 ratio, O=C<u>C</u>H), 66.4 and 68.0 (4 : 1 ratio, CHO). Each diastereoisomer was separated by preparative TLC (3 : 1 ether-hexane, developed 2 times). **A Threo Isomer:** R_f 0.42; ^{1}H NMR ($CDCl_3$) δ=1.4—3.2 (br, 9H, aliphatic CH), 3.9 (br, 1H, OH), 4.85 (d, J=8.2 Hz, CHO), 6.30 (m, 2H, CH=C), and 7.38 (m, 1H, C=CH-O); IR (CCl_4) 1702 (C=O) and 3560 cm^{-1} (OH). Found: C, 67.72; H, 7.27%. Calcd for $C_{11}H_{14}O_3$: C, 68.02; H, 7.23%. **An Erythro Isomer:** R_f 0.48; ^{1}H NMR ($CDCl_3$) δ=1.4—3.2 (br, 10H, aliphatic CH and OH), 5.24 (d, J=3.0 Hz, 1H, CHO), 6.30, (m, 2H, CH=C) and 7.33 (m, 1H, C=CHO); IR (CCl_4) 1968 (C=O) and 3580 cm^{-1} (OH).

2-[(2-Thienyl)trimethylsiloxymethyl]cyclohexanone (14). A mixture of diastereomers (threo : erythro=3 : 1): bp 150 °C (bath temp)/0.5 Torr; ^{1}H NMR ($CDCl_3$) δ=0.01 and 0.04 (two s, 3 : 1 ratio, 9H, CH_3Si), 1.4—2.6 (br, 9H, aliphatic CH), 5.39 (d, J=6.8 Hz, CHO, threo), 5.55 (d, J=4.8 Hz, CHO, erythro), 6.9 (m, 2H, CH=C), and 7.2 (m, 1H, C=CHS); IR (CCl_4) 1708 cm^{-1}(C=O); GC (OV-1, 170 °C, 1.0 kg cm^{-2}) t_R 9.1 min (threo), 9.6 min (erythro).

2-[(2-Thienyl)hydroxymethyl]cyclohexanone. A mixture of diastereomers obtained from **14** by hydrolysis: ^{1}H NMR ($CDCl_3$) δ=1.4—2.9 (br, 9H, aliphatic CH), 3.8 (br, 1H, OH), 5.07 (d, J=8.3 Hz, CHO, threo), 5.53 (d, J=3.0 Hz, CHO, erythro), 7.0 (m, 2H, CH=C), and 7.3 (m, 1H, C=CHS); ^{13}C NMR ($CDCl_3$) δ=57.2 and 57.8 (1 : 3 ratio, O=C<u>C</u>H), 68.2 and 70.6 (1 : 3 ratio); IR (CCl_4) 1702 (C=O) and 3560 cm^{-1} (OH). Found: C, 62.81; H, 6.83%. Calcd for $C_{11}H_{14}O_2S$: C, 62.83; H, 6.71%.

2-(3-Methyl-1-trimethylsiloxybutyl)cyclohexanone (15). bp 130 °C (bath temp)/0.5 Torr; GC (PEG-HT, 120 °C, 0.5 kg cm^{-2}) t_R 10.8 min (erythro), 11.1 min (threo). Each diastereoisomer was separated by preparative TLC (15 : 1 hexane-ether, developed 5 times). **A Threo Isomer:** R_f 0.59; ^{1}H NMR ($CDCl_3$) δ=0.12 (s, 9H, CH_3Si), 0.94 (d, J=6.0 Hz, 6H, CHC<u>H</u>$_3$), 1.2—2.5 (br, 9H, aliphatic CH), and 4.15—4.45 (m, 1H, CHO); IR (CCl_4) 1712 cm^{-1} (C=O). **An Erythro Isomer:** R_f 0.63; ^{1}H NMR ($CDCl_3$) δ=0.12 (s, 9H, CH_3Si), 0.92 (d, J=6.0 Hz, 6H, CHC<u>H</u>$_3$), 1.2—2.5 (br, 9H, aliphatic CH), and 4.20—4.50 (m, 1H, CHO); IR(CCl_4) 1712 cm^{-1} (C=O).

2-(1-Hydroxy-3-methylbutyl)cyclohexanone. Obtained from **15** by hydrolysis. A mixture of diastereomers (threo : erythro=3 : 2): ^{13}C NMR; δ=55.4 and 56.7 (2 : 3 ratio, O=C<u>C</u>H), 67.0 and 69.8 (2 : 3 ratio, CHO). Found: C, 71.71; H, 10.83%. Calcd for $C_{11}H_{20}O_2$: C, 71.70; H, 10.94%. **A Threo Isomer:** ^{1}H NMR ($CDCl_3$) δ=0.90 and 0.92 (two d, J=6.1, 6.1 Hz, 6H, CH_3), 1.2—2.5 (br, 13H, aliphatic CH), 3.79 (ddd, J=9.0, 7.0, 4.5 Hz, 1H, CHO), and 4.6 (s, 1H, OH); IR (CCl_4) 1708 cm^{-1} (C=O). **An Erythro Isomer:** ^{1}H NMR ($CDCl_3$) δ=0.92 (d, J=6.0 Hz, 6H, CH_3), 1.2—2.5 (br, 14H, aliphatic CH and OH), 4.21 (ddd, J=9.0, 3.6, 2.7 Hz, 1H, CHO), and 4.6 (s, 1H, OH); IR (CCl_4) 1708 cm^{-1} (C=O).

2-(Methoxyphenylmethyl)cyclohexanone (16).[2b] A mixture of diastereomers (threo : erythro=1 : 6): bp 145 °C (bath temp)/0.8 Torr; ^{1}H NMR ($CDCl_3$) δ=1.4—2.6 (br, 9H, aliphatic CH), 3.20 and 3.27 (two s, 1 : 6 ratio, 3H, OCH_3), 4.56 (d, J=8.6 Hz, CHO, threo), 4.79 (d, J=4.1 Hz, CHO, erythro), and 7.30 (s, 5H, C_6H_5); IR (CCl_4) 1712 cm^{-1} (C=O); GC (OV-1, 180 °C, 0.5 kg cm^{-2}) t_R 9.9 min (erythro), 10.2 min (threo).

2-(1-Methoxy-2-methylpropyl)cyclohexanone (17).[2b] bp 110 °C (bath temp)/2 Torr; GC PEG-HT (110 °C, 1.0 kg cm^{-2}) t_R 6.4 min (erythro), 8.5 min (threo). Each diastereoisomer was separated by preparative TLC (5 : 1 hexane-ether, developed 2 times). **A Threo Isomer:** R_f 0.42; ^{1}H NMR ($CDCl_3$) δ=0.91 and 0.94 (two d, J=6.7, 6.7 Hz, 6H, CH_3), 1.4—2.6 (br, 10H, aliphatic CH), 3.3—3.5 (m, 1H, CHO), and 3.43 (s, 3H, OCH_3); IR (CCl_4) 1712 cm^{-1} (C=O). **An Erythro Isomer:** R_f 0.58; ^{1}H NMR ($CDCl_3$) δ=0.88 and 0.93 (two d, J=6.5, 6.5 Hz, 6H, CH_3), 1.4—2.6 (br, 10H, aliphatic CH), 3.43 (s, 3H, OCH_3), and 3.4—3.6 (m, 1H, CHO); IR (CCl_4) 1708 cm^{-1} (C=O).

2-Methyl-1-phenyl-1-trimethylsiloxy-3-pentanone (18). A mixture of diastereomers (threo : erythro=3.2 : 1): bp 110 °C/0.4 Torr; ^{1}H NMR ($CDCl_3$) δ=−0.08 and 0.02 (two s, 3.2 : 1 ratio, 9H, CH_3Si), 0.73 (d, J=8.0 Hz, 3H, CHC<u>H</u>$_3$), 1.08 (t, J=8.9, Hz, 3H, CH_2C<u>H</u>$_3$), 1.9—3.2 (m, 3H, CH and CH_2), 4.65 (d, J=9.3 Hz, CHO, threo), 4.81 (d, J=8.0 Hz, CHO, erythro), 7.24 and 7.29 (two s, 5H, C_6H_5); IR (CCl_4) 1714 cm^{-1} (C=O). These diastereomers were inseparable by GC. The isomer ratio was determined by NMR.

1-Hydroxy-2-methyl-1-phenyl-3-pentanone.[30] Obtained from **18** by hydrolysis: ^{1}H NMR ($CDCl_3$) δ=0.8—1.2 (m, 6H, CH_3), 2.3—3.0 (m, 3H, C<u>H</u>$_2$COC<u>H</u>), 3.1 (br, 1H, OH), 4.73 (dd, J=8.3, 2.7 Hz, CHO, threo), 5.00 (d, J=4.8 Hz, CHO, erythro), and 7.31 (s, 5H, C_6H_5); IR (CCl_4) 1712 (C=O) and 3500 cm^{-1} (OH).

2,4,4-Trimethyl-1-phenyl-1-trimethylsiloxy-3-pentanone (19).[23] **A Threo Isomer:** bp 135 °C (bath temp)/0.3 Torr; ^{1}H NMR ($CDCl_3$) δ=−0.13 (s, 9H, CH_3Si), 0.73 (d, 3H, J=7.0 Hz, CHC<u>H</u>$_3$), 1.20 (s, 9H, t-Bu), 3.2 (m, 1H, C<u>H</u>CH$_3$), 4.71 (d, 1H, J=9.8 Hz, CHO), and 7.29 (s, 5H, C_6H_5); IR (CCl_4) 1703 cm^{-1}; GC (OV-1, 160 °C , 0.85 kg cm^{-2}) t_R 8.9 min (erythro), 9.3 min (threo). An authentic sample of an erythro isomer was prepared according to the literature.[23]

4,6-Dimethyl-5-trimethylsiloxy-3-heptanone (20). A mixture of diastereomers (threo : erythro=3 : 1): bp 125 °C (bath temp)/15 Torr; ^{1}H NMR ($CDCl_3$) δ=0.02 and 0.06 (two s, 3 : 1 ratio, 9H, CH_3Si), 0.8—1.2 (m, 12H, CH_3), 1.6 (m, 1H, $CHMe_2$), 2.3—2.9 (m, 3H, C<u>H</u>$_2$COC<u>H</u>), and 3.6—3.9 (m, 1H, CHO); IR (CCl_4) 1713 cm^{-1} (C=O); GC (PEG-HT, 80 °C, 1.0 kg cm^{-2}) t_R 5.1 min (threo), 6.0 min (erythro).

5-Hydroxy-4,6-dimethyl-3-heptanone.[29] Obtained from **20** by hydrolysis. A mixture of diastereomers (threo : eryth-

ro=3:1): ^{1}H NMR ($CDCl_3$) δ=0.8—1.2 (m, 12H, CH_3), 1.7 (m, 1H, $CHMe_2$), 2.3—2.9 (m, 3H, $C\underline{H}_2COC\underline{H}$), 2.6 (s, 1H, OH) and 3.3—3.6 (m, 1H, CHO); IR (CCl_4) 1697 (C=O), and 3520 cm^{-1} (OH); ^{13}C NMR ($CDCl_3$) δ=47.5 and 48.3 (1:3 ratio, O=CCH), 76.4 and 78.4 (1:3 ratio, CHO).

4-Benzyloxy-1-phenyl-3-trimethylsiloxy-1-pentanone (23). A mixture of diastereomers (**23a**:**23b**=2:1) purified by TLC. ^{1}H NMR ($CDCl_3$) δ=0.05 and 0.08 (two s, 2:1 ratio, 9H, CH_3Si), 1.27 (d, J=6.0 Hz, 3H, CH_3), 3.20 (d, 2H, J=6.2 Hz, CH_2CO), 3.6 (m, 1H, CHOSi), 4.4 (m, 1H, $C\underline{H}OCH_2Ph$), 4.6 (m, 2H, CH_2Ph), 7.3 (s, 5H, $CH_2C_6\underline{H}_5$), and 7.4—8.1 (m, 5H, C_6H_5CO); IR (CCl_4) 1692 cm^{-1} (C=O); GC (OV-1, 220 °C, 1.0 kg cm^{-2}) t_R 10.1 min (**23a**), 10.4 min (**23b**). An authentic sample of **23a** was prepared using a $TiCl_4$-mediated reaction.[13]

Methyl 4-Benzyloxy-2,2-dimethyl-3-trimethylsiloxypentanoate (25). A solution of **21** (1 mmol) and **24** (1 mmol) in CH_2Cl_2 (4 ml) was treated with Al-Mont (0.2 g) at 25 °C for 1 h to afford **25** in 62% yield. A mixture of diastereomers (isomer ratio =54:46): bp 180 °C (bath temp)/0.5 Torr; ^{1}H NMR ($CDCl_3$) δ=0.12 and 0.16 (two s, 1:1 ratio, 9H, CH_3Si), 1.1—1.3 (m, 9H, CCH_3), 3.39 and 3.60 (two s, 1:1 ratio, 3H, CH_3O), 3.3—3.6 (m, 1H, $CH_3C\underline{H}O$), 3.96 and 4.00 (two d, 1:1 ratio, J=5.2, 6.0 Hz, 1H, CHOSi), 4.44 and 4.47 (two d, 1:1 ratio, J=5.1, 4.7 Hz, 2H, $PhCH_2$), and 7.31 (s, 5H, C_6H_5); IR (CCl_4) 1730 cm^{-1} (C=O); GC (OV-1, 180 °C, 1.0 kg cm^{-2}) t_R 10.7 min, 11.2 min.

1,4-Diphenyl-3-trimethylsiloxy-1-pentanone (27). A mixture of diastereomers purified by TLC: ^{1}H NMR ($CDCl_3$) δ=−0.08 (s, 9H, CH_3Si), 1.33 (d, J=7.0 Hz, 3H, CH_3), 2.7—3.2 (m, 3H, CH_2 and PhCH), 4.56 (ddd, J=7.3, 6.6, 4.0 Hz, 1H, CH), 7.27 (s, 5H, $C_6\underline{H}_5CH$), and 7.3—8.0 (m, 5H, C_6H_5CO); IR (CCl_4) 1686 cm^{-1} (C=O); GC (OV-1, 180 °C, 1.0 kg cm^{-2}) t_R 24.9 min (**27b**), 25.6 min (**27a**). An authentic sample of **27a** was prepared from **21** and acetophenone by use of LDA.[15]

2-(1-Hydroxy-2-methylpropyl)cyclohexanone (28).[2a] A solution of **1** (1 mmol) and **10** (1.5 mmol) in CH_2Cl_2 (4 ml) was treated with CF_3SO_3H (0.02 mmol) at −30 °C for 0.5 h. Hydrolysis of the silylated aldol product with 1 mol dm^{-3} HCl gave **28** in 38% yield. A mixture of diastereomers (isomer ratio =57:43): ^{1}H NMR ($CDCl_3$) δ=0.7—1.0 (m, 6H, CH_3), 1.3—2.6 (m, 10H, aliphatic CH and OH), and 3.2—3.8 (m, 1H, CHO); IR (CCl_4) 1712 (C=O) and 3500 cm^{-1} (OH); GC (OV-1, 110 °C, 0.8 kg cm^{-2}) t_R 12.0, 12.3 min.

Al-Mont is also a good catalyst for the Michael addition of silyl enol ethers to α,β-unsaturated carbonyl compounds: M. Kawai, M. Onaka, and Y. Izumi, *J. Chem. Soc., Chem. Commun.*, **1987**, 1203.

9) The diastereoselectivity of the reaction was independent of the amount of Al-Mont used. The dependence of diastereoselectivity on solvent has not been reported in the aldol reaction using silyl enol ether.

10) Furfural (**7**) is so labile under acidic conditions that the reaction of **1** with **7** gave a complex mixture by use of $TiCl_4$. A $BF_3 \cdot OEt_2$-mediated reaction in CH_2Cl_2 gave lower yield of the aldol product (64%, threo:erythro=40:60) than an Al-Mont-mediated reaction in CH_2Cl_2.

11) A sample of Al-Mont was dried under the same conditions as those for the aldol reaction. Detailed discussion with respect to maximum acid strength is mentioned later in this paper.

Chemistry of Germanium Atoms. II. Reactions of Thermally Evaporated Germanium Vapor with Organic Halides[1,2]

Kunio MOCHIDA,* Kumiko TASHIRO, Yasuhiro YOSHIDA, and Yasuhisa MIZUNO
Department of Chemistry, Faculty of Sciences, Gakushuin University, 1-5-1 Mejiro, Tokyo 171
(Received September 18, 1987)

Thermally generated germanium atoms were found to react with organic halides by insertion into carbon-halogen bonds. The resulting germylenes abstracted halogens from organic halides to form trihalogermyl derivatives. Tetrahalogermanes were also formed by the abstraction of halogens with germanium atoms.

The study of a group 4B element-vapor reaction has been of considerable interest in organometallic chemistry and organic synthesis during the last few decades.[3] With this method, it is proving feasible to synthesize organometallic compounds containing group 4B elements which would be difficult, if not impossible, to prepare by other methods and to study their reactive intermediates. The study of carbon and silicon atoms as homologue of the germanium atom has been fairly well investigated, while the chemical properties of germanium atoms have been little studied.[4-8] In this paper, we report on the reactions of thermally evaporated germanium vapor (atoms) with organic halides.

The reactions of carbon atoms and silicon atoms with compounds containing carbon-halogen bonds for good trapping agents have been reported.[9,10] Under these circumstances, we have undertaken a co-condensation of germanium atoms with organic halides. The present finding is valuable for understanding not only the chemical properties of germanium atoms but also organogermanium intermediates in solutions.

Results and Discussion

The apparatus described in the Experimental section was used. Germanium metal was evaporated at a temperature of ca. 1200—1300 °C using a filament of tungsten in vacuo (ca. 5×10^{-3} Torr, 1 Torr=133.322 Pa) at a rate of ca. 10 mg min^{-1}.[11] During the vaporization of germanium metal, an excess of organic halide was introduced, as vapor, into a reaction flask. Germanium atoms and organic halide vapor was co-condensed on the walls of the reaction vessel which was cooled at 77 K. The color of co-condensation product, thus prepared, was muddy brown. After the germanium evaporation and introduction of the organic halide were completed, the reaction flask was warmed to room temperature. The co-condensation product of germanium atoms and organic halide vapor turned black. The products were identified by comparing their GC-MS and retention times on GLC with those of authentic samples. The yields of products were calculated by GLC with an internal standard.

The reactions of thermally vaporized germanium atoms with organic halides were examined. The products containing germanium are summarized in Table 1.

The reaction of germanium atoms with CCl_4 produced $GeCl_4$ (<10%), CCl_3GeCl_3 (7.0%), CCl_3CCl_3 (6.5%), and several high-boiling-point products (No. 1). The high-boiling-point products obtained did not contain germanium atoms. McGlinchey and Tan reported on a similar co-condensation of germanium atoms with CCl_4, but did not observe the formation of $GeCl_4$.[7] The yields of products were increased when a mixture of germanium atoms/copper atoms and germanium atoms/chromium atoms was used (Nos. 2 and 3, respectively). The formation of CCl_3GeCl_3 shown in Table 1 is explained by the insertion of germanium atoms into C-Cl bonds of CCl_4 to form $ClGeCCl_3$. The resulting germylene is known to abstract chlorines.[12] The compound $GeCl_4$ presumably arises as a result of abstraction of four chlorine atoms from CCl_4 by germanium atoms in a stepwise manner. The reason for increased yields of products for germanium atoms/copper atoms and germanium atoms/chromium atoms is not clear.

Other tetrahalomethanes showed a similar behavior; the reactions of germanium atoms with $CFCl_3$ and $BrCCl_3$ gave mainly $CFCl_2GeCl_3$ (1.6%) and CCl_3GeBr_3 (7.8%), respectively (Nos. 4 and 5).

The reaction of germanium atoms with $CHCl_3$ gave $CHCl_2GeCl_3$ (8.0%) as trihalogermyl compounds (No. 6). When CH_2Cl_2 and CH_2Br_2 were used as substrate, the trihalogermyl compounds formed were $CH_2ClGeCl_3$ (0.3%) and $CH_2BrGeBr_3$ (0.7%), respectively (Nos. 7 and 8).

Taking the results (Nos. 1—8) shown in Table 1 into consideration, the order of decreasing reactivity towards carbon-halogen insertion by germanium atoms is C-Br>C-Cl≫C-F. This may be a reflection of the carbon-halogen bond strengths.

The reaction of germanium atoms with MeI produced GeI_4 (14.0%), $MeGeI_3$ (11.0%), and Me_2GeI_2 (0.5%) (No. 9). Other alkyl iodides showed a similar behavior; the reactions of germanium atoms with EtI, *n*-PrI, *i*-PrI, and *n*-BuI gave $EtGeI_3$ (2.8%) (No. 10), *n*-$PrGeI_3$ (2.7%) (No. 11), *i*-$PrGeI_3$ (5.3%) (No. 12), and *n*-$BuGeI_3$ (1.0%) (No. 13), respectively. Compound GeI_4 was also produced in all reactions of germanium atoms with alkyl iodides. No reactions occurred with

alkyl monobromides and alkyl monochlorides.

On the other hand, the reaction of germanium atoms with PhBr produced Ph_2GeBr_2 (0.05%) and Ph_3GeBr (0.01%) (No. 16). With PhCl, germanium atoms reacted to give only PhH and Ph-Ph. The reactivity observed for polyhalomethanes and alkyl iodides is not consistent with those for aryl halides used in this study. The reactions of germanium atoms with aryl halides may involve a radical-initiated process.[13]

Blank experiments were carried out under identical conditions. As a result, the products shown in Table 1 were attributable to the interaction of germanium atoms with the starting organic halides.

A probable pathway for the products shown in Table 1 is outlined in Scheme 1. Thermally evaporated germanium atoms possess a ^3P ground state. ^3P germanium atoms inserted into a carbon-halogen bond of organic halides to form triplet divalent species (germylenes) (Eq. 1). The intially formed triplet germylenes rapidly relax to the singlet state (Eq. 2). The ground state of R_2Ge (R=H, Me) and GeI_2 has been shown to be a singlet by quantum chemical calculations and chemical reactions.[14-16] The singlet germylenes abstract halogens from organic halides in a stepwise manner characteristic of germyl radicals (Eq. 3). Halogen abstraction has also been reported for singlet germylenes.[12]

Table 1. The Reaction of Germanium Atoms with Organic Halides[a]

No.	Substrate	Products (Yield/%[b])
1	CCl_4	$GeCl_4$ (<10[c]), CCl_3GeCl_3 (7.0)
2[d]	CCl_4	$GeCl_4$ (<10[c]), CCl_3GeCl_3 (12.0)
3[e]	CCl_4	$GeCl_4$ (<10[c]), CCl_3GeCl_3 (10.4)
4	$CFCl_3$	$GeCl_4$ (0.6), $CFCl_2GeCl_3$ (1.6)
5	$BrCCl_3$	$GeCl_4$ (5.8), $GeBrCl_3$ (0.6), $GeBrCl_3$ (0.6), $GeBr_4$ (0.7), $CCl_3GeBrCl_2$ (0.6), CCl_3GeBr_3 (7.8)
6	$CHCl_3$	$GeCl_4$ (15.0), $CHCl_2GeCl_3$ (8.0)
7	CH_2Cl_2	$GeCl_4$ (1.6), $CH_2ClGeCl_3$ (0.3)
8	CH_2Br_2	$GeBr_4$ (2.0), $CH_2BrGeClBr_3$ (0.7)
9	MeI	GeI_4 (14.0), $MeGeI_3$ (11.0), Me_2GeI_2 (0.5)
10	EtI	GeI_4 (17.0), $EtGeI_3$ (2.8)
11	*n*-PrI	GeI_4 (3.0), *n*-$PrGeI_3$ (2.7)
12	*i*-PrI	GeI_4 (5.1), *i*-$PrGeI_3$ (5.3)
13	*n*-BuI	GeI_4 (1.0), *n*-$BuGeI_3$ (1.0)
14	*n*-BuBr	No product
15	*n*-BuCl	No product
16	PhBr	Ph_2GeBr_2 (0.05), Ph_3GeBr (0.01)
17	PhCl	No product

a) Reactions were performed at room temperature for 1.5 h. b) Yields of products were determined on the basis of the amount of the germanium metal consumed on the assumption that all of the vaporized germanium metal completely reacted with organic halides. c) The retention time of $GeCl_4$ on GLC was overlapped with that of CCl_4. The yields of $GeCl_4$ could not be accurately determined by GLC. d) A mixture of germanium atoms and copper atoms. e) A mixture of germanium atoms and chromium atoms.

$$^1[R\text{-}\dot{G}e\text{-}X] \xrightarrow{R\text{-}X} R\dot{G}eX_2 \xrightarrow{R\text{-}X} RGeX_3 \quad (3)$$

$$^1[R\text{-}\dot{G}e\text{-}X] \xrightarrow{R\text{-}X} R_2GeX_2 \quad (4)$$

Scheme 1. The mechanism for germylene intermediates.

On the other hand, singlet germylenes also undergo double insertions (Eq. 4).

C-X bonds of organic halides may also be activated by clusters rather than germanium atoms.

Experimental

^1H NMR spectra were recorded on a Varian FT 80A with tetramethylsilane as an internal-standard. GC-MS spectra were obtained on a JEOL JMS-DX 303 mass spectrometer. Infrared spectra were recorded on a Hitachi 260-10 spectrometer. Gas chromatography was performed on a Shimadzu GC-6A and 8A with 1 m 5% and 20% SE30 columns.

Materials. Organic halides are commercially available and purified prior to use. Copper metal, chromium metal, $GeCl_4$, and GeI_4 are commercially available. CCl_3GeCl_3,[17] $MeGeI_3$,[18] Me_2GeI_2,[18] $EtGeI_3$,[19] *n*-$PrGeI_3$,[19] *n*-$BuGeI_3$,[19] Ph_2GeBr_2,[20] Ph_3GeBr,[21] were prepared as described in the cited references.

Reactions of Germanium Atoms with Organic Halides. As a typical example, the reaction of germanium atoms with chloroform ($CHCl_3$) is described. Germanium atoms were produced by using essentially the same apparatus as described in the literature.[1] Germanium metal (0.5 g, 6.9 mmol) was vaporized at a temperature of 1200—1300 °C by using a resistively heated, alumina-coated tungsten spiral crucible at 6.0—7.0 V, 15A, which was connected to copper electrodes, in vacuo (ca. 5×10^{-3} Torr) at a rate of 10 mg min^{-1}. During vaporization of the germanium metal, $CHCl_3$ (ca. 15 cm^3) was co-condensed on the walls of a quartz reaction flask containing crucible and a perforated inlet tube through which $CHCl_3$ was introduced as vapor. The crucible was maintained at 1200—1300 °C and the reaction flask immersed in liquid nitrogen during germanium vaporization and the introduction of $CHCl_3$. After germanium vaporization and the introduction of $CHCl_3$ were completed, the reaction flask was warmed to room temperature and allowed to stand for 1.5 h. Products were identified by comparing their GC-MS and retention times on GLC with those of authentic samples. The amounts of products were calculated by GLC with an internal-standard method. $GeCl_4$ (15.0%), $CHCl_2GeCl_3$ (8.0%), and several high boiling products were produced. The high boiling products were confirmed to exclude germanium atoms by GC-MS. The yields of products were determined on the basis of the germanium metal consumed by supposing that the germanium metal except for germanium metal that remained in the crucible completely reacted with $CHCl_3$ vapor. Therefore, by taking into consideration that the unreacted germanium metal attaches on the walls of a reaction flask, the yields of products may be underestimated.

Identification of Products. The known compounds were identified by comparing their GC-MS and retention times on GLC with those of authentic samples. The unknown compounds were carefully identified by comparing their GC-MS with those of similar samples and by parent peaks and cleavage patterns considering the natural abundance of germanium (ratio, $^{70}Ge/^{72}Ge/^{73}Ge/^{74}Ge/^{76}Ge=56/75/21/100/21$). $^{74}Ge,^{79}Br^{35}Cl_3$ (parent ion peak at $m/z=258$), $m/z=222$ (22), 179 (22), 153 (15), and 74 (17). $^{74}Ge^{79}Br_3{}^{35}Cl$ (parent ion peak at $m/z=346$), $m/z=347$ (10), 268 (60), 153 (54), 109 (80), and 74 (7). $CF^{35}Cl_2{}^{74}Ge^{35}Cl_3$ (parent ion peak at $m/z=280$), $m/z=245$ (18), 179 (26), 101 (100), 82 (36), and 66 (6). $C^{35}Cl_3{}^{74}Ge^{79}Br_3$ (parent ion peak at $m/z=428$), $m/z=428$ (1), 395 (12), 350 (4), 312 (100), 231 (8), 153 (53), 119 (50), 82 (30), and 74 (10). $C^{79}Br^{35}Cl_2{}^{74}Ge^{79}Br_3$ (parent ion peak at $m/z=474$), $m/z=475$ (0.4), 440 (1), 394 (11), 350 (3.5), 312 (22), 231 (3), 163 (100), 153 (27), and 74 (6). $CH^{35}Cl_2{}^{74}Ge^{35}Cl_3$ (parent ion peak at $m/z=262$), $m/z=227$ (2), 179 (18), 144 (2), 109 (18), and 83 (100). $CH_2{}^{35}Cl^{74}Ge^{35}Cl_3$ (parent ion peak at $m/z=228$), $m/z=194$ (17), 179 (65), 159 (100), 144 (12), 109 (65), and 74 (20). $CH_2{}^{79}Br^{74}Ge^{79}Br_3$ (parent ion peak at $m/z=404$), $m/z=405$ (24), 327 (77), 313 (100), 232 (26), 153 (44), and 74 (6).

The authors thank professor Yoshihito Takeuchi and Mr. Katsumi Shimoda of Tokyo University for a gift of $GeBr_4$. We also thank Mitsubishi Metal Corporation for a gift of germanium metal. This work was supported in part by Grant-in-Aid for Special Project Research (Nos. 61125004 and 62115003) provided by the Ministry of Education, Science and Culture.

Palladium-Catalyzed Double-Carbonylation of Alkenyl Halides with Secondary Amines To Give α-Keto Amides

Tae-il Son, Hisayoshi Yanagihara, Fumiyuki Ozawa, and Akio Yamamoto*
Research Laboratory of Resources Utilization, Tokyo Institute of Technology, Nagatsuta, Midori-ku, Yokohama 227
(Received September 28, 1987)

The double-carbonylation reaction of alkenyl halides with diethylamine in the presence of palladium catalysts has been examined in detail. The reaction gives α-keto amide together with amide, the single-carbonylation by-product. The yield of α-keto amide is strongly dependent on the nature of alkenyl halide. Alkenyl bromides or iodides having phenyl group(s) as substituent(s) on the vinyl group are successfully double-carbonylated under appropriate reaction conditions and the corresponding α-keto amides are obtained in good to modest yields together with amides. In contrast, the reactions of alkenyl halides without a phenyl group give amides exclusively. In order to clarify the reason for the substrate-specificity in the reaction, series of alkenyl- and alkenoylpalladium(II) complexes, the presumed intermediates in the catalytic reactions, have been prepared and their reactions with secondary amines, carbon monoxide, and alkenyl halides were examined. The study suggests the operation of three types of processes for amide formation in the catalytic reactions. Possible mechanisms for amide as well as α-keto amide formation are discussed.

Recently novel double-carbonylation reactions of organic halides catalyzed by palladium complexes have been discovered.[1-3]

$$RX + 2CO + 2R'_2NH \xrightarrow{[Pd]} RCOCONR'_2 + R'_2NH_2X \quad (R = \text{aryl, alkenyl; } X = Br, I; R' = \text{alkyl}) \quad (1)$$

$$ArX + 2CO + ROH + Et_3N \xrightarrow{[Pd]} ArCOCOOR + Et_3NHX \quad (Ar = \text{aryl; } X = I, (Br); R = \text{alkyl}) \quad (2)$$

$$ArI + 2CO + H_2O + Base \xrightarrow{[Pd]} ArCOCOOH + Base \cdot HI \quad (Base = Et_3N, Ca(OH)_2) \quad (3)$$

Double-carbonylation reactions of aryl halides have been extensively examined and a variety of aryl bromides and iodides were shown to be converted into α-keto amides,[1] α-keto esters,[2] and α-keto acids[3] in good to modest yields by proper choice of nucleophiles used in the catalytic systems. On the other hand, double-carbonylation reactions of other types of organic halides have been explored less extensively.

In this study we examined the double-carbonylation reaction of alkenyl halides in detail. Alkenyl halides can be successfully double-carbonylated only by process (1) using secondary amines. Further study has revealed that yield of α-keto amide in process (1) is strongly dependent on the kind of alkenyl halide. Namely, alkenyl halides having phenyl group(s) as substituent(s) on the vinyl group give α-keto amides together with amides, whereas in the reactions of alkenyl halides without phenyl groups, only amides are formed without any α-keto amide formation. For getting information regarding the substrate-specificity in the double-carbonylation, we prepared alkenyl- and alkenoylpalladium(II) complexes as models of intermediates assumed in the catalytic reactions and examined their reactivity toward secondary amines, carbon monoxide, and alkenyl halides.

Results

Catalytic Reaction. First we sought appropriate conditions for double-carbonylation of alkenyl halides by using styryl bromide and diethylamine as starting materials. Based on the previous results regarding the double-carbonylation of aryl halides,[1] diethylamine was chosen as the most suitable secondary amine for getting α-keto amides. Table 1 summarizes catalytic activities of palladium complexes having several kinds of tertiary phosphine ligands. No product other than α-keto amide and amide was observed in the reactions as confirmed by GLC. Among the complexes examined, the palladium complex coordinated with 1,4-bis(diphenylphosphino)butane (dppb) was found to serve as the most effective catalyst regarding the selectivity for α-keto amide formation as well as conversion of the bromide.

The highest selectivity for α-keto amide formation was achieved at moderate reaction temperatures of 50 °C (Table 1, Runs 5, 8, and 9). Higher CO pressure caused increase in selectivity for α-keto amide formation but significantly retarded the progress of reaction (Runs 5—7). The similar trend of the effect of CO pressure has been observed in the double-carbonylation of aryl bromides and secondary amines.

Although styryl bromide was used as a mixture of *Z* and *E* isomers, only (*E*)-α-keto amide was obtained as double-carbonylation product, presumably for a thermodynamic reason. In contrast, amide, the single-carbonylation by-product, was formed as a mixture of the both isomers.[4]

Table 2 summarizes the results of double carbonylation of various alkenyl halides. In the double-carbonylation of alkenyl bromides and iodides having phenyl group(s), α-keto amides were formed in good to modest selectivities (Runs 1—6). In contrast, no α-keto amide formation was observed when alkenyl halides without phenyl group were employed as starting materials (Runs 7—12).

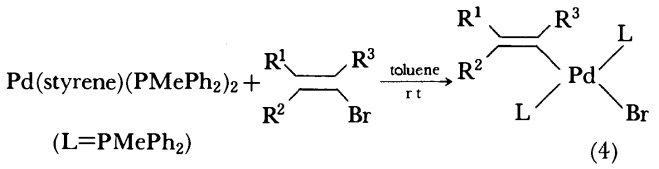
a) Reactions were carried out by using 6 mmol of alkenyl halides without solvent; alkenyl halide/Et_2NH/catalyst=1/6/0.01 (molar ratio). b) A, $PdCl_2(Ph_2P(CH_2)_4PPh_2)$; B, $PdMe_2(PMePh_2)_2$; C, $PdCl_2(PMePh_2)_2$. c) Initial value measured at room temperature. d) Confirmed by means of GLC. e) Not measured. f) Obtained as $Et_2NCH_2CH_2CONEt_2$. Z/E ratio: g), 1/6.5; h), E only; i), 1/3; j), 1/9.9; k), 1/6.1.

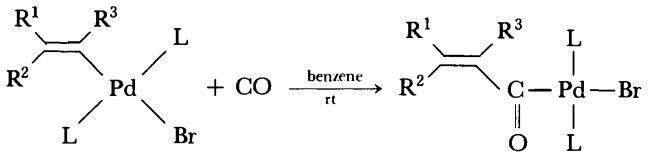
Preparation of Alkenyl- and Alkenoylpalladium(II) Complexes. Series of alkenylpalladium(II) complexes having $PMePh_2$ ligands **1a—1d** were prepared as possible intermediates in the catalytic systems.



1a: R^1=R^2=R^3=H
1b: R^1=Me, R^2=R^3=H
1c: R^1=Ph, R^2=R^3=H
1d: R^1=R^2=Ph, R^3=H

Reactions of $Pd(styrene)(PMePh_2)_2$[5] with phenyl-substituted vinyl bromides proceeded smoothly in toluene at room temperature to give alkenyl complexes **1c**[6] and **1d** in good yields. In contrast, treatment of $Pd(styrene)(PMePh_2)_2$ with vinyl bromide or 1-propenyl bromide under the same conditions gave $PdBr_2(PMePh_2)_2$ instead of the desired alkenyl complex **1a** or **1b**. Formation of butadiene and 2,4-hexadiene was also noted in the reactions. The reactions may involve the alkenyl complexes **1a** and **1b** as intermediates, which undergo further interaction with alkenyl bromides to give dibromopalladium and butadiene derivatives. Indeed, the reaction of isolated **1b** with 1-propenyl bromide in toluene at room temperature afforded $PdBr_2(PMePh_2)_2$ and 2,4-hexadiene. Addition of free $PMePh_2$ to the reaction systems containing $Pd(styrene)(PMePh_2)_2$ and the alkenyl halides, effectively retarded the formation of the dibromide complex, and **1a** and **1b** could be isolated in good yields.

The alkenyl complexes thus prepared underwent CO insertion into the Pd-C bond in solution to form corresponding alkenoylpalladium complexes **2a—2d** with retention of the trans configuration.



(L=$PMePh_2$)

2a: $R^1=R^2=R^3=H$
2b: $R^1=Me$, $R^2=R^3=H$
2c: $R^1=Ph$, $R^2=R^3=H$
2d: $R^1=R^2=Ph$, $R^3=H$ (5)

The alkenyl- and alkenoylpalladium(II) complexes were characterized by means of elemental analysis and spectroscopy (see Experimental section).

Reactions of the Alkenyl- and Alkenoylpalladium(II) Complexes with Secondary Amines under CO Pressure. 1. Effect of Amine. Reactions of the isolated alkenyl- and alkenoylpalladium(II) complexes with secondary amines under CO pressure smoothly proceeded in solution at room temperature to give corresponding α-keto amides and amides together with ammonium salts. The relative yields of α-keto amide and amide markedly varied with the nature of amine employed for the reaction.

Table 3. Reactions of the Styrylpalladium Complex **1c** with Various Secondary Amines under CO Pressure[a)]

Run	Amine	Product ratio		Total yield (%/Pd)
		α-keto amide	amide	
1	Pr_2NH	51	49	26
2	Et_2NH	87	13	55
3	piperidine	25	75	100
4	pyrrolidine	2	98	100

a) Reactions were carried out by using **1c** (0.05 mmol) and amine (1 mmol) in benzene (3 cm^3) under 50 atm of CO at room temperature for 2 h.

Table 4. Reactions of the Cinnamoylpalladium Complex **2c** with Various Secondary Amines under CO Pressure

Run	Amine	Product ratio		Total yield (%/Pd)
		α-keto amide	amide	
1	Pr_2NH	46	54	30
2	Et_2NH	87	13	46
3	piperidine	100	0	100
4	pyrrolidine	99	1	80

a) Reactions were carried out by using **2c** (0.05 mmol) and amine (1 mmol) in benzene (3 cm^3) under 50 atm of CO at room temperature for 2 h.

Tables 3 and 4 show effects of amines on the reactions of styryl and cinnamoyl complexes **1c** and **2c**. The reactions listed in the tables were carried out for 2 h under the same reaction conditions. In the reactions of the styryl complex **1c** (Table 3), selectivity for α-keto amide formation decreased in the order of diethylamine > dipropylamine > piperidine > pyrrolidine. The order is approximately similar to the selectivity order of these amines in the catalytic double-carbonylation of aryl halides to the α-keto amides except for the reversal of the order of diethylamine and dipropylamine. The selectivity order is inversely related with the previously observed reactivity order of the secondary amines in the reaction of *trans*-$PhCOPdI(PMePh_2)_2$ with the amines under CO.[1a)] The reactivity order of the amines is also reflected in the values of the total yields in Table 3,[7)] namely the reaction proceeds at higher rate with the more compact and reactive amines, such as piperidine and pyrrolidine, to give more amides rather than α-keto amides. However, examination of the reaction of the amines with the cinnamoylpalladium complex **2c** (Table 4) revealed that the reactivity of the alkenoyl complex differs from that of the aroyl complex.[1a,8)] Whereas the reaction of the benzoylpalladium complex with the amines and CO gave only α-keto amides, the reactions of the cinnamoylpalladium complex **2c** afforded also considerable amounts of amides when less reactive diethylamine and dipropylamine were used even under 50 atm of CO, although at higher pressure over 70 atm of CO the amide formation from **2c** became negligible.

2. Effect of Alkenyl Halide. Similarly to the reactions of **1c** and **2c**, reactions of 1-propenyl- and crotonoylpalladium complexes **1b** and **2b** derived from 1-propenyl bromide with diethylamine were found to give α-keto amide in relatively high selectivity under CO pressure (Table 5, Runs 1 and 4). These results are in contrast with those obtained in the catalytic reactions of 1-propenyl bromide, where no α-keto amide formation was observed (Table 2). Since the difference

Table 5. Reactions of Propenyl (**1b**) and Crotonoylpalladium Complex **2b** with Et_2NH under CO Pressure in the Absence and Presence of Propenyl Halides[a)]

Run	Complex	Additive (equiv/Pd)	Product ratio		Total yield (%/Pd)
			α-keto amide	amide	
1	**1b**	—	65	35	45
2	**1b**	MeCH=CHBr (50)	0	100	88
3	**1b**	MeCH=CHI (10)	0	100	250
4	**2b**	—	62	38	43
5	**2b**	MeCH=CHBr (50)	0	100	41

a) Reactions were carried in benzene under 50 atm of CO at room temperature for 2 h. Initial conditions: complex (ca. 0.05 mmol), Et_2NH (1 mmol), and benzene (3 cm^3).

in the reaction conditions between the stoichiometric and the catalytic reactions is the presence of the excess amount of 1-propenyl bromide in the catalytic systems, we next examined effect of 1-propenyl bromide on the reactions of **1b** and **2b** with diethylamine under CO pressure.

As seen from Table 5, in the presence of 1-propenyl bromide, the α-keto amide formation was completely suppressed and only amide was produced (Runs 2 and 5). Furthermore, in the presence of 1-propenyl iodide, **1b** yielded more than a stoichiometric amount of amide without formation of α-keto amide. The observation strongly suggests that 1-propenyl halides may interact with an intermediate species for α-keto amide formation derived from **2b**, carbon monoxide, and diethylamine to alter the reaction course into amide formation.

Kinetic Study on Amide Formation from Cinnamoylpalladium Complex 2c and Diethylamine in the Absence of Carbon Monoxide. The alkenoyl complexes prepared in the present study were found to have higher tendency to afford amides on interaction with amines than the previously reported aroylpalladium complexes.[1a,8] Therefore, we carried out kinetic examination of the amide formation process using cinnamoyl complex **2c** and diethylamine to get further information on the reaction mechanism.

$$\underset{(\mathbf{2c})}{PhCH=CHCOPd(Br)L_2} + 2HNEt_2 \xrightarrow[\text{toluene}]{\text{dmm}} PhCH=CHCONEt_2 + Pd(dmm)L_2 + H_2NEt_2Br \quad (6)$$

(L=$PMePh_2$, dmm=dimethyl maleate[9])

The reaction of **2c** and diethylamine in toluene containing dimethyl maleate[9] under N_2 atmosphere at 40 °C proceeded obeying the first-order kinetics up to 80% conversion of **2c** and gave a quantitative amount of amide. The first-order rate constant (k_{obsd}) increased with increase in the concentration of Et_2NH, while the reaction was effectively retarded by addition of free $PMePh_2$ to the system (Table 6). The k_{obsd} value was inversely proportional to [$PMePh_2$], the concentration of added $PMePh_2$ (Fig. 1).

Table 6. First-Order Rate Constants (k_{obsd}) for the Reaction of *trans*-Pd(COCH=CHPh)Br($PMePh_2$)$_2$ (**2c**) and Et_2NH in Toluene Containing Dimethyl Maleate at 40 °C[a]

Run	[$HNEt_2$]/ mol l^{-1}	[$PMePh_2$]/ mol l^{-1}	$10^4\,k_{obsd}$/s^{-1}	r[b]

a) Initial conditions: [**2c**]=0.025 mol l^{-1}, [dimethyl maleate]=0.20 mol l^{-1}. b) Correlation coefficient for the first-order plot up to 70% conversion of **2c**.

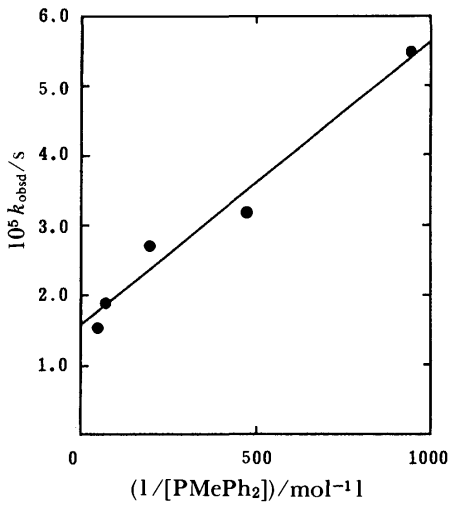

Fig. 1. Plot of k_{obsd} vs. 1/[$PMePh_2$] in the reaction of *trans*-Pd(COCH=CHPh)Br($PMePh_2$)$_2$ (**2c**) and Et_2NH to give amide.

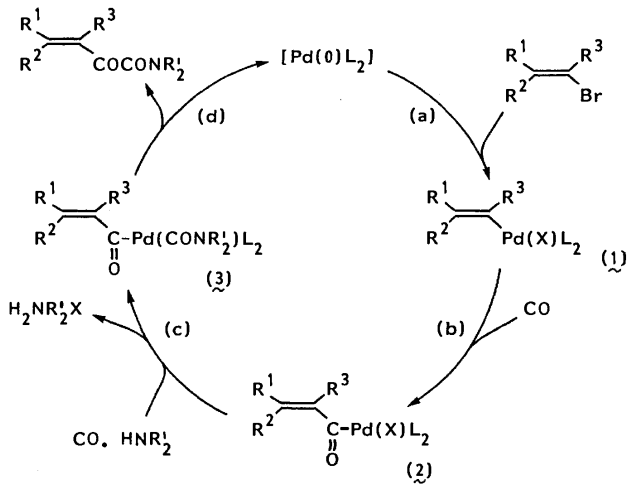
Discussion

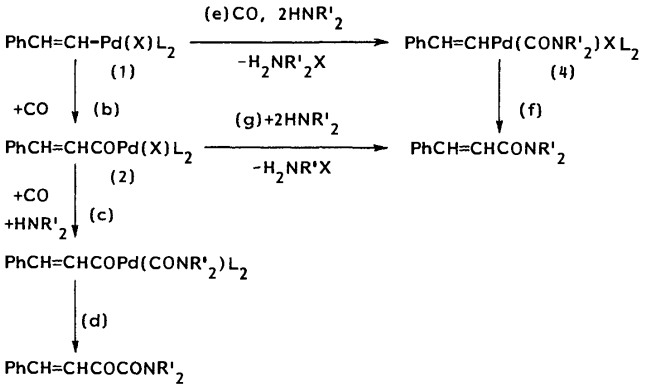
The results obtained in the present study regarding reactivity of the isolated alkenyl- and alkenoylpalladium complexes toward CO and amines support the involvement of these organopalladium species as intermediates in the catalytic system for the α-keto amide formation. Scheme 1 represents a catalytic cycle for the α-keto amide formation proposed on the basis of the present study together with information derived in the previous studies.

The alkenyl complex **1**, which is formed by oxidative addition of alkenyl halide to a [Pd(0)L_2] species, undergoes CO insertion into the Pd-C bond to give an alkenoyl complex **2**. Interaction of **2** with CO and amine gives an alkenoyl(carbamoyl)palladium species **3**, which reductively eliminates α-keto amide accompanied by reproduction of a [Pd(0)L_2] species as a carrier of the subsequent catalytic cycle. Since the oxidative addition of alkenyl halide (process (a) in Scheme 1) and the CO insertion (process (b)) are known to proceed with retention of the original configuration at the alkenyl group,[10] the *Z* to *E* isomerization of the alkenyl group observed in the doublecarbonylation of styryl bromide should occur after formation of **3**. It is likely that the highly electron-withdrawing $COCONR'_2$ group induces the *Z* to *E* isomerization after formation of the α-keto amide.

In the previous studies where the aryl halides have been carbonylated in the presence of CO and amines to give α-keto amides and amides, the formation of α-keto amide was accounted for by a scheme analogous to Scheme 1, whereas the formation of amide was accounted for most reasonably by assuming the reac-



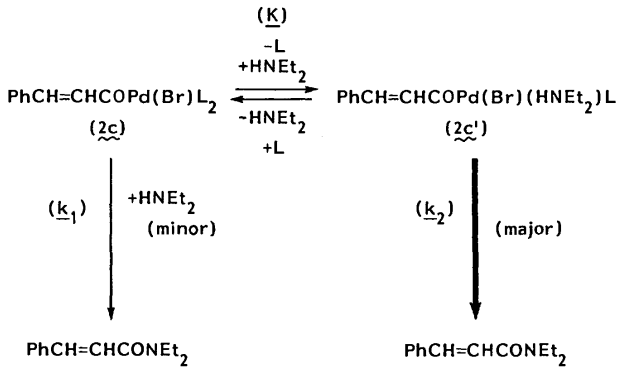
Scheme 1. Proposed mechanism for the palladium-catalyzed double-carbonylation of alkenyl halides and secondary amines to give α-keto amides.



Scheme 2. Possible processes for amide formation in the reaction of alkenylpalladium with secondary amine.

tion of a CO-coordinated arylpalladium complex with amine to give an aryl-carbamoylpalladium complex that subsequently reductively eliminates amide. The results shown in Table 3 regarding the reaction of the styrylpalladium complex **1c** with various amines and CO suggest the operation of similar two routes to give α-keto amide (route b→c→d in Scheme 2) and amide (route e→f).

The formation of α-keto amides in higher yields in the reactions of styryl complex **1c** with amines and CO when less reactive amines are used can be accounted for reasonably by assuming the competitive two routes as in the reaction of the corresponding arylpalladium complexes with CO and the amines. When the reactive amine such as piperidine and pyrrolidine is employed the reaction of the styrylpalladium complex gives amide through the reaction paths (e) and (f), whereas the less reactive amine such as diethylamine and dipropylamine allows the CO insertion to take place through path (b) giving the cinnamoyl complex. Then the reaction of amine with the cinnamoyl complex under CO gives the α-keto amide through paths



Scheme 3. Proposed mechanism for the amide formation in the reaction of *trans*-Pd(COCH=CHPh)-Br(PMePh$_2$)$_2$ (**2c**) and Et$_2$NH.

(c) and (d) as shown in Scheme 2.

However, the results shown in Table 4 and the kinetic studies of the cinnamoylpalladium complex **2c** with the secondary amines indicate that the amides can be formed by the reaction of the cinnamoyl complex with amines, whereas the corresponding reaction of the benzoylpalladium complex with amines and CO gave α-keto amides exclusively.[1a,8] Thus we have to consider another pathway to give amide from the cinnamoyl complex reacting with the amines as shown by path (g) included in Scheme 2.

In fact the kinetic study of the reaction of the cinnamoyl complex **2c** with diethylamine showed that amide can be readily formed in the reaction of **2c** with diethylamine in the absence of CO, the reaction being retarded in the presence of tertiary phosphine. The results of the kinetic study can be accounted for by assuming Scheme 3 where partial dissociation of the tertiary phosphine ligand from **2c** is involved.

In the major path to give the cinnamoyl amide from **2c** on reaction with HNEt$_2$, participation of an amine-coordinated species **2c′** is assumed. The retardation of the amide formation by addition of L suggests that one of the two tertiary phosphine ligands in **2c** is dissociated. The amide formation from the amine-coordinated intermediate complex **2c′** constitutes the main pathway. As indicated by observation of the intercept in Fig. 1, addition of an excess of L does not inhibit the amide formation completely. Thus we have to assume the presence of a minor pathway to give the amide directly from **2c** without partial dissociation of L.

Assumption of a rapid equilibrium between **2c** and **2c′**[11] and the rate-determining formation of amide from **2c** and **2c′** in Scheme 3 leads to the kinetic expressions given by Eqs. 7 and 8, where $K=[\mathbf{2c'}][L]/[\mathbf{2c}][HNEt_2]$ and $[PdCOR]=[\mathbf{2c}]+[\mathbf{2c'}]$.

$$\frac{d[\text{amide}]}{dt} = \frac{k_1[L]+k_2[K]}{[L]+K[HNEt_2]}[HNEt_2][PdCOR] \quad (7)$$

$$k_{obsd} = \frac{k_1[L]+k_2[K]}{[L]+K[HNEt_2]}[HNEt_2] \quad (8)$$

If one can assume [**2c**]≫[**2c'**] in the reaction solution containing an excess amount of added L, k_{obsd} value should be expressed by Eq. 9, because $[L]+K[HNEt_2] = [L](1+[\mathbf{2c'}]/[\mathbf{2c}]) \approx [L]$.

$$k_{obsd} = k_1[HNEt_2] + \frac{k_2 K[HNEt_2]}{[L]} \quad (9)$$

Equation 9 is compatible with the kinetic observation as shown in Fig. 1.

The behavior of the crotonoylpalladium complex **2b** with CO and Et_2NH shows a striking difference from that of the cinnamoyl complex as shown in Table 5 in that addition of propenyl halides to the reaction of **2b** with CO and Et_2NH completely inhibits the formation of α-keto amide.

$$\text{MeCH=CHCOPd(X)L}_2 \xrightarrow{+\text{CO, HNEt}_2} \text{MeCH=CHCOCONEt}_2 + \text{MeCH=CHCONEt}_2$$
$$\text{MeCH=CHCOPd(X)L}_2 \xrightarrow[+\text{MeCH=CHX (X=Br, I)}]{+\text{CO, HNEt}_2} \text{only MeCH=CHCONEt}_2 \quad (10)$$

Exclusive formation of amide in the catalytic conversion of alkenyl halides without a phenyl substituent (Table 2) is compatible with the behavior of the alkenoyl complex with CO and $HNEt_2$ in the presence of alkenyl halide. The exact reason for diversion of the reaction course that gives considerable amount of α-keto amide in the reaction of the alkenoyl complex with CO and $HNEt_2$ in the absence of alkenyl halide to that giving only amide is presently unclear and merits the further study.

Experimental

Infrared spectra were measured on a Hitachi 295 spectrometer by using KBr pellets for solid and KBr plates for liquid samples. NMR spectra were measured on JEOL FX-100 and PS-100 spectrometers by Dr. Y. Nakamura and Ms. R. Ito of our laboratory. ^{1}H NMR signals are referred to Me_4Si as internal standard and $^{31}P\{^1H\}$ NMR signals to PPh_3 as external standard. Microanalysis (C, H, N, and halogen) was carried out by Mr. T. Saito and Dr. M. Tanaka of our laboratory by using Yanagimoto CHN Autocorder Type MT-2 and Yazawa Halogen Analyzer. Mass spectra were measured on a Hitachi M-80 GC-mass spectrometer.

Solvents and amines were dried in the usual manner, distilled, and stored under a nitrogen atmosphere. Vinyl bromide, 1-propenyl bromide, and styryl bromide were used as purchased without further purification. $Ph_2C{=}CHBr$,[12] $Ph_2C{=}C(Ph)Br$,[13] $Ph(Me)C{=}CHBr$,[14] $Me_2C{=}C(Me)Br$,[15] $CH_2{=}C(Bu)I$,[16] $CH_2{=}C(Bu)Br$,[16] $BrCH{=}C(Me)COOH$,[17] $PhCH{=}CHI$,[18] $MeCH{=}CHI$[18] were prepared according to the methods in literature. Dichlorobis(tertiary phosphine)-palladium(II) complexes were prepared by the reactions of $PdCl_2(PhCN)_2$ with corresponding tertiary phosphines.

Catalytic Double-Carbonylation Reactions. A typical procedure (Table 1, Run 5) is as follows: styryl bromide (*Z*/*E*)=1/6.5; (1.0 g, 5.6 mmol) and diethylamine (3.6 cm^3, 34 mmol) were added to a 100 cm^3 stainless steel pressure bottle containing $PdCl_2(Ph_2P(CH_2)_4PPh_2)$ (0.034 g, 0.057 mmol) under nitrogen atmosphere. After evacuation of the system, 50 atm of CO gas was introduced at room temperature, and the mixture was magnetically stirred at 50 °C for 67 h. After purging the CO gas, the reaction solution was analyzed by means of GLC (Shimadzu GC-6A; column, PEG 20M 1 m) by using *o*-terphenyl as internal standard. The GLC analysis revealed the formation of $PhCH{=}CHCOCONEt_2$ (*E*-form; 70%/styryl bromide) and $PhCH{=}CHCONEt_2$ (*Z*/*E*= 1/10; 30%) at 100% conversion of styryl bromide. The α-keto amide and amide produced were isolated by column chromatography (Merck, Lobar column, LiChroprep Si 60; hexane-Et_2O) after removal of palladium catalyst by bulb-to-bulb distillation (Shibata GTO-250R), and identified by means of elemental analysis, IR and NMR spectroscopy, and mass spectrometry. (*E*)-$PhCH{=}CHCOCONEt_2$: IR (KBr plate) 1640 cm^{-1} (vs); ^{1}H NMR ($CDCl_3$) δ=1.19 (3H, t, *J*=7 Hz, CH_3), 1.24 (3H, t, *J*=7 Hz, CH'_3), 3.28 (2H, q, *J*=7 Hz, CH_2), 3.25 (2H, q, *J*=7 Hz, CH'_2), 6.85 (1H, d, *J*=16 Hz, =CH), 7.58 (1H, d, *J*=16 Hz, =CH'), and 7.2—7.6 (5H, m, Ph). Found: C, 72.6; H, 7.4; N, 6.0%; M$^+$, 231. Calcd for $C_{14}H_{17}NO_2$. C, 72.7; H, 7.4; N, 6.1%; M, 231. $PhCH{=}CHCONEt_2$: Found: C, 76.7; H, 8.5; N, 6.8%; M$^+$, 203. Calcd for $C_{13}H_{17}NO$: C, 76.8; H, 8.4; N, 6.9%; M, 203.

α-Keto amides and amides prepared in this study gave satisfactory analytical and spectroscopic data. The data for α-keto amides are as follows. $Ph_2C{=}CHCOCONEt_2$: mp 80 °C; IR (KBr disk) 1640 cm^{-1} (vs); ^{1}H NMR (CCl_4) δ=0.89 (3H, t, *J*=7 Hz, CH_3), 1.16 (3H, t, *J*=7 Hz, CH'_3), 3.08 (2H, q, *J*=7 Hz, CH_2), 3.11 (2H, q, *J*=7 Hz, CH'_2), 6.72 (1H, s, =CH), and 7.1—7.4 (10H, m, Ph). Found: C, 78.2; H, 6.8; N, 4.6%; M$^+$, 307. Calcd for $C_{20}H_{21}NO_2$: C, 78.1; H, 6.9; N, 4.6%; M$^+$, 307. $Ph_2C{=}C(Ph)COCONEt_2$: mp 118—120 °C; IR (KBr disk) 1680 (s) and 1640 cm^{-1} (vs); ^{1}H NMR (CCl_4) δ=0.64 (3H, t, *J*=7 Hz, CH_3), 1.16 (3H, t, *J*=7 Hz, CH'_3), 2.98 (2H, q, *J*=7 Hz, CH_2), 3.05 (2H, q, *J*=7 Hz, CH'_2), and 7.0—7.4 (15H, m, Ph). Found: C, 81.5; H, 6.4; N, 3.7%; M$^+$, 383. Calcd for $C_{26}H_{25}NO_2$: C, 81.4; H, 6.4; N, 3.7%; M$^+$, 383. (*E*)-$Ph(Me)C{=}CHCOCONEt_2$: IR (KBr plate) 1680 (s) and 1650 cm^{-1} (vs); ^{1}H NMR (CCl_4) δ=1.18 (3H, t, *J*=7 Hz, CH_3), 1.23 (3H, t, *J*=7 Hz, CH'_3), 2.61 (3H, s, $=CCH_3$), 3.33 (2H, q, *J*=7 Hz, CH_2), 3.42 (2H, q, *J*=7 Hz, CH'_2), 6.74 (1H, s, =CH), 7.1—7.6 (5H, m, Ph). Preparation of *trans*-Pd(CH=CH$_2$)Br(PMePh$_2$)$_2$ (1a). To a Schlenk tube containing *trans*-$PdEt_2(PMePh_2)_2$[19] (2.12 g, 3.75 mmol) were added toluene (3 cm^3) and styrene (1.7 cm^3, 15 mmol) at −30 °C under nitrogen atmosphere. The heterogeneous white mixture was stirred at 30 °C for 2 h to give a homogeneous pale yellow solution of $Pd(styrene)(PMePh_2)_2$ with evolution of quantitative amounts of ethane and ethene.[5] After cooling the system to −30 °C, $PMePh_2$ (0.34 cm^3, 3.75 mmol) and vinyl bromide (1 cm^3, 15 mmol) were added to the solution. On stirring the system at room temperature, a white precipitate was gradually formed from the solution. After 3 h the system was concentrated to almost dryness and 15 cm^3 of Et_2O was added at −30 °C to give a white solid. The solid formed was recrystallized from CH_2Cl_2-Et_2O to yield a white crystalline powder of **1a** (2.03 g, 88%): decomp 122—124 °C; ^{1}H NMR ($CDCl_3$, −40 °C) δ=2.13 (6H, t(br), PCH_3), 4.43 (1H, dt, $^3J_{HH}$=16.6 Hz, $^4J_{HP}$=2.5 Hz, =CH cis to Pd), 5.03 (1H, dt, $^3J_{HH}$=8.8 Hz, $^4J_{HP}$=6.1 Hz, =CH trans to Pd), 5.98 (1H, ddt, $^3J_{HH}$=16.6 and

8.8 Hz, $^3J_{HP}$=10.3 Hz, =CH geminal to Pd), 7.3—7.7 (20H, m, PPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, −40 °C) 15.1 ppm (s). Found: C, 54.9; H, 4.9; Br, 12.5%. Calcd for $C_{28}H_{29}P_2BrPd$: C, 54.8; H, 4.8; Br, 13.0%.

Complex **1b** was similarly prepared by using 1-propenyl bromide instead of vinyl bromide (54%): decomp 117—120 °C; ^1H NMR ($CDCl_3$, −50 °C) δ=2.14 (6H, t(br), PMe), 1.06 (3H, m, =CMe), 4.43 (1H, m, =CH cis to Pd), 5.10 (1H, dtq, $^3J_{HH}$=14.9 Hz, $^3J_{HP}$=10.3 Hz, $^4J_{HH}$=1 Hz), 7.3—7.8 (20H, m, PPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, −50 °C) 15.8 ppm (s). Found: C, 55.4; H, 4.5; Br, 12.2%. Calcd for $C_{29}H_{31}P_2BrPd$: C, 55.5; H, 5.0; Br, 12.7%.

Preparation of *trans*-Pd(CH=CHPh)Br(PMePh$_2$)$_2$ (1c). To a homogeneous toluene solution of Pd(styrene)-(PMePh$_2$)$_2$ (3.50 mmol, 3 cm^3)[5] was added (*E*)-styryl bromide (1.8 cm^3, 14 mmol)[6] at −30 °C under nitrogen atmosphere. On stirring the system at room temperature, a white precipitate was gradually formed from the solution. After 2 h 10 cm^3 of hexane was added to the system, and the white precipitate formed was collected by filtration, washed with hexane (10 cm^3) and then Et_2O (10 cm^3), and dried in vacuo. The crude product was recrystallized from CH_2Cl_2-Et_2O to yield white crystals of **1c** (2.0 g, 84%): decomp 132—134 °C; ^1H NMR ($CDCl_3$, −40 °C) δ=2.12 (6H, t, *J*=3.4 Hz, PMe), 5.51 (1H, dt, $^3J_{HH}$=15.9 Hz, $^4J_{HP}$=2 Hz, =CH cis to Pd), 6.41 (1H, dt, $^3J_{HH}$=15.9 Hz, $^3J_{HP}$=9.6 Hz, =CH geminal to Pd), 6.3—6.4 (2H, m, =CPh), 7.0—7.1 (3H, m, =CPh), 7.3—7.7 (20H, m, PPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, −40 °C) 15.5 ppm (s). Found: C, 58.9; H, 4.9; Br, 12.4%. Calcd for $C_{34}H_{33}P_2BrPd$: C, 59.2; H, 4.8; Br, 11.6%.

Complex **1d** was similarly prepared by using Ph_2C=CHBr instead of styryl bromide (81%): decomp 178—182 °C; ^1H NMR ($CDCl_3$, −40 °C) δ=2.00 (6H, t(br), PMe), 6.62 (1H, t, $^3J_{HP}$=9.4 Hz, =CH), 6.4—6.5 (2H, m, =CPh), 7.0—7.6 (28H, m, PPh and =CPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, =40 °C) 14.6 ppm (s). Found: C, 62.0; H, 5.1; Br, 11.1%. Calcd for $C_{40}H_{37}P_2BrPd$: C, 62.7; H, 4.9; Br, 10.4%.

Preparation of *trans*-Pd(COCH=CH$_2$)Br(PMePh$_2$)$_2$ (2a). To a Schlenk tube containing *trans*-Pd(CH=CH$_2$)Br(PMe-Ph$_2$)$_2$(**1a**; 0.27 g, 0.45 mmol) was added benzene (3 cm^3) under nitrogen atmosphere. After evacuating the system, atmospheric pressure of CO gas was introduced, and the resulted colorless solution was magnetically stirred at room temperature. The color of the solution was quickly changed into yellow. After 2 h, the CO gas was purged and the system was concentrated to almost dryness. Addition of 20 cm^3 of Et_2O to the system at −30 °C gave a yellow precipitate, which was collected by filtration, washed with Et_2O (15 cm^3×3), and dried in vacuo. The yellow powder thus obtained was recrystallized from CH_2Cl_2-Et_2O to yield yellow crystals of **2a** (0.21 g, 67%): decomp 122—125 °C; IR (KBr) 1635 cm^{-1} (vs), ^1H NMR ($CDCl_3$, room temperature) δ=2.11 (6H, t, *J*=3.7 Hz, PMe), 5.19 (1H, ddt, $^3J_{HH}$=17 and 8 Hz, $^4J_{HP}$=1 Hz, =CH geminal to CO), 5.46 (1H, dd, $^3J_{HH}$=8 Hz, $^2J_{HH}$=1 Hz, =CH trans to CO), 6.08 (1H, dd, $^3J_{HH}$=17 Hz, $^2J_{HH}$=1 Hz, =CH cis to CO), 7.2—7.8 (20H, m PPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, room temperature) 8.9 ppm (s). Found: C, 53.7; H, 4.6; Br, 13.5%. Calcd for $C_{29}H_{29}OP_2BrPd$: C, 54.3; H, 4.6; Br, 12.5%.

Similarly prepared were *trans*-Pd(COCH=CHMe)Br-(PMePh$_2$)$_2$ (**2b**; 53%) and *trans*-Pd(COCH=CHPh)Br-(PMePh$_2$)$_2$ (**2c**; 75%). **2b**: decomp 131—135 °C; IR (KBr) 1633 cm^{-1} (vs); ^1H NMR ($CDCl_3$, room temperature) δ=2.10 (6H, t, *J*=3.4 Hz, PMe), 1.34 (3H, dd, $^3J_{HH}$=6.8 Hz, $^4J_{HH}$=1.5 Hz, =CMe), 4.91 (1H, dq, $^3J_{HH}$=15.4 Hz, $^4J_{HH}$=1.5 Hz, =CH geminal to CO), 6.68 (1H, dq, $^3J_{HH}$=15.4 Hz, $^3J_{HH}$=6.8 Hz, =CH trans to CO), 7.2—7.9 (20H, m, PPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, room temperature) 8.7 ppm (s). Found: C, 55.6; H, 4.9; Br, 12.9%. Calcd for $C_{30}H_{31}OP_2BrPd$: C, 54.9; H, 4.8; Br, 12.2%. **2c**: decomp 132—134 °C; IR (KBr) 1640 cm^{-1} (vs); ^1H NMR ($CDCl_3$, room temperature) δ=2.12 (6H, t, *J*=3.5 Hz, PMe), 5.48 (1H, dt, $^3J_{HH}$=15.9 Hz, $^4J_{HP}$=1.5 Hz, =CH geminal to CO), 7.1—7.2 (2H, m, =CPh), 7.3—8.1 (24H, m, PPh, =CPh, and =CH cis to CO); $^{31}P\{^1H\}$ NMR ($CDCl_3$, room temperature) 9.0 ppm (s). Found: C, 57.9; H, 4.6; Br, 11.2%. Calcd for $C_{35}H_{33}OP_2BrPd$: C, 58.6; H, 4.6; Br, 11.1%.

Preparation of *trans*-Pd(COCH=CPh$_2$)Br(PMePh$_2$)$_2$ (2d). To a test tube containing *trans*-Pd(CH=CPh$_2$)Br(PMePh$_2$)$_2$ (**1d**; 0.21 g, 0.28 mmol) was added 3 cm^3 of benzene under nitrogen atmosphere. The test tube was placed in a 100 cm^3 stainless steel pressure bottle, and 10 atm of CO gas was introduced at room temperature. After the system was stirred for 8 h at room temperature, the CO gas was purged and the resulted reddish yellow solution was replaced into a Schlenk tube. The solution was concentrated to ca. half in volume. Addition of 20 cm^3 of hexane to the system yielded a yellow powder, which was recrystallized from CH_2Cl_2-Et_2O to give yellow crystals of **2d** (0.43 g, 43%): decomp 179—183 °C; IR (KBr) 1651 cm^{-1}; ^1H NMR ($CDCl_3$, room temperature) δ= 2.12 (6H, t, *J*=3 Hz, PMe), 6.60 (1H, s, =CH), 6.33 (2H, dd, *J*= 8 and 1 Hz, =CPh), 6.72 (2H, dd, *J*=8 and 1 Hz, =CPh′), 6.9—7.8 (26H, m, =CPh, =CPh′ and PPh); $^{31}P\{^1H\}$ NMR ($CDCl_3$, room temperature) 7.7 ppm (s). Found: C, 62.0; H, 5.1; Br, 11.1%. Calcd for $C_{41}H_{37}OP_2BrPd$: C, 62.0; H, 4.7; Br, 10.1%.

Reactions of Organopalladium Complexes with CO and Amines. General Procedure. To a test tube containing an organopalladium complex (ca. 0.05 mmol) were added benzene (3 cm^3), amine (1 mmol), and/or the additive under nitrogen atmosphere. The test tube was placed in a 100 cm^3 stainless steel pressure bottle, and CO gas was introduced at room temperature. After the system was magnetically stirred at room temperature for 2 h, the CO gas was quickly purged and the reaction solution was analyzed by means of GLC.

Kinetic Study on the Amide Formation from 2c and Et$_2$NH. To a Schlenk tube containing **2c** (ca. 25 mmol) and *o*-terphenyl (ca. 0.17 mmol) as an internal standard for GLC analysis, were added toluene (10 cm^3) and adequate amounts of Et_2NH and $PMePh_2$ under argon atmosphere. The Schlenk tube was placed in a thermostated bath (HAAKE F2) controlled to 40.0±0.5 °C. At intervals, a part of the reaction solution (ca. 0.1 cm^3) was sampled and quickly added into an aqueous HCl solution (ca. 1 mol dm^{-1}, 0.5 cm^3) for quenching the reaction. The organic layer separated out from the aqueous solution was analyzed by means of GLC.

The present work was supported by a Grant-in-Aid for Developmental Scientific Research from the Ministry of Education, Science and Culture (No. 62850147).

9) In the absence of dimethyl maleate (dmm), Reaction 6 did not proceed according to the first-order kinetics, probably due to interference by a $[Pd(0)L_2]$ species generated in the reaction. Since dmm serves as a good trapping agent of$[Pd(0)L_2]$ species to from stable $Pd(dmm)L_2$ complex,[5] the reaction was followed in the presence of dmm to get a well behaved kinetic results.

Studies on Lignan Lactone Antitumor Agents. IV. Synthesis of Glycosidic Lignan Variants Related to α-Peltatin

Hitoshi SAITO, Yoshio NISHIMURA,* Shinichi KONDO, Tomio TAKEUCHI, and (the late) Hamao UMEZAWA
Institute of Microbial Chemistry, 3-14-23 Kamiosaki, Shinagawa-ku, Tokyo 141
(Received October 12, 1987)

Glycosidic variants of 1-β-hydroxy-α-peltatin and 1-β-hydroxy-8-*O*-methyl-α-peltatin were synthesized by glycosidation of 4′,8-di-*O*-benzyloxycarbonyl-1-β-hydroxy-α-peltatin or 4′-*O*-benzyloxycarbonyl-1-β-hydroxy-8-*O*-methyl-α-peltatin with the corresponding glucopyranose or 2-amino-2-deoxyglucopyranose derivatives. Among synthesized compounds, cyclic acetal of 1-*O*-β-(β-D-glucopyranosyl)-8-*O*-methyl-α-peltatin showed antitumor activity in mice with leukemia L-1210.

The lignan lactone antitumor agents, VP-16-213 (etoposide, **1**) and VM-26 (teniposide, **2**), are used for cancer chemotherapy.[1,2] Due to their clinical efficacy, the synthesis of new active analogues of podophyllotoxin glycoside has been of considerable interest. We have previously reported the syntheses of new active aminoglycosidic variants of podophyllotoxin **3**—**5**, which were found to have the superior activities to **1**.[3,4]

The hitherto-known structural modifications of podophyllotoxin glycoside on sugar or on lignan moiety suggested that the following factors played an important role in increasing the antitumor activity; a) the glucose configuration, b) β-glycosidic linkage, c) 4″,6″-*O*-cyclic acetal group, d) β-configuration at C-1, e) trans-fused lactone and f) 4′-phenolic hydroxyl group. In connection with our interest in investigation on the relationship between structure and antitumor activity among lignan lactone glycosides, we undertook the syntheses of glucosidic analogues of α-peltatin **11**, **17**, and **20**. The starting aglycone, 4′,8-di-*O*-benzyloxycarbonyl-1-β-hydroxy-α-peltatin (**7**) was prepared from α-peltatin.[1] Several methods were examined to introduce 1-β-hydroxyl group by a direct bromination and a subsequent substitution of the bromine with a hydroxyl group. The bromination at C-1 of α-peltatin by treatment with *N*-bromosuccinimide (NBS) in THF[5] failed, affording the dibrominated product on both of the aromatic ring B and E which was simultaneously demethylated on the ring E. The attempts of bromination of 4′,8-di-*O*-benzyloxycarbonyl-α-peltatin (**6**) with NBS in THF, and with that in the presence of benzoyl peroxide[6] were also unsuccessful. Finally, an introduction of 1-β-hydroxyl group into **6** was successfully carried out by two-step sequences (bromination and hydrolysis) in a one-pot procedure. Treatment of **6** with bromine in a mixture of aqueous barium carbonate solution and carbon tetrachloride in the presence of α,α′-azobis(isobutyronitrile) (AIBN)[7] gave **7** and an aromatized product **8** in a yield of 58 and 10%, respectively. Condensation of **7** with 2,3-di-*O*-chloroacetyl-4,6-*O*-ethylidene-β-D-glucopyranose (**9**)[8] in dichloromethane in the presence of boron trifluoride diethyl etherate[9] afforded 1-*O*-β-(2,3-di-*O*-chloroacetyl-4,6-*O*-ethylidene-β-D-glucopyranosyl)-4′,8-di-*O*-benzyloxycarbonyl-α-peltatin (**10**) as a sole product in a yield of 72%. The reaction was carried out stereoselectively by the same fashion through a benzyl cation at C-1 of the aglycone moiety generated by BF_3 as has been reported in the previous synthesis.[3,4,8,9] The stereochemistry of the glycoside was also controlled by the anomeric configuration of the original pyranose moiety. Removal of protecting groups in **10** by catalytic hydrogenolysis followed by the treatment with ethylenediamine in pyridine yielded 1-*O*-β-(4,6-*O*-ethylidene-β-D-glucopyranosyl)-α-peltatin (**11**).

Fig. 1.

Compound **11** showed no antitumor activity against mouse leukemia L-1210 (Table 1). Compound **10** was transformed into 1-β-methoxy-α-peltatin (**12**) having no antitumor activity under the conditions employed in the synthesis of podophyllotoxin glycoside[8] to remove chloroacetyl group [$Zn(OAc)_2$, CH_3OH, reflux]. These results suggested that the glycosidic bond was easily hydrolyzed by the electronic effect of the neighbouring hydroxyl group at C-8.[10] In order to improve its stability, we undertook the synthesis of the methylated compound at C-8, 1-*O*-β-(4,6-*O*-ethylidene-β-D-glucopyranosyl)-8-*O*-methyl-α-peltatin (**17**). Catalytic hydrogenolysis of **7** with 10% palladium on carbon in

Table 1. The Antitumor Activities of α-Peltatin Analogues (T/C%)

Dose (μg/mouse)	Compound No.			
	11	**12**	**17**	**20**
25	105	128	156	119
6.25	117	103	100	95

The T/C values are the percentage ratios of the mean survival period of five treated mice to the mean survival period of the control group. L-1210 cells (10^6 cells) were inoculated intraperitoneally and the intraperitoneal treatment was started on day 1 and continued for 10 days.

ethyl acetate at −20 °C gave 4′-*O*-benzyloxycarbonyl-1-β-hydroxy-α-peltatin (**13**) and 1-β-hydroxy-α-peltatin (**14**) in 70 and 25% yield, respectively. When the same catalytic hydrogenolysis was carried out at room temperature, **14** was obtained as a sole product. Compound **13** was methylated with methyl iodide in the presence of potassium carbonate in acetone to afford quantitatively 4′-*O*-benzyloxycarbonyl-1-β-hydroxy-8-*O*-methyl-α-peltatin (**15**). Condensation of **15** with **9** followed by removal of protecting groups by the same procedure as mentioned above gave **17** in a good yield. Compound **17** was found to have the superior antitumor activity to **11**.

In relation to these syntheses, we were interested in the replacement of the sugar moiety of **17** with an amino sugar. Condensation of **15** with 2-benzyloxycarbonylamino-3-*O*-chloroacetyl-4,6-*O*-ethylidene-β-D-glucopyranose (**18**)[8] and a successive deprotection of the masking groups were carried out by the similar sequences described above to afford 1-*O*-β-(2-amino-2-deoxy-4,6-*O*-ethylidene-β-D-glucopyranosyl)-8-*O*-methyl-α-peltatin (**20**) in an excellent yield. Compound **20** showed no antitumor activity (Table 1). Further study for antitumor activity of synthesized compounds is in progress.

Experimental

General Methods. Melting points were determined with a Yamato apparatus and were uncorrected. IR spectra were determined on a Hitachi Model 260-10 and Jasco IR-810 spectrophotometers. Optical rotations were measured with a Perkin-Elmer Model 241 polarimeter. ^{1}H NMR spectra were recorded with Varian EM-390, Jeol GX-270 and Jeol GX-400 spectrometers. Chemical shifts are expressed in δ values (ppm) with tetramethylsilane as an internal standard. The mass spectra were taken by a Hitachi RMN-7M for field-desorption (FD) and a Jeol D-300 for fast atom bombardment (FAB). Natural α-peltatin was provided by Nippon Kayaku Co., Ltd.

4′,8-Di-*O*-benzyloxycarbonyl-α-peltatin (6). To a solution of α-peltatin (800 mg) in dichloromethane (5 ml) containing pyridine (400 mg) was added a solution of benzyloxycarbonyl chloride (800 mg) in dichloromethane (1 ml) at 0 °C, and the mixture was stirred for 1 h. The solution was washed with water and dried over $MgSO_4$. Evaporation of the solvent gave a solid. The solid was subjected to column chromatography on silica gel. Elution with acetone–toluene (1 : 19) gave **6** (1.1 g, 82%), which was recrystallized from methanol: mp 98—99 °C; $[\alpha]_D^{24}$ −90° (*c* 0.69, $CHCl_3$); IR (KBr) 1770, 1602, 1240, and 1128 cm^{-1}; ^{1}H NMR ($CDCl_3$, 270 MHz) δ=2.40 (1H dd, *J*=5 and 15 Hz, H-1), 2.65 (1H m, H-2), 2.72 (1H dd, *J*=4.7 and 13.7 Hz, H-3), 3.01 (1H dd, *J*=5 and 15 Hz, H-1), 3.69 (6H s, 2×OCH_3), 3.87 (1H t, *J*=9 Hz, H-11), 4.43 (1H dd, *J*=6.6 and 9 Hz, H-11), 4.64 (1H d, *J*=4.7 Hz, H-4), 5.26 and 5.31 (2H each s, 2×$C\underline{H}_2$Ph), 6.01 (2H s, methylene), 6.36 (2H s, H-2′ and 6′), 6.50 (1H s, H-5) and 7.3—7.5 (10H m, 2×Ph); MS (FAB) *m/z* 669 (M^+ +H), 533, and 381.

4′,8-Di-*O*-benzyloxycarbonyl-1-β-hydroxy-α-peltatin (7). To a suspension of **6** (334 mg), AIBN (200 mg) and $BaCO_3$ (500 mg) in a mixture of water (5 ml) and carbon tetrachloride (30 ml) was added bromine (33 μl), and the mixture was stirred at room temperature for 2 h. After evaporation, the mixture was dissolved in a mixture of acetone (30 ml) and water (1 ml), and the solution was stirred at 40 °C for 2 h. The insoluble matter was filtered off, and the filtrate was evaporated to give an oil. The oil was chromatographed on silica gel with the solvent system of acetone–toluene (1 : 5) to give solids of **7** (200 mg, 58%) and **8** (33 mg, 10%). Each solid was recrystallized from ethanol. **7**: mp 105—106 °C. $[\alpha]_D^{23}$ −78° (*c* 0.46, $CHCl_3$); IR (KBr) 1772, 1602, 1482, 1240, 1210 cm^{-1}; ^{1}H NMR ($CDCl_3$, 270 MHz) δ=2.72 (1H m, H-2), 3.32 (1H dd, *J*=5 and 14 Hz, H-3), 3.68 (6H s, 2×OCH_3), 4.37 (2H m, H-11), 4.66 (1H d, *J*=5 Hz, H-4), 5.02 (1H d, *J*=3.4 Hz, H-1), 5.26 and 5.33 (2H each s, 2×$C\underline{H}_2$Ph), 6.04 and 6.06 (2H each d, *J*=1.3 Hz, ethylidene), 6.29 (2H s, H-2′ and 6′), 6.52 (1H s, H-5) and 7.3—7.5 (10H m, 2×Ph); MS (FD) *m/z* 684 (M^+), 640, 599, and 550. **8**: mp 215—216 °C; $[\alpha]_D^{23}$ 0° (*c* 0.5, $CHCl_3$); IR (KBr) 1788, 1615, 1280, and 1228 cm^{-1}; ^{1}H NMR ($CDCl_3$, 270 MHz) δ=3.79 (6H s, 2×OCH_3), 5.33 (2H s, $C\underline{H}_2$Ph), 5.36 (2H s, H-11), 5.38 (2H s, $C\underline{H}_2$Ph), 6.15 (2H s, methylene), 6.55 (2H s, H-2′ and 6′), 7.08 (1H s, H-5), 7.3—7.5 (10H m, 2×Ph), and 7.81 (1H s, H-1); MS (FD) *m/z* 664 (M^+) and 529.

1-*O*-β-(2,3-*O*-Chloroacetyl-4,6-*O*-ethylidene-β-D-glucopyranosyl)-4′,8-di-*O*-benzyloxycarbonyl-α-peltatin (10). To a solution of a mixture of **7** (200 mg) and 2,3-di-*O*-chloroacetyl-4,6-*O*-ethylidene-β-D-glucose (130 mg, **9**) in dichloromethane (5 ml) was added dropwise boron trifluoride etherate (200 μl) at −20 °C, and the mixture was stirred at −20 °C for 1.5 h, then quenched with pyridine (200 μl). Dichloromethane (20 ml) was added, and the solution was washed with water, dried over $MgSO_4$, and filtered. The filtrate was evaporated to give a solid, which was subjected to column chromatography on silica gel. Elution with toluene–acetone (9 : 1) gave a solid of **10** (214 mg, 72%), which was recrystallized from ethanol: mp 116—117 °C, $[\alpha]_D^{23}$ −81° (*c* 0.55, $CHCl_3$); IR (KBr) 1772 and 1240 cm^{-1}; ^{1}H NMR ($CDCl_3$, 90 MHz) δ=1.34 (3H d, *J*=5 Hz, CH_3 of ethylidene), 3.66 (6H s, 2×OCH_3), 6.1 (2H s, methylene), 6.23 (2H s, H-2′ and 6′), 6.50 (1H s, H-5), and 7.2—7.6 (10H m, 2×Ph); MS (FAB) *m/z* 1025 (M^+ +H) and 890.

1-*O*-β-(4,6-*O*-Ethylidene-β-D-glucopyranosyl)-α-peltatin (11). A solution of **10** (180 mg) in ethyl acetate (10 ml) was stirred with 10% Pd/C (10 mg) under atmosphere of hydrogen at room temperature for 2 h. The catalyst was filtered off, and the filtrate was evaporated to give a solid (100 mg). The solid was dissolved in pyridine (1 ml), and to the solution was added ethylenediamine (25 μl) at 0 °C, and then the mixture was stirred at 0 °C for 1.5 h. The mixture was di-

luted with chloroform (30 ml), and washed with 5% aqueous $KHSO_4$ solution and water. The chloroform solution was dried over Na_2SO_4, and evaporated to give a solid. The solid was chromatographed on silica gel with the solvent system of toluene–acetone (2:1) to afford a solid of **11** (72 mg, 68%). The solid was recrystallized from chloroform: mp 208—209 °C (decomp); $[\alpha]_D^{25}$ −96° (*c* 0.3, CH_3OH); IR (KBr) 1758, 1625, 1482, and 1062 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ=1.44 (3H d, *J*=5 Hz, CH_3 of ethylidene), 3.26 (1H m, H-2), 3.55 (1H dd, *J*=5 and 14 Hz, H-3), 3.69 (2H m, H-4″ and 5″), 3.75 (6H s, 2×OCH_3), 4.04 (1H t, *J*=8 Hz, H-2″), 4.32 (1H t, *J*=8 Hz, H-3″), 4.38 (1H t, *J*=8 Hz, H-11), 4.80 (1H dd, *J*=9 and 11 Hz, H-11), 4.88 (1H d, *J*=5 Hz, H-4), 4.91 (1H q, *J*=5 Hz, CH of ethylidene), 5.74 (1H d, *J*=3.5 Hz, H-1), 5.76 (1H d, *J*=8 Hz, H-1″), 5.84 and 5.91 (2H ABq, *J*=1 Hz, methylene), 6.45 (1H s, H-5), and 6.86 (2H s, H-2′ and 6′); MS (FD) *m/z* 604 (M^+) and 398.

1-β-Methoxy-α-peltatin (12). A solution of debenzyloxycarbonylated compound of **10** (54 mg) in methanol (5 ml) was refluxed in the presence of zinc acetate (25 mg) for 4 h. After being diluted with chloroform (10 ml), the solution was washed with water, dried over $MgSO_4$, and filtered. Evaporation of the filtrate gave a solid, which was subjected to preparative thin-layer chromatography on silica gel developed with chloroform–methanol (1:5). Compound **12** was obtained as a solid in a yield of 66%. **12** was recrystallized from acetone to give a colorless crystal: mp 209—211 °C (decomp); $[\alpha]_D^{20}$ −92° (*c* 0.57, $CHCl_3$); IR (KBr) 1772, 1630, 1518, 1478, 1217, 1113 and 1062 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.70 (1H m, H-2), 3.28 (1H dd, *J*=5 and 14 Hz, H-3), 3.53 (3H s, OCH_3), 3.78 (6H s, 2×OCH_3), 4.35 (2H m, H-11), 4.60 (1H d, *J*=5 Hz, H-11), 4.86 (1H d, *J*=3 Hz, H-1), 5.40 (1H s, OH), 5.61 (1H s, OH), 5.96 (2H m, methylene), 6.22 (1H s, H-5), and 6.28 (2H s, H-2′ and 6′); MS (FD) *m/z* 430 (M^+).

4′-O-Benzyloxycarbonyl-1-β-hydroxy-α-peltatin (13). A solution of **7** (200 mg) in ethyl acetate (20 ml) was stirred under atmosphere of hydrogen in the presence of 10% Pd/C (10 mg) at −20 °C for 1 h. Catalyst was removed by filtration, and the filtrate was evaporated to give a solid. The solid was subjected to preparative thin-layer chromatography on silica gel developed with toluene–acetone (4:1). Compound **13** and 1-β-hydroxy-α-peltatin (**14**) were obtained as solids in yields of 70 and 25%, respectively. Each solid was recrystallized from methanol. **13**: mp 172—174 °C; $[\alpha]_D^{20}$ −55° (*c* 0.34, $CHCl_3$); IR (KBr) 1780, 1618, 1268, and 1140 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.75 (1H m, H-2), 3.25 (1H dd, *J*=5 and 14 Hz, H-3), 3.69 (6H s, 2×OCH_3), 4.36 (1H t, *J*=8 Hz, H-11), 4.47 (1H dd, *J*=8 and 11 Hz, H-11), 4.63 (1H d, *J*=5 Hz, H-4), 5.21 (1H d, *J*=4.3 Hz, H-1), 5.26 (2H s, $C\underline{H}_2Ph$), 5.98 (2H s, methylene), 6.24 (1H s, H-5), 6.34 (2H s, H-2′ and 6′) and 7.3—7.5 (5H m, Ph); MS (FD) *m/z* 550 (M^+), 532 and 398. **14**: mp 212—214 °C; $[\alpha]_D^{20}$ −74° (*c* 0.25, $CHCl_3$); IR (KBr) 1778, 1615, and 1110 cm^{-1}; ^1H NMR ($CDCl_3$ 270 MHz) δ=2.77 (1H m, H-2), 3.23 (1H dd, *J*=4.7 and 14 Hz, H-3), 3.78 (6H s, 2×OCH_3), 4.34 (1H t, *J*=8 Hz, H-11), 4.46 (1H dd, *J*=8 and 11 Hz, H-11), 4.61 (1H d, *J*=4.7 Hz, H-4), 5.23 (1H broad s, H-1), 5.99 (2H s, methylene), 6.26 (1H s, H-5), and 6.32 (2H s, H-2′ and 6′), MS (FD) *m/z* 416 (M^+) and 398.

4′-O-Benzyloxycarbonyl-1-β-hydroxy-8-O-methyl-α-peltatin (15). A solution of **13** (168 mg) in acetone (5 ml) was refluxed with methyl iodide (150 μl) in the presence of potassium carbonate (140 mg) for 1 h, and the mixture was further refluxed with an additional methyl iodide (100 μl) for 1 h. Evaporation of the solvent gave an solid, which was dissolved in chloroform. The solution was washed with water, dried over Na_2SO_4, and filtered. The solvent was evaporated to give a solid. The solid was subjected to preparative thin-layer chromatography on silica gel developed with toluene–acetone (2:1). Compound **16** was obtained as a solid (174 mg) quantitatively. The solid was recrystallized from methanol: mp 107—108 °C $[\alpha]_D^{27}$ −57° (*c* 0.55, $CHCl_3$); IR (KBr) 1770, 1256, 1218, and 1130 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=2.72 (1H m, H-2), 3.27 (1H dd, *J*=5 and 14 Hz, H-3), 3.70 (6H s, 2×OCH_3), 4.17 (3H s, OCH_3), 4.40 (2H m, H-11), 4.62 (1H d, *J*=5 Hz, H-4), 5.15 (1H d, *J*=3.5 Hz, H-1), 5.26 (2H s, $C\underline{H}_2Ph$), 5.95 (2H s, methylene), 6.29 (1H s, H-5), 6.37 (2H s, H-2′ and 6′), and 7.3—7.5 (5H m, Ph); MS (FAB) *m/z* 565 (M^++H), 547 and 429.

1-O-β-(2,3-Di-O-chloroacetyl-4,6-O-ethylidene-β-D-glucopyranosyl)-4′-O-benzyloxycarbonyl-8-O-methyl-α-peltatin (16). Procedure used was similar to that used for the preparation of **10** from **7** and **9** (78% yield). **16**: mp 129—130 °C; $[\alpha]_D^{23}$ −63° (*c* 0.53, $CHCl_3$); IR (KBr) 1775, 1480, 1258, 1206, and 1130 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=1.35 (3H d, *J*=5 Hz, CH_3 of ethylidene), 2.73 (1H m, H-2), 3.67 (6H s, 2×OCH_3), 4.16 (3H s, OCH_3), 5.96 (2H s, methylene), 6.29 (3H s, H-5, 2′ and 6′), and 7.3—7.5 (5H m, Ph); MS (FAB) *m/z* 905 (M^+ +H), 770, and 547.

1-O-β-(4,6-O-Ethylidene-β-D-glucopyranosyl)-8-O-methyl-α-peltatin (17). Procedures used were similar to those used for the preparation of **11** from **10** (69% yield). **17**: mp 221—222 °C; $[\alpha]_D^{23}$ −91° (*c* 0.54, $CHCl_3$); IR (KBr) 1777, 1618, 1220 and 1118 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz), δ=1.39 (3H d, *J*=5 Hz, CH_3 of ethylidene), 2.53 (1H broad s, 2″-OH), 2.70 (1H broad s, 3″-OH), 2.75 (1H m, H-2), 3.19 (1H dd, *J*=5.5 and 14 Hz, H-3), 3.38 (1H t, *J*=8 Hz, H-2″), 3.55 (1H m, H-6″), 3.77 (6H s, 2×OCH_3), 4.14 (3H s, OCH_3), 4.17 (1H dd, *J*=8 and 9 Hz, H-11), 4.46 (1H dd, *J*=9 and 11 Hz, H-11), 4.58 (1H d, *J*=5.5 Hz, H-4), 4.75 (1H q, *J*=5 Hz, CH of ethylidene), 4.84 (1H d, *J*=8 Hz, H-1″), 5.15 (1H d, *J*=3.5 Hz, H-1), 5.40 (1H s, 4′-OH), 5.94 and 5.96 (2H ABq, *J*=1.5 Hz, methylene), 6.26 (1H s, H-5), and 6.26 (2H s, H-2′ and 6′), MS (FAB) *m/z* 618 (M^+) and 413.

1-O-β-(2-Benzyloxycarbonylamino-3-chloroacetyl-2-deoxy-4,6-O-ethylidene-β-D-glucopyranosyl)-4′-O-benzyloxycarbonyl-8-O-methyl-α-peltatin (19). Procedure used was similar to that used for the preparation of **10** from **7** and **9** (92% yield). **19**: mp 219—220 °C; $[\alpha]_D^{18}$ −53° (*c* 0.52, $CHCl_3$); IR (KBr) 1790, 1775, 1700, 1246, 1211, and 1132 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=1.33 (3H d, *J*=5 Hz, CH_3 of ethylidene), 2.73 (1H m, H-2), 3.67 (6H s, 2×OCH_3), 4.31 (3H s, OCH_3), 5.62 and 5.86 (1H each s, methylene), 6.24 (1H s, H-5), 6.29 (2H s, H-2′ and 6′) and 7.2—7.5 (10 H m, 2×Ph); MS (FAB) *m/z* 984 (M^+ +Na), 828, and 547.

1-O-β-(2-Amino-2-deoxy-4,6-O-ethylidene-β-D-glucopyranosyl)-8-O-methyl-α-peltatin (20). A solution of **19** (40 mg) in a mixture of dichloromethane (2 ml) and pyridine (1 ml) was stirred in the presence of ethylenediamine (30 μl) at 0 °C for 2 h. The mixture was diluted with chloroform (5 ml), and the solution was washed with 5% aqueous $KHSO_4$ solution and water. The chloroform layer was dried over Na_2SO_4, and filtered. The solvent was evaporated to give a crude solid (40 mg). The solid was dissolved in ethyl acetate–ethanol (3:2, 2 ml), and the solution was stirred under atmosphere of hydrogen in the presence of 10% Pd/C (10 mg)

at room temperature for 1 h. After removal of catalyst, the solvent was evaporated to afford a solid, which was subjected to preparative thin-layer chromatography on silica gel developed with chloroform–methanol (9 : 1). Compound **20** was obtained as a solid in a yield of 66%. The solid was recrystallized from methanol: mp 215—220 °C (decomp); $[\alpha]_D^{20}$ −82° (*c* 0.84, $CHCl_3$); IR (KBr) 1778, 1615, 1480, and 1100 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.38 (3H d, *J*=5 Hz, CH_3 of ethylidene), 2.61 (1H dd, *J*=8 and 10 Hz, H-2″), 2.74 (1H m, H-2), 3.22 (1H dd, *J*=5.5 and 14 Hz, H-3), 3.77 (6H s, 2×OCH_3), 4.13 (3H s, OCH_3), 4.16 (1H dd, *J*=8 and 9 Hz, H-11), 4.45 (1H dd, *J*=9 and 11 Hz, H-11), 4.58 (1H d, *J*=5.5 Hz, H-4), 4.75 (1H d, *J*=8 Hz, H-1″), 4.75 (1H q, *J*=5 Hz, CH of ethylidene), 5.14 (1H d, *J*=3.5 Hz, H-1), 5.94 and 5.96 (2H, ABq, *J*=1.5 Hz, methylene), and 6.26 (3H s, H-5, 2′ and 6′); MS (FAB) *m/z* 618 (M^+ +H) and 413.

(Received October 12, 1987)

Heat-stable enterotoxins, produced by various enteric bacteria such as enterotoxigenic *Escherichia coli*, *Yersinia enterocolitica*, and *Vibrio cholerae* non-01, have common segments consisting of 13 amino acid residues (T. Takao et al., *FEBS Lett.*, **193**, 250 (1985)). These segments have full enterotoxigenic activity and are bound by three intramolecular disulfide bonds. The linkages of these three disulfide bonds in a heat-stable enterotoxin (ST_p) produced by a porcine strain of enterotoxigenic *E. coli* were determined to be

Cys-Cys-Glu-Leu-Cys-Cys-Asn-Pro-Ala-Cys-Ala-Gly-Cys

by stepwise and selective formation of disulfide bonds using different types of removable protecting groups for Cys residues. These disulfide linkages were identical with those of a heat-stable enterotoxin (ST_h) produced by a human strain of enterotoxigenic *E. coli* (Y. Shimonishi et al., *FEBS Lett.*, **215**, 165 (1987)).

Pathogenic enteric bacteria such as enterotoxigenic *Escherichia coli, Yersinia enterocolitica,* and *Vibrio cholerae* non-01 produce heat-stable enterotoxins (STs), which cause acute diarrhea in children in developing countries in the tropics. We and others purified STs to homogeneity from the culture supernatants of these pathogenic enteric bacteria and determined their primary structures,[1-5] as shown in Fig. 1. On the basis of chemical syntheses of various analogues of the STs and measurements of their toxicities, we found that a segment with 13 amino acid residues containing 6 half-cystines (Fig. 1) has the full enterotoxigenic activity of STs.[6] On the other hand, reduction of the three disulfide linkages of the STs resulted in loss of their enterotoxigenic activities. These results indicated that the structural element(s) required for the toxicities of STs is located on the three dimensional structure formed by the three disulfide bonds in the segment with 13 amino acid residues. Recently, we determined that the disulfide bonds of an ST (ST_h) produced by a human strain of enterotoxigenic *E. coli*[7] were as shown in Fig. 7. We also found that these disulfide bonds in ST_h were very important for its toxicity. This observation prompted us to examine whether other STs have the same disulfide linkages as those in ST_h and to investigate the effect of amino acid substitution on the mode of disulfide bond formation or construction of the three dimensional structure and toxicity of ST_h.

In this work, we examined the mode of disulfide bond formation in an ST (ST_p) produced by a porcine strain of enterotoxigenic *E. coli*, in which the primary structure in the common 13 amino acid residues differs from that of ST_h only at position 15. The mode of three disulfide bond formation in ST_p was the same as that in ST_h of a human strain of enterotoxigenic *E. coli*, indicating that other STs produced by enteric bacteria have the same mode of disulfide bond formation.

Experimental

The general and analytical methods used were as described previously.[6] All chemicals used for synthetic experiments were of reagent grade, while those used for analysis were of guaranteed grade and solvents were distilled before use. All amino acids except glycine were of the L-configuration and Boc-amino acid derivatives were purchased from the Peptide Institute Inc. (Minoh, Osaka). A reversed-phase resin (YMC-ODS,s-5) was purchased from Yamamura Chemical Laboratories Co. (Kyoto) and packed into a column of 8×300 mm

| | | |

for analytical and preparative purposes in our laboratory. The abbreviations used in this paper are those recommended by the IUPAC-IUB [*J. Biol. Chem.*, **261**, 1 (1986)]. Additional abbreviations are: Acm, acetamidomethyl; HONSu, *N*-hydroxysuccinimide; DMF, *N,N*-dimethylformamide; MBzl, *p*-methylbenzyl; TFA, trifluoroacetic acid; TEA, triethylamine; DMSO, dimethyl sulfoxide.

General Procedures for Peptide Synthesis in Solution. As a typical procedure the coupling of compound **4** with compound **8** to give compound **9** is described as follows : Compound **4** (1.6 g, 0.75 mmol) was stirred with TFA (10 ml) at room temperature for 30 min and concentrated to a syrup. Meanwhile, compound **8** (0.82 g, 0.85 mmol) was dissolved in DMF (5 ml), cooled below −20 °C, and mixed with 6.72 M HCl (1M=1 mol dm^{-3}) in dioxane (0.88 ml) and isopentyl nitrite (0.13 ml). The solution was stirred at −20 °C for 25 min and mixed with a solution of the above syrup in DMF (10 ml) and TEA (0.94 ml). The mixture was further stirred at 0 °C for 1 day. The precipitate formed in the reaction mixture was separated by filtration and the filtrate was concentrated to a syrup under reduced pressure. The syrup was triturated to a solid in chilled 0.1M HCl. The recrystallization of the solid from EtOH gave **9** (1.40 g).

The deprotection of Z groups, hydrazinolysis of peptide esters, and formation of peptide bonds by an active ester method were carried out as described previously.[6]

Solid-Phase Peptide Synthesis. Peptide synthesis by the solid-phase method[9] was performed as described in a previous paper.[7]

Removal of Protecting Groups by HF and Oxidation by Iodine. The protected peptides (25 μmol each) were treated with anhydrous liquid hydrogen fluoride[10] and air-oxidized as described previously.[6c] The solutions containing the air-oxidized peptides were partially concentrated by lyophilization and purified by HPLC, as described below. The purified peptides with an intramolecular disulfide bond(s) and Acm groups were oxidized by iodine at a peptide-to-iodine molar ratio of 1 : 40 in a mixture of MeOH and 0.1 M HCl as described in a previous paper.[7] The iodine-oxidized peptides were directly purified by HPLC, as described below.

High-Performance Liquid Chromatography (HPLC). The HPLC apparatus consisted of a Waters M600 multisolvent delivery system (Milford, MA) connected with a Hitachi UV 655A variable wavelength UV monitor and D-2000 chromato-integrator (Tokyo, Japan). The HPLC column was equilibrated with 10% CH_3CN in 0.05% TFA or 0.01M ammonium acetate (pH 5.7) and after injection of the sample solution, was developed with a linear-gradient of 10—40% CH_3CN with increase in CH_3CN of 0.5 or 1% min^{-1} at a flow rate of 2 ml min^{-1}. Eluates were monitored for absorption at 220 nm.

Amino Acid Analysis and Fast Atom Bombardment (FAB) Mass Spectrometry. The amino acid compositions and molecular weights of purified peptides were determined as described previously.[3]

Biological Assay. Toxicity of synthetic peptides was assayed in suckling mice of 2 days old (1.7±0.1 g) as described previously.[11]

Results and Discussion

Previously,[7] to determine the mode of disulfide bond formation in ST_h (Fig. 7) we adopted a synthetic procedure in which disulfide bonds in ST_h were formed stepwise and selectively using different types of removable protecting groups for Cys residues. We found that this synthetic procedure was suitable for determination of disulfide bond formation in ST_h. Therefore, in the present work we applied this procedure for determination of the positions of disulfide linkages in ST_p.

The three disulfide linkages in ST_h between Cys^6 and Cys^{11}, Cys^7 and Cys^{15}, and Cys^{10} and Cys^{18}, are shown in Fig. 7. These disulfide linkages were expected to be similar in ST_p, because the 13 amino acid sequence including 6 half Cys residues in ST_p differs only at Ala at the fourth position from the C-terminus from that in ST_h and has almost the same biological activity as the corresponding ST_h peptide. Accordingly, we synthesized three kinds of protected linear peptides with the segment from Cys^5 to Cys^{17} of ST_p with two Cys residues at Cys^5 and Cys^{10} or Cys^6 and Cys^{14} or Cys^9 and Cys^{17} protected by an Acm group and the other four Cys residues protected by an MBzl group, which correspond to the sequence from Cys^6 to Cys^{18} in ST_h, as shown in Figs. 2—4. Table 1 summarizes data on protected peptides **1**—**21**. The protected linear peptides thus obtained were treated with liquid

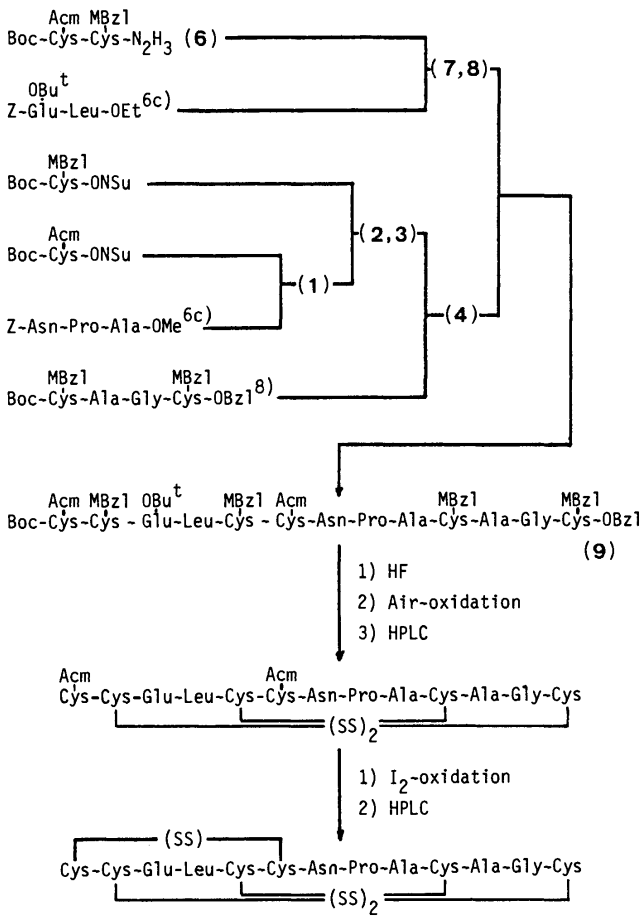

Fig. 2. Scheme for synthesis of a shorter peptide of ST_p linked by a disulfide bond between Cys^5 and Cys^{10}.

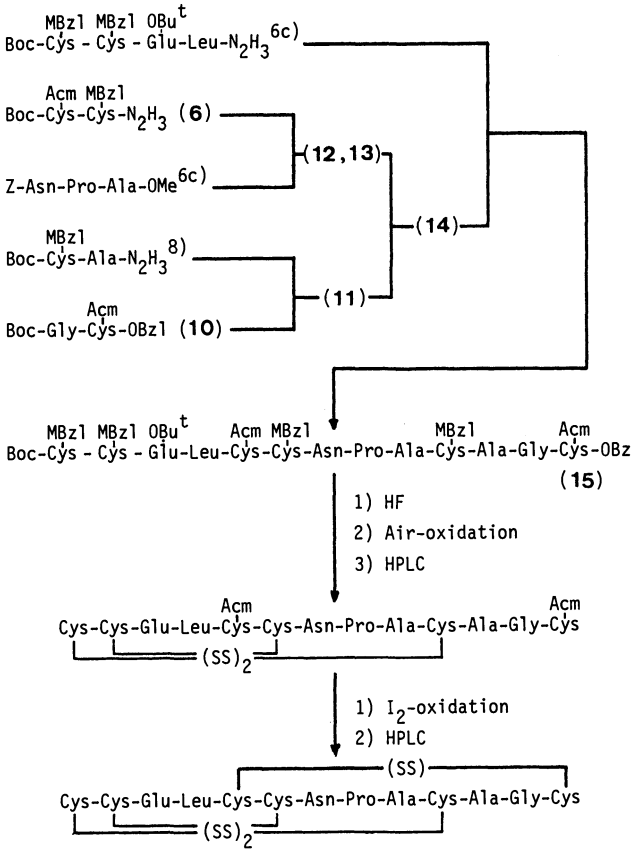

Fig. 3. Scheme for synthesis of a shorter peptide of ST_p linked by a disulfide bond between Cys^9 and Cys^{17}.

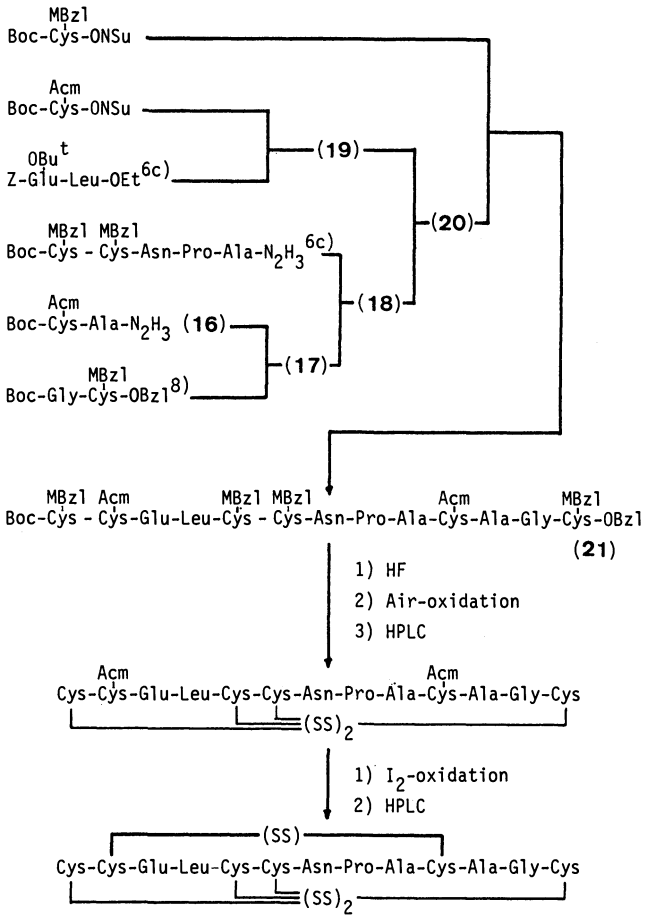

Fig. 4. Scheme for synthesis of a shorter peptide of ST_p linked by a disulfide bond between Cys^6 and Cys^{14}.

anhydrous hydrogen fluoride to remove all the protecting groups except Acm groups and air-oxidized to form intramolecular disulfide bonds between the four Cys residues, which had been protected by MBzl groups. The air-oxidized products were purified by HPLC on a reversed-phase column, as shown in Figs. 5a—5c. On the bases of amino acid and molecular weight analyses of the separated fractions, peptides with two disulfide bonds were concluded to be eluted in the peak fractions shown by asterisks (*) in Figs. 5a—5c. The yields of these peptides, for example those in Fig. 5a, were 14, 20, and 16% in order of their elution on the basis of the protected linear peptide. In this treatment, three kinds of peptides with two intramolecular disulfide bonds should theoretically be obtained. Figure 6 illustrates the HPLC profile of peak *2 in Fig. 5a, which was reduced by dithiothreitol and reoxidized spontaneously in air. Three peptide fractions were obtained similarly to those shown in Fig. 5a except for their peak ratios. However, peptides with a disulfide bond between two vicinal Cys residues were presumably formed with difficulty. In fact, when two disulfide bonds were formed in peptides **15** and **21**, only two of three possible peptides could be isolated by HPLC, as shown in Figs. 5b and 5c. The amino acid compositions, mass values, and biological activities of these peptides with two disulfide bonds are summarized in Table 2.

Then, these monomeric peptides with two disulfide bonds were selectively oxidized by iodine to form a third disulfide linkage at the two Cys residues that had been protected by Acm groups. The peptides with three disulfide linkages were separated and compared by HPLC with standard ST_p peptide, which consists of 13 amino acid residues including 6 Cys residues and has the same disulfide bond formation as native ST_p.[6b] Selective formation of a third disulfide bond between Cys^5 and Cys^{10} or Cys^9 and Cys^{17} in peptides *1 and *5 in Figs. 5a and 5b, respectively, yielded peptides that were identical with standard ST_p peptide on HPLC, as shown by arrows in Figs. 5e and 5f. Peptides *2, *3, and *4 in Figs. 5a and 5b, respectively, did not yield a peptide that was identical with standard ST_p peptide. The results indicated that the disulfide bonds in ST_p were linked between Cys^5 and Cys^{10} and Cys^9 and Cys^{17}, and therefore that the remaining disulfide bond should be between Cys^6 and Cys^{14}. However, when the third disulfide bond was linked between Cys^6

and Cys^{14} in two peptides *6 and *7 prepared from peptide **21** (Fig. 5c), no peptide was detected with the same retention time on HPLC as standard ST_p peptide. Figure 5g shows an HPLC profile of the peptide which was prepared by reaction of peptide *7 with iodine. Then, the three disulfide bonds were linked in reverse order; that is, we synthesized a protected linear peptide with two Cys residues at Cys^6 and Cys^{14} protected by an MBzl group and the remaining four Cys residues protected by an Acm group by a solid-phase procedure. The first disulfide bond was formed between Cys^6 and Cys^{14}, and then the second and third disulfide bonds were formed between the remaining four Cys residues, as shown in Figs. 5d and 5h, respectively. When the peak fraction indicated by an asterisk in Fig. 5d was oxidized by iodine, the peak fraction *16 shown by an arrow in Fig. 5h was eluted in the same position as standard ST_p peptide by HPLC. The amino acid compositions and mass values of the peptides in the peak fractions shown by asterisks in Figs. 5e—5h are summarized in Table 3. The peptides eluted by HPLC in the same position as standard ST_p peptide shown in Figs. 5e, 5f, and 5h showed toxicities at doses of 0.8—1.0 ng/mouse, which were almost the same as that of standard ST_p peptide (0.7 ng), as described in Table 3. Thus, we concluded that the three intramolecular disulfide bonds of ST_p were between Cys^5 and Cys^{10}, Cys^6 and Cys^{14}, and Cys^9 and Cys^{17}, as shown in Fig. 7. Other disulfide bond linkages except those described above were not examined, because the positions of the disulfide bonds of ST_p determined above were the same as those of ST_h.[7]

When a third disulfide bond was linked between Cys^5 and Cys^{10} and Cys^9 and Cys^{17} in peptides *1 and *5 in Figs. 5a and 5b, respectively, they gave two peak fractions on HPLC, as shown in Figs. 5e and 5f, respectively. On HPLC one of them was eluted at the same position as standard ST_p peptide, while the other was eluted earlier. When a third disulfide bond was linked between Cys^6 and Cys^{14} in peptide *7 in Fig. 5c, interestingly it gave only a peak fraction with the same retention time as peaks *9 and *11 in Figs. 5e and 5f, respectively. Moreover, these two peak fractions showed different circular dichroism spectra from each other in the range from 190 nm to 260 nm (not shown). These two peptides were not interconvertible, but stable on storage for a long time in a refrigerator. These findings suggested that two topologically stable and different conformers are present in peptides with the same three disulfide linkages and also that only one or both the two conformers are produced dependent upon the order of disulfide bond formation.

While peptide *1 was eluted as a single peak under the conditions for Fig. 5a, it was separated into two broad peak fractions on HPLC under different conditions from that in Fig. 5a, as depicted in Fig. 8. Each fraction showed the same profile on repeated HPLC as that before separation (not shown). Peptides in the

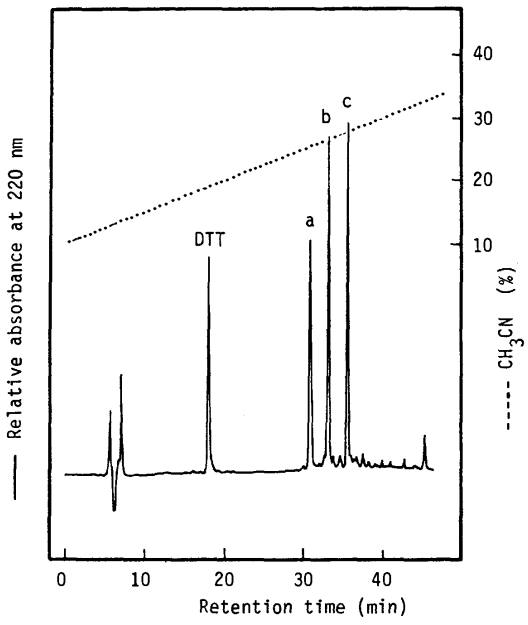

Fig. 6. HPLC profile of peptide *2 in Fig. 5a, which was reduced and reoxidized by air. Peaks a, b, and c had the same retention times as those of peaks *1, *2, and *3 in Fig. 5a, respectively.

two peak fractions 1 and 2 shown in Fig. 8 were oxidized by iodine immediately after their elution from an HPLC column. The peptide in the first fraction gave two peaks like that shown in Fig. 9a, one of which was identical with standard ST_p peptide, whereas the peptide in the second fraction gave only a peptide that was not identical with standard ST_p peptide, as shown in Figs. 9b and 9c, respectively. These findings suggested that peptide *1 consisted of two components, which were rapidly interconvertible and therefore were in equilibrium. These peptides are presumed to be two conformers with cis and trans configurations around the peptide bond between Asn^{11} and Pro^{12}, one of them corresponding to a peptide in the first fraction, and the other to a peptide in the second fraction in Fig. 8. One of the two conformers yielded two peptides, and the other only one peptide, when they were oxidized by iodine. Since peptide *5 gave two peak fractions on treatment with iodine (Fig. 5f), it was considered to consist of two components like peptide *1. However, peptide *5 could not be separated by HPLC under the same conditions as for peptide *1 in Fig. 8. The two conformers in peptide *1 might have dissimilar physicochemical properties and those in peptide *5 similar properties, or they might be rapidly equilibrated, because on reversed-phase HPLC peptide *1 could be separated but peptide *5 could not be separated.

Houghten et al.[12] proposed the mode of disulfide bond formation of ST_p from an experiment on the reoxidation kinetics of ST_p, which they synthesized according to the amino acid sequence proposed previously,[13] although the amino acid sequence was later revised to the sequence shown in Fig. 1.[2] The pro-

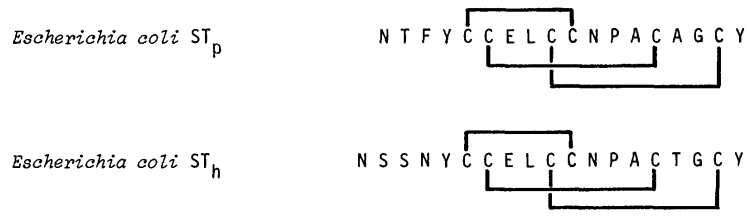

Fig. 7. Modes of three disulfide linkages of heat-stable enterotoxins (ST_p and ST_h[7]) of porcine and human strains, respectively, of enterotoxigenic *E. coli*.

posed disulfide bonds were between Cys^5 and Cys^{14}, Cys^6 and Cys^{10}, and Cys^9 and Cys^{17}. This disulfide bond formation is not consistent with that determined in this work. That is, the partners of Cys^5 and Cys^6 in disulfide bond formation are reversed. These mismatched pairings of disulfide linkages might be because they used a peptide with a different amino acid sequence from that shown in Fig. 1. If they had used a peptide with the correct amino acid sequence, they might have obtained the same results as ours.

