Laser Photolysis. An NEC SLG 2009 ruby laser was used for laser photolysis.[20] The concentration of the deaerated sample solutions was in the range 5.0×10^{-4} to 2.0×10^{-3} mol l^{-1} in chromophore units. The concentration of BP used as the triplet sensitizer was 2.5×10^{-3} mol l^{-1} for all sample solutions. Samples were excited by the second-harmonic pulse (347 nm, 16 ns, 3.02×10^{-8} einstein/pulse). The laser power was attenuated by a suitable combination of filters, so that the absorbance of the $T_n\leftarrow T_1$ absorption was less than 0.2. Under such conditions, the T–T annihilation process became negligibly small.

Photoirradiation. Photoirradiation was carried out for 0.5 h in a thermostat kept at 25 °C. A Toshiba 300-W high-pressure mercury lamp was used as the excitation source. A 365-nm mercury line was selected through a combination of filters: a Toshiba UVD-2 and a Corning C.S. 0-52. The concentration of bichromophoric compounds in the deaerated solution was adjusted to be 2.0×10^{-3} mol l^{-1} with respect to the chromophore concentration. The concentration of BP was 2.5×10^{-3} mol l^{-1}. All sample solutions were filled in a 1-cm quartz cell and deaerated by several freeze-pump-thaw cycles at ca. 10^{-6} Torr (1 Torr=133.322 Pa).

The number of photons at 365 nm was measured to be 1.89×10^{-9} Einstein cm^{-2} s^{-1} by the potassium trioxalatofer-

rate(III) actinometry.[21]

Product Analysis. Intra- and intermolecular photoreaction products were analyzed by a Toyo Soda HLC 802 UR gel permeation chromatograph with double G2000H columns eluted by THF. UV, IR, NMR spectra of the products were measured by a Shimadzu UV-200 S double-beam spectrophotometer, by a JASCO IR-G infrared spectrophotometer, and by a JEOL FX-90 Q NMR spectrometer using TMS as an internal standard, respectively. The spectroscopic data for the obtained products were as follows. The IR spectra for the intra- and intermolecular products showed the same characteristic spectra: IR (KBr); 1660 (s, C=O), 1450 cm^{-1} (m, CH). All intermolecular reaction products showed the same characteristic ^1H NMR spectra: ^1H NMR (CD_2Cl_2); δ=1.9—2.7 (m, methylene), 3.4—3.7 (m, oxyethylene), 6.9 (s, ethylenic), 7.1—7.5 (m, aromatic). For all intramolecular cyclomers the chemical shifts of the ^1H NMR spectra were as follows: ^1H NMR (CD_2Cl_2); δ=2.5—4.1 (m, oxyethylene), 4.0 (s, methine), 6.9—7.7 (m, aromatic).

Results and Discussion

Intra- and Intermolecular End-to-End Interactions Measured by Nanosecond Laser Photolysis. The absorption spectra of a series of bichromophoric compounds, DE-n (n=0—10), in dichloromethane were found to be independent of the chain length (l) and were identical with the monomeric compound, 5-valeryl-DBA (λ_{max}=287 nm).[4] This fact shows that a pair of terminal DBA groups of these bichromophoric compounds do not have any specific interaction with each other in the ground state.

Intra- and intermolecular end-to-end interactions in the excited triplet state were examined by nanosecond laser photolysis through the kinetic analysis of the deactivation processes of the terminal DBA triplet. Benzophenone (BP) sensitized $T_n \leftarrow T_1$ absorption spectra of the bichromophoric compounds in dichloromethane at room temperature were independent of the chain length (l) and identical with those of the bichromophoric polymethylene compounds reported previously.[1] The $T_n \leftarrow T_1$ absorption band of the DBA triplet for DE compounds (λ_{max}=420 nm) hardly overlaps with that of the BP triplet (λ_{max}=520 nm). Therefore, the decay curves at 400 nm and 520 nm were unambiguously analyzed. Figure 2 shows the scheme of BP sensitization and the deactivation processes of the sensitized DBA triplet in the bichromophoric compounds. In this figure, BP and $^3BP^*$ represent benzophenone in the ground state and in the excited triplet state, respectively. DBA-DBA represents a bichromophoric molecule in the ground state and $^3DBA^*$-DBA in the excited triplet state of the bichromophoric molecule. The rate constant, k_n^s, is the sum of the rate constants for all unimolecular decay processes of the triplet BP, and k_t the rate constant for the triplet-triplet (T-T) energy transfer from BP to a terminal DBA group. The rate constant, k_n, is the sum of the rate constants for all unimolecular decay processes of the excited triplet state of DBA, k_n^{intra} the rate constant of the triplet deactivation by intramolecular quenching, and k_d^{intra} the rate constant of the intramolecular ring-closure reaction, and k_n^{inter} the rate constant of the deactivation by intermolecular quenching, k_d^{inter} the rate constant of intermolecular cycloaddition reaction. The decay processes are roughly divided into two routes: one is a decay path in which the excited triplet DBA group is self-quenched and gives no reaction product, a kind of genuine concentration quenching process; the other is a decay path in which the terminal DBA group in the excited state reacts with that in the ground state and gives the photoproducts. Each decay path consists of intramolecular and intermolecular processes.

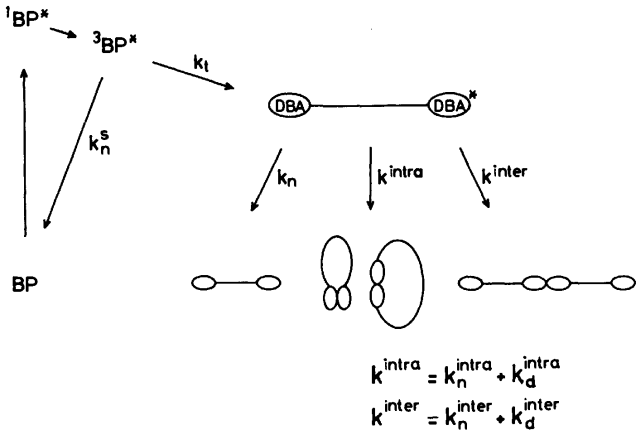

Fig. 2. T-T energy transfer from benzophenone to the bichromophoric compounds and deactivation processes of the excited triplet state of the bichromophoric compounds.

The lifetime of the BP triplet (τ^D) was measured at several concentrations of DE molecules which were the triplet energy acceptor. The Stern-Volmer equation for the lifetime of the BP triplet is expressed as follows:

$$\tau_0^D/\tau^D = 1 + \tau_0^D k_t[DBA], \quad (1)$$

where τ_0^D is the lifetime of the BP triplet in the absence of the DE molecule (τ_0^D=3.6×10^{-6} s),[4] and [DBA] the concentration of DBA chromophore. The plot of τ_0^D/τ^D against the concentrations of DBA chromophore for all DE compounds showed a straight line, and from the slope of the line the rate constant for a T-T energy transfer, k_t, was estimated for each DE compound. Figure 3 shows the chain-length dependence of the k_t value. The k_t value is almost independent of the chain length of DE compounds and is close to the diffusion-controlled rate constant ($k_t \simeq 2\times10^9$ M^{-1} s^{-1}). This tendency and the k_t value itself are almost the same as those for the polymethylene system.[1] In this low-molecular-weight region, the diffusion rate constant is presumed to be independent of the molecular size.[22]

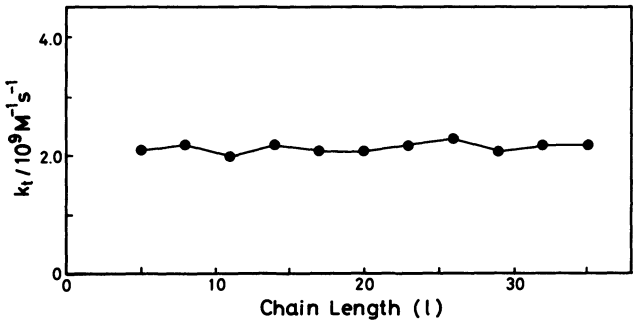

Fig. 3. Chain length dependence of the rate constant of T-T energy transfer, k_t, from benzophenone to a terminal DBA group of poly(oxyethylene) compound in dichloromethane at room temperature.

The lifetime of the terminal DBA triplet, τ^A, in this reaction system is represented by the following equation:

$$1/\tau^A = k_n + k^{intra} + k^{inter}[DBA], \quad (2)$$

where k^{intra} is the sum of the rate constants of k_n^{intra} and k_d^{intra} ($k^{intra}=k_n^{intra}+k_d^{intra}$), k^{inter} the sum of k_n^{inter} and k_d^{inter} ($k^{inter}=k_n^{inter}+k_d^{inter}$). The lifetime of the terminal DBA triplet was measured for several concentrations of the DE compound, and the plot of $1/\tau^A$ against the concentration of the terminal DBA group gave a straight line for each compound. From the intercept in this plot, the k_n+k^{intra} value was obtained. The k^{intra} value for each bichromophoric compound was determined by subtracting the k_n value from the k_n+k^{intra} value, since the k_n value is considered to be inherent to the DBA chromophore. In this case, the k_n value is assumed to be equal to the k_n^A value obtained for the monomeric compound, 5-valeryl DBA, which was reported previously ($k_n=k_n^A=5.9\times10^4$ s^{-1}).[4] Figure 4 shows a plot of the k^{intra} value obtained in this reaction system against the chain length of the bichromophoric compounds, together with the results obtained in the previous polymethylene system. In this figure, it is apparent that the k^{intra} value is strongly dependent on the chain length. The peak of the k^{intra} value corresponding to the first peak in the polymethylene system was not observed in the poly(oxyethylene) system. In the present system, the shortest chain length (l) was 5 (n=0). Therefore, the first peak for intramolecular interaction exists presumably at a chain length shorter than l=5.

In the range of the chain length l=5 to 11, the k^{intra} values are very small compared with those of other chain lengths. This tendency in this system is almost the same as that in the polymethylene system reported previously. This means that poly(oxyethylene) chains in this region can hardly take a favorable or stable ring conformation intramolecularly.

On the other hand, the k^{intra} value increases with increasing chain length beyond l=11 and the maximum value appears at l=20. This indicates that

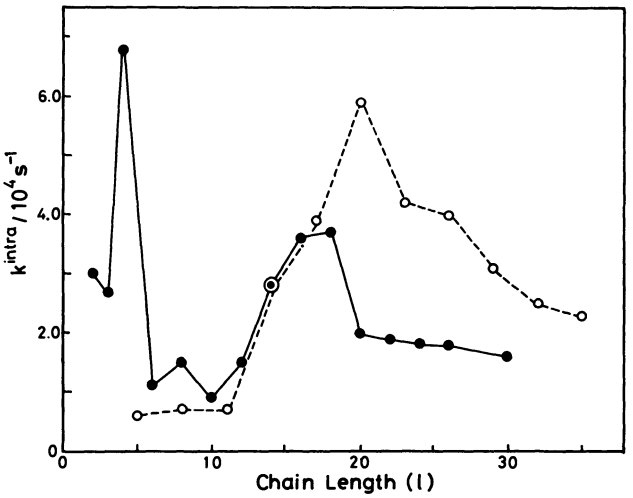

Fig. 4. Chain length dependence of the rate constant of intramolecular interaction, k^{intra}, for poly(oxyethylene) system (○), and polymethylene system (●) at room temperature.

a strong interaction occurs intramolecularly between a pair of terminal DBA groups with this extent of separation. At this chain length, the poly(oxyethylene) chain takes a favorable conformation for the terminal DBA groups to interact with each other. This experimental finding indicates that ring-closure probability of a poly(oxyethylene) chain reaches the maximum at the chain length l=20. For the poly(oxyethylene) system, the chain length which gives the maximum value of k^{intra} is slightly longer than that for the polymethylene system. This effect is due to an increasing contribution of k_d^{intra} to the k^{intra} value, which will be discussed in the following section. That is, the k_d^{intra} value increases sharply at l=20 in the poly(oxyethylene) system and the chain length for the maximum value of k^{intra} shifts to a longer region than that for the polymethylene system.

A theoretical treatment for the intramolecular ring-closure probability of a poly(oxyethylene) chain (C-O-(-C-C-O-)$_m$-C, m=3—20) was carried out by Sisido et al.[23] They calculated the ring-closure probability of a poly(oxyethylene) chain by the Monte Carlo Method. In their calculation, the maximum ring-closure probability appears at m=4 or 5 (the number of atoms in the chain is 15 or 18) under the critical distance between the chain ends, r_0=6 or 4 Å, respectively. The calculated result is different from their experimental findings. They concluded that this discrepancy is attributed to the effect of the bulky terminal groups attached to the poly(oxyethylene) chain. In our experimental examination, the maximum k^{intra} value appears at n=5 (l=20). This chain length is also longer than the chain length of the maximum ring-closure probability calculated by the Monte Carlo Method. The difference between our experimental findings in the present system and their

calculated results may be attributed to the effect of the terminal DBA groups.

In the region of the chain length $l \geqq 17$, the k^{intra} values in this system are larger than those in the polymethylene system. This indicates that the collisional frequency of the terminal reactants in the poly(oxyethylene) system is higher than that in the polymethylene system. The difference of collisional frequencies in the two systems is due to the difference of the flexibility between two molecular chains connecting terminal DBA groups. Yamakawa et al. have investigated the chain stiffness of flexible chain polymers on the basis of helical wormlike chains.[24,25] They defined the parameters λ^{-1} and τ/τ^0 as the static chain stiffness and the dynamic chain stiffness, respectively, where τ and τ^0 are the correlation time of a flexible chain and that of the monomer unit, respectively. The larger the parameter λ^{-1}, the statically stiffer the chain, and the larger the parameter τ/τ^0, the dynamically stiffer the chain. They showed that there is a good correlation between the dynamic stiffness τ/τ^0 and the static stiffness λ^{-1}; τ/τ^0 is a monotonically increasing function of λ^{-1}. According to their theoretical estimate, the value λ^{-1} is 14.5 and 12.0 Å for the polymethylene chain and for the poly(oxyethylene) chain, respectively. Hence, the poly(oxyethylene) chain is considered to be more flexible than the polymethylene chain from a dynamic standpoint as well as from a static one. Our experimental results agree well with their theoretical prediction.

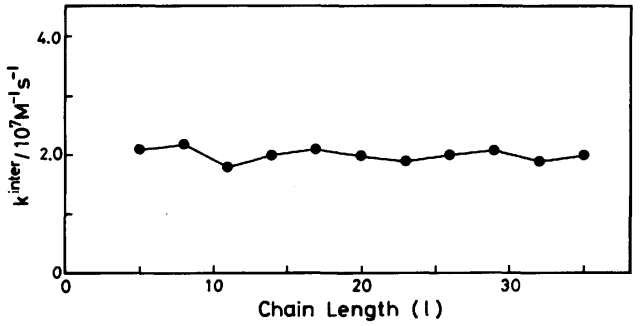

Fig. 5. Chain length dependence of the rate constant of intermolecular interaction, k^{inter}, for bichromophoric poly(oxyethylene) compounds in dichloromethane at room temperature.

The rate constant, k^{inter}, was determined from the slope of the straight line obtained by the plot of $1/\tau^A$ against the DBA concentration. Figure 5 shows a plot of the k^{inter} value against the chain length of the DE compounds. It is apparent that the rate constant for the deactivation by intermolecular interaction k^{inter}, is independent of the chain length of the poly(oxyethylene) chain. The k^{inter} values in this system are nearly equal to those in polymethylene system reported previously ($(1—2)\times10^7$ M^{-1} s^{-1}).[1] The absence of the influence of chain length on the rate constant k^{inter} is partly due to an activation-controlled process[26] and partly due to the rather small molecular weights of the bichromophoric compounds.

In this section, the ring-closure probability of a poly(oxyethylene) chain was examined through an analysis of the intramolecular deactivation rate constant, k^{intra}; the experimental results indicate that the flexibility of a moleculr chain exerts a great influence upon the ring-closure probability.

Intra- and Intermolecular End-to-End Cycloaddition Reactions. A series of bichromophoric compounds, DE-n (n=0—10), which are excited by a T-T energy transfer from BP, have two kinds of reaction paths (Fig. 2): intramolecular ring-closure reaction and intermolecular dimer formation reaction.

Figure 6 shows typical GPC diagrams of the reaction products obtained after 0.5 h irradiation. For DE-1, only one intermolecular reaction product **2** was

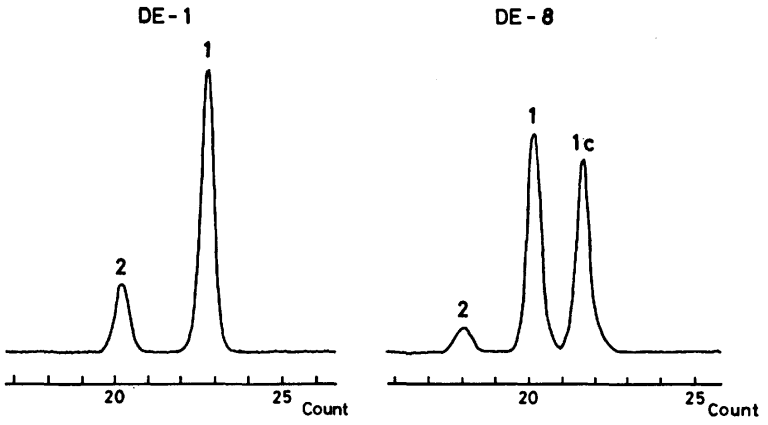

Fig. 6. Typical GPC diagrams of photoreaction products obtained by 0.5 h irradiation of bichromophoric compounds, DE-1 and DE-8. Unreacted monomer **1**, intramolecular ring-closure product **1c**, and intermolecular dimer **2**.

detected at 20.2 counts, together with the residual unreacted monomer **1** at 22.7 counts. This situation is the same as that for the shorter-chain compounds. The intramolecular reaction does not occur, since the oxyethylene chain is too short for a pair of terminal DBA group to form intramolecularly. On the other hand, with longer-chain compounds, such as DE-8, not only the intermolecular reaction product **2** at 18.0 counts but also the intramolecular ring-closure product **1c** at 21.6 counts was detected together with the unreacted monomer **1** at 20.0 counts. A GPC analysis showed that an intramolecular ring-closure product is produced for samples of $l \geqq 14$, but not for samples of $l \leqq 11$. These experimental facts can be explained in terms of the configuration of the terminal groups; DBA group forms only anti-cyclobutane ring[4] and for the compounds having an oxyethylene chain shorter than $l=14$, a pair of terminal DBA groups cannot take a favorable orientation to form an anti-cyclobutane ring intramolecularly. Such a chain-length dependence of the intramolecular ring-closure reaction for this system is almost the same as that for the polymethylene system; in the polymethylene system, the intramolecular ring-closure product cannot be detected for the compounds having a chain shorter than $l=14$.[1]

The quantum yields of both the intra-and intermolecular cycloaddition reactions in each bichromophoric compound were determined by the quantitative analyses of the reaction products with GPC. In these BP-sensitized systems, the quantum yields for the intramolecular ring-closure product (ϕ_d^{intra}) and for the intermolecular dimer (ϕ_d^{inter}) are defined as follows:

ϕ_d^{intra} = the number of intramolecular ring-closure products/the number of photons absorbed by BP,

ϕ_d^{inter} = the number of intramolecular dimers/the number of photons absorbed by BP.

As described in the previous section, the rate constant of a T–T energy transfer, k_t, is almost independent of the chain length, and the efficiency of a triplet energy transfer from BP to the terminal DBA group is close to unity. Therefore, the values, ϕ_d^{intra} and ϕ_d^{inter}, are nearly equal to the quantum yields defined by the ratio of the number of the product molecules to the number of initial molecules in the excited triplet state.

The effect of the chain-length dependence of the intramolecular ring-closure reaction was examined. Figure 7 shows a plot of the quantum yield for intramolecular ring-closure reaction against the chain length, l ($l=3n+5$) for the poly(oxyethylene) system, together with the values obtained for the polymethylene system. The quantum yield increases sharply for a chain length $l=20$ and the maximum quantum yield of the intramolecular ring-closure reaction appears at $l=26$ (DE-7). The chain length that gives the

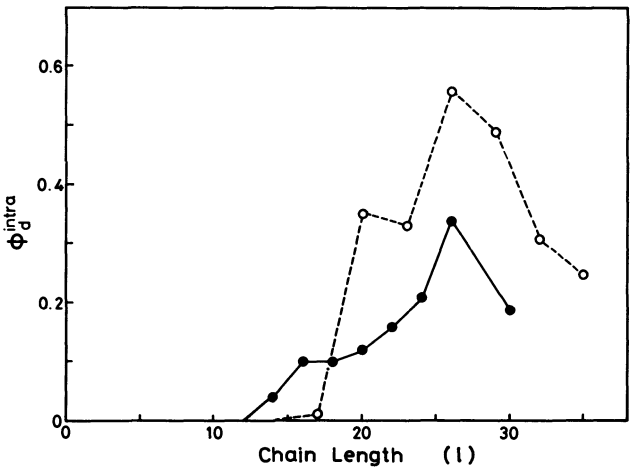

Fig. 7. Chain length dependence of the quantum yield of intramolecular ring-closure reaction, ϕ_d^{intra}, for bichromophoric compounds, poly(oxyethylene) system (○), and polymethylene system (●), in dichloromethane at 25°C.

maximum quantum yield of the intramolecular ring-closure reaction is different from that of the intramolecular end-to-end interaction: in other words, the chain length for the maximum quantum yield of intramolecular ring-closure reaction shifts to chains longer than that for the maximum intramolecular deactivation rate constant. The NMR examination shows that a pair of terminal DBA groups of intramolecular ring-closure products forms an anti-cyclobutane ring. This suggests that a pair of terminal DBA groups take the most favorable orientation for the anti-cyclobutane formation at the chain length $l=26$, i.e., the ring-closure probability for a pair of terminal bonds to be put in an opposite direction becomes maximum at $l=26$. The chain length which gives the maximum quantum yield ϕ_d^{intra} for the poly(oxyethylene) system is in fair agreement with that for the polymethylene system.

Figure 8 shows a plot of the quantum yield of the intermolecular dimerization against the chain length. In this figure, the ϕ_d^{inter} values show a marked dependence on the chain length. This is in contrast to the independence of the k^{inter} value on the chain length in the previous section (Fig. 5). This chain-length dependence of the ϕ_d^{inter} value is probably due to the influence of the triplet lifetime of the terminal DBA group. The lifetime is mainly determined by the k^{intra} value. Compounds $l \geqq 14$ have large k^{intra} values compared with compounds $l \leqq 11$. This therefore reduces the intermolecular reaction rate for the longer-chain compounds. That is, because of the short lifetime for $l \geqq 14$, these compounds have little chance to react with other DBA groups intermolecularly. Hence, ϕ_d^{inter} values are low in this region of chain length. In addition, the ϕ_d^{inter} values in the poly(oxyethylene) system are nearly the same as those of the previous polymethylene system in the range of

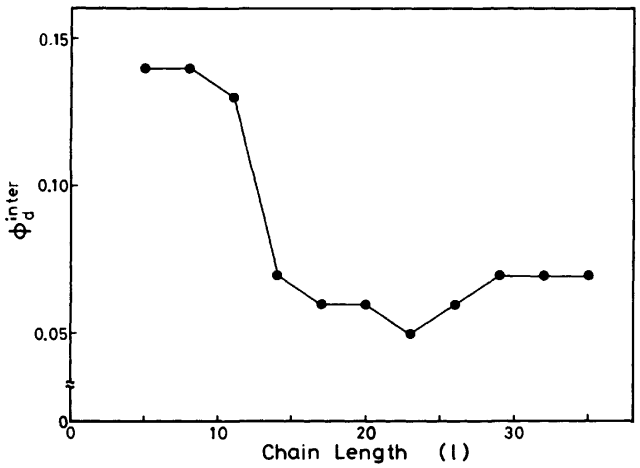

Fig. 8. Chain length dependence of the quantum yield of intermolecular dimerization, ϕ_d^{inter}, for bichromophoric poly(oxyethylene) compounds in dichloromethane at 25°C.

the short chain length ($\phi_d^{inter} \simeq 0.14$). This trend implies that intermolecular dimerization is not affected by the nature of a molecular chain: it is controlled by the lifetime of the terminal reactants.

In the present work, the chain length which gives the highest ring-closure probability of a poly(oxyethylene) chain was found to be l=20 (n=5) by laser photolysis. On the other hand, the maximum quantum yield for the ring-closure reaction appears at a longer chain length, l=26 (n=7): that is, a longer chain length is needed for the intramolecular ring-closure reaction. In this case, the terminal bonds must point to opposite directions to take anti-configuration, that is, the chain length which yields the maximum quantum yield for the ring-closure reaction shifts to a longer chain length. In the present system, the steric factor of a pair of terminal groups must be considered in an examination of the intramolecular reaction probability. It is concluded that the reaction yield of the intramolecular ring-closure reaction is determined by the equilibrium ring-closure probability of a molecular chain with a certain direction of terminal bonds. Furthermore, the ϕ_d^{intra} values for the poly(oxyethylene) system are larger than those for the polymethylene system. This means that the effective concentration of a terminal group of poly(oxyethylene) in the vicinity of the other terminal group is higher than that in a polymethylene system, i.e., the ring-closure probability of a poly(oxyethylene) chain in equilibrium is higher than that of a polymethylene chain. The flexibility of a molecular chain is said to be one of the most important factors in determining intrachain reactivity.

Department of Chemistry, Faculty of Science, Tohoku University, Aramaki, Sendai 980
(Received January 9, 1988)

2,3-Dipyridylnorbornadienes were prepared using the Diels–Alder reaction of the HBF_4 salts of dipyridylacetylenes with cyclopentadiene. Their absorptions extend to 380 nm and are red-shifted in an acidic media. They underwent photocyclization to give quadricyclanes which reverted to norbornadienes upon heating or encountering a Co(II)–TPP catalyst. 2,3-Bis(1-methylpyridinio)norbornadienes were also prepared by a Diels–Alder reaction of bis(1-methylpyridinio)acetylenes with cyclopentadiene. Irradiation of 1-methyl-2-pyridinio and 1-methyl-3-pyridinio derivatives led to the photostationary state between them and the corresponding quadricyclanes, while a 1-methyl-4-pyridinio derivative gave a water or methanol adduct in the presence of water or methanol. Electron-transfer reactions of bis(1-methylpyridinio)norbornadienes were investigated by cyclic voltammetry. The radical cations formed by their reduction were unstable compared with those of the corresponding *trans*-bis(1-methylpyridinio)ethylenes. Steric factors were shown to strongly affect the reactivities.

Valence isomerization between norbornadienes and quadricyclanes has attracted considerable attention from the viewpoint of the reaction mechanism[1] as well as solar energy storage.[2] Since norbornadiene, itself, does not have absorptions above 300 nm, many derivatives have been prepared to extend the absorptions to longer wavelengths.[2] 2,3-Dicyano-1,5,6-trimethyl derivative **1** is a typical compound which shows absorption extending to 400 nm, due to an intramolecular charge-transfer interaction between the dicyanoethylene and dimethylethylene parts.[2c] The mechanism for the photochemical cyclization to give the corresponding quadricyclane was investigated in detail and the high quantum yield could be attributed to the excited state having a charge-transfer property.[3] In this connection, 2,3-dipyridyl derivatives **2** are of interest since they can be easily led to the quaternary salts **3** in which the intramolecular interaction resulting in the shifts of absorptions to longer wavelengths is possible. The photochemistry of **2** and **3**, which contain a cis-fixed dipyridylethylene moiety, is intriguing for comparisons with that of dipyridylethylenes in which a cis–trans isomerization occurs.[4] The redox reactions of bis(1-methylpyridinio) derivatives **3** are also interesting since they have a Weitz-type redox system,[5] which is regarded as a viologen analogue. The particularly interesting point is that the bis(1-methylpyridinio)ethylene part is cis-fixed and cannot undergo cis–trans isomerization. The C_5–C_6 double bond may affect the redox reactions. From these viewpoints, we have prepared dipyridylnorbornadienes and investigated their properties.[6]

Results and Discussion

Preparation of Dipyridylnorbornadienes. 2,3-Dipyridylnorbornadienes (**2**) were considered to be prepared by a Diels–Alder reaction of dipyridylacetylenes with cyclopentadiene. However, dipyridylacetylenes are weak dienophiles and the reported examples only involve reactions of the 2-pyridyl derivative with tetraphenylcyclopentadienone[7] and coumarin,[8] which require severe conditions. In fact, dipyridylacetylenes

4a—**c**[9] did not undergo a Diels–Alder reaction with cyclopentadiene at all. Therefore, we tried the reaction of the HBF_4 salts of **4a**—**c**, which are considered to be stronger dienophiles due to the more electron-withdrawing property of the pyridinium substituents lowering the LUMO level of the acetylene moiety. The reaction of the HBF_4 salts of **4a**—**c** with cyclopentadiene followed by a treatment with an aqueous sodium hydrogencarbonate solution gave 2,3-dipyridylnorbornadienes **2a**—**c**. The reactivity of the conjugated acid of **4** as a dienophile for the Diels–Alder reaction was dependent on the position of the nitrogen atom in the pyridyl substituents, as can be seen in the reaction conditions listed in Table 1. 2-Pyridyl derivative is the most reactive, while a reaction of the 3-pyridyl derivative requires severe conditions and the yield is poor. The poor reactivity of 3-pyridyl derivative can be explained by considering that the positive charge on the nitrogen atom cannot be delocalized to the acetylenic bond at the meta position. Similarly, the reactivity of *trans*-dipyridylethylene as a dienophile in the Diels–Alder reaction could be enhanced by protonation. Thus, *trans*-di-4-pyridylethylene was recovered upon heating with cyclopentadiene under toluene reflux for 24 h; however, the HBF_4 salt gave *trans*-5,6-di-4-pyridylnorbornene (**5**) in 90% yield upon heating with cyclopentadiene under acetonitrile reflux for 24 h followed by neutralization.

Bis(1-methylpyridinio)acetylenes (**6**) were prepared by the reaction of **4** with trimethyloxonium tetrafluoroborate in good yields. The reaction of **6** with cyclopentadiene under the conditions shown in Table 1 gave 2,3-bis(1-methylpyridinio)norbornadienes (**3**).

Properties of Dipyridylnorbornadienes. The electronic spectra of dipyridylnorbornadienes **2a**—**c** are shown in Fig. 1. All of the norbornadienes **2a**—**c** have end-absorptions around 380 nm, indicating that the introduction of the pyridyl groups shifts the absorption maxima to longer wavelengths. The absorptions are red-shifted in the acidic medium relative to those in a neutral solvent. The 4-pyridyl derivative **2a** has an absorption maximum at 360 nm in an acidic medium. The spectrum of the 2-pyridyl derivative is pH dependent (as shown in Fig. 1), but those of **2a** and **2b** are not. The pH dependence may be attributed to the fact that the conjugated acid has two separate pK_a values, which were determined to be 1.1 and 7.2 by an absorptiometric method. This behavior can be explained by considering that the two pyridyl groups interpose a proton, as shown in the structure **7**,[10] since the absorption of the monoprotonated species is red-shifted compared with that of the di-protonated species; such separate pK_a values are observed in chelate reagents such as 2,2′-bipyridyl and 1,10-phenanthroline. The spectra of 1-methylpyridinium derivatives **3a**,**b**, shown in Fig. 2, are similar to those of the corresponding protonated species. The red shifts caused by quaternarization indicate the presence of a charge-transfer interaction between two olefinic parts. This is also supported by the fact that the absorption of **3a** is red-shifted compared with the corresponding norbornene **8**. On

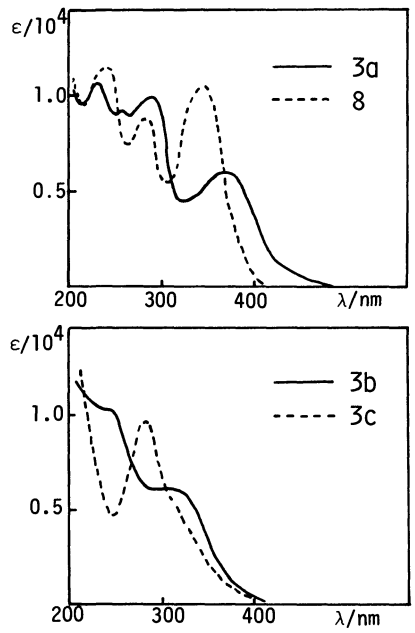

Fig. 2. Electronic spectra of 2,3-bis(1-methylpyridinio)norbornadienes (**3**) and norbornene (**8**).

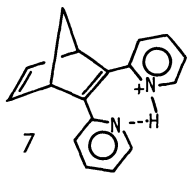
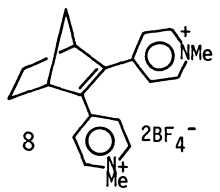
the other hand, the absorption maximum of **3c** is rather blue-shifted compared with that of the neutral species **2c**. This fact may be attributed to the twisting structure of the 1-methylpyridinium derivative, resulting in a loss of the conjugation of the pyridinium groups with the double bond.





Pyridine derivatives, such as 2,2′-bipyridyl, are well-known to be good ligands for metal ions and to form complexes. In the presence of CuCl or $FeSO_4$, red shifts of the absorptions of 4- and 2-pyridyl derivatives **2a** and **2c** were observed, indicating that coordination occurs. On the other hand, the spectrum of 3-pyridyl derivative **2b** was not changed by the addition of CuCl or $FeSO_4$. The reason for no coordination in **2b** is still ambiguous.

Valence Isomerization Reaction. Irradiation of an acetonitrile solution of **2a—c** with Rayonet RUL-3000 Å lamps gave quadricyclanes **9a—c** quantitatively. The quantum yields in acetonitrile were very high and insensitive to the substituents (**2a**; ϕ 0.72, **2b**; ϕ 0.78, **2c**; ϕ 0.79). The yields in cyclohexane were nearly equal (**2a**; ϕ 0.72, **2b**; ϕ 0.71). The photoreaction was affected neither by triplet quenchers, such as 2,5-dimethyl-2,4-hexadiene, 1,3-cyclohexadiene, and oxygen, nor by biacetyl which sensitizes the cis-trans isomerization of dipyridylethylenes. This fact suggests that the reaction proceeds via a singlet state. This is consistent with the fact that the intersystem crossing in dipyridylethylenes is inefficient.[11] The photoisomerization of **2a** also proceeded in a solid state quantitatively when a KBr pellet of **2a** was irradiated with a 300-W xenon lamp.

Irradiation of the dimethyl derivatives **3b, c** with Rayonet RUL- 3500 Å lamps led to a photostationary state between **3b, c** and quadricyclanes **10b, c** (**3b**:**10b**=1:4, **3c**:**10c**=2:5). This can be explained by the fact that the resulting quadricyclanes **10b, c** have end-absorptions around 350 nm and undergo cycloreversion under the irradiation conditions. A similar photostationary state was observed upon irradiating a diprotonated derivative **11b** with RUL-3500 Å lamps (**11b**: quadricyclane **12b**=3:7). The irradiation of a monoprotonated derivative **7** with RUL-3000 Å lamps led to a photostationary state between **7** and quadricyclane **13** (**7**:**13**=1:4). However, irradiation with RUL-3500 Å lamps gave **13** quantitatively. This wavelength dependence is explicable by the fact that quadricyclane **13** has no absorption around 350 nm and is stable under the irradiation conditions with 3500 Å lamps. In contrast, irradiation of 4-pyridyl derivative **3a** with RUL-3500 Å lamps in acetonitrile gave a complex mixture of products. Irradiation in the presence of a small amount of water or methanol led to the formation of a water adduct **14a** or a methanol adduct **14b**, respectively.[12] In the case of diprotonated derivative **11a**, **15a** or **15b** was isolated after neutralization.[12] A treatment of quadricyclane **9a** with HBF_4 in acetonitrile containing methanol followed by neutralization gave **15b**. This result suggests that adducts **14** are formed by a nucleophilic attack of water or methanol on the initially formed quadricyclanes.

Quadricyclanes **9a—c** underwent a cycloreversion reaction to give norbornadienes **2a—c** upon heating. The activation parameters were calculated (Table 2) from the first-order rate constants determined by a UV spectroscopic method in ethanol. Those values indicate that the introduction of the two pyridyl groups significantly lowers the activation energy compared with that of dicyano[13] and bis(methoxycarbonyl) substituents.[14] The position of nitrogen of pyridyl substituents has little effect on the reactivities. The salts **10b, c, 12b**, and **13** also underwent a cycloreversion reaction upon heating at 60 °C in acetonitrile.

Transition metals are well-known to catalyze the cycloreversion reaction of quadricyclanes to norbornadienes.[15] However, $Mo(CO)_6$, $Fe_2(CO)_9$, Rh/C, $RhCl(PPh_3)_3$, $Pd(PPh_3)_2Cl_2$, and Fe-TPP (tetraphenylporphyrin) were ineffective for the cycloreversion of quadricyclanes **9a—c** to norbornadienes **2a—c**. Only Co(II)-TPP catalyzed the reaction. The activity of Co(II)-TPP may be attributed to a radicophilic attack of the metal to the electronegative substituted quadricyclanes, as reported by Yoshida et al.[16] On the other hand, Co(II)-TPP did not catalyze the cycloreversion of dications **10b, c** and **12b** although it catalyzed that of monocation **13**. This fact may be caused by a Coulomb repulsion which makes it difficult for the catalyst to approach the dications.

Electron-Transfer Reactions of 2,3-Bis(1-methylpyridinio)norbornadienes (3). Norbornadienes **3** possess a Weitz-type redox system,[5] as shown in Scheme 1. The electron-transfer reactions of **3**, which have a cis-fixed bis(1-methylpyridinio)ethylene skeleton, are of particular interest since bis(1-methylpyridinio)ethylenes usually undergo cis-trans isomerization upon reduction.[17] The reduction potentials of **3a—c** and norbornene **8** measured by cyclic voltammetry (c.v.) are summarized in Table 3. The waves for **3a, 3c**, and **8** are reversible or quasi-reversible for the following reasons. The current ratios, i_{pa}/i_{pc}, were near unity. They and the half-wave reduction potentials, $E^{red}_{1/2}$, were independent on the scan rates, v. The cathodic peak current, i_{pc}, was proportional to $v^{1/2}$. In contrast, the wave for **3b** was irreversible. Since the i_{pc} was proportional to $v^{1/2}$, the irreversible property can be attributed to the lability of a product formed by the reduction on the c.v. time scale. This seems to be

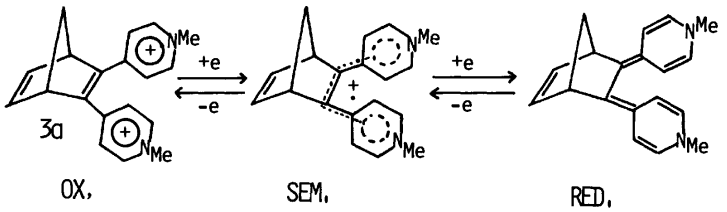

Scheme 1.

related to the nature of the meta-derivative in which the cation or radical cannot conjugate with the double bond.

Since norbornadiene **3a** has the same electron-accepting part as norbornene **8**, the differences in the behavior of the electron-transfer reactions are considered to reflect the difference in the structures. Both of their c.v. revealed only one wave in *N,N*-dimethylformamide (DMF) and acetonitrile. However, the peak widths, $\Delta E_{p/2}$, are different from that for the usual one-electron transfer (56.5 mV), suggesting that a one-electron transfer occurs closely in two stages. In fact, the separated potentials were observed in dichloromethane. The cation radical species are more stabilized in dichloromethane than in acetonitrile.[18] The differences between the first and second reduction potentials (E_1-E_2) were calculated according to the Myers and Shain's method,[19] as shown in Table 3. The semiquinone formation constants, K_{sem}, calculated as log $K_{sem}=(E_1-E_2)/0.058$ are also shown in Table 3. Those values are much smaller than that of *trans*-bis(1-methylpyridinio)ethylenes whose pyridinio groups are coplanar.[20] The first reduction potential of **3a** is a little higher than that of **8**. This may be caused by the interaction between the two olefinic parts, which lowers the LUMO level of the bis(1-methylpyridinio)ethylene moiety.

On the other hand, the c.v. of 2-pyridinio derivative **3c** revealed one peak with small values of $\Delta E_{p/2}$ even in dichloromethane. The (E_1-E_2) values determined by Myers and Shain's method are zero or nearly zero as shown in Table 3. This fact shows that a one-electron transfer occurs very closely in two stages or a two-electron transfer occurs in one stage. The reason for this may be attributed to a steric effect for the 1-methyl groups, decreasing the conjugation between the 2-pyridinio groups and the double bond.

The radical cations of **3a** and **8**, generated electrochemically in degassed acetonitrile containing 0.1 mol dm^{-3} of tetraethylammonium perchlorate, were observed in the ESR spectrum. The *g*-values were both 2.0025, which were determined using 2,2-diphenyl-1-picrylhydrazyl as a standard. Interestingly, the lifetime for the radical cation of **3a** ($t_{1/2}$=104 s at 20 °C) was longer than that for the radical cation of **8** ($t_{1/2}$=36 s at 18 °C). The decay of the former obeyed second-order kinetics, indicating disproportionation, while that of the latter was first-order, indicating a reaction with a substance such as the solvent or the electrolyte. This result shows that the nonconjugated double bond decreased the reactivity of the radical cation species.

Experimental

Electronic spectra were obtained on a Hitachi 340 spectrophotometer. IR spectra were taken on a Shimadzu IR-27G spectrometer. Mass data were collected on a Hitachi M-52 mass spectrometer. ^1H and ^{13}C NMR spectra were obtained at 90 MHz on a Varian EM-390 and at 50 MHz on a Varian XL-200 spectrometer, respectively. Redox potentials were measured on a Yanako p-1000 voltammetric analyzer. Dichloromethane and acetonitrile were distilled from calcium hydride. Melting points are uncorrected.

HBF_4 Salts of Dipyridylacetylenes (4). To a solution of

200 mg (1.1 mmol) of di-4-pyridylacetylene (**4a**) in 200 ml of ether, 1 ml of 42% HBF_4 was added with vigorous stirring. The precipitated colorless solid was collected by filtration and dried to give 370 mg (88%) of the HBF_4 salt of **4a**: mp 260—270 °C (decomp). Found: C, 40.64; H, 2.82; N, 8.10%. Calcd for $C_{14}H_{18}N_2BF_4$: C, 40.51; H, 2.83; N, 7.87%. Similarly, the HBF_4 salts of **4b** and **4c** were obtained as colorless solids. **4b**-2HBF_4: mp 240—270 °C (decomp). Found: C, 40.90; H, 2.88; N, 8.42%. Calcd for $C_{14}H_{18}N_2BF_4$: C, 40.51; H, 2.83; N, 7.87%. **4c**-2HBF_4: mp 235—245 °C (decomp). Found: C, 40.00; H, 2.91; N, 8.25%. Calcd for $C_{14}H_{18}N_2BF_4$: C, 40.51; H, 2.83; N, 7.87%.

2,3-Di-4-pyridylbicyclo[2.2.1]hepta-2,5-diene (2a). A solution of 302 mg (0.85 mmol) of the HBF_4 salt of **4a** and 1.1 ml of cyclopentadiene in 30 ml of dry acetonitrile was refluxed for 8 h. After the solvent was removed, 50 ml of water containing a small amount of HBF_4 was added and the mixture was extracted with dichloromethane (3×30 ml). The aqueous layer was neutralized with $NaHCO_3$ and extracted with dichloromethane (4×30 ml). The organic extract was dried over Na_2SO_4 and the solvent was removed to give 178 mg (85%) of **2a**, which was recrystallized from hexane to give **2a** as colorless needles: mp 110—111 °C; IR (KBr) 1620, 1591, 1551, 1529, 1492, 1443, 1408, 1391, 1210, 1068, 1050, 978, 943, 872, 850, 800, 718 cm^{-1}; UV (EtOH) 243 nm (log ε 4.06), 315 (3.83); MS (25 eV) *m/z* (relative intensity) 246 (M^+, 100%), 181 (78%); ^1H NMR ($CDCl_3$, 90 MHz) δ=2.15 (dt, 1H, *J*=6.3, 3.0 Hz), 2.39 (dt, 1H, *J*=6.3, 3.0 Hz), 3.92 (m, 2H), 6.99 (m, 6H), 8.43 (m, 4H); ^{13}C NMR ($CDCl_3$) δ=57.23, 71.45, 121.95, 143.15, 144.75, 150.60, 151.26. Anal. ($C_{17}H_{14}N_2$) C, H, N.

2,3-Di-3-pyridylbicyclo[2.2.1]hepta-2,5-diene (2b). A mixture of 318 mg (0.83 mmol) of the HBF_4 salt of **4b** and 3 ml of cyclopentadiene in 15 ml of argon-purged dry acetonitrile was sealed in a Pyrex tube. Heating at 160 °C for 3 d and similar workup as for **2a** gave a yellow oil, which was separated by thin-layer chromatography on alumina (4:1 dichloromethane–ether) to give 32 mg (16%) of **2b**. Recrystallization from hexane gave **2b** as colorless leaflets: mp 100—101 °C; IR (KBr) 3040, 2980, 2950, 1565, 1483, 1405, 1284, 1012, 722, 680 cm^{-1}; UV (MeCN) 231 nm (log ε 4.08), 252 (3.96), 306 (3.92); MS (25 eV) *m/z* (relative intensity) 246 (M^+, 58), 181 (100), 180 (81); ^1H NMR ($CDCl_3$) δ=2.13 (dm, 1H, *J*=6.0 Hz), 2.42 (dm, 1H, *J*=6.0 Hz), 3.90 (m, 2H), 6.95 (m, 2H), 7.30 (dd, 2H, *J*=7,5, 4.5 Hz), 7.85 (dm, 2H, *J*=7.5 Hz), 8.2—8.6 (m, 4H). Anal. ($C_{17}H_{14}N_2$) C, H, N.

2,3-Di-2-pyridylbicyclo[2.2.1]hepta-2,5-diene (2c). A solution of 596 mg (1.56 mmol) of the HBF_4 salt of **4c** and 1 ml of cyclopentadiene in 80 ml of dry acetonitrile was heated under nitrogen at 50 °C for 30 min. A similar workup as that for **2a** gave 224 mg (54%) of **2c**, which was recrystallized from hexane to give colorless needles: mp 72—73 °C; IR (KBr) 1582, 1576, 1452, 1428, 1419, 1282, 1269, 771, 761, 730, 713, 676, 668 cm^{-1}; UV (EtOH) 223 nm (log ε 4.06), 316 (3.93); MS (25 eV) *m/z* (relative intensity) 245 (M^+, 100), 181 (34), 168 (73); ^1H NMR ($CDCl_3$) δ=2.10 (dt, 1H, *J*=6.2, 3.0 Hz), 2.42 (dt, 1H, *J*=6.2, 3.0 Hz), 4.20 (m, 2H), 7.18 (m, 8H), 8.55 (m, 2H). Anal. ($C_{17}H_{14}N_2$) C, H, N.

***trans*-5,6-Di-4-pyridylbicyclo[2.2.1]hept-2-ene (5).** A solution of 150 mg (0.42 mmol) of the HBF_4 salt of *trans*-1,2-di-4-pyridylethylene and 2 ml of cyclopentadiene in 100 ml of dry acetonitrile was heated under reflux for 24 h. A similar workup as that for **2a** gave 94 mg (90%) of **5** as colorless needles: mp 92—94 °C (from hexane); IR (KBr) 3000, 1600, 1553, 1412, 1335, 985, 845, 830, 795, 770, 725, 640, 590 cm^{-1}; MS (25 eV) *m/z* (relative intensity) 248 (M^+, 14), 183 (100), 180 (50).

Bis(1-methylpyridinio)acetylenes (6a—c). A mixture of 2.1 g (14 mmol) of trimethyloxonium tetrafluoroborate and 500 mg of di-4-pyridylacetylene (**4a**) in 18 ml of nitromethane was stirred under nitrogen at r.t. for 2 d. After 2 ml of methanol was added, the mixture was stirred for an additional 2 h and poured into 300 ml of ether with vigorous stirring to give 1.06 g (100%) of **6a**. Recrystallization from acetonitrile–dichloromethane–ether gave **6a** as colorless needles: mp 270—280 °C (decomp). Anal. ($C_{14}H_{14}N_2B_2F_8$) C, H, N. In a similar manner, 3-pyridyl derivative **6b** and 2-pyridyl derivative **6c** were prepared. **6b**: mp 255—265 °C (decomp). Anal. ($C_{14}H_{14}N_2B_2F_8$) C, H, N. **6c**: mp 260—268 °C (decomp). Anal. ($C_{14}H_{14}N_2B_2F_8$) C, H, N.

2,3-Bis(1-methyl-4-pyridinio)bicyclo[2.2.1]hepta-2,5-diene Bis(tetrafluoroborate) (3a). A solution of 165 mg (0.42 mmol) of acetylene **6a** and 1.5 ml of cyclopentadiene in 20 ml of dry acetonitrile was heated during reflux under nitrogen for 12 h. The cooled mixture was poured into 200 ml of ether to give 152 mg (90%) of **3a**: mp 220—225 °C (decomp) (from acetonitrile–ether); IR (KBr) 3050, 1640, 1560, 1520, 1470, 1285, 1050, 840, 730, 530, 515 cm^{-1}; UV (MeCN) 223 nm (log ε 4.03), 255 (3.98), 286 (4.00), 364 (3.80); ^1H NMR (CD_3CN) δ=2.23 (dm, 1H, *J*=7.5 Hz), 2.57 (dm, 1H, *J*=7.5 Hz), 4.20 (m, 2H), 4.35 (s, 6H), 7.08 (t, 2H, *J*=1.5 Hz), 7.68 (d, 4H, *J*=6.0 Hz), 8.45 (d, 4H, *J*=6.0 Hz). ^{13}C NMR (CD_3CN) δ=46.68, 58.58, 72.66, 126.48, 143.68, 146.41, 152.27, 156.32. Anal. ($C_{19}H_{20}N_2B_2F_8$) C, H, N.

2,3-Bis(1-methyl-3-pyridinio)bicyclo[2.2.1]hepta-2,5-diene Bis(tetrafluoroborate) (3b). A solution of 184 mg (0.48 mmol) of acetylene **6b** and 2 ml of cyclopentadiene in 20 ml of dry acetonitrile was heated during reflux under nitrogen for 2 d. A similar work-up as that for **3a** gave 32 mg of **3b**: mp 180—185 °C (decomp) (from acetonitrile–ether); IR (KBr) 3300, 1630, 1552, 1468, 1280, 1250, 1050, 795, 670, 515 cm^{-1}; UV (MeCN) 245 nm (log ε 4.03), 280 sh (3.84), 314 (3.79); ^1H NMR (CD_3CN) δ=2.20 (dm, 1H, *J*=6.0 Hz), 2.55 (dm, 1H, *J*=6.0 Hz), 4.05 (tm, 2H, *J*=1.5 Hz), 4.25 (s, 6H), 7.10 (tm, 2H, *J*=1.5 Hz), 7.85 (dm, 2H, *J*=7.5 Hz), 8.20 (dm, 2H, *J*=7.5 Hz), 8.45—8.60 (m, 4H). Anal. ($C_{19}H_{20}N_2B_2F_8$) C, H, N.

2,3-Bis(1-methyl-2-pyridinio)bicyclo[2.2.1]hepta-2,5-diene Bis(tetrafluoroborate) (3c). A solution of 130 mg (0.36 mmol) of acetylene **6c** and 2 ml of cyclopentadiene in 15 ml of dry acetonitrile was heated under nitrogen at 50 °C for 10 h. A similar workup as that for **3a** gave 119 mg (74%) of **3c**: mp 235—255 °C (decomp) (acetonitrile–ether); IR (KBr) 3100, 1625, 1580, 1510, 1455, 1265, 1050, 778, 762, 735, 720, 512 cm^{-1}; UV (MeCN) 284 nm (log ε 3.99), 328 (3.64); ^1H NMR (CD_3CN) δ=2.35 (dm, 1H, *J*=7.0 Hz), 2.80 (dm, 1H, *J*=7.0 Hz), 4.10 (s, 6H), 4.30 (tm, 2H, *J*=1.5 Hz), 7.10 (t, 2H, *J*=1.5 Hz), 7.52 (dm, 2H, *J*=8.0 Hz), 7.85 (ddm, 2H, *J*=8.0, 6.0 Hz), 8.25 (tm, 2H, *J*=8.0 Hz), 8.65 (dm, 2H, *J*=6.0 Hz). Anal. ($C_{19}H_{20}N_2B_2F_8$) C, H, N.

2,3-Di-4-pyridylbicyclo[2.2.1]hept-2-ene. In a hydrogenation apparatus, 202 mg (0.82 mmol) of norbornadiene **2a** was hydrogenated in 22 ml of ethyl acetate with 5 ml of 5% Pd-C. Removal of the catalyst and solvent followed by recrystallization from hexane gave 115 mg (57%) of a norbornene derivative as colorless needles: mp 121—123 °C;

IR (KBr) 3075, 2980, 2870, 1592, 1538, 1414, 1271, 1115, 810, 760, 588, 518 cm^{-1}; UV (MeCN) 227 (log ε 4.06), 239 (3.97), 288 (3.98); MS (25 eV) *m/z* (relative intensity) 248 (M^+, 46%), 220 (100%); ^1H NMR ($CDCl_3$) δ=1.2—1.4 (m, 3H), 1.6—2.1 (m, 5H), 3.30 (brs, 2H), 7.05 (dm, 4H, *J*=6.0 Hz), 8.46 (dm, 4H, *J*=6.0 Hz); ^{13}C NMR ($CDCl_3$) δ=26.40, 47.90, 49.55, 123.14, 144.17, 144.64, 150.89. Anal. ($C_{17}H_{16}N_2$) C, H, N.

2,3-Bis(1-methyl-4-pyridinio)bicyclo[2.2.1]hept-2-ene Bis(tetrafluoroborate) (8). A solution of 76 mg (0.31 mmol) of 2,3-di-4-pyridylnorbornene and 250 mg (1.68 mmol) of trimethyloxonium tetrafluoroborate in 8 ml of nitromethane was stirred at room temperature for 2 d. After 1 ml of methanol was added, the mixture was stirred for 1 h, concentrated to 4 ml, and then poured into 80 ml of ether with vigorous stirring. The resulting crystals were filtered and washed with cold acetone to give 74 mg (53%) of **8** as colorless needles: mp 220—225 °C, IR (KBr) 2950, 1640, 1520, 1470, 1270, 1050, 832, 513 cm^{-1}; UV (MeCN) 238 nm (log ε 4.08), 280 (3.96), 341 (4.04); ^1H NMR (CD_3CN) δ=1.35—1.6 (m, 4H), 1.8—2.2 (m, 2H), 3.50 (m, 2H), 4.26 (s, 6H), 7.70 (d, 4H, *J*=7.5 Hz), 8.47 (d, 4H, *J*=7.5 Hz). ^{13}C NMR (CD_3CN) δ=25.91, 48.58, 48.68, 50.43, 127.28, 146.31, 147.94, 151.99. Anal. ($C_{19}H_{22}N_2B_2F_8$) C, H, N.

1,5-Di-4-pyridyltetracyclo[3.2.0.0^{2,7}.0^{4,6}]heptane (9a). A solution of 102 mg (0.61 mmol) of norbornadiene **2a** in 70 ml of acetonitrile was irradiated through a Pyrex filter with Rayonet RUL-3000 Å lamps under nitrogen bubbling for 1 h. Removal of the solvent followed by recrystallization from pentane gave 86 mg (84%) of **9a** as colorless needles: mp 92.5—93 °C; IR (KBr) 1588, 1531, 1491, 1405, 1200, 1141, 972, 797, 780, 761, 502 cm^{-1}; UV (EtOH) 261 nm (log ε 3.99); MS (25 eV) *m/z* (relative intensity) 246 (M^+, 100), 181 (97), 66 (93); ^1H NMR (CCl_4) δ=2.00 (m, 2H), 2.38 (m, 4H), 6.72 (m, 4H), 8.24 (m, 4H). Anal. ($C_{17}H_{14}N_2$) C, H, N.

In a similar manner, 3-pyridyl derivative **9b** and 2-pyridyl derivative **9c** were obtained in 80—90% yields. **9b**: mp 95—98 °C; IR (KBr) 3050, 1570, 1482, 1420, 1150, 1010, 822, 798, 708, 617 cm^{-1}; UV (MeCN) 246 nm (log ε 3.89), 270 (3.79); MS (25 eV) *m/z* (relative intensity) 246 (M^+, 58), 181 (100), 180 (81); ^1H NMR ($CDCl_3$) 1.95 (dm, 2H, *J*=4.5 Hz), 2.28 (dm, 1H, *J*=12.0 Hz), 2.33 (d, 2H, *J*=4.5 Hz), 2.48 (dm, 1H, *J*=12.0 Hz), 7.07 (ddm, 2H, *J*=7.5, 4.5 Hz), 7.27 (dt, 2H, *J*=7.5 Hz), 8.2—8.5 (m, 4H). Anal. ($C_{17}H_{14}N_2$) C, H, N. **9c**: mp 61—62 °C; IR (KBr) 1582, 1558, 1468, 1428, 819, 769, 751, 738 cm^{-1}; UV (EtOH) 239 nm (log ε 3.92), 273 (3.85); MS (25 eV) *m/z* (relative intensity) 246 (M^+, 93), 181 (44), 168 (100); ^1H NMR ($CDCl_3$) δ=2.20 (m, 3H), 2.50 (m, 3H), 6.93 (m, 4H), 7.35 (m, 2H), 8.37 (m, 2H). Anal. ($C_{17}H_{14}N_2$) C, H, N.

Irradiation of the HBF_4 Salt 7. A solution of 30 mg (0.090 mmol) of **7** in nitrogen-purged acetonitrile was irradiated with Rayonet RUL-3500 Å lamps for 30 min. Removal of the solvent gave quadricyclane **13** as yellow needles quantitatively: mp 245—250 °C (decomp); IR (KBr) 1610, 1590, 1480, 1432, 890, 778, 765, 585, 515 cm^{-1}; ^1H NMR (CD_3CN) δ=2.37 (dm, 1H, *J*=6.0 Hz), 2.58 (d, 2H, *J*=4.0 Hz), 2.60 (dm, 1H, *J*=6.0 Hz), 2.94 (d, 2H, *J*=4.0 Hz), 7.05 (dm, 2H, *J*=9.0 Hz), 7.43 (tm, 2H, *J*=7.5 Hz), 7.97 (ddm, 2H, *J*=9.0, 7.5 Hz), 8.63 (dm, 2H, *J*=6.0 Hz). Anal. ($C_{17}H_{15}N_2BF_4$) C, H, N.

Irradiation of Dimethyl Derivatives 3b, c. A solution of 30 mg (0.067 mmol) of **3b** in 5 ml of argon-purged acetonitrile was irradiated with Rayonet RUL-3500 Å lamps for 1 h. Removal of the solvent gave a mixture of **3b** and quadricyclane **10b** whose ^1H NMR spectrum showed the ratio of **3b** and **10b** to be 1:4. The ratio was not changed by prolonged irradiation. Similarly, irradiation of **3c** with Rayonet RUL-3500 Å lamps gave a mixture of **3c** and **10c** whose ratio was 2:5 from the ^1H NMR spectrum.

Irradiation of Dimethyl Derivative 3a. A solution of 30 mg (0.067 mmol) of **3a** in argon-purged acetonitrile–methanol (3:1) was irradiated through a Pyrex filter with Rayonet 3500 Å lamps for 1 h. Removal of the solvent gave a yellow solid of **14b** whose structure was deduced from the ^1H NMR spectrum: (CD_3CN) δ=1.8—2.3 (m, 5H), 2.7—2.9 (m, 1H), 3.19 (s, 2.2H), 3.34 (s, 0.8H), 3.8—4.0 (m, 1H), 4.14 (s, 3H), 4.27 (s, 3H), 7.46 (d, 2H, *J*=6.0 Hz), 7.71 (d, 2H, *J*=6.0 Hz), 8.33 (d, 2H, *J*=6.0 Hz), 8.49 (d, 2H, *J*=6.0 Hz).

Irradiation of the HBF_4 Salt 11a. A solution of 80 mg (0.19 mmol) of **11a** in 10 ml of nitrogen-purged acetonitrile through a Pyrex filter with Rayonet RUL-3500 Å lamps for 30 min. A mixture obtained after removal of the solvent was dissolved in water, neutralized with $NaHCO_3$, and then extracted with dichloromethane. After the organic extract was dried over Na_2SO_4, removal of the solvent gave **15a** as a pale yellow oil, whose structure was deduced from the ^1H NMR spectrum: ($CDCl_3$) δ=1.5—2.3 (m, 7H), 3.9—4.2 (m, 1H), 6.84 (m, 2H), 7.02 (m, 2H), 8.3—8.5 (m, 4H).

Similarly, irradiation of **11a** in acetonitrile–methanol (3:1) gave **15b** as a yellow oil: ^1H NMR ($CDCl_3$) δ=1.6—1.9 (m, 2H), 2.0—2.5 (m, 3H), 3.19 (s, 2.2H), 3.34 (s, 0.8H), 3.4—4.9 (m, 2H), 6.79 (dm, 2H, *J*=6.0 Hz), 6.99 (dm, 2H, *J*=6.0 Hz), 8.38 (m, 4H).

Quantum Yield Determinations. Samples were irradiated with an Ushio 150-W xenon lamp on a Hitachi MPF-4 spectrometer (λ_{ex}=334±10 nm). The number of photons incident on the samples were determined by using a potassium trioxalatoferrate(III) actinometer. The reactions were followed by the electronic spectra.

Rate Constant Determinations. Solutions of 0.9—1.3×10^{-4} mol dm^{-3} of quadricyclanes **9a**—c in absolute ethanol were heated in a thermostat (RAUDA-WB20D). The rate constants were determined by an absorptiometric method.

The authors thank Dr. Kimio Akiyama and Professor Yusaku Ikegami at Tohoku University for providing the measurements of the ESR spectra.

The Preparation of Photoresponsive Cyclobutanocrown Ethers by Means of Intramolecular [2+2]Photocycloaddition

Sadatoshi AKABORI,* Takeshi KUMAGAI, Yoichi HABATA, and Sadao SATO†
Department of Chemistry, Faculty of Science, Toho University, Funabashi, Chiba 274
†Analytical and Metabolic Research Laboratories, Sankyo Co., Ltd., Hiromachi, Shinagawa-ku, Tokyo 140
(Received January 9, 1988)

The reaction of *o*-bis(3-hydroxy-1-oxapropyl)benzene (**7b**) with 3,3′-(trimethylenedi-4,1-phenylene)bis[2-propenoyl chloride] gave 8,9-benzo-4,7,10,13-tetraoxa[16.3]paracyclopha-1,8,15-triene-3,14-dione (**8b**) in a 6.5% yield, together with its dimer in a 12.3% yield. Also, 5,6-benzo-4,7-dioxa[10.3]paracyclopha-1,5,9-triene-3,8-dione (**8a**) and 11,12-benzo-4,7,10,13,16,19-hexaoxa[22.3]paracyclopha-1,11,21-triene-3,20-dione (**8c**) were obtained by the same method in 7.0 and 8.0% yields, together with their respective dimers (**9a**: 6.0%, **9c**: 10.8%). X-Ray analysis of **8b** revealed the two double bonds to be trans and the distances between the two olefinic carbon atoms (C_{17}–C_{35}) and (C_{18}–C_{34}) to be 5.341(11) and 5.906(9) Å respectively. These distances are too long for intramolecular [2+2]photocycloaddition to occur in the crystalline state. However, the irradiation of the solutions of the crown ethers **8a** and **8b** in acetonitrile by Pyrex-filtered UV light (>300 nm) gave two intramolecular [2+2]photocycloadducts, cyclobutanocrown ethers **10a** and **10b**, in 95.7 and 91.8% yields respectively. Subsequently, **10a** and **10b** were transformed to **8a** and **8b** in 37 and 29% yields respectively upon irradiation with 220 nm UV light. The structures of **10a** and **10b** were confirmed to be the β-form.

Both intermolecular and intramolecular [2+2]photocycloadditions of a large number of olefinic compounds have recently been investigated extensively by many research groups from the points of view of molecular design and the synthetic method for novel organic compounds.[1] Several kinds of photoresponsive crown ethers have been investigated by several research groups with the aim of controlling the extraction ability of crown ethers by light or thermal means.[2-4] It is well-known that macrocyclic polyethers can be complexed with various metal ions, although the corresponding open chain polyethers show poor complexing abilities.[5] Recently, several kinds of cyclobutanocrown ethers formed by the intramolecular [2+2]photocycloaddition of open-chain polyethers which contain two vinyl or vinyloxy groups at both terminals have received much attention in connection with the synthetic method for crown ethers.[6-9] However, these reports did not discuss the possibility of a photoreversible cleavage of the cyclobutanocrown ethers in order to control the complexing abilities. Egerton et al.[10] reported that the irradiation of cinnamic acid with >300 nm UV light gave a dimer by means of intermolecular [2+2]photocycloaddition, while the irradiation of the dimer with 200 nm UV light gave, on the contrary, the corresponding starting monomer. In connection with this finding, we ourselves reported on the syntheses of cyclobutanocrown ethers by means of the intramolecular [2+2]photocycloaddition of α,ω-dicinnamoyl polyethylene glycol derivatives **1** with >300 nm UV light and their photoreversible reactions with 220 nm light.[11] However, the rates of the intramolecular [2+2]photocycloaddition of the dicinnamates were extremely slow (e.g., the half-life periods of **1a**, **1b**, and **1c** were 590.7, 98.7, and 105.9 min respectively), and the structures of the main cycloadducts **2** were of the δ-form which is disadvantageous for complexation with metal cations. We will, therefore, present in this paper the syntheses of new types of photoresponsive cyclobutanocrown ethers **10** by means of the intramolecular [2+2]photocycloaddition of **8** and their photoreversible cleavage reaction in order to deal with the above problems.

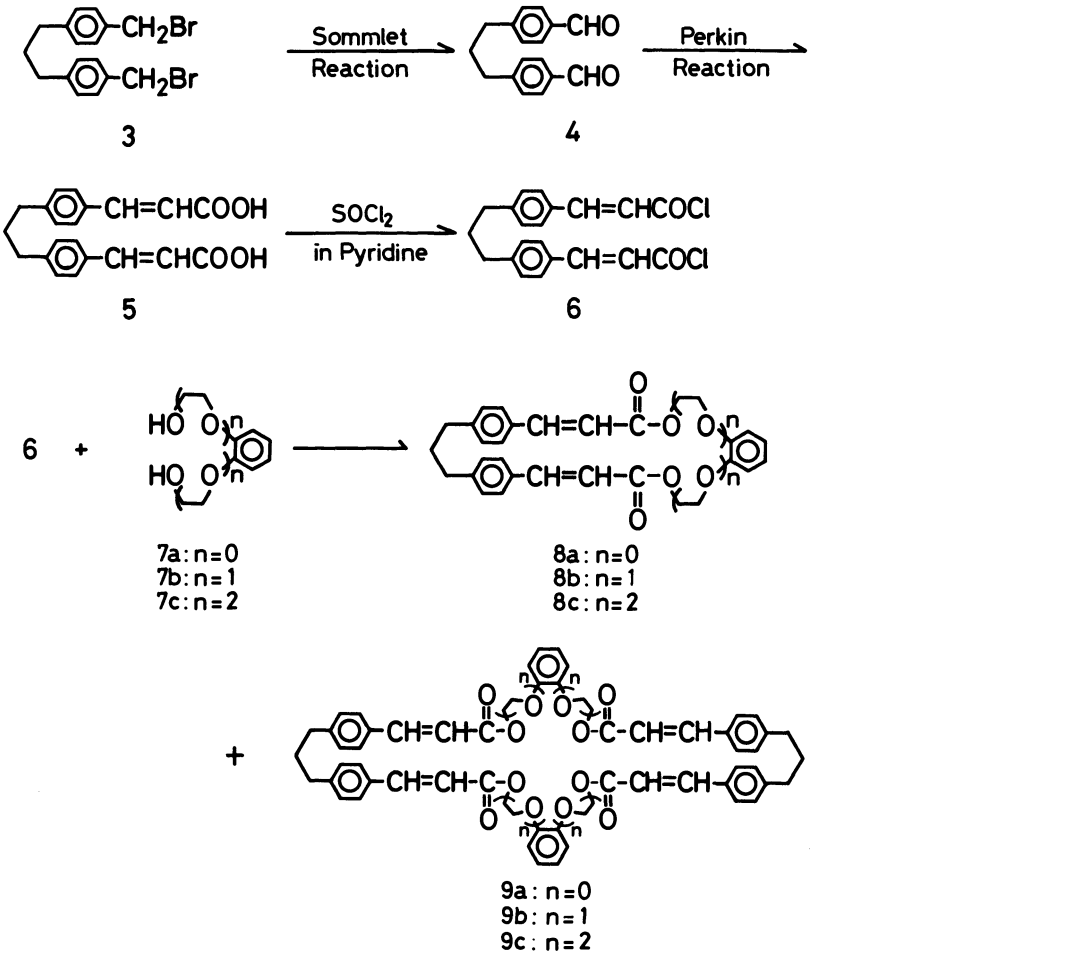
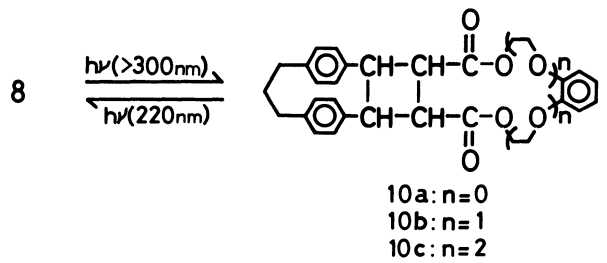
Results and Discussion

Syntheses of 8. Compound **6** was prepared by the following methods. Dialdehyde **4** was obtained in a 95% yield as a pale yellow oil by the Sommelet reaction of the corresponding dibromide **3** according to the method in the literature.[12] The reaction of **4** with malonic acid in the presence of piperidine in pyridine gave **5** in a 91% yield as a colorless powder. The carboxyl groups of **5** were chlorinated with thionyl chloride to give **6** in a 71% yield.[13] The condensation of **6** with **7a** gave **8a** in a 7.0% yield, together with its dimer **9a** in a 6.0% yield. Also, **8b**, **8c**, **9b**, and **9c** were obtained by the same method. The structures of these products were established by their ^{1}H NMR and elemental analysis and mass spectral data and/or gel-permeation chromatography. As is shown in Fig. 1, the ^{1}H NMR spectrum of **8b** showed the signals of the trimethylene protons at δ 2.72(t, J=5.8 Hz, 4H) and 2.24—2.17(m, 2H) respectively, and the signals of the *p*-phenylene protons as a pair in the A_2B_2 pattern at δ 6.95(d, J=8.2 Hz, 4H) and 6.71(d, J=8.2 Hz, 4H) together with the signals of the olefinic protons as a pair in the A_2B_2 pattern at δ 7.52(d,



J=16.0 Hz, 2H) and 6.24(d, J=16.0 Hz, 2H). However, the signals of the *p*-phenylene protons of the dimers **9a**—**c** shifted upfield (ca. 0.50 ppm) compared with those of its monomers as a result of decreases in the anisotropic effect of the opposite aromatic rings upon each other. Furthermore, the parent peaks of the dimers of the mass spectra could not be obtained, although the M^+ values of the corresponding monomers agreed well with the calculated values. We then examined the gel-permeation chromatography of **9a**—**c**. Compounds **9a**—**c** had a longer retention time than the corresponding compounds **8a**—**c**. The molecular weights of **9a**—**c**, which were calculated from the retention times using the calibration curves, were nearly all consistent with the expected values of the dimers.

Conversion of 8 to 10. The intramolecular [2+2]-photocycloaddition of **8a**—**c** was carried out as follows, while the yields were calculated from the intensity of the absorption band at 275 nm in the steady state. The irradiation of **8b** in acetonitrile for 1 h with a 450W high-pressure mercury lamp through a Pyrex filter in the absence of any sensitizer gave **10b** in a 91.8% yield (isolated yield: 71.3%). The irradiation of **8a** (0.25 h) also yielded **10a** in a 95.7% yield (isolated yield: 18%). It is well known that the trans–cis



isomerization of the carbon–carbon double bonds in ethyl cinnamate generally competes with the photodimerization.[1] In the above photoreaction, however, the isolated intramolecular [2+2]photocycloadducts were β-isomers, as will be described below, although very tiny side reaction products were observed by means of TLC. Therefore, the intramolecular [2+2]photocycloaddition of **8a** and **8b** can be said to proceed because of the proximity of the two carbon–carbon double bonds prior to the trans–cis isomerization of the carbon–carbon double bonds. However, **10c** could not be obtained because the irradiation of **8c** gave many tiny products. The solutions of **8a** and **8b** were measured by means of their UV spectra at appropriate intervals during irradiation. The change in the UV spectra of **8b** is

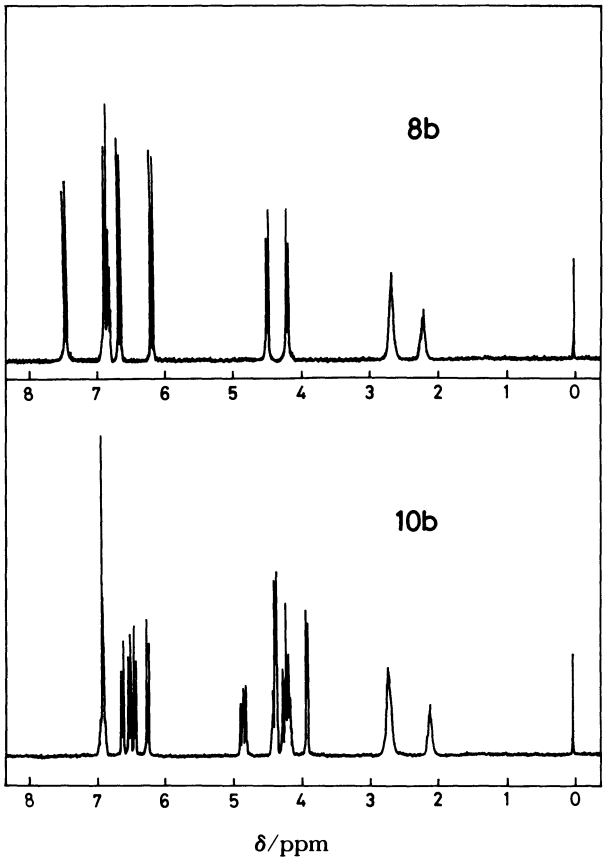


Fig. 1. 400 MHz ^{1}H NMR spectra of **8b** and **10b**.

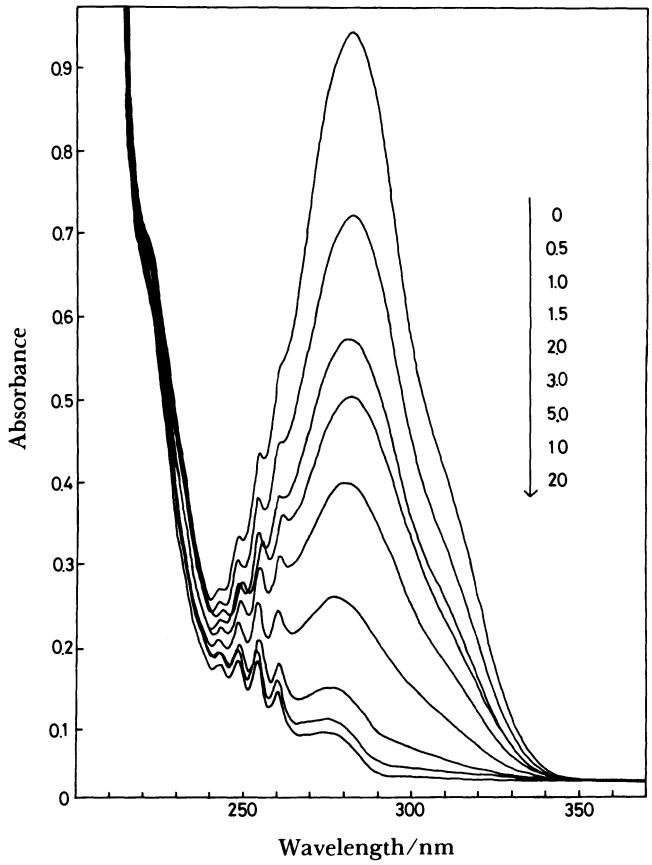

Fig. 2. Spectral changes of **8b** to **10b** in acetonitrile (4×10^{-5} mol dm^{-3}). The numbers beside the arrow are the elapse of irradiation time (min).

shown in Fig. 2. The half-life periods of the intramolecular [2+2]photocycloaddition of **8a** and **8b** were only 29 min and 40 s respectively; these values are very fast compared with those of the corresponding open-chain dicinnamates **1a** and **1b**. The difficulty in the ring closure of **8c** to **10c** is due to the longer intramolecular distance between the two double bonds compared with those of **8a** and **8b**. Therefore, the photoreaction of **8c** caused the intramolecular [2+2]-photocycloaddition, together with other side reactions (for example, trans–cis isomerization, intramolecular [2+2]photocycloaddition of the cis isomerized products, the intermolecular addition of **8c**, and the cleavage of ester groups). The template-type intramolecular [2+2]photocycloaddition of **8** in the presence of the alkali metal ion was also determined; however, the yields were not improved. This fact agrees with the finding that **8** lacks any extraction ability, as will be described below, because if **8** were complexed with an alkali metal cation, the rate of photocyclization would be improved due to the approach of the two double bonds.

Structures of 8 and 10. In order to investigate this problem in more detail, the structure of **8b** was confirmed by means of single crystal X-ray analysis. The conformation of **8b** is illustrated in Fig. 3 together with its atomic numbering, while the selected bond distances and bond angles are summarized in

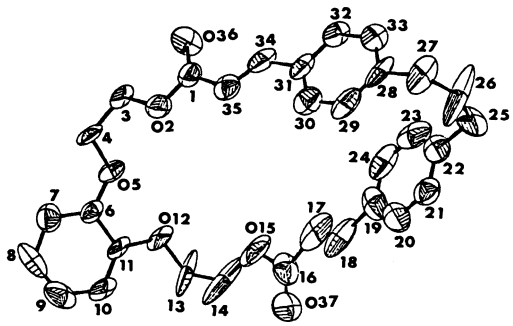

Fig. 3. **ORTEP** drawing of the molecule **8b** with atomic numbering scheme.

Tables 1 and 2 respectively. As is shown in Fig. 3, the two double bonds are trans and are situated in such positions relative to each other as to make the ring closure possible. The torsion angles of C_{16}–C_{17}–C_{18}–C_{19} and C_{33}–C_{34}–C_{35}–C_{36} are −179.8(5) and 179.7(5)° respectively. Also, the torsion angles of O_2–C_3–C_4–O_5 and C_{12}–C_{13}–C_{14}–C_{15} are −73.7(4) and −24.8(11)° respectively. The two benzene rings are face-to-face, albeit slightly distorted, and the dihedral angle is 20.6(2)°. The distances between the two olefinic carbon atoms (C_{17}–C_{35} and C_{18}–C_{34}) are 5.341(11) and 5.906(9) Å respectively. These values are significantly

longer than the value of 4.0 Å for the compounds in which intermolecular [2+2]photocycloaddition in the crystalline state occurred.[1] Indeed, the attempted intramolecular [2+2]photocycloaddition of **8** in the solid state failed. These facts suggest that the intramolecular [2+2]photocycloaddition of **8b** in the solution occurred after the distance between the two double bonds was closed within 4.0 Å due to the molecular flexibility of **8** in the solution. The respective configurations of the photoadducts were elucidated by a comparative ^{1}H NMR study of **10a,b** and the corresponding starting materials **8a** and **8b**. As is shown in Fig. 1, the ^{1}H NMR spectrum of **10b** showed the signals of the trimethylene protons at δ 2.11 (bs, 2H) and 2.71 (bs, 4H), the signals of the oxyethylene protons at δ 4.23—4.27 (m, 4H) and 4.84—4.88 (m, 4H), and the signals of the methine protons of the cyclobutane ring at δ 3.92 (m, 2H) and 4.38 (m,

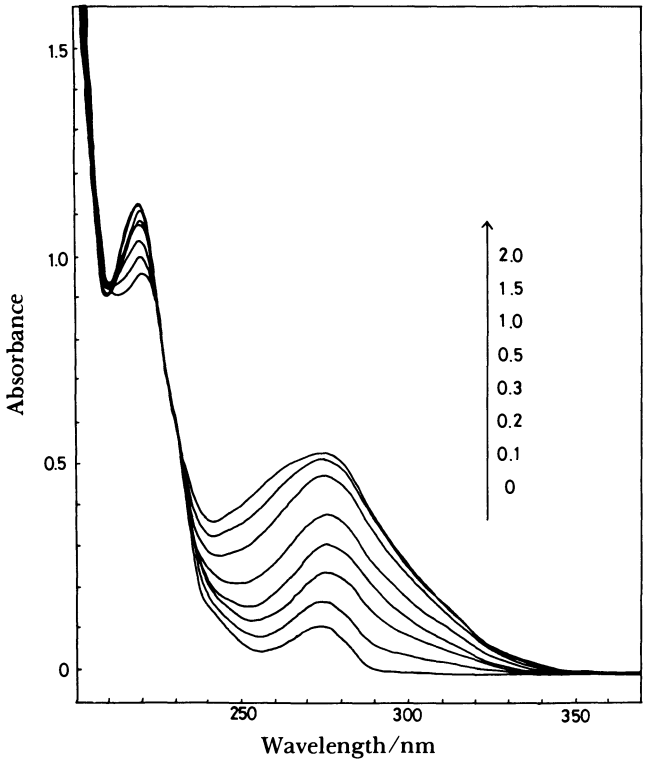

Fig. 4. Spectral changes of **10b** to **8b** in acetonitrile (4×10^{-5} mol dm^{-3}). The numbers beside the arrow are the elapse of irradiation time (h).

2H) as the AA'BB' pattern, together with the aromatic ring protons, due to the *p*-phenylene groups and the catechol moiety, at δ 6.26—6.66 (two pairs of A_2B_2, 8H) and 6.95 (A_2B_2, 4H) respectively. The aromatic protons of the *p*-phenylene groups shifted upfield (ca. 0.3—0.5 ppm) compared with those of the starting material **8b**. This upfield shift and the two pairs of *p*-phenylene protons in the A_2B_2 pattern suggest that the two benzene rings are opposite each other in the solution. Furthermore, the chemical shifts and the split pattern of the cyclobutane ring protons are consistent with those of the dimethyl β-toluxinate reported by Ben-Efrain et al.[14] Also, the trimethylene group of **8a—c** is too short to allow the formation of a δ-isomer. Therefore, these intramolecular [2+2]-photocycloadducts must be β-isomers.

Photoreversible Reaction between 10 and 8. An acetonitrile solution of the pure **10b** was irradiated with a 220 nm UV light. As is shown in Fig. 4, the UV spectra of the solution were then measured at appropriate intervals. The absorption band at 275 nm increased with the UV irradiation of the solution, and a steady state was attained within 2 h. The structures of the irradiated products were confirmed by a direct comparison of the values of TLC and the spectral data with those of authentic samples. The irradiation of the pure **10a** was also carried out by the same method. The photoreversible cleavages of **10a** and **10b** gave **8a** and **8b** in 37 and 29% yields respectively, calculated

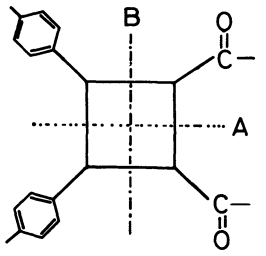

Fig. 5.

from the intensities of the absorption bands at 275 nm in the steady state. Also, the yields of the reversible reactions (**8**⟷**10**) were measured by means of irradiation by >300 nm and 220 nm UV lights one after the other. As has been described above, the irradiation of acetonitrile solutions of **8a** and **8b** with >300 nm UV light gave **10a** and **10b** in 95.7 and 91.8% yields respectively. The subsequent irradiation of the above irradiated mixtures of **8a** and **8b** with 220 nm UV light gave **8a** and **8b** in 39.0 and 22.0% yields respectively. Furthermore, one more irradiation of the above solutions with >300 nm UV light gave **10a** and **10c** in 43.8 and 54.0% yields respectively. The absolute concentrations of **8** and **10** under the photoirradiation were derived from these values of the UV spectra. The yields of **10**→**8** are relatively low compared with those of **8**→**10**. The results suggest that, in the photoreaction of **10**→**8**, the cleavage (Fashion A) of the C–C single bonds in the cyclobutane ring[10] occurred together with the cleavage (Fashion B) of the C–C bonds, as is shown in Fig. 5, although another cleavage cannot be ruled out. The above results imply that the photoreversible reaction of **10**⟷**8** can be controlled by UV light, although the yields of the reversible reactions are relatively low because of the side reactions.

Extraction Abilities of 8 and 10. The extraction abilities of **8** and **10** toward alkali and alkaline earth metal cations were examined according to Pedersen's method.[15] These results are summarized in Table 3. An irradiated mixture of **8c** was used instead of pure **10c**, because **10c** could not be isolated, as has been described above. Compound **8c** and the irradiated mixture of **8c** showed a significant extraction ability toward alkali and alkaline earth metal ions, although the extraction ability of **8b** and **10b** toward these metal ions was negligible. The insignificant extraction ability of **8b** and **10b** may be attributed to the smaller number of oxygen atoms which can effect the complexing ability. Only two oxygen atoms of the four in the crown ether moiety of **8b** can contribute to the complexing ability, for the electron density of the two oxygen atoms of the ester groups is lower than that of the ether-linkage oxygen atom. Also, the negligible extraction ability of **10b** can be ascribed to the same reason, although a CPK model suggests that the hole size of **10b** would fit better than that of **8b** to

Table 3. Extraction of Metal Picrates from the Aqueous to the Organic Phase(%)

Compd	Li^+	Na^+	K^+	Rb^+	Cs^+	Mg^{2+}	Ca^{2+}	Sr^{2+}	Ba^{2+}
8b	0	0	0	0	0	0	0	0	0
10b	0	0	0	0	0	0	1	0	0
8c	1	1	3	4	3	3	4	3	5
Irradiated mixtures of **8c**	8	7	7	7	7	7	7	7	5

incorporate the guest metal ions. In **8c** there are four ether-linkage oxgen atoms. Therefore, the extraction ability of **8c** is higher than that of **8b**, although the values are relatively poor because of the presence of the ester moieties in the macrocycle, as has been described in a previous paper.[11] The extraction ability of the irradiated mixture of **8c** is slightly higher than that of **8c**. However, the reason for this higher extraction ability has not been defined, for the irradiated mixture contain several products as has been described above. The above results suggest that the photoreversible crown ethers **8** and **10** showed low or negligible extraction abilities and could not, therefore, control the extraction ability toward alkali and alkaline earth metal ions.

Experimental

The melting points are uncorrected. The UV spectra were obtained on a Hitachi 330 spectrometer. The IR spectra were measured on a JASCO IRA-2 Diffraction Grating Infrared Spectrometer. The ^1H NMR spectra were obtained on a JEOL GX400 Spectrometer, with TMS as the internal standard. For the irradiation of **8** on a preparative scale, the solution was charged with dry nitrogen for 10 min and then internally irradiated with an USHIO high-pressure mercury lamp (HPL)(UM-452). Also, the photocleavage of **10** to **8** was carried out by means of a 220 nm UV light using a grating monochromator (Model JASCO CT-10), with a 500W xenon lamp (JASCO PS-X500) and a band width of 0.5 nm. The gel-permeation chromatography was carried out on a Hitachi 635 high-pressure liquid chromatograph using a Hitachi Gelpack W-520 apparatus as the GLC column (10.7×30 mm L). Chloroform was used as the eluting solvent. UV was detected at 254 nm.

Materials. *o*-Bis(2-hydroxyethoxy)benzene (**7b**),[16] and *o*-bis[2-(2-hydroxyethoxy)ethoxy]benzene (**7c**),[17] and 1,3-bis-(*p*-formylphenyl)propane (**4**)[12] were prepared according to the methods in the literature. The other reagents employed were either commercial or prepared by the usual methods. The solvents were purified by distillation.

3,3′-(Trimethylenedi-4,1-phenylene)bis[2-propenoic acid] (5): A solution of 1,3-bis(*p*-formylphenyl)propane (**4**) (6.25 g, 24.8 mmol) and malonic acid (18.0 g, 182.7 mmol) in dry pyridine (60 cm^3) was refluxed for 8 h in the presence of piperidine (2.2 cm^3). The reaction mixture was cooled to room temperature and then was added to a mixture of ice (100 g) and concentrated hydrochloric acid (80 cm^3). The resulting precipitate was filtered, washed with water, and dried. Recrystallization from acetic acid gave **5** in a 91% yield as a white powder. Mp 262.0—266.0 °C. Found: C, 73.42, H, 6.22%. Calcd for $C_{21}H_{20}O_4 \cdot 1/4CH_3COOH$: C, 73.42, H, 5.98%. MS (70 eV) *m/z* 336 (M^+). ^1H NMR (DMSO-d_6) δ=7.57 (d, *J*=16.0 Hz, 2H), 7.69—7.06 (A_2B_2 pattern, m, 8H), 6.44 (d, *J*=16.0 Hz, 2H), 1.75 (bs, 2H), and 2.14—1.60 (m, 4H).

3,3′-(Trimethylenedi-4,1-phenylene)bis[2-propenoyl chloride] (6): A mixture of thionyl chloride (20 cm^3) and **5** (1.50 g, 4.5 cm^3) was stirred for 2 h at 30—35 °C. The excess of thionyl chloride was removed in vacuo, and the residual solid was used for the next reaction without further purification.

Reaction of 6 with 7. Compound **6** (1.90 g, 5.1 mmol) in benzene (100 cm^3) and **7a** (1.01 g, 5.1 mmol) in benzene (100 cm^3) were added to a benzene solution (400 cm^3) containing pyridine (9 cm^3) at the same rate over a period of 27 h and then refluxed further for 15 h. The reaction mixture was cooled and evaporated, and the residue was extracted with chloroform. The extract was washed with aqueous 10% hydrochloric acid and water, dried, and evaporated in vacuo. The residue was chromatographed on silica gel, using chloroform as the eluent. The first fraction was collected and concentrated. The recrystallization of the residual oil from benzene–hexane gave **8a** in a 7.0% yield as colorless needles. Mp 240.0—242.0 °C. Found: C, 80.00, H, 5.74%. Calcd for $C_{27}H_{22}O_4 \cdot 1/2C_6H_6$:C, 80.15, H, 5.62%. ^1H NMR ($CDCl_3$) δ=7.63 (d, *J*=16.0 Hz, 2H), 6.37 (d, *J*=16.0 Hz, 2H), 7.28 (s, 4H), 6.97 (d, *J*=8.2 Hz, 4H), 6.75 (d, *J*=8.2 Hz, 4H), 2.76 (t, *J*=5.8 Hz, 4H), and 2.25—2.16 (m, 2H). Crude **9a** was obtained from the second fraction. Recrystallization from toluene gave **9a** in a 6.0% yield as a colorless powder. Mp 245.0—247.0 °C. Found: C, 78.12, H, 5.52%. Calcd for $C_{54}H_{44}O_8 \cdot 1/2H_2O$: C, 78.15, H, 5.46%. ^1H NMR ($CDCl_3$) δ=7.80 (d, *J*=16.0 Hz, 2H), 7.31—7.26 (A_2B_2 pattern, 4H), 7.41 (d, *J*=8.2 Hz, 4H), 7.14 (d, *J*=8.2 Hz, 4H), 2.62 (t, *J*=7.8 Hz, 4H), and 1.90 (q, *J*=7.8 Hz, 2H).

Compounds **8b**, **8c**, **9b**, and **9c** were obtained by a method similar to that described above.

8b. Yield, 6.5%. Mp 213.0—214.0 °C. Found: C, 74.50, H, 6.25%. Calcd for $C_{31}H_{30}O_6$: C, 74.68, H, 6.07%. 9c. Yield, 10.8%. Mp 145.5—146.5 °C. Found: C, 71.43,H, 6.75%. Calcd for $C_{70}H_{76}O_{16}$: C, 71.65, H, 6.53%. ^1H NMR ($CDCl_3$) δ=7.64 (d, J=16.0 Hz, 2H), 6.39 (d, J=16.0 Hz, 2H), 6.93—6.88 (A_2B_2 pattern, 4H), 7.37 (d, J=8.0 Hz, 4H), 7.11 (d, J=8.0 Hz, 4H), 2.58 (t, J=7.6 Hz, 4H), 1.87 (q, J=7.6 Hz, 2H), 4.37 (t, J=4.8 Hz, 4H), 4.18 (t, J=4.8 Hz, 4H), 3.90 (t, J=4.8 Hz, 4H), and 3.87 (t, J=4.9 Hz, 4H).

Gel-Permeation Chromatography. Compounds **8a**, **8b**, **8c**, **9a**, **9b**, and **9c** were submitted to gel-permeation chromatography. The retention times were 12.83, 11.89, 11.48, 10.84, 10.40, and 10.13 min respectively. The molecular weights of **8** and **9** were obtained from the calibration curves of the polyethylene glycols and epoxy resins of known molecular weights.

Preparation of 10 by the Photoreaction of 8. A solution of **8b** in acetonitrile (4×10^{-5} M; 1 M=1 mol dm^{-3}) was irradiated internally with a high-pressure mercury lamp (450 W) through a Pyrex filter at the temperature of running water for 1.0 h. The solvent was then evaporated, and the residue was chromatographed on silica gel, using chloroform as the eluent. The first fraction was concentrated and recrystallized from acetonitrile to give **10b** as white leaves. Yield, 71.3%. Mp 218.0—219.0 °C. Found: C, 74.39, H, 6.46%. Calcd for $C_{31}H_{30}O_6$: C, 74.68, H, 6.06%. MS (70 eV) m/z 498 (M^+). ^1H NMR ($CDCl_3$) δ=6.98—6.92 (m, A_2B_2 pattern, 4H, aromatic H), 6.66—6.26 (m, two pair of A_2B_2 pattern, 8H, aromatic H), 4.90—4.16 (m, 8H, -OCH_2-), 4.40—4.36 (m, 2H, C_α-H), 3.95—3.90 (m, 2H, C_β-H), 2.71 (bs, 4H, -CH_2-), and 2.11 (bs, 2H, -CH_2-).

10a was also obtained by the method described above. Yield, 18%. Mp 148.0—150.0 °C. Found: C, 78.40, H, 5.39%. Calcd for $C_{27}H_{22}O_4$: C, 79.01, H, 5.40%. MS (70 eV) m/z 410 (M^+). ^1H NMR ($CDCl_3$) δ=7.49—7.37 (m, A_2B_2 pattern 4H, aromatic H), 6.55 (d, J=8.1 Hz, 4H, aromatic H), 6.33—5.99 (m, A_2B_2 pattern, 4H, aromatic H), 4.66—4.63 (m, 2H, C_α-H), 3.53—3.49 (m, 2H, C_β-H), 2.77—2.59(m 4H, -CH_2-), and 2.12—2.04 (m, 2H, -CH_2-).

Photoreversible Cleavage of 10. An acetonitrile solution of **10** (4.0×10^{-5} M) was placed in a quartz cell (1×1×4 cm) and irradiated at room temperature with a 220 nm UV light using a grating monochromater with a xenon lamp (500 W). The UV spectral changes were recorded during irradiation and a steady state was attained within 2 h. The solution was then checked on thin-layer chromatography, using chloroform as the eluent, and the results were compared with the R_f values of authentic samples **8a** and **8b**. The photoreversible yields of **10** were calculated from the intensity of the absorption band at 275 nm in the steady state. The yields of **8a** and **8b** were 37 and 29% respectively.

Photoreversible Reaction between 8 and 10. An acetonitrile solution of **8** (4.0×10^{-5} M) was irradiated by means of high-pressure mercury lamp through a Pyrex filter at the temperature of running water for 1 h. The yields of the irradiated products, **10a** and **10b**, were 95.7 and 91.8% respectively. A part of this solution was placed in a quartz cell (1×1×4 cm) and irradiated at 220 nm UV light, using a grating monochromator with a 500 W xenon lamp, for 2 h. The photoreversible yields of **8a** and **8b** were 39.0 and 20.0% respectively. Furthermore, the solutions were irradiated again with 300 nm UV light to give **10a** and **10b** in 43.8 and 54.0% yields respectively. These values were calculated from the intensity of the absorption band at 275 nm in the steady state. The structures of the irradiated product **10a** and **10b**, and of the photoreversible products, **8a** and **8b**, were confirmed by a comparison of the R_f values of the silica-gel TLC, the melting points, and the spectral data of the authentic samples.

Solvent Extraction. Equal volumes (5 cm^3) of dichloromethane containing 7×10^{-4} M of crown ethers **8b** and **8c** and a photoirradiated mixture of **8b** and **8c**, and an aqueous solution containing 1×10^{-1} M metal nitrate and 7×10^{-5} M picric acid were agitated. The solution was then separated by the use of a centrifugal separator. The upper solution was then withdrawn, and its electronic spectrum was recorded. A similar extraction was performed with pure dichloromethane. Similar extraction abilities were calculated by means of the following equation:

$$\text{Extraction ability}=(A_0-A)/A_0\times100.$$

A_0 was the absorbance in the absence of metal nitrate, while A was the absorbance in its presence.

X-Ray Crystallography. A crystal with dimensions of 0.4×0.2×0.15 mm was used for the X-ray crystallography. The crystal data are as follows: $C_{31}H_{30}O_6$, Mw=498.6, triclinic, $P\bar{1}$, a=11.880(1), b=10.085(1), c=11.480(1) Å, α=93.65(1), β=78.60(1), γ=82.62(1)°, U=1331.5 Å^3, Z=2, D_x=1.24 g cm^{-1}, μ(Cu $K\alpha$)=6.6 cm^{-1}. The intensity data for $2\theta<128°$ were recorded on a Rigaku AFC-5R apparatus with graphite monochromatized Cu $K\alpha$ irradiation. A total of 4440 independent reflections was corrected for Lorentz and polarization factors, but not for absorption. The structure was solved by direct methods using MULTAN84,[19] and refined by block diagonal least-square methods. The positions of the hydrogen atoms were estimated using standard geometry. The final refinements, with anisotropic temperature factors for the non-hydrogen atoms and isotropic temperatures for the hydrogen atoms, were lowered R values 0.113 (R_w=0.096, $w=1/\sigma2(F_o)$, 3125 observed reflections within $F_o\geq2\sigma(F_o)$). The parameters for the bond lengths, angles, and structure factors (observed and calculated) are kept at the Chemical Society of Japan (Document No. 8804).

We are grateful to Mr. Hisashi Kumagai of Toho University for his kind help in the synthesis of **8**. We also wish to thank Mr. Yoshiyuki Mukoyama of the Ibaragi Research Center, Hitachi Kasei Kogyo Co., Ltd., for his kind help in the measurement of the gel-permeation chromatography. The present work was supported by a Grant-in-Aid for Scientific Research (No. 61540384) from the Ministry of Education, Science and Culture.

Synthesis of α-Helices Having a Positively Charged Random Coil-Block on Either N- or C-Terminal

Sho TAKAHASHI,* Takeshi HIBINO, and Seiji SAWADA†
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611
†Department of Science, Kyoto University of Education, Fujinomori, Fushimi-ku, Kyoto 612
(Received January 13, 1988)

To study a charge-induced stabilization of α-helix, α-helical peptides having a positively charged random-coil block on either N- or C-terminal of the helix, and having a strictly defined length, $(Ala)_{20}(X)_{20}Phe$ and $(X)_{20}(Ala)_{20}Phe$ (X=Lys or Orn), were synthesized. Component dipeptides were coupled on *p*-(oxymethyl)-phenylacetamidomethyl polystyrene.

A peptide bond is not symmetric and a polypeptide chain has a direction. As a consequence, properties inherent to α-helix and extrinsic effects of surrounding groups exerting upon α-helix might be different at the N- and C- terminal parts of a helix. We intended to discriminate the difference, and tried to approach the problem by studying the stabilities of polyalanine helix having a negatively charged random coil block either on an N- or C-terminal side of the helix.[1,2] The result showed that the difference in stabilities of two polymers was not solely depended on an enthalpic term (electrostatic interaction between external charges and a helix dipole) but also contributed from an entropic term, suggesting a contribution of helix-intrinsic properties on helical stability was different at the parts near N- and C-terminals. Since the stabilities of secondary structures are fundamental problem to study protein folding, asymmetry in the stability of α-helix has been called much attention recently[3] and a study of a system similar to that stated above but with positive charges has been requested.[4] If we could estimate a stability of polyalanine helix having a positively charged block on either N- or C-terminal, a combined analysis with the previous result for the helix with negative charges would make a comparison of the effects of opposite electric charges on the stability of α-helix possible. Furthermore, an estimation of intrinsic stabilities of α-helix at N- and C-terminal parts will be possible, under an assumption that the effect of positive and negative charges on an electric dipole was symmetric.

From a standpoint of peptide synthesis, preparations of homooligopeptides meet troubles not encountered in synthesis of peptides which incorporate various amino acid residues as naturally occurring ones. An application of a solution method for the preparation of oligopeptides having identical amino acid residues is sometimes extremely difficult, as such a peptide became less and less soluble in most of the solvents used in peptide chemistry when the number of residues increased. The other choice, a solid-phase method, is free from such a problem, however, purification of the product is difficult since immature peptides (namely, peptides having lesser numbers of residues than that was intended) will have similar properties with the desired one. Since the number of residues included in a peptide is most critical to stabilities of peptide secondary structures, it is crucial to have peptides with strictly defined length for a study of peptide conformation. In the present paper, we tried a coupling of dipeptide unit with a solid-phase methodology: in this case, immature peptides lacked two or multiples of two residues were expected to be discriminated more readily from the desired peptide.

Results and Discussion

Synthesis of $(Ala)_{20}(Lys)_{20}Phe$, (1), $(Lys)_{20}(Ala)_{20}Phe$, (2), $(Ala)_{20}(Orn)_{20}Phe$, (3), and $(Orn)_{20}(Ala)_{20}Phe$, (4). Merrifield's solid-phase procedure with *p*-(oxymethyl)-phenylacetamidomethyl (PAM)-resin[6] was used to synthesize **1—4**. The peptides have a general formula, $(L\text{-}Ala)_n(L\text{-}X)_nPhe$ or $(L\text{-}X)_n(L\text{-}Ala)_nPhe$ (X=Lys or Orn), in which poly-L-alanine block assumes α-helix (at least partly), and a block of positively charged lysine or ornithine forms a random-coil. The number of residues, *n*, was 20, which was consistent with the previous work.[1] The side chain of lysine is long and a hydrophobic nature of alkyl chain sometimes induces ordered structures, for example, β-structure. As we hoped to minimize such a possibility in the following study, peptides containing ornithine, which had one less methylene group were also synthesized. C-Terminal phenylalanine was incorporated as an internal marker during the synthesis. As the length of α-helix is most critical to its stability, dipeptide coupling was employed to ensure the desired product free from immature peptides. With dipeptide coupling, the inmature peptides differed by two amino acid residues and separation from the desired peptide was expected easier.[5] PAM-resin[6] was prepared with a slight modification: *p*-(bromomethyl)phenylacetic acid phenacyl ester was obtained from phenacyl alcohol (readily prepared from styrene oxide and dimethyl sulfoxide[7]) and trifluoroacetic anhydride, the procedure simpler and with higher yield. Dipeptide coupling was carried out with dicyclohexyl-

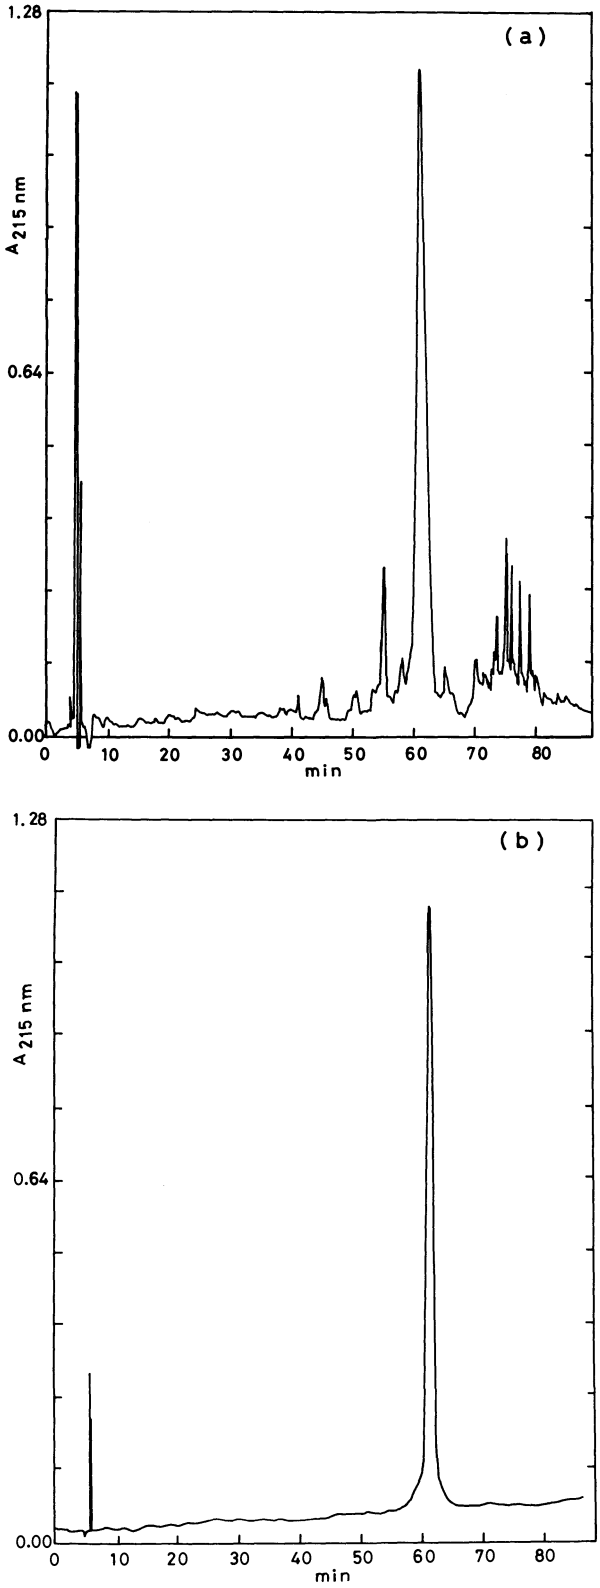

Fig. 1. HPLC analysis (Cosmosil 5C_{18}-P, 4.6×150 mm) of **1**.
(a) Crude product obtained by HF-cleavage. (b) After purification with preparative HPLC.
Peptide was eluted with an H_2O–acetonitrile gradient containing 0.05% TFA (10 to 20% acetonitrile over a period of 0 to 60 min and 20 to 40% acetonitrile from 60 to 90 min). Flow rate, 1 ml min^{-1}.

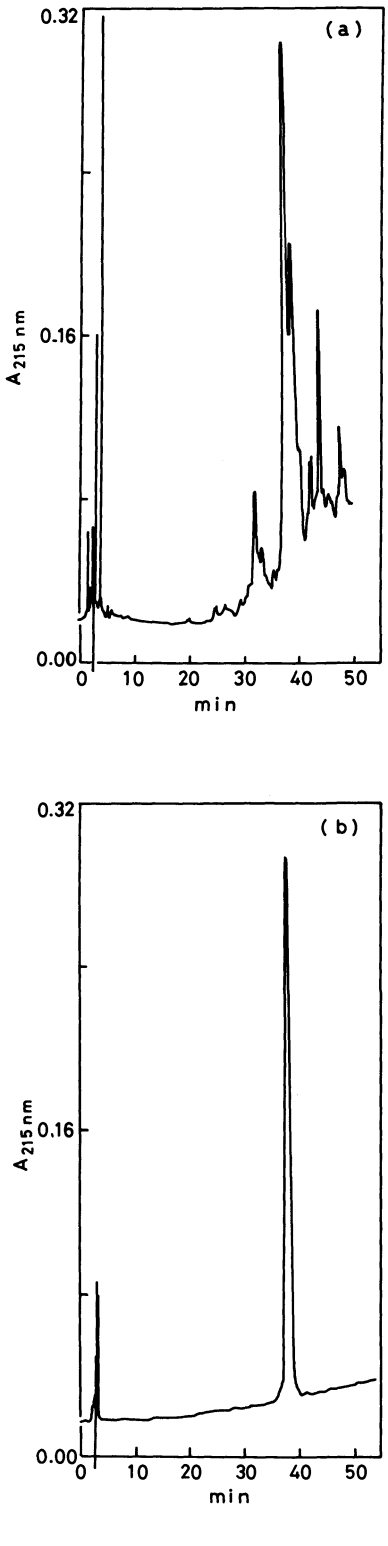

Fig. 2. HPLC analysis (Cosmosil 5C_{18}-P, 4.6×150 mm) of **2**.
Peptide was eluted with an H_2O–acetonitrile gradient containing 0.05% TFA (20 to 30% acetonitrile over a period of 0 to 30 min and 30 to 40% acetonitrile from 30 to 45 min). Flow rate, 1 ml min^{-1}.
(a) Crude product obtained by HF-cleavage. (b) After purification with preparative HPLC.

Column: Cosmosil 5C_{18}-P, 10×250 mm, flow rate, 3 ml min^{-1}. Linear gradient elution: 0.05% aq.TFA: CH_3CN (100:0)→(67:23) for 0→80 min. About 2 mg of peptide was loaded. Peak assignment follows amino acid analysis: (1) $Ala_{2\,or\,4}Lys_{14\,or\,16}Phe$, (2) $Ala_6Lys_{18}Phe$, (3) $Ala_{8\,or\,10}Lys_{18}Phe$, (4) $Ala_{12}Lys_{18}Phe$, (5) $Ala_{16}Lys_{18}Phe$, (6) $Ala_{18}Lys_{20}Phe$, (7) peptide, **1**, (8) $Ala_{18}Lys_{16}Phe$, (9) $Ala_{20}Lys_{18}Phe$, (10) $Ala_{20}Lys_{16}Phe$.

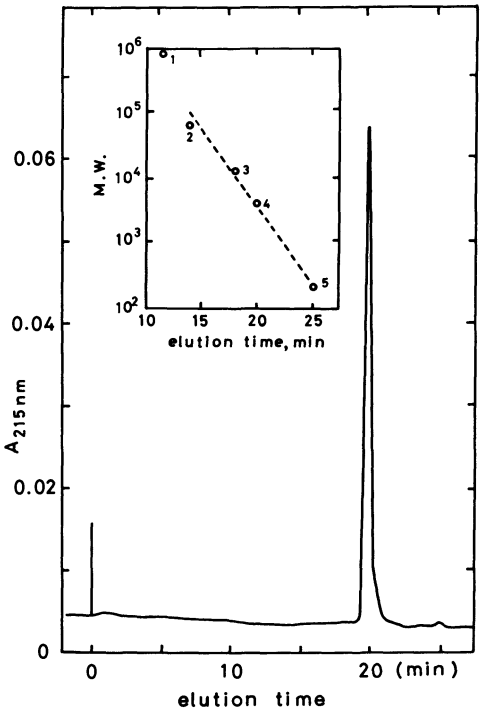

Fig. 4. Size exclusion chromatography of peptide **2**. Column: TSK Gel G2000SWXL (7.5×300 mm), elution with 0.1% TFA–0.2M KCl at a flow rate of 0.5 ml min^{-1}, at room temperature. Sample: 2 μg in 1 μl of 0.1% of TFA. Inset, Calibration of the column. 1, Blue Dextran (Pharmacia); 2, bovine serum albumin; 3, bovine pancreatic ribonuclease A; 4, peptide **2**, 5, GlyHis. M.W.: molecular weight, in logarithmic scale.

carbodiimide in the presence of 1-hydroxybenzotriazole. After the desired number of coupling, the products were cleaved from resin support with HF and were purified with high-performance liquid chromatography (HPLC). The results for peptides **1** and **2** are shown in Figs. 1 and 2, respectively. We characterized some of the satellite products and confirmed separation of the desired 41-residue peptides from immature peptides. As an example, the case of peptide **1** is shown in Fig. 3. Ion-exchange chromatography with carboxymethylcellulose was also employed to check the purity of HPLC-purified materials. We found only a single symmetric peak in every case. The overall yield of peptide **1**—**4** was from 9 to 19%.

Gel filtraion profiles of peptides **1**—**4** with TSK Gel G2000 (or 3000) SW may need some remarks. Each of the peptides gave a single peak at the position of expected elution position (as a typical example, Fig. 4 shows a chromatogram for peptide **2**, nearly identical results were obtained for the other peptides), but it was much retarded at higher pH. In the case of polylysines having molecular weights higher than 50000, such retardation of peak position as observed even at pH 3.0. The observed molecular weights of peptides **1** and **2** in solution derived from sedimentation equilibrium analysis at pH 4.65 (0.01 M KH_2PO_4–0.1 M KCl 1 M=1 mol dm^{-3}) were 4100 (c=0.668 mg ml^{-1}) and 4130 (c=0.789 mg ml^{-1}), respectively.

Check of Racemization. Athough 1-hydroxybenzotriazole[8] was included in dicyclohexylcarbodiimide-mediated coupling of dipeptide, racemization at the C-terminal amino acid of dipeptide might be a problem. We checked the content of D-amino acids with a modified[5] Manning-Moore procedure,[9] coupled with an HPLC separation of diastereomeric peptides.[10] The amounts (± 0.5%) of D-amino acids detected were: Ala in **1** or **3**, 0.7%; Ala in **2**, 1.0%; Ala in **4**, 0.6%; Orn in **3**, 1.5%; Orn in **4**, 1.9%; Lys in **1**, 1.0%; Lys in **2**, 0.8%.

Experimental†

All amino acids are of L-configuration. Melting points were measured on a micro hotplate and described without correction. Dipeptides, N^{α}-Boc-Lys(N^{ε}-*o*-Cl-Z)-Lys(N^{ε}-*o*-Cl-Z)-OH, N^{α}-Boc-Orn(N^{ε}-*o*-Cl-Z)-Orn(N^{ε}-*o*-Cl-Z)-OH, and Boc-AlaAla-OH, were prepared from Boc-amino acid succinimido esters. Elemental analysis and melting points are summarized in Table 1.

$BrCH_2C_6H_4CH_2COOH$. A solution of *p*-tolylacetic acid (25 g, 0.17 mol) and Br_2 (29.5 g, 1.1 equiv) in 200 ml CCl_4

† Abbreviations used: Boc, *t*-butyloxycarbonyl; *o*-Cl-Z, *o*-chlorobenzyloxycarbonyl; DCC, dicyclohexylcarbodiimide; DCHA, dicyclohexylamine; DIEA, *N*,*N*-diisopropylethylamine; DMF, *N*,*N*-dimethylformamide; HOBT, 1-hydroxybenzotriazole; TLC, thin-layer chromatography.

Table 1.

Compound	Melting point/°C[a]	Formula
N^{α}-Boc-Lys(N^{ε}-*o*-Cl-Z)-OSu	102—103 (AcOEt-Et_2O)	$C_{23}H_{30}O_8N_3Cl$
N^{α}-Boc-[Lys(N^{ε}-*o*-Cl-Z)]$_2$-OH·DCHA	142—143 (EtOH-AcOEt)	$C_{45}H_{67}O_9N_5Cl_2$
H-Orn(N^{δ}-*o*-Cl-Z)-OH	245—250 decomp (H_2O)	$C_{13}H_{17}O_4N_2Cl$
N^{α}-Boc-Orn(N^{δ}-*o*-Cl-Z)-OH	122—123 (AcOEt)	$C_{18}H_{25}O_6N_2Cl$
N^{α}-Boc-Orn(N^{δ}-*o*-Cl-Z)-OSu	152—156 (EtOH)	$C_{22}H_{28}O_8N_3Cl$
N^{α}-Boc-[Orn(N^{δ}-*o*-Cl-Z)]$_2$-OH	130 (MeOH-H_2O)	$C_{31}H_{40}O_9N_4Cl$
N^{α}-Boc-[Orn(N^{δ}-*o*-Cl-Z)]$_2$-OH·DCHA	166—169 (AcOEt)	$C_{43}H_{63}O_9N_5Cl_2$
Boc-Phe-$OCH_2C_6H_4CH_2CO_2CH_2COC_6H_5$	80—82 (AcOEt)	$C_{31}H_{33}O_7N$
Boc-Phe-$OCH_2C_6H_4CH_2CO_2H$	100—102 (Et_2O-pet.ether)	$C_{23}H_{27}O_6N$

a) Solvent for recrystallization in parentheses.

was stirred at room temperature and illuminated with a 60-W reflector lamp. The distance between the lamp and the reaction vessel was determined to give a moderate reaction. As the separated crystals of the product inhibited the reaction by reflecting back the incident light, the reaction mixture was filtered three times to collect crystals during 24 h of the photoreaction. If the solution became colorless, up to 3 ml of Br_2 was added to the reaction mixture. After the reaction had been completed (checked with TLC), the solvent was evaporated to give an additional amount of *p*-(bromomethyl)phenylacetic acid, which was recrystallized from acetone-hexane. Yield, 72%; mp 179—180 °C.

Br$CH_2C_6H_4CH_2COOCH_2COC_6H_5$. *p*-(Bromomethyl)-phenylacetic acid, 2.29 g, and 2.5 ml of trifluoroacetic anhydride were dissolved in 5 ml of benzene with warming. The mixture was kept at room temperature for 1 h and evaporated. The residue was dissolved in a mixture of 5 ml benzene and 1.55 g of phenacyl alcohol[7] with warming. Unreacted bromo acid was recovered with filtration after 3 h at room temperature and the filtrate was washed with aq. $NaHCO_3$ and concentrated to afford the phenacyl ester, which was recrystallized from ethyl acetate-cyclohexane, mp 88—90 °C. Yield, 79% (after correction of recovered acid).

Boc-Phe-$OCH_2C_6H_4CH_2COOCH_2COC_6H_5$. A solution of 2.8 g (8 mmol) of *p*-(bromomethyl)phenylacetic acid phenacyl ester, 4.25 g (16 mmol) of Boc-Phe-OH, and 2.8 ml (16 mmol) of DIEA in 60 ml DMF was stirred at room temperature for 24 h. After 8 h from the start of the reaction, TLC showed the bromo ester was consumed. Evaporation of DMF afforded an oil, which was dissolved in AcOEt (filtration was sometimes necessary to remove a mass of DIEA·HBr) and washed successively with 5% aq. citric acid and 0.5 M carbonate buffer, pH 10. Concentration of AcOEt layer gave needles, which were recrystallized from AcOEt. Yield, 93%.

Boc-Phe-$OCH_2C_6H_4CH_2COOH$. The compound was synthesized by a Zn-reduction of *p*-[(Boc-phenylalanyl)oxymethyl]phenylacetic acid phenacyl ester in a similar way as described in Ref. 6. Yield, 69%.

Boc-Phe-$OCH_2C_6H_4CH_2CONHCH_2$-Resin. Polystyrene beads (BioRad SX-1, 200—400 mesh) were aminomethylated according to the method described.[6] The content of amino group was 0.3 mmol g^{-1} resin from picric acid titration of the product. The resin was coupled[6] to Boc-Phe-OCH_2-$C_6H_4CH_2COOH$ and treated with 1-acetylimidazole (3 g/20 g resin) to block the residual free amino groups, if any. The product, which showed 0.285 mmol phenylalanine per g of resin on amino acid analysis, was used for the solid-phase peptide synthesis.

Solid-Phase Synthesis of H-$(Lys)_{20}(Ala)_{20}$Phe-OH, (1); H-$(Ala)_{20}(Lys)_{20}$Phe-OH, (2); H-$(Orn)_{20}(Ala)_{20}$Phe-OH, (3); and H-$(Ala)_{20}(Orn)_{20}$Phe-OH, (4). Solid-phase peptide synthesis was carried out according to the schedule outlined in Table 2. Double coupling was applied in every cycle except first 3 cycles of **1** and **3**. After each cycle was finished, an aliquot of the peptide resin was removed and checked by the Kaiser test.[11] Another aliquot was hydrolyzed and analyzed on an amino acid analyzer. After completion of required cycles, peptide resin was first treated with 50% TFA in dichloromethane, then with HF-20% anisole at 0 °C for 1 h. The residue was extracted with water (peptides **2** and **4**) or with 30% AcOH (peptides **1** and **3**). In the latter case, extracts were dialyzed against water and centrifuged to remove insolubles. The lyophilized peptides were dissolved in 0.05% TFA and purified with HPLC on a C_{18} column, with a linear gradient of acetonitrile containing 0.05% of TFA. The final yield of the purified peptide: **1**, 10%; **2**, 19%; **3**, 8.6%; **4**, 13.4%. Amino acid composition: **1**, Ala:Lys: Phe=21.4:21.0:1.0; **2**, Ala:Lys:Phe=20.6:19.3:1.0; **3**, Ala: Orn:Phe=20.8:20.2:1.0; **4**, Ala:Orn:Phe=19.3:19.4:1.0.

Check of Racemization. Peptide-resin and free peptides (about 1 μ mol peptide) were hydrolyzed with concd HCl-propionic acid (1:1, v/v, 110 °C, 24—48 h) or 6M HCl-0.15% phenol (110 °C, 24—48 h), respectively. To the hydrolyzate

Table 2.

2. Deprotection. 50% TFA in CH_2Cl_2, 30 min×1.
3. Wash. CH_2Cl_2, 2 min×5.
4. Neutralization. 5% DIEA in CH_2Cl_2, 2 min×2 (or 3[a]) for first coupling, 2 min×1 for second coupling.
5. Wash. CH_2Cl_2, 2 min×5.
6. Dipeptide,[b] 2 min.
7. HOBT[c] in DMF, 2 min.
8. DCC[d] in CH_2Cl_2. 6—18 h[e] for first coupling, 7—9 h for second coupling.
9. Wash. CH_2Cl_2–DMF(1:1) 2 min×2; CH_2Cl_2, 2 min×3.
10. Kaiser test.

The synthesis was started with 5 g (equivalent to 1.5 mmol of Boc-Phe groups) of Boc-Phe-PAM-resin. The volume of solvent was gradually increased from 50 to 80 ml according to swelling of the resin. First and second coupling mean the respective cycles when double coupling was employed. When a second coupling was employed, the step 4 and so on followed the step 10.

a) At the cycle later than the 5th. b) 4.5 mmol in the first coupling, 2.3 mmol in the second coupling. Boc-AlaAla-OH was dissolved in 30 ml of 30% DMF in CH_2Cl_2, lysine- and ornithine-dipeptides were dissolved in CH_2Cl_2. c) One and a half equivalent to dipeptide was used as a solution in 5 ml. d) An equivalent amount to dipeptide was used as a solution in 5 ml. e) 6—9 h for the first 5 cycles for **1** and **3** (coupling of BocAlaAlaOH) and first 10 cycles for **2** (coupling of BocLys(*o*-Cl-Z)Lys(*o*-Cl-Z)OH); 12—18 h for the other cycles.

were added 1.2 ml of 1 M $NaHCO_3$ and 50 μl of Boc-L-leucine succinimido ester (0.4 g/5 ml CH_3CN or 0.25 mmol ml^{-1}. 0.25 equiv to amino groups) and the mixture was evaporated after standing at room temperature for 2 h. The residue was treated with TFA or HCl and analyzed by HPLC in a similar way as described by Takaya et al.[10] Separation of diastereomeric peptides was achieved with Cosmosil $5C_{18}$-P (4.6×150 mm) at a flow rate of 1 ml min^{-1}. Elution times (min) of L-Leu-(X) were: (with 0.01 M potassium phosphate, pH 3.5) X=L-Lys, 16.5; D-Lys, 18.1; L-Orn, 8.5; D-Orn, 9.5; (with 0.01 M potassium phosphate, pH 3.5–CH_3CN=97:3) L-Ala, 5.5; D-Ala, 16.0. After a necessary correction for racemization during acid hydrolysis (estimated from free amino acids exposed to the same hydrolytic conditions), the degrees of racemization were estimated.

Chromatography. A Jasco Trirotar liquid chromatograph system was used for HPLC. For purification of peptides, Cosmosil $5C_{18}$-P (10×250 mm, Nakarai Chem. Co.) or YMC-ODS 5 μm (20×250 mm, Yamamura Kagaku), for analytical purpose, Cosmosil $5C_{18}$-P (4.6×150 mm), and for gel filtration, TSK G2000SWXL (7.5×300 mm, TOSO Co.) or G3000SW (7.5×600 mm) columns were used. Peptides were detected by UV absorption at 215 nm. For carboxymethylcellulose chromatography, the procedure described by Erickson and Merrifield[12] was followed.

Amino Acid Analysis. Peptide-resin and peptides were hydrolyzed at 130 °C for 12—24 h in concd HCl–propionic acid (1:1, v/v) or in TFA–concd HCl (9:1, v/v). In the latter case, a correction of amino acid recovery under the conditions was made: Ala, 98.4%; Phe, 96.4%; Orn, 75%; Lys, 97%, after 24 h. Amino acid analysis was carried out with a Jasco amino acid analyzer (single column operation, pH 5.25 ($[Na^+]$=0.2 M) and pH 5.0 ($[Na^+]$=1.6 M) buffers used).

Ultracentrifuge Analysis. Sedimentation equilibrium analysis was carried out with a Beckman Spinco E analytical ultracentrifuge, at 29500 rpm.

Encouragement by Prof. Tatsuo Ooi, Kyoto University, and ultracentrifuge analysis by Mr. E.-H. Kim are greatly acknowledged. This work was supported in part by a grant from the Ministry of Education, Science and Culture.

(Received January 21, 1988)

The Knoevenagel reactions of *p*-nitrobenzaldehyde (**1**) with β-keto acids, methylmalonic (**2a**) and α-methylacetoacetic acids (**2b**) were carried out in the presence of a tertiary amine such as pyridine. We have isolated the corresponding β-hydroxy intermediate (**3a**) by the reaction of **2a** which positively suggested the reaction proceeded by the Hann and Lapworth mechanism. A kinetic study using ^{1}H NMR revealed the existence of the reversibility between the starting materials and the β-hydroxy intermediate and that the rate determining step was decarboxylattion. But, when using the secondary amine, both the β-hydroxy acid and the corresponding condensation product were obtained via this reaction. These findings led to the conclusion that the reaction proceeded according to the two competing mechanisms, i.e., the Hann and Lapworth and Knoevenagel mechanisms. It was further clarified that either the decarboxylation step or the formation of the bis(dialkylamino) derivative was the rate determining step. The stereoselectivity of the β-hydroxy saturated compound has been closely related to the fact that the conformation of the intermediate possesses an intramolecular hydrogen bond to a hydroxyl group.

Some mechanisms,[1] depending on the kind of amine catalysts, have been proposed for the Knoevenagel reaction between an aldehyde and an active methylene compound. The Hann and Lapworth mechanisms[2] containing a β-hydroxy intermediate was expected when using tertiary amines. The Knoevenagel mechanism[3] has been predicted for the reaction which gives a condensation product via a bis(dialkylamino) derivative formed from a secondary amine and an aldehyde. However, these expectations were not realized because the condensation product was mainly obtained in both mechanisms.

For active methylene compounds such as malonic, cyanoacetic, and acetoacetic acids which accompanies decarboxylation, it is not yet clear that either dehydration or decarboxylation preferentially proceeds from the β-hydroxy intermediate in the presence of a tertiary amine.

An active methine compound such as β-keto acid was reacted with an aromatic aldehyde instead of an active methylene one. Gensler et al.[4] have reported that reaction of *p*-nitrobenzaldehyde with methylmalonic acid at 90 °C in the presence of piperidine–pyridine gave the corresponding cinnamic acid, but Fujiwara et al.[5] obtained 3-hydroxy-2-methyl-3-(*p*-nitrophenyl)propionic acid via the same reaction in pyridine. Yuan et al.[6] have considered the reaction mechanism operated by both catalysts at room temperature. However, the intermediate could not be confirmed in all cases. Tanikaga et al.[7] have reported that various aromatic aldehydes reacted with active methylene compounds in the presence of piperidine to isolate bispiperidides and that this reaction proceeded via the Knoevenagel mechanism. Lopez et al.[8] have shown that 2,3-*O*-isopropylidene-D-glyceraldehyde and α-methylacetoacetic acid reacted in toluene in the presence of diethylamine to give the β-ketol and α,β-enone. Inoue et al.[9] have stated that the reaction of *m*-nitrobenzaldehyde with *p*-nitrophenylacetic acid in the presence of secondary amines also proceeded via the Hann and Lapworth mechanism, i.e., the reaction proceeded via the β-hydroxy intermediate as in the case of tertiary amine catalysts. Thus, the mechanism for the Knoevenagel reaction accompanying decarboxylation is not yet clear.

To elucidate these problems, we carried out the Knoevenagel reactions of *p*-nitrobenzaldehyde (**1**) with methylmalonic (**2a**) and α-methylacetoacetic acids (**2b**) using secondary and tertiary amines. We report the isolation of the β-hydroxy intermediate and the mechanistic determination of the role of amines.

Results and Discussion

Synthesis of the β-Hydroxy Intermediate 3a and the β-Hydroxy Acid 4a. To a mixture of **1** (0.03 mol) and **2a** (0.06 mol), pyridine (0.18 mol) was added at room temperature and the mixture was kept for 6 h. The reaction time was determined in advance by ^{1}H NMR. From the residue remaining after the removal of the unreacted substances the β-hydroxy intermediate, **3a**, was isolated in a 54% yield after extraction with ether under acidic conditions (pH 2).

The β-hydroxy acid, **4a**, was obtained in a 46% yield by decarboxylation of the corresponding β-hydroxy intermediate. The structure of **4a** was identified with ^{1}H NMR, IR, and elemental analyses. The threo- and erythro-compound, **4a**, have been distinguished and their configurations were established by ^{1}H NMR at 4.89 (J=8.4 Hz) and 5.71 (J=4.2 Hz), respectively.

It may be affirmed by the isolation of **3a** that this

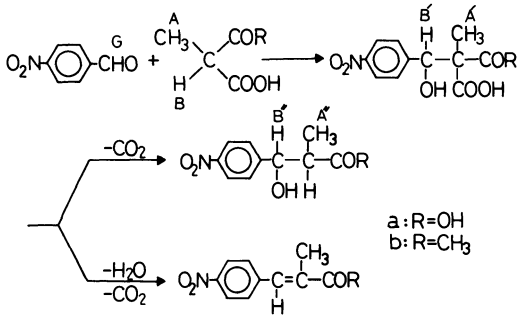
† Present address: Sanwa Kagaku Kenkyusho Co., Ltd., Higashisotobori-cho, Higashi-ku, Nagoya.

reaction proceeded via the Hann and Lapworth mechanism.

Kinetic Studies on Addition and Decarboxylation Stages. A mixture of **1**, **2a** (1.04 mmol, each) and pyridine-d_5 (3.11 mmol) was put into a sealed NMR tube and the reaction was run for 30 days at room temperature, then the ^{1}H NMR spectra of the mixture were measured. The signals were assigned as follows (Scheme 1): A, A′, and A″ are methyl proton signals of **2a**, **3a**, and **4a**, respectively, B for α-CH signal of **2a**, and B′ and B″ for β-CH signals of **3a** and **4a**, respectively and G refers to the proton signal of an aldehyde, where the intergral of B″ was calculated by the total amount of β-CH signals of the threo- and erythro- β-hydroxy acids. The integrated intensities of their signals are the mean values of more than three observed values. Relative concentrations of the compounds were calculated by the total amount of the groups (A+A′+A″).

Time dependences of the relative concentration of **3a** and **4a** measured by ^{1}H NMR during 30 days are shown in Fig. 1. The concentration of the β-hydroxy intermediate, **3a**, showed a maximum in about 3.5 h, while the β-hydroxy acid, **4a**, began to appear after 24 h.

The different formation times between **3a** and **4a** have suggested that the rate of the decarboxylation reaction was slower than that of the addition reaction at room temperature under these reaction conditions.



Scheme 1.

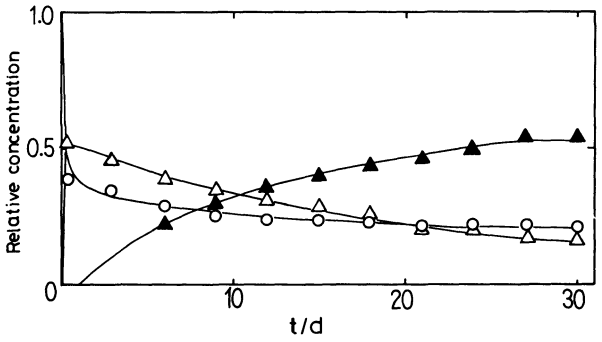


Fig. 1. Reaction of **1** with **2a** in the presence of pyridine and DMSO at room temperature. O: Starting material, △: β-hydroxy intermediate, ▲: β-hydroxy acid.

Figure 2 shows the initial part of Fig. 1. From this figure it can be assumed that the concentrations of **3a** become almost unchangeable after 200 min. Further, when the **3a** isolated in pure form was dissolved in pyridine at room temperature, a part of **3a** was cleaved into **1** and **2a**. This result has suggested the reversible reaction between starting materials and the intermediate, in accordance with the reports by Kinastowski et al.[10] They have demonstrated that there is a linear relation between the rate constant and the concentration of the catalyst at an addition stage and that the catalytic rate was fairly faster than the rate of the spontaneous chemical reaction. In practice, we have experienced great difficultly in calculating the rate sequence, **1**+**2**⇄**3**→**4**. To overcome this difficulty, an analysis based on a preequilibrium was considered. We tried to conveniently determine the apparent reaction rates at a constant catalytic concentration by dividing it into two stages: (a) the addition stage, and (b) the decarboxylation stage.

(a) The Addition Stage. From Fig. 2, we assumed that there exists a reversibility between second-order (forward reaction k_1) and first-order (reverse reaction k_2) rates and that the concentration of an aldehyde (C_1) is equal to that of an active methine compound (C_2), that is, $C_1=C_2$. The rate constants are expressed by:

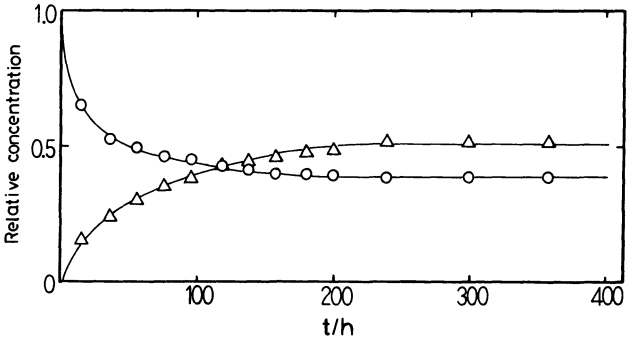

Fig. 2. Reaction of **1** with **2a** in the presence of pyridine and DMSO at room temperature. O: Starting material, △: β-hydroxy intermediate

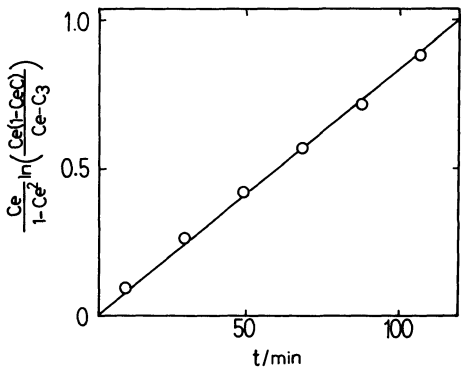

Fig. 3. Second-order plots vs. time in the reaction of **1** with **2a**.

$$k_1 t = \frac{C_e}{1 - C_e} \ln \frac{C_e(1 - C_e C_3)}{C_e - C_3}, \quad (1)$$

$$k_2 = \frac{k_1(C_0 - C_e)^2}{C_e}, \quad (2)$$

where C_0 is the initial concentration of aldehyde, and C_3 and C_e are the concentration and the preequilibrium concentrations of the β-hydroxy intermediate, respectively. In Fig. 3, the right side of Eq. 1 is plotted against reaction time. The plot gives a satisfactory straight line passing through the origin, from which the rate constants, k_1=4.56×10^{-1} and k_2=1.98×10^{-1} h^{-1}, and the preequilibrium constant, $K(=k_1/k_2)$= 2.30, could be estimated.

(b) The Decarboxylation Stage. By using the C_e value determined from Fig. 2, the rate of decarboxylation originating from the β-hydroxy intermediate was calculated by assuming a first-order reaction (k_3):

$$k_3 t = \ln \frac{C_e}{C_e - C_4}, \quad (3)$$

where C_4 is the concentration of the β-hydroxy acid. Figure 4 shows the relation between the right side in Eq. 3 and reaction time. As shown in this figure, a satisfactory straight line was also suggested by the results of a regression analysis. The rate constant, k_3, was 4.17×10^{-3} h^{-1}. The decarboxylation rate in this system was 10^{-2}-fold slower than the addition one. The reactions of *p*-substituted (cf. CN, Br) benzaldehydes with **2a** showed the same results.

We may firmly suggest that there is a reversibility between the starting materials and the β-hydroxy intermediate, and that the decarboxylation process is the rate determining step. The careful and exact observations by NMR have indicated that the β-hydroxy acid consisted of threo and erythro isomers and that the reaction rate of threo isomer was faster than that of the erythro. These details will be demonstrated later.

The Knoevenagel Reaction in the Presence of Piperidine. For the Knoevenagel reaction in the presence of a tertiary amine, the Hann and Lapworth mechanism was firmly demonstrated by our experiments. On the other hand, for the reaction promoted by the presence of secondary amines, another mechanism has been proposed by Knoevenagel himself; the catalyst reacts with an aldehyde to form a bis(dialkylamino) derivative, which then reacts with an active methylene compound to produce an unsaturated compound. However, the Knoevenagel reaction catalyzed by a secondary amine as reported by Lopez or Inoue et al. cannot be explained only by the Knoevenagel mechanism. To elucidate the complete mechanism of the reaction conducted in the presence of secondary amines, we studied similar reaction at room temperature by the use of ^{1}H NMR. To a solution of **1** and **2a** (1.04 mmol, each) in CD_3CN, piperidine was added dropwise (1/10, 1/3 and 1 mole per mole of aldehyde). Time dependences of the relative concentrations of **3a**, **4a** and α,β-unsaturated compound **6a** measured with ^{1}H NMR during 100 h are shown in Fig. 5. In all cases of the added piperidine, the β-CH-proton signal of **3a** appeared at δ 5.5 immediately after the initiation of the reaction. The concentration of this intermediate increased with increasing piperidine. After the appearance of the β-CH signal, **6a** was recognized. The product, **4a**, increased as the piperidine was decreased (1/10 and 1/3 mole per mole of an aldehyde). But, since the

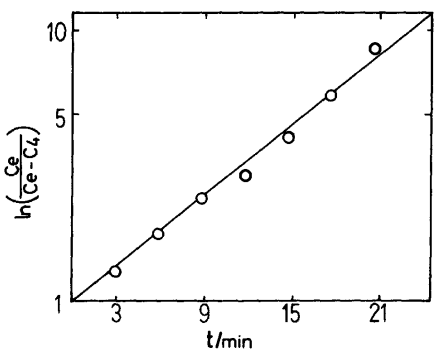

Fig. 4. First-order plots vs. time in the reaction of **1** with **2a**.

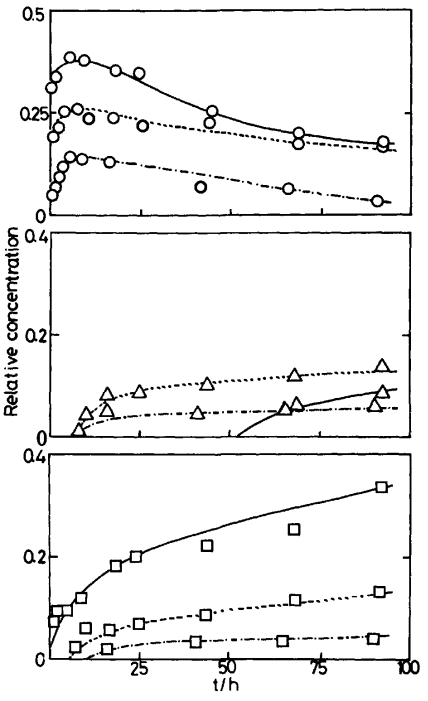

Fig. 5. Reaction of **1** with **2a** in the presence of piperidine. Piperidine concn. (mole per mole of aldehyde): —— (1 equiv), ------ (1/3 equiv), -·-·- (1/10 equiv). ○: β-Hydroxy intermediate, △: β-hydroxy acid, □: α,β-unsaturated compound.

dehydration from both the β-hydroxy intermediate and the β-hydroxy acid is usually difficult to occur under such reaction conditions, we have no convictions about the formation of **6a**. Therefore, the reactions of the β-hydroxy intermediate with amine catalysts were subsequently carried out.

Reaction from the β-Hydroxy Intermediate 3a. The reactions using **3a** (1.04 mmol) as a starting material were carried out in an NMR tube at room temperature with the $CDCl_3$–DMSO-d_6 solutions of piperidine (0.35 mmol) or pyridine (1.04 mmol). Time dependences of the relative concentrations of reactants in the presence of piperidine measured with ^1H NMR for 200 h are shown in Fig. 6. In both systems, **1** and **2a** were immediately produced and **4a** was obtained in a small amount. In the presence of piperidine, **6a**, which was not obtained in the presence of pyridine, was produced after the formation of **1** and **2a**. Further, when piperidine (2 mmol) was added to a solution of **1** (1 mmol) in $CDCl_3$, this solution showed the CH-proton signal of bispiperidide (**5a**) at δ 3.5. **6a** was produced immediately after addition of **2a** to the CD_3CN solution of **5a**. It gave additional credence that **3a** was easily decomposed into **1** and **2a** in the presence of piperidine, whereas only **4a** was obtained in the presence of pyridine. The product ratio, **4a**/**6a**, was dependent on the quantity of added piperidine. Judging from this fact, we may safely say that a slight amount of piperidine promotes the decarboxylation of **3a**, as supported by the study of Patai et al.[11] In other words, **6a** was not directly supplied by either the dehydration of **3a** or **4a**, but produced by the reaction via the Knoevenagel mechanism. From the above results there may exist a different mechanism between the presence of pyridine or piperidine. Therefore, we can advance the suggestion that the reaction accompanying the decarboxylation in the presence of piperidine proceeds by two competing mechanisms; the Hann and Lapworth(path A) and the Knoevenagel (path B) mechanisms as shown in Scheme 2, and that both decarboxylation from **3a** and the formation of **5a** are the rate determining steps of these competing reactions.

Reaction in the Presence of Various Secondary Amine Catalysts. Several reactions of **1** with **2a** were carried out in toluene–DMSO at room temperature using several kinds of secondary amines such as piperidine, morpholine, diethylamine, and dicyclohexylamine, in order to make a comparison with the reaction using the tertiary amine such as pyridine. The results are shown in Table 1. In all cases using the secondary amines as a catalyst, the mixture of **4a** and **6a** was obtained, but in pyridine, **6a** was not formed. The product ratio, **4a**/**6a**, depended on the type of the secondary amine catalyst, i.e., the yield of **6a** was somewhat higher than that of **4a**, when piperidine and morpholine were used, while that of **4a** was preferentially produced when diethylamine and dicyclohexylamine were used.

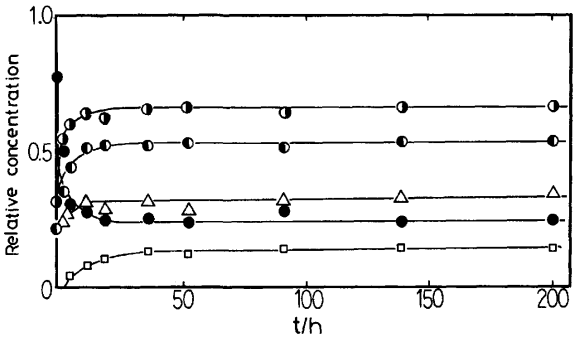

Fig. 6. Reaction from β-hydroxy intermediate in the presence of piperidine (1/3 equiv). ●: β-Hydroxy intermediate, ◐: **1**, ◑: **2a**, △: β-hydroxy acid, □: α,β-unsaturated compound.

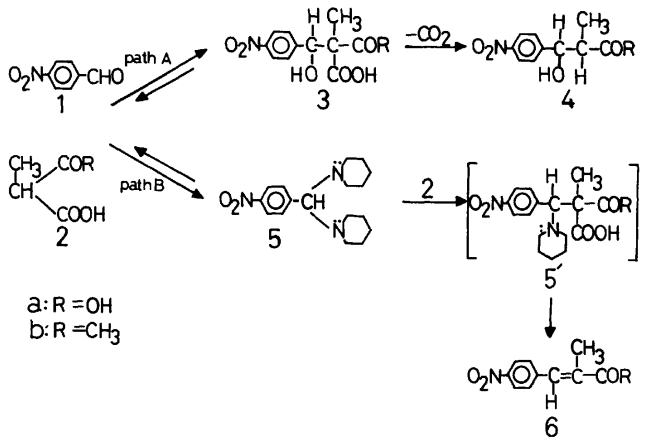

Scheme 2.

Table 1. Reaction of **1** with **2a**

Catalyst	pK_a	Yield/%		Selectivity	
		4a	**6a**	Erythro	: Threo
Pyridine	5.2	92.1	—	16	84
Piperidine	11.2	42.2	54.4	12	88
Morpholine	8.5	35.9	58.7	16	84
Diethylamine	10.8	81.3	15.5	10	90
Dicyclohexylamine	11.2	85.4	8.3	7	93
—[a]		—	—	59	41

a) This is not estimated from isolated product.

These results have given active support to the existence of the two competing mechanisms. In the reactions of **1** with diethylamine or dicyclohexylamine in $CDCl_3$ solutions in an NMR tube at room temperature, the bis(dialkylamino) derivatives can be hardly recognized. The order of the difficulty for detection of bis(dialkylamino) derivatives is as follows: dicyclohexylamine>diethylamine≫morpholine, piperidine.

We may thus conclude that the yield of the bis(dialkylamino) derivative increased by decreasing the steric hindrance of the secondary amines in accordance with the previously mentioned results.

Reaction of α-Methylacetoacetic Acid (2b). To verify the existence of another rate determining step, namely the difficulty of the decarboxylation, the reaction of **1** with **2b**, which was easier than **2a** during decarboxylation, was carried out using various secondary and tertiary amines in toluene. The reaction finished at −18 °C for a short period, about 2 days, compared well with the reaction of **2a** done for one month at room temperature. The β-hydroxy intermediate could not be determined due to the rapid decarboxylation. The yields of **4b** and **6b** are shown in Table 2. **4b** was preferentially obtained in all cases, but of these, **6b** was slightly produced using only secondary amines. The ratio of **4b** to **6b** varied with the kind of secondary amines and this tendency was somewhat similar to that of the reaction with **2a**.

We concluded that **1** reacted with α-substituted active methine compounds accompanying decarboxylation in the presence of secondary amines to afford the preferential formation of the β-hydroxy acid, when the active methine compound possible for decarboxylation and/or bulky amines were used. The existence of competing pathways in the reaction mentioned above was thus reconfirmed.

Stereochemistry of the Knoevenagel Reaction. In the Knoevenagel reaction of **1** with **2a**, the stereochemical data were also tabulated in Tables 1 and 2. The threo/erythro ratios were determined by ^1H NMR and compared with the results of Yuan et al. It was inconclusive that the stereoselective formation of the product was explainable by kind, bulkiness, and pK_a of the catalyst. But, we could draw a clear distinction between the presence or the absence of catalysts in both cases. Also, there was a subtle difference between the two active methine compounds. The ratio of the erythro isomer in the case of the reaction with **2b** is somewhat high.

Moreover, the reactions with **2b** were run with varying amounts of pyridine, giving the results shown in Table 3. The formation of the threo isomer was inclined to increase with an increase in pyridine while using 9-fold moles of pyridine, the *threo*-**4b** was obtained exclusively, although **2b** itself is apt to evolve carbon dioxide, resulting in a lower yield of **4b**. The basicity of the reaction system may contribute to this trend.

In general, the β-hydroxy intermediate obtained by the Knoevenagel reaction in the presence of a tertiary amine would be a mixture of diastereomers. For the Knoevenagel reaction with a planar prochiral compound, e.g., **1**, **3b** may include the threo isomer equivalent to the erythro, although **3b** could not be isolated. The fact will be experimentally verified in a subsequent paper on the reaction of **1** with *p*-nitrophenylacetic acid.[12] So, when the difference in the stereoselectivity of the saturated product can be detected, the fact is undoubtedly due to the decarboxylation stage initiated from the intermediate. In this reaction, it is theorized that the conformations cannot be exchanged in the course of the decarboxylation since we believe that the reaction conditions are hard to produce epimerization between threo and erythro isomers.[13] In addition, the coupling constants of **4b** (J=8.0 and 4.0 Hz) also correspond to those of **4a**. On an analogous discussion of Yuan et al., **3b** seems to possess an intramolecular hydrogen bonding.

Table 3. Reaction of **1** with **2b** in Pyridine

Pyridine/mol[a]	Yield/% **4b**	Selectivity Erythro	: Threo
0.1	60.1	33	67
0.5	57.8	50	50
1.5	31.4	25	75
4.0	32.7	16	84
9.0	28.7	0	100

a) Per mole of aldehyde.

Table 2. Reaction of **1** with **2a** in Toluene

Catalyst	pK_a	Yield/% **4a**	**6b**	Selectivity Erythro	: Threo
Pyridine	5.2	88.9	—	37	63

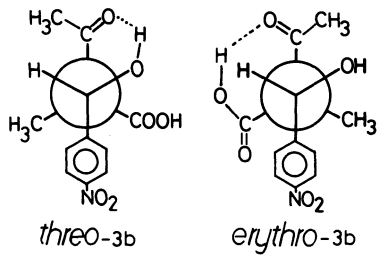
—		64.1	—	67	33

a) These reactions were carried out without toluene.



Scheme 3.

The intramolecular hydrogen bonding suggests to us the reactivity or stability of the intermediate, which will be demonstrated in a forthcoming report.

Taking into account the above statements, the conformations of **3b** are illustrated in Scheme 3. Each is invariable during decarboxylation. Further, the conformations of the corresponding saturated compounds were deduced by Karplus' equation.

When β-keto acids are used as the active methine compounds, we must consider the decarboxylation from a few types; the keto acid[14] or the hydroxy acid type,[15] and in the presence or in the absence of amine catalysts. The acetyl group of **3b** is able to be linked to both hydroxyl and carboxyl groups by intramolecular hydrogen bonding. In the absence of amine catalysts, we may propose the mechanism which would induce the spontaneous decarboxylation of the keto acid type instead of the hydroxy acid one. This argument is suggested by the fact that the erythro isomer was preferentially obtained. The representation of the erythro isomer is then carried out by a figure of conformation of the intramolecular bonding between acetyl and carboxyl groups.

On the contrary, the acetyl group of the threo conformation prefers the hydroxyl group to the carboxyl. This conformation is more stable than the other in the presence of amine catalysts, since the reverse reaction forming starting materials is relatively difficult to produce owing to the hydrogen bond.

Accordingly, the amine catalyst at first draws a free proton from the carboxyl group, and subsequently accelerates the decarboxylation of *threo*-**3b**, while it acts on the reversible reaction of *erythro*-**3b**. This might be supported by the fact that the appearance of *threo*-**4b** was easier and that in excess pyridine the threo isomer was exclusively produced.

Experimental

The melting points were measured with a Yanagimoto Melting-point Apparatus and are presented without correction. Solvents and other commercially obtained materials were purified by distillation. The IR spectra were recorded with a Shimadzu IRA-435 spectrometer and the ^{1}H NMR spectra using a JEOL JNM-MH100 (100 MHz) or a JEOL GX-400 (400 MHz) spectrometer with TMS as an internal standard. GLC analysis was performed on a Shimadzu GC-6AM gas chromatography using FID detector. All analyses were carried out on 2 m×3 mm in 10% Silicone SE-30.

β-Hydroxy Intermediate 3a. A mixture of **1** (0.03 mmol), **2a** (0.06 mmol), and pyridine (0.18 mmol) was kept at room temperature for 6 h. To the mixture was added 4 M HCl (1 M=1 mol dm^{-3}) until pH 2. Then the mixture, except pyridine, was extracted with ether. After the ether was evaporated, dil. Na_2CO_3 was added to the residue to pH 11, then an unreacted aldehyde was extracted with benzene. The remaining aqueous solution was acidified (pH 2) with concd. HCl, extracted with ether, and the ether solution was washed with water, and dried with anhydrous Na_2SO_4. After removing the remaining ether, pale yellowish crystals obtained were recrystallized from methanol–water solution (4.36 g, 54% yield). Mp 130—131 °C; Found: C, 49.29; H, 4.12; N, 5.04%. Calcd for $C_{11}H_{11}O_7N$: C, 49.08; H, 4.12; N, 5.20%. ^{1}H NMR (400 MHz) δ=1.289 (s, 3H), 5.534 (s, 1H), 7.619, 8.137 (2d, 4H), 10.285 (s, 3H). IR(KBr) 3500, 1710, 1350 cm^{-1}.

3-Hydroxy-2-methyl-3-(*p*-nitrophenyl)propionic Acid (4a). A mixture of **1** (0.03 mol), **2a** (0.06 mol) and pyridine (0.18 mol) was kept at room temperature for a month, and was added 4 M HCl until pH 2. The mixture was extracted with ether. After the ether was evaporated, dil. Na_2CO_3 was added to the residue to pH 11, then an unreacted aldehyde was extracted with benzene. The aqueous solution was acidified (pH 2) with concd. HCl and again was extracted with ether. The extract was washed with water, and dried with anhydrous Na_2SO_4. Ether was evaporated and the residue was recrystallized from methanol–water solution. (3.10 g, 46% yield); mp 139—141 °C. Found: C, 53.41; H, 5.01; N, 6.01%. Calcd for $C_{10}H_{11}O_5N$; C, 53.33; H, 4.93; N, 6.22%; ^{1}H NMR($CDCl_3$) δ=5.66 (br, 1H), 8.97 (br, 1H), 8.16, 7.58 (dd, 4H), 5.71 (d, β-CH, J=4.2 Hz, erythro), 4.89 (d, β-CH, J=8.4 Hz, threo), 2.80 (m, α-CH,erythro), 2.67 (m, α-CH, threo), 1.15 (d, CH_3, erythro), 0.95 (d, CH_3, threo); IR (KBr) 3500, 1710, 1350 cm^{-1}.

Bispiperidide (5a). A mixture of **1** (1 mol) and piperidine (3 mol) was kept at room temperature for about 5 h, and subsequently the reaction mixture was freeze-dried to yield quantitatively red brown crystals. Mp 79—82 °C; ^{1}H NMR ($CDCl_3$) δ=8.15—7.35 (dd, 4H), 3.65 (s, 1H), 2.30, 1.45 (dd, 10H).

Preparation of 6a from 5a and 2a. A mixture of (0.041 mol) **2a** and **5a** (0.041 mol) was kept at room temperature for about 4 days, and into the mixture 4M HCl was poured until pH 2 to yield crude yellowish crystals. They were recrystallized from methanol–water solution (7.38 g, 87% yield). Mp 205—206 °C; ^{1}H NMR ($CDCl_3$) δ=8.15, 7.35 (dd, 4H), 7.72 (s, 1H), 2.00 (s, 3H); IR (KBr) 1710, 1680, 1510, 1350, 860 cm^{-1}.

α-Methylacetoacetic Acid (2b). To α-methylacetoacetic acid ethyl ester (0.1 mol) 1 M NaOH aqueous solution (110 ml) was dropped at room temperature for about 12 h, the solution was extracted with ether (50 ml×2), concentrated until one-third volume, to which dil. H_2SO_4 (H_2SO_4=15 ml:3.5 ml) was added in the ice bath, saturated with NaCl, and extracted with ether. The extraction was continued until no α-methylacetoacetic acid in water layer was detected with $FeCl_3$ test. The extract was dried with anhydrous Na_2SO_4. Ether was evaporated in the ice-water bath to obtain the product (8.8 g, 76% yield). ^{1}H NMR

($CDCl_3$) δ=7.6—8.0 (br, 1H), 3.4 (q, 1H), 2.2 (s, 3H), 1.3 (d, 3H).

4-Hydroxy-3-methyl-4-(*p*-nitrophenyl)-2-butanone (4b) and 3-Methyl-4-(*p*-nitrophenyl)-3-buten-2-one (6b). A mixture of **1** (0.05 mol), **2b** (0.1 mol), and pyridine (0.025 mol) was kept at −50 °C in the Dry Ice bath, to −18 °C for 48 h under closed pressure, and opened in the nitrogen atmosphere. The reaction was continued until a disappearance of an aldehyde signal of **1** in an NMR spectrum. The unreacted catalyst was excluded from the solution in vacuo and the residue was washed with benzene to precipitate yellowish crystals, 4-hydroxy-3-methyl-4-(*p*-nitrophenyl)-2-butanone (4.21 g, 37.8% yield). Mp 93—95 °C; ^{1}H NMR ($CDCl_3$) δ=8.24, 7.60 (dd, 4H), 5.32 (d, β-CH, J=4.0 Hz, erythro), 4.92 (d, β-CH, J=8.0 Hz, threo), 4.60 (br, 1H), 2.96 (q, 1H), 2.26 (s, CH_3, erythro), 2.24 (s, CH_3, threo), 1.04 (d, α-CH_3, erythro), 0.98 (d, α-CH_3, threo); IR (KBr) 3400, 1710, 1510, 1350 cm^{-1}.

On the other hand, using piperidine–pyridine (0.1 mol, each) the same method was performed to obtain the mixture **4b** and **6b**. The residue was washed with benzene, and with additional methanol to yield crystals, 3-methyl-4-(*p*-nitrophenyl)-3-buten-2-one (0.27 g, 2.6% yield). Mp 205—206 °C; ^{1}H NMR ($CDCl_3$) δ=8.28—7.76 (dd+s, 5H), 2.40 (s, 3H, E), 2.00 (s, 3H); IR (KBr) 1650, 1510, 1350 cm^{-1}

Synthesis of Isoindoles. Acid or Base Induced Cyclization of 2-Cyanobenzaldehyde with Alcohols

Ryu SATO,* Michiko OHMORI, Fumiko KAITANI, Akiko KUROSAWA, Toshihide SENZAKI, Takehiko GOTO, and Minoru SAITO
Department of Resource Chemistry, Faculty of Engineering, Iwate University, Morioka 020
(Received January 25, 1988)

Various 3,3-dialkoxy-2,3-dihydro-1-hydroxy-1*H*-isoindoles (**2**) were obtained by treating 2-cyanobenzaldehyde (**1**) with alcohols in the presence of an acid catalyst such as silica gel. In the reaction using a base catalyst such as triethylamine and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), 3-alkoxy-2,3-dihydro-1*H*-isoindol-1-ones (**4**) were formed via 3-alkoxy-1,3-dihydro-1-isobenzofuranimine (**3**). The use of 1,4-diazabicyclo[2.2.2]octane (DABCO) and *N,N,N',N'*-tetramethylethylenediamine (TMEDA) gave **2** besides **3** and **4**. A convenient and selective synthesis of isoindoles and its derivatives are described.

In the recent extensive studies on the chemistry of isoindoles, many chemists have directed their attention to the synthesis of 2,3-dihydro-1*H*-isoindol-1-ones and its derivatives, some of which are recognized to exhibit pharmacological and pesticidal activities.[1] In the previous paper we described the one-step formation of 3-amino-2,3-dihydro-1*H*-isoindol-1-ones from 2-cyanobenzaldehyde (**1**) with various amines and the 2-alkylation of the isoindole by the phase-transfer catalyst system.[2] To our knowledge, there have been only a few papers for the syntheses of 3-alkoxy-2,3-dihydro-1*H*-isoindol-1-ones by alkoxylation of 2,3-dihydro-3-hydroxy-1*H*-isoindol-1-one, which was prepared by electrolytic reduction from phthalimide, and its related reactions.[3] Hence our attention centered on the direct synthesis of the isoindoles and its derivatives having an alkoxy group on the isoindole ring by cyclization of **1** with alcohols. It is well-known that the nucleophilicities of alcohols are very poor, compared with those of amines. Therefore, based on the our previous results,[2] activation of substrates or reagents is necessary to bring about the reaction at ambient temperature. Recent interesting investigations on silica gel induced reactions[4] encouraged us to explore a facile formation of some isoindoles and its derivatives by acid, e.g. silica gel, or base, e.g. DABCO, induced cyclization of **1** with various alcohols. Here we describe the novel selective synthesis of isoindoles and its related compounds.

Results and Discussion

Reaction of 1 with Alcohols in the Presence of Acid Catalysts. Without catalyst, **1** did not react at all with any alcohols even under reflux conditions (Table 1, Run 1, Scheme 1), whereas in the presence of acid

catalysts (phenol and silica gel) **1** readily reacted with methyl alcohol to give 2,3-dihydro-1-hydroxy-3,3-dimethoxy-1*H*-isoindole (**2**) in high yields (Runs 2—4). In this reaction the use of silica gel of large grain size (Wako gel G), even if the silica gel was employed without drying, gave a better yield of **2** than that when a small grain size silica gel (Wako gel C-300) which was dried at 150 °C for 5 h under vacuum was used (Runs 3 and 4). Other solid acid catalyst, for example, alumina (neutral) also catalyzed this reaction (Run 7). Interestingly, tetrabutylammonium iodide behaved similarly to other acid catalysts to give **2** in good yield (Run 8). The use of aluminium chloride and hydrogen chloride gave, however, an acetal compound, 2-cyanobenzaldehyde dimethyl acetal (Runs 5 and 6). Thus, the catalytic effect of silica gel for cyclization of **1** with methyl alcohol was confirmed and a generality of this procedure was also shown in Table 1 (Runs 9—14). Characteristically, butyl and isobutyl alcohols also gave **2** in good yields, but isopropyl and *t*-butyl alcohols did not react with **1** under the same conditions. These results suggest that a steric bulkiness of alcohols used is an important factor in this reaction. Although, unfortunately, α,ω-alkanediols such as ethylene glycol did not react with **1** even at high temperature such as 100 °C, the present silica gel induced cyclization of **1** with various alcohols should provide a novel and convenient synthetic method for new isoindoles such as **2a—e**.

Reactions of 1 with Alcohols in the Presence of Base Catalysts. Compound **1** was treated with various alcohols in the presence of base catalysts such as triethylamine, DBU, DABCO, and TMEDA. In the presence of triethylamine, interesting product, isobenzofurans **3a,b** and **d** were obtained in yields as shown in Table 2. To our surprise, however, **2b** and **2d**, which were the same type of products in the silica gel induced reactions, were also obtained (Runs 2 and 3). Next we employed DBU as a strong base in the reaction of **1** with methanol. Thus, in the reaction at

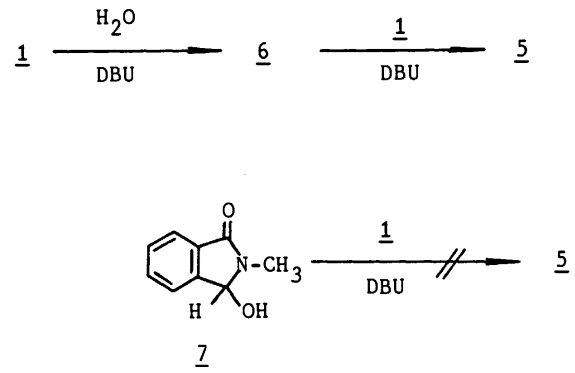
a) Substrate: 0.5 mmol, alcohol: 4 ml. b) Isolated yields based on the substrate.

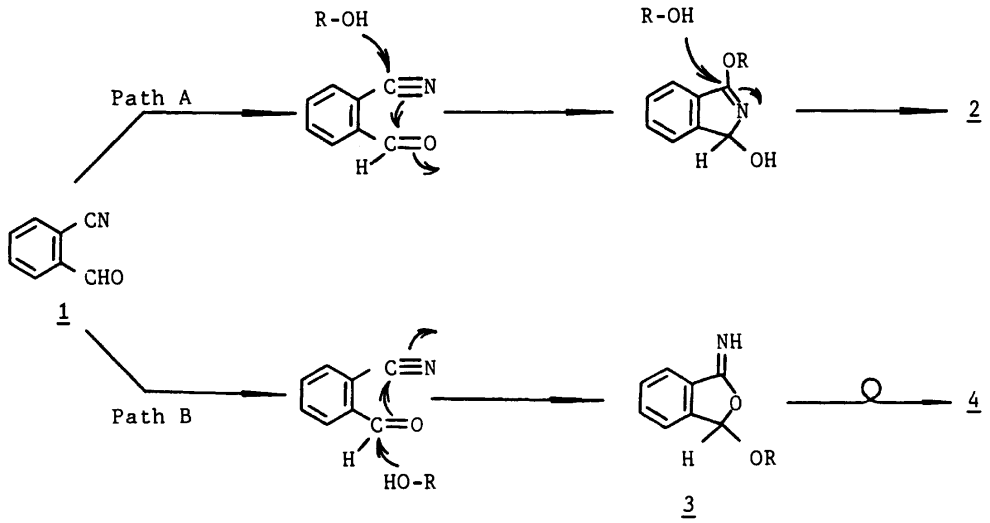
15 °C, **3a** was obtained in yield of 27% together with 2,3-dihydro-3-methoxy-1*H*-isoindol-1-one (**4a**, 58%) (Run 4), while only **4a** was given at 30 °C in yield of 87% (Run 5). In order to confirm an intermediacy, **3a** was actually treated with methanol in the presence of DBU under the same conditions, to afford the expected **4a** quantitatively. In the reaction of **1** with ethanol in the presence of DBU, a little different results were obtained. Thus, desired isoindole, 3-ethoxy-2,3-dihydro-1*H*-isoindol-1-one (**4b**), was given in a 30% yield. Furthermore, we found that 3′-hydroxy-1,2′-bi-2*H*-isoindole-1′,3(1*H*)-dione (**5**) was formed in 66% yield at 50 °C for 78 h together with 2,3-dihydro-3-hydroxy-1*H*-isoindol-1-one (**6**) (trace) when a small amount of water was present in the system (Scheme 3). To clarify the pathway of the formation of **5** and **6**, we carried out some related reactions. Compound **6** was obtained quantitatively when **1** was treated with water in the presence of DBU at room temperature. It is very interesting that **6** reacted easily with **1** at 50 °C for 3 h under the same conditions, to give **5** quantitatively (see Experimental). This result suggests that the NH group of **6** was activated with DBU and then reacted with **1** as a nucleophile to give **5**. Further evidence for the formation of **5** was obtained by the reaction of **1** with 2,3-dihydro-3-hydroxy-2-methyl-1*H*-isoindol-1-one (**7**) under the similar conditions. Thus, **7** did not react at all with **1**, and **7** was recovered completely. Based on these results, the formations of **5** and **6** are illustrated as shown in Scheme 4.



Scheme 4.

It should be noted that unexpected products **2**, which were given by the silica gel induced reaction, were obtained as major product when **1** was treated with methanol in the presence of DABCO (Table 2, Run 9). Moreover, 2,3-dihydro-3,3-dimethoxy-1-hydroxy-1*H*-isoindole (**2a**) was formed exclusively under reflux (Table 2, Run 10). In contrast to these results, upon treating **1** with methanol in the presence of TMEDA, **3a** was exclusively obtained (Run 13), though the reactions with other alcohols, e.g. ethanol (Run 14) and 1-butanol (Run 15), gave a mixture of **2** and **3**. Based on these results, it seems that methanol behaves as a special nucleophile in connection with the points of reactivity and stereochemistry. In the reaction of **1** with alcohols, there are apparently two pathways, i. e., (1) double nucleophilic additions of alcohol toward cyano group involving cyclization (Scheme 5, path A) and (2) nucleophilic attack of alcohol toward formyl group and sequent intramolecular rearrangement after cyclization (Scheme 5, path B). Therefore, it is possible that in the presence of an acid catalyst the reaction path A is predominant, while both reactions, path A and B, could take place simultaneously in the presence of a base catalyst. These results also suggest that triethylamine, DABCO, and TMEDA can serve as conjugated acids.[5]

In conclusion, the selective synthesis of isoindoles, such as **2** and **4**, was performed by the reaction of **1** with alcohols in the presence of various acid or base catalysts.



Scheme 5.

Experimental

All melting points were uncorrected. IR spectra were obtained on a Hitachi 295 spectrophotometer and ^{1}H NMR spectra were obtained on a Hitachi R-22 spectrometer using tetramethylsilane as an internal standard. Mass spectra were taken with a Hitachi RMU-6M mass spectrometer. Elemental analyses were carried out with a Yanagimoto MT-3. All reactions were monitored by TLC (Merck Kiesel gel 60-GF 254).

Materials. All reagents were obtained from Wako Pure Chemical Industries Ltd., Tokyo Kasei Co., Ltd., or Aldrich Chemical Co. The reagents used were further purified by usual methods such as recrystallization or distillation. The silica gel used as an acidic catalyst (Wako gel G) was employed without drying, but Wako gel C-300 was dried under vacuum at 150 °C for 5 h.

General Procedure for Synthesis of 2 by Reactions of 1 with Alcohols in the Presence of Silica Gel. To a solution of **1** (66 mg, 0.5 mmol) in 4 ml of an alcohol was added silica gel (60 mg, Wako gel G) and the mixture was refluxed for 16—75 h. After filtration and evaporation of the alcohol, the residue obtained was chromatographed on silica gel using the mixture of chloroform and methyl alcohol (8/1, v/v) as an eluent to give **2a—e.**

3,3-Dibutoxy-2,3-dihydro-1-hydroxy-1*H*-isoindole (2d): Colorless crystals ($CHCl_3$); mp 72 °C; IR (KBr) 3180 and 3325 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.90 (6H, t, *J*=7.5 Hz, CH_3×2), 1.20—1.76 (8H, m, CH_2×4), 3.45—3.73 (4H, m, CH_2×2), 5.78 (1H, s, CH), 6.03 (1H, br, OH), and 7.28—7.82 (5H, m, NH and arom); MS *m/z* 206 (M^+—OBu). Found: C, 68.87; H, 8.85; N, 5.27%. Calcd for $C_{16}H_{15}NO_3$: C, 68.79; H, 9.02; N, 5.27%.

2,3-Dihydro-1-hydroxy-3,3-diisobutoxy-1*H*-isoindole (2e): Colorless crystals ($CHCl_3$); mp 93 °C; IR(KBr) 3180 and 3395 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.96 (12H, d, *J*=7.0 Hz, CH_3×4), 1.75—2.15 (2H, m, *J*=7.0 Hz, CH×2), 3.36 (4H, dd, *J*=7.0 and 1.5 Hz, CH_2×2), 5.81 (1H, s CH), 6.10 (1H, br, OH), and 7.31—7.90 (4H, m, arom and NH); MS *m/z* 206 (M^+—OBu-i). Found: C, 68.89; H, 9.26; N, 5.02%. Calcd for $C_{16}H_{25}NO_3$: C, 68.79; H, 9.02; N, 5.01%.

General Procedure for Synthesis of 3 and 4 by Reactions of 1 with Alcohols in the Presence of Base Catalyst. To a solution of **1** (66 mg, 0.5 mmol) in 4 ml of an alcohol was added triethylamine, DBU, DABCO, or TMEDA (0.1—0.5 mmol, respectively) and the mixture was stirred at 15—60 °C for 0.5—16 h. After evaporation of the alcohol, the residue obtained was chromatographed on silica gel using the mixture of chloroform and methyl alcohol (8/1, v/v) as eluent, to give **3** and **4**.

1,3-Dihydro-1-imino-3-methoxyisobenzofuran (3a): Colorless crystals ($CHCl_3$); mp 129 °C; IR (KBr) 1640 and 3200 cm^{-1}; ^{1}H NMR ($CHCl_3$) δ=4.10 (3H, s, CH_3), 6.10 (1H, s, CH), and 7.30—7.90 (5H, m, arom and NH); MS *m/z* 132(M^+—OMe). Found: C, 65.82; H, 5.53; N, 8.49%. Calcd for $C_9H_9NO_2$: H, 66.25; H, 5.56; N, 8.58%.

3-Ethoxy-2,3-dihydro-1-iminoisobenzofuran (3b): Colorless crystals ($CHCl_3$); mp 112 °C; IR (KBr) 1620 and 3140 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.48 (3H, t, *J*=7.0 Hz, CH_3), 4.51 (2H, q, *J*=7.0 Hz,-CH_2-), 6.15 (1H, s, CH), and 7.30—7.73 (5H, m, NH and arom); MS *m/z* 177 (M^+). Found: C, 67.69; H, 6.15; N, 7.96%. Calcd for $C_{10}H_{11}NO_2$: C, 67.76; H, 6.26; N, 7.90%.

3-Butoxy-2,3-dihydro-1-iminoisobenzofuran (3d): Colorless crystals ($CHCl_3$); mp 63 °C; IR (KBr) 1620 and 3100 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.02 (3H, t, *J*=7.0 Hz, CH_3), 1.02—2.03 (4H, m, -CH_2CH_2-), 4.46 (2H, t, CH_2), 6.16 (1H, s, CH), and 7.30—7.72 (5H, m, NH and arom); MS *m/z* 205 (M^+). Found: C, 70.04; H, 7.49; N, 6.64%. Calcd for $C_{12}H_{15}NO_2$: C, 70.22; H, 7.37; N, 6.82%.

4a: Colorless crystals ($CHCl_3$); mp 100 °C (lit, 99 °C[3]).

4b: Colorless crystals ($CHCl_3$); mp 105 °C (lit, 108 °C[3]).

4d: Colorless crystals ($CHCl_3$); mp 92 °C; IR (KBr) 1720 and 3170 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.88 (3H, t, *J*=7.0 Hz, CH_3), 1.13—1.76 (4H, m, -CH_2CH_2-), 3.18—3.66 (2H, m, CH_2), 5.96 (1H, s, CH), and 7.36—8.04 (5H, m, NH and arom); MS *m/z* 205 (M^+). Found: C, 70.25; H, 7.45; N, 6.80%. Calcd for $C_{12}H_{15}NO_2$: C, 70.22; H, 7.37; N, 6.82%.

Reaction of 3a with Methanol in the Presence of DBU. To a solution of **3a** (82 mg, 0.5 mmol) in methanol (4 ml) was added DBU (15 mg, 0.1 mmol) and the solution was stirred at 20 °C for 3 h. After evaporation of methanol, the residue was chromatographed on silica gel using mixture of chloroform and ether (8/1, v/v), to give **4a** (81 mg, ca. 100%).

Reaction of 1 with Water in the Presence of DBU. To a solution of **1** (66 mg, 0.5 mmol) in water (4 ml) was added DBU (45 mg, 0.3 mmol) and the solution was heated at 50 °C for 3 h with stirring. After evaporation of water under vacuum, the residue was chromatographed on silica gel using the mixture of chloroform and methanol (10/1, v/v), to give **6** (70 mg, 93%) and **5** (5 mg, 7%).

Reaction of 1 with 6 in the Presence of DBU. To a solution of **1** (33 mg, 0.25 mmol) and DBU (30 mg, 0.2 mmol) in ethanol (4 ml) was added **6** (37 mg, 0.25 mmol) and the mixture was heated at 50 °C for 3 h with stirring. After evaporation of ethanol the residue was chromatographed on silica gel using the mixture of chloroform and methanol (10/1, v/v), to give **5** quantitatively (70 mg, 100%).

5: Colorless crystals (MeOH); mp 225 °C; IR (KBr) 1700 and 3220 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=5.74 (1H, d, *J*=9.1 Hz, CH), 6.45 (1H, s, CH), 6.63 (1H, d, *J*=9.1 Hz,

OH), 7.40—7.80 (8H, m, arom), and 8.77 (1H, s, NH); MS *m/z* 148 and 132. Found: C, 68.30; H, 4.29; N, 9.76%. Calcd for $C_{16}H_{12}N_2O_3$: C, 68.57; H, 4.32; N, 9.99%.

6: Colorless crystals (MeOH); mp 165 °C (lit, 178,[3] 184[6] °C); IR (KBr) 1700 and 3450 cm^{-1}; ^1H NMR (DMSO-d_6) δ=5.86 (1H, d, J=9.1 Hz, CH), 6.29 (1H, d, J=9.1 Hz, OH), 7.40—7.80 (4H, m, arom), and 8.70—9.00 (1H br, NH); MS *m/z* 149 (M^+). Found: C, 64.22; H, 9.36; N, 4.67%. Calcd for $C_8H_7NO_2$: C, 64.42; H, 9.39; N, 4.73%.

7: This compound was synthesized by alkylation of phthalimide followed by reduction with sodium borohydride according to the method as shown in the literature.[6] Colorless crystals ($CHCl_3$); mp 130 °C (lit, 129 °C[7]).

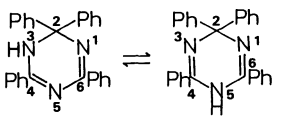
The Crystal and Molecular Structures of 2,2,4,6-Tetraphenyldihydro-1,3,5-triazine Acetone Solvate and 2-Propanol Solvate

Yukie MORI, Yuji OHASHI, and Koko MAEDA*
Department of Chemistry, Faculty of Science, Ochanomizu University,
Otsuka, Bunkyo-ku, Tokyo 112
(Received January 29, 1988)

The crystal and molecular structures of 2,2,4,6-tetraphenyldihydro-1,3,5-triazine acetone solvate (**1**) which turns red on exposure to UV light, and 2-propanol solvate (**2**) which shows no photocoloration, have been determined by the X-ray method. The crystals of both inclusion compounds are monoclinic. For **1** the space group is $P2_1/n$; Z=4, with a=16.385(2), b=11.987(2), c=12.939(2) Å, and β=92.24(2)°. For **2** the space group is $C2/c$; Z=8, with a=21.967(3), b=13.418(1), c=19.576(4) Å, and β=118.73(1)°. The final R values were 0.082 and 0.083 for **1** and **2** respectively. In both crystals, the dihydrotriazine ring exists in 2,3-dihydro form, which is one of the two possible tautomeric forms. In **1** each acetone molecule interacts with only one molecule of tetraphenyldihydrotriazine by N(3)–H(3)···O hydrogen bond, while in **2** tetraphenyldihydrotriazine and 2-propanol molecules are alternately connected by N(3)–H(3)···O and N(5)···H–O hydrogen bonds to construct a ribbon-like structure. It was suggested that the N(3)–H(3)···O–H···N(5) hydrogen bonds which exist in **2** but not in **1** inhibit photocoloration of **2**.

2,2,4,6-Tetraphenyldihydro-1,3,5-triazine (hereafter abbreviated as triazine) was synthesized by Lottermoser in 1896 and reported to exhibit photochromism in the solid state,[1] but the structure of the colored species has been undetermined. It has been reported that triazine exists in an equilibrium mixture of 2,3-dihydro (a) and 2,5-dihydro (b) forms, which are



(a) (b)

prototropic tautomers, in solutions and in the solid state.[2] During the course of the investigation on the photocoloration of triazine we found that triazine forms crystalline inclusion compounds with various solvent molecules having one hetero atom with molar ratio of 1:1 on the recrystallization. These inclusion compounds could be classified into two types in terms of their photochemical behavior. The inclusion compounds composed of acetone, chloroform, tetrahydrofuran or 2-methyltetrahydrofuran turned red or reddish violet on exposure to UV light and the color faded gradually in the dark, while the ones composed of ethanol, 2-propanol or propylamine showed no photocoloration. The crystal and molecular structure of 2,2,4,6-tetraphenyldihydro-1,3,5-triazine ethanol solvate (**3**) has been determined and it was assumed that two types of hydrogen bonds might inhibit the photocoloration of the crystals.[3] In order to confirm the assumption and to reveal the structural differences between photo-active and photo-inactive inclusion compounds, the molecular and crystal structures of the title compounds were determined.

Experimental

Triazine was synthesized by the method of Lottermoser.[1] Colorless plate-like crystals of **1** and **2** were obtained by recrystallization of triazine from acetone or 2-propanol, respectively. In both cases a crystal was sealed in a glass capillary and set up on a RIGAKU AFC-4 diffractometer. Cell parameters were refined by least squares on the basis of 16 and 18 independent 2θ values for **1** and **2** respectively. Crystal data and some experimental conditions are listed in Table 1. Intensities were measured with graphitemonochromated Mo $K\alpha$ or Cu $K\alpha$ radiation, using the ω–2θ scan technique. Background counts were accumulated for 5 s before and after each scan. Three standard reflections were monitored for every 50 reflections and no significant variations in intensities were observed. Reflections of $|F_o|>3\sigma(|F_o|)$ were considered as observed and used for structure determination. Corrections for the Lorentz and polarization factors were made, but no correction for absorption was applied.

The structure of **1** was solved by the direct method with the program MULTAN 78[4] and refined by the full-matrix least squares with the program SHELX 76.[5] All the hydrogen atoms were found on the difference map. The atoms of acetone molecule were disordered between three sets of positions and were treated as rigid molecules with the usual geometry. The occupancy factor for each set was fixed to 0.33333, considering from the temperature factors. The final refinement was made with the anisotropic temperature factors for non-hydrogen atoms of triazine molecule and the isotropic ones for hydrogen atoms and the atoms of acetone molecule. The quantity minimized was $\sum w(|F_o|-|F_c|)^2$ and $w=[\sigma^2(|F_o|)+0.0021|F_o|^2]^{-1}$. The final R and R_w values became 0.082 and 0.092 for 3488 observed reflections. No peaks higher than 0.35 e Å^{-3} were found on the final difference map.

The procedure of the structure determination for **2** was similar to that for **1**. Some of hydrogen atoms were found on the difference map. The others were calculated geometrically and refined with C–H distances constrained to 1.00 Å. The atoms of 2-propanol molecule were disordered between three sets of positions but were refined with no constraint. The occupancy factors were fixed to 0.5 for one set and 0.25 for the other two sets. The final refinement was made with the anisotropic temperature factors for non-hydrogen atoms of triazine molecule and the isotropic ones for hydrogen

atoms and the atoms of 2-propanol. The weighting scheme was $w=[\sigma^2(|F_o|)+0.0313|F_o|^2]^{-1}$. The final R and R_w values became 0.083 and 0.110 for 2997 observed reflections. No peaks higher than 0.31 e Å^{-3} were found on the final difference map. The atomic scattering factors were taken from the International Tables for X-Ray Crystallography.[6] The final atomic coordinates and equivalent isotropic temperature factors for non-hydrogen atoms are given in Tables 2 and 3. The lists of the anisotropic temperature factors for non-hydrogen atoms, atomic coordinates and temperature factors for hydrogen atoms, and the observed and calculated structure factors are kept in the office of the Chemical Society of Japan (Document No. 8814). The computation was carried out on HITAC M-280 computer at the Computer Center of the University of Tokyo.

Results and Discussion

The structure of triazine with the atom-numbering in **1** is shown in Fig. 1. For **2** the same numbering

Table 3. Final Atomic Coordinates Multiplied by 10^4 and Equivalent Thermal Parameters, B_{eq}(Å^2), for Non-Hydrogen Atoms of 2-Propanol Solvate (**2**). scheme is used. The crystal structures of **1** and **2** are shown in Fig. 2. Selected bond distances and angles of **1** and **2** are listed in Table 4, and the torsion angles, the dihedral angles and the hydrogen bond distances of **1** and **2** are listed in Table 5, together with the corresponding ones of **3**.[3] The molecular structures of **1** and **2** are closely similar to that of **3**. During the refinements the difference maps showed that N(3), not N(5), is bound to a hydrogen atom, that is, the dihydrotriazine exists in 2,3-dihydro form, in both **1** and **2**, as was reported in **3**. The triazine structure is also confirmed by the bond distances: N(3)-C(4) is longer than N(5)-C(4). The dihydrotriazine ring in **1** and **2** was found to exist in the boat conformation with the apexes of C(2) and N(5), as was observed in **3**, but the dihedral angles between the least-squares plane of N(1), C(6), C(4), and N(3) and the plane through N(1), C(2), and N(3) or that through C(4), N(5), and C(6) varied with the kind of included solvent. In **1** these dihedral angles are smaller than

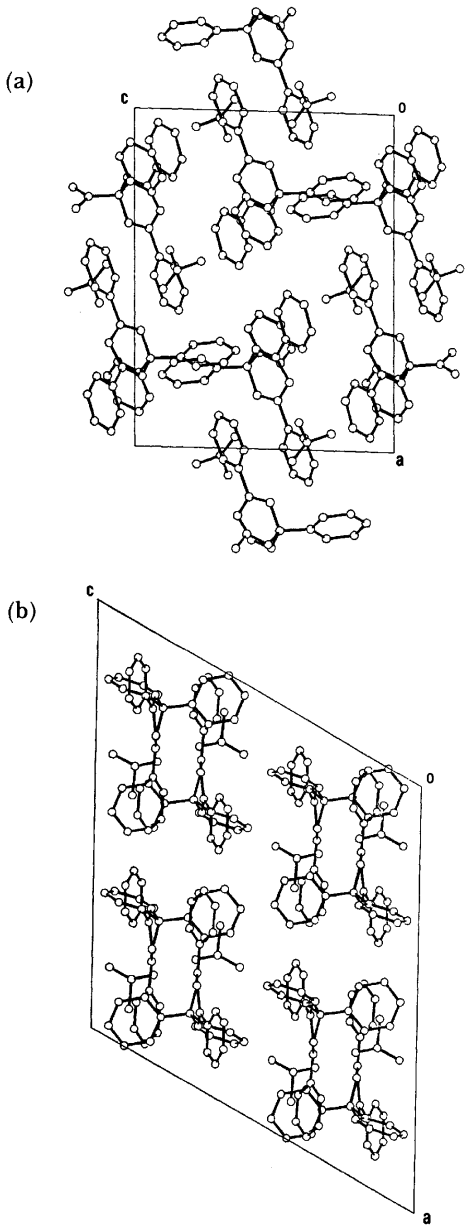

Fig. 2. Crystal structure viewed along the b axis. (a) **1** and (b) **2**. For the solvent molecules the atoms with prime or double prime are omitted.

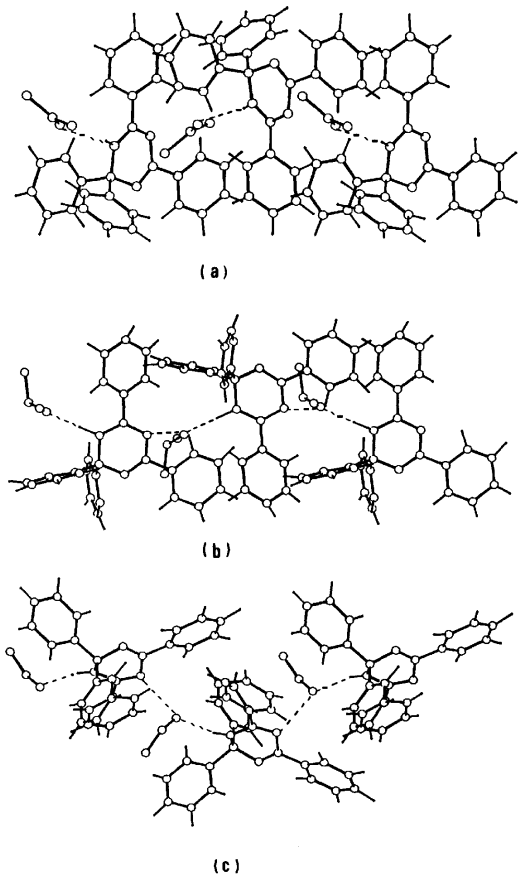

Fig. 3. Hydrogen bonding scheme drawn schematically for (a) **1**, (b) **2**, and (c) **3**. The hydrogen bonds are indicated by broken lines. For the solvent molecules the atoms with prime or double prime are omitted.

those in **2** or **3**, which means that the dihydrotriazine ring in **1** is more planar. The corresponding bond distances and angles of the three inclusion compounds are almost consistent within experimental error, except that the angle C(2)-N(3)-C(4) of **1** (121.6°) is slightly larger than that of **2** (119.4°) or of **3** (119.5°). In the three inclusion compounds the torsion angles N(5)-C(6)-C(7)-C(8) and N(3)-C(4)-C(13)-C(14) are relatively small, indicating that the two phenyl rings at 4- and 6-positions are nearly coplanar with the dihydrotriazine ring. On the other hand, the two phenyl rings at 2-position are perpendicular to the dihydrotriazine ring. The two perpendicular phenyl rings serve to prevent the close packing of triazine molecules and in both crystals of **1** and **2** each acetone or 2-propanol molecule is placed in a cavity which is formed by phenyl rings of neighboring triazines, respectively. In both crystals solvent molecules are disordered, probably since there is enough space around them. Oxygen atoms in both solvent molecules are located near N(3) of triazine and involved in hydrogen bonds. However, the hydrogen bonding scheme is significantly different between **1** and **2**. As is shown in Fig. 3(b), the triazine and solvent molecules in **2** are alternately connected to form an infinite helix around the two-fold screw axis by the two types of hydrogen bond: N(3)-H(3)···O and N(5)···H-O. This hydrogen bonding scheme was also seen in **3** (Fig. 3(c)) and the pitch of the helix, that is, the value of b of **2** (13.418 Å) is similar to that of **3** (13.527 Å). On the other hand, in the case of **1**, although the crystal packing is similar to that of **2** or **3**, each acetone molecule interacts with one triazine molecule by the hydrogen bond of N(3)-H(3)···O and each hydrogen bonding pair is isolated (Fig. 3(a)). The distances N(5)···O and N(3)···O of **2** are similar to those of **3**, but the distance N(3)···O of **1** is longer as is shown in

Table 5. Comparison of the Torsion Angles, the Dihedral Angles[a] (deg) and the Hydrogen Bond Distances (Å)

N(3)-O(31″)	3.17(1)	2.88(1)	
O(31)-N(5)		2.94(1)	2.90(1)
O(31′)-N(5)		2.92(1)	2.78(2)
O(31″)-N(5)		2.90(1)	

a) [1]: the angle between the least-squares plane of N(1), C(6), N(3), and C(4) (plane A) and that of C(19), C(20), C(21), C(22), C(23), and C(24), [2]: the angle between the plane A and the least-squares plane of C(25), C(26), C(27), C(28), C(29), and C(30), [3]: the angle between the plane A and the plane of N(1), C(2), and N(3), [4]: the angle between the plane A and the plane of C(4), N(5), and C(6). b) The distances of O(31)···H(3), O(31′)···H(3), and O(31″)···H(3) are 2.51(3), 2.35(4), and 2.31(3)Å, respectively.

Table 5. In **2** and **3** the solvent molecules seem to interact more strongly with triazine through the two types of hydrogen bonds than in **1**. Except for the hydrogen bonds, there are no unusually short contacts in **1** and **2** as well as **3**.

On the basis of the crystal structures of the three inclusion compounds **1**, **2**, and **3** and the molecular structures of triazine in them, the difference in the photochemical behavior between the two types of inclusion compounds is probably ascribable to the difference in the hydrogen bonding scheme. Although the structure of the colored species is still open to the question, it is strongly suggested that the N(3)-H(3)···O-H···N(5) hydrogen bonds, by which triazine and solvent molecules are alternately connected in **2** and **3**, inhibit the photocoloration. If the colored species is formed on irradiation, because of the instability of the electronic state, it would easily change back to the stable initial state due to the chain like hydrogen bonds. On the other hand, the crystal of **1** exhibits the photocoloration because each N(3)-H(3)···O hydrogen bond is isolated.

Studies on Lignan Lactone Antitumor Agents. V. 1-*O*-(Aminoethyl) Ether of 4′-*O*-Demethyl-1-epipodophyllotoxin

Hitoshi SAITO, Yoshio NISHIMURA,* Shinichi KONDO, Keiko KOMURO, and Tomio TAKEUCHI
Institute of Microbial Chemistry, 3-14-23 Kamiosaki, Shinagawa-ku, Tokyo 141
(Received February 2, 1988)

1-*O*-(2-Aminoethyl)-4′-*O*-demethyl-1-epipodophyllotoxin derivatives were synthesized by a stereoselective BF_3-catalyzed coupling of 4′-*O*-benzyloxycarbonyl-1-epipodophyllotoxin with the corresponding 2-aminoethanol derivatives, and with ethylene glycol followed by reductive amination of its aldehyde. Some 1-*O*-(2-aminoethyl) ethers of 4′-*O*-demethyl-1-epipodophyllotoxin prolonged markedly survival periods in mice with leukemia L-1210.

Due to the clinical efficacy and intriguing mechanism of action, the synthetic podophyllotoxin glycosides, VP-16-213 (**1**) and VM-26 (**2**)[1,2] have attracted considerable interest in the synthesis of new active analogues of podophyllotoxin. In the previous paper of this series,[3-5] the systematic chemical modification of podophyllotoxin and α-peltatin based on glycosidation with amino sugar derivatives were reported. 2-Amino-, 3-amino-, and 2-dimethylamino-β-D-glucosidic variants (**3**, **4**, and **5**) were found to have the superior antitumor activity to **1**.

Changes in the 1-*O*-glycosyl group are also interest for simplified structure which might retain the activity of **3**, **4**, and **5**, and be accessible to practical industrialization. The basic amino substituent of the sugar moiety is proved to be important for increasing the activity, but considerable simplification in the sugar structure might be permitted so long as the amino group is retained in the same distance from the linkage at C-1. In the chemical modification of podophyllotoxin glycosides, it also appears that β-configuration at C-1 of aglycone, podophyllotoxin, is indispensable for increasing an antitumor activity and decreasing a toxic side effect.[1]

Here we wish to present the synthesis of 1-*O*-(aminoethyl)-4′-*O*-demethyl-1-epipodophyllotoxin derivatives (**8a—8j** and **12k—12m**) having a β-configuration at C-1, and their biological activities. Acid-catalyzed coupling using boron trifluoride diethyl etherate, as a key step, was successfully used in these syntheses. The synthesis was achieved by the following three methods. Condensation of 4′-*O*-benzyloxycarbonyl-4′-*O*-demethyl-1-epipodophyllotoxin (**6**) with 2-(benzyloxycarbonylamino)ethanol analogues (**7a**, **7b**, and **7c**) in dichloromethane in the presence of $BF_3 \cdot OEt_2$,[6,7] followed by removal of the masking groups gave the corresponding 1-*O*-(2-aminoethyl)-4′-*O*-demethyl-1-epipodophyllotoxins (**8a**, **8b** and **8c**), respectively, in good yields. Compound **8a** was further transformed into dimethylamino and diethylamino derivatives **8e** and **8f** upon a reductive amination with the corresponding aldehydes using sodium cyanotrihydroborate.[8] Alternative BF_3-catalyzed coupling was successfully accomplished when **6** was added into a solution of 2-(phenylamino)-ethanol (**7d**) and 2-(dialkylamino)ethanol analogues (**7e—7j**) with $BF_3 \cdot OEt_2$ in dichloromethane. Thus, 1-*O*-[2-(phenylamino)ethyl]-4′-*O*-demethyl-1-epipodophyllotoxin (**8d**) and 1-*O*-[2-(dialkylamino)ethyl]-4′-*O*-demethyl-1-epipodophyllotoxins (**8e—8j**) were synthesized by one step in excellent yields. BF_3-catalyzed coupling in dichloromethane was also successful in a formation of an ether bond with ethylene glycol, and 1-*O*-(2-hydroxyethyl)-4′-*O*-benzyloxycarbonyl-4′-*O*-demethyl-1-epipodophyllotoxin (**9**) was obtained in an excellent yield. Compound **9** was converted to an aldehyde **10** by Swern oxidation, and the successive reduction with the corresponding alkylamines **11c**, **11f**, and **11k—12m** by sodium cyanotrihydroborate gave 1-*O*-[2-(alkylamino)ethyl]-4′-*O*-demethyl-1-epipodophyl-

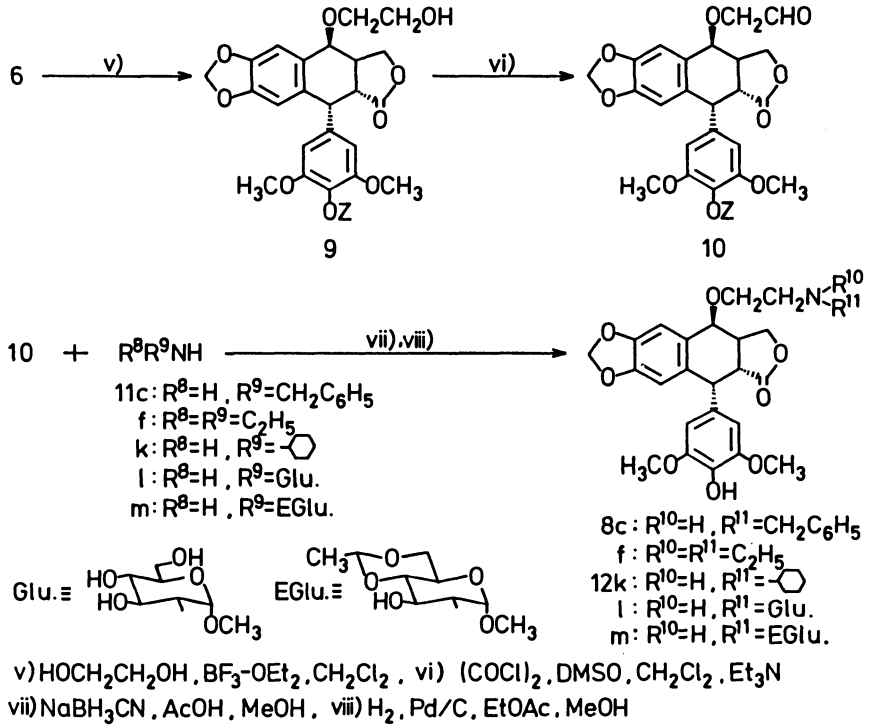

Scheme 2.

Table 1. The Antitumor Activities of **1**, **5**, and 1-*O*-(2-Aminoethyl) Ethers of 4′-*O*-Demethyl-1-epipodophyllotoxin (T/C%)

Dose (μg/mouse)	Compound No.														
	1	**5**	**8a**	**8b**	**8c**	**8d**	**8e**	**8f**	**8g**	**8h**	**8i**	**8j**	**12k**	**12l**	**12m**
25	184	438	130	188	139	109	270	139	72	113	145	172	108	95	102
6.25	139	164	162	271	108	103	141	108	72	104	133	135	108	95	102

The T/C values are the percentage ratios of the mean survival period of five treated mice to the mean survival period of the control group. L-1210 cells (10^6 cells) were inoculated intraperitoneally and the intraperitoneal treatment was started on day 1 and continued for 10 days.

lotoxins (**8c**, **8f**, and **12k—12m**) in good overall yields. Condensations in all cases were carried out stereoselectively by the same fashion through a benzyl cation at C-1 generated by $BF_3 \cdot OEt_2$ as has been reported in a previous synthesis.[4,6,9]

Synthesized compounds **8a—8j** and **12k—12m**, compared with **1** and **5**, were screened for antitumor activities using lymphocytic leukemia L-1210 in mice. Test results are shown in Table 1. Compounds **8a**, **8b**, **8e**, **8i**, and **8j** produced a good survival time increase in mice with leukemia L-1210. Interestingly, prototypal structures such as **8b** and **8e** showed a significant antitumor activity alongside **1** and **5**. These results suggest further elaboration of the amino side chain to optimize their structures. Further study for antitumor activity of synthesized compounds is in progress.

Experimental

General Methods. Melting points were determined with a Yamato apparatus and were uncorrected. IR spectra were determined on a Hitachi Model 260-10 and Jasco IR-810 spectrophotometers. Optical rotations were measured with a Perkin-Elmer Model 241 polarimeter. ^1H NMR spectra were recorded with Varian EM-390, Jeol GX-270 and Jeol GX-400 spectrometers. Chemical shifts are expressed in δ values (ppm) with tetramethylsilane as an internal standard. The mass spectra was taken by a Jeol D-300 for fast atom bombardment (FAB).

1-*O*-(2-Aminoethyl)-4′-*O*-demethyl-1-epipodophyllotoxin (8a). To a solution of a mixture of **6** (320 mg) and 2-(benzyloxycarbonylamino)ethanol (142 mg) in dichloromethane (8 ml) was added $BF_3 \cdot OEt_2$ (200 μl) at −10 °C, and the mixture was stirred at −10 °C for 1 h. After being quenched with pyridine (200 μl), the solution was washed with water and dried over $MgSO_4$. Evaporation of the solvent gave a solid. The solid was dissolved in ethyl acetate–methanol (1:1, 30 ml), and the solution was stirred under atmosphere of hydrogen in the presence of 10% Pd/C (40 mg) at room temperature for 1 h. After removal of catalyst, the solvent was evaporated to afford a solid. The solid was chromatographed on a column of silica gel with chloroform–methanol (4:1) to give a solid of **8a** (191 mg, 72%). The solid was recrystallized from methanol to give a crystal of **8a**: mp 182—184 °C; $[\alpha]_D^{23}$ −46° (*c* 0.4, MeOH); IR (KBr) 1775, 1760, 1483 1230, and 1110 cm^{-1}; ^1H NMR (C_5D_5N, 270 MHz) δ=3.18 (3H m, H-2 and $-OCH_2C\underline{H}_2N-$), 3.58 (1H dd, *J*=5 and 14 Hz, H-3), 3.71 (6H s, $2\times OCH_3$), 3.84 and 3.98 (1H each m, $-OC\underline{H}_2CH_2N-$), 4.39 (1H t, *J*=8 Hz, H-11), 4.51 (1H dd, *J*=8 and 11 Hz, H-11), 4.62 (1H d, *J*=3.0 Hz, H-1), 4.76 (1H d, *J*=5 Hz, H-4), 5.98 (2H d, methylene), 6.66 (2H s, H-2′ and 6′), 6.74 (1H s, H-5), and 7.15 (1H s, H-8); MS (FAB) *m/z* 444 (M^++H) and 383.

1-*O*-[2-(Dimethylamino)ethyl]-4′-*O*-demethyl-1-epipodophyllotoxin (8e). To a solution of 2-(dimethylamino)-ethanol (30 mg) in dichloromethane (1 ml) was added $BF_3 \cdot OEt_2$ (110 μl) at −15 °C and the mixture was stirred at −15 °C for 10 min. Then to the mixture was added dropwise a solution of **6** (108 mg) in dichloromethane (1 ml) at −15 °C, and the mixture was stirred at −15 °C for 30 min. The similar work-up and purification to those used for preparation of **8a** were used (43% overall yield).

From **8a**: To a solution of **8a** (88 mg) in methanol (3 ml) was added 37% aqueous solution of formaldehyde (50 μl) and sodium cyanoborohydride (30 mg), and the mixture was stirred at room temperature for 30 min. After being diluted with dichloromethane (10 ml), the solution was washed with water, dried over $MgSO_4$, and filtered. The filtrate was evaporated to give a solid, which was subjected to preparative thin-layer chromatography on silica gel developed with chloroform–methanol (4:1). A solid of **8e** was obtained in a yield of 90%. The solid was recrystallized from methanol to give a crystal of **8e**: 195—197 °C; $[\alpha]_D^{22}$ −57° (*c* 0.5, MeOH); IR (KBr) 1760, 1483, 1227, 1108, and 1080 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.27 (6H s, $2\times NCH_3$), 2.53 (2H t, *J*=6 Hz, $-OCH_2C\underline{H}_2N-$), 2.87 (1H m, H-2), 3.39 (1H dd, *J*=5.1 and 14 Hz, H-3), 3.61 and 3.80 (1H each m, $-OC\underline{H}_2CH_2N-$), 3.77 (6H s, $2\times OCH_3$), 4.35 (2H m, H-11), 4.45 (1H d, *J*=3.4 Hz, H-1), 4.59 (1H d, *J*=5.1 Hz, H-4), 5.95 and 5.99 (2H ABq, *J*=1.5 Hz, methylene), 6.26 (2H s, H-2′ and 6′), 6.54 (1H s, H-5), and 6.84 (1H s, H-8); MS (FAB) *m/z* 472 (M^++H) and 383.

1-*O*-(2-Hydroxyethyl)-4′-*O*-benzyloxycarbonyl-4′-*O*-demethyl-1-epipodophyllotoxin (9). To a solution of **6** (1 g) and ethylene glycol (0.2 ml) in dichloromethane (15 ml) was added dropwise a solution of $BF_3 \cdot OEt_2$ (0.6 ml) in dichloromethane (1 ml) at −15 °C, and the mixture was stirred at −15 °C for 2 h. After being quenched with pyridine (0.6 ml), the solution was washed with water and dried over $MgSO_4$. Evaporation of the solvent gave a solid, which was subjected to column chromatography on silica gel. Elution with toluene–acetone (5:1) gave **9** (980 mg, 90%), which was recrystallized from methanol: mp 182—183 °C; $[\alpha]_D^{22}$ −51° (*c* 0.66, $CHCl_3$); IR (KBr) 1770, 1602, 1482, 1234, and 1125 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.88 (1H m, H-2), 3.40 (1H dd, *J*=14 and 5.1 Hz, H-3), 3.68 (6H s, $2\times OCH_3$), 4.51 (1H, d, *J*=3 Hz, H-1), 4.64 (1H d, *J*=5.1 Hz H-4), 5.26 (2H s, $OC\underline{H}_2Ph$), 6.28 (2H s, H-2′ and 6′), 6.55 (1H s, H-5), 6.85 (1H s, H-8), and 7.15—7.45 (5H, Ph); MS (FAB) *m/z* 579 (M^++H), 517, and 443.

1-*O*-(2-Oxoethyl)-4′-*O*-demethyl-1-epipodophyllotoxin (10). A solution of dichloromethane (0.5 ml) and dimethyl sulfoxide (120 μl) was added to a stirred solution of dichloromethane (2 ml) and oxallyl dichloride (70 μl) at −60 °C. To the solution was added a solution of **9** (360 mg) in dichloromethane (2 ml) within 5 min, and the mixture was stirred at −60 °C for 15 min. Triethylamine (0.4 ml) was added and the reaction mixture was stirred for 5 min and then allowed to warm to room temperature. After being quenched with water, the mixture was extracted with dichloromethane (10 ml). The organic layer was washed with a saturated NaCl solution and dried over $MgSO_4$. The filtered solution was evaporated to give a solid, which was subjected to a column chromatography on silica gel. Elution with toluene–acetone (2:1) gave a solid of **10** (250 mg, 69%). The solid was crystallized from methanol: mp 96—98 °C; $[\alpha]_D^{22}$ −57 ° (*c* 0.48, $CHCl_3$); IR (KBr) 1770, 1602, 1482, 1235, and 1127 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=3.67 (6H s, $2\times OCH_3$), 5.26 (2H s, $OC\underline{H}_2Ph$), 5.98 (2H s, methylene), 6.28 (2H s, H-2′ and 6′), 6.59 (1H s, H-8), 7.25—7.50 (5H broad s, Ph), and 9.66 (1H s, CHO); MS (FAB) *m/z* 599 (M^++Na) and 517.

Methyl 2-Amino-2-deoxy-4,6-*O*-ethylidene-α-D-glucopyranoside (11m). To a suspension of methyl 2-benzyloxy-

carbonylamino-2-deoxy-α-D-glucopyranoside (100 mg) and acetaldehyde diethyl acetal (0.3 ml) in dichloromethane (5 ml) was added *p*-toluenesulfonic acid (5 mg) at room temperature, and the mixture was stirred for 2 h. The solution was washed with a saturated $NaHCO_3$ solution and water, and dried over $MgSO_4$. Evaporation of the filtered solution gave a solid, which was crystallized from methanol to give a crystal of methyl 2-benzyloxycarbonylamino-2-deoxy-4,6-*O*-ethylidene-α-D-glucopyranoside (**13**) (88 mg, 81%): mp 176—177 °C; $[\alpha]_D^{22}$ +65° (*c* 0.5, $CHCl_3$). Compound **13** (70 mg) was dissolved in ethanol (5 ml), and the solution was stirred under atmosphere of hydrogen in the presence of 10% Pd/C (10 mg) at room temperature for 1 h. After removal of catalyst, the solvent was evaporated to afford solid. The solid was subjected to a next step without purification.

13: IR (KBr) 1693, 1542, 1280, and 1130 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=1.36 (3H d, CH_3 of ethylidene), 3.34 (3H s, OCH_3), 5.13 (2H s, OCH_2Ph), and 7.3—7.5 (5H m, Ph); MS (FAB) *m/z* 354 (M^++H) and 322.

1-*O*-[2-(Cyclohexylamino)ethyl]-4′-*O*-demethyl-1-epipodophyllotoxin (12k). A solution of cyclohexylamine (20 mg) and sodium cyanoborohydride (10 mg) in methanol (2 ml) was adjusted pH value to 4—5 with acetic acid, and to the solution was added **10** (58 mg), and then the mixture was stirred at room temperature for 1 h. After dilution with chloroform (10 ml), the mixture was washed with a saturated $NaHCO_3$ solution and water, and dried over $MgSO_4$. Evaporation of the solvent gave a solid, which was dissolved in ethyl acetate–methanol (1:1). The mixture was stirred under atmosphere of hydrogen in the presence of 10% Pd/C (10 mg) at room temperature for 1 h. After removal of catalyst, evaporation of the solvent gave a solid. The solid was subjected to preparative thin-layer chromatography on silica gel with chloroform–methanol (4:1) to give a solid of **12k** (34 mg, 64%). The solid was recrystallized from methanol to give a crystal of **12k**: mp 169—171 °C; $[\alpha]_D^{22}$ −57° (*c* 0.5, $CHCl_3$); IR (KBr) 2935, 1765, 1482, 1228, and 1110 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=1.0—2.0 (10H m, methylene protons of cyclohexyl), 2.45 (1H m, methine proton of cyclohexyl), 2.83 (2H t, *J*=5 Hz, $-OCH_2C\underline{H}_2N-$), 3.40 (1H dd, *J*=5 and 14 Hz, H-3), 3.77 (6H s, 2×OCH_3), 4.34 (2H d, *J*=9 Hz, H-11), 4.46 (1H d, *J*=3 Hz, H-1), 4.60 (1H d, *J*=5 Hz, H-4), 5.97 (2H m, methylene), 6.28 (2H s, H-2′ and 6′), and 6.55 (1H s, H-5); MS (FAB) *m/z* 526 (M^++H) and 383.

8b: **8b** was obtained from **6** (0.6 mmol) and 2-benzyloxycarbonyl-2-(methylamino)ethanol (0.7 mmol) by the similar procedure for the preparation of **8a** (yield 73%): mp 182 °C (crystallized from ethanol); $[\alpha]_D^{23}$ −60° (*c* 0.5, MeOH); IR (KBr) 1775, 1480, 1328, 1227 and 1115 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.45 (3H s, NCH_3), 2.77 (2H m, $OCH_2C\underline{H}_2N$), 2.87 (1H m, H-2), 3.37 (1H dd, *J*=5.4 and 14 Hz, H-3), 3.64 and 3.82 (1H each m, $-OC\underline{H}_2CH_2N-$), 3.76 (6H s, 2×OCH_3), 4.34 (2H d, *J*=9 Hz, H-11), 4.45 (1H d, *J*=3.4 Hz, H-1), 4.76 (1H d, *J*=5.4 Hz, H-4), 5.97 (2H d, methylene), 6.26 (2H s, H-2′ and 6′), 6.54 (1H s, H-5), and 6.81 (1H s, H-8); MS (FAB) *m/z* 458 (M^++H) and 383.