Recently, we determined the mode of disulfide bond formation of ST_h produced by a human strain of enterotoxigenic *E. coli*, as shown in Fig. 7, and also of ST produced by *Vibrio-mimicus*.[5] The positions of the disulfide linkages were identical with those of ST_p examined in this work. These results imply that the three dimensional structure in the common 13 amino acid region as shown in Fig. 1 is very similar in all ST's examined to date. Further elucidation of this spatial structure should be useful in understanding the structure-activity relation of ST and its mechanism of binding to receptor proteins on the membranes of

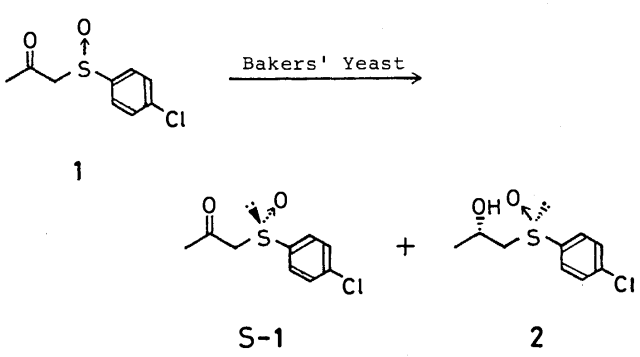
A General Method for the Synthesis of Both Enantiomers of Optically Pure β-Hydroxy Esters from (*S*)-(*p*-Chlorophenylsulfinyl)acetone Easily Obtainable by Kinetic Resolution with Bakers' Yeast

Tamotsu FUJISAWA,* Atsushi FUJIMURA, and Toshio SATO
Chemistry Department of Resources, Mie University, Tsu, Mie 514
(Received October 15, 1987)

Both enantiomers of various optically pure (*R*)- and (*S*)-β-hydroxy esters were generally synthesized from (*S*)-(*p*-chlorophenylsulfinyl)acetone obtained by kinetic resolution with bakers' yeast, followed by γ-alkylation, diastereoselective reduction, subsequent introduction of ester group and reductive elimination of the sulfinyl group. The key step of the diastereoselective reduction of (*S*)-β-keto sulfoxides was performed with diisobutylaluminum hydride to give (*R*)c-(*S*)s-β-hydroxy sulfoxides or after complexation with zinc chloride followed by addition of diisobutylaluminum hydride to give (*S*)c-(*S*)s-β-hydroxy sulfoxides which were easily separated in an optically pure form by easy crystallization or separation by silica-gel chromatography due to the *p*-chlorophenyl moiety in the β-hydroxy sulfoxides. The utility of the present method could be successfully demonstrated in the synthesis of both (+)- and (−)-corynomycolic acids from optically pure methyl esters of (*R*)- and (*S*)-3-hydroxyoctadecanoic acid by alkylation with tetradecyl iodide at α-position and hydrolysis.

Optically active β-hydroxy esters are well-known as important intermediates for the synthesis of various natural products. They are prepared by a number of procedures; for example, asymmetric aldol reaction[1] by use of chiral α-sulfinyl esters,[2] lithium enolates,[3] zirconium enolates,[4] boron enolates,[5] tin enolates, and chiral diamines,[6] the Reformatsky reaction using sparteine,[7] regioselective epoxide ring opening,[8] cleavage of oxetanones,[9] and asymmetric reduction of β-keto ester with bakers' yeast.[10] Most of them give optically active β-hydroxy esters in high yields with very high optical purity, but they can not give both of the enantiomers from the same starting material. We report here a general method for the synthesis of both enantiomers of optically pure β-hydroxy ester **6** starting from (*S*)-(*p*-chlorophenylsulfinyl)acetone (**S-1**), which is easily obtainable by kinetic resolution of the corresponding racemic sulfinylacetone **1**, followed by γ-alkylation, diastereoselective reduction, subsequent introduction of ester group, and reductive elimination of the sulfinyl group. By use of the present method, both (+)- and (−)-corynomycolic acids **10** were synthesized in optically pure state.

Recently diastereoselective reduction of chiral β-keto tolyl sulfoxides with diisobutylaluminum hydride has been reported to give both diastereomers of β-hydroxy sulfoxides.[11] In spite of many attempts, we have found that it is quite difficult to isolate each diastereomer. In the case of *p*-chlorophenyl group combined to sulfinyl group, however, each diastereomer of the corresponding β-hydroxy sulfoxide was found to be easily isolated in an optically pure state, which could apply to the synthesis of optically pure β-hydroxy esters (vide infra).



Scheme 1.

Racemic (phenylsulfinyl)acetone is known to be resolved to (*S*)-(phenylsulfinyl)acetone by bakers' yeast.[12] In the reduction of racemic (*p*-chlorophenylsulfinyl)acetone (**1**) with bakers' yeast, one enantiomer was reduced to (*S*)c-(*R*)s-2-hydroxypropyl *p*-chlorophenyl sulfoxide (**2**) and (*S*)-(*p*-chlorophenylsulfinyl)-acetone (**S-1**) remained intact. This keto sulfoxide **S-1** could be separated from the hydroxy sulfoxide by silica-gel chromatography more easily than (phenylsulfinyl)acetone is separated from the corresponding alcohol. The optically pure acetone derivative **S-1** was easily obtained by recrystallization from benzene-hexane in a yield of 38% from the racemate. Methylation at γ-position of **S-1** was carried out by use of sodium hydride and butyllithium in THF to generate the dianion, followed by addition of methyl iodide at 0 °C to yield 2-oxobutyl sulfoxide **3a**(R=CH_3) in 67% yield.[13] The β-keto sulfoxide **3a** was reduced with diisobutylaluminum hydride at −90 °C in THF to give optically active (*R*)c-(*S*)s-alcohol **4a** in 80% yield, which was easily recrystallized from benzene-hexane to give optically pure (*R*)c-(*S*)s-alcohol **4a** in 50% yield. Various β-hydroxy sulfoxides **4** were obtained by alkylation of **S-1**, with allyl bromide, benzyl bromide, benzyloxymethyl chloride, and tetradecyl iodide, respectively, followed by diastereoselective reduction with diisobutylaluminum hydride. All of these β-hydroxy sulfoxides except **4e**(R=$C_{14}H_{29}$), which was recrystallized from methanol, were recrystallized from benzene-hexane to give optically pure ones in 50—58% yields. Then carboxylation at α-position by treatment of **4a** with two

equivalents of methyllithium in THF at 0 °C to produce the dianion of **4a**, followed by pouring them into powdered Dry Ice, then esterification with diazomethane in methanol gave ester **5a**. Elimination of the sulfinyl group from **5a** by treatment with aluminum amalgam[14] in THF-water furnished optically pure methyl (*R*)-3-hydroxypentanoate (**R-6a**). Yields and values of physical properties of various optically pure methyl ester of (*R*)-β-hydroxy acids **R-6**, synthesized by the present method, were listed in Table 1.

On the other hand, when the β-keto sulfoxide **3** was reduced with diisobutylaluminum hydride in the presence of zinc chloride in THF, (*S*)c-(*S*)s-β-hydroxy sulfoxide **7** was mainly obtained. In the case of the diastereomeric mixtures of methyl- and allyl-substituted hydroxy sulfoxides **7a** and **7b**, which are oily and not crystallized, each diastereomers of them were isolated by use of silica-gel chromatography to give optically pure **7**. The (*S*)c-(*S*)s-isomers of β-hydroxy sulfoxides substituted with benzyl, and benzyloxymethyl group, **7c** and **7d**, were easily recrystallized from benzene-hexane, and substituted one with tetradecyl group **7e** was recrystallized from methanol in an optically pure state. Then introduction of ester group to prepare **8**

and elimination of the sulfinyl group in the same manner as above gave methyl esters of (*S*)-β-hydroxy acids **S-6** (Table 2).

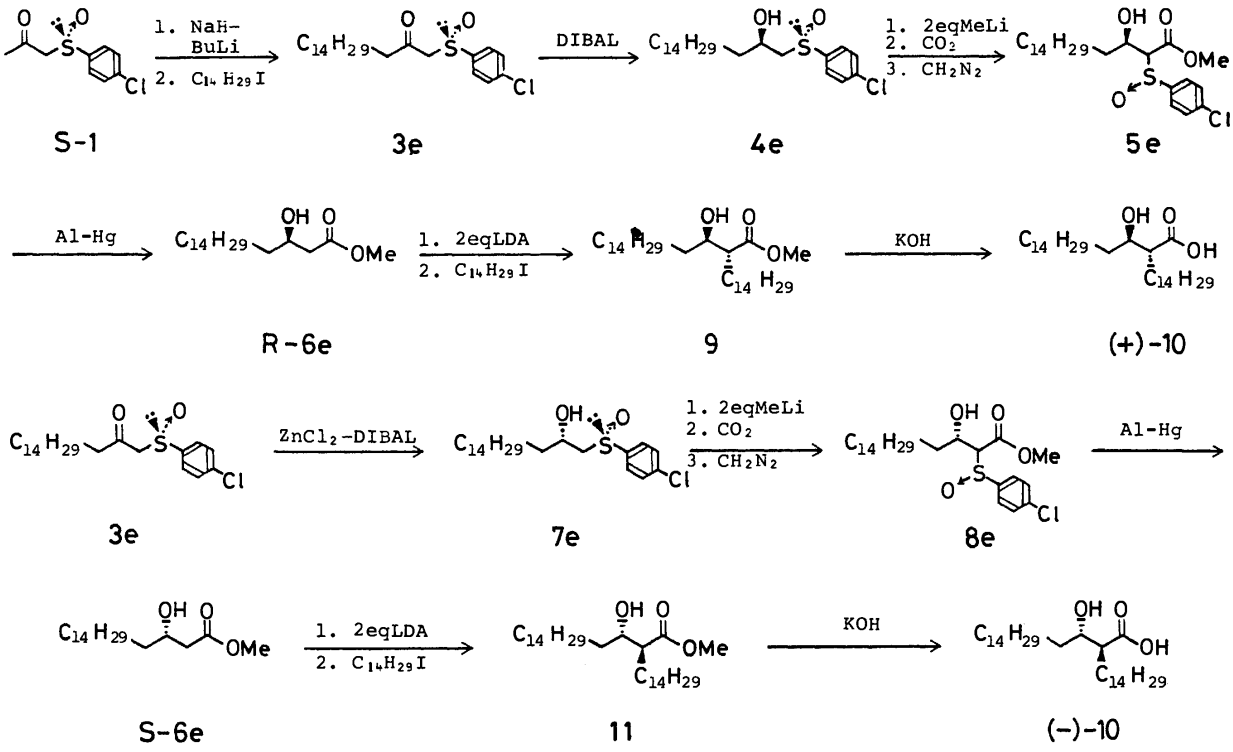
Corynomycolic acid **10** is one of the mycolic acids produced from coryne bacteria and its trehalose 6,6'-diester has various biological activities such as adjuvant, antibacterial, antitumor, and antiparasitic.[18] Optically active (+)-corynomycolic acid has been prepared in one report,[19] but (−)-comycolic acid has not been synthesized so far. The precursor of both enantiomers of corynomycolic acids is methyl 2-hydroxyoctadecanoate which can be easily prepared by the present method. Tetradecyl iodide was added to the dianion of β-keto sulfoxide **S-1** to furnish β-keto sulfoxide **3e** (R=$C_{14}H_{29}$) in 61% yield and reduction with diisobutylaluminum hydride afforded (*R*)c-(*S*)s-alcohol **4e** in 81% yield. Recrystallization from methanol gave optically pure **4e**. Subsequent carboxylation and esterification afforded ester **5e** and elimination of sulfinyl group gave methyl (*R*)-3-hydroxyoctadecanoate (**6e**). Then alkylation at α-position with tetradecyl iodide by Fráter's method[20] gave (2*R*,3*R*)-β-hydroxy ester **9** in 67% yield with (2*R*,3*R*):(2*S*,3*R*) ratio of 92:8, which was determined by HPLC of the corresponding β-benzoyloxy esters. After hydrolysis and recrystallization from methanol-hexane, optically pure (+)-corynomycolic acid (+)-**10** was obtained in 85% yield. Similarly the reduction of β-keto sulfoxide **3e** (R=$C_{14}H_{29}$) with diisobutylaluminum hydride in the presence of zinc chloride gave (*S*)c-(*S*)s-alcohol **7e** in 87% yield, and recrystallization from methanol afforded optically pure alcohol **7e**. In the same manner as above, (2*S*,3*S*)-β-hydroxy ester **11** with a (2*S*,3*S*):(2*R*,3*S*) ratio of 91:9 was hydrolyzed and recrystallized to give optically pure (−)-corynomycolic acid (−)-**10**.

In conclusion, each diastereomer of β-hydroxyalkyl *p*-chlorophenyl sulfoxides obtained by kinetic resolution of (*p*-chlorophenylsulfinyl)acetone with bakers' yeast followed by γ-alkylation and diastereoselective reduction, was easily separated to an optically pure form, and both enantiomers of optically pure (*R*)- and (*S*)-β-hydroxy esters were conveniently synthesized by using the present method.

Experimental

Melting points were uncorrected. The IR spectra were recorded on JASCO IR 810. The ^{1}H NMR spectra were recorded on JEOL JNM-PMX60si. High-pressure liquid chromatography was performed on Finepak SIL or Finepak SIL C_{18} using JASCO UVIDEC-100V. Elemental analyses were carried out by Yanaco CHN CORDER MT-3. Optical rotations were determined at ambient temperature with Union PM-101. Tetrahydrofuran (THF) was freshly distilled on sodium benzophenone ketyl.

(*S*)-(*p*-Chlorophenylsulfinyl)acetone (S-1). To a mixture of 450 ml of water and 70 g of sucrose with rapid stirring was added 45 g of bakers' yeast (Oriental Yeast Co.). After stirring for 0.5 h at ambient temperature, the solution of 4.4 g (20 mmol) of racemic (*p*-chlorophenylsulfinyl)acetone (**1**) in 40 ml of ethanol was added dropwise. After the mixture was stirred vigorously for 12 h, 200 ml of ethyl acetate was added. Stirring was continued for 0.5 h, then 40 g of celite was added, and the mixture was filtered. The solids were washed



Scheme 3.

with ethyl acetate, and the combined filtrate was extracted with ethyl acetate. The organic layer was dried with sodium sulfate and concentrated. The crude material was purified by chromatography on silica gel (eluent; ethyl acetate : hexane=1 : 3) to give 1.73 g (8.0 mmol) of **S-1** (40% yield) $[\alpha]_D^{23}$ −219 ° (*c* 1.00, MeOH). Recrystallization of **S-1** from benzene–hexane afforded 1.65 g (7.6 mmol) of optically pure **S-1** (38% yield); mp 109—110 °C; $[\alpha]_D^{23}$ −231 ° (*c* 1.16, MeOH).

General Procedure for the Preparation of (*S*)-β-Keto Sulfoxide (3).[13] To a suspension of sodium hydride (1.1 mmol) in THF (2 ml) at 0 °C was added 216 mg (1 mmol) of (*S*)-(*p*-chlorophenylsulfinyl)acetone (**S-1**) in THF (3 ml). Then 1.57 mol dm^{-3} hexane solution of butyllithium (0.7 ml) was added to the reaction mixture. After stirring for 30 min at the same temperature, alkyl halide (1.1 mmol) in THF (3 ml) was added to the reaction mixture. After stirring for 3 h at 0 °C, saturated aqueous NH_4Cl was added to the reaction mixture and extracted with ethyl acetate. The organic layer was dried over sodium sulfate and the solvent was evaporated. The crude material was purified by chromatography on silica gel (eluent; ethyl acetate : hexane=1 : 3) to give (*S*)-β-keto sulfoxide.

(*S*)-1-(*p*-Chlorophenylsulfinyl)-2-butanone (3a): 67% yield; $[\alpha]_D^{23}$ −201° (*c* 0.99, MeOH); mp 96—98 °C; IR ($CHCl_3$) 1010, 1050, 1090, 1390, 1470, 1710, and 2970 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.04 (t, *J*=7.2 Hz, 3H), 2.55 (q, *J*=7.1 Hz, 2H), 3.83 (s, 2H), and 7.55 (s, 4H). Found: C, 52.14; H, 4.80%. Calcd for $C_{10}H_{11}SO_2Cl$: C, 52.11; H, 4.77%.

(*S*)-1-(*p*-Chlorophenylsulfinyl)-5-hexen-2-one (3b): 63% yield; $[\alpha]_D^{23}$ −206° (*c* 0.34, MeOH); mp 104—105 °C; IR ($CHCl_3$) 1090, 1385, 1470, 1705, 2900, and 3000 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=2.03—2.91 (m, 4H), 3.85 (s, 2H), 4.73—5.26 (m, 2H), 5.34—6.06 (m, 1H), and 7.57 (s, 4H). Found: C, 56.33; H, 5.25%. Calcd for $C_{12}H_{13}SO_2Cl$: C, 56.20; H, 5.07%.

(*S*)-1-(*p*-Chlorophenylsulfinyl)-4-phenyl-2-butanone (3c): 52% yield; $[\alpha]_D^{23}$ −168° (*c* 1.01, $CHCl_3$); mp 119—120 °C; IR ($CHCl_3$) 1000, 1095, 1470, 1720, 2925, and 3000 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.84(s, 4H), 3.78(s, 2H), and 6.81—7.80(m, 9H). Found: C, 62.60; H, 5.17%. Calcd for $C_{16}H_{15}SO_2Cl$: C, 62.68; H, 4.89%.

(*S*)-1-(*p*-Chlorophenylsulfinyl)-4-benzyloxy-2-butanone (3d): 54% yield; $[\alpha]_D^{23}$ −111° (*c* 1.08, $CHCl_3$); mp 56—58 °C; IR ($CHCl_3$) 1005, 1025, 1050, 1090, 1360, 1390, 1480, 1700, 2900, 3025, and 3050 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.72 (t, *J*=6.0 Hz, 2H), 3.71(t, *J*=5.9 Hz, 2H), 3.84(s, 2H), 4.45(s, 2H), 7.11(s, 5H), and 7.71(s, 4H). Found: C, 60.98; H, 5.17%. Calcd for $C_{17}H_{17}SO_3Cl$: C, 60.68; H, 5.05%.

(*S*)-1-(*p*-Chlorophenylsulfinyl)-2-heptadecanone (3e): 61% yield; $[\alpha]_D^{23}$ −121° (*c* 1.04, $CHCl_3$); mp 95—97°C; IR ($CHCl_3$) 1005, 1040, 1705, 2850, and 2950 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.61—1.90 (m, 29H), 2.47 (t, *J*=6.0 Hz, 2H), 3.80 (s, 2H), and 7.25—7.81 (m, 4H). Found: C, 66.90; H, 9.10%. Calcd for $C_{23}H_{37}SO_2Cl$: C, 66.98; H, 8.98%.

General Procedure for the Preparation of (*R*)c-(*S*)s-β-Hydroxy Sulfoxides 4. To a solution of (*S*)-β-keto sulfoxide **3** (1 mmol) in THF (4 ml) was dropwise added 1.4 ml of a 1.5 mol dm^{-3} solution of diisobutylaluminum hydride in hexane at −90 °C. After stirring for 5 h at −90 °C, 2 mol dm^{-3} HCl solution (3 ml) was added to the reaction mixture and the products were extracted with ethyl acetate. The organic layer was dried over sodium sulfate and the solvent was evaporated. The crude material was purified by chromatography on silica gel (eluent; CH_2Cl_2) to give (*R*)c-(*S*)s-β-hydroxy sulfoxide **4**. The yields, the diastereomeric ratios and the yields of optically pure **4** recrystallized from benzene–hexane were listed in Table 1.

(2*R*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-2-butanol (4a): $[\alpha]_D^{23}$ −233° (*c* 1.02, MeOH); mp 96—98 °C; IR ($CHCl_3$) 1020, 1090, 1120, 1450, 2950, 3000, and 3400 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.94 (t, *J*=6.6 Hz, 3H), 1.58 (m, 2H) 2.70 (dd, *J*=3.2, 13.2 Hz, 1H) 3.06 (dd, *J*=9.6, 13.2 Hz, 1H), 3.79—4.40 (m, 2H), and 7.62(s, 4H). Found: C, 51.43; H, 5.56%. Calcd for $C_{10}H_{13}SO_2Cl$: C, 51.66; H, 5.59%.

(2*R*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-5-hexen-2-ol (4b): $[\alpha]_D^{23}$ −237° (*c* 1.03, MeOH); mp 77—79 °C; IR ($CHCl_3$) 1005, 1020, 1090, 1475, 2950, and 3350 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.38—1.87 (m, 2H), 1.95—2.47 (m, 2H), 2.80 (dd, *J*=4.0, 13.4 Hz, 1H), 3.04 (dd, *J*=8.4, 13.4 Hz, 1H), 4.26 (m, 2H), 4.77—5.28 (m, 2H), 5.46—6.26 (m, 1H), and 7.64 (s, 4H). Found: C, 55.67; H, 6.04%. Calcd for $C_{12}H_{15}SO_2Cl$: C, 55.77; H, 5.80%.

(2*R*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-4-phenyl-2-butanol (4c): $[\alpha]_D^{23}$ −192° (*c* 1.02, MeOH); mp 69—71 °C; IR ($CHCl_3$) 1005, 1040, 1090, 1260, 1390, 1450, 1480, 2900, 3000, and 3400 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.92 (t, *J*=6.0 Hz, 2H), 2.49—3.18 (m, 4H), 3.94—4.45 (m, 2H), and 7.19 (s, 5H), 7.44 (s, 4H). Found: C, 62.51; H, 5.71%. Calcd for $C_{16}H_{17}SO_2Cl$: C, 62.28; H, 5.51%.

(2*R*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-4-benzyloxy-2-butanol (4d): $[\alpha]_D^{23}$ −174° (*c* 0.92, MeOH); mp 74—75 °C; IR ($CHCl_3$) 1000, 1090, 1470, 2850, 3000, and 3450 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.9 (t, *J*=6.0 Hz, 2H), 2.76 (dd, *J*=3.6, 13.6 Hz, 1H), 3.07 (dd, *J*=7.2, 13.6 Hz, 1H), 3.65 (t, *J*=5.7 Hz, 2H), 4.16—4.70 (m, 2H), 4.53 (s, 2H), 7.08 (s, 5H), and 7.73 (s, 4H). Found: C, 60.40; H, 5.57%. Calcd for $C_{17}H_{19}SO_3Cl$: C, 60.32; 5.61%.

(2*R*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-2-heptadecanol (4e): $[\alpha]_D^{23}$ −146° (*c* 0.52, MeOH); mp 76—77 °C; IR ($CHCl_3$) 1000, 1040, 1095, 1390, 1460, 2850, 2900, and 3400 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.65—1.80 (m, 31H), 2.70 (dd, *J*=3.2, 13.6 Hz, 1H), 3.03 (dd, *J*=8.8, 13.6 Hz, 1H), 3.94—4.50 (m, 2H), and 7.73 (s, 4H). Found: C, 66.70; H, 9.54%. Calcd for $C_{23}H_{39}SO_2Cl$: C, 66.66; H, 9.41%.

General Procedure for the Preparation of (*S*)c-(*S*)s-β-Hydroxy Sulfoxides 7.[11] To a suspension of anhydrous zinc chloride (1.1 mmol) in THF (2 ml) was added (*S*)-β-keto sulfoxide **3** (1 mmol) in THF (4 ml). After stirring for 30 min at room temperature, the reaction mixture was cooled to −90 °C, and 1.4 ml of 1.5 mol dm^{-3} solution of diisobutylaluminum hydride in hexane was added. After stirring for 5 h at −90 °C, the reaction mixture was treated with 2 mol dm^{-3} HCl solution and extracted with ethyl acetate. The organic layer was dried with sodium sulfate and the solvent was evaporated. The crude material was purified by chromatography on silica gel (eluent; CH_2Cl_2) to give (*S*)c-(*S*)s-β-hydroxy sulfoxide. The yields, the diastereomeric ratio and the yields of optically pure **7** were listed in Table 2.

(2*S*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-2-butanol (7a): $[\alpha]_D^{23}$ −137° (*c* 0.87, MeOH); IR (neat) 1020, 1090, 1120, 1450, 2950, 3000, and 3400 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.96 (t, 7.4 Hz, 3H), 1.72 (m, *J*=7.4 Hz, 2H), 2.77 (dd, *J*=4.0, 12.8 Hz, 1H), 3.10 (dd, *J*=8.0, 12.8 Hz, 1H), 3.58—4.39 (m, 2H), and 7.63 (s, 4H). Found: C, 51.37; H, 5.59%. Calcd for $C_{10}H_{13}SO_2Cl$: C, 51.66; H, 5.59%.

(2*S*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-5-hexene-2-ol (7b): $[\alpha]_D^{23}$ −135° (*c* 1.03, MeOH); IR (neat) 1005, 1070, 1090, 1475, 2950, and 3350 cm^{-1}: ^{1}H NMR ($CDCl_3$) δ=1.23—1.92 (m,

2H), 1.92—2.44 (m, 2H), 2.78 (dd, J=4, 12.6 Hz, 1H), 3.02 (dd, J=7.6, 12.6 Hz, 1H), 3.80—4.51 (m, 2H), 4.79—5.28 (m, 2H), 5.46—6.19 (m, 1H), and 7.63 (s, 4H). Found: C, 55.69; H, 5.70%. Calcd for $C_{12}H_{15}SO_2Cl$: C, 55.77; H, 5.80%.

(2*S*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-4-phenyl-2-butanol (7c): $[\alpha]_D^{23}$ −91.0° (*c* 1.01, MeOH); mp 59—61 °C; IR ($CHCl_3$) 1005, 1040, 1090, 1260, 1390, 1450, 1480, 2900, 3000, and 3400 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.93 (t, J=6.1 Hz, 2H), 2.56—3.11 (m, 3H), 3.67 (s, 1H), 4.08—4.49 (m, 2H), 7.23 (s, 5H), and 7.53 (s, 4H). Found: C, 62.42; H, 5.41%. Calcd for $C_{16}H_{17}SO_2Cl$: C, 62.28; H, 5.51%.

(2*S*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-4-benzyloxy-2-butanol (7d): $[\alpha]_D^{23}$ −73.6° (*c* 1.02, MeOH); mp 66—67 °C; IR ($CHCl_3$) 1000, 1090, 1470, 2850, 3000, and 3450 cm^{-1}, ^1H NMR ($CDCl_3$) δ=1.83 (t, J=5.6 Hz, 2H), 2.83 (dd, J=4.8, 13.2 Hz, 1H), 3.14 (dd, J=7.2, 13.2 Hz, 1H), 3.65 (t, J=5.4 Hz, 2H), 3.90—4.60 (m, 2H), 4.46 (s, 2H), 7.10 (s, 5H), and 7.53 (s, 4H). Found: C, 60.59; H, 5.45%. Calcd for $C_{17}H_{19}SO_3Cl$: C, 60.32; H, 5.61%.

(2*S*)-1-[(*S*)-*p*-Chlorophenylsulfinyl]-2-heptadecanol (7e): $[\alpha]_D^{23}$ −71.7° (*c* 0.51, MeOH); mp 84—85 °C; IR ($CHCl_3$) 1000, 1040, 1095, 1390, 1460, 2850, 2900, and 3400 cm^{-1}, ^1H NMR ($CDCl_3$) δ=0.67—1.79 (m, 31H), 2.77 (dd, J=3.6, 12.8 Hz, 1H), 3.03 (dd, J=7.6, 12.8 Hz, 1H), 3.94—4.58 (m, 2H), and 7.75 (s, 4H). Found: C, 66.48; H, 9.59%. Calcd for $C_{23}H_{39}SO_2Cl$: C, 66.66; H, 9.41%.

General Procedure for the Preparation of Esters. To a solution of β-hydroxy sulfoxide **4** or **7** (1 mmol) in THF (2 ml) at −5 °C was added 1.48 ml (2 mmol) of a 1.35 mol dm^{-3} solution of methyllithium in ether. After stirring for 1 h at 0 °C, the reaction mixture was cooled to −70 °C, then poured onto 20 g of powdered Dry Ice, and shaken for 15 min. The reaction mixture was acidified with 5 ml of 2 mol dm^{-3} HCl solution and extracted with ethyl acetate. The organic layer was dried over sodium sulfate and the solvent was evaporated. The residue was dissolved in 5 ml of methanol and 0.3 mol dm^{-3} diazomethane solution in ether was added until the yellow color of the solution did not fade. After removal of the solvent, the crude material was purified by chromatography on silica gel (eluent; ethyl acetate : hexane=1 : 2) to give 3-hydroxy-2-sulfinyl ester **5** or **8**.

Methyl (3*R*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxypentanoate (5a): 50% yield; $[\alpha]_D^{23}$ −180.9° (*c* 1.06, MeOH); mp 110—111 °C; IR ($CHCl_3$) 1040, 1090, 1380, 1450, 1740, 2950, 2975, and 3300 cm^{-1}: ^1H NMR ($CDCl_3$) δ=0.73—1.23 (m, 3H), 1.25—2.67 (m, 2H), 3.23—4.03 (m, 5H), 4.29 (s. 1H), and 7.64 (m, 4H). Found: C, 49.64; H, 5.24%. Calcd for $C_{12}H_{15}SO_4Cl$: C, 49.62; H, 5.16%.

Methyl (3*R*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxy-6-heptenoate (5b): 68% yield; $[\alpha]_D^{23}$ −134° (*c* 1.26, MeOH); mp 85—87 °C; IR ($CHCl_3$) 1010, 1090, 1300, 1730, 2950, and 3400 cm^{-1}: ^1H NMR ($CDCl_3$) δ=1.34—1.91 (m, 2H), 2.01—2.56 (m, 2H), 3.29—3.87 (m, 4H), 4.28 (s, 2H), 4.76—5.40 (m, 2H), 5.44—6.26 (m, 1H), and 7.04—7.94 (m, 4H). Found: C, 52.96; H, 5.54%. Calcd for $C_{14}H_{17}SO_4Cl$: C, 53.13; H, 5.37%.

Methyl (3*R*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxy-5-phenylpentanoate (5c): 70% yield; $[\alpha]_D^{23}$ −119 ° (*c* 1.15, MeOH); mp 82—83 °C; IR ($CHCl_3$) 1010, 1090, 1300, 1350, 1730, 2850, 2940, and 3450^{-1}; ^1H NMR ($CDCl_3$) δ=1.67—2.17 (m, 2H), 2.58—3.07 (m, 2H), 3.16—4.43 (m, 6H), 7.20 (s, 5H), and 7.50 (s, 4H). Found: C, 59.22; H, 5.28%. Calcd for $C_{18}H_{19}SO_4Cl$: C, 58.98; H, 5.18%.

Methyl (3*R*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxy-5-(benzyloxy)pentanoate (5d): 69% yield; $[\alpha]_D^{23}$ −98° (*c* 1.16, MeOH); mp 82—84 °C; IR ($CHCl_3$) 1005, 1095, 1485, 1730, 2350, 3000, and 3450 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.57—2.10 (m, 2H), 3.33—3.93 (m, 8H), 4.57 (s, 2H), and 7.00—7.76 (m, 9H). Found: C, 57.81; H, 5.33%. Calcd for $C_{19}H_{21}SO_5Cl$: C, 57.56; H 5.30%.

Methyl (3*R*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxyoctadecanoate (5e): 65% yield; $[\alpha]_D^{23}$ −146.7° (*c* 0.51, MeOH); mp 76—79 °C; IR ($CHCl_3$) 1095, 1310, 1460, 1718, 2850, 2950, and 3400 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.64—1.78 (m, 31H), 3.25—4.19 (m, 6H), and 7.53 (s, 4H). Found: C, 63.55; H, 8.52%. Calcd for $C_{25}H_{41}SO_4Cl$: C, 63.69; H, 8.70%.

Methyl (3*S*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxypentanoate (8a): 69% yield; $[\alpha]_D^{23}$ −164° (*c* 0.96, MeOH); mp 53—55 °C; IR ($CHCl_3$) 1040, 1090, 1380, 1450, 1740, 2950, 2975, and 3300 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.93—1.21 (m, 3H), 1.25—2.23 (m, 2H), 3.44—4.71 (m, 6H), and 7.61 (m, 4H). Found: C, 49.73; H, 5.43%. Calcd for $C_{12}H_{15}SO_4Cl$: C, 49.62; H, 5.16%.

Methyl (3*S*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxy-6-heptenoate (8b): 62% yield; $[\alpha]_D^{23}$ −102° (*c* 1.54, MeOH); mp 42—43 °C; IR ($CHCl_3$) 1010, 1090, 1300, 1730, 2950, and 3400 cm^{-1}: ^1H NMR ($CDCl_3$) δ=1.39—1.94 (m, 2H), 2.03—2.60 (m, 2H), 3.31—4.04 (m, 3H), 4.47 (s, 1H), 4.79—5.41 (m, 2H), 5.46-6.31 (m, 1H), 7.07—7.82 (m, 4H). Found: C, 53.32; H, 5.39%. Calcd for $C_{12}H_{15}SO_4Cl$: C, 53.13; H, 5.37%.

Methyl (3*S*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxy-5-phenylpentanoate (8c): 70% yield; $[\alpha]_D^{23}$ −102° (*c* 1.02, MeOH); mp 68—70 °C; IR ($CHCl_3$) 1010, 1090, 1300, 1350, 1730, 2850, 2940, and 3450 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.82—2.13 (m, 2H), 2.61—3.15 (m, 2H), 3.20—4.48 (m, 5H), 7.31 (s, 5H), and 7.61 (s, 4H). Found: C, 58.71; H, 5.35%. Calcd for $C_{18}H_{19}SO_4Cl$: C, 58.98; H, 5.18%.

Methyl (3*S*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxy-5-(benzyloxy)pentanoate (8d): 65% yield; $[\alpha]_D^{23}$ −85 ° (*c* 1.2, MeOH); mp 76—78 °C; IR ($CHCl_3$) 1005, 1095, 1485, 1730, 2350, 3000, and 3450 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.68—2.23 (m, 2H), 3.47—3.93 (m, 8H), 4.57 (s, 2H), 7.17—7.80 (m, 9H). Found: C, 57.60; H, 5.22%. Calcd for $C_{19}H_{21}SO_5Cl$: C, 57.56; H, 5.30%.

Methyl (3*S*)-2-[(*S*)-*p*-Chlorophenylsulfinyl]-3-hydroxyoctadecanoate (8e): 60% yield; $[\alpha]_D^{23}$ −83.2 ° (*c* 0.59, MeOH); mp 95—97 °C; IR ($CHCl_3$) 1095, 1310, 1460, 1718, 2850, 2950, and 3400 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.65—2.07 (m, 31H), 3.27—4.72 (m, 6H), and 7.54 (s, 4H). Found: C, 63.63; H, 8.61%. Calcd for $C_{25}H_{41}SO_4Cl$: C, 63.69; H, 8.70%.

General Procedure for the Preparation of β-Hydroxy Esters 6.[14] To a solution of 3-hydroxy-2-sulfinyl ester (1 mmol) in 10% aqueous THF (10 ml) was added 0.2 g of aluminum amalgam at 0 °C. The reaction mixture was stirred at room temperature in hydrogen atmosphere. After stirring for 3 h, the reaction mixture was filtered and washed with ether, and the product was extracted with ether. The organic layer was dried over sodium sulfate, and the solvent was evaporated. The crude material was purified by chromatography on silica gel (eluent; ethyl acetate : hexane=1 : 4) to give methyl β-hydroxy ester **6**.

Methyl (*R*)-3-Hydroxypentanoate (*R*-6a): 75% yield; $[\alpha]_D^{23}$ −37.0° (*c* 2.00, $CHCl_3$) (lit,[15] $[\alpha]_D$ −36.9°).

Methyl (*R*)-3-Hydroxy-6-heptenoate (*R*-6b): 74% yield; $[\alpha]_D^{23}$ −22.3° (*c* 0.7, $CHCl_3$) (lit,[16] $[\alpha]_D$ −22.1°); IR (neat) 1100, 1285, 1640, 1740, 2900, and 3500 cm^{-1}; ^1H NMR (CCl_4) δ=1.19—2.56 (m, 6H), 3.69 (s, 3H), 4.24 (m, 2H),

4.77—5.33 (m, 2H), and 5.59—5.95 (m, 6H). Found: C, 45.52; H, 6.58%. Calcd for $C_{18}H_{14}O_3$: C, 45.61; H, 6.33%.

Methyl (*R*)-3-Hydroxy-5-phenylpentanoate (*R*-6c): 80% yield; $[\alpha]_D^{23}$ −12.2° (*c* 1.16, $CHCl_3$); IR (neat) 1100, 1280, 1310, 1720, 2900, and 3500 cm^{-1}; ^1H NMR (CCl_4) δ=1.43—1.82 (m, 2H), 2.34—3.03 (m, 4H), 3.67 (s, 3H), 3.81—3.97 (m, 2H), and 6.97 (s, 5H). Found: C, 69.06; H, 7.65%. Calcd for $C_{12}H_{16}O_3$: C, 69.26; H, 7.67%.

Methyl (*R*)-3-Hydroxy-5-(benzyloxy)pentanoate (*R*-6d): 78% yield; $[\alpha]_D^{23}$ −11.5° (*c* 2.5, $CHCl_3$). The ^1H NMR and IR spectra were in agreement with the literature.[21]

Methyl (*R*)-3-Hydroxyoctadecanoate (*R*-6e): 74% yield; $[\alpha]_D^{23}$ −15.1° (*c* 0.56, $CHCl_3$) (lit,[17] $[\alpha]_D$ −15°).

Methyl (*S*)-3-Hydroxypentanoate (*S*-6a): 78% yield; $[\alpha]_D^{23}$ +36.7° (*c* 0.60, $CHCl_3$).

Methyl (*S*)-3-Hydroxyheptenoate (*S*-6b): 79% yield; $[\alpha]_D^{23}$ +22.1° (*c* 0.60, $CHCl_3$); IR (neat) 1100, 1285, 1640, 1740, 2900, and 3500 cm^{-1}; ^1H NMR (CCl_4) δ=1.18—2.58 (m, 6H), 3.68 (s, 3H), 4.33 (m, 2H), 4.91—5.36 (m, 2H), and 5.43—5.97 (m, 1H). Found: C, 45.44; H, 6.58%. Calcd for $C_{18}H_{14}O_3$: C, 45.61; H, 6.33%.

Methyl (*S*)-3-Hydroxy-5-phenylpentanoate (*S*-6c): 79% yield; $[\alpha]_D^{23}$ +12.2° (*c* 0.98, $CHCl_3$). IR (neat) 1100, 1280, 1310, 1720, 2900, and 3500 cm^{-1}; ^1H NMR (CCl_4) δ=1.43—1.96 (m, 2H), 2.36—3.04 (m, 4H), 3.59 (s, 3H), 3.75—4.05 (m, 2H), 7.07 (s, 5H). Found: C, 69.33; H, 7.71%. Calcd for $C_{12}H_{16}O_3$: C, 69.26; H, 7.67%.

Methyl (*S*)-3-Hydroxy-5-(benzyloxy)pentanoate (*S*-6d): 77% yield; $[\alpha]_D^{23}$ +11.6° (*c* 2.6, $CHCl_3$). The ^1H NMR and IR spectra were in agreement with the literature.[21]

Methyl (*S*)-3-Hydroxyoctadecanoate (*S*-6e): 62% yield; $[\alpha]_D^{23}$ +14.8° (*c* 0.55, $CHCl_3$).

Corynomycolic Acids ((+)- and (−)-10). To a solution of diisopropylamine (100 mg, 1 mmol) in THF (0.5 ml) was added 0.65 ml of an 1.54 mol dm^{-3} solution of butyllithium in hexane at 0 °C. The solution of lithium diisopropylamide was cooled to −50 °C, and 150 mg (0.48 mmol) of methyl 3-hydroxyoctadecanoate (**6e**) in THF (2 ml) was added. After stirring for 1 h at the same temperature, a solution of tetradecyl iodide (162 mg, 0.5 mmol) in 1 g of HMPA was added, and the mixture was stirred for 3 h at −30 °C. The mixture was poured on ice-water and extracted with ether. The ethereal layer was dried over sodium sulfate, and the solvent was evaporated. The crude material was purified by chromatography on silica gel (eluent; ethyl acetate: hexane=1 : 3) to give methyl corynomycolate **9** or **11**.

Methyl (2*R*,3*R*)-3-Hydroxy-2-tetradecyloctadecanoate (9): 67% yield; $[\alpha]_D^{23}$ +4.2° (*c* 0.53, $CHCl_3$); mp 58—60 °C.

Methyl (2*S*,3*S*)-3-Hydroxy-2-tetradecyloctadecanoate (11): 65% yield; $[\alpha]_D^{23}$ −4.0° (*c* 0.52, $CHCl_3$); mp 58—60 °C.

To a solution of methyl corynomycolate **9** or **11** (510 mg, 1 mmol) in 50 ml of methanol was added 5 ml of an 1 mol dm^{-3} solution of potassium hydroxide in methanol at 30 °C. After stirring for 5 h, the solvent was evaporated. The residue was dissolved into water (20 ml) and washed with ether. After acidification with 2 mol dm^{-3} HCl solution (10 ml), the acid was extracted with ether. The organic layer was dried over sodium sulfate and the solvent was evaporated. The residue was recrystallized from methanol–petroleum ether to give optically pure corynomycolic acid (**10**).

(+)-Corynomycolic Acid ((+)-10): 85% yield; $[\alpha]_D^{23}$ +7.2° (*c* 0.40, $CHCl_3$) (lit,[18] $[\alpha]_D$ +7.2°); mp 68—70 °C (lit,[18] mp 70 °C).

(−)-Corynomycolic Acid ((−)-10): 83% yield; $[\alpha]_D^{23}$ −7.3° (*c* 0.50, $CHCl_3$); mp 68—69 °C.

Methyl 2-Tetradecyl-3-(benzoyloxy)octadecanoate. To a solution of **9** or **11** (51 mg, 0.1 mmol) and catalytic amount of 4-dimethylaminopyridine (2 mg) in pyridine (2 ml) was added benzoylchloride (30 mg, 0.2 mmol) at room temperature. After stirring for 15 h, 2 mol dm^{-3} HCl solution (2 ml) was added to the reaction mixture. The products were extracted with dichloromethane, dried over sodium sulfate and evaporated. The crude material was purified by chromatography on silica gel (eluent; ethyl acetate : hexane=5 : 1) to give methyl 2-tetradecyl-3-(benzoyloxy)octadecanoate.

Methyl (2*R*,3*R*)-2-Tetradecyl-3-(benzoyloxy)octadecanoate; 85% yield. The ratio of (2*R*,3*R*) : (2*S*,3*R*) was determined to be 92 : 8 by HPLC on a Finepak SIL column using hexane : 2-propanol=600 : 1. IR (neat) 1275, 1460, 1720, 2850, and 2925 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.95—1.35 (m, 60H), 2.20 (m, 1H), 3.65 (m, 4H), and 7.30 (m, 5H).

Methyl (2*S*,3*S*)-2-Tetradecyl-3-(benzoyloxy)octadecanoate; 90% yield. The ratio of (2*S*,3*S*) : (2*R*,3*S*) was determined to be 91 : 9 by HPLC on a Finepak SIL column using hexane : 2-propanol=600 : 1. IR (neat) 1260, 1500, 1720, 2850, and 2920 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.98—1.35 (m, 60H), 2.21 (m, 1H), 3.70 (m, 4H), and 7.38 (m, 5H).

(Received October 17, 1987)

The synthesis of the title compound, a double-layered annulene with 10π-rings, is described. The examination of ^{1}H NMR and electronic spectra suggests that the layered compound exhibits appreciable interaction between two [10]annulene rings.

A progress in the annulene chemistry stimulates our interest in the layered annulenes made up of a various ring size to investigate the transannular interaction between the annulene rings. Although the two annulenophanes, [2]paracyclo[2](2,7)(1,6-methano[10]-annuleno)phane (**1**) and [2](1,5)naphthaleno[2](2,7)-(1,6-methano[10]annuleno)phane (**2**) which consist of the benzenoid ring and 1,6-methano[10]annulene, have been synthesized by Matsumoto et al.[1] and it has been shown that the compound **2** shows appreciable transannular interaction between 1,6-methano[10]-annulene ring and naphthalene ring, none of the layered annulenes has been reported.

On the other hand, 11-methylene-1,6-methano[10]-annulene (**3**) and 1,6-methano[10]annulen-11-one (**4**) were prepared by Vogel et al.[2] and by Itô et al.,[3] respectively, and both the compounds **3** and **4** proved to be like the parent 1,6-methano[10]annulene[4] and to show no interaction between the p_z orbitals of the bridge and peripheral 10π-electron system.[2,3]

In this paper, we describe the first synthesis of the novel double-layered annulene **5**[5] which has two [10]annulene rings held together symmetrically with one ethylenic bridge.

Results and Discussion

The ketone **4** was initially thought to be a key intermediate for the synthesis of the title compound **5**, since **4** has a convenient carbonyl "hand" on the central position of [10]annulene ring for an intermolecular reductive coupling by McMurry method.[6] However, the attempted coupling of **4**, prepared according to the procedure of Itô et al.,[3] employing $TiCl_3$ and $LiAlH_4$ in THF[7] did not give the desired dimeric product **5**, but gave only naphthalene. We reasoned that the failure to obtain **5** from **4** is ascribed to the instability of the ketone **4** under the reaction conditions, as has been observed by us in the couplings of several fully conjugated polyenediynedials.[8] Then we directed our efforts to a two-stage approach which involves an initial coupling of the more stable ketone **6** and a subsequent dehydrogenation of the resulting dimeric hydrocarbon. Thus the reductive coupling of the ketone **6** as before[7] afforded the dimer, 1,1 : 2,2-bis(cyclodeca-2,4,8-triene-1,6-diyl)ethylene, as a mixture of syn- (**7a**) and anti-isomer (**7b**), which could not be separated by column chromatography on silica gel. When a mixture of **7a**, **b** and 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ) in benzene was heated in a sealed tube under nitrogen atmosphere at 110—120 °C for 24 h, dehydrogenation took place to afford the title compound **5** as stable yellow crystals in 5.9% yield, which was isolated by column chromatography on silica gel.

The ^{1}H NMR and electronic spectral data of **5** are listed in Table 1, together with those of the reference model compounds **3** and **4**. As shown in Table 1, the ring protons of **5** resonate in A_2B_2-type as similar to the cases of **3** and **4**,[2,3] and do in lower field than the olefinic protons of **7a**, **b** (Experimental), revealing that the annulene rings of **5** sustain diamagnetic ring current. Comparison of the central chemical shifts of the annulene protons among **3**, **4**, and **5** indicates that the protons of **5** (δ 6.96) resonate in higher field than those of **3** (δ 7.20) and **4** (δ 7.46). This high-field shift of the annulene protons observed in **5** is reasonably ascribed to diamagnetic anisotropy of the opposite annulene ring. Thus, this suggests that the two annulene rings in **5** are very suitable to overlap to each other.

The electronic absorption spectra, taken in cyclohexane, are illustrated in Fig. 1. As is seen from Fig. 1, all the spectra exhibit three bands which arise from [10]annulene chromophore[9] and which is characteris-

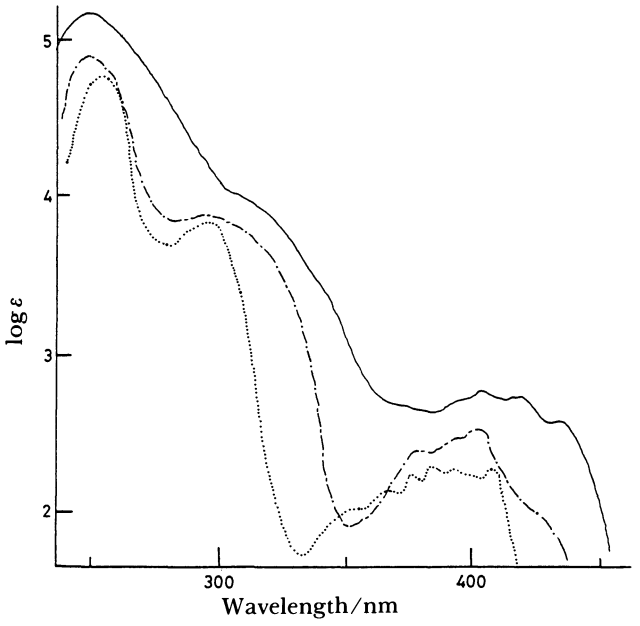

Fig. 1. Electronic spectra of **3** (----), **4**, (-·-·-), and **5** (——) in cyclohexane.

tic of $[4n+2]\pi$-electrons.[10] However, the longest wavelength band of **5** shows a remarkable bathochromic shift (20—30 nm) (Table 1), when compared with those of **3** and **4**, demonstrating that the transition associated with the longest wavelength band of [10] annulene chromophore is affected by the transannular interaction between the two annulene rings.

Experimental

Melting points are uncorrected. IR spcctra were measured on Hitachi 260-10 spectrophotometer as KBr disc; only significant maxima are reported. Electronic spectra were recorded on Hitachi 220-A spectrophotometer in nm, in cyclohexane solution. Mass spectra were measured with JEOL JMX-303 spectrometer at 70 eV using a direct inlet system. ^{1}H NMR spectra were taken on JEOL GX-500 (500 MHz) spectrometer, and refer to solutions in $CDCl_3$, in δ-values with TMS as an internal standard. The coupling constants (J) are given in Hz. Silica gel (Merck) was used for column chromatography.

The Reductive Coupling of the Ketone 4. $LiAlH_4$ (95 mg, 2.5 mmol) was added in one portion to titanium trichlo-

ride ($TiCl_3$) (0.77 g, 5 mmol) in dry THF (300 ml) under argon. The resultant black mixture was heated under reflux for 30 min. To the mixture, a soln of the ketone **4** (350 mg, 2.24 mmol) in dry THF (25 ml) was added dropwise during 30 min and then the mixture was stirred under reflux for further 4 h. Then after addition of ethanol (10 ml), the mixture was filtered through Hyflo Super-Cel under suction to remove inorganic materials and was washed with THF. The filtrate was concentrated under reduced pressure and the residue was chromatographed on silica gel (30 g). The fractions eluted with hexane afforded naphthalene (55 mg).

1,1:2,2-Bis(cyclodeca-2,4,8-triene-1,6-diyl)ethylene (7a,b). To the refluxing mixture of $LiAlH_4$ (0.92 g, 24.2 mmol) and $TiCl_3$ (7.50 g, 48.4 mmol) in dry THF (200 ml), prepared as described above, was added dropwise a soln of the ketone **6** (3.50 g, 21.8 mmol) in dry THF (200 ml) under argon and the mixture was stirred under reflux for further 4 h. After work-up as described above, the residue was chromatographed on silica gel (120 g). The initial fractions eluted with hexane gave a colorless liquid (310 mg) which proved to be a complex mixture of hydrocarbons by analysis of gas chromatography. The structures of the hydrocarbons are not established. The later fractions eluted with the same solvent afforded the desired dimer **7a,b** (100 mg, 3.1%) as a solid. Recrystallization from hexane afforded colorless needles: mp 138—139 °C; MS *m/z* 288 (M^+, 70%) and 234 (100); mol wt 288.4; IR 1595 (C=C), 710 and 705 cm^{-1} (cis C=C); UV λ_{max} (cyclohexane) 250 (9500), 261 (9800), and 273 nm sh (8600); ^1H NMR δ=5.93—5.88 (m, H^3, H^4, 4H), 5.77—5.73 (m, H^2, H^5, 4H), 5.57—5.55 (m, H^8, H^9, 4H), 3.79—3.76 (m, H^1, H^6, 4H), 2.56—2.50 (m, H^7, H^{10} or $H^{7'}$, $H^{10'}$, 4H), 2.19—2.13 (m, H^7, H^{10} or $H^{7'}$, $H^{10'}$, 4H).

Found: C, 91.29; H, 8.45%. Calcd for $C_{22}H_{24}$: C, 91.61; H, 8.39%.

1,1:2,2-Bis([10]annulene-1,6-diyl)ethylene (5). A mixture of the hydrocarbons **7a,b** (70 mg, 0.243 mmol) and DDQ (270 mg, 1.2 mmol) in dry benzene (4 ml) was heated in a sealed tube under nitrogen atmosphere at 110—120 °C for 24 h. After removing insoluble materials by filtration under suction and washing with benzene, the filtrate was concentrated. The residue was chromatographed on silica gel (10 g). The fractions eluted with hexane afforded the layered annulene **5** (4.0 mg, 5.9%) as a solid. Recrystallization from hexane-benzene afforded pale yellow needles: mp 245—247 °C; MS *m/z* 280 (M^+, 100%); mol wt 280.3; IR 750 cm^{-1} (cis C=C); UV: see Table 1 and Fig. 1; ^1H NMR: see Table 1.

Found: C, 93.69; H, 5.87%. Calcd for $C_{22}H_{16}$: C, 94.25; H, 5.75%.

The authors thank Professor Shô Itô, Tohoku University, for providing us the details for preparing the ketone **4** and helpful suggestions, Professor Yoshiteru Sakata, Osaka University, for helpful discussion, and Professor E. Vogel, Köln University, for providing us the electronic spectrum of **3**.

Electron Coupled Proton Transport Mediated by $[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]^{2-}$ in Liquid Membrane

Koji TANAKA,* Mari MASANAGA, and Toshio TANAKA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-Oka, Suita, Osaka 565
(Received October 28, 1987)

Electrochemical reduction of $[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]^{2-}$ ($[4\text{-Fe}]^{2-}$) dissolved in a CH_2Cl_2 phase of the CH_2Cl_2/H_2O two phase system is followed by protonation to give $[4\text{-Fe}]^{3-}\text{-}H^+$ when the pH of the H_2O phase is lower than 7.0, and protonated and deprotonated $[4\text{-Fe}]^{3-}$ exist as an equilibrium mixture in the CH_2Cl_2 phase. On the other hand, no protonation takes place upon the reduction of $[4\text{-Fe}]^{2-}$ in the CH_2Cl_2 phase contacting with the H_2O phase with the pH higher than 7.0. The electron transport conducted in a liquid membrane composed of the H_2O (W_1), CH_2Cl_2, and H_2O (W_2) phases containing sodium dithionite as an electron donor, $(n\text{-}Bu_4N)_2[4\text{-Fe}]$ as a mediator, and disodium anthraquinone-1,5-disulfonate (Na_2AQS) as an electron acceptor, respectively, revealed that protonated $[4\text{-Fe}]^{3-}\text{-}H^+$ mediates electron coupled proton transport in the liquid membrane, while the deprotonated cluster has no ability of electron transport in the same system.

Electron transport across a cell membrane plays key roles not only in various biological redox reactions but also in ATP synthesis in mitochondria or chloroplasts. Model studies for the electron transport have, therefore, widely been conducted by using bilayer lipid membranes[1-5] or liquid membranes.[6-9] Electron transport in biological membranes takes place according to an electrochemical proton gradient, where electrons and protons are transported from the high proton concentration side to the low proton concentration side across a biomembrane.[10-14] A pH dependence of the redox potential of an oxidation-reduction component in a biomembrane provides evidence for a proton participation in the redox reaction. Mitochondrial cytochromes which show the shift of −60 mV/pH for their half-reduction potentials have, therefore, been considered to take part in electron coupled-proton transport.[15-17] The intermediary which plays in such a role at negative potentials more than the redox reactions of cytochromes, however, has not been elucidated so far.

Iron-sulfur proteins widely distributed in plants, bacteria, and mammals are considered soley to function as electron transfer catalysts in various biological redox reactions such as nitrate reduction, CO_2- and N_2-fixation, H_2-evolution, and so on.[18] In accordance with this, the redox potentials of most Fe-S proteins show a relatively small shift (0 to −24 mV/pH) with the change of pH,[19-21] while that of the mitochondrial Fe-S Center N-2 shows a slope of −60 mV/pH,[22,23] implying a stoichiometric one electron and one proton participation in the redox reaction. Mitochondrial Fe-S Center N-2, therefore, has been proposed to function not only as electron but also as proton carriers in biomembranes.[22]

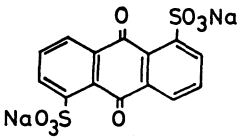
The interactions between synthetic Fe_4S_4 clusters and protons have also been studied; the pK_a values determined spectrophotometrically[24,25] and electrochemically[26-30] fall in the range 3.9 to 9.0. We have, recently, elucidated that reduction-linked proton binding to $[Fe_4X_4(YC_{12}H_{25})_4]^{3-}$ (X, Y=S and Se) takes place at the sulfur or selenium atom of the Fe_4X_4 core rather than that of terminal alkanethiolate and -selenolate ligands on the basis of their pK_a values in aqueous Triton X-100 micellar solutions.[31] The ability of proton binding to the Fe_4S_4 cluster solubilized in hydrophobic spheres in aqueous micellar solutions suggests that the synthetic Fe_4S_4 cluster can be used as a mediator of the electron coupled proton transport in a liquid membrane. In fact, $[Fe_4S_4(SPh)_4]^{3-}$ prepared by reduction of $[Fe_4S_4(SPh)_4]^{2-}$ with Cr^{II} in a toluene/water two phase system is protonated and releases the proton upon reoxidation with methylviologen.[32] This paper describes electron coupled proton transport from aqueous sodium dithionite ($Na_2S_2O_4$) to disodium anthraquinone-1,5-disulfonate solutions across a CH_2Cl_2 phase containing $[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]^{2-}$.

Experimental

General. All manipulations were carried out under an N_2 atmosphere. The iron-sulfur cluster $(n\text{-}Bu_4N)_2[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]$ ($(n\text{-}Bu_4N)_2[4\text{-Fe}]$) was prepared according to the literature.[28]

Physical Measurements. Cyclic voltammograms were obtained by the use of a Hokuto Denko potentialstat HB-401, a Hokuto Denko function generator HB-107, and a Yokogawa Electric X-Y recorder 3077. The electrolysis cell was equipped with a nozzle for bubbling N_2. The concentrations of Na^+ in aqueous solutions were determined by the use of a Nippon Jarrell-Ash atomic absorption spectrophotometer AA-8500.

Cyclic Voltammetry of $[4\text{-Fe}]^{2-}$ in an H_2O/CH_2Cl_2 Two Phase System. An aqueous H_3PO_4-NaOH buffer (0.1 mol dm^{-3}) solution (pH 9.4 or 6.5, 20 cm^3) containing $n\text{-}Bu_4NBr$ (0.6 g, 1.8 mmol) was poured in a CH_2Cl_2 solution (20 cm^3) containing $(n\text{-}Bu_4N)_2[4\text{-Fe}]$ (20 mg, 12 μmol) and $n\text{-}Bu_4NBr$ (0.6 g, 1.8 mmol), and the mixture was stirred by bubbling N_2 for several minutes. Then, the cell was allowed to stand until the CH_2Cl_2 and H_2O phases were separated completely. The proton concentration in the H_2O phase was adjusted by addition of a small amount of either aqueous NaOH or H_3PO_4 solution to the H_2O phase, followed by



AQS^{2-} : $E_{1/2}$ = -0.43 V (pH 7.0)

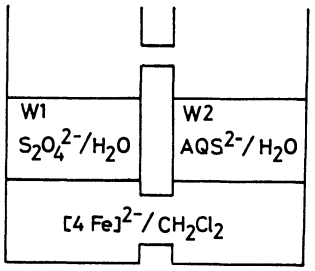


Fig. 1. A liquid membrane cell.

stirring the mixture by the same method. The pH of the H_2O phase was measured with a Toa Electronics pH meter HM-7B. The cyclic voltammogram of $(n\text{-}Bu_4N)_2$[4-Fe] solubilized in the CH_2Cl_2 phase was obtained by using a Yanaco glassy carbon disk electrode GC-2P, a Pt auxiliary electrode, and a luggin capillary of a reference electrode (SCE), all of which were immersed into the CH_2Cl_2 phase.

Electron Coupled Proton Transport across a Liqid Membrane. The electron coupled proton transport across a liquid membrane, mediated with $(n\text{-}Bu_4N)_2$[4-Fe] was conducted by using a liquid membrane cell (16 mm inner diameter) (Fig. 1). After the cell was thoroughly flushed with N_2 to remove air, a CH_2Cl_2 solution (20 cm^2) of $(n\text{-}Bu_4N)_2$[4-Fe] (2.5—20 mg, 1.5—12 μmol) was charged into the cell with syringe techniques through a septum cap attached to the top of the cell. Then, aqueous H_3PO_4-NaOH buffer solutions (0.1 mol dm^{-3}, 5 cm^3) of $Na_2S_2O_4$ (0.108 g, 0.62 mmol) and of disodium anthraquinone-1,5-disulfonate (Na_2AQS) (4.9—25 mg, 0.12—0.61 mmol) were introduced into the cell as an electron donor (W_1 phase) and an electron acceptor (W_2 phase), respectively, and the CH_2Cl_2 layer was stirred magnetically at 20 °C for 16 h in the dark owing to instability of Na_2AQS toward light. Electron transport from the W_1 to the W_2 phases through the CH_2Cl_2 phase was monitored by the change of an absorption band centered around 450 nm due to the reduced species of AQS^{2-} formed in the W_2 phase, and the electrons transported from the W_1 phase to the W_2 phase were determined from the absorbance at 450 nm. In the present study, the 450 nm band has been assigned to a two-electron reducticon product of AQS^{2-}, though several reduced species of AQS^{2-} exist as an equilibrium mixture in aqueous solutions.[33] The apparent amount of the reduced species of AQS^{2-} was calculated from the absorbance at 450 nm upon dissolving a given amount of $Na_2S_2O_4$ (as a two electron donor) in aqueous Na_2AQS solutions with the same concentration as the W_2 phase at various pH.

Results and Discussion

The Redox Behavior of $(n\text{-}Bu_4N)_2[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]$ in an H_2O/CH_2Cl_2 Two Phase System. As reported previously, redox potentials of the $[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]^{2-/3-}$ ([4-Fe]$^{2-/3-}$) couple in aqueous micellar[27,28,30] and lecithin vesicle solutions[29] are largely influenced by proton concentrations owing to the redox-linked protonation of the cluster. Thus, the redox behavior of the same cluster dissolved in the CH_2Cl_2 phase of a CH_2Cl_2/H_2O two phase system was examined with the intention of applying to an electron coupled proton transfer catalyst in a liquid membrane. The cyclic voltammogram of $(n\text{-}Bu_4N)_2$[4-Fe] in a CH_2Cl_2/H_2O (pH 9.40) two phase system shows a pair of cathodic and anodic waves due to the [4-Fe]$^{2-/3-}$ redox couple at −0.99 and −0.85 V vs. SCE, respectively, at the sweep rate 10 mV s^{-1} (Fig. 2). The cathodic and anodic peak potentials are moved in dif-

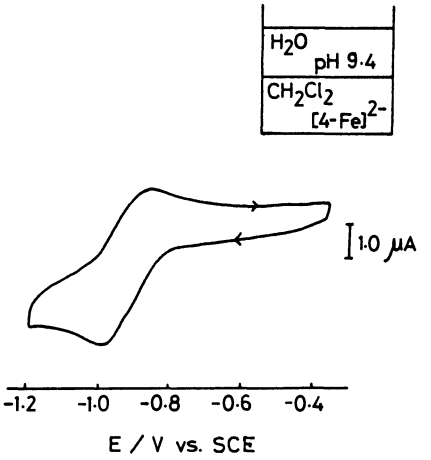

Fig. 2. Cyclic voltammogram of $(n\text{-}Bu_4N)_2[Fe_4S_4(SC_6H_4\text{-}p\text{-}n\text{-}C_8H_{17})_4]$ solubilized in the CH_2Cl_2 layer (0.60 mmol dm^{-3}) in the H_2O/CH_2Cl_2 two phase system; dE/dt=10 mV s^{-1}.

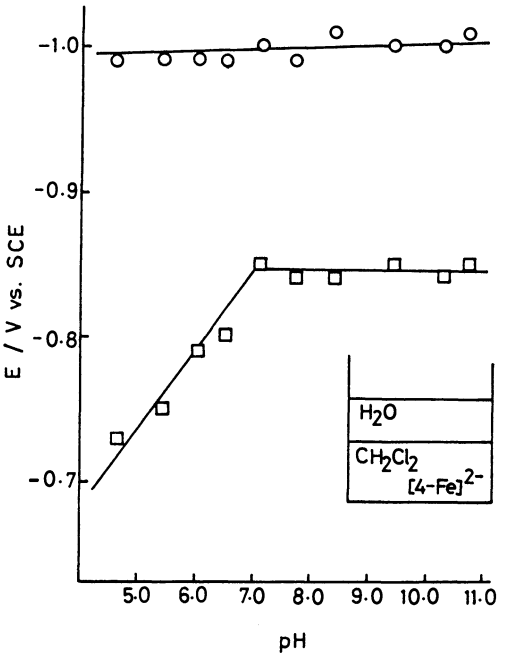

Fig. 3. Plots of the cathodic (○) and anodic peak potentials (□) of the [4-Fe]$^{2-/3-}$ redox couple in the H_2O/CH_2Cl_2 system vs. pH of the H_2O phase.

ferent fashions from each other upon change of the proton concentration in the H_2O phase (Fig. 3); the cathodic peak potential is almost independent of pH of the H_2O phase in the pH range 4.6 to 11.0 (circles in Fig. 3), suggesting that no proton transport is involved in the reduction of $[4\text{-Fe}]^{2-}$ in the H_2O-saturated CH_2Cl_2 phase. On the other hand, the anodic peak potential of the redox couple varies with a slope −55 mV/pH in the pH range 4.6 to 7.0, while it is independent of pH in the range higher than 7.0 (squares in Fig. 3). Such characteristic pH dependences of the cathodic and anodic peak potentials of the $[4\text{-Fe}]^{2-/3-}$ couple in the H_2O-saturated CH_2Cl_2 layer may be explained by assuming Eqs. 1—4. The cluster in the

$$[4\text{-Fe}]^{2-} + e^- \longrightarrow [4\text{-Fe}]^{3-} \quad (1)$$

$$[4\text{-Fe}]^{3-} + H^+ \overset{pH<7}{\rightleftharpoons} [4\text{-Fe}]^{3-}\text{-}H^+ \quad (2)$$

$$[4\text{-Fe}]^{3-} - H^+ \overset{pH<7}{\longrightarrow} [4\text{-Fe}]^{2-} + e^- + H^+ \quad (3)$$

$$[4\text{-Fe}]^{3-} \overset{pH>7}{\longrightarrow} [4\text{-Fe}]^{2-} + e^- \quad (4)$$

CH_2Cl_2 phase undergoes one-electron reduction to afford $[4\text{-Fe}]^{3-}$ (Eq. 1), followed by protonation, probably at the sulfur atom of the Fe_4S_4 core[31] in the CH_2Cl_2 phase when pH of the H_2O phase is lower than 7, where protonated and deprotonated clusters exist as an equilibrium mixture (Eq. 2). Upon subsequent oxidation, the protonated cluster $[4\text{-Fe}]^{3-}\text{-}H^+$ may release the proton owing to decreasing electron density of the Fe_4S_4 core (Eq. 3). On the other hand, the cluster may be subject to the redox reaction without undergoing protonation (Eqs. 1 and 4) in the pH range of the H_2O phase higher than 7.0, explaining the anodic peak potential being almost invariant in that pH range (squares in Fig. 3). The pK_a value 7.0 of $[4\text{-Fe}]^{3-}\text{-}H^+$ obtained from the turning point of the anodic peak potential[34] (Fig. 3) is smaller than that in aqueous micellar solutions (pK_a 9.0).[27,28] This result may partly be due to low proton concentrations in the H_2O-saturated CH_2Cl_2 phase compared with those in hydrophobic spheres in micells.

Electron Coupled Proton Transport across a Liquid Membrane Mediated with (n-Bu_4N)$_2$[4-Fe]. A proton binding to $[4\text{-Fe}]^{3-}$ in the CH_2Cl_2/H_2O two phase system suggests that the present cluster has an ability of the electron coupled proton transport. Thus, the electron transport mediated with the cluster was conducted by using a liquid membrane (Fig. 1); aqueous buffer solutions (H_3PO_4-NaOH) of sodium dithionite (W_1 phase) and of disodium anthraquinone-1,5-disulfonate (Na_2AQS) (W_2 phase) were used as an electron donor and an electron acceptor, respectively, on the CH_2Cl_2 phase containing (n-Bu_4N)$_2$[4-Fe]. The pH values of the W_1 (pH_1) and W_2 (pH_2) phases were adjusted at 6.2 and 10.7, respectively. Electron transport conducted by stirring the CH_2Cl_2 phase results in the occurrence of a strong absorption band centered around 450 nm due to the reduced species of AQS^{2-} in the electronic spectrum of the W_2 phase (a solid line in Fig. 4). On the other hand, no absorption band appears around 450 nm in the absence of (n-Bu_4N)$_2$-[4-Fe] in the CH_2Cl_2 phase under otherwise the same conditions (a broken line in Fig. 4). Thus, the iron-sulfur cluster in the CH_2Cl_2 phase mediates electron coupled H^+ or Na^+ transport from the W_1 to the W_2 phases, since no other counter cation is involved in this system. In view of the fact that protonation to $[4\text{-Fe}]^{3-}$ takes place only in the pH region lower than 7.0 of the H_2O phase in the CH_2Cl_2/H_2O two phase system, the electron coupled proton transport mediated

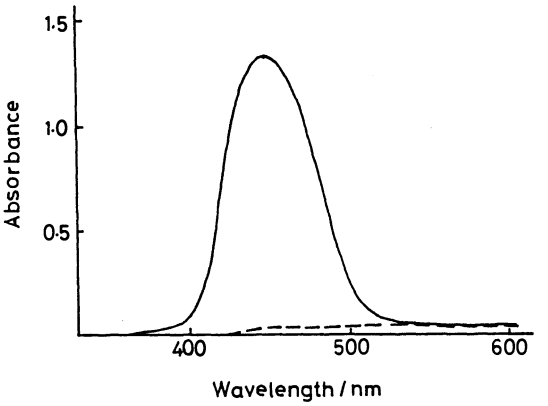

Fig. 4. Electronic absorption spectra of the reduced species of AQS^{2-} formed in the W_2 phase in the absence (----) and the presence of (n-Bu_4N)$_2$[4-Fe] (10 μmol) (——) in the CH_2Cl_2 (20 cm^3) phase after electron transport for 16 h; the concentrations of both $Na_2S_2O_4$ in the W_1 (H_2O, 5 cm^3; pH 6.2) and Na_2AQS in the W_2 (H_2O, 5 cm^3; pH 10.7) phases are 1.2×10^{-1} mol dm^{-3}.

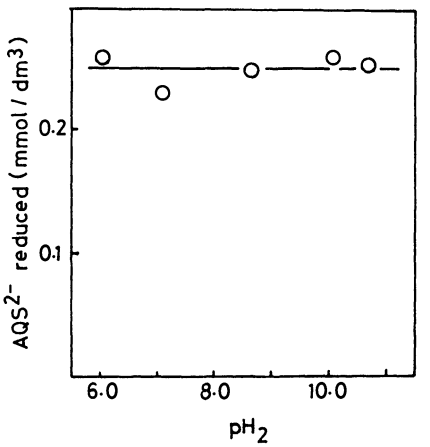

Fig. 5. Amounts of the reduced species of AQS^{2-} formed in the electron transport mediated with $[4\text{-Fe}]^{2-}$ at various pH of the W_2 phase for 16 h; the concentrations of $Na_2S_2O_4$ in the W_1 (H_2O, 5 cm^3; pH 6.2), (n-Bu_4N)$_2$[4-Fe] in the CH_2Cl_2 (20 cm^3), and Na_2AQS in the W_2 (H_2O, 5 cm^3) phases are 1.2×10^{-1}, 1.5×10^{-4}, and 1.2×10^{-1} mol dm^{-3}, respectively.

with $[4\text{-Fe}]^{3-}$ across the CH_2Cl_2 phase may largely be influenced by proton concentrations of the H_2O phase.

The amounts of the reduced species of AQS^{2-} formed in the W_2 phase is essentially constant irrespective of pH of this phase (pH) as far as pH of the W_1 phase (pH_1) is kept to be lower than 7; Fig. 5 is an example at pH_1 6.2. Thus, pH of the W_2 phase (pH_2) little influences the electron transfer from the reduced species of the cluster to AQS^{2-} at the CH_2Cl_2/W_2 interface. On the other hand, pH_1 largely influences on the formation of the reduced species of AQS^{2-} in the W_2 phase with pH_2 10.7; the amount of the reduced species of AQS^{2-} is rapidly decreased with increasing the pH value of the W_1 phase (Fig. 6). The agreement of the turning point (pH_1 7.0) in Fig. 6 with the pK_a value of $[4\text{-Fe}]^{3-}$-H^+ obtained from the plot of the anodic peak potential of the cluster vs. pH in the CH_2Cl_2/H_2O two phase system (Fig. 3) suggests that $[4\text{-Fe}]^{3-}$-H^+ rather than deprotonated cluster $[4\text{-Fe}]^{3-}$ mediates the electron transport from the W_1 phase to the W_2 phase. As an electron carrier, $[4\text{-Fe}]^{3-}$-H and $[4\text{-Fe}]^{3-}$ may exhibit a fairly different behavior from each other, since the former may have an ability of the electron coupled proton transport, while the latter mediates electron coupled Na^+ transport. The active species, $[4\text{-Fe}]^{3-}$-H^+ or $[4\text{-Fe}]^{3-}$, which mediates the electron transport from the W_1 to W_2 phases may, therefore, be assigned by determining the amount of Na^+ transported into the W_2 phase accompanied by the electron transport. The electron transport conducted by using $NaOH$-H_3PO_4 and KOH-H_3PO_4 buffer solutions in the W_1 and the W_2 phases, respectively, also produced

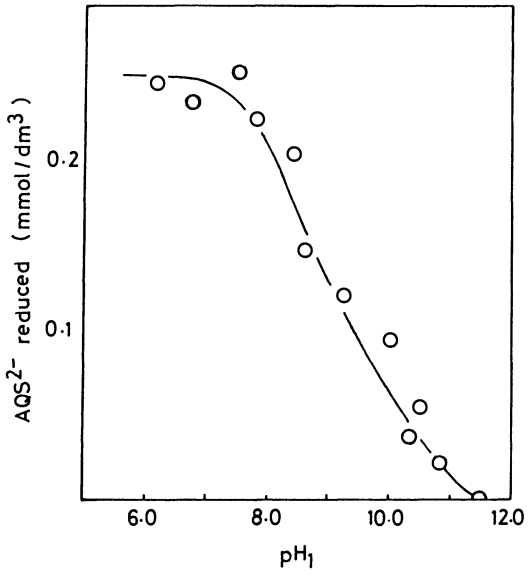

Fig. 6. The amount of the reduced species of AQS^{2-} formed in the electron transport mediated with $[4\text{-Fe}]^{2-}$ at various pH_1 (W_1 phase) for 16 h; the concentrations of $Na_2S_2O_4$ in the W_1 (H_2O, 5 cm³), $(n\text{-}Bu_4N)_2[4\text{-Fe}]$ in the CH_2Cl_2 (20 cm³), and Na_2AQS in the W_2 (H_2O, 5 cm³; pH 10.7) phases are 1.2×10^{-1}, 1.5×10^{-4}, and 1.2×10^{-1} mol dm^{-3}, respectively.

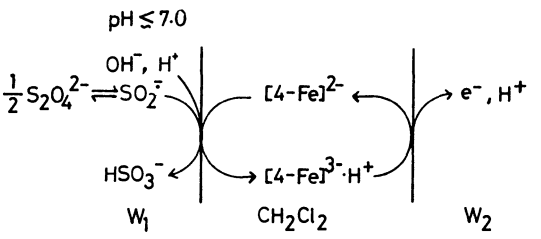

Scheme 1.

the same amounts of the reduced species of AQS^{2-} in the W_2 phase as those in Fig. 6.[35] In addition, no appreciable change of the amount of Na^+ in the W_2 phase (resulting from Na_2AQS) was observed between before and after the electron transport. It may, therefore, be concluded that no appreciable Na^+ transport from the W_1 phase to the W_2 phase takes place in the present study. Thus $[4\text{-Fe}]^{3-}$-H^+ functions as an electron carrier in the liquid membrane. The maximum electrons transported in the present study was 2.0 on the basis of the amount of $(n\text{-}Bu_4N)_2[4\text{-Fe}]$ in the CH_2Cl_2 phase for 16 h.[36] Such a low value may be resulted from an endothermic electron transfer from $S_2O_4^{2-}$ (E=−0.90 V vs. SCE in H_2O at pH 9.0)[37] to $[4\text{-Fe}]^{2-}$ (E_{red}=−0.99 V in CH_2Cl_2) at the W_1/CH_2Cl_2 interface.

Electron Pathway in the Liquid Membrance. A most possible electron pathway for the present electron coupled proton transport mediated with $(n\text{-}Bu_4N)_2$-[4-Fe] is depicted in Scheme 1; a partial dissociation $S_2O_4^{2-} \rightleftarrows 2SO_2^{\cdot-}$ in the W_1 phase generates the active reductant $SO_2^{\cdot-}$ [37] which may reduce $[4\text{-Fe}]^{2-}$ at the W_1/CH_2Cl_2 interface to afford $[4\text{-Fe}]^{3-}$ and SO_2. The former undergoes a protonation probably at sulfur of the Fe_4S_4 core[31] in the CH_2Cl_2 phase when pH_1 is lower than 7.0, and the latter reacts with OH^- to afford HSO_3^- in the W_1 phase. The protonated $[4\text{-Fe}]^{3-}$-H^+ thus formed in the CH_2Cl_2 phase is oxidized by AQS^{2-} at the CH_2Cl_2/W_2 interface with liberating the proton into the W_2 phase. The resulting oxidized cluster $[4\text{-Fe}]^{2-}$ moves back to the W_1/CH_2Cl_2 interface, regenerating $[4\text{-Fe}]^{3-}$-H^+. When pH_1 is higher than 7.0, however, the reduction of $[4\text{-Fe}]^{2-}$ hardly takes place at the W_1/CH_2Cl_2 interface unless a strong hydrophilic Na^+ in the W_1 phase migrates into the CH_2Cl_2 phase to cancel the extra negative charge of $[4\text{-Fe}]^{3-}$. Thus, protons are much more superior to Na^+ as a counter ion of the electron transport in the liquid membrane system. The mechanism proposed in Scheme 1[38] reasonably explains the vectrial electron flow from a high proton concentration side to a low proton concentration side in biomembrane, since the reverse electron transport is effectively suppressed so long as the pK_a value of the cluster is smaller than the pH value of the low proton concentration side. The present study strongly suggests that some of iron-sulfur proteins participate in the transport of protons as well as electrons in biomembrane.

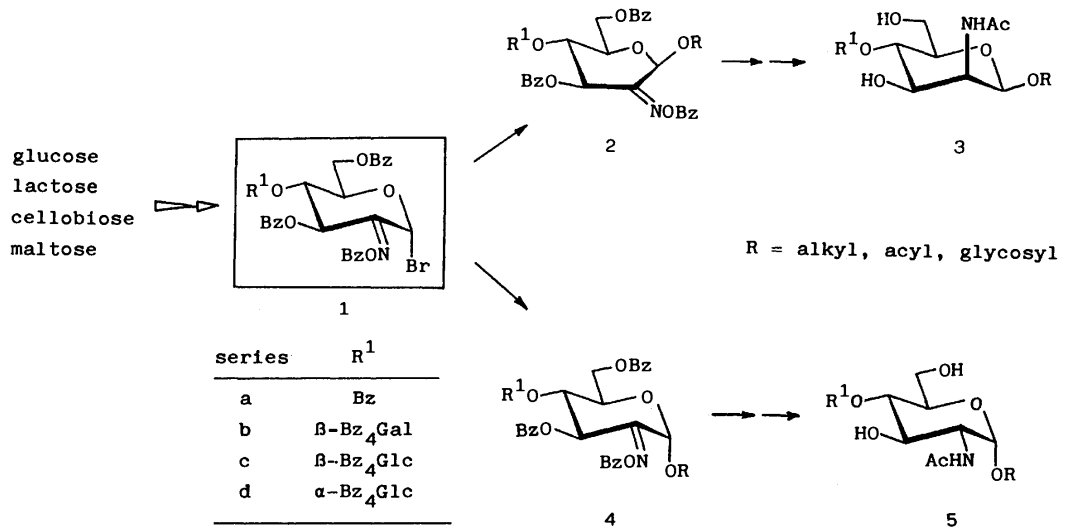
(Received October 29, 1987)

Highly stereoselective, expedient syntheses are described for three immunologically relevant β-glycosides of *N*-acetyl-D-mannosamine, i.e. β-D-Man*p*NAc-1-OMe (**8**), β-D-Man*p*NAc-(1→6)-D-Gal (**15**), and β-D-Man*p*NAc-(1→4)-α-D-Glc*p*-1-OMe (**23**). Basic mannosamine progenitor in each case is 3,4,6-tri-*O*-benzoyl-2-(benzoyloxyimino)-2-deoxy-α-D-*arabino*-hexopyranosyl bromide (**1a**), which via the three step-sequence β-selective glycosidation → hydroboration → deblocking is converted to **8**, **15**, and **23** in overall yields of 61, 56, and 39% for the glycosyl acceptors methanol, 1,2:3,4-di-*O*-isopropylidene-α-D-galactose, and methyl 2,3,6-tri-*O*-benzyl-α-D-glucopyranoside, respectively.

β-Glycosidically linked 2-acetamido-2-deoxy-D-mannopyranose (*N*-acetyl-β-D-mannosamine) carries a type-specific immunogeneity in various bacteria associated with invasive diseases.[1,2] Even simple alkyl glycosides such as methyl *N*-acetyl-β-D-mannosaminide acts as a specific hapten against the immunoglobulin of IgA class originated from a mouse myeloma MOPC 406;[3] more complex *N*-acetyl-β-D-mannosaminides constitute a number of bacterial K antigens of capsular polysaccharides[2] as well as O antigens of lipopolysaccharides.[4]

Investigations directed towards the molecular design of artificial antigens require as a principal prerequisite preparatively useful, chemical procedures for the practical construction of oligosaccharides containing *N*-acetyl-β-D-mannosamine. Such procedures are still lacking despite of the possibility of using 2-azido-2-deoxy-D-mannopyranosyl halides,[5,6] which are accessible in syrupy form via low yield, multistep reaction sequences, and furthermore, require careful optimization of glycosidation conditions to reach useful β-selectivities.[5] A similarly laborious approach[7] comprises the *a priori* construction of the respective disaccharide for example, and the *a posteriori* introduction of the 2-amino function via oxidation of a 2-hydroxyl group, oximation and subsequent reduction.[7]

Our approach to the problem of a practical synthesis for β-D-mannosaminides, that has been elaborated on lactose-derived derivatives,[8,9] comprises 2-(benzoyloxyimino)glycosyl bromides of type **1** as the key compounds readily accessible from glucose[10,11] or disaccharides[8] in a few high-yielding steps and in crystalline form. These key building blocks **1** are ideal β-D-mannosamine progenitors, since β-selective glycosidation, reduction of the benzoyloxyimino function to amino group, and deprotection yielding β-D-mannosamine-containing oligosaccharides, a protocol, which combines high stereoselectivity with efficiency of operation and large-scale adaptability



Scheme 1.

(Scheme 1).

In complementation of previous work concentrating on trisaccharides with central β-D-mannosamine units,[9] we here wish to describe[12] the utilization of the D-glucose-derived monosaccharide building block **1a** for the preparation of disaccharides with a nonreducing *N*-acetyl-β-D-mannosamine residue, of which one, i.e. **23**, constitutes a disaccharide unit of the capsular polysaccharide from *Streptococcus pneumoniae* type 9N[2] and 19F.[13]

Methyl *N*-Acetyl-β-D-mannosaminide (8) A preparatively reliable synthesis of methyl *N*-acetyl-β-D-mannosaminide (**8**), as of now, is not available, since direct glycosidation of 2-acetamido-2-deoxy-D-mannose with methanol in the presence of acid (Fischer method) results in a mixture of the four possible methyl *N*-acetyl-D-mannosaminides from which the β-D-pyranoside (**8**) is isolable in yields of 1—2% only.[14] The major isomers were α-D-pyranoside (9%), α-D-furanoside (8%), and β-D-furanoside (2—3%).

Our synthesis of **8** involves methanolysis of the building block **1a**, reduction of the resultant β-glycoside **6** to mannosaminide, *N*-acetylation, and *O*-debenzoylation, so that the synthetic efficiency depends on the β-selective methanolysis and manno-selective reduction (Scheme 2).

The glycosidation of **1a** with excess methanol (ten-fold molar amount) in the presence of several kinds of condensation promotors are summarized in Table 1. Of a variety of reaction conditions examined, only silver carbonate in dichloromethane resulted in good yield (93%) and high stereoselectivity (α:β≃5:95). Other conditions employed, such as silver triflate-tetramethylurea or 2,4,6-collidine-I_2 (cf. Runs 2—5,

a) Estimated on the basis of ^1H NMR signals for the anomeric protons. b) Silver trifluoromethanesulfonate/1,1,3,3-tetramethylurea. c) 1,2:3,4-Di-*O*-isopropylidene-α-D-galacto-pyranose (**11**). d) Methyl 2,3,6-tri-*O*-benzoyl-α-D-glucopyranoside (**17**). e) Contaminated with by-products that impeded the estimation of α:β ratio. f) Methyl 2,3,6-tri-*O*-benzyl-α-D-glucopyranoside (**16**).

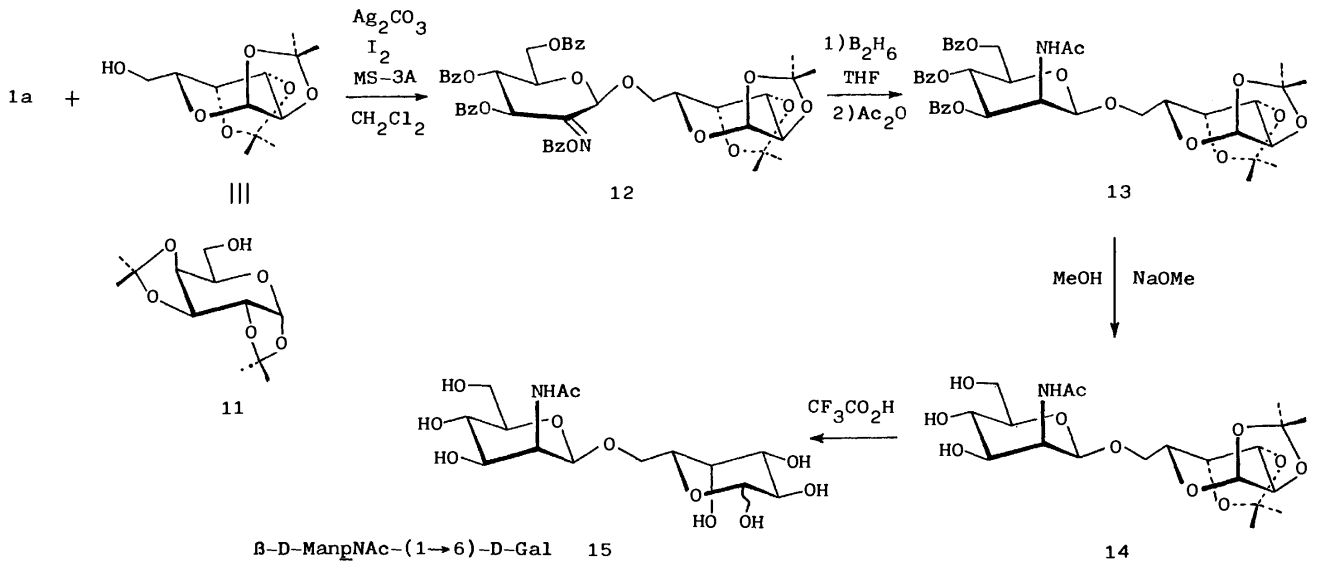
Table 1) gave anomeric mixtures with only partial predominance of β-anomers. β-Glycoside **6** was then subjected to hydroboration with twelve-fold molar excess diborane in tetrahydrofuran to afford on *N*-acetylation methyl *N*-acetyl-tri-*O*-benzoyl-β-D-mannosaminide (**7**) in 88% yield. The corresponding β-D-gluco isomer **10** was isolated in only 1.3% yield, so that the preference for the β-D-manno form is in the remarkable, practically very useful range of around 50 : 1. The subsequent *O*-debenzoylation of **7** was cleanly effected with 0.05 M sodium methoxide (1 M=1 mol dm^{-3}) in methanol (Zemplén method) to furnish methyl *N*-acetyl-β-D-mannosaminide (**8**) in 87% yield. Furthermore, **8** was hydrolyzed with 1 M hydrochloric acid giving D-mannosamine hydrochloride **9** in quantitative yield, which was unequivocally identified by comparison with an authentic sample.

The following stereochemical aspects are worthy of note: β-oriented methyl 2-(benzoyloxyimino)glycoside **6** seems to be distorted towards the twist-boat form as indicated in the formula considering from relatively small coupling constant of $J_{3,4}=J_{4,5}=5.7$ Hz. In contrast, **1a** and **7** prefer $^4C_1$ coformation, as evidenced by $J_{3,4}$ and $J_{4,5}$ values of 8.4—9.6 Hz. This may be attributed to substantial steric congestion caused by the 2-benzoyloxyimino and anomeric methoxyl groups in **6**. Similar conformational propensity for 2-(benzoyloxyimino)-β-glycosides were observed previously.[8,9]

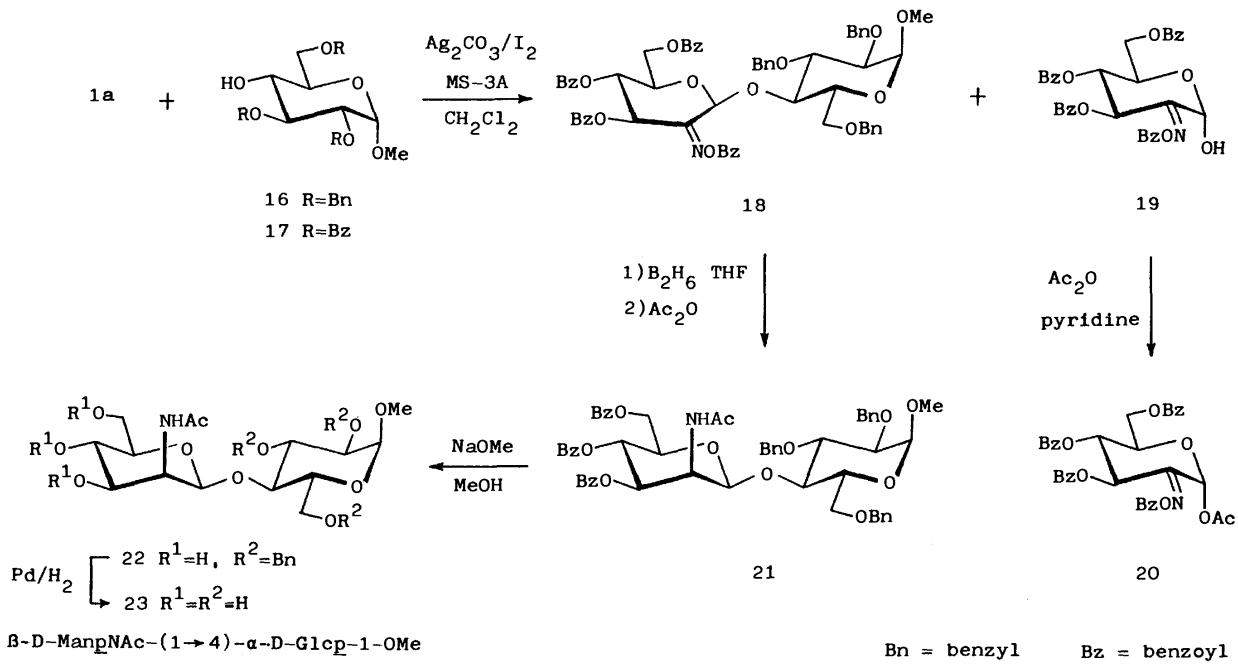
^1H and ^{13}C NMR spectra of methyl β-D-mannosaminide **8** were fully elucidated with the aid of ^1H-^1H and ^1H-^{13}C shift correlated two-dimentional (2D) NMR spectra. ^1H-^1H coupling of $J_{1,2}=1.5$ and $J_{2,3}=4.5$ Hz cogently reflect β-D-manno configuration, and a $J_{C1,H1}$ coupling of 163.6 Hz agrees well with that (ca. 160 Hz) of methyl β-glycopyranosides with axial H-1.[15] A calculation of differences of ^{13}C-chemical shifts ($\Delta\delta_c$) by $\delta_{gluco}-\delta_{manno}$ between methyl *N*-acetyl-β-D-mannosaminide and the corresponding glucosaminide[16] showed that major differences appeared at C-2 ($\Delta\delta_c=-4.1$ ppm) and C-4 (−3.2), whilst they are less pronounced at C-3 (−2.0), C-1 (−1.5), C-5 (+0.5), and C-6 (−0.4). These findings were found to be helpful in the structural elucidation of β-D-mannosamine-containing oligosaccharides.

***N*-Acetyl-β-D-mannosaminyl-(1→6)-D-galactose (15) and Methyl *N*-Acetyl-β-D-mannosaminyl-(1→4)-α-D-glucopyranoside (23).** Replacement of the glycosyl acceptor in the above glycosidation **1a**→**6** by suitably blocked sugar alcohols similarly gave the desired disaccharide derivatives in preparatively highly useful fashion. Thus, glycosylation of 1,2 : 3,4-di-*O*-isopropylidene-D-galactose (**11**)[17] with (benzoyloxyimino)glycosyl bromide **1a** in the presence of silver carbonate-iodine in dichloromethane (Run 7 in Table 1) cleanly gave the β-glycoside **12** in the satisfactory yield of 94% (Scheme 3). In contrast, silver triflate in dioxane (Run 8) gave rise to α-predominance (α : β≈70 : 30), a distinct promotor-dependent inversion, that was also observed in the glycosylation of **11** with the disaccharide donor **1b**.[9] The β-glycoside **12** was then subjected to hydroboration and subsequent *N*-acetylation as described for **7** to give **13** in 74% yield, whereby the presence of the β-D-gluco epimer could not be detected. *O*-Debenzoylation of **13** followed by removal of isopropylidene groups with 95% aqueous trifluoroacetic acid gave *N*-acetyl-β-D-mannosaminyl-(1→6)-D-galactose (**15**) in 81% yield. The structure of **15** was confirmed by ^{13}C NMR spectroscopy.

Scheme 4 depicts the synthetic pathway to methyl *N*-acetyl-β-D-mannosaminyl-(1→4)-α-D-glucopyranoside (**23**). Glycosidations of **1a** with partially protected methyl glucopyranosides with a free C-4 hydroxyl group were somewhat troublesome because of the low reactivity of the secondary hydroxyl function. After



Scheme 3.



Scheme 4.

much attempts shown in Table 1, the $\beta(1\rightarrow4)$-glycoside (**18**) could be secured in 55% yield (Run 13 in Table 1) by the use of methyl 2,3,6-tri-*O*-benzyl-α-D-glucopyranoside (**16**)[18] as an acceptor and silver carbonate-iodine as the promotor, whilst methyl 2,3,6-tri-*O*-benzoyl-α-D-glucopyranoside (**17**)[19] afforded multi-component mixtures in all the cases tested (Runs 9—11). Other glycosylation catalysts, such as silver oxide, silver perchlorate, or the allegedly highly superior[20] silver silicate were noneffective (Runs 14—16).

Under the conditions of Run 13, i.e. glycosylation of **16** with two molar equivalents of **1a** and Ag_2CO_3 in dichloromethane, substantial amounts of 1-hydroxy derivative **19** was generated, its identity being established by its conversion into the 1-acetate **20α**, that in turn was unequivocally identified by comparison with an authentic sample prepared by reaction of **1a** with sodium acetate in dioxane. Hydroboration of **18** was carried out as for **6**→**7**, yet proceeded in an essentially stereospecific manner, to provide the protected *N*-acetyl-β-D-mannosaminide (**21**) in a yield of 81%. Subsequent debenzoylation readily gave **22** (96% yield), which was catalytically hydrogenated over palladium/carbon to quantitatively afford desired methyl *N*-acetyl-β-D-mannosaminyl-(1→4)-α-D-glucopyranoside (**23**).

The concise, practical route reported here for the chemical synthesis of methyl or glycosyl *N*-acetyl-β-D-mannosaminides, as of now, appears to be the most straightforward methodology for the construction of heterooligosaccharides with a terminal β-D-mannosamine unit; it can be expected to find application for the immunologically relevant repeating units of *Streptococcus pneumoniae*-derived capsular polysaccharide and a series of others, some of which we hope to report in due course.

Experimental

General. Melting points were determined on a Yamato MP-1 apparatus and are uncorrected. Spectral data were recorded on the following instruments; IR; Jasco IR-810 spectrophotometer; $[\alpha]_D$: Jasco DIP-180 digital polarimeter; MS: JMS D-100 Spectrometer; ^{1}H NMR: Varian EM-390 (90 MHz), VXR-300 (300 MHz), or XL-400 (400 MHz) spectrometers in chloroform-*d* solution unless otherwise noted. ^{1}H-^{1}H and ^{1}H-^{13}C shift correlated 2D NMR and ^{13}C NMR: Varian VXR-300 or XL-400 spectrometer. TLC was carried out on silica gel 60 F_{254} (Merck Art. 5735) developed with the same solvent systems as described for column chromatography in the individual experimental section. The spots were detected by UV light (254 nm) or charring with 10% aq. sulfuric acid. Column chromatography was achieved on a silica gel 60 (Merck Art. 7734). Paper chromatography (PC) was carried out on Toyo filter paper No. 525 and detected with 0.2% ninhydrin in pyridine solution at 100 °C for 10 min.

Methyl 3,4,6-Tri-*O*-benzoyl-2-(benzoyloxyimino)-2-deoxy-β-D-*arabino*-hexopyranoside (6). (Benzoyloxyimino)glycosyl bromide **1a**[10] (135 mg, 0.2 mmol) was added to a mixture of methanol (0.08 ml, 2 mmol), silver carbonate (279 mg, 1 mmol), and iodine (51 mg, 0.2 mmol) in dry dichloromethane (2 ml) containing Molecular Sieves 3A (100 mg, powder). The mixture was stirred in the dark at room temperature for 3 days, whereafter all the educt had been consumed (TLC). Dilution with dichloromethane (10 ml), filtration through Celite, consecutive washing of the filtrate with saturated aq. $NaHCO_3$ (10 ml) and water (3×10 ml), drying (Na_2SO_4) and evaporation to dryness in vacuo gave a residue which was eluted from a silica-gel column with toluene-ethyl acetate (8:1). The major fraction was concentrated and crystallized from diethyl ether–pentane: 116 mg (93%) of

6; mp 57—65 °C (decomp); $[\alpha]_D^{20}$—42.8° (*c* 1.0, $CHCl_3$); ^1H NMR (400 MHz) δ=3.70 (3H, s, CH_3), 4.51 (1H, m, H-5), 4.77 (1H, dd, H-6a), 4.84 (1H, dd, H-6b), 5.92 (1H, dd, H-4), 5.93 (1H, s, H-1), 6.25 (1H, d, H-3), 7.3—8.1 (aromatic H); $J_{3,4}=J_{4,5}=J_{5,6a}=5.5$, $J_{5,6b}=7.0$, $J_{6a,6b}=11.5$ Hz; ^{13}C NMR (100 MHz) δ=57.02 (OMe), 64.64 (C-6), 68.42 (C-3), 68.61 (C-4), 73.24 (C-5), 93.98 (C-1), 128.2—133.7 (phenyl C), 156.56 (C-2), 162.29, 164.52, 164.74, and 165.82 (benzoyl C=O).

Found: C, 67.09; H, 4.61; N, 2.36%. Calcd for $C_{35}H_{29}NO_{10}$: C, 67.41; H, 4.69; N, 2.25%.

Methyl 2-Acetamido-3,4,6-tri-*O*-benzoyl-β-D-mannopyranoside (7). A 1 M solution of diborane in tetrahydrofuran (15.5 ml) was added to a solution of **6** (807 mg, 1.3 mmol) in tetrahydrofuran (15 ml) at −10 °C under atmosphere of nitrogen. The mixture was stirred at −10 °C for 0.5 h and at ambient temperature for 2 h. Excess reductant was quenched with methanol (15 ml) followed by addition of acetic anhydride (8 ml) for *N*-acetylation. After stirring for 1 h at ambient temperature, the mixture was passed through a basic resin (Amberlite IR-45), and washed with methanol. The eluate was concentrated in vacuo and the residue was purified by elution from a silica-gel column with chloroform-ethyl acetate (1 : 1). The major fraction was concentrated and the residue crystallized from ethyl acetate-diethyl ether (1:2)-pentane to give 622 mg (88%) of **7**: mp 95—105 °C; $[\alpha]_D^{22}$ −55.8 ° (*c* 0.5, $CHCl_3$); IR (KBr) 3450, 3380 cm^{-1} (NH); ^1H NMR (400 MHz) δ=2.03 (3H, s, $COCH_3$), 3.55 (3H, s, OCH_3), 4.11 (1H, td, H-5), 4.57 (1H, dd, H-6a), 4.64 (1H, dd, H-6b), 4.79 (1H, d, H-1), 4.98 (1H, td, H-2), 5.47 (1H, dd, H-4), 5.87 (1H, d, NH), 7.3—8.1 (aromatic H); $J_{1,2}=2.0$, $J_{2,3}=4.0$, $J_{2,NH}=8.5$, $J_{3,4}=9.5$, $J_{4,5}=9.0$, $J_{5,6a}=6.0$, $J_{5,6b}=3.5$, $J_{6a,6b}=12.0$ Hz; ^{13}C NMR (100 MHz) δ=23.38 ($COCH_3$), 50.19 (C-2), 57.15 (OCH_3), 63.46 (C-6), 67.45 (C-4), 71.92 (C-3), 72.60 (C-5), 100.12 (C-1), 128.2—133.5 (phenyl C), 165.32, 165.53, and 165.86 (3×C=O), 170.28 (NHCO).

Found: C, 65.70; H, 5.35; N, 2.84%. Calcd for $C_{30}H_{29}NO_9$: C, 65.80; H, 5.34; N, 2.56%.

On concentration of the minor fraction, dissolution of the residue in diethyl ether, and addition of pentane, β-D-gluco isomer **10** was obtained in a yield of 9.4 mg (1.3%): mp 80—88 °C; $[\alpha]_D^{22}$ +8.8° (*c* 0.25, $CHCl_3$); ^1H NMR (90 MHz) δ=1.85 (3H, s, $COCH_3$).

Methyl 2-Acetamido-2-deoxy-β-D-mannopyranoside (8). A solution of **7** (212 mg, 0.39 mmol) in 0.05 M methanolic sodium methoxide (20 ml) was stirred at ambient temperature for 20 h and was subsequently neutralized with a dry acidic resin (Dowex 50W×8) and filtered. The filtrate was evaporated to dryness and the residue was partitioned between dichloromethane (30 ml) and water (30 ml). The aqueous layer was separated, washed with dichloromethane (2×40 ml), and concentrated to dryness. The residue was purified by elution from a silica-gel column with chloroform-methanol (1 : 1), followed by concentration and crystallization from methanol-diethyl ether to give 71 mg (74%) of **8** as 1/2 hydrate: mp 123—127 °C; $[\alpha]_D^{23}$−70° (*c* 0.25, H_2O; lit,[14] $[\alpha]_D^{24}$ −68 °(*c* 1.5, H_2O)); ^1H NMR (D_2O, 400 MHz) δ=1.95 (3H, s, $COCH_3$), 3.29 (1H, td, H-5), 3.29 (3H, s, OCH_3), 3.40 (1H, dd, H-4), 3.69 (1H, dd, H-3), 3.70 (1H, dd, H-6a), 3.80 (1H, dd, H-6b), 4.37 (1H, dd, H-2), 4.58 (1H, d, H-1); $J_{1,2}=1.5$, $J_{2,3}=4.5$, $J_{3,4}=J_{4,5}=9.5$, $J_{5,6a}=5.0$, $J_{5,6b}=2.5$, $J_{6a,6b}=12.0$ Hz; ^{13}C NMR (D_2O, 100 MHz), δ=22.82 ($COCH_3$), 53.83 (C-2), 57.81 (OCH_3), 61.24 (C-6), 67.60 (C-4), 72.83 (C-3), 77.22 (C-5), 101.24 (C-1), 176.24 (NHCO); $J_{C1,H1}=163.6$ Hz.

Found: C, 44.23; H, 7.22; N, 5.62%. Calcd for $C_9H_{17}NO_6$ 1/2H_2O: C, 44.26; H, 7.43; N, 5.73%.

The monohydrate of **8** was also isolated in a yield of 13 mg (14%) along with the 1/2 hydrate; Found: C, 42.84; H, 7.61; N, 5.40%. Calcd for $C_9H_{17}NO_6$ H_2O: C, 42.68; H, 7.56; N, 5.53%.

2-Amino-2-deoxy-D-mannopyranose Hydrochloride (9). Methyl *N*-acetyl-β-D-mannosaminide (**8**) 1/2 hydrate (30 mg, 0.124 mmol) was dissolved in 1 M HCl (10 ml) and heated at 95 °C for 2 h. After concentration of the solution, the residue crystallized from methanol-diethyl ether to afford 27 mg (quantitative yield) of **9** as colorless crystals: mp 173—175 °C (decomp); $[\alpha]_D^{24}$−4.2° (*c* 0.5, H_2O), (lit,[21] mp 178—180 °C, $[\alpha]_D^{23}$−3.0° (*c* 2.0, H_2O)); PC (*n*-BuOH-pyridine-H_2O, 6 : 4 : 3 v/v): R_{Glc}=0.73 (cf., authentic D-Man*p*N HCl: R_{Glc}=0.73, D-Glc*p*N HCl: R_{Glc}=0.68).

6-*O*-[3,4,6-Tri-*O*-benzoyl-2-(benzoyloxyimino)-2-deoxy-β-D-*arabino*-hexopyranosyl]-1,2 : 3,4-di-*O*-isopropyridene-α-D-galactopyranose (12). A mixture of diacetonegalactose (**11**)[17] (573 mg, 2.2 mmol), silver carbonate (2.76 g, 10 mmol), iodine (508 mg, 2.0 mmol), and (benzoyloxyimino)glycosyl bromide **1a** (1.35 g, 2.0 mmol) in dry dichloromethane (20 ml) with Molecular Sieves 3A (2.0 g, powder) was stirred in the dark at ambient temperature for 3 days. Subsequent dilution with dichloromethane (50 ml), filtration through celite, washing of the filtrate with 1 M aqueous $Na_2S_2O_3$ (50 ml), water (50 ml), saturated aqueous $NaHCO_3$ (50 ml), and water (3×100 ml) was followed by drying (Na_2SO_4) and evaporation to dryness. The residue was eluted through a silica-gel column with toluene-ethyl acetate (6 : 1). Concentration of the major fraction, followed by crystallization from diethyl ether-pentane gave 1.61 g (94%) of **12**: mp 83—86 °C; $[\alpha]_D^{22}$ −95.6° (*c* 0.5, $CHCl_3$); ^1H NMR (400 MHz) δ=1.27, 1.28, 1.35, and 1.40 (each 3H, s, 2×Me_2C), 3.90 (1H, dd, H-6a), 4.04 (1H, td, H-5), 4.12 (1H, dd, H-4), 4.24 (1H, dd, H-6b), 4.28 (1H, dd, H-2), 4.47 (1H, m, H-5′), 4.54 (1H, dd, H-3), 4.84 (2H, m, H-6′a,b), 5.46 (1H, d, H-1), 5.92 (1H, t, H-4′), 6.09 (1H, s, H-1′), 6.25 (1H, d, H-3′), 7.3—8.2 (aromatic H); $J_{1,2}=5.0$, $J_{2,3}=2.5$, $J_{3,4}=8.0$, $J_{4,5}=2.0$, $J_{5,6a}=6.8$, $J_{5,6b}=5.5$, $J_{6a,b}=9.7$, $J_{3',4'}=J_{4',5'}=5.3$ Hz; ^{13}C NMR (100 MHz) δ=24.32, 24.89, 25.88, and 25.96 (2×Me_2C), 64.55 (C-6′), 66.74 (C-5), 68.65 (C-3′), 68.86 (C-4′ and 6), 70.45 (C-2), 70.60 (C-3), 70.89 (C-4), 73.03 (C-5′), 93.19 (C-1′), 96.22 (C-1), 108.65 and 109.45 (2×$Me_2\underline{C}$), 128.0—134.0)phenyl C), 156.21 (C-2′), 162.68, 164.70, 164.92, and 165.91 (4×C=O).

Found: C, 64.60; H, 5.29; N, 1.59%. Calcd for $C_{46}H_{45}NO_{15}$: C, 64.86; H, 5.32; N, 1.64%.

6-*O*-(2-Acetamido-3,4,6-tri-*O*-benzoyl-2-deoxy-β-D-mannopyranosyl)-1,2 : 3,4-di-*O*-isopropylidene-α-D-galactopyranose (13). A solution of the disaccharide **12** (426 mg, 0.5 mmol) in dry tetrahydrofuran (6 ml) was treated with a 1 M solution of diborane in tetrahydrofuran (6 ml) as described for **6**→**7**. Termination with methanol (6 ml) and subsequent *N*-acetylation with acetic anhydride (3 ml) followed by processing of the mixture as described for **7** gave a syrup, which crystallized from ethyl acetate-diethyl ether (1 : 2)-pentane providing 288 mg (74%) of **13**: mp 171—173 °C; $[\alpha]_D^{22}$ −66.1° (*c* 0.5, $CHCl_3$); ^1H NMR (90 MHz) δ=1.29 and 1.40 (each 6H, s, 2×Me_2C), 1.98 (3H, s, $COCH_3$), 4.27 (1H, dd, H-2), 4.53 (1H, dd, H-3), 4.55—4.70 (2H, m, H-6a,b), 4.90 (1H, td, collapsed to dd on deuteration), 7.2—8.1 (aromatic H), 3.7—4.2 (other protons); $J_{1,2}=5.1$, $J_{2,3}=2.4$, $J_{3,4}=7.8$, $J_{1',2'}=3.0$, $J_{2',3'}=3.6$,

$J_{2',NH}$=8.4, $J_{3',4'}$=7.2, $J_{4',5'}$=7.8 Hz.

Found: C, 63.23; H, 5.81; N, 1.64%. Calcd for $C_{41}H_{45}NO_{14}$: C, 63.48; H, 5.85; N, 1.81%.

6-*O*-(2-Acetamido-2-deoxy-β-D-mannopyranosyl)-D-galactopyranose (15). A solution of **13** (343 mg, 0.44 mmol) in 0.05 M methanolic sodium methoxide (20 ml) was stirred at ambient temperature for 20 h. Subsequent neutralization (Dowex 50 W×8), filtration through Celite, and evaporation to dryness gave a residue, which was eluted through a silica-gel column with chloroform–methanol (4:1). Concentration of the major fraction gave debenzoylated product **14** as a colorless syrup (200 mg, quantitative), which was subjected to further deblocking of the isopropylidene groups without further purification.

The syrup was dissolved in 95% aqueous trifluoroacetic acid (3 ml) and stirred at ambient temperature for 20 min. Evaporation of the mixture was followed by co-evaporation with methanol to give a residue, which crystallized from ethanol–diethyl ether affording 140 mg (81%) of **15** as a monohydrate: mp 170 °C (decomp, with sintering at 115 °C): $[\alpha]_D^{21}$ −14° (*c* 0.25, H_2O): ^{1}H NMR (D_2O, 90 MHz) δ=1.90 (3H, s, $COCH_3$), 7.73 (1H, d, NH); ^{13}C NMR (D_2O, 25.4 MHz) δ=22.8 ($CO\underline{C}H_3$), 53.9 (C-2′), 61.3 (C-6′), 67.6 (C-4′), 69.1 and 69.6 (C-6 for respective anomers), 77.3 (C-5′), 93.2 (C-1 for α-anomer), 97.3 (C-1 for β-anomer), 101.6 (C-1′), 176.5 (NHCO). The anomeric carbon signals of the reducing end suggested that the ratio of the anomers was estimated as α:β=ca. 2:3.

Found: C, 41.68; H, 6.50; N, 3.38%. Calcd for $C_{14}H_{25}NO_{11}$ H_2O: C, 41.89; H, 6.78; N, 3.49%.

Methyl 4-*O*-[3,4,6-Tri-*O*-benzoyl-2-(benzoyloxyimino)-2-deoxy-β-D-*arabino*-hexopyranosyl]-2,3,6-tri-*O*-benzyl-α-D-glucopyranoside (18). Silver carbonate (138 mg, 0.5 mmol) and iodine (25 mg, 0.1 mmol) were added to a stirred solution of methyl 2,3,6-tri-*O*-benzyl-α-D-glucopyranoside (**16**)[18] (93 mg, 0.2 mmol) in dry dichloromethane (1 ml) containing Molecular Sieves 3A (100 mg, powder) and then stirred in the dark for 1 h under atmosphere of nitrogen. A solution of (benzoyloxyimino)glycosyl bromide **1a** (67 mg, 0.1 mmol) in dry dichloromethane (1 ml) was added and the mixture was further stirred at ambient temperature for 2 days. The mixture was diluted with dichloromethane (10 ml) and filtered through Celite. The filtrate was washed with saturated aqueous $NaHCO_3$ (10 ml) and water (3×15 ml). Drying (Na_2SO_4) and evaporation in vacuo gave a syrup, which was eluted through a silica-gel column with toluene–ethyl acetate (6:1). The major fraction eluted first was concentrated and the residue crystallized from diethyl ether–pentane to give 58 mg (55%) of **18**: mp 57—59 °C; $[\alpha]_D^{20}$+21.8° (*c* 0.5, $CHCl_3$); ^{1}H NMR (90 MHz), δ=3.29 (3H, s, OCH_3), 4.98 (1H, s, H-1), 5.92 (1H, t, H-4′), 6.22 (1H, d, H-3′), 6.74 (1H, s, H-1′), 3.4—4.9 (15H, other protons), 6.9—8.2 (aromatic H); $J_{3',4'}$=$J_{4',5'}$=5.4 Hz.

Found: C, 70.51; H, 5.44; N, 1.33%. Calcd for $C_{62}H_{57}NO_{15}$: C, 70.69; H, 5.20; N, 1.30%.

The minor fraction eluted next was treated as above to give 10.5 mg (18%) of **19** as 1/2 hydrate: mp 177—179 °C (decomp); $[\alpha]_D^{20}$ +32.4° (*c* 0.25, $CHCl_3$); IR (KBr) 3400 cm^{-1} (OH); ^{1}H NMR (DMSO-d_6, 90 MHz), δ=4.5—4.7 (2H, m, H-6a,b), 4.75 (1H, m, H-5), 5.87 (1H, t, H-4), 6.36 (1H, d, H-3), 6.50 (1H, t, H-1), 8.27 (1H, d, OH, disappeared on deuteration), 7.3—8.2 (aromatic H); $J_{1,OH}$=6.0, $J_{3,4}$=$J_{4,5}$=10.5 Hz.

Found: C, 66.29; H, 4.42; N, 2.19%. Calcd for $C_{39}H_{27}NO_{10}$ 1/2H_2O: C, 66.02; H, 4.56; N, 2.26%.

Acetylation of **19** with acetic anhydride–pyridine in a usual manner gave the corresponding 1-acetate **20α** which proved to be identical with the product obtained by acetylation of **1a** as described below.

1-*O*-Acetyl-3,4,6-tri-*O*-benzoyl-2-(benzoyloxyimino)-2-deoxy-α-D-*arabino*-hexopyranose (20α) and Its β-Anomer (20β). A mixture of (benzoyloxyimino)glycosyl bromide **1a** (1.0 g, 1.5 mmol), sodium acetate (369 mg, 4.5 mmol), and Molecular Sieves 3A (1 g, powder) in dry dioxane (20 ml) was stirred at ambient temperature for 3 days. The resulting mixture was diluted with dichloromethane (50 ml) and filtered through Celite. The filtrate was washed with water (3×50 ml), dried (Na_2SO_4), and evaporated to dryness. Elution of the residue through a silica-gel column with toluene–ethyl acetate (6:1) provided both anomeric isomers, which crystallized from diethyl ether–pentane to afford 365 mg (37%) of **20α** and 200 mg (20%) of the corresponding β-anomer **20β**.

20α: Mp 75—77 °C; $[\alpha]_D^{22}$ +53.4° (*c* 0.3, $CHCl_3$); ^{1}H NMR (90 MHz) δ=2.25 (3H, s, $COCH_3$), 4.4—4.7 (2H, m, H-6a,b), 4.68 (1H, m, H-5), 5.98 (1H, dd, H-4), 6.44 (1H, d, H-3), 7.2—8.2 (H-1 and aromatic H); $J_{3,4}$=9.6, $J_{4,5}$=9.0 Hz.

Found: C, 66.46; H, 4.49; N, 2.18%. Calcd for $C_{36}H_{29}NO_{11}$: C, 66.36; H, 4.49; N, 2.15%.

20β: Mp 64—66 °C (with sintering at 60 °C); $[\alpha]_D^{23}$ −43.2° (*c* 0.5, $CHCl_3$); ^{1}H NMR (90 MHz) δ=4.5—5.0 (3H, m, H-5 and 6a,b), 5.88 (1H, dd, H-4), 6.28 (1H, d, H-3), 7.2—8.2 (H-1 and aromatic H); $J_{3,4}$=5.1, $J_{4,5}$=4.8 Hz.

Found: C, 66.74; H, 4.46; N, 2.21%. Calcd for $C_{36}H_{29}NO_{11}$: C, 66.36; H, 4.49; N, 2.15%.

Methyl 4-*O*-(2-Acetamido-3,4,6-tri-*O*-benzoyl-2-deoxy-β-D-mannopyranosyl)-2,3,6-tri-*O*-benzyl-α-D-glucopyranoside (21). A solution of **18** (618 mg, 0.59 mmol) in dry tetrahydrofuran (8 ml) was treated with a 1 M solution of diborane in tetrahydrofuran (7.1 ml) as described for **6**→**7**. Subsequent acetylation with acetic anhydride (4 ml) followed by processing of the mixture as described for **7** gave 461 mg (81%) of syrupy **21**. Crystallization from diethyl ether afforded 411 mg of **21** as colorless prisms: mp 163—164 °C (decomp); $[\alpha]_D^{22}$ −21.2° (*c* 0.25, $CHCl_3$); IR (KBr) 3430 (NH), 1720 (ester C=O), 1685 cm^{-1} (amide C=O); ^{1}H NMR (300 MHz) δ=1.83 (3H, s, $COCH_3$), 3.37 (3H, s, OCH_3), 3.48 (1H, m, H-5′), 3.49 (1H, dd, H-2), 3.65—3.75 (3H, m, H-5 and H-6a,b), 3.88 (1H, t, H-3), 4.01 (1H, t, H-4), 4.24 (1H, dd, H-6′a), 4.39 (1H, dd, H-6′b), 4.55, 4.72, and 4.91 (each 2H, dd, 3×$C\underline{H}_2$Ph), 4.61 (1H, d, H-1), 4.81 (1H, td, H-2′), 4.86 (1H, d, H-1′), 5.12 (1H, dd, H-3′), 5.49 (1H, t, H-4′), 5.70 (1H, d, NH), 7.2—8.0 (aromatic H); $J_{1,2}$=3.5, $J_{2,3}$=$J_{3,4}$=$J_{4,5}$=9.3, $J_{1',2'}$=1.5, $J_{2',NH}$=8.7, $J_{2',3'}$=4.0, $J_{3',4'}$=$J_{4',5'}$=10.0, $J_{5',6'a}$=5.0, $J_{5',6'b}$=3.5, $J_{6'a,b}$=12.0 Hz; ^{13}C NMR (75 MHz) δ=23.05 ($CO\underline{C}H_3$), 51.09 (C-2′), 55.29 (OCH_3), 63.25 (C-6′), 67.26 (C-4′), 68.45 (C-6), 69.35 (C-5), 72.34 (C-5′) 72.43 (C-3′), 73.44, 73.56, and 75.00 (3×$\underline{C}H_2$Ph), 76.51 (C-4), 79.38 (C-2), 80.41 (C-3), 98.27 (C-1), 98.87 (C-1′), 126.6—139.2 (aromatic C), 165.64, 165.64, and 165.90 (3×C=O), 170.34 (NHCO).