8c: **8c** was obtained from **6** (0.6 mmol) and 2-benzyloxycarbonyl-2-(benzylamino)ethanol (0.7 mmol) by the similar procedure for the preparation of **8a** (yield 70%). **8c** was also prepared from **10** (0.1 mmol) and benzylamine (0.2 mmol) by the similar procedure for the preparation of **12k** (yield 75%): mp 146—148 °C (recrystallized from methanol); $[\alpha]_D^{22}$ −51° (*c* 0.5, $CHCl_3$); IR (KBr) 1763, 1482, 1228, and 1108 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=2.82 (2H t, *J*=5 Hz, $-OCH_2C\underline{H}_2N-$), 3.10 (1H m, H-2), 3.36 (1H dd, *J*=5 and 14 Hz, H-3), 3.75 (6H s, 2×OCH_3), 3.81 (2H s, $OC\underline{H}_2Ph$), 4.32 (2H d, *J*=9 Hz, H-11), 4.43 (1H d, *J*=3 Hz, H-1), 4.59 (1H d, *J*=5 Hz, H-4), 5.95 (2H m, methylene), 6.26 (2H s, H-2′ and 6′), 6.53 (1H s, H-5), and 6.81 (1H s, H-8); MS (FAB) *m/z* 534 (M^++H) and 383.

8d: **8d** was obtained from **6** (0.2 mmol) and 2-(phenylamino)ethanol (0.3 mmol) by the similar procedure for the preparation of **8e** from **6** (yield 67%): mp 157—158 °C (recrystallized from methanol); $[\alpha]_D^{20}$ −60° (*c* 0.4, $CHCl_3$); IR (KBr) 1779, 1619, 1520, 1498, 1240, and 1121 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.87 (1H m, H-2), 3.35 (3H m, H-3 and $-OCH_2C\underline{H}_2N-$), 3.73 and 3.87 (1H each m, $-OC\underline{H}_2CH_2N-$), 3.76 (6H s, 2×OCH_3), 4.30 (2H m, H-11), 4.45 (1H d, *J*=3.4 Hz, H-1), 4.61 (1H d, *J*=5 Hz, H-4), 5.40 (1H broad s, 4′-OH), 5.97 and 5.99 (2H ABq, *J*=1.3 Hz, methylene), 6.25 (2H s, H-2′ and 6′), 6.56 (1H s, H-5), 6.61, 6.74 and 7.19 (2H, 1H and 2H each m, Ph), and 6.77 (1H s, H-8); MS (FAB) *m/z* 520 (M^++H) and 383.

8f: **8f** was obtained from **6** (0.2 mmol) and 2-(diethylamino)ethanol (0.3 mmol) by the similar procedure for the preparation of **8e** from **6**, and from **8c** (0.2 mmol) by the similar procedure for the preparation of **8e** from **8a** in yields of 80 and 88%, respectively. **8f** was also prepared from **10** (0.1 mmol) and diethylamine (0.2 mmol) by the similar procedure for the preparation of **12k** (yield 69%): mp 196—198 °C (recrystallized from methanol); $[\alpha]_D^{22}$ −73° (*c* 0.5, $CHCl_3$); IR (KBr) 1760, 1482, 1228, and 1110 cm^{-1}; ^1H NMR ($CDCl_3$ 90 MHz) δ=1.05 (6H t, *J*=7 Hz, 2×$-NCH_2C\underline{H}_3$), 2.62 (4H q, *J*=7 Hz, 2×$NC\underline{H}_2CH_3$), 2.70 (2H t, *J*=6 Hz, $-OCH_2C\underline{H}_2N-$), 2.90 (1H m, H-2), 3.37 (1H dd, *J*=5 and 14 Hz, H-3), 3.77 (6H s, 2×OCH_3), 4.36 (2H d, *J*=9 Hz, H-11), 4.47 (1H d, *J*=3 Hz, H-1), 4.60 (1H d, *J*=5 Hz, H-4), 5.98 (2H m, methylene), 6.27 (2H s, H-2′ and 6′), 6.54 (1H s, H-5), and 6.86 (1H s, H-8); MS (FAB) *m/z* 500 (M^++H) and 383.

8g: **8g** was obtained from **6** (0.2 mmol) and 2-(cyclopentylamino)ethanol (0.3 mmol) by the similar procedure for the preparation of **8e** from **6** (yield 81%): mp 227—228 °C (recrystallized from methanol); $[\alpha]_D^{22}$ −48° (*c* 0.5, MeOH); IR (KBr) 1758, 1610, 1482, 1225, 1108, and 1080 cm^{-1}; ^1H NMR ($CDCl_3/C_5D_5N$=2/1, 270 MHz) δ=1.8—2.0 and 2.9—3.4 (4H and 8H each m, H-2, H-3 and pyrrolidine), 3.68 (6H s, 2×OCH_3), 3.96 and 4.06 (1H each m, $-OC\underline{H}_2CH_2N-$), 4.31 (2H m, H-11), 4.59 (1H d, *J*=3.8 Hz, H-1), 5.92 (2H s, methylene), 6.36 (2H s, H-2′ and 6′), 6.59 (1H s, H-5), and 6.97 (1H s, H-8); MS (FAB) *m/z* 498 (M^++H) and 383.

8h: **8h** was obtained from **6** (0.2 mmol) and 2-(2-hydroxyethyl)pyrrolidone (0.3 mmol) by the similar procedure for the preparation of **8e** from **6** (yield 91%): mp 212—214 °C (recrystallized from ethanol); $[\alpha]_D^{22}$ −82° (*c* 0.8, $CHCl_3$); IR (KBr) 1762, 1682, 1610, 1480, 1220, and 1110 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.99 (2H m, $-NCOCH_2C\underline{H}_2-$), 2.38 (2H t, *J*=8 Hz, $-NCOC\underline{H}_2CH_2-$), 2.89 (1H m, H-2), 3.77 (6H s, 2×OCH_3), 4.29 (2H m, H-11), 4.47 (1H d, *J*=3 Hz, H-1), 4.60 (1H d, *J*=5.1 Hz, H-4), 5.40 (1H s, 4′-OH), 5.98 and 6.00 (2H ABq, *J*=1.3 Hz, methylene), 6.24 (2H s, H-2′ and 6′), 6.56 (1H s, H-5), and 6.77 (1H s, H-8); MS (FAB) *m/z*

512 (M^++H) and 383.

8i: **8i** was obtained from **6** (0.2 mmol) and 1-piperidineethanol (0.3 mmol) by the similar procedure for the preparation of **8e** from **6** (yield 73%): mp 199—200 °C (recrystallized from methanol); $[\alpha]_D^{23}$ −73° (*c* 0.4, $CHCl_3$); IR (KBr) 1772, 1481, 1237, 1223, and 1120 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.4—1.65 (6H m, piperidine), 2.45 (4H t, *J*=4 Hz, 2X-NCH_2- of piperidine), 2.56 (2H t, *J*=6 Hz, -OCH_2CH_2N-), 2.85 (1H m, H-2), 3.37 (1H dd, *J*=5.1 and 14 Hz, H-3), 3.76 (6H s, 2XOCH_3), 4.35 (2H m, H-11), 4.45 (1H d, *J*=3.0 Hz, H-1), 4.60 (1H d, *J*=5.1 Hz, H-4), 5.40 (1H s, 4'-OH), 5.95 and 5.98 (2H ABq, *J*=1.3 Hz, methylene), 6.26 (2H s, H-2' and 6'), 6.53 (1H s, H-5), and 6.88 (1H s, H-8); MS (FAB) *m/z* 512 (M^++H).

8j: **8j** was obtained from **6** (0.2 mmol) and 4-(2-hydroxyethyl)morpholine (0.3 mmol) by the similar procedure for the preparation of **8e** from **6** (yield 80%): mp 220—224°C (recrystallized from methanol); $[\alpha]_D^{23}$ −73° (*c* 0.5, $CHCl_3$); IR (KBr) 1774, 1480, 1230, and 1120 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=2.4—2.7 (6H m, -OCH_2CH_2N- and 2X-NCH_2- of morpholine), 2.92 (1H m, H-2), 3.40 (1H dd, *J*=5 and 14 Hz, H-3), 3.77 (6H s, 2XOCH_3), 4.46 (1H d, *J*=3 Hz, H-1), 4.63 (1H d, *J*=5 Hz, H-4), 6.00 (2H broad s, methylene), 6.30 (2H s, H-2' and 6'), 6.56 (1H s, H-5), and 6.89 (1H s, H-8); MS (FAB) *m/z* 514 (M^++H) and 383.

12l: **12l** was obtained from **10** (0.1 mmol) and methyl 2-amino-2-deoxy-α-D-glucopyranoside (0.2 mmol) by the similar procedure for the preparation of **12k** (yield 73% based on **10**): mp 178—180 °C (recrystallized from methanol); $[\alpha]_D^{23}$ +14° (*c* 0.5, MeOH); IR (KBr) 1763, 1482, 1230, and 1112 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=3.36 and 3.76 (3H and 6H each s, 3XOCH_3), 4.33 (2H d, *J*=9 Hz, H-11), 4.46 (1H d, *J*=3 Hz, H-1), 4.60 (1H d, *J*=5 Hz, H-4), 5.86 (1H d, *J*=3 Hz, H-1 of glucopyranoside), 5.97 (2H broad s, methylene), 6.26 (2H s, H-2' and 6'), 6.56 (1H s, H-5), and 6.81 (1H s, H-8); MS (FAB) *m/z* 620 (M^++H) and 383.

12m: **12m** was obtained from **10** (0.1 mmol) and methyl 2-amino-2-deoxy-4,6-*O*-ethylidene-α-D-glucopyranoside (0.2 mmol) by the similar procedure for the preparation of **12k** (yield 59% based on **10**): mp 179—181 °C (recrystallized from methanol); $[\alpha]_D^{22}$ +7° (*c* 0.5, $CHCl_3$); IR (KBr) 1762, 1482, 1228, and 1110 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz) δ=1.36 (3H d, *J*=5 Hz, CH_3 of ethylidene), 3.36 and 3.76 (3H and 6H each s, 3XOCH_3), 4.35 (2H d, *J*=9 Hz, H-11), 4.46 (1H d, *J*=3 Hz, H-1), 4.61 (1H d, *J*=5 Hz, H-4), 5.98 (2H m, methylene), 6.27 (2H s, H-2' and 6'), 6.56 (1H s, H-5), and 6.81 (1H s, H-8); MS (FAB) *m/z* 646 (M^++H) and 607 and 515.

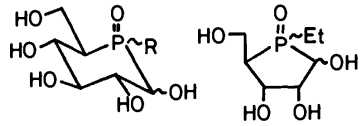
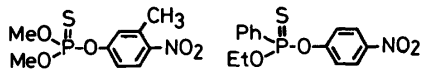
Synthesis and Structural Analysis of 5-Deoxy-3-*O*-methyl-5-*C*-[(*R*)- and (*S*)-phenylphosphinothioyl]-α- and β-D-xylopyranoses

Tadashi HANAYA, Nobuyuki SHIGETOH, and Hiroshi YAMAMOTO*
Department of Chemistry, Faculty of Science, Okayama University,
Tsushima, Okayama 700
(Received February 3, 1988)

Treatment of 5-deoxy-5-iodo-1,2-*O*-isopropylidene-3-*O*-methyl-α-D-xylofuranose with ethyl phenylphosphinothioate in the presence of NaH in DMF gave a 1:1 mixture of the 5-deoxy-5-*C*-[(*R*)- and (*S*)-(ethoxy)phenylphosphinothioyl] derivatives. Reduction of these D-xylofuranoses with sodium dihydrobis(2-methoxyethoxy)aluminate, followed by the acid hydrolysis, provided the title compounds, which are the first sugar analogues having a phosphinothioyl group in the hemiacetal ring. These compounds were converted into four, separable 1,2,4-tri-*O*-acetates, the structures and conformations of which were established by spectroscopy. The corresponding per-*O*-acetyl-5-deoxy-5-*C*-[(*R*)- and (*S*)-phenylphosphinyl] analogues were also prepared and their previously presented structures were revised. Complete ^{1}H NMR (500-MHz) parameters of these two types of compounds are given for a comparative, structural study.

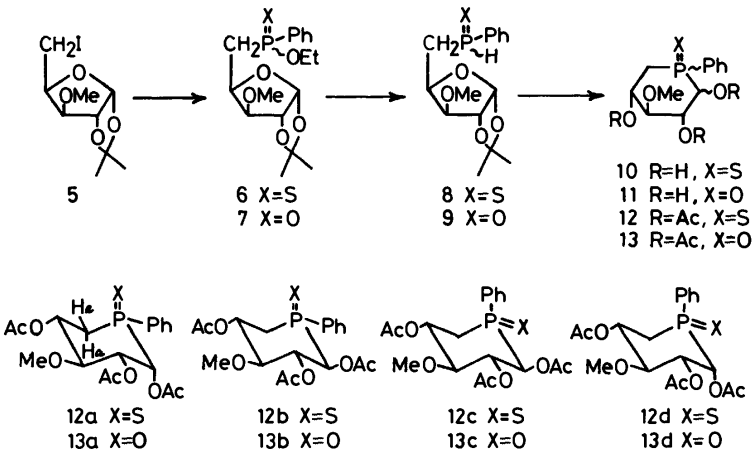
A large number of sugar analogues having a phosphorus atom in place of oxygen in the hemiacetal ring have been prepared in recent years:[1] e.g., D-glucopyranose type **1**[2] and D-ribofuranose type **2**.[3] Such compounds are of interest from the viewpoint of their physicochemical properties and potential biological activity.[1] All of these analogues possess an alkyl-, aryl-, or hydroxyphosphinyl group in the hemiacetal ring, but no derivatives containing a phosphinothioyl group in the ring have been prepared so far. On the other hand, it is well-known that many organophosphorus insecticides of P=S type, such as fenithion[4] (**3**) and EPN[5] (**4**), are in wide use and the P=S functional group of these compounds is effective in the relatively facile permeability through the skin of insects and then the slow oxidative desulfurization to generate the active P=O form by the action of a microsomal oxidase in vivo.[6] In this paper we wish to describe a detailed study on the two synthetic routes to the first sugar analogue having a phosphinothioyl group in the hemiacetal ring, as well as a comparative study with the corresponding 5-*C*-(phenylphosphinyl) derivatives, taking a 3-*O*-methyl-D-xylopyranose analogue as a model compound.[7]





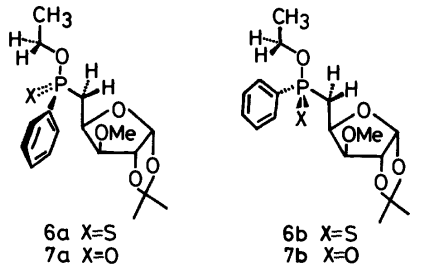
Results and Discussion

After examination of various reaction conditions, introduction of a phosphinothioyl group to the model compound was found to be best achieved by the reaction of 5-deoxy-5-iodo-1,2-*O*-isopropylidene-3-*O*-methyl-α-D-xylofuranose[8] (**5**) with ethyl phenylphos-



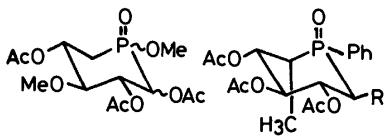
Scheme 1. Synthesis of 5-deoxy-3-*O*-methyl-5-*C*-(phenylphosphinothioyl)-D-xylopyranoses.

phinothioate[9] in dry *N,N*-dimethylformamide (DMF) containing an equivalent of sodium hydride at 0 °C for 3 h under argon (see Scheme 1). Thus the 5-*C*-[(*R*)- and (*S*)-(ethoxy)phenylphosphinothioyl] derivatives **6a,b** were obtained in 84% yield as a 1:1 mixture which were chromatographically inseparable. Compound **6** was obtained in less satisfactory yields when the reaction was carried out at room temp in DMF (3 h, 40% yield) or at elevated temps in benzene or xylene (19 h, ca. 9% yield). Complete ^{1}H NMR spectral parameters of both **6a** and **6b** were obtained at 500-MHz and are summarized in Table 1, by taking into consideration the similar spectral data of the 5-*C*-[(ethoxy)phenylphosphinyl] analogues **7a** and **7b** which were separable by chromatography (see later). On inspecting the molecular models of these *P*-epimers (see formulas **6a** and **6b**), the characteristic upfield shift of the δ value for MeO-3 of **6a** (δ 2.99) from the normal value of **6b** (δ 3.41) strongly suggests the most likely configurations of the P atom of **6a** and **6b** to be (*R*) and (*S*), respectively, because a stronger shielding effect on the MeO-3 group apparently exists in **6a** by the *P*-phenyl group in the vicinity.

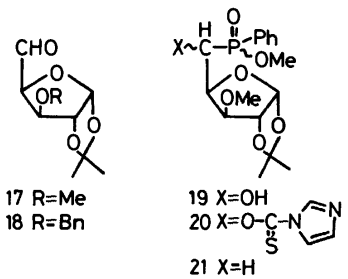


Reduction of **6** with sodium dihydrobis(2-methoxyethoxy)aluminate (SDMA) in dry benzene or tetrahydrofuran (THF) was found to proceed much slower than that of the alkoxyphosphinyl analogues which normally completes within 30 min at 0 °C.[1-3] Thus, the reduction was carried out at 20 °C for 17 h to give the unstable 5-*C*-(phenylphosphinothioyl) compound **8**. Other conditions such as with SDMA in benzene (at 50 °C for 30 h or 20 °C for 35—44 h), SDMA in THF (0 °C, 26 h) or $LiAlH_4$ in ether (20 °C, 60 h) have been found so far to result in less satisfactory yields of **8** from **6**; in most cases the starting material **6** remains unchanged. The acid-catalyzed deprotection of 1,2-*O*-isopropylidene group of **8** and the subsequent ring-transposition in oxygen-free 0.5 M HCl-EtOH (1:1 v/v) (1 M=1 mol·dm^{-3}) at 80 °C for 2 h provided 5-deoxy-3-*O*-methyl-5-*C*-(phenylphosphinothioyl)-D-xylopyranoses (**10**).

The structural assignment of **10** was made by converting them into the 1,2,4-tri-*O*-acetates **12** by treatment with acetic anhydride-pyridine at 20 °C for 20 h as in the case of the previous phosphorus-containing sugar analogues.[1-3] Purification of the crude mixture by column chromatography on silica gel using ethyl acetate-hexane as eluant and then recrystallization gave four, crystalline diastereomers: 5-deoxy-3-*O*-methyl-5-*C*-[(*S*)-phenylphosphinothioyl]-α-D-xylopyranose (**12a**, 1.8% overall yield from **6**), the 5-*C*-[(*S*)-P]-β- (**12b**, 1.8% yield), the 5-*C*-[(*R*)-P]-β- (**12c**, 3.4% yield), and the 5-*C*-[(*R*)-P]-α-isomer (**12d**, 2.3% yield). The identical molecular composition ($C_{18}H_{23}O_7PS$) of **12a—d** was confirmed by the high-resolution MS. The precise configurations and the $^4C_1$(D) conformation of **12a—d** were established on the basis of the 500-MHz ^{1}H NMR spectra by taking into account the known parameters of structurally similar compounds obtained before; e.g., the four diastereomers (with respect to the C-1 and ring-P atom) of per-*O*-acetyl-5-deoxy-5-*C*-(methoxyphosphinyl)-3-*O*-methyl-D-xylopyranoses[8,10] (**14**) and other related compounds such as 5-*C*-[(*S*)-(phenylphosphinyl)]-α-L-idopyranoses[11] (**15**) and L-iditol[11] (**16**). The complete NMR assignments of **12a—d** are listed in Table 1 and will be discussed later.



14 15 R=OAc 16 R=H



Meanwhile, the corresponding four 5-*C*-phenylphosphinyl derivatives **13a—d** of the above thioyl compounds have been prepared by Seo,[12] employing 1,2-*O*-isopropylidene-3-*O*-methyl-α-D-*xylo*-pentodialdo-1,4-furanose[13] (**17**) as the starting material by sequence **17**→**19**→**20**→**21**→**9**→**11**→**13**; structural assignments of the final products were made on the evidence of the insufficiently resolved 60-MHz ^{1}H NMR data and the values of optical rotations.[12] Having found some ambiguity in a part of the reported NMR assignments for **13a—d** and felt necessity of a comparative study of the exact parameters of **12a—d** with those of **13a—d** for further structural proof for the former compounds, we decided to prepare **13a—d**, by using **7** as the starting material. Thus, **7** was readily obtained from **5**[14] by the Michaelis-Arbusov reaction with diethyl phenylphosphonite in 91% yield as a 1:1 mixture of the two

a) The assignments of all signals were made by employing a first-order analysis with the aid of decoupling technique and the parameters were confirmed by a computer-assisted simulation analysis. Very slight corrections were made on a few of the parameters for **12c, d** that were reported in Ref. 7, because the spectra of pure **12c** and **12d** have now become available. b) The assignments of acetoxyl groups may have to be interchanged. c) Approximate J values for meta-coupling of the *P*-phenyl ring protons: $J_{2,4'}$, $J_{2,6'}$, and $J_{3,5}$.

diastereomers, which were separable by chromatography into pure components **7a** and **7b**. From the analysis of the complete ^{1}H NMR data (see Table 1) the most likely configuration of the phosphorus atom of **7a** and **7b** were assigned to (*R*) and (*S*), respectively, on the same grounds taken into consideration in the case of **6a,b** shown above.

For the preparative purpose, however, the crude mixture **7** (without separation) can be subjected to the reduction with SDMA, because both **7a** and **7b** afford the identical 5-deoxy-5-*C*-phenylphosphinyl compound **9**[12] (see Scheme 1). Thus, after following the usual procedures,[1-3] **9** was led to **11** and then to **13**, from which the four diastereomers, **13a** (colorless needles, mp 202—203 °C, 11% overall yield from **7**), **13b** (colorless needles, mp 296—298 °C, 11% yield), **13c** (colorless syrup, 5% yield), and **13d** (colorless needles, mp 148—149 °C, 6% yield) were separated by silica-gel chromatography. As in the case of **12a—d** shown above, these compounds were characterized by MS and 500-MHz ^{1}H NMR (see Table 1 for the summarized parameters) as 5-deoxy-3-*O*-methyl-5-*C*-[(*S*)-phenylphosphinyl]-α-D-xylopyranose (**13a**), 5-*C*-[(*S*)-P]-β- (**13b**), 5-*C*-[(*R*)-P]-β- (**13c**), and 5-*C*-[(*R*)-P]-α- isomer (**13d**), in contrast to the previously reported assignments[12] of the structures 5-*C*-[(*R*)-P]-β-, 5-*C*-[(*R*)-P]-α-, 5-*C*-[(*S*)-P]-β-, and 5-*C*-[(*S*)-P]-α- isomer, respectively.

The ^{1}H NMR data of **12** and **13** generally follow the characteristic features in the δ and *J* values for 5-deoxy-5-*C*-(alkyl-, aryl-, and methoxyphosphinyl)-D-aldopyranoses approximately in the $^4C_1$(D) conformation.[1-3] Namely, the axial orientations (*S*) of the ring P=S and P=O groups in **12a,b** and **13a,b** are established by the downfield shift (0.7—1.1 ppm) of the H-2 and H-4 signals from those of **12c,d** and **13c,d** having equatorial P=S and P=O groups (see the δ values in Table 1). The α-orientation of C-1 is derived by considering the small magnitudes of $J_{1,2}$ (2.6—2.8 Hz) and $J_{1,5e}$ (2.0—2.3 Hz) values of **12a,d** and **13a,d**, whereas the β-anomers **12b,c** and **13b,c** show large $J_{1,2}$ (10.3—11.0 Hz) and negligible $J_{1,5e}$. It is noteworthy to mention some characteristic features in the spectral data of **12** and **13** more in detail for the purpose of comparison:

1) The proton signals of H-2 and H-4 of **12a** and **12b** appear at a slightly lower field (0.1—0.3 ppm) compared with those of **13a** and **13b**. The axial P=S group in the $^4C_1$(D) conformation therefore seems to excert a larger down-field shift on the signals of protons at the 1,3-diaxial positions in comparison with the same effect by the axial P=O group.

2) Appreciable differences in the magnitudes of the $J_{1,P}$, $J_{5a,P}$, and $J_{5e,P}$ are observed between the corresponding diastereomers of **12a—d** and **13a—d** (e.g., compare the $J_{1,P}$ values of **12a** and **13a**).

3) All of the AcO-1 signals of **12a,b** and **13a,b** appear at a rather high field (δ 1.91—1.99), indicating that these acetoxyl groups are most likely to be situated at the positions above the plane of the vicinal, equatorial *P*-phenyl ring. Significant down-field shifts (ca. 0.4 ppm) are observed for the δ values of H_a-5 of **12a,b** from those of the corresponding **13a,b** which seem to have normal values. Taking into consideration of the known values of the torsion angles (determined by X-ray crystallography[1,11]) between the P=O bond and the plane of the *P*-phenyl ring of compounds **15** and **16** (see Fig. 1), the most probable torsion angle between P=S and the plane of the *P*-phenyl ring of **12a** and **12b** in $CDCl_3$ solution is illustrated in Fig. 1, which would account for the above unusual δ values of H_a-5 and AcO-1 of these compounds.

However, exact reasons for these interesting features of the NMR parameters of the P=S compounds compared with those of the P=O analogues have remained to be further clarified employing a larger number of similar sugar analogues; particularly, the relation to their $^4C_1$(D) conformational deviations as well as intrinsic characters of P=S bonding affecting

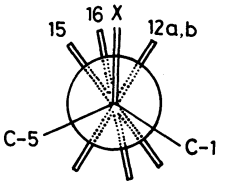

Fig. 1. "Newman" projection down the P–C(phenyl) bond illustrating the phenyl ring. [The digits mark the phenyl rings for compounds **15** (15, X=O),[11] **16** (16, X=O),[11] **12a**, and **12b** (12a, b, X=S)].

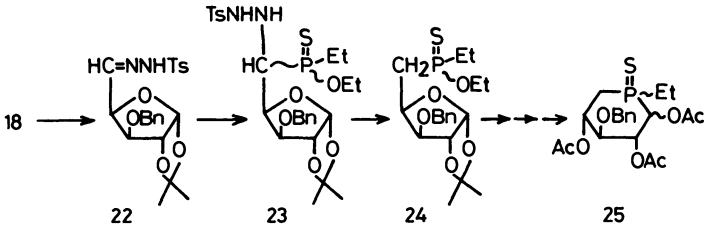

Scheme 2. Synthesis of 5-deoxy-3-*O*-benzyl-5-*C*-(ethylphosphinothioyl)-D-xylopyranoses.

the δ and J values of the neighboring groups would be of interest. Nevertheless, these exact parameters for **12a—d** are certainly of value in determining other 5-deoxy-5-*C*-phosphinothioyl-D-aldopyranoses that are still unknown.

Another approach for the synthesis of the sugar analogues having a P=S group in the ring was also made (see Scheme 2) utilizing a similar scheme employed for the synthesis of D-ribofuranose analogues[3] **2**. Namely, condensation of 3-*O*-benzyl-1,2-*O*-isopropylidene-α-D-*xylo*-pentodialdo-1,4-furanose[15] (**18**) with tosylhydrazine in methanol at 20 °C for 2 h gave the hydrazone **22** (85% yield), which was treated with ethyl ethylphosphinothioate[9] in the presence of trifluoromethanesulfonic acid at 0—20 °C for 7 h, thus affording the 5-*C*-[(ethoxy)ethylphosphinothioyl] derivative **23** (73%). Although reduction of **23** with sodium borohydride in THF was repeatedly examined at 25—50 °C for 7—48 h, the desired compound **24** was obtained in fluctuating yields (10—55%) besides a large amount of unidentified by-products. The same treatment of **24** (as in the case of **6** and **7**) with SDMA, followed by the 0.5 M HCl-EtOH and then acetic anhydride-pyridine afforded a diastereomeric mixture of 1,2,4-tri-*O*-acetyl-3-*O*-benzyl-5-deoxy-5-*C*-[(*R*)- and (*S*)-ethylphosphinyl]-α,β-D-xylopyranoses (**25**, colorless syrup) in only 1.6% overall yield from **24**. Compounds **25** were not separable into each diastereomers by chromatography. Therefore the synthetic approach shown in Scheme 2 seems to be less satisfactory than that described in Scheme 1.

Although improvement of the yields of some steps particularly of the reduction and the subsequent ring-enlargement reactions of the D-xylofuranoses **6** and **24** remains to be done, present work demonstrates an effective way for the preparation of 5-deoxy-5-*C*-(phenylphosphinothioyl)-D-xylopyranoses from an appropriate precursor. This scheme is therefore expected to be applicable to the preparation of various other 5-deoxy-5-*C*-phosphinothioyl-D- and L-aldofuranoses and pyranoses, which is currently under investigation.

Experimental

Melting points were determined with a Yanagimoto MP-S3 instrument and were uncorrected. All reactions were monitored by TLC (Merck silica gel 60F, 0.25 mm) with an appropriate solvent. Column chromatography was performed with Wako C-200 silica gel [or Merck Lobar prepacked silica gel (Size A) for rechromatography of **12** and **13**]. The ^{1}H NMR spectra were measured in $CDCl_3$ with a Hitachi R-600 (60-MHz, FT) or Varian VXR-500 instrument (500-MHz, the CS-NMR Lab., Okayama Univ.) at 27 °C. Chemical shifts (at 60-MHz unless otherwise specified) were recorded as δ values relative to tetramethylsilane as internal standard. The mass spectra were taken on a Shimadzu LKB-9000 low-resolution or a JEOL JMX-HX100 high-resolution instrument and were given in terms of m/z (rel intensity) compared with the base peak.

5-Deoxy-5-*C*-[(*R*)- and (*S*)-(ethoxy)phenylphosphinothioyl]-1,2-*O*-isopropylidene-3-*O*-methyl-α-D-xylofuranoses (6a, b). In a 100 cm^3 two-necked flask was placed sodium hydride (60% in oil, 688 mg, 1.2 equiv), which was then washed twice with dry hexane under argon and diluted with dry DMF (10 cm^3). To this suspension was dropwise added a solution of ethyl phenylphosphinothioate[9] (4.00 g, 1.5 equiv) in dry DMF (10 cm^3) at room temp under argon. After the consumption of sodium hydride to form the sodium salt of the thioate, a solution of **5**[8] (4.50 g) in dry DMF (10 cm^3) was dropwise added at 0 °C, followed by stirring at this temp for 3 h. The solvent was evaporated in vacuo (pump). The residue was dissolved in chloroform and washed with water. The organic layer was dried (Na_2SO_4) and evaporated in vacuo. The residue was purified by column chromatography with 1:3 AcOEt-hexane, giving an inseparable, 1:1 (by ^{1}H NMR) mixture of **6a** and **6b** (presumably 5-*C*-[(*R*)-P] and (*S*)-P diastereomer, respectively): A colorless syrup (4.50 g, 84%); R_f=0.65 (1:2 AcOEt-hexane); ^{1}H NMR (500-MHz), see Table 1; MS m/z 373 (M+1; 27.5), 372 (≃0), 340 (42), 312 (12), 311 (15), 287 (17), 282 (25), 186 (100), 185 (18), 157 (39), 153 (41), and 142 (21).

Found: m/z 373.1190. Calcd for $C_{17}H_{26}O_5PS$: M+1, 373.1239.

1,2,4-Tri-*O*-acetyl-5-deoxy-3-*O*-methyl-5-*C*-[(*R*)- and (*S*)-phenylphosphinothioyl]-α,β-D-xylopyranoses (12a—d). A solution of SDMA (490 mg, 70% in toluene, 3.0 equiv) in dry benzene (3 cm^3) was dropwise added into a solution of **6** (300 mg) in dry benzene (5 cm^3) at 5 °C under argon, followed by stirring at 20 °C for 18 h. Cold water (ca. 0.5 cm^3) was slowly added at 0 °C under stirring to decompose excess SDMA. The resulting white ppt was centrifuged and washed with benzene. Combined benzene solutions were concentrated in vacuo to give crude 5-deoxy-1,2-*O*-isopropylidene-3-*O*-methyl-5-*C*-[(*R*)- and (*S*)-phenylphosphinothioyl]-α-D-xylofuranoses (**8**) as a colorless syrup.

This was immediately dissolved in oxygen-free ethanol (5 cm^3) and 0.5 M hydrochloric acid (5 cm^3). The mixture (pH ca. 1) was degassed with argon and then refluxed for 2 h. The cooled mixture was neutralized by adding enough Amberlite IRA-45. The resin was filtered off and washed with aq ethanol. The filtrate was evaporated in vacuo to give crude 5-deoxy-3-*O*-methyl-5-*C*-[(*R*)- and (*S*)-phenylphosphinothioyl]-α,β-D-xylopyranoses (**10**) as a colorless syrup.

This was dissolved in pyridine (2 cm^3) and acetic anhydride (1 cm^3) at 5 °C. The mixture was stirred at 20 °C overnight, diluted with a small amount of cold water, and concentrated in vacuo. The residue was dissolved in chloroform and washed with water. The organic layer was dried (Na_2SO_4) and evaporated in vacuo. The residue was chromatographed with 1:2 AcOEt-hexane to give **12a—d**; **12d** was separated from **12c** by recrystallization (three times).

12a (5-*C*-[(*S*)-Phosphinothioyl]-α-isomer): Colorless needles (6.0 mg, 1.8% overall yield from **6**); mp 177—178 °C (from 1:1 AcOEt-hexane); R_f=0.24 (1:1 AcOEt-hexane); ^{1}H NMR (500-MHz), see Table 1; MS m/z 414 (M$^+$; 12.5), 382 (12), 356 (16), 355 (38), 324 (29), 323 (56), 322 (57), 313 (20), 294 (19), 281 (52), 280 (100), 265 (27), 264 (28), 239 (43), 238 (28), 222 (31), 171 (22), 87 (23), 71 (31), and 43 (68).

Found: *m/z* 414.0825. Calcd for $C_{18}H_{23}O_7PS$: M, 414.0902.

12c (5-*C*-[(*R*)-Phosphinothioyl]-β-isomer): Colorless needles (7.7 mg, 2.3% yield from **6**); mp 231—232 °C (from 1:1 AcOEt–hexane); R_f=0.44 (1:1 AcOEt–hexane); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 414 (M^+; 2.5), 355 (13), 354 (38), 295 (72), 294 (45), 254 (19), 253 (100), 252 (66), 157 (20), 155 (66), 113 (68), and 43 (72).

Found: *m/z* 414.0914. Calcd for $C_{18}H_{23}O_7PS$: M, 414.0902.

12d (5-*C*-[(*R*)-Phosphinothioyl]-α-isomer): Colorless needles (11.3 mg, 3.4% yield from **6**); mp 181—182 °C (from 1:1 AcOEt–hexane); R_f=0.44 (1:1 AcOEt–hexane); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 414 (M^+; 30.7), 354 (16), 296 (24), 295 (54), 294 (49), 281 (23), 253 (94), 252 (79), 237 (53), 128 (40), 127 (45), 113 (96), 71 (84), and 43 (100).

Found: *m/z* 414.0902. Calcd for $C_{18}H_{23}O_7PS$: M, 414.0902.

5-Deoxy-5-*C*-[(*R*)- and (*S*)-(ethoxy)phenylphosphinyl]-1,2-*O*-isopropylidene-3-*O*-methyl-α-D-xylofuranoses (7a,b). A mixture of **5** (500 mg) and diethyl phenylphosphonite (1.58 g, 5.0 equiv) was heated at 160 °C for 4 h under nitrogen and then concentrated below ca. 80 °C in vacuo. The residue was dissolved in ether and washed with water. The organic layer was dried (Na_2SO_4) and evaporated in vacuo. The residue was chromatographed with 1:1 AcOEt–hexane to give a 1:1 (by ^{1}H NMR) mixture of **7a** and **7b** as a colorless syrup (516 mg, 91% yield). The mixture was separated by careful rechromatography into the pure diastereomers.

7a (5-*C*-[(*R*)-P] isomer): Colorless syrup (170 mg, 30%); R_f=0.28 (2:1 AcOEt–hexane); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 356 (M^+).

7b (5-*C*-[(*S*)-P] isomer): Colorless syrup (190 mg, 34%); R_f=0.23 (2:1 AcOEt–hexane); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 356 (M^+).

1,2,4-Tri-*O*-acetyl-5-deoxy-3-*O*-methyl-5-*C*-[(*R*)- and (*S*)-phenylphosphinyl]-α,β-D-xylopyranoses[12] (13a—d). Similar procedures to those for **12** from **6** were employed. Thus, **7** (320 mg) was treated with SDMA (218 mg, 1.2 equiv) at 5 °C for 30 min, giving **9** as a colorless syrup. This was refluxed with 1:1 ethanol–0.5 M HCl (10 cm^3, oxygen-free) to afford **11** as colorless syrup. This was acetylated with Ac_2O–pyridine to give a mixture of **13**, which was separated by column chromatography with a gradient solution of 2:1 AcOEt–hexane→AcOEt→19:1 AcOEt–EtOH.

13a (5-*C*-[(*S*)-Phenylphosphinyl]-α-isomer): Colorless needles (39 mg, 11% yield from **7**); mp 202—203 °C (from 1:1 AcOEt–hexane, Ref. 12, mp 295—296 °C); R_f=0.44 (AcOEt); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 398 (M^+).

13b (5-*C*-[(*S*)-P]-β-isomer): Colorless needles (40 mg, 11% yield from **7**); mp 296—298 °C (from 1:1 AcOEt–hexane, Ref. 12, mp 200—200.5 °C); R_f=0.44 (AcOEt); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 398 (M^+).

13c (5-*C*-[(*R*)-P]-β-isomer): Colorless syrup (17 mg, 5% yield from **7**); R_f=0.33 (AcOEt); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 398 (M^+).

13d (5-*C*-[(*R*)-P]-α-isomer): Colorless needles (20 mg, 6% yield from **7**); mp 148—149 °C (from AcOEt–hexane, Ref. 12, syrup); R_f=0.22 (AcOEt); ^{1}H NMR (500-MHz), see Table 1; MS *m/z* 398 (M^+).

3-*O*-Benzyl-1,2-*O*-isopropylidene-α-D-*xylo*-pentodialdo-1,4-furanose 5-Tosylhydrazone (22). To a solution of **18**[15] (300 mg) in dry methanol (15 cm^3) was added tosylhydrazine (200 mg, 1.07 equiv) at 0 °C. The mixture was stirred at room temp for 2 h and then evaporated in vacuo. The residue was dissolved in chloroform, dried (Na_2SO_4), concentrated in vacuo, and then purified by column chromatography, giving **22** as colorless needles (406 mg, 85% yield): mp 129—132 °C (from AcOEt–hexane); R_f=0.68 (1:1 AcOEt–hexane); ^{1}H NMR δ=1.31, 1.48 (6H, 2s, Me_2C), 2.42 (3H, s, Me-C_6-S), 4.02—4.80 (5H, m, H-2,3,4, CH_2-O-3), 5.94 (1H, d, $J_{1,2}$=3.4 Hz, H-1), 7.15, 7.82 (2H, each, 2brd, *J*=8 Hz, C_6H_4-S), 7.25 (6H, brs, C_6H_5-C-O-3, NH), and 8.13 (1H, s, H-5); MS *m/z* 446 (M^+).

(*R*)- and (*S*)-3-*O*-Benzyl-5-deoxy-1,2-*O*-isopropylidene-5-*C*-[(*R*)- and (*S*)-(ethoxy)ethylphosphinothioyl]-5-*C*-[(2-tosyl)-hydrazino]-α-D-*xylo*-pentofuranose (23). A mixture of **22** (200 mg) and ethyl ethylphosphinothioate[9] (320 mg, 5 equiv) was degassed with argon. Trifluoromethanesulfonic acid (25 mg, 0.4 equiv) was dropwise added to the above mixture at 0 °C with stirring under argon, followed by stirring at 20 °C for 7 h. The mixture was diluted with chloroform (ca. 30 cm^3) and neutralized by washing with cold, saturated aq $NaHCO_3$. The organic layer was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by column chromatography with 1:2 AcOEt–hexane, giving **23** as a yellow syrup (192 mg, 73%): R_f=0.68 (1:1 AcOEt–hexane); ^{1}H NMR δ=0.65—1.65 (6H, m, MeC-P, MeC-O-P), 1.28, 1.48 (6H, 2s, Me_2C), 1.7—2.4 (2H, m, C-CH_2-P), 2.39 (3H, s, MeC_6-S), 3.4—5.0 (7H, m, H-2,3,4, CH_2-O-P, NH), 4.64 (2H, s, CH_2-O-3), 5.93 (1H, d, $J_{1,2}$=3.5 Hz, H-5), and 6.8—7.9 (10H, m, H-5, C_6H_5-C-O-3, C_6H_4-S); MS *m/z* 584 (M^+).

3-*O*-Benzyl-5-deoxy-1,2-*O*-isopropylidene-5-*C*-[(*R*)- and (*S*)-(ethoxy)ethylphosphiothioyl]-α-D-xylofuranose (24). To a solution of **23** (100 mg) in dry THF (10 cm^3) was slowly added sodium borohydride (32 mg) at 5 °C. The mixture was degassed with argon, stirred at 50 °C for 13 h, and then refluxed for 9 h (under argon). It was diluted with ether and an aq saturated solution of Na_2SO_4 was added. After separation, the aq layer was extracted with ether. The combined ethereal layer was dried (Na_2SO_4) and evaporated in vacuo. The residue was purified by column chromatography to give **24** as a yellow syrup (38 mg, 55% yield): R_f=0.6 (1:2 AcOEt–hexane); ^{1}H NMR δ=0.8—1.6 (6H, m, MeC-P, MeC-O-P), 1.34, 1.49 (6H, 2s, Me_2C), 1.6—2.4 (4H, m, 2H-5, CH_2-P), 3.5—4.9 (5H, m, H-2,3,4, CH_2-O-P), 4.58, 4.66 (2H, 2s, CH_2-O-3), 5.91 (1H, d, $J_{1,2}$=3.8 Hz, H-1), and 7.34 (5H, s, C_6H_5-C-O-3); MS *m/z* 400 (M^+).

1,2,4-Tri-*O*-acetyl-3-*O*-benzyl-5-deoxy-5-*C*-[(*R*)- and (*S*)-ethylphosphinothioyl]-α,β-D-xylopyranoses (25). The same procedures as those for **12** and **13** were employed. Thus, **24** (66 mg) was treated with SDMA (0.05 cm^3) at 5 °C for 5.5 h, followed by the usual procedures, giving an inseparable mixture of **25** as a pale yellow syrup (1.2 mg, 1.6% yield from **24**): R_f=0.5—0.7 (1:1 AcOEt–hexane); ^{1}H NMR δ=0.8—1.6 (3H, m, MeC-P), 1.6—2.1 (2H, m, $MeCH_2$-P), 1.88, 2.02, 2.09 (9H, 3brs, 3AcO), 2.2—3.5 (2H, m, 2H-5), 3.5—4.0 (1H, m, H-3), 4.60 (2H, brs, CH_2O-3), and 4.8—6.0 (3H, m, H-1,2,4); MS *m/z* 442 (M^+; 28.1), 383 (9), 336 (14), 332 (19), 305

(13), 292 (14), 262 (30), 245 (59), 203 (29), 185 (100), 157 (20), 138 (23), 137 (21), 109 (38), 91 (81), and 43 (33).

Found: *m/z* 442.1243. Calcd for $C_{20}H_{27}O_7PS$: M, 442.1208.

We are grateful to Mr. Shin-ichi Takekuma (Kinki University) for the measurement of mass spectra.

Addition of Diphenyldiazomethane to Unsubstituted and Chloro-Substituted 1,4-Benzoquinones. Effects of Chloro Substituents on the Addition Modes

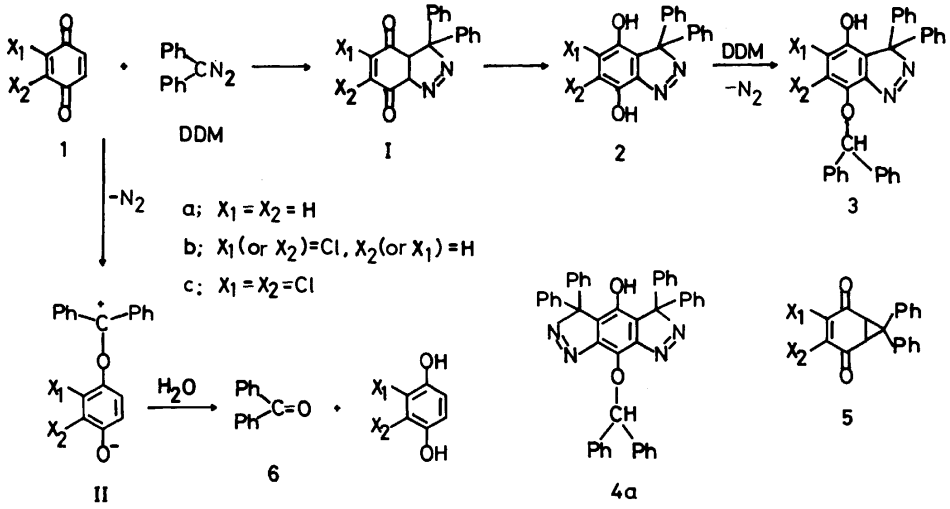
Takumi OSHIMA* and Toshikazu NAGAI
Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560
(Received February 3, 1988)

Unsubstituted 1,4-benzoquinone (**1a**) reacted with diphenyldiazomethane (DDM) at the C=C double bonds to give dihydroxy-3*H*-indazole (**2a**) and its benzhydryl ether (**3a**) together with benzodipyrazole derivative (**4a**). Similarly, reactions of 2-chloro- and 2,3-dichloro-1,4-benzoquinones (**1b** and **1c**) with DDM yielded the corresponding dihydroxy-3*H*-indazoles (**2b**, **2b'**, and **2c**) and their benzhydryl ethers (**3b**, **3b'**, and **3c**) along with 5—13% benzophenone (**6**). On the other hand, reaction of 2,6-dichloro-1,4-benzoquinone (**1e**) with DDM gave bicyclic **5e** and tricyclic diones (**7e**), together with benzophenone dimethyl acetal (**9**) in the presence of added methanol. In the same conditions, 2,3,5-trichloro-1,4-benzoquinone (**1f**) provided bicyclic dione (**5f**) and **9**. Formation of **6** and **9** was interpreted as arising from the hydrolysis and methanolysis of the 1:1 betaine intermediates given by the addition of DDM to the quinonoid C=O double bonds. The C=O addition increased with increasing chlorine substituents.

Additions of diazoalkanes to quinones are of synthetic and mechanistic interest because quinones, with the conjugated C=C and C=O double bonds, show two possible modes of addition which are markedly affected by the substituents and structural natures of these reactants, affording various types of products.[1] Diphenyldiazomethane (DDM), one of the most familiar diazoalkanes, is reported to add only to the C=C double bond of 1,4-benzoquinone (**1a**) giving 3*H*-indazole derivative **2a**.[2] Recently, it has been found that DDM reacts with 2,5-dichloro-1,4-benzoquinone (**1d**) at the C=C and C=O double bonds to yield bicyclic dione **5d** and poly(2,5-dichlorohydroquinone benzhydryl ether), respectively.[3] Further, tetrachloro-1,4-benzoquinone (**1g**) is known to undergo the addition of DDM only at the C=O double bond to afford poly(tetrachlorohydroquinone benzhydryl ether).[4] These striking changes in the reaction fashions with increasing chlorine substituents of 1,4-benzoquinones prompted us to extend the reaction of DDM to all of other chloro-substituted 1,4-benzoquinones. In this paper, we wish to report a systematic investigation of the products of reaction of DDM with 2-chloro-, 2,3- and 2,6-dichloro-, and 2,3,5-trichloro-1,4-benzoquinones, together with a reinvestigation of the product in the prior study of DDM and unsubstituted 1,4-benzoquinone. The effects of the substitution patterns of the chlorines on the addition modes of these quinones are also discussed.

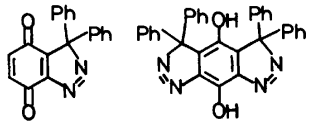
Results and Discussion

Reaction of DDM with 1,4-Benzoquinone (1a), 2-Chloro- (1b) and 2,3-Dichloro-1,4-benzoquinone (1c). In 1931 Fieser and his co-worker have reported that DDM adds to 1,4-benzoquinone (**1a**) to give in nearly quantitative yield dihydroxy-3*H*-indazole (**2a**).[2] However, besides **2a** (40%), two additional products, benzhydryl ether **3a** (39%) of **2a** and bis(3*H*-pyrazole) adduct **4a** (9%), were obtained in the present equimolar reaction in same benzene solution at 25 °C (Scheme 1).



Scheme 1.

This reaction consists in dipolar addition of DDM to **1a** and dienolization of the first product, pyrazoline (**Ia**). The compound **3a** appears to be the secondary product formed from the resulting **2a** and DDM. Indeed, equimolar reaction of **2a** and DDM yielded **3a** in 77% yield. Here, it seems likely that DDM prefers the unhindered phenolic OH of **2a** to avoid the steric repulsion due to the bulky diphenylmethylene moiety. With respect to the formation of **4a**, two possible routes can be put forward. One is the dehydrogenative conversion of **Ia** and/or **2a** into a 3*H*-indazole-4,7-dione (**III**) which would undergo addition of DDM to lead a precursor **IV** of **4a** after dienolization. Another



III IV

one is direct addition of DDM to **Ia** followed by dehydrogenation and dienolization yielding **IV**. The symmetric orientation of **4a** was established by the ^{13}C NMR spectrum which contains six signals for the twelve unprotonated C-atoms of the aromatic rings and one signal for the two diphenyl-substituted C-atoms of the 3*H*-pyrazole rings, respectively; asymmetric one would require nine and two signals for the corresponding C-atoms.

Similarly, equimolar reaction of DDM with **1b** and **1c** gave two principal products, 3*H*-indazole derivatives (**2b**, its regioisomer **2b'**, and **2c**) and their benzhydryl ethers (**3b**, **3b'**, and **3c**), together with 5—13% amounts of benzophenone (**6**) (Scheme 1). The **1b**, as expected, allowed the two addition direction at the unchlorinated C=C bond and thus provided the two sets of isomers, **2b** and **2b'**, **3b** and **3b'**. Each of the isomers could be isolated by column chromatography on silica gel, but it is not yet possible to make the structural assignments. In contrast with the above unchlorinated **1a**, these chlorinated **1b** and **1c** afforded **6**; the yield of **6** for dichlorinated **1c** was nearly twice that for the monochlorinated **1b**. The origin of **6** appears to be water-sensitive 1 : 1 betaine intermediates **II** given by addition of DDM to the C=O double bond. Such hydrolyzable betaines were the key intermediates in the previous reactions of DDM with tetrachloro-1,4-benzoquinone (**1g**)[4] and 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ),[5] where the additions take place only at the C=O bonds. It is also noted that the chlorinated C=C bonds of **1b** and **1c** remain intact for the dipolar addition of DDM. According to FMO (Frontier Molecular Orbital) theory, cycloadditions of simple diazoalkanes to electron-deficient olefins are classified as being controlled by the interaction of the highest occupied molecular orbitals (HOMOs) of diazoalkanes and the lowest unoccupied molecular

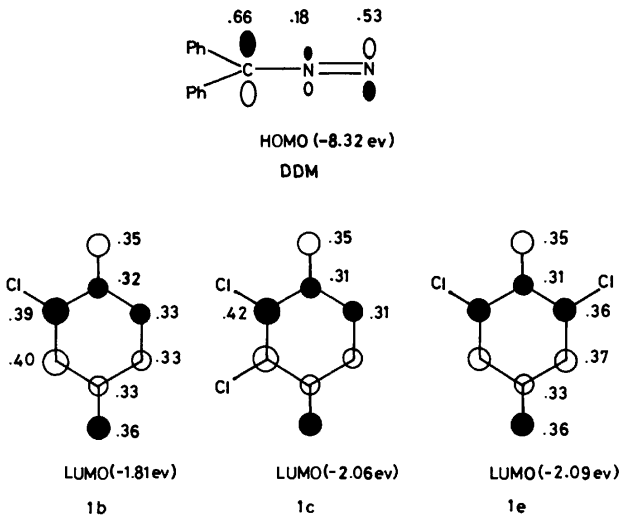


Fig. 1. MNDO π-orbital shapes and energies (in parentheses) of DDM and of 2-chloro-(**1b**), 2,3-dichloro-(**1c**), and 2,6-dichloro-1,4-benzoquinones (**1e**). Only coefficients of diazo function are shown for DDM.

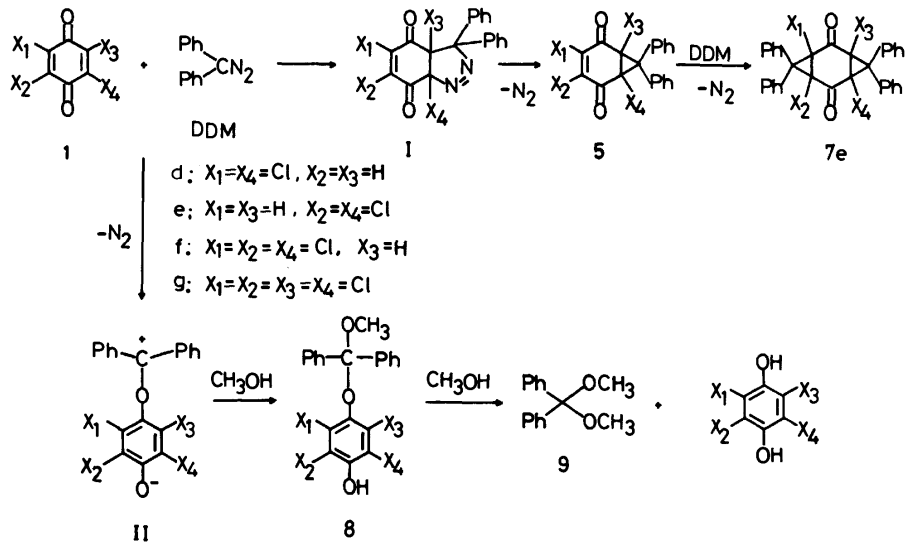
orbitals (LUMOs) of olefins.[6] Figure 1 denotes the HOMO of DDM and LUMO of some quinones by MNDO calculation.[7] The concept of FMO predicts addition of DDM to the chloro-substituted C=C bonds rather than to the unsubstituted ones of **1b** and **1c**, because of the larger LUMO coefficients. This discrepancy is apparently attributable to the steric repulsion due to the chlorine substituents.

It has been found that, in refluxing benzene, these reaction systems of DDM and quinones **1a—c** showed no substantial changes in the product distributions except the formation of small amounts of nitrogen free bicyclic diones, **5a** (12%), **5b** (15%), and **5c** (5%). The **5a—c** supposedly arise by nitrogen release from **I** or by addition of diphenylcarbene to **1a—c**.[8]

Reaction of DDM with 2,6-Dichloro- (1e) and 2,3,5-Trichloro-1,4-benzoquinones (1f). We have previously reported that DDM and 2,5-dichloro-1,4-benzoquinone (**1d**) yield bicyclic dione **5d** and hydroquinone acetal (**8d**) in the presence of added methanol,[3] as shown in Scheme 2. The **5d** is the product given by loss of nitrogen from the initial dipolar adduct, pyrazoline (**Id**), whose chloro substituent prohibits the rearrangement into 3*H*-indazole derivative. While, the **8d** can be accounted for on the basis of a 1:1 betaine intermediate **IId**. Here, methanol was added as a capture of **IId**, otherwise, **IId** tends to polymerize into poly(2,5-dichlorohydroquinone benzhydryl ether).[3]

A study has now been made of reactions of DDM with 2,6-dichloro- (**1e**) and 2,3,5-trichloro-1,4-benzoquinones (**1f**), both of which are designed to avoid dienolization upon the dipolar addition to the C=C bonds as well as above **1d**. In the presence of 5 equiv of methanol, quinone **1e** reacted with DDM to give



Scheme 2.

Table 1. Effects of the Chloro Substituents on the Addition Modes of 1,4-Benzoquinones (**1a—g**) to DDM in Benzene

Quinone	Temp/°C	Substituted position	Addition mode/%	
			C=C addition	C=O addition
1a	25	—	100	0
1a	80	—	100	0
1b	25	2-	91[a]	9
1b	80	2-	90[a]	10
1c	25	2,3-	78[a]	22
1c	80	2,3-	83[a]	17
1d[b]	30	2,5-	49	51
1e	25	2,6-	50[c]	50
1f	25	2,3,5-	40[d]	60
1g[e]	30	2,3,5,6-	0	100

a) For unchlorinated C=C bond. b) Ref. 3. c) Estimated as the sum of **5e** and **7e**. d) For monochlorinated C=C bond. e) Solvent: tetrahydrofuran, see Ref. 4.

bicyclic dione **5e** (43%) and tricyclic dione **7e** (5%) in addition to benzophenone dimethyl acetal **9** (45%). Apparently, the behavior of **1e** is different from that of above **1d** in that the former involved the dipolar addition to both the C=C bonds to give **7e** and caused the redoxical acetalization into **9** and 2,6-dichlorohydroquinone. Indeed, bicyclic dione **5e** reacted slowly with DDM to provide **7e**; $k=1.57\times10^{-4}/s^{-1}\,mol^{-1}$ (30 °C, benzene). This value of k is only one twentieth of the overall rate ($k=3.36\times10^{-3}$) for the reaction of DDM and **1e**,[9] reflecting the above product distribution. However, **5d** derived from **1d** remained unchanged even on 2 day's standing with DDM under the same conditions. The stereochemistry of tricyclic dione **7e** is unknown. The ^1H NMR spectrum of **7e** (δ=2.66, s, two bridgehead H) can not allow the stereochemical assignment in view of the fact that the corresponding protons of similar tricyclic diones, *syn*- and *anti*-tricyclo[5.1.0.$0^{3,5}$]octane-2,6-diones, do not resonate with each other.[10]

As for the process giving the 1:1 betaine **IIe**, it is more likely that DDM preferably attacks the C=O bond meta to the chloro-substituents in the light of the steric effects and of the results of the MNDO calculation[7] of **1e** which indicates slightly larger LUMO coefficients for this meta C=O bond (Fig. 1). Such an addition appears to be responsible for the higher reactivity of **8e**, because the combination of two meta chlorine substituents do make the diphenylmethylene moiety more positive than do the combination of ortho and meta chlorine-substituents in the comparable **8d**.

Introduction of one more chlorine atom to the quinone nucleus of **1e** brought about slight increase of the relative reactivity of the C=O to the C=C bonds, as exhibited by the product ratio (55:37) of acetal **9** to bicyclic dione **5f** for the reaction of 2,3,5-trichloro-1,4-benzoquinone (**1f**).

The product distributions are shown in Table 1. This table clearly shows the increase of C=O additions

with increasing Cl substituents as well as the lack of temperature effects (i.e., **1a—c**).

Experimental

All the melting points were uncorrected. The IR, ^{1}H NMR, ^{13}C NMR, and mass spectra were recorded on a Perkin Elmer 983 G, a Varian EM 390, a Hitachi 90 H, and a Hitachi RMU 6E spectrometers respectively.

Materials. The diphenyldiazomethane (DDM) was prepared by the oxidation of benzophenone hydrazone with yellow mercury oxide and recrystallized from petroleum ether; mp 29—30 °C. All quinones were purified before use by column chromatography on silica gel (hexane–benzene (3:1) as an eluent) and recrystallization from a mixture of hexane and benzene. The 1,4-benzoquinone (**1a**) and 2-chloro-1,4-benzoquinone (**1b**) were of commercial origin; mp 113—115 °C and 57—58 °C respectively. The 2,3-dichloro- (**1c**) and 2,6-dichloro-1,4-benzoquinone (**1e**), and 2,3,5-trichloro-1,4-benzoquinone (**1f**) were prepared according to the literature methods; mp 100—101 °C (lit,[11] 100—101 °C), 121—122 °C (lit,[12] 120.5—121 °C), and 167—168 °C (lit,[13] 169—170 °C) respectively.

4,7-Dihydroxy-3,3-diphenyl-3*H*-indazole (2a), 7-Benzhydryloxy-4-hydroxy-3,3-diphenyl-3*H*-indazole (3a), and 8-Benzhydryloxy-3,6-dihydro-4-hydroxy-3,3,5,5-tetraphenylbenzo[1,2-*c*:5,4-*c*']dipyrazole (4a). To begin with, it should be kept in mind that all the yields are based on DDM used. A benzene solution (10 ml) of DDM (540 mg, 2.78 mmol) and 1,4-benzoquinone **1a** (300 mg, 2.78 mmol) was allowed to stand for 10 h at 25 °C. The solvent was removed and the residue was column-chromatographed on silica gel. Elution with hexane–benzene (20 to 100%) gave successively recovered **1a** (20 mg), **4a** (55 mg, 9%), and **3a** (255 mg, 39%). Further elution with benzene–ether (10%) yielded **2a** (339 mg, 40%). Recrystallization of **2a** from a mixture of hexane and ether gave yellow crystals: mp 208—209 °C (lit,[2] 210 °C); IR (KBr) 3405, 1501, 1454, 1272, 696 cm^{-1}; ^{1}H NMR (acetone-d_6) δ=6.60 (s, 1H, aromatic H), 6.87 (s, 2H, aromatic H), 7.2—7.5 (m, 9H, aromatic H), 8.23 (s, 1H, OH, exchangeable with CD_3OD), 9.07 (s, 1H, OH, exchangeable with CD_3OD); MS, *m/z* 302 (M^+). Anal. ($C_{19}H_{14}O_2N_2$) C, H, N. The compound **3a** was recrystallized from a mixture of hexane and benzene: mp 188—190 °C, yellow plates; IR (KBr) 3423, 1500, 1274, 697 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.80 (s, 1H, OH, exchangeable with CD_3OD), 6.6—7.6 (m, 23H, aromatic H+$Ph_2C\underline{H}$); MS, *m/z* 468 (M^+). Anal. ($C_{32}H_{24}O_2N_2$) C, H, N. Recrystallization of **4a** from a mixture of hexane and benzene provided pale yellow prisms: mp 201—203 °C; IR (KBr) 3534, 1490, 1185, 1022, 754, 697 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.50 (s, 1H, OH, exchangeable with CD_3OD), 6.9—7.8 (m, 30H, aromatic H), 7.93 (s, 1H, $Ph_2C\underline{H}$); ^{13}C NMR ($CDCl_3$) δ=87.1 ($Ph_2\underline{C}H$), 101.8 ($Ph_2\underline{C}$=), 127.0, 127.5, 127.9, 128.1, 128.5, 128.9 (protonated aromatic C), 134.7, 135.9, 138.8, 140.7, 141.3, 150.5 (unprotonated aromatic C); MS, *m/z* 660 (M^+). Anal. ($C_{45}H_{32}O_2N_2$) C, H, N.

7,7-Diphenylbicyclo[4.1.0]hept-3-ene-2,5-dione (5a). To a refluxing benzene (5 ml) containing **1a** (300 mg, 2.78 mmol) was added dropwise over 10 min a benzene solution (5 ml) of DDM (540 mg, 2.78 mmol). After 1 h refluxing, the solvent was removed and the residue was column-chromatographed on silica gel. Elution with hexane–benzene (30%) provided benzophenone azine (35 mg, 7%) and recovered **1a** (30 mg). The bicyclic dione **5a** (91 mg, 12%) was eluted with hexane–benzene (50%). The **4a** (25 mg, 4%), **3a** (282 mg, 43%), and **2a** (252 mg, 30%) were yielded on further chromatographic treatment as above. Recrystallization of **5a** from a mixture of hexane and benzene yielded pale yellow needles: mp 173—174 °C; IR (KBr) 1666, 1493, 1302, 707 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.33 (s, 2H, cyclopropyl H), 6.18 (s, 2H, vinyl H), 7.2—7.6 (m, 10H, aromatic H); MS, *m/z* 274 (M^+). Anal. ($C_{19}H_{14}O_2$) C, H.

5- or 6-Chloro-4,7-dihydroxy-3,3-diphenyl-3*H*-indazole (2b or 2b') and 7-Benzhydryloxy-5- or 6-chloro-4-hydroxy-3,3-diphenyl-3*H*-indazole (3b or 3b'). A benzene solution (20 ml) of DDM (700 mg, 3.61 mmol) and 2-chloro-1,4-benzoquinone **1b** (515 mg, 3.61 mmol) was allowed to stand for 10 h at 25 °C. The solvent was removed and the residue was column-chromatographed on silica gel. Elution with hexane–benzene (20 to 100%) gave successively benzophenone **6** (35 mg, 5%), recovered **1b** (100 mg), **3b** (248 mg, 27%), and **3b'** (265 mg, 29%). Further elution with benzene–ether (5%) yielded **2b'** (210 mg, 17%) and **2b** (85 mg, 7%). The **2b** and **2b'** were converted into **3b** and **3b'** respectively, when treated with DDM. Recrystallization of **2b** from benzene provided yellow crystals: mp 180 °C (decomp); IR (KBr) 3473, 1460, 1401, 1242, 696 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.05 (broad s, 1H, OH, exchangeable with CD_3OD), 5.50 (broad s, 1H, OH, exchangeable with CD_3OD), 7.1—7.4 (m, 11H, aromatic H); MS *m/z* 336 (M^+). Anal. ($C_{19}H_{13}O_2N_2Cl$) C, H, N. Recrystallization of **2b'** from benzene gave yellow crystals: mp 172—174 °C; IR (KBr) 3398, 1493, 1452, 1228, 696 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.83 (broad s, 1H, OH, exchangeable with CD_3OD), 5.40 (broad s, 1H, OH, exchangeable with CD_3OD), 7.2—7.4 (m, 11H, aromatic H); MS, *m/z* 336 (M^+). Anal. ($C_{19}H_{13}O_2N_2Cl$) C, H, N. Recrystallization of **3b** from a mixture of hexane and benzene provided yellow crystals of mp 86—88 °C; IR (KBr) 3429, 1480, 1460, 1230, 1040, 697 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=5.33 (s, 1H, OH, exchangeable with CD_3OD), 7.00 (s, 1H, $Ph_2C\underline{H}$), 7.1—7.7 (m, 21H, aromatic H); MS, *m/z* 502 (M^+). Anal. ($C_{32}H_{23}O_2N_2Cl$) C, H, N. Recrystallization of **3b'** from benzene yielded yellow crystals which decomposed at 178 °C (decomp); IR (KBr) 3429, 1491, 1460, 1240, 697 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.77 (s, 1H, OH, exchangeable with CD_3OD), 6.87 (s, 1H, $Ph_2C\underline{H}$), 6.9—7.8 (m, 21H, aromatic H); MS, *m/z* 502 (M^+). Anal. ($C_{32}H_{23}O_2N_2Cl$) C, H, N.

3-Chloro-7,7-diphenylbicyclo[4.1.0]hept-3-ene-2,5-dione (5b). To a refluxing benzene (10 ml) containing **1b** (515 mg, 3.61 mmol) was added dropwise over 10 min a benzene solution (10 ml) of DDM (700 mg, 3.61 mmol). After 1 h refluxing, the solvent was removed and the residue was column-chromatographed on silica gel. Elution with hexane–benzene (20—50%) gave successively **6** (40 mg, 6%), recovered **1b** (90 mg), and benzophenone azine (25 mg, 4%). The bicyclic dione **5b** (171 mg, 15%) was eluted with hexane–benzene (50%) and recrystallized from a mixture of hexane and benzene to yield pale yellow prisms: mp 104—105 °C; IR (KBr) 1684, 1661, 1595, 707 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.2—3.3 (m, 2H, cyclopropyl H), 6.33 (d, *J*=1.5 Hz, 1H, vinyl H), 7.0—7.3 (m, 10H, aromatic H); MS, *m/z* 308 (M^+). Anal. ($C_{19}H_{13}O_2Cl$) C, H. The **3b** (205 mg, 23%), **3b'** (230 mg, 25%), **2b'** (125 mg, 10%), and **2b** (63 mg, 5%) were obtained on further column-chromatographic treatment as above.

5,6-Dichloro-4,7-dihydroxy-3,3-diphenyl-3*H*-indazole (2c) and 7-Benzhydryloxy-5,6-dichloro-4-hydroxy-3,3-diphenyl-3*H*-indazole (3c). A benzene solution (10 ml) of DDM (290 mg, 1.49 mmol) and 2,3-dichloro-1,4-benzoquinone **1c** (260 mg, 1.47 mmol) was allowed to stand for 10 h at 25 °C. The solvent was removed and the residue was column-chromatographed on silica gel. Elution with hexane–benzene (30 to 100%) gave successively **6** (35 mg, 13%), recovered **1c** (120 mg), and **3c** (240 mg, 60%). Further elution with benzene–ether (5%) yielded 2,3-dichlorohydroquinone (13 mg, 5%) and **2c** (93 mg, 17%). Recrystallization of **2c** from a mixture of hexane and ether provided yellow glanulates: mp 173—174 °C; IR (KBr) 3427, 1451, 1099, 696 cm^{-1}; ^1H NMR (acetone-d_6) δ=2.9 (broad s, 1H, OH, exchangeable with CD_3OD), 7.30 (s, 10H, aromatic H), 8.30 (broad s, 1H, OH, exchangeable with CD_3OD); MS, *m/z* 370 (M^+). Anal. ($C_{19}H_{12}O_2N_2Cl_2$) C, H, N. Recrystallization of **3c** from a mixture of hexane and benzene provided pale yellow crystals: mp 166—168 °C; IR (KBr) 3431, 1438, 696 cm^{-1}; ^1H NMR ($CDCl_3$) δ=5.48 (s, 1H, OH, exchangeable with CD_3OD), 7.0—7.7 (m, 20H, aromatic H), 7.80 (s, 1H, $Ph_2C\underline{H}$); MS, *m/z* 536 (M^+). Anal. ($C_{32}H_{22}O_2N_2Cl$) C, H, N.

3,4-Dichloro-7,7-diphenylbicyclo[4.1.0]hept-3-ene-2,5-dione (5c). To a refluxing benzene (5 ml) containing **1c** (260 mg, 1.47 mmol) was added dropwisely over 10 min a benzene solution (5 ml) of DDM (290 mg, 1.49 mmol). After 1 h refluxing, the solvent was removed and the residue was column-chromatographed on silica gel. Elution with hexane–benzene (30%) gave successively **6** (30 mg, 11%), recovered **1c** (75 mg), and bicyclic dione **5c** (25 mg, 5%). Recrystallization from benzene yielded pale yellow prisms: mp 237—238 °C; IR (KBr) 1691, 1561, 1277, 708 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.38 (s, 2H, cyclopropyl H), 7.2—7.5 (m, 10H, aromatic H); MS, *m/z* 343 (M^+). Anal. ($C_{19}H_{12}O_2Cl_2$) C, H. The **3c** (212 mg, 53%), 2,3-dichlorohydroquinone (15 mg, 6%), and **2c** (125 mg, 23%) were obtained on further column-chromatographic treatment as above.

1,3-Dichloro-7,7-diphenylbicyclo[4.1.0]hept-3-ene-2,5-dione (5e), 1,3-Dichloro-4,4,8,8-tetraphenyltricyclo[5.1.0.$0^{3,5}$]-octane-2,6-dione (7e), and Benzophenone Dimethyl Acetal (9). A benzene solution (10 ml) of DDM (350 mg, 1.80 mmol), 2,6-dichloro-1,4-benzoquinone **1e** (320 mg, 1.81 mmol), and 5 equiv of methanol (300 mg) was allowed to stand for 15 h at 25 °C. The solvent was removed and the pasty residue was immediately submitted for ^1H NMR measurement. The absolute yields of bicyclic dione **5e** (43%), tricyclic dione **7e** (5%), and benzophenone dimethyl acetal **9** (45%) were determined by the integral ratios with 1,1,1,2-tetrachloroethane (δ=4.20) as an internal standard. Extraction with pentane (5 ml×3) left solid residue. Combined pentane extracts were column-chromatographed on alumina to yield acetal **9** (83 mg, 20%) and hydrolyzed **6** (60 mg, 18%) with hexane–benzene (20%). The structure of **9** was confirmed by comparison of the IR and NMR spectra with those of authentic sample. The solid residue was column-chromatographed on silica gel to give successively **7e** (49 mg, 5%) and **5e** (235 mg, 38%) with hexane–benzene (50%), and 2,6-dichlorohydroquinone (135 mg, 42%) with benzene–ether (10%). Recrystallization of **5e** from a mixture of hexane and benzene gave pale yellow prisms: mp 149—151 °C; IR (KBr) 1706, 1671, 709 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.54 (d, *J*=1.8 Hz, 1H, cyclopropyl H), 6.45 (d, *J*=1.8 Hz, 1H, vinyl H), 7.1—7.6 (m, 10H, aromatic H); MS, *m/z* 342 (M^+). Anal. ($C_{19}H_{12}O_2Cl_2$) C, H. Recrystallization of **7e** from a mixture of hexane and benzene yielded pale yellow prisms: mp 285 °C (decomp); IR (KBr) 1710, 1693, 706 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.66 (s, 2H, cyclopropyl H), 7.2—7.4 (m, 20H, aromatic H); MS, *m/z* 508 (M^+). Anal. ($C_{32}H_{22}O_2Cl_2$) C, H.

1,3,4-Trichloro-7,7-diphenylbicyclo[4.1.0]hept-3-ene-2,5-dione (5f). A benzene solution (10 ml) of DDM (440 mg, 2.27 mmol), 2,3,5-trichloro-1,4-benzoquinone **1f** (480 mg, 2.27 mmol), and 5 equiv of methanol (360 mg) was allowed to stand for 15 h at 25 °C. The solvent was removed and the pasty residue was submitted for ^1H NMR measurement to determine the absolute yields of bicyclic dione **5f** (37%) and **9** (55%). After complete hydrolysis of **9** by adding few drops of dilute hydrochloric acid, the reaction products were column-chromatographed on silica gel. Elution gave successively **6** (195 mg, 47%) and **5f** (290 mg, 34%) with hexane–benzene (30%), and 2,3,5-trichlorohydroquinone (265 mg, 55%) with benzene–ether (20%). Recrystallization of **5f** from a mixture of hexane–benzene yielded pale yellow prisms: mp 189—190 °C; IR (KBr) 1698, 1257, 1103, 712 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.73 (s, 1H, cyclopropyl H), 7.0—7.5 (m, 10H, aromatic H); MS, *m/z* 376 (M^+). Anal. ($C_{19}H_{11}O_2Cl_3$) C, H.

Cycloaddition Reactions of Highly Stabilized Isoquinolinium Methylides to Nonactivated Olefins and Electron-Rich Olefins

Otohiko TSUGE,* Shuji KANEMASA, Kazushige SAKAMOTO, and Shigeori TAKENAKA

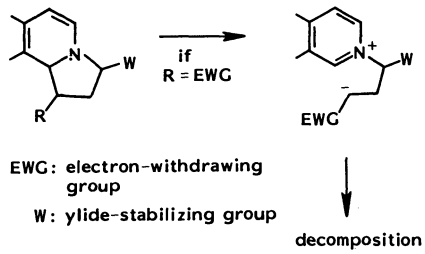
Interdisciplinary Graduate School of Engineering Sciences,
Kyushu University, Kasugakoen, Kasuga 816
(Received February 3, 1988)

Highly stabilized isoquinolinium methylides bearing two electron-withdrawing substituents at the ylide carbon undergo cycloadditions with aryl-substituted olefins (acenaphthylene, (*E*)- and (*Z*)-stilbenes, indene, and styrene), alkyl-substituted olefins (norbornene, (*Z*)-3-hexene-1,6-dinitrile, 1-hexene, 2-propen-1-ol, and 3-(trimethylsilyloxy)propene), and electron-rich olefins (vinylene carbonate, butyl vinyl ether, and phenyl vinyl sulfide). These cycloadditions proceed in an exclusively regioselective and mostly stereoselective manner.

Heteroaromatic *N*-ylides belong to highly reactive and easily accessible azomethine ylide 1,3-dipoles.[1] Their cycloadditions to electron-deficient activated olefins take place frequently in regio- and stereoselective manners to produce stereochemically pure fused pyrrolidine rings.[2] However the cycloadducts are not often highly stable since cycloaddition stage of heteroaromatic *N*-ylides involves loss of aromaticity of the heterocyclic ring. A major route of decomposition of the cycloadducts involves cleavage of the carbon–carbon bond newly formed in the cycloaddition step generating betaine intermediates. Anion-stabilizing substituents (R=EWG) introduced from the olefin dipolarophiles must accelerate this cleavage.[3]



Several attempts to increase the stability of cycloadducts were previously applied to avoid the undesired decomposition.[4] Replacement of the electron-withdrawing substituent R=EWG with such an ordinary substituent as aryl, alkyl, or electron-donating moiety can be an effective method of stabilization. Formally such stabilized cycloadducts would be accessible from the cycloadditions of heteroaromatic *N*-ylides to the olefins bearing no electron-withdrawing substituent.

Introduction of two anion-stabilizing substituents at the ylide carbon of heteroaromatic *N*-ylides lowers both levels of the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) so that the reactivity with electron-deficient activated olefins may be decreased but the reactivity with electron-rich olefins may be increased instead. So highly stabilized and isolable heteroaromatic *N*-ylides are expected to undergo cycloadditions with electron-rich olefins under a control of $LUMO_{dipole}$–$HOMO_{dipolarophile}$ interaction.[5]

Although several examples have been reported for the cycloadditions of azomethine ylides with nonactivated olefins,[6–8] the reactivity of heteroaromatic *N*-ylides with nonactivated olefins is unknown. The only example is the reaction of isoquinolinium bis(ethoxycarbonyl)methylide with enamines.[9]

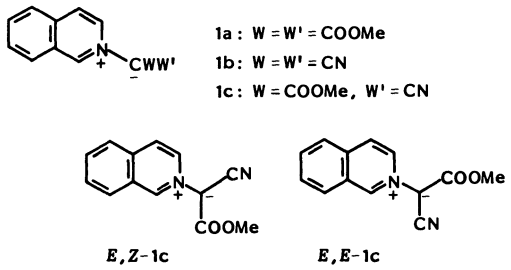
The present paper describes the first example of cycloadditions of highly stable and isolable isoquinolinium ylides with aryl-substituted, alkyl-substituted, and electron-rich olefins. These reactions are found to be exclusively regioselective regardless of the ylide-stabilizing substituent, and mostly stereoselective when the ester-stabilized ylides are employed.

Results and Discussion

Three types of isoquinolinium methylides **1a—c** were employed in the present work. They are all stable enough to be isolated: Bis(methoxycarbonyl)-**1a** and cyano(methoxycarbonyl)methylide **1c** can be prepared via *N*-alkylisoquinolinium bromides and such a weak base as isoquinoline, triethylamine, or aqueous potassium carbonate, and dicyanomethylide **1b** is directly accessible from isoquinoline and tetracyanooxirane. A mixture of ylide and olefin is heated in dry toluene or xylene under nitrogen and the reaction is monitored on TLC. After removal of the solvent, the crude reaction mixture is inspected by means of ^{1}H NMR spectrum to see the content of isomeric cycloadducts.

Two geometric isomers, (*E,Z*)-**1c** and (*E,E*)-**1c**, are possible for the cyano(methoxycarbonyl)methylide **1c** as shown below. As it is already known that the anti forms (or *E,Z*-forms) of carbonyl-stabilized heteroaromatic *N*-ylides show relatively high stability by 1,5-dipole stabilization and are exclusively involved in their cycloadditions to electron-deficient olefins,[2,10] the selective participation of isomer (*E,Z*)-**1c** is anticipated.

Both ^{1}H and ^{13}C NMR spectra of ylide **1c** measured in deuteriochloroform show no contamination by any



isomeric form, indicating either its existence in a single isomeric form, probably in an *E,Z*-form, or a free rotation around the ylide carbon–nitrogen bond. Since both the ester groups of bis(methoxycarbonyl)-methylide **1a** are magnetically equivalent as shown in its ^{1}H and ^{13}C NMR spectra measured at room temperature, the energy barrier for the ylide isomerization of such highly stabilized heteroaromatic *N*-ylides as **1a—c** may not be high so as to restrict the rotation.

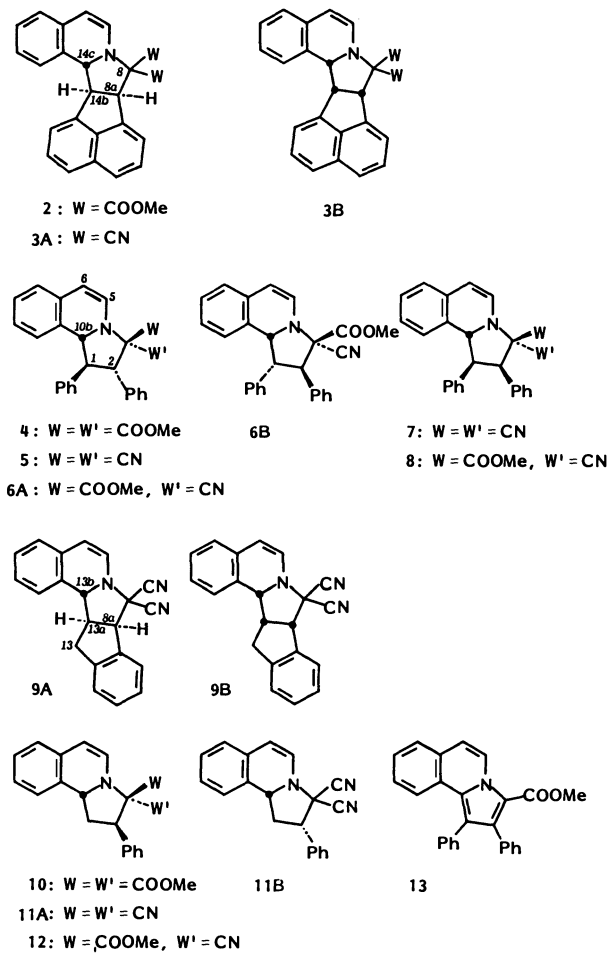
Though NMR spectra of dicyanomethylide **1b** was not available due to its low solubility in organic solvent, the other two **1a** and **1c** as well as 2-[bis(methoxycarbonyl)methyl]isoquinolinium bromide as a precursor of **1a** gave informative ^{1}H and ^{13}C NMR spectra. Both 1- and 3-Cs of cyano(methoxycarbonyl)methylide **1c** (1-C: δ=137.56 and 3-C: 132.88) appear in much upper field than those of bis(methoxycarbonyl)-methylide **1a** (1-C: 153.41 and 3-C: 141.32), indicating that the ylide anion of **1a** hardly flows into the isoquinoline ring but is stabilized by delocalization through the two ester moieties. Thus ylide **1a** and the precursor salt of **1a** show 1-C (**1a**: δ=153.41 and the precursor: 152.85) very close to each other. Stabilization of the anion of ylide **1c** is mainly made by its conjugation with the isoquinoline π-orbitals rather than the delocalization through the ylide-stabilizing cyano and ester moieties so that electron density at the 1-position is relatively increased.

On the other hand, ^{1}H chemical shifts of **1a** and **1c** are inconsistent with the corresponding ^{13}C chemical shifts. Ylide **1c** shows its 1- and 3-Hs (1-H: δ=10.11 and 3-H: 8.83) in much lower field than those of **1a** (1-H: 9.32 and 3-H: 8.33). The low-field shifts of 1- and 3-Hs are presumably caused by anisotropy from the ylide-stabilizing ester moiety. The ester moiety of **1c** can stay in the same plane to the isoquinoline ring so that the 1- and 3-Hs are strongly deshielded. However, the plane including the ylide carbon and two ester moieties of ylide **1a** is forced to cross to the isoquinoline plane due to a considerable steric congestion, deshielding of the 1- and 3-Hs from the ester groups being relatively decreased.

Cycloadditions to Aryl-Substituted Olefins. Heating isoquinolinium bis(methoxycarbonyl)methylide (**1a**) or dicyanomethylide (**1b**), under reflux in toluene, with acenaphthylene as a symmetrically aryl-substituted cyclic olefin produced the cycloadduct **2** or **3**. Though the cycloadduct **2** was obtained as a single isomer, **3** consists of two stereoisomers (3:1 by ^{1}H NMR) whose separation from each other through column chromatography was unsuccessful (Scheme 1 and Table 1). Compared to the major isomer **3A** (5-H: δ=6.02, 6-H: 6.49, and 14c-H: 4.99), the minor isomer **3B** shows strong magnetic shieldings at 5-H (5.03) and 6-H (5.87) as well as deshielding at 14c-H (5.22) from the fused acenaphthylene ring, confirming the exo and endo structures of **3A** and **3B**, respectively.

Similar reactions of the ylides **1a**, **1b**, and isoquinolinium cyano(methoxycarbonyl)methylide (**1c**) with (*E*)- and (*Z*)-stilbenes produced *E*-specific **4—6** and *Z*-specific cycloadducts **7**, **8**, respectively, while **1a** could not be trapped by (*Z*)-stilbene and recovered in 52% yield under reflux in toluene for 72 h (Scheme 1 and Table 1). Heating **1b** with (*Z*)-stilbene under reflux in toluene or xylene for 71 or 76 h gave 34 or 45% yield of cycloadduct **7**, respectively, but no cycloadduct was formed at 110 °C in *N,N*-dimethylformamide (DMF).[11] Thus polar solvents are disfavored in these cycloadditions.

Both relatively small trans couplings for J_{1-2} (2.0 Hz) and J_{1-10b} (6.2 Hz) of **4** and big trans couplings for J_{1-2} (11.3 Hz) and J_{1-10b} (8.0 Hz) of **5**



Scheme 1.

result from the same 1-exo-2-endo substitution as shown in the following discussion using molecular models: When the 3-endo substituent W′ is small, the most stable conformation of the fused pyrrolidine ring of the 1-exo-2-endo-cycloadduct of ylide **1** to an (*E*)-olefin ($R^1CH=CHR^2$) has trans diaxial geometry between the adjacent two of 10b-, 1-, and 2-Hs (conformer **A** in Fig. 1). The cycloadduct **5** occupies this conformation **A** (W=W′=CN, $R^1=R^2$=Ph) showing two big vicinal couplings J_{1-2} and J_{1-10b}. If the 3-endo substituent W′ becomes bulkier in the conformer **A**, the substituent W′ can not stay at the congested axial position and goes outside by rotations around the C(1)-C(2) and C(2)-C(3) bond leading to conformer **B**. The cycloadduct **4** occupies this conformation **B** (W=W′=COOMe, $R^1=R^2$=Ph) in which very small J_{1-2} (2.0 Hz) is observed.

The cycloadduct of **1c** to (*E*)-stilbene includes two isomers **6A** and **6B** in a 42:33 ratio of isolated products, although two more isomers are possible in this case depending upon the geometry at the 3-position. Both the isomers **6A** and **6B** exhibit big vicinal couplings for J_{1-2} (**6A**: 12.1 and **6B**: 10.9 Hz) which are assigned to a typical trans diaxial geometry. Together with magnetic shielding of the 3-COOMe of **6B** (δ=3.25) by the adjacent 2-phenyl, **6A** and **6B** are assigned to be 1-exo-2-endo and 1-endo-2-exo cycloadducts to the *E,Z*-form of ylide **1c**, respectively. The other big vicinal couplings J_{1-10b} (**6A**: 9.1 and **6B**: 8.2 Hz) are consistent with the assigned stereochemistry. Thus **6A** and **6B** exist as conformations **A** and **C**, respectively (Scheme 1 and Fig. 1, $R^1=R^2$=Ph, W=COOMe, W′=CN).

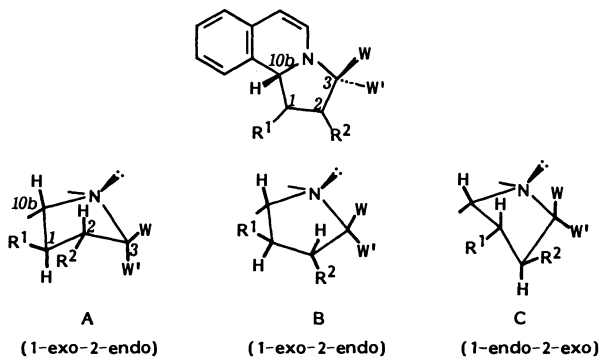


Fig. 1. Stable conformation of the cycloadducts of **1** to (*E*)-olefins.

The cycloadducts **7** and **8** to (*Z*)-stilbene bear trans diaxial stereochemistry between 1-H and 10b-H (J_{1-10b}=10.0 Hz) and are assigned to be the exo-cycloadducts.

The side product **13** obtained together with **4** in the reaction of **1a** with (*E*)-stilbene was assigned as methyl 1,2-diphenylpyrrolo[2,1-*a*]isoquinoline-3-carboxylate. Its formation presumably arose from **4** by homolytic thermal decarboxylation since **4** was quantitatively converted into **13** on treatment with chloranil under reflux in toluene for 0.5 h.[12]

Ylides **1** similarly react with such unsymmetrically aryl-substituted olefins as indene and styrene. In the cycloaddition of **1b** to indene an inseparable mixture of two cycloadducts was obtained in a 3:2 ratio (^{1}H NMR). As both the isomers show 8a-H and 13b-H as doublets, they are stereoisomeric mixtures of regioselective cycloadducts **9A** and **9B** (Scheme 1 and Table 1). The major isomer **9A** showing relatively big $J_{13a-13b}$ (9.5 Hz) and the major one **9B** showing smaller $J_{13a-13b}$ (5.2 Hz) are assigned to be the exo- and endo-cycloadducts, respectively.

The cycloadditions with styrene are also regioselective. Though ester-stabilized ylides **1a** and **1c** produced 2-exo-phenyl-substituted cycloadducts **10** and **12** as single products (Scheme 1 and Table 1), dicyanomethylide **1b** afforded a 3:2 mixture of two stereoisomers (by ^{1}H NMR of the crude reaction mixture). When this mixture is chromatographed over silica gel (hexane:ethyl acetate=10:1 v/v), the major isomer **11A** is isolated in 88% yield, indicating that the minor isomer **11B** has isomerized into **11A** during the chromatographic procedure.

This epimerization is most likely to be acid-

Table 1. Cycloadditions of Isoquinolinium Ylides **1** to Aryl-Substituted Olefins

Olefin	Equiv	Ylide	Solvent	Time/h	Product (Yield/%)[a]	Isomer ratio[b]

a) Yield of isolated products. b) Isomer ratio of isolated products. c) Inseparable mixture whose ratio was determined by ^{1}H NMR spectrum. d) Recovered **1b**: 19%. e) Isomer ratio of the crude reaction mixture (^{1}H NMR). f) Compound **11B** isomerizes into **11A** on silica-gel chromatography.

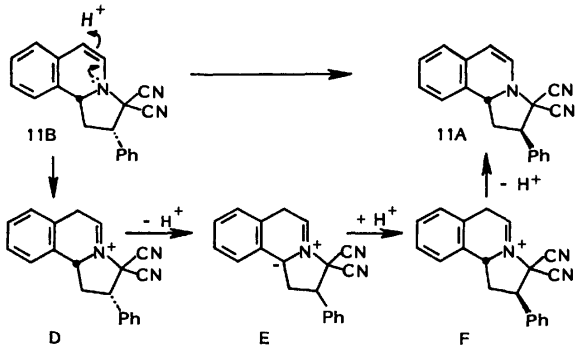

Fig. 2. Possible mechanism for the isomerization of **11B** into **11A**.

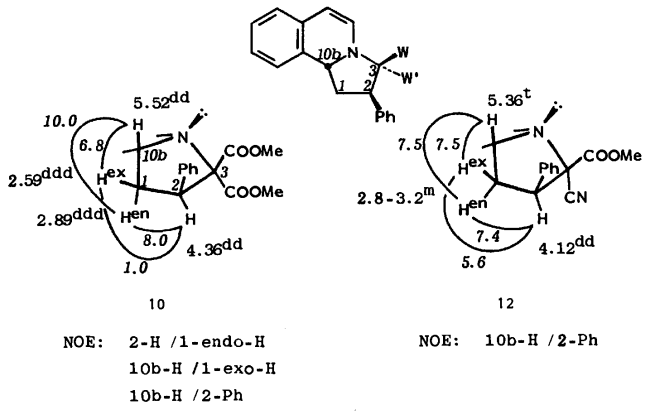

Fig. 3. Stereostructures of two styrene adducts **10** and **12**.

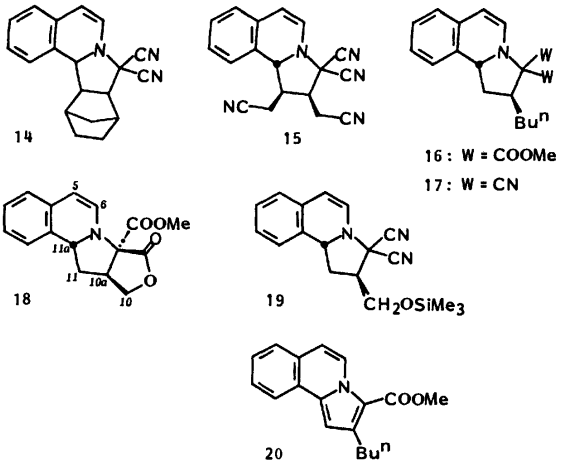
catalyzed via azomethine ylide 1,3-dipole intermediate **D** (Fig. 2). Although neither acetic acid nor phenol in aprotic solvents such as chloroform and dimethyl sulfoxide effects this epimerization, the epimerization is completed on treatment of the mixture of **11A** and **11B** (2:1) with Molecular Sieves 4A in dichloromethane for 3 days or with a catalytic amount of trifluoroacetic acid in ethanol for 1 day, both at room temperature. The epimerization on chromatography is found to be most effective.

Stereostructures of **10** and **12** were determined as the 2-exo-phenyl cycloadducts of **1a** and (*E*,*Z*)-**1c**, respectively, on the basis of the spectral data in which NOE difference spectrum was most informative. Thus notable NOE's were observed between 10b-H/2-phenyl of **10** and **12**, 2-H/1-endo-H of **10**, and 10b-H/1-exo-H of **10** indicating the 2-exo-phenyl substitution. Both cycloadducts **10** and **12** exhibit quite different coupling patterns among the methylene and methine hydrogens on the newly constructed fused pyrrolidine ring as shown in Fig. 3. This difference arises from the bulkiness of the 3-endo substituent W' (**10**: COOMe and **12**: CN).

Since **11A** and **11B** derived from dicyanomethylide **1b** and styrene are thermodynamic and kinetical



Scheme 2.

products as described above, respectively, the 2-exo-phenyl structure for **11A** and 2-endo-phenyl structure for **11B** are reasonable. Coupling patterns of **11A** (J_{1-2}=8.0, 7.0 and J_{1-10b}=8.0, 7.8 Hz) are close to those of **12** which is carrying a small cyano group as the 3-endo substituent, confirming the 2-exo-phenyl stereochemistry of **12**. The 2-endo-phenyl isomer **11B** has the anti diaxial relationship between 10b-H and 1-endo-H and between 1-endo-H and 2-H as confirmed on the basis of the coupling patterns (J_{1-2}=12.0, 6.6 and J_{1-10b}=9.0, 5.9 Hz).

Cycloadditions to Alkyl-Substituted Olefins. Norbornene as a symmetrically substituted olefin of nonactivated type is so reactive to ylide **1b** that 89% yield of the cycloadduct **14** was produced under reflux in toluene for 0.7 h (Scheme 2 and Table 2). The product **14** consists of two stereoisomers in a 3:1 ratio which can not be separated from each other by silica-gel column chromatography. Among four possible stereostructures (exo, exo-, exo, endo-, endo, exo-, and endo, endo-isomers) in respect of the ylide (exo or endo)-norbornene (exo or endo) approach, **14** would be assigned to be the exo-exo and exo-endo stereoisomers on the basis of the exo-selective cycloadditions of ylides **1** with alkyl-substituted olefins discussed below.

Contrary to the high reactivity of strained norbornene, (*Z*)-3-hexene-1,6-dinitrile as a 1,2-disubstituted acyclic (*Z*)-olefin is less reactive. Heating ylide **1b** with this olefin at reflux in toluene for 8 days under nitrogen gave 24% yield of cycloadduct **15** as a single stereoisomer and 55% of the starting ylide **1b** was recovered. 1-Hexene as an unsymmetrically substituted 1-olefin regioselectively traps the ylide **1a** and **1b** to furnish 2-exo-butyl-substituted cycloadducts **16** and **17**. In the former case, part of the cycloadduct **16** was again aromatized by the elimination of an ester moiety at the 3-position to give **20**.

The reaction of ylide **1a** with O-unprotected 2-propen-1-ol takes place under similar conditions to

Table 2. Cycloadditions of Isoquinolinium Ylides **1** to Alkyl-Substituted Olefins

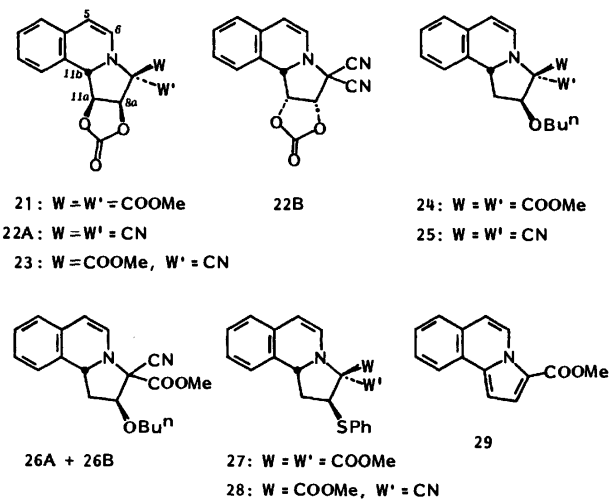
provide a lactone **18** in 32% yield (Scheme 2 and Table 2), indicating the regio- and stereoselective formation of 2-exo-hydroxymethyl-substituted cycloadduct followed by an internal lactonization with the 3-exo-ester group. The stereostructure of **18** is confirmed by the shielding of 11a-H (δ=4.12) from the carbonyl group of the fused lactone ring. Similarly 3-(trimethylsilyl-oxy)propene as O-protected 2-propen-1-ol reacts with ylide **1b** to give the 2-exo-substituted cycloadduct **19**.

Cycloadditions to Electron-Rich Olefins. The strained and electron-rich double bond of vinylene carbonate undergoes cycloadditions with electron-deficient ylides **1a—c** under reflux in toluene to give the corresponding cycloadducts **21—23** (Scheme 3 and Table 3). Though **21** and **23** are single isomers, **22** consists of exo- **22A** and endo-cycloadduct **22B** in a 40:13 ratio of isolated products. The major isomer **22A** which shows 11b-H as a singlet signal ($J_{11a-11b}$=0 Hz) is determined to be the exo structure; the single product **23** produced from ylide **1c** is also assigned as the exo-cycloadduct based upon the zero coupling between 11a-H and 11b-H.

The cycloadduct **21** bearing two relatively bulky ester groups at the 8-position must occupy a conformation different from that for the other two exo-cycloadducts **22A** and **23** which bear a small cyano moiety as the 8-endo substituent. The 8-endo-ester group would move to outer side in order to avoid steric congestion so that the coupling between 11a-H and 11b-H becomes bigger. Thus **21** was assigned as the exo-cycloadduct whose $J_{11a-11b}$ is 5.5 Hz. Similar



Scheme 3.

difference has been observed above between the two exo-cycloadducts to acenaphtylene **2** and **3A** ($J_{14b-14c}$: **2**: 7.8 and **3A**: 0 Hz).

Butyl vinyl ether or phenyl vinyl sulfide as an electron-rich olefin readily reacts with ylides **1a—c** to give the regio- and stereoselective 2-exo-butoxy- **24—26** or 2-exo-phenylthio-substituted cycloadducts **27,28** (Scheme 3 and Table 3). The cycloadduct **27** is thermally labile so as to undergo eliminative and decarboxylative aromatization leading to methyl [2,1-*a*]isoquinoline-3-carboxylate (**29**). An authentic sample of **29** is available in the reaction of **1a** with

phenyl vinyl sulfoxide in good yield.

The 2-exo-butoxy stereochemistry of **24** was confirmed on the basis of NOE difference spectrum which showed clear NOE's between 1-endo-H and 2-H and between 1-exo-H and 10b-H. Coupling constants $J_{1\text{-}10b}$(trans)=10.6 and $J_{1\text{-}2}$(trans)=0 Hz are also consistent with the assigned structure.

The other cycloadducts **25**, **27**, and **28** show similar coupling patterns to those of the cycloadducts to 1-hexene **16—17** and are assigned to be the 2-exo-substituted cycloadducts as shown in Scheme 3. Resemblance of the coupling patterns of the isomeric cycloadducts **26A** and **26B** indicates the same configuration, and even almost the same conformation, around the 1-, 2-, and 10b-positions. They are assigned as the 3-epimers each other, while it was unsuccessful to determine which is which.

Regioselectivity. As described above, the cycloadditions of highly stabilized isoquinolinium ylides **1a—c** with aryl- and alkyl-substituted and electron-rich olefins proceeded all in regioselective manners to give the single regioisomers of cycloadducts **10—12**, **16—19**, and **24—28** bearing the substituent from olefins at the 2-position.

This exclusive regioselection can be explained in terms of frontier molecular orbital (FMO) theory.[13] Interaction between LUMO of ylides **1** and HOMO of olefins would predominantly control reactivity and regioselectivity of their cycloadditions since the ylides **1** are electron-deficient and the olefins are relatively electron-rich. The LUMOs of ylides **1** must carry larger atomic orbital coefficients at the γ-carbon rather than the ylide carbon; β-coefficients must be larger than those at the α-carbons in HOMOs of the olefins employed in the present work (Fig. 4).

Stereoselectivity. Cycloadditions of bis(methoxycarbonyl)methylide **1a** were exclusively stereoselective: The exo-cycloadducts **2** and **21**, 1-exo-2-endo-cycloadduct **4**, and 2-exo-cycloadducts **10**, **16**, **18**, **24**, and **27** were produced. Though there are a few exceptions the *E,Z*-ylide isomer of cyano(methoxycarbonyl)methylide **1c** was mostly involved in its stereoselective cycloadditions with olefins leading to **8**, **12**, **23**, and **28**: Only in the reactions with (*E*)-stilbene and butyl vinyl ethers two isomeric cycloadducts **6** and **26** were formed. Compared with these stereoselective reactions of ester-stabilized ylides **1a** and **1c**, cycloadditions using dicyanomethylide **1b** are frequently poor in stereoselectivity: Mixtures of two isomeric cycloadducts **3**, **9**, **11**, **14**, and **22** were formed in the reactions with acenaphthylene, indene, styrene, norbornene, and vinylene carbonate.

In several cases, stereoselectivity can be explained on the basis of secondary orbital interaction and steric repulsion as shown below.

There are two approaches possible for the cycloaddition of ylides **1a—c** to (*E*)-stilbene, 1-exo-2-endo **G** and 1-endo-2-exo approach **H** (Fig. 5). Attractive secondary orbital interaction would work between the phenyl and the ester moiety W′ (=COOMe in the approach **G**) or W (=COOMe in **H**), while repulsion would be present in the approach **H** between the phenyl and the isoquinolinium ring. Thus ylide **1a** (W=W′=COOMe) and **1b** (W=W′=CN) react with (*E*)-stilbene through 1-exo-2-endo-selective approach **G** furnishing **4** and **5**. On the other hand, the approach **G** competes with **H** since steric repulsion caused by one of the phenyls is cancelled by attractive interaction working between the ester W (=COOMe) and the other phenyl plane.

The exo-selective cycloadditions of ylides **1b** and **1c** to (*Z*)-stilbene via approach **I** are reasonable from the standpoints of steric repulsion and attractive interaction (Fig. 5).

The ylides **1a** and **1c** which carry at least one ester moiety underwent exo-selective cycloadditions to styrene affording **10** and **12**. Attractive interaction between the phenyl of styrene and the ester W (=COOMe) probably determined the stereoselectivity. If such attraction is absent, both exo and endo approaches occur. Thus two stereoisomers **11A** and

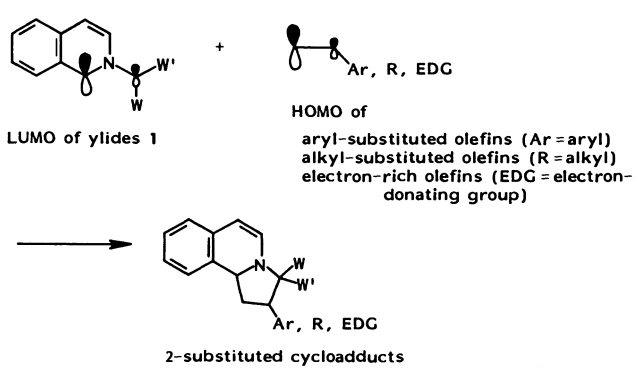


Fig. 4. $LUMO_{ylide}$–$HOMO_{dipolarophile}$ interaction leading to regioselective cycloadducts.

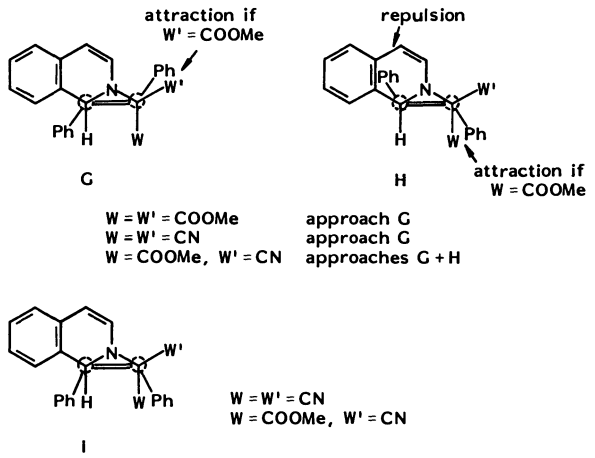

Fig. 5. Stereoselectivity between ylides **1** and (*E*)- and (*Z*)-stilbenes.

11B were formed in the reaction of dicyanomethylide **1b** with styrene.

The competitive formation of sterically unfavorable endo-cycloadducts **3B 9B**, one of **14**, and **22B** in the cycloadditions of dicyanomethylide **1b** can not be interpreted so far. The decrease of ylide-specificity observed in the reaction of ylide **1c** with butyl vinyl ether leading to **26A** and **26B** is not be solved yet.

Use of Other Heteroaromatic N-Ylides. At an early stage of the present work, several derivatives of pyridinium methylides were employed. Compared to satisfactory reactivity of the three isoquinolinium methylides **1a—c**, their pyridinium analogs are absolutely inert to nonactivated olefins: Thus pyridinium dicyanomethylide was recovered intact in the reactions with styrene (reflux in toluene for 33 h), butyl vinyl ether (reflux in toluene for 84 h or at 140 °C for 20 h), and vinylene carbonate (reflux in toluene for 66 h). Attempted cycloadditions of 3,5-dimethylpyridinium bis(methoxycarbonyl)methylide with styrene, vinylene carbonate, or butyl vinyl ether as well as that of 4-methoxypyridinium bis(methoxycarbonyl)methylide with styrene produced no corresponding cycloadducts, but decomposition of the ylides was observed.

Both energy levels of LUMO (+2.046 eV) and HOMO (−8.792 eV) of pyridinium methoxycarbonylmethylide are calculated to be higher than those of isoquinolinium methoxycarbonylmethylide (LUMO: +0.588 and HOMO: −9.082 eV).[14] Accordingly pyridinium methylides must show relatively less enhanced reactivity than the corresponding isoquinolinium methylides, especially in the cycloadditions under control of $LUMO_{dipole}$–$HOMO_{dipolarophile}$. The observed low reactivity of these pyridinium methylides is the case.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 Hz), a JEOL FX-100 (100 MHz), or a JEOL GSX-270 instrument (270 MHz) and ^{13}C NMR on a JEOL FX-100 (25.05 MHz) or a GSX-270 spectrometer (67.94 MHz). Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. High resolution mass spectra were also obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a Lobar column (20×180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

Materials. Isoquinolinium dicyanomethylide (**1b**)[15] or cyano(methoxycarbonyl)methylide (**1c**)[16] is directly available from the reaction of isoquinoline with tetracyanooxirane or methyl 2-bromocyanoacetate, respectively, according to the reported method. 2-[Bis(methoxycarbonyl)methyl]isoquinolinium bromide[16] can be prepared from isoquinoline and dimethyl bromomalonate. Ylide **1a**[16] is either isolated on treatment of the salt with aqueous potassium carbonate or generated in situ by the action with triethylamine in an appropriate reaction solvent. 2-[Bis(methoxycarbonyl)methyl]isoquinolinium bromide: ^{1}H NMR (DMSO-d_6) δ=3.92 (6H, s, COOMe), 7.55 (1H, br s, CH), 8.0—9.1 (6H, m, Ar), and 10.50 (1H, br s, 1-H); ^{13}C NMR (DMSO-d_6) δ=54.45 (COOMe), 71.68 (ylide C), 124.78, 126.36, 127.30, 131.08, 131.44, 136.31, 137.75, 138.35, 152.85 (1-C), and 163.05 (COOMe). **1a:** ^{1}H NMR ($CDCl_3$) δ=3.75 (6H, s, COOMe), 7.7—8.3 (5H, m, 3-, 4-, 5-, 6-, and 7-H), 8.33 (1H, dd, J=8.0 and 1.0 Hz 3-H), and 9.32 (1H, s, 1-H); ^{13}C NMR ($CDCl_3$) δ=50.65 (COOMe), 97.26 (ylide C), 123.44, 126.75, 127.66, 129.67, 130.10, 135.53, 136.28, 141.32 (3-C), 153.41 (1-C), and 165.70 (COOMe); **1c:** ^{1}H NMR ($CDCl_3$) δ=3.80 (3H, s, COOMe), 7.7—8.1 (5H, m, 4-, 5-, 6-, 7-, and 8-H), 8.83 (1H, dd, J=8.0 and 1.0 Hz, 3-H), and 10.11 (1H, s, 1-H); ^{13}C NMR ($CDCl_3$) δ=50.81 (COOMe), 121.02 (CN), 124.29, 126.69, 128.02, 128.49, 130.67, 130.88, 132.11, 132.88 (3-C), 137.56 (1-C), and 165.00 (COOMe).

General Procedure for the Cycloadditions of Isoquinolinium Methylides 1 to Olefins. A mixture of isoquinolinium methylide **1** (1 mmol) and olefin in dry toluene or xylene was heated at reflux under nitrogen. After the reaction was over, the reaction mixture was cooled to room temperature. When some precipitate appeared, it was collected on a filter. The filtrate was evaporated in vacuo and the residue as chromatographed over silica gel by using hexane–ethyl acetate.

2: The residue obtained from the crude reaction mixture by evaporation of the solvent was chromatographed over silica gel with hexane–ethyl acetate (10:1 v/v) to give **2**: Pale yellow prisms (benzene–hexane); mp 209—210 °C; IR (KBr) 1750, 1723, 1610, 1250, 1230, and 770 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.07, 3.86 (each 3H, s, COOMe), 4.68 (1H, dd, J=8.0 and 7.8 Hz, 14b-H), 4.81 (1H, d, J=8.0 Hz, 8a-H), 5.17 (1H, d, J=7.8 Hz, 14c-H), 5.71 (1H, d, J=7.6 Hz, 5-H), 6.65 (1H, d, J=7.6 Hz, 6-H), and 6.9—7.7 (10H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=50.53 (d, 8a-C), 51.82, 53.36 (each q, COOMe), 55.95 (d, 14b-C), 67.18 (d, 14c-C), 76.65 (s, 8-C), 106.06 (d, 5-C), 120.07, 121.48, 123.48, 123.66, 123.95, 124.54, 126.30, 127.74, 128.25, 131.60, 131.89, 133.83, 134.89, 139.12, 141.30, 144.60, and 169.59 (s, 2C of COOMe); MS m/z (rel intensity, %) 411 (M^+, 19), 260 (16), 259 (base peak), 201 (38), and 143 (25). Found: C, 76.05; H, 5.16; N, 3.46%. Calcd for $C_{26}H_{21}NO_4$: C, 75.90; H, 5.14; N, 3.40%.

3A+3B: The crude reaction mixture was chromatographed, after evaporation of the solvent in vacuo, over silica gel with hexane–ethyl acetate (10:1 v/v) to give an inseparable mixture of **3A** and **3B** (3:1 by ^{1}H NMR): Colorless solid; IR (KBr) 2360, 1620, 1250, 1169, 783, and 773 cm^{-1}; ^{1}H NMR ($CDCl_3$) **3A**: δ=4.48 (1H, d, J=6.9 Hz, 8a-H), 4.82 (1H, dd, J=8.8 and 6.9 Hz, 14b-H), 4.99 (1H, d, J=8.8 Hz, 14c-H), 6.02 (1H, d, J=7.6 Hz, 5-H), 6.49 (1H, d, J=7.6 Hz, 6-H), and 7.0—8.0 (10H, m, Ar). **3B**: δ=4.6—4.8 (2H, m, 8a- and 14b-H), 5.03 (1H, d, J=7.6 Hz, 5-H), 5.22 (1H, d, J=6.0 Hz, 14c-H), 5.87 (1H, d, J=7.6 Hz, 6-H), and 7.0—8.0 (9H, m, Ar); MS m/z (rel intensity, %) 345 (M^+, 3),

194 (16), 193 (base peak), 166 (17), 152 (48), 139 (16), 129 (21), 128 (19), and 102 (13). Found: C, 83.38; H, 4.38; N, 12.15%. Calcd for $C_{24}H_{15}N_3$: C, 83.46; H, 4.38; N, 12.16%.

4 and 13: When the crude reaction mixture was subjected to column chromatography over silica gel with hexane-ethyl acetate (10:1 v/v), a mixture of **4** and **13** was obtained. This mixture was again chromatographed with hexane-ethyl acetate (20:1 v/v) to give **13** (6%) and then **4** (23%). As compound **4** is so susceptible as to suffer from ready decarboxylative aromatization leading to **13**, only ^{1}H NMR spectrum is available. **4**: ^{1}H NMR ($CDCl_3$) δ=3.08, 3.72 (each 3H, s, COOMe), 3.97 (1H, dd, J=6.2 and 2.0 Hz, 1-H), 4.58 (1H, d, J=2.0 Hz, 2-H), 5.53 (1H, d, J=7.5 Hz, 6-H), 5.99 (1H, d, J=6.2 Hz, 10b-H), 6.34 (1H, br d, J=7.5, 10-H), 6.63 (1H, d, J=7.5 Hz, 5-H), and 6.5—7.4 (13H, m, Ar). **13**: Colorless prisms (diethyl ether); mp 223—224 °C; IR (KBr) 1690, 1430, 1365, 1245, 1190, 1065, and 700 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.59 (3H, s, COOMe), 7.00 (1H, d, J=7.5 Hz, 6-H), 7.1—7.7 (15H, m, Ar), and 9.33 (1H, d, J=7.5 Hz, 5-H); MS m/z (rel intensity, %) 377 (M^+, 99), 346 (15), 320 (13), 319 (41), 318 (20), 317 (33), 316 (18), 315 (19), 227 (16), 226 (base peak), and 168 (13). Found: C, 82.85; H, 5.16; N, 3.90%. Calcd for $C_{26}H_{19}NO_2$: C, 82.74; H, 5.07; N, 3.71%.

5: Part of **5** precipitated out when the crude solution was cooled to room temperature. Silica-gel chromatography of the filtrate, after evaporation of the solvent in vacuo, with hexane-ethyl acetate (10:1 v/v) afforded major part of **5**. Colorless prisms (diethyl ether); mp 182—182.5 °C; IR (KBr) 2220, 1630, 1454, 1294, 1256, 1167, 779, 761, and 706 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.09 (1H, dd, J=11.3 and 1.0 Hz, 1-H), 4.27 (1H, dd, J=11.3 and 8.0 Hz, 2-H), 5.32 (1H, br d, J=8.0 Hz, 10b-H), 5.95 (1H, d, J=7.8 Hz, 6-H), 6.40 (1H, d, J=7.8 Hz, 5-H), and 6.6—7.5 (14H, m, Ar); MS m/z (rel intensity, %) 373 (M^+, 2), 194 (14), 193 (base peak), 180 (32), 179 (50), 178 (34,) 166 (22), 165 (35), 139 (16), 129 (24), 128 (24), 115 (12), 103 (13), and 102 (20). Found: C, 83.66; H, 5.12; N, 11.20%. Calcd for $C_{26}H_{19}N_3$: 83.62; H, 5.13; N, 11.25%.

6A and 6B: Column chromatography of the crude reaction mixture over silica gel with hexane-ethyl acetate (15:1 v/v) provided **6A** and then **6B**. **6A**: Pale yellow needles (benzene-diethyl ether); mp 215—215 °C; IR (KBr) 3020, 1750, 1620, 1240, and 770 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.84 (3H, s, COOMe), 3.99 (1H, d, J=12.1 Hz, 2-H), 4.26 (1H, dd, J=12.1 and 9.1 Hz, 1-H), 5.47 (1H, d, J=9.1 Hz, 10b-H), 5.72 (1H, d, J=7.5 Hz, 6-H), 6.12 (1H, d, J=7.5 Hz, 5-H), and 6.6—7.4 (14H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=54.18 (q, COOMe), 55.29 (d, 2-C), 61.83 (d, 1-C), 64.00 (d, 10b-C), 71.77 (s, 3-C), 106.71 (d, 6-C), 115.66 (s, CN), 124.07, 124.48, 126.83, 127.95, 128.18, 128.89, 129.00, 129.13, 129.36, 132.25, 138.18, and 167.71 (s, COOMe); MS m/z (rel intensity, %) 406 (M^+, 4), 227 (13), 226 (base peak), 168 (29), 143 (18), 140 (13), and 115 (10). Found: C, 79.82; H, 5.55; N, 6.83%. Calcd for $C_{27}H_{22}N_2O_2$: C, 79.78; H, 5.46; N, 6.89%. **6B**: Pale yellow prisms (benzene-hexane); mp 160—162 °C; IR (KBr) 3010, 1750, 1610, 1440, 1290, 1220, 770, and 700 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.25 (3H, s, COOMe), 4.11 (1H, d, J=10.9 Hz, 2-H), 4.30 (1H, dd, J=10.9 and 8.2 Hz, 1-H), 5.32 (1H, d, J=8.2 Hz, 10b-H), 5.74 (1H, d, J=7.8 Hz, 6-H), 6.28 (1H, d, J=7.8 Hz, 5-H), and 6.6—7.4 (14H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=53.30 (q, COOMe), 53.42 (d, 2-C), 63.83 (d, 1-C), 64.24 (d, 10b-C), 70.06 (s, 3-C), 107.07 (d, 6-C), 117.83 (s, CN), 123.83, 124.36, 126.77, 127.95, 128.24, 128.83, 129.01, 129.42, 129.89, 131.01, 132.60, 133.95, 138.72, and 165.83 (s, COOMe); MS m/z (rel intensity, %) 406 (M^+, 5), 227 (15), 226 (base peak), 217 (10), 168 (27), 143 (19), and 140 (13). Found: C, 79.85; H, 5.46; N, 6.87%. Calcd for $C_{27}H_{22}N_2O_2$: C, 79.78; H, 5.46; N, 6.89%.

7: Unreacted **1b** (19%) was recovered when the mixture was cooled to room temperature. The filtrate was chromatographed over silica gel by using hexane-ethyl acetate (10:1 v/v) to give **7**. Colorless prisms (diethyl ether-hexane); mp 155—156 °C; IR (KBr) 2220, 1628, 1489, 1454, 1294, 1261, 1137, 785, and 698 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.03 (1H, d, J=7.0 Hz, 2-H), 4.53 (1H, dd, J=10.0 and 7.0 Hz, 1-H), 5.54 (1H, d, J=7.0 Hz, 10b-H), 6.06 (1H, d, J=7.0 Hz, 6-H), 6.48 (1H, d, J=7.0 Hz, 5-H), and 6.7—7.3 (14H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=55.03 (d, 2-C), 59.33 (d, 1-C), 59.86 (d, 10b-C), 60.25 (s, 3-C), 111.33 (d, 6-C), 112.21, 115.00 (each s, CN), 124.12, 125.10, 126.22, 127.93, 128.22, 128.37, 128.80, 128.91, 129.00, 129.20 129.98, 131.05, 133.05, and 135.49; MS m/z (rel intensity, %) 373 (M^+, 20), 194 (17), 193 (base peak), 180 (34), 179 (57), 178 (39), 166 (15), 165 (32), 154 (24), 153 (13), 139 (11), 129 (18), 128 (29), 127 (21), 115 (13), 103 (29), and 102 (20). Found: C, 83.50; H, 5.15; N, 11.19%. Calcd for $C_{26}H_{19}N_3$: C, 83.62; H, 5.13; N, 11.25%.

8: Column chromatography of the reaction mixture over silica gel with hexane-ethyl acetate (10:1 v/v) gave **8**. Colorless prisms (ethyl acetate-hexane); mp 225—227 °C; IR (KBr) 1760, 1650, 1245, 770, and 705 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.40 (3H, s, COOMe), 4.05 (1H, d, J=7.0 Hz, 2-H), 4.57 (1H, dd, J=10.0 and 7.0 Hz, 1-H), 5.71 (1H, d, J=10.0 Hz, 10b-H), 5.89 (1H, d, J=7.5 Hz, 6-H), 6.49 (1H, d, J=7.5 Hz, 5-H), 6.58 (1H, br d, J=7.0 Hz, 10-H), and 6.7—7.2 (13H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=53.47 (q, COOMe), 55.12 (d, 2-C), 60.24 (d, 1-C),69.95 (d, 10b-C), 108.95 (d, 6-C), 118.36 (s, CN), 60.24 (d, 1-C), 69.95 (d, 10b-C), 108.95 (d, 6-C), 118.36 (s, CN), 124.24, 124.41, 127.07, 127.42, 127.89, 128.25, 128.42, 128.60, COOMe); MS m/z (rel intensity, %) 406 (M^+, 6), 227 (16), 226 (base peak), 168 (82), and 143 (12). Found: C, 79.65; H, 5.46; N, 7.00%. Calcd for $C_{27}H_{22}N_2O_2$: C, 79.78; H, 5.46; N, 6.89%.

9A and 9B: The crude reaction mixture was chromatographed over silica gel with chloroform to give a mixture of **9A** and **9B** (59%, 3:2 by ^{1}H NMR). This mixture was separated through flash chromatography in a Lobar column with hexane-ethyl acetate (20:1 v/v) to give **9A** and then **9B**. **9A:** Colorless prisms (diethyl ether-hexane); mp 148—149 °C; IR (KBr) 1620, 1480, 1450, 1410, 1290, 1240, and 1160 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.11 (1H, dd, J=16.0 and 3.3 Hz, 13-exo-H), 3.50 (1H, dd, J=16.0 and 9.4 Hz, 13-endo-H), 3.6—3.7 (1H, m, 13a-H), 4.36 (1H, d, J=8.4 Hz, 8a-H), 4.64 (1H, d, J=10.3 Hz 13b-H), 5.97 (1H, d, J=7.7 Hz, 5-H), 6.48 (1H, d, J=7.7 Hz, 6-H), and 7.1—7.6 (8H, m, Ar); MS m/z (rel intensity, %) 309 (M^+, 10), 194 (16), 193 (base peak), 166 (18), 139 (21), 129 (16), 128 (17), 116 (69), and 115 (77). Found: C, 81.75; H, 4.66; N, 13.39%. Calcd for $C_{21}H_{15}N_3$: C, 81.53; H, 4.89; N, 13.58%. **9B**: Pale yellow prisms (diethyl ether-hexane); mp 115—156 °C; IR (KBr) 1620, 1450, 1400, 1290, 1240, and 1180 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.26 (1H, dd, J=16.0 and 9.2 Hz, 13-endo-H), 3.34 (1H, dd, J=16.0 and 7.0 Hz, 13-exo-H), 3.8—3.9 (1H, m, 13a-H), 4.43 (1H, d, J=7.7 Hz, 8a-H), 5.07 (1H, d, J=5.1 Hz, 13b-H), 5.79 (1H, d, J=7.7 Hz, 5-H), 6.36 (1H, d, J=7.7 Hz, 6-H), and 7.0—7.5 (8H m, Ar); MS m/z (rel intensity, %) 309 (M^+, 8), 193 (95), 166 (22), 139 (21), 129 (24), 128 (29), 116 (77), 115 (base peak), 89 (23), 77 (22), and 63 (26). Found: C, 81.34; H, 4.72; N,

13.43%. Calcd for $C_{21}H_{15}N_3$: C, 81.53; H, 4.89; N, 13.58%.

10: The crude reaction mixture was chromatographed, after evaporation of the solvent in vacuo, over silica gel with hexane-ethyl acetate (5:1 v/v) to afford **10**: Colorless prisms (ethyl acetate-hexane); mp 164 °C; IR (KBr) 1757, 1734, 1608, 1454, 1288, 1271, 1227, 1207, 1038, 769, and 706 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.59 (1H, ddd, J=12.5, 6.8, and 1.0 Hz, 1-endo-H), 2.89 (1H, ddd, J=12.5, 10.0, and 8.0 Hz, 1-exo-H), 3.20, 3.67 (each 3H, s, COOMe), 4.36 (1H, dd, J=8.0 and 1.0 Hz, 2-H), 5.52 (1H, dd, J=10.0 and 6.8 Hz, 10b-H), 5.62 (1H, d, J=7.5 Hz, 6-H), 6.61 (1H, d, J=7.5 Hz, 5-H), 6.7—7.4 (4H, m, Ar), and 7.22 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=37.00 (t, 1-C), 50.47 (d, 2-C), 51.95, 52.83 (each q, COOMe), 60.36 (d, 10b-C), 103.77 (d, 6-C), 123.07, 123.36, 125.83, 127.36, 128.48, 128.72, 131.19, 132.89, 133.30, 140.72, 168.78 (q, COOMe), and 169.07 (q, COOMe); MS m/z (rel intensity, %) 363 (M^+, 17), 304 (35), 245 (20), 244 (78), 243 (33), 201 (29), 167 (64), 166 (24), 143 (88), 130 (25), 129 (46), 128 (38), 116 (26), 115 (73), 104 (72), and 103 (32). Found: C, 72.65; H, 5.94; N, 4.09%. Calcd for $C_{22}H_{21}NO_4$: C, 72.71; H, 5.82; N, 3.85%.

11A: The crude product obtained by evaporation of the solvent in vacuo was subjected to ^1H NMR measurement which showed a 3:2 mixture of **11A** and **11B**, and then chromatographed over silica gel with hexane-ethyl acetate (10:1 v/v) to provide 88% of **11A** as a single product: Colorless prisms (diethyl ether); IR (KBr) 2773, 2229, 1618, 1456, 1406, 1290, 1253, 1217, 773, and 702 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.90 (1H, dd, J=8.0 and 7.0 Hz, one of 1-H), 2.92 (1H, dd, J=8.0 and 7.8 Hz, the other of 1-H), 4.08 (1H, dd, J=8.0 and 7.0 Hz, 3-H), 4.94 (1H, dd, J=8.0 and 7.8 Hz, 10b-H), 6.01 (1H, d, J=7.5 Hz, 6-H), 6.47 (1H, d, J=7.5 Hz, 5-H), 6.9—7.3 (4H m, Ar), and 7.42 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=33.36 (t, 1-C), 54.83 (d, 2-C), 59.00 (d, 10b-C), 61.00 (s, 3-C) 110.77 (d, 6-C), 123.60, 124.95, 127.71, 128.25, 128.54, 129.36, 129.48, 129.66, 131.36, and 134.54; MS m/z (rel intensity, %) 297 (M^+, 13), 194 (16), 193 (base peak), 166 (13), 129 (15), 128 (17), 115 (16), 104 (916), 103 (14), 102 (12), and 77 (15). Found: C, 80.80; H, 5.10; N, 14.06%. Calcd for $C_{20}H_{15}N_3$: C, 80.78; H, 5.08; N, 14.13%.

^1H NMR spectrum ($CDCl_3$) of **11B** which was abstracted from the spectrum of the mixture with **11A**: δ=2.7—3.0 (2H, m, 1-H), 4.14 (1H, dd, J=12.0 and 6.6 Hz, 2-H), 5.10 (1H, dd, J=9.0 and 5.9 Hz, 10b-H), 5.87 (1H, d, J=7.3 Hz, 6-H), and 6.33 (1H, d, J=7.3 Hz, 5-H).

12: The reaction mixture was evaporated in vacuo to dryness to give residue which solidified on standing: Colorless prisms (diethyl ether); mp 130—132 °C; IR (KBr) 2240, 1750, 1605, 1450, 1220, 1210, 765, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.8—3.2 (2H, m, 1-H), 3.38 (3H, s, COOMe), 4.12 (1H dd, J=7.4 and 5.6 Hz, 2-H), 5.36 (1H, t, J=7.5 H, 10b-H), 5.86 (1H, d, J=7.5 Hz, 6-H), 6.34 (1H, d, J=7.5 Hz, 5-H), 6.8—7.5 (4H, m, Ar), and 7.29 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=35.65 (t, 1-C), 53.06 (q, COOMe), 54.47 (d, 2-C), 59.65 (d, 10b-C), 70.42 (s, 3-C), 107.89 (d, 6-C), 117.71 (s, CN), 123.42, 124.13, 126.95, 127.60, 128.36, 128.77, 129.77, 130.95, 131.83, 136.72, and 165.72 (s, COOMe); MS m/z (rel intensity, %) 330 (M^+, 56), 329 (29), 271 (45), 227 (17), 226 (base peak), 168 (29), 143 (98), 129 (22), and 115 (26). Found: C, 76.27; H, 5.58; N, 8.41%. Calcd for $C_{21}H_{18}N_2O_2$: C, 76.34; H, 5.49; N, 8.48%.

14 (an inseparable mixture of two stereoisomers (3:1 by ^1H NMR)): The crude reaction mixture was evaporated in vacuo and the residue was chromatographed over silica gel with hexane-ethyl acetate (5:1 v/v) to give **14** as a 3:1 mixture of two isomers): Colorless crystals (diethyl ether); IR (KBr) 2964, 1622, 1483, 1456, 1409, 1284, 1250, 1178, 777, and 710 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.0—2.0 (6H, m, CH_2), 2.4—3.0 (4H, m, CH), 4.15 (3/4H, d, J=5.9 Hz, 10b-H), 4.83 (1/4H, d, J=6.1 Hz, 10b-H), 5.72 (1/4H, d, J=8.0 Hz, =CH), 5.91 (3/4H, d, J=7.8 Hz, =CH), 6.33 (1/4H, d, J=8.0 Hz, =CHN), 6.42 (3/4H, d, J=7.8 Hz, =CHN), and 6.9—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) major isomer: δ=27.59, 28.47, 34.37 (each t, CH_2), 38.72, 39.21, 52.88 (each d, CH), 57.67 (d and s, CH and q-C), 63.87 (d, CHN), 110.55 (d, =CH), 112.74, 114.65 (each s, CN), 123.48, 124.75, 127.54, 128.07, 128.76, 131.15, and 131.74; minor isomer: δ=27.59, 29.25, 34.96 (each t, CH_2), 36.67, 40.67, 47.02, 56.59 (each d, CH), 57.32 (s, q-C), 62.65 (d, CHN), 108.40 (d, =CH), 112.04, 113.50 (each s, CN), 125.20, 125.82, 126.86, 129.69, and 132.56; MS m/z (rel intensity, %) 287 (M^+, 7), 194 (19), 193 (73), 166 (32), 165 (21), 139 (24), 129 (base peak), 128 (36), 103 (21), 102 (45), 91 (20), 79 (63), and 77 (52). Found: C, 79.20; H, 5.94; N, 14.56%. Calcd for $C_{19}H_{17}N_3$: C, 79.41; H, 5.96; N,14.62%.

15: Unreacted ylide **1b** precipitated out when the reaction mixture was cooled to room temperature. The filtrate was evaporated in vacuo and chromatographed over silica gel with hexane-ethyl acetate (3:1 v/v) to afford **15.** The fraction eluted with hexane-ethyl acetate (1:1 v/v) gave additional **1b** (The combined yield of recovered **1b** was 55%): Colorless plates (diethyl ether-hexane); mp 151—152 °C; 2220, 1620, 1405, 1280, 1245, 1170, and 770 cm^{-1}: ^1H NMR ($CDCl_3$) δ=2.6—3.6 (6H, m, 1-, 2-H, and CH_2), 5.14 (1H, d, J=4.9 Hz, 10b-H), 5.72 (1H, d, J=7.5 Hz, 6-H), 6.63 (1H, d, J=7.5 Hz, 5-H), and 6.9—7.3 (4H, m, Ar); MS m/z (rel intensity, %) 299 (M^+, 6), 194 (15), 193 (base peak), 192 (10), and 129 (14). Found: C, 72.08; H, 4.37; N, 23.16%. Calcd for $C_{18}H_{13}N_3$: C, 72.23; H, 4.38; N, 23.40%.

16: The reaction mixture was chromatographed, after evaporation of the solvent in vacuo, over silica gel with hexane-ethyl acetate (8:1 v/v) to give **16** and then **20: 16**: Colorless liquid; IR (neat) 2980, 1750, 1740, 1610, 1455, and 770 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.7—1.6 (9H, m, n-Bu), 2.40 (2H, dd, J=8.1 and 4.5 Hz, 1-H), 2.8—3.2 (1H, m, 2-H), 3.65, 3.77 (each 3H, s, COOMe), 4.91 (1H, t, J=8.1 Hz, 10b-H), 5.49 (1H, d, J=7.5 Hz, 6-H), 6.50 (1H, d, J=7.5 Hz, 5-H), and 6.7—8.2 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=13.94 (q, n-Bu), 22.59, 29.30, 30.06 (each t, n-Bu), 33.24 (t, 1-C), 44.36 (d, 2-C), 52.47, 52.83 (each q, COOMe), 58.77 (d, 10b-C), 77.71 (s, 3-C), 102.30 (d, 6-C), 123.07, 123.30, 125.54, 127.36, 131.07, 133.13, 133.89, 169.25 (s, COOMe), and 169.72 (s COOMe); MS m/z (rel intensity, %) 343 (M^+, 10), 284 (17), 132 (90), 100 (18), 85 (71), and 83 (base peak). HRMS Found: m/z 343.1778. Calcd for $C_{20}H_{25}NO_4$: M, 343.1782. **20**: Colorless prisms (hexane); mp 80—81 °C; IR (KBr) 2980, 1680, 1440, and 1350 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.1 (3H, m, n-Bu), 1.2—2.0 (4H, m, n-Bu), 3.00 (2H, t, J=7.5 Hz, n-Bu), 3.96 (3H, s, COOMe), 6.88 (1H, s, 1-H), 6.92 (1H d, J=7.5 Hz, 6-H), 7.3—7.7 (3H, m, Ar), 7.9—8.2 (1H, m, Ar), and 9.20 (1H, d, J=7.5 Hz, 5-H); MS m/z (rel intensity, %) 281 (M^+, 48), 239 (base peak), 181 (20), 180 (42), and 41 (25). Found: C, 76.62; H, 6.84; N, 4.72%. Calcd for $C_{18}H_{19}NO_2$: C, 76.84; H, 6.81; N, 4.98%.

17: The crude mixture was chromatographed over silica gel by using hexane-ethyl acetate (10:1 v/v) to provide **17**: Colorless viscous liquid; IR (neat) 2958, 2926, 2210, 1618,

1456, 1406, 1256, 1178, and 775 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—3.0 (12H, m, 1-, 2-H, and *n*-Bu), 4.59 (1H, dd, *J*=8.2 and 7.5 Hz, 10b-H), 5.90 (1H, d, *J*=7.5 Hz, 6-H), 6.42 (1H, d, *J*=7.5 Hz, 5-H), and 6.8—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=13.82 (q, *n*-Bu), 22.53, 29.77, 31.06 (each t, *n*-Bu), 33.00 (t, 1-C), 49.47 (d, 2-C), 58.36 (d, 10b-C), 59.00 (s, 3-C), 110.13 (d, 6-C), 111.77, 114.00 (each s, CN), 123.60, 124.83, 127.54, 128.18, 128.48, 131.19, and 131.66; MS *m/z* (rel intensity, %) 277 (M^+, 18), 276 (11), 194 (16), and 193 (base peak). HRMS Found: *m/z* 277.1583. Calcd for $C_{18}H_{19}N_3$: M, 277.1578.

18: The crude reaction mixture was chromatographed over silica gel with hexane-ethyl acetate to afford **18**: Pale yellow prisms (diethyl ether-hexane); mp 158—159 °C; IR (KBr) 1760, 1740, 1610, 1240, 1175, 1020, and 760 cm^{-1}: ^1H NMR ($CDCl_3$) δ=2.3—2.7 (2H, m, 11-H), 3.3—3.6 (1H, m, 10a-H), 3.79 (3H, s, COOMe), 4.12 (1H, dd, *J*=9.5 and 4.5 Hz, 11a-H), 4.61 (1H, dd, *J*=9.5 and 3.0 Hz, one of 10-H), 4.67 (1H, dd, *J*=9.5 and 5.0 Hz, the other of 10-H), 5.60 (1H, d, *J*=7.8 Hz, 5-H), 6.68 (1H, *J*=7.8Hz, 6-H), and 6.8—7.2 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=34.41 (t, 11-C), 44.18 (d, 10a-C), 53.42 (q, COOMe), 59.18 (d, 11a-C), 71.83 (s 7a-C), 72.24 (t, 10-C), 104.13 (d, 5-C), 123.48, 123.77, 126.07, 127.89, 130.30, 131.95, 133.30, 168.54 (s, 8-C), and 172.03 (s, COOMe); MS *m/z* (rel intensity, %) 285 (M^+, 50), 284 (base peak), 226 (40), 182 (13), 181 (20), 180 (27), 168 (19), 167 (47), 143 (28), 129 (41), 128 (21), and 115 (29). Found: C, 67.39; H, 5.34; N, 4.86%. Calcd for $C_{16}H_{15}NO_4$: C, 67.36; H, 5.30; N, 4.91%.

19: The crude mixture was chromatographed over silica gel with hexane-ethyl acetate (7:1 v/v) to give **19**: Colorless prisms (hexane); mp 92—93 °C; IR (KBr) 2950, 1610, 1470, 1450, 1400, 1245, 1080, 855, and 830 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.19 (9H, s, $SiMe_3$), 2.13 (1H, ddd, *J*=12.1, 7.5, and 5.9 Hz, 1-endo-H), 2.53 (1H, ddd, *J*=12.1, 10.0, and 8.5 Hz, 1-exo-H), 3.0—3.2 (1H, m, 2-H), 3.89 (1H, d, *J*=8.4 Hz, one of 2-CH_2), 3.90 (1H, d, *J*=7.0 Hz, the other of 2-CH_2), 4.58 (1H, dd, *J*=8.5 and 7.5 Hz, 10b-H), 5.91 (1H, d, *J*=7.5 Hz, 6-H), 6.49 (1H, d, *J*=7.5 Hz, 5-H), and 6.8—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=0.64 (q, $SiMe_3$), 29.12 (t, 1-C), 51.53 (d, 2-C), 57.53 (s, 3-C), 58.95 (d, 10b-C), 62.24 (t, CH_2O), 110.18 (d, 6-C), 111.24, 114.01 (each s, CN), 123.77, 125.01, 127.66, 128.42, 128.83, 131.48, and 131.83; MS *m/z* (rel intensity, %) 323 (M^+, 11), 308 (19), 281 (15), 220 (29), 194 (12), 193 (60), 145 (12), 144 (base peak), and 73 (14). Found: C, 66.62; H, 6.60; N, 12.80%. Calcd for $C_{18}H_{21}N_3OSi$: C, 66.84; H, 6.54; N, 12.99%.

21: This compound was obtained by column chromatography of the crude reaction mixture over silica gel with hexane-ethyl acetate (5:1 v/v): Colorless viscous liquid; IR (neat) 2960, 1820, 1750, 1620, 1560, 1440, and 780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.67, 3.84 (each 3H, s, COOMe), 5,03 (d, *J*=5.5 Hz, 11b-H), 5.43 (1H, dd, *J*=7.5 and 5.5 Hz, 11a-H), 5.72 (1H, d, *J*=7.5 Hz, 8a-H), 5.75 (1H, d, *J*=7.8 Hz, 5-H), 6.52 (1H d, *J*=7.8 Hz, 6-H), and 6.8—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=53.59 (q, 2C, COOMe), 66.54 (d, 11b-C) 75.59 (s, 8-C), 80.01, 81.77 (each d, 8a- and 11a-C), 107.66 (d, 5-C), 120.77, 123.12, 124.42, 127.19, 128.65, 131.19, 132.18, 153.13 (s, 10-C), 165.77, and 166.37 (each s, COOMe); MS *m/z* (rel intensity, %) 345 (M^+, 5), 259 (9), 226 (16), 225 (base peak), 194 (32), 167 (34), 166 (26), 139 (18), 129 (82), 128 (20), 102 (20), and 91 (17). HRMS Found: *m/z* 345.0846. Calcd for $C_{17}H_{15}NO_7$: M, 345.0847.

22A and 22B: When the reaction mixture was cooled to room temperature, less soluble **22A** precipitated out. The filtrate was evaporated in vacuo and the residue was chromatographed over silica gel by using hexane-ethyl acetate (10:1 v/v) to provide **22B**. **22A:** Pale yellow prisms (benzene-ethanol); mp 177—178 °C; IR (KBr) 1813, 1632, 1377, 1255, 1167, 1093, 962, 777, and 761 cm^{-1}; ^1H NMR (DMSO-d_6:$CDCl_3$=1:4 v/v) δ=4.78 (1H, br s, 11b-H), 5.85, 5.87 (each 1H, s, 8a- and 11a-H), 5.98 (1H, d, *J*=7.8 Hz, 5-H), 6.46 (1H, d, *J*=7.8 Hz, 6-H), and 7.0—7.4 (4H, m, Ar); MS *m/z* (rel intensity, %) 279 (M^+, 8), 194 (15), 193 (base peak), 129 (24), and 128 (13). Found: C, 64.53; H, 3.50; N, 14.99%. Calcd for $C_{15}H_9N_3O_3$: C, 64.52; H, 3.25; N, 15.05%. **22B**: Pale yellow needles (benzene-ethanol); mp 193—194 °C; IR (KBr) 1808, 1628, 1182, 1159, 1149, and 775 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.82 (1H, d, *J*=3.6 Hz, 11b-H), 5.46 (1H, d, *J*=6.5 Hz, 8a-H), 5.64 (1H, dd, *J*=6.5 and 3.6 Hz, 11a-H), 6.02 (1H, d, *J*=8.0 Hz, 5-H), 6.42 (1H, d, *J*=8.0 Hz, 6-H), and 7.0—7.2 (4H, m, Ar); MS *m/z* (rel intensity, %) 279 (M^+, 5), 193 (54), 166 (11), 130 (12), 129 (81), 128 (52), 115 (15), 103 (19), 102 (40), and 86 (base peak). Found: C, 64.55; H, 3.41; N, 14.89%. Calcd for $C_{15}H_9N_3O_3$: C, 64.52; H, 3.25; N, 15.05%.

23: The reaction mixture was chromatographed, after evaporation of the solvent in vacuo, over silica gel with hexane-ethyl acetate (3:1 v/v) to give **23**: Colorless prisms (diethyl ether); mp 154—156 °C; IR (KBr) 2220, 1830, 1795, 1770, 1620, 1210, 1140, and 755 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.95 (3H, s, COOMe), 5.22 (1H, br s, 11b-H), 5.53 (2H, m, 8a- and 11a-H), 5.94 (1H, d, *J*=7.5 Hz, 5-H), 6.33 (1H, d, *J*=7.5 Hz, 6-H), and 6.9—7.2 (4H, m, Ar); MS *m/z* (rel intensity, %) 312 (M^+, 8), 227 (15), 226 (base peak), 209 (15), 168 (36), 144 (40), 143 (26), 129 (30), 128 (18), and 115 (14). HRMS Found: *m/z* 312.0749. Calcd for $C_{16}H_{12}N_2O_5$: M, 312.0745.

24: The mixture was evaporated in vacuo and the residue was chromatographed over silica gel with hexane-ethyl acetate (10:1 v/v) to give **24**: Pale yellow prisms (diethyl ether-hexane); mp 101—102 °C; IR (KBr) 2970, 1770, 1740, 1600, 1460, 1420, 1210, 1120, 1070, and 765 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.7 (7H, m, *n*-Bu), 2.26 (1H, ddd, *J*=12.5, 10.6 and 4.1 Hz, 1-endo-H), 2.64 (1H, dd, *J*=12.5 and 5.0 Hz, 1-exo-H), 3.3—4.0 (2H, m OCH_2), 3.64, 3.76 (each 3H, s, COOMe), 4.63 (1H, d, *J*=4.1 Hz, 2-H), 5.06 (1H, dd, *J*=10.6 and 5.0 Hz, 10b-H), 5.45 (1H, d, *J*=7.5 Hz, 6-H), 6.51 (1H, d, *J*=7.5 Hz, 5-H), and 6.8—7.1 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=13.82 (q, *n*-Bu), 19.30, 31.88 (each t, *n*-Bu), 35.59 (t, 1-C), 52.59, 52.95 (each q, COOMe), 59.42 (d, 10b-C), 70.42 (t, OCH_2), 78.30 (s, 3-C), 82.95 (d, 2-C), 101.78 (d, 6-C), 123.12, 123.48, 125.54, 127.48, 130.95, 133.01, 133.95, 167.95 (s, COOMe), and 168.30 (s, COOMe); MS *m/z* (rel intensity, %) 359 (M^+, 38), 358 (20), 300 (30), 259 (22), 226 (27), 225 (22), 201 (22), 167 (34), 143 (base peak), and 130 (11). Found: C, 67.39; H, 5.34; N, 4.86%. Calcd for $C_{20}H_{25}NO_5$: C, 67.36; H, 5.30; N, 4.91%.

25: The crude reaction mixture was chromatographed over silica gel with hexane-ethyl acetate (10:1 v/v) to provide **25**: Pale yellow prisms (diethyl ether-hexane); mp 79—80 °C; IR (KBr) 2933, 1622, 1456, 1402, 1254, 1182, 1108, and 777 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.93 (3H, t, *J*=6.9 Hz, *n*-Bu), 1.2—1.8 (4H, m, *n*-Bu), 2.59 (2H, dd, *J*=8.0 and 5.0 Hz, 1-H), 3.5—4.0 (2H, m, OCH_2), 4.51 (1H, t, *J*=5.0 Hz, 10b-H), 4.85 (1H, t, *J*=8.0 Hz, 2-H), 5.85 (1H, d, *J*=7.5Hz, 6-H), 6.35 (1H, d, *J*=7.5 Hz, 5-H), and 6.8—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=13.82 (q, *n*-Bu), 19.14, 31.59 (each t,

n-Bu), 35.84 (t, 1-C), 58.25 (d, 10b-C), 59.62 (s, 3-C), 72.27 (t, OCH_2), 85.74 (d, 2-C), 109.62 (d, 6-C), 111.13, 113.67 (each s, CN), 123.78, 124.90, 127.59, 127.93, 128.27, 130.86, and 131.45; MS *m/z* (rel intensity, %) 293 (M^+, 3), 193 (33), 58 (40), and 42 (base peak). Found: C, 73.55; H, 6.54; N, 14.31%. Calcd for $C_{18}H_{19}N_3O$: C, 73.70; H, 6.53; N, 14.32%.

26A and 26B: The crude mixture was chromatographed over silica gel with hexane–ethyl acetate (10:1 v/v) to give **26A** and **26B** which are still contaminated by each other. They were further purified by preparative thin-layer chromatography using the same eluent to give pure **26A** and **26B**. **26A**: Colorless liquid; IR (neat) 2970, 2200, 1760, 1740, 1620, 1560, and 770 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.7 (7H, m, *n*-Bu), 2.50 (1H, ddd, *J*=13.0, 9.5, and 5.0 Hz, 1-endo-H), 2.77 (1H, ddd, *J*=13.0, 6.0, and 2.0 Hz, 1-exo-H), 3.4—3.8 (2H, m, OCH_2), 3.88 (3H, s, COOMe), 4.54 (1H, dd, *J*=5.0 and 2.0 Hz, 2-H), 5.22 (1H, dd, *J*=9.5 and 6.0 Hz, 10b-H), 5.66 (1H, d *J*=7.5 Hz, 6-H), 6.26 (1H, d, *J*=7.5 Hz, 5-H), and 6.8—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=13.77 (q, *n*-Bu), 19.12, 31.65 (each t, *n*-Bu), 37.00 (t, 1-C), 53.65 (q, COOMe), 58.83 (d, 10b-C), 69.89 (s, 3-C), 71.30 (t, OCH_2), 85.24 (d, 2-C), 105.59 (d, 6-C), 116.95 (s, CN), 123.71, 124.18, 126.60, 127.77, 129.83, 130.72, 132.18, and 165.07 (s, COOMe); MS *m/z* (rel intensity, %) 326 (M^+, 24), 227 (21), 226 (96), 195 (18), 194 (22), 193 (72), 192 (56), 168 (97), 167 (20), 143 (base peak), 140 (23), 139 (19), 129 (37), 128 (33), and 115 (38). HRMS Found: *m/z* 326.1627. Calcd for $C_{19}H_{22}N_2O_3$: M, 326.1629. **26B**: Colorless liquid; IR (neat) 2970, 2200, 1750, 1620, 1560, 1455, 1240, and 760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—1.8 (7H, m, *n*-Bu), 2.50 (1H, dd, *J*=9.5 and 5.5 Hz, 1-endo-H), 2.54 (1H, dd, *J*=6.8 and 2.8 Hz, 1-exo-H), 3.4—4.0 (2H, m, OCH_2), 3.81 (3H, s, COOMe), 4.40 (1H, dd, *J*=5.5 and 2.8 Hz, 2-H), 4.92 (1H, dd, *J*=9.5 and 6.8 Hz, 10b-H), 5.34 (1H, d, *J*=7.5 Hz, 6-H), 6.34 (1H, d, *J*=7.5 Hz, 5-H), and 6.8—7.3 (4H, m, Ar); MS *m/z* (rel intensity, %) 326 (M^+, 10), 269 (14), 227 (19), 226 (88), 194 (24), 193 (base peak), 192 (56), 168 (61), 167 (23), 143 (54), 140 (25), 129 (40), 128 (33), and 115 (33). HRMS Found: *m/z* 326.1630. Calcd for $C_{19}H_{22}N_2O_3$: M, 326.1629.

27 and 29: The crude mixture was chromatographed over silica gel with hexane–ethyl acetate (5:1 v/v) to give a mixture of **27** and **29**. As compound **27** was so susceptible as to suffer from the decarboxylative aromatization leading to **29**, only ^1H NMR spectrum was measured. **27**: ^1H NMR ($CDCl_3$) δ=2.6—2.8 (2H, m, 1-H), 3.60, 3.64 (each 3H, s, COOMe), 4.54 (1H, m, 10b-H), 5.10 (1H, dt, *J*=8.0, 8.0, and 1.0 Hz, 2-H), 5.47 (1H, d, *J*=7.0 Hz, 6-H), 6.48 (1H, d, *J*=7.0 Hz, 5-H), and 6.6—7.7 (9H, m, Ar). Authentic sample of **29** was synthesized according to the following procedure: A mixture of 1-[bis(methoxycarbonyl)methyl]isoquinolinium bromide (0.34 g, 1 mmol), phenyl vinyl sulfoxide (0.152 g, 1 mmol), and triethylamine (0.14 ml, 1 mmol) in dry toluene (5 ml) was heated under reflux for 64 h. The mixture was poured into water (100 ml), extracted with dichloromethane (30 ml×2), the combined extracts were dried over magnesium sulfate, and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane to give diphenyl disulfide (0.051 g, 47%) and the fraction eluted with hexane–ethyl acetate (10:1 v/v) afforded **29** (0.102 g, 45%). **29**: Colorless prisms (diethyl ether); mp 111—112 °C; IR (KBr) 1685, 1530, 1355, 1260, 1190, 1110, 785, and 745 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.89 (3H, s, COOMe), 6.9—7.2 (2H, m), 7.3—7.8 (4H, m), 8.0—8.2 (1H, m), and 9.20 (1H, d, *J*=7.7 Hz); MS *m/z* (rel intensity, %) 225 (M^+, 90), 194 (57), 167 (base peak), 166 (69), 140 (33), and 139 (51). Found: C, 74.55; H, 4.96; N, 6.20%. Calcd for $C_{14}H_{11}NO_2$: C, 74.65; H, 4.92; N, 6.22%.

28: The crude reaction mixture was chromatographed over silica gel by using hexane–ethyl acetate (4:1 v/v) to give **28**: Colorless prisms (diethyl ether); mp 109—111 °C; IR (KBr) 2220, 1775, 1620, 1250, and 780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.84 (1H, ddd, *J*=13.0, 7.2, and 4.0 Hz, 1-endo-H), 3.02 (1H, ddd, *J*=13.0, 8.0, and 6.5 Hz, 1-exo-H), 3.74 (3H, s, COOMe), 4.24 (1H, dd, *J*=6.5 and 4.0 Hz, 10b-H), 5.17 (1H, dd, *J*=8.0 and 7.2 Hz, 2-H), 5.76 (1H, d, *J*=7.3 Hz, 6-H), 6.25 (1H, d, *J*=7.3 Hz, 5-H), and 6.7—7.8 (9H, m, Ar); MS *m/z* (rel intensity, %) 362 (M^+, 8), 253 (39), 226 (20), 194 (27), 193 (base peak), 192 (43), 168 (28), 167 (27), 143 (23), 129 (22), 110 (22), and 109 (56). Found: C, 69.80; H, 5.03; N, 7.68%. Calcd for $C_{21}H_{18}N_2O_2S$: C, 69.61; H, 4.97; N, 7.73%.

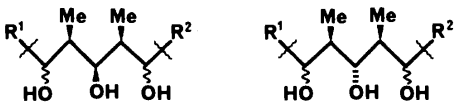
Stereoselective Syntheses of 1,3,5-Trihydroxy-2,4-dimethylpentane Equivalents from Methyl α-Mannopyranosides

Kuniaki TATSUTA,* Yoshihito KOGUCHI, and Motohiro KASE
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku, Yokohama 223
(Received February 12, 1988)

The optically active 1,3,5-trihydroxy-2,4-dimethylpentane equivalents: methyl 2,4-dideoxy-2,4-di-*C*-methyl-α-D-ido- and talopyranosides and their enantiomers, which should be suitable for the syntheses of propionate-derived natural products, were stereo- and regioselectively prepared from methyl α-D- and L-mannopyranosides through the reactions of the 3,4-anhydro-2-*O*-mesyl- and 3,4-anhydro-2-*C*-methyl-altropyranoside derivatives with methylmagnesium bromide and methylmagnesium chloride.

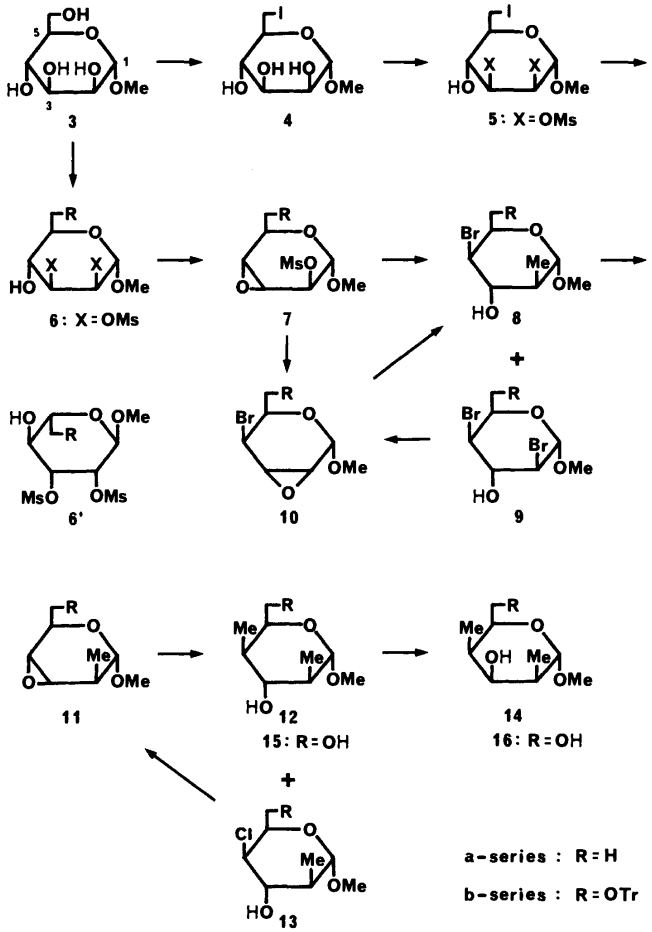
In recent years an impressive number of natural products have been synthesized from carbohydrate derivatives.[1] The syntheses have required fragments with the correct relative and absolute configurations, together with functionality which allows them to be incorporated into the synthetic schemes. Especially, such chiral fragments as 1,3,5-trihydroxy-2,4-dimethylpentane units **1** and **2** can be found in the structures of biologically active natural products including erythromycin A,[2] monensin,[3] rifamycin S,[4] ionomycin,[5] and tirandamycin.[6] Several methods have been developed to affect these stereoselective syntheses by mainly using 1,6-anhydro-β-D-glucopyranose[7] as a chiral source, although alternative strategies including aldol type reactions[8] have been recently reported.



In this paper, we report the novel stereoselective syntheses of such fragment equivalents (**12ab**, **14ab**, **15**, and **16**) and their enantiomers from readily and enantiomerically available methyl α-mannopyranoside derivatives. Repeated alkylation of the intermediary epoxides with methylmagnesium bromide–*t*-butyl bromide and methylmagnesium chloride–CuCl[7c] reagents results in the stereo- and regiospecific introduction of *C*-methyl groups through the trans diaxial opening of their epoxide rings.

The study commenced with the synthesis of the 6-deoxy derivatives **12a** (in the a-series, R=H) and **14a** from methyl α-D-mannopyranoside (**3**). Methyl α-D-mannopyranoside (**3**) was converted by the published procedure[9] into the corresponding 6-iodo compound **4**, which was mesylated to give exclusively the 2,3-di-*O*-mesyl derivative **5** in a quantitative yield. The compound **5** was dehalogenated by tributylstannane to methyl 6-deoxy-2,3-di-*O*-mesyl-α-D-mannopyranoside (**6a**).

The corresponding L-enantiomer (**6'a**) of **6a** could be directly obtained by mesylation of methyl α-L-rhamnopyranoside[10] in a 90% yield for the L-series.



The compound **6a** was treated with sodium methoxide to give methyl 3,4-anhydro-6-deoxy-2-*O*-mesyl-α-D-altropyranoside (**7a**) in an 86% yield. Treatment of the 3,4-epoxide **7a** in dichloromethane with an ethereal methylmagnesium bromide solution and *t*-butyl bromide gave methyl 4-bromo-2,4,6-trideoxy-2-*C*-methyl-α-D-idopyranoside (**8a**) and methyl 2,4-dibromo-2,4,6-trideoxy-α-D-idopyranoside (**9a**) in 56 and 29% yields, respectively, both of which could be reasonably formed by the following sequence: (i) an attack of the Br anion on the C-4 position with the first diaxial opening of the epoxide; (ii) an adjacent attack of the intermediary hydroxide anion on the C-2 position with the *O*-mesyl group leaving to give the

2,3-epoxide **10a**; (iii) an attack of the methyl anion or Br anion on the C-2 position with the second diaxial opening of the epoxide to give **8a** and **9a**. This epoxide-swinging reaction could be traced by the stepwise reactions as follows. The compound **7a** reacted with LiBr to give the same methyl 2,3-anhydro-4-bromo-4,6-dideoxy-α-D-gulopyranoside (**10a**) in an 80% yield, which was converted into the compounds **8a** and **9a** in 62 and 24% yields by the aforesaid conditions using methylmagnesium bromide and *t*-butyl bromide. Then, the by-product **9a** was selectively led to the 2,3-epoxide **10a** by treatment with sodium methoxide in an 83% yield and recycled to the desired compound **8a**.

In the transformation of **7a** into **8a**, other couples[7] of organometallic reagents (methylmagnesium iodide, methylmagnesium bromide, methylmagnesium chloride, lithium dimethylcuprate(I) and methyllithium) and additives (tetrabutylammonium bromide, LiBr, CuI, CuBr, CuCl, $MgBr_2$, Li_2CuCl_4, phenylmagnesium iodide, phenylmagnesium chloride, *t*-butyl bromide, and trimethylsilyl bromide) were investigated in several solvents (ether, dichloromethane, dibromomethane, THF, and dioxane), but they gave **8a** only in lower yields.

The compound **8a** was converted by NaH into the 3,4-epoxide, methyl 3,4-anhydro-2,6-dideoxy-2-*C*-methyl-α-D-altropyranoside (**11a**) in an 85% yield, which was treated with methylmagnesium chloride and CuCl in THF to give methyl 2,4,6-trideoxy-2,4-di-*C*-methyl-α-D-idopyranoside **12a** and methyl 4-chloro-2,4,6-trideoxy-2-*C*-methyl-α-D-idopyranoside **13a** in 60 and 28% yields, respectively, as results of the diaxial opening of the epoxide. Also, in the latter reaction, a large number of variables[7] including reagents, additives and solvents were assayed as mentioned above, but in vain. The by-product **13a** was recycled to **12a** through **11a**, which was obtained by treatment with NaH.

The stereochemistry of **12a** was confirmed by the ^1H NMR analysis. In the $CDCl_3$ solution, the spectrum showed $J_{1,2}$=4.0 Hz, $J_{2,3}=J_{3,4}$=5.5 Hz, and $J_{4,5}$=4.5 Hz, supporting that the idopyranoside **12a** could exist in the C_1^4 chair form[11] (Fig. 1) due to an intramolecular hydrogen-bond between the C-1 and C-3 position, as suggested by Lemieux and Levine,[12] rather than other possible conformations including the C_4^1 chair form.[11] However, in the deuterated acetone solution, the spectrum showed $J_{1,2}$=7.4 Hz, $J_{2,3}=J_{3,4}$=9.1 Hz, and $J_{4,5}$=5.6 Hz, indicating that **12a** existed in the C_4^1 form as shown in Fig. 1.[12]

Inversion of the stereochemistry at the C-3 position of **12a** was cleanly achieved by oxidation to the corresponding ketone with pyridinium chlorochromate followed by borohydride reduction to give methyl 2,4,6-trideoxy-2,4-di-*C*-methyl-α-D-talopyranoside (**14a**) in an 82% yield with a little of **12a**. The coupling constants ($J_{1,2}$=3.5 Hz, $J_{2,3}=J_{3,4}$=4.8 Hz, and $J_{4,5}$=4.2 Hz) in the $CDCl_3$ solution supported that **14a** was favoured in the C_1^4 chair form spread by a strong repulsion between the C-2 and C-4 methyl groups. Consequently, **12a** and **14a** are equivalent to the pentane units **1** and **2**, respectively.

The corresponding L-isomers of **12a** and **14a**, which are equivalent to the antipodes of **1** and **2**, were derived from methyl α-L-rhamnoside through **6'a** by the same conditions as described above.

On the other hand, the 6-hydroxy derivatives **15** and **16** were also synthesized from methyl α-D-mannopyranoside (**3**) by the similar manner with the aforesaid sequences.

Tritylation of **3** followed by mesylation afforded methyl 2,3-di-*O*-mesyl-6-*O*-trityl-α-D-mannopyranoside (**6b**: in the b-series, R=OTr), which was converted into the 3,4-epoxide (**7b**) in a 73% overall yield. The epoxide **7b** was treated with methylmagnesium bromide and *t*-butyl bromide to give methyl 4-bromo-2,4-dideoxy-2-*C*-methyl-6-*O*-trityl-α-D-idopyranoside (**8b**) and methyl 2,4-dibromo-2,4-dideoxy-6-*O*-trityl-α-D-idopyranoside (**9b**) in 55 and 27% yields, respectively. The latter product **9b** was recycled into **8b** through **10b** in a 54% overall yield as described in the recovery of **8a** through **10a**. Reaction of **8b** with NaH afforded the 3,4-epoxide **11b** in an 89% yield, which was treated with methylmagnesium chloride and CuCl to give methyl 2,4-dideoxy-2,4-di-*C*-methyl-6-*O*-trityl-α-D-idopyranoside (**12b**) and methyl 4-chloro-2,4-dideoxy-2-*C*-methyl-6-*O*-trityl-α-D-idopyranoside (**13b**) in 60 and 29% yields. The by-product **13b** was also recycled to **12b** through **11b**. The compound **12b** was transferred into the C-3 epimer **14b** by pyridinium chlorochromate oxidation and borohydride reduction. Removal of *O*-trityl group in **12b** and **14b** by acidic conditions did not give the desired products **15** and **16**, but the

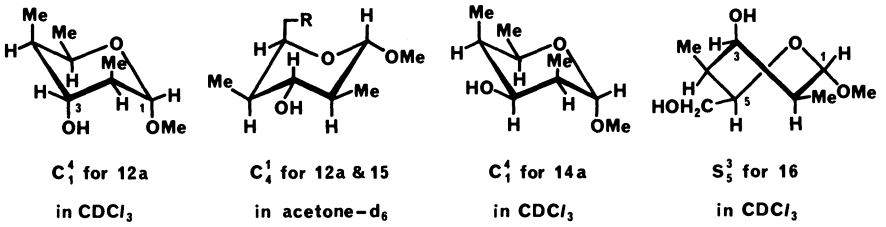


Fig. 1. Preferred conformations of **12a**, **14a**, **15**, and **16** in $CDCl_3$ or acetone-d_6.

corresponding 1,6-anhydro derivatives. Then, by hydrogenolysis with palladium hydroxide, methyl 2,4-dideoxy-2,4-di-*C*-methyl-α-D-ido- and talopyranosides (**15** and **16**) were obtained in 75 and 87% yields, respectively.

The stereochemistry of **15** and **16** was confirmed by their ^{1}H NMR spectra, the coupling constants (see the Experimental section) of which revealed that **15** existed in the C_4^1 chair form in the deuterated acetone solution and **16** in the S_5^3-like skew conformation[11] in the $CDCl_3$ solution as shown in Fig. 1. Hence, **15** and **16** are equivalent to the chiral units **1** and **2**, respectively.

The enantiomers of **15** and **16** could be reasonably derived from methyl α-L-mannopyranoside by the same reaction sequences to generate the antipode units of **1** and **2**.

In conclusion, an efficient, stereo- and regiospecific preparation of synthetic equivalents of the structural fragments **1** and **2** and their enantiomeric fragments have been developed, starting from methyl α-D- and L-mannopyranosides.

Experimental

Melting points were determined on a micro hot-stage Yanaco MP-S3 and were uncorrected. Optical rotations were measured with a JASCO DIP-360 photoelectric polarimeter in chloroform unless otherwise stated. IR spectra were recorded on a Hitachi Perkin-Elmer 225 spectrometer, and ^{1}H NMR spectra on a Varian EM-390, a Bruker WM 250 or a JEOL GX-400 spectrometer in $CDCl_3$ using TMS as internal standard unless otherwise noted. Mass spectra were measured with a Hitachi M-80 mass spectrometer or a Hitachi RMU-6M mass spectrometer. TLC was carried out on Merck TLC plates (60F-254, 0.25 mm). Column chromatography was performed on silica gel, Wakogel C-200. In general, organic solvents were purified and dried by the appropriate procedures, and evaporation and concentration were carried out under reduced pressure below 35 °C, unless otherwise noted.

Methyl 6-Deoxy-6-iodo-2,3-di-*O*-mesyl-α-D-mannopyranoside (5). The starting methyl 6-deoxy-6-iodo-α-D-mannopyranoside (**4**) was prepared from methyl α-D-mannopyranoside (**3**) according to the reported procedure.[9]

To a stirred and ice-cooled solution of **4** (88.8 g) in pyridine (620 ml) were added 4-dimethylaminopyridine (17.8 g) and mesyl chloride (68 ml), and stirring was continued at room temperature for 24 h. After addition of ethanol (52 ml), the mixture was evaporated and co-evaporated with toluene to a residue, which was partitioned between ethyl acetate and a saturated aqueous $NaHCO_3$ solution. The combined layers were evaporated to a residue, which was chromatographed on silica gel (670 g) with 2:1 benzene–ethyl acetate to give an amorphous solid of **5** (130.8 g, 97%): R_f 0.36 (2:1 benzene–ethyl acetate); $[\alpha]_D^{31}$ +29° (*c* 0.60); IR (KBr): 1350 cm^{-1} (OMs); ^{1}H NMR (400 MHz): δ=2.79 (1H, d, OH-4, $J_{4,OH}$=4.5 Hz), 3.15 and 3.17 (each 3H, s, Ms), 3.37 (1H, dd, H-6, $J_{5,6}$=7.7 Hz, $J_{6,6'}$=10.9 Hz), 3.48 (3H, s, OMe), 3.56 (1H, ddd, H-5, $J_{4,5}$=9.5 Hz, $J_{5,6'}$=2.9 Hz), 3.63 (1H, dd, H-6′), 3.82 (1H, dt, H-4, $J_{3,4}$=9.5 Hz), 4.92 (1H, d, H-1, $J_{1,2}$=1.6 Hz), 4.92 (1H, dd, H-3, $J_{2,3}$=3.5 Hz), and 4.96 (1H, dd, H-2); MS *m/z* 460 (M$^+$).

Methyl 6-Deoxy-2,3-di-*O*-mesyl-α-D-mannopyranoside (6a). A solution of **5** (58.2 g) in toluene (466 ml) was stirred with tributylstannane (51.2 ml) and α,α′-azobis(isobutyronitrile) (2.08 g) at 90 °C for 3 h under argon. The resulting solution was evaporated and co-evaporated with ethyl acetate to a solid, which was recrystallized from ethyl acetate–hexane to give a solid of **6a** (36.7 g, 87%), which was used for the next step.

An analytically pure sample was obtained by chromatography on silica gel with 3:2 benzene–ethyl acetate followed by recrystallization from ether to afford cubes of **6a**: R_f 0.31 (2:1 benzene–ethyl acetate); mp 143—145 °C; $[\alpha]_D^{34}$ +6.9° (*c* 0.94); IR (KBr): 1347 cm^{-1} (OMs); ^{1}H NMR (400 MHz): δ=1.38 (3H, d, Me-5, $J_{5,Me}$=6.0 Hz), 2.64 (1H, d, OH-4, $J_{4,OH}$), 3.15 and 3.17 (each 3H, s, Ms), 3.41 (3H, s, OMe), 3.66 (1H, dt, H-4, $J_{3,4}$=9.4 Hz, $J_{4,5}$=9.4 Hz), 3.74 (1H, dq, H-5), 4.83 (1H, d, H-1, $J_{1,2}$=1.6 Hz), 4.85 (1H, dd, H-3, $J_{2,3}$=3.0 Hz), and 4.92 (1H, dd, H-2).

Methyl 6-Deoxy-2,3-di-*O*-mesyl-α-L-mannopyranoside (6′a). A solution of methyl α-L-rhamnopyranoside[10] (0.94 g) in pyridine (9.4 ml) was stirred with mesyl chloride (0.86 ml) at room temperature for 4 h. After addition of ethanol (1 ml), the resulting mixture was evaporated and co-evaporated with toluene to a residue, which was chromatographed on silica gel with 15:1 chloroform–methanol followed by recrystallization from ether to give cubes of **6′a** (1.61 g, 90%): mp 142—145 °C; $[\alpha]_D^{30}$ −6.9° (*c* 1.0). The physicochemical properties were identical with those of **6a** except for the sign of the optical rotation.

Methyl 3,4-Anhydro-6-deoxy-2-*O*-mesyl-α-D-altropyranoside (7a). A solution of **6a** (7.93 g) in chloroform (79 ml) was stirred with a 28% methanolic sodium methoxide solution (6.0 ml) at room temperature for 48 h. The reaction mixture was partitioned between chloroform and water, and the combined organic layers were dried and evaporated to a residue. This was chromatographed on silica gel (85 g) with 4:1 benzene–ethyl acetate followed by recrystallization from ethyl acetate–hexane to give plates of **7a** (4.85 g, 86%): R_f 0.55 (2:1 benzene–ethyl acetate); mp 88—90 °C; $[\alpha]_D^{33}$ +64° (*c* 0.98); IR (KBr): 1345 cm^{-1} (OMs); ^{1}H NMR (400 MHz): δ=1.45 (3H, d, Me-5, $J_{5,Me}$=7.2 Hz), 3.09 (1H, d, H-4, $J_{3,4}$=3.5 Hz, $J_{4,5}$=0 Hz), 3.12 (3H, s, OMs), 3.42 (3H, s, OMe), 3.44 (1H, d, H-3, $J_{2,3}$=0 Hz), 4.31 (1H, q, H-5), 4.56 and 4.63 (each 1H, d, H-1 and H-2, vice versa, $J_{1,2}$=4.2 Hz).

Found: C, 40.34; H, 5.86%. Calcd for $C_8H_{14}O_6S$: C, 40.33; H, 5.92%.

Methyl 4-Bromo-2,4,6-trideoxy-2-*C*-methyl-α-D-idopyranoside (8a) and Methyl 2,4-Dibromo-2,4,6-trideoxy-α-D-idopyranoside (9a). A) From 7a: To a stirred and ice-cooled solution of **7a** (105 mg) in dichloromethane (0.53 ml) were added *t*-butyl bromide (0.149 ml) and dropwise a 3 M† ethereal methylmagnesium bromide solution (1.48 ml) under argon, and stirring was continued at the same temperature for 15 min and then at room temperature for 2.5 h. After the reaction was quenched with a saturated aqueous NH_4Cl solution (1.5 ml), the reaction mixture was extracted with ethyl acetate (1.5 ml×3). The combined

† 1 M=1 mol dm^{-3}.

extracts were dried and evaporated to a residue, which was chromatographed on silica gel (10 g) with 6:1 benzene–ethyl acetate to give **8a** (59 mg, 56%) and **9a** (39 mg, 29%) having the R_f-values of 0.35 and 0.48 (6:1 benzene–ethyl acetate) respectively.

8a: Needles from ether–hexane; mp 116—118 °C; $[\alpha]_D^{34}$ +114° (*c* 0.93); ^{1}H NMR (400 MHz): δ=1.28 (3H, d, Me-2, $J_{2,Me}$=7.4 Hz), 1.37 (3H, d, Me-5, $J_{5,Me}$=6.7 Hz), 1.95 (1H, m, H-2), 3.33 (1H, d, OH, $J_{3,OH}$=8.0 Hz), 3.41 (3H, s, OMe), 3.92 (1H, dt, H-3, $J_{2,3}$=$J_{3,4}$=4.8 Hz), 4.04 (1H, dd, H-4, $J_{4,5}$=3.5 Hz), 4.28 (1H, dq, H-5), 4.51 (1H, d, H-1, $J_{1,2}$=3.5 Hz).

B) From 10a: To a stirred and ice-cooled solution of **10a** (3.80 g) in dichloromethane (19 ml) was added dropwise a 3 M ethereal methylmagnesium bromide solution (42 ml) under argon, and stirring was continued at room temperature for 2 h. After the reaction was quenched with a saturated aqueous NH_4Cl solution (38 ml), the mixture was partitioned between ethyl acetate and water. The combined organic layers were dried and evaporated to a residue, which was chromatographed on silica gel (133 g) with 7:1 benzene–ethyl acetate to give **8a** (2.52 g, 62%) and **9a** (1.23 g, 24%).

Methyl 2,3-Anhydro-4-bromo-4,6-dideoxy-α-D-gulopyranoside (10a). A) From 7a: A solution of **7a** (4.29 g) in 1,4-dioxane (43 ml) was stirred with LiBr (3.13 g) under argon at 100 °C for 68 h. The salt was filtered and washed with dichloromethane. The filtrates and washings were combined and partitioned between dichloromethane and water. The combined organic layers were dried and evaporated to a residue, which was chromatographed on silica gel (80 g) with 4:1 hexane–ethyl acetate to give a solid of **10a** (3.20 g, 80%), which was used for the next step.

An analytically pure sample was obtained by distillation under reduced pressure (bath temp 85 °C/4 mmHg††) as a syrup which was changed into cubes of **10a**: R_f 0.60 (5:1 benzene–ethyl acetate); mp 56 °C; $[\alpha]_D^{32}$ −14° (*c* 1.0); ^{1}H NMR (90 MHz): δ=1.30 (3H, d, Me-5, $J_{5,Me}$=7 Hz), 3.60 (1H, m, H-3), 3.65 (3H, s, OMe), 3.82 (1H, dd, H-2, $J_{1,2}$=3.3 Hz, $J_{2,3}$=2.7 Hz), 4.16 (1H, dq, H-5, $J_{4,5}$=2 Hz), 4.41 (1H, t, H-4, $J_{3,4}$=2 Hz), and 5.17 (1H, d, H-1).

Found: C, 37.42; H, 4.86%. Calcd for $C_7H_{11}O_3Br$: C, 37.69; H, 4.97%.

B) From 9a: A solution of **9a** (6.47 g) in 1,4-dioxane (97 ml) was stirred with a 28% methanolic sodium methoxide solution (5.2 ml) at room temperature for 1 h. The reaction mixture was partitioned between chloroform and water, and the combined organic layers were dried and evaporated to a residue. This was chromatographed on silica gel (145 g) with 5:1 hexane–ethyl acetate to give a solid of **10a** (3.94 g, 83%).

Methyl 3,4-Anhydro-2,6-dideoxy-2-*C*-methyl-α-D-altropyranoside (11a). A) From 8a: A solution of **8a** (3.06 g) in 1,2-dimethoxyethane (46 ml) was stirred with a 55% oily NaH powder (670 mg) at room temperature for 30 min. After addition of ethanol (1 ml), the resulting mixture was partitioned between ethyl acetate and a saturated aqueous NaCl solution, and the combined organic layers were dried and evaporated under atmospheric pressure to give a residue. This was purified by distillation under reduced pressure (bath temp 86 °C/2—3 mmHg) to give a syrup of **11a** (1.71 g, 85%): R_f 0.32 (6:1 benzene–ethyl acetate); bp ca. 66 °C (2 mmHg); $[\alpha]_D^{32}$ +122° (*c* 0.54); ^{1}H NMR (90 MHz): δ=1.17 (3H, d, Me-2, $J_{2,Me}$=7.5 Hz), 1.44 (3H, d, Me-5, $J_{5,Me}$=7.2 Hz), 2.27 (1H, dq, H-2, $J_{1,2}$=3.0 Hz, $J_{2,3}$=0 Hz), 3.11 (2H, apparently s, H-3 and H-4, $J_{3,4}$=4 Hz), 3.50 (3H, s, OMe), 4.38 (1H, q, H-5, $J_{4,5}$=0 Hz), and 4.43 (1H, d, H-1). MS *m/z* 127 (M^+−31).

B) From 13a: A sample of **13a** (611 mg) was treated by the procedure described in the preparation from **8a** and then worked up to give a syrup of **11a** (432 mg, 87%).

Methyl 2,4,6-Trideoxy-2,4-di-*C*-methyl-α-D-idopyranoside (12a) and Methyl 4-Chloro-2,4,6-trideoxy-2-*C*-methyl-α-D-idopyranoside (13a). A 3 M methylmagnesium chloride solution (37 ml), which was prepared in situ from magnesium (2.7 g) and a large excess of methyl chloride in THF, was added dropwise to a suspension of **11a** (1.60 g) with CuCl (400 mg) in THF (8 ml) with stirring at 5 °C under argon, and then stirring was continued at room temperature for 18 h. After the reaction was quenched with a saturated aqueous NH_4Cl solution (50 ml), the resulting mixture was partitioned between ethyl acetate and water. The combined organic layers were dried and evaporated to a residue, which was chromatographed on silica gel (88 g) with 5:2 benzene–ethyl acetate to give **12a** (1.05 g, 60%) and **13a** (0.55 g, 28%) having the R_f-values of 0.19 and 0.36 (3:1 hexane–ethyl acetate) respectively.

12a: Needles from ethyl acetate–hexane; mp 102—104 °C; $[\alpha]_D^{35}$ +111° (*c* 1.04); ^{1}H NMR (400 MHz): δ=1.00 and 1.08 (each 3H, d, Me-2 and Me-4, vice versa, *J*=7.0 and 7.4 Hz), 1.17 (3H, d, Me-5, $J_{5,Me}$=6.8 Hz), 1.77 (2H, m, H-2 and H-4), 2.62 (1H, d, OH, $J_{3,OH}$=8.2 Hz), 3.40 (1H, dt-like, H-3, $J_{2,3}$=$J_{3,4}$=5.5 Hz), 3.40 (3H, s, OMe), 4.23 (1H, dq, H-5, $J_{4,5}$=4.5 Hz), and 4.40 (1H, d, H-1, $J_{1,2}$=4.0 Hz); ^{1}H NMR (400 MHz, acetone-d_6): δ=0.93, 1.01, and 1.12 (each 3H, d, Me-2, Me-4, and Me-5, vice versa, *J*=7.2 Hz, *J*=6.7 Hz, and *J*=6.7 Hz), 1.44 (1H, m, H-2), 1.68 (1H, m, H-4), 2.80 (1H, broad s, OH), 3.10 (1H, t, $J_{2,3}$=$J_{3,4}$=9.1 Hz), 3.32 (3H, s, OMe), 4.08 (1H, dq, H-5, $J_{4,5}$=5.6 Hz, $J_{5,Me}$=6.7 Hz), and 4.22 (1H, d, H-1, $J_{1,2}$=7.4 Hz).

Found: C, 61.84; H, 10.23%. Calcd for $C_9H_{18}O_3$: C, 62.04; H, 10.41%.

Methyl 2,4,6-Trideoxy-2,4-di-*C*-methyl-α-D-talopyranoside (14a). To a stirred and ice-cooled solution of **12a** (22.4 mg)

†† 1 mmHg≅133.322 Pa.

in dichloromethane (0.45 ml) were added Molecular Sieves 3A powder (193 mg) and pyridinium chlorochromate (111 mg), and stirring was continued at room temperature for 1 h. The mixture was diluted with ether and passed through a silica-gel column (1.0 g) with ether to give a crude syrup (23 mg) of the keto compound.

The syrup was stirred with $NaBH_4$ (9.7 mg) in methanol (0.49 ml) at room temperature for 1 h. The reaction mixture was neutralized with Amberlite CG-50 (H type), filtered and then evaporated to a residue, which was chromatographed on silica gel (2.2 g) with 3:1 hexane–ethyl acetate to afford **14a** (18 mg, 82%) and the starting **12a** (2.2 mg, 10%) having R_f-values of 0.24 and 0.19 (3:1 hexane–ethyl acetate) respectively.

14a: syrup; $[\alpha]_D^{31}$ +107° (*c* 0.69); ^{1}H NMR (400 MHz): δ=0.97 and 1.05 (each 3H, d, Me-4 and Me-2, $J_{4,Me}=J_{2,Me}$=7.2 Hz), 1.22 (3H, d, Me-5, $J_{5,Me}$=6.7 Hz), 1.51 (1H, broad s, OH), 1.90 (2H, m, H-2 and H-4), 3.36 (3H, s, OMe), 3.99 (1H, t, H-3, $J_{2,3}=J_{3,4}$=4.8 Hz), 4.04 (1H, dq, H-5, $J_{4,5}$=4.2 Hz), and 4.51 (1H, d, H-1, $J_{1,2}$=3.5 Hz). HRMS Found: *m/z* 174.1229. Calcd for $C_9H_{18}O_3$: M, 174.1255.

Methyl 3,4-Anhydro-2-*O*-mesyl-6-*O*-trityl-α-D-altropyranoside (7b). To a stirred and ice-cooled solution of **3** (40.4 g) in pyridine (400 ml) were added 4-dimethylaminopyridine (1.26 g) and trityl chloride (63.2 g), and stirring was continued at room temperature for 24 h. After cooling again, mesyl chloride (33.7 ml) was added, and the resulting mixture was allowed to stand with stirring at room temperature for 8 h. After addition of ethanol (23 ml), the mixture was evaporated and co-evaporated with toluene to a residue, which was partitioned between ethyl acetate and a saturated aqueous $NaHCO_3$ solution. The combined organic layers were washed with a saturated aqueous NaCl solution, dried, and evaporated to give a crude syrup of **6b** (approximately 150 g): R_f 0.28 (6:1 benzene–ethyl acetate).

To an ice-cooled solution of the crude syrup in chloroform (750 ml) was added dropwise a 28% methanolic sodium methoxide solution (65.7 ml) with stirring, and the mixture was stirred at room temperature for 14 h and then partitioned between chloroform and water. The combined organic layers were washed with water, dried and evaporated to a residue, which was chromatographed on silica gel (1 kg) with 10:1 benzene–ethyl acetate followed by recrystallization from benzene–ethyl acetate to give cubes of **7b** (75.4 g. 73% overall yield from **3**): R_f 0.30 (20:1 benzene–ethyl acetate); mp 150—151 °C; $[\alpha]_D^{31}$ +17° (*c* 1.0); IR (KBr): 1367 and 1176 cm^{-1} (OMs); ^{1}H NMR (400 MHz): δ=3.09 (3H, s, Ms), 3.27 (1H, d, H-4, $J_{3,4}$=3.5 Hz, $J_{4,5}$=0 Hz), 3.37 (3H, s, OMe), 3.47 (1H, dd, H-6, $J_{5,6}$=4.3 Hz, $J_{6,6'}$=10.3 Hz), 3.51 (1H, dd, H-6′, $J_{5,6'}$=4.3 Hz), 3.53 (1H, d, H-3, $J_{2,3}$=0 Hz), 4.22 (1H, t, H-5), 4.65 (1H, d, H-1, $J_{1,2}$=4.5 Hz), 4.82 (1H, d, H-2), and 7.24—7.47 (15H, m, Tr).

Found: C, 65.10; H, 5.60%. Calcd for $C_{27}H_{28}O_7S$: C, 65.31; H, 5.68%.

Methyl 4-Bromo-2,4-dideoxy-2-*C*-methyl-6-*O*-trityl-α-D-idopyranoside (8b) and Methyl 2,4-Dibromo-2,4-dideoxy-6-*O*-trityl-α-D-idopyranoside (9b). A) From 7b: A sample of **7b** (1.26 g) was treated by the procedure described in the preparation of **8a** and **9a** from **7a**, and then worked up to give amorphous solids of **8b** (694 mg, 55%) and **9b** (386 mg, 27%) having the R_f-values of 0.41 and 0.47 (20:1 benzene–ethyl acetate) respectively.

8b: $[\alpha]_D^{27}$ +25° (*c* 1.0); ^{1}H NMR (400 MHz): δ=1.27 (3H, d, Me-2, $J_{2,Me}$=7.2 Hz), 1.99 (1H, m, H-2), 3.24 (1H, dd, H-6, $J_{5,6}$=4.8 Hz, $J_{6,6'}$=9.8 Hz), 3.43 (3H, s, OMe), 3.44 (1H, d, OH, $J_{3,OH}$=8.0 Hz), 3.52 (1H, dd, H-6′, $J_{5,6'}$=6.7 Hz), 3.91 (1H, dt, H-3, $J_{2,3}=J_{3,4}$=3.2 Hz), 4.02 (1H, t, H-4, $J_{4,5}$=3.2 Hz), 4.14 (1H, m, H-5), 4.57 (1H, broad s, H-1, $J_{1,2}$=0 Hz), and 7.22—7.49 (15H, m, Tr); MS *m/z* 498 and 496 (M$^+$).

9b: $[\alpha]_D^{31}$ +37° (*c* 1.0); ^{1}H NMR (400 MHz): δ=2.96 (1H, d, OH, $J_{3,OH}$=5.2 Hz), 3.49 (3H, s, OMe), 3.52 (1H, dd, H-6, $J_{5,6}$=3.8 Hz, $J_{6,6'}$=10.7 Hz), 3.63 (1H, dd, H-6′, $J_{5,6'}$=5.4 Hz), 3.78 (1H, dd, H-2, $J_{1,2}$=6.4 Hz, $J_{2,3}$=7.5 Hz), 4.04 (1H, dd, H-4, $J_{3,4}$=7.5 Hz, $J_{4,5}$=4.6 Hz), 4.15 (1H, m, H-5), 4.37 (1H, dt, H-3), 5.10 (1H, d, H-1), and 7.23—7.49 (15H, m, Tr); MS *m/z* 564, 562, and 560 (M$^+$), and 482 (M$^+$−Br).

B) From 10b: A sample of **10b** (172 mg) was treated by the procedure described in the preparation of **8a** and **9a** from **10a**, and then worked up to give **8b** (114 mg, 64%) and **9b** (54 mg, 27%).

Methyl 2,3-Anhydro-4-bromo-4-deoxy-6-*O*-trityl-α-D-gulopyranoside (10b). A sample of **9b** (294 mg) was treated by the procedure described in the preparation of **10a** from **9a**, and then worked up to give a syrup of **10b** (213 mg, 85%): R_f 0.58 (20:1 benzene–ethyl acetate); $[\alpha]_D^{31}$ −31° (*c* 0.99); ^{1}H NMR (400 MHz): δ=3.04 (1H, dd, H-6, $J_{5,6}$=5.8 Hz, $J_{6,6'}$=9.3 Hz), 3.39 (1H, dd, H-6′, $J_{5,6'}$=6.4 Hz), 3.45 (1H, dd, H-2, $J_{1,2}$=2.9 Hz, $J_{2,3}$=3.9 Hz), 3.50 (3H, s, OMe), 3.62 (1H, dd, H-3, $J_{3,4}$=2.0 Hz), 4.09 (1H, m, H-5), 4.41 (1H, t, H-4, $J_{4,5}$=2.0 Hz), 4.98 (1H, d, H-1), and 7.21—7.45 (15H, m, Tr); MS *m/z* 482 and 480 (M$^+$).

Methyl 3,4-Anhydro-2-deoxy-2-*C*-methyl-6-*O*-trityl-α-D-altropyranoside (11b). A) From 8b: A sample of **8b** (1.32 g) was treated by the procedure described in the preparation of **11a** from **8a**, and then worked up to give an amorphous solid of **11b** (987 mg, 89%): R_f 0.33 (20:1 benzene–ethyl acetate); $[\alpha]_D^{30}$ +44° (*c* 1.1); ^{1}H NMR (400 MHz): δ=1.15 (3H, d, Me-2, $J_{2,Me}$=8.0 Hz), 2.20 (1H, dq, H-2, $J_{1,2}$=2.4 Hz, $J_{2,3}$=0 Hz), 3.05 and 3.20 (each 1H, d, H-3 and H-4, vice versa, $J_{3,4}$=4.5 Hz, $J_{4,5}$=0 Hz), 3.33 (3H, s, OMe), 3.36 (1H, dd, H-6, $J_{5,6}$=4.8 Hz, $J_{6,6'}$=9.5 Hz), 3.43 (1H, dd, H-6′, $J_{5,6'}$=4.8 Hz), 4.13 (1H, t, H-5), 4.37 (1H, d, H-1), and 7.22—7.49 (15H, m, Tr); MS *m/z* 417 (M$^+$+1).

B) From 13b: A sample of **13b** (1.01 g) was treated by the procedure described in the preparation of **11a** from **8a** or **13a**, and then worked up to give **11b** (931 mg, 99%).

Methyl 2,4-Dideoxy-2,4-di-*C*-methyl-6-*O*-trityl-α-D-idopyranoside (12b) and Methyl 4-Chloro-2,4-dideoxy-2-*C*-methyl-6-*O*-trityl-α-D-idopyranoside (13b). A sample of **11b** (1.88 g) was treated by the procedure described in the preparation of **12a** and **13a** from **11a**, and then worked up to give amorphous solids of **12b** (1.17 g, 60%) and **13b** (587 mg, 29%) having the R_f-values of 0.25 and 0.44 (3:1 hexane–ethyl acetate) respectively.

12b: $[\alpha]_D^{33}$ +25° (*c* 1.1); ^{1}H NMR (400 MHz): δ=0.80 and 1.06 (each 3H, d, Me-2 and Me-4, vice versa, *J*=7.2 Hz), 1.75—1.92 (2H, m, H-2 and H-4), 2.91 (1H, dull d, OH, $J_{3,OH}$=7.8 Hz), 3.02 (1H, dd, H-6, $J_{5,6}$=4.5 Hz, $J_{6,6'}$=9.8 Hz), 3.33 (1H, dd, H-6′, $J_{5,6'}$=6.9 Hz), 3.42 (1H, m, H-3), 3.49 (3H, s, OMe), 4.26 (1H, dt, H-5, $J_{4,5}$=4.5 Hz), 4.52 (1H, d, H-1, $J_{1,2}$=2.7 Hz), and 7.20—7.50 (15H, m, Tr); MS *m/z* 433 (M$^+$+1).

13b: $[\alpha]_D^{33}$ +23° (*c* 0.69); ^{1}H NMR (400 MHz): δ=1.22 (3H, d, Me-2, $J_{2,Me}$=7.8 Hz), 1.99 (1H, ddq, H-2, $J_{1,2}$=1 Hz,

$J_{2,3}$=2.5 Hz), 3.28 (1H, dd, H-6, $J_{5,6}$=4.9 Hz, $J_{6,6'}$=10.0 Hz), 3.43 (3H, s, OMe), 3.46 (1H, d, OH, $J_{3,OH}$=8.3 Hz), 3.52 (1H, dd, H-6′, $J_{5,6'}$=6.4 Hz), 3.82 (1H, ddd, H-3, $J_{3,4}$=2.9 Hz), 3.95 (1H, t, H-4, $J_{4,5}$=2.9 Hz), 4.26 (1H, m, H-5), 4.58 (1H, broad s, H-1), and 7.21—7.49 (15H, m, Tr); MS *m/z* 453 and 452 (M^+).

Methyl 2,4-Dideoxy-2,4-di-*C*-methyl-6-*O*-trityl-α-D-talopyranoside (14b). A sample of **12b** (99 mg) was treated by the successive procedure in the preparation of **14a** through the keto compound, and then worked up to give **14b** (83 mg, 84%) and the starting **12b** (7.7 mg, 7.6%) having the R_f-values of 0.30 and 0.25 (3:1 hexane–ethyl acetate) respectively.

14b: syrup; $[\alpha]_D^{33}$ +59° (*c* 0.30); ^{1}H NMR (400 MHz): δ=0.73 (3H, d, Me-4, $J_{4,Me}$=7.4 Hz), 1.04 (3H, d, Me-2, $J_{2,Me}$=7.0 Hz, 1.88 (1H, m, H-2), 1.96 (1H, d, OH, $J_{3,OH}$=6.2 Hz), 2.04 (1H, m, H-4), 3.16 (1H, dd, H-6, $J_{5,6}$=4.2 Hz, $J_{6,6'}$=10.2 Hz), 3.29 (1H, dd, H-6′, $J_{5,6}$=6.4 Hz), 3.49 (3H, s, OMe), 3.89 (1H, dt, H-3, $J_{2,3}$=$J_{3,4}$=4.4 Hz), 4.03 (1H, dt, H-5, $J_{4,5}$=4.2 Hz), 4.65 (1H, d, H-1, $J_{1,2}$=4.1 Hz), and 7.21—7.51 (15H, m, Tr); MS *m/z* 433 (M^++1).

Methyl 2,4-Dideoxy-2,4-di-*C*-methyl-α-D-idopyranoside (15). A solution of **12b** (152 mg) in ethanol (3.6 ml) was shaken with palladium hydroxide on carbon and 3-atm hydrogen at room temperature for 38 h, filtered and evaporated to give a residue. This was chromatographed on silica gel (8 g) with ethyl acetate followed by recrystallization from ethyl acetate to give needles of **15** (49.8 mg, 75%): R_f 0.33 (ethyl acetate); mp 149—150 °C; $[\alpha]_D^{31}$ +99° (*c* 1.0); ^{1}H NMR (400 MHz): δ=1.00 and 1.11 (each 3H, d, Me-2 and Me-4, vice versa, *J*=7.2 Hz), 1.81—1.96 (3H, m, H-2, H-4, and OH-3), 2.99 (1H, broad signal, OH-6), 3.42 (1H, m, H-3), 3.42 (3H, s, OMe), 3.58 (1H, dd, H-6, $J_{5,6}$=3.6 Hz, $J_{6,6'}$=11.2 Hz), 3.76 (1H, dd, H-6′, $J_{5,6'}$=9.0 Hz), 4.19 (1H, dt, H-5, $J_{4,5}$=3.6 Hz), and 4.51 (1H, d, H-1, $J_{1,2}$=2.9 Hz); ^{1}H NMR (400 MHz, acetone-d_6): δ=0.99 (3H, d, Me-4, $J_{4,Me}$=6.8 Hz), 1.02 (3H, d, Me-2, $J_{2,Me}$=6.8 Hz), 1.55 (1H, m, H-2), 1.77 (1H, m, H-4), 3.17 (1H, dt, H-3, $J_{2,3}$=8.8 Hz, $J_{3,4}$=$J_{3,OH}$=6.8 Hz), 3.35 (3H, s, OMe), 3.47 (1H, dd, OH-6, $J_{6,OH}$=6.4 Hz, $J_{6',OH}$=4.4 Hz), 3.57 (1H, ddd, H-6, $J_{5,6}$=4.9 Hz, $J_{6,6'}$=11.2 Hz), 3.67 (1H, d, OH-3), 3.70 (1H, ddd, H-6′, $J_{5,6'}$=7.3 Hz), 3.99 (1H, dt, H-5, $J_{4,5}$=4.9 Hz), and 4.35 (1H, d, H-1, $J_{1,2}$=6.8 Hz).

Found: C, 56.63; H, 9.25%. Calcd for $C_9H_{18}O_4$: C, 56.82; H, 9.54%.

Methyl 2,4-Dideoxy-2,4-di-*C*-methyl-α-D-talopyranoside (16). A sample of **14b** (97.5 mg) was treated by the procedure described in the preparation of **15**, and then worked up to give a syrup of **16** (37.3 mg, 87%): R_f 0.40 (ethyl acetate); $[\alpha]_D^{32}$ +106° (*c* 1.0); ^{1}H NMR (400 MHz): δ=0.99 (3H, d, Me-2, $J_{2,Me}$=7.1 Hz), 1.05 (3H, d, Me-4, $J_{4,Me}$=7.2 Hz), 1.82 (1H, ddq, H-2, $J_{1,2}$=5.8 Hz, $J_{2,3}$=3.6 Hz), 2.13 (1H, m, H-4), 2.25—2.50 (2H, broad signal, OH-3 and OH-6), 3.43 (3H, s, OMe), 3.67 (1H, dd, H-6, $J_{5,6}$=3.3 Hz, $J_{6,6'}$=11.2 Hz), 3.85 (1H, dd, H-6′, $J_{5,6'}$=6.6 Hz), 3.87 (1H, dd, H-3, $J_{2,3}$=3.6 Hz, $J_{3,4}$=7.4 Hz), 3.99 (1H, ddd, H-5, $J_{4,5}$=5.3 Hz), and 4.63 (1H, d, H-1); MS *m/z* 190 (M^+).

We are grateful to Prof. Sumio Umezawa, Institute of Bioorganic Chemistry, and the late Prof. Hamao Umezawa, Institute of Microbial Chemistry for their generous support of our program. Financial support by the Ministry of Education, Science and Culture (Grant-in-Aid for Scientific Research) is gratefull acknowledged.

Synthesis and Reactions of 2-Arylhydrazinotropones. I. Preparation of 2-(2-Arylhydrazino)tropones and the 4-Substituted Derivatives[1)]

(Received March 9, 1988)

A wide variety of 2-(2-arylhydrazino)tropones were prepared by the reactions of 2-tosyloxytropone with arylhydrazines. The dimeric compounds 6,6′-bis(arylhydrazono)-1,1′-bi(2,4-cycloheptadiene)-7,7′-diones, 2-anilinotropones, and 3-(2-arylhydrazino)tropones were isolated as minor products in some cases. Similarly, starting with 2-tosyloxytropones bearing an isopropyl, isopropenyl, (1-acetamidoethyl), and protected acetyl group at the 5-position, 4-substituted 2-(2-arylhydrazino)tropones were obtained as the major products by the abnormal substitution reaction. These 2-(2-arylhydrazino)tropones are expected to effectively serve as precursors for a convenient synthesis of 5-aryl-substituted tropolones via benzidine-type rearrangement. ^{1}H NMR (200 or 500-MHz) parameters for these 4-substituted 2-(2-arylhydrazino)tropones are given for their unambiguous structural assignments.

Many hydrazoarenes and 1,2-diarylhydrazines (ArNHNHAr′) are prepared by reduction of nitro-, azo-, and azoxyarenes.[2)] As for troponoids,[3)] several arylhydrazinotropones have been reported to be made by the substitution reaction of 2-methoxy-,[4)] 2-chloro-,[1a)] and 2-tosyloxytropones[1b,5)] with arylhydrazines. Meanwhile, it became known that some 2-(2-arylhydrazino)-tropones exhibited interesting physiological activity but were somewhat unstable towards acid.[6)] We wish to describe in this paper a detailed study on preparation of a wide variety of 2-(2-arylhydrazino)tropones with or without a *C*-substituent at the 4-position. These compounds are expected to be valuable as the precursors for our attempt to exploit a convenient, general method of preparing B-ring-open colchicine analogues of type **2**, by utilizing a novel benzidine type rearrangement of these 2-(2-arylhydrazino)tropones.[1)] This is because colchicine itself (**1**), though possessing highly important biological activity,[7)] is often too toxic clinically and thus various analogues of **1** are drawing an increasing interest from the viewpoint of pharmacological activity.[8)]

Results and Discussion

As model compounds for the synthetic study on the B-ring-open analogues of type **2**, six kinds of tropolones **3a—f** were chosen as the starting materials: namely, those bearing no substituent, an isopropyl, isopropenyl, acetyl, (1-acetamidoethyl), and a protected acetyl group at the 5-position. Among these, 5-(1-acetamidoethyl)- (**3e**) and 5-(2,5,5-trimethyl-1,3-dioxan-2-yl)tropolone (**3f**) were newly synthesized from 5-acetyltropolone[9)] (**3d**) by an application of the three-step procedure[10,11)] (i.e., by the reaction with hydroxylamine, followed by hydrogenation over Pd-C and then acetylation with acetic anhydride) and by treatment with 2,2-dimethyl-1,3-propanediol in the presence of acid, respectively; the overall yields of these products are given in Table 1. These tropolones were then led to the tosylates **4a—f** by the reaction with tosyl chloride in pyridine (see Table 1 for the

yields of **4**).

The tosylates **4** were treated with an excess (2—3 equiv) of various arylhydrazines **6a—o** (hydrochloride) either in refluxing methanol (or ethanol) for 6—24 h or in *N,N*-dimethylformamide (DMF) at 0—25 °C for 3—48 h in the presence of an excess (3—4 equiv) of triethylamine under nitrogen (see Scheme 1). After the usual work-up procedures including chromatographic separation, 27 kinds of 2-(2-arylhydrazino)tropones **7a—z'** were isolated mostly as the main product in good to moderate yields. Besides **7**, certain amounts of by-products **8a—g, j—o, 9a,l**, and **10—13** were

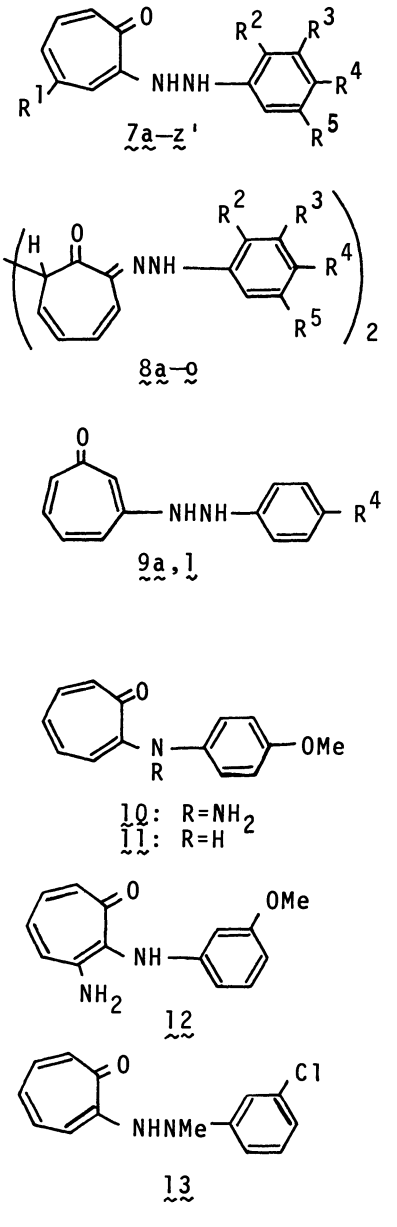

Scheme 1.

isolated by the additional or unusual reactions of **4a** with some kinds of **6**; for further discussion on these minor products **8—13**, see below. The yields of these products are summarized in Table 2. 5-Acetyltropolone tosylate (**2d**), which was rather unstable at room temp, did not afford any of the expected 4-acetyl-2-(2-arylhydrazino)tropones. Also, the reaction of 2-methoxytropone (**5a**) with some of the arylhydrazines **6** was conducted in refluxing methanol. However, the yields of the products by this combination tend to become lower than those obtained by the reaction starting with tosylate **4a** and the corresponding arylhydrazines, as had also been observed in the case[1a] with 2-chlorotropone (**5b**) (see Table 2).

Structures of these products were established by spectroscopy [UV, IR, ^{1}H NMR, MS, and ^{13}C NMR (for some compds)] and elemental analysis; their exact data and the rational assignments for the spectral parameters are described in the Experimental section. The unequivocal assignments of the *C*-substituents of **7p—z′** to the 4-position, not 5-position, were based on the careful analysis of the 200 or 500-MHz ^{1}H NMR data by taking into account the parameters established earlier for similar compounds, such as 4-substituted 2-methoxytropones.[11] Characteristic features in the δ and J values for these 4-substituted 2-(2-arylhydrazino)-tropones are summarized in Table 3. These data are obviously of considerable value in precisely determining the positions of substituents even of hitherto unreported polysubstituted troponoids, such as those of type **2**.[12] It should be noticed that the 4-substituted products **7p—z′** were smoothly derived by the abnormal (ciné) substitution reactions of 5-substituted tropolone tosylates **4b—f** with arylhydrazines at room temperature in a polar aprotic solvent (DMF) as in the case of the reaction of **4b,c** with liquid ammonia.[13,14]

By taking the parent tosylate **4a** as a representative, model compound, an effort to isolate the minor products **8—13** was made for the purpose of machanistic study on this rather subtle, substitution reactions with primary arylhydrazines.[15] The dimeric structures, 6,6′-bis(arylhydrazino)-1,1′-bi(2,4-cycloheptadiene)-7,7′-diones, were assigned for **8** primarily on the ground of their elemental analysis, IR, and doubly overlapping NMR signals, although MS gave no molecular ions but two intense fragment peaks presumably assignable to moieties **7** (m/z $M^+/2+1$) and the corresponding 2-arylazotropones (m/z $M^+/2-1$) derived from **8** as the result of facile fission by a disproportionation reaction. The dimers **8** are considered to be produced by oxidation of the monomeric arylhydrazinotropones **7**, since **8a** was obtained in 93% yield by refluxing **7a** in benzene in the presence of benzoyl peroxide.[15]

Another type of the minor products obtained in the case of the reaction of **4a** with **6a** and **6l** were 3-(2-arylhydrazino)tropones **9a** (6% yield) and **9l** (10%), respectively. These products are apparently derived as the result of the abnormal attack of the hydrazino

Table 2. Synthesis of 2-(2-Arylhydrazino)tropones

a, b) Values in parentheses are for starting materials **5a** and **5b**, respectively. c) Ref. 4. d) Ref. 1a. e, f) Values obtained when the free bases **6f** and **6g** were used, respectively.

Table 3. Characteristic Features in the δ and J Values (Hz) for 4-Substituted 2-(2-Arylhydrazino)tropones **7p—z′**

Proton	δ	J
NH-2	8.3—8.1	
H-3	7.0—7.3	$J_{3,5}\simeq 1.5$
R-4	a, b, c, d)	
H-5	6.7—6.95	$J_{5,6}=9.5$, $J_{5,7}\simeq 1.0$
H-6	7.2—7.3	$J_{6,7}=11.5$—12.0
H-7	7.05—7.15	
NH-1′	5.6—6.3	
H-2′	6.3—6.8	$J_{2',3'}=8.0$—8.5, $J_{2',4'}\simeq J_{2',6'}\simeq 2$
H-3′	6.9—7.35	$J_{3',4'}=7.5$—8.0
H-4′	6.2—6.9	$J_{4',5'}=7.5$—8.0, $J_{4',6'}=1.5$—2.0
H-5′	6.9—7.25	$J_{5',6'}=7.5$—8.0
H-6′	6.3—6.8	

a) For *i*-Pr: δ=1.66 (6H, d, J=7.0 Hz) and 2.81 (1H, sept). b) For Isopropenyl: δ=2.02—2.05 (3H, dd or t, J=1.0—1.5 Hz), 5.09—5.13 (1H, dq or quint, J=1.0—1.5 Hz), and 5.13—5.20 (1H, brs). c) For (1-acetamido)ethyl: δ=1.3—1.4 (3H, d, J=7.0 Hz) 1.85—1.9 (3H, s), 4.8—4.9 (1H, brq), and 5.7—6.3 (1H, brd, J=6.5 Hz). d) For 2,5,5-trimethyl-1,3-dioxan-2-yl: δ=0.55 (3H, s), 1.20 (3H, s), 1.47 (3H, s), and 3.19 (4H, brs).

group at C-3 of **4a** as was observed[16] in the case of the initial step of the degradative alkaline hydrolysis of **5b** to salicylaldehyde.

The reaction of **4a** with the hydrochloride of **6g** gave, besides **7g** and **8g** (see Table 2), 2-(*N*-amino-4-methoxyanilino)tropone (**10**) in 7% yield. However, 2-(4-methoxyanilino)tropone (**11**) was mainly obtained (33% yield) besides **10** (10%) when **6g** hydrochloride had been converted to the free base with triethylamine before being treated with **4a**; it was later confirmed that compound **10** was converted into **11** in refluxing methanol in the presence of hydrochloric acid. Similarly, the reaction of free **6f** with **4a** gave 3-amino-2-(3-methoxyanilino)tropone (**12**) in 29% yield. These results indicate that *m*- and *p*-methoxyphenylhydrazines (**6f,g**) tend to afford much more complex products depending upon the reaction conditions, whereas *o*-methoxyphenylhydrazine (**6e**) appears to give no product of the anilino-substituted type.

From the reaction of **4a** with **6k**, 2-[2-(3-chlorophenyl)-2-methylhydrazino]tropone (**13**) was also isolated in 3% yield, the reason for which, however, remains to be clarified.[15]

The 2-(2-arylhydrazino)tropones thus conveniently obtained in the present study are considered to be not only of interest from the view point of their potential biological activity but also useful precursors to various 5-aryl-substituted troponoids via benzidine-type rearrangement reaction, which is currently under intensive investigation.[12]

Experimental

Melting points were determined with a Yanagimoto MP-S3 instrument and are uncorrected. All reactions were monitored by TLC (Merck silica gel 60F, 0.25 mm) with appropriate solvent systems (mostly with MeOH–$CHCl_3$, $CHCl_3$–AcOEt, ether–benzene, and/or AcOEt–hexane). Preparative TLC and column chromatography were performed with Merck Kiesel Gel 60G and Wako C-200 silica gel, respectively. Yields of **3**, **4**, and **7**—**13** are given in Tables 1 and 2. The IR spectra were taken with a JASCO A-102 or Hitachi 215 spectrometer in chloroform (unless otherwise stated). The UV spectra were recorded in MeOH with a Hitachi EPS-3T spectrophotometer. The ^1H NMR spectra were measured in $CDCl_3$ (unless otherwise stated) with a Hitachi R-24 or R-600 (60-MHz), JEOL-FX200 (200-MHz, Kinki University), and/or Varian VXR-500 instrument (500-MHz, the SC-NMR Lab., Okayama University) at 27 °C. Chemical shifts are reported as δ values rel to tetramethylsilane as the internal standard measured at 60-MHz (unless otherwise stated). The assignment of all signals were made by employing a first-order analysis with the aid of decoupling technique and the parameters were confirmed by a computer-assisted simulation analysis. ^{13}C NMR spectra were recorded with a JEOL FX-100 (25-MHz, Kyushu Univ.). Mass spectra were taken on a JEOL DX-300 low resolution, or JEOL JMX-HX100 (with a JEOL JMA-DA5000 mass data system) high-resolution instrument and are given in terms of *m/z* (rel intensity) compared with the base peak.

5-(1-Acetamidoethyl)tropolone (3e). A slightly modified procedure of Nozoe et al.[10,11] for 4-cinnamoyltropolones was applied. Thus, a solution of **3d**[9] (211 mg, 1.29 mmol) and hydroxylammonium chloride (168 mg, 2.42 mmol) in dry ethanol (7 cm^3) was refluxed under argon for 1 h. After cooling, the precipitate was filtered off and washed with cold water to give the oxime of **3d** as a brown powder. This was dissolved in acetic acid (7 cm^3) containing concd HCl (0.5 cm^3) and then hydrogenated in the presence of 5% Pd on carbon (127 mg). The catalyst was filtered off and washed thoroughly with hot ethanol. The filtrate was evaporated in vacuo. The residue was dissolved in acetic anhydride (3 cm^3) and heated at 60 °C for 5 min. The excess acetic anhydride was evaporated in vacuo. The residue was chromatographed in a column of silica gel with $CHCl_3$, giving 5-(1-acetamidoethyl)-2-acetoxytropone as an amber oil (160 mg, 50% overall yield from **3d**): ^1H NMR δ=1.40 (3H, d, J=7.0 Hz, MeC-5), 1.98 (3H, s, AcN), 2.35 (3H, s, AcO), 4.92 (1H, brquint, J=7 Hz, HC-5), and 6.9—7.45 (5H, m, aromatic H, NH).

A mixture of this acetate (160 mg), ethanol (3 cm^3), and 1 M KOH (1.5 cm^3) (1 M=1 mol·dm^{-3}) was stirred under argon overnight at 20 °C. The solvent was evaporated in vacuo. The residue was diluted with cold water, taken to pH 4 with dil HCl at 5 °C, and extracted with CH_2Cl_2. The combined organic layers were dried (Na_2SO_4) and evaporated in vacuo, giving **3e** as a pale yellow syrup: ^1H NMR δ=1.41 (3H, d, J=7.0 Hz, MeC-5), 1.98 (3H, s, AcN), 4.93 (1H, brquint, $J\simeq$7 Hz, HC-5), 7.0 (1H, brm, NH), 7.35 (2H, d, J=11 Hz, H-3,7), 7.40 (2H, d, J=11 Hz, H-4,6), and 7.98 (1H, brm, OH); MS *m/z* 207 (M^+; 100) and 148 (72).

Found: *m/z* 207.0861. Calcd for $C_{11}H_{13}NO_3$: M, 207.0895.

5-(2,5,5-Trimethyl-1,3-dioxan-2-yl)tropolone (3f). A solution of **3d** (50 mg, 0.31 mmol) and 2,2-dimethyl-1,3-propanediol (40 mg, 0.39 mmol) in dry benzene (3 cm^3) containing *p*-toluenesulfonic acid (6 mg) was refluxed for 13 h (using a Dean-Stark apparatus). After cooling, the mixture was diluted with cold water and then extracted with $CHCl_3$. The combined organic layers were extracted with 2 M NaOH. The aq layer was taken to pH 4 with 3 M HCl and then extracted with CH_2Cl_2. The combined organic layers were dried (Na_2SO_4) and evaporated in vacuo. The residue was chromatographed in a column of silica gel with 1:19 MeOH–$CHCl_3$ to give **3f** as colorless needles: mp 109—110 °C (from cyclohexane); IR (KBr) 3205 (OH) and 1615 cm^{-1} (C=O); ^1H NMR δ=0.63 [3H, s, (*Z*)-Me-5′], 1.24 [3H, s, (*E*)-Me-5′], 1.52 (3H, s, Me-2′), 3.39 (4H, brs, 2H-4′,6′), 7.37 (2H, d, J=11 Hz, H-3,7), 7.66 (2H, d, J=11 Hz, H-4,6), and 8.75 (1H, brm, OH); MS *m/z* 250 (M^+; $\simeq$0), 235 (100), 167 (21), and 149 (50).

Found: *m/z* 235.0959. Calcd for $C_{13}H_{15}O_4$: M−CH_3, 235.0970.

General Procedure for the Preparation of 5-Substituted Tropolone Tosylates (4a—f). To a cold solution of a 5-substituted tropolone **3** (1.00 g) in dry pyridine (2.5 cm^3) was added tosyl chloride (1.1—1.2 equiv mol) at 5 °C. The mixture was stirred at 20 °C for 10—16 h (but 20 min for **4d**), and then diluted with cold water. The precipitate was filtered off and washed with cold water to give **4**. The filtrate was concentrated in vacuo and extracted with CH_2Cl_2, giving an additional **4** after chromatographic

purification in a column of silica gel.

2-Tosyloxytropone[17] (4a): Colorless needles; mp 155.5—157 °C lit,[17] 159—159.5 °C).

5-Isopropyl-2-tosyloxytropone[13] (4b): Colorless needles; mp 120.5—121.5 °C (from benzene–hexane, lit,[13] 122—123 °C); ^{1}H NMR δ=1.22 (6H, d, J=7.0 Hz, Me_2C-5), 2.46 (3H, s, Me-4′), 2.85 (1H, sept, J=7 Hz, HC-5), 6.89 (1H, dd, $J_{3,4}$=9.5, $J_{4,6}$=1.5 Hz, H-4), 7.17 (1H, d, $J_{6,7}$=11.0 Hz, H-7), 7.23 (1H, dd, H-6), 7.39 (2H, brd, J=8.5 Hz, H-3′,5′), 7.47 (1H, d, H-3), and 7.98 (2H, brd, J=8.5 Hz, H-2′,6′).

5-Isopropenyl-2-tosyloxytropone[14] (4c): Colorless crystals; mp 125.5—126.5 °C (from benzene–hexane, lit,[14] mp 126—127 °C); ^{1}H NMR δ=2.10 (3H, brd, $J\simeq$1.0 Hz, MeC-5), 2.44 (3H, s, Me-4′), 5.29 [1H, brs, (*E*)-HC=C-5], 5.38 [1H, brs, (*Z*)-HC=C-5], 7.00 (1H, dd, $J_{3,4}$=11.0, $J_{4,6}$=1.5 Hz, H-4), 7.12 (1H, d, $J_{6,7}$=12.5 Hz, H-7), 7.35 (2H, brd, J=8.5 Hz, H-3′,5′), 7.41 (1H, dd, H-6), 7.44 (1H, d, H-3), and 7.92 (2H, brd, J=8.5 Hz, H-2′,6′).

5-Acetyl-2-tosyloxytropone (4d): Pale yellow prisms; mp 115—115.5 °C (from AcOEt–cyclohexane); ^{1}H NMR δ=2.47 (3H, brs, Me-4′), 2.61 (3H, s, Ac), 7.19 (1H, d, $J_{6,7}$=12.5 Hz, H-7), 7.37 (2H, brd, J=8.5 Hz, H-3′,5′), 7.55 (1H, brd, $J_{3,4}\simeq$11.5 Hz, H-3), 7.68 (1H, brdd, $J_{4,6}$=1.5 Hz, H-4), 7.84 (1H, brdd, H-6), and 7.91 (2H, brd, J=8.5 Hz, H-2′,6′); MS m/z 318 (M^+; ≃0), 254 (37), 164 (27), 155 (57), 149 (15), 139 (16), 121 (17), 91 (100), 65 (20), and 43 (18). **4d** decomposes on setting aside at room temp (or rapidly on silica gel).

Found: m/z 254.0939. Calcd for $C_{16}H_{14}O_3$: M−SO_2, 254.0943.

5-(1-Acetamidoethyl)-2-tosyloxytropone (4e): A pale yellow syrup; ^{1}H NMR δ=1.39 (3H, d, J=7.0 Hz, MeC-5), 1.97 (3H, s, AcN), 2.46 (3H, s, Me-4′), 4.82 (1H, brquint, J=7 Hz, HC-5), 6.97 (1H, brm, NH), 6.98 (2H, brd, $J_{3,4}\simeq J_{6,7}\simeq$10.5 Hz, H-3,7), 7.27 (1H, brd, H-4), 7.31 (1H, brd, H-6), 7.35 (2H, brd, J=8.5 Hz, H-3′,5′), and 7.98 (2H, brd, J=8.5 Hz, H-2′,6′); MS m/z 361 (M^+; 5.5), 302 (17), 295 (100), 239 (18), 238 (42), and 139 (25).

Found: m/z 361.0957. Calcd for $C_{18}H_{19}NO_5S$: M, 361.0984.

5-(2,5,5-Trimethyl-1,3-dioxan-2-yl)-2-tosyloxytropone (4f): Colorless crystals (89% yield from **3f**); mp 114—116 °C (from EtOH); IR 1632 cm^{-1} (C=O); ^{1}H NMR δ=0.67 [3H, s, (*Z*)-Me-5″], 1.22 (3H, s, (*E*)-Me-5″], 1.49 (3H, s, Me-2″), 2.48 (3H, s, Me-4′), 3.39 (4H, brs, 2H-4″,6″), 7.28—7.62 (4H, m, aromatic H), 7.37 (2H, brd, J=8 Hz, H-3′,5′), and 7.98 (2H, brd, J=8 Hz, H-2′,6′); MS m/z 404 (M^+; ≃0), 389 (27), 361 (22), 341 (27), 340 (100), 326 (15), 325 (60), 275 (15), 249 (11), 155 (23), 129 (25), 107 (9), 91 (17), and 69 (19).

Found: m/z 389.1049. Calcd for $C_{20}H_{21}O_6S$: M−CH_3, 389.1059.

General Procedure for the Preparation of 2-(2-Arylhydrazino)tropones (7a—z′) (with the Formation of By-products 8—13). A. Procedure for 7a—o: A mixture of **4a** (1.38 g, 5 mmol) and an arylhydrazine **6** (or its hydrochloride, 10 mmol) in methanol (or ethanol for **6m—o**, 150 cm^3) was refluxed for 6—24 h under nitrogen in the presence of triethylamine (5 mmol, or 15 mmol when the arylhydrazine hydrochloride was used).

B. Procedure for 7p—z′: To a solution of a 5-substituted 2-tosyloxytropone **4** (250 mg) in dry DMF (6 cm^3) were successively added, under argon at −20 °C, arylhydrazine hydrochloride **6** (3.0 equiv mol) and triethylamine (4.0 equiv mol, dropwise), followed by stirring at −20 °C for 1 h and then at 20 °C for 7—20 h.

C. Procedure Using Free 6f,g: Triethylamine (1.01 g, 10 mmol) was added to a suspension of hydrochloride (1.75 g, 10 mmol) of **6** in methanol (150 cm^3). To the resulting solution was added **4a** (1.38 g, 5 mmol), and the mixture was refluxed for 8 h under nitrogen.

D. Procedure for 7b—d Using 5a as the Starting Material: The same method as **A** described above was employed except for using **5a** (in place of **4a**).

When the starting material **4** or **5** almost disappeared (by TLC), the solvent was evaporated in vacuo. The residue was diluted with cold water and extracted with CH_2Cl_2 or $CHCl_3$. The organic layer was dried (Na_2SO_4) and evaporated in vacuo. The residue (when it was a solid) was recrystallized from an appropriate solvent (see below) to give the corresponding product **7**; the filtrate was concentrated in vacuo and the residue was chromatographed on preparative thin-layer plates (with $CHCl_3$–AcOEt) or in a column of silica gel (with MeOH–$CHCl_3$ or AcOEt–hexane), giving an additional amount of **7** and other by-products.

2-(2-Phenylhydrazino)tropone[1a,4] (7a): Yellow prisms (by Procedure **A**); mp 163—165 °C (from benzene, lit,[1a,4] 168 °C).

2-[2-(*o*-Tolyl)hydrazino]tropone[1a] (7b): Brown prisms (by Procedures **A** and **D**); mp 90—91 °C (from benzene, lit,[1a]

2-[2-(*m*-Tolyl)hydrazino]tropone[1a] (7c): Yellow prisms (by Procedures **A** and **D**); mp 148 °C (from benzene, lit,[1a] 147 °C).

2-[2-(*p*-Tolyl)hydrazino]tropone[1a] (7d): Yellow prisms (by Procedures **A** and **D**); mp 162—164 °C (from benzene, lit,[1a] 158 °C).

2-[2-(2-Methoxyphenyl)hydrazino]tropone (7e): Yellow prisms (by Procedure **A**); mp 118—119 °C (from benzene); IR 3300 (NH) and 1605 cm^{-1} (C=O); UV λ_{max} 250 (log ε 4.58), 339 (4.12), and 402 nm (4.10); ^{1}H NMR δ=3.48 (3H, s, MeO-2′), 6.25 (1H, brm, NH-1′), 6.5—7.3 (9H, m, aromatic H), and 8.2 (1H, brm, NH-2); MS m/z 242 (M^+; 93), 123 (100), 122 (49), and 108 (48).

Found: m/z 242.1045. Calcd for $C_{14}H_{14}N_2O_2$: M, 242.1055.

2-[2-(3-Methoxyphenyl)hydrazino]tropone (7f): Yellow prisms (by Procedures **A** and **C**); mp 148—150 °C (from benzene); IR 3305 (NH) and 1605 cm^{-1} (C=O); UV λ_{max} 248 (log ε 4.50), 339 (4.47), and 406 nm (4.07); ^{1}H NMR δ=3.71 (3H, s, MeO-3′), 6.15 (1H, brm, NH-1′), 6.3—7.4 (9 H, m, aromatic H), and 8.3 (1H, brm, NH-2).

Anal. ($C_{14}H_{14}N_2O_2$) C, H, N.

2-[2-(4-Methoxyphenyl)hydrazino]tropone (7g): Yellow prisms (by Procedures **A** and **C**); mp 137—139 °C (from benzene); IR 3300 (NH) and 1605 cm^{-1} (C=O); UV λ_{max} 250 (log ε 4.51), 339 (4.07), and 405 nm (4.08); ^{1}H NMR δ=3.71 (3H, s, MeO-4′), 5.7 (1H, brm, NH-1′), 6.5—6.9 (1H, m, H-5), 6.71 (4H, s, H-2′,3′,5′,6′), 6.9—7.4 (4H, m, H-3,4,6,7), and 8.25 (1H, brm, NH-2).

Anal. ($C_{14}H_{14}N_2O_2$) C, H, N.

2-[2-(2,3-Dimethoxyphenyl)hydrazino]tropone (7h): Yellow prisms (by Procedure **A** using **6h**[18]); mp 103—105 °C (from benzene–hexane); IR 3305 (NH) and 1605 cm^{-1} (C=O); UV λ_{max} 250 (log ε 4.49), 339 (4.04), and 405 nm (4.07); ^{1}H NMR δ=3.83 (3H, s, MeO-3′), 3.90 (3H, s, MeO-2′), 6.25—6.65 (3H, m, H-4′,5′,6′), 6.35 (1H, brm, NH-1′), 6.7—7.4 (5H, m, aromatic H), and 8.23 (1H, brm, NH-2); MS m/z 272 (M^+; 100), 153 (92), 153 (31), 138 (57), and 137 (29).

Found: m/z 272.1156. Calcd for $C_{15}H_{16}N_2O_3$: M, 272.1161.

2-[2-(2,3-Dimethoxy-5-methylphenyl)hydrazino]tropone (7i): Yellow prisms (by Procedure **A** using **6i**[18]); mp 73—75 °C (from benzene–hexane); IR 3305 (NH) and 1605 cm^{-1} (C=O); UV λ_{max} 250 (log ε 4.54), 339 (4.08), and 405 nm (4.11); ^1H NMR δ=2.15 (3H, s, Me-5′), 3.84 (3H, s, MeO-3′), 3.88 (3H, s, MeO-2′), 6.16 (1H, d, J=1.8 Hz, H-4′), 6.28 (1H, d, J=1.8 Hz, H-6′), 6.35 (1H, brm, NH-1′), 6.5—7.5 (5H, m, aromatic H), and 8.2 (1H, brm, NH-2); MS m/z 286 (M^+; 100), 167 (76), 166 (28), 152 (66), 151 (24), 139 (25), 138 (21), and 123 (21).

Found: m/z 286.1304. Calcd for $C_{16}H_{18}N_2O_3$: M, 286.1317.

2-[2-(2-Chlorophenyl)hydrazino]tropone (7j): Yellow prisms (by Procedure **A**); mp 91—93 °C (from benzene); IR 3320 (NH) and 1595 cm^{-1} (C=O); UV λ_{max} 249 (log ε 4.58), 338 (4.12), and 402 nm (4.14); ^1H NMR δ=6.35 (1H, brm, NH-1′), 6.5—7.4 (9H, m, aromatic H), and 8.25 (1H, brm, NH-2); MS m/z 248 (M^+; 19), 246 (M^+; 58), 129 (33), and 127 (100).

Found: m/z 246.0561. Calcd for $C_{13}H_{11}ClN_2O$: M, 246.0566.

2-[2-(3-Chlorophenyl)hydrazino]tropone (7k): Yellow prisms (by Procedure **A**); mp 159—161 °C (from benzene); IR 3320 (NH) and 1595 cm^{-1} (C=O); UV λ_{max} 248 (log ε 4.38), 338 (3.91), and 403 nm (3.93); ^1H NMR δ=6.25 (1H, brm, NH-1′), 6.5—7.4 (9H, m, aromatic H), and 8.35 (1H, brm, NH-2).

Anal. ($C_{13}H_{11}ClN_2O$) C, H, N.

2-[2-(4-Chlorophenyl)hydrazino]tropone (7l): Yellow prisms (by Procedure **A**); mp 118—120 °C (from ethanol–benzene); IR 3300 (NH) and 1595 cm^{-1} (C=O); UV λ_{max} 251 (log ε 4.48), 338 (4.00), and 403 nm (4.02); ^1H NMR δ=5.9 (1H, brm, NH-1′), 6.7—7.4 (5H, m, H-3—7), 6.71 (2H, brd, J=8.5 Hz, H-2′,6′), 7.18 (2H, brd, J=8.5 Hz, H-3′, 5′), and 8.3 (1H, brm, NH-2).

Anal. ($C_{13}H_{11}ClN_2O$) C, H, N.

2-[2-(2-Nitrophenyl)hydrazino]tropone (7m): Yellow prisms (by Procedure **A**); mp 178—179 °C (from benzene); IR 3320 (NH) and 1610 cm^{-1} (C=O); UV λ_{max} 245 (log ε 4.57), 327 (4.11), and 405 nm (4.25); ^1H NMR δ=6.5—7.8 (8H, m, aromatic H), 8.23 (1H, m, H-3′), and 9.55 (2H, brm, NH-1-,2).

Anal. ($C_{13}H_{11}N_3O_3$) C, H, N.

2-[2-(3-Nitrophenyl)hydrazino]tropone[1a] **(7n):** Yellow prisms (by Procedure **A**); mp 178—180 °C (from ethanol, lit,[1a] 180 °C).

2-[2-(4-Nitrophenyl)hydrazino]tropone[1a] **(7o):** Yellow prisms (by Procedure **A**); mp 185 °C decomp (from ethanol, lit,[1a] 191 °C).

4-Isopropyl-2-(2-phenylhydrazino)tropone (7p): Pale yellow needles (by Procedure **B** with phenylhydrazine free base); mp 152.5—153.5 °C (from EtOH); ^1H NMR (200-MHz) δ=1.16 (6H, d, J=7.0 Hz, Me_2C-4), 2.81 (1H, sept, J=7.0 Hz, HC-4), 5.71 (1H, brs, NH-1′), 6.73 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 6.82 (2H, brd, $J_{2',3'}=J_{5',6'}$=8.0 Hz, H-2′,6′), 6.93 (1H, brt, $J_{3',4'}=J_{4',5'}$=7.0 Hz, H-4′), 7.11 (1H, d, $J_{6,7}$=12.0 Hz, H-7), 7.13 (1H, d, $J_{3,5}$=1.5 Hz, H-3), 7.25 (2H, brdd, H-3′,5′), 7.29 (1H, dd, H-6), and 8.31 (1H, brs, NH-2); MS m/z 254 (M^+; 74), 211 (4), 163 (7), 163 (7), 105 (9), 93 (100), and 77 (30).

Found: m/z 254.1422. Calcd for $C_{16}H_{18}N_2O$: M, 254.1419.

4-Isopropenyl-2-(2-phenylhydrazino)tropone (7q): Yellow needles (by Procedure **B**); mp 176—178 °C (from EtOH); ^1H NMR (200-MHz) δ=2.04 (3H, brt, $J\simeq$1.2 Hz, MeC-4), 5.12 [1H, brquint, $J\simeq$1.5 Hz, (*E*)-HC=C-4], 5.17 [1H, brs, (*Z*)-HC=C-4], 5.17 (1H, brs, NH-1′), 6.81 (2H, brd, $J_{2',3'}=J_{5',6'}$=8.5 Hz, H-2′,6′), 6.81 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 6.92 (1H, brt, $J_{3',4'}=J_{4',5'}$=7.5 Hz, H-4′), 7.14 (1H, dd, $J_{6,7}$=11.5, $J_{5,7}$=1.0 Hz, H-7), 7.25 (2H, brdd, H-3′,5′), 7.28 (1H, d, $J_{3,5}$=1.5 Hz, H-3), 7.30 (1H, dd, H-6), and 8.30 (1H, brs, NH-2); MS m/z 252 (M^+; 72.8), 161 (11), 93 (100), and 77 (33).

Found: m/z 252.1271. Calcd for $C_{16}H_{16}N_2O$: M, 252.1263.

4-Isopropenyl-2-[2-(*o*-tolyl)hydrazino]tropone (7r): Yellow needles (by Procedure **B**); mp 141—142 °C (from ether); ^1H NMR (200-MHz) δ=2.05 (3H, brt, J=1.2 Hz, MeC-4), 2.29 (3H, s, Me-2′), 5.12 [1H, brquint, J=1.2 Hz, (*E*)-HC=C-4], 5.17 [1H, brs, (*Z*)-HC=C-4], 5.64 (1H, brs, NH-1′), 6.75 (1H, brd, $J_{5',6'}$=8.0 Hz, H-6′), 6.86 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 6.87 (1H, td, $J_{3',4'}=J_{4',5'}$=7.5, $J_{4',6'}$=1.0 Hz, H-4′), 7.11 (1H, brt, H-5′), 7.14 (1H, brd, H-3′), 7.14 (1H, d, $J_{6,7}$=11.5 Hz, H-7), 7.28 (1H, d, $J_{3,4}$=1.5 Hz, H-3), 7.32 (1H, dd, H-6), and 8.28 (1H, brs, NH-2); MS m/z 266 (M^+; 52.5), 161 (8), 145 (4), 133 (13), 107 (100), 106 (55), and 91 (16).

Found: m/z 266.1397. Calcd for $C_{17}H_{18}N_2O$: M, 266.1419.

4-Isopropenyl-2-[2-(*m*-tolyl)hydrazino]tropone (7s): Yellow needles (by Procedure **B**); mp 165—167 °C (from ether); ^1H NMR (200-MHz) δ=2.05 (3H, brt, $J\simeq$1.2 Hz, MeC-4), 2.27 (3H, s, Me-3′), 5.13 [1H, qd, J=1.5, 1.0 Hz, (*E*)-HC=C-4], 5.19 [1H, brs, (*Z*)-HC=C-4], 5.65 (1H, brs, NH-1′), 6.62 (1H, brd, $J_{4',5'}$=8.5 Hz, H-4′), 6.64 (1H, brs, H-2′), 6.74 (1H, brd, $J_{5',6'}$=7.5 Hz, H-6′), 6.86 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 7.15 (1H, brdd, H-5′), 7.16 (1H, brdd, $J_{6,7}$=11.5, $J_{5,7}\simeq$1.0 Hz, H-7), 7.26 (1H, brd, $J_{3,5}$=1.5 Hz, H-3), 7.31 (1H, dd, H-6), and 8.28 (1H, brs, NH-2); MS m/z 266 (M^+; 43.1), 223 (5), 161 (4), 145 (6), 133 (15), 132 (12), 107 (100), and 91 (20).

Found: m/z 266.1432. Calcd for $C_{17}H_{18}N_2O$: M, 266.1419.

4-Isopropenyl-2-[2-(2-methoxyphenyl)hydrazino]tropone (7t): Yellow needles (by Procedure **B**); mp 122—123.5 °C (from ether–light petroleum); ^1H NMR (500-MHz) δ=2.05 (3H, brd, J=1.5 Hz, MeC-4), 3.92 (3H, s, MeO-2′), 5.11 [1H, brquint, J=1.5 Hz, (*E*)-HC=C-4], 5.17 [1H, brs, (*Z*)-HC=C-4], 6.24 (1H, brm, NH-1′), 6.74 (1H, brd, $J_{3',4'}$=7.4 Hz, H-3′), 6.84 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 6.83—6.88 (3H, m, H-5′,4′,6′), 7.12 (1H, brd, $J_{6,7}$=11.7 Hz, H-7), 7.26 (1H, brd, $J_{3,5}$=1.5 Hz, H-3), 7.29 (1H, dd, H-6), and 8.22 (1H, brm, NH-2); MS m/z 282 (M^+; 69.2), 161 (10), 132 (21), 123 (100), 122 (42), 108 (42), 94 (97), and 80 (43).

Found: m/z 282.1364. Calcd for $C_{17}H_{18}N_2O_2$: M, 282.1368.

4-Isopropenyl-2-[2-(3-methoxyphenyl)hydrazino]tropone (7u): Yellow needles (by Procedure **B**); mp 165—166 °C (from ether); ^1H NMR (200-MHz) δ=2.03 (3H, brd, J=1.5 Hz, MeC-4), 3.71 (3H, s, MeO-3′), 5.08 [1H, brq, J=1.5 Hz, (*E*)-HC=C-4], 5.13 [1H, brs, (*Z*)-HC=C-4], 5.65 (1H, brs, NH-1′), 6.30 (1H, t, $J_{2',4'}\simeq J_{2',6'}\simeq$2.0 Hz, H-2′), 6.35 (1H, ddd, $J_{4',5'}$=8.0, $J_{4',6'}$=1 Hz, H-4′), 6.40 (1H, dd, $J_{5',6'}$=8.0 Hz, H-6′), 6.79 (1H, ddd, $J_{5,6}$=9.5, $J_{3,5}$=1.5, $J_{5,7}$=1.0 Hz, H-5), 7.05 (1H, dd, $J_{6,7}$=12.0 Hz, H-7), 7.07 (1H, t, H-5′), 7.19 (1H, d, H-3), 7.23 (1H, dd, H-6), and 8.19 (1H, brs, NH-2); MS m/z 282 (M^+; 53.3), 161 (8), 132 (18), 123 (100), 122 (43), 108 (38), 94 (82), and 80 (50).

Found: m/z 282.1365. Calcd for $C_{17}H_{18}N_2O_2$: M, 282.1368.

4-Isopropenyl-2-[2-(2,3-dimethoxyphenyl)hydrazino]tropone (7v): A yellow oil (by Procedure **B**); ^1H NMR (200-MHz) δ=2.02 (3H, dd, J=1.5, 1.0 Hz, MeC-4), 3.85 (3H, s, MeO-3′), 3.90 (3H, s, MeO-2′), 5.09 [1H, qd, J=1.5, 1.0 Hz, (*E*)-HC=C-4], 5.16 [1H, quint, J=1.0 Hz, (*Z*)-HC=C-4], 6.27 (1H, brs, NH-1′), 6.36 (1H, dd, $J_{4',5'}$=8.0, $J_{4',6'}$=1.5 Hz, H-4′), 6.40 (1H, dd, $J_{5',6'}$=8.0 Hz, H-6′), 6.82 (1H, ddd, $J_{5,6}$=9.5,

$J_{3,5}$=1.5, $J_{5,7}$=1 Hz, H-5), 6.87 (1H, t, H-5′), 7.09 (1H, dd, $J_{6,7}$=12.0 Hz, H-7), 7.22 (1H, d, H-3), 7.27 (1H, dd, H-6), and 8.17 (1H, brs, NH-2); MS *m/z* 312 (M^+; 3), 153 (72), and 138 (100).

Found: *m/z* 312.1470. Calcd for $C_{18}H_{20}N_2O_3$: M, 312.1474.

4-Isopropenyl-2-[2-(2,3-dimethoxy-5-methylphenyl)hydrazino]tropone (7w): A yellow oil (by Procedure **B**); ^{1}H NMR (200-MHz) δ=2.07 (3H, brs, MeC-4), 2.19 (3H, s, Me-5′), 3.85 (3H, s, MeO-3′), 3.88 (3H, s, MeO-2′), 5.12, 5.20 (1H each, both brs, H_2C=C-4), 6.21 (1H, brd, $J_{4',6'}$=1.5 Hz, H-4′), 6.24 (1H, brs, NH-1′), 6.30 (1H, brd, H-6′), 6.84 (1H, ddd, $J_{5,6}$=9.5, $J_{3,5}$=1.5, $J_{5,7}$≃0.5 Hz, H-5), 7.13 (1H, d, $J_{6,7}$=12.0 Hz, H-7), 7.28 (1H, d, H-3), 7.29 (1H, dd, H-6), and 8.18 (1H, brs, NH-2); MS *m/z* 326 (M^+; 90), 331 (8), 295 (5), 175 (14), 167 (100), 161 (48), 152 (97), 136 (84), and 91 (57).

Found: *m/z* 326.1611. Calcd for $C_{19}H_{22}N_2O_3$: M, 326.1630.

4-(1-Acetamidoethyl)-2-[2-(2-methoxyphenyl)hydrazino]tropone (7x): A pale amber syrup (by Procedure **B**); ^{1}H NMR δ=1.41 (3H, d, *J*=7.5 Hz, MeC-4), 1.88 (3H, s, AcN), 3.97 (3H, s, MeO-2′), 4.87 (1H, brquint, *J*=7.5 Hz, HC-4), 5.6 (1H, brd, *J*≃6.5 Hz, HNC-4), 6.3 (1H, brs, NH-1′), 6.65—7.40 (8H, m, aromatic H), and 8.10 (1H, brs, NH-2); MS *m/z* 327 (M^+; 81), 268 (42), 124 (100), and 107 (91).

Found: *m/z* 327.1556. Calcd for $C_{18}H_{21}N_3O_3$: M, 327.1583.

4-(1-Acetamidoethyl)-2-[2-(3-methoxyphenyl)hydrazino]tropone (7y): A yellow oil (by Procedure **B**); ^{1}H NMR (200-MHz) δ=1.34 (3H, d, *J*=7.0 Hz, MeC-4), 1.86 (3H, s, AcN), 3.72 (3H, s, MeO-3′), 4.80 (1H, brquint, *J*≃7 Hz, HC-4), 5.77 (1H, brd, *J*≃6.5 Hz, HNC-4), 5.83 (1H, brs, NH-1′), 6.28 (1H, brt, $J_{2',4'}$≃$J_{4',6'}$≃2.0 Hz, H-2′), 6.33 (1H, brdt, $J_{4',5'}$=8.0, $J_{4',6'}$=2 Hz, H-4′), 6.40 (1H, brdd, $J_{5',6'}$=8.0 Hz, H-6′), 6.71 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 6.99 (1H, brd, $J_{3,5}$≃1 Hz, H-3), 7.05 (1H, brd, $J_{6,7}$=12.0 Hz, H-7), 7.08 (1H, t, H-5′), 7.22 (1H, dd, H-6), and 8.21 (1H, brs, NH-2); MS *m/z* 327 (M^+; 92), 268 (63), 124 (100), and 107 (88).

Found: *m/z* 327.1565. Calcd for $C_{18}H_{21}N_3O_3$: M, 327.1583.

4-(1-Acetamidoethyl)-2-[2-(2,3-dimethoxyphenyl)hydrazino]tropone (7z): A yellow oil (by Procedure **B**); ^{1}H NMR (200-MHz) δ=1.33 (3H, d, *J*=7.0 Hz, MeC-4), 1.87 (3H, s, AcN), 3.88 (3H, s, MeO-3′), 3.95 (3H, s, MeO-2′), 4.83 (1H, brquint, *J*=7 Hz, HC-4), 5.72 (1H, brd, *J*=6.5 Hz, HNC-4), 6.30 (1H, brs, NH-1′), 6.37 (1H, brdd, $J_{4',5'}$=8.0, $J_{4',6'}$=1.5 Hz, H-4′), 6.49 (1H, brdd, H-6′), 6.76 (1H, brd, $J_{5,6}$=9.5 Hz, H-5), 6.89 (1H, t, $J_{5',6'}$=8.0 Hz, H-5′), 6.96 (1H, brd, $J_{3,5}$≃1.5 Hz, H-3), 7.10 (1H, brdd, $J_{6,7}$=11.5, $J_{5,7}$=1.0 Hz, H-7), 7.26 (1H, dd, H-6), and 8.22 (1H, brs, NH-2); MS *m/z* 357 (M^+; 69), 298 (39), 206 (28), 163 (32), 153 (100), and 138 (49).

Found: *m/z* 357.1736. Calcd for $C_{19}H_{23}N_3O_4$: M, 357.1689.

4-(2,5,5-Trimethyl-1,3-dioxan-2-yl)-2-[2-(2-methoxyphenyl)hydrazino]tropone (7z′): Yellow needles (by Procedure **B**); mp 145—146.5 °C (from ether–light petroleum); IR (KBr) 3320 (NH) and 1598 cm^{-1} (C=O); ^{1}H NMR δ=0.54 [3H, s, (*Z*)-Me-5″], 1.20 [3H, s, (*E*)-Me-5″], 1.47 (3H, s, Me-2″), 3.19 (4H, brs, 2H-4″,6″), 3.92 (3H, s, MeO-2′), 6.27 (1H, m, NH-1′), 6.80 (1H, d, $J_{5,6}$≃9.5 Hz, H-5), 6.55—7.0 (4H, m, H-3′,4′,5′,6′), 7.16 (1H, brd, $J_{6,7}$≃11 Hz, H-7), 7.23 (1H, brs, H-3), 7.30 (1H, brdd, H-6), and 8.29 (1H, m, HN-2); MS *m/z* 370 (M^+; 100), 355 (14), 129 (30), 123 (50), 108 (17), 69 (13), and 43 (18).

Found: *m/z* 370.1892. Calcd for $C_{21}H_{26}N_2O_4$: M, 370.1893.

6,6′-Bis(phenylhydrazono)-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8a): Bright yellow needles (by Procedure **A**); mp 183—184 °C decomp (from benzene); IR 3350 (NH) and 1635 cm^{-1} (C=O); ^{1}H NMR (100-MHz) δ=3.82 (2H, brt, $J_{1,2}$=3.0, $J_{1,3}$=2.5 Hz, H-1,1′), 5.48 (2H, brddd, $J_{2,3}$=9.0, $J_{2,4}$=2.5 Hz, H-2,2′), 6.33 (2H, m, $J_{4,5}$=11.0, $J_{3,5}$=2.0 Hz, H-5,5′), 6.34 (2H, m, $J_{3,4}$=2.5 Hz, H-3,3′), 6.66 (2H, brdt, H-4,4′), 6.9—7.4 (10H, m, 2Ph), and 13.6 (2H, brm, NH-6,6′); ^{13}C NMR δ=50.3 (C-1), 115.5, 123.4, 124.2, 124.8, 129.2, 129.4, 129.9, 135.0 (C-1′), 142.4 (C-6), and 187.6 (C-7); MS *m/z* 212 (41), 210 (97), 193 (24), 182 (19), 181 (22), 154 (26), 119 (38), and 91 (100).

Anal. ($C_{26}H_{22}N_4O_2$) C, H, N.

6,6′-Bis[(*o*-tolyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8b): Bright yellow needles (by Procedure **A**); mp 161—162 °C decomp (from benzene); IR 3450 (NH) and 1635 cm^{-1} (C=O); ^{1}H NMR δ=1.95 (6H, s, 2 Me-2″), 3.8—3.95 (2H, m, H-1,1′), 5.3—5.7 (2H, m, H-2,2′), 6.15—7.8 (14H, m, aromatic H), and 13.9 (2H, brm, NH-6,6′).

Anal. ($C_{28}H_{26}N_4O_2$) C, H, N.

6,6′-Bis[(*m*-tolyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8c): Bright yellow needles (by Procedure **A**); mp 179—181 °C decomp (from benzene); IR 3410 (NH) and 1630 cm^{-1} (C=O); ^{1}H NMR δ=2.22 (6H, s, 2Me-3″), 3.65—3.85 (2H, m, H-1,1′), 5.2—5.6 (2H, m, H-2,2′), 6.1—7.2 (14H, m, aromatic H), and 14.4 (2H, brm, NH-6,6′).

Anal. ($C_{28}H_{26}N_4O_2$) C, H, N.

6,6′-Bis[(*p*-tolyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8d): Bright yellow needles (by Procedure **A**); mp 174—175 °C decomp (from benzene); IR 3450 (NH) and 1630 cm^{-1} (C=O); ^{1}H NMR δ=2.30 (6H, s, 2Me-4″), 3.65—3.9 (2H, m, H-1,1′), 5.3—5.7 (2H, m, H-2,2′), 6.15—7.3 (6H, m, H-3,3′,4,4′,5,5′), 7.20 (8H, m, 2H-2″,3″,5″,6″), and 13.8 (2H, brm, NH-6,6′).

Anal. ($C_{28}H_{26}N_4O_2$) C, H, N.

6,6′-Bis[(2-methoxyphenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8e): Bright yellow needles (by Procedure **A**); mp 174—176 °C decomp (from benzene); IR 3400 (NH) and 1640 cm^{-1} (C=O); ^{1}H NMR δ=3.40 (6H, s, 2MeO-2″), 3.90 (2H, m, H-1,1′), 5.3—5.6 (2H, m, H-2,2′), 6.2—7.8 (14H, m, aromatic H), and 13.4 (2H, brm, NH-6,6′).

Anal. ($C_{28}H_{26}N_4O_4$) C, H, N.

6,6′-Bis[(3-methoxyphenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8f): Bright yellow needles (by Procedure **A**); mp 162—163 °C decomp (from benzene); IR 3390 (NH) and 1635 cm^{-1} (C=O); ^{1}H NMR δ=3.65—3.85 (2H, m, H-1,1′), 3.70 (6H, s, 2MeO-3″), 5.3—5.6 (2H, m, H-2,2′), 6.1—7.3 (14H, m, aromatic H), and 13.75 (2H, brm, NH-6,6′).

Anal. ($C_{28}H_{26}N_4O_4$) C, H, N.

6,6′-Bis[(4-methoxyphenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8g): Bright yellow needles (by Procedure **A**); mp 158—160 °C decomp (from benzene); IR 3200 (NH) and 1630 cm^{-1} (C=O); ^{1}H NMR δ=3.7—3.8 (2H, m, H-1,1′), 3.71 (6H, s, 2MeO-4″), 5.25—5.6 (2H, m, H-2,2′), 6.15—7.35 (6H, m, H-3,3′,4,4′,5,5′), 6.73 (4H, brd, *J*=8.5 Hz, 2H-3″,5″), 7.11 (4H, brd, *J*=8.5 Hz, 2H-2″,6″), and 14.0 (2H, brm, NH-6,6′).

Anal. ($C_{28}H_{26}N_4O_4$) C, H, N.

6,6′-Bis[(2-chlorophenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8j): Bright yellow needles (by Procedure **A**); mp 173—175 °C decomp (from benzene); IR 3450 (NH) and 1635 cm^{-1} (C=O); ^{1}H NMR δ=3.9—4.05 (2H, m, H-1,1′), 5.15—5.55 (2H, m, H-2,2′) 6.1—7.7 (14H, m, aromatic H), and 13.6 (2H, brm, NH-6,6′).

Anal. ($C_{26}H_{20}Cl_2N_4O_2$) C, H, N.

6,6′-Bis[(3-chlorophenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8k): Bright yellow needles (by Procedure **A**); mp 180—181 °C decomp (from benzene); IR 3415 (NH) and 1630 cm^{-1} (C=O); ^1H NMR δ=3.85—3.95 (2H, m, H-1,1′), 5.45—5.8 (2H, m, H-2,2′), 6.3—7.75 (14H, m, aromatic H), and 13.6 (2H, brm, NH-6,6′).

Anal. ($C_{26}H_{20}Cl_2N_4O_2$) C, H, N.

6,6′-Bis[(4-chlorophenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8l): Bright yellow needles (by Procedure **A**); mp 175—176 °C decomp (from benzene); IR 3410 (NH) and 1630 cm^{-1} (C=O); ^1H NMR δ=3.7—3.95 (2H, m, H-1,1′), 5.4—5.75 (2H, m, H-2,2′), 6.3—7.0 (6H, m, H-3,3′,4,4′,5,5′), 7.35 (8H, s, 2H-2″,3″,5″,6″), and 14.1 (2H, brm, NH-6,6′).

Anal. ($C_{26}H_{20}Cl_2N_4O_2$) C, H, N.

6,6′-Bis[(2-nitrophenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8m): Bright yellow needles (by Procedure **A**); mp 182—184 °C decomp (from ethyl acetate); IR 3390 (NH) and 1655 cm^{-1} (C=O); ^1H NMR almost insoluble for the measurement.

Anal. ($C_{26}H_{20}N_6O_6$) C, H, N.

6,6′-Bis[(3-nitrophenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8n): Bright yellow needles (by Procedure **A**); mp 180—182 °C decomp (from ethyl acetate); IR 3420 (NH) and 1640 cm^{-1} (C=O); ^1H NMR δ=3.65—3.75 (2H, m, H-1,1′), 5.25—5.45 (2H, m, H-2,2′), 6.2—8.4 (14H, m, aromatic H), and 13.85 (2H, brm, NH-6,6′).

Anal. ($C_{26}H_{20}N_6O_6$) C, H, N.

6,6′-Bis[(4-nitrophenyl)hydrazono]-1,1′-bi(2,4-cycloheptadiene)-7,7′-dione (8o): Bright yellow needles (by Procedure **A**); mp 189—191 °C decomp (from ethyl acetate); IR 3450 (NH) and 1640 cm^{-1} (C=O); ^1H NMR δ=3.65—3.8 (2H, m, H-1,1′), 5.2—5.6 (2H, m, H-2,2′), 6.2—8.4 (14H, m, aromatic H), and 13.85 (2H, brm, NH-6,6′).

Anal. ($C_{26}H_{20}N_6O_6$) C, H, N.

3-(2-Phenylhydrazino)tropone (9a): Pale yellow crystals; mp 140—142 °C (from benzene); IR 3250 (NH) and 1600 cm^{-1} (C=O); UV λ_{max} 248 (log ε 4.19), 305 (4.06), and 354 nm (4.39); ^1H NMR δ=6.6—7.6 (9H, m, aromatic H), 7.35 (1H, brm, NH-1′), 7.63 (1H, s, H-2), and 10.82 (1H, brm, NH-3).

Anal. ($C_{13}H_{12}N_2O$) C, H, N.

3-[2-(4-Chlorophenyl)hydrazino]tropone (9l): Brownish yellow crystals; mp 168—170 °C (from benzene); IR 3320 (NH) and 1600 cm^{-1} (C=O); UV λ_{max} 242 (log ε 4.15), 316 (4.21), and 355 nm (4.40); ^1H NMR δ=6.7—7.8 (8H, m, aromatic H), 8.24 (1H, s, H-2), and 10.25 (2H, brm, NH-3, NH-1′); MS *m/z* 248 (M^+; 29), 246 (M^+; 100), 127 (94), and 126 (53).

Found: *m/z* 246.0546. Calcd for $C_{13}H_{11}ClN_2O$: M, 246.0560.

2-(*N*-Amino-4-methoxyanilino)tropone (10): Reddish orange prisms; mp 105—107 °C (from hexane); IR 3350 (NH) and 1615 cm^{-1} (C=O); UV λ_{max} 250 (log ε 4.22), 285 sh (3.94), 368 (3.83), and 428 nm (3.93); ^1H NMR δ=3.80 (3H, s, MeO-4′), 4.8 (2H, brm, NH_2), 6.5—7.5 (5H, m, aromatic H), 6.82 (2H, brd, *J*=9.0 Hz, H-3′,5′), and 7.16 (2H, brd, *J*=9.0 Hz, H-2′,6′).

Anal. ($C_{14}H_{14}N_2O_2$) C, H, N.

2-(4-Methoxyanilino)tropone (11): Yellow prisms; mp 74—75 °C (from light petroleum); IR 3300 (NH) and 1605 cm^{-1} (C=O); UV λ_{max} 246 (log ε 4.39), 284 sh (3.85), 350 (4.02), and 411 nm (4.19); ^1H NMR δ=3.81 (3H, s, MeO-4′), 6.4—7.3 (5H, m, H-3—7), 6.97 (2H, brd, *J*=9.5 Hz, H-3′,5′), 7.19 (2H, brd, *J*=9.5 Hz, H-2′,6′), and 8.6 (1H, brm, NH).

Anal. ($C_{14}H_{13}NO_2$) C, H, N.

3-Amino-2-(3-methoxyanilino)tropone (12): Orange needles; mp 145—147 °C (from benzene); IR 3450, 3375, 3275 (NH), and 1600 cm^{-1} (C=O); UV λ_{max} 242 (log ε 4.41), 250 sh (4.38), 346 (3.91), and 413 nm (4.16); ^1H NMR δ=3.82 (3H, s, MeO), 3.9 (2H, brm, NH_2), 6.5—6.9 (4H, m, H-4—7), and 8.6 (1H, brm, NH-2).

Anal. ($C_{14}H_{14}N_2O_2$) C, H, N.

3-[2-(3-Chlorophenyl)-2-methylhydrazino]tropone (13): Red needles; mp 118—120 °C (from benzene); IR 3350 (NH) and 1600 cm^{-1} (C=O); UV λ_{max} 269 (log ε 3.76) and 363 (4.10); ^1H NMR δ=3.86 (3H, s, MeN), 5.6—7.5 (9H, m, aromatic H), and 7.59 (1H, brm, NH); MS *m/z* 262 (M^+; 34), 260 (M^+; 100), 247 (15), 245 (46), 134 (40), 111 (64), and 91 (35).

Found: *m/z* 260.0729. Calcd for $C_{14}H_{13}ClN_2O$: M, 260.0716.

Conversion of 10 to 11. A solution of **10** (33 mg) in methanol (5 cm^3) containing concd HCl (0.2 cm^3, 2 equiv) was refluxed for 8 h, diluted with water, neutralized with a saturated aq $NaHCO_3$, and extracted with chloroform. The combined organic layers were washed with water, dried (Na_2SO_4), and evaporated in vacuo. The residue was purified by preparative TLC with chloroform to give **11** (4 mg, 13%) and the recovered **10** (36%).

We are very grateful to Dr. Yukio Sugimura (Sankyo Co., Ltd., Tokyo) and Professor Kahai Takese (Tohoku University) for their valuable advice and help. Thanks are also due to Professor Hitoshi Takeshita (Kyushu Univ.) for the measurement of the ^{13}C NMR spectrum, Mr. Shin-ich Takekuma (Kinki Univ.) for 200-MHz ^1H NMR and MS, and Dr. Hiromichi Matsuura (Wakunaga Pharmaceutical Co., Ltd.) for the high-resolution mass spectra. The present work was partially supported by Grant-in-Aids for Scientific Research Nos. 60540331 (to H. Y.), 60540336, and 61540381 (to K. I.) from the Ministry of Education, Science and Culture.

Promoter Effect of Platinum on Liquid-Phase Dehydrogenation of 2-Propanol by a Nickel Fine-Particle Catalyst

Michio NODA,* Sumio SHINODA,† and Yasukazu SAITO
Institute of Industrial Science, University of Tokyo,
7-22-1 Roppongi, Minato-ku, Tokyo 106
(Received November 2, 1987)

A platinum-deposited nickel fine-particle catalyst was shown to be more active than a nickel-alone catalyst. A study of the temperature dependence of a rate constant revealed that platinum increased the frequency factor of the rate constant. An experiment regarding poisoning showed that the number of active sites was the same for the two catalysts. Thus the promoter effect was ascribed to an increase in the frequency factor per active site.

Liquid-phase dehydrogenation of 2-propanol proceeded by means of a metallic catalyst[1-4] or a complex catalyst in solution[5-9] or on a support.[10,11]

$$(CH_3)_2CHOH \longrightarrow (CH_3)_2CO + H_2$$

Nickel fine particles that were prepared by a gas-evaporation method[12,13] were also a suitable catalyst for the reaction.[14,15]

The surface modification of a metallic catalyst with a platinum-group metal has long been applied in order to increase the reaction rate. For example, platinum salts promoted hydrogenation activity of the Raney nickel catalyst.[16,17] In the present work, the promoter effect was studied through catalysis using nickel fine particles, since their shape and components are sufficiently simple to provide a clear explanation.

Experimental

1. Materials. Nickel fine particles were prepared by means of a gas-evaporation method of Vacuum Metallurgical Co., Ltd. (Chiba Pref., Japan). They comprised black, light powder. Their average diameter and BET surface area were 19.7 nm and 43.8 $m^2 g^{-1}$. Their surfaces were covered with oxide layers in order to prevent the particles from burning in air. Partial reduction of the surface oxide by heating nickel fine particles under hydrogen was necessary in order to reveal catalytic activity.[18]

Bis(acetylacetonato)platinum(II) ($Pt(acac)_2$) was purchased from Nippon Engelhard Ltd..

2. Pretreatment. Nickel fine particles were pretreated and a reaction rate was measured using the technique described in a previous paper.[15] A prescribed amount (200 mg) of nickel fine particles was put into a round-bottom three-neck flask. After evacuation, the nickel fine particles were heated under hydrogen up to 160 °C in 15 min, held at 160 °C for 1 min and rapidly cooled. The amount of consumed hydrogen was measured with a gas buret. After evacuation, a prescribed amount (200 ml) of 2-propanol was added under nitrogen or argon. The nickel fine-particle catalyst was suspended in 2-propanol by means of vibration with a supersonic cleaner.

Platinum was deposited on the catalyst as follows: A prescribed amount (9 mg) of $Pt(acac)_2$ was dissolved in 2-propanol beforehand. After a nickel fine-particle catalyst was suspended in the solvent, hydrogen was blown into the stirred suspension through a glass straw for 30 min at room temperature. Hydrogen reduced any divalent platinum in the complex. If part of a catalyst suspension was placed on a magnet, the nickel fine particles contained in it precipitated during a day. The visible and ultraviolet spectra of a supernatant were recorded with a Shimadzu UV-365 spectrometer. An XRD pattern of the catalyst was recorded with a Rigaku-Denki Geigerflex D-9C X-ray diffractometer.

3. Measurement. A catalyst suspension was heated under boiling conditions with stirring. The height of the level of the suspension equaled that of an oil bath in which the reactor was soaked. A gas buret was connected to the reactor through a water-cooled condenser. The reaction rate was determined by the volume of gas that accumulated in the gas buret. Products in a gas phase and in the liquid phase were analyzed by gas chromatography using an active carbon column and a PEG-1000 column, respectively.

The temperature dependence of the reaction rate was investigated by addition of hexane to a catalyst suspension, since hexane reduces the boiling point of a solvent. The frequency factor and the coefficient of exponential T^{-1} were determined for the rate constant k and the equilibrium constant of acetone adsorption K.[4]

The number of active sites of a nickel fine-particle catalyst was estimated by means of poisoning. The reaction rate was plotted against an amount of a poison such as water, triethylamine, pyridine, thiophene, or triphenylphosphine. Each poison was easily dissolved in 2-propanol and was added to a catalyst suspension.

Results and Discussion

1. Promoter Effect of $Pt(acac)_2$. Platinum chloride promoted catalytic activity of the Raney nickel in various hydrogenation reactions.[16,17] Nevertheless, a slight amount of $PtCl_2$ extremely retarded any liquid-phase dehydrogenation of 2-propanol that was catalyzed by nickel fine particles. Instead of $PtCl_2$, $Pt(acac)_2$ was selected as a supply source of platinum. Platinum was deposited on a nickel fine-particle catalyst by means of reducing the complex with hydrogen. The disappearance of a characterestic peak of $Pt(acac)_2$ at 344 nm in visible and ultraviolet spectra

† Present address: Department of Industrial Chemistry, Faculty of Engineering, Seikei University, 3-3-1 Kichijyoji-Kitamachi, Musashino-Shi, Tokyo 180.

of a supernatant indicated that the platinum in the complex was reduced. No platinum peak was observed in the XRD pattern of the catalyst after a reaction. This showed that the reduced platinum did not form a particle.

A platinum-deposited nickel fine-particle catalyst was more active than a nickel-alone catalyst, as shown in Fig. 1. Both catalysts exclusively produced hydrogen and acetone.

2. Retardation Effect of Acetone. A gradual decrease in the reaction rate was observed for various nickel catalysts in liquid-phase dehydrogenation of 2-propanol. The decrease in activity was ascribed to an adsorptive retardation of the produced acetone. Reaction rates are well expressed by

$$v = k/(1 + K[\text{acetone}]), \qquad (1)$$

where k is a rate constant and K is an equilibrium constant of acetone adsorption.[1-4,15] Symbol [acetone] refers to the amount of acetone, expressed in units of mmol.

Equation 1 also expressed the reaction rate provided by a platinum-deposited nickel fine-particle catalyst. Though the boiling point of the solvent decreased from 82.4 to 80.7 °C after a 5-h reaction, this change hardly affected the constants k and K. Figure 2 illustrates a linear relation between v^{-1} and the amount of acetone, into which data of Fig. 1 were converted. Values of k and K were determined from the section and the slope of Fig. 2; k was 330 mmol h^{-1} g^{-1} and K was 0.0403 $mmol^{-1}$. As for a nickel-alone catalyst, k was 116 mmol h^{-1} g^{-1} and K was 0.0301 $mmol^{-1}$.[15]

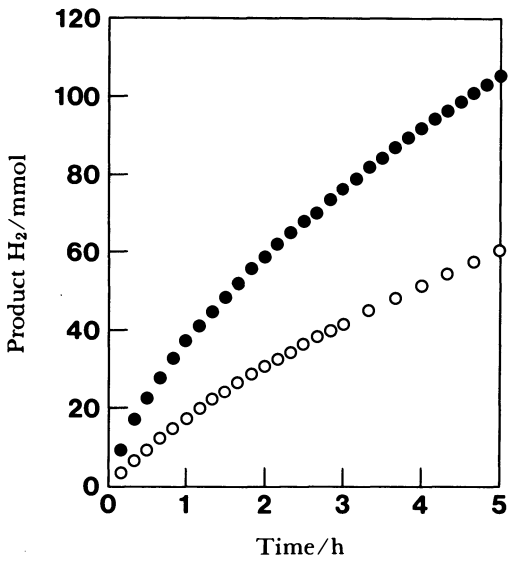

Fig. 1. The time course of H_2 evolution in the liquid-phase dehydrogenation of 2-propanol by a nickel fine-particle catalyst. Nickel alone (○) or platinum-deposited nickel (●) in 2-propanol (200 mg/200 ml).

3. Temperature Dependence of the Reaction Rate. It is already known that a normal alkane does not adsorb on nickel near the boiling point of 2-propanol and does not affect the reaction rate.[3] Mears and Boudart have reported that the addition of hexane (48 vol%) to 2-propanol reduces the boiling point to 62 °C and that Eq. 1 holds for the reaction of a suspended nickel boride catalyst in the solvent.[4] The method of adding hexane was followed in the present study.

The boiling point of a mixture of 2-propanol (200 ml) and hexane (7, 15, 25, and 40 ml) decreased to

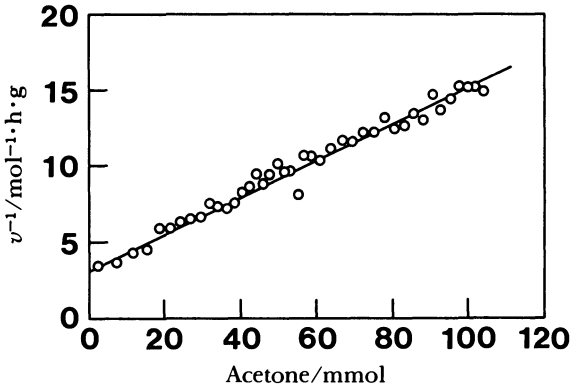

Fig. 2. The analysis of the retardation effect of produced acetone on a platinum-deposited nickel fine-particle catalyst. Data of Fig. 1 were converted into the form of Eq. 1.

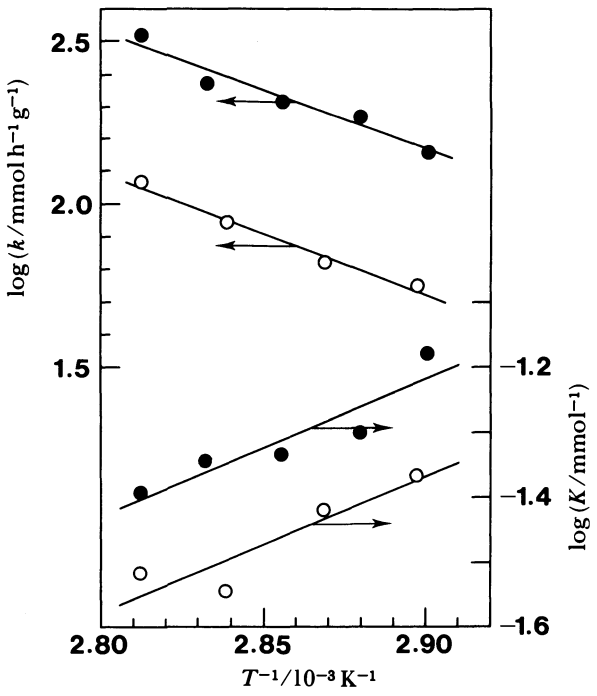

Fig. 3. The temperature dependence of the rate constant k and the equilibrium constant of acetone adsorption K of a nickel fine-particle catalyst. Nickel alone (○) and platinum-deposited nickel (●).

79.9, 77.0, 74.1, and 71.4 °C from the boiling point of 2-propanol (82.4 °C). The reaction rate was measured for 5 h at each temperature. Values of k and K were determined in terms of Eq. 1 and are plotted against T^{-1} in Fig. 3. Data regarding the nickel-alone catalyst are those found in the previous paper.[15]

Figure 3 shows that a pair of lines were parallel; the correlation coefficients in the least-square method were 0.913—0.981 for plots of v^{-1} against [acetone] and 0.973—0.991 for the Arrhenius plots in Fig. 3. The value of the activation energy or adsorption heat of acetone was much the same between the platinum-deposited nickel and the nickel-alone catalysts. On the other hand, the frequency factor of k of the former catalyst was larger than that of the latter catalyst. Hence, the increase in the activity of the platinum-deposited nickel catalyst could be ascribed to an increase in the frequency factor of the rate constant k.

The accumulated acetone lowered the boiling point of a solvent mixture slightly (0.3—1.7 degrees) in a 5-h run. Values of the frequency factors of k and K, the activation energy and the adsorption heat of acetone were determined in terms of the least-square method while taking account of all the experimental values of the rates and boiling points in the five runs. Consequently, the activation energy was 79.3 kJ mol^{-1} and the adsorption heat of acetone was −24.7 kJ mol^{-1} for a platinum- deposited nickel fine-particle catalyst. These values were similar to those of other metallic catalysts.[1,4,15] The activation energy slightly surpassed the enthalpy change of this endothermic reaction (69.9 kJ mol^{-1}).

4. Effect of Poisons. The effects of five kinds of poisons were studied. Water of 1.0 mmol or triethylamine of 1.4 mmol did not change the reaction rate, but the other three poisons affected the activity of a nickel fine-particle catalyst. A prescribed amount of a poison such as pyridine, thiophene, or triphenylphosphine was continually added to a catalyst suspension, and the reaction rate was plotted against the amount of accumulated poison. Table 1 shows the amount of a poison that made a rate half per 200 mg of a nickel fine-particle catalyst.

A plot of v^{-1} against the amount of a poison resembled Fig. 2 for a small amount of poison. Thus the reaction rate could be expressed by

$$v = k/(1 + K'[\text{poison}]). \quad (2)$$

The initial rate was substituted for the rate constant k, because the two values were approximately the same under conditions of no poison and little acetone in the initial state. Table 1 shows the inhibition constant of a poison K'. This table also contains the equilibrium constant of acetone adsorption K and the amount of acetone producing half the rate, for the purpose of comparison.

The retardation effect of triphenylphosphine and thiophene was strong and the effect of pyridine was intermediate. Equation 2 fitted experimental data up to 0.05 mmol of pyridine, but it did not fit the data for more than 0.01 mmol of triphenylphosphine and thiophene. According to the principle of hard and soft acids and bases, soft bases adsorb on metal surfaces which are a soft acid.[19] The order of the effect of the poisons, that is,

triphenylphosphine, thiophene>pyridine>acetone, triethylamine, water

corresponded to the order of softness as a base and was explained in terms of the principle. This fact showed that the properties of active sites of this catalyst could be explained by concepts of usual metallic catalysts.[20]

The value of the inhibition constant of every poison in Table 1 or its amount which produced half the rate was almost the same between the platinum-deposited nickel and the nickel-alone catalysts. This fact showed that the number of active sites was almost the same for the two catalysts. Therefore, the increase in the frequency factor of the rate constant k of a platinum-deposited nickel fine-particle catalyst was ascribed to a change of the frequency factor per active site. Probably the change also caused a slight difference in the frequency factor of an equilibrium constant of acetone adsorption K between the two catalysts.

5. Properties of Active Sites. As shown in studies of bonding orbitals of a metal-hydrogen cluster, the 5d orbitals chiefly work in a platinum cluster, though the 4s orbital of nickel works more than its 3d orbitals.[21-23] The difference in the frequency factor or reaction probability per active site can be ascribed to a

Table 1. Effect of Poisons on the Reaction Rate

Poison	Half-rate amount[a]/mmol		K'[b]/mmol^{-1}	
	Ni	Pt/Ni	Ni	Pt/Ni
Acetone[c]	33	25	0.0301	0.0403
Pyridine	0.014	0.011	57	76
Thiophene	0.006	0.009	169	113
Triphenylphosphine	0.006	0.006	178	191

a) The amount of a poison producing half the rate per 200 mg of a platinum-deposited nickel or a nickel-alone fine-particle catalyst. b) The inhibition constant of Eq. 2. c) The value of a half-rate amount was calculated from the constant K of Eq. 1.

difference in a valence orbital working in the rate-determining step.

The platinum-deposited nickel and nickel-alone fine-particle catalysts were similar to other metallic catalysts, because the values of activation energy and adsorption heat of acetone resembled the reported ones, in addition to the fact that the time course of the reaction rate fitted Eq. 1. The cleavage of a methine C-H bond was regarded as the rate-determining step of liquid-phase dehydrogenation of 2-propanol by means of a nickel boride catalyst.[4] We also think that the cleavage of a methine C-H bond is the most important among the elementary steps.

Appendix

1. Effect of Experimental Conditions. The rate constant k and the equilibrium constant of acetone adsorption K depended on the reducing conditions and on the amount of a catalyst or a solvent, as summarized in Table 2.

The usual pretreatment under hydrogen removed about 10% of the oxygen from surface-oxide layers of nickel fine particles. When a pretreatment under hydrogen was continued for 30 min at 160 °C, about 50% of the oxygen was removed. This severe reducing condition made values of k and K large.

A catalyst of 100 mg showed large values of k and K, in spite of the usual pretreatment. Nickel fine particles piled on the bottom of a reactor (a flask) through a hydrogen pretreatment. When the amount of particles was 100 mg, the particles were sufficiently exposed to hydrogen. Probably the surface oxide of 100-mg particles was considerably reduced after much exposure to hydrogen.

The amount of 2-propanol was varied from 200 ml to 6.4 ml. A reactor of different size was selected in response to it. The rate constant k decreased with the volume of the solvent, or rather, the reactor. The reaction and boiling essentially required heat, which was transmitted through the wall of the reactor soaked in an oil bath. Probably any decrease in a thermal-conduction area reduced heat supply and, consequently, the rate constant k. The heat supply was so small that the boiling of 2-propanol was suppressed when the thermal-conduction area was 22 or 28 cm^2.

The decrease in the amount of 2-propanol increased the value of K by about two orders of magnitude. However, any comparison should be based on a common measure, namely, molarity. If the amount of acetone is expressed in units of molarity, the units of K become $mmol^{-1} \cdot l$ and the value of K has to be multiplied by the volume of the solvent. In fact, the value of K multiplied by the volume of 2-propanol was almost constant as shown in Table 2, suggesting that the conversion of the value of K was reasonable.

2. Other Attempts for Promoting Catalysis with $Pt(acac)_2$. The divalent platinum in 9 mg of $Pt(acac)_2$ was also reduced, when a catalyst suspension containing the complex was held at about 40 °C for 2 h with stirring. The reductant was 2-propanol at that time. Constants k and K were 325 $mmol\ h^{-1}\ g^{-1}$ and 0.0430 $mmol^{-1}$. This method resulted in much the same promoter effect as that of reducing platinum by means of blowing hydrogen into a catalyst suspension. The two methods seemed to sufficiently draw out a promoter effect from 9 mg of $Pt(acac)_2$.

A mixture of 60 ml of acetone and 140 ml of 2-propanol dissolved 100 mg of $Pt(acac)_2$. After the reduction of platinum, acetone was removed under vacuum and then 2-propanol was added to make up for the lost volume. An observed promoter effect, however, did not surpass that of 9 mg of $Pt(acac)_2$; k was 226 $mmol\ h^{-1}\ g^{-1}$ and K was 0.0463 $mmol^{-1}$. Furthermore, a peak of platinum appeared in the XRD pattern of the catalyst after a reaction. Probably, excessive platinum coagulated and scarcely showed a promoter effect. The promoter effect of platinum reached a limit when the amount of $Pt(acac)_2$ was 9 mg.

Table 3 shows the reaction rate in a high mole fraction of acetone. The value was compared with that calculated from Eq. 1, by taking account the temperature dependence of k and K for a catalyst promoted by 9 mg of $Pt(acac)_2$ or a nickel-alone catalyst. The two values were approximately the same. This is consistent with the fact that coagulated platinum scarcely showed a promoter effect.

Table 2. Effect of Experimental Conditions on the Reaction Rate

Synthesis of C_3 and C_4 Paraffins from Synthesis Gas with Hybrid Catalyst

Kaoru FUJIMOTO,* Hitoshi SAIMA, and Hiro-o TOMINAGA
Department of Synthetic Chemistry, Faculty of Engineering, University of Tokyo,

(Received December 24, 1987)

Hybrid catalysts composed of the physical mixture of methanol synthesis catalysts and Y-type zeolites gave C_3 and C_4 paraffins from synthesis gas at 2.1 MPa, with a selectivity higher than 70%. The product contained small methane and little aromatic hydrocarbons. The hydrid catalyst kept its activity and selectivity at almost constant level for 50 h. The yield of hydrocarbon was much higher than the level estimated from the thermodynamic equilibrium of methanol formation from synthesis gas. The yield of hydrocarbon increased monotonically with the increase in temperature while the carbon number distribution of the product shifted to lower side between 523 and 623 K. The production of hydrocarbon was accompanied by the nearly equal amount of CO_2.

Several attempts to make LPG (C_3 and C_4 paraffins) selectively from synthesis gas have been made by using catalysts such as a supported Fe-Mn-Cu,[1] a fused iron,[2] and a supported molybdenum.[3] However, since these catalysts are so-called Fischer-Tropsch catalysts their product distributions closely follow the Anderson-Schulz-Flory distribution law,[4] the selectivity of LPG is only about 33% at most and 18% of methane selectivity is inevitable.[4]

It has been reported that the synthesis gas reaction on a hybrid catalyst comprising physical mixtures of methanol synthesis catalysts and zeolites gives hydrocarbon mixtures whose composition are much different from those of a Fischer-Tropsch synthesis.[5-10] In the hybrid catalyst system, methanol formed on the methanol synthesis catalyst is successively converted in situ to hydrocarbons on the zeolite catalyst. We have already reported that on the hybrid catalyst composed of a Cu-Zn mixed oxide catalyst and H-ZSM-5 or DAY (dealuminated Y-type zeolite), aliphatic paraffins with 3—6 carbon atoms were predominantly produced from synthesis gas with a low methane selectivity,[10] while the hybrid catalyst composed of a Pd/SiO_2 and H-ZSM-5 or mordenite gave aromatic hydrocarbons with high selectivity.[8]

This study focused on developing hybrid catalysts which make C_3 and C_4 hydrocarbons selectively and clarifying the effects of several operating factors which control the product selectivity.

Experimental

The methanol synthesis catalyst, Cu-Zn (H) was prepared according to the method described by Shimomura et al.[11] The catalysts composition was Cu:40, Zn:23, Al:27 (atm%). Cu-Zn (C) was commercially available one (BASF S8-45). Dealuminated Y-type zeolite (DAY) was supplied by Shokubai Kasei Co. REY was obtained by calcining Linde type SK-500 in air at 723 K for 3 h. Pt-Y was prepared from SK-40 by ion exchanging with aqueous ammonium hexachloroplatiniate and the loading was 0.1 wt%. Some of the physical properties of the zeolites are shown in Table 1.

The hybrid catalysts were prepared as follows: Equal weights of methanol synthesis catalyst and zeolite were physically mixed and were powdered under 100 mesh. Then, they were pressed to a disk and were finally crushed to granules with 20/40 mesh. About 2.0 g of the hybrid catalyst was placed in a tubular reactor with a 6 mm inner diameter and was activated in a hydrogen flow at 723 K.

A pressurized, flow-type reaction apparatus was used for the synthesis gas reaction.[6]

Results and Discussion

Synthesis of Hydrocarbons with a Variety of Hybrid Catalysts. Table 2 shows the catalytic properties of a variety of hybrid catalyst prepared by combining Pd/SiO_2, Cu-Zn(H), and Cu-Zn(C) with Y-type zeolite and ZSM-5. It is clear from the data that any Y-type zeolite exhibited an excellent LPG selectivity of C_3 and C_4 hydrocarbons, while the activity itself was strongly influenced by the methanol synthesis catalyst. ZSM gave a small amount of aromatic hydrocarbons which was mainly composed of tri- and tetramethylbenzenes.

The high selectivity of LPG fraction on the Y-type zeolite system should be attributed to the quick

Table 1. Physical Properties of Zeolites Used for Preparing Hybrid Catalyst

Zeolite	SiO_2/Al_2O_3 mole ratio	Pore size	Content of Al_2O_3	Acidity
		Å	mmol g^{-1}	meq. g^{-1}

Methanol catalyst/zeolite: 1/1 (weight ratio), temperature: 573 K, pressure: 2.06 MPa, H_2/CO: 2/1 (mole ratio), W/F: 3.4 g-cat h mol^{-1}.

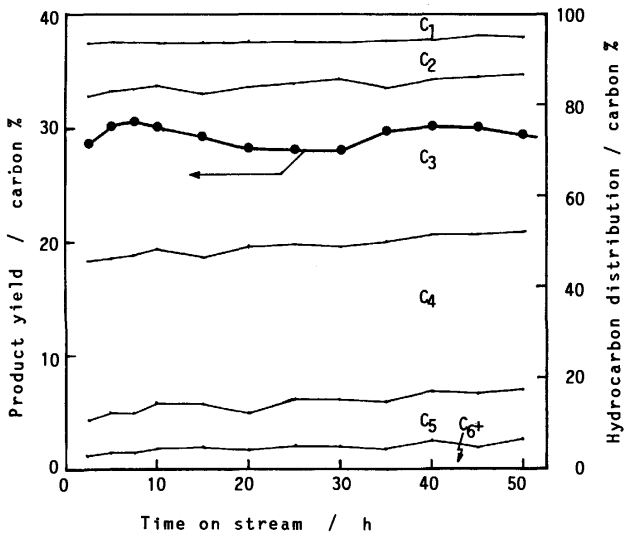

Fig. 1. Durability of hybrid catalyst: Cu-Zn(H)+DAY (1/1 by weight); Temperature 623+5 K; pressure 2.1 MPa; W/F=3.1 g-cat h mol^{-1}; H_2/CO=2/1 (mole ratio).

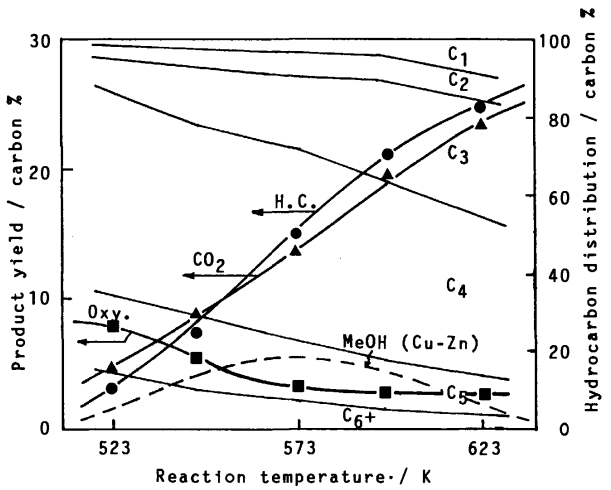

Fig. 2. Product yield and hydrocarbon distribution as a function of reaction temperature: Cu-Zn(H)+DAY (1/1 by weight); pressure 2.1 MPa; W/F=3.1 g-cat h mol^{-1}; H_2/CO=2/1 (mole ratio).

diffusion of olefins, which are the primary products of methanol conversion and their hydrogenation on the methanol synthesis catalyst.[10]

Durability of Hybrid Catalyst. Figure 1 shows the results of the synthesis gas reaction over a hybrid catalyst composed of Cu-Zn (H) and DAY. The catalytic activity was kept at almost a constant level over 50 hours, while a slight change in the hydrocarbon distribution occurred.

The level of synthesis gas conversion might be controlled by the activity of either catalyst of the hybrid catalyst, because the synthesis gas is first converted to methanol on the methanol synthesis catalyst and then the methanol is converted to hydrocarbons. Since the rate of synthesis gas conversion was substantially controlled by the rate of methanol formation in the present case, the constant activity of the present case should be attributed to the constant activity of the methanol synthesis catalyst. If the activity of DAY dropped quickly, which usually occur during the methanol conversion on the Y-type zeolite,[12] the product distribution should change quickly. The data in Fig. 1 indicate that the decrease in the zeolite activity was also quite slow. The slow deactivation of the zeolite should be attributed to the quick hydrogenation of olefins on the methanol synthesis catalyst,[8] which inhibits the polymerization of olefins to aromatics or coke.

Operational Factors Controlling Catalyst Activity and Product Selectivity. The catalytic activity and the product selectivity of the hybrid catalyst are influenced by several operational factors as demonstrated in figures through 2 to 5.

a. Temperature. As shown in Fig. 2, the hydro-

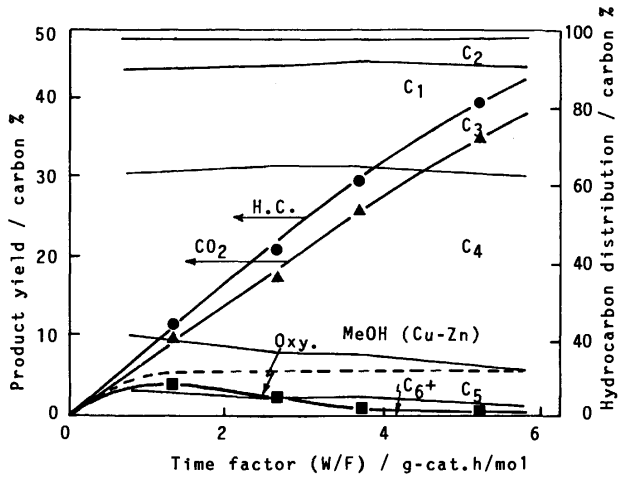

Fig. 3. Product yield and hydrocarbon distribution as a function of time factor: Cu-Zn(H)+DAY (1/1 by weight); temperature 623 K; pressure 2.1 MPa; $H_2/CO=2/1$ (mole ratio).

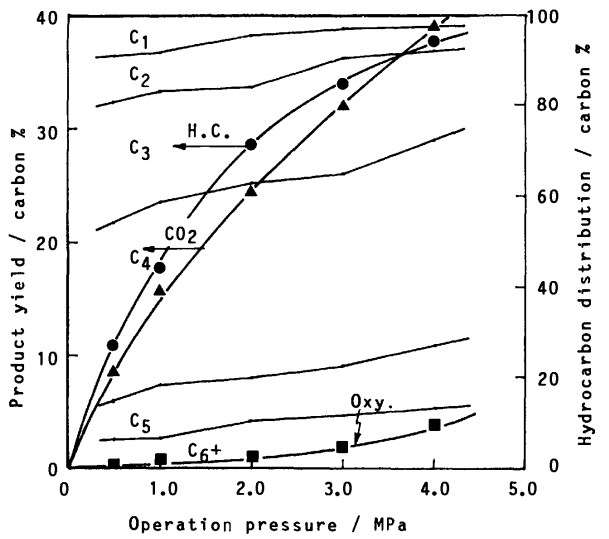

Fig. 4. Product yield and hydrocarbon distribution as a function of time factor: Cu-Zn(H)+DAY (1/1 by weight); temperature 623 K; W/F=3.1 g-cat h mol^{-1}; $H_2/CO=2/1$ (mole ratio).

carbon yield increased monotonically and the yield of oxygenated compounds decreased with increasing reaction temperature while the product yield from the synthesis gas conversion on Cu-Zn(H) alone (broken line) reached a maximum level (ca. 5%) at approximately 573 K and then decreased due to the thermodynamic limitation of the methanol formation from synthesis gas. The high level of synthesis gas conversion on the hybrid catalyst could be attributed to the successive conversion of methanol to hydrocarbons on the zeolite as shown below.

$$2nCH_3OH \rightleftarrows nCH_3OCH_3 \longrightarrow C_nH_m + nH_2O$$

Product distribution is also strongly influenced by reaction temperature. At 573 K or lower, a significant amount of oxygenates (mostly dimethyl ether) was observed in the product suggesting the incomplete conversion of methanol to hydrocarbons on DAY at such low temperatures. The degree of carbon chain growth decreased monotonically with an increase in temperature. It is characteristic that the selectivity of C_4 paraffins was extraordinarily high and reached a maximum as high as 50% at 573 K. Among C_4 paraffins, the fraction of isobutane was about 3 times higher than that of normal butane. This value is much higher than that of the butane mixture in thermodynamic equilibrium. The reason is not clear yet.

b. Contact Time. The hydrocarbon yield was almost proportional to the contact time (W/F) as shown in Fig. 3, while methanol yield on the Cu-Zn(H) catalyst was independent of the time factor (dotted line). It suggests that products such as light paraffins or carbon dioxide have little suppressive effect on either methanol formation or methanol conversion to hydrocarbons. Also, the hydrocarbon distribution was never affected by the contact time, which suggests that apparently no significant secondary reactions of product hydrocarbon took place.

c. Reaction Pressure. Figure 4 shows how the reaction pressure affects the synthesis gas conversion on the hybrid catalyst. The hydrocarbon yield increased monotonically with an increase in the pressure, however, the promotional effect of pressure on this catalyst is not as remarkable as that on the Pd/SiO_2 based catalyst.[8] A slight increase in the hydrocarbon formation and a marked increase in the oxygenated formation above 3 MPa could be attributed to the relative rate of methanol formation and its conversion. The increase in the reaction pressure contributes only to the increase in the methanol formation. However, since the rate-determining step on this hybrid catalyst (Cu-Zn(H)/DAY=1/1 by weight) is the conversion of methanol to hydrocarbon,[12] the increase in methanol formation should have little effect on hydrocarbon formation but it should contribute to the increase in the oxygenates formation.

d. Composition of Synthesis Gas. The composition of synthesis gas (H_2/CO ratio) exhibited a complicated effect on the product yield and selectivity (Fig. 5). The hydrocarbon yield was in the similar level between $H_2/CO=3/1$, and 2/1 and then decreased markelly with decreased H_2/CO ratio, while that of oxygenates decreased drastically when the H_2/CO ratio in the feed was decreased from 3/1 to 1/1.

These phenomena are explained as follows: in principle, the rate of methanol formation is proportional to the partial pressure of hydrogen,[13] and thus the product yield should be higher at high H_2/CO ratios. The hydrocarbon yield at $H_2/CO=3/1$, however, was in the same level to that at $H_2/CO=2/1$.

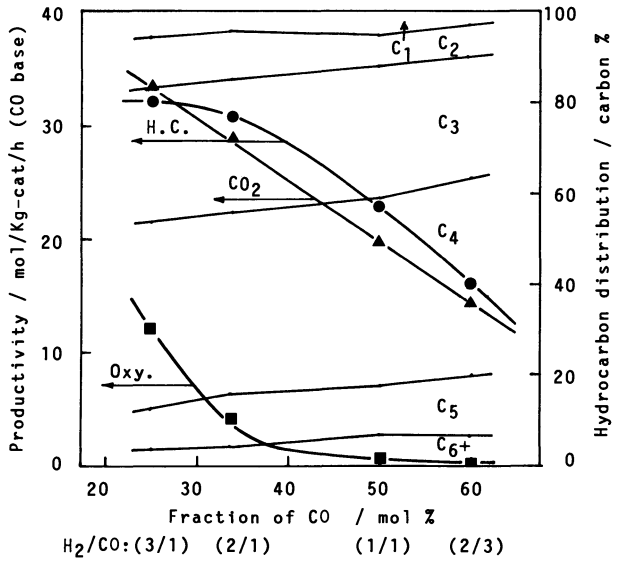

Fig. 5. Space time yield of each product and hydrocarbon distribution as a function of feed gas composition: Cu-Zn(H)+DAY (1/1 by weight); temperature 623 K; pressure 2.1 MPa; W/F=3.1.

The phenomena can be attributed to the fact that the rate-determining step of the present hybrid catalyst, where the hybrid catalyst is composed of equal weights of Cu-Zn(H) and DAY, is the methanol conversion step. Thus, the high H_2/CO ratio contributes only to the increase in the methanol (and DME) concentration in the catalyst bed. In fact, the yield of DME was much higher with the feed gas at $H_2/CO=3/1$. On the other hand, when the H_2/CO ratio is 1/1 or lower the methanol formation should be the rate limiting and thus, the rate of hydrocarbon formation decreases with the decrease in the H_2/CO ratio. The idea is also supported by the fact that little oxygenates is formed when the H_2/CO ratio is 1/1 or lower.

Conclusion

It has been confirmed that the hybrid catalysts composed of Cu-Zn mixed oxide methanol synthesis catalyst and Y-type zeolite exhibits a highly active, selective and stable catalysis for making LPG from synthesis gas. The catalytic activity is substantially controlled by the activity of the methanol synthesis catalyst. Other catalytic properties such as the product selectivity, the temperature characteristic, the pressure characteristic are explained in terms of the relative rate of methanol synthesis and its conversion to hydrocarbons.

The Polymerization of Benzene Catalyzed by a Copper(I) Chloride-Aluminium Chloride-Oxygen System

Naoki TOSHIMA,* Keiichi KANAKA, Atsunori KOSHIRAI, and Hidefumi HIRAI
Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received January 6, 1988)

The polymerization of benzene to poly(1,4-phenylene) (PPP) has been done successfully using copper(I) chloride and aluminium chloride as catalysts under oxygen. Since copper(I) chloride and aluminium chloride form a double salt (aluminium copper(I) chloride, $AlCuCl_4$) and are soluble in benzene, a high homogeneity of the reaction system has been achieved and the polymerization reaction proceeds without any evolution of hydrogen chloride. The polymerization products contained an insoluble dark brown solid and a benzene-soluble tarry mass. The solid product has been determined to be PPP by comparison with an authentic sample. The product PPP was obtained in a yield of more than 100%, based on the molar quantity of copper(I) chloride, by controlling the quantity of aluminium chloride. For example, the treatment of benzene with aluminium chloride and copper(I) chloride (20:3:1 in molar ratio) under 1 atm of oxygen at 70 °C for 24 h gave PPP in a 187% yield, based on copper(I) chloride. This reaction could be carried out by the use of oxidants other than oxygen and by the use of low-valent metal salts other than copper(I) chloride, although a copper(I) chloride–aluminium chloride–oxygen system is most suitable for the polymerization of benzene in terms of the yield of PPP and the convenience of the reaction.

The aromatic hydrocarbon polymer is an interesting organic material in that it is thermally stable[1] and can be electrically conductive upon doping with various dopants.[2] Poly(1,4-phenylene) (PPP) has a structure characteristic of this type of polymer. The methods of synthesizing it and its character have been investigated for a long time.[1,2]

Several methods for the direct synthesis of PPP from benzene have been investigated. One well-known procedure is the oxidative cationic polymerization of benzene by a Lewis acid-oxidant system reported by Kovacic et al.;[3]

$$n\,C_6H_6 + 2n\,CuCl_2 \xrightarrow{AlCl_3} (C_6H_4)_n + 2n\,CuCl + 2n\,HCl \quad (1)$$

Usually, aluminium chloride is used as a Lewis acid, and copper(II) chloride, as an oxidant.[4] Molybdenium(V) chloride[5] and iron(III) chloride,[6] which have functions of both a Lewis acid and an oxidant, are also used. In this method, the polymerization reaction proceeds under mild conditions, and the yield of PPP is fairly high. The polymerization of alkylbenzenes, such as toluene,[7] halogenated benzenes,[8] and thiophenes,[9] has also been attempted by the use of this method. However, the vigorous evolution of a large amount of hydrogen chloride is unavoidable in this method, since the polymerization of 1 mol of benzene produces 2 mol of hydrogen chloride, according to Eq. 1. Furthermore, it is difficult to stir the reaction mixtures, even at the beginning of the reaction, because the metal salts do not dissolve in benzene, resulting in slurried conditions. Since the oxidizing metal salts are consumed during the reaction, the yield of PPP based on the oxidant is always less than 100%. Recently, the polymerization of benzene by the use of a superacid composed of aluminium chloride and copper(II) chloride was reported,[10] although the evolution of hydrogen chloride is unavoidable in this method also. The electrolytic polymerization of benzene in the presence of a supporting electrolyte was found to produce a film of PPP.[11] The structure-definite PPP was synthesized by the dehalogenation of dihalogenated benzene in the presence of nickel-complex catalysts.[12]

The direct polymerization of benzene by Kovacic's method does not give the PPP in so high a molecular weight. The heterogeneity of the reaction system and the insolubility of PPP in organic solvents might be the reasons for this lower molecular weight. Against this background, the methods via a soluble precusor polymer have been investigated. It has previously been reported that PPP could be synthesized by the dehydrogenation of the polymer of 1,3-cyclohexadiene.[13] However, the yield of PPP synthesized by this method was also low, and the purification of the polymer was difficult. Recently, it was also reported that the polymer of acylated 3,5-cyclohexadiene-1,2-diol, which can be synthesized by a biotechnical procedure, is thermally converted into PPP with a high molecular weight.[14] By this method, it is possible to make films at the stage of the precusor polymer.

The present authors have now tried to polymerize benzene to PPP by taking advantage of aluminium copper(I) chloride ($AlCuCl_4$), which is known to be soluble in various aromatic compounds[15] and which should be formed at the termination step in Kovacic's method. Thus, the polymerization of benzene was attempted by producing the active species (Cu(II) ion) for polymerization by using $AlCuCl_4$ and an oxidant under highly homogeneous conditions, where copper(I) chloride would be expected to work as a catalyst. The present paper reports on the synthesis of PPP in a

system of aluminium chloride, copper(I) chloride, and an oxidant, where not only $AlCuCl_4$ but also excess $AlCl_3$ and an oxidant are required by the reaction. The syntheses by the use of double salts other than $AlCuCl_4$ have also been successful.

Experimental

Materials. The aluminium chloride (Kishida Chemical Co.) was purified by vacuum sublimation. The copper(I) chloride (Koso Chemical Co.) was reprecipitated from an aqueous hydrochloric acid solution by the addition of distilled water, followed by successive washing with ethanol and diethyl ether; it was then dried in vacuo at 100 °C for 24 h. The aluminium bromide, copper(I) bromide, cobalt(II) chloride, nickel(II) chloride, and copper(II) chloride were commercially (guaranteed grades) obtained and were used without further purification.

The benzene was distilled over metallic sodium. The 1-bromopropane was distilled after drying by anhydrous magnesium sulfate.

The chloranil and potassium permanganate were commercially obtained (guaranteed and extra pure grade respectively) and were used without further purification. The 18-crown-6 (1,4,7,10,13,16-hexaoxacyclooctadecane) was purified by recrystallization from acetonitrile. The oxygen was passed through columns of Molecular Sieves 3A and diphosphorus pentaoxide before use.

Analysis. The ^1H NMR spectrum was obtained with a JEOL model FX 90Q spectrometer at 89.55 MHz. The infrared absorption spectra (KBr disks and liquid film with KBr plates) were obtained with a JASCO model A-3 spectrometer. The GPC was recorded on a TOYO SODA model HLC-802UR chromatograph equipped with two TSK-GEL 2000H columns.

Polymerization of Benzene by a $CuCl$-$AlCl_3$-O_2 System. One gram (10.1 mmol) of copper(I) chloride, 4.04 g (30.3 mmol) of aluminium chloride, and 18.2 cm^3 (202 mmol) of benzene were placed in a 100 cm^3 Kjeldahl flask, and the mixture was stirred at room temperature for 2 h under dry nitrogen. In this stage, the copper(I) chloride was dissolved completely and a highly homogeneous solution was obtained, leaving some excess aluminium chloride. The reaction was carried out by replacing the solution atmosphere with oxygen at 60 °C for 24 h. As the reaction proceeded, the color of the reaction mixture changed from yellow to dark brown at the beginning of the reaction. At the end of the reaction, brownish black precipitates appeared at the bottom of the reaction vessel. During the reaction, no evolution of hydrogen chloride was observed. Polymerization was terminated by adding an 18% hydrochloric acid solution to the reaction mixtures. After the filtration of the reaction mixtures with a sintered glass disk, the remaining solid was repeatedly washed with a boiling solution of 18% hydrochloric acid and then with boiling water. The subsequent drying of the dark brown solid product at 100 °C for 24 h, yielded 0.458 g (119% yield based on the charged copper(I) chloride) of PPP. The filtrate was extracted by benzene, and the benzene solution was also washed several times with an 18% hydrochloric acid solution and water. After the evaporation of the benzene under reduced pressure and then drying for 24 h, 0.177 g (46.0% yield based on charged CuCl) of a reddish brown, tarry product was obtained.

The solid product was quite insoluble in various organic solvents. The elemental analysis data are shown in Table 3. The IR spectra of the solid product showed bands at 800 (C–H out-of-plane vibration of a para-disubstituted benzene ring), 1000 (C–H in-plane vibration of the same species), and 1480 cm^{-1} (C=C skeletal in-plane vibration).

The results of the elemental analysis of the benzene-soluble product were: C, 85.4; H, 6.3; Cl, 3.2%. Thus, the C/H ratio is 1.14, between the calculated values of $(C_6H_4)_n$ (1.50) and $(C_6H_6)_n$ (1.00). The IR spectrum has bands at 700, 760, 800, 1450, 1500, 1600, 2870, 2950, 3040, and 3070 cm^{-1}. The ^1H NMR spectrum in $CDCl_3$ shows its peaks at δ 1.25, 5.4—5.5, and 7.2—7.3 (refer to TMS).

Polymerization of Benzene by the Use of Other Metal Salts and Oxidants. In the case of using other metal salts, polymerization was carried out by the procedure described above. Polymerization by the use of copper(II) chloride was carried out according to Kovacic's method.[4]

When potassium permanganate was used as an oxidant, the reaction was carried out in the presence of 18-crown-6, thus enabling this oxidant to dissolve in benzene. When chloranil was used as an oxidant, unreactive chloranil was removed from the solid product by extraction with benzene using a Soxhlet extractor. The experimental conditions are shown in Tables 4 and 5, as well as the yield of polymers.

Alkylation of PPP. The alkylation of PPP was achieved by 1-bromopropane according to the method in the literature.[16]

Elemental analysis:

Alkylated PPP prepared by the $CuCl$-$AlCl_3$-O_2 method:
Found: C, 87.9; H, 9.9; Cl, 0.7% (C/H ratio, 0.75).
Calcd for $[C_6H_2(C_3H_7)_2]_n$: C, 89.9; H, 10.1% (C/H ratio, 0.75).

Alkylated PPP prepared by Kovacic's method:
Found: C, 84.8; H, 9.0; Cl, 0.6% (C/H ratio, 0.79).
Calcd for $[C_6H_{2.5}(C_3H_7)_{1.5}]_n$: C, 90.6; H, 9.5% (C/H ratio, 0.81).

Results and Discussion

Synthesis of PPP by the Use of the $CuCl$-$AlCl_3$-Oxygen System. The direct polymerization of benzene to PPP by a copper(II)-aluminium chloride ($CuCl_2$-$AlCl_3$) system, as reported by Kovacic et al., is one of the best known methods. However, this method has some problems: (1) the vigorous evolution of hydrogen chloride, (2) difficulty in stirring the slurried reaction mixtures caused by the insolubility of the metal salts in benzene, and (3) the limited yield of PPP based on $CuCl_2$ because of the consumption of the $CuCl_2$ used as a reagent. As copper(I) chloride ($CuCl$) is a by-product of the preparation of PPP from benzene in this method, it is considered that polymerization can be continued if this $CuCl$ is oxidized to Cu(II) species again. Thus, copper chloride is thought to be able to participate repeatedly in the polymerization as a catalyst. On the other hand, it is known that $AlCl_3$ and $CuCl$ can form a double salt of aluminium copper(I) chloride ($AlCuCl_4$),

which is soluble in benzene by the coordination of benzene to the salt.[15] From this point of view, the polymerization of benzene might proceed efficiently because of the homogeneity of the reaction system.[17]

Table 1 shows the results of polymerization using CuCl-$AlCl_3$ (1:1 in charged molar ratio) and adding various oxidants. Though oxygen, iodine, and potassium permanganate ($KMnO_4$) were added as oxidants, polymerization did not occur. Even when $CuCl_2$ was added, PPP was not obtained at all. These results indicate that $AlCl_3$ loses its activity as a Lewis-acid catalyst by forming the double salt $AlCuCl_4$.

The polymerization was successfully attempted by the addition of an excess of $AlCl_3$ with respect to the CuCl under oxygen. The results are shown in Table 2. The addition of the excess $AlCl_3$ caused benzene to polymerize smoothly, resulting in a dark brown solid. The structure of this solid product has been proved by IR spectral measurements to be almost identical with that of the PPP synthesized by Kovacic's method. However, under nitrogen, no reaction at all occurred in spite of the use of an excess of $AlCl_3$ relative to CuCl. These results indicate that oxygen is required for polymerization. When more than twice as much $AlCl_3$ as CuCl was used, PPP was obtained in a yield of more than 100%, based on the CuCl. This result clearly indicates that CuCl works as a catalyst.

On the other hand, when $AlCl_3$ and benzene (3:20 in charged molar ratio) were treated at 60 °C under oxygen without CuCl, the yield of PPP was only about 1% of that in the presence of CuCl. This result demonstrates that the polymerization is not achieved by only $AlCl_3$ and oxygen, but that it is greatly promoted by copper(I) species in cooperation with oxygen in this reaction system. The necessity of oxygen for polymerization is well supported by the consumption of oxygen during polymerization. For example, when 258 mmol of benzene was polymerized by the use of 12.8 mmol of CuCl and 38.6 mmol of $AlCl_3$ at 70 °C for 24 h, at the beginning of the reaction no appreciable amount of oxygen was consumed, but as the reaction proceeded further, the uptake of oxygen gradually increased, in all, about 12 mmol of oxygen was consumed, resulting in PPP. The yield of PPP (16.5 mmol) nearly corresponds to twice amount of oxygen consumed. The time course of the oxygen uptake is comparable to the change in

the yield of PPP with the reaction time (Fig. 1).

The yield of PPP was strongly influenced by the quantity of the excess $AlCl_3$; that is, the more the quantity of excess $AlCl_3$ used, the higher the yield of PPP. Furthermore, the yield increased up to 803% by the extra addition of a 3.8-fold quantity of $AlCl_3$ after a 24-h reaction and continuous stirring for another 24 h. These results indicate that excess $AlCl_3$ is consumed during the reaction. $AlCl_3$ is considered to be deactivated by water generated from oxygen and protons which will be eliminated from benzene in the course of the reaction.

The yield of PPP rose drastically with a rise in the reaction temperature. In contrast, the molar ratio of benzene to CuCl had little influence on the yield of PPP. The reaction under dry air also gave PPP, but the yield was remarkably low in comparison with that obtained by the reaction under pure oxygen. The yield of PPP also increased with a lengthening of the reaction time. In the initial stage of the reaction, however, a few hours' induction period was observed (Fig. 1).

Structure of PPP. Table 3 shows the results of the elemental analyses of the various polymerization products prepared by a $CuCl-AlCl_3-O_2$ system as well as a $CuCl_2-AlCl_3$ system. The C/H ratio of the PPP prepared at 50 °C was 1.50, identical with that of an ideal PPP structure, $(C_6H_4)_n$. The C/H ratios of the other products were also near to that of PPP. The contamination of chlorine may be due to the partial chlorination of the aromatic rings of the polymers. The C/H ratio and the content of chlorine atoms increased as the reaction temperature rose.

In the present polymerization reaction, a product which was soluble in benzene was obtained as well as an insoluble solid product. In the IR spectrum, remarkable peaks located at 700 and 760 cm^{-1} were observed; they were attributed to the C-H in-plane vibration of a mono-substituted benzene ring. From the IR spectrum, the molecular weight of this benzene-soluble product was proved to be very low. On the other hand, the peaks located at 2870 and 2950 cm^{-1} indicated that the benzene-soluble product was not completely aromatized, for these peaks were attributable to the C-H stretching vibration of alkanes. This consideration was also supported by the ^1H NMR spectroscopy, that is, the peaks assigned to nonaromatic and vinyl protons were observed around δ 1.25 and 5.4—5.5 respectively. The proposed structure for the soluble product is shown in Fig. 2 as well as that for the insoluble product. This structure of the soluble product is also supported by the experimental result that the soluble product could be rearomatized by oxidation with the $CuCl-AlCl_3-O_2$ system in carbon tetrachloride, producing insoluble PPP.

Molecular Weight of PPP. PPP exhibits characteristic infrared absorptions around 650—900 cm^{-1} corresponding to the C-H out-of-plane vibration of a benzene ring. These absorptions involve the peaks at 760 and 800 cm^{-1}, as for a monosubstituted and a para-disubstituted benzene ring respectively. The former peak arises from the end phenyl units of PPP, and the latter, from the internal phenylene units. By a comparison of the ratios of the two peak intensities, it

Calcd for $(C_6H_4)_n$		94.70	5.30	0.00	1.50

is possible to estimate the molecular weight of PPP.[16] As is depicted in Fig. 3, the PPP prepared by using CuCl-$AlCl_3$-O_2 shows a little stronger absorption at 760 cm^{-1} than that prepared by using $CuCl_2$-$AlCl_3$, suggesting that the molecular weight of the former PPP is a little lower than that of the latter PPP.

The Friedel-Crafts alkylation of these PPPs by 1-bromopropane resulted in the dissolution in organic solvents. In either case, the alkylated PPP showed a light brown color and could be dissolved in various organic solvents. It was estimated, on the basis of the results of the elemental analyses, that the number of alkyl groups introduced to benzene rings of PPP prepared by the CuCl-$AlCl_3$-O_2 method was 2 per benzene ring, in contrast with 1.5 per ring in the case of Kovacic's PPP, where the degree of polymerization was 15.[16] Figure 4 shows some typical GPC spectra of the alkylated PPPs. From these GPC spectra, it has become apparent that the PPP prepared by the CuCl-$AlCl_3$-O_2 method has a somewhat lower molecular weight than does Kovacic's PPP.

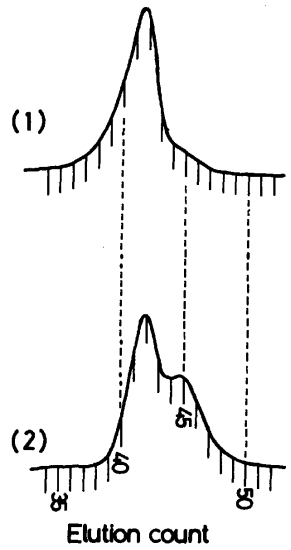

Fig. 4. Gel permeation chromatograms (chloroform as a carrier) of PPP alkylated by 1-bromopropane in the presence of $AlCl_3$. The original PPP were prepared by a Kovacic's method (1) and a CuCl-$AlCl_3$-O_2 method (2).

Syntheses of PPP by CuCl and $AlCl_3$ Using Other Oxidants. The successful preparation of PPP by the use of excess $AlCl_3$ with respect to CuCl under oxygen as an oxidant suggested that PPP could also be prepared using other oxidants under the same conditions. Table 4 shows the results of the polymerization of benzene using $KMnO_4$, chloranil, iodine, and so on as oxidants. When $KMnO_4$ was used instead of oxygen, polymerization occurred without CuCl. However, the yield of PPP got higher in the presence of CuCl. That is to say, the combination of CuCl and $KMnO_4$ influenced the acceleration of the polymerization reaction. When chloranil was used instead of oxygen, the acceleration of the reaction by a combination of CuCl and chloranil was not observed, since the 44% yield based on chloranil was achieved only with $AlCl_3$ in Kovacic's method.[18] This result indicates that the polymerization of benzene occurs independently in the absence of $AlCuCl_4$ when chloranil is used. In the case of iodine as an oxidant, the yield of the insoluble solid product was high. However, the content of iodine in the product was also very high (86.1%).

The polymerization using chloranil or iodine as an oxidant is supposed not to be suitable for the synthesis of PPP because of the difficulty of removing the oxidant from the polymer. When sodium periodate was used instead of oxygen, only a little PPP was obtained.

Syntheses of PPP by Other Metal Salts under Oxygen. It has become possible to polymerize benzene to PPP catalytically by the use of low-valent copper(I) chloride, $AlCl_3$, and oxygen. Low-valent metal salts other than CuCl were examined for the polymerization of benzene. Table 5 shows the results of these examinations. When cobalt(II) chloride ($CoCl_2$) and nickel(II) chloride ($NiCl_2$) were stirred with an excess of $AlCl_3$ in benzene, the color of the solution turned green[19] and deep yellow respectively, resulting in the formation of double salts with $AlCl_3$ and a consequent dissolution in benzene. By the use of these metal salts instead of CuCl, benzene could be polymerized to produce PPP. However, the yield of a benzene-soluble product was relatively high in

comparison with the case of $AlCuCl_4$, even though the yield of a benzene-insoluble product was not changed. In these reactions, the solubility of these salts in benzene is less than that of $AlCuCl_4$, resulting in less effective polymerization. The use of aluminium bromide ($AlBr_3$) instead of $AlCl_3$ made the double salts much more soluble in benzene than in the case of $AlCl_3$. The yield of benzene-insoluble PPP, however, was lower than that when $AlCl_3$ was used. The rearomatization of the polymeric precursor is thought to take place inefficiently in the case of $AlBr_3$ because the oxidation power of the copper ion is lowered by an increase in the charge density on copper caused by the lower electronegativity of bromine than chlorine. As is shown in Table 3, the PPPs prepared by metal bromides are highly contaminated with bromine atoms and give a high C/H ratio because of the bromination of the benzene rings.

Mechanism for Polymerization. In the polymerization of benzene by using $CuCl_2$ and $AlCl_3$, Kovacic et al. proposed that the polymerization was initiated by the generation of the benzene-cation radical,[20] propagated by the coordination of an appreciable number of benzene nuclei as stair-steps, and terminated by rearomatization by means of the oxidative elimination of protons by $CuCl_2$ from the delocalized stair-step cation radical (stair-step mechanism).[21]

In the method reported here, the polymerization has occurred under oxygen by the use of excess $AlCl_3$ with respect to CuCl, in contrast to no polymerization under nitrogen in spite of the presence of excess $AlCl_3$. Thus, the present reaction is described by Eq. 2, not by Eq. 1 as in the case of the Kovacic reaction:

$$2n\,C_6H_6 + n\,O_2 \xrightarrow{AlCl_3/CuCl} 2(C_6H_4)_n + 2n\,H_2O \quad (2)$$

Furthermore, when the molar ratio of $AlCl_3$ to CuCl was unity in the present system, benzene did not polymerize at all, not even under oxygen. These results suggest that the cooperation of excess $AlCl_3$ and the oxygenated copper(I) ion produces the cation radical species and initiates the polymerization. The induction period of only a few hours in this reaction is thought to be due to the lowering of the initiation activity of the benzene-cation radicals because of the interaction of the radicals with $AlCl_3$.

By the ESR experiments in the present system, the cation radical has been proved to be produced before the reaction atmosphere is replaced by oxygen. Thus, the signal observed under nitrogen with excess $AlCl_3$ (g=2.0025) has been identified as an organic radical. After the reaction under oxygen for 24 h, no additional signal was observed except that for the organic radical (g=2.0026). This result indicates that the copper(II) species do not take part in the polymerization reaction. Presumably, the oxygen activated by $AlCuCl_4$ participates in the reaction to withdraw hydrogen in the rearomatization step. The fact that a considerable amount of the benzene-soluble product was obtained in the present reaction is attributable to the weaker oxidative power of the activated oxygen than $CuCl_2$ in Kovacic's method.

As has been described before, the yield of PPP can be raised by increasing the quantity of excess $AlCl_3$ or by the addition of extra $AlCl_3$ in the course of the reaction. These results suggest the generation of water, by which $AlCl_3$ is consumed during the reaction. That is to say, the water is considered to be produced by oxygen and protons eliminated from the dihydropolymer in the termination stage.

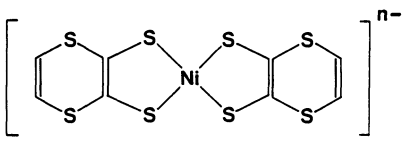
(Received November 9, 1987)

The crystal structure of tetrabutylammonium salt of a new multi-sulfur 1,3-dithiolene complex, (Bu^n_4N)[Ni(ddt)$_2$] (ddt=1,4-dithiin-2,3-dithiolato) has been determined by the single-crystal X-ray diffraction technique. Crystals are monoclinic, space group $C2/c$, a=66.107(40), b=9.182(5), c=19.119(12) Å, β=147.29(3)°, V=6271(1) Å^3, and Z=8. The structure was solved by the heavy atom method, and refined by a block-diagonal least-squares method to R=0.070. There are two crystallographically independent molecules of Ni(ddt)$_2$, molecule-A and molecule-B. Molecule-B forms segregated uniform stacks along the b-axis. The (Bu^n_4N)$^+$ cations are located between two molecular planes of molecule-A. The Ni(ddt)$_2$ molecules are almost planar except two terminal vinylene moieties, which are folded to opposite side each other and the folding angles of molecule-A and molecule-B are 28° and 39°, respectively.

The intermolecular transverse interaction between multi-chalcogen π-donor and/or π-acceptor molecules is essential to enhance the dimensionality of the molecular metals, which is useful for the suppression of the Peierls instability which is the characteristic of the quasi-one-dimensional molecular metals. The structure of BEDT-TTF (BEDT-TTF=bis(ethylenedithio)tetrathiafulvalene) complexes clearly showed the way to introduce the transverse interactions and therefore to obtain 2-dimensional (2D) molecular conductors.[1] The superconductors, θ- and κ-(BEDT-TTF)$_2$I$_3$ are the most successful examples.[2,3] Recently, the 1D molecular metals without metal instabilities became to be noticed. In these systems, "multi-Fermi surface" nature of the molecular metals has been found to be important for supressing the Peierls instability and stabilizing the metallic state down to low temperature.[4,5] Two superconductors of metal 1,3-dithiolene complex (TTF)[Ni(dmit)$_2$]$_2$,[4] and [$(CH_3)_4N$][Ni(dmit)$_2$]$_2$[6] (dmit=2-thioxo-1,3-dithiolene-4,5-dithiolato) have been reported to be the examples of multi-Fermi surface systems. The stable metallic state of (DMe-DCNQI)$_2$Cu has been proposed to be originated from the same reason.[5]

Although a considerable number of studies have been made on the physical properties of the M(mnt)$_2$ (mnt=1,2-dicyano-1,2-ethylnendithiolato) and M(dmit)$_2$ compounds (M=Ni, Pd, Pt), reports on the syntheses of a new type of metal dithiolene complex are very few. A new multi-sulfur dithiolene complexes (Ni and Pd complexes of ddt; ddt=1,4-dithiin-2,3-dithiolato), which are expected to be a possible candidate to give highly conducting organic complexes, have been synthesized recently.[7] In this paper, the crystal structure of tetrabutylammonium salt of Ni(ddt)$_2$, (Bu^n_4N)[Ni(ddt)$_2$] will be reported.



[Ni(ddt)$_2$]$^{n-}$

Experimental

Brown needle-type crystals of (Bu^n_4N)[Ni(ddt)$_2$] were prepared by the method reported previously.[7] The unit cell parameters were determined by a least-squares fit of 2θ angles for 20 reflections (17°<2θ<30°) measured with Mo $K\alpha$ radiation on an automated Rigaku AFC-6 four-circle diffractometer.

Details of the crystal data and experimental parameters along with data collection are summarized in Table 1. Three standard reflections were monitored every 100 reflections and their intensities showed random variation of ±0.6% throughout the data collection. The intensity data were corrected for Lorentz and polarization factors but not for absorption because of the small size of the crystal (<0.25 mm).

The structure was solved by Patterson method, and refined by a block-diagonal least-squares method. From the sharpened Patterson map, the positions of the nickel atoms were determined. A total of 33 non-hydrogen atoms were identified in the Fourier map calculated from the structure factors phased with heavy atoms. All the coordinates of the hydrogen atoms were calculated and were included in the final refinement cycles. Anisotropic thermal parameters were adopted for non-hydrogen atoms and the hydrogen atoms were refined isotropically. The weighting scheme $w=(1.0+0.004|F_o|^2)^{-1}$ for $|F_o|<12.0$ and $(\sigma(|F_o|)^2+0.004|F_o|^2)^{-1}$ for $|F_o|\geq 12.0$ was employed. The atomic scattering factors were taken from International Tables for X-ray Crystallography.[8] All the calculations were performed on HITAC M-680H computer at the Computer Centre of the University of Tokyo, using the program UNICS III.[9]

a) $R=\sum\||F_o|-|F_c\|/\sum|F_o|$. b) $R_2=[\sum w(|F_o|-|F_c|)^2/\sum|F_o|^2]^{1/2}$. c) g.o.f.$=[\sum w(|F_o|-|F_c|)^2/(N-M)]^{1/2}$, where N=number of reflections, M=number of parameters.

Results and Discussion

The atomic coordinates are listed in Table 2.** The bond distances and angles are shown in Fig. 1. The crystal structure is shown in Fig. 2.

There are two types of $Ni(ddt)_2$ molecules (A and B) which are crystallographically independent. Both of them are located on the centers of the symmetry. The monoclinic unit cell contains eight $Ni(ddt)_2$ molecules (four molecule-As and four molecule-Bs), and eight $(Bu^n_4N)^+$ cations. The averaged Ni–S distances are 2.148 Å in molecule-A and 2.137 Å in molecule-B, which are close to those of other monoanionic dithiolato-nickelate.[10] The $Ni(ddt)_2$ molecules are almost planar except the terminal vinylene moieties while the VT molecules in usual cases are not planar (bis(vinylenedithio)tetrathiafulvalene, BVDT-TTF, is abbreviated as VT; in $Ni(ddt)_2$, the central C=C double bond of VT is replaced by the Ni atom). The planarity of $Ni(ddt)_2$ molecules is better than that of the $VT^{+1/2}$ molecules in VT_2PF_6 which is better than that of VT^0 molecules in neutral VT.[11] The two terminal vinylene groups of the each side of a $Ni(ddt)_2$ molecule are folded to opposite side each other, and the folding angles of molecule-A and molecule-B are 28° and 39°, respectively. The shapes of $Ni(ddt)_2$) molecules (A and B) and the folding angles are shown in Fig. 1.

The molecule-B forms the independent uniform stacks along the b-axis on the position of x/a=0, 1/2. The interplanar distances within the stacks of molecule-B are 4.03 Å. $(Bu^n_4N)^+$ cations are located between two molecular planes of molecule-A. There is

no short intermolecular S···S (<3.70 Å) contacts within the $Ni(ddt)_2$ molecules.

The amplitudes of LUMO (lowest unoccupied molecular orbital) of $[Ni(ddt)_2]^-$ anion were calculated on the basis of extended Hückel approximation (Fig. 3). The LUMO of $[Ni(ddt)_2]^-$ has the same symmetry as those of $[Ni(dmit)_2]^-$, the well-known metal 1,3-dithiolene complex, and $[Ni(dddt)_2]^-$.[12] In the case of $[Ni(dmit)_2]^-$, shown in Table 3, the amplitudes of LUMO of the "outer sulfur atoms" (a_o) are one-fifth as small as those of the "inner sulfur atoms" (a_i) therefore the side-by-side interactions of the $Ni(dmit)_2$ molecules are not so strong.[4] In the case of $[Ni(dddt)_2]^-$, which have ethylene moieties instead of thioxo group of $Ni(dmit)_2$ in the outer side of the molecule, the ratio of a_o, to a_i are one-half. Consequently, compared with $[Ni(dmit)_2]^-$, $[Ni(dddt)_2]^-$ is considered to be liable to form the 2D molecular conductor. In the case of $[Ni(ddt)_2]^-$, the

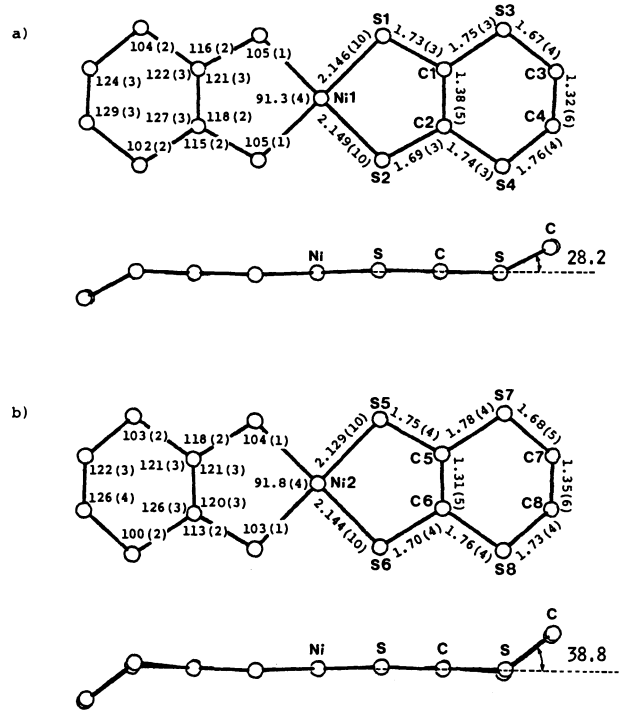

Fig. 1. Molecular structure, bond distances (l/Å), bond angles (ϕ/°), and folding angles (ϕ/°) of a) molecule-A and b) molecule-B of $Ni(ddt)_2$.

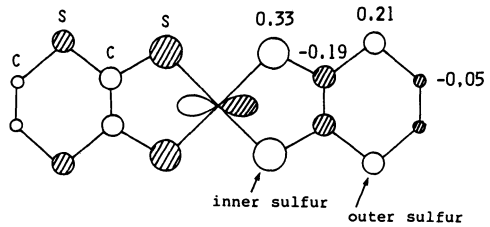

Fig. 3. Schematic drawing of LUMO of $[Ni(ddt)_2]^-$.

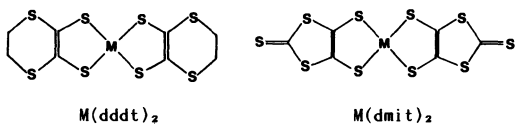
Table 3. Comparison of the a_i and a_o Values of the Monoanionic Dithiolatonickelates

	a_i	a_o	a_o/a_i
$[Ni(ddt)_2]^-$	0.33	0.21	64%
$[Ni(dddt)_2]^-$	0.37	0.18	49%
$[Ni(dmit)_2]^-$	0.42	0.08	19%



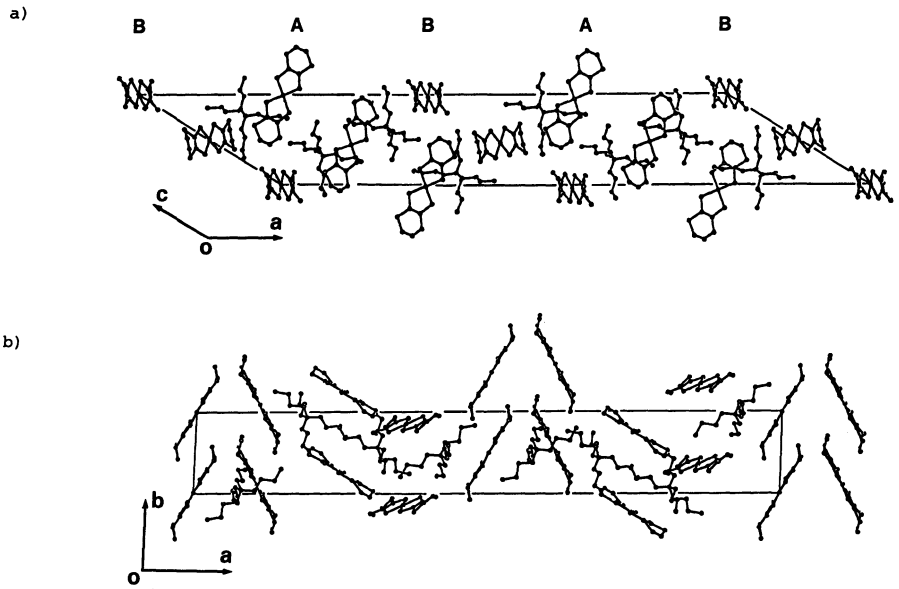


Fig. 2. Crystal structure of $(Bu^n_4N)[Ni(ddt)_2]$ projected along a) the b-axis and b) the c*-axis.

ratio of a_o to a_i is three-fifth which is larger than that of $[Ni(dddt)_2]^-$. But in case of synthesizing the real molecular conductor, the electrochemical property of $Ni(ddt)_2$ molecule become an important factor. As reported by Nakamura et al.,[7] the $\Delta E(=E_1-E_2)$[13] value of $[Ni(ddt)_2]^-$, which is a measure of the on-site Coulomb repulsion, lies between that of $[Ni(dmit)_2]^-$ and that of $[Ni(dddt)_2]^-$.

The Crystal Structure of 1,5-Dithioniabicyclo[3.3.0]octane Bis(trifluoromethanesulfonate). The First Structural Characterization of Dithionia Dication and Strong S···O Interactions between Cations and Anions

Fujiko Iwasaki,* Nobuhiko Toyoda, Ryouichi Akaishi,† Hisashi Fujihara,† and Naomichi Furukawa†

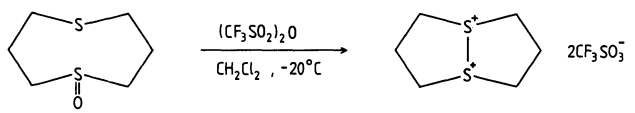
Department of Applied Physics and Chemistry, University of Electro-Communications, Chofu-shi, Tokyo 182

†Department of Chemistry, The University of Tsukuba, Tsukuba-shi, Ibaraki 305

(Received December 26, 1987)

The crystal structure of 1,5-dithioniabicyclo[3.3.0]octane bis(trifluoromethanesulfonate) has been determined by the X-ray method to elucidate the structure of a dithionia dication. Crystal data; $C_6S_2H_{12}^{2+}\cdot 2CF_3SO_3^-$, F_w=446.43, orthorhombic, Pccb, a=16.775(2), b=9.893(3), c=19.592(3) Å, V=3251(1) Å^3, Z=8, D_x=1.825 Mg m^{-3}. There are two independent dications, **A** and **B**, in the crystals, each of which has a crystallographic twofold axis. The mean S$^+$–S$^+$ distance is 2.124 Å. The conformation of the eight-membered ring is a distorted chair-chair form. Very strong interactions were observed between S$^+$ of dications and O atoms of counter anions. The average distance of S$^+$···O is 2.724 Å and colinear arrangements of O···S–S···O are formed with the central twofold axis. Other weak S···O interactions (2.903—3.153 Å) were also observed between dications and anions. The coordination around S is a roughly distorted octahedron with two C and two O atoms in a plane and apical S and O atoms.

The presence of cyclic dithionia dications was reported by means of spectroscopic studies.[1] No crystallographic studies of these salts have been reported because of the difficulties to obtain stable crystals. Recently the title salt could be isolated from a reaction of 1,5-dithiacyclooctane *S*-oxide and $(CF_3SO_2)O$ in CH_2Cl_2.[2] The X-ray analysis was undertaken to confirm the existence of a dication and to reveal a structural feature of a transanuular effect between sulfurs. Some sulfur-bonded 1-thionia-5-thiacyclooctane salts and 1,5-dithiacyclooctanes have been found to have a relatively short transannular S···S contact in the range 3.121—3.271 Å[3] because of the hypervalency of the sulfur atom.[4] It is also interesting to compare the structure of 1,5-dithioniacyclooctane with those of 1,5-dithiacyclooctanes. This is the first report about the structure of a cyclic dithionia dication.



Experimental

Colorless plate with dimension of 0.45×0.30×0.15 mm was sealed in a thin glass capillary because crystals were unstable in air. Crystal data and some experimental conditions are listed in Table 1. Intensities were collected on a Rigaku automatic diffractometer with graphite-monochromated Mo$K\alpha$ (λ=0.71073 Å) radiation, using ω–2θ scan technique. At both ends of the scan range 10 s background counts were taken for each reflection. Three reflections were monitored for each 50 reflections. Variation of intensities of the monitored reflections were within 2%. Reflections with $|F_o|\geq 3\sigma(F)$ were considered to be observed. No absorption nor extinction corrections were applied. Three S atoms were picked up from the E-map obtained by MULTAN78.[5] The other atoms were obtained from the succesive F- and D-maps. Block-diagonal least-squares were carried out with anisotropic temperature factors for non-H and isotropic ones for H atoms. Four strong reflections considered to be affected by an extinction effect

were omitted from the final refinement. $\Sigma w(|F_c|-k^{-1}|F_o|)^2$ was minimized with $w=1/(9.1852-0.1234|F_o|+0.0013|F_o|^2)$. The final R was 0.065 for 2196 refined reflections and an R value for 2200 reflections with $|F_o|\geq 3\sigma(F)$ was 0.069. Atomic scattering factors were taken from International Tables for X-Ray Crystallography.[6] All computations were performed on a HITAC M260 Computer of the Data Processing Center of the University of Electro-Communications with the programs UNICS III,[7] ORTEP II.[8]

Results and Discussion

Crystal Structure. The final atomic parameters are listed in Table 2.[9] There are two independent dications, **A** and **B**, in the crystals, each of which has a crystallographic twofold symmetry as shown in Fig. 1(a). Thus there are two halves of the dications and two independent anions in an asymmetric unit. These two independent dications are related with each other by a local pseudo mirror at $x=0.125$. The molecules are stacked along the a axis in a manner of **AABBAA**···. The environment of the anion **A** is different from that of **B**: the anions **A** are located between methylene groups of the two dications while the anions **B** are located between sulfur atoms. Figure 1(b) shows the molecular arrangement viewed along the a axis.

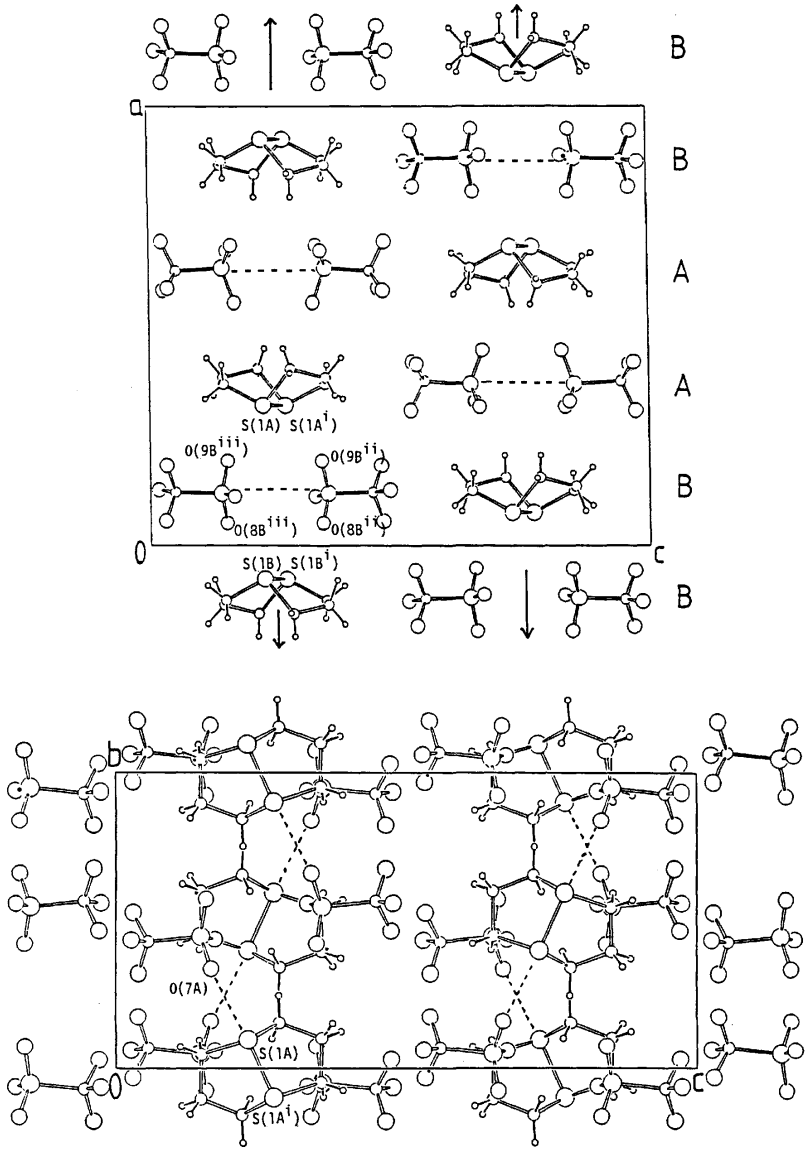

Fig. 1. The projection of the crystal structure, (a) viewed along the b axis within the range from $x=0.0$ to 0.5. Dotted lines show the pseudo local mirror between the dications **A** and **B**. (b) Viewed along the a axis within the range from $x=0.25$ to 0.75. Only dications **A** and anions **A** are shown in this range. Dotted lines show the S···O interaction between dications **A** and anions **A**.

Structure of Dication. The structure of the dication with the atom-numbering is shown in Fig. 2 and the bond distances and angles are listed in Table 3. The S(1)-S(1^{i}) (i=x,$-y$,1/2$-z$) lengths are 2.126(3) and 2.122(3) Å,[10] for **A** and **B**, respectively, which are only slightly longer than the normal S-S single bond (2.08 Å). Therefore a bond formation of S^{+}-S^{+} is confirmed unequivocally and the structure of the dication is not an open cyclooctane ring but a bicyclooctane. On the other hand relatively short transannular S···S contacts in some sulfur-bonded 1-thionia-5-thiacyclooctane salts and 1,5-dithiacyclooctanes are in the range of 3.121—3.271 Å.[2] The S-C lengths are 1.842(7) and 1.828(6) Å for the dication **A** and 1.829(7) and 1.830(6) Å for **B**. These values are also slightly longer than the normal S-C single bond length, while C-C lengths are slightly shorter than the normal Csp^3-Csp^3 bond. The bond angles of C-S-C are 104.1(3)° and 104.6(3)° for **A** and **B**, respectively and those of S-S-C are 92.7(2)—95.9(2)°. The torsion angles of the dications are listed in Table 4. The conformation of the eight-membered ring is a

distorted chair-chair form, while in the case of 1-thionia-5-thiacyclooctanes and 1,5-dithiacyclooctanes a chair-boat conformation is dominant.

S···O Interaction between Cations and Anions. Very strong interactions were observed between S^+ of the dications and O(7) atoms of the counter anions. The distance of $S^+ \cdots O$ are 2.682(6) and 2.766(6) Å for **A** and **B**, respectively, which are remarkablely shorter than the van der Waals contact of 3.35 Å. The angles of S-S···O are 176.3(2) and 166.8(1)°, for **A** and **B**, respectively. Nearly colinear interactions of O···S-S···O, especially in **A**, are formed with the central two fold symmetry as shown in Fig. 3. A linear O···S-S arrangement with a short S···O distance is a typical feature of the hypervalent sulfur compounds.[4] Intramolecular interactions with such a linear O···S-S···O interaction have been reported in 3,5-diacetamido-1,2-dithiolium bromide,[11] bis(*o*-nitrophenyl) disulfide,[12] dimethyl 2,2′-dithiodibenzoate,[13] and N,N′-dimethyl-2,2′-dithiodibenzamide.[14] The S···O distances of these compounds are 2.52—2.89 Å.

Other short nonbonded interactions between dications and anions are also shown in Fig. 3. S(1**A**) has nonbonded contacts to O(9**B**^{ii}) and O(9**B**^{iii}) (ii=$-x$, $y-1/2$, $1/2-z$; iii=$-x$, $1/2-y$, z) at the distances of 3.151(5) and 2.903(5) Å, respectively. These oxygen atoms, in turn, have bifurcate contacts with S(1**A**) and S(1**A**^{i}). The similar situation is observed between S(1**B**) and O(8**B**). The distances of S(1**B**)···O(8**B**^{ii}) and S(1**B**)···O(8**B**^{iii}) are 3.153(5) and 3.034(5) Å, respectively. Thus the coordination around S(1) is a roughly distorted octahedron with two C and two O atoms in a plane and an apical S-S bond and S···O contact. Some interatomic distances and angles related with the S···O interactions are summalized in Table 5. S(1**A**) deviates by 0.277 Å from the plane defined by four atoms C(2**A**), C(4**A**^{i}), O(9**B**^{ii}), and O(9**B**^{iii}). The angle between this plane and S(1**A**)···O(7**A**) is 67.9°. The corresponding deviation and the angle for the dication **B** are 0.260 Å and 56.1°, respectively.

All the O atoms of the anion **B**, which is located between S atoms of both dications **A** and **B**, coordinate

to the sulfur atoms. On the other hand for the anion **A** only O(7) is used for the coordination. These facts relate with a larger deviation from the linearity of O···S–S···O and a longer S···O distance in the case of **B** rather than those of **A**. The temperature factors of O atoms of the anion **B** and O(7**A**) are smaller than those of the other O and F atoms. This is another evidence of the strong interactions between S^+ and O. It may be attributed to these strong interactions between the dications and the anions to obtain the crystals of this salt successfully, since an attempt to obtain stable crystals with different anions such as $H_2SO_4^{2-}$ and BF_4^- was failed.

Solid-State ^2H NMR Study of Discotic Benzenehexayl Hexaheptanoate. Conformational Transition of Alkyl Side Chains

(Received January 21, 1988)

A ^2H NMR study of discotic benzenehexayl hexaheptanoate carrying perdeuterated alkyl side chains (BH7-d_{78}) is reported. Solid-state ^2H NMR measurements reveal that the conformational transition of the heptanoate chains takes place at 230 K from nearly static to mobile state. The chains above 230 K undergo flip-flop type reorientational motion, with the degree increasing upon heating. This temperature coincides with the solid-to-solid phase transition temperature, indicating that the phase transition takes place accompanied by the conformational melting of the flexible alkyl side chains. A spectrum measured in the discotic mesophase is also reported.

Extensive efforts have been devoted to characterize the conformational properties of alkyl chains appended to liquid crystalline molecules. In particular, their effects on the structure and stability of liquid crystals have been of both theoretical and practical interest. It is now generally recognized that the chain flexibility has a major contribution to the entropy of melting, hence it exerts significant influence on the phase transition behavior of liquid crystals. The deuterium NMR (^2H NMR) has emerged during the course of these studies as a powerful technique for investigating the conformational and dynamic properties of molecules in the mesomorphic state.[1,2] Yet, so far, only little is known about the alkyl chain conformation in the solid state and therefore its effect on the solid to liquid crystal phase transition is still open to debate.

For a homologous series of disc-like liquid crystals, benzenehexayl hexaalkanoates (BHn), $C_6(OCOC_{n-1}H_{2n-1})_6$, Sorai et al.[3-5] have carried out heat capacity measurements and shown that these compounds undergo a series of solid-state phase transitions before forming the discotic mesophase. These transitions are ascribed to the conformational melting of pendent alkyl chains, and the formation of the discotic mesophase of BHn is suggested to be a phenomenon appearing as one stage of successive phase transition driven by the side-chain conformational changes. In this communication, we report a solid-state ^2H NMR study of benzenehexayl hexaheptanoate (BH7) and show how the conformational melting of flexible alkyl chains proceeds in the solid phases.

Experimental

The sample of BH7-d_{78}, carrying perdeuterated heptanoate chains, was synthesized from tetrahydroxy-*p*-benzoquinone and heptanoic-d_{13} acid (MSD isotopes) according to the published method.[6,7] The reaction product was purified by repeated recrystallization from absolute ethanol and dried under vacuum to give white needle crystals of BH7-d_{78}. Solid-state ^2H NMR spectra were recorded on a Bruker CXP-300 spectrometer at 46.07 MHz using the quadrupole echo pulse sequence ($90^\circ_{\pm x}$-τ-90°_{y}-τ-echo) with a 90° pulse duration of 4.0 μs and a delay time τ=50 μs. Typically 100—200 spectra were accumulated with a repetition time of 0.2—0.5 s. The ^2H NMR spectrum of BH7-d_{78} in the mesomorphic state was measured by a JEOL GSX-270 spectrometer at 41.27 MHz using the single pulse sequence with a 90° pulse length of 5.0 μs. In both experiments, the temperature of the sample was controlled within ±1 °C with nitrogen gas flow.

Results and Discussion

Figure 1 shows the temperature dependence of the ^2H NMR spectrum of BH7-d_{78} in the solid state. The spectra at low temperatures consist of superposition of two axially symmetric quadrupolar powder patterns. The outer component is assigned to the methylene deuterons of pendent heptanoate chains and the inner component is assigned to the methyl deuterons. Although the parallel shoulders of the outer powder component (arising from methylene deuterons with C-D bond vectors oriented parallel to the field direction; θ=0° orientation) are lost outside of the spectrum, the perpendicular peaks (corresponding to θ=90° orientation) are clearly resolved with a peak separation of 123 kHz. Since a rigid-limit axially-symmetric powder spectrum of polycrystalline sample appears as superposition of properly weighted quadrupolar doublets, each of which has a spacing[8]

$$\Delta\nu = \frac{3}{2}\frac{e^2qQ}{h}P_2(\cos\theta) \qquad (1)$$

(e^2qQ/h is the quadrupolar coupling constant), the separation between perpendicular peaks (θ=90°) measures a value (3/4)(e^2qQ/h). The observed peak separation $\Delta\nu$=123 kHz yields e^2qQ/h=164 kHz, which is in good agreement with the literature value of the quadrupolar coupling constant of methylene deuterons.[8] The separation between parallel edges of the

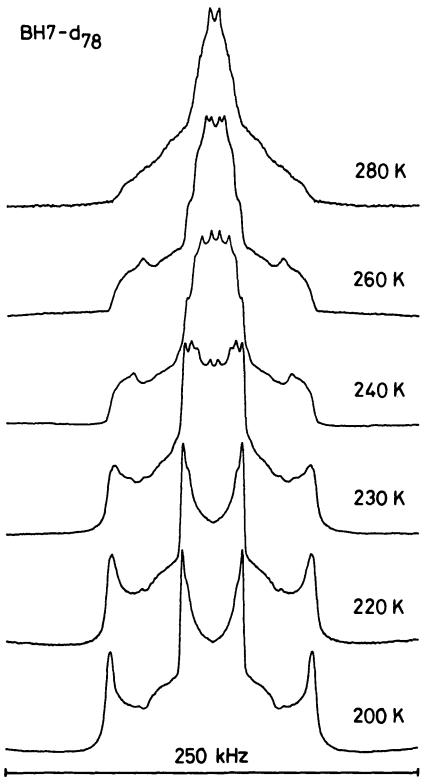

Fig. 1. Temperature dependence of solid-state ^{2}H NMR spectrum of BH7-d_{78} carrying perdeuterated heptanoate side chains.

methyl powder pattern ($\Delta\nu$=71.8 kHz) is just twice as large as its perpendicular peak separation ($\Delta\nu$= 35.8 kHz) in accord with the prediction of Eq 1. If the terminal methyl group, having the tetrahedral geometry (with the C-C-D bond angle β=109.47°), undergoes rapid rotation about its C_3 symmetry axis, separation of peaks is scaled down by a factor $|(1/2)(3\cos^2\beta-1)|=1/3$. The observed peak separation (35.8 kHz) is however slightly smaller than the expected value (41.0 kHz). This additional reduction in $\Delta\nu$ is indicative of either a departure of the methyl group structure from the ideal tetrahedral geometry or the presence of librational motions of the methyl symmetry axis.[9,10] Nevertheless, for the heptanoate chain as a whole, the degree of reorientational motion should be quite low (or the rate is slow on the ^{2}H NMR frequency scale), since the quadrupolar coupling constant observed for the inner methylene deuterons is large and reproduces its rigid-limit value.

Above 230 K the spectral shape changes substantially. A sizable build-up of intensity occurs in the central part of the spectrum, while the intensity of the outermost peaks is decreased and the linewidth is broadened. The 230 K spectrum shows several pairs of powder-pattern peaks in the central pattern indicating that the inner methylene segments aquire the reorientational freedom at this temperature. The narrowing of the central spectral component proceeds

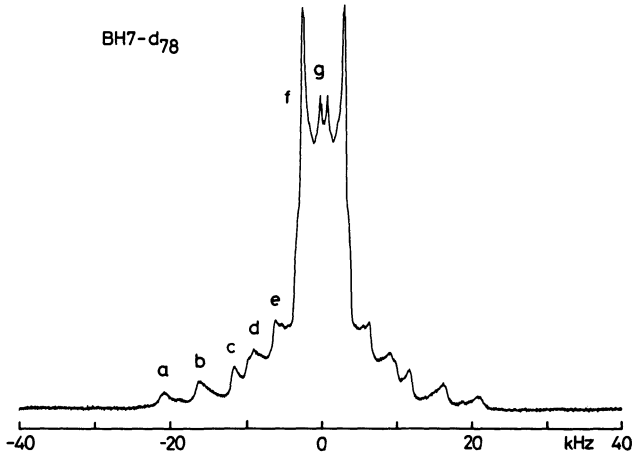

Fig. 2. ^{2}H NMR spectrum of BH7-d_{78} in the discotic mesophase at 354 K.

continuously with increasing temperature, and eventually results in the line shape such as that observed at 280 K. This pattern, i.e., the biaxial powder pattern which would arise when the C-D bond axis jumps rapidly between discrete sites, suggests the flip-flop type motion of the heptanoate chain. In this connection, it is noteworthy that the 280 K spectrum still preserves a broad component with a separation between extreme edges of ca. 110 kHz. The coexistence of spectral components with widely varying quadrupolar coupling constants is consistent with the flip-flop motion of the chain suggested above; namely, the methylene segment undergoes an increasing degree of motion as it approaches to the chain terminal.

The onset of the aforementioned changes in the ^{2}H NMR line shape was observed at 230 K. This temperature coincides with the first-order solid-to-solid phase transition temperature (230.81 K) determined calorimetrically by Sorai and Suga.[4] They have also reported the results of infrared measurements and pointed out that the molecular and crystal structures are different between these two solid phases. Our present ^{2}H NMR studies clearly demonstrate that the melting of the alkyl chain conformation takes place at this temperature from nearly static state (the chain being in the lowest energy all-trans conformation) to mobile state (undergoing the flip-flop motion). The spectral shape remains essentially unchanged above room temperature (except for the occurrence of continuous narrowing) until the transition to the discotic mesophase at 353.79 K.

Shown in Fig. 2 is the ^{2}H NMR spectrum of BH7-d_{78} recorded in the discotic mesophase. For the measurement the sample was first heated to the isotropic liquid phase (T_{iso}=359.28 K), then cooled down slowly to turn into the mesophase. The spectrum shows five discrete quadrupolar doublets (a—e) with $\Delta\nu$ values ranging from 42 to 12 kHz,

which are attributable to the five methylene groups. The innermost doublet (g) with $\Delta\nu$=0.96 kHz is then assigned to the terminal methyl group by taking account of the signal intensity. These discrete quadrupolar doublets arise from BH7-d_{78} molecules oriented uniaxially in the field. Elucidation of the average alkyl chain conformation from the $\Delta\nu$ pattern is possible in terms of the theories described previously.[11,12] However, these doublet patterns are dominated by an intense powder-like component (f). Its peak separation $\Delta\nu$=5.6 kHz is comparable to a value $\Delta\nu$=6.6 kHz observed for peaks in the solid-state spectrum at 280 K in Fig. 1. Obviously, there should coexist unoriented molecules. Corresponding ^2H NMR spectra reported for triphenylene-type discotic liquid crystals exhibit only discrete quadrupolar doublets.[13,14] The coexistence of "oriented" and "unoriented" components in our spectrum suggests that the diamagnetic anisotropy of the central benzene core of BH7-d_{78} is not larger than that of the triphenylene core and thereby cannot suffice to cause homogeneous orientation.

In summary, we have demonstrated that the solid-state deuterium NMR is successful in analyzing the conformational properties of flexible alkyl chains appended to liquid crystalline molecules. The observed ^2H NMR line shape shows marked differences between phases, reflecting the changes in the mode and degree of reorientational motions of alkyl side chains. Lifshitz, et al.[15] have recently carried out ^2H NMR measurements of BH6 (a hexanoate homologue of BH7) and shown that the hexanoate side chains undergo very similar solid-state conformational transitions. Thus, the sequential melting of side-chain conformation at the phase transition appears to be a general characteristic of this class of disc-like liquid-crystalline molecules.

We thank Professor M. Sorai of Osaka University for directing our attention to this problem and for valuable informations concerning the sample synthesis. We are also grateful to JEOL for measuring the spectrum in Fig. 2.

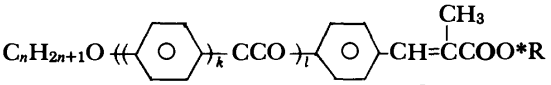
Thermal and Ferroelectric Properties of Novel Ferroelectric Liquid Crystals Containing α-Methylcinnamoyl Moiety in the Core Structure

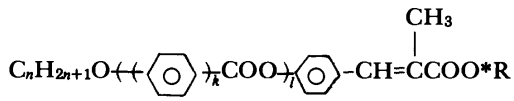
Jun NAKAUCHI* and Yoshitaka KAGEYAMA
Tokyo Research Laboratory, Mitsubishi Rayon Co. Ltd., Noborito, Tama-ku, Kawasaki, Kanagawa 214
(Received February 10, 1988)

Six homologous series of novel ferroelectric liquid crystals containing α-methylcinnamoyl moiety in the core structure:



(IA: k=1, l=1, *R=-$CH_2^*CHC_2H_5$, n=8—16; IB: k=1, l=1, *R=$^*CHC_6H_{13}$, n=8—16; IIA: k=1, l=2, *R=-$CH_2^*CHC_2H_5$, n=9—16; IIB: k=1, l=2, *R=$^*CHC_6H_{13}$, n=8—14; IIIA: k=2, l=1, *R=-$CH_2^*CHC_2H_5$, n=9—16; IIIB: k=2, l=1, *R=$^*CHC_6H_{13}$, n=9—16) have been synthesized and their thermal and ferroelectric properties have been investigated. The mesomorphic transition temperatures and the spontaneous polarization for the homologous series (IA, IB, IIA, IIB, IIIA, and IIIB) depend on the core structure, the chiral group, and the terminal alkoxyl chain length. These homologous series show the chiral smectic C phase over wide temperature ranges including room temperature and the values of their maximum spontaneous polarization are in the range of 30 to 800 μC m^{-2}. The thermal stability of the mesophase and the magnitude of the spontaneous polarization have been discussed from the view point of the molecular structure and the local molecular interactions.

It was recently shown that the thin cell containing ferroelectric liquid crystals was applied to high-speed switching devices.[1] Since then, much attention has been given to the synthesis of ferroelectric liquid crystals which show the chiral smectic C (Sm*C) phase over a wide temperature range including room temperature and have large spontaneous polarization.[2-6] However, there are few liquid crystals which exhibit the Sm*C phase in the region of lower temperature than room temperature and have large spontaneous polarization. Therefore, eutectic mixtures which show the enantiotropic Sm*C phase over a wide temperature range covering room temperature have been prepared by mixing several compounds.[7-10] In addition to such practical approach, the synthesis of novel compounds and the investigation of the correlation between the physical properties and the molecular structure are necessary in order to design the materials with higher quality than those reported so far. In the previous paper,[11] we reported that the homologues with longer alkoxyl chain of (*S*)-2-methylbutyl esters or 4-(4-*n*-alkoxybenzoyloxy)-α-methylcinnamic acid (IA homologues shown below) show enantiotropic Sm*C phase around room temperature. In addition to these homologues (IA), we have synthesized other five homologous series (IB, IIA, IIB, IIIA, and IIIB) as shown in the following general formula:



IA: k = 1, l = 1, *R = -$CH_2^*CHC_2H_5$, n = 8—16,

IB: k = 1, l = 1, *R = $^*CHC_6H_{13}$, n = 9—16,

IIA: k = 1, l = 2, *R = -$CH_2^*CHC_2H_5$, n = 9—16,

IIB: k = 1, l = 2, *R = $^*CHC_6H_{13}$, n = 8—14,

IIIA: k = 2, l = 1, *R = -$CH_2^*CHC_2H_5$, n = 9—16,

IIIB: k = 2, l = 1, *R = $^*CHC_6H_{13}$, n = 9—16,

In the present paper, we discuss the effect of the core, the chiral part, and the terminal alkoxyl chain in the molecular structure on the mesomorphic transition temperatures and the magnitude of the spontaneous polarization in the Sm*C phase.

Experimental

Preparation of Materials. All the reagents purchased from Tokyo Kasei Co., Ltd. were used without further purification. *p*-Hydroxy-α-methylcinnamic acid was prepared by a Perkin reaction according to the literature.[12] (*S*)-2-Methylbutyl or (*R*)-1-methylheptyl ester of *p*-hydroxy-α-methylcinnamic acid were synthesized by an esterification reaction of *p*-acetoxy-α-methyl-cinnamoyl chloride with (*S*)-2-methyl-1-butanol or (*R*)-1-methyl-1-heptanol using triethylamine as a base, followed by the hydrolysis of the acetoxyl group selectively in the mixed solvent of tetrahydrofuran and methanol (volume ratio : 9/1) containing equimolar 1 mol dm^{-3} LiOH. The specific rotations $[\alpha]_D$ measured in chloroform at 23 °C were 3.56° and −26.73° for the (*S*)-2-methylbutyl ester and the (*R*)-1-methylheptyl ester, respectively. 4′-Alkoxy-1-biphenylcarboxylic acids were synthesized by the hydrolysis of the 4′-alkoxy-4-cyanobiphenyls, which were synthesized by a reaction or 4′-cyanobiphenyl-4-ol with the corresponding alkyl bromides in cyclohexanone containing K_2CO_3, in NaOH–H_2O–ethylene glycol solution. (*S*)-2-Methylbutyl or (*R*)-1-methylheptyl esters of *p*-hydroxybenzoyloxy-α-methylcinnamic acid were synthesized by an esterification reaction of *p*-acetoxybenzoyl chloride with (*S*)-2-methylbutyl or (*R*)-1-methylheptyl esters of *p*-hydroxy-α-methylcinnamic acid using triethylamine as a base, followed by the hydrolysis of the acetoxyl group selectively in the mixed solvent of tetrahydrofuran and methanol (volume ratio: 9/1) containing equimolar 1 mol dm^{-3} LiOH at room temperature.

The homologous series (IB, IIA, IIB, IIIA, and IIIB) were prepared by an esterification reaction of the *p*-hydroxy-α-methylcinnamates or the 4-(4-hydroxybenzoyloxy)-α-methylcinnamates with the corresponding *p*-alkoxybenzoyl chlorides or 4′-alkoxy-1-biphenylcarboxylic acid chlorides using triethylamine as a base. The products were purified by column chromatography (silica gel, benzene–hexane), followed by the recrystallization from ethanol.

Their elementary analysis data are listed in Table 1.

Measurement of Physical Properties. An identification of the mesophase was carried out using a Nikon polarizing microscope equipped with a Mettler FP-52 heating stage. Transition temperatures were measured using a Daini Seikosha SSC-560 differential scanning calorimeter (DSC) at a scanning rate of 2.5 °C min^{-1} under N_2 atmosphere. The spontaneous polarization (Ps) was determined by a triangular wave method reported by Miyasato et al.[13] The frequency, the maximum amplitude, and the cell thickness were 10 Hz, 150 V, and 50 μm, respectively.

Results and Discussion

The melting points and the mesomorphic transition temperatures for the homologous series (IA, IB, IIA, IIB, IIIA, and IIIB) are summarized in Table 2. All the homologous series except a IA homologue with terminal octyloxyl chain and IB homologues with shorter alkoxyl chains (n=8—10) exhibit the enantiotropic Sm*C phase. Their phase sequences above Sm*C are isotropic (Iso)-smectic A(SmA)-Sm*C for the homologues (IA, IB, IIB, IIIA, and IIIB) and IIA homologues with longer alkoxyl chains (n=14,16) and are Iso-cholesteric(Ch)-SmA-Sm*C for IIA homologues with shorter alkoxyl chains (n=9—12). The IB homologues with longer alkoxyl chains (n=11—16) and the IIIA and IIIB homologues with shorter alkoxyl chains (n=9—12) exhibit other smectic phases (Sm 3) below the Sm*C. However, these phases have not been determined at this stage, yet. As is

a) Sm3; unidentified smectic phase, Sm*C; chiral smectic C, SmA; smectic A, Ch; cholesteric, Iso; isotropic liquid.
b) ( ); monotropic transition.

evident from the table, the transition temperatures from the SmA phase to the Sm*C one for IB homologues are very low and the temperature range of the enantiotropic Sm*C phase for the homologous series IIA and IIIA is significantly wide. Such mesomorphic properties are comparable with those for the well-known MORE series with broad-band Sm*C phase, although their values of the spontaneous polarization are very small.[14,15] The IB homologue with terminal nonyloxyl chain exhibits the lowest transition temperature from SmA phase to Sm*C at 5°C monotropically, and the IIIA homologue with the terminal nonyloxyl chain exhibits the widest temperature range of the enantiotropic Sm*C phase from 62.1 to 159.8 °C. These results indicate that the α-methylcynnamoyl moiety is a suitable structure for the appearance of the Sm*C phase.

The transition temperatures from SmA phase to Iso or from SmA phase to Ch against the carbon number in terminal alkoxyl chain are plotted in Fig. 1. Compared with the transition temperatures for the homologous series IIA, IIB, IIIA, and IIIB, those for the homologous series IA and IB are little dependent on the terminal alkoxyl chain length. This result can be interpreted as follows: the thermal stability of SmA phase of the IA and IB homologues is a little affected by the thermal motion of the flexible alkoxyl chain because of their transition temperatures much lower than those for the other homologous series. Another characteristic feature is the effect of the chiral groups

on the transition temperatures. On changing a 2-methylbutyl group to a 1-methylheptyl group, the Ch phase observed in the homologous series IIA disappears in the homologous series IIB, and the transition temperatures for the homologous series IB, IIB, and IIIB become about 30—50 °C lower than those for the corresponding homologous series IA, IIA, and IIIA. The effects of the chain branching on the thermal stability of the mesophase have been investigated on the Schiff base compounds with branched alkylcinnamate moieties by Gray and Harrison and have been discussed in terms of a steric effect between the branched methyl group and the ester group.[16] Our results are similar to those reported previously[16] and can be interpreted in terms of the difference of the steric hindrance between the 1-methyl branch and the 2-methyl branch. The former interacts with the carbonyl oxygen much stronger than the latter and lies out of the plane of the mesogen, thus leading to decrease greatly both Ch and SmA thermal stabilities.

The transition temperatures from Sm*C phase to SmA against the carbon number in the terminal alkoxyl chain are plotted in Fig. 2. As is pointed out by McMillan,[17] de Jue,[18] and Patel and Goodby,[19] the transition temperatures from Sm*C to SmA depend strongly on the core structure with local dipole moments and the terminal chain length. As seen in Fig. 2, the transition temperatures for IA and IB homologues gradually increase with the terminal alkoxyl chain length and those for IIA and IIB homologues increase steeply with the terminal alkoxyl chain length in the range of lower carbon number and are approaching to the constant value in the region of higher carbon number. On the other hand, the transition temperatures for IIIA and IIIB homologues slightly decrease with the terminal alkoxyl chain length. These facts indicate that the effect of the terminal alkoxyl chain on the thermal stability of the Sm*C phase is quite different if the compounds have different core structures. The effect of the chiral group on the thermal stability of the Sm*C is a little different from that of the SmA phase, that is, the degree of depression of the transition temperature from Sm*C to SmA by replacing the 2-methylbutyl group into the 1-methylheptyl group is not so large as that from Iso or Ch phase to SmA and depends on the core structures. These facts also indicate that the position of the bulky methyl branch

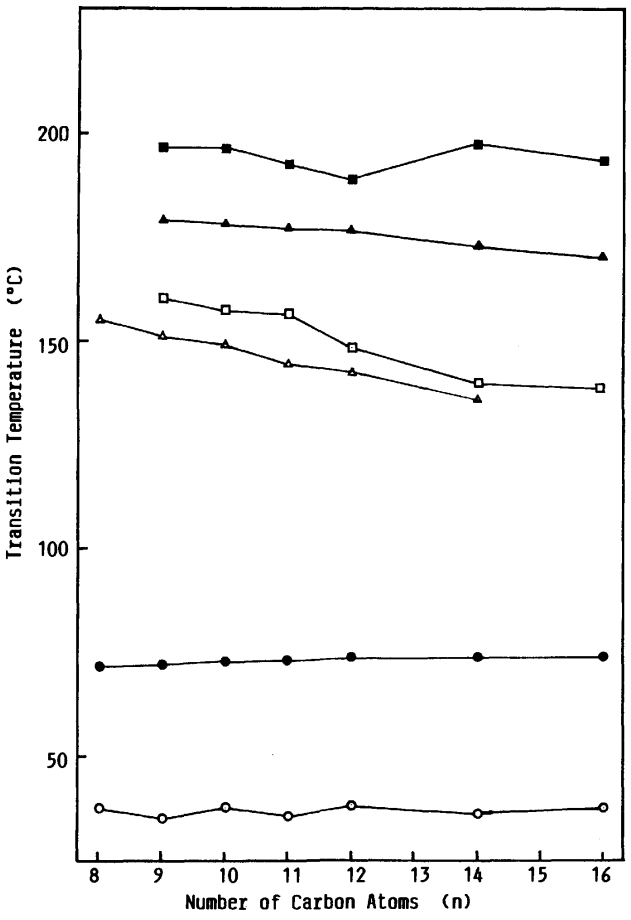

Fig. 1. Plots of the transition temperatures from SmA phase to Iso or Ch phse against the number of carbon atoms in the *n*-alkoxyl chain of the homologous series IA(-●-), IB(-○-), IIA(-▲-), IIB(-△-), IIIA(-■-), and IIIB(-□-).

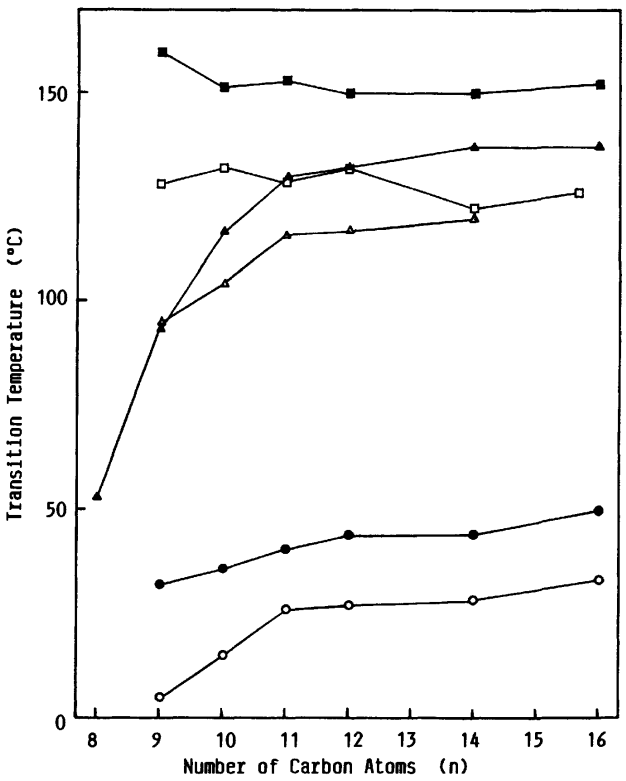

Fig. 2. Plots of the transition temperatures from Sm*C phase to SmA against the number of carbon atoms in the *n*-alkoxyl chain of the homologous series IA(-●-), IB(-○-), IIA(-▲-), IIB(-△-), IIIA(-■-), and IIIB(-□-).

and the chain length of the chiral group play some role for the appearance of Sm*C phase as well as the core structure and the terminal alkoxyl chain length.

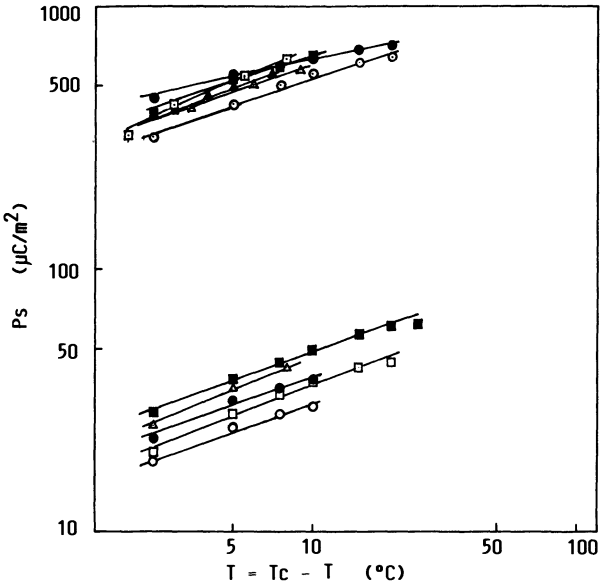

Fig. 3. Logarithmic plots of the temperature dependence of the spontaneous polarization for the homologous series IA and IB: n=9(-○-); n=10(-●-); n=11(-□-); n=12(-■-); n=14(-△-); n=16(-▲-). The cell thickness, the frequency, and the maximum amplitude of applied voltage are 50 μm, 10 Hz, and 150 V, respectively.

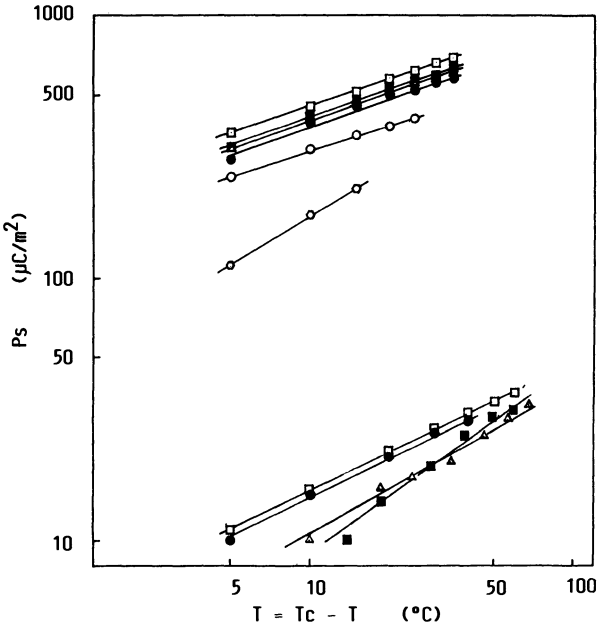

Fig. 4. Logarithmic plots of the temperature dependence of the spontaneous polarization for the homologous series IIA and IIB: n=8(-○-); n=9(-○-); n=10(-●-); n=12(-■-); n=14(-△-). The cell thickness, the frequency, and the maximum amplitude of applied voltage are 50 mm, 10 Hz, and 150 V, respectively.

The temperature dependence of the spontaneous polarization in the Sm*C phase for a number of the homologues in the homologous series (IA and IB), (IIA and IIB), and (IIIA and IIIB) are shown in Figs. 3, 4, and 5, respectively. It is clearly shown that the temperature dependence of the measured values for all the IA, IB, IIA, IIB, and IIIB homologues except that for IIIA homologues is represented by the expression $P_s=A(\Delta T)^a$. The log-log plots of P_s vs. ΔT for the IIIA homologues form nonlinear curve, which could be divided into two linear lines with different gradient. This fact may indicate that two processes concerned with the temperature dependence of the spontaneous polarization exist in the Sm*C phase of the IIIA homologues.

As is expected from the effect of the position or the asymmetric carbon in the chiral part on the spontaneous polarization reported so far,[20,21] the magnitude of the spontaneous polarization for the homologous series IB, IIB, and IIIB with 1-methylheptyl group is one order higher than that for the corresponding homologous series IA, IIA, and IIIA with 2-methylbutyl group. Some relation between the spontaneous polarization and the core structure is also seen among the homologous series (I, II, and III), that is, the values of the spontaneous polarization for the homologous series I, II, and III are approximately in the order of III>I>II. Additionally, in each homologous series, the magnitude of the spontaneous polarization shows the maximum value at a certain length of the terminal alkoxyl chain.

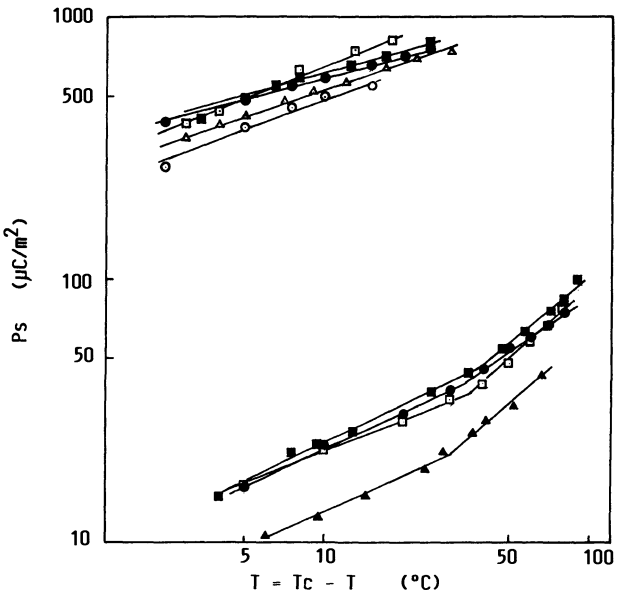

Fig. 5. Logarithmic plots of the temperature dependence of the spontaneous polarization for the homologous series IIIA and IIIB: n=9(-○-); n=10(-●-); n=11(-□-); n=12(-■-); n=14(-△-); n=16(-▲-). The cell thickness, the frequency, and the maximum amplitude of applied voltage are 50 μm, 10 Hz, and 150 V, respectively.

The magnitude of the spontaneous polarization is considered to depend on the size of the lateral component of dipole moment of the ester group adjacent to the chiral part and on the degrees of the restriction of a rotation about the molecular long axis and of an internal rotation around the bond between the chiral part and the core. The effect of the restriction of the internal rotation around the bond between the chiral part and the core on the spontaneous polarization is clearly seen in the homologous series A with the 1-methyl branch and in the series B with the 2-methyl branch. In comparison with the 2-methyl branch in the chiral group, the 1-methyl branch restricts the internal rotation around the bond between the chiral part and the core more strongly due to the steric hindrance. The difference of the values of the spontaneous polarization among the homologous series (I, II, and III) with the same chiral group is not so large. This result may be attributed to the reason that the core structure near the chiral part for the homologous series I, II, and III is identical, and then, the size of the net dipole moment related to the spontaneous polarization is considered to be almost same. However, the effect of the core and the terminal alkoxyl chain length on the magnitude of the spontaneous polarization cannot be well explained at this stage, because the temperature range of Sm*C phase among these homologous series is quite different one another, therefore the degree of the restriction of the rotation about the molecular long axis cannot be estimated.

More detailed study on the molecular motion and the structure in the Sm*C phase must be necessary in order to elucidate the correlation between the spontaneous polarization and the molecular structure.

The authors thank Dr. Toshio Yoshihara for his helpful discussion and also thank Mrs. Mioko Uematsu and Mr. Yoshihiro Sako for their assistance of experiments.

(Received February 29, 1988)

The low-frequency Raman bands of the tetramethyl- and tetramethyl-d_{12}-pyrazine crystals and their hydrated crystals were studied at various temperatures between 4.2 and 298 K. The isotopic factors and the temperature effects on the frequencies of the Raman bands indicate that the low-frequency Raman bands observed in the crystal are to be ascribed to the rotational lattice vibrations. A smooth curve of the plot of the Raman frequency versus temperature suggests that no apparent temperature-induced phase transition takes place in the tetramethylpyrazine crystal. Classification of the rotational lattice vibrations into symmetry species was made based on the polarization behavior of the Raman bands. It was also observed that tetramethylpyrazine hydrates quite easily with a trace of moisture in the air.

The low-frequency Raman bands due to the lattice vibrations of the aromatic compounds in crystals have been studied by many workers.[1-6] Ito et al. observed the low-frequency Raman bands of the benzene and pyrazine crystals and calculated the mean square amplitudes of the rotational motions of the molecules in the crystals.[3,4] Suzuki et al.[5] and Bonadeo et al.[6] observed the polarized Raman spectra of the naphthalene and benzene crystals, respectively, and classified the Raman bands arising from the rotational lattice vibrations into symmetry species. Recently, Calvé et al. studied the temperature effects on the frequencies of the lattice vibrations of the 4-methylpyridine crystal and discussed about the phase transition.[7] They also observed the temperature dependence of the torsional vibration of the methyl group and showed that the rotation of the methyl group is free in the crystal phases above 100 K, while the rotation is hindered in the phase below 100 K.

Braam et al. determined the crystal structure of tetramethylpyrazine and showed that four molecules are involved in the unit cell.[8] Thus, based on the knowledge of the crystal structure, the lattice vibrations of the tetramethylpyrazine crystal can easily be distinguished from the torsional vibrations of the methyl group, which will be observed in the same low-frequency region, by measuring the temperature effects and isotopic factors of the frequencies of the Raman bands.

The intramolecular vibrations of tetramethylpyrazine were studied through the analyses of the polarized Raman and infrared spectra and the assignments of the normal vibrations were made based on the oriented gas model approximation.[9] It was known that when the tetramethylpyrazine crystal is grown in aqueous solution, one obtains the trihydrated crystal.[10] It is interesting to investigate whether the oriented gas model approximation can be applied to the assignments of the intermolecular vibrations or not, and to study how the lattice vibrations are affected by hydration.

In this paper the lattice vibrations of the tetramethyl- and tetramethyl-d_{12}-pyrazine crystals are discussed based on the isotopic factors and temperature effects on the Raman frequencies and the polarization behavior of the Raman bands, and then the effects of hydration on the lattice vibrations are studied.

Experimental

Material. Tetramethyl-d_{12}-pyrazine (TMP-d_{12}) was synthesized by the exchange reaction of tetramethylpyrazine (TMP-d_0) obtained from Aldrich Chemical Co. with D_2O. The isotopic purity of the product was confirmed by the nuclear magnetic resonance measurement. The samples were purified by zone refining of about 100 passages. The hydrated crystals were prepared by adjusting the amount of moisture adding to the TMP-d_0 and TMP-d_{12} crystals.

Optical Measurements. The sample was sealed in a glass tube of about 3 mm in diameter and was excited with the 514.5 nm line from an Ar^+ ion laser. The Raman spectra were observed with a JEOL 400 T Laser Raman Spectrophotometer at various temperatures between 298 and 155 K. The temperature was regulated with an automatic temperature controller of JEOL Model RS-VTC 41. The Raman scattering and excitation light beams were at right angles. The Raman spectra were also observed at 77 and 4.2 K. The preparation of the single crystal and the method of the measurement of the polarized Raman spectrum were exactly the same as those described previously.[9]

Results and Discussion

Tetramethylpyrazine crystallizes in the orthorhombic space group D_{2h}^{15} with four molecules in the unit cell, each molecules being located at the site of symmetry C_i.[8] There are twenty one optical branches of the lattice vibrations, of which nine are the vibrations of the translational modes and twelve are of the rotational modes. According to the group theory the six lattice vibrations of the nine translational modes are infrared active and the three of them are

inactive both in the infrared and Raman spectra, while the twelve lattice vibrations of the rotational modes are all Raman active. The twelve rotational lattice vibrations are classified into four symmetry species A_g, B_{1g}, B_{2g}, and B_{3g}, and three vibrations belong to each symmetry species. Each mode of the rotational lattice vibrations can be represented by a linear combination of the in-phase and out-of-phase rotational oscillations of the four molecules in the unit cell about the u, v, and w axes of the molecule. The u axis is taken perpendicular to the molecular plane and the v and w axes are in the plane with the w axis passing through the nitrogen atoms.

The Raman spectra of the TMP-d_0 and TMP-d_{12} crystals in the low-frequency region observed at 4.2 K are shown in Fig. 1. The twelve Raman bands were clearly observed and their frequencies are given in Fig. 1 and Table 1. If the low-frequency Raman bands are ascribable to the rotational lattice vibrations, the isotopic factor of the corresponding bands of the TMP-d_0 and TMP-d_{12} crystals is given by $\tilde{\nu}(d_0)/\tilde{\nu}(d_{12})=\{I_r(d_{12})/I_r(d_0)\}^{1/2}$, where $\tilde{\nu}$ is the Raman frequency and I_r the moment of inertia of the molecule about the axis r (=u, v, or w). The values of the moments of inertia of the TMP-d_0 and TMP-d_{12} molecules were calculated

using the molecular structure give by Braam.[8] The values are ranged in a order $I_u > I_w > I_v$. The isotopic factors were calculated to be 1.09, 1.09, and 1.10 at 100 and 300 K for the rotational lattice vibrations about the u, v, and w axes, respectively. The observed Raman frequencies for the TMP-d_0 and TMP-d_{12} crystals at 4.2, 77, and 298 K are given in Table 1 and the temperature effects on the frequencies of the Raman bands are shown in Figs. 2 and 3 for TMP-d_0 and TMP-d_{12}, respectively. The spectral structures observed at various temperatures are exactly the same as that observed at 4.2 K except for the width of the bands, which increases with increasing temperature. It is readily seen from Table 1 and Figs. 2 and 3 that (1) the observed isotopic factors are about 1.1 for all the corresponding Raman bands, (2) the frequencies increase with decreasing temperature, and (3) the observed Raman frequencies lie on a smooth curve against temperature within the experimental errors. These facts suggest that (1) the observed low-frequency Raman bands can be ascribed to the rotational lattice vibrations in the crystals and (2) no apparent phase transition takes place between 298 and 4.2 K in the TMP crystal. This is consistent with the fact that the crystal structure of TMP belongs to the space group D_{2h}^{15} at 300 and 100 K.[8] Calvé et al. observed the Raman bands arising from the torsional vibration of the methyl group in the 4-methylpyridine crystal at various temperatures between 4.2 and 100 K and pointed out that the isotopic factor of the torsional vibration of the methyl group is about 1.4 and the frequency increases with increasing temperature, unlike the behavior of the rotational lattice vibrations.[7] The Raman bands giving such high value of the isotopic factor could not be observed in our experiment.

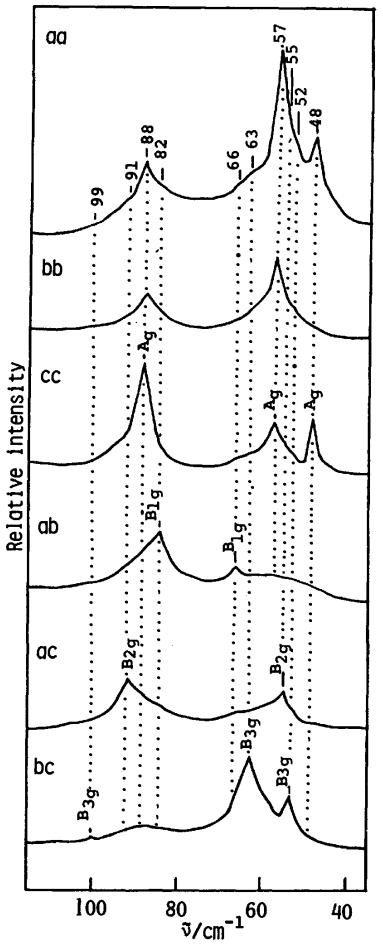

Fig. 4. The polarized Raman spectra of the tetramethylpyrazine crystal in the low-frequency region observed at 298 K.

The polarized Raman spectra of the TMP-d_0 and TMP-d_{12} crystals observed at 298 K are given in Figs. 4 and 5, respectively. Notations of the spectra such as aa and bb are exactly the same as those given in the previous paper reported on the intramolecular vibrations of TMP-d_0.[9] The observed polarization behavior of the Raman bands arising from the rotational lattice vibrations of the TMP-d_0 crystal is the same as that of the TMP-d_{12} crystal. The calculated squared values of the elements of the Raman (derived polarizability) tensor based on the oriented gas model for the TMP crystal are given in Table 2.[9] According to Table 2, the lattice vibrations belonging to the symmetry species A_g will be observed in the aa, bb, and cc spectra and those belonging to the B_{1g}, B_{2g}, and B_{3g} species in the ab, ac, and bc spectra, respectively. Figures 4 and 5 show that the Raman bands having frequencies of 52(47), 63(58), and 99(91) cm^{-1} are clearly observed in the bc spectrum, those of 55(50) and 91(83) cm^{-1} are in the ac spectrum, those of 66(60) and 82(74) cm^{-1} are in the ab spectrum, and those of 48(43), 57(52), and 88(80) cm^{-1} are in the aa, bb, and cc spectra, where the first numbers refer to

Table 2. Squared Values of Elements of Raman Tensor for Tetramethylpyrazine

Crystal		Molecule		
		$b_{1g}(R_w)$	$b_{2g}(R_v)$	$b_{3g}(R_u)$
A_g	$(A_{aa})^2$	0.19	0.76	0.10
	$(A_{bb})^2$	0.08	0.06	0.91
	$(A_{cc})^2$	0.53	0.39	0.41
B_{1g}	$(A_{ab})^2$	0.40	0.15	0.05
B_{2g}	$(A_{ac})^2$	0.10	0.01	0.24
B_{3g}	$(A_{bc})^2$	0.10	0.23	0.00

the frequencies for the TMP-d_0 crystal and the numbers in parentheses to the TMP-d_{12} crystal. These observed facts indicate that the 52(47), 63(58), and 99(91) cm^{-1} bands are to be assigned to the B_{3g} lattice vibrations, the 55(50), 91(83) cm^{-1} bands to the B_{2g} vibrations, the 66(60) and 82(74) cm^{-1} bands to the B_{1g} vibrations, and the 48(43), 57(52), and 88(80) cm^{-1} bands to the A_g vibrations. These assignments are given in Table 1 and Figs. 4 and 5. Table 2 also indicates that for the A_g rotational lattice vibrations the relative intensities of the Raman bands arising from the rotational oscillations of the molecule about

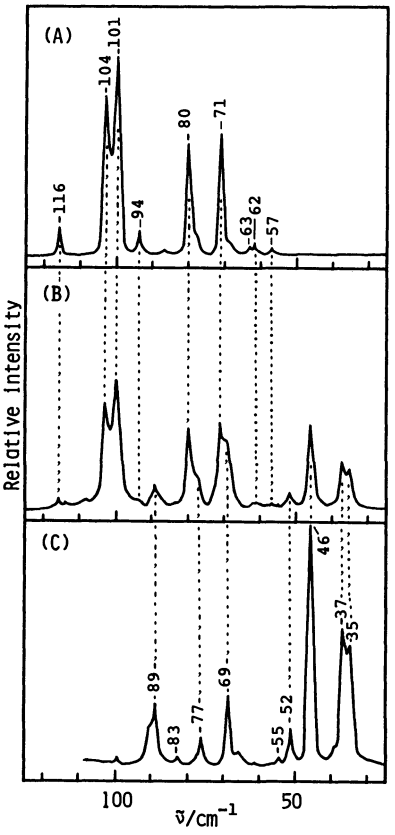

Fig. 6. The Raman spectra of the unhydrated(A), partially hydrated(B), and completely hydrated(C) tetramethylpyrazine crystals.

Table 3. Root Mean Square Amplitudes (degree) of Rotational Lattice Vibrations of Tetramethyl-d_0- and Tetramethyl-d_{12}-pyrazine Crystals about v Axis

	4.2 K	77 K	298 K
TMP-d_0	1.5	1.8	3.6
TMP-d_{12}	1.5	1.8	3.6

the u, v, and w axes are strongest in the bb, aa, and cc spectra, respectively. However, the observed relative intensities are not consistent with the expectation, although the observed intensities of the bands for the intramolecular vibrations are quantitatively consistent with the expected values.[9] This phenomenon may be caused by mode mixing among the rotational lattice vibrations about the u, v, and w axes and also by coupling of the rotational lattice vibrations with the torsional vibrations of the methyl groups. This means that the oriented gas model is rather a poor approximation for the determination of modes of the rotational lattice vibrations.

The moment of inertia of TMP about the v axis is smaller than those about the u and w axes, and linear combinations of the in-phase and out-of-phase rotational oscillations of four molecules about the v axis in the crystal give four rotational lattice

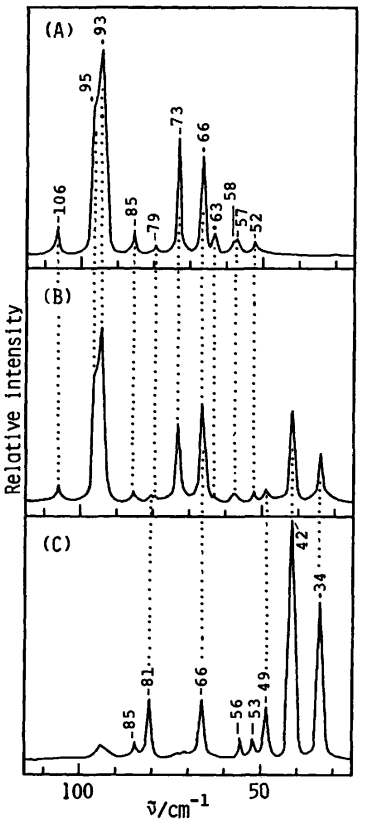

Fig. 7. The Raman spectra of the unhydrated(A), partially hydrated(B), and completely hydrated(C) tetramethyl-d_{12}-pyrazine crystals.

vibrations belonging to symmetry species A_g, B_{1g}, B_{2g}, and B_{3g}. Thus, the Raman bands observed at 82, 88, 91, and 99 cm^{-1} in the TMP crystal could be assigned to the lattice vibrations arising mainly from the oscillation about the v axis, because these bands are located in the higher wavenumber region than the other bands and showed the B_{1g}, A_g, B_{2g}, and B_{3g} polarization behavior, respectively, although these vibrations might couple with the rotational motions about the u and w axes as described above. The mean square amplitudes of the rotational motions about the v axis of the molecule in the crystal can be calculated. Calculation was made using the equation given by Cruickshank[11] and the results are given in Table 3. The values of the rotational mean square amplitude decrease with decreasing temperature.

It has been known that TMP crystallizes with three molecules of water of crystallization when the crystal is grown in aqueous solution.[10] The Raman spectra of the hydrated TMP-d_0 and TMP-d_{12} crystals in the low-frequency region are shown in Figs. 6 and 7, respectively. The spectra shown in (A), (B), and (C) of the figures are for the unhydrated, partially hydrated, and completely hydrated TMP crystals, respectively. The crystal structure of the trihydrated TMP crystal belongs to the monoclinic space group C_{2h}^5 with four molecules in the unit cell and thus, the rotational lattice vibrations are all Raman active. The Raman bands arising from the rotational lattice vibrations of the hydrated crystal were located in the lower wavenumber region of the bands of the unhydrated crystal. This may be due to differences of the mass and potential field of the hydrated TMP from those of the unhydrated TMP in crystals. The Raman bands arising from the lattice vibrations of the hydrated TMP crystal are observed when the unhydrated TMP crystal is exposed in the humid air. Thus, the preparation of the TMP crystal was made in the air free from moisture.

Crystal Face Anisotropy of Propylene Oxidation on Molybdenum Trioxide

Shigeo Ted OYAMA†
Catalytica, 430 Ferguson Drive, Building 3, Mt. View, CA 94305, U.S.A.
(Received February 23, 1987)

Samples of MoO_3 consisting of unsupported oriented crystallites exposing primarily the (010) plane and of randomly oriented powders were used to study the partial oxidation of propylene and allyl iodide. The materials were characterized by scanning electron microscopy, X-ray diffraction, infrared spectroscopy, laser Raman spectroscopy, temperature programmed desorption of ammonia and surface area measurements. The unoriented powders were twice as active as the oriented crystallites in the oxidation of propylene, but both were similar in activity in the oxidation of allyl iodide. Thus, the reactions depended only slightly on the structure of the MoO_3.

The concept of structure-sensitivity has been useful in the study of the catalytic activity of metals, but has been little exploited in the case of nonmetallic catalysts such as sulfides or oxides. The bonding in nonmetals is more highly localized and directional than on metals. Thus, on nonmetals geometrical constraints for surface intermediates are likely to be greater than on metals, and surface structure might be expected to play a greater role in nonmetal reactivity. Investigations of the catalytic activity of different faces of nonmetal single crystals were pioneered by Tanaka and Okuhara[1-3] who found that isomerization and hydrogen exchange of olefins proceed on the edge planes of MoS_2 whereas the isomerization of 2-methyl-1-butene occurs on the basal planes. Berlowitz and Kung[4] report that dehydrogenation of 2-propanol to acetone on zinc oxide proceeds three to five times faster on polar crystal faces where zinc atoms are exposed than on similar polar faces where oxygen is exposed.

Structure-sensitive reactions may be defined to be those whose rates change appreciably with the atomic structure of the surface.[5-8] There is no clear dividing line between structure-sensitive and insensitive reactions, although the former on metals often show activity differences of tens, hundreds, it not thousands, between samples of different structure. Structure-sensitive reactions studied over different crystalline faces of a solid should also show pronounced reactivity differences, and this will be referred to as crystal face anisotropy.

In recent years there have been a number of attempts to study this topic, with MoO_3 receiving considerable attention. Volta et al., have investigated the oxidation of propylene on oriented crystallites of MoO_3 supported on graphite[9-13] and have concluded that the various faces catalyze different reactions. They correlated small changes in selectivity to the amounts of different exposed crystal faces determined from microphotographs and inferred that for propylene oxidation the (010) basal face produces exclusively carbon oxides, while the (100) and (101) edge faces produce acrolein.[13] The present paper seeks to examine these conclusions and reopen the question of the crystal face anisotropy of the reaction. The investigation is carried out on oriented crystallites of MoO_3, materials similar to the ones used by Volta et al., except that they leave out the support and, therefore, its possible influence.

Tatibouët and Germain have used the same system, unsupported crystallites of MoO_3 preferentially exposing different faces, in the oxidation of methanol[14] and ethanol.[15,16] These investigators concluded that the (010) face carries active centers for the oxidative dehydrogenation of methanol to formaldehyde. Ohuchi et al., have compared the temperature-programmed reaction and desorption of methanol from MoO_3 single crystals and powder.[17,18] These investigators found formaldehyde desorbing from the powder and only methanol desorbing from the (010) face of the single crystal. From this they reached an opposite conclusion from that of Tatibouët and Germain, namely, that the (010) face is inactive for the partial oxidation of methanol. These studies on MoO_3 have inspired theoretical work by Ziólkowski[19] and by Allison and Goddard.[20] The latter propose that the molybdenum dioxo groups found on the (010) plane are particularly effective for the oxidation of methanol, thus supporting the findings of Tatibouët and Germain.

The unit cell of MoO_3 is orthorhombic with lattice parameters a_o=396.28±0.07 pm, b_o=1385.5±0.3 pm, and c_o=369.64±0.06 pm.[21] Figure 1 illustrates the crystal structure. The structure consists of double layers of MoO_6 octahedra held together by covalent forces in the (100) and (001) directions, but by van der Waals forces in the (010) direction. As a consequence, large MoO_3 crystallites have elongated slab-like habits preferentially exposing the (010) direction.

Experimental

Reagent grade MoO_3 powder (Mallinckrodt, 99.95%) was used as received. Propylene (Linde, 99.0%) was purified by passage through a reduced Ni/SiO_2 trap and through a Molecular Sieve 3A trap. Allyl iodide (Aldrich, 98%), high purity ammonia (Linde, 99.995%), oxygen (Linde, 99.99%), nitrogen (Linde, 99.998%), and helium (Linde, 99.995%) were used without further purification.

† Present address: Dept. of Chemical Engineering, Clarkson Univ., Potsdam, New York 13676, U.S.A.

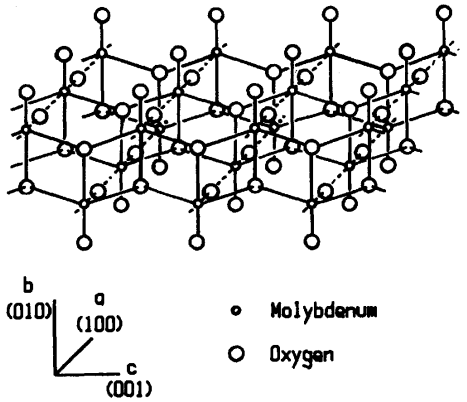

Fig. 1. Structure of orthorhombic MoO_3.
Terminal oxygen atoms extend in the (010) direction, two-fold coordinate oxygen atoms in the (100) direction and three-fold coordinate oxygen atoms in the (001) direction.

X-Ray diffraction patterns were taken with a Norelco 12206/7 spectrometer using Cu Kα radiation. Samples were lightly pressed onto a shallow indentation in an aluminium sample holder to provide a flat 1 cm×1 cm surface. Infrared spectra of the powder were taken with a Perkin Elmer 1330 spectrometer with about 0.1 wt% of the sample pressed in KBr pellets. Laser Raman spectra were obtained with a Cary 81 spectrometer equipped with 90° optics and using the 632.8 nm output of a 50 mW He-Ne laser. Scanning electron micrographs were measured with a JEOL JSM 35 microscope with samples sprayed with a palladium gold coating to prevent charging effects. Surface area and temperature-programmed desorption measurements were carried out in a flow system equipped with a single-filament TC detector (Hewlett-Packard 19302-60530), with samples treated in flowing He at 473 K prior to measurement. Absolute absorbate amounts were obtained by comparing the areas under the desorption peaks to those under standard calibration pulses from a sampling valve. Single-point BET areas were obtained by equilibrating the sample with a 30 mol% N_2 in He stream at liquid nitrogen temperatures followed by flash desorption of the adsorbed nitrogen. Ammonia TPD spectra were obtained by saturating samples held at 273 K with NH_3, purging the samples in the He carrier and then monitoring the desorption peaks as the temperature was raised linearly at 0.17 K s^{-1}. Because of the use of a thermal conductivity detector the possibility of NH_3 oxidation as well as desorption cannot be ruled out. However, the technique was used primarily to show differences between samples.

Reactivity measurements were carried out in two separate reactor systems of almost identical design which could be used in both flow and pulse modes. The only difference between the systems was that for analysis of products one used an on-line gas chromatograph (Hewlett-Packard 5880 GC) whereas the other used an on-line mass spectrometer (Hewlett-Packard 5995 GC-MS). The reactor with the gas chromatograph was used in a flow mode for the propylene oxidation work, whereas the reactor with the mass spectrometer was used primarily in a pulse mode for the allyl iodide oxidation investigations. However, propylene oxidation data taken in one system could readily be reproduced in the other. The gas chromatograph used an octane on Porasil C column and an OV-101 column which were respectively connected to a TC and a FI detector. The mass spectrometer simultaneously monitored the ion masses of all product species. Injections of pulses of N_2 as a standard allowed the calibration of the sensitivity of the mass spectrometer prior to each run and, thus, the quantification of the products of the reaction. For the pulse reaction an average reaction rate was obtained by integrating the concentration of each species through the duration of each pulse (60 s).

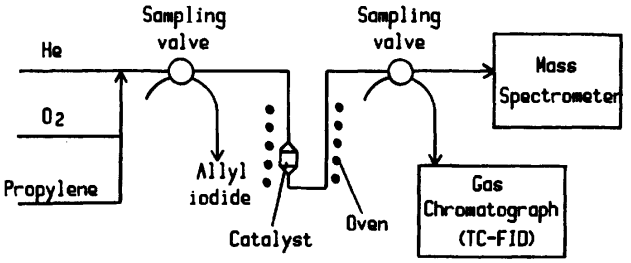

Fig. 2. Schematic diagram of the flow reactor apparatus.

A schematic diagram common to both flow systems is presented in Fig. 2. Electronic mass flow controllers (Brooks 5850) delivered gases in precise proportions. For the allyl iodide experiments a sampling valve injected pulses of He carrier gas containing the vaporized liquid reactant. The catalysts were in packed beds held in Pyrex or 316 stainless steel tubes by either sintered glass frits or packed glass wool. Furnaces surrounded the tubes and heated them. Thermocouples clamped to the outside of the tubes monitored the temperature of the beds. Heated transfer lines led the effluent to the analyzers.

Table 1 summarizes the conditions at which the steady-state propylene oxidation data were obtained. Flow rates are expressed in units of μmol s^{-1} which can be converted to units of cm^3 (NTP) min^{-1} by multiplication by 1.5. The contact time is defined as the bed volume divided by the volumetric flow rate. To compare accurately the reactivity of the needles and powder, quantities of catalyst corresponding to the same total surface area of 0.18 m^2 were employed. Furthermore, since the MoO_3 powder was denser than the needles, the former was diluted with inert, acid-washed ground quartz to achieve equal bed volumes of 2.2 cm^3. Rates are reported as areal rates, i.e., per unit surface area.

The allyl iodide oxidation data were obtained with amounts of catalyst and conditions similar to those employed for the propylene oxidation measurements. The flow rate of the helium and oxygen were 60 and 6 μmol s^{-1}, and the delivery rate of allyl iodide was 0.13 μmol s^{-1}. This delivery rate corresponds to the injection of pulses containing 7.6 μmol of allyl iodide every 60 s.

Neither reactor material nor shape had an influence on the results except at the highest temperatures (>800 K). Above this temperature blank runs with acid washed quartz showed there was some contribution to the reactivity from the reactor or from homogeneous gas phase reactions. All conclusions from this study will be drawn from the lower

temperature, lower conversion region of the data. At all conversions carbon mass balances of 100±5% were obtained.

Results

Synthesis of MoO_3 Single Crystals. Single crystals of MoO_3 were prepared following the method reported by Wanklyn,[22] consisting of vaporizing a MoO_3 powder and condensing the product crystals a short distance away. Approximately 50 g of MoO_3 were loaded in a shallow, covered alumina crucible which was placed in a temperature-controlled oven. Unlike in the work of Wanklyn who used a constant temperature of 993 K, the temperature here was allowed to oscillate between 987 and 997 K. This resulted in the formation of larger crystallites, probably by an Ostwald ripening process.

Different products were obtained depending on the duration of the synthesis. From an initial micrometer-sized powder, hundred-fold larger needle-shaped crystallites could be collected after 40 hours. After 150 hours even larger, centimeter-sized single crystal slabs were formed. In the following sections these materials will be simply referred to as powders, needles, and slabs. Because of the low surface area of the slabs, the catalytic work will concentrate on the powder and needles.

Characterization. Figure 3 shows scanning electron micrographs of the three samples at various magnifications that indicate the variation in external morphology of the powder, needles, and slabs. Table 2 summarizes the physical characteristics of the samples. The size of the crystallites in the samples is estimated without carrying out a statistical analysis. The dimensions are used to roughly calculate the relative proportions of basal and edge planes, as well as the surface areas. The measured surface areas are also reported.

Figure 4 compares the X-ray diffraction patterns of the MoO_3 powders and needles. The MoO_3 powder displays a pattern characteristic of randomly oriented crystallites. The needles, however, exhibit a pattern

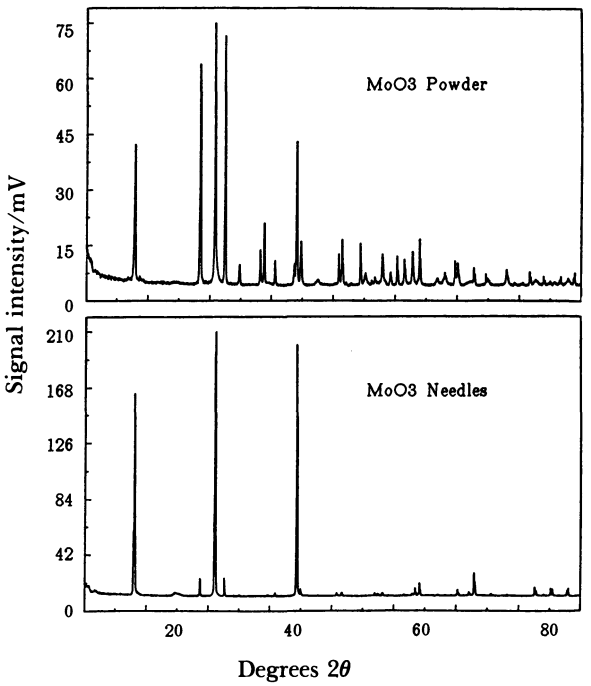

Fig. 4. X-Ray diffraction patterns of MoO_3 samples. Top, MoO_3 powder. Bottom, MoO_3 needles.

with strong intensity in the (020) family of reflections.

Figure 5 shows the transmission infrared and Raman spectra of molybdenum trioxide powder taken at room temperature. It is interesting to note the much greater resolution of the Raman spectra. This is generally observed with oxides.

Figure 6 reports the temperature-programmed desorption (TPD) profiles of ammonia from the needles and powder. The needles had a single desorption peak at 330 K whereas the powder had two desorption peaks at 320 and 430 K. Integration of the areas under the desorption peaks allowed the calculation of the surface number density of ammonia molecules absorbed. These values were 4.0×10^{19} m^{-2} for the needles and 6.7×10^{19} m^{-2} for the powder.

Reactivity Results. Figures 7 and 8 present the

propylene oxidation data for the needles and powder at various oxygen partial pressures. The only products that were detected were acrolein and carbon dioxide. For both catalysts the rate of carbon dioxide production per unit surface area was similar. As the temperature was raised, this rate increased to a plateau and then slowly decreased. The rate in the region of the plateau varied with the first order of the oxygen

partial pressure, $v_{CO_2}=kP_{O_2}^{1.0}$.

The data for the rate of acrolein production in Figs. 7 and 8 are presented in Arrhenius form in Fig. 9. The rate was independent of oxygen partial pressure, $v_{ACR}=kP_{O_2}^{0}$, and was uniformly higher by a factor of about 2 on the powder than on the needles. The apparent activation energy, E_{APP}, was the same for both samples within experimental error (±2 kJ mol^{-1}), 43 kJ mol^{-1} for the powder and 42 kJ mol^{-1} for the needles.

The allyl iodide oxidation data taken in a pulse mode are presented in Figs. 10 and 11. The oxidation produced a number of products, acrolein, benzene, carbon dioxide, acrylic acid and propylene. The behavior of the needles and the powder was very similar, although at higher conversions the needles produced more acrolein than the powder (0.21 vs. 0.16 μmol m^{-2} s^{-1}).

Discussion

Structure of the Catalysts. Transmission infrared spectroscopy and laser Raman spectroscopy characterize the bulk of the MoO_3 crystallites; scanning electron microscopy and X-ray diffraction reveal the external macroscopic morphology and orientation; and TPD of ammonia gives information about their surface.

The scanning electron micrographs of the MoO_3 powder and needles show that the samples have different morphologies. The powder consists of small crystallites with little tendency to expose a preferred orientation. The needles consist of larger crystallites with a substantial proportion of flat faces. The X-ray

diffraction pattern of the needles shows that the flat faces are those perpendicular to the (010) direction. The high intensity of the diffraction peaks in that direction are due to preferential orientation of the flat crystallites in the plane of the sample holder.

The surface areas of the materials was calculated from the average size of the crystallites obtained from the scanning electron micrographs. This was done by first calculating the number of such crystallites in one gram using the bulk density of MoO_3 (4.692 g cm^{-3}), and then calculating the corresponding geometric area of the crystallites using their known dimensions. This gave calculated surface areas for the powder and needles of 0.72 and 0.047 $m^2 g^{-1}$. These are in reasonable agreement with the measured values of 0.81 and 0.080 $m^2 g^{-1}$. The lower calculated value for the needles is probably due to underestimating the number of smaller crystallites.

The TPD spectra of ammonia provide direct evidence that the surfaces of the samples are significantly different and that, hence, the samples are appropriate for investigating crystal face anisotropy. The needles show a single desorption feature at 330 K, whereas the powder shows a similar feature at 320 K and a broad desorption peak centered at 430 K. The peak at 320—330 K in both samples is probably due to desorption of ammonia from the basal (010) planes. For the powder the broad peak at 430 K is probably due to the presence of a substantial proportion of other planes, as was shown by the scanning electron micrographs. The surface number density of adsorbed ammonia was 4.0×10^{19} m^{-2} for the needles and 6.7×10^{19} m^{-2} for the powder. The number density of exposed surface molybdenum atoms on the low index planes of MoO_3 are 7.81×10^{18} m^{-2} for the (100) plane, 6.83×10^{18} m^{-2} for the (010) plane and 7.28×10^{18} m^{-2} for the (001) plane. Because of the MoO_3 stoichiometry the total surface atom density, including oxygen atoms, will be roughly four times the above values. Thus, the quantity of adsorbed ammonia corresponds approximately to a monolayer.

General Aspects of the Allylic Oxidation of Propylene. There are two features of the selective oxidation of propylene on molybdate catalysts that are generally accepted. The first feature is that the rate-determining step in the reaction is the abstraction of an allylic hydrogen atom to form an adsorbed allyl radical.[23-27] This will be discussed in more detail below. The second feature is that the oxygen species responsible for selective oxygenation is lattice oxygen.[26-29] Absorbed oxygen species, especially those that are electrophilic in nature (O_2^-, O_2^{2-}, O^{2-}), are thought to be responsible for complete oxidation.[30,31]

Our results for the propylene oxidation reaction agree with the above view. The lack of dependence of acrolein formation on oxygen partial pressure is consistent with the participation of lattice oxygen in the reaction. Similarly, the dependence of carbon dioxide formation on oxygen partial pressure is consistent with the reaction of propylene or some propylene-derived species with absorbed oxygen. Indeed, it is precisely in the region where CO_2 is observed, 700—900 K, that $^{16}O_2$–$^{18}O_2$ exchange, and thus probably chemisorption, on MoO_3 is found to begin.[32,33] The observation in this study of a decrease in the rate of formation of CO_2 in the region of the plateau can be explained by the expected decrease in the amount of chemisorbed oxygen as the temperature increases.

Molybdenum trioxide is generally described as a selective but inactive catalyst for propylene oxidation. In this study the low selectivity obtained is probably due to the high temperatures employed. The activation energy obtained for the production of acrolein, close to 43 kJ mol^{-1}, is low. This is understandable as the value is an apparent activation energy that includes contributions from a number of reactions, including the further oxidation of acrolein.

Allyl Iodide Oxidation. The results obtained in this study for the oxidation of allyl iodide are similar to those found in previous examinations of the reaction by the group of Haber[34] and by Burrington and Grasselli.[35] In the present work, however, provision was taken to cofeed oxygen so as to maintain the surface of the catalyst oxidized. In molybdenum trioxide alteration of the structure on reduction occurs by a crystallographic shear mechanism[36,37] in which corner-sharing octahedra become

edge sharing by the loss of an oxygen atom. This is characterized by the formation of striations in the crystals. In this study, X-ray diffraction patterns of the used catalysts revealed no evidence for this phenomenon. The catalysts did exhibit a purple colored discoloration, probably from deposition of iodine. There was no change in activity as the catalysts were taken to high temperature and then brought down.

The selectivity results obtained here agree well with those in the work cited above (Table 4). In those investigations, conducted mainly at 593 K in the absence of oxygen, the main product was acrolein, with side products consisting of propylene, and traces of acrylic acid, acetaldehyde, 1,5-hexadiene and phenol. In this study the last three products were not observed, probably due to their further oxidation in the presence of oxygen. At higher temperatures substantial amounts of benzene were obtained. The observed product distribution at these temperatures are unlikely to be due to gas-phase free-radical reactions because of the absence of the characteristic products, propylene oxide and acetaldehyde.[38] In this study a lower conversion of propylene was obtained than in the previous work. At 593 K the conversion was 7% as opposed to 100% for the other measurements. This is probably due to the use of a significantly lesser quantity of catalyst than previously. This work used a total of 0.18 m^2, whereas the other studies used 5.3 m^2 and 8 m^2.

Burrington and Grasselli have indicated that allyl iodide does not produce free allyl radicals as suggested by the group of Haber. Rather they propose that allyl iodide adsorbs on MoO_3 prior to reaction. Whatever the mechanism, the crucial observation is that allyl iodide reacts much more readily than propylene by bypassing the difficult hydrogen atom abstraction step. An intermediate resembling adsorbed allyl radical is likely.

Crystal Face Specificity of Propylene Oxidation on MoO_3. Figure 9 reports the rate of acrolein formation on unsupported MoO_3 needles and powder. Table 3 takes part of this data at low temperature and compares it to findings obtained on a similar system, oriented MoO_3 crystallites supported on graphite.[10,11] The results in both studies are very similar, the selectivity to acrolein is higher on the non-oriented samples by a factor of about two. On the basis of this selectivity difference and a statistical analysis of exposed planes, Volta et al., concluded that the various planes of MoO_3 catalyze different reactions.[13]

A similar analysis can be made here using the estimated average dimensions of the powder and needle crystallites. From these dimensions it can be calculated that there is approximately four times more edge plane surface area on the powder than on the needles (Table 2). If these are the planes solely responsible for acrolein formation, as Volta et al., suggest, the results here are in qualitative agreement with this suggestion. This study finds that the powder is twice as selective as the needles in the oxidation of propylene, and the approximate factor of four can account for this. However, noting that it is difficult to accurately measure the quantity of exposed planes by electron microscopy and, furthermore, recognizing that the differences between samples is exceedingly small, we defer here the question of determining crystal face specificity by this type of analysis until a more definitive study is undertaken.

The low selectivity to the product of interest in propylene oxidation (<ca. 10%) raises the question of whether a possible greater crystal face specificity is erased by the combination of the high temperatures employed and the presence of the unselective total oxidation reaction. For this reason it is desirable to examine the behavior of more reactive probe molecules. Table 5 reports the results obtained in the allylic oxidation of a number of propylene analogues on oriented and unoriented samples of MoO_3. There is a notable trend of increasing overall selectivity toward allylic oxidation products as the allylic bond strength decreases. In addition, in comparing the basal and edge oriented samples, there is less

Table 5. Allylic Oxidation of Propylene Analogues

Molecule	Bond energy / kJ mol^{-1}	Selectivity/% Basal sample	Selectivity/% Edge sample	Selectivity ratio	Ref.
CH_2=CH-CH_2-H Propylene	361[39]	3	6	2	This work
CH_2=CH-CH(CH_3)-H 1-Butene	345[39]	9	12	1.3	Ref. 13[a,b]
CH_2=C(CH_3)-CH_2-H Isobutene	322[40]	27	36	1.3	Ref. 13[a,c]
CH_2=CH-CH_2-I Allyl iodide	184[41]	99	99	1	This work

a) Basal sample=85% (010) plane, 15% edge planes. b) Edge sample=55% (010) plane, 45% edge planes. c) Edge sample=61% (010) plane, 39% edge planes.

variability in the selectivities as the bond strength decreases. For propylene, 1-butene, isobutene, and allyl iodide oxidation the selectivities change by factors of only 2, 1.3, 1.3, and 1, respectively. This is understandable as those molecules whose allylic positions are easier to activate are expected to show lesser sensibility to the structure of the surface. Factors like the above are small in catalysis, and they suggest that allylic oxidation on MoO_3 is only slightly sensitive to the structure of the surface. However, the differences are reproducible[10,11] and do demonstrate trends, indicating a variability of the rate with the structure of the surface. Thus, we must recognize here a contribution of the structure to the reactivity, even though it is outside the confines of a range of variation of rate characteristic of structure-sensitive reactions.

Conclusion

Oriented crystallites of MoO_3 in the shape of needles and a random powder were used to investigate the partial oxidation of propylene and allyl iodide. Only a small difference in reactivity of both materials in propylene oxidation is observed, indicating that the reaction depends only slightly on the structure of the MoO_3.

The author thanks Dr. Leo Volpe for taking the scanning electron micrographs, Prof. Richard W. Gaver for the usage of the Cary 81 Raman spectrometer, Prof. Michel Boudart for extensive discussions, and Catalytica for permission to publish this work.

Conductance Study of Alkali Metal Chlorides and Ammonium Chloride in 1,2-Dimethoxyethane-Water Mixtures at 25 °C

P. V. S. S. PRABHU*,† and M. V. RAMANAMURTI
Department of Chemistry, Faculty of Science, Banaras Hindu University, Varanasi-221005, India
(Received September 21, 1987)

Conductance data for alkali metal chlorides and ammonium chloride in 1,2-dimethoxyethane (DME)-water mixtures (14.00<dielectric constant<56.76) at 25 °C are reported in the concentration range 0.0001—0.06 mol·dm^{-3}. The data have been analyzed by Fuoss (1978) conductance-concentration relation. Preferential solvation of cations by water does not show systematic trend depending on the cationic size. Walden product variations indicated the complex dependence of conductance of alkali metal cations on solvent sorting and structural effects. The energy (E_s) values suggest that alkali metal cations and chloride ions in majority exist as contact pairs in these solutions.

A series of investigations[1-6] on the influence of solvent structure on limiting ionic mobilities of alkali metal cations and halide ions in water-organic solvent mixtures have been carried out in the recent past. Of these the most important contributions are by Kay et al.[1-3] and also Petrella et al.[4-6] In their studies the ionic Walden products have been analyzed in terms of the short range ion-solvent interactions. For cations (alkali metal) and anions (halide) they found that the curves for W_p (designated by us), the ratio of the limiting Walden product for the mixture to that of water, show maxima in water-rich regions where the long range order of water is increased by the addition of organic solvent. However, for anions the W_p values are less than unity in solvent mixtures where structure breaking occurs. Also a systematic decrease of W_p value with the increase in cationic or anionic sizes was observed irrespective of the type of change induced by the cosolvent on water structure. With the objective to examine how far these observations could be reproducible for alkali metal chlorides and ammonium chloride in 1,2-dimethoxyethane (DME)-water mixtures analogous conductance studies have been undertaken. DME is a dipolar aprotic solvent and weakly interacts with anions.[7] The electrolytes in the present study have chloride (Cl^-) as the common anion so that the variations observed in Walden products are considered to be mainly due to the alkali metal cations only. This paper, therefore, deals with the conductance study of LiCl, NaCl, KCl, RbCl, CsCl, and NH_4Cl in 1,2-dimethoxyethane-water mixtures at 25 °C.

Experimental

Conductivity water (κ=0.2—0.5×10^{-6} mho cm^{-1}) was prepared by distillation of double distilled water in the presence of $KMnO_4$ in an all Pyrex glass set.

1,2-Dimethoxyethane (Riedel-De-Haenag) was kept two days over KOH and then refluxed for 24 h. This was distilled over sodium and refluxed again for 24 h. Then the sample was distilled and middle fraction was directly used for measurements.[8]

Lithium chloride (AR), sodium chloride (AR, BDH), rubidium chloride (E. Merck), cesium chloride (E. Merck), and ammonium chloride (AR, BDH) were recrystallized twice from conductivity water and dried in a vacuum desiccator. Potassium chloride (AR, BDH) was recrystallized as suggested by Hawes and Kay.[9]

Results and Discussion

The physical properties, density (ρ), viscosity (η) and dielectric constant (D) of DME-water mixtures are given in Table 1. The molar conductance values Λ (S·cm^2·mol^{-1}) as a function of concentration C (mol·dm^{-3}) in six compositions of DME-water mixtures at 25 °C are shown in Table 2. Conductance data in the present investigation are analyzed by the Fuoss conductance-concentration relation.[10] The use of any other equation or incorporation of slight modification[11] may introduce small changes in the individual fitting parameters but will not alter the overall conclusions which can be deduced from trends in these parameters. For a set of conductance data (C_j, Λ_j; J=1, N) the three adjustable parameters (Λ_o, K_Λ, and R) are derived from the following three equations:

$$\Lambda = p[\Lambda_o(1 + \Delta X/X) + \Delta\Lambda_e] \quad (1)$$

$$\gamma = 1 - K_\Lambda C \gamma^2 f^2 \quad (2)$$

Table 1. Physical Properties of the Solvent Mixtures (DME-Water) at 25 °C

$$\ln f = -\beta\kappa/2(1 + \kappa R) \quad (3)$$

Here $\Delta X/X$ and $\Delta\Lambda_e$ are the relaxation and electrophoretic terms respectively and expressions used for these terms are the same as these used by Fuoss.[10] The detailed method of analysis of the data has been described earlier.[12] Various parameters thus derived from the conductance data are assembled in Table 3. Limiting molar conductance values obtained in our present investigation for all the electrolytes, viz., chlorides of Li, Na, K, Rb, Cs, and NH_4 in water at 25 °C are in agreement with the reported values.[13–17] Also the Λ_o values for CsCl in DME–water mixtures obtained in present work are in good agreement with the already reported values.[18] These facts substantiate the accuracy of our experimental results and the computational procedures.

The limiting molar conductance variations as well as the viscosity variation with the mole fraction of DME are depicted in the Fig. 1. DME has been characterized as a structure promoter in water rich mixtures through viscosity studies.[19] On structural characteristics of DME–water mixtures no further information is available in the literature. A decrease in limiting molar conductance for each electrolyte with a corresponding increase in viscosity of the solvent mixtures has been observed both in the water rich and DME rich mixtures. The maximum viscosity and the minimum in the limiting molar conductance ($\Lambda_{o_{min}}$) of any electrolyte does not occur at the same mole fraction of DME and also $\Lambda_{o_{min}}$ is shifted towards the DME rich region. This is because of the pre-

Table 3. Derived Conductance Parameters

Mole fraction of DME	$\Lambda_o \pm \Delta\Lambda_o$	K_A	K_R	K_S	R	σ%	$\Lambda_o \cdot \eta$	E_s/kT
	$S \cdot cm^2\ mol^{-1}$				Å		$\Omega^{-1}\ cm \cdot mol^{-1}P$	J^{-1}

ferential solvation of cations (Cl^- common anion) by water as DME is less polar than water. The shift in $\Lambda_{o_{min}}$ towards the DME rich region may be due to gradual replacement of water molecules by DME molecules in the cationic shells as a result of breakdown of the water polymeric structure at higher concentrations of DME.