Found: C, 70.00; H, 5.87; N, 1.42%. Calcd for $C_{57}H_{57}NO_{14}$: C, 69.85; H, 5.86; N, 1.43%.

Methyl 4-*O*-(2-Acetamido-2-deoxy-β-D-mannopyranosyl)-2,3,6-tri-*O*-benzyl-α-D-glucopyranoside (22). A 0.05 M solution of sodium methoxide in dry methanol (18 ml) was added to **21** (352 mg, 0.36 mmol). The solution was stirred at

ambient temperature for 20 h, neutralized with acidic resin (Dowex 50W×8), and filtered through Celite. The filtrate was concentrated in vacuo to give a residue, which was eluted through a silica-gel column with chloroform–methanol (8:1). Concentration of the major fraction, followed by recrystallization from methanol–pentane gave 210 mg (87%) of **22** as colorless needles: mp 170—172 °C; $[\alpha]_D^{22}$ +14.2° (*c* 0.5, CH_3OH); IR (KBr) 3400—3300 (NH and OH), 1640 cm^{-1} (amide C=O); ^1H NMR (DMSO-d_6, 90 MHz) δ=1.83 (3H, s, $COCH_3$), 3.29 (3H, s, OCH_3), 7.04 (1H, s, NH), 7.1—7.5 (aromatic H), 2.8—5.1 (other protons).

Found: C, 64.98; H, 6.89; N, 2.04%. Calcd for $C_{36}H_{45}NO_{12}$: C, 64.75; H, 6.79; N, 2.10%.

Methyl 4-*O*-(2-Acetamido-2-deoxy-β-D-mannopyranosyl)-α-D-glucopyranoside (23). A solution of **22** (172 mg, 0.26 mmol) in acetic acid (10 ml) was hydrogenated in the presence of 10% palladium on carbon (85 mg) under atmosphere of hydrogen (3.45×10^5 Pa) for 24 h. The mixture was filtered through Celite and the filtrate was concentrated in vacuo to give a syrup, which was purified by elution from a silica-gel column with chloroform–methanol (1:2). The major fraction was concentrated and the residual solid was washed with diethyl ether to give 110 mg (quantitative) of **23** as 1/2 hydrate: mp 190 °C (decomp, with sintering at 110 °C); $[\alpha]_D^{23}$ +45.2° (*c* 0.25, H_2O); ^{13}C NMR (D_2O, 25.4 MHz) δ=22.8 ($CO\underline{C}H_3$), 54.1 (C-2′), 55.8 (OCH_3), 60.9 and 61.3 (C-6 and 6′), 67.5 (C-4′), 70.8 (C-2), 71.9, 72.5, and 72.8 (C-3, C-3′, and C-5), 77.4 (C-5′), 79.6 (C-4), 99.2 (C-1), 100.2 (C-1′), 176.4 (CONH).

Found: C, 44.62; H, 7.13; N, 3.16%. Calcd for $C_{15}H_{27}NO_{11}$ $1/2H_2O$: C, 44.33; H, 6.94; N, 3.45%.

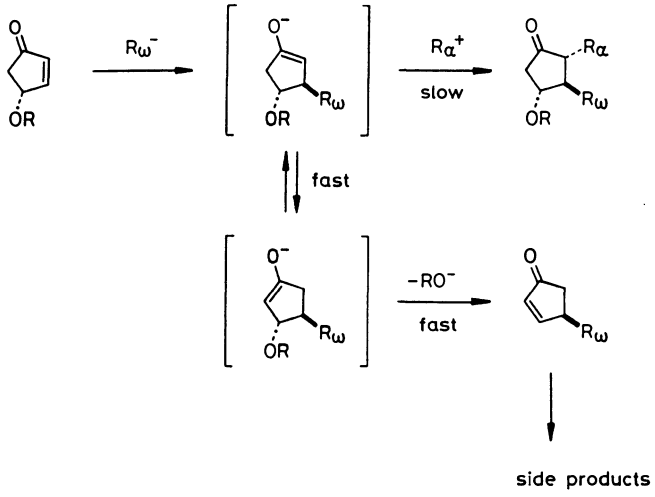
Three-Component Coupling Synthesis of Prostaglandins: The Aldol Route[1)]

Masaaki SUZUKI, Toshio KAWAGISHI, Akira YANAGISAWA, Takehiko SUZUKI, Noriaki OKAMURA,[2)] and Ryoji NOYORI*
Department of Chemistry, Nagoya University, Chikusa, Nagoya 464
(Received November 13, 1987)

A one-pot, high yield construction of the whole prostaglandin (PG) skeleton is accomplishable by combination of the copper-mediated conjugate addition of an ω side-chain unit to a 4*R*-oxygenated 2-cyclopentenone derivative and aldol condensation of the in situ generated enolate with an α side-chain aldehyde. Subsequent removal of the 7-hydroxyl group from the adducts and deblocking of the protective groups give PGs of E series. PGE_1 has been prepared in 56% overall yield through the five-step sequence. Selective transformation of the PGE to PGD structure can be realized simply by appropriate selection of the hydroxyl protective groups in the five-membered ring and ω side-chain units. The vicinal carba-condensation using methyl 6-formyl-5-hexynoate as the α side-chain aldehyde unit followed by deoxygenation from the aldol products gives the 5,6-didehydro-PGE_2 derivatives which serve as key intermediates in the general synthesis of various natural PGs. An efficient method for resolution of 4-hydroxy-2-cyclopentenone is also described.

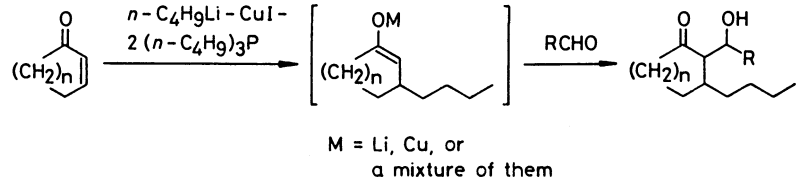
The prostaglandin (PG) skeleton is constituted by the oxygenated cyclopentanone ring and the seven-and eight-carbon (α and ω, respectively) side-chains. Obviously, the three-component coupling process, viz., consecutive nucleophilic/electrophilic introduction of the two side-chain units to (*R*)-4-hydroxy-2-cyclopentenone derivatives, is regarded as the simplest converging synthesis (Scheme 1).[3)] One may anticipate that well-known organocuprate conjugate addition of the ω side-chain unit to the enone followed by reaction with alkyl halides completes the desired vicinal carba-condensation.[4,5)] However, extensive studies along this line have revealed that such direct vicinal carba-condensation is not easy to achieve.[5p,6,7)] The difficulty is presumably attributable to the complex nature of the reaction system which causes a facile double-bond migration of the initially formed enolate,[3,5p)] causing concomitant dehydration to give the cyclopentenone products. The slow alkylation reaction cannot compete with such side sequences.[8)] However, use of highly reactive electrophiles is capable of suppressing the undesired reaction and the successful trapping has indeed been achieved with acyl chlorides[5n,o,9)] and ketene bis(methylthio)acetal monoxide, a strong Michael acceptor.[5p)] The aldol route is even more attractive.[5l,m,q-v,10)] Stork and Isobe thus employed very reactive formaldehyde as a trapping agent to introduce hydroxymethyl group at C-2 regiospecifically,[5k)] and constructed the full prostanoic acid skeleton by supplementing a six-carbon unit forming the full α side chain and the rectification of the oxidation state of the functional groups. They synthesized natural $PGF_{2\alpha}$ in 9% overall yield from a racemic 4-cumyloxy-2-cyclopentenone.[5k)] We intended to realize a one-pot construction of the full PG skeleton by the aldol strategy.[11)]



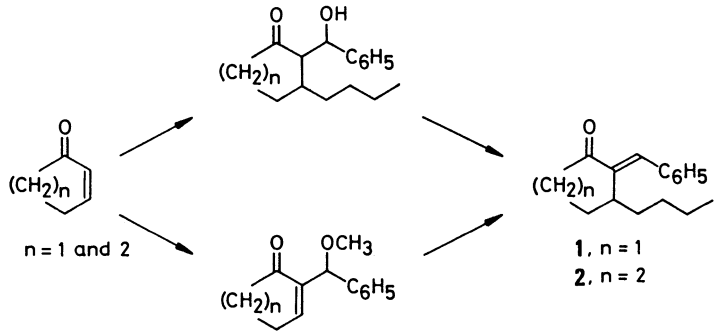
Scheme 1.

Results and Discussion

A. Vicinal Carba-Condensation of α,β-Unsaturated Ketones via the Tandem Organocopper Conjugate Addition/Aldol Reaction. We recently found a new recipe for the organocopper conjugate addition to α,β-unsaturated ketones using an organolithium (RLi), copper(I) iodide, and tributylphosphine in 1:2—3 mole ratio.[12)] The organocopper reagents undergo the conjugate addition to enones smoothly by employing 1:1 R/enone ratio and, in addition, the regio-defined enolate intermediates can be trapped effectively with equimolar amounts of aldehydes (Scheme 2). This stoichiometry-controlled, high-yield combination of the organometallic reagents and enone substrates, unlike under ordinary reaction conditions using excess organometallics, generates enolate species as only strong nucleophile present in the reaction system and, therefore, the latter reacts cleanly with one equivalent of the aldehyde trap, giving the aldol products. The results of the reaction of 2-cyclopentenone or -hexenone, the butylcopper reagent, and aldehydes are summarized in Table 1. The three-component joining effected with 1:1:1 molar ratio was general for a wide range of aldehydes including formaldehyde, simple alkanals, and α,β-unsaturated or aromatic aldehydes.



Scheme 2.



Scheme 3.

Table 1. Vicinal Carba-Condensation with α,β-Unsaturated Ketones via the Organocopper/Aldehyde Joining Process[a]

Entry	Enone	Aldehyde trapping	Aldol product Yield/%[b]
1	2-Cyclopentenone	Formaldehyde[c]	66[d]
2	2-Cyclopentenone	Butanal	98[e]
3	2-Cyclopentenone	2-Methylpropanal	93[e]
4	2-Cyclopentenone	2,2-Dimethylpropanal	71[e]
5	2-Cyclopentenone	Benzaldehyde	91[f]
6	2-Cyclopentenone	(*E*)-Cinnamaldehyde	94[f]
7	2-Cyclopentenone	2-Hexynal	72[f]
8	2-Cyclohexenone	Formaldehyde[c]	60[e]
9	2-Cyclohexenone	Acetaldehyde	91[f]
10	2-Cyclohexenone	Butanal	88[e]
11	2-Cyclohexenone	2-Methylpropanal	94[e]
12	2-Cyclohexenone	Benzaldehyde	96[f,g], 89
13	2-Cyclohexenone	(*E*)-Cinnamaldehyde	92[f]

a) The butylcopper phosphine complex was prepared in situ by mixing coppe(I) iodide, butyllithium, and tributylphosphine in 1:1:2 mole ratio at −78 °C in ether. The conjugate addition was conducted at −40 to −78 °C. Enolate trapping was carried out at −78 °C for 5—60 min. b) Yield after silica-gel column chromatography. c) Introduced with an argon stream after cracking of paraformaldehyde. d) A 59:1 stereomixture. e) A single isomer. f) A mixture of stereoisomers. g) Yield determined by ^{1}H NMR analysis.

Alkanals as the trapping agent tend to produce single coupling adducts, whereas acetaldehyde and aromatic or other α,β-unsaturated aldehydes give rise to a mixture of stereoisomers.

The two side chains are incorporated in the vicinal positions in a regiospecific manner via kinetically defined, nonequilibrating enolates. This is confirmed, for examples, by comparison of the samples of 2-benzylidene-3-butylcycloalkanones, **1** and **2**, derived from the corresponding aldols by dehydration and those prepared by an unambiguous method consisting of the combination reaction of α-alkoxyalkylation[13] and organocopper conjugate addition (Scheme 3). No α′,β-condensation products associated with possible enolate equilibration were detected in the reaction mixture.

B. Chiral Building Blocks. The optically active building blocks requisite for convergent PG synthesis are accessible in various ways.[3a] The ω side-chain alcohol having S configuration, **3**, is available by optical resolution,[14a] kinetic resolution by asymmetric epoxidation,[14b] or asymmetric reduction of the corresponding enone by chemical,[14c] or enzymatic[14d] method. The R cyclopentenone derivative, **6**, is obtainable by chemical[15a,b] or chromatographic resolution,[15c] transformation from D-tartaric acid ((2*S*,3*S*)-(−)-tartaric acid),[15d] chemical kinetic resolution of racemic 4-hydroxy-2-cyclopentenone,[15e] enzymatic kinetic resolution of the acetate,[15f] and asymmetric reduction of 2-cyclopentene-1,3-dione,[14c] etc. We now found that **6** was obtainable by efficient optical resolution of the racemate[16] using the resolving agent **9** derived from chrysanthemic acid.[17] Thus condensation of (±)-**6** with **9** in the presence of pyridinium *p*-toluenesulfonate gave the two diastereomeric mixture **10** in 99% yield based on **9**. The diastereomers separated by silica-gel column chromatography were subjected to hydrolysis in aqueous dioxane at 70 °C to give desired (*R*)-4-hydroxy-2-cyclopentenone (**6**) and its antipode in 88% and 82% of theory, respectively. No racemization was observed under these conditions. The resolving reagent **9** was recovered in >75% yield and could be recycled for the resolution precedure. The hydroxyl group of **6** was protected by a silyl or tetrahydropyranyl group by conventional methods[18]

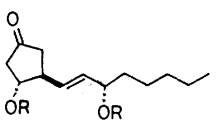
10

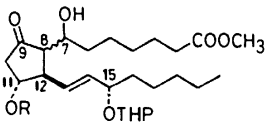
for the purpose of the organometallic operation.

C. A Short Synthesis of PGE_1 and PGD_1. When organocopper reagent formed from **4** was coupled with (*R*)-siloxy enone **7**, a single adduct **11** was obtained after aqueous work-up.[3a] The C-3/C-4 trans relationship was established simply by nonbonded interaction between the siloxy moiety and the entering organometallic. Encouraged by the clean trans stereochemistry induced in the conjugate addition step, we then moved to the aldehyde trapping of the enolate intermediate. The conjugate addition using the enone **8** and the organocopper reagent formed from the alkenyl iodide **5** was followed by aldol trapping of the enolate with one equivalent of methyl 6-formylhexanoate. As expected, the desired aldol **12** (a threo/erythro[19] mixture) possessing the whole PG framework was obtained in 83% yield.[20] The undesired β-elimination leading to the PGA type structure could not be observed. Removal of the C-7 hydroxyl group from **12** was accomplished via the enone **14** formed by dehydration with methanesulfonyl chloride and 4-(dimethylamino)pyridine (92% yield). Exposure of **14** to excess zinc dust in a 95:5 2-propanol-acetic acid mixture gave the saturated PGE_1 derivative **16** in 84% yield. Heating of **14** with tributyltin hydride in the presence of a catalytic amount of di-*t*-butyl peroxide increased the product yield up to 90%. Deblocking the tetrahydropyranyl protective groups gave PGE_1 methyl ester (**18**) in 92% yield. The spectroscopic and chromatographic behavior was identical with that of authentic PGE_1 methyl ester. Hydrolysis of the ester function by porcine liver esterase (86% yield)[22] completes the synthesis of natural PGE_1. Thus PGE_1 was synthesized in 56% overall yield through the five-step sequence from the starting enone **8**. PGE_1 possesses four asymmetric carbons. Here the absolute configuration at C-11 and C-15 is inherently determined at the stage of the starting enone and ω side-chain components, and the mutual trans relationship of the three ring substituents at C-11, C-12, and C-8 is established automatically through the vicinal carba-condensation and the following functional group manipulation.

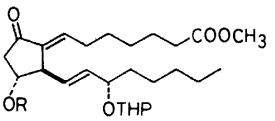
PGD_1 was also accessible by fundamentally the same strategy. PGD_1, like PGE_1, has the β-hydroxycyclopentanone structure but bears a hydroxyl group at C-9 and a keto function at C-11. The choice of proper hydroxyl protective groups in the starting five-membered ring and ω side-chain units allows ready arrangement of such functional groups. Trialkylsilyl protection of 4-hydroxy-2-cyclopentenone and tetrahydropyranyl blocking of the ω side-chain alcohol were the best choice in view of their different profiles of the removal conditions. Thus the vicinal carba-condensation of the enone **7** under our standard conditions by using **5** and methyl 6-formylhexanoate as side-chain components gave the aldol **13** (a threo/erythro[19] mixture) in 70% yield. Treatment of **13** with methanesulfonyl chloride and 4-(dimethylamino)pyridine gave the dehydration product **15** in 75% yield, which upon exposure to excess tributyltin hydride and di-*t*-butyl peroxide catalyst afforded **17** in 88% yield. The oxidation states of the C-9 and C-11 positions was easily rectified as follows. Requisite stereoselective reduction of the 9-keto group was accomplished with L-Selectride (lithium tri-*s*-butylborohydride) in THF to



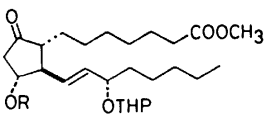
11, R = $Si(CH_3)_2$-*t*-C_4H_9



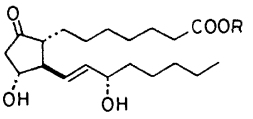
12, R = THP
13, R = $Si(CH_3)_2$-*t*-C_4H_9



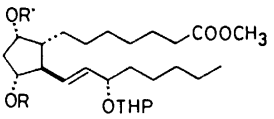
14, R = THP
15, R = $Si(CH_3)_2$-*t*-C_4H_9



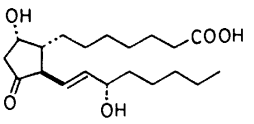
16, R = THP
17, R = $Si(CH_3)_2$-*t*-C_4H_9



18, R = CH_3
19, R = H



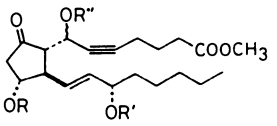
20, R = $Si(CH_3)_2$-*t*-C_4H_9; R' = H
21, R = $Si(CH_3)_2$-*t*-C_4H_9; R' = THP
22, R = H; R' = THP



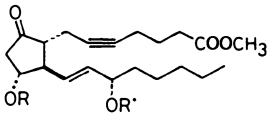
23

give the 9α alcohol **20** exclusively in 92% yield. After tetrahydropyranylation of 9-hydroxyl in **20** under standard conditions leading to **21** (94%), removal of the silyl protective group with tetrabutylammonium fluoride gave **22** in 84% yield. Alkaline hydrolysis of the methyl ester, Jones oxidation of the C-11 hydroxyl function, and final deblocking of the tetrahydropyranyl protective groups completed the synthesis of PGD_1 (**23**) as crystals in 61% overall yield from **22**. These three operations were conducted successively without purification of the intermediates. The ester hydrolysis at the stage of 9,15-*O*-bis(tetrahydropyranyl)-$PGF_{1\alpha}$, rather than the final step, turned out to be more appropriate in view of the instability of PGD_1 causing dehydration.

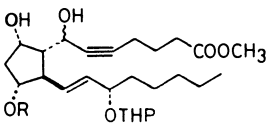
D. Synthesis of 5,6-Didehydro-PGE_2 Derivatives. Introduction of the unsaturation at the C-5 and C-6 positions (PG numbering) using methyl 6-formyl-5-hexynoate, an acetylenic aldehyde, as the α side-chain unit leads to a promising, general way to PGs. The tandem conjugate addition/aldol reaction was conducted by using the enone **7**, an (*E*)-alkenylcopper reagent derived from **4**, and methyl 6-formyl-5-hexynoate in ether to give the aldol adduct **24** (a 1 : 1 mixture of the C-7 epimers[23]) in 50% yield. This yield has been improved up to 83% by conducting the conjugate addition in THF, followed by addition of one equivalent of boron trifluoride etherate prior to the treatment with the aldehyde. Although attempts to remove the C-7 hydroxyl function in **24** by the above described dehydration/reduction procedure failed, the Barton deoxygenation[26] of secondary alcohols proved useful for this purpose. Thus treatment of the aldol **24** with thiobenzoyl chloride and 4-(dimethylamino)-pyridine afforded the thiobenzoate **26** in 71% yield, which upon heating at 50 °C with tributyltin hydride with a catalytic amount of di-*t*-butyl peroxide gave a single deoxygenated compound **28**[27] in 98% yield. The successful removal of the thiobenzoate moiety relies heavily on the presence of the 5,6-triple bond which effects propargylic resonance stabilization to the radical intermediate.[28] The acetylenic compound **28** acts as a key intermediate for synthesis of various naturally occuring PGs including prostacyclin.[3a]



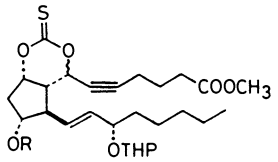
24, R = R′ = $Si(CH_3)_2$-*t*-C_4H_9; R″ = H
25, R = $Si(CH_3)_2$-*t*-C_4H_9; R′ = THP; R″ = H
26, R = R′ = $Si(CH_3)_2$-*t*-C_4H_9; R″ = C(=S)C_6H_5
27, R = $Si(CH_3)_2$-*t*-C_4H_9; R′ = THP; R″ = C(=S)C_6H_5



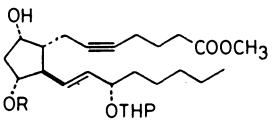
28, R = R′ = $Si(CH_3)_2$-*t*-C_4H_9
29, R = $Si(CH_3)_2$-*t*-C_4H_9; R′ = THP



30, R = $Si(CH_3)_2$-*t*-C_4H_9



31, R = $Si(CH_3)_2$-*t*-C_4H_9



32, R = $Si(CH_3)_2$-*t*-C_4H_9

This method also allows the preparation of PGD intermediates. The aldol **25** (a mixture of the C-7 epimers) was available by the vicinal carba-condensation of the silylated hydroxycyclopentenone **7** with equimolar amounts of the tetrahydropyranylated ω side-chain unit **5** and methyl 6-formyl-5-hexynoate in 65% yield. Application of the Barton deoxygenation procedure[26] to this aldol product gave **29** in 66% yield via the corresponding thiobenzoate **27**. Removal of the C-7 hydroxyl function in **25** was also realized via the cyclic thiocarbonate intermediate.[31] Thus reduction of the more polar isomer of **25** with sodium borohydride gave the diol **30** stereoselectively in 77% yield (9α : 9β=97.5 : 2.5). Treatment of **30** with 1,1′-thiocarbonyldiimidazole and 4-(dimethylamino)pyridine afforded the cyclic thiocarbonate **31** in 92% yield. Then exposure of **31** to tributyltin hydride and di-*t*-butyl peroxide followed by alkaline treatment gave the C-7 deoxygenated compound **32** in 77% yield. The same compound was also derived in 35% overall yield from the less polar isomer of **30** via the corresponding thiocarbonate intermediate. It should be added that reduction of the less polar isomer of **30** with sodium borohydride gave a mixture of the 9α and 9β alcohols in 54 and 14% yield, respectively.

This expeditious tandem conjugate addition/aldol reaction sequence is synthetically flexible enough to apply to the synthesis of a variety of natural and unnatural PG derivatives. A range of artificial PGs can be prepared by using the 7-hydroxyl group as trigger functionality. The aldol product **24** is an important synthetic intermediate of stable PGI_2 analogues, (7*R*)- and (7*S*)-fluoro-PGI_2.[3a,32] It should be added that **12**, **13**, and the 11,15-*O*-bis-silylated analogue serve as synthetic precursors of Δ^7-PGA_1, an artificial strong antineoplastic prostaglandin.[33]

Experimental

General. (a) Spectrometers: IR spectra were obtained with a JASCO IRA-1 spectrometer. NMR spectra were determined on a JEOL PMX-60, FX-90Q, Varian HA-100, or NEVA NV-21 spectrometer. Chemical shifts are reported as δ vaules in parts per million relative to tetramethylsilane (δ=0). Splitting patterns are indicated as s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet, and br means a broad

signal. Mass spectra (MS) were obtained with a JEOL D-10 mass spectrometer under an ionization potential of 75 eV. High-resolution mass spectra (HRMS) were recorded with a JEOL TMS-DX 300 spectrometer. Optical rotation was measured on a JASCO DIP-4 or DIP-181polarimeter. (b) Chromatography: R_f values on TLC were recorded on E. Merck precoated (0.25 mm) Silica Gel 60 F_{254} plates. The plates were sprayed with a solution of 2% *p*-anisaldehyde in 5% ethanolic sulfuric acid and then heated until the spots became clearly visible. Column chromatography was conducted under Florisil (Nakarai, M7P4145), silica gel (E. Merck, 7734, 70—230 mesh, or Fuji Devison, BW-80, 80—200 mesh), or deactivated silica gel (E. Merck) by mixing with water (6—9 wt%). Column chromatography at low temperature (0 °C) was conducted using a glass column equipped with a cold jacket. High-performance liquid chromatography (HPLC) was conducted on Waters 6000A instrument using a column packed with Develosil 100-5 (3.8 mmϕ×250 mm). (c) Solvents: Dry ether, THF, toluene, and benzene were prepared by distillation over Na-benzophenone ketyl under argon. Dry dichloromethane was prepared by distillation over P_4O_{10}. Dry hexamethylphosphoric triamide (HMPA), *N,N*-dimethylformamide (DMF), acetonitrile, *t*-C_4H_9OH, and dimethyl sulfoxide (DMSO) were prepared by distillation from CaH_2. The solution obtained after extraction was dried over anhydrous Na_2SO_4 or $MgSO_4$ and evaporated by a rotary evaporator under aspirator pressure. (d) Reagents and materials: Copper(I) iodide (CuI) (Nakarai) was continuously extracted with THF in a Soxhlet extractor overnight and dried in vacuo at room temperature for several hours. Tributylphosphine (Nakarai) was purified by distillation before use. *n*-C_4H_9Li (Mitsuwa or Nakarai), *t*-C_4H_9Li (Aldrich), and a THF solution of L-Selectride (Aldrich) were used directly from the bottles. Molarity of alkyllithiums were determined by titration[34] and stored at 4 °C. Zn powder was used after treatment with 2% HCl aqueous solution followed by drying in vacuo. Formaldehyde was generated from paraformaldehyde (excess) by flash heating with a heat gun and introduced into a enolate system with a stream of agron. Jones reagent was prepared by mixing CrO_3 (26.72 g) and concd sulfuric acid (23 mL) in water (50 mL). Methyl 6-formylhexanoate was prepared by ozonolysis of 1-methoxycycloheptene[35] or cycloheptene.[36] Ozonolysis of 1-methoxycycloheptene: Ozone was introduced into a mixture of 1-methoxycycloheptene (24 g, 0.19 mol) and methanol (150 mL) at −78 °C for 3 h. Remaining ozone dissolved in the solution was excluded by introducing argon into the mixture for 10 min at this temperature. To this was added dimethyl sulfide (20 mL) at −78 °C and then the mixture was slowly warmed up to room temperature over a period of 2 h. After stirring for 2 days at room temperature, the mixture was concentrated under reduced pressure and the residual oil was dissolved in a 1 : 1 mixture of ether and petroleum ether (100 mL) and the mixture was washed with water (50 mL) and dried. After evaporation of the solvent using a rotary evaporator, the residual oil was distilled under reduced pressure to give methyl 6-formylhexanoate (20.5 g, bp 82—86 °C/5 mmHg,† 68% yield) as colorless oil: ^{1}H NMR (CCl_4) δ=1.3—1.9 (m, 6H, 3 CH_2), 2.2—2.6 (m, 4H, 2 CH_2CO), 3.60 (s, 3H, OCH_3), 9.68 (br s, 1H, CHO). Methyl 6-formyl-5-hexynoate was prepared by the Swern oxidation[37] of the corresponding propargylic alcohol:[38] In a 100-mL two-necked round-bottomed flask were placed CH_2Cl_2 (20 mL) and DMSO (3.0 mL, 42 mmol) and the atmosphere was replaced with argon. After cooling to −78 °C, to this was added trifluoroacetic anhydride (4.5 mL, 32 mmol) over a period of 10 min and the mixture was stirred at this temperature for 20 min. To this mixture was added a solution of methyl 7-hydroxy-5-heptynoate (3.30 g, 21.1 mmol) in CH_2Cl_2 (5 mL) at −78 °C over a period of 15 min and the mixture was stirred for 30 min at this temperature, followed by the addition of triethylamine (9.1 mL, 65 mmol) over a period of 10 min. The mixture was stirred for 10 min at the same temperature and the cold bath was removed. After stirring for 1 h, the mixture was poured into satd $NaHCO_3$ aqueous solution (50 mL) and the resulting mixture was extracted three times with CH_2Cl_2 (30 mL each). The combined extracts were dried and evaporated. The residual material was subjected to column chromatography on silica gel (100 g) using a 5 : 1 mixture of hexane and ethyl acetate as eluant to give methyl 6-formyl-5-hexynoate (2.31 g, 71%) as colorless oil: IR (neat) 2280, 2200, 1740, 1670 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.7—2.7 (m, 6H, 3 CH_2), 3.70 (s, 3H, OCH_3), 9.20 (s, 1H, CHO). HRMS Found: *m/z* 153.0522. Calcd for $C_8H_{13}O_3$: M−H, 153.0552. (*S,E*)-3-Hydroxy-1-iodo-1-octene (**3**) was prepared by optical resolution of the racemate[14a] or asymmetric reduction[14c] of the corresponding enone followed by the purification through the crystalline salt of the corresponding hydrogen phthalate and (−)-α-methylbenzylamine.[14a] Silylated **4**, $[\alpha]_D^{23}$ −37.5° (*c* 0.97, CH_3OH) and tetrahydropyranylated **5**, $[\alpha]_D^{22}$ −65.9° (*c* 1.05, CH_3OH), were used in the reaction. These optically pure compounds were supplied from Teijin Co. Racemic 4-hydroxy-2-cyclopentenone was prepared by our previous procedure,[16a] acid-catalyzed rearrangement of furfuryl alcohol,[39] or oxidative dimethoxylation of 2-methylfuran[40] followed by phosphate-buffer treatment.[41] (*R*)-4-Hydroxy-2-cyclopentenone (**6**) was obtained by optical resolution using the lactol **9**.

Optical Resolution of 4-Hydroxy-2-cyclopentenone. In a 1-L one-necked round-bottomed flask equipped with a Dean-Stark water separator were placed (1*R*,2*S*)-cis-2-formyl-3,3-dimethylcyclopropane-1-carboxylic acid (**9**)[17] (a cyclic hemiacylal form) (71 g, 0.50 mol, mp 116 °C, $[\alpha]_D^{20}$−102° (*c* 0.5, C_2H_5OH), >97% ee), racemic 4-hydroxy-2-cyclopentenone (69 g, 0.70 mol), pyridinium *p*-toluenesulfonate (63 g, 0.25 mol), and dry benzene (500 mL). When the mixture was heated at reflux under stirring for ca. 5 h, the theoretical amount of water (9 mL) was collected in the separatory condenser. After removal of benzene on a rotary evaporator, the residual material was dissolved in ethyl acetate (500 mL) and washed twice with water, once with satd $NaHCO_3$ aqueous solution (200 mL),[42] and three times with water. The organic solution was dried and concentrated on a rotary evaporator to give a crude mixture of the condensation product **10** (110 g, 99% yield based on **9**).[43] Chromatography of this material on silica-gel column using a 1 : 1 mixture of hexane and ethyl acetate as eluant afforded the less polar material (41 g, 37% yield based on **9**) and more polar one (44 g, 40% yield based on **9**). The less polar material: mp 89.0—90.5 °C; $[\alpha]_D^{23}$−45° (*c* 0.36, CH_3OH); IR (KBr) 1775, 1760, 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.16 (s, 3H, CH_3), 1.18 (s, 3H, CH_3), 2.04 (s, 2H, 2 CH), 2.27 (dd, 1H, *J*=18 and 2.5 Hz, a proton of CH_2), 2.72 (dd, 1H, *J*=18 and 5.5 Hz, a proton of CH_2), 4.9—5.0 (m, 1H, CHO), 5.27 (s, 1H, OCHO),

†1 mmHg≈133.322 Pa.

6.21 (dd, 1H, J=6 and 1.5 Hz, CH=CHCO), 7.58 (dd, 1H, J=6 and 2 Hz, CH=CHO). The more polar material: mp 97.5—98 °C; $[\alpha]_D^{22.6}$—222° (c 0.71, CH_3OH), IR (KBr) 1776 (shoulder), 1760, 1710 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.15 (s, 3H, CH_3), 1.17 (s, 3H, CH_3), 2.03 (s, 2H, 2 CH), 2.37 (dd, 1H, J=19 and 3 Hz, a proton of CH_2), 2.82 (dd, 1H, J=19 and 5.5 Hz, a proton of CH_2), 4.8—5.1 (m, 1H, CHO), 5.30 (s, 1H, OCHO), 6.25 (dd, 1H, J=6 and 1 Hz, CH=CHCO), 7.55 (dd, 1H, J=6 and 2.5 Hz, CH=CHCO).

A mixture of the less polar material (41 g, 0.18 mol) obtained above, dioxane (50 mL), and water (100 mL) was placed in a 500-mL one-necked round-bottomed flask and heated at 80 °C for 1 h under stirring. After cooling, the mixture was mixed with toluene (100 mL) and concentrated on a rotary evaporator. To the aqueous residue was added satd $NaHCO_3$ aqueous solution (100 mL) and then $NaHCO_3$ powder until the system became basic. The aqueous mixture was extracted five times with ethyl acetate (200 mL each). The combined extracts were dried and evaporated to afford (*R*)-4-hydroxy-2-cyclopentenone (**6**) (16 g, 88% yield, $[\alpha]_D^{22}$ +90.1° (c 0.43, CH_3OH), >97% ee) as a colorless oil. The optical purity was assayed by ^1H NMR analysis of the corresponding α-methoxy-α-(trifluoromethyl)phenylacetate.[44] Recovery of the resolving agent **9**: After acidification of the $NaHCO_3$ solution with 4 mol dm^{-3} HCl, the mixture was extracted with ethyl acetate (500 mL). The organic solution was washed twice with water, dried and evaporated, giving a crude hemiacylal resolving agent which was recrystallized from ether to afford pure hemiacylal **9** in 75% yield. Hydrolysis of the polar material (44 g, 0.20 mol) under similar conditions gave (*S*)-4-hydroxy-2-cyclopentenone (16 g, 82% yield). (4*R*)-4-(Tetrahydropyran-2-yloxy)-2-cyclopentenone (**8**), $[\alpha]_D^{22}$ +90.3° (c 1.02, CH_3OH), and (*R*)-4-(*t*-butyldimethylsiloxy)-2-cyclopentenone (**7**), $[\alpha]_D^{22}$ +67.4° (c 0.4, CH_3OH), were used for the synthesis of PGs. These optically pure materials were supplied from Teijin Co.

Standard Procedure for Vicinal Carba-Condensation via Organocopper Conjugate Addition/Aldol Condensation. Prior to introduction of solvents and materials, the reaction vessel was evacuated and dried by heating in vacuo with a heat gun and then, after cooling, the system was replaced with argon. Addition or transfer of the materials in the reaction was conducted under argon atmosphere. The typical procedure is illustrated in the synthesis of 3-butyl-2-(1-hydroxy-2-methylpropyl)cyclopentanone (Entry 3 in Table 1): In a 150-mL ampule was placed CuI (390 mg, 2.05 mmol) under argon atmosphere. To this was added successively dry ether (20 mL) and tributylphosphine (1.02 mL, 4.10 mmol) under stirring. The suspension was further stirred at room temperature until giving a clear solution (ca. 10 min). After cooling to −78 °C, to this was added a solution of butyllithium (1.64 mol dm^{-3}, 1.25 mL, 2.05 mmol) in hexane by using a glass syringe under stirring. After 5 min at −78 °C, a solution of 2-cyclopentenone (164 mg, 2.0 mmol) in dry ether (5 mL) was added over a period of 5 min at this temperature under stirring. After 10 min at −78 °C, a solution of 2-methylpropanal (148 mg, 2.05 mmol) in dry ether (5 mL) was added at −78 °C. After stirring for 10 min at this temperature, the mixture was quenched with satd aqueous NH_4Cl solution (50 mL) at −78 °C under vigorous shaking. The organic layer was separated and the aqueous layer was extracted with ether (10 mL). The combined ethereal extracts were dried and evaporated. The residue was subjected to column chromatography on silica gel (50 g), eluted with a 4 : 1 mixture of hexane and ethyl acetate, to give the aldol (396 mg, 93% yield) as a colorless oil: R_f 0.42 (5 : 1 benzene/ethyl acetate); IR (neat) 3450, 1735 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.1 (m, 6H, 2 CH_3), 1.2—2.0 (m, 13H, 6 CH_2 and CH), 2.2—2.4 (m, 3H, CH_2CO and CHCO), 2.68 (br, 1H, OH), 3.73 (dt, 1H, J=7.2 and 4.4 Hz, CHO). Found: C, 73.36; H, 11.49%. Calcd for $C_{13}H_{24}O_2$: C, 73.54; H, 11.39%.

Unless otherwise stated, the reaction indicated in Table 1 was conducted by a similar procedure.

3-Butyl-2-(hydroxymethyl)cyclopentanone (Entry 1). A 59 : 1 stereomixture. Liquid chromatography (LC): SiO_2, 2 : 1 petroleum ether/ethyl acetate as eluant. IR (neat) 3440, 3738 cm^{-1}; ^1H NMR (CCl_4) δ=0.8—2.5 (m, 15H, 5 CH_2, 2 CH, and CH_3), 2.78 (m, 1H, OH), 3.3—4.0 (m, 2H, CH_2O); ^{13}C NMR ($CDCl_3$) (major stereoisomer) δ=14.1, 22.9, 27.3, 29.5, 34.4, 38.4 (2C), 57.3, 59.7, 221.2. Found: C, 70.35; H, 10.69%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

3-Butyl-2-(1-hydroxybutyl)cyclopentanone (Entry 2). LC: SiO_2, 10 : 1 benzene/ethyl acetate as eluant. TLC R_f 0.42 (5 : 1 benzene/ethyl acetate); IR (neat) 3450, 1735 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.1 (m, 6H, 2 CH_3), 1.2—2.0 (m, 13H, 6 CH_2 and CH), 2.2—2.4 (m, 3H, CH_2CO and CHCO), 2.68 (br, 1H, OH), 3.73 (dt, 1H, J=7.2 and 4.4 Hz, CHO). Found: C, 73.36; H, 11.49%. Calcd for $C_{13}H_{24}O_2$: C, 73.54; H, 11.39%.

3-Butyl-2-(2,2-dimethyl-1-hydroxypropyl)cyclopentanone (Entry 4). LC: SiO_2, 6 : 1 hexane/ethyl acetate as eluant. TLC R_f 0.35 (4 : 1 hexane/ethyl acetate); IR (neat) 3450, 1729 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.1 (m, 12H, 4 CH_3), 1.1—2.4 (m, 13H, 5 CH_2, 2 CH, and OH), 3.31 (s, 1H, CHO). Found: C, 74.21; H, 11.66%. Calcd for $C_{14}H_{26}O_2$: C, 74.29; H, 11.58%.

3-Butyl-2-(hydroxyphenylmethyl)cyclopentanone (Entry 5). LC: SiO_2, 5 : 1 petroleum ether/ether as eluant. TLC R_f 0.41 (1 : 1 petroleum ether/ether); IR (neat) 3440, 1730, 694 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.7—2.5 (m, 15H, 5 CH_2, 2 CH, and CH_3), 3.39 (d, 0.36H, J=6.2 Hz, OH), 4.28 (d, 0.64H, J=1.5 Hz, OH), 4.75 (dd, 0.63H, J=7.8 and 1.5 Hz, CHO), 5.20 (dd, 0.37H, J=6.2 and 3.0 Hz, CHO), 7.32 (m, 5H, phenyl). HRMS Found: m/z 246.1594. Calcd for $C_{16}H_{22}O_2$: M, 246.1619.

3-Butyl-2-(1-hydroxy-3-phenyl-2-propenyl)cyclopentanone (Entry 6). LC: SiO_2, 4 : 1 hexane/ethyl acetate as eluant. TLC R_f 0.41 and 0.36 (2 : 1 hexane/ethyl acetate); IR (neat) 3480, 1723, 962 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.90 (m, 3H, CH_3) 1.1—1.9 (m, 8H, 4 CH_2), 1.9—2.6 (m, 4H, CH_2CO and 2 CH), 3.35 (d, 0.33H, J=8.0 Hz, OH), 3.45 (d, 0.67H, J=3.0 Hz, OH), 4.48 (m, 0.67H, CHO), 4.63 (m, 0.33H, CHO), 6.19 (dd, 0.33H, J=16.0 and 6.6 Hz, vinyl), 6.32 (dd, 0.67H, J=16.0 and 6.8 Hz, vinyl), 6.60 (d, 1H, J=16.0 Hz vinyl), 7.32 (m, 5H, phenyl). HRMS Found: m/z 272.1755. Calcd for $C_{18}H_{24}O_2$: M, 272.1776.

3-Butyl-2-(1-hydroxy-2-heptynyl)cyclopentanone (Entry 7). LC: SiO_2, 3 : 1 hexane/ether as eluant. TLC R_f 0.31 (1 : 1 hexane/ether); IR (neat) 3450, 2230, 1739 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.0 (m, 6H, 2 CH_3), 1.2—1.8 (m, 12H, 6 CH_2), 1.8—2.5 (m, 7H, 2 CH_2, 2 CH, and OH), 4.63 (m, 1H, CHO). Found: C, 76.75; H, 10.50%. Calcd for $C_{16}H_{26}O_2$: C, 76.75; H, 10.47%.

3-Butyl-2-(hydroxymethyl)cyclohexanone (Entry 8). LC: SiO_2, 2 : 1 petroleum ether/ether as eluant. TLC R_f 0.23 (1 : 1 petroleum ether/ether); IR (neat) 3400, 1700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.93 (t, 3H, CH_3), 1.1—2.5 (m, 14H, 6 CH_2 and 2 CH), 2.6 (br, 1H, OH), 3.5—4.1 (m, 2H, CH_2O); ^{13}C NMR

($CDCl_3$) δ=14.0, 22.9, 25.7, 28.2, 30.3, 33.2, 40.1, 41.9, 56.9, 59.5, 214.8. Found: C, 71.63; H, 10.99%. Calcd for $C_{11}H_{20}O_2$: C, 71.70; H, 10.94%.

3-Butyl-2-(1-hydroxyethyl)cyclohexanone (Entry 9). LC: SiO_2, 10:1 benzene/ethyl acetate as eluant. TLC R_f 0.43 and 0.40 (2:1 benzene/ethyl acetate); IR (neat) 3430, 1709 cm^{-1}; ^1H NMR (CCl_4) δ=0.90 (t, 3H, CH_3), 1.1—2.5 (m, 17H, 6 CH_2, 2 CH, and CH_3), 2.78 (br, 1H, OH), 4.0 (br, 1H, CHO). Found: C, 72.77; H, 11.09%. Calcd for $C_{12}H_{22}O_2$: C, 72.68; H, 11.18%.

3-Butyl-2-(1-hydroxybutyl)cyclohexanone (Entry 10). LC: SiO_2, 3:1 petroleum ether/ether as eluant. TLC R_f 0.31 (1:1 petroleum ether/ether); IR (neat) 3400, 1698 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.93 (m, 6H, 2 CH_3), 1.1—3.0 (m, 19H, 8 CH_2, 2 CH, and OH), 3.8 (m, 1H, CHO). Found: C, 74.19; H, 11.63%. Calcd for $C_{14}H_{26}O_2$: C, 74.28; H, 11.58%.

3-Butyl-2-(1-hydroxy-2-methylpropyl)cyclohexanone (Entry 11). LC: SiO_2, 8:1 to 6:1 hexane/ethyl acetate as eluant. TLC R_f 0.31 (1:1 ether/petroleum ether); IR (neat) 3480, 1697 cm^{-1}; ^1H NMR (CCl_4) δ=0.8—1.0 (m, 9H, 3 CH_3), 1.1—2.2 (m, 12H, 5 CH_2 and 2 CH), 2.2—2.4 (m, 3H, CH_2CO and CHCO), 3.16 (dd, 1H, J=8.4 and 3.2 Hz, CHO). Found: C, 74.05; H, 11.72%. Calcd for $C_{14}H_{26}O_2$: C, 74.29; H, 11.58%.

3-Butyl-2-(hydroxyphenylmethyl)cyclohexanone (Entry 12). LC: SiO_2, 4:1 hexane/ethyl acetate as eluant. The less polar isomer: 18% yield; TLC R_f 0.48 (2:1 hexane/ethyl acetate); IR ($CHCl_3$) 3600, 3490, 1701 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—2.6 (m, 17H, CH_3, 6 CH_2, CH, and OH), 2.64 (dd, 1H, J=5.7 and 5.7 Hz, CHCO), 5.13 (d, 1H, J=5.5 Hz, CHO), 7.33 (m, 5H, phenyl). The more polar isomer: 71% yield; TLC R_f 0.32 (2:1 hexane/ethyl acetate); IR ($CHCl_3$) 3595, 3530, 1697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85 (t, 3H, CH_3), 1.0—2.1 (m, 11H, 5 CH_2 and CH), 2.3—2.5 (m, 2H, CH_2CO), 2.63 (dd, 1H, J=5.9 and 5.9 Hz, CHCO), 3.05 (br, 1H, OH), 4.96 (d, 1H, J=5.9 Hz, CHO), 7.35 (m, 5H, phenyl). Found: C, 78.38; H, 9.30%. Calcd for $C_{17}H_{24}O_2$: C, 78.42; H, 9.29%.

3-Butyl-2-(1-hydroxy-3-phenyl-2-propenyl)cyclohexanone (Entry 13). LC: SiO_2, 8:1 hexane/ethyl acetate as eluant. TLC R_f 0.16 and 0.10 (4:1 hexane/ethyl acetate); IR (neat) 3400, 1704, 964, 740, 685 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.91 (m, 3H, CH_3), 1.2—2.2 (m, 11H, 5 CH_2 and CH), 2.2—2.7 (m, 3H, CH_2CO and CHCO), 3.01 (br, 0.7H, OH), 3.56 (br, 0.3H, OH), 4.50 (br, 1H, CHO), 6.37 (dd, 1H, J=15.8 and 6.2 Hz, vinyl), 6.59 (dd, 1H, J=15.8 and 2.0 Hz, vinyl), 7.1—7.6 (m, 5H, phenyl). Found: M, 286.1938; M−H_2O, 268.1844. Calcd for $C_{19}H_{26}O_2$: M, 286.1933; M−H_2O, 268.1844.

***(E)*-2-Benzylidene-3-butylcyclopentanone (1).** To a solution of 3-butyl-2-(hydroxyphenylmethyl)cyclopentanone (49.2 mg, 0.20 mmol) in CH_2Cl_2 (2 mL) was added 4-(dimethylamino)pyridine (73 mg, 0.60 mmol) and the mixture was cooled to 0 °C. To this was added methanesulfonyl chloride (23 μL, 0.30 mmol) at 0 °C and the mixture was stirred for 2 h at 25 °C. Additional 4-(dimethylamino)-pyridine (146 mg, 1.20 mmol) and methanesulfonyl chloride (46 μL, 0.60 mmol) were added to the mixture and the mixture was further stirred for 10 h. The resulting mixture was poured into satd $NaHCO_3$ aqueous solution and extracted twice with CH_2Cl_2 (15 mL each). The combined extracts were washed successively with dil HCl and satd brine and dried. After evaporation of the solvent, the residual material was subjected to column chromatography on silica gel (5 g) using a 4:1 mixture of hexane and ether as eluant to give the enone **1** (33 mg, 77% yield): TLC R_f 0.55 (1:1 hexane/ether); IR (neat) 1717, 1618, 751, 687 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.91 (t, 3H, CH_3), 1.1—1.7 (m, 6H, 3 CH_2), 1.8—2.1 (m, 2H, CH_2), 2.1—2.5 (m, 2H, CH_2CO), 3.17 (br, 1H, CH), 7.2—7.6 (m, 6H, vinyl and phenyl); MS m/z: 228 (M^+). Found: C, 84.18; H, 9.11%. Cacld for $C_{16}H_{20}O$: C, 84.16; H, 8.83%. The compound **1** prepared here was identical in all respects with the product derived from the regio-controlled authentic synthesis[14] starting from 2-cyclopentenone as follows: To a solution of phenyl trimethylsilyl selenide (1.70 g, 7.42 mmol) in CH_2Cl_2 (15 mL) was added successively a solution of trimethylsilyl trifluoromethanesulfonate (0.097 mol dm^{-3}, 1.55 mL, 0.15 mmol) in CH_2Cl_2 and a solution of 2-cyclopentenone (609 mg, 7.42 mmol) in CH_2Cl_2 (5 mL) at −78 °C with stirring under argon atmosphere. After stirring at this temperature for 1 h, to this was added a solution of benzaldehyde dimethyl acetal (1.16 g, 7.62 mmol) in CH_2Cl_2 (5 mL) at −78 °C. The mixture was stirred −78 °C for 1 h and then −27 °C for 17 h. After successive addition of pyridine (0.5 mL) and 30% H_2O_2 (4.5 mL, 40 mmol), the mixture was stirred at −20 to 0 °C for 20 min and then quenched with water. The organic extract was evaporated and the residual material was subjected to column chromatography on silica gel (50 g) using a 10:1 mixture of benzene and ethyl acetate as eluant to afford 2-methoxyphenylmethyl-2-cyclopentenone (301 mg, 20% yield). IR (neat) 1703 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.3—2.5 (m, 2H, CH_2), 2.5—2.7 (m, 2H, CH_2) 3.33 (s, 3H, OCH_3), 5.02 (dd, 1H, J=2 Hz, CHO), 7.33 (br, 5H, phenyl), 7.51 (dt, 1H, J=3.0 and 1.5 Hz, vinyl). MS m/z: 202 (M^+). The butylcopper phosphine complex was prepared by the standard procedure[12b] using CuI (200 mg, 1.05 mmol), tributylphosphine (0.52 mL, 2.10 mmol), butyllithium (1.55 mol dm^{-3}, 0.68 mL, 1.05 mmol), and dry ether (15 ml) under argon atmosphere. To this solution was added a solution of 2-methoxyphenylmethyl-2-cyclopentenone (202 mg, 1.00 mmol) in ether (3.5 mL) at −78 °C over a period of 5 min. After stirring at −78 °C for 10 min and −40 °C for 10 min, the mixture was quenched with satd NH_4Cl aqueous solution (15 mL) with vigorous shaking. The organic layer was separated and the aqueous layer was extracted twice with ether (10 mL each). The combined ethereal extracts were dried and evaporated. Column chromatography on silica gel (20 g) using a 6:1 mixture of hexane and ether as eluant gave a mixture of **1** and 3-butyl-2-(methoxyphenylmethyl)-cyclopentanone (90.4 mg). This mixture was further treated with 1.8-diazabicyclo[5.4.0]undec-7-ene (DBU) (0.29 mL, 1.91 mmol) in benzene (4.5 mL) under reflux for 44 h. After being diluted with benzene (20 mL), the mixture was washed with dil HCl (36 mL×2) and then satd brine (36 mL). The solution was dried over magnesium sulfate and evaporated. Column chromatography on silica gel (18 g) using a 8:1 mixture of petroleum ether and ether gave a pure **1** (63.5 mg) as colorless oil.

***(E)*-2-Benzylidene-3-butylcyclohexanone (2).** To a solution of the more polar stereoisomer (R_f 0.32) of 3-butyl-2-(hydroxyphenylmethyl)cyclohexanone (313 mg, 1.20 mmol) and triethylamine (1.67 mL, 12 mmol) in CH_2Cl_2 (10 mL) was added methanesulfonyl chloride (0.46 mL, 6.0 mmol) at 0 °C. After being stirred at 0 °C for 30 min and 25 °C for 3 h, the mixture was diluted with ether (10 mL) and then washed twice with 1 mol dm^{-3} HCl (10 mL each). The ethereal layer was dried and evaporated. The residual material was dissolved in benzene (20 mL) and the mixture was heated with DBU (0.36 mL, 2.40 mmol) under reflux for 2 h. The mix-

ture was dissolved in benzene (20 mL) and washed with 1 mol dm^{-3} HCl (15 mL). The organic layer was dried over magnesium sulfate and evaporated. Column chromatography on silica gel (15 g) using a 4:1 mixture of hexane and ethyl acetate as eluant afforded **2** (187 mg, 64% yield) as colorless oil: TLC R_f 0.61 (2:1 hexane/ethyl acetate); IR (neat) 1689, 1599, 757, 691 cm^{-1}; ^1H NMR (CCl_4) δ=0.85 (m, 3H, CH_3), 1.0—2.0 (m, 10H, 5 CH_2), 2.1—2.6 (m, 2H, CH_2CO), 3.23 (br, 1H, CH), 7.08 (s, 1H, vinyl), 7.29 (m, 5H, phenyl); MS *m/z*: 242 (M^+). Found: C, 84.45; H, 9.22%. Calcd for $C_{17}H_{22}O$: C, 84.25; H, 9.15%. The compound prepared here was identical in all respects with the product derived from 2-cyclohexenone by the regio-controlled synthesis.[14]

7-Hydroxy-11,15-bis-*O*-(tetrahydropyran-2-yl)PGE$_1$ Methyl Ester (12). In a 20-mL test tube equipped with a septum rubber was placed (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-iodo-1-octene (**5**), (744 mg, 2.20 mmol) and the atmosphere was replaced with argon. Dry ether (10 mL) was added and the mixture was cooled to −95 °C. A solution of *t*-butyllithium (3.19 mL, 4.40 mmol) in pentane was added to this mixture at this temperature and then the resulting mixture was stirred at −78 °C for 3 h, giving the white suspension containing (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-octenyllithium. In a separated 150-mL ampule equipped with a septum rubber was placed CuI (419 mg, 2.20 mmol) and the system was evacuated under heating in vacuo. After cooling, the system was replaced with argon. To this was added dry ether (40 mL) and tributylphosphine (1.43 mL, 5.72 mmol) and the mixture was stirred until the suspension became a clear solution. The solution was cooled to −78 °C and to this was added the ethereal suspension containing (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-octenyllithium prepared above at −78 °C through a stainless steel cannula under argon atmosphere. The test tube was rinsed with an additional dry ether (10 mL) and this ethereal solution was added to the reaction mixture. After stirring the mixture for 10 min at this temperature, a solution of 4-(tetrahydropyran-2-yloxy)-2-cyclopentenone (**8**) (364 mg, 2.00 mmol) in dry ether (20 mL) was slowly added along the cooled (−78 °C) wall of the reaction vessel over a period of 35 min under stirring. After stirring the mixture for 15 min, a solution of methyl 6-formylhexanoate (348 mg, 2.20 mmol) in dry ether (5 mL) was added at −78 °C under stirring. The mixture was stirred at this temperature for 15 min and quenched with satd NH_4Cl aqueous solution (40 mL) and shaken vigorously. The organic layer was separated and the aqueous layer was extracted twice with ether (25 mL each). The combined organic extracts were dried and evaporated. The residual material was subjected to column chromatography on deactivated silica gel (30 g) using a 3:1 to 1:1 mixture of hexane and ethyl acetate as eluant to give the aldol product **12** (919 mg, 83% yield, a mixture of two stereoisomers) as a colorless oil: TLC R_f 0.17 (2:1 hexane/ethyl acetate); IR (neat) 3480, 1746, 974 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, 3H, CH_3), 1.0—1.9 (m, 29H, 14 CH_2 and OH), 2.2—2.5 (m, 5H, 2 CH_2 and CH), 2.78 (dd, 1H, *J*=18.0 and 7.4 Hz, CH), 3.68 (s, 3H, OCH_3), 3.2—4.3 (m, 7H, 2 CH_2O and 3 CHO), 4.68 (br, 2H, 2 OCHO), 5.4—5.8 (m, 2H, vinyls); $[\alpha]_D^{22}$ −52.3° (*c* 1.02, CH_3OH). HRMS Found: *m/z* 384.2488. Calcd for $C_{21}H_{36}O_6$: M−$C_{10}H_{16}O_2$, 384.2512.

(7*E*)-7,8-Didehydro-11,15-bis-*O*-(tetrahydropyran-2-yl)-PGE$_1$ Methyl Ester (14). To a solution of the 7-hydroxy derivative **12** (480 mg, 0.87 mmol) in dry CH_2Cl_2 (5 mL) was added 4-(dimethylamino)pyridine (531 mg, 4.35 mmol) and the atmosphere was replaced with argon. To this was added methanesulfonyl chloride (0.17 mL, 2.17 mmol) at 18 °C and then stirred at 18 °C for 15 min and at 40 °C for 20 min. The mixture was diluted with CH_2Cl_2 (20 mL) and washed with satd $NaHCO_3$ aqueous solution (15 mL), 1 mol dm^{-3} HCl (15 mL), and satd brine (15 mL). After the mixture was dried and evaporated, the residual material was subjected to column chromatography on deactivated silica gel (10 g) using a 4:1 mixture of hexane and ethyl acetate as eluant to give the dehydrated product **14** (429 mg, 92% yield) as colorless oil: TLC R_f 0.40 (2:1 hexane/ethyl acetate); IR (neat) 1736, 1728, 1646, 974 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, CH_3), 1.0—2.0 (m, 26H, 13 CH_2), 2.0—2.6 (m, 6H, 2 CH_2CO and CH_2C=), 3.68 (s, 3H, OCH_3), 3.3—4.3 (m, 7H, 2 CHO, 2 CH_2O, and CHC=), 4.5—4.8 (br, 2H, OCHO), 5.29 (d, 1H, *J*=14.0 and 7.9 Hz, vinyl), 5.63 (ddd, 1H, *J*=14.0, 6.3, and 3.2 Hz, vinyl), 6.75 (dt, 1H, *J*=9.7 and 1.9 Hz, vinyl); $[\alpha]_D^{22}$ +29.5° (*c* 1.01, CH_3OH). HRMS Found: *m/z* 330.2194. Calcd for $C_{21}H_{30}O_3$: M−$C_{10}H_{20}O_4$, 330.2195.

11,15-Bis-*O*-(tetrahydropyran-2-yl)PGE$_1$ Methyl Ester (16). Method A: The mixture of the enone **14** (12.0 mg, 0.022 mmol), (n-C_4H_9)$_3$SnH (0.5 mL), and di-*t*-butyl peroxide (4 mg, 0.027 mmol) was stirred at 110 °C for 25 min under argon. After cooling to room temperature, the mixture was directly chromatographed on a column of silica gel (3 g) by using a 12:2:1 mixture of hexane, benzene, and ethyl acetate as eluant to give **16** (10.8 mg, 90% yield) as colorless oil. Method B: To a solution of **14** (161 mg, 0.30 mmol) in a 95:5 mixture of 2-propanol and CH_3COOH (4 mL) was added zinc powder (1.46 g, 22.3 mmol) in several portions over a period of 2 h. The mixture was filtered through Celite 545 and the Celite was washed successively with ethyl acetate (10 mL) and ether (15 mL). The combined filtrates were washed with satd $NaHCO_3$ aqueous solution (15 mL) and then satd brine (15 mL), dried, and evaporated. Column chromatography on deactivated silica gel (6 g) using a 4:1 mixture of hexane and ethyl acetate as eluant gave **16** (126 mg, 78% yield) as a colorless oil: TLC R_f 0.41 (2:1 hexane/ethyl acetate); IR (neat) 1750, 974 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, 3H, CH_3), 1.0—2.0 (m, 30H, 15 CH_2), 2.0—2.6 (m, 5H, 2 CH_2CO and CHCO), 2.76 (dd, 1H, *J*=18.0 and 7.2 Hz, CHC=), 3.68 (s, 3H, OCH_3), 3.3—4.4 (m, 6H, 2 CHO and 2 CH_2O), 4.70 (br, 2H, 2 OCHO), 5.4—5.8 (m, 2H, vinyls); $[\alpha]_D^{22}$ −85.4° (*c* 0.99, CH_3OH); HRMS Found: *m/z* 434.3029. Calcd for $C_{26}H_{42}O_5$: M−$C_5H_{10}O_2$, 434.3033.

PGE$_1$ Methyl Ester (18). The mixture of the tetrahydropyranylated derivative **16** (17.2 mg, 0.032 mmol) and a 3:1:1 mixture of acetic acid, water, and THF (2 mL) was stirred at 19 °C for 18 h. Then the mixture was placed in vacuo to evaporate the volatile materials. The resulting residual material was further co-evaporated three times with toluene under reduced pressure and then subjected to column chromatography on silica gel (1.7 g) using a 1:3 mixture of hexane and ethyl acetate as eluant to give PGE$_1$ methyl ester (**18**) (10.9 mg, 92% yield): TLC R_f 0.22 (1:3 hexane/ethyl acetate); IR (neat) 3390, 1748, 970 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, 3H, CH_3), 1.1—1.8 (m, 18H, 9 CH_2), 1.8—2.6 (m, 7H, 2 CH_2CO, CHCO, and 2 OH), 2.73 (dd, 1H, *J*=18.0 and 7.6 Hz, CHC=), 3.68 (s, 3H, OCH_3), 3.9—4.3 (m, 2H, 2 CHO), 5.63 (m, 2H, vinyls); ^{13}C NMR ($CDCl_3$) δ=14.0 (C-20), 22.6, 24.8, 25.1, 26.6, 27.8, 28.8, 29.3, 31.7, 34.0, 37.4, 45.9 (C-10), 51.4 (OCH_3), 54.5 (C-12), 54.8 (C-8), 72.0 (C-11), 73.0 (C-15),

131.8 (C-13), 136.9 (C-14), 174.2 (C-1), 214.4 (C-9); $[\alpha]_D^{22}$ −53.8° (*c* 1.04, CH_3OH).

Reaction of commercial PGE_1 with diazomethane followed by HPLC (Develosil, hexane:ethyl acetate: CH_3OH= 1 : 9 :0.05 as eluant) afforded a sample indicating $[\alpha]_D^{23}$−54.0° (*c* 1.08, CH_3OH). The spectral data (IR, ^1H and ^{13}C NMR) and chromatographic behavior of **18** were identical with those of this authentic material.

11-*O*-(*t*-Butyldimethylsilyl)-7-hydroxy-15-*O*-(tetrahydropyran-2-yl)PGE_1 Methyl Ester (13). This compound was synthesized by the similar reaction procedure to the synthesis of **12**. (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-octenyllithium was prepared by adding a solution of *t*-butyllithium (3.21 mL, 4.40 mmol) in pentane to a solution of (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-iodo-1-octene (**5**) (744 mg, 2.20 mmol) in dry ether (10 mL) at −95 °C and then by stirring the mixture at −78 °C for 1.5 h. The organocopper complex was prepared by adding the organolithium compound prepared above to a solution of CuI (491 mg, 2.20 mmol) and tributylphosphine (1.43 mL, 5.72 mmol) in ether (50 mL) at −78 °C. The conjugate addition reaction was conducted by slow addition of a solution of (*R*)-4-(*t*-butyldimethylsiloxy)-2-cyclopentenone (**7**) (425 mg, 2.00 mmol) in dry ether (20 mL) to the organocopper complex prepared above at −78 °C over a period of 40 min. The aldehyde trapping of the enolate were conducted by addition of a solution of methyl 6-formylhexanoate (348 mg, 2.20 mmol) in dry ether (15 mL) at −78 °C. The reaction mixture was quenched with satd ammonium acetate aqueous solution (40 mL) with vigorous shaking at −78 °C. The organic layer was separated and aqueous layer was extracted twice with ether (20 mL each). The combined organic extracts were washed with a 20 : 5 : 1 mixture of water, benzene, and DMSO (52 mL) and then with satd brine (40 mL). After the solvent was dried and evaporated, the residual material was chromatographed at 0 °C on a two-layer column filled with Florisil (10 g, upper portion) and deactivated silica gel (100 g, lower portion) by using a 6 : 1 : 1 mixture of hexane, ethyl acetate, and benzene as eluant to give the aldol **13** (811 mg, 70%, four stereoisomers) as a pale yellow oil: TLC R_f 0.44 (2 : 1 hexane/ethyl acetate); IR ($CHCl_3$) 3600—3300, 1730 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.06 (s, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—2.9 (m, 29H, 13 CH_2, 2 CH, and OH), 3.1—4.2 (m, 8H, OCH_3, 3 CHO, and CH_2O), 4.63 (m, 1H, OCHO), 5.4—5.7 (m, 2H, vinyls); $[\alpha]_D^{20}$ +14.3° (*c* 1.74, CH_3OH). HRMS Found: *m*/*z* 480.3283. Calcd for $C_{27}H_{48}O_5Si$: M−$C_5H_{10}O_2$, 480.3271.

(7*E*)-11-*O*-(*t*-Butyldimethylsilyl)-7,8-didehydro-15-*O*-(tetrahydropyran-2-yl)PGE_1 Methyl Ester (15). To a solution of **13** (348 mg, 0.60 mmol) in dry CH_2Cl_2 (20 mL) was added 4-(dimethylamino)pyridine (728 mg, 6.96 mmol) at 0 °C and the atmosphere was replaced with argon. To this was added methanesulfonyl chloride (0.23 mL, 2.97 mmol) at 0 °C and the mixture was stirred at 24 °C for 29 h. The reaction mixture was washed with satd $NaHCO_3$ aqueous solution (15 mL) and then satd brine (15 mL). After the organic layer was dried and evaporated, the residual oil was chromatographed on a column of deactivated silica gel (35 g) by using a 12:1 mixture of hexane and ethyl acetate as eluant to give **15** (255 mg, 75%) and its 7*Z*-isomer (9.2 mg, 2.7%). 7*E*-isomer **15**: TLC R_f 0.37 (4 : 1 hexane/ethyl acetate); IR (neat) 1742, 1642 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.05 (s, 6H, 2 $SiCH_3$), 0.7—1.0 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.0—2.7 (m, 26H, 13 CH_2), 3.3—4.3 (m, 8H, OCH_3, 2 CHO, CH_2O, and CH), 4.60 (m, 1H, OCHO), 5.0—5.8 (m, 2H, vinyls); 6.73 (dt, 1H, *J*=6.7 and 2.0 Hz, vinyl); $[\alpha]_D^{20}$ +16.0° (*c* 0.80, CH_3OH). HRMS Found: *m*/*z* 507.3141. Calcd for $C_{28}H_{47}O_6Si$: M−C_4H_9, 507.3142.

11-*O*-(*t*-Butyldimethylsilyl)-15-*O*-(tetrahydropyran-2-yl)-PGE_1 Methyl Ester (17). The mixture of the enone **15** (169.3 mg, 0.30 mmol), $(n\text{-}C_4H_9)_3SnH$ (1.0 mL, 3.72 mmol), and di-*t*-butyl peroxide (5 mg, 0.034 mmol) was heated at 110 °C for 15 min under argon. After cooling to room temperature, the reaction mixture was directly chromatographed on a column of deactivated silica gel (20 g) by using a 15 : 2 : 1 mixture of hexane, benzene, and ethyl acetate as eluant to give **17** (149 mg, 88%) as a colorless oil: TLC R_f 0.48 (4 : 1 hexane/ethyl acetate); IR ($CHCl_3$) 1740, 1735 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.05 (s, 6H, 2 $SiCH_3$), 0.7—1.0 (m, 12H, $Si(CH_3)_3$ and CH_3), 1.0—2.8 (m, 30H, 14 CH_2 and 2 CH), 3.3—4.2 (m, 7H, OCH_3, 2CHO, and CH_2O), 4.68 (m, 1H, OCHO), 5.4—5.6 (m, 2H, vinyls); $[\alpha]_D^{23}$ −66.2° (*c* 0.60, CH_3OH). MRMS Found: *m*/*z* 566.4015. Calcd for $C_{32}H_{58}O_6Si$: M, 566.4003.

11-*O*-(*t*-Butyldimethylsilyl)-15-*O*-(tetrahydropyran-2-yl)-$PGF_{1\alpha}$ Methyl Ester (20). In a 10-mL Schlenk tube was placed **17** (38.5 mg, 0.0679 mmol) and dissolved in dry THF (3 mL). After cooling to −78 °C, a solution of L-Selectride in THF (0.081 mL, 0.0815 mmol) was added at this temperature. After stirring at −78 °C for 20 min, 3% aqueous H_2O_2 solution (2mL) was added to the mixture at −78 °C with vigorous shaking and then diluted with ether (4 mL). The organic layer was separated and the aqueous layer was extracted with ether (4 mL). After the combined organic extracts were dried and evaporated, the residual oil was chromatographed on a column of silica gel (4 g) by using a 1 : 5 mixture of ethyl acetate and hexane as eluant to give **20** (35.4 mg, 92%) as a colorless oil: TLC R_f 0.25 (1 : 4 ethyl acetate/hexane); IR ($CHCl_3$) 3600—3320, 1725 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.04 (s, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—2.7 (m, 31H, 14 CH_2, 2 CH, and OH), 3.3—4.3 (m, 8H, OCH_3, 3 CHO, and CH_2O), 4.67 (m, 1H, OCHO), 5.2—5.6 (m, 2H, vinyls); $[\alpha]_D^{20}$ −13.8° (*c* 0.62, CH_3OH). HRMS Found: *m*/*z* 511.3423. Calcd for $C_{28}H_{51}O_6Si$: M−C_4H_9, 511.3455.

11-*O*-(*t*-Butyldimethylsilyl)-9,15-bis-*O*-(tetrahydropyran-2-yl)$PGF_{1\alpha}$ Methyl Ester (21). In a 10-mL test tube was placed **20** (102.8 mg, 0.181 mmol) and the atmosphere was replaced with argon. Dry CH_2Cl_2 (1 mL) was added and the mixture was cooled to 0 °C. To this were added 3,4-dihydro-2*H*-pyran (33.4 mg, 0.398 mmol) and then pyridinium *p*-toluenesulfonate (13.5 mg, 0.0543 mmol) at 0 °C. After being stirred for 10 min at 0 °C and then 5 h at 30 °C, the mixture was diluted with CH_2Cl_2 (5 mL), followed by the addition of satd brine (10 mL). After shaking, the organic layer was separated and the aqueous layer was extracted twice with CH_2Cl_2 (10 mL each). After the combined organic extracts were dried and evaporated, the residual material was chromatographed on a column of silica gel (12 g) by using a 1 : 10 mixture of ethyl acetate and hexane as eluant to give **21** (110.8 mg, 94%) as a colorless oil: TLC R_f 0.54 (1 : 4 ethyl acatate/hexane); IR ($CHCl_3$) 1730 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.01 (s, 6H, 2 $SiCH_3$), 0.7—1.0 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—2.5 (m, 36H, 17 CH_2 and 2 CH), 3.3—4.2 (m, 10H, OCH_3, 3 CHO, and 2 CH_2O), 4.5—4.8 (m, 2H, 2 OCHO), 5.40 (m, 2H, vinyls); $[\alpha]_D^{25}$ +15.9° (*c* 0.37, CH_3OH). HRMS Found: *m*/*z* 550.4028. Calcd for $C_{32}H_{58}O_5Si$: M−$C_5H_{10}O_2$,

550.4054.

9,15-Bis-*O*-(tetrahydropyran-2-yl)PGF$_{1\alpha}$ Methyl Ester (22). In a 10-mL round-bottomed flask was placed **21** (103.5 mg, 0.158 mmol) and dissolved with THF (1 mL). To this was added a solution of tetrabutylammonium fluoride (1 mol dm^{-3}, 1.58 mL, 1.58 mmol) in THF at 23 °C and the mixture was stirred for 5 h at this temperature. THF (5 mL) and satd brine (5 mL) were added and the mixture was shaken vigorously. The organic layer was separated and the aqueous layer was extracted twice with ethyl acetate (5 mL each). After the combined extracts were dried and evaporated, the residual material was chromatographed on a column of silica gel (10 g) by using a 1 : 4 to 1 : 1 mixture of ethyl acetate and hexane as eluant to give **22** (71.7 mg, 84%) as a colorless oil: TLC R_f 0.17 (1 : 4 ethyl acetate/hexane); IR ($CHCl_3$) 3620—3280, 1730 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=4.5 Hz, CH_3), 1.1—2.5 (m, 37H, 17 CH_2, 2 CH, and OH), 3.3—4.3 (m, 10H, OCH_3, 3 CHO, and 2 CH_2O), 4.5—4.8 (m, 2H, 2 OCHO), 5.45 (m, 2H, vinyls); $[\alpha]_D^{25}$ +0.65° (*c* 0.59, CH_3OH). HRMS Found: *m/z* 436.3165. Calcd for $C_{26}H_{44}O_5$: M−$C_5H_{10}O_2$, 436.3189.

PGD$_1$ (23). In a 10-mL test tube was placed **22** (15.6 mg, 0.0290 mmol) and dissolved in CH_3OH (1 mL). After cooling to 0 °C, 20% NaOH aqueous solution (1 mL) was added. The mixture was stirred for 3.7 h at 25 °C and acidified by 1 mol dm^{-3} aqueous oxalic acid solution (5 mL). The resulting mixture was extracted three times with ethyl acetate (10 mL each) and the organic extracts were washed with satd brine (10 mL), dried, and evaporated. The residual oil was placed in a 10-mL test tube and dissolved in acetone (0.8 mL). After cooling to −30 °C, Jones reagent (2.4 mol dm^{-3}, 18.1×10^{-3} mL, 0.0434 mmol) was added slowly to the mixture. The mixture was stirred for 40 min at this temperature and then ethyl acetate (10 mL) and satd $NaHCO_3$ aqueous solution (10 mL) were added. The mixture was neutralized by 1 mol dm^{-3} aqueous oxalic acid (10 mL) and the organic layer was separated. The aqueous layer was extracted twice with ethyl acetate (10 mL each). After the combined extracts were dried and evaporated, the residual oil was dissolved in a 3 : 1 : 1 mixture of acetic acid, water, and THF (2 mL) and the mixture was stirred at 25 °C for 23 h. The mixture was concentrated by exposing in vacuo and the residual material was dissolved in toluene. The toluene solution was evaporated under reduced pressure and this azeotropic operation was repeated three times. The residual oil was subjected to column chromatography on silica gel (1.5 g) using a 4 : 2 1 mixture of cyclohexane, ethyl acetate, and acetone and then pure acetone as eluant to give (+)-PGD$_1$ (**23**) (6.3 mg, 61%) as a white crystal: mp 64.5—65 °C; TLC R_f 0.14 (4 : 1 ethyl acetate/hexane); IR ($CHCl_3$) 3720—2300, 1740, 1715 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=6.0 Hz, CH_3), 1.1—2.1 (m, 19H, 9 CH_2 and CH), 2.35 (t, 2H, J=6.4 Hz, CH_2C=O), 2.44 (d, 2H, J=2.6 Hz, CH_2C=O), 2.1—3.4 (br m, 4H, CHC=O, 2 OH, and CO_2H), 4.12 (br q, 1H, J=6.0 Hz, CHO), 4.51 (m, 1H, CHO), 5.53 (m, 2H, vinyls); $[\alpha]_D^{26}$ +9.8° (*c* 0.17, THF).

11,15-Bis-*O*-(*t*-butyldimethylsilyl)-5,6-didehydro-7-hydroxy-PGE$_2$ Methyl Ester (24). In a 150-mL ampule equipped with a spiral tube was placed (*E*,3*S*)-3-(*t*-butyldimethylsiloxy)-1-iodo-1-octene (**4**) (1.41 g, 3.83 mmol) and the atomsphere was replaced with argon. Dry ether (15 mL) was added and the mixture was cooled to −95 °C. To this was added a solution of *t*-butyllithium (4.41 mL, 7.80 mmol) in pentane at this temperature and the resulting mixture was further stirred at −78 °C for 3 h, giving the white suspension containing (*E*,3*S*)-3-(*t*-butyldimethylsiloxy)-1-octenyllithium. In a separaed 50-mL test tube equipped with a septum rubber was placed CuI (729 mg, 3.83 mmol) and the atmosphere was replaced with argon. To this was added dry ether (15 mL) and tributylphosphine (2.48 mL, 9.95 mmol) and the mixture was stirred until the suspension became a clear solution. After cooling to −78 °C, to this was added the suspension containing (*E*,3*S*)-3-(*t*-butyldimethylsiloxy)-1-octenyllithium prepared above through a stainless steel cannula under argon atmosphere. The test tube was rinsed with dry ether (15 mL) and the ethereal solution was added to the reaction mixture. After stirring the mixture at −78 °C for 5 min, a solution of 4-(*t*-butyldimethylsiloxy)-2-cyclopentenone (**7**) (796 mg, 3.75 mmol) in dry THF (30 mL) was slowly added at −78 °C along the cooled (−78 °C) wall of the reaction vessel over a period of 30 min under stirring. After stirring the mixture for 1 h, boron trifluoride etherate (0.461 mL, 3.75 mmol) was added at −78 °C and the mixture was stirred at −78 °C for 3 h. The mixture was cooled to −95 °C and then a solution of methyl 6-formyl-5-hexynoate (637 mg, 4.13 mmol) in dry ether (15 mL) was added at this temperature. The mixture was stirred at −78 °C for 1 h and quenched with satd NH_4Cl aqueous solution (30 mL) under vigorous shaking. The organic layer was separated and the aqueous layer was extracted twice with ether (20 mL each). The combined ethereal extracts were washed with a 1 : 5 : 20 mixture of DMSO, benzene, and water (52 mL) and then satd brine (20 mL). After the organic layer was dried and evaporated, the residual oil was chromatographed at 0 °C on a two-layered column filled with Florisil (10 g, upper layer) and deactivated silica gel (70 g, lower layer) by using a 1 : 10 : 2 mixture of ethyl acetate, hexane, and benzene and then a 1 : 5 mixture of ethyl acetate and hexane as eluants to give the aldol product **24** (1.90 g, 83%, a mixture of two stereoisomers) as a slightly yellow oil: The less polar material: TLC R_f 0.44 (3 : 1 hexane/ethyl acetate); IR (neat) 3630—3180, 1743 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.02, 0.03, 0.06 and 0.07 (s each, 12H, 4 $SiCH_3$), 0.89 (s, 18H, 2 $SiC(CH_3)_3$), 0.8—0.9 (hidden in this region, 3H, CH_3), 1.2—3.0 (m, 18H, 8 CH_2 and 2 CH), 3.68 (s, 3H, OCH_3), 3.86 (d, 1H, J=10 Hz, OH), 4.10 (m, 2H, 2 CHO), 4.46 (m, 1H, CHO), 5.59 (m, 2H, vinyls); ^{13}C NMR ($CDCl_3$) δ=−4.5 (3C), −4.1, 13.9, 18.1, 18.4 (2C), 22.6, 24.2 25.0, 25.9 (3C), 26.0 (3C), 32.0, 33.0, 38.7, 48.3, 50.9, 51.4, 59.1, 62.1, 73.0, 73.6, 80.2, 85.9, 128.2, 136.9, 173.2, 214.8; $[\alpha]_D^{19}$ −34.3° (*c* 0.91, CH_3OH). HRMS Found: *m/z* 608.3931. Calcd for $C_{33}H_{60}O_6Si_2$: M, 608.3929. The more polar material: TLC R_f 0.40 (3 : 1 hexane/ethyl acetate); IR (neat) 3620—3200, 1745 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.02, 0.04, 0.06 and 0.07 (s each, 12H, 4 $SiCH_3$), 0.87 and 0.88 (s each, 18H, 2 $SiC(CH_3)_3$), 0.8—0.9 (hidden in this region, 3H, CH_3), 1.2—3.0 (m, 19H, 8 CH_2, 2 CH, and OH), 3.68 (s, 3H, OCH_3), 4.10 (m, 2H, 2 CHO), 4.66 (m, 1H, CHO), 5.63 (m, 2H, vinyls); ^{13}C NMR ($CDCl_3$) δ=−4.5 (3C), −4.1, 14.0, 18.1, 18.4 (2C), 22.6, 24.1, 25.0, 25.9 (3C), 26.1 (3C), 32.0, 33.0, 38.7, 48.0, 51.4 (2C), 59.4, 62.9, 73.0, 73.6, 80.1, 85.9, 129.3, 136.7, 173.2, 213.7; $[\alpha]_D^{19}$ −15.1° (*c* 1.03, CH_3OH).

The two isomers of **24** were converted independently to the corresponding 7-benzoyloxy-PGE$_2$ derivative by the catalytic hydrogenation using Lindlar catalyst followed by benzoylation with benzoyl chloride in the presence of pyridine.[45] The benzoate derivative from the less polar isomer of **24**: CD

(cyclohexane) λ_{ext} 226 nm ($\Delta\varepsilon$+10.5°). The benzoate from the more polar isomer of **24**: CD (cyclohexane) λ_{ext} 226 nm ($\Delta\varepsilon$ −7.37°). These results indicate that the benzoyl derivative from the less polar isomer of **24** has 7*R* configuration and the other possesses 7*S* configuration. Turning back to the starting hydroxy derivatives, the less polar and the more polar isomers of **24** proved to have 7*S* and 7*R* configurations, respectively. This assignment was confirmed chemically by transformation to 7-hydroxy PGI_2 derivatives.[25]

11,15-Bis-*O*-(*t*-butyldimethylsilyl)-5,6-didehydro-7-thiobenzoyloxy-PGE$_2$ Methyl Ester (26). To a solution of the aldol **24** (126 mg, 0.21 mmol) in dry CH_2Cl_2 (2.5 mL) was added 4-(dimethylamino)pyridine (55 mg, 0.45 mmol) and then a solution of thiobenzoyl chloride (65 mg, 0.41 mmol) in CH_2Cl_2 (0.5 mL) at 21 °C under stirring. After stirring at this temperature for 70 min, the mixture was diluted with CH_2Cl_2 (20 mL) and washed successively with satd $NaHCO_3$ aqueous solution (20 mL), dil HCl (20 mL), and satd brine (20 mL) and then dried over magnesium sulfate. After evaporation of the solvent, the residual material was chromatographed on a column of silica gel (15 g) by using a 10:1 mixture of hexane and ethyl acetate as eluant to give the thiobenzoate **26** (108 mg, 71% yield, two stereoisomers at C-7) as yellow-brown oil: TLC R_f 0.29 (5:1 hexane/ethyl acetate); IR (neat) 2230, 1743, 1596, 1210 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ= −0.09, −0.04, 0.07, and 0.08 (s, each, 12H, 4 $SiCH_3$), 0.8—1.0 (m, 21H, 7 CCH_3), 1.1—3.2 (m, 18H, 8 CH_2 and 2 CH), 3.65 and 3.66 (s each, 3H, OCH_3), 3.9—4.3 (m, 2H, 2 CHO), 5.4—5.9 (m, 2H, vinyls), 6.28 and 6.60 (br, 0.5H each, CHOC(=S)), 7.3—7.7 (m, 3H, aromatic), 8.1—8.4 (m, 2H, aromatic); $[\alpha]_D^{22}$+2.64° (*c* 1.21, CH_3OH). Found: C, 65.83; H, 8.78%. Calcd for $C_{40}H_{64}O_6SSi$: C, 65.88; H, 8.85%.

11,15-Bis-*O*-(*t*-butyldimethylsilyl)-5,6-didehydro-PGE$_2$ Methyl Ester (28). A mixture of the thiobenzoate **26** (93 mg, 0.13 mmol), (n-C_4H_9)$_3$SnH (0.7 mL, 2.65 mmol), and di-*t*-butyl peroxide (4 mg) was heated at 50 °C under argon atmosphere for 30 min. The mixture was directly subjected to column chromatography on a column of silica gel (5 g) using a 1:20:5 mixture of ethyl acetate, hexane, and benzene as eluant to give **28** (74.2 mg, 98% yield) as colorless oil: TLC R_f 0.50 (5:1 hexane/ethyl acetate); IR (neat) 1746, 1246, 827, 767 cm^{-1}; ^{1}H NMR ($CDCl_3$–CCl_4) δ=0.04 and 0.06 (s each, 12H, 4 $SiCH_3$), 0.89 (s, 18H, 2 $SiC(CH_3)_3$), 0.92 (t, 3H, J=6.5 Hz, CH_3), 1.1—1.5 (m, 8H, 4 CH_2), 1.7—2.9 (m, 12H, 2 CH_2CO, 2 CH_2C=, 2 CH, and CH_2), 3.65 (s, 3H, OCH_3), 4.05 (m, 2H, 2 CHO), 5.4—5.7 (m, 2H, vinyls); ^{13}C NMR ($CDCl_3$) δ=−4.7, −4.5 (2C), −4.2, 13.6, 14.0, 16.9, 18.0, 18.2, 22.6, 24.2, 25.0, 25.8 (3C), 25.9 (3C), 31.9, 32.7, 38.6, 47.7, 51.4, 51.9, 52.9, 72.7, 73.1, 77.3, 80.8, 128.2, 136.8, 173.4, 213.4; $[\alpha]_D^{21}$−13.9° (*c* 1.59, CH_3OH); HRMS Found: m/z 592.3956. Calcd for $C_{33}H_{60}O_5Si_2$: M, 592.3979. Spectral data (IR and ^{1}H NMR) of **28** were identical with those of the authentic sample gifted from Dr. C. H. Lin of Upjohn Co.

11-*O*-(*t*-Butyldimethylsilyl)-5,6-didehydro-7-hydroxy-15-*O*-(tetrahydropyran-2-yl)PGE$_2$ Methyl Ester (25). This compound was synthesized by similar reaction and work-up procedures to those of the synthesis of **13**. (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-octenyllithium was prepared by adding a *t*-butyllithium pentane solution (2.87 mL, 3.93 mmol) to a solution of (*E*,3*S*)-3-(tetrahydropyran-2-yloxy)-1-iodo-1-octene (**5**) (664 mg, 1.96 mmol) in ether (10 mL) at −95 °C and then stirring the mixture −78 °C for 1.5 h. The organocopper complex was prepared by adding the lithium compound prepared above to a solution of CuI (374 mg, 1.96 mmol) and tributylphosphine (1.27 mL, 5.10 mmol) in ether (40 mL) at −78 °C. The conjugate addition was conducted by slow addition of a solution of (*R*)-4-(*t*-butyldimethylsiloxy)-2-cyclopentenone (**7**) (379 mg, 1.78 mmol) in ether (20 mL) to the organocopper reagent prepared above and at −78 °C. The aldehyde trapping of the enolate was conducted by addition of a solution of methyl 6-formyl-5-hexynoate (303 mg, 1.96 mmol) in ether (15 mL) at −78 °C. After work-up, column chromatography was performed at 0 °C on a two-layer column filled with Florisil (10 g, upper layer) and deactivated silica gel (100 g, lower layer) by using a 6:1:1 mixture of hexane, ethyl acetate, and benzene and then a 3:1 mixture of hexane and ethyl acetate as eluants to give **25** (670.2 mg, 65%, two stereoisomers) as a pale yellow oil. The less polar material: TLC R_f 0.45 (1:2 ethyl acetate/hexane); IR ($CHCl_3$) 3720—3000, 1735 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.0—0.1 (m, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—3.2 (m, 25H, 11 CH_2, 2 CH, and OH), 3.3—4.8 (m, 9H, OCH_3, CH_2O, 3 CHO, and OCHO), 5.51 (m, 2H, vinyls); $[\alpha]_D^{26}$ −80.2° (*c* 0.5, CH_3OH). HRMS Found: m/z 521.2950. Calcd for $C_{28}H_{45}O_7Si$: M−C_4H_9, 521.2935. The more polar material: TLC R_f 0.41 (1:2 ethyl acetate/hexane); IR ($CHCl_3$) 3700—3000, 1735 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.0—0.1 (m, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—3.1 (m, 25H, 11 CH_2, 2 CH, and OH), 3.4—4.2 (m, 8H, OCH_3, CH_2O, and 3 CHO), 4.68 (m, 1H, OCHO), 5.57 (m, 2H, vinyls); $[\alpha]_D^{26}$ −26.2° (*c* 0.19, CH_3OH).

11-*O*-(*t*-Butyldimethylsilyl)-5,6-didehydro-15-*O*-(tetrahydropyran-2-yl)-7-thiobenzoyloxy-PGE$_2$ Methyl Ester (27). To a solution of **25** (100 mg, 0.173 mmol) in dry CH_3CN (10 mL) was added 4-(dimethylamino)pyridine (69.8 mg, 0.571 mmol) and then a solution of thiobenzoyl chloride (81.3 mg, 0.519 mmol) in CH_3CN (4 mL) at −40 °C under stirring. After stirring at −30 °C for 18 h, the mixture was diluted with CH_2Cl_2 (20 mL) and washed with satd $NaHCO_3$ aqueous solution (10 mzL), dil HCl (10 mL), and then satd brine (10 mL). After the mixture was dried and evaporated, the residual material was chromatographed on a column of silica gel (10 g) by using a 10:1 mixture of hexane and ethyl acetate as eluant to give **27** (93.2 mg, 77%) as brown oil: TLC R_f 0.62 and 0.57 (2:1 hexane/ethyl acetate); IR ($CHCl_3$) 1730, 1600 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=−0.1—0.2 (m, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—3.2 (m, 24H, 11 CH_2 and 2 CH), 3.2—4.3 (m, 7H, OCH_3, 2 CHO, and CH_2O), 4.5—4.8 (m, 1H, OCHO), 5.1—5.8 (m, 2H, vinyls), 6.3—7.2 (m, 1H, CHOC(=S)), 7.2—8.3 (m, 5H, phenyl). HRMS Found: m/z 596.2962. Calcd for $C_{34}H_{48}O_5SSi$: M−$C_5H_{10}O_2$, 596.2992.

11-*O*-(*t*-Butyldimethylsilyl)-5,6-didehydro-15-*O*-(tetrahydropyran-2-yl)PGE$_2$ Methyl Ester (29). A mixture of thiobenzoate **27** (34.3 mg, 0.0491 mmol), (n-C_4H_9)$_3$SnH (0.5 mL, 1.86 mmol), and di-*t*-butyl peroxide (4 mg) was heated at 50 °C for 7.5 h under argon atmosphere. The reaction mixture was directly chromatographed on a column of silica gel (3 g) by using a 1:15:2 mixture of ethyl acetate, hexane, and benzene as eluant to give **29** (23.4 mg, 85%) as colorless oil: TLC R_f 0.31 (4:1 hexane/ethyl acetate); IR (neat) 1740 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.0—0.1 (two s, 6H, 2 $SiCH_3$), 0.7—1.0 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.0—3.0 (m, 26H, 2 CH_2CO, 10 CH_2, and 2 CH), 3.3—4.3 (m, 7H, OCH_3, 2 CHO, and CH_2O), 4.69 (m, 1H, OCHO), 5.4—5.7 (m, 2H, vinyls); $[\alpha]_D^{26}$−46.1° (*c* 0.38, CH_3OH). HRMS Found: m/z 505.2967.

Calcd for $C_{28}H_{45}O_6Si$: M−C_4H_9, 505.2986.

11-*O*-(*t*-Butyldimethylsilyl)-5,6-didehydro-7-hydroxy-15-*O*-(tetrahydropyran-2-yl)-PGF$_{2\alpha}$ Methyl Ester (30). To a solution of the more polar isomer of **25** (R_f 0.41, 1:2 ethyl acetate/hexane) (226.1 mg, 0.39 mmol) in CH_3OH (15 mL) was added $NaBH_4$ (147.8 mg, 3.9 mmol) at 0 °C under stirring. After 5 min at this temperature, the mixture was poured into satd NH_4Cl aqueous solution (15 mL) at 0 °C under stirring. After the evolution of H_2 gas ceased, the mixture was extracted three times with ethyl acetate (20 mL each). After the combined organic extracts were dried and evaporated, the residual material was chromatographed on a column of silica gel (20 g) by using a 1:3 mixture of ethyl acetate and hexane as eluant to give the diol **30** (174.2 mg, 77%) as colorless oil: TLC R_f 0.62 (1:1 hexane/ethyl acetate); IR ($CHCl_3$) 3720—3300, 1730 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.0—0.1 (m, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—3.0 (m, 26H, CH_2CO, 10 CH_2, 2 CH, and 2 OH), 3.3—4.2 (m, 7H, OCH_3, 2 CHO, and CH_2O), 4.3—4.7 (m, 3H, 2 CHO and OCHO), 5.3—5.6 (m, 2H, vinyls); $[\alpha]_D^{26}$−38.4° (*c* 0.50, CH_3OH). HRMS Found: *m/z* 523.3063. Calcd for $C_{28}H_{47}O_7Si$: M−C_4H_9, 523.3091.

11-*O*-(*t*-Butyldimethylsilyl)-5,6-didehydro-7-hydroxy-7,9-*O*-thiocarbonyl-15-*O*-(tetrahydropyran-2-yl)PGF$_{2\alpha}$ Methyl Ester (31). To a solution of the diol **30** (57.6 mg, 0.0992 mmol) in dry CH_3CN (3 mL) were added 1,1′-thiocarbonyldiimidazole (26.5 mg, 0.149 mmol) and 4-(dimethylamino)-pyridine (36.4 mg, 0.298 mmol) at 0 °C under stirring. After stirring at 25 °C for 12 h, the mixture was diluted with CH_2Cl_2 (7 mL) followed by the addition of satd NH_4Cl aqueous solution (10 mL). The organic layer was separated and the aqueous layer was extracted twice with CH_2Cl_2 (10 mL each). The combined extracts were washed with satd brine (10 mL), dried, and evaporated. The residual material was chromatographed on a column of silica gel (5 g) by using a 1:5:1 mixture of ethyl acetate, hexane, and benzene as eluant to give the thiocarbonate **31** (56.7 mg, 92%) as yellow oil: TLC R_f 0.49 (2:1 hexane/ethyl acetate); IR ($CHCl_3$) 1730 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.04 (two s, 6H, 2 $SiCH_3$), 0.7—1.1 (m, 12H, $SiC(CH_3)_3$ and CH_3), 1.1—2.8 (m,, 24H, CH_2CO, 10 CH_2, and 2 CH), 3.3—4.2 (m, 7H, OCH_3, 2 CHO, and CH_2O), 4.63 (m, 1H, OCHO), 4.9—5.1 (m, 2H, 2 CHO), 5.4—5.6 (m, 2H, vinyls); $[\alpha]_D^{27}$−7.66° (*c* 0.32, CH_3OH). HRMS Found: *m/z* 565.2643. Calcd for $C_{29}H_{45}O_7SiS$: M−C_4H_9, 565.2656.

11-*O*-(*t*-Butyldimethylsilyl)-5,6-didehydro-15-*O*-(tetrahydropyran-2-yl)PGF$_{2\alpha}$ Methyl Ester (32). A mixture of the thiocarbonate **31** (41.5 mg, 0.0666 mmol), (n-C_4H_9)$_3$SnH (0.4 mL, 1.49 mmol), and di-*t*-butyl peroxide (4 mg) was heated at 50 °C for 1.5 h under argon atmosphere. To this mixture was added a 1 mol dm^{-3} solution of CH_3ONa in CH_3OH (1 mL) and dry THF (1 mL) and the mixture was stirred at 20 °C for 14.5 h. To this were added THF (10 mL) and then satd NH_4Cl aqueous solution (10 mL). The organic layer was separated and the aqueous layer was extracted twice with ethyl acetate (10 mL). After the combined organic extracts were dried and evaporated, the residual oil was chromatographed on a column of silica gel (2.5 g) by using a 1:6 mixture of ethyl acetate and hexane as eluant to give **32** (29.0 mg, 77%) as colorless oil: TLC R_f 0,53 (2:1 hexane/ethyl acetate); IR ($CHCl_3$) 3720—3300, 1730 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.03 (two s, 6H, 2 $SiCH_3$), 0.6—1.1 (m, 12H, $SiC(CH_3)$ and CH_3), 1.1—2.7 (m, 27H, CH_2CO, 11 CH_2, 2 CH, and OH), 3.3—4.4 (m, 8H, OCH_3, 3 CHO, and CH_2O), 4.66 (m, 1H, OCHO), 5.2—5.6 (m, 2H, vinyls); $[\alpha]_D^{26}$−28.8° (*c* 1.30, CH_3OH). HRMS Found: *m/z* 564.3828. Calcd for $C_{32}H_{56}O_6Si$: M, 564.3846.

A generous gift of chrysanthemic acid from Sumitomo Chemical Co. for the preparation of **9** is acknowledged. We deeply appreciate Ono Pharmaceutical Co. for the supply of precious samples of PGE_1, PGD_1 and for the identification of PGD_1 by 200-MHz ^{1}H NMR measurement. We also thank Dr. C. H. Lin of Upjohn Co. for sending us IR and ^{1}H NMR spectra of **28**. We also indebted to Teijin Co. for generous supply of the homochiral 4-hydroxy-2-cyclopentenone and side-chain units.

Enhancement of Sulfation of CaO by Fe_2O_3 in the Oxidative-Sorption Process for SO_2 Removal Using Fe_2O_3/CaO Binary Sorbents

Yukinori DAIRAKU, Satoshi SATO, Toshiaki SODESAWA, and Fumio NOZAKI*
Department of Industrial Chemistry, Faculty of Engineering, Chiba University, Yayoi-cho, Chiba 260
(Received May 8, 1987)

For the oxidative sorption of SO_2 using Fe_2O_3/CaO binary sorbents prepared by the usual impregnation method, reactivities and capacities for SO_2 removal have been investigated with TG measurements at temperatures near 500 °C in a stream of air containing SO_2 in concentration from 2 to 11%. Both the reactivities and the capacities of the sorbents were exceedingly enhanced by addition of Fe_2O_3 into CaO such small amounts as 0.1—0.8wt%, and further Fe_2O_3-loading over 1.0wt% resulted in a lowering in promoting effects. The changes in surface area and pore-size distribution with a variation of Fe_2O_3 content were also measured in order to discuss the correlation between chemical reactivity for SO_2 removal and physical property of the Fe_2O_3/CaO sorbents. In addition, Fe_2O_3-CaO mechanically mixed sorbents and the other binary sorbents such as Fe_2O_3/MgO or V_2O_5/CaO were tested to compare with the Fe_2O_3/CaO sorbents.

A large number of investigations has been made to develop process for waste gas desulfurization. Wet processes, such as alkali or limestone scrubbing, are being predominantly developed on a commercial scale. However, dry recovery processes are not always worthless since they would produce a usefull product and would avoid both flue gas reheating and the crystallization phenomena usually encountered in flue gas scrubbing.

In one of the dry recovery processes the waste gas is brought into contact with CaO or limestone, where upon SO_2 reacts with O_2 to produce $CuSO_4$ through the chemical reaction $SO_2+1/2O_2+CaO \rightarrow CaSO_4$.[1-3] However, in the cases of these investigations, such high temperatures as 700—1000 °C are required to facilitate the desulfurization reaction.

It has been reported that chemical activation of the limestone sorbent can be achieved by the addition of small amounts of Fe_2O_3 into the limestone.[4,5] These investigations were, however, made from the standpoint of practical technology for clean combustion of coal at the high temperature as 900 °C and the experimentals were not systematic.

In preliminary experiments, we have observed that Fe_2O_3/CaO sorbents exhibit high reactivities for SO_2 removal even at low temperatures near 500 °C. In this paper, details of the experimental results are reported together with a discussion of the relationship between chemical reactivity for SO_2 removal and physical property of the Fe_2O_3/CaO sorbents. In addition, we describe informations regarding Fe_2O_3-CaO mechanically mixed sorbents and the other binary sorbents such as Fe_2O_3/MgO or V_2O_5/CaO.

In this report, however, as a matter of convenience in experiments, sulfation tests of the sorbents were carried out by using the reactant gas containing SO_2 in

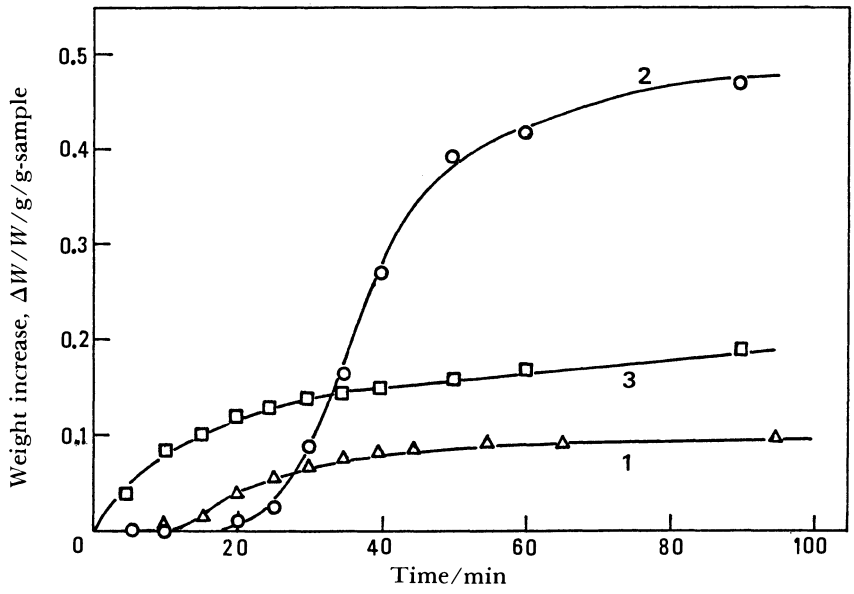

Fig. 1. Weight increase curves of various sorbents. 1: CaO, 2: Fe_2O_3 (0.11 wt%)/CaO, 3: Fe_2O_3 (0.95 wt%)/CaO. Reaction temperature: 500 °C, SO_2 concentration in the gas phase: 10.7%.

high concentration from 2 to 11%, instead of using such as a reactant gas with low concentration of SO_2 and with high concentration of CO_2 and H_2O as simulated combution gas.

Experimental

Materials. Commercial available powder of CaO reagent (Wako Pure Chemical Industries Ltd.,) was used as the sorbent after calcined at 500 °C for 2 h in a stream of air. The binary Fe_2O_3/CaO sorbent was prepared by the usual impregnation method: The prescribed mounts of $Fe(NO_3)_3$ aqueous solution were impregnated with the powders of CaO. The resulting mixture was air-dried at 120 °C, and calcined at 500 °C for 2 h in a stream of air. Several samples of Fe_2O_3/CaO sorbents differing the Fe_2O_3 content in the range of 0.1 to 3wt% were prepared by the same procedure. Mechanically mixed samples of Fe_2O_3-CaO were also prepared for the comparison with the Fe_2O_3/CaO samples prepared by the impregnation method. In the preparation of mechanically mixed Fe_2O_3-CaO sorbents, the measured amounts of Fe_2O_3, which was obtained by the calcination of $Fe(NO_3)_3$ at 500 °C, were throughly mixed with CaO powders by using agate mortar and pestle. The resulting mixtures were calcined again at 500 °C before use.

All the samples of sorbents used in this study were 12—20 mesh size. The other chemicals used were reagent grade and the gases were prepurified grade.

Apparatus and Experimental Procedure. The reactivity and capacity of various sorbents were measured in a TG reactor. The TG measurements were performed at 1 atm total pressure using a thermobalance equipped with quartz-spring which had a sensitivity of 50 μg. A small quartz boat with an area of about 1.3 cm^2 was used as the sample holder. About 200 mg of the sorbent sample was spread into a thin layer on the holder. The sample was heated to 500 °C in a stream of air and then allowed to stand for at least 30 min until there was no further weight loss. At the same temperature of 500 °C, the sufation reaction immediately followed in a flowing gas mixture of 10.7% SO_2 and the balance air, unless otherwise specified. Flow rates of the sulfating gas for the reaction were 170 ml (STP) min^{-1}, corresponding to a linear velocity of about 2 cm s^{-1}. The velocity was predetermined to be high enough to minimize gas-film diffusion resistance.

Results and Discussion

Time Course of Sulfation and Reaction Rates. Typical examples of weight increase with reaction time were illustrated in Fig. 1. Figure 1 indicates clearly that both the reactivity and the capacity of CaO reacting with SO_2 are appreciably increased by small amounts of Fe_2O_3 impregnated: CaO alone (curve 1) is usually very slow to react and its sulfation has an induction period of the order of 10 min. In contrast, CaO impregnated with about 1.0 wt% Fe_2O_3 (curve 3) is readily sulfated and there is no induction period. Fe_2O_3(0.11 wt%)/CaO sorbent (curve 2) exhibits a characteristic behavior that both the reactivity and the capacity for SO_2 removal are exceedingly enhanced by the impregnation of Fe_2O_3 such small amounts as 0.11 wt%, although the induction period has been elongated up to about 25 min.

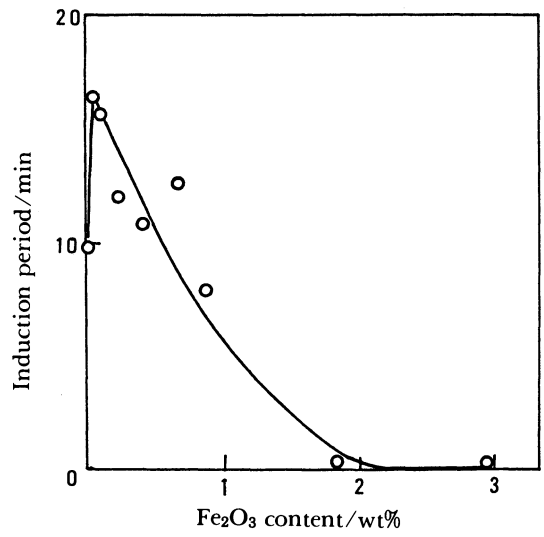

Fig. 2. Change in the induction period with Fe_2O_3 content.

As is shown in Fig. 2, the induction period in the sulfation reaction has been found to become progressively greater as the Fe_2O_3 content decreases, although the value shows some scatter. The reasons for occurrence of the induction period and for its mode of variation with the Fe_2O_3 content are still uncertain.

After the sulfation of sorbent was allowed to continue for about 100 min, X-ray diffractogram of the sorbent sample showed the pattern which was identified as those of the mixture consisting of CaO, $CaSO_4$, and Fe_2O_3. In addition, the X-ray diffractograms have proved that sulfated products such as $CaSO_3$ or $Fe_2(SO_4)_3$ are not present even in trace amounts. Thus we have tentatively speculated the reaction pathway of sulfation as the following consecutive steps:

$$SO_2\,(g) + 1/2\,O_2\,(g) \rightarrow SO_3\,(g) \quad (1)$$

$$SO_3\,(g) + CaO\,(s) \rightarrow CaSO_4\,(s) \quad (2)$$

where the oxidation step (1) of SO_2 proceeds catalytically over the surface of Fe_2O_3 and subsequent sulfation step (2) of CaO results in the formation of $CaSO_4$, accompanying weight increase in the sorbent sample.

In the weight increase-vs.-time relationship, the S-shaped curves have been observed in certain cases in which there are induction period between the start of sulfation process and the main acceleration of sulfation reaction. In these cases, the sulfation rates were varied complicatedly with the passage of time. Thus, the reactivities (the sulfation rates) were, for convenience, expressed in terms of the maximum slope of the TG measurement curves.

The sulfation rates (r) varied with SO_2 concentration of feed gas in such a way that the first-order kinetics can be roughly approximated on the basis of the data shown in Fig. 3.

Thus, it may be represented as

$$r = \left[\frac{d(\Delta W/W)}{dt}\right]_{max} = k'C_{SO_2} \quad (3)$$

where k'=apparent first-order rate constant (min^{-1} $\%^{-1}$), C_{SO_2}=SO_2 concentration in the gas phase (%).

Effects of Fe_2O_3 Content upon the Sulfation. The reactivities of sorbents were extremely affected by the variation of Fe_2O_3 content. The rate constants k' calculated from Eq. 3 are shown in Fig. 4 as a function of the Fe_2O_3 content.

As is shown in Fig. 1, the weight increase during the course of sulfation depicts a steep rise within 90 min and then levels off. Thus, it can be accepted that the conversion of CaO into $CaSO_4$ beyond reaction times of 90 min is nearly equal to the maximum conversion being expected as the sulfation process of sorbent has been saturated. Figure 5 shows the dependence of the maximum conversion of CaO with the Fe_2O_3 content.

Figures 4 and 5 show a complete similarity of shape which tends to vary from sharp peak to rounded hump. From these results, it has been found that the Fe_2O_3 content favorable to rapid sulfation and large capacity for SO_2 removal lies in the vicinity of 0.3 to 0.7 wt%. The exact mechanism for such complicated changes in the reactivity and capacity with the Fe_2O_3 content is still not understood, however, we have tentatively speculated as follows: In the case of sorbent with a low Fe_2O_3 content below 0.3 wt%, the oxidation step of SO_2 over the surface of Fe_2O_3, Eq. 1 is a rate-limiting step in the reaction sequence and thus the over-all rate of sulfation is increased with an increase in the Fe_2O_3 content. In contrast, in the samples of sorbents with a high Fe_2O_3 content above 0.7 wt%, a rate-determining step is probably allowed to move from the catalytic oxidation step of SO_2 to the diffusion step of SO_2 or SO_3 through micro-pores of Fe_2O_3/CaO binary sorbent. The diameter of the micro-pores and/or the porosity of Fe_2O_3/CaO sorbent samples seem to be reduced with an increase in the amount of Fe_2O_3 coating surface of CaO sorbent, and subsequently a fraction of the entrances to a micro-pore is blocked with an additional deposition of Fe_2O_3 when Fe_2O_3/CaO sorbent is prepared by the impregnation method. Thus, the global rates in the sulfation of Fe_2O_3/CaO sorbents with a high Fe_2O_3 content is allowed to be rapidly lowered with increasing of the Fe_2O_3 content.

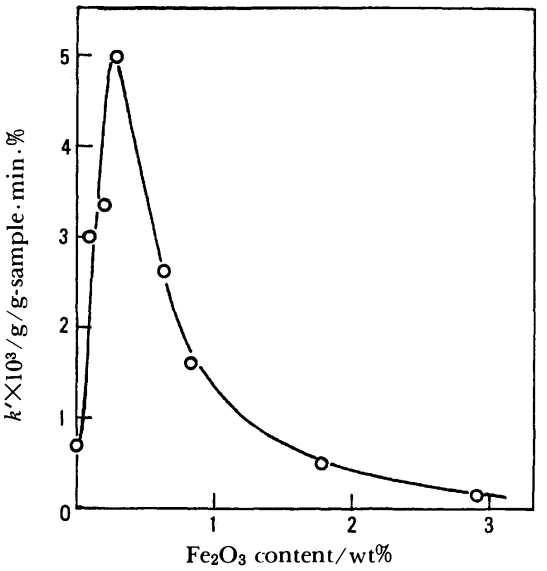

Fig. 4. Variation in rate constant k' at 500°C with Fe_2O_3 content.

The sulfation of CaO into $CaSO_4$ is well-known to be heterogeneous solid-gas reaction accompanying a change in volume of solid phase.[2] With the passage of

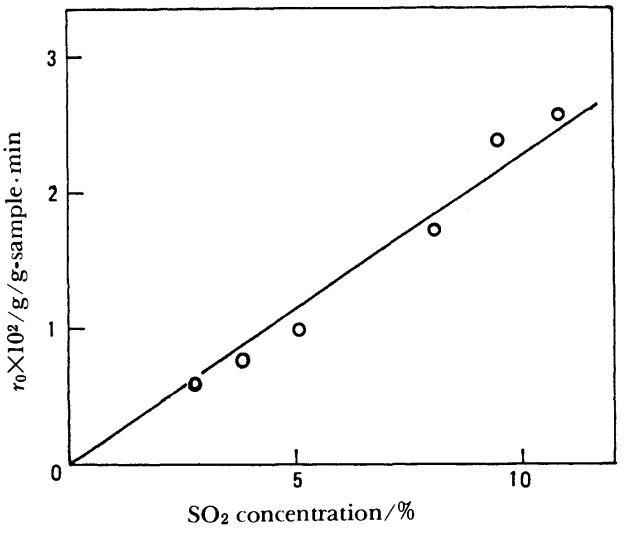

Fig. 3. Initial rates in the sulfation of Fe_2O_3 (0.11 wt%)/CaO as a function of SO_2 concentration in the gas phase. Reaction conditions are the same as for Fig. 1.

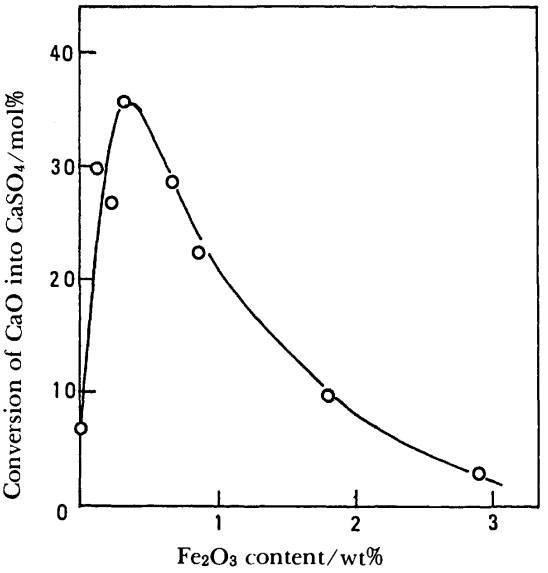

Fig. 5. Dependence of the maximum conversion of CaO with Fe_2O_3 content.

sulfation process the pore closing arises from the formation of product layer. The fraction conversion of CaO into $CaSO_4$ is ultimately limited, therefore, to the level of less than 40%, as is shown in Fig. 5.

Reactivities of Mechanically Mixed Fe_2O_3-CaO Sorbents. The sulfation experiments using mechanically mixed Fe_2O_3-CaO sorbents were separately conducted in order to compare with Fe_2O_3/CaO sorbents prepared by the impregnation method. The data of the rate constant and the conversion of CaO are shown in Fig. 6 as a function of Fe_2O_3 wt%. Figure 6 indicates that the data increase monotonically up to about 2 wt% of Fe_2O_3 content and then go up to a constant value. The shape of curves is simple and distinct clearly from such complicated curves shown in Figs. 4 and 5. However, the saturated values in both the rate constant and the conversion of CaO are close to the maximum values in Figs. 4 and 5, respectively. This fact suggests that the sulfation process proceeds consecutively through the catalytic oxidation step, Eq. (1), and the sulfation step, Eq. (2), as mentioned in the previous section. In addition, application of physically mixed Fe_2O_3-CaO sorbents is also anticipated to provide a simple and convenient method for SO_2 removal, although much larger quantities of Fe_2O_3 should be mixed with CaO in comparison with the case of sorbents prepared by the impregnation method.

Surface Area, Pore-Size Distribution and SEM-Photograph of the Sorbents Prepared by Impregnation Method. The change in surface areas of sorbents differing the Fe_2O_3 content was depicted in Fig. 7. The surface areas were determined by BET method using N_2 as the adsorbate. Figure 7 indicates that surface area of Fe_2O_3/CaO binary sorbent results in a steep rise in a very narrow interval of Fe_2O_3 content ranging from 0.1 to 0.2 wt% and then is allowed to decrease rapidly to about one-half its value in the Fe_2O_3 content of 1.0 wt% or more. The steep rise in surface area of

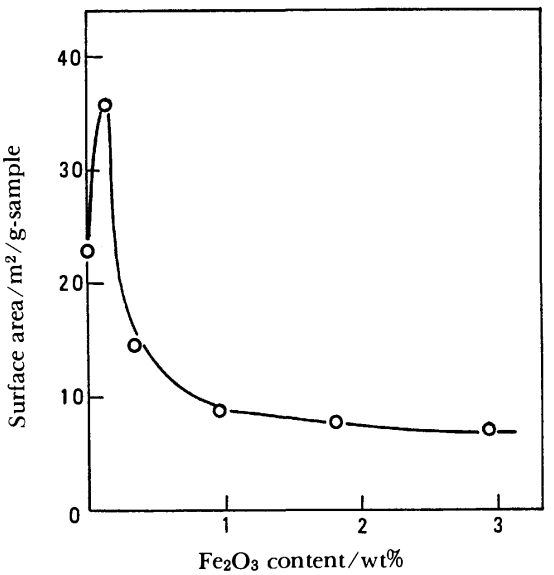

Fig. 7. Change in surface areas of Fe_2O_3/CaO samples with Fe_2O_3 content.

Fe_2O_3/CaO sorbents with a low content of Fe_2O_3 is probably due to overlapping of the surface areas of CaO itself and Fe_2O_3 finely deposited on the surface of CaO. On the other hand, the decrease in surface area in the sorbents with a high content of Fe_2O_3 over 1.0 wt% is possibly ascribed to pore closing in micro-pores of CaO by the further deposition of much larger quantities of Fe_2O_3.

The pore-size distribution measured with a mercury porosimeter is shown in Fig. 8. From the data shown in Fig. 8, it can be speculated that deposition of Fe_2O_3 trends to shrink or clog smaller pores in preference to large pores.

The scanning electron microscopic (SEM) measurements of various sorbents have clearly demonstrated that, as the amount of Fe_2O_3 impregnated is increased, fine particles constituting of solid phase of

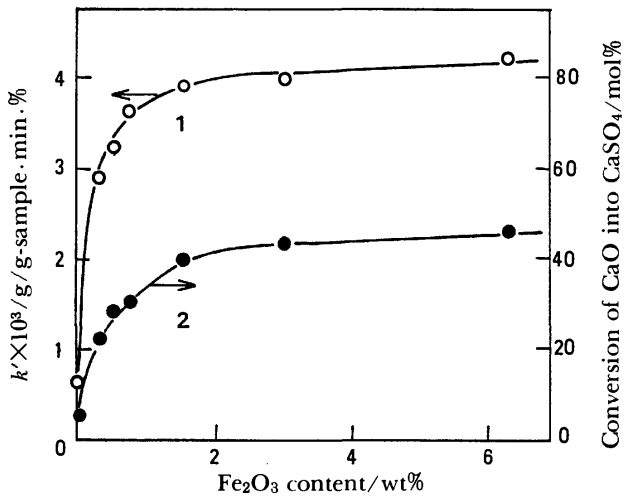

Fig. 6. Sulfation data relating to mechanically mixed Fe_2O_3-CaO samples. Reaction conditions are the same as for Fig. 1.