The Walden product ($\Lambda_o \cdot \eta$) maximum is observed around 0.1 mole fraction of DME (Fig. 2) for all the alkali metal cations and ammonium ion (Cl^- being the common anion). This behavior of alkali metal cations is similar to that observed by Kay et al., for the

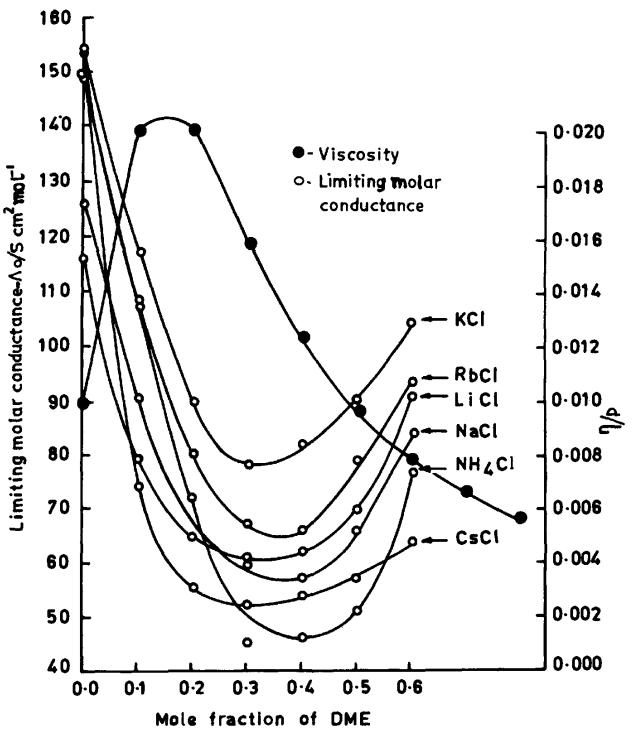

Fig. 1. Variation of viscosity (η) and limiting molar conductances (Λ_o) of alkali metal chlorides and ammonium chloride with mole fraction of DME in water.

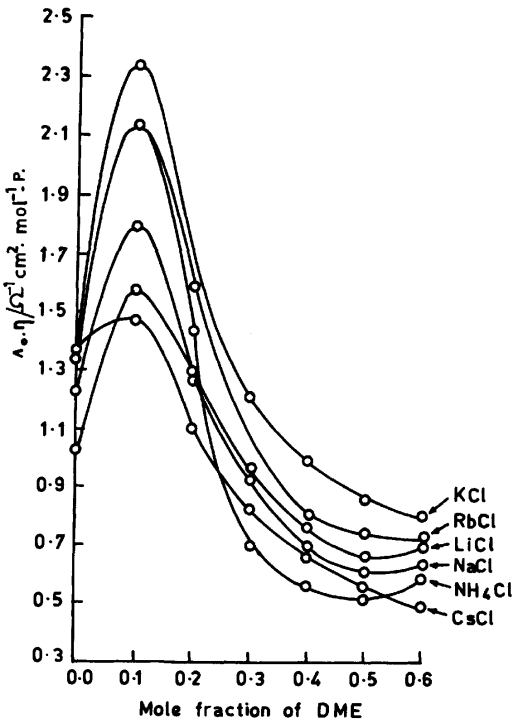

Fig. 2. Variation of Walden products ($\Lambda_o \cdot \eta$) of alkali metal chlorides and ammonium chloride with respect to mole fraction of DME in water.

same ions in other aqueous binary mixtures of the solvents dioxane,[1] ethanol,[2] and *t*-butyl alcohol.[3] Petrella et al. have also observed similar Walden product maxima for alkali metal cations and halide ions in sulfolane-water,[4] acetonitrile-water,[5] and dimethyl sulfoxide-water[6] mixtures. They have explained the existence of maximum on the basis of Kay's "solvent sorting model".[2] Several other significant reasons[20-22] were also suggested for this variation, and their mathematical treatments[23-30] also have been given by different workers from time to time. The most recent model proposed by Nakahara et al.[30] demonstrates the superiority of residual friction coefficient ($\Delta\zeta$) over the Walden product to explain long range interactions in the case of smaller ions. However, due to the lack of experimental data on intermediate frequency dielectric constants (ε_c) and infinite frequency dielectric constants (ε_∞) for these electrolyte solutions of DME-water mixtures it would not be possible to follow the method of Nakahara. Alternatively, the Walden product maximum observed in the present study has been explained by Kay's model.

In water-DME mixtures the ion water interactions are stronger than ion DME interactions, and therefore in the ionic cosphere there is a higher percentage of water than in the bulk mixture. Due to preferential solvation of these ions by water in this region of the solvent mixtures, viscosity of the solvent in the vicinity of these ions is lower than that of the bulk solvent. Since the bulk viscosity value is used in the calculation of Walden product, the calculated values of $\Lambda_o \cdot \eta$ are too high up to the point corresponding to the viscosity maximum after which they are low, and therefore a maximum in Walden product occurs. The bulk viscosity of DME - water mixtures also goes through a maximum and since the alkali metal cations as well as ammonium ion have water-rich solvation shells in dilute DME - water mixtures, the observed behavior of these ions is consistent with Kay's model.

However, the height of the Walden product maximum relative to that in pure water (designated as W_p), does not show systematic dependence on the cationic size in the present results (Fig. 2). This is in contrast to the earlier observations.[1-6] The observed order of variation of W_p value, i.e.

$$W_p(Cs^+) < W_p(Li^+) < W_p(Na^+) < W_p(Rb^+) \approx W_p(NH_4^+) < W_p(K^+),$$

cannot be explained on the basis of sorting mechanism alone. Petrella et al.[3-6] have shown that alkali metal cations are sensitive to sorting effect and halide ions are influenced by structural effects. Parker et al.[31] have however concluded through their analogous conductance studies that the behavior of ions (cations and anions) is quite complex and may be influenced by a combination of such factors as solvent

sorting and structural changes due to the solvent mixing. Therefore, a plausible explanation may be given as follows for the observed order of variation of W_p value. Let us first consider the Li^+ and Cs^+ ions. As the sorting effect will be more accentuated in the case of smaller ions the order $W_p(Li^+)>W_p(Cs^+)$ is consistent with the sorting model. However, in the case of Na^+ and K^+ ions the order $W_p(K^+)>W_p(Na^+)$ is not in agreement with this model. Na^+ and K^+ ions behave as structure breakers in water. As DME-water mixtures are more structured than water, Na^+ and K^+ may behave as better structure breakers in the mixtures than in water. The largest ion will show the greatest increase and hence the order observed for Na^+ and K^+ ions. In the case of NH_4^+ and Rb^+ the magnitudes of heights of Walden product maxima are equal, which suggests that the contribution of structure breaking effect of these two ions of equal size is the same in these solutions. These results indicate that alkali metal cations are not only sensitive to sorting effect but also influenced by structural effects.

Association constant values (K_A) for all the electrolytes given in Table 3 are greater than 10 indicating significant association in DME-water mixtures. This pairing constant (K_A) is the product of two terms,[10] one (K_R) of which depends explicitly on dielectric constant of the solvent. While the other (K_S) is system-specific depending on short-range ion-ion and ion-solvent interactions. The relationship is represented as,

$$K_A = K_R(1 + K_S). \tag{4}$$

Where

$$K_R = \frac{4\pi N \cdot R^3}{3000} \exp(e^2/RDkT), \tag{5}$$

and

$$K_S = \frac{\alpha}{1-\alpha} = \exp(-E_s/k \cdot T) = \exp(-\varepsilon). \tag{6}$$

N is Avogadro's number, e is electronic charge, k is Boltzmann's constant, D is dielectric constant, R is cosphere (Gurney) diameter, and T is absolute temperature. The plot of $\log K_R$ vs. $1/D$ is therefore expected to show linear variation (Fig. 3) in the present study. But the variation of E_s/kT vs. $1/D$ will not be linear (Fig. 4) as K_S depends on specific ion-solvent interactions.[32] If α is the time average fraction of diffusion pairs (for which $a \leqslant r \leqslant R$) which are in contact, the equilibrium between solvent separated pairs and contact pairs is described[32] by Eq. 6, where E_s is the difference in free energy between states defined as $r=R$ and $r=a$. The magnitude of E_s may give an insight into the mechanism of process of ionic association in these solutions. The values of K_R, K_S, and E_s are shown in Table 3 for all the electrolytes in DME-water mixtures. A remarkable decrease in E_s values from pure water to those of mixtures for all the electrolytes is observed (Fig. 4). Also there is no systematic decrease in these values with the increase in content of DME in the mixtures. This pattern of behavior of E_s becoming less positive as polarizability of the solvent decreases was observed in other systems[32] also. This suggests the predominance of

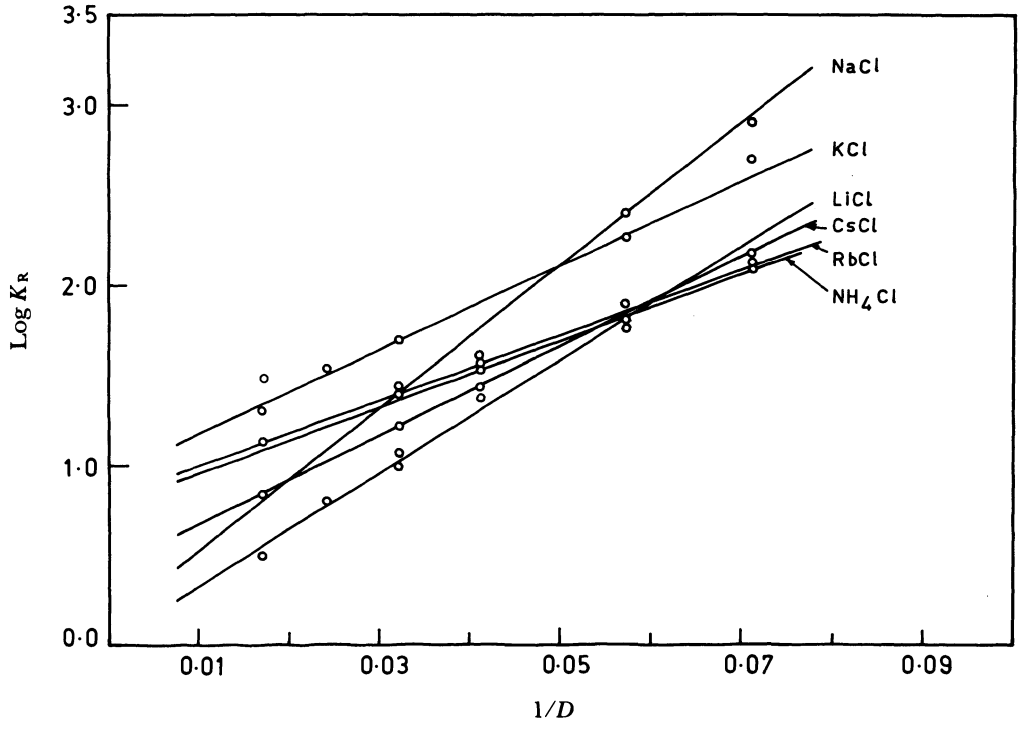

Fig. 3. Plot of $\log K_R$ vs. $1/D$.

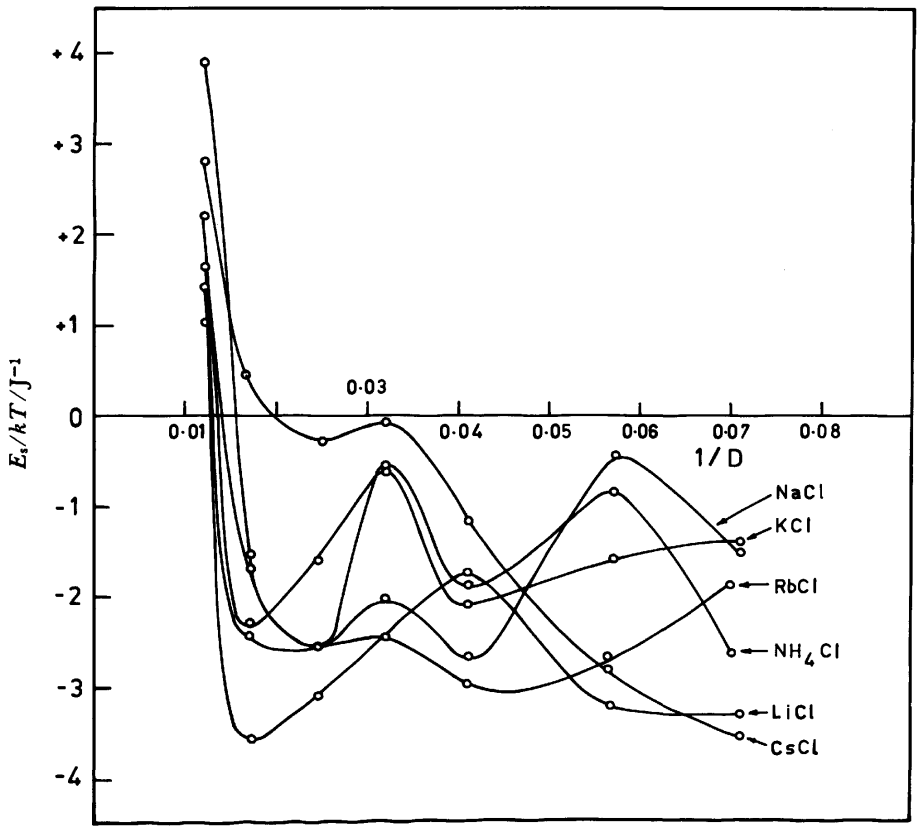

Fig. 4. Variation of E_s/kT with the reciprocal of dielectric constant ($1/D$).

electrostatic effect in the E_s and indicate formation of more contact ion pairs. Even though there is every possibility for the formation of solvent separated ion pairs through the donor-acceptor type of interaction[33-37] in these electrolyte solutions, as there are two bonding oxygen sites available in DME, the trend of the variation in E_s values suggests that alkali metal cations and chloride ions in majority exist as contact pairs. This may be due to the less polarizability of DME which allows the interionic attraction to become greater in these solutions. However, the variations of E_s/kT vs. $1/D$ are not systematic (Fig. 4) because of the competition between the donor-acceptor interactions and electrostatic interactions.

Electrical Conductance of a Mixture of Sodium and Potassium Thiocyanates in Aqueous Medium at 25 °C

Ratan Lal GUPTA and Kochi ISMAIL*
Department of Chemistry, North-Eastern Hill University,

(Received September 28, 1987)

Electrical conductance measurements of $[x\mathrm{NaSCN}+(1-x)\mathrm{KSCN}]+R\mathrm{H_2O}$ system were made as functions of x and R at 25 °C. The mixed alkali effect was found to be negligible when $R>10$ and it increased sharply with increase in concentration in the range $R\leqslant 10$. The concentration dependence of molar conductance (Λ) has been described satisfactorily by the expression, $\Lambda=\Lambda_{FH}\exp(Bm+Cm^2)$ where Λ_{FH} is the Falkenhagen-Leist-Kelbg equation for Λ, m is the molality and the parameters B and C are the empirical constants.

In a glassy or molten medium containing mixed alkali ions deviations from additivity are observed in isotherms of various physical properties as a function of composition which is varied by progressively replacing one alkali ion by another.[1,2] This phenomenon is termed as the mixed alkali effect (MAE) and it is most pronounced for properties related to ionic transport. For instance, in glasses of constant alkali content the electrical conductivity of mixed glasses can be reduced by a factor of about 10^4 or 10^5 in comparison with the conductivity of single alkali glasses measured at the same temperature.[3] According to Ingram et al.[4] such large departures from additivity indicate a major breakdown of the principle of independent migration of ions which works well for dilute aqueous electrolytes.

Recently attempts have been made to look for MAE in media other than glassy or molten media. Aqueous medium is one of such suitable medium. There are some very old reports on the conductivities of mixed aqueous electrolytes containing alkali halides and nitrates.[5] In recent years only one report is made on the study of MAE in aqueous medium.[4] One of the characteristics of MAE is that it shows a complicated dependence on the total alkali ion concentration.[6] With a view to understanding better the dependence of MAE on the total alkali ion concentration we have made in the present study measurement of electrical conductance of a mixture of NaSCN and KSCN in aqueous medium with varying amounts of water.

Experimental

Molal solutions were prepared using recrystallized NaSCN (SD, R grade) and KSCN (SD, R grade). Before using these salts they were dried for several days over $CaCl_2$ in vacuum desiccator. Conductivity measurements were made using the CDM83 conductivity meter (Radiometer, Copenhagen) and a dip-type CDC304 conductivity cell. The instrument was calibrated by adjusting the cell constant knob of the instrument till the specific conductance value of the reference solution (0.1 M KCl (1 M=1 mol dm^{-3})) was displayed. For measuring density a calibrated glass pycnometer was used. All measurements were made in a thermostated (±0.02 °C) water bath.

Results and Discussion

The experimental values of molar conductance (Λ) at 25 °C of $[x\ \mathrm{NaSCN}+(1-x)\ \mathrm{KSCN}]+R\mathrm{H_2O}$ system as functions of x and R are presented in Table 1. The molar concentrations (c) of these solutions are also evaluated using the measured density values and are included in Table 1. The present values of Λ of NaSCN and KSCN solutions are found to be in good agreement with the reported data[7,8] as apparent from Fig. 1. In the case of KSCN solution since the literature values of Λ at 25 °C were not readily available, the comparison of the experimental and reported data[8] was made at 20 °C. The measured values of conductance were found to be reproducible within ±0.75% accuracy.

Variation of Λ with x. The variation of Λ with x at different R values is shown in Fig. 2. Λ tends to deviate more and more from additivity as R decreases. The non-additivity in Λ are represented here in terms of r-factor defined as $r=[x\Lambda_1+(1-x)\Lambda_2]/\Lambda$, where Λ_1 is

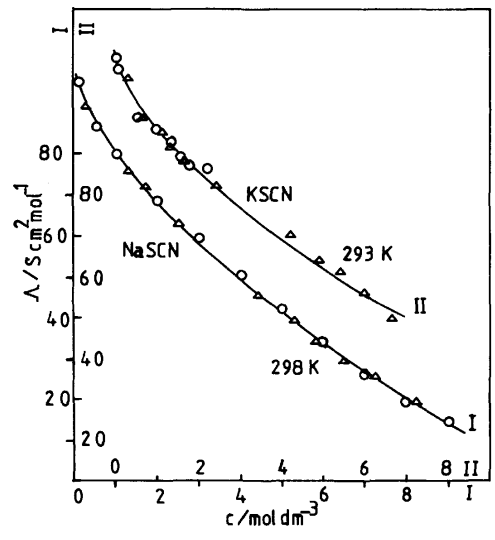

Fig. 1. Plots of Λ vs. molar concentration for NaSCN and KSCN solutions (Δ-experimental, O-reported).

Molar concentration data are within the parentheses.

the molar conductance of NaSCN solution and Λ_2 that of KSCN solution. The dependence of r on concentration is illustrated in Fig. 3 for x=0.5. r varies negligibly upto a particular concentration and thereafter increases sharply with increasing concentration. Similar trend in the variation of r-factor with R is found at other x values also. Such a dependence of r on R therefore clearly indicates that the MAE is dependent on the total alkali ion concentration. For the system under study the value of r appears to increase sharply above ca. 10R (ca. 5.6 m) concentration. It is interesting to note that this concentration falls in the range where the specific conductance of NaSCN solution becomes maximum. Moreover, in this concentration range the viscosity of NaSCN solution starts increasing exponentially with concentration.[7,9] Every electrolytic solution exhibits a particular concentration range of this type and it is identified as the region where a transition from primitive structure to quasi-crystalline structure takes

place.[10,11] For KSCN solution such a concentration range of structural transition falls around ca. 6R (ca. 9.2 m). In a mixed electrolyte containing NaSCN and KSCN a quasi-crystalline type structure may therefore be considered to start appearing from ca. 10R and the extent of quasi-crystallinity keeps on increasing beyond this concentration. Therefore in aqueous medium the MAE seems to become significant when the solution attains a quasi-crystalline type structure. This inference is in accordance with the empirical fact that the MAE is much prominant in the glassy media having very rigid-like structure. In the present system of interest the MAE observed for the highest concentration (=4R) studied is about 8.6%, i.e., the percentage of deviation of Λ from additivity.

The dependence of r-factor or MAE on concentration may be explained in terms of the anion polarization model.[12,13] According to this model, the MAE is due to the asymmetry created in the electrical field around the thiocyanate ion owing to its competitive polarization by the unlike cations. Such a competitive polarization can cause significant MAE only when the ionic concentration is large enough. Moreover, the effect of competitive polarization is expected to be maximum when the two cations are in equal concentration. This is, in fact, observed as evident from the plot (Fig. 3) of r vs. x which passes through a maximum in the range x=ca. 0.5.

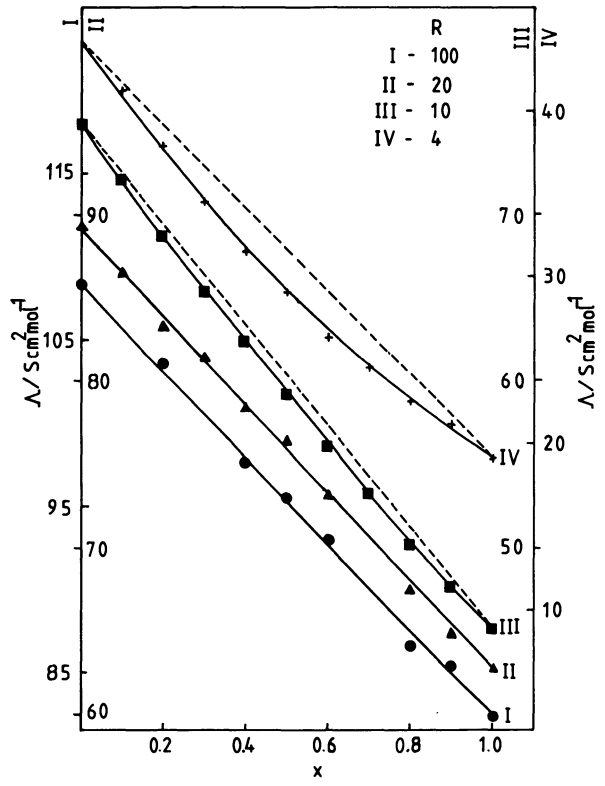

Fig. 2. Variation of Λ of [x NaSCN+(1−x)KSCN]+ RH$_2$O system with x at different R values.

Variation of Λ with R. A successful theoretical expression is not available to describe the concentration dependence of Λ in the higher concentration range. Recently we have reported[11] an expression of the form

$$\Lambda = A\exp(Bm + Cm^2) \quad (1)$$

for describing the conductance of aqueous electrolytes upto very high concentrations. In Eq. 1 A, B, and C are adjustable parameters. This equation was shown to be obtainable from the Adam-Gibbs configurational entropy model.[14] However, Eq. 1 was found to be only partly successful in describing the conductance data of concentrated aqueous solutions. The incomplete success of Eq. 1 was attributed to the fact that this expression accounts only for the short-range interactions in the solution. An attempt has been made here to improve Eq. 1 by accounting for the long-range interactions. This is achieved by substituting Λ_{FH} term for Λ where Λ_{FH} refers to the Falkenhagen-Leist-Kelbg[15] equation for Λ and is of the form

$$\Lambda_{FH} = (\Lambda_o - \frac{B_1c^{1/2}}{1 + B_oa_oc^{1/2}})(1 - \frac{B_2c^{1/2}F}{1 + B_oa_oc^{1/2}}) \quad (2)$$

B_1=82.501/$\eta_o(DT)^{1/2}$, B_2=82.04×10^4/$(DT)^{3/2}$, B_o=50.29/$(DT)^{1/2}$, and F=(exp(0.2929B_oa_o)−1)/0.2929B_oa_o. Λ_o is the equivalent conductance of the solution at infinite dilution, η_o is the vicosity of water, D is the dielectric constant of water, and T is the absolute temperature. a_o is a term which accounts for the finite size of the ions and is known as the ion-size parameter. The conductance data of the system under study were therefore least squares fitted to the equation

$$\Lambda = \Lambda_{FH}\exp(Bm + Cm^2). \quad (3)$$

For least-squares fitting the conductance data to Eq. 3,

a) Literature value. b) Estimated values using additivity principle.

we have chosen in the case of solutions with $x=0$ and $x=1$ the reported values of Λ_o and for compositions with x values other than 0 or 1 the Λ_o values are estimated using the additivity principle. Therefore Eq. 3 becomes an expression with three adjustable parameters. The best-fit values of a_o, B, and C corresponding to the lowest standard deviations were computed and are given in Table 2.

The value of a_o=5.27 Å for NaSCN solution is comparable with the value 5.5 Å reported for this solution by Janz et al.[7] The higher value for a_o= 5.78 Å of KSCN is expected due to the larger ionic size of the K^+ ion. For the mixed electrolyte, however, no regular trend in the variation of a_o with x has been observed. It may be pointed out as suggested by others[17] also that a_o behaves more like an adjustable parameter than a physically significant parameter.

The value of B appears to decrease with increasing x. A comparison of Eq. 3 with the Wishaw-Stokes[18] equation reveals that the exponential part of Eq. 3 is related to the viscosity of the solution. Accordingly, a decrease in the value of B with increasing x appears to be due to the increasing viscosity of the solution as the content of NaSCN increases. We also made an attempt to estimate the viscosity of NaSCN solution at different concentrations by equating $\exp(Bm+Cm^2)$ to the reciprocal of the relative viscosity. The viscosity of NaSCN solution estimated in this fashion was found to be in agreement with the experimental values[7] only at lower concentrations. This envisages that the Wishaw-Stokes equation[18] can describe the conductance data only at concentrations where the relative viscosity is low.[19] Furthermore, it may be seen that Eq. 3 reduces to the form of Postler equation[20] at low concentrations.

We acknowledge the financial support received from the Council of Scientific & Industrial Research (New Delhi) to carry out this work.

Molecular Orbital Treatment of Some Amino Acids

R. Abu-Eittah,*,† A. Obaid, S. Basahl, and E. Diefallah
Department of Chemistry, Faculty of Science, King Abdulaziz University, Jeddah, Saudi Arabia
(Received October 14, 1987)

INDO-molecular orbital calculations have been performed on a number of amino acids, namely, alanine, phenylalanine, some tyrosines and histidine. Computations on *N*-acetylhistidine are included for comparison. The results obtained for the charge densities and dipole moments were used to get a "structure-function" correlation.

Proteins perform virtually all types of work in an organism. The standard amino acids, constituting proteins, differ only with respect to their side chain. Each side chain is so specific that it cannot be replaced by another one.

Several CNDO/2 calculations predict that the neutral form of glycine is more stable than the ionic form.[1-3] Conformational analysis performed with CNDO/2[4-7] and INDO[8] as well as the corresponding ab initio calculations,[9-11] reveals a number of interesting results. CNDO/2 calculations on systems of two, three, and four members (-$CONHCH_2$-) were carried out and the most stable conformation of glycine trimer was predicted.[5] Cooperative conformational studies have been carried out on glycine.[12]

Luke et al.[13] have studied the STO-3G and STO-3G* optimized structures of glycine and found that it has three or four low-lying stable conformations. The molecule can easily rearrange to any of them. Intermediate water structures in the solution of alanine dipeptide were investigated.[14] With the ST2 water model, the solute, alanine dipeptide, is hydrated.

Ladik et al.[15] have presented some new results on the quantum mechanical investigation using localized orbitals of DNA. The results show an excellent localization of the occupied orbitals and a rather good one for the virtuals (both for the σ- and π-orbitals) of the four nucleotide bases. Interaction energy calculations between a polyglycine chain in different conformations and polynucleotide chain were performed.

In the last years, substantial progress has been achieved in the quantum mechanical investigation of DNA including the water and ion structure around it,[16] and band structure calculations using a whole nucleotide as a unit cell.[17] Pilot calculations have been performed to assess the effect of water structure on a nucleotide base stack[18] for the investigation of polynucleotide-polypeptide (polyglycine) interaction[19] and for the treatment of a periodicity in DNA macromolecules.[20]

The negative factor counting technique in its ab initio form[21] was used to calculate the total density of states of nonperiodic polynucleotides and polypeptides.[22] Computations were performed on a periodic and nonperiodic poly(-gly-cys-asp-ser-) chain.

A number of theoretical investigations have been devoted to the determination of the energy band stuctures and of the possible pathway for electron delocalization in proteins.[23] All calculations were represented by the very simple periodic models, mostly poly(gly) with the exception of MINDO/3 all-valence electron crystal orbital calculations of aperiodic β-polypeptide.[24] The effect of some factors on the energy band structure on some protein models was calculated with the aid of the CNDO/2 crystal orbital method.[25]

In this work INDO-molecular orbital calculations have been carried out on a number of amino acids in an attempt to understand the "structure-function" relationship for them. Such a study has not been reported before.

Method of Calculations. INDO-CI procedures have been followed, details and parameterization of the procedures are found elsewhere.[26] Interaction was considered between nine configurations which correspond to electronic transitions between the three highest occupied molecular orbitals and the three lowest unoccupied molecular orbitals.

Results and Discussion

A. Alanine and Phenylalanine. Alanine is considered as the α-amino acid with the smallest nonpolar side chain whereas phenylalanine is the amino acid with the largest nonpolar side chain. Figure 1 shows the configuration used in MO calculations with the INDO values of total charge in units of 10^{-3} e. Table 1 gives the values of some of the calculated parameters. It can be seen that phenylalanine has a weaker dipole than alanine indicating that the polarization of the benzene ring is in the opposite direction to that of the -COOH group. The total charge densities on the groups: $-NH_2$, -OH, and -COOH are only slightly higher than they are in alanine. This result explains the fact that phenylalanine is a stronger acid (K_a=6.7×10^{-3}) than alanine (K_a=4.89×10^{-3}).[27] The built up of a slight negative charge on the benzene ring (0.052) suggests that phenylalanine can act as electron donor as well as an electron acceptor.

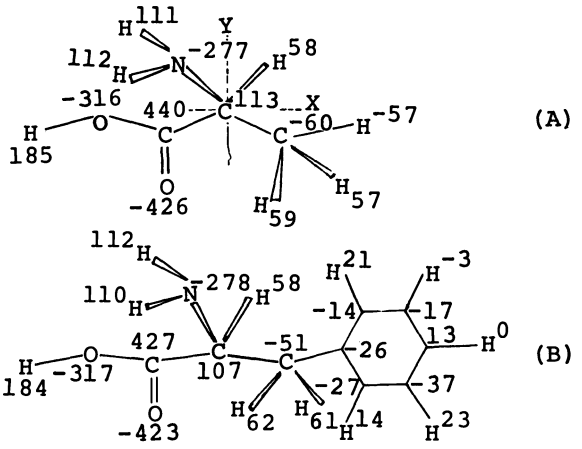

Fig. 1. Configuration and total charge density($\times 10^3$) on: (A) alanine, (B) phenylalanine.

Figures 2 and 3 show the electronic absorption spectra of alanine and phenylalanine using methanol as a solvent. A weak band appears in the spectrum of alanine (240—290 nm) which agrees satisfactory with the calculated transition energy (3.88 eV). The spectrum of phenylalanine shows two absorption bands, the lower energy one (ca. 260 nm) shows the characteristic vibrational components of the $^1L_b \leftarrow {}^1A$ transition of the benzene nucleus. The correspondance between the calculated (4.91, 5.70 eV) and the experimental (4.81, 5.90 eV) transition energies is satisfactory.

B. Tyrosine and Hydroxytyrosines. Figures 4A,B and 5 show the configurations of the molecules and the calculated total charge density in units 10^{-3} e. Table 2 gives the values of the calculated parameters. It can be seen that tyrosines have strong dipoles and hence their position and sequence in proteins is totally different from those of alanine and phenyl-

a) See Figs. 4A, B and 5. b) Net total charge on the side chain.

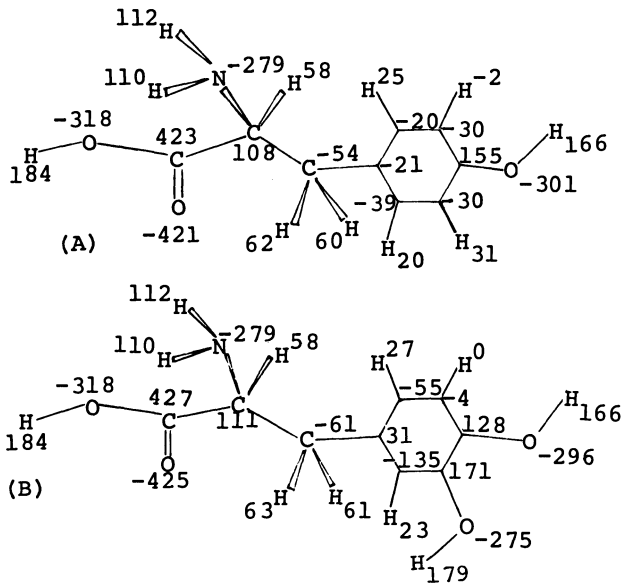

Fig. 4. Configuration and total INDO charge density($\times 10^3$ e): (A) tyrosine, (B) 3-hydroxytyrosine.

alanine. The charge densities on different functional groups ($-NH_2$, -OH, and -COOH) did not differ significantly from tyrosine to hydroxytyrosines. However, a net negative charge is built up on the side chain and increases in the order: 3,5-dihydroxytyrosine>tyrosine>3-hydroxytyrosine. On the other hand a net positive charge is built on the benzene ring and increases in the order: 3,5-dihydroxytyrosine>3-hydroxytrosine>tyrosine. Tyrosine is a much stronger acid ($K_{a_1}=6.7\times10^{-3}$) than 3-hydroxytyrosine ($K_{a_1}=1.32\times10^{-5}$).

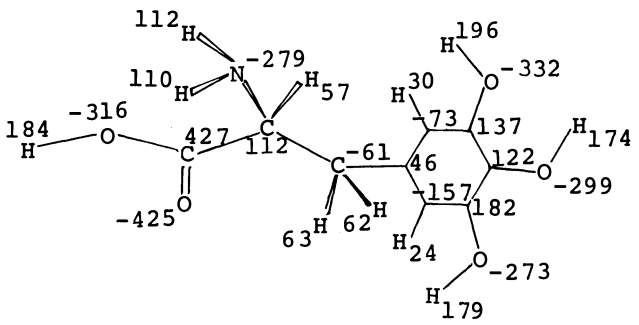

Fig. 5. Configuration and total INDO charge density($\times 10^3$ e) for 3,5-dihydroxytyrosine.

Figure 6 shows the absorption spectrum of tyrosine in methanol. Two electronic transitions are observed and correspond to the $^1L_b \leftarrow {}^1A$ and $^1L_a \leftarrow {}^1A$ of the perturbed benzene nucleus. The correspondance between the observed transition energies (4.51, 5.51 eV) and the calculated (5.04, 5.48) seems to be satisfactory.

C. Histidine and *N*-Acetylhistidine. The presence of imidazole ring in the side chain of histidine is a determining factor in the properties of histidine. Table 3 gives the calculated parameters and Fig. 7 shows the total charge density on the different atoms of the molecule. Computations on *N*-acetylhistidine are included for comparison. Acetylation led to a pronounuced increase in the dipole moment and a decrease of charge density on the imidazole ring compared to histidine.

The results of calculations (Table 3) show that histidine has a much stronger dipole than tyrosine or

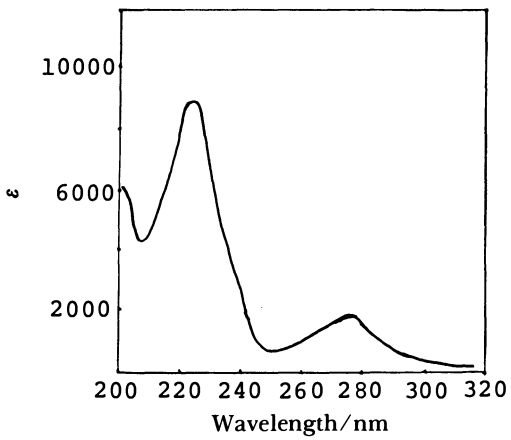

Fig. 6. Electronic absorption spectrum of tyrosine in methanol.

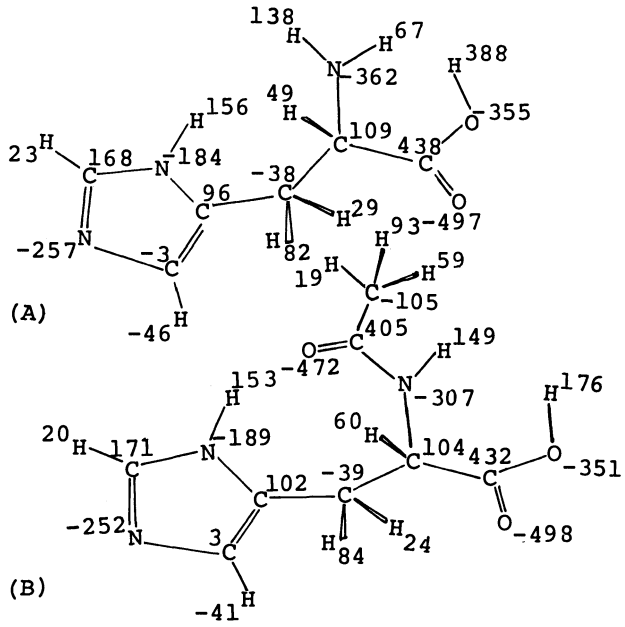

Fig. 7. Configuration and INDO total charge density($\times 10^3$ e): (A) histidine, (B) *N*-acetylhistidine.

hydroxytyrosine. This explains the activity of the acid and its existence in the most active center of the enzyme. The net negative charge built on the functional groups is higher than on the same groups in tyrosine and hydroxytyrosines. A net negative charge is built on the imidazole ring of histidine contorary to the net positive charge built on the benzene ring of phenylalanine and tyrosines. Histidine can act as an electron donor.

The electronic absorption spectrum of histidine (Fig. 8) shows two electronic transitions at 3.97 and 5.21 eV which corresponds nicely with the calculated (3.97 and 5.21 eV).

Conclusion

The position and function of the amino acid in the protein series is dependent on its electronic structure in addition to other properties as size, geometry and nature of its side chain. The results of this work explains many experimental observations. Calculations showed that phenylalanine has a weaker dipole than alanine. There is a weak built up of negative charge density on the benzene nucleus (−0.052) and this renders phenylalanine to act as an electron donor as well as an electron acceptor. Phenylalanine is a stronger acid than alanine which could be due to the higher charge densities of the functional groups in phenylalanine.

Tyrosines have strong dipoles and this determines their position in the protein series. A net positive charge is built on the benzene nucleus and tyrosines

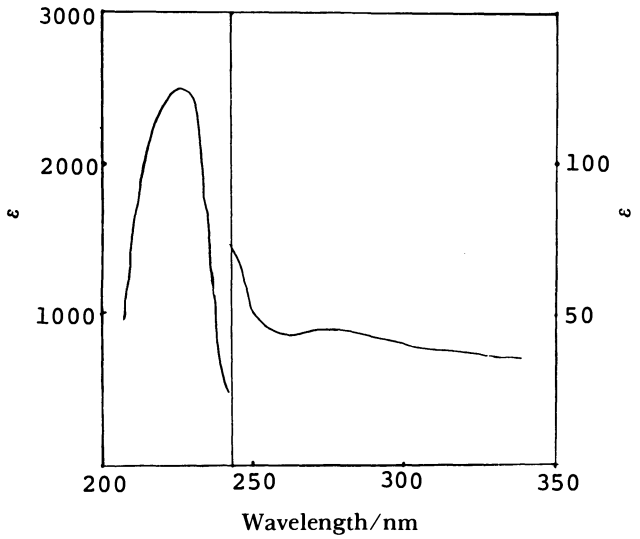

Fig. 8. Electronic absorption spectrum of histidine in methanol.

act as electron acceptors. The theoretical results account for the activity of histidine and its existence at the active center of the enzyme. Histidine can act as an electron donor, a net negative charge is built on its imidazole ring. Acetylation decreases this charge.

Complete Computer Analysis of NQR Data

Bolesław NOGAJ†
Institute of Physics, A. Mickiewicz University, Grunwaldzka 6, 60-780 Poznań, Poland
(Received June 6, 1987)

Theories explaining temperature dependences of frequency, line width and spin-lattice relaxation times in Nuclear Quadrupole Resonance (NQR) spectroscopy have been presented in the form of mathematical expressions. Hence a complete analysis of experimental data can easily be implemented on any microcomputer. This was demonstrated by the results obtained from ^{35}Cl NQR studies of *p,p'*-DDT. The computer analysis allowed to separate different mechanisms of quadrupole relaxation and determine characteristic parameters: moments of inertia of the molecule, librational frequencies and activation energies of rotating molecular groups. Besides numerical values, the printer working with the computer can produce plots of experimental points in different coordinate systems as well as the fit curves.

The parameters most frequently studied in NQR spectroscopy are the resonance frequency (ν_Q), line width ($\delta\nu_Q$), and spin-lattice relaxation time (T_1). Temperature studies of these parameters allow for determination of molecular dynamics in solids, mainly librations and hindered rotations of atomic groups. There are many theories relating individual spectroscopic parameters to molecules and their dynamics. All these theories can be expressed as more or less complex mathematical formulas. The accurate fit of experimental results to these expressions allows for a direct determination of physical parameters of interest. The aim of this paper is to show that the complete numerical and graphical analysis of NQR data can successfully be achieved on any accessible microcomputer.

Temperature Dependences of Basic Parameters in NQR Spectroscopy

Let us consider the influence of molecular motions on individual parameters of NQR spectrum studied as a function of temperature. As is known from infrared studies, the librational frequencies in molecular crystals range from 10^{11} Hz to 10^{13} Hz, so they exceed considerably the NQR frequencies of 10^6—10^8 Hz. Therefore the librational motions cause only an averaging of electric field gradient seen by the resonant nuclei. Bayer[1] assumed that NQR frequency decreases with increasing temperature only due to an increase in the amplitude of librational motions. He treated a molecule as a quantum harmonic oscillator and obtained the following expression for a temperature dependence of NQR frequency:

$$\nu_Q(T) = a - \frac{b}{\exp(c/T) - 1}, \tag{1}$$

$$a = \nu_Q(0), \tag{2}$$

$$b = \frac{6\hbar\nu_Q(0)}{4I\omega_l - 3\hbar}, \tag{3}$$

$$c = \frac{\hbar\omega_l}{k}. \tag{4}$$

$\nu_Q(0)$ is the NQR frequency at 0 K, I is the relevant moment of inertia, ω_l is the librational frequency of the molecule. However, experiments have yielded only qualitative agreement with Bayer's theory. Better agreement with the theory could have been obtained if other types of molecular vibrations as well as thermal expansion had been taken into account. This has been done by Kushida, Benedek and Bloembergen (KBB),[2] who have come to the following relation:

$$\nu_Q(T) = a_0 + a_1T + a_2T^{-1}, \tag{5}$$

$$a_0 = \nu_Q^S, \tag{6}$$

$$a_1 = -\frac{3}{2}k\nu_Q^S\sum_{i=1}^{M}\frac{A_i}{\omega_i^2}, \tag{7}$$

$$a_2 = -\frac{\hbar^2}{8k}\nu_Q^S\sum_{i=1}^{M}A_i, \tag{8}$$

where ν_Q^S is the resonance frequency in a fictitious "static" lattice, ω_i is the frequency of the i-th lattice vibrational mode, and A_i is a coefficient which for librations is equal to the reciprocal of the relevant moment of inertia.

A few years later Brown[3] took into account anharmonicity of librations, assuming a linear temperature dependence of librational frequency:

$$\omega_i = \omega_i^0(1 - g_iT). \tag{9}$$

Moreover Brown limited his considerations to the appropriately high temperatures for which the term a_2T^{-1} of Eq. 5 can be neglected. Under this assumption he obtained:

$$\nu_Q(T) = a_0 + a_1T + a_2T^2, \tag{10}$$

$$a_0 = \nu_Q(0), \tag{11}$$

$$a_1 = -\frac{3}{2}k\nu_Q(0)\sum_{i=1}^{M}\frac{A_i}{(\omega_i^0)^2}, \tag{12}$$

$$a_2 = -3k\nu_Q(0)\sum_{i=1}^{M}\frac{g_iA_i}{(\omega_i^0)^2}. \tag{13}$$

† For correspondence: Solid State Spectroscopy Laboratory, Institute of Physics, A. Mickiewicz University, Grunwaldzka 6, 60-780 Poznań, Poland.

As this dependence describes quite well most of experimentally obtained data $\nu_Q(T)$ for the temperatures above 77 K, we attempted to extend this approach to study the influence of molecular motions on NQR frequency in the temperatures lower than 77 K. After the calculations similar to those of Brown[3] and taking into account the term a_2T^{-1} in Eq. 5 we have come to:

$$\nu_Q(T) = a_0 + a_1T + a_2T^2 + a_3T^{-1}, \quad (14)$$

$$a_0 = \nu_Q^S, \quad (15)$$

$$a_1 = -\frac{3}{2}k\nu_Q^S\sum_{i=1}^{M}\frac{A_i}{(\omega_i^0)^2}, \quad (16)$$

$$a_2 = -3k\nu_Q^S\sum_{i=1}^{M}\frac{g_iA_i}{(\omega_i^0)^2}, \quad (17)$$

$$a_3 = -\frac{\hbar^2}{8k}\nu_Q^S\sum_{i=1}^{M}A_i. \quad (18)$$

In IR and Raman spectroscopy the square dependence of librational frequency on temperature has been observed for a significant number of compounds:

$$\omega_i = \omega_i^0(1 - g_iT - f_iT^2). \quad (19)$$

Taking into account Eq. 19 in our calculations we obtain:

$$\nu_Q(T) = a_0 + a_1T + a_2T^2 + a_3T^3, \quad (20)$$

$$a_0 = \nu_Q(0), \quad (21)$$

$$a_1 = -\frac{3}{2}k\nu_Q(0)\sum_{i=1}^{M}\frac{A_i}{(\omega_i^0)^2}, \quad (22)$$

$$a_2 = -3k\nu_Q(0)\sum_{i=1}^{M}\frac{g_iA_i}{(\omega_i^0)^2}, \quad (23)$$

$$a_3 = -3k\nu_Q(0)\sum_{i=1}^{M}\frac{f_iA_i}{(\omega_i^0)^2}. \quad (24)$$

Equation 20 can be applied to appropriately high temperatures similarly as the Brown's relation—Eq. 10. Extending the above treatment of the influence of librations on NQR spectrum to very low temperatures we obtain:

$$\nu_Q(T) = a_0 + a_1T + a_2T^2 + a_3T^3 + a_4T^{-1}, \quad (25)$$

$$a_0 = \nu_Q^S, \quad (26)$$

$$a_1 = -\frac{3}{2}k\nu_Q^S\sum_{i=1}^{M}\frac{A_i}{(\omega_i^0)^2}, \quad (27)$$

$$a_2 = -3k\nu_Q^S\sum_{i=1}^{M}\frac{g_iA_i}{(\omega_i^0)^2}, \quad (28)$$

$$a_3 = -3k\nu_Q^S\sum_{i=1}^{M}\frac{f_iA_i}{(\omega_i^0)^2}, \quad (29)$$

$$a_4 = -\frac{\hbar^2}{8k}\nu_Q^S\sum_{i=1}^{M}A_i. \quad (30)$$

As follows from the above theories, the accurate fit of experimentally obtained NQR frequencies vs. temperature to the relations found allows one to determine the librational frequencies and the corresponding moments of inertia of the molecules studied.

The other NQR spectroscopy parameters—the line width ($\delta\nu_Q$) and spin-lattice relaxation time (T_1)—are sensitive to greater changes in electric field gradient caused by hindered rotations of (i) atomic groups or molecules including the resonant nuclei or (ii) atomic groups or molecules situated in the neighborhood of the resonant nuclei. In general, we can state that the line width is a resultant effect of static broadening (both electric and magnetic) associated with a crystal lattice, and dynamic broadening associated with some kind of motion (e.g., with a hindered rotation). If the resonant nuclei rotate, the line becomes broadened, and if neighboring groups containing protons rotate the NQR line narrows. In general, the line width observed can be expressed as:[4,5]

$$(\delta\nu_Q)^{observ.} = (\delta\nu_Q)^{static} + (\delta\nu_Q)^{narrow.} + (\delta\nu_Q)^{broad.}, \quad (31)$$

$$(\delta\nu_Q)^{narrow.} = -A\exp(-E_a'/RT), \quad (32)$$

$$(\delta\nu_Q)^{broad.} = B\exp(-E_a/RT), \quad (33)$$

where A and B are constants and E_a and E_a' are the activation energies for hindered rotations analyzed, R is the gas constant.

Let us now consider the nuclear quadrupole spin-lattice relaxation. According to Bayer[1] as well as Woessner and Gutowsky[6] the fluctuations of electric field gradient caused by librational motions lead to the following relation between the relaxation time T_1 and temperature (T):

$$T_1^{-1} = aT^n \quad (34)$$

where a is a constant and $n\approx2$.

Abrupt changes in electric field gradient due to hindered rotation of molecular groups containing quadrupole nuclei (e.g., CCl_3 group) lead to the exponential temperature dependence of the relaxation time:[7]

$$T_1^{-1} = b\exp(-E_a/RT) \quad (35)$$

where b is a constant, E_a is the activation energy for hindered rotation.

If atomic groups in the neighborhood of the resonating nuclei undergo a rotation with a frequency close to the observed NQR freguency, then in the temperature dependence of T_1 a so-called modulation minimum is observed that can be described by the formula:[6,8]

$$T_1^{-1} = [d\exp(E_a'/RT) + g\exp(-E_a'/RT)]^{-1} \quad (36)$$

where

$$d = 3\tau_0\left(\frac{q'_{zz}}{q_{zz}}\right)^{-2}, \quad (37)$$

$$g = \frac{3}{\omega_Q^2\tau_0}\left(\frac{q'_{zz}}{q_{zz}}\right)^{-2}. \quad (38)$$

E'_a is the activation energy for hindered rotation of the corresponding molecular groups, τ_0 is the correlation time at infinitely high temperature, and q'_{zz} is the contribution of motions of adjacent groups or molecules to the whole electric field gradient q_{zz}.

The Application of Microcomputer in Analysis of NQR Data

After discussion of the present theories we may state that in most cases the fit of experimental data to the above relations is sufficient for determination of searched parameters. All these relations have been reduced to a few general equations:

$$y = a - b[\exp(c/x) - 1]^{-1} \quad (39)$$

$$y = a_0 + a_1x + a_2x^2 + \cdots + a_px^p \quad (40)$$

$$y = a_0 + a_1x + a_2x^2 + \cdots + a_{p-1}x^{p-1} + a_px^{-1} \quad (41)$$

$$y^{-1} = ax^n \quad (42)$$

$$y^{-1} = b\exp(-c/x) \quad (43)$$

$$y^{-1} = ax^n + b\exp(-c/x) + A[d\exp(f/x) + g\exp(-f/x)]^{-1} + B[k\exp(m/x) + l\exp(-m/x)]^{-1} \quad (44)$$

$$y = h + d\exp(f/x) + g\exp(-m/x) \quad (45)$$

Eqs. 39—41 refer to the NQR frequency, Eqs. 42—44 to the T_1 relaxation time and Eq. 45 to the NQR line width.

A SINCLAIR ZX81 microcomputer with a memory extended to 64 kB and with High Resolution Graphics add-on was used to do all the calculations. The programs prepared in ZX81 BASIC are based on the standard least squares approximation and the gradient method. The programs applied allow to determine the parameters of interest as well as the quality of the fit by error analysis. The quality of the fit may also be observed on the monitor, as the fit curve is displayed together with the experimental points. The diagrams may be plotted in the following systems of coordinates: x, $\ln x$, $1/x$, x^n (the same refers to the y axis). Each diagram seen on the monitor may be copied by a printer. Experimental data may be entered manually or loaded from a cassette-recorder.

An Example of NQR Data Analysis

The computer analysis will be demonstrated by results obtained from ^{35}Cl NQR studies of *p,p'*-DDT/1,1,1-trichloro-2,2-bis(*p*-chlorophenyl)ethane; $CCl_3CH(C_6H_4Cl)_2$/. The ^{35}Cl NQR data for *p,p'*-DDT include all the effects discussed previously. We deal here with hindered rotation of the resonant nuclei (CCl_3 groups) and with the influence of rotating neighboring groups (phenyl rings). The motion of phenyl rings leads to a narrowing of ^{35}Cl NQR line, while the hindered rotation of CCl_3 groups is observed as a rapid broadening of the resonance lines. In the temperature dependences of the relaxation times we observe two modulation minima due to the rotating phenyl rings. Molecular dynamics of *p,p'*-DDT and the results of ^{35}Cl NQR studies are reported in more

Table 1. Parameters of the Fit of Experimental $\nu_Q^3(T)$ Values for *p,p'*-DDT to the Proper Theories-Formulas: Eqs. 1, 5, 10, 14, 20, and 25. For the Sake of Clarity All Parameters Standing at T^{-1} in Formulas Are Denoted by a Common Symbol d

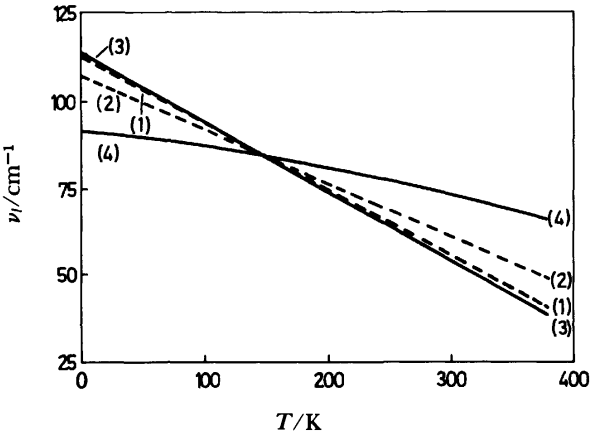

Fig. 7. Temperature dependence of mean librational frequency (ν_l) for chlorine atom (of the CCl_3 group in p,p'-DDT) obtained from fitting the $\nu_Q^3(T)$ data to the proper theories-formulas: Eqs. 10, 14, 20, and 25. The line (1) and (2) represent the dependence $\nu_l=\nu_1^0(1-gT)$ while the lines (3) and (4) stand for $\nu_l=\nu_1^0(1-gT-fT^2)$. The values of ν_1^0, g and f are given in Table 2.

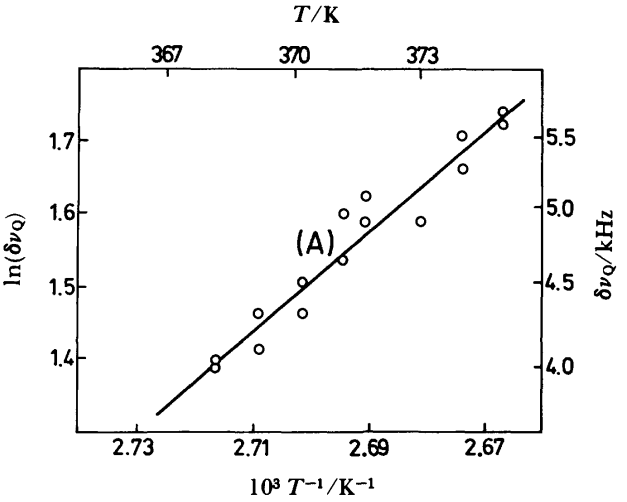

Fig. 8. Temperature dependence of ^{35}Cl NQR line width for rotating chlorines of the CCl_3 group (lines ν_Q^3, ν_Q^4, ν_Q^5 in p,p'-DDT). O—experimental points; solid line (A)—fit to Eq. 33 or 45 for $h=0$ and $d=0$.

detail in Refs. 9—13. In this paper we shall concentrate on the analysis of some experimental results.

We shall illustrate the temperature dependence of ^{35}Cl NQR frequency for the ν_Q^3 line which is one of the five resonance lines observed for p,p'-DDT.[9-13] The parameters of the fit of the experimental dependence $\nu_Q=\nu_Q^3=f(T)$ to individual theories — formulas are given in Table 1 while Figs. 1—6 illustrate the quality of the fits. The formulas in Table 1 are arranged according to increasing standard deviation. As follows from Table 1 the best agreement between the experimental data and the three basic theories (Bayer, KBB, and Brown) was obtained for Brown's formula, Figs. 1 and 2. Thus, it validated the introduction of anharmonicity of vibrations through the linear temperature dependence of their frequencies. The fit improves when we modify the Brown's dependence to extend its validity also at relatively low temperatures, Eq. 14, see curves (D) in Figs. 3 and 4. However, the best fit has been obtained by assuming the square temperature dependence of librational frequency, Eq. 25, see curve (F) in Fig. 6 and Table 1. Despite some really good fits of $\nu_Q(T)$ obtained, none of the equations applied does describe the experimental dependence sufficiently well in very low temperatures, below 20 K. Nevertheless, using these fits we can find the appropriate moments of inertia, librational frequencies and the parameters describing the temperature dependence of librational frequency. Table 2 presents the appropriate parameters for linear and square temperature dependences of mean librational frequency of the Cl atom considered, while Fig. 7 illustrates $\nu_l(T)$ dependences. Curve (4) in Fig. 7 shows the dependence $\nu_l(T)$ obtained from the best fit of $\nu_Q(T)$. The square temperature dependence of librational frequency presented as curve (4) in Fig. 7 is the closest approximation of the real situation for the p,p'-DDT. A detailed analysis of other parameters obtained from individual fits of $\nu_Q(T)$ is given in Refs. 9, 10, and 13.

The width of the resonance line ($\delta\nu_Q$) may be analyzed with the help of the computer program finding the fit of $\delta\nu_Q(T)$ to Eq. 45. As an example we shall analyze the width of the resonance lines due to

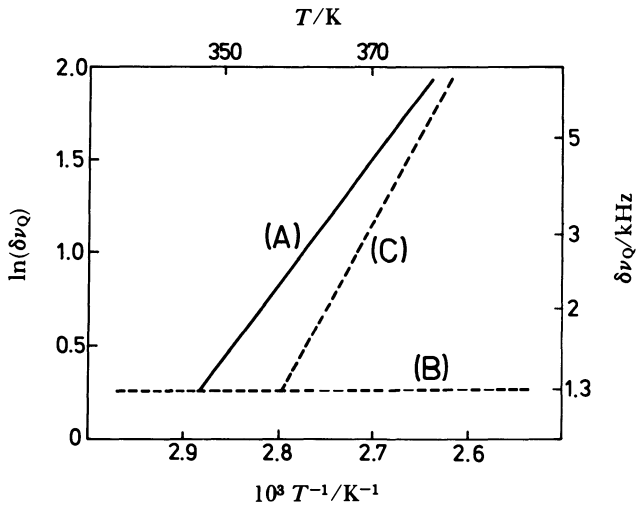

Fig. 9. Separation of ^{35}Cl NQR line width observed (line (A) in Figs. 8 and 9) into line width related to hindered rotation of CCl_3 groups (line (C)) and line width being the resultant effect of static line width and dynamical narrowing due to hindered rotation of phenyl rings in *p,p'*-DDT (line (B)).
$(\delta\nu_Q)^{observed} = (\delta\nu_Q)' + B\exp(-E_a/RT)$
(A) (B) (C)

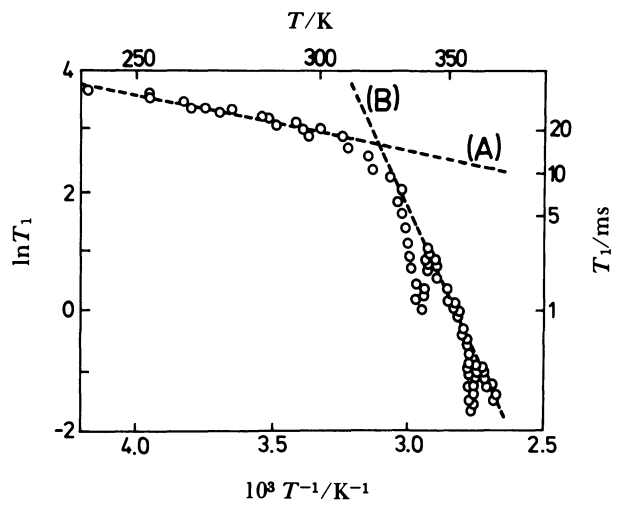

Fig. 10. Temperature dependence of nuclear quadrupole spin-lattice relaxation time (T_1) (lines ν_Q^3, ν_Q^4, ν_Q^5 in *p,p'*-DDT). O—experimental points; (A)—fit function taking into account only librations (Eq. 34 or 42); (B)—fit function taking into account only hindered rotations of CCl_3 groups (Eq. 35 or 43).

chlorine atoms of CCl_3 group in *p,p'*-DDT. As a result of growing rate of hindered rotation of CCl_3 group with increasing temperature the lines undergo significant broadening, which is shown in Fig. 8. The separation of line width being the resultant effect of static line width and dynamical narrowing from the observed line width leads to obtaining the pure effect of line broadening due to hindered rotation of CCl_3 group (see Fig. 9). This procedure also allows us to determine the activation energy for hindered rotation of CCl_3 group which in the case considered is 77.9 kJ mol^{-1}. The computer analysis of resonance line widths in *p,p'*-DDT is given in more detail in Refs. 9, 10, and 13.

As an example of the computer analysis of quadrupole relaxation time T_1 let us consider the relaxation times studied on chlorine nuclei of CCl_3 group in *p,p'*-DDT. We shall consider the temperature range from 200 to 378 K, within which there are several relaxation mechanisms: the mechanism associated with librations of Cl atoms of CCl_3 group, another associated with hindered rotation of CCl_3 groups and the modulation mechanism associated with hindered rotation of the two dynamically nonequivalent groups of phenyl rings. All these mechanisms influence the measured relaxation times T_1:

$$(T_1^{-1})^{observed} = (T_1^{-1})^{librations} + (T_1^{-1})^{CCl_3\ rot.} + (T_1^{-1})_I^{modul.} + (T_1^{-1})_{II}^{modul.} \quad (46)$$

Using Eqs. 34—36 we come to:[12]

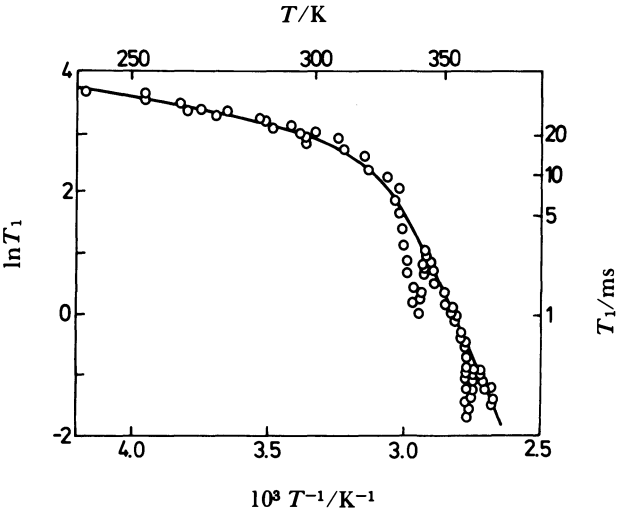

Fig. 11. Temperature dependence of nuclear quadrupole spin-lattice relaxation time (T_1) (lines ν_Q^3, ν_Q^4, ν_Q^5 in *p,p'*-DDT). O—experimental points; solid line-fit function taking into account both librations and hindered rotations of CCl_3 groups (Eq. 44 for $A=0$ and $B=0$).

$$(T_1^{-1})^{observed} = aT^n + b\exp(-E_a/RT) + [d\exp(E_a'/RT) + g\exp(-E_a'/RT)]^{-1} + [k\exp(E_a''/RT) + l\exp(-E_a''/RT)]^{-1} \quad (47)$$

The most important parameters in the above equation are activation energies for hindered rotation of individual atomic groups: E_a for CCl_3 group, E_a' and E_a'' for the two groups of phenyl rings. Figures 10—14 show the computer fit of the experimentally obtained $T_1(T)$ to Eqs. 47 and 44 where various mechanisms are

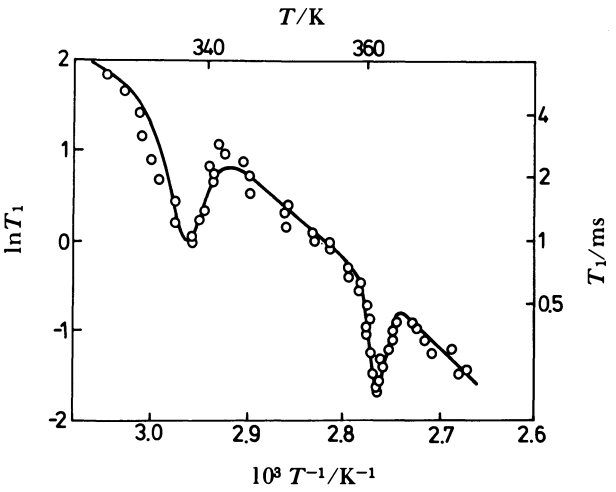

Fig. 12. Temperature dependence of nuclear quadrupole spin-lattice relaxation time (T_1) (lines ν_Q^3, ν_Q^4, ν_Q^5 in *p,p'*-DDT). O—experimental points; solid line-fit function taking into account librations, hindered rotations of CCl_3 groups and the influence of rotating two nonequivalent phenyl groups (two modulation minima) (Eq. 44 for $A=1$ and $B=1$ or Eq. 47).

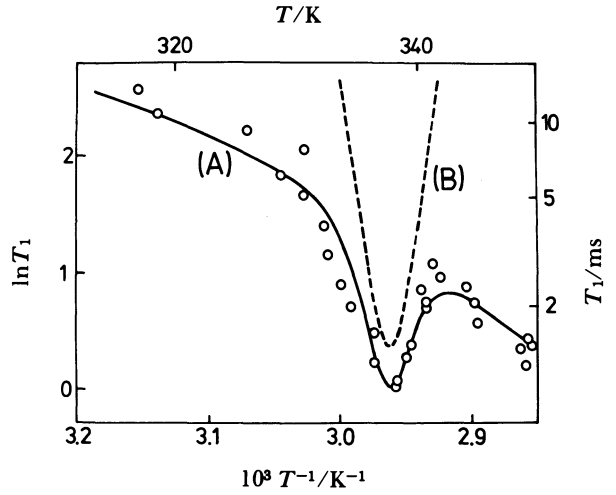

Fig. 13. Temperature dependence of nuclear quadrupole spin-lattice relaxation time (T_1) (lines ν_Q^3, ν_Q^4, ν_Q^5 in *p,p'*-DDT)—the first modulation minimum. O—experimental points; (A)—fit function taking into account librations, hindered rotations of CCl_3 groups and the influence of rotating phenyl rings (Eq. 44 for $A=1$ and $B=1$ or Eq. 47); (B)—function describing only the modulation effect due to rotation of one group of phenyl rings (Eq. 36 or 44 for $a=0$, $b=0$, $A=1$, and $B=0$).

taken into account. From these fits we determined the following activation energies: E_a=86.6 kJ mol^{-1}, E'_a= 84.5 kJ mol^{-1}, and E''_a=91.0 kJ mol^{-1}.[12] Moreover, derived mathematical expression for the curve $T_1^{-1}=f(T)$ allows us to determine accurately the temperature at which the relaxation time reaches its minimum value. This, in turn, enables finding activation energy of the atomic group as well as contribution of the modulated (due to phenyl rings

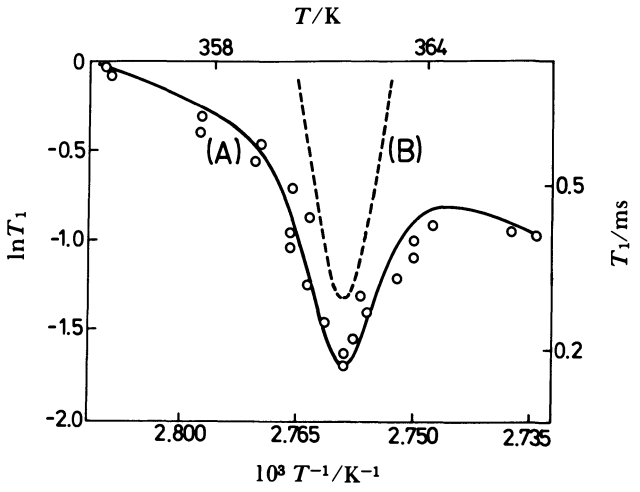

Fig. 14. Temperature dependence of nuclear quadrupole spin-lattice relaxation time (T_1) (lines ν_Q^3, ν_Q^4, ν_Q^5 in *p,p'*-DDT)—the second modulation minimum. O—experimental points; (A)—fit function taking into account librations hindered rotations of CCl_3 groups and the influence of rotatings (Eq. 44 for $A=1$ and $B=1$ or Eq. 47); (B)—function describing only the modulation effect due to rotation of one (the other than in Fig. 13) group of phenyl rings (Eq. 36 or 44 for $a=0$, $b=0$, $A=0$, and $B=1$).

rotation) q'_{zz} gradient to the total electric field gradient q_{zz} on the chlorine nucleus.[12] Complete analysis of the results obtained from the computer fits of $T_1(T)$ data is given in Refs. 10 and 12.

In conclusion we can say that all kinds of temperature dependences of fundamental parameters in NQR spectroscopy may be described by more or less complex mathematical formulas. Further, it is sufficient to perform an accurate computer fit which may be done even with the help of a personal computer. The parameters determined from the fits are the functions of the physical parameters describing the electronic structure and dynamics of the molecules studied.

Kinetics of Substitution of Aqua-Ligands from *cis*-Diaquobis(ethylenediamine)-cobalt(III) Complex by β-Alanine and DL-Valine in Various EtOH-Water Mixtures

Debabrata CHATTERJEE and G. S. DE*
Department of Chemistry, University of Burdwan, Burdwan 713104, India
(Received July 30, 1987)

The kinetics of above titled reaction has been studied spectrophotometrically in various water-ethanol mixtures at different temperatures (45—60 °C). The following rate law has been established in the pH range 3.2 to 4.5.

$$\frac{d[Co(en)_2(H_2O)(LH)^{3+}]}{dt} = \frac{k_a K_E [Co(en)_2(H_2O)_2^{3+}]_T [LH]}{1 + K_E[LH]}$$

where LH represents the zwitterionic form of the amino acids viz. β-alanine and DL-valine. K_E is the ion-pair equilibrium constant between substrate complex ion and zwitterionic ligand the values of which increase with the increase of organic component of medium, where reverse is true for k_a, the interchange rate constant from outersphere complex to innersphere product. It was observed that at higher ligand concentration a limiting rate is attained, which has been explained due to completion of ion-pair formation. Increasing effect of pH and special catalytic effect of NO_3^- have been observed. Activation parameters (ΔH^* and ΔS^*) have been calculated and compared with isotopic water exchange reaction and other deaquation reactions. A dissociative interchange mechanism (I_d) involving ion-pair formation has been suggested.

Elucidation of the mechanism of deaquation reactions on Co(III) center in still a lively issue. No single mechanism can be adequate to explain the variety of observations in the water replacement reactions on Co(III) complexes. However, thorough survey[1-7] reveals a general pattern of the mechanism in which replacement of water molecule occurred through either purely dissociative or dissociative interchange pathway. In case of dissociative interchange process, substrate Co(III) complex ion first forms an ion pair with incoming ligand in a very rapid step, then in a slower rate determining step interchange between coordinated water molecule and incoming ligand occurs to give final product. Deviations from the above mechanism are also noticed in which associative (A) and associative interchange (I_a) mechanism have been suggested.[8-10] Therefore the controversy regarding mechanism in water replacement reactions of well studied cobalt(III) aqua-amine (or ammine) system still persists. The variation of substitution rate with solvent composition has also been proved useful for diagnosis of mechanism in octahedral substitution reactions.[11-14] In response to the above fact we have studied the kinetic behavior of *cis*-$[Co(en)_2(H_2O)_2]^{3+}$ with amino acid ligands viz. glycine,[15] DL-alanine,[16] and L-serine[17] which behaved as good bidentate ligands (NO). The present work is a continuation of our earlier studies having the purpose of assessing the role of solvent composition on water replacement reactions in octahedral Co(III) complex.

Experimental

Substrate complex *cis*-$[Co(en)_2(H_2O)_2](NO_3)_3$ was prepared by following the literature method[18] and characterized by elemental analysis and spectral data obtained were compared with the data reported in literature.[19] Crystal forms of reaction products were not separated due to their hygroscopic nature. To determine the composition of the reaction product in each case equal volume of solution of substrate complex (0.01 M†) and ligand (β-alanine, DL-valine) was mixed separately in three different molar ratios 1:1, 1:2, and 1:3 at fixed pH 4.2. The mixtures were kept at 50 °C for 24 hours. Absorption spectra of all the mixtures were taken and spectral data obtained were compared with the data shown for the product complexes. There is very little difference in absorbances between our product complexes and those cited in literature.[20] Further 1:1 metal-ligand composition of reaction products in solution was verified by Job's method in both cases. There are three possible products expected in solution: (a) $[Co(en)_2L]^{2+}$, (b) $[Co(en)_2(H_2O)(LH)]^{3+}$, and (c) $[Co(en)_2(LH)_2]^{3+}$. Experiment on Job's method of continuous variation, ruled out the possibility of formation of $[Co(en)_2(LH)_2]^{3+}$. To establish the composition of the product between (a) and (b) we have performed pH metric titration with the reaction product in solution. The result indicates the formation of (b), i.e. $[Co(en)_2(H_2O)(LH)]^{3+}$. Thus the zwitterionic ligand ^-OOC-R-NH_3^+ coordinated to metal center through its O- end.

Kinetic Run. The course of the reaction was followed by a HILGER UVISPEK spectrophotometer at 495 nm bacause substantial differences exist in the absorption of substrate complex and it's reaction product (Fig. 1). Equal volume of Complex 1 (substrate complex) and amino acid ligand [LH]≫[Co] was mixed as such that the pseudo-first-order condition is applicable and the pseudo-first-order rate constant values (k_{obs}) were obtained by plotting $\log[(A_\alpha - A_0)/(A_\alpha - A_t)]$ against time, where A_0, A_t, and A_∞ are the absorbance values initially, after time t, and after the

† 1 M=1 mol dm^{-3}.

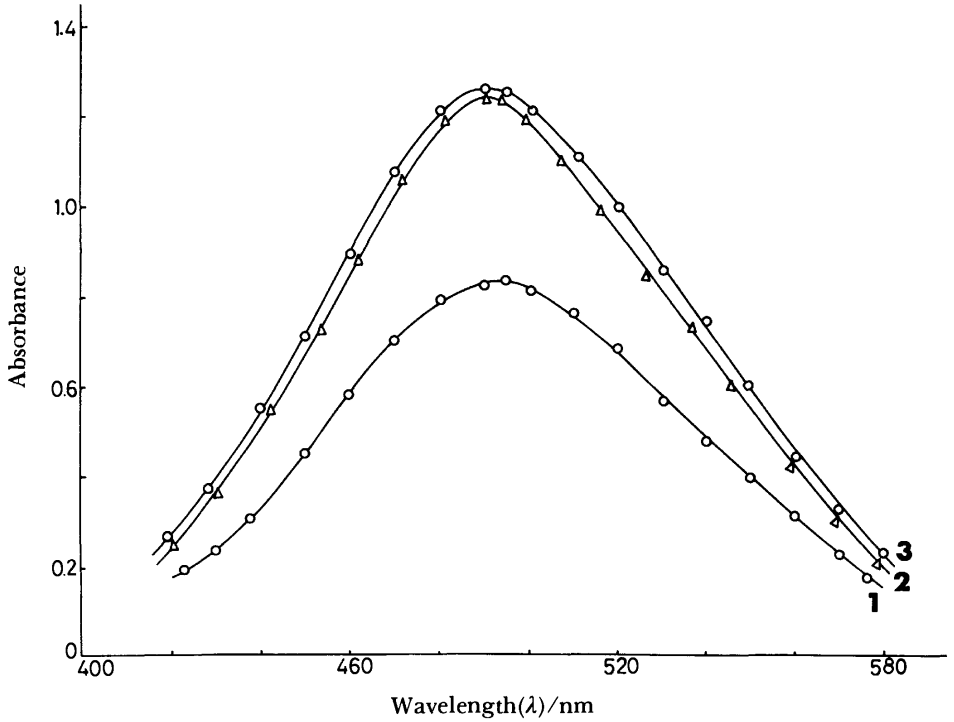

Fig. 1. Spectra of substrate complex *cis*-$[Co(en)_2(H_2O)_2]^{3+}$ (**1**) and it's products $[Co(en)_2(H_2O)$-(valH)$]^{3+}$ (**2**) and $[Co(en)_2(H_2O)(\beta$-alaH$)]^{3+}$ (**3**).

completion of the reaction respectively. The plot of $\log[(A_\alpha-A_0)/(A_\alpha-A_t)]$ vs. time t gave a good straight line passing through the origin. This linearity is observed from start to finish of the reaction which ruled out the possibility of any consecutive reactions.

Results and Discussion

i) Effect of [Complex 1] on Rate. At fixed ligand concentration [Complex 1] was varied in the range 0.0025 to 0.0075 M keeping pH and ionic strength of the medium fixed at 4.2 and 0.05 M respectively. It is seen that the values of $k_{obs}\times(10^4\ s^{-1})$ are 2.60, 2.61, and 2.64 at [Complex 1]=0.0025, 0.005, and 0.0075 M, where anating ligand is β-alanine. In case of ligand valine pseudo-first order rate constant $k_{obs}\times10^4\ s^{-1}$ values are 1.92, 1.90, and 1.94 at 0.0025, 0.005, and 0.0075 M complex concentrations respectively. These k_{obs} values at different Complex 1 concentrations are in good agreement with the first order rate law with respect to the Complex 1 concentration.

ii) Effect of Varying pH on Rate. When the anating ligand is β-alanine the values of k_{obs} $(\times10^4\ s^{-1})$ are 0.73, 0.95, 1.63, 2.61, and 3.5 at pH 3.2, 3.5, 3.8, 4.2, and 4.5 respectively and for DL-valine k_{obs} $(\times10^4\ s^{-1})$ are 0.87, 1.1, 1.42, 1.90, and 2.30 at the above mentioned pH respectively. Now in the studied pH range 3.2 to 4.5 both the ligand β-alanine and DL-valine exist in zwitterionic forms as β-alaH and DL-valH respectively in solution.[21] Therefore ligands nature is not altered appreciably in the solution. Acid dissociation equilibrium of substrate complex can be represented as follows.

$$cis\text{-}[Co(en)_2(H_2O)_2]^{3+} \overset{K_1}{\rightleftharpoons} cis\text{-}[Co(en)_2(OH)(H_2O)]^{2+} + H^+$$

where the value of pK_1 is 5.8 at 25 °C.[22]

Now considering the above equilibrium effect of pH on observed rate constant can be expressed as follows.

$$k_{obs} = k_1 + k_2K_1[H^+]^{-1} \quad (1)$$

where k_1 is the observed rate constant when reacting species is diaquo complex and k_2 is the observed rate constant for hydroxoaquo complex. It is seen from Eq. 1 that the increase in pH i.e. decrease in hydrogen ion concentration increases the reaction rate. Plot of k_{obs} vs. $1/[H^+]$ gave a good straight line and deperture from linearity started at higher pH. Actually in the studied pH range 3.2 to 4.5 percentage of diaquo complex in the solution is maximum, however increase in small amount of hydroxaquo complex increases the reaction rate because hydroxoaquo complex is much more reactive (reacts 60 times more faster than diaquo complex)[22] than diaquo species. Again hydroxide ion facilitates the formation of very reactive hydroxo complex which also increases the reaction rate.

iii) Effect of Variation of Ligand Concentration on Rate. The ligand concentration was varied in the range 0.05 to 0.15 M at four different temperatures

Table 1. Values of k_{obs} in Various Ethanol-Water Mixtures at Different Temperatures $[Co(en)_2(H_2O)_2^{3+}]$=0.005 M, pH=4.2, Ionic Strength=0.03 M

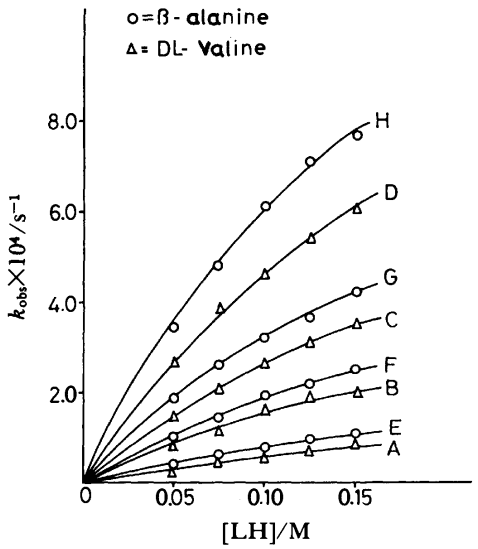

Fig. 2. Effect of ligand concentration (LH) on rate constant (k_{obs}) at different temperatures A) 45 °C, B) 50 °C, C) 55 °C, D) 60 °C; E) 45 °C, F) 50 °C, G) 55 °C, and H) 60 °C.

keeping Complex 1 (0.005 M), pH (4.2) and ionic strength (0.03 M) fixed. The result shown in Table 1 exhibits that for both β-alanine and DL-valine the rate increases with the increase of ligand concentration and reaches a limiting value at higher ligand concentration (Fig. 2). This is due to completion of ion pair formation with the substrate complex ion and amino acid ligands through its negative end. Actually when the zwitterionic amino acid ligand is brought to react with the triply charged substrate complex ion it occupies the near vicinity of complex ion replacing the solvent molecule. Thus an ion pair species is formed in a very rapid process. Then ligand molecule occupies the site vacated by the leaving water molecule in a slower rate determining step. Now increase in ligand concentration increases the concentration of ion pair in the solution and lastly at certain ligand concentration ion pair formation is completed. Further addition of ligand increases it's amount in bulk solution.

The following scheme commensurating the above fact can be set up to explain the variation of rate with ligand concentration.

$$cis\text{-}[Co(en)_2(H_2O)_2]^{3+} + LH \overset{K_E}{\rightleftharpoons} \underset{IP}{cis\text{-}[Co(en)_2(H_2O)_2]^{3+}\cdot LH}$$

$$cis\text{-}[Co(en)_2(H_2O)_2]^{3+}\cdot LH \xrightarrow{k_a} cis\text{-}[Co(en)_2(H_2O)(LH)]^{3+} + H_2O$$

Considering ion pair equilibrium (K_E) and rate determining step (k_a) a familiar rate expression has been established

$$\frac{d[Co(en)_2LH^{3+}]}{dt} = \frac{k_a K_E [Co(en)_2(H_2O)_2^{3+}]_T [LH]}{1 + K_E[LH]}$$

$$= k_{obs}[Co(en)_2(H_2O)_2^{3+}] \qquad (2)$$

Now

$$k_{obs} = \frac{k_a K_E[LH]}{1 + K_E[LH]} \quad (3)$$

or

$$1/k_{obs} = 1/k_a + 1/k_a K_E[LH] \quad (4)$$

Here $[Co(en)_2(H_2O)_2^{3+}]_T$=concentration of total unreacted complex, and [LH] represents the concentration of β-alanine or DL-valine in their respective zwitterionic forms.

From Eq. 3 plot of $1/k_{obs}$ vs. 1/[LH] at a constant pH gives a straight line (Fig. 3) with an intercept $1/k_a$ and slope $1/k_aK_E$. The values of k_a are given in Table 2. K_E values were found to be more or less temperature independent, but at a given temperature K_E values increase with the increase in organic component i.e. lowering of dielectric constant of the medium, range from 1.8 to 6.2 M^{-1}. In proposing the above scheme it was resonably assumed that under experimental conditions only cis-diaquo complex is involved in the reaction.

iv) Effect of Ionic Strength on Rate Constant. At fixed [Complex 1] (0.005 M), [ligand] (0.075 M) and pH 4.2 the ionic strength of the medium was varied by adding (a) $NaNO_3$ and (b) $NaClO_4$. It is observed that at 55 °C k_{obs} values increase with the increase in NO_3^- concentration. The values of $k_{obs}(\times 10^4\ s^{-1})$ at 55 °C are 2.61, 2.93, 3.11, 3.43, and 3.93 (for β-alanine) and 1.90, 2.10, 2.98, 3.64, and 4.60 (for DL-valine) at different ionic strengths 0.03, 0.1, 0.25, 0.5, and 1.0 M respectively. Whereas ClO_4^- ion cannot make any change in the k_{obs} values. Considering the net charge of the zwitterionic amino acid ligands being zero the reaction rate should have been independent of ionic strength of the medium,[23] hence the variation of ionic strength made by adding ClO_4^- did not produce any change in rate constant values. But it was shown by Brown and Harris[2] that NO_3^- has greater tendency to attack coordinated water molecule rather than water molecules attached to the ligands and this facilitates Co-OH_2 bond fission and thus increase of rate occurs.

v) Effect of Variation of Dielectric Constant on Rate Constant. Effect of solvent composition on the water replacement reactions of *cis*-$[Co(en)_2(H_2O)_2]^{3+}$ with amino acids was studied in three different ethanol-water mixtures (10, 20, and 30% v/v). Table 2 shows that at a particular temperature the values of interchange rate constant k_a decrease with the increase

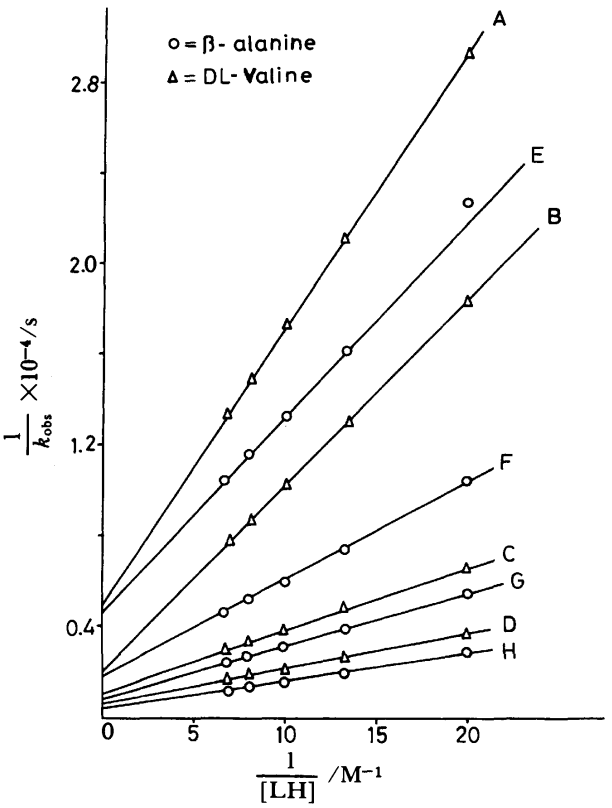

Fig. 3. Plot of $1/k_{obs}$ vs. 1/[LH] at different temperatures A) 45 °C, B) 50 °C, C) 55 °C, and D) 60 °C; E) 45 °C, F) 50 °C, G) 55 °C, and H) 60 °C.

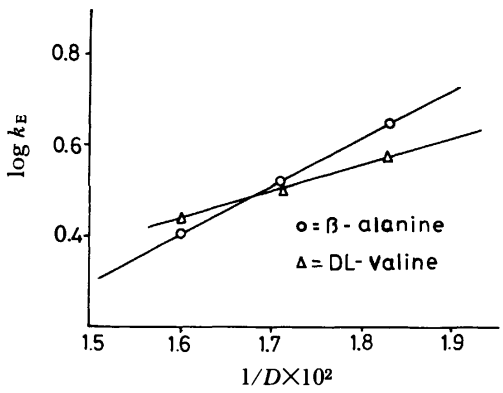

Fig. 4. Plot of log K_E vs. $1/D$ at 55 °C.

Table 2. Values of k_a at Different Temperatures in Various Ethanol-Water Mixtures

Temp	$k_a \times 10^4/s^{-1}$					
	β-Alanine			DL-Valine		
°C	% of ethanol (v/v)			% of ethanol (v/v)		
	10	20	30	10	20	30
45	3.13	2.77	2.12	2.97	2.51	2.01
50	7.24	6.35	5.18	6.85	5.63	5.00
55	12.30	11.31	10.10	11.90	10.10	9.52
60	25.30	22.81	21.30	25.10	22.30	20.00

of organic component of the medium. But reverse is true for K_E values ranging from 1.8 to 6.2 M^{-1}. Actually this is in good agreement with the ion pair formation that lowering of dielectric constant i.e., increases in organic component of the medium increases the forces of attraction between two ions, which favors the ion pair formation (Fig. 4).

According to the electrostatic theory, the dependence of the rate constant of the ion dipole typed reaction on the dielectric constant of the medium is best represented by the Laidler-Eyring equation.[23] In our case considering the total charge on the amino acid ligand is zero the Laidler-Eyring equation can be represented in a simplified way.

$$\frac{d \ln k_a}{d(1/D)} = \frac{e^2Z^2}{2kT}(1/r_1 - 1/r_2) \quad (5)$$

Here, Z is the charge on the complex ion, r_1 and r_2 represent the effective radii of the ion pair in the ground state and in activated state (activated ion pair) respectively, k=Boltzmann constant, T=temperature in absolute degree and D represents the changing dielectric constant. It is seen from Eq. 5, that if $r_2 < r_1$, plot of ln k_a vs. $1/D$ will give a straight line having a negative slope. Now for dissociative interchange process one water molecule is lost in the activated state consequently size of the activated species is lowered i.e. r_2 becomes smaller than r_1. Had it been followed an associative path, the elongation of metal-water bond in the activated states increases the size of the activated species i.e. r_2 becomes larger than r_1. In practice we got a good straight line by ploting ln k_a against $1/D$ with a small negative slope (Fig. 5). This is because r_1 and r_2 do not differ markedly since size of lost water molecule is small in comparison to the large complex ion. Another equation[13] which shows the relation between the rate constant of the ion-dipole reaction and dielectric constant of the medium is as follows:

$$\frac{d \ln k_a}{d(1/D)} = -\frac{Z^2 e^2}{kTr_0^2}\mu_{LH}\cos\theta \quad (6)$$

Here μ_{LH} is the dipole moment of the amino acid ligand, θ is the angle which the negative end of the dipole makes with the line joining the center of the dipole to the complex ion. r_0 is the critical ion-dipole distance which is more or less the same in ground state or activated state as stated earlier. In case of dissociative interchange mechanism one water molecule is dissociated from the metal ion and as a result metal ion attracts the negatively charged oxygen atom in carboxylate group of the amino acid ligand towards on itself. Consequently in this case the value of angle θ cannot exceed the value 90° and thus plot of ln k_a against $1/D$ always gives a straight line with a negative slope. In case of associative interchange process θ may be greater than 90° because complete detachment of water molecule dose not occur in activated state, which increases the steric effect that pushes the negative end of the dipole far from its equilibrium position. However, the small difference obtained in the values of k_a (Table 2) may be due to other non-electrostatic solvent-solute interaction. An interesting point to be noted here is that the values of k_{obs} (Table 1) increase with the increase in organic component of the medium. This is due to increasing effect of K_E on k_{obs} is larger than that of opposite effect of k_a on k_{obs} (Eq. 4).

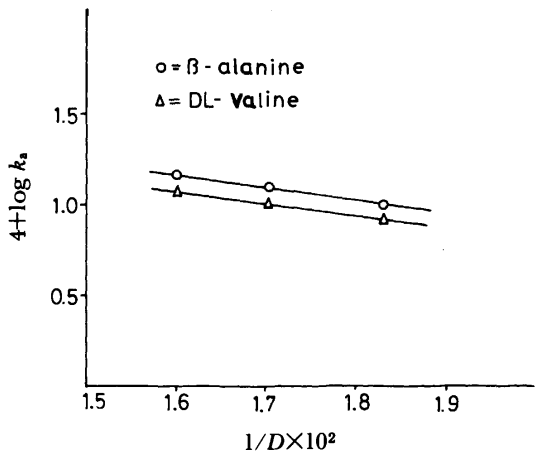

Fig. 5. Plot of log k_a vs. $1/D$ at 55°C.

vi) Effect of Temperature on Rate Constant. The reactions were studied at four different temperatures for media of three different dielectric constants. Activation parameters were calculated by using the Eyring equation and the data obtained were checked by a least squares method and compared with data shown for isotopic water exchange process[25] and other substitution reactions (Table 3). It is seen from Table 3 that the $\Delta H^{\neq}$ and $\Delta S^{\neq}$ values increase with as the dielectric constant of the medium decreases.

Table 3. Values of $\Delta H^{\neq}$ and $\Delta S^{\neq}$ in Different Ethanol-Water Mixtures

% of ethanol (v/v)	β-Alanine		DL-Valine	
	$\Delta H^{\neq}$	$\Delta S^{\neq}$	$\Delta H^{\neq}$	$\Delta S^{\neq}$
	kcal mol^{-1}	cal deg^{-1}	kcal mol^{-1}	cal deg^{-1}
10	26.2	13.3	25.8	12.2
20	27.7	14.1	27.4	13.9
30	30.0	18.1	29.1	15.7

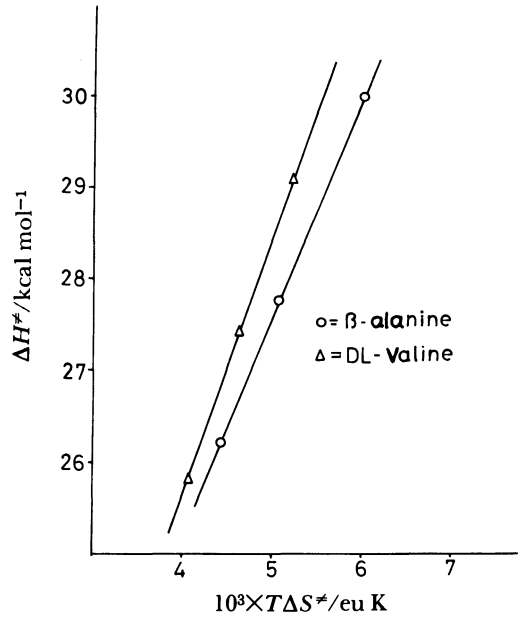

Fig. 6. Isokinetic plot of $\Delta H^{\neq}$ vs. $T\Delta S^{\neq}$.

Though the reactions are performed in water rich media, but crowding of non-polar solvent molecule in the outersphere zone diminishes the rate of Co–OH_2 bond dissociation and thus higher activation energy is required, which is reflected from Table 3. Again increase in organic component effects the solvation of reacting species as well as activated species. Increase in $\Delta S^{\neq}$ values observed is mainly due to change in solvation of the system concerned. Interestingly plots of $\Delta H^{\neq}$ vs. $T\Delta S^{\neq}$ are linear for both the water replacement reactions (Fig. 6). It may be inferred that the similar transition states are formed in the studied range of the composition of the solvent pair.

Conclusion

Basing the above facts a dissociative interchange mechanism (I_d) has been suggested in which complex *cis*-$[Co(en)_2(H_2O)_2]^{3+}$ first forms an ion pair with the incoming amino acid ligands viz. β-alanine and DL-valine in a very rapid step, then slow replacement of water molecule occurs through a dissociative pathway in which amino acid ligand takes the position vacated by leaving water molecule.

We are thankful to CSIR for senior research fellowship to DC.

Molecular Rearrangements. XXVIII. Thermolysis and Photolysis of Some Hydroxamic Acid Derivatives

M. Z. A. Badr, A. M. Fahmy,* S. A. Mahgoub, and M. M. Aly
Chemistry Department, Faculty of Science, Assiut University, Assiut, Egypt, A.R.E.
(Received July 7, 1987)

Thermolysis and photolysis of benzohydroxamic acid and some of its derivatives have been investigated. Thermolysis of benzohydroxamic acid (BHA) either by heating in air or in a sealed tube gives NH_3, H_2O, CO, benzil, aniline, *o*- and *p*-aminophenols, phenoxazine, benzanilide, and benzoic acid. Whereas, thermolysis of *N*-(benzyloxy)benzamide (BBA) affords toluene, benzaldehyde, bibenzyl, stilbene, phenanthrene, acridine, and *o*- and *p*-aminodiphenylmethane in addition to the previous products. Analogous products were also obtained on pyrolysis of phenylacetohydroxamic acid. Photolysis of BHA and BBA in acetonitrile gives similar results to those of pyrolysis. A free-radical mechanism involving homolysis at different sites was postulated to account for the formation of such products.

Hydroxamic acids which have long been used for treatment of recurrent kidney stone formation were incriminated as potential carcinogens.[1] The current concept is that the carcinogenic activity is further enhanced by *O*-esterification. The base-catalyzed rearrangement of hydroxamic acids to primary amines was first described by Lossen.[2] Later, Tiemann[3] reported the noncatalyzed Lossen rearrangement where he obtained aniline and CO_2 by the destructive distillation of benzohydroxamic acid. Moreover, refluxing of some hydroxamic acid derivatives in dimethyl sulfoxide as polar solvent was reported[4,5] to proceed through an ionic mechanism, where *o*-(aroyloxy)arenecarboxanilides were obtained from *N,O*-diacyl-*N*-phenylhydroxylamine through heterolysis of the N-O bond. This prompted us to study the thermal and photostability characteristics of such class of compounds.

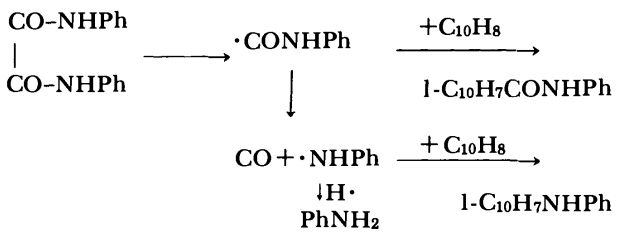
Thermolysis of benzohydroxamic acid (BHA) by heating in air at 240 °C for 30 min. leads to the formation of ammonia, water, carbon monoxide, benzil, aniline, *o*- and *p*-aminophenols, phenoxazine, benzanilide, benzoic acid, and ammonium benzoate (Table 1).

Similary, thermolysis of *N*-(benzyloxy)benzamide (BBA) under the same conditions gives the above mentioned products in addition to toluene, benzaldehyde, benzyl alcohol, bibenzyl, stilbene, phenanthrene, *o*- and *p*-aminodiphenylmethane, and acridine (Table 1).

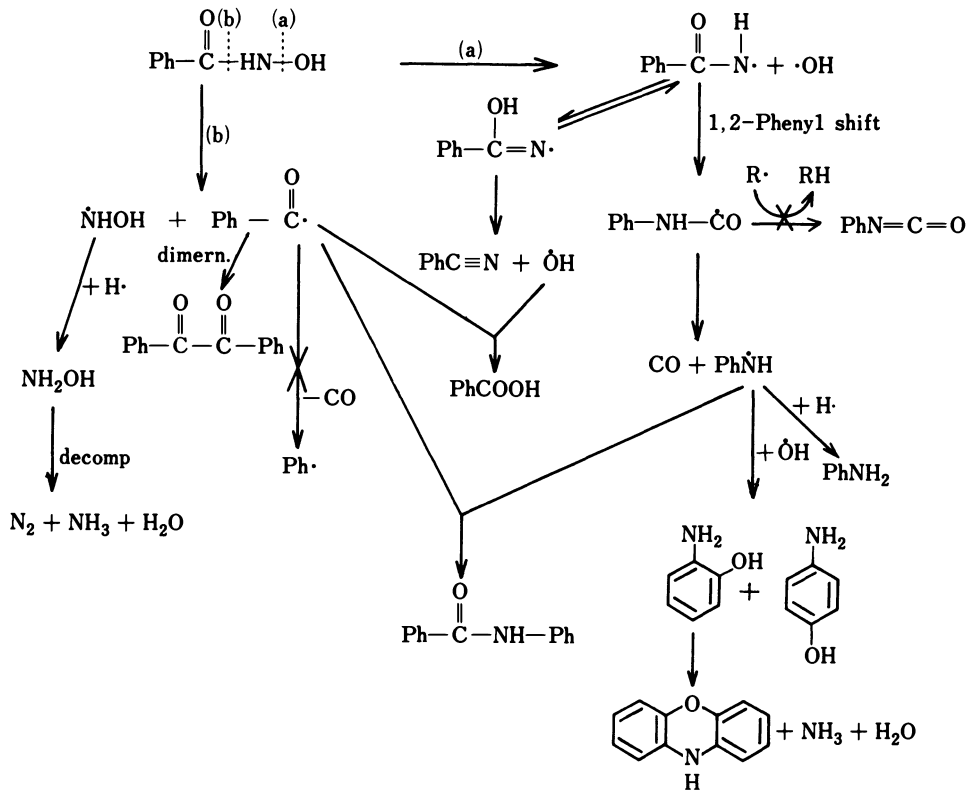
Phenylacetohydroxamic acid (PAH) on similar treatment gives ammonia, toluene, benzaldehyde, bibenzyl, stilbene, phenanthrene, and *N*-benzylphenylacetamide (Table 2). When pyrolysis of PAH was affected by heating at 270 °C for 10 h in a sealed tube under nitrogen, the same products except benzaldehyde were also obtained, in addition to another unknown by-product with mp 147—148 °C; ν_{NH_2} at 3320 and 3120 cm^{-1} and $\nu_{C=O}$ at 1625 cm^{-1}, whereas its microanalysis result points to the formula $C_{12}H_{13}NO_2$.

The formation of the identified products strongly points to a free radical mechanism starting by the preferential homolysis of the N-O bond of BHA (Scheme 1, route a) rather than C-N bond (route b) forming benzoylaminyl and hydroxyl free radicals on basis of bond energy values being of the order 48 and 70 kcal mol^{-1} respectively as observed by other workers.[5] The benzoylaminyl radicals undergo rearrangement into *N*-phenylaminocarbonyl free radicals through a process of 1,2-phenyl shift involving a bridged radical intermediate. Subsequent decarbonylation of such radical leads to the formation of phenylaminyl radical which passes into aniline, *o*- and *p*- aminophenols, and phenoxazine as shown in Scheme 1.

Further evidence for the intermediate formation of *N*-phenylaminocarbonyl free radicals is the results obtained from pyrolysis of *N,N'*-diphenyloxamide in presence of naphthalene as solvent where substitution of the *N*-phenylaminocarbonyl radicals on the naphthalene nucleus occurs at position-1 forming 1-naphthanilide in addition to other fragmentation products of such radicals namely aniline, *N*-phenyl-1-naphthylamine, and carbon monoxide.



The observed low yield of *o*-aminophenol can be attributed to its incorporation in the formation of phenoxazine, ammonia and water. The formation of phenyl isocyanate was ruled out due to the absence of its condensation product with aniline, namely, *N,N'*-diphenylurea among the pyrolysis products. The probability of homolysis of the C-N bond (route b) into benzoyl and hydroxyaminyl radicals is worth considering to account for the formation of benzil, benzoic acid, and benzanilide as shown in Scheme 1. The benzoyl free radicals are involved in the formation of benzil, benzoic acid, and benzanilide



Scheme 1. Pyrolysis of BHA.

through processes of dimerization or coupling with hydroxyl or phenylaminyl radicals respectively. On the other hand, the hydroxyaminyl radicals undergo H-abstraction forming hydroxylamine, which ultimately decomposes into ammonia and water.[6]

Thermolysis of BBA is suggested to proceed through homolysis of the N–O bond (route a; Scheme 2) forming benzyloxyl and benzoylaminyl radical pairs. The benzyloxyl radical are the precursor of benzaldehyde and benzyl alcohol through a disproportionation process, whereas the benzoylaminyl radical is transformed into benzonitrile. Other fates of benzoylaminyl radicals such as fragmentation into phenyl radicals and isocyanic acid, which ultimately undergoes hydrolysis by water to give ammonia and carbon dioxide, were ruled out due to the absence of CO_2 and biphenyl among the products.

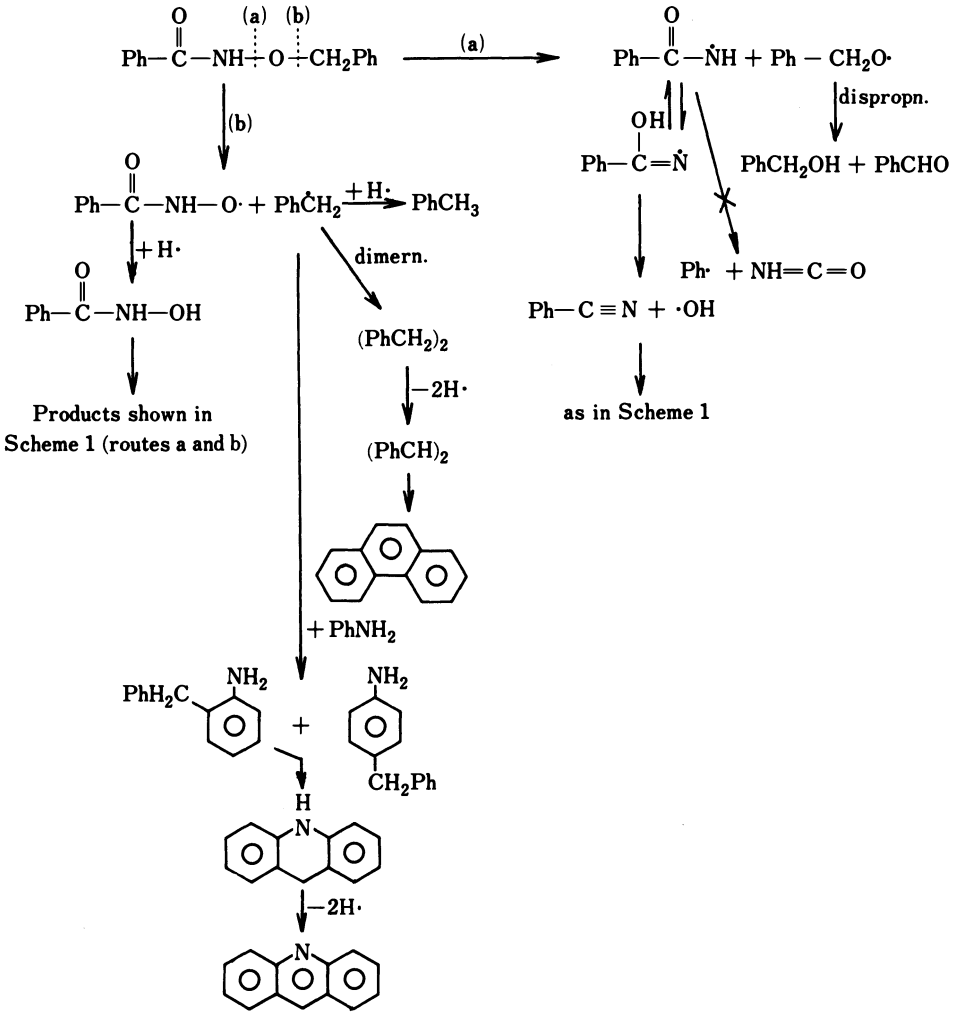
However, formation of products derived from benzyl radicals necessitates another pathway, involving homolysis of the benzyl–O bond (route b, Scheme 2) forming benzyl and benzohydroxamoyl radical pairs. The benzyl radicals are involved in the formation of toluene, bibenzyl, stilbene, and phenanthrene through processes of H-abstraction and/or dimerization, followed by dehydrogenation and cyclization respectively.

The formation of *o*- and *p*-aminodiphenylmethanes can be assumed to take place through attack of benzyl radicals on aniline formed in the reaction medium. Radical oxidative cyclization of some *o*-aminodiphenylmethane will ultimately lead to the formation of acridine.[7] A result which explains the low yield of *o*-aminodiphenylmethane as compared with its *p*-isomer. On the other hand, benzohydroxamoyl free radicals abstract hydrogen to form benzohydroxamic acid which passes into the products identified in Scheme 1, namely; benzil, benzoic acid, benzanilide, aniline, *o*- and *p*-aminophenols, phenoxazine, carbon monoxide, ammonia, and water.

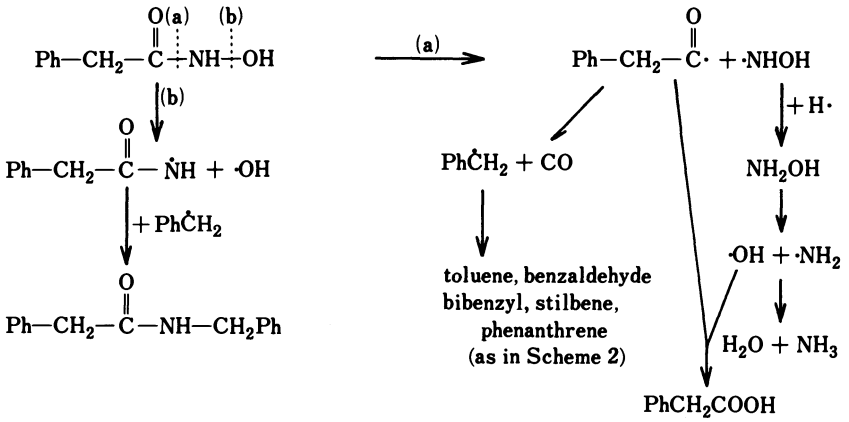
The products formed from pyrolysis of PAH by refluxing imply the homolysis of the $-\overset{O}{\overset{\|}{C}}-\overset{H}{\overset{|}{N}}-$ bond (route a), forming phenylacetyl and hydroxyaminyl radical paris (Scheme 3).

The phenylacetyl radicals decarbonylate[8] mainly into benzyl free radicals which are considered as the precursor of toluene, benzaldehyde, bibenzyl, stilbene, and phenanthrene as shown previously, whereas some of the phenylacetyl radicals form phenylacetic acid on coupling with hydroxyl free radicals which are considered as intermediates in the decomposition of hydroxylamine.[6]

The formation of benzaldehyde can be reasonably assumed to be through atmospheric oxidation of benzyl radicals since absence of air on heating PAH in a sealed tube in nitrogen atmosphere does not give benzaldehyde among the products. The formation of *N*-benzylphenylacetamide necessitates homolysis of



Scheme 2. Pyrolysis of BBA.



Scheme 3. Pyrolysis of PHA.

the N–OH bond (route b) forming hydroxyl and phenylacetylaminyl radicals. The latter subsequently couples with the benzyl radical. The normal fate of hydroxyaminyl free radicals is the formation of hydroxylamine as shown in case of BHA.

N-(Benzyloxy)phenylacetamide (BPAA) on pyrolysis by reflux in air gives the same products in addition to benzyl alcohol and benzaldehyde which are suggested to be formed through homolysis of the $-\overset{O}{\overset{\|}{C}}-\overset{|}{N}-$ bond forming phenylacetyl and benzyloxyaminyl free radicals.

The normal fate of phenylacetyl free radicals was discussed previously (Scheme 3), whereas the benzyl-

oxyaminyl radical abstracts hydrogen to form *O*-benzylhydroxylamine which subsequently undergoes homolysis of the N-O bond as shown in (Scheme 4). This was further confirmed by the results obtained from pyrolysis of *O*-benzylhydroxylamine where NH_3, H_2O, benzyl alcohol, and benzaldehyde were identified among the products.

Photolysis of BHA and BBA in acetonitrile solution at 280 nm at 25 °C affords analogous products to those obtained on pyrolysis. Hence it is reasonable to assume that the photolysis of these hydroxamic acid derivatives involves the homolytic cleavage of the N-O bond in the excited state forming aroylamino and alkyloxyl free radicals, which either react within the solvent cage affording the rearrangement products or escape out of the cage to give the fragmentation products so identified.

analysis were carried out on a Pye-Unicam IR spectrophotometer, Model Sp. 200 G. GLC was carried out using a Pye-Unicam gas chromatograph series 104, with dual flame ionization detector, Model 24 and the column used was 20% SE 30 on Chromosorb W (35—80 mesh) at temperature 185 °C using nitrogen as carrier gas. Molecular weight determination of some reaction products was carried out by mass spectrophotometer, Model A.E.I.M.S. 902. Ultraviolet irradiation was carried out using Mallinkrodt 150 W mercury discharge lamp and the solutions were contained in open topped Pyrex beakers. ^{1}H NMR spectrum for some reaction products were obtained using EM-390 90 MHz NMR spectrometer.

Thermolysis of Arene-, Arylalkanehydroxamic Acids and *O*-Benzyl Derivatives: The arene- and arylalkanehydroxamic acid (10 g) was heated on an oil bath (bath temp 240 °C) for 30 min where frothing takes place or in a sealed tube under nitrogen atmosphere. The carbon monoxide evolved was detected by platinum chloride test paper. The ammonia gas evolved was detected by HCl. The products were separated into neutral, basic, phenolic and acidic components as in a previous work.[7] The separated products were subjected to further separation into their constituents by column chromatography and identified by TLC and GLC or by comparison of their infrared spectra with those of authentic samples.

The *O*-benzyl derivatives of these hydroxamic acids were pyrolyzed by refluxing for 5 h in air whereby ammonia and carbon monoxide were evolved and detected by chemical means. The pyrolysate was separated and detected as described before. The results are given in Tables 1 and 2.

Photolysis of Benzohydroxamic Acid and *O*-Benzyl Derivatives: A solution of BHA or BBA (1 g) in dry acetone (50 ml) was irradiated at room temperature (25 °C) for 20 h. The photolysate was separated as indicated in a previous work[9] into amine, acid and neutral products and analyzed by GLC as compared with authentic samples using nitrobenzene as internal standard. The results are summarized in Table 3.

Pyrolysis of *O*-Benzylhydroxylamine: *O*-Benzylhydroxylamine (10 g) was refluxed for 10 h. The ammonia evolved was detected by chemical means. The dark brown viscous product was subjected to fractional distillation under reduced pressure whereby the following products were obtained:

Product	Bp θ_b/°C /100 mmHg	gram(%)
NH_3	Evolved	—
Benzaldehyde	68	3.0(30)
Benzyl alcohol	85	3.15(31.5)

The Effect of "Chemiluminescence Quenching" on the Chemiluminescence Quantum Yields from 9-Benzylacridine and 9-Benzyl-10-methylacridinium Iodide

Isao KAMIYA,* Takashi SUGIMOTO, and Kuniaki YAMABE†
Department of Chemistry, College of General Education, Nagoya University, Chikusa-ku, Nagoya 464-01
†Department of Industrial Chemistry, Sasebo Technical College, Sasebo 857-11
(Received October 29, 1987)

Synopsis. A visible chemiluminescence (CL) has been found from the air oxidation of 9-benzyl-10-methylacridinium iodide, in contrast to the case of 9-benzylacridine, from which only a feeble CL could be detected. The difference in the CL quantum yields from the acridinium salt and acridine is interpreted in terms of a "CL quenching" of the chemiexcited species by benzaldehyde generated simultaneously in a solvent cage.

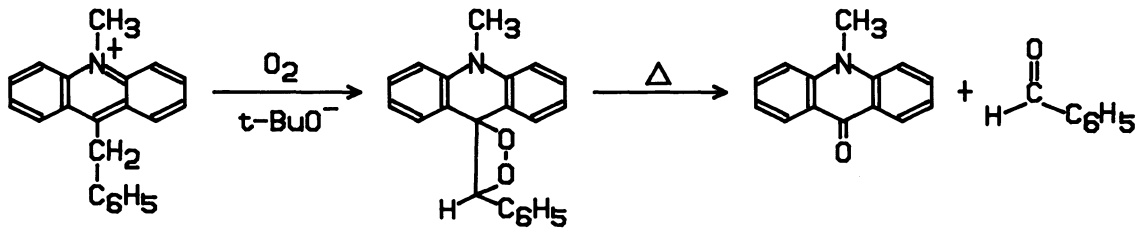
We have found a visible chemiluminescence (CL) of 9-benzyl-10-methylacridinium iodide[1] (**1**) upon base-catalyzed air oxidation: a solution of potassium *t*-butoxide (*t*-BuOK) in *t*-butyl alcohol (*t*-BuOH) (2×10^{-2} mol dm^{-3}, 0.2 cm^3) was added to an aerated solution of **1** in *N*,*N*-dimethylformamide (DMF) (1.0×10^{-4} mol dm^{-3}, 2.0 cm^3) at 313 K. The CL emission with a peak at 415 nm showed the same spectral distribution as that of the fluorescence of 10-methylacridone (**3**) and the spent reaction mixture. Benzaldehyde was detected as one of the reaction products by gas chromatography. The overall CL quantum yield was determined to be 2.5×10^{-3}. The reaction pathway involving the cleavage of 10-methyl-4′-phenylspiro[acridine-9(10*H*),3′-[1,2]-dioxetane] **2** shown in Scheme 1 seems most probable for the CL of **1**, since **2** is known to give singlet, excited 10-methylacridone (**3***), together with benzaldehyde, on decomposition.[2] In a previous paper,[3] a similar reaction pathway via the cleavage of a dioxetane intermediate **5** to give excited singlet acridone anion (**6***), shown as Scheme 2, was presented as the mechanism[4] for the CL of 9-alkylacridines. Among these, 9-methylacridine (**4c**) produced the excited product **6*** in a relatively high CL quantum yield (6.3×10^{-3}), while 9-benzylacridine (**4a**) and 9-(diphenylmethyl)acridine (**4b**) produced **6*** in extremely low yields (1.5×10^{-6} and 1.1×10^{-5} respectively), in spite of the high yield of unexcited acridone anion (**6**). Thence, there remained the problem of why the CL quantum yields from **4a** and **4b** are far lower than those from **4c** and **1**.

Recently, Perkizas and Nikokavouras[5] have proposed a "CL quenching" process of an excited moiety by the simultaneously produced leaving moiety in a solvent cage: an efficient quenching would arise through molecular collision inside the solvent cage if the quenching probability per collision were great. This paper will present some experimental results giving support to the idea that the low CL quantum yields from **4a** and **4b** are due to a CL quenching.

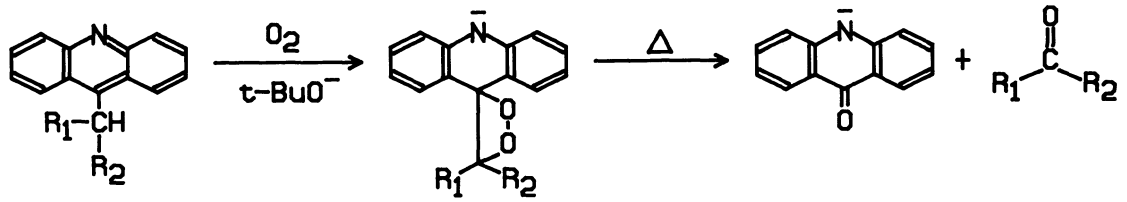
When the CL quenching arises through the collision of two moieties produced inside a solvent cage, the apparent CL quantum yield (Φ) is given approximately by the following equation:

$$\Phi = \Phi^\circ k_{-d}/(k_{-d} + k_e)$$

where Φ° is the proper CL quantum yield, obtained as the product of the yield of the excited product from the substrate and the fluorescence quantum yield of the



Scheme 1.



Scheme 2.

excited product, k_{-d} is the rate constant of the moieties to get out of the cage, and k_e is the rate constant for energy transfer by collision.

The Stern-Volmer constant (K_{sv}) for the quenching is given by the following convenient equation:

$$K_{sv} = (I_0/I - 1)/[Q] = k_q\tau$$

where I_0 and I are the fluorescence intensities of an excited species in the absence and in the presence of a quencher Q at a given concentration [Q], k_q is the quenching rate constant, and τ is the lifetime of the excited species in the absence of Q. When the quenching arises via a diffusion controlled encounter in a solvent cage, k_q is given approximately by the following equation:

$$k_q = k_d k_e/(k_e + k_{-d}) = k_d p$$

where k_d is the rate constant for the molecular diffusion in the fluid solution and p is the quenching probability per encounter. Thus, Φ is given by:

$$\Phi = \Phi^\circ(1 - k_q/k_d) = \Phi^\circ(1 - p)$$

If the two CL systems, I and II, are assumed to posses similar k_d and Φ°, the following relation is established:

$$\Phi(\mathrm{I})/\{1 - p(\mathrm{I})\} = \Phi(\mathrm{II})/\{1 - p(\mathrm{II})\} = \Phi^\circ$$

Thus, the effect of the CL quenching on the CL quantum yield can be interpreted by taking account of the value of p ($=k_q/k_d$) obtained from the Stern-Volmer analysis.

The plot of $I_0/I-1$ versus [Q] for the quenching of **3*** and **6*** by benzaldehyde and of **6*** by benzophenone in DMF solutions containing *t*-BuOK and *t*-BuOH at 313 K were determined; the slopes of the lines gave the values of K_{sv}(**1**)=10.3, K_{sv}(**4a**)=145, and K_{sv}(**4b**)=144 $dm^3\,mol^{-1}$.[6] From the values of K_{sv} and τ (7.6×10^{-9} s)[7,8], k_q(**1**), k_q(**4a**), and k_q(**4b**) were calculated to be 1.4×10^9, 1.9×10^{10} and 1.9×10^{10} $dm^3\,mol^{-1}\,s^{-1}$ respectively.

These experimental values give the following relation:

$$1.5\times10^{-6}/\{1 - p(\mathbf{4a})\} = 1.1\times10^{-5}/\{1 - p(\mathbf{4b})\} = 2.5\times10^{-3}/\{1 - p(\mathbf{1})\} = \Phi^\circ$$

Since $\Phi^\circ \geqq 2.5\times10^{-3}$, the values of $1-p$(**4a**) and $1-p$(**4b**) might be very small, indicating that $k_d \sim k_q$(**4a**)$\sim k_q$(**4b**)$\sim 1.9\times10^{10}$ $dm^3\,mol^{-1}\,s^{-1}$, though the value is somewhat larger than that calculated by the use of $k_d = 8RT/3\eta$.[9] Taking $k_d = 1.90\times10^{10}$ $dm^3\,mol^{-1}\,s^{-1}$, a large value of $1-p$(**1**) is obtained by the following calculation:

$$1 - p(\mathbf{1}) = 1 - 1.4\times10^9/1.9\times10^{10} = 0.93$$

It is, therefore, reasonable to conclude that an efficient CL quenching arises in the CL system of **4a** and **4b** because of the extremely low value of $1-k_q/k_d$ whereas no remarkable CL quenching occurs in the CL of **1** because of the large value of $1-k_q/k_d$.

No appreciable quenching of **6*** by formaldehyde[10] was observed. Thence, the much higher CL quantum yield from **4c** than from the analogues seems to be attributable to the absence of "CL quenching".

Experimental

Materials. The 10-methyl-9(10*H*)-acridone (Aldrich) and 9(10*H*)-acridone (Tokyo Kasei) were chromatographically pure. The luminol was recrystallized from dilute hydrochloric acid prior to use. The benzaldehyde and benzophenone were purified by distillation prior to use.

Measurement of CL and Fluorescence. The intensity and spectrum of CL were measured on a Opelecs CLS-1 chemiluminescence spectrophotometer equipped with a R446 photomultiplier and 1200/mm grating. The overall CL quantum yield, defined as (total light per unit volume)/(the initial concentration of the substrate), was determined from the ratio of the total light emitted from the CL of the substrate to that from a standard luminol solution in the same way as has been described previously.[3] The fluorescence spectrum was measured on a Hitachi MPF-2A fluorescence spectrophotometer.

We wish to express our gratitude to Prof. Jiro Tanaka and Dr. Nobuaki Kanamaru (Department of Chemistry, Faculty of Science, Nagoya University) for the measurement of the lifetime of the excited species and to Prof. Motoo Yasuda and Mr. Kiyoshi Mizutani (Department of Chemistry, College of General Education, Nagoya University) for the measurement of the viscosity.

6) For the quenching of **3*** by benzaldehyde, we use the symbol K_{sv}(**1**), since **3*** and benzaldehyde are produced from **1**. Similarly, K_{sv}(**4a**) and K_{sv}(**4b**) are used to symbolize the quenching of **6*** by benzaldehyde and benzophenone respectively.

7) Since the values of τ of **3*** and **6***, as determined on a nano-second fluorimeter equipped with a Lomonics TE-type XeCl Laser (excited at 308 nm), were both ca. 1×10^{-8} s, the value (7.6×10^{-9} s) in the literature[8] was employed for the calculation of k_q.

8) K. D. Legg and D. M. Hercules, *J. Am. Chem. Soc.*, **91**, 1902 (1969).

9) The viscosity of DMF containing *t*-BuOK and *t*-BuOH was determined to be 6.6×10^{-4} $kg\,m^{-1}\,s^{-1}$ at 313 K. Using the value, k_d was calculated to be 1.1×10^{10} $dm^3\,mol^{-1}\,s^{-1}$.

10) A solution of formaldehyde in DMF (ca. 0.5 mol dm^{-3}, 0.2 cm^3), prepared by dissolving gaseous formaldehyde (*Org. Synth.*, Coll. Vol. 1, p. 80), was added to 2.0 cm^3 of a solution of acridone anion or 10-methylacridone in DMF containing *t*-BuOK.

The ^1H and ^{13}C NMR of the Tetraphenylcyclopentadienone Dianion

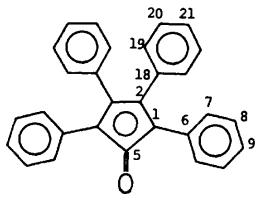
(Received December 1, 1987)

Synopsis. The stable monomer dianion of the title compound was formed by the contact of its tetrahydrofuran-d_8 or 1,2-dimethoxyethane-d_{10} solution with sodium metal at 5 °C and was characterized by means of its ^1H and ^{13}C NMR spectra.

It has been known that the alkali metal salts of aromatic ketyls ($A^{\cdot-}M^+$) generated by alkali-metal reduction in an ethereal solvent tend to change competitively to a diamagnetic dimer dianion ($A_2^{2-}2M^+$) and a diamagnetic monomer dianion ($A^{2-}2M^+$) via a paramagnetic ketyl dimer $(A^{\cdot-}M^+)_2$[1] and that the latter change is dominant in 2-methyltetrahydrofuran, generally causing a pronounced ion pairing with alkali metal.[1a] Recently, the monomer dianion of fluorenone has been precisely investigated by means of NMR in our laboratory.[2] We wish to report here on the monomer dianion of sterically hindered tetraphenylcyclopentadienone (**1**).



1

Experimental

Compound **1** (Aldrich Co., Ltd.) was used without further purification. Tetrahydrofuran(THF)-d_8 and 1,2-dimethoxyethane(DME)-d_{10} (Canada MSD Co., Ltd.) used as the solvents were dried, degassed, and stored over sodium/potassium in vacuo. 0.2 mol dm^{-3} THF-d_8 and DME-d_{10} solutions of **1** were in contact with a clean sodium mirror in high vacuum at 5 °C in a Pyrex cell fused with an NMR tube. The ^1H NMR spectra were measured on JEOL GX-400 (400 MHz) and Varian XL-200 (200 MHz), and the ^{13}C NMR spectra on JEOL FX-90Q (22.5 MHz) and Varian VXR-300 (75 MHz) at room temperature. The ESR and ENDOR spectra were observed on JEOL JES-FE1XG and Varian E-1700, respectively in order to confirm the disappearance of the ketyl radical of **1**. The MO calculation of the charge density was performed on HITAC M-240H at Ibaraki University, the program used for the CNDO calculation being Y4CB04[3] in the library programs of the University of Tokyo.

Results and Discussion

The contact of **1** with sodium in THF-d_8 or DME-d_{10} gave first a reddish-purple species revealing an ESR and an ENDOR spectra, which can be identified with the radical anion of **1**.[4] Upon continued contact, it gradually turned orange, the ESR signal of $\mathbf{1}^{\cdot-}$ disappeared, and a new NMR spectrum developed simultaneously. The ^1H and ^{13}C NMR spectra of this new diamagnetic species **1a**, as observed in THF-d_8 after complete reduction, are shown in Figs. 1 and 2 respectively, along with those of **1**. The addition of a reducible aromatic compound, 2-nitroacetophenone, to **1a** led to the ESR spectrum of the radical anion of this compound, while the quenching of **1a** with oxygen gas regenerated **1**. The ^1H spectrum of **1a** consists of two sets of AA'BB'C patterns separated from each other; they can be clearly distinguished in terms of the H-H shift correlation 2D NMR, and its spectral center of gravity shifts toward a field higher by 0.29 ppm than that of **1** (Table 1). The observed number of lines in the ^{13}C spectrum of **1a** is equal to that in **1**; furthermore, a line with a particularly weak intensity is included, as in **1**. Its center of gravity was found to shift toward a field higher by 5.73 ppm than that of **1**. The fact that both the ^1H and ^{13}C NMR patterns of the orange species produced in THF are completely identical with those in THF-d_8 implies that **1a** does not arise from a possible diamagnetic anion formed by the subtraction of a proton from the solvent. The ^{13}C line with a particularly weak intensity appears at a field much lower than an aliphatic region, although it shifts toward a considerably higher field than that of **1**. These experimental

results thus show that **1a** can be attributed to a monomer dianion of **1**, $\mathbf{1}^{2-}$, or its disodium salt, $\mathbf{1}^{2-}2Na^+$, and that the formation of a possible pinacolate-type dimer dianion can, therefore, be ruled out.

The higher-field doublet in the ^1H NMR of **1** was assigned to H_{19} using lanthanoid-induced shifts due to Eu(fod)$_3$. In the ^1H spectrum of $\mathbf{1}^{2-}$ it may be considered that an AA'BB'C group with a much lower-field doublet corresponds to the C_6—C_{11} ring, considering the anisotropic effect of the carbonyl group. The assignment of the ^{13}C spectrum of **1** was that in the literature.[5)] For $\mathbf{1}^{2-}$, all the tertiary carbons were assigned using the C–H shift correlation 2D NMR combined with proton assignments. C_5 can be distinguished from the other quaternary carbons in terms of its long T_1, as in **1**. The MO calculations by the INDO method[6)] reveal that most of the excess π-charge densities of $\mathbf{1}^{2-}$ from **1**, Δq_c^{π}'s, occupy the cyclopentadienone moiety; the calculated ^{13}C shifts of $\mathbf{1}^{2-}$ from **1** ($\Delta\delta_c$), estimated using the standard value of k_c, 160 ppm/electron, in $\Delta\delta_c=k_c\cdot\Delta q_c^{\pi}$, are 19.5, 62.5, and 46.6 ppm for C_1, C_2, and C_5 respectively.[7)] With the aid of these results, the lines appearing at δ 116.16 and 105.97 were assigned to C_1 and C_2 respectively, while those at δ 144.59 and 143.59 were assigned to C_6 and C_{18}, but C_6 and C_{18} were indistinguishable from each other. Thus, the observed ^{13}C shift pattern of $\mathbf{1}^{2-}$ is, on the whole, consistent with that expected from theoretical considerations.

7) For the phenyl carbons, the pattern of the values of $\Delta\delta$(calcd) does not correlate well with that of $\Delta\delta$(obsd). Also, for the ring protons, the values of $\Delta\delta_H$ calculated using k_H=10.7 ppm/electron in $\Delta\delta_H=k_H\cdot\Delta q_c^{\pi}$ does not correspond well with those of $\Delta\delta_H$(obsd). These results may be accounted for by the fact that the polarization effect of the excess π-charge density at a carbon atom on the ^1H or ^{13}C shift does not become predominant over some other contributions to the ^1H or ^{13}C shift of the dianion from its neutral precursor, for the excess π-charges in the phenyl rings decrease considerably because of the very weak π-conjugation between the cyclopentadienyl and phenyl rings.

Studies of the Stabilities of Scandium, Yttrium, and Lanthanoid-Ion Complexes of 2-Nitroso-5-(*N*-propyl-3-sulfopropylamino)phenol

Isao YOSHIDA,* Fumio SAGARA, and Keihei UENO
Department of Industrial Chemistry, Kumamoto Insutitute of Technology,
Ikeda 4-22-1, Kumamoto 860
(Received December 4, 1987)

Synopsis. The stability constants of the 1:1 complexes formed by 2-nitroso-5-(*N*-propyl-3-sulfopropylamino)phenol (NPSAP: H_2L) with tervalent scandium, yttrium, and lanthanoids, but not promethium, have been determined potentiometrically in aqueous solutions at an ionic strength of 0.1 with potassium nitrate and at 25 °C. The stability constants of the 1:1 complexs increased with the increase in the atomic number of the lanthanoid, with the slight decrease at gadolinium. The stability constant of the 1:1 complex of scandium was the highest among the metal complexes investigated, while that of the yttrium complex was found to be between those of the cerium and praseodymium complexes.

Many studies have been reported on the complexing behavior of *o*-nitrosonaphthols,[1-6] such as 2-nitroso-1-naphthol-4,8-disulfonic acid with tervalent lanthanoid ions, and the stability constants for these complexes, including those for scandium(III) and yttrium(III) complexes,[5] have been discussed with respect to the structures of the ligands, the basicity of the donor atoms, and the relative sizes of central metal ions.[4]

Recently, 2-nitroso-5-(*N*-propyl-3-sulfopropylamino) phenol (NPSAP: H_2L) has been synthesized as a water-soluble nitrosophenol derivative and found to be a useful chromogenic reagent for iron[7] and cobalt.[8] The chelating behavior of the reagent with some bi- and ter-valent metal ions has also been described.[9] This paper will report on the chelating behavior of this particular ligand for tervalent lanthanoid ions, including scandium(III) and yttrium(III) ions, in order to provide more detailed information on the nature of *o*-nitrosophenols as ligands.

Experimental

The apparatus and methods were the same as those described in a recent paper.[9] All the measurements were carried out at 25±0.5 °C and at an ionic strength of 0.1 with potassium nitrate. All of the 0.01 M (1 M=1 mol dm^{-3}) stock solutions of the metal ions, except for those of thulium and lutetium, were prepared by dissolving their chlorides or nitrates in water. As to the two metal ions mentioned, their oxides were dissolved in hydrochloric acid; the solution was then boiled to dryness to expel the excess hydrochloric acid and subsequently diluted with water. The metal-ion concentrations, of the stock solutions were determined by EDTA titration.[10] The mathematical analysis of the chelating behavior of the ligand and the calculations of their stability constants were carried out by the use of the SUPERQUAD program[11] on potentiometric data, using $\log K_1^H=8.23$ and $\log K_2^H=2.61$ as the protonation constants of the ligand.[9]

Results and Discussion

The interpretation of the potentiometric data obtained from the titration of a 3:1 (ligand-to-metal) mixture of NPSAP with each of the lanthanoids, scandium, and yttrium ions indicated that, in most cases, only 1:1 complexes were formed when $-\log[H^+]$ was raised to about 4.8 by adding potaasium hydroxide. The results obtained on the stability constants for the 1:1 complexes are given in Table 1, as $\log \beta_1$, where $\beta_1=[ML^+]/[M^{3+}][L^{2-}]$, together with their computed standard deviations. The formation of the 2:1 complexes was observed on some metal ions; these results are also given in Table 1, as $\log \beta_2$, where $\beta_2=[ML_2^-]/[M^{3+}][L^{2-}]^2$.

No protonated or polynuclear complex species could be found in this system. It was impossible to increase the value for $-\log[H^+]$ to such an extent that any reliable data for the possible higher complexes could be found. The increase in the ligand-to-metal ratio would result in the formation of higher complexes; however, the titrations on such a mixture were not carried out in this experiment. A series of stability constants for the 1:1 complexes with fourteen lanthanoid metal ions is illustrated in Fig. 1, together

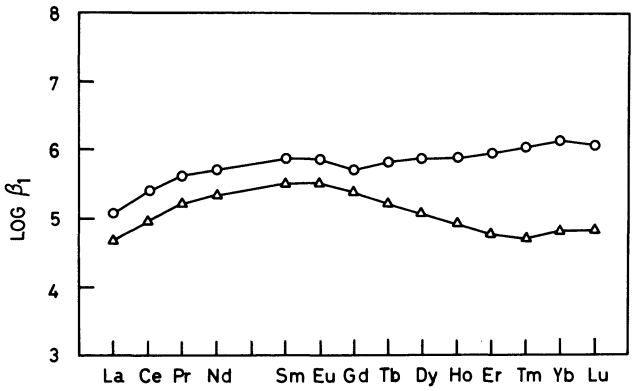

Fig. 1. Stability constants of the 1:1 complexes of lanthanoid ions with NPSAP (-○-) and 2-nitroso-1-naphthol-4,8-disulfonic acid (-△-) at 25°C and at I=0.1 (KNO_3).

with the corresponding values for 2-nitroso-1-naphthol-4,8-disulfonic acid.[4]

It seems from this figure that the stability trends of the complexes with the earlier half of the series of metal ions resemble each other among the two ligands. However, as to the later half of the series, the stability trends of the complexes with both ligands show a rather noticeable difference. The stability constants of the NPSAP complexes increase very slightly with an increase in the atomic number from gadolinium to ytterbium, whereas those of 2-nitroso-1-naphthol-4,8-disulfonic acid decrease from gadolinium to thulium.

According to Moeller et al., the trends in the stability-constant data for the lanthanoid elements heavier than gadolinium can be divided qualitatively into three groups; a group of ligands for which there is a regular increase in the stability constants, a group of ligands for which the stability constants have nearly the same values, and a group of ligands for which the stability constants decrease slightly.[12] The stability trend of NPSAP may be classified as that of the second group of ligands.

It has also been pointed out by the same authors that the value of the stability constant of the yttrium complex of this group of ligands was among those for light lanthanoid elements. The fact that the position of the stability constant of the yttrium complex with NPSAP was found between cerium and praseodymium complexes also suggests that NPSAP belongs to the second group.

The stability constants of the NPSAP comlexes with all of the lanthanoid ions are higher than that of 2-nitroso-1-naphthol-4,8-disulfonic acid, as is shown in Fig. 1. The relatively higher values of the stability constants of NPSAP compared with those for nitrosonaphthols were also observed on other metal ions, such as zinc(II) and copper(II).[9] Such a high stability of the NPSAP complexes may be ascribed to its higher basicity of phenolic oxygen compared to that of nitrosonaphthols.[9]

The stability constant of the scandium(III) complex is markedly higher than those of the lanthanoid complexes; this may be due to the smaller ionic radius of the scandium ion compared to those of the lanthanoid ions.[13]

The stability constants of the yttrium and lanthanum complexes of NPSAP are found to be in the order of $Cu^{2+}>Ni^{2+}>Y^{3+}>La^{3+}>Zn^{2+}$,[9] just as one can see in the case of the nitroso R acid complexes.[14]

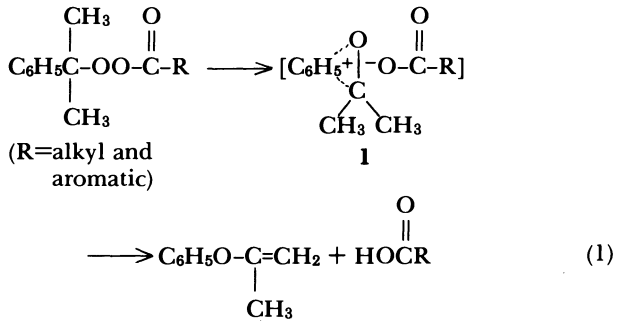
The Thermal Decomposition of 1-Methyl-1-phenylethyl 2,2-Dimethylperoxypropionate in Cumene

Takeshi KOMAI, Kenji KATO, and Kazuo MATSUYAMA*
Chemical & Explosives Research Laboratory, Nippon Oil & Fats Co., Ltd.,
Taketoyo-cho, Chita-gun, Aichi-ken 470-23
(Received October 29, 1987)

Synopsis. The thermal decomposition of 1-methyl-1-phenylethyl 2,2-dimethylperoxypropionate was studied in cumene. Based on the kinetic parameters and the decomposition products, it was concluded that the peroxyester was decomposed mainly by means of the radical process in cumene.

Most studies[1] concerning the thermal decomposition mechanism of 1-methyl-1-phenylethyl peroxyesters have indicated that these peroxyesters are rather decomposed ionically as is shown in Eq. 1, compared with 1,1-dimethylethyl analogues which



are decomposed by a radical process.[2] Leffler and Scrivener[3] have reported that 1-methyl-1-phenylethyl peroxyacetate is decomposed in toluene by means of competing radical (75%) and ionic (25%) pathways, based on the decomposition product. However, several reports[4] and patents[5] published more recently, have indicated that 1-methyl-1-phenylethyl 2,2-dimethylperoxypropionate (**2**) and 2,2-dimethylperoxyoctanoate can initiate the radical polymerization of vinyl monomers, such as methyl methacrylate, vinyl chloride, and ethylene. For the purpose of understanding this contradiction, we studied the thermal decomposition of **2** in cumene.

Results and Discussion

The rates of the thermal decomposition of **2** in cumene were determined by following the decrease in the peroxycarbonyl in the infrared spectra. The first-order rate constants were obtained with no appreciable change for a 10-fold increase in the peroxyester concentration. The results are given in Table 1 in order to compare them with those of the 1,1-dimethylethyl analogue.[2b] The liquid part of the decomposition products was analyzed using GLC; the results are shown in Table 2. In a separate analysis with HPLC, phenol was detected, but the amount was only 0.004 mol per mol of the decomposed peroxyester. These results indicate that the **2** was decomposed almost quantitatively by means of the radical process in cumene. The first reason is that the activation parameters are similar to those of the 1,1-dimethylethyl analogue (Table 1). This means that **2** in cumene decomposes homolytically in the same

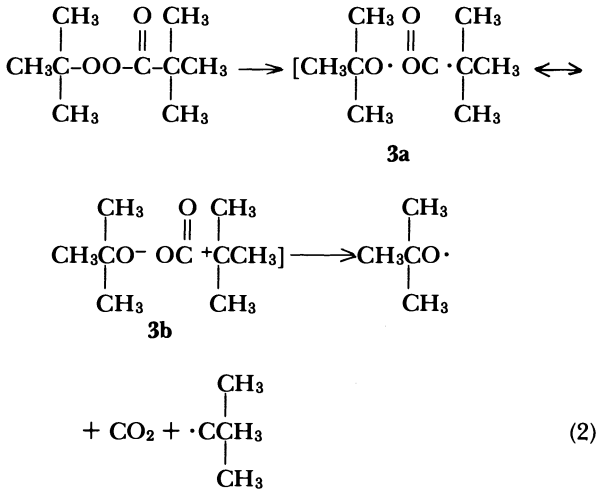


Table 1. Decomposition Rates and Activation Parameters in Cumene

a) Decomposition conditions: initial concentration of **2**, 0.050 mol dm^{-3}; decomposition, 96 h at 50 °C under a nitrogen atmosphere.

fashion to the 1,1-dimethylethyl analogue (Eq. 2), because the ionic decomposition of peroxyesters has a considerably smaller activation entropy than does the radical one.[1d)] The second reason involves the decomposition products. That is, the products in Table 2 can be explained as having been obtained from the 1-methyl-1-phenylethoxyl radical. Criegee rearrangement products, such as 2-phenoxypropene, phenol and 2,2-dimethylpropionic acid, could be detected in only small amounts; not at all. The higher yield of 2-phenyl-2-propanol compared with Leffler's results may be explained by the decomposition temperature and the disproportionation of the radicals in the solvent cage. Our experiment was done at a lower temperature (50 °C). The ratio of the β-scission of the alkoxyl radical to the hydrogen abstraction increased with the reaction temperature.[6)] The alkoxyl radical is much more likely to disproportionate with the 1,1-dimethylethyl radical than with the methyl radical in the solvent cage.[7)]

The peroxyester **2** decomposes more homolytically than does 1-methyl-1-phenylethyl peroxyacetate.[3)] This may be correlated with the acidity of the parent acids. Because the dissociation constant[8)] of 2,2-dimethylpropionic acid (8.91×10^{-6}) was smaller than that of acetic acid (1.23×10^{-5}), the peroxyester **2** is less acceptable as an ionic intermediate **1**, as is shown in Eq. 1. The rate constants in the decomposition of 1,1-dimethylethyl and 1-methyl-1-phenylethyl peroxyacetates in diphenylmethane and toluene at 100 °C were 1.23×10^{-5} [9)] and 3.43×10^{-5} s^{-1}, [1d)] respectively, and the later decomposed about 2.8 times faster than the former. However, the peroxyester **2** decomposed about 3.5 times faster than the 1,1-dimethylethyl analogue (Table 1). These differences indicate that the polar structure of **2**, similar to **3b**, may be stabilized by the electron-withdrawing phenyl substituent and that the contribution of the exothermic decarboxylation to the transition state may accelerate the homolitic decomposition of **2**.[10)]

Experimental

The peroxyester **2** was prepared by the reaction of 2,2-dimethylpropionyl chloride with 1-methyl-1-phenylethyl hydroperoxide in the presence of a 20% KOH aqueous solution in a method similar to that in the reference.[10)] The cumene was purified by the method described in Ref. 11. The decomposition rates were determined by following the carbonyl band of **2** at 1767 cm^{-1}. The decomposition products were determined by means of standard analytical techniques[10)] using gas-liquid chromatography (GLC) and high-performance liquid chromatography (HPLC).

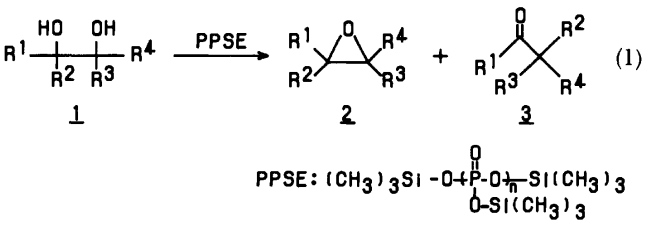
Pinacol-Pinacolone Rearrangement Promoted by Polyphosphoric Acid Trimethylsilyl Ester (PPSE)

Masa-aki KAKIMOTO,* Takuya SERI, and Yoshio IMAI
Department of Organic and Polymeric Materials, Tokyo Institute of Technology, Meguro-ku, Tokyo 152
(Received November 16, 1987)

Synopsis. Pinacols afforded the corresponding pinacolones in high yields in the presence of the polyphosphoric acid trimethylsilyl ester (PPSE) at a temperature above 80 °C. Tetraphenylethylene oxide, in addition to benzopinacolone, was obtained in the reaction of benzopinacol under milder conditions. The solvent effect suggested that the rearrangement proceeded via the carbonium-ion intermediate.

Pinacol-pinacolone rearrangement has been known as an acid-catalyzed rearrangement which involves the carbonium-ion intermediate.[1] Strong acids, such as sulfuric acid,[2] iodine-acetic acid,[3] and trifluoroborane,[4] have been used as catalysts. We have previously investigated the reactivity of the polyphosphoric acid trimethylsilyl ester (PPSE), which is readily soluble in aprotic solvents. Because PPSE has the characteristics of both a Lewis acid and a dehydrating agent, it has been successfully applied to the Pummerer rearrangement of sulfoxides,[5] to the synthesis of dithioacetals from carbonyl compounds and thiols,[6] and to the synthesis of amidines from carboxylic acids and amines.[7] In this article, we describe the pinacol-pinacolone rearrangement promoted by PPSE.



Results and Discussion

The results of the pinacol-pinacolone rearrangement are summarized in Table 1. Benzopinacol (**1a**) afforded both tetraphenylethylene oxide (**2a**) and benzopinacolone (**3a**) in a ratio depending markedly on the reaction conditions as shown in Entries 1—3. The use of an excess amount of PPSE or a higher reaction temperature (150 °C) afforded **3a** in a high yield. These results suggested that epoxide **2a** was an intermediate of the final rearrangement product **3a**. In fact, **2a** was completely converted into **3a** by treatment with an equimolar amount of PPSE in dichloroethane at 150 °C for 2 h. The acceleration effect of a polar solvent, tetrahydrothiophene 1,1-dioxide, sug-

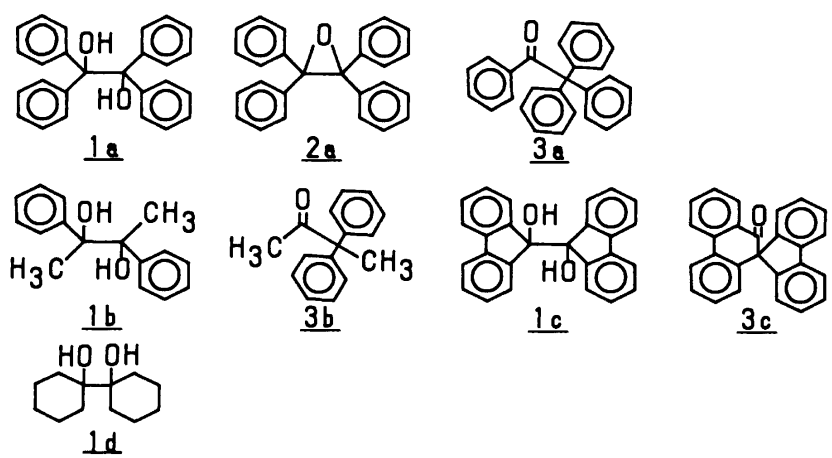

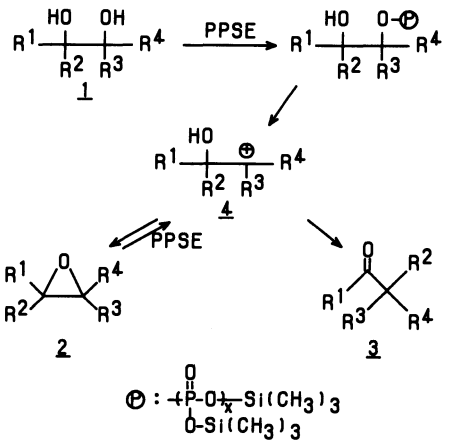

Scheme 1.

gested that the rearrangement proceeded via an ionic intermediate (Entries 4 and 7). In the reaction of pinacols **1b** and **1c**, the corresponding epoxides **2** were not obtained, and the reactions afforded only pinacolones **3b** and **3c**, respectively, in high yields. The reaction of aliphatic pinacol **1d** and PPSE afforded an unknown mixture whose IR spectrum indicated that it did not include either alcohols or carbonyl functions. The formation of olefins with the elimination of water was a possible reaction from the NMR spectrum, but it did not succeed in isolating the olefinic products.

As shown in Scheme 1, the present reaction should involve the paths of the phosphorylation of a pinacol and the formation of the carbonium ion **4** by the elimination of the silylated phosphoric acid. There are two possible paths starting from **4**. One is the direct formation of pinacolone **3**, and the other is the formation of epoxide **2**. Epoxide **2** is also rearranged in the presence of PPSE via the carbonium ion **4**.

The details of the reaction mechanism will be reported in the near future. The pinacol-pinacolone rearrangement promoted by PPSE should have a wide range of application in organic synthesis, because the reaction proceeds under more neutral and milder conditions than usual acid-catalyzed rearrangements.

Experimental

A typical procedure was as follows: PPSE (20.00 mmol) was prepared in 10 ml of 1,2-dichloroethane as has been described in a previous paper.[7] To this solution, 1.830 g (5.00 mmol) of benzopinacol (**1a**) was added, and the mixture was stirred at 80 °C for 5 h. The resulting solution was poured into 100 ml of a 1 M aqueous sodium hydroxide solution (1 M=1 mol dm^{-3}) and then extracted with dichloromethane. Benzopinacolone (**3a**) (1.046 g, 60%), and tetraphenylethylene oxide (**2a**) (0.471 g, 27%), were obtained by the column chromatography (Silica gel, dichloromethane/hexane=1/2) of the crude product.

3a: mp 179—180 °C (lit, 180—181 °C);[8] IR (KBr plate) ν/cm^{-1}=1680, 1590, 1490.

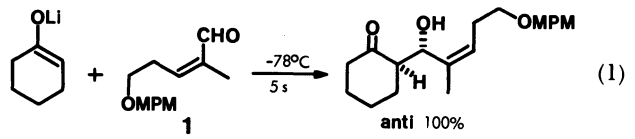
Reinvestigation of the Diastereoselectivity of Kinetic Aldol Condensation of Cyclohexanone Lithium Enolate with Benzaldehyde

Masahiro HIRAMA,* Takeshi NODA, Shoichi TAKEISHI, and Shô ITÔ
Department of Chemistry, Tohoku University, Sendai 980
(Received January 21, 1988)

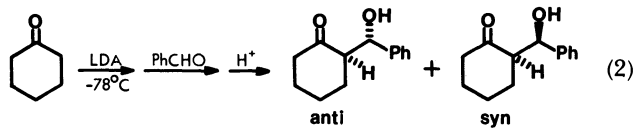
Synopsis. Aldol condensation of cyclohexanone lithium enolate with benzaldehyde has been shown to give a considerably higher stereoselectivity at low temperature than that reported previously.

It has been well-established that the aldol condensations from lithium (*E*)-enolates exhibit rather low anti diastereoselectivity.[1] In particular, lithium enolate of cyclohexanone with benzaldehyde has been recorded to give 1:1[2] anti/syn ratio at −20 °C and 1.1:1[3] even at −72 °C. Accordingly several devices using other metal ions have been developed to improve the selectivity.[2b,4] In connection with our synthetic study on a stereocontrolled construction of hexahydrobenzofuran subunit of the avermectins and the milbemycins, we examined the diastereoselectivity of kinetic aldol condensation of cyclohexanone lithium enolate with α,β-unsaturated aldehyde **1**, and have found that it gives a complete anti selectivity (Eq. 1).[5] These extreme results prompted us to reinvestigate the kinetic aldol reaction of the cyclohexanone lithium enolate with benzaldehyde (Eq. 2).



(1)

As the stereoselectivity might depend strongly on reaction temperature, the temperature of reaction mixture in a flask was controlled carefully and directly monitored by digital thermometer. The anti/syn ratios obtained under various conditions are summarized in Table 1. Contrary to the previous result,[3] considerably high ratios were obtained at low temperature in a short reaction period (entries 1, 3). The apparent ratio (ca. 5:1) at −78 °C is likely to be kinetic at this temperature because equilibration appears to be slow at −78 °C (entry 2), only reasonably rapid at −50 °C (entries 3, 4) and very rapid at −20 °C (entry 5). The temperature of reaction mixture was found to rise by up to 5 °C at the moment benzaldehyde was added to the enolate solution, even though the aldehyde solution was precooled.



(2)

Thus, the rapid equilibration of the lithium ketone enolates requires careful temperature control and short reaction period to get kinetic stereoselectivity in the condensation of cyclohexanone lithium enolate with benzaldehyde, as recognized in the condensations of other ketones such as propiophenone.[3]

Kinetic stereoselectivities with crotonaldehyde, isobutyraldehyde and trans isomer of **1**[5] at −78 °C were also obtained to be 7.0:1,[6] 28:1, and 20:1, respectively, which suggest that steric bulk owing to methyl group at α-position of α,β-unsaturated aldehydes such as **1** would play an important role for high kinetic diastereoselectivity.

Experimental

^{1}H NMR spectra were run for $CDCl_3$ solutions with Me_4Si as the internal standard on Varian XL200 and JEOL FX-90Q spectrometers. Infrared spectra were recorded on a JASCO IRA-2 diffraction grating spectrophotometer. Melting points were measured on a Yanaco MP-S3 hot stage melting point apparatus and were uncorrected. Elemental analyses were performed at Instrumental Analysis Center for Chemistry, Tohoku University. Reaction temperature was measured on a DELTA MC-20R digital thermometer with MC-20R-01 sensor (Pt 100 Ω).

THF was distilled from sodium benzophenone ketyl. Merck silica gel 60 (230—400 mesh) was used for column chromatography. Analytical thin-layer chromatography (TLC) was performed by using plates precoated with Wako silica gel 70 F_{254} (0.25 mm thick). HPLC analysis (column: Develosil 30-3, 15 cm×4 mm; solvent: Et_2O:hexane=3:2, 2 ml min^{-1}) was performed on a GILSON HPLC system (Model 302—802) with GILSON 111B UV detector (254 nm)

Table 1. Diastereoselectivity of Aldol Condensation of Cyclohexanone Lithium Enolate with Benzaldehyde

and Shimadzu Chromatopac C-R3A. All reactions were carried out in a three or two necked 10 ml flask equipped with the sensor of digital thermometer under an argon atmosphere.

General Procedure: A 1.61 M† hexane solution of butyllithium (0.650 ml, 1.05 mmol) was added to a solution of diisopropylamine (0.154 ml, 1.1 mmol) in dry THF (2 ml) at −78 °C and stirred at 0 °C for 10 min. To this LDA solution was added dropwise a solution of cyclohexanone (98 mg, 1.0 mmol) in dry THF (0.5 ml) at −78 °C. After 20 min at this temperature, a cooling bath was replaced to set the solution at a specific temperature. After the temperature became specific, to this solution was added quickly a cold (−78 °C) solution of an aldehyde (0.112 ml, 1.0 mmol) in dry THF (0.5 ml) by a syringe or via a cannula at the temperature. After 3 s, a saturated aqueous NH_4Cl (5 ml) was added and the mixture was warmed up to room temperature, extracted with ether (3×10 ml). The combined organic layer was dried over $MgSO_4$ and concentrated. A diastereomer ratio of the aldol was determined by ^1H NMR spectroscopy (relative intensity of carbinol methine proton) or HPLC analysis of crude product. The crude mixture was chromatographed on SiO_2 column with AcOEt/hexane (1:3) as an eluent to give pure aldols from benzaldehyde in the yield shown in Table 1 or a mixture of diastereomers (70% yield) from the other aldehydes.

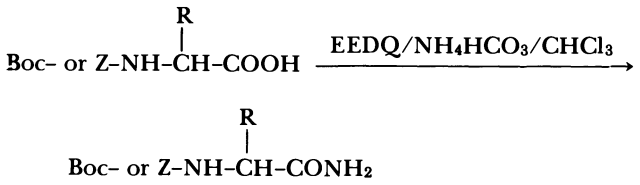
Convenient Synthesis of *N*-Protected Amino Acid Amides[1)]

Sukekatsu NOZAKI* and Ichiro MURAMATSU†
Faculty of Pharmaceutical Sciences, Josai University, Sakado, Saitama 350-02
†Department of Chemistry, College of Science, Rikkyo University, Nishi-Ikebukuro, Tokyo 171
(Received February 19, 1988)

Synopsis. Boc- or Z-amino acids were conveniently amidated at room temperature by a one-pot procedure employing ammonium hydrogencarbonate and *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline in yields of 81—96%. The benzyl ester-type protector for the side chains of aspartic acid and glutamic acid was not affected by the procedure.

Amino acid amides, an important starting material in peptide synthesis, are usually prepared by ammonolysis of amino acid esters, or by coupling of *N*-protected amino acids with ammonia.[2)] The former procedure is somehow inconvenient, since ammonia, a reagent often troublesome for handling, is required and the reaction is rather slow. In the latter, care must be paid to prevent possible racemization during activation of the amino acids, especially when mixed anhydride method[3)] was employed for the purpose.

We report here that by addition of ammonium hydrogencarbonate and *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ),[4,5)] a mild mixed anhydride-type coupling reagent stable to amines,[5)] Boc- or Z-amino acids in chloroform are conveniently converted to the corresponding amides at room temperature.



The reaction proceeded smoothy with gentle evolution of carbon dioxide, although ammonium hydrogencarbonate is scarcely soluble in the solvent. The amides were readily isolated in satisfactory yields after removal of the excess ammonium hydrogencarbonate by washing the reaction mixture with water. By this procedure, the benzyl ester-type protecting group for the β- or γ-carboxylic acid part of aspartic acid or glutamic acid, respectively, was not affected. No racemization occurred during the amidation when an *N*-protected amino acid with a urethane-type protector was employed as the starting compound. However, this method cannot be applied to the preparation of a peptide amide consisting of an optically active amino acid at the C-terminal, since in a test preparation, Boc-L-leucyl-L-leucine gave a considerable amount of the diastereomeric product (14%), Boc-L-leucyl-D-leucinamide. The data are summarized in Table 1.

Experimental

Melting points were uncorrected. Merck precoated silica-gel plates were used for TLC analysis with a solvent system of chloroform–MeOH (19:3). For HPLC analysis, a LiChrosorb RP-18 column (4×250 mm) was employed with a solvent system of MeOH–water (1:1) at a flow rate of 1.83 ml min^{-1}. The column effluent was monitored at 220 nm, and the peak area was recorded by a Shimadzu C-R3A integrator.

Preparation of Boc-Glu(OBzl)-NH_2 (General Procedure).

a) Each compound gave a single spot on TLC. Satisfactory data of microanalysis was obtained for each compound within an error range of ±0.3%. b) Mp 156—157 °C in lit;[6)] mp 157—158 °C in lit.[7)] c) Mp 142 °C, $[\alpha]_D^{25}$ +1.6° (*c* 1, MeOH) in lit.[8)] d) Mp 161—162 °C in lit;[9)] mp 164—165 °C, $[\alpha]_D^{20}$ −4.9° (*c* 1.5, 80% AcOH) in lit;[10)] mp 163—164 °C, $[\alpha]_D^{25}$ −6.3° (*c* 2, DMF) in lit.[11)] e) Mp 187—188 °C in lit.[12)]

Boc-Glu(OBzl)-OH (0.675 g, 2 mmol), EEDQ (0.544 g, 2.2 mmol), and ammonium hydrogencarbonate (0.474 g, 6 mmol) were suspended in chloroform (5 ml), and the mixture was stirred overnight at room temperature. The mixture was then washed with water (2 ml×1, 1 ml×1) and evaporated to give a solid, which was recrystallized from ethyl acetate-hexane; 0.603 g (90%); mp 120—122 °C. Found: C, 61.00; H, 7.39; N, 8.22%. Calcd for $C_{17}H_{24}O_5N_2$: C, 60.70; H, 7.19; N, 8.33%.

Preparation of Boc-Ala-NH_2 and Boc-Pro-NH_2. Prepared according to the general procedure with modification: the aqueous washing phase was extracted with chloroform (2 ml×6) to recover the water soluble products. The desired amides were obtained from the combined organic layer.

Preparation of Z-Trp-NH_2. Prepared according to the general procedure with modification: a larger volume of chloroform (25 ml) was used as the solvent because of the poor solubility of the product.

Racemization Test. a) In Amidation of Amino Acid: Boc-Leu-NH_2 (0.326 g, 1.42 mmol) prepared by the general procedure described above was dissolved in 4 M† HCl/dioxane (5 ml) at room temperature. After 15 min, the mixture was evaporated and the residue was triturated in ether to give a solid (0.232 g), which was then dissolved in chloroform (10 ml) and triethylamine (0.20 ml, 1.44 mmol). To this solution was added Boc-Leu-ONSu (0.473 g, 1.44 mmol) and the mixture was stirred overnight at room temperature. The mixture was then washed successively with 0.1 M HCl (2 ml×1, 1 ml×1), water (2 ml), 0.5 M $NaHCO_3$ (2 ml×1, 1 ml×1), and water (2 ml×2). An aliquot (0.002 ml) of the chloroform solution was analyzed by the HPLC to determine the ratio of Boc-Leu-Leu-NH_2 (the retention time of the authentic sample, 24 min) and Boc-Leu-D-Leu-NH_2 (30 min). Similarly Boc-Phe-NH_2 obtained was converted to Boc-Leu-Phe-NH_2 and the purity of the product was also examined by the HPLC (the retention time of an authentic Boc-Leu-Phe-NH_2, 34 min; Boc-Leu-D-Phe-NH_2, 44 min). In either case, no peak corresponding to the D-amino acid containing peptide was observed (less than 0.2%).

b) In Amidation of Peptide: Boc-Leu-Leu-OH (0.344 g, 1 mmol), EEDQ (0.272 g, 1.1 mmol), and ammonium hydrogencarbonate (0.237 g, 3 mmol) were allowed to react in chloroform (5 ml) overnight at room temperature. The reaction mixture was washed with water (2 ml×1, 1 ml×1) and evaporated to give an oil, which was then dissolved in AcOEt. By addition of hexane, a viscous oil was separated. The oil collected by decantation was dissolved in MeOH and analyzed by the HPLC.

Selective Synthesis of Ethylene by Dehydrogenative Coupling of Methane by Use of Thermal Diffusion Column

Tatsuaki YAMAGUCHI* and Chiaki SAITO
Laboratory of Organic Chemistry, Chiba Institute of Technology,
Tsudanuma, Narashino-shi, Chiba 275
(Received February 8, 1988)

Synopsis. Ethylene was found to be obtained dehydrogenatively from methane in extremely high selectivities (91.5% at 9.4% conversion of methane) with the downward introduction to the modified thermal diffusion column with electrically heated tungusten wire at 1200 °C.

From the challenging viewpoint of the utilization of natural gas, the partial oxidative conversion of methane into more useful chemicals such as ethylene[1] and methanol[2] has been investigated more and more extensively. Nevertheless, less attention has been now taken on the direct dehydrogenative coupling of methane to ethylene because it requires temperatures higher than 1000 °C. But the by-production of hydrogen is the advantage of this process over the oxidative one.

$$2CH_4 \longrightarrow CH_2{=}CH_2 + 2H_2$$

Half a century ago, Clusius and Dickel invented a powerful separation column based on thermal diffusion and thermal convection.[3] A few years later Hirota applied this separation column to the thermal polymerization of methane and succeeded in getting condensed hydrocarbon oil in a good yield.[4]

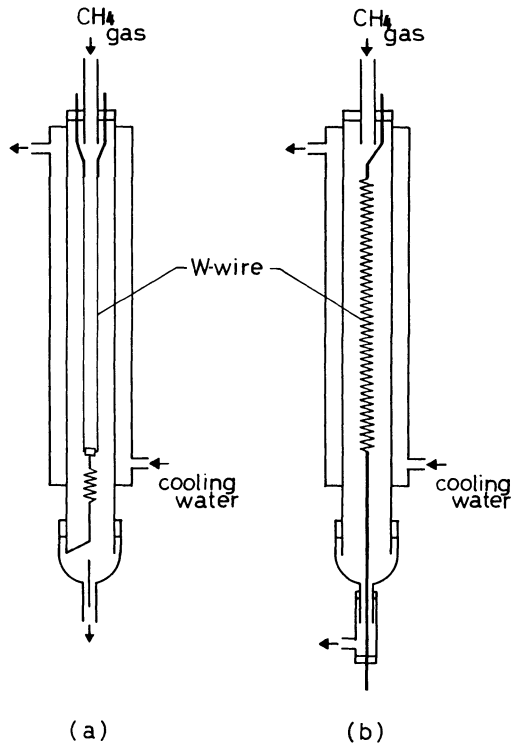

Fig. 1. Clusius-Dickel type thermal diffusion column reactor. The tungsten wire is modified in a) U-type, b) spiralled type.

By the upward flow (linear velocity 3.8 m h^{-1}) of methane in a water-cooled Pyrex-glass column of 1 m in length and 2 cm in diameter centering a straight tungsten wire of 70 cm in length and 0.5 mm in diameter, which was heated electrically at 1200 °C on surface, we could fully reproduce Hirota's results obtaining hydrocarbon oil in the yield of 62% of methane feeded. However, the operation in downward flow of methane with the similar apparatus in the same conditions was found to give a quite different result. Thus, ethylene was obtained in the yield of 5.4% with 90% selectivity at 1200 °C accompanying with far less amount of oily matter.[5]

With intent of enhancing the methane conversion, the shape of the tungsten wire is now modified from a straight line to a U-type (Fig. 1a) or a spiral (Fig. 1b) in this paper.

Experimental

Deoxygenated methane gas was introduced from the top of the thermal diffusion column (Fig. 1, length 40 cm, inner diameter 2.0 cm) without preheating under ordinary pressure, and the out-let gas from the bottom was analyzed by a gaschromatograph (Shimadzu GC-9A). The surface temperature of the tungsten wire was measured pyroptically by a radiation pyrometer (Minolta IR-120). And the amount of the alternating current was measured by a clamp tester (SOAR Model 2220).

Results and Discussion

The results are summarized in Table 1 with experimental details. In the case of Run 1, substantially 100% selectivity to total C_2 compounds was obtained. But in other cases oily matter condensed on the cold wall of column as by-products. Especially carbonaceous product was observed in Run 7. This means too much heating of the gas phase causes unfavorable results on ethylene selectivity. As expected, increasing the contact chance of methane molecule on the high-temperature tungsten surface gave the favorable effect increasing the methane conversion and the hydrogen yield with high selectivities of ethylene (Runs 1—3). The ethane yields were as low as 0.3% in every run.

Figure 2 shows variations of the product yields with the linear velocity of gas flow in the column with U-type tungsten wire. The higher linear velocity resulted in decrease of the methane conversion and increase of the ethylene selectivity. The maximum of the ethylene yield was given around 6 m h^{-1} with this type of reactor. The ethane productions were limited in a very low yield in this case again.

Table 1. Results with the Modified Column

Run No.	W wire length	Heating zone	Electric power	Methane conv.	Ethylene		Ethane		Hydrogen yield
					yield	selec.	yield	selec.	
	cm	cm	W	%	%	%	%	%	%
1	30	30	150	2.6	2.3	89.5	0.3	10.5	5
2	60[a)]	30	450	9.4	8.6	91.5	0.3	3.4	27
3	120[b)]	30	675	14.2	12.6	88.8	0.3	2.0	43
4	30[c)]	24	150	3.5	2.9	82.1	0.3	8.6	8
5	30[c)]	18	150	4.2	3.8	90.6	0.3	6.6	11
6	30[c)]	12	150	9.1	7.1	78.1	0.3	2.9	23
7	30[c)]	6	150	26.1	15.0	58.1	0.2	0.7	56

Methane feed rate 1.8 dl h^{-1}, linear velocity 5.76 m h^{-1}, average surface temperature of W wire 1200 °C. Values for selectivities were based on the methane conversion. Yields of ethylene and ethane were defined as the product of the conversion and the selectivity. Hydrogen yields were calculated from the molar ratio of produced hydrogen to methane feeded. a) Folded in U-type. b) Folded in W-type. c) Spiralled 4 mm in diameter.

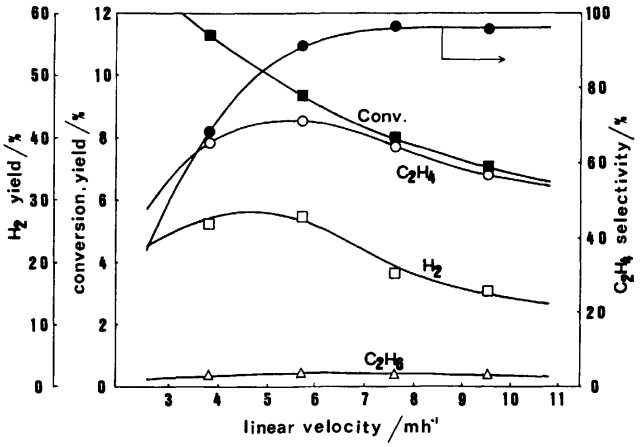

Fig. 2. The influence of the linear velocity of methane in the column.
Tungsten wire 0.5 mm×60 cm, U-type (heating zone 30 cm), surface temperature 1200 °C. Methane conversion: ■. Ethylene selectivity: ●. Yields: ○, ethylene; △, ethane; □, hydrogen.

The phenomenon giving high selectivity of ethylene production may be understood in terms of two theoretical considerations. First, the thermodynamic data give the favorable free energy change for the gas-phase conversion of methane to ethylene at 1200 °C over that to ethane. This is suggested from the fact of the very low yield of ethane throughout the experiments at this temperature. Secondly, the thermal diffusion due to the temperature gradient between the surfaces of the heated tungsten wire and the cold wall of the column permits the produced ethylene molecule, which is of the highest molecular weight in the system, to leave the heated surface for the cold wall. Following by the thermal convection the ethylene molecule is driven downward along with the cold wall and the hydrogen molecule driven upward as pointed out by Clusius. The observation of less brightness in the upper part of the tungsten wire suggests a higher concentration of hydrogen around this part of the column. By this effect the produced ethylene may be prevented from the recombination with hydrogen. Further polymerization of ethylene which occured by its recycling to the high-temperature surface may be limited because its downward direction along the cold wall is with the current when the overall feed flow in the column is downward.

From the practical viewpoint, it should be noted that the electric power required in this procedure would be rather low since it is not necessary to heat the whole gas phase up to 1200 °C.

Diverse Kinetic Behaviors of the β-Structure Formation. A Study on Poly(*S*-carboxymethyl-L-cysteine)

Kazuhiro FUKADA,* Hideyuki HATTORI, Hiroshi MAEDA,* and Shoichi IKEDA*
Department of Chemistry, Faculty of Science, Nagoya University, Nagoya 464-01
(Received December 4, 1987)

Synopsis. The pH jump kinetics of random coil-to-β-structure convertsion of poly(*S*-carboxymethyl-L-cysteine) were examined on two samples of degree of polymerization (DP) of 330 and 560. Various kinetic behaviors were observed depending on polymer chain length and concentration: single exponential with or without a lag and two exponential behavior. In unbuffered solutions, the rate enhancement of β-formation was confirmed.

Kinetics of the β-structure formation of polypeptides have been studied mainly on two polypeptides; poly(L-lysine)(PLL)[1-5] and poly(L-tyrosine) (PLT).[6,7] Conversion from the α-helix to the β-structure of PLL with degree of polymerization (DP) 240 or 1000 by a temperature change followed first-order kinetics and the rate was independent of concentration below about 10—20 mg L^{-1}.[2] In the kinetics of coil-to-β conversion of PLL (DP=700) induced by an isothermal pH jump at high temperature, however, there was a slow initiation step and the progress of reaction was sigmoidal.

In the case of β-formation by pH jump of PLT, the kinetics were described in terms of superposition of two exponential terms without any sigmoidal behavior.

These results show that two polypeptides behave differently with respect to kinetics of chain folding. This aspect was already pointed out[6] and hence diverse kinetic behaviors are ascribed to different kinds of side chains of the polypeptides. However, it will be shown in the present study that various kinetic behaviors previously found on PLL and PLT were all observed on the kinetics of pH induced coil-to-β conversion of poly(*S*-carboxymethyl-L-cysteine) (poly[Cys(CH_2COOH)]), another well characterized model β-polypeptide.[8-10]

Experimental

Average degrees of polymerization (DP) of the two samples of poly[Cys(CH_2COOH)] used in the present study were 330 and 560. Residue ellipticity at 210 nm, $[\theta]_{210}$, varied from $-(4—5)\times10^3$ to $(1.0—1.1)\times10^4$ and that at 205 nm, $[\theta]_{205}$, varied from $-(8—10)\times10^3$ to $(2.6—2.9)\times10^4$ accompanying to coil-to-β conversion. The conversion occurred at about pH 4.9 in 50 mM sodium salt aqueous solutions (1M=1 mol dm^{-3}). We used $[\theta]_{210}$ or $[\theta]_{205}$ as a measure of the β-formation. Circular dichroism (CD) was recorded on a Jasco J-40A circular dichrograph at 25(±0.1) °C, using cells of 2, 10 and 20 mm light paths.

Kinetics of the β-formation were carried out as follows. The solution in a test tube containing poly[Cys(CH_2COOH)] and 50 mM $NaClO_4$, with or without sodium acetate buffer (pH≈7), was brought to acid pH (between 4.7—4.9) by the addition of a small amount of 0.1 M HCl followed by immediate mixing. It took only a few seconds to attain complete mixing. A part of the mixed solution was introduced into the cell and $[\theta]_{210}$ or $[\theta]_{205}$ was continuously recorded for about 1.5×10^3 s. The earliest reliable readings were obtained at about 15 s after the pH jump. Afterward, CD spectra (200—260 nm) were measured at selected time intervals until the reaction was completed. The rest of the solution was used for pH measurement. An Iwaki M 225 pH meter was used to determine the pH when the reaction were completed.

Results and Discussion

Diverse Kinetic Behaviors of the β-Formation of Poly[Cys(CH_2COOH)]. Kinetic study of the β-formation in acetate buffer solutions was performed at two polymer concentrations (C_p) on the sample of DP=330 (see Fig. 1). The dependence of the rate of β-formation on pH is shown in Fig. 1(a). At a C_p of 5×10^{-4} M (80 mg L^{-1}), the β-formation proceeded faster as the pH became lower, where β-structure carried a smaller number of charges. The effect of concentration can be seen in Fig. 1(b), where β-formation is slower at the polymer concentration of 1×10^{-4} M (16 mg L^{-1}) than at 5×10^{-4} M. Figure 1(b) further indicates that the β-formation at $C_p=1\times10^{-4}$ M hardly proceeds within 5×10^3 s (a time lag) and the whole kinetic curve is sigmoidal.

These kinetic data were analyzed as follows. The extent of unreacted fraction after pH jump is given with Eq. 1 as a function of time.

$$f(t) = ([\theta]_{210}(\infty) - [\theta]_{210}(t))/([\theta]_{210}(\infty) - [\theta]_{210}(0)) \quad (1)$$

Here, $[\theta]_{210}(t)$ denotes the residue ellipticity at time t, and $[\theta]_{210}(\infty)$ is the value at equilibrium. Semilogarithmic plots of f versus time are indicated in the insets of Fig. 1(a) and (b). As shown in the inset of Fig.1 (a), at $C_p=5\times10^{-4}$ M the time course $f(t)$ could not be fitted with a single exponential term but by the superposition of two exponential terms shown below

$$f(t) = A\exp(-t/\tau_1) + (1 - A)\exp(-t/\tau_2) \quad (2)$$

Here, τ_1 and τ_2 are the phenomenological time constants for the fast and slow processes, and A is the amplitude of the fast process. It was confirmed that the two-term exponential decay curves gave better fit to all the experimental data shown in Fig. 1(a) than single exponential curves. This kinetic pattern is in accord with the kinetics of PLT.[6,7]

At $C_p=1\times10^{-4}$ M, on the other hand, the reaction approximately follows a single exponential decay after a time lag (see inset of Fig. 1(b)). Single exponential decay with a lag was also found in the isothermal pH jump kinetics of PLL. It is to be noted that the lag in the case of PLL was obtained with light scattering and fluorescence but not with optical activity as was done in the present study.[5] It was expected that at very dilute solutions such as

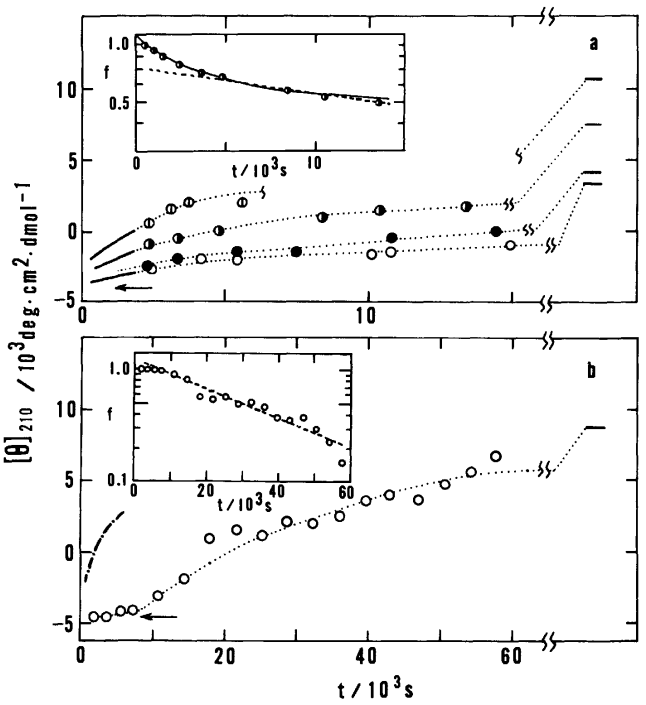

Fig. 1. Kinetics of the β-formation of the sample of DP=330 in 20 mM sodium acetate buffer +50 mM $NaClO_4$. Values of $[\theta]_{210}$ are represented with various circles and with solid thick lines for the initial stage where measurements were carried out continuously. Arrows indicate the initial value of $[\theta]_{210}$.
(a) $C_p=5\times10^{-4}$ M; pH=4.90 (○), 4.87 (●), 4.84 (◑), and 4.74 (Φ). Inset: A semilogarithmic plot of the unreacted fraction f (defined by Eq. 1) versus time of the data at pH 4.84. A solid line indicates the two-term exponential curve, i.e., $f=0.42\exp(-t/2700)+0.58\exp(-t/140000)$. A broken line indicates the single exponential decay curve fitted to the data of long time region.
(b) $C_p=1\times10^{-4}$ M; pH=4.76. A chain line indicates the data at $C_p=5\times10^{-4}$ M (pH=4.74). Inset: A semilogarithmic plot of f versus time. A broken line indicates the single exponential decay curve with a lag time of 5×10^3 s.

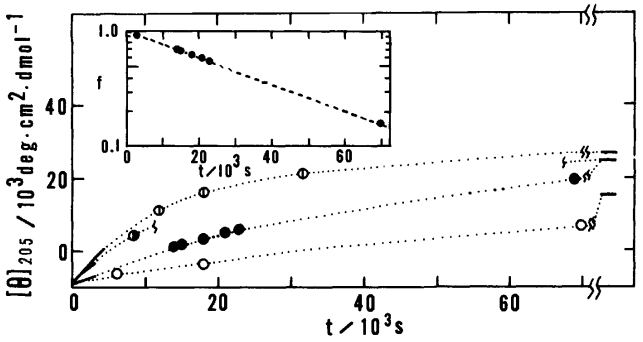

Fig. 2. Kinetics of the β-formation of the sample of DP=560 at different values of pH and concentrations. $C_p=2\times10^{-4}$ M; 10 mM sodium acetate buffer +50 mM $NaClO_4$: pH=4.86 (○) and 4.79 (◑). $C_p=5\times10^{-5}$ M; 2 mM sodium acetate buffer +50 mM $NaClO_4$: pH=4.74 (●) and 4.71 (Φ). Inset: A semilogarithmic plot of f versus time for the data at pH 4.74 ($C_p=5\times10^{-5}$ M).

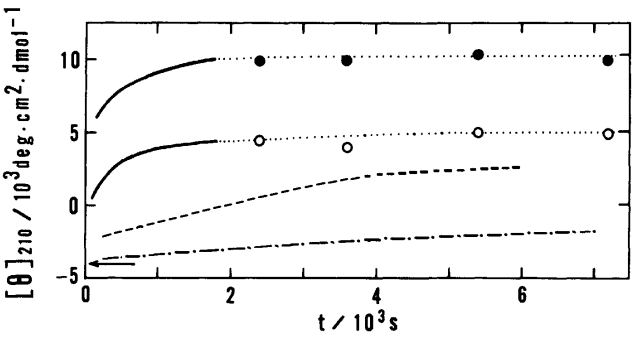

Fig. 3. Kinetics of the β-formation in unbuffered solutions at $C_p=5\times10^{-4}$ M in 50 mM $NaClO_4$ for the sample of DP=330. (○) pH 4.90 and (●) pH 4.80. Solid thick lines represent the values of $[\theta]_{210}$ for initial stage where measurements were carried out continuously. The broken (chain) curve represents the kinetic data at similar concentration in acetate buffer of similar ionic strength at pH 4.74 (4.90). Those data are taken from Fig. 1(a) and given for the sake of comparison.

1×10^{-4} M, β-formation of poly[Cys(CH_2COOH)] proceeded by two-step mechanism of slow nucleation followed by fast growth.

In Fig. 2, kinetic data of the sample of DP=560 are summarized for different pH and concentrations. No lag was observed even at lower concentration of 5×10^{-5} M (8 mg L^{-1}) for this long chain sample. All kinetics shown in Fig. 2 followed the first-order rate law, as indicated in the inset for an example. The first-order kinetic behavior is consistent with the case of thermally induced α→β conversion of PLL.[2-4] Thermal coil-to-β conversion of poly[Cys(CH_2COOH)] showed kinetic behavior too complex to be described with two exponential terms.[12]

From these results, it was confirmed that various kinetic behaviors previously found on PLL and PLT were all observed in the β-formation of poly[Cys(CH_2COOH)] depending on polymer chain length and concentration: single exponential behavior with or without a lag and two exponential behavior. Therefore, we expect that diverse kinetic behaviors accompanying the β-formation originate rather from diverse aspects of the kinetics of polypeptide chains in general than from different kinds of side chains as has been supposed to be. It is to be noted that the β-formation of homopolypeptide chains consists of many elementary steps and hence various kinetic behaviors manifest themselves depending on which step is rate-limiting. In addition, the polydispersity of samples may possibly contribute to the diverse behaviors. A simple kinetic theory explicable of diverse kinetic patterns of intramolecular β-formation has been recently presented.[13]

Rate Enhancement of the β-Formation in Unbuffered Solutions. In Fig. 3, the rates of β-formation in unbuffered solutions are compared with those in buffer at similar conditions. At the same pH of 4.90, the rate of the β-formation is faster in the absence of

acetate buffer. Within 4×10^3 s the β-formation is completed at both pH 4.80 and pH 4.90 in the case of unbuffered solution.

It was confirmed that acetate buffer had little effect on the stability of the β-structure of poly[Cys-(CH_2COOH)],[11] hence its specific effect on the kinetics can be ignored.

The observed rate enhancement could be explained in terms of either or both of the two mechanisms: the seeding effect and the different pathways. The formation of seed may occur as follows. When 0.1 M HCl is added to and mixed with the polymer solution, the added 0.1 M HCl will be dispersed in a number of small drops, hence microscopic inhomogeniety with respect to pH will result. In the presence of buffer, this inhomogeniety disappears rapidly due to the fast diffusion of both H^+ and acetate ions. In the absence of buffer, however, this equilibration process takes a long time. At the early stage of the process, the conversion of polymer molecules from random coils to the β-structure nuclei takes place in the interface region between the low pH small drops and the polymer solution. There remain these nuclei, more or less, after pH becomes uniform. They play the role of the seed in the folding of unfolded molecules.

On the other hand, it is likely that the reaction proceeds via different pathways for buffered and unbuffered solutions. While the coil-to-β conversion proceeds at constant pH in buffered solutions, it proceeds at nearly constant charges in the case of unbuffered solutions (random coil polymers are protonated at first by the added acid, and then converted to β-structure under the constant charges).

We carried out pH jump kinetic experiments with unbuffered solutions using a mixing unit for stopped-flow apparatus (MODEL MX-7, Union Giken Company, Osaka) which mixed solutions at most within 0.1 s. The rate enhancement was again observed by means of this device nearly to the same extent as with manual mixing. This result supports the latter mechanism rather than the former, unless the β-structure nuclei were formed within 0.1 s.

The Lowest Triplet States of 2-Amino- and 2-Amino-d_2-pyrimidines

Yoshinori NIBU, Masayoshi MAEHARA,† Hiroko SHIMADA,† and Ryoichi SHIMADA*
Department of Chemistry, Faculty of Science, Kyushu University 33,

(Received December 12, 1987)

Synopsis. The vibrational analyses of the sublevel phosphorescence spectra of 2-amino- and 2-amino-d_2-pyrimidines were made. The result shows that the lowest triplet $^3A_1(\pi,\pi^*)$ state is strongly perturbed by closely lying $^3B_1(n,\pi^*)$ and $^3A_2(n,\pi^*)$ states and the polarization of the very weak 0–0 bands in the dark sublevel spectra suggests that the symmetry of the molecular structure in the lowest triplet state is slightly lowered from the point group C_{2v} to the C_2.

Kleinwacher et al.[1] studied the absorption and emission spectra of 2-aminopyrimidine and assigned the lowest triplet state to a $^3A_1(\pi,\pi^*)$ state based on the polarization behavior of the phosphorescence. Since $^3B_1(n,\pi^*)$ and $^3A_2(n,\pi^*)$ states were considered to lie closely above the phosphorescent state,[2,3] it was expected that the lowest triplet state would be strongly perturbed by these two $^3(n,\pi^*)$ states. Nishi and Kinoshita[4] studied the individual sublevels of the lowest triplet state of 2-aminopyrimidine by the microwave induced delayed phosphorescence method and showed that the short-, medium-, and long-lifetime phosphorescences originate from the y, z, and x sublevels, respectively. They analyzed the phosphorescence spectrum based on the normal vibrations determined by Lafaix and Lebas[5] and concluded that the most effective phosphorescence mechanism for the y sublevel of the phosphorescent state is the first-order spin-orbit coupling between the $^1B_1(n,\pi^*)$ and $^3A_1(\pi,\pi^*)$ states, and that of the z sublevel is the second-order spin-orbit-vibronic coupling between the $^1A_1(\pi,\pi^*)$ and $^3A_1(\pi,\pi^*)$ states via the $^3A_2(n,\pi^*)$ state.

Very recently we reexamined the assignments of the normal vibrations of 2-amino- and 2-amino-d_2-pyrimidines and gave new assignments.[6] In this paper the vibrational analyses of the sublevel phosphorescence spectra of 2-amino- and 2-amino-d_2-pyrimidines are discussed based on the polarization behavior of the phosphorescence bands and normal vibrations newly determined and the phosphorescence processes of these molecules are restudied.

Experimental

Materials. 2-Amino-d_2-pyrimidine was obtained by the exchange reaction of 2-aminopyrimidine (Tokyo Kasei) with D_2O. The samples were purified by repeated distillation under reduced pressure. The solvent, benzene (Dotite Spectrosol Grade), was completely desiccated with an alloy of sodium and potassium because 2-amino-d_2-pyrimidine turned into 2-amino-d_1- and/or 2-aminopyrimidines quite easily by the exchange reaction with water containing in the solvent.

Optical Measurements. The phosphorescence lifetimes and the time-resolved phosphorescence spectra of 2-amino- and 2-amino-d_2-pyrimidines were measured in benzene matrices at 1.4 K. Using the relative values of the populations and radiative rate constants and the lifetimes for the lowest triplet sublevels of 2-aminopyrimidine determined by Nishi and Kinoshita,[4] the intensity ratio of the 0–0 bands of the phosphorescence spectra originating from the y, z, and x sublevels was calculated changing the sampling time after interrupting the excitation. The calculated intensity ratios indicate that the three sublevel phosphorescence could be mechanically separated if the adequate sampling time was chosen.

The short-lifetime phosphorescence was observed by sampling the emission from 3 ms to 40 ms after the cessation of the excitation. For the observation of the medium- and long-lifetime phosphorescences, the sampling times were set at 300—400 ms and 4000—5000 ms, respectively, after cutting off the exciting light.

The polarized phosphorescence spectrum was observed in a benzene host crystal at 1.4 K in the same way as described previously.[7] Since we have no knowledge about the orientation of the 2-aminopyrimidine molecule in the benzene single crystal, the polarized phosphorescence spectrum was observed with a rotatable polarizer whose orientation was set in such a way that the intensity of the 0–0 band in the short-lifetime spectrum became strongest and the rotation of the polarizer by 90° made the intensity weakest. The spectra observed at the former and latter orientations of the polarizer are drawn with solid and dotted lines and are referred to as solid and dotted spectra hereafter, respectively. The optical and electric apparatus used for the measurements of the time-resolved phosphorescence spectra, the polarized phosphorescence spectra and the phosphorescence lifetimes are exactly the same as those described previously.[7–9]

Results and Discussion

The phosphorescence lifetimes of 2-amino- and 2-amino-d_2-pyrimidines in benzene at 1.4 K were determined through the analysis of the phosphorescence decays. The short-, medium-, and long-lifetimes obtained for 2-amino-d_2-pyrimidine were 35, 395, and 1500 ms, respectively, and the lifetimes obtained for 2-aminopyrimidine were approximately equal to the sublevel lifetimes determined by Nishi and Kinoshita in p-xylene.[4] The mechanically resolved sublevel phosphorescence spectra of 2-amino- and 2-amino-d_2-pyrimidines in benzene at 1.4 K are shown in Figs. 1 and 2, respectively, where the intensity of the strongest band in each spectrum is normalized to unity.

The vibrational analysis of the short-lifetime phosphorescence spectrum of 2-aminopyrimidine will be discussed first. The shortest wavelength band at 27646 cm^{-1}, whose intensity is the strongest in the spectrum, was taken as the 0–0 band. The strong bands

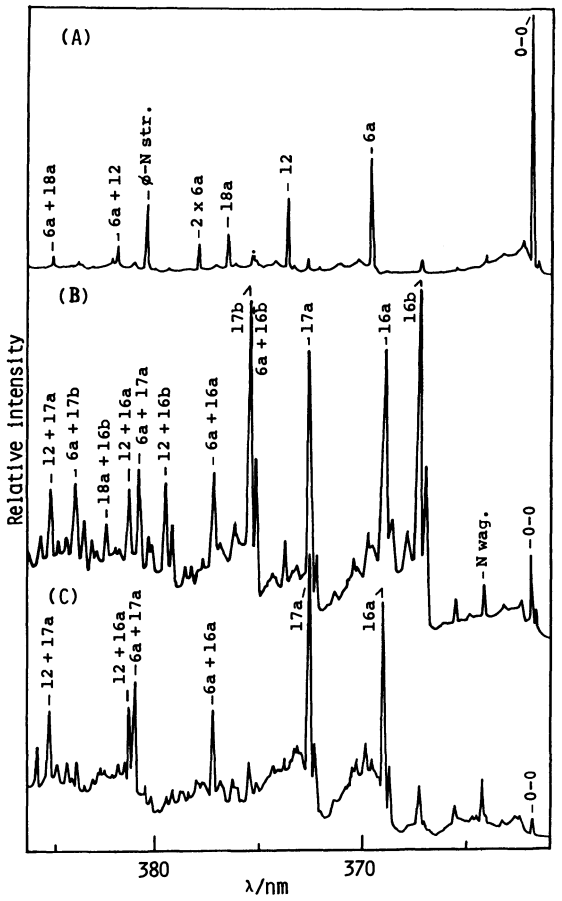

Fig. 1. The (A) short-, (B) medium-, and (C) long-lifetime phosphorescence spectra of 2-aminopyrimidine in benzene at 1.4 K.

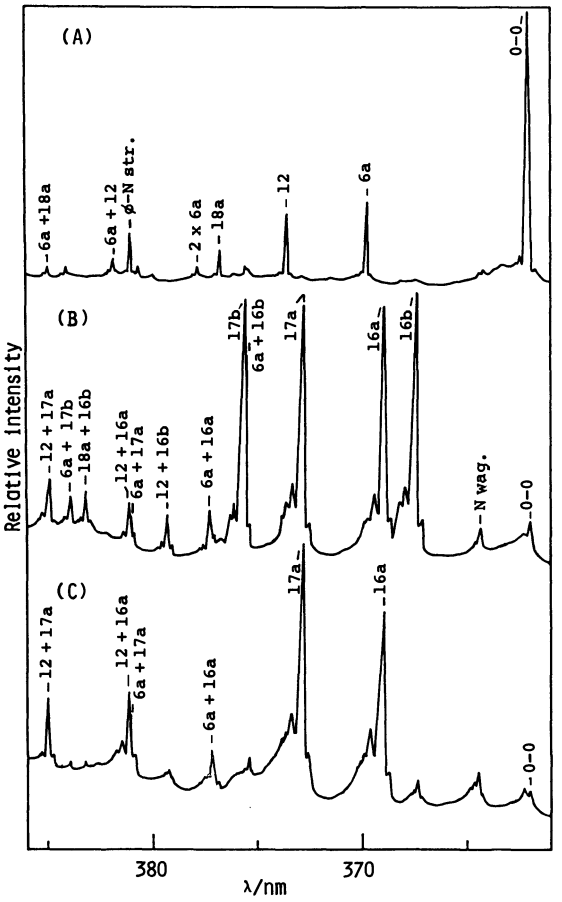

Fig. 2. The (A) short-, (B) medium-, and (C) long-lifetime phosphorescence spectra of 2-amino-d_2-pyrimidine in benzene at 1.4 K.

separated by 586, 876, 1090, and 1357 cm^{-1} from the 0–0 band were assigned to the totally symmetric ν_{6a}, ν_{12}, ν_{18a}, and ϕ–N stretching vibrations, respectively. The overtone and combination bands of these vibrations were also observed with medium or weak intensity.

The polarized time-resolved phosphorescence spectra of a benzene single crystal doped with 2-aminopyrimidine are shown in Fig. 3. For the 0–0 and totally symmetric ν_{6a} and ν_{12} bands observed in the polarized short-lifetime spectrum, the intensity of the solid spectrum is stronger than that of the dotted one. Since the symmetry representation of the y sublevel is B_1, the 0–0, ν_{6a}, and ν_{12} bands are to be polarized along the x direction. The x-polarized bands were also observed at 532 and 807 cm^{-1} from the 0–0 bands in the polarized long-lifetime spectrum. Since the symmetry representation of the x sublevel is B_2, these bands should be assigned to the a_2 vibration. We assigned these bands to the ν_{16a} and ν_{17a} vibrations. The ν_{16a} and ν_{17a} vibronic bands were also observed in the medium-lifetime spectrum where the band intensity of the dotted spectrum is stronger than that of the solid one. The z sublevel belongs to the symmetry representation A_2 and thus these bands are to be polarized along the z direction. The z-polarized bands were also observed at 190, 409, and 1000 cm^{-1} from the 0–0 band in the short-lifetime spectrum. These bands should be ascribed to the b_1 vibration and thus the bands were assigned to the N wagging, ν_{16b}, and ν_{17b} vibrations, respectively. The ν_{16b} and ν_{17b} vibronic bands were strongly observed in the medium-lifetime spectra with nearly equal intensity of the solid and dotted spectra. These bands are to be polarized along the y direction. The observed characteristic polarization behavior of these vibronic bands in the time-resolved phosphorescence spectra clearly shows that the main bands observed in the short-, medium-, and long-lifetime spectra are the bands originating from the y, z, and x sublevels, respectively.

The spectral structure of the sublevel phosphorescence spectra of 2-amino-d_2-pyrimidine is essentially the same as that of 2-aminopyrimidine. The strong bands separated by 570, 848, 1076, and 1366 cm^{-1} from the 0–0 band located at 27619 cm^{-1} in the short-lifetime spectrum were assigned to the ν_{6a}, ν_{12}, ν_{18a}, and ϕ–N stretching vibrations, respectively. The prominent bands separated by 522 and 785 cm^{-1} from the 0–0 band in the long-lifetime spectrum were assigned to the ν_{16a} and ν_{17a}, vibrations, respectively. In addition to the ν_{16a} and ν_{17a} bands, relative strong bands were observed at 407 and 990 cm^{-1} from the 0–0 band in the medium-lifetime spectrum and these bands were assigned to the ν_{16b} and ν_{17b} vibrations, respectively.

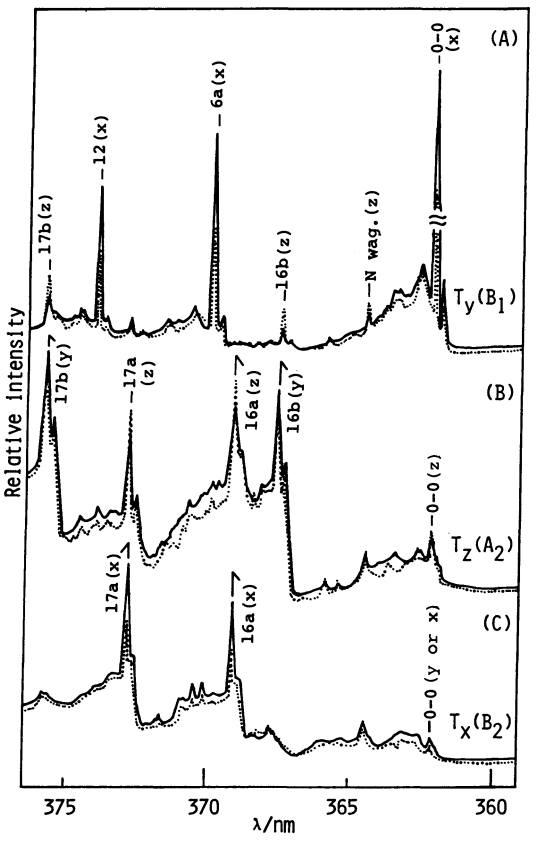

Fig. 3. The polarized (A) short-, (B) medium-, and (C) long-lifetime phosphorescence spectra of 2-aminopyrimidine in a benzene single crystal at 1.4 K. (x), (y), and (z) indicate the polarization directions of the bands.

The detailed vibrational analyses are given in Figs. 1 and 2.

The vibrational analyses made on two molecules distinctly indicate that (1) the emission from the y sublevel borrows the intensity from the $^1B_1(n,\pi^*)$-$^1A_1$ transition through the first-order spin-orbit coupling, (2) the emission from the z sublevel borrows the intensity almost equally from the $^1A_1(\pi,\pi^*)$-$^1A_1$ and $^1B_2(\pi,\pi^*)$-$^1A_1$ transitions via the $^3A_2(n,\pi^*)$ and $^3B_1(n,\pi^*)$ states, respectively, through the second-order spin-orbit-vibronic coupling, although Nishi and Kinoshita considered only the second-order process via the $^3A_2(n,\pi^*)$ state as the main perturbing process, and (3) the emission from the x sublevel borrows the intensity from the $^1B_1(\sigma,\pi^*)$-$^1A_1$transition via the $^3A_2(n,\pi^*)$ state. The dominant vibronic coupling is expected to take place among the triplet states because of the small energy separation between the $^3A_1(\pi,\pi^*)$ and $^3A_2(n,\pi^*)$ or $^3B_1(n,\pi^*)$ states.

A question that may be asked is: why do the dark $z(A_2)$ and $x(B_2)$ sublevels give the 0–0 bands polarized along the z and y(or x) directions, respectively? If the symmetry of the molecular structure reduces to the point group C_s due to the amino-substitution, the symmetry representations of the y, z, and x sublevels turn into the symmetry species A′, A″, and A″, respectively. This molecular geometry gives the 0–0 bands polarized along the y direction in both the z and x sublevel spectra contrary to the observaton. If the molecular structure reduces to the point group C_2, the symmetry representations of the y, z, and x sublevels turn into the species B, A, and B, and the z and x sublevel spectra could show the 0–0 bands polarized along the z direction and in the xy plane, respectively, in accord with the observation. However, the distortion of the molecular geometry, which may be caused by the vibronic coupling or the crystal force, should be small because the intensity of the 0–0 bands is much weaker than that of the a_2 and b_1 vibronic bands in the dark sublevel spectra, and the overtone bands of the ν_{16a} and ν_{17a} vibrations belonging to the a_2 symmetry species could not be observed. In the parent molecule, pyrimidine, whose lowest triplet state is the $^1B_1(n,\pi^*)$ state, the molecular distortion and the second-order spin-orbit-vibronic coupling give almost equal contributions to the phosphorescence processes for the dark sublevel.[7]

Spherical Aromaticity of Buckminsterfullerene

Jun-ichi AIHARA* and Haruo HOSOYA†
Department of Chemistry, Faculty of Science, Shizuoka University, Oya, Shizuoka 422
†Department of Chemistry, Ochanomizu University, Bunkyo-ku, Tokyo 112
(Received December 14, 1987)

Synopsis. Aromatic stabilization of buckminsterfullerene is not large enough to guarantee isolation in macroscopic amounts. This does not rule out the possibility that such carbon clusters are formed in sooting flames and/or in dark interstellar space.

Carbon clusters are produced in a pulsed supersonic beam apparatus using laser vaporization of a graphite disk.[1] Kroto et al. presented evidence for the existence of a remarkably stable C_{60} cluster in the vaporization products.[2-4] The stability has been presumed to arise from the ability of a graphitic sheet to close into a spheroidal shell, thereby eliminating its reactive edges.[2-4] The structure proposed was a truncated icosahedron with 12 pentagons and 20 hexagons arranged on the surface of a sphere. The ultraviolet spectrum of C_{60}[5] and the photoelectron spectrum of its anion[6] are apparently consistent with this structure. Kroto et al. named the molecule having this structure (**1**) buckminsterfullerene.[2,7] If the C_{60} cluster is really buckminsterfullerene, it will be of great interest in connection with the problem of spherical aromaticity.

Various molecular orbital (MO) methods have been used to obtain the energy structure of buckminsterfullerene.[8-24] Dewar resonance energy was estimated by use of Herndon-Simpson and conjugated circuit resonance theories[10,12] and by the Hess-Schaad method based on Hückel MO theory.[10,13] The topological resonance energy (TRE) is known to be an excellent measure of aromatic stabilization.[25-29] It can be calculated exactly within the Hückel framework. However, no one has ever calculated the TRE of buckminsterfullerene because it is not easy to evaluate the non-adjacent numbers[30,31] of a very large conjugated system.

The situation has changed recently. Hosoya overcame this difficulty,[32] and succeeded in construct ing the matching polynomial (i.e., the reference polynomial[25]) of buckminsterfullerene, which is shown below:[32]

$$\begin{aligned}R(X)=&X^{60}-90X^{58}+3825X^{56}-102120X^{54}+1922040X^{52}\\&-27130596X^{50}+298317860X^{48}-2619980460X^{46}\\&+18697786680X^{44}-109742831260X^{42}+534162544380X^{40}\\&-2168137517940X^{38}+7362904561730X^{36}\\&-20949286202160X^{34}+49924889888850X^{32}\\&-99463457244844X^{30}+165074851632300X^{28}\\&-227043126274260X^{26}+256967614454320X^{24}\\&-237135867688980X^{22}+176345540119296X^{20}\\&-104113567937140X^{18}+47883826976580X^{16}\\&-16742486291340X^{14}+4310718227685X^{12}\\&-783047312406X^{10}+94541532165X^{8}-6946574300X^{6}\\&+269272620X^{4}-4202760X^{2}+12500\end{aligned} \quad (1)$$

According to our standard interpretation,[25-29] this is a characteristic polynomial for an olefinic reference structure of buckminsterfullerene. Here, an olefinic reference structure stands for a hypothetical molecule obtained by replacing all bonds in a given molecule by those found in acyclic polyenes.

Hückel MO calculations of buckminsterfullerene have been published repeatedly.[8-13,16,18,19,33] Total π-electron energy of this molecule is $60\alpha+93.1616\beta$. That of its olefinic reference structure is $60\alpha+91.5189\beta$, which was obtained from the roots of the equation $R(X)=0$. The TRE is then given as the difference between these two energies. It is 1.6427β for buckminsterfullerene. Since this molecule is more stable than its olefinic reference structure, it can be classified as an aromatic molecule or a molecule of spherical aromaticity.

However, an aromatic molecule is not always stable enough to exist in the condensed phase. In order to see relative stabilities of buckminsterfullerene and related molecules, we evaluated the percent resonance energies (%RE's). The %RE of a given molecule is defined as 100 times the TRE, divided by the total π-electron energy of its olefinic reference structure.[28,34-36] Owing to the wide variation in the size of molecules compared, we feel that %RE is a better way of comparing stabilities than using the total TRE's. The %RE's calculated for buckminsterfullerene and related species are listed in Table 1.

The %RE of buckminsterfullerene is 1.79, which is smaller than those of typical benzenoid hydrocarbons

Table 1. Topological Resonance Energies of Buckminsterfullerene and Related Hydrocarbons

Species	TRE/β	%RE
Buckminsterfullerene (**1**)	1.643	1.79
Buckminsterfullerene*	1.010	1.10
Buckminsterfullerene^{2+}	0.530	0.58
Buckminsterfullerene^{2-}	1.489	1.63
Corannulene (**2**)	0.735	2.63
Naphthacene	0.553	2.27
Pentacene	0.630	2.11
Hexacene	0.706	1.99
Heptacene	0.783	1.91
Acenaphthylene (**3**)	0.354	2.18
Cyclopenta[*cd*]pyrene (**4**)	0.565	2.27
Pyracylene (cyclopent[*fg*]-acenaphthylene) (**5**)	0.106	0.55

(2.2—3.3).[35,36] In the benzenoid hydrocarbons, a %RE of this size does not guarantee stability or isolability in macroscopic amounts.[28] In the polyacene series, even hexacene and heptacene have a larger %RE. Note that hexacene (%RE=1.99) must be handled under nitrogen and that heptacene (%RE=1.91) is so unstable that it has never been obtained in a pure state. Hess and Schaad also noted insufficient stability of buckminsterfullerene.[13] Thus, this molecule is predicted not to be isolable although it has as many as 12500 Kekulé structures.[10,12,32]

Each carbon in buckminsterfullerene is equivalent to every other carbon, being the vertex joining one pentagon and two hexagons. As in graphite, each atom is involved in two single bonds and one double bond to its neighbors. Graphite has a total π-electron energy per carbon of $\alpha+1.5746\beta$.[37] If we assume that the olefinic reference structures of buckminsterfullerene and graphite have the same total π-electron energy per carbon, the %RE of graphite is calculated to be 3.23, which is slightly less than twice the %RE of buckminsterfullerene. This again suggests insufficient stability of the icosahedral C_{60} cluster.

To make matters worse, each C-C resonance integral in buckminsterfullerene cannot take the standard value (β) since all C-C bonds are bent on the surface of the sphere. Taking this structural factor into account, Haddon et al. showed that the resonance integrals in buckminsterfullerene must be reduced to 0.877β.[11] This further decreases the TRE of buckminsterfullerene. The TRE of buckminsterfullerene in Table 1 must likewise be multiplied by 0.877.

The structural unit of the truncated icosahedron is a pentagon surrounded by five hexagons. Corannulene (**2**) is a hydrocarbon in such a structure. This molecule is shaped like a bowl,[38] and isolable in accord with its large %RE (2.63). As stated by Hess and Schaad,[13] the isolation of corannulene which has a considerably larger %RE than buckminsterfullerene does not imply the potential isolation of buckminsterfullerene.

Heath et al. obtained evidence for the formation of stable complexes of the formula $C_{60}M$ by laser evaporation of a graphite disk impregnated with M, where M=La, Ba, Sr, Ca, etc.[39] Stability of the dianion in a supersonic beam might be rationalized well by the %RE, which is comparable to that of the neutral species. As can be seen from the structure, buckminsterfullerene has a nonalternant hydrocarbon skeleton but without hydrogens. The dication has a much smaller %RE than the dianion.

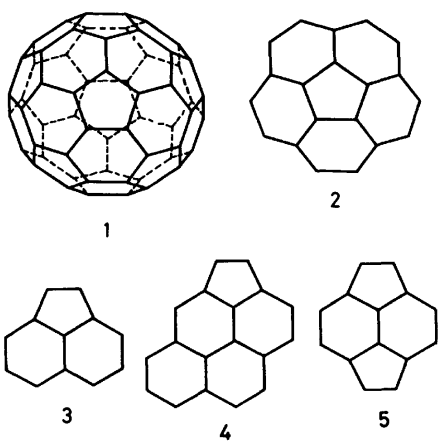
Kroto et al. speculated about the possibility that the C_{60} cluster might be the carrier of the diffuse interstellar ultraviolet band.[2,40] As in a supersonic beam, buckminsterfullerene may be formed somewhere in the hydrogen-deficient interstellar or circumstellar medium. At present, there is no reason to doubt the existence of this molecule in dark interstellar space. In fact, the C_{60} cluster in a supersonic beam is very resistant to chemical attack by such small molecules as NO, H_2, CO, SO_2, O_2, and NH_3.[3]

Léger and Puget[41] and Allamandola et al.[42] proposed recently that there must be abundant polycyclic aromatic hydrocarbons (PAH's) in the interstellar medium. In previous papers,[35,36] Aihara suggested that such interstellar PAH's must have a large %RE both in the ground and excited states since they are placed in the intense radiation field. As shown in Table 1, the %RE of buckminsterfullerene is very small in the first excited state. Therefore, it does not seem stable enough to exist in the intense radiation field. Buckminsterfullerene* in Table 1 indicates the excited-state species.

Soot is formed by incomplete combustion of organic matter. One of the striking features known about soot is that it is almost always found in the form of spheres, arranged in strands of beads or more complicated structures.[2,43] The polycyclic hydrocarbons are detectable in high concentrations in sooting flames. They may adopt pentagonal rings as they grow, so as to generate spheroidal structures which maximize the number of C-C linkages.[2]

Acenaphthylene (**3**) and cyclopenta[*cd*]pyrene (**4**) are formed in sooting flames.[43] Even pyracylene (cyclopent[*fg*]acenaphthylene) (**5**) is suspected to exist in flames.[43] These molecules are not highly aromatic PAH's. Synthetic pyracylene is far from isolable from solution.[44,45] Fluorene and indene are also detectable in flames.[43] Since in flames there are many such hydrocarbons with pentagonal rings, it seems likely that soot or large spheroidal carbon clusters are formed starting from these molecules. However, this does not imply that buckminsterfullerene is isolable even if it is formed in flames.[46] As pointed out above, the %RE of buckminsterfullerene is too small.

Localization energy is a typical reactivity index for aromatic molecules.[47] The cation and anion localization energies of buckminsterfullerene are 2.767 and 2.490, respectively, at all constituent carbons. These values are very large as compared with those at the peripheral carbons of polycyclic benzenoid hydrocarbons (1.90—2.55).[47] It should be noted that most reactions of benzenoid hydrocarbons occur at these peripheral carbons. If in future buckminsterfullerene is found to be isolable, the stability will be ascribed to the absence of peripheral reactive carbons,



thereby being kinetic rather than thermodynamic in nature.

In this connection, Iijima prepared a spherical particle of graphitic carbon by arc discharge between two carbon rods, and found that there seems to be a C_{60} cluster at the core of the particle.[48] The innermost carbon cluster is obviously protected from danger by many outer spheres made of carbon atoms.

Absorption and CD Spectral Properties of Bis(ethylenediamine)cobalt(III) Complexes with *O*-Bonded Sulfoxide and Seleninate

Takumi KONNO,* Ken-ichi OKAMOTO, and Jinsai HIDAKA
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received December 17, 1987)

Synopsis. The absorption and CD spectral behavior of $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$ and $[Co\{OSe(O)CH_2CH_2NH_2\}(en)_2]^{2+}$ was discussed. The *O*-bonded seleninato isomer, Λ-$(+)_{500}^{CD}$-$[Co\{OSe(O)CH_2CH_2NH_2\}(en)_2]^{2+}$, showed racemization at the chiral selenium atom in an aqueous solution and a shift of the equilibrium between the (*R*) and (*S*) configurations of the chiral selenium atom through the protonation on the pendant oxygen atom.

Several bis(diamine)cobalt(III) complexes containing a coordinated chiral sulfur or selenium atom have been investigated,[1-11] and some stereochemical differences between cobalt(III) complexes with a selenium-containing ligand and those with a sulfur-containing ligand have been reported.[8-10] Recently, the two diastereomers due to the non-coordinated chiral sulfur atom, $\Lambda(R)$ and $\Lambda(S)$,[12] have been isolated for the *O*-bonded sulfinato complex, $[Co\{OS(O)CH_2CH_2NH_2\}(en)_2]^{2+}$.[13] On the other hand, the single crystal X-ray analysis indicated that the chiral selenium atom in the corresponding *O*-bonded seleninato complex, $(-)_{500}^{CD}$-$[Co\{OSe(O)CH_2CH_2NH_2\}(en)_2]^{2+}$, selectively takes the (*S*) configuration in the crystal state.[14]

Here we report on the stereochemical behavior of Λ-$(+)_{500}^{CD}$-$[Co\{OSe(O)CH_2CH_2NH_2\}(en)_2]^{2+}$ in solution, together with that of the newly prepared two diastereomers of the *O*-bonded sulfoxide complex, $\Lambda(R)$- and $\Lambda(S)$-$[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$. The absorption and CD spectra of the *O*-bonded seleninato complex are discussed in comparison with those of the corresponding *O*-bonded sulfinato and sulfoxide complexes.

Experimental

Complexes. (1) Λ-$(+)_{500}^{CD}$-$[Co\{OSe(O)CH_2CH_2NH_2\}(en)_2](ClO_4)_2$. Fairly large crystals of this complex were prepared by the method described in a previous paper.[14]

(2) $\Lambda(S)$-$(-)_{500}^{CD}$-$[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2](ClO_4)_3\cdot H_2O$ and $\Lambda(R)$-$(+)_{500}^{CD}$-$[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2](ClO_4)_3$. These isomers were prepared by a procedure similar to that used for $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$,[6,15] using $\Lambda(R)$- and $\Lambda(S)$-$[Co\{S(O)CH_2CH_2NH_2\}(en)_2](ClO_4)_2$[9] instead of $[Co\{S(O)CH_2CH_2NH_2\}(en)_2](ClO_4)_2$. To a dimethyl sulfoxide solution (3 cm^3) of $\Lambda(R)$- or $\Lambda(S)$-$[Co\{S(O)CH_2CH_2NH_2\}(en)_2](ClO_4)_2$ (0.15 g) was added an excess amount of CH_3I (1.0 g); the mixture was then allowed to stand at room temperature for three days. After the excess CH_3I and dimethyl sulfoxide had been extracted with diethyl ether, to the remaining oily product was added a small amount of water, after which the solution was passed through a column (2.5 cm×25 cm) of QAE-Sephadex A-25 (ClO_4^- form) while being eluted with water. The reddish eluate was concentrated to a small volume with a rotary evaporator. The addition of a small amount of ethanol to the concentrate, followed by cooling in a refrigerator overnight, yielded crystals of the desired *O*-bonded sulfoxide isomer. The $(-)_{500}^{CD}$ and $(+)_{500}^{CD}$ isomers thus obtained showed the same absorption spectrum as the racemic $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$.[6,15] No CD spectral change was observed for the two isomers, at least for one day. Found for the $\Lambda(S)$ isomer: C, 13.97; H, 4.49; N, 11.67%. Calcd for $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2](ClO_4)_3\cdot H_2O=C_7H_{27}N_5O_{14}SCl_3Co$: C, 13.95; H, 4.52; N, 11.62%. Found for the $\Lambda(R)$ isomer: C, 14.45; H, 4.31; N, 11.98%. Calcd for $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2](ClO_4)_3=C_7H_{25}N_5O_{13}SCl_3Co$: C, 14.38; H, 4.31; N, 11.97%. Attempts to prepare the corresponding selenoxide complex, $[Co\{OSe(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$, by the reaction of $\Lambda(R)$-$[Co\{Se(O)CH_2CH_2NH_2\}(en)_2](ClO_4)_2$[9] (0.1 g) with CH_3I (0.7 g) were unsuccessful; instead, the selenide complex, $\Lambda(R)$-$[Co\{Se(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$,[9] was formed. An SP-Sephadex chromatographic investigation of the reaction solution (after ca. 10 min) revealed the formation of the selenolato complex, Λ-$[Co(SeCH_2CH_2NH_2)(en)_2]^{2+}$,[9] besides the selenide complex.

Measurements. The electronic absorption spectra were recorded with a JASCO UVIDEC-1 spectrophotometer, and the CD spectra with a JASCO J-20 spectropolarimeter in an aqueous solution at room temperature. The ^1H and ^{13}C NMR spectra were recorded with a JEOL JNM-FX-100 or -FX-90Q NMR spectrometer in a D_2O or $HClO_4$–D_2O solution at room temperature. Sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) was used as the internal reference.

Results and Discussion

The two isomers of the *O*-bonded sulfoxide complex, $(-)_{500}^{CD}$- and $(+)_{500}^{CD}$-$[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$, were prepared by the reaction of $\Lambda(R)$- and $\Lambda(S)$-$[Co\{S(O)CH_2CH_2NH_2\}(en)_2]^{2+}$ respectively with CH_3I. As shown in Fig. 1 their absorption spectra show an intense shoulder at ca. 37.0×10^3 cm^{-1} besides the first absorption band (ca. 19.5×10^3 cm^{-1}) and the second absorption band (ca. 27.5×10^3 cm^{-1}). In the first absorption band region, the CD patterns of the *O*-bonded sulfoxide isomers coincide well with those of the parental $\Lambda(R)$ and $\Lambda(S)$ sulfenato isomers[9] (Fig. 1), suggesting that the isomers retain the Λ configuration of the parental sulfenato isomers. The $(-)_{500}^{CD}$ isomer derived from the $\Lambda(R)$ sulfenato isomer exhibits a sharp ^1H NMR peak arising from the methyl group of the ligand at 2.93 ppm, while the $(+)_{500}^{CD}$ isomer derived from the $\Lambda(S)$ isomer exhibits a peak at 2.83 ppm. Furthermore, the methylation of $[Co\{S(O)CH_2CH_2NH_2\}(en)_2]^{2+}$ to $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$ is known to proceed with a retention of the absolute configuration at the chiral sulfur atom.[15,16] Taking these facts into consideration, it is probable that the methylation reaction of the $\Lambda(S)$ and $\Lambda(R)$ sulfenato isomers produce the $\Lambda(R)$ and $\Lambda(S)$ *O*-bonded sulfoxide isomers respectively. The $\Lambda(R)$ and $\Lambda(S)$ isomers of $[Co\{OS(CH_3)CH_2CH_2NH_2\}(en)_2]^{3+}$

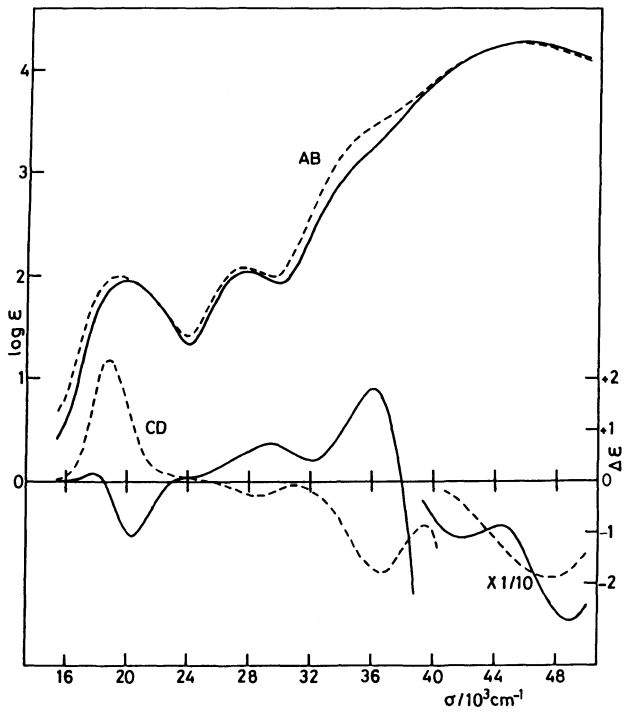

Fig. 1. Absorption and CD spectra of $\Lambda(S)$-[Co{OS(CH$_3$)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ (——) and $\Lambda(R)$-[Co{OS(CH$_3$)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ (----).

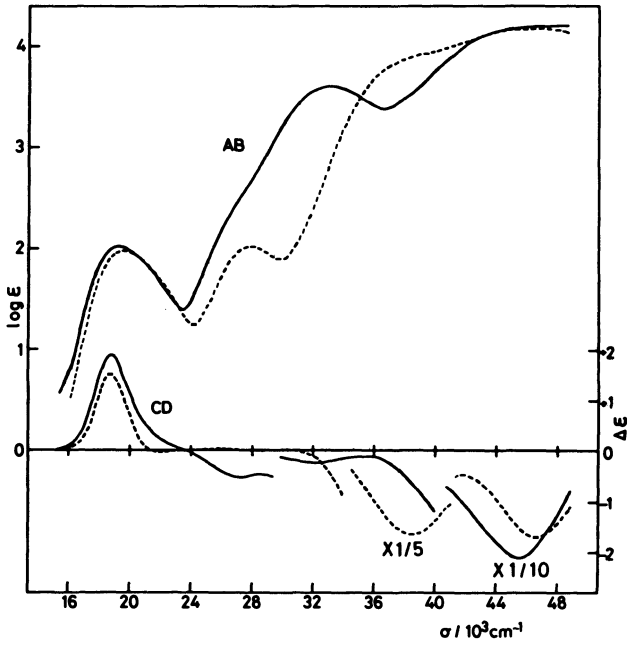

Fig. 2. Absorption and CD spectra of Λ-(+)$^{CD}_{500}$-[Co{OSe(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ in water (——) and Λ-(+)$^{CD}_{500}$-[Co{OSe(OH)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ in 6% HClO$_4$ (----).

show almost enantiomeric CD spectra in the region of 18—38×10^3 cm^{-1} (Fig. 1), indicating that the non-coordinated chiral sulfur atom in the sulfoxide complex contributes significantly to the CD spectrum, just as in the case of the coordinated chiral sulfur atoms in [Co{S(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$,[9] and [Co{S(OH)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$.[8] The methylation of the selenenato complex, $\Lambda(R)$-[Co{Se(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$, produced the selenide complex, $\Lambda(R)$-[Co{Se(CH$_3$)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$; no selenoxide complex was detected. The presence of the selenolato complex, Λ-[Co(SeCH$_2$CH$_2$NH$_2$)(en)$_2$]$^{2+}$, in the reaction solution (after ca. 10 min) besides the selenide complex suggests that the selenide complex was formed via the intermediate, Λ-[Co(SeCH$_2$CH$_2$NH$_2$)(en)$_2$]$^{2+}$, which retained the Λ configuration of $\Lambda(R)$-[Co{Se(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$.

The *O*-bonded seleninato complex, [Co{OSe(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$, shows an instantaneous and reversible absorption spectral change with the pH change in an aqueous solution. The pK_a value for this complex at 25 °C and μ=1.0 mol dm^{-3} (NaClO$_4$) has been determined to be 1.91±0.05 in a previous paper.[14] For the *O*-bonded seleninato complex, there are three possible protonation sites: the coordinated oxygen atom, the pendant oxygen atom, and the selenium atom. As shown in Fig. 2 the first absorption band of the protonated complex is quite similar to that of the parental *O*-bonded seleninato complex, suggesting that the coordinated oxygen atom is not protonated. The charge-transfer band at ca. 33×10^3 cm^{-1} characteristic of the *O*-bonded seleninato complex[14] disappears in the protonated complex. Furthermore, the protonated complex exhibits a new intense shoulder at ca. 39×10^3 cm^{-1} and the second absorption band at 27.86×10^3 cm^{-1}. This absorption spectral behavior of the protonated complex is in good agreement with that of the corresponding *O*-bonded sulfoxide complex, [Co{OS(CH$_3$)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ (Figs. 1 and 2). Taking account of the fact that the absorption spectra of [Co{Se(OH)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ and [Co{S(CH$_3$)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$ behave quite similarly to each other,[8] it is probable to consider that the protonation of the *O*-bonded seleninato complex occurs on the pendant oxygen atom to form [Co{OSe(OH)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{3+}$.

In the crystal state, the chiral selenium atom in the *O*-bonded seleninato isomer, Δ-(−)$^{CD}_{500}$-[Co{OSe(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$, takes selectively the (*S*) configuration with the axial pendant oxygen atom.[14] Thus, the Λ-(+)$^{CD}_{500}$ isomer should have the (*R*) configurational selenium atom in the crystal state. When the Λ-(+)$^{CD}_{500}$ isomer was dissolved in water, a slight intensity change in the CD spectrum (ca. 12% decrease at 500 nm) was observed and the solution attained equilibrium after ca. 10 min. No change in the absorption spectrum was observed during the CD measurement. The ^{13}C NMR spectrum of Λ-(+)$^{CD}_{500}$-[Co{OSe(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$ in a D$_2$O solution exhibits ten peaks for the six carbon atoms of the complex (Fig. 3(a)). This ^{13}C NMR spectral behavior is similar to that of a mixture of the $\Lambda(R)$ and $\Lambda(S)$ isomers of the corresponding *O*-bonded sulfinato complex, [Co{OS(O)CH$_2$CH$_2$NH$_2$}(en)$_2$]$^{2+}$; the peaks at 32.94, 45.45, 46.86, 47.08, and 51.09 ppm correspond to those for the $\Lambda(R)$ *O*-bonded sulfinato isomer, and

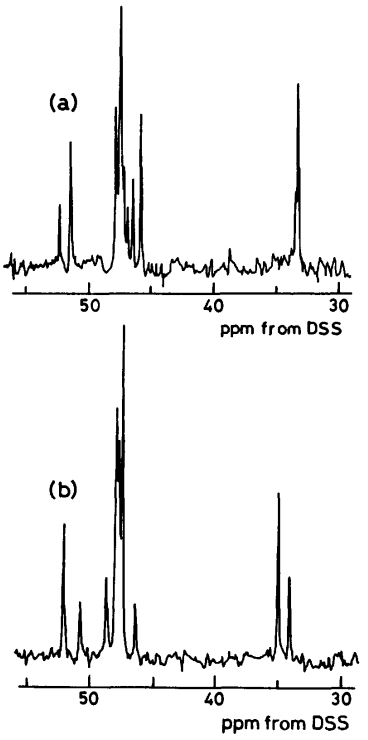

Fig. 3. ^{13}C NMR spectra of Λ-(+)$^{CD}_{500}$-[Co{OSe(O)-$CH_2CH_2NH_2$}$(en)_2]^{2+}$ in D_2O (a) and Λ-(+)$^{CD}_{500}$-[Co·{OSe(OH)CH_2CH_2NH}$(en)_2]^{3+}$ in 6% $HClO_4$–D_2O (b).

the peaks at 33.10, 46.10, 46.53, 47.51, and 51.95 ppm to those for the $\Lambda(S)$ isomer.[13] These facts mean that Λ-(+)$^{CD}_{500}$-[Co{OSe(O)$CH_2CH_2NH_2$}$(en)_2]^{2+}$ exists in a mixture of the $\Lambda(R)$ and $\Lambda(S)$ isomers in an aqueous solution because of the inversion at the chiral selenium atom. The $\Lambda(R)$ isomer seems to be dominant in the mixture, considering the intensity of the ^{13}C NMR peaks for the two isomers. In order to confirm the presence of the two isomers, the SP-Sephadex column chromatographic separation was attempted for Λ-(+)$^{CD}_{500}$-[Co{OSe(O)$CH_2CH_2NH_2$}$(en)_2]^{2+}$. However, only one absorbed band appeared, and all of its fractions showed the same CD spectra, though the corresponding *O*-bonded sulfinato isomers, $\Lambda(R)$- and $\Lambda(S)$-[Co{OS(O)$CH_2CH_2NH_2$}$(en)_2]^{2+}$, have been separated by the use of an SP-Sephadex column.[13] These facts indicate that the inversion at the chiral selenium atom in [Co{OSe(O)$CH_2CH_2NH_2$}$(en)_2]^{2+}$ is faster than that at the chiral sulfur atom in [Co{OS(O)CH_2-CH_2NH_2}$(en)_2]^{2+}$.

The Λ-(+)$^{CD}_{500}$ *O*-bonded seleninato isomer shows an instantaneous and reversible CD spectral change with the pH change corresponding to the absorption spectral change. The positive CD band at 18.76×10^3 cm^{-1} in the first absorption band region of the protonated (+)$^{CD}_{500}$-[Co{OSe(OH)$CH_2CH_2NH_2$}$(en)_2]^{3+}$ suggests that the protonation reaction proceeds with a retention of the Λ configuration (Fig. 2). The ^{13}C NMR spectrum of Λ-(+)$^{CD}_{500}$-[Co{OSe(OH)CH_2CH_2-NH_2}$(en)_2]^{3+}$ exhibits nine peaks for the six carbon atoms of the complex (Fig. 3(b)). This ^{13}C NMR spectral behavior indicates the coexistence of the $\Lambda(R)$ and $\Lambda(S)$ isomers as the parental Λ-(+)$^{CD}_{500}$-[Co{OSe-(O)$CH_2CH_2NH_2$}$(en)_2]^{2+}$. For each pair of peaks at ca. 34 and 51 ppm, however, the peak at the higher magnetic field appears weaker than that at the lower one, in contrast with the case of the parental Λ-(+)$^{CD}_{500}$-[Co{OSe(O)$CH_2CH_2NH_2$}$(en)_2]^{2+}$ (Fig. 3). Furthermore, the CD spectrum of Λ(+)$^{CD}_{500}$-[Co{OSe(OH)CH_2-CH_2NH_2}$(en)_2]^{3+}$is quite similar to that of $\Lambda(R)$-[Co-{OS$(CH_3)CH_2CH_2NH_2$}$(en)_2]^{3+}$ (Figs. 1 and 2), where the (*R*) configuration of the latter complex corresponds to the (*S*) configuration of the former one.[16] The ^{13}C NMR and CD spectral behavior suggests that a shift of the equilibrium between the (*R*) and (*S*) configurations taskes place through the protonation reaction and that the protonated Λ-(+)$^{CD}_{500}$ isomer takes the (*S*) configuration dominantly.

A New Method for Determining Cyclodextrin Complex Formation Constants with Electrolytes in Aqueous Medium

Isao SANEMASA,* Motohisa FUJIKI, and Toshio DEGUCHI
Department of Chemistry, Faculty of Science, Kumamoto University,
Kurokami 2-39-1, Kumamoto 860
(Received December 24, 1987)

Synopsis. By making use of the volatilization rate of iodine from aqueous into gaseous phase, association constants of α-cyclodextrin with electrolytes (chlorides, nitrates, and perchlorates) have been determined at 25 °C; the counter cations are found to be largely responsible for the association.

Among several methods so far available for determining cyclodextrin (CyD) complex formation constants, four techniques, i.e., conductometry,[1-3] calorimetry,[4] kinetic inhibition,[5] and spectral competitive inhibition[6-9] have been used for the systems where electrolytes having neither absorption nor fluorescence are involved.

We have studied CyD associations with volatile guests such as iodine, benzene, alkylbenzenes, naphthalenes.[10-12] The present work is concerned with a further development of the study; iodine is used as a volatile guest which serves as an indicator and α-CyD is used as a host.

By introducing an inert gas at a constant flow rate into aqueous solutions, iodine molecules are driven out into the gaseous phase. The volatilization rate is reduced in the presence of CyD owing to the host-guest association. The decrease in rate gives the complex formation constant. Now consider the presence of an electrolyte which does not interact with iodine, but does associate with CyD. Under such a circumstance, the iodine volatilization rate is expected to be accelerated as a result of competition with the electrolyte.

Associations of some inorganic electrolytes with CyD have been well demonstrated and anions are thought to be responsible for the association. Is there any contribution of the counter cation? It is another object of this work to elucidate the effect of counter cation.

Experimental

Distilled deionized water was used throughout this work. Electrolytes, NaCl, KCl, HNO_3, $NaNO_3$, $HClO_4$, $LiClO_4$, $NaClO_4$, $KClO_4$, and $(CH_3)_4NClO_4$, of analytical reagent grade were used as purchased and each stock solution was, when necessary, standardized by alkalimetry after passing a suitable portion of the stock solution through H^+-form cation-exchange resin. Preparations of α-CyD (Nakarai Chemical Co.) and iodine aqueous solutions, the iodine standardization method, experimental procedures, and apparatus were described in the previous paper.[10]

A brief statement of the experimental procedure will be made here. A 50 cm^3 portion of the sample solution in which both iodine and electrolyte to be studied are present with or without CyD, was transferred into a 2.5φ×25 cm cylindrical glass tube immersed in a bath thermostated at 25.0±0.1 °C. N_2 gas was blown in the sample solution through a capillary glass tube at a constant flow rate of 600 $cm^3\ min^{-1}$. The I_2 concentration in this work was lower than that used in our previous study, and N_2 gas was blown at a much higher flow rate to expel I_2 effectively. The N_2 gas flow rate was kept the same irrespective of the presence of CyD. The iodine carried out of the solution by N_2 gas stream was trapped in a 5×10^{-4} M $Na_2S_2O_3$ solution of 20 cm^3 and the amount of I_2 expelled during a fixed time, ΔQ_{I_2}, was determined.

The concentration in M unit (M≡ mol dm^{-3}) used in most of the runs was as follows; iodine (1.57×10^{-5}), α-CyD (1.57×10^{-4}), NaCl (2.12×10^{-2}), KCl (1.00×10^{-2}), HNO_3 (5.00×10^{-2}), $NaNO_3$ (5.00×10^{-2}), $HClO_4$ (5.04×10^{-2}), $LiClO_4$ (4.24×10^{-2}), $NaClO_4$ (5.00×10^{-2}), $KClO_4$ (5.45×10^{-2}), and $(CH_3)_4NClO_4$ (3.51×10^{-2}). The association constants were determined on average of three or four measurements.

Results and Discussion

It is well established that both the molecular iodine and the electrolyte used in this study form 1:1 complex with α-CyD. Then, the reactions that should be taken into account are:

$$CyD + I_2 \rightleftharpoons CyD\cdot I_2, \quad K_{I_2}, \tag{1}$$

$$CyD + X \rightleftharpoons CyD\cdot X, \quad K_X, \tag{2}$$

and

$$I_2(aq) \longrightarrow I_2(gas), \quad k, \tag{3}$$

where K_{I_2} and K_X are association constants with iodine and electrolyte (X), respectively, and k is the rate constant for the transfer of iodine molecules from aqueous to gaseous phase. The iodine molecules expelled into the gaseous phase are collected successively by the absorbent, and the total amount, Q_{I_2}, which is the sum of ΔQ_{I_2}, is measured as a function of aeration time, t. The iodine volatilization rate at a constant N_2 gas flow rate is of the first-order with respect to the concentration of free iodine species in the solution as follows:

$$dQ_{I_2}V^{-1}/dt = k[I_2], \tag{4}$$

where V is the volume of the aqueous solution.

The mass-balance equations are:

$$C_{CyD} = [CyD] + [CyD\cdot I_2] + [CyD\cdot X] = [CyD](1 + K_{I_2}[I_2] + K_X[X]), \tag{5}$$

and

$$C_{I_2} = [I_2] + [CyD\cdot I_2] + Q_{I_2}V^{-1} = [I_2](1 + K_{I_2}[CyD]) + Q_{I_2}V^{-1} \tag{6}$$

where C_{CyD} and C_{I_2} denote the total concentration of CyD and that of iodine, respectively. Substituting Eq.

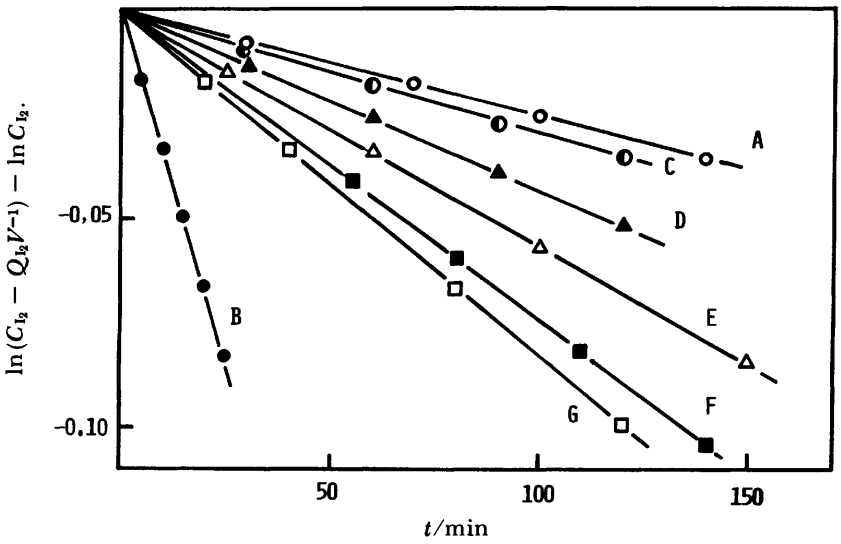

Fig. 1. The plots of $\ln(C_{I_2}-Q_{I_2}V^{-1})-\ln C_{I_2}$ vs. t in the presence (A) and absence (B) of CyD. N_2 flow rate: 600 $cm^3 min^{-1}$; C_{I_2}: 1.57×10^{-5} M, C_{CyD}: 7.99×10^{-4} M; Electrolyte ($C_X/10^{-2}$ M): (C) $(CH_3)_4NClO_4$ (3.51), (D) $LiClO_4$ (4.24), (E) $NaClO_4$ (5.00), (F) $KClO_4$ (5.45), (G) $HClO_4$ (5.04).

6 into Eq. 4 and integration ($Q_{I_2}=0$ at $t=0$) yield

$$\ln(C_{I_2} - Q_{I_2}V^{-1}) = -kt/(1 + K_{I_2}[CyD]) + \ln C_{I_2}. \quad (7)$$

Here we set experimental conditions as follows: the equilibrium concentration of iodine is sufficiently low so that the product $K_{I_2}[I_2]$ can be neglected and that of electrolyte is so large that [X] can be taken as its total concentration, C_X. Then, Eq. 7 becomes

$$\ln(C_{I_2} - Q_{I_2}V^{-1}) = -kt/\{1 + K_{I_2}C_{CyD}(1 + K_XC_X)^{-1}\} + \ln C_{I_2}. \quad (8)$$

Plots of $\ln(C_{I_2}-Q_{I_2}V^{-1})$ vs. t (Fig. 1) gave straight lines over the aeration time investigated; the slope corresponds to $-k$ in the absence of CyD, to $-k/(1+K_{I_2}C_{CyD})$ in the absence of the associating electrolyte, and to $-k/\{1+K_{I_2}C_{CyD}(1+K_XC_X)^{-1}\}$ in the presence of both CyD and electrolyte. The K_{I_2} value thus determined was 1.5×10^4 M^{-1}, which agrees with our previous result.[10] The association constants of CyD with the electrolytes studied here are given in Table 1 together with literature values available.

The association constants determined in this work seem to be significantly larger than the literature data. It is not clear at present whether or not the present results are reasonable, because the data so far available are limited and, moreover, considerable disagreement exists among them.

It is generally accepted that the CyD association constant decreases in the order, ClO_4^->SCN^->I^->Br^->NO_3^-.[7] As for the cation, on the other hand, little attention has been paid. For instance, K_X was reported for α-CyD-ClO_4^- system without specifying the counter cation.[6] In spite of different cation being used, the relative magnitude of K_X value of a given anion was compared for α- and β-CyDs.[7] Based on the data obtained by the spectral competitive inhibition method, Buvári and Barcza pointed out the importance of the counter cation: potassium salts associate more strongly with β-CyD than the sodium salts.[8]

Table 1. Association Constants for the Complex Formation between Electrolytes and α-Cyclodextrin at 25°C

Electrolyte	Association constant/M^{-1}	
	This work[a]	Literature
NaCl	3	negligible[4]
KCl	5	
HNO_3	11	
$NaNO_3$	4	1.4 (KNO_3)[1]
$HClO_4$	60	39.8[4]
$LiClO_4$	22	
$NaClO_4$	35	20.4,[4] 30.6[2]
$KClO_4$	48	28.9,[1] 37[9]
$(CH_3)_4NClO_4$	8	

a) The relative standard deviation is roughly estimated to be 30% for the association constant lower than 5 and 15% for that higher than 10.

The present study indicates that the counter cation plays an important role in the α-CyD association with electrolytes; the association constant decreases in the order, H^+>K^+>Na^+>Li^+>$(CH_3)_4N^+$. In light of the order of anions, this order of alkali ions is understandable: counter cation with less affinity with water is favorable to association with CyD. The behavior of H^+ is particular and should be ascribed to hydrogen bonding to CyD; H^+ bound to primary or secondary alcohol group of the CyD rim attracts its counter anion and holds it inside the CyD cavity, when the anion has low affinity with water. The

small K_X observed for $(CH_3)_4N^+$ ion may be attributable to that this ion cannot enter into the α-CyD cavity.[3] The counter cation effect is thus explainable on the assumption that electrolyte exists as ion-pair inside or in the entrance of CyD cavity with anion preferentially included in the cavity, although there has been no direct experimental evidence supporting this idea.

There are two essential requirements for the present method to be successufully applied. One is that the difference between the tow slopes, $-k$ at $C_{CyD}=0$ and $-k/(1+K_{I_2}C_{CyD})$ at $C_X=0$, be as large as possible. Any volatile guest substance with sufficiently large association constant can be used as an indicator; iodine is suitable for α-CyD, but not for β-CyD; in the latter case different guest should be used. Another requirement is that the product, K_XC_X, should not be too small compared with unity. When K_X is small, as is the present case, C_X should be made large. In such a case, care must be taken for the so-called salt effect.

The spectral competitive inhibition method makes use of the fact that the presence of electrolyte shifts the CyD association equilibrium with a certain guest substance as an indicator, usually, azo dye. Our method resembles this spectral method with respect to competing the electrolyte with the indicator guest for the CyD bonding site. It should be noted that, as was pointed out by Mochida et al.,[13] the presence of electrolyte does not always inhibit the indicator guest association with CyD, but, on the contrary, promotes the association by reducing the activity of water surrounding the indicator guest molecule. It depends on the nature of both cation and anion constituting the electrolyte which governs promotion or inhibition. The spectral method usually needs electrolyte of high concentration to cause measurable absorbance changes of the indicator guest. If a counter ion has more or less a promoting effect, the K_X value for this electrolyte is to be underestimated. These situations hold for the present method. It is, however, easy to study the salt effect by our method. The volatilization rate of the indicator guest is measured in the presence of salt of desired concentration and is compared with that in the absence of salt. If there is no change between them, the salt effect can be ignored. The salt concentration used in this work did not affect the iodine volatilization rate constant, k.

When iodine is used as an indicator guest, association constants of such electrolytes as SCN^-, I^-, and Br^- cannot be determined by the present method.

Synopsis. The crystal structure of a binuclear cobalt(II) complex of *N,N',N'',N'''*-tetrakis(2-aminoethyl)-1,4,8,11-tetraazacyclotetradecane (taec), $[Co_2(taec)(OH)](ClO_4)_3$, was determined by the single-crystal X-ray diffraction method. The two cobalt ions are bridged by a single hydroxide ion in the cavity of taec. The cyclic voltammogram showed an irreversible profile with two anodic peaks at ca. 1.4 and 1.8 V vs. SCE.

In the previous paper, we reported the preparation of the μ-hydroxo-bridged cobalt(II) complexes with an octadentate ligand, *N,N',N'',N'''*-tetrakis(2-aminoethyl)-1,4,8,11-tetraazacyclotetradecane (abbreviated as taec), $[Co_2(taec)(OH)]X_3$ (X=ClO_4 and PF_6).[1] The taec ligand exclusively forms binuclear complexes where each metal ion is coordinated by two cyclam-ring nitrogens and two pendant amino nitrogens.[1-6] On the basis of infrared and electronic spectra and magnetic susceptibility data, we assumed that the two cobalt ions are bridged by only one hydroxide ion in the "cavity" of taec. Monohydroxo-bridged complexes are rare, although recently some examples have been reported for copper(II) complexes.[7] Interestingly these cobalt(II) complexes are inert toward aerobic or chemical oxidation. Attempts to obtain cobalt(III) species of taec were all unsuccessful. We assumed that the resistance to oxidation is due to the sterical difficulty in achieving six-coordination.[1] In this study, we have examined the electrochemical property and the X-ray crystal structure of $[Co_2(taec)(OH)](ClO_4)_3$ in order to confirm our assumption.

Experimental

The crystals were prepared as described in Ref. 1.

automated four-circle diffractometer was used for all measurements at 25±1 °C. Crystal data and details of the data collections are given in Table 1. Lattice constants were determined by least-squares refinement based on 50 reflections with $20°<2\theta<30°$. The intensity data were corrected for Lorentz-polarization effects and for absorption. The structure was solved by the direct method. Refinements were carried out by the block-diagonal least-squares method. Hydrogen atoms were inserted in their calculated positions and fixed at their positions. The final discrepancy factors, $R=\sum||F_o|-|F_c||/\sum|F_o|$ and $R_w=[\sum w(|F_o|-|F_c|)^2/\sum w|F_o|^2]^{1/2}$ are listed in Table 1. The thermal parameters of the ClO_4^- ions are high probably due to the partial disorder. The hydrogen atom of the bridging hydroxide ion could not be located on a final difference Fourier map.

The atomic scattering factors for all the atoms and the anomalous dispersion corrections for all the nonhydrogen atoms were taken from Ref. 8. All the calculations were carried out on the HITAC M-680H computer at the Computer Center of the Institute for Molecular Science using a local version of the MULTAN 78,[9] UNICS-III,[10] and ORTEP[11] programs. Atomic coordinates and thermal parameters of nonhydrogen atoms are listed in Table 2. The anisotropic thermal parameters of nonhydrogen atoms, the atomic coordinates and thermal parameters of hydrogen atoms, and the F_o-F_c tables have been deposited at the Office of the Chemical Society of Japan as a Document No. 8812.

Physical Measurement. Cyclic voltammetric measurement was carried out by using a Hokuto Denko HA-501 potentiostat with a Hokuto Denko HF-201 function generator and a Yokogawa 3086-11 X-Y recorder. A three-electrode cell consisting of a glassy carbon electrode, a platinum-flug counter electrode, and a saturated caromel references electrode (SCE) was used.

Results and Discussion

The crystal consists of binuclear cations $[Co_2(taec)(OH)]^{3+}$ and perchlorate ions. A perspective view of $[Co_2(taec)(OH)]^{3+}$ is shown in Fig. 2. The coordination mode of taec is the same as that of $[Cu_2(taec)Y](ClO_4)_3$ (Y=F, Br, I, N_3, NCO, NO_2).[1,5,6] The two

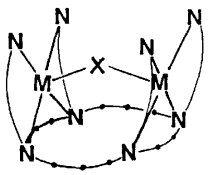

Fig. 1. Coordination mode of taec.

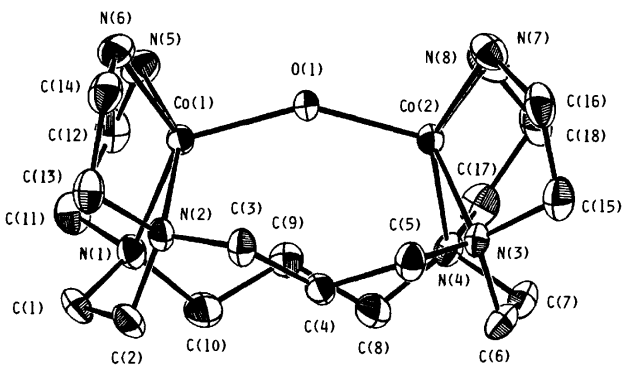

Fig. 2. ORTEP diagram of $[Co_2(taec)(OH)]^{3+}$.

cobalt ions are bridged by a single hydroxide ion. The geometry around each cobalt ion can be described as a distorted square pyramid. The basal plane is formed by two nitrogens of the cyclam ring and two pendant amino nitrogens. The deviations of the basal atoms from the mean plane are within ±0.22 Å, and Co(1) and Co(2) are displaced by 0.66 and 0.69Å, respectively, from the mean planes toward the hydroxide ion. The Co(1)-Co(2) distance of 3.727(1) Å is significantly shorter than the Cu-Cu distances of $[Cu_2(taec)Y](ClO_4)_3$ (4.299(2)—4.841(3) Å).[1,5,6] This may be attributed to the fact that the cobalt ions are further apart from the basal planes than are the copper ions of

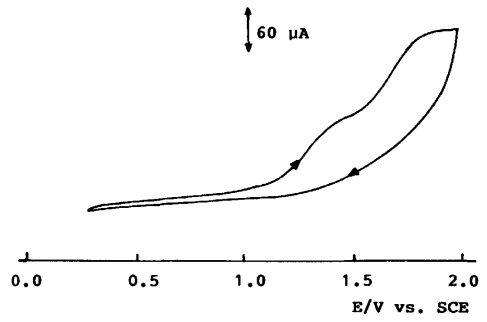

Fig. 3. Cyclic voltammogram of $[Co_2(taec)(OH)](ClO_4)_3$ (1/2 mM) (1 M=1 mol dm^{-3}) in acetonitrile containing 0.1 M $(C_2H_5)_4NBF_4$. The scan rate is 100 mV s^{-1}.

$[Cu_2(taec)Y](ClO_4)_3$ (0.37—0.48 Å).[1,5,6] In this structure, the sixth coordination site of the cobalt ion is blocked by the methylene groups of taec. Thus, the result also consists with our previous assumption that the strong resistivity to the oxidation from Co(II) to Co(III) in these complexes arises mainly from prohibition against six-coodination which stabilizes Co(III) oxidation state characteristically.[1]

Cyclic voltammetric measurements were carried out with a glassy carbon electrode in acetonitrile solution. The cyclic voltammogram showed an irreversible profile with two anodic peaks at ca. 1.4 and 1.8 V vs. SCE (Fig. 3). The remarkable high oxidation potentials agree with the fact that the chemical oxidation of the cobalt(II) of this complex is very difficult. The complex was oxidized electrolytically at ca. 1.4 V vs. SCE in acetonitrile solution. The solution turned from purple to reddish orange yielding an amorphous precipitate at the anode. Attempts to obtain a cobalt(III) complex were unsuccessful. The degradation of ligand seemed to take place with the oxidation.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 62540478 from the Ministry of Education, Science and Culture.

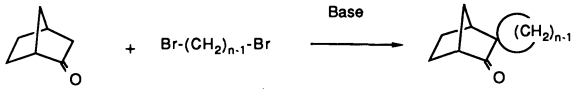
A Convenient Synthesis of Spironorcamphors

Kimihiko HORI, Naotake TAKAISHI,* and Yoshiaki INAMOTO
Tochigi Research Laboratories, Kao Corporation,
2606 Akabane, Ichikaimachi, Tochigi 321-34
(Received November 30, 1987)

Synopsis. The effects of the base, molar ratio of the reagent, solvent and reaction temperature on the cycloalkylation of norcamphor with 1,4-dibromobutane were explored, and optimum conditions for the preparation of spiro[bicyclo[2.2.1]heptane-2,1′-cyclopentan]-3-one have been established. 3-*exo*-(4-Bromobutyl)norcamphor was isolated and characterized as a reaction intermediate. A series of spironorcamphors with various ring sizes were obtained in good yields using a 1:1.5:2.5 ratio of norcamphor/α,ω-dibromoalkanes /$NaNH_2$ in Et_2O.

The syntheses and reactions of spiro compounds have attracted considerable attention in recent years.[1] As one part of our continuing interest in the chemistry of tricycloundecane derivatives,[2] we have required a convenient method for the preparation of spiro[bicyclo[2.2.1]heptane-2,1′-cyclopentan]-3-one (**3c**).[2d] It seemed that the most direct route to **3c** would be cycloalkylation[1b,3] of norcamphor (bicyclo[2.2.1]heptan-2-one **1**) with 1,4-dibromobutane (**2c**) in the presence of the base.



1 **2** **3**

a : n=3

e : n=7

Although a lot of examples for the synthesis of spiroketones via cycloalkylation have been described,[1b] a survey of the literature has indicated that only one example has been reported by Sauers et al.,[4] on the reaction of **1**, giving spiro[bicyclo[2.2.1]heptane-2,1′-cyclobutan]-3-one (**3b**) in low yield by treatment with 1,3-dibromopropane (**2b**) in the presence of $NaNH_2$. We now report on a general method for the synthesis of spironorcamphors (**3**) involving the cycloalkylation of **1** with α,ω-dibromoalkanes (**2**) in the presence of a base.

Initial attempts to alkylate **1** with **2c** to the spiroketone **3c** were carried out under similar conditions employed for the preparation of **3b**.[4] Treatment of **1** with $NaNH_2$ (3 equiv) in Et_2O gave an enolate which upon treatment with **2c** (10 equiv) at ambient temperature for 48 h afforded **3c** (48%) along with monoalkylated product, 3-*exo*-(4-bromobutyl)-norcamphor (*exo*-**4c**, 31%) (Table 1, entry 1). The structure of **3c** was confirmed by a comparison of the physical properties with previously reported data.[2d] The configuration of the substituent of *exo*-**4c** was evidenced by comparing the ^{13}C NMR chemical shifts with those of the related 3-alkylnorcamphors.[5] A marked upfield shift at C-7 was observed due to the presence of an exo substituent at C-3 in *exo*-**4c**, which can be classified as a γ-syn effect.[5]

10	1.5	*t*-BuOK (2.5)	Benzene	Reflux	3	53	
11	10	*t*-BuOK (2.5)	Benzene	Reflux	3	45	9
12	1.5	LDA (2.5)	THF	−78°C→r.t.	60	8	33
13	1.2	LDA (1.2)	THF	−78°C→r.t.	60	12	41

a) Determined by GLC analysis using dodecane as an internal standard.

The exclusive formation of the *exo*-**4c** is rationalized based on a selective exo attack of the alkylating reagent **2c**.[6] The isolated ketone *exo*-**4c** was cyclized in the presence of $NaNH_2$ to afford **3c** in 89% yield.[7] This means that *exo*-**4c** is the intermediate in the above-mentioned cycloalkylation reaction. The lack of its epimer, *endo*-**4c**, implies a rapid cyclization of the enolate anion derived from *exo*-**4c**, compared to a proton-exchange reaction.[8]

Various efforts were devoted to optimize the yield of **3c**. Similar results were obtained through a treatment of a mixture of **1** and **2c** with $NaNH_2$ in boiling Et_2O[9] (entry 2). However, the yield and selectivity of **3c** were highly increased upon decreasing the amounts of **2c** (entries 3—6). The highest yield of **3c** could be attained when the reaction was performed using a 1:1.5:2.5 ratio of **1**/**2c**/$NaNH_2$ in Et_2O (entry 5). A large excess of **2c** caused side reactions with $NaNH_2$.

The use of hexane (entry 7) or toluene (entries 8 and 9) instead of Et_2O gave a decreased yield of **3c**. It has been reported[10] that cyclohexanone affords spiro[4.5]-decan-6-one in 70% yield when treated with **2c** in the presence of potassium *t*-butoxide (*t*-BuOK). By using these conditions, we obtained a slightly decreased yield of **3c** (entries 10 and 11). On the other hand, upon treatment with lithium diisopropylamide (LDA),[11] *exo*-**4c** was obtained as a major product (entries 12 and 13).

These improved reaction conditions (entry 5) were successfully applied to a reaction of **1** with other α,ω-dibromoalkanes **2**, giving the corresponding spironorcamphors **3** in moderate to good yields. Interestingly, **3b** was isolated in 52% yield as compared to 3% reported in the literature.[4] Although none of the monoalkylated product, 3-*exo*-(3-bromopropyl)norcamphor (*exo*-**4b**), was detected in the products, allylation[12] became a significant side reaction, a fact possibly attributable to the formation of allyl bromide by the ready dehydrobromination of **2b** compared to the other α,ω-dibromoalkanes. A mixture of allylated compounds, 3-*exo*-allylnorcamphor (*exo*-**5**, 7%),[11b,c] 3-*endo*-allylnorcamohor (*endo*-**5**, 4%), and 3,3-diallylnorcamphor (**6**, 1%) was isolated as by-products. Enol ether, which would be derived from *exo*-**4b** by intramolecular O-alkylation, was not observed.[13]

It is noteworthy that spiro[bicyclo[2.2.1]heptane-2,1′-cycloheptan]-3-one (**3e**) containing a seven-membered ring was produced in moderate yield, since the corresponding spirocyclohexanone has been obtained in only 8% yield from cycloalkylation of cyclohexanone with **2e**.[14] Although the preparation of a three-membered ring by alkylation is a kinetically favored process,[3a] we were not able to isolate the spiro[bicyclo[2.2.1]heptane-2,1′-cyclopropan]-3-one (**3a**).[15]

In conclusion, spironorcamphors (**3**) can now be easily obtained in good yields from the reaction of norcamphor (**1**) with α,ω-dibromoalkane (**2**) in the presence of $NaNH_2$. This ready availability should enhance the attractiveness of these compounds as starting materials for several reactions, including dehydration-rearrangement reactions.[1a,2b]

Experimental

Preparation of Spironorcamphors (3). General Procedure. To a magnetically stirred solution of norcamphor (**1**) (5.51 g, 50 mmol) and α,ω-dibromoalkane (**2**) (75 mmol) in dry Et_2O (150 ml) was added $NaNH_2$ (4.88 g, 125 mmol) in one portion. After being refluxed under a nitrogen atmosphere for 24 h, the reaction mixture was cooled to room temperature and poured into cold water (150 ml). The organic layer was separated, and the aqueous portion was extracted two times with Et_2O. The ethereal extracts were washed with a saturated NaCl solution, dried over Na_2SO_4, filtered and concentrated in vacuo. Purification of the residue by column chromatography on silica gel using hexane–Et_2O (10:1) as an eluent afforded **3** as a colorless liquid.

Spiro[bicyclo[2.2.1]heptane-2,1′-cyclobutan]-3-one (3b): Yield 52%; IR (neat) 2975, 1750, 1465 cm^{-1}; ^1H NMR δ= 1.30—2.25 (m, 12H), 2.45—2.60 (m,2H); ^{13}C NMR δ=15.1 (t), 21.9 (t), 24.4 (t), 25.4 (t), 30.4 (t), 34.1 (t), 45.4 (d), 49.6 (d), 54.4 (s), 221.3 (s); MS *m/z* 150 (M^+), 122, 84, 81,67.

Capillary GLC analysis of the crude reaction mixture at 90 °C showed that 7% of 3-*exo*-allylnorcamphor (*exo*-**5**), 4% of 3-*endo*-allylnorcamphor (*endo*-5) and 1% of 3,3-diallylnorcamphor (**6**) were present as by-products. The mass spectrum and GLC retention time of *exo*-**5** were identical with those of an authentic sample, which was prepared by alkylation of **1** with allyl bromide in the presence of LDA. The other products, *endo*-**5** and **6**, isolated by preparative GLC, had the following properties:

***exo*-5**:[11b,c] IR (neat) 2975, 1755, 920 cm^{-1}; ^1H NMR δ=1.26—2.13 (m, 8H), 2.25—2.61 (m, 3H), 4.97—5.11 (m, 2H), 5.70—5.89 (m, 1H); ^{13}C NMR δ=23.9 (t), 28.0 (t), 33.3 (t), 34.6 (t), 38.5 (d), 49.6 (d), 53.2 (d), 116.1 (t), 136.4 (d), 219.0 (s); MS *m/z* 150 (M^+), 109, 81, 67, 41.

***endo*-5**: IR (neat) 2975, 1755, 920 cm^{-1}; ^1H NMR δ=1.32—2.18 (m, 8H), 2.43—2.67 (m, 3H), 4.97—5.11 (m, 2H), 5.70—5.89 (m, 1H); ^{13}C NMR δ=21.0 (t), 25.3 (t), 30.6 (t), 37.0 (t), 38.2 (d), 50.5 (d), 53.3 (d), 115.8 (t), 136.4 (d), 218.9 (s); MS *m/z* 150 (M^+), 109, 81, 67, 41; Found: *m/z*, 150.1039. Reaction of 1,4-Dibromobutane (2c) with Enolate Generated from 1 and $NaNH_2$ (Table 1, Entry 1). A variation of the procedure of Sauers et al.[4] was utilized. To a magnetically stirred solution of **1** (1.10 g, 10 mmol) and dodecane(0.85 g, 5 mmol; internal standard) in dry Et_2O (40 ml) was added $NaNH_2$ (1.17 g, 30 mmol) in one portion. After reflux under a nitrogen atmosphere for 4.5 h, the resulting mixture was poured onto **2c** (21.59 g, 100 mmol) and stirred at room temperature for 2 days. The reaction mixture was poured into cold water (50 ml), and the organic layer was separated. The aqueous portion was extracted two times with Et_2O. The combined organic extracts were washed with a saturated NaCl solution and dried over Na_2SO_4. A GLC analysis showed the presence of two major products [48% of **3c** and 31% of 3-*exo*-(4-bromobutyl)norcamphor (*exo*-**4c**)], which were purified by preparative GLC. *exo*-**4c**: IR (neat) 2975, 1750, 1470 cm^{-1}; ^1H NMR δ=1.10—2.08 (m, 13H), 2.35—2.70 (m, 2H, CH-CO-CH), 3.42 (t, J=6.6 Hz, 2H, CH_2Br); ^{13}C NMR δ=24.0 (t), 26.9 (t), 28.0 (t), 28.3 (t), 32.6 (t), 33.5 (t), 34.8 (t), 39.2 (d), 49.5 (d), 53.7 (d), 219.9 (s); MS *m/z* 246 (M^++2), 244 (M^+), 95, 82, 67, 41; Found: *m/z*, 244.0442. Calcd for $C_{11}H_{17}OBr$: M, 244.0462.

Reaction of 1 with 2c in the Presence of Potassium *t*-Butoxide (*t*-BuOK)[10] (Table 1, Entry 10). To a magnetically stirred solution of **1** (1.10 g, 10 mmol), **2c** (3.24 g, 15 mmol) and dodecane (0.85 g, 5 mmol; internal standard) in dry benzene (40 ml) was added *t*-BuOK (2.81 g, 25 mmol) in one portion. The resulting mixture was heated 3 h at reflux under a nitrogen atmosphere. Upon cooling to room temperature, the reaction mixture was poured into water (50 ml). The organic layer was separated and the aqueous portion was extracted two times with Et_2O. The combined organic extracts were washed with a saturated NaCl solution and dried over Na_2SO_4. A GLC analysis showed the presence of **3c** as the main product (53% yield).

Reaction of 1 with 2c in the Presence of Lithium Diisopropylamide (LDA)[11] (Table 1, Entry 12). A 1.6 M (1 M=1 mol dm^{-3}) hexane solution of butyllithium (7.8 ml, 12.5 mmol) was added to a stirred solution of diisopropylamine in dry THF (10 ml) at −78 °C. The solution was stirred at −78 °C for 1 h and at 0 °C for an additional 1 h, and again cooled to −78°C. To the resulting LDA solution was added dropwise a solution of **1** (0.55 g, 5 mmol) in dry THF (10 ml). After stirring for 1 h at −78 °C, a solution of **2c** (1.62 g, 7.5 mmol) in dry THF (5 ml) was added into the mixture. The reaction mixture was allowed to warm to 0 °C, stirred at that temperature for 1 h and at room temperature for 60 h, and then poured into water (50 ml). The mixture was extracted three times with Et_2O. The combined extracts were washed with saturated NaCl solution and dried over Na_2SO_4. GLC analysis of the solution indicated the formation of **3c** (8%) and *exo*-**4c** (33%).

Cyclization of *exo*-4c to 3c in the Presence of $NaNH_2$. To a magnetically stirred solution of *exo*-**4c** (0.50 g, 2.04 mmol) and dodecane (0.185 g, 1.08 mmol; internal standard) in dry ether (15 ml) was added $NaNH_2$ (0.12 g, 3.06 mmol) in one portion. The resulting mixture was refluxed under nitrogen for 24 h, allowed to cool, and then poured into water (50 ml). The organic layer was separated and the aqueous portion was extracted two times with Et_2O. The combined extracts were washed with saturated NaCl solution and dried over Na_2SO_4. A GLC analysis showed that **3c** was formed in 87% yield.

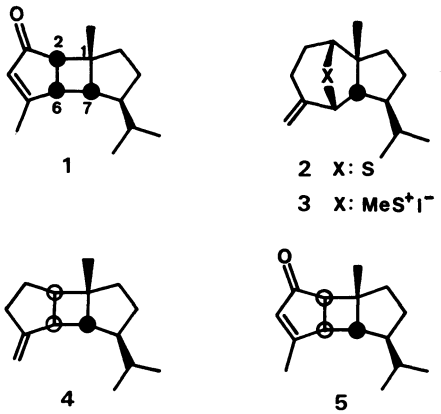
Stereospecific Synthesis of 3-Oxo-α-bourbonene and the Cisoid Isomer for Structural Determination of the Toxic Component of *Lansium domesticum*

Tadao UYEHARA,* Ichiro SUZUKI, and Yoshinori YAMAMOTO
Department of Chemistry, Faculty of Science, Tohoku University, Aramaki-Aoba, Sendai 980
(Received December 2, 1987)

Synopsis. The cis-cisoid-cis isomer of 3-oxo-α-bourbonene, (**1**), the original structure proposed for the toxic principle of *Lansium domesticum*, has been prepared from (−)-mintsulfide. Neither spectral data of **1** nor of 3-oxo-α-bourbonene itself, derived from β-bourbonene, are not identical with those of the toxic componet.

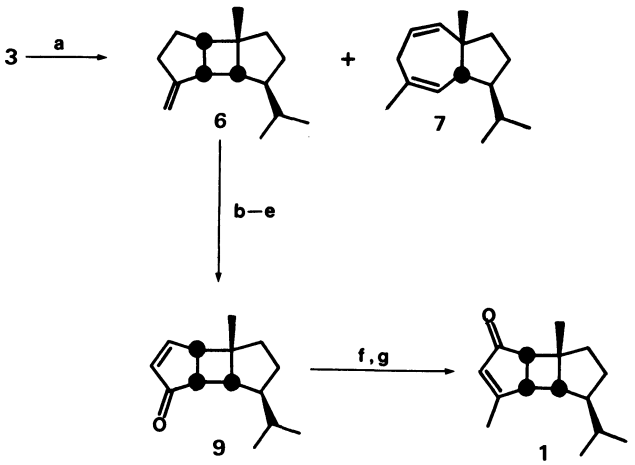
Recently, it has been reported that one of the toxic principles (fish poisons) of *Lansium domesticum* Jack v.duku, a Meliaceous plant, is the cis-cisoid-cis isomer of 3-oxo-α-bourbonene, (**1**).[1] Because of this unique cisoid-[5-4-5] fused-ring skeleton, we have designed a stereospecific synthesis of **1** starting from the sulfur-bridged sesquiterpene, (−)-mintsulfide (**2**) whose absolute stereostructure had been established.[2] We report herein the synthesis of **1** from **2**, a similar transformation of β-bourbonene (**4**) into 3-oxo-α-bourbonene (**5**), and the findings that the toxic component has not any [5-4-5] fused ring skeleton.



Results and Discussion

The methylsulfonium iodide of (−)-mintsulfide, (**3**),[3] is the actual starting material of the synthesis of **1**. By treating with alkyllithium, **3** reacts in competitively. One is the [2,3]sigmatropic rearrangement of the resulting sulfonium methylide to give the homologous sulfur-bridged compound. The other is the sulfide extrusion to yield the cis-cisoid-cis isomer of β-bourbonene, **6**, and the [5-7] fused-ring diene **7** via the hypothetical diradical intermediate.[3,4] The ratio of these products was reported to depend upon the reaction conditions, while **6** was the minor product.[3] After several attempts, the yield of **6** was increased up to 41% by treating with methyllithium at 0 °C.

Ozonization of **6** in ethanol followed by treatment with zinc dust gave the cyclopentanone (**8**) in 85% yield. In order to transform **8** into the α,β-unsaturated ketone **9** by palladium-catalyzed oxidation,[5] the allyl enol carbonate was derived from **8** using potassium *t*-butoxide and allyl chloroformate. Treatment of the carbonate with palladium acetate (10%) in boiling acetonitrile gave **9** in 84% overall yield from **8**. Conversion of **9** into **1** was achieved by consecutive treatment with methyllithium and pyridinium chlorochromate (PCC)[6] in 85% yield.



Scheme 1. Preparation of *cis-cisoid-cis*-3-oxo-α-bourbonene (**1**).
(a): MeLi, THF, (b): O_3, EtOH, (c): Zn, AcOH, EtOH–H_2O, (d) *t*-BuOK, THF, $ClCOOCH_2CH=CH_2$, (e): $Pd(OAc)_2$, CH_3CN, (f): MeLi, ether, (g): PCC, CH_2Cl_2.

Compound **1** shows reasonable spectral characteristics. The cis-cisoid-cis arrangement of **1** is clearly supported by the ^1H NMR spectrum ($J_{2,6}$=5.8 Hz and $J_{6,7}$=9.6 Hz) and the NOEDIF spectra which show certain interactions between the C-1 methyl protons (δ=1.33) and the C-2 proton (δ=2.60), the C-2 proton and the C-6 proton (δ=3.24), and the C-6 proton and the C-7 proton (δ=2.33). Upon irradiation of the C-1 methyl protons, NOE enhancement was also observed at C-7 proton. However, the spectral data of **1** are completely different from those of the toxic principle of *Lansium domesticum*.

Cis-transoid-cis isomer of **1**, namely **5**,[7] has been prepared in a similar manner as above starting from β-bourbonene (**4**) which was derived photochemically from (−)-germacrene-D.[8] The spectral characteristics of **5**, including ^{13}C NMR spectrum, are also different from those of that fish poison. Now it is clear that the

toxic principle has no [5-4-5] fused ring skeletons. Remaining candidates for the toxic principle seem to be ylangene or copaene type compounds containing an *r*-1, *t*-2, *c*-3, *t*-4-tetrasubstituted cyclobutane ring.

Experimental

General. Melting points were determined with a Yamato MP-21 capillary melting point apparatus and are uncorrected. UV and IR spectra were recorded on Hitachi Model 323 and 215 spectrometers, respectively. NMR spectra were obtained on JEOL JNM-PMX60, Varian EM-390, Varian XL-200, and JEOL GX-400 NMR spectrometers, using tetramethylsilane as an internal standard. The mass spectral studies were conducted using a Hitachi M-52 spectrometer and a JEOL DX-303 mass spectrometer. Optical rotations were measured on a Perkin-Elmer 241 Polarimeter. Elemental analyses were performed by the Microanalytical Laboratory of Tohoku University. All reactions were monitored by analytical TLC using E. Merck precoated silica gel $60F_{254}$ plates. Column chromatography was carried out with E. Merck silica gel 60 (70—230 mesh ASTM). Ozone was generated using a Nippon Ozone type O-1-2 laborastory ozonator.

(1*S*)-*cis*-1-*cisoid*-1,2-*cis*-2-Bourbonene ((1*S*)-*cis*-8-Isopropyl-1-methyl-5-methylenetricyclo[5.3.0.$0^{2,6}$]decane 6). The procedure used for preparation of **6** was essentially that of Ohnuma[9] with following modification. To a mixture of methylsulfonium iodide of mintsulfide (**3**, 4.42 g, 11.7 mmol) and THF (40 ml) was added 1 M methyllithium solution (1 M=1 mol dm^{-3}) in ether (14 ml, 1.2 equiv) at 0 °C under argon and stirred for 30 min. To the reaction mixture was added saturated aqueous ammonium chloride solution and extracted with three portions of ether. The combined extracts were washed with water and saturated brine, and dried over $MgSO_4$. After removal of the solvent, the remaining oil (2.61 g) was chromatographed on silica gel (50 g; hexane) to yield a mixture of hydrocarbons (1.85 g). Silver nitrate impregnated silica-gel chromatography (50 g; hexane) of the mixture gave **6** (0.946 g, 4.74 mmol, 41% yield) **7** (0.579 g, 2.83 mmol, 24% yield), and a mixture of them (0.109 g). **6**: Colorless oil; $[\alpha]_D^{25}$+188.41° (*c* 0.0820, $CHCl_3$); IR (CCl_4) 3070 (w), 1640 (w), and 890 (m) cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.83 (3H, d, *J*=6.8 Hz), 0.86 (3H, d, *J*=6.8 Hz), 1.12 (3H, s), 1.1—1.8 (9H, m), 1.86 (1H, m), 2.3—2.5 (2H, m), 3.12 (1H, dd, *J*=9.5 and 8.1 Hz), 4.68 (1H, broad s, $W_{1/2}$=4.0 Hz), and 5.00 (1H, $W_{1/2}$=4.0 Hz); ^{13}C NMR ($CDCl_3$) δ=21.86 (q), 21.98 (q), 27.73 (t), 30.23 (q), 31.79 (t), 33.02 (t), 34.48 (d), 36.32 (t), 41.49 (d), 44.72 (s), 46.20 (d), 49.50 (d), 52.10 (d), 107.73 (t), and 155.15 (s). Found: C, 88.42; H, 11.73%. Calcd for $C_{15}H_{24}$: C, 88.16; H, 11.84%.

(1*R*)-*cis*-8-Isopropyl-1,5-dimethyl-*cis*-bicyclo[5.3.0]deca-2.5-diene 7: Colorless oil; $[\alpha]_D^{25}$ −97.80° (*c* 1.452, $CHCl_3$); IR (CCl_4) 1460 (w), 820 (w), 730 (w), 705 (m), and 680 (w) cm^{-1}; ^1H NMR (CCl_4) δ=0.85 (3H, d, *J*=6.8 Hz), 0.88 (3H, d, *J*=6.8 Hz), 1.09 (3H, s), 1.72 (3H, broad s), 1.1—2.2 (7H, m), 2.63 (1H, dd, *J*=21.3 and 3.3 Hz), 2.83 (1H, broad d. *J*=21.3 Hz. $W_{1/2}$=7.8Hz), 5.25 (1H, d, *J*=12.0 Hz), and 5.00 (1H, $W_{1/2}$=4.0 Hz). Found: C, 88.15: H, 11.90%. Calcd for $C_{15}H_{24}$: C, 88.16; H, 11.84%.

(1*R*)-*cis*-10-Isopropyl-7-methyl-*cis*-1-*cisoid*-1,2-*cis*-2-tricyclo[5.3.0.$0^{2,6}$]decan-3-one (8). To a solution of **6** (844.1 mg, 4.13 mmol) in ethanol (20 ml) at −78 °C was treated with ozone until it was faintly blue. The reaction mixture was diluted with water (30 ml) and then treated with zinc (1.37 g) and acetic acid (2.4 ml). The resulting suspension was stirred at room temperature for 2 h and then filtered. The filtrate was diluted with saturated aqueous ammonium chloride solution and extracted with three portions of ether. The combined extracts were washed with saturated sodium hydrogencarbonate solution and saturated brine, and dried over $MgSO_4$. Removal of the solvent followed by chromatography of the remaining oil (847.3 ml) on silica gel (25 g; 10:1 hexane–ethyl acetate) gave **8** (720.3 mg, 3.49 mmol, 85% yield); colorless oil; $[\alpha]_D^{20}$ +251.2° (*c* 0.400, $CHCl_3$) 1720cm^{-1}; ^1H NMR (CCl_4) δ=0.87 (6H, d, *J*=6.0 Hz), 1.18 (3H, s), and 1.2—2.8 (13H, m). Found *m/z* 206.1668. Calcd for $C_{14}H_{22}O$: M, 206.1670.

(1*R*)-*cis*-10-Isopropyl-7-methyl-*cis*-1-*cisoid*-1,2-*cis*-2-tricyclo[5.3.0.$0^{2,6}$]dec-4-en-3-one (9). To a solution of potassium *t*-butoxide (580 mg, 6.10 mmol) in THF (20 ml) was added a solution of **8** (614.4 mg, 3.0 mmol) in THF (20 ml) at −70°C under argon and the resulting mixture was stirred for 1 h. Allyl chloroformate (0.80 ml, 909 mg, 8.0 mmol) was added to the deep yellow solution and the mixture was stirred for 1 h at −78°C and then allowed to warm to room temperature. After stirring overnight, the mixture was treated with saturated aqueous NH_4Cl solution (40 ml) and then extracted with three portions of ether. The combined extracts were washed with saturated brine, dried over $MgSO_4$, and concentrated. Chromatography of the remaining oil (1.105 g) on silica gel (30 g; 20:1 hexane–ethyl acetate) gave the allyl enol carbonate (743.4 mg, 3.00 mmol) as a colorless oil.

Palladium acetate (67 mg, 0.30 mmol) was added to a solution of the carbonate in acetonitrile (10 ml) and the mixture was heated at 80 °C for 1 h under nitrogen. After filtration through a Celite layer, the solvent was romoved in vacuo. Chromatography of the residue on silica gel (50 g; 20:1 hexane–ethyl acetate) gave **9** (510.3 mg, 2.50 mmol, 84%); colorless oil; $[\alpha]_D^{20}$ +487.8° (*c* 1.07, $CHCl_3$); IR ($CHCl_3$) 1685 (s) cm^{-1}; ^1H NMR δ=0.85 (3H, d, *J*=6 Hz), 0.92 (3H, d, *J*=6 Hz), 1.33 (3H, s), 2.13 (1H, broad dd, *J*=11.7 and 3.8 Hz), 2.77 (1H, dd, *J*=11.7 and 5.9 Hz), 2.77 (1H, dddd, *J*=5.9, 3.3, 1.2, and 0.9 Hz), 6.25 (1H, dd, *J*=5.6 and 1.8 Hz), and 7.48 (1H, ddd, *J*=5.6, 3.3, and 0.7 Hz); MS *m/z* (rel intensity) 204 (M^+, 12.5), 189 (8.1), 161 (48.8), 123 (100), and 81 (95). Found *m/z* 204.1514. Calcd for $C_{14}H_{20}O$: M, 204.1513.

(1*S*)-*cis*-8-Isopropyl-1,5-dimethyl-*cis*-1-*cisoid*-1,2-*cis*-2-tricyclo[5.3.0.$0^{2,6}$]dec-4-en-3-one (1). To a solution of **9** (314.6 mg, 1.54 mmol) in THF (10 ml) was added 1 M methyllithium solution in ether (3 ml) at −78 °C under argon and stirred for 30 min. To the reaction mixture was added saturated aqueous ammonium chloride solution and extracted with three portions of ether. The combined extracts were washed with saturated brine, and dried over $MgSO_4$. Removal of the solvent gave a colorless oil (351 mg). To a solution of PCC (665 mg, 3.08 mmol) in dichloromethane (16 ml) was added a solution of the product in dichloromethane (12 ml) and the mixture was stirred for 3.2 h. The resulting mixture was diluted with ether (40 ml) and the supernatant was decanted from the black solid. The residue was washed with several portions of ether. The combined ethereal solutions were washed successively with 5% NaOH solution, 5% HCl, saturated $NaHCO_3$ solution, and saturated brine, dried over $MgSO_4$, and concentrated. Chromatography of the residue (389 mg) on silica gel (23 g; 10:1 hexane–ethyl acetate)gave **1** (289.5 mg, 1.31 mmol, 85% yield); colorless prisms; mp 50.5—51.5 °C (ether); $[\alpha]_D^{20}$ −331.5° (*c* 0.97); UV (EtOH) λ_{max} 238 (ε 9370) and 318 nm (94); IR ($CHCl_3$) 1680 (broad s) and 1610 (m) cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.86 (3H, d, *J*=6.2 Hz), 0.90 (3H, d, *J*=6.4 Hz), 1.25—1.52 (4H, m), 1.33 (3H, s), 1.54—1.68 (2H, m), 2.11 (3H, broad s, $W_{1/2}$=2.5 Hz), 2.23 (1H, dd, *J*=9.6 and 3.8 Hz), 2.60 (broad, d, *J*=5.8 Hz, $W_{1/2}$=2 Hz), 3.24 (1H, dddd, *J*=9.6, 5.8, 0.8, and 0.8 Hz), and

6.11 (1H, brosd s, $W_{1/2}$=3.5 Hz); ^{13}C NMR ($CDCl_3$) δ=19.29 (5-Me), 20.85 (-CHMe-Me), 21.94 (-CHMe-Me), 28.70 (1-Me), 32.12 (9 or 10), 33.33 (-CHMe$_2$), 35.58 (9 or 10), 41.96 (6), 46.65 (1), 50.03 (8), 50.90 (7), 52.90 (2), 135.68 (4), 179.35 (5), and 211.08 (3). MS *m/z* (rel intensity) 218 (M^+, 12.3), 203 (6.5), 189 (4.0), 175 (20.5), 149 (18.0), 123 (100), and 81 (69.5). Found *m/z* 218.1671. Calcd for $C_{15}H_{22}O$: M, 218.1670.

Transformation of β-Bourbonene (4) into 3-Oxobourbonene ((1*S*)-*cis*-8-Isopropyl-1,5-dimethyl-*cis*-1-*transoid*-1,2-*cis*-2-tricyclo[5.3.0.0^{2,6}]dec-4-en-3-one (5)). β-Bourbonene was derived photochemically by using the literature procedure[7] from (−)-germacrene-D which was isolated from peppermint oil (*Mentha peperita*). In a procedure similar to that employed for the synthesis of **9**, **4** was transformed into (1*R*)-*cis*-10-isopropyl-7-methyl-*cis*-1-*transoid*-1,2-*cis*-tricyclo-[5.3.0.0^{2,6}]dec-4-en-3-one (^{1}H NMR ($CDCl_3$) δ=0.88 (3H, d, *J*=6.5 Hz), 0.90 (3H, d, *J*=6.5 Hz), 1.03 (3H, s), 1.30 (1H, d-sept, *J*=9.5 and 6.5 Hz), 1.58 (1H, ddd, *J*=13.0, 10.5, and 6.8 Hz), 1.65 (1H, m, 10-H), 1.72 (1H, ddd, *J*=13.0, 6.8, and 3.5 Hz), 1.80 (1H, dddd, *J*=16.5, 7.0, 3.5, and 1.0 Hz), 1.93 (1-H, broad s), 1.96 (1H, ddd, *J*=13.4, 10.8, and 6.5), 2.33 (2-H, ddd, *J*=4.9, 3.8, and 0.2 Hz), 2,97 (6-H, ddd, *J*=4.9, 3.2, and 1.2 Hz), 6.40 (4-H, ddd, *J*=5.6, 1.2, and 0.2 Hz), and 7.73 (5-H, ddd, *J*=5.6, 3.2, and 0.3 Hz); Found *m/z* 204.1519). This α,β-unsaturated ketone was converted into **5** in a manner similar to that adopted to prepare **1** from **9**. **5**: Colorless oil; $[\alpha]_D^{20}$ +336.3° (*c* 0.30, $CHCl_3$); UV (EtOH)λ_{max} 234 (ε 11700) and 315 nm (95); IR ($CHCl_3$) 1675 (s) and 1615 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.90 (3H, d, *J*=6.3 Hz), 0.91 (3H, d, *J*=6.3 Hz), 1.07 (3H, s), 1.34 (1H, d-sept, *J*=9.2 and 6.3 Hz), 1.50 (ddd, *J*=13.0, 11.0 and 6.5 Hz), 1.52—1.62 (1H, m), 1.78 (1H, dddd, *J*=13.0, 6.8, 3.0, and 0.8 Hz), 1.82 (1H, $W_{1/2}$=5 Hz), 1.93 (1H, dddd, *J*=13.0, 11.0, 6.5, and 6.5 Hz), 2.12 (3H, d, *J*=1.2 Hz), 2.57 (2,6-H, broad s, $W_{1/2}$=1.5 Hz), and 5.98 (4-H, q, *J*=1.2 Hz); ^{13}C NMR ($CDCl_3$) δ=17.08 (5-Me), 21.26 (-CHMe-Me), 21.65 (-CHMe-Me), 24.12 (1-Me), 29.35 (9 or 10), 30.54 (-CHMe$_2$), 40.72 (9 or 10), 45.79 (1), 47.06 (2 or 6), 50.82 (8), 53.32 (2 or 6), 54.60 (7), 132.10 (4), 180.87 (5), and 211.20 (3); MS (25 eV) *m/z* (rel intensity) 218 (M^+, 0.8), 175 (15.9), 124 (5.1), 123 (100), 122 (25.0), and 81 (47.3). Found *m/z* 218.1663. Calcd for $C_{12}H_{22}O$: M, 218.1670.

We wish to thank Professor Yuji Hayashi of Osaka City University for fruitful discussion and Takasago Perfumery Co., Ltd., for generous gift of peppermint oil (*Mentha piperita*). We also thank Professor Kuninobu Kabuto of Tohoku University for measurement of optical rotations.

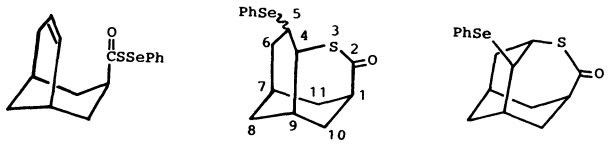
(Received December 8, 1987)

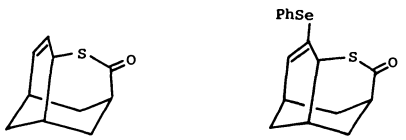
Synopsis. Heating *Se*-phenyl bicyclo[3.3.1]non-6-ene-3-(selenothioperoxy)carboxylate with AIBN gives 5-phenylseleno-3-thia-2-homoprotoadamantan-2-one which is unexpectedly converted to the vinyl selenide via the selenoxide by oxidation with hydrogen peroxide or *m*CPBA.

Se-Phenyl (selenothioperoxy)carboxylates are useful reagents for introducing both a thioester and a phenylseleno group into a molecule. Intermolecular addition of *Se*-phenyl(selenothioperoxy)benzoate to olefins gave addition products, i.e. *S*-phenylselenoalkyl thiobenzoate,[1] whereas *Se*-phenyl (selenothioperoxy)carboxylates bearing an unsaturated bond resulted in intramolecular selenothiolactonization to give phenylseleno-substituted thiolactones.[2] These reactions proceed via a free-radical pathway[1] involving the inter- or intramolecular attack of initially formed thiyl radical on the olefinic carbon and subsequent chain transfer of the carbon radical with the (selenothioperoxy)carboxylate. The construction of polycyclic molecules such as adamantane analogs could be of great interest because of their unique structures and reactivities.[3] We here disclose a new free-radical cyclization of *Se*-phenyl bicyclo[3.3.1]non-6-ene-3-(selenothioperoxy)carboxylate (**1**) into 5-phenylseleno-3-thia-2-homoprotoadamantan-2-one (5-phenylseleno-3-thiatricyclo[5.3.1.$0^{4,9}$]undecan-2-one) (**2**) and also an oxidative conversion of **2** to unexpected 5-phenylseleno-3-thia-2-homoprotoadmant-5-en-2-one (**5**).

(Selenothioperoxy)carboxylate **1** was prepared[4] in 87% overall yield according to the following sequence: Bicyclo[3.3.1]non-6-ene-3-carboxylic acid[5] was converted to acid chloride, which was then transformed to thiocarboxylic acid. The thiocarboxylic acid was treated with *N*-(phenylseleno)phthalimide to give compound **1**. A 0.04 M (1 M=1 mol dm^{-3}) solution of (selenothioperoxy)carboxylate **1** in benzene was heated under reflux for 4 h in the presence of azobis(isobutyronitrile) (AIBN) (10 mol%). After removing the solvent the mixture was purified by chromatography to give 5-phenylseleno-3-thia-2-homoprotoadamantan-2-one (**2**) in 97% yield. There was no indication of the formation of any significant amount of 4-thiahomoadamantan-5-one derivative **3**. Compound **2** was shown to be homogeneous by an inspection of its ^{13}C NMR spectrum, although the configuration of the phenylseleno group in **2** is uncertain at present.[6] We have observed the formation of both trans and cis isomers in the selenothiolactonization[2] as well as in the addition reactions of *Se*-phenyl (selenothioperoxy)benzoate to cycloalkenes.[1] But in the present case there must exist a stronger steric requirement for a chain transfer of the intermediate carbon radical, leading to the exclusive formation of one isomer.



1 **2** **3**



4 **5**

The present cyclization shows a notable reaction feature via a radical intermediate; i.e. the cyclization led to thiahomoprotoadamantanone **2**, but not to thiahomoadamantanone **3**. These results seem to be in accord with the predominant cyclization of 1-hexenyl radicals to five-membered rings.[7] Thus, the cyclization to thiahomoprotoadamantanone **2** can probably be ascribed to the stereoelectronically more favorable approach of the thiyl radical to the C-6 olefinic carbon than to the C-7 carbon, although a theoretical calculation is not presently available. In contrast, the ionic ring-closure of bicyclo[3.3.1]non-6-enes carrying internal nucleophiles at the 3-position generally results in an exclusive formation of homoadamantane ring systems, e.g., 4-thiahomoadamantane[8] from 3-mercaptomethylbicyclo[3.3.1]non-6-ene epoxide, 4-oxahomoadamantane[9] from 3-hydroxymethylbicyclo[3.3.1]non-6-ene, 2-bromo-4-oxatricyclo-[4.3.1.$1^{3,8}$]undecan-5-one[10] from the corresponding 3-carboxylic acid derivative.

Anticipating the formation of thiahomoprotoadamantenone **4**, we attempted on oxidation of the seleno group in **2** by hydrogen peroxide in the presence of pyridine in dichloromethane at ambient temperature, followed by heating the crude selenoxide under reflux in benzene for 1.5 h. This reaction, however, did not lead to the elimination of benzeneselenenic acid (PhSeOH), which would give thiahomoprotoadamantenone **4**. Instead, it gave unexpected selenothiahomoprotoadamantenone **5** bearing a vinyl selenide moiety in 82% yield. Oxidation of selenide **2** by *m*-

chloroperbenzoic acid (*m*CPBA) in dichloromethane at −40°C and subsequent heating under reflux with pyridine in benzene also gave vinyl selenide **5** in 70% yield. The spectral data showed an assigned structure that was concretely confirmed by the X-ray analysis (see Tables 1 and 2).

It is noteworthy that the oxidation of selenide **2** under conditions which usually induce the PhSeOH elimination to an olefin,[11] did not result in the formation of olefin **4** but, instead, gave vinyl selenide **5**. Sterically compressed steroidal sulfoxides have been reported[12] to give vinyl sulfoxides under the Pummerer reaction conditions involving the inevitable step of acylation of the corresponding sulfoxides. Another example is the oxidation of α-silyl selenides via the silyl rearrangement to the oxygen of the selenoxides, the reaction course of which is similar to that of the Pummerer reaction.[13] The present conversion of selenide **2** to vinyl selenide **5** via the selenoxide was carried out under conditions different from those for the typical Pummerer reaction. The selenoxide could not undergo a smooth syn-elimination of PhSeOH, probably because of its highly strained arrangement. Instead, it afforded vinyl selenide **5** through a possible proton-abstraction from the α-carbon attached to the selenoxide. Unfortunately, there is presently insufficient evidence to permit an equivocal conclusion regarding the mechanism. Further experiments are now in progress that are designed to assess the steric factor in the above reaction as well as in the radical cyclization of bridged bicyclic compounds.

Experimental

***Se*-Phenyl Bicyclo[3.3.1]non-6-ene-3-(selenothioperoxy)-carboxylate (1).** To a suspension of sodium hydride (60% oil dispersion, 29 mg, 0.73 mmol), washed three times with pentane, in tetrahydrofuran (0.8 ml) was added at 0 °C a solution of bicyclo[3.3.1]non-6-ene-3-carboxylic acid (110 mg, 0.66 mmol) in tetrahydrofuran (0.5 ml). The reaction mixture was stirred for further 15 min after the evolution of hydrogen had ceased. The solvent was evaporated under reduced pressure and to the residual solid was added dry benzene (1.2 ml) and pyridine (0.1 ml). Then, oxalyl dichloride (0.17 ml, 1.97 mmol) was added to the ice-cooled mixture over a period of 6 min and the mixture was stirred for 20 min at that temperature, while white precipitate appeared. The mixture was filtered and solvent was removed by evaporation under reduced pressure to leave crude acid chloride. The acid chloride was taken up to tetrahydrofuran (2 ml) and the solution was added dropwise at 5 °C under vigorous stirring to a solution of sodium hydrogensulfide (70% purity, 265 mg, 3.31 mmol) in 80% aqueous ethanol (0.34 ml). The mixture was stirred for 5 min after the addition and, then, concentrated under reduced pressure. To the residue were added diethyl ether (15 ml) and water (5 ml). The aqueous layer was acidified with 1 M HCl (1 M=1 mol dm^{-3}). The organic layer was separated and the aqueous layer was extracted with diethyl ether (10 ml). The combined ethereal extracts were washed with brine several times, dried over anhydrous $MgSO_4$, and concentrated under reduced pressure to give crude thiocarboxylic acid as a colorless solid. It was dissolved in dichloromethane (2 ml) and the solution was added to a solution of *N*-(phenylseleno)phthalimide (240 mg, 0.79 mmol) in dichloromethane (0.5 ml) at −70 °C. The reaction was completed within a minute. Hexane (15 ml) was then added and the resultant precipitate was filtered off. Evaporation under reduced pressure gave a crude product, which was purified by flash column chromatography (silica gel 18 g, hexane/ethyl acetate 200:1 and then 99:1) to give (selenothioperoxy)carboxylate **1** (194 mg, 87%). ^{1}H NMR (CCl_4) δ=1.48—2.93 (m, 11H), 4.89—5.70 (m, 2H), 7.00—7.75 (m, 5H); IR (film) 1715 cm^{-1}; MS (70 eV) *m/z* (rel intensity) 338, 336 (M^+, ^{80}Se, 17, ^{78}Se, 9), 314, 312 ($(PhSe)_2$, ^{80}Se, 9, ^{78}Se, 5), 189, 187 ($PhSeS^+$, ^{80}Se, 10, ^{78}Se, 7), 181 (24), 157, 155 ($PhSe^+$, ^{80}Se, 69, ^{78}Se, 34), 149 (100), 121 (99). Found: C, 56.83; H, 5.52%. Calcd for $C_{16}H_{18}OSSe$: C, 56.97; H, 5.38%.

5-Phenylseleno-3-thiatricyclo[5.3.1.0^{4,9}]undecan-2-one (2). A mixture of (selenothioperoxy)carboxylate **1** (185 mg, 0.55 mmol) and azobis(isobutyronitrile) (9 mg, 0.055 mmol) in degassed benzene (13 ml) was heated for 7 h. After removing the solvent by evaporation under reduced pressure, the residue was purified by flash column chromatography (silica gel 5 g, hexane/ethyl acetate 95:5) to give thiahomoprotoadamantanone **2** (180 mg, 97%), mp 57—58 °C (from diethyl ether). ^{1}H NMR (500 MHz, $CDCl_3$) δ=1.57 (dddd, *J*=13.0, 5.6, 3.6, 1.6 Hz, C-8H), 1.96 (ddd, *J*=13.7, 6.3, 4.9 Hz, C-11H), 1.99 (m, C-11H′), 2.00 (ddd, *J*=13.6, 6.3, 4.9 Hz, C-10H), 2.07 (m, C-10H′), 2.12 (dddd, *J*=14.3, 3.9, 2.5, 1.9 Hz, C-6H), 2.14—2.22 (m, C-7H, C-8H), 2.43 (m, C-9H), 2.88 (ddd, *J*=14.3, 6.3, 3.8 Hz, C-6H′), 3.08 (tt, *J*=6.3, 2.5 Hz, C-1H), 3.17 (ddd, *J*=6.3, 2.5, 1.0 Hz, C-5H), 4.10 (dddd, *J*=1.9, 1.6, 1.0, 0.1 Hz, C-4H), 7.25—7.60 (m, phenyl H); ^{13}C NMR ($CDCl_3$) δ=26.4 (CH), 29.5 (CH_2), 29.8 (CH_2), 31.4 (CH_2), 32.4 (CH), 34.4 (CH_2), 40.9 (CH), 50.7 (CH), 52.7 (CH), 127.9 (CH), 129.5 (CH), 129.7 (C), 133.9 (CH), 209.7 (C=O); IR (KBr) 1653 cm^{-1}; MS (70 eV) *m/z* (rel intensity) 338, 336 (M^+, ^{80}Se, 3, ^{78}Se, 2), 306 (13), 278 (12), 261 (5), 181 (100), 157 (15), 155 (8), 149 (40). Found: C, 50.07; H, 5.58%. Calcd for $C_{16}H_{18}OSSe$: C, 56.97; H, 5.38%.

5-Phenylseleno-3-thiatricyclo[5.3.1.0^{4,9}]undec-5-en-2-one (5). Method A: To a solution of (selenothioperoxy)carboxylate **1** (54 mg, 0.16 mmol) and pyridine (54 μl, 0.66 mmol) in dichloromethane (7 ml) was added 35% hydrogen peroxide (150 μl, 0.87 mmol) under vigorous stirring at room temperature and the mixture was stirred until all the starting selenide was converted to the selenoxide, which could easily be confirmed by TLC (selenide; R_f=0.28, hexane/ethyl acetate 9:1, selenoxide; R_f=0.38, chloroform/methanol 95:5). After 1 h diethyl ether (30 ml) was added to the mixture and the resulting solution was washed succesively with water and brine. The organic solution was dried over anhydrous $MgSO_4$. The solvent was removed by evaporation under reduced pressure. Benzene (3 ml) was then added to the residue and the solution was refluxed for 1.5 h. The residue obtained after removing the solvent by evaporation under reduced pressure was purified by flash column chromatography to give vinyl selenide **5** (45 mg, 82%).

Method B: To a solution of (selenothioperoxy)carboxylate **1** (23 mg, 0.068 mmol) in dichloromethane (0.5 ml) was added *m*CPBA (80% purity, 16 mg, 0.74 mmol) at −40 °C. The mixture was stirred for 10 min at this temperature. After the cooling bath had been removed, pyridine (22 μl, 0.27 mmol) and benzene (1 ml) were added to the mixture. The reaction mixture was then heated under reflux for 6 h. The mixture was allowed to cool to room temperature and solvent was removed by evaporation under reduced pressure to give a residue which was purified as mentioned above to afford vinyl selenide **5** (16 mg, 70%). ^{1}H NMR (200 MHz,

6) The ^{1}H NMR study in which each proton was assigned by the double resonance technique showed that the cyclohexane ring bearing a phenylseleno group might adopt a pseudo boat form since C-4 proton attached to the thio ester showed two long range couplings with C-6 and C-8 protons. Furthermore, from the model study the vicinal coupling constants between C-5 proton, attached to the phenylseleno group, and protons at C-4, C-6, and C-6′ position are more likely in accord with those anticipated from their dihedral angles in the structure having the anti configuration.

Synopsis. The cis and trans isomers of 3-isopropyl-6,6-dimethyl-5-arylamino-1,2,4-trioxanes have been clearly identified and the anomerization of arylaminotrioxanes has been detected by the ^{13}C NMR spectra in chloroform-*d*.

The 1,2,4-trioxanes have interested researchers since they play the active role in Arteannuin (Qinghosu),[1] an antimalarial remedy. Several methods for synthesizing 1,2,4-trioxanes have been reported;[2] recentry we obtained 5-arylamino-3-isopropyl-1,2,4-trioxanes (**3**) from one-pot reactions of arylamines (**1a—p**) and 2-methylpropanal (**2**) (molar ratio 1:3) in the presence of oxygen.[3] (Scheme 1) After purification by column chromatography, the liquid trioxanes were found by NMR spectra to be a mixture of two isomers. From a hexane, or occasionally a hexane-ethyl acetate, solution of the liquid, one of the isomers of **3** slowly crystallized into colorless prisms. Based on X-ray crystal-structure analyses of the prisms, the structures of the trioxane ring in **3a**[4] and **3k**[5] were found to be different from each other. The structure of **3a** was the chair conformation of the trioxane ring with the naphthylamino group bonding at an equatorial position (cis isomer), while that of **3k** bonded to the 2-chloroanilino group occupying an axial position (trans isomer). We now report on the distinction between these cis and trans isomers of **3** on the basis of ^{13}C NMR spectra.

Results and Discussion

The sixteen synthesized trioxanes (**3**) were divided into three groups according to ^{13}C NMR chemical shifts (Table 1). The *gem*-dimethyl groups at C-6 of **3** were assigned by comparing their NMR signals with those of other trioxanes having one methyl at C-6 (5-arylamino-6-methyl-6-phenyl-3-(1-phenylethyl)-1,2,4-trioxanes[6]). The trioxanes of group 1, including **3a**, exhibited the C-3 signals at a lower field (δ 107.3—107.1) than those of the group 2, including **3k** (δ 99.7—99.4), whereas axial methyl signals at C-6 of group 1 appeared at higher fields (δ 17.7—17.4) than those of group 2 (δ 23.8—23.6). Since the C-3 and axial methyl carbons are in the γ-position relative to the nitrogen, the difference between these chemical shifts may be interpreted according to the suggestion that the γ-gauche-effect is stronger than the γ-trans-effect for nitrogen.[7] When the $CDCl_3$ solutions of group 1 were allowed to stand at room temperature for a long time, new ^{13}C signals appeared in the higher fields where the trioxanes of group 2 had shown signals. Similarly, when the $CDCl_3$ solutions of group 2 were allowed to stand, new ^{13}C signals were observed in the lower fields where those of group 1 had appeared. (These new signals are shown in parentheses in Table 1.) These changes in the spectra can be explained in terms of the establishment of an equilibrium between cis and trans isomers: the change is caused by an anomerization at C-5 of the 1,2,4-trioxane ring. Since the intensity ratio of the two isomers reached a constant value within about two days, it may be reasonable to assume that these two isomers reached equilibrium during this period. Molar fractions of cis isomer (x_{cis} were derived from average intensities of distinguishable ^{13}C signals at

a) Newly appeared signals in solution are given in parentheses.

equilibrium. Thus, the free-energy difference of this change ($G°_{cis}-G°_{trans}$) was evaluated from x_{cis} by the equation $G°_{cis}-G°_{trans}=RT\ln(1-x_{cis})/x_{cis}$ at 25 °C (Table 2). These $G°_{cis}-G°_{trans}$ values were very close to those of 2-(arylamino)tetrahydropyrans.[8] Thus, there would be no appreciable dipole interaction between arylamino substituent and the three oxygen atoms of the trioxane ring.

When the $CDCl_3$ solutions of the trioxanes of group 3 were allowed to stand at room temperature, no ^{13}C signal of another isomer (corresponding to trans) was observed in solution, and only signals of the prducts of trioxane decomposition (acetone and 2-methylpropanal) were observed. The observed spectra of group 3 were very similar to those of group 1 except for the C-5 signal which shifted to a lower field. All trioxanes of group 3 are bonded with a 2,6-disubstituted arylamino group at C-5. These low-field shifts in ^{13}C NMR spectra, having the above similarity, have been recognized in the methyl signal of *N*-methylaniline derivatives having two substituents at ortho positions (Table 3). Therefore, it is considered that in group 3 there exists only a cis isomer with an arylamino group rotated along the N-C bond.

(Received January 11, 1988)

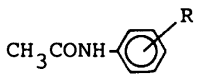
Synopsis. The reaction of acetanilides with tetraalkylammonium polyhalides, such as tetrabutylammonium tribromide, benzyltrimethylammonium tribromide, and benzyltrimethylammonium chlorobromate(1−), in dichloromethane-methanol at room temperature gave bromo-substituted acetanilides in good yields, respectively.

In general, bromo-substituted acetanilides (**2**) have been prepared from the acetylation of bromoanilines with acetyl chloride,[2] or acetic anhydride in acetic acid,[3] further, from the reaction of acetanilides (**1**) with bromine in acetic acid.[4] As a special brominating agent for **1**, *N*,*N*-dibromobenzenesulfonamide has also been used instead of bromine.[5]

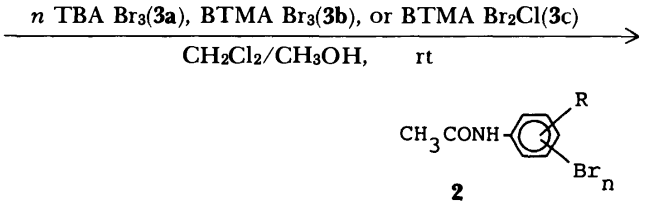
Recently, we have shown that benzyltrimethylammonium tribromide (BTMA Br_3) (**3b**) is a useful brominating agent to anilines.[6] In the present paper, we wish to report on the bromination of **1**, *N*-acetyl-protected anilines, by the use of tetraalkylammonium polyhalides, such as tetrabutylammonium tribromide (TBA Br_3) (**3a**), **3b** and benzyltrimethylammonium chlorobromate(1−) (BTMA Br_2Cl) (**3c**).

Results and Discussion

The reaction of **1** with **3a**,[7] **3b**,[8] and **3c** in dichloromethane-methanol at room temperature gave **2** in good yields, respectively.



1



2

The results are summarized in Table 1. This table shows that **3c** is the strongest brominating agent to **1**, and that these brominations of **1**, except hydroxy- and amino-substituted acetanilides (e.g., **1h**, **1i**, and **1j**), have usually given predominantly the corresponding para-bromo derivatives.[15] The reaction of hydroxy- or amino-substituted acetanilides with these brominating agents gave mono-, di-, or tribromo-substituted derivatives which were products controlled mainly by the effect of the hydroxy or amino group on the orientation.

Recently, Berthelot et al.[16] reported that the bromination of **1a** with **3a** in chloroform at room temperature did not proceeded at all. However, as shown in the table, in the presence of methanol, the reaction of **1** with **3** in dichloromethane at room temperature easily gave **2** in good yields. In these cases, it can be presumed that the active species is probably the methyl hypobromite produced from the reaction of **3** with methanol.[17]

Since aminophenols and phenylenediamines are so sensitive for **3**, isolations of mono-, di-, or tribromo derivatives of these compounds are considerably difficult. However, the selective brominations of *N*-acetyl-protected anilines, such as 2-hydroxyacetoanilide (**1h**), 3-hydroxyacetanilide (**1i**), and 3-aminoacetanilide (**1j**), by use of **3** under mild conditions occured most readily, as shown in the table. Accordingly, bromo-substituted aminophenols and phenylenediamines should be obtained by the hydrolyses of these corresponding acetanilides.

We believe that these tetraalkylammonium polyhalides such as TBA Br_3, BTMA Br_3, and BTMA Br_2Cl are more useful brominating agents for **1** than bromine or *N*,*N*-dibromobenzenesulfonamide, because of their solid character, stability and nontoxicity.

Experimental

Benzyltrimethylammonium Chlorobromate(1−) (BTMA Br_2Cl) (3c). To a solution of bromine (15.98 g, 0.1 mol) in dichloromethane (100 ml) was added dropwise a solution of benzyltrimethylammonium chloride (18.57 g, 0.1 mol) in water (100 ml) under stirring at room temperature. After the mixture was stirred for 30 min, the dichloromethane layer was separated and dried with magnesium sulfate, and then evaporated in vacuo to give a residue which was recrystallized from dichloromethane-ether (10:1) affording BTMA Br_2Cl as stable orange crystals; yield 24.50 g (71%); mp 101—102 °C. Found: C, 34.88; H, 4.63; N, 4.01; Br_2Cl, 56.31%. Calcd for $C_{10}H_{16}NBr_2Cl$: C, 34.76; H, 4.67; N, 4.05; Br_2Cl, 56.51%.

4-Bromoacetanilide (2a); Typical Procedure: To a solution of acetanilide (**1a**) (0.50 g, 3.70 mmol) in dichloromethane (50 ml)-methanol (20 ml) was added **3c** (1.41 g, 4.08 mmol) at room temperature. The mixture was stirred for 20 min until a decoloration of the orange color took place. The solvent was distilled and to the obtained residue was added water (20 ml). The mixture was extracted with ether (40 ml×4). The ether layer was then dried with

a) Yield of isolated product. b) A mixture of mono- and dibromo compounds was obtained. c) A mixture of di- and tribromo compounds was obtained. d) Product **2j-1** precipitated almost immediately as soon as the solution of **3c** was added into the solution of **1j**.

magnesium sulfate and evaporated in vacuo to give a residue which was recrystallized from ethanol-water (1:3) affording **2a** as colorless crystals; yield 0.77 g (97%); mp 163—164 °C (lit,[9] mp 168.8 °C).

4-Bromo-3,5-dimethylacetanilide (2g). Compound **2g** was prepared from the reaction of 3,5-dimethylacetanilide (**1g**) with equimolecular amount of **3** by a similar procedure to that discribed above: colorless crystals; mp 180—181 °C (ethanol-water (1:3)): IR (KBr) 1670 cm^{-1} (CO); ^1H NMR ($CDCl_3$) δ=2.05 (3H, s, $COCH_3$), 2.34 (6H, s, 3 and 5-CH_3), 7.34 (2H, s, 2 and 6-H), 9.63 (1H, br. s, NH). Found: C, 49.58; H, 4.92; N, 5.74%. Calcd for $C_{10}H_{12}NOBr$: C, 49.61; H, 4.99; N, 5.79%.

2,4-Dibromo-5-hydroxyacetanilide (2i-1). Compound **2i-1** was prepared from 3-hydroxyacetanilide (**1i**) and 2 equiv of **3** by a similar procedure to that discribed above: colorless

crystals; mp 237—238 °C (ethanol–water (1:3)); IR (KBr) 1680 cm^{-1} (CO); ^1H NMR ($CDCl_3$) δ=2.17 (3H, s, CH_3), 7.55 (1H, s, 6-H), 7.75 (1H, s, 3-H), 8.38 (1H, br. s, OH), 10.08 (1H, br. s, NH). Found: C, 30.98; H, 2.19; N, 4.49%. Calcd for $C_8H_7NO_2Br_2$: C, 31.10; H, 2.29; N, 4.53%.

3-Hydroxy-2,4,6-tribromoacetanilide (2i-2). Compound **2i-2** was prepared similary from **1i** and 3 equiv of **3b** or **3c**: colorless crystals, mp 205 °C (ethanol–water (1:3)); IR (KBr) 1675 cm^{-1} (CO); ^1H NMR ($CDCl_3$) δ=2.08 (3H, s, CH_3), 3.50 (1H, br. s, OH), 7.73 (1H, s, 5-H), 9.69 (1H, br. s, NH). Found: C, 24.81; H, 1.60; N, 3.60%. Calcd for $C_8H_6NO_2Br_3$: C, 24.77; H, 1.56; N, 3.61%.

5-Amino-2,4-dibromoacetanilide (2j-1). Compound **2j-1** was prepared similary from **1j** and 2 equiv of **3**: colorless crystals, mp 162—163 °C (ethanol–water (1:3)); IR (KBr) 1655 cm^{-1} (CO); ^1H NMR ($CDCl_3$) δ=2.12 (3H, s, CH_3), 4.25 (2H, br. s, NH_2), 7.38 (1H, s, 6-H), 7.45 (1H, s, 3-H), 8.67 (1H, br. s, NH). Found: C, 30.97; H, 2.52; N, 8.90%. Calcd for $C_8H_8N_2OBr_2$: C, 31.20; H, 2.62; N, 9.10%.

3-Amino-2,4,6-tribromoacetanilide (2j-2). Compound **2j-2** was prepared similary from **1j** and 3 equiv of **3b** or **3c**: colorless crystals, mp 218—218.5 °C (ethanol–water (1:3)); IR (KBr) 1675 cm^{-1} (CO); ^1H NMR ($CDCl_3$) δ=2.10 (3H, s, CH_3), 4.28 (2H, br. s, NH_2), 7.62 (1H, s, 5-H),9.48 (1H, br. s, NH). Found: C, 24.97; H, 1.79; N, 6.98%. Calcd for $C_8H_7N_2OBr_3$: C, 24.84; H, 1.82; N, 7.24%.

We wish to thank Dr. Mamoru Nakai and Mr. Katsumasa Harada, Ube Laboratory, Ube Industries, Ltd., for elemental analysis.

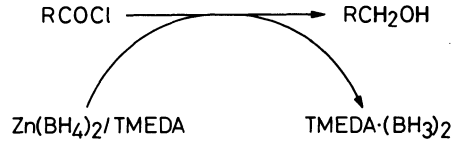
Synopsis. Aliphatic and aromatic acyl chlorides were efficiently reduced to give the corresponding alcohols when treated with $Zn(BH_4)_2$ in the presence of *N,N,N',N'*-tetramethylethylenediamine. The reactions with other bases were also examined.

The reductive synthesis of primary alcohols from carboxylic acid derivatives is a very common procedure in organic chemistry and numerous reagents have been developed.[1] In our separate work, we have required methods for the selective and mild reduction of acyl chloride function in the presence of esters.[2] The use of a well-known reagent such as $LiAlH_4$ was not satisfactory for our purpose because of its strong reducing ability. As previously reported, however, the use of $Zn(BH_4)_2$ with *N,N,N',N'*-tetramethylethylenediamine (TMEDA) was found to be a remarkably mild method for the reduction of acyl chlorides to the corresponding alcohols.[3] In this paper we would like to report a more detailed study of this reaction.

Contrary to the description given in the literature,[4] the reduction of benzoyl chloride with $Zn(BH_4)_2$ was very slow and showed less synthetic utility. Fortunately, we found that the reaction was highly accelerated by using one equivalent of TMEDA and gave a clean product. As listed in Table 1 for a comparison, this new reagent system is superior to the usual reagents. Under these conditions a wide variety of aliphatic and aromatic acyl chlorides could be efficiently reduced into the corresponding alcohols in high yields (Table 2). Only one exception was phthaloyl dichloride, which gave a considerable amount of phthalide along with the desired diol. Since under the same conditions phthalide was not reduced, this product must be formed by intramolecular acylation. In these reductions the functional selectivity is particularly noteworthy. Thus, chloro, nitro, ester, and conjugated double bonds were not affected by this reagent system. The limitation is a compound containing an isolated double bond, such as 3-cyclohexenecarbonyl chloride, because of the concomitant hydroboration on this function.

Coupled with this observation, we found that a TMEDA·$(BH_3)_2$ complex,[15] mp 179—180 °C (lit,[16] 179—179.5 °C), was also formed under these reactions, although the yield depended upon the runs (usually in around 40 %). As is well-known, this complex is not only exceedingly stable toward the conventional workup conditions but is insoluble in most organic solvents.[16] Therefore, the product alcohols can be simply separated from the mixture by filtration. From this evidence we concluded that during the reaction borane was generated and trapped by TMEDA. Namely, TMEDA can be regarded as an effective borane scavenger leading to clean reactions, as illustrated in Scheme 1.



Scheme 1.

With these results in hand we have examined the effect of amine on the reduction of *m*-chlorobenzoyl chloride. The result is summarized in Table 3. It will be apparent that among the several amines TMEDA is the best one. DABCO also showed a comparable yield, probably due to a similar stability of its borane complex.[16] Interestingly, the use of *N,N*-dimethylaniline or 2,6-lutidine gave *m*-chlorobenzyl *m*-chlorobenzoate as a major product. The formation of this ester probably accounts for the fast esterification of the starting acyl chloride with the formed alcohol catalyzed with these amines. However, attempts to develop this finding as a general procedure have been unsuccessful.

Though cyclohexene and 2,5-norbornadiene were also employable as a borane scavenger,[17] in these cases the isolation of alcohols from the mixture was not so easy.

Although there are several methods available for the reduction of acyl chlorides, we believe that the present method offers considerable advantages in terms of simpleness, functional selectivity, readily available reagents, and very mild conditions.

Experimental

An ethereal solution of $Zn(BH_4)_2$ was prepared from

Table 1. Reduction of Benzoyl Chloride to Benzyl Alcohol with Several Reducing Agents

a) Ether as solvent, unless otherwise stated. b) Identified by GLC, IR, ^1H NMR, and high resolution mass spectrometry. c) Yields represent pure isolated products, value in parentheses was determined by GLC. d) Kugelrohr distillation bath temperature. All melting points and boiling points are uncorrected. e) THF/ether as solvent. f) After 92% conversion.

$NaBH_4$ and $ZnCl_2$ according to the literature method;[18] the concentration was determined by injecting aliquots of the solution into water and then measuring the evolved hydrogen.

General Procedure for the Reduction of Acyl Chlorides with $Zn(BH_4)_2$/TMEDA. To a THF or ether solution (1.8 ml) of acyl chloride (1 mmol) at 0 °C were added successively $Zn(BH_4)_2$ (0.21 M†; 6.7 ml, 1.4 mmol) and TMEDA (1 mmol). The mixture was then stirred at 0 °C or at the indicated temperature (see Table 2) until completion of the reaction, as monitored by TLC or GLC analysis. During the reaction, a white insoluble substance was gradually formed. After quenching by the addition of dilute HCl, the mixture was extracted with AcOEt. The extracts were washed with dilute HCl, satd $NaHCO_3$, and satd NaCl, dried ($MgSO_4$), and evaporated. The obtained crude product was filtered in order to remove any insoluble TMEDA·$(BH_3)_2$ complex. Then, the filtrate was purified by distillation or flash column chromatography, providing the corresponding alcohol. All of the products were known compounds and were identified by comparisons with authentic samples.

Reduction of *m*-Chlorobenzoyl Chloride with $Zn(BH_4)_2$/*N,N*-Dimethylaniline. To a THF solution (1.8 ml) of *m*-chlorobenzoyl chloride (175 mg, 1 mmol) at 0 °C were added $Zn(BH_4)_2$ (6.7 ml, 1.4 mmol) and *N,N*-dimethylaniline

† 1 M=1 mol dm^{-3}.

Dehydrooligopeptides. IX. Syntheses and Conversions of α-Dehydroglutamine Derivatives to *N*-Carboxy-α-dehydroglutamine Anhydride and Δ^1-Dehydroglutaminyldipeptides[1)]

Yasuchika YONEZAWA, Nobuo TAKEFUJI, Nobuyuki TAKAHASHI, and Chung-gi SHIN*

(Received January 29, 1988)

Synopsis. Various kinds of Cbz-α-dehydroglutamine derivatives were synthesized by the reaction of Cbz-α-dehydroglutamic acids with a few primary amines, including L-α-amino acid ester, and subsequently transformed to *N*-carboxy-α-dehydroglutamine anhydride and several Δ^1-dehydroglutaminyldipeptides.

In connection with the syntheses and reactions of α-dehydroamino acids (DHA) and dehydrooligopeptides (DHP), *N*-carboxy-α-dehydroamino acid anhydride (ΔNCA), derived by the cyclization of *N*-benzyloxycarbonyl (Cbz)-DHA with $SOCl_2$, were found to be a very important substrate for the transformation to various kinds of other DHA and DHP.[2-4)] So far, we reported on the syntheses of various kinds of ΔNCAs, derived from neutral (alkyl and aryl), acidic, and basic DHAs, which corresponded to the proteinic L-α-amino acid (AA).[5-8)] However, at present, the DHA and its ΔNCA corresponding to α,β-unsaturated derivatives of asparagine and glutamine, for example, α-dehydroglutamine (ΔGln) and its *N*-carboxy-α-dehydroglutamine anhydride (ΔGln·NCA) have never been synthesized.

In this paper, we wish to report on the syntheses of various kinds of Cbz-α-dehydroglutamine derivatives [Cbz-ΔGln(R)-OY: **2** (Y=Bu^t) and **3** (Y=H); **a**; R=H, **b**; R=Bu^t, **c**; R=NHBu^t, **d**; R=CH_2COOMe] and X-ΔGln(Bu^t)·NCA derivatives (**4**; X=H and **5**; X=Boc), by utilizing (*Z*)-isomer of Cbz-α-dehydroglutamic acid *t*-butyl ester (Cbz-ΔGlu-OBu^t) (**1**).[6)] Moreover, the coupling of DHA (**3b**) with an appropriate L-α-AA-OMe was also tried successfully to give the Δ^1-dehydrodipeptides.

The starting compound **1** was derived from α-oxoglutaric acid in six steps, according to a method reported previously.[6)] For the subsequent amidation of γ-carboxyl group of the side chain in ΔGlu, first a treatment of **1** with *N*-hydroxysuccinimide (HOSu) in tetrahydrofuran (THF) was carried out in the presence of *N,N'*-dicyclohexylcarbodiimide (DCC) to form the expected γ-active ester as an intermediate. It was found that the γ-ester, thus yielded, reacted smoothly with aqueous ammonium to give Cbz-α-dehydroglutamine *t*-butyl ester (Cbz-ΔGln-OBu^t) (**2a**) in 86% yield. In a similar manner, the reaction of the active ester with *t*-butylamine was worked up to give Cbz-ΔGln(Bu^t)-OBu^t (**2b**) in 74% yield. Furthermore, the coupling of the above ester with H-AA-OMe, e.g., glycine methyl ester in the presence of both DCC and HOSu also proceeded to give Cbz-ΔGln(CH_2COOMe)-OBu^t (**2d**) in 84% yield. In the case of *t*-butyloxycarbonylhydrazine, however, compound **1** was directly treated in the presence of DCC to give Cbz-ΔGln(NHBoc)-OBu^t (**2c**) in 85% yield.

On the other hand, in order to obtain α-acid free Cbz-ΔGln derivatives, which are anticipated to convert to the corresponding ΔNCA, the α-ester cleavage of ΔGln-OBu^t (**2**) was carried out. When compounds **2a, b, d** were treated, respectively, with gaseous hydrogen chloride in THF or ethyl acetate, the corresponding Cbz-ΔGln-OH derivatives **3a, b, d** were readily obtained in ca. 87% yield.

Subsequently, in order to synthesize the ΔGln·NCA derivative by a method reported previously,[5] compound **3b** was chosen and then treated with $SOCl_2$ to give the desired ΔGln(Bu^t)·NCA (**4**) in 70% yield. Subsequent *N*-acylation of **4** with di-*t*-butyl dicarbonate [$(Boc)_2O$] was carried out to form Boc-ΔGln·NCA (**5**) as an intermediate, which was treated in situ with methanol to give Boc-ΔGln(Bu^t)-OMe (**6**) almost quantitatively, as illustrated in Scheme 1. Consequently, it was found that compound **4** also had a high reactivity with alcohol, such as the hitherto obtained ΔNCA derivatives.[5]

As summarized in Table 1, it can be seen that the yields of **2** and **3** were very high with an average value of 84%. In addition, the spectral data of **2** and **3** show the configurational structure of DHA to be a (*Z*)-isomer remain unchanged during the amidation and consecutive ester cleavage.

Futhermore, according to Scheme 2, the synthesis of Cbz-Δ^1-dehydroglutaminyldipeptides were successfully tried by the usual peptide synthetic method. The coupling of **3b** with an appropriate H-AA-OMe (AA=Gly, Ala, Leu, Phe) was carried out to give

3b + H-AA-OMe ⟶ Cbz-ΔGln(Bu^t)-AA-OMe

7: AA; **a**; Gly, **b**; Ala, **c**; Leu, **d**; Phe

Scheme 2.

Cbz-ΔGln(Bu^t)-AA-OMe (**7**) in a good yield, as summarized in Table 2.

In conclusion, it is firmly believed that the synthesis of the ΔGln·NCA derivative is surely available for the synthesis of various kinds of DHP containing the ΔGln residue.

Experimental

Melting points were determined with a Yamato (Model Mp-21) micro melting-point apparatus, and were not corrected. IR spectra were recorded with a Hitachi EPI-G2 grating spectrometer. ^{1}H NMR spectra were measured with a JEOL JMN PS-100 spectrometer in a $CDCl_3$ solution with tetramethylsilane as the internal standard. The specific rotations were measured in a 0.5-dm tube using a JASCO DIP-4 polarimeter (Japan Spectroscopic Co., Ltd.).

General. To a solution of **1** (45.0 mmol) and HOSu (50.0 mmol) in diethylene glycol dimethyl ether (65 ml) was added portionwise DCC (51.0 mmol) under cooling. After stirring the resulting solution at room temperature for 12 h, the solution was again cooled at 5—10 °C. After removal of the *N,N'*-dicyclohexylurea separated out, the filtrate was concentrated under reduced pressure to give the corresponding active ester as an intermediate, which was utilized for the following amidation.

Preparation of 2a. To a solution of the active ester, thus obtained, in THF (50.0 ml) was added, with stirring, 28% aqueous ammonium (11.0 ml) at −10 °C. After continuing the stirring for 15 min and then at room temperature 15 min, the reaction solution was concentrated under reduced pressure. The residual product was dissolved with chilled ethyl acetate (30.0 ml) and then HOSu deposited was filtered off. The filtrate was further diluted with ethyl acetate (40 ml) and the resultant solution was washed twice with 15% NaCl aqueous solution and then dried over anhydrous Na_2SO_4. After removal of the solvent under reduced pressure, the residual crystals were collected and then recrystallized from diisopropyl ether–ethyl acetate to give **2a** as colorless needles.

Preparation of 2b and 2d. To a solution of the active ester in CH_2Cl_2 (40 ml) was added drop by drop, with stirring, a solution of *t*-butylamine or glycine methyl ester (50.0 mmol) in CH_2Cl_2 (15 ml) under cooling. After stirring for 30 min and then at room temperature for 1 h, the reaction mixture was concentrated under reduced pressure. The residue, thus obtained, was dissolved with chilled ethyl acetate (30 ml) and then HOSu deposited was filtered off. The filtrate was again diluted with ethyl acetate (40 ml) and the resulting solution was washed successively with 10% citric acid, saturated $NaHCO_3$ aqueous solution, and then water and finally dried over anhydrous Na_2SO_4. After removal of the solvent under reduced pressure, the residual syrup was purified on silica-gel column using a mixture of $CHCl_3$ and acetone (20:1 v/v) as the eluent. The fraction was concentrated to give **2b** or **2d** as a pale-yellow syrup.

Preparation of 2c. A solution of **1** (2.7 mmol) in CH_2Cl_2 (10 ml) was cooled at −5 °C and then DCC (3.0 mmol) was added, with stirring, for 30 min. To the resultant solution was added Boc-$NHNH_2$ (3.0 mmol) with stirring; then the reaction solution was stirred continuously at room temperature for 12 h. After removing the solvent and then adding chilled ethyl acetate (5 ml) to the residue, the *N,N'*-dicyclohexylurea deposited was filtered off. The filtrate was diluted with ethyl acetate (15 ml); then the resultant solution was washed successively with 10% citric acid, saturated $NaHCO_3$ aqueous solution, 15% NaCl aqueous solution, and then water and finally dried over anhydrous Na_2SO_4. After concentrating the solution under reduced pressure, the residual syrup was purified on a silica-gel column using a mixture of chloroform and acetone (20:1 v/v) as the eluent. The concentration of the fraction gave **2c** as a yellow syrup.

Preparation of 3a, b, d. A solution of **2** (10.0 mmol) in THF (50 ml) was saturated with HCl gas under cooling and then allowed to stand at room temperature for 1 h. After removing the solvent under reduced pressure, the residual substance was dissolved in $CHCl_3$ (30 ml) and the resultant solution was again concentrated. The crude crystals, thus obtained, were collected by using diisopropyl ether. Recrystallization from diisopropyl ether–ethyl acetate gave **3a, b, d** as colorless prisms.

Preparation of 4. To thionyl chloride (15 ml) was added a suspension of **3b** (5.0 mmol) in diethyl ether (15 ml), drop by drop, with stirring at −10 °C. After stirring vigorously for 30 min at −5—−8 °C. After removing the excess $SOCl_2$ under reduced pressure below 30 °C, the residue, thus obtained, was dissolved in carbon tetrachloride and the resultant solution was again condensed. This procedure was repeated three times and then the final residue, thus obtained, was purified on a silica-gel column using $CHCl_3$ to give crystalline product. Recrystallization from a mixture of benzene and ethyl acetate gave **4** as colorless prisms, yield 75%, mp 150—151 °C. ν_{max}^{KBr} 1840, 1780 (-CO-O-CO-), 1640 (C=C) cm^{-1}. ^1H NMR δ=5.86 (t, 1H, -CH=), 7.62 [s, 1H, -NH- (ring)]. Found: C, 53.28; H, 6.19; N, 12.45%. Calcd for $C_{10}H_{14}N_2O_4$: C, 53.09; H, 6.24; N, 12.38%.

Preparation of 6. To a solution of **4** (2.2 mmol) in THF (8 ml) was added $(Boc)_2O$ (2.6 mmol) and pyridine (30 µl) under cooling. After stirring for 4 h, the solution prepared was treated with methanol (8 ml) and then made to pH 8—9. The reaction mixture was further stirred at room temperature for 12 h and then concentrated under reduced pressure. The residual syrup, thus obtained, was dissolved in ethyl acetate (30 ml) and the resultant solution was washed successively with 10% citric acid, saturated $NaHCO_3$ aqueous solution, and then water, and finally dried over anhydrous Na_2SO_4. After removing the solvent under reduced pressure, the residue, thus obtained, was purified on a silica-gel column using a mixture of $CHCl_3$ and acetone (15:1 v/v) to give **6** as colorless syrup. Yield 95%. ν_{max}^{KBr} 1650, 1545 (-NHCO-), 1640 (C=C) cm^{-1}. ^1H NMR δ=6.56 (bs, 1H, 2 -NH-), 6.74 (t, 1H, -CH=). Found: C, 57.22; H, 8.53; N, 9.07%. Calcd for $C_{15}H_{26}N_2O_5$: C, 57.31; H, 8.34; N, 8.91%.

Preparation of 7. A suspension of an appropriate H-AA-OMe·HCl (1.80 mmol) in THF (6 ml) in the presence of TEA (1.80 mmol) was stirred under cooling for 30 min. To the prepared suspension was successively added **3b** (1.50 mmol), HOSu (1.70 mmol), and DCC (1.70 mmol); the resulting solution was returned to room temperature and then stirred for 2 h. After removing the solvent under reduced pressure, ethyl acetate (15 ml) was added to the residue obtained and the resultant solution was chilled and then filtered. The filtrate was washed successively with 10% citric acid, saturated $NaHCO_3$ aqueous solution, and water and then dried over anhydrous Na_2SO_4. After concentrating the solution under reduced pressure, the residual crystalline product was collected by using diisopropyl ether. Recrystallization from a mixture of hexane and ethyl acetate gave colorless needles. When the residue was syrup, purification on a silica-gel column using a mixture of $CHCl_3$ and ethyl acetate gave **7** as a colorless syrup. See Table 2.

(Received February 2, 1988)

Synopsis. 2-Amino- (**2**) and 2-hydroxy-1, 3-diazaazulenes (**3**) underwent smoothly electrophilic bromination under basic conditions to give 2-amino-4,6,8-tribromo- (**4**) and 6-bromo-2-hydroxy-1,3-diazaazulenes (**7**), respectively. Bromo derivatives **4** and **7** underwent some nucleophilic substitutions, e.g., **4** reacted with ease with sodium methoxide to give 2-amino-4,6,8-trimethoxy-1,3-diazaazulene (**10**).

1,3-Diazaazulene (cycloheptimidazole) (**1**) and its derivatives are of theoretical interest in relation to the structural chemistry of nonbenzenoid aromatics and of biological interest in relation to naturally occurring cycloheptimidazole derivatives such as zoanthoxanthin[1a] epizoanthoxanthin,[1b] and paragracine.[1c]

1,3-Diazaazulene (**1**) would be difficult of undergoing an electrophilic substitution, because **1** has a large contribution of dipolar structure (**1a**) to the ground state[2] causing an enhanced diatropicity of the seven-membered ring and moreover the electron-rich 1- and 3-positions are blocked by nitrogen atoms. In fact it has been reported that, on treatment with bromine in chloroform or acetic acid, **1**,[3] 2-amino- (**2**),[4] and 6-amino-1,3-diazaazulene[5] give the corresponding diazaazulene-bromine molecular compounds which easily decompose regenerating respective starting diazaazulenes without giving any bromo-substituted product. There has appeared only one paper dealing with the electrophilic substitution in which 2-dimethylamino-1,3-diazaazulene affords brominated products in chloroform but in very poor yields.[6a] Most derivatives of **1**, therefore, have to be synthesized by condensation of the corresponding substituted 2-chloro- or 2-methoxytropones with guanidine or thiourea.[3,4,6-8] However, we have presumed that **2** and 2-hydroxy-1,3-diazaazulene (**3**),[3] carrying an electron-donating substituent at the 2-position and being in equilibrium with imino (**2a**) and keto (**3a**) forms,[9] respectively, may undergo effectively electrophilic substitutions at the seven-membered ring if any suitable reaction conditions are explored.[10] In order to clarify the fundamental reactivities of **2** and **3**, and to develop a new synthetic method for the preparation of 1,3-diazaazulene derivatives, we have now carried out a brief study on the electrophilic and nucleophilic substitution reactions of **2** and **3**, which is dealt with herein.

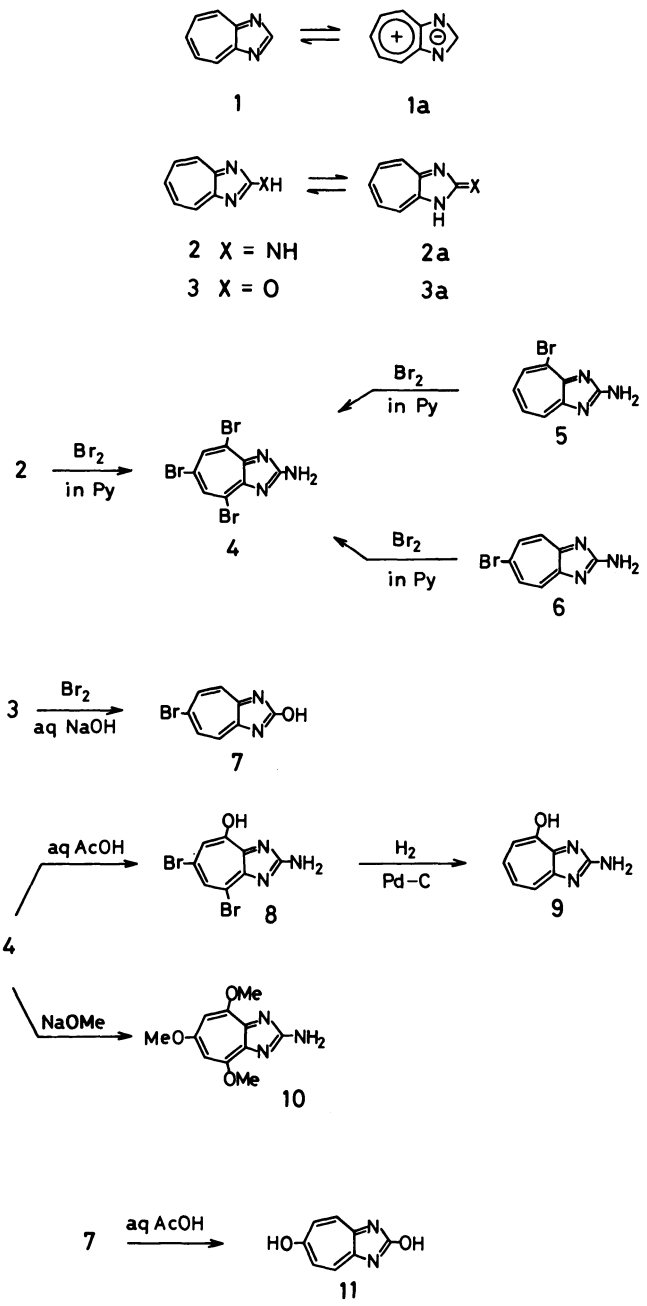
When 2-amino-1,3-diazaazulene (**2**) was allowed to react with an excess amount of bromine (4 molar equivalents) in pyridine solution at room temperature, 2-amino-4,6,8-tribromo-1,3-diazaazulene (**4**) was formed in good yield.[11] Even when a lesser amount of bromine was employed in this reaction, the same tribromo compound **4** was obtained in low yield, neither monobromo- nor dibromo-substituted product being obtained. The position of the bromo substituents of **4** is elucidated by the ^{1}H NMR spectrum which showed only one singlet in the region of the ring protons, and further by the formation of **4** on bromination of known compounds **5**[6b,12] and **6**[7] in pyridine.

The bromination of **3** in aq sodium hydroxide solution gave 6-bromo-2-hydroxy-1,3-diazaazulene (**7**) in moderate yield. Contrary to the case of **2**, neither dibromo- nor tribromo-substituted product of **3** was produced even when an excess amount of bromine was applied. The position of the bromo substituent of **7** was evidenced by the A_2B_2 type of signals in the ^{1}H NMR spectrum and by the fact that **7** was converted to known **11**[7] (vide post).

It has also been known that the substituent at the seven-membered ring of **5**[6b,12] and **6**[7] undergoes nucleophilic substitution, which is quite reasonable on considering the significant contribution of **1a** to the ground state of **1**. In order to obtain a further insight into the influence of an electron-donating amino or hydroxyl group on nucleophilic substitution, the solvolysis of **4** and **7** was then examined. When an aq acetic acid solution of **4** was heated to reflux, 2-amino-4,6-dibromo-8-hydroxy-1,3-diazaazuene (**8**) was formed in moderate yield. The ^{1}H NMR of **8** showed two unequivalent signals in the region of ring protons and the catalytic hydrogenation of **8** over Pd-C gave a known debrominated compound **9**,[6b,12] elucidating the structure of **8**. This fact indicates that **4** is attacked by a nucleophile first at the 4- (or 8-) position, presumably via the intermediate formation of a hydrogen-bonded chelate bridge among the nucleophile, protonated N-1 and electropositive C-8.[13] More interestingly when a methanolic solution of **4** was refluxed with sodium methoxide, 2-amino-4,6,8-trimethoxy-1,3-diazaazulene (**10**) was formed in good yield. The ^{1}H NMR spectrum of **10** showed only one singlet for the seven-membered ring protons (H-5,7). It is worthy of special notice that all the bromo substituents of **4** are easily replaced by the nucleophile even under the influence of the electron-donating 2-amino group. Similarly, reflux of an aq acetic acid solution of **7** afforded **11**.[7]

As a consequence, it has been proved that, although 1,3-diazaazulene (**1**) is electron-deficient at the seven-membered ring, the derivatives of **1** carrying an electron-donating amino or hydroxyl group at the 2-position, e.g., **2** and **3**, are reactive enough to undergo smooth electrophilic bromination under basic conditions, and that bromo-substituted 2-amino- and 2-

hydroxy-1,3-diazaazulenes, e.g., **4** and **7**, are capable of undergoing nucleophilc substitution with considerable ease under both acidic and basic conditions (despite the electron-donating influence of the 2-substituent).



Experimental

2-Amino-4,6,8-tribromo-1,3-diazaazulene (4). a) Bromination of 2-Amino-1,3-diazaazulene (2): Into a suspension of 2[4] (1 g, 6.89 mmol) in pyridine (40 ml) was dropped a solution of bromine (6.9 g, 42 mmol) in pyridine (10 ml) at room temperature in a 10 min period, during which time the suspension went into solution and then a yellow powder precipitated again. After being diluted with water (20 ml), the precipitate was collected and washed with methanol to give crude **4**, yellow powder (2.1—2.3 g, 80—87% yield). An analytical sample of **4** was obtained by recrystallization from pyridine as yellow needles, mp>350°C. IR (KBr) 3340, 3130, 1685, 1522, 1508, 1362, 1010, 879 (m), 843, 830 cm^{-1}. ^1H NMR (CF_3COOH) δ=9.10 (2H, s, H-5,7), 7.6 (br. $\overset{+}{N}H_3$). Found: C, 25.05; H, 1.35; N, 10.75%. Calcd for $C_8H_4N_3Br_3$: C, 25.16; H, 1.06; N, 11.01%.

b) Bromination of 2-Amino-4-bromo-(5) and 2-Amino-6-bromo-1,3-diazaazulene (6): A suspension of 5[6b,12] or 6[7] (200 mg, 0.893 mmol) in pyridine (10 ml) was treated with a solution of bromine (430 mg, 2.7 mmol) in pyridine (1 ml). The same work-up as described in a) afforded **4** (240—260 mg, 70—75% yield).

6-Bromo-2-hydroxy-1,3-diazaazulene (7). Into a solution of 3[3] (200 mg, 1.37 mmol) in 0.2 M sodium hydroxide (8 ml) (1 M=1 mol dm^{-3}) was dropped a solution of bromine (440 mg, 2.75 mmol) in 2 M sodium hydroxide (3 ml) at room temperature. Neutralization with dilute hydrochloric acid gave a precipitate, which was collected and recrystallized from saturated sodium hydrogencarbonate solution to give **7** (160 mg, 51.9% yield) as a yellow crystalline powder, mp>330 °C. Soluble in both dilute hydrochloric acid and dilute alkali. IR (KBr) 3450, 3020 2600, 1695, 1618, 1590, 1542 (m), 1467, 1430, 1387, 1355, 1322, 1295, 1055 (m), 955 848, 780 cm^{-1}. ^1H NMR (CF_3COOH) δ=8.98 (2H, d, J=10.5 Hz, H-5,7 or H-4,8), 8.51 (2H, d, J=10.5 Hz, H-4,8 or H-5,7). Found: C, 42.96; H, 2.29; N, 12.27%. Calcd for $C_8H_5ON_2Br$: C, 42.70; H, 2.24; N, 12.45%.

2-Amino-4,6-dibromo-8-hydroxy-1,3-diazaazulene (8). A suspension of **4** (500 mg, 1.31 mmol) in 95% acetic acid (50 ml) was refluxed for 3 h. The resulting solution was concentrated, diluted with water and a precipitate which separated was collected and recrystallized from glacial acetic acid (50 ml) to give **8**, yellow fibrous needles (260 mg, 62.2% yield), mp>320 °C. IR (KBr) 3430, 3095, 1978, 1580 (m), 1550, 1520 (m), 1490, 1393 (m), 1286, 913 (m) cm^{-1}. ^1H NMR (CF_3COOH) δ=8.31 (1H, d, J=1.3 Hz, H-5), 8.15 (1H, d, J=1.3 Hz, H-7), 7.6 (br. $\overset{+}{N}H_3$). Found: C, 30.21; H, 1.57; N, 13.30%. Calcd for $C_8H_5ON_3Br_2$: C, 30.12; H, 1.58; N, 13.18%.

Debromination of 8 to 2-Amino-4-hydroxy-1,3-diazaazulene (9). A solution of **8** (100 mg, 0.314 mmol) in 5% potassium hydroxide (20 ml) was shaken with hydrogen over 5% Pd-charcoal (50 mg) and 2 equivalents (14 ml) of hydrogen were uptaken. Usual work-up gave pale yellow needles of **9** (40 mg, 79% yield), identical in all respects with an authentic sample.[6b,12]

2-Amino-4,6,8-trimethoxy-1,3-diazaazulene (10). Compound **4** (500 mg, 1.31 mmol) was suspended in a sodium methoxide solution prepared from sodium (92 mg, 0.004 atom) and anhydrous methanol (40 ml) and then refluxed for 2.5 h. The methanol was evaporated and the residue was recrystallized from water (10 ml) to give **10** (250 mg, 66.0% yield), deep yellow needles, dp 240—245 °C. IR (KBr) 3370, 3300, 3120, 1643, 1610, 1563, 1515, 1458 (m), 1422 (m), 1378, 1250, 1208 (m), 1073 (m), 990, 839 (m), 778 (w) cm^{-1}. ^1H NMR (CF_3COOH) δ=4.34 (3H, s, OMe-6), 4.42 (6H, s, OMe-4,8), 7.40 (2H, s, H-5,7), 7.90 (br. $\overset{+}{N}H_3$). Found: C, 45.63; H, 6.39; N, 14.89%. Calcd for $C_{11}H_{13}O_3N_3 \cdot 3H_2O$: C, 45.63; H, 6.62; N, 14.53%.

2,6-Dihydroxy-1,3-diazaazulene (11). A suspension of **7** (200 mg, 0.889 mmol) in 95% acetic acid (20 ml) was refluxed for 3 h. Concentration of the resulting solution and recrystallization of a separated precipitate from water afforded **11** (110 mg, 68.7% yield) as yellow fibrous needles, entirely identical with an authentic sample.[7]

The authors are grateful to Assistant Professor Juzo Nakayama for his technical assistance.

Hydrostannation and Hydrogermylation of Allenes

Yoshifumi ICHINOSE, Koichiro OSHIMA,* and Kiitiro UTIMOTO
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Kyoto 606
(Received February 26, 1988)

Synopsis. Treatment of allenes with Ph_3SnH or Ph_3GeH in the presence of $Pd(PPh_3)_4$ catalyst provides the corresponding allylic stannanes or allylic germanes in good yields. Et_3B induced radical addition of Ph_3SnH or Ph_3GeH to allenes are also described.

Previously reported reaction of Ph_3SnH or Ph_3GeH with acetylenic compounds in the presence of a catalytic amount of palladium[1] or Et_3B[2] affords a simple and general access to the corresponding vinylic triphenylstannanes or vinylic triphenylgermanes. In furhter extension of these techniques, we have examined the reaction of allenic compounds with Ph_3SnH or Ph_3GeH.

Treatment of allenic compounds with triphenylstannane or triphenylgermane[3] in the presence of a catalytic amount of $Pd(PPh_3)_4$ resulted in exclusive formation of allylic triphenylstannanes or allylic triphenylgermanes. The typical results are summarized in Table 1. We are tempted to assume the following reaction mechanism: (1) Oxidative addition of Ph_3SnH (Ph_3GeH) to Pd(0), (2) stannylpalladation (germylpalladation) to give vinylpalladium, and (3) reductive elimination to produce allylic stannanes (allylic germanes) and regenerate the palladium(0) (Scheme 1). Palladium always attacked the central carbon of allenic linkage and Ph_3Sn (Ph_3Ge) group added to end carbon in the stannylpalladation (germylpalladation) step. The distribution of two regioisomeric products, allylic stannanes or allylic germanes,

Table 1. Hydrostannation and Hydrogermylation of Allenes

Entry	Allene	Ph_3SnH (Ph_3GeH)	Catalyst	Product (Yield/%)
1	$CH_2=C=CH_2$[a]	Ph_3SnH	$Pd(PPh_3)_4$	$CH_2=CHCH_2SnPh_3$ (40) **5**

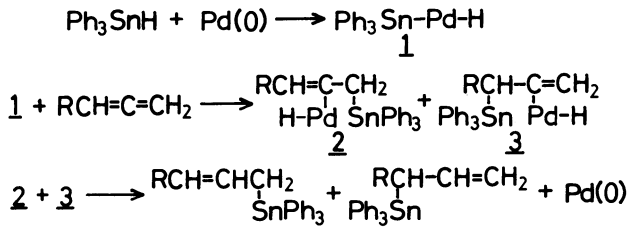
13	6,7-Tridecadiene	Ph_3GeH	$Pd(PPh_3)_4$	n-$C_5H_{11}CH=CHCH(GePh_3)$-C_5H_{11} (79)
14		Ph_3SnH	Et_3B	n-$C_5H_{11}CH=C(SnPh_3)CH_2$-$C_5H_{11}$ (E/Z=32/68, 81)
15	1,2-Cyclononadiene	Ph_3SnH	Et_3B	1-(Triphenylstannyl)cyclononene (74)

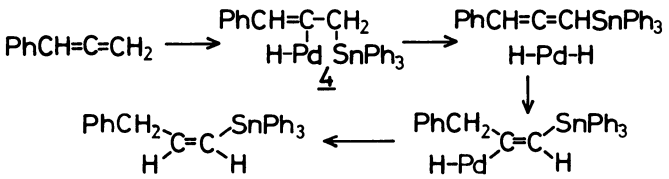
a) Excess (3.0 mmol) of 1,2-propadiene was employed. Yields were based on an amount of Ph_3SnH (or Ph_3GeH) employed.

depended on the nature of the substitution pattern of the starting allenic compounds. For instance, hydrogermylation of 1,2-tridecadiene afforded 3-triphenylgermyl-1-tridecene selectively, while 1-dimethylphenylsilyl-1,2-propadiene gave a mixture of 1-dimethylphenylsilyl-3-triphenylgermyl-1-propene and 3-dimethylphenylsilyl-3-triphenylgermyl-1-propene upon treatment with Ph_3GeH–Pd(0).



Scheme 1.

The formation of (*Z*)-3-phenyl-1-triphenylstannyl-1-propene from 1-phenyl-1,2-propadiene presumably is explained by the following reaction path: Elimination of palladium hydride from vinylpalladium species **4** and subsequent readdition in the opposite end of 1,2-diene, followed by reductive elimination (Scheme 2). The exclusive generation of (*Z*)-olefin as a single stereoisomer may be ascribed to the selective readdition of Pd–H to $PhCH{=}C{=}CHSnPh_3$ from less hindered face.



Scheme 2.

On the other hand, triphenylstannyl radical attacked allenes at the center carbon of monosubstituted allenes, $RCH{=}C{=}CH_2$, or disubstituted ones, $RCH{=}C{=}CHR$ to give vinylic stannanes selectively,[4] in the case of Et_3B induced radical reaction. With unsubstituted 1,2-propadiene, triphenylstannyl radical added to both end and middle carbons to give a mixture of allyltriphenylstannane and 2-triphenylstannyl-1-propene. Triphenylgermyl radical was less reactive than triphenylstannyl radical and disubstituted allenes were reluctant to react with Et_3B–Ph_3GeH system. Reaction of unsubstituted or monosubstituted allenes afforded allylic germanes selectively.

Experimental

The IR spectra were determined on a JASCO IR-810 spectrometer, the ^1H NMR and ^{13}C NMR spectra were recorded on a Varian XL-200 spectrometer. The chemical shifts of the proton NMR are given in δ with TMS as an internal standard. The analyses were performed at the Elemental Analyses Center of Kyoto University. Tetrahydrofuran was dried in benzophenone ketyl and distilled.

General Procedure for the Reaction of Allenic Compounds with Triphenylstannane (or Triphenylgermane) in the Presence of $Pd(PPh_3)_4$. The reaction of 1,2-tridecadiene with Ph_3GeH is representative. $Pd(PPh_3)_4$ (58 mg, 0.05 mmol) was added to a solution of 1,2-tridecadiene (0.18 g, 1.0 mmol) and Ph_3GeH (0.37 g, 1.2 mmol) in tetrahydrofuran (10 ml) under an argon atmosphere. The reaction mixture was stirred at 25 °C for 5 h, then poured into water, and extracted with ethyl acetate (3×20 ml). The combined organic extracts were dried (Na_2SO_4) and concentrated in vacuo. Purification by preparative TLC on silica gel provided 3-triphenylgermyl-1-tridecene (0.26 g) in 53% yield: IR (neat) 3066, 3048, 2994, 2922, 2850, 2034, 1484, 1431, 1091, 998, 732, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, *J*=6.5 Hz, 3H), 1.06—1.44 (m, 16H), 1.55—1.83 (m, 2H), 2.60—2.78 (m, 1H), 4.90—5.03 (m, 2H), 5.80 (m, 1H), 7.28—7.43 (m, 9H), 7.43—7.61 (m, 9H); ^{13}C NMR ($CDCl_3$) δ=14.1, 22.7, 29.0, 29.1, 29.3, 29.5, 29.6, 29.9, 31.9, 34.5, 113.6, 128.0, 128.8, 135.5, 136.3, 139.6.

General Procedure for the Et_3B-Induced Radical Reaction of Ph_3SnH (or Ph_3GeH) with Allenes. The reaction of 1,2-tridecadiene with Ph_3GeH is representative. A hexane solution of Et_3B (1.0 M, 1 M=1 mol dm^{-3}, 1.2 ml, 1.2 mmol) was added to a solution of Ph_3GeH (0.37 g, 1.2 mmol) and 1,2-tridecadiene (0.18 g, 1.0 mmol) in benzene (10 ml) at 25 °C. After stirring for 2 h at 25 °C, the reaction mixture was poured into water and extracted with ethyl acetate. Purification by preparative tlc gave (*E*)-1-triphenylgermyl-2-tridecene (0.40 g, 82% yield) as a colorless oil: IR (neat) 3064, 3048, 2920, 2850, 1654, 1484, 1465, 1431, 1091, 1026, 998, 963, 732, 696 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, *J*=6.1 Hz, 3H), 1.04—1.45 (m, 16H), 1.79—1.99 (m, 2H), 2.40 (d, *J*=7.4 Hz, 2H), 5.35 (dt, *J*=15.2, 6.4 Hz, 1H), 5.51 (dt, *J*=15.2, 7.4 Hz, 1H), 7.30—7.44 (m, 9H); ^{13}C NMR ($CDCl_3$) δ=13.7, 19.5, 22.7, 29.1, 29.4, 29.6, 29.9, 30.0, 31.9, 32.7, 125.1, 128.1, 128.9, 131.0, 135.0, 136.9. Found: C, 77.12; H, 8.66%. Calcd for $C_{31}H_{40}Ge$: C, 76.73; H, 8.31%.

Allyltriphenylstannane, 2-Triphenylstannyl-1-propene, Allyltriphenylgermane. The reaction of 1,2-propadiene[5] with Ph_3SnH (Ph_3GeH) gave the title compounds whose spectral data were identical with the authentic samples.[6,7]

(*Z*)-2-Triphenylstannyl-2-tridecene (7Z), (*E*)-2-Triphenylstannyl-2-tridecene (7E), and 2-Triphenylstannyl-1-tridecene (8) (a 35:50:15 Mixture): IR (neat) 3062, 3046, 2922, 2850, 1637, 1480, 1458, 1429, 1074, 1022, 997, 726, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, *J*=6.0 Hz, 3H), 1.06—1.50 (m, 16.3H), 1.86—2.08 (m, 2.5H, $=CCH_3$ (**7E**) and $=CCH_2$ (**7E**)), 2.13—2.31 (m, 1.75H, $=CCH_3$ (**7Z**) and $=CCH_2$ (**7Z**)), 2.36—2.48 (m, 0.3H, $=CCH_2$ (**8**)), 5.08—5.12 (m, 0.15H, $=CH_2$ (**8**)), 5.78—5.89 (m, 0.5H, =CH (**7E**)), 5.94—5.99 (m, 0.15H, $=CH_2$ (**8**)), 6.33—6.43 (m, 0.35H, =CH (**7Z**)), 7.31—7.52 (m, 9H), 7.52—7.77 (m, 6H); ^{13}C NMR ($CDCl_3$) δ=14.2, 22.7, 28.6, 29.4, 29.6, 29.7, 32.0, 33.3, 116.9, 128.5, 128.6, 128.8, 128.89, 128.93, 136.8, 137.1, 137.2, 138.8, 143.1. Found: C, 70.09; H, 7.68%. Calcd for $C_{31}H_{40}Sn$: C, 70.07; H, 7.59%.

(*E*)-1-Triphenylstannyl-2-tridecene (9). The compound was separated from other three isomers (**7E**, **7Z**, **8**) by preparative thin layer chromatography in pure form. ^1H NMR ($CDCl_3$) δ=0.89 (t, *J*=6.0 Hz, 3H), 1.06—1.50 (m, 16H), 1.85—2.04 (m, 2H), 2.41 (d, *J*=8.0 Hz, 2H), 5.31—5.58 (m, 1H), 5.58—5.80 (m, 1H), 7.31—7.52 (m, 9H), 7.52—7.77 (m, 6H).

(*Z*)-1-Triphenylstannyl-3-phenyl-1-propene: Mp 69 °C; IR (KBr) 3060, 3014, 2986, 1636, 1494, 1481, 1429, 1075, 1045, 1022, 997, 959, 749, 727, 696 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.62 (d, *J*=7.9 Hz, 2H), 6.33 (d, *J*=15.7 Hz, 1H), 6.49 (dt, *J*=15.7, 7.9 Hz, 1H), 7.09—7.34 (m, 5H), 7.34—7.51 (m, 9H), 7.51—7.78 (m, 6H); ^{13}C NMR ($CDCl_3$) δ=17.6, 125.5, 126.2, 127.7,

128.1, 128.4, 128.6, 129.1, 137.1, 138.2, 138.3. Found: C, 69.14; H, 5.01%. Calcd for $C_{27}H_{24}Sn$: C, 69.41; H, 5.18%.

1-Dimethylphenylsilyl-3-triphenylstannyl-1-propene: IR (neat) 3062, 2950, 1597, 1429, 1247, 1111, 1075, 997, 843, 822, 726, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.20 (s, 6H), 2.59 (dd, J=8.2, 1.1 Hz, 2H), 5.66 (dt, J=18.2, 1.1 Hz, 1H), 6.34 (dt, J=18.2, 8.2 Hz, 1H), 7.20—7.46 (m, 12H), 7.46—7.95 (m, 8H); ^{13}C NMR ($CDCl_3$) δ=—2.4, 21.7, 124.8, 127.6, 128.5, 128.6, 129.0, 129.1, 133.8, 137.1, 137.2, 138.2. Found: C, 66.09; H, 5.60%. Calcd for $C_{29}H_{30}SiSn$: C, 66.30; H, 5.76%.

A Mixture of 1-Dimethylphenylsilyl-3-triphenylgermyl-1-propene (10) and 3-Dimethylphenylsilyl-3-triphenylgermyl-1-propene (11) (a 61:39 Mixture): IR (neat) 3064, 3044, 2952, 1604, 1485, 1430, 1248, 1113, 1091, 827, 732, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=—0.01 (s, 3.66H, Me_2Si (**10**)), 0.18 (s, 2.34H, Me_2Si (**11**)), 0.98 (d, J=12 Hz, 0.39H, CH (**11**)), 2.58 (dd, J=1.2, 8.0 Hz, 1.22H, CH_2 (**10**)), 4.82 (dd, J=2.0, 16.5 Hz, 0.39H, =CH_2 (**11**)), 4.86 (dd, J=2.0, 10.0 Hz, 0.39H, =CH_2 (**11**)), 5.65 (dt, J=18.4, 1.3 Hz, 0.61H, =CHSi (**10**)), 5.88 (ddd, J=10.0, 12.0, 16.5 Hz, 0.39H, =CH (**11**)), 6.20 (dt, J=18.4, 8.0 Hz, 0.61H, =CH (**10**)), 5.68—6.08 (m, 20H); ^{13}C NMR ($CDCl_3$) δ=—2.0, 24.6, 25.0, 114.3, 127.5, 127.6, 127.9, 128.2, 128.3, 128.65, 128.72, 128.9, 129.0, 133.8, 134.1, 135.0, 135.4, 136.4, 136.5, 137.2, 138.7, 143.1, 144.9. Found: C, 72.63; H, 6.25%. Calcd for $C_{29}H_{30}GeSi$: C, 72.68; H, 6.31%.

A Mixture of 3-Dimethylphenylsilyl-2-triphenylstannyl-1-propene (12) and 1-Dimethylphenylsilyl-2-triphenylstannyl-1-propene (13) (a 68:32 Mixture): IR (neat) 3060, 2950, 1480, 1428, 1247, 1112, 1074, 997, 833, 808, 726, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.14 (s, 4.08H, Me_2Si (**12**)), 0.41 (s. 1.92H, Me_2Si (**13**)), 2.13—2.25 (m, 2.32H, CH_2 (**12**) and =CCH_3 (**13**)), 5.30—5.41 (m, 0.68H, =CH_2 (**12**)), 5.78—5.84 (m, 0.68H, =CH_2 (**12**)), 6.31—6.38 (m, 0.32H, =CH (**13**)), 7.20—7.48 (m, 14H), 7.48—7.73 (m, 6H); ^{13}C NMR ($CDCl_3$) δ=—2.8, 29.2, 127.7, 127.8, 128.0, 128.1, 128.5, 128.6, 128.8, 128.9, 133.6, 133.7, 136.8, 137.2, 138.7, 143.1. Found: C, 66.11; H, 6.06%. Calcd for $C_{29}H_{30}SiSn$: C, 66.30; H, 5.76%.

8-Triphenylgermyl-6-tridecene: IR (neat) 2952, 2922, 2852, 1654, 1485, 1458, 1431, 1090, 969, 732, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85 (t, J=5.5 Hz, 6H), 0.99—1.34 (m, 14H), 1.81—1.99 (m, 2H), 2.50—2.68 (m, 1H), 5.125—5.39 (m, 2H), 7.26—7.41 (m, 9H), 7.41—7.58 (m, 6H); ^{13}C NMR ($CDCl_3$) δ=13.3, 22.5, 22.6, 25.6, 28.7, 29.4, 30.5, 31.2, 31.4, 32.6, 33.1, 127.9, 128.7, 130.2, 130.7, 135.5, 136.7. Found: C, 76.73; H, 8.34%. Calcd for $C_{31}H_{40}Ge$: C, 76.73; H, 8.31%.

A Mixture of (*Z*)-7-Triphenylstannyl-6-tridecene and (*E*)-Isomer (a 65:35 Mixture): IR (neat) 3062, 2952, 2922, 2850, 1618, 1578, 1480, 1458, 1428, 1377, 1074, 1022, 997, 725, 697 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.65—0.82 (m, 6H), 0.82—1.51 (m, 14H), 1.89—2.08 (m, 1.3H, =$C(SnPh_3)CH_2$ (*Z*)), 2.12—2.33 (m, 2H, =CCH_2 (*E* and *Z*)), 2.39 (t, J=7.3 Hz, 0.7H, =$C(SnPh_3)CH_2$ (*E*)), 5.80 (t, J=7.1 Hz, 0.35H, =CH (*E*)), 6.29 (t, J=7.3 Hz, 0.65H, =CH (*Z*)), 7.47—7.51 (m, 9H), 7.51—7.76 (m, 6H); ^{13}C NMR ($CDCl_3$) δ=13.9, 14.0, 22.4, 22.5, 22.6, 28.6, 28.7, 29.0, 29.6, 30.3, 30.7, 31.3, 31.5, 31.6, 32.9, 35.7, 40.3, 127.9, 128.4, 128.6, 128.7, 128.8, 136.4, 137.0, 137.2, 137.4, 139.7, 140.2, 143.5. Found: C, 70.17; H, 7.64%. Calcd for $C_{31}H_{40}Sn$: C, 70.07; H, 7.59%.

1-(Triphenylstannyl)cyclononene: Mp 88—89 °C; IR (KBr) 3060, 3012, 2984, 2922, 2850, 1480, 1074, 726, 698 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.20—1.65 (m, 10H), 2.06—2.40 (m, 2H), 2.45—2.65 (m, 2H), 6.03 (t, J=8.0 Hz, 1H), 7.20—7.75 (m, 15H); ^{13}C NMR ($CDCl_3$) δ=24.6, 25.46, 25.52, 25.8, 26.0, 27.7, 31.3, 128.4, 128.7, 128.9, 137.2, 137.5, 139.1, 145.0. Found: C, 68.43; H, 6.39%. Calcd for $C_{27}H_{30}Sn$: C, 68.53; H, 6.39%.

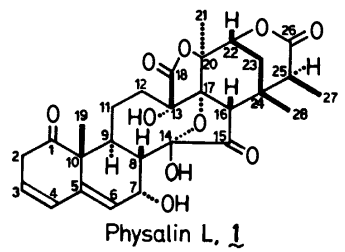
(Received March 15, 1988)

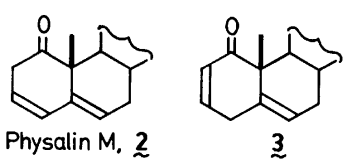
Synopsis. The structure of physalin M, isolated from *Physalis alkekengi* var. *francheti* was determined as 7-deoxyphysalin L by spectroscopic studies and chemical correlation with a known compound. Physalin M exhibited weak cytotoxicity against tumor cells.

Since the isolation of the first physalin, a novel 13,14-seco-16,24-cyclosteroid, from *Physalis alkekengi* var. *francheti* (Japanese name; Hôzuki),[1] more than ten physalins were isolated from *Physalis* plants grown in Japan[2-4] and in India.[5-11] Physalins were also isolated from *Witheringia coccoloboides* as cytotoxic constituents against tumor cells.[12] Very recently we reported the isolation and structure determination of a new physalin named physalin L (**1**) as a constituent of *P. alkekengi* var. *francheti*.[13] Unlike other physalins **1** possesses a conjugated diene structure in the A-B ring moiety instead of the conjugated cyclohexenone structure. In this note we will also report the isolation and structure determination of another new physalin which is structurally closely related to **1**.

From the extract of *P. alkekengi* var. *francheti*[13] a new compound, whose R_f value in SiO_2-TLC was the same as that of physalin B in benzene-ethyl acetate system but was lower than that of physalin B in chloroform-methanol system, was isolated and named physalin M (**2**). The new physalin **2** crystallized from 2-propanol as colorless prisims, mp 224—227 °C, and its molecular formula was established as $C_{28}H_{32}O_9$ by high-resolution mass spectroscopy and elemental analysis. Spectral data of **2** indicated that **2** possesses the similar structural characteristics to those of **1** as follows: i) Chemical shifts of olefinic protons (δ=5.67, 5.70, and 6.08) in the ^{1}H NMR spectrum (CD_3SOCD_3) and carbonyl stretching frequencies (1775, 1760, 1730, and 1695 cm^{-1}) in the IR spectrum indicated absence of the conjugated cyclohexenone moiety which is present in all known physalins except **1**. ii) Presence of a trisubstituted conjugated diene moiety was demonstrated by the UV absorption band at 228 nm (ε 11000) and by the three olefinic proton signals in the ^{1}H NMR spectrum. iii) Presence of a secondary methyl group (δ=1.14, d, J=7 Hz) in addition to three tertiary methyl groups (δ=1.18, 1.27, and 1.76) was also shown by the ^{1}H NMR spectrum. Assuming that **2** possesses the skeletal structure of physalins, the secondary methyl group was located at C(27) position as are the cases for **1** and also for the cytotoxic physalin from *Witheringia* species, namely 25-epi-25,27-dihydrophysalin C (**3**). Regarding the configuration of the secondary methyl group, a correlation between the stereochemistry at C(25) and the proton chemical shifts of C(27) and C(28) methyl groups was proposed;[12,13] i.e., in CD_3SOCD_3 solution C(27) methyl protons resonate at δ=1.07—1.10 and C(28) methyl protons at δ=1.42—1.48 for the compounds with the secondary methyl group in α-configuration, while C(27) and C(28) methyl protons resonate at δ=1.13—1.26 and at δ=1.14—1.30, respectively, for those with a β-methyl group. From the chemical shifts of C(27) and C(28) methyl groups of **2** (δ=1.14 and 1.27, respectively), β-configuration was assigned to the C(27) methyl group of **2**. The conjugated diene carrying three olefinic hydrogens could be placed only in the A-B ring moiety of the physalin skeleton. Thus two possible structures of **2** were obtained, i.e., one with the double bonds at C(3)-C(4) and C(5)-(6) positions and the other at C(4)-C(5) and C(6)-C(7). The former structure corresponds to the analog of **1** in which the secondary hydroxyl group is replaced by a hydrogen, namely 7-deoxyphysalin L, while the latter (**4**) is the known compound which was obtained by acid dehydration of tetrahydrophysalin A.[3] Spectral



Physalin L, 1



Physalin M, 2 3

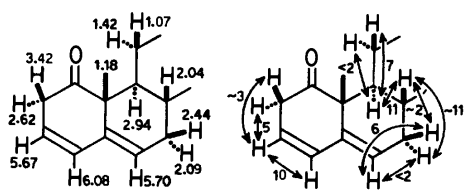

Fig. 1. Chemical shifts (δ) and vicinal coupling constants (Hz) of protons in the A-B ring moiety of physalin M (**2**) measured in CD_3SOCD_3 solution.

comparison clearly indicated that **2** is different from **4**, while the IR, UV, and ^1H and ^{13}C NMR spectral data of **2** resembled closely to those of **1**. The structure of physalin M (**2**) was thus reasonably assumed to be 7-deoxyphysalin L.

Detailed analysis of 400 MHz ^1H NMR spectrum of **2** was performed to ascertain the assumed structure. Homonuclear spin-spin decoupling experiment in combination with COSY analysis enabled the assignment of all of the 32 protons, and their chemical shifts and coupling constants were consistent with the 7-deoxyphysalin A structure. The results of ^1H NMR analysis in CD_3SOCD_3 solution concerning the A-B ring moiety of **2** is given in Fig. 1. Out of 28 carbons of the structure of **2**, 27 carbon resonances were observed in the ^1H noise-decoupled ^{13}C NMR spectrum recorded in CD_3SOCD_3 solution and remaining one carbon, which overlapped solvent signals, could be detected by DEPT (distortionless enhancement by polarization transfer) method. Chemical shifts of all the 4 methyl, 5 methylene, 8 methine, and 11 quaternary carbons were in consistent with the proposed structure as given in the experimental part.

In order to confirm the structure further, chemical tansformation of **2** to the known compound was attempted. Catalytic hydrogenation of **2** in methanol in the presence of palladium-charcoal was found to afford the expected tetrahydro derivative **5**, which was identical in all respects with the known 25-epi-7-deoxy-2,3,5,6,25,27-hexahydrophysalin A.[3,14] Thus, the structure of physalin M (**2**) has been established unequivocally as 7-deoxyphysalin A, namely 25-epi-3,4-dehydro-7-deoxy-2,3,25,27-tetrahydrophysalin A.

Physalins are of interest because of their antitumor activities.[12,13] The new physalin **2**, however, was found to show only very weak cytotoxicity against HeLa cells (IC_{50} 27.6 μg ml^{-1}). The low activity was not unexpected considering the lack of cytotoxicity of the 7-hydroxy analog **1**.[13] Taking into account the potential in vivo and in vitro activity of the double bond isomer (**3**) of **2**, having a double bond at C(2)-C(3) instead of C(3)-C(4),[12] it has been concluded that the conjugated cyclohexenone moiety at the A ring is quite important for the antitumor activity of physalins.

Experimental

Column chromatography and TLC were performed using SiO_2 (Merck, Silicagel 60, 7734) and precoated SiO_2 plates (Merck, Silica Gel 60 F_{254}), respectively. Melting points were determined with a Yanagimoto micro melting point apparatus and uncorrected. Optical rotation and UV spectrum were measured using a JASCO DIP-4 digital polarimeter and HITACHI 124 spectrophotometer, respectively. IR spectrum of **2** was recorded on a JASCO IRA-1 spectrometer with a KBr disk and FT-IR spectra of **5** were recorded on a JEOL JIR-100 spectrometer using a diffuse reflectance accessory. High-resolution MS was measured with a Hitachi M-80 mass spectrometer. ^1H NMR (400 MHz) and ^{13}C NMR (100 MHz) were recorded on a JEOL JNM-GX 400 spectrometer, respectively. Elemental analysis was performed at Elemental Analysis Center of Kyoto University and cytotoxicity test was performed at Pharmaceuticals Laboratory, Life Science Research Sector, Research Center of Mitsubishi Chemical Industries Ltd.

Isolation of Physalin M (2). Water-$CHCl_3$ extract (10 g) of *P. alkekengi* var. *francheti*[13] was subjected to repeated column chromatography with the solvent systems $CHCl_3$-CH_3OH and C_6H_6-$CH_3CO_2C_2H_5$ to give a fraction (350 mg) which showed a single spot (R_f 0.75) on TLC with C_6H_6-$CH_3CO_2C_2H_5$ (3:7), but it showed two spots (R_f 0.70 and 0.58) when developed with $CHCl_3$-CH_3OH (9:1). Column chromatography of the fraction using $CHCl_3$-CH_3OH as eluent afforded physalin B (130 mg) and physalin M (**2**, 140 mg), and the latter was crystallized from 2-propanol to give colorless prisms of **2**: mp 224—227 °C; R_f 0.58 ($CHCl_3$:CH_3OH=9:1); $[\alpha]_D^{24}$ −106° (*c* 0.34, CH_3COCH_3); IR (KBr) 3480, 1775, 1760, 1730, and 1695 cm^{-1}; UV (CH_3OH) 228 nm (ε 11000); ^1H NMR (CD_3SOCD_3) δ=1.04 (6H, d, *J*=6 Hz, 2-propanol), 1.07 (1H, m, H-11β), 1.14 (3H, d, $J_{27,25}$=7 Hz, CH_3-27), 1.18 (3H, s, CH_3-19), 1.27 (3H, s, CH_3-28), 1.42 (1H, dd, $J_{11\alpha,11\beta}$=17 and $J_{11\alpha,12\alpha}$=9 Hz, H-11α), 1.64 (1H, d, $J_{23,23'}$=15 Hz, H-23), 1.76 (3H, s, CH_3-21), 1.86 (1H, dd, $J_{12\beta,12\alpha}$=16 and $J_{12\beta,11\beta}$=6 Hz, H-12β), 2.04 (1H, m, H-8), 2.08 (1H, m, H-23′), 2.09 (1H, m, H-7α), 2.18 (1H, ddd, $J_{12\alpha,12\beta}$=16, $J_{12\alpha,11\beta}$=12, and $J_{12\alpha,11\alpha}$=9 Hz, H-12α), 2.44 (1H, br dd, $J_{7\beta,7\alpha}$=15 and $J_{7\beta,6}$=6 Hz, H-7β), 2.62 (1H, dd, $J_{2\alpha,2\beta}$=20 and $J_{2\alpha,3}$=5 Hz, H-2α), 2.70 (1H, q, $J_{25,27}$=7 Hz, H-25), 2.78 (1H, s, H-16), 2.94 (1H, dd, $J_{9,8}$=11 and $J_{9,11\beta}$=7 Hz, H-9), 3.42 (1H, H-2β, partially overlapping H_2O signal), 3.77 (1H, m, 2-propanol), 4.35 (1H, d, *J*=4 Hz, 2-propanol), 4.48 (1H, d, $J_{22,23'}$=3 Hz, H-22), 5.67 (1H, m, H-3), 5.70 (1H, br d, $J_{6,7\beta}$=6 Hz, H-6), 6.08 (1H, br d, $J_{4,3}$=10 Hz, H-4), 6.20 (1H, s, OH), and 6.47 (1H, s, OH); ^{13}C NMR (CD_3SOCD_3) δ=16.6 and 18.0 (C-27 and C-28), 20.8 (C-19), 24.2 (C-11), 25.4 (2-propanol), 25.5 (C-21), 25.7, 26.1, and 29.0 (C-7, C-12, and C-23), 32.4 (C-9), 34.3 (C-24), 39.5 (C-2), 40.8 and 40.9 (C-8 and C-25), 54.0 (C-16), 55.1 (C-10), 62.0 (2-propanol), 76.4 (C-22), 78.8, 82.0, and 82.3 (C-13, C-17, and C-20), 101.2 (C-14), 122.5, 126.4, and 128.0 (C-3, C-4, and C-6), 140.4 (C-5), 171.7 and 172.2 (C-18 and C-26), 209.6 (C-1), and 215.8 (C-15). Found: C, 63.31; H, 6.84%; *m/z* 512.2031. Calcd for $C_{28}H_{32}O_9 \cdot C_3H_8O \cdot H_2O$: C, 63.04; H, 7.17%. Calcd for $C_{28}H_{32}O_9$: M, 512.2043.

Hydrogenation of Physalin M. Physalin M (9 mg) in CH_3OH (5 ml) was hydrogenated at room temperature and atmospheric pressure over platinum black (2 mg) for 18 h. TLC of the product showed two spots (R_f 0.65 and 0.55, $CHCl_3$:CH_3OH=9:1) and the compound having lower R_f value (3 mg) was isolated by column chromatography using $CHCl_3$ as eluent. Crystallization from CH_3COCH_3 gave colorless prisms: mp>300 °C. The FT-IR spectra of this product and authentic 25-epi-7-deoxy-2,3,5,6,25,27-hexahydrophysalin A (**5**)[3] prepared from physalin A were indistinguishable.

The authors are grateful to Mr. Jun'ichi Ohya of Pharmaceuticals Laboratory, Mitsubishi Chemical Industries Ltd. for the assay of cytotoxic activity and to FT-IR division of Instrument Center, Nagoya Institute of Technology for FT-IR measurement. Thanks are also to Professor Teruo Matsuura of Kyoto University and Professor Ruka Nakashima of Tottori University for helpful discussions.

(Received October 30, 1987)

An effort has been made to determine the partition coefficients from the physical quantities based on the molecular structure. The quantities are representatives of energies which constitute the solvation energy of the solute molecule. The log *P* value is expressed with them as

$$\log P = -1.26 + 3.78\,\phi_{ct} - 0.72\,\mu_1 - 1.28\,\mu_2$$
(N=244, R=0.959, S.D.=0.54, F=934).

For the practical use, the following equation is recommended:

$$\log P = -1.36 + 3.89\,\phi_{ct} - 1.09\,\mu_2 - 0.085U_H + 0.021U_C - 0.134U_N - 0.198U_O$$
(N=244, R=0.976, S.D.=0.42, F=787).

Here, ϕ_{ct} is the representative related to the charge-transfer energy and μ_1, μ_2, U_H, U_C, U_N, and U_O are those related to the electrostatic energy. The molecular structure of the solute molecule has been shown to be very important in the determination of the log *P* value. A log *P* value with a higher precision can be obtained by modifying the approximations used.

For almost one hundred years, many investigators have been carrying out studies of partition coefficients in both basic and applied fields.[1] However, the results of their studies were not sufficiently good to satisfy all of the investigators. For example, despite the fact that a partition coefficient is a physicochemical quantity, it still cannot be elucidated theoretically and universally. The difficulties in calculating it are due to the complexity of the phenomena in a liquid; the system is a cluster of many characteristic particles. These particles have a diversity of structures and electronic states. The collective state of molecules in a liquid or a solution shows properties over a wide range, from order to disorder. It is difficult to provide systematic explanations for such complexity. These days, however, progress in computer systems is enabling researchers to directly approach the subject.

The partition coefficients have been explained by a linear free-energy relationship. Under this relationship, the logarithm of the partition coefficient of a molecule, log *P* value, has been determined by the sum of the values given to the molecular fragment, the so-called fragment constants.[2] In recent years, this method has been refined[3] and the fragment constants have been specified as various values.[4] Although this method is convenient to use, the physicochemical and microscopical significance of the fragment constants are not clear. The calculation techniques were inadequate during the initial stage of the physicochemical study.[5] The trials[6,7] which determine the fragment constant using the physicochemical method did not make the essence of the subject clear. Those trials should reveal the inherent limit of the method. There is a method which expresses the log *P* value by using the observed physical quantities;[8] however, it is not useful for the designed molecules.

Thus, it is necessary to formulate a partition coefficient faithfully along the general concept of the free energy. The log *P* value of a solute molecule is derived from the transfer energy which is the difference in the standard free energy between two phases. The standard free energy of a solute in a solvent corresponds to the solvation energy in an infinite dilution.

By modifying the previous studies[9,10] in our present study, the solvation energy could be expressed by the summation of various types of energy in a molecular system which consists of a solute molecule and solvent molecules. The representatives of each of the energies could be obtained by examining each energy type. The solvation energy is represented by a linear combination of these representatives. Some approximations were introduced in order to determine the representatives. As a result, in some cases there may be a disagreement between the observed and the calculated values, since the approximation is not appropriate for these particular molecules. Such results suggest the elimination of the approximation, or at least an improvement in it. Thus, these modifications provided a better understanding of the phenomena. It is therefore important to discuss the applied approximation and its result.

To use alternatively both the molecular dynamics method and the super molecular approach method is desired as a technical method for calculations, but it is difficult on account of the costly computer facilities. The method stated in the report has been worked out, taking into account the first solvation layer and the continuum model.[11]

Method

The partition coefficient P of a non-associated solute molecule is given by the transfer energy $\Delta\mu_{12}^{\circ}$ per solute molecule between two phases, the solvent 1 and 2,[12]

$$\log P_{12} = -\Delta\mu_{12}^{\circ}/2.303\ kT, \tag{1}$$

where k is Boltzmann's constant, and T is the absolute temperature. If solvent 1 and 2 are water and 1-octanol, respectively, $\log P_{12}$ is the so-called $\log P$.

Solvation Energy and Transfer Energy. The solvation energy $\Psi(\mathrm{M})$ of a solute molecule is given by

$$\Psi(\mathrm{M}) = \psi_{\mathrm{M}}(\mathrm{M}) + \psi_{\mathrm{S}}(\mathrm{M}) + \psi_{\mathrm{MS}}(\mathrm{M}), \tag{2}$$

where M represents the state of the solute in the solvent S. $\psi_{\mathrm{M}}(\mathrm{M})$ is the intramolecular free energy of the solute in state M. $\psi_{\mathrm{S}}(\mathrm{M})$ is the free energy of cavity formation of the solute in the solution.[13] $\psi_{\mathrm{MS}}(\mathrm{M})$ is the sum of the interaction energies between the solute and the solvent molecules. The transfer energy is given by

$$\Delta\mu_{12}^{\circ} = \Psi_2(\mathrm{M2}) - \Psi_1(\mathrm{M1}), \tag{3-1}$$

$$= \phi_{\text{solute}} + \phi_{\text{solution}} + \phi_{\text{inter}}. \tag{3-2}$$

The energies expressed in Eq. 3-2 are given by following equations:

$$\phi_{\text{solute}} = \psi_{\mathrm{M}}(\mathrm{M2}) - \psi_{\mathrm{M}}(\mathrm{M1}), \tag{4-1}$$

$$\phi_{\text{solution}} = \psi_{\mathrm{S}_2}(\mathrm{M2}) - \psi_{\mathrm{S}_1}(\mathrm{M1}), \tag{4-2}$$

and

$$\phi_{\text{inter}} = \psi_{\mathrm{MS}_2}(\mathrm{M2}) - \psi_{\mathrm{MS}_1}(\mathrm{M1}), \tag{4-3}$$

where subscripts 1 snd 2 denote solvents 1 and 2, respectively.

Linear Free Energy Relationship. The linear free energy relationship from Eqs. 1 and 3-2 are obtained as follows:

$$\log P = \sum_i f(i)/2.303\ kT, \tag{5}$$

where $f(i)$ is the energy of the i-th element. The additivity of the $\log P$ value is attributed to the property of the energy. If the energy, $f(i)$, is a linear combination of a physicochemical quantity, Q_{ij}, which itself corresponds to each of the energies, then the value of $\log P$ is given as

$$\log P = \sum_i \sum_j \alpha_{ij} \cdot Q_{ij}, \tag{6}$$

where α_{ij} is the coefficient of Q_{ij}. α_{ij} is determined deductively by the physical meaning or inductively by the least squares method when the $\log P$ values are observed.

Analysis

Approximations. Calculations of the $\log P$ values are almost impossible without using approximations. A water-methane system can be considered in place of a water-1-octanol system (approx. 1), since the dielectric properties of methane resemble that of 1-octanol, compared to water. The size and shape of methane gives merit to the calculation, and leaves no problem in the theory. Water and methane are hereinafter considered to be the two solvents, 1 and 2, respectively.

The transfer energy $\Delta\mu_{12}^{\circ}$ can be explained by three terms: ϕ_{solute}, ϕ_{solution}, and ϕ_{inter}. If the structure of a solute molecule in methane is assumed to be the same as that in water, then $\phi_{\text{solute}}=0$ (approx. 2). The contribution of ϕ_{solution} is neglected, since there is insufficient information regarding the configuration and the orientation of solvent molecules on the solute surface (approx. 3). As for ϕ_{inter}, the attractive forces are generally the main interactions in the liquid state. They are the induction energy, dispersion energy, charge-transfer energy, and electrostatic energy. The induction energy can be neglected, since it is usually small.[14] The dispersion energy can also be neglected because of the difficulty in its estimation. The charge-transfer energy, which is a short-range interaction, and the electrostatic energy, which is a long-range interaction, are denoted by Ect and Ecoul, respectively. Thus, the interaction energy is given by

$$E = E_{\mathrm{ct}} + E_{\mathrm{coul}} \quad \text{(approx. 4)}. \tag{7}$$

This is known as the Klopman-Hudson equation.[15]

$\psi_{\mathrm{MS}}(\mathrm{M})$ in Eq. 2 is given by the summation of all interactions among the solute molecule and all of the solvent molecules surrounding it:

$$\psi_{\mathrm{MS}}(\mathrm{M}) = \sum_j \sum_k E_{jk} \cdot \Delta\tau_j \cdot \Delta\tau_k, \tag{8}$$

where $\Delta\tau_j$ and $\Delta\tau_k$ are the volume elements, and E_{jk} is the interaction energy between the volume elements. Generally speaking, the contribution of the solvent outside the solvation layer is negligible. In order to simplify the calculation, solvent molecules are estimated only in the first layer (approx. 5). If the thickness of the layer is fixed, the summation in Eq. 8 is replaced by that on the surface of the solute. The solvent accessible surface (SAS)[16] is adopted as the molecular surface.

Representatives of Charge-Transfer Energy. In order to simplify the calculation, the orientation of a solvent molecule is assumed to be such that an atom in the solvent molecule faces the solute molecule in proportion to its ratio, R_k, covering the surface of the solvent one. The total charge-transfer energy, ψ_{ct}, then, is given as follows according to Eq. 8:

$$\psi_{\mathrm{ct}} = \sum_j \sum_k \sum_p \sum_q [E_{\mathrm{ct}}]_{pq} \cdot \delta_{pj} \cdot \delta_{qk} \cdot \Delta s_j \cdot R_k, \tag{9-1}$$

where

$$R_k = \Delta s_k / S_{\mathrm{slv}}, \tag{9-2}$$

and δ_{pj} and δ_{qk} are Kronecker's δ; thus, $\delta_{pj}=1$ if the

p-th STO of the solute molecule belongs to the j-th atom of the same molecule, and $\delta_{pj}=0$ otherwise. The existing probability of a solvent molecule in the volume element $\Delta\tau_j$ is proportional to the surface area element Δs_j if the thickness of the layer is fixed. $\sum_j$ corresponds to the sum of all the solvent molecules in the first solvation layer. $\delta_{qk}=1$ if the q-th STO of the solvent molecule belongs to the atom in the volume element $\Delta\tau_k$, and $\delta_{qk}=0$ otherwise. $\sum_k$ indicates the sum for taking the average of the orientation of the solvent. S_{slv} is the total surface area of the solvent molecule, and Δs_k is the surface area element. $[E_{ct}]_{pq}$ is given as follows:[15]

$$[E_{ct}]_{pq} = -2\left(\sum_m^{Oc.}\sum_n^{Un.} - \sum_m^{Un.}\sum_n^{Oc.}\right)\frac{C_{mp}^2 \cdot C_{nq}^2}{\varepsilon_n - \varepsilon_m}\beta_{pq}^2 \quad (10)$$

The resonance integral β_{pq} is strongly dependent on the interatomic distance. Therefore, it is sufficient to take only the atoms exposed to the molecular surface, as the object of the calculation of β_{pq}. The sum of two van der Waals radii[17] of atoms, which face each other across the solute surface, is used as the interatomic distance in the calculation.

Thus, the contribution of the charge-transfer energy in the water-methane system is given by

$$\phi_{ct}=\psi_{2,ct}-\psi_{1,ct}, \quad (11)$$

where $\psi_{1,ct}$ and $\psi_{2,ct}$ are the charge-transfer energy in the water and methane solvent, respectively.

Representatives of Electrostatic Energy. Since a methane molecule is minimally polarized in such a mild field as the solution, the electrostatic energy between the solute and the solvent molecules in the methane solvent is negligible for any solutes:

$$\psi_{2,coul}=0.$$

The contribution of the electrostatic energy is given by

$$\phi_{coul} = \psi_{2,coul} - \psi_{1,coul} = -\psi_{1,coul}, \quad (12)$$

where $\psi_{1,coul}$ is the electrostatic energy in water. The simplest form of $\psi_{1,coul}$ is given as

$$\psi_{1,coul}=-\boldsymbol{\mu}\cdot\boldsymbol{E}, \quad (13)$$

where $\boldsymbol{\mu}$ is the molecular dipole moment of the solute and $\boldsymbol{E}$ is the electric field applied to the solute. If $\boldsymbol{E}$ is fixed over any solute molecules, $\psi_{1,coul}$ depends on $\boldsymbol{\mu}$. The molecular dipole moment is calculated as the sum of two terms,[18]

$$\boldsymbol{\mu}=\boldsymbol{\mu}_1+\boldsymbol{\mu}_2, \quad (14)$$

where the first contribution term $\boldsymbol{\mu}_1$ is obtained from the net charges located at the nuclear position and the second contribution term $\boldsymbol{\mu}_2$ is essentially a hybridization term. Thus, the absolute values of $\boldsymbol{\mu}_1$ and $\boldsymbol{\mu}_2$ are adopted as the representatives of $\phi_{1,coul}$.

$$\mu_1=|\boldsymbol{\mu}_1|, \quad \mu_2=|\boldsymbol{\mu}_2|. \quad (15)$$

Multiple Linear Regression. Thus, ϕ_{ct}, μ_1, and μ_2 are representatives of the energies based on the molecular structure. These are not on the same level as the approximations. According to Eq. 6, the $\log P$ value is given by a linear combination of these representatives. The relationship is obtained by applying a multiple linear regression analysis.

Observed Log P Values and Molecular Structures. The observed $\log P$ values used in the analysis are those of 265 molecules. These were selected according to the order of the molecular size with the following atomic types of H, C, N, and O atoms on the Hansch-Leo data base.[19]

All of the structures of the 265 molecules were geometrically optimized by using the MNDO method.[20] The analyses on the conformation were carried out for 26 molecules, and there was a wide gap between the observed value and the calculated one in the preliminary work. One of the criteria used in the conformational analysis was the total energy for the optimized structure; another one was the stabilization owing to the solvation. The former was obtained directly by a MNDO calculation, but the latter was not so easily obtained. Some conformers, ranging from the lowest energy to one about 3 kcal mol^{-1} higher, are the objects of investigations. As for tautomers, the structures generally considered were fully optimized by the MNDO calculation.

A solvent molecule with a radius of 1.50 Å was used in order to calculate the area of the SAS. The molecular volume was defined as that of the space surrounded by SAS. The other molecular properties were obtained by NNDO calculations.

Results

The following equation was obtained by using the representatives of ϕ_{ct}, μ_1, and μ_2:

$$\log P = -1.26(\pm0.17)+3.78(\pm0.15)\phi_{ct} - 0.72(\pm0.03)\mu_1 - 1.28(\pm0.07)\mu_2 \quad (16)$$
$$(N=244,\ R=0.959,\ \text{S.D.}=0.54).$$

In addition, an equation for more practical use than Eq. 16 is

$$\log P = -1.36(\pm0.17)+3.89(\pm0.19)\phi_{ct} - 0.085(\pm0.014)U_H + 0.021(\pm0.008)U_C - 0.134(\pm0.017)U_N - 0.198(\pm0.018)U_O - 1.09(\pm0.06)\mu_2 \quad (17)$$
$$(N=244,\ R=0.976,\ \text{S.D.}=0.42),$$

where U_H, U_C, U_N, and U_O are the representatives instead of μ_1. Figure 1 shows the relationship between the observed $\log P$ value and the calculated one through Eq. 17.

Derivations of U_H, U_C, U_N, and U_O, and the values of each parameter in Eqs. 16 and 17 are deposited as Document No. 8808 at the Office of the Editor of Bull. Chem. Soc. Jpn.

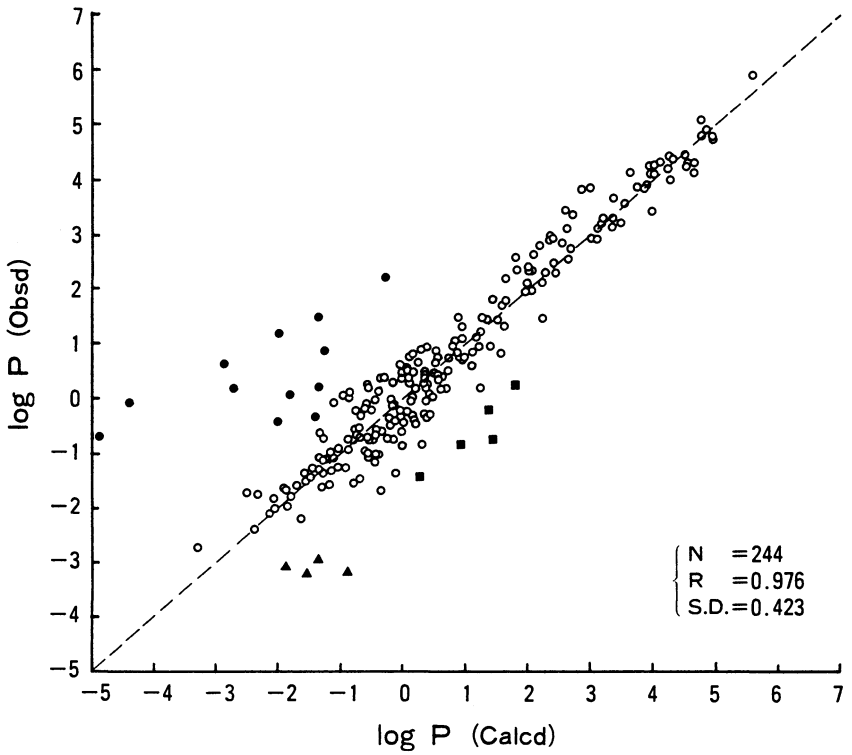

Fig. 1. Observed log$P$ values plotted against values calculated through Eq. 17. ○: Molecules in the group A, B, C, D, and E, ●: Nitro compounds (Group F), ▲: Amino acids (Group G), ■: Symmetrical molecules (Group H). For details of the groups, Document should be referred to.

Discussion

The results showed excellent agreement between the observed and calculated log$P$ values for 244 molecules among 265. The remaining 21 molecules could not be the objects of the analysis.

Characteristics of the 21 Molecules. There were 12 nitro compounds, 4 amino acids, and 5 molecules with a high structure symmetry. In the nitro compounds, the molecular structures optimized by the MNDO method were geometrically unnatural; the C-NO_2 bond is too long (e.g. MNDO; 1.546 Å, 6-31G; 1.479 Å). Therefore, the representatives calculated from the molecular structure may be inappropriate for applications to the analysis. Amino acids are not appropriate for approx.2; the conformations in two solvents are considered to be different. In molecules with high symmetry, the contribution due to the dipole moment is of no value.

Limitation of Fragment Constant Method. If $f(i)$ in Eq. 5 is the energy of the i-th fragment in a molecule, and all fragments are independent of one another, the fragment constant method is valid. This method is, however, invalid if the procedure for dividing the molecule into fragments is inappropriate, and/or if the intra- and the intermolecular interactions involve long-range interactions. For example, though the hydrocarbons are satisfied with the additivity in the log$P$ values, it is difficult to validate the additivity in molecules, having hetero atoms like nitrogen and oxygen atoms.

Correlations of S, V, and ϕ_{ct}. There is a close correlation between the molecular surface area S and the volume V (e.g. R=0.998, N=244). There is also a close correlation between ϕ_{ct} and V (e.g. R=0.984, N=244). The former fact is the reason that the radius of each atom in the molecule is almost the same. As for the latter, if E_{ct} in Eq. 9-1 is fixed, ϕ_{ct} is directly proportional to S, so that ϕ_{ct} has a close correlation with V. Thus, S. V, and ϕ_{ct} have close correlations to one another in a molecule without any long-range interaction, such as the electrostatic interaction.

The interactions of the saturated hydrocarbons, except for the dispersion energy, must be negligible. The log$P$ values in these molecules also seem to depend on ϕ_{ct} in Eqs. 16 and 17. The dependency is considered to be derived from the energies represented by S and/or V. The energies may be the dispersion energy and/or the energy of the cavity formation. Although these energies are not taken up here, the dependency suggests that they are significant for the saturated hydrocarbons.

Log P Value and Molecular Structure. The strength of the intra- and the intermolecular interaction depends upon the molecular structure, so thst a molecular property like the log$P$ value is also

changed.

i) Conformer: Table 1 shows the value of the intramolecular energy, the magnitude of the dipole moment, and the observed and the calculated log *P* values of various conformers of three molecules: urea, dioxane, and cyclohexane.

The typical conformers of urea are shown in Fig. 2. Although conformer A1 has the lowest energy in the planar forms, the calculated log *P* value does not agree with the observed value. The calculated log *P* value of conformer A2 is the nearest to the observed one. Dioxane has two typical conformers: a chair form and a boat form. The energy of the chair form is lower than that of the boat form, but the observed value of log *P* shows better agreement with the calculated value of the boat form than that of the chair form. In cyclohexane, the calculated log *P* values are similar to both the chair and the boat forms, but the energy of the chair form is clearly lower than that of the boat form.

ii) Tautomer: Table 2 and Fig. 3 show an example of the tautomer in tetrazole. The observed log *P* value is closer to the calculated one of the 2*H*-type than that of the 1*H*-type. On the other hand, the results of the 6-31G**, calculated by Mazurek and Osman[21] reverse the evaluation of the energy in comparison with the MNDO calculations.

Conclusion

The partition coefficient of the solute molecule is determined by the transfer energy which is the difference of the standard free energy between two phases. The standard free energy consists of the intramolecular free energy of the solute molecule, the free energy of the cavity formation, and the interaction energy between the solute molecule and the solvent ones. These energies depend on the molecular structure of the solute. The log P values are represented by linear combination of the representatives of each energy.

This method has a characteristic of being applicable to the molecules, regardless of their types. In the analysis for instance, the log P value was investigated over the wide range of about −3 to 6, where 38% of the molecules were found to have a negative log P value.

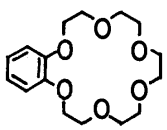
A Conductance Study of 1 : 1 Complexes of 1,2-Bis[2-(2-methoxyethoxy)-ethoxy]benzene (Noncyclic Polyether) with Alkali Metal Ions in Nonaqueous Solvents

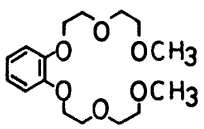
Yasuyuki TAKEDA,* Shinichi SAKAMOTO, Naohiko OHASHI, and Naoaki FUKADA
Department of Chemistry, Faculty of Science, Chiba University, Yayoi-cho, Chiba 260
(Received November 18, 1987)

Conductivities of alkali metal salts in the presence of 1,2-bis[2-(2-methoxyethoxy)ethoxy]benzene (AC·B18C6), which is a linear counterpart of benzo-18-crown-6 (B18C6), were measured at 25 °C in acetonitrile, propylene carbonate, and methanol. Formation constants and limiting ionic molar conductivities of the 1 : 1 AC·B18C6–alkali metal ion complexes were determined. Selectivity of AC·B18C6 for alkali metal ions is lower than that of B18C6. The selectivity order of AC·B18C6 for K^+, Rb^+, and Cs^+ is consistent entirely with that of B18C6 ($K^+ > Rb^+ > Cs^+$), but the selectivity order of AC·B18C6 for Na^+ differs from that of B18C6. The AC·B18C6–alkali metal ion complex is less stable than the corresponding B18C6 complex. The AC·B18C6 complex may be entropy-destabilized due to the two flexible arms. The AC·B18C6–alkali metal ion complex is more mobile than the corresponding B18C6 complex; the mobility of the AC·B18C6 complex is less sensitive to a variety of the alkali metal ions in the complexes than that of the B18C6 complex. This indicates that the alkali metal ion in the AC·B18C6 complex is coordinated with the two arms and the surface charge of the alkali metal ion in the AC·B18C6 complex is more effectively shielded than that in the B18C6 complex.

In order to clarify the macrocyclic effect (i.e., enhanced stabilities of crown compound-cationic species complexes), complexation reactions of crown compounds and their corresponding open-chain analogs with metal ions have been studied from thermodynamic and kinetic points of view.[1] However, few data on solvation behavior and structures in solutions of the resulting complexes have been reported. In this study, conductivities of alkali metal salts in the presence of 1,2-bis[2-(2-methoxyethoxy)ethoxy]benzene (AC·B18C6), which is a linear counterpart of benzo-18-crown-6 (B18C6), were measured at 25 °C in acetonitrile, propylene carbonate, and methanol. Formation constants and limiting ionic molar conductivities of the 1 : 1 AC·B18C6-alkali metal ion complexes were determined. Stabilities and mobilities of the AC·B18C6 complexes in the solvents were compared with those of the B18C6 complexes to obtain information on the macrocyclic effect of B18C6, and solvation properties and structures in solutions of the AC·B18C6 complexes.



B18C6



AC·B18C6

Experimental

Materials. AC·B18C6 was prepared by the reaction of catechol with 2-(2-methoxyethoxy)ethyl chloride in aqueous sodium hydroxide–1-butanol mixture according to the literature method.[2,3] The crude light yellow oil was distilled three times to give colorless viscous oil: 65%; bp 225—230 °C/19 Torr (1 Torr≃133.322 Pa); MS m/z, 314 (M^+). Found: C, 60.97; H, 8.20%. Calcd for $C_{16}H_{26}O_6$: C, 61.13; H, 8.34%. Extremely pure $LiCl \cdot H_2O$, NaCl, KCl, RbCl, and CsCl were obtained from Merck Japan Ltd., and were used without further purification. Rubidium and caesium perchlorates were prepared by adding a little excess of perchloric acid to aqueous solutions of the RbCl and CsCl, respectively. Lithium, sodium, and potassium perchlorates were purchased from Merck Japan Ltd. All the perchlorates were recrystallized four times from distilled water. The alkali metal chlorides and perchlorates were, prior to use, dried at 150 °C in a vacuum oven.

The method of purification of acetonitrile,[4] propylene carbonate,[5] and methanol[6] was previously described. Middle 70% of distillate of the solvents was used. Conductivities of the purified acetonitrile, propylene carbonate, and methanol were less than 3×10^{-7}, 6×10^{-8}, and 3×10^{-7} $\Omega^{-1}cm^{-1}$, respectively.

Alkali metal chlorides were employed for the methanol system and alkali metal perchlorates for the other solvent systems.

Apparatus and Procedure. The conductance measurements were made on a Fuso conductivity apparatus, model 362A, in a water bath thermostated at 25±0.005 °C. Three cells were used with cell constants of 0.13545, 0.090741, and 0.031112 cm^{-1}.

The experimental procedure to obtain formation constants and limiting ionic molar conductivities of AC·B18C6–alkali metal ion complexes was almost the same as that described in a previous paper.[5]

Results and Discussion

The procedure for obtaining formation constants (K_{ML^+}) and limiting ionic molar conductivities (λ^0) of AC·B18C6–alkali metal ion complexes was just the same as that reported in a previous paper,[5] where $K_{ML^+}=[ML^+]/[M^+][L]$. M^+ and L denote an alkali metal ion and AC·B18C6, respectively. In this study, it is assumed that the association between a cation and an anion is negligible and that AC·B18C6 forms the 1 : 1 complex with an alkali metal ion. Corrections for viscosity changes were neglected. The log K_{ML^+} and λ^0

values of the AC·B18C6-alkali metal ion complexes are summarized in Tables 1 and 2, respectively, together with the literature values.

The molar conductivity (Λ) vs. $[L]_t/[M]_t$ plots in acetonitrile, propylene carbonate, and methanol are given in Figs. 1, 2, and 3, $[L]_t$ and $[M]_t$ being total concentrations of AC·B18C6 and an alkali metal ion, respectively. The Λ vs. $[L]_t/[M]_t$ plots show a decrease in Λ with an increase in the AC·B18C6 concentration, except for all the Li^+ systems and the Na^+-CH_3OH system. This indicates that the moving entity of the AC·B18C6-alkali metal ion complex is larger than that of the corresponding alkali metal ion. In the case of the Li^+ system, a small increase in Λ is found with an increase in the AC·B18C6 concentration, indicating that, if a complex is formed between AC·B18C6 and Li^+, the moving entity of the AC·B18C6-Li^+ complex is smaller than that of Li^+. For the Na^+-CH_3OH system, scarcely any change in Λ is observed in spite of an increase in the AC·B18C6 concentration. Consequently, the conductometric determination of the complex-formation constant is impossible for the Li^+-acetonitrile and -methanol systems and the Na^+-methanol system. From the fact that the AC·B18C6-Na^+ complex is formed in CH_3OH,[3] the changeless Λ may be caused by low stability of the AC·B18C6 complex and/or nearly equal mobilities of the AC·B18C6 complex and Na^+ in CH_3OH.

It can be seen from Figs. 1, 2, and 3 that no clear breaking point is observed at $[L]_t/[M]_t=1$; whereas, the reverse holds for B18C6 systems.[7] This is attributed largely to much lower stabilities of AC·B18C6-alkali metal ion complexes compared with B18C6-alkali metal ion complexes (Table 1).

Stabilities of AC·B18C6 Complexes. The difference in logK_{ML^+} values of AC·B18C6 between neighboring alkali metal ions in the periodic table in the same solvent is smaller than that of B18C6 except for the cases of Rb^+, Cs^+ in acetonitrile and Na^+, K^+ in propylene carbonate. The difference between the

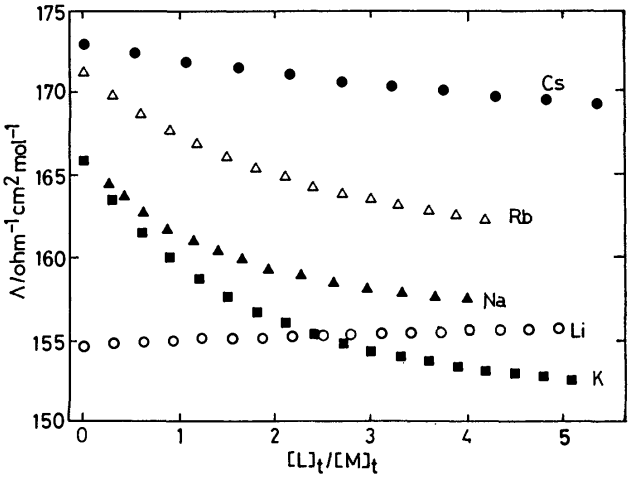

Fig. 1. Λ vs. $[L]_t/[M]_t$ curves for AC·B18C6-alkali metal perchlorate systems in acetonitrile at 25 °C. $[M]_t=1.5\times10^{-3}$ mol dm^{-3}.

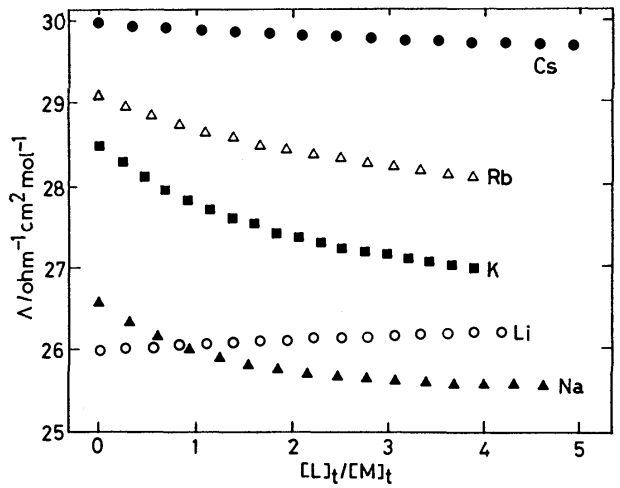

Fig. 2. Λ vs. $[L]_t/[M]_t$ curves for AC·B18C6-alkali metal perchlorate systems in propylene carbonate at 25 °C. $[M]_t=1.5\times10^{-3}$ mol dm^{-3}.

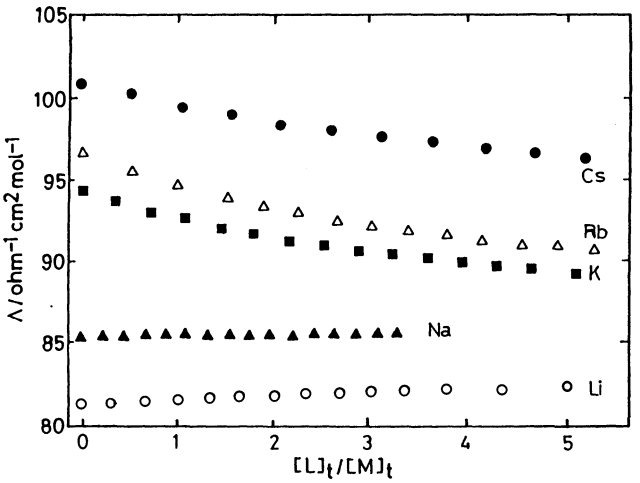

Fig. 3. Λ vs. $[L]_t/[M]_t$ curves for AC·B18C6–alkali metal chloride systems in methanol at 25 °C. $[M]_t=1.5\times10^{-3}$ mol dm^{-3}.

largest and the smallest $\log K_{ML^+}$ values of AC·B18C6 complexes among alkali metal ions in a given solvent is smaller than that of B18C6. Thus, the selectivity of AC·B18C6 for alkali metal ions is lower than that of B18C6. Since AC·B18C6 has two relatively flexible arms, each of which contains three donor ether oxygen atoms, AC·B18C6 may trap the alkali metal ion with the two arms and adopt the most favorable conformation according to the size of the alkali metal ion at the complexation reaction. Thus, since smaller alkali metal ions may attract the donor oxygen atoms of the two arms of AC·B18C6 more strongly than larger alkali metal ions, values of both enthalpy ($\Delta H°$) and entropy ($\Delta S°$) of complexation are expected to be negative and small for smaller alkali metal ions and are expected to be negative and large for larger alkali metal ions. By way of example, values of thermodynamic quantities of pentaethylene glycol dimethyl ether–Na^+ and K^+ complexes in 99 wt.% methanol at 25 °C are as follows.

	$\log K_{ML^+}$	$\Delta H°$/kJ mol^{-1}	$T\Delta S°$/kJ mol^{-1}
Na^+ [11]	1.0	−38.2	−32
K^+ [12]	2.27	−34.1	−21.2

However, it seems that differences in $\Delta H°$ and $\Delta S°$ among AC·B18C6–alkali metal ion complexes are not so large on account of its flexible structure compared with the case of rigid B18C6. The same tendency for $\Delta H°$ and $\Delta S°$ values is found for relatively rigid 18C6- and flexible dibenzo-24-crown-8–alkali metal ion complexes.[1] Consequently, enthalpy and entropy changes compensate each other, resulting in lower selectivity of AC·B18C6 for alkali metal ions.

The selectivity order of AC·B18C6 for K^+, Rb^+, and Cs^+ is consistent entirely with that of B18C6 ($K^+ > Rb^+ > Cs^+$), but the selectivity order of AC·B18C6 for Na^+ among alkali metal ions differs from that of B18C6. This shows that, in the cases of K^+, Rb^+, and Cs^+, the size and shape of a pseudocavity formed by the two arms at the ortho position may be similar to those of the B18C6 cavity, and that a smaller Na^+ ion may cause a larger conformational change on complexation with AC·B18C6 than K^+, Rb^+, and Cs^+ compared with the case of B18C6.

As can be seen from Table 1, an AC·B18C6–alkali metal ion complex is less stable than the corresponding B18C6 complex in the same solvent. Since the two arms of AC·B18C6 are flexible, the entropy contribution seems to play a more dominant role in destabilizing the AC·B18C6–alkali metal ion complex compared with the case of the corresponding B18C6 complex.

For each of the AC·B18C6–Na^+, K^+, and Rb^+ complexes, the $\log K_{ML^+}$ value in CH_3OH is the smallest of all the solvents, and $\log K_{ML^+}$ values in the three solvents of the AC·B18C6–Cs^+ complex are almost the same; however, for each of the B18C6–K^+, Rb^+, and Cs^+ complexes, the $\log K_{ML^+}$ value in CH_3OH is the largest. This may be attributed to stronger hydrogen bonding between uncomplexed AC·B18C6 and CH_3OH compared with the case of B18C6. On the basis of a thermodynamic study on Ni^{2+} complexes in water of tetramine ligands, Hinz and Margerum proposed that a cyclic ligand, being much more compact, is less solvated than a noncyclic, and consequently less energy is expended at its desolvation step.[13] It was reported that, from the data of transfer activity coefficients of Na^+, Na^+ is solvated most strongly in CH_3OH among all the solvents used here.[7] This may be responsible for the fact that $\log K_{ML^+}$ value of the B18C6–Na^+ complex in CH_3OH is the smallest of all the solvents.

Transport Phenomena of AC·B18C6 Complexes. Limiting molar conductivities (Λ_0) of AC·B18C6 complexes determined in this study are as follows:

	Λ_0/Ω^{-1} cm^2 mol^{-1} values at 25 °C	
	Propylene carbonate	Acetonitrile
(Na·AC·B18C6)ClO_4	26.45±0.09	162.3±0.9
(K·AC·B18C6)ClO_4	26.81±0.08	161.8±0.7

Although, when the two arms of AC·B18C6 form a pseudocavity, the size and shape of AC·B18C6 are similar to those of B18C6, an AC·B18C6–alkali metal ion complex is more mobile than the corresponding B18C6 complex (Table 2). This indicates that the alkali metal ion in the AC·B18C6 complex is coordinated with the two arms, and the surface charge of the alkali metal ion in the AC·B18C6 complex is more effectively shielded than that in the B18C6 complex. The effective shielding seems to be ascribed to high flexibility of the two arms. For Na^+, λ^0 values of the complex increase from B18C6 to AC·B18C6 by $10._3$ and $12._0$% in acetonitrile and propylene carbonate, respectively; for K^+, λ^0 values of the complex increase from B18C6 to AC·B18C6 by 2.8_3 and 7.9_7% in acetonitrile and propylene carbonate, respectively. For the

rate of increase in λ^0 values of the complex from B18C6 to AC·B18C6, Na^+ is much larger than K^+. Since Na^+ is smaller than K^+, Na^+ may attract the two flexible arms of AC·B18C6 more strongly than K^+, resulting in more efficient shielding of Na^+ in the complex by the two arms from surrounding solvent molecules on going from B18C6 to AC·B18C6 compared with the case of K^+.

Mobilities of AC·B18C6-Na^+ and K^+ complexes in acetonitrile are almost the same; λ^0 values of AC·B18C6 and B18C6 complexes in propylene carbonate increase from Na^+ to K^+ by 4.4 and 8.4%, respectively; the λ^0 value of the B18C6 complex in acetonitrile increases by 6.4%. Mobilities of the B18C6 complexes vary with a variety of metal ions in the complexes much more than those of the AC·B18C6 complexes. These data support the above discussion, i.e., much more effective shielding of surface charge of the metal ion in the AC·B18C6 complex owing to the two flexible arms compared with the case of B18C6.

Walden products of the AC·B18C6 complexes with Na^+ and K^+ at 25 °C are as follows:

	Acetonitrile	Propylene carbonate
η_0/mP	3.39[14]	25.3[14]
Na^+	0.19_8	0.20_6
K^+	0.19_6	0.21_5

where η_0 denotes viscosity and 1 P = 0.1 Pa s. Walden products of the AC·B18C6-alkali metal ion complexes in propylene carbonate, dielectric constant of which (64.4 at 25 °C[14]) is larger than that of acetonitrile (35.95 at 25 °C[14]), are slightly greater than those in acetonitrile.

Electrochemical Oxidation of Ruthenium and Iron Complexes at Rotating Disk Electrode in Acetonitrile Solution

Masayuki MORITA,* Yoshinori TANAKA, Keisuke TANAKA,
Yoshiharu MATSUDA, and Takeko MATSUMURA-INOUE†
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
†Department of Chemistry, Nara University of Education, Takabatake-cho, Nara 630
(Received December 9, 1987)

The diffusion coefficient and the apparent rate of charge-transfer have been determined for various ruthenium and iron complexes in an acetonitrile solution by using a rotating disk electrode (RDE) method. The diffusion coefficients of $[Ru(bpy)_3]^{2+}$, $[Ru(acac)_3]$, and $[Fe(bpy)_3]^{2+}$ (bpy: 2,2′-bipyridine, acac: acetylacetone), being similar to each other, were about 2×10^{-10} m^2 s^{-1} in acetonitrile containing 0.1 mol dm^{-3} $(C_2H_5)_4NBF_4$. The apparent rate of electrochemical oxidation increased in the order $[Ru(bpy)_3]^{2+}<[Ru(acac)_3]<[Fe(bpy)_3]^{2+}$. The order of the rates was reciprocal to the order of their oxidation potentials in the same electrolyte.

The electrochemistry of transition-metal complexes with organic ligands has been widely investigated by many workers.[1] Some complexes such as Fe, Co, Ru, and Os with 2,2′-bipyridine (bpy), ethylenediamine (en), and 1,10-phenanthroline (phen) as ligands are oxidized and reduced reversibly. The multi-step valence changes of these complexes can be utilized in a rechargeable battery system.[2] The authors have proposed new-type redox batteries consisting of Ru complexes as active materials and organic electrolyte solutions.[3,4] It has been found that the performances of such redox batteries are greatly influenced by the electrochemical reversibility, i.e. the rates of charge-transfer and the diffusion of the electroactive species. The heterogeneous rate constants of Ru complexes have been determined at Pt or a dropping mercury electrode (DME) in aqueous and nonaqueous solutions by some workers.[5,6] However, to our knowledge, the diffusion coefficients and rate constants at the carbon electrode in organic media have not been reported. This paper presents the diffusion coefficients and the heterogeneous charge-transfer rates of some Ru and Fe complexes in an acetonitrile solution. These parameters have been determined by using a rotating disk electrode (RDE) method which would be useful to estimate the parameters simultaneously.

Experimental

The metal complexes used here were tris(2,2′-bipyridine)-ruthenium(II) tetrafluoroborate, $[Ru(bpy)_3](BF_4)_2$, tris(acetylacetonato)ruthenium(III), $[Ru(acac)_3]$, and tris(2,2′-bipyridine)iron(II) tetrafluoroborate, $[Fe(bpy)_3](BF_4)_2$. These were prepared and purified by methods described in the literature.[7-9] The solvent acetonitrile (CH_3CN) was dehydrated and purified by the usual distillation method.[10] The supporting electrolyte was tetraethylammonium tetrafluoroborate (Et_4NBF_4). The concentration of the supporting electrolyte was 0.1 mol dm^{-3} throughout the experiments. The solution contained 0.5×10^{-3}—2.0×10^{-3} mol dm^{-3} of the metal complex.

A one-compartment glass cell (ca. 200 cm^3 volume) was used for the electrochemical measurements. The working electrode was a Pt ring-glassy carbon (GC) disk electrode, whose surface areas were 0.24 and 0.22 cm^2, respectively. Before use, the working electrode was mechanically polished with fine powder of alumina, throughly washed with distilled water and with acetone in a ultrasonic cleaner, and finally rinsed with a test solution. A Pt wire was used as the counterelectrode. The reference electrode was an SCE, which was connected to the working electrode through a salt bridge and a Luggin capillary filled with the test solution. Thus, the electrode potential in this paper is indicated with respect to the SCE. Dry N_2 was introduced into the electrolytic solution for about 30 min before a measurement in order to purge any O_2 dissolved in the electrolyte: then the top of the cell was filled with dry N_2 throughout the measurements.

The current-potential relations were measured by using cyclic voltammetry and an RDE method. The rate of the potential sweep during voltammetry measurements was usually 0.1 or 0.3 V s^{-1}. The potential of the ring-disk electrode and the rotation rate of the electrode were controlled by a dual-potentio/galvanostat (Nikko Keisoku DPGS-1) and a rotation controller unit (Nikko Keisoku RRDE-1, SC-1), respectively. The rotation rate, N, of the electrode was varied from 0 to 4500 rpm (rotation per minute). In some experiments the error in the electrode potential due to uncompensated solution resistance was estimated by a current-interrupting technique: it was negligibly small in most cases. These electrochemical experiments were carried out at room temperature (17—21 °C). The viscosity of the electrolytic solution was measured by a modified Ostwald viscometer in a water bath thermostatted at 20 °C.

Results and Discussion

The cyclic voltammograms for $[Ru(bpy)_3](BF_4)_2$, $[Fe(bpy)_3](BF_4)_2$ and $[Ru(acac)_3]$ at the stationary GC-disk electrode (N=0 rpm) are shown in Fig. 1. The shapes of the voltammograms are quite consistent with those shown in previous work.[11-14] The peak couples are attributable to simple one-electron transfer reactions of the complexes. The potential difference (ΔE_p) of each redox couple apparently showed that the reaction proceeds almost reversibly (ΔE_p=59—62 mV).