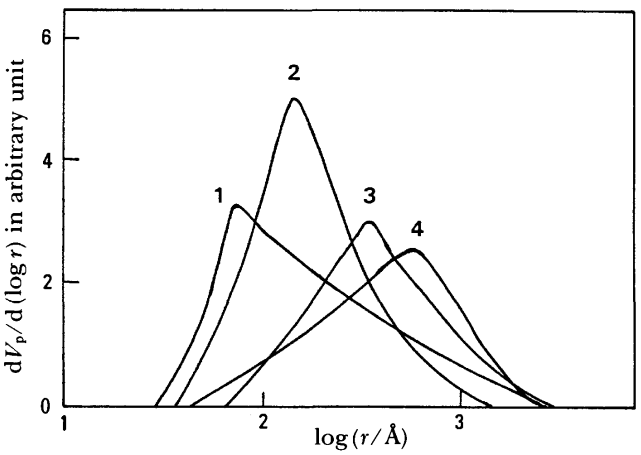

Fig. 8. Pore-size distribution in the samples. 1: CaO, 2: Fe_2O_3 (0.22 wt%)/CaO, 3: Fe_2O_3 (0.31 wt%)/CaO, 4: Fe_2O_3 (0.95 wt%)/CaO. r: pore radius in Å, V_p: pore volume.

sorbent become progressively greater in the range of about several microns to twenty microns. Similarly it has been revealed that the grain size of sorbent is allowed to appreciably enlarge by the product layer of sulfation reaction.

Other Promoters and Sorbents for Catalyzed Sulfation. In the previous sections, only the binary system consisting of Fe_2O_3 and CaO has been investigated as the sorbent. In this section, we will describe experimental results with respect to the other promoters and sorbents.

Various metal oxides such as V_2O_5, MnO_2, NiO, or CoO, other than Fe_2O_3, have been also loaded into CaO in the content of 0.3 wt% by the similar impregnation method as for Fe_2O_3/CaO sorbent. All of these oxides exhibited more or less the promotive action for catalyzed sulfation of CaO. The promoting action decreased in the order: $MnO_2 > V_2O_5 > Fe_2O_3 \gg NiO \cong CoO$. Two kinds of oxides, MnO_2 and V_2O_5, have catalytic properties somewhat superior to that of Fe_2O_3, however, application of these oxides must be avoided in the practical point of view and their high costs.

In analogy with CaO, alkaline earth oxides such as MgO or BaO are to be expected for a suitable sorbent. The sulfation tests using Fe_2O_3/MgO or Fe_2O_3/BaO have been made in order to compare their reactivities with that of Fe_2O_3/CaO.

The sorbent samples of Fe_2O_3/MgO or Fe_2O_3/BaO with a different Fe_2O_3 content were prepared by the similar impregnation method as that of Fe_2O_3/CaO. The commercial reagents of $Mg(OH)_2$ and $BaCO_3$ were used as the starting material in the preparation of the respective sorbent. These two powders of reagents were calcined at 500 °C for 2 h in a stream of air, and then were impregnated with the prescribed amount of $Fe(NO_3)_3$ aqueous solution. The resulting mixtures were hereinafter treated with the similar manner as that of the preparation of Fe_2O_3/CaO sorbent.

In the experiments used Fe_2O_3/MgO as the sorbent, the sulfation rates and the conversion of MgO into $MgSO_4$ were altered with the Fe_2O_3 content as shown in Fig. 9. Figure 9 indicates that both the rate constant k' and the conversion of MgO are lowered about one order of magnitude compared to the values of Fe_2O_3/CaO sorbent. In addition, it can be seen from Fig. 9 that capacities for SO_2 removal are increased monotonically with a low ratio by increasing Fe_2O_3 content. These facts seem to be due to poor chemical reactivity of MgO with SO_3 to the formation of $MgSO_4$. In the sulfation reaction using Fe_2O_3/MgO sorbents, the induction period was completely missing and this was also distinct from the cases of Fe_2O_3/CaO sorbents.

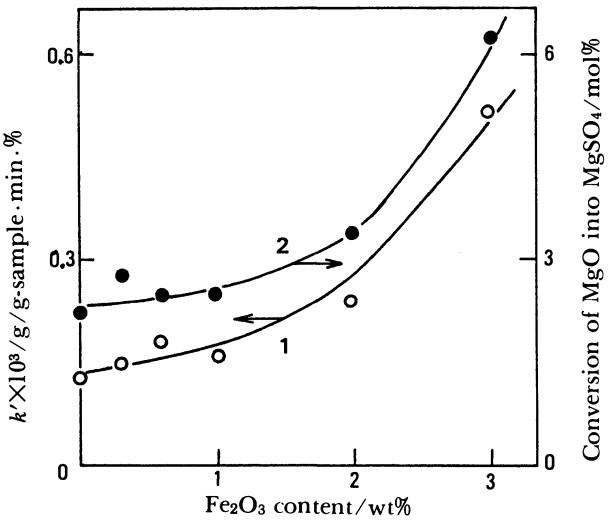

Fig. 9. Sulfation data relating to Fe_2O_3/MgO samples. Reaction conditions are the same as for Fig. 1.

The reactivities and the capacities for SO_2 removal of Fe_2O_3/BaO or Fe_2O_3/SrO sorbents were substantially comparable to that of Fe_2O_3/MgO. Consequently, the adoptability of sorbents for SO_2 removal can be summarized as $Fe_2O_3/CaO > Fe_2O_3/MgO \cong Fe_2O_3/SrO > Fe_2O_3/BaO$.

The Oxidative Polymerization of 2-Methyl-6-(3,7-dimethyl-2,6-octadienyl)phenol

Department of Polymer Chemistry, Waseda University, Tokyo 160
†Junior College of Technology, Shizuoka University, Hamamatsu 432
(Received September 10, 1987)

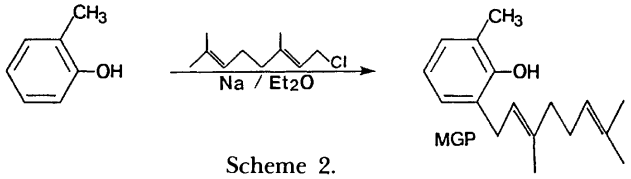
2-Methyl-6-(3,7-dimethyl-2,6-octadienyl)phenol (MGP) was prepared by the reaction of *o*-cresol and 1-chloro-3,7-dimethyl-2,6-octadiene in the presence of sodium. This MGP was then oxidatively polymerized with a copper-pyridine catalyst to yield poly[oxy[3-methyl-5-(3,7-dimethyl-2,6-octadienyl)-1,4-phenylene]]. The MGP and 2,6-dimethylphenol (DMP) copolymerized with a similar reactivity to form copolymer. The properties of the polymers were also studied.

The oxidative polymerization of 2,6-disubstituted phenols with a copper-pyridine complex as a catalyst produces poly[oxy(3,5-disubstituted phenylene)] under an oxygen atmosphere at room temperature.[1-3] Phenolic derivatives bearing isoprenoid substituents exist in nature. They are also interesting as monomers of the oxidative polymerization because they provide poly(oxyphenylene) with bulky and rigid isoprenoid groups. For example, poly[oxy(3,5-dimethyl-1,4-phenylene)] is known to show a high permselectivity of oxygen in preference to nitrogen in spite of its low permeability. Thus, it is interesting to study the effect of the bulky isoprenoid group of poly(oxyphenylene) on its gas permeability.

The present authors have previously reported the preparation of 2,6-diprenylphenol and 2-methyl-6-butenylphenol and their oxidative polymerization,[4,5] and preliminarily reported the preparation of 2-methyl-6-(3,7-dimethyl-2,6-octadienyl) phenol (2-methyl-6-geranylphenol, MGP).[6] The present paper will describe the preparation and oxidative polymerization of MGP and the copolymerization of MGP with 2,6-dimethylphenol (DMP). The reactivity of the 3,7-dimethyl-2,6-octadienyl group in the copolymer and the polymerization mechanism will also be reported.

Experimental

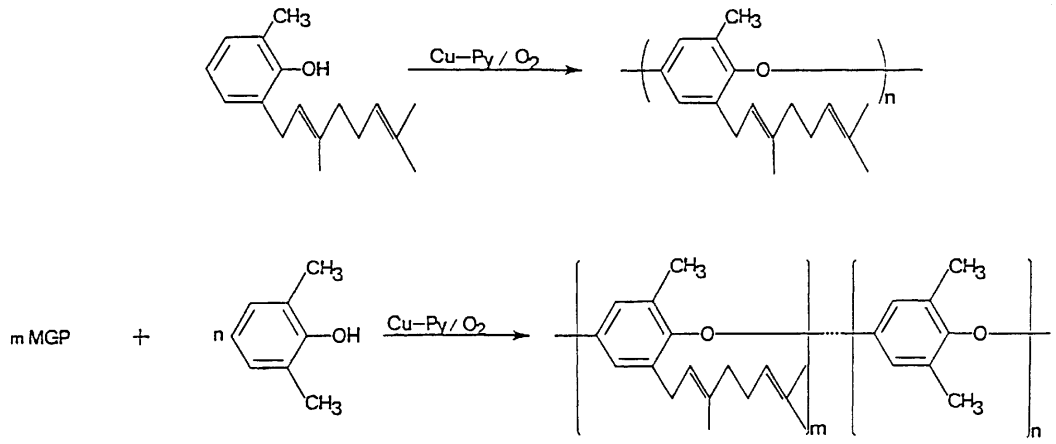
Materials: MGP was prepared as follows; *o*-cresol (1.08 g, 0.01 mol) was dissolved in dry diethyl ether (15 ml), and then metallic sodium (0.3 g, 0.013 g, atom) was added at room temperature. After 0.5 h, 1-chloro-3,7-dimethyl-2,6-octadiene (1.73 g, 0.01 mol) was slowly stirred into the mixture, and the mixture was refluxed for 1.5 h. After a usual work-up, a light yellow oil (2.68 g) was distilled i.vac.; bp 111—113 °C/0.2 mmHg (1 mmHg=133.322 Pa); yield, 71% (1.72 g). ^{1}H NMR of MGP (CCl_4, TMS standard): δ=1.60, 1.66 (s, 6H, =C(CH_3)$_2$), 1.72 (s, 3H, =(CH_3)-), 2.05 (m, 4H, -CH_2CH_2-), 2.19 (s, 3H, Ar-CH_3), 4.42 (d, J=7 Hz, 2H, O-CH_2-), 5.0 (m, 1H, -CH=C), 5.42 (t, 1H, -CH=) and 6.53—7.0 (m, 4H, Ar-H).



Scheme 2.

The DMP was a commercial one which was purified by recrystallization from hexane. the copper(I) chloride was prepared by the reduction of copper(II) chloride. The pyridine was purified by distillation after having been dried over KOH.

Preparative Polymerization. The polymerization of MGP was carried out in a benzene solution with the copper-pyridine complex as follows: CuCl (25 mg, 0.25 mmol) was dissolved in pyridine (5 ml) in a sealed flask equipped with an oxygen inlet tube, a dropping bottle, and a magnetic stirrer, and then 30 ml of benzene was added. This solution was vigorously stirred under an oxygen atmosphere to oxidize



Scheme 1.

the Cu(I) ion to Cu(II) and to obtain deep-green colored copper-pyridine complex catalytic solution. A benzene solution (15 ml) of MGP (1.22 g, 5 mmol) was then added to this catalytic solution, after which the mixture was stirred for 1 h at room temperature. The reaction mixture was then stirred into 500 ml of methanol containing a small amount of hydrochloric acid; the viscous, light brown polymer thus obtained was washed with methanol and dried i. vac. Yield, 94%.

The structure of the polymer was confirmed by NMR, IR, and elemental analysis. ^{1}H NMR of the polymer ($CDCl_3$, TMS standard): δ=1.57, 1.69 (9H, $-CH_3$), 1.94 (4H, $-CH_2CH_2-$), 2.0 (3H, $-CH_3$), 3.12 (2H, $-CH_2-$), 5.08 (2H, -CH), and 6.34—6.63 (2H, Ar-H). The intrinsic viscosity of the toluene solution of the polymer was measured at 25 °C. The content of double bonds in the polymer was determined by the method of Wijs by adding an excess of ICl to the polymer solution in the dark and by titrating the excess with $Na_2S_2O_3$. It was ascertained by the titration that no replacement reaction of the phenol ring occurred.

The copolymerization of MGP and DMP was carried out in the same way. The light yellow powder thus precipitated was filtered, washed with methanol, and dried i. vac. Yield, 91%. H NMR ($CDCl_3$, TMS standard): δ=1.59, 1.70 (9H, $-CH_3$), 1.95 (4H, $-CH_2CH_2-$), 2.1 (9H, $-CH_3$), 3.12 (2H, $-CH_2-$), 5.08 (2H, -CH=) and 6.45 (4H, Ar-H). The fraction of the MGP residue in the copolymer was determined by means of the NMR spectra.

Measurement of the Polymerization Rate. The polymerization rate was followed by means of the oxygen uptake, as the oxidation of Cu(I) was very fast under the polymerization conditions. The oxygen uptake was measured with a Warburg apparatus.

Spectroscopic Measurement. The visible absorption spectrum of the mixture of the copper-pyridine complex and phenol was measured in a pyridine solution at room temperature under an oxygen-free atmosphere.

Oxidative-Peak-Potential Measurement. The oxidative peak potential of the phenols vs. Ag/AgCl was measured by means of a cyclic voltammogram in methanol, with potassium hydroxide as the supporting electrolyte.

Addition of Bromine. One gram of the copolymer was dissolved in 50 ml of CCl_4, and then 0.2 g of bromine was stirred, drop by drop, into the solution in the dark. After 1 h, the reaction mixture was poured into methanol, and the precipitate was filtered and dried i. vac. The amount of bromine introduced to the copolymer was determined by the Volhard method.

Permeation Measurement. A membrane of the MGP copolymer was prepared by casting a chloroform solution of the copolymer on a Gore-tex film and dried i. vac. at room temperature over a two-day period before measurement. The oxygen and nitrogen permeation coefficients were measured with a low-vacuum permeation apparatus (Rika Seiki Inc. Model K-315 N-031) and were calculated from the slopes of the steady-state straight lines of the permeation curves.

Results and Discussion

The oxygen-uptake curve of the polymerization of the MGP catalyzed by the copper-pyridine complex is shown in Fig. 1. After mixing the solution of MGP with a solution of a catalytic amount of the copper-pyridine complex, a linear oxygen uptake with time is observed after an induction period. The reaction is in a stationary state, the oxygen uptake being based on the oxidation of MGP. The oxygen uptake corresponds to the polymerization of MGP, since the polymer is the only reaction product.

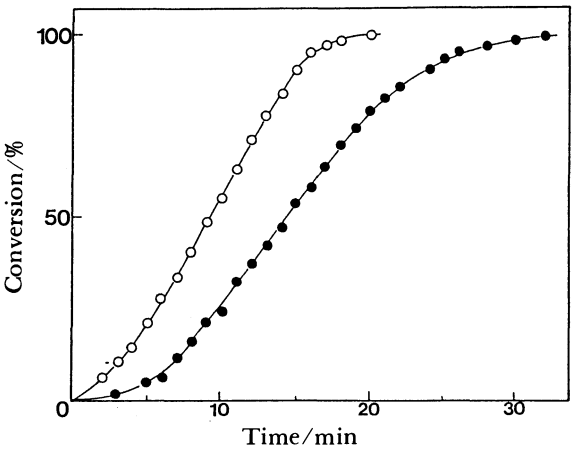


Fig. 1. Polymerization curves of MGP and DMP in benzene solution. ○: MGP, ●: DMP at 30 °C under oxygen atmosphere [Cu]=0.01 mol·l^{-1}, Pyridine 20 vol% in benzene solution.

The IR spectra of the polymers showed that the new absorptions at 990 and 1180 cm^{-1}, assigned to an ether bond, and the absorption at 3400 cm^{-1} corresponding to the hydroxyl group has almost disappeared. The ^{1}H NMR spectra were in complete agreement with those of MGP (see Experimental section).

MGP was also copolymerized with DMP. The fraction of MGP units in the copolymers and the intrinsic viscosity of the copolymers are shown in Fig. 2. Figure 2 indicates that MGP is copolymerized with DMP with a similar reactivity, but that the molecular weight of

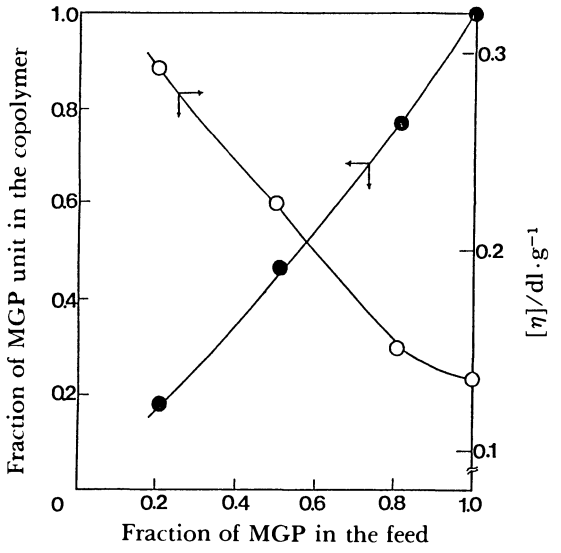

Fig. 2. Effect of the feed fraction of MGP on the composition and the intrinsic viscosity of the copolymer.

the copolymer decreases with the increase in the fraction of MGP units.

The initiation mechanism of the oxidative polymerization of phenols with the copper-pyridine complex is considered to be the following:[2] the coordination step of the phenol to the Cu(II) catalyst, the electron-transfer step from the coordinated phenol to the Cu(II) ion, the dissociation step of the activated phenol from the catalyst, and the reoxidation step of Cu(I). The previous authors have also reported[2] that the polymerization of the phenols proceeds according to a Michaelis-Menten mechanism; the following kinetic constants are estimated: the intermediate formation constants of phenol and the catalyst, K (the reciprocal of the Michaelis constant), and the reaction-rate constant, k:

$$\text{Phenol} + \text{Cu(II)} \overset{K}{\rightleftarrows} \text{Phenol-Cu} \overset{k}{\rightarrow} \text{Activated phenol} + \text{Cu(I)} \quad (1)$$

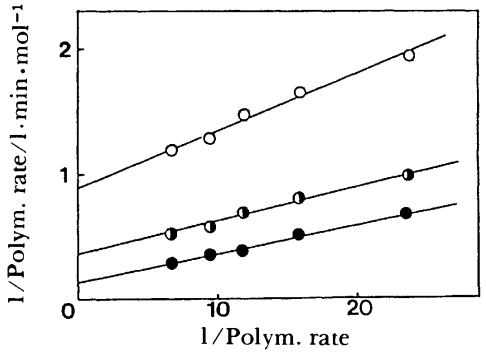

Fig. 3. Lineweaver-Burk plots for the polymerization. ○: DMP, ○: DMP-MGP (feed fraction 0.5), ●: MGP, [Cu]=1 mmol·l^{-1}, in benzene solution at 30°C under oxygen atmosphere.

The polymerization rates in a steady state for MGP and DMP were plotted with the feed phenol concentrations; their reciprocals (Lineweaver-Burk plot) show linear relationships, as in Fig. 3, supporting this mechanism. The K and k values calculated from the slopes and intercepts of the straight lines are given in Table 1.

The K value for MGP is smaller than that for DMP because the bulky 2-substituted geranyl group hinders the coordination of MGP to the copper catalyst. However, the k for MGP is larger than for DMP, leading to the relatively high polymerization rate of MGP.

Table 1. Kinetic Parameters for the Polymerization of MGP and DMP

Feed monomer fraction of MGP	K / l mol^{-1}	k / min^{-1}	k_e / min^{-1}
0	1.0	0.14	0.31
0.5	0.69[a]	0.25[a]	—
1	0.10	0.67	0.46

a) Apparent values.

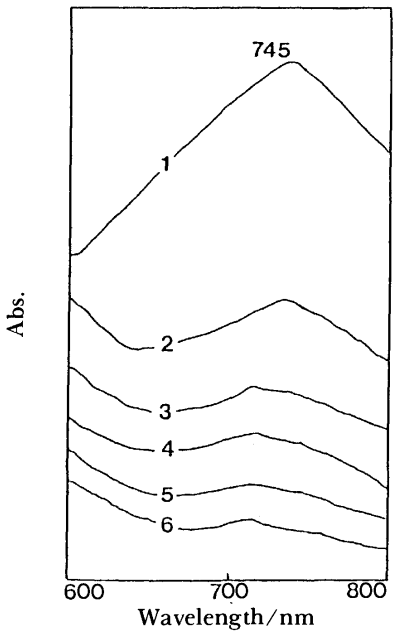

Fig. 4. Visible spectral change of the reaction mixture with time [Cu]=5 mmol·l, [MGP]=0.1 mol·l, in pyridine solution 1; without MGP, 2: 0.5 min, 3: 1.5 min, 4: 3.5 min, 5: 5,5 min, 6: 13.5 min.

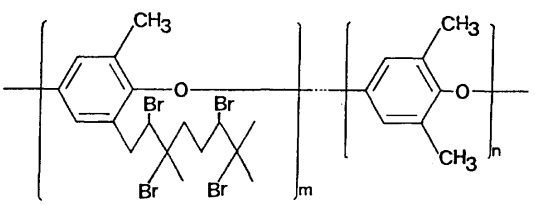
This high reactivity of MGP was further studied spectroscopically. The deep-green color of the catalyst solution is based on the Cu(II) complex. After the addition of the phenol to the catalyst solution, it turned brown, which corresponds to the Cu(I) complex formation or the electron transfer from the phenol to the Cu(II) catalyst. The change in the visible absorption is shown in Fig. 4. The measurement of the decrease in d-d absorption at 745 nm under an oxygen-free atmosphere provides the rate constant (electron transfer step: k_e). The k_e value given also in Table 1 is larger for MGP, which agrees with the result for k. This behavior is consistent with the overall polymerization as has been shown in Fig. 1. The step represented by k or k_e is the rate-determining step in this polymerization.

The oxidation-peak potential of the phenols was measured by cyclic voltammetry and is given in Table 2. This indicates that MGP is more readily oxidized than DMP, a finding which agrees with the kinetic and spectroscopic results. The electron-donating 3,7-dimethyl-2,6-octadienyl group probably reduces the oxidation peak-potential of phenol and enhances its reactivity in the polymerization.



Scheme 3.

Table 2. Oxidation-Peak Potential

Phenol	Volt
MGP	0.34
DMP	1.6

The 3,7-dimethyl-2,6-octadienyl groups in the polymer showed enough chemical reactivity, e.g. for the addition of bromine. Two bromine molecules were introduced per monomer unit of the polymer; i.e., >98% of the geranyl group was reacted with bromine. The brominated polymer is interesting for its self-extinguishing property.

The oxygen- and nitrogen-permeability coefficients are given in Table 3. The gas permeability of the MGP copolymer is comparable with that of poly[oxy-(3,5-dimethyl-1,4-phenylene)], and the copolymer shows a good permselectivity.

This work was partially supported by a Grant-in-Aid from the Ministry of Education, Science and Culture.

Equilibrium and Kinetic Studies of the Interaction between Orange I and Bovine Serum Albumin

Kiyofumi MURAKAMI
Department of Chemistry, Faculty of Science, Yamaguchi University, Yoshida 1677-1, Yamaguchi 753
(Received July 20, 1987)

The interaction between Orange I (sodium 4-[(4-hydroxy-1-naphthalenyl)azo]benzenesulfonate) and bovine serum albumin (BSA) at pH=7.0 and 25 °C has been studied by equilibrium dialysis, spectrophotometry, and the temperature-jump method. Equilibrium dialysis has revealed the existence of sixteen equivalent binding sites with the binding constant of $K=9.7\times10^3$ M^{-1}. All of them were found to be equivalent also in the sense of spectrophotometry. That is, Orange I interacts with BSA in a typically nonspecific manner. Five relaxations were found by the temperature-jump measurements. These relaxation times, distributed over the time range from 10 μs to 0.1 s, were determined over a wide range of reactant concentrations. The fastest relaxation becomes slow, but the four slower ones become fast, with the increase in the concentration of the free ligand. The data were interpreted by means of a combination of the bimolecular binding processes and the four isomerization modes of BSA. The results were discussed in the light of the role of the configurational adaptability of albumin molecules in the ligand-binding mechanism.

A unique property of serum albumin is its capacity to bind reversibly a variety of ions and organic molecules, such as metal ions, fatty acids, bilirubin, hormones, amino acids, and drugs. This enables albumin molecules to play their inherent role as the carrier and the reservior of those ligands in blood. The physicochemical origin of this unique property has been thought attributable to (1) configurational adaptability:[1] binding sites on albumin molecule can assume a large number of configurations in equilibrium with each other and can, in the presence of a ligand, adopt the configuration which is most suitable for interaction or to (2) pronounced flexibility:[2] a ligand molecule, during the binding process, is able to modify the configuration of a binding region in such a way that a greater congruence between the ligand molecule and parts of the region is achieved.

In recent years, many kinetic studies of albumin-ligand binding have been performed in order to elucidate the binding mechanism.[3-8] The general conclusion of these studies is that the ligand binding occurs through several steps: the first step is probably the diffusion-controlled bimolecular binding reaction, while the subsequent ones are the stabilization processes of the complex. This conclusion seems to be in harmony with the concept of the pronounced flexibility of albumin molecules. However, the kinetic studies have been concerned only with specific ligands which have one or few strong primary sites and several weak secondary sites and with a concentration range where only primary bindings occur. If nonspecific ligands, which have only one kind of relatively weak binding site, are used, we may obtain different features of the ligand-binding mechanism of albumin molecules.

The present paper will describe the equilibrium and the kinetics of the interaction between Orange I and bovine serum albumin (BSA) and will suggest that the configurational adaptability is also operative for albumin-ligand binding.

Experimental

Materials. The albumin (fraction V from bovine serum) was purchased from Armour and was defatted by means of charcoal treatment in an acid solution,[9] lyophilized, and stored at 4 °C. The molar concentration of BSA was determined from the absorbance at 280 nm ($E^{1\%}_{1cm}=6.6$[10]), assuming the molecular weight of 67000. The Orange I (sodium 4-[(4-hydroxy-1-naphthalenyl)azo]benzenesulfonate) was purchased from Wako Pure Chemical Industries, purified by repeated recrystallization from sodium acetate and aqueous ethanol solutions, and dried at 110 °C in a vacuum for 20 hours. All the other chemicals used were reagent-grade. All the sample solutions were prepared in a 0.1 M† phosphate buffer at pH=7.00±0.02.

Methods. The extent of binding was determined by the use of the equilibrium dialysis technique. Visking dialysis tubing (24/32) cut to a length of 9 cm was treated with a 1% $NaHCO_3$ aqueous solution at 100 °C for 60 min, soaked in a 0.3% EDTA solution, and then exhaustively rinsed with distilled water. 5 ml of the BSA solution ([BSA]=5×10^{-5} M) placed inside the dialysis tubing was dialysed against 10 ml of the dye solution at 25 °C for 24 h. After equilibration, the concentration of the Orange I solution was determined spectrophotometrically using a molar-extinction coefficient, $\varepsilon_{475}=3.24\times10^4$ $M^{-1}cm^{-1}$.

The spectrophotometric measurements were carried out with Shimadzu UV-200S and UV-100 spectrophotometers.

The kinetic experiments were performed with a Unisoku TF-102 fluorescence temperature-jump spectrophotometer. The details of the apparatus have been reported elsewhere.[11] The data were obtained at the temperature-rise intervals of 5 °C. All the experiments were performed at 25±0.2 °C.

Results and Discussion

Binding Parameters. Figure 1 illustrates a Scatchard plot[12] of the interaction of Orange I with BSA at pH=7.0 and 25 °C. The well-defined linearity of the plot shows that the binding sites of Orange I on BSA can be regarded as identical and independent. The binding parameters for the interaction were determined using the Scatchard equation:

† 1 M=1 mol dm^{-3}.

$$\frac{\bar{\nu}}{L} = nK - \bar{\nu}K \quad (1)$$

where $\bar{\nu}$ is the number of moles of the ligand bound per molecule of the protein, L is the free ligand concentration, and n and K are the number of binding sites and the association constant respectively. n and K were determined from the slope and the intercept of the plot as n=15.6 and K=9.7×10^3 M^{-1}. That is, Orange I binds nonspecifically to sixteen sites on BSA.

Spectrophotometric Titration. Figure 2 shows the absorption spectra of Orange I in the presence of BSA at several concentrations. The absorbance around 475 nm is reduced with the increase in the concentration of BSA, showing approximate isosbestic points at 415 nm and 525 nm. The existence of the isosbestic points suggests the following equilibrium between free and bound forms of the ligand:

$$\mathbf{L} + \mathbf{S} \rightleftharpoons \mathbf{C} \quad (2)$$

where **L**, **S**, and **C** denote the free ligand, the free binding site, and the complex between them respectively. The apparent molar-extinction coefficient at a given wavelength can be expressed by:

$$\varepsilon = (\varepsilon_F - \varepsilon_B)\alpha + \varepsilon_B \quad (3)$$

where ε_F and ε_B are the molar-extinction coefficients of the free and bound ligands respectively and where α is the free fraction of the ligand. α can be estimated from n, K, and the initial concentrations of the ligand and the protein (L_0 and P_0) as:

$$\alpha = \frac{-\{K(nP_0 - L_0)\} + [\{K(nP_0 - L_0)\}^2 + 4KL_0]^{1/2}}{2KL_0} \quad (4)$$

If all the sixteen sites determined by the equilibrium dialysis contribute equally to the spectral change (Fig. 2), the ε vs. α plot (Eq. 3) must be a straight line, and the ε_B's, which can be determined independently from the slope and the intercept of the plot, must agree with each other. The plots shown in Fig. 3 for 460, 475, and 490 nm indicate a good linearity. Furthermore, the values of ε_B (ε_{460}=1.96×10^4 M^{-1}cm^{-1}, ε_{475}=2.15×10^4 M^{-1}cm^{-1}, and ε_{490}=2.08×10^4 M^{-1}cm^{-1}) determined from the slope agree well with those (ε_{460}=1.94×10^4 M^{-1}cm^{-1}, ε_{475}=2.14×10^4 M^{-1}cm^{-1}, and ε_{490}=2.08×10^4 M^{-1}cm^{-1}) determined from the intercept. These results suggest that the sixteen sites are spectrophotometrically equivalent with each other.

Temperature-Jump Relaxations. The temperature-jump measurements revealed that the interaction between Orange I and BSA was characterized by five relaxation processes. Some typical relaxation curves

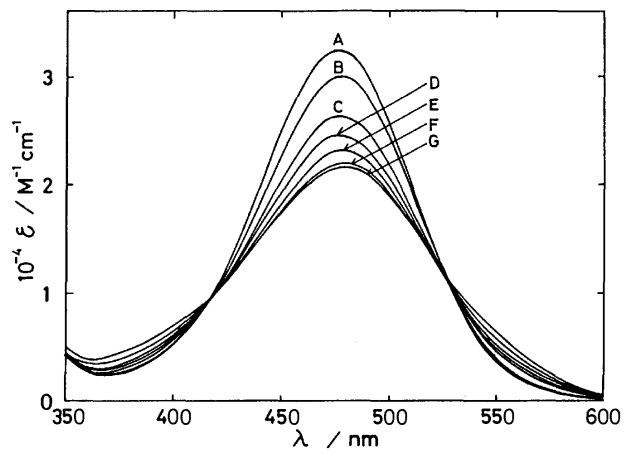

Fig. 2. Absorption spectra of Orange I in the presence of BSA at several concentrations. The data were obtained at 25°C, pH=7.0 and L_0=1.00×10^{-5}M. A: dye only, B: P_0=1.82×10^{-6}M, C: P_0=9.10×10^{-6}M, D: P_0=1.82×10^{-5} M, E: P_0=3.64×10^{-5}M, F: P_0=9.10×10^{-5}M, G: P_0=1.82×10^{-4}M.

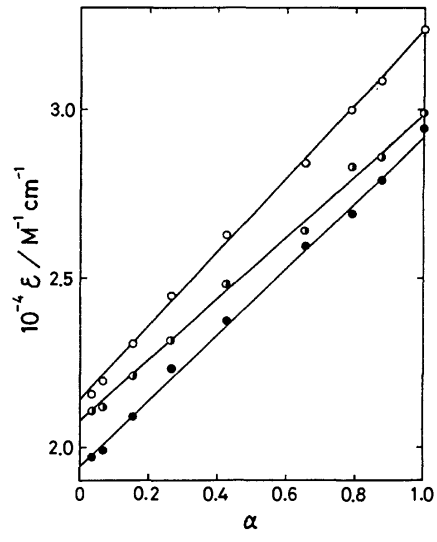

Fig. 3. Plots of ε vs. α at 460 nm (●), 475 nm (○), and 490 nm (◑). The solid lines represent least-square fits to the data.

observed at L_0/P_0 (ligand to protein ratio)=2 are shown in Fig. 4. The data were obtained at either 475 nm or 555 nm so as to give a good signal-to-noise ratio. The fastest relaxation (Fig.4(A)) was characterized by a single relaxation time (τ_1), while the second (Fig. 4(B): τ_2 and τ_3) and the third (Fig. 4(C): τ_4 and τ_5) were

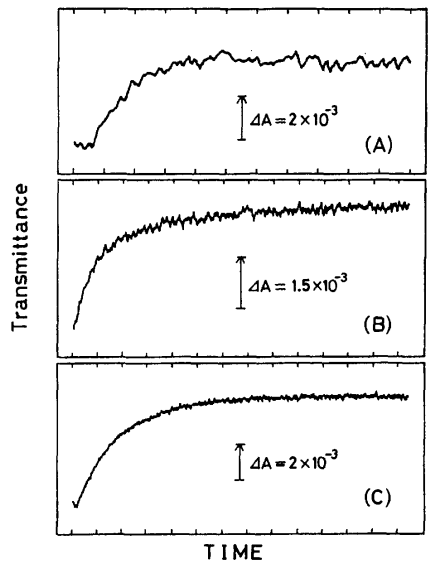

Fig. 4. Typical relaxation curves observed for the Orange I-BSA system at 25°C , pH=7.0, P_0= 5×10^{-5} M, and L_0/P_0=2. (A) λ=555 nm, 5 μs per division, (B) λ=555 nm, 1 ms per division, (C) λ=475 nm, 20 ms per division. The arrow designated for each curve shows the magnitude and the direction of the positive absorbance change.

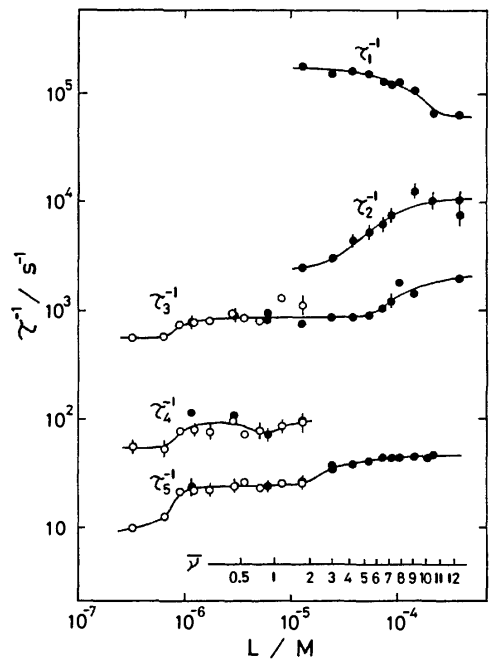

Fig. 5. Plots of τ^{-1} vs. L. The data were collected for two kinds of concentration dependence: (○) P_0/L_0 dependence (from 0.2 to 20) at $L_0=2\times10^{-5}$ M, (●) L_0/P_0 dependence (from 0.2 to 20) at $P_0=5\times10^{-5}$ M. The scale of $\bar{\nu}$ is also designated at the bottom of the figure.

double relaxations. To cover a wide range of reactant concentrations, the relaxation time of each process was determined for two kinds of concentration dependence: (1) P_0/L_0 dependence at $L_0=2\times10^{-5}$ M and (2) L_0/P_0 dependence at $P_0=5\times10^{-5}$ M. Figure 5 shows a plot of the reciprocal relaxation times versus the free-ligand concentration (L) as well as versus the $\bar{\nu}$ values, which were calculated using the values of n and K determined from the equilibrium dialysis measurement. It can be seen from this figure that the reciprocal relaxation times are increasing functions of L, except in the case of τ_1^{-1}. Furthermore, it can be seen that τ_4^{-1} disappears above $\bar{\nu}=2$ and that, in the same region, τ_2^{-1} becomes observable.

Reaction Scheme. Although the scheme of Eq. 2 is consistent with the equilibrium dialysis and the spectrophotometric data, it is obvious that this scheme is too simple to interpret the observed multiple relaxation and that it is not applicable to the present kinetic data.

Almost all the kinetic studies of albumin-ligand interaction have been concerned with specific ligands, such as bilirubin,[3,4] hemin,[7] fatty acids,[5] warfarin,[6] and Bromphenol Blue,[8] which have one strong or extremely strong primary binding site on the albumin molecule. Moreover, the data were collected over the reactant concentration range where only the primary binding occurs. A common feature of the schemes established by these studies is that a rapid bimolecular binding is followed by subsequent unimolecular stabilizations of the complex. That is,

$$\mathrm{L+S} \rightleftarrows \mathrm{C_1} \rightleftarrows \mathrm{C_2} \rightleftarrows \cdots \rightleftarrows \mathrm{C_m} \qquad (5)$$

This type of scheme predicts the reciprocal relaxation time for the i th isomerization as:[13]

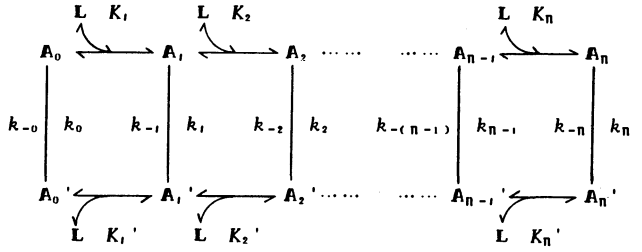
$$\tau_i^{-1} = k_i + k_{-i} \qquad (6)$$

in the case of a rapid isomerization between slow ones or:

$$\tau_i^{-1} = k_i \frac{E\,(L+S)}{1+F\,(L+S)} + k_{-i} \qquad (7)$$

in the case of an isomerization slower than the preceding steps. In these equations, k_i and k_{-i} are the forward and backward rate constants of the ith step respectively, while E and F are functions of the equilibrium constants of the preceding steps. According to these equations, the reciprocal relaxation time for any of the isomerization steps must be concentration-independent or an increasing function of $L+S$. Based on a calculation using the binding parameters determined from the dialysis measurements, it can be seen that $L+S$ decreases with the increase in L at $L<7\times10^{-4}$ M, the area where almost all the relaxations were measured. Therefore, Fig. 5 shows that the reciprocal relaxation times of the four slower processes are decreasing functions of $L+S$. That is, Eq. 5 also is not applicable to the present system.

To obtain an insight into the binding scheme, we must take notice of the fact that the reciprocal relaxation times (τ_3^{-1}, τ_4^{-1}, τ_5^{-1}) are functions of only L. This fact suggests the following basic scheme for one of the relaxation times:[14]



(8)

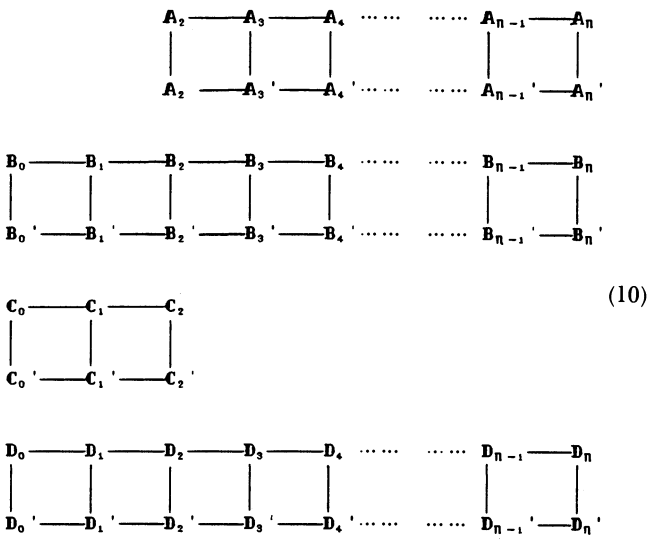
where $\mathbf{A}_i$ and $\mathbf{A}_i'$ are two isomeric forms of BSA which bind i ligands and where K_i and K_i' are association constants to form two ith complexes, $\mathbf{A}_i$ and $\mathbf{A}_{i-1}$, from $\mathbf{A}_{i-1}$ and $\mathbf{A}_{i-1}$ respectively, and where n is the maximum number of bound ligands. The equilibrium between $\mathbf{A}_0$ and $\mathbf{A}_0'$ ($\mathbf{A}_0 \rightleftharpoons \mathbf{A}_0'$) represents a mode of isomerization in the absence of a ligand, which shifts to $\mathbf{A}_1 \rightleftharpoons \mathbf{A}_1'$, $\mathbf{A}_2 \rightleftharpoons \mathbf{A}_2'$, ·····, and finally to $\mathbf{A}_n \rightleftharpoons \mathbf{A}_n'$ with the increase in the number of bound ligands. k_i and k_{-i} are the forward and backward rate constants of the ith isomerization. Assuming that bimolecular bindings are rapid compared with the isomerizations and that the concentration changes of L are negligible during the slow isomerizations, the reciprocal relaxation time for the slow steps becomes:[14]

$$\tau^{-1} = \frac{k_0 + k_1K_1L + k_2K_1K_2L^2 + \cdots\cdots + k_nK_1K_2\cdots K_nL^n}{1 + K_1L + K_1K_2L^2 + \cdots\cdots + K_1K_2\cdots K_nL^n} + \frac{k_{-0} + k_{-1}K_1'L + k_{-2}K_1'K_2'L^2 + \cdots + k_{-n}K_1'K_2'\cdots K_n'L^n}{1 + K_1'L + K_1'K_2'L^2 + \cdots\cdots + K_1'K_2'\cdots K_n'L^n} \quad (9a)$$

$$= \frac{k_0A_0 + k_1A_1 + k_2A_2 + \cdots\cdots + k_nA_n}{A_0 + A_1 + A_2 + \cdots\cdots + A_n} + \frac{k_{-0}A_0' + k_{-1}A_1' + k_{-2}A_2' + \cdots\cdots + k_{-n}A_n'}{A_0' + A_1' + A_2' + \cdots\cdots + A_n'} \quad (9b)$$

As can be seen in Eq. 9a, τ^{-1} is expressed as a function of L alone, in agreement with the present data (Fig. 5). On the other hand, Eq. 9b shows that τ^{-1} is the apparent rate constant of the isomerization , averaged over the existing complex species. At the limit of dilution, Eq. 9a can be approximated by k_0+k_{-0}. With an incease in L, the terms of the higher powers of L in both the numerator and the denominator in Eq. 9a become significant. If the terms of the ith power of L are predominant, Eq. 9a can be approximated as $\tau^{-1}=k_i+k_{-i}$ (apparent rate constant of the isomerization of the ith complex). That is, the τ^{-1} of Eq. 9 follows the rate of the isomerization of predominantly existing complexes at a given ligand concentration.

On the basis of these considerations, we may construct a scheme applicable to the present kinetic data:



(10)

where $\mathbf{A}_i \rightleftharpoons \mathbf{A}_i'$, $\mathbf{B}_i \rightleftharpoons \mathbf{B}_i$, $\mathbf{C}_i \rightleftharpoons \mathbf{C}_i'$, and $\mathbf{D}_i \rightleftharpoons \mathbf{D}_i'$ represent the four modes of isomerization which are characterized by the relaxation times of τ_2, τ_3, τ_4, and τ_5 respectively. The horizontal lines are steps of the ligand binding, where the symbols associated with the ligand (see Eq. 8) are dispensed with. According to this scheme, the observed data may be interpreted as follows.

In the absence of a ligand, there are three intrinsic modes of isomerization, designated by $\mathbf{B}_0 \rightleftharpoons \mathbf{B}_0'$, $\mathbf{C}_0 \rightleftharpoons \mathbf{C}_0'$, and $\mathbf{D}_0 \rightleftharpoons \mathbf{D}_0'$. The apparent rate constants of these modes can be evaluated from the asymptotic values of τ_3^{-1}, τ_4^{-1}, and τ_5^{-1} within the limits of the diluted ligand concentrations (Fig. 5) as 570, 55, and 7—8 s^{-1} respectively. With an increase in the concentration of free ligands, these modes shift toward those of the complex species, accompanying the increase in the apparent rate constants. At the ligand concentration where $\bar{\nu}>2$, Mode C ceases to be observable; instead, Mode A appears at a very rapid rate. This implies that the binding of two ligands freezes Mode C by displacing the equilibrium almost completely to either of the isomers or, by inducing some kind of conformational change in the complex, alternatively causes another fast mode (Mode A). With a further increase in L, the apparent rate constants increase further and reach plateau values. It may be worth noting that the relaxation amplitude of each mode has a maximum at a $\bar{\nu}$ value between 4 and 6.5 and that this relaxation amplitude decreases (Modes B and D) or increases (Mode A) with a further increase in L, suggesting that Mode A is the most predominant mode at high $\bar{\nu}$ values.

Contrary to the case of the slower relaxations, τ_1^{-1} decreases with the increase in L (Fig. 5); that is, it increases with $L+S$. Considering the very rapid rate as well, this behavior may be interpreted by attributing the relaxation to the bimolecular binding step between the free ligand and the free binding site, such as in Eq. 2. The reciprocal relaxation time for the binding step

becomes:

$$\tau_1^{-1} = k_a(L+S) + k_d \quad (11)$$

where k_a and k_d are the rate constants of association and dissociation respectively. Figure 6 shows the plot of τ_1^{-1} vs. $L+S$, which was calculated using these binding parameters: $n=16$ and $K=9.7\times10^3$ M^{-1}. In agreement with Eq. 11, the plot shows a linear dependency in the region where τ_1^{-1} is larger than 1.2×10^5 s^{-1} and where $\bar{\nu}$ is smaller than 8. The deviation from the linearity at $\bar{\nu}>8$ may arise from interactions between sites attributable to some kind of conformational change in the complex. The slope and the intercept of the plot yield $k_a=2.4(\pm0.5)\times10^8$ $M^{-1}s^{-1}$ and $k_d=1.0(\pm2.9)\times10^4$ s^{-1} respectively. From these values, the binding constant can be calculated as $K=k_a/k_d=2.4\times10^4$ M^{-1}. Considering the estimated errors, this value may be regarded as consistent with the binding constant used for this analysis. This self-consistency confirms the present assignment for τ_1.

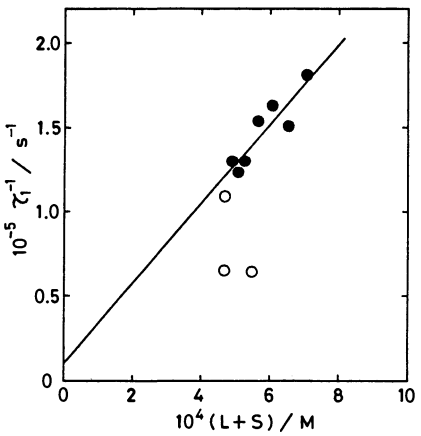


Fig. 6. Plot of τ_1^{-1} vs. $L+S$. The solid line represents the least-square fit to the data (filled circles) in the region where $\bar{\nu}<8$. Open circles show the data observed at $\bar{\nu}>8$.

Role of Isomerization Modes in Ligand-Binding Mechanism. Karush,[1] in 1950, proposed a concept of the "configurational adaptability" of albumin molecules in order to interpret their unique capability in the binding of diverse kinds of ligands. By this term, he meant that an albumin molecule in an aqueous solution is not a single form but an ensemble of many structural species in equilibrium with each other and of approximately equal energies. In the presence of a ligand, the isomeric form is stabilized by preferential interaction with the ligand, resulting in a stable complex. On the other hand, Kragh-Hansen, in his review[2] of ligand binding to serum albumin, pointed out another possibility for the binding mechanism. Many previous kinetic studies have revealed this general binding scheme (Eq. 5): a very rapid bimolecular binding, followed by sequential stabilization processes. This scheme has led him to propose a "pronounced flexibility" mechanism: a ligand molecule is, during the binding process, able to modify the configuration of a binding region so as to produce a greater congruence between the ligand molecule and parts of the region. The present scheme (Eq. 10), however, shows that BSA has, in the absence of a ligand, three modes of conformational change between isomeric forms in equilibrium. The addition of a ligand shifts the set of modes toward that of the complex species accompanying rate change, mode freezing, and the production of another mode. This behavior may be interpreted as the response of the system aimed at acquiring the most stable state as the pressure of the

ligand concentration increases. This seems to be just the case with the configurational adaptability in the sense of Karush.

Table 1 lists the rates of the isomerization steps of complex formation reported for albumin-ligand systems at around 25 °C and in the neutral-pH region, as well as those of conformational transitions observed under similar conditions. It can be seen from this table that (1) there are four modes of isomerization, which may be classified according to the rate as: A (10^3—10^4 s^{-1}), B (10^2—10^3 s^{-1}), C (10—10^2 s^{-1}), and D (1—10 s^{-1}); (2) the number of observable modes depends on the ligand species, and finally (3) the rates, i.e., the activation free energies, which belong to a mode for different ligands are all similar to each other, regardless of the structure of the ligand. Kuwajima et al.,[23] by studying the pH-jump from the E and F states to the N state[25] of albumin molecules, observed time-dependent absorbance changes at 296 nm which are characteristic of the ionization states of tyrosyl residues. The rates of these changes (50, 4 s^{-1}), listed in Table 1, agree well with those classified in Mode C and Mode D for albumin-ligand systems. Using a pressure-jump technique with circular dichroism (CD) detection, Gruenewald and Knoche[24] observed a CD change at 222 nm. Its rate (4—10 s^{-1}) is classifiable in Mode D (Table 1). This fact suggests that Mode D is an isomerization which accompanies a change in the helix content of albumin molecules. From the pH-dependence of the rates of Mode D in the Phenol Red-BSA system,[16] Mode C in the warfarin-HSA system,[21] and the Mode D observed by the pressure-jump CD measurement,[24] it can be seen that these modes are closely related to the N⇄B transition[25] of albumin molecules. Mode A and Mode B have not been well characterized from the point of view of the conformational state of the protein. Because Mode A was observed only at high L_0/P_0 values, it is not necessarily attributable to an isomerization of native albumin, but seems to arise from the albumin-ligand complex. There may also be another slow mode of isomerization ($\tau^{-1}<1$ s^{-1}),[23,26] but it is not discussed in the present paper.

These observations suggest that the modes of isomerization of pure albumin molecules are closely related to the ligand-binding mechanism. In the absence of a ligand, albumin molecules are distributed among many structural species, each of which is characterized by a set of isomers of those modes, and the structures of the albumin molecules fluctuate between those species on several time scales and to several spatial extents. Immediately after the addition of a ligand, and before the fastest mode of isomerization takes place, the ligand molecules will at first come into a rapid binding equilibrium with the instantaneous structural species. In this stage, extremely fast (faster than, or comparable to, the relaxation time of the diffusion-controlled bimolecular binding process) rearrangements of the side chains and mobile segments in the vicinity of the binding site slightly stabilize each of the isomeric forms and also slightly alter the free-energy profile of each mode. Because of the time limitation, possible structural changes must be restricted to a very local region of the protein molecule. The alteration is, therefore, probably so small that the free-energy profile and the distribution of albumin molecules among the structural species are essentially the same as those in the pure albumin solution. In the second stage, the ligand molecules will come into an equilibrium with the fastest mode of isomerization. At this stage, albumin molecules are able to use slower and larger structural changes than those in the previous step to establish a preferable interaction with ligand molecules. Each of the isomers of the fastest mode may be stabilized by the structural changes, but they may be destabilized if such a preferable interaction can not be attained because of structural restrictions, resulting in an alteration of the free-energy profile along the reaction coordinate of the fastest mode. If the activation free energy is lowered, the rate of the isomerization becomes fast and the redistribution of the complex species among the isomers is achieved through the altered mode. On the other hand, if the activation free energy becomes large, the rate becomes slow and the redistribution will be achieved mainly through the mode of pure albumin. Within the limits of a large activation free energy, however, this mode is practically prohibited. Furthermore, it may also be possible that a strong interaction between ligand and binding site causes some kinds of conformational transitions of albumin molecules and extinguishes the mode of isomerization, alternatively causing another, new isomerization mode. In each subsequent equilibration step, similar changes will occur along another reaction coordinate in still larger spatial and slower time scales, keeping the equilibrium in the faster modes. When all the modes come into an equilibrium with the ligand molecules, a stable distribution of the complexes is established. In the case of the present system, it is likely that the activation free energy of each mode is progressively lowered with the increase in the number of bound ligands and that some kinds of conformational change take place when two ligand molecules are bound. Some kinds of ligand molecules may interact selectively with either of the isomers. Even in such a case, though, it is also possible that the stabilization of the complex takes place through the reaction coordinates of the isomerization modes; that is, a bimolecular binding step is followed by subsequent unimolecular isomerizations (Eq. 5). This may correspond to the case of the interaction between albumin and such specific ligands as bilirubin.[3,4] In this way, the existence of the isomerization modes of albumin molecules may be closely connected with the formation of stable albumin-ligand complexes.

Gamma-Irradiation Effect on the Catalytic Behavior of Binary Oxide Catalysts

E. A. Hassan,* K. M. Abd El-Salaam, and A. A. Said
Chemistry Department, Faculty of Science, Assiut University, Assiut, Egypt
(Received February 18, 1986)

Decomposition of hydrogen peroxide in aqueous solution was used for testing the effect of gamma radiation on the catalytic activity of $Co_xFe_{3-x}O_4$, with $0 \leqslant x \leqslant 3.0$. The activity variation was interpreted in terms of the catalysts electronic structure. The presence of Co^{2+} on octahedral sites is superior to Fe^{2+} in the catalytic process. However, γ-irradiation can produce a considerable effect on the catalytic activity due to its influence on the active site concentration and cation distribution.

Results of most studies[1-3] on H_2O_2 decomposition indicate that among the decisive factors governing the catalytic activity is the presence of ions in various valency state as a catalytically active component. Cobalt-iron spinel oxides which can be represented as Co_x-$Fe_{3-x}O_4$ with $0 \leqslant x \leqslant 3.0$ were reported[4] to possess an activity towards H_2O_2 decomposition. As the activity can be explained in terms of intrinsic factors such as the electronic structure of the catalysts, the sensitivity of catalysts to ionizing radiation can be account.

Effect of γ-irradiation on the activity of various catalysts has been studied by several workers.[5-7] Caffrey and Allen[5] have found that the catalytic activity of silica gel in the decomposition of pentane was increased by γ-irradiation. Kohn and Taylor[7] have reported that these changes in the catalytic activities of silica gel and alumina in deuterium-hydrogen exchange were related to changes in the internal pore structures of the irradiated catalysts.

The present study is devoted to the effects of γ-irradiation on the catalytic behavior of cobalt iron oxides, in which intrinsic factors are taken into account.

Experimental

Cobalt-iron oxides over the complete composition range of the system ($0 \leqslant x \leqslant 3.0$) were prepared using analar basic cobalt(II) carbonate, iron(III) carbonate, and freshly prepared iron(II) carbonate. Iron(II) carbonate in molar ratio $(1-x)$ was added in the composition range $0 \leqslant x \leqslant 1.0$. The appropriate amounts of the carbonates were suspended in distilled water, stirred well, evaporated to dryness and then dried at 110 °C. The preparations were calcined in air at 300 °C for 4 h. The x values were 0, 0.5, 1.0, 1.5, 2.0, 2.5, and 3.0.

All samples calcined at 300 °C for 4 h, were γ-irradiated at ambient temperature with gamma rays using ^{60}Co cell with a dose rate of 27 rad s^{-1} for 70 h.

X-Ray diffraction patterns (XRD) for unirradiated and γ-irradiated samples were obtained with the aid of philips unit, type PW 2103100 using a Cu target and Ni filter.

Infrared spectra for specimens were recorded using the KBr technique in the range of 1000—200 cm^{-1} with the aid of infrared spectrophotometer Model 599B, Perkin Elmer.

The activity of the catalysts towards H_2O_2 decomposition was evaluated in the liquid phase using the gasometric technique of Cota et al.[8] Catalyst samples (100 mg) were introduced into a thermostated reaction vessel containing standardized 25 ml of 0.4 M H_2O_2 (1 M=1 mol dm^{-3}).

Results

The XRD patterns (Fig. 1) show that cobalt-iron spinel oxides have indeed been formed at 300 °C. The existence of XRD lines corresponding to d-values of 2.53, 1.48, and 1.61 Å as the more intensive lines in the spinels after γ-irradiation reveals that, at our experimental conditions, γ-irradiation preserves the spinel structure of all samples.

The recorded IR spectra for unirradiated and γ-irradiated cobalt-iron oxides are shown in Fig. 2. The expected absorption bands for the ferrites have two intense broad frequency bands sited in the region of 550—600 cm^{-1} (ν_1) and 370—390 cm^{-1} (ν_2) depending

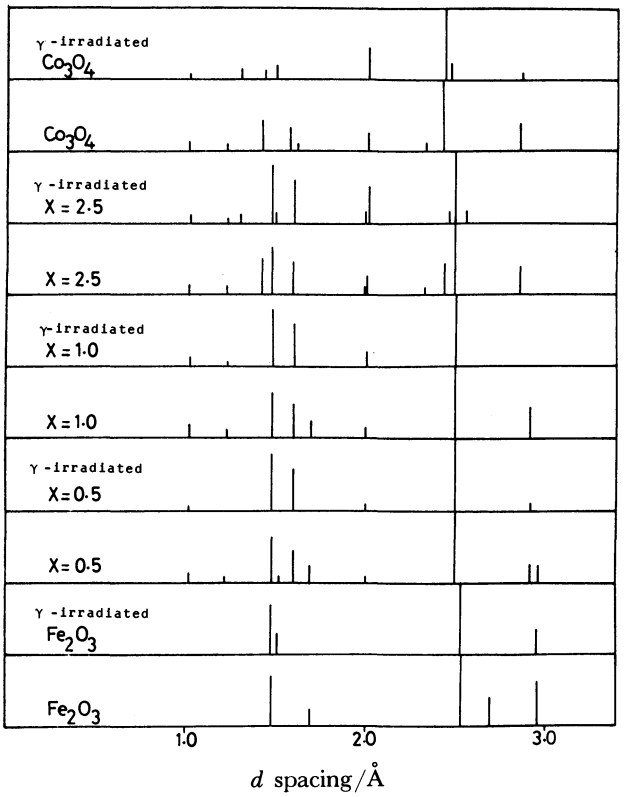

Fig. 1. XRD for unirradiated and γ-irradiated samples.

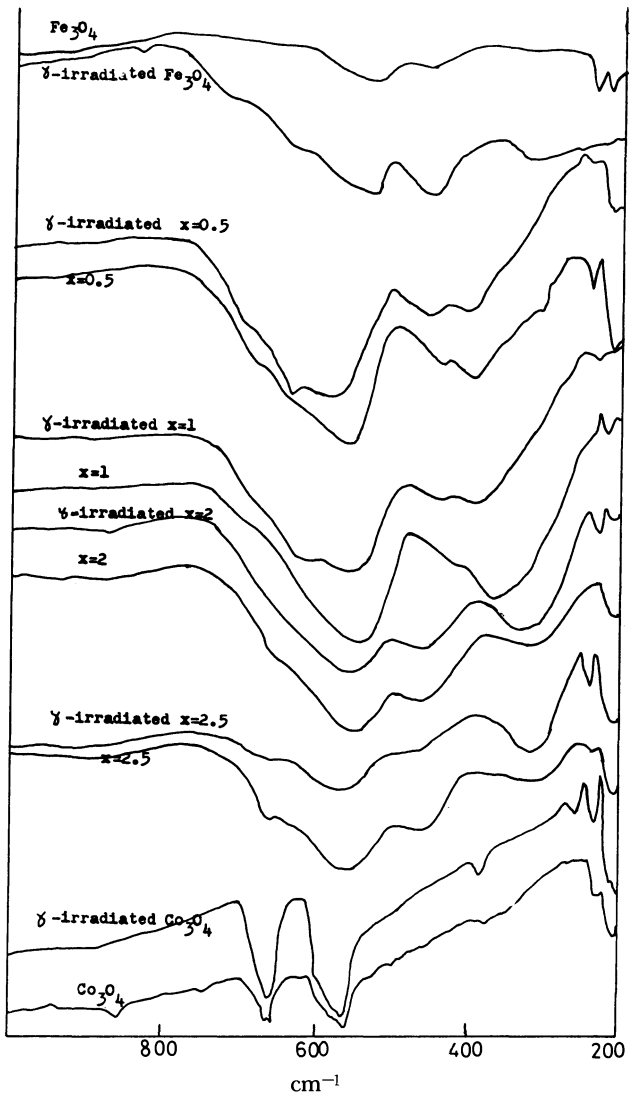

Fig. 2. IR spectra for unirradiated and γ-irradiated cobalt–iron oxides.

on the composition. At 330—350 cm^{-1} there is other band (ν_3) appeared with high concentration of cobalt (x=2.0, 2.5). At 260 cm^{-1} a small band (ν_4) was assigned. Waldron[9] attributed the ν_1-band to the intrinsic vibration of the tetrahedral groups and ν_4 to the octahedral groups. The ν_3-band was reported[9] to be assigned to the vibrations of the bivalent metal ion-oxygen complex. Preudhomme and Tarte[10] reported that ν_4 depends on the mass of bivalent tetrahedral cations. The presence of two-side band around 400 cm^{-1} in rich-iron specimens, in the present study, reveals the presence of Fe^{2+} ions in octahedral sites as confirmed in $Ni_{1-x-y}Fe_x^{2+}Zn_yFe_2^{3+}O_4$.[11]

When cobalt-iron spinels were treated with gamma rays, a displacement of the frequency bands was observed. This displacement can be attributed to gamma-induced different metal valencies and/or cation redistribution. The appearance of ν_3 in both Co_3O_4 and Fe_3O_4 informed an increase in the crystallinity of Co_3O_4 and Fe_3O_4 after γ-irradiation.

The reactivity of the unirradiated and γ-irradiated

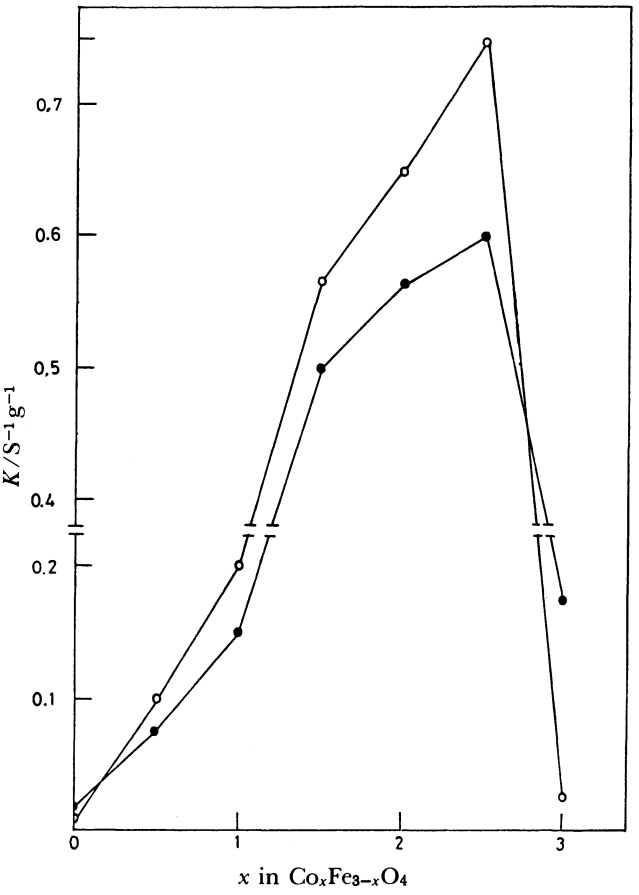

Fig. 3. Initial rate for H_2O_2 decomposition over unirradiated and γ-irradiated $Co_xFe_{3-x}O_4$, at 30°C. ●: Unirradiated, ○: γ-irradiated.

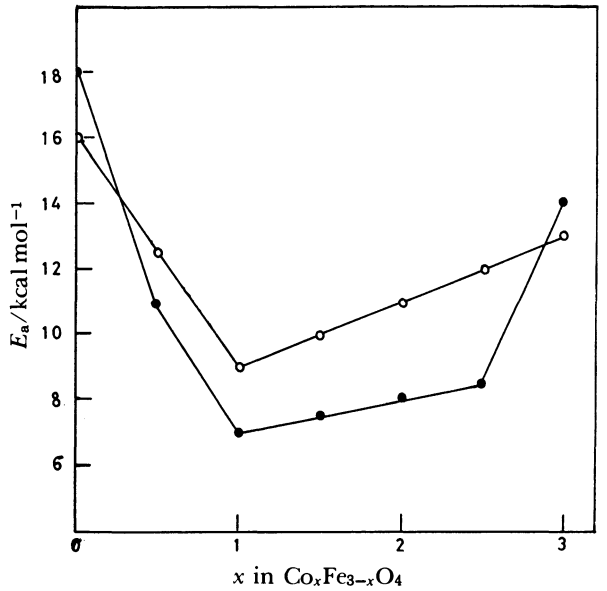

Fig. 4. Activation energy for H_2O_2 decomposition versus composition for unirradiated and γ-irradiated $Co_xFe_{3-x}O_4$. ●: Unirradiated, ○: γ-irradiated.

spinels is illustrated in Figs. 3 and 4. The H_2O_2 decomposition kinetics were found to follow a first order rate equation with respect to H_2O_2, with induced

correction for self decomposition at the experimental conditions. Gamma-irradiation increased the specific rate constants for $0 \leqslant x \leqslant 3.0$ and decreased that of $x=3.0$ sample.

Since the initial rates are dependent on the catalyst microstructure, surface morphology[12] and activation energy was selected independently. As shown in Fig. 4, γ-irradiation induces a marked change in E_a for the catalytic decomposition of H_2O_2 over $Co_xFe_{3-x}O_4$.

Discussion

In cobalt iron oxides, there are two types of bivalent ions readily promoted to the trivalent state, i.e., Fe^{2+} and Co^{2+}. The electronic structures of Co_3O_4 and Fe_3O_4 were reported as $(Co^{2+})_t[Co_2^{3+}]_oO_4$[13] and $(Fe_t^{3+})_t[Fe_t^{2+}Fe_t^{3+}]_oO_4$[14] respectively. Although Co^{2+} in Co_3O_4 is positioned on isolated tetrahedral sites, it has greater activity in H_2O_2 decomposition than octahedral Fe^{2+} ion in the inverse spinel Fe_3O_4, as seen in Fig. 4. Moreover Hart et al.[15] reported that p-type semiconducting oxides are more active catalysts for H_2O_2 decomposition than n-type which is confirmed in the present study. Jonker reported an n-type behavior for $x \leqslant 1.0$ in the $Co_xFe_{3-x}O_4$ system, while those with composition of $x \geqslant 1.0$ were p-type semiconductors. The fact that there is a contradiction between the trend of rate variation in Fig. 3 and activation energy values, reveals that the microstructure parameter controls the rate values. Cota et al.,[8] when normalized H_2O_2 decomposition rates to unit BET surface area yields intrinsic catalytic activities, which follow the trend of activation energy. Thus, the intrinsic factor in the present study is the activation energy.

Considering the spinel electronic structure as Co_x-$Fe_{3-x}O_4$, when cobalt ions are substituted into the Fe_3O_4 lattice, they first replace Fe^{2+} ions on the octahedral sites (B sites), while the Fe^{3+} ions still occupy the tetrahedral sites (A sites). In cobalt-rich region with $x \geqslant 2.0$, Co^{2+} ions occupy only the A sites as represents in Table 1.

The effect of γ-irradiation on the catalytic activity is shown in Fig. 4 can be interpreted according to the induced ionization of the ions (Co^{2+} and Fe^{2+}) with formation of free change carriers (electrons). The negative effect of γ-irradiation on the activity of p-type Co_3O_4 can be attributed to the creation of anionic vacancies, while the same effect for n-type Fe_3O_4 is attributed to the cation random distribution such as $(Fe_{1-\alpha}^{3+}Fe_\alpha^{2+})_t[Fe_{1-\alpha}^{2+}Fe_{1+\alpha}^{3+}]_oO_4$ as detected by ν_2-band lowering.

The catalytic behavior for γ-irradiated mixed oxides can be ascribed to the electron diffusion from the bulk to the surface, and recombining with the higher-valency states (Fe^{3+} and Co^{3+}). Hence the concentration of the active centers (Fe^{2+} and Co^{2+}) increased. For cobalt-rich spinels, ν_1- and ν_2-band intensities and increasing in ν_3-band intensity induced by X-irradiation suggest partially inverse structure, i.e., some Co^{3+} ions on B sites invert with Co^{2+}, giving a distribution of the form $(Co_{1-\alpha}^{2+}Co_\alpha^{3+})_t[Co_\alpha^{2+}Co_{2-x\cdot\alpha}^{3+}Fe^{3+}]_oO_4$ instead of the simple distribution $(Co_t^{2+})_t[Co_{2-x}^{3+}Fe_x^{3+}]_oO_4$. In iron-rich region, highering of ν_1- and ν_2-bands by γ-irradiation reveals formation of lower-valency states as the active sites on both A and B sites, with larger ionic radius leading to an activity increase as predicted.

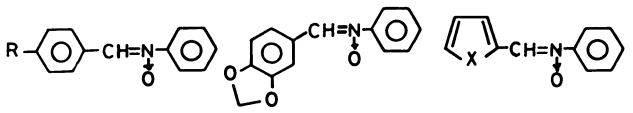
Charge-Transfer Complexes of Nitrones. VI. Molecular Complexes of Nitrones with Iodine

Ahmed M. Nour EL-DIN* and Abdel-Razak TAWFIK†
Chemistry Department, Faculty of Science, El-Minia University, El-Minia, A. R. Egypt
†Chemistry Department, Faculty of Education, Ain Shams University, Cairo, A. R. Egypt
(Received April 30, 1986)

Charge-transfer (CT) complexes between some α-aryl and α-(heterocyclic substituted)nitrones and iodine as σ-acceptor in dichloromethane have been investigated spectrophotometrically. From the energies of the charge-transfer transitions, the ionization potentials of the nitrones have been obtained. The stoichiometry of the complexes has been determined. All the results are in agreement with the n-σ* nature of these complexes with some involvement of the π-orbital of the donor.

In our earlier reports,[1-4] it has been shown that nitrones form 1 : 1 CT complexes with the π-acceptors like tetracyanoethylene (TCNE), 7,7,8,8-tetracyanoquinodimethane (TCNQ), and 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ). The results indicate also that, these complexes are weak in nature and the Ph-CH=N→O moiety is responsible for the complexation with π-acceptors. Therefore, it seemed interesting to investigate the ability of nitrones to form CT complexes with σ-acceptors like iodine.

This work reports the spectrophotometric results for CT complexes of some α-aryl and α-(heterocyclic substituted) nitrones **1a—f**, **2**, and **3a,b** as donors and iodine as σ-acceptor. The role of the nitrone group, >C=N→O, as well as the aryl and heterocyclic moieties of the electron donors on the formation and stabilization of the CT complexes with iodine have been discussed. The stoichiometry and formation constant values of the different CT complexes studied have been determined. Furthermore, the ionization potentials (I.P) of the donors under investigation have been calculated.



1a—f **2** **3a, b**

1a: R = OC_2H_5; **1b**: R = OCH_3; **3a**: X = S;
1c: R = CH_3; **1d**: R = H; **3b**: X = O.
1e: R = Cl; **1f**: R = NO_2.

Fig. 1.

Experimental

E. Merck G. R. quality iodine was resublimed under reduced pressure. The nitrones **1a—f**, **2**, and **3a**, **b** were prepared according to the literature.[5] Dichloromethane was purified following Vogel[6] dried and distilled. The formation constants K_{ct} and the stoichiometry of the CT complexes were determined utilizing the Benesi-Hildebrand equation[7] and the conventional continuous variation method[8] (Job's method), respectively. For the purpose of determining the formation constants, the concentration of I_2 was 7.505×10^{-5} M (1M=1 mol dm^{-3}), while those of the donors **1a—f**, **2**, and **3a**, **b** ranged from 3×10^{-3} to 1.5×10^{-2} M. However, for the determination of the soichiometry, stock solutions (3×10^{-3} M) of donors and acceptors were prepared. The electronic spectra were recorded from 200—750 nm with a Beckman spectrophotometer model 26, using 5 cm stoppered silica cells.

Results and Discussion

A new band in the visible region (484—499 nm) is observed on mixing dichloromethane solutions of each of nitrones **1a—f**, **2**, as well as **3a**, **b** and iodine. This broad band is attributed to the formation of CT complexes, since neither the nitrones nor the iodine alone absorb in this region. However, after standing overnight, the violet color of the solutions varied to a more yellowish hue, and sometimes a fine brownish precipitation was produced. This behavior may be ascribed to a chemical reaction between the nitrones (reactive 1,3-dipoles) and iodine. Similar behavior was observed in the CT complexes of nitrones with the π-acceptor TCNE.[3,9]

According to the electronic structure of nitrones[10] **1a—f**, **2**, and **3a**, **b**, the formation of CT complexes with iodine can be attributed to either n-σ* or π-σ* interactions. In other words, n-electrons of oxygen atom of the nitrone functional group (>C=$\overset{+}{N}$-$\overline{O}$) or π-electrons of the aromatic rest can be involved in the CT complexation process. Information on this could come from the observation of the substituent effect on λ_{max} and K_{ct} of the CT complexes formed.[11] Data in Table 1 show that, the effect of different substituent on λ_{max} s and K_{ct} s is relatively small. Although there is a great difference in both inductive and mesomeric effects between the moieties which attached to the nitrone functional group, e.g. thienyl and *p*-nitrophenyl moieties, the λ_{max} values of the CT complexes lie in a narrow range (484—499 nm). In addition, a plot of transition energies of the substituted nitrones **1a—f** against the Hammett σ_p constants[12] gave a linear fit with slope (ρ)=0.42 and shows that the substituents (OC_2H_5, OCH_3, CH_3, H, Cl, and NO_2) exert weak electronic effects upon the transition energies of the CT complexes. This result indicates that, the transmission of the substituent effect in the nitrone-iodine

Table 1. Maximum Absorption Wavelengths λ_{max} (nm), Transition Energies E (kcal mol^{-1}), Molar Extinction Coefficients ε (l mol^{-1} cm^{-1}) and Formation Constants K_{ct} (l mol^{-1}) for the CT Complexes between the Nitrones **1a—f**, **2**, and **3a**, **b** and Iodine in CH_2Cl_2 at 25 °C, as well as the Ionization Potentials I.P (eV) of the Donors **1a—f**, **2**, and **3a**, **b**

Donor	λ_{max}/nm	E	ε	K_{ct}	I.P
		kcal mol^{-1}	l mol^{-1} cm^{-1}	l mol^{-1}	eV
1a	499	57.31	3395	23.27	6.69
1b	498	57.43	3360	22.19	6.70
1c	496	57.66	3291	21.10	6.71
3a	495	57.77	2950	21.15	6.72
2	493	58.01	3385	20.11	6.73
1d	492	58.13	3188	19.69	6.74
1e	491	58.25	2922	19.12	6.75
3b	491	58.25	2560	18.55	6.75
1f	484	59.09	2265	16.83	6.80

complexes is small and implies that the interaction between the nitrone and iodine may be ascribed to the lone pair electrons of the oxygen atom of the nitrone functional group, i.e. the n-σ^* nature of these CT complexes. On the other hand, comparison of this ρ value with the corresponding value of the analogous π-σ^* complexes[7] shows that, the nitrone **1a—f**-I_2 complexes exhibits low ρ value and give an evidence for the n-σ^* nature. Moreover, the formation constant K_{ct} values of the CT complexes (Fig. 2) follow the same pattern as λ_{max} and gives another evidence for the n-σ^* nature of the CT complexes. Hence, it can be inferred that the complexation process between the nitrones and iodine is due to the lone-pair electrons of oxygen atom. In addition, the extra negative charge on the oxygen atom should make it a better electron donor according to charge transfer theory[7,13] and consequently the center reasonably seems to be the oxygen atom. However, as was stated previously,[13] 2p π electrons of the oxygen atom in nitrones are conjugated with the rest of the π-electron system and the N-O bond has about 30% of double bond character.[14] Thus, it can be concluded that, the complexation process between the nitrones and iodine can be attributed to n-σ^* interaction, with small involvement of the π-orbital of the aromatic rest of the nitrones.

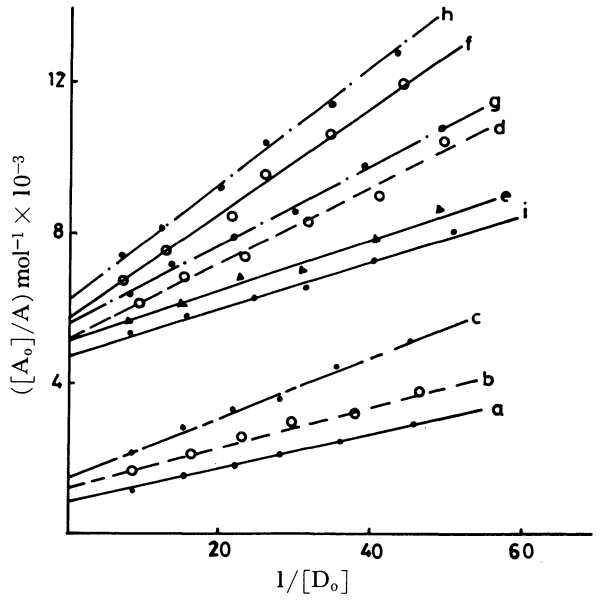


Fig. 2. Typical plots employed in the calculation of formation constants of complexes: (a) **1a**-I_2, (b) **1b**-I_2, (c) **1c**-I_2, (d) **3c**-I_2, (e) **2**-I_2, (f) **1d**-I_2, (g) **1e**-I_2, (h) **3b**-I_2, (i) **1f**-I_2; $[A_o]=7.505\times10^{-5}$ M and $[D_o]=3\times10^{-3}$ to 1.5×10^{-2} M. Dichloromethane used as solvent.

The ionization potential values listed in Table 1 were estimated from the energies of the CT bands applying the following empirical equation:[7,11]

$$\text{I.P (eV)} = 2.90 + 1.89\times10^{-4}\,\tilde{\nu}_{I_2}\,(\text{cm}^{-1})$$

Recently,[15] the complexation process between α-aryl nitrones and π-acceptors (TCNE and 1,4-benzoquinones) has been attributed to π-π^* interaction. A comparison of the I.P values of the nitrones **1b—e** in the case of iodine complexes with those values in cases of DDQ and TCNE complexes indicates that there is a reasonable difference between both I.P values (Table 2). Such difference suggests that the orbital of nitrones involved in the interaction with iodine acceptor is different from that involved in cases of DDQ and TCNE. Again, this result reinforces the suggestion of the n-σ^* nature of the nitrones-iodine complexes.

The stoichiometry of the molecular complexes formed were determined by application of Job's method[8] (continuous variation method). The plots of the intensity of the CT band maxima against the mole fraction of the donors (Fig. 3) furnished symmetrical curves with maxima at mole fraction 0.5 indicating

Condensation and Cyclization Reactions of 2-Hydrazinobenzimidazole, -benzoxazole, and -benzothiazole

M. Z. A. Badr,* A. M. Mahmoud, S. A. Mahgoub, and Z. A. Hozien
Chemistry Department, Faculty of Science, Assiut University, Assiut, Egypt
(Received June 16, 1986)

2-Hydrazinobenzoxazole (**1**), -benzimidazole (**2**), and benzothiazole (**3**) were condensed with ethyl chloroformate and/or diethyl oxalate to produce, 1,2,4-triazolo- and 1,2,4-triazino-fused ketones of the title azoles respectively. Condensation of **1** and **2** with aromatic aldehydes and/or acetic anhydride produced, 3-aryl- and 3-methyl-substituted 1,2,4-triazolo-fused azoles respectively. The hydrazines **1** and **2** cyclized with acetylacetone to produce the corresponding 2-(1-pyrazolyl) derivatives. 2-Acetylthiazolobenzimidazole reacted with hydroxylamine and/or alkylamines, to produce the corresponding condensation products. Also it condensed with aromatic aldehydes to give the chalcones. When reacted with benzenediazonium salt, it gave the corresponding 2-arylazo-substituted compounds.

Thiazolo[3,2-*a*]benzimidazole derivatives have long been known for their antibacterial activity[1] and their quaternary salts as hypoglycaemicagents.[2] Fungicidal,[2,3,5] herbicidal,[4] insecticidal,[5] and plant-growth-regulating[6] properties of thiazolobenzimidazoles have also been reported. On the other hand, benzimidazoles have been reported to be used as anthelmintics,[7] for treatment of *Echinoccus granulosus* or *Tinea hydatigena*[8] and as antiabesity together with other variable applications.

In the present paper we report new procedures for synthesis of new benzimidazoles, benzoxazoles, and benzothiazoles and the thiazolo[3,2-*a*]benzimidazoles through variable condensation and cyclization reactions.

Results and Discussion

As a continuation for our studies[9] on synthesis of fused heterocyclic ring systems constituting triazolo, triazino, and tetrazolo moiety, through cyclization

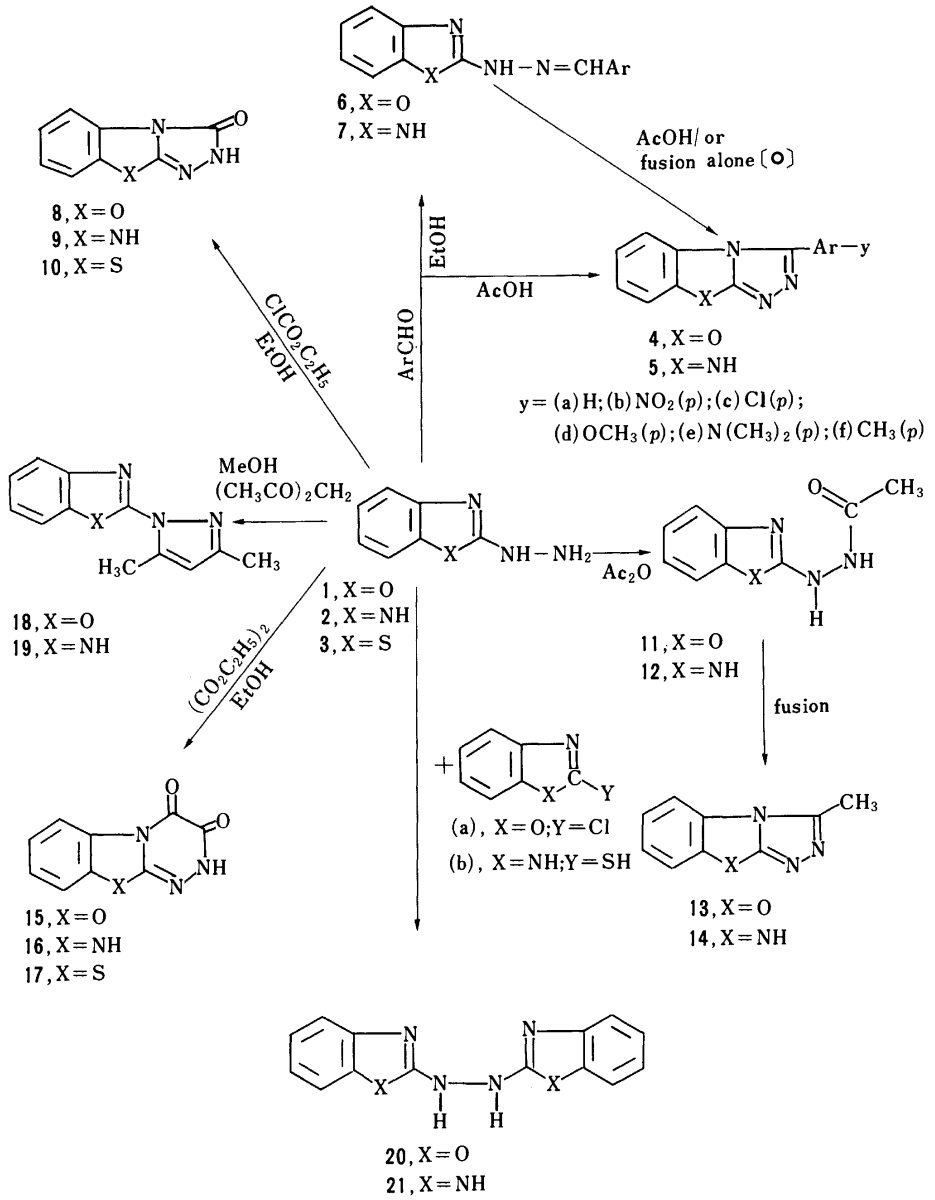
a) Compound **8**, IR(KBr) 3385 (NH), 1710 (C=O enolic), 1660 (C=N), 1100 (C-O-C), 1610, 1590, 1560 cm^{-1} (oxazole); **10**, IR(KBr) 3300 (NH), 1590 (C=O), 1640 (C=N), 1240 cm^{-1} (C-O-C); **11**, IR(KBr) 3310 (NH), 1725 cm^{-1} (C=O), **12**, IR(KBr) 3315 (NH), 1670 cm^{-1} (C=O), ^{1}H NMR ($CDCl_3$) δ=2.50 (s, 3H), 7.40 (m, 4H) δ of NH is downfield; **15**, IR(KBr) 1695, 1645 (COCONH), 1610 (C=N), 1605, 1585, 1555 (oxazole), 1090 cm^{-1} (C-O-C); **16**, IR(KBr) 1710, 1703 (COCONH), 1675 (C=N), 3220 (NH), 1185 cm^{-1} (C-N); **17**, IR (KBr) 1590 (COCONH), 1620 (C=N), 3300 (NH), 1200 cm^{-1} (C-S-C); **18**, ^{1}H NMR ($CDCl_3$) δ=2.60 (s, 3H), 3.20 (s, 3H), 7.3—8.0 (m, 5H, 4HAr+1H, C=CH); **19**, ^{1}H NMR ($CDCl_3$) δ=2.15 (s, 3H), 2.35 (s, 3H), 7.15—7.77 (m, 5H, 4HAr+1H, C=CH), 11.50 (1H, NH).



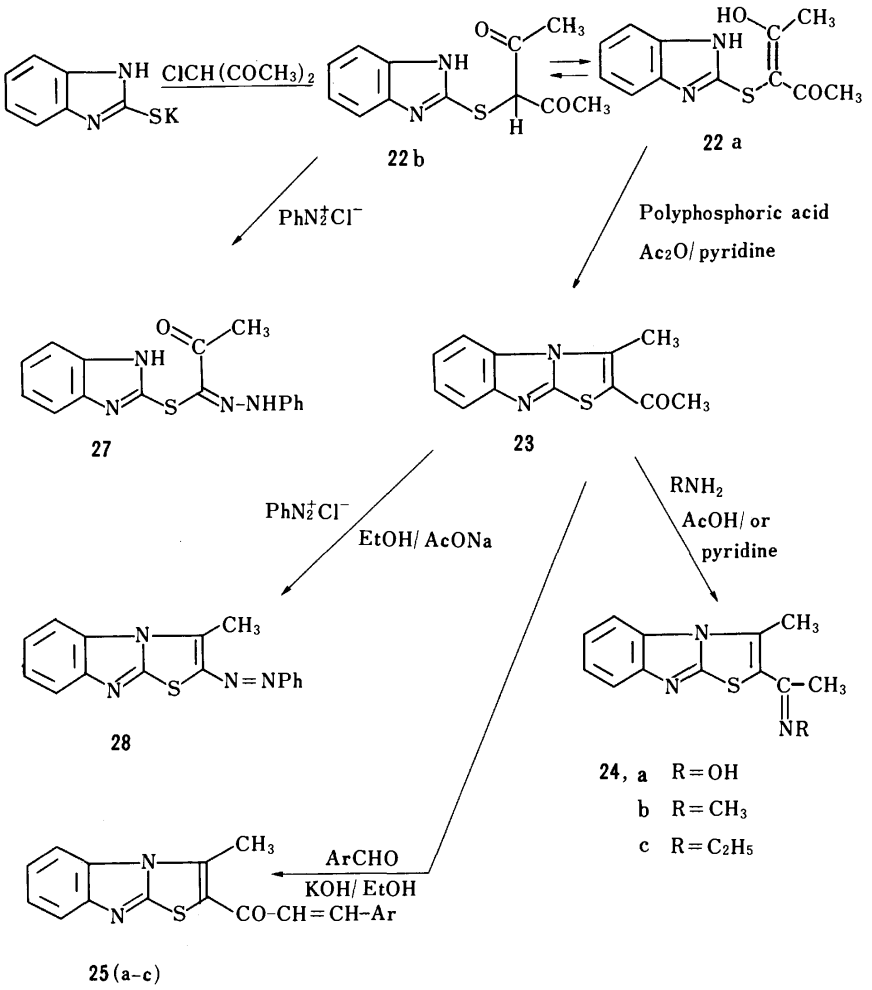
Scheme 1.

reactions, we had discussed the synthesis of comparable heterocycles constituting benzoxazoles, benzimidazoles, and benzothiazoles and thiazolobenzimidazole ring systems.

Reaction of 2-hydrazinobenzoxazole (**1**)[10] and/or 2-hydrazinobenzimidazole (**2**)[10] with benzaldehyde and its *p*-nitro, *p*-chloro, *p*-methoxy, *p*-dimethylamino, and *p*-methyl derivatives in glacial acetic acid gave the corresponding 3-aryl-1,2,4-triazolo[4,3-*b*]benzoxazoles (**4a—f**) and 3-aryl-1,2,4-triazolo[4,3-*a*]benzimidazoles (**5a—f**) respectively. The IR spectra (Table 1) of **4** and **5** showed no (NH_2) bands at 3300, 3200, and 3350, 3250 cm^{-1}, but exhibited (C=N) bands at 1610—1680 and 1650—1700 cm^{-1} together with other characteristic bands. The NMR spectrum of (**5a**) (in DMSO-d_6) showed multiplet at δ 7.1—7.45 (9H, aromatic protons) and broad singlet at δ 9.1—9.85 (1H, NH proton). Compounds **4** and **5** were further produced through ring closure reactions of the corresponding aldehyde (2-benzoxazolyl)hydrazones (**6a—f**) and/or aldehyde (2-benzimidazolyl)hydrazones (**7a—f**) by their refluxing with glacial acetic acid or by its fusion through air oxidation[9,11] (Table 2).

Refluxing **1**, **2**, and **3** with ethyl chloroformate in absolute ethanol produced 1,2,4-triazolo[4,3-*b*]benzoxazol-3(2*H*)-one (**8**); 9*H*-1,2,4-triazolo[4,3-*a*]benzimidazol-3(2*H*)-one (**9**) and/or 1,2,4-triazolo[4,3-*b*]benzothiazol-3(2*H*)-one (**10**) respectively (Table 3).

Refluxing **1** and/or **2** with acetic anhydride produced the corresponding monoacetyl derivatives (**11** and **12**) which cyclized on heating over its melting points into 3-methyl-1,2,4-triazolo[4,3-*b*]benzoxazole (**13**) and 3-methyl-9*H*-1,2,4-triazolo[4,3-*a*]benzimidazole (**14**) respectively in comparable cyclization mechanism as recorded before.[9,12] The IR spectra of both **11** and **12** showed disappearance of (NH_2) bands



Scheme 2.

and the presence of (NH) group which was also characterized by other spectral means (Table 3).

Similarly, refluxing **1**, **2**, and **3** with diethyl oxalate in absolue ethanol produced the cyclization products, 2*H*-1,2,4-triazino[4,3-*b*]benzoxazole-3,4-dione (**15**), 1,2,4-triazino[4,3-*a*]benzimidazole-3,4-dione (**16**) and 1,2,4-triazino[4,3-*b*]benzothiazole-3,4-dione (**17**) respectively. The IR spectra showed characteristic bands (Table 2). On the other hand, refluxing **1** and **2** with 2,4-pentanedione in methanol produced, 2-(3,5-dimethyl-1-pyrazolyl)benzoxazole (**18**) and 2-(3,5-dimethyl-1-pyrazolyl)benzimidazole (**19**) respectively in similar cyclization step as before,[13,14] which showed characteristic NMR spectra (Table 3). Moreover, refluxing **1** with 2-chlorobenzoxazole and refluxing **2** with benzimidazole-2-thiol in absolute ethanol produced 2,2′-hydrazobis(benzoxazole) dihydrochloride (**20**) and 2,2′-hydrazobis(benzimidazole) (**21**) respectively. Their IR spectra showed disappearance of (NH_2) bands at 3300, 3200 and 3350, 3250 cm^{-1}.

Heating of 3-(2-benzimidazolylthio)-2,4-pentanedione (**22b**) with polyphosphoric acid or refluxing in acetic anhydride-pyridine mixture produced 2-acetyl-3-methylthiazolo[3,2-*a*]benzimidazole (**23**).[15] Its IR spectrum showed the disappearance of the (enolic OH) and (NH) bands at 3370 and 3350 cm^{-1}. Its NMR (in $CDCl_3$) showed singlet at δ 2.48 (3H, CH_3), singlet at δ 3.03 (3H, $COCH_3$) and multiplet at δ 7.05—8.15 (4H, aromatic protons).

Coupling of compounds **22b** and **23** with benzenediazonium salt and sodium acetate in ethanol had resulted into a Japp-Klingemann type reaction[16] producing the corresponding products, 1-(2-benzimidazolylthio)-1-(arylhydrazono)-2-propanone (**27**) and 2-phenylazo-3-methylthiazolo[3,2-*a*]benzimidazole (**28**) respectively. The IR spectrum of **27** showed appearance of bands at 1650 (C=O) and 3150 cm^{-1} (NH), while that of **28** showed disappearance of (C=O) band at 1645, and appearance of (N=N) band at 1640 cm^{-1} together with other characteristic bands.

Refluxing **23** with hydroxylamine, methylamine, and/or ethylamine hydrochloride in acetic acid or in pyridine produced the corresponding oxime **24a** and/or Schiff's bases **24b** and **c**. Higher aliphatic alkyl and aromatic amines were unsuccessfully condensed under variaty of conditions which may be attributed to steric factors. The IR spectra of **24a—c** showed no (C=O) band at 1645, but (C=N) band at 1610 and a broad (OH) band at 3450 cm^{-1} in the oxime **24a** spectrum.

Table 4. Physical and Analytical Data of Compound **24** and **25**

Compd[a]	Mp(θ_m/°C) (Solvent)	Yield/%	Molecular formula	Anal. (Calcd / Found)/%			
				C	H	N	S
24a	285 (AcOH)	75	$C_{12}H_{11}N_3OS$	58.78 58.76	4.49 4.50	17.14 17.20	13.06 13.10

a) Compound **25a**, ^{1}H NMR (DMSO) δ=2.5 (s, 3H), 6.9—7.8 (m, 11H, 9HAr+2H, HC=CH); **25b**, ^{1}H NMR (DMSO) δ=2.51 (s, 3H, CH_3), 7.2—8.5 (m, 10H, 8HAr+2H, CH=CH).

Condensation of **23** with benzaldehyde and its *p*-nitro and *p*-dimethylamino substituents in ethanolic KOH produced the corresponding 2-(3-aryl-1-oxo-2-propenyl)-3-methylthiazolo[3,2-*a*]benzimidazoles (**25a—c**) (Table 4).

Experimental

Melting points were uncorrected. Infrared spectra were recorded on Unicam SP 200 g. Perkin-Elmer 599B and Shimadzu infrared spectrophotometers using potassium bromide Wafer technique. Ultraviolet spectra in ethanol were measured on Shimadzu 200S spectrophotometer and NMR spectra were recorded on Varian A60 and EM-390 (90MHz). MS were recorded on AEI MSI2 spectrophotometer at 70 eV.

Reactions of 2-Hydrazinobenzoxazole and 2-Hydrazinobenzimidazole (1 and 2) with Aromatic Aldehydes: i) (2-Benzoxazolyl)hydrazones (6a—f) and (2-Benzimidazolyl)hydrazones (7a—f): The hydrazino compounds[10] **1** and/or **2** (0.1 mol) and aromatic aldehydes (0.01 mol), namely benzaldehyde (**a**) and *p*-nitro- (**b**), *p*-chloro- (**c**), *p*-methoxy- (**d**), *p*-dimethylamino- (**e**), and *p*-methylbenzaldehyde (**f**) were refluxed in ethanol. The solids were separated on cooling, filtered and recrystallized from the proper solvent to give the corresponding hydrazones **6** and **7** which show characteristic mps as listed in Table 2.

ii) 3-(*p*-Substituted phenyl)-1,2,4-triazolo[4,3-*b*]benzoxazoles (4) and 3-(*p*-Substituted phenyl)-1,2,4-triazolo[4,3-*a*]benzimidazole:[5] **General Procedure:** A mixture of the hydrazino compound **1** and/or **2** (0.01 mol) and the aromatic aldehydes (0.01 mol) was refluxed in glacial acetic acid. After cooling, the separated solid was recrystallized from proper solvent, which gave the characteristic mps as shown in Table 1. The same compounds were produced from the corresponding hydrazones **6** and **7** on refluxing in glacial acetic acid for 8 h or on heating over their mp for 10 min.

1,2,4-Triazolo[4,3-*b*]benzoxazol-3(2*H*)-one (8), 9*H*-1,2,4-Triazolo[4,3-*a*]benzimidazol-3(2*H*)-one (9), and 1,2,4-Triazolo-[4,3-*b*]benzothiazol-3(2*H*)-one (10): A mixture of corresponding hydrazino compounds **1—3** (0.01 mol) and ethyl chloroformate (0.1 mol) in absolute ethanol (10 ml) was refluxed for 4 h. The solid separated was filtered and recrystallized from proper solvent to separate the corresponding triazolo compounds in Table 3.

3-Methyl-1,2,4-triazolo[4,3-*b*]benzoxazole (13) and 3-Methyl-9*H*-1,2,4-triazolo[4,3-*a*]benzimidazole (14): i) A mixture of hydrazino compounds **1** and **2** (0.1 mol) and acetic anhydride was refluxed for 8 h. The solid separated on cooling, filtered, and recrystallized from proper solvent to give the corresponding monoacetyl compounds **11** and **12** respectively as in Table 3.

ii) The monoacetyl compounds **11** and **12** were heated over their melting points for 30 min, cooled and recrystallized from 1-butanol to produce the corresponding methyltriazoles **13** and mp 170 °C and **14** mp 231 °C[17] respectively. Found: C, 62.42; H, 4.10; N, 24.33%. Calcd for $C_9H_7N_3O$ (**13**): C, 62.43; H, 4.05; N, 24.3%.

2*H*-1,2,4-Triazino[4,3-*b*]benzoxazole-3,4-dione (15), 1,2,4-Triazino[4,3-*a*]benzimidazole-3,4-dione (16), and 1,2,4-Triazino[4,3-*b*]benzothiazole-3,4-dione (17): A mixture of the corresponding hydrazino compounds (0.1 mol) and diethyl oxalate (0.1 mol) in absolute ethanol (10 ml) refluxed for 3 h. The solid separated on cooling was filtered and recrystallized from proper solvent to give corresponding triazino compounds as in Table 3.

2-(3,5-Dimethyl-1-pyrazolyl)benzoxazole (18) and 2-(3,5-Dimethyl-1-pyrazolyl)benzimidazole (19): A mixture of the corresponding hydrazino compounds (0.1 mol) and 2,4-pentanedione (0.1 mol) in methanol (20 ml) was refluxed for 3 h. The solid separated on cooling, filtered and recrystallized from proper solvent into the corresponding pyrazolyl compounds **18**[18] and **19** respectively as in Table 3.

2,2′-Hydrazinobis(benzoxazole) (20): A mixture of **1** (0.1 mol) and 2-chlorobenzoxazole (0.1 mol) in absolute ethanol was refluxed for 2 h. The solid separated on cooling, filtered, and recrystallized from ethanol as white crystals of **20** as hydrochloride; yield 60%, mp 198 °C. Found: C, 49.50; H, 3.48; N, 16.40; Cl, 20.88%. Calcd for $C_{14}H_{10}N_4O_2 \cdot 2HCl$: C, 49.41; H, 3.59; N, 16.47; Cl, 21.17%.

2,2′-Hydrazinobis(benzimidazole) (21): A mixture of **2** (0.1 mol) and 2-mercaptobenzimidazole (0.1 mol) was heated at 290—300 °C for 5 h. After cooling, the solid separated filtered and recrystallized from ethanol as colorless crystals, yield 52%, mp 257 °C. Found: C, 63.60; H, 4.60; N, 31.91%. Calcd for $C_{14}H_{12}N_6$: C, 63.64; H, 4.55; N, 31.82%.

2-Acetyl-3-methylthiazolo[3,2-*a*]benzimidazole (23): i) A mixture of 2-mercaptobenzimidazole (1.5 g) and KOH 85%

(0.75 ml) in ethanol (12 ml) was heated at 80 °C for 10 min. To the cooled reaction mixture was added 3-chloro-2,4-pentanedione (1.4 ml) and stirred for 4 h. The separated solid from ice-water mixture was filtered and recrystallized from ethanol as pale brown crystals of 3-(2-benzimidazolylthio)-2,4-pentanedione (**22**), yield 52%, mp 218 °C. Spectral analysis confirm the tautomeric enol form **22a** where the IR spectrum showed (OH) strong band at 3370 cm^{-1}. The ^1H NMR spectrum (in DMSO) showed signals at δ=2.4 (s, 6H, $2CH_3$), 3.4 (br, 2H, NH-OH), and 7.1—7.6 (m, 4H, Ar). Found: C, 58.18; H, 4.90; N, 11.31; S, 12.88%. Calcd for $C_{12}H_{12}N_2O_2S$: C, 58.07; H, 4.84; N, 11.29; S, 12.09%.

ii) A mixture of **22** (2 g) and polyphosphoric acid (10 g) was heated at 100 °C for 1 h, then at 125 °C for 15 min. The solid separated with ice-water, was filtered and recrystallized from ethanol into white crystals of **23**, yield 49%, mp 169—170 °C. The same compound was separated in 90% yield or refluxing **22** with acetic anhydride-pyridine (2:3) mixture for 2 h. Found: C, 62.65; H, 4.39; N, 12.20; S, 13.96%. Calcd for $C_{12}H_{10}N_2OS$: C, 62.61; H, 4.35; N, 12.17; S, 13.91%.

Reaction of Benzenediazonium Salt with Compounds 22 and 23: To ice-cooled mixture of **22** (1.3 g) and/or **23** (1.3 g) and sodium acetate (3 g) in ethanol (20 ml) was added benzenediazonium chloride (from 1.3 g aniline) while stirring, then left for 1 h and poured on cooled water. The separated solid was filtered and recrystallized from benzene into corresponding yellow compounds, 1-(2-benzimidazolylthio)-1-(arylhydrazone)-2-propanone (**27**), yield 50%, mp 99 °C and 2-phenylazo-3-methylthiazolo[3,2-*a*]benzimidazole (**28**), yield 68%, mp 183 °C respectively. **27**: Found: C, 61.98; H, 4.50; N, 18.01; S, 10.36%. Calcd for $C_{16}H_{14}N_4OS$: C, 61.94; H, 4.52; N, 18.07; S, 10.32%. **28**: Found: C, 65.80; H, 4.07; N, 19.20; S, 10.97%. Calcd for $C_{16}H_{12}N_4S$: C, 65.75; H, 4.11; N, 19.18; S, 10.96%.

Reactions of 23 with the Appropriate Amino Compounds: General Procedure: A mixture of **23** (1 mol) and the aliphatic amines (1.1 mol), namely, hydroxylamine, methylamine, and/or ethylamine hydrochloride, ether in glacial acetic acid or in pyridine, was refluxed, and cooled. The separated solid filtered and recrystallized from proper solvent into the corresponding oxime and/or Schiff's bases (**24a—c**) respectively as in Table 4.

2-(3-Aryl-1-oxo-2-propenyl)-3-methylthiazolo[3,2-*a*]benzimidazoles (25a—c): A mixture of **23** (0.1 mol) and aromatic aldehydes (0.01 mol), benzaldehyde and its *p*-nitro and *p*-dimethylamino derivatives together with KOH solution (10 ml, 4%) in ethanol (50 ml). The mixture was kept overnight, acidified with dilute acetic acid. The separated chalcones filtered and recrystallized from proper solvent as in Table 4.

M. Z. A. Badr is thankful to Dr. Kevin S. Peters of Harvard University, U.S.A., for his assistance with some NMR and mass spectral analyses.

Synthesis and Application of Some 1-[8-Hydroxy-5(or 7)-quinolinyl]-alkylidene-Substituted Heterocycles as Bactericides, Funjicides, and Bioregulator

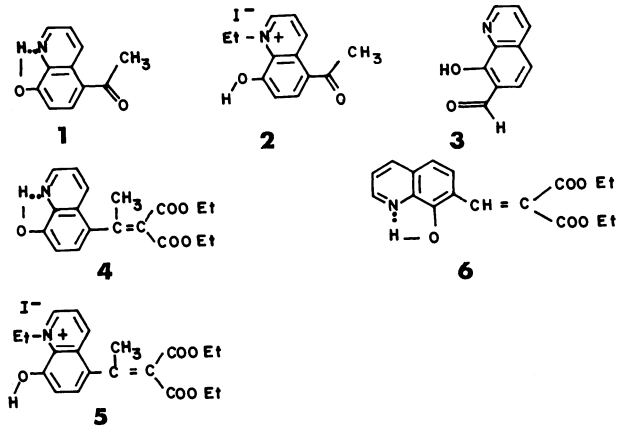
Zarif Haleem KHALIL, Amal Sabet YANNI,* Ali Ali KHALAF, Ali Ali ABDEL-HAFEZ, and Raafat Foaad ABDO
Chemistry Department, Faculty of Science, Assiut University Assiut, Egypt
(Received December 2, 1986)

Interaction of 5-acetyl-8-quinolinol, corresponding 1-ethylquinolinium iodides, and 8-hydroxyquinoline-7-carbaldehyde with diethylmalonate under basic condition gave the corresponding of **4—6**. Further reaction of **4—6** with hydrazine, phenyl hydrazine, hydroxylamine, urea, and/or thiourea gave the corresponding 1-[8-hydroxy-5(7)-quinolinyl]alkylidene-substituted heterocyclic derivatives (**7—16**) and corresponding 1-ethylquinolinium iodides (**17—21**). The structure of the synthesized compounds was confirmed by elemental and spectral analysis. The biological activity of 5-substituted 8-quinolinol was tested as microbicidal and bioregulator agents, the results obtained were interpreted according to their structure-activity relationships.

The biological activity of azoles and barbituric acid derivatives is of interest.[1-3] Pharmacological studies showed that some of these compounds possessed hypolipidimic central nervous system depressant[4] and antitumor activities.[5] In this work 5(7)-heteroarylidenemethyl-8-hydroxyquinolines were prepared to evaluate the effect of substitution on the biological activity of 8-quinolinol nucleus as antimicrobial and bioregulator agents. Structure activity relationships has also been studied to detect the preferable structures required for such purposes.

Results and Discussion

The reaction of 5-acetyl-8-quinolinol (**1**), its corresponding 1-ethylquinolinium iodide (**2**), and 8-hydroxyquinoline-7-carbaldehyde (**3**) with diethyl malonate in the presence of sodium ethoxide gave the corresponding ethyl 2-ethoxycarbonyl-3-(8-hydroxy-5-quinolinyl)-2-butenoate (**4**), corresponding 1-ethylquinolinium iodide (**5**), and ethyl 2-ethoxycarbonyl-3-(8-hydroxy-7-quinolinyl)-2-propenoate (**6**) respectively.



Further reaction of **4—6** with hydrazine hydrate, phenylhydrazine, hydroxylamine hydrochloride, urea, and thiourea gave the corresponding 4-[1-(8-hydroxy-5-quinolinyl)ethylidene]-3,5-pyrazolidinedione (**7**), 4-[1-(8-hydroxy-5-quinolinyl)ethylidene]-1-phenyl-3,5-pyrazolidinedione (**8**), 4-[1-(8-hydroxy-5-quinolinyl)-ethylidene]-3,5-isoxazolidinedione (**9**), 5-[1-(8-hydroxy-5-quinolinyl)ethylidene]barbituric acid (**10**), 5-[1-(8-hydroxy-5-quinolinyl)ethylidene]-2-thiobarbituric acid (**11**); corresponding 1-ethylquinolinium iodides (**17—21**); and 4-[(8-hydroxy-7-quinolinyl)methylene]-3,5-pyrazolidinedione (**12**), 4-[(8-hydroxy-7-quinolinyl)-methylene]-1-phenyl-3,5-pyrazolidinedione (**13**), 4-[(8-hydroxy-7-quinolinyl)methylene]-3,5-isoxazolidinedione (**14**), 5-[(8-hydroxy-7-quinolinyl)methylene]barbituric (**15**) and 2-thiobarbituric acid (**16**). The structures of the synthesized compounds were confirmed by elemental and spectral analysis. The infrared and ultraviolet spectral data are given in Table 3. All of the synthesized compounds 1-[8-hydroxy-5(or 7)-quinolinyl]alkylidene-substituted heterocyclic compounds showed the presence of ν_{-NH} group at 3100—3190 cm^{-1} and the lack of ν_{-NH_2}. The NMR ($CDCl_3$) of compound **11** showed signals at δ 2.7 (3H, CH_3, s), 6.8—7.7 (5H, aromatic, m), and 11.3—11.5 (2H, NH, s).

The compounds **3**, **6**—**9**, and **12**—**14** have no effect for all the fungi used. The compounds **3**—**21** have no effect for all the bacteria used (except **18** and **21**).

compounds. Thus 5-acetyl-8-quinolinol (**1**) is quite potent as fungicides especially *Stachybotrys atra* (71 mm inhibition zone at 100 ppm, cf. Table 2). Quaternization of **1** decreases its potency. Substitution of 5-acetyl by a butenoate moiety decreases its potency. 6-Membered barbituric and thiobarbituric heterocycles are more effective as fungicides than 5-membered (azoles) ones. On the other hand the above compounds are less potent as bactericides. The results are given in Table 2. Water-soluble compounds were choosen as bioregulator for *Vicia faba* seeds. Germination as expressed in the seedling height after 14 days versus the concentration with respect to the control was studied. It is clear that some of these compounds e.g. (**2**, **7**, **10**, **11**, **17**) enhance the seedling growth. The results are shown in Fig. 1.

More than one shoot per seedling was observed with percentage of 10% at the concentration of 100 ppm for compounds **1** and **7**; 50 and 1000 ppm for compound **17** and 500 ppm for compounds **10** and **11**. The difference in seedling height and the multishooted per seedling phenomena in the treated seeds led us to the

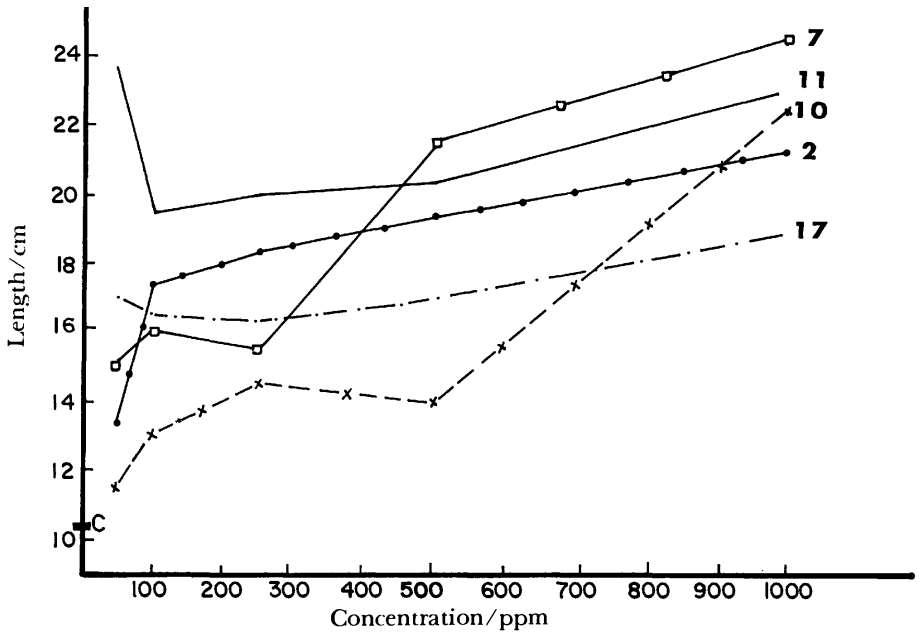

Fig. 1. Germination of *Vicia faba* seeds as expressed in seedling height after 14 days versus the concentration with respect to the control C.

cytological examination in the anatelophase. Rootless of the treated seeds showed chromosomal aberation as bridge and/or fragments with respect to the control. This chromosomal aberation is responsible for this behavior of the treated *Vicia faba* seeds (Fig. 2).

Experimental

All melting points are uncorrected. Infrared spectra were determined with a Perkin-Elmer 599 B spectrophotometer using the KBr wafer technique. NMR spectra were carried out in $CDCl_3$ using a Varian EM 390 (90 MHz). UV spectra were recorded in ethanolic solutions using a Cary 219 spectrophoto-meter.

5-Acetyl-[6] and 7-formyl-8-quinolinol[7] were prepared according to literature method reported earlier.

Synthesis of 5-Acetyl-1-ethyl-8-hydroxyquinolinium Iodide (2): A mixture of 10 g (0.054 mol) of 5-acetyl-8-quinolinol[6] (**1**) and 15 ml of ethyl iodide was heated in a sealed tube at 105 °C for 7 h. The product was filtered off, air dried and recrystallized from ethanol to give 19.4 g (82%) of the product

2 in the form of yellowish brown crystals, mp 285—287 °C. Found: N, 4.15%. Calcd for $C_{13}H_{14}NO_2I$: N, 4.08%.

Synthesis of Ethyl 2-Ethoxycarbonyl-3-(8-hydroxy-5-quinolinyl)-2-butenoate (4), Its Ethiodide (5), and Ethyl 2-Ethoxycarbonyl-3-(8-hydroxy-7-quinolinyl)-2-propenoate (6): Diethylmalonate (1.6 g, 0.01 mol) was added to ethanolic sodium ethoxide solution (0.1 g Na in 30 ml absolute ethanol) and the mixture was stirred at room temperature for 1 h. To the resulting sodiomalonate was added an equivalent amount of ethanolic solution from 5-acetyl-8-quinolinol[6] (**1**, 1.9 g in 30 ml), or its ethiodide (**2**, 3.4 g in 50 ml), or 8-hydroxy-7-quinolinecarbaldehyde (**3**, 1.7 g in 30 ml) in one portion. The reaction mixture was heated under reflux for 7 h, cooled and neutralized with acetic acid. The precipitated solid was filtered by suction and air dried. Physical and analytical data are given in Table 1.

Synthesis of 1-[8-Hydroxy-5(or 7)-quinolinyl]alkylidene-Substituted Azolidinediones and Barbituric Acid Derivatives (7—16), and Their Ethiodides (17—21). A mixture of **4**, **5**, or **6** (0.01 mol), hydrazine hydrate, phenylhydrazine, urea, or thiourea (0.01 mol) in ethanolic sodium ethoxide solution (0.1 g Na in 30 ml absolute ethanol) was heated under reflux for 7 h. The reaction mixture was filtered while hot and the filtrate was cooled and neutralized with acetic acid. The precipitated solid was filtered with suction and air dried. Physical and analytical data are given in Table 1.

Biological Activity of Selected New Synthesized Compounds as Antimicrobial and Plant Growth Regulator. The Antimicrobial Activity: The selected new synthesized compounds were dissolved in ethylene glycol (10 mg/100 ml, 100 ppm) and transfered to filter paper disc (15 mm), diffusion plate method.[8] The antifungal activity was determined against *Penicillium notatum*, *Aspergillus flavus*, and *Stachybotrys atra*. The antibacterial effect of the same compounds was determined against *Bacillus subtilis*, *Micrococcus luteus*, and *Serratia Sp*.

Bacterial suspension was prepared by adding 10 ml of sterile distilled water to 10 d old culture of the test bacteria grown on a nutrient agar of NA.[9] The culture consisted of beef extract (10 $g L^{-1}$), peptone (10 $g L^{-1}$), NaCl (5 $g L^{-1}$), and agar (10 $g L^{-3}$) at pH 7.4. One milliliter aliquots of the bacterial suspension were added to NA Petri dishes (one plate/test compound). The excess liquid has removed and filter paper disc (15 mm diameter) containing the test compound was placed on the plate. Plates were then incubated at 37 °C, and the diameter of the inhibition zones were measured after 24 h. These experiments were repeated thrice. The results are given in Table 2.

Spore suspension was prepared by adding 10 ml of sterile distilled water to 10-d-old culture of the test fungus grown on potato-D-glucose-agar (PDA) potatose (peeled and sliced, 200 $g dm^{-3}$), D-glucose (20 $g dm^{-3}$), and agar (17 $g dm^{-3}$) at pH 6.5.[10] One ml aliquots of the spore suspension were added to PDA Petri dishes (plate/test compound). The excess liquid was removed and filtered paper disc containing the tested compound was placed on the plate, then the plate is incubated at 37 °C and the inhibition zones were measured after 3 d. The experiments were carried out in triplicate. The results are given in Table 2.

Biological Effects on the Germination of *Vicia faba* (Variety Giza 2) Seeds: Materials and Methods: Seeds of *Vicia faba* (variety Giza 2) were treated with five concentrations 50, 100, 250, 500, and 1000 ppm of the selected compounds. Fresh solution of the required concentration were prepared using distilled water. A total of 100 seeds were used for each of the five treatments and the control. Seeds were immersed in the solution at room temperature of 25±2 °C for 4 h. Control seeds were treated with distilled water. After treatment, the seeds were washed thoroughly with distilled water to eliminate the solution traces. The seeds of each concentration was germinated on wet germinating papers in the Petri dishes for estimating the germination percentage, seedling height and for cytological studies. After 14 d, germinating and nongerminating seeds were counted and the percentage of germination was determined for each treatment and the number of seeds with more than one shoot were counted for each concentration. The results are shown in Fig. 1.

Cytological Examination: Secondary rootlets of 5—10 mm in length were excised and fixed in a 3:1 ethanol-glacial acetic acid mixture for 12 h and stored in 70% ethanol in a refrigerator. Fixed rootlets were prepared for cytological examination by the acetocarmine Smear technique.[11] For each treatment, preparations from 4 seedling were examined. The chromosomal aberrations were determined in the anaphase stage as bridges and fragments. The experiment was repeated twice and the results are shown in Fig. 2.

Behavior of the Enthalpy of Mixing in the Ternary Systems Lead-Antimony-Tin, Bismuth-Lead-Tin, and Bismuth-Cadmium-Tin at 950 K. I. Experimental Investigation

Walid Ahmad Badawi
Department of Chemistry, Faculty of Science, Al-Fateh University, Tripoli, Libya
(Received October 29, 1986)

Calorimetric studies on the enthalpies of mixing in the ternary systems Pb-Sb-Sn, Bi-Pb-Sn, and Bi-Cd-Sn have been carried out at 950 K. The partial enthalpy of mixing in the system Pb-Sb-Sn at quasi-binary section drawings goes through positive and negative regions. The partial enthalpy of mixing of lead is positive, while that of antimony is negative and takes a minimum between the quasi-binary section drawings $x_{Sn}=0$ and $x_{Sn}/x_{Pb}=6/4$. The partial molar enthalpy of mixing of bismuth in the ternary systems Bi-Cd-Sn and Bi-Pb-Sn shows level minima and the same behavior as observed for the partial enthalpy of mixing of antimony in the related system Pb-Sb-Sn. The partial enthalpy of mixing of tin in the system Bi-Pb-Sn is positive, while that of lead takes positive and negative values. Also the partial molar enthalpy of mixing of Cd in the system Bi-Cd-Sn shows a level minimum.

The binary systems of metals and metalloids have been studied in details.[1-3] In fact we have also contributed in this area.[4,5] However it appears that ternary systems have not received similar attention. Thus, the study of ternary systems from both theoretical and experimental approaches seemed of interest.