Figure 2 shows the voltammograms for $[Ru(bpy)_3](BF_4)_2$ at a rotating ring-disk electrode (RRDE). The increase in the disk current at 1.2 V or above is based on the oxidation of Ru(II) to Ru(III), and the ring current corresponds to the reverse reaction. The col-

lection efficiency obtained experimentally was in good agreement with that calculated from the electrode geometry: this also suggested the reaction is reversible. The steady-state limiting current at the disk electrode, $i_{D,l}$, depended on the rotation rate of the electrode: that is, it yielded the Levich equation:

$$i_{D,l} = 0.62\pi r^2 nFD^{3/2}\nu^{-1/6}\omega^{1/2}c, \quad (1)$$

where r, n, F, D, ν, ω, and c are the radius of the disk electrode, number of transferred electron (here, n=1), Faraday constant, diffusion coefficient of the complex ion, kinematic viscosity of the solution, rate of the electrode rotation (ω=120 πN, where N is rotation per minute), and concentration of the complex, respectively. Figure 3 shows a typical $i_{D,l}$ vs. $\omega^{1/2}$ plot. The diffusion coefficient, D, was determined from the slope of the plot. Table 1 summarizes the D's of $[Ru(bpy)_3]^{2+}$, $[Fe(bpy)_3]^{2+}$, and $[Ru(acac)_3]$ in Et_4NBF_4/CH_3CN. In the present electrolyte system, D was dependent neither on the central metal cation nor on the ligand of the complex. That is, there is little difference in the size of the diffusing species among the three complexes, in spite of some differences in the

1.0	1.8	2.3	2.3
2.0	2.1	2.1	2.1

ionic radius of the metal and in the size of the ligand. This is probably due to some compensation effects of the solvent, though details have not yet been made clear.[13]

As shown in Fig. 3, plots of $i_{D,l}$ vs. $\omega^{1/2}$ slightly deviate from a straight line that intersects the origin. This suggests that some kinetic step is involved in the electron transfer reaction.[15] The inconsistency of the results obtained at the RDE with those from cyclic voltammetry may be attributed to a difference in the experimental conditions. That is, the reaction rates observed under the steady-state condition of the RDE method might be somewhat different from those of cyclic voltammetry. If the disk current is considered to be formally expressed by Eq. 2, which is applicable to a totally irreversible reaction,

$$1/i_D = 1/i_{D,k} + 1/i_{D,l}, \quad (2)$$

where $i_{D,k}$ represents the current in the absence of mass transfer effects, the intercepts of the $1/i_D$ vs. $\omega^{-1/2}$ plots will give the disk current at $\omega \to \infty$, i_D^{∞} ($=i_{D,k}$). Figure 4 is an example of the $1/i_D$ vs. $\omega^{-1/2}$ plots, where the intercept of each line indicates $1/i_D^{\infty}$ at a given potential. The plots of log (i_D^{∞}) against the disk potential gave Tafel relations, which are shown in Figs. 5, 6, and 7. The Tafel slope, b, was about 0.2 V/decade for each anodic line. Thus, the apparent exchange current, $i_{0,app}$, is obtained by extrapolation of anodic log (i_D^{∞})—E_D curve to the reversible potential, E_r, which had previously determined by the cyclic voltammogram at the stationary electrode. The resulting $i_{0,app}$'s are

summarized in Table 2. If one tentatively estimates the heterogeneous rate constant, k, from Eq. 3,

$$i_0 = nFkc \quad (3)$$

k will be 3.4×10^{-5} m s^{-1} for the $[Ru(bpy)_3]^{2+}$ system. This value is rather small compared with those deter-

Table 2. Apparent Exchange Current ($i_{0,app}$) for the Anodic Oxidation of the Complex in 0.1 mol dm^{-3} Et_4NBF_4/CH_3CN at 20 °C

2.0	0.64	2.7	9.1

mined previously in similar nonaqueous systems, but by different methods.[7,16] A possible reason for this is that the apparent i_0 obtained in this work is essentially based on the deviation of the rate equation from that for a totally reversible reaction.[15] Thus, the apparent rate, $i_{0,app}$, might involve a somewhat different meaning from the heterogeneous rate constant that were previously determined by cyclic voltammetry. However, a discussion of $i_{0,app}$ obtained under a steady-state condition will also be meaningful from the standpoint of any application of the redox system to a practical battery.[3,4]

The rate varies significantly with both the central metal cation and the ligand, in contrast to little variation of the diffusion constant among the complexes. The order of the rates,

$$[Ru(bpy)_3]^{2+} < [Fe(bpy)_3]^{2+} < [Ru(acac)_3],$$

was in agreement with the reciprocal order of the redox (reversible) potentials,

$$[Ru(bpy)_3]^{2+/3+}\ (1.27\ V) > [Fe(bpy)_3]^{2+/3+}\ (1.07\ V) > [Ru(acac)_3]^{0/+}\ (1.00\ V),$$

The reason for this result has not yet been made clear. The relation between the redox potential and the electronic structure of the complex among the series of analogs has been widely investigated by means of cyclic voltammetry and polarography.[13,14,17–20] However, only a few studies have been carried out concerning the correlation between the charge-transfer rate and the structure of the complex.[5] This is probably due to the insufficiency of reliable data concerning the rate constant. Our present interest is how the rates of charge transfer and diffusion of the complexes influence the charge-discharge performance of the redox batteries with this type of complex. Some experiments are now in progress and the results will be reported in the near future.

Summary

The diffusion coefficients and the electron-transfer rates of some Ru and Fe complexes have been measured at a rotating disk electrode. The results are summarized as follows:

1. The cyclic voltammetry shows that the heterogeneous redox reactions of $[Ru(bpy)_3]^{2+}$, $[Fe(bpy)_3]^{2+}$, and $[Ru(acac)_3]$ proceed reversibly in an acetonitrile-based electrolyte.

2. The diffusion rate was almost constant among the complexes examined, while the current based on the electron transfer varied according to the structure of the complex.

3. The rate of electron transfer tended to increase with the decrease in the redox potential.

Dielectric Properties of the Hydrogen-Bonded Liquids. Steric Effects on Dielectric Properties in Isomeric Methylcyclohexanols

Kimiya TAKESHITA, Eiji IKADA,* and Michio ASHIDA
Department of Industrial Chemistry, Faculty of Engineering, Kobe University, Nada, Kobe 657
(Received December 28, 1987)

The dielectric properties of 2- and 4-methylcyclohexanols were studied in order to elucidate the molecular geometric dependences of the dielectric properties of alcohols. The Kirkwood correlaton factors g of the trans isomers are larger than those of the cis isomers. Especially the g of *cis*-2-methylcyclohexanol at 298 K is 0.75. The dielectric relaxation of all the methylcyclohexanols studied shows the characteristics of the Debye-like behavior frequently reported for primary alcohols. The activation energy of dielectric relaxation of 2-methylcyclohexanol is much larger than that of the other methylcyclohexanols. These facts are discussed in terms of the difference of the steric hindrance for the association through the hydrogen bond.

It is well-known that alcohol molecules in a liquid state are generally self-associated by intermoleculer hydrogen bonding; therefore, the alcohols show abnormal physical properties.[1] The abnormal behaviors in dielectric properties have been revealed in earlier investigations.[2]

The dielectric susceptibility of many organic liquids can be predicted from the magnitude of their dipole moments while that of the alcohols can not. This can be explained by the fact that the dipoles of alcohol molecules do not follow an electric field independently, owing to the self-association through the hydrogen bond. Further, their dielectric relaxation times are longer than those of many organic molecules in a liquid state due to the large interaction of the hydrogen bond. In the dielectric relaxation process, the dipoles of many organic molecules reorient independently under an alternative electric field, while the dipoles of alcohol molecules reorient cooperatively for the hydrogen bond. After all, the abnormal dielectric behavior of the alcohols also results from the hydrogen bond.

The association through the hydrogen bond and the hydrogen bond network system governing the dielectric relaxation have been investigated by changing the molecular geometry of alcohols: Secondary alcohols and tertiary alcohols, with the more sterically hindered association in a liquid state, are known to have different tendencies of dielectric properties from primary alcohols. Many investigators have mainly studied linear alcohols and have discussed the steric effect for the association and the dielectric relaxation.[3,4] Most of these linear molecules, however, have a freedom of intramolecular dipolar rotation for the dipole, which is considered to denature the association and the hydrogen bond system, itself. Therefore, these investigators have neglected the significance of the change of the molecular geometry and did not separate the segmental dipolar reorientation process from the whole dielectric relaxation.

In order to discuss the different tendencies of secondary alcohols and tertiary alcohols in further detail, we studied the dielectric properties of cyclohexanol derivatives which have less freedom of the segmental dipolar reorientation motion and of changing the molecular geometry than the linear molecules.

Experimental

2-Methylcyclohexanol. The trans isomer (Guaranteed reagent, Tokyo Kasei Co.) and the cis isomer synthesized according to the literature[5] were used to prepare the isomeric mixture. The commercial isomeric mixture (Extra pure reagent, 23% cis content by GC, Tokyo Kasei Co.) was also used.

3-Methylcyclohexanol. The commercial isomeric mixture (Extra pure reagent, 67% cis content by GC, Tokyo Kasei Co.) was used.

4-Methylcyclohexanol. The trans isomer (Analytical reagent, Aldrich Chemical Co.) and the cis isomer (Analytical reagent, Aldrich Chemical Co.) were used to prepare the isomeric mixture. The commercial isomeric mixture (Extra pure reagent, 37% cis content by GC, Tokyo Kasei Co.) was also used.

Purification. Dielectric measurments are sensitive to water as an inpurity, so that all these alcohols were dried by refluxing over calcium hydride before distillation. These purities were checked using a Hitachi GC-063 gas chromatograph with a thermal conductivity detecter and a stainless-steel column (1m long, 3mm diameter) packed with PEG 20M.

Dielectric Measurements. The measurements were carried out using a ratio-arm transformer bridge (TR-1C, Ando Electric Co.) and a glass cell with a platinum concentric electrode over a frequency range from 100 Hz to 3 MHz. Dipole measurements were carried out by the Halverstadt-Kumler method[6] in CCl_4 using another more precise ratio-arm transformer bridge (TR-10C, Ando Electric Co.). The accuracy of the temperature control was maintained within 0.1 K. All data regarding dielectric relaxation were analyzed with a least-square method.

Viscosity Measurement. Measurements were carried out with an Ostwald-type viscometer calibrated with the "standard liquid" (Cosmo Oil Co.). The accuracy of the temperature control was maintained within 0.1 K.

Results and Discussion

Static Dielectric Constants and the Association. The

temperature dependences of static dielectric constants of 2-methylcyclohexanol and 4-methylcyclohexanol studied are shown in Fig. 1. There are linear correlations between the static dielectric constants and the reciprocal absolute temperature for the trans isomer of these two isomers, while small deviations from the linear correlation can be seen for the cis isomers. Such deviations have been frequently found in the neighborhood of the melting temperature. The melting temperature of a cis isomer is generally higher than that of the trans isomer.[7] The maximum point is found for *cis*-2-methylcyclohexanol, whose melting temperature is ca. 280 K.[8]

As is shown in Fig. 1, a very weak dependence of the dielectric constant on temperature was found for *cis*-2-methylcyclohexanol. This phenomenon is peculiar for the alcohols, i.e. associated molecules, though it is generally found for nonpolar molecules. Upon mixing one substance with an associated one, a correlation between the dielectric constant and its mole fraction maintains an experimentally linear relationship since the density is almost the same.[9] Figure 2 shows the change in the dielectric constants with the mixing

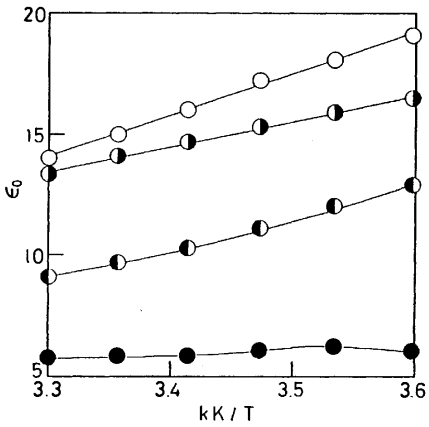

Fig. 1. Dielectric constants for some methylcyclohexanols as a function of T^{-1}. ○: *trans*-2-methyl, ◐: *trans*-4-methyl, ◑: *cis*-4-methyl, ●: *cis*-2-methyl.

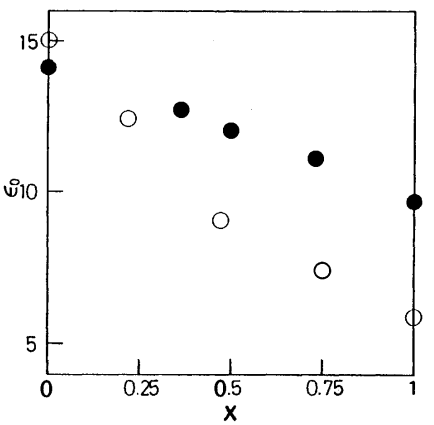

Fig. 2. Dielectric constants for some methylcyclohexanols as a function of x at 298 K. ○: 2-methyl, ●: 4-methyl.

ratio of the cis isomer and the trans isomer. x is the mole fraction of the cis isomer. A linear correlation was also found in a mixture of these two isomers. This fact shows that the cis isomer associates with the trans isomer and that such a self-association of these alcohols could also be confirmed by an IR spectroscopic study.

The dielectric constant generally depends on the temperature, density and dipole moment. For associated molecules, however, an estimation of the orientational angle between the two neighboring dipoles is important for a determination of the dielectric constant. The Kirkwood theory for liquid dielectrics includes this correlation factor, g, which is used to evaluate the dipole-dipole correlation:[10]

$$g = 1 + z\langle\cos\theta\rangle = \frac{9kTV}{4\pi N\mu^2}\,\frac{(\varepsilon_0-\varepsilon_\infty)(2\varepsilon_0+\varepsilon_\infty)}{\varepsilon_0(\varepsilon_\infty+2)^2}, \quad (1)$$

where z is the number of nearest-neighbor dipoles, θ the orientational angle between a dipole and its nearst neighbors, k the Boltzmann constant, T the absolute temperature, V the molar volume, N Avogadro's number, and μ the gas-phase dipole moment ε_0 and ε_∞ are, respectively, the static dielectric constant and the high-frequency limiting value of ε, and the bracket indicates the average over the ensemble. We used $\varepsilon_\infty=1.1\,n_D^2$ according to Dannhauser and Bahe,[11] and μ in CCl_4 solution instead of that in gas phase. Since z is not known for almost all organic molecules, g was used to estimate and discuss the dipole-dipole correlation. It is difficult to estimate the degree of aggregation of dipoles from g, but it gives a criterion for cluster formation. The calculated experimental g is shown in Table 1.

The g of both trans isomers in this table is larger than unity, indicating a parallel alignment of these dipoles. This phenomenon is similar to that of primary alcohols, which generally form a linear chain multimer of various lengths. On the other hand, the g of these cis isomers does not have the same characteristic as that of their trans isomers. The g of *cis*-4-methylcyclohexanol is larger than unity, that is the same case of the trans isomer. The g of *cis*-2-methylcyclohexanol, however, is smaller than unity, which indicates the possibility that *cis*-2-methylcyclohexanol forms a cyclic multimer.

In order to discuss the steric hindrance for the association through the hydrogen bonding, we took the

Table 1. Dielectric Properties for Some Methylcyclohexanols at 298 K

Isomer	d[a]/g cm^{-3}	ε_0	n_D	μ/D[b]	g
cis-2-Methyl	0.93181	5.85	1.4608	1.88	0.75

a) From Ref. 25. b) 1 D=3.3356×10^{-30} C m.

role of the conformation of these methylcyclohexanols into account.

Cyclohexane skeletons have been well-studied in stereo chemistry. The structure of such a molecule can be roughly divided into the two types of conformations: a boat and a chair form. The latter conformation is more stable than the former one. Here, we consider only the chair conformation while discussing the dielectric properties of this alcohol since this form is predominant at room temperature. A substituent has two positions: axial and equatorial. The former position has an "1,3-diaxial" interaction, a large steric repulsion of a methyl substituent with the two axial hydrogen atoms on the same side of a cyclohexane skeleton. For this reason a large substituent prefers the equatorial position to the axial one.

There have been many conformational studies of these methylcyclohexanols.[12-14] The predominant position of the two substituents is determined as follows: The hydroxyl group has an axial position and the methyl group, which is larger than hydroxyl group, has an equatorial position for the cis isomer, while both these substituents have an equatorial position for the trans isomer. Therefore, the cis isomer, having an 1,3-diaxial interaction, can be said to have a larger steric hindrance for the association than the trans isomer. 2-Methyl isomer evidently has a larger steric hindrance for the hydroxyl group than the 4-methyl isomer, which is considered to have the absence of a direct steric hindrance.[7]

Alcohols with a strong steric hindrance have the tendency to form a cyclic dimer or trimer.[15,16] The position of the methyl group attached to the same or the neighboring carbon with the hydroxyl group has been reported to make the g smaller than unity for the case of secondary alcohols.[3,4] Therefore, the g of *cis*-2-methylcyclohexanol is smaller than unity. However, that of *cis*-4-methylcyclohexanol, having the 1,3-diaxial interaction as well as *cis*-2-methylcyclohexanol, is larger than unity. It can be, therefore, considered that the steric hindrance of the 1,3-diaxial interaction enlarges the average dipolar orientation angle, though this hindrance is not sufficient to form a cyclic multimer.

It is strange to say that the larger the number of carbon atoms for the homolog of the primary alcohol, the larger is g.[17] This suggests that the steric hindrance is favorable for making the g larger upon forming a linear multimer. This may be the reason why *trans*-2-methylcyclohexanol has a larger g than *trans*-4-methylcyclohexanol. It is interesting to see how strong the association is sterically hindered to form the cyclic multimer.

Dielectric Relaxation. The typical dielectric relaxation for the methylcyclohexanol investigated is shown in Fig. 3. In general, the dielectric relaxation for monohydric alcohol is reported as a Debye type, formulated in Eq. 2, while a dielectric relaxation for diol and triol is reported as a Davidson-Cole type, formulated in Eq. 3:

$$\varepsilon^* = \varepsilon_0 + \frac{\varepsilon_0 - \varepsilon_\infty}{1 + i\omega\tau_m} \tag{2}$$

and

$$\varepsilon^* = \varepsilon_0 + \frac{\varepsilon_0 - \varepsilon_\infty}{(1 + i\omega\tau_m)^\beta} \tag{3}$$

where ε^* is the complex dielectric constant, ω the angular frequency, $\tau_m=(2\pi f_m)^{-1}$ the relaxation time, and β the Davidson-Cole parameter. The Davidson-Cole type is used in the following discussion because the standard deviation of the residual of the Davidson-Cole type is smaller than that of the Debye type with an analysis by the least-square method.

Fitted parameters are shown in Table 2. The β are nearly equal to unity, indicating a "Debye-like" behavior of the relaxation frequently reported for the

monohydric alcohols. The relaxation time of 2-methylcyclohexanol is larger than that of the 4-methyl isomer, but the dependence of that on the fraction of the cis isomer cannot be estimated because of a lack of data points. Activation parameters of the dielectric relaxation process are shown in Table 3. The activation energy and the preexponential factor of 2-methylcyclohexanol are larger than those of 4-methyl isomers, although they depend on the fraction of the cis isomer. The spectral shape parameters,[19] m and n, are shown in Table 4. m is the index of "correlation of the intercluster exchange of relaxation motions," and n is that of "the intracluster correlation of relaxation motions." These parameters of all the methylcyclohexanol investigated are approximately the same regardless of the fraction of the cis isomer; this fact shows that the motion of an intercluster exchange of the dipole is almost free and that the motion of the dipole in its local environment couples weakly.

The Debye-like behavior for monohydric alcohols is explained on "the dipole relaxation of clusters of alcohol molecules hydrogen-bonded with each

other."[20] The relaxation time of primary alcohols can be evaluated by Bertolini et al. using the hydrogen bond lifetime and the probability that the bond is randomly intact.[4] The relaxation time of secondary alcohols and tertiary alcohols, however, could not be evaluated; this suggests an additional intramolecular relaxation of dipoles with the intermolecular one.

Secondary and tertiary alcohols have the same tendencies for the dielectric relaxation in that the activation energy and the preexponential factor are larger than primary alcohols having the same number of carbon atoms, as shown in Table 5. At first glance, the activation energy and the preexponential factor become larger with the increasing size of the alkyl group and the increasing degree of branching. Our results in Table 3 are similar to this tendency with respect to the point of the degree of the branching. The large activation energy cannot be attributed to the additional intramolecular relaxation because the activation entropy of the relaxation of these methylcyclohexanols, ca. 400—500 J mol^{-1} K^{-1}, is too large for such an additional intramolecular relaxation motion of the dipole. There seems to be another reason for the large activation energy.

Crossely et al. found a large Eyring activation enthalpy, ca. 60—100 kJ mol^{-1} for the dielectric relaxation of some simple hydrocarbons at temperatures just above their glass temperatures, T_g.[28] They concluded that this phenomenon resulted from a dipolar cooperative reorientation in the amorphous clusters and that the activation enthalpy reflected the ability of the molecules to interact. However, the activation enthalpy of methylcyclohexane in their work is almost equal to that of 3- and 4-methylcyclohexanol which clearly have a larger interaction than methylcyclohexane.

The dielectric relaxation process, which can be regarded as a molecular rotation process, is often discussed in contrast with viscosity or a shear process. The activation energies of the shear process are also listed in Table 3. The dependence on the fraction of the cis isomer cannot be evaluated due to the small quantity to be measured. The difference between the dielectric activation energy and the viscous activation energy of 2-methylcyclohexanol is larger than that of 3- or 4-methyl isomer. The difference between the two activation energies may be explained by the difference of hydrogen-bond breaking and reforming mechanisms between rotation and translation. From this point of view, the larger activation energy and the longer relaxaton time of 2-methylcyclohexanol are attributed to the steric effect of the neighboring methyl group for the hydrogen bond as well as the association.

Surface Properties of Microcrystalline Hydrous Titanium Oxide as Obtained by Thermal Hydrolysis from a $TiCl_4$ Solution

Kenta Ooi,* Yoshitaka Miyai, Shunsaku Katoh, and Kazuhiko Sugasaka
Government Industrial Research Institute, Shikoku, 2-3-3 Hananomiya-cho, Takamatsu-shi 761
(Received January 20, 1988)

The surface properties of hydrous titanium oxides (HTiO's), as obtained by refluxing $TiCl_4$ or urea-containing $TiCl_4$ solutions at 373 K, were examined by means of nitrogen adsorption/desorption at 77 K and of fluoride ion adsorption. Their crystal phases and particle shapes were investigated by X-ray diffraction analyses and electronmicroscopic observations, respectively. The HTiO obtained from a 0.03 or 0.1 mol·dm^{-3} $TiCl_4$ solution was of an anatase type, consisting of small (about 10 nm) particles. They had pores that were 2 nm in radius, with an narrow size distribution. The HTiO obtained from a 1.0 mol·dm^{-3} $TiCl_4$ solution was of a rutile type, consisting of acicular particles. It had pores that were greater than 2 nm in radius, with a broad size distribution. All of the HTiO's obtained from ($TiCl_4$+urea) solutions were anatase types. The most probable pore radius increased from 1.9 to 3.6 nm with the increase in the initial $TiCl_4$ concentration from 0.03 to 1.0 mol·dm^{-3}. The surface properties of the anatase-type HTiO's were discussed based on the sizes and shapes of the primary crystallites and on their spatial distribution.

The adsorptive or catalytic activity of HTiO depends strongly on its surface properties. These surface properties themselves vary depending on the preparation method and conditions. There have been many studies of the surface properties of the HTiO's obtained through different methods of preparation.[1-20]

The thermal hydrolysis of titanium(IV) salt in solution is one of the most common methods for the preparation of HTiO. However, the physical properties of the HTiO precipitated vary widely, depending on the starting titanium(IV) salt compound and on the precipitation conditions.[14] Moreover, the addition of a water-soluble material during precipitation results in HTiO's with different physicochemical properties.[5] The addition of HCl helps to make a stabilized rutile structure, while the addition of sulfate ions accelerates anatase formation. The anatase formation can be explained by the fact that the formation of sulfate complexes ($Ti(OH)_3HSO_4$, $Ti(OH)_2HSO_4^+$) prefers the growth of a monofunctional complex of anatase.[16] Aqueous dispersions of monodispersed titanium dioxide spheres with modal diameters of 1 to 4 μm have been obtained by the thermal hydrolysis of highly acidic solutions of $TiCl_4$ in the presence of sulfate ions.[17] A method involving the addition of urea has also been tried[18] by analogy with the homogeneous precipitation method. The added urea stabilizes the anatase structure and depresses any change in the pore structure during heat aging.[19]

The HTiO's with high surface areas can be classified into two types in terms of their crystal phases: the amorphous and micro-crystalline types. The former is X-ray amorphous and can be thought to have a structure of a three-dimensional network of $-\overset{|}{\underset{|}{Ti}}-O-\overset{|}{\underset{|}{Ti}}-$ chains.[3] Therefore, its pore structure may depend on the degree of closslinking of the $-\overset{|}{\underset{|}{Ti}}-O-\overset{|}{\underset{|}{Ti}}-$ chains. The latter type has an X-ray diffraction pattern of anatase, rutile, or brookite, with a character of broad diffraction peaks. Since they are aggregates consisting of extremely small crystallites, their pore structures are controlled both by the size and shape of the primary crystallites and by their spatial distribution.[21]

In the present study, we investigated the surface properties of the HTiO's obtained through the thermal hydrolysis method. The effects of the initial concentration of $TiCl_4$ and of the addition of urea during thermal hydrolysis on the surface properties of HTiO were studied. The surface properties were examined by means of nitrogen adsorption/desorption at 77 K and of fluoride ion adsorption. Since the HTiO's obtained by this method are usually microcrystalline anatase or rutile, the difference in the pore structures was discussed based on a packing model for small spheres.

Experimental

Preparation of HTiO. A $TiCl_4$ solution of 0.03, 0.1, 0.3, or 1.0 mol·dm^{-3}, prepared by diluting a stock solution of 3.0 mol·dm^{-3} $TiCl_4$, was refluxed with vigorous stirring at 373 K. After 7 hours of reflux, a white precipitate which had thus been precipitated was left standing for 10 hours at room temperature, washed with water, air-dried, crushed, and sieved to a 200—300 mesh size. The products were named H-0.03, H-0.1, etc. so that the numbers corresponded to the starting $TiCl_4$ concentrations.

The concentration of the titanium(IV) ions in the reacting solution was determined by atomic absorption spectrometry in order to determine a given fraction of precipitated HTiO.

In the case of urea addition, HTiO's were prepared by the same procedure using solutions of urea-containing $TiCl_4$. The molar concentrations of urea were adjusted to twice those of $TiCl_4$. The products were named N-0.03, N-0.1, etc. as above.

The water, urea, and chloride-ion contents of the products were measured as has previously been reported.[19,20]

X-Ray Diffraction Analysis and Electronmicroscopic Observation. X-Ray diffraction analyses were made on a Rigaku-Denki D3F X-ray diffractometer using Cu $K\alpha$ radia-

tion. Transmission electronmicroscopic observations were carried out by use of a Hitachi H-800 electron microscope at 200 kV.

Nitrogen Adsorption/Desorption Isotherm. Nitrogen adsorption/desorption isotherms were obtained on a Carlo Erba 1800 Sorptomatic apparatus with samples outgassed for 4 hours below 10^{-3} mmHg (1 mmHg≈133.322 Pa) at 333 K. V_l-t plots were made from adsorption isotherms using de Boer's t-values (Al_2O_3 standard).[22] The pore-size distribution curves were calculated from the desorption branches using the method of Mikhail et al., assuming cylindrical pores.[23]

Fluoride Ion Adsorption. The amounts of the surface hydroxyl group were determined by means of fluoride ion adsorption from a acetic acid-sodium acetate buffer solution (pH 4.6)[24] using a fluoride ion-selective electrode.

Results and Discussion

Bulk Properties. The rate of HTiO precipitation was fast and was independent of the starting $TiCl_4$ concentration and of the urea concentration. More than 90% of the titanium(IV) ions were precipitated by heating for 1 hour.

The urea and chloride ion contents were less than 0.1% for all of the HTiO's. The water contents are given in Tables 1 and 2. The crystal phases varied from anatase (H-0.03, H-0.1), mixture of anatase and rutile (H-0.3), to rutile (H-1) with the increase in the initial $TiCl_4$ concentration in the case of $TiCl_4$ solutions (Fig. 1). The H-0.03 and H-1 samples correspond to the microcrystalline anatase and rutile, respectively, reported in a previous paper.[21] A previous paper showed a conversion of anatase phase into rutile during heat-aging at 353 K in the case of a 1.0 mol·dm^{-3} $TiCl_4$ solution.[19] The conversion proceeds by means of a dissolution/recrystallization mechanism. The concentrations of free titanium(IV) ions in

Symbols are the same as those in Table 1.

the mother solutions were measured in the present case, after a 3-hour reflux, as 1.9, 2.0, 10, and 13 mmol·dm^{-3} at the $TiCl_4$ concentrations of 0.03, 0.1, 0.3, and 1 mol·dm^{-3}, respectively. A comparison of the solubility data with the crystal phases of the HTiO's suggests that the conversion takes place at a $TiCl_4$ concentration above 0.3 mol·dm^{-3}, while only a reinforcement of the primary particles is dominant below 0.1 mol·dm^{-3}. The crystallite sizes calculated using the Scherrer equation[25] were about 5 nm for the anatase-type HTiO's (Table 1). In the case of the ($TiCl_4$+urea) solutions, all of the HTiO's showed the X-ray diffraction patterns corresponding to that of anatase (Fig. 2).

Electronmicrographs showed that the rutile type was an aggregate of acicular particles, while the anatase types were aggregates of extremely small, nearly spherical particles (Figs. 3a and 3b). The shapes of the particles differed slightly between N-1 and N-0.03; the particles were less spherical, and their boundaries were less clear for N-1. H-0.3 was a mixture of irregular-shaped particles about 100 nm in size and spherical particles about 10 nm in size.

Surface Properties of HTiO's Obtained from $TiCl_4$ Solutions. The nitrogen adsorption/desorption isotherms were classified as being the BDDT IV type for all of the samples (Fig. 4); this is a characteristic of mesoporous materials.[26] Hysteresis loops existed at a relative pressure of around either 0.5 or 0.9; this cor-

responds to the presence of two types of pores in these HTiO's. The BET surface area showed a tendency to decrease with an increase in the initial $TiCl_4$ concentration, probably because of the increase in the crystallite size. The V_l-t plots for H-1 and H-0.1 showed upward deviations from straight lines at $t>0.65$ and $t>0.54$ nm, respectively, due to the capillary condensation of nitrogen in the mesopores (Fig. 5). At a still higher value of t, the slope of the plot for H-0.1 tended to decrease because of the filling of the pores with liquid nitrogen. The V_l-t plots for H-0.03 and H-0.3 showed downward deviations at $t>0.57$ nm due to pore filling of nitrogen. The surface areas calculated from the slopes of the straight lines (St) agreed well with the corresponding BET surface areas (Table 1). The pore-volume distribution curves showed the presence of two types of pores: pores of a 2-nm radius with a narrow size distribution and pores with radii greater than 2 nm with a broad size distribution (Fig. 6). The former were found for the anatase-type HTiO's, and the latter, for the rutile-type HTiO. The difference in the crystal phase of the product may be responsible for the variation in pore structure in the case of $TiCl_4$ solution. The broad size distribution of the pores in the rutile-type HTiO may be caused by an irregular orientation of the rod-like particles in an aggregate.

The amounts of the surface hydroxyl group (N_{OH}) are given in Table 1. The surface densities of the hydroxyl group per unit area (D_{OH}) were calculated by using the S_{BET} values. The D_{OH} values were about 4

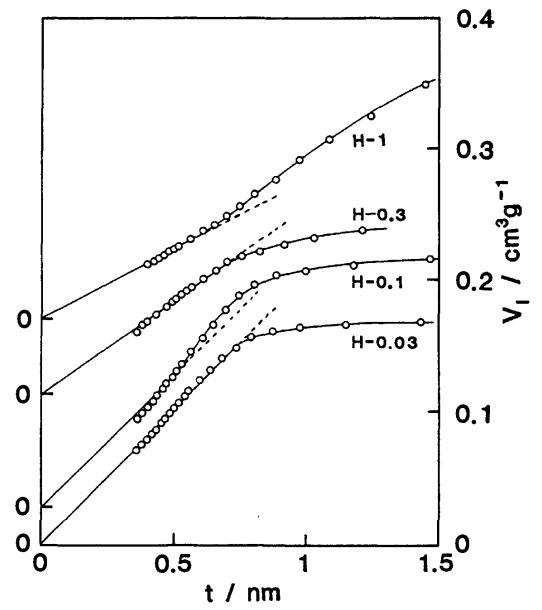

Fig. 5. V_l-t plots from nitrogen adsorption data.

OH/nm^2 for the anatase types, while it was slightly larger (4.5 OH/nm^2) for the rutile type (Table 1).

Surface Properties of HTiO's Obtained from ($TiCl_4$+ Urea) Solutions. The nitrogen adsorption/desorption isotherms also belonged to the BDDT IV classification for all of the HTiO's (Fig. 7). The hysteresis loop shifted to a higher relative pressure with an increase in the initial $TiCl_4$ concentration, indicating an increase in the pore size. The BET surface area increased slightly with an increase in the $TiCl_4$ concentration, while the pore volume increased markedly. The V_l-t plots showed upward deviations from straight lines at $t>0.57$ nm for N-0.1, N-0.3, and N-1 (Fig. 8). At a still higher value of t, however, the slopes of the plots for N-0.1 and N-0.3 tended to decrease. The V_l-t plot showed a downward deviation for N-

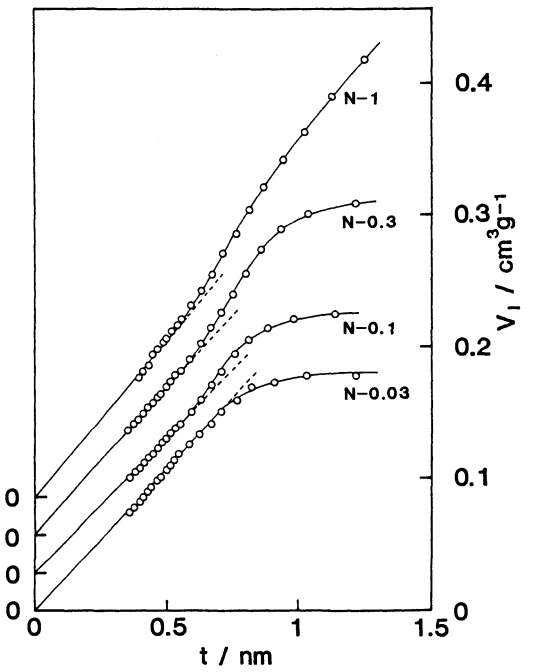

Fig. 8. V_1–t plots from nitrogen adsorption data.

0.03. The pore-volume distribution curves showed that the most probable pore radius (R_p) increased from 1.9 to 3.6 nm with an increase in the initial $TiCl_4$ concentration, accompanied by a broadening of the distribution curve (Fig. 9).

A previous study has shown that the crystal phase

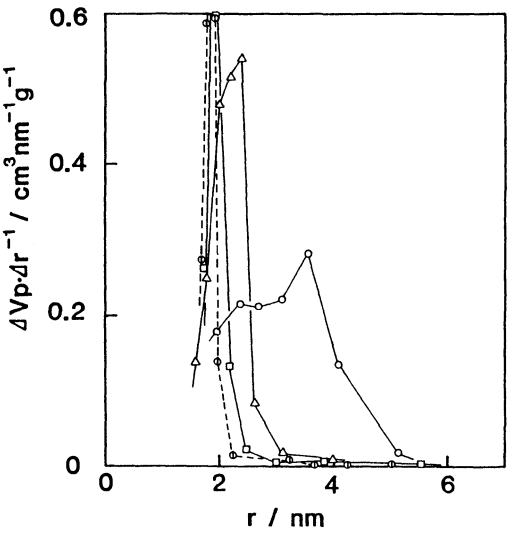

Fig. 9. Pore volume distribution curves. ○: N-1, △: N-0.3, □: N-0.1, ◇: N-0.03.

and pore structure of the precipitates are scarcely influenced by the step of heat-aging at 353 K in the case of a ($TiCl_4$+urea) solution.[19] Therefore, the pore structure is controlled mainly by the conditions during the step when the primary crystallites are precipitated and become an aggregate of a gel network. The increase in the porosity with the initial $TiCl_4$ concentration in the ($TiCl_4$+urea) system can be thought of as being due to the presence of urea at higher concentration. The addition of a water-soluble organic material before gel formation serves to provide a gel with a greater porosity.[12] Urea may play the same role.

Analysis Based on Packed-Sphere Model. The previous calculations of the surface areas of microcrystalline anatase and rutile showed that the BET surface areas correspond mainly to the external surface of the primary crystallites.[21] Therefore, their pore structures can be represented by the spatial distribution of the primary crystallites. The pore distributions of the anatase-type HTiO's could be analyzed by the use of a packed-sphere model, in which a system consisting of spherical particles of a uniform size was assumed.[27,28] According to this model, the radius of the circle (R') inscribed in the throat of the cavity among spheres can be calculated as a function of the cordination number (n) between the particles.[28] A crude estimation of the n-value can be derived from the porosity (P) of a material; this can be evaluated from the pore volume (V_p) and the particle density (ρ) as:

$$P(\%) = 100 \cdot V_p/((1/\rho) + V_p). \quad (1)$$

The porosity of the HTiO increased from 41 to 59% with an increase in the initial $TiCl_4$ concentration from 0.03 to 1 mol·dm^{-3} in the case of a urea-containing $TiCl_4$ system (the particle densities were assumed to be equal to that of anatase, ρ=3.8 g·ml^{-1})[29] (Table 3). This indicated a looser packing of the anatase crystallites with an increase in the initial

Table 3. Porosity (P), Coordination Number (n), and Pore Radius Evaluated by the Packed-Sphere Model

Sample	P	n	R'	R_p
	%		nm	nm
N-0.03	41	8	1.3	1.9
N-0.1	43	8		2.0
N-0.3	50	6		2.3
N-1	59	4—6	1.2—2.1	3.6

The packing model used was that of Avery and Ramsay.[28]
R': Radius of circle inscribed in the throat of a cavity, R_p: most probable pore radius in Fig. 9.

$TiCl_4$ concentration. The increase in the porosity corresponded to a decrease in the cordination number (n) from 8 to about 5.

The R' values could be calculated using the averaged particle radii, which could themselves be evaluated by studying the electronmicrographs of 100 particles (3.2 nm for N-0.03 and 2.9 nm for N-1). In the case of N-0.03, the calculated R' value agreed comparatively well with the most probable pore radius (R_p), as determined by the nitrogen isotherm (Table 3). This suggested the validity of the application of the packed-sphere model to anatase-type HTiO. However, the agreement between the R_p- and R'-values was not so good in the case of N-1; the R_p value was about twice as large as the R' value. The larger R_p value in N-1 may be due to an irregular packing of the crystallites compared to the theoretical packing of primitive cubic (n=6) or tetrahedral (n=4). The irregular packing could be presumed from the broadening of the pore distribution of N-1 in Fig. 9.

The above calculations suggest the suitability of the packed-sphere model for describing the pore structure of anatase-type HTiO when the packing of the microcrystallites is relatively compact ($n>8$). In the case of a looser packing ($n<6$), however, it may be necessary to consider the diversity of the coordination number in describing an appropriate packing image of the pore structure.

The authors are grateful to Hitachi, Ltd., for its helpful support of the electronmicroscopic observation.

(Received January 20, 1988)

The binding of 2-(4-hydroxyphenylazo)benzoic acid (HABA) to bovine serum albumin (BSA) was studied in a dilute phosphate buffer of pH 7.0 and ionic strength 0.014 at 25 °C. Binding measurements were made for both undefatted BSA and defatted BSA (the protein naturally contains 2.4—2.5 mol/mol fatty acid). A metachromasy band appeared at 480 nm at the expense of the original absorption band at 350 nm in the presence of BSA. An isosbestic point in the absorption spectra was observed in the vicinity of 380 nm only in the limited range of the molar mixing ratios of HABA to BSA (D_0/P_0), where the ratio was 1—10 in the above buffer, regardless of the absence and presence of fatty acids. However, the isosbestic point was not observed by any feasible change of the D_0/P_0 ratio in a buffer containing 0.1 M NaCl. This fact seemed to indicate that the binding nature depended on the ionic strength as well as the D_0/P_0 ratio. Then, binding measurements were carried out in the limited range of D_0/P_0 ratios in a dilute phosphate buffer. The amount of HABA bound to BSA was determined by curve-fitting for changes of the apparent molar extinction coefficient, ε, between 300 and 550 nm, assuming one class of binding site: that is, only two species (free and bound dyes) contributing to the absorption changes. The simulated curves of ε were in good agreement with those obtained experimentally. By the use of the Scatchard plot, the binding parameters were determined. The binding constant was larger for defatted BSA than for undefatted BSA, the values being of the order of 10^5 M^{-1}. The number of binding sites of HABA was 1.4—1.5, not being affected very much by the absence and presence of fatty acids.

The azo dye, 2-(4-hydroxyphenylazo)benzoic acid (HABA) is well-known to exhibit a new absorption band characteristically, when it binds to serum albumin, which generally serves as a carrier protein for a wide variety of substances.[1] Consequently, the mode of interaction between HABA and serum albumin has been attracting renewed interest. During the last two decades, the system of HABA and bovine serum albumin (BSA) has often been studied.[2-7] The exhibition of a new band has been attributed to the azo-hydrazone tautomeric transition of the dye induced upon its binding to the protein.[2-9] However, most of these studies have been carried out by changing the HABA concentration over wide ranges, from 10^{-6} or 10^{-5} to 10^{-3} M (1 M=1 mol dm^{-3}), at a constant BSA concentration in rather concentrated buffers. In the present work, the interaction depended on both the ionic strength of the buffer and the molar mixing ratio of HABA to BSA, D_0/P_0. An isosbestic point in the absorption spectra of HABA was observed only over a limited range of the D_0/P_0 ratios and only in the buffer of low ionic strength. Some important facts seem to have been overlooked, probably because most of the preceding studies regarding the interaction were made under the above-stated experimental conditions. The present results suggest that a certain chemical equilibrium in the binding system exists only within a particular range of D_0/P_0 ratios.

Experimental

The crystalline BSA was purchased from Miles Laboratories Inc.[10] The preceding studies concerning this system emphasized the importance of the purity of the protein.[6] Therefore, the BSA sample was purified by passing it through Pharmacia MONOQ HR5/5 (ionic-exchange media) and Superose 12 (gel filtration media) using a Pharmacia high-performance liquid chromatography FPLC. HABA was purchased from Tokyo Kasei Co. and was purified by recrystallization from methanol before use. The protein concentration was determined spectrophotometrically using $E^{1\%}_{1\,cm}$=6.8 at 280 nm.[11] The molar extinction coefficient of HABA was assumed to be 18800 at 350 nm. A sodium phosphate buffer of pH 7.0 was extensively used. The final concentrations of NaH_2PO_4 and Na_2HPO_4 in the buffer were 3.33 and 3.56 mM, respectively; the ionic strength of the buffer was 0.014.[10]

The content of fatty acids in the present BSA was determined to be 2.4—2.5 mol/mol by the Dole method.[12] The removal of fatty acids was carried out by an acid-charcoal treatment.[13] The BSA fractionated as described above was mixed with charcoal, the amount of which was approximately half of that of the protein in weight. The pH of the BSA–charcoal solution was lowered to 3 by the addition of 0.2 M HCl. After the solution was stirred at 0—2 °C for 4 days, the charcoal was then removed by centrifugation. The period of 4 days was determined on the basis of a relation obtained between the stirring time and the quantity of fatty acids remaining in the BSA treated by charcoal. The clarified solution was brought to pH 7.0 by the addition of 0.2 M NaOH, and then dialyzed against the phosphate buffer of pH 7.0.

Absorbance measurements were made at 25 °C with a Hitachi double-beam spectrophotometer U-3200.

Results and Discussion

The binding properties of HABA to serum albumin have been studied so far by equilibrium dialysis,[2,5,9] rotating-disk polarography,[14] ultrafiltration,[14] spectrophotometric analysis,[3,5,6] and gel chromatography[7]

at rather high ionic strengths using mostly 0.05—0.1 M phosphate buffers.[2-9] The HABA concentration was in the range 10^{-6} or 10^{-5} to 10^{-3} M and the BSA concentration in the range 10^{-5} to 10^{-4} M in these preceding studies. When HABA binds to serum albumin, it exhibits a metachromasy band at 480 nm at the expense of the original absorption band at 350 nm, as has been observed by Baxter[2] and Moriguchi et al.[3,4] They concluded that the absorption band at 480 nm is due to the formation of a hydrazone form of HABA;[2-4] Terada et al. have supported this conclusion.[6] There are two kinds of binding sites for HABA in the protein. Sakurai et al. have shown that the absorption bands at 350 and 480 nm originate in HABA bound to a non-metachromasy site and a metachromasy site of BSA, respectively.[5] They have concluded that there are, at least, 5 binding sites consisting of 1.5—2 metachromasy sites and 3.5—3 non-metachromasy sites (Fig. 1 in Ref. 5).

Figure 1 shows the absorbances of 1×10^{-5} M HABA at various BSA concentrations in the present dilute buffer. The absorbance at the metachromatic band clearly increased with an increase in the BSA concentration up to a protein concentration of 1×10^{-5} M,

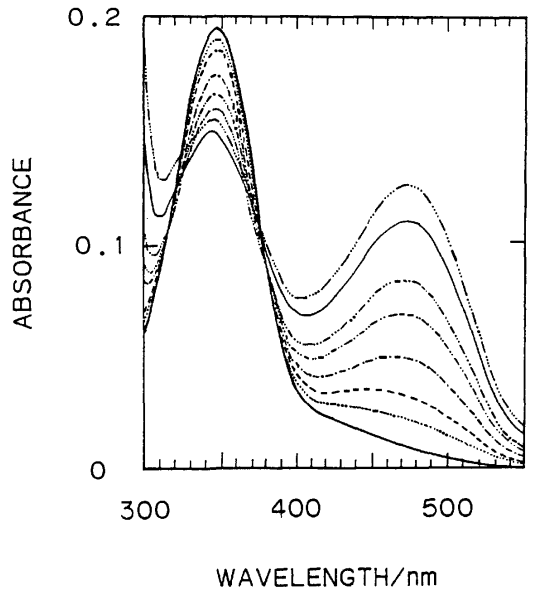

Fig. 1. Absorbance of 1.0×10^{-5} M HABA in the presence of defatted BSA of 0 (——), 1.0×10^{-6} (·····), 2.0×10^{-6} (– – –), 4.0×10^{-6} (–·–·–), 7.0×10^{-6} (–·····–), 1.0×10^{-5} (–·–·–·–), 2.0×10^{-5} (——), and 3.0×10^{-5} M (–·–·–·–) at 25°C.

showing an isosbestic point in the vicinity of 380 nm. However, when the BSA concentration was beyond 1.0×10^{-5} M against 1.0×10^{-5} M HABA, the spectrum did not pass through the isosbestic point. The absorption spectrum of HABA in 2×10^{-5} M BSA crossed the spectrum of HABA, itself, at a different wavelength from that of the isosbestic point obtained below 1×10^{-5} M BSA. The spectrum of HABA in 3×10^{-5} M BSA crossed the spectrum of HABA, itself, at another different wavelength. These results suggest that the HABA-BSA interaction, itself, differs with each other above and below this particular BSA concentration (1×10^{-5} M) at the constant HABA concentration: that is, the binding mechanism depends on the D_0/P_0 ratio.

Although absorbance measurements were also performed in a phosphate buffer of ionic strength 0.1 and in the present dilute buffer containing 0.1 M NaCl, the isosbestic point was not observed at any feasible concentration range of BSA at a constant concentration of HABA. In the present dilute buffer containing 0.1 M NaCl, the decreasing magnitude of the absorbance around 350 nm upon the addition of BSA was rather small (not shown) compared with that in a buffer without NaCl (Fig. 1). Figure 2 shows the effect of the added NaCl on the apparent molar extinction coefficients at 350 and 480 nm, ε_{350} and ε_{480}, in the presence of 1×10^{-5} M BSA. The value of ε_{350} increased and that of ε_{480} decreased with increasing NaCl concentration, indicating qualitatively that the increment of ionic strength inhibits the HABA binding to the protein.

The amount of HABA bound to BSA was determined spectrophotometrically by applying a curve-fitting method to the apparent molar extinction coefficient changes in the wavelength region 300—550 nm. This is the same method that has often been used to estimate the fractions of secondary structures, such as a helix in a polypeptide, using a reference circular dichroism spectra of the corresponding structures.[15-17] Assuming that only two species, the free HABA and the HABA bound to the protein, contribute to the absorption, the following relation is obtained:

$$\varepsilon_{obs}=f_{free}\,\varepsilon_{free}+f_{bound}\,\varepsilon_{bound},$$

where ε_{obs} is the experimentally observed apparent molar extinction coefficient of HABA in the presence of BSA; ε_{free} and ε_{bound} are the molar extinction coeffi-

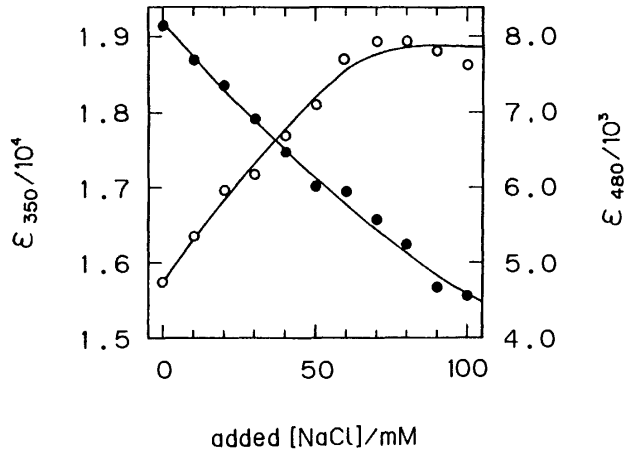

Fig. 2. Changes of extinction coefficients of HABA, ε_{350} (○) and ε_{480} (●) as a function of NaCl concentration added to the buffer of ionic strength 0.014 at 25°C. BSA concentration was kept at 1.0×10^{-5} M.

cients of the free and bound species, respectively. The notations of f_{free} and f_{bound} are fractions of the free and bound species, respectively, and $\sum f_i=1$. Since the solution of HABA obeyed Beer's law in the concentration range used here (in the order of 10^{-5} M), the value of ε_{free} was easily determined at each wavelength. However, it was actually impossible to obtain the value of ε_{bound} only by the spectrophotometrical method, since the absorbance of 1×10^{-5} M HABA continued to increase with increasing BSA concentration up to 1×10^{-3} M. Then, the values of ε_{bound} were determined by the combined use of the equilibrium dialysis at the particular ratios of D_0/P_0 which enable the absorption spectra of HABA to pass through the isosbestic point in Fig. 1. The binding quantity estimated by the equilibrium dialysis method corresponds to the total amount of HABA bound to both the metachromasy and non-metachromasy sites. However, the dye is considered to bind predominantly to the metachromasy site under the present experimental conditions, because the binding numbers obtained in the present work are similar to those already obtained spectrophotometrically so far (as stated below). When the total HABA concentration (free HABA+bound HABA) was 1×10^{-5} M in the presence of 1×10^{-5} M BSA, the concentration of bound HABA was determined to be 8.8×10^{-6} M by an interpolation of the binding data obtained by equilibrium dialysis. Thus, the value of ε_{bound} was obtained at an arbitrary wavelength. The simulated wavelength region covers the two characteristic absorption bands. This method seems to be more reliable than an estimation at a particular wavelength. Figure 3 shows an example of the fitting of the simulated molar extinction coefficient to the experimentally obtained value in the above-mentioned wavelength region. The calculated curve agrees excellently with the experimentally obtained curve. This good agreement and the existence of the isosbestic point might suggest that the dye binds to one class of binding site in BSA. The binding profile was also examined in a dilute buffer containing 0.1 M NaCl. In this case, the binding number of the dye to the defatted BSA was determined by changes of ε_{obs} between 400 and 550 nm, since the absorbance below 400 nm did not change systematically with a change in the BSA concentration in the presence of 0.1 M NaCl.

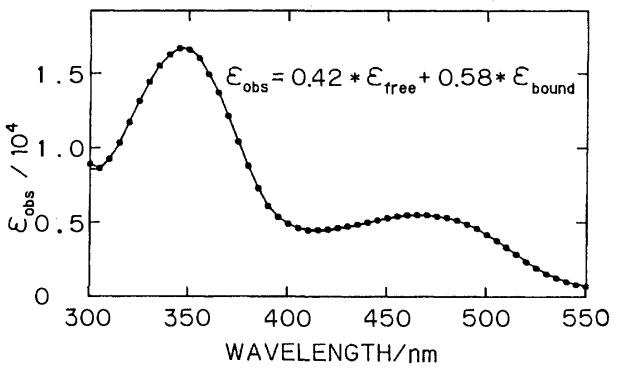

Fig. 3. Computed (——) and experimentally determined (-⊖-) molar extinction coefficient, ε_{obs}, of HABA in 5.3×10^{-6} M BSA. The scheme in the figure indicates that the computed spectrum consists of 42% of extinction coefficient of free HABA and 58% of extinction coefficient of bound HABA (see text). The binding quantity of HABA was calculated by the multiplication of the constant HABA concentration (1.0×10^{-5} M) by 0.58 and the subsequent division of it by the BSA concentration.

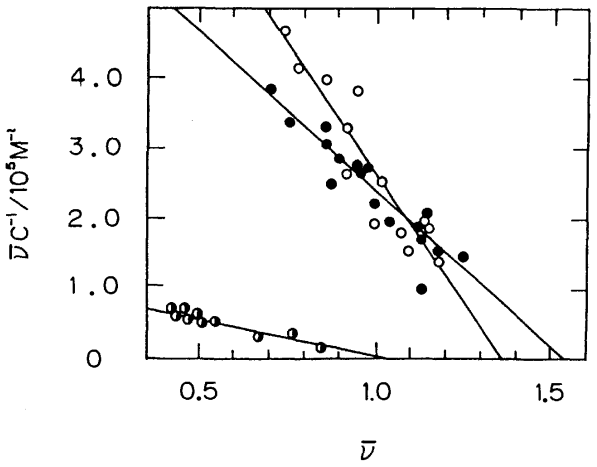

Fig. 4. Scatchard plot of binding of HABA to BSA. (O); defatted BSA, (●); undefatted BSA, (O); defatted BSA in 0.1 M NaCl. The binding data were taken in the range of D_0/P_0 between 1 and 10 at 25°C.

Scatchard plots for these three kinds of binding profiles are shown in Fig. 4. The intercept to the ordinate equals the product of nK (n: number of binding site, K: binding constant) according to the Scatchard equation. Each product was of the order of 10^5 M^{-1}. Accordingly, the values of K are of the order of 10^5 M^{-1}, being larger by one order than those so far reported.[2,3,5–7] The values of K and n are listed in Table 1.

The magnitude of K was influenced by the presence of 0.1 M NaCl. At a low ionic strength, the BSA molecule more or less expands. Thus, the protein is in a more expanded state at an ionic strength of 0.014 than at a higher ionic strength. The metachromasy of HABA has been considered to be caused by its binding to the hydrophobic interior of a BSA molecule.[2,4,6]

Table 1. Binding Parameters of HABA to BSA

	Native BSA	Defatted BSA	Defatted BSA in 0.1 M NaCl
K_{int}[a]/10^5 M^{-1}	4.55	7.44	1.05
n[b]	1.5	1.4	1.0

a) Intrinsic binding constant obtained from the Scatchard plot. b) Number of binding site obtained in the same plot.

The environmental change of the binding site due to the expansion might be the reason for the increase in K with a lowering of the ionic strength. As can be seen in Table 1, the value of K is appreciably larger for defatted BSA than for undefatted BSA. Spector and Imig have studied an effect of the palmitate concentration on HABA binding to human serum albumin by means of equilibrium dialysis.[9] In their Scatchard plot (Fig. 1 in Ref. 9), the intercept on the ordinate (corresponding to the value of nK) is clearly larger in the absence of palmitate than in its presence, indicating a similar effect of the fatty acid on K to that observed in the present work.

The values of n are substantially compatible with those obtained spectrophotometrically at higher ionic strengths by Sakurai et al. (Fig. 1 in Ref. 5) and by Terada et al.[6] As can be seen in Table 1, however, the addition of 0.1 M NaCl decreases the number of binding sites in defatted BSA. This might also be related to an expansion of the BSA molecule at a low ionic strength. On the other hand, the removal of the fatty acids causes no appreciable difference in the number of binding sites (Table 1). Thus, it is believed that HABA binds to the same metachromasy sites independently of the fatty acids, although the removal of the fatty acids increases the magnitude of K.

Using a medium of such low ionic strength, we encountered the fact that the isosbestic point was observed in the restricted range of D_0/P_0 ratios in a dilute buffer. Assuming only two species, a good agreement was observed between the curve of experimentally observed apparent extinction coefficients and that of simulated ones. These suggest that only one kind of binding site exists under the present restricted conditions. Therefore, the reason why such an isosbestic point is not observed at higher ionic strengths might be due to a simultaneous appearance of plural kinds of binding sites. The difference in the numbers of binding site classes seems to be caused by the expansion nature of BSA due to a decrease in the ionic strength. The binding nature of BSA appeared to be easily affected by the coexistence of fatty acids or electrolytes. We can state that this is one of the aspects of serum albumin which serves as a carrier protein for various substances.

This work was partly supported by a Grant-in-Aid for Scientific Research No. 61540342 to K. T. from the Ministry of Education, Science and Culture.

Proton Transfer and Aggregation Reactions in Aqueous Solutions of Isobutylamine and Isopentylamine Studied by Ultrasonic Methods

Sadakatsu NISHIKAWA,* Yukio YOSHIDA, and Ayumi NAKANO
Department of Chemistry, Faculty of Science and Engineering, Saga University, Saga 840
(Received January 29, 1988)

Ultrasonic absorption and velocity measurements have been performed in aqueous solutions of isobutylamine and isopentylamine at 25 °C. Two different relaxation phenomena are observed in these sample solutions. One of them, observed at a high frequency range, has been attributed to a proton transfer reaction of amines from the concentration dependence of the relaxation frequency and the maximum excess absorption per wavelength. The rate and thermodynamic constants have been determined for ion-pair formation and dissociation. The other, observed at a low frequency range becomes more striking as the hydrophobicity of the solute increases; it has been considered that the cause of the relaxation may be associated with a hydrophobic interaction. The formation of small aggregates has been speculated in both solutions. The rate and thermodynamic constants for the association and dissociation reactions of nonionized amine molecules have been estimated from the concentration dependences of the relaxation frequency and the maximum excess absorption per wavelength. Furthermore, the coupling effect of the two relaxation processes has been discussed briefly.

In a previous study[1] concerning the ultrasonic absorption mechanisms in aqueous solutions of isomeric butylamines, we have shown the existence of two different relaxational processes in the frequency range from 6.5 to 220 MHz from the measurements of the absorption coefficients as a function of the frequency. One of these processes has been attributed to a perturbation of the $R\text{-}NH_3^+ + OH^- \leftrightarrow R\text{-}NH_3^+ \cdots OH^-$ equilibrium. We have predicted from some experimental facts that the other may be due to the aggregation reaction of a nonionized solute.[2] The ultrasonic property due to this reaction is very dependent on the size of the hydrophobic groups. Atkinson et al.,[3] on the other hand, have analyzed the ultrasonic absorption results in an aqueous solution of *t*-butylamine on the basis of the hydrolysis and fluctuation model proposed by Romanov et at.[4] In order to clarify the justification of the interpretation of the ultrasonic absorption results in aqueous solutions of various amines over a wide concentration range and in order to substantiate the effect of the size of the hydrophobic groups on the ultrasonic absorption properties, the accumulation of many ultrasonic absorption results has been earnestly desired. The purpose of the present investigation is to report the ultrasonic absorption and velocity results for aqueous solutions of isobutylamine and isopentylamine as a function of their concentrations and to provide information about the dynamics of their solutions. Further, the analytical procedure of the relaxation times for the studies of fast reactions in solutions is examined for a system where two relaxation processes are observed in an equivalent time region.

Experimental

The isobutylamine and isopentylamine were purchased from Wako Pure Chemicals and then distilled. The desired concentrations of the aqueous solutions were prepared with doubly distilled water by weight.

The ultrasonic measurements were performed over the frequency range from 3.5 to 220 MHz by the use of semiautomatic pulse equipment connected with an 8 bit microcomputer. The computer programs had been developed so as to obtain the absorption spectrum elegantly. It is necessary to see the linearity of the attenuation vs. the moving distance of the transducer in order to obtain the absorption coefficient accurately. Such plots are seen on a display just after the measurements; when the error of the plots is less than 2%, the absorption coefficient is stored. Once the measurements at the available frequencies are performed, the computer program goes to the determination of the ultrasonic parameters. The details of the calculation procedure have been described elsewhere.[5]

The sound velocity was measured by a sing around method at 1.92 MHz and by use of an interferometer at 2.5 MHz. The accuracies are within 1 $m\,s^{-1}$. The densities of the solutions were determined by the use of a pycnometer, volume of which was about 4 cm^3. The pH's of the solutions were measured by means of a Hitachi-Horiba pH meter with a glass electrode. All the ultrasonic and pH measurements were carried out under a dry nitrogen gas in order to prevent the contamination of the solutions with carbon dioxide.

Results and Discussion

In order to interpret the ultrasonic absorption mechanisms, there are several procedures. The most effective one is to see how the absorption coefficient, α, depends on the measurement frequency, f.[6] When the absorption is related to the fluctuation in solutions attributable to the critical mixtures, as is occasionally seen in various amine aqueous solutions, the absorption would show unusual tendencies, e.g., an abnormal increase in the absorption coefficient when the system is close to the critical point. However, in the amine solutions studied here, the absorption did not show such trends in our frequency range and the values of α/f^2 tend to show a plateau at a low frequency range. Therefore, the absorption coefficients, as a function of the frequency in the aqueous solutions of the two amines, have been tested by the equation

associated with the usual relaxation process.[6]

$$\alpha/f^2=\sum_i A_i/[1+(f/f_{ri})^2]+B, \quad (1)$$

or

$$\mu=\sum_i A_i fc/[1+(f/f_{ri})^2], \quad (2)$$

where f_{ri} is the relaxation frequency for the i-th process. μ the excess absorption per wavelength, c the sound velocity, and A_i and B the constants. Some typical ultrasonic spectra for isopentylamine and isobutylamine are shown in Figs. 1 and 2 respectively.

For the isopentylamine aqueous solution, a double relaxational equation (i=2 for Eq. 1 or 2) has been found to fit the experimental data well in the concentration range from 0.4 to 1.77 mol dm^{-3}. In the range less than 0.4 mol dm^{-3}, the ultrasonic spectra are well-expressed by a single relaxational equation, i.e. i=1 in Eq. 1 or 2. The ultrasonic parameters, f_{ri}, A_i, and B have been determined by means of a nonlinear least-mean-square method; the solid curves indicate the calculated values. The parameters obtained are listed in Table 1.

For the isobutylamine solution, the spectra in the concentrations below 0.719 mol dm^{-3} are well fitted to the single relaxational equation. Further, with increase in the concentration the spectra still look like those associated with a single relaxation process. Figures 3 and 4 show the amplitude of the excess absorption, A, and the relaxation frequency, f_r which have been determined by a single relaxational equa-

The ultrasonic parameters indicated in parentheses for the solution of isobutylamine are those calculated by a single relaxational equation. Those indicated by the super asterisk are calculated using Eqs. 4 and 7.

tion as a function of the analytical concentration, C_o, for the isobutylamine solution. As may be seen in these figures, the excess absorption amplitude, A, increases suddenly around 1 mol dm^{-3} and goes through a maximum. Further, the relaxation frequency also indicates an unusual trend at around 1 mol dm^{-3}. Therefore, it is considered that the cause of the absorption in the high concentration range differs from that in the low concentration range. Therefore, it may be necessary to distinguish the multiple relaxation processes, which we will describe later.

Firstly, in order to analyze the excess absorption mechanisms in the two solutions, the absorptions in a relatively low concentration range (less than 0.4 mol dm^{-3} for isopentylamine and less than 1 mol dm^{-3} for isobutylamine) are considered. The characteristic properties of the ultrasonic absorption are that the relaxation frequencies increase monotonously with the analytical concentration and that the amplitudes of the excess absorption indicate a plateau, as may be

seen in Table 1. Such dependences have been observed in various amine solutions, and the absorptions have been well analyzed by the reaction kinetics of the hydrolysis.[1,2,7-9] As has been pointed out in a previous report,[1] the amine hydrolysis in aqueous media proceeds through an intermediate, which is expressed by the next equilibria:

$$\mathrm{R\text{-}NH_3^+ + OH^-} \underset{k_{21}}{\overset{k_{12}}{\longleftrightarrow}} \mathrm{R\text{-}NH_3^+ \cdots OH^-} \underset{k_{32}}{\overset{k_{23}}{\longleftrightarrow}} \mathrm{R\text{-}NH_2 + H_2O} \quad (3)$$

This reaction mechanism was originally proposed by Eigen.[8] When the relaxation frequencies associated with the above two steps are close to each other, the coupling effects on the relaxation frequencies and the amplitudes of the relaxations should be taken into account. However, the observed ultrasonic absorption spectra is clearly expressed by a single relaxational equation. When the coupling effect is considered, an unreasonable dissociation constant, K_b, is obtained, which has been described in detail in Ref. 1. Therefore, we have assumed that the observed relaxation phenomena are due only to a perturbation of the equilibrium of the first step in Eq. 3. The relation between the relaxation frequency and the reactant concentration is simply expressed as:

$$2\pi f_{r1} = \gamma^2([\mathrm{R\text{-}NH_3^+}]+[\mathrm{OH^-}])k_{12} + k_{21}, \quad (4)$$

where f_{r1} is the relaxation frequency observed in the higher frequency range and γ the ion activity coefficient which is calculated by the use of the Davies equation.[10] Figure 5 shows the plots of f_{r1} vs. $\gamma^2[\mathrm{OH^-}]$, the intercept and slope of which provide the rate constants. These good linearities confirm that the cause of the excess absorption is the hydrolysis of the amines. The rate constants obtained are tabulated in Table 2. The dissociation constant, K_b, is related to each equilibrium constant as

$$K_b = K_{12}/(1+K_{32}^{-1}) \quad (5)$$

where $K_{12}=k_{21}/k_{12}$ and $K_{32}=k_{32}/k_{23}$. Therefore, K_{32} may be calculated; it is also shown in Table 2. The relation between the relaxation frequency and the analytical concentration is derived, under the same assumption, as:[1]

$$2\pi f_{r1} = k_{12}[-K_b + (-K_b^2 + 4\gamma^2 C_o K_b)^{1/2}] + k_{21}. \quad (6)$$

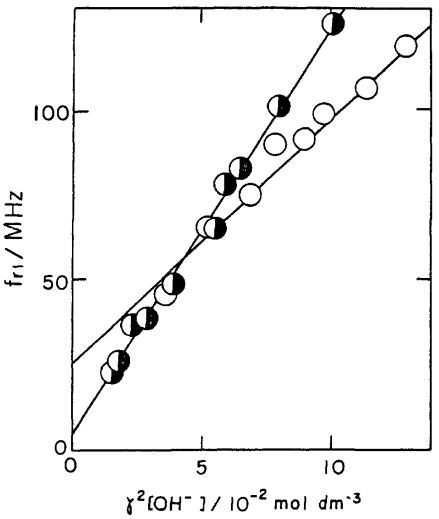

Fig. 5. The plots of f_{r1} vs. $\gamma^2[\mathrm{OH^-}]$ for the analysis of the proton transfer reaction. ◑: isopentylamine, ○: isobutylamine.

Using this equation, it is possible to estimate whether or not the above interpretation is reasonable. The dissociation constants, K_b, have been calculated; they are close to those in the literature.[11]

Another important parameter obtained by the ultrasonic absorption and velocity measurements is the maximum excess absorption per wavelength, μ_{m1};[6]

$$\mu_{m1} = 0.5A_1 f_{r1} c = \pi\rho c^2 \Gamma(\Delta V_1 - \alpha_p \Delta H/\rho C_p)^2/2RT, \quad (7)$$

where ρ is the solution density, ΔV_1 the standard volume change of the reaction, ΔH the standard enthalpy change of the reaction, α_p the thermal expansion coefficient at the high frequency limit, C_p the specific heat, and Γ the concentration term, which is expressed for the reaction under consideration as:

$$\Gamma = \{1/[\mathrm{R\text{-}NH_3^+}] + 1/[\mathrm{OH^-}] + 1/[\mathrm{R\text{-}NH_3^+ \cdots OH^-}]\}^{-1}. \quad (8)$$

Since the enthalpy term can be quite small compared with the volume term for proton transfer reactions in general, the enthalpy term is neglected. As a result, the plots of μ_{m1} vs. $\rho c^2\Gamma$, which are shown in Fig. 6, provide the standard volume change of the reaction. The results are also given in Table 2. The volume changes thus obtained are very close to those for other amine hydrolysis obtained by use of the ultrasonic method.[8]

Table 2. The Rate and Thermodynamic Constants for Proton Transfer Reaction in Aqueous Solutions of Isopentylamine and Isobutylamine at 25 °C

Solute	$10^{-10}\,k_{12}$ / mol^{-1} dm^3 s^{-1}	$10^{-8}\,k_{21}$ / s^{-1}	K_{32}	$10^4\,K_b$[a] / mol dm^{-3}	ΔV_1 / cm^3 mol^{-1}
Isobutylamine	2.3	1.7	0.035	2.5 (3.3)	27
Isopentylamine	3.7	0.39	0.51	3.7 (4.4)	26

a) The dissociation constants have been determined from the ultrasonic absorption measurements using Eq. 6. The values in parentheses are those in the literature.[11]

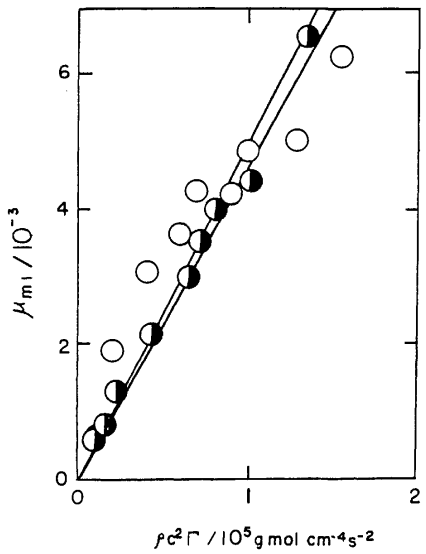

Fig. 6. The plots of μ_{m1} vs. $\rho c^2\Gamma$ for the determination of the standard volume change of the reaction. ◑: isopentylamine, O: isobutylamine.

However, they seem to be slightly larger than those obtained by the static method.[12] This might be because the latter are the over all results for the hydrolysis reaction, while the former are those for only the first step of the ion-pair formation process. The forward rate constants are reasonable for diffusion controlled reactions in the aqueous media. The equilibrium constant, K_{32}, which is smaller than unity, indicates that the intermediate concentration is small.

Secondly, the excess absorption mechanism in the concentrated solutions will now be considered. This phenomenon is observed in the lower frequency range. In the analysis of the absorption spectra, it is now necessary to distinguish the multiple relaxations. When two relaxation frequencies are far apart in a measured frequency range, it might be suitable to analyze the experimental results using eigher Eq. 1 or 2, as i=2. This may be appropriate in the case of the isopentylamine aqueous solution. The calculated ultrasonic parameters are listed in Table 1 in the concentration range above 0.6 mol dm^{-3}. However, for aqueous solutions of isobutylamine, the spectra look like a single relaxation one, so the above procedure for the determination of the ultrasonic parameters is not adequate. The parameters calculated using the single relaxational equation are indicated in the parentheses in Table 1 for the concentration range above 1 mol dm^{-3}. Fortunately, the excess absorption associated with the hydrolysis, which is observed in the higher frequency range and in the dilute solutions, may be expected to take place also in the concentrated solutions. Therefore, once the concentrations of the reactants for the hydrolysis are determined, the amplitude of the excess absorption and the relaxation frequency can be predicted by the use of Eqs. 4, 7, and 8. We have, then, assumed that the ultrasonic absorption due to the hydrolysis should be subtracted from the experimental data. As a result, it is possible to see if the residual absorptions fit Eq. 1 or 2. It is found that they have been well-analyzed by the single relaxational equation. The ultrasonic parameters obtained in this way are listed in Table 1 for the isobutylamine solutions in the concentration range above 1.13 mol dm^{-3}. Figure 7 shows an example of an absorption in which the two relaxation processes in the solution are distinguished. The experimental values all fit the calculated curves perfectly. There is some experimental evidence[2] concerning the excess absorption under consideration. (1) Such excess absorption is not observed in the aqueous solutions of propylamine and ethylamine. (2) The amplitude of the excess absorption increases and then decreases with the concentration; this is the so called "PSAC" (peak sound absorption concentration). This phenomenon becomes more striking with an increase in the hydrophobicity of the solute and is also observed in aqueous solutions of alcohols and ethers. (3) In an orgaic solvent, however, it is not found. (4) When the solute is ionized, the excess absorption disappears. These facts lead us to predict that the excess absorption may be associated with the hydrophobic effect of the nonionized solute molecules. The most plausible mechanism seems to be a molecular aggregation reaction by means of the hydrophobic interaction, which might be close to the micelle formation of surface active agents. However, such big micelles may not be formed because the hydrophobic groups of isobutylamine and isopentylamine are not very large. Actually, there have been several theories[13,14] to interpret the micelle formation

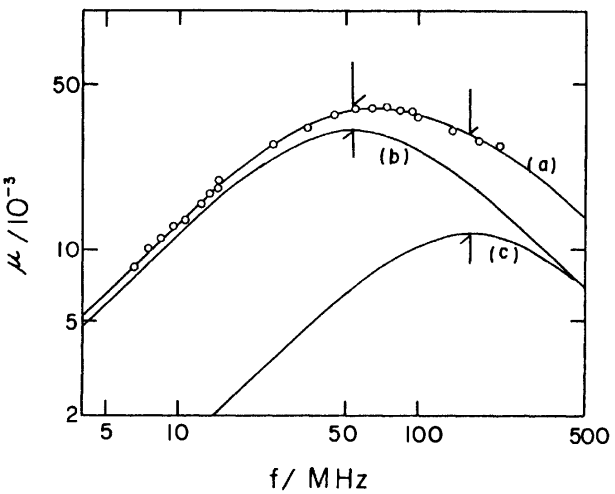

Fig. 7. The frequency dependence of the excess absorption per wavelength for 1.59 mol dm^{-3} isobutylamine aqueous solution. O's are the experimental values. The curve (c) is the calculated excess absorptions per wavelength associated with the proton transfer reaction and the curve (b) is those associated with the aggregation reaction. The solid curve (a) is the sum of the two relaxational curves, (b) and (c).

and breakage kinetics. However, they all assume the distribution of the aggregates, which is only applicable when the aggregation number is quite large. Therefore, we will simply consider the perturbation of the following equilibrium by the sound wave:

$$nA \underset{k_{43}}{\overset{k_{34}}{\longleftrightarrow}} A_n, \tag{9}$$

when n is the aggregation number. The relation between the relaxation frequency and the reactant concentration is given by the next equation:[15,16]

$$2\pi f_{r2} = 1/\tau = k_{34}n^2[A]^{(n-1)} + k_{43}, \tag{10}$$

where τ is the relaxation time and [A] the equilibrium concentration of the free nonionized solute. If the equilibrium constant (dissociation constant), K_b, in the concentration range is still satisfactorily expressed by $K_b=\gamma^2[R\text{-}NH_3^+][OH^-]/[R\text{-}NH_2]$, it is possible to determine the monomer concentration, [A], from the pH measurement, because the two equilibrium constants in Eq. 3 have been determined. Then, it may be possible to estimate the rate constants using an appropriate aggregation number, n. The plots of f_{r2} vs. $[A]^{(n-1)}$ are shown in Fig. 8. The best straight lines have been obtained for the aqueous solution of isobutylamine when n=4 and for that of isopentylamine when n=5. For the isobutylamine solution, the forward and backward rate constants have been determined from the slope and the intercept. They are listed in Table 3. However, the intercept of the plots for the isopentylamine solution is very close to zero. Therefore, it is not suitable for determining the backward rate constant. Equation 10 is also expressed in a different form with the analytical concentration as follows:[16]

$$2\pi f_{r2} = k_{43}n^2C_o/[A] + (1-n)k_{43}. \tag{11}$$

If the above procedure is correct, the same rate constant may be determined by the use of Eq. 11. For the isobutylamine solution, the values of k_{43} have been determined to be 2.7×10^8 s^{-1} from the slope and 3.0×10^8 s^{-1} from the intercept; these values are very close to that in Table 3. For the isopentylamine solution, the values have been determined to be 1.5×10^7 s^{-1} and 1.4×10^7 s^{-1} from the slope and the intercept respectively; the mean values are listed in Table 3.

Now, the concentration dependence of the maximum excess absorption per wavelength, μ_{m2}, will be explained. It is derived as follows:[16]

$$\mu_{m2} = \pi\rho c^2(\Delta V_2)^2 k_{34}[A]^n\tau/2RT, \tag{12}$$

where ΔV_2 is the standard volume change of the aggregation reaction. For simplicity, only the volume relaxation has been assumed. The plots of $\ln(\mu_{m2}/\rho c^2\tau)$ vs. $\ln[A]$ provide the aggregation numbers, which have been found to be 3.7±0.2 for the isobutylamine solution and 4.9±1.2 for the isopentylamine solution. These results also confirm that the cause of the excess absorption is the aggregation reaction by the nonionized solute molecules. The standard volume changes of the reaction, ΔV_2 have been calculated with the help of Eq. 12; they are listed in Table 3, along with the results for butylamine[16] and pentylamine[2] solutions. As may be seen in the table, the association rate constant tends to increase with an increase in the hydrophobicity of the solute. On the other hand, the dissociation rate constant seems to decrease with an increase in the carbon number. These results may reflect the stability of the aggregate. Cabani et al.[17] have studied in detail the volumetric properties in aqueous solutions of various nonelectrolytes including amines. They have speculated a presence of the solute-solute interaction of butylamines in aqueous solutions. We consider that such interacting molecules may corre-

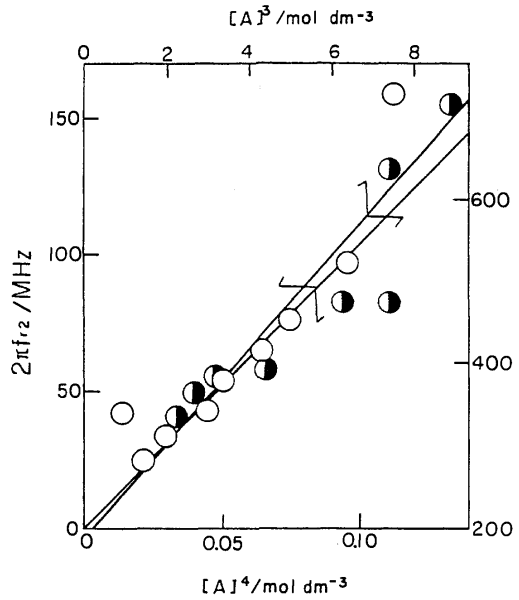

Fig. 8. The plots of $2\pi f_{r2}$ vs. $[A]^{(n-1)}$ for the two aqueous solutions. ◑: isopentylamine, ○: isobutylamine.

Table 3. The Rate Constants for the Aggregation Reaction for Aqueous Solutions of Butylamines and Pentylamines at 25 °C

Solute	n	$10^{-6}\,k_{34}$ / $(\text{mol}^{-1}\,\text{dm}^3)^{n-1}\,\text{s}^{-1}$	$10^{-7}\,k_{43}$ / s^{-1}	ΔV_2 / $\text{cm}^3\,\text{mol}^{-1}$	Reference
Isobutylamine	4	3.7	28	19	This work

Butylamine	4	2.2	9.0	14	16
Pentylamine	5	4.7	3.0	17	2

spond to the aggregate under consideration.

As has been described previously, the coupling effect of the two reactions should be taken into account, as the processes of the hydrolysis and the aggregation reaction have been observed experimentally in the equivalent time range. The reaction mechanisms under consideration may be generally expressed as follows when the two reactions shown by Eqs. 3 and 9 are taken into account.

$$\mathrm{R\text{-}NH_3^+ + OH^- \underset{k_{21}}{\overset{k_{12}}{\longleftrightarrow}} R\text{-}NH_3^+ \cdots OH^- \underset{k_{32}}{\overset{k_{23}}{\overset{H_2O}{\longleftrightarrow}}}}$$

$$\mathrm{R\text{-}NH_2 \underset{k_{43}}{\overset{k_{34}}{\longleftrightarrow}} \frac{1}{n}(R\text{-}NH_2)_n}. \qquad (13)$$

As has been explained, the ultrasonic relaxation process due to the hydrolysis has been well-interpreted on the basis of the fact that the second step in the above reaction scheme may not affect the first step very much. We consider that the second step may be too fast to couple with the first step, as the second step is the intramolecular proton exchange. In our time region, the second step may be estimated to be in the steady state. The third step, associated with the aggregation reaction, is observed in a lower frequency range than the first step. Therefore, the third process may not be so affected by the second step. That is, the independent procedures of absorption analysis may be appropriate for the aqueous solutions of amines investigated in this study.

New Mesomorphic Compounds: *N,N',N''*-Trialkanoyl-2,4,6-trimethyl-1,3,5-benzenetriamines

Yukimasa HARADA and Yoshio MATSUNAGA*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received February 8, 1988)

The homologous series of *N,N',N''*-trialkanoyl-2,4,6-trimethyl-1,3,5-benzenetriamines has been prepared. The viscous birefringent melts are given by the butyryl to hexadecanoyl derivatives. The X-ray diffraction pattern recorded for the octanoyl derivative and the higher homologous members consists of two sharp inner peaks and a broad outer one assignable to the 100, 110, and 001 reflections respectively, indicating that the phase is hexagonal disordered columnar (D_{hd}). A more-structured high-temperature phase is displayed at lower temperatures by the nonanoyl to hexadecanoyl derivatives.

A number of single compounds composed of disk-like molecules are known to form stable or metastable mesophases. The first series, reported by Chandrasekhar et al. in 1977, consists of three homologous members of hexakis(alkanoyloxy)benzenes.[1] The hexaalkoxytriphenylenes, discovered by Billard et al., constitute the second series.[2] These disk-like molecules are made of a planar rigid core fully surrounded by a planar ring of paraffinic chains. Nevertheless, our earlier study revealed that *N,N',N''*-trialkyl-1,3,5-benzenetricarboxamides (**1**), the molecule of which has only three long alkyl groups and is far from the shapes of discogens discovered to date, can exhibit hexagonal disordered columnar (D_{hd}) mesophases.[3]

In this paper, we wish to describe a new series of mesomorphic compounds designed on the basis of their isomers: *N,N',N''*-trialkanoyl-1,3,5-benzenetriamines. Since the enthalpy change upon melting of *N,N'*-dioctadecanoyl-1,3-benzenediamine, 81 kJ mol^{-1}, is larger by about 70% than that of *N,N'*-dioctadecyl-1,3-benzenedicarboxamide,[4] the appearance of a mesophase in the above-mentioned isomeric compounds does not seem highly probable. However, the enthalpy change upon a transformation into an isotropic liquid can be considerably reduced by methyl substitution, as disclosed also by the same work. For example, *N,N'*-dioctadecanoyl-2-methyl-1,3-benzenediamine is transformed into an isotropic liquid with an enthalpy change of 26 kJ mol^{-1} and the corresponding 2,4,6-trimethyl compound with 0.7 kJ mol^{-1}. Consequently, *N,N',N''*-trialkanoyl-2,4,6-trimethyl-1,3,5-benzenetriamines (**2**) seemed to be good candidates for new mesomorphic compounds.

Experimental

Materials. Trinitromesitylene was prepared by the nitration of mesitylene with a mixture of concentrated sulfuric acid and fuming nitric acid.[5] The product was reduced with metallic tin and concentrated hydrochloric acid. The reaction between 2,4,6-trimethyl-1,3,5-benzenetriamine and acyl chloride was carried out in benzene by the addition of pyridine. The compounds were purified by repeated recrystallization from appropriate solvents: methanol for the propanoyl to octanoyl derivatives, ethanol for the nonanoyl to dodecanoyl derivatives, and mixtures of benzene and ethanol for the remaining two. The results of elemental analysis are in good agreement with the composition of the desired compounds. For example, Found: C, 71.79; H, 10.19; N, 8.33%. Calcd for $C_6(CH_3)_3(NHCOC_6H_{13})_3$: C, 71.81; H, 10.24; N, 8.37%.

Measurements. Calorimetric, X-ray, and NMR measurements were made as reported in our previous work.[4]

Results and Discussion

The compounds prepared for this investigation are listed in Table 1 along with their transition temperatures and the associated enthalpy changes. By an examination using a polarizing microscope the appearance of viscous birefringent melts was noted with the butyryl to hexadecanoyl derivatives. In addition,

another high-temperature phase, tentatively called a mesophase because of low rigidity, was observed at lower temperatures for the nonanoyl to hexadecanoyl derivatives. In this table, K, M_1, M_2, and I stand for crystalline, mesophases appearing at higher and lower temperatures, and isotropic phase respectively.

The mesophases (M_1) of the present series are thermally much more stable than those of the previously studied isomeric series **1**, the difference in the transition temperature between the corresponding members being greater than 100 °C. This stability enhancement may be ascribed to an increase in the intermolecular interaction by the substituents $NHCOC_nH_{2n+1}$ outweighing the decrease by three methyl groups. The steady and rather drastic falling of melting point (K-M_1 or K-M_2 transition temperature) is noted as the series is ascended. Nonetheless, its lowest temperature is comparable with the highest melting point observed for series **1**. The clearing point (M_1-I transition temperature) is also lowered by the increase of alkyl chain length, up to the octanoyl derivative, but no consistent variation has been found for the higher homologous members. Because of the high clearing point, compounds **2** are not stable above this temperature and the reversible transition cannot be recorded by calorimetry. The focal conic texture may be observed when the M_1 phase, heated to relatively high temperatures, is cooled. Finally, it may be added that the enthalpy change at the clearing point is much larger than that given by the corresponding *N,N'*-dialkanoyl-2,4,6-trimethyl-1,3-benzenediamine, reflecting the intermolecular interaction strengthened by the introduction of an extra $NHCOC_nH_{2n+1}$ group to the molecule.

Since the high-temperature phases of the lower homologous members are located at temperature ranges too high to carry out X-ray measurements, the diffraction patterns were recorded for the octanoyl to hexadecanoyl derivatives. The patterns observed with the unoriented M_1 phases are similar to those reported for compounds **1**.[3] The sharp innermost peak is strong and is accompanied by a weak peak, the spacing of which is about $1/\sqrt{3}$ times that given by the innermost peak. This ratio is characteristic of a hexagonal lattice. Such a symmetry may be achieved by the rotation of the molecular core around the columnar axis, even if the molecule has only three alkyl groups. The innermost peak may be assigned to the 100 reflection and the other one to the 110 reflection. The two spacings defined by these peaks are independent of the temperature. They increase linearly with the alkyl chain length. The spacing d_{100} given by the octanoyl derivative is 1.48 nm and that given by the hexadecanoyl derivative is 1.93 nm. A broad peak located at a large Bragg angle gives a spacing of about 0.46 nm throughout the series. This spacing is characteristic of the melted state of the paraffinic moieties in mesophases and gives the average stacking distance between

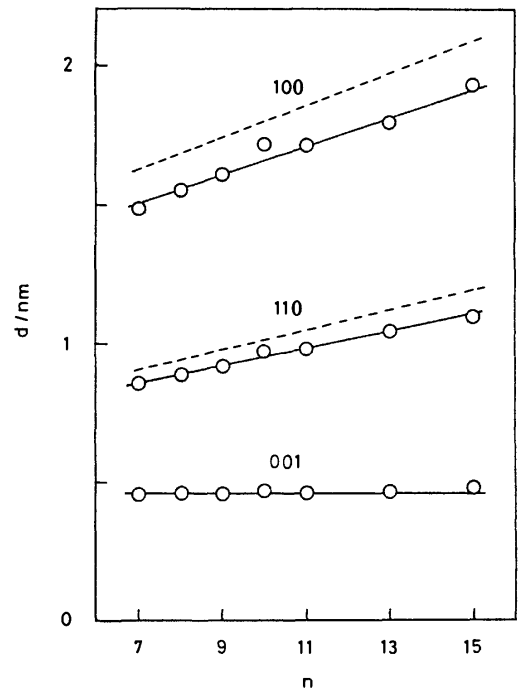

Fig. 1. Plots of spacings measured in M_1 phases against the number of carbon atoms in the alkyl group for compounds **2**. Broken lines indicate the corresponding spacings of compounds **1**.

the molecular planes irregularly spaced in a column. Thus, the observed feature is of the hexagonal disordered columnar (D_{hd}) structure. The M_1 phase, given by the heptanoyl derivative, is probably of the same nature; however, those exhibited by the butyryl to hexanoyl derivatives may be more-structured because of about twice larger enthalpy changes upon the transformation into an isotropic liquid.

In Fig. 1, the broken lines represent the spacings d_{100} and d_{110} plotted against the number of carbon atoms in the alkyl group measured for the mesophases of compounds **1**.[3] The spacings in the present series are consistently shorter than those of series **1**. For example, the spacing d_{100} of the octanoyl derivative (n=7) is 1.48 nm and that of the heptyl derivative in series **1** is 1.63 nm. The former value is essentially the same as that found for hexakis(octanoyloxy)benzene, 1.50 nm, reported by Chandrasekhar et al.[1] On the basis of these differences in the spacing, one might suggest that the alkyl chains in the present series of compounds are conformationally more disordered than those in series **1**. The enthalpy changes at the clearing point are 15 kJ mol^{-1} for the present compound, 12 kJ mol^{-1} for the corresponding compound **1**,[3] and 19 kJ mol^{-1} for the hexasubstituted compound.[1] It must be noted that the clearing point of the present compound, 328 °C, is appreciably higher than that of the previously studied one, 214 °C, and also that of the compound reported by Chandrasekhar et al., 83.4 °C. Therefore, the entropy changes at the clearing point in the former two are

actually close to each other but are smaller by a factor of two than that for hexakis(octanoyloxy)benzene. Three long alkyl groups carried by the molecules in our two series appear to be disordered nearly to the same extent in the mesophases; therefore, the shorter spacing may imply that the alkyl groups in series **2** are more interdigitated than those in series **1**.

The diffraction pattern recorded for the M_2 phase of the hexadecanoyl derivative shows four sharp peaks and two relatively broad ones. The sharp peak at the lowest Bragg angle is accompanied by its second and third order reflections. The spacing is markedly longer than that shown by the corresponding M_1 phase, namely 4.25 versus 1.93 nm. There are three peaks at relatively high Bragg angles giving spacings of 0.42, 0.46, and 0.55 nm respectively. The second one is sharp and the other two are rather broad. The shortest and the second shortest spacings are common to all the diffraction patterns of the M_2 phases. The spacing given by the innermost peak decreases almost linearly by the decrease in the alkyl chain length and 2.73 nm is obtained for the nonanoyl derivative. The diffraction pattern becomes more complicated as the series is descended. A few extra weak peaks appear in the intermediate Bragg angles. The phase is viscous but may have a three-dimensional lattice.[7] The innermost peak in the diffraction pattern recorded for the crystalline phases gives a spacing a little longer than that of the M_2 phase of the same compound; for example, 2.78 versus 2.73 nm for the nonanoyl derivative and 4.02 versus 3.81 nm for the tetradecanoyl derivative.

The conformational melting of the alkyl chains in the M_1 and M_2 phases is firmly supported by the small second moments of the broad-line proton NMR spectra (the mean-square widths of the resonance line), $<\Delta H^2>$, recorded above the melting point. The tetradecanoyl derivative gives a moment of about 12 G^2 (1 $G=10^{-4}$ T) at room temperature. The value decreases continuously to about 3 G^2 by the melting point and then rather abruptly to 0.5 G^2 of the M_2 phase. The moment remains at this value up to the M_2–M_1 transition temperature. The value as small as 0.03 G^2 observed for the M_1 phase is close to those observed for the mesophases of *N,N′,N″*-trioctyl- and *N,N′,N″*-trihexadecyl-1,3,5-benzenetricarboxamides and also *N,N′*-dihexadecanoyl-2,3,5,6-tetrakis(hexadecanoyloxy)-1,4-benzenediamine.[3,6] Their X-ray diffraction patterns are essentially the same and are attributable to the hexagonal disordered columnar structure.

Some Aspects through Sedimentation Study on the Extremely Elongated Micelle Formed in Cationic Surfactant-Aromatic Additive Systems

Yuko SAKAIGUCHI and Hirotaka HIRATA*
Niigata College of Pharmacy, Department of Physical Chemistry, 2-13-5 Kamishin'eicho Niigata 950-21
(Received February 12, 1988)

Sedimentation studies were carried out upon systems composed of HTAB or HPB, a cationic surfactant, and several aromatic additives which were accompanied by remarkable viscoelasticity in a solution in which the existence of extremely elongated gigantic rod-like micelles was previously established by the authors as images under an electron microscope. Those elongated rod-like micelle systems appeared to be separated into two components: one showed floatation and the other sedimentation under a 6×10^4 rpm force field, providing rather pertinent values of $S_{20\omega}$ in the order of 10^{-13}s, compared with several proteins or other polymeric substances. After attaining an equilibrium state during sedimentation, the micellar particle weight was deduced to be about 1.2×10^7 amu. The obtained values seemed to be considerably smaller than those expected from the electron microscope images where the length of the rod-like micelles were assumed to be infinitely elongated. The discrepancy is likely to have been brought about by a degradation of the micelle chain under a strong centrifugal force field.

Several cationic surfactants with appropriate chain lengths, such as hexadecyltrimethylammonium bromide (HTAB) and *N*-hexadecylpyridinium bromide (HPB), when added to various aromatic substances such phenolic derivatives like iodophenol and salicylic acid or its sodium salt, form infinitely elongated rod-like micelles. The occurrence of these extremely elongated rod-like micelles has been established through electron microscope studies[1,2] by the authors for a wide variety of pairs of surfactant-additive systems.[3] A solution composed of these substances possesses a remarkable viscoelasticity in solution, which reflects an entanglement of those extremely elongated rof-like micelles with each other.

These solution behaviors aroused the interest of several investigators who investigated the solution structure etc. in more detail through many field measurements of NMR,[4] light scattering,[5] neutron scattering,[6] flow[7] and electric birefringence[8] and dynamics.[9]

The values of the micelle length, obtained through these experiments are not very great, only several thousand Å at most. These values are far smaller than those which are suggested from observations of electron micrographs.

The reasons for this discrepancy are unknown. Whether it is caused by specimens being in a dry condition for electron microscopy, or in a wet condition for other measurements in solutions, is one of the most relevant problems that needs to be urgently solved. Hence, we intended to determine the micellar particle weights and selected a sedimentation measurement technique as an alternative direct method to approach this problem. A knowledge of the micellar particle weight is also a requisite in order to disclose the solution behavior as the remarkable viscoelasticity in these systems.

Experimental

Cationic surfactants, HTAB and HPB, were commercially available and used after one recrystallization from an acetone–methanol mixture. Aromatic additive substances were all of a special pure grade and used as purchased. Measurements of the sedimentation velocity and micellar particle weight in equilibrium were achieved by using a Hitachi Seisakusho Co. centrifugal separator attached to it with a UV scanner (ABS-7, Hitachi Co) under a controlled temperature of 20 °C. All analyses of the obtained data were automatically processed by a Hitachi data analyzer DA-7 online with the above apparatus. The progress of the sedimentation was detected by the UV absorption fitted to the appropriate absorption wavelength of the additive substances. The values of specific volume, $\bar{v}$, required to estimate the micellar particle weight which referred to $M=2RT/(1-\bar{v}\rho)\omega^2\cdot d\ln C/dr^2$ were measured as to the sediment deposited on the bottom of a centrifugal separation cell. The sediment was filled into a Lipkin–Devison type pycnometer held at 20 °C thermostat in which the densitometry deduced the values of $\bar{v}$.

The conductance measurement relied on a conductivity meter, CM-30ET (TOA Electronics Ltd.). Values were directly obtained by using a cell equipped with a meter for reading the specific conductivity in units of $S\,m^{-1}$ ($\Omega^{-1}\,m^{-1}$). Measurements were always carried out for solutions thermostated at 20 °C. For a frozen-dried sample of sediments prepared beforehand, an analysis of the surfactant content was carried out by a volumetric method in which any color change of congo red, an indicator, was detected as the end point by a wolframophosphoric acid solution of a known titer.

Results and Discussion

Measurements were mainly carried out upon systems containing HTAB–iodophenols, which showed rather clearer sedimentation profiles on diagrams for any analysis (Fig. 1), whereas HTAB-salicylic acid, the most typical viscoelastic system, showed no clear profiles of sedimentation under a 6×10^4 rpm centrifugal force field for an hour or so. In Fig. 1 it is obviously shown that these systems are composed of two entities, one of which moves to the upper part and the other to

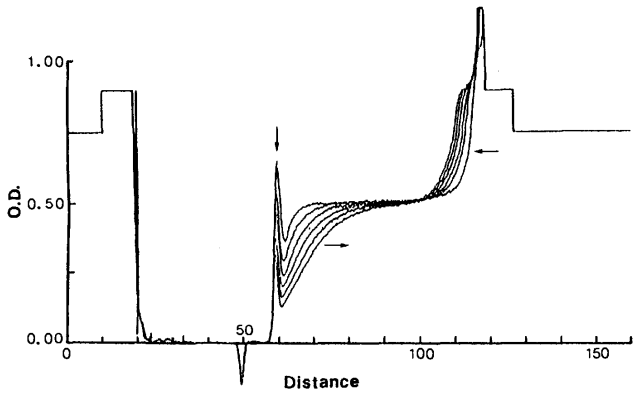

Fig. 1. Concentration traces observed for each ten minutes lapse in a system of HTAB-*o*-iodophenol under a 6×10^4 rpm centrifugal force field. HTAB concentration was 5×10^{-3} mol l^{-1} and the mixing molar ratio was unity. O. D. values were from 305 nm absorption of *o*-iodophenol. Arrows show the direction of the shift of the concentration traces with the lapse of time.

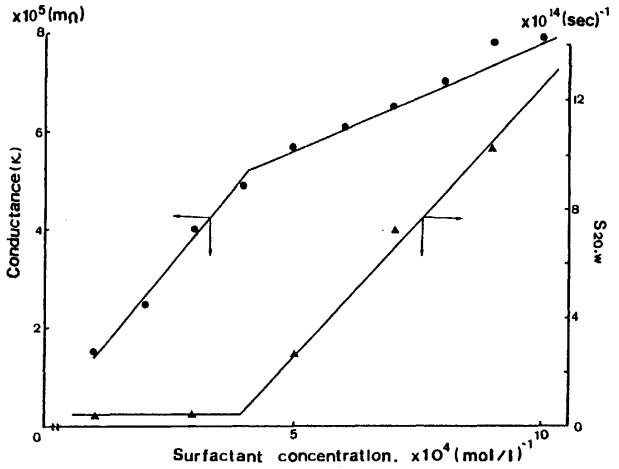

Fig. 2. The relation of conductance and $S_{20,\omega}$ vs. surfactant (CPB) concentration.

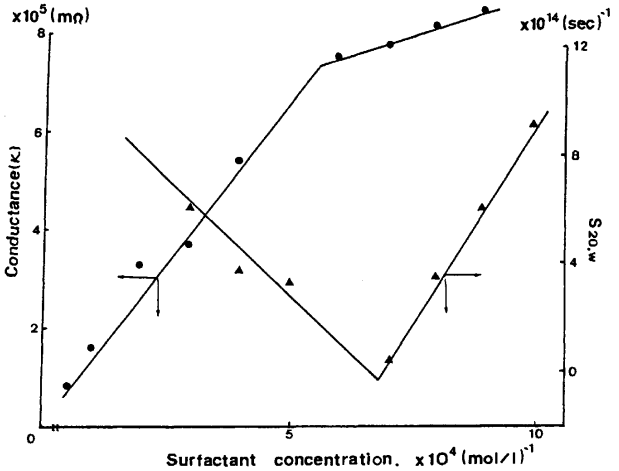

Fig. 3. The relation of conductance and $S_{20,\omega}$ vs. surfactant (CTAB) concentration.

the bottom side of a cell as time passes. The sedimentation coefficients, $S_{20\omega}$, obtained from each separated part in several systems, are summarized in Table 1; values having either a plus or minus sign show the sedimentation or the floatation, respectively. In ionic surfactants such values as $S_{20\omega}$, which indirectly suggest a state of surfactant aggregation, are sensitively affected by any surface charge. In order to avoid those effects arising from an electric charge which cause interactions between micellar particles, a supporting electrolyte is generally added to the systems to be studied. However, in our systems a special electrolyte was not added at all so as not to cause any inevitable changes in the aggregation states (shapes, degrees, or numbers etc.) due to the electrolyte added. Because viscoelastic extremely elongated gigantic micelles are also very sensitive to the coexistence of any other substance, such as electrolytes. The values of $S_{20\omega}$ appear, however, to fit the generally accepted magnitude, nearly of 10^{-13} s,[11] in their order.

In each system of HPB- and HTAB-*o*-iodophenol the dependence of $S_{20\omega}$ on the surfactant concentrations are shown in Figs. 2 and 3, respectively, in which the conductance behaviors are also exhibited in order to show the distinct relation of $S_{20\omega}$ or κ to the surfactant concentration. As is common knowledge, a conductivity measurement is one of the most reliable methods for estimating the cmc of any surfactant, which is represented as a sharp break point in a κ vs. concentration diagram. In both systems the curves of

Table 1. $S_{20,w}$ Values of Several Surfactant/Additive Systems

System surfactant/additive[a]	Concentration mol l^{-1}	$S_{20,w}$/s	
HTAB/*o*-iodophenol	1×10^{-3}	1.01×10^{-13}	-2.76×10^{-14}
	5×10^{-3}	1.13×10^{-13}	-5.47×10^{-14}
	1×10^{-2}	1.99×10^{-13}	
HTAB/*p*-iodophenol	5×10^{-3}	1.01×10^{-13}	-2.84×10^{-14}
	1×10^{-2}	1.89×10^{-13}	
HTAB/salicylic acid	1×10^{-3}		-2.16×10^{-13}
HTAB/sodium salicylate	1×10^{-2}	0.13×10^{-13}	
HTAB/sodium biphthalate	1×10^{-2}		-0.03×10^{-13}
HPB/*o*-iodophenol	5×10^{-3}	1.04×10^{-13}	-1.34×10^{-13}

a) Mixing molar ratios of each surfactant/additive systems are equal to unity.

conductance vs. surfactant concentration had clear break points which were assumed to be the cmc's of each surfactant-additive system, above which concentration the micelles were formed in those composed solutions. The values of the composed systems were a little smaller, but in good coincidence, compared with those for each single surfactant system of HPB[12] and HTAB[13] reported hitherto. Some lack of uniformity concerning $S_{20\omega}$ values was found over the low concentration range in an HTAB-*o*-iodophenol system, whereas no lack in HPB-*o*-iodophenol; this seems to be due to a difficulty in the appraisal of the sedimentation distance on a diagram of the former system necessary to determine the $S_{20\omega}$ value. Thus, we were provided with a good correspondence of aggregation states with $S_{20\omega}$ under a support of gradual increase of the micellar weight with an increase in the surfactant concentration above cmc, though it is imposed with several assumptions that micelle structure, say its form and density etc., is left unchanged during micelle growth. The same behavior of succeeding aggregation with an increase in the surfactant concentration in those viscoelastic systems has been reported by some investigators in various studies.[9,14]

The results of an analysis on the sediments deposited at the cell bottom under a 6×10^4 rpm centrifugal force for 1 h are presented in Table 2. It should be noted that the above-mentioned sediments do not refer to some crystalline or other materials. The sediments gathered at cell bottom were, of course, clear and appeared something like jelly in a test tube, being kept without flowing down in its up-side-down state. The sediments were a little enriched in iodophenol compared with those of the initial component ratio, increasing with an increase in the molar ratio of the surfactant/iodophenol until a level off at a ratio of 1.0. The values, however, suggest that in those systems the elongated micelles comprise two components of surfactant and iodophenol in a nearly unity composition at optimum states. This idea has been supported from many facts: e.g. the viscoelasticity[3,15] is most remarkably induced at a mixing molar ratio of unity with both components.

Table 2. Analyses of Sediments of HTAB/*o*-Iodophenol Systems

Original mixing molar ratio (HTAB/*o*-iodophenol)	HTAB weight %[a]	*o*-Iodophenol weight %[a]	Assayed value in molar ratio of HTAB/*o*-iodophenol
1/0.5	73.2	26.8	1/0.6
1/1	57.7	42.3	1/1.2
1/2	56.8	43.2	1/1.3

a) Water contents of the sediments were nearly the same to be given as averaged 97.1% in weight, values shown were referred to the frozen-dried samples as total materials.

In addition to the analyses of sediments, the densities of the sediments were measured by using a Lipkin-Devison type pycnometer, being determined at 20 °C to be 1.0035 $cm^{-3}g^{-1}$ for HTAB-iodophenol system referred to water at 20 °C. In our systems composed of HTAB or HPB and aromatics such as iodophenol, the values appeared to be much smaller compared with those of single surfactants reported concerning their micellar form, though the available data were very few, especially regarding cationics.

Studies of sedimentation equilibrium based on the Archibald method provided the particle weight of the elongated rod-like micelle by introducing the above obtained specific volume of the sedimentating micellar particle. An equilibrium state for those micellar systems was presumed to be attained after 30 h operation of the apparatus under 6000 rpm force. An averaged value of the micellar particle weight in several times trials resulted in 1.2×10^7 amu; this seemed to be very much smaller than that expected from the electron microscopic images.

It seems that there's no decisive conclusion about the variation of micellization under a centrifugal force field, especially in an electrically perturbed state of ionic surfactants: various effects concerning the concentration gradient on the micellar size, structure and/or a shift of aggregation equilibrium. While in our systems of HTAB- or HPB-aromatic additives, which provide an extremely elongated gigantic micelle, the circumstances are presumably very much similar to those explained by the concept of the Phase Separation Model. In other words, in the Mass Action Law Model or the Mutiple Equilibrium Model, the gigantic micelles are very stable and almost undissociable in solution: that is, equilibrium deviates extremely to the side of gigantic micelle formation having a large equilibrium constant. It cannot easily be moved to produce shorter, smaller aggregates or to be dissociated to single surfactant molecules with only a little change in the micellar and monomer concentrations. A smooth shift of the concentration traces (Fig. 1) with the centrifugation time lapses seems to prove this view point to be reasonable.

The apparent discrepancies between the obtained values and the expected one from the electron microscopic images might be due to some degradation effect of a long micellar chain into smaller fragments under a strong force field. Those micellar chains of infinite length are evidently in firmly entangled states, also as shown in the electron micrographs.[3] They can form a gigantic tight network structure all over the whole system. We were not able to obtain a sedimentation profile in HTAB-salicylic acid systems which showed the most typical viscoelastic behavior with some gel-like appearance. These micellar chains of HTAB-salicylic acid system seem to form too firm a frame-work in structure to suffer from fragmentation. The elongated micellar chain in a HTAB-iodophenol system is per-

haps easier than the micellar chain of HTAB-salicylic acid to be broken into fragments to become shorter chains of which micellar particle weight might be so reasonably decreased, as has been obtained as the above value. In electron micrographs the thickness of the micellar chain was evidently different from each other between these two systems, it being thinner in HTAB-iodophenol than in HTAB-salicylic acid.[3] The experimental fact support the result of sedimentation.

At any rate, the value was, however, not so much different from those which had been reported by several authors concerning several analogous viscoelastic systems by many different method.[4,13] Moreover, it was approximately one order larger compared with values[16] measured in these cationic surfactant systems added with a simple salt, such as NaBr etc. The particle weight obtained here implies that the micellar chain has a length of about 1710 nm from the following consideration and results based on a treatment[17] of a contour length estimation etc.: A rod-like micellar chain is cylindrically constructed by surfactant molecules accompanied by phenolic derivatives as ionic counterparts in about a one-to-one ratio, which are arranged with a hydrocarbon core surrounded by hydrophilic groups. The cylindrical micelle is assumed to be a stack of thin elementary discs composed of fewer surfactant molecules than twenty in a disc.[16] The molecular weight of the thin elementary disc is nearly 7×10^3 nm^{-1}, it being postulated that the additives are localized only at a micelle surface. Through this consideration, therefore, the stacking number of discs can be deduced to about 1940 by dividing the averaged micellar chain molecular weight by the elementary disc molecular weight; the micellar chain length can subsequently be derived, as described above, to be about 17100 Å through an appraisal of the disc thickness to be ca. 9 Å.[16]

Whether such a length of micellar chain is suitable for explaining the viscoelastic solution behavior is now yet ambiguous because of insufficiency of directly comparable data of both in qualities and in quantities. We are undertaking a more reasonable elucidation of the viscoelastic solution behavior, which might be reflected by the micellar structure etc. through more extensive and detailed data.

Catalytic Activity of Nonstoichiometric Niobium Oxide with Controlled Composition, $NbO_{2.488-2.500}$, for Butene Isomerization

Yasushi MURAKAMI, Yuji WADA, and Akira MORIKAWA*
Department of Chemical Engineering, Tokyo Institute of Technology, Meguro-ku, Tokyo 152
(Received February 26, 1988)

The composition of niobium oxide was controlled between $NbO_{2.488}$ and $NbO_{2.500}$ by treating with mixture of water vapor and hydrogen gas at 873K. X-ray diffraction (XRD) study of the treated niobium oxide showed that only a phase of nonstoichiometric T-Nb_2O_5 was found in the range of $NbO_{2.488-2.500}$ and a phase of NbO_2 coexisted with the T-Nb_2O_5 phase by further reduction. The catalytic activity of the oxide for *cis*-2-butene isomerization had a maximum value at the O/Nb ratio of 2.494. The electron spin concentration of Nb^{4+} ion, and the amount of nitrogen monoxide adsorbed on the niobium oxide also showed a maximum value at the O/Nb ratio of 2.496 and 2.494, respectively. Coincidence in the dependences, on the composition of the reduced niobium oxide, of the catalytic activity, the spin concentration of Nb^{4+} ion, and of the amount of adsorbed nitrogen monoxide shows that isolated Nb^{4+} ion with unsaturated coordination is a catalytically active site.

Niobium oxide has been often used as a promoter of catalysts, but has been recently examined as a main component of catalysts by several investigators.[1-10]

Morikawa et al. have reported that niobium oxide supported on silica became catalytically active for dimerization of ethylene both by UV light irradiation in the presence of olefin and by reduction with hydrogen at high temperature.[1] The catalytic activity of the niobium oxide catalyst activated by both the processes has been attributed to a reduced niobium species like Nb^{4+} ion. Many phases are present for reduced niobium oxide.[11] It has been reported that a specific phase of the various oxide catalysts, tungsten,[12-14] vanadium,[15] and rhenium oxides,[16] plays an important role on their obtaining catalytic activities. It is therefore supposed that the catalytic activity of niobium oxide should be closely related to the composition of niobium and oxygen atom, or the type of phase of the oxide.

We have found in this study that the composition of niobium oxide is controlled between $NbO_{2.488}$ and $NbO_{2.500}$ without change of its phase by the treatment with mixtures of water vapor and hydrogen gas in various ratios. The reaction experiment with the isomerization of butene carried out on the niobium oxide with the various controlled compositions have revealed the relationship between the structure of the oxide and its catalytic activity.

Experimental

Materials. A standard material of niobium oxide, $NbO_{2.500}$ was prepared from niobic acid manufactured by CBMM INT. LTDA. (#AD378). This niobic acid contained the impurities of Fe (40 ppm), Na (23 ppm), K (27 ppm), and Si (490 ppm). Niobic acid was dried in air at 673 K for 3 hours and calcined at 873 K for 30 hours. The X-ray diffraction (XRD) pattern of the oxide was attributed to the T-Nb_2O_5 structure.[17] Oxygen and hydrogen were purified by passing through 4A Molecular Sieve cooled to the Dry Ice temperature. Water and *cis*-2-butene were used after bulb-to-bulb distillation in vacuo.

Control of the Composition of Niobium Oxide. The treatment of niobium oxide for its control of the composition was carried out with a closed gas-circulation system. The standard oxide of 1 g was heated up to 873 K in the stream of oxygen gas. After the oxygen gas was evacuated for 30 min, the H_2O-H_2 mixture was brought into contact with the oxide. The H_2O-H_2 mixture was circulated by a magnetically driven piston pump installed in the gas-circulation loop. Excess amount of water was stored at U shape trap of the circulation system cooled at a temperature between 233 and 283 K to keep a constant partial pressure of water vapor in the H_2O-H_2 mixture. Initial pressure of hydrogen was 13.3 kPa. After the pressure drop of the gas was ceased, the sample was quenched by rapid cooling to 298 K. The composition of niobium oxide prepared by the treatment is calculated from the pressure decrease of the mixture. The composition is expressed by the atomic ratio, O/Nb, with precision of ±0.0005. The surface area (15 $m^2 g^{-1}$) of the oxide was unchanged by the treatment.

Reaction Experiments and Spectroscopy. The reaction of *cis*-2-butene was carried out at 298 K with a closed circulation system. The reaction mixture was analyzed by gas chromatography. XRD was measured with Rikadenki Rotaflex RU-200. Electron spin resonance (ESR) spectra were recorded at 77 K by JEOL-PE-IX spectrometer. The sample was transferred to an ESR tube and sealed in vacuo.

Results

Control of O-Nb Composition. In Fig. 1, the changes in the composition of niobium oxide indicated by the ratio, O/Nb, during the treatments at 873 K with the H_2O-H_2 mixtures of various H_2O/H_2 ratios are displayed. When the standard sample was treated in the H_2O-H_2 mixture of the partial pressure ratio of $P_{H_2O}/P_{H_2}=9.0\times10^{-3}$, the ratio of oxygen and niobium atom in the oxide was decreased up to the value of O/Nb=2.498 and no further reduction was observed. This composition did not change even after 6 hours of the treatment. When the sample which was preliminarily reduced to the ratio of O/Nb=2.482 was kept into contact with the H_2O-H_2 mixture of ratio, $P_{H_2O}/P_{H_2}=9.0\times10^{-3}$, the O/Nb value was increased to 2.498, which was coincident with the value observed when the standard sample with O/Nb=2.500 was

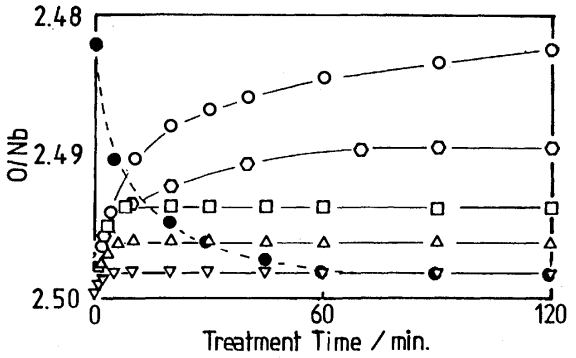

Fig. 1. Change in the O-Nb composition during the treatment with H_2O-H_2 mixture at 873 K. The ratios of the mixture, P_{H_2O}/P_{H_2}, are 2.0×10^{-3} (○), 4.0×10^{-3} (○), 8.0×10^{-3} (□), 3.0×10^{-2} (△), and 9.0×10^{-2} (▽). The broken line shows change in the composition of $NbO_{2.483}$, when it was treated with the H_2O-H_2 mixture of the P_{H_2O}/P_{H_2} ratio, 9.0×10^{-2} (●).

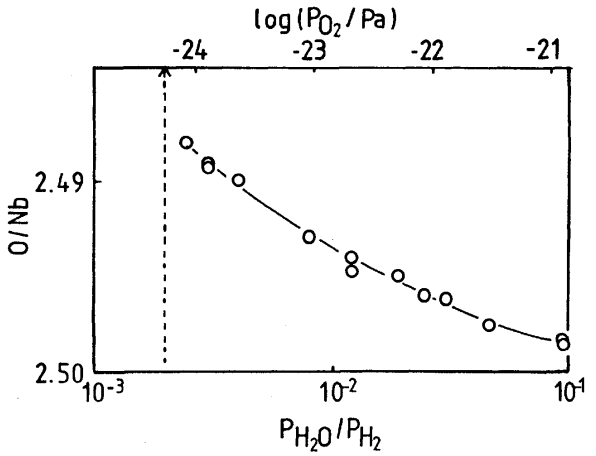

Fig. 2. Dependence of the equilibrium composition of niobium oxide on P_{H_2O}/P_{H_2} at 873 K. The partial pressure of oxygen is denoted by P_{O_2}.

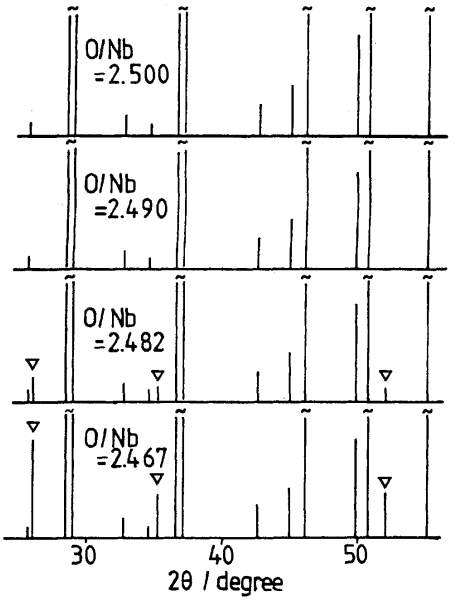

Fig. 3. XRD patterns of niobium oxide of the various composition obtained by the treatment. ($K\alpha$= 0.15418 nm).

treated by the H_2O-H_2 mixture of the same ratio. It is, therefore, stressed that oxidation and reduction of the oxide are reversible and the oxide is in equilibrium with the H_2O-H_2 mixture.

The treatment with the H_2O/H_2 mixture of the ratio 3.0×10^{-2}, 8.0×10^{-3}, or 4.0×10^{-3}, gave the reduced oxides with the corresponding O/Nb ratio, 2.496, 2.493, or 2.490, respectively. When the mixture of $P_{H_2O}/P_{H_2}=2.0\times10^{-3}$ was used, the O/Nb value continuously decreased and did not show a stable equilibrium composition. It was reduced to the O/Nb ratio further less than 2.475 by the treatment of 6 hours.

The careful examination of the O/Nb values corresponding to the various P_{H_2O}/P_{H_2} values of the reducing gas mixture in the range of 1.0×10^{-1}—2.5×10^{-3} yielded the result shown in Fig. 2. The partial pressure of oxygen calculated from the equilibrium of water decomposition is expressed in the figure. The value of the O/Nb ratio decreased with decrease in the ratio of P_{H_2O}/P_{H_2} between 1.0×10^{-1} and 2.5×10^{-3}. A discontinuity in the O-Nb phase at the O/Nb ratio of 2.488 was present in Fig. 2.

XRD Measurements of Niobium Oxide. Figure 3 shows X-ray diffraction patterns of niobium oxide which was rapidly quenched by cooling after the treatment described in the above section. The standard Nb_2O_5 (non-reduced) is identified as T-Nb_2O_5 type crystal structure by XRD pattern.[17] The observed XRD patterns show that niobium oxide reduced up to the composition of O/Nb=2.490 maintains the crystal structure of T-Nb_2O_5, although the careful analysis of the patterns revealed a slight lattice expansion by the reduction in respect to all the three crystal axes. It is, therefore, suggested that only a nonstoichiometric T-Nb_2O_5 phase is present in the range of the O/Nb ratio, 2.500—2.488.

When the oxide was further reduced to $NbO_{2.482}$, new peaks marked by ▽ signs in the figure appeared at d values of 0.343, 0.255, and 0.176 nm, which were attributed to NbO_2.[18] The intensity of the peaks due to NbO_2 increased with decrease in the O/Nb ratio of the oxide. Therefore, it is concluded that two phases coexist below the O/Nb ratio of 2.488 and the nonstoichiometric Nb_2O_5 phase is transformed into NbO_2 phase with decrease of the O/Nb ratio.

ESR Spectrum of Nb^{4+} Ion. No ESR signal was observed for the standard oxide. The ESR absorption by the oxide was induced by its reduction. An ESR spectrum of the niobium oxide reduced to the O/Nb ratio of 2.496 by the treatment was observed as shown in Fig. 4. Its g value was 1.85 ± 0.03. The spectrum was attributed to Nb^{4+} ion as discussed in the following section.

The intensity of the ESR signal changed as shown in Fig. 5 when the O/Nb composition of niobium

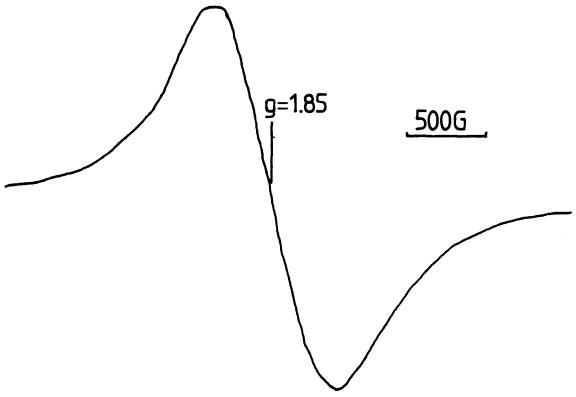

Fig. 4. ESR spectrum of niobium oxide (O/Nb=2.496) measured at 77 K after the treatment with the H_2O-H_2 mixture.

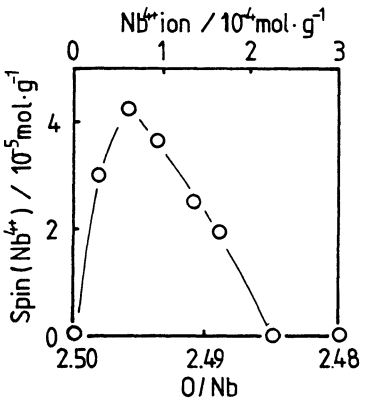

Fig. 5. Dependence of the spin concentration of Nb^{4+} ion upon the composition of niobium oxide. The spectrum was measured at 77 K. The concentration of Nb^{4+} ion estimated from the O/Nb ratio is shown.

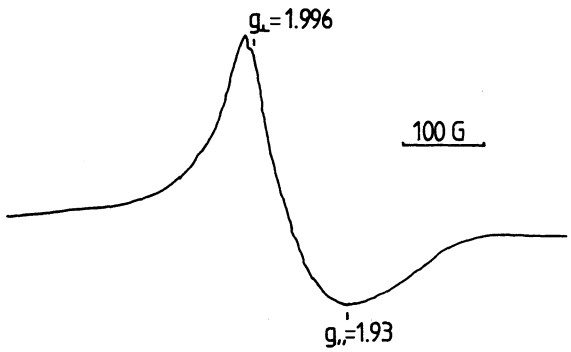

Fig. 6. ESR spectrum of nitrogen monoxide adsorbed on the treated niobium oxide (O/Nb=2.494) measured at 77 K.

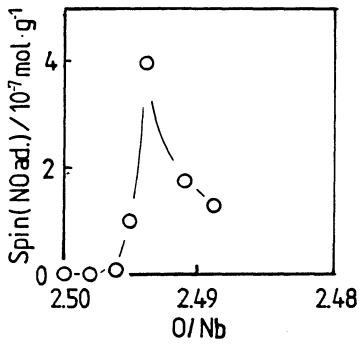

Fig. 7. Dependence of the spin concentration of nitrogen monoxide adsorbed on niobium oxide upon the composition of niobium oxide. The spectrum was measured at 77 K.

oxide was varied. The g value was independent of the composition. The spin concentration of Nb^{4+} ion increased with decrease of the O/Nb ratio and reached a maximum value at O/Nb=2.496. The spin concentration of Nb^{4+} determined by ESR was coincided well with the amount of Nb^{4+} ions estimated from the composition of the oxide only at the low extent of reduction. Further decrease of the O/Nb ratio depressed the spin concentration and, finally, no ESR signal was observed at the O/Nb ratio below 2.485.

Adsorption of NO. The asymmetric broad signal was observed by ESR spectroscopy after the adsorption of nitrogen monoxide on the niobium oxide of the O/Nb ratio between 2.489 and 2.498 as shown in Fig. 6. The perpendicular and parallel g values of the signal are 1.996 ±0.001 and 1.93±0.01, respectively.

Figure 7 shows the change of the spin concentration of nitrogen monoxide adsorbed on the niobium oxides of the various O/Nb compositions. The spin concentration showed a maximum at the O/Nb value of 2.494, while it is lowered for the O/Nb values both lower and higher than this value.

Isomerization of *cis*-2-Butene. The standard sample of niobium oxide was catalytically inactive for isomerization of *cis*-2-butene. Reduction of the oxide by the treatment with the H_2O-H_2 mixture induced its catalytic activity. Change in the amounts of isomers, *trans*-2-butene and 1-butene observed at 298K on the niobium oxide with the O/Nb ratio of 2.494, is displayed in Fig. 8. No other product was found. A short induction period was observed at the initial stage of the reaction, and the isomerization proceeded linearly to the reaction time. The slope of the linear part was taken as the rate of the isomerization of *cis*-2-butene to each isomer. The ratio of the amount of *trans*-2-butene to that of 1-butene produced was constant at the value of 10 during the reaction. The catalytic activity is represented by the rate of *trans*-2-butene formation observed at a constant pressure of the reactant, *cis*-2-butene, in this paper.

As shown in Fig. 9, the catalytic activity depended upon the O/Nb composition of niobium oxide. The catalytic activity increased with increase in the extent of the reduction, and reached a maximum value at O/Nb=2.494 and decreased with further decrease in the O/Nb value. The oxide with the O/Nb value less than 2.488 showed a very little, constant catalytic activity.

The catalytic activity observed on the oxide of the O/Nb ratio, 2.494, was poisoned completely by nitro-

gen monoxide of the amount, 5×10^{-6} mol, admitted both before and during the reaction.

Discussion

Crystal Structure of Niobium Oxide. It has been demonstrated that the composition of niobium oxide is controlled by the treatment with the H_2O-H_2 mixture at 873 K between the O/Nb ratio, 2.500 and 2.488. The oxide reaches in equilibrium with the H_2O-H_2 mixture in this range as described in the above section. XRD studies (Fig. 3) have clarified that the oxide maintains the T-Nb_2O_5 phase in the region between 2.500 and 2.488 of the O/Nb ratio. The continuous change of the O/Nb value against the ratio, P_{H_2O}/P_{H_2} (Fig. 2), with the slight expansion of the crystal lattice shows that T-Nb_2O_5 phase is nonstoichiometric. Continuous increase in the lattice parameters with increase in the extent of reduction observed by XRD ensures that the whole bulk of niobium oxide particles is homogeneously reduced by the treatment.

Phase relations, defect structures, and thermodynamic properties of the oxygen-niobium system above 1273 K have been reported by many investigators and have been intensively reviewed by Naito and Matsui.[11] Several oxide phases, $Nb_{12}O_{29}$, $Nb_{22}O_{54}$, $Nb_{47}O_{116}$, $Nb_{25}O_{62}$, and $Nb_{53}O_{132}$ have been recognized between NbO_2 and Nb_2O_5 at 1573—1673 K by Schäfer et al.[19] and Kimura.[20] At lower temperatures 1273—1373 K, Marucco has found only two phases $Nb_{12}O_{29}$ and $Nb_{25}O_{62}$ within the same composition range.[21] In the present work, however, niobium oxide with T-Nb_2O_5 phase structure directly transforms into NbO_2 at the O/Nb ratios less than 2.488 and no suboxide phase between NbO_2 and $NbO_{2.5}$ has been found. This absence of suboxide phases is explained by the discussion of Naito et al., who have reported that the several suboxide phases with the composition between NbO_2 and $NbO_{2.5}$ were less stable at temperature lower than 1273 K.[22]

The ESR absorption observed for niobium oxide of the O/Nb ratio, 2.496, obtained by the treatment with H_2O-H_2 mixture (Fig. 4) is attributed to reduced niobium ions. The ESR absorption due to Nb^{4+} ion in pure niobium oxide was observed for the first time owing to the controlled slight reduction by the treatment with the H_2O-H_2 mixture instead of that with hydrogen gas. An ESR study of Nb^{4+} ions in silicate glasses ($n$$Na_2O$·(98−$n$)$SiO_2$·2$Nb_2O_5$ n=11 and 22) has been reported by Yafaev and Garif'yanov.[23] The g value in our spectrum, 1.85±0.03, was close to their g values, 1.89 and 1.92. Their ESR spectrum of Nb^{4+} ions has hyperfine structure due to the interaction of a single 4d electron with the nucleus (I=9/2) of the natural niobium isotope ^{93}Nb. The parallel and perpendicular hyperfine constants were 310 and 145 Oe in Yafaev's results. In our experiment the hyperfine structure was not observed because the spectrum was extremely broad, in which the width of magnetic field of the absorption band was about 3000 Oe as shown in Fig. 4. The spectrum of Nb^{4+} ions in our system must have been broadened by various crystallographic environment of Nb^{4+} ions in the oxide so that the hyperfine structure has been indistinguishable.

As shown in Fig. 5, when the niobium oxide is reduced further from the value of the O/Nb ratio of 2.496, the spin concentration of Nb^{4+} ion measured by ESR is decreased in spite of increase in the extent of reduction. This inconsistency is attributed to a magnetic coupling between Nb^{4+} ions. Though Nb^{4+} ion is paramagnetic and hence its signal should be observed by ESR, no ESR signal of Nb^{4+} ion was observed for NbO_2. The crystal structure of NbO_2 is described as the distorted rutile structure, resulting Nb-Nb bonding.[24,25] Thus the pairs of Nb^{4+} ions bring about spin coupling resulting in a diamagnetic character of NbO_2. In the case of molybdenum oxide the concentration of Mo^{5+} ions determined by ESR spectroscopy is lower than that evaluated from the measurement of the composition,[26] and that deter-

mined by X-ray photoelectron spectroscopy.[27,28] Abdo et al. have suggested that the Mo^{5+} ions undetectable by ESR must be strongly, magnetically coupled.[29] Our result shows that Nb^{4+} ions are detectable by ESR in nonstoichiometric Nb_2O_5 phase, because they are isolated each other in the Nb_2O_5 matrix.

A simple interpretation is given for the result shown in Fig. 5. As far as the amount of Nb^{4+} ions is very small, isolated Nb^{4+} ion is increased in T-Nb_2O_5 structure when the oxide is progressively reduced. However, when the concentration of Nb^{4+} ions exceeds a certain value, Nb^{4+} ions couple each other, causing their magnetic character to be ESR-inactive. Thus, the spin concentration determined by ESR is less than that estimated from the O/Nb ratio at a large extent of reduction. No ESR signal is observed when most of Nb^{4+} ions couple at the ratio of O/Nb greater than 2.485.

Adsorption Site of NO. ESR spectrum of nitrogen monoxide adsorbed on the niobium oxide reduced by the H_2O-H_2 mixture was observed as shown in Fig. 6. Its shape is similar to that of nitrogen monoxide adsorbed on alumina reported by Lunsford.[30] Nitrogen monoxide adsorbed on niobium oxide should provide 30 hyperfine lines due to the interaction with the nucleus of ^{14}N (I=1) and ^{93}Nb (I=9/2), but this type of hyperfine structure was ambiguous in the present experiment.

According to Lunsford's work nitrogen monoxide is adsorbed on aluminum ion which is exposed to the surface with an oxygen ion vacancy. It is plausible that the adsorption of nitrogen monoxide occurs on the oxygen ion vacancy of reduced niobium oxide. Therefore, the change of the spin concentration of nitrogen monoxide adsorbed on the reduced niobium oxide depending on the O/Nb ratio reflects the change in the amount of Nb^{4+} ion which is exposed to the surface with an oxygen ion vacancy. The similar changes of the spin concentration of Nb^{4+} and of adsorbed nitrogen monoxide along with decrease in the O/Nb ratio lead us to a new assumption that isolated Nb^{4+} ion must provide an oxygen ion vacancy, in other words, isolated Nb^{4+} ions are coordinatively unsaturated. When the isolated Nb^{4+} ions are paired, they lose coordinatively unsaturation.

Active Sites for Isomerization. Isomerization of 1-butene on niobium oxide catalyst prepared by degassing of $Nb_2O_5 \cdot nH_2O$ has been studied by Iizuka et al.[2] $Nb_2O_5 \cdot nH_2O$ degassed at 373K exhibits a substantial catalytic activity for the isomerization, attributed to a very strong Brønsted acid. Degassing of $Nb_2O_5 \cdot nH_2O$ at temperatures higher than 773 K results in a remarkable decrease in the acidity and, therefore, niobium oxide prepared by calcination at 873 K exhibits little activity for the isomerization. Therefore, it is stressed that the catalytic activity for butene isomerization on the reduced niobium oxide observed in the present work originates hardly from its acid catalysis. Actually, the addition of ammonia of which amount was in excess of that of all the reduced species on the surface did not result in the complete loss of the activity, but reduced the activity to only one-half of its original value.

No catalytic activity was observed for the non-reduced niobium oxide, while the activity for the catalytic isomerization of butene was resulted from reduction of niobium oxides, indicating that the catalytically active site of the reduced niobium oxide catalyst is attributed to the reduced species of niobium ion. Thermodynamic data tell us that Nb^{5+} ion is reduced only to Nb^{4+} but not to a lower valence niobium ions in our experimental conditions. Formation of Nb^{4+} by the treatment with the H_2O-H_2 mixture was assured by ESR spectroscopy.

As discussed above, the observed spin concentration of Nb^{4+} reflects the amount of isolated and coordinatively unsaturated Nb^{4+}. Since nitrogen monoxide strongly poisons the catalytic activity, it was adsorbed on the catalytically active site of butene isomerization. It is concluded that the catalytically active site is identical with the nitrogen monoxide adsorption site, that is, isolated Nb^{4+} ion with coordinative unsaturation. This conclusion is supported by the general agreement between the catalytic activity and the amount of the adsorbed nitrogen monoxide (Figs. 7 and 9). The reason for the difference between these two measurements on the slightly reduced catalyst is ambiguous at present.

Among the tungsten oxide catalysts, WO_{3-x}, nonstoichiometric phase shows the high activity and selectivity for the reactions, for example, oxidation of propylene,[12] and allyl iodide,[13] and decomposition of N_2O.[14] On the other hand, stoichiometric oxides, WO_3, WO_2 or a tunnel structure oxide of $WO_{2.72}$, are less active or inactive for those reactions. Metathesis of propylene on ReO_3 catalyst is enhanced by a slight reduction of the catalyst with CO, but its catalytic activity is lowered when the extent of reduction exceeds a critical value.[16] Importance of nonstoichiometric phase for the catalysis demonstrated in these systems may be explained by the same idea that isolation of catalytically active species to keep the state of coordinative unsaturation is essential to maintain high catalytic activities as demonstrated in the present system.

We would like to thank CBMM INTERNACIONAL LTDA. for their kind supply of niobium samples and financial support.

A Systematic Investigation of the Effects of Axial Ligands and Peripheral Substituents on the Electronic Structures of Zinc(II) Tetraphenylporphyrin π-Cation Radicals: Electrochemical EPR and Spectroscopic Observation

Kohji Ichimori, Hiroaki Ohya-Nishiguchi,* and Noboru Hirota
Department of Chemistry, Faculty of Science, Kyoto University, Sakyo-ku, Kyoto 606
(Received February 29, 1988)

A detailed study of the effect of axial ligand and peripheral substituent on the π-system of zinc(II) tetraphenylporphyrin π-cation radical has been made using an electrochemical EPR technique. It is confirmed from the EPR spectra that most of the anions and bases examined coordinate the radicals axially. The spin density on the nitrogen nuclei in the radicals increases with the polarizability of the axial ligand estimated from the optical spectra of the parent neutral complexes. For the fourteen complexes with different substituents on the phenyl groups examined here, there is a linear correlation between the Hammett substituent constant and the spin density. It is also shown that the para position of the phenyl group carries the spin density comparable to that of the ortho position, which indicates considerable conjugation between the porphyrin ring and the phenyl groups. In most cases, there exist two kinds of radical species which give rise to broad and sharp EPR spectra at low temperature. It is suggested that the difference in the motional states of the phenyl groups in the radicals is responsible for the different EPR spectra.

The redox behavior of metalloporphyrins has been investigated widely from biological interest.[1,2] Metalloporphyrins are known to undergo two different kinds of redox reactions; the reaction of a central metal ion and of a porphyrin ring.[3] The redox properties of metalloporphyrins have been studied by making systematic variations in central metal ions,[4] peripheral substituents,[5-8] axial ligands and solvents.[9-12] Not only the metal-centered redox, but also the oxidation of a porphyrin ring are of great importance and π-cation radicals generated by the oxidation act as active species in biological systems.[13,14]

The electronic structures and characters of frontier orbitals of the π-cation radicals have been studied by means of EPR,[15,16] optical,[17,18] and MCD[19] spectroscopies combined with electrochemical techniques in addition to cyclic voltammetry.[3,17,18,20] There are two factors which influence the electronic state of the π-system: One is the axial ligand and the other is the peripheral substituent. The axial ligand are known to play important roles in the biological functions of metalloporphyrins, but their effects on the π-system have not been investigated sufficiently. The effects of peripheral substitution have been investigated in relation to basicity of free base,[21] redox potentials,[5,8,22] base addition reactions,[5,23-27] rates of metal incorporation,[28] chemical shifts,[29,30] and other physicochemical properties.[25,31-35] But their effects on the electron distribution of the π-system have not been studied directly.

Recently a systematic investigation was made on the effects of axial ligands and solvents on the π-cation radicals of 5,10,15,20-tetraphenylporphyrinatocobalt(III), $[Co(III)(tpp)]^{2+\cdot}$, in our laboratory using an electrochemical EPR technique.[36,37] It was demonstrated that axial ligands affect largely the hyperfine coupling constants (hfcc) of the nitrogen and cobalt nuclei. The changes in spin distributions caused by the axial ligands were determined directly from the analysis of the EPR spectra.

Since the zinc(II) porphyrin π-cation radicals are very stable, the techniques applied to the studies on the $[Co(III)(tpp)]^{2+\cdot}$ π-cation radical can be applied to this system as well. Moreover, zinc(II) porphyrins are free from metal-centered redox and d-π mixing in the frontier orbitals.[38] It is known that zinc(II) porphyrins can coordinate only one axial ligand.[38-42] The naturally abundant zinc nucleus carries no nuclear spin. Therefore, one can expect much simpler EPR spectra for zinc complexes than for cobalt ones. By making systematic variations of the axial ligand and peripheral substituent, their effects on the spin-density distribution of the π-cation radicals can be investigated in detail.

The EPR spectra of Zn(tpp) π-cation radical were first observed by Fajer et al., with electrochemical oxidation[43] and several works have been done subsequently.[44-47] It was shown that the π-cation radical can axially coordinate one halogen anion or one pyridine molecule,[45] but the effects of the axial ligand on the π-system have not been studied in detail. Here, we have investigated the effects of the axial ligand and peripheral substitution on the EPR spectra of the π-cation radical to see how these two factors affect the π-system.

In this paper we first describe the general feature of the EPR analysis of the zinc(II) tetraarylporphyrin π-cation radicals briefly. Second, we examine the EPR spectra of the Zn(II)(tpp) π-cation radicals obtained in the presence of various anions and bases and deduce their structures in solution. Electronic effects of the axial ligands on the π-system are also discussed. Third, the effects of the peripheral substituents on the electronic states of the Zn(tpp) π-cation radical exam-

ined are discussed by correlating the EPR parameters with the Hammett constants of the substituents. Finally the origin of the two paramagnetic species observed in most cases is discussed.

Experimental

Materials. 5,10,15,20-Tetraarylporphyrin free bases with various peripheral substituents, hereafter abbreviated as H_2 (substituents on phenyl groups)(tpp), were prepared by the literature procedures[23,51,56] followed by modified purification process. In Table 1, the absorption spectra of their zinc(II) complexes are summarized together with the preparative references of free bases.

The zinc(II) complexes of these porphyrins were prepared by the method of Adler et al.[57,58] and purified by chromatography on neutral alumina with CH_2Cl_2 or $CHCl_3$ as the eluent. All synthesized zinc complexes were recrystallized from mixed solvents such as CH_2Cl_2–CH_3OH and identified by elemental analysis, TLC, and optical spectra.

CH_2Cl_2 and butyronitrile of spectroscopic grade were distilled from CaH_2 and dried over activated neutral alumina for the use of EPR measurements. Tetrabutylammonium salts (TBAX, where X=BF_4, ClO_4, NO_3, and F) were obtained by the method reported previously.[37] The preparations of dibenzo-18-crown-6 complexes with potassium salts (DB18C6-KX, where X=CN, SCN, and OAc) were carried out according to the method given by Pedersen.[59] The other reagents were commercially obtained and used without further purification.

Apparatus and Procedure. The EPR spectra were taken with JEOL PE-3X and FE-3X spectrometers equipped with a temperature controller. The π-cation radicals were generated by electrochemical one-electron oxidation of the corresponding zinc complexes using various TBA salts as electrolytes with/without bases. The applied voltages was +1.7 to +3.0 V, depending on the peripheral substituent and solvent: The voltage in n-C_3H_7CN was ca. 0.4 V higher than that in CH_2Cl_2. The procedures for the electrochemical EPR measurement and the field calibration were previously described in detail.[37,60] A Takeda Riken TR5211 frequency counter was used for measuring precise microwave frequencies. The simulation of the EPR spectra was carried out by using the literature program.[61] Absorption spectra were measured with a Shimadzu UV-2005 spectrophotometer.

Results and Discussion

EPR Analysis. The EPR spectra of zinc(II) tetraarylporphyrin π-cation radicals depended on axial ligands, peripheral substituents, and temperature. In most cases the room-temperature spectra of the Zn(tpp) π-cation radical exhibited broad nine-line structures due to four equivalent pyrrole nitrogens, indicating that the unpaired electron resides in the a_{2u} π-orbital. At sufficiently low temperatures, the spectra were often resolved further.

Using $TBAClO_4$ as a supporting electrolyte in n-C_3H_7CN, a partially resolved spectrum has been observed at −55 °C, as was reported by Fajer et al.[44] This sectrum could not be simulated without assuming superposition of two spectra; a broad nine-line spectrum identical with that observed at room temperature and a sharp spectrum resolved further by phenyl protons but with the same nitrogen coupling constant as that for the former.

In the previous works by Fajer et al. the well resolved spectra of the π-cation radical were simulated by considering the splittings due to only eight ortho-phenyl protons, because it was considered that the phenyl groups are nearly perpendicular to the mean plane of the porphyrin ring and only the ortho protons give rise to hyperfine splittings (hfs) due to the direct overlap with the unpaired electron. In our systems of the acetate-ligated and para substituted π-cation radicals, it was confirmed that the para positions carry spin densities comparable to those of the ortho positions. In the present work, therefore, 4N and 12H are assumed in the simulations of the spectra of all Zn(II)(tpp) π-cation radicals.

Dual structures of the spectra were observed in most of our systems and we succeeded in the simulation by means of the superposition of sharp and broad components. In general, the intensity of the broad component was much higher than that of the sharp one and the sharp component often disappeared at room temperature, The cause for the existence of the two paramagnetic species responsible for these two species will be discussed in the last section.

The Effects of Axial Ligands on Zn(tpp) π-Cation Radical. The axial-ligand effects on the EPR spectra were examined using the unsubstituted tpp ring. The EPR spectra were delicately influenced by the coordination of the coexisting anion or base. The results obtained from the EPR spectra are summarized in Table 2. The structures and electronic states of the radicals in solution are described in the following five parts which are classified according to the coordinating power[37] and charges of the axial ligands. The effects of the axial ligands on the electronic states of

the π-system are presented in the last part.

(1) Weak-Ligand Anions (ClO_4^-, BF_4^-, PF_6^-, and NO_3^-): When TBAX (X=ClO_4, BF_4, or PF_6) was used as a supporting electrolyte at room temperature, a nine-line spectrum was observed in both CH_2Cl_2 (Fig. 1a) and n-C_3H_7CN. The spectrum in $TBAClO_4/CH_2Cl_2$ could be simulated by assuming hyperfine coupling constants (hfcc) of 4N (0.156 mT) and unresolved 12H (0.030 mT). The hfcc of nitrogens (a_N) in the system is the smallest of all, which reflects the smallest axial perturbation. Furthermore, the change of the anions has no effect on the spectrum, indicating that the radical is free from an axial ligand. It was shown by X-ray and IR results[62] that a perchlorate ion is bound to the radical in CH_2Cl_2 as well as in the solid state. Therefore, it is considered that the perturbation caused by the perchlorate ion is negligibly small. When cooled in CH_2Cl_2, the spectrum remained broad down to ca. −85 °C, but a partially resolved spectrum was obtained at around −94 °C (Fig. 1c).

In n-C_3H_7CN the same spectra as reported by Fajer et al., were observed with these three anions. The fact that a_N in n-C_3H_7CN (0.158 mT) is slightly larger than that in CH_2Cl_2 (see Table 2) indicates solvent ligation. The coordination of nitrile to neutral Zn(tpp) has been established from the optical spectra by Nappa and Valentine.[42] Therefore, it is reasonable to conclude that the π-cation radical is ligated by the solvent and is not influenced by these weak anions.

When $TBANO_3$ was used as the supporting electrolyte in CH_2Cl_2, the spectrum was almost identical with that in $TBAClO_4/n$-C_3H_7CN system, indicating that the effects of a nitrate ion is similar to that of n-

C_3H_7CN.

(2) Intermediate Anions (F^-, Cl^-, and Br^-): In the presence of the halogen anions, the spectra at room temperature in CH_2Cl_2 were broad. With lowering the temperature down to −50 °C, however, the spectrum for TBAF as the supporting electrolyte showed a partially resolved structure (Fig. 2a). The spectrum could

be simulated with 4N, 12H, and 1F, which means that one fluoride ion ligates to the species responsible for both the sharp and broad spectra. In simulating the spectrum, coexistence of the two paramagnetic species with the same hfcc's but different linewidth was taken into account (Fig. 2b) with the ratio of the sharp and broad components being 1 : 206. The same phenomenon was observed at lower temperatures, when TBACl was used. In the case of TBABr, however, the spectrum consisting of broad four lines due to Br^- with I=3/2 was not resolved further on cooling.

(3) Strong Anions (CN^-, SCN^-, and AcO^-) in CH_2Cl_2: These anions were introduced in the form of DB18C6-KX complexes with TBAPF$_6$ as a supporting electrolyte as reported previously.[37] It was confirmed by the large spectral changes from the above cases (1) and (2) that these strong anions ligate the π-cation radical. The spectra in the presence of these anions also showed the dual structures at low temperatures. In the presence of cyanide, no spectrum could be observed at room temperature because of instability of the radical. But at around −70 °C, a spectrum with the largest a_N was observed, accompanied with the fine splittings due to phenyl protons (Fig. 3a). This indicates ligation by cyanide. The spectrum could be simulated by a set of 4N and 12H and assuming Sharp and Broad=1 : 289 (Fig. 3b).

In the presence of thiocyanide, a spectrum with eleven-line structure could be observed even at room temperature. This could be simulated by a set of 4N and 12H, and an additional nitrogen hfcc larger than that of the porphyrin ring. This indicates that thiocyanate ligates the π-cation radical by nitrogen, not by sulfur. At around −60 °C the spectrum was also resolved further and could also be simulated by using

the same set of hfcc, as shown in Fig. 4b (Sharp: Broad=1 : 45).

The spectrum in the presence of the acetate shows much different temperature dependence. Even at room temperature, the spectrum had a dual structure which could be simulated by a set of 4N and 12H with the sharp-to-broad ratio of 1 : 130 at −10 °C. With lowering the temperature, the spectrum was once broadened but the sharp component appeared again with a more complicated structure below −55 °C. Due to the broadening on both sides of the spectrum, the simulation could not reproduce the observed spectrum well. This results from the nitrogen m_I dependence of the linewidth of the sharp component.[63]

(4) Base Ligation: Besides the anionic ligands, the electrically neutral ligands such as 4-CNpy, 4-CH_3py, and $P(C_6H_5)_3$ were also examined using $TBAPF_6$ as the electrolyte. The radical generated by the electrooxidation in the presence of these bases was unstable and the EPR spectra was not observed at room temperature. When the pyridine derivatives were used as the base, the nine-line structure described above collapsed into broad single line with slight undulation. Such broadening is probably due to the hyperfine contribution from pyridine nitrogen.

A remarkable change was seen in the spectrum, when $P(C_6H_5)_3$ was added (Fig. 5a). The central broad line was due to the unligated radical species. On both sides of the central line, a pair of nine-line spectrum was observed, which indicates clearly the ligation of one phosphine with $I=1/2$ in $P(C_6H_5)_3$. In n-C_3H_7CN the lines on both sides were very weak compared with the central line. Such solvent dependence of the relative intensity supports the identification mentioned above.

Extensive works about the axial ligand effects on the redox potential have been done using nitrogenous bases[17,20] and the reactions of the radical in the presence of these nucleophile have been investigated in detail.[64] The EPR spectra of $Zn(tpp)^+$ with axial pyridine reported by Fujita et al.[45b] show that the complex formation of the radical with pyridine results in an 10% increase in a_N. This is in accord with the trend in the anion ligation described above.

(5) The Effect of Axial ligands on the Electronic States of the π-Cation Radical: In the previous work on the Co(III)(tpp) π-cation radical, it was noted that ligation by chloride or cyanide ion increases a_N from 0.18 mT to 0.28 mT.[37] This increase was rationalized on the bases of the result of a CNDO/2 calculation which predicts an increase of a_N with the increase of the axial ligand field. As shown in Table 2, a_N becomes larger when a strong anion coordinates to the π-cation radical. This trend qualitatively agrees with that found for the cobalt complex. However, the increase of a_N in the zinc complex is much smaller than in the cobalt one, which may be primarily due to the fewer charge of the metal cation and fewer numbers of the axial ligand.

The effects of the axial ligands on the electronic states of regular metalloporphyrins have been parametrized by means of the visible absorption spectra, which include so-called α and β bands (see Table 1).[65] In neutral Zn(tpp), considerable red shifts of these bands and the increase of the intensity ratio of α band over β band ($\varepsilon_\alpha/\varepsilon_\beta$) have been observed by introducing a wide variety of axial ligands.[42] It has been considered that $\varepsilon_\alpha/\varepsilon_\beta$ represents the electronic polarizability of the axial ligand: As more charge of the axial ligand transfers to the porphyrin ring through the metal ion, $\varepsilon_\alpha/\varepsilon_\beta$ becomes larger. We have examined the correlation between a_N and $\varepsilon_\alpha/\varepsilon_\beta$. The plot given in Fig. 6 clearly shows a correlation between these parameters except for the case of $P(C_6H_5)_3$ with neutral charge: a_N becomes larger with the increase of $\varepsilon_\alpha/\varepsilon_\beta$. It is therefore concluded that the spin density on the nitrogen nuclei increases as the polarizability of the axial ligand increases.

The Effects of Peripheral Substituents on the Zn(tpp) π-Cation Radicals. The EPR spectra of zinc-

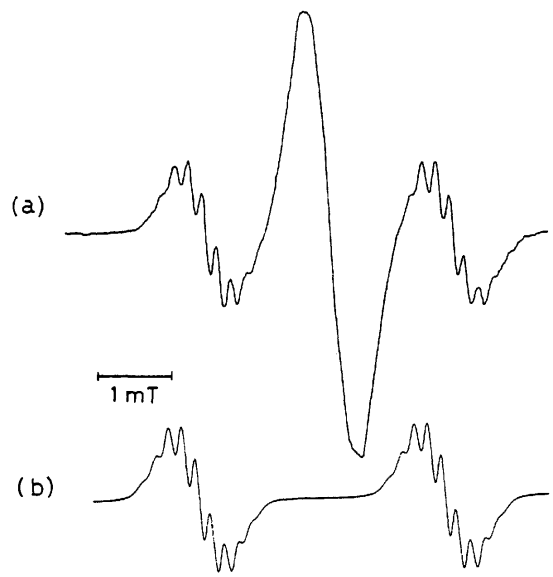

Fig. 5. The EPR spectra of the Zn(II)(tpp) π-cation radical in $P(C_6H_5)_3$($TBAPF_6$)/CH_2Cl_2 system, (a) observed at −80°C, and (b) simulated.

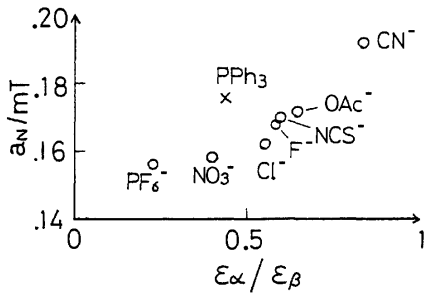

Fig. 6. Correlation between nitrogen hfcc (a_N) and the intensity ratio ($\varepsilon_\alpha/\varepsilon_\beta$). $\varepsilon_\alpha/\varepsilon_\beta$ was obtained from Ref. 42 or measured in C_6H_6.

(II) tetraarylporphyrin π-cation radicals also depended on the nature of peripheral substituents. Effects of peripheral substituents were examined with fourteen complexes by fixing the counter ion to nitrate and the solvent to CH_2Cl_2. Some typical spectra are shown in Fig. 7 to 9 and the results of the analysis are listed in Table 3.

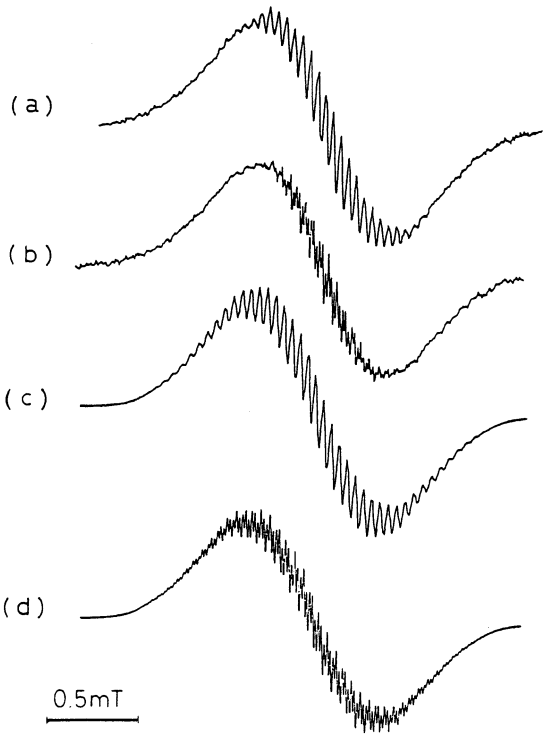

Fig. 7. The EPR spectra of the Zn(4-CH_3)(tpp) π-cation radical in $TBANO_3/CH_2Cl_2$ system, (a) observed at −60 °C and (b) observed at −80 °C. (c) and (d) are the simulated spectra corresponding to (a) and (b), respectively.

As shown in Fig. 7 and Table 3, hfs due to substituents are clearly observed in the 4-CH_3, 4-F, 4-CF_3, and 2-F complexes. This indicates that the spin density in the porphyrin ring permeates the phenyl rings and that the spin distribution can be influenced by the para substitution. This also supports our analysis which includes four para protons in simulating the spectra of the Zn(tpp) π-cation radicals.

These hfcc of the para substituents can be compared with those of the phenoxyl radical which has a_H=1.02 mT for the para proton.[66] By para substitution, a_H= 1.25 mT for 4-CH_3, a_F=2.70 mT for 4-F, and a_F=0.95 mT for 4-CF_3 have been obtained. The hfcc are amplified by factors of 1.23, 2.65, and 0.93, respectively. In the zinc complexes, the factors obtained from Table 3 are 1.33, 1.94, and 0.79, respectively. Thus the mechanism to produce the splittings due to the para substituents in both systems are quite similar. This result indicates that there is considerable conjugation between the phenyl groups and the porphyrin ring, possibly due to the wagging motion of the phenyl group. We can also conclude that the hfs of the phenyl protons are due to the spin polarization caused by the delocalized unpaired π-electron.

The dual structure mentioned in the previous section was also seen in several cases. The π-cation radicals with ortho substituents did not have sharp component. On the other hand, Zn(3,4,5-OCH_3)(tpp) π-cation radical showed a very sharp spectrum even at room temperature, as shown in Fig. 9 (Sharp : Broad= 2 : 1). The temperature at which the sharp component had the maximum intensity varied depending on the nature of substituent. These results are discussed in the last section.

Table 3. The EPR Parameters of Zn(tpp) π-Cation Radicals with Peripheral Substituents[a]

a) In $TBANO_3/CH_2Cl_2$ system. b) 8H : 0.032 at −60 °C. c) From Ref. 16. Counterion and solvent are not described. d) σ_p=0.262 and σ_m=0.12 are assigned for OCH_3 group. Therefore, $4\sigma=4(\sigma_p+2\sigma_m)=-0.12$ can be assumed for Zn(3,4,5-OCH_3)(tpp). e) This shows a broad spectrum without splittings. The a_N may be the smallest of all because this has the smallest total linewidth.

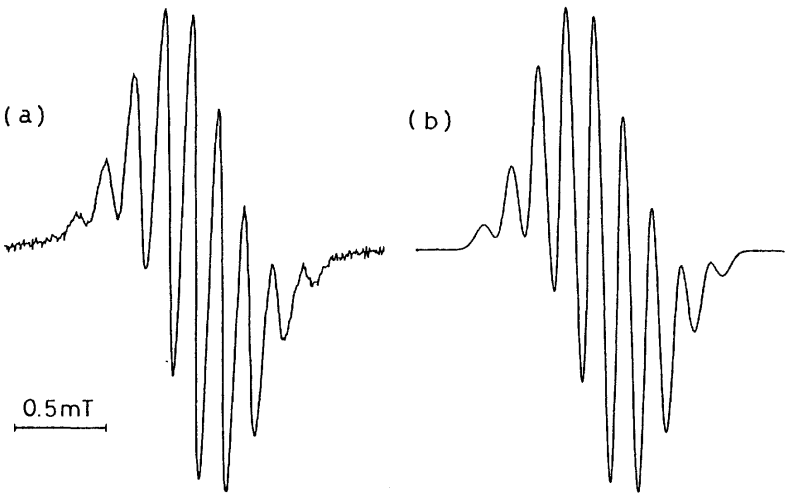

Fig. 8. The EPR spectra of Zn(2,4,6-OCH_3)(tpp) π-cation radical in $TBANO_3/CH_2Cl_2$ system, (a) observed at 0°C, and (b) simulated.

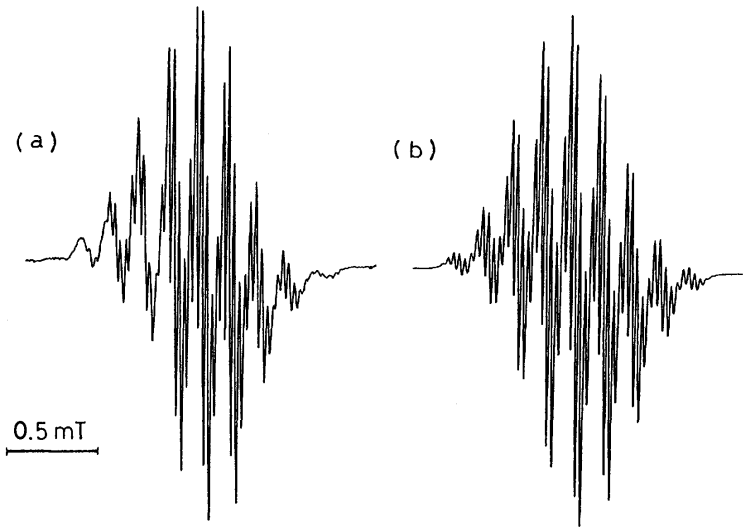

Fig. 9. The EPR spectra of Zn(3,4,5-OCH_3)(tpp) π-cation radical in $TBANO_3/CH_2Cl_2$ system (a) observed at 10°C, and (b) simulated.

The physical properties such as redox potentials and stability constants for complex formation measured in connection with the peripheral substitution have been shown to correlate with the sigma constant of the Hammett equation,[23]

$$P = 4\sigma\rho \quad (1)$$

where P is an observed physical property, σ the Hammett substituent constant, and ρ is a proportionality constant. From the analysis of base addition reactions[23,26] and minute NMR measurements,[29] it has been shown that there is a significant contribution from π-induction in the transmission of the phenyl substituent effect to the whole porphyrin π-system, despite the lack of coplanarity between the porphyrin ring and phenyl groups.[67] Thus a substantial effect may be detectable on a_N which is determined by the spin densities on the nitrogens of the π-cation radicals. The values of 4σ are listed in Table 3 together with the EPR parameters. The hfcc of a_N and a_H vs. 4σ are plotted in Fig. 10. We find considerable substituent effects on the EPR parameters and a clear Hammett linear relation between a_N and 4σ. It is seen that both a_N and a_H increase with the electron donating power of the para substituent. In the previous CNDO/2 calculations for the Co(III)(tpp)X_2 π-cation radical,[37] it was shown that the spin densities on the meso carbons increase together with those on nitrogen as the bond length between cobalt and axial ligands are shortened. This is consistent with the observed increase of a_N and a_H, because the spin density in the phenyl groups is brought by the conjugation through the meso carbons.

From the above discussion, 2,4,6-OCH_3 and 2,4,6-CH_3 are expected to have larger a_N than 4-CH_3, But

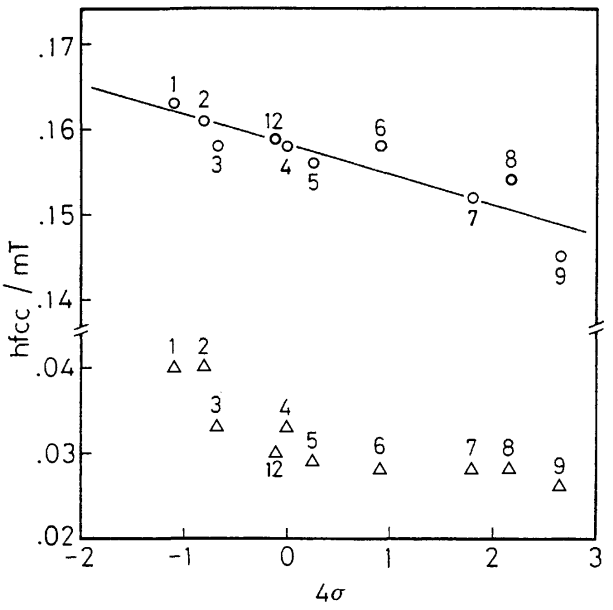

Fig. 10. Plots of a_N (O) and a_H (Δ) vs. Hammett constant (σ). Numbers in the figure refer to the π-cation radicals in Table 3.

2,4,6-OCH_3 and 2-F have smaller a_N values and 2,4,6-CH_3 has a comparable value compared with that of unsubstituted tpp. In these complexes the phenyl groups stand almost vertically to the porphyrin ring in so as disrupting π-conjugation. Therefore, deviations from the linear correlation between a_N and 4σ are expected in these complexes. This steric effect can also be seen in the decrease of the g-values from ca. 2.0031 to 2.0028.

Dual Structure of the Spectra. The EPR spectra of the π-cation radicals exhibit the dual structures in most cases as described above. The coexistence of the two paramagnetic species observed as the dual structure is interpreted by the equilibria between (1) the ligated and unligated radicals, (2) the radicals with different interactions with solvent, and (3) the radicals with different motional states of the phenyl groups. The most probable reason for the coexistence of two paramagnetic species is due to the change in the motional states of the phenyl groups. The ratio of the sharp and broad components is much dependent on the substituents on the phenyl groups. The π-cation radicals with ortho substituents do not have any sharp component. On the other hand, most of the other radicals exhibit substantially sharp component. Especially Zn(3,4,5-OCH_3)(tpp) π-cation radical shows the sharp component with high intensity ratio of 2 : 1 even at room temperature. Thus, it is likely that the broad component is related to the species with hindered rotations of the phenyl groups. When the rotation of the phenyl group is slow in the EPR time scale, broadening of each hyperfine line is expected because of the incomplete averaging of the unequivalent isotropic hfs as well as the anisotropic parts of hfs. The hindered rotations of the phenyl groups of the metalloporphyrins have been investigated by NMR[52,68] and the rates of the rotations and the activation energies have been determined for rutheniumcarbonyl, titanyl, indium, and gallium complexes.[34,35] These rates were indeed found to be slow in the EPR time scale. Thus it is reasonable to consider that the broad component is due to the species with hindered rotational state of the phenyl groups.

On the other hand, the sharp component in the dual structure is highly related to the free rotation of the phenyl groups. Fajer et al. have investigated the π-cation radical of Zn(II) *meso*-tetramethylporphyrin which has no sterically hindered phenyl groups,[69] and observed only the sharp component in the spectrum. It may be unlikely that the phenyl groups rotate freely. If four phenyl groups rotate cooperatively, however, apparent free rotation visualized as the sharp component becomes quite possible.

Concluding Remarks

We have investigated the effects of axial ligand and peripheral substituent on the EPR spectrum of the π-cation radical of Zn(tpp). It is shown that both the axial ligand and the peripheral substituent have large effects on the spin densities on the nitrogen atoms. The axial ligand is known to have a large effects on the behavior of the central metal ion,[33] but the present work shows that the π-system of the zinc complex is also affected by the axial ligand considerably as in the case of the cobalt complex.[37] The nitrogen hfs, a_N, is found to be sensitive to the peripheral substituent, different from the EPR[23,25] and Mössbauer[31,32] parameters of the central metal ions. A good correlation between a_N and the Hammett σ constant as well as the presence of the spin densities on the para positions indicates effective conjugation of the π-system between the porphyrin ring and the phenyl group. It is known that the energy level of the π-system is shifted by the peripheral substituents, but the present result directly shows the effect of the peripheral substitution on the π-system. It is suggested that the presence of the sharp and broad components of the EPR spectra are ascribed to the difference in the motional states of the phenyl groups.

The authors gratefully acknowledge Dr. Kiyoko Yamamoto of JEOL Co. for her kind advice to the sample preparations and kind gift of Zn(tpp) in early stage of this investigation. This work was partially supported by the Grant-in-Aid for Scientific Research on Priority Area of "Macromolecular Complexes (No. 62612005)" from the Ministry of Education, Science and Culture.

Synthesis, Properties, and Crystal and Molecular Structure of Chloro[*N*,*N*-bis(2-hydroxyethyl)glycinato]copper(II)

Hiromitsu YAMAGUCHI,* Makoto NAGASE, Yasuhiko YUKAWA,† Yoshie INOMATA, and Toshio TAKEUCHI
Department of Natural Sciences, Faculty of Science and Technology, Sophia University, 7-1 Kioi-cho, Chiyoda-ku, Tokyo 102
(Received March 8, 1988)

The crystal and molecular structure of the title copper(II) complex was determined by the X-ray diffraction method. The crystal is orthorhombic with the space group Pbca, Z=8, a=14.18(1), b=15.835(7), c=8.188(3) Å. Full matrix least-squares refinements have led to a final R value of 0.047 for 2128 reflections. The copper atom is in a trigonal-bipyramidal geometry, ligated by a nitrogen atom, an oxygen atom of carboxylato group, two hydroxyl oxygen atoms and a chlorine atom. The complex has three five-membered chelate rings which are formed by one copper, one nitrogen, one oxygen, and two carbon atoms. There are two hydrogen bonds formed between the non-coordinated carboxylato oxygen atom and the hydroxyl hydrogen atom. The powder diffuse reflection spectrum of this complex exhibits a band characteristic of trigonal bipyramidal structure at 1000 nm. In the far-infrared absorption spectra of this complex, the bands at 340, 317, and 275 cm^{-1} are assigned to the stretching vibrations of Cu-N, Cu-Cl, and Cu-O (carboxylato), respectively.

Some of the present authors have previously reported on the syntheses and properties of bivalent metal complexes of *N*,*N*-bis(2-hydroxyethyl)glycine (Hbheg).[1] In that work two copper(II) complexes with Hbheg have been prepared; one is [Cu(bheg)$_2$] and the other is [CuCl(bheg)].

Anan'eva et al. have determined by an X-ray diffraction study that in the former complex the copper atom occupied the center of inversion and that the coordination number was six in an elongated tetragonal bipyramid formed by two nitrogen atoms and four oxygen atoms from two ligands.[2]

As for the latter complex, it has been presumed that the copper atom is coordinated through an oxygen atom of the carboxylato group, a nitrogen atom and two oxygen atoms of two hydroxyl groups.[1]

However, there are many types of coordination for a hydroxyl group. For example, in the case of bis(triethanolamine)nickel(II) nitrate, the nickel atom is ligated by two oxygen atoms out of the three hydroxyl groups in one triethanolamine molecule, and the other oxygen atom is not associated with the coordination;[3] for bis(triethanolamine)strontium(II) nitrate, three hydroxyl oxygen atoms coordinate the identical strontium atom.[4]

It is therefore difficult to determine from the infrared spectra how these hydroxyl oxygen atoms coordinate the copper atom in [CuCl(bheg)].

In this work, the structure of [CuCl(bheg)] was determined by an X-ray diffraction study; the behavior of the two hydroxyl groups is discussed in detail. In addition, this structure is compared with the structure of copper(II) chloride complex with *N*,*N*-diethylglycine (Hdeg), [CuCl(deg)],[5] previously investigated in our laboratory, and an interpretation of the properties has been carried out based on the proposed structure.

† Present address: Division of Chemistry, General Education Department, Niigata University, 8050, Ikarashi, Ninocho, Niigata 950-21.

Experimental

Preparation of the Sample. The samples for the X-ray diffraction study were prepared as follows: equimolar amounts of $CuCl_2 \cdot 2H_2O$ and Hbheg were mixed in aqueous solution. Green crystals were obtained from this solution by keeping it in a desiccator containing ethanol for several days.

X-Ray Measurements and Structure Determination. The crystal data are given in Table 1. The reflection intensities were collected by the ω-2θ scan technique ($2\theta < 70°$) on a Rigaku AFC-6A automated four-circle diffractometer, with graphite monochromated Mo$K\alpha$ radiation (λ=0.71073 Å). The 2128 intensities ($|F_o| > 3\sigma(|F_o|)$) were corrected for Lorentz and polarization factors, but not for absorption, because of the low magnitude of μr($<$1.0).

All calculations were carried out on a Hitachi M-680H computer at the Computer Center of The University of Tokyo, using UNICS III[6] and ORTEP.[7] The scattering factors were taken from tables.[8] The structure was solved by the heavy-atom method. The position of the copper atom was obtained from the three-dimensional Patterson function, while the positions of all other non-hydrogen atoms were successively located by Fourier syntheses and were refined by a block-diagonal least-squares method and only in the last cycle by a full matrix least-squares method. The positions of hydrogen atoms were obtained by difference-Fourier syntheses. In the last cycle of the full matrix least-squares refinement with anisotropic temperature factors for all non-hydrogen atoms, all the parameter shifts were less than one-third of the corresponding standard deviations. The weighting scheme was $W = 1/\{a \times (|F_o|)^2 + b \times |F_o| + c\}$. These coefficients were automatically computed in the program system. The final R value was 0.047.

Powder Diffuse Reflection and Electronic Spectra. These

Table 1. Crystal Data

$CuCl(C_6H_{12}NO_4)$	F.W.=261.17
Orthorhombic	Pbca
a=14.18(1) Å	b=15.835(7) Å
c=8.188(3) Å	U=1838(2) Å^3
Z=8	
D_m=1.871(3) g cm^{-3}	D_x=1.887 g cm^{-3}
μ(Mo$K\alpha$)=26.6 cm^{-1}	

spectra were obtained from 800 to 1500 nm with a JASCO UVIDEC-590 spectrophotometer. The spectra from 400 to 800 nm were obtained with a Hitachi 624 digital spectrophotometer. Both spectrophotometers were equipped with a standard reflection attachment and a magnesium oxide standard for measurements of powder diffuse reflection spectra.

Infrared and Far-Infrared Absorption Spectra. Infrared absorption spectra from 4000 to 400 cm^{-1} were measured using a Hitachi spectrophotometer, type EPI-G_2. Far-infrared absorption spectra from 700 to 200 cm^{-1} were measured using a Hitachi spectrophotometer, type EPI-L. Samples were prepared as KBr disks and Nujol mulls. The spectra were calibrated with polystyrene and atmospheric water vapor.

Results and Discussion

Structure of [CuCl(bheg)]. The final atomic parameters are listed in Table 2,[9] the interatomic distances in Table 3,[9] and the bond angles in Table 4.

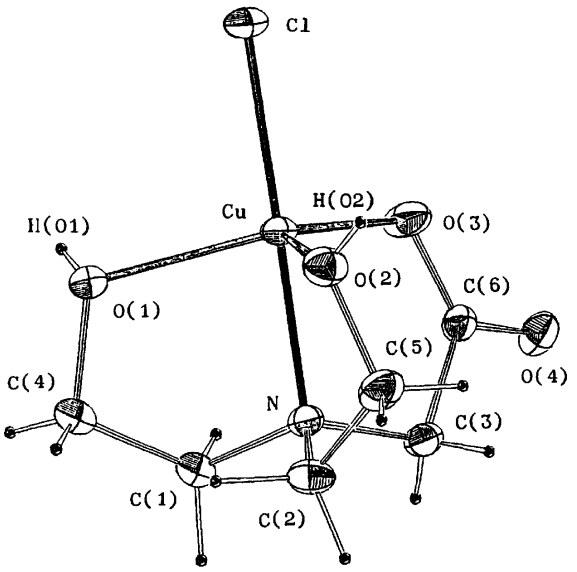

Fig. 1. The molecular structure of [CuCl(bheg)] and the numbering scheme of the atoms.

The deviations of atoms from least-squares planes are shown in Table 5. The molecular structure of the complex and the numbering scheme of the atoms, except alkyl hydrogen atoms, are shown in Fig. 1.

The stucture of the complex is trigonal-bipyramid.

The copper atom is surrounded by five atoms: one carboxylato oxygen atom, two hydroxyl oxygen atoms, one nitrogen atom and one chlorine atom. The nitrogen atom and the chlorine atom are at the apical position. The angle Cl-Cu-N is 179.29(9)° and three coordinated oxygen atoms form a triangle around the copper atom. The copper atom is 0.24 Å above the plane formed by the three ligating oxygen atoms. The bond length of Cu-O (carboxylato) (1.963 Å) is shorter than those of Cu-O (hydroxyl) (2.140 and 2.078 Å).

The complex has three five-membered *N*,*O*-chelate rings. They are all distorted because of the small N-Cu-O angles. As shown in Table 5, plane (4) shows the least deviation among the chelate rings because it includes one sp^2 carbon atom. All C-C bond lengths are slightly shorter than the usual general C-C bond lengths: this is the same trend as those of the free ligand already reported.[10] The three C-N bonds become shorter than those of the free ligand (1.508, 1.505, and 1.504 Å) because the nitrogen atom of the free ligand is protonated. The distances between carboxylato carbon atom and carboxylato oxygen atom: C(6)-O(3) (coordinated); 1.252(4) Å and C(6)-O(4) (non-coordinated), 1.246(4) Å, are not so different, since O(4) forms two hydrogen bonds with the neighboring unit. The bond lengths of the O-H are shorter than the usual general O-H bond lengths. The free ligand also has the same trend.[10]

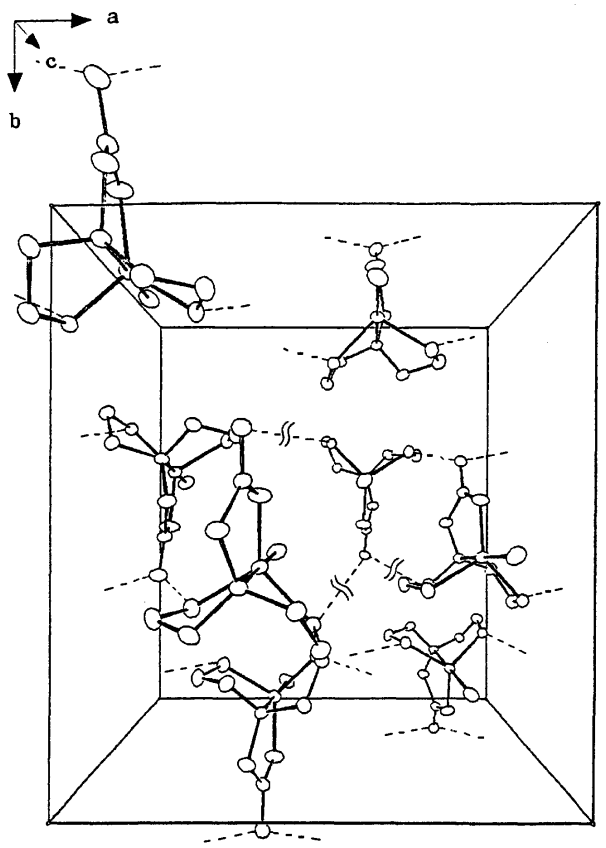

Fig. 2. The crystal structure of [CuCl(bheg)]. (----: Hydrogen bonding).

Let us now compare the structure of this complex with that of [CuCl(deg)]. The coordination number of [CuCl(deg)] is five,[5] like that of [CuCl(bheg)]. In [CuCl(deg)], the copper atom is surrounded by three carboxylato oxygen atoms, one nitrogen atom, and one chlorine atom, and the structure consists of a one-dimensional polymer chain bridged by only one carboxylato group of *N*,*N*-diethylglycine. This [CuCl(bheg)] has no bridging carboxylato groups and so is a monomer with the coordination of hydroxyl groups.

The molecular packing of the complex is shown in Fig. 2. There are no intermolecular interactions except at the two hydrogen bonds, which are formed between the non-coordinated carboxylato oxygen atom and the hydroxyl hydrogen atom. They are parallel to the ac plane. No intermolecular interactions parallel to b axis are found. This agrees with the easy cleavage of this crystal along this axis.

Powder Diffuse Reflection and Electronic Spectra. The reflection spectrum shows a broad band at about 1000 nm. This wavelength is different from those of copper(II) chloride complexes with *N*-substituted amino acids previously investigated in our laboratory, as shown in Table 6, but it is near to the value of the reflection band (900 nm) for 1-(2-ammonioethyl)piperazinediium pentachlorocuprate(II) dihydrate, which has a typical trigonal bipyramidal structure.[14] The electronic spectrum in aqueous solution shows a band at 760 nm. As this spectrum is similar to that of octahedral configurations, the structure of this complex seems to change in aqueous solution.

Infrared Absorption Spectra. There is a strong broad band at 3025 cm^{-1} for [CuCl(bheg)]. It is assigned to the OH stretching vibration, because of its disappearance on deuteration and the absence of bands in this region for [CuCl(deg)]. As this band is observed at a lower frequency region than for the free ligand (3186 and 3089 cm^{-1}), the strengths of the O-H bonds seem to become weaker on coordination.

For the free ligand, the COO^- antisymmetric and symmetric stretching vibrations appear at 1639 and 1401 cm^{-1}, respectively. In [CuCl(bheg)] the former

Table 6. Powder Diffuse Reflection Spectra of Copper(II) Chloride Complexes with *N*-Substituted Amino Acids

Complex	λ/nm	Coordination number[a]	Reference
CuCl(pro)·MeOH	754	5+1	11
CuCl(hpro)·H_2O	755	5+1	12
CuCl(pro)·H_2O	730	5	13
CuCl(deg)	626	4+1	5
CuCl(bheg)	1000	5	This work

Hpro=L-proline, Hhpro=4-hydroxy-L-proline.
a) Coordination Number: For example "5+1" stands for that the complex has 5 usual coordination bonds and 1 weak bond.

shifts to a somewhat lower frequency region (1578 cm^{-1}) and the latter shifts to a higher one (1406 cm^{-1}). The frequency separation between these two frequencies for [CuCl(bheg)] (172 cm^{-1}) is smaller than that of the free ligand. It has been reported that the frequency separation betweeen the two COO^- stretching vibrations in an unidentate complex is generally larger than that of a free ligand.[15] Though [CuCl(bheg)] shows an opposite tendency, this vibrational spectrum pattern is consistent with the result of X-ray analyses that the bond lengths of the C-O (coordinated) and the C-O (non-coordinated) are almost the same.

Far-Infrared Absorption Spectra. Two new bands (340 and 275 cm^{-1}) which were not observed in the ligand appear in [CuCl(bheg)]. They are assigned to Cu-N and Cu-O (carboxylato) stretching vibrations, by comparing this spectrum with those of [$Cu(bheg)_2$] and metal complexes with other amino acids.[16-18] From the molecular structure determined by X-ray analysis, it is clear that this molecule has a Cs symmetry. Therefore in view of the five atoms which form a trigonal-bipyramid around the copper atom, there are twelve normal vibrations. They are divided into two symmetries (8A'+4A") which are all infrared active. Since the bond lengths of the Cu-OH are longer than that of Cu-O (carboxylato), two Cu-OH stretching vibrations appear at a lower frequency region than where Cu-O (carboxylato) stretching vibration is observed. Therefore, it is reasonable to assign the band at 275 cm^{-1} to the Cu-O (carboxylato) stretching vibration.

The band at 317 cm^{-1} is assigned as a terminal Cu-Cl stretching vibration, by comparison with the spectra of [$Cu(bheg)_2$], [CuCl(deg)][5] (344 cm^{-1}) and other copper(II) complexes containing chlorine atoms.[19,20]

Such behavior in infrared and far-infrared spectra is in good agreement with the results of X-ray diffraction study of [CuCl(bheg)].

The authors wish to express their thanks to Professor Akira Ouchi of The University of Tokyo for X-ray diffractometer measurements. They would also like to thank Dr. F.S. Howell of Sophia University for correcting this manuscript.

Structures and Properties of Divalent Metal Complexes of an N_2O_2 Type Ligand, 6,6′-Bis(benzoylamino)-2,2′-bipyridine

Masaki YAMADA, Koji ARAKI,* and Shinsaku SHIRAISHI*
Institute of Industrial Science, The University of Tokyo, 7-22-1 Roppongi, Minato-ku, Tokyo 106
(Received March 9, 1988)

Complex formations of an N_2O_2 tetradentate ligand, 6,6′-bis(benzoylamino)-2,2′-bipyridine ($babpH_2$) with various divalent metal ions were investigated. $BabpH_2$ complexes of Ni(II), Co(II), and Zn(II) were obtained as dinitrate and/or diacetate, and their deprotonated complexes, [Ni(babp)], [Co(babp)], and [Zn(babp)], where babp represents the deprotonated form of amide protons of $babpH_2$, were also isolated. The deprotonated complexes were shown to have high thermal stability up to 300 °C. The structures, stabilities, and spectral properties of these complexes were discussed in relation to the copper(II) complexes of $babpH_2$ and babp.

Recently we reported the syntheses, structures, and some properties of a new type of tetradentate N_2O_2 ligand, 6,6′-bis(acylamino)-2,2′-bipyridines and their copper(II) complexes.[1] Deprotonation of the amide protons of copper(II) complex **1a** takes place in weakly acidic to neutral pH range, giving the deprotonated complex **2a** which have a similar structure to those of salen complexes in their N_2O_2 tetradentate coordination sites, square-planar structure, and the anionic sites on oxygens. In addition, our preliminary results showed that the deprotonated type of the cobalt(II) complex of 6,6′-bis(benzoylamino)-2,2′-bipyridine ($babpH_2$), [Co(babp)], serves as a better catalyst for oxygenation of phenols by molecular oxygen compared to cobalt(II)-salen complexes.[2,3] In this report, complex formations of $babpH_2$ with various divalent metal ions including cobalt(II) and the structural elucidation of the complexes are described.

Results

Syntheses of Complexes. Syntheses of 1 : 1 complexes of $babpH_2$ with various divalent metal ions are shown in Scheme 1, and their characterization data are summarized in Table 1. $BabpH_2$ complexes of nickel(II) as a nitrate (**1b**), cobalt(II) and zinc(II) as acetates (**1′c** and **1′d**, respectively), were obtained by mixing $babpH_2$ with corresponding metal salts. The cobalt(II) (**1c**) and zinc(II) (**1d**) complexes were also obtained in nitrate form from **1′c** and **1′d**, respectively (see experimental section). All of the non-deprotonated complexes were soluble in water. The nitrate of the non-deprotonated nickel(II) complex **1b** was very stable in water even under highly acidic conditions, while the non-deprotonated complexes of cobalt(II) and zinc(II) acetates (**1′c** and **1′d**, respectively) or nitrates (**1c** and **1d**, respectively) released the metal ions in weakly acidic or even in neutral water to give metal-free $babpH_2$ quantitatively.

In the case of nickel(II), use of nickel(II) acetate directly yielded the deprotonated-type complex [Ni(babp)] (**2b**), being similar to the case of copper (II).[1] The deprotonated-type of cobalt(II) complex [Co(babp)] (**2c**) was obtained as a precipitate by addition of twice molar amount of KOH to **1′c** in methanol under anaerobic atmosphere.[4] Similar attempt to obtain the deprotonated-type complexe of zinc(II) from **1′d** resulted in recovery of metal-free $babpH_2$ (see experimental section). But the thermolysis of **1′d** (see thermal properties section) successfully afforded the zinc(II) complex [Zn(babp)] (**2d**). These deprotonated complexes, **2b—2d**, are insoluble in water and not release metal ions in acid-free water.

IR Spectra. The nitrates of the non-deprotonated complexes, **1b**, **1c**, and **1d**, showed quite similar IR spectra to that of the corresponding copper(II) complex **1a**,[1] and the deprotonated complexes, **2b**, **2c**, and **2d** to that of the corresponding copper(II) complex **2a** (Table 2),[1] showing that either $babpH_2$ or babp serves as a tetradentate N_2O_2 ligand in those complexes similarly to **1a** and **2a**.[1,5,6]

1'd	3334	1658 1694	1538	1266	1578 (ν(C-O) of acetate)

a) Ref. 1. b) Shoulder peak.

On the other hand, IR spectra of the acetates of the non-deprotonated complexes, **1′c** and **1′d**, are quite different in amide carbonyl region (amide I) from those of nitrates (Table 2). The amide I bands of the acetates appear at higher wavenumber compared with that of metal-free babpH_2. Similar blue shift of the amide I band was reported for the non-deprotonated palladium(II) complex of 2-(acetylamino)pyridine in which the ligand coordinates only with its ring nitrogen but not with its amide oxygen.[6] Therefore, it may be implyed that babpH_2 in **1′c** and **1′d** coordinates to metal ions only with its ring nitrogens but not with its amide oxygens. The structures of the acetates are remained uncertain.

Electronic Spectra. The electronic spectra of the complexes in dimethyl sulfoxide (DMSO) are shown in Fig. 1. The acetates of the non-deprotonated complexes, **1′c** and **1′d**, showed the similar spectra to those of the corresponding deprotonated-type complexes (**2c** and **2d**, respectively). Therefore, it is quite likely that the amide protons of these complexes were dissociated under the measured conditions.

Dropwise addition of nitric acid to the solution of the deprotonated nickel(II) complex **2b** in DMSO up to twice molar amount caused gradual spectral change to that of **1b** in two-steps (Fig. 2). This result shows

$$[Ni(babpH_2)]^{2+} \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} [Ni(babpH)]^{+} \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} [Ni(babp)]$$

Scheme 2.

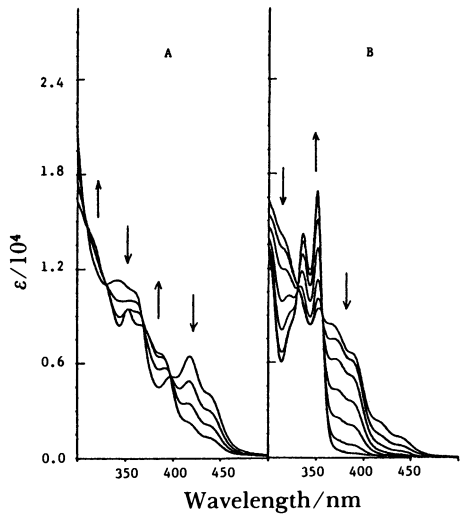

Fig. 2. The spectral change of **2b** in DMSO (6.67×10^{-5} M) by addition of nitric acid at 20°C. Molar ratio of added nitric acid were as follows; A: 0.0, 0.2, 0.4, and 0.6, B: 0.6, 0.8, 1.0, 1.2, 1.6, 1.8, and 2.0.

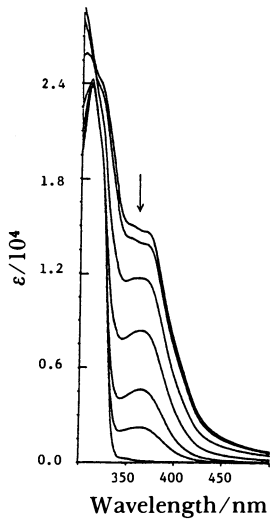

Fig. 3. The change of electronic spectra of **2c** by addition of nitric acid in DMSO (6.67×10^{-5} M) at 20°C. Molar ratio of added nitric acid were 0.0, 0.5, 1.0, 1.5, 2.0, 2.2, and 2.5.

that protonation to the deprotonated species **2b** in DMSO takes place stepwisely via intermediacy of monoprotonated species (Scheme 2). Similar result has been observed for the copper(II) complex **2a**.[1] The spectra of the cobalt(II) and zinc(II) complexes, **2c** and **2d**, in DMSO changed to that of metal-free babpH_2 by addition of nitric acid (Fig. 3).[7]

Thermal Properties of Complexes in Solid State. Thermal properties of the complexes were analyzed by TG and DTA, and the results are summarized in Table 3. Figure 4 represents the typical TG curves of the complexes, **1b**, **1′d**, and **2b**. Those of the copper(II) complexes are also included which were not reported in the preceding paper.[1]

Table 3. Thermal Properties of Complexes[a)]

Complex	Temperature/°C
1a	63—76($-H_2O$) 136—161($-H_2O$) 224—238($-2HNO_3\rightarrow$**2a**)

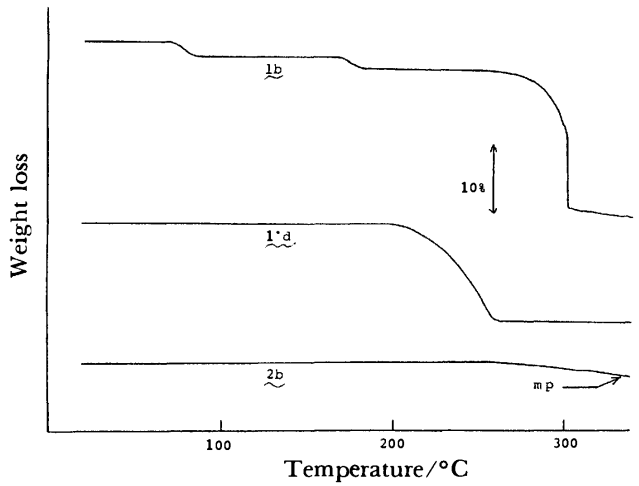

Fig. 4. Typical TG curves of the complexes, **1b**, **1'd**, and **2b**.

In the case of the nitrate salts of the non-deprotonated complexes, **1a—1d**, small weight loss during 50—190 °C accounted for loss of two water molecules took place endothermically. Further heating caused gradual weight decrease endothermically at above 220 °C, followed by abrupt weight loss with sharp exothermic peak in DTA. In the case of **1a** and **1b**, these weight losses were accounted for the loss of nitric acid, and IR spectra of the residual solids were identical to those of **2a** and **2b**, respectively. While, weight of **1c** and **1d** decreased much more than those accounted for loss of two nitric acid molecules indicating the thermal decomposition of the ligand, and, indeed, IR spectra of the residues were different from those of the deprotonated complexes. Instead, heating the acetate salts, **1'c** and **1'd**, up to 260 °C successfully afforded the deprotonated complexes of cobalt(II) and zinc(II), respectively, by elimination of acetic acid, though elimination took place more slowly in these cases. IR spectra of the residual solids were characteristic to those of the deprotonated complexes. Thus, it was shown that thermolysis of the non-deprotonated complexes yielded the corresponding deprotonated complexes. It is worth to note that the deprotonated complex **2d**, [Zn(babp)] was isolated only by thermolysis of **1'd** but not by deprotonation in solution under basic conditions.

The deprotonated complexes **2a—2c** showed clear melting points near 330 °C, and were stable up to these temperatures. Decomposition of these complexes were only observed when they were heated above their melting points. The deprotonated complex of zinc(II) **2d** did not show any weight loss up to 370 °C, and decomposed without showing any apparent melting above this temperature.

Discussion

Structure and Stability of the Complexes. The ligand $babpH_2$ is shown to coordinate as N_2O_2 tetradentate ligand to form two types of the complexes, one is the non-deprotonated type (nitrate salts), **1a—1d**, and the other the deprotonated ones, **2a—2d**. The structure of the complexes were elucidated by their IR spectra[1,5,6] and elemental analyses. In the case of acetates of the non-deprotonated complexes, **1'c** and **1'd**, however, $babpH_2$ was suggested to serve as an N_2 bidentate ligand from their IR spectra.

The non-deprotonated complexes of copper(II)[1] and nickel(II) were stable even in acidic aqueous solution, while those of cobalt(II) and zinc(II) were not stable in water. This difference in the stability of the non-deprotonated complexes were in agreement with Irving-Williams'[8] and Mellor-Malley's[9] laws. The deprotonated complexes, **2a—2d**, were stable enough not to suffer any change in neutral acid-free water.

Dissociation of Amide Protons. Amide proton is very weak acid and the pK_a is higher than 13 in most cases.[10] Complexation of metal ions at amide oxygen is known to increase their acidity.[10] Spectrometric titration of the nitrate salt of the non-deprotonated nickel(II) complex, **1b**, in water with pottasium hydroxide solution indicated that the two amide protons dissociated almost simultanously at pH 5.8 and the deprotonated complex **2a** precipitated. Titration of copper(II) complex **1a** by similar method showed that dissociation of both of its amide protons took place at pH 5.2.[1] Titration of the cobalt(II) complex could not be carried out because of its instability in water. Complexation of $babpH_2$ and cobalt(II) acetate gave the non-deprotonated complex, though com-

plexation with nickel(II) or copper(II) acetate gave the deprotonated complex, suggesting that the acidity of the amide protons of the cobalt(II) complex is lower than that of copper(II) or nickel(II) complex. Thus acidities of the amide protons of the $babpH_2$ complexes follow the order, Co(II)<Ni(II)<Cu(II). Acidities of metal-chelated amide protons in peptides were also known to follow this order.[10]

In most cases amide groups are known to coordinate to metal ions by their oxygens, while, amide groups in deprotonated form by their nitrogens. In the cases of $babpH_2$, however, both $babpH_2$ and babp served as an N_2O_2 tetradentate ligand, and high acidity of amide protons in nitrate salts of the non-deprotonated complexes were observed. One of the reason why the amide protons in the complexes of $babpH_2$ have high acidity might be due to the high stability of the deprotonated complexes. They are thought to be stabilized by intramolecular charge transfer because they contain strong O-donor (deprotonated amide oxygens) and heteroaromatic N-donor having relatively strong π-electron accepting abilities (2,2′-bipyridine moiety).[11] This effect has been proposed as "intramolecular mixed ligand" effect[10,12] to explain the stability of the complexes of 8-quinolinol[13] and the deprotonated palladium(II) complex of 2-(acetylamino)pyridine.[6,10]

Thermal Properties. The results of thermal analyses of the non-deprotonated complexes indicated that dissociation of amide protons took place by heating in solid state. In some cases, thermolysis is an effective process to obtain deprotonated complexes, because dissolution of the complexes in aqueous solution sometimes causes the release of the metal ions from the complexes.

It is noteworthy that the deprotonated complexes **2a—2d** are thermally stable up to 300°C under aerobic atmosphere. This also enable thermal dissociations of acid moieties of the non-deprotonated complexes to give deprotonated ones.[14]

Experimental

Materials. 6,6′-Bis(benzoylamino)-2,2′-bipyridine ($babpH_2$) was prepared from 6,6′-diamino-2,2′-bipyridine[15] and benzoyl chloride according to the method previously reported.[1] Other chemicals were obtained commercially, and some of them were purified by conventional methods prior to use.

Spectral Measurements. IR spectra were measured by JASCO IR-700 spectrophotometer. Electronic spectra were recorded on a JASCO UVIDEC-505 spectrophotometer at 20 °C. Measurement of cobalt(II) complexes in this report were carried out under anaerobic conditions because they interact with molecular oxygen in solution.[2,3]

Thermal Analyses. TG and DTA curves were recorded simultanously on Shimadzu DTG-30 Thermal Analyzer with heating rate of 5 °C min^{-1} under aerobic conditions.

Nickel(II) Complex 1b: This was obtained from 78 mg (0.2 mmol) of $babpH_2$ and 58 mg (0.2 mmol) of $Ni(NO_3)_2 \cdot 6H_2O$ by complexation in methanol in a similar manner to the preparation of copper(II) complex **1a**.[1] Recrystallization from water gave 83 mg (68%) of pale green plates of $Ni(babpH_2)(H_2O)_2(NO_3)_2$.

Nickel(II) Complex 2b: This was obtained from 78 mg (0.2 mmol) of $babpH_2$ and 50 mg (0.2 mmol) of $Ni(OAc)_2 \cdot 4H_2O$ by complexation in chloroform in a similar manner to the preparation of copper(II) complex **2a**.[1] Recrystallization from benzene gave orange needles of [Ni(babp)], yield 57 mg (63%).

Cobalt(II) Complex 1′c: A mixture of 78 mg (0.2 mmol) of $babpH_2$ and 50 mg (0.2 mmol) of $Co(OAc)_2 \cdot 4H_2O$ in 100 cm^3 of chloroform was stirred at room temperature until the suspension became a homogeneous brown solution. Then the solvent was removed by evaporation to leave pink powder, which was washed by benzene, yielding 80 mg (66%) of $Co(babpH_2)(OAc)_2(H_2O)_2$.

Zinc(II) Complex 1′d: A mixture of 78 mg (0.2 mmol) of $babpH_2$ and 44 mg (0.2 mmol) of $Zn(OAc)_2 \cdot 2H_2O$ in 100 cm^3 of tetrahydrofuran was stirred at room temperature until the suspension became a homogeneous pale brown solution. Then solvent was removed by evaporation. Residual white powder was recrystallized from benzene to give 72 mg (62%) of $Zn(babpH_2)(OAc)_2$.

Cobalt(II) Complex 1c and Zinc(II) Complex 1d: A mixture of 78 mg (0.2 mmol) of $babpH_2$ and 50 mg (0.2 mmol) of $Co(OAc)_2 \cdot 4H_2O$ in 100 cm^3 of tetrahydrofuran was stirred at room temperature until the suspension became a homogeneous brown solution. Then 0.4 cm^3 of 1M HNO_3 (1 M=1 mol dm^{-3}) was added and was allowed to stand for 24 h at room temperature. The precipitated pale brown powder was collected by filtration, yielding 110 mg (90%) of **1b**, $Co(babpH_2)(H_2O)_2(NO_3)_2$. Compound **1d** was obtained from 78 mg (0.2 mmol) of $babpH_2$ and 44 mg (0.2 mmol) of $Zn(OAc)_2 \cdot 2H_2O$ in a similar manner to the preparation of **1c**, yielding 98 mg (79%) of $Zn(babpH_2)(H_2O)_2(NO_3)_2$ as white needles. Non-deprotonated complxes **1c** and **1d** were not obtained pure form by direct complexation of $babpH_2$ and nitrate.

Cobalt(II) Complex 2c: Under nitrogen gas bubbling, a mixture of 78 mg (0.2 mmol) of $babpH_2$ and 50 mg (0.2 mmol) of $Co(OAc)_2 \cdot 4H_2O$ in 20 cm^3 of methanol was stirred at room temperature until the mixture became a homogeneous brown solution. To this solution, 0.8 cm^3 of 0.5 M-methanolic KOH was added. The color of the solution changed to dark red followed by precipitation of red solid. After stirring another 1 h under nitrogen atmosphere at room temperature, the red solid was collected by filtration. Recrystallization from benzene gave red needles of **2c**, [Co(babp)], yield 60 mg (67%). When similar process was performed under aerobic atmosphere or oxygen bubbling, reaction mixture retained homogeneous after addition of alkali, and removal of most of methanol gave 55 mg of yellow powder, which showed almost the same IR spectrum as that of **2c** except that the former has strong absorption band at 1403 cm^{-1}.

Zinc(II) Complex 2d: Compound **1′d** (116 mg, 0.2 mmol) was heated at 280 °C under reduced pressure for 20 h. Yellow powder of [Zn(babp)], **2d**, was obtained as a residue, yield 84 mg (92%). Compound **2d** was not obtained as a precipitate by addition of potassium hydroxide to a solution of **1d** or **1′d** in methanol. Extraction by benzene from residual solid after removal of methanol gave only metal free $babpH_2$ as extract and $Zn(OH)_2$ as insoluble solid.

Effect of the *N*-Methylation of Dodecylammonium Chloride on the Adsorption from Its Micellar Solution

Makoto ARATONO,* Toru OKAMOTO, Norihiro IKEDA, and Kinsi MOTOMURA
Department of Chemistry, Faculty of Science, Kyushu University 33, Fukuoka 812
(Received April 6, 1988)

The surface tension of the aqueous solution of dodecylmethylammonium chloride (DMAC) and dodecyldimethylammonium chloride (DDAC) was measured as a function of temperature under atmospheric pressure at concentrations below and above the critical micelle concentration (cmc). The entropy and energy of adsorption from the monomeric state in the aqueous solution and the micellar state were evaluated by applying the thermodynamic equations of adsorption to the surface tension values. The thermodynamic quantities were compared with those of the aqueous solutions of dodecylammonium chloride (DAC) and dodecyltrimethylammonium chloride (DTAC). It was found that the successive *N*-methylation of DAC has a considerable effect on the adsorbed film with changes in its surface density, entropy, and energy brought about by changes in the geometry and the hydrophilicity of the polar head group.

The adsorption of dodecylammonium chloride (DAC) and dodecyltrimethylammonium chloride (DTAC) from their micellar solution at water/air interface has been investigated in our previous papers.[1,2] It has been shown that the thermodynamic quantity changes associated with the adsorption and micelle formation are greatly influenced by the chemical structure of the head group; for example, both entropy changes associated with adsorption from the monomeric state in the solution and the micellar state were negative for DAC and positive for DTAC, while the corresponding energy changes were positive for the two surfactants.

Now the systematic study is required on the effect of the chemical structure of the head group on the adsorption and micelle formation. In this paper we are concerned with the effect of the successive *N*-methylation of dodecylammonium chloride on the adsorption and micelle formation; the adsorption of dodecylmethylammonium chloride (DMAC) and dodecyldimethylammonium chloride (DDAC) at the aqueous solution/air interface at concentrations around the critical micelle concentrations is investigated in detail. The surface tension is measured as a function of temperature at fixed concentrations under atmospheric pressure. The thermodynamic quantities are evaluated by applying the thermodynamic equations developed previously[1] to the measured values of surface tension. By comparing the results with those of DAC and DTAC, the influence of the chemical structure of the head group is considered systematically.

Experimental

To synthesize dodecylmethylammonium chloride, dodecylmethylamine was prepared first according to the following way.[3] Acrylonitrile and dodecylamine were mixed slowly, stirred for 30 minutes, and refluxed for six hours. After removal of the excess acrylonitrile in vacuo, resulting *N*-(2-cyanoethyl)dodecylamine was obtained by the fractional distillation of the mixture under reduced pressure. The reaction of *N*-(2-cyanoethyl)dodecylamine with formic acid and formaldehyde yielded *N*-(2-cyanoethyl)-*N*-methyldocecylamine.[4] Its pyrolysis at 250—270 °C and 450 mmHg (1 mmHg≈133.322 Pa) followed by distillation under reduced pressure gave *N*-methyldodecylamine. As the second step the amine was neutralized by hydrochloric acid and the salt was purified by repeated recrystallization from ethanol–ethyl acetate mixture.

To obtain dodecyldimethylammonium chloride, *N,N*-dimethyldodecylamine was prepared as the first step as follows;[4] formic acid, ethanol solution of dodecylamine, and formaldehyde were mixed and, after reflux for 15 hours, neutralized by 25% aqueous sodium hydroxide solution, *N,N*-dimethyldodecylamine being separated as the upper phase. The amine was dried over sodium hydroxide and then distilled under reduced pressure. Dodecyldimethylammonium chloride was obtained by the reaction of the amine with hydrochloric acid and recrystallized from benzene–ethyl acetate mixture and then from ethanol–ethyl acetate mixture for five times. The purity of surfactants was confirmed by observing no minimum on the surface tension vs. concentration curves.

Water was distilled three times from alkaline permanganate solution. The surface tension was measured by the drop volume apparatus and procedure described previously,[5] and the experimental error was within 0.05 mN m^{-1}.

Results and Discussion

The surface tension γ was measured as a function of temperature T at constant molalities m_1 of the surfactant under atmospheric pressure. The surface tension value of the aqueous solution of DMAC is plotted against temperature in Fig. 1. Figure 2 shows the γ vs. m_1 curves depicted by taking up the γ values in Fig. 1 at a given temperature. It is seen that the curve has a sharp break point, of which the concentration is referred to as a critical micelle concentration (cmc). Looking at Fig. 1, it is observed that the γ vs. T curve has a minimum at a concentration between about 5 mmol kg^{-1} and the cmc, while it is a straight line with a slightly positive slope at a concentration above the cmc. Since the shape of γ vs. m_1 curve changes abruptly at the cmc, the γ vs. T curve has a break point as indicated by an arrow. For the aqueous DDAC

solution/air interface, similar measurements were made; the γ vs. T curves at constant molalities and the γ vs. m_1 curves at constant temperatures are drawn in Figs. 3 and 2, respectively. Comparing the curves in Fig. 3 with those in Fig. 1, we notice that the γ vs. T curve of DDAC has no minimum at a concentration below the cmc and its slope remains negative at a concentration above the cmc.

In Figs. 4 and 5, respectively, the critical micelle concentration vs. temperature curves and the surface

tension vs. concentration curves at 298.15 K of the aqueous solutions of DMAC and DDAC are shown with the corresponding curves of DAC and DTAC. It is seen that the temperature dependence of the cmc value is remarkably large and has a minimum. It is also seen that the cmc and its surface tension γ^{cmc} are correlated to the chemical structure of the polar headgroup of surfactant; the *N*-methylation of dodecylammonium chloride successively raises the cmc and

γ^{cmc} values and the differences in the cmc and the γ^{cmc} values seem to be remarkable between dodecyldimethylammonium chloride and dodecyltrimethylammonium chloride. Such a behavior was also observed in the case of the electric conductivity measurements of the surfactants.[6]

It has been shown that the derivative of surface tension with respect to temperature is the one of the useful quantities to elucidate the adsorption from the micellar solution.[1,2,5,7-9] The $-\partial\gamma/\partial T$ values obtained from Figs. 1 and 3 are shown as functions of molality at constant temperature in Fig. 6. At concentrations below the cmc, they decrease with increasing concentration and raising temperature. At concentrations above the cmc, however, they seem to be almost constant. It should be noted that the $-\partial\gamma/\partial T$ vs. m_1 curves change discontinuously at the cmc.

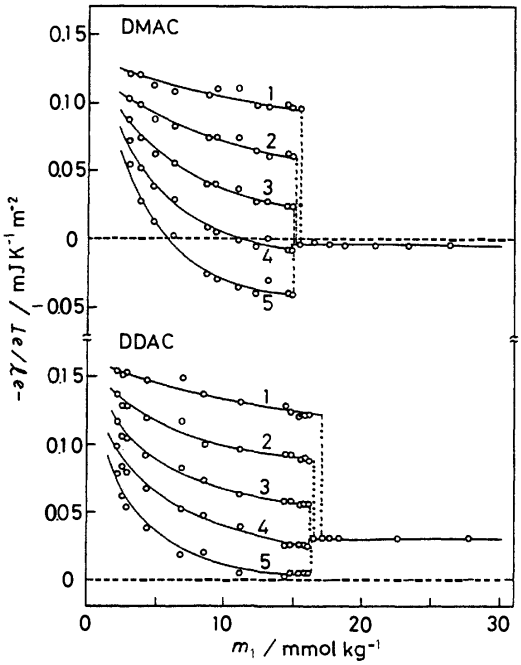

Fig. 6. Derivative of surface tension with respect to temperature vs. concentration curves at constant temperature under atmospheric pressure: (1) T=288.15 K; (2) 293.15; (3) 298.15; (4) 303.15; (5) 308.15.

Now we proceed to analyze the above results with the aid of the thermodynamics of the adsorption of surfactant from its micellar solution.[1] The adsorbed film is described by the excess thermodynamic quantities with reference to the two dividing plane surfaces

which make the excess numbers of moles of water and air zero. Defining as the thermodynamic quantities of the micelle particle the excess ones with reference to the dividing spherical surface which makes the excess number of moles of water zero, the micelle formation has been shown to be satisfactorily treated as if a new macroscopic phase appears in the solution. At a concentration below the cmc, the entropy change associated with the adsorption of surfactant from the monomeric state in the aqueous solution $\Delta s(1)$ defined by

$$\Delta s(1)=\Gamma_1^{\mathrm{H}}(s^{\mathrm{H}}/\Gamma_1^{\mathrm{H}}-s_1) \tag{1}$$

is evaluated by the derivative of surface tension with respect to temperature;

$$\Delta s(1)=-(\partial\gamma/\partial T)_{p,m_1},\ m_1<\mathrm{cmc}. \tag{2}$$

Here Γ_1^{H} and s^{H} are respectively the surface excess number of moles of surfactant and surface excess entropy per unit area and s_1 is the partial molar entropy of monomeric surfactant in the aqueous solution. At a concentration above the cmc, the entropy change associated with the adsorption of surfactant from the micellar state $\Delta s(\mathrm{M})$ defined by

$$\Delta s(\mathrm{M})=\Gamma_1^{\mathrm{H}}(s^{\mathrm{H}}/\Gamma_1^{\mathrm{H}}-s^{\mathrm{M}}/N_1^{\mathrm{M}}) \tag{3}$$

is evaluated by

$$\Delta s(\mathrm{M})=-(\partial\gamma/\partial T)_{p,m_1},\ m_1\geqq\mathrm{cmc}, \tag{4}$$

where N_1^{M} and s^{M} are the excess number of surfactant ions in the micelle and the excess molar entropy of micelle, respectively.

Bearing Eqs. 2 and 4 in mind and looking at the $-\partial\gamma/\partial T$ vs. m_1 curve in Fig. 6, we may say that the entropy change associated with the adsorption of surfactant from the monomeric state in the aqueous solution is strongly dependent on temperature and concentration, while the corresponding quantity from the micellar state is practically independent of both of them. Similar results have been obtained for the adsorption of DAC and DTAC.[1,2] It turns out, therefore, that the dependence of the entropy of surfactant on temperature and concentration in the adsorbed film is analogous to that in the micelle though different from that in the aqueous solution.

It is worth noting that the $\Delta s(\mathrm{M})$ value of DMAC is approximately zero and that of DDAC is obviously positive. Let us consider this point in further detail. Since the surface density of surfactant Γ_1^{H} usually is a large value at a concentration near the cmc, Eqs. 1 and 3 can be approximated respectively as

$$\Delta s(1)/\Gamma_1^{\mathrm{H}}=\bar{s}_1^{\mathrm{H}}-s_1 \tag{5}$$

and

$$\Delta s(\mathrm{M})/\Gamma_1^{\mathrm{H}}=\bar{s}_1^{\mathrm{H}}-\bar{s}_1^{\mathrm{M}}, \tag{6}$$

where $\bar{s}_1^{\mathrm{H}}$ and $\bar{s}_1^{\mathrm{M}}$ are the mean partial molar entropy of surfactant in the adsorbed film and the micelle, respectively.[8] Using the Γ_1^{H} vs. m_1 curve obtained by applying

$$\Gamma_1^{\mathrm{H}}=-(m_1/2RT)(\partial\gamma/\partial m_1)_{T,p} \tag{7}$$

to the γ vs. m_1 curve (Fig. 7), we can calculate the left hand sides of Eqs. 5 and 6. The resulting values are given as a function of molality at 298.15 K with those of DAC and DTAC in Fig. 8. It can be seen that the $\Delta s(\mathrm{M})/\Gamma_1^{\mathrm{H}}$ value varies regularly from a negative one for DAC to a positive one for DTAC with the *N*-methylation of dodecylammonium chloride. Therefore we may say that the *N*-methylation has a different effect on the entropy of surfactant in the adsorbed film from that in the micelle. This view is supported by the fact that the aggregation number of the DAC micelle is

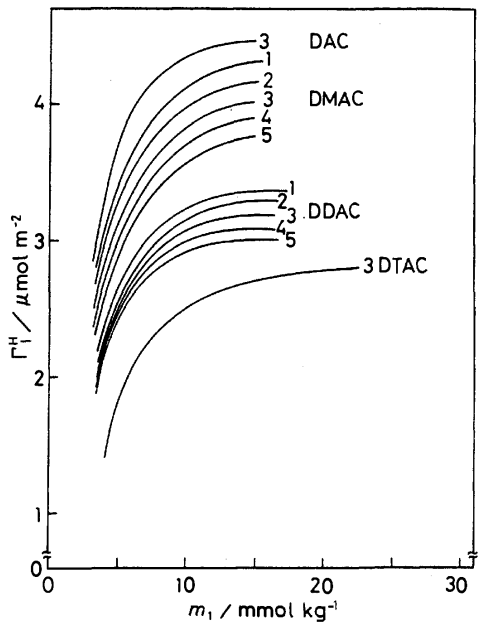

Fig. 7. Surface excess number of moles vs. concentration curves at constant temperature under atmospheric pressure: (1) T=288.15 K; (2) 293.15; (3) 298.15; (4) 303.15; (5) 308.15.