The measurements of enthalpy of mixing for binary systems and their correlation to the factors which determine the excess function behavior proved to be useful in getting insight into the behavior of such systems. It is expected that a similar approach to the ternary systems will yield better understanding of these systems. Hence we have been studying the systems Bi-Pb-Sn, Cd-Bi-Sn, and Pb-Sb-Sn in our adiabatic shield calorimeter. The experimental results of the enthalpy of mixing determinations are reported in the present paper. The analysis of the experimental results and theoretical approach to ternary solutions form the subject matter of another paper.

Experimental

Sample. The metals used were: lead of extra purity grade (E. Merck Company), 99.8 mass percent antimony (Schuchardt Company, Germany) and zone-refined 99.9999 mass percent pure tin (Koch-Light Laboratories, Ltd. England). The mixture of metals with a total mass of 149.213 g was sealed in the sample container of silica glass together with about 50 cm of 2.5 diameter silica cord. The silica cord was coiled spirally in the sample space and its purpose was to prevent breakage of the container on fusion and thermal cycling of the sample.

Calorimetric Technique. The slightly modified calorimetric apparatus was described before.[1] The calorimeter is operated with primary indirect provision of energy under adiabatic conditions. The procedures adopted were similar to those used earlier.[6,7] The 30 cm^3 sample container of silica glass has holes for heater, stirrer (made of ceramic) and a Pt-to-(Pt+10 mass per cent Rh) thermopile, axially located in the cylindrical silver calorimeter. The calorimeter-sample assembly is suspended inside a thermostat of steel (Thermax 10 FAL, production no. 4742, Germany). Below the thermostat is a heated guard system also of silver. The whole assembly is placed in a vertical tube furnace which in turn was protected by another larger one in order to obtain a double thermostat principle.

The temperature differences between the calorimeter and thermostat were measured by means of a set of fifteen differential Pt-PtRh thermopiles. These were serial connected and calibrated on a standard Pt-PtRh thermopile. The accuracy of the temperature values obtained was found to be ±0.1 K. The temperature of the guard body is kept automatically 0.2 K below that of the shield, while the temperature of the furnace is kept 5 K lower to secure satisfactory operation of the control units.

Heat capacity measurements of the empty calorimeter and thermostat were carried out in a seperate series of experiments. The C_p of the calorimeter was found to be 300 $J K^{-1}$ and that of the thermostat 5 $kJ K^{-1}$. The calibration of the calorimeter occured on exactly measured enthalpy of a standard sample of tin.[1] The time needed to reach equilibrium was registered to 430 s. The short-term fluctuation of the null point was measured to 0.3×10^{-3} K min^{-1}. The "interchange of heat constant" of the calorimeter at 973 K was estimated to 0.55 $W K^{-1}$. The sensibility of the calorimeter was measured to 630 $\mu V K^{-1}$. The thermometer resistence was measured with a Mueller bridge (Leeds & Northrup Model 8072), automated locally with stepping motors and a gated null detector, operated by a computer (Hewlett-Packard 2114B). The derived temperatures are judged to correspond with the IPTS-68 to within 0.01 K at 500 K and 0.1 K at 1000 K. In fact, the temperature increments were precisely measured to 0.0003 K.

The computer-operated energy imputs from a constant-current supply (John Fluke Current Calibrator Model 382 A) were measured with an integrating voltmeter (Hewlett-Packard Model 2401 C).

Results and Discussion

The data have been treated with the computer program Algol which searches for a set of parameters that minimizes the error square sum $h^m=(h^m_{calc}-h^m_{exp})^2$. The selected measurements comprise 36 data points corresponding the schema:

$x_1=0, 1\ j; x_2=1\ k; x_3=0\ 1\ l;$

$j, k, l=1 \cdots\cdots 8; j+k+l=10.$

These were symmetrical distributed in the Gibbs Triangle (x_1, x_2, and x_3 are the mole fractions of component 1, 2, and 3, respectively).

In order to save computer time, the measurement points and the values belonging to them are expressed as adjustable polynomial functions:

$$Y^e = Y^e(x_i, x_j) = \sum_{k,l} a_{kl}\, x_i^k\, x_j^l = \sum_{i,j} b_{ij}\, x_3^i\, x_1^j, \quad (1)$$

where i, j=1, 2 or 2, 3 or 3, 1. In this case, the following condition must be satisfied:

$$a_{00} = \sum_k a_{k0} = \sum_i a_{01} = 0. \quad (2)$$

x_1, x_2, and x_3 indicate 10 x the mole fraction of antimony, lead, and tin, respectively. The point 631 (for example) means x_1=0.6, x_2=0.3, x_3=0.1. X means 1.0.

The calculations of the coefficients b_{ij} from those a_{kl} occur by means of Algol program.

Results of the enthalpy of mixing determinations in the ternary system Pb-Sb-Sn are presented in Table 1. A number within parenthesis is the estimated standard deviation (esd.) calculated by the program. The average error of the individual measurement was found to be 1%. In fact the accuracy of the measurement results is considerably better since the enthalpy of mixing in the region near the pair Pb-Sb is small and this yields a large percentage error. To the best of our knowledge, there does not seem to be any report on the data for the enthalpy of mixing in the ternary system Pb-Sb-Sn. However, data for the binary systems Sb-Pb, Sb-Sn, and Pb-Sn with an accuracy of 1—2% have been reported earlier.[2-3,7] These date are in reasonable agreement with those obtained (for the above given pairs) in the present study on the ternary system Pb-Sb-Sn. The molar enthalpy of mixing, h^m, and the partial one of antimony at the quasi-binary section drawings Sb-Pb and Sb-Sn in the system Pb-Sb-Sn are shown in Fig. 1. The adjustable values of the integral enthalpy of mixing at the quasi-binary section drawing Pb-Sb beginning from the apex Sn are given in Table 2.

In Tables 3—5 are collected the values of the partial enthalpy of mixing of Pb, Sb, and Sn at the section

drawings Sb-Sn, Sn-Pb, and Pb-Sb beginning with the apices Pb, Sb, and Sn, respectively. From these data one may observe that h^m_{Sb} takes only negative values, h^m_{Pb} is positive while h^m_{Sn} goes through positive and negative regions. Figure 2 shows the partial enthalpy of mixing of antimony at the quasi-binary section drawing Sn-Pb beginning from the apex Sb in the system Pb-Sb-Sn. It is clearly observable that h^m_{Sb} takes a minimum between the quasi-binary section drawings $x_{Sn}=0$ and $x_{Sn}/x_{Sb}=6/4$.

It is expected that the partial molar enthalpy of mixing of bismuth in the ternary systems Bi-Cd-Sn and Bi-Pb-Sn shows the same behavior as observed for h^m_{Sb} in the related system Pb-Sb-Sn. In order to decide this, we have also been studying these two systems. In Tables 6 and 7 are presented the values of h^m_{Bi} at quasi-binary section drawings in the systems Bi-Pb-Sn and Bi-Cd-Sn beginning from the apex Bi. Figure 3 shows the integral enthalpy of mixing, h^m, at the quasi-binary section drawings in the system Bi-Pb-Sn. h^m_{Si} is also shown in this figure. The integral enthalpy of mixing takes positive values in the pairs Pb-Sn and

Sn-Bi, while h^m is negative in the pair Bi-Pb. This was also recognized by Wittig in his study on these binary systems.[1,2] A somewhat surprising observation is that h^m_{Bi} in Bi-Pb-Sn indicates a level minimum in the region between the quasi-binary section drawings $x_{Sn}=0$ and $x_{Pb}/x_{Sn}=6/4$. As indicated in Fig.4, h^m_{Sn} takes positive values while h^m_{Pb} goes through positive and negative regions.

Figure 5 shows the integral enthalpy of mixing, h^m, and the partial molar one of Bi, h^m_{Bi}, at the quasi-binary

section drawings Bi-Cd and Bi-Sn in the system Bi-Cd-Sn. It is clearly observable that h^m takes a maximum at $x_{cd}=x_{Sn}=0.5$. h^m is also positive in the pairs Bi-Cd and Sn-Bi. As we have expected, h^m_{Sb} takes also a striking level minimum in the region $x_{Sn}=0$ to $x_{Cd}/x_{Sn}=6/4$. This means that there exists a general property for ternary systems.

Figure 6 shows the partial molar enthalpy of mixing of Cd and Sn at the quasi-binary section drawings Bi-Cd and Bi-Sn. h^m_{Cd} exhibits also a level minimum. However, the level minimum of Cd and the bend joined to this minimum disappear rapidly when the mole fraction of Sn increases. At the same time the bend of h^m_{Bi} in the pairs Bi-Cd and Bi-Sn shows always positive trends.

On the basis of our discussion, we come to the following conclusion: There exists a general property which predicts the behavior of mixing in ternary systems. This property could be overlapped by other ones belonging to the pairs of components in the ternary systems. In fact, this property is recognized in the present study and will be reported together with the theoretical analysis of the experimental results in the second part of this work.

Sorption of Uranyl Ions on Hydrous Oxides. A New Surface Hydrolysis Model

Anand Ram GUPTA* and Balakrishnan VENKATARAMANI
Chemistry Division, Bhabha Atomic Research Centre, Bombay 400085, India
(Received July 24, 1986)

Sorption of uranyl ions on hydrous titanium oxide(HTiO), magnetite(MAG), and hydrous thorium oxide(HThO) has been studied as a function of pH. Hydrous oxides have been characterized by their pH-titration curves, intrinsic dissociation constants(pK_{ai}^*) and point of zero charge (pH_{pzc}). The fraction of protonated surface hydroxyl groups as well as the surface pH(pH_{surf}) as a function of solution pH have been computed. The distribution of various hydrolyzed species of uranyl ions with solution pH have been compared with uranyl sorption isotherm on these oxides. Sorption edge in all the cases occurs when free hydroxyl groups are available on the surface and pH_{surf} is sufficiently high to favor the formation of dimer-like species on the surface. A new model for the sorption process, called surface hydrolysis model, which explains these and other features of uranyl sorption on hydrous oxides has been proposed. The model visualizes the sorption process as linking of uranyl ions with two adjacent free surface hydroxyl groups without deprotonation (provided the surface pH is high for the hydrolysis of uranyl ions) and formation of dimer-like structures on the surface. The new model has been successfully applied to the present and other available data on uranyl ion sorption on hydrous oxides.

There has been a great interest in the study of the sorption of hydrolysable metal ions on hydrous oxides. Though many features of the sorption behavior are well-understood, a complete picture is still not available. The sorption process depends upon the properties of the metal ions (e.g. hydrolysability), characteristics of the oxide surface (e.g. point of zero charge, pzc) and experimental conditions (e.g. pH of the solution) Dugger et al.[1] viewed the sorption of transition metal ions on hydrous oxides as an ion exchange reaction between the surface hydroxyl groups and the metal ions:

$$m(\mathrm{SOH}) + \mathrm{M}^{m+} \rightleftarrows (\mathrm{SO})_m\,\mathrm{M} + m\mathrm{H}^+, \qquad (1)$$

where (SOH) is the surface hydroxyl group and M is the metal ion being sorbed. The variation in the sorption of different metal ions was attributed to the strength of the M-O bond which was correlated with the stability constants of monohydroxo complexes of cations.[1] This was applicable when the solution pH was such that hydrolysis of metal ions did not take place. In the sorption isotherms, an abrupt increase was observed as a function of pH, James and Healy[2] suggested that ionic charge on the sorbing metal ion was lowered by hydrolysis or ligand complex formation, facilitating closer approach to the interface and the sorption process.

More recently, the sorption process has been looked upon as surface complexation of metal ions by suface hydroxyl groups, so that the hydrolysis of metal ions in solution was not a pre-requisite of the sorption mechanism.[3,4] The deprotonation of the surface groups accompanied the sorption of the metal ions. In general, the soption of metal ions is viewed[5] as a competition between the surface hydroxyl groups and any ligand present in solution for the complexation of free metal ion. The sorption of ligands or anions of the oxide surface is also taken into consideration[6] to explain the sorption data. Recently, a precipitation model[7] for the sorption of metal ions on hydrous oxides has been proposed to account for the non-limiting sorption capacities of the oxides. Essentially the model is based on Eq. 1 but allows for precipitation of sorbing metal ion and solid solution formation, provided the solubility product of the sorbing metal cation is exceeded on the surface.

The above models, however, do not explain satisfactorily the observation that the abrupt increase in the sorption of metal ions on hydrous oxides occurs at a pH where the oxide surface is positively charged. These models also fail to explain the observed incease in the positive charge and the shift in pzc of the oxide as a result of sorption.[2,8] With a view to understand the sorption process on hydrous oxides, we had undertaken a detailed study of the sorption of metal cations on different hydrous oxides. In this communication we are presenting our results on the sorption of uranyl ions on hydrous titanium and thorium oxides and hydrous magnetite. A new sorption mechanism which accounts for all the features of the sorption process (including the hitherto unexplained ones) is proposed.

Experimental

Peparation of the Hydrous Oxides. Hydrous Titanium Oxide (HTiO): HTiO was prepared by adding 2 mol dm^{-3} NaOH to a hot solution of Ti(IV) in concd H_2SO_4 under constant stirring. The precipitate was digested in the mother liquor at 353 K for 4 h, allowed to cool and stand for 2 d. It was then filtered, washed free of alkali and air dried. The product, which is the same used in an earlier study,[9] did not contain any sulfate but sodium ions were present making the material alkaline. The sodium ions incorporated in it were removed by repeatedly treating it with dil $HClO_4$ and washing with water. This was continued till the pH of the water in contact with HTiO was neutral.

Hydrous Thorium Oxide (HThO): HThO was prepared by adding 1 mol dm^{-3} NaOH to a hot solution of thorium (IV) nitrate in HNO_3. The precipitate was later digested in

Table 1. Characteristics of the Hydrous Oxides

Hydrous oxide	Capacity (C) / mmol g^{-1}	$pK_a=pK_a^*+m\cdot q$	$pH_{pzc}=\frac{1}{2}(pK_{a1}^*+pK_{a2}^*)$
HTiO	0.65	$pK_{a1}=4.79-0.43\times10^4 q$	
		$pK_{a2}=8.3-0.26\times10^4 q$	6.55
HThO	0.23	$pK_{a1}=3.18+0.88\times10^3 q$	
		$pK_{a1}=10.4-0.35\times10^4 q$	6.79
MAG	0.14	$pK_{a1}=2.88+0.48\times10^4 q$	
		$pK_{a1}=10.05-0.45\times10^4 q$	6.47

hot condition, aged for 2 d, filtered, washed, and air dried.

Hydrous Magnetite (MAG): MAG was prepared by the method of Benton and Horsfall.[10] To a hot 5L solution containing sulfuric acid, 25 g KNO_3 and 90 g $FeSO_4\cdot7H_2O$, NaOH was added under constant stirring. The green precipetate initially formed turned black. The precipitate was digested in hot condition, aged for 2 d, filtered, washed and air dried.

All the air dried hydrous oxides were broken in water, washed, dried and finally crushed and sieved. For sorption experiments −100 BSS samples were used. X-Ray analysis of the oxides showed that HTiO and HThO were amorphous; and MAG was crystalline.

pH Titration. Continuous pH titration were carried out with 0.4 g of the air dried samples in 50 cm^3 of 0.1 mol dm^{-3} $NaNO_3$ with 0.1 mol dm^{-3} HNO_3 or NaOH. The pH of the slurry was measured using Elico Digital pH-meter. After the addition of acid or alkali, solutions were stirred continuously for 10 min before pH measuement.

Sorption Experiments. All sorption experiments were done at a total ionic strength of about 0.1 mol dm^{-3} $NaClO_4$. 0.1 g of the oxide was equilibrated with 25 cm^3 of the solution of 10^{-4} mol dm^{-3} uranyl nitrate in $NaClO_4$, preadjusted to a known pH using $HClO_4$ or NaOH. The solid-solution mixture was equilibrated for 4 h at constant room temperature (298±1 K). Later the pH of the supernatant solution was measured. The uranium in the equilibrated solution was estimated spectrophotometrically using H_2O_2 at 400 nm.[11] The difference in the uranium concentration before and after equilibration gave the amount sorbed on the oxide.

Results and Discussion

Characteristics of the Hydrous Oxides. Capacity Determination: The capacity of the hydrous oxide is the ion sorption capacity of the material (mmol g^{-1}). It is equal to the total number of hydroxyl groups taking part either in Reaction 2 or 3. It has been determined as the limiting value of H^+ ions consumed in the acid region of the pH-titration curve or the limiting value of OH^- ions consumed in the alkaline region of the titration curve. Its value has also been estimated from the limiting amounts of Na^+ or Cl^- ions sorbed by the oxides. The values for capacities obtained by different procedures were in reasonable agreement with one another and are listed in Table 1.

Analysis of pH-Titration Curves: The pH-titration curves of the three oxides in the acidic as well as alkaline regions are given in Fig. 1. The steep rise (alkaline region) and decline (acidic region) of pH in the titration curve of HThO and MAG compared to HTiO reflect their lower capacities vis-a-vis HTiO. As the hydrous oxides are amphoteric in character, the following reactons take place:

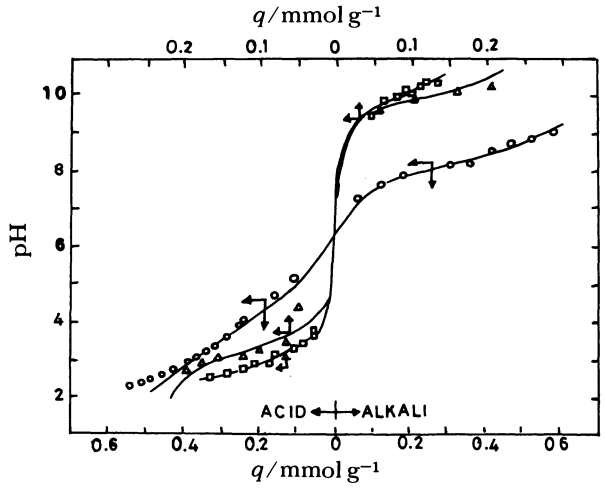

Fig. 1. pH-titration curves of hydrous oxides (○): HTiO; (△): HThO; (□): Magnetite. Solid lines based on pK_{a1} and its dependence on q (Table 1).

$$\text{acidic rigion: } SOH_2^+ \rightleftharpoons SOH + H^+, \quad (2)$$

$$\text{alkaline region: } SOH \rightleftharpoons SO^- + H^+. \quad (3)$$

The coresponding equilibrium constants are given by:

$$K_{a1} = N_{(SOH)}\, m_{H^+}/N_{(SOH_2^+)}, \quad (4)$$

$$K_{a2} = N_{(SO^-)}\, m_{H^+}/N_{(SOH)}, \quad (5)$$

where m_{H^+}, $N_{(SOH_2^+)}$, $N_{(SOH)}$, and $N_{(SO^-)}$ are molality of H^+ in solution and mole fractions of protonated, undissociated and dissociated surface hydroxyl groups in the oxide.

These equilibrium constants can be computed from the pH-titration curves by the method given by Schindler and Gamsjaeger.[12] Similar procedures have been recommended by other workers also.[13] The function q defined by $q=[SOH_2^+]-[SO^-]$, is computed from:

$$q = \frac{V(H-h)}{a} \quad (\text{mol } g^{-1}). \quad (6)$$

Where V is the volume of the solution taken for titration (dm^3); H is the amount of acid or base added

(mol dm^{-3}); h is the equilibrium H^+ concentration in solution (mol dm^{-3}); and a is the amount of hydrous oxides used (g). Assuming that SOH_2^+ is zero in alkaline region and SO^- is zero in acidic region, the equilibrium constants are:

$$K_{a1} = \frac{h(C-q)}{q} = \frac{h(1-\alpha)}{\alpha} \quad \text{(acidic region)}, \quad (7)$$

$$K_{a2} = \frac{h \cdot q}{C-q} = \frac{h(\alpha)}{(1-\alpha)} \quad \text{(alkaline region)}, \quad (8)$$

where C(mol g^{-1}) is the capacity of the hydrous oxide, and $\alpha = q/C$, is the fraction of the surface hydroxyl groups in either SOH_2^+ (Eq. 7) or SO^- (Eq. 8) form. The values of the equilibrium constants vary with q. A plot of pK_{ai} ($=-\log_{10} K_{ai}$, i=1 or 2) versus q were straight lines. The y-intercept gives the intrinsic dissociation constant (pK_{ai}^*) of the surface groups of the hydrous oxides. The slopes of the linear plots ('m') were either positive or negative. The equations describing the linear relationship between pK_{a1} and q are given in Table 1. Using these equations the pH-titration curves of the three hydrous oxides were calculated, which were in good agreement with experimental data (Fig. 1). The point of zero charge, pH_{pzc}, is the pH where the net surface charge is zero, implying that $[SOH_2^+]$ and $[SO^-]$ are equal at this point. pH_{pzc} is calculated from the relation:

$$pH_{pzc} = \frac{1}{2}(pK_{a1}^* + pK_{a2}^*). \quad (9)$$

The values of pK_{ai}^* and pH_{pzc} for HTiO and MAG are in the range reported for these oxides.[2,12-17]

The surface hydrogen ion concentration, h^*, is given by the relations:

$$K_{a1}^* = \frac{h^*(C-q)}{q} = \frac{h^*(1-\alpha)}{\alpha} \quad \text{(acidic region)}, \quad (10)$$

$$K_{a2}^* = \frac{h^* q}{C-q} = \frac{h^*(\alpha)}{(1-\alpha)} \quad \text{(alkaline region)}. \quad (11)$$

Using these equations surface pH, pH_{surf}, ($=-\log_{10} h^*$) for different α values have been evaluated.

Sorption of Uranium. Sorption isotherms of uranium as a function of pH on the three hydrous oxides are given in Fig. 2(A). An abrupt increase in the sorption within a narrow pH range is observed in all the three cases. The sorption edge, however, occurs at different solution pH (pH_{soln}) for the three hydrous oxides. As pH_{pzc} of these oxides are higher than the sorption edge pH, the sorption of uranyl ions occurs on positively charged surfaces.

For a particular value of $\alpha(=q/C)$, the value of K_{a1} can be calculated with the help of data given in Table 1. Using this value of K_{a1}, the value of the solution pH ($=-\log_{10} h$) was calculated from Eq. 7. Plots of α vs. solution pH for the SOH_2^+ group present on the three hydrous oxides are given in Fig. 2(C). The plots clearly show that the sorption edge for HTiO (Fig. 2A) occurs when 90% of the surface hydroxyl groups are in SOH_2^+ form. In HThO and MAG, 20% and 15% of surface hydroxyl groups, respectively, are in SOH_2^+ form at the sorption edge.

Earlier models[18] regarded the sorption process as surface complexation accompanied by the dissociation of surface hydroxyl groups, even at pH lower than their pH_{pzc}, just as the deprotonation of hydroxyl groups of the ligands on complex formation with metal cations. Such a model does not account for the data in Fig. 2, in particular for HTiO where more than one proton per hydroxyl group has to be released for forming a single $SO\text{-}UO_2^{2+}$ link, i.e. the formation of oxo bridges between uranyl ions and the surface is ruled out. Another aspect of the earlier models, namely the participation of hydrolyzed metal ion species in the sorption process, was also examined. For this purpose, the distribution of hydrolyzed species of uranium as a function of pH at a total uranium concentration of 10^{-4} mol dm^{-3}, was computed using the following stability constants:[1]

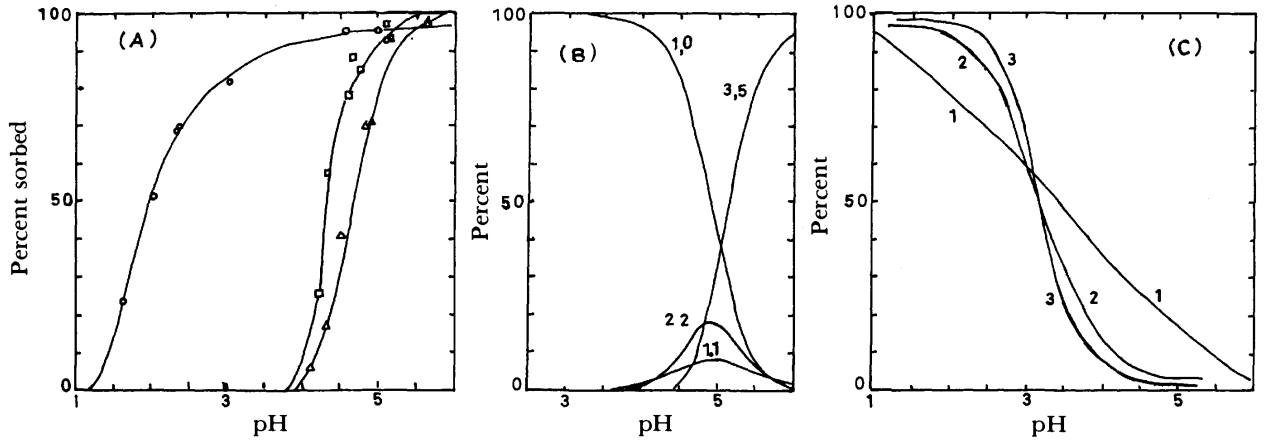

Fig. 2. (A) Uranyl sorption isotherm on hydrous oxides $\sum U = 10^{-4}$ mol dm^{-3}. (○) HTiO; (□) HThO; (△) Magnetite. (B) Distribution of hydrolyzed uranyl species vs. pH. (1,0)=UO_2^{2+}; (1,1)=$(UO_2)(OH)^+$; (2,2)=$(UO_2)_2(OH)_2^{2+}$; (3,5)=$(UO_2)_3(OH)_5^+$. (C) Percent of SOH_2^+ groups vs. pH; (1) HTiO; (2) HThO; (3) Magnetite.

$$UO_2^{2+} + H_2O \rightleftharpoons UO_2OH^+ + H^+;\ \log \beta_{11} = -5.7, \quad (12)$$

$$2UO_2^{2+} + 2H_2O \rightleftharpoons (UO_2)_2(OH)_2^{2+} + 2H^+;\ \log \beta_{22} = -5.92, \quad (13)$$

$$3UO_2^{2+} + 5H_2O \rightleftharpoons (UO_2)_3(OH)_5^+ + 5H^+;\ \log \beta_{35} = -16.5. \quad (14)$$

Distribution plots for various species in Fig. 2(B) demonstrate that uranium is present only as UO_2^{2+} at the sorption edge for HTiO and hydrolysis of uranyl ions starts only after 90% of uranium has been absorbed. In the case of HThO and MAG sorption edge occurs at a pH where the hydrolysis of uranium has not started and uranium is essentially present as uranyl ions.

The New Model-Surface Hydrolysis Model. The above analysis clearly demonstrates that the sorption of uranium on the three hydrous oxides, studied in this investigation, can not be accounted for by the existing models. Neither the hydrolyzed species of uranium participate in the sorption process nor does the sorption takes place under conditions where the surface complexation and conversion of surface hydroxyl groups to oxo groups would be a likely process. Sorption occurs on positively charged surfaces which are, as in HTiO, predominantly in SOH_2^+ form. Besides another feature of the sorption process observed in earlier studies,[2,18,20] namely, the increase in the positive charge of the oxide surface as a result of the sorption of metal ions, can not be explained by any of the existing models. In order to account for these features of the sorption process, a new model for the sorption of hydrolyzable metal cations on hydrous oxides is proposed.

Essential Features of the Model Are: 1) The main postulate of the model is that the sorption of metal ions on the surface of hydrous oxides occurs by attachment to surface hydroxyl groups without deprotonation of hydroxyl groups. On positively charged surfaces having SOH_2^+ groups, sorption of metal ions occurs only on free hydroxyl groups, i.e. SOH groups. The availability of free SOH groups is, thus, an essential requirement of the sorption process. (Fig. 3, A)

Schematically, the sorption process according to the new surface hydrolysis model is shown in Fig. 3.

2) In order to overcome the coulombic repulsion between positively charged metal ions and positively charged surfaces as well as to make the sorption process to be energetically favorable in comparison with the protonation of surface hydroxyl groups, it is further postulated that metal ion is simultaneously attached to two adjacent surface hydroxyl groups forming bridged hydroxo complexes with the surface in much the same manner as in dimerized hydroxo species, $(M^{+z}\langle^{OH}_{OH}M^{+z})^{2z-2}$ formed during the hydrolysis of metal cations (B).

3) For the sorption process described in postulate (2), to be thermodynamically feasible, the model requires that the surface pH of the oxide at the sorption edge, as distinct from the solution pH, which defines the sorption edge, should correspond to the pH where dimerized hydroxo species are formed in solution, i.e. pH_D.

4) As surface pH increases, dimer or trimer-like species can be formed on the surface (C). pH_T is the pH at which trimeric species are formed in solution. In the limit when pH_{surf} approaches precipitation pH, i.e. pH_{ppt}, precipitation of the metal cation on the surface and solid solution formation takes place (E).

5) When $pH_{surf} \geqslant pH_{pzc}$, sorption process is governed by Eq. 1 (D). (In Fig. 3, pH_{surf} is indicated as pH_{su}).

The model thus predicts that the surface becomes more positively charged as a consequence of the adsorption process—a feature hitherto unexplained by the existing models of the sorption process. The validity of the various postulates of the model has been tested by analyzing the present data on the sorption of uranyl ions on the three hydrous oxides. Subse-

(A) Positively charged oxide surface having SOH_2^+ groups. (B) Dimer-like structure formed by the unhydrolyzed metal ion on the surface. (C) Trimer-like structure formed by the hydrolyzed dimeric species on the surface. (D) Negatively charged oxide surface. (E) Solid solution formation.

quently, the model has been applied to those studies on uranyl sorption on other hydrous oxides where data required for the application of the model are available.

Hydrous Titanium Oxide. Besides the sorption isotherms of uranyl ions as a function of solution pH, the model also requires information about the variation of the fraction of surface hydroxyl groups in SOH_2^+ form with solution pH. Such data plotted in Fig. 2(C) clearly show that at sorption edge pH (1.3) free SOH groups are available for the sorption of uranyl ion. Then the oxide surface corresponds to A in Fig 3. At this pH, uranyl ions in the solution phase exist only as unhydrolyzed uranyl ions. In order to apply the model, surface pH, pH_{surf}, is also required. This has been computed using Eq. 10. pH_{soln} as a function of α were calculated using Eq. 7. Table 2 lists values of pH_{surf} and pH_{soln} for various values of α. It is seen that pH_{surf} for HTiO is considerably higher than pH_{soln}. For this oxide, at the sorption edge pH_{soln} is 1.3, SOH_2^+ is 90%, and pH_{surf} is 3.9. The distribution diagram of various hydrolyzed uranium species shows that the hydrolysis of uranyl ions starts at pH 3.5 (formation of monomeric $UO_2(OH)^+$ (1, 1) in Fig. 2(B)) and at pH 3.8, (pH_D in Fig. 3) formation of dimeric species ((2, 2) in Fig. 2(B)), $(UO_2)_2(OH)_2^{2+}$, starts. At the sorption edge, pH_{surf} is very close to this. Thus, at the sorption edge, when solution pH is 1.3 and only free UO_2^{2+} (aq) ions exists in solution, conditions on the surface are favorable for the process A→B to occur (Fig. 3), which results in the formation of dimer-like species on the surface. In the dimeric species in solution, two OH groups form two bridges between two uranyl ions, $[UO_2\overset{OH}{\underset{OH}{<}}UO_2]_{sol}$. In the dimer-like species on the surface, two OH groups form two bridges between a uranyl ion and the surface $[\overset{-OH}{\underset{-OH}{>}}UO_2]_{surf}$. Thus the uranyl ions are sorbed without the dissociation of OH groups, with the formation of dimer-like structures on the surface.

The fact that sorption edge occurs when pH_{surf} is 3.9 and not at 3.5, when UO_2OH^+ species or structures resembling such species (in the same sense as dimer-like structures) could exist on surface implies that sorption process corresponds to A→B (Fig. 3). Such a sorption mechanism, that is, attachment of uranyl ions on hydroxyl groups to form dimer-like structures, is supported by a recent Raman study of the interaction of uranyl ions with Th(IV) hydrolyzed polymer networks[21] in homogeneous systems.

As the solution pH increases, the solution contains hydrolyzed (dimeric) species of uranyl ions and pH_{surf} approaches pH_T (solution pH when trimecic species are formed in solution) and the condition on surface becomes favorable for A→C or B→C (Fig. 3) $[\overset{-OH}{\underset{-OH}{>}}UO_2\overset{OH}{\underset{OH}{<}}UO_2]_{surf}$. If precipitation pH, pH_{ppt}, is less than pH_{pzc}, process C→E can occur, otherwise, C→E occurs when pH_{surf} exceeds pH_{pzc}.

Table 2. pH_{sol} and pH_{surf} as a Function of α

α	HTiO		HThO		MAG	
	pH_{sol}	pH_{surf}	pH_{sol}	pH_{surf}	pH_{sol}	pH_{surf}
0.1	5.4	5.7	4.1	4.13	3.95	3.83
0.2	4.8	5.39	3.8	3.78	3.6	3.48
0.3	4.3	5.16	3.6	3.55	3.45	3.25
0.4	3.8	4.97	3.4	3.36		
0.5	3.4	4.79				
0.6	2.95	4.61				
0.7	2.4	4.42				
0.8	1.9	4.19				
0.9	1.3	3.89				

Hydrous Thorium Oxide and Magnetite. The sorption isotherms of uranyl ions on these two oxides are very similar. The data (Fig. 2(A)) show that the sorption edge in both the oxides occur at about pH_{soln} 3.9, which is also the pH at which dimeric species, $(UO_2)_2(OH)_2^{2+}$, are formed in solution. The surface pH for both the oxides (Table 2) is nearly equal to solution pH. On both the oxides nearly 90% of the surface groups are in the undissociated SOH form (Fig. 2(C)). Thus, in these oxides A→C (Fig. 3) is likely to be the preferred process.

To summarize, the present data indicate that uranyl ions are sorbed on positively charged oxide surface. The sorption edge occurs when pH_{surf} is favorable for the formation of dimer-like or trimer-like structures on the oxide surface. At the sorption edge, undissociated surface hydroxyl groups are present and sorption of uranyl ion involves simultaneous attachment to two adjacent undissociated surface groups. Thus, our data conforms to the basic postulates of the surface hydrolysis model.

Application of the Model to Other Oxides. Haematite: In a recent study of the sorption of uranyl ions on haematite,[22] Ho and Doern correlated the sorption edge at pH ≈5.0 with the marked increase of $(UO_2)_3(OH)_5^+$ species in solution phase at that pH and concluded that the trimer species are the sorbed species on the surface.

Their electrophoretic mobillity data on pure haematite (no uranyl sorption) clearly show that electrophoretic mobility remains constant between pH 3 and 5 and decreases beyond pH 5. This indicates that below pH 5 surface hydroxyl groups are totally in SOH_2^+ form and only after pH 5 free SOH groups become available on the surface. Even at pH 4 the dimeric species of uranyl ions will be present in solution.

The striking feature of the data of Ho and Doern.[22] is that though solution conditions are favorable for the sorption of uranyl ions even at pH 4, the sorption edge on haematite occurs only after pH 5.0 due to non-availability of free surface hydroxyl groups at pH<5.0 thus satisfying one of the prime requirement of the surface hydrolysis model for the sorption of uranyl

ions. In this case, reaction A→C (Fig. 3) is likely to be the preferred process.

γ-Alumina: In another study,[23] Mikami et al. have studied the sorption of uranyl ions on γ-alumina by pressure jump technique. γ-Alumina used had a pK_{al}^*=6.8, pH_{pzc}=8.5 and sorption edge was at $pH_{soln} \geqslant 4.0$. They also concluded that $(UO_2)_3(OH)_5^+$ species are sorbed on the oxide.

Based on their pK_{al}^* value, it is found that for all values of α between 0.9—0.1, pH_{surf} is greater than 6.0. This indicates that the surface pH conditions are favorable for the formation of trimer-like species (reaction A→C Fig. 3). The sorption edge occurs in the decreasing part of the ξ-potential curve, which indicates that some SOH_2^+ groups have already deprotonated to give free SOH groups. Though the solution pH conditions are not favorable for trimeric species, the pH_{surf} favors the formation of trimer-like species on the surface (reaction A→C in Fig. 3) as soon as free surface hydroxyl groups become available.

Conclusion

In contrast to the above two oxides, free surface hydroxyl groups are available on MAG and HThO even at pH 3 (Fig. 2(C)), but sorption of uranyl ions on MAG and HThO occrts only when pH_{surf} approaches 4 when dimer-like species can be formed on the surface. Hence it is the characteristics of the oxide surface, (pK_{al}^*, pH_{surf}) and availability of free SOH groups which govern the sorption of uranyl ions. Sorption is not governed by the presence or absence of hydrolyzed uranyl species in the solution. This point is strikingly demonstrated by HTiO where the sorption edge occurs when uranium is present only as unhydrolyzed uranyl ion in solution.

Authors wish to thank Dr V. K. Kelkar for his help in computer calculations.

Peroxy Acid Oxidations. II.† A Kinetic and Mechanistic Study of Oxidation of α-Diketones

Radhasyam PANDA,* Akhil Krishna PANIGRAHI, Chakrapani PATNAIK, Sabita Kumari SAHU, and Sabita Kumari MAHAPATRA
Department of Chemistry, Khallikote College, Berhampur 760001, Orissa, India
(Received November 11, 1986)

The kinetics of Baeyer-Villiger oxidation of biacetyl and benzil by peroxomonophosphoric acid and peroxomonosulfuric acid have been studied in different pH ranges at 308 K. The reactions are second order; first order each in peroxy acid and in diketone concentrations at constant pH. The oxidation rate is strongly pH-dependent; the rate increases with increase in pH. From the pH-rate data the reactivity of different peroxo species, in the oxidation, has been determined. A mechanism consistent with rate-determining nucleophilic attack of peroxo species on carbonyl carbon of the diketone molecule has been proposed. Acetic acid and benzoic acid are respectively found to be the products of oxidation of biacetyl and benzil.

Oxidation of α-diketones by peroxidic reagents[1] have been reported to yield carboxylic acids. These reactions are known to involve the intermediary formation of anhydrides which on hydrolysis yield corresponding carboxylic acids. In the reaction[2] of benzil with H_2O_2, in benzene, Leffler isolated benzoic anhydride, which gave benzoic acid on hydrolysis. The first kinetic study on the oxidation of benzils by peracetic acid in the presence of H_2SO_4 was reported by Furuya et al.[3] They described this reaction as a sort of Baeyer-Villiger reaction; both the acid-catalyzed and uncatalyzed oxidations have been discussed. Foote and Sawaki,[4] in the oxidation of benzil by alkaline H_2O_2, have ruled out the dioxetane and epoxide mechanisms basing on high energy requirements, product and isotopic studies; the acyclic Baeyer-Villiger type mechanism was supported.

Although peroxomonophosphoric acid and peroxomonosulfuric acid are known to be potential Baeyer-Villiger reagents, there have been only a few reports on the oxidation of carbonyl compounds using these peroxy acids. Recently we reported our studies[5] on the oxidation of acetylacetone by peroxomonophosphoric acid in alkaline pH.

As part of an effort to study the oxidation of dicarbonyl compounds by peroxy acids, we wish to report here the kinetic studies on the Baeyer-Villiger oxidation of α-diketones by peroxomonophosphoric acid (PMPA) and peroxomonosulfuric acid (PMSA) in aqueous and in aqueous-acetonitrile solution of different pH. The study has enabled us to estimate the relative reactivities of different peroxo species.

It is of interest that the pH dependence of the oxidation rate is quite contrary to that observed in the acetylacetone oxidation[6] in acid pH.

Experimental

PMPA solutions were prepared by acid hydrolysis[7,8] of $K_4P_2O_8$. The potassium salt of Caro's acid, oxone ($2KHSO_5 \cdot KHSO_4 \cdot K_2SO_4$), was obtained from Dupont Chemical Co., U. S. A., and was used to prepare PMSA solutions. All other chemicals used were of AnalaR grade. Biacetyl (Riedel) was distilled just before use (bp 89—91 °C). Benzil was prepared by means[9] of benzoin obtained from benzaldehyde, and was recrystallized from ethanol, mp 94 °C (lit, mp 94—96 °C). Acetonitrile was distilled over P_2O_5 (bp 80—82 °C). Sodium perchlorate, prepared in situ by neutralizing perchloric acid with carbonate-free sodium hydroxide, was used for adjusting ionic strength of the medium. All the solutions were prepared in doubly distilled water, the second distillation being from $KMnO_4$. Acidity of the solution was maintained by adding calculated amounts of $HClO_4$ or standard buffers. Measurements of pH were made on a Systronics Digital pH Meter 335.

The kinetics was followed by measuring the rate of disappearance of peroxy acid, the estimation of which was made iodometrically using standard thiosulfate; PMPA estimation was done in an acetate buffer of pH 4—5 with a drop of ammonium molybdate solution.[10] The observed second-order rate constant (k_2' obs) was calculated by dividing pseudo-first-order rate constant with respect to peroxy acid disappearance by the substrate concentration. The rate constants were reproducible to ±5%. The self-decomposition of PMPA or PMSA was found to be either nil or negligibly small under our experimental conditions. The temperature was constant to within ±0.1 °C. Computations were done with a DCM Micro System 1121.

Product Study. A solution of PMSA (1.2×10^{-4} mol) in water (10 ml) was added to a solution of benzil (5×10^{-4} mol) in acetonitrile (10 ml). Before the addition was started the pH was adjusted to 10. The reaction mixture was allowed to stand for 12 h at room temperature. It was then poured into water (100 ml) and acidified with dil HCl. The product extracted with chloroform was identified as benzoic acid (mp 122 °C).

In the oxidation of biacetyl, the product acetic acid was detected by spot tests.[11]

The stoichiometry of the PMSA-biacetyl reaction with excess PMSA over biacetyl was determined by estimating the left over PMSA when the reaction was complete (PMSA= 27.5×10^{-4} mol dm^{-3}, biacetyl=9.84×10^{-4} mol dm^{-3}, pH= 4.08, 308 K). The biacetyl: PMSA ratio for the reaction was found to be 0.91. The overall reaction can, hence, be represented as,

$$HSO_5^- + CH_3COCOCH_3 + H_2O \rightarrow 2CH_3COOH + HSO_4^-.$$

†Part I, Ref. 5.

Results and Discussion

The kinetics of oxidation of biacetyl and benzil by peroxomonophosphoric acid and by peroxomonosulfuric acid have been investigated at 308 K. The reactions, at constant pH and ionic strength, I, were shown to exhibit second-order kinetics; first order each in peroxy acid concentration and in diketone concentration (Tables 1 and 2), the rate law being,

$$\text{Rate} = k_2' \text{ [Peroxy acid]}_t \text{ [Diketone]},$$

where k_2' is the observed second-order rate constant and 't' denotes total concentration.

The rate was not influenced by ionic strength. Addition of acrylamide also had no effect on the oxidation rate (Tables 1 and 2).

The kinetics of oxidation of biacetyl and benzil by PMPA have been investigated in the pH ranges 0—5.5 and 7.2—11 respectively, and that by PMSA in the pH ranges 0.3—4 and 5—9.7. The influence of pH on the oxidation rate are presented in Tables 3 and 4, and shown in Fig. 1.

It is observed, in both PMPA and PMSA reactions with biacetyl, that variation of pH in the lower range (0—1.3 in PMPA and 0—0.7 in PMSA oxidation) did not significantly change the rate. However, the rate increased linearly with pH in the range 2.1—5.5 in PMPA oxidation, and 1—4 in PMSA oxidation. Such an observation is quite contrary to that made in the oxidation of acetylacetone,[6] a β-diketone, by PMPA in the pH range 0.4—7.75, where the rate first decreased with increase of pH in the range 0.4—3, and then increased (pH range 4—7.75).

In case of benzil, the rate (in both PMPA and PMSA oxidations) increased with increase of pH. The reactions were instantaneous at pH values higher than the

reported range.

Our attempt to collect a few kinetic runs with H_2O_2 in the presence of H^+, for comparison purpose, was frustrated owing to no definite kinetic order with respect to H_2O_2 disappearance.

PMPA is a tribasic acid having the following dissociation equilibria in solution.[7]

$$H_3PO_5 \overset{K_1}{\rightleftharpoons} H_2PO_5^- + H^+, \quad (1)$$

$$H_2PO_5^- \overset{K_2}{\rightleftharpoons} HPO_5^{2-} + H^+, \quad (2)$$

$$HPO_5^{2-} \overset{K_3}{\rightleftharpoons} PO_5^{3-} + H^+. \quad (3)$$

The dissociation constants K_1, K_2, and K_3 are 8.0×10^{-2}, 4.2×10^{-6}, and 1.6×10^{-13} mol dm^{-3} respectively at 298 K and I=0.2 mol dm^{-3}.

In the pH range 0—5.5 PMPA exists[7,8] as H_3PO_5, $H_2PO_5^-$, and HPO_5^{2-}. The reaction scheme for biacetyl oxidation in this pH range can, therefore, be presented by Eqs. 4—6.

$$H_3PO_5 + \text{biacetyl} \xrightarrow{k_1} \text{products}, \quad (4)$$

$$H_2PO_5^- + \text{biacetyl} \xrightarrow{k_2} \text{products}, \quad (5)$$

$$HPO_5^{2-} + \text{biacetyl} \xrightarrow{k_3} \text{products}, \quad (6)$$

which lead to the rate expression,

$$-\frac{d[PMPA]_t}{dt} = (k_1[H_3PO_5] + k_2[H_2PO_5^-] + k_3[HPO_5^{2-}])[\text{biacetyl}], \quad (7)$$

where $[PMPA]_t$ represents the total stoichiometric concentration of PMPA, and can be expressed by Eq. 8.

$$[PMPA]_t = [H_3PO_5] + [H_2PO_5^-] + [HPO_5^{2-}] \quad (8)$$

From Eqs. 1, 2, and 8 we get,

$$[H_3PO_5] = \frac{[H^+]^2[PMPA]_t}{K_1K_2 + K_1[H^+] + [H^+]^2}, \quad (9)$$

$$[H_2PO_5^-] = \frac{K_1[H^+][PMPA]_t}{K_1K_2 + K_1[H^+] + [H^+]^2}, \quad (10)$$

and

$$[HPO_5^{2-}] = \frac{K_1K_2[PMPA]_t}{K_1K_2 + K_1[H^+] + [H^+]^2}. \quad (11)$$

Substituting Eqs. 9, 10, and 11 in Eq. 7, we get,

$$-\frac{d[PMPA]_t}{dt} = \left\{\frac{k_1[H^+]^2 + k_2K_1[H^+] + k_3K_1K_2}{K_1K_2 + K_1[H^+] + [H^+]^2}\right\} \times [PMPA]_t[\text{biacetyl}], \quad (12)$$

or

$$k_2' = \frac{k_1[H^+]^2 + k_2K_1[H^+] + k_3K_1K_2}{K_1K_2 + K_1[H^+] + [H^+]^2}. \quad (13)$$

The values of k_2 and k_3, calculated by a method of least-squares using Eq. 13, are 0.087 and 10.0 dm^3 mol^{-1} s^{-1} respectively. The value of k_1 is small and negative and hence, could be approximated to zero. This allows us to rule out the path involving H_3PO_5 (Eq. 4). These values of k_1, k_2, and k_3 have been used to obtain k_2' calcd, which are presented in Table 3.

The PMPA species contributing to the rate of oxidation of benzil, in the pH range 7—11, are HPO_5^{2-} and PO_5^{3-}. Hence, the steps of the oxidation can be written as,

$$HPO_5^{2-} + OH^- \overset{K_4}{\rightleftharpoons} PO_5^{3-} + H_2O, \quad (14)$$

$$HPO_5^{2-} + \text{benzil} \xrightarrow{k_4} \text{products}, \quad (15)$$

$$PO_5^{3-} + \text{benzil} \xrightarrow{k_5} \text{products}. \quad (16)$$

The rate law is,

$$-\frac{d[PMPA]_t}{dt} = (k_4[HPO_5^{2-}] + k_5[PO_5^{3-}])[\text{benzil}], \quad (17)$$

$$= \left\{\frac{k_4K_h + k_5[OH^-]}{K_h + [OH^-]}\right\}[PMPA]_t[\text{benzil}], \quad (18)$$

where

$$[PMPA]_t = [HPO_5^{2-}] + [PO_5^{3-}], \quad (19)$$

and

$$K_h = [H_2O]/K_4. \quad (20)$$

Equation 18 can be rearranged to give Eq. 21

$$k_2' = \frac{k_4K_h + k_5[OH^-]}{K_h + [OH^-]}, \quad (21)$$

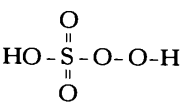
which has been used to calculate the rate constant k_2' (calcd) in Table 4.

The K_h value for PMPA species, as determined from Eq. 22 using the literature reported K_3 value, is 6.25×10^{-2} mol dm^{-3}.

$$K_h = K_w/K_3 \tag{22}$$

The statistical analysis of Eq. 21 was repeated by allowing the K_h value to vary until optimal values of k_4 and k_5 were obtained. These values are K_h=7.35×10^{-2} mol dm^{-3}, k_4=6.77×10^{-3} dm^3 mol^{-1} s^{-1} and k_5=188 dm^3 mol^{-1} s^{-1}.

The structure of peroxomonosulfuric acid has been shown[10] to be



of which one proton is a sulfuric acid proton and the other is a hydrogen peroxide proton. The pK_a value of the sulfuric acid proton lies in the high acidity region, while the hydrogen peroxide proton has a pK_a value[12] of 9.4.

In aqueous solution PMSA exists as HSO_5^- and SO_5^{2-}

$$HSO_5^- \overset{K_5}{\rightleftharpoons} SO_5^{2-} + H^+,\ K_5 = 4\times10^{-10}\ \text{mol dm}^{-3}. \tag{23}$$

For the oxidation of α-diketones by PMSA, in the range of pH studied, the dependence on pH can be explained by a mechanism in which the diketone molecule reacts simultaneously with HSO_5^- and SO_5^{2-} in two parallel reactions.

For biacetyl oxidation, in the pH range 0.3—4, the reaction steps are,

$$HSO_5^- + \text{biacetyl} \xrightarrow{k_6} \text{products}, \tag{24}$$

$$SO_5^{2-} + \text{biacetyl} \xrightarrow{k_7} \text{products}, \tag{25}$$

which follow the rate expression,

$$-\frac{d[PMSA]_t}{dt} = \left\{k_6[HSO_5^-] + k_7[SO_5^{2-}]\right\}[\text{biacetyl}], \tag{26}$$

from which we get,

$$-\frac{d[PMSA]_t}{dt} = \frac{k_6[H^+] + k_7K_5}{K_5 + [H^+]}[PMSA]_t[\text{biacetyl}], \tag{27}$$

where

$$k_2' = \frac{k_6[H^+] + k_7K_5}{K_5 + [H^+]}. \tag{28}$$

In the pH range 0.3—4,

$$K_5 \ll [H^+]. \tag{29}$$

Equation 28 may, therefore, be written as,

$$k_2' = \frac{k_6[H^+] + k_7K_5}{[H^+]}. \tag{30}$$

Equation 30 has been used to determine the reactivity of HSO_5^- and SO_5^{2-} in biacetyl oxidation. The values of k_6 and k_7 are respectively found to be 1.82×10^{-2} dm^3 mol^{-1} s^{-1} and 2.39×10^6 dm^3 mol^{-1} s^{-1}.

The reaction steps for benzil oxidation, in pH range 5—9.7 are postulated as,

$$HSO_5^- + OH^- \overset{K_6}{\rightleftharpoons} SO_5^{2-} + H_2O, \tag{31}$$

$$HSO_5^- + \text{benzil} \xrightarrow{k_8} \text{products}, \tag{32}$$

$$SO_5^{2-} + \text{benzil} \xrightarrow{k_9} \text{products}. \tag{33}$$

Equations 31—33 lead to the rate equation,

$$k_2' = \frac{k_8K_h' + k_9[OH^-]}{K_h' + [OH^-]}, \tag{34}$$

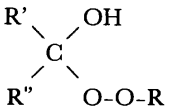
where K_h'=K_w/K_5.

A least squares solution of Eq. 34, using K_h'=K_w/K_5, gave us the values of k_8 and k_9. These values are k_8=1.34×10^{-2} dm^3 mol^{-1} s^{-1} and k_9=30.9 dm^3 mol^{-1} s^{-1}, which have been used to calculate k_2' calcd. in Table 4.

Peroxo species which participate in the reaction with α-diketones are $H_2PO_5^-$, HPO_5^{2-}, and PO_5^{3-} in PMPA oxidation, and HSO_5^- and SO_5^{2-} in PMSA oxidation. From the magnitude of rate constants (Table 5) for these species, it is evident that the reaction is facilitated by the more nucleophilic peroxo species; the reactivity of H_3PO_5 is negligible in the oxidation. The reactivity of SO_5^{2-} is approximately eight orders of magnitude higher than that of HSO_5^- in biacetyl oxidation. The reduced reactivity of benzil might be due to the decrease in electrophilic character of the carbonyl carbon.

Baeyer-Villiger reaction of aldehydes or ketones with hydrogen peroxide or peroxy acids are well-known.[1] Acid catalysis is an important feature of these oxidations.

The fundamental step in the reaction of carbonyl compounds with peroxides is rapid addition[13] of the peroxide molecule to the carbonyl group to give 'Criegee intermediate' of type I,



(I)

which then rearranges to give the product. The rate-determining step, in these reactions, may be either addition of peroxy acid to >C=O or migration from adduct depending on the substrate.

In the oxidation[14] of acetophenones by PMPA, cata-

Scheme 1.

lyzed by H_2SO_4, the migration step was shown to be rate determining, while in perbenzoic acid oxidation[15] the rate-determining step was the acid-catalyzed addition of peroxy acid to >C=O.

α-Diketones have been shown to react readily with Baeyer-Villiger reagents in both acid and alkaline media.[1] The product was either an anhydride or a carboxylic acid depending on the nature of solvent used.

The oxidation of benzil by peracetic acid was reported[3] to be acid-catalyzed. The acid catalysis has been traced to protonation of the carbonyl group, which was then attacked by peroxy acid in a rate-determining step.

In the oxidation of benzil by alkaline H_2O_2, from both product and isotopic studies, it has been established[4] that the reaction involves a Baeyer-Villiger type acyclic mechanism. Even though the migratory aptitude of the acyl group is very low in carbon-to-carbon migrations,[16] the acyl shift to peroxide oxygen has been shown to be facile.[17]

A significant observation, in the present study, is that the reactions are not acid-catalyzed. The increased reactivity in higher pH points to the nucleophilic behavior of peroxo species in the oxidation.

The initial step in the reactions of α-diketones by PMPA or PMSA is now believed to be the rate-determining nucleophilic addition of peroxy acid to the carbonyl carbon to form an adduct **1**. This adduct, can, then rearrange to the anhydride **2**, which is hydrolyzed, under reaction conditions, giving the corresponding carboxylic acid (Scheme 1).

The authors are grateful to Professor G. P. Panigrahi, Department of Chemistry, Berhampur University for helpful discussions. They are also grateful to Professor S. C. Padhi, Department of Chemistry, Khallikote College, for providing necessary facilities, and encouragement. A financial help from UGC, New Delhi is gratefully acknowledged.

Synthesis, Ion-Exchange Properties, and Analytical Applications of Anilinium Tin(IV) Phosphate

Dhruv Kumar SINGH* and Anjana DARBARI
Department of Chemistry, Harcourt Butler Technological Institute, Kanpur-208002, India
(Received January 13, 1987)

A new inorganic ion-exchanger anilinium tin(IV) phosphate (ATP) has been synthesized under varying conditions. The effects of mixing ratio of reagents and the pH of the mixture on the properties of the material have been studied. The sample ATP_1 has been chosen for detailed studies, such as ion-exchange capacity, chemical and thermal stabilities, chemical composition, pH titration, break-through curve, and IR analysis. Distribution coefficients of 16 metal ions have been studied in water, hydrochloric acid and acetone-hydrochloric acid media. On the basis of K_d values some analytically important separations of metal ions have been achieved on the small columns of anilinium tin(IV) phosphate.

There have been continuous efforts to improve the chemical, thermal, and mechanical stabilities of ion-exchangers and to make them highly selective for particular metal ions. Hahn and Klein[1] introduced organic ammonium ions in place of inorganic ammonium ion in ammonium hexacyanoferrate(II) compound of cobalt(II) and reported that the ammonium compounds have excellent exchange properties for ^{137}Cs. Ammonium tin(II) hexacyanoferrate(II),[2] ammonium tin(IV) hexacyanoferrate(II),[3] tin(IV) diethanolammonium,[4] iron(III) diethanolammonium,[5] and tin(IV) phosphate[6,7] have already been reported and utilized for the separations of metal ions. Anilinium tin(IV) phosphate has not been studied so far. The present paper summarizes the synthesis, ion-exchange properties and analytical applications of anilinium tin(IV) phosphate as a new inorganic ion-exchanger.

Experimental

Reagants. Tin(IV) chloride pentahydrate (Poland), aniline, and orthophosphoric acid (BDH, India) were used. All other reagents were of analytical grade.

Apparatus. Bausch and Lomb Spectronic 20 for spectrophotometry, Systronic digital pH meter for pH measurements and Perkin Elmer model 599 B Spectrophotometer for IR studies, were used. An electric rotary shaking machine IEC-56 was used for shaking purpose.

Synthesis. An excess of aniline (ca. 5 cm^3) was added dropwise to 10 cm^3 of 1 mol dm^{-3} orthophosphoric acid solution with constant stirring to prepare dianilinium hydrogenphosphate $[(C_6H_5NH_3)_2HPO_4]$. It was dissolved in demineralized water (DMW) and diluted up to 200 cm^3. This solution was added to 0.1 mol dm^{-3} tin(IV) chloride solution with constant stirring as outlined in Table 1. The pH of the sample solution in each case was adjusted by adding hydrochloric acid solution dropwise. After 24 h the product was filtered, washed with DMW and dried at 40 °C. The material broke into small particles when immersed in DMW and was converted into H^+ form on treatment with 1 mol dm^{-3} nitric acid for 24 h with occasional shaking and renewal of the acid. The excess of the acid was removed after several washings with DMW. The samples were dried at 40 °C.

Ion-Exchange Capacity. The ion-exchange capacity of various samples of anilinium tin(IV) phosphate was determined by the column method (Tables 1 and 2). One gram exchanger in H^+ form was taken in the column of 7.2 mm (i.d.). The H^+ ions were eluted by percolating the required 1 mol dm^{-3} cationic solution through the column. The feed was passed until its pH became equal to that of the effluent collected. The hydrogen ions so eluted were titrated against standardized 0.1 mol dm^{-3} NaOH. The neutral salt decomposition capacity with different uni- and bivalent ions is reported in Table 3.

Chemical Composition. The well-powdered material (0.5 g) was fused with a 1 : 1 mixture of potassium and sodium carbonates. The fused mixture was extracted with hot water, the undissolved portion was ignited and weighed as SnO_2. The diphosphorus pentoxide present in the dissloved portion was precipitated as ammonium molybdophosphate, filtered and determined gravimetrically.[8] For the determination of aniline, another 0.5 g sample of the exchanger was introduced into a Kjeldahl digestion flask. After digestion 25 cm^3 potassium hydroxide solution (50%) was added dropwise. The amine distilled into 50 cm^3 boric acid solution (1%) was titrated with 0.1 mol dm^{-3} HCl using a mixed indicator (Bromocresol Green and Methyl Red).[9]

Chemical Stability. A 0.2 g of the material (sample ATP_1) was shaken with 20 cm^3 of the solution concerned at 30±2 °C for 6 h. Tin, phosphorus, and aniline were determined spectrophotometrically with phenylfluorone,[10] molybdovanadophosphoric acid,[11] and iron(III) nitrate[12] respectively.

pH Titration. Topp and Peppers'[13] method was used for pH titrations using NaOH-NaCl system. A quarter gram samples of dry exchanger (ATP_1) in H^+ form were shaken with 25 cm^3 portions of 0.1 mol dm^{-3} (NaCl+NaOH) cationic solution in different conical flasks at 30±1 °C. The concentration ratio of NaCl/NaOH was varied from 0.096 mol dm^{-3}/0.004 mol dm^{-3} to 0.004 mol dm^{-3}/0.096 mol dm^{-3} in the equilibrating solution of the flasks. After 24 h pH of the supernatant solution of each flask was recorded and plotted against the mEq of OH^- added per 0.25 g of dry exchanger (Fig. 1).

Break-through Curve. The break-through curves[14] were observed for Zn^{2+}, Cd^{2+}, and Hg^{2+} by passing 0.02 mol dm^{-3} solution (pH≈6) of each metal ion through a glass column, i.d. 7.2 mm and 30 cm length packed with 4 g of anilinium thin(IV) phosphate in H^+ form (Sample ATP_1). The flow rate was maintained 1 cm^3 min^{-1}. The results are presented in Fig. 3.

Table 1. Synthesis and Properties of Anilinium Tin(IV) Phosphate[a, b]

Sample No.	Volume of 0.1 mol dm^{-3} Tin(IV) chloride/cm^3	pH	Ion-exchange capacity for K^+ meq (dry g)$^{-1}$	Composition Sn: $C_6H_5NH_2$: PO_4^{3-}	Yield g
ATP_1	50	1	1.68	4:2:1	1.06
ATP_2	100	1	1.52	—	—
ATP_3	200	1	1.40	—	—
ATP_4	50	2	1.53	—	—
ATP_5	50	3	1.44	4.6:2:1	—
ATP_6	50	5	1.30	5:2:1	—

a) Tin(IV) chloride solution was added to 200 cm^3 of 5×10^{-2} mol dm^{-3} $(C_6H_5NH_3)_2HPO_4$ solution. b) Appearance of precipitate was white gelatinous and appearance of beads after drying at 40 °C was white.

Table 2. Reproducibility of the Synthesis

Batch No.	Ion-exchange capacity for K^+ meq (dry g)$^{-1}$	Composition Sn : $C_6H_5NH_2$: PO_4^{3-}
1	1.68	4 : 2 : 1
2	1.70	4 : 2 : 1
3	1.68	4.02 : 2 : 1
4	1.66	4 : 2 : 1
5	1.70	4.02 : 2 : 1

Distribution Coefficient. Distribution coefficients (K_d values) of a number of metal ions in water, hydrochloric acid and acetone-hydrochloric acid systems were determined by a batch process.[15] A quarter gram of the exchanger in H^+ form (50—100 mesh) was equilibrated with 25 cm^3 cation solutions (4×10^{-3} mol dm^{-3}) at 30±1 °C for 6 h in a 100 cm^3 Erlenmeyer flask. The amount of cation in the solution after and before the treatment with the exchanger was determined by EDTA titration except Pt^{4+} which was determined with tin(II) chloride[16] spectrophotometrically. K_d values were calculated from

$$K_d(\text{cm}^3\,\text{g}^{-1}) = \frac{\text{Amount of metal ion in exchanger phase per gram}}{\text{Amount of metal ion in solution phase per cm}^3}$$

The results are presented in Table 5.

Quantitative Separations. Quantitative separations of some important metal ions of analytical utility were achieved on the columns of anilinium tin(IV) phosphate. Two grams of the exchanger in H^+ form (50—100 mesh) was taken into a glass column of i.d. 3.9 mm. The column was first washed with about 20 cm^3 of 80% acetone-hydrochloric acid (0.01 mol dm^{-3}) and then the mixture of metal ions having concentration 0.644 to 1.044 mg/10 cm^3 was introduced into the column and allowed to be adsorbed. The metal ions were then eluted separately using suitable eluting reagents and determined by EDTA titrations except Pt^{4+} which was determined spectrophotometrically.[16] The flow rate was maintained about 0.2 cm^3 min^{-1} throughout the elution process. Results of separations achieved have been reported in Table 6.

Results and Discussion

The ion-exchange capacities and the compositions of the samples of anilinium tin(IV) phosphate are presented in Table 1. In the synthesis of anilinium tin(IV) phosphate, increased pH and volume of 0.1 mol dm^{-3} tin(IV) chloride results in decreased ion-exchange capacity. The maximum ion-exchange capacity (1.7 meq (dry g)$^{-1}$) is observed for sample ATP_1 prepared by mixing 50 cm^3 of 0.1 mol dm^{-3} tin(IV) chloride solution to the anilinium phosphate solution at pH 1. The ion-exchange capacity of ATP_1 is higher than the reported capacity, 1.4 meq (dry g)$^{-1}$

Table 3. Ion-Exchange Capacity of Anilinium Tin(IV) Phosphate (Sample ATP_1) for Various Cations

Cation[a]	pH	Hydrated radii/nm	I.E.C. meq (dry g)$^{-1}$
Li^+	6.8	0.340	1.28
Na^+	6.8	0.276	1.64
K^+	6.8	0.232	1.70
Mg^{2+}	6.5	0.700	1.00
Ca^{2+}	6.5	0.630	1.46
Sr^{2+}	6.2	—	1.50
Ba^{2+}	6.2	0.590	1.62

a) Used as chloride (1 mol dm^{-3}).

Table 4. Chemical Stability of Anilinium Tin(IV) Phosphate (ATP_1)

Solvent	Solubility (mg/20 cm^3)		
	Sn released	$C_6H_5NH_2$ released	P released
Demineralized water	0.00	0.02	0.06
1 mol dm^{-3} Nitric acid	0.06	0.04	0.12
4 mol dm^{-3} Nitric acid	1.30	0.84	1.86
1 mol dm^{-3} Hydrochloric acid	0.20	0.37	0.28
4 mol dm^{-3} Hydrochloric acid	2.58	2.14	3.60
0.1 mol dm^{-3} Sodium hydroxide	0.04	3.00	1.62
Acetone	0.00	0.00	0.10
Methanol	0.00	0.04	0.16

of tin(IV) phosphate.[6,7] ATP_1 shows reproducible properties as is evident from data presented in Table 2.

The ion-exchange capacity measured for various cations is given in Table 3. The data show that ion-exchange capacity for alkali metals are higher than alkaline earths. In both cases the capacity increases with the decrease in hydrated radii of ions. The effect of drying temperature on the ion exchange capacity was studied. The results shown in Fig. 2 indicate that this exchanger can be used up to 100 °C without loss in ion-exchange capacity; above 100 °C there is a decrease in ion-exchange capacity but the decrease is much less than in anilinium hexacyanoferrate(II) of tin(II) and tin(IV).

The results of chemical stability measurements (Table 4) indicate that the product is fairly stable in water, acetone, ethanol, 0.1 mol dm^{-3} NaOH and up to 1 mol dm^{-3} nitric acid and hydrochloric acid.

Analytical data of sample ATP_1 are as follows: amount of exchanger taken, 1.000g; $C_6H_5NH_2$ obtained after distillation, 0.217±0.003 g (2.333 mmol); amount o Sn(IV) found, 0.544±0.002 g (4.583 mmol); amount of PO_4^{3-} found, 0.108±0.002 g (1.137 mmol); molar ratio of Sn(IV): $C_6H_5NH_2$: PO_4^{3-}, 4 : 2 : 1. The products prepared at pH values greater than one contained more tin.

The capacity which is utilized until break-through occurs is called break-through capacity. The break-through behavior of anilinium tin(IV) phosphate for Zn^{2+}, Cd^{2+}, and Hg^{2+} was studied. The results are plotted in Fig. 3.

The results of pH titrations indicate that ATP_1 in

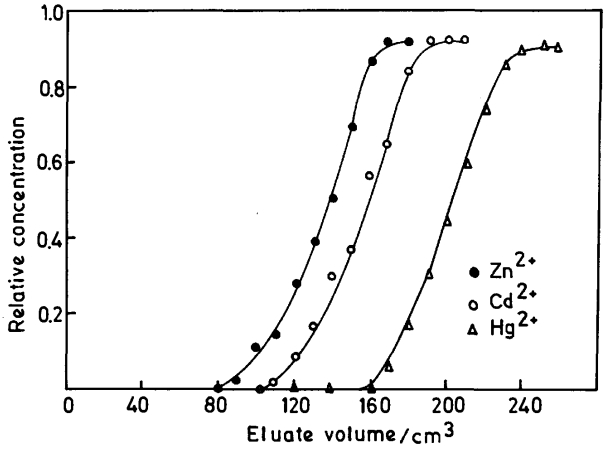

Fig. 3. Break-through curves of ATP_1 for three bivalent cations.

H^+ form behaves as a diprotic acid (Fig. 1). The total ion-exchange capacity is 3.6 meq g^{-1} calculated at the neutralization point. This gives the maximum number of replaceable counter ions and is independent of the nature of the cation.

The IR spectrum of anilinium tin(IV) phosphate is in accord with the proposed composition.

In order to study the analytical potentialities of the ion-exchanger the distribution coefficients of 16 metal ions in seven systems were determined, the results are shown in Table 5. Anilinium tin(IV) phosphate shows selective behavior (higher K_d values) for Hg^{2+}, Pb^{2+} and Pt^{4+}. The data in Table 5 show that K_d values decrease with the increase in concentration of hydrochloric acid and increase in solutions with greater percentage of acetone. On the basis of this behavior (K_d values) separations were tried. Those experimentally successfully achieved are reported in Table 6. The relative order of elution for Zn^{2+}-Cd^{2+}-Hg^{2+} is similar to that of break-through curves (Fig. 3). It is interesting that no significant tailing was observed during the elution of various metal ions and only small volumes of eluents were required to give compact chromatograms.

Mg^{2+} is eluted ahead of Ca^{2+} (binary separation of Mg^{2+}-Ca^{2+}) with suitable hydrochloric acid-acetone solution, hence the columns of anilinium tin(IV) phosphate may be utilized to separate magnesium from calcium in dolomite.[17] Usually, 0.1 to 0.5% cadmium is present in zincblende (Sphalerite) and Calamine.[18] The ternary separation of Zn^{2+}-Cd^{2+}-Hg^{2+} may be utilized to recover Cd^{2+} from these ores using suitable eluents. Zircon contains usually less than 1 per cent of thorium oxide.[19] The binary separation of Th^{4+}-Zr^{4+} can be applied for the recovery of Th^{4+} from Zr^{4+}. Iron and lead occur in major to trace concentrations in zinc bearing ores.[20] Zn^{2+}, Fe^{3+}, and Pb^{2+} can be eluted by different hydrochloric acid-acetone solutions using anilinium tin(IV) phosphate columns.

Nitriles in Organic Synthesis. The Chemical Behavior of [1-(2-Furyl)-ethylidene]- and [1-(2-Thienyl)ethylidene]malononitriles

Mohamed Abdallah EL-MAGHRABY,† Kamal Usef SADEK,†† Maghraby Ali SELIM,† and Mohamed Hilmy ELNAGDI*

(Received January 26, 1987)

The chemical behavior of [1-(2-furyl)ethylidene]- and [1-(2-thienyl)ethylidene]malononitriles **1a** and **b** toward electrophilic reagents, active methylene reagents and (arylmethylene)malononitriles is described.

The chemistry of nitriles has received considerable recent attention.[1,2] A variety of new systems has been efficiently synthesized utilizing simple nitriles as starting components.[3,4] In conjunction with our program directed for developing utility of polycyano compounds in organic synthesis we have recently reported a novel synthesis of pyridazines and 3,5-disubstituted-2,6-dicyanoanilines utilizing (1-phenylethylidene)malononitrile (**1c**) as starting material.[5] In order to see if reactions of the type reported above can be extended to constitute general route for the synthesis of pyridazines and 3,5-disubstituted-2,6-dicyanoanilines , we report here the results of our investigations to conduct similar reactions with [1-(2-furyl)], and [1-(2-thienyl)ethylidene]malononitriles (**1a** and **b**).

In contrast to the reported formation of [1-phenyl-2-(phenylhydrazono)ethylidene]malononitrile on coupling **1c** with benzenediazonium chloride, compounds **1a** and **b** coupled with the same reagent to yield (phenylazo)malononitrile (**2**). The formation of **2** in this reaction is assumed to proceed via coupling of benzenediazonium chloride with malononitrile, the latter is assumed to be formed via action of water on **1a** or **b** (cf. route (a)). Possible formation of **2** via route (b) seems unlikely, although it cannot be ruled out. The difference in behavior between **1a,b** and **1c** can be attributed to a decrease in the acidity of the methyl group in **1a** and **b** by the effect of the electron-rich heterocycles which counterbalance the electron-attracting effect of the two cyano functions.[6]

Compound **1a** reacted with (arylmethylene)malononitriles 3**a**—**c** to yield products of condensation via HCN elimination. Two isomeric structures seemed possible for the reaction product (cf. structures **4** and **5**). Structures **4a**—**c** were established for the reaction products based on their syntheses via reactions of **6** with malononitrile. Compounds **6** were obtained in turn via reaction of **1a, b** with furfural and 2-thiophenecarbaldehyde. Compound **4a** was also found identical with authentic sample prepared as has been previously described.[5] Similarly, compound **1b** rected with (arylmethylene)malononitriles **3a** and **b** to yield the 3,5-disubstituted-2,6-dicyanoanilines **4c** and **d**. In contrast, compound **1b** reacted with **3c** to yield 1 : 1 adduct. The pyridine structure **7** was established for the reaction product based on its analytical and spectral data (cf. Experimental).

The behavior of **1a** and **b** toward malononitrile was also investigated. It has been found that **1a** reacted with malononitrile to yield a compound of molecular formula $C_{12}H_8ON_4$ (M^+=224; m/z). This compound can be formulated as the pyridine derivative **8** or the isomeric benzene derivative **9**. Structure **8** was readily eliminated based on ^{1}H NMR which revealed the absence of CH_2 function. Thus, structure **9** was considered for the reaction product. Attempts at addition of **1b** to malononitrile under the same experimental conditions were unsuccessful. The reactants were recovered almost unchanged after reflux in sodium-dioxane mixture.

In contrast to the reported addition of **1c** to trichloroacetonitrile,[5] attempts at addition of **1a** and **b** to the same reagents has failed.

The results obtained in our investigation clearly reveal the effect of C-1 substituent on the reactivity of methyl grorup in [1-substitutedethylidene]malononitriles. Electron-rich substituents counterbalance the electron-attracting force of the cyano groups which result in the decrease of the reactivity of methyl group.

Experimental

All melting points were uncorrected. IR spectra were recorded (potassium bromide) on a Shimadzu-408 spectrophotometer. ^{1}H NMR were measured in DMSO on a Varian EM-390 spectrophotometer at 90 MHz with TMS as internal reference and chemical shifts were expressed as δ (ppm). Microanalytical data (C, H, N, S.) were obtained from the Microanalytical Data Unit at Cairo University.

[1-(2-Furyl)ethylidene]- and [1-(2-Thienyl)ethylidene]-malononitriles (1a and b). General Procedure: Malononitrile (0.01 mol) was added to a suspension of 2-acetylfuran or 2-acetylthiophene (0.01 mol) in a mixture of benzene-acetic acid (50 : 5) in the presence of β-alanine (2 g). The reaction miture was heated under reflux in the presence of a water separator until complete removal of water (2 h) then evaporated in vacuo. The solid product, so formed, was collected by filtration and crystallized from the appropriate solvent (see Table 1).

Coupling of Compounds 1a and b with Benzenediazonium Chloride: An ice cold solution of 0.01 mol of benzenediazonium chloride (prepared from 0.01 mol of aniline

and the appropriate amount of sodium nitrite and hydrochloric acid) was added to a solution of **1a** or **b** (0.01 mol) in ethanol (50 ml) containing sodium acetate (5 g). The precipitate was filtered off and crystallized from ethanol. The product was identical with authentic sample of (phenylazo)malononitrile.

Condensation of Compounds 1a and b with (Arylmethylene)malononitrile Derivatives 3a—c. General Procedure: A solution of compound **1a** or **b** (0.01 mol) and the appropriate (arylmethylene)malononitrile derivatives **3a—c** (0.01 mol) in ethanol (50 ml) was treated with piperidine (1.0 ml). The reaction mixture was heated under reflux for 3 h and then evaporated in vacuo. The solid product, so formed, was collected by filtration and recrystallized from the appropriate solvent (see Table 1).

The same products were obtained by the follwing procedure: To a solution of compound **1a** or **b** (0.01 mol) in ethanol (50 ml) was added to the appropriate aromatic aldehyde in the presence of piperidine (1.0 ml). The reaction mixture was heated under reflux for 1—2 h (TLC monitor). To this solution, malononitrile (0.01 mol) was added and the reaction mixture was heated under reflux for additional 2 h. The solvent was then evaporated in vacuo and the solid product, so formed, was collected by filtration.

Compound **4a** was also found identical with authentic sample prepared as was previously described.[5]

Reaction of 1a with Malononitrile. Equimolecular amounts (0.01 mol) of **1a** and malononitrile were heated under reflux in 50 ml of dioxane with 0.01 mol of sodium metal for 4 h. The mixture was then evaporated in vacuo and neutralized with HCl. The solid product, so formed was collected by filtration and recrystallized from the appropriate solvent (see Table 1).

Alkylation of Phenol by C_9 and C_{12} Olefins

Rajeev Anand RAJADHYAKSHA* and Dilip Devidas CHAUDHARI
Department of Chemical Technology, University of Bombay, Matunga, Bombay 400019, India
(Received November 17, 1986)

Alkylation of phenol by 1-dodecene, propylene tetramer and trimer is investigated using a variety of acid catalysts. The catalytic activity of perfluorinated sulfonic acid resin Nafion-H, the recently described 'sulfate treated' zirconia and trifluoromethanesulfonic acid is compared with that of cation exchange resin (CER) catalyst which is commonly employed in industrial practice. The activity of zirconia is observed to be comparable to CER and Nafion-H. In view of its low cost and higher thermal and structural stability, this catalyst shows considerable promise for practical application.

Alkylation of phenol with higher olefins in C_8 to C_{15} range does not take place as readily as with the lower olefins.[1] Among these alkylated phenols, nonyl- and dodecylphenol are of considerable commercial importance, especially in the manufacture of surfactants and lube oil additives.[2] Propylene oligomers have branched chain structure and the resultant alkylphenols are nonbiodegradable. Hence, for use in biodegradable surfactants linear α-olefins such as 1-dodecene, 1-nonene, or linear olefins with internal double bond are preferred.

These alkylation reactions have been studied on a variety of acid catalysts such as *p*-toluenesulfonic acid, boron trifluoride, boron trifluoride etherate, hydrofluoric acid, aluminium chloride-sulfuric acid,[3] hydrofluoric acid-carbon dioxide,[4] cation exchange resin,[5] bentonite clay,[6] zinc chloride-hydrochloric acid,[7] and silica-alumina.[8] Most of the literature is in the form of patents and hence provides limited information. Most of the catalysts mentioned above suffer from various drawbacks such as problems of separation from reaction products, corrosion and nonreusability. Boron trifluoride and CER catalysts seem to be preferred in industrial practice. Use of solid catalysts has clear advantage due to the ease of separation from the products and noncorrosive nature of reaction medium. In the present work, catalytic activity of a variety of solid acid catalysts is investigated for alkylation of phenol with 1-dodecene, propylene tetramer and trimer. The catalysts include the perfluorinated sulfonic acid resin Nafion-H, and the 'sulfate treated' zirconia recently described by Arata and Hino.[9-11] The catalytic activity of these catalysts is compared with that of CER catalysts. Trifluoromethanesulfonic acid (triflic acid) is one of the strongest acids known and unlike many other super acids, it is stable in a variety of reaction media and is also reusable.[1,2] The catalytic activity of this acid was also investigated.

Experimental

Materials. Phenol, 1-dodecene Fluka, zirconium dichloride oxide of A.R. grade, while propylene trimer (135—137 °C, ρ=0.739 g cm^{-3}) and propylene tetramer (187—188 °C, ρ=0.770 g cm^{-3}) were used in the present study.

Catalysts. The superacid catalysts Nafion-H and triflic acid [$\geqslant$98%] were obtained from Du Pont and Fluka respectively. The 'sulfate treated' zirconia was prepared by treating zirconium hydroxide with 0.5 M sulfuric acid (1 M=1 mol dm^{-3}) followed by drying and calcination at 650 °C for 3 h. This zirconium hydroxide was prepared from zirconium dichloride oxide by hydrolysis with aq ammonia.[9] 98% Sulfuric acid of A.R. grade was used. The CER [Polystyrene-DVB crosslinked resin sulfonic acid, Indion-130] was procured from Ion Exchange India. The solid catalysts were dried at 110 °C for 1 h just before use.

General Reaction Procedure and Analysis. The reactor consisted of a flat bottom glass vessel of 5.0 cm i.d. and 200 ml volume. The reactor was equipped with baffles and was stirred by a glass turbine stirrer at 1000 rpm. The reactor was kept in a constant temperature bath. In a typical run, 29 g of phenol (0.31 mol) was brought to the required temperature under agitation and 0.73 g of catalyst [2.5% (w/w) of phenol] and 34.7 g of 1-dodecene [0.207 mol] were added. This was considered as zero time. Samples of the reaction mixture (0.5 ml) were withdrawn from time to time. Samples were analyzed by gas chromatography using a s.s. column containing 5% SE-30 on Chromosorb-W [HP] as stationary phase and flame ionization detector.

Results and Discussion

In all experiments, the alkylated product consisted of the para isomer exclusively.

Alkylation of Phenol with 1-Dodecene. Alkylation of phenol with 1-dodecene was studied in the temperature range of 100—145 °C using zirconia catalyst. The conversions observed at different reaction time are given in Table 1. The data could be fitted to a simple

Table 1. Alkylation of Phenol with 1-Dodecene

min	100 °C	115 °C	130 °C	145 °C
15	8	23	30	35
30	13	33	49	51
60	27	48	62	65
90	37	55	75	77
120	45	68	77	79

Mole ratio, phenol: 1-dodecene=1.5: 1.
Loading of zirconia=2.5% (w/w) of phenol.

Table 2. Alkylation of Phenol with 1-Dodecene Effect of Mole Ratio on Activity

Mole ratio phenol: 1-dodecene	% Conversion of 1-dodecene at time in min					
	15	30	45	60	120	180
1 : 1	10	25	32	38	60	70
1.5 : 1	35	49	53	64	78	
1 : 1.5	2	11	17	20	27	31

Temperature 130 °C. Loading of zirconia 2.5% (w/w) of phenol.

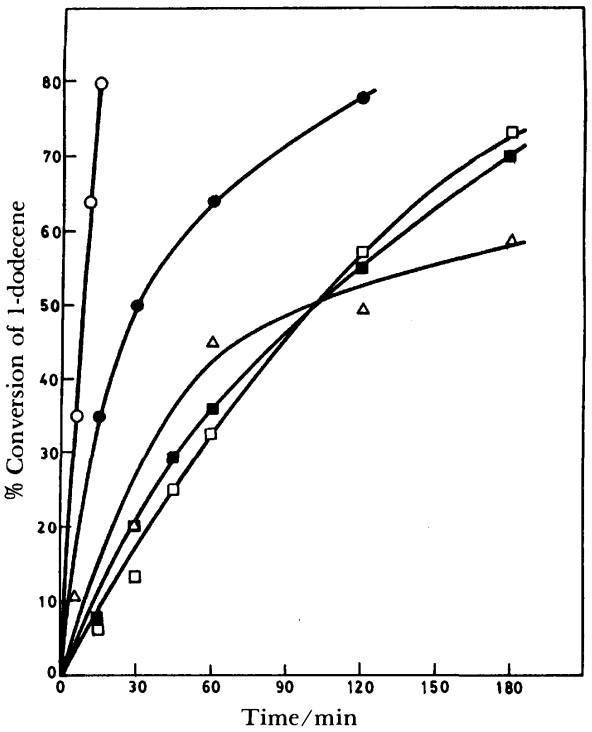

Fig. 1. Alkylation of phenol with 1-dodecene; comparison of activity of different catalysts. Mole ratio of phenol:1-dodecene 1.5:1, 130°C, catalyst 2.5% (w/w) of phenol: ● zirconia, ■ Nafion-H, ○ triflic acid, □ CER, △ 98% sulfuric acid.

second-order kinetic expression. The activation energy was found to be 7.5 kcal mol^{-1}. The reaction was also carried out using different initial mole ratio of reactants. The results are give in Table 2.

Figure 1 compares the catalytic activities of Nafion-H, triflic acid, CER, 98% sulfuric acid, and zirconia. Equal weights of all the catalysts were employed in these experiments. Triflic acid exhibited highest activity while sulfuric acid showed lowest activity. The product was deeply colored when these two homogeneous acids were used. The three solid acid catalysts showed comparable activity. Repetitive experiments were carried out to investigate the reusability of these catalysts. No change of activity could be observed after two recycles.

Alkylation of Phenol with Propylene Tetramer. Alkylation of phenol with propylene tetramer was observed to be considerably slower than that with 1-dodecene and hence much higher loading of the catalysts had to be employed. The tetramer has branched skeletal structure and the double bond is located anywhere in the skeleton. This probably results in steric hindrance in the reaction between the tetramer and phenol. Table 3 shows the progress of the reaction at different temperatures. The data were fitted to a simple second-order kinetic expression. The variation of the rate constants with temperature gave an activation energy of 8.0 kcal mol^{-1}.

The activity of different catalysts is compared in Fig.

Table 3. Alkylation of Phenol by Propylene Tetramer: Effect of Temperature on Activity

Time	% Conversion of propylene tetramer at temp			
min	100 °C	115 °C	130 °C	145 °C
15	8	19	27	30
30	20	25	48	50
60	32	41	60	67
90	43	52	70	78
120	48	61	78	80

Mole ratio: phenol, propylene tetramer=1.5: 1. Loading of zirconia: 15% (w/w) of phenol.

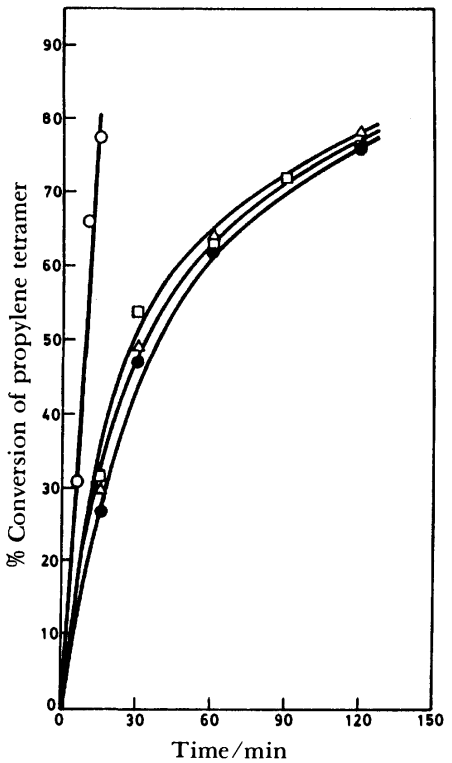

Fig. 2. Alkylation of phenol with propylene tetramer. Comparison of activity of different catalysts. Mole ratio of phenol: propylene tetramer, 1.5:1, 130°C. Catalyst [%(w/w) of phenol]: ● Zirconia [15%], □ Nafion-H [15%], ○ triflic acid [2.5%], △ CER [15%].

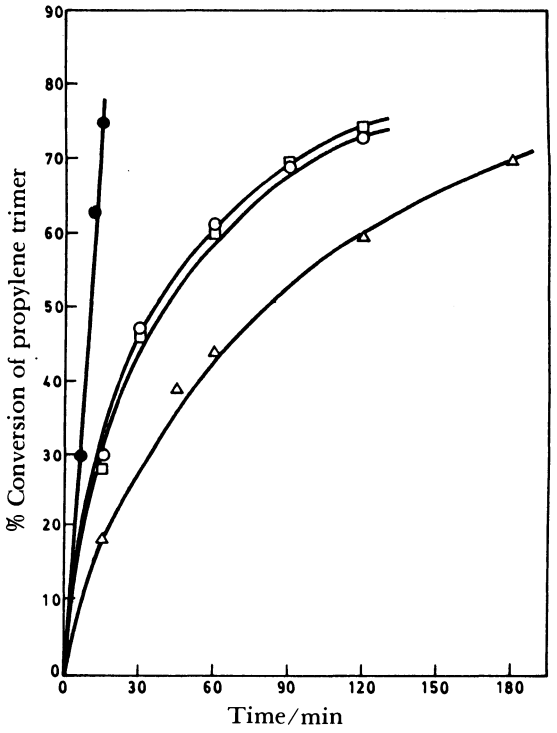

Fig. 3. Alkylation of phenol with propylene trimer. Comparison of activity of different catalysts. Molar ratio of phenol: propylene trimer 1.5:1, 130°C. Catalyst [%(w/w) of phenol]: △ Zirconia [20%], ○ Nafion-H [20%], ● triflic acid [2.5%], □ CER [20%].

2. The order of activity for the different catalysts is similar to that observed in alkylation with 1-dodecene.

Alkylation of Phenol with Propylene Trimer. The reaction was observed to be slower than that in the case of propylene tetramer. Comparable conversions were obtained at 20% [(w/w) of phenol] loading of zirconia and hence subsequent experiments were carried out at this loading. In the temperature range of 100—130 °C, the activation energy was found to be 10.3 kcal mol^{-1}.

The comparison of the activities of the different catalysts is shown in Fig. 3. Once again the order of activity is similar to that observed with the previous systems. Among the solid acid catalysts, zirconia showed somewhat lower activity than Nafion-H and CER.

Conclusion

Triflic acid exhibits the highest activity for the reactions, however, its use always results in deeply colored products and hence this catalyst appears unsuitable for practical use. Nafion-H is considerably more expensive as compared to CER and zirconia and exhibits similar activity. The zirconia catalyst, on the other hand, can be relatively inexpensive as compared to the polymer resin catalyst and at the same time has higher thermal and structural stability. Thus the present work demonstrates the promise of this novel catalyst for an industrially useful class of reactions.

One of us (DDC) wishes to thank CSIR, New Delhi, for the award of a Senior Research Feffowship.

†Instituto Nacional del Carbón y sus Derivados, C. S. I. C., Apartado 73, 33080 Oviedo, Spain
(Received December 25, 1986)

Oxidation of propene on a $Mo_4Pr_{0.5}Bi_{0.5}O_x/SiO_2$ catalyst was studied in order to establish the reaction network. In the temperature range 598—653 K the primary reaction products were propenal (main product), acetone, acetaldehyde, and carbon dioxide. Other products (mainly aldehydes and acids) could be classified as secondary reaction products. From studies of oxidation of the primary unstable products and the kinetics of formation of minor primary products it is concluded that both, acetaldehyde and carbon dioxide, are formed through parallel and consecutive reactions. Acetone formation is strongly influenced by reaction temperature, probably due to changes in the active centers of the catalyst.

Catalytic oxidation of olefins gives rise to a large number of products, and only a close control of catalyst characteristics and/or operation conditions may selectively favor a given type of reaction: allylic oxidation, oxyhydration, or scission reactions.[1,2]

A limited amount of published work has dealt with establishment of the overall reaction network in olefin selective oxidation processes. For allylic oxidation of propene only propenal and carbon oxides formation pathways have generally been taken into account.[3-5] However, many other products are usually originated in this process through parallel and/or consecutive reactions. For different catalytic systems, various authors[6-8] have proposed that propenal forms directly form propene while acetaldehyde and carbon oxides are formed through both, parallel and consecutive reactions; the origin of acetaldehyde and carbon oxides is not clear. Margolis[9] proposed that acetaldehyde forms directly by oxidation of the double bond, while Keulks et al.[10] suggested that acetaldehyde comes almost exclusively from propenal oxidation. In the case of CO_2, the situation is much more complicated since, depending on the catalyst used, parallel-consecutive pathways by propene and propenal oxidation,[11] as well as only consecutive reactions from propenal[9,10] have been proposed.

In a previous work, the kinetics of propene and isobutene oxidation at 653 K were studied on a (Mo-Pr-Bi)O/SiO_2 catalyst. It was deduced that similar mechanisms operate for both reactants,[12] and that propenal is formed from propene through a redox mechanism.[13] The aim of the present work is to establish the reaction network for propene oxidation on the same catalyst, from analysis of: i) Products distribution; ii) oxidation of primary reaction products; iii) influence of operation conditions on formation of minor primary products; and iv) kinetics of formation of minor primary products.

Experimental

Catalyst Preparation and Characterization. The catalyst was prepared by sequential impregnation of BASF D-11-11 silica particles. Impregnations were carried out respectively with an aqueous solution of $(NH_4)_6Mo_7O_{24}\cdot 4\,H_2O$ (Merck, p.a.) and with an acid solution of $Bi(NO_3)_3$ (Koch Light) and $Pr(NO_3)_3\cdot 5\,H_2O$ (Fluka, a.g.). The final calcination was carried out at 823 K for 16 h.[13]

The atomic ratio in the oxide catalyst was Mo:Pr:Bi=4:0.5:0.5, with a concentration of MoO_3 of 20 wt%. The BET surface area was 55.6 $m^2\,g^{-1}$ the pore volume being 1.31 $cm^3\,g^{-1}$ and the mean pore radius 40 nm. X-Ray diffraction showed the presence of three crystalline phases: MoO_3, α-Bi_2O_3, and Bi_2MoO_6. By means of Analytical Electron Microscopy the presence of highly dispersed praseodimium on the catalyst surface was observed.

Methods. The flow system and calculations used for catalytic activity and selectivity determination have been described previously.[14] Catalyst samples with a particle size of 0.042—0.059 cm, in amounts from 0.2 to 0.8 g, were diluted with carborundum (0.059 cm particle size) in order to keep a constant catalytic bed volume (5.6 cm^3). Blank tests were carried out with a reaction mixture of molar composition $C_3H_6:O_2:He:H_2O$=20:30:30:20. In the absence of catalyst, total conversion at 673 K was lower than 0.3% (molar). No diffusion effects on reaction rate were found at 653 K for propene flows greater than 1.1×10^{-2} mol h^{-1} and catalyst particle sizes lower than 0.141 cm. Prior to each experiment, the catalyst was placed in the reactor and heated to 573 K in a helium stream. Then, the reaction mixture was introduced while heating until reaching the reaction temperature. The system was left to reach stead-state conditions for 1.5 h before analyzing the reaction products. Duplicated experiments showed the constancy of catalytic activity with time.

Results

Nature and Stability of Products. In Fig. 1 the influence of contact time, W/F (g cat. h mol^{-1} C_3H_6) on total propene conversion at different temperatures (593—653 K) for a mixture containing a molar ratio $C_3H_6:O_2:He:H_2O$=20:30:30:20 is shown. From yields to the different products selectivity curves, as proposed by Corma et al.,[15,16] were obtained. The plots corresponding to a temperature of 653 K are given in Fig. 2 (qualitatively similar results were

obtained at the other temperatures studied).

We detected a number of products in propene oxidation on our catalyst. They originate either from partial oxidation, partial degradation or total oxidation reactions. From the shape of selectivity curves one can establish the nature and stability of the different products.[15] It can be deduced from plots in Fig. 2 that propenal, acetone, and acetaldehyde are primary products, while acrylic acid, acetic acid, formic acid, and ethylene are secondary products. In the case of CO and CO_2 it is not possible from Fig. 2 to differentiate clearly if they are either primary or secondary products.

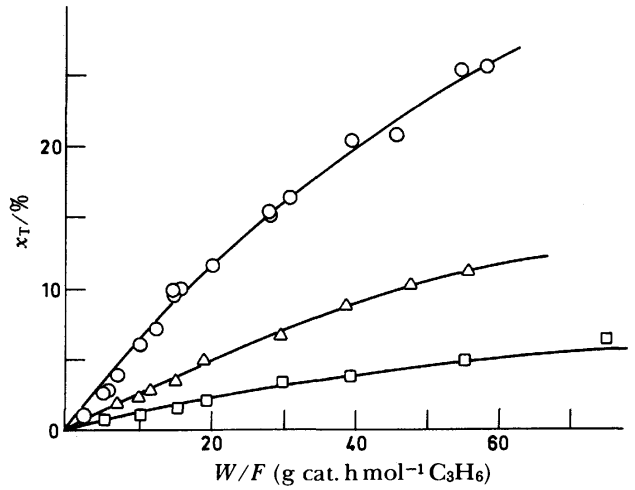

Fig. 1. Effect of contact time, W/F, on total conversion at 593 K (○), 623 K (△), and 653 K (□). Molar composition of the reaction mixture: 20% propene, 30% oxygen, 30% helium, and 20% water.

From plots of selectivity to each product (S_i) vs. total conversion (Fig. 3) it can be observed that selectivities decrease with increasing total conversion in the case of propenal, acetone, and acetaldehyde, thus clearly showing that these products are unstable. In the case of CO and CO_2 it is deduced that, while CO_2 is a primary+secondary product (with a selectivity of 6% at $x_T \rightarrow 0$), CO is merely a secondary product (selectivity at $x_T \rightarrow 0$ equal to zero or very small). On the other hand, at lower temperatures and/or for propene-poor reaction mixtures, the presence of CO was not detected at total conversions lower than 5%.

In the case of acetic acid, formic acid, and ethylene, selectivities initially increase with total conversion and afterwards remain constant or diminish. This shows

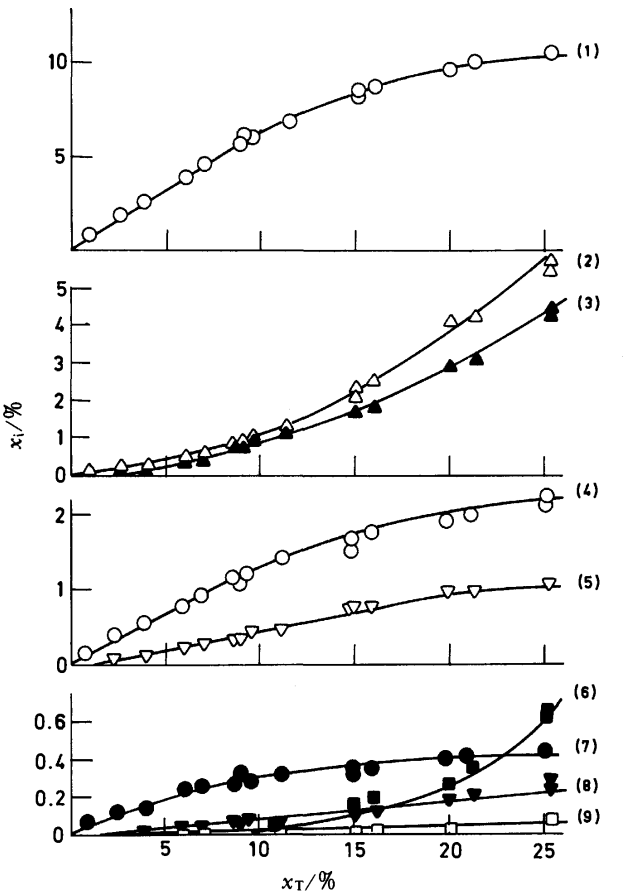

Fig. 2. Variation of yields to the different reaction products of propene oxidation with total conversion at 653 K. Same reaction conditions as for Fig. 1. (1), propenal; (2), CO_2; (3), CO; (4), acetaldehyde; (5), acetic acid; (6), acrylic acid; (7), acetone; (8), formic acid; (9), ethylene.

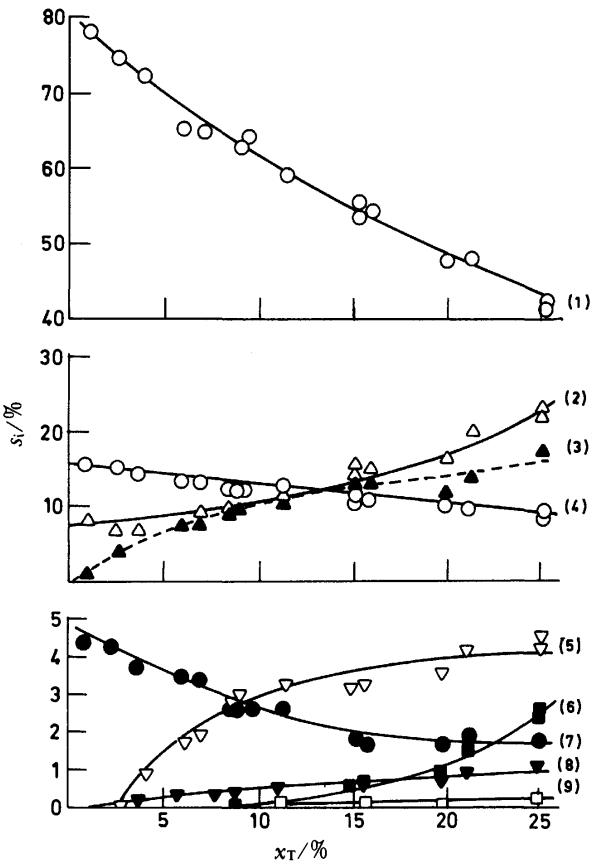

Fig. 3. Variation of selectivities to the different reaction products of propene oxidation with total conversion at 653 K. Same reaction conditions and symbols as for Fig. 2.

the stable character of these products. The very low yield of acrylic acid make it difficult to evaluate the stability of this product, especially at high temperatures and/or high conversions.

Oxidation of Primary Products. Experiments to study oxidation of unstable primary products were carried out in reaction conditions similar to those used for propene oxidation, i.e. at 653 K and molar ratio reactant: O_2 : He : H_2O=20 : 30 : 30 : 20.

In propenal and acetaldehyde oxidations it was observed that homogeneous reaction takes place in a large extent, it being thus impossible to carry out a quantitative study on the nature and type of reaction products. However, the remarkable differences between homogeneous and catalytic reaction permit to make a qualitative study. The results obtained for both, propenal and acetaldehyde, are shown in Table 1.

Propenal: In homogeneous oxidation of propenal, CO appears as the main reaction product. The other products (in a decreasing selectivity order) are CO_2, acetic acid, ethylene, formic acid, acetaldehyde, and small amounts of acrylic acid. However, a significant increase in selectivity to acrylic acid and acetaldehyde is observed for the catalytic reaction in addition to a moderate increase for acetic acid and CO_2 and an important decrease in CO production. Consequently, it seems that propenal oxidation leads preferentially to formation of acrylic acid as well as degradation products: acetaldehyde, acetic acid, CO, and CO_2.

Acetaldehyde: In homogeneous oxidation of acetaldehyde, carbon oxides, and formic acid predominates as reaction products while an increase of CO_2, acetic acid, ethylene, methane, and formaldehyde formation and a decrease of formic acid and CO production are observed in the catalyzed reaction. In catalytic reaction conditions, oxidation to acetic acid could take place simultaneously with two degradation pathways, the one leading to formaldehyde and methane and the other to total oxidation products.

Acetone: No homogeneous oxidation was detected in the case of acetone. Study of the nature of oxidation products was carried out by varying the contact time, W/F. CO_2, CO, formic acid, and acetaldehyde were the main reaction products in addition to small amounts of butandione, propenal, and ethylene.

In Table 2 the results obtained at 653 K for different contact times are given. From these results it can be concluded that both, CO and CO_2, are primary+secondary stable products; formic acid, acetaldehyde, and acetic acid are primary, unstable products, while ethylene, propenal, and butandione are secondary, unstable products.

Influence of Operation Conditions on Primary Products Formation. For the study of influence of reaction temperature and/or oxygen: propene ratio in the reaction mixture, changes in yield to the different reaction products and in initial selectivities (i.e., selectivities for $x_T \rightarrow 0$) to the primary reaction products were monitored. This study was carried out at temperatures ranging from 593 to 653 K, and oxygen: propene ratios varying from 1.5 to 6. The corresponding results are shown in Table 3.

No changes in nature of the primary reaction products were found. An increase of reaction temperature led to increase of initial selectivity to propenal and to an important decrease of initial selectivities to acetone and CO_2, the decrease being less marked the case of acetaldehyde. On the other hand, increase of oxygen: propene ratio in the reaction mixture caused a decrease of initial selectivities to propenal and acetone, and an increase of selectivities to acetaldehyde and CO_2.

Kinetics of Minor Primary Products Formation. The detailed kinetic analysis of propenal formation

during propene oxidation over the same catalyst used in the present work was carried out previously and published elsewhere.[13] However, the important differences found among the kinetics of formation of the rest of products justified to undertake a more detailed analysis, which was made by the initial rates technique, i.e., at total converisons lower than 7%. Influence of the main operation variables (temperature, contact time, and partial pressure) was examined. For studying the influence of reaction mixture composition, the conventional technique of modifying the concentration of one reactant while keeping constant the concentration of the rest of reactants was used.

Kinetic measurements were carried out in the following ranges: propene partial pressure, 0.047—0.374 atm (with oxygen partial pressure constant and equal to 0.280 atm); oxygen partial pressure, 0.065—0.470 atm (with propene partial pressure constant and equal to 0.190 atm); reaction temperature, 593—653 K. In all cases a constant water partial pressure of 0.190 atm was kept, as well as a helium partial pressure balance to 1 atm.

For the study of dependence of the rates of formation of the different reaction products on composition of the reaction mixture an empirical rate equation was used:

$$\ln r_i = \ln k_i + a \ln p_H + b \ln p_O, \quad (1)$$

where k_i is the rate constant for formation of product i, and a and b are the apparent reaction orders for propene and oxygen, respectively. From plots of ln r_i vs. ln p_H or ln p_O (p_H and p_O being the partial pressures of propene and oxygen, respectively), straight lines were obtained whose slopes gave the apparent reaction order for a given reactant (Table 4).

In the cases of acetaldehyde and CO_2 and at temperatures of 593 and 623 K two different reaction orders for propene were found: at pressures lower than 0.19 atm the apparent order was greater than unity, while it was lower than 1 at pressures greater than 0.19 atm. This kind of behavior was not observed in the case of oxygen.

Values of k_i were determined by linear fitting of experimental and calculated rate values for the different products at 593, 623, and 653 K; they are given with their 95% confidence intervals (in parenthesis) in Table 4. In the case of acetaldehyde and CO_2 the values reported were determined at reaction temperatures of 593 and 623 K from results obtained at propene partial pressures lower than 0.19 atm, while at 653 K results correspond to the whole partial pressure range (0.047—0.374 atm). Finally, from plots of ln k_i vs. $1/T$, apparent activation energies for each product were calculated. Their values are given in Table 5.

Discussion

Reaction Network. From the results of selectivity curves (Figs. 2 and 3), a first scheme can be drawn for propene oxidation:

propene → propenal + acetone + acetaldehyde + CO_2.

Primary products containing three carbon atoms (propenal and actone) are both unstable. Therefore, increase of temperature influences unequally selectivities to these products (Table 3). Propenal is usually

obtained at temperatures above 523 K, while acetone forms below this temperature.[1] This effect of reaction temperature on selectivities probably depends on the different ways of oxygen incorporation to the catalyst surface. In a previous study carried out in this laboratory, oxygen adsorption experiments were carried out on the same catalyst used in the present work in the temperature range corresponding to the catalytic reaction.[13] The oxygen adsorption isobar exibited an ascending branch; for example, oxygen coverages at 25 mmHg (1 mmHg=133.322Pa) increased from 0.05% (572 K) to 1.39% (621 K). This increase of oxygen adsorption with temperature is probably associated with the appearance of dissociative adsorption.

If both, oxyhydration and allylic oxidation reactions are competitive, selectivities to acetone or propenal will depend on the relative formation rates of these products.[17] The reactivity of either adsorbed species or oxygen ions present in the catalyst will monotonically increase with reaction temperature. Consequently, as reaction temperature increases, a change in the nature of reactive centers and, hence, in the reaction mechanism will take place.[18,19]

From results of studying catalytic oxidation of propenal, secondary reactions may be summarized as follows:

$$\text{propenal} \rightarrow \text{acrylic acid} + \text{acetic acid} + \text{acetaldehyde} + CO_2 + CO.$$

Margolis[9] proposed that propenal oxidation leads preferentially to formaldehyde and carbon oxides. Cathala and Germain[6] found carbon oxides and acetaldehyde when this reaction was carried out on Mo-Bi-O catalysts. Indeed, reactions of propene methatesis are well characterized on MoO_3/SiO_2 catalysts working at high temperature, ethylene being formed.[20] The auto-oxidation processes proposed by Semenov[21] may explain formation of the different products. Finally, it is clear that acetic acid proceeds from propenal consecutively.

Catalytic oxidation of acetone leads to the following products:

$$\text{acetone} \rightarrow \text{acetic acid} + \text{acetaldehyde} + \text{formaldehyde} + CO + CO_2.$$

Acetone forms by propene oxidation; however, 2-propanol was not detected, contrary to reports of some authors[22,23] concerning both, propene and acetone oxidation. This absence of 2-propanol may be due either to a small yield to acetone in propene oxidation, and/or to a rapid conversion of this alcohol into ketone.[22,24]

Acetaldehyde is a primary product (from propene degradation), but it also forms by decomposition of C_3-oxygenated products. Different possible pathways have been suggested for acetaldehyde formation, either from propene via allylic intermediate,[9] or by double-bond break[25] and/or by propenal oxidation.[6,26] In catalytic oxidation of acetaldehyde:

$$\text{acetaldehyde} \rightarrow \text{acetic acid} + \text{formic acid} + CO + CO_2,$$

carbon oxides formation seems to be the main reaction pathway, and takes place through decomposition of the different secondary products.[6,27]

In summary, carbon oxides seem to be the only stable reaction products. However, while CO_2 is a primary+secondary product, CO is merely a secondary product (Fig. 3). On the other hand, the possibility that at higher temperatures CO may be produced directly from propene cannot be discarded. In any case, CO production at high temperatures by consecutive reaction is higher than that of CO_2; this fact could explain why, at high conversions, the amount of CO produced is higher than that of CO_2.

Concerning the main secondary reaction products, formation of acrylic acid may be ralated to propenal oxidation on the catalyst surface; this is in agreement with IR spectroscopic studies of propenal adsorption on different catalysts.[28] Acetic acid comes from oxidation of primary products,[23,24] but the most favorable route is acetaldehyde oxidation. Finally, the presence of large amounts of acetic acid can be explained as due to consecutive oxidation of acetaldehyde.

From the above consideration, the overall reaction network given in Fig. 4 is proposed. Formation of ethylene and methane was not taken into account in this scheme because these products appeared in very minor concentrations. Formation of these products seems to take place through a pathway very different from those observed for the rest of reaction products. Their appearance could be explained on the basis of auto-oxidation processes of propenal and acetaldehyde, respectively.[6,10,21]

Kinetic Results. In a previous work[13] the activation energy for propenal formation from propene oxi-

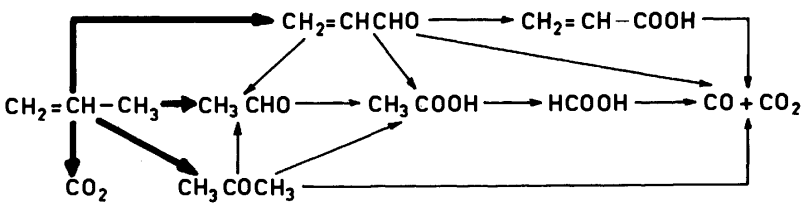

Fig. 4. Simplified reaction network for the oxidation of propene on $Mo_4Pr_{0.5}Bi_{0.5}O_x/SiO_2$ catalyst. ➡, primary reactions; →, secondary reactions.

dation over the $Mo_4Pr_{0.5}Bi_{0.5}O_x/SiO_2$ catalyst was determined, its value being similar to that one obtained for USb_3O_{10}[5] but much lower than that one reported for bismuth molybdate.[29]

An important feature is the low activation energy (1.7 kJ mol^{-1}) found for acetone formation, in contrast to values obtained for the rest of products. This can be interpreted as due to a decrease of the number of active centers present in catalyst surface with increasing temperatures. Moreover, increase of reaction temperature favorises acetone elimination via secondary reactions. The poor fit obtained for the influence of temperature on the rate constant, for acetone formation is due to the combined effect of these two phenomena.

Apparent reaction orders for acetaldehyde and CO_2 formation were strongly dependent on the hydrocarbon partial pressure; only at a temperature of 653 K constant values were obtained for the apparent reaction orders along the whole propene partial pressure range, their values being 1.26 for acetaldehyde and 1.41 for CO_2. It is rather unusual to obtain values for reaction orders greater than unity; however, such values have been previously reported in both, acetaldehyde[7] and carbon oxides[4,30] formation. This fact could be explained by simultaneous presence of both, consecutive and parallel pathways in propene degradation. However, this fact alone cannot explain the effect observed if a value of 1 is considered for the reaction order corresponding to both pathways.

It seems logical to conclude that acetaldehyde and CO_2 formation on our catalyst follow similar pathways, namely both, consecutive reaction (from primary products), and parallel reaction (from propene). Consequently, a complex kinetic equation results taking into account these two different pathways. On the other hand, the similarity of values obtained for activation energies for acetaldehyde and CO_2 formation (69.4 and 78.6 kJ mol^{-1}, respectively) is a further evidence for the similarity of these phenomena.

Finally, it seems convenient to recall some characterization results in order to compare our catalyst with the well-known bismuth molybdate catalyst. The $Mo_4Pr_{0.5}Bi_{0.5}O_x$ catalyst shows a high selectivity for propene oxidation to propenal[13] (redox mechanism) but a low selectivity for 2-methyl propene oxidiation to 2-methyl propenal[31,32] (competitive redox and stationary state of adsorption mechanism). The most active and selective binary Mo-Pr oxide catalysts (i.e., those with Mo/Pr=4—6.7) for propene oxidation contain Pr_2O_3 instead of Pr_6O_{11}, as well as a highly dispersed MoO_3 phase.[33] For a Mo/Pr ratio equal to 4, the most active and selective ternary Mo-Pr-Bi catalysts (those with Mo/Bi=13.3) show the highest surface acidity in this series.[34] The increase of selectivity is ascribable to the well-known ability of bismuth to active propene in the form of allylic species.[35] On the other hand, ESR studies on Mo-Pr-Bi/SiO_2 catalysts, indicate that the presence of Pr in the Mo/Bi catalysts increase the dispersion of bismuth molybdates.[36] Additional work is in progress in our laboratories in order to get some further insight on the role of praseodimium in selective oxidation catalysts.

Synthesis of [5$_2$](1,2)Ferrocenophane

Masao HISATOME,* Rin-ichi YAMASHITA, Jun WATANABE, and Koji YAMAKAWA
Faculty of Pharmaceutical Sciences, Science University of Tokyo, 12 Ichigaya-Funagawara, Shinjuku-ku, Tokyo 162
(Received October 31, 1987)

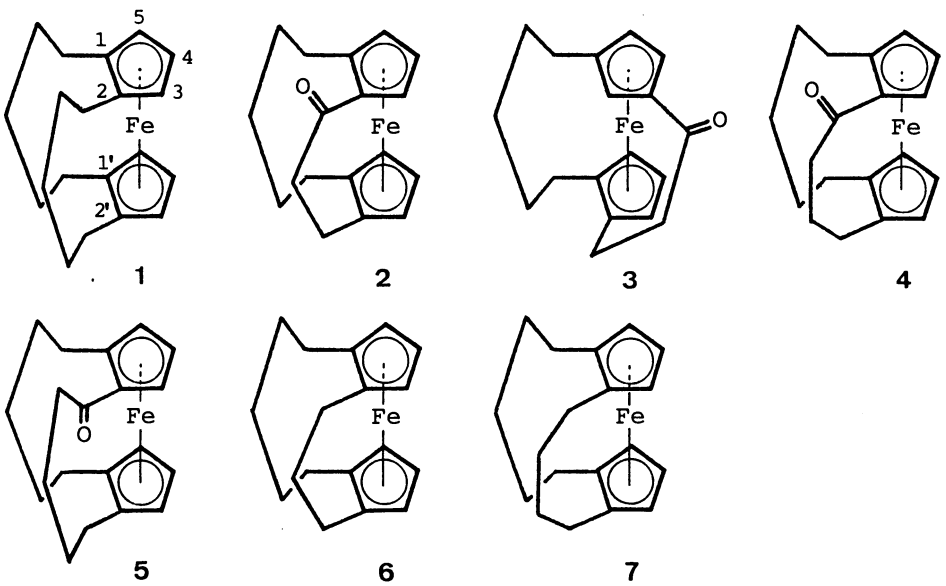
Synopsis. The title compound **1** has been synthesized via bridge enlargement of compound **2** which was formed by cyclization of [5]ferrocenophane-2-propionic acid. By this study the structure of **2**, which was discrepantly described by two groups, has been established as [5]-α-oxo[3](1,2)ferrocenophane.

In the previous papers,[1,2] we reported on the synthesis of [5$_2$](1,3)-, [5$_3$](1,2,4)-, and [5$_4$](1,2,3,4)ferrocenophanes[3,4] multi-bridged with pentamethylene chains. However, [5$_2$](1,2)ferrocenophane (**1**) bridged with two chains at the neighboring positions each other has not yet been synthesized. The compound **1** might be derived from [5]-α-oxo[3](1,2)ferrocenophane (**2**) by application of a general method that we developed for insertion of two methylene units into the trimethylene bridge of ferrocenophanes.[1,2]

Brown and Winstead[5] described that the compound **A** (77%, mp 156—158 °C) given in the cyclization of [5]ferrocenophane-2-propionic acid was phane **2**, but Struchkov et al.[6] claimed for the structure of the compound **A** to be revised. They obtained a dibridged compound **B** (2.5%, mp 149—151 °C) as a by-product in the reaction of [5]ferrocenophane with acryloyl chloride and $AlCl_3$, and assigned the compound **B** to [5](1,1′)-α-oxo[3](3,2′)ferrocenophane (**3**), a slantwise dibridged ferrocenophane. They mentioned that Brown's compound **A** was phane **3**, because **B** was almost identical with **A** in melting point and spectral data. Both groups described the chemical shift values of the cyclopentadienyl (Cp) ring proton signals in ^{1}H NMR spectra but not the multiplicities and coupling constants of the signals. Accordingly, the proper structure of **A** or **B** cannot be judged only by their descriptions.

In the first place, we reinvestigated the reaction reported by Brown and Winstead in order to solve the discrepancy between the descriptions of the two groups. [5]Ferrocenophane-2-propionic acid was treated with trifluoroacetic anhydride in dichloromethane to give two products **2** (75%, mp 163—163.5 °C) and **3** (6.3%, mp 75—78 °C) which both showed the molecular ion peak at m/z 308 in the mass spectra. The melting point of **2** is close to those of compounds **A** and **B**, and the chemical shift values of **2** are also almost similar to the data of **A** and **B**. Accordingly, the phane **2** definitely corresponds to **A** and **B**. In the ^{1}H NMR spectra, the two triplet signals of the Cp ring protons of **2** at δ 4.24 and 4.38 are split by 2.4 and 2.6 Hz, respectively, whereas two triplets of **3** at δ 4.08 and 4.78 have the coupling constants of 2.4 and 1.4 Hz. The usual ortho and meta coupling constants in multibridged ferrocenophanes are 2.0—3.1 and 1.0—1.6 Hz, respectively.[1,2,7,8] Therefore, the three protons appearing as triplet with a larger coupling constant have hydrogens at two ortho positions in the Cp rings, and only one proton of **3** has hydrogens at two meta positions. The spectra indicate that compound **2** have a symmetrically bridged structure at 1,2-positions and **3** is a slantwise bridged ferrocenophane.

Bridge enlargement of **2** with diazomethane and BF_3 etherate according to the method used in the synthesis of multibridged [5$_n$]ferrocenophanes[1,2] afforded two enlarged ketones **4** and **5**. The mass spectra of **4** and **5** indicated that they were produced by insertion of one and two units of methylene group, respectively. Reduction of **5** with $LiAlH_4$ and $AlCl_3$ afforded compound **1**. The C_{2v} symmetric structure of **1** was deter-



1 2 3 4

5 6 7

mined by NMR spectrometry. The Cp ring protons of **1** appear as only two signals at δ 3.93(d) and 4.18(t). The ^{13}C NMR spectrum of **1** shows a simple pattern which consists of only three methylene carbon and three ring carbon signals.

The NMR spectra of **6** and **7** obtained by reduction of **2** and **4**, respectively, indicate their C_s symmetric structure. The melting point (153—153.5 °C) and the chemical shift values of the Cp ring protons of **6** are almost similar to those of reduction product (mp 153—154 °C[5]) of compound **A**. Therefore, it has been confirmed that the description by Brown and Winstead was correct.

Experimental

All melting points were uncorrected. Spectra were measured on the same instruments as those used in the synthesis of [5$_4$]ferrocenophane.[2] All reactions were carried out according to the procedures described in the previous reports.[1,2]

Bridging Reaction of [5]Ferrocenophane-2-propionic Acid (8). The starting material **8** was prepared by condensation of 2-formyl[5]ferrocenophane[1] with malonic acid and piperidine in pyridine followed by hydrogenation with H_2/Pd-C in acetone. The acid **8** (260 mg) was treated with trifluoroacetic anhydride (550 mg) in dichloromethane (20 ml). The crude product was column-chromatographed over silica gel with benzene. The first band yielded [5]-α-oxo[3](1,2)ferrocenophane (**2**) (177 mg, 75%), which was recrystallized from ethyl acetate to give orange rodlike crystals; mp 163—163.5 °C (lit, mp 156—158 °C,[5] 149—151 °C[6]). IR (KBr) 1665 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.30—3.50 (14H, m, -CH_2-), 3.70 (1H, dd, J=1.4 and 2.4 Hz, 3'- or 5'-H), 4.04 (1H, dd, J=1.4 and 2.6 Hz, 3- or 5-H), 4.24 (1H, t, J=2.4 Hz, 4'-H), 4.38 (1H, t, J=2.6 Hz, 4-H), 4.54 (1H, dd, J=1.4 and 2.4 Hz, 3'- or 5'-H), 4.78 (1H, dd, J=1.4 and 2.6 Hz, 3- or 5-H); MS m/z (rel intensity) 308 (100, M$^+$).

The second band yielded [5](1,1')-α-oxo[3](3,2')ferrocenophane (**3**) (15 mg, 6.3%), which was recrystallized from ethyl acetate to give orange prisms; mp 75—78 °C. IR(KBr) 1650 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.50—3.80 (14H, m, -CH_2-), 3.94 (1H, dd, J=1.5 and 2.4 Hz, 3'- or 5'-H), 4.08 (1H, t, J=2.4 Hz, 4'-H), 4.16 (1H, dd, J=1.4 and 2.4 Hz, 5-H), 4.30 (1H, dd, J=1.5 and 2.4 Hz, 3'- or 5'-H), 4.47 (1H, dd, J=1.4 and 2.4 Hz, 4-H), 4.78 (1H, t, J=1.4 Hz, 2-H); MS m/z (rel intensity) 308 (100, M$^+$).

Found: m/z 308.0847. Calcd for $C_{18}H_{20}OFe$: M, 308.0862.

Bridge Enlargement of Ketone 2. Ketone **2** (900 mg) in benzene (150 ml) was allowed to react with alcohol-free diazomethane (50 ml of an ether solution) in the presence of BF_3 etherate (1.0 ml). The crude product was column-chromatographed over silica gel with benzene–ethyl acetate (50:1). The first band yielded [5]-β-oxo[4](1,2)ferrocenophane (yellow crystals, 161 mg, 17%). IR(KBr) 1695 (C=O) cm^{-1}. The β-ketone was contaminated with further enlarged products, and could not be purified.

The second band yielded [5]-α-oxo[5](1,2)ferrocenophane (**5**) (333 mg, 35%), which was recrystallized from ethyl acetate to give red plates; mp 134—135 °C. IR(KBr) 1648 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.30—3.20 (18H, m, -CH_2-), 3.85 (1H, t, J=2.0 Hz, 4'-H), 4.15 (2H, m, Cp-H), 4.27 (1H, t, J=2.0 Hz, 4-H), 4.57 (2H, m, Cp-H); MS m/z (rel intensity) 336 (100, M$^+$), 308 (6), 322 (2).

Found: C, 71.51; H, 7.12; m/z 336.1191. Calcd for $C_{20}H_{24}OFe$: C, 71.44; H, 7.19; M, 336.1175.

The starting material **2** (98 mg, 11%) was yielded from the third band. The fourth band yielded [5]-α-oxo[4](1,2)ferrocenophane (**4**) (216 mg, 23%), which was recrystallized from ethyl acetate to give orange needles; mp 157—158 °C. IR (KBr) 1645 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.20—3.00 (16H, m, -CH_2-), 3.95 (2H, m, Cp-H), 4.15 (1H, t, J=2.5 Hz, 4'-H), 4.27 (1H, t, J=2.0 Hz, 4-H), 4.51 (2H, m, Cp-H); MS m/z (rel intensity) 322 (100, M$^+$), 298 (5).

Found: C, 70.80; H, 6.81; m/z 322.1019. Calcd for $C_{19}H_{22}OFe$: C, 70.82; H, 6.88; M, 322.1018.

[5][3](1,2)Ferrocenophane (6). Ketone **2** (40 mg) was reduced with $LiAlH_4$ (20 mg) and $AlCl_3$ (70 mg) in ether (10 ml). Phane **6** (35 mg, 92%), isolated from the crude product by column chromatography over silica gel with benzene, was recrystallized from hexane to give yellow needles; mp 153—153.5 °C (lit, mp 153—154 °C[5]). ^{1}H NMR ($CDCl_3$) δ=1.20—3.20 (16H, m, -CH_2-), 3.78 (4H, d, J=2.4 Hz, 3,3',5,5'-H), 4.14 (2H, t, J=2.4 Hz, 4,4'-H); ^{13}C NMR ($CDCl_3$) δ=21.10, 21.44, 22.27, 26.46, and 34.65 (methylene-C), 66.58, 68.09, and 69.35 (unsubstd. Cp-C), 83.20 and 85.78 (substd. Cp-C); MS m/z (rel intensity) 294 (100, M$^+$); λ_{max} (THF) 442 nm (ε=221).

[5][4](1,2)Ferrocenophane (7). Ketone **4** (40 mg) was reduced with $LiAlH_4$ (20 mg) and $AlCl_3$ (70 mg) in ether (10 ml). Phane **7** (38 mg, quant.) was isolated by column chromatography over alumina with benzene and recrystallized from ethyl acetate to give yellow needles; 137—138 °C. ^{1}H NMR ($CDCl_3$) δ=1.30—3.00 (18H, m, -CH_2-), 3.82 (2H, dd, J=1.4 and 3.2 Hz, 3,3'-H), 3.97 (2H, dd, J=1.4 and 3.2 Hz, 5,5'-H), 4.04 (2H, t, J=3.2 Hz, 4,4'-H); ^{13}C NMR ($CDCl_3$) δ=22.27, 22.86, 25.39, 26.37, and 26.71 (methylene-C), 65.65, 67.06, and 68.77 (unsubstd. Cp-C), 85.88 and 86.12 (substd. Cp-C); MS m/z (rel intensity) 308 (100, M$^+$); λ_{max} (THF) 444 nm (ε=110).

Found: C, 74.12; H, 7.82; m/z 308.1213. Calcd for $C_{19}H_{24}Fe$: C, 74.40; H, 7.85; M, 308.1225.

[5$_2$](1,2)Ferrocenophane (1). Ketone **5** (39 mg) was reduced with $LiAlH_4$ (18 mg) and $AlCl_3$ (62 mg) in ether (10 ml). Phane **1** (35 mg, 95%) was isolated by column chromatography over alumina with benzene and recrystallized from ethyl acetate to give orange plates; mp 130—132 °C. ^{1}H NMR ($CDCl_3$) δ=1.20—3.00 (20H, m, -CH_2-), 3.93 (4H, d, J=2.4 Hz, 3,3',5,5'-H), 4.18 (2H, t, J=2.4 Hz, 4,4'-H); ^{13}C NMR ($CDCl_3$) δ=22.42, 22.81, and 25.78 (methylene-C), 66.72 and 67.55 (unsubstd. Cp-C), 85.14 (substd. Cp-C); MS m/z (rel intensity) 322 (100, M$^+$); λ_{max} (THF) 446 nm (λ=109).

Found: C, 74.14; H, 8.00; m/z 322.1379. Calcd for $C_{20}H_{26}Fe$: C, 74.54; H, 8.13; M, 322.1382.

^{35}Cl NQR Study and Addition Reactions to Cyclohexene of Cyclic *N*-Chloro Amides (Imides)

Yoshitaka NAGAO* and Shigeyoshi KATAGIRI
Department of Chemistry, Faculty of Science, Hirosaki University, Bunkyo-cho, Hirosaki 036
(Received April 11, 1987)

Synopsis. ^{35}Cl NQR frequencies were measured for *N*-chloro-2-pyrrolidinone, *N*-chloro-4,4-dimethyl-2-oxazolidinone, *N*-chloro-2-oxazolidinone, *N*-chloroglutarimide, and *N*-chlorosuccinimide. The ionicities of the N-Cl bonds were estimated on the basis of those measurements. These ionicities were related to the total yields of the 1,2-addition in the photochemical reaction with cyclohexene. When the value of the ionicity neared zero, the total yield increased.

N-Chloro imides are effective reagents for the chlorination and the oxidation of olefins, alcohols, and carbonyl compounds. Thus, it seems that it would be interesting to investigate the character of the N-Cl bonds in *N*-chloro amides (imides). It is worth while to measure the ^{35}Cl NQR frequencies of *N*-chloro amides (imides), because these frequencies give information on the bond character of N-Cl bonds. If the quadrupole coupling constant is obtained from the observed ^{35}Cl NQR frequency, the bond ionicity may be evaluated. In a previous paper,[2] the ^{35}Cl NQR frequencies for some *N*-chloro imides were observed, and the N-Cl bond ionicities of these compounds were evaluated. The ionicities were related to the reactivities of these compounds. If the value of the ionicity is near zero, the chlorine radical is produced easily and a high yield can be expected in a radical reaction.

In this study, we observed the ^{35}Cl NQR frequencies for the cyclic *N*-chloro amides(imides) shown below and estimated the ionicities of these compounds. The ionicities were then compared with the yields of 1,2-addition in the photochemical reaction of these compounds with cyclohexene.

Experimental

The *N*-chloro amides(imides) were prepared as follows: *N*-Chloro-2-oxazolidinone (**3**) and *N*-chloro-4,4-dimethyl-2-oxazalidinone (**2**) were obtained by the method of Kosugi et at.[4] after the corresponding amides had been prepared by Homeyer's method.[5] The *N*-chloro-3-pyrrolidinone (**1**) was prepared by passing chlorine gas into 2-pyrrolidinone dissolved in water containing sodium hydrogencarbonate.[6] The *N*-chloroglutarimide (**4**) was obtained by the reaction of glutarimide with a bleaching-powder solution[7] after the glutarimide had been prepared by the reaction of glutaric anhydride with aqueous ammonia.[8] These compounds were purified several times by recrystallization.

The NQR spectrometer described by Dean was employed.[9] The signals were modulated by the reference signal from a lock-in amplifier (FM Circuit Design Block Co., Ltd., Model LI-572B) and were displayed on a CRO screen (National, VP-5250). The frequency measurement was made by a method described previously.[2,3] All the measurements were made at the temperature of liquid nitrogen. Glass vessels containing 8—10 g of the samples were used.

Results and Discussion

The ^{35}Cl NQR frequencies of the *N*-chloro compounds at the temperature of liquid nitrogen are given in Table 1. The resonance lines appear in the region from 52.7 to 54.1 MHz. This region lies in the ^{35}Cl NQR frequency range of the N-Cl bond with a tr^1 tr^1 tr^1 π^2 hybridized nitrogen atom proposed by Hart and Whitehead.[1] The resonance frequency of **3** is higher than that of **1**. This difference results from the fact that **3** has an oxygen which is electron-attractive instead of the methylene group in **1**. In the cases of **2** and **3**, the latter has a higher frequency than the former. The presence of methyl groups is responsible for the decrease in the resonance frequency of **2**, for the methyl group is electron-donative. The resonance frequency of **5** is higher than that of **1** because of having another electron-attractive carbonyl group on the ring. Cyclic compounds show an increase in the nuclear quadrupole resonance frequency which rises with an increase in the ring strain.[10] This tendency is observed in the cases of both **4** and **5**.

The pure quadrupole resonance frequency can be expressed as functions of the quadrupole coupling constant, e^2Qq/h, and the asymmetry parameter, η, of the field gradient. These two parameters cannot be determined uniquely from the observed frequencies. However, if it is assumed that $\eta=0$, the coupling constant is equal to twice the resonance frequency for the chlorine atom with a 3/2 nuclear spin. On this assumption, we have calculated the coupling constants given in Table 1. The adequacy of this assumption for the compounds cited in Table 1 is supported by a consideration of the resonance structures, for the most probable main factor leading to the asymmetry of the field gradient in molecules of this type is the π-bond character of the nitrogen-chlorine bond and the axially symmetric charge distribution of σ-electrons does not contribute to the parameter. The calculated quadrupole coupling constants for *N*-chloro compounds are lower than that of the chlorine atom (109.74 MHz for ^{35}Cl). This indicates that the chlorine

Table 1. ^{35}Cl NQR Parameters of *N*-Chloro Compounds at the Temperature of Liquid Nitrogen and the Total Yield of the 1,2-Addition Reaction to Cyclohexene

Compound	ν/MHz	e^2Qq/h	i[a]	Yield/%[d]
N-Chloro-2-pyrrolidinone	51.732	103.46	−0.06	9
N-Chloro-4,4-dimethyl-2-oxazolidinone	52.244	104.49	−0.05	
N-Chloro-2-oxazolidinone	52.805	105.61	−0.04	34
	52.914			
N-Chloroglutarimide	53.096			
	(53.005)[c]	106.01	−0.03	
N-Chloroglutarimide	54.095[b]	108.19	−0.01	54

a) The minus sign indicates that the chlorine atom has a negative fractional charge. b) From Ref. 1. c. 2. c) Averaged values. d) From Ref. 1. c. 12.

atom of the *N*-chloro compound cited in Table 1 has a negative fractional charge. According to Dailey and Townes,[11] $(e^2Qq)_{mol}$ is expressed by:

$$(e^2Qq)_{mol}=(1-i)(e^2Qq)_{atom}$$

where i stands for the bond ionicity and where $(e^2Qq)_{atom}$ denotes the e^2Qq value of the atomic chlorine. In this equation, the contribution from the s character of the bonding orbital of chlorine is assumed to be zero, for the electronegativity of chlorine is practically the same as that of nitrogen. The contribution from the d character is ignored because it is always less than 5% for the chlorine atom. The ionic characteristics of the N-Cl bonds shown in Table 1 were calculated from this relation.

Lessard et al.[12] investigated the total yield of 1,2-addition in the photochemical reaction of cyclic *N*-chloro amides (imides) with cyclohexene. They proposed that 1,2-addition occurs through a radical-chain mechanism as follows:

$$\text{-CO-N-Cl} \xrightarrow{h\nu} \text{-CO-N}\cdot + \text{Cl}\cdot \quad (1)$$

$$\text{-CO-N}\cdot + \text{C=C} \longrightarrow \text{-CO-N-C-C}\cdot \quad (2)$$

$$\text{-CO-N-C-C}\cdot + \text{Cl-N-CO-} \longrightarrow \text{-CO-N-C-C-Cl} + \cdot\text{N-CO-} \quad (3)$$

They also suggested that the total yield of the 1,2-addition reaction increases when the *N*-chloro compound in Reaction 3 is a good chlotine-atom donor. When the *N*-chloro compound is a good chlorine-atom donor, the value of the ionicity of the N-Cl bond should be near zero. Thus, we compared the total yield of the 1,2-addition with the ionicity of the *N*-chloro compound. The total yield for the photochemical addition to cyclohexene is shown in Table 1. *N*-Chlorosuccinimide (**5**) gives rise to the highest yield and has the nearest value to zero for the ionicity. When the value of the ionicity is far from zero, the yield decreases.

Optical Resolution of α-Ethylbenzylamine and Its Application as a Resolving Agent

Hiroyuki NOHIRA,* Misako NOHIRA, Shin-ichi YOSHIDA,
Ayako OSADA, and Daiyo TERUNUMA
Department of Applied Chemistry, Faculty of Engineering, Saitama University, Shimo-ohkubo, Urawa 338
(Received September 8, 1987)

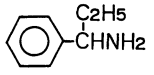
Synopsis. (±)-α-Ethylbenzylamine ((±)-**1**) was efficiently resolved into a pair of enantiomers by fractional crystallization as its *cis*-2-benzamidocyclohexanecarboxylic acid (**2**) salt. Moreover, it was found that each of both enantiomers was obtained by mutual resolution between (±)-**1** and (±)-**2**. The optically active amine (**1**) was substantially capable of resolving a variety of chiral carboxylic acids.

Among the many synthetic resolving agents, optically active α-methylbenzylamine is widely used for resolving chiral carboxylic acids. But the amine is not necessarily an effective resolving agent for all chiral carboxylic acids. Especially, it is not so effective for resolving such chiral carboxylic acids as chrysanthemic acid (**3**)[1] and pantolactone (**4**). We therefore intend to report on the optical resolution and effective application of **1** as a new synthetic resolving agent which can be used widely.

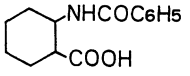
Optically active α-ethylbenzylamine (**1**) is expected to be as effective as α-methylbenzylamine on account of their structural similarity. Although many attempts have been made so far for resolving (±)-**1** by fractional crystallization as the salts with (*S*)-(−)-malic acid and (2*R*, 3*R*)-(+)-tartaric acid,[2] and *N*-acetyl-3,5-dibromo-L-tyrosine,[3] no successful method have been reported since a recrystallization of the diastereomeric salt must be repeated several times. Moreover, optically active amine **1** as a resolving agent remains unexplored.

(±)-**1** is readily synthesized from propiophenone, which is commercially available in large quantities by reductive amination with ammonia and hydrogen in the presence of a Raney nickel catalyst.

After primary examinations looking for a suitable resolving agent for (±)-**1**, it was found that optically active *cis*-2-benzamidocyclohexanecarboxylic acid (**2**)[4] gave almost pure (+)- and (−)-**1** in good yields without any recrystallization.



1

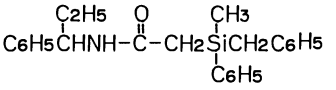


2

In the process of the optical resolution described above, such physical properties as the melting point and solubility, infrared spectra of the less soluble salts ((+)-**1**·(−)-**2** and (−)-**1**·(+)-**2**) and those of the racemic salt ((±)-**1**·(±)-**2**) were determined. The less soluble salts did have higher melting points (mp 190—191 °C) and lower solubilities toward methanol than the racemic salt (mp 156—157 °C), and their infrared spectra were found to be identical. These results indicate that crystals of the racemic salt are deposited as a conglomerate and that the racemic salt is resolvable by preferential crystallization, namely mutual resolution.

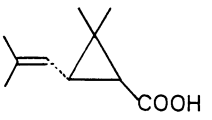
Actually, (+)-**1**·(−)-**2** salt could be cleanly crystallized from a supersaturated solution of (±)-**1**·(±)-**2** salt in methanol when (+)-**1**·(−)-**2** salt was seeded in the solution. Alternate seeding of (−)-**1**·(+)-**2** or (+)-**1**·(−)-**2** salt to the supersaturated solution gave (−)-**1**·(+)-**2** or (+)-**1**·(−)-**2** salt in moderate to high optical purity. Then, crystals having the same sign of optical rotation were combined, recrystallized, and decomposed with an alkaline solution and hydrochloric acid to give optically pure (+)-**1**, (−)-**2** and (−)-**1**, (+)-**2**, respectively.

The optical purities of the resolved amines were determined by measuring the ^{1}H NMR spectra of the diastereoisomeric amides (**5**) derived from (+)-**1** or (−)-**1** and (+)-(benzylmethylphenylsilyl)acetic acid.[5]

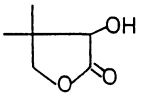


5

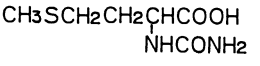
Then, the optically active amine (**1**) was applied in order to resolve such chiral carboxylic acids as chrysanthemic acid (**3**), pantolactone (**4**), and *N*-carbamoylmethionine(**6**), which were not efficiently resolved using α-methylbenzylamine.



3



4



6

As summarized in Table 1, the amine (**1**) have apparently clear advantages for the optical resolution of the above-mentioned chiral carboxylic acids.

Experimental

All melting points were measured by a Laboratory Devices MEL-TEMP apparatus and are uncorrected. Optical rotations were measured on a JASCO DIP-360 Digital Polarime-

Table 1. Resolution of Racemic Carboxylic Acids Using (+)- or (−)-**1**

Salt					Liberated acid			
	Recrystallization solvent	Mp/°C	$[\alpha]_D$/° a) (°C)			Total yield/%b)	$[\alpha]_D$/° (°C)	Optical purity (%)

a) (*c* 1.0, MeOH). b) Based on half the amount of (±)-carboxylic acid used. c) Based on $[\alpha]_D^{25}$−14.01° (*c* 1.535, EtOH) from Merk Index. d) Based on $[\alpha]_D^{25}$−50.7° (*c* 2.05, H_2O) and $[\alpha]_D^{25}$+50.1° (*c* 2.0, H_2O) from Merk Index. e) Based on $[\alpha]_D^{26}$+17.4° (*c* 1.0, EtOH), optically active *N*-carbamoylmethionine derived from optically pure methionine.

ter. The ^1H NMR spectra were recorded with a JEOL FX-90Q spectrometer. The IR spectra were determined on a JASCO A-302 spectrophotometer.

Fractional Crystallization of 1·2 Salt. A clear solution of (±)-**1** (20.25g, 150 mmol) and (+)-**2** (29.68 g, 120 mmol) in methanol (150 ml) at an elevated temperature was allowed to cool slowly at room temperature and stand overnight. The white precipitates which appeared were collected by filtration to give almost pure (−)-**1**·(+)-**2** salt (20.97 g, 54.8 mmol) without any recrystallization: Mp 187—190 °C: $[\alpha]_D^{26}$+27.4° (*c* 1.00, MeOH).

Found: C, 72.07; H, 7.84; N, 7.30%. Calcd for $C_{23}H_{30}N_2O_3$: C, 72.22; H, 7.90; N, 7.23%.

To the salt was added a 1M NaOH solution (65 ml) in order to decompose the salt. The liberated amine was extracted with ether (2×45 ml), and the ethereal extracts were combined, dried over potassium hydroxide pellets, and concentrated under reduced pressure to give (−)-**1** (7.26 g, 53.7 mmol): $[\alpha]_D^{24}$−6.27° (*c* 1.276, EtOH); optical purity 95% ee.

The plus enriched amine recovered from the mother liquor (12.4 g, 92.2 mmol) was similarly reacted with (−)-**2** (22.80 g, 92.2 mmol) in methanol on heating. Cooling the solution at room temperature gave (+)-**1**·(−)-**2** salt (18.17 g, 47.5 mmol): Mp 187—191 °C ; $[\alpha]_D^{20}$−26.2° (*c* 1.098, MeOH). The similar treatment of the salt gave (+)-**1** (6.16 g, 45.6 mmol): $[\alpha]_D^{8}$+5.98° (*c* 1.00, EtOH); 91% ee.

Preferential Crystallization of (±)-1·(±)-2 Salt. A refluxed clear solution of an equimolar amount of (±)-**1** (3.53 g) and (±)-**2** (6.47 g) in methanol (35 ml) was allowed to cool at about 40 °C, seeded with (−)-**1**·(+)-**2** salt (41 mg, Mp 190—191 °C, $[\alpha]_D^{30}$+28.8° (*c* 1.00, MeOH)) and kept overnight at room temperature. The precipitates which appeared were collected by filtration, washed with a small amount of methanol, and dried over P_2O_5 to give 0.25 g of (−)-**1**·(+)-**2** salt ($[\alpha]_D^{28}$+24.6° (*c* 0.85, MeOH)). Successively, (±)-**1**·(±)-**2** salt (0.30 g) was added to the filtrate and dissolved at an elevated temperature. The solution was similarly cooled, seeded with (+)-**1**·(−)-**2** salt (46 mg, Mp 190—191 °C, $[\alpha]_D^{27}$−28.8° (*c* 1.00, MeOH)) and kept overnight at room temperature to yield 0.29 g of (+)-**1**·(−)-**2** salt ($[\alpha]_D^{26}$−27.1° (*c* 0.96, MeOH)). The process was repeated in a similar manner by supplying about 0.50 g of (±)-**1**·(±)-**2** salt in each run to give 0.30—0.63 g of optically active **1**·**2** salt. From the initial six runs, 1.34 g of (+)-**1**·(−)-**2** salt and 0.93 g of (−)-**1**·(+)-**2** salt were obtained, and recrystallized from methanol to give 0.98 g of (+)-**1**·(−)-**2** salt (Mp 190—191 °C, $[\alpha]_D^{27}$−28.8° (*c* 1.11, MeOH)) and 0.65 g of (−)-**1**·(+)-**2** salt (Mp 189—191 °C, $[\alpha]_D^{27}$+28.2° (*c* 1.00, MeOH)). Decomposition of the salts gave (+)-**1** (0.29 g), (−)-**2** (0.60 g) and (−)-**1** (0.21 g), (+)-**2** (0.40 g) respectively.

(+)-**1**: $[\alpha]_D^{30}$+6.6° (*c* 1.49, EtOH); 100 % ee.

(−)-**2**: Mp 205—207 °C; $[\alpha]_D^{26}$−36.4° (*c* 1.00, EtOH); 100% ee.

(−)-**1**: $[\alpha]_D^{30}$−6.5° (*c* 2.00, EtOH); 98% ee.

(+)-**2**: Mp 202—205 °C; $[\alpha]_D^{31}$+35.6° (*c* 0.86, EtOH); 98% ee.

Resolution of (±)-Pantolactone ((±)-4) with (−)-1 and (+)-1. A solution of 6.50 g (50 mmol) of (±)-**4** in water (25 ml) was treated with sodium hydroxide (2.24 g) and heated to 80—90 °C to hydrolyze the lactone. After cooling the the solution, the pH of the solution was adjusted to 8.5 with 2M HCl (1M=1 mol dm^{-3}). To the solution was added 6.76 g (50 mmol) of (−)-**1**, which was dissolved in 2M HCl (25 ml). The solution was concentrated under reduced pressure and the organic salts were extracted with 2-butanone (MEK) (60 ml). The extract was concentrated (10 ml) and allowed to stand overnight. The white precipitates which appeared were collected by filtration and dried over P_2O_5 to yield the salt (4.27 g, 15.1 mmol) of (+)-2,4-dihydroxy-3,3-dimethylbutyric acid ((+)-**4′**) and (−)-**1**: Mp 123—125 °C; $[\alpha]_D^{21}$+22.2° (*c* 1.00, MeOH).

After treating the salt with 1M NaOH (18 ml), the liberated amine was extracted with ether (2×10 ml). To the aqueous layer was added 2M HCl (10 ml); the solution was then evaporated in vacuo. The residue was then extracted with ether (2×5 ml) and dried over Na_2SO_4; the solvent was evaporated to give (−)-**4** (1.82 g, 14.0 mmol): Mp 84—87 °C; $[\alpha]_D^{25}$−40.7° (*c* 1.00, H_2O); 80.3% ee.

A similar treatment of the plus enriched lactone recovered from the mother liquor with (+)-**1** (4.72 g, 34.9 mmol) gave (−)-**4′**·(+)-**1** salt (4.54 g, 16.0 mmol): Mp 125—127 °C; $[\alpha]_D^{25}$−25.3° (*c* 1.00, MeOH). Decomposition of the salt gave (+)-**4** (1.96 g, 15.1 mmol): Mp 85—88 °C; $[\alpha]_D^{24}$+47.8° (*c* 1.00, H_2O); 95.4% ee.

Results of the resolution of (±)-**3** and (±)-**5** with (+)-**1** are shown in Table 1.

The authors thank Daicel Chemical Industries Ltd. for a gift of racemic α-ethylbenzylamine.

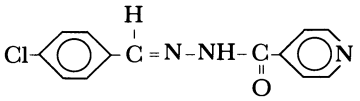
Polarographic and Cyclic Voltammetric Reduction of *p*-Chlorobenzaldehyde Isonicotinoylhydrazone

Papammagari Raveendra REDDY† and Sukuru Brahmaji RAO*
Department of Chemistry, Sri Krishnadevaraya University, Anantapur-515 003, India
†Lecturer in Chemistry, SSBN College, Anantapur-515 001, India
(Received January 8, 1987)

Synopsis. *p*-Chlorobenzaldehyde isonicotinoylhydrazone (*p*-Cl-BAINH) exibits a single wave in acid buffered solutions (pH 2—6) and two waves in alkaline buffered solutions (pH 7—9). However, the compound exhibits three cathodic peaks in acid solution and two cathodic peaks in alkaline solutions. The electrode reactions are attributed to the reductive cleavage of =N-N- linkage and the reduction of the amide formed in the cleavage.

Isonicotinohydrazide derivatives of carbonyl compounds are used extensively as theraptic agents.[1-4] *p*-Chlorobenzaldehyde isonicotinoylhydrazone (*p*-Cl-BAINH) with the following structure



p-Cl-BAINH

is one of such compounds. This compound offers interesting features for electrochemical reduction studies since it possesses more than one reducible sites in its molecule. The authors have therefore undertaken polarographic and cyclic voltammetric studies in solutions of pH 2 to 9. The results are communicated here.

Experimental

p-Cl-BAINH was prepared by refluxing a mixture (1 : 1) of *p*-chlorobenzaldehyde and isonicotinohydrazide for 2 h. The product was purified by repeated recrystallization from hot aqueous ethanol. The compound was characterized by infrared spectral data and melting point (measured value 217 °C, lit, 217—218 °C). All the other chemicals used in the investigations were of analytical reagent grade.

Current-voltage curves were recorded in Britton-Robinson buffers (pH 2—9) with a DC pen recording polarograph (CL 25, ELICO, India). The dropping mercury electrode had the following characteristics: t=3.0 s, m=1.93 mg s^{-1} at a height of 85 cm of mercury column in water under open circuit conditions. Cyclic voltammograms were recorded with a polarographic analyzer (model 174 A, Applied Research Company of Princeton, USA) coupled with an X-Y recorder (model RE 0074) and universal programmer (model 175). Hanging mercury drop electrode (HMDE, Metrohm model 9323), platinum wire electrode and SCE were used as working electrode, counter electrode, and reference electrode respectively. The results are presented in Tables 1 and 2.

Results and Discussion

Electrochemical Reduction in Acid Solutions. *p*-Cl-BAINH exhibits a single polarographic wave in acid solutions (pH 2—6). Semi-logarithemic analysis of the wave reveals that the wave is irreversible. The limiting current varied linearly with the concentration of the hydrazone and with the square root of the mercury column height indicating that the wave is diffusion-controlled. Half-wave potential shifts towards more negative values with increase in pH. This indicates that protons are taking part in the reduction process.

The cyclic voltammogram of the hydrazone shows three cathodic peaks in acid solutions in the forward scan. In the reverse scan, no peak is observed. This indicates the irreversible nature of the electrode process. This is also confirmed by the negative shift in the peak potentials with increasing sweep rates.

The total number of electrons involved in the polarographic process is established experimentally to be 8. On the basis of the three peaks observed in cyclic voltammogram and the number of electrons involved in the single reduction wave noticed and on the basis of the reported behavior in the literature[5] of semicarbazones (compounds bearing structural relationship with the present hydrazone) it is proposed that the single polarographic wave observed is a composite wave representing the reductive cleavage of =N-N-

linkage and the reduction of the imine and the amide formed in the cleavage. The appearance of a single wave suggests that these reduction steps take place at potentials very close to each other. This is clear from the almost same potentials of the peaks in the cyclic voltammogram. Bulk electrolysis and subsequent chemical identification of the products in acid solutions revealed the presence of amine and alcohol. The electrolysis was carried out in solutions of pH 4 at an applied voltage of −1.2 V vs. SCE with mercury pool as cathode. The catholyte after electrolysis was concentrated and extracted with ether. The extract responded to the tests for the primary amine (diazotization and coupling with 2-naphthol) and for the primary alcohol (oxidation and condensation with 2,4-dinitrophenylhydrazine).

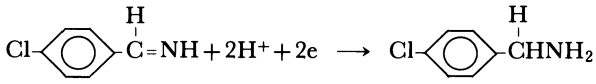
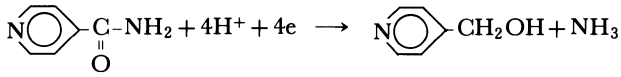
Peak 1

E_2



Peak 2

E_3



Peak 3

$E_1 \approx E_2 \approx E_3$ in acidic solutions
E_1, E_3 in alkaline solutions
(E: Half-wave potential).

Electrochemical Reduction in Alkaline Solutions. *p*-Cl-BAINH exhibits two polarographic waves in alkaline solutions. The effect of mercury column height and concentration on the wave height suggests that the waves are diffusion-controlled. The wave is found irreversible by the semi-logarithemic analysis.

The cyclic voltammogram of the compound exhibits two cathodic peaks in the forward scan. In the reverse scan, no peak is observed. This fact indicates the irreversible nature of the electrode process. This is also confirmed by the negative shift in the peak potentials with increasing sweep rates.

It was reported that semicarbazones undergo reductive cleavage of =N-N- linkage and the imine formed in the cleavage is resistant to further reduction.[6] Imine undergoes reduction only in the protonated form. The absence of imine reduction in alkaline solution can therefore be attributed to the significant decrease in the recombination rate. It was reported that amides undergo reduction to the corresponding alcohols.[7] Bulk electrolysis and subsequent identification reveal the formation of alcohol as well as the aldehyde in alkaline solutions. The aldehyde, formed is attributed to the decomposition of Ar-CH=NH to Ar-CHO in alkaline solution. The two waves appeared therefore indicate the =N-N- cleavage (first wave) and the amide reduction (second wave), respectively. The reduction of the amide being made difficult in alkaline solutions is understood since protonated amide alone is susceptible to reduction. The appearence of two peaks with potentials similar to the half-wave potentials supports the mechanism proposed.

One of the authors (PRR) is thankful to the authorities of Sri Krishnadevaraya University, Anantapur for providing the necessary facilities.

Temperaturabhängigkeit der Fluoreszenz von Gd^{3+} in Wässriger Lösung

Markus BAUMANN
Alvenslebenstr. 20, D-1000 Berlin 30, B. R. D.
(Received December 8, 1986)

Synopsis. The effects of pressure and temperature on the fluorescence of aqueous Gd^{3+} solution have been studied, the following results being obtained: (a) The pressure up to 100 MPa gives no influence on emission. (b) The fluorescence diminishes with temperature rise, nearly disappearing at 200 °C.

Die Temperaturabhängigkeit der Fluoreszenzeigenschaften wässriger Lanthanoidlösungen ist Gegenstand mehrerer Untersuchungen.[1-6] In den Arbeiten sind Unterschiede in der Temperaturabhängigkeit der Fluoreszenz wässriger Lanthanoidlösungen (zum Teil) bis zu 98 °C aufgezeigt und diskutiert. Eine Literaturrecherche in den Chemical Abstracts, Publikationen bis 1985 umfassend, ergab keine Anhaltspunkte, daß der Meßbereich erweitert wurde. Der Grund liegt wahrscheinlich in den bis zu dieser Temperatur apparativ leicht zugänglichen Versuchsbedingungen.

In dieser Arbeit wird untersucht, wie sich die Fluoreszenzemission des Gadoliniumions in heißer wässriger Lösung bei Temperaturen bis zu 200 °C verhält. Für die in-situ-Analytik hydrothermaler (geochemisch relevanter) Lanthanoidlösungen mittels fluorimetrischer Methoden erweist sich die Kenntnis über das Ausmaß des Fluoreszenzquenching, verursacht durch die Temperatur der Lösung, als unerläßlich.

Ergebnisse und Diskussion

In einer Hochdrucksichtzelle wurde bei Temperaturen bis zu 200 °C und einem Druck von 100 MPa die Fluoreszenzemission von wässrigen Gadolinium(III)-Lösungen vermessen. Die Lösungen wurden zunächst mit dem Druck von 100 MPa beaufschlagt und auf Änderungen der Emissionseigenschaften hin untersucht, anschließend bei konstant gehaltenem Druck bis auf 200 °C erhitzt.

Es wurde gefunden, daß ein Druck von 100 MPa ohne Einfluß auf die Fluoreszenzeigenschaften ist. Einzuschränken ist, daß ungünstige optische Bedingungen, durch die Hochdruckanordnung verursacht, es nicht zuließen, Intensitätsänderungen von weniger als 5% als signifikant anzusehen.

Bewirkt eine hohe Druckbelastung keine Beeinträchtigung der Fluoreszenz, so führt jedoch eine Temperaturerhöhung zu einer erheblichen Verminderung der Emission. Bei 100 °C können nur noch 45% des Ausgangswertes unter Normalbedingungen, bei 200 °C 10% der ursprünglichen Intensität gemessen werden (siehe auch Abb. 1).

Eine Aussage über die unterschiedliche Beeinflussung der übergänge $^6P_{5/2}$-$^8S_{7/2}$ (306 nm) und $^6P_{7/2}$-$^8S_{7/2}$ (312 nm) war nicht möglich. Die zur Unterscheidung dieser Banden erforderliche optische Auflösung konnte, wegen der geringen Intensitäten bei höher Temperatur, nicht vorgenommen werden.

Das aufgezeigte Fluoreszenzverhalten des Gadoliniumions unterscheidet sich erheblich von den unter vergleichbaren Bedingungen gemessenen Terbium(III)- und Samarium(III)-Lösungen.[2,8] Bei diesen Lanthanoiden bringt eine Temperaturerhöhung auch bis zu 200 °C keine Verminderung der Fluoreszenz. Diese Untersuchungsergebnisse unterstreichen die Bedeutung des energetischen Abstandes zwischen den beiden ersten Fluoreszenzniveaus der Seltenen Erden für temperaturbedingtes Fluoreszenzquenching.[1-6]

Abschließend sei erwähnt, daß auch ein (für die Analytik oft unvorteilhaftes) Fluoreszenzquenching einer praktischen Nutzung zugeführt werden kann, und zwar in der Verwendung der Temperaturabhängigkeit der Fluoreszenz als Temperatursensor.[9]

Experimentelles

Meßlösungen. Die untersuchten Lösungen waren 0,01 molar an Gd^{3+}, 1 M an NaCl sowie 1 M an HCl (1 M=1 mol dm^{-3}).

Probenbehälter. Während der Messung befand sich die Lösung in einem Probenbehälter bestehend aus den Materialien Saphir und PTFE. Zur Temperatur- und Druckbeaufschlagung wurde diese Probekammer in eine mit Saphirfenstern ausgestattete Hochdrucksichtzelle gestellt. Der Stahlkörper dieses Druckbehälters (ohne Saphirfenster)

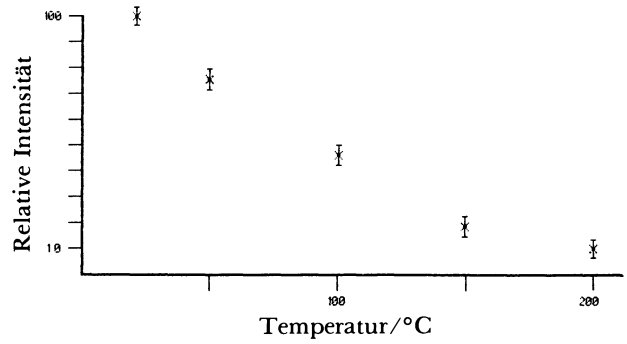

Abb. 1. Fluoreszenintensität in Abhängigkeit von der Temperatur in System: Gd^{3+} 0.01 M, HCl 1 M, NaCl 1 M; Druckbelastung 100 (±3) MPa bei allen Temperaturen.

*Die Durchsicht der Literatur sowie eigene Erfahrungen im Umgang mit heißen wässrigen Lanthanoidlösungen veranlassen dazu anzumerken, daß bei fluorimetrischen Untersuchungen an solchen Lösungen der Bildung von Hydrolyseprodukten vermehrte Beachtung geschenkt werden muß. Ein bei Normaltemperatur sonst unkritischer pH-Wert um 5 führt auch bei wenig erhöhter Temperatur zur teilweisen Hydrolyse des Lanthanoidions, wobei die Fluoreszenzeigenschaften, d.h. Intensität und Lebensdauer der Fluoreszenz der betreffenden Lanthanoidspezies, vergleichsweise zu der des Aqua-Ions, verschlechtert werden können. Neben dem pH-Wert ist auch die Standzeit der Lösung bei der betreffenden Untersuchungstemperatur von Bedeutung.

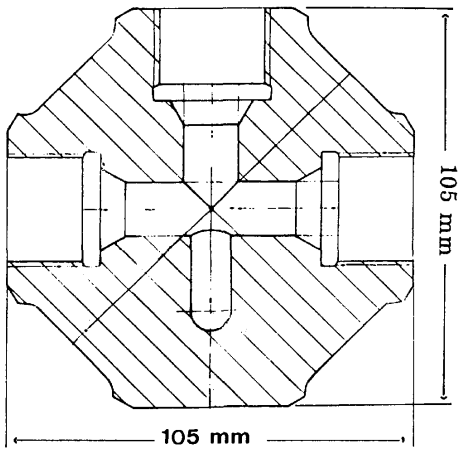

Abb. 2. Autoklavenkörper zur Druck- und Temperaturbeaufschlagung mit den Maßen: 105 mm (Höhe), 70 mm (Breite).

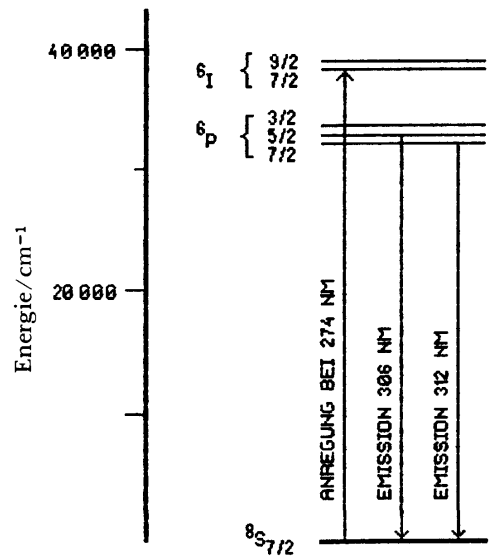

Abb. 3. Partielles Termschema von Gd^{3+}; Energiewerte aus CARNALL et al. (1968).[7]

ist in Abb. 2 widergegeben. In den Stahlkörper sind neben den Öffnungen für die optischen Fenster jeweils noch eine Bohrung zur Druckübertragung und zur Temperaturmessung eingelassen (nicht aus der Zeichnung ersichtlich). Zur Druckerzeugung diente ein Kompressor mit Argon als Druckmedium. Eine geregelte Widerstandsheizung (Heizdrähte in einen dem Stahlkörper angepaßten Kupfermantel eingebettet) sorgte für die Temperierung. Es sei noch angemerkt, daß eine Berechnung der maximalen Druckbelastung bei dem aufgezeigten Zellentyp schwierig ist. Es empfiehlt sich bei sehr hohen Drücken eine zylindrische Form für den Autoklavenkörper zu wähen.

Optische Auswertung. Die optische Verbindung zwischen Sichtzelle und Spektrometer erfolgte mit Quarzlichtleitern, da aus Sicherheitsgründen die Zelle in einem Stahlbehältnis untergebracht war. Die Messung der Fluoreszenzemission erfolgte mit einem Fluoreszenzspektrometer der Fa. SPEX, USA (Modell: Fluorolog II) bei einer Anregungswellenlänge von 274 nm. Zur Auswertung kam die Emission bei 312 nm, siehe auch partielles Termschema des Gd^{3+} in Abb. 3 .

Die vorliegende Arbeit beruht auf experimentellen Ergebnissen des Verfassers während seines Aufenthaltes am Hahn-Meitner-Institut für Kernforschung GmbH, Berlin. Die Hochdrucksichtzelle ist eine Konstruktion von A. Truong, Hahn-Meitner-Institut für Kernforschung GmbH, Berlin.

Halogenation Using Quaternary Ammonium Polyhalides. IX.[1] One-Step Syntheses of Acylureas and Carbamates from Amides by Use of Tetrabutylammonium Tribromide and DBU

Shizuo FUJISAKI, Kazushi TOMIYASU, Akiko NISHIDA, and Shoji KAJIGAESHI*
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
(Received June 15, 1987)

Synopsis. The reaction of amides with tetrabutylammonium tribromide (TBA Br_3) (0.5 equiv) and DBU (one equiv) in dichloromethane at room temperature gave *N*-substituted acylureas in fairly good yields. In the presence of alcohols, the reaction of amides with TBA Br_3 (one equiv) and DBU (two equiv) gave *N*-substituted carbamates.

Tetraalkylammonium polyhalides have recently been reported to act as useful, selective halogenating reagents.[2] In this paper, we wish to report on a one-step synthesis of *N*-substituted acylureas and carbamates from amides by the use of tetrabutylammonium tribromide[2a] (TBA Br_3) in the presence of a base, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU).

Results and Discussion

Recently, it has been noted that acylureas reveal the physiological actitivities of insects. That is, derivatives of *N*-benzoyl-*N'*-phenylurea are known to inhibit a formation of the epidermis of insects during their ecdyses.[3]

Rand et al. have already reported that a treatment of *N*-chlorobenzamide with potassium fluoride gave *N*-benzoyl-*N'*-phenylurea. In this case, they showed that an initial proton abstraction by the fluoride followed by a Hofmann-type rearrangement gave intermadiate phenyl isocyanate; then, the addition of residual *N*-chlorobenzamide to the isocyanate with a subsequent hydrolysis yielded the product.[4]

$$\text{Ph-CONH-Cl} \xrightarrow[\text{benzene}]{\text{KF}} [\text{Ph-N=C=O}] \xrightarrow{\text{PhCONHCl}}$$

$$\text{Ph-NH-CO-N(Cl)-COPh} \xrightarrow{H_2O} \text{PhNHCON(H)-COPh} \quad (1)$$

The reaction of amides with TBA Br_3 (half equiv) and DBU (one equiv) in commercially available dichloromethane (contained a catalytic amount of methanol) gave *N*-substituted acylureas in fairly good yields. In these cases, isocyanates should also be produced as reaction intermadiates. Since the presence of methanol considerably promotes the reaction,[5] it is assumed that the main active species is probably methyl hypobromite produced from the reaction of TBA Br_3 with methanol.[2b] Therefore, the reaction which affords acylureas can be presented in the following equations:

$$(C_4H_9)_4NBr_3 + CH_3OH + DBU \rightarrow CH_3OBr + (C_4H_9)_4N^+Br^- + DBU(HBr), \quad (2)$$

$$\underset{\mathbf{1}}{RCONH_2} + CH_3OBr \rightarrow \underset{\mathbf{2}}{RCONH\text{-}Br} + CH_3OH, \quad (3)$$

$$\mathbf{2} + DBU \rightarrow \underset{\mathbf{3}}{R\text{-}N=C=O} + DBU(HBr), \quad (4)$$

$$\mathbf{3} + \mathbf{2} \rightarrow \underset{\mathbf{4}}{RNHCON(Br)\text{-}COR}, \quad (5)$$

and

$$\mathbf{4} + \mathbf{1} \rightarrow \underset{\mathbf{5}}{RNHCONH\text{-}COR} + \mathbf{2}. \quad (6)$$

Equation 7 can be derived from Eqs. 2—6.

$$2\underset{\mathbf{1}}{RCONH_2} + (C_4H_9)_4NBr_3 + 2DBU \rightarrow \underset{\mathbf{5}}{RNHCONHCOR} + 2DBU(HBr) + (C_4H_9)_4NBr. \quad (7)$$

a) Purified dichloromethane was used. b) Yield of isolated product.

The results are summarized in Table 1.

In the presence of a large excess of alcohols (≫20 equiv), the reaction of amides with TBA Br_3 (one equiv) and DBU (two equiv) in dichloromethane gave carbamates as main products.[6] That is, as shown in the following Eq. 8, intermediary isocyanates react with alcohols to afford carbamates:[7]

$$\underset{\mathbf{3}}{\text{R-N=C=O}} + \underset{\mathbf{6}}{\text{R'-OH}} \rightarrow \underset{\mathbf{7}}{\text{RNH-CO}_2\text{R'}}. \quad (8)$$

Equation 9 can be obtained from Eqs. 2—4 and 8.

$$\underset{\mathbf{1}}{\text{RCONH}_2} + (C_4H_9)_4NBr_3 + \underset{\mathbf{6}}{\text{R'OH}} + 2\text{DBU} \rightarrow \underset{\mathbf{7}}{\text{RNHCO}_2\text{R'}} + (C_4H_9)_4NBr + 2\text{DBU(HBr)}. \quad (9)$$

The results are summarized in Table 2.

These methods would be useful in the preparation of **5** or **7** from the readily available starting materials **1** and TBA Br_3 by one-step under mild conditions.

Experimental

All melting points are uncorrected. The ^{1}H NMR spectra were recorded on a JMN-MH-100 spectrometer with tetramethylsilane as an internal standard. The IR spectra were obtained on a JASCO IRA-1 spectrometer.

***N*-Benzoyl-*N'*-phenylurea (5a). Typical Procedure.** To a solution of benzamide (0.48 g, 4.0 mmol) and TBA Br_3 (1.00 g, 2.07 mmol) in commercially available dichloromethane (contained a catalytic amount of methanol) (20 ml) was added DBU (0.64 g, 4.2 mmol) in dichloromethane (5 ml) at room temperature. After the mixture was stirred for 30 min the solvent was distilled in vacuo. To the residue was added a small amount of ether and water; then the precipitate obtained was filtered and washed with ether and water to give **5a** as colorless crystals; yield 0.33 g (70%); mp 206—207 °C (lit,[3] mp 206—208 °C).

***N*-(2-Nitrobenzoyl)-*N'*-(2-nitrophenyl)urea (5c).** Compound **5c** was prepared similarly: Yield 77%; pale yellow crystals; mp 213—215 °C; IR (KBr) 3210 (ArN-H), 3100 (N-H), 1700 (ArC=O), and 1680 cm^{-1} (C=O); ^{1}H NMR (DMSO-d_6) δ=7.38—8.68 (8H, m, 2Aromatics), and 11.60—12.00 (2H, m, 2NH). Found: C, 50.66; H, 3.25; N, 17.06%. Calcd for $C_{14}H_{10}O_6N_4$: C, 50.91; H, 3.05; N 16.97%.

Methyl Phenylcarbamate (7a). Typical Procedure. To a solution of benzamide (0.61 g, 5.0 mmol) and TBA Br_3 (2.50 g, 5.18 mmol) in dichloromethane (15 ml)-methanol (40 ml, 1 mol) was added DBU (1.70 g, 11.2 mmol) in dichloromethane (5 ml) at room temperature. After the mixture was stirred for 1 h the solvent was distilled in vacuo and the obtained precipitate was extracted with ether. The ether layer was dried with magnesium sulfate and evaporated. A crude product was purified by column chromatography on silica gel (3:1 hexane-benzene) to afford **7a** as colorless crystals; yield 0.49 g (65%); mp 47—48.5 °C (lit,[9] mp 48 °C).

The authors wish to thank Professor Masashi Tashiro, Institute of Advanced Material Study, Kyushu University, for the elemental analyses.

Effects of Aryl Substituents on Electron-Transfer-Mediated Photochemical Addition of Alcohol to 1,1,2-Triarylcyclopropanes

Hideo TOMIOKA* and Osamu INOUE
Department of Industrial Chemistry, Faculty of Engineering, Mie University, Tsu, Mie 514
(Received July 16, 1987)

Synopsis. Direct irradiation of 1,1,2-triarylcyclopropanes in alcohol resulted in the formation of all possible products arising from trimethylene biradicals, while DCB-sensitized irradiation gave a novel "anti-Markownikoff" addition product of alcohol almost exclusively. In order to get insight into the nature and fate of intermediates in the reactions, the effects of nucelophiles and aryl substituents are examined.

Since the early 1980s the scope of cyclopropane photochemistry[1] was greatly broadened through electron transfer sensitized reaction. Among the important features of electron-transfer sensitization are higher reactivity and anomalous but simpler product distributions.[2] Thus, Hixson et al.[3] found that 1,4-dicyanobenzene (DCB)-sensitized photolysis of several phenylcyclopropanes in methanol-acetonitrile resulted in a novel "anti-Markownikoff" addition of methanol to the cyclopropane ring. The reactions are rationalized as proceeding via initial electron transfer from the cyclopropane to the excited DCB to give the cyclopropane cation radicals.

As a part of our program of work on the photochemical generation of ionic intermediates,[4] we became interested in the nature of intermediates that are involved in the electron-transfer-sensitized reaction of cyclopropanes. Thus, we have irradiated several 1,1,2-triarylcyclopropanes in the presence of sensitizers (electron acceptors) in alcohols and examined the effects of nucleophiles and aryl substituents on the product distributions.

Results and Discussion

Irradiation of 1,1,2-triphenylcyclopropane (**1c**) in ethanol-acetonitrile with a light of 300W Hg lamp through quartz was monitored by GC which revealed the gradual disappearance of the starting cyclopropane along with the formation of at least five products. Separation followed by characterization of each components demonstrated that these products are diphenylethoxymethane (**2c**, R=Et), 1,1,3-triphenylpropene (**3c**), 1,1,3-triphenylpropane (**4c**), 1,1,3-triphenyl-1-ethoxypropane (**5c**, R=Et), and 1,1,3-triphenyl-3-ethoxypropane (**6c**, R=Et), all of which are the most commonly observed photoproducts of arylcyclopropanes in alcohols as a result of ring opening.[5] In a marked contrast, similar irradiation of **1** in the presence of *p*-dicyanobenzene (DCB) resulted in a rapid disappearance of **1c** and concurrent appearance of single major product which was assigned as polar addition product **6c** (R=Et) of the OH bond across the ring in "anti-Markownikoff" fashion.

Similar marked enhancement of photoreactivity of the triphenylcyclopropane caused by DCB was also observed when other alcohols are employed as a trapping reagent although yield of anti-Markownikoff addition product decreased in *t*-butyl alcohol (Table 1). In 2,2,2-trifluoroethanol (TFE), **1c** was equally rapidly photolyzed in the presence of DCB, but the addition product was formed in only 12% yield. This

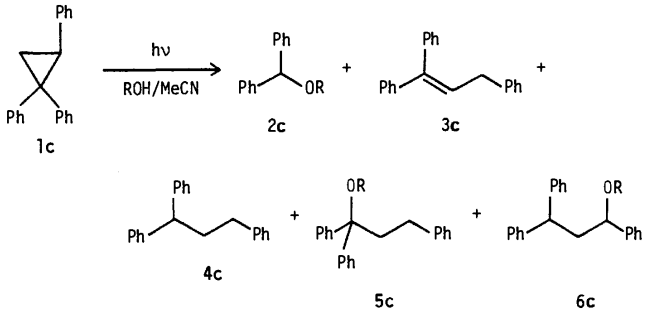

Table 1. Irradiation of **1c** in Various Alcohols[a]

ROH	Condition[b]	Irradiation time/h	Conversion %	Yield/%[c] 2c	3c	4c	5c	6c
MeOH	D	16	68.7	15.8	28.2	<1	<1	<1
	S	2	98.1	5.3	0	0	0	75.0
EtOH	D	16	75.9	15.9	4.6	<1	5.6	3.1
	S	2	95.2	4.3	0	0	0	85.3

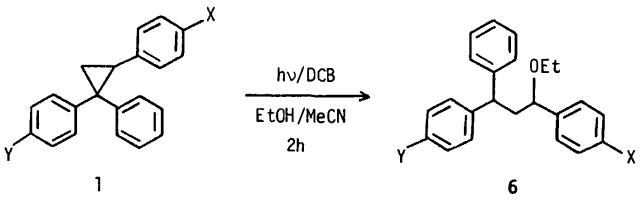
	S	2	93.9	0	0	0	0	12.1

a) Direct irradiations were conducted on 10 mM solution of **1c** in ROH/MeCN (1 : 4) at 10 °C in quartz tubes. For sensitized run, *p*-DCB (10 mM) was added to the solution. b) D refers to direct irradiation while S refers to sensitized run. c) Determined by GC.

Table 2. Effect of Aryl Substituents on DCB-Sensitized Photoreaction of 1,1,2-Triarylcyclopropane in EtOH/MeCN[a)]

1	X	Y	OX $E_{1/2}/V^{b)}$	ΔG/kJ·mol$^{-1c)}$	Conversion %	6/%
a	MeO	H	0.98	−138.2	96.8	72.3
b	Me	H	1.25	−112.7	98.1	57.5
c	H	H	1.25	−112.7	95.2	85.3
d	CN	H	1.40	−97.8	30.2	23.6
e	NO_2	H	1.47	−91.3	4.8	0
f[d)]	H	MeO	1.17	−120.7	96.1	63.4
g[d)]	H	CN	1.39	−99.0	90.7	44.6
h[d)]	H	NO_2	1.41	−97.1	2.4	0

a) All irradiations were conducted on 10 mM solution of **1** in the presence of 10 mM of *p*-DCB in EtOH/MeCN (1 : 4) for 2 h in quartz tubes. Yields were determined by GC. b) Oxidation potentials were obtained by cyclic voltammetry: Pt electrode, tetraethylammonium perchlorate (0.1 mol dm^{-3}) in acetonitrile solution, vs. Ag/Ag$^+$. c) Calculated using Eq. 1. d) Roughly 1 : 1 cis-trans mixtures were used.

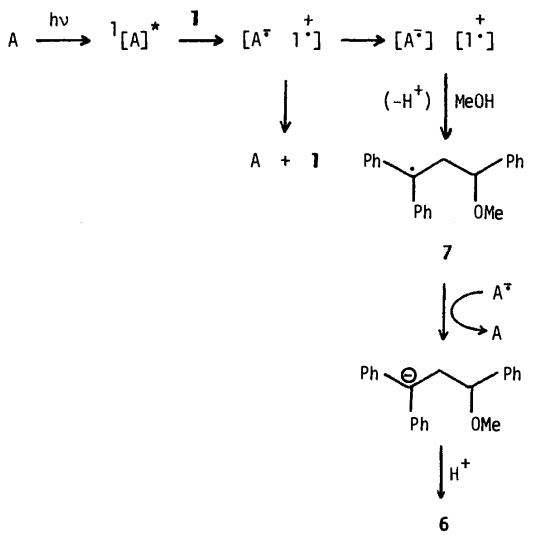


1 6

suggests that an intermediate generated by the interaction of excited DCB with **1c** is not efficiently trapped by TFE presumably due to its decreased nucleophilicity. Complete absence of addition products in the direct run, however, indicates that the intermediate formed in the DCB-sensitized run should be considerably electrophilic.

A series of *p*-monosubstituted triphenylcyclopropanes (**1a,b,d—h**) were prepared by conventional method and the effect of these substituents on the electron-transfer-mediated photoreaction was investigated. The results summarized in Table 2 suggest that the introduction of strongly electron-withdrawing group (i.e., nitro) suppressed the reaction almost completely. It is also noted that the reaction is somewhat more sensitive to the substituent (X) on 2-phenyl ring than that (Y) on 1-phenyl ring. Thus, the reaction was essentially unaffected by *p*-cyano group on 1-phenyl ring while the same group on 2-phenyl ring considerably suppressed the reaction.

The foregoing observations are explained in terms of the mechanism involving electron transfer originally proposed by Hixson.[3)] Thus, excitation of the sensitizer is followed by electron transfer from the cyclopropane to the sensitizer[6)] to give the geminate sensitizer anion radical-cyclopropane cation radical pair. The initially formed radical cation has the three-membered ring intact since it has been suggested that the electron has been taken from a phenyl ring.[7)] This radical ion pair can either deactivate by back electron transfer, or dissociate to separated radical ions, where the radical cation is attacked by alcohol followed by proton loss to afford diphenylmethyl radical (**7**).



Reduction of **7** with the sensitizer anion radical ($A^{-\cdot}$) leads to the adduct **6**.

What is the origin of the effect of ring substituents, then? A possible explanation would be that electron transfer becomes less feasible as more electron withdrawing groups are introduced on phenyl ring. The free energy change (ΔG) associated with the electron-transfer process can be estimated using Wellers' equation[8)] originally proposed to account for fluorescence quenching by electron-transfer mechanism,

$$\Delta G(\mathrm{kJ\,mol^{-1}}) = 96.8[E(\mathrm{D/D^+})_v - E(\mathrm{A/A^-})_v - e^2/(\varepsilon a)] - Es \quad (1)$$

where $E(\mathrm{D/D^+})$ and $E(\mathrm{A/A^-})$ are the oxidation potentials of the donor (in this case the cyclopropanes) and the reduction potential of the acceptor (in this case the sensitizer), respectively. Thus, the oxidation potential of **1** were measured by cyclic voltammetry and the free energy of electron transfer to DCB (Es=408.4 kJ mol^{-1}, $E_{1/2}^{red}$=2.00 eV)[9)] from various cyclopropanes **1a—h** in MeCN was estimated (Table 3). In all cases ΔG is significantly negative. This means that the electron transfer process should be spontaneous for all cyclopropanes employed.

Complete lack of reactivity of the cation radical from *p*-nitro derivatives, then, can be interpreted as indicating that the lifetime of the cation radical is too short, due to the strongly destabilizing effect of *p*-nitro group, to be trapped by alcohol and hence it undergoes the back electron transfer in the geminate pair before it dissociates and/or is intercepted by alcohol.[10)]

Experimental

Instrumentation. UV spectra were recorded on a Hitachi 220-S spectrophotometer. IR spectra were measured on a JASCO A-100 spectrometer and ^{1}H NMR spectra were determined with JEOL JNM-MH-100 NMR spectrometer in CCl_4 with Me_4Si as an internal reference. Mass spectra were recorded on Shimadzu QP-1000 mass spectrometer (70 eV). Oxidation potentials were measured on Yanaco polarographic analyzer P-1100.

Materials. All 1,1,2-triarylcyclopropanes (**1a—h**) were prepared by the reaction of the corresponding diaryldiazomethanes with styrenes in refluxing benzene, followed by

column chromatography. The data are shown below.

1a: Yield 24.7%; mp 109—112 °C (lit,[11a] 111—112 °C).

1b: Yield 78.1%; Liquid; ^{1}H NMR δ=7.10—6.96 (10H, m), 6.79—6.56 (4H, m), 2.74 (1H, dd), 2.19 (3H, s), 1.93—1.63 (2H, m); MS *m/z* 284.

1c: Yield 73.5%; mp 47—48.5 °C (lit,[11b] 49.5—50.0 °C).

1d: Yield 55.5%; mp 111.0—112.0 °C; ^{1}H NMR δ=7.20—6.45 (14H, m), 2.92—2.70 (1H, m), 2.02—1.68 (2H, m); MS *m/z* 295.

1e: Yield 76.4%; mp 97.2—99.8 °C; ^{1}H NMR δ=7.79 (2H, d), 7.40—6.80 (12H, m), 2.85 (1H, dd), 2.10—1.80 (2H, m); MS *m/z* 315.

1f: Yield 79.0%; mp 57.0—59.5 °C; ^{1}H NMR δ=7.10—6.40 (14H, m), 3.60 and 3.56 (each s, 3H), 2.76—2.60 (1H, m), 1.87—1.54 (2H, m); MS *m/z* 300.

1g: Yield 53.5%; mp 55.0—57.0 °C; ^{1}H NMR δ=7.40—6.60 (14H, m), 2.90—2.60 (1H, m), 2.10—1.60 (2H, m); MS *m/z* 295.

1h: Yield 85.3%; mp 120.0—121.0 °C; ^{1}H NMR δ=8.10—7.80 (2H, m), 7.40—6.80 (12H, m), 3.10—2.80 (1H, m), 2.20—1.70 (2H, m); MS *m/z* 315.

Authentic samples of **3c—5c** were prepared according to the literature procedures.[5,12] The ethers **6** were isolated from the DCB-sensitized photolytic mixtures by preparative TLC and characterized spectroscopically. ^{1}H NMR data are shown below.

6a (R=Et): ^{1}H NMR δ=7.2—6.6 (14H, m), 4.12 (1H, dd), 3.94 (1H, dd), 3.58 (3H, s), 3.35—2.87 (2H, m), 2.56—2.02 (2H, m), 1.06 (3H, t).

6b (R=Et): ^{1}H NMR δ=7.1—6.5 (14H, m), 4.10 (1H, dd), 3.80 (1H, dd), 3.38—2.90 (2H, m), 2.54—2.00 (2H, m), 2.18 (3H, s), 1.05 (3H, t).

6c (R=Me): ^{1}H NMR δ=7.6 (15H, bs), 4.10 (1H, dd), 3.82 (1H, dd), 3.03 (3H, s), 2.60—2.05 (2H, m).

6c (R=Et): ^{1}H NMR δ=7.5—6.8 (15H, m), 4.17 (1H, dd), 3.87 (1H, dd), 3.30—2.95 (2H, m), 2.46—2.00 (2H, m), 1.08 (3H, t).

6c (R=^{i}Pr): ^{1}H NMR δ=7.4—6.9 (15H, m), 4.12 (1H, dd), 3.95—3.40 (2H, m), 2.52—2.00 (2H, m), 1.20 (3H, d).

6c (R=^{t}Bu): ^{1}H NMR δ=7.6 (15H, bs), 4.12 (1H, dd), 3.90 (1H, dd), 2.75—2.00 (2H, m), 1.20 (9H, s).

6c (R=CH_2CF_3): ^{1}H NMR δ=7.4—6.8 (15H, m), 4.15 (1H, dd), 3.98 (2H, q), 3.90 (1H, dd), 2.50—2.09 (2H, m).

6d (R=Et): ^{1}H NMR δ=7.4—6.6 (14H, m), 4.12 (1H, dd), 3.85 (1H, dd), 3.32—2.87 (2H, m), 2.55—2.00 (2H, m), 1.08 (3H, t).

6f (R=Et): ^{1}H NMR δ=7.3—6.5 (14H, m), 4.2—4.0 (1H, m), 4.0—3.8 (1H, m), 3.66, 3.63, (3H, s), 3.5—2.8 (2H, m), 2.6—2.1 (2H, m), 1.10 (3H, t).

6g (R=Et): ^{1}H NMR δ=7.5—7.0 (14H, m), 4.14 (1H, dd), 3.85 (1H, dd), 3.4—2.9 (2H, m), 2.5—2.1 (2H, m), 1.09 (3H, t).

Irradiation for Product Identification. In a typical run, a solution of **1** (1 mmol) and *p*-DCB (1 mmol) in ROH (10 dm^3)-MeCN (40 dm^3) was placed in a quartz tube and irradiated using a high pressure, 300W, Hg lamp with a water-cooled quartz jacket. The progress of the reaction was monitored by TLC. After irradiation of 5 h, the irradiation mixtures were concentrated on a rotary evaporator and chromatographed on preparative TLC (silica gel) eluted with chloroform-hexane.

Irradiation for Analysis Purposes. All irradiations outlined in Tables were carried out on 10 mM solutions of **1** in a quartz tube of 5 dm^3 capacity at 15 °C. The yields were conveniently determined by standard GC techniques, and the identity of the products was confirmed by GC-MS comparison with authentic samples prepared as above.

Authors wish to thank Professor Yasuji Izawa of Aichi Institute of Technology and Dr. Kazuhiko Mizuno of Osaka Prefectural University for their helpful discussion and Professor Katsuhiko Takagi of Nagoya University for the measurement of cyclic voltammetry.

Synthesis of 2-Benzylidene-3(2*H*)-benzofuran-3-ones (Aurones) by Oxidation of 2′-Hydroxychalcones with Mercury(II) Acetate

Haruo SEKIZAKI
Faculty of Pharmaceutical Science, Higashi Nippon Gakuen University, Ishikari-Tobetsu, Hokkaido 061-02
(Received August 7, 1987)

Synopsis. The reaction of 2′-hydroxychalcones with mercury(II) acetate in acetic acid gives predominantly 2-benzylidene-3(2*H*)-benzofuran-3-ones (aurones) in 28—62% yield accompanied by flavanones in 5—21% yield.

2′-Hydroxychalcones are one of the important intermediates for the synthesis of flavonoids, and afford various products (flavone, flavonol, 3-hydroxyflavanone and aurone) according to the different oxidizing agents.[1] Hydrogen peroxide is the most historical reagent for the oxidation of 2′-hydroxychalcones to flavonols or aurones, but 6′-methoxyl group is necessary for the synthesis of aurones.

On the other hand, the oxidation of 2′-hydroxychalcones with selenium(IV) oxide,[1] palladium(II) lithium chloride,[2] 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ),[3] thallium(III) nitrate trihydride[4] and a combination of nickel chloride, zinc powder and potassium iodide[5] provide only flavones. While, Kurosawa et al.,[6,7] reported that the oxidation of 2′-hydroxychalcones with lead(IV) acetate or manganese(III) acetate in acetic acid gave the aurones as main products, but Ollis et al.,[8] reported that thallium(III) acetate gave the rearranged products. Thus oxidation of 2′-hydroxychalcones with metal acetates afford different products depending on the metal.

This report deals with the synthesis of aurones by the oxidation of 2′-hydroxychalcones with mercury(II) acetate in acetic acid. These results are similar to those of Kurosawa described above but a chalcone (**1c**) having hydroxyl group at 4-position also afforded the product **2c** as a pure crystal. The results are shown in Table 1.

2′-Hydroxychalcones **1a—i** were prepared by the usual potassium hydroxide-catalyzed condensation of the corresponding 2′-hydroxyacetophenones and benzaldehyde or its derivatives. The products **1a—i** were identified by their physical properties and spectroscopic analyses.

2′-Hydroxychalcones **1** were dehydrogenatively cyclized to the aurones **2** on heating at 90—95 °C for 8 h with two equivalents of mercury(II) acetate in acetic acid. The reaction mixture was separated by the addition of saturated sodium chloride solution followed by extraction with ethyl acetate and column chromatography on silica gel to give aurone **2** accompanied by flavanone **3** produced from acid-catalyzed cyclization of 2′-hydroxychalcone **1**. The aurones **2a—i** and flav-

Experimental

The melting points were determined on a Yanaco micro-melting point apparatus and are uncorrected. The IR spectra were taken on a Hitachi 270-30 infrared spectrophotometer. The ultraviolet spectra were determined by a Shimadzu UV-210 digital spectro-photometer. The ^{1}H NMR spectra were recorded on a JEOL FX 90Q spectrometer. Chemical shifts are given on the δ (ppm) scale with tetramethylsilane as an internal standard (s, singlet; d, doublet; t, triplet; m, multiplet). The MS were taken on a Shimadzu LKB-9000 and a JEOL JNM-PM-60 spectrometer by the direct inlet method; ionization voltage 70 eV.

Preparation of Chalcones. A solution of an equimolar amount of 2′-hydroxychalcone and benzaldehyde in a small volume of ethanol was treated with 10% ethanolic potassium hydroxide with stirring at 35—40 °C for 12 h. The reaction mixture was poured into ice-water and acidified with dilute hydrochloric acid. The resulting precipitate was collected by filtration and washed with water. The crude product was purified by column chromatography on silica gel and recrystallized from ethanol. **1f:** IR (KBr) 1635 and 1584 cm^{-1}. UV (C_2H_5OH) 250 (log ε 4.04) and 345 nm (4.30). ^{1}H NMR ($CDCl_3$) δ=3.84 (3H, s, OCH_3), 3.85 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 5.96 (1H, d, J=2.2 Hz, H-3′), 6.10 (1H, d, J=2.2 Hz, H-5′), 6.80—7.30 (4H, m, H-2, 4, 5 and 6), and 7.80 (2H, d, J=4.4 Hz, H-α and β). UV (C_2H_5OH) 250 (log ε 4.10) and 365 nm (4.54). ^{1}H NMR ($CDCl_3$) δ=3.83 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 5.11 (2H, s, -C$\underline{H}_2$Ph), 5.93 (1H, d, J=2.2 Hz, H-3′), 6.01 (1H, d, J=2.2 Hz, H-5′), 6.96 (2H, d, J=8.8 Hz, H-3 and 5), 7.39 (5H, s, PhH), 7.52 (2H, d, J=8.8 Hz, H-2 and 6), and 7.78 (2H, s, H-α and β). MS m/z (rel intensity) 390 (M^+; 22), 271 (18), 181 (22), and 91 (100). High MS Found: m/z 390.1489, Calcd for $C_{24}H_{22}O_5$: M, 390.1466. **1i**: IR (KBr) 1629 and 1581 cm^{-1}. UV (C_2H_5OH) 245 (log ε 4.00) and 371 nm (4.50). ^{1}H NMR ($CDCl_3$) δ=3.82 (6H, s, 2×OCH_3), 3.93 (3H, s, OCH_3), 5.20 (2H, s, -C$\underline{H}_2$Ph), 5.92 (1H, d, J=2.2 Hz, H-3′), 6.10 (1H, d, J=2.2 Hz, H-5′), 6.90 (1H, d, J=8.4 Hz, H-2 or 3), 7.15 (1H, d, J=2.2 Hz, H-6), 7.40 (6H, m, PhH and H-2 or 3), and 7.68 (2H, s, H-α and β). MS m/z (rel intensity) 420 (M^+; 34), 181 (42), 180 (31), and 91 (100). High MS Found: m/z 420.1563, Calcd for $C_{25}H_{24}O_6$: M, 420.1571.

Mercury(II) Acetate Oxidation of Chalcones. A solution of chalcone (**1**) (5 mol dm^{-3}) and mercury(II) acetate (10 mol dm^{-3}) in 100 cm^3 of acetic acid was heated at 90—95 °C for 8 h. After removal of the acetic acid in vacuo, the resulting solid was treated with saturated sodium chloride solution and then extracted with ethyl acetate. The ethyl acetate layer was separated and evaporated. The residue was dissolved in a small amount of a mixture of benzene-ethyl acetate (6/1 volume ratio) and separated by silica-gel column chromatography with a mixture of benzene-ethyl acetate (6/1 volume ratio) as eluant. Aurones **2** were obtained as the first fraction and flavanones **3** were obtained as the second fraction. **2i**: IR (KBr) 1692, 1673, 1614, and 1595 cm^{-1}. UV (C_2H_5OH) 252 (log ε 3.68), 265 (sh, 3.62), 380 (sh, 4.08), and 395 nm (4.15). ^{1}H NMR ($CDCl_3$) δ=3.93 (3H, s, OCH_3), 3.95 (6H, s, 2×OCH_3), 5.24 (2H, s, -C$\underline{H}_2$Ph), 6.12 (1H, d, J=1.8 Hz, H-5), 6.29 (1H, d, J=1.8 Hz, H-7), 6.68 (1H, s, H-10), 6.93 (1H, d, J=8.4 Hz, H-5′), and 7.45 (7H, m, PhH, H-2′ and 6′). MS m/z (rel intensity) 418 (M^+; 42), 327 (41), 299 (14), 181 (31), and 91 (100). High MS Found: m/z 418.1406, Calcd for $C_{25}H_{22}O_6$: M, 418.1414. **3f**: IR (KBr)1674, 1608, and 1566 cm^{-1}. Stereoselective Synthesis of 3,5-Alkadienoic Esters from 2,4-Dienoic Isomers

Sadao TSUBOI,* Jun-ichi SAKAMOTO, Akihisa KURODA, Masanori UTAKA, and Akira TAKEDA
Department of Synthetic Chemistry, School of Engineering, Okayama University, Tsushima, Okayama 700
(Received August 19, 1987)

Synopsis. The treatment of (2*E*,4*Z*)-2,4-alkadienoic esters with lithium diisopropylamide (LDA) at −80 °C gave (3*E*,5*E*)-isomers with 81—98% stereoselectivity. In contrast, the treatment of (2*E*,4*E*)-isomers under the same conditions gave (3*E*,5*Z*)-isomers with 72—80% stereoselectivity. The application to the synthesis of megatomoic acid is described. Carbon-13 NMR data regarding these 3,5-dienoates were obtained.

Some natural products containing a 3,5-dienoic acid moiety are reported. For example, an antibiotic mycomycin **1**[1] and an insect pheromone, megatomoic acid **2**,[2] are well-known.

$HC{\equiv}C\text{-}C{\equiv}C\text{-}CH{=}C{=}CH\text{-}CH{=}CHCH{=}CHCH_2CO_2H$
mycomycin **1**

megatomoic acid **2**

Conjugated diene groupings are useful for the synthesis of natural products via a Diels-Alder reaction.[3] To our knowledge, synthetic methods for 3,5-alkadienoic esters are quite limited. The conventional method consists of the combination of a Wittig reaction and a hydrogenation of triple bonds. On the other hand, Chiusoli reported the synthesis of 3,5-alkadienoates via the isomerization of 2,5-alkadienoates.[4] Krebs[5] and Kende et al.[6] reported that deconjugative alkylation of (*E*)- and (*Z*)-2-alkenoates with strong bases, such as lithium diisopropylamide (LDA) or potassium hexamethyldisilazide, gave, respectively, (*Z*)- and (*E*)-3-alkenoate with high stereoselectivities. We recently reported the highly stereo- and regioselective alkylation of alkylidenemalonates.[7] This paper reports a detailed description of the previous communication[8] concerning the deconjugative protonations of (2*E*,4*Z*)- and (2*E*,4*E*)-2,4-alkadienoates with LDA.[9]

In 1982 we reported a convenient synthesis of (2*E*,4*Z*)-alkadienoic esters **3** by the stereoselective rearrangement of β-allenic esters promoted with alumina.[10] As a result of our continuous interest in the chemistry of **3**,[11] we treated **3** with LDA at −80 °C. The reaction gave (3*E*,5*E*)-isomers **4** in good yield. On the other hand, a treatment of (2*E*,4*E*)-2,4-alkadienoates **5** with LDA afforded (3*E*,5*Z*)-isomers **6**. Various alkadienoates **3** and **5** were prepared and treated with LDA in THF/hexamethylphosphoric triamide (HMPA). These results were tabulated in Tables 1 and 2. The transformation of **3** to **4** proceeded with 81—98% stereoselectivity, while that of **5** to **6** proceeded with 72—80%. To improve the stereoselectivity, various lithium amides such as lithium dicyclohexylamide, lithium bis(trimethylsilyl)amide, and lithium diethylamide were used as a base. However, a notable improvement could not be established. The stereoselectivity decreased slightly as the substituent became larger. The geometry of the rearrangement products was determined by ^1H NMR spectral data with the aid of a shift reagent Eu(dpm)$_2$ and a proton decoupling technique. For example, both $J_{3,4}$ and $J_{5,6}$ in ethyl (3*E*,5*E*)-3,5-decadienoate (**4c**) were 15 Hz, which shows a trans geometry. The coupling constants of ethyl (3*E*,5*Z*)-3,5-decadienoate were $J_{3,4}$=15.4 Hz and $J_{5,6}$=10.8 Hz. The ^{13}C NMR spectra of compounds prepared in this work were measured and tentatively assigned as shown in Table 3. In general, signals of cis olefinic carbons of **6** appeared at a higher field than those of trans, trans-olefins **4** as a result of a steric effect.[12] These data afford an additional support for the structural assignment of **4** and **6**.

a) Analyzed by GLC fitted with Golay column (SE-30 silicone gum rubbers, 0.5 mm×45 m) or 10% SE-30 on Chromosorb W column (3 mm×1 m).

The stereochemical outcome in the present transformation can be explained by the assumption of carbanion intermediates[6] (**3′**, **3″**, **5′**, and **5″**), as shown in Chart 1. The deprotonation of **3** directly yields the minimum energy carbanion stereoisomer **3′**, which gives rise to the observed (3*E*,5*E*)-product. The alternative carbanion **3″** is unfavorable because of a severe 1,3-allylic strain between R and $CH{=}CHCO_2Et$. The deprotonation of **5** gives carbanion intermediates **5′** and **5″**, leading to the (3*E*,5*Z*)-and (3*E*,5*E*)-products, respectively. The formation of the carbanion **5′** leading to (3*E*,5*Z*)-product is favorable, since the cis form for the crotyl anion system is usually more stable than the trans form.[6] A higher stereoselectivity in the transformation of **3** to **4** than that of **5** to **6** is attributable to a larger energy difference between **3′** and **3″** than that between **5′** and **5″**.

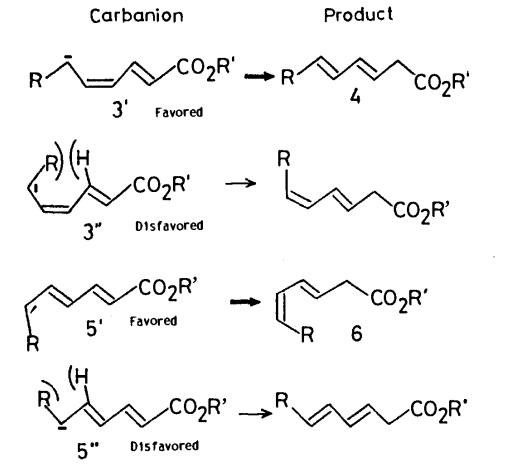

Chart 1.

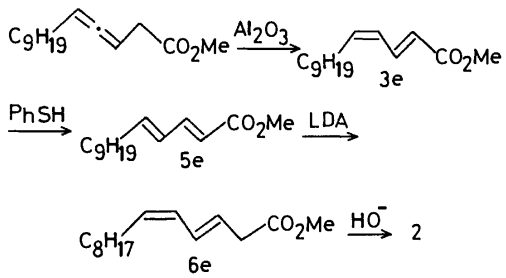

Scheme 1.

The present system was applied for the synthesis of megatomoic acid **2**, the sex attractant of the black carpet beetle.[2] The reaction sequence is shown in Scheme 1. The starting material, (2*E*,4*E*)-2,4-tetradecadienoate (**3e**), was prepared in 70% yield by a highly stereoselective rearrangement of methyl 3,4-tetradecadienoate, promoted with alumina, as reported previously.[7] The conversion of **3e** to methyl (2*E*,4*E*)-2,4-tetradecadienoate (**5e**) was established in 81% yield by a thermal treatment catalyzed by thiophenol and 2,2′-azobis(isobutyronitrile)(AIBN).[13] The treatment of **5e** with LDA gave a mixture of methyl (3*E*,5*Z*)-3,5-tetradecadienoate (**6e**) and the (3*E*,5*E*)-isomer **4e** (75:19). Spectral data were consistent with those reported previously.[11a] It has been reported that the hydrolysis of **6e** purified with GLPC gave megatomoic acid.[11a]

The present method will be useful for the stereoselective synthesis of polyenoic compounds, such as insect pheromones and leukotrienes.

Experimental

The boiling points are uncorrected. Elemental analyses were carried out by Mr. Eiichiro Amano of our laboratory. Analytical determinations by GLC were performed on a Hitachi Model 163 gas chromatograph fitted with 10% Silicone SE-30 on Chromosorb W column (3 mm×1 m) or Golay column (SE-30 silicone gum rubbers, 0.5 mm×45 m). IR spectra were taken on a JASCO Model A-102 spectrometer. ^1H NMR spectra (60 MHz) were recorded with a JEOL JNM-PMX60SI apparatus. ^{13}C NMR spectra (25 MHz) were obtained with a JEOL JNM-FX100 apparatus, using $CDCl_3$ as a solvent. Column chromatography was accomplished with 100—200 mesh Wakogel C-200. High-performance liquid chromatography (HPLC) was obtained with Yanagimoto liquid chromatograph L-2000 fitted with Yanapak SA-I (6 mm×250 mm). Tetrahydrofuran (THF) was distilled from sodium benzophenone ketyl under an atmosphere of nitrogen. Hexamethylphosphoric triamide (HMPA) was distilled from CaH_2 under reduced pressure. All experiments of the isomerization were carried out under an atmosphere of argon.

(2*E*,4*Z*)-2,4-Alkadienoates **3** was prepared according to the procedure reported previously.[10] (2*E*,4*E*)-2,4-Alkadienoates **5** was obtained from **3** by the procedure of the literature[13] and purified by preparative TLC (SiO_2, hexane/ethyl acetate=15/1) developed twice. The sample was purified by preparative TLC (SiO_2, hexane/ethyl acetate=15/1) developed twice. Some representative preparation of **4** and **6** are described below.

Table 3. ^{13}C NMR Data of (3*E*,5*E*)-3,5-Alkadienoates **4** and (3*E*,5*Z*)-3,5-Alkadienoates **6**

* May be exchangeable.

Methyl (3*E*,5*E*)-3,5-Octadienoate (4a). To a solution of diisopropylamine (0.289 ml, 2.10 mmol) in THF (4.5 ml) was added dropwise 1.18 ml of 1.65 M BuLi (1M=1 mol dm^{-3}) at 0 °C. After 30 min, HMPA (0.4 ml) was added and the mixture was cooled to −80 °C. A solution of **3a** (236 mg, 0.992 mmol) in THF (1.5 ml) was added dropwise; then, the mixture was stirred for 1 h and poured into ice water. After the mixture was acidified with dil. HCl, the organic materials were extracted with ether. The combined extracts were washed with water, dried over $MgSO_4$, and concentrated. The residual oil was chromatographed on SiO_2 to give 189 mg of an oil, of which GLC analysis (golay column, 130 °C) showed two peaks at R_t 3.2 and 3.4 min in a ratio of 4:96. Each component was separated by preparative GLC. The major fraction was identified as **4a**.[13] The minor fraction gave **6a**:[14] IR (neat) 1640 and 1600 cm^{-1}; ^1H NMR (CCl_4) δ=0.95 (t, 3H, CH_3), 2.16 (m, 2H, CH_2CH_3), 3.05 (d, 2H, J=7 Hz, CH_2CO), 3.59 (s, 3H, CO_2CH_3), 5.05—6.48 (m, 4H, $(CH{=}CH)_2$).

Ethyl (3*E*,5*E*)-3,5-Decadienoate (4c). To a solution of 0.046 ml (0.38 mmol) of dicyclohexylamine in 2 ml of dry THF was added at −15 °C 0.208 ml (0.38 mmol) of 1.65 M butyllithium in hexane. After 20 min, 0.1 ml of HMPA was added and then a solution of 65 mg (0.33 mmol) of **3c** in 2.5 ml of THF was added dropwise at −80 °C. The mixture was stirred for 1 h at −80 °C and then poured into ice water. The organic materials were extracted with ether, washed with water, dried over $MgSO_4$, and the solvent was evaporated. Analysis of the residual oil (67 mg) with GLC [column, SE-30 (3 mm×1 m), 120 °C; carrier gas, N_2 (0.5 kg cm^{-2})] gave two peaks. The structure was determined by comparison of the retention time with that of the authentic sample. The peaks, compounds, retention times, and integrated percentages were as follow: 1, **6c**, 3.9, 10%; 2, **4c**,[15] 4.1, 87%.

Methyl (3*E*,5*Z*)-3,5-Tetradecadienoate (6e). A solution of **5e** (98 mg, 0.41 mmol) in THF (0.1 ml) was treated with LDA prepared from diisopropylamine (0.069 ml, 0.5 mmol), 1.65 M butyllithium (0.273 ml, 0.5 mmol), and HMPA (0.15 ml) at −72 °C for 1 h, as shown in the preparation of **4c**. The mixture was worked up as usual and a crude product was obtained as an oil (93 mg) which was analyzed by GLC [column: SE-30 (3 mm×1 m), 170 °C; carrier gas, N_2 (0.5 kg cm^{-2})]. The peaks, retention times, and integrated peak areas are as follows: 1, 3.7 min, 80%; 2, 4.4 min, 20%. Component 1 was identified as **6e** (75% yield) by comparison of spectral data and the retention times with those of an authentic sample.[11a] Component 2 was identified as **4e** (19% yield) by a comparison of the spectral data and the retention time with those of a sample prepared from **3e**.

Synthesis and Epoxidation of Methyl *trans*-5,6-Diacetoxy-1,3-cyclohexadiene-1-carboxylate

Seiichiro OGAWA* and Tohei TAKAGAKI
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Yokohama 223
(Received October 3, 1987)

Synopsis. The (±)-methyl 1,3-cyclohexadiene-1-carboxylate, a useful intermediate for synthesis of derivatives of shikimic acid, was prepared by bromination of (±)-methyl (1,3/2)-2,3-diacetoxy-4-cyclohexene-1-carboxylate, followed by debromination of the major dibromide obtained with zinc dust. Epoxidation of the diene with peracid gave selectively two 3,4-monoepoxides.

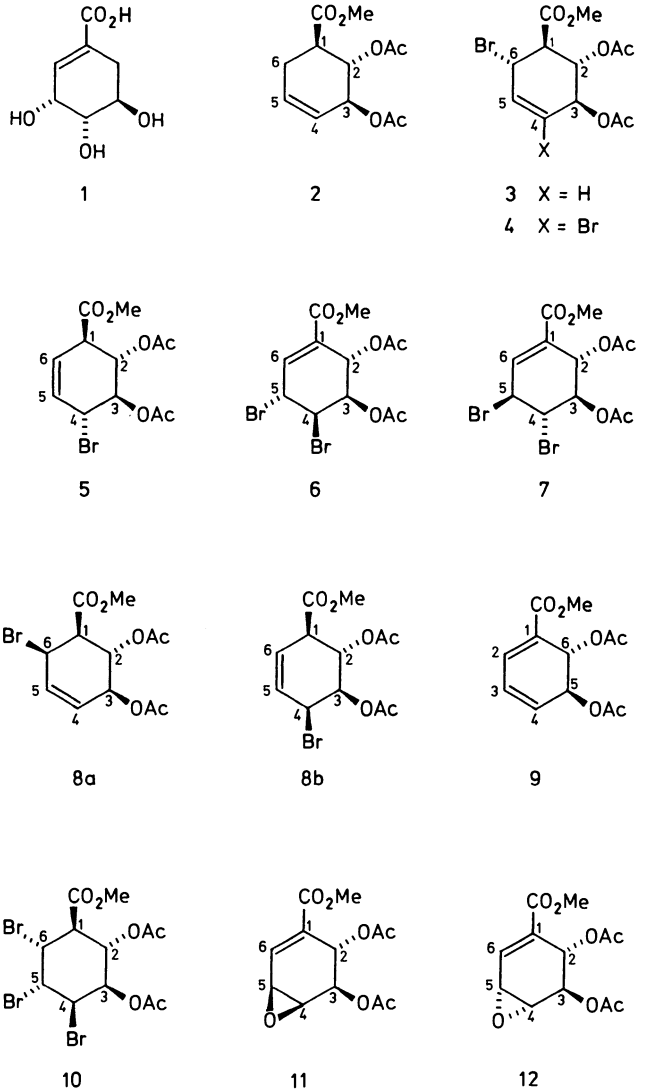
Shikimic acid (**1**) occupies an important position in biosynthesis (shikimate pathway) of aromatic amino acids in nature.[1,2] On the other hand, some related compounds derived from **1**, viz. glyoxalase I inhibitor,[3] rancinamycins,[4] dioxolamycin,[5] etc., have been known to possess an interesting biological activity. We now describe a synthesis of the title compound, substituted (±)-methyl 1,3-cyclohexadiene-1-carboxylate, a versatile precursor for preparation of derivatives[2,6] of shikimic acid and analogs of naturally occurring cyclohexene oxides.[7]

Bromination of (±)-methyl (1,3/2)-2,3-diacetoxy-4-cyclohexene-1-carboxylate[8] (**2**) with 2 molar equiv of *N*-bromosuccinimide (NBS) in carbon tetrachloride in the presence of a trace amount of α,α'-azobisisobutyronitrile (AIBN) at reflux temperature for 2 h produced one major and four minor components. The products were separated by chromatography on silica gel to give two monobromides **3** (5%) and **5** (4%), and three dibromides **4**[9] (2%), **6** (50%), and **7**[10] (7%). Their structures were deduced on the basis of the previous results[11] on the reaction of the corresponding benzoyloxy and bromomethyl derivatives[12] with NBS, and finally confirmed by the ^{1}H NMR spectra (data in Experimental).

Mechanistically, four monobromides **3**, **5**, **8a**, and **8b** are considered to be formed initially by allylic bromination. The highly unstable isomer **8a**, in which the bromo group exists in quasi-axial position and cis to the 1-methoxycarbonyl group, readily undergoes elimination of hydrogen bromide to yield a diene **9**, which rapidly reacts with bromine generated in situ to give the dibromides **6** and **7**. The formation of the dibromide **4** might be deduced that the monobromide **3** possibly reacts with bromine to give a tribromide **10** which is convertible to **4** by elimination of hydrogen bromide under these reaction conditions or during chromatography on a silica-gel column.

Debromination of **6** was effected by treatment with zinc dust in acetic acid to give 83% yield of the diene **9**[13] as crystals. When ethanol was used as a solvent, partial *O*-deacetylation occurred to produce a mixture of two monoacetates and dihydroxy compound, together with a low yield of **9**. Since racemic **2** can readily be optically resolved,[14] and the absolute configurations of both enantiomers have already been established, it may be possible to provide optically active **9**.

In order to demonstrate the reactivity of the diene system, oxidation of **9** with equimolar *m*-chloroperbenzoic acid (MCPBA) was carried out in dichloromethane in the presence of phosphate buffer (pH 8) at room temperature. Two monoepoxides **11** (13%) and **12** (45%) were obtained selectively, and the structures were confirmed on the basis of the ^{1}H NMR spectra. The favored conformation of **11**, deduced by consideration of $J_{2,3}$ (7.5 Hz), would adopt the twist form with the 2- and 3-OAc groups being oriented in diequatorial positions. On the other hand, two acetoxyl groups of **12** seems to situate in diaxial positions ($J_{2,3}$=2.3 Hz). Each conformation is compatible with that of the corresponding benzoyloxymethyl derivatives.[11]



Experimental

Melting points were determined in an open capillary tube in a MEL-TEMP melting point apparatus and are uncorrected. ^{1}H NMR spectra were recorded in chloroform-*d* solution with tetramethylsilane as an internal standard. The peak positions are given in δ values. TLC was performed on precoated silica gel 60 F-254 (E. Merck, Darmstadt; 0.2 mm thickness). The silica gel used for column chromatography was Wakogel C-300 (Wako Co., Osaka; 300 mesh). Organic solutions were concentrated below 30 °C under reduced pressure.

Bromination of (±)-Methyl (1,3/2)-2,3-Diacetoxy-4-cyclohexene-1-carboxylate (2) with NBS. A mixture of **2**[8] (0.50 g, 2.0 mmol), NBS (0.71 g, 4.0 mmol), AIBN (5 mg), and carbon tetrachloride (10 ml) was refluxed under nitrogen atmosphere for 2 h. TLC (2-butanone-toluene 1 : 5) showed a disappearance of **2** (R_f 0.46), and a formation of one major (R_f 0.56) and several minor components (R_f 0.67, 0.63, 0.50, and 0.46). Succinimide formed was removed by filtration and the filtrate was concentrated. The residue (0.98 g) was chromatographed on silica gel (50 g) with 2-butanone-toluene (1 : 20) as eluent to give as the first fraction (±)-methyl (1,3/2,6)-2,3-diacetoxy-4,6-dibromo-4-cyclohexene-1-carboxylate (**4**) (22 mg, 2%) as crude crystals (from ethanol): Mp 112—113 °C. ^{1}H NMR ($CDCl_3$) δ=2.03 (3H, s) and 2.07 (3H, s) (OAc), 3.44 (1H, dd, $J_{1,2}$=9 Hz, $J_{1,6}$=7.2 Hz, H-1), 3.75 (3H, s, CO_2Me), 5.00 (1H, ddd, $J_{3,6}$=2.3 Hz, $J_{5,6}$=3.3 Hz, H-6), 5.36 (1H, dd, $J_{2,3}$=6 Hz, H-2), 5.66 (1H, ddd, $J_{3,5}$=1.3 Hz, H-3), 6.49 (1H, dd, H-5).

The above mother liquid of **4** was concentrated and the residue was rechromatographed on silica gel (8 g) with acetone-hexane (1 : 15) as eluent to give (±)-methyl (2,4/3,5)-2,3-diacetoxy-4,5-dibromo-6-cyclohexene-1-carboxylate (**7**) (57 mg, 7%) as a syrup contaminated with an unidentified compounds. ^{1}H NMR ($CDCl_3$) δ=2.03 (3H, s) and 2.10 (3H, s) (OAc), 3.81 (3H, s, CO_2Me), 4.54 (1H, dd, $J_{3,4}$=7.5 Hz, $J_{4,5}$=5.3 Hz, H-4), 5.01 (1H, br dd, $J_{5,6}$=3 Hz, H-5), 5.32 (1H, dd, $J_{2,3}$=4.5 Hz, H-3), 5.87 (1H, br dd, $J_{2,6}$=1.5 Hz, H-2), 7.13 (1H, br dd, H-6).

The second fraction (R_f 0.56) gave a syrup which crystallized from ethanol to give (±)-methyl (2,5/3,4)-2,3-diacetoxy-4,5-dibromo-6-cyclohexene-1-carboxylate (**6**) (0.40 g, 50%) as prisms: Mp 115—116 °C. ^{1}H NMR ($CDCl_3$) δ=2.07 (3H, s) and 2.12 (3H, s) (OAc), 3.80 (3H, s, CO_2Me), 4.57 (1H, dd, $J_{3,4}$=2.7 Hz, $J_{4,5}$=4 Hz, H-4), 4.97 (1H, t, $J_{5,6}$=4 Hz, H-5), 5.49 (1H, dd, $J_{2,3}$=6.5 Hz, H-3), 6.03 (1H, d, H-2), 7.10 (1H, d, H-6).

Found: C, 34.97; H, 3.45; Br, 38.83%. Calcd for $C_{12}H_{14}Br_2O_6$: C, 34.81; H, 3.41; Br, 38.60%.

The third fraction (R_f 0.50) gave a syrup which crystallized from ethanol to give (±)-methyl (1,3/2,4)-2,3-diacetoxy-4-bromo-5-cyclohexene-1-carboxylate (**5**) (27 mg, 4%) as needles: Mp 91.5—93 °C. ^{1}H NMR ($CDCl_3$) δ=2.03 (3H, s) and 2.08 (3H, s) (OAc), 3.53 (1H, ddd, $J_{1,2}$=8.8 Hz, $J_{1,5}$=2.5, $J_{1,6}$=1.8 Hz, H-1), 3.74 (3H, s, CO_2Me), 4.06 (1H, ddd, $J_{3,4}$=7 Hz, $J_{4,5}$=2.5 Hz, $J_{4,6}$=1.8 Hz, H-4), 5.38—5.47 (2H, m, H-2 and H-3), 5.72 (1H, dt, $J_{5,6}$=10 Hz, H-6), 5.99 (1H, dt, H-5).

Found: C, 43.13; H, 4.59; Br, 23.97%. Calcd for $C_{12}H_{15}BrO_6$: C, 43.01; H, 4.51; Br, 23.84%.

The last fraction was concentrated to give a syrup (0.22 g) which was rechromatographed on silica gel (13 g) with acetone-hexane (1 : 5) as eluent to give as a major component (±)-methyl (1,3/2,6)-2,3-diacetoxy-6-bromo-4-cyclohexene-1-carboxylate (**3**) (32 mg, 5%) as needles (from benzene-hexane): Mp 78—79 °C. ^{1}H NMR ($CDCl_3$) δ=2.03 (6H, s, 2 OAc), 3.29 (1H, dd, $J_{1,2}$=10.5 Hz, $J_{1,6}$=9 Hz, H-1), 3.75 (3H, s, CO_2Me), 5.01 (1H, ddd, $J_{4,6}$=1.5 Hz, $J_{5,6}$=2.7 Hz, H-6), 5.24 (1H, dd, $J_{2,3}$=7.2 Hz, H-2), 5.47—5.66 (2H, m, H-3 and H-4), 6.03 (1H, dt, $J_{3,5}$=2.7 Hz, $J_{4,5}$=10 Hz, H-5).

Found: C, 43.22; H, 4.57; Br, 23.90%. Calcd for $C_{12}H_{15}BrO_6$: C, 43.01; H, 4.51; Br, 23.84%.

(±)-Methyl *trans*-5,6-Diacetoxy-1,3-cyclohexadiene-1-carboxylate (9). To a stirred solution of **6** (100 mg, 0.24 mmol) in acetic acid (1.0 mL) was added portionwise zinc dust (63 mg, 0.96 matom) at room temperature. After 10 min, TLC (2-butanone-toluene 1 : 5) showed a disappearance of **6** and formation of a single component (R_f 0.41). An insoluble material was removed by filtration and washed with ether (15 ml). The filtrate and washing were combined and washed successively with water, saturated sodium hydrogen carbonate, and aqueous sodium chloride, dried, and concentrated. The residual syrup (80 mg) was crystallized from aqueous ethanol to give **9** (52 mg, 83%) as prisms: Mp 80—81 °C. ^{1}H NMR ($CDCl_3$) δ=2.04 (6H, s, 2 OAc), 3.80 (3H, s, CO_2Me), 5.27 (1H, dd, $J_{4,5}$=4.5 Hz, $J_{5,6}$=1.7 Hz, H-5), 5.92 (1H, d, H-6), 6.33 (2H, m, H-3 and H-4), 7.28 (1H, dd, $J_{2,3}$=4.5, $J_{2,4}$=1.5 Hz, H-2).

Found: C, 56.46; H, 5.53%. Calcd for $C_{12}H_{14}O_6$: C, 56.69; H, 5.55%.

Epoxidation of 9 with MCPBA. A mixture of **9** (110 mg, 0.43 mmol), MCPBA (0.13 g, ca. 0.43 mmol), dichloromethane (3 ml), and phosphate buffer (pH 8, 3 ml) was stirred vigorously at room temperature for 3 d. TLC (ethyl acetate-hexane 1 : 3) showed a formation of one major (R_f 0.20) and one minor component (R_f 0.23). The mixture was diluted with dichloromethane (20 ml) and the solution was washed with aqueous 10% sodium thiosulfate, saturated sodium hydrogencarbonate, and water, and dried and concentrated. The residual syrup (0.11 g) was chromatographed on silica gel (5 g) with ethyl acetate-hexane (1 : 4) as eluent to give as a first fraction (±)-methyl 2,3-di-*O*-acetyl-4,5-anhydro-(2/3,4,5)-2,3,4,5-tetrahydroxy-6-cyclohexene-1-carboxylate (**11**) (15 mg, 13%) as prisms: Mp 82—84 °C (from ethanol). ^{1}H NMR ($CDCl_3$) δ=2.00 (3H, s) and 2.13 (3H, s) (OAc), 3.53 (1H, t, $J_{4,5}$= $J_{5,6}$=3.3 Hz, H-5), 3.64 (1H, dd, $J_{3,4}$=1.5 Hz, H-4), 3.74 (3H, s, CO_2Me), 5.33 (1H, dd, $J_{2,3}$=7.5 Hz, H-3), 5.88 (1H, dd, $J_{2,6}$=2.3 Hz, H-2), 7.05 (1H, dd, H-6).

Found: C, 53.36; H, 5.24%. Calcd for $C_{12}H_{14}O_7$: C, 53.34; H, 5.22%.

The second fraction gave (±)-methyl 2,3-di-*O*-acetyl-4,5-anhydro-(2,4,5/3)-2,3,4,5-tetrahydroxy-6-cyclohexene-1-carboxylate (**12**) (53 mg, 45%) as needles (from ethanol): Mp 104—105.5 °C. ^{1}H NMR ($CDCl_3$) δ=2.07 (6H, s, 2 OAc), 3.51 (1H, t, $J_{4,5}$= $J_{5,6}$=3.8 Hz, H-5), 3.72 (1H, dt, $J_{2,4}$= $J_{3,4}$=2.3 Hz, H-4), 3.80 (3H, s, CO_2Me), 5.46 (1H, t, $J_{2,3}$=2.3 Hz, H-3), 5.82 (1H, t, H-2), 7.50 (1H, d, H-6).

Found: C, 53.62; H, 5.30%.

We thank Mr. Saburo Nakada and Mr. Akio Takahashi for their elemental analyses.

Ring Size Effect on [2+2] Photochemical Cycloaddition of Enones with Cyclic Olefins

Masahiro TADA* and Yuuki NIEDA
Tokyo University of Agriculture and Technology, Laboratory of Bio-organic Chemistry, Fuchu, Tokyo 183
(Received October 3, 1987)

Synopsis. Photochemical reaction of 3-substituted 2-cyclohexen-1-ones with methyl 1-cyclohexene-1-carboxylate gave only head-to-tail, cis-transoid-cis photoadduct. The photoadducts of 3-methyl-2-cyclohexen-1-one with methyl 1-cyclopentene-1-carboxylate and with methyl 1-cyclobutene-1-carboxylate had head-to-head, cis-transoid-cis ring systems.

Photochemical [2+2] cycloaddition of enones with olefins is one of the most famous photochemical reactions. The application of this reaction for the synthesis of natural products has been well-documented.[1] Corey et al.[2] and Loutfy and De Mayo[3] investigated the mechanism of photocycloaddition of enones with olefins in an attempt to explain the regio- and stereoselectivity. Weedon made a general statement concerning the stereochemistry of enone photochemical cycloaddition.[4] Wender reported that irradiation of 3-methyl-2-cyclohexen-1-one (**1**) with methyl 1-cyclobutene-1-carboxylate (**2**) produced a head-to-head, cis-transoid-cis photoadduct **3** in dichloromethane.[5] Lange obtained a similar head-to-head, cis-transoid-cis photoadduct **5** by the photochemical reaction of enone **1** with methyl 1-cyclopenetene-1-carboxylate (**4**) in toluene.[6] In the course of our synthetic investigation of natural products using photochemical cycloaddition, we found that the products of 3-substituted 2-cyclohexen-2-ones with methyl 1-cyclohexene-1-carboxylate have a head-to-tail, cis-transoid-cis ring system. We report here that the regiochemistry of the photoadducts of enone with cycloolefins is dependent on the ring size of the cycloolefins.

Results and Discussion

A dichloromethane solution of equimolar mixture of 3-methyl-2-cyclohexen-1-one (**1**) and methyl 1-cyclohexene-1-carboxylate (**6**) was irradiated by a 100 W high-pressure Hg-lamp for 8 hours. The photoadduct **7** was obtained in 74.4% yield along with unreacted starting materials. The same adduct was also obtained as a major product by the photochemical reaction of **1** with **6** in methanol, or in CH_3CN. The structure of the compound **7** was determined as follows. The compound **7** showed the M^+ at m/z 250 by mass spectrum and was found to have a ketone and an ester group by IR spectrum (1726, 1697, 1223. and 1155 cm^{-1}). The ^{13}C NMR spectrum of the compound **7**, showed the signals assigned to a ketone, a methyl ester, two methyls, 7 methylenes, 2 methines, a quaternary carbon and no C=C double bond. In the ^1H-^1H COSY of the compound **7** spectrum,[7] a large coupling (J=10.8 Hz) between the C-12H (δ 2.50, d, J=10.8 Hz) and the C-12H (δ 2.96, ddd, J=2.1, 5.2, 10.8 Hz) was observed. The coupling constants ($J_{1,12}$=10.8, $J_{12,11}$=5.2, and $J_{12,11}$=2.1 Hz) of compound **7** could be satisifactorily assigned only by one of the conformations of the cis-transoid-cis ring system. In the NOESY spectrum[8] of the compound **7**, cross peaks were appeared between C-6Me and C-1H. Whereas no NOE was observed between C-12H and C-1H, between C-12H and C-6Me and between C-12H and the ester methyl. Finally, the compound **7** was converted to a hydroxy ketone **8** by the successive treatment of acetalization, reduction, and hydrolysis (acetone-TsOH). The signal of C-12H of compound **8** was observed at higher chemical shift (δ 2.36, dd, J=5.0, 10.2 Hz) compared to that of the compound **3**, whereas no remarkable change of chemical shifts were observed on C-1H and C-6Me in ^1H NMR. These results reveal that the photoadduct **7** has a head-to-tail, cis-transoid-cis ring system.

The regiochemistry of the photoadduct **7** is different from that of the photoadducts **3** and **5**. The photochemical reaction of the other six-membered ring compounds were examined from the mechanistic interest.

The photochemical reaction of the enone **1** with 1-cyclohexene-1-carboxylic acid (**9**) gave a major product **10** under the similar conditions in CH_2Cl_2. The major product **10** was converted to the compound **7** by methylation with diazomethane showing that the major product of the photochemical reaction of the enone **1** with the acid **9** is a similar head-to-tail, cis-transoid-cis adduct **10** (9.3%). The photochemical reaction of the enone **1** with 1-cyclohexenylmethanol was very slow and no photoadduct obtained under similar conditions. Irradiation of the CH_2Cl_2 solution of the 2-cyclohexen-1-one (**11**) and the ester **6** for **5** hours gave a major product **12** (7.4%) with unreacted starting materials. The structure of **12** was clarified by the NMR spectra (^1H, ^{13}C NMR, and ^1H-^1H COSY) as in the case of the compound **7**. No photochemical reaction product was obtained by the irradiation of the CH_2Cl_2 solution of 3-methoxy-2-cyclohexen-1-one (**13**) and the ester **6** for 16 hours. Acetophenone (1%) was thus, used for a photosensitizer and the solution was irradiated for 8 hours to give a head-to-tail, cis-transoid-cis compound (**14**) in a yield of 10.5%. The structure proof of the product **14** was obtained from the NMR experiments (^1H, ^{13}C NMR, ^1H-^1H COSY, and NOESY). The signal of the C-12H (δ 2.47, ddd, J=2.5, 5.4, 10.8 Hz) of compound **14** was appeared in very similar splittung pattern as that of compound **7**.

In summary, photochemical cycloaddition of 3-substituted 2-cyclohexen-1-one with cyclohexene-1-carboxylic acid and with its ester gave head-to-tail, cis-transoid-cis compounds. The regiochemistry of the adduct **7**, **10**, **12**, and **14** are opposite to the photoadducts **3** and **5**. These results suggest that the difference of the regiochemistry of the photoadducts depends on

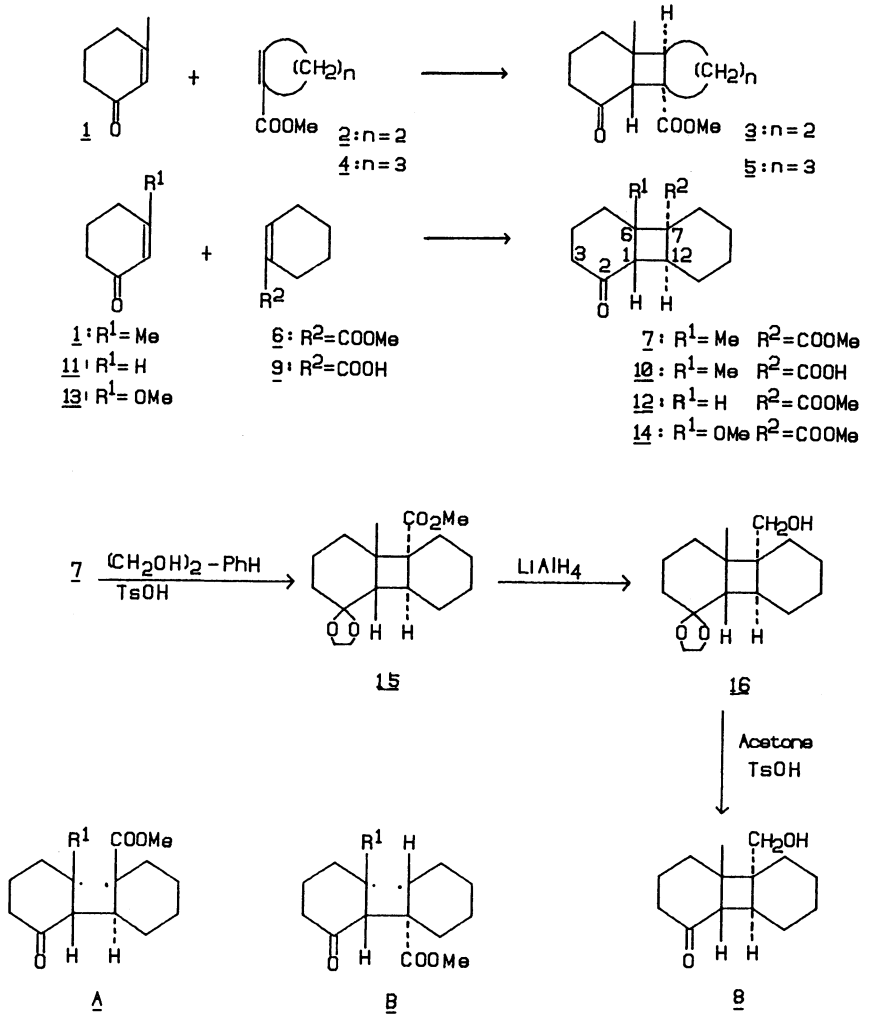

Fig. 1.

the ring size of the cyclic olefinic esters.

The photoadducts **7**, **10**, **12**, and **14** should be produced via the more stable biradical **A** rather than the less stable biradical **B**. The unambigious mechanistic explanation for the ring size effect could not be accomplished yet.

Experimental

NMR spectra were measured with a JEOL GX-270 spectrometer in $CDCl_3$ solution containing tetramethylsilane as an internal standard. IR spectra measured on JASCO IR-810 spectrometer. HPLC was performed on JASCO BIP-1 HPLC system with RI detector (RID-300) and silica-gel column (LiChrosorb Si-60 10 μm, 7,5 *500 mm). Thin-layer chromatography was carried out on Kieselgel GF_{254} (Merck) in 0.25 mm thickness. Wakogel C-200 (Wako Pure Chemical Industries) was used for column chromatography.

General Procedures for Irradiation of Enone with Olefin. The enone **1** (1 m mol, 110 mg) and the ester **6** (1 m mol, 140 mg) were dissolved in 50 ml of CH_2Cl_2, and the mixture was irradiated through Pyrex glass vessel for 8 h under nitrogen atmosphere with 100 W high-pressure Hg-lamp. The reaction mixture was concentrated, and the residue was column chromatographed on silica gel eluted with hexane-EtOAc and purified by HPLC to give 186.0 mg (74.4%) of **7**: IR (neat) 1726, 1697, 1223, 1155 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.72 (3H, s), 2.96 (1H, ddd, J=2.1, 5.2, 10.8 Hz), 2.50 (1H, d, J=10.8 Hz), 1.14 (3H, s); ^{13}C NMR ($CDCl_3$) δ=20.51(q), 21.15(t), 21.24(t), 21.59(t), 23.54(t), 27.54(t), 31,39(t), 36.83(d), 38.14(t), 44.92(s), 49.64(s), 50.17(d), 51.16(q), 175.70(s), 211.79(s); MS m/z 250.

Photochemical reaction of the other enones with olefins were performed by the similar procedures. The acid **10** was methylated with a ether solution of diazomethane as usual procedures before the separation. Acetophenone (1 mg) was added to the benzene (50 ml) solution of the enone **13** (117.5 mg) and the ester **6** (126.3 mg) as a photosensitizer before the irradiation. Compound **12**: ^1H NMR ($CDCl_3$) δ=3.70 (3H, s), 3.07 (1H, dd, J=5.4, 10.8 Hz), 2.90 (1H, dd, J=7.0, 10.8 Hz); ^{13}C NMR ($CDCl_3$) δ=21.29, 21.93, 22.32, 24.10, 24.32, 32.64, 38.79, 38.90, 41.51, 44.06, 46.81, 51.53, 175.56, 212.55; compound **14**: IR 1723, 1698 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.75 (3H, s), 3.31 (3H, s), 2.66 (1H, d, J=10.8 Hz), 2.47 (1H, ddd, J=2.5, 5.4, 10.8 Hz); ^{13}C NMR ($CDCl_3$) δ=19.18, 20.94, 21.15, 23.45, 25.08, 25.26, 23.03, 38.54, 50.34, 51.72, 51.88, 52.97, 80.52, 175.55, 210.78.

Acetalization of the Photoadduct 7. A mixture of **7** (96.6 mg), ethylene glycol (1 g), TsOH (5 mg), and benzene (20 ml) was refluxed for 12 h with Dean-Stark water trap. The raction mixture was poured into brine, and extracted with ether. The organic layer was washed with aqueous sodium carbonate (5%) and brine, dried over sodium sulfate and concentrated. The residue was column chromatographed on silica gel eluted with EtOAc to give the acetal **15** (70.4 mg, 62%): IR(neat) 1725, 1225, 1207 cm^{-1}; ^1H NMR ($CDCl_3$) δ= 1.08 (3H, s), 2.63 (1H, dd), 3.65 (1H, s), 3.9 (4H, m); ^{13}C NMR

($CDCl_3$) δ=19.93(t), 20.48(q), 21.88(t), 22.08(t), 24.06(t), 27.78(t), 31.70(t), 32.25(t), 33.78(d), 42.92(s), 43.36(d), 49.94(s), 51.00(q), 64.10(t), 64.14(t), 109.42(s), 176.68(s).

Reduction of Acetal 15. A solution of the acetal **15** (262.6 mg) in ether (10 ml) was added dropwise to a stirred slurry of lithium aluminum hydride (75 mg) in ether (10 ml). After being stirred for 3 h, saturated aqueous sodium sulfate solution was added and the product was extracted with ether. The ether solution was washed with brine, dried over sodium sulfate and evaporated. The silica-gel column chromatographed of the residue afforded the hydroxy acetal **16** (198 mg, 83.4%): IR (neat) 3450 (br.), 1093 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.05 (3H, s), 3.58 (1H, d, J=10.5 Hz), 3.67 (1H, d, J=10.5 Hz), 3.9 (4H, m); ^{13}C NMR ($CDCl_3$) δ=20.07, 21.63, 22.10, 22.14, 24.74, 25.57, 30.08, 32.28, 34.43, 41.10, 43.16, 43.58, 64.08, 64.12, 64.89, 109.83.

Deprotection of the Hydroxy Acetal 16. A solution of the hydroxy acetal **16** (53 mg) and TsOH (50 mg) in acetone (15 ml) was stirred for 16 h at room temperature. The reaction mixture was evaporated and the residue was disolved in EtOAc. The solution was washed with 5%-Na_2CO_3 and brine, and evaporated. The product was purified with HPLC to give the hydroxy ketone **8** (33 mg, 75%): IR (neat) 3480, 1680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.73 (1H, d, J=11.1 Hz), 3.66 (1H, d, 11.1 Hz), 2.57 (1H, d, J=10.2 Hz), 2.36 (1H, dd, J=5.0, 10.2 Hz), 1.13 (3H, s); ^{13}C NMR ($CDCl_3$) δ=21.16, 21.28, 21.84, 22.06, 24.35, 25.70, 29.59, 37.77, 38.76, 43.12, 43.44, 50.84, 64.36, 213.54.

Unusual Concentration-Rate Profiles for Oxidation of a Pair of Associating Thiols

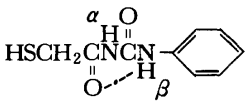
Jun-ichi KATO, Masato M. ITO, Kazuomi HAGINO, Narumi NAITOH, Makoto MISAKA, Einosuke FUJISHIRO, and Tadashi ENDO*

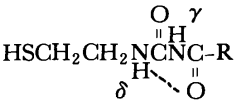
Department of Chemistry, College of Science and Engineering, Aoyama Gakuin University, Chitosedai, Setagaya-ku, Tokyo 157

(Received October 5, 1987)

Synopsis. In base-catalyzed oxidation of a pair of associating thiols [$HSCH_2$-CONHCONH-Ph and $HSCH_2CH_2$-NHCONHCO-C_6H_{13}] with oxygen, there are concentration regions where initial rates decrease with increasing concentrations of the thiols. For a pair of nonassociating thiols [$HSCH_2CO_2C_2H_5$ and $HSCH_2CH_2OH$], initial rates increase linearly with concentrations of the thiols.