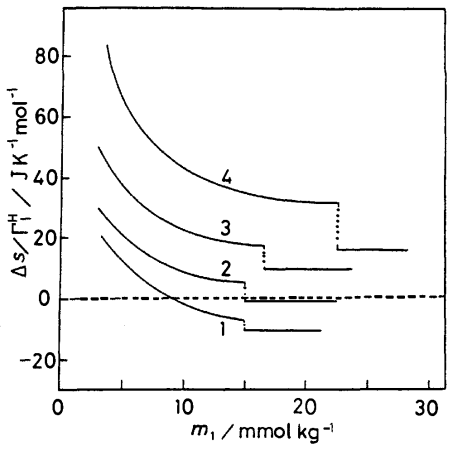

Fig. 8. Entropy change associated with the adsorption per mole of surfactant vs. concentration curves at 298.15 K under atmospheric pressure: (1) DAC; (2) DMAC; (3) DDAC; (4) DTAC.

more than 2 times that of the DTAC micelle at 298.15 K.[10] Figure 8 also shows that the $\Delta s(1)/\Gamma_1^H$ value of surfactants regularly varies with the *N*-methylation of the head group. Comparing with Fig. 7, it is understandable that the variation of $\Delta s(1)/\Gamma_1^H$ is primarily correlated to that of the saturated value of Γ_1^H and accordingly to the geometry of the head group.

Let us now consider the abrupt change of the temperature derivative of surface tension seen in Fig. 6. If the micelle formation can be treated like an appearance of a new phase in the aqueous solution, we have

$$[\Delta s(1)-\Delta s(M)]/\Gamma_1^H=-(2RT/\text{cmc})(\partial \text{cmc}/\partial T)_p. \quad (8)$$

In Fig. 9, the value of the left hand side, which was evaluated by using the $-\partial\gamma/\partial T$ vs. m_1 curve given in Fig. 6 and the Γ_1^H vs. m_1 curve given in Fig. 7, is plotted against temperature by the circle and, on the other hand, the value of the right hand side, which was evaluated from the slope of the cmc vs. T curve given in Fig. 4, is drawn by the full line. It is seen that the values of both sides are in fair agreement with each other within the experimental error. This finding justifies the validity of our thermodynamic treatment of the micelle formation.

Taking into account Eqs. 5 and 6, we have the relation

$$[\Delta s(1)-\Delta s(M)]/\Gamma_1^H=\bar{s}_1^M-s_1, \quad (9)$$

the right hand side being regarded as the entropy of micelle formation $\Delta_W^M s$. It is seen from Fig. 9 that the value $\Delta_W^M s$ decreases with increasing temperature and becomes negative. Noting that the value of $\Delta_W^H s$ defined by

$$\Delta_W^H s=\bar{s}_1^H-s_1 \quad (10)$$

also decreases with increasing temperature, we may say that the s_1 value increases remarkably with increasing temperature. Further it is seen that the difference in $\Delta_W^M s$ between DAC and DTAC is about 10 $J\,K^{-1}\,mol^{-1}$ while that in $\Delta_W^H s$ is about 40 $J\,K^{-1}\,mol^{-1}$ at 298.15 K. This observation supports the view that the adsorbed film at a plane interface is influenced more significantly by the *N*-methylation of DAC than the spherical micelle.

It is now useful to examine the adsorption of the surfactants from their micellar solutions from the viewpoint of energy. The energy changes associated with adsorption from the monomeric state in the aqueous solution $\Delta u(1)$ and from the micellar state $\Delta u(M)$ are evaluated by

$$\Delta u(1)=\gamma+T\Delta s(1)-p\Delta v(1) \quad (11)$$

and

$$\Delta u(M)=\gamma+T\Delta s(M)-p\Delta v(M), \quad (12)$$

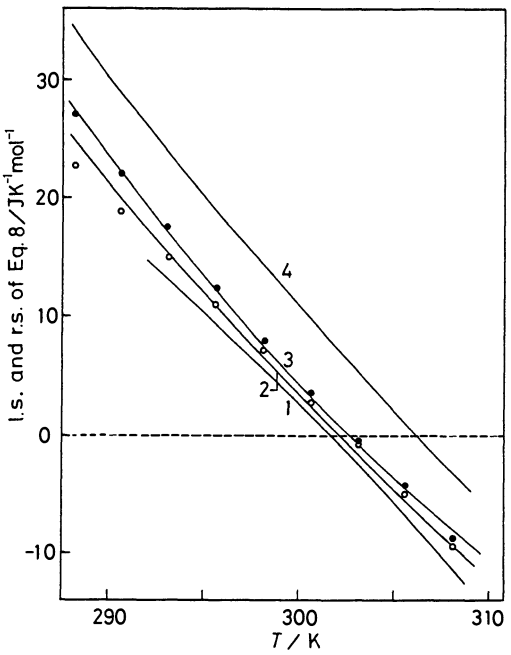

Fig. 9. Comparison between the left and the right side of Eq. 8: (○,●) left side; (——) right side; (1) DAC; (2) DMAC; (3) DDAC; (4) DTAC.

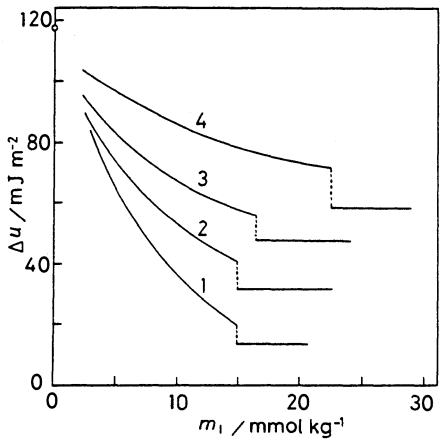

Fig. 10. Energy change associated with the adsorption vs. concentration curves at 298.15 K under atmospheric pressure: (1) DAC; (2) DMAC; (3) DDAC; (4) DTAC.

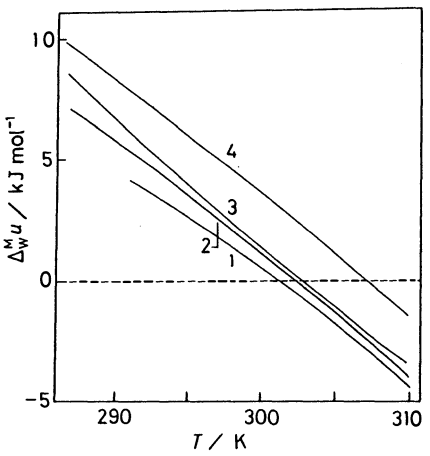

Fig. 11. Energy change of micelle formation vs. temperature curves under atmospheric pressure: (1) DAC; (2) DMAC; (3) DDAC; (4) DTAC.

respectively. Here $\Delta v(1)$ and $\Delta v(M)$ are the corresponding volume changes; the $p\Delta v$ terms are negligibly small compared with the others under atmospheric pressure.[11] The $\Delta u(1)$ and $\Delta u(M)$ values evaluated are shown as functions of concentration at 298.15 K under atmospheric pressure in Fig. 10. The curve appears to behave similarly to the Δs vs. m_1 curve; the *N*-methylation of dodecylammonium chloride regularly increases the values of $\Delta u(1)$ and $\Delta u(M)$. This behavior may be explicable by the increase in the hydrophilicity of the head group of surfactant by its successive *N*-methylation. On the other hand, energy of micelle formation $\Delta_W^M u$ defined by

$$\Delta_W^M u = \bar{u}_1^M - u_1, \tag{13}$$

where $\bar{u}_1^M$ and u_1 are respectively the mean partial molar energy in the micelle and the partial molar energy in the aqueous solution, is evaluated by use of the equation

$$\Delta_W^M u = [\Delta u(1) - \Delta u(M)]/\Gamma_1^H. \tag{14}$$

Its value is depicted in the form of $\Delta_W^M u$ vs. T plot in Fig. 11, which bears a striking resemblance to Fig. 9. Therefore we can say that the u_1 value increases remarkably with increasing temperature. In conclusion, it is possible to say that the successive *N*-methylation of DAC exercises considerable effect on the adsorbed film with changes in its surface density, entropy, and energy brought about by changes in the geometry and the hydrophilicity of the polar head group.

The Determination of a Small Amount of Biological Constituent by the Use of Chemiluminescence. XIII. High Sensitive Metal Chelate Affinity Chromatography

Tadashi HARA,* Kazuhiko TSUKAGOSHI, and Tatsunari YOSHIDA
Department of Chemical Engineering, Faculty of Engineering, Doshisha University, Karasuma Imadegawa, Kamigyo-ku, Kyoto 602
(Received September 10, 1987)

A chemiluminescence detector using a 1,10-phenanthroline-hydrogen peroxide-copper(II) system was successfully combined with a metal chelate affinity column. A mixture comprising bovine serum albumin, lysozyme, and bovine serum γ-globulin as model proteins was completely separated by the pH-gradient elution method on a TSK gel Chelate-5PW adsorbed with zinc ions, also, each protein could be quantitatively determined. According to the present method, using a 0.4 cm^3 column of bed volume, 1) the determinable concentration range for bovine serum γ-globulin was formed to be 1.0×10^{-4}—1.0×10^{-1} g dm^{-3} with a detection limit of 5 ng for a 50 mm^3 of injection volume, 2) the recovery of 1.0×10^{-3} g dm^{-3} bovine serum γ-globulin was 85% with 7.9% of the coefficient of variation (n=5), and 3) the time necessary for an analysis was about 50 min. The present method was about 200 times more sensitive than that using an ultraviolet detector and was also applicable to a human serumn sample.

In order to separate and determine each small amount of protein in the mixture by high-performance liquid chromatography (HPLC), highly sensitive HPLC was attempted using a chemiluminescence (CL) detector. In the present study, metal chelate affinity chromatography (MCAC) was used since the authors were interested in the affinity between metal ions and proteins;[1] MCAC using the affinity is a relatively new method for the separation of a mixture of various proteins.

The concept of metal chelate affinity chromatography was first described by Porath and co-worker.[2] Its sensitivity when using a conventional ultraviolet (UV) detector was still unsatisfactory for the determination of a small amount of biological constituent.

In order to improve the sensitivity of MCAC, an attempt to combine it with CL detection using a 1,10-phenanthroline (phen)-hydrogen peroxide (H_2O_2)-copper(II) (Cu(II)) catalyst system was carried out in the present study. The determination of a protein is based on a measurement of the decreasing catalytic activity of Cu(II) for a CL reaction in the presence of the protein.[3] In this case, the stable Cu(II)-protein complex formed as a result of heating caused a lowering of the free Cu(II) concentration.[1] Chemiluminescence detection, developed by the authors, is characterized by the following: 1) high sensitivity, 2) application to HPLC (including the determination of a small amount of protein without labeling), 3) a wide dynamic range, and 4) a relatively simple apparatus.[1,3,4]

By using a CL detector, which was developed by the authors for the determination of various proteins, they could be determined over a concentration range 5.0×10^{-6}—1.0×10^{-1} g dm^{-3}, with a detection limit of 250 pg (for a 50 mm^3 of injection volume).[3] Though the CL detector was shown by the authors to be applicable to immunoaffinity chromatography in which a specific single protein in a serum could be analyzed by an immune reaction,[4] no investigation has been made with regard to the applicability of the CL detector to the determination of a small amount of protein separated by HPLC.

The CL detector was shown to be highly sensitive and its response was influenced by the pH, salt content, solvent, flow-rate, and temperature.[3] Therefore, suitable conditions for elution using the CL detector were investigated, and the experimental conditions necessary for the acquisition of a well-defined chromatogram were optimized. A metal chelate affinity column was successfully connected to the CL detector (developed by the authors), and a mixed sample containing bovine serum albumin, lysozyme, and bovine serum γ-globulin as a model proteins was subjected to pH-gradient elution, followed by CL detection. The sensitivity of the present method was about 200 times as high as that of the conventional UV method.

Experimental

Reagents. All of the reagents used were of a commercially available special grade. Deionized water was distilled for use. A phen solution, a H_2O_2 solution, and a Cu(II) catalyst solution were prepared as described in a previous paper,[2] except for the use of a borate buffer of pH 12.19 for the preparation of a Cu(II) catalyst solution. The borate buffer solution (Buff-A; pH 8.04) contained 5.0×10^{-3} mol dm^{-3} boric acid (H_3BO_3), 5.0×10^{-4} mol dm^{-3} potassium hydroxide (KOH), and 2.0×10^{-1} mol dm^{-3} sodium chloride (NaCl). The borate buffer solution (Buff-B; pH 12.19) used for the preparation of a Cu(II) catalyst solution contained 2.0×10^{-1} mol dm^{-3} H_3BO_3 and 2.0×10^{-1} mol dm^{-3} KOH. An acetic acid solution for pH-gradient elution was prepared by dissolving 2.5×10^{-2} mol acetic acid in 1 dm^3 Buff-A. The sample solution of bovine serum albumin (BSA) (Sigma Chemical Co.), human serum albumin (HSA) (Sigma Chemical Co.), bovine serum α-globulin (BαG) (Sigma Chemical Co.), bovine serum γ-globulin (BγG) (Sigma Chemical Co.), lysozyme (from chicken egg white) (Sigma Chemical Co.), α_2-macroglobulin (from human) (Sigma Chemical Co.),

apoferritin (from human) (ICN Pharmaceuticals, Inc.), α-fetoprotein (AFP) (Midorijuji Co.), and control serum (Q-PAC-Chemistry Control Serum I) (HYLAND) were prepared by dissolving them in Buff-A and by diluting them with Buff-A.

Preparation of an MCAC Column. The following columns were used for MCAC: TSK gel Chelate-5PW (7.5 mm i.d.×75 mm) (Toyo Soda, Tokyo), and HR-5/5 (5 mm i.d.×50 mm) (Pharmacia) charged with Chelating Sepharose 6B (Pharmacia). Their bed volumes were 3.3 cm^3, 0.4 cm^3, in the above-mentioned order. All of the charged gel, which has an iminodiacetic acid group at the end of a spacer, showed a chelate-forming ability against such metal ions as Cu(II), zinc(II) (Zn(II)), and cobalt(II); each 1 cm^3 of the charged gel was capable of adsorbing at least a 20 μmol of the metal ion.

Zinc(II) was selected as an added metal ion in the present study because Zn(II) could not be detected in an eluate using a CL detector and several proteins were selectively adsorbed and eluted on the Zn(II) containing gel.

An MCAC column was prepared as follows: A definite volume of 0.03 mol dm^{-3} Zn(II) solution (pH 4), prepared by dissolving zinc chloride in a dilute acetic acid solution, was delivered into a column through a sampling loop. In practice, the column was loaded with Zn(II) calculated on the basis of its adsorbing capacity, only to 67% of its length in order to avoid any contamination of the eluate with Zn(II). Thereafter, the column was preconditioned by feeding Buff-A (equivalent to 15 times of a bed volume) at a flow rate of 1.0 cm^3 min^{-1}. All of the fundamental experiments for the elution of proteins from a column were carried out using a Zn(II) loaded TSK gel Chelate-5PW; HR-5/5 was in order to improve of the sensitivity, based upon a reduction of the bed volume.

Apparatus and Procedure. The MCAC method was carried out using the HPLC system (Fig. 1) equipped with a CL detector and an apparatus for the pH-gradient. The CL detector used was the same one as described in previous papers.[3,4] A 50 mm^3 portion of a protein sample solution was injected into the eluent solution line, that is, an MCAC column (j) through the sampling loop (i) and the six-way cock (g). Then, the protein was adsorbed on an MCAC column.

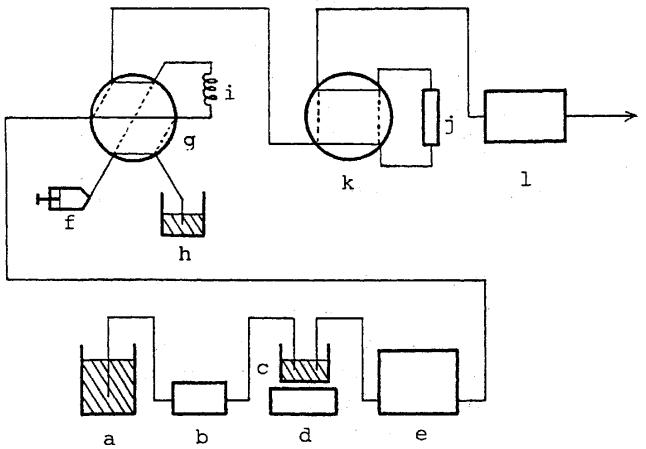

Fig. 1. Schematic diagram of the HPLC-CL system. a: Acetic acid solution, b: peristaltic pump, c: gradient-mixer, d: magnetic stirrer, e: constant flow pump, f: syringe, g: six-way cock, h : sample solution, i: sampling loop, j: MCAC column, k: four-way cock, and l: CL detector.

The pH-gradient elution was carried out as follows: The sample adsorbed on the MCAC column was eluted by a pH-gradient elution method. An acetic acid solution (a) for pH-gradient elution was fed into a gradient-mixer (c), which was charged with 50 cm^3 Buff-A at a flow rate of 0.5 cm^3 min^{-1} using a peristaltic pump (b). The solution in a gradient-mixer was well-stirred by a magnetic stirrer (d) and was fed into the MCAC column at a flow rate of 1.0 cm^3 min^{-1} using a constant flow pump (e). The protein eluted from the MCAC column was detected by a CL detector (l) as described in previous papers.[3,4]

The FIA method using direct-injection was carried out by injecting a sample solution (h) into the eluent line and by operating a four-way cock (k) and a six-way cock (g) equipped with a sampling loop (i).

Results and Discussion

Connection of the CL Detector with an MCAC Column. In a previous paper,[3] the optimum pH value of the solution during the CL reaction of a phen-H_2O_2-Cu(II) system was reported to be about 10.2 for the determination of a protein. Since the adsorption of a protein onto an MCAC column and the elution of a protein from it were usually carried out in the pH range of 8.0—4.0,[2,5-7] the pH value and buffer capacity of the solution during the CL reaction had to be adjusted to about pH 10.2 with a Cu(II) catalyst solution. Judging from the experimental result, this was accomplished by an adding a Cu(II) solution containing a borate buffer solution of pH 12.19 (Buff-B). A phen solution and a H_2O_2 solution were prepared as described in a previous paper.[2] Under these conditions, calibration curves for BSA, lysozyme, and BγG were obtained by an FIA method (Fig. 2). These proteins in a concentration range of 2.0×10^{-5}—1.0×10^{-1} g dm^{-3} could be determined by injecting each 50-mm^3 sample into an FIA system, with a detection limit of 1 ng (S/N=2) and a coefficient of variation (CV) of 5.9% (n=6) at 1.0×10^{-3} g dm^{-3} protein. Hereafter, the detection limit is based on S/N=2.

The different calibration curves of BSA, lysozyme, and BγG seemed to be due to differences between in their molecular structures. Relatively linear calibration curves were obtained in a previous study,[3] while the calibration curves shown in Fig. 2 are sigmoid. Since the concentration of NaCl was different in the experiment for the preparation of both calibration curves, the effect of NaCl on the form of the calibration curve was examined and a linear calibration curve was found to assume a sigmoid form with an increasing amount of NaCl. Though there might be some other causes for the sigmoid form, a calibration curve for protein by CL detection was mostly obtained as a sigmoid form.[8-10]

pH-Gradient. A protein adsorbed on an MCAC column can be eluted by such methods as 1) lowering

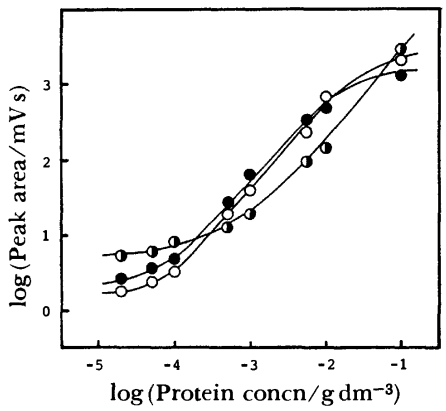

Fig. 2. Calibration curves for proteins by FIA. ○: BSA, ●: BγG, and ◑: lysozyme.

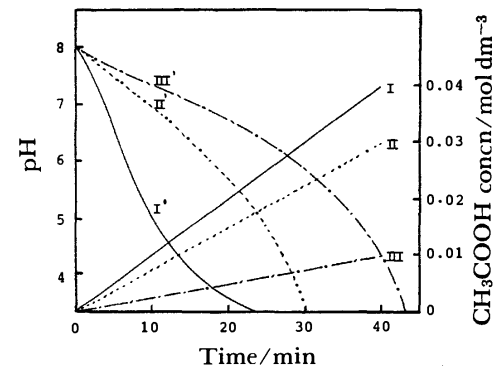

Fig. 3. Relationship among pH, time, and concentration of an acetic acid. Line-I, -II, and -III: relationship between C_A and t and curve-I′, -II′, and -III′: relationship between pH and t.

of the pH, 2) adding a competitor,[7] and 3) adding ethylenediaminetetraacetic acid. Among these methods, methods 2) and 3) were unsuitalbe for the present purpose because they did not give smooth base-lines on the CL detector, whereas method 1) was shown to be useful. Since any protein adsorbed on a Zn(II) column was eluted at an individual pH-band and all the proteins used in this study were completely eluted near pH 4, a pH-gradient method in which the pH of the eluent changed continuously from 8.0 to 4.0 was proposed. During the course of an investigation regarding the preparation of the pH-gradient, it was found that 1) the base-line of the CL detector was most stable as a result of adding a definite concentration of acetic acid to Buff-A and by lowering the pH of the eluent, and 2) that the stability of the CL detector was further improved by adding salt (NaCl) to Buff-A. The pH-gradient of the eluent was prepared by using the gradient apparatus based on principle of a single stage of a continuously stirred tank reactor; the optimum conditions could be obtained. The pH change of the eluate from the Zn(II) column against a linear increase in the concentration of acetic acid (C_A) in the eluent is shown in Fig. 3. Line-I,-II, and -III show the relationship between C_A and the feed time (t), while curve-I′, -II′, and -III′ show the relationship between pH and t. Line-III and curveIII′ were best for the separation of proteins since the base-line stability of the CL detector was excellent and an approximately linear pH-gradient could be applied.

Effect of NaCl. A definite amount of salt was usually added to the eluent in MCAC in order to avoid any undesirable ion exchange and any association between proteins. According to the preliminary experiment, the retention time of BSA, lysozyme, and BγG varied according to the concentration of NaCl. However, the sensitivity of the CL detector became lower upon increasing the amount of NaCl. Therefore, their relations were examined in detail. So far, it has been experimentally accepted that the base-line separation of a binary mixture is feasible if the peak resolution

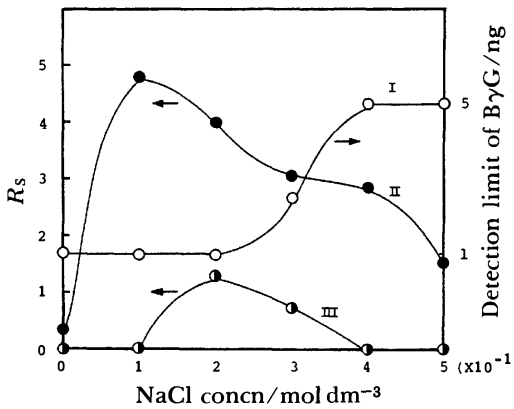

Fig. 4. Effect of NaCl on detection limit and R_S. ○: detection limit of BγG, ●: R_S between BSA and BγG, and ◑: R_S between BSA and lysozyme.

(R_S) exceeds 1.25 in a chromatogram.

The effect of the NaCl concentration on the detection limit of BγG and on the R_S between BSA and BγG as well as between BSA and lysozyme are shown in Fig. 4. As can be seen from curve-I in Fig. 4, the detection limit of BγG increases with increasing the concentration of NaCl. From curve-II in Fig. 4, BSA and BγG could also be completely separated when the eluent contained more NaCl than 0.1 mol dm^{-3} (R_S exceeded 1.25). From curve-III in Fig. 4, BSA and lysozyme could also be separated when the eluent contained 0.2 mol dm^{-3} NaCl (where R_S exceeded 1.25). On the basis of these results, an eluent containing 0.2 mol dm^{-3} NaCl was shown to be most suitable for a sensitive detection of BSA, lysozyme, and BγG as well as for the base-line separation of a BSA and BγG mixture or a BSA and lysozyme mixture. Therefore, an eluent containing 0.2 mol dm^{-3} NaCl was used for the separation of BSA, lysozyme, and BγG in the present experiment. Though the retention times of these proteins varied according to the concentration of NaCl in the eluent, the reason for such a phenomenon still remains unsolved.

Affinity against a Zn(II) Column. The affinity of various proteins against a Zn(II) column was examined under the above-mentioned conditions and the results are shown in Table 1. Judging from the retention time, 1) both BSA and HSA showed no affinity, 2) lysozyme showed moderate affinity, and 3) BαG, BγG, α_2-macroglobulin, and HγG showed strong affinity. α-Fetoprotein, a cancer marker, also showed no affinity.

Separation and Determination of Proteins by MCAC. As can be seen from the above results, BSA, lysozyme, and BγG, all the retention times that were mutually different, were selected as model proteins. The separation of a mixture consisting of the above-mentioned three proteins and the determination of individual proteins were carried out by MCAC. A protein mixture (50 mm^3) dissolved in Buff-A was injected onto a Zn(II) column, and pH-gradient elution was started 7 min after the injection of a sample solution. A chromatogram is shown in Fig. 5. As can be seen from Fig. 5, BSA, lysozyme, and BγG could be almost completely separated. Calibration curves of BSA, lysozyme, and BγG were obtained by MCAC using a Zn(II) column (Fig. 6). Both BSA and BγG in 50 mm^3 were determinable in the concentration range of 5.0×10^{-4}—1.0×10^{-1} g dm^{-3}, with a detection limit of each 25 ng. Lysozyme was also determinable in a concentration range of 8.0×10^{-4}—1.0×10^{-1} g dm^{-3}, with detection limit of 40 ng. Bovine serum γ-globulin of 1.0×10^{-3} g dm^{-3} was determined with an average recovery of 78% and a CV of 10.9% (n=6). The time necessary for an analysis was about 150 min. The detection limit of FIA method was 2.0×10^{-5} g dm^{-3} (1 ng) BγG but that of the MCAC method was 5.0×10^{-4} g dm^{-3} (25 ng) BγG. These differences seem to be due to the fact that the MCAC method is accompanied by an the extreme band broadening during separation, while the FIA method is not. The poor results in the above-mentioned average recovery and CV could be explained on the basis of the extreme band broadening. It was, therefore, concluded that the bed volume of a TSK gel Chelate-5PW was too large for the successful analysis of a low concentration of protein mixture using a CL detector.

Reduction of Bed Volume. In order to improve the detectability of a CL detector by reducing bed volume of a Zn(II) column, HR-5/5 having a bed volume 0.4 cm^3 was prepared and applied to a mixture of BSA, lysozyme, and BγG. Each calibration curve was obtained and is shown in Fig. 7. Both BSA and BγG

Table 1. Affinity Against a Zn(II) Column

Protein	Sample load/ng	Retention time/s
BSA	50	210
HSA	50	227
Apoferritin	50	227
AFP	38.8	287
Lysozyme	50	563
BαG	50	1487
BγG	50	1496
α_2-Macroglobulin	50	1559
HγG	50	1498

in a 50 mm^3 sample solution were determinable in a concentration range of 1.0×10^{-4}—1.0×10^{-1} g dm^{-3}, with a detection limit of 5 ng each. Lysozyme was also determinable in the concentration range 3.0×10^{-4}—1.0×10^{-1} g dm^{-3}, with a detection limit of 15 ng. Bovine serum γ-globulin in a concentration of 1.0×10^{-3} g dm^{-3} could be determined with an average recovery of 85%, and a CV of 7.8% (n=5). The detection limit of BγG against HR-5/5 (0.4 cm^3 bed volume) was 5 ng whereas that of a TSK gel Chelate-5PW (3.3 cm^3 bed volume) was 25 ng under the same conditions. The time necessary for an analysis was about 60 min. Moreover, HR-5/5 could be confirmed from Fig. 7 to be satisfactorily usable for analyzing of a mixture consisting of a low concentration of proteins.

The lowest detectable concentration of BγG using a UV detector and a CL detector were compared under the same conditions using a TSK gel Chelate-5PW: 1.0×10^{-1} g dm^{-3} BγG for a UV detector, and 5.0×10^{-4} g dm^{-3} BγG for a CL detector. The sensitivity of a CL detector was about 200 times as high as that of a UV detector.

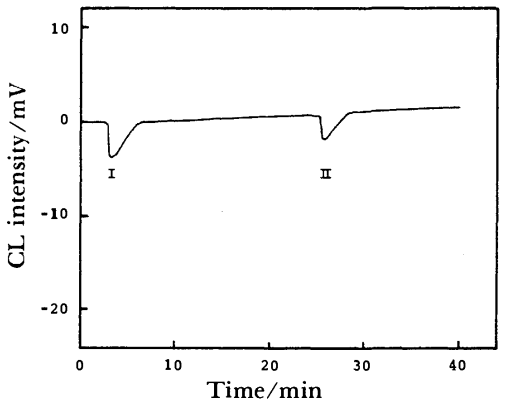

Fig. 8. A chromatogram of human serum. I: HSA and II: human serum globulins.

Finally, a control serum was diluted 5000 times with Buff-A and an aliquot (50 mm^3) was analyzed by the present method using a TSK gel Chelate-5PW (Fig. 8). As shown in the figure, there are two peaks: peak I corresponds to HSA and peak II to human serum globulins.

It has been concluded from the results that by the use of a CL detector and an MCAC column having a small bed volume, sensitive MCAC suitable for the separation and determination of low concentrations of proteins could be established. The present study suggests the possibility of combining a CL detector with a wide range of columns, including an MCAC column.

The authors wish to thank Tsutomu Hashimoto for providing TSK gel Chelate-5PW for the present study.

Relaxation of Short-Lived ^{57}Fe-Species in ^{57}Co-Labeled $Co(IO_3)_2$ Studied by Time-Resolved Emission Mössbauer Spectroscopy

Yasuo WATANABE,* Kazutoyo ENDO, and Hirotoshi SANO
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya, Tokyo 158
(Received January 5, 1988)

KX-Ray-gated and time resolved emission Mössbauer spectra of ^{57}Co-labeled $Co(IO_3)_2$ were measured at room temperature, using a coincidence technique. No remarkable difference was found on the relative intensity of Fe(II)/Fe(III) between the X-ray-gated and normal emission spectra. A lifetime for unstable ^{57}Fe(II)-species formed through EC-decay was estimated to be 43±5 ns and the initial distribution of Fe(II)/Fe(III) at 14.4 keV nuclear level to be 0.47±0.13 from the time-resolved emission Mössbauer spectrum. The results are discussed in terms of the chemical stability of the environments of the decayed ^{57}Fe-atoms.

Investigations on the lifetime and electronic state of short-lived chemical species provide very attractive fields for understanding chemical bond and reaction mechanism. Emission Mössbauer spectroscopy is useful for dynamic study of such short-lived chemical species in its nuclear lifetimes or the same order of magnitude; it has the advantage that it detects the chemical states of Mössbauer active atoms decayed from the parent nuclide in ultra-microquantities in the solid. The concentration of metastable or unstable species produced after EC-decay is usually too low to be detected by ordinary physicochemical techniques. By combining emission Mössbauer spectroscopy with a coincidence technique, more detailed and selected information can be provided. If a Mössbauer spectrum gated with a particular radiation among several ones associated with the de-excitation of nuclear or atomic states, we expect to extract information accompanied by the transition. In the present study, two simple coincidence systems were built to elucidate the relaxation processes of unstable chemical species formed through EC-decay. One of the systems involves an X,γ-coincidence and another a γ,γ-coincidence. In X,γ-ray coincidence, a Mössbauer spectrum gated with 6.4 keV KX-ray from decayed ^{57}Fe is observed, which reflects information relating the chemical effects of the KX-ray emission. Kobayashi and Friedt examined the effects of KX-ray emission on ^{57}Co-labeled $CoCl_2 \cdot nH_2O$ (n=2—6), finding a different chemical distribution of ^{57}Fe atoms between the normal and the X-ray-gated emission Mössbauer spectra.[1] In γ,γ-coincidence, the spectrum is taken at an appropriate time interval of the nuclear lifetime, which enables us to study dynamic chemical states of decayed ^{57}Fe atoms. Hoy et al. showed a filtering spectrum of a single resonance line,[2] and analyzed it based on Hamermesh's treatment.[3] Triftshäuser and Craig observed no time dependence of the intensity ratio of Fe(III)/Fe(II) on ^{57}Co-labeled CoO, $CoSO_4$, and $CoCl_2 \cdot 4H_2O$ on the time resolved Mössbauer spectra.[4] Gol'danskii's group estimated the intramolecular electron charge transfer rate from ^{57}Fe atoms to Fe(III) atoms in the system of $^{57}Co_3[Fe(III)(CN)_6]_2$.[5] Gütlich's group reported the lifetime of unstable high-spin Fe(II)-species formed in ^{57}Co-labeled $[Co(phen)_3](ClO_4)_2 \cdot 2H_2O$ at various temperatures.[6] In the present study, we examined the chemically unstable ^{57}Fe-species formed through EC-decay in ^{57}Co-labeled $Co(IO_3)_2$ using both coincidence systems. The labeled compound was selected because the iodate anion is highly oxidizable and its rather simple chemical structure is suitable for examining the stabilization mechamism of the decayed ^{57}Fe-species.

Experimental

Source Preparation. To prepare ^{57}Co-doped $Co(IO_3)_2 \cdot nH_2O$, the procedure described in the literature was modified for small scale synthesis.[7] $Co(NO_3)_2 \cdot 6H_2O$ was dissolved in dil. nitric acid containing ca. 3.0×10^6 Bq of ^{57}Co, and iodic acid was added dropwise to this solution. After heating the solution on a steam bath at 80 °C for ten minutes, the purple blue products were filtered, washed with distilled water and then dried under vacuum. The radioactivity of the sample was estimated to be ca. 2.2×10^6 Bq. Thermogravimetric analysis and X-ray diffraction of the product prepared without ^{57}Co by the same procedure proved it to be an anhydride.

Measurement of X,γ-Ray Coincidence Mössbauer Spectra. The X,γ-ray coincidence system used in the present experiment is shown in Fig. 1. For detecting the 6.4 keV KX-rays two NaI(Tl) crystals of 0.8 mm in thickness and 1″ in diameter were used, and a crystal of 1 mm×1″ NaI(Tl) crystal for 14.4 keV γ-rays. These scintillators were coupled to photomultipliers; Hamamatsu R580, of which cathodes were set to operate at the photocathode potential of −1200 V with respect to the ground. The magnetic shield of Hamamatsu-E989 was used for the photomultiplier, which was effective for fast timing operation to eliminate the magnetic field of the Mössbauer transducer. The bleeder strings assemblies were built by us using low noise resistors, and the current was 0.4 mA. The anode signals from two photomultipliers for detection of KX-rays were fed into fast discriminators (ORTEC-473A) and then each logic signal was summed. The pulses from the third photomultiplier for measuring the Mössbauer spectra were amplified in pulse-height by a linear amplifier (CANBERRA-2011) and then 14.4 keV γ-rays were selected with a timing-SCA (ORTEC-551). These signals were gated by the logic pulses (0.5 μs in pulse width) of the summed 6.4 keV KX-rays.

Measurement of γ,γ-Coincidence Mössbauer Spectra. The γ,γ-coincidence system used in the present experiment

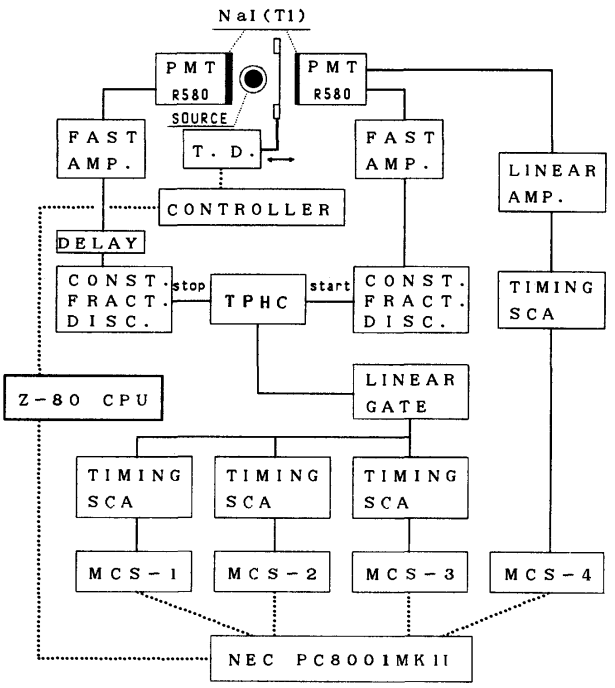

Fig. 2. Block diagram of the apparatus for the delayed coincidence Mössbauer experiments; a transducer controller and all memory units were supervised by a Z-80 CPU. PMT=photomultiplier, AMP=amplifier, T.D.=transducer, SCA=single-channel analyzer, TPHC=time-to-pulse height converter, CONST.FRACT.DISC=constant fraction discriminator, LINEAR GATE=linear gate and stretcher, CONTROLLER=Austine S-600 Mössbauer controller, MCS-1,2,3,4=data acquisition system, CPU=central processing unit.

is shown in Fig. 2. A NaI(Tl) crystal of 1″ in thickness and 1″ in diameter was used to detect 122 keV γ-ray and another crystal of 0.8 mm in thickness and 1″ in diameter for 14.4 keV γ-ray. Anode signals from each multiplier were fed into a fast amplifier (ORTEC-574), the constant fraction discriminator (ORTEC-473A) and then to TPHC (ORTEC-467) as start and stop signals, respectively. In order to reduce the dead time of the time conversion to amplitude at TPHC, the busy start signals of 122 keV were delayed with a coaxial cable for about 2.0×10^{-7} s. Voltage signals from the 11th dynode of the multiplier with a thinner scintillator were used for energy selection of 14.4 keV. With the gated signals of transmitted γ-ray, a Mössbauer spectrum were measured. An Austine Mössbauer spectrometer (S-600) was used together with a data taking system. The latter built by us was a four-channel parallel-mode (4×512 channel) system which is essentially a microprocesser(Z80)-aided multichannel scaler and a memory unit. A microcomputer NEC PC-8001MKII was used for an auxiliary controller of this data acquisition system. The time resolution of γ,γ-coincidence was estimated to be (10.0±0.3) ns using annihilation radiations of ^{22}Na. The windows of the timing SCA were set at the same condition as were used in ^{57}Fe Mössbauer measurement. The time-resolved Mössbauer spectra were measured at the time windows of A(0-45 ns), B(45-88 ns), D(88-148)ns, and E(0-infinity), or A(0-45 ns), C(45-148 ns), and E(0-infinity) in a separate run, respectively. The oscillation due to the time filtering effects on the time resolved Mössbauer spectrum was hardly observed, because the preset time window was rather wide. By subtracting the randomly-coincided fraction from the observed spectrum, the truly-coincided spectra were tentatively analyzed with two sets of quadrupole doublets using a least square fitting of a Gaussian function. Gauss-Newton iteration method was used in the "SALS" least square fitting program developed by Nakagawa and Oyanagi.[9]

Results and Discussion

X,γ-Ray Coincidence Spectrum. An emission Mössbauer spectrum gated with KX-ray is shown in Fig. 3, together with the normal emission spectrum. The former was obtained by subtracting the randomly coincided spectrum from the observed spectrum. The contribution of the random coincidence was estimated to be 30% in the present experimental conditions. The resulting X-ray-gated spectrum does not show remarkable difference from the normal one in their parameters. It has been reported that in various kinds of chemical compounds, an Auger process plays an important role in determining the final chemical state of hot atoms produced through the de-excitation associated with the nuclear transformation. The low energy electrons and/or vacancies produced in Auger cascades dissipate their energies to neighbouring atoms. The Auger process is expected to emit a large

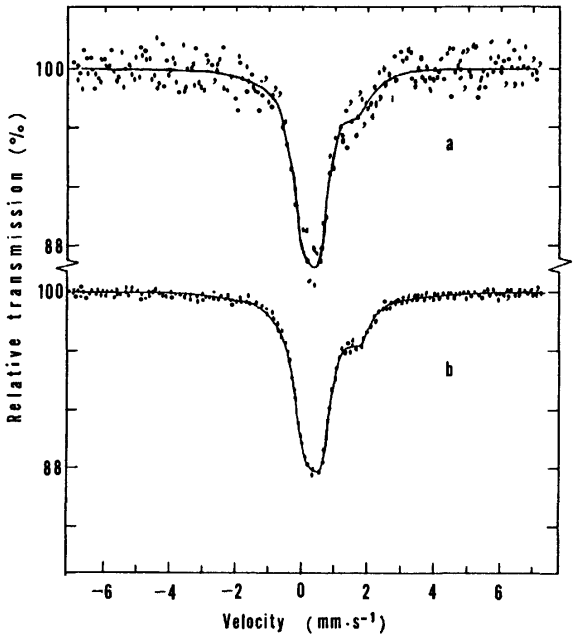

Fig. 3. (a) X,γ-Ray-gated and (b) normal emission Mössbauer spectra of ^{57}Co-labeled $Co(IO_3)_2$ at room temperature.

number of electrons than the competitive X-ray emission process; i.e., the former will give a large influence to the chemical species formed through the EC-decay. Multiple ionization will be larger in Auger electron emission than in X-ray emission. However, even if any unstable chemical species are formed by Auger processes and are different from those of the X-ray emission, such chemical species cannot be observed if their lifetimes are too short to be discriminated by the experimental set-up used. These considerations suggest that different chemical species to be discriminated by the present method are not formed in the labeled compound.

γ,γ-Coincidence. Line Width: Time-resolved Mössbauer spectra are shown in Fig. 4, together with a time integral spectrum for comparison. A gradual decrease was observed in the linewidth of both trivalent and divalent species with an increase in the delay time. This trend can be understood qualitatively from the uncertainty principle, as shown in Fig. 5. The line broadening has been observed in many source experiments. This effect arises from several factors. One is to use a thick absorber in order to increase the sensitivity of measurement. Secondly, it arises from superimposition of various kinds of hyperfine parameters corresponding to many electronically excited states formed through EC-decay in the insulator. Thirdly, it is caused by the slow relaxation time of spin-spin and spin-lattice interactions. The former effect is observed in some source experiments of a diamagnetic insulator host lattice where the decayed ^{57}Fe species are placed in a magnetically-diluted material. In the present work, a similar time-dependence of the line widths observed

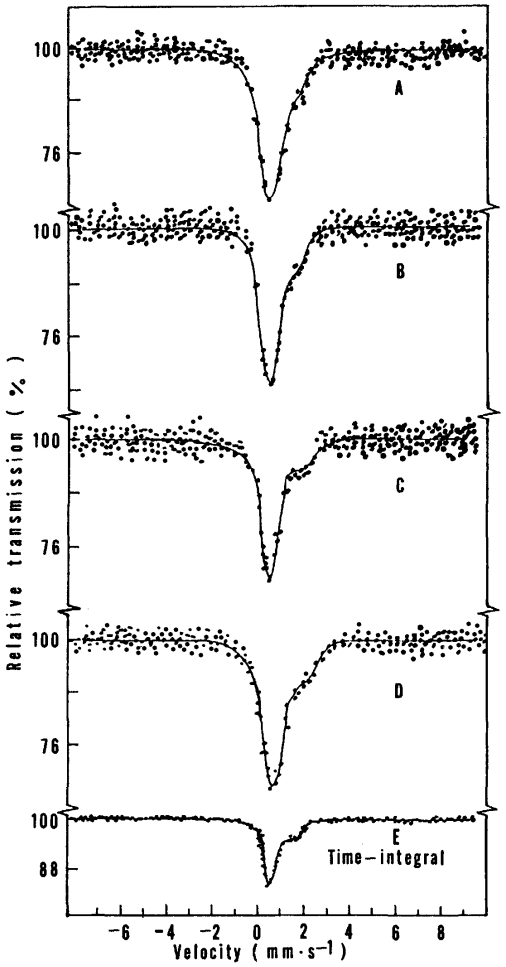

Fig. 4. Time-resolved Mössbauer spectra of ^{57}Co-labeled $Co(IO_3)_2$ at room temperature. The time windows were set to be A=0—45 ns, B=45—88 ns, C=45—148 ns, D=88—148 ns, E=0—infinity.

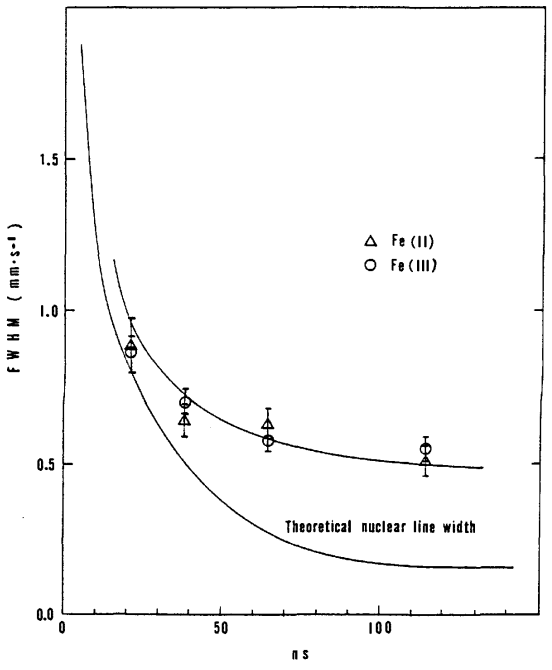

Fig. 5. Line width of the time resolved Mössbauer spectra plotted against the mean time of the windows. Theoretical line width (2Γ) is also plotted.

for the two species shows that the line broadening due to the uncertainty principal predominates over other factors such as the time-dependent population of given species in the present compound.

Evaluation of Relative Intensity on Time-Resolved Spectra: The ratio of the absorption peak area of ^{57}Fe(II) to ^{57}Fe(III) is plotted against the mean time, t, of the time windows in Fig. 6. The mean time for the time window was evaluated by the equation as

$$\frac{t}{\tau_N} = \int_{T_A}^{T_B} Te^{-T}\,dT \Big/ \int_{T_A}^{T_B} e^{-T}\,dT \qquad (1)$$

where t is the mean time in the interval $T_A \leqq t \leqq T_B$, and τ_N the mean nuclear lifetime of the first excited state of ^{57}Fe. The chemical decay constant of the unstable ^{57}Fe(II)-species is estimated in the following manner. Several factors are assumed to facilitate the discussion; Debye-Waller factors of ^{57}Fe(II)- and ^{57}Fe(III)-species are the same at every time window. Fe(II)-species decay with a pseudo-first order kinetics of a chemical decay constant, λ_c, and Fe(III) once formed are stable during the time in question, since the anion concentration in the vicinity of the decayed ^{57}Fe-atoms may be regarded as constant. The chemical reaction of ^{57}Fe(II)-species can be assumed to be the electron transfer from the species to the highly oxidizable iodate anion. Let the distributions of ^{57}Fe(II) and ^{57}Fe(III) be $P_2(t)$ and $P_3(t)$ at t after the emission of 122 keV γ-ray and their ratio at $t=0$ be R.
Then, $P_2(t)+P_3(t)=1$ and

$$R = P_2(0)/P_3(0). \qquad (2)$$

With the decay constant, λ_c, of the Fe(II)-species, the populations found at time t after the emission 122 keV gamma-ray can be written as

$$P_2(t) = P_2(0)e^{-\lambda_c t}, \qquad (3)$$

$$P_3(t) = P_2(0)(1-e^{-\lambda_c t}) + P_3(0). \qquad (4)$$

Since emission Mössbauer spectroscopy gives us information on the electronic states of "nucleogenic" probe atoms, the observable quantities with this probe at time t should be those of Eqs. 3 and 4 multiplied by $\exp(-\lambda_N t)$, where λ_N is the nuclear decay constant of ^{57}Fe at the 14.4 keV level.

Actually, time-resolved Mössbauer spectroscopy offers a spectrum integrated with respect to the preset time window between T_A and T_B. Then, Eqs. 3 and 4 should be written as

$$\int_{T_A}^{T_B} P_2(t)\,dt = \int_{T_A}^{T_B} P_2(0)e^{-\lambda_c t}dt, \qquad (5)$$

$$\int_{T_A}^{T_B} P_3(t)\,dt = \int_{T_A}^{T_B} [P_3(0) + P_2(0)(1-e^{-\lambda_c t})]dt. \qquad (6)$$

Due to the finite resolution of the equipment, the observed spectrum involves a time distribution of Gaussian type, $G(t-t', 2\tau_0)$, where $2\tau_0$ is a full width at half maximum of the time resolution and estimated to be 10.0±0.3 ns by the measurement of annihilation radiations of ^{22}Na in Al metal. Taking the resolution function into consideration, the observed intensity ratio of Fe(II) to Fe(III), at time interval between T_A and T_B, can be described as follows using Eqs. 2, 5, and 6.

$$\{I_2(t)/I_3(t)\}_{ob} \equiv \frac{R\int_{T_A}^{T_B}\left[\int_0^\infty e^{-\lambda_c t'}e^{-\lambda_N t'}G(t-t';2\tau_0)dt'\right]dt}{\int_{T_A}^{T_B}\left\{\int_0^\infty\left[1+R(1-e^{-\lambda_c t'})\right]e^{-\lambda_N t'}G(t-t',2\tau_0)dt'\right\}dt} \qquad (7)$$

where $G(t-t';2\tau_0) = \dfrac{1}{\sqrt{2\pi(2\tau_0)^2}} \exp\left\{\dfrac{-(t-t')^2}{(2\tau_0)^2}\right\}$

Numerical calculation of Eq. 7 was carried out with a computer. The initial distribution ratio of Fe(II)- to Fe(III)-species, R=0.46±0.13, and the chemical decay constant of Fe(II)-species, $\lambda_c = 2.33\times10^{-2}$ ns^{-1} (or τ_c= 43±5 ns), were obtained. In Fig. 6, the obtained and calculated relative intensities of spectral area are plotted vs. mean time t. The integral value, shown as oblique lines, is obtained by the normal emission Mössbauer spectrum without gate. The relative intensities of ^{57}Fe(II) and ^{57}Fe(III) against time calculated by using the values of R, λ_c, and Eqs. 3, 4 are shown in Fig. 7. The intensity of ^{57}Fe(III)-species just after the 122 keV γ-ray emission is taken as an unity. Although the present method for analyzing the relative intensity on the time resolved spectrum is similar to that used by Gütlich's group,[6] the initial distribution ratio of Fe(II)- to Fe(III)-species at 14.4 keV nuclear level was taken as an arbitrary parameter, R, in the present work.

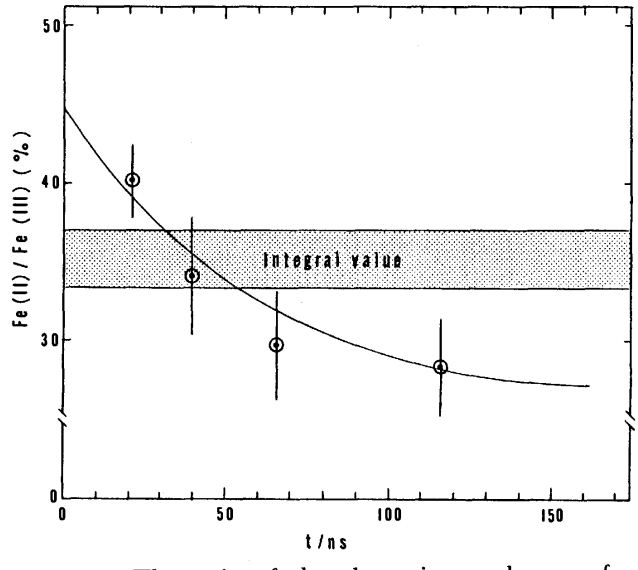

Fig. 6. The ratio of the absorption peak area of ^{57}Fe(II) to ^{57}Fe(III) plotted against the mean time, t, of the time windows. The line is the best-fitted values calculated using Eq. 7.

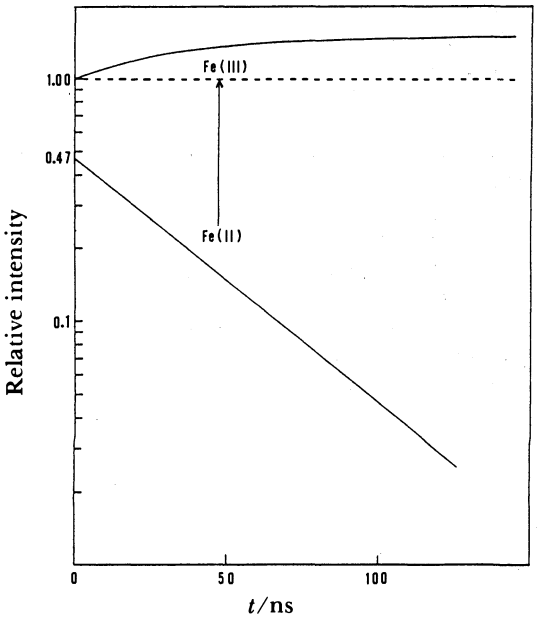

Fig. 7. Growth curve of ^{57}Fe(III)-species and decay curve of ^{57}Fe(II)-species are depicted based on Eqs. 3 and 4. The intensity of ^{57}Fe(III)-species just after the 122 keV γ-ray emission is taken as an unity.

Charge State of ^{57}Fe: The observed lifetime of the short-lived ^{57}Fe-species is 43±5 ns and the initial distribution of Fe(II)/Fe(III) at 14.4 keV level is obtained to be 0.46±0.13 by assuming the divalent ^{57}Fe-species are oxidized monotonically to trivalent species. Although the evaluation of the data for the time-resolved Mössbauer spectra is not the same as that used in the present work, Gol'danskii and his co-workers obtained the electron transfer rate of 1×10^8 or 5.5×10^7 s^{-1} in ^{57}Co-labeled $Co_3[Fe(CN)_6]_2$, and reporting the value of the mean lifetime of the order 10—20 ns.[5] They attributed such fast decay rate to the transition from an electronically excited level in a narrow well of Fe(II) to various kinds of levels in a deep well of $[Fe(II)(CN)_6]^{3-}$. Gütlich's group reported that the lifetime of anomalous high-spin species is of the order of 23.0±5.0 ns at 223 K in ^{57}Co-labeled $[Co(phen)_3](ClO_4)_2\cdot2H_2O$, assuming the initial distribution of high-spin Fe(II) equal to that of low-spin Fe(II). On the other hand, no time dependence has been observed on CoO, and $CoCl_2\cdot4H_2O$ as mentioned in the introduction. It seems likely from the results on many systems reported so far the normal emission spectroscopy that the stabilization of the ^{57}Fe charge state does not depend on the charge state of the parent cobalt atoms in their compounds but on the radiation stability of the neighboring atoms, ligands, and/or anions.[10-15] The present results may suggest that the chemical stability may affect the lifetime of the unstable Fe-species observed by time-resolved Mössbauer spectroscopy. In fact, Fe(II) iodate is very sensitive for oxidation even under nitrogen atmosphere.

In the decay of radioactive nuclide or nuclear transformations, the recoiled atoms are often found in aliovalent states. In the case of ^{57}Co EC-decay, the recoil energy associated with the 122 keV γ-ray emission and neutrino emission (600 keV maximum) are 0.14 and 3.5 eV, respectively, which is smaller than the displacement energy of ^{57}Co atoms in the solid. Then, the initial chemical effects in the EC-decay of ^{57}Co will be the electronic excitation of ^{57}Fe atoms. This excitation is caused by Anger cascade following the EC-decay. The Auger ionization processes have been calculated by Pollak, using Watson wave functions.[16] His result predicts a distribution of charge states ranging from Fe^{2+} to Fe^{7+} with most probability for a Fe^{5+} configuration for free $^{57}Co^{2+}$ and from Fe^{1+} to Fe^{6+} with a most probability for Fe^{4+} for free neutral ^{57}Co atoms. Highly-charged states other than Fe^{4+}, however, relax rapidly in the solid, even in insulators, and have not been observed with Mössbauer spectroscopy. It seems likely that the neutralization of such highly-charged states is much faster than the Mössbauer time scale. In addition, the initial distribution ratio of ^{57}Fe(II)/^{57}Fe(III)-species at 14.4 keV nuclear level indicated the short-lived ^{57}Fe(II)-species formed through EC-decay exhibits a relatively small distribution even immediately after the emission of 122 keV gamma-rays; i.e., since the second excited state of ^{57}Fe has a lifetime of 12.4 ns, the chemical species once formed and relaxed after the EC-decay can be observed by time-resolved Mössbauer spectrum.

Conclusion

No remarkable differences between X-ray gated and normal spectra were observed, although when a KX-ray is emitted, the total numbers of low energy electrons and vacancies generated by the Auger cascade are about a half compared with those generated when a K-Auger electron is emitted. In the present system, gate signals of 0.5 μs both for X-ray and 14.4 keV γ-ray were used in order to avoid the time filtering effect on the spectrum. It may be reasonable to conclude from the lifetime obtained that the unstable Fe(II)-species will fully relax or decay into the stable Fe(III)-species within the resolving time on X-ray-gated spectrum and that the chemical effects on X-ray emission will produce no remarkable difference in $Co(IO_3)_2$. It is also noted that the chemical lifetime and the distribution ratio of ^{57}Fe(II)/^{57}Fe(III) at 14.4 keV nuclear level are closely related to the chemical instability of the corresponding iron compound.

Determination of Trace Metals in Seawater by Graphite Furnace Atomic Absorption Spectrometry after Preconcentration Using Synergistic Extraction

Kazumasa UEDA,* Katsutoshi KUBO, Osamu YOSHIMURA, and Yoshikazu YAMAMOTO
Department of Industrial Chemistry, Faculty of Technology, Kanazawa University, Kodatsuno, Kanazawa 920
(Received February 20, 1988)

Trace Cd, Mn, Pb, Co, Ni, and Cu have been quantitatively separated and concentrated from seawater matrices with a low concentration (mmol dm^{-3} level) of 1,1,1-trifluoro-4-mercapto-4-(2-thienyl)-3-buten-2-one and trioctylphosphine oxide cyclohexane solution. The synergistic extract was directly injected into the furnace and a reproducible signal with little memory effect was obtained. The extracted adduct enhanced the AAS sensitivity during thermal decomposition processes, and simultaneously resulted in depression of the interferences. The detection limits of the analytes ranged from several ng dm^{-3} to 100 ng dm^{-3}. The proposed technique provides both the preconcentration and determination for trace analysis by a single extraction using a small volume of sample. Coastal seawater samples were analyzed by the method.

The determination of trace metals in seawater, particulary toxic or neutrient elements, has received increasing attension in analytical and environmental chemistry. Graphite furnace atomic absorption spectrometry (GF-AAS) is one of the most widely used methods for this purpose. Since the concentrations of many elements are extremely low, adequate preconcentration techniques are usually required prior to GF-AAS measurement.[1-5] However, most of them are troublesome due to the use of a large volume of sample and often cause contamination or loss of the analytes. A simple and reliable preconcentration method is required.

The synergistic extraction is a useful technique for separation and concentration of trace metals. Although the analytical importance has been well recognized, the applications combined with AAS are relatively few.[6,7] Recently, Itoh et al.[8] reported a convenient method for determining cadmium in river water, in which synergistic extract with dithizone-tributylphosphine oxide was directly injected into the furnace. Direct analysis of the organic extract is highly desirable to simplify sample pretreatment steps. Though similar attempts in GF-AAS have been undertaken by utilizing the conventional extraction, e.g., ammonium 1-pyrrolidinecarbodithioate[9] and thiocyanate-zephiramine systems,[10] they were not sufficiently sensitive for accurate analysis of seawater.

In this study, synergistic extraction with 1,1,1-trifluoro-4-mercapto-4-(2-thienyl)-3-buten-2-one (STTA)-trioctylphosphine oxide (TOPO) is evaluated for the preconcentration followed by GF-AAS measurement. The extraction conditions and recovery of trace metals from saline waters are examined in detail.

Experimental

Apparatus. A Nippon Jarrel-Ash Model AA-8500 atomic absorption spectrophotometer with a FLA-10 graphite furnace atomizer was used. A deuterium lamp was used for background correction and tube temparature was measured with a Keisoku Electric Co. Model OPA optical pyrometer. Solvent extractions were carried out by a centrifuge tube (volume: 50 cm^3) with glass stopper. An Iwaki KM type shaker and a Kubota K80 centrifuge were also used.

Reagents. All reagents used were of analytical reagent or better grade. Deionized distilled water was used. The standard solutions (1000 mg dm^{-3}) for Cd, Mn, Pb, Co, Ni, and Cu were prepared by dissolving pure metals or their salts in 0.1 M (M=mol dm^{-3}) HNO_3. STTA was synthesized by the method of Berg et al.[11] and purified repeatedly by recrystallization from absolute ethanol. TOPO was purchased from Dojindo Co. Ltd. Stock reagent solutions (50 mM) for synergistic extraction were prepared by dissolving STTA and TOPO in cyclohexane. The working solution was prepared by mixing and diluting them with cyclohexane before use. HCl, HNO_3, and acetic acid were of extra pure grade purchased from Wako Chemical Co. Ltd., and NaOH was of suprapure grade from Merck. Buffer solutions were purified by washing with the extracting solution, and cyclohexane.

Seawater Samples. Surface seawater was collected at the coast of Noto Peninsula. The waters was filtered through a 0.45 μm Toyo Roshi membrane filter immediately after sampling, acidified to pH 1.5 with HNO_3 and stored in polyethylene bottles. Artificial seawater was prepared according to Japanese Industrial Standard K 2510. All glass wares and polyethylene bottles were rinsed well with pure water after soaking in (1+2) HNO_3 for over 3 days. Centrifuge tube was thoroughly washed with the extracting solution and cyclohexane just before use. Membrane filter was soaked in (1+1) HCl for over 5 days.

Analytical Procedure. An aliquot of seawater (up to 30 cm^3) was transferred into centrifuge tube and neutralized with 1 M NaOH. The pH was adjusted with 5 cm^3 of 0.1 M acetate or 0.05 M borax buffer solution; the total volume of the solution was controlled within the optimum volume for each metal. Then, 5.0 cm^3 of synergistic extracting solution was added and the mixture was shaked for 20 min. After centrifugal separation, 20 μL of the upper organic phase was directly injected into graphite furnace. The atomic absorption peak height for each metal was measured. The metal concentration was determined by the calibration method, except for Co by the standard addition method. Analytical conditions were determined for artificial or natural seawater by comparing the signal height with that for aqueous standard. Optimum analytical parameters obtained for furnace operation and synergistic extraction are shown in

Table 1. Optimum Analytical Parameters for Furnace Operation and SynergistiC Extraction

Table 1.

Results and Discussion

Operating Conditions. Operating conditions for GF-AAS differ a little from those of the usual method, because synergistic extract is directly injected into the furnace. On graphite surface, the following chemical reactions will take place: evaporation of cyclohexane, fussion and decomposition of extracting reagents and adduct chelates, and vaporization of metals in drying, ashing, and atomization processes. The establishment of ashing temperature was especially important, because the extracting reagent acted as a flux. Figure 1 shows the effect of ashing current on the absorption signals of trace metals spiked into artificial seawater. The maximum absorbance was obtained at the current of 90 A (1000 °C) for Pb, up to 60 A (640 °C) for Mn and Co, and up to 100 A (1100 °C) for Cu. The signals for Cd and Ni markedly decreased even at low currents. Berg and Reed[11] have reported that the thermal stability of STTA chelate is relatively low. Although the thermal stability of TOPO adducts is not well-known, the abrupt decrease of Cd and Ni signals would be attributable to the sublimation of the adducts. On the other hand, the loss of Cu and Co by volatilization was little even at elevated temperatures, presumably due to forming a stable fussion product or metallic carbide during decomposition of chelating agents. The ashing temperature of each metal was set high enough to eliminate matrix interferences at the atomization step and ashing time was selected to make background signal became zero or minimum. The drying conditions were established by considering only the evaporation of cyclohexane.

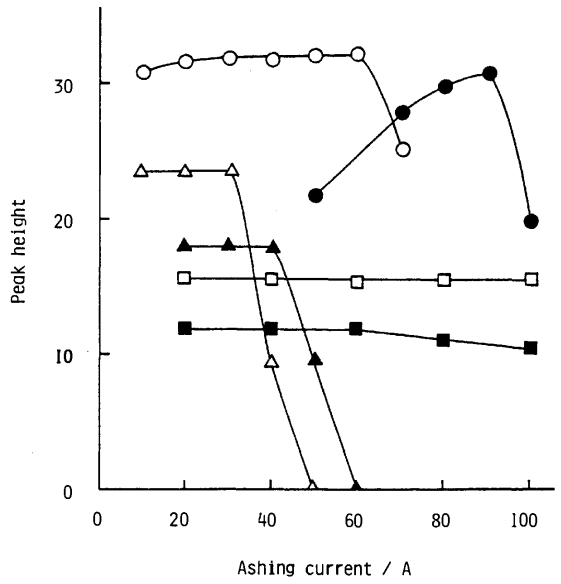

Fig. 1. Effect of ashing current on absorption signal of each metal. ○: Mn 40 ng, ●: Pb 125 ng, △: Cd 5 ng, ▲: Ni 300 ng, □: Cu 250 ng, ■: Co 100 ng.

Absorption Profiles. When the analyte spiked into alkali or alkaline earth metal chloride solution was directly supplied into the furnace, a background signal with multiple peaks appeared and a large depressive effect on the analyte peak was observed in the following sequence, Cs > Na > Mg > Ca. Whereas, when the synergistic extract was applied, a reproducible single peak with little memory effect was obtained, which was compatible with the aqueous analyte standard. Synergistic extraction was effective not only for preconcentration of trace metals from saline waters but also for reduction of the desired metal during thermal decomposition processes, because the synergist acted as a reductant. Furthermore, the extracted adduct showed favorable effects on the AAS measurement, e.g., extension of thermal contact area in the furnace, depression of analyte volatilization at the ashing step, prevention of metal oxide formation, and acceleration of thermal decomposition of the extracted matrix.

Selection of Synergistic Extractants. When a common fluorinated β-diketone, such as thenoyltrifluoroacetone (TTA) or benzoyltrifluoroacetone, was used as a chelating reagent, matrix elements in seawater were coextracted and the detection of the analyte, especially Cd, Mn and Pb, became difficult. However, the interferences could be almost neglected when a low concentration of STTA was used. Figure 2 shows the effect of Ca or Mg matrices on Mn and Pb signals. The constant signals were obtained by the STTA-TOPO extraction at the seawater level of Ca and Mg, whereas the TTA-TOPO extraction gave the decreased signals

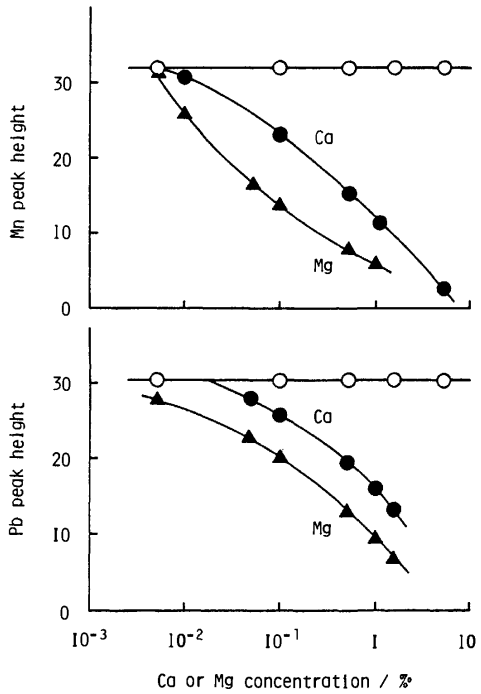

Fig. 2. Effect of Ca or Mg concentration on Mn and Pb absorption signals. Open symbols: 1 mM STTA–1 mM TOPO extraction. Closed symbols: 1 mM TTA–1 mM TOPO extraction.

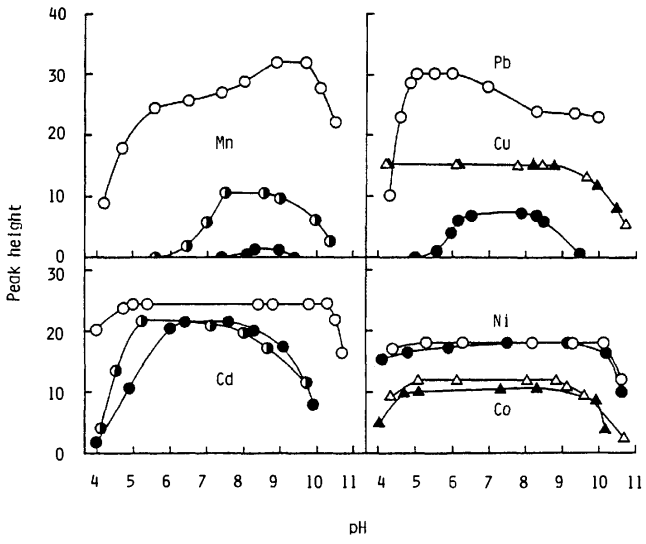

Fig. 3. Effect of extraction pH on absorption signals of each metal. Open and closed symbols denote the absorbances by STTA-TOPO and STTA extraction, respectively, except for STTA-TBP extraction (◑). The reagent and metal concentrations are identical to those shown in Table 1 and Fig. 1, respectively.

with the increase of matrix concentration, especially for Mg. Similar decreased signals were also recognized for Cd, Co and Ni, except for Cu. As a synergist, alkylphosphine oxides and pyridine bases were examined. The analyte peaks were generally enhanced in the following order: pyridine, piperidine < α-picoline, α-pipecoline, 2,6-lutidine < γ-picoline, γ-pipecoline, 2,4-lutidine ≪ tributyl phosphate (TBP) < TOPO. Although the order differed a little from the ordinary base effect for synergistic extraction,[12] TOPO showed a constant signal over wider pH region with the largest enhancement effect. As for the diluent, the signals were increased in the following sequence: chloroform < carbon tetrachloride < benzene < hexane < cyclohexane. Cyclohexane was easier to volatilize than chlorinated solvent, that showed the depressive effect in pH range over 9.

Effect of Extraction pH. Figure 3 shows the effect of pH on the signals of each metal by extraction with STTA-TOPO (or TBP) or STTA only. The maximum and constant absorbances were obtained over wider pH ranges of 8.9—9.7 for Mn, 5.0—10.3 for Cd, 5.0—6.0 for Pb, 4.2—8.5 for Cu, 5.3—10.1 for Ni, and 5.0—8.8 for Co, respectively. Comparing with the signal of STTA only, the peak height increased about 23-fold for Mn and 4.2-fold for Pb, and these enhancement effects were recognized in the following order: Mn ≫ Pb > Cd > Co > Ni ≈ Cu. The order agrees nearly with that of synergistic extractability, but Cu and Ni did not show any significant effect, presumably due to low stability of the adducts. In order to make the phenomena clearer, the extraction equilibria of the TOPO adducts were analyzed by the curve fitting method with 0.05 M STTA at μ=0.1 ($NaClO_4$). The extracted species of Cd, Pb and Zn were found to be $MR_2 \cdot L$ type adduct with one molecule of TOPO, and those of Mn and Co are of $MR_2 \cdot L_2$ type, while Ni formed an ambiguous adduct. Copper was completely extracted with STTA only even at pH 0.5 or below. The primary stability constants of the adducts increased in the order of Cd > Mn > Pb > Co > Zn. These facts suggest that the more STTA chelate is stabilized by adduct formation, the more the sensitivity for GF-AAS is increased.

STTA and TOPO Concentrations. The maximum and constant signals were obtained in the following STTA concentration ranges; 0.1—1 mM for Cu, 0.1—5 mM for Cd, 0.5—1 mM for Pb and Co, 1—5 mM for Mn, and 5—50 mM for Ni. Above the concentrations, the decreases of the signal height, except for Ni, were observed, especially for Mn and Pb. The effect of TOPO concentrations is shown in Fig. 4, where constant absorbances are obtained in the following ranges: 5—10 mM for Mn, 1—10 mM for Pb, 0.5—5 mM for Cd, up to 1 mM for Ni and 0.1 mM for Cu, and 0.1—10 mM for Co, respectively. Above 10 mM, the decreases of absorbance arising from the antagonism were observed for Cd, Ni, and Cu.

Shaking Time and Aqueous Phase Volume. The constant signals were obtained by shaking for over 5 min for Mn, Co, Ni and Cu, 10 min for Pb, and 15 min for Cd, respectively, up to 60 min in each case. The effect of aqueous phase volume was also examined by shaking for 20 min with 3.0 cm^3 of organic phase. The peak height of each metal was little affected by the

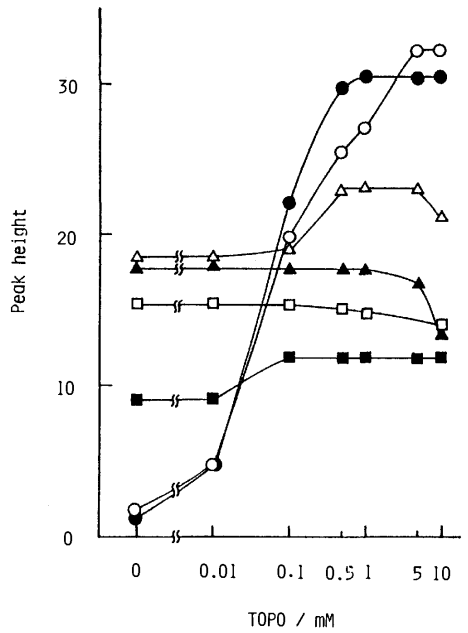

Fig. 4. Effect of TOPO concentration. Symbols and experimental conditions are identical to those shown in Fig. 1 and Table 1, respectively.

volume ratio (V_{aq}/V_{org}) up to 10, but at the ratio of 15, peak height of Cd, Mn, and Ni decreased by about 7, 8, and 15%, respectively.

Recovery of Spikes and Calibration Curves. Known amounts of metals were spiked into seawater aliquots (20 cm^3) to evaluate the net recovery of the extracted metals by comparing with the aqueous standards. The spikes were added before pH adjustment and the solutions were equilibrated for at least 6 h prior to extraction. The spikes were extracted into 5.0 cm^3 of organic phase with above 99% recovery at the concentration up to 5 ng for Cd, 40 ng for Mn, and 125 ng for Pb and Co, and below these concentrations, favorable linear relationships were obtained by a single extraction. The straight lines were also obtained for Cu up to 250 ng and Ni up to 400 ng, although the mean recovery fell to 94.5 and 87.3%, respectively. Since the spikes of Cu and Ni can be quantitatively extracted by synergistic extraction with 1 mM STTA-TOPO,[13] low recovery from seawater matrices would be attributed to the non-extractable metal species.[14] In practice, found values of Cu and Ni were corrected by the calibration graphs.

Table 2. Blanks and Detection Limits

	Blank/ng cm^{-3} a)	Detection limit/ng cm^{-3}
Cd	0.010±0.004	0.008

Pb	0.84±0.16	0.32
Co	<0.20	<0.20
Ni	0.3±0.1	0.2
Cu	0.5±0.1	0.2

a) Mean and standard deviation for five determinations.

Blanks and Detection Limits. The blank in the extraction procedure consists of metals in the reagents used as well as those introduced during sampling and extraction steps. A reagent blank was prepared by re-extracting the previously extracted seawater. A preextracted seawater sample (500 cm^3) was washed with two 10 cm^3 portions of cyclohexane, and the aliquots were submitted to the analysis. Replicate blanks for each metal studied are shown in Table 2. As for Co, the metal concentration corresponding to the peak unit of 0.1 is regarded as a blank, due to it's weak signal. The detection limits are based on twice the standard deviation of the blank, which are lower than those obtained by the dithiocarbamate extraction-GF-AAS.[9]

Analysis of Seawater. The analytical results of coastal seawater samples are summarized in Table 3. Each metal was determined within the relative standard deviation of 10%, but the concentration of Co was near or below the detection limit and the values found had poor analytical precision. The results of six elements were lower than those found in Seto Inland Sea and Tokyo Bay,[15] especially for Mn and Pb. The results of Monzen were compared with those obtained by the chelex-100 resin preconcentration-GF-AAS.[16] The concentrations obtained by two analytical methods were agreed closely with each other, indicating that the proposed method is accurate enough to apply to the determination of trace metals in seawater.

Conclusion

Synergistic extraction by using a low concentration synergist is useful for preconcentration of trace metals

Table 3. Analytical Results of Trace Metals in Seawater

in saline water. The method is convenient and rapid, as the extraction is carried out in a centrifuge tube and an aliquot of cyclohexane extract in the upper layer can be directly served for GF-AAS. This enables the use of smaller amounts of samples and reagents compared with those in the conventional methods. As an another merit of synergistic extraction, the group separation of trace metals is achievable, that is now under investigation for simultaneous multielement analyses.

Mechanistic Study on the Photochemical Conversion of Disilanyliron(II) Complexes to Monosilyliron(II) Complexes

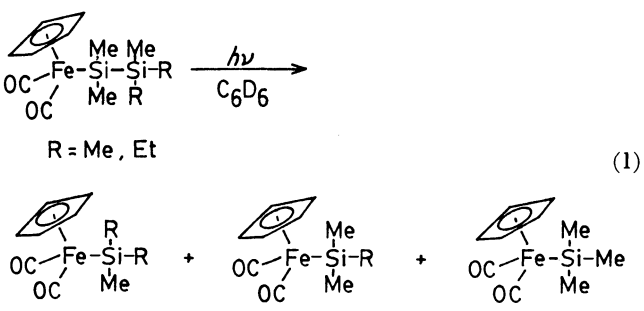
Hiromi Tobita, Keiji Ueno, and Hiroshi Ogino*
Department of Chemistry, Faculty of Science, Tohoku University, Sendai 980
(Received March 5, 1988)

Photolysis of a C_6D_6 solution of $CpFe(CO)_2SiMe_2SiMe_3$ ($Cp=\eta^5$-C_5H_5) or $(MeCp)Fe(CO)_2SiMe_2SiMe_3$ ($MeCp=\eta^5$-C_5H_4Me) resulted in the formation of monosilyl derivative, $CpFe(CO)_2SiMe_3$ or $(MeCp)Fe(CO)_2SiMe_3$ in 64 or 59% yield, respectively, together with small quantities of ferrocene and $Cp_2Fe_2(CO)_4$ or their methylated derivatives. The yield of $CpFe(CO)_2SiMe_3$ increased to 88% when the photolysis was carried out under a carbon monoxide atmosphere, while decreased to 22% when argon was vigorously bubbled through the reaction mixture. These results are consistent with a mechanism involving dissociation and recombination of a carbonyl ligand which are common processes in photoreactions of transition-metal carbonyl derivatives. Dimethylsilylene moiety released during the photolysis was tried to be trapped with a hydrosilane, diene, and cyclotrisiloxane, but none of the expected products from the trapping reactions was detected, even in a trace amount. Photolysis of $CpFe(CO)_2SiMe_2SiMeEt_2$ afforded, accompanying alkyl migration between silicon atoms, $CpFe(CO)_2SiMeEt_2$, $CpFe(CO)_2SiMe_2Et$, and $CpFe(CO)_2SiMe_3$ in 26, 33, and 4% yields, respectively. Photolysis of a 1 : 1 mixture of $CpFe(CO)_2SiMe_2SiMeEt_2$ and $(MeCp)Fe(CO)_2SiMe_2SiMe_3$ provided only products expected from intramolecular alkyl migration mechanism. A possible mechanism involving silyl(silylene)iron intermediates is proposed to explain these results.

Divalent silicon species, silylene, is important as a key intermediate for many reactions containing silicon compounds.[1,2] Its existence is well established by many trapping reactions as well as low-temperature matrix isolation techniques.[3-5] However, the only known divalent silicon species stable at room temperature are decamethylsilicocene, $(\eta^5$-$C_5Me_5)_2Si$,[6] and a metallocarborane, $[(Me_3Si)_2C_2B_4H_4]Si$,[7] and no usual σ-substituted silylene has been isolated so far under normal conditions because of its lability and instability. Carbene is also a very reactive species, but it is well known to be stabilized by coordination to a metal atom and becomes isolable.[8] Therefore, we can expect that silylene is also stabilized as a ligand on a transition metal.

There is no genuine silylene complex isolated at present,[9] although some neutral[10,11] and cationic[12] base-stabilized silylene complexes have been reported. There are also several reactions in which silylene complexes are proposed as reactive intermediates during the courses of reactions; e.g. decomposition reactions of silicon containing organometallic complexes,[13,14] metal-catalyzed reactions of organosilicon compounds,[15] and reactions of transition-metal ions with methylsilanes in gas phase.[16]

Recently, Pannell et al. suggested the formation of novel silyl(silylene)iron complexes as intermediates in the photochemical conversion of $CpFe(CO)_2SiMe_2SiPh_3$ to $CpFe(CO)_2SiPh_nMe_{3-n}$ (n=1—3).[17] Our independent study on the photoreaction of $CpFe(CO)_2SiMe_2SiMeR_2$ (R=Me, Et) (Eq. 1) led us to almost the same mechanism which we reported previously in a preliminary communication.[18] We now give the evidence for the intramolecular mechanism for this reaction as well as the full detail of the mechanistic study.



Experimental

General Details. All experiments were performed under a nitrogen atmosphere by using standard Schlenk techniques. Hexane, pentane, and tetrahydrofuran (THF) were reagent grade and were freshly distilled from sodium-benzophenone ketyl under nitrogen. Chlorotrimethylsilane, dichlorodimethylsilane, and ethyl bromide were obtained from Wako Pure Chemical Industries, Ltd. and distilled under nitrogen before use. 2,3-Dimethyl-1,3-butadiene was obtained from Tokyo Chemical Industry Co., Ltd. and used after distillation. Chloropentamethyldisilane,[19] 1-chloro-2,2-diethyl-1,1,2-trimethyldisilane,[20] chlorodiethylmethylsilane,[21] diethylmethylsilane,[22] $Cp_2Fe_2(CO)_4$,[23] $(MeCp)_2Fe_2(CO)_4$,[23] $CpFe(CO)_2SiMe_3$ (**2a**),[24] $CpFe(CO)_2SiMe_2SiMe_3$ (**1a**),[25] $(MeCp)Fe(CO)_2SiMe_3$ (**2b**),[26] and hexamethylcyclotrisiloxane[27] were prepared according to the published procedures.

Measurements. Electronic spectra were recorded on a Hitachi 330 or a Shimadzu UV-260 spectrophotometer using a quartz cell of 1 cm optical path length. Infrared spectra were recorded on a JASCO IRA-1 spectrophotometer, and gas chromatography-mass spectra (70 eV) on a JEOL JMS-D300 mass spectrometer. NMR spectra were measured on a JEOL FX-90Q Fourier-transform spectrometer in C_6D_6 at 25 °C. Gas chromatograms were obtained on a Hitachi 263-30 (FID) with a glass column (1 m) packed with 10% SE-30 using nitrogen as a carrier gas. The measurements of HPLC were carried out using a Hitachi 655 with a Gasukuro Kogyo UNISIL Q-30-5 silica-gel column (4.6 mm×250 mm), a

Hitachi 638-41 variable wavelength UV detector, and a Hitachi 655-61 data processor.

Preparation of Compounds. $CpFe(CO)_2SiMe_2SiMeEt_2$ (1c). A solution of $Na[FeCp(CO)_2]$ (5.2 mmol) in 15 cm^3 of THF was added dropwise over 30 min to a solution of 1-chloro-2,2-diethyl-1,1,2-trimethyldisilane (1.05 g, 2.6 mmol) in THF (15 cm^3) with vigorous stirring at room temperature. After the solution was stirred for additional 18 h, solvent was removed from the reaction mixture under reduced pressure and the dark brown residue was extracted with three 10 cm^3 portions of hexane. The extracts were filtered through a Celite pad, and the filtrates were combined and concentrated. Molecular distillation of the dark red residue at 0.15 Torr† and 80 °C yielded an orange oil of **1c** (1.29 g, 73%); ^1H NMR (C_6D_6) δ=4.14 (5H, s, Cp), 1.2—0.6 (10H, m, Et), 0.57 (6H, s, Me), 0.14 (3H, s, Me); ^{13}C NMR (C_6D_6) δ=215.9 (CO), 83.1 (Cp), 8.5 (CH_3 of Et), 6.4 (CH_2 of Et), 4.5 (Me), −5.2 (Me); MS *m/z* 336 (M^+, 16.3), 235 (34.0), 207 (15.6), 179 (12.5), 159 (100), 131 (95.2), 121 (24.0). Found: C, 50.15; H, 7.25%. Calcd for $C_{14}H_{24}FeO_2Si_2$: C, 50.00; H, 7.19%.

$CpFe(CO)_2SiMeEt_2$ (2c). In a similar manner, the reaction of $Et_2MeSiCl$ (0.73 g, 5.3 mmol) with $Na[FeCp(CO)_2]$ (5.2 mmol) in THF followed by molecular distillation at 0.02 Torr and 80°C gave an orange oil of **2c** (0.95 g, 68%); ^1H NHR (C_6D_6) δ=4.07 (5H, s, Cp), 1.3—0.7 (10H, m, Et), 0.44 (3H, s, Me); ^{13}C NMR (C_6D_6) δ=216.2 (CO), 83.2 (Cp), 14.4 (CH_2), 9.4 (Me), 2.2 (Me); MS *m/z* 278 (M^+, 10.8), 250 (4.8), 249 (3.6), 220 (9.3), 192 (24.9), 164 (11.6), 121 (11.8), 101 (48.0), 93 (23.3), 73 (100). Found: C, 52.05; H, 6.58%. Calcd for $C_{12}H_{18}FeO_2Si$: C, 51.81; H, 6.52%.

$CpFe(CO)_2SiMe_2Et$ (2d). To a solution of dichlorodimethylsilane (10.9 g, 84.5 mmol) in THF (50 cm^3) was added dropwise over 3 h a solution of ethylmagnesium bromide prepared from magnesium ribbon (2.48 g, 0.102 mol) and ethyl bromide (11.0 g, 0.101 mol) in THF (50 cm^3). After the reaction mixture was stirred at room temperature for 24 h, a solution of $Na[FeCp(CO)_2]$ (56 mmol) in THF (150 cm^3) was added dropwise over 2 h to the reaction mixture. The resulting mixture was stirred at room temperature for additional 12 h and then THF was removed in vacuo. To the reddish brown residue was added 200 cm^3 of hexane and the slurry was filtered through a Celite pad. After evaporation of hexane from the filtrate, the resultant dark red oil was purified by molecular distillation at 0.3 Torr and 90 °C yielding an orange oil of **2d** (10.1 g, 68%); ^1H NMR (C_6D_6) δ=4.04 (5H, s, Cp), 1.2—0.7 (5H, m, Et), 0.45 (6H, s, Me); ^{13}C NMR (C_6D_6) δ=216.1 (CO), 83.3 (Cp), 16.4 (CH_2), 9.2 (Me), 4.8 (Me); MS *m/z* 264 (M^+, 27.1), 236 (16.5), 208 (10.0), 206 (34.5), 180 (41.6), 178 (23.3), 121 (26.6), 93 (27.6), 87 (77.4), 59 (100). Found: C, 49.93; H, 6.06%. Calcd for $C_{11}H_{16}FeO_2Si$: C, 50.02; H, 6.11%.

$(MeCp)Fe(CO)_2SiMe_2SiMe_3$ (1b). This compound was prepared by a procedure similar to that of $CpFe(CO)_2SiMe_2SiMeEt_2$ (**1c**). $Me_3SiSiMe_2Cl$ (1.75 g, 10.5 mmol) and $Na[Fe(MeCp)(CO)_2]$ (5.24 mmol) were used as starting materials, and after the usual work-up, molecular distillation at 0.09 Torr and 65 °C gave an orange oil of **1b** (2.42 g, 72%): ^1H NMR (C_6D_6) δ=4.2—3.9 (4H, m, ring protons of MeCp), 1.52 (3H, s, Me of MeCp), 0.55 (6H, s, Me), 0.23 (9H, s, Me); ^{13}C NMR (C_6D_6) δ=216.3 (CO), 101.0 (ring carbon of MeCp), 13.2 (Me), 3.5 (Me), 0.5 (Me); MS *m/z* 322 (M^+, 11.0), 294 (5.0), 264 (11.4), 249 (45.4), 193 (11.3), 131 (100), 73 (50.0). Found: C, 48.20; H, 6.73%. Calcd for $C_{13}H_{22}FeO_2Si_2$: C, 48.45: H, 6.88%.

The IR and electronic spectral data of all disilanyl- and silyliron complexes which were used in this work were listed in Table 1.

Photolysis. Unless otherwise noted, photolysis was carried out as follows: Iron complex(es) and, in some cases, a trapping agent were placed in a Pyrex NMR sample tube (5 mm o.d.) and dissolved in deoxygenated C_6D_6. It was then immersed in the water at room temperature and irradiated with a 450 W medium pressure Hg arc lamp (Ushio UV-450) placed in a water-cooled, quartz jacket. The distance between the light source and the sample tube was about 3 cm. A ^1H NMR spectrum or gas chromatogram of the reaction mixture was taken periodically to monitor the reaction. Identification of products was accomplished by taking gas chromatograms, gas chromatography-mass spectra, ^1H NMR spectra and, in some cases, high performance liquid chromatograms of the reaction mixture and comparing them with the authentic samples prepared by the independent methods. Yields of products were determined by gas chromatography with dodecane as an internal standard and calculated for the consumed starting materials.

Results and Discussion

Photolyses of $CpFe(CO)_2SiMe_2SiMe_3$ (1a) and $(MeCp)Fe(CO)_2SiMe_2SiMe_3$ (1b). Irradiation of a solution of disilanyl complex $CpFe(CO)_2SiMe_2SiMe_3$ (**1a**) with a 450 W medium pressure Hg lamp in a Pyrex tube for 7 min at room temperature consumed 80% of **1a** and gave monosilyl complex $CpFe(CO)_2SiMe_3$ (**2a**) in 64% yield together with ferrocene (4%) and $Cp_2Fe_2(CO)_4$.[18] Similarly, the photolysis of methylcyclopentadienyl derivative $(MeCp)Fe(CO)_2SiMe_2SiMe_3$ (**1b**) for 3 min yielded $(MeCp)Fe(CO)_2$-

The reactions were monitored either by ^1H NMR spectroscopy or by gas chromatography. Figures 1 and 2 show the changes of ^1H NMR spectrum and gas chromatogram of the reaction mixture of **1a**, respectively. It can be seen that the ^1H NMR signals or the GC peak of **1a** is weakened and those of **2a** newly appear instead. The absence of well-resolved Si-Me signals except that of **2a** on the ^1H NMR spectrum of the final reaction mixture (conversion: 98%) implies that a dimethylsilylene unit, which is considered to be extruded from **1a**, forms a number of oligomeric and/or polymeric products. Results similar to this are also observed for the photolysis of **1b**.

Electronic spectra of disilanyliron complexes **1a—1c** show two characteristic absorption maxima at ca. 285 nm and ca. 330 nm (Table 1, Fig. 3). This fact suggests that the choice of the light source is critical. In fact, irradiation with a low pressure Hg lamp using a quartz NMR tube as a reaction vessel made the reaction more complicated.

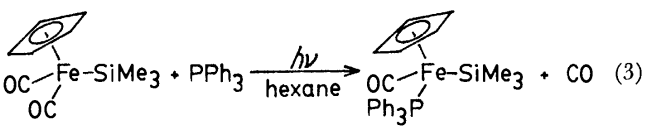
Effect of CO Concentration on the Photoreaction of $CpFe(CO)_2SiMe_2SiMe_3$ (1a). $CpFe(CO)_2SiMe_3$ (**2a**) is known to lose one of the coordinated carbonyl ligands by near UV irradiation. Thus, the irradiation of **2a** in the presence of PPh_3 forms $CpFe(CO)(PPh_3)SiMe_3$ as a main product (Eq. 3).[24] By analogy with this reaction, the initial step of the photoreaction of **1a** is likely to be



(3)

Table 2. Photolysis of $CpFe(CO)_2SiMe_2SiMe_3$ (**1a**) under a Nitrogen Atmosphere, a Carbon Monoxide Atmosphere, and with a Vigorous Argon Bubbling

Entry	Reaction condition	Conversion/%	Product and yields/%	
			(**2a**)	ferrocene
1	N_2 atmosphere, 7 min	80	64	4
2	CO atmosphere, 4 min	73	88	9
3	Ar bubbling,[a] 5 min	83	22	3

a) Dry argon saturated with benzene vapor was bubbled through the reaction mixture. Flow rate $>15\ cm^3\ s^{-1}$.

the loss of CO.

The effect of CO on the photoreaction of **1a** was investigated by the following two experimental procedures: In the first procedure a solution of **1a** was saturated with CO before irradiation. In the second procedure CO which was considered to be liberated from **1a** was efficiently removed from the system by vigorous argon bubbling through the reaction mixture.[28] The results of these experiments along with that of photolysis under nitrogen atmosphere are summarized in Table 2.

The large decrease of the yield of **2a** in entry 3 is in accord with the light-induced CO loss mechanism. In a preliminary experiment, irradiation of vigorously argon bubbled solution of **2a** in the same conditions as in entry 3 caused decomposition of only 14% of **2a**. Therefore the decrease of **2a** during the photolysis in entry 3 is considered to be almost negligible. The substantial increase of the yield of **2a** in entry 2 comes from the efficient bimolecular CO recombination process. An analogous photochemical behavior including dissociative loss and following recombination of CO is reported with respect to the photolyses of $Me_3SiCo(CO)_4$[29] and $(\eta^5\text{-}C_5Me_5)Fe(CO)_2SiMe_3$[30] in the presence of R_3SiH by Wrighton et al.

Photolysis of $CpFe(CO)_2SiMe_2SiMe_3$ (1a) in the Presence of Silylene-Trapping Agents. As mentioned above, the formation of monosilyl complex **2a** from disilanyl complex **1a** must be a result of expulsion of Me_2Si moiety. Thus, in hopes of trapping this Me_2Si moiety, we employed three different types of silylene-trapping agents, i.e., 2,3-dimethyl-1,3-butadiene (**3**),[31] diethylmethylsilane (**4**),[1] and hexamethylcyclotrisiloxane (**5**).[32] It is known that each of them undergoes a certain type of reaction with dimethylsilylene to give a specific product, **6**, **7**, or **8**, respectively (Eq. 4).

A benzene solution of $CpFe(CO)_2SiMe_2SiMe_3$ (**1a**) and two- to twenty-fold excess of a silylene-trapping agent was irradiated under conditions similar to those of the simple photolysis of **1a**. Contrary to our expectations, no silylene-trapped product was detected from each of those reaction mixtures by means of GC and GC-MS.

From the photolysis of **1a** in the presence of **3** or **5**, formation of a reasonable amount of **2a** was observed. On the other hand, the photolysis of **1a** in the presence of eighteen-fold excess of **4** provided significant amount of $CpFe(CO)_2SiMeEt_2$ (**2c**) (15%) besides **2a** (24%) (conversion: 90%). The formation of **2c** can be interpreted as a result of the silyl group exchange on iron complexes through successive oxidative addition and reductive elimination of hydrosilanes (Scheme 1).[29,30] In fact, when **2a** was irradiated in the presence

$$CpFe(CO)_2SiMe_2R \overset{h\nu}{\rightleftarrows} CpFe(CO)SiMe_2R + CO$$

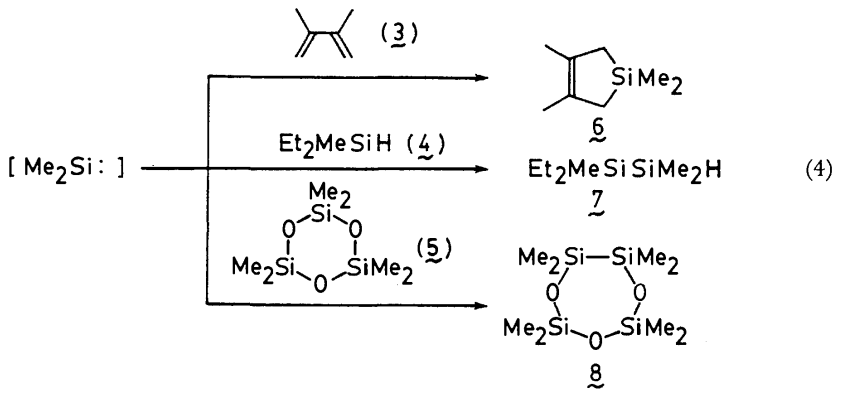
$$CpFe(CO)H(SiMe_2R)(SiMeEt_2) \rightleftarrows CpFe(CO)SiMeEt_2 + RMe_2SiH$$

$$CpFe(CO)SiMeEt_2 + CO \overset{h\nu}{\rightleftarrows} CpFe(CO)_2SiMeEt_2 \quad (\mathbf{2c})$$

Scheme 1.



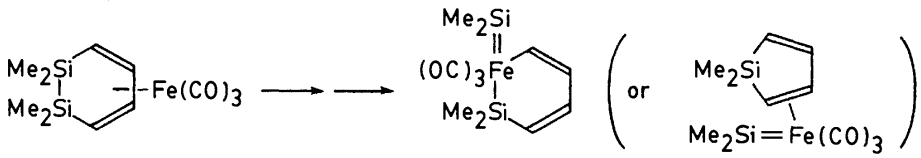
(4)

of 10 mol equiv of Et_2MeSiH, **2c** was formed in 53% yield based on 55% conversion of **2a**.

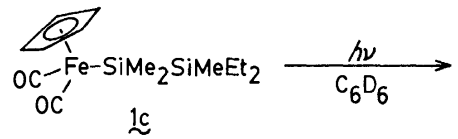
Carbon monoxide generated during the photolysis might be a silylene trapping agent. However, the following two respects seem to make this possibility unlikely: (a) The concentration of free carbon monoxide in the reaction mixture is thought to be extremely low compared with that of added trapping agent throughout the reaction; (b) since the yield of **2a** is 64% under a nitrogen atmosphere, the amount of extruded dimethylsilylene exceeds that of carbon monoxide liberated into the solution. This means that all dimethylsilylene can not be trapped by carbon monoxide if one carbon monoxide reacts with one dimethylsilylene. Therefore these results suggest the existence of some unknown route of excluding Me_2Si unit without generating free dimethylsilylene. Loss of Me_2Si unit from silylene-metal intermediate without being trapped with some trapping agents are also reported by Pannell et al. in the photolysis of $CpFe(CO)_2SiMe_2$-$SiPh_3$[17] and by Sakurai et al. in the pyrolysis of disilacyclohexadiene iron complexes (Eq. 5).[13]

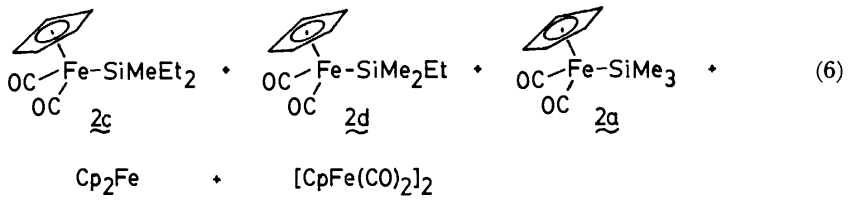
Photolysis of $CpFe(CO)_2SiMe_2SiMeEt_2$ (1c). The fact that Me_2Si unit is extruded from **1a** without being trapped suggests the complexity of the mechanism of photochemical conversion from **1a** to **2a**. To probe the structure and reactivity of intermediates in this reaction, two methyl groups on **1a** was changed to ethyl groups and the diethyl derivative **1c** was photolyzed under the same reaction conditions. Surprisingly, after 69% conversion of **1c**, three monosilyliron complexes, $CpFe(CO)_2SiMeEt_2$ (**2c**), $CpFe(CO)_2SiMe_2Et$ (**2d**), and $CpFe(CO)_2SiMe_3$ (**2a**) were obtained in 26, 33, and 4% yields, respectively, together with 7% of ferrocene (Eq 6). Monosilyl complexes **2d** and **2a** can not be formed by only the cleavage of relatively weak Si-Si and Si-Fe bonds of **1c**. Therefore it is necessary to postulate the alkyl migration between silicon atoms, although that type of reaction is very rare. To our knowledge, there are two sorts of reactions accompanying alkyl migration between two silicon atoms: The one is the 1,3-migration of a methyl group between the two silicon atoms in a cationic intermediate generated in the reaction of $(Me_3Si)_3CSiR_2I$ with silver salts,[33] and the other is the [1,3]sigmatropic shifts of methyl and phenyl groups from a saturated Si atom to an unsaturated one in dimethyl[bis(trimethylsilyl)methylene]silane or its phenyl- or *t*-butyl-substituted derivatives.[34-37] Particularly, the degenerate [1,3]-sigmatropic shift of the methyl group in dimethyl[di-*t*-butylmethylsilyl(trimethylsilyl)methylene]silane (**9**) is fast enough even at 30°C to broaden the peaks in the ^1H NMR spectrum (Eq. 7).[37]

Concerted, symmetry-allowed reaction mechanism undoubtedly plays an important role for these systems to decrease the activation energy of alkyl migration. A

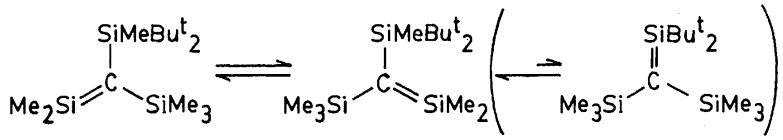


(5)





(6)



(7)

9

similar concerted mechanism and perhaps a similar structure of intermediates involving an unsaturated silicon atom seem to be necessary to explain the unusually fast shift of alkyl groups in the photoreaction of **1c**. A possible mechanism will be discussed later in datail.

Photolysis of a 1 : 1 Mixture of $(MeCp)Fe(CO)_2SiMe_2SiMe_3$ (1b) and $CpFe(CO)_2SiMe_2SiMeEt_2$ (1c). It is important to determine whether the photochemical conversion from disilanyl complex to monosilyl complex proceeds intramolecularly or intermolecularly. If only an intramolecular mechanism is operative in the reaction, we can discard some mechanisms including split intermediates such as radicals, solvent separated ion pairs, etc., and possible mechanisms can be greatly limited. The lack of triethylsilyl derivative $CpFe(CO)_2SiEt_3$ in the products of the photolysis of **1c** as shown in the previous section is suggestive of the intramolecular mechanism. Thus, to obtain more reliable answer to this question, we performed the cross reaction of two substrates, **1b** and **1c**, in which the former has an iron atom labeled with methylcyclopentadienyl ligand and a disilanyl group labeled with five methyls, while the latter has an iron atom labeled with unsubstituted cyclopentadienyl ligand and a disilanyl group labeled with two ethyls and three methyls. It is apparent from the result mentioned above that a methyl group on the cyclopentadienyl ligand has almost no effect on the photoreaction (Eq 2).

When a benzene solution of a 1:1 mixture of $(MeCp)Fe(CO)_2SiMe_2SiMe_3$ (**1b**) and $CpFe(CO)_2SiMe_2SiMeEt_2$ (**1c**) was irradiated under a nitrogen atmosphere, ferrocene, 1-methylferrocene, 1,1′-dimethylferrocene, $CpFe(CO)_2SiMe_3$ (**2a**), $(MeCp)Fe(CO)_2SiMe_3$ (**2b**) (39%), $CpFe(CO)_2SiMe_2Et$ (**2d**) (28%), and $CpFe(CO)_2SiMeEt_2$ (**2c**) (21%) were detected by GC-MS. Yields of ferrocenes and $CpFe(CO)_2SiMe_3$ (**2a**) were not determined because the GC peaks of them were not fully separated (Fig. 4).

Scheme 2 shows the products expected from intramolecular and intermolecular alkyl migrations. Here, the intermolecular alkyl migrations include not only the intermolecular migration of an alkyl group itself but also that of silyl groups, e.g., $SiMeEt_2$, $SiMe_2Et$, etc. None of the products which are expected only from intermolecular alkyl migrations was detected in the reaction mixture by GC-MS. Therefore the possibility of intermolecular alkyl migration mechanisms is effectively ruled out.

Mechanism of Photochemical Conversion from Disilanyliron Complexes to Monosilyliron Complexes. The following points were revealed in this study: (1) The reaction may be initiated by a light-induced CO loss and completed by a CO re-coordination; (2) unusually fast intramolecular alkyl migration from one silicon atom to the other occurs during the photoreaction, and the existence of concerted process such as the sigmatropic shift is suggested; (3) The R_2Si unit

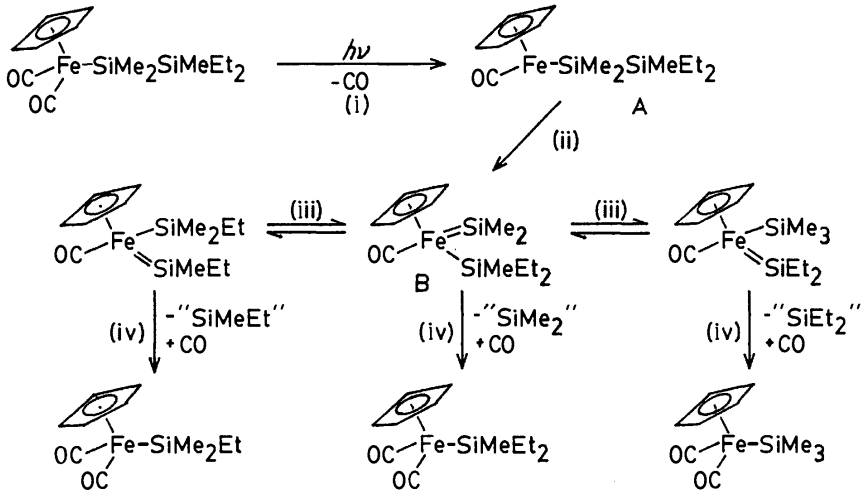
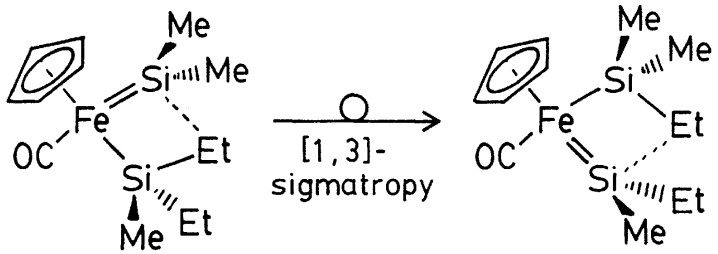
Scheme 2.

extruded in this photochemical conversion could not be trapped with usual silylene trapping agents. This fact implies the existence of some unknown route of excluding R_2Si unit without generating free silylene.

Although the third point is still obscure, we can construct the principal framework of the possible mechanism as shown in Scheme 3. The key intermediate is silyl(silylene)iron complex B which is very likely to be formed by 1,2-migration of the terminal silyl group to the 16e metal center of intermediate **A**. Moreover, it is worth noticing that this intermediate **B**



Scheme 3.



Scheme 4.

takes an ideal geometry for [1,3]sigmatropic shift of an alkyl group from a saturated Si atom to an unsaturated one as depicted in Scheme 4.

The mechanism contains four successive reactions which are essentially similar to those proposed by Pannell et al. for the photoreaction of $CpFe(CO)_2SiMe_2$-$SiPh_3$:[18] (i) Photochemically induced loss of CO to generate a coordinatively unsaturated complex A; (ii) 1,2-shift of the terminal silyl group to the Fe atom; the formation of a silyl(silylene)iron complex B; (iii) [1,3]sigmatropic alkyl shift from a saturated Si atom to an unsaturated one; and (iv) ligand substitution of dialkylsilylene by carbonyl.

The product ratio in the photolysis of $CpFe(CO)_2$-$SiMe_2SiMeEt_2$ turned out to be $CpFe(CO)_2SiMe_3$: $CpFe(CO)_2SiMe_2Et$: $CpFe(CO)_2SiMeEt_2$=0.7 : 6 : 4.7. Therefore interconversion between three silyl(silylene)-iron complexes (iii) seems to be quicker than the ligand substitution of dialkylsilylene by carbonyl, since the observed product ratio is relatively close to the statistically predicted product ratio after reaching an equilibrium of the interconversion: $CpFe(CO)_2Si$-Me_3 : $CpFe(CO)_2SiMe_2Et$: $CpFe(CO)_2SiMeEt_2$=1 : 6 : 3 on the assumption that methyl and ethyl groups behave identically.

Low-temperature photolysis of **1a** was carried out in hopes of observing the silyl(silylene)iron complexes. However, irradiation in a methylcyclohexane matrix at 77 K resulted in little net photoreaction. In comparison with the efficient photochemical conversion of $(\eta^5\text{-}C_5Me_5)Fe(CO)_2CH_2SiMe_2H$ to $(\eta^5\text{-}C_5Me_5)Fe(CO)$-$(CH_2SiMe_2)H$ at 77 K,[38] this low efficiency may be attributable to the difficulty of migration of bulky trimethylsilyl group in a relatively hard methylcyclohexane matrix.

The authors are greatly indebted to Prof. Hideki Sakurai, Tohoku University, for his warm encouragement and helpful discussion during the course of this work. This work has been supported by Grants-in-Aid for Special Project Research, No. 61125007, and for Scientific Research, Nos. 60430011 and 62740340, from the Ministry of Education, Science and Culture.

The Synthesis, and the Crystal and Molecular Structures of Tetraethylammonium [Aquaheptakis(thiocyanato)lanthanoidate(III)], $[(C_2H_5)_4N]_4[M(SCN)_7(H_2O)]$, (M=La, Ce, Pr; Nd, Dy, Er): The Complexes in a Cubic Octa-Coordination Geometry

(Received March 5, 1988)

The title complexes have been synthesized, and their crystal and molecular structures were determined by the X-ray diffraction method using their single crystals. Among them, the crystals of the La, Ce, and Pr complexes are isomorphous; cubic, space group $Pm\bar{3}$, $Z=1$, and the cell constants of the Pr complex, for example, are $a=11.513(2)$ Å, $U=1526.1(5)$ Å^3, and the final R value was 0.093. The Nd, Dy, and Er complexes, another group of the isomorphous complexes obtained almost by the same synthetic method, are tetragonal, space group $I4/m$, $Z=2$, and the cell constants of the Er complex, for example, are $a=11.564(2)$, $c=22.627(4)$ Å, $U=3026(3)$ Å^3, and the final R value was 0.071. The coordination geometry around the metal atoms of both types of complexes are almost the same: seven thiocyanato nitrogen and one water oxygen atoms are coordinated in a cubic geometry, being disordered as if each ligating atomic position is equally occupied by 1/8 atom of the water oxygen and 7/8 atoms of the thiocyanato nitrogen. In the lattice of the former three complexes, the tetraethylammonium nitrogen atoms occupy all Cl^- ionic positions of the NaCl-type lattice, while the metal atoms only the apex Na^+ ionic positions; not the face-center ones. The unit cells of the latter three complexes are apparently consist of the two former cubic type cells being piled on the c-axis direction, where the arrangement of the atoms is different from the former only on the plane where two original cells are contact: metal and ammonium nitrogen positions slide 0.5 both to a- and b-axis directions. Thus each metal atom of the both type complexes is surrounded by six tetraethylammonium nitrogen atoms on both sides of the a, b, and c-axis directions.

Lanthanoids(III) are known to be very hard elements,[1] and oxygen-coordinating ligands are most easily bonded to them. However, it is known that some nitrogen-containing ligands are also capable of being ligated to the metal atoms, forming stable complexes, when they are synthesized in anhydrous medium:[2] the structures of lanthanoid complexes with some such ligands were already reported.[3-5]

A thiocyanate ion (SCN) shows a variety of very interesting behaviors in its metal complexes: depending on the hardness of the metal, it is coordinated with its nitrogen or sulfur atom. In other cases it forms anionic complexes of the type $(M^{m+}(SCN)_n]^{(n-m)-}$ or the polymeric complexes connected by the [M-SCN-M']-type bridgings.[6] In some anionic thiocyanato complexes, the structure changes sensitively depending on the kinds of counter cations. For example, in the case of the tris(thiocyanato)cadmates, its rubidium, cesium, and tetramethylammonium salts have the respective types of network strucrtures.[7,8]

Only a few structural data of the thiocyanato complexes of lanthanoids(III) have been reported so far. The structures of the tetrabutylammonium salts of hexakis(thiocyanato)lanthanoidates(III), where the metals are praseodymium through ytterbium or yttrium, were reported: their metal atoms are ligated with six SCN nitrogen atoms being in an octahedral geometry.[9] It is very interesting that the coordination number of the metal atom is of such low value, even though the SCN ion is not a massive ligand. On the other hand, Lazarev has reported the structures of some aqua-thiocyanato mixed complexes of neodymium and europium, where four water oxygen as well as four SCN nitrogen atoms are ligated in a square-antiprism geometry.[10] In cases of the SCN complexes of uranium(IV), $[(C_2H_5)_4N]_4[U(SCN)_8]$, the central metal atom is in a cubic geometry, while in its cesium salt, the metal atom is in a square-antiprism geometry.[11,12] Referring to these data, it was thought to be interesting to study in more detail the structures of the thiocyanato complexes of lanthanoids.

Since we could obtain the crystals of the title complexes, their crystal and molecular structures were determined by the X-ray diffraction method, using their single crystals.

Experimental

Synthesis of Tetraethylammonium [Aquaheptakis(thiocyanato)praseodymate(III)]. The metal and tetraethylammonium thiocyanates were obtained by metathesis reactions between their hydrated chlorides and potassium thiocyanate in methanolic medium, as in the cases of the other metal thiocyanates.[13] As the starting metal thiocyanate, the obtained methanolic solution was used directly without drying up.

To the methanolic solution of the praseodymium thiocyanate (15 cm^3, containing 2.0 mmol of Pr), tetraethylammonium thiocyanate (1.5 g, 8.0 mmol), and 0.5 cm^3 of water were added. The mixed solution was left standing in a silica gel desiccator until the volume of the solution reduced to about 8 cm^3, and the deposited crystals were separated, washed with a little portion of methanol, and dried in air. Yield: 1.3 g (1.2 mmol, 60%). Almost by the same way, the isomorphous lanthanum and cerium salts were obtained: starting from 2.0 mmol of the lanthanum(III) or cerium(III)

thiocyanate in methanolic solution, 0.5 cm^3 of water, and tetraethylammonium thiocyanate (1.5 g, 8.0 mmol), the yield of their complexes were 1.5 g (1.4 mmol, 69%), and 1.4 g (1.3 mmol, 65%), respectively.

Their elemental analyses are shown in Table 1.

Although these complex crystals were not deposited from the severely dried medium, several tenths of a gram of water per one mmol of metal salt is sufficient to synthesize the products: the included water was hardly removed, even when they were left standing in a silica gel desiccator for several days; however, they became dehydrated after a longer time. On the other hand, the use of the solvent containing more water (the authors have tried up to 2 : 1=v/v in concentration of the methanol-water mixture) gave the same product; however, as the complexes were readily soluble in such a solvent, we had to evaporate the solvent more, and the yield as well as the purity were inferior.

Attempts to synthesize such complexes of the heavier lanthanoids were not successful: in such cases, the complexes written in the following section were always obtained.

The Synthesis of Tetraethylammonium [Aquaheptakis(thiocyanato)erbate(III)]. The starting materials, metal and tetraethylammonium thiocyanates, were obtained in the same way. To a methanolic solution of erbium(III) thiocyanate (15 cm^3, including 2.0 mmol of Er), tetraethylammonium thiocyanate (1.5 g, 8.0 mmol), and 0.5 cm^3 of water were added and dissolved. The solution was kept in a silica-gel desiccator until about 80% of the solvent was evaporated off. The deposited crystals were separated, washed with a small portion of methanol, and dried in air. Yield: 1.2 g (1.1 mmol, 54%). The neodymium and the dysprosium salts were obtained almost in the same way: started from 2.0 mmol of neodymium or dysprosium thiocyanate in methanolic solution, the yields of the complexes were 1.6 g (1.5 mmol, 74%), and 1.4 g (1.3 mmol, 63%), respectively.

Their elemental analyses are shown in Table 1.

In these cases, too, when more water was added into the solution, the yields of the products were lowered. By this synthetic process, neither lanthanum through prasedymium complexes of this type were obtained.

X-Ray Structure Analysis. The crystallographic data, the sizes of the used crystals (approximately parallelepiped in shape, and the colors are; the Pr salt, pale green, the Nd salt, pale violet; the Er salt, pale pink; the others, colorless), and various experimental conditions are listed in Tables 2A and 2B. Reflections were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer with graphite monochromated Mo $K\alpha$ radiation (λ=0.71073 Å), ω-2θ scan technique being employed (scan speed was 4° min^{-1} (θ)). The intensities were corrected for Lorentz and polarization factors, but no correction was made for the absorption and extinction.

Structure Determination. The crystal system of the La, Ce, and Pr complexes, which are isomorphous with each other, was ascertained by the facts that the respective Weisenberg photographs rotated around three unit-cell axes are the same, and that the measured intensities of the corresponding reflections are almost the same. The space group of the Nd, Dy, and Er complexes, which are isomorphous with each other, was ascertained by the regular extinction of the reflections, and the comparison of the measured intensities of the corresponding reflections of both the Weisenberg pho-

tographs rotated around the unit cell axes, as well as of the intensity data obtained by a diffractometer.

The structures of the praseodymium and the erbium salts were solved by the heavy-atom method, respectively. The positions of the metal and sulfur atoms were deduced from their three-dimensional Patterson map; other non-hydrogen atoms were located by successive Fourier syntheses. Their positional, isotropic and, then, anisotropic thermal parameters were refined by a block-diagonal least-squares method. All hydrogen atoms were excluded from the structure factor calculations. The structure analyses of the other isomorphous salts were started from their final positional and final isotropic thermal parameters of the praseodymium or the erbium complex; they were refined in the same way.

All calculations were carried out on a HITAC M-680H computer at the Computer Center of the University of Tokyo, using a local version of the UNICS progrm.[14] The atomic scattering factors were taken from Ref. 15.

In the case of the praseodymium complex, according to the request of the symmetry regulations of the space group, many positional as well as anisotropic thermal parameters were fixed or equated with each other. Other than the ruled ones, the x and z coordinates of C(11) and C(13) atoms are assumed to be equal to the x and y coordinates of the C(12) and C(14) atoms, respectively, because they take equivalent positions around the nitrogen atom from each other.

The metal atom is at the center of symmetry, 0 0 0, and the atoms of the SCN ions are restricted to be arranged on the [±1±1±1] axes. However, from the result of their elemental analyses, as well as from the charge balance aspect, each complex contains only seven SCN ions; one water atom is coordinated to the metal atom other than the SCN ions. Attempted structure analyses assuming other lower symmetry space groups did not result in much improvement, except in some cases where a slightly better R values were obtained. However, these may only have been due to increase in the number of parameters. Therefore, we have assumed the disorder of the water molecule and the thiocyanate ions: respective eight coordinating positions around the metal atom are occupied equally by 1/8 molecules of water and 7/8 ions of SCN. Excepting this comples, in $[Co(NCS)(NH_3)_5]Cl_2$[16] too, all six coordinating positions around the cobalt atom are occupied equally by a disordered SCN ion (1/6) and ammonia molecules (5/6). During the calculation, the input positional parameters of the ligating oxygen atom was fixed as if the atom was on the [111] axis, and the distance from the metal atom is the sum of the metal (coordination number is 8, valence is 3+), and an oxygen (coordination number is 2, valence is 2−) atomic radii proposed by Shannon.[17]

There are crystallographically two independent kinds of tetraethylammonium ions; their ethyl carbon atoms are also disordered. The positions of the carbon atoms around the N(11) and N(21) atoms are shown schematically in Figs. 1A and 1B, respectively. Although one possible selection of the four ethyl group position are shown in the respective figures by thick lines, there are many other possible selections keeping the tetrahedrally bonding geometry around the nitrogen atom as well as the sp^3 angles of the N-C-C bonds: we have assumed that all equivalent positions of the respective carbon atoms are equally occupied. The multiplicities of the respective atoms used in the calculation are shown in Table 3.

In the cases of the erbium and its isomorphous salts, their anionic complex ions are approximately in a cubic (though not exact cube) coordination geometry around their metal atoms, which are at the centers of symmetry, 0 0 0 and 0.5 0.5 0.5. To these complexes, too, the same type of disorder of the water molecule and of the SCN ions around each metal atom is assumed: each coordination position is occupied by 1/8 atom of the water oxygen and 7/8 atoms of the SCN nitrogen atoms. The position of the coordinated water oxygen atom was fixed as in the case of the light lanthanoid complexes. The ethyl carbon atoms around a central tetraethylammonium nitrogen atom are also disordered. Arrangements of the ethyl carbon atoms around both N(11) and N(21) atoms are in the type schematically shown in Fig. 1A, and the occupancies of the respective equivalent positions of the car-

Fig. 1. g) Multiplicities. h) The equivalent isotropic temperature factors were computed using the following expression: $B_{eq}=4/3(B_{11}a^2+B_{22}b^2+B_{33}c^2)$. The B_{ij}'s are defined by: $T=\exp[-(h^2B_{11}+k^2B_{22}+l^2B_{33}+2hkB_{12}+2hlB_{13}+2klB_{23})]$. i) $x=y=z$. j) As C(11) and C(12), and C(13) and C(14) are equivalent respectively, x and z of the formers are defined to be the same as x and y of the latters, respectively. k) O(1) was fixed at the position.

bon atoms are assumed to be equal. The multiplicities used in the calculations are shown in Table 4. Attempts to perform structure factor calculations using other lower symmetry space groups did not yield improved results.

As shown in the results, the atomic positions as well as the temperature factors of these complexes did not converged well as the usual crystals: this was probably due to the existence of much disordering of the atoms.

Infrared Absorption Spectrum Measurements. They were obtained by means of JASCO A-202 grating infrared spectrophotometer, using liquid paraffin and hexachloro-1,3-butadiene mull.

Results and Discussion

The final positional parameters, their multiplicities used in the calculation, and their isotropic equivalent temperature factors of the praseodymium and erbium complexes are shown in Tables 3 and 4; selected interatomic distances as well as bond angles of the six complexes are shown in Tables 5 and 6. The perspective drawings of the praseodymium and the erbium complexes and their numbering scheme of the atoms are shown in Figs. 2 and 4, while their crystal packing diagrams in Figs. 3 and 5, respectively.[18]

In the praseodymium complex, the metal atom (at 0 0 0) is octa-coordinated being in a cubic geometry: seven SCN nitrogen atoms, and one water oxygen atoms are ligated to the metal atom, being disordered to occupy the eight positions equally, as shown in the previous paragraph. Since the SCN ions are arranged on the [±1±1±1] axes, the angles M-N(1)-C(1) as well as N(1)-C(1)-S(1) angles are 180°.

The Pr-N(1) bond length is 2.50(2) Å, which is shorter than the sum of their Shannon's ionic radii, 2.58 Å,[17] while the Pr-O(1) bond length is fixed as 2.477 Å.[17] The interatomic distance S(1)···S(1^{v}), the edge length of the complex anion cube, is 6.00(2) Å.

N(1)-M-N(1^{i})	110.2(10)	110.4(10)	111.3(10)

Key to the symmetry operations: i, −x, −y, z; ii, −y, x, z; iv, x, y, −z. l) and m): see the footnote of Table 5.

As shown schematically in Fig. 6, the crystal lattice of this complex resembles that of rock salt. The tetraethylammonium nitrogen atoms occupy the Cl^- ionic position, the N(11) atoms are at the midpoints of the respective edges, and the N(21) atom is at the body center of the unit cell. The metal atoms occupy only the apex Na^+ ionic positions of the NaCl-type crystal lattice, and the face center positions are vacant. Therefore, each metal atom is surrounded by six N(11) atoms from both sides of the a, b, and c axis directions. No bridging was found between these anions and cations.

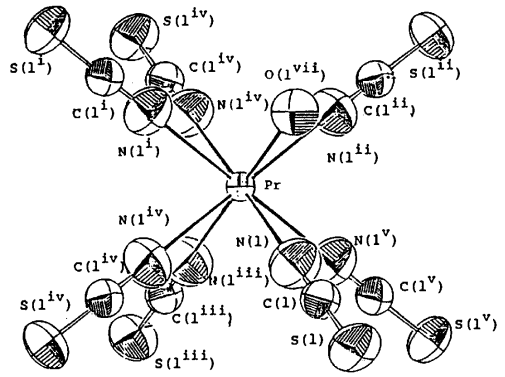

Fig. 2. A perspective drawing of the praseodymium complex around the metal atom (one of the possible arrangement). The key to the symmetry operations are: i, $-x$, $-y$, z; ii, $-x$, y, $-z$; iii, x, $-y$, $-z$; iv, $-x$, $-y$, $-z$; v, x, y, $-z$; vi, x, $-y$, z; vii, $-x$, y, z.

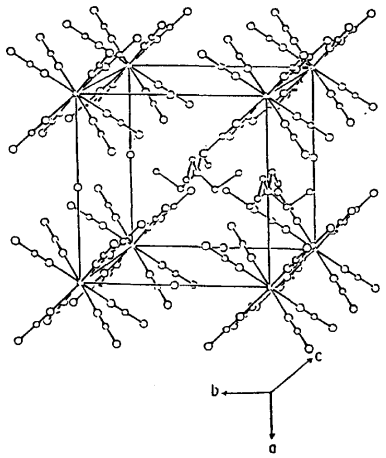

Fig. 3. Crystal packing diagram of the praseodymium complex.

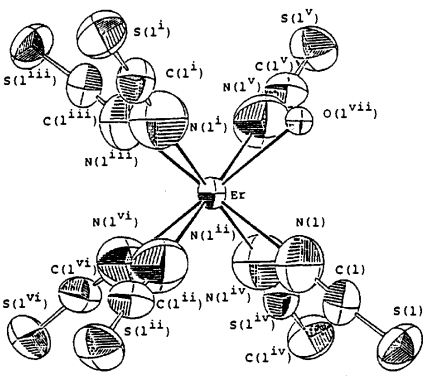

Fig. 4. A perspective drawing of the erbium complex around the metal atom (one possible arrangement). The key to the symmetry operations are: i, $-x$, $-y$, z; ii, $-y$, x, z; iii, $-x$, $-y$, $-z$; iv, x, y, $-z$; v, y, $-x$, $-z$; vi, $-y$, x, $-z$; vii, y, $-x$, z;

The structure of the isomorphous lanthanum and cerium complexes are fundamentally the same as that of the praseodymium complex. However, as the cell volume decreases, depending on the atomic number of the metal atom, the M···N(11) distance (the separation between the cation and anion) decreases in the order. The M-N(1) bond length (La-N(1), 2.60(3); Ce-N(1), 2.568(16); Pr-N(1), 2.50(2) Å) also decreases in the same order; it decreases more rapidly than the sum of their Shannon's ionic radii (La-N, 2.62; Ce-N, 2.60; Pr-N, 2.58 Å).[17]

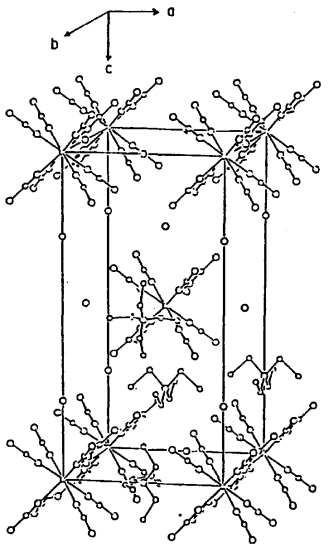

Fig. 5. Crystal packing diagram of the erbium complex.

The complex ion of the erbium salt has approximately the same structure as that of the light lanthanoid complexes. The metal atoms (at 0 0 0 and 0.5 0.5 0.5) are octa-coordinated, being approximately in a cubic geometry: seven SCN nitrogen and one water oxygen atoms are ligated to the metal atom, being disordered to occupy all eight coordinating positions equally.

The edge lengths of the complex anion cube are: S(1)···S(1^{ii}), 5.817(12); and S(1)···S(1^{iv}), 5.92(3) Å (key to the symmetry operations: ii, $-y$, x, z; iv, x, y, $-z$). The bond length of Er-N(1) is 2.36(3) Å, which is shorter than the sum of the Shannon's ionic radii, 2.46 Å.[17] The Er-O(1) distance was fixed as 2.35 Å.[17] The bond angles Er-N(1)-C(1), and N(1)-C(1)-S(1) are 177(2) and 179(2)°, respectively, which are almost 180°. The bond angles N(1)-Er-N(1^{i}) and N(1)-Er-N(1^{ii}) are 111.3(10) and 71.4(8)°, respectively (key to the symmetry operations: i, $-x$, $-y$, z; ii, $-y$, x, z).

As shown in Fig. 6, the crystal lattice of the erbium complex is a modified form of the praseodymium complex lattice. Its unit cell apparently consists of two latter cubic cells piled along the c-axis direction, and the positions of the metal and ammonium nitrogen atoms on the contact plane of the original two cells are shifted as shown in the following. The relative arrangement of the metal and the tetraethylammonium nitrogen atoms on the plane **1** and **2** (see Fig. 6) of the erbium complex, which are parallel to the ab-plane and intersect the c-axis at 0.0 and 0.5, is the same, but all of their positions on plane **2** are shifted

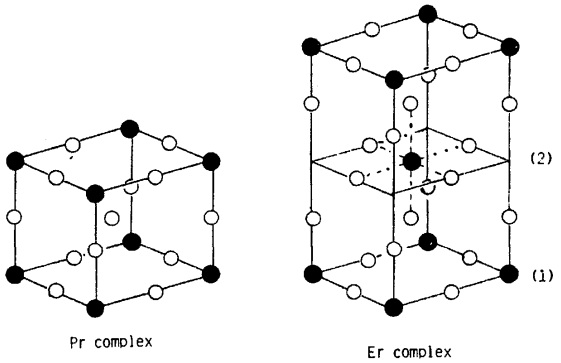

Fig. 6. Schematic presentation of the metal and tetraethylammonium nitrogen atomic positions in the crystal lattices of the praseodymium and erbium complexes. ●: metal atoms, ○: tetraethylammonium nitrogen atoms.

by 0.5 along both the a- and b-axis directins from the respective positions on plane 1. The **1** and **2** type planes appear alternately along the c-axis. On the other hand, in the erbium complex, the N(11) atoms at the midpoint of the c-edge as well as the body-centered N(21) atoms of the praseodymium complex are apparently kept at their positions: they are on the planes parallel to the ab-plane intersecting the c-axis at about 0.25 and 0.75, respectively.

As a result, as shown in Fig. 6, in the erbium complex, too, the metal atom is surrounded by six tetraethylammonium nitrogen atoms in about equidistances on both sides along a-, b-, and c-axis directions: Er···N(11), 5.782(1); Er···N(21), 5.828(17) Å.

The neodymium and dysprosium complexes have essentially the same type of structure. The M-N(1) bond lengths (Nd-N(1), 2.49(3); Dy-N(1), 2.40(3); and Er-N(1), 2.36(3) Å) are shorter than the respective sums of the Shannon's ionic radii (Nd-N, 2.57; Dy-N, 2.49; Er-N, 2.46 Å), and the differences are larger than the values found in the series of the light lanthanoid complexes. Therefore, it is likely that, through the both series of these complexes, the M-N(SCN) bonds have the more covalent-bonding character in the higher metal-atomic-number complexes.

The infrared absorption spectra of these complexes were examined. Not only the general feature, but also the maximum wavenumbers of the respective peaks of the title six complexes were not much different from each other. Therefore, the respective average wavenumbers of the peak maxima will be discussed.

Although some of them partially overlapped with the bands due to the tetraethylammomium ion, the typical bands due to the SCN ion were observed: ν(CN), 2050(s); ν(CS), 735(sh); and δ(NCS), 475(m) cm^{-1}, respectively (here, s, strong; sh, shoulder; m, medium). These values are all in a reasonable region for the bands of the N-bonded SCN ions.[19] The ν(OH) band of the coordinated water was found at about 3370 cm^{-1} in the spectra of all of these complexes, although it is broad and weak. The maximum wavenumbers of the tetraethylammonium ion peaks, 1490, 1440, 1393, 1170, 1050, 998, 780, and 720 cm^{-1}, were not much different from those of tetraethylammonium chloride.

The authors wish to thank the Shin-Etsu Chemical Ind. Co. Ltd., for presenting us with the highly pure lanthanoid oxides.

The process of the thermal decomposition of various tin(IV) *cyclo*-phosphates, $SnP_4O_{12}\cdot 4H_2O(P_{4m})$, $Sn_3(P_6O_{18})_2\cdot 12H_2O$ (P_{6m}), and $Sn_2P_8O_{24}\cdot 5H_2O(P_{8m})$, was investigated using X-ray analysis, DTA-TG, and HPLC-FIA. P_{4m} lost the water of crystallization at about 105 °C. In the region of 400—500 °C, P_{4m} changed to *cyclo*-triphosphate (P_{3m}) without any other species of phosphates. Therefore, the change of P_{4m} to P_{3m} probably proceeded as a radical reaction. At temperatures above 580 °C, P_{3m} changed to insoluble polyphosphates ($P_{high\ poly}$). P_{6m} lost the water of crystallization at about 110 °C. In the region of 500—570 °C, P_{6m} changed to $P_{high\ poly}$ through P_{3m}. P_{8m} lost the water of crystallization at about 140 °C. At about 255 °C, P_{8m} decomposed to oligo phosphates($n<8$)(P_{oligo}), soluble polyphosphates($15<n<20$)(P_{poly}), and amorphous insoluble polyphosphates ($P^*_{high\ poly}$). Under a higher water vapor pressure, these decomposition and subsequent condensation reactions proceeded rather faster than in a lower one. At about 300 °C, $P^*_{high\ poly}$ changed to P_{3m} again. At higher temperatures, P_{3m} changed to $P_{high\ poly}$.

It is well-known that, upon heating, phosphates hydrolyze or condense to form various kind of phosphates.[1-13] These reactions are affected by the kind of metal, the atmosphere, the temperature, the time and rate of heating, etc., thus resulting in the formation of different phosphates. In a previous paper,[14] we reported the effect of water vapor on the thermal decomposition of lead *cyclo*-tetraphosphate. As regards the thermal decomposition of tin(IV) *cyclo*-phosphates, though, little work has been reported. Therefore, in this paper, we wish to present the experimental results of the atmospheric dependence of the thermal decomposition of tin(IV) *cyclo*-phosphates and also discuss the mechanisms of their thermal decomposition. The process of the thermal decomposition of *cyclo*-phosphates was investigated by means of X-ray analysis, thermal analysis (DTA-TG), and high performance liquid chromatography-flow injection analysis (HPLC-FIA).

Experimental

Chemicals. The tin(IV) *cyclo*-phosphates—$SnP_4O_{12}\cdot 4H_2O$ (P_{4m}), $Sn_3(P_6O_{18})_2\cdot 12H_2O(P_{6m})$, and $Sn_2P_8O_{24}\cdot 5H_2O$ (P_{8m})— were prepared by methods similar to those described in the literature.[5,14-16] Tin(IV) *cyclo*-triphosphate(P_{3m}) could not be obtained by the above method. Unless otherwise stated, guaranteed reagents were used without further purification. The analytical procedures and apparatus were essentially the same as those used in the previous paper.[14]

Results and Discussion

Thermal Decomposition of $SnP_4O_{12}\cdot 4H_2O$ (P_{4m}). Figure 1 shows the DTA-TG curves of P_{4m} at atmospheric pressure. Three endothermic peaks at about 70 and 105 (with a weight loss), and at 580 °C, and an exothermic peak at about 630 °C were observed. To clarify these thermal changes at each temperature, X-ray measurements of the products on heating were performed. Figure 2 shows the X-ray diffraction patterns of products heated at various temperatures in an electric furnace for 30 min. In the 300—450 °C region, no change in the X-ray diffraction patterns was observed. In the 495—510 °C region, though, some new peaks began to appear. In the 610—660 °C region, other new peaks began to appear, gradually increasing with the heating temperature. From the X-ray diffraction pat-

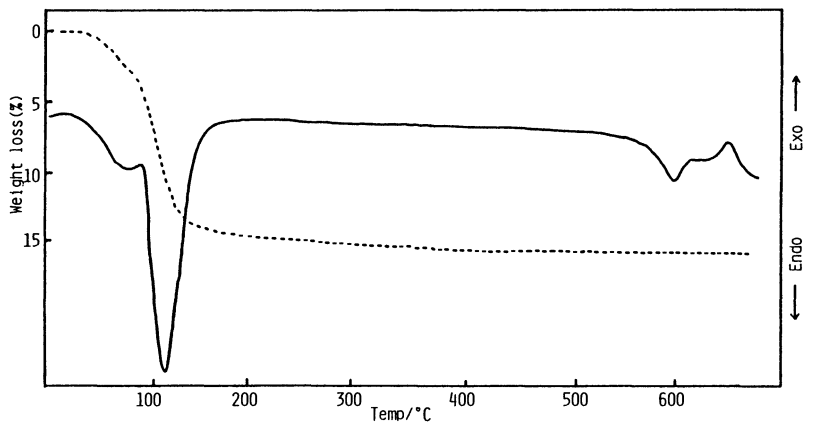

Fig. 1. DTA-TG curves of $SnP_{4m}\cdot 4H_2O$. Solid line: DTA, dotted line: TG.

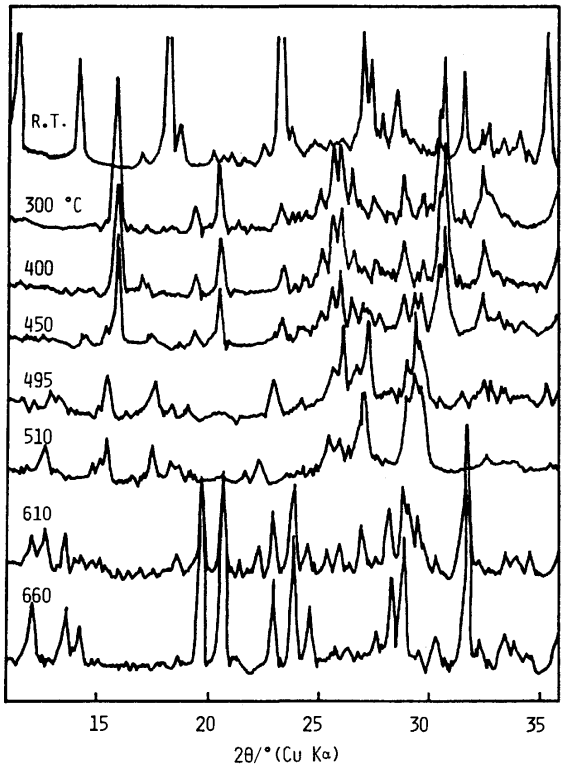

Fig. 2. X-Ray diffraction patterns of products on heating. Sample: $SnP_{4m}\cdot 4H_2O$.

terns and HPLC, it seems that P_{4m} dehydrated to form an anhydride at about 105 °C and that it thereafter remained unchanged up to 450 °C. At temperatures above 500 °C, P_{4m} began to decompose and changed to P_{3m} and/or $P_{high\ poly}$. Although the DTA-TG curves do not have a definite peak in Fig. 1, P_{4m} gradually decomposed above 500 °C. Therefore, the influence of water vapor upon thermal decomposition was investigated at 400 and 450 °C. Table 1 shows the changes in the amounts of phosphates in the samples heated at each temperature. At 400 °C in a dry air atmosphere (r.h.=0%), 35% of the starting material has already changed to P_{3m}, while in the 15—90% range of relative humidity (at 25 °C), about 12—15% of the starting material changed to P_{3m}. At 450 °C in a dry air atmosphere (r.h.=0%), most of the P_{4m} changed to P_{3m}, while in r.h.=15—90, 30—36% of that remained unchanged. From the X-ray diffraction pattern and the HPLC of the product heated at 610 °C, the endothermic peak at 580 °C shows the phase transition of P_{3m} to $P_{high\ poly}$, while the exothermic peak at 630 °C shows the crystallization of $P_{high\ poly}$. When P_{4m} changed to P_{3m}, no other species of phosphates except P_{4m} and P_{3m} were observed, indicating that its rearrangement probably proceeded radically.[17] For a reason similar to that noted above and from the fact that no weight change was observed in the TG curve (Fig. 1), the change of P_{3m} to $P_{high\ poly}$ probably proceeded radically.

Table 1. Changes in the Amounts of Phosphates (Starting Material: P_{4m})

	90	0	36.4	63.6	0	0

Thermal Decomposition of $Sn_3(P_6O_{18})_2\cdot 12H_2O$ (P_{6m}). Figure 3 shows the DTA-TG curves of P_{6m} at atmospheric pressure. Five endothermic peaks, at about 60 and 110 (with a weight loss), and at 550, 570, and 610 °C, were observed. From the results of HPLC, P_{6m} remained unchanged up to the 500 °C region, while in the region near 560 °C it completely decomposed to a mixture of P_{oligo}, P_{3m}, and $P_{high\ poly}$. Figure 4 shows the X-ray diffraction patterns of products heated at various temperatures in an electric furnace for 30 min. In the 210—500 °C region, only the peaks for anhydride were observed. In 570 °C, the diffraction pattern changed to another pattern, that of $P_{high\ poly}$. The higher the temperature, the more intense the peaks became. Table 2 shows the changes in the amounts of phosphates in the samples heated at 500 and 570 °C. At 500 °C, the temperature before the endothermic peak in Fig. 3, we expected a remarkable effect of the water vapor upon the decomposition of

	90	5.6	0	30.3	1.9	62.2

P_{6m}. In a dry air atmosphere (r.h.=0%), the amounts of P_{6m} decreased and P_{3m} was formed in about a 15% yield. In a 15—90% relative humidity atmosphere (at 25 °C), P_{3m} was formed in about a 10% yield. The ratio of the amounts of P_{3m} to P_{6m} decreased with the increase in the humidity. At 570 °C, the P_{6m} completely disappeared throughout the humidity region and considerable amounts of P_{3m} and $P_{high\ poly}$ were produced along with some soluble linear phosphates (P_{oligo} and P_{poly}). The amount of $P_{high\ poly}$ in r.h.=15—90% was larger than that in r.h.=0%, while that of P_{3m} had an opposite tendency. It seems from the above results that P_{3m} begins to decompose and changes to $P_{high\ poly}$ at 550—570 °C, while P_{3m} completely decomposes at 610 °C near an endothermic peak and $P_{high\ poly}$ forms in a large quantity. When P_{6m} changed to $P_{high\ poly}$ through P_{3m}, scarcely no other species of phosphates were found in these reaction processes (maximum of P_{oligo}=10%). Consequently, these rearrangements probably proceed in the same manner as is the case with the P_{3m} system.

Thermal Decomposition of $Sn_2P_8O_{24} \cdot 5H_2O$ (P_{8m}). Figure 5 shows the DTA-TG curves of P_{8m} at atmospheric pressure. Four endothermic peaks — at about 65, 140, 270, and 635 °C — were observed. A large exothermic peak was shown at 320 °C. The endothermic peaks with a weight loss at 65 and 140 °C are attributable to the dehydration of the water of crystallization. From the results of the X-ray analysis and the HPLC of products heated at various temperatures, it seems that P_{8m} existed in anhydride at 180 °C and decomposed to P_{oligo} and $P^*_{high\ poly}$ in the 250—300 °C region, except for the changing of P_{8m}, in part, to P_{3m}. At higher temperatures, P_{3m} decomposed and then condensed $P_{high\ poly}$. Table 3 shows the changes in the amounts of phosphates in the samples heated at sev-

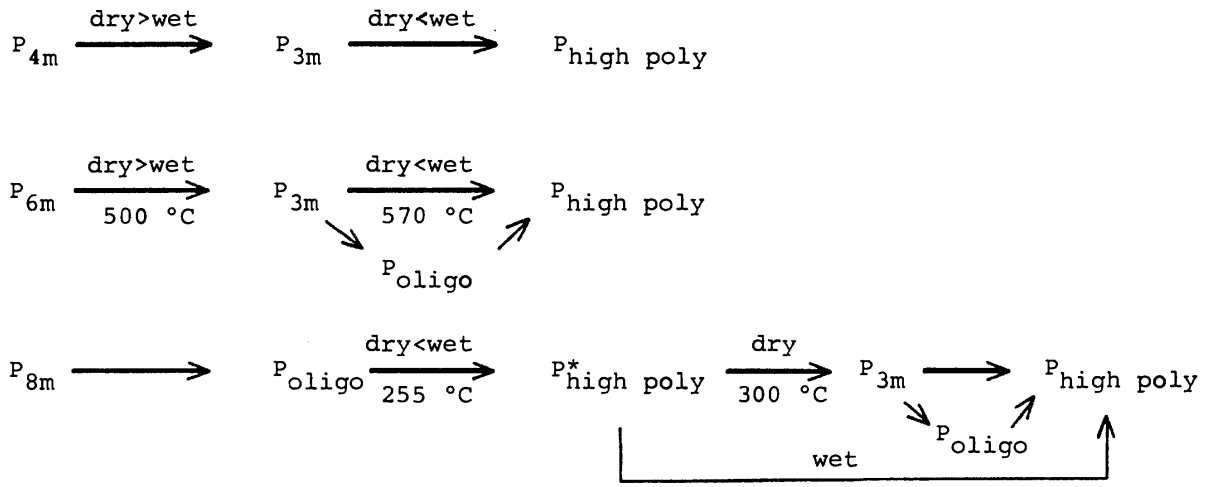

Scheme 1.

eral temperatures. At 255 °C in a dry air atmosphere (r.h.=0%), about 80% of the P_{8m} has already changed to P_{oligo}, P_{poly}, and $P^*_{high\ poly}$ in about equal quantities, while in a relative humidity of 15—90% (at 25 °C) the P_{8m} disappeared completely, while $P^*_{high\ poly}$ was formed in a large quantity. Further, at 300 °C in a dry air atmosphere (r.h.=0%), P_{3m} formed again in about a 85% yield with the decrease in P_{oligo}, P_{poly} and $P^*_{high\ poly}$, while in a relative humidity of 15—90% (at 25 °C), no remarkable change was observed in the amounts of phosphates as compared with the results at 255 °C. In the humid atmosphere, there might be a path of $P^*_{high\ poly}$ to $P_{high\ poly}$ without going through P_{3m}.

Based upon the results described above, the process of the thermal decomposition of tin(IV) *cyclo*-phosphates under several humid atmospheres may be summarized schematically as in Scheme 1. In a previous paper,[17] Takenaka et al. reported that, in a humid atmosphere, the radicals formed from P_{4m} may be considered to combine with water molecules in the atmosphere, so the water molecules could be expected to inhibit the radical polymerization. In this work, when P_{4m} decomposed in a humid atmosphere, the amount of the P_{3m} was small compared with that in a dried atmosphere. Consequently, P_{3m} is produced by the recyclization of the radicals which result from the cleavage of P_{4m}. Therefore, the mechanisms of P_{4m} to $P_{high\ poly}$ through P_{3m} may be considered to be as follows:

(1) $P_{4m} \xrightarrow[\text{lower temp}]{\text{decompn.}} \cdot\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\cdots\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O}\cdot$

(Formation of radical)

(2) $3\ \cdot\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\cdots\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O}\cdot \longrightarrow 4P_{3m}$

(Recyclization)

(3) $\cdot\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\cdots\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O}\cdot + \text{H-O:H} \longrightarrow \text{H-O:}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\cdots\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O:H}$

(Stop of radical reaction)

(4) $P_{3m} \longrightarrow \cdot\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\text{O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O}\cdot \xrightarrow{\text{radical polymn.}} P_{high\ poly}$

(5) $\text{H-O:}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\text{O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O:H} \xrightarrow[\text{higher temp.}]{\text{dehydration condensation, } -H_2O} \longrightarrow (\text{H-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-}\cdots\cdots\text{O-}\overset{\overset{\|}{O}}{\underset{|}{P}}\text{-O-H})_{high\ poly}$

Since no P_{oligo} was detected, and since the TG curve indicated no weight change, at a lower temperature, it seems that the thermal reaction of P_{4m} to P_{3m} proceeds mainly according to Processes (1) and (2), while at a higher temperature the thermal polymerization of P_{3m} to $P_{high\ poly}$ proceeds mainly by Process (4), not Process(5). In the case of P_{6m}, the thermal reactions probably proceed by similar mechanisms except for the formation of a small amount of P_{oligo}.

On the other hand, P_{8m} decomposes at a rather low temperature (at about 250 °C) compared with the other two *cyclo*-phosphates. Consequently, it can be said that the water vapor very much influenced the thermal reaction and that P_{oligo} is formed by Process (3), followed by the change to $P^*_{high\ poly}$ by means of the dehydration-condensation reaction (Process (5)). $P^*_{high\ poly}$ in a dry air atmosphere (r.h.=0%) changed radically to $P_{high\ poly}$ through P_{3m} by means of Process (4), while in a humid atmosphere it probably crystallizes or changes to $P_{high\ poly}$ by means of the dehydration-condensation reaction (Process (5)).

The Crystal Structures of Δ-, Λ-, and Pseudoracemic Forms of Bis(ethylenediamine)oxalatocobalt(III) Aspartates

Hideko KIRIYAMA*,† and Michihito IGAKI
Department of Chemistry, Faculty of Science, Kobe University, Nada, Kobe 657
(Received March 7, 1988)

The crystal structures of Δ-[Co(ox)(en)$_2$](L-Hasp)·3H$_2$O, Λ-[Co(ox)(en)$_2$](L-Hasp)·3H$_2$O and *rac*-[Co(ox)(en)$_2$](L-Hasp) have been determined by means of X-ray diffraction. The absolute configurations of (−)-and (+)-cations were assigned as Δ($\delta\lambda$) and Λ($\delta\lambda$), respectively, on the basis of that of L-Hasp$^-$ ion. The counter ion is extended with C-C-C-C near 180° in all cases, but the other torsion angles are somewhat affected by surroundings. Both α and β carboxyl groups of the anion are ionized, therefore its NH$_2$ group is protonated. In the three compounds, the cations and the anions are alternately arranged, forming a layer through N-H···O hydrogen bonds in a very similar way to each other. The lattice of the more soluble Δ-isomer consists of such single cation-anion layers, between which water molecules are inserted. In the less soluble Λ-diastereoisomer the cation-anion layers are doubled by N-H···O bonds between cations from neighboring layers. The less soluble racemic salt is anhydride where the similar cation-anion layers are connected by hydrogen bonds between cations and between anions alternately. In connection to optical resolution, the difference in solubility was discussed in terms of the density, unoccupied fraction and electrostatic energy.

An useful method to isolate one of the enantiomers for a racemic mixture is to add a suitable chiral reagent. When a cationic racemate is precipitated with an optically active anion, two different diastereoisomeric salts may result and sometimes their solubility difference allows both of them to be isolated. In view of this, Kuramoto et al. have developed structural studies of optical resolution on various pairs of diastereoisomeric salts.[1,2] Gajhede and Larsen have recently related the crystal structure to solubility for the diastereoisomeric salts which are obtained from bis(ethylenediamine)glycinatocobalt(III) and bis-μ-[(*R*,*R*)-tartrato(4−)]-diantimonate(III).[3] On the other hand, an application of L-amino acid anion as a resolving agent for some metal complexes was examined on the systems of (−)$_{589}$- and (+)$_{589}$-[Co(ox)(en)$_2$]X with X=L-hydrogenglutamate (L-Hglu$^-$) and L-hydrogenaspartate (L-Hasp$^-$) by Yamanari et al.[4] They determined these solubility phase diagrams and confirmed that the former anion L-Hglu$^-$ is an excellent resolving agent, while the latter anion L-Hasp$^-$ forms the pseudoracemate, *rac*-[Co(ox)(en)$_2$](L-Hasp). We have succeeded in preparing (−)$_{589}$-, (+)$_{589}$-, and *rac*-[Co(ox)(en)$_2$](L-Hasp) and also (−)$_{589}$- and (+)$_{589}$-[Co(ox)(en)$_2$](L-Hglu) salts as suitable single crystals for X-ray analysis. In the hydrogenaspartate system, [Co(ox)(en)$_2$](L-Hasp)·*n*H$_2$O, the (−)$_{589}$ diastereoisomer (*n*=3) **1** is more soluble than the (+)$_{589}$ isomer (*n*=3) **2** and the rac-complex (*n*=0) **3**; for example the values of solubility as expressed by grams of anhydrous salt in 100 g water are 71.0, 12.4, and 11.9 at 20 °C and 127, 44.8, and 18.8 at 60 °C for **1**, **2**, and **3**, respectively. On the other hand, in the hydrogenglutamate system [Co(ox)(en)$_2$](L-Hglu)·*n*H$_2$O the (−)$_{589}$ diastereoisomer (*n*=2) **4** is more soluble than the (+)$_{589}$ isomer (*n*=5) **5**. In order to understand such an appreciable difference in solubility the crystal structures of these five complexes have been determined by X-ray diffraction methods. The absolute configuration of the common cation [Co(ox)(en)$_2$]$^+$ was determined by reference to that of the L-amino acid anion. The present paper is concerned with the results of the hydrogenaspartates and the next with the hydrogenglutamate ones.

† Present address: Imajuku 1-12, Ogaki, Gifu 503.

Experimental

Preparation. The three aspartates were prepared by the methods described in the previous paper and recrystallized from water.[4] The density was measured by pycnometry with kerosine or floatation with kerosine-bromoform mixture. The number of water of crystallization was estimated by thermogravimetry and precisely determined from X-ray structure analysis. The prepared samples were identified by elemental analysis, thermal analysis, absorption and circular dichroism spectra.[4]

X-Ray Structure Determination. The lattice parameters and the space groups were determined preliminary with Weissenberg and precession cameras and confirmed by single crystal diffractometers. Intensity data were collected on Rigaku AFC-4 (Mo*Kα*, 30 kV, 200 mA) for **1** and **3** and on Rigaku AFC-5 (Mo*Kα*, 50 kV, 150 mA) for **2**. Graphite monochromated Mo*Kα* radiation (λ=0.71069 Å) and the ω-2θ scan technique (at 4° min^{-1} in ω) were used throughout the experiment. Intensities were corrected for Lorentz-polarization and absorption effects; empirical absorption correction factors on *F* were 0.993—1.013 about [c] axis for **1**, 1.009—1.034 about [b] for **2** and 1.020—1.131 about [c] for **3**.[5] Other experimental conditions and refinement details are listed in Table 1.

Every structure was solved by a direct method based on MULTAN78[6] and refined by block-diagonal least-squares on F. Most of O, N and C atoms were located by Fourier syntheses and their remaining atoms and most H atoms were found in difference Fourier maps. Anisotropic thermal parameters were applied to all non-hydrogen atoms in **1** and **2**, while they were only to Co atoms in **3** because of its poor intensity data. In the final refinements all H atoms were included at fixed positions (calculated from C-H=1.10,

Neutral atomic scattering factors and anomalous dispersion terms were taken from International Tables for X-ray Crystallography.[7] The programs MULTAN78, ORTEPII and UNICS-OSAKA were used for calculations at the Information Processing Center of Kobe University.[6,8,9] The final atomic parameters are listed in Tables 2—4.[10]

Crystal Data. Crystal data are as follows:

(**1**) $[Co(C_2O_4)(C_2H_8N_2)_2]^+$ $(C_4H_6NO_4)^-\cdot 3H_2O$, M_r=453.3, triclinic, $P\bar{1}$, a=8.968(3), b=9.953(4), c=6.084(2) Å, α=103.49 (3), β=79.17(3), γ=117.43(3)°, V=466.7(3) Å^3, Z=1, D_m=1.58 (2), D_x=1.61 g cm^{-3}, $F(000)$=238, T=298 K, μ(Mo $K\alpha$)=10.05 cm^{-1}.

(**2**) $[Co(C_2O_4)(C_2H_8N_2)_2]^+(C_4H_6NO_4)^-\cdot 3H_2O$, M_r=453.3, monoclinic, $P2_1$, a=14.319(4), b=6.1043(7), c=10.771(2) Å, β=96.96(3)°, V=934.5(3) Å^3, Z=2, D_m=1.61(2), D_x=1.61 g cm^{-3}, $F(000)$=476, T=298 K, μ(Mo $K\alpha$)=10.24 cm^{-1}.

(**3**) $[Co(C_2O_4)(C_2H_8N_2)_2]^+$ $(C_4H_6NO_4)^-$, M_r=399.2, triclinic, $P\bar{1}$, a=10.363(3), b=12.964(4), c=6.091(1) Å, α=102.78 (2), β=86.47(3), γ=104.59(3)°, V=772.4(3) Å^3, Z=2, D_m=1.73 (2), D_x=1.72 g cm^{-3}, $F(000)$=416, T=298 K, μ(Mo $K\alpha$)= 12.22 cm^{-1}.

Results and Discussion

Cation and Anion Geometries. The perspective drawings of the $(-)_{589}$- complex cation and the counter anion are given in Fig. 1 with the atomic numbering scheme. The absolute configurations of the $(-)_{589}$-$[Co(ox)(en)_2]^+$ and the $(+)_{589}$-$[Co(ox)(en)_2]^+$ cations were identified to be $\Delta(\delta\lambda)$ and $\Lambda(\delta\lambda)$, respectively, on the basis of L-aspartate ion as an internal reference. These configurations are consistent with the assignments made by analyses of the circular dichroism spec-

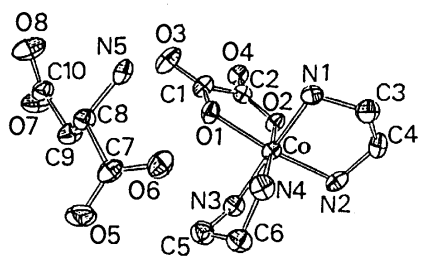

Fig. 1. Absolute configurations of (−)$_{589}$-[Co(ox)(en)$_2$]$^+$ cation and L-Hasp$^-$ anion.

tra of the complexes.[4] The assignments also agree with those in the compounds with various counter ions such as Br$^-$,[11] (+)$_{589}$-[Co(CN)$_2$(mal)(NH$_3$)$_2$]$^-$,[12] and H-*d*-tart$^-$.[1,2] It was therefore confirmed that the *lel-ob* conformation is the most stable form among the possible three, *lel-lel*, *lel-ob*, *ob-ob*, for the two ethylenediamine ligands. Selected bond lengths and angles within the ions are listed in Table 5. The corresponding values for the four complex cations are in fair agreement with each other, as well as with those found in the literature.[2,11]

The bond lengths and angles in the L-aspartate ion are consistent with the values reported for the free acid and its metal complexes.[13-15] In the present cases, the L-Hasp$^-$ ion is not coordinated to the Co(III) atom, but acts as a counter anion to the complex cation

a) $B_{eq}=(4/3)\sum_i\sum_j\beta_{ij}\boldsymbol{a}_i\cdot\boldsymbol{a}_j$. b) Atom was not refined.

[Co(ox)(en)$_2$]$^+$. The anion is therefore extended with the carbon atom skeleton, C(7)-C(8)-C(9)-C(10), in almost planar, zigzag conformation. The molecule in the crystalline state of free L-aspartic acid (LASP) is in the zwitterionic form and the ionized α-carboxyl group and the un-ionized β-carboxyl group are clearly distinguished; the C-O distances in the ionized COO$^-$ group are 1.242 and 1.252 Å, whereas in the un-ionized COOH group they are 1.202 and 1.306 Å.[14] A comparison with these values indicates that both α and β car-

boxyl groups are ionized and consequently the amino groups are protonated in crystals of **1**, **2**, and **3**. The torsion angles of the L-Hasp$^-$ ions are compared in Table 6, where the corresponding values for LASP and DL-aspartic acid (DLASP) are also included.[14,15] The angles other than the carbon skeleton described above are more or less different from each other, possibly owing to the packing effect, especially to the hydrogen bonding scheme. The variation in torsion angle among the aspartates **1**, **2**, and **3** is considerably less than that between the two glutamates **4** and **5**, which are described in the next paper.

Crystal Structures. The crystal structures of the three aspartates are shown in Figs. 2—4. The distances and angles for intermolecular hydrogen bonds are given in Table 7.

***Δ*-(−)[Co(ox)(en)$_2$](L-Hasp)·3H$_2$O (1):** In the most soluble aspartate, (−)[Co(ox)(en)$_2$]$^+$ cations and L-Hasp$^-$ anions are arranged alternately to form a layer parallel to (100) and water molecules are sandwiched between these layers (Fig. 2). Each complex cation donates its eight NH hydrogen atoms to eight oxygen atoms of one cation, four anions and two water molecules, forming eight N-H···O hydrogen bonds with distances ranging from 2.79 to 3.27 Å (av 2.96 Å). The ammonio group -NH$_3^+$ of the anion is hydrogen bonded to three oxygen atoms from two cations and one water molecule with a mean N-H···O distance of 2.99 Å, while three kinds of water molecules form six O-H···O hydrogen bonds (av 2.86 Å) with six oxygen atoms of two cation, three anions and one water molecule. Thus, the two types of hydrogen bonds, N-H···O and O-H···O, contribute to stabilize the crystal lattice, in addition to electrostatic interaction.

Recently, Miyoshi et al. have proposed an instructive mechanism of chiral recognition of octahedral metal complexes such as $[Co(en)_3]^{3+}$ and the related cations by bis-μ-(*d*-tartrato)-diantimonate(III) anion in solution.[16] It is pointed out in their association model that two amine protons of the octahedral cation are doubly hydrogen bonded to two oxygen atoms of the chiral $[Sb_2(d\text{-tart})_2]^{3-}$ ion along the C_3 or C_2 axis of the octahedron. In the present case three pairs of double hydrogen bonding are recognized between a given cation and the three surrounding anions; these are a pair of N(2)-H(3)···O(7^{iii}) and N(4)-H(8)···O(8^{iii}), a pair of N(3)-H(5)···O(6^{v}) and N(5^{v})-H(10^{v})···O(3) and a pair of N(4)-H(7)···O(6) and N(5)-H(9)···O(1), as can be seen in Table 7.

Δ-(+)[Co(ox)(en)$_2$](L-Hasp)·3H$_2$O (2): The less soluble aspartate has a crystal symmetry of $P2_1$ in contrast to $P1$ for compound 1. Owing to the presence of twofold screw axes 2_1, the complex cations and the counter anions are packed into double layers parallel to (100), between which layers water molecules are inserted as shown in Fig. 3. Four NH_2 groups of each cation form eight N-H···O hydrogen bonds (av 2.95 Å) with eight oxygen atoms from two cations, four anions and one water molecule. The NH_3 group of an anion participates in only two N-H···O hydrogen bonds with two oxygen atoms of two cations (av 3.00 Å), and the remaining NH hydrogen atom is free. Three kinds

of water molecules donate their six hydrdogen atoms to six oxygen atoms from three anions and three water molecules, forming O-H···O bonds with the average distance 2.74 Å.

In the complex **2**, three pairs of double N-H···O hydrogen bonds are also found between the cation and three surrounding anions in the same scheme as in **1**. Therefore, the formation of such double hydrogen bonds may not contribute to chiral discrimination. In both diastereoisomers, the chiral $[Co(ox)(en)_2]^+$ cations and L-Hasp$^-$ anions are alternately arranged into layers through N-H···O hydrogen bonds. Additionally, in the complex **2**, two cations which are related by the twofold screw axis are hydrogen bonded, giving rise to the double layered structure against the single layer in **1**.

***rac*-[Co(ox)(en)$_2$](L-Hasp) (3):** The least soluble pseudoracemate **3** is anhydride, different from the optically active diastereomers **1** and **2**. The unit cell contains the *Δ*-complex cation centered at Co(A) and the *Λ*-cation centered at Co(B) in the molar ratio 1 : 1, as shown in Fig. 4. Each complex cation is surrounded by six counter anions and vice versa, suggesting dominant electrostatic interaction. The cation labeled 'A' (or 'B') forms eight N-H···O hydrogen bonds with seven oxygen atoms of two cations, A and B, and of four anions A (or B); the average distance is 2.90 Å for cation A (or 2.95 Å for B). Anion A (or B) also acts as hydrogen donor to two oxygen atoms of one cation A (or B) and one anion B (or A) with an average N-H···O distance of 2.89 (or 2.88) Å.

In the pseudoracemate **3**, two pairs of double hydrogen bonds are also formed between either cation and the neighboring L-Hasp$^-$ ions; one pair is N(2A)-H(4A)···O(8A) and N(4A)-H(8A)···O(7A) and the other is N(4A)-H(7A)···O(6A^{ii}) and N(5A^{ii})-H(9A^{ii})···O(1A) for *Δ*-cation. As compared in Table 7, these schemes which are found in *Λ*-cation as well, are identical to two of three found in **1** and **2**. Two types of layers, one of which consists of *Δ*-cations and L-Hasp$^-$ ions and the other of *Λ*-cations and L-Hasp$^-$ ions, are stacked parallel to (010) plane. Thus formed layers are connected by hydrogen bonds between two different types of cations and between two anions alternately. Such anion-anion approach via N-H···O hydrogen bonds is recognized only in **3**. Besides these, no existence of water molecules provides the most dense packing for the least soluble **3**, as discussed later.

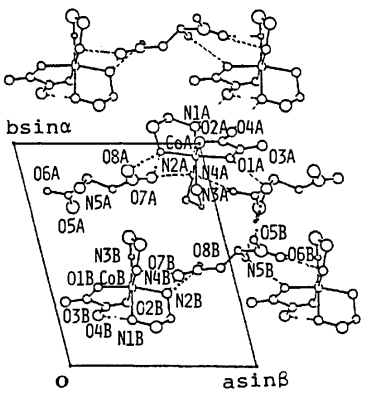

Fig. 4. Crystal structure of pseudoracemic salt **3** projected along [001]. Broken lines denote hydrogen bonds. Thermal ellipsoids are shown at 50% probability level.

Solubility and Crystal Structure. According to Yamanari et al. the *Δ*-salt is much more soluble in water than the other two aspartates.[4] Such difference in solubility must be caused by the difference in packing scheme, because the three complexes are composed of the same cations and the same anions. Moreover, the numbers of water molecule of crystallization are equally three for the two diastereoisomers. The present X-ray study revealed that the three salts possess a common structural principle such that $[Co(ox)(en)_2]^+$ cations and L-Hasp$^-$ anions form a layer by N-H···O hydrogen bonding in a very similar way to each other. The crystal lattice of *Δ*-isomer consists of such single cation-anion layers, while those of *Λ* and pseudoracemic salts contain doubled and multipled cation-anion layers, respectively. It was supposed that the difference in arrangement of ionic species and water molecules is responsible for the differences in density and solubility. However, the X-ray (or measured) densities are 1.61 (or 1.58), 1.61 (or 1.61), and 1.72 (or 1.73) for **1**, **2**, and **3**, respectively, indicating the increasing density is not necessarily correlated to the decreasing sulubility.

Another scale such as unoccupied (cavity) fraction CV/V where CV is the unoccupied space by atoms and V the unit cell volume was introduced to compare the extent of molecular packing. The calculation with van der Waals radii for peripheral atoms of ions or water molecules gave the values 31.3, 30.3, and 28.7% for **1**, **2**, and **3**, respectively.[17] Although the order of magnitude of CV/V is compatible with that of solubility, this measure is still not sufficient to account for the solubility difference relatively. If the solubility is governed by molecular packing, the solubility difference between the pseudoracemic and *Λ* compounds would be greater than the observation.[4]

In general, solubility is explicitly related to the change in the free energy upon solution. For the present diastereoisomers, fortunately, their entropy changes and hydration enthalpies would be equal and then the solubility difference would be attributed to the difference in enthalpy change. Such consideration lead us to estimate the electrostatic term of the lattice energy in accordance with the lattice sum method.[18] The lattice sum was carried out over 125 (5×5×5 along ***a***, ***b***, ***c*** axes) unit cells around a given unit cell. The calculation was based on the electroneutrality principle and distributions of the charges of the cation, anion and water molecule on their peripheral atoms.[19] The charge distributions for both ions were assigned from the elec-

tronegativity difference between bonding atoms as follows:[20] For the cation Co, −1.06; N, 0.23; H(N), 0.17; C(en), 0.05; H(C), 0.05; O(Co), 0.60; C(ox), 1.39; O(C), −1.20 and for the anion N, 0.35; H(N), 0.17; C(O), 1.39; O, −1.20; C(CH), 0.10; C(CH$_2$), −0.09; H(C), 0.05. On the other hand, the "ST 2" model proposed by Stillinger and Rahman was adopted for the formal charges on a water molecule.[21] Such a typical set of charge distribution yielded electrostatic energies of −1214, −1476, and −1246 kJ mol^{-1} for **1**, **2**, and **3**, respectively. This order of magnitude was unchanged even for the electronic structure with the extreme ionic bonds. It was therefore ascertained that the less soluble isomer is characterized by the electrostatic energy higher than that of the more soluble *Δ* isomer.

In conclusion, the solubility difference between the *Δ*- and *Λ*-diastereoisomers could be explained in terms of density, unoccupied fraction and electrostatic interaction. However, there remained some uncertainty with respect to the solubility of the pseudoracemate, because this salt is anhydride, different from the other two. Other factors such as hydration enthalpy, hydrogen bonding interaction and entropy changes must be taken into account, but these terms are too complicated to be considered.

Studies on the Reaction Products of Antitumor Platinum Complex with d(ApG), d(GpA), and d(pGpA). 2′-Deoxy Sugar Is Favourable for G-N7, A-N1 Chelation

Kenji INAGAKI,* Akihito TOMITA, and Yoshinori KIDANI
Faculty of Pharmaceutical Sciences, Nagoya City University, 3, Tanabe-dori, Mizuho-ku, Nagoya 467
(Received March 9, 1988)

The reaction products of dichloro[(1*R*,2*R*)-1,2-cyclohexanediamine]platinum(II), Pt(*R*,*R*-dach)Cl_2, with dinucleotides, d(ApG), d(GpA), and d(pGpA) have been separated by HPLC, and each product fractionated has been characterized by UV and CD spectral analyses. The reaction of Pt(*R*,*R*-dach)Cl_2 with d(ApG) yields Pt(*R*,*R*-dach)(d(ApG)-*N1(1),N7(2)*) (**1**, 16%), Pt(*R*,*R*-dach)(d(ApG)-*N7(1),N7(2)*) (**2**, 80%) and uncharacterized minor product (4%). The reaction with d(GpA) yielded two Pt(*R*,*R*-dach)(d(GpA)-*N7(1),N1(2)*), (**3**, 22% and **5**, 61%), and Pt(*R*,*R*-dach)(d(GpA)-*N7(1),N7(2)*), (**4**, 17%), but surprisingly **5** isomerizes very slowly to **3** and **4** under the subsequent incubation (half life of **5**; about 6 days at 37 °C). The reverse reaction (**3** and **4**→**5**) was not observed. The reaction with d(pGpA) also yielded two Pt(*R*,*R*-dach)(d(pGpA)-*N7(1),N1(2)*), (**3′**, 8% and **5′**, 80%) and Pt(*R*,*R*-dach)(d(pGpA)-*N7(1),N7(2)*), (**4′**, 12%). The adduct, **5′**, also isomerizes to **3′** and **4′**. The platinum adducts, **3′**, **4′**, and **5′**, are compatible with **3**, **4**, and **5**, respectively, after removal of the 5′-phosphate group upon treatment with alkaline phosphatase. A competition reaction between d(ApG) and d(GpA) for Pt(*R*,*R*-dach)Cl_2 indicates that d(ApG) was about 2 times more reactive than d(GpA). The reactivity decreases along the series; d(pGpA)>d(ApG)>d(GpA).

In the mechanism of action of antitumor platinum drugs, DNA has been considered to be the primary target.[1-3] Studies on the reactions with DNA and its constituents have indicated that the N7 of guanine base is a strongly preferred platinum binding site. The interaction between the bifunctional platinum compound and the guanine base, especially the intrastrand crosslink between two adjacent guanine bases,[4-8] appears to play an important role in cell killing.[9,10] The enzymatic digestion of platinum modified DNA has been indicated that such intrastrand crosslinked compound is the most prominent platinum adduct.[11-15] An intriguing observation is that only an intrastrand crosslinked compound between adjacent adenine and guanine base, d(ApG)-chelate, but no d(GpA)-chelate has been found after digestion in the reaction products with DNA.[12,13] The d(ApG)-chelate is a major platinum adduct next to the d(GpG)-chelate. An important question is why only the d(ApG)-chelate is found in the reaction with DNA, and this has led us to the present study.

In the previous paper,[16] we reported that the reaction of r(GpA) with *cis*-Pt$(NH_3)_2Cl_2$ gives two platinum adducts and that one of them is *cis*-Pt$(NH_3)_2$-(r(GpA)-*N7(1),N7(2)*).[17] Very recently, Chottard et al.[18] investigated *cis*-Pt$(NH_3)_2$-adducts with r(ApG) and r(GpA) by means of NMR, in which the reaction between *cis*-Pt$(NH_3)_2Cl_2$ and r(ApG) gave *cis*-Pt$(NH_3)_2$-(r(ApG)-*N7(1),N7(2)*) as a major platinum adduct (>95%). The reaction[18] of *cis*-Pt$(NH_3)_2Cl_2$ with r(GpA) yielded *cis*-Pt$(NH_3)_2$(r(GpA)-*N7(1),N7(2)*) (68%) and *cis*-Pt$(NH_3)_2$(r(GpA)-*N7(1),N1(2)*) (32%). The present paper describes about the reaction products of Pt(*R*,*R*-dach)Cl_2 with d(ApG), d(GpA), and d(pGpA) and the competition reaction between d(ApG) and d(GpA), with a common reactant Pt(*R*,*R*-dach)Cl_2. Our results are somewhat different from those obtained from the reaction[18] between *cis*-Pt$(NH_3)_2Cl_2$ and r(ApG) or r(GpA).

Experimental

The dinucleotides used were purchased from Pharmacia Co., Ltd. The platinum complexes, Pt(*R*,*R*-dach)Cl_2 and [Pt$(NH_3)_3$Cl]Cl, were prepared according to the literature.[19,20] For the purpose of characterization of the reaction products, the dinucleotide, d(ApG), d(GpA), or d(pGpA), was allowed to react with a stoichiometric amount of Pt(*R*,*R*-dach)Cl_2 in a deionized and distilled water at 37 °C for 1 day. The reaction products formed are separated and fractionated by a Hitachi 655 liquid chromatograph with Shimadzu Chromatopak C-R5A and with variable wavelength UV monitor. Fractions of 3—4 cm^3 were collected to characterize each product separated by HPLC. The parameters of the run of HPLC are as follows: Column, Cosmosil $5C_{18}$ (0.46 cm i.d.×15 cm); detector, UV at 260 nm; flow rate, 0.8 $cm^3\,min^{-1}$; mobil phase, 0.02 mol dm^{-3} phosphate buffer (pH=8.0) in 10% methanol solution. Retention time: **3**, 6.0

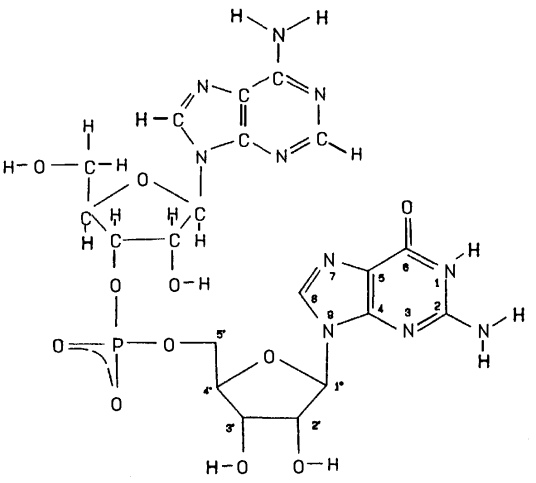

Fig. 1. Schematic structure of r(ApG) with the base and deoxyribose numbering scheme.

min; **4**, 12.2 min; **5**, 18.8 min; d(GpA), 23.2 min. For the competition reaction: Cosmosil $5C_{18}$ (0.46 cm i.d.×25 cm); Mobil phase, 0.25 mol dm^{-3} KH_2PO_4 in 9% methanol solution. Retention time: **1**, 12.2 min; **2**, 29.7 min; **3**, 12.2 min; **4**, 22.1 min; **5**, 19.8 min; **3′**, 12.0 min; **4′**, 31.1 min; **5′**, 13.5 min; d(ApG), 60.4 min; d(GpA), 62.2 min; d(pGpA), 17.4 min.

The platinum content of each product was determined by a Shimadzu AA-670G atomic absorption spectrometer. The UV and UV difference spectra were recorded on a Hitachi 557 dual-wavelength double beam spectrometer. In the measurement of UV difference spectrum, the reference cell contained a pH=5—6 solution of the each product. The CD spectrum was recorded on a JEOL J-40 spectrometer. The values are given per mole of platinum.

Results and Discussion

HPLC Analysis.[21] The reaction between Pt(*R*,*R*-dach)Cl_2 and d(ApG) yields two products, with a minor product (less than 4%). The two main platinum adducts are called **1** and **2**, according to their elution order. The reaction was followed at suitable time intervals by means of HPLC. The reactants are almost completely converted into **1** and **2** after 1 day reaction at 37 °C (see Figs. 8 and 9). The relative ratio of **1** (16 %) to **2** (80%) did not change throughout the reaction, suggesting parallel reaction. The Pt/base ratio (r=[Pt]/[Base], r=0.5 and 0.25) in the initial reaction solution also did not change the product ratio. The reaction of Pt(*R*,*R*-dach)Cl_2 with d(GpA) resulted in three platinum adducts, **3**, **4** and **5**. Figure 2 shows a time-dependence of the reaction. Relative ratios of each product to all the platinum adducts were almost constant for the first 10 hours, **3** (21—22%), **4** (16—18%) and **5** (62—59%). Afterward, the relative ratios, however, gradually change with the subsequent incubation because of an isomerization of **5** to **3** and **4**, as being mentioned later. The similar behaviour is also observed in the reaction between Pt(*R*,*R*-dach)Cl_2 and

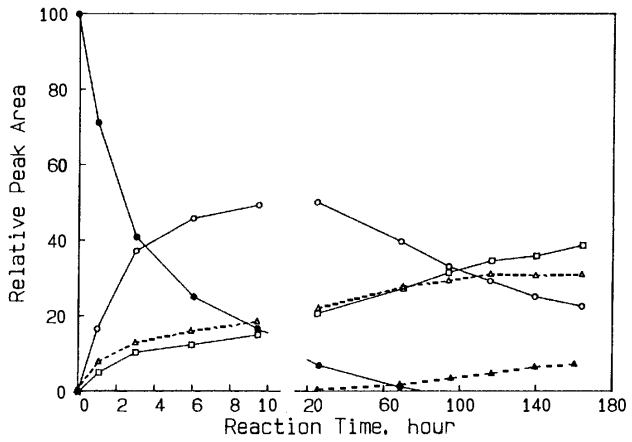

Fig. 2. Time-dependence of the reaction products of Pt(*R*,*R*-dach)Cl_2 with d(GpA) at 40 °C in water. (●), unreacted d(GpA); (○), Pt(*R*,*R*-dach)(d(GpA)-*N7(1),N1(2)*), **5**; (△), Pt(*R*,*R*-dach)(d(GpA)-*N7(1),N1(2)*), **3**; (▲), unknown; (□), Pt(*R*,*R*-dach)-(d(GpA)-*N7(1),N7(2)*), **4**.

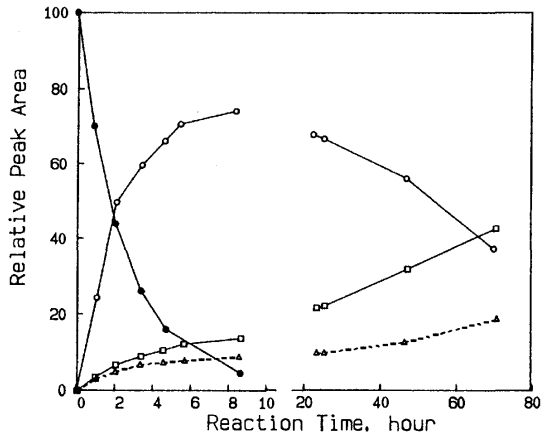

Fig. 3. Time-dependence of the reaction products of Pt(*R*,*R*-dach)Cl_2 with d(pGpA) at 40 °C in water. (●), unreacted d(pGpA); (○), Pt(*R*,*R*-dach)(d(pGpA)-*N7(1),N1(2)*), **5′**; (□), Pt(*R*,*R*-dach)(d(pGpA)-*N7(1),N7(2)*), **4′**: (△), Pt(*R*,*R*-dach)(d(pGpA)-*N7(1),N1(2)*), **3′**.

d(pGpA). The reaction also yielded three platinum adducts, **3′** (8—9%), **4′** (10—15%), and **5′** (81—77%), in which the figures in parenthesis indicate the product ratio obtained for the first 10 hours. The reaction products, **3′**, **4′**, and **5′** were identified by HPLC after treating with alkaline phosphatase. The resulting products were completely compatible with **3**, **4**, and **5**. It is noteworthy that the product ratio of **5′** is significantly greater, compared with that of **5**, i.e. formation of **5′** largely predominates due to the presence of the 5′-phosphate group. The reaction of Pt(*R*,*R*-dach)Cl_2 with r(GpA) yields four platinum adducts, **8**, **9**, **10**, and **11**. In the first 10 hours reaction, the relative ratios of each product to all the platinum adducts are as follows; **8** (6%), Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N1(2)*); **9** (12%), Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N1(2)*); **10** (44%), Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N7(2)*); **11** (38%), Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N1(2)*). Afterward, the product ratios gradually change because **11** isomerizes to **8**, **9**, and **10**.

Characterization of Platinum Adducts. In general, the possible binding sites for platination are expected to be guanine N7 and adenine N7 and N1. The 6-NH_2 group of adenine base is also a possible platinum binding site,[22] but it would be a very weak binding site for platination because the lone pair of electrons of the 6-NH_2 group delocalizes into the π-system of the purine ring. Table 1 shows the platinum binding sites of the products obtained in this work. The platinum adducts, **1**—**5**, were fractionated from HPLC, and their platinum binding sites were determined as follows.

(1) From UV and AAS spectrophotometry, a molar extinction coefficient of 23000—25000/mol Pt was calculated at 260 nm, suggesting a presence of the 1 : 1 species. (2) The UV spectrum of **1** was in agreement with that of **3**. The UV spectral pattern of **1** and **3** was also in agreement with the calculated UV spectrum of

Table 1. Platinum Adducts Obtained from the Reaction of Pt(*R*,*R*-dach)Cl_2 with d(ApG), d(GpA), and d(pGpA)

Reactants	Reaction product	Yield/%[a]
Pt(*R*,*R*-dach)Cl_2+d(ApG)	**1**, Pt(*R*,*R*-dach)(d(ApG)-*N1(1),N7(2)*)	16

	10, Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N7(2)*)	44[b]
	11, Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N1(2)*)	38[b]

a) Relative ratio of each product to all the platinum adducts.[21] b) The values obtained in the first 10 hours reaction.

Pt(NH_3)$_3$(G-*N7*) and Pt(NH_3)$_3$(A-*N1*),[16,23] suggesting platination at the *G-N7* and the *A-N1*. (3) The UV spectral pattern of **2** and **4** was in agreement with the calculated UV spectrum of Pt(NH_3)$_3$(G-*N7*) and Pt(NH_3)$_3$(A-*N7*),[16,23] suggesting platination at the *G-N7* and the *A-N7*. (4) From the pH-UV titration curve, the pK_a values at the N1 of the G base for **1**, **2**, **3**, **4**, and **5** were in the range of 8.0—8.5, a value significantly lower than the corresponding one of the unplatinated G base (pK_a ca. 9.6). Platination at the N7 of the G base results in the well-known lowering of the pKa of the N1. (5) No protonation reaction at the N7 of the G base was observed, suggesting that the N7 of the G base has already been occupied by the platinum atom. (6) The UV difference spectral change of **1**—**5** as a function of pH, — arising from the deprotonation reaction at the N1 of the G base —, agreed with that of the N7-platinated guanine derivatives.[16,23] These results ((4)—(6)) are good evidences for platination at the *G-N7*. (7) No protonation reaction at the N1 of the A base was observed for **1**, **3**, and **5**, suggesting platination at the N1 of the A base. (8) The pK_a values at the N1 of the A base of **2** and **4** were in the range of 1.7—1.9. Such decrease in the pK_a at the N1, compared with unplatinated A base (pK_a=3.6), is an evidence for platination at the N7 of the A base.[23-25] The binding sites of the platinum adducts containing r(GpA) were also determined by the same method described above.

Figures 4—6 show the CD spectra of the platinum dinucleotide adducts. The CD band in the 260 nm region is likely to arise from an interaction between the two purines. The CD spectrum of **2** is quite similar to that[18] of the structurally characterized compounds, *cis*-Pt(NH_3)$_2$(r(ApG)-*N7(1),N7(2)*) with A_{anti}, G_{anti}, which was characterized by NMR and CD spectroscopy.[18] Examination of the molecular models indicates that the interbase crosslink between the *A-N7* and *G-N7* seems to be favorable under the configuration of A_{anti} with the N-type conformer and G_{anti} with

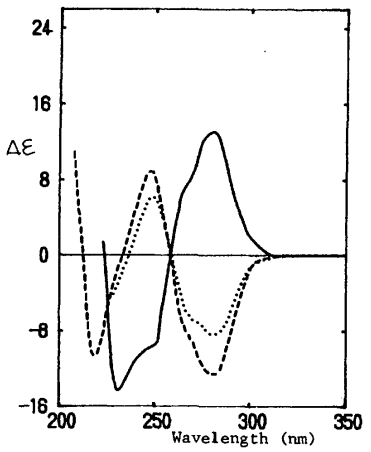

Fig. 5. Circular dichroism spectra of *G-N7*, *A-N1* platinum adducts (pH=4.6). (——), Pt(*R*,*R*-dach)(d(ApG)-*N1(1),N7(2)*), **1**; (------), Pt(*R*,*R*-dach)(d(GpA)-*N7(1),N1(2)*), **3**; (----), Pt(*R*,*R*-dach)(r(GpA)-*N7(1),N1(2)*), **9**.

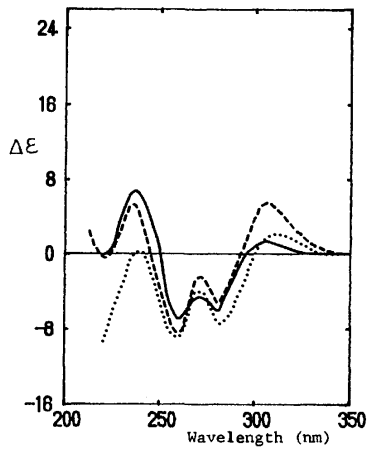

Fig. 6. Circular dichroism spectra of *G-N7*, *A-N1* platinum adducts (pH=4.6). (——), Pt(*R,R*-dach)(d(GpA)-*N7(1),N1(2)*), **5**; (----), Pt(*R,R*-dach)(r(GpA)-*N7(1),N1(2)*), **11**; (------), *cis*-$Pt(NH_3)_2$(r(GpA)-*N7(1),N1(2)*).[18]

the S-type conformer in the sugar moieties and that the product **2** is likely to have such sugar conformations because of the similarity of the CD spectra (see Fig. 4). Such conformation in the sugar moieties has been also found in *cis*-$Pt(NH_3)_2$(d(GpG)-*N7(1),N7(2)*).[4-7] Figure 4 also shows the CD spectra of Pt(*R,R*-dach)(r(GpA)-*N7(1),N7(2)*), (**10**), and *cis*-$Pt(NH_3)_2$(r(GpA)-*N7(1),N7(2)*).[17] The CD spectra of the both adducts are very similar to each other except for a difference in the intensity and are also similar to those of the sequence isomers, i.e. **2** and *cis*-$Pt(NH_3)_2$(r(ApG)-*N7(1),N7(2)*), except for an inversion of sign. That is, the CD spectral pattern of the adducts with platination at *G-N7* and *A-N7* have a common feature. However, the CD spectrum of **4** appears to be different from the other *G-N7* and *A-N7* adducts. This may be due to a presence of conformational isomers (probably, equilibrium mixture of syn and anti conformations).[18] In HPLC analysis, **4** shows an unusually broad peak (retention time of **4** (12.2 min) is shorter than that of **5** (18.8 min), and a half width of the peak of **4** is about 20 times larger than that of **5**.

The CD of **1** is almost mirror image of that of **3**, suggesting the reverse of the direction of the transition moments and the similarity in the overlap of the two purines (see Fig. 5). Inversion of CD bands in Fig. 5 has been also observed in the CD spectra of *cis*-$Pt(NH_3)_2$(r(GpC)-*N7(1),N3(2)*) and *cis*-$Pt(NH_3)_2$(r(CpG)-*N3(1),N7(2)*).[24] It should be stressed that the formation of the species **1** and **3** has not been found in the study of Chottard et al.[18] The species **1** and **3** are considered to be a platinum adduct with G_{anti} configuration. The CD spectral pattern of **3** is in agreement with that of *cis*-$Pt(NH_3)_2$(d(GpA)-*N7(1),N1(2)*)[27] with G_{anti} configuration which has been characterized by NMR. Figure 6 also shows CD spectra of the adducts with platination at *G-N7* and *A-N1*. They are characteristically observed in the platinum adducts with GA-sequence. The band above 300 nm, probably due to $n \rightarrow \pi^*$ electronic transition, may arises from a significant interaction between the 6-NH_2 group of the A base and O6 of the G base. The CD of **5** is also similar to that of Pt(*R,R*-dach)(r(GpA)-*N7(1),N1(2)*),(**11**) and *cis*-$Pt(NH_3)_2$(r(GpA)-*N7(1),N1(2)*).[18] Chottard et al. assigned *cis*-$Pt(NH_3)_2$(r(GpA)-*N7(1),N1(2)*) to the platinum adduct with G_{syn} configuration.[18] The CD spectral pattern of the Pt-adducts obtained in this work is hardly influenced by the presence and absence of the 2′-OH group of the sugar, though the CD of d(ApG) and d(GpA) are different from those of r(ApG) and r(GpA).[28]

Isomerization of 5. In the reaction of Pt(*R,R*-dach)Cl_2 with d(GpA), the relative ratios of each product for all the platinum adducts were almost constant at least for the first 10 hours. But the subsequent incubation results in a decrease of **5** and an increase of **3** and **4**. The platinum adduct, **5**, is not a monodentate intermediate but a chelate compound which platinum bound to *G-N7* and *A-N1* as described above. In order to make this point much clear, we performed further two experiments. (1) The reaction solution of Pt(*R,R*-dach)Cl_2 with d(GpA) was treated with snake venom phosphodiesterase.[14-16] The resulting solution gave dG and 5′-dAMP as an enzymatic digestion products, but **3**, **4**, and **5** were not digested at all by the enzyme. The dG and 5′-dAMP come from the enzymatic digestion of the unreacted d(GpA). This strongly suggests that **5** is a chelate compound.[29,30] The enzymatic digestion of $Pt(NH_3)_3$(d(GpA)-*N7(1)*) gave $Pt(NH_3)_3$(dG-*N7*) and 5′-dAMP under the same conditions. (2) The reaction of $[Pt(R,R\text{-dach})(OH_2)_2]^{2+}$ with d(GpA) gave the platinum adducts, **3**—**5**, via a monodentate intermediate, probably Pt(*R,R*-dach)(OH_2)(d(GpA)-*N7(1)*).

Isomerization of **5** was followed by means of HPLC. The solutions containing each **1**, **2**, **3**, **4**, and **5**, which were fractionated from HPLC, was incubated at 37°C. The product **5** was slowly converted into **3** and **4** (see Fig. 7), but the reverse reaction was not observed. This suggests that **3** and **4** are a thermodynamically more stable species and that **5** is likely to be a kinetically preferred species. The product **3** is further converted into unknown compound under further incubation. The half life of **5** was about 6 days at 37 °C. Addition of halogen ions (Cl^-, Br^-, and I^-) to the solution of **5** promotes the isomerization reaction. The more detail study is now under investigation.[31] Conversion between **1** and **2** was not observed.

Competition Reaction. In order to examine a relative reactivity of Pt(*R,R*-dach)Cl_2 with d(ApG) and d(GpA), a competition experiment was carried out. Stoichiometric amounts of d(ApG) and d(GpA) were incubated with half equivalent of Pt(*R,R*-dach)Cl_2 at 37 °C. Figure 8 shows a change of the unreacted dinucleotides and the products as a function of time. The reaction appeared to be complete within 1 day. Quan-

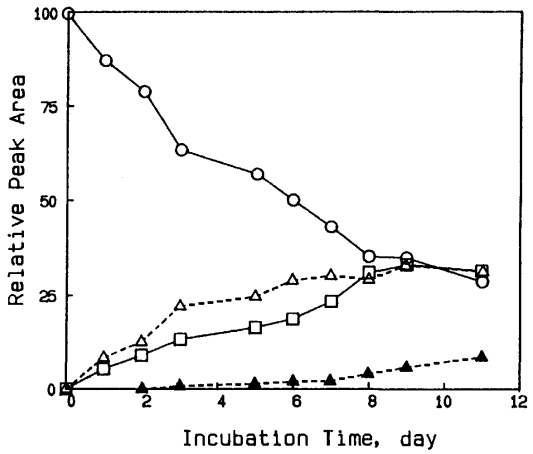

Fig. 7. Isomerization of Pt(*R,R*-dach)(d(GpA)-*N7(1),N1(2)*), **5**, to Pt(*R,R*-dach)(d(GpA)-*N7(1),N1(2)*), **3**, and Pt(*R,R*-dach)-(d(GpA)-*N7(1),-N7(2)*), **4**, at 37°C (pH=4.6). (○), Pt(*R,R*-dach)-(d(GpA)-*N7(1),N1(2)*), **5**; (△), Pt(*R,R*-dach)(d(GpA)-*N7(1),N1(2)*), **3**; (□), Pt(*R,R*-dach)(d(GpA)-*N7(1),-N7(2)*), **4**; (▲), unknown compound, which forms from **5** via **3**.

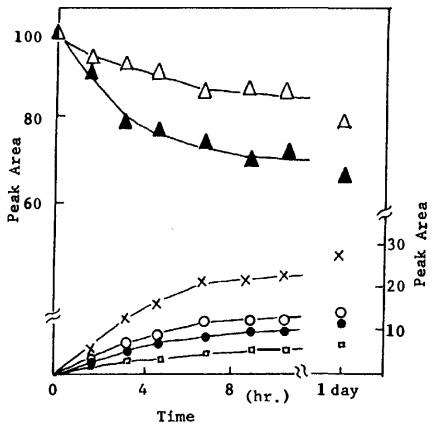

Fig. 8. Competition reaction of Pt(*R,R*-dach)Cl_2 with an equimolar mixture of d(ApG) and d(GpA) at 37°C (in water), r=0.25. (△), unreacted d(GpA); (▲), unreacted d(ApG); (×), **2**; (○), **5**; (●), **1**+**3**; (□), **4**.

titation result of the unreacted dinucleotides showed that d(ApG) is more reactive for platination than d(GpA) by a factor of about 1.7—1.9. The result is also supported by the quantitation result of the reaction products. The reaction between bifunctional platinum compound and d(ApG) or d(GpA) occurs via a two step mechanism.[32,33] The first step corresponds to formation of the 1 : 1 intermediate, and the second step to formation of the interbase crosslinked compound. In order to make the first step reaction clear, the reaction between monofunctional platinum complex, [Pt-(NH_3)$_3$Cl]Cl, and d(ApG) or d(GpA) was examined. The reaction product was exclusively Pt(NH_3)$_3$(d-(ApG)-*N7(2)*), (**6**), and Pt(NH_3)$_3$(d(GpA)-*N7(1)*), (**7**). The result agrees well with other studies.[34-36] Quantitation of the products in the competition reaction

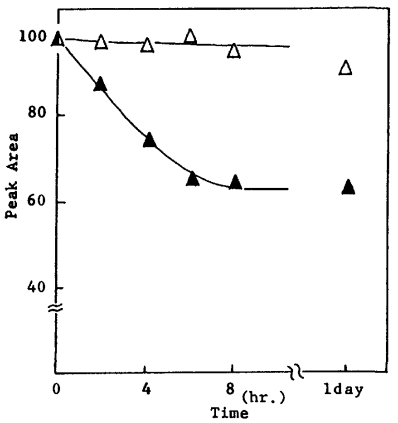

Fig. 9. Competition reaction of Pt(*R,R*-dach)Cl_2 with an equimolar mixture of d(ApG) and d(pGpA) at 37°C (in water), r=0.25. (△), unreacted d(ApG); (▲), unreacted d(pGpA).

indicated that formation of **6** is 2 times easier than that of **7**. This strongly suggests that the 1 : 1 intermediate formed in the reaction of Pt(*R,R*-dach)Cl_2 with d(ApG) or d(GpA) is the compound which platinum bound to the N7 of the G base, and that a preference in the reactivity is governed by a degree of formation of the 1 : 1 intermediate. The preference in the relative reactivity of d(ApG), compared with d(GpA), can be explained by an effect of the 5′-connected phosphodiester group, as being reported by Reedijk et al.[34] and Chottard et al.[18] i.e. interaction between the aquated platinum species and phosphodiester group on the 5′ side. To confirm the idea, the competition reaction between d(pGpA) and d(ApG) for Pt(*R,R*-dach)Cl_2 was also examined. As can be seen in Fig. 9, the reaction of Pt(*R,R*-dach)Cl_2 with d(pGpA) is much more reactive than that with d(ApG), i.e. the reactivity is greatly promoted by the presence of the 5′-phosphate group. This implies that a charge interaction, in addition to hydrogen bonding interaction, between the aquated platinum species and the 5′-phosphate group contributed to the reaction preference. It has been known that the reaction rate of *cis*-Pt(NH_3)$_2$(OH_2)$_2$ with 5′-dGMP is faster than that with 3′-dGMP.[37,38]

Concluding Remarks

The reaction between Pt(*R,R*-dach)Cl_2 and d(ApG) resulted in Pt(*R,R*-dach)(d(ApG)-*N7(1),N7(2)*) and Pt(*R,R*-dach)(d(ApG)-*N1(1),N7(2)*), i.e. **2** and **1**. The former product, **2**, contains 80% of the reaction products. Formation of the latter product has not been found in the reaction[18] between *cis*-Pt(NH_3)$_2$$Cl_2$ and r(ApG). The reaction of Pt(*R,R*-dach)Cl_2 with d(GpA) resulted in Pt(*R,R*-dach)(d(GpA)-*N7(1),N1(2)*),(**3** and **5**) and Pt(*R,R*-dach)(d(GpA)-*N7(1),N7(2)*), (**4**). The platinum adduct, **5**, isomerizes very slowly to **3** and **4**. The reaction between Pt(*R,R*-dach)Cl_2 and r(GpA) yields Pt(*R,R*-dach)(r(GpA)-*N7(1),N7(2)*), (**10**), and Pt(*R,R*-dach)(r(GpA)-*N7(1),N1(2)*), (**8**, **9**, and **11**), and

11 also isomerizes to **8**, **9**, and **10**. In the initial process of the reactions (up to 10 hours), the Pt(*R,R*-dach)(d(GpA)-*N7(1),N1(2)*) adducts contains more than 80% of all the reaction products, while the product ratio of the Pt(*R,R*-dach)(r(GpA)-*N7(1),N1(2)*) adducts is less than 60%. The interesting difference seems to arise from the difference at the C2′ position of the sugar (2′-deoxy and 2′-oxy). The absence of the 2′-OH group of the sugar seems to be favourable to the binding at the *A-N1*.

The two purine bases in **5** appears to have the same sugar orientations as *cis*-Pt(NH_3)$_2$(r(GpA)-*N7(1), N1(2)*)[18] because of the similarity of the both CD spectra. Examination of molecular model indicates that when the 1 : 1 intermediate has G_{syn} configuration with the N-type conformer, subsequent chelation is very likely to occur at the N1 of the A base. In general, the reaction between platinum complex and nucleic acid base appears to be controlled by kinetic rather than thermodynamic in character. The relative preference of **5** to **3** and **4** may originate from such a kinetic reason. Although the product **5** is a kinetically preferred species, it is thermodynamically unstable species. In the reaction of Pt(*R,R*-dach)Cl_2 with d(pGpA), formation of **5′** is much more preferred, compared with the case of the reaction with d(GpA). The presence of 5′-phosphate group may allows an increase of G_{syn} configuration, probably in the 1 : 1 intermediate.

In the reaction of antitumor platinum complex with DNA, formation of the platinum adduct,**5**, seems to be unfavorable because it requires large conformational changes of the sugar moiety. Moreover, the N1 of adenine base is involved in base pairing in double stranded DNA. This may be one of the reason why the d(GpA)-chelate was not found after the enzymatic digestion of the platinum modified DNA.

We thank Professor Jan Reedijk for helpful suggestions.

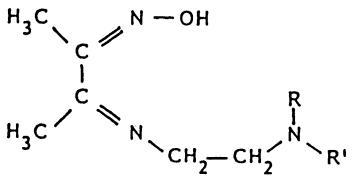
(Received March 14, 1988)

Reaction of copper(I) thiocyanate with imino oximes 3-[[2-(alkylamino)ethyl]imino]-2-butanone oximes or 3-[[2-(dialkylamino)ethyl]imino]-2-butanone oximes, (abbreviated as Hdox-enRR'), gave a series of copper(II) complexes which consist of binuclear complexes $[Cu_2(dox\text{-}enRR')_2(NCS)_2]$ with a thiocyanate anion coordinated to the copper(II) ion. The magnetic susceptibilities over the temperature range 77—320 K show a strong antiferromagnetic spin coupling through the N–O bridge for these complexes. The magnetic behavior can be explained by using the Bleaney–Bowers equation.

It has been shown previously that imino oximes (Hdox-enRR' **1**) form various transition metal complexes, in which they function in various manners, namely as bidentate, terdentate or bridging quadridentate ligands, depending upon the nature of the central metal ion on one hand and the substituents R and R' on the other.[1-4] We have reported that the reactions of nickel(II) thiocyanate with imino oximes **1** yield paramagnetic nickel(II) complexes, which are



Hdox-enRR'
1

hexa-coordinated with two thiocyanate ions bonded to the metal ion in cis-positions.[1] This result is in contrast to the results on the corresponding nickel(II) halides and perchlorate complexes with the same ligands.[2-4] Examination has been extended to the corresponding copper(II) thiocyanate complexes in the present study. Since the stereochemistry of copper(II) complexes is known to be significantly different from, although similar in many ways to, that of nickel(II) complexes, it is interesting to compare the copper(II) imino oxime complexes with the corresponding nickel(II) complexes. For example, the behavior of the thiocyanate ion in the copper(II) complexes may be different from that in the nickel(II) complexes. Although copper(II) perchlorate complexes with these ligands were reported previously,[4] there remain important problems about related complexes. Moreover, it is worthwhile to investigate the effects of the anions on the structure and the bonding of copper(II) complexes formed. Another important feature often observed with the copper(II) complexes is the spin–spin interaction between copper(II) ions, whereas the interaction of a similar type rarely occurs in the corresponding nickel(II) complexes. The present paper describes synthesis and characterization of the copper(II) thiocyanato complexes, including examination of their magnetic properties.

Experimental

Materials. Biacetyl monoxime, *N*-alkylethylenediamine, *N,N*-dialkylethylenediamine, and copper(I) thiocyanate were commercially available and used as received.

Synthesis. Cu(dox-enMe)NCS (R'=H, R=Me; 2a). A mixture of biacetyl monoxime (1.11 g, 0.011 mol) and copper(I) thiocyanate (0.61 g, 0.005 mol) in 2-propanol (40 cm^3) was heated at 70 °C for 1 h. To the solution was added *N*-methylethylenediamine (0.74 g, 0.01 mol) at 60 °C and stirred for 2 h. Filtration and subsequent washing with ethanol gave dark-green crystalline complex (0.45 g) in 32% yield, which appeared green when ground. Mp 151 °C. Found: C, 34.55; H, 5.04; N, 20.05%. Calcd for $C_7H_{14}N_3OCuNCS$: C, 34.57; H, 5.07; N, 20.16%.

Cu(dox-enEt)NCS (R'=H, R=Et; 2b). A mixture of biacetyl monoxime (1.11 g, 0.011 mol) and copper(I) thiocyanate (0.61 g, 0.005 mol) in 2-propanol (40 cm^3) was heated at 70 °C for 1 h. To the solution was added *N*-ethylethylenediamine (0.88 g, 0.01 mol) at 60 °C and stirred for 2 h. The filtered solution was allowed to stand in a refrigerator. Dark-green crystalline complex (0.57 g) was obtained in 39% yield. Mp 143 °C. Found: C, 37.32; H, 5.68; N, 19.09%. Calcd for $C_8H_{16}N_3OCuNCS$: C, 37.04; H, 5.53; N, 19.29%.

Cu(dox-enPr)NCS (R'=H, R=Pr; 2c). A mixture of biacetyl monoxime (1.11 g, 0.011 mol) and copper(I) thiocyanate (0.61 g, 0.005 mol) in 2-propanol (40 cm^3) was heated at 70 °C for 1 h. To the solution was added *N*-propylethylenediamine (1.01 g, 0.01 mol) at 60 °C and stirred for 2 h. The reaction solution was evaporated spontaneously at room temperature and dark-green crystals were collected by filtration and washed with ethanol to give the complex (0.40 g) in 26% yield. Mp 145 °C. Found: C, 39.26; H, 5.88; N, 18.27%. Calcd for $C_9H_{18}N_3OCuNCS$: C, 39.26; H, 5.93; N, 18.32%.

Cu(dox-enMe$_2$)NCS (R'=R=Me; 2d). This complex was prepared by a similar method which was used for the preparation of Cu(dox-enMe)NCS, except that *N,N*-dimethylethylenediamine (0.88 g, 0.01 mol) was used in place of *N*-methylethylenediamine. Complex **2d** (1.36 g) was obtained in 93% yield. Mp 153 °C. Found: C, 37.32; H, 5.46; N,

Table 1. Main Spectral Data of Copper(II) Complexes

Complex	d-d band	IR(oxime)	IR(NCS)		
	10^3 cm^{-1}	cm^{-1}	cm^{-1}		
		ν(C=N)	ν(C-N)	ν(C-S)	δ(N-C-S)

2b	15.4	1645	2080	797	425
2c	15.2	1648	2072	805	425
2d	15.9	1648	2077	776	457
2e	15.2	1643	2096	775	452
2f	16.3	1649	2087	786	453

19.44%. Calcd for $C_8H_{16}N_3OCuNCS$: C, 37.04; H, 5.53; N, 19.29%.

Cu(dox-enEt$_2$)NCS (R′=R=Et; 2e). To a solution of copper(I) thiocyanate (0.61 g, 0.005 mol) in ethanol (40 cm^3) was added a ligand (Hdox-enEt$_2$ 1.99 g, 0.01 mol) which was prepared beforehand.[1] The mixture was stirred at 60 °C for about 1 h. Filtration and washing with ethanol gave dark-green crystalline complex (1.52 g) in 95% yield. Mp 146 °C. Found: C, 41.51; H, 6.34; N, 17.63%. Calcd for $C_{10}H_{20}N_3$-OCuNCS: C, 41.29; H, 6.30; N, 17.51%.

Cu(dox-enBu$_2$)NCS (R′=R=Bu; 2f). A suspension of biacetyl monoxime (1.01 g, 0.01 mol) and *N,N*-dibutylethylenediamine (1.72 g, 0.01 mol) in 2-propanol (20 cm^3) was refluxed at 70 °C for 2 h. The resulting solution was added dropwise to a suspension of copper(I) thiocyanate (0.61 g, 0.005 mol) in ethanol (30 cm^3) and stirred at 60 °C for several hours. The solution was allowed to evaporate spontaneously at room temperature nearly to dryness. Dark needle-like crystals were filtered and washed with ethanol to yield 1.76 g (94%) of complex. Mp 115 °C. Found: C, 46.47; H, 7.21; N, 14.77%. Calcd for $C_{14}H_{28}N_3ONCS \cdot 1/2H_2O$: C, 46.79; H, 7.33; N, 14.55%.

Measurements. Electronic absorption spectra and infrared spectra were measured at room temperature on a Shimadzu MPS 5000 spectrophotometer and a Perkin-Elmer 938G infrared spectrophotometer, and all samples were mulled with Nujol. Magnetic susceptibilities were measured by the Gouy method at room temperature and by the Faraday method in a manner as described previously[5] at temperatures between 77K and 320K.

Results and Discussion

Synthesis and Characterization of the Thiocyanato (imino oximato)copper(II) Complexes. A possibility was explored in the present work to employ copper(I) thiocyanate as a starting compound for the preparation of copper(II) complexes with the imino oximes, partly because copper(II) thiocyanate was not available in the stable form. Reactions of copper(I) thiocyanate with the imino oximes yielded copper(II) complexes of the type Cu(dox-enRR′)NCS, copper(I) being oxidized to copper(II) by the atmospheric oxygen under the reaction conditions.

As discussed later in more detail, d-d bands and magnetic properties indicate that the products isolated are copper(II) complexes. It is important to note that this method using a copper(I) salt as a starting substance may be applied to the preparation of other copper(II) complexes, in case the copper(II) salts as a starting compounds are not available or do not give successful results.

Table 2. Magnetic Moments and Exchange Parameters of Copper(II) Complexes

Complex	μ	g	$-2J$	$N\alpha\times10^6$	p[a]
	BM		K	cm^{3}mol^{-1}	
2a	0.96	2.33	822	20	0.08

2c	0.99	2.34	792	37	
2d	0.92	2.24	830	65	
2e	0.76	2.32	938	18	
2f	0.66	2.32	1100	55	0.05

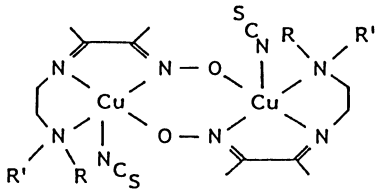
a) the percentage of the impurity species.

The composition determined from elemental analysis indicates that the imino oximes lose a proton on coordination to the copper(II) ion. This assumption is borne out by infrared spectra of these complexes, which exhibit no absorption bands due to the free oxime OH group in the region between 3000 and 3500 cm^{-1}. In other words, the imino oximes are coordinated to the copper(II) ion as monoanions. Moreover, the bands due to imino oxime C=N (Table 1) shift from the vibration 1623—1630 cm^{-1} of the free ligand indicating that imino oxime C=N is bound to the copper(II) ion. Infrared bands due to thiocyanate ions, as shown in Table 1 also indicate that the thiocyanate anion is coordinated to the copper(II) ion through the nitrogen atom.[6,7] Tentative assignments[8,9] are given in Table 1.