Intermolecular association plays a very important role in controlling chemical reactions.[1-3] Recently, it has been found that, in oxidation of a pair of associating thiols (**1** and **2**), rate enhancement with time occurs in protic media.[4] We report here the unusual behavior of initial rates toward concentrations of the associating thiols in their oxidation.





1 **2a** R = $(CH_2)_3CH_2CH_2CH_3$

b R = $(CH_2)_3CH(CH_3)_2$

c R =

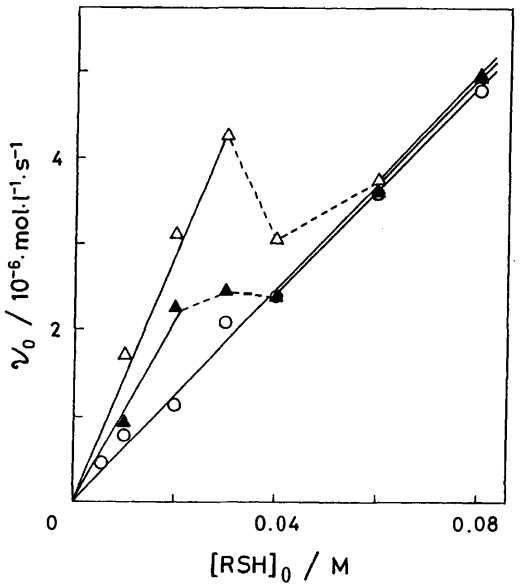


Fig. 1. Dependence of overall initial rates (v_0) for oxidation of 1:1 mixtures of **1** and **2** on initial concentrations of the thiols ([RSH]$_0$) in MeCN at 35.0°C. [RSH]$_0$=[**1**]$_0$+[**2**]$_0$; [Et_3N]=2.0×10^{-3} M. ▲, **1** and **2a**; △, **1** and **2b**; ○, **1** and **2c**.

Figure 1 plots the overall initial rates (v_0) — average rates until 5% consumption of thiols — for oxidation of 1:1 mixtures of **1** and **2** against the initial concentrations of the thiols ([RSH]$_0$) in oxygen-saturated acetonitrile (MeCN) at the fixed concentration of triethylamine (Et_3N) as a catalyst (35.0 °C). The v_0 for a cyclohexyl (c-C_6H_{11}) group used as R increases linearly with increasing [RSH]$_0$. On the other hand, for n-hexyl and isohexyl groups as R there exist concentration regions where the v_0 remains almost unaltered with [RSH]$_0$ (0.02—0.04 M (1 M=1 mol dm^{-3})) and decreases with increasing [RSH]$_0$ (0.03—0.04 M), respectively.

The concentration-initial rate profiles were further investigated in ethanol (Fig. 2). The v_0 for R=n-C_6H_{13} has proved to decrease with increasing [RSH]$_0$ in the 0.02—0.03 M range. In contrast, for R=c-C_6H_{11} the v_0 seems not to show appreciable changes in the 0.02—0.04 M range.

It appears that a deviation from a straight line in the concentration-initial rate profiles (Figs. 1 and 2) becomes more remarkable in EtOH than in MeCN: for R=c-C_6H_{11} a "normal linear" profile in MeCN changes into a "plateau" one in EtOH, for R=n-C_6H_{13} a "plateau" profile in MeCN changing into a "decrease" one in EtOH.

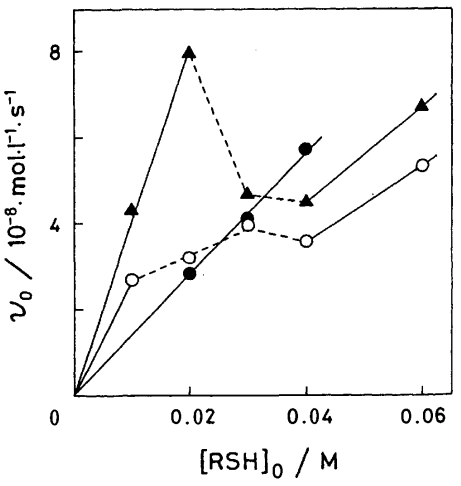

Fig. 2. Dependence of overall initial rates (v_0) for oxidation of 1:1 mixtures of **1** and **2** (or **3** and **4**) on initial concentrations of the thiols ([RSH]$_0$) in EtOH at 35.0°C. [RSH]$_0$=[**1**]$_0$+[**2**]$_0$ (or [**3**]$_0$+[**4**]$_0$); [Et_3N]=2.0×10^{-3} M. ▲, **1** and **2a**; ○, **1** and **2c**; ●, **3** and **4**.

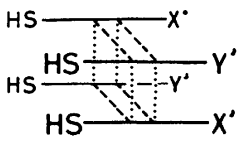

5

Fig. 3. Association scheme in a typical tetramer **5**. ----, Hydrogen bonds in dimers; ·····, noncovalent weak interactions responsible for stabilization of tetramers. The symbols X' and Y' represent Ph and R, respectively.

The $[RSH]_0$-v_0 plot for a pair of nonassociating thiols (**3** and **4**) shows a straight line in EtOH (Fig. 2). This control experiment demonstrates that "rate decrease" occurs for the associating thiols (**1** and **2**).

$HSCH_2CO_2C_2H_5$ $HSCH_2CH_2OH$

3 **4**

Thiols **1** and **2** have been shown to associate strongly with each other as well as with themselves in $CDCl_3$ via two NH···O intermolecular hydrogen bonds between the inner -NHCO- units in the -CONHCONH- group to form tetramers (reaction intermediates) such as **5** (Fig. 3).[1b,1c,5] In an attempt to elucidate the relationship between intermolecular association and the observed kinetic behavior, the following two experiments were carried out. First, NMR spectra of 1:1 mixtures of thiols **1** and **2b** were measured under nearly the same conditions as for the oxidation [i.e., at total concentrations of **1** and **2b** ($[RSH]$)=0.020, 0.030, and 0.040 M in CD_3CN at 35 °C].[6] The chemical shifts for the NH^{β} and NH^{δ} protons, which participate in intramolecular hydrogen bonds, remain constant [δ 10.28 (H^{β}) and 8.54 (H^{δ})] with [RSH], whereas the NH^{α} and NH^{γ} protons, which participate in intermolecular hydrogen bonds, undergo slight downfield shifts with increasing [RSH] from δ 8.69 to 8.74 (H^{α}) and from 8.27 to 8.33 (H^{γ}). Second, plots of $\ln([RSH]/[RSH]_0)$ against time in MeCN at 35.0 °C (Fig. 4) have revealed that oxidation of **1** and **2b** at $[RSH]_0$=0.020[4] and 0.030 M follows pseudo first-order kinetics, whereas at $[RSH]_0$=0.040 M an upward curvature is observed.[7] Though these results appear to be related to the unusual kinetic behavior mentioned above, it is difficult to explain the behavior by them.

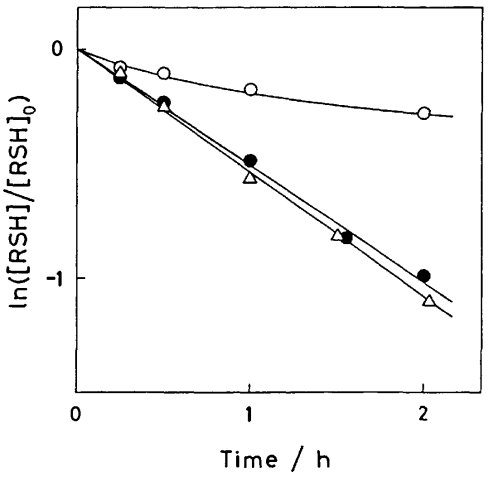

Fig. 4. First-order kinetic plots for oxidation of 1:1 mixtures of **1** and **2b** in MeCN at 35.0 °C. $[RSH]_0$=$[\mathbf{1}]_0$+$[\mathbf{2}]_0$; $[Et_3N]$=2.0×10^{-3} M. △, $[RSH]_0$=2.0×10^{-2} M; ●, $[RSH]_0$=3.0×10^{-2} M; ○, $[RSH]_0$=4.0×10^{-2} M.

From the experimental evidence presented here, it seems reasonable to conclude that intermolecular association is responsible for the unusual concentration-initial rate profiles for the oxidation.

Experimental

The melting points were uncorrected. ^1H NMR (270 MHz) spectra were measured on a JEOL GX-270 spectrometer using tetramethylsilane as an internal standard. The mass spectra were taken on a Hitachi RMU-6M mass spectrometer.

Materials. Organic solvents were dried by proper procedures,[8] and purified by distillation. Water was purified through Millipore Milli-Q water purification system followed by distillation. The iodine solution (0.001 M) containing potassium iodide (0.005 M) was titrated with 1.00×10^{-3} M aqueous sodium arsenite standard solution before use.

Thiol **1** was prepared as described previously,[1b] recrystallized from benzene-hexane, and had the following properties: Mp 127—128 °C; ^1H NMR (CD_3CN) δ=2.34 (1H, s), 3.34 (2H, s), 7.11 (1H, t, J=7 Hz), 7.33 (2H, dd, J=7 and 8 Hz), 7.51 (2H, d, J=8 Hz), 8.70 (1H, s, NH^{α}), 10.27 (1H, s, NH^{β}). Found: C, 51.32; H, 4.77; N, 13.21; S, 15.24%; M^+, 210. Calcd for $C_9H_{10}N_2O_2S$: C, 51.41; H, 4.79; N, 13.32; S, 15.25%; M, 210.

Thiols **2** were prepared as described before,[1b,9] and had the following properties.

2b: Mp 102.5—103.0°C (hexane-ether); ^1H NMR (CD_3CN) δ=0.88 (6H, d, J=6 Hz), 1.15—1.24 (2H, m), 1.50—1.65 (4H, m), 2.27 (2H, t, J=7 Hz), 2.60—2.68 (2H, m), 3.35—3.42 (2H, m), 8.38 (1H, s, NH^{γ}), 8.53 (1H, s, NH^{δ}). Found: C, 51.98; H, 8.55; N, 12.09; S, 13.99%; M^+, 232. Calcd for $C_{10}H_{20}N_2O_2S$: C, 51.70; H, 8.68; N, 12.06; S, 13.78%; M, 232.

2c: Mp 147—148 °C (ether); ^1H NMR (CD_3CN) δ=1.23—2.30 (11H, m), 2.60—2.68 (2H, m), 3.34—3.42 (2H, m), 8.34 (1H, s), 8.58 (1H, s). Found: C, 52.22; H, 7.94; N, 12.14; S, 13.80%; M^+, 230. Calcd for $C_{10}H_{18}N_2O_2S$: C, 52.15; H, 7.88; N, 12.16; S, 13.92%; M, 230.

Other thiols and Et_3N were purified by distillation through a fractionating column.

Kinetics. Equimolar amounts of the two thiols [**1** and **2** (or **3** and **4**)] were weighed into a two-necked flask, and dissolved in 10.00 ml of the reaction solvent. The solution was stirred under an oxygen atmosphere for at least 4 h in a well-stirred water bath thermostated to ±0.1 °C. Oxidation of thiols was negligible in the absence of Et_3N. At time zero, 2.0×10^{-5} mol of Et_3N was added to the solution with a microsyringe, and time measurement was begun. At appropriate time intervals, a 0.50 ml portion of the reaction mixture was pipetted out, and quenched in 5 ml of a 1:9 mixture of 3 M hydrochloric acid with the solvent. The amount of remaining thiols in the quenched solution was then determined by titration with the 0.001 M iodine solution. Each plot in Figs. 1 and 2 represents the average of generally six, or more runs.

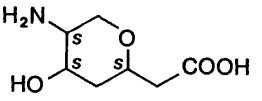
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received October 9, 1987)

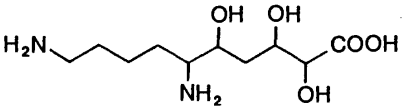
Synopsis. A new amino acid named galantinamic acid was found as one of the constituent amino acids in a peptide antibiotic galantin I. The primary structure of galantinamic acid was determined chemically and spectrometrically to be 6,10-diamino-2,3,5-trihydroxydecanoic acid.

A peptide antibiotic galantin I was isolated from a culture broth of *Bacillus pulvifaciens* by Shoji et al.[1] The structure of galantin I was determined as shown in Fig. 1, in which we recognized two new amino acids, i.e., galantinic acid (**1**) and galantinamic acid (**2**).[2] An absolute structure of galantinic acid was determined chemically, spectrometrically,[3] and finally synthetically[4] to be (2*S*,4*S*,5*S*)-5-amino-2-carboxymethyl-4-hydroxytetrahydropyran. In this paper, we describe the determination of primary structure of galantinamic acid.

An isolation of galantinamic acid was carried out by ion-exchange column chromatography of the acid hydrolyzate of galantin I. For preparation of galantinamic acid, the acid hydrolysis of the peptide was ceased for 10 h in order to avoid an easy decomposition of this amino acid during the hydrolysis.[5] The observed pK_a values, 3.2, 8.7, and 10.5, for galantinamic acid suggested that this amino acid must be a diamino monocarboxylic acid but not an α-amino acid whose pK_1' value is generally around 2.4. The molecular formula of galantinamic acid was deduced to be $C_{10}H_{22}N_2O_5$ from the results of an elemental analysis and a determination of molecular weight by FD-MS spectrometry (m/z=251 $(M+H)^+$). This fact suggested the presence of three hydroxyl, two amino and one carboxyl groups in the molecule.



1 Galantinic acid



2 Galantinamic acid

The result of ^{1}H NMR analysis of galantinamic acid was summarized in Table 1. Four methine carbon atoms must carry OH or NH_2 as judged from the values of chemical shifts of their protons. Of these methine proton signals, a characteristic one appearing as doublet at δ 3.91 was first assigned to be α-methine proton connected to a carboxyl group suggesting us a presence of a partial structure such as -CH(**Y**)-CH(**X**)-COOH (**X**,**Y**=OH or NH_2). Since galantinamic acid is not an α-amino acid as described above, **X** is now deduced to be OH. The other proton at the highest field (δ 3.39) was assigned to be -CH(NH_2)-, since an irradiation to this proton caused a collapse at regions of two methine protons centered at δ 4.13 and of methylene protons centered at about δ 1.8 corresponding to -C-CH_2-C-. However, this proton did not couple with α-methine proton at δ 3.91. Thus, we could assign OH for **Y** to lead another partial structures of -C-CH_2-CH(NH_2)-CH(OH)- as well as -CH(OH)-CH(OH)-COOH. Furthermore, methylene signal at δ 3.01 was assigned to be NH_2CH_2- adjacent to -CH_2-C- type of methylene from the value of chemical shift and the coupling mode.

When we prepared *N*-benzoyl derivative of galantinamic acid, the IR spectrum of the derivative showed the absorption at 1735 cm^{-1} corresponding to ester or δ-lactone. Since there was no possibility of ester formation, δ-lactone was assumed to be formed under the acidic conditions after the *N*-benzoylation. Therefore, a partial structure can now be extended to -CH(OH)-

Table 1. ^{1}H NMR of Galantinamic Acid in D_2O

δ	Multiplicity	Supposed partial structure
1.8 (8H)	Multiplet	-C-**CH_2**-C- (×4)
3.01 (2H)	Triplet	-C-**CH_2**-N-
3.39 (1H)	Multiplet	-**CH_2**-N-
3.91 (1H)	Doublet	-CH-**CH**-COOH
4.13 (2H)	Multiplet	-**CH**-O- (×2)

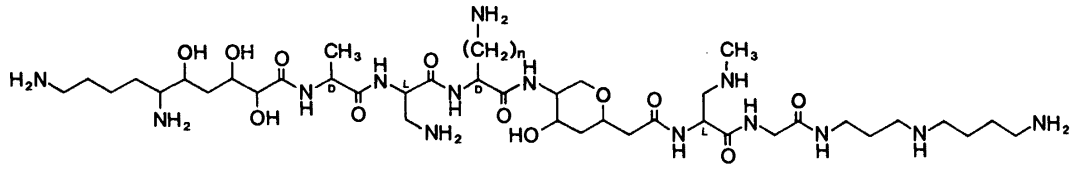


Fig. 1. The structure of galantin I which is a mixture of two congeners. Lysine (n=4) and ornithine (n=3) are found in a ratio of 9:1.

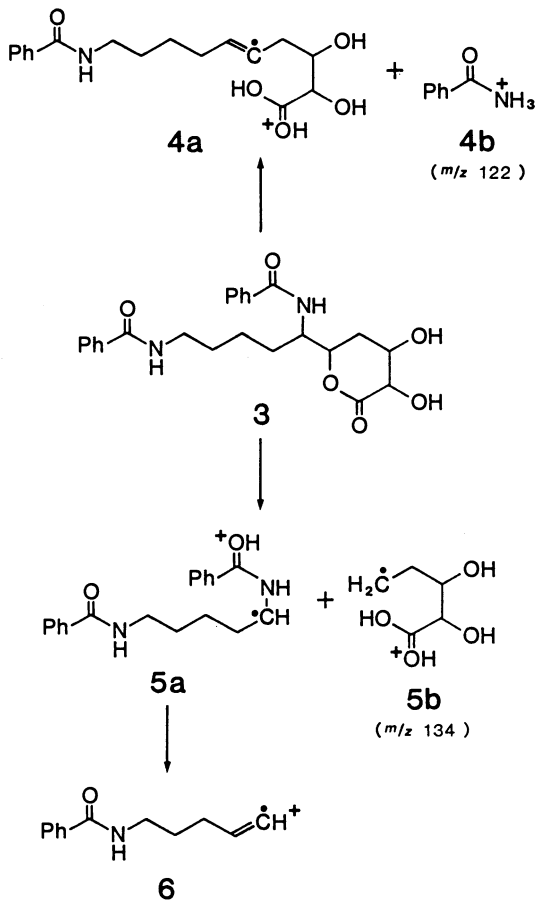

Fig. 2. Significant fragment ions observed in EI-MS spectrum of *N,N'*-dibenzoylgalantinamic acid lactone (**3**). The masses of fragments **4a**, **5a**, and **6** were exactly measured by high resolution method as summarized in Table 2.

Table 2. The Results of High-Resolution Mass Sprctrometry of Fragments **4a**, **5a**, and **6**.

Fragment	Molecular formula	EI-MS	
		Observed (*m/z*)	Calcd (M)
4a	$C_{17}H_{23}NO_5$	321.1590	321.1577
5a	$C_{19}H_{22}N_2O_2$	310.1710	310.1683
6	$C_{12}H_{14}NO$	188.1055	188.1076

C-CH(OH)-CH(OH)-COOH. As the results of above considerations, we can propose a following whole structure of galantinamic acid:

$NH_2CH_2CH_2CH_2CH_2CH(NH_2)$-
$CH(OH)CH_2CH(OH)CH(OH)COOH$.

The proposed structure was then confirmed chemically and spectrometrically. First, periodic acid oxidation followed by permanganate oxidation produced 5-aminovaleric acid which was derived from a part of $NH_2CH_2CH_2CH_2CH_2CH(NH_2)CH(OH)$-. Secondly, a study of high resolution EI-mass spectrometry of *N,N'*-dibenzoylgalantinamic acid lactone (**3**) gave quite important informations as shown in Fig. 2 and Table 2. For example, a fragment ion **5a** corresponding to $PhCONHCH_2CH_2CH_2CH_2CHNHC(=OH)^+Ph$ (*m/z* 310.1710) showed consistency with the molecular weight calculated as $C_{19}H_{22}N_2O_2$ (*m/z* 310.1683). Another two fragments, **4a** and **6**, also supported the proposed structure.

As described above, we could determine the primary structure of galantinamic acid, albeit the absolute structure was not assigned yet.[6]

Experimental

The NMR spectra were obtained with Varian XL-100-15 spectrometer for ^1H and JEOL JNM-FX-90Q spectrometer for ^{13}C in D_2O or CD_3OD. Sodium 2,2-dimethyl-2-silapentane-5-sulfonate was used as an external standard in D_2O or tetramethylsilane as an internal standard in CD_3OD. The chemical shifts were given in δ-value (ppm) from the standard. FD and EI mass spectra were measured with a JEOL JMS-O1SG-2 mass spectrometer. Amino acid analysis was carried out with a Hitachi KLA-5 amino acid analyzer.

Isolation of Galantinamic Acid. The acid hydrolyzate of galantin I (1.76 g)[3] was subjected to column chromatography over Amberlite IRC-50 (100—200 mesh, NH_4^+ form, 1.5×140 cm). Neutral amino acids were first eluted from the column by a gradient elution with 0.1—1.5% aqueous ammonia (1L). Basic amino acids were next separated by use of 1.5—5.6% aqueous ammonia (1L). The fractions containing galantinamic acid were concentrated in vacuo to obtain 160 mg of the crude material as hygroscopic powder. A part of crude galantinamic acid (110 mg) was dissolved in water and pH of the solution was adjusted to 6.5 with 0.01M HCl (1M=1 mol dm^{-3}). The neutralized solution was once concentrated in vacuo. To a solution of the residue in a small amount of water was added methanol. The methanolic solution was kept in a refrigerator to precipitate crystalline hydrochloride of galantinamic acid, yield 78 mg, mp 207.5—209 °C (decomp), $[\alpha]_D^{22}$ −0.4° (*c* 0.5, 1M HCl), amino acid analysis: 34 min (7.5 cm column, Hitachi #2611 resin, 0.35M citrate buffer (pH 5.28)). ^{13}C NMR (D_2O) δ=22.72 (C_8), 26.89 (C_9), 27.16 (C_7), 35.28 (C_4), 39.73 (C_{10}), 56.56 (C_6), 67.57 (C_5), 68.96 (C_3), 74.36 (C_2), 176.07 (C_1).

Found: C, 41.53; H, 8.23; N, 9.64; Cl, 12.10%. Calcd for $C_{10}H_{22}N_2O_5 \cdot HCl$: C, 41.88; H, 8.10; N, 9.77; Cl, 12.36%.

***N,N'*-Dibenzoylgalantinamic Acid δ-Lactone.** To a solution of free galantinamic acid (33 mg, 0.13 mmol) in water (4 mL) were added aqueous Na_2CO_3 (110 mg in 2 mL of H_2O) and benzoyl chloride gradually. A progress of the reaction was checked by TLC and addition of reagents was continued until the starting material disappeared. The alkaline solution was extracted with ether and ethyl acetate. Aqueous layer acidified with 1M HCl was extracted with ether twice and then concentrated in vacuo until colorless crystals deposited out. Crude product thus obtained was recrystallized from water, yield 42 mg (70%), mp 117.5—119.5°C. FD-MS: *m/z* 441 $[(M+H)^+]$, ^1H NMR(CD_3OD) δ=1.4—2.0 (m, 2H×4); 3.40 (t, 2H); 3.8—4.3 (m, 1H×4); 7.4 (m, 6H); 7.8 (m, 4H), IR (KBr): 1540, 1635, 1735 cm^{-1}.

Periodic-Permanganate Oxidation of Galantinamic Acid. To a solution of galantinamic acid (1.3 mg, 5.2 μmol) in 0.5 ml of water was added periodic acid ($HIO_4 \cdot 2H_2O$, 3.0 mg, 13 μmol) and the mixture was allowed to stand overnight at room temperature. To the solution was added 0.2% potassium permanganate solution until pale purple color remained. A small amount of MnO_2 was filtered off and the filtrate was used for TLC or amino acid analysis.

The authors wish to express their thanks to Dr. Junichi Shoji, Shionogi Research Laboratory,

Shionogi & Co. Ltd., for his generous supply of galantin I. We are grateful to Dr. Yasufumi Ohfune, Suntory Institute for Bioorganic Research, for his kind information about the synthetic study of galantinamic acid.

Asymmetric Catalytic Hydrogenations of Oximes and Benzylimino Derivatives of Chiral Pyruvamides

Toratane MUNEGUMI and Kaoru HARADA*
Department of Chemistry, University of Tsukuba, Tennoudai, Tsukuba, Ibaraki 305
(Received November 6, 1987)

Synopsis. Oximes and benzylimino derivatives of chiral pyruvamides were hydrogenated over palladium hydroxide on charcoal in several solvents. Oximes of pyruvamides containing (*R*)-α-ethylbenzylamine as a chiral source gave (*S*)-alanine in excess (up to 70% e.e.) through the hydrolyses of the hydrogenated products.

In the previous study,[1] oximes of benzoylformamides whose chiral centers were (*S*)-α-methylbenzylamine, were hydrogenated over palladium on charcoal and then hydrolyzed to afford (*S*)-phenylglycine in a low e.e. (5.5%). On the other hand, the catalytic hydrogenations of chiral pyruvamides have given *N*-(*S*)-lactoyl-(*S*)-α-alkylbenzylamine with good asymmetric yields (up to 62%).[2] In the asymmetric catalytic hydrogenations, it was found that α-alkylbenzylamines were useful chiral moieties to stabilize the "chelated intermediates"[3] as shown in Fig. 1. However, asymmetric catalytic hydrogenations of oximes and Schiff bases of pyruvamides whose chiral centers are α-alkylbenzylamines have not been studied.

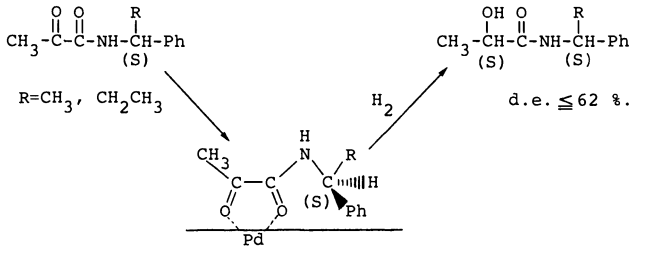

Fig. 1. Possible steric course in the catalytic hydrogenations of chiral pyruvamides **3a**, **b**.[3] d.e.: diastereoisomeric excess.

In this paper, we wish to report on the results of the asymmetric catalytic hydrogenations of oximes **5a—c** and Schiff bases **5d—f** of pyruvamides over palladium hydroxide on charcoal. Substrates **5a—f** were prepared as shown in Scheme 1. The catalytic hydrogenations were carried out in several solvents at 30 °C. After hydrolyses of the hydrogenated products, the chemical yields of alanine were determined by amino acid analyses and the enantiomeric excess (e.e.) were determined by gas chromatographic separation of the derivatized DL-alanine[*N*-(trifluoroacetyl)alanine isopropyl ester].

Results and Discussion

The results of the catalytic hydrogenations are shown in Table 1. Substrates **5a**, **b** whose chiral sources were (*S*)-amine and (*R*)-amine, gave (*R*)-alanine and (*S*)-alanine in excess respectively after hydrolyses of hydrogenated products. Substrate **5b** gave higher e.e. (up to 70%) than **5a** gave. Substrate **5c** whose chiral source was (*R*)-amine gave (*S*)-alanine with low e.e. These results suggested that the asymmetric induction was affected by the difference of the bulkiness between H and R groups bonded to the chiral carbon in the substrate molecules. There are two possible steric courses through which oximes **5a** give (*R*)-alanine. Those are steric course A (non-chelation mechanism) and B (chelation mechanism) as shown in Fig. 2.[4] In the first step (A-1) of the steric course A, the carbonyl and the imino groups take s-trans conformation owing to their electrostatic repulsion, and the H and R groups which are bonded to the chiral carbon interpose the NH group. The substrate molecule taking

a) Configuration of chiral amine in the amide moiety. b) Configuration of alanine.

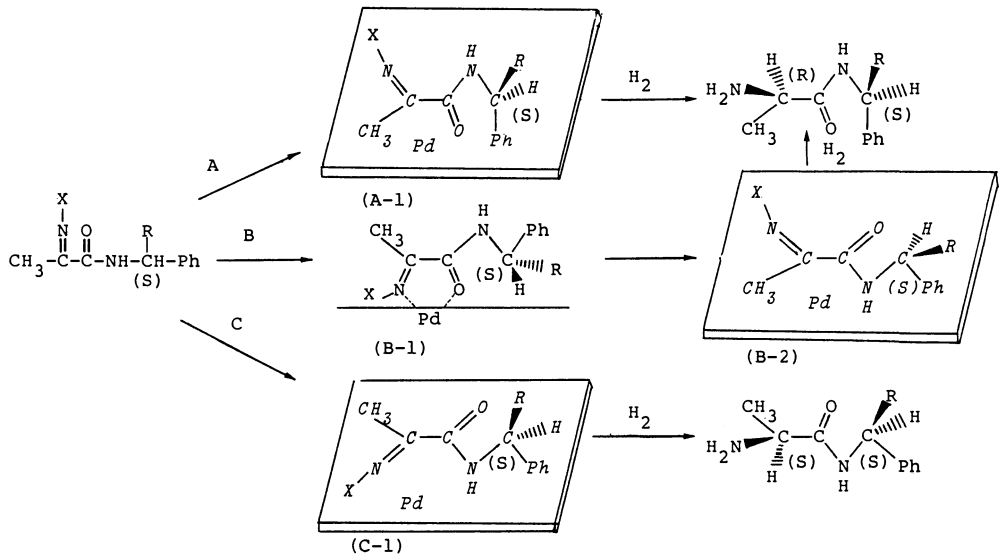

Fig. 2. Possible steric courses in the catalytic hydrogenations of oximes **5a—c** and *N*-benzylimino derivatives **5d, f.** X=OH, OCH_2Ph, CH_2Ph, CH(Me)Ph.

this conformation could be adsorbed on the palladium surface at the less bulky side of the molecule, and be hydrogenated from the catalyst side to give (*R*)-alanyl-(*S*)-amine. However, the steric course A seemed to contribute little to the asymmetric induction, since A-1 would be unstable due to the steric repulsion between C=O and Ph groups.

On the other hand, the steric course B could explain the stereochemistry of the catalytic hydrogenations. In the first step (B-1), the substrate molecule would stand on the catalyst surface by the carbonyl and oxime groups to form the "chelated intermediate," and the H and R groups interpose the carbonyl group as shown in Fig. 2. In the second step (B-2), the intermediate would be adsorbed at the less bulky side of the substrate on the catalyst, and then hydrogenated from the catalyst side to afford (*R*)-alanyl-(*S*)-amine. The steric course B could explain that the asymmetric induction in the catalytic hydrogenations was caused by the difference of the bulkiness between H and R groups of the asymmetric moiety.

The conformation around the N-C (chiral carbon)

bond of the "chelated intermediate" (B-1) is different from that in Fig. 1, which has been proposed[3] for the hydrogenation of pyruvamides **3a**, **b**. Since the bond length of α-carbonyl group(-C=O) of **3a**, **b** is shorter than that of oxime group (-C=N-OH) of **5a**, **b**, the space between the catalyst and the asymmetric moiety of **5a**, **b** is smaller than that of **3a**, **b**. Therefore, the H and R groups would prefer to interpose the amide carbonyl as shown in B-1 in Fig. 2. The low ee of alanine obtained from substrates **5c**, **d** could also be explained by the steric course B and C. The population of the substrate molecule which passes through the steric course B could be much smaller in the hydrogenations of substrates **5c**, **d** than **5a**, **b**, because the OCH_2Ph and CH_2Ph groups in the imino moiety would disturb the formation of the stable "chelated intermediates." And a part of the substrate molecules would pass through the steric course C rather than B, and afford (*S*)-alanine with low ee.

Although substrates **5e**, **f** have two chiral centers in the amide moiety(*R*) and the imino moiety[(*S*) or (*R*)], these substrates **5e**, **f** gave alanine with low ee. These low ee could also be explained by the instabilization of the "chelated intermediate" like in substrates **5c**, **d**.

In this study, the steric course in the catalytic hydrogenations of oximes **5a**, **c** and *N*-benzylimino derivatives **5d**, **f** of the chiral pyruvamides could be explained by the chelation mechanism. And a maximum ee (70%) of (*S*)-alanine was obtained in the hydrolysis of the hydrogenated product of substrate **5b** in methanol.

Experimental

The melting points were uncorrected. The optical rotations were measured with a Jasco DIP-181 Digital Polarimeter. The gas chromatographic analyses were carried out with a Hitachi 163 gas chromatograph, and the peaks on the chromatograms were integrated with a Sic Chromatocoda II. NMR spectra were measured with a Hitachi R-24 High Resolution NMR spectrometer. IR spectra were measured with a Hitachi 260-50 infrared spectrometer. Palladium hydroxide (10%) on charcoal were prepared by the similar manner in the literature.[5]

Materials. Chiral amines **2a** and **2c** were purchased from Aldrich chemical Co. **2a**. $[\alpha]_D^{20}$ −39.0 (neat), 96% ee[6] **2c**. $[\alpha]_D^{20}$ +39.0 (neat), 96% ee[6] **2b**. $[\alpha]_D^{17}$ +19.0 (neat) 95% ee.[7]

***N*-Pyruvoyl Amines 3a, b.** **3a**, **b** were prepared by the manner in the literature.[2]

Oximes of *N*-Pyruvoyl Amines 5a—c. Pyruvamides **3a** (1.03 g, 10 mmol) and hydroxylamine hydrochloride (2.08 g, 30 mmol) were dissolved in a mixture of ethanol and pyridine. The solution was refluxed for 3 h. The reaction mixture was evaporated in vacuo to dryness. The residue was redissolved in water (20 ml) and the solution was extracted with three 20 ml portions of ethyl acetate. The ethyl acetate layer was dried with anhydrous magnesium sulfate and was evaporated to give oily product. The oily product was purified with silica-gel column chromatography (benzene-ethyl acetate (5 : 1)) to give 1.13 g **5a** (55%). Calcd for $C_{18}H_{20}N_2O_2$: C, 72.94; H, 6.80; N, 9.45%. Found: C, 72.87; H, 6.83; N, 9.41%. $[\alpha]_D^{20}$ −63.4 (*c* 1.03, methanol).

***N*-(2-Imino-1-oxopropyl) Amines 5d—f.** *N*-Pyruvoylamines **3c**, **d** (20 mg, 0.1 mmol) and benzylamine (50 μl, 0.46 mmol) were dissolved in dry benzene. The solution was stirred over anhydrous magnesium sulfate (600 mg) for 24 h. After drying agent was filtered off, the resulting filtrate was evaporated to dryness.

Catalytic Hydrogenation of Substrates 5a—f. Substrates **5a—f** (0.1 mmol) were dissolved in 3 ml of methanol, ethanol, 2-propanol, and ethyl acetate, and were hydrogenated over 10% palladium hydroxide on charcoal. After one to seven day's reaction at 30°C, the catalyst was filtered off and the filtrate was evaporated to dryness. The residue was used for hydrolysis without further purification.

Hydrolysis of Hydrogenated Products. The residue obtained by the evaporation of the hydrogenated product was hydrolyzed in 6M HCl (1M=1 mol dm^{-3}) for 12 h.

Determination of Chemical Yield and Enantiomeric Excess of Alanine. Chemical yields of alanine were determined by means of an amino acid analyzer. Enantiomeric excess of alanine was determined by the resolution of derivatized enatiomers of alanine [*N*-(trifluoroacetyl)alanine isopropyl ester) using a gas liquid chromatography equipped with a chiral glass capillary column (Chirasil-Val).[8]

Catalytic Activity of *catena*-μ-Cyano-(phthalocyaninato)cobalt(III) for the Cathodic Reduction of Oxygen

Osamu IKEDA,†,* Shuji ITOH, and Hiroshi YONEYAMA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, 2-1 Yamadaoka, Suita, Osaka 565
(Received August 28, 1987)

Synopsis. *catena*-μ-Cyano-(phthalocyaninato)cobalt(III) showed a 4-electron reducibility for the cathodic reduction of oxygen at low overpotentials, which was not observed for (phthalocyaninato)cobalt(II) and chloro(phthalocyaninato)-cobalt(III).

Many of metal complexes of phthalocyanine, porphyrin and tetraazaannulene possess electrocatalytic activities for the cathodic reduction of oxygen. However, most of them catalyze the 2-electron pathway ($O_2+H_2O+2e^-\rightarrow HO_2^-+OH^-$). Therefore, the conversion of the 2-electron pathway to the 4-electron pathway ($O_2+2H_2O+4e^-\rightarrow 4OH^-$) has been tried by means of molecular designs; The preparations of face-to-face or cofacial porphyrins[1,2] and a planar binuclear complex[3] are typical examples. In the present study, catalytic activities of *catena*-μ-cyano-(phthalocyaninato)-cobalt(III) ($[Co^{III}(pc)CN]_n$), which has a stacked structure bridged by cyanide ions[4] as shown in Fig. 1, have been investigated to examine the effect of molecular designs.

Experimental

$[Co^{III}(pc)CN]_n$ was prepared from $Co^{II}(pc)$ via dichloro-(phthalocyaninato)cobal(III) $[Co^{III}(pc)(Cl)_2]$ and then via dicyano (phthalocyaninato)cobalt(III) $[Co^{III}(pc)(CN)_2]$.[4] $Co^{III}(pc)Cl$ was obtained by the thermal decomposition of $[Co^{III}(pc)(Cl)_2]$ in Ar atmosphere at 320 °C.[5] The formation of catenary $[Co^{III}(pc)CN]_n$ was confirmed by an IR spectrum ($\nu_{C\equiv N}$=2158 cm^{-1}) and a high conductivity ($\sigma=2\times10^{-3}$ $S\,cm^{-1}$)[5] of the resulting powders.

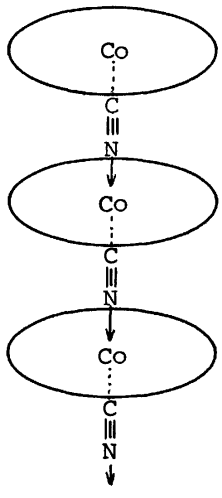

Fig. 1. Stacked structure of $[Co^{III}(pc)CN]_n$. Ellipses represent the phthalocyanine ring (pc(−2)).

(Phthalocyaninato)cobalt-coated disc electrodes were prepared by coating with use of a microsyringe *N,N*-dimethylacetamide (DMA) solutions containing either one of the above-mentioned (phthalocyaninato)cobalts onto a top surface of a glassy carbon rod (Tokai Carbon GC20; 6 mm diameter and 10 mm length) preheated to 80 °C on a hot plate. The amount of coating was 2×10^{-7} mol cm^{-2} for all cases. The GC rod was then installed into the disc cavity of a ring-disc electrode. The potential of the Pt ring was fixed to 0.3 V vs. SCE, where diffusion limiting currents due to oxidation of peroxide ions (HO_2^-) as a reduction intermediate of oxygen were observed. Aqueous 1 M (=mol dm^{-3}) KOH was used as the electrolytic solution.

Results and Discussion

Axial ligands of metallomacrocycles are apt to exchange with other competing ligands. In fact, $[Co^{III}(pc)CN]_n$ is known to be decomposed by organic bases (L) such as pyridine and piperadine to give monemeric $Co^{III}(pc)(CN)L$.[4] Since the catalytic activities for oxygen reduction were studied in an alkaline solution, it was then examined whether or not the phthalocyanines used were decomposed in contact with hydroxide ions. For this purpose, visible light absorption spectra were measured before and after addition of 1 M KOH to the DMA solutions of $Co^{III}(pc)Cl$ and $[Co^{III}(pc)CN]_n$, and before and after immersion of $[Co^{III}(pc)CN]_n$ and $Co^{III}(pc)Cl$-coated quartz plates into 1 M KOH. $Co^{III}(pc)Cl$ showed a spectrum change both in the DMA solution and in the coated films, suggesting that $Co^{III}(pc)Cl$ changed into $Co^{III}(pc)OH$ in the presence of OH^-. On the other hand, the spectra of $[Co^{III}(pc)CN]_n$ were little changed by contact with OH^-, suggesting that the Co-CN-Co bond is stable against OH^-. The stability of the axial ligand or the strength of the ligand-metal bond seems to roughly correspond to spectrochemical series for Co^{III}-complexes ($Cl^-<OH^-\ll CN^-$).

Figure 2 shows disc currents and ring currents of the rotating ring-disc electrodes as a function of the disc potential in oxygen-saturated 1 M KOH. There are differences in the electrochemical behaviors of the three kinds of (phtalocyaninato)cobalts at rising portion of the disc currents. In the case of $Co^{II}(pc)$ and $Co^{III}(pc)Cl$, though the actual form of the latter will be $Co^{III}(pc)OH$, disc and ring currents have the same onset potential. In the case of $[Co^{III}(pc)CN]_n$, however, there are negligible ring currents in an onset potential region of the disc currents. The results seem to suggest that oxygen is reduced to OH^- through the 4-electron pathway at the $[Co^{III}(pc)CN]_n$ but not at the $Co^{II}(pc)$ and $Co^{III}(pc)Cl$ electrodes.

In order to evaluate the 4-electron reducibility of the three kinds of (phtalocyaninato)cobalts, the apparent

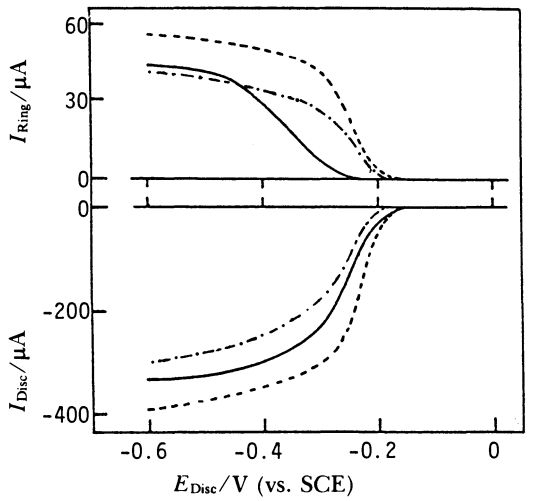

Fig. 2. Disc currents and ring currents at the ring(Pt)-disc(GC) coated with (----) Co^{II}(pc), (-·-·-) Co^{III}(pc)Cl, and (——) $[Co^{III}(pc)CN]_n$ electrodes as a function of disc potential in O_2-saturated 1 M KOH. Rotation rate, 1000 rpm; ring potential, 0.3 V vs. SCE; sweep rate at the disc, 20 mV s^{-1}; the disc area, 0.28 cm^2.

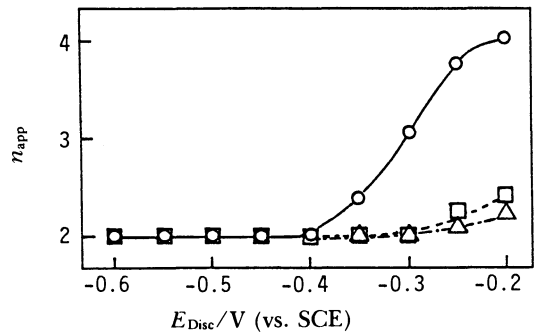

Fig. 3. Variation of n_{app} (apparent number of electrons involved in O_2 reduction) with disc potential for (○) $[Co^{III}(pc)CN]_n$, (△) Co^{III}(pc)Cl, and (□) Co^{II}(pc), respectively.

number of electrons involved in the oxygen reduction (n_{app}) was determined as a function of the disc electrode potentials. In the determination n_{app}, it was assumed that the O_2 reduction at the disc consisted of a mixed reaction of the 2-and 4-electron pathways. Thus, n_{app} was evaluated by the next relation: $n_{app}=4I_{Disc}/(I_{Disc}+I_{Ring}/N_{corr})$, where I_{Disc} and I_{Ring} are the disc and ring currents at a potential, respectively, and N_{corr} is the collection efficiency for HO_2^-, corrected for a deviation from coplanality between the Pt ring and the (phtalocyaninato)cobalt-coated disc.[4] The results are shown in Fig. 3. It is obvious from this figure that catenary $[Co^{III}(pc)CN]_n$ has a high 4-electron reducibility compared with monomeric Co^{II}(pc) and Co^{III}-(pc)Cl for oxygen reduction at low overpotentials.

In order to clarify the participation of redox of metal sites in the above oxygen reduction, the electrochemistry of Co^{II}(pc), Co^{III}(pc)Cl and $[Co^{III}(pc)CN]_n$ was studied by means of cyclic voltammetry of these (phtalocyaninato)cobalt-coated glassy carbon electrodes in deaerated 1 M KOH. However, clear redox peaks were not observed in the cyclic voltammograms between 0 V and −0.6 V vs. SCE for all catalysts. Furthermore, no detectable change was observed in visible absorption spectra of Co^{II}(pc), Co^{III}(pc)Cl, and $[Co^{III}(pc)CN]_n$ on an optically transparent electrode (In_2O_3/quartz) between 0 V and −0.6 V vs. SCE. Each spectrum was almost the same as that at open circuit in 1 M KOH. These results suggest that the oxygen reduction mechanism in the present catalysts is not controlled by the redox of metal sites.

Therefore, the results for oxygen reduction in Figs. 2 and 3 are discussed on the basis of d-electron configuration of cobalt ions and molecular conformation of the phtalocyanines as follows. The effective magnetic moment μ_{eff} of Co^{II}(pc) has been reported to be 2.7 μ_B (Bohr Magneton),[7] and the d-electron configuration of Co(II) is estimated to be $(d_{xy})^2(d\pi)^4(d_z^2)^1$.[8] Exerimental values of μ_{eff} for Co^{III}(pc)Cl and $[Co^{III}(pc)CN]_n$ were 3.1 and 1.0 μ_B, respectively. The spin only equation for magnetically diluted substances roughly predicts that the number of unpaired electrons is 2 for Co^{III}(pc)Cl and 0 for $[Co^{III}(pc)CN]_n$. Consequently, the d-electron configuration of Co^{III}(pc)OH which will be the actual form of Co^{III}(pc)Cl in 1 M KOH, will be the same as that of Co^{III}(pc)Cl, because the ligand field strength would not be so different between Cl^- and OH^-.

Both Co^{II}(pc) and Co^{III}(pc)Cl have an unpaired electron on d_z^2 orbital of the central cobalt ions, which facilitates an interaction with the oxygen $1\pi_g^*$ orbital. This interaction leads to the 2-electron pathway for oxygen reduction through its end-on coordination.[9] The cobalt ion in $[Co^{III}(pc)CN]_n$ has an empty d_z^2 orbital, which offers a favorable condition for the 4-electron pathway, because the σ-coordination of the oxygen $1\pi_u$ electron to the empty cobalt d_z^2 orbital and the π-back donation of d_π electrons to the oxygen $1\pi_g^*$ orbital facilitate the side-on coordination of oxygen.[10] However, such a side-on coordination is expected only at the terminal cobalt ions in the stacked structure of $[Co^{III}(pc)CN]_n$. In order to obtain the observed peculiar effect of the Co-CN-Co bridge for the 4-electron reduction of oxygen, we have to assume that an oxygen makes a bridge type coordination between two cobalt ions.[11] The intermetallic distance separated by the cyanide ions of $[Co(pc)CN]_n$ was estimated to be 4—5 Å, which is fitted well in making the bridge type coordination of oxygen.[1] However, the interaction between a filled d_π orbital or paired electrons and the oxygen $1\pi_g^*$ orbital electron seems to be weak, because the latter has a radical character. The μ_{eff} of $[Co(pc)CN]_n$ was not real zero but 1.0 μ_B, suggesting that there is a small unparing character in the d_π orbital. Probably, this unpairing character allows the bridge type coordination of oxygen leading to the 4-electron pathway, but it may disappear with increasing the overpotential. Thus, the 2-electron pathway becomes predominant.

The potential dependence of n_{app} for $[Co^{III}(pc)CN]_n$ was reproduced even after 100 potential sweep cycles between 0 V and −0.6 V vs. SCE. The result suggests that the molecular conformation of $[Co^{III}(pc)CN]_n$ is

also stable against the potential sweep cycles.

New Description of the Substituent Effect on Electronic Spectra by Means of Substituent Constants. V. n-π^* Transition of Aliphatic Carbonyl Groups

Bunji UNO, Kenji KANO, Noriya HOSOI, and Tanekazu KUBOTA*
Gifu Pharmaceutical University, 5-6-1, Mitahora-higashi, Gifu 502
(Received August 31, 1987)

Synopsis. The substituent (X) effect on the carbonyl n-π^* band of CH_3COX is discussed on the basis of a general equation, theoretically derived in order to express the substituent effect on electronic spectra using substituent constants. The results have been successful and are supported by MO calculations.

In this series[1] we have reported a new description of the substituent effect on the electronic spectra by means of substituent constants, since the theoretical background of this kind study has so far been ambiguous.[1] We have used Eqs. 1 and 2 by focusing special attention on the fact that the substituent effect on the electronic ground and excited states is very different:[2]

$$^{1,3}E^{UV}_{ho\rightarrow lu} = aF + bR + c \quad (1)$$

and

$$^{1,3}E^{UV}_{ho\rightarrow lu} = \alpha\sigma_i + \beta\sigma_\pi^+ + \gamma\sigma_\pi^- + c. \quad (2)$$

Here, F and R are Swain's substituent constants,[3] and σ_i, σ_π^+, and σ_π^- are Yukawa-Tsuno-Sawada's substituent constants.[4] Singlet or triplet transition energy is expressed by $^{1,3}E^{UV}_{ho\rightarrow lu}$, which is mainly contributed from the HOMO→LUMO transition and has the same spectral character in a series of substituents. These equations were derived as an extension of Eq. 3, discussed previously:[5]

$$(E^{oxd}_{1/2} - E^{red}_{1/2}) = k_1 \cdot {}^{1,3}E^{UV}_{ho\rightarrow lu} + k_2. \quad (3)$$

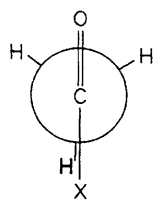
It is noteworthy to point out that the substituent dependence of half-wave oxidation ($E^{oxd}_{1/2}$) and reduction ($E^{red}_{1/2}$) potentials is quite different,[1,5] just as a different behaviour is observed for the substituent effect on the electronic ground and excited states.[2] An important condition is that the various kinds of substituent constants (σ_p, σ_m, σ^+, σ^-, σ^* etc.) reported hitherto can be expressed in the form $[fF+rR+c]$ for aromatic and aliphatic systems, or by $[l\sigma_i+m\sigma_\pi^+ + n\sigma_\pi^-]$ for π-electron systems. The former and the latter are satisfied by employing the substituent constants proposed by Swain[3] and Yukawa-Tsuno-Sawada,[4] respectively. In addition to our foregoing results that the HOMO→LUMO type π-π^* bands, n-π^* bands of aromatic systems, and charge-transfer spectra of EDA complexes well satisfy Eqs. 1 and 2, we report here that the n-π^* band of aliphatic carbonyl groups of the type CH_3COX is also well described by the application of Eq. 1.

Experimental

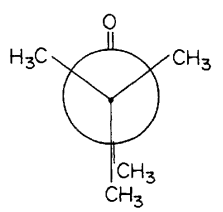
Samples. Here, we have used substances of the type CH_3COX, where X is H, CH_3, C_2H_5, $C(CH_3)_3$, CF_3, Cl, Br, OH, OCH_3, OC_2H_5, $O(CH_2)_2CH_3$, NH_2, $COCH_3$, $COOC_2H_5$. All the samples are commercially available. Special guaranty reagents or spectrograde purity reagents of X=CH_3, C_2H_5, $C(CH_3)_3$, OCH_3, OC_2H_5, $O(CH_2)_2CH_3$ were repeatedly distilled in normal or reduced pressure under a nitrogen atmosphere. Analyzed-grade acetic acid for precise analytical chemistry was used without further treatment. The other samples (X=H, Cl, Br, $COCH_3$, $COOC_2H_5$, CF_3) were all special guaranty reagents and were employed for spectral measurements without further treatment.

Spectral Measurements. These were performed in the usual manner with a Hitachi spectrophotometer, Model 323, at room temperature. In order to make it possible to record the spectra at shorter wavelengths (as much as possible), the inside air in the spectrometer and the cell compartment was replaced with N_2 gas, and a gas stream was maintained during measurements. Although 10- and 2-mm matched quartz cells were usually used for spectral measurements, in the case of samples having a hydrogen bond formation ability, just like acetic acid, we also used quartz cells with long pass lengths, so that diluted solutions of the samples would be possible for recording the spectra; also, the hydrogen bonding effect on n-π^* bands was diminished, since this kind of effect brings about a blue shift of the bands.[2] Nevertheless, the concentration of acetic acid was about 3×10^{-3} mol dm^{-3}. The dimer formation constant of acetic acid was reported as being 2370 in CCl_4,[6] so that about 67% of 3×10^{-3} mol dm^{-3} was still in the dimer form. We then excluded acetic acid from the present regression study. Also, CH_3CONH_2 was not employed here, since it is not only insoluble in heptane, but its n-π^* band is not clearly recorded in CH_3CN, since that band is hidden in the tail of the strong carbonyl π-π^* band.[7] Solvents used were heptane and acetonitrile of spectrograde purity, which were dried over CaH_2 and then carefully distilled.

Molecular Orbital (MO) Calculation. In order to analyze the character of the n-π^* bands of the carbonyl groups we performed a MO calculation by means of the CNDO/S method proposed by the Jaffé and Duke groups.[8] Such parameter values as the Slater exponent (μ), bonding constant ($-\beta_X^0$), one-center repulsion integral (γ_{XX}), ($I_P^S+E_A^S$), and ($I_P^P+E_A^P$) are the same as those employed in our previous papers.[1] The molecular geometries were assumed to be as follows. When X in CH_3COX is alkyl or alkoxyl groups the carbon or oxygen atom in the substituent X, which bonds directly to the C=O group carbon atom, is put in the same plane as that of (H_3)**C-C=O**, where the carbonyl group carbon atom is in sp^2 hybridization ($\angle120°$). The conformation was assumed to be staggerd, as in Form I, and such substitu-



Form I



Form II

ents (X) as *O*-alkyl, $OCOCH_3$, $COCH_3$, $COOC_2H_5$, and alkyl groups are linearly extended in a zig-zag type arrangement, which seems to be in the most reduced steric hindrance. In the case of $X=C(CH_3)_3$ the configuration of Form II was used. All the bond lengths are taken from Ref. 9. The bond angles used are 109°28′, except for the sp^2 carbon atoms with 120°. The substituent effect on n- and π-orbital energies was also checked by ab initio calculations using the 4-31G basis set under the same molecular geometries as mentioned above. CNDO/S calculations were carried out with a FACOM M-382 computer in the Nagoya University Computation Center, the 4-31G ab initio calculations being made with a HITAC M-680 Computer at the Institute for Molecular Science (IMS) using the IMS library program "IMSPACK".

Results and Discussion

The Nature of n-π* Bands of Aliphatic Carbonyl Substances. Aliphatic carbonyl compounds are typical examples that show clearly weak n-π* bands in a near UV region; thus many studies have been made and reported. Nagakura, Baba, McMurry, Kasha, and McConnell first interpreted the electronic structures and spectra of carbonyl substances by means of molecular orbital theory and discussed the substituent and solvent effects on the n-π* bands.[10] They thus gave a theoretical background regarding the experimental facts that n-π* bands bring about a blue shift by the introduction of electron donating substituents, like OH and NH_2, and also in solvents with a hydrogen bonding ability. Many subsequent investigations have supported these results. We discuss the above substituent effect from the viewpoint of substituent constants. The aliphatic ketones employed here clearly exhibit an n-π* band in the near UV region (200—400 nm) with $\varepsilon=10$—60, some typical spectra in heptane being illustrated in Fig. 1. In Table 1 are listed the spectral data and the orbital energies of the n-HOMO and π*-LUMO calculated by an ab initio 4-31G basis set and

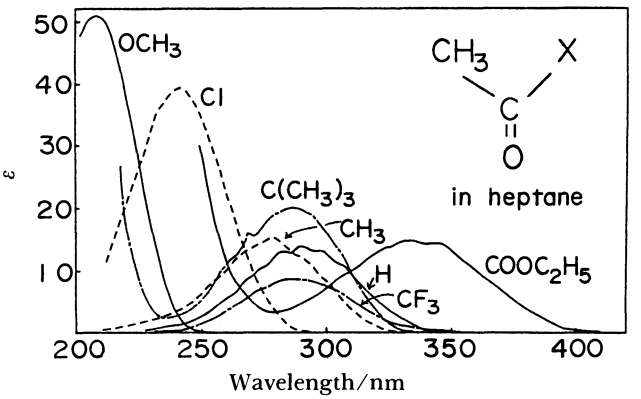


Fig. 1. Absorption spectra of carbonyl n-π* bands of CH_3COX with various substituents X.

the CNDO/S method. The character of the n-π* band of ketones studied was checked by a CNDO/S-CI calculation, which clearly showed that the above-mentioned n-π* bands are strongly (more than 90%) localized in a single configuration contributed from the transition to a π-type LUMO from an n-type HOMO and, thus, having a similar spectral nature. Exceptional compounds are, however, $X=COCH_3$ and $COOC_2H_5$. These have two carbonyl groups in a molecule, so that nonbonding orbitals localized in the two carbonyl group oxygen atoms interact with each other; there therefore occur two n-type occupied MO's, localized mainly at the carbonyl group oxygen atoms. Consequently, the second n-π* configuration is mixed in the first n-π* transition, that is the main configuration, and the longest wavelength n-π* band is quite red shifted.[11] The correlation of the observed n-π* band energies ($E^{obs}_{n-\pi^*}$) to the CNDO/S calculated ones ($E^{calcd}_{n-\pi^*}$) is however relatively good: $E^{obs}_{n-\pi^*}=1.82E^{calcd}_{n-\pi^*}-1.50$ in eV unit with a correlation coefficient $r=0.914$ (sample number $n=11$: see Table 1).

a) ε_{max} means molar absorption coefficient at the wavenumber of the maximum absorption. b) Acetonitrile solution of acetylbromide is unstable and gradually turns out to be yellow. c) This spectral data are not for the monomer alone, but for the mixture of dimer and monomer of acetic acid. See experimental section in the text. d) The spectra of acetic acid was not recorded because of the end absorption of CH_3CN.

Application of Substituent Constants to the n-π* Band of Aliphatic Ketones. The conditions discussed in the foregoing section necessarily lead to the conclusion that the carbonyl n-π* bands can be explained using Eq. 1, except for diketones. The results of a multiregression analysis for the spectral data in heptane is given in Fig. 2. The agreement between the observed and calculated n-π* band energies is very good. Experimental data in CH_3CN (see Table 1) also gave a regression equation similar to that given in Fig. 2: i. e. $^1E^{UV}_{n-\pi^*}=0.960F-0.629R+4.28$ ($n=9$, $r=0.996$). In these regression equations the fact that the contribution of the F term is larger than that of the R term seems to be reasonable (as discussed below). The n and π* orbital energies are listed in Table 1. Regression equations using the F and R constants for 4-31G calculation results are as follows: $\varepsilon_n=-1.941F-0.243R-11.255$ ($n=9$, $r=0.952$) for the n-orbitals, and $\varepsilon_{\pi^*}=-1.206F-0.881R+3.800$ ($n=9$, $r=0.992$) for the π*-LUMO orbitals. It is understood that both the n and π* orbital energies are well described by the two substituent constants, but that the contribution from the F term is extraordinarily large for the ε_n values, showing that the field and inductive effect is predominant for the substituent effect on the nonbonding orbital. The same conclusion as these was also obtained from an analysis utilizing the CNDO/S orbital energies. This is of course reflected in the regression equation in Fig. 2. Kobayashi and Nakamoto[12] discussed in 1949 the substituent effect on aliphatic carbonyl n-π* bands as a function of the charge density at the alpha-atom of >C=O group. Later, Rao et al.[13] studied only the alkyl (X) group substituent effect on the CH_3COX n-π* bands using the Taft σ* constant. In principle, however, attention was only payed to the substituent effect on the ground state, and the effect on n-π* excited states was explicitly disregarded. Our present treatment makes it possible for the first time to describe the ground and excited states by the same substituent constants; also, the present results applied to the carbonyl n-π* bands are quite good and are compatible with the results from the MO calculations. The correlation equation given in Fig. 2 leads to 6.16 eV (201 nm) for the n-π* band of CH_3CONH_2 in heptane. We think that the accurate singlet n-π* band position of CH_3CONH_2 has still not been reported,[7] and that the data estimated by some authors are contradictory to each other.[7,14-17] Our present estimation shows that the n-π* band is at a shorter wavelength than that (211 nm in heptane) of CH_3COOCH_3; this is in agreement with Nagakura's opinion,[7] who says that the n-π* band of CH_3CONH_2 may occur at a shorter wavelength than 200 nm on the basis of an MO consideration.

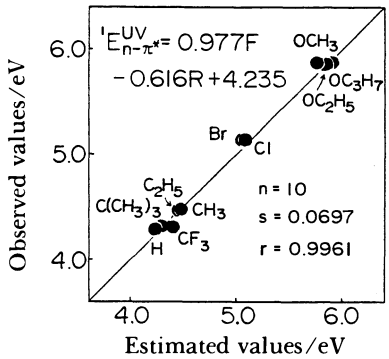

Fig. 2. Linear-least-squares correlation of observed n-π* band energies to the estimated ones using Swain's substituent constants.

The Crystal Structure of the β'_1 Form of Optically Active α-Monostearin

Midori GOTO,* Kozo KOZAWA,† and Tokiko UCHIDA†
National Chemical Laboratory for Industry, 1-1, Higashi, Tsukuba, Ibaraki 305

(Received September 5, 1987)

Synopsis. The crystal structure of the β'_1 form of (*R*)-α-monostearin has been determined. The space group is $P2_12_12_1$, with a=4.943(1), b=8.858(2), c=101.05(1)Å, and Z=8. The two independent molecules in the title compound have different conformations.

The polymorphism of the α-monoglycerides has been reported mainly in racemic forms.[1] The modifications named the sub-α, α, β', and β forms (β_1, β_2) have been known.[1,2] The β_1 form is a stable form and the structure has been determined in α-monolaurin.[3]

The pioneer work on the optically active α-monoglycerides was carried out by Larsson. Four modifications, the α, β'_1, β'_2, and β forms were found. He described the lattice constants and the space groups of two β' forms of monostearin, but did not solve their structures.[2] Recently Iwahashi et al. reported the thermodynamic behavior, infrared and NMR spectra of optically active monoglycerides.[4] The present authors obtained a single crystal of the β'_1 form of (*R*)-α-monostearin and undertook an X-ray crystal structure analysis.

Experimental and Structure Determination

The (*R*)-α-monostearin was obtained from Fluka AG-(Switzerland). The phase of the β'_1 form can be made from solvents as precipitates and is considered the stable form at room temperature. A crystal for the X-ray work could be obtained by slow evaporation at 20 °C from a acetone–chloroform mixed solution (1 : 1 volume ratio). A crystal with dimensions of 0.3×0.3×0.1 mm^3 was used. The unit cell parameters and intensities were measured on a Rigaku-Denki AFC-4 four-circle diffractometer by using graphite monochromated Cu $K\alpha$ radiation (λ=1.54184 Å). 4020 independent reflections within the range of $5°<2\theta<120°$ were collected by the $2\theta/\omega$ scan mode, with a scan width ω of $0.7+0.35\tan\theta$, and a scan speed of 4° min^{-1}. The standard reflections, monitored every 50 reflections showed no decline. 1855 independent reflections with $|F_o|\geq 3\sigma(|F_o|)$ were used for the analysis. The 1 0 0 reflection (F_o=15.5) was observed. Attempts to refine the structure in the $P2P2_1P2_1$ space group remained unsatisfactory. Therefore, it was concluded that the existence of the 1 0 0 reflection might be due to some disorders in the lattice, and so this reflection was excluded from the reflection data. Crystal data: $C_{21}H_{42}O_4$, M=358.6, orthorhombic, $P2_12_12_1$, a=4.943(1), b=8.858(2), c=101.05(1) Å, cell volume=4424.2(11) Å^3, Z=8, D_c=1.08 g cm^{-3}, μ=5.76 cm^{-1}. The structure could be solved by MULTAN 84.[5] The hydrogen atoms of the carbon chains were placed at the calculated positions. The structural parameters were refined by a block-diagonal least-squares method, using scattering factors from the International Tables for X-ray Crystallography (1974).[7] Anisotropic thermal parameters were assumed for the non-hydrogen atoms, and isotropic parameters for the hydrogen atoms. All the calculations except MULTAN 84 were carried out in a Facom M-380 Computer, using the UNICS III system.[7] The final refinement led to the R value of 0.110 (W=1.0). The maximum and minimum heights on the final difference Fourier map were 0.28 and −0.32 e Å^{-3} respectively; no other significant features were observed.

Results and Discussion

The numbering of the atoms in the molecules is shown in Fig. 1, while the final atomic coordinates are given in Table 1.[8]

The asymmetric unit contains two crystallographically independent molecules, which differ in the conformation of their glycerol parts. They will hereafter be named A and B. The differences in conformation are illustrated in Fig. 1, while the dihedral angles are shown in Table 2, together with the case of racemic α-monolaurin. The larger temperature factors of the O1A and O1B atoms might be due to the disorder.

The packing of the molecules in the crystal is shown in Fig. 2. In the packing of the hydrocarbon chains, every second hydrocarbon plane is approximately perpendicular to the other chain planes. This packing is common in fatty acids or paraffin crystals (named O⊥

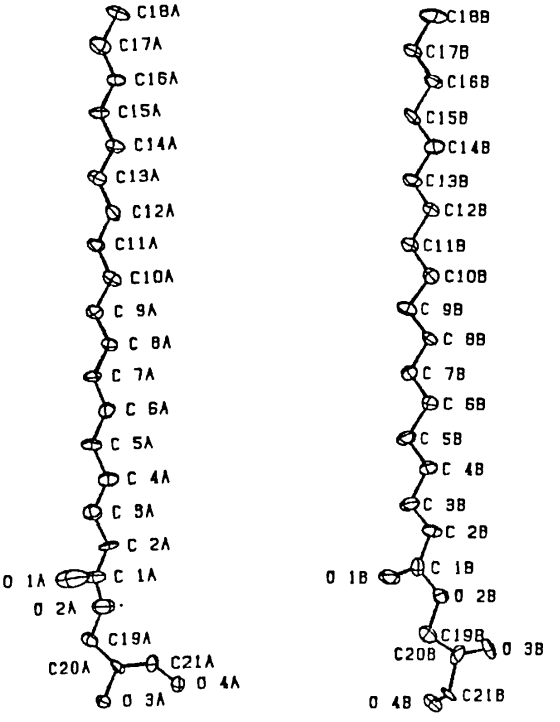

Fig. 1. ORTEP drawing and the numbering systems of atoms. The ellipsoids are drawn to enclose 40% probability.

The Photocyclization of *N,N*-Dialkyl β-Oxo Amides Adsorbed on Silica Gel

Tadashi HASEGAWA,* Jun-ichi MORIBE, and Michikazu YOSHIOKA†
Department of Chemistry, Tokyo Gakugei University, Nukuikitamachi, Koganei, Tokyo 184
†Department of Chemistry, Saitama University, Shimooukubo, Urawa, Saitama 338
(Received June 13, 1987)

Synopsis. β-Oxo amides 1 adsorbed on silica gel underwent photocyclization via δ-hydrogen abstraction to give the five-membered lactams **2**. No severe restrictions on the molecular motion could be observed in the photoreaction on the silica-gel surface. However, the relative photoreactivity of *N,N*-dibenzyl-2-benzoylacetamide (**1a**) to *N,N*-dibenzyl-2-benzoylpropionamide (**1b**) increased greatly on the silica-gel surface compared to that in solution, probably because of the greater keto content on the surface.

The photochemistry and photophysics of organic molecules adsorbed on silica gel have been studied well and compared with their solution counterparts.[1-5] The mobility of excited molecules or radical pair intermediates has received particularly much attention because they are unique surface probes.[3d] Most of the photochemical studies have, however, been concerned with photodecompositions via radical-pair intermediates, and much less attention has been focussed on the intramolecular photoreactions of organic molecules on the dry silica gel surface.[5] We will report here as the photocyclization of *N,N*-dialkyl β-oxo amides via intramolecular δ-hydrogen abstraction by the excited carbonyl group on a dry silica-gel surface.

Experimental

Materials. Silica gel (Merck Kiesel Gel 60, Art. #9385) was used as received. The β-oxo amides **1a—d** were prepared according to a previously described method.[6] Valerophenone was purified by fractional distillation with a Taika SM-NB spinning-band distilation apparatus. Phenanthrene (Tokyo Kasei Co.), a calibrant for the HPLC analysis, was recrystallized from ethanol. Hexadecane (Tokyo Kasei Co.), a calibrant for the GC analysis, was purified by passing it through silica gel.

General Procedure. Preparative Irradiation of the β-Oxo Amides 1 on Dry Silica Gel: The β-oxo amide **1** (ca. 0.1 mmol) in 5 cm^3 of dichloromethane was added to 2 g of silica gel in a Pyrex tube (30×200 mm). The mixture was sonicated for 5 min, and then the solvent was evaporated under reduced pressure. The tube was rotated and irradiated for 10 h with a 100 W high-pressure mercury lamp (Taika Co.). Acetonitrile (10 cm^3) was then added to the mixture, the mixture was sonicated, and the adsorbed material was extracted with acetonitrile.[7] After the removal of the solvent, the residue was chromatographed on silica gel. Elution with a mixture of benzene-ethyl acetate (10/1 (v/v)) gave the unreacted β-oxo amide **1** and the lactam **2**. The structures of **2a—d** were determined by comparison with authentic samples.[6,8] The yields of the lactam **2** are summarized in Table 1.

The Quantitative Photolysis of the β-Oxo Amides 1 on Dry Silica Gel: The β-oxo amide **1** (ca. 0.03 mmol) in 1 cm^3 of dichloromethane was added to 0.5 g of silica gel in a Pyrex tube (18×180 mm). In the quenching experiments, appropriate amounts of 2,5-dimethyl-2,4-hexadiene in dichloromethane were added. The mixture was sonicated for 5 min, and then the solvent was evaporated under reduced pressure. The tubes were rotated and irradiated with a 100 W high-pressure mercury lamp. The adsorbed material was sonicated and extracted with acetonitrile. To the acetonitrile solution was added 1 cm^3 of an acetonitrile solution containing a known amount of phenanthrene (ca. 0.001 mmol) as a calibrant for the HPLC analyses. The analyses were performed using a Gasukuro Kogyo 570B high-pressure liquid chromatograph with a Model 511 single-wave UV detector (254 nm). A Unishil QC18 column (4×250 mm) was used, and a mixture of methanol-water (7/3 (v/v)) was employed as the moving phase at a flow rate of 0.7 ml min^{-1}.

Photolysis of Valerophenone on Dry Silica Gel: Valerophenone (ca. 0.03 mmol) in 1 cm^3 of dichloromethane was adsorbed on 0.5 g of silica gel and irradiated as has been described above. After the extraction with acetonitrile, 1 cm^3 of an acetonitrile solution containing a known amount of hexadecane (ca. 0.001 mmol) as a calibrant was added. The mixture was then analyzed using a Shimazu GC-4B gas chromatograph equipped with a flame ionization detector. Analysis was performed on a 2 m×4 mm column packed with 5% DCQF-1 and 1% EGS on Chromosorb P.

Results and Discussion

The irradiation of *N,N*-dibenzyl-2-benzoylacetamide (**1a**) adsorbed on silica gel with a 100 W high-pressure mercury lamp gave a five-membered lactam, 1-benzyl-

4-hydroxy-4,5-diphenyl-2-pyrrolidinone (**2a**), in an 83% yield. Similarly, the irradiation of two β-oxo amides, **1b** and **1c**, on dry silica gel gave the lactam **2b** and **2c** in 91 and 63% yield respectively. The yields of the lactams **2a**—**c** from photolyses of the β-oxo amides **1a**—**c** on silica gel are similar to those in photoreactions in solution[8] (Table 1). The formation of the lactams **2a**—**c** on silica gel can be explained in terms of the intramolecular δ-hydrogen shift to the carbonyl oxygen, as in photoreactions in solution.[6] The rates at which the β-oxo amides **1** adsorbed on silica gel undergo conformational change should be as fast as the rate at which they react chemically from their electronically excited states.

The β-oxo amide **1a** exhibits the keto-enol tautomerism. We have previously reported that the enol-form of the β-oxo amides 1 acted as an internal filter in solution photochemistry; the quantum yield for the production of the lactam from **1a** in benzene was 33 times lower than that from 1b (ϕ_{2a}/ϕ_{2b}=0.03).[6] The enol tautomer may reduce the photoreactivity of the β-oxo amides **1** on silica gel. However, the rate of the disappearance of the β-oxo amide **1a** on silica gel was equal to that of **1b** (Fig. 1). This result may be explained in two ways; the efficiency of the photoreaction of **1a** may be increased, or that of 1b may be decreased, by the steric effect of the 2-methyl group. However, it seems that the latter possibility can be excluded because the quantum yield for the production of **2b** from **1b**[6] is comparable to that for acetophenone formation from valerophenone[9] in solution photochemistry (Φ_{2b}/Φ_{PhCOMe}=0.79). The reaction rate for the production of **2b** from **1b** on the silica gel surface relative to that of acetophenone formation from valerophenone on the surface was also comparable (Φ_{2b}/Φ_{PhCOMe}=0.56). This result indicates that the photoreactivity of **1a** on the silica gel surface is increased to the same level as that of **1b**. The efficient photoreactivity of **1a** might indicate that the β-oxo amide **1a** exists nearly completely as in the keto form on the surface. The enol content of **1a** in a solution depends on the solvent polarity. The enol content of **1a** as well as other β-oxo amides[10] decreases with an

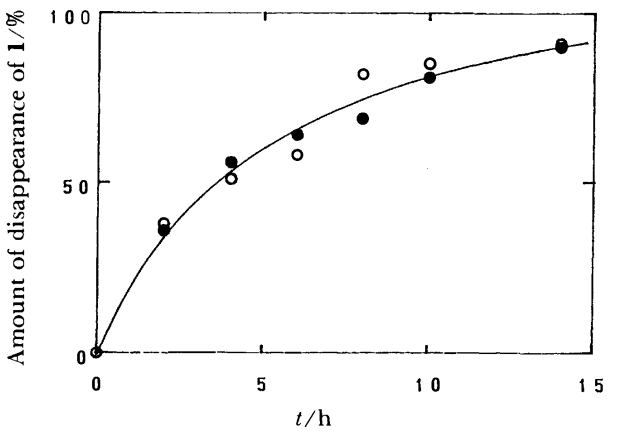

Fig. 1. Disappearance of the β-oxo amide **1a** (○) and **1b** (●) on silica gel. In each case 0.028 mmol of the oxo amides was used.

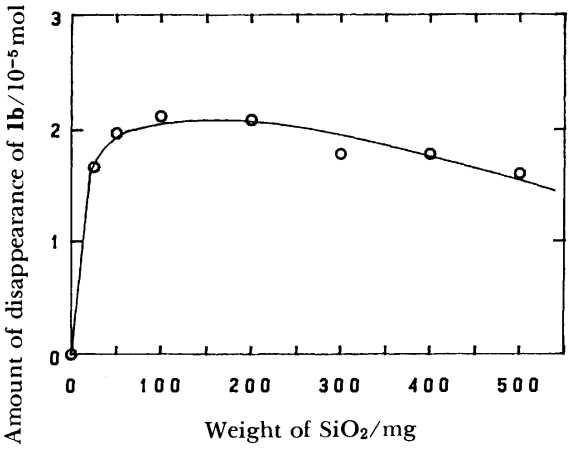

Fig. 2. Efficiency of the photoreaction of **1b** on silica gel. In each case 0.028 mmol of **1b** was used.

increase in the solvent polarity.[8] The increment of the keto form of **1a** may be due to the polar property of the silica-gel surface. The surface of silica gel is presumed to be a suitable field for a photoreaction from only the keto tautomer of β-dicarbonyl compounds.

The rate of the disappearance of the β-oxo amides **1** on silica gel depended on the amounts of the β-oxo amides adsorbed on a unit gram of silica gel (Fig. 2). The amount of **1b** (0.028 mmol) which disappeared increased with the increase in the amounts of silica gel and reached its maximum at about 100 mg of silica gel. This suggests that 100% coverage is achieved with 0.028 mmol of **1b** per 100 mg of silica gel. This idea was supported by the following calculation. The surface area of silica gel (Merck Kiesel Gel 60, Art #9385) was 444 $m^2\ g^{-1}$. Consequently, the surface area occupied by one molecule can be calculated to be 2.6×10^{-18} m^2. The longest molecular chain of **1b** was calculated to be 15Å by using the values of bond lengths and bond angles.[11] From the experimental results described above, it was expected that the molecule of the β-oxo amides **1** on the silica gel surface could change its conformation within the lifetime of the excited state. Therefore, the surface area occupied by one molecule of the β-oxo amide **1b** can be approximated by the square model (15×15 $Å^2=2.3\times10^{-18}$ m^2). This value is almost entirely consistent with the experimental value. Therefore, 0.028 mmol of **1b** per 100 mg of silica gel corresponds to 100% monomolecular-layer coverage. When the ratio of the β-oxo amide **1b** to silica gel is over 0.028/100 mmol/mg, multiple layers might be formed. The molecules of the β-oxo amides on the monomolecular layer might act as filter for the β-oxo amide molecules in the layer.

The irradiation of **1b** in the solid state without silica gel under the same conditions resulted in the formation of a trace of the lactam **2b**, and more than 95% of the starting material was recovered.[12] The use of silica gel as an adsorbent effectively promotes the photoreaction of the β-oxo amides because silica gel has a wide surface area and because the β-oxo amide can be widespread on the silica-gel surface.

The quenching of the photoreaction of the β-oxo amides **1** on silica gel with 2,5-dimethyl-2,4-hexadiene

was attempted. Scarecely no quenching was observed on **1a**, while the photoreaction of **1b** was remarkably quenched. These results are consistent with the photochemical behavior of the β-oxo amides in solution. The photoreaction of **1a** is presumed to occur through the charge-transfer intermediate. The $k_q\tau$ values could not be determined from the slopes in the Stern-Volmer plots because the diene was consumed during the irradiation.[13]

The π,π^* excited state of ketones is generally not sensitive to direct hydrogen abstraction, while the n,π^* state is sensitive to it.[14] The irradiation of the β-oxo amide **1d**, which is expected to have the π,π^* configuration in its lowest excited state, on silica gel also gave the lactam **2d** in a 7% yield. This result also suggests that electron transfer from nitrogen to the carbonyl group occurs prior to the hydrogen shift, even on silica gel, while the yield of **2d** is low.

The authors are grateful to Dr. Yoshimasa Inoue of the Central Research Laboratory, Sumitomo Metal Mining Co., for the surface-area determination.

Synthesis of 1,2,5a-Triazacyclohept[*a*]azulen-5(2*H*)-ones

Noritaka ABE* and Yoshifumi EMOTO
Department of Chemistry, Faculty of Sciences, Yamaguchi University, Yamaguchi 753
(Received August 24, 1987)

Synopsis. Reactions of 2-hydrazino-1-azaazulenes with acetylacetone gave 2-(3,5-dimethyl-1-pyrazolyl)-1-azaazulenes. Cyclizations of diethyl (1-azaazulen-2-yl)hydrazinomethylenemalonates in refluxing *t*-butylbenzene or on silica gel gave 1,2,5a-triazacyclohept[*a*]azulen-5(2*H*)-ones.

The chemistry of azaazulenes has attracted considerable attention because of their interesting chemical behavior and physicochemical properties.[1] Although many studies regarding hetero-annulated 1-azaazulenes have been made,[2-9] azepine-annulated 1-azaazulene, which would have a 16π-electronic antiaromaticity, has not been synthesized. In this paper, an attempt to synthesize of 1,2,5a-triazacyclohept[*a*]azulene is described. Although the conversion to a full conjugated 16π-electronic system was not successful, the publication of the synthesis of a novel tricyclic 1,2,5a-triazacyclohept[*a*]azulen-5(2*H*)-one seemed worthwhile, which is considered to be precursor of 1,2,5a-triazacyclohept[*a*]azulene.

It is known that hydrazino-substituted heterocycles have often been used in the synthetic design of annulated triazepines.[10-12] We therefore employed 2-hydrazino-1-azaazulenes[13] (**1**) as starting materials.

The treatment of **1a** and **1b** with acetylacetone (AA) gave 2-(3,5-dimethyl-1-pyrazolyl)-1-azaazulenes (**2a** and **2b**) in good yields, respectively. Compounds **2a** and **2b** were identical with the products derived from 2-chloro-1-azaazulenes (**3a** and **3b**) and 3,5-dimethylpyrazole, respectively.

Reaction of **1a** with ethyl acetoacetate (EAA) gave **4** as orange prisms in 63% yield, which was assigned as 2-(3-methyl-5-oxo-3-pyrazolin-1-yl)-1-azaazulene on the basis of the spectroscopic data as well as elemental analysis.

Since a direct construction of the triazepine ring using **1** and AA or EAA was unsuccessful, we carried out the synthesis and cyclizations of diethyl (1-azaazulen-2-yl)hydrazinomethylenemalonate (**5**).

The treatment of **1** with diethyl ethoxymethylenemalonate (DEEM) in refluxing ethanol gave **5** in good yields. Heating of **5a** in *t*-butylbenzene under reflux for 30 min gave **6a** in 92.5% yield, which was assigned as ethyl 2,5-dihydro-5-oxo-1,2,5a-triazacyclohept[*a*]-azulene-4-carboxylate on the basis of the spectroscopic data as well as HRMS. Compound **6a** was also obtained in 56% yield through a treatment of **5a** with silica gel for 7 d. In the ^{1}H NMR spectrum of **6a**, a low-field resonated 1H multiplet, owing to a deshielding effect of C-5 carbonyl, was observed at δ 9.20—9.27, which could be assigned to the C-6 proton. Other signals were observed at δ 7.23 (s, H-11), 7.75—7.95 (m, H-3, 7, 8, and 9), and 8.41 (d, J=10.4 Hz, H-10) together with ethyl ester signals.[14]

The treatment of **5b** in refluxing *t*-butylbenzene gave **6b**, but a treatment of **5b** with silica gel did not.

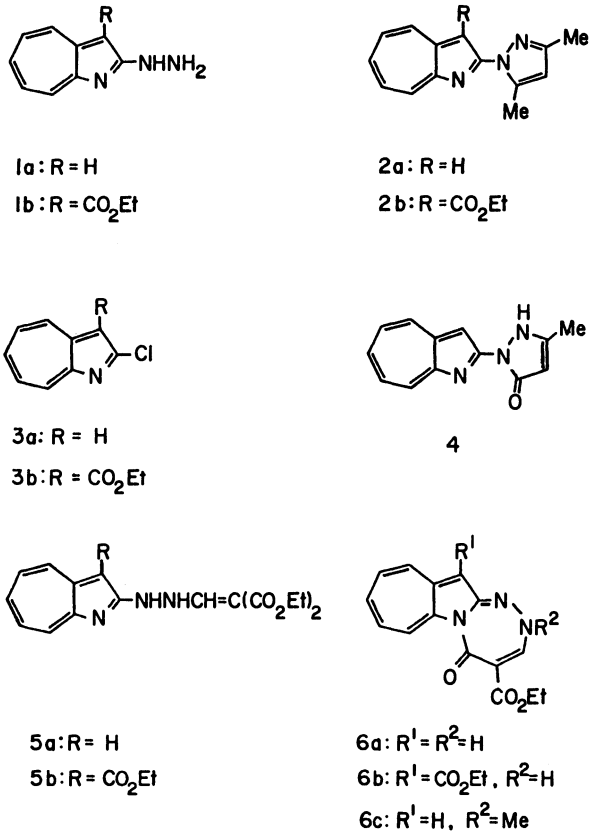

Fig. 1.

In the ^{13}C NMR spectrum of **6b**, signals of seven membered carbons (C-6, 7, 8, 9, and 10) are observed at δ 134—140. In its ^{1}H NMR spectrum, signals of H-6 and 10 were observed at δ 8.96 (dd, J=6.8 and 2.4 Hz) and 9.01 (d, J=12.2 Hz), respectively, which were deshielded by the carbonyl group at C-5 and ester group at C-11, respectively. Other signals of seven-membered ring protons (H-7, 8, and 9) were observed at δ 7.90—8.15 (m). Although these observations suggest that **6b** should be fundamentally aromatic, the large divergence of the coupling constants ($J_{6\text{-}7}$—$J_{9\text{-}10}$=5.4 Hz) shows that the contribution of heptafulvene form should be considerably large.

Compounds **6a** and **6b** were somewhat decomposed and changed to unidentified reddish violet compounds by prolonged heating or prolonged contact with silica gel.

For leading to full conjugated system, acetylation and methylation of **6a** were attempted. The treatment of **6a** with acetic anhydride gave no distinct product. The treatment of **6a** with methyl iodide in the presence of a base gave **6c**, which was assigned as an *N*-methylated product on the basis of the spectroscopic data; no *O*-methylated compound was obtained. *N*-Methyl protons appeared at δ 4.11 in the ^{1}H NMR

spectrum of **6c** and *N*-methyl carbon at δ 41.2 in its ^{13}C NMR spectrum.

Reactions and successive cyclizations of diethyl ethoxymethylenemalonate and heterocycles have been exclusively used for the preparation of fused pyrimidines.[9,15,16] Now we extended the reaction for the preparation of fused triazepine, as described above.

Experimental

Melting points were uncorrected. ^1H NMR spectra (250 MHz) and ^{13}C NMR spectra (62.87 MHz) were recorded on a Hitachi R-250H spectrometer using deuteriochloroform as a solvent (tetramethylsilane as an internal standard), unless otherwise stated. IR spectra were recorded for Nujol mulls with a Hitachi 270-50 infrared spectrophotometer. Mass spectra were determined with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. High-resolution mass spectra were obtained on the same instrument. Column chromatography was performed on Kieselgel 60.

Reaction of 1 with AA. a) A mixture of **1a** (318 mg, 2 mmol) and AA (405 mg, 4 mmol) in ethanol (30 ml) was refluxed for 3 h and evaporated. Chromatography of the residue with chloroform–ethyl acetate (1 : 1) gave **2a** (430 mg, 96%), which was crystallized from cyclohexane to give orange needles (359 mg, 80%), mp 86—88 °C, ^1H NMR δ=2.36 (3H, s, Me), 2.87 (3H, s, Me), 6.06 (1H, s, H-4′), 7.58 (1H, s, H-3), 7.50—7.75 (3H, m, H-5, 6, and 7), 8.39 (1H, d, J=9.8 Hz, H-4), 8.45—8.53 (1H, m, H-8). Found: C, 75.45; H, 5.94; N, 18.65%. Calcd for $C_{14}H_{13}N_3$: C, 75.31; H, 5.87; N, 18.82%.

When above reaction was carried out in refluxing benzene or acetic acid, **2a** was obtained in 95% and 91%, respectively.

b) A mixture of **1b** (463 mg, 2 mmol), AA (452 mmol, 4.5 mmol), and trifluoroacetic acid (0.1 ml) in ethanol (30 ml) was refluxed for 20 h and evaporated. Chromatography of the residue with chloroform gave **2b** (512 mg, 87%) as yellow oil. ^1H NMR (60 MHz) δ=1.25 (3H, t, Me), 2.32 (3H, s, Me), 2.47 (3H, s, Me), 4.28 (2H, q, OCH_2), 5.96 (1H, s, H-4′), 7.58—7.96 (3H, m, H-5, 6, and 7), 8.45—8.70 (1H, m, H-8), 9.05—9.25 (1H, m, H-4); IR 1702 cm^{-1} (ester C=O). Picrate of **2b**, yellow scales (from ethanol), mp 151—153 °C, Found: C, 52.61; H, 3.77; N, 16.13%. Calcd for $C_{23}H_{20}N_6O_9$: C, 52.67; H, 3.84, N, 16.02%.

Reaction of 3 with 3,5-Dimethylpyrazole. A mixture of **3a** (146 mg, 1mmol) and 3,5-dimethylpyrazole (120 mg, 1.25 mmol) in 1-butanol was refluxed for 17 h and evaporated. To the residue water was added, and the mixture was neutralized with sodium hydrogencarbonate and extracted with chloroform. The extract was dried (Na_2SO_4) and evaporated. Chromatography of the residue with chloroform gave **2a** (38%).

Similar treatment of **3b** with 3,5-dimethylpyrazole gave **2b** in a 54% yield.

Reaction of 1a with EAA. A solution of **1a** (318 mg, 2 mmol) and EAA (390 mg, 3 mmol) in ethanol (30 ml) was refluxed for 5 h and evaporated. Chromatography of the residue with ethyl acetate gave **4** (0.284 mg, 63%), which was crystallized from hexane to give orange prisms (37%), mp 198—200 °C; ^1H NMR δ=2.31 (3H, s, Me), 5.46 (1H, s, H-4′), 7.46 (1H, s, H-3), 7.60—7.80 (3H, m, H-5, 6, and 7), 8.35—8.41 (1H, m, H-4), 8.41 (1H, d, J=9.8 Hz, H-8);[14] IR 3250—2800 (NH), 1646 cm^{-1} (amido C=O). Found: C, 69.48; H, 4.96; N, 18.71%. Calcd for $C_{13}H_{11}N_3O$: C, 69.32; H, 4.92; N, 18.65%.

Reaction of 1 with DEEM. A solution of **1a** (318 mg, 2 mmol) and DEEM (451 mg, 2.1 mmol) in ethanol (30 ml) was refluxed for 1 h and evaporated. The residue was crystallized from cyclohexane–dichloromethane to give **5a** (602 mg, 92%) as red needles, mp 163—165 °C; ^1H NMR δ=1.25 (3H, t, J=7.0 Hz, Me), 1.38 (3H, t, J=7.0 Hz, Me), 4.19 (2H, q, J=7.0 Hz, OCH_2), 4.30 (2H, q, J=7.0 Hz, OCH_2), 6.28 (1H, s, H-3), 6.63—7.00 (4H, m, H-4, 5, 6, and 7), 7.23 (d, J=11.6 Hz, H-8), 8.46 (d, J=10.4 Hz, =CHNH), 11.60 (bd, J=10.4 Hz, =CHNH, exch.);[14] IR 3200—2650 (NH), 1674 (ester C=O), and 1634 cm^{-1} (C=N). Found: C, 62.13; H, 5.90; N, 12.71%. Calcd for $C_{17}H_{19}N_3O_4$: C, 62.00; H, 5.81; N, 12.76%.

In a similar manner, reaction of **1b** (463 mg, 2.0 mmol) and DEEM (895 mg, 4.14 mmol) in refluxing ethanol (40 ml) for 30 min gave **5b** (774 mg, 96%), which was crystallized to give yellow needles (592 mg, 74%), mp 119—121 °C; ^1H NMR δ=1.35 (3H, t, J=7.3 Hz, Me), 1.40 (3H, t, J=6.7 Hz, Me), 1.52 (3H, t, J=7.3 Hz, Me), 4.36 (2H, q, J=6.7 Hz, OCH_2), 4.40 (2H, q, J=7.3 Hz, OCH_2), 4.53 (2H, q, J=7.3 Hz, OCH_2), 7.75—7.85 (3H, m, H-5, 6, and 7), 8.28—8.35 (1H, m, H-8), 8.81 (1H, d, J=3.1 Hz, =CHNH), 8.96 (1H, d, J=3.1 Hz, =CHNH), 9.20 (1H, d, J=9.15 Hz, H-4), 10.09 (1H, bs, NH); IR 3328 (NH), 3200—2650 (NH), 1714 and 1664 (ester C=O), and 1604 cm^{-1} (C=N). Found: C, 59.91; H, 5.83; N, 10.28%. Calcd for $C_{20}H_{23}N_3O_6$: C, 59.84; H, 5.77; N, 10.47%.

Cyclization of 5a. a) A solution of **5a** (1.00 g, 3.04 mmol) in *t*-butylbenzene (10 ml) was refluxed for 30 min and evaporated. The residue was chromatographed with acetone to give **6a** (796 mg, 92.5%), which was crystallized from cyclohexane–dichloromethane to give red needles (650 mg, 76%), mp 232—234 °C; ^1H NMR δ=1.18 (3H, t, J=6.7 Hz, Me), 4.14 (2H, q, J=6.7 Hz, OCH_2), 7.23 (1H, s, H-11), 7.75—7.95 (3H, m, H-7, 8, and 9), 7.87 (1H, s, H-3), 8.41 (1H, d, J=10.4 Hz, H-10), 9.20–9.27 (1H, m, H-6);[14] IR 3150 (NH), 1722 (ester C=O), 1630 (amido C=O), and 1615 (C=N); MS *m/z* (rel intensity) 283 (M^+; 100), 238 (77), 237 (68), 211 (55), 129 (16), and 102 (36). HRMS Found: *m/z* 283.0954. Calcd for $C_{15}H_{13}N_3O_3$: M, 283.0956.

b) A mixture of **5a** (250 mg, 0.76 mmol) and silica gel (5.0 g) in chloroform (50 ml) was left to stand at room temperature for 7 d and then chromatographed. Elution with chloroform–ethyl acetate (1 : 1) gave recovered **5a** (25 mg, 10%). Elution with acetone gave **6a** (120 mg, 56%).

Cyclization of 5b. A solution of **5b** (402 mg, 1.00 mmol) and *t*-butylbenzene (10 ml) was refluxed for 40 min and cooled. The precipitate was collected by filtration to give **6b** (262 mg, 74%), which was crystallized from cyclohexane–dichloromethane to give red needles (185 mg, 52%), mp 186—188 °C; ^1H NMR δ=1.34 (3H, t, J=7.3 Hz, Me), 1.39 (3H, t, J=7.3 Hz, Me), 4.31 (2H, q, J=7.3 Hz, OCH_2), 4.48 (2H, q, J=7.3 Hz, OCH_2), 7.90—8.15 (3H, m, H-7, 8, and 9), 7.99 (1H, s, H-3), 8.96 (1H, dd, J=6.8 and 2.4 Hz, H-6), 9.01 (1H, d, J=12.2 Hz, H-10), and 9.50 (1H, bs, NH); ^{13}C NMR δ=14.14 (q), 14.55 (q), 59.34 (t), 61.53 (t), 93.18 (s), 106.34 (s), 134.45 (d), 134.72 (d), 134.87 (d), 135.80 (d), 139.47 (d), 144.03 (s), 146.31 (d), 149.45 (s), 151.51 (s), 162.06 (s), 163.26 (s), 163.84 (s); IR 3200—2650 (NH), 1734, 1710 (ester C=O), 1630 (amido C=O), and 1610 cm-1 (C=N); MS *m/z* (rel intensity) 355 (M^+; 100), 310 (22), 309 (38), 264 (71), 237 (94), 129 (22), and 110 (31). HRMS Found: *m/z* 355.1087. Calcd for $C_{18}H_{17}N_3O_5$: M, 355.1167.

Methylation of 6a. To the mixture of **6a** (100 mg, 0.35 mmol) and potassium hydroxide 180 mg, 3.2 mmol) in 90% aq ethanol (50 ml), methyl iodide (500 mg) was added, and the mixture was refluxed for 16 h and evaporated. The residue was dissolved in water, neutralized with 1M hydrochloric acid (1M=1 mol dm^{-3}), and extracted with chloroform. The extract was dried over sodium sulfate and evaporated. The residue was chromatographed with chloroform–ethyl acetate (1 : 1) gave **6c** (25 mg, 24%), which was crystallized from hexane–dichloromethane to give orange needles (18 mg, 17%), mp 173—174 °C, ^1H NMR δ=1.38 (3H, t, J=7.3 Hz, Me), 4.11 (3H, s, NMe), 4.35 (2H, q, J=7.3 Hz, OCH_2), 7.63—7.83 (3H, m, H-7, 8, and 9), 7.97 (1H, s, H-11), 8.10 (1H, s,

H-3), 8.52 (2H, d, J=9.2 Hz, H-6 and 10); ^{13}C NMR δ=14.42 (q), 41.21 (q), 60.11 (t), 100.25 (s), 104.84 (d), 129.32 (d), 129.77 (d), 134.15 (d), 134.61 (d), 135.98 (d), 146.75 (s), 148.21 (d), 154.76 (s), 155.53 (s), 160.85 (s), 162.01 (s); IR 1716 (ester C=O) and 1668 cm-1 (amido C=O); MS m/z (rel intensity) 297 (M^+; 65), 268 (20), 224 (55), 223 (42), 195 (100), 184 (74), 171 (78), 144 (44), 129 (53), and 102 (29). HRMS Found: m/z 297.1112. Calcd for $C_{16}H_{15}N_3O_3$: M, 297.1109.

We thank Dr. Masafumi Yasunami (Tohoku University) and Dr. Akira Mori (Kyushu University) for the measurements of the Mass spectra and elemental analyses.

Synopsis. The adsorption isotherms of cholesterol from ethanol and cyclohexane (at 25 and 35 °C), and of egg-lecithin from ethanol and ethanol-water mixed solvent (at 25 °C) onto active carbon have been determined. The isotherms can be represented by Dubinin-Radushkevich equation. The results indicate that the adsorption of cholesterol and lecithin from solutions onto active carbon can be explained by the mechanism of micropore filling.

The model biological membrance is of great theoretical and practical importance. The model lipid monolayer formed on solid surface by adsorption method has been studied by Poltorak and Chukhrai,[1] Kamyshnyi et al.,[2] Benko et al.[3] Tamamushi[4] studied the adsorption of lipids from solutions. The adsorbents used in these studies were mostly nonporous or had macro-pores. In the present work the adsorption of cholesterol and lecithin from ethanol, cyclohexane, and ethanol-cyclohexane mixtures on active carbon has been studeid. The effect of solvents on the adsorption and the mechanism of the adsorption are discussed.

The egg-lecithin was extracted from egg yolk. The MS analysis showed that the molecular weight of the egg-lecithin obtained was 701. The purity of the egg-lecithin was examined by means of thin-layer chromatography. Pure cholesterol was supplied by E. Merck Co. The melting point was 148.5 °C, in agreement with literature.[5] The granular active carbon GH was supplied by Guang Hua Wood Factory and was treated further with acetic acid and hydrofluoric acid repeatedly. The excess acids were washed out with hot water and finally the active carbon was dried in air at 120 °C. The BET surface area from the N_2 adsorption method was 1410 $m^2 \cdot g^{-1}$, the pore volume was 0.609 $cm^3 \cdot g^{-1}$ by the saturated CCl_4 vapor adsorption method, and the average pore radius was 8.6 Å.

The adsorption experiments were carried out with a shaker-bath, at 25 or 35 °C (±0.5 °C), using 25 cm^3 flasks, with 0.1g active carbon samples, 10.0 cm^3 solution and a 24 h shaking time (previous experiments showed that equilibrium was achieved within 12 h). After settling, the supernatant liquid was analyzed by UV absorption. The adsorbed amount (a $g \cdot g^{-1}$) was calculated according to

$$a = \frac{V\Delta C}{m},$$

where ΔC ($g \cdot dm^{-3}$) is the change in concentration of solute coused by adsorption, V is the total volume of solution, and m is the mass of adsorbent.

The adsorption isotherms of cholesterol from the solution of ethanol and cyclohexane (both at 25 and 35 °C), and of lecithin from ethanol and mixed solvent of ethanol-water (volume ratio 4 : 1) (at 25 °C) are plotted in Figs. 1 and 2, respectively. Figure 1 shows that the adsorbed amount of cholesterol from ethanol is smaller than that from cyclohexane in the experimental concentration range. Figure 2 shows that the adsorbed amount of lecithin from the mixed solvent is smaller than that from ethanol when the concentration is higher than 2 $g \cdot dm^{-3}$.

For porous adsorbents, particularly active carbon with micropores whose radius is smaller than 1 nm, the effect of increasing adsorption potentials as a result of overlapping of the fields of opposite walls of the pores is prominent. The characteristic adsorption isotherm due to Dubinin and Radushkevich,[6] which

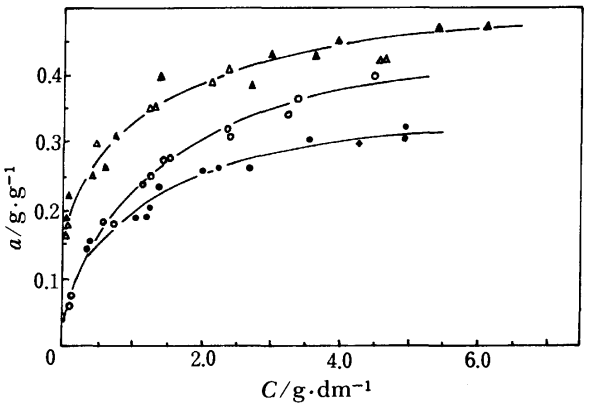

Fig. 1. Adsorption isotherms of cholesterol from ethanol (○, 25 °C; ●, 35 °C) and cyclohexane (△, 25 °C; ▲, 35 °C) on active carbon GH.

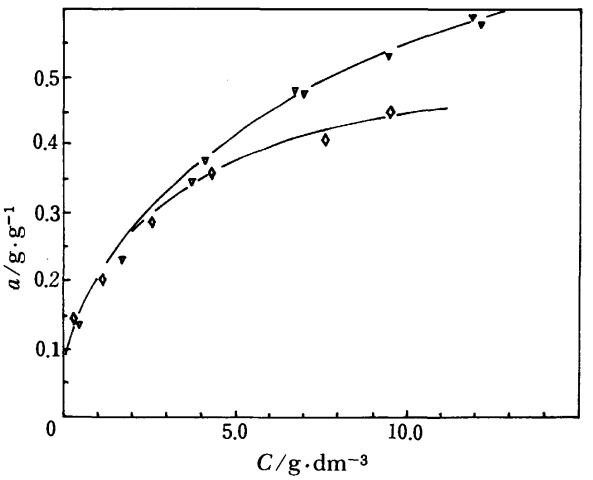

Fig. 2. Adsorption isotherms of egg-lecithin from ethanol (▽, 25 °C) and ethanol-water (volume ratio 4:1) mixed solvent (◇, 25 °C) on active carbon GH.

Table 1. Adsorption of Cholesterol and Lecithin on Active Carbon GH

Adsorbate	Cholesterol				Lecithin	
Solvent	Ethanol		Cyclohexane		Ethanol	Ethanol–water
Temperature/°C	25	35	25	35	25	25
Pore volume of the adsorbent, W_0/ml · g^{-1}	0.609	0.609	0.609	0.609	0.609	0.609
Maximumm volume of adsorbed solute, W_m/ml · g^{-1}	0.439	0.356	0.498	0.492	0.573[a)]	0.454
W_m/W_0	0.72	0.58	0.82	0.81	0.94	0.75

a) This value is calculated from maximum adsorbed amount, as the solubility data are not available.

was later modified by Dubinin and Zaverina,[7] can be written in the form,

$$\ln W - \ln W_0 = -A\varepsilon^2, \quad (1)$$

where W is the volume of adsorbed substance, W_0 is the total volume of adsorption space that represents the volume of micropores of the active carbon, parameter the A is a kind of distribution function of volume of the pores according to sizes, and ε is the Polanyi potential. According to the Polanyi theory of adsorption, ε is the work required to transfer a molecule from the gas phase at pressure P to the liquid phase at saturated pressure P_0

$$\varepsilon = kT \ln(P_0/P), \quad (2)$$

and k is the Boltzmann constant. Relationship 1, which is known as the DR equation,[8] together with its extension,[9] is used to describe pore filling as pressure increases. When dealing with the adsorption from solutions, the DR equation can be written as

$$\log a - \log a_m = -B\left(\log \frac{C_0}{C}\right)^2, \quad (3)$$

where a and a_m are the amount and maximum amount of the adsorbed substance, respectively, C and C_0 are the equilibrium concentration and saturated concentration of adsorbate, respectively, and B is a constant. A plot of $\log a$ against $(\log C_0/C)^2$ should give a straight line with an intercept $\log a_m$ and a slope $-B$, from which the two constant a_m and B can be evaluated.

Figure 3 gives the plots illustrating the applicability of the DR equation to the adsorption of cholesterol and lecithin from solution on active carbon. It should be noted that the constant B in Eq. 3 depends not only on the adsorbent but also on the solute and solvent. The maximum volume of the adsorbed solute, W_m, can be calculated from a_m and the density of the solute. Table 1 shows that the maximum adsorbed volume of cholesterol and lecithin from solutions are 58—82% and 75—94% of the total pore volume of the adsorbent, respectively. Obviously, the rest of the pore volume should be filled with the solvent. Similar results have been obtained by Koganovskii and Levchenko[10] for the adsorption of 1-propanol, 1-butanol, and 1-hexanol from aqueous solution onto active carbon.

It is well-known that the adsorption of the solute must be accompanied by a displacement of the solvent.

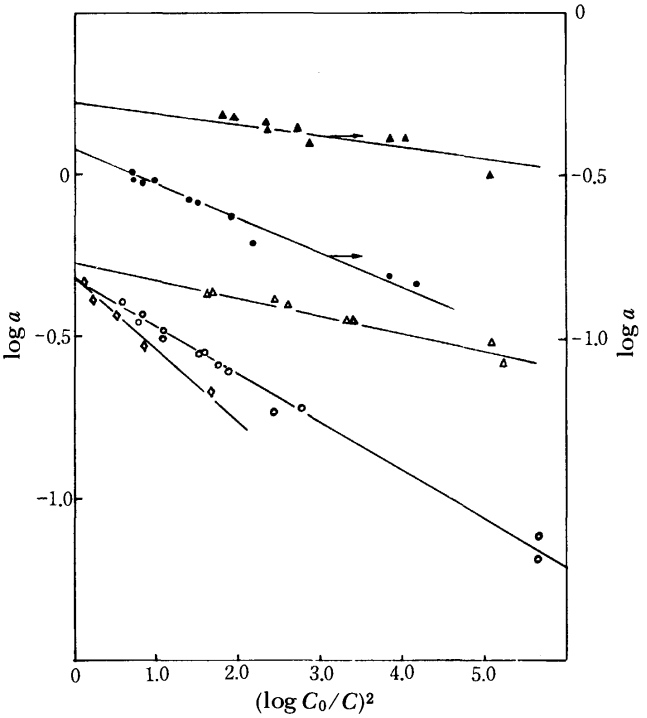

Fig. 3. Adsorption isotherms of cholesterol and lecithin from solutions on active carbon GH, Legend as in Figs. 1 and 2.

Based on the thermodynamics, the free energy of this displacement becomes progressively greater as the interface interaction and the number of solvent molecules on the surface or in the pore space becomes less.[11] In other words, the solvent molecules cannot be completely displaced from the solid surface (pore space).

It should be noted that one of the main reasons for the failure of attempts to predict W_m has been the failure to account for solvent remaining in the adsorbed phase. Only when the solubility of the solute in solvent or the miscibility of the solute with solvent is very low and the interaction between the solute and solid surface is very strong, the maximum adsorption volume of solute should be approximately equal to the pore volume of adsorbent. An example is the adsorption of *p*-chlorophenol, *p*-chloroaniline, nitrobenzene, chloroform, and benzene from aqueous solution onto active carbon by Koganokvskii et al.[12]

Chlorothionitrene Complexes of Tungsten. Synthesis, Characterization, and Chemical Behavior of Tungsten(VI) Thionitrene Complexes

Jyoti SETH, Minu GUPTA, and U. C. AGARWALA*
Department of Chemistry, I. I. T., Kanpur, India
(Received January 20, 1987)

Synopsis. The syntheses of Tungsten(VI) chlorothionitrene complexes have been described and their chemical behavior was studied. The compounds were characterized by microanalyses, vibrational, electronic, ESR, NMR spectral and other Chemical studies.

Although the chemistry of metal nitrosyls has been extensively studied,[1,2] it is only recently that there has been considerable interest in the study of the reactivity of NSCl with various transition metal complexes for the syntheses of thionitrosyls.[3-9] Characterization of its interaction products indicates that S-N species formed from NSCl and bonded to the metal center are quite diverse. Due to this intriguing behavior of thionitrosyl chloride, many investigations have been devoted to study such complexes. In addition, our efforts in recent years have been in a direction to search the possibility of using trimeric thionitrosyl chloride as a thionitrosylating agent for the synthesis of metal thionitrosyls,[3-5,10,11] a field which is still in an embryonic state. While making these efforts, the reactions of $(NSCl)_3$ with substituted tungsten(II) carbonyl complexes having 2,2′-bipyridine or 1,10-phenanthroline as coligand afforded complexes in which NSCl is bonded to W(VI) in the form of chlorothionitrene group $M{=}N{=}S\diagdown_{Cl}$, a bonding mode which has been fairly studied. This paper focuses on the detailed syntheses and characterization of these componds.

Experimental

Materials and Methods. All the chemicals used were of reagent or AnalaR grade. Tungsten hexacarbonyl, tungsten hexachloride, 2,2′-bipyridine and 1,10-phenanthroline, and Sephadex LH-20 resin were purchased from the Aldrich Chemical Company and were used as such. The starting materials $[W(CO)_3(L\text{-}L)X_2]$ (L-L=bpy or *o*-phen; X=Br or I), $[W(NSCl)Cl_4)]_2$ and trimeric thionitrosyl chloride were prepared by the literature methods.[12-14] Solvents were purified and dried by standard methods.[15] and degassed prior to use. All experiments were performed under nitrogen atmosphere. Details of the physicochemical methods are given elsewhere.[16]

Preparations. (A) Reaction Medium-Dichloromethane. (a) Reaction of $(NSCl)_3$ with $[W(CO)_3(L\text{-}L)X_2]$ (L-L=bpy or *o*-phen; X=Br or I). A solution of $(NSCl)_3$ (ca. 0.03 mmol) in 10 ml of dichloromethane was added to a stirred solution of $[W(CO)_3(L\text{-}L)X_2]$ (ca. 0.1 mmol) in 15 ml of dichloromethane. After the mixture was stirred for approximately 1 h and gas evolution had ceased, the resulting solution was concentrated under reduced pressure to about 5 ml. The product (I) was precipitated from the concentrate with light petroleum ether, which was filtered and washed with a little of benzene and then with copious amounts of petroleum ether. The product was recrystallized from dichloromethane-petroleum ether. The recrystallized product was further purified by column chromatography using Sephadex LH-20 column (25 cm×2.5 cm) and 1 : 1 mixture of dichloromethane and chloroform as the eluent (elution rate, approximately 1—2 ml min^{-1}). A broad brown band formed on the column top was eluted by CH_2Cl_2 and the eluent was concentrated under reduced pressure to about 5 ml and kept at 0 °C for a few days for crystallization. Thereby microcrystals (II) were deposited on the sides of the flask. These were collected washed with a little benzene, petroleum ether, dried under vacuum. The same compound was also obtained by precipitating it from the concentrated eluent with light petroleum ether and drying it under vacuum (yield 50%). The compounds I and II were found to be identical as has been found from chemical analysis, mp, mixed mp, IR and UV-visible spectral data. The compound has the formulation $[W(NSCl)Cl_3X'\ (L\text{-}L)]$ (X′=Cl or Br).

(b) (Reactions of 2,2′-Bipyridine and 1,10-Phenanthroline with $[W(NSCl)Cl_4]_2$. A stoichiometric amount of bpy or *o*-phen was added to a stirred suspension of $[W(NSCl)Cl_4]_2$ (ca. 0.1 mmol) in 25 ml of dichloromethane and stirring was continued for 1 h when the solution attained brown color. It was filtered and the filtrate was concentrated under reduced pressure. The concentrate was processed as described in A(a) (yield 60%).

(B) Reaction Medium-Tetrahydrofuran. The reactions were carried out by the same procedure as described in A(a) and A(b) except that tetrahydrofuran was used as the reaction medium in the place of dichloromethane. The working up of the reaction product, recrystallization of the compounds and their purification by column chromatography were done as described in (A).†

(C) Thermolysis of $[W(NSCl)Cl_3X'\ (L\text{-}L)]$ (L-L=bpy or *o*-phen; X′=Cl or Br). Thermolysis of $[W(NSCl)Cl_3X'\text{-}(L\text{-}L)]$ (exactly weighed) was carried out at about 250 °C for 4 h in a two necked flask having an inlet and outlet tube. Through the inlet tube a slow stream of nitrogen gas was allowed to pass slowly, while the gaseous products coming out of the outlet tube were bubbled into water. The hydrolyzed products were then analyzed for sulfur and chloride ion. The compound after thermolysis changed to pinkish grey color and was analyzed for $[WNCl_2X'\ (L\text{-}L)]_n$ (III).

In another experiment, the known weight of $[W(NSCl)\text{-}Cl_3X'\ (L\text{-}L)]$ was heated at 250 °C for 4 h over a watch glass. After cooling the change in weight was recorded. The loss in weight of the complex corresponded approximately to one mole of SCl_2 per mole of the complex.

Results and Discussion

The reactions of trimeric thionitrosyl chloride with $[W(CO)_3(L\text{-}L)X_2]$ yielded the novel compounds of empirical formula $[W(NSCl)Cl_3X'(L\text{-}L)]$ (**1**) (cf. Table 1). Apart from being a ligand linked to the metal ion as $(NSCl)^{-2}$, the trimeric thionitrosyl chloride oxidizes tungsten from II to VI oxidation state. In

† In THF, compounds became oily during recrystallization process.

270 (w)	δ (NSCl)		

a) IR bands due to coordinated 2,2′-bipyridine and 1,10-phenanthroline were observed in the expected region.

iodo complexes, both the iodide ions and in bromo ones only one bromide ion were substituted by the chloride ions in their respective products. The approximate amount of liberated iodine during the reaction was iodometrically estimated which conformed to two moles of iodide ions per mole of the complex.

The compounds are soluble in halo-substituted solvents and decompose in methanol to yield polymeric nitrido compound of empirical formula $[W_2N(L\text{-}L)\text{-}S_2Cl_5]$ as suggested by analytical and IR data. These when solubilized in $POCl_3$ yielded the moisture sensitive adduct $[W(NSCl)Cl_3X'(L\text{-}L)]\cdot POCl_3$ similar to the behavior of $[W(NSCl)Cl_4]_2$.

The compounds in general were preserved at low temperature (0 °C) as they undergo slow decomposition at room temperature yielding a pinkish grey compound. This was further corroborated by the results of the thermolysis experiments (vide infra). The gaseous products obtained by pyrolyzing the compound were hydrolyzed by bubbling in water and the halogen and sulfur contents were estimated. The results corresponded to the loss of a molecule of SCl_2 per molecule of the compound, as also suggested by the loss of weight of the compound after thermolysis. It appears that the complexes lose a molecule of SCl yielding pink nitrido complexes from which another chloride ion could be lost to preserve the charge balance similar to the earlier reported $M{=}N{=}S\diagdown_{Cl}$ complexes.[6] These may further be reduced partially to other polymeric tungsten nitrides in +V oxidation state.

The infrared spectra of all the compounds showed three medium to intense bands in the region 1000—900 cm^{-1} assignable to the stretching modes of M≡N=S moiety.[6,14,17,18] The bonding mode of NSCl moiety is further corroborated by the following chemical evidence.

The coordinatively unsaturated compound $[W(NSCl)\text{-}Cl_4]_2$ had been shown to have $[W{=}N{=}S\diagdown_{Cl}]$ unit by X-ray crystal structure studies. The reaction of this compound with bpy or *o*-phen yielded compounds of the type $[W(NSCl)Cl_4(L\text{-}L)]$ which were found to be identical to the compounds synthesized by the procedure A(a). The identical nature of these complexes, as also shown by X-ray powder patterns, gives one sufficient reason to believe that the (NSCl) moiety in our compounds have a $[M{=}N{=}S\diagdown_{Cl}]$ type of bonding, assuming reactions of bpy or *o*-phen do not affect the bonding mode of (NSCl).[19] Further the bands due to ν(WNS) of $[W(NSCl)Cl_3X'(L\text{-}L)]$ disappeared in the vibrational spectra of the pinkish grey thermolysis product and an intense band appeared at 990 cm^{-1}, assigned to ν(W≡N).[20,21] The shift of ν(W≡N) band position to lower wave numbers compared to that of W(VI) nitrido compounds (viz. 1040 cm^{-1}) could be attributed to the partial reduction of W(VI) to W(V)[20,21] (vide infra). The assignments of bands due to lack of crystal structure are somewhat tentative and additional studies are required to confirm their

identity.

The electronic spectral features of the compounds are given in Table 1. The spectra showed a band at around 250 nm, assigned to $\pi(X) \rightarrow d\pi(W(VI))$ charge transfer transition.[23] The band at around 500 nm was found to be split in general and one of its components along with 380 nm band could be attributed to the π(bpy or *o*-phen)$\rightarrow d\pi(W(VI))$ charge transfer transition. Preliminary solvent dependent studeis indicated the solvatochromism[23,24] associated with one of the components of the band at around 500 nm and this was utilized as a criterion for differentiating the charge transfer band. Its other component may possibly arise due to intraligand transition involving $=N=S\diagdown_{Cl}$ moiety or due to charge transfer transition of the $[M=N=S\diagdown_{Cl}]$ unit. All the compounds were found to be diamagnetic and their ESR spectra were recorded, wherein no signal was obtained. This indicates the presence of tungsten in VI oxidation state, substantiating further the linkage of NSCl as $M=N=S\diagdown_{Cl}$.

In the compounds preparted in tetrahydrofuran the solvated formulation viz. $[W(NSCl)Cl_3X'(L\text{-}L)]\cdot$ THF could be preferred over the coordinated one based on the following observations.

(i) The NMR spectra showed practically no shift in the resonances of the THF protons as compared to that of the free THF molecule.

(ii) The color and the mp's of the compounds were almost similar to those of the compounds prepared in dichloromethane.

(iii) The compounds were analyzed to $[W(NSCl)Cl_4(L\text{-}L)]\cdot$THF. The efforts to remove the solvated THF completely by different means were unsuccessful.

On the basis of the foregoing discussions the compounds were assigned the heptacoordinate structure $[W(NSCl)Cl_3X'(L\text{-}L)]$ with the metal ion in VI oxidation state. Although seven coordination is commonly not encountered in compounds of tungsten in higher oxidation states, it is however not unlikely.[25]

Thermodynamic Stability of Polycyclic Aromatic Hydrocarbons Detected in Our Environment

Jun-ichi AIHARA
Department of Chemistry, Faculty of Science, Shizuoka University, Oya, Shizuoka 422
(Received June 16, 1987)

Various polycyclic aromatic hydrocarbons (PAHs) are distributed widely in our environment. Diesel particulate extract contains many larger PAHs. All these PAHs have a percent resonance energy larger than 2.50. Dibenzo[def,mno]chrysene and anthracene constitute the most unstable PAHs among them. A couple of reaction paths to the formation of ovalene are discernible in flames by inspecting the combustion products. It seems likely that a similar type of reactions take place in the envelopes of carbon stars to give large compact PAHs and graphite.

Polycyclic aromatic hydrocarbons (PAHs) are formed abundantly by incomplete combustion of organic matter and fossil fuel.[1,2] As a result, they are distributed virtually everywhere in our environment. Although reaction mechanisms in flames remain very elusive, formation of many PAHs has been confirmed by means of chromatographic and spectroscopic methods.[1,2] Recently, Jinno et al. elaborately analyzed the Diesel particulate extract, and identified many very large PAHs.[3-6] Most PAHs detectable both in our environment and in the Diesel particulate extract are devoid of side chains and substituents. PAHs can nowadays be detected in the interstellar medium.[7,8] In this paper we attempt to find a rationale for the presence of such PHAs not only in our environment but also in the combustion products.

We previously defined the percent resonance energy (%RE) of a given molecule[8-11] as 100 times the graph-theoretically defined resonance energy,[9,12-15] divided by the total π-electron energy of the olefinic reference structure.[8-11] Many examples indicate that the %RE is an excellent index for determining the thermodynamic stability of a cyclic conjugated system. We first estimate the degree of thermodynamic stability for widely detectable PAHs by evaluating the %REs. We then seek for the formation mechanisms of PAHs in incomplete combustion. Analysis of combustion processes might give an important clue to the question as to why there are large compact PAHs and graphite in the interstellar medium.[7,8] Simple Hückel theory is used to calculate %REs.

Results and Discussion

The %REs of all PAHs investigated are listed in Table 1. The PAHs distributed widely in air, water, soil, and tissue are classified as group-A PAHs.[1,2] They are usually formed by incomplete combustion of fossil fuel, organic matter, and plants, polluting our entire environment. It is noteworthy that all group-A PAHs have a %RE larger than 2.50 in the ground electronic state. Group-B PAHs are the ones identified in the Diesel Particulate extract by Jinno et al.[5,6] These very large PAHs again have a %RE larger than 2.50. Most of the group-A PAHs are of course detectable in the Diesel Particulate extract.[3,4] Thus, automobile exhaust is full

Table 1. Percent Resonance Energies of Polycyclic Aromatic Hydrocarbons

PAH	RE/β	%RE	PAH	RE/β	%RE
Group A			Benzo[*rst*]pentaphene (**19**)	0.861	2.60

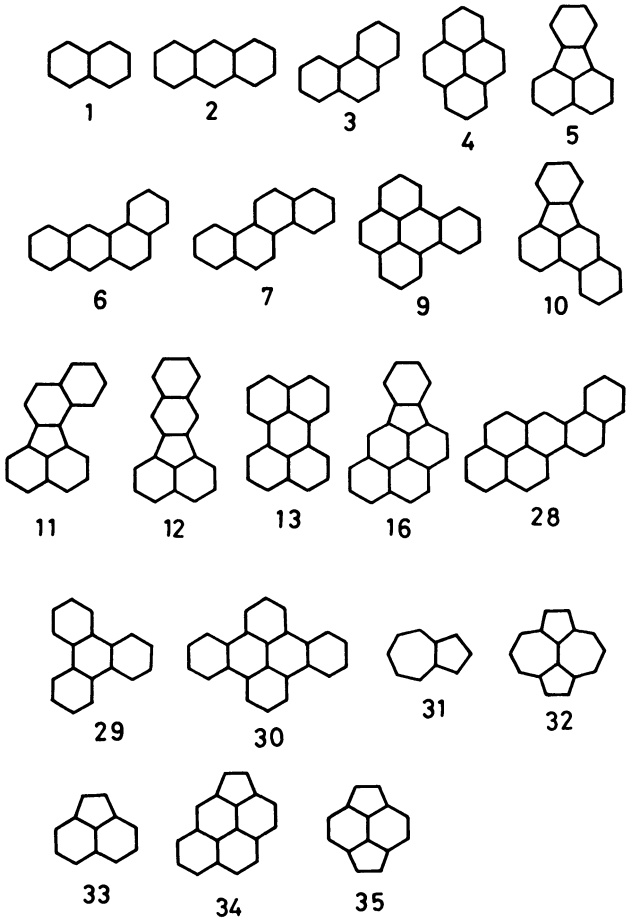
Indeno[1,2,3-*cd*]pyrene (**16**)	0.785	2.57	Azupyrene (**32**)	0.217	0.99
Coronene (**17**)	0.947	2.82	Acenaphthylene (**33**)	0.354	2.18
			Cyclopenta[*cd*]pyrene (**34**)	0.565	2.27
Group B			Pyracylene (**35**)	0.106	0.55
Naphtho[1,2,3,4-*def*]chrysene (**18**)	0.925	2.79			

of PAHs. Dibenzo[*def,mno*]chrysene (**14**) and anthracene (**2**) constitute the most unstable PAHs among them.

Schmidt stressed that the thermodynamic stability of PAHs plays only a secondary role in determining the composition of combustion products.[16] This never means that the composition of the PAHs found in our environment are not governed by any thermodynamic factor. There are many PAHs which are less stable than dibenzo[*def,mno*]chrysene (**14**) and anthracene (**2**).[17,18] However, they have not been detected around us. Therefore, we might say that some thermodynamic factor indeed operates in the combustion process and in our environment.

Labile PAHs may be formed in substantial amounts in flames, but readily degrade thereafter. Therefore, the %REs of group-A and group-B PAHs give a good criterion for choosing PAHs which have a possibility of surviving in our environment. In other words, the %RE of 2.50 marks a borderline between stable and unstable PAHs. If a given PAH has a %RE larger than 2.50, it would not degrade readily. Such PAHs are being accumulated in our environment, polluting air, soil, water, and food.[1,2] In the polyacene series, the %REs of naphthacene and higher members are smaller than 2.50.[8] They are missing not only in the Diesel exhaust but also in our environment.[1-6]



Let us briefly review the formation mechanism of PAHs in incomplete combustion. Numerous intermediate species are involved whose sequential formation and destruction give a progression to decreasing amounts of larger species.[19-26] The largest amounts of species being produced and consumed in combustion are acetylene, 1,3-butadiyne (diacetylene), and 1-buten-3-yne (vinylacetylene).[20,21,25] These unsaturated aliphatics have been identified as important species for the growth of PAH and soot by addition reactions with aromatic radicals. Specifically, the combined presence of aromatic radicals and acetylene is particularly favorable to the growth of PAHs.[20,25]

In a hydrogen-deficient environment, rather compact PAHs with a low H/C ratio are produced preferentially. Non-compact PAHs provide active bonding sites for the attachment of smaller unsaturated species in Diels-Alder and cycloaddition reactions.[16] Compact PAHs must be less reactive in flames full of acetylenic species than non-compact ones. In this sense, the stability of compact PAHs are not only thermodynamic but also kinetic in nature. Compact PAHs, such as pyrene (**4**), dibenzo[*def,*

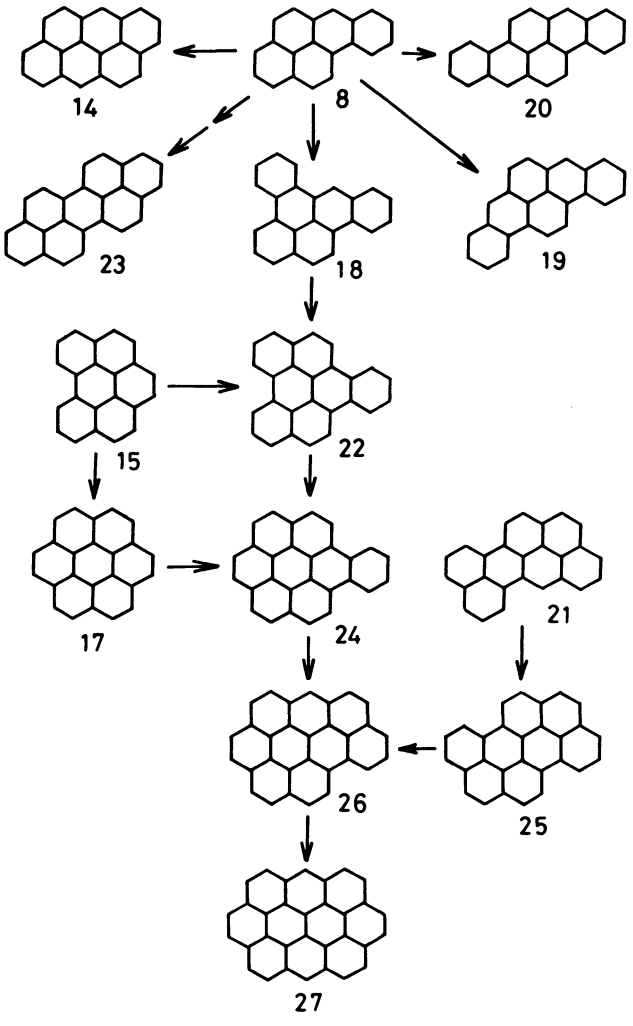


Fig. 1. Possible reaction paths in a Diesel engine.

mno]chrysene (**14**), coronene (**17**), and ovalene (**27**), are neither mutagenic nor carcinogenic.[1,27] Lack of carcinogenicity coincides with the non-existence of L and bay regions.

With such combustion chemistry in mind, possible reactions in a Diesel engine[3–6] can be inferred from the composition of combustion products. As shown in Fig. 1, most group-B PAHs can be arranged in such a manner that they constitute a couple of thermodynamically favored routes for building up ovalene (**27**), a typical large compact PAH. According to the reaction scheme of Stein[23] and Bockhorn et al.,[25] each PAH in this figure represents addition of one ring at a time. Starting with benzo[*a*]pyrene (**8**) and naphtho-[8,1,2-*bcd*]perylene (**21**), individual rings are added by the formal addition of either C_4H_2 or C_2 units. Since most group-B PAHs can be arranged in this manner, it is highly probable that they are formed consecutively according to the analogous reaction scheme. Many other reaction pathways are in principle possible.

It is known that individual PAHs themselves serve to accelerate the formation of larger members of the group.[26] This further rationalizes the reaction scheme given in Fig. 1. Benzo[*ghi*]perylene (**15**) and coronene (**17**) coexist fairly abundantly in the automobile exhaust.[19] Therefore, air in Los Angeles is rich in **15** and **17**.[28] Such a comparative study supports the existence of a reaction route along which **17** is formed from **15**. There is a discontinuity between benzo[*a*]-pyrene (**8**) and dibenzo[*cd,lm*]perylene (**23**) in Fig. 1. Naphtho[2,1-*a*]pyrene (**28**) must intervene between them. Although this PAH was not detected in the Diesel exhaust, it has been detected in the hard-coal combustion effluents.[16]

Various dimerization products are obtained by pyrolysis of naphthalene (**1**), among which are benzo-[*j*]fluoranthene (**11**), benzo[*k*]fluoranthene (**12**), and perylene (**13**).[29] Thus, there are reaction paths along which small PAHs grow into larger ones through dimerization with elimination of hydrogen. By analogy, fluoranthenes (**5**, **10**, **11**, **12**) and indeno[1,2,3-*cd*]pyrene (**16**) are presumably prepared by the condensation of two smaller aromatics.

Fully benzenoid hydrocarbons are the PAHs whose Clar structures consist of aromatic sextets only.[30] They are the PAHs of supreme thermodynamic stability.[8,17,18] Triphenylene (**29**) and dibenzo[*fg,op*]-naphthacene (**30**) belong to the PAH family of this type. However, such PAHs are scarcely detected in the Diesel particulate extract and in our environment.[1–6] It was this fact that convinced Schmidt that thermodynamic factors are of secondary importance in combustion processes.[16] Fully benzenoid hydrocarbons have three or more bay regions, which are susceptible at high temperatures to reaction with acetylenic species.

In general, the carbon skeleton of a benzenoid PAH is stable towards isomerization and cleavage. Azulene (**31**) and azupyrene (dicyclopenta[*ef,kl*]heptalene) (**32**) thermally isomerize to naphthalene (**1**) and pyrene (**4**), respectively.[31,32] However, no reverse reaction occurs. This is why such nonbenzenoid PAHs are not found in our environment.[1–6] This is also why Fig. 1 consists of benzenoid PAHs alone. Semibenzenoid PAHs, such as fluoranthenes (**5**, **10**, **11**, and **12**) and indeno[1,2,3-*cd*]pyrene (**16**), seem to be free from this type of isomerization. Bay regions adjacent to a five-membered ring of a fluoranthene-type molecule appear to be much less reactive toward dienophiles.

Recently, infrared (IR) astronomy revealed that a set of discrete IR lines are emitted from many astronomical objects, such as reflection nebulae and active galaxies.[7] In 1984 Léger and Puget proposed that these IR bands can be assigned reasonably to fundamental vibrations of large compact PAHs in the interstellar medium.[33–36] These PAHs are presumably placed in the intense radiation field since they must be excited electronically in advance of IR emission. In a previous paper,[8] we supported the view of Léger and Puget by showing that many large compact PAHs have large %REs both in the ground and excited states.

Formation mechanisms of PAHs and graphite in the interstellar medium have not been clarified yet.[7] There is no evidence for the existence of small PAHs in the astronomical IR spectra. We showed that small PAHs are photochemically very unstable.[8] Then, the most plausible formation mechanism of PAHs in the intense radiation field is shattering of graphitic carbon grains in shocks.[34,37,38] However, if interstellar matter is rather dense, and if it is not exposed to hard UV radiation, the growth of PAHs and graphite from small molecular pieces is possible. This condition might be satisfied in such places as envelopes of carbon stars.[22,34]

In case PAHs are formed from smaller molecules in space, the combustion processes discussed above will give an important clue to the details of their formation mechanism. There are abundant acetylenic hydrocarbons not only in flames but also in the interstellar medium.[7] Reactions in flames must resemble those in the interstellar medium, in that large compact PAHs are formed preferentially. Thus, the formation of graphitic carbon grains and PAHs and their injection into the interstellar medium is explainable.[22,34]

Concluding Remarks

The PAHs which are formed in incomplete combustion and survive in our environment were found to be thermodynamically fairly stable. In general, the %REs of widely detectable PAHs are greater than 2.50. The PAHs with the %REs$<$2.50 presumably degrade rapidly in our environment. Some PAHs with the

%RE>2.50 are missing or very scanty in our environment, which may imply that they are scarcely formed in flames. For example, perylene (**13**) is very scanty in our environment for a very stable PAH.[1)]

Acenaphthylene (**33**) has been detected in flames.[16,20)] Cyclopenta[cd]pyrene (**34**) was isolated exceptionally from carbon black.[39)] These PAHs have an olefinic C-C double bond, and their %REs are much less than 2.50. Since these PAHs are not very stable, it seems unlikely that they can survive long in our environment. Pyracylene (cyclopent[*fg*]acenaphthylene) (**35**) is essentially olefinic with a very small positive %RE. It has been reported that this compound is also formed in flames.[20,22)] Synthetic pyracylene is stable only in solution, and far from isolable.[40,41)]

Most of group-A and group-B PAHs are photochemically unstable with negative or small positive %REs in the electronically excited state.[8)] This implies that the photochemical instability is not a crucial factor for determining the composition of combustion products. This is in marked contrast to the situation in the interstellar medium, where photochemically stable PAHs alone are probably abundant due to strong UV radiation.[8)]

Helpful discussion with Prof. Kiyokatsu Jinno (Toyohashi Univ. Technol.) is gratefully acknowledged.

The Crystal Structure and Intramolecular Electron Transfer of 1′,1‴-Diethylbiferrocenium Triiodide at 298 and 140 K

Michiko KONNO* and Hirotoshi SANO†,*
Department of Chemistry, Faculty of Science, Ochanomizu University, Otsuka, Bunkyo-ku, Tokyo 112
†Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya-ku, Tokyo 158
(Received September 3, 1987)

The crystal structure of 1′,1‴-diethylbiferrocenium triiodide, $(EtFcFcEt)^+ I_3^-$, was determined by means of X-ray diffraction. The crystals at 298 and 140 K are found to be monoclinic, with the $P2_1/c$ space group and with $Z=2$. At 298 K, $a=9.7557(10)$, $b=9.9772(12)$, $c=13.8216(13)$ Å, $\beta=107.625(9)°$, and $U=1282.18(23)$ Å^3, while at 140 K, $a=9.6931(17)$, $b=9.8065(22)$, $c=13.7373(19)$ Å, $\beta=107.642(15)°$, and $U=1244.4(4)$ Å^3. The structures are refined to $R=0.049$ at 298 K and $R=0.036$ at 140 K. The $(EtFcFcEt)^+$ cations and I_3^- anions sit on a crystallographic center of symmetry both at 298 and at 140 K, and the two ferrocenyl(Fc) units are crystallographically equivalent. The ethyl group in each ethylcyclopentadienyl(EtCp) group is not parallel to the fulvalene moiety, but the terminal CH_3 group moves away with the 60° inclination from the Cp plane. An appreciable interaction seems to exist between the Cp ring of the cation and the I_3^- anion along the $a+c/2$ direction, but the interaction among the cations along the a axis seems to be so weak as to be negligible.

Recently, a number of monooxidized salts of binuclear ferrocene derivatives have been studied in order to clarify the mechanism of the intramolecular electron transfer between the metal atoms through the bridged ligands by measurements of the ^{57}Fe-Mössbauer, IR, and EPR spectra. It has been reported[1,2] that biferrocenium and 1′,1‴-dialkylbiferrocenium (alkyl=ethyl, propyl, butyl) triiodides show the temperature dependences of the valence state of iron atoms. We ourselves have previously reported[3] that the crystal structure of 1′,1‴-dipropylbiferrocenium($Pr^nFcFcPr^n$) triiodide changes from the state of an equivalent set of two Fc units and a triiodide anion with a symmetric I–I–I structure at 298 K to the state of an unequivalent set of ferrocene- and ferrocenium-like units and a triiodide anion with an unsymmetric structure I–I···I, showing positional disorder in the triiodide anions on the (110) plane at 110 K. These results agree with the Mössbauer spectroscopic data, which show a change from two doublets to one doublet around 240 K. On the other hand, 1′,1‴-dihalobiferrocenium salts[4] show no temparature dependence of the valence state of iron atoms. A comparison of the crystal structures of 1′,1‴-diiodo- or 1′,1‴-dibromobiferrocenium cations, which show an averaged valence state, with the structure of 1′,1‴-dichlorobiferrocenium$^+$ cations, which show a trapped valence state, suggests that the valence state of iron atoms is greatly affected by the symmetric or unsymmetric interaction of the triiodide anions with the cations. The Mössbauer spectra of biferrocenium salts[5] show that the transition temperature is lowered by 150 K when the I_3^- anions are replaced with Br_2I^- anions. The crystal structure of biferrocenium triiodide, which shows a trapped valence state at 296 K, indicates that the two Fc units are crystallographically equivalent. The 1′,1‴-diethylbiferrocenium (EtFcFcEt) triiodide shows a transition from the trapped to the averaged valence state around 270 K, as $(Pr^nFcFcPr^n)^+I_3^-$ does around 240 K in the Mössbauer spectra. In the present paper, we will report the crystal structures of $(EtFcFcEt)^+I_3^-$ at 298 and 140 K and discuss the differences in the crystal structures and IR spectra between $(EtFcFcEt)^+I_3^-$ and $(Pr^nFcFcPr^n)^+I_3^-$ in order to elucidate the infuluence of molecular packing and the effects of the triiodide anion and of different substituted groups on the intramolecular electron transfer in the cations and, therefore, on the valence state of iron atoms.

Experimental

X-Ray Measurements. The crystals of $(EtFcFcEt)^+I_3^-$ were kindly supplied by Dr. Seiichi Iijima. A dark-green thin plate crystal was sealed into a Lindemann-glass capillary for the intensity measurements. Preliminary oscillation and Weissenberg photographs taken at room temperature by means of Cu $K\alpha$ radiation showed that the crystal is monoclinic with the space group of $P2_1/c$. The final lattice constants were determined by the least-squares procedure based on the θ values of 33 reflections at 298 K and of 20 reflections at 140 K measured by a diffractometer using Ag $K\alpha$ radiation. The crystal specimen was cooled by a stream of cold N_2 gas surrounded by a warmer N_2 gas curtain. The temperature was controlled electrically at 140±2 K by monitoring with a chromel-almel thermocouple throughout the experiment. The intensities were collected on a Rigaku automated four-circle diffractometer using graphite-monochromated Ag $K\alpha$ radition ($\lambda=0.5609$ Å). Three standard reflections ($10\bar{2}$ 300 020) were measured for every fifty reflections. The intensity data were corrected for Lorentz and polarization effects, but no corrections for absorption and extinction were made. The crystal data and experimental conditions are summarized in Table 1.

Infrared Measurements. The infrared spectra were recorded on a Fourier-transform spectrometer (NICOLET 7199). All samples were prepared as KBr pellets 13 mm in diameter. For the low-temperature measurements, the sample mounted in a holder was cooled by means of a copper plate linked to liquid nitrogen in a Dewar apparatus with KRS-5 windows.

Structure Determination

The position of the Fe and I atoms were deduced from three-dimensional sharpened Patterson maps. The electron density Fourier maps using the phases calculated on the basis of the coordinates of these atoms revealed the position of all the C atoms. Difference Fourier maps were used to locate the position of all the H atoms. The structure was refined by a full-matrix least-squares program RADIEL[6] on the basis of F magnitudes with unit weight for all the reflections. Anisotropic thermal parameters and isotropic thermal parameters were applied to the non-hydrogen atoms and the hydrogen atoms respectively. Atomic scattering factors for the non-hydrogen atoms were taken from International Table for X-Ray Crystallography,[7] and those for H atoms, from the data reported by Stewart et al.[8] The initial atomic

coordinates at 140 K were readily deduced from those at 298 K. Refinements at 140 K were carried out in the same way as those at 298 K. The *R* factors converged to 0.049 at 298 K and to 0.036 at 140 K. The final atomic parameters are given in Table 2.††

Results and Discussion

Description of the Crystal Structure. The projections of the structure along the a and b axes at 140 K are shown in Figs. 1 and 2 respectively. The $(EtFcFcEt)^+$ cations have a trans-configuration, with the two iron atoms on opposite sides with respect to the fulvalene moiety. Both the $(EtFcFcEt)^+$ cations and the I_3^- anions sit on a crystallographic center of symmetry at 298 and 140 K. The presence of the center of symmetry requires two Fc units in a cation which are crystallographically equivalent at both temperatures. The interplanar distances between the two five-membered rings in each Fc unit in the cation and their dihedral angles are, respectively, 3.351 Å and 4.8° at 298 K and 3.355 Å and 4.6° at 140 K. The distances from the iron to the least-squares planes of the two

Primed and unprimed atoms are related by the inversion center at the center of the molecule.

five-membered rings are 1.670(7) and 1.683(3) Å at 298 K and 1.674(3) and 1.684(1) Å at 140 K for inner or fulvalene and outer or ethylcyclopentadienyl(EtCp) rings respectively. The bond distances (298 and 140 K) and bond angles (298 K) are given in Table 3. The mean Fe-C distances are estimated to be 2.065 and 2.060 Å at 298 K and 2.068 and 2.072 Å at 140 K for the inner and the outer rings respectively. These values agree well with the mean Fe-C distances of 2.059, 2.071, and 2.060 Å observed in the $(Pr^nFcFcPr^n)^+$,[3] 1′,1‴-diiodobiferrocenium$^+$,[4] and biferrocenium$^+$[2] cations respectively. The C-C bond distances in the fulvalene moiety are distributed from 1.418(14) to 1.443 (12) Å, with the mean bond distance of 1.431 Å, while those in the cyclopentadienyl(Cp) ring are found in the range from 1.356(25) of C(7)-C(8) to 1.429(21) Å of C(6)-C(7) at 298 K. These large deviations found in the Cp ring are to be ascribed to the interaction between the Cp ring and the I_3^- anion along the $a+c/2$ direction; that is, the linear I_3^- anions come close to the Cp rings, with distances of 3.709 Å (298 K) and 3.641 Å (140 K) from the Cp plane and inclinations of 60.3° (298 K) and 61.1° (140 K) to its plane pointing to the middle of the C(6)-C(7) bond.

It has previously been reported that two Mössbauer doublets converge to one doublet above 270 and 240 K in $(EtFcFcEt)^+I_3^-$ and $(Pr^nFcFcPr^n)^+I_3^-$ respectively, revealing that a trapped valence state, Fe(II) and Fe(III), at low temperatures become an averaged valence state with two iron atoms which cannot be distinguished in the Mössbauer time scale, ca. 10^{-7} s, above the transition temperatures. The results of the Mössbauer spectra of $(EtFcFcEt)^+I_3^-$ require two kinds of valence states of Fe atoms in the Fc units below 140 K in the Mössbauer time scale, while the crystal structure at 140 K indicates that $(EtFcFcEt)^+$ cations sit on the center of symmetry and are crystallographically equivalent, contradicting the results of the Mössbauer spectra. If an electron was hopping between the two Fc units more slowly than the Mössbauer time scale, ca. 10^{-7} s, or was localized in a static state to form Fe(II) and Fe(III), disordering the cations in space, it should be reflected in an unusually high thermal motion and a large anisotropy of each atom, especially those of the Cp rings in the cations. The thermal parameters are, however, very well defined, with equivalent thermal parameters, U_{eq}, in the range from 0.0181(16) to 0.0255(18) Å^2 for C atoms in Cp rings and fulvalene moieties and 0.0192(2) and 0.0246(1) Å^2 for I atoms at 140 K, in comparison with the range from 0.0368(25) to 0.0670(54) Å^2 for C atoms and 0.0452(3) and 0.0605(3) Å^2 for I atoms at 298 K. These values for the C atoms at 140 K correspond to the root mean-square amplitudes from 0.13 to 0.16 Å. The anisotropic temperature factors of U_{11} and U_{22} for all the atoms except the C(9) and C(10) atoms are larger than those of U_{33} at 140 and 298 K respectively, and their U_{11}/U_{33} and U_{22}/U_{33} rations at 140 K become slightly larger than those at 298 K. In 1′,1‴-dibutylbiferrocenium$^+I_3^-$ and 1′,1‴-dichlorobiferrocenium$^+I_3^-$, both with a trapped valence state, Fe(II)-Fe(III), the interplanar distances between two five-membered rings in ferrocene- and ferrocenium-like units are found to be 3.313 and 3.390 Å for the 1′,1‴-dibutylbiferrocenium salt[2] and 3.26 and 3.38 Å for the 1′,1‴-dichlorobiferrocenium salt[4] respectively.

The difference between ferrocene- and ferrocenium-like units is about 0.10 Å, therefore, the displacement in the position of the Cp rings between ferrocene- and ferrocenium-like units is estimated to be about 0.05 Å. The overall amplitude of about 0.15 Å due to the thermal motion of the molecules and the mosaicity of the crystal may sufficiently smear this positional difference.

In $(Pr^nFcFcPr^n)^+I_3^-$, the cations and the anions sit on the crystallographic center of symmetry at 298 K, while the center of symmetry is lost on the (110) plane and two unequivalent Fc units are observed at 110 K. However, if the whole crystal has no center of symmetry, a dipole moment will remain in only one direction. Hence, one ordered structure on the (110) plane and its reversely ordered structure, in which Fe(II) and Fe(III) units in a cation and an I_3^- anion are inverted in relative to the former structure, are stacked at random or in an orderly manner along the $\boldsymbol{a}+\boldsymbol{b}$ direction, and the whole structure should have a center of symmetry. The comparison of the molecular structure and the packing in $(EtFcFcEt)^+I_3^-$ with those in $(Pr^nFcFcPr^n)^+I_3^-$ or biferrocenium$^+I_3^-$ gives an important suggestion with regard to investigating the effect of anions on the electron-transfer process between the two Fc units. The packings of the cations and anions on the (100) plane of $(EtFcFcEt)^+I_3^-$ and biferrocenium$^+I_3^-$ and on the (001) plane of $(Pr^nFcFcPr^n)^+I_3^-$ are the same as that on the (100) plane of the NaCl type, but different inclinations of the two ions in the direction perpendicular to these planes are found because substituent groups give rise to different stacking modes on the (010) plane for $(EtFcFcEt)^+I_3^-$, the $(\bar{1}11)$ plane for biferrocenium$^+I_3^-$, and the (110) plane for $(Pr^nFcFcPr^n)^+I_3^-$ as is shown in Fig. 3. In the $(EtFcFcEt)^+$ cations, the ethyl group of ethylcyclopentadienyl(EtCp) is found not to be parallel to the fulvalene moiety, but the terminal CH_3 moves away with the 60° inclination from the Cp plane, as observed in neutral 1′,1‴-diethylbiferrocene.[9] The ethyl groups in a cation contact ethyl groups in adjacent cations along the a axis in a longer distance than the van der Waals' contact, hence, the intermolecular interaction among cations along the a axis should be very weak, while an appreciable interaction between the Cp ring of a cation and an I_3^- anion is found along the $\boldsymbol{a}+\boldsymbol{c}/2$ direction. In $(Pr^nFcFcPr^n)^+$ cations, the propyl groups of Pr^nCp go parallel to the fulvalene moiety, and a π–π interaction between the Cp rings between the adjacent cations along the c axis is found to exist with the interplanar distance of 3.47 Å, providing a segregated column structure of cations and anions along the c axis. In biferrocenium$^+I_3^-$, an interaction between the Cp rings of adjacent cations and an overlapping between a fulvalene moiety of the cation and an I_3^- anion are observed on the $(\bar{1}11)$ plane. If one Fc unit in a cation has a more positive charge, one of the I atoms in an I_3^- anion in the vicinity of the cation along the $-\boldsymbol{a}+\boldsymbol{b}$ direction will have a more negative charge and one of the I–I bonds in the anion will get a longer bond distance, such as I(1)–I(2)=2.948 Å and I(2)–I(3)=2.902 Å at 110 K in $(Pr^nFcFcPr^n)^+I_3^-$, whereas a symmetric relative position is found with respect to a Fc unit and an I_3^- anion along the $\boldsymbol{c}$ and $\boldsymbol{b}+\boldsymbol{c}$ directions, putting a more negative charge in the central I atom in the I_3^- anion in both $(EtFcFcEt)^+I_3^-$ and biferrocenium$^+I_3^-$. The intermolecular distances between iron and iodine atoms given in Table 4 show the symmetric relative position in $(EtFcFcEt)^+I_3^-$.

The segregated column structrue and the presence of a rotational disorder of propyl group in a Pr^nCp in $(Pr^nFcFcPr^n)^+I_3^-$ may provide the driving force for an ordered structure on the (110) plane with the distinguishable Fe(II) and Fe(III) states observed at 110 K. On the other hand, the presence of isolated cations and the weak interaction between the cations and anions may bring about a disordered symmetric structure of the cations at low temperatures in $(EtFcFcEt)^+I_3^-$.

Infrared Spectroscopy. It is difficult to judge whether both the ground states of the $(EtFcFcEt)^+$ and

$(Pr^nFcFcPr^n)^+$ cations at 300 K are to be ascribed to the complete delocalization of the electrons or to the rapid intramolecular electron hopping. The IR spectra of $(EtFcFcEt)^+I_3^-$ and $(Pr^nFcFcPr^n)^+I_3^-$ at 294 and 78 K are illustrated in Fig. 4. Strong, new bands are observed in the vicinity of 680 and 1525 cm^{-1} in the IR spectra when the neutral $Pr^nFcFcPr^n$, EtFcFcEt, 1′,1‴-diiodo-, 1′,1‴-dibromo-, and 1′,1‴-dichlorobifferocene[4] are monooxidized. Moreover, the intensities of these two bands are very strong in their trapped valence states, while they become weak in their averaged valence states, judging from the Mössbauer spectra. The single bands at 700 and 703 cm^{-1}, observed in the IR spectra[10] of fulvalene(Cp_2) and carbene(Cp) respecively, are assigned to an out-of-plane C–H deformation. Two new bands around 680 cm^{-1} may be the same bands as those for the Cp and fulvalene moieties. The intensity of the single band at 1525 cm^{-1} is unusually strong in the trapped valence states. The C=C skeletal stretching vibrations are observed from near 1500 to 1600 cm^{-1} in aromatic compounds. The fulvalene has a center of symmetry in the unoxidized compounds, but loses it in monooxidized cations if the cations are not in a delocalized ground state. Hence, the band at 1525 cm^{-1} may be assigned to a C=C stretching mode of the fulvalene ring, and the coupling of this vibration mode with the electrons distributed unsym-

metrically in the fulvalene moiety may be considered to give rise to the unusually strong intensity at 78 K. On the other hand, this band does not vanish at 294 K. This indicates that the hole of the cation in the averaged-valence state is not completely delocalized.

Conclusion

Alkyl groups in the monooxidized biferrocenium derivatives affect the packing between the cations and anions, and the different interaction of anions with cations gives a different phase transition temperature. The electronic state of cations will couple with a phonon mode because a positive charge of a cation and a negative charge of an anion attract each other. However, in 1′,1‴-dibromo- and 1′,1‴-diiodobiferrocenium$^+I_3^-$, a strong intramolecular interaction resulting from the overlap between the iodine or bromine group and one of the Cp rings of the fulvalene moiety will generate an averaged valence state, even at a low temperature.

NQR of ^{35}Cl, ^{127}I, and ^{121}Sb in $I_3Cl_2SbCl_6$ and ICl_2SbCl_6

Mitsuo MISHIMA* and Tsutomu OKUDA†
Department of Chemistry, Shimane Medical University, Izumo 693
†Department of Chemistry, Faculty of Science, Hiroshima University, Hiroshima 730
(Received September 7, 1987)

NQR spectra due to ^{35}Cl, ^{127}I, and ^{121}Sb in $I_3Cl_2SbCl_6$ and ICl_2SbCl_6 have been observed in the temperature range 77 K to melting point. The Zeeman effect on the single crystals of these complexes has been examined. In $I_3Cl_2SbCl_6$ the η-values for the I atoms contributing to the higher and the lower NQR frequencies are 0.73 to 0.09, respectively, whereas in ICl_2SbCl_6 the η-value for the I atom is 0.15. In these complexes the ^{35}Cl NQR lines which yield large η-values (0.42 to 0.56) are assigned to the bridging Cl atoms. The η-values for the other Cl atoms, except the Cl atoms in the ICl_2^+ ion which have η-values of 0.13 to 0.15, are negligibly small. The Sb atoms in both complexes have considerably large η-values (0.39). The orbital populations have been calculated from the NQR parameters. The bonding in the cations is explained on the basis of an approximation using only p orbitals of the I atom.

The NQR investigations on a number of polyhalogen anions shed light on the charge distribution and the interaction between these anions and the surrounding cations.[1-8] Above all, the bonding in trihalides was satisfactorily explained in terms of a three-center four-electron (3c-4e) bond or a resonance hybrid X-Y $X^- \longleftrightarrow X^-$ Y-X. On the other hand, polyhalogen cations are less stable,[9] and the crystal structures of a few compounds were determined by X-ray analysis. The NQR data on the polyhalogen cations were reported for the first time by Evans and Lo,[10] who assigned the ^{35}Cl resonance lines in ICl_2AlCl_4 roughly to the ICl_2^+ and the $AlCl_4^-$ ions. Merryman et al.[9,11] observed the resonances of ^{35}Cl and ^{127}I in $I_2ClSbCl_6$, $I_2ClAlCl_4$, I_3AlCl_4, and I_5AlCl_4, and estimated atomic charges and bond populations. From the known crystal structures of polyhalogen derivatives,[12-16] it is inferred that bridging halogen atoms construct infinite chains of cations and anions. It is therefore important to elucidate the bond character in detail.

Birchall and Myers[14] reported the crystal structure of $I_3Cl_2SbCl_6$ and threw doubt on the presence of $I_2ClSbCl_6$ on the basis of the unit cell parameters and the Raman spectrum. They followed the method of Shamir and Lustig[17] in an attempt to prepare $I_2ClSbCl_6$. It is of interest to know whether this complex is present or not. Although ICl_2SbCl_6 is one of the first compounds in which the presence of the polyhalogen cation was well established by crystallographic study,[12] this complex has not been investigated by NQR yet, so far as we know.

In this paper we describe the results of the NQR Zeeman investigations on single crystals of the complexes $I_3Cl_2SbCl_6$ and ICl_2SbCl_6. The choice of the $SbCl_5$-complexes was favored since the resonances of ^{35}Cl, ^{127}I, and ^{121}Sb could be observed in the course of the experiment. Furthermore a comparison of the Zeeman data with the structural ones was considered to yield useful information on the assignment of the NQR lines and charge distribution.

Experimental

Complexes of $I_3Cl_2SbCl_6$ and ICl_2SbCl_6 were prepared in the manner described in the literatures.[14,18] These were identified by the melting points and the halogen contents. The procedure of Merryman and Corbett[11] was followed in an attempt to prepare $I_2ClSbCl_6$. The NQR spectra of this complex were essentially, except for some parts, identical with those in the literature.[11] Single crystals were grown by Bridgman's method.

A superregenerative spectrometer of Dean's type and a superregenerative parallel transmission line spectrometer were used for detecting the NQR lines. The absorption lines were observed on an oscilloscope. The resonance frequencies were determined with a frequency counter, TR-4142G, of Takeda Riken Co. The Zeeman effect was measured by means of the zero-splitting cone method. The Zeeman field was supplied by means of a Helmholtz coil. Temperature was measured by the use of a copper-constantan thermocouple.

Results

The NQR frequencies for ^{35}Cl, ^{121}Sb, and ^{127}I in $I_3Cl_2SbCl_6$ and ICl_2SbCl_6 are listed in Tables 1 and 2, respectively. Figures 1 and 2 show the temperature dependence of the resonance frequencies for ^{35}Cl

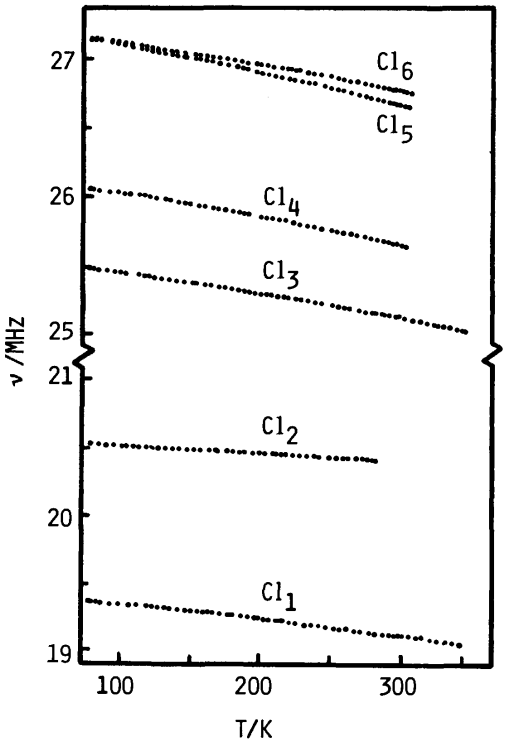

Fig. 2. Temperature dependence of ^{35}Cl NQR frequencies in ICl_2SbCl_6.

bonded to the Sb atom in $I_3Cl_2SbCl_6$ and ICl_2SbCl_6, respectively, in the temperature range from 77 K to the melting points. In $I_3Cl_2SbCl_6$, the NQR lines of the Cl_2 and Cl_3 atoms faded out at around 320 K, whereas the resonance of the Cl_1 atom could be detected up to the melting point. In ICl_2SbCl_6, similarly, the resonance lines of the Cl_1 and Cl_3 atoms could be detected up to near 350 K, and those of the other Cl atoms faded out in the range from 280 to 300 K. This suggests that the Sb–Cl_1 bond in $I_3Cl_2SbCl_6$ and the Sb–Cl_1 and Sb–Cl_3 bonds in ICl_2SbCl_6 are nearly parallel to the reorientational axis of the $SbCl_6$ group.[19,20] The other lines due to ^{35}Cl, ^{127}I, and ^{121}Sb in these complexes were observed up to their melting points.

The Zeeman effect on ^{35}Cl, ^{123}Sb, and ^{127}I in $I_3Cl_2SbCl_6$ was examined at room temperature. The zero-splitting loci are shown in Fig. 3. A single pattern was obtained for each resonance line. This is in agreement with the crystal structure which belongs to the space group $P\bar{1}$.[14] The calculated asymmetry parameters (η) are listed in Table 1 along with the coupling constants (e^2Qqh^{-1}). The Cl_1, I_2, and Sb atoms are characterized by their large η-values. The assignment of the NQR lines on the Cl atoms is based on a comparison of orientation of the efg axis at the

resonant nucleus with the corresponding bond directions, as seen in Table 3. The I_1 and I_2 atoms cannot be unequivocally assigned because of the parallelism of their efg axes and because of unreliability in the intensity ratio of the resonance lines. The assignment of these was decided by considering the relationship between the orientation of the efg axes and the charge distribution, as described below. The efg axes at the atoms Cl_2, Cl_3, and Cl_4 coincide in direction with the bond axes. The

Table 3. Angles between efg Axes and Bond Angles in $I_3Cl_2SbCl_6$

Bond	Cl_1–Sb	Cl_2–Sb	Cl_3–Sb	Cl_4–I_2
Cl_2–Sb	87.25°			
	(89.56)			
Cl_3–Sb	85.80	89.63		
	(89.71)	(89.97)

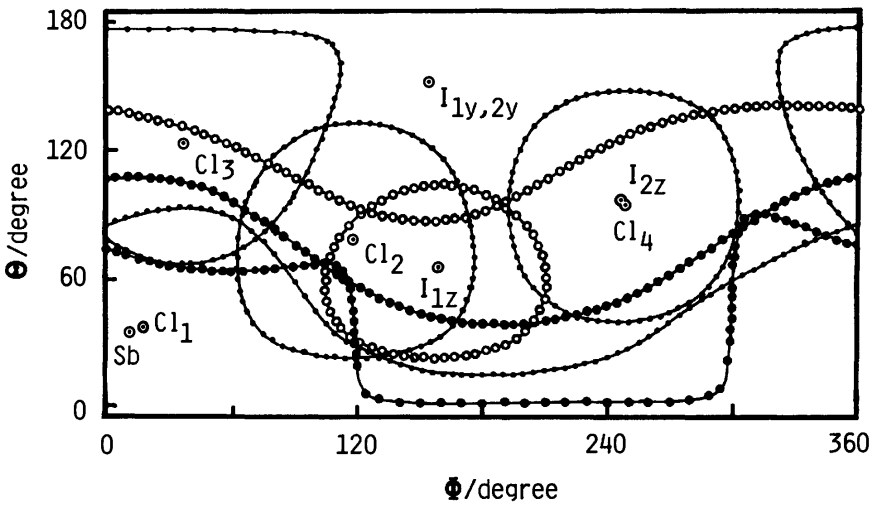

Fig. 3. Zero-splitting loci of ^{35}Cl, ^{127}I, and ^{121}Sb (ν_1, ν_2) Zeeman lines in $I_3Cl_2SbCl_6$.

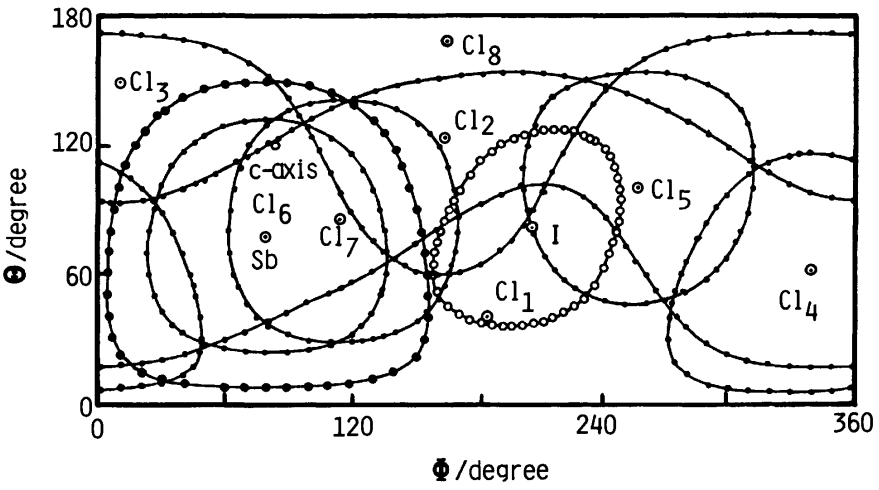

Fig. 5. Zero-splitting loci of ^{35}Cl, ^{127}I, and ^{121}Sb (ν_2) Zeeman lines in ICl_2SbCl_6. Cl_8 indicates the direction of the efg z axis calculated from the other crystal sites.

z axis at the bridging atom Cl_1 deviates from the Sb–Cl bond axis by ca. 6°, as shown in Fig. 4.

In ICl_2SbCl_6, forty zero-splitting loci for ^{35}Cl, ^{127}I, and ^{121}Sb are expected to be observed from its crystal structure, which belongs to the tetragonal space group $P4_1$.[12] However, only thiry-one loci could be found, since some efg z axes are nearly parallel to the rf field. The Zeeman effect on the Cl atoms bonded to the Sb atom was observed at 233 K, and that for the other atoms was observed at room temperature. The zero-splitting loci relating to one of the crystal sites are shown in Fig. 5. The NQR parameters are listed in Table 2. The η-value for the Cl_1 atom at room temperature was 0.6 percent less than that at 233 K. The efg axes and the corresponding bond directions are compared in Table 4, and the significant efg axes are shown in Fig. 6. The coupling constant of the I atom is comparable to the value of 3066±37 MHz at 4.2 K obtained from the ^{127}I Mössbauer effect.[13]

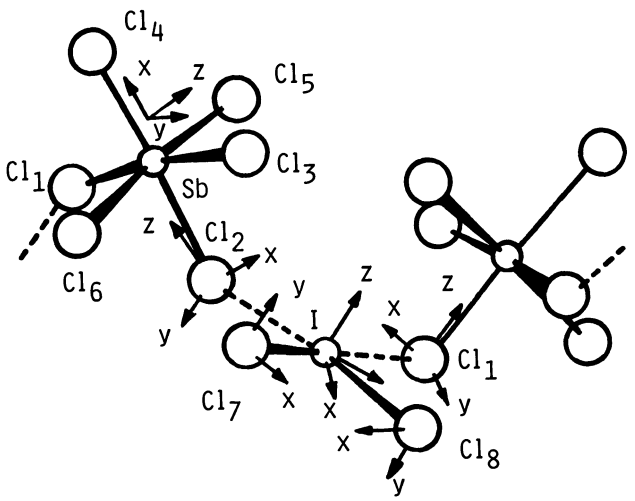

Fig. 6. Molecular shape of ICl_2SbCl_6.

Discussion

$I_3Cl_2SbCl_6$. The NQR spectrum is very similar to that reported previously for $I_2ClSbCl_6$,[11] except for some parts. The sample prepared by the method of Merryman and Corbett[11] exhibited the same spectrum as $I_3Cl_2SbCl_6$. This is verified by examining some samples. They reported that the absorption line due to ^{35}Cl was veiled by the very broad ^{121}Sb line and the corresponding ^{37}Cl line. These lines could not be seen, although the NQR spectrum was examined at various temperatures. The other parts of the spectrum in $I_3Cl_2SbCl_6$ were identical with that reported for $I_2ClSbCl_6$, except that the resonance frequency for the I_2 atom was somewhat different.

The I–I–I bond in the centrosymmetric planar $I_3Cl_2^+$ ion is completely linear. The I–I distance (2.906 Å) is considerably longer than a covalent I–I distance,[14] and is comparable to that in a symmetrical I_3^- ion of $(C_6H_5)_4AsI_3$ (2.90 Å).[21] In the present study the bonding in the I_3 part of the $I_3Cl_2^+$ ion was interpreted in terms of the 3c-4e bond. The atoms Cl_1, Cl_4, I_1, and I_2 are almost coplanar. The bridging $Cl_1\cdots I_2$ bond and the terminal Cl_4–I_2 bond make angles of 89.55° and 92.62°, respectively, to the I_1–I_2 bond. The $Cl_1\cdots I_2$–Cl_4 bond is almost linear and is orthogonal to the I–I–I bond. The $Cl_1\cdots I_2$ distance (2.94 Å) is considerably shorter than the sum of van der Waals radii (3.9 Å), although the Cl_4–I_2 distance (2.33 Å) is nearly equal to the sum of the covalent radii. The $Cl_1\cdots I_2$–Cl_4 bond can therefore be regarded as an asymmetrical three-center bond.

Taking the Sb–$Cl_1\cdots I_2$ angle of 109.75° into account, the orbitals on the bridging Cl atom can be approximated by sp^3 hybridization. The orbital directed toward the Sb atom (ϕ_1) is nonequivalent to that directed toward the I_2 atom (ϕ_2). The latter is

Table 4. Angles between efg Axes and Bond Angles in ICl_2SbCl_6

a) The value in parentheses is the corresponding bond angle. b) The value in brackets was calculated from the atomic positions (Ref. 12).

presumed to be intermediate between ϕ_1 and the lone pair orbitals (ϕ_3 and ϕ_4). The orbital populations of ϕ_1 and ϕ_2 cannot be determined unequivocally. The populations, however, can be estimated by considering the following extremes: in one extreme ϕ_2 is equivalent to ϕ_1 (C_{2v} symmetry) and in another ϕ_2 is equivalent to the lone pair orbitals (C_{3v} symmetry). The hybrid orbitals belonging to the symmetry C_{2v} are expressed as follows;

$$\begin{aligned}
\phi_1 &= s\psi_s + (1 - s^2)^{1/2}\psi_{p_z},\\
\phi_2 &= s\psi_s + (1 - s^2)^{1/2}\{\psi_{p_z}\cos\theta + \psi_{p_x}\sin\theta\},\\
\phi_3 &= \{(1 - 2s^2)/2\}^{1/2}\psi_s\\
&\quad - s\{\psi_{p_z}\cos(\theta/2) + \psi_{p_x}\sin(\theta/2)\} + 2^{-1/2}\psi_{p_y},\\
\phi_4 &= \{(1 - 2s^2)/2\}^{1/2}\psi_s\\
&\quad - s\{\psi_{p_z}\cos(\theta/2) + \psi_{p_x}\sin(\theta/2)\} - 2^{-1/2}\psi_{p_y},
\end{aligned} \tag{1}$$

where $s^2=2^{-1}\{1-\cot(\theta/2)\}$ and θ is the angle between the bonds Sb–Cl_1 and $Cl_1\cdots I_2$. The z axis is taken along the Sb–Cl_1 and the x axis in the plane $SbCl_1I_2$, although the efg z axis deviates slightly from the Sb–Cl_1 bond. If ϕ_1 and ϕ_2 are occupied by a and b electrons, respectively, then the coupling constant data may be analyzed by the equations;

$$\begin{aligned}
&(2 - a)\cos^2(\theta/2) = \eta U_p/3,\\
&(2 - a) + (2 - b)\{1 - (3/2)\sin^2\theta\} = 2U_p\sin^2(\theta/2),
\end{aligned} \tag{2}$$

where $U_p=(e^2Qq)_{obs}/(e^2Qq)_{atom}$.

The hybrid orbitals belonging to the symmetry C_{3v} are given by[22]

$$\begin{aligned}
\phi_1 &= s_1\psi_s + (1 - s_1^2)^{1/2}\psi_{p_z},\\
\phi_2 &= s_2\psi_s + (1 - s_2^2)^{1/2}(\psi_{p_z}\cos\theta + \psi_{p_x}\sin\theta),\\
\phi_3 &= s_2\psi_s + (1 - s_2^2)^{1/2}\{\psi_{p_z}\cos\theta - (1/2)\psi_{p_x}\sin\theta\\
&\qquad + (3^{1/2}/2)\psi_{p_y}\sin\theta\},\\
\phi_4 &= s_2\psi_s + (1 - s_2^2)^{1/2}\{\psi_{p_z}\cos\theta - (1/2)\psi_{p_x}\sin\theta\\
&\qquad - (3^{1/2}/2)\psi_{p_y}\sin\theta\},
\end{aligned} \tag{3}$$

where $s_1^2=2\cot^2\theta$ and $s_2^2=1-2/(3\sin^2\theta)$, and therefore

$$\begin{aligned}
&2 - b = \eta U_p,\\
&\{(2 - a) - (2 - b)/3\}(1 - 2\cot^2\theta) = U_p.
\end{aligned} \tag{4}$$

Using the experimental bond angle, the values of a=1.46 and b=1.84 are obtained for the symmetry C_{2v}, and those of a=1.45 and b=1.84, for the symmetry C_{3v}. Even when the deviation of the z axis on the Cl_1 atom from the Sb–Cl_1 axis is taken into account, the variations in the populations of ϕ_1 and ϕ_2 are less than 0.5 percent.

Each I atom in the $I_3Cl_2^+$ ion is positively charged. The efg components can be written in terms of the population N_i on the i-th p orbital as follows;

$$\begin{aligned}
q_{ii} &= [N_i - (N_j - N_k)/2]q_{atom}(1 + \varepsilon)^{\rho},\\
&\quad i, j, k = x, y, z
\end{aligned} \tag{5}$$

where ρ is the charge at the I atom and ε is the correction parameter for the ionization of the I atom. The value of ε=0.12 was used for the I atom.[23] If only the p_z and p_x orbitals on the I atom participate on bonding and the p_y orbital is completely filled, the charge on the I atom is approximated by

$$\rho = [U_p(1 + \eta) - 1]/[U_p\varepsilon(1 + \eta) + 1]. \tag{6}$$

The populations deduced from Eqs. 1—6 are listed in Table 5.

The electron numbers for the I_2–I_1–I_2 and $Cl_1\cdots I_2$–Cl_4 bonds are 3.83 and 3.88, respectively, assuming that the s character for the bonding orbital of the Cl_4 atom is 0.15. These values are close to the expected value 4, notwithstanding neglect of the s and d character of the central I atom, and accordingly these bonds can be explained essentially in terms of the 3c-4e bond. The total charges of the I_1 and I_2 atoms are estimated to be +0.30 and +0.66, respectively. These values are comparable to the values of +0.2 and +0.5 which were calculated by using the relationship between bond length and bond order.[14,24]

Table 5. Electronic Distributions of Polyhalogen Cations and Surrounding Chlorine Atoms in $I_3Cl_2SbCl_6$ and ICl_2SbCl_6

Compound	Atom	N_x[a]	N_y[a]	N_z[a]	N_σ[b]	
$I_3Cl_2SbCl_6$	Cl_1	1.90	(2)	1.58	$1.45<a<1.46$	(Sb)
					$b=1.84$	(I_2)
	Cl_4	(2)	(2)	1.20	1.18	
	I_1	1.93	(2)	0.77		
	I_2	1.53	(2)	0.81		
ICl_2SbCl_6	Cl_1	1.87	(2)	1.58	$1.48<a<1.53$	(Sb)
					$1.78>b>1.75$	(I)
	Cl_2	1.88	(2)	1.58	$1.42<a<1.44$	(Sb)
					$b=1.81$	(I)
	Cl_7	1.93	(2)	1.27	1.14	
	Cl_8	1.93	(2)	1.25	1.11	
	I	0.95	0.84	(2)		

a) The value in the parentheses is assumed to be 2. b) The population in the bonding atomic orbital. The symbols in parentheses indicate the atom toward which the hybrid orbital directs.

ICl_2SbCl_6. According to X-ray analysis,[12] the atoms I, Cl_1, Cl_2, Cl_7, and Cl_8 are almost coplanar. The z axis for the I atom is normal to this plane, and the x axis almost coincides with the bisector of the angle $\angle Cl_7ICl_8$. The z axes at the Cl_1 and Cl_2 atoms are nearly parallel to the corresponding Sb–Cl bond (see Table 4). The z axis at each bridging atom lies in the Sb-Cl···I plane. According to the ^{127}I Mössbauer effect, the value e^2Qqh^{-1} is positive.[13] This is in agreement with the results of the Zeeman effect of NQR.

The angles $\angle SbCl_7I$ and $\angle SbCl_8I$ are 116.8° and 114.8°, respectively. The valence orbitals at these bridging Cl atoms can be approximated by sp^2 hybridization. The wave functions can be written as follows:

$$\begin{aligned}\phi_1 &= s_1\psi_s + s_2\psi_{p_z},\\ \phi_2 &= (1/2)s_2\psi_s + 2^{-1/2}s_1\psi_{p_z} + 2^{-1/2}\psi_{p_x},\\ \phi_3 &= (1/2)s_2\psi_s + 2^{-1/2}s_1\psi_{p_z} + 2^{-1/2}\psi_{p_x},\\ \phi_4 &= \psi_{p_y},\end{aligned} \tag{7}$$

where $s_1=\cot\theta$ and $s_2=(1-\cot^2\theta)^{1/2}$. If the populations in ϕ_1 and ϕ_2 are set equal to a and b, respectively, the relations between the NQR parameters and the orbital populations are given by

$$\begin{aligned}2 - b &= (4/3)\eta U_p,\\ \{(2 - a) - (2 - b)/2\}(1 - \cot^2\theta) &= (1 - \eta/3)U_p.\end{aligned} \tag{8}$$

The ranges of the orbital populations can be estimated in a similar manner as above. These are listed in Table 5. According to X-ray analysis,[12] the distances of the bonds Sb–Cl_1, Sb–Cl_2, Cl_1···I, and Cl_2···I are 2.33, 2.29, 2.85, and 3.00 Å, respectively. The values of a and b correlate to the corresponding bond distance, as can be seen in Table 5. The populations of the valence p orbitals were calculated by assuming $N_z=2$. The net charge on the I atom is estimated to be +1.21. This is comparable to the value (+1.26) for I_2Cl_6[10] and that (+1.13) calculated for the isolated ICl_2^+ ion.[24]

If sp^3 hybridization with C_{2v} symmetry is adopted to the I atom, the interorbital angle is calculated to be 92.6° by using the relation $\eta=-3\cos\theta$.[25] This value is in good agreement with the crystallographically known angle of $\angle Cl_7ICl_8$ (92.5°).[12] The shortness of the distances I···Cl_1 and I···Cl_2 suggests that the interaction between the I atom and the surrounding Cl atoms cannot be described by simple sp^2 hybrid orbitals at the I atom.

The atomic arrangement around the I atom can be represented as a resonance $ICl_2^+SbCl_6^- \longleftrightarrow ICl_4^-SbCl_4^+$, and is similar to that in the ICl_4^- ion.[12] The bonding in the ICl_4^- ion and I_2Cl_6 could be satisfactorily explained by considering only the valence p orbitals.[3,10] If this is the case for the ICl_4 part in ICl_2SbCl_6, the total number of electrons that take part in σ-bonding is 8. Examination of Table 5 reveals that the total electron number is about 7.6. Although this is somewhat smaller than the expected value, it is considered that the I atom in this complex presents essentially only the p orbitals for bonding, as well as the $I_3Cl_2^+$ ion. The comparatively large η-values for the terminal Cl atoms may be ascribed to the π-interaction of the p_x orbital at each Cl atom with the p_x and p_y orbitals at the I atom.

The η-values of ^{121}Sb in $I_3Cl_2SbCl_6$ and ICl_2SbCl_6 are significantly large. There is no experimental atomic coupling constant for ^{121}Sb. If the calculated value of 1300 or 945 MHz is used for $(e^2Qqh^{-1})_{atom}$,[26,27] the imbalance in the orbital population is estimated to be at most 0.02 to 0.03. Hence, a slight imbalance in the population of the p orbitals brings about the large η-value. This is ascribable to the large ionic character of the Sb atom.

The hydrodynamic behavior of amylose with and without sodium dodecyl sulfate (SDS) has been examined by viscosity measurements. Two distinct viscosity phenomena have been observed by complexation; one is the increase at the first stage of binding of SDS, which disappears by an addition of salt, and the other is the subsequent decrease in the region of further binding of SDS. These results are interpreted by an idea that the expansion of the complex occurs by an electrostatic repulsion of the bound SDS molecules and the contraction of the complex by a hydrophobic interaction of cooperatively bound SDS molecules. This idea was confirmed further by experiments using amyloses of different length and homologous surfactants of SDS.

It is known that surfactants interact with amylose in the same way as iodine, aliphatic acids, and alcohols, forming complexes where these guest molecules are included in the amylose helix.[1-4] The helical conformation of amylose has been established in the solid state, while the conformation of amylose in solution still remains uncertain. Three models have so far been proposed for the structure of amylose in solution, i.e., (1) entirely random coil model, (2) interrupted helical model, and (3) entirely helical model.[5,6] Banks and Greenwood claimed that the conformation of amylose is the model (1)[7] and Szejtli et al. proposed the model (2),[8] and Senior et al. proposed a model which is characterized by the regions of loose and extended helices which alternate with shorter random coil regions.[9] We also conducted a series of studies on the complex formation of amylose and proposed a model similar to the model (2) and revealed the properties of the cooperative binding of guest molecules to amylose.[10-13] These results indicate a probability of structural change of the amylose by the complexation.

In the present study, the viscosity of the amylose solution with and without SDS was investigated in connection with the cooperative binding and is discussed from a viewpoint of the structural changes of the amylose by the complexation.

Experimental

Materials. Potato amylose, purchased from Pierce Chemicals, was purified by precipitation three times from 1-butanol. Its average degree of polymerization (DP) was estimated to be 1100 by gel filtration. Amyloses of small DPs were prepared as described in the previous paper.[10] Wet 1-butanol complex of amylose was dissolved in water and 1-butanol was subsequently removed by distillation for 30 min in a boiling water bath with bubbling nitrogen gas. After cooling, the solution was filtered through a G3 sintered glass filter. The concentration was determined by the phenol-sulfuric acid method.[14] Sodium alkyl sulfates were synthesized according to the method of Dreger et al.[15] Other chemicals used were of guaranteed grade.

Measurements. Amylose solutions were prepared in the concentration range of 0.10—1.50 mg ml^{-1} for the amyloses of DP 100, 300, and 1100 and 10—15 mg ml^{-1} for those of DP 42 and 57. Fresh amylose solutions were pipetted into the viscometer and the same volume of 2 mM surfactant solution (1 M=1 mol dm^{-3}) was added. The mixed solution was held for 30 min in the water bath before runs. Since the amylose-surfactant complexation is rapid all the reactions were presumed to be fully equilibrated on this time scale.[16] The viscosity was measured by Ubbelohde type viscometers at 20.0±0.1 °C. The efflux times of pure water were around 180—240 s and the kinetic energy corrections were negligible. The measurements were repeated for solutions prepared by subsequent addition of surfactant solution. The concentration of bound surfactants was determined potentiometrically as described in the previous paper.[12] To rule out any effect due to the micellization, the concentration of surfactant was kept below the critical micelle concentration.

Results

The specific viscosity, η_{sp}, was measured for the amylose solution in the absence or in the presence of SDS and the reduced viscosity, η_{sp}/C_p, was obtained for the concentration of amylose, C_p. The reduced viscosity was constant for free amylose or SDS solutions. For the amylose-SDS system, on the other hand, the value of η_{sp}/C_p increases rapidly in the first stage and then decreases with the SDS concentration as seen in Fig. 1.

These results are indicative of two-step hydrodynamic changes of the amylose complex, and systematic experiments were carried out by changing various experimental factors as follows. Firstly, the viscosity of the SDS-amylose solution was measured by changing the concentration of amylose under the constant concentration of SDS. As seen in Fig. 2, the η_{sp}/C_p value was independent of the concentration of amylose in the concentration range of 0.10 to 0.50 mg ml^{-1} for various concentrations of SDS. Secondly, the viscosity was measured for the SDS-amylose solution in the presence of NaCl and the results are shown in Fig. 3. Here, the experiments were carried out at relatively low NaCl concentration in order to avoid

aggregation of the complex. As seen in the figure, the characteristic increase of the viscosity in the first stage disappeared, i.e., the viscosity was constant in the range of [SDS]<0.03 mM, and above this concentration, the viscosity decreased uniformly with increase of SDS. Thirdly, the viscosity was measured by changing the surfactant to the homologues of SDS, i.e., $C_nH_{2n+1}SO_4Na$ (n=8—14). As seen in Fig. 4, the concentration dependency behavior of η_{sp}/C_p differs greatly between the surfactants of C_8 and C_{10} and those of C_{12} and C_{14}. In the former systems, only the increase of the viscosity was observed with increase of the surfactant concentration and the viscosity decreasing process is absent. While in the latter systems, the viscosity increases at first and then decreases. The increasing behavior observed for the surfactant-amylose systems disappeared on an addition of salt. Fourthly, the viscosity of the solutions of SDS and amyloses of small DP was examined in the same way as that of amylose of DP 1100 system studied above. The values of η_{sp}/C_p for the amyloses of DP 42 and DP 57 were independent of the SDS concentration (Fig. 1), and the result is in contrast to the behavior of the amylose of DP 1100. Those of the amyloses of DP 100 and 300 are similar.

The amount of bound surfactant was measured by potentiometric titration. As seen in Fig. 5, the amount of bound SDS does not change on the addition of salt under the present experimental concentration range.

Discussion

As the origin of the characteristic viscosity behavior observed above, two effects may be considered. One is the intermolecular effect of amylose or its SDS complex. This may be discounted, because the viscosity of the solution of amylose or its complex was independent of their concentration. The result suggests that the amylose retains the same binding state irrespective of the amylose concentration as long as the SDS concentration is constant. This suggestion was supported by the fact that the amount of bound SDS was proportional only to the amylose concentration under the present experimental condition. The other possibility is the intramolecular effect which has been proposed by some workers.

Rao et al. have observed the viscosity decrease on complexation for the SDS-amylose system and ascribed it to the propagation of the helix.[17] According to them, SDS first binds to the originally helical part of amylose, which is not accompanied by any change of viscosity. Further binding induces a helix propagation accompanying a decrease of viscosity. Their idea is applicable to our data for SDS-amylose system (Fig. 6) indicating the original helical part of amylose corresponds to about 5% of the total amount of SDS binding. If their interpretation is applied to the binding of C_8 surfactant system, similar viscosity behavior to those of SDS system is expected since the amount of its binding exceeds fully that for the originally helical part of amylose.[12] However, this expectation was not satisfied as seen in Fig. 6 and the idea of Rao et al., therefore, is questionable. For a complexation of amylose with iodine, Banks et al. observed a decrease of viscosity and ascribed it to the conformational change of amylose from a random coil to a helix.[7] While, Senior et al. insisted that the decrease is due to a shortening of the linear dimension of the polymer chain.[9] All these experiments have been performed in the presence of electrolyte, and only the decrease in viscosity by complexation has been observed. Therefore, these interpretations cannot be applied satisfactorily to either the lack of decrease of viscosity in C_8 and C_{10} surfactant systems or the increase of viscosity in C_{12} and C_{14} surfactant systems. Recently, Francois et al. observed an increase in viscosity on the complexation of poly(oxyethylene) with SDS and claimed that the polymer complexes with SDS micelles.[18] However, this idea is not applicable to the present system where the surfactant concentration is much lower than the critical micelle concentration. As a consequence, we developed our own idea in the following way.

It is said that amylose is composed of several segments which are composed of about 60 anhydroglucose units; there is however some discrepancy in the literature values.[10,19-21] Taking this fact into consideration, the amyloses of DP 42 and 57 are composed of a single segment and DP 100, 300, and 1100 of several segments. These facts show that the characteristic viscosity behavior appears when the amylose is composed of more than two segments. So, segment-segment interactions of the SDS complex are the origins of the increase and/or the decrease of viscosity.

Further information on these interactions are derived from the salt effects on the viscosity. Since the binding of SDS was not affected appreciablely by the presence of salt, the disappearance of the viscosity increasing behavior on the addition of salt should not be ascribed to the decomposition of the complex. Instead it implies that the segment-segment interaction contributing to the viscosity increase is interrupted by the addition of salt, i.e., the interaction may

be an electrostatic one. Therefore, the viscosity increase indicates an expansion of the complex by electrostatic repulsion among the segments charged by the initial binding of SDS. On the other hand, the interaction contributing to the viscosity decrease may be nonelectrostatic since the viscosity decrease process was not affected by the addition of salt.

We have investigated the binding isotherm of surfactant to amylose by the potentiometric titration and clarified that (i) SDS binds to isolated binding sites in the region of [SDS]$<$0.03 mM while it binds cooperatively in the region of 0.03 mM$\leqq$[SDS]$\leqq$0.20 mM, (ii) the cooperativity is approved for the bindings of C_{12} and C_{14} surfactants but not for those of C_8 and C_{10} surfactants, (iii) the cooperativity is approved for amyloses composed of more than two segments, i.e., it is related to the segment-segment interaction.[12] These facts, together with the viscosity data, indicate that the boundary concentrations of SDS in the viscosity behavior shown in Fig. 3 are in good agreement with those observed in the binding curve, respectively. The viscosity constant region in the first stage of SDS binding also corresponds to the binding on the isolated sites while the decreasing behavior in the subsequent stage corresponds to the cooperative binding. Therefore, it is clear that the viscosity decrease indicates a contraction of the complex by the nonelectrostatic segment-segment interaction induced by the additional binding of SDS. In accordance with this conclusion, it is interesting to see that the cooperativity is observed also for the iodine-amylose system, and the viscosity decrease observed by Banks et al.[7] and Senior et al.[9] will be due to the contraction of the complex induced by the cooperative binding of iodine. Furthermore, lack of the viscosity decrease process in the binding of the C_8 and C_{10} surfactants to amylose (DP 1100) is also compatible with the lack of the cooperativity in their bindings.

These characterization of viscosity behavior supports a model previously proposed for the SDS-amylose complex, where SDS molecules are binding at each end of the helical segment and the cooperativity is ascribed to the hydrophobic interaction between the alkyl chains of bound SDS.[12] Based on this model, we conclude that the viscosity increase observed at the first stage of the SDS binding is due to the expansion of the complex by electrostatic repulsion between the charged head groups of SDS bound to the isolated sites of the helical segments. The viscosity decrease observed in the second stage is due to the contraction of the amylose complex induced by the hydrophobic interaction of the bound SDS.

The above interpretation is also applicable to the results for the C_8 and C_{10} surfactant systems and to those for SDS-amyloses of low DPs. The C_8 and C_{10} surfactants bind to amylose non-cooperatively due to their somewhat shorter alkyl chain, and the bindings do not induce the contract of the complex because the electrostatic repulsion among the segments with charged surfactants is predominant. Hence, only the viscosity increase process is observed and the decrease process is not observed in their bindings. In the binding of SDS to amyloses of DP 42 and 57, the interaction between the segments in the complex and the cooperativity are not expected because they consist of a single segment. Therefore, any characteristic hydrodynamic behavior is not observed.

Mixed Surfactant Bilayers on Monodispersed Ferric Hydro Sols

Kunio Esumi,* Yuichi Sakamoto, Keiko Yoshikawa, and Kenjiro Meguro
Department of Applied Chemistry, Institute of Colloid and Interface Science,
Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received September 9, 1987)

The properties of mixed surfactant bilayers on monodispersed ferric hydro sol were studied by measuring the amount of surfactant adsorbed, particle size, and pyrene fluorescence spectra. The positively charged sols flocculated upon addition of sodium dodecyl sulfate (SDS) or lithium perfluoro-1-octanesulfonate (LiFOS) were redispersed by further addition of poly(oxyethylene) nonyl phenyl ether (NP7.5) due to the formation of a mixed surfactant bilayer on the sols. The mixed surfactant bilayer of SDS–NP7.5 on the sols was more easily formed than LiFOS–NP7.5. Fluorescence fine structure of pyrene gave information on the polarity of the microenvironment in the mixed surfactant layer on the sols.

The dispersion behavior of particles upon addition of surfactants has been extensively investigated[1-7] in order to elucidate the interaction between surfactants and particles and further to apply to many fields such as flotation, oil recovery, and paints etc. It has been demonstrated[1] in the past by measuring the zeta potential and particle size that positively charged particles flocculate upon addition of anionic surfactants and that on further addition, the particles redisperse due to formation of surfactant bilayers.

Recently, the structural characteristics of the surfactant layer on solids have been elucidated by fluorescence[8-11] and electron spin resonance probing methods.[12] Chandar et al.[8] have reported that highly organized surfactant aggregates of sodium dodecyl sulfate at alumina–water interface are formed by the association of hydrocarbon chains from pyrene and dinaphthylpropane fluorescence probes. A similar experiment for Triton X-100-silica has been studied.[11]

On the other hand, Meguro et al.[13] have demonstrated that positively charged particles flocculated upon addition of an anionic surfactant can be redispersed upon addition of another surfactant owing to the formation of a mixed surfactant adsorbed layer. Their results have not, however, been discussed in detail.

In this work we studied the formation of mixed surfactant layers on monodispersed ferric hydro sols by measurements of the zeta potential, particle size, adsorbed amount, and fluorescence probe. The surfactants used were two different mixed systems: sodium dodecyl sulfate–poly(oxyethylene)nonyl phenyl ether and lithium perfluoro-1-octanesulfonate–poly(oxyethylene) nonyl phenyl ether.

Experimental

Materials. As surfactants, sodium dodecyl sulfate (SDS), lithium perfluoro-1-octanesulfonate (LiFOS), and poly(oxyethylene) nonyl phenyl ether having average oxyethylene chains of 7.5(NP7.5) were used. SDS and LiFOS were synthesized in our laboratory and purified. NP7.5 was obtained from Nikko Chemical Co. Ltd. and used without further purification. The cmc's of these surfactants in the presence of 10 mmol·dm^{-3} nitrates were 3.0 for SDS, 3.4 for LiFOS, and 3.0×10^{-2} mmol·dm^{-3} for NP-7.5, respectively. The water used in all experiments was purified by passing through a Milli-Q system until its specific conductivity fell below $10^{-7}\,\Omega^{-1}\,cm^{-1}$.

Hydro sols consisting of spherical hematite particles with a narrow size distribution were prepared by essentially the same procedure as Matijević et al.[14] described. The final stock sol had a concentration of 3.17 mg·cm^{-3}, as determined directly by dry-weight measurement, and was kept at pH 5.8. The mean particle size was determined by a Particle analyser (Autosizer Model 700, Malvern Co. Ltd.); the average diameter was 160 nm with a polydispersity of 0.03. Alumina was supplied by Showa Denkou Co. The surface area and the average diameter of the alumina particles were 10.1 m^2·g^{-1} and 500 nm, respectively.

Methods. As the ferric hydro sol had an isoelectric point of pH 7.9, the ferric hydro sol was allowed to flocculate upon addition of LiFOS or SDS at pH 3.5. Then, NP7.5 was added into the flocculated sol. The concentration of the sol in all the experiments except the fluorescence measurement was 3.17 mg/5 cm^3. In order to keep the ionic strength constant, all the measurements were carried out in 10 mmol·dm^{-3} sodium nitrate or lithium nitrate solution at 25 °C. Nitric acid was used to adjust the pH of the mixtures.

For the fluorescence experiments, pyrene dissolved in ethanol was first introduced into a flask and the solvent allowed to evaporate. Then, the ferric hydro sol (the concentration of the sol; 0.32 mg/5 cm^3) was added and sonificated.

Measurements. The amount of anionic surfactants adsorbed on the ferric hydro sol was determined from the difference in concentrations before and after the adsorption. The concentration of anionic surfactants was determined by means of isotachophoresis (Shimadzu Co. Ltd.). That of NP7.5 was also determined by means of a UV spectrophotometer (200A, Hitachi Co.). The zeta potential of the ferric hydro sol was measured by means of an electrophoresis apparatus Laser-Zee meter Model-500 (Pen Kem Inc.).

Steady-state emission spectra were obtained using a Hitachi 650-10S fluorescence spectrophotometer. A portion of the dispersion sample was transferred to a 1 cm quartz cell. The concentration of pyrene ranged from 1×10^{-6} to 1×10^{-7} mol·dm^{-3}. The pyrene containing samples were excited at 335 nm.

Results and Discussion

In order to characterize the ferric hydro sols, the zeta potential was measured as a function of pH. Since the isoelectric point of the sol was estimated to be pH 7.9, the interaction between the sol and the anionic surfactants due to electric attraction forces plays an important role in the range below pH 7.9. Accordingly, in this study, all the measurements were conducted at pH 3.5 where the zeta potential of the ferric hydro sols was about +25 mV.

Figure 1 shows the adsorption isotherms of anionic surfactants on the ferric hydro sols. In both cases, the amount adsorbed increased gradually and then sharply, following a plateau level. This behavior has been observed by other workers.[8,15] At the same time, the dispersion behavior of the ferric hydro sols was observed: the sol flocculated upon addition of SDS or LiFOS (flocculation region pointed by the arrow) and then redispersed by further addition of the same surfactant.[16] Here, the optimum additive concentration for the flocculation of ferric hydro sol was about 0.2 mmol·dm^{-3} for both cases, although the amount of SDS adsorbed was twice that of LiFOS.

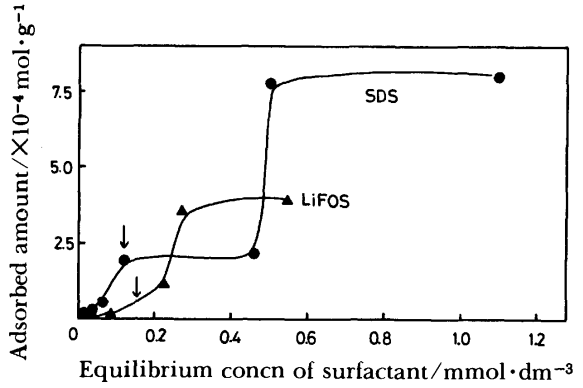

Fig. 1. Adsorption isotherms of anionic surfactants on ferric hydro sols at pH 3.5 in 10 mmol·dm^{-3} nitrates.

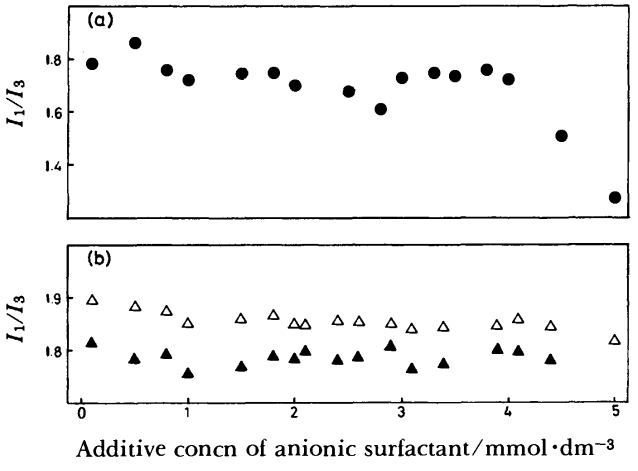

Fig. 2. (a) I_1/I_3 ratio of pyrene in SDS-ferric hydro sols. (b) I_1/I_3 ratio of pyrene in LiFOS-ferric hydro sols: ▲, in dispersion; △, in supernatant.

The pyrene fluorescence fine structure has been found to be remarkably dependent on the solvent: the intensity ratio of I_1/I_3(I_1, first vibrionic and I_3 third vibrionic bands at 373 and 383 nm, respectively) is sensitive to the solvent polarity.[17] This fluorescence method was applied to the dispersion system in order to obtain the polarity of environment of surfactant adsorbed layer on the ferric hydro sol. The change in intensity ratio of, I_1/I_3, of pyrene in SDS-sol and LiFOS-sol dispersion as a function of additive concentration of anionic surfactant is given in Fig. 2. In the case of SDS-ferric hydro sol, no pyrene was detected in the supernatants of the dispersion, which suggests that pyrene is almost solubilized in the adsorbed layer. The I_1/I_3 values of the probe were constant up to 4 mmol·dm^{-3} SDS, corresponding to the region of the cmc, and then decreased rapidly to a value of 1.30. The above result suggests that the solubilization site for pyrene above 4 mmol·dm^{-3} SDS is probably the hydrocarbon region which is formed by association of SDS hydrocarbon chains on the surface. A similar result has been reported on SDS-alumina system using pyrene steady-state fluorescence.[8] On the other hand, in the LiFOS-ferric hydro sol, the I_1/I_3 values were almost constant(1.80) over the whole concentration region of LiFOS, whose values coincide with that for pyrene in water. The I_1/I_3 values in the supernatants were also constant (1.86). This indicates that the pyrene is only very weakly solubilized in the fluorocarbon chain layer of LiFOS on the sol. This speculation is also supported by the fact that the I_1/I_3 value of pyrene solubilized into the LiFOS micelles is about 1.51[18] and the amount of adsorbed pyrene in the adsorbed layer is negligibly low.

In order to elucidate the interaction of the anionic surfactant and NP7.5 on the ferric hydro sols, NP7.5 was added to the sol which had been flocculated upon addition of 0.2 mmol·dm^{-3} anionic surfactant.

Figure 3 shows the amount of the anionic surfactant adsorbed and of NP7.5 on the ferric hydro sols as a function of the additive concentration of NP7.5. As can be seen, the amount of the anionic surfactant adsorbed on the sols is almost constant even after addition of different concentrations of NP7.5. This indicates that the anionic surfactant required for flocculation is adsorbed strong enough on the sol due to the electric attraction between the charged head group of the surfactant and the charged site of the sol. Upon addition of NP7.5, the amount of NP7.5 adsorbed increased for both the SDS-NP7.5 and the LiFOS-NP7.5 systems, although the amount adsorbed was larger for SDS-NP7.5 than for LiFOS-NP7.5. This result can be interpreted as follows: In

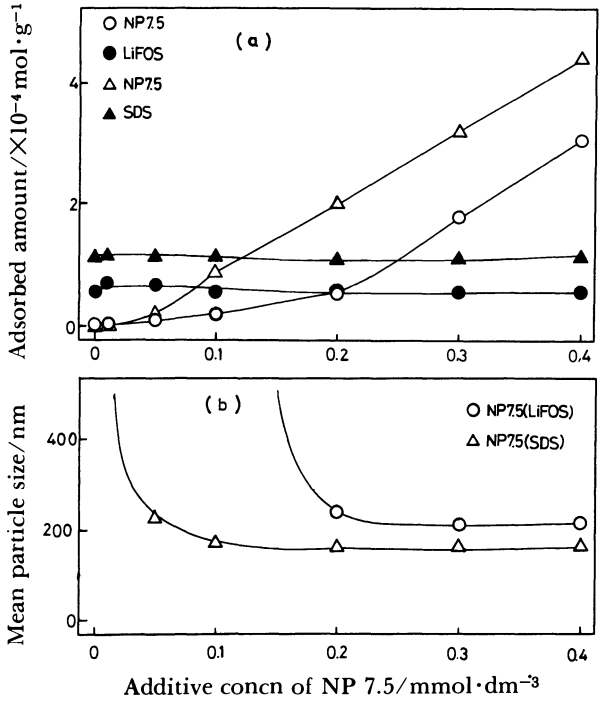

Fig. 3. (a) Amount adsorbed of anionic surfactant and of NP7.5 on ferric hydro sol in presence of 0.2 mmol·dm^{-3} of anionic surfactant as a function of additive concentration of NP7.5. (b) Particle size of ferric sols flocculated by addition of anionic surfactant (0.2 mmol·dm^{-3}) as a function of additive concentration of NP7.5.

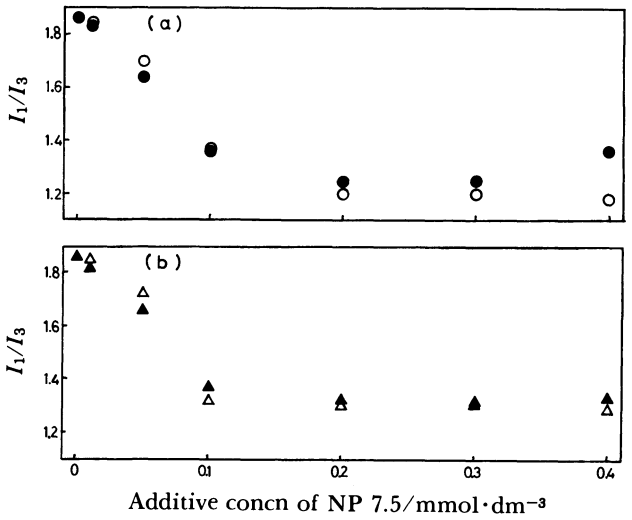

Fig. 4. I_1/I_3 ratio of pyrene for systems shown in Fig. 3. (a) SDS-NP7.5-ferric hydro sols: ●, in dispersion; O, in supernatant. (b) LiFOS-NP7.5-ferric hydro sols: ▲, in dispersion; △, in supernatant.

SDS-NP7.5, the flocculated ferric sol, upon addition of SDS is fully covered with SDS molecules, orienting their hydrocarbon chain to the aqueous solution. This dense hydrocarbon layer allows the adsorption of NP7.5 easily where the hydrocarbon chains of NP7.5 forms hydrophobic bond with the hydrocarbon layer of SDS, resulting in the formation of a mixed surfactant bilayer. Scamehorn et al.[19] studied the adsorption of mixtures of anionic and nonionic hydrocarbon surfactants on kaolinite and alumina and they reported the adsorption amount of mixed surfactant, but not the interaction between the mixed bilayer. On the other hand, due to a lower adsorption density of LiFOS, NP7.5 can not easily be adsorbed on the LiFOS layer. Further, since it is known[20] that the interaction between the hydrocarbon and fluorocarbon is weaker than that between hydrocarbon and hydrocarbon, this factor also governs the magnitude in the adsorption of NP7.5 on LiFOS layer.

In order to examine the dispersing state of ferric hydro sols for SDS-NP7.5 and LiFOS-NP7.5, the particle size of the sol was also measured (Fig. 3). Upon addition of SDS or LiFOS to the positively charged sol, the sol flocculated and its particle size became too large to detect by the Autosizer. When NP7.5 was added to the flocculated sol, the particle size decreased remarkably upon addition of more than some concentration of NP7.5: 0.05 mmol·dm^{-3} for SDS-NP7.5 and 0.2 mmol·dm^{-3} for LiFOS-NP7.5. These concentrations of NP7.5 were above the cmc of NP7.5(3.0×10^{-2} mmol·dm^{-3}). The decrease in the particle size corresponds to the redispersion state of the sol. Compared to the amount of NP7.5 adsorbed required to attain the redispersion of the sol, the amount for SDS-NP7.5 decreases to one third of that for LiFOS-NP7.5. This result also supports the view that the hydrocarbon-hydrocarbon interaction is preferred to the fluorocarbon-hydrocarbon interaction.

The properties of the mixed surfactant adsorbed layer on the sol were also examined using the pyrene probe method. Figure 4 shows the changes in intensity ratio of I_1/I_3 of pyrene in the SDS-NP7.5 and LiFOS-NP7.5 containing sols. The I_1/I_3 values decreased and then became constant (1.34) above 0.1 mmol·dm^{-3} NP7.5 for both cases. This value is almost the same as that in micelles of NP7.5. Accordingly, pyrene is solubilized into mainly hydrocarbon chains of NP7.5 for both cases, but there is no strict distinction whether pyrene is solubilized in aqueous micelles of NP7.5 or in mixed bilayer on the sols. So, in order to clarify this point, a highly concentrated dispersion system is necessary to obtain information from the bilayer on the solids. In this case, we used an alumina instead of a ferric hydro sol because alumina does not significantly scatter fluorescence light, compared with ferric hydro sol. Figure 5 shows the I_1/I_3 ratios of pyrene for SDS-NP7.5-alumina and LiFOS-NP7.5-alumina. Here, the amount of alumina used was 0.3 g/10 ml. The I_1/I_3 values for pyrene in SDS-NP7.5-alumina ranged between 1.05 and 1.34

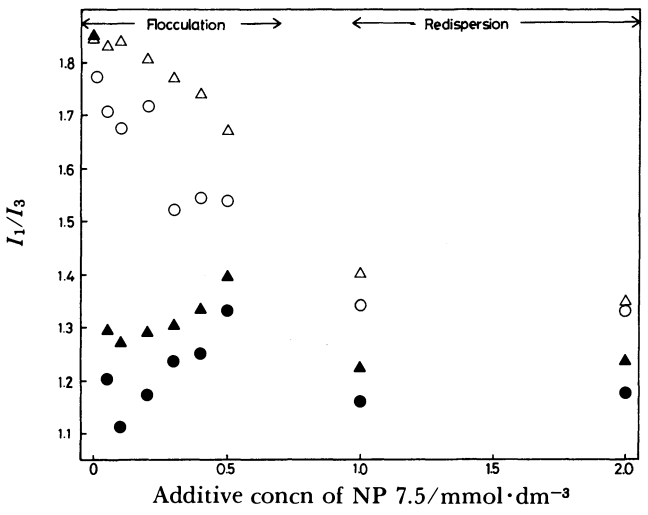

Fig. 5. I_1/I_3 ratio of pyrene for SDS-NP7.5-alumina (●, ○) and LiFOS-NP7.5-alumina (▲, △): filled symbols, in dispersion; empty symbols, in supernatant.

where the alumina particles were flocculated. Above 1 mmol·dm^{-3} of NP7.5, the alumina particles were redispersed due to formation of a mixed bilayer on the alumina and the I_1/I_3 values became constant (1.17). On the other hand, the I_1/I_3 values in the supernatants decreased with an increase of concentration of NP7.5 and reached a constant value (1.34). This suggests that the mixed bilayer of SDS and NP7.5 on the alumina is more densely compact than that of their mixed micelles. In the case of LiFOS-NP7.5-alumina, the I_1/I_3 values of pyrene decreased steeply from 1.85 to 1.30 upon an addition of 0.05 mmol·dm^{-3} NP7.5 and ranged between 1.27 and 1.39 below 0.5 mmol·dm^{-3} NP7.5 where the alumina particles were flocculated. Upon further addition of NP7.5, the alumina particles were redispersed and the I_1/I_3 values decreased to 1.23. The I_1/I_3 values in the supernatants decreased with an increase of concentration of NP7.5 and reached a value of 1.35. The I_1/I_3 value of pyrene(1.17) in SDS-NP7.5-alumina, for the redispersion state is smaller than that (1.23) in LiFOS-NP7.5-alumina, suggesting that pyrene is solubilized in the higher polarity environment of the mixed bilayer for LiFOS-NP7.5-alumina than for SDS-NP7.5-alumina. The isoelectric points of alumina and ferric hydro sol are 9.0 and 7.9, and the zeta potential values at pH 3.5 are +30 mV for the former, +25 mV for the latter. It might be expected from these values that alumina and ferric hydro sol would show a similar interaction behavior against the surfactants. Consequently, these microenvironment results obtained from the dispersion systems containing alumina would reflect the dispersion system containing ferric hydro sol.

From the above results, it is concluded that ferric hydro sols flocculated upon addition of SDS or LiFOS redisperse by further addition of NP7.5 due to formation of a mixed surfactant bilayer and the difference in mixed surfactant bilayer on the sols between SDS-NP7.5 and LiFOS-NP7.5 are characterized by measuring the amount adsorbed and the pyrene fluorescence spectra.

A Simulation of Bromate-Cerium-Oxalic Acid Oscillations

Yoshihiro SASAKI
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611
(Received September 9, 1987)

The oscillation behavior of the bromate-cerium-oxalic acid system was simulated within the FKN framework with bromine-hydrolysis control, where a radical-chain reaction of HOBr with oxalic acid and the formation of $HCO_2\cdot$ by the reduction of Ce(IV) were assumed. When $[(COOH)_2]=0.03$ mol dm^{-3} and $k_{13}=0.075$ s^{-1} (k_{13}: the rate constant of bromine removal), the oscillation behavior was qualitatively consistent with the experimental results. Excitability in the reduced and oxidized steady states, induced by a sudden change in the concentration of bromine, was simulated. No bistability was found. When $[(COOH)_2]=0.03$ mol dm^{-3}, no hysteresis near the bifurcation points was observed. However, when $[(COOH)_2]=0.001$ mol dm^{-3}, hysteresis was observed in the transition between the oxidized steady state and the oscillatory state.

The FKN mechanism seems widely accepted at present as a qualitatively adequate description of the exotic Belousov-Zhabotinskii (BZ) oscillation.[1] In the mechanism, bromide is a control intermediate, and a stoichiometric factor is used in order to simplify the complicated processes of the reduction of Ce(IV) and the formation of bromide by malonic acid and its brominated compound.[2,3] The BZ oscillation in the presence of silver ions could also be simulated within the FKN framework.[4]

Recently Noszticzius et al.[5,6] reported characteristic oscillation behavior of the bromate-cerium-oxalic acid system under batch conditions, and Gáspár and Galambosi,[7] in the CSTR mode. In this system, the bromine had to be removed physically or chemically in order to sustain the oscillations between the explicit oxidized steady state and the reduced steady state, and the time period of the oscillations depended on the magnitude of the bifurcation parameters. Moreover, excitability in the steady states and bistability were observed.

Field and Boyd simulated the oscillation of the bromate-cerium-oxalic acid-acetone system by using the Oregonator model with bromine-hydrolysis control,[8] supporting the idea that bromide is an intermediate in the system as well. Gáspár and Galambosi also reported a simulation for the bromate-cerium-oxalic acid system within a revised Oregonator model.[7] However, these simulations did not reproduce the oscillation behavior described above. The inconsistency seems to be ascribable to the excessive simplification of the reduction process of HOBr by oxalic acid. The bromate-cerium-oxalic acid system is one of the simplest BZ-type oscillations because oxalic acid cannot be brominated. Thus, when we simulate the oscillation behavior of this system, we have to take account of the processes of the reduction of Ce(IV) and of the formation of bromide in detail. Noyes,[9] as well as Field and Boyd,[8] has proposed the formation of $HCO_2\cdot$ and $Br\cdot$ radicals in the processes of the reduction of Ce(IV) by oxalic acid and the formation of bromide. In this paper, we will simulate the oscillation behavior of the bromate-cerium-oxalic acid system by using the FKN mechanism with bromine-hydrolysis control and by assuming the formation of $HCO_2\cdot$ and $Br\cdot$ radicals, according to the proposals of Noyes and of Field and Boyd.

Reaction Mechanism and Method of Calculation

Bromate and oxalic acid react in the presence of a cerium catalyst to give bromine and CO_2:[5]

$$2BrO_3^- + 5(COOH)_2 + 2H^+ \longrightarrow 10CO_2 + Br_2 + 6H_2O \quad (a)$$

In this study, the following mechanism will be assumed for Reaction a:

$$Br^- + BrO_3^- + 2H^+ \longrightarrow HOBr + HBrO_2 \quad (1)$$

$$Br^- + HOBr + H^+ \rightleftharpoons Br_2 + H_2O \quad (2)$$

$$Br^- + HBrO_2 + H^+ \longrightarrow 2HOBr \quad (3)$$

$$BrO_3^- + HBrO_2 + H^+ \rightleftharpoons 2BrO_2\cdot + H_2O \quad (4)$$

$$BrO_2\cdot + Ce(III) + H^+ \rightleftharpoons Ce(IV) + HBrO_2 \quad (5)$$

$$2HBrO_2 \longrightarrow HOBr + BrO_3^- + H^+ \quad (6)$$

$$HOBr + (COOH)_2 \longrightarrow HCO_2\cdot + Br\cdot + H_2O + CO_2 \quad (7)$$

$$Ce(IV) + (COOH)_2 \longrightarrow Ce(III) + HCO_2\cdot + CO_2 + H^+ \quad (8)$$

$$HCO_2\cdot + HOBr \longrightarrow Br\cdot + H_2O + CO_2 \quad (9)$$

$$Br\cdot + (COOH)_2 \longrightarrow HCO_2\cdot + Br^- + CO_2 + H^+ \quad (10)$$

$$Br\cdot + Br\cdot \longrightarrow Br_2 \quad (11)$$

$$HCO_2\cdot + HCO_2\cdot \longrightarrow (COOH)_2 \quad (12)$$

$$Br_2 \longrightarrow Br_2(gas) \quad (13)$$

Table 1. Rate Constants Used in the Calculations

k_1	$2.1\ M^{-3}\ s^{-1}$	k_6	$4.0\times10^7\ M^{-1}\ s^{-1}$
k_2	$8.0\times10^9\ M^{-2}\ s^{-1}$	k_7	$25\ M^{-1}\ s^{-1}$
k_{-2}	$110\ s^{-1}$	k_8	$27.5\ M^{-1}\ s^{-1}$
k_3	$2.0\times10^9\ M^{-2}\ s^{-1}$	k_9	$2.0\times10^7\ M^{-1}\ s^{-1}$
k_4	$1.0\times10^4\ M^{-2}\ s^{-1}$	k_{10}	$2000\ M^{-1}\ s^{-1}$
k_{-4}	$2.0\times10^7\ M^{-1}\ s^{-1}$	k_{11}	$1.0\times10^8\ M^{-1}\ s^{-1}$
k_5	$6.0\times10^5\ M^{-2}\ s^{-1}$	k_{12}	$1.2\times10^9\ M^{-1}\ s^{-1}$
k_{-5}	$5.0\times10^7\ M^{-1}\ s^{-1}$		

(1 M=1 mol dm^{-3})

The mechanism consisted of the FKN mechanism with bromine-hydrolysis control and the formation of $HCO_2\cdot$ and $Br\cdot$ radicals in a reaction between HOBr and oxalic acid. That is, HOBr reacted with oxalic acid to give $HCO_2\cdot$ and $Br\cdot$ radicals, and the radicals consumed HOBr and oxalic acid according to a radical-chain reaction composed of Reactions 9 and 10 or vanished according to Reactions 11 and 12. Reaction 14 was ignored because it was thought to make no contribution to the BrO_3^-–oxalic acid reaction:[8]

$$Br\cdot + HCO_2\cdot \longrightarrow Br^- + CO_2 + H^+ \quad (14)$$

Ce(IV) was assumed to give $HCO_2\cdot$ according to Reaction 8 and was thus explicitly concerned with the consumption of HOBr. Reaction 13 represents a process of the first order, where the bromine produced was removed from the BrO_3^-–Ce–$(COOH)_2$ system.[6,7] Reaction 15, which is a part of the FKN mechanism, is not important because it is very slow ($k_{15}=9.6\ mol^{-1}\ s^{-1}$ and $k_{-15}=1.3\times10^{-4}\ mol^{-3}\ s^{-1}$):[10]

$$Ce(IV) + BrO_2\cdot + H_2O \rightleftharpoons Ce(III) + BrO_3^- + 2H^+ \quad (15)$$

The rate constants of Reactions 1—12 are shown in Table 1. The k_1—k_{-4} and k_6 rate constants are according to Bar-Eli and Ronkin,[10] and k_5 and k_{-5}, according to Tyson.[11] The other rate constants agreed with those estimated by Field and Boyd.[8] Ce(IV) is reduced to Ce(III) by oxalic acid according to Reactions 8 and 16:[12,13]

$$Ce(IV) + HCO_2\cdot \longrightarrow Ce(III) + CO_2 + H^+ \quad (16)$$

We ignored Reaction 16 and assumed a larger k_8 value than that obtained experimentally.[8]

The numerical integration of the differential equations generated from Reactions 1—13 was performed using the Gear algorithm.[14] In the calculations we assumed that $[H^+]=1$ mol dm^{-3} and that $[Ce]_{total}(=[Ce(III)]+[Ce(IV)])=0.0005$ mol dm^{-3}, while k_{13} and $[BrO_3^-]$ were regarded as bifurcation parameters.

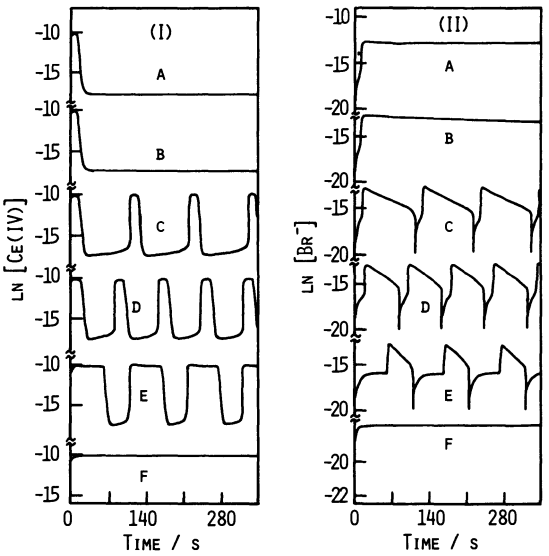

Fig. 1. The change in the oscillation pattern with k_{13}. $[BrO_3^-]=0.03$ mol dm^{-3}, $[(COOH)_2]=0.03$ mol dm^{-3}. k_{13} A: 0.001 s^{-1}, B: 0.005 s^{-1}, C: 0.05 s^{-1}, D: 0.075 s^{-1}, E: 0.1 s^{-1}, F: 0.25 s^{-1}.

Results and Discussion

When $[(COOH)_2]=0.03$ mol dm^{-3}. Figure 1 shows the change in the oscillation pattern with k_{13}. When $k_{13}=0.001\ s^{-1}$, the bromate–cerium–oxalic acid system stayed at a reduced steady state (steady-state LO by Noszticzius et al.[6]) characterized by a small concentration of Ce(IV). On the other hand, when $k_{13}=0.25\ s^{-1}$, the system stayed at an oxidized steady state (steady-state HI) characterized by a large concentration of Ce(IV). When $0.005\ s^{-1}\leq k_{13}\leq 0.1\ s^{-1}$, the system exhibited sustained oscillations between the two steady states. The time period of the oscillations, T, and the time that the system spent in either steady state, τ, depended on the value of k_{13}.

Figure 2 shows the relationship between the oscillation pattern and the concentration of bromate. When $[BrO_3^-]=0.006$ mol dm^{-3}, the system existed in a reduced steady state, and when $[BrO_3^-]=0.045$ mol dm^{-3}, in an oxidized steady state. When 0.007 mol $dm^{-3}\leq[BrO_3^-]\leq 0.0425$ mol dm^{-3}, the sustained oscillations between the two steady states appeared. T and τ depended on the value of $[BrO_3^-]$, but the amplitude of the oscillations was approximately constant. Hysteresis was not observed in the transitions from the monostable steady states to the oscillatory state, or vice versa.

Figure 3 shows the excitability of a reduced steady state induced by a sudden decrease in the concentration of bromine. The value of $[Br_2]$ at the steady state was 1.2857×10^{-8} mol dm^{-3}. When $[Br_2]=1.02\times10^{-8}$ mol dm^{-3}, the system returned to the reduced steady state with a damped oscillation. When $[Br_2]=1.01\times$

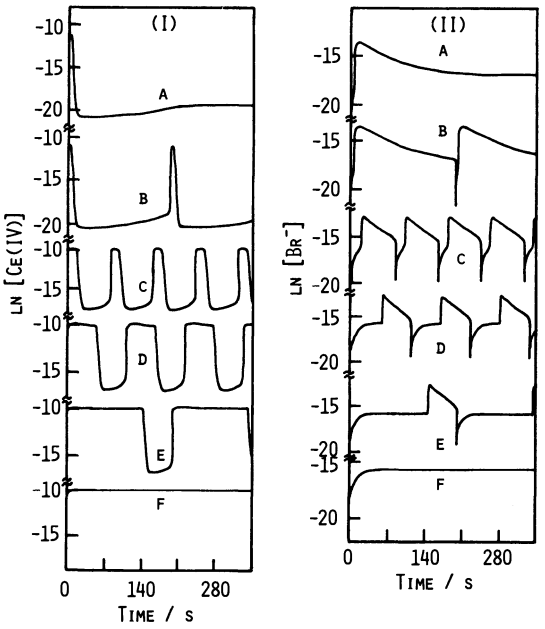

Fig. 2. The change in the oscillation pattern with $[BrO_3^-]$.
$[(COOH)_2]=0.03$ mol dm^{-3}, $k_{13}=0.075$ s^{-1}. $[BrO_3^-]$ A: 0.006 mol dm^{-3}, B: 0.007 mol dm^{-3}, C: 0.03 mol dm^{-3}, D: 0.04 mol dm^{-3}, E: 0.0425 mol dm^{-3}, F: 0.045 mol dm^{-3}.

10^{-8} mol dm^{-3}, the system started to vary after ca. 15 s and then returned to the reduced steady state after ca. 240 s. When $[Br_2]=5.0\times10^{-9}$ mol dm^{-3}, the system immediately started to vary.

Figure 4 shows the excitability of an oxidized steady state induced by a sudden increase in the concentration of bromine. When $[Br_2]=1.3079\times10^{-4}$ mol dm^{-3}, the system returned to the oxidized steady state with a damped oscillation. When $[Br_2]=1.3080\times10^{-4}$ mol dm^{-3}, the system started to vary after ca. 8 s and returned to the oxidized steady state after ca. 150 s.

Figures 3 and 4 reveal that, when the change in the concentration of bromine is below a certain threshold, [Ce(IV)] and $[Br^-]$ undergo modest changes, while the change in $[Br_2]$ exceeds the threshold, [Ce(IV)] and $[Br^-]$ undergo major changes.

When $[(COOH)_2]=0.001$ mol dm^{-3}. As is shown in Fig. 5, when $[BrO_3^-]=0.002$ mol dm^{-3}, [Ce(IV)] gave rise to a jagged oscillation. When $[BrO_3^-]=0.0003$ mol dm^{-3}, the system stayed much larger in the reduced steady state. The time period of the oscillations was much larger than that when $[(COOH)_2]=0.03$ mol dm^{-3}. The amplitude of the oscillations depended on the concentration of bromate.

Figure 6 depicts the bifurcation diagram of the system studied here. The system could exist in both

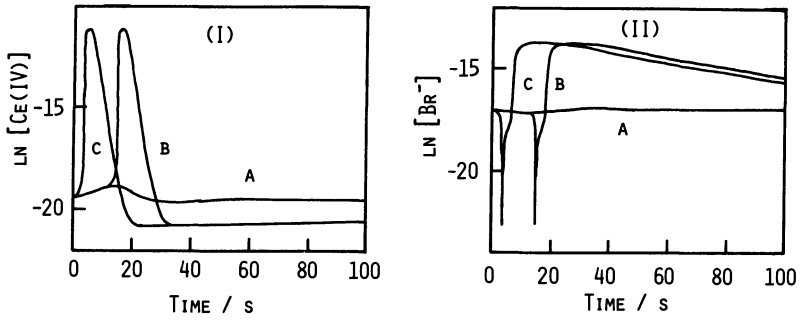

Fig. 3. The excitability of the reducd steady state induced by the changes in $[Br_2]$.
$[BrO_3^-]=0.006$ mol dm^{-3}, $[(COOH)_2]=0.03$ mol dm^{-3}, $k_{13}=0.075$ s^{-1}, $[Br_2]_{ss}=1.2857\times10^{-8}$ mol dm^{-3}. $[Br_2]$ A: 1.02×10^{-8} mol dm^{-3}, B: 1.01×10^{-8} mol dm^{-3}, C: 5.00×10^{-9} mol dm^{-3}.

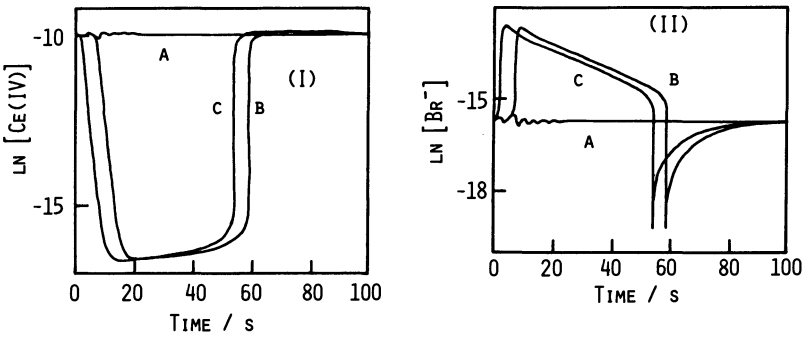

Fig. 4. The excitability of the oxidized steady state induced by the changes in $[Br_2]$.
$[BrO_3^-]=0.045$ mol dm^{-3}, $[(COOH)_2]=0.03$ mol dm^{-3}, $k_{13}=0.075$ s^{-1}, $[Br_2]_{ss}=1.2751\times10^{-4}$ mol dm^{-3}. $[Br_2]$ A: 1.3079×10^{-4} mol dm^{-3}, B: 1.3080×10^{-4} mol dm^{-3}, C: 1.3250×10^{-4} mol dm^{-3}.

reduced and oxidized steady states and in the oscillatory state, but no bistability was found in the system.

Figure 7 shows the relationship between the concentration of bromate and the time period of the oscillations. Up to now, the bromate-cerium-oxalic acid system has been simulated by using Reactions 17 and 18 instead of Reactions 7—12:[7,8]

$$HOBr + (COOH)_2 \longrightarrow Br^- + 2CO_2 + H_2O + H^+ \quad (17)$$

$$Ce(IV) + (COOH)_2 \longrightarrow Ce(III) + \text{inert products} \quad (18)$$

The model did not reproduce the characteristic oscillations of the system. That is, it has been reported that the experimental value of τ is dependent on the bifurcation parameters, such as k_{13} and $[BrO_3^-]$,[6,7] but the τ estimated from the model depended little on the parameters. Figure 7(A), which was obtained according to the model, was also not consistent with the experimental results reported by Gáspár and Galambosi.[7] Figures 7 (B) and 7 (C) were obtained on the basis of Reactions 1—13. The dependency of the time period of the oscillations on $[BrO_3^-]$ (Fig. 7(B)), as well as that of τ on the bifurcation parameters (Figs. 1 and 2) and the excitability (Figs. 3 and 4), were qualitatively consistent with the experimental results. However, the bistability could not be reproduced, and the rate constant of the bromine removal (k_{13}) and the amplitudes of the oscillations in Figs. 1 and 2 were larger than the values obtained experimentally. The failure to reproduce the bistabi-

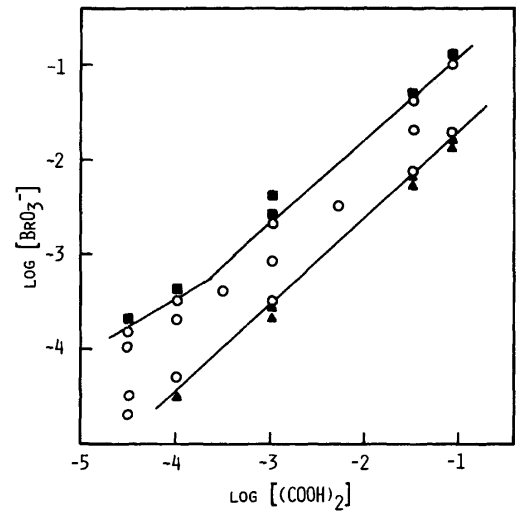

Fig. 6. The bifurcation diagram when $k_{13}=0.075$ s^{-1}.
■: oxidized steady state, ▲: reduced steady state, ○: oscillatory state.

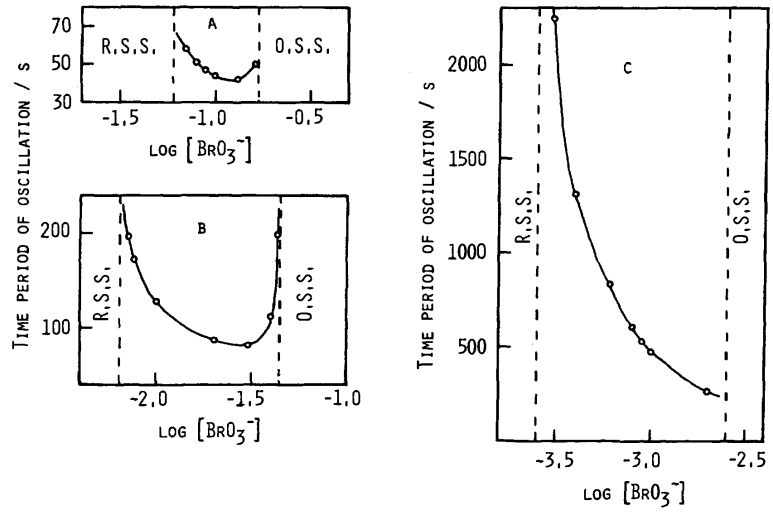

Fig. 7. The relationship between the time period of the oscillations and $[[BrO_3^-]$.
A: $[(COOH)_2]=0.05$ mol dm^{-3}, $k_{13}=0.13$ s^{-1}. Calculated by using Reactions 1—6, 13, 17, and 18.
B: $[(COOH)_2]=0.03$ mol dm^{-3}, $k_{13}=0.075$ s^{-1}. C: $[(COOH)_2]=0.001$ mol dm^{-3}, $k_{13}=0.075$ s^{-1}.

lity may be ascribed to inaccuracy in the rate constants in Table 1, for it seems difficult to determine the values of all the rate constants precisely. For the FKN mechanism, a revised set of the rate constants was developed.[15]

Maselko proposed four fundamental possibilities for bifurcation, leading from a steady state to a stable periodic orbit, and vice versa, in chemical systems.[16] There is a controversy as to the bifurcations in the classical BZ reaction.[17,18] In the bromate-cerium-oxalic acid system, the transitions from the monostable steady states to the oscillatory state have been reported to occur via saddle-node infinite-period (SNIPER) bifurcation.[6,7] The simulation in this study gave suggestions as to the bifurcations in the system. That is, the results in Figs. 1, 2, and 7(B) (the time period and the amplitude of the oscillations), and the fact that there is no hysteresis near the bifurcation points when $[(COOH)_2]=0.03$ mol dm^{-3}, were consistent with SNIPER bifurcation. On the other hand, when $[(COOH)_2]=0.001$ mol dm^{-3}, hysteresis was observed in the transition between the oxidized steady state and the oscillatory state, and not in the transition between the reduced steady state and the oscillatory state. These and the oscillation patterns in Fig. 5 suggest that the former transition occurs via subcritical Hopf bifurcation, and the latter transition, via SNIPER bifurcation.

In the reaction mechanism used in this study, HOBr is reduced by oxalic acid through both Reactions 17 and 19, under the stationary-state approximation for $HCO_2\cdot$ and Br$\cdot$ radicals:[19]

$$2HOBr + (COOH)_2 \longrightarrow Br_2 + 2CO_2 + 2H_2O \quad (19)$$

It is interesting that we can simulate the oscillation patterns of the bromate-cerium-oxalic acid system when the mechanism presented here is used, but not when Reactions 17 and 18 are used instead of Reactions 7—12. In bromate-cerium-oxalic acid-cyclohexanone system, more complicated bifurcation phenomena were observed.[20] Thus, the oscillation behavior in the bromate-cerium-oxalic acid system seems to be sensitive to the feed-back part of the reaction mechanism.

Molecular and Crystal Structure of the Lipid-Model Amphiphile, Dioctadecyldimethylammonium Bromide Monohydrate

Kenji Okuyama,* Yoshie Soboi, Naomi Iijima, Kiyoshi Hirabayashi, Toyoki Kunitake,† and Tisato Kajiyama†
Faculty of Technology, Tokyo University of Agriculture and Technology, Koganei, Tokyo 184
†Faculty of Engineering, Kyushu University, Fukuoka 812
(Received September 14, 1987)

Dioctadecyldimethylammonium bromide monohydrate ($2C_{18}N^+2C_1Br^-\cdot H_2O$), $C_{38}H_{80}NBr\cdot H_2O$, was crystallized from its solution in chloroform and hexane. The crystals are triclinic with the space group $P\bar{1}$, $Z=2$, a (normal to the bilayer surface)=3.811(2), b=0.7890(2), c=0.7418(2) nm, α=104.37(3), β=103.06(4), and γ=74.93(3)°. The structure was solved by the direct method and refined by the block-diagonal least-squares procedure: R=0.08 for 3121 observed reflections. The crystal structure consists of bimolecular layers stacking regularly along the a-direction. The two amphiphile molecules in the unit cell are related by centrosymmetry and pack tail to tail in a bilayer structure with tilting hydrocarbon chains by about 45° to the bilayer surface. The packing cross section per molecule in the layer plane is 0.567 nm². The hydrocarbon chains pack with an triclinic ($T//$) subcell with dimensions of a_s=0.42, b_s=0.49, c_s=0.26 nm, α_s=88, β_s=104, and γ_s=111°. One of the two alkyl chains bends near the nitrogen atom and conforms a part of a head region. Two water oxygen atoms with half occupancies were found in an asymmetric unit and accomodated statistically in a unit cell. These water molecules are linked with bromide anions by hydrogen bonds with the distance of about 0.34 nm. Bromide anions and ammonium cations are on the same plane parallel to the bilayer surface.

Dialkyldimethylammonium bromide, $2C_nN^+2C_1Br^-$, is a first totally synthetic amphiphile which conforms the biological membrane-like bilayer structure.[1,2] Their bilayer structures have been studied by electron microscopy,[1,2] differential scanning calorimetry and wide- and small-angle X-ray analysis,[3] and it has shown that the similarity of the molecular assembly of $2C_nN^+2C_1Br^-$ to those of phospholipids found in biological membranes. In the case of $2C_{18}N^+2C_1Br^-$, the electron micrograph showed the multilamellar liposome with mean thickness of 4.2 nm when the amphiphile solution was sonicated in the presence of uranyl acetate. The small-angle X-ray diffraction pattern taken at 25 °C (the crystal liquid-crystal transition temperature, T_c=51 °C) showed the long period of about 3.6 nm, independent of the water concentration.[3] This long period seems to correspond to the lamellar periodicity of the electron-dense striations in the electron micrograph. Since the extended bimolecular length of $2C_{18}N^+2C_1Br^-$ is about 5.0 nm on the assumption of the planar zigzag conformation of two dioctadecyl groups, it was speculated that the hydrocarbon chains of $2C_{18}N^+2C_1Br^-$ inclined at 47° to the lamellar surface in the bimolecular structure.[3]

Recently, the totally synthetic amphiphiles become important because of their ability to conform desired bilayer assemblies in the form of the single crystals, casting films and Langumuir-Blogett films. For a proper understanding of the physicochemical properties of these molecular assemblies, detailed structural information on an atomic level is required. In the cases of $2C_nN^+2C_1Br^-$ (n=18 and 16), single crystals suitable for X-ray analysis were obtained as the first example for the totally synthetic amphiphiles which could conform bimolecular layer.[4] In this paper, we discuss the structure of $2C_{18}N^+2C_1Br^-$ determined by X-ray single crystal analysis. Since this compound is chemically simple as a lipid-model able to conform the biological membrane-like bilayer structure, the precise structure on the atomic level will be useful for the better understanding of the physicochemical properties for more complicated amphiphilic compounds.

Experimental and Structure Determination

Dioctadecyldimethylammonium bromide, $2C_{18}N^+2C_1Br^-$, was prepared by stepwise alkylation of dimethylamine.[1] $2C_{18}N^+2C_1Br^-$ (50 mg) was dissolved in 2 ml of chloroform. After complete dissolution, 8 ml of hexane was added. Transparent, plate-like crystals formed at the bottom of the vessel by keeping the solution for several days at room temperature (ca. 20 °C). The size of the large crystals reached 5 mm×5 mm×0.1 mm. Many of them were usually multiple crystals with the common axis normal to the plate surface. Large plate-like crystals were cut into small pieces in order to obtain those with suitable dimensions for X-ray analysis. After many trials of X-ray investigation of such crystals, single crystals available for X-ray diffraction study were found. Approximate dimensions of the crystal used in this analysis were 0.8 mm×0.5 mm×0.01 mm.

Lattice parameters and diffraction intensities were measured on a Rigaku four-circle diffractometer with Ni-filtered Cu $K\alpha$ radiation (λ=0.154184 nm). The lattice parameters were refined by the least-squares fit using 25 reflections in the 2θ range of 19°—65°. By using the ω-scan mode at a scan rate of 10° min^{-1}, intensities of 3919 reflections were measured up to 100° in 2θ. The scan width was $\Delta\omega=(1.8+0.15\tan\theta)°$. Three reference reflections monitored every 50 reflections showed no significant intensity deterioration during the data collection. Corrections were made for the Lorentz and polarization factors, but not for absorption and extinction effects. However, the (h00) reflections with $h<12$ were excluded from the data set

because of an absorption effect on these reflections as shown in the later. A total of 3121 reflections greater than $3\sigma(F_o)$ were used in the following analysis.

Density was measured by flotation method using aqueous solution of sodium chloride. On the basis of the measured density and a unit cell volume, the unit cell contains two $2C_{18}N^+2C_1Br^-$ molecules and seems to contain one or two water molecules. While the elemental analysis showed the monohydrated structure of this amphiphile (Calcd for $C_{38}H_{80}NBr \cdot H_2O$: C, 70.33; H, 12.74; N, 2.16%. Found: C, 70.18; H, 12.75; N, 2.12%.). Further, the result of X-ray structure analysis also supported monohydrated structure as shown below.

Crystal Data: $C_{38}H_{80}NBr \cdot H_2O$, F.W.=648, triclinic, space group $P\bar{1}$, Z=2, a=3.811(2), b=0.7890(2), c=0.7418(2) nm, α=104.37(3), β=103.06(4), γ=74.93(3)°, V=2.055(2) nm^3, D_x=1.047, D_m=1.04 g cm^{-3}, ρ(Cu $K\alpha$)=10.2 cm^{-1}.

Determination and Refinement of the Structure. The direct method with the MULTAN 78 program[5] was applied for $P1$ and $P\bar{1}$ space groups. Only for the latter space group, two planar zigzag alkyl chains could be readily discerned. The vector between two bromide anions related by the centrosymmetric operation for the $P\bar{1}$ space group was clearly appeared in the three-dimensional Patterson map, which also supported this space group for the $2C_{18}N^+2C_1Br^- \cdot H_2O$ crystal. After several cycles of block-diagonal least-squares refinement starting from the coordinates of all the non-hydrogen atoms of the amphiphile obtained by the direct method, difference Fourier syntheses revealed the several peaks, which was assumed to be oxygen atoms of water molecules. After several refinement cycles including these newly found water positions, it was found that two water molecules with half occupancies were able to be accomodated statistically in an asymmetric unit in terms of