Their magnetic moments (0.66—1.05 BM) at room temperature are much lower than the spin-only moment (1.73 BM) for the d^9 system, as shown in Table 2. The subnormal magnetic moments imply that a sort of spin-spin interaction is present between copper(II) ions in these complexes.

All the findings discussed above indicate that one of the most probable structures for these copper(II) complexes is a binuclear one, as shown in **2**, in analogy to a copper(II) complex with a similar composition, Cu(dox-enMe$_2$)ClO$_4 \cdot$ H$_2$O having a subnormal magnetic moment (0.6 BM at room temperatuire).[10] Thus the copper(II) ion has a square-pyramidal coordination geometry, with one thiocyanate ion at the apex, as

also presumed from the infrared bands. This is also in agreement with the crystal structure analysis of one of the present complexes. According to preliminary results of the X-ray analysis,[11] Cu(dox-enPr)NCS in the crystalline state consists of binuclear complexes, represented by structure **2**. The coordination polyhed-



Cu(dox-enRR′)(NCS)
2

ron around the copper(II) ion is square-pyramidal with one thiocyanate ion at the apex, and the binuclear skeleton is somewhat distorted from the strictly planar structure. A similar binuclear structure may be assumed for the other complexes of the type Cu(dox-enRR′)NCS.

The maxima of the first d-d bands of the copper(II) complexes, as shown in Table 1, are consistent with the structure in which copper(II) ion is in the square-pyramidal environment with one thiocyanate ion at the apex.[12,13]

The discussion outlined above shows that copper(II) has a higher tendency to form binuclear complexes with the imino oximate N-O bridges in comparion with nickel(II). In this regard, it is interesting to note a marked difference in the structure between the copper(II) and nickel(II) complexes with these imino oximes. Hexa-coordinate copper(II) complexes have not been isolated in the present work, whereas nickel(II) forms hexa-coordinated complexes of the type *cis*-[Ni(NCS)$_2$(Hdox-enRR′)$_2$].[1] The present work indicates that the capacity of copper(II) ion with a $3d^9$ configuration to form hexa-coordinated complexes is obviously lower than that of nickel(II) ion having a $3d^8$ configuration. One of the main reasons for this may be the Jahn-Teller effect, which is operative in copper(II) complexes having a $3d^9$ configuration.

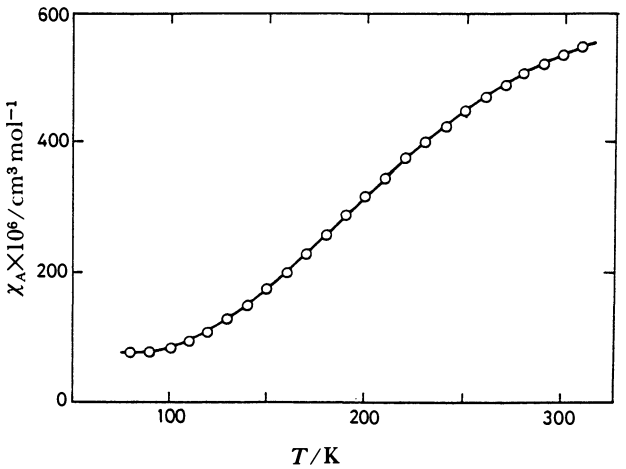


Fig. 1. Temperature dependence of the magnetic susceptibilities for Cu(dox-enEt)(NCS). The solid line was calculated from Eq. 1 with $2J=-719$ K, $N\alpha=65\times10^{-6}$ cm^3 mol^{-1}.

Magnetic Properties of Thiocyanato(imino oximato)-copper(II) Complexes. Variable-temperature magnetic susceptibilities of all the copper(II) complexes obey the Bleaney-Bowers equation for the pair of $S=1/2$ metal ions, Eq. 1,

$$\chi_A = \frac{Ng^2\beta^2}{kT}\,\frac{1}{3+\exp(-2J/kT)} + N\alpha \qquad (1)$$

or its modification, Eq. 2,

$$\chi_A = \frac{Ng^2\beta^2}{kT}\,\frac{1}{3+\exp(-2J/kT)}(1-p) + \frac{Ng^2\beta^2}{4kT}\cdot p + N\alpha \qquad (2)$$

where g, J, $N\alpha$, and p are, respectively, g factor, exchange integral, T. I. P. and percentage of the impurity species.

A typical example of the data is shown in Fig. 1. The figure shows that the experimental data fit to the theoretical expression given above. In Table 2 are also given the magnetic moments of the complexes and the values for the main parameters estimated from the variable-temperature data. All the copper(II) complexes in the present work exhibit large negative J values, showing antiferromagnetic interaction between copper(II) ions. The interaction is considered to arise from superexchange through the bridging N-O groups. The $|J|$ values of these copper(II) complexes are in the range reported for the related binuclear complex, for example, Cu(dox-enMe$_2$)ClO$_4\cdot$H$_2$O,[10] which also contain similar bridging N-O groups.

Photochemical Alkylation, Hydroxyalkylation, and Alkoxylation of Pyridinecarboxamides in Alcohol

Akira SUGIMORI,* Hiroshi ITOH, (the late) Mitsuharu KANAI, Nobuko ITOH, and Toru SUGIYAMA
Department of Chemistry, Faculty of Science and Technology, Sophia University, Kioi-cho 7-1, Chiyoda-ku, Tokyo 102
(Received August 7, 1987)

The UV-irradiation of 2- and 4-pyridinecarboxamides in alcohol brings about alkylation and/or hydroxyalkylation in the pyridine ring. In the irradiation of 3-pyridinecarboxamide in the presence of sulfuric acid, ionic reaction (alkoxylation at the 2- and 6-position) and radical reaction (alkylation at the 4- and 6-position) occur in parallel. The effects of quenchers indicate that two alkylation products originate from one excited triplet state which is quenched by energy-transfer mechanism and that two alkoxylation products originate from the excited singlet state.

In the preceding papers,[1-8] we have reported the remarkable photoreactivities of pyridinecarboxylic esters: parallel occurrence of ionic and radical reactions and simultaneous participation of several excited states of the same multiplicity. The most characteristic example is the photoreaction of methyl 3-pyridinecarboxylate in methanol in the presence of sulfuric acid.[2,3] It has been concluded that an excited singlet state, the n-π* triplet state, and the π-π* triplet state coexist and that the excited singlet state gives the products methoxylated at the 2- and 6-positions, while the π-π* and the n-π* triplet states give the methylation products at the 4- and 6-positions. The parallel occurrence of ionic and radical reactions has been observed in the photoreactions of 2-pyridinecarbonitrile in alcohol.[9]

In the present paper, we report the photoreactions of pyridinecarboxamides in alcohol, in order to compare their photochemical behavior with that of the esters.[10]

Results and Discussion

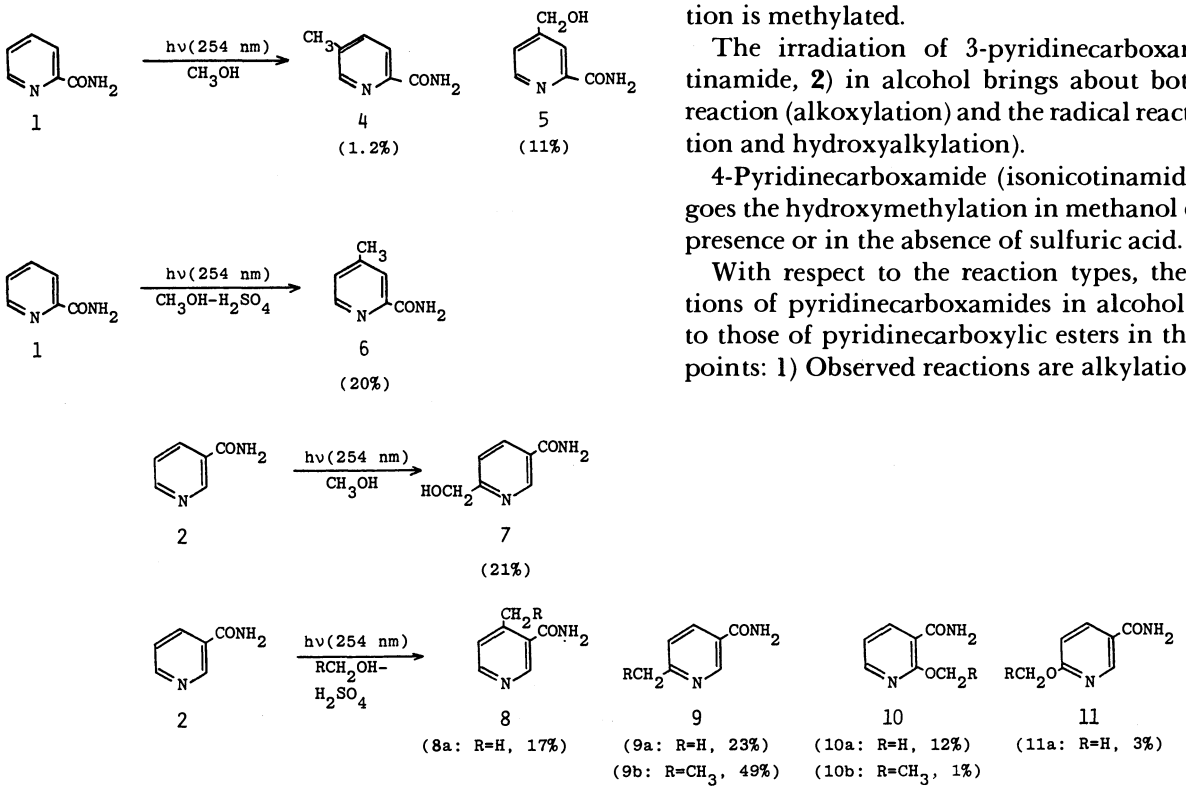
Types of Photoreactions of Pyridinecarboxamides. In the UV-irradiation of 2-pyridinecarboxamide (picolinamide, **1**) in methanol in the absence of added acid, methylation and hydroxymethylation occur in parallel. Irradiation in the presence of sulfuric acid gives a methylation product.

The position of the methylation depends on the presence and the absence of sulfuric acid. In the absence of the acid, the 5-position is methylated, whereas in the presence of sulfuric acid the 4-position is methylated.

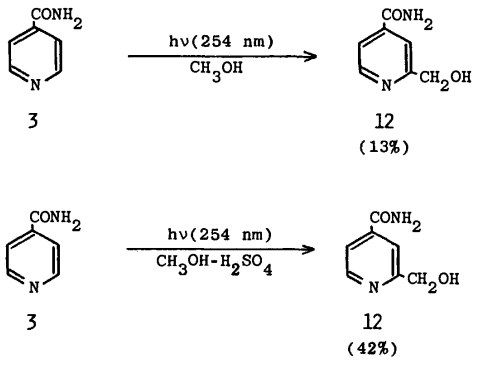
The irradiation of 3-pyridinecarboxamide (nicotinamide, **2**) in alcohol brings about both the ionic reaction (alkoxylation) and the radical reaction (alkylation and hydroxyalkylation).

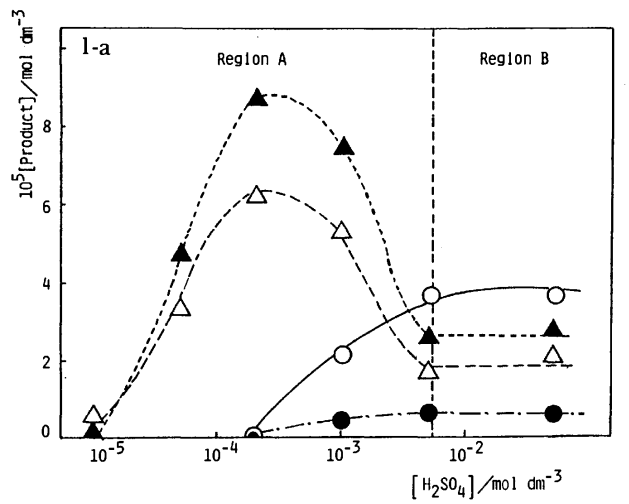
4-Pyridinecarboxamide (isonicotinamide, **3**) undergoes the hydroxymethylation in methanol either in the presence or in the absence of sulfuric acid.

With respect to the reaction types, the photoreactions of pyridinecarboxamides in alcohol are similar to those of pyridinecarboxylic esters in the following points: 1) Observed reactions are alkylation, hydroxy-



1 → 4 (1.2%), 5 (11%)
1 → 6 (20%)
2 → 7 (21%)
2 → 8 (8a: R=H, 17%), 9 (9a: R=H, 23%; 9b: R=CH3, 49%), 10 (10a: R=H, 12%; 10b: R=CH3, 1%), 11 (11a: R=H, 3%)





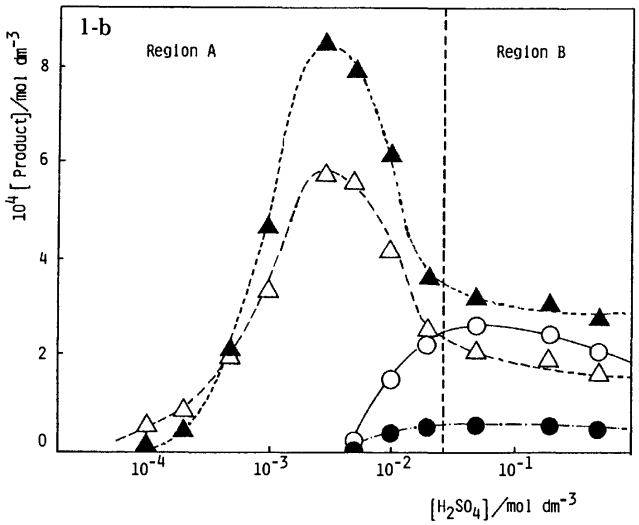


Fig. 1. Dependence of photoreactions of 3-pyridinecarboxamide (**2**) in methanol on the concentration of H_2SO_4. 1-a: [**2**]=1.0×10^{-2} mol dm^{-3}; 30 °C; irradiation time, 3 h. 1-b: [**2**]=1.0×10^{-3} mol dm^{-3}; 30 °C; irradiation time, 20 min. —△—, **8a**; ----▲----, **9a**; —○—, **10a**; ···●···, **11a**.

alkylation, and alkoxylation. In particular, the photoreactions of 3-pyridinecarboxamide (**2**) are very similar to those of the corresponding ester[2,3] (in the reaction type as well as in the positions of the reaction). 2) The change of alcohol from methanol to

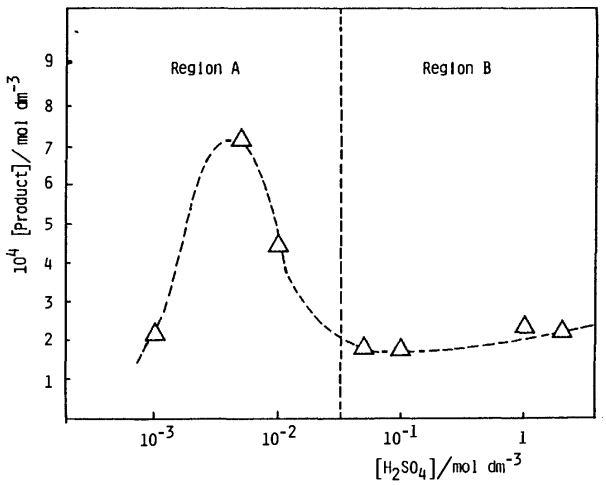

Fig. 2. Dependence of the photomethylation of 2-pyridinecarboxamide (**1**) at the 4-position on the concentration of H_2SO_4. [**1**]=1.0×10^{-2} mol dm^{-3}; irradiation time, 4 h.

ethanol causes the change in the product distribution in the photoreaction of 3-pyridinecarboxamide. In ethanol alkoxylation decreases, while alkylation increases. In ethanol alkoxylation occurs selectively at the 4-position. 3) Similar to methyl 2-pyridinecarboxylate,[4] 2-pyridinecarboxamide (**1**) undergoes the methylation at the 5-position in the absence of sulfuric acid but at the 4-position in its presence. Although the similarities should be stressed as a whole, the details of the photoreactivities of the amides are different from those of the esters: UV-irradiation of 2- and 4-pyridinecarboxamides gives only the products from radical reactions (alkylation or hydroxyalkylation), whereas the corresponding esters give alkoxylation products in addition to the alkylation and hydroxyalkylation products.[4,5]

Photoreactivity and Form of Substrate in Solution. The photoreactions of pyridinecarboxamides are controlled by an added acid. The photoreactions of 2- and 3-pyridinecarboxamide in the presence of sulfuric acid are different from those in its absence. The remarkable dependences of the photoreactions on the concentrations of added sulfuric acid are observed in cases of 2- and 3-pyridinecarboxamides (Figs. 1 and 2).

In UV-irradiation of 3-pyridinecarboxamide in methanol (Figs. 1-a and 1-b), the methylation occurs effectively at lower concentrations of sulfuric acid (Region A), while the methylation and methoxylation occur in parallel at higher concentrations of sulfuric acid (Region B). This type of acidity dependence is similar to that of methyl 3-pyridinecarboxylate.[3]

In Fig. 3 are shown the correlations between the molar absorption coefficient of **2** and the concentration of added sulfuric acid. The change in the molar absorption coefficient shows the change in the form of **2**. Figures 1 and 3 indicate that **2** exists in the pyridinium form in Region B and that the pyridinium form

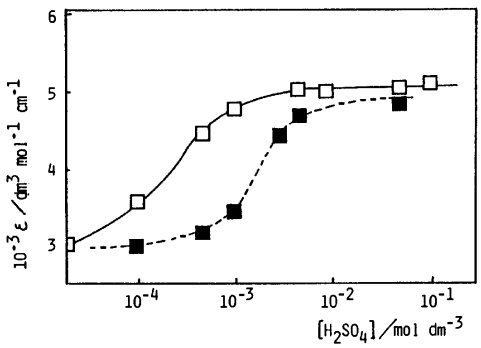

Fig. 3. Relation between molar absorption coefficient of 3-pyridinecarboxamide (**2**) at 262 nm and concentration of added sulfuric acid. —□—: [**2**]=1.0×10^{-3} mol dm^{-3}; ---■---: [**2**]=3.0×10^{-3} mol dm^{-3}.

and the free base form of **2** coexist in Region A. The correlation between the photoreactivity and the forms of **2** in solution is also similar to that for methyl 3-pyridinecarboxylate. However, there exists a remarkable difference between the amide and the ester: In methyl 3-pyridinecarboxylate the peak for the methylation in Region A becomes lower as the concentration of the substrate is lowered,[3] whereas in 3-pyridinecarboxamide such a dependence of the methylation on the concentration of the substrate was not observed.

Mechanism of Photoreactions of Pyridinecarboxamides. A significant feature of the photoreactions of pyridinecarboxylic esters is the simultaneous participation of various kinds of excited states. Do pyridinecarboxamides show the similar photochemical fea-

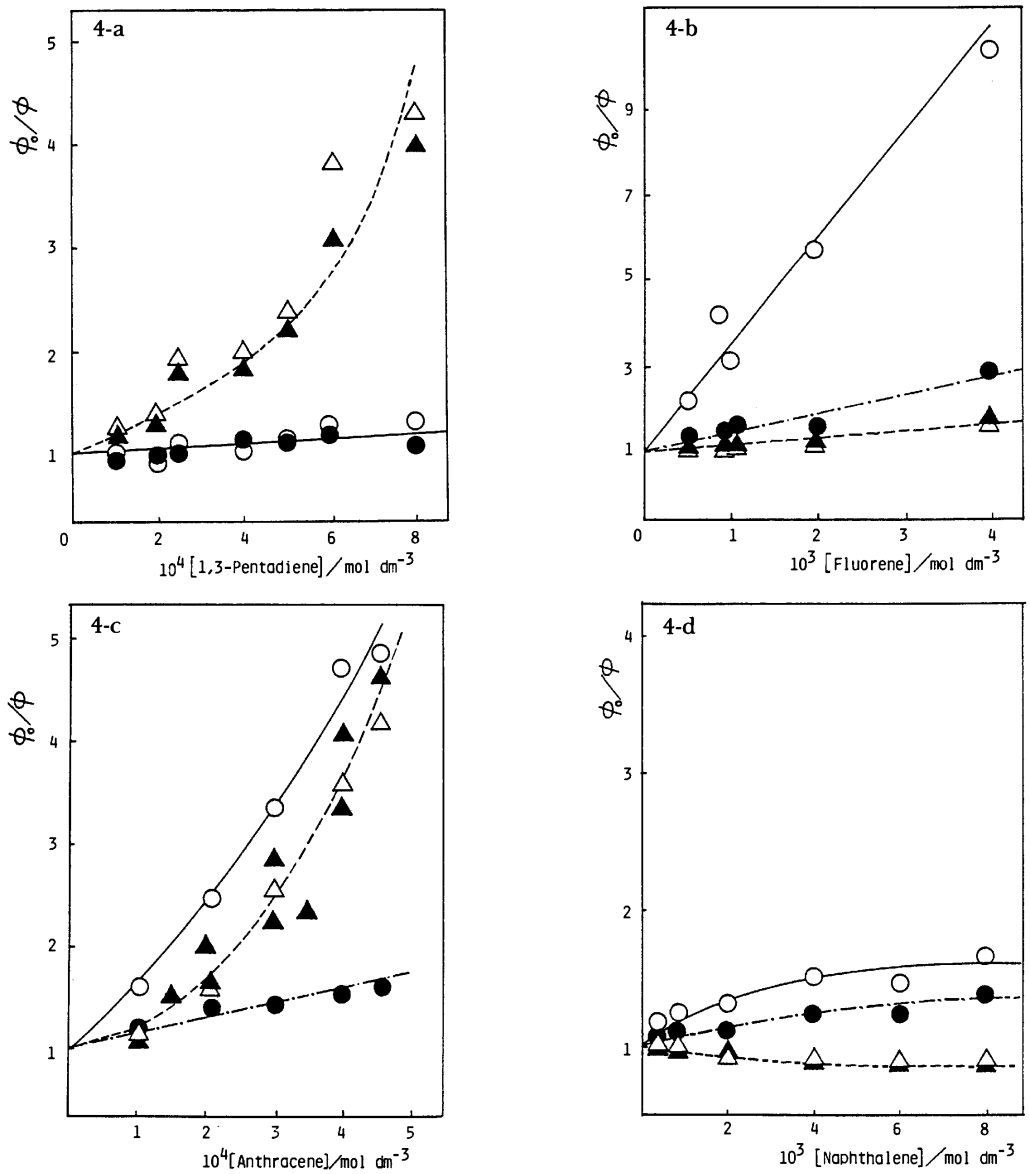

Fig. 4. Stern-Volmer plots for quenching of the photoreactions of 3-pyridinecarboxamide(**2**) in methanol by 1,3-pentadiene (4-a), fluorene (4-b), anthracene (4-c), and naphthalene (4-d). [**2**]=1.0×10^{-2} mol dm^{-3}; [H_2SO_2]=5×10^{-2} mol dm^{-3}; irradiation time, 3 h; 30 °C. ----△----, methylation at the 4-position; ----▲----, methylation at the 6-position; —○—, methoxylation at the 2-position; —●—, methoxylation at the 6-position.

ture? We analyze the photoreactions by means of the effects of quenchers in order to identify the excited states which may participate in the photoreactions.

For the Stern-Volmer analysis of the effects of additives, the quantum yields are calculated on the basis of the light quanta which are absorbed by the substrate.[11] The values Y and L are defined as,

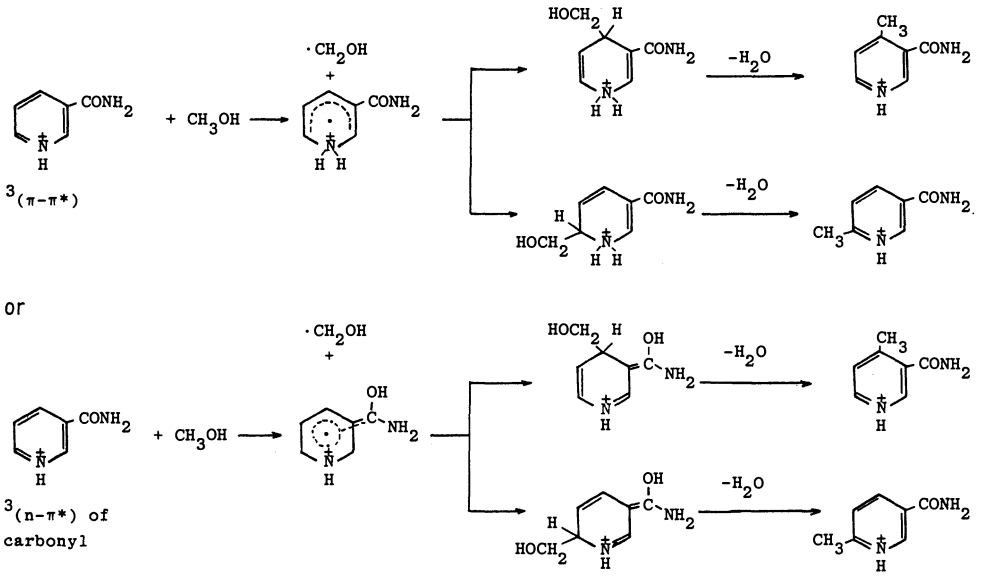
$$Y = \frac{\text{Yield of product in the presence of quencher}}{\text{Yield of product in the absence of quencher}},$$

$$L = \frac{\text{Light absorbed by substrate}}{\text{Light absorbed by substrate and quencher}}.$$

Thus, $\phi_0/\phi = L/Y$.

Photoreaction of 3-Pyridinecarboxamide in Strongly Acidic Alcoholic Solution (Reaction in Region B in Fig. 1-a). The Stern-Volmer plots for the effects of 1,3-pentadiene, fluorene, naphthalene, and anthracene on the photoreactions of **2** in methanol in the presence of sulfuric acid ($[H_2SO_4]=5\times10^{-2}$ mol dm^{-3}; $[2]=1.0\times10^{-2}$ mol dm^{-3}) are shown in Figs. 4-a—4-d.

With respect to the effects of the additives, the photoreactions of 3-pyridinecarboxamide in strongly acidic methanolic solutions can be classified into 3 groups: the two methylation reactions (the formation of **8a** and **9a**), the methoxylation at the 2-position (the formation of **10a**), and the methoxylation at the 6-position (the formation of **11a**). The formation of **8a**



Scheme 1.

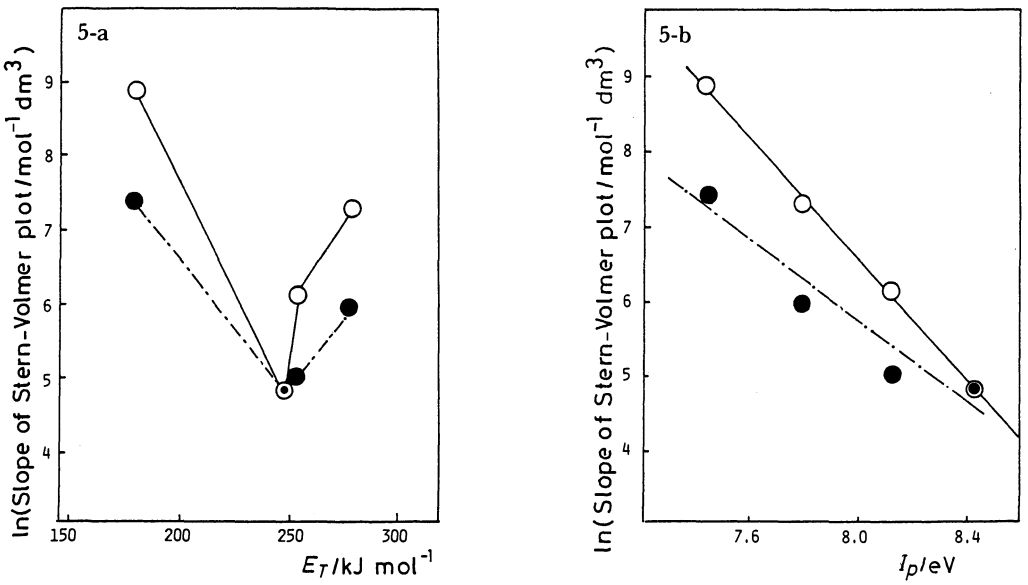


Fig. 5. Relations between the slope of Stern-Volmer plot and triplet energy (5-a) as well as between the slope of Stern-Volmer plot and ionization potential (5-b) of the additives in the quenching of the photomethoxylation of 3-pyridinecarboxamide in methanol. —○—, methoxylation at the 2-position; ···●···, methoxylation at the 6-position.

and **9a** is affected by the additives always to the same extent. The effects of quenchers on the methoxylation differ from those on the methylation and, furthermore, the effects of additives on the formation of **10a** and **11a** are different from each other.

The photomethylation reactions are quenched[12] by the additives with low triplet energies (anthracene: E_T=176 kJ mol^{-1}; 1,3-pentadiene: E_T=248 kJ mol^{-1})[13] but are slightly affected or even promoted by the additives with higher triplet energies (fluorene: E_T=285 kJ mol^{-1}; naphthalene: E_T=255 kJ mol^{-1}). These facts suggest that the methylation reactions originate from an excited triplet state. The photomethylation reactions at the 4- and 6-positions can be explained either by $^3(\pi\text{-}\pi^*)$ or by $^3(n\text{-}\pi^*)$ of carbonyl (Scheme 1).

The slopes of Stern-Volmer plots for photomethoxylation are plotted against the triplet energy values[13] (Fig. 5-a) and the ionization potential values[14] (Fig. 5-b) of the additives. The slopes correlate well with the I_p values of the quenchers, while those have no correlation with the E_T values of the quenchers.

The photomethoxylation reactions should originate from the excited singlet state(s), because the inhibition of the photomethoxylation is not correlated with the triplet energies of the quenchers.

The methoxylation is inhibited by the electron transfer from the electron-rich aromatic hydrocarbons to the excited states or precursors for the methoxylation products. The inhibition would not be due to the direct attack of the quencher to the excited singlet state of 3-pyridinecarboxamide, because the lifetime of the species to be quenched would be too long for an excited singlet state. The lifetime of the reactive species is in the order of 10^{-6} s, when we calculate it from the $k_q\tau$=2.6×10^3 mol^{-1} dm^3 (in the inhibition by fluorene) and the assumed k_q value of 10^9 mol^{-1} dm^3 s^{-1}. The inhibition of the photomethoxylation would occur in the attack of the quenchers to the certain intermediates which are formed from the excited singlet state of **2**.

The following fact also supports the above conclusion. In the presence of fluorene the methoxylation at the 2-position is inhibited but the both methylation reactions (via the excited triplet state) are not inhibited. If the singlet state itself is quenched, the yield of the excited triplet state, which is formed from the excited singlet state, should be decreased. Therefore, if we assume that the inhibition of the methoxylation is due to the quenching of the excited singlet state of the substate, the methylation reactions which originate from an excited triplet state should be inhibited by fluorene to the similar or greater extent than the methoxylation (the reaction from the excited singlet state). This type of phenomena was not observed in

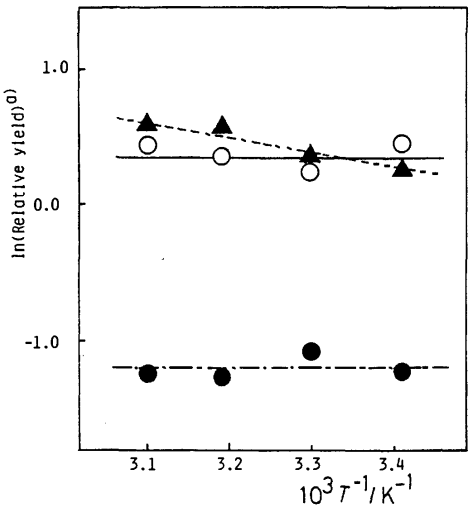

Fig. 6. Temperature dependence of the relative yields of the products from the photoreaction of 3-pyridinecarboxamide in methanol. ----▲----, yield of **9a**/yield of **8a**; —○—, yield of **10a**/yield of **8a**; —●—, yield of **11a**/yield of **8a**.

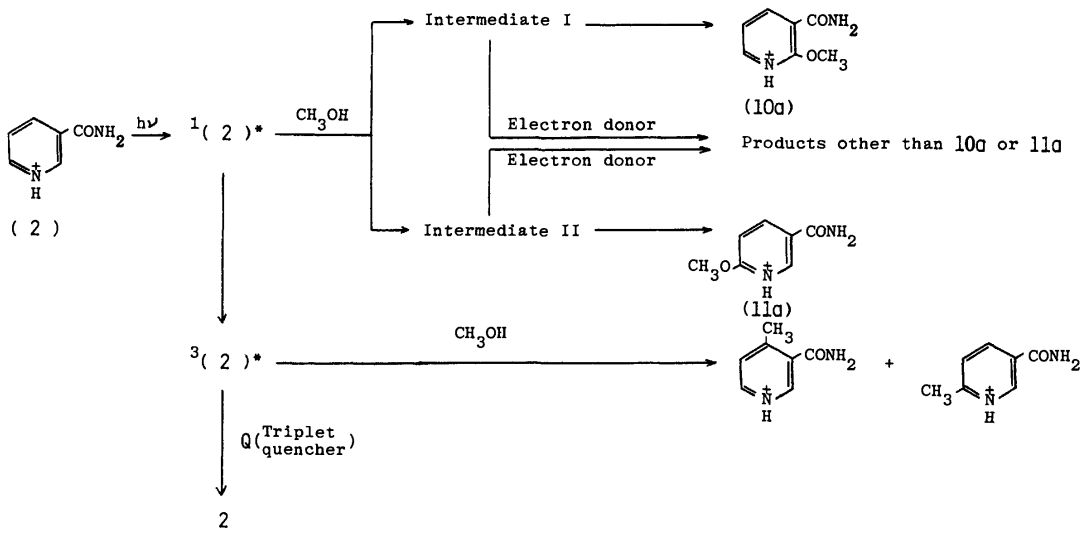

Scheme 2.

the quenching of the photoreaction of 3-pyridinecarboxamide by fluorene. The photoreaction of 3-pyridinecarboxamide shows no remarkable temperature dependence unlike that of the ester (Fig. 6).

The photoreactions of 3-pyridinecarboxamide in methanol acidified with sulfuric acid are summarized in Scheme 2.

Photoreaction of 3-Pyridinecarboxamide in the Presence of Chloride Ion. The UV-irradiation of 3-pyridinecarboxamide in alcohol in the presence of HCl resulted in the increase in the yields of the alkylation products and in the decrease in the yields of the alkoxylation products as shown in Table 1. This observation is similar to that in the photoreaction of methyl 3-pyridinecarboxylate.

More detailed studies by means of Stern-Volmer analysis by using LiCl as an additive in the photoreactions of 3-pyridinecarboxamide in the presence of sulfuric acid (Fig. 7) reveals that chloride ion inhibits the two types of photomethoxylation and, furthermore, to different extents. On the other hand, chloride ion promotes the methylation reactions at the 4- and 6-position to the same extent.

As the roles of chloride ions, we can consider two possibilities: 1) chloride ion accelerates the intersystem crossing of the excited 3-pyridinecarboxamide and 2) chloride ion donates an electron to the excited state(s) of 3-pyridinecarboxamide to give chlorine atom which would bring about the methylation in a radical process (Scheme 3).

We can not determine which process occurs actually. The fact that the isomeric ratio of the photomethylation products is not affected by chloride ion supports

Table 1. Difference in Effect of H_2SO_4 and HCl on Photoreaction of 3-Pyridinecarboxamide (**2**) in Alcohol[a)]

Alcohol	Acid	Irr. time	[Product]/10^{-4} mol dm^{-3}			
		h	**8**	**9**	**10**	**11**

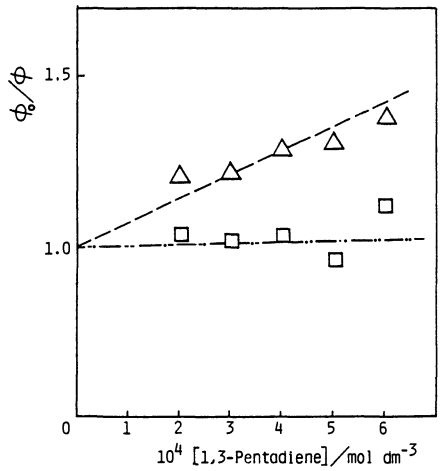

Fig. 8. Stern-Volmer plots for quenching of the photoreactions of 2-pyridinecarboxamide (**1**) by 1,3-pentadiene in the absence of sulfuric acid. [**1**]=9.9×10^{-3} mol dm^{-3}; irradiation time, 10 h. ----△----, methylation at the 5-position; -···□···-, hydroxymethylation at the 4-position.

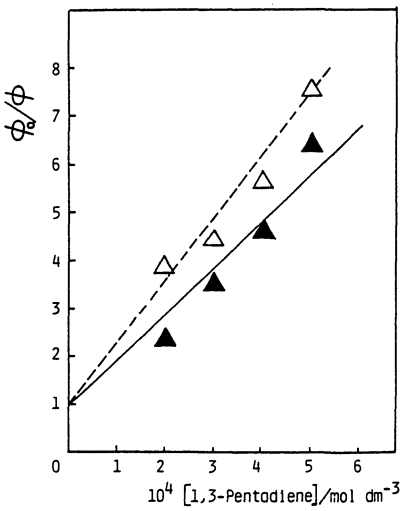

Fig. 9. Stern-Volmer plots for quenching of the photomethylation at the 4-position of 2-pyridinecarboxamide (**1**) by 1,3-pentadiene in the presence of sulfuric acid. [**1**]=1.0×10^{-2} mol dm^{-3}; irradiation time, 4 h. —▲—, $[H_2SO_4]=5\times10^{-3}$ mol dm^{-3}; --△--, $[H_2SO_2]=2\times10^{-1}$ mol dm^{-3}.

the mechanism of the acceleration of the intersystem crossing. However, the different quenchings of chloride ion on the two methoxylation reactions can not be explained by the acceleration of the intersystem crossing, but can be explained more easily by the electron transfer from the intermediates to chloride ion.

Dependence of Photoreaction on Concentration of 3-Pyridinecarboxamide. The photoalkoxylation reactions of 2-pyridinecarboxylic acid,[15] 2-pyridinecarboxylic ester,[4] and 2-pyridinecarbonitrile[9] are characterized by the dependences on the concentration. The reaction occurs effectively at the higher concentrations of the substrate. The alkoxylation reactions of these compounds have been explained by a mechanism via an excimer. The photoreactions of 3-pyridinecarboxamide, however, show only a small concentration dependence as shown in Table 2. It is suggested that an excimer plays no important role in the photoreactions of 3-pyridinecarboxamide in strongly acidic methanolic solutions.

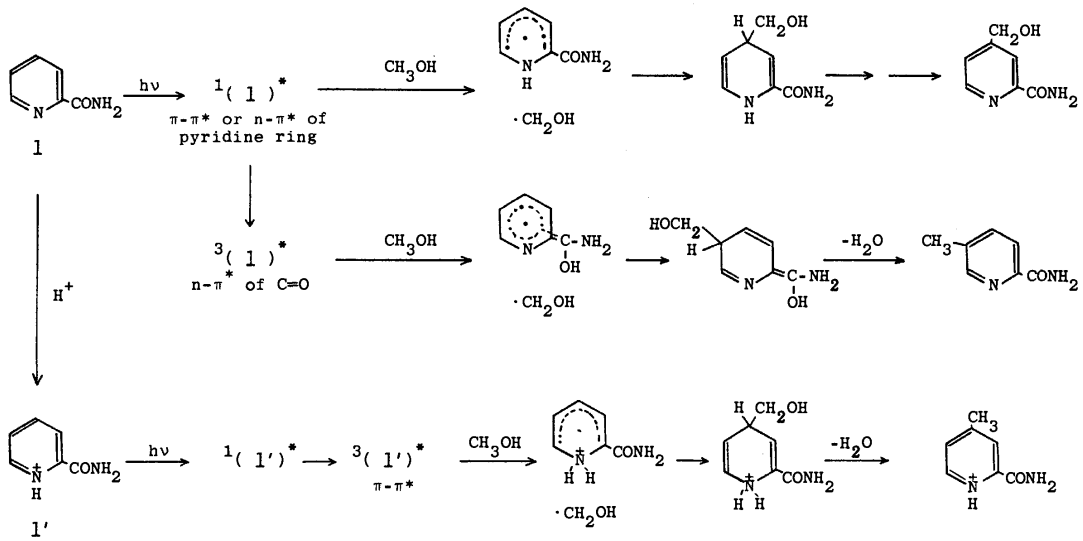
Photoreaction of 2-Pyridinecarboxamide in Methanol. In contrast to methyl 2-pyridinecarboxylate, 2-pyridinecarboxamide (**1**) gives no methoxylation product (the products in ionic reaction). However, the radical type photoreactions of **1** are similar to those of the ester: the methylation at the 5-position in the absence of added acid and the methylation at the 4-position in the presence of H_2SO_4.

The effects of 1,3-pentadiene on the photoreactions of 2-pyridinecarboxamide in the absence of sulfuric acid (Fig. 8) suggest that the methylation at the 5-position and the hydroxymethylation at the 4-position occur from the different kinds of excited species: The formation of **4** is inhibited by a triplet quencher, 1,3-pentadiene, while that of **5** is not affected by 1,3-pentadiene. Therefore, the photoreaction of **1** in the absence of acid might occur via the triplet n-π^* state of amide carbonyl to give **4** but via the singlet n-π^* or π-π^* state of the pyridine ring to give **5**.

The photomethylation at the 4-position in the presence of sulfuric acid is quenched by 1,3-pentadiene (Fig. 9). Anthracene ([anthracene]=4×10^{-4} mol dm^{-3} for [**1**]=1.0×10^{-2} mol dm^{-3} and $[H_2SO_4]=0.2$ mol dm^{-3}) inhibits the formation of **6** completely. These facts suggest that the photomethylation at the 4-position originates from an excited triplet state.

The photomethylations at the 4- and 5-positions are explained by the hydrogen abstractions by the n-π^* of the amide carbonyl and π-π^* of the pyridinium, respectively (Scheme 4).

Photoreaction of 4-Pyridinecarboxamide. The photoreaction of 4-pyridinecarboxamide (**3**) is simpler than those of 2- and 3-pyridinecarboxamide. The UV-irradiation of **3** in methanol gives 2-hydroxymethyl-4-pyridinecarboxamide (**12**) either in the presence or in the absence of an added acid. The photohydroxymethylation was not inhibited by 1,3-pentadiene either



Scheme 4.

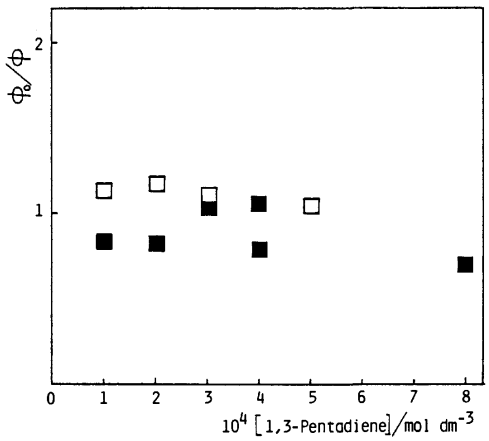


Fig. 10. Stern-Volmer plots for quenching of the photohydroxymethylation of 4-pyridinecarboxamide (**3**) in methanol by 1,3-pentadiene. [**3**]= 1.0×10^{-3} mol dm^{-3}. □, in the absence of sulfuric acid (irradiation time, 30 min); ■, in the presence of sulfuric acid ([H_2SO_2]=5×10^{-2} mol dm^{-3}; irradiation time, 90 min).

in the presence or in the absence of sulfuric acid (Fig. 10). The excited singlet states of protonated and non-protonated **3** might be responsible for the formation of **12**.

Experimental

Materials. Commercial 2- and 4-pyridinecarboxamide (GR-grade of Tokyo Kasei Co.) were purified by recrystallization from benzene and from benzene-ethanol, respectively. 3-Pyridinecarboxamide supplied by Yuki Gosei Yakuhin Co. was recrystallyzed from benzene-ethanol. 2-Pyridinecarboxamide, mp 106 °C; 3-pyridinecarboxamide, mp 126—127 °C; 4-pyridinecarboxamide, mp 152—153 °C.

1,3-Pentadiene (GR-grade of Wako Junyaku Co.), anthracene (analytical standard reagent of BDH Chemical Co.), naphthalene (Reagent for scintillator made by Dojindo Laboratories), and fluorene (zone-refined U.P. grade reagent of Tokyo Kasei Co.) were used without further purification.

UV-Irradiation. Methanolic or ethanolic solutions containing pyridinecarboxamide (in most cases, 1.0×10^{-2} mol dm^{-3}), sulfuric acid, and additives were deaerated by bubbling nitrogen or argon through for 40 min before irradiation.

In the quenching experiment with 1,3-pentadiene, the quencher was added after the deaeration of the substrate solutions in order to avoid the evaporation of the quencher during the bubbling of an inert gas.

For the quenching expeiment, a "merry-go-round" irradiation apparatus was employed, and the solutions (each 20 cm^3) were irradiated with a low-pressure mercury lamp at about 30 °C.

Isolation of Photoproducts. After the irradiation, the solvent was evaporated under reduced pressure. The solution was neutralized with sodium hydrogencarbonate (when the photoreaction has been carried out in the presence of sulfuric acid) and the products were extracted with ethyl acetate. The products were separated by means of TLC (plate, GF_{254} (Type 60) of E. Merck Co.; the developing solvent was ethyl acetate-methanol (9:1) for the products from 2- and 3-pyridinecarboxamides and ethyl acetate-methanol-NH_3 (9:1:small amount) for the products from 4-pyridinecarboxamide.). The separation of the photoproducts from 2- and 3-pyridinecarboxamides was carried out by HPLC (column, RP-18 of E. Merck Co.; eluent, methanol-water (2:8) for the products from 3-pyridinecarboxamide and methanol-water (35:65) for the products from 2-pyridinecarboxamide).

Identification of Photoproducts. The identification of 4-methyl-2-pyridinecarboxamide (**6**), 4-methyl-3-pyridinecarboxamide (**8a**), 6-methyl-3-pyridinecarboxamide (**9a**), and 2-hydroxymethyl-4-pyridinecarboxamide (**12**) was described in our earlier paper.[16]

2-Methoxy-3-pyridinecarboxamide (10a): Mp 131—133 °C; lit,[17] 130—131 °C); IR(KBr disk) 3460, 1670, and 1650 cm^{-1}; ^{1}H NMR (D_2O) δ=4.01 (3H, s), 7.12 (1H, t, J=6.2 Hz, H at the 5-position), and 8.20 (2H, d, J=6.2 Hz, H at the 4-and 6-positions).

2-Ethoxy-3-pyridinecarboxamide (10b) was identified by

the similarity of its spectra to those of **10a**. ^{1}H NMR (D_2O) δ=1.49 (3H, t, J=7.0 Hz), 4.51 (2H, q, J=7.0 Hz), 7.18 (1H, t, J=6.4 Hz, H at the 5-position), and 8.27 (2H, d, J=6.4 Hz, H at the 4- and 6-positions).

6-Methoxy-3-pyridinecarboxamide (11a): Mp 167—168 °C; IR(KBr disk) 3420, 3170, 1670, and 1625 cm^{-1}; ^{1}H NMR (D_2O) δ=4.03 (3H, s), 7.01 (1H, d, J=9.4 Hz, H at the 5-position), 8.16 (1H, dd, J=9.4 and 3.0 Hz, H at the 4-position), and 8.60 (1H, d, J=3.0 Hz, H at the 2-position). Found: C, 54.6; H, 5.3; N, 18.1%. Calcd for $C_7H_8N_2O_2$: C, 55.2; H, 5.3; N, 18.4%.

6-Ethyl-3-pyridinecarboxamide (9b): Mp 161—163 °C; IR(KBr disk) 3220 and 1655 cm^{-1}; ^{1}H NMR (D_2O) δ=1.30 (3H, t, J=7.2 Hz), 2.88 (2H, q, J=7.2 Hz), 7.40 (1H, d, J=8.0 Hz, H at the 5-position), 8.09 (1H, dd, J=8.0 and 2.0 Hz, H at the 4-position), and 8.84 (1H, d, J=2.0 Hz, H at the 2-position); Found: C, 63.7; H, 6.7; N, 18.9%. Calcd for $C_8H_{10}N_2O$: C, 64.0; H, 6.7; N, 18.7%.

5-Methyl-2-pyridinecarboxamide (4) was identified by the similarity of its spectra to those of methyl 5-methyl-2-pyridinecarboxylate. ^{1}H NMR ($CDCl_3$) δ=2.41 (3H, s), 7.62 (1H, dd, J=8.0 and 2.0 Hz, H at the 4-position), 8.08 (1H, d, J=8.0 Hz, H at the 3-position), and 8.37 (1H, d, J=2.0 Hz, H at the 6-position); MS (70 eV) m/z (rel intensity) 137 ($(M+1)^+$; 4), 136 (M^+; 51), 118 ($(M-NH_2)^+$; 8), 94 (7), 93 ($(M-CONH_2)^+$; 100), 92 (46), 66 (25), and 64 (30).

4-Hydroxymethyl-2-pyridinecarboxamide (5) was not obtained in pure form and was identified spectroscopically. ^{1}H NMR (CD_3COCD_3) δ=4.75 (2H, s), 7.50 (1H, dd, J=5.0 and 1.5 Hz, H at the 5-position), 8.08 (1H, d, J=1.5 Hz, H at the 3-position), and 8.49 (1H, d, J=5.0 Hz, H at the 6-position); MS (70 eV) m/z (rel intensity) 153 (5), 152 (M^+; 43), 109 (100), 108 ($(M-CONH_2)^+$; 23), 80 (21), and 78 (14).

Found: m/z 152.0562. Calcd for $C_7H_8N_2O_2$: M, 152.0584.

Quantitative Analysis of Photoproducts. The quantitative analyses of the photoproducts in the quenching experiments were carried out by means of gas chromatography for 4- and 5-methyl-2-pyridinecarboxamides (column, 1 m column of PEG 5%; column temperature, 160 °C). Analyses with HPLC were applied for 4-hydroxymethyl-2-pyridinecarboxamide and for the photoproducts from 3-pyridinecarboxamide (column, 25 cm column of Zorbax ODS of DuPont Co.; eluent, acetonitrile-water (1 : 9) buffered at pH=6.7—7.1 with phosphate buffer) and for the photoproducts from 4-pyridinecarboxamide (column, 25 cm column of Zorbax-ODS; eluent, methanol-water (2 : 8)).

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 60470028 from the Ministry of Education, Science and Culture.

11) When the quencher absorbs the light, the effective concentration of the quencher might be smaller than the charged concentration, because a part of the quencher is in the excited state. However, the decrease in the effective concentrations of the quencher is negligible under our reaction conditions, where the stationary irradiation with a "merry-go-round" irradiation apparatus equipped with a 17 W low pressure mercury lamp was employed. The measured light quanta absorbed by 20 cm^3 of the solution was 4×10^{16} s^{-1} (3×10^{-6} mol dm^{-3} s^{-1}). If we consider the reported triplet lifetimes of the quenchers (for anthracene in ethanol: 3000+2000 μs (D. N. Dempstor, T. Morrow, and M. F. Quinn, *J. Photochem.*, **2**, 399 (1974) and 150±45 μs (G. Porter and M. W. Windsor, *Discuss. Faraday Soc.*, **17**, 178 (1954); for fluorene in hexane at 300 K: 150 μs (W. Heinzelmann and H. Laphart, *Chem. Phys. Lett.*, **4**, 20 (1969)) the stationary concentration of these quenchers in their excited states should be much lower than the charged concentration of the quenchers (ca. 10^{-4} mol dm^{-3}).

12) We observed the upward-curved Stern-Volmer plots for the quenching of the photomethylation reactions. It indicates that the inhibition of the photomethylation does not occur in a simple triplet energy transfer mechanism.

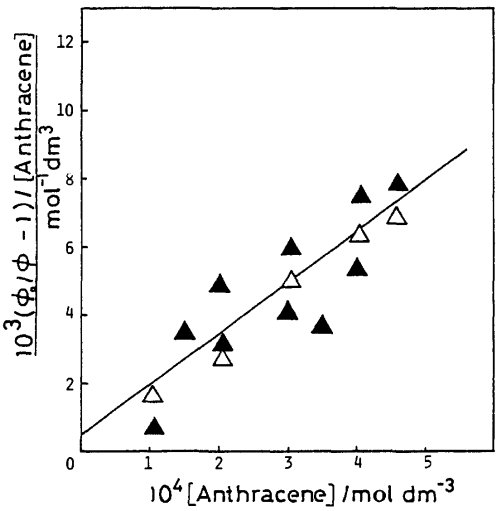

Fig. 11. Plot of $(\phi_0/\phi-1)$/[anthracene] vs. [anthracene] in the quenching of photomethylation reactions of **2** by anthracene. Reaction conditions are the same for Fig. 4-c. —△—, methylation at the 4-position; —▲—, methylation at the 6-position.

The Stern-Volmer plots curved upward are observed (1) in the case of the participation of the static quenching and (2) in the case of the participation of two excited states ((2.1) in the case where each of two states, whether in equilibrium or not, is quenched and the lower one is reactive and (2.2) in the case where two reactive states which are quenched react in parallel) (P. J. Wagner, "Energy Transfer Kinetics in Solution," in "Creation and Detection of the Excited State" ed by A. A. Lamola, Marcel Dekker, Inc. New York (1971), Vol. 1, part A, Chap. 4, pp. 173—212). The concentrations of 1,3-pentadiene in our reaction conditions for quenching (10^{-4}—10^{-3} mol dm^{-3}) are much lower than those which are required for the simple statistical chance that the reactant and the quencher will be nearest neighbors (it occurs under the conditions of [quencher]$>$0.1 mol dm^{-3}). The evidence for the formation of "a complex" between **2** and 1,3-pentadiene which will cause the static quenching at lower concentrations of the quencher has not been obtained in the careful examination of UV-vis. spectra of their mixtures. The Stern-Volmer plots curved upward can be explained by the mechanism (2.1) which involves two states (R_1^* and R_2^*) both of which are quenched and one of which is reactive.

$$R_1^* + Q \xrightarrow{k_{t1}} R_0 + Q_1^* \text{ (Q: Quencher)}$$

$$R_1^* \xrightarrow{k_i} R_0$$

$$R_1^* \xrightarrow{k_{t2}} R_2^*$$

$$R_2^* + Q \xrightarrow{k_{t2}} R_0 + Q_2^*$$

$$R_2^* \xrightarrow{k_d} R_0$$

$$R_2^* \xrightarrow{k_{r2}} I \longrightarrow P \text{ (I: Intermediate; P: product)}$$

When R_1^* and R_2^* are in equilibrium, we add,

$$R_2^* \xrightarrow{k_{21}} R_1^*$$

In this mechanism the Stern-Volmer plots should be parabolic and a linear relationship between $(\phi_0/\phi-1)/$[quencher] and [quencher] should be expected.

In the case where R_1^* and R_2^* are not in equilibrium,

$$\frac{(\phi_0/\phi-1)}{[Q]} = (k_{t1}\tau_1 + k_{t2}\tau_2) + k_{t1}\tau_1 k_{t2}\tau_2[Q].$$

In the case where R_1^* and R_2^* are in equilibrium,

$$\frac{(\phi_0/\phi-1)}{[Q]} = (X_2 k_{t2} + X_1 k_{t1})\tau_e + \frac{k_{t1}k_{t2}}{k_{12}+k_{21}}[Q].$$

In the equation, we define as $X_1=k_{21}/(k_{12}+k_{21})$ and $X_2=k_{12}/(k_{12}+k_{21})$, The apparent lifetime is expressed as τ_e.

The plot for the quenching of photomethylation by anthracene fits this kinetics (Fig. 11).

The participation of two excited triplet states in the photomethylation of 3-pyridinecarboxamide can be conceivable, because $^3(\pi-\pi^*)$ and $^3(n-\pi^*$ of carbonyl) states could contribute to the photomethylation. The photomethylation reactions at the 4- and 6-positions can be explained either by $^3(\pi-\pi^*)$ or by $^3(n-\pi^*$ of carbonyl) (Scheme 1). The fact that the ratio of the two photomethylation products is not affected by the quenchers supports that the reactive state to undergo methylation would be one of them (the lower excited triplet state). Therefore, the mechanism (2.2) which involve two reactive states is less probable.

We have not yet determine which of the excited triplet states, $^3(\pi-\pi^*)$ or $^3(n-\pi^*$ of carbonyl) undergoes the photomethylation reactions.

(Received October 12, 1987)

Molecular structures of three purinophanes, dithia[4.3](6,9)(6′,9′)purinophane (**1**), dithia[4.4](6,9)(6′,9′)-purinophane (**2**), and dithia[3.3](6,9)(9′,6′)purinophane (**3**), have been determined by means of X-ray diffraction. **1**: monoclinic, space group $P2_1/n$, a=10.561(1), b=16.674(3), c=9.136(1) Å, β=90.29(1)°, V=1608.8(4) Å^3, D_c=1.529 g cm^{-3} for Z=4. **2**: monoclinic, space group $P2_1/n$, a=10.870(2), b=17.058(2), c=9,289(1) Å, β=94.15(1)°, V=1717.9(4) Å^3, D_c=1.487 g cm^{-3} for Z=4. **3**: monoclinic, space group $P2_1/n$, a=8.068(1), b=27.841(2), c=6.913(1) Å, β=111.0(1)°, V=1449.8(2) Å^3, D_c=1.631 g cm^{-3} for Z=4. All structures were solved by the direct method, and refined anisotropically by the least-squares procedure. Final R values are 0.045, 0.053, and 0.050 for **1**, **2**, and **3**, respectively. Molecular structures of **1** and **2** take very similar crossed form, whereas that of **3** reveals a different crossed form.

Previously, we reported syntheses and spectral properties of a few [*m.n*](6,9)purinophanes, in which two purine rings are intramolecularly stacked with each other, for studying relationship between such a base-to-base stacking structure and remarkable hypochromic effect (ca. 40%) in the electronic spectra of DNA.[1,2] In general, although two conformational isomers are theoretically expected for the stacking structures of all purinophanes, their structures can be presumed on the basis of chemical shifts of purine ring protons which would be shifted to higher field by magnetic anisotropy of faced another purine ring. The preferential formation of less overlapped conformer to decrease π-electron repulsive interaction was similarly proposed for all of the double-bridged purinophanes according to NMR assignment. For the confirmation of NMR determined structure and the structural relationship of hypochromism in electronic spectra, molecular structures of dithia[4.3](6,9)(6′,9′)-purinophane (**1**), dithia[4.4](6,9)(6′,9′)purinophane (**2**), and dithia[3.3](6,9)(9′,6′)purinophane (**3**) have been determined by means of X-ray diffraction.

Experimental

Crystal data: **1**, $C_{15}H_{14}N_8S_2$, M 370.45, monoclinic, space group $P2_1/n$, a=10.561(1), b=16.674(3), c=9.136(1) Å, β=90.29(1)°, V=1608.8(4) Å^3, D_c=1.529 g cm^{-3} for Z=4; **2**, $C_{16}H_{16}N_8S_2$, M 384.47, monoclinic, space group $P2_1/n$, a=10.870(2), b=17.058(2), c=9.289(1) Å, β=94.15(1)°, V=1717.9(4) Å^3, D_c=1.487 g cm^{-3} for Z=4; **3**, $C_{14}H_{12}N_8S_2$, M 356.43, monoclinic, space group $P2_1/n$, a=8.068(1), b=27.841(2), c=6.913(1) Å, β=111.0(1)°, V=1449.8(2) Å^3, D_c=1.631 g cm^{-3} for Z=4.

Colorless prismatic crystals with approximate dimensions of 0.25×0.20×0.20 (**1**), 0.25×0.20×0.10 (**2**), and 0.10×0.10×0.10 mm (**3**) were used. X-Ray experiments were carried out on a Rigaku automated, four-circle diffractometer combined with a rotating-anode X-ray generator at the Crystallographic Research Center, Institute for Protein Research, Osaka University. Nickel-filtered Cu $K\alpha$ radiation (λ=1.5418 Å) was used.

Intensity data of each crystal were collected by the θ-2θ scan technique at a 2θ scan rate of 8° min^{-1} and scan width $\Delta 2\theta$=(2.4+0.3 tan θ)°. Backgrounds were counted for 4 s at both ends of a scan. Three standard reflections were measured after every 60 reflections to monitor the stability and orientation of the crystal, which showed no significant decay throughout the data collection. Totals of 2130 reflections out of 2394 (**1**), 2478 out of 2561 (**2**), and 1842 out of 2150 (**3**) were observed ($|F_o|>3\sigma(F_o)$), where $\sigma(F_o)$ is the standard deviation obtained by the counting statistics of intensities. Usual Lorentz and polarization corrections were made but

absorption correction was ignored [μ(Cu $K\alpha$)=30.9, 29.2, and 34.0 cm^{-1} for **1**, **2**, and **3**, respectively].

Structure Solution and Refinement

The structure of each crystal was established by the direct method (*MULTAN* 78),[3] and refined anisotropically by the block-diagonal least-squares procedure (*HBLS* V).[4] Hydrogen atoms could be located on the difference Fourier map, which were included in the refinement with isotropic temperature factors. Final R values were 0.045 (R_w=0.070) for **1** and 0.053 (R_w=0.079) for **2**, and 0.050 (R_w=0.064) for **3** for observed reflections. Weighting schemes used in the final cycles of the refinements were $\{\sigma^2(F_o)-0.0071|F_o|+0.0017|F_o|^2\}^{-1}$ for **1**, $\{\sigma^2(F_o)-0.2283|F_o|+0.0116|F_o|^2\}^{-1}$ for **2**, and $\{\sigma^2(F_o)-0.0281|F_o|+0.0001|F_o|^2\}^{-1}$ for **3** for observed reflections. Atomic parameters of non-hydrogen atoms are given in Table 1 with equivalent isotropic temperature factors.**[5] Atomic scattering factors were taken from those of International Tables for X-Ray Crystallography.[6] Calculations were done on ACOS 900 and ACOS 850 computers at the Crystallographic Research Center, Institute for Protein Research, Osaka University.

Results and Discussion

Molecular Structure. Throughout the three purinophanes the corresponding bond distances and bond angles in two purine rings are respectively equal within the range of error (Table 2). Each of these is not significantly different from the corresponding bond distances and bond angles in 6-(methylthio)-purine[8] and also from that in purine in the 2 : 1 complex of purine and urea.[9]

The characteristic feature of molecular structures of **1** and **2** is that these purinophanes take similar crossed form as to the overlapping of two purine rings (Fig. 1,a). However, because of the shorter -$(CH_2)_3$- bridge than -S-$(CH_2)_2$-S- the upper purine ring in **1** bent slightly convex upward (Fig. 1,b). Very close inter-purine ring nonbonded atomic distances are observed between atoms located near the -$(CH_2)_3$-bridge: the closest distance is 3.081(3) Å (between the N(9) and N(9′) atoms) and the others ranging from 3.172(4) Å (between the C(4) and N(9′) atoms) to 3.490(4) Å (between the N(1) and N(7′) atoms). Two purine rings in **2** are planar, and the tilting direction of the upper purine ring relative to the lower one differs from that in **1** because of the longer -$(CH_2)_4$- bridge. All the inter-purine nonbonded distances except N(1)···N(7′) [3.520(3) Å], N(3)···C(8)[3.489(3) Å], and C(5)···C(5′)-[3.538(3) Å] are longer than 3.6 Å.

Similar to the cyclophanes and heterophanes, the pyrimidine moiety of purine rings showed a tendency to be folded slightly at the N(1)···C(5) or N(1′)···C(5′) line while the imidazole moiety at the C(4)···C(8) or C(4′)···C(8′) line. The dihedral angle between the plane defined by the N(1), C(2), C(4), and C(5) atoms and that made by the N(1), C(5), and C(6) is only 4.8(3), which is the largest in **1**. In **2**, all the dihedral angles

** Tables of anisotropic temperature factors, atomic parameters of hydrogen atoms, and observed and calculated structure factors are kept at the Chemical Society of Japan, Document No. 8816.

In **3**			
N(1)···N(1′)[a]	3.586(5)		
N(1)···C(2′)[a]	3.553(6)		
C(2)···N(1′)[a]	3.386(6)	Key	
C(6)···C(5′)[a]	3.373(6)	a) x, y, $-1+z$;	
N(3)···C(91)[b]	3.443(6)	b) $-1+x$, y, z;	
N(1)···C(91)[c]	3.344(6)	c) $1+x$, y, z.	

through the midpoint of the C(2) and C(2′) atoms and that of the N(7) and N(7′), and two purine rings are approximately parallel to each other (Fig. 1, b). Close inter-purine nonbonded atomic distances observed are ranging from 3.289(6) Å (between the C(6) and N(9′) atoms) to 3.395(5) Å (between the C(5) and C(5′)).

Two purine rings in **3** are symmetrically connected by the -S(CH$_2$)$_2$- bridges. Only the dihedral angles concerned with the folding of the pyrimidine moiety have significant values. The angle made by the N(9)-C(91) (or N(9′)-C(93)) bond and the plane formed by the C(4), C(8), and N(9) (or C(4′), C(8′), and N(9′)) atoms [5.5(4)(or 6.7(5))°] is larger than the corresponding angle at the C(6)(or C(6′)) atom. In **3**, the

structures of two -S-$(CH_2)_2$- bridges are very similar to each other.

Based on the structures determined in this study, detailed discussions about the relationship between the stacked orientations of two purine rings and hypochromism values as well as the arguments of NMR determined structures are given in a separate paper.[10]

Crystal Structure. Crystal structures of **1**, **2**, and **3** are drawn in Fig. 2. Among the three, crystals of **1** and **2** show the similar mode of packings. Molecules are packed closely: the closest intermolecular atomic contacts are 3.348(4) Å [C(5)(x, y, z)···C(2′) ($-0.5+x$, $0.5-y$, $-0.5+z$)] and 3.397(3) Å [C(8′)(x, y, z)···N(7)($-0.5+x$, $0.5-y$, $0.5+z$)] in **1** and **2**, respectively (Table 5). In **3**, the shortest non-bonded distance between adjacent molecules is 3.344(6) Å [N(1)(x, y, z)···C(91)($1+x$, y, z)].

The authors wish to express their deep thanks to Miss Nobuko Kanehisa who helped them with computations at the final stage of the refinement and *ORTEP* drawings.

Iodine- or Iodine Monobromide-Catalyzed Alkoxy-Alkoxy Exchange Reactions of Alkylalkoxysilanes: Formation of the Catalyst-Alkoxysilane Complexes and the Reaction Mechanism

Katsuko Ito* and Takeshi Ibaraki
Department of Natural Science, Osaka Women's University, Daisen-cho 2-1, Sakai, Osaka 590
(Received December 7, 1987)

The formation of charge-transfer complexes of iodine and of iodine monobromide with alcohols and alkoxysilanes has been established spectroscopically, and the formation constants of iodine-ethoxytriethylsilane and iodine-diethoxydimethylsilane complexes has been determined as 0.55±0.01 and 0.61±0.02, respectively. On the basis of these observations and the kinetic information recently reported, the previously proposed mechanism for the iodine or iodine monobromide catalyzed alkoxy-alkoxy exchange reactions of alkoxysilanes is discussed afresh. It has been confirmed that a mechanism involving a four-centered transition state containing a CT-complex is most favorable.

In our previous work we disclosed that halogens and interhalogen compounds were extremely favorable catalysts for quantitative studies of the alcoholysis and redistribution reactions of alkoxysilanes.[1,2] These catalysts accelerate the alkoxy-alkoxy exchange reactions at ordinary temperature without any by-products, unlike conventional catalysts such as various acids and bases.

Among these catalysts, iodine and iodine monobromide that are easier to handle than others were preferred for the determination of alcoholysis and redistribution equilibrium constants, and the extensive data at 20 °C and 40 °C could be successfully observed.[1,2]

Since only a few redistribution equilibria have so far been examined at 150 °C[3,4] and 120 °C[5] in the absence of a catalyst and no alcoholysis equilibria have been examined, halogens and interhalogen compounds may be the first catalysts to make it possible to investigate these equilibria quantitatively at ordinary temperature.

A kinetic study on the following iodine-catalyzed alcoholysis was undertaken, in order to ascertain the catalytic activity of iodine quantitatively and to provide information about the mechanism of the reaction, $Et_3SiOBu^n+Bu^sOH \rightleftarrows Et_3SiOBu^s+Bu^nOH$ Both forward and reverse reactions were of first order with respect to butoxysilane, to butanol and also to iodine.[7]

Hologens and interhalogen compounds are expected to form charge-transfer complexes (CT-complexes) with alkoxysilanes as well as alcohols,[6] and the present reactions have been assumed to proceed via four-centered transition states containing such CT-complexes as intermediates.

To confirm the formation of these CT-complexes, we have now made spectrophotometric studies of iodine and iodine monobromide solutions in various alkoxysilanes, and determined the formation constants of iodine complexes with ethoxytriethylsilane and with diethoxydimethylsilane. Based on the results obtained here and of the kinetic studies mentioned above, the reaction mechanism previously proposed has been confirmed.

Results and Discussion

Studies on Alkoxy-Alkoxy Exchange Equilibria of Alkoxysianes. The following two iodine-catalyzed alcoholysis and three iodine monobromide-catalyzed redistribution equilibria of alkylalkoxysilanes were examined at 20 °C, and the equilibrium constants K were evaluated from the equilibrium compositions determined by gas chromatographic analysis.

R=Et, R'=Pr^n (No. 4); R=Me, R'=Bu^n (No. 5)

In each of the Nos. 1, 2, and 3 reactions, equilibrium was approached from both directions. As for reaction No. 4 and 5, however, the following four processes were examined (A, B, C, and D-series).

A-series $R_2Si(OEt)_2+Et_3SiOR' \longrightarrow$
B-series $R_2Si(OEt)(OR')+Et_3SiOEt \longrightarrow$
C-series $R_2Si(OEt)(OR')+Et_3SiOR' \longrightarrow$
D-series $R_2Si(OR')_2+Et_3SiOEt \longrightarrow$

The results are summarized in Table 1.

Each reaction reached equilibrium within several hours at 20 °C without formation of any by-products, and equilibrium constants obtained from both directions agreed well with each other.

Catalytic Action of Iodine or Iodine Monobromide and of Conventional Catalysts. Various acids and bases have so far been used to promote alkoxy-alkoxy exchange reactions. As acid catalysts, *p*-toluenesulfonic acid[8,9] and others[10-14] are employed, while base catalysts such as sodium or sodium alkoxides[8,10,15-20] are most frequently utilized.

Catalyses of such acids and bases were examined by tracing the following reaction by means of gas-liquid partition chromatography (GLC). $Et_3SiOBu^n+Bu^sOH \rightleftarrows Et_3SiOBu^s+Bu^nOH$

Sodium exhibited little activity to this alcoholysis at ordinary temperature and reflux was required to cause the reaction to proceed.

A sample of one hour heating indicated little progress of the reaction, while a sample of thirty hours heating contained larger quantities of the products, along with fairly large amounts of impurities, especially the condensate $(Et_3Si)_2O$.

In general, acids promote alcoholysis more significantly than bases, but they also accelerate the condensation of alkoxysilanes markedly, if water coexists even slightly.[21,22] For example, *p*-toluenesulfonic acid (monohydrate) promoted the reaction appreciably at ordinary temperature, but a fair amount of condensed compound and other impurities were always formed. Trifluoroacetic acid[14] accelerated the reaction remarkably, but even in this case the concentration of the condensed compound increased with the lapse of time.

Halogen and interhalogen compounds such as iodine and iodine monobromide are favorable catalysts as mentioned above. Iodine monobromide is more active than iodine, and is well suited for promotion of the redistribution reactions and the alcoholyses associated with tertiary alcohols. Iodine is conveniently used in other alcoholyses.

Consequently, they are especially favorable catalysts for the quantitative work on the alkoxy-alkoxy exchange reactions of alkoxysilanes.

Absorption Spectra of Iodine or Iodine Monobromide Solutions in Alkoxysilanes or Disiloxanes. Since iodine and iodine monobromide exhibit excellent catalytic action in the present reactions, it is expected that specific interactions must occur between these catalysts and the alkoxysilanes.

Iodine and iodine monobromide appear to form CT-complexes with alkoxysilanes, and it can reasonably be assumed that these CT-complexes facilitate the reactions.

However little is known concerning the formation of such molecular complexes, except for the following spectroscopic study on the solvation of iodine. A solution of iodine in octamethylcyclotetrasiloxane $(Me_2SiO)_4$ is reddish violet, and the absorption maximum λ_{max} is observed at 518 nm. A solution in tetraethoxysilane is brown, having the λ_{max} at 475 nm.[23] This blue shift in the absorption spectrum may be attributed to the formation of a CT-complex in the latter solution.[28]

Iodine or iodine monobromide was dissolved in various alkoxysilanes and disiloxanes, and the λ_{max} values of these solutions were determined in order to see if CT-complexes were formed.

Table 1. Alcoholysis and Redistribution Equilibrium Constants of Alkylalkoxysilanes at 20 °C

Reaction system	Equilibrium constant

Absorption spectra of four disiloxane solutions of iodine were measured, and the absorption maxima were observed as follows.

$(Me_3Si)_2O$: 517—518 nm

$(Me_2EtSi)_2O$, $(MeEt_2Si)_2O$, $(Et_3Si)_2O$: 520 nm

The solutions are reddish violet and the λ_{max} values are around 520 nm similarly to the value in $(Me_2SiO)_4$ solution. A linear plot passing through the origin was always found between the absorbance at λ_{max} and iodine concentration in each solution, suggesting no interaction between iodine and disiloxane.

The λ_{max} in the visible region of the iodine or iodine monobromide spectrum in non-polar solvents is around 520 nm (I_2) or 490—500 nm (IBr). On the other hand, the λ_{max} values of alkoxysilane solutions were at 474—500 nm (I_2) or 425—455 nm (IBr), indicating blue shifts, and new peaks were also observed in the ultraviolet region. These results prove the formation of CT-complexes between iodine or iodine monobromide and alkoxysilanes.

The observed absorption maxima are given in Table 2.

In general, the peaks in the visible region are gently sloping, and some peaks are shifted a little with change of concentration.

Table 2. Wavelength of Absorption Peaks Observed on the Solutions of Iodine or Iodine Monobromide in Alkoxysilanes (λ_{max}/nm in ultraviolet and visible regions)

Alkoxysilane	λ_{max}/nm (I_2 solution)		λ_{max}/nm (IBr solution)	
	UV	Visible	UV	Visible
$Me_2Si(OEt)_2$	228	474	229	428
$Me_2Si(OEt)(Opr^n)$	243	474	244	428
$Me_2Si(OPr^n)_2$	233	478	238	428
$Me_2Si(OEt)(OBu^n)$	228	475	234	428
$Me_2Si(OBu^n)_2$	225	475	225	430
$Me_2Si(OEt)(OBu^s)$	230	482	223	430
$Me_2Si(OBu^s)_2$	237	492	218	436
$Me_2Si(OEt)(OBu^i)$	238	482	229	429

Et_3SiOBu^i	238	490	233	455

Formation Constants of Iodine-Ethoxytriethylsilane and Iodine-Diethoxydimethylsilane Complexes. As iodine-alkoxysilane complexes have absorption maxima at about 262 nm in carbon tetrachloride solutions, as shown in Fig. 1 and 2, the absorbances were measured at several wavelengths around the λ_{max} at about 22 °C.

Formation constants K_f were evaluated by employing the approximate equation developed by Ketelaar et al.[25]

$$C_I/(A-A_0) = 1/\{(\varepsilon_C-\varepsilon_I)K_f \cdot C_D\} + 1/(\varepsilon_C-\varepsilon_I)$$

where

A : Observed absorbance of the sample solution.
A_0 : Absorbance of I_2-CCl_4 solution.
C_I : Initial concentration of iodine.
C_D : Initial concentration of the alkoxysilane.
ε_C : Molar extinction coefficient of the complex.
ε_I : Molar extinction coefficient of iodine.

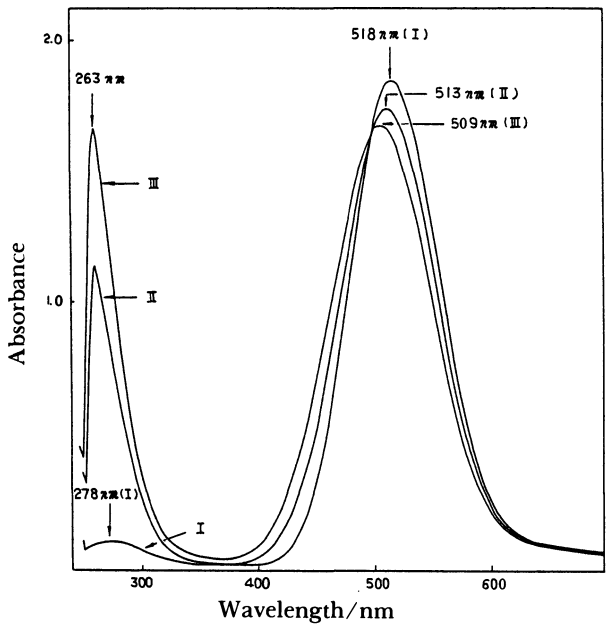

Fig. 1. The absorption spectra of the solutions I, II, III. I: iodine in carbon tetrachloride, II, III: ethoxytriethylsilane and iodine in carbon tetrachloride, $[I_2]=2\times10^{-3}$ mol dm^{-3}, $[Et_3SiOEt]=0.57$ (II), 1.01 (III) mol dm^{-3}.

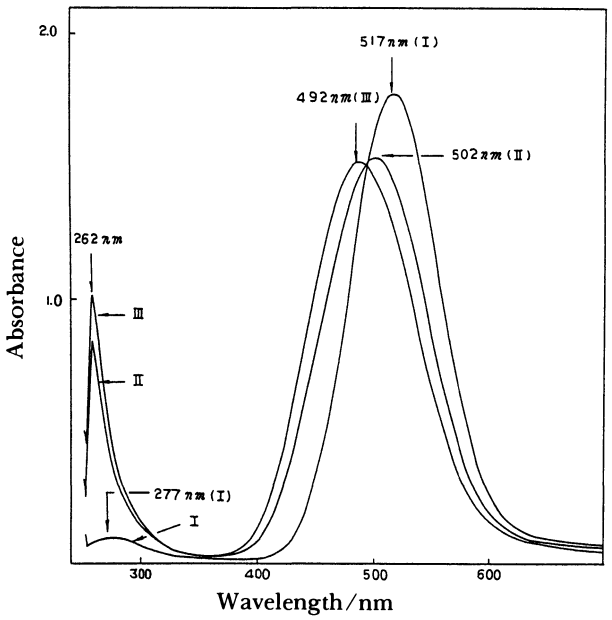

Fig. 2. The absorption spectra of the solutions I, II, III. I: iodine in carbon tetrachloride, II, III: diethoxydimethylsilane and iodine in carbon tetrachloride, $[I_2]=2\times10^{-3}$ mol dm^{-3}, $[Me_2Si(OEt)_2]=1.13$ (II), 2.10 (III) mol dm^{-3}.

This equation is derived with the approximation $C_D - C_C \fallingdotseq C_D$, as the complex concentration in which C_C is negligibly small compared to C_D under the operating conditions of $C_D \gg C_I$. The conditions of the present experiments satisfy the above approximation, because C_D/C_I is 50—200 (I_2-Et_3SiOEt-CCl_4 solutions) or 80—200 (I_2-$Me_2Si(OEt)_2$-CCl_4 solutions).

Typical examples of the results are illustrated in Fig. 3, and the formation constant of each complex was evaluated as follows.

K_f=0.55±0.01

(I_2-Et_3SiOEt complex in CCl_4 solutions).

K_f=0.61±0.02

(I_2-$Me_2Si(OEt)_2$ complex in CCl_4 solutions).

These are intermediate values between K_f=0.92 (20 °C) of iodine-ethanol complex in heptane solution[6] and K_f=0.176 (25 °C) of iodine-benzene complex in carbon tetrachloride solution.[26]

An alkoxysilane acts as a n-donor toward iodine, but the stability of this CT-complex seems to be lower than the iodine-ethanol complex, because of the smaller polarity of alkoxysilane than that of ethanol. This complex appears to be more stable than the iodine complex of benzene which is a π-donor. Consequently, the formation constants observed here may be regarded as reasonable.

Reconsideration of the Reaction Mechanism

The catalytic action of iodine or iodine monobromide was interpreted by a mechanism which involves a four-centered transition state containing a catalyst-alkoxysilane or alcohol CT-complex as an intermediate, as previously proposed.[1,2]

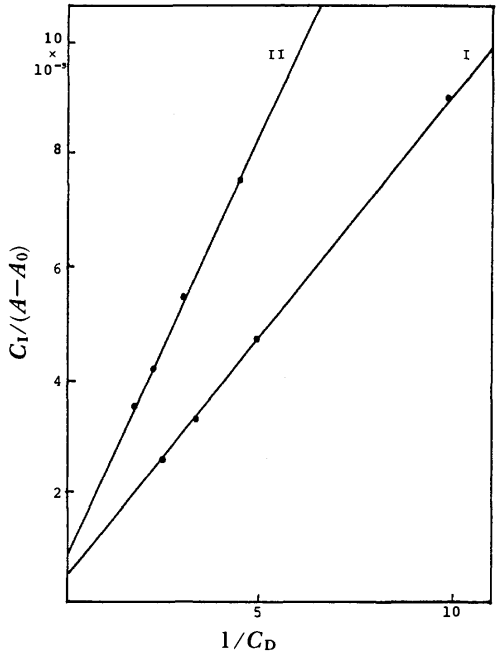

Fig. 3. Application to the Ketelaar's equation. Typical examples of plots of $C_I/(A-A_0)$ vs. $1/C_D$. I: I_2-Et_3SiOEt complex K_f=0.55, II: I_2-$Me_2Si(OEt)_2$ complex K_f=0.61.

Based on the results of the present spectroscopic work and the previously reported kinetic study on the alcoholysis,[7] together with the extensive work on the alkoxy-alkoxy exchange equilibria,[1,2] this mechanism is considered afresh.

Iodine and iodine monobromide promote both the alcoholysis and redistribution reaction of alkoxysilanes, with the latter catalyst being the more active. Therefore, it is proposed that in such a mechanism iodine and iodine monobromide promote both reactions in a similar manner, unlike the conventional mechanisms of base- or acid-catalyzed alcoholyses which can not apply to the redistribution reactions.

The mechanism should also satisfy the following requirements together with the above essential need.

(a) Iodine monobromide is more active than iodine.

(b) Alcoholyses proceed more rapidly than redistribution reactions in the presence of these catalysts.

(c) The reaction would be a bimolecular process, because the reaction is first order in both components at a constant catalyst concentration.

(d) The mechanism must proceed by a pathway via the transition state containing a catalyst molecule, as the reaction rate is first order with respect to the catalyst.

(e) The transition state should be of ionic character, because the rate constants of the alcoholysis increase with increasing alcohol contents, that is, with increasing polarity of the reaction mixture.

(f) The polarized transition state is also inferred from the large lowering of the activation entropy.

(g) Since alcohols as well as alkoxysilanes can form CT-complexes with iodine or iodine monobromide, such complexes should be used to form the transition state.

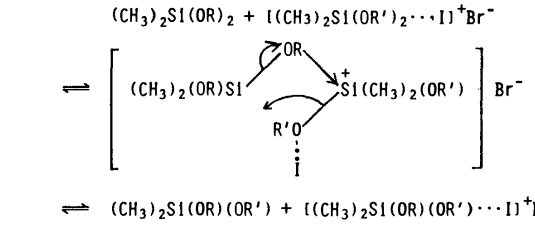
In regard to redistribution reactions among alkoxysilanes, no mechanism has been reported, but some mechanisms concerning the reactions with alkylsilanes or halosilanes or the like are reported in the literature. A mechanism involving a four-centered transition state has been proposed by Russell for the disproportionation of ethyltrimethylsilane catalyzed by aluminum bromide.[27] He concluded such a transition state with ionic character to be most favorable, based on arguments against other proposals. The present alcoholyses and redistribution reactions seem to be favorably interpreted by a mechanism analogous to this.

Iodine and iodine monobromide form charge-transfer complexes with alkoxysilanes as described above. A CT-complex is usually represented as a resonance hybrid of a no-bond form and a dative bond form. The dative bond forms of iodine or iodine monobromide-alkoxysilanes are regarded as $[(C_2H_5)_3SiOR\cdots I]^+I^-$ and $[(CH_3)_2Si(OR)_2\cdots I]^+ Br^-$, etc.

Since these CT-complexes are apparently of ionic character, and the silicon-alkoxy bond is considerably polar compared with the silicon-alkyl bond, the reaction systems involving alkoxysilanes can be shifted more smoothly.

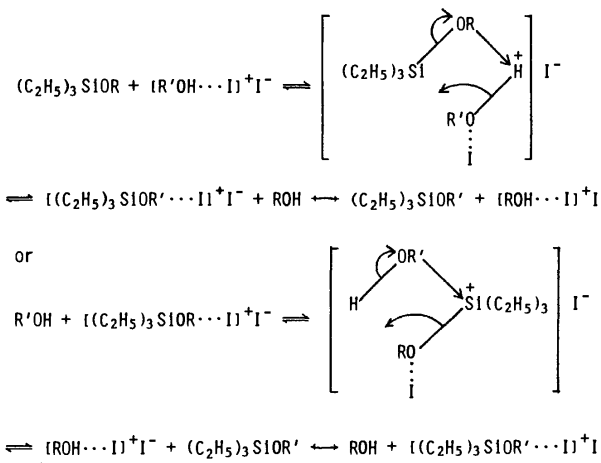
The formation of such transition states will be followed by cleavage of a Si–O bond and not of a C–O bond, in a similar manner to the case of the acid-catalyzed redistribution between optically active di-*s*-butoxydimethylsilane and diethoxydimethylsilane.[9]

The following reaction mechanism may be satisfactorily assumed for the iodine monobromide-catalyzed redistribution reactions among dialkoxydimethylsilanes.



Iodine appears to form a complex with ethanol more readily than with alkoxysilanes, since the formation constants K_f of the iodine-ethanol complex in heptane solution is 0.92 (24 °C),[6] while the observed K_f values of iodine-ethoxytriethylsilane and -diethoxydimethylsilane complexes are 0.55 and 0.61, respectively. In addition, alkoxysilane-alcohol complexing has also been suggested.[28]

Consequently, the four-centered transition state can be more favorably realized in the alcoholysis of alkoxysilanes than in the redistribution reaction. Thus the reaction mechanism of the alcoholysis of alkoxytriethylsilane can be proposed as follows.



The redistribution reaction as well as the alcoholysis can be satisfactorily interpreted by an identical reaction mechanism involving a four-centered transition state, which meets the requirements as described above.

Experimental

Reagents. Ethoxytriethylsilane, diethoxydiethylsilane, triethoxyethylsilane, and ethoxytrimethylsilane were prepared by the reactions of tetraethoxysilane with ethyl- or methylmagnesium bromide.

Diethoxydimethylsilane was prepared by the reaction of octamethylcyclotetrasiloxane with tetraethoxysilane in the presence of potassium hydroxide.[29]

Other alkoxytriethylsilanes, dialkoxydiethylsilanes and dialkoxydimethylsilanes were prepared by iodine-catalyzed alcoholysis of the above ethoxysilanes.

Four disiloxanes used for the spectroscopic work were synthesized by condensation of the corresponding trialkylethoxysilanes.

The crude products were purified by repeated fractional distillation at atmospheric or reduced pressure.

Alcohols, iodine and iodine monobromide were purified by methods similar to those previously reported.[1,2]

Analysis. Analyses of the reaction mixtures were performed by GLC using a Shimadzu model GC-4B gas chromatograph with a thermal conductivity detector. The stationary phases of the packings used in these GLC analyses were PEG 1000 (Reaction No. 1, Table 1), PEG 4000 (Nos. 2 and 3), PEG 6000 (No. 4) and Shinchrom E-71 (No. 5). PEG 6000 was also employed in examining the catalytic actions of the conventional catalysts.

General Procedure. The equilibrium constants of the various exchange reactions were determined by methods similar to those previously reported.[1,2] The compositions of the reaction mixtures were as follows.

Nos. 1, 2 [Alkoxysilane]: [Alcohol]≒1 : 3—6; [I_2]<0.1 mol%
No. 3 [$Me_2Si(OEt)_2$]: [$Me_2Si(OPr^n)_2$]: [C_6H_{14}]≒1 : 1 : 16; [$Me_2Si(OEt)(OPr^n)$]: [C_6H_{14}]≒2 : 16; [IBr]=0.03—0.4 mol%
Nos. 4, 5 [dialkoxydialkylsilane]: [Alkoxytriethylsilane] ≒1 : 1 or 1 : 2; [IBr]=0.3—1 mol%

The compositions of the reaction mixtures used in examining the catalytic actions of the conventional catalysts were approximately as follows. Et_3SiOBu: 0.013 mol; BuOH: 0.05 mol; Na: 0.01 mol, or acids: 10^{-3}—10^{-4} mol.

Spectrophotometric Measurements. The absorption spectra were measured with a Shimadzu model UV-200 double-beam spectrophotometer, using stoppered silica cells with a path length of 10 mm at 20—22 °C.

The compositions of the sample solutions for determining the formation constants of CT-complexes were as follows.

I_2–Et_3SiOEt–CCl_4 solutions
C_I (Iodine concentration)≒2×10^{-3} mol dm^{-3}
C_D (Alkoxysilane concentration)≒0.1, 0.2, 0.3, 0.4 mol dm^{-3}

I_2–$Me_2Si(OEt)_2$–CCl_4 solutions
C_I≒2.8×10^{-3} mol dm^{-3}
C_D≒0.22, 0.34, 0.45, 0.56 mol dm^{-3}

A Novel Synthesis of (±)-Prostaglandin B_1 Methyl Ester

Hirokazu NAORA,* Takashi OHNUKI, and Asao NAKAMURA
Applied Research Dept., Central Laboratories, Ajinomoto Co., Inc., 1-1, Suzuki-cho, Kawasaki, Kanagawa 210
(Received January 8, 1988)

Five simple preparative methods of (±)-prostaglandin B_1 (PGB_1) methyl ester are described. All routes were started from a common intermediate, 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoic acid derived from cyclooctanone via two steps. The key reaction of these routes is a palladium-catalyzed vinylation. The methods provided other PGB_1 congeners and are applicable to synthesize 11-functionalized PG systems.

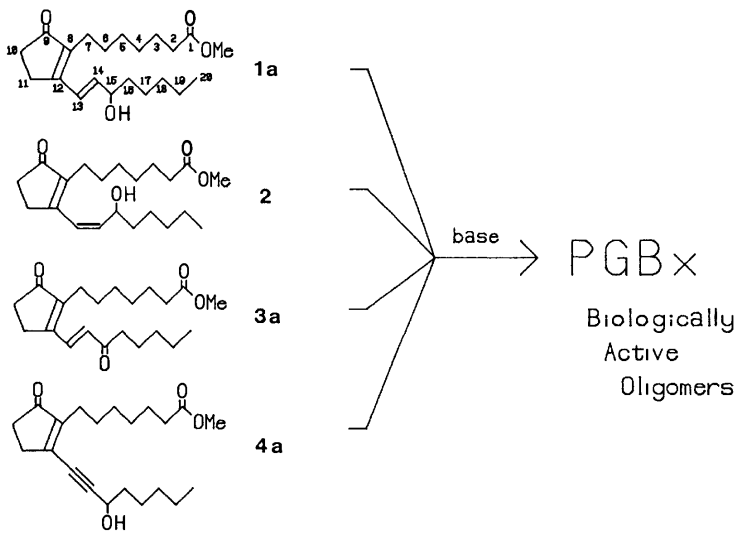
PGB_x[1] is an oligomeric mixture of prostaglandin B series, and has unique biological activities which are quite different from the ordinary prostaglandin activities. For example, it conserves oxidative phosphorylation in rat liver mitochondria in vitro and reverses the damaging effect of experimentally induced ischemia in heart and brain of monkey and dog in vivo.[1] 15-DehydroPGB_1 methyl ester (**3a**) is usually used as a monomer for the synthesis of PGB_x. Instead of **3a**, PGB_1 methyl ester (**1a**), 13, 14-cisPGB_1 methyl ester (**2**), and 13,14-dehydroPGB_1 methyl ester (**4a**) can also be used (Scheme 1). To elucidate structures and biological activities of the oligomers, it is necessary to prepare various PGB_x from some closely related monomers. Although the total syntheses of PGB_1 or its equivalents have already been known,[2-4] multi-step reactions and severe conditions are required in most of the cases. For the study of new biologically active features of PGB_x, it is important to develop a novel synthetic method by which enough amount of PGB_1 and the starting materials for PGB_x can be obtained in a few steps and in simple procedures.

As the preliminary investigation of a new short synthetic sequence to prepare (±)-PGB_1 methyl ester and its related compounds, we have already reported synthesis of 15-dehydroPGB_1 methyl ester (**3a**) via four steps.[5] We have also reported the synthetic methods to obtain the key intermediate **7** from commercially available cyclooctanone via two steps and to derive other synthons for prostaglandins from **7** (Scheme 2).[6]

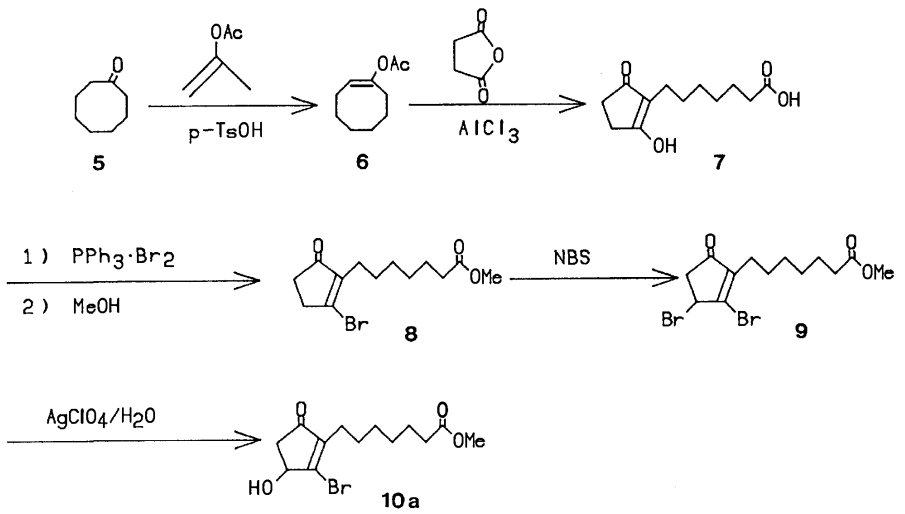
In this report, we describe the facile synthetic method to form a sort of PGB_1 methyl esters from the key intermediate **8** and its application to a 11-functionalized PG analogue in detail (Schemes 3 and 4).

The ω-chain moieties of PGB_1 methyl esters were successfully introduced to the synthetic intermediates **8** by applying the palladium-catalyzed vinylation reaction.[7] Coupling reaction of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**8**) with (±)-3-(*t*-butyldimethylsiloxy)-1-octene (**12b**) gave (±)-methyl 15-(*t*-butyldimethylsiloxy)-9-oxoprost-8(12),13-dienoate {(±)-15-(*t*-butyldimethylsiloxy)PGB_1 methyl ester} (**1b**) in a 92% yield. The reaction was catalyzed by a few molar percent of the mixture of palladium diacetate and triphenylphosphine (1: 2 mole ratio). Triethylamine was also added for trapping hydrogen bromide. Desilylation of **1b** with tetrabutylammonium fluoride gave (±)-PGB_1 methyl ester (**1a**) in a 96% yield.

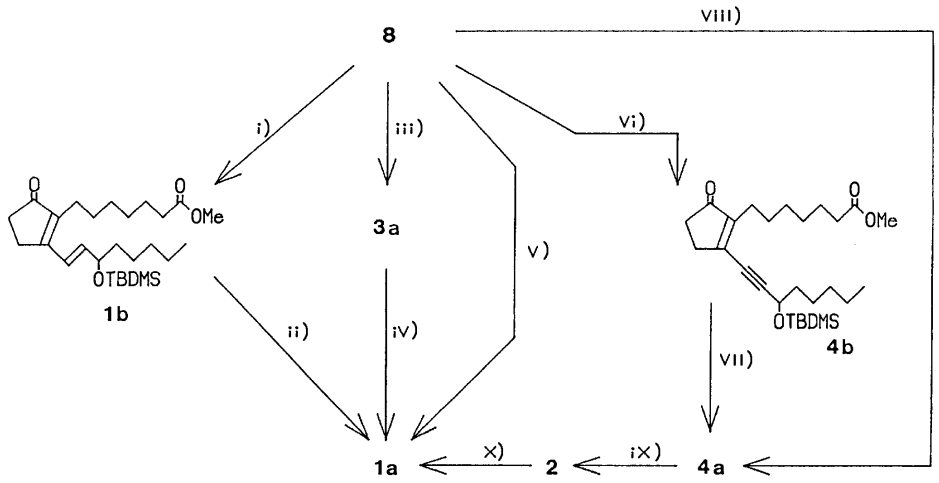
Coupling reaction of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**8**) with 1-octen-3-one (**12c**) gave 15-dehydroPGB_1 methyl ester (**3a**) in an 80% yield



Scheme 1.



Scheme 2.



Scheme. 3. i)[a] (±)-3-(*t*-Butyldimethylsiloxy)-1-octene (**12b**). ii) Bu_4NF/THF. iii)[a] 1-Octen-3-one (**12c**). iv) $NaBH_4/CH_3OH$. v)[a] (±)-1-Octen-3-ol (**12a**). vi)[a] (±)-3-(*t*-Butyldimethylsiloxy)-1-octyne (**13b**). vii) Bu_4NF/THF. viii)[a] (±)-1-Octyn-3-ol (**13a**). ix) H_2, Lindlar catalyst/CH_3CH_2OH. x) I_2/C_6H_{12}, $CHCl_3$. a) $Pd(OAc)_2 \cdot 2PPh_3$ and Et_3N were used.

and 15-dehydro-13,14-dihydroPGB$_1$ methyl ester (**3b**) as a by-product in a 3% yield. Compound **3a** was easily converted to **1a** by the reduction with sodium borohydride in a 78% yield.

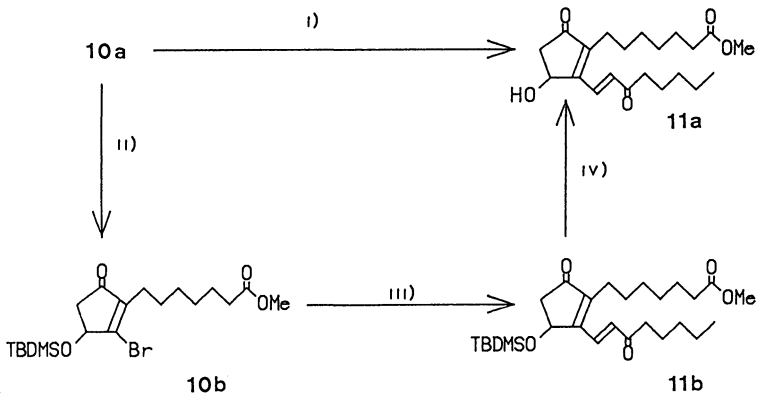
(±)-PGB$_1$ methyl ester (**1a**) could be obtained by the coupling reaction of **8** and (±)-1-octen-3-ol (**12a**) directly in a 42% yield. Under the reaction conditions, the double-bond isomer [15-dehydro-13,14-dihydro-PGB$_1$ methyl ester (**3b**)] and the oxidized compound [15-dehydroPGB$_1$ methyl ester (**3a**)] were obtained in 24 and 11% yields, respectively.

(±)-Methyl 15-(*t*-butyldimethylsiloxy)-9-oxoprost-8(12)-en-13-ynoate {(±)-15-(*t*-butyldimethylsiloxy)-13,14-dehydroPGB$_1$ methyl ester} (**4b**) was obtained from methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**8**) and (±)-3-(*t*-butyldimethylsiloxy)-1-octyne (**13b**) in a 50% yield (69% based on the consumed **8**). Desilylation of **4b** with tetrabutylammonium fluoride gave (±)-13,14-dehydroPGB$_1$ methyl ester (**4a**) in a 97% yield.

(±)-13,14-DehydroPGB$_1$ methyl ester (**4a**) was also obtained directly from **8** and (±)-1-octyn-3-ol (**13a**) in a 33% yield. In this case, 15-dehydroPGB$_1$ methyl ester (**3a**) was obtained in a 10% yield. The α,β-enone **3a** is an isomer of the β,γ-ynol **4a**.

Hydrogenolysis of (±)-13,14-dehydroPGB$_1$ methyl ester (**4a**) over Lindlar catalyst gave (±)-13,14-cisPGB$_1$ methyl ester (**2**) in an 89% yield. Any other isomeric compounds, such as (±)-8,12-dihydro-, (±)-13,14-dihydro-, and (±)-13,14-transPGB$_1$ methyl ester, were not detected in this reaction.

Double-bond isomerization of **2** was achieved with iodine in a 98% yield. That is, (±)-13,14-cisPGB$_1$ methyl ester (**2**) was converted to (±)-PGB$_1$ methyl



Scheme. 4. i)[a] 1-Octen-3-one (**12c**). ii) TBDMSCl, Et_3N, DMAP/CH_2Cl_2. iii)[a] 1-Octen-3-one (**12c**). iv) Bu_4NF/THF. a) $Pd(OAc)_2 \cdot 2PPh_3$ and Et_3N were used.

ester (**1a**) by treating with iodine in dark at 40 °C for 13 h. In this case, equilibrium was completely inclined to the trans isomer.

The synthetic strategy described above was also extended to the 11-functionalized PG systems (Scheme 4).

Reaction of (±)-methyl 7-(2-bromo-3-hydroxy-5-oxo-1-cyclopentenyl)heptanoate (**10a**) with 1-octen-3-one (**12c**) gave directly (±)-15-dehydro-11-hydroxyPGB_1 methyl ester (**11a**) in a 15% yield. Reaction of (±)-methyl 7-[2-bromo-3-(*t*-butyldimethylsiloxy)-5-oxo-1-cyclopentenyl]heptanoate (**10b**), which was derived from **10a**, and 1-octen-3-one (**12c**) gave (±)-11-(*t*-butyldimethylsiloxy)-15-dehydroPGB_1 methyl ester (**11b**) in a 76% yield. Desilylation of **11b** with tetrabutylammonium fluoride gave (±)-15-dehydro-11-hydroxy-PGB_1 methyl ester (**11a**) in a 49% yield.

Experimental

Instrumentation. The ^1H NMR spectra were measured with a Varian EM-390 (90 MHz) spectrometer. The chemical shifts are expressed in parts per million (ppm) (δ) downfield from tetramethylsilane. The infrared spectra were obtained using a JASCO IR-810 Spectrometer. The low-resolution mass spectra (MS) and the high-resolution mass spectra (HRMS) were determined on a JEOL D-300 Mass Spectrometer. The boiling points are uncorrected.

Materials and Substances. 1-Octen-3-one (**12c**)[8] was obtained from (±)-1-octen-3-ol (**12a**) by the Jones' oxidation. (±)-3-(*t*-Butyldimethylsiloxy)-1-octene (**12b**)[9] and (±)-3-(*t*-butyldimethylsiloxy)-1-octyne (**13b**)[10] were obtained from (±)-1-octen-3-ol (**12a**) and (±)-1-octyn-3-ol (**13a**), respectively with *t*-butylchlorodimethylsilane. Solvents were dried over Zeolite A-3 or A-4 when necessary.

(±)-15-(*t*-Butyldimethylsiloxy)PGB_1 Methyl Ester (1b). A mixture of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate [**8**; 119.5 mg (0.39 mmol)], (±)-3-(*t*-butyldimethylsiloxy)-1-octene [**12b**; 158.3 mg (0.65 mmol)], and triethylamine [72.0 mg (0.71 mmol)] with 8.5 mg of the palladium catalyst (a mixture of palladium diacetate and triphenylphosphine; 1 : 2 mole ratio) was heated to 100 °C in a reaction tube under Ar for 24 h. The reaction mixture was dissolved in 3 ml of ether and insoluble components were filtered off. After evaporation, the reaction mixture was separated by a medium-pressure silica-gel column chromatography (LiChroprep Si 60), and 167. 2 mg (92.0%) of **1b** was obtained. Starting material **8** (3.9 mg: 1.3%) was also recovered.

1b: ^1H NMR ($CDCl_3$) δ=6.69 (d, J=15 Hz, 1H), 6.13 (dd, J=15, 5.4 Hz, 1H), 4.25 (m, 1H), 3.55 (s, 3H), 2.1—2.7 (m, 8H), 1.15—1.75 (m, 16H), 0.90 (s, 9H), 0.75—1.0 (m, 3H), 0.06 (s, 3H) and 0.03 (s, 3H); IR (film) 2930, 2860, 1740, 1695, and 1640 cm^{-1}; Found: m/z 464.3340. Calcd for $C_{27}H_{48}O_4Si$: M, 464.3323.

15-DehydroPGB$_1$ Methyl Ester (3a).[2] A mixture of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate [**8**; 146.3 mg (0.48 mmol)], 1-octen-3-one [**12c**; 142.7 mg (1.15 mmol)], and triethylamine [156.4 mg (1.55 mmol)] with 5.6 mg of the palladium catalyst was heated to 100 °C in a reaction tube under Ar for 24 h. The reaction mixture was dissolved in 3 ml of ether and insoluble components were filtered off. After evaporation, separation with medium-pressure silica-gel column chromatography (LiChroprep Si 60) gave 133.0 mg (79.6%) of **3a** and 4.9 mg (2.6%) of 15-dehydro-13,14-dihydroPGB_1 methyl ester (**3b**).[3] Starting material **8** (9.8 mg: 6.7%) was also recovered.

3a: ^1H NMR ($CDCl_3$) δ=7.51 (d, J=16.5 Hz, 1H), 6.45 (d, J=16.5 Hz, 1H), 3.60 (s, 3H), 2.15—2.75 (m, 10H), 1.2—1.9 (m, 14H), and 0.90 (t, J=6 Hz, 3H); IR (film) 2930, 2850, 1735, 1705, and 1630 cm^{-1}.

3b: ^1H NMR ($CDCl_3$) δ=3.67 (s, 3H), 2.05—2.75 (m, 14H), 1.1—1.8 (m, 14H), and 0.89 (t, J=6.6 Hz, 3H); IR (film) 2930, 2860, 1740, 1720, 1700, and 1640 cm^{-1}.

(±)-15-(*t*-Butyldimethylsiloxy)-13,14-dehydroPGB_1 Methyl Ester (4b). A mixture of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate [**8**; 304.7 mg (1.01 mmol)], (±)-3-(*t*-butyldimethylsiloxy)-1-octyne [**13b**; 264.2 mg (1.10 mmol)], and triethylamine [106.7 mg, (1.06 mmol)] with 37.5 mg of the palladium catalyst was heated to 100 °C in a reaction tube under Ar for 23 h. Ether (3 ml) was added and filtrated. By medium-pressure silica-gel column chromatography (LiChroprep Si 60), 230.1 mg (49.5%) of **4b** was afforded. Compound **8** (88.0 mg: 28.9%) was recovered.

4b: Bp 122 °C/0.15 mmHg (1 mmHg=133.322 Pa); ^1H NMR ($CDCl_3$) δ=4.5 (t, J=6 Hz, 1H), 3.6 (s, 3H), 2.2—2.6 (m, 8H), 1.2—1.9 (m, 16H), 0.93 (s, 9H), 0.8—0.95 (m, 3H), and

0.16 (s, 6H); IR (film) 2950, 2930, 2860, 1740, 1705, and 1615 cm^{-1}; Found: C, 69.97; H, 10.04%. Calcd for $C_{27}H_{46}O_4Si$: C, 70.08; H, 10.02%.

(±)-13,14-DehydroPGB$_1$ Methyl Ester (4a).[2,4] a) To a solution of 0.37 g (0.80 mmol) of **4b** in 20 ml of THF was added 2 ml of 1 M (1 M=1 mol dm^{-3}) tetrabutylammonium fluoride in THF. The reaction mixture was stirred at room temperature for 2 h. To the resultant mixture was added 20 ml of ether. The ethereal layer was washed with equal volumes of water twice and brine, dried over anhydrous magnesium sulfate. After medium-pressure silica-gel column chromatography (LiChroprep Si 60), 0.27 g (97%) of (±)-13,14-dehydroPGB$_1$ methyl ester (**4a**) was obtained.

b) A mixture of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)-heptanoate [**8**; 62.0 mg (0.20 mmol)], (±)-1-octyn-3-ol [**13a**; 39.9 mg (0.32 mmol)], and triethylamine [26.0 mg (0.26 mmol)] with 2.0 mg of palladium diacetate and 4.6 mg of triphenylphosphine was heated to 100 °C in a reaction tube under Ar for 5 h. Ether (3 ml) was added and filtrated. Separation with medium-pressure silica-gel column chromatography (LiChroprep Si 60) gave 23.5 mg (33.0%) of **4a** and 7.0 mg (10%) of 15-dehydroPGB$_1$ methyl ester (**3a**). Starting material **8** (1.9 mg: 3%) was also recovered.

4a: ^{1}H NMR ($CDCl_3$) δ=4.6 (t, J=6 Hz, 1H), 3.6 (s, 3H), 2.2—2.8 (m, 8H), 1.2—1.9 (m, 16H), and 0.9 (t, J=6 Hz, 3H); IR (film) 3400, 1735, 1700, 1600, 1435, and 1360 cm^{-1}.

(±)-13,14-cisPGB$_1$ Methyl Ester (2).[2,4] Hydrogenolysis of 0.50 g (1.4 mmol) of (±)-13,14-dehydroPGB$_1$ methyl ester (**4a**) was achieved over Lindlar catalyst[11] in ethanol under atmospheric pressure. The reaction mixture was filtered and after removal of ethanol, ether (30 ml) was added. The resultant solution was washed with 20 ml of 0.1 M HCl three times, 20 ml of water three times and brine, and dried. Removal of solvents gave 0.45 g (89%) of (±)-13,14-cisPGB$_1$ methyl ester (**2**).

2: ^{1}H NMR ($CDCl_3$) δ=6.38 (d, J=12 Hz, 1H), 5.75 (dd, J=12, 9 Hz, 1H), 4.6 (m, 1H), 3.6 (s, 3H), 2.6—2.85 (m, 2H), 2.1—2.5 (m, 6H), 1.2—1.8 (m, 16H), and 0.9 (t, J=6 Hz, 3H); IR (film) 3400, 1730, 1690, 1620, 1585, 1330, and 1260 cm^{-1}.

(±)-PGB$_1$ Methyl Ester (1a).[2-4] a) To a solution of 142.0 mg of **1b** in 20 ml of THF and 2 ml of water was added 1 ml of 1 M tetrabutylammonium fluoride/THF solution. The reaction mixture was stirred at room temperature for 7 days and poured into 30 ml of water. The reaction mixture was extracted with 100 ml and then 50 ml of ether. Combined organic layer was washed with 50 ml of water twice and dried. After evaporation, the mixture was separated with medium-pressure silica-gel column chromatography, and 102.7 mg (95.9%) of (±)-PGB$_1$ methyl ester (**1a**) was obtained.

b) A solution of 20 mg of sodium borohydride in dry methanol (2 ml) was added dropwise at 0 °C to a solution of 98.1 mg (0.28 mmol) of 15-dehydroPGB$_1$ methyl ester (**3a**) in methanol (3 ml). After stirring for 15 min at 0 °C, 0.5 ml of acetone was added. The reaction mixture was poured into 5 ml of water and extracted with 5 ml of ether three times. Combined ethereal layer was washed with equal volumes of water three times and brine, and dried. After evaporation, separation with medium-pressure silica-gel column chromatography (LiChroprep Si 60) gave 76.2 mg (78%) of (±)-PGB$_1$ methyl ester (**1a**).

c) A mixture of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate [**8**; 83.3 mg (0.28 mmol)], (±)-1-octen-3-ol [**12a**; 47.3 mg (0.37 mmol)], and triethylamine [42.1 mg (0.42 mmol)] with 1.4 mg of palladium diacetate and 3.6 mg of triphenylphosphine was heated to 100°C in a reaction tube under Ar for 22 h. Ether (3 ml) was added and filtrated. The reaction mixture was separated with medium-pressure silica-gel column chromatography (LiChroprep Si 60), and 40.1 mg (41.7%) of **1a**, 10.3 mg (10.8%) of 15-dehydroPGB$_1$ methyl ester (**3a**), and 22.6 mg (23.5%) of 15-dehydro-13,14-dihydroPGB$_1$ methyl ester (**3b**) were obtained. Starting material **8** (12.0 mg: 14.4%) was also recovered.

d) To a solution of 0.42 g (1.2 mmol) of (±)-13,14-cisPGB$_1$ methyl ester (**2**) in 2 ml of a solvent (cyclohexane: chloroform=20: 1) was added 2 ml of iodine solution (0.5% w/v in the solvent described above) and allowed to stand in dark at 40 °C for 13 h. The reaction mixture was diluted with 20 ml of ether and washed with 10 ml of sodium thiosulfate three times and brine, and dried. Removal of solvents gave 0.41 g (98%) of (±)-PGB$_1$ methyl ester (**1a**).

1a: ^{1}H NMR ($CDCl_3$) δ=6.73 (d, J=16 Hz, 1H), 6.20 (dd, J=16.6 Hz, 1H), 4.3 (m, 1H), 3.6 (s, 3H), 2.5—2.7 (m, 2H), 2.2—2.5 (m, 6H), 1.2—1.7 (m, 16H), and 0.9 (t, J=6 Hz, 3H); IR (film) 3450, 1735, 1690, 1635, 1590, and 1370 cm^{-1}.

(±)-11-(*t*-Butyldimethylsiloxy)-15-dehydroPGB$_1$ Methyl Ester (11b). (±)-Methyl 7-(2-bromo-3-hydroxy-5-oxo-1-cyclopentenyl)heptanoate [**10a**: 0.50 g (1.6 mmol)] was silylated in dichloromethane by *t*-butylchlorodimethylsilane [0.69 g (4.6 mmol)] with triethylamine [0.51 g (5.1 mmol)] and 4-(dimethylamino)pyridine [40 mg (0.33 mmol)] to give (±)-methyl 7-[2-bromo-3-(*t*-butyldimethylsiloxy)-5-oxo-1-cyclopentenyl]heptanoate [**10b**; 0.62 g (91%)]; ^{1}H NMR ($CDCl_3$) δ=4.63 (dd, J=6, 3 Hz, 1H), 3.49 (s, 3H), 2.70 (dd, J=16.5, 6 Hz, 1H), 2.0—2.4 (m, 5H), 1.2—1.8 (m, 8H), 0.8 (s, 9H), 0.1 (s, 3H), and 0.06 (s, 3H); IR (film) 2950, 2940, 2860, 1740, 1720, and 1635 cm^{-1}; Found: m/z 377.0604, 375.0674. Calcd for $C_{15}H_{24}O_4BrSi$: M−C_4H_9, 377.0606, 375.0720. A mixture of (±)-methyl 7-[2-bromo-3-(*t*-butyldimethylsiloxy)-5-oxo-1-cyclopentenyl]heptanoate [**10b**; 439.6 mg (1.01 mmol)], 1-octen-3-one [**12c**; 143.6 mg (1.14 mmol)], and triethylamine [124.2 mg (1.23 mmol)] with 15.8 mg of the palladium catalyst was heated to 100 °C in a reaction tube under Ar for 80 h. Ether (3 ml) was added and filtrated. Separation by medium-pressure silica-gel column chromatography (LiChroprep Si 60) gave 370.0 mg (76.2%) of **11b**; ^{1}H NMR ($CDCl_3$) δ=7.45 (d, J=16.5 Hz, 1H), 6.78 (d, J=16.5 Hz, 1H), 5.11 (dd, J=3, 6 Hz, 1H), 3.71 (s, 3H), 2.0—2.9 (m, 8H), 1.2—1.9 (m, 14H), 1.0 (s, 9H), 0.9—1.1 (m), 0.33 (s, 3H), and 0.27 (s, 3H); IR (film) 2940, 2860, 1740, 1705, 1675, and 1590 cm^{-1}; MS m/z 478 (M^+), 447 (M−MeO), 421 (M−Bu+H), 389 (M−Bu−MeO); Found m/z 478.3132. Calcd for $C_{27}H_{46}O_5Si$: M, 478.3114.

(±)-15-Dehydro-11-hydroxyPGB$_1$ Methyl Ester (11a).[3] a) A mixture of (±)-methyl 7-(2-bromo-3-hydroxy-5-oxo-1-cyclopentenyl)heptanoate [**10a**; 75.8 mg (0.32 mmol)], (±)-1-octen-3-ol [**12a**; 42.4 mg (0.34 mmol)], and triethylamine [43.4 mg (0.43 mmol)] with 2.4 mg of the palladium catalyst was heated to 100 °C in a reaction tube under Ar for 48 h. Ether (3 ml) was added and filtrated. After purification with medium-pressure silica-gel column chromatography (LiChroprep Si 60), 13.2 mg (15.3%) of **11a** was obtained; ^{1}H NMR ($CDCl_3$) δ=7.39 (d, J=15 Hz, 1H), 6.89 (d, J=15 Hz, 1H), 5.05 (m, 1H), 3.60 (s, 3H), 2.15—3.0 (m, 8H), 1.1—1.9 (m, 14H), and 0.9 (t, J=6 Hz, 3H); IR (film) 3450, 2930, 2860, 1740, 1705, and 1590 cm^{-1}; MS m/z 364 (M^+), 346 (M−H_2O), 314 (M−H_2O−MeOH); Found: m/z 364.2239. Calcd for

$C_{21}H_{32}O_5$: M, 364.2247.

b) To a solution of 20.4 mg of (±)-11-(*t*-butyldimethylsiloxy)-15-dehydroPGB$_1$ methyl ester (**11b**) in 3 ml of THF was added 0.06 ml of 1 M tetrabutylammonium fluoride/THF solution, and the mixture was stirred at room temperature for 10 min. To the resultant mixture was added 10 ml of ether and water. The organic layer was washed with equal volumes of water and brine, and dried. After removal of solvents, silica-gel column chromatography gave 7.6 mg (50%) of (±)-15-dehydro-11-hydroxyPGB$_1$ methyl ester (**11a**).

Direct Synthesis of Ethylene Glycol from Carbon Monoxide and Hydrogen by Use of Rhodium Catalyst. The Effect of Amine Promoters and Their Roles

Takashi MASUDA,* Kazuhisa MURATA, and Akio MATSUDA
National Chemical Laboratory for Industry, Higashi, Tsukuba, Ibaraki 305
(Received January 23, 1988)

The influence of addition of amines on the direct synthesis of ethylene glycol (EG) has been investigated using a rhodium catalyst under a high pressure (1800 kg cm^{-2}). The addition of amines improved the catalyst activity and selectivity for the EG formation and the stability of the catalyst. The addition of amines further resulted in glycerol (GL) formation. Optimum amine/rhodium ratios for the EG formation were 50—100 in tetrahydrofuran solvent with a low polarity and 1—3 in γ-butyrolactone solvent with a high polarity. Optimum N/Rh ratios and IR spectra of reaction solutions suggested that amine promoters serve to accelerate the formation of mononuclear Rh species from the catalyst precursor. It was also suggested that amines promote formation of a Rh-CH_2OH complex and insertion of CO. Bulky amines such as triisobutylamine, *N*-ethylcarbazole, triisopropanolamine, and tribenzylamine were especially effective promoters for the formation of EG and GL. The effectiveness of bulky amines as the promoter is discussed.

Attention is focused on the direct synthesis of ethylene glycol (EG) as one of researches on the synthesis of useful chemicals from synthesis gas.[1] Researchers of Union Carbide discovered that rhodium compounds are useful as catalyst precursors for the EG direct synthesis. Further, they have so far made many proposals on promoters for improving the activity and selectivity of Rh catalysts for the EG formation.[1] Amine is one of such promoters. Amines promote the formation of anionic rhodium complex as proton bases.[1b] Rhodium cluster anion has been postulated to be the catalyst or its immediate precursor for the EG formation.[1b] Kaplan[2] has proposed that ion pairing between rhodium complex anions and counterions, R_3NH^+, has an adverse effect on the catalytic activity for the EG formation. However, details on the role of amine promoters are still left unclear. Deluzarche et al.[3] have reported that rhodium-2-hydroxypyridine catalyst system shows an effect on the GL formation. Keim et al.[4] have reported that the catalytic activity of iridium for hydrogenation of carbon monoxide is largely enhanced by addition of amines. And amines act as inhibitors in cobalt-catalyzed hydrogenation of carbon monoxide.[4]

In this study, the influence of addition of amines on the direct synthesis of EG was investigated at a high pressure (1800 kg cm^{-2}) to elucidate the behavior of amine promoters. We describe some roles of the amine promoter and effects of bulky amines on the EG formation.

Experimental

All reagents were commercially available. All experiments were carried out in a 20 ml rocking batch reactor made of Inconel Alloy at a constant pressure. Oxygenated compounds, i.e., methyl alcohol (MeOH), ethylene glycol (EG), methyl formate (MF), ethyl alcohol (EtOH), and glycerol (GL), were formed as products. The products were analyzed by gas chromatography using a Chromosorb 102 column. Sulfolane was used as an internal standard. Infrared spectra of catalytic reaction solutions were measured in a KRS cell under ambient conditions after reaction. Rates of formation of products were given in turnover frequency, defined as the number of moles of the product formed per gram-atom of metal per hour. The turnover frequency of EG, *N*(EG), is obtained by

$$N(\mathrm{EG}) = \mathrm{mol(EG)}/(\text{g-atom Rh})\mathrm{h}.$$

Product selectivity is defined as the carbon efficiency on the basis of reduced carbon monoxide in a product obtained. The selectivity value of EG, Sel.(EG), is obtained by

$$\mathrm{Sel.(EG)} = \frac{2\mathrm{EG} \times 100}{\mathrm{MeOH} + \mathrm{MF} + 2(\mathrm{EtOH} + \mathrm{EG}) + 3\,\mathrm{GL}}.$$

Results and Discussion

Influence of Some Solvents on the EG Formation. Table 1 shows the influence of solvents on the EG formation in the presence of triethylamine (Et_3N). An addition of Et_3N to a nonpolar solvent such as tetrahydrofuran (THF) or toluene in a molar ratio of Et_3N to Rh of 100 improved the activity and selectivity for the EG formation to a great extent (Nos. 2 and 4). When γ-butyrolactone (γ-BL) having a high polarity, on the other hand, is employed, an addition of Et_3N (N/Rh=100) remarkably decreased the catalytic activity (No. 6). From these results, it is suggested that the effect of addition of amines varies with the polarity of solvents to a considerable extent.

Influence of Amines on the $Rh_4(CO)_{12}$-THF System. Table 2 shows the influence of addition of some amines (N/Rh=100) on the $Rh_4(CO)_{12}$-THF system. Triisobutylamine ($(i\text{-Bu})_3N$) gave a remarkable effect on the activity and selectivity for the EG formation (No. 5) compared to straight-chain trialkylamines. (i-$Bu)_3N$ showed a remarkable effect also on the GL formation.

a) Reaction conditions: 1800 kg cm^{-2}, P_{H_2}/P_{CO}=1, solvent THF (7 ml), $Rh_4(CO)_{12}$ 0.1 mg-atom, 230 °C, 1 h.

Then, we have investigated the effect of addition of amines having branched alkyl groups. As shown in Table 3, an addition of amines having α- or β-branched alkyl group such as *N*,*N*-diisopropylethylamine (No. 3), *N*-ethylcarbazole (No. 8), or tribenzylamine (No. 7) gave an improving effect on the selectivity for the EG formation. Tribenzylamine showed a remarkable effect also on the GL formation. The sum of the selectivities to EG and GL exceeded 90%.

No effect was observed by addition of triphenylamine (No. 6). Triisopentylamine having γ-branched alkyl groups produced a relatively small effect on the selectivity to EG (No. 5). The selectivity to EG was

almost the same as that attained by addition of the straight-chain alkylamines.

Table 4 shows the effect of (hydroxyalkyl)amines on the $Rh_4(CO)_{12}$-THF system. Triisopropanolamine (No. 3) and 3-(1-pyrrolidinyl)-1,2-propanediol (No. 4) which have a β-substituent gave an improving effect on the activity and selectivity for the EG formation, compared to triethanolamine (No. 2). Triisopropanolamine and 3-(1-pyrrolidinyl)-1,2-propanediol showed an effect also on the GL formation. The results of Tables 2 to 4 show that bulky amines are effective as the promoter for C-C bond formation.

We have further investigated the influence of amounts of Et_3N and $(i\text{-}Bu)_3N$ on the $Rh_4(CO)_{12}$-THF system. The addition of the amines increased the selectivity to EG and decreased the selectivities to MeOH and MF (Figs. 1 and 2). The rate of decrease in the selectivity to MF was larger than that of decrease in the selectivity to MeOH. The addition of Et_3N increased the yield of MeOH as well as EG up to the N/Rh ratio of about 100 (Fig. 1). Consequently, the EG selectivity was as much as 60% or lower. The addition of $(i\text{-}Bu)_3N$, on the other hand, suppressed the formation of MeOH and MF (Fig. 2). As a result, the EG selectivity exceeded 70%. $(i\text{-}Bu)_3N$ showed a remarkable effect also on the GL formation compared to Et_3N.

Influence of CO Partial Pressure on the $Rh_4(CO)_{12}$-THF System. Increase in CO partial pressure increased the selectivities to EG and MF as shown in Fig. 3. On the contrary, it decreased the selectivity to MeOH. Fahey[5] has reported that formaldehyde is trapped as its ethylene glycol acetal in a Rh-catalyzed direct synthesis of EG. Therefore, a reaction path con-

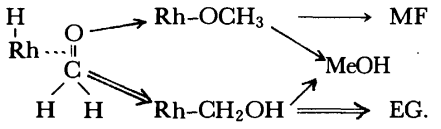
(1)

taining hydroxymethyl and methoxy intermediates, like that of the $Co_2(CO)_8$-toluene system already reported,[6] is suggested for the formation of EG, MF, and MeOH in the $Rh_4(CO)_{12}$-THF system. That is, the increase in CO partial pressure is considered to promote the insertion of CO and increase the selectivities to EG and MF.

In the $Co_2(CO)_8$-toluene system, the increase in CO partial pressure decreases the amount of MeOH and increases the amounts of EG and MF.[6] On the contrary, the increase in CO partial pressure increased the amount of MeOH as well as EG and MF in Fig. 3. This increase in the amount of MeOH can be explained by considering that the increase in CO partial pressure serves to improve the formation of the active species in the $Rh_4(CO)_{12}$-THF system.

As shown in Figs. 1 and 2, the addition of amines increases the selectivity to EG and decreases the selectivities to MeOH and MF. The rate of decrease in MF selectivity is larger than that in MeOH selectivity. This larger rate of decrease in MF selectivity and the improvement of EG selectivity by the addition of amines suggest that amines contribute advantageously to the formation of $Rh-CH_2OH$ intermediate compared to $Rh-OCH_3$ intermediate in the sequence



(2)

The decrease in MeOH selectivity and the increase in EG selectivity by the addition of amines in Figs. 1 and 2 suggest that the insertion of CO is promoted by the amines. The contribution of amines to the formation of $Rh-CH_2OH$ intermediate in Eq. 2 can be explained in terms of a nucleophilic attack on the carbonyl C atom of formaldehyde by Rh whose electron density is increased by amine coordination.

Amines show an effect also on the GL formation. The GL formation can be explained on the basis of the sequence

$$Rh-COCH_2OH \xrightarrow{H_2} Rh-CH(OH)CH_2OH \xrightarrow{CO} Rh-COCH(OH)CH_2OH,$$

$$Rh-COCH(OH)CH_2OH \xrightarrow{H_2} Rh-CH(OH)CH(OH)CH_2OH \xrightarrow{H_2} GL, \quad (3)$$

including $Rh-CH(OH)CH_2OH$ and $Rh-CH(OH)CH(OH)CH_2OH$ intermediates similar to $Rh-CH_2OH$ intermediate.

Influence of Catalyst Concentration. Figures 4 and 5 show the influence of catalyst concentrations on the $Rh_4(CO)_{12}$-Et_3N-THF and $Rh_4(CO)_{12}$-$(i\text{-}Bu)_3N$-THF systems, respectively. The $Rh_4(CO)_{12}$-Et_3N-THF system was affected by the catalyst concentration to a large extent. The selectivities to EG and GL were decreased and the MeOH selectivity was increased with increase in catalyst concentration. It is suggested that MeOH is formed advantageously at a high catalyst concentration by the diatomic reaction

$$Rh-CH_2OH + Rh-H \longrightarrow MeOH. \quad (4)$$

On the contrary, the influence of the catalyst concentration on the selectivities to EG, GL, and MeOH was small in the $Rh_4(CO)_{12}$-$(i\text{-}Bu)_3N$-THF system. It is suggested that the diatomic reaction mentioned above is relatively unlikely to proceed in the $Rh_4(CO)_{12}$-$(i\text{-}Bu)_3N$-THF system because of the bulkiness of $(i\text{-}Bu)_3N$ ligand. $(i\text{-}Bu)_3N$ which gives a

higher EG selectivity at a high catalyst concentration can give a high space time yield (STY: g EG/l h) of EG. Amines that can provide a high STY are favorable as the promoter from the practical point of view. Tribenzylamine (No. 7, Table 3), *N*-ethylcarbazole (No. 8, Table 3), and triisopropanolamine (No. 3, Table 4) which give higher EG selectivities as compared with Et_3N, are also favorable promoters.

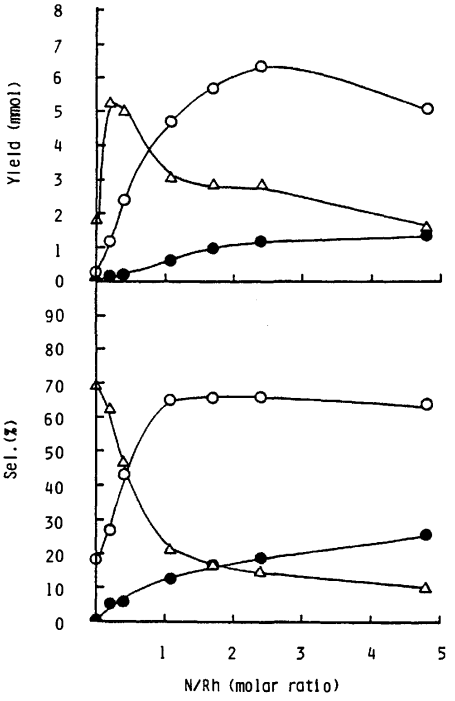

Fig. 8. Influence of $(i\text{-Bu})_3N/Rh$ ratio. 1800 kg cm^{-2}, P_{H_2}/P_{CO}=1, γ-BL (7 ml), 230 °C, $Rh_4(CO)_{12}$ 0.1 mg-atom, 1 h. ○: EG, △: MeOH, ●: GL.

Influence of Amines on the $Rh_4(CO)_{12}$-γ-BL System. The influence of amounts of amines was also investigated using γ-BL with a high polarity as a solvent. Figures 6 and 7 illustrate the relationship of

Table 5. Effect of Et_3N on the $Rh_4(CO)_{12}$-TGM System[a)]

Expt. No.	Et_3N (mmol)	Temp °C	Product/mmol					N(EG)	Sel.(EG)
			MeOH	MF	EtOH	EG	GL

2	—	250	4.79	0.32	0.30	0.14	0	1.4	4.7
3	10	250	16.70	2.28	0.80	18.68	1.71	186.8	59.2

a) Reaction conditions: 1800 kg cm^{-2}, P_{H_2}/P_{CO}=1, solvent TGM (7 ml), $Rh_4(CO)_{12}$ 0.1 mg-atom, 1 h.

yields of MeOH, MF, EG, and GL and their selectivities with the amount of $(n\text{-Bu})_3N$ added. The yields of EG and GL increase with increase in N/Rh ratio (Fig. 6). The maximum value of the yields of EG and GL was obtained at the N/Rh ratio of 1. On the other hand, the yield of MeOH showed the maximum value at the N/Rh ratio of about 0.2. And the yield of MF decreased with increase in N/Rh ratio (Fig. 7). An increasing tendency of the MeOH selectivity was observed in Fig. 6 when the N/Rh ratio exceeded 1. A suppression of the coordination of an additional CO leading to the C_2 species may be caused by an excessive amount of $(n\text{-Bu})_3N$. This tendency of MeOH selectivity is similar to that of Fig. 1 at N/Rh ratios ranging from 100 to 200. The GL selectivity decreased with increasing amount of $(n\text{-Bu})_3N$ at N/Rh ratios above 1 (Fig. 6). This variation of GL selectivity will not contradict with the tendency of MeOH selectivity.

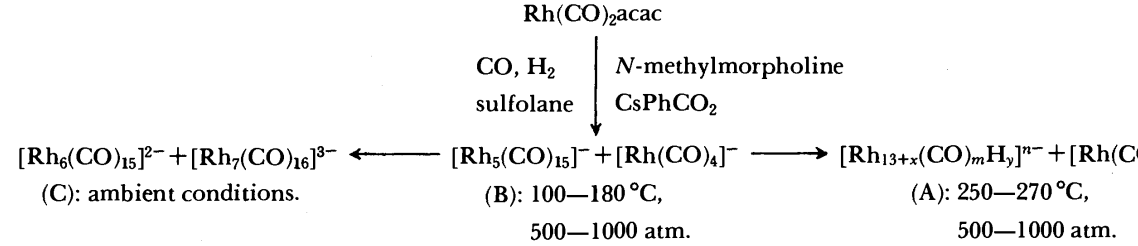
Figures 8 and 9 illustrate the relationship of yields of MeOH, MF, EG, and GL and their selectivities with the amount of $(i\text{-Bu})_3N$ added. The addition of $(i\text{-Bu})_3N$ also improved the selectivities to EG and GL and decreased the selectivities to MeOH and MF. The optimum N/Rh ratio for the EG formation was in the range from 2 to 3. This optimum N/Rh ratio for the EG formation in γ-BL solvent with a high polarity is remarkably smaller than that obtained in THF solvent with a low polarity (Fig. 2).

The addition of a small amount of $(n\text{-Bu})_3N$ increases the yield of MeOH (Fig. 6). This effect became more remarkable in the case of $(i\text{-Bu})_3N$ as shown in Fig. 8. The activity for the MeOH formation became maximum at N/Rh ratios ranging from 0.2 to 0.4. Simultaneously, the activity for the MF formation became maximum at the same N/Rh molar ratio (Fig. 9). The $Rh_4(CO)_{12}$-tribenzylamine-γ-BL system also showed the same effects. The maximum value for the yields of MeOH and MF was obtained at the N/Rh ratio of about 0.5.[7)]

The effectiveness order for the EG selectivity derived from the maximum activities for the EG formation in Figs. 6 and 8 is $(i\text{-Bu})_3N > (n\text{-Bu})_3N$. However, the difference in EG selectivity between $(i\text{-Bu})_3N$ and $(n\text{-Bu})_3N$ in γ-BL solvent is not so much as that obtained in THF solvent (Figs. 1 and 2 and Table 2). One possible explanation for this small difference in EG selectivity in γ-BL solvent is that the diatomic reaction (Eq. 4) is relatively unlikely to proceed in the $Rh_4(CO)_{12}$-$(n\text{-Bu})_3N$-γ-BL system because of the low concentration of the active species. The concentration of the active species in γ-BL solvent seems to be lower than that in THF, as will be described later.

Influence of Addition of Amine at a High Temperature. Table 5 shows the influence of addition of Et_3N on the $Rh_4(CO)_{12}$-tetraglyme (TGM) system at a high temperature. The $Rh_4(CO)_{12}$-TGM system produced Rh precipitates in the reaction solution after the reaction at 250 °C (No. 2). The catalytic activity in the reaction at 250 °C (No. 2) was lower than that at 230 °C (No. 1). However, an addition of Et_3N to the $Rh_4(CO)_{12}$-TGM system caused no Rh precipitation after the reaction at 250 °C and improved the activity for the EG formation remarkably (No. 3). The addition of Et_3N serves for a stabilization of the catalyst in addition to the improvement of the activity for the EG formation and of the EG selectivity.

IR Spectra of Reaction Solutions. As shown in Scheme 1 below, Vidal and Walker[8)] observed absorption bands of the cluster anion $[Rh_{13+x}(CO)_mH_y]^{n-}$ and the mononuclear species $[Rh(CO)_4]^-$ as a result of IR spectral measurement on a catalytic reaction solution of $Rh(CO)_2$acac-*N*-methylmorpholine-$CsPhCO_2$-sulfolane solvent system under condition (A) for the direct EG synthesis:



Scheme 1.

Under condition (B) of low temperature, absorption bands of $[Rh_5(CO)_{15}]^-$ and $[Rh(CO)_4]^-$ anions were observed. Similar results are obtained when solutions of rhodium carbonyl clusters such as $Rh_4(CO)_{12}$ and $Rh_6(CO)_{16}$ are treated in the same way. They also observed absorption bands of Rh cluster anions, $[Rh_6(CO)_{15}]^{2-}$ and $[Rh_7(CO)_{16}]^{3-}$, under condition (C) of ambient temperature and pressure.

On the other hand, we observed that the IR spectrum of the catalyst system of Fig. 6 obtained at the N/Rh ratio of 1, where the activity for the EG formation became maximum, gave an absorption band (I) at 1900 cm^{-1} under ambient IR measurement conditions as shown in Fig. 10-a. This absorption band (I) at 1900 cm^{-1} seems to be due to the mononuclear Rh species $[Rh(CO)_4]^-$.[9] This IR spectrum gave also a broad absorption band (II) at about 1960 cm^{-1}. The absorption intensity of (I) decreased remarkably over a short period of time (5—30 min) as shown in Fig. 10-b. Simultaneously with the decrease in absorption intensity of (I), the absorption band (II) had its breadth widened and its intensity increased relative to (I).

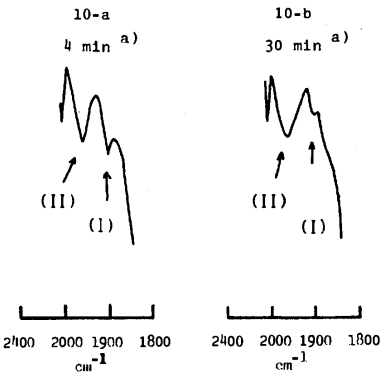


Fig. 10. IR spectra of the catalyst system of Fig. 6 obtained at the N/Rh ratio of 1. a) A time period from withdrawal of the reaction mixture from the autoclave to measurement for IR spectrum.

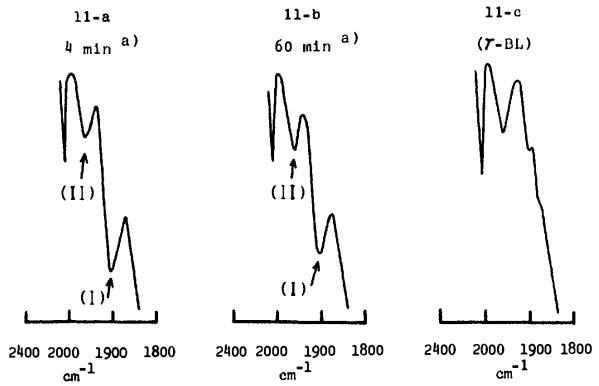

Fig. 11. IR spectra of the catalyst system of Fig. 6 obtained at the N/Rh ratio of 5.6. a) A time period from withdrawal of the reaction mixture from the autoclave to measurement for IR spectrum.

$[Rh_6(CO)_{15}]^{2-}$ has absorption bands at 1960 cm^{-1} and 1980 cm^{-1}.[9] Therefore, the above-mentioned variation of the absorption bands of (I) and (II) with time suggests a decrease in concentration of $[Rh(CO)_4]^-$ and an increase in concentration of $[Rh_6(CO)_{15}]^{2-}$.

On the other hand, in the case of the catalyst system of Fig. 6 obtained at the N/Rh ratio of 5.6, the absorption band of (I) was relatively stable as shown in Figs. 11-a and 11-b. Since γ-BL solvent has a shoulder at 1900 cm^{-1} (Fig. 11-c), the shoulder was removed from the IR spectra of Figs. 11-a and 11-b by the compensation method. Consequently, it was confirmed that the IR spectra of the catalyst system of Fig. 6 obtained at the N/Rh ratio of 5.6 have a strong absorption band due to $[Rh(CO)_4]^-$ at 1900 cm^{-1} as shown in Figs. 12-a and 12-b.

The catalyst system of Vidal and Walker[8] composed of $Rh(CO)_2acac$, *N*-methylmorpholine, and cesium carboxylate contains $[Rh(CO)_4]^-$ anion under conditions of catalytic reaction such as elevated temperature (250—270 °C) and high pressure (500—1000 atm). And this $[Rh(CO)_4]^-$ anion changes into a cluster anion under ambient temperature and pressure as shown in Scheme 1. Therefore, in the case of the catalyst systems of Fig. 6 obtained at N/Rh=1—5.6 where the absorption band of $[Rh(CO)_4]^-$ anion is observed under ambient temperature and pressure, it is suggested that a mononuclear Rh species is present in the reaction solution under the reaction conditions of 230 °C and 1800 $kg\,cm^{-2}$. It seems that the formation of the mononuclear Rh species at 1800 $kg\,cm^{-2}$ of synthesis

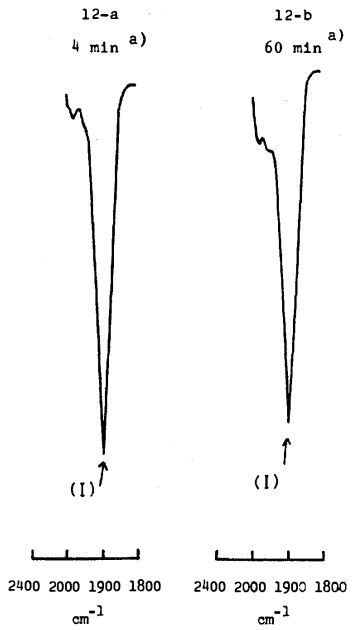

Fig. 12. IR spectra of the catalyst system of Fig. 6 obtained at the N/Rh ratio of 5.6. Absorption bands of γ-BL solvent were removed by compensation method. a) A time period from withdrawal of the reaction mixture from the autoclave to measurement for IR spectrum.

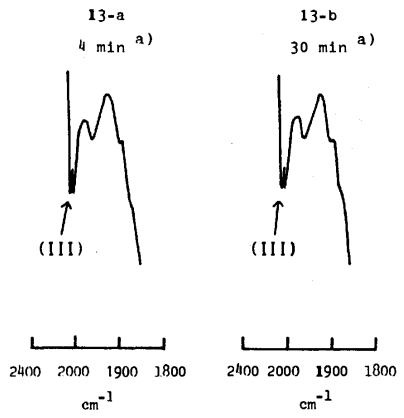

Fig. 13. IR spectra or the catalyst system of Fig. 6 obtained at the N/Rh ratio of zero. a) A time period from withdrawal of the reaction mixture from the autoclave to measurement for IR spectrum.

gas is easier than that at 500—1000 atm used by Vidal and Walker.[8]

The IR spectrum of the catalyst system of Fig. 6 obtained at the N/Rh ratio of zero showed an absorption band (III) assignable to $[Rh_{12}(CO)_{30}]^{2-}$ anion[9] at 2053 cm^{-1} (Fig. 13-a). The absorption band (III) is stable as shown in Figs. 13-a and 13-b. Further, it was confirmed by the compensation method that the shoulder[10] at 1900 cm^{-1} in Fig. 13-a was due to γ-BL.

Active Species. The above results of the IR spectra in Figs. 10—13 suggest that $(n\text{-Bu})_3N$ serves for the formation of mononuclear Rh species from the Rh catalyst precursor under the catalytic reaction conditions. Because the activity for the EG formation shows the maximum value at N/Rh=1 in Fig. 6, a mononuclear Rh species containing $(n\text{-Bu})_3N$ is suggested to be a species for the catalytic activity at N/Rh=1. Further, the main product of the catalyst systems of Fig. 6 obtained at N/Rh ratios ranging from 1 to 5.6 was also EG. From the results of Figs. 11 and 12, a mononuclear species of Rh containing $(n\text{-Bu})_3N$ is likewise suggested to be an active species of the catalyst systems of Fig. 6 obtained at N/Rh ratios ranging from 1 to 5.6.

The IR spectrum of the catalyst system of Fig. 8 obtained at N/Rh 2.5, where the yield of EG became maximum, showed also an absorption band of $[Rh(CO)_4]^-$ anion. A mononuclear Rh species containing $(i\text{-Bu})_3N$ is likewise considered as an active species of the catalyst system of Fig. 8 obtained at N/Rh=2.5.

The optimum amine/Rh ratios for the EG formation are 50—100 in THF solvent with a low polarity (Figs. 1 and 2) and 1—3 in γ-BL solvent with a high polarity (Figs. 6 and 8). And the addition of excess Et_3N (N/Rh=100) decreases remarkably the catalytic activity in γ-BL solvent (No. 6, Table 1). Further, in our previous paper, we reported that a high catalyst activity for the EG formation is observed in $(n\text{-Bu})_3N$ solvent with a low polarity at 1800 kg cm^{-2} of synthesis gas.[12] Considering these results, in γ-BL solvent with a high polarity, factors diminishing the catalyst activity are suggested to include the formation of $[Rh(CO)_4]^-$ anion by an excessive amine. Therefore, a mononuclear species of neutral Rh complex containing amine, $HRh(CO)_3(R_3N)$ (**2**), is suggested as an active species.[13] A possible reaction path for the formation of **2** may be written as the sequence

$$Rh_4(CO)_{12}+R_3N \xrightarrow{CO+H_2} [Rh(CO)_4]^- R_3NH^+,$$
$$[Rh(CO)_4]^- R_3NH^+ \rightleftharpoons \underset{\mathbf{1}}{HRh(CO)_4}+R_3N,$$
$$HRh(CO)_4+R_3N \rightleftharpoons \underset{\mathbf{2}}{HRh(CO)_3(R_3N)}+CO. \quad (5)$$

The concentration of the neutral active species **2** in γ-BL solvent seems to be lower than that in THF because of the higher polarity of γ-BL. The effect of amine on the EG formation by Eq. 2 can be explained in terms of the nucleophilic attack on the carbonyl C atom of formaldehyde by Rh whose electron density is increased by amine coordination.

However, $Rh_4(CO)_{12}$-$(n\text{-Bu})_3N$ catalyst system (Fig. 6) in γ-BL solvent with a high polarity seems to show high EG selectivities compared to those (Fig. 1 and Run Nos. 2—4, Table 2) in THF solvent with a low polarity. Therefore, there is a possibility that the proton of $[Rh(CO)_4]^- R_3NH^+$ contributes to the formation of Rh-CH_2OH complex, an intermediate in the EG formation, by an electrophilic attack on the carbonyl O atom of the coordinated formaldehyde shown by Eq. 2. Another possible reason for the high EG selectivity of the $Rh_4(CO)_{12}$-$(n\text{-Bu})_3N$-γ-BL system is that the diatomic reaction (Eq. 4) is relatively unlikely to proceed because of the low concentration of the active species.

The activity for the MeOH formation becomes maximum at N/Rh ratios ranging from 0.2 to 0.4 as shown in Fig. 8. Further, Tables 1 and 2 show that the catalyst systems without nitrogen-containing compounds form MeOH as the main product. $(i\text{-Bu})_3N$ is considered to be weaker in coordination ability than $(n\text{-Bu})_3N$ because of the bulkiness of $(i\text{-Bu})_3N$. From this and the above results and a related result,[10] a mononuclear Rh species, $HRh(CO)_4$ (**1**), shown in Eq. 5 is suggested as an active species for the MeOH formation of the catalyst system of Fig. 8 obtained at lower N/Rh ratios (0—0.5). $HRh(CO)_4$ is also suggested as an active species for the MF formation of the catalyst system of Fig. 9 obtained at lower N/Rh ratios (0—0.5).

The absorption band (I) of $[Rh(CO)_4]^-$ anion was observed also in the IR spectrum of the catalyst system of Fig. 1 obtained at Et_3N/Rh=100. But this catalyst system caused precipitaion of Rh species during the IR spectrum measurement at ambient conditions. This indicates that the stability of $[Rh(CO)_4]^-$ anion is low in THF solvent with a low polarity.

It is known[14] that alkyl manganese pentacarbonyls

react with amines producing amine acyl manganese tetracarbonyl complexes according to

$$RMn(CO)_5 + \text{amine} \longrightarrow [\text{amine} \rightarrow Mn(R)(CO)_5] \longrightarrow RCOMn(CO)_4(\text{amine}). \quad (6)$$

This study seems to provide a support for the C-C bond formation via a hydroxy acetyl Rh complex containing amine.

NMR Spectra of Organogermanium Compounds. VI.[1] NMR Spectra and Molecular Mechanics Calculations of 3-Methyl- and 3,3-Dimethylgermacyclohexanes

Yoshito TAKEUCHI,* Yasuko ICHIKAWA, Katsumi TANAKA, and Norihiro KAKIMOTO†
Department of Chemistry, The College of Arts & Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153
†ASAI Germanium Research Institute, Komae-shi, Tokyo 201
(Received February 8,1988)

Several 3-methyl- or 3,3-dimethylgermacyclohexanes were prepared and their ^{13}C and ^{73}Ge NMR spectra were determined. Steric energies for all of stereoisomers of some of these germacyclohexanes were calculated by MM2 program. The effect of axial 3-methyl group of germacyclohexanes upon its C-5 is much the same with the corresponding effect in cyclohexanes, and is much smaller than the effect caused by axial methyl on germanium upon C-3,5. A large upfield shift is recorded for germanium nuclei when there is an axial methyl on C-3 of germacyclohexanes.

In the previous communication[2] we have reported the ^{13}C NMR spectra and molecular mechanics calculations of a variety of germacyclohexanes, i.e., germacyclohexane (**1G**) and such methyl-substituted germacyclohexanes as 1-methyl- (**2G**), 3-methyl- (**3G**), 1,1-dimethyl- (**4G**), 1,3-dimethyl- (**5G**) 1,4-dimethyl- (**6G**), and 1,1,3-trimethyl- (**9G**) germacyclohexanes. It revealed that (i) the ring is flattened around the germanium and that (ii) a methyl group on germanium has a slight preference to axial conformation to the equatorial, which is in line with the results for the corresponding silacyclohexanes.[3]

	R_1	R_2	R_3	R_4	R_5

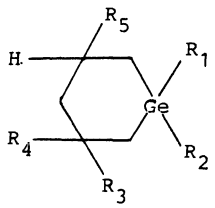
9G	Me	Me	Me	H	H
10G	Me	H	Me	Me	H
11G	Me	Me	Me	Me	H



Furthermore, both ^{13}C and ^{73}Ge NMR data indicate that **2G** is a ca. 60:40 mixture of axial and equatorial conformers. Attempts to observe directly the two conformers by freezing the inversion on NMR timescale, however, failed because of the very low barrier for inversion. Instead, we prepared a mixture of *trans*-**6G** and *cis*-**6G** where the methyl group on germanium remains equatorial and axial, respectively. This pair of compounds is interesting as a model to estimate the magnitude of γ-gauche effect by an axial methyl group on germanium in germacyclohexanes. The chemical shift difference (1.30 ppm; the cis isomer gives the signal in a higher field) observed for C-3,5 resonances for the two compounds[4] is much smaller as compared with the corresponding difference for equatorial and axial methylcyclohexane (**2C**; 5.40 ppm).[5]

Qualitatively this is not unexpected in view of the prolonged distance between the axial methyl group on germanium and axial hydrogens on C-3,5. γ-gauche effect is also clear for the ^{13}C resonances of methyl carbon itself. Thus, the methyl groups on germanium of *trans*-**6G** and *cis*-**6G** resonate at −5.77 and −7.83 ppm, respectively.[4]

In the germacyclohexane derivatives with an axial methyl group on C-3 the axial methyl group and the germanium nuclei are in the γ-gauche relation. Hence it is expected that NMR data of such compounds will show us whether the germanium shift is also susceptible to γ-effect, and that, if ever it exists, whether the direction of this effect is upfield (as in the case of ^{13}C shifts) or not.

Study on the γ-effect in the system where a heteroatom is involved in the four-atom unit has been the target of continuing interests.[6,7] No attempt has, however, been done to observe γ-effect associated with germanium nuclei. Germanium should be very suitable for the probe of γ-effect since it does not have the lone-pair electrons which will bring in some new effect to obscure the analysis.

For this purpose we prepared 3,3-dimethyl- (**7G**), 3,5-dimethyl- (**8G**), 1,1,3-trimethyl- (**9G**), 1,3,3-trimethyl- (**10G**), and 1,1,3,3- tetramethyl-(**11G**) germacyclohexanes and determined their NMR spectra. The molecular mechanics calculation of these compounds were also carried out.

Results and Discussion

^{73}Ge Chemical Shifts. ^{73}Ge and ^{13}C NMR spectra of these germacyclohexanes were determined and the results together with the data of relevant compounds, such as **1G**, **2G**, **3G**, **4G**, *cis*-**5G**, *trans*-**5G**, and **9G**, which are necessary for comparison, were included in the Table 1.

In our previous communication,[2] we have shown that ^{73}Ge chemical shift (δ value) of germacyclohexanes without any methyl group on germanium is ca. −130 ppm, that with an axial methyl is ca. −70 ppm, that with an equatorial methyl is ca. −60 ppm and that

Table 1. $^{73}Ge^{a)}$ and $^{13}C^{b)}$ Chemical Shifts of Germacyclohexanes (**1**—**11**)

Number of compound	Position of Me	Ge-1	C-2	C-3	C-4	C-5	C-6	Me-1	Me-3

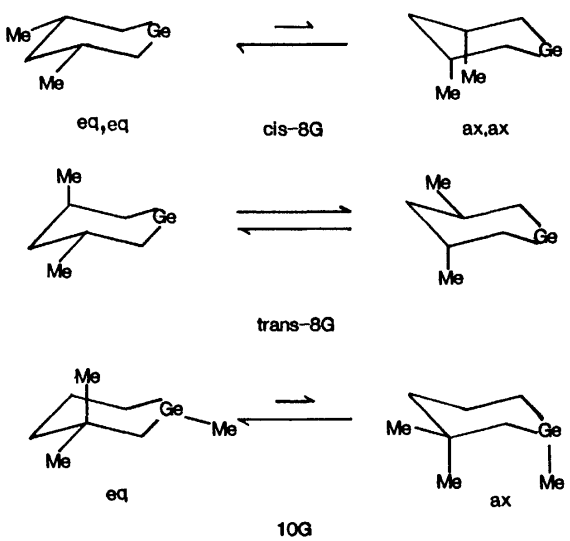
a) In ppm relative to external $GeMe_4$ (δ=0). b) In ppm relative to internal $SiMe_4$ (δ=0).

with two methyl groups is ca. −15 ppm.[4]

The sample of **8G** is in fact a mixture of trans and cis isomers. The ^{13}C NMR spectrum gave two sets of signals corresponding to two isomers, the ratio of which is ca. 6 : 1. The signal due to C-2 of the major stereoisomer is in the highest field among ring carbon signals, and is in higher field than that of the minor isomer. Thus, the major compenent of **8G** is the trans isomer since the ax,ax conformer of *cis*-**8G** has much higher energy than the eq,eq isomer where there is no axial methyl group.

The ^{73}Ge chemical shift of the major component, i.e., *trans*-**8G**, is −145.0 ppm, about 15 ppm upfield as compared with that of **3G**. This upfield shift is to our knowledge the first example of γ-gauche shift associated with ^{73}Ge resonances.



As compared with a very large upfield shift of ^{73}Ge caused by axial methyl group on C-3 of *trans*-**8G**, the effect caused by geminal 3,3-dimethyl group upon ^{73}Ge is somewhat smaller. Thus, **7G** resonates at −142.1 ppm, 10.9 ppm upfield as compared with **3G**, and **11G** resonates at −18.7 ppm, only 6.5 ppm upfield as compared with **9G**. As described later, this difference is likely due to the difference in the dihedral angle associated with the germanium atom. Thus, the upfield shift is smaller for compounds in which the ring is more flattened around the germanium. At any rate the existence of γ-effect upon ^{73}Ge chemical shifts in germacyclohexanes is now well-established.

It is worthwhile to mention that ^{73}Ge chemical shift of **10G** clearly indicates the predominance of equatorial conformation of methyl group on germanium. Otherwise, the ^{73}Ge nucleus should resonate at ca. −80 ppm. This in turn indicates that 1,3-diaxial dimethyl interaction is operative between *Ge*-methyl and *C*-methyl groups.

^{13}C Chemical Shifts. The ^{13}C chemical shifts of compounds **1G**—**6G** and **9G** were previously reported.[4] The assignments of ^{13}C signals of **7G**, **8G**, **10G**, and **11G** were carried out based on the conventional strategy. Where appropriate, SFORD (single-frequency off-resonance decoupling) and INEPT (insensitive nuclei enhancement by polarisation transfer) spectra were recorded for facilitating the assignments. The assignments based on the multiplicity and chemical shifts consideration are consistent with the additivity relations which have been established for the germacyclohexanes.[2,4]

The effect on the ^{13}C chemical shifts of germacyclohexanes caused by an axial methyl group on C-3 can be estimated by two ways. One way is the chemical shift difference between **7G** and **3G**, or between **11G** and **9G**. This difference can be compared with the case of carbon analog, i.e., the chemical shift difference between 1,1-dimethylcyclohexane (**4C**) and methylcyclohexane (**2C**). The differences estimated from the ^{13}C chemical shifts of these compounds are tabulated in Table 2.

The other way is the chemical shift difference between **8G** and **3G**, which can be compared with the corresponding difference in methylcyclohexanes, i.e., that between *trans*-1,3-dimethylcyclohexane (*trans*-**5C**) and **2C**. The results are also included in Table 2.

Table 2. Effects of an Axial Methyl Group at C-3 upon ^{13}C Chemical Shifts[a)]

a) For definition of each component steric energies, see text.

The effects of an axial methyl group at C-3 upon other carbon shifts of germacyclohexanes are, roughly speaking, similar with these for cyclohexanes. There are, however, some difference between the substituent parameters for cyclohexanes and germacyclohexanes. Thus, in geminal dimethyl compounds, germacyclohexanes exhibit a smaller β-effect, but its γ-effect is somewhat larger. α-Effects are scattering, and it is hard to draw any definite conclusion.

In *trans*-3,5-dimethyl series, the methyl substituent parameters are much the same for cyclohexanes and germacyclohexanes.

Molecular Mechanics Calculations. In Table 3, MM2[8)] steric energies of germacyclohexanes **4G**, **5G**, **7G**, **8G**, **10G**, and **11G** are listed together with relevant cyclohexanes **4C** and **5C**. For **5C**, **5G**, and **8G**, all stereoisomers associated with the orientation of methyl group are taken into consideration.

In MM2 calculations, total steric energies (E_s) are the sum of component energies, i.e., compression energy (E_c), bending energy (E_b), strech-bend energy (E_{sb}), tortional energy (E_t), and van der Waals energy which is subdivided into the energy associated with 1,4-interaction ($E_{1,4}$) and that with other interactions (E_{other}).

Two conclusions were drawn from the previous results.[2)] It has been shown that the axial and equatorial methyl group on germanium contributes to the steric energy to much the same extent. Though the change of C-5 chemical shifts caused by an axial methyl group at C-3 of germacyclohexanes is not so much different from the corresponding value of cyclohexanes, the difference in steric energy is large. Thus, the increment of steric energies caused by geminal dimethyl groups as estimated from the difference between **7G** (7.39 kcal mol^{-1}) and **1G** (5.72 kcal mol^{-1} [2)]) (i.e., 1.67 kcal mol^{-1} difference) is much smaller than that between **4C** (9.27 kcal mol^{-1}) and **1C** (6.55 kcal mol^{-1}) (i.e. 2.72 kcal mol^{-1} difference).

Next, we attempted to compare the magnitude of 1,3-diaxial dimethyl interaction under different steric environment from the difference of steric energies among 1,3 (or 3,5)-diequatorial conformer, 1,3 (or 3,5)-equatorial, axial conformer and 1,3 (or 3,5)-diaxial conformer of the identical geometrical isomers.

Thus, for **5C**, the steric energy difference between eq,eq isomer and eq,ax isomer is +1.81 kcal mol^{-1}, while that between eq,ax isomer and ax,ax isomer is +5.32 kcal mol^{-1}. When the ring is a germacyclohexane but two methyl groups are at C-3 and C-5 as is the case with **8G**, the corresponding differences are +1.39 and +3.15 kcal mol^{-1}, respectively. This is in line with

the results of the comparison given above.

When one of the methyl groups is at germanium, as is the case with **5G**,[4] the difference between 1-eq,3-eq and 1-ax,3-eq isomers is −0.23 kcal mol^{-1}, in line with the preference of axial conformation for this type of methyl group. The difference between 1-eq,3-eq and 1-eq,3-ax conformers is +1.35 kcal mol^{-1}, which is essentially identical with the value for **5C** and **8G**. The difference between 1-eq,3-eq and 1-ax,3-ax isomers of **5G** is only +2.09 kcal mol^{-1} in a sharp contrast with two previous cases, where the differences are +5.34 (*cis*-**5C**) and +4.54 kcal mol^{-1} (*cis*-**8G**), respectively. Thus, the 1,3-diaxial dimethyl interaction is smaller in germacyclohexane as compared with that in cyclohexane, and this is particularly so when one of the methyl is at germanium.

It is interesting to examine how the molecular mechanics calculations predict the structural change upon introduction of methyl groups on germanium and C-3. In Table 4, the predicted structures by MM2 for all the compounds discussed are summerized. Of all possible stereoisomers, high energy conformers are not taken into consideration.

It is clear from a glance of Table 4 that all the parameters, the bond lengths (r), the bond angles (θ), and the dihedral angles (ω) are not largely changed by the number and position of methyl groups introduced. It is slightly different from the case of methylcyclohexanes where a small change in bond length is invoked upon introduction of methyl groups.[2] A more relaxed structure of germacyclohexane as compared with cyclohexane is responsible for this phenomenon.

In one particular case where there exists a 1,3-diaxial dimethyl interaction with the buttress effect as is with **11G**, the change in dihedral angle caused by methyl groups is substantial. Thus, for germacyclohexanes without any 1,3-diaxial dimethyl interaction, the dihedral angle $\omega_{1,2}$ is in the range of 47°—49°. When there is a 1,3-diaxial dimethyl interaction present, the angle changes to 43°—44°, a substantial change. The ring is now further flattened around the germanium atom. This is also reflected in the dihedral angle $\omega_{2,3}$ which is nearly 50° for **11G**. A similar change is invoked when there is geminal 3,3-dimethyl group is present. The angle $\omega_{2,3}$ reduced to 54°.

That this change is associated with 1,3-diaxial di-

a) The definition of the structural parameters is as follows: $r_{1,2}$ is the distance between Ge-1 and C-2 in nm, θ_1 is the bond angle C-6-Ge-1-C-2 in degrees and $\omega_{1,2}$ is the tortion angle in degrees defined by the C-6-Ge-1-C-2-C-3 moiety. The other parameters are defined analogously.

methyl group is evident since a similar change is invoked in $\omega_{5,6}$ and $\omega_{6,1}$ where there is a 1,5-diaxial dimethyl interaction.

Thus, an introduction of several methyl groups in germacyclohexane is calculated to cause no significant change in the bond length and bond angle of the ring. A substantial change in the dihedral angle is predicted instead. We are continuing efforts to demonstrate experimentally these characteristics of germacyclohexanes.

Experimental

Preparation of Germacyclohexanes. The necessary precursor for 3,3-dimethylgermacyclohexanes, 1,5-dibromo-2,2-dimethylpentane does not seem to have previously been described. This arises from the fact that the treatment of 2,2-dimethyl-1,5-pentanediol with the standard brominating reagents such as hydrogen bromide or phosphorus tribromide causes a migration of β-methyl group (a Wagner-Meerwein rearrangement) to result in the formation of unexpected compound. Hence we treated the diol with dibromotriphenylphosphorane[9] to end up with the desired dibromopentane.

The dibromopentane was converted to the bis-Grignard reagent, which was caused to react with tetrachlorogermane to give 1,1-dichlorogermacyclohexanes. Treatment of dichlorogermacyclohexanes with lithium aluminum hydride(LAH) afforded 1,1-dihydrogermacyclohexanes (**7G** and **8G**). 1,1-Dichlorogermacyclohexanes were treated with methylmagnesium bromide to give the 1,1-dimethylgermacyclohexanes (**9G** and **11G**). Treatment of bis-Grignard reagent with dichloromethylgermane gave **10G**. The details of these procedures were described in our previous communication.[2] 1,5-dibromo-2,2-dimethylpentane. 2,2-Dimethylglutaric acid was esterified with ethanol under an acidic condition, and the ester was reduced to 2,2-dimethyl-1,3-pentanediol by means of LAH in a conventional manner.

The diol (10.0 g; 0.075 mol) and triphenylphosphine (43.8 g; 0.167 mol) were dissolved in dry *N*,*N*-dimethylformamide (DMF; 80 ml), to which bromine (27.5 g; 0.169 mol) was added dropwise under the atmosphere of argon and ice-cooling. During the addition the temperature was kept at 10—20 °C. Stirring was further continued for another 20 h at 25 °C. The forerun of the distillation under the reduced pressure (fraction of bp 63—66 °C/30 mmHg (1 mmHg≈133.322 Pa)) was discarded and the second fraction (bp 60—68 °C/4 mmHg) was collected, and this was poured into the ice-water. The heavy oil was extracted with dichloromethane, which was washed with water, dried over anhydrous calcium carbonate, and the solvent evaporated. The residue was reduced in vacuo to afford yellow oil of 2,2-dimethyl-1,5-dibromopentane (10.32 g; 53% overall), bp 125—127 °C/29 mmHg. ^{1}H NMR (90.0 MHz; $CDCl_3$) δ=1.03 (6H, s), 3.26 (2H, s), 3.38 (2H, t. J=7 Hz).

Found: C, 32.48; H, 5.50%. Calcd for $C_7H_{14}Br_2$: C, 32.59, H, 5.47%.

3,5-Dimethylpiperidine (Tokyo Kasei Co.) and benzoyl chloride were caused to react in aqueous NaOH to give 1-benzoyl-3,5-dimethylpiperidine (91%), mp 95 °C. IR (KBr) 1615 (C=O).

Found: C, 77.44; H, 8.79; N, 6.40%. Calcd for $C_{14}H_{19}NO$: C, 77.37; H, 8.81; N, 6.44%.

The benzoyl derivative was treated with PBr_3/Br_2 to afford 1,5-dibromo-2,4-dimethylpentane, bp 105—107 °C/1.5 mmHg.

Preparation of germacyclohexanes has been carried out based on the procedure described in the previous report.[2] Thus, the reaction between the bis-Grignard reagent of 1,5-dibromo-2,2-dimethylpentane and tetrachlorogermane afforded 1,1-dichloro-3,3-dimethylgermacyclohexane which, without isolation, was converted to **7G** by means of LAH, or to **11G** by the reaction with methylmagnesium bromide. Treatment of the same dibromide with dichloromethylgermane afforded **10G**.

The reaction between the bis-Grignard reagent of 1,5-dibromo-2,4-dimethylpentane and tetrachlorogermane afforded 1,1-dichloro-3,5-dimethylgermacyclohexane which, without isolation, was converted to **8G** by means of LAH. The physical properties of these germacyclohexanes are summerized in Table 5.

Measurements of Spectra. Infrared spectra were obtained with a JASCO A102 grating infrared spectrophotometer as a liquid film.

The ^{1}H NMR spectra were recorded with a Varian EM-390 spectrometer as $CDCl_3$ solution containing a small amount of tetramethylsilane (TMS) as the internal standard.

The ^{13}C NMR spectra of germacyclohexanes were recorded as solutions of $CDCl_3$ or C_6D_6 on a JEOL FX-90Q spec-

Table 5. Physical Properties of Germacyclohexanes (**7G—11G**)

Compound (formula)	Yield[a] %	Bp θ_m °C/mmHg	IR(Ge-H) ν_H(neat)	^{1}H NMR δ_H(90MHz; $CDCl_3$)	MS m/z[b]
7G ($C_7H_{14}Ge$)	14	88—90/22	2040	1.00 (6H, s, 3,3-diMe) 3.60 (2H, m, 1-H)	
8G ($C_7H_{14}Ge$)	8	97—100/17	2045	1.00 (6H, d, J=7 Hz, 3,5-Me) 3.63 (2H, m, 1-H)	
9G ($C_8H_{16}Ge$)	7	85—87/26	—	0.13 (6H, s, 1,1-diMe) 0.93 (3H. d, J=7 Hz, 3-Me)	
10G ($C_6H_{16}Ge$)	6	90—93/13	2050	0.21 (3H, d, J=3 Hz, 1-Me) 0.98 (6H, s, 3,3-diMe) 3.88 (1H, m, 1-H)	160.1 (M^+), 145.2 (M^+-15) 132.2 (M^+-28)
11G ($C_9H_{18}Ge$)	12	98—100/18	—	0.15 (6H, s, 1,1-diMe) 0.95 (6H, s, 3,3-diMe)	160.1 (M^+), 132.2 (M^+-28)

trometer at 22.50 MHz in 10 mm tube at 30°C. The condition of measurements are the standard ones.

The ^{73}Ge NMR spectra of germacyclohexanes were recorded as solutions in $CDCl_3$ (1 : 1 v/v) on a JEOL FX-90Q spectrometer equipped with an NM-IT 10LF low-frequency insert, operating at 3.10 MHz, in a 10 mm tube at 30°C. Typical measurement conditions were as follows: pulse width, 150 μs (90°); spectral width, 2000 Hz: number of scans, 5000; pulse delay, 100 ms; data points, 4096. The ^{13}C NMR spectra were determined for the same solutions on the same instrument at 22.50 MHz. Typical measurement conditions were as follows: pulse width. 13 μs (40°): spectral width, 2000 Hz: number of scans, 500; pulse delay, 1 s; data points, 4096.

GC/MS spectra were obtained on a Hewlett-Packard 5995A instrument controlled by a Hewlett-Packard 9825 desktop computer system with a 25 m (ϕ 0.2 mm) cross-linked methyl silicone column.

Molecular Mechanics Calculations. The program used was Allinger's MM2. Since in MM2 the parameters for germanium are not available, we installed the parameters reported by Ouellette[10] in MM2. Since the parameters were prepared for the older force field of Allinger[11] (before MM1) based on the experimental values of methylgermane and dimethylgermane, there is some doubt as for the consistency between parameters for germanium and for other atoms. This point has been discussed in the previous communication[2] where it has been shown that the use of the combination of MM2 and germanium parameters of Ouellette[10] is acceptable, and this combination is used throughout this investigation.

For the sake of comparison, calculations were also carried out for the corresponding cyclohexanes, and the results were also included in Table 2.

The authors thank the Ministry of Education, Culture and Health for Grant-in-Aid.

Formation of 4-Benzamidoisoxazole Derivatives[1)]

Shonosuke ZEN,* Kazuho HARADA, Hikaru NAKAMURA,† and Yoichi IITAKA†

(Received February 10, 1988)

The titled compounds (**3**) were synthesized by the reaction of nitrile oxides with 1-azirines and also the reaction of aliphatic nitro compounds with dibenzoylmethane derivatives in the presence of acetyl chloride and sodium methoxide. The structure of **3** was established by single crystal X-ray analysis. A mechanism of the formation for **3** is proposed.

This is dealing with an one-pot synthesis of 4-benzamidoisoxazole derivatives **3** through the reaction of nitrile oxides **1**[2)] with 1-azirines **2**.[3,4)] **3** was synthesized by the two methods as follows: (I) Nitrile oxides **1a—1c**, which are isolated or generated in situ by the acylation[5)] of aliphatic nitro compounds **4a—4c** with acetyl chloride, are allowed to react with 2-benzoyl-1-azirines (**2a—2c**) in the presence of NaOMe. In this case furazan 2-oxides (**6**),[2)] dimers of **1**, were obtained as main products. (II) Dibenzoylmethanes (**5a, 5b**) are reacted with two molecular equivalents of **4a, b** in the presence of acetyl chloride and NaOMe also (Scheme 1). The results of these procedures are summarized in Table 1.

The structure of **3** was determined by single crystal X-ray analysis with **3e** (Fig. 1) and also by alternative preparations of **3c** and **3g** from **9f** and **9g**[6)] respectively (III) (Scheme 1). Compound **3c** obtained via (I) was identical to that obtained from the reaction (III).

The postulated mechanism of the formation of **3** was illustrated by Scheme 2: Nitrile oxide **1** generated from **4** reacts with dibenzoylmethane derivative **5** in an 1,3-dipolar cycloaddition to give an isoxazoline intermediate **10**. A fission of N-O bond[7)] of **10** in basic conditions followed by elimination of benzoic acid affords nitrene intermediate **11**, which isomerizes[8)] to 1-azirine **2**. Subsequently, nucleophilic attack of methoxide anion to **2** gives aziridine intermediate **12**. Furthermore a fission of C-C bond[9)] of **12** gives olefinic intermediate **13**, which cyclizes with another **1** to finally lead to **3**.

This mechanism was also supported by the following experimental results: i) Isolated nitrile oxide **1b** reacts with **5a** to give the corresponding 1-azirine **2b**.[10)] ii) Isoxazoles (**7** and **8**) were isolated as by-products in

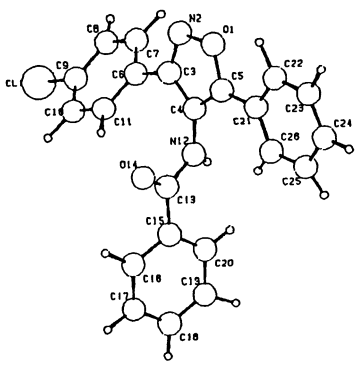

Fig. 1. Molecular structure of the compound **3e**.[15)]

the reaction (II). This result shows that the above mechanism includes intermediate **10**, for **7** is a dehydroxy compound of **10**, and **8** is considered to be formed from **11**.[8]

The reactivity of **3** was also studied as follows: i) *N*-Methylations of **3a—3d** were carried out with CH_3I to afford **14a—14d** in good yields as summarized in Table 1. ii) Hydrogenation of **3** with Raney Ni afforded *β*-aminoenone (**15**), which was hydrolyzed to give **16** and/or imidazole **17** (Scheme 3).

The authors (Z. and H.) reported[11] previously the reaction of **1** with **2** to give **3** and assigned the structure of **3** to 4*H*-1,2,4-oxadiazine derivative based on spectroscopic analysis and also a ring opening reaction mentioned above. However, the structure of **3** was established to be 4-benzamido-3,5-diarylisoxazole, as illustrated in Fig. 1 by X-ray analysis. Accordingly, the authors (Z. and H.) correct the structure of **3** herein.

Experimental

Reaction of *p*-Tolunitrile Oxide (1b) with 3-Benzoyl-2-phenyl-1-azirine (2a). General Procedure for Method(I): To a solution of **2a**[12] (57.0 mg, 0.26 mmol) in anhydrous *N,N*-dimethylacetamide (DMA) (5 cm^3) was added freshly prepared **1b**[13] (37.0 mg, 0.26 mmol) and 1 mol dm^{-3} NaOMe in MeOH (0.52 cm^3) with ice-cooling. After stirring at room temperature overnight, the reaction mixture was partitioned between ice-water (20 cm^3) and benzene (10 cm^3). The aqueous phase was extracted with benzene (3×10 cm^3), dried (Na_2SO_4) and concentrated to dryness. The residue (46.2 mg) was separated by column chromatography on silica gel with AcOEt–hexane (5 : 1) as an eluent to afford 3,4-di-*p*-tolylfurazan 2-oxide (**6b**) (20.1 mg, 54%) and 4-benzamido-5-phenyl-3-(*p*-tolyl)isoxazole (**3b**) (11.9 mg, 13%): mp 188—190 °C (EtOAc–hexane).

Reaction of Phenylnitromethane (4a) with 3-Benzoyl-2-phenyl-1-azirine (2a): To a solution of **4a** (137 mg, 1.0 mmol) in anhydrous DMA (15 cm^3) was added 1 mol dm^{-3} NaOMe in MeOH (1.0 cm^3), acetyl chloride (0.70 cm^3, 1.0 mmol), **2a** (221.0 mg, 1.0 mmol) with ice-cooling. After further addition of 1 mol dm^{-3} NaOMe in MeOH (4.0 cm^3), the reaction mixture was stirred at room temperature overnight. Then, the reaction mixture was poured into ice-water (20 cm^3). After neutralization with 1 mol dm^{-3} HCl, the aqueous phase was extracted with benzene (3×15 cm^3), dried (Na_2SO_4) and concentrated to dryness. The residue (284 mg) was chromatographed on silica gel with EtOAc–hexane (5 : 1) as an eluent to give 3,5-diphenylisoxazole (**8a**) (79.0 mg, 35%), 3,4-di-*p*-tolylfurazan 2-oxide (**6a**) (13.0 mg, 54%), and 4-benzamido-3,5-diphenylisoxazole (**3a**) (68.0 mg, 20%): mp 202—203 °C (MeOH–H_2O).

Reaction of Phenylnitromethane (4a) with Dibenzoylmethane (5a). General Procedure for Method(II): To a solution of **4a** (548 mg, 4.0 mmol) in anhydrous DMA (20 cm^3) was added 1 mol dm^{-3} NaOMe in MeOH (4 cm^3), acetyl chloride (0.29 cm^3, 4.1 mmol), **5a** (448 mg, 2.0 mmol) with ice-cooling. After further addition of 1 mol dm^{-3} NaOMe in MeOH (16 cm^3), the reaction mixture was poured into ice-water (120 cm^3). After neutralization with 1 mol dm^{-3} HCl, the aqueous phase was extracted with benzene (3×40 cm^3), dried (Na_2SO_4) and concentrated to dryness. The residue (887.5 mg) was chromatographed on silica gel with benzene–EtOAc (20 : 1) as an eluent to give **8a** (140.5 mg, 32%), 4-benzoyl-3,5-diphenylisoxazole (**7a**) (195.3 mg, 30%), methyl benzoate (33.0 mg, 12%), acetophenone (28.0 mg, 12%) and **3a** (108.2 mg, 16%).

X-Ray Analysis of 4-Benzamido-3-(*p*-chlorophenyl)-5-phenylisoxazole (3e): X-Ray specimen of **3e** of approximate dimensions 0.35×0.1×0.06 mm was recrystallized from hexane–EtOAc. Diffraction intensities were measured using Cu $K\alpha$ radiation monochromated by a graphite plate. The crystal data are: 4-Benzamido-3-(*p*-chlorophenyl)isoxazole, $C_{22}H_{15}N_2O_2Cl$, MW=374.8. Monoclinic, space group $P2_1/n$, Z=4. Unit cell dimensions, a=21.833(10), b=7.339(5), c=11.448(7) Å, β=99.02(6)°, U=1812 Å^3. D_{cal}=1.374 g cm^{-3}, μ for Cu $K\alpha$=31 cm^{-1}. Number of observed reflections as above the 2δ(I) level was 2390 out of 3947 within the 2θ range of 6° through 156°. The crystal structure was determined by the direct method and refined by the method of block-diagonal matrix least-squares to an R value of 0.058 including 27 heavier atoms and 42 hydrogen atoms. The hydrogens were

located on the difference electron-density map and their positional and isotropic temperature factors were included in the least-squares refinement. The molecular structure of **3e** is shown in Fig. 1. The molecule consists of an isoxazole ring(A), two phenyl groups (B and C, B ring bears a chlorine atom at *p*-position), and a benzamido group (D). The dimensions of each part of the molecule are quite normal. The torsional angles along the bonds connecting each group are listed in Table 3.

***N*-Benzoylation of 4-Amino-5-phenyl-3-(*p*-tolyl)isoxazole (9f):** A mixture of **9f** (30 mg, 0.12 mmol), *p*-toluoyl chloride (19 mg, 0.12 mmol) and K_2CO_3 (18 mg, 0.12 mmol) in a ether–benzene–H_2O (1 : 3 : 1) mixed solution was stirred at 0—5 °C for 15 h. The mixture was poured into ice-water and extracted with toluene (5 $cm^3 \times 3$), dried (Na_2SO_4) and concentrated to dryness. The residue (47.4 mg) was chromatographed on silica gel with hexane–EtOAc (3 : 1) as an eluent to give **3c** (33.6 mg, 76%): mp 218—220 °C (MeOH–H_2O).

***N*-Methylation of 3a:** A mixture of **3a** (20 mg, 0.06 mmol), KOH (3.9 mg, 0.06 mmol), and 18-crown-6 (0.25 mg, 0.001 mmol) in benzene (2 cm^3) was refluxed for 2 h. After the addition of CH_3I (14 mg, 0.1 mmol) in benzene (1 cm^3), the reaction mixture was refluxed for 4 h and concentrated in vacuo. After washing with H_2O, the crude product was recrystallized from EtOAc–hexane to give 4-(*N*-methylbenzamido)-3,5-diphenylisoxazole (**14a**) (19.0 mg, 92%).

Reductive Ring Opening Reaction of 3a: A solution of **3a** (100 mg, 0.26 mmol) in MeOH (30 cm^3) was hydrogenated (1 atm, r.t.) for 3 h in the presence of activated Raney Ni-Tl. After the solution was filtered, the filtrate was concentrated to dryness. The residue (95.2 mg) was chromatographed on silica gel with hexane–EtOAc (3 : 1) as an eluent to furnish 3-amino-2-benzamido-1,3-diphenyl-2-propen-1-one (**15a**) (64.6 mg, 64%).

Hydrolysis of 15a: A mixture of **15a** (50 mg, 0.15 mmol) and 1 mol dm^{-3} HCl (1 cm^3) in MeOH (2 cm^3) was refluxed for 2h. After cooling, the reaction mixture was diluted with 5 cm^3 of cooled H_2O, and the resultant precipitates were collected. 2-Benzamido-1,3-diphenyl-1,3-propanedione (**16a**) (7.0 mg, 14%): mp 173—175 °C (MeOH) (lit,[14] 173.5—174.5 °C). The filtrate was neutrallized with 2 mol dm^{-3} NaOH and the resultant precipitates were collected. 2-Benzoyl-3,5-diphenylimidazole (**17**) (37.0 mg, 74%): mp 201—202 °C (MeOH).

Dual-Mode Behavior in Doping-Undoping of Polypyrrole with Alkanesulfonate

Takeo SHIMIDZU,* Akira OHTANI, and Kenichi HONDA
Division of Molecular Engineering, Graduate School of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received February 15, 1988)

Polypyrrole (PPy) films incorporated with a series of 1-alkanesulfonates, $R_nSO_3^-$ ($C_nH_{2n+1}SO_3^-$, n=3—10), were prepared by the electrochemical polymerization of pyrrole in H_2O containing sodium salt of $R_nSO_3^-$. The mass transfer in the PPy matrix of the $R_nSO_3^-$ incorporated PPy (PPy/$R_nSO_3^-$) films were investigated by electrochemical measurements. The electrochemical properties of PPy/$R_nSO_3^-$ were affected by the chain length of the incorporated $R_nSO_3^-$. The incorporation and release of cationic species into the PPy/$R_nSO_3^-$ matrix during an electrochemical oxidation-reduction of PPy were observed and the contribution of cationic species during the doping-undoping process was increased with the dopant size. The PPy/$R_nSO_3^-$ showed a dual-mode behavior during the electrochemical doping-undoping process.

Conducting PPy[1-6] has applications in such equipment as, electronic devices,[7,8] electrochromic displays,[9-11] polymer batteries,[12-15] polymer modified electrodes,[16] functional membranes,[17,18] etc. In these applications, the oxidation-reduction capability accompanying the incorporation-release of ions, which is called "doping-undoping," is an important feature of PPy.[19] Though PPy has been studied most widely, it has not provided any advantageous properties from a practical point of view. Many hybridization procedures of PPy with various functional molecules have been developed so as to improve the properties of PPy.[20-31] Especially, a hybridization procedure utilizing an anodic doping process during the electrochemical polymerization of pyrrole has been actively studied, and many kinds of PPy/functional anion composites were prepared. However, there is a question whether PPy/functional anion composites show stable properties under all redox states of PPy, because incorporated anions (dopants) are usually released from the PPy matrix when PPy is reduced. We reported that the size of the dopant affected the doping-undoping capability of PPy.[32] In recent years, studies of mass transfer in the PPy matrix on the oxidation-reduction of PPy have been reported.[33-36] Either anion releasing or cation incorporating was observed when PPy was electrochemically reduced. In this study, a series of 1-alkanesulfonates was chosen as the dopant[37] and the detailed electrochemical property of PPy/$R_nSO_3^-$ during the electrochemical oxidation-reduction process is discussed.

Experimental

Materials. Pyrrole (Aldrich Chemical Co.) was distilled and stored under an N_2 atmosphere. Potassium chloride (Wako Chemical Co.) and sodium 1-alkanesulfonates, such as sodium 1-propanesulfonate, 1-butanesulfonate, 1-pentanesulfonate, 1-hexanesulfonate, 1-heptanesulfonate, 1-octanesulfonate, 1-nonanesulfonate, and 1-decanesulfonate (Nakarai Chemicals), were used without further purification.

Preparation of PPy. PPy/$R_nSO_3^-$ films on an indium-tin oxide (ITO) electrode (7 cm^2) for elemental analyses, measurements of conductivity, and deionization experiments were prepared by the electrochemical polymerization of pyrrole (0.1 mol dm^{-3}) in H_2O containing sodium salt of $R_nSO_3^-$ (0.1 mol dm^{-3}) under 10 mA galvanostatic electrolysis for 1 h. The thicknesses of these films were estimated by an optical microscopic photograph of the cross section of the PPy/$R_nSO_3^-$. PPy/$R_nSO_3^-$ films on a Pt electrode (0.047 cm^2) for cyclic voltammetry were prepared by an electrochemical polymerization of pyrrole (0.1 mol dm^{-3}) in H_2O containing sodium salt of $R_nSO_3^-$ under potentiostatic electrolysis (1.0 V vs. SCE) for 4.9 mC. A chloride anion incorporated PPy (PPy/Cl^-) on an ITO electrode (7 cm^2) was prepared by the electrochemical polymerization of pyrrole (0.2 mol dm^{-3}) in 0.5 mol dm^{-3} KCl aqueous solution under 10 mA galvanostatic electrolysis for 1 h. The reduced PPy/Cl^- (PPy/Cl^-(red.)) for deionization experiments was prepared by a −2.0 mA galvanostatic electrolysis of the PPy/Cl^- anode in a 0.1 mol dm^{-3} KCl aqueous solution until the potential reached −1.0 V vs. SCE, at which point the incorporated Cl^- was quantitatively released.

Electrochemical Measurements. Cyclic voltammetries were carried out in H_2O containing a 0.1 mol dm^{-3} sodium salt of $R_nSO_3^-$ or KCl. Deionization experiments were carried out by potentiostatic electrolysis of the PPy/Cl^- (red.) anode and the PPy/$R_nSO_3^-$ cathode. The concentration of K^+ in a KCl aqueous solution was measured by an atomic absorption analysis (Shimadzu AA-670). All electrochemical experiments were carried out at room temperature under an N_2 atmosphere using a potentiogalvanostat (Nikko Keisoku NPGS- 301), a function generator (Nikko Keisoku NFG-3), and a coulomb/ampere-hour meter (Hokuto Denko Ltd. HF-201).

Results and Discussion

Electrochemical Properties of PPy/$R_nSO_3^-$. The dopant ratio and conductivity are indicative characteristics for the electrochemical properties of conducting polymers. Table 1 shows elementary analyses and film thickness of the PPy/$R_nSO_3^-$. The S/N ratio, which allowed us to estimate the ratio of incorporated anions to the pyrrole moiety (dopant ratio), increased with the dopant size. The resulting film thickness also increased with the dopant size. Figure 1 shows the conductivity of the PPy/$R_nSO_3^-$ films. The conduc-

a) Sweep rate was 50 mV s^{-1}.

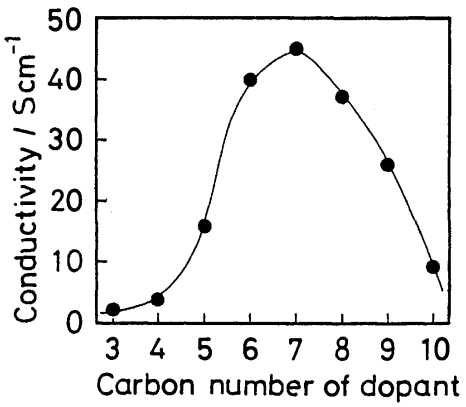

Fig. 1. Relationship between conductivity and carbon number of dopant for $PPy/R_nSO_3^-$.

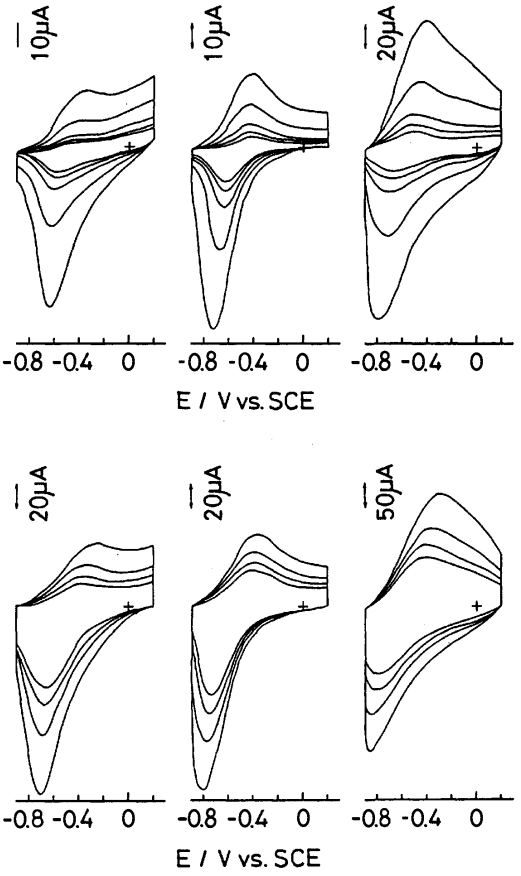

Fig. 2. Cyclic voltammograms of $PPy/R_3SO_3^-$ (left), $PPy/R_5SO_3^-$ (middle), and $PPy/R_{10}SO_3^-$ (right) in H_2O containing the incorporated anion (0.1 mol dm^{-3}) as a supporting electrolyte. Sweep rate was 20—100 mV s^{-1} (upper) and 200—500 mV s^{-1} (bottom).

tivity of the $PPy/R_nSO_3^-$ first increased with the dopant size (n=3—7) and then decreased (n=7—10). In general, the conductivity of the conducting polymer increases with the dopant ratio. However, the optimum conductivity was observed with $PPy/R_7SO_3^-$. The decrease of the conductivity was explained by the decrease of the electron carrier density, which was governed by the alkyl-chain length of the incorporated anion.

Cyclic voltammetry is one of the most important measurement techniques for investigating the electrochemical properties of PPy. Figure 2 shows typical cyclic voltammograms (sweep rates were 20—500 mV s^{-1}) of $PPy/R_nSO_3^-$ (n=3, 5, and 10) in H_2O containing the incorporated anion (0.1 mol dm^{-3}) as a supporting electrolyte. These cyclic voltammograms reflect the doping-undoping behavior of the incorporated anion, not involving any exchange reactions of incorporated anions (as stated below). Table 2 shows the redox potentials of $PPy/R_nSO_3^-$ at a sweep rate of 50 mV s^{-1}. The redox potentials of $PPy/R_nSO_3^-$ appeared in the range −520—−643 mV, and decreased with the dopant size. It has already been reported that the redox potential is affected by the properties of the incorporated anion.[33)]

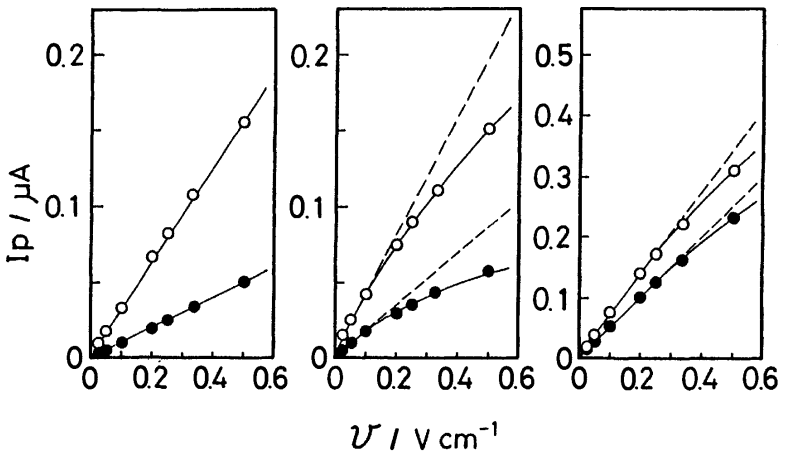

Fig. 3. Relationship between i_p and v for the cyclic voltammograms of $PPy/R_3SO_3^-$ (left), $PPy/R_5SO_3^-$ (middle), and $PPy/R_{10}SO_3^-$ (right). (●); anodic peak current, (○); cathodic peak current.

It is well-known that the relationship between the peak current (i_p) and the sweep rate (v) in a cyclic voltammogram shows the characteristics of mass transfer in the electroactive film on the electrode. The power number (X), the slope of the linear relationship between $\log(i_p)$ and $\log(v)$, is a convenient factor for estimating the mobility of the ionic species in the matrix. In general, $X=1$ shows that the mobility of the ionic species is higher than the electron-transfer rate, which is called "a surface wave;" $X=0.5$ shows that the mobility of the ionic species is lower than the electron-transfer rate, "a diffusion-controlled wave." In fact, X can have values from 0.5 to 1.0. Therefore, the contribution of the diffusion-controlled wave behavior is estimated by the X-value. It has been reported that the charge propagation mechanism, surface wave behavior or diffusion-controlled wave behavior, is affected by the properties of the counter ions in a polymer-modified electrode.[38] Figure 3 shows typical i_p-v relationships obtained from Fig. 2. In a surface wave ($X=1$) i_p is proportional to v, and in a diffusion-controlled wave ($X=0.5$) i_p is proportional to $v^{1/2}$. At $v<100$ mV s^{-1} all $PPy/R_nSO_3^-$ showed the surface-wave behavior, as in some previous studies on ordinary PPy. However, at $v>100$ mV s^{-1}, $PPy/R_3SO_3^-$ (small-size dopant) and $PPy/R_{10}SO_3^-$ (large-size dopant) showed almost the surface-wave behavior, and $PPy/R_5SO_3^-$ did not show the surface-wave behavior. Figure 4 shows the relationship between the X-value and the carbon number of the dopant (n). The X-value was estimated to be in the range 200—500 mV s^{-1}. The X-value decreased with the dopant size at $n<5$, and gradually increased with the dopant size at $n>6$. The X-value reflects the mobility of ionic species in the PPy matrix. In other words, when $X=1$, the mobility of ionic species is high, but when $X=0.5$, that of ionic species is low. Accordingly, it was concluded that the mobilities of the ionic species in $PPy/R_3SO_3^-$ and

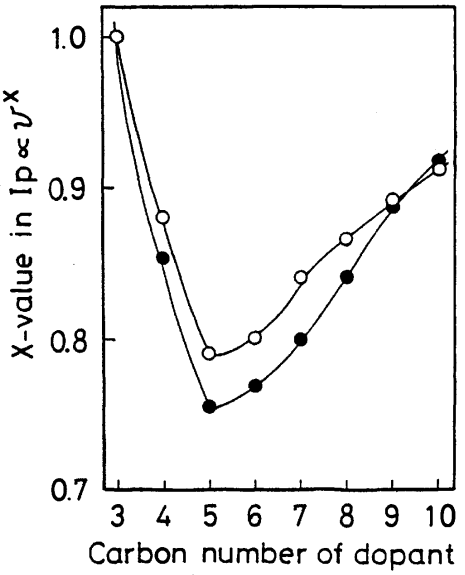

Fig. 4. Relationship between X and carbon number of dopant for $PPy/R_nSO_3^-$. X-Values were estimated from the slope between $\log(i_p)$ and $\log(v)$ (v were in the range 200—500 mV s^{-1}).

$PPy/R_{10}SO_3^-$ were high, and that in $PPy/R_5SO_3^-$ was low. Assuming only the anion can be transported in the PPy matrix, the mobility of $R_{10}SO_3^-$ was higher than that of $R_5SO_3^-$. Thus, the present observation can not be explained only by the dopant size. It was considered that other ionic species, an electrolyte cation, contributed to the electrochemical doping-undoping process. We had already reported that in the case that the polymer anion incorporated PPy (PPy/PA), the electrolyte cation was incorporated into the PPy matrix in lieu of the anion, when the PPy was electrochemically reduced.[32]

Cyclic voltammetry for $PPy/R_nSO_3^-$ in H_2O containing KCl was carried out in order to estimate only

the mobility of the anion. Figure 5 shows typical cyclic vltammograms of PPy/$R_nSO_3^-$ (n=3, 5, and 10) in H_2O containing 0.1 mol dm^{-3} KCl as a supporting electrolyte. We have already reported that the PPy/Cl^- had a more positive redox potential (>0 V vs. SCE) than the PPy/$R_5SO_3^-$, and that the potential sweeps in cyclic voltammetry for PPy/$R_5SO_3^-$ in a KCl aqueous solution induced an exchange reaction of the dopants (PPy/$R_5SO_3^-$ → PPy/Cl^-).[33] The rate of dopant exchange is controlled by the mobility of the original dopant in the PPy matrix, so that the diffusion rate of the original dopant can be estimated by the rate of the dopant-exchange reaction. Changes of the cyclic voltammograms during 5 sweeps can be observed in Fig. 5. The redox peaks at low and high potentials corresponded to the oxidation-reduction of PPy/$R_nSO_3^-$ and PPy/Cl^-, respectively. The redox peaks of PPy/$R_nSO_3^-$ decreased and those of PPy/Cl^- increased in all cyclic voltammograms. The cyclic voltammograms for PPy/$R_3SO_3^-$ and PPy/$R_5SO_3^-$ were profoundly changed. On the contrary, the cyclic voltammogram for PPy/$R_{10}SO_3^-$ was hardly changed. The rate of change of the peak currents decreased with the dopant size. Upon the first reduction of PPy, the original dopant, $R_nSO_3^-$, was partly released from the PPy matrix. On the successive oxidation, Cl^- in the electrolytic solution was partly incorporated into the PPy, since the concentration of Cl^- in the electrolytic solution was much higher than that of $R_nSO_3^-$. We defined a convenient dopant exchange rate as

$$\Phi = 1 + (i_{pc}(Cl^-)/i_{pc}(R_nSO_3^-)) \text{ at 5th cycle,} \quad (1)$$

Φ increased with the mobility of $R_nSO_3^-$. Figure 6 shows the relationship between Φ and the carbon number of the dopant. Φ decreased with the dopant size, which indicates that the mobility of the $R_nSO_3^-$ decreased with the dopant size. This conclusion could not explain the profile of Fig. 4, in which the mobility of the ionic species does not monotonously decrease with the dopant size. The increasing mobility observed for the longer alkyl dopants (n=5—10) in Fig. 4 should be explained by the incorporation of an electrolyte cation into the PPy matrix. We already reported that the electrolyte cation, e.g., K^+, was incorporated into the PPy matrix in order to conserve the electro-neutrality in the PPy matrix when the PPy/PA was electrochemically reduced. In this case, the polymer anion dopant was not released from the PPy matrix, owing to its macromolecularity. We called this observation "a pseudo-cathodic doping" and the polymer anion dopant "an immobilized dopant." It was suggested that the long alkyl dopants, such as $R_{10}SO_3^-$, were partly immobilized in the PPy matrix as a polymer anion dopant, so that the electrolyte cation was partly incorporated and released upon the oxidation and reduction of PPy. Because K^+ is much smaller than $R_nSO_3^-$, the increasing mobility observed for longer alkyl dopants in Fig. 4 could be explained by the incorporation of K^+ instead of the release of $R_nSO_3^-$.

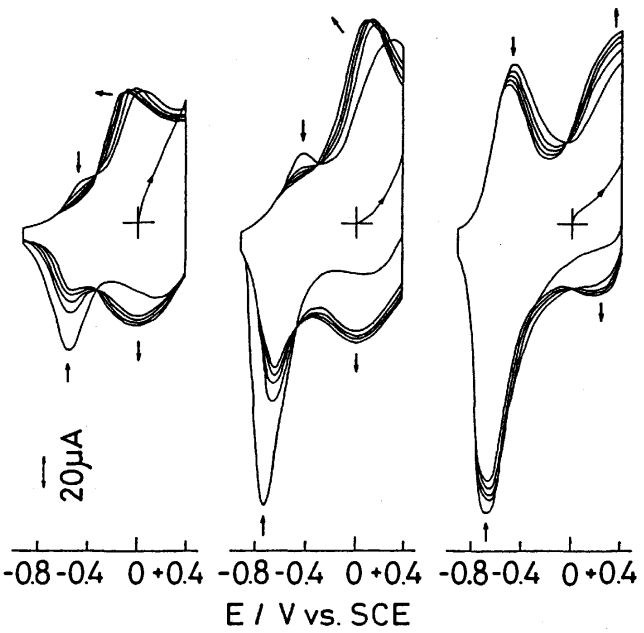

Fig. 5. Cyclic voltammograms of PPy/$R_3SO_3^-$ (left), PPy/$R_5SO_3^-$ (middle), and PPy/$R_{10}SO_3^-$ (right) in H_2O containing KCl (0.1 mol dm^{-3}) under potential sweep. Sweep rate was 200 mV s^{-1}.

Cation-Exchange Capability of PPy/$R_nSO_3^-$. We have reported that a novel type of electrochemical deionization system was constructed using a PPy/Cl^- (red.) anode and a PPy/PA cathode.[39,40] In this system an electrolyte anion was incorporated into the PPy/Cl^- by ordinary doping and an electrolytic cation was incorporated into PPy/PA by pseudo-cathodic doping. Thus, the PPy/Cl^- had an anion-exchange ability, and the PPy/PA had a cation-exchange ability. Electrochemical deionization experiments were carried out using an PPy/Cl^- (red.) anode and the present PPy/$R_nSO_3^-$ cathode in order to reveal a cation-

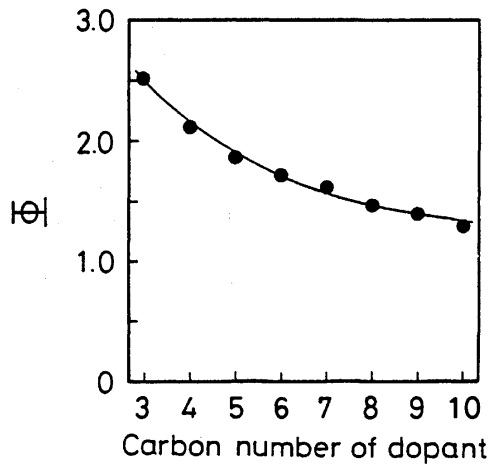

Fig. 6. Relationship between Φ and carbon number of dopant. Φ is defined by Eq. 1.

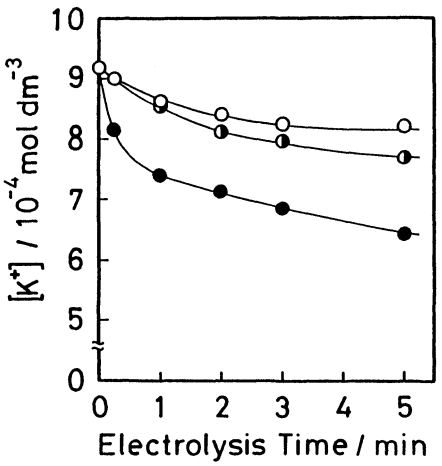

Fig. 7. Change of K^+ concentration in KCl aqueous solution with deionization time on 4 V potentiostatic electrolysis, using a PPy/Cl^- (red.) anode and a PPy/$R_nSO_3^-$ cathode. (○); PPy/$R_3SO_3^-$, (◑); PPy/$R_5SO_3^-$, and (●); PPy/$R_{10}SO_3^-$.

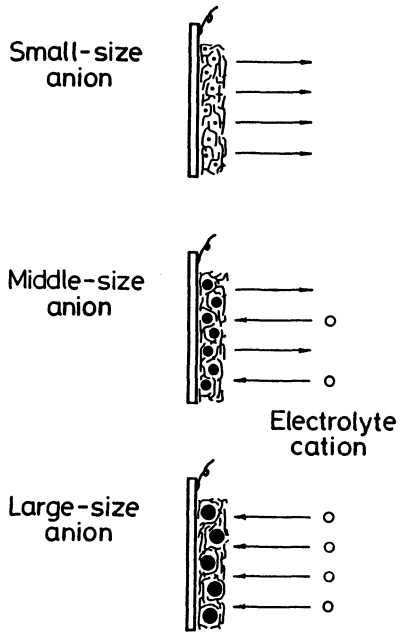

Fig. 8. A proposed model for the doping-undoping behavior of PPy/$R_nSO_3^-$.

exchange capability, i.e., the pseudo-cathodic doping, of the PPy/$R_nSO_3^-$. In these experiments the PPy/Cl^- (red.) was used as an anode in order to prevent any pH change in the solution and to promote the effective deionization of K^+.[40] Figure 7 shows the concentration change of K^+ in a KCl aqueous solution (original; 9.2×10^{-4} mol dm^{-3}) treated by the potentiostatic electrolysis (4 V) of the two electrodes. The concentration of K^+ decreased as a result of this treatment. The quantity of incorporated K^+ increased with the dopant size. This observation indicated that PPy/$R_nSO_3^-$ had a considerable capability of pseudo-cathodic doping. Moreover, the capability of pseudo-cathodic doping increased with the dopant size.

Figure 8 shows a proposed model for the doping-undoping behavior of PPy/$R_nSO_3^-$. Controlling such a dual-mode behavior, the release of an anion or the incorporation of a cation, of the present films will provide a prismatic electerochemical material.

This work was partly supported by a Grant-in-Aid from the Ministry of Education.

The Reaction of 1-Amino-2,3-diphenylcyclopropenium Ions with 1,3-Diketones to Afford 2,4-Cyclopentadien-1-ols: The Regioselective Ring-Opening of 1-Amino-cyclopropene Intermediates

(Received February 20, 1988)

1-Amino-2,3-diphenylcyclopropenium tetrafluoroborates (**4**) reacted with cyclic or acyclic 1,3-dicarbonyl derivatives (**5**) such as 1,3-diketones, β-keto esters, or gem-diesters in the presence of triethylamine to give 2,4-cyclopentadien-1-ols in moderate to good yields. Some isolated cyclopropene intermediates were, upon heating, converted to the corresponding cyclopentadienols. The factors that influence on the reactivities of **4** and **5** (basicities of the amino groups of **4** and bulkiness of the substituents of **4** and **5**) are discussed qualitatively.

The chemistry of cyclopropene derivatives has attracted considerable interest because of the high strain energy associated with the unsaturated three-membered ring. A number of studies on the photochemical and thermal ring-opening reactions of cyclopropenes have appeared in recent years.[1,2]

We have recently reported the reaction of 1-(methylthio)-2,3-diphenylcyclopropenium ion (**1**) with 2,4-pentanedione and with 1,3-cyclohexanedione to yield cyclopentadienol (**2**)[3] and 2*H*-pyran derivative (**3**),[4] respectively (Scheme 1). In this connection we have been interested in the effect of heteroatom substituents (such as alkoxy, alkylthio, and amino groups) on the attacking position of cyclopropenium ions and ring opening of the resulting cyclopropenes.[2-4] This paper describes the reaction of 1-amino-2,3-diphenylcyclopropenium ions (**4**) with 1,3-dicarbonyl compounds **5** to afford cyclopropenes **6**, followed by regioselective ring opening to give cyclopentadienols **7**.

1-Amino-2,3-diphenylcyclopropenium tetrafluoroborates (**4**) were prepared by a reaction of 2,3-

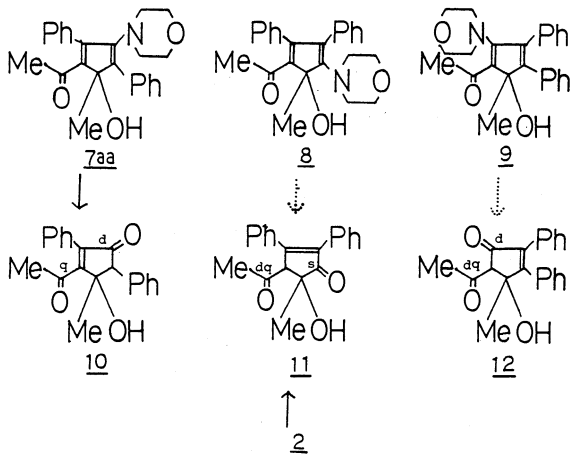

Scheme 3.

diphenylcyclopropenone with triethyloxonium tetrafluoroborate, followed by a treatment with secondary amines.[5-7] A mixture of 1-morpholino-2,3-diphenylcyclopropenium tetrafluoroborate (**4a**), 2,4-pentanedione (**5a**), and triethylamine in a mole ratio of 1 : 1.1 : 2 was stirred in dry benzene at room temperature for 1 h to yield the reaction product **X** as yellow needles. The ^{1}H and ^{13}C NMR, and mass spectra of **X** revealed the structure to be a cyclopentadienol derivative arising from a 1 : 1 adduct of **4a** and **5a**, but did not permit a clear choice among mechanistically possible isomers (**7aa**, **8**, and **9** in Scheme 3).

Upon hydrolysis **7aa**, **8**, and **9** might give cyclopentenones **10**, **11**, and **12** respectively (Scheme 3). Previously we have shown[3] that desulfurization of **2** yields 2-cyclopentenone **11** (mp 184—185 °C), whose ^{13}C NMR spectrum shows two carbonyl carbons at δ=204.9 (dq, $\underline{C}OCH_3$) and 206.8 (s, C_1). Cyclopentenone **12** might yield two carbonyl carbons as a dq ($\underline{C}OCH_3$ due to coupling with $COC\underline{H}_3$ and $C_5\underline{H}$) and a d (C_1 due to $C_5\underline{H}$). Hydrolysis of **X** under mild conditions (formic acid in benzene) afforded cyclopentenone as a colorless crystalline mass (mp 159—161 °C), whose ^{13}C NMR spectrum showed a d at 203.1 ($^{2}J_{CCH}$=6.8 Hz, C_1) and a q at 204.1 ($^{2}J_{CCH}$=6.0 Hz, $\underline{C}OCH_3$) due to carbonyl carbons, establishing the structure of the cyclopentenone to be **10**. Consequently, **X** was unambigously revealed to be 1-acetyl-2,4-diphenyl-5-hydroxy-5-methyl-3-morpholinocyclopentadiene (**7aa**).

Although stable under basic conditions (NaOH in ethanol) **7aa** upon being treated with trifluoroacetic acid produced complex mixtures. In a mixture of chloroform and ethanol containing a small amount of trifluoroacetic acid, **7aa** yielded the cyclopentadienone **13** in quantitative yield, which underwent a Diels-Alder addition with dimethyl acetylenedicarboxylate (DMAD) to give the hexasubstituted benzene **14** in a 28% yield.

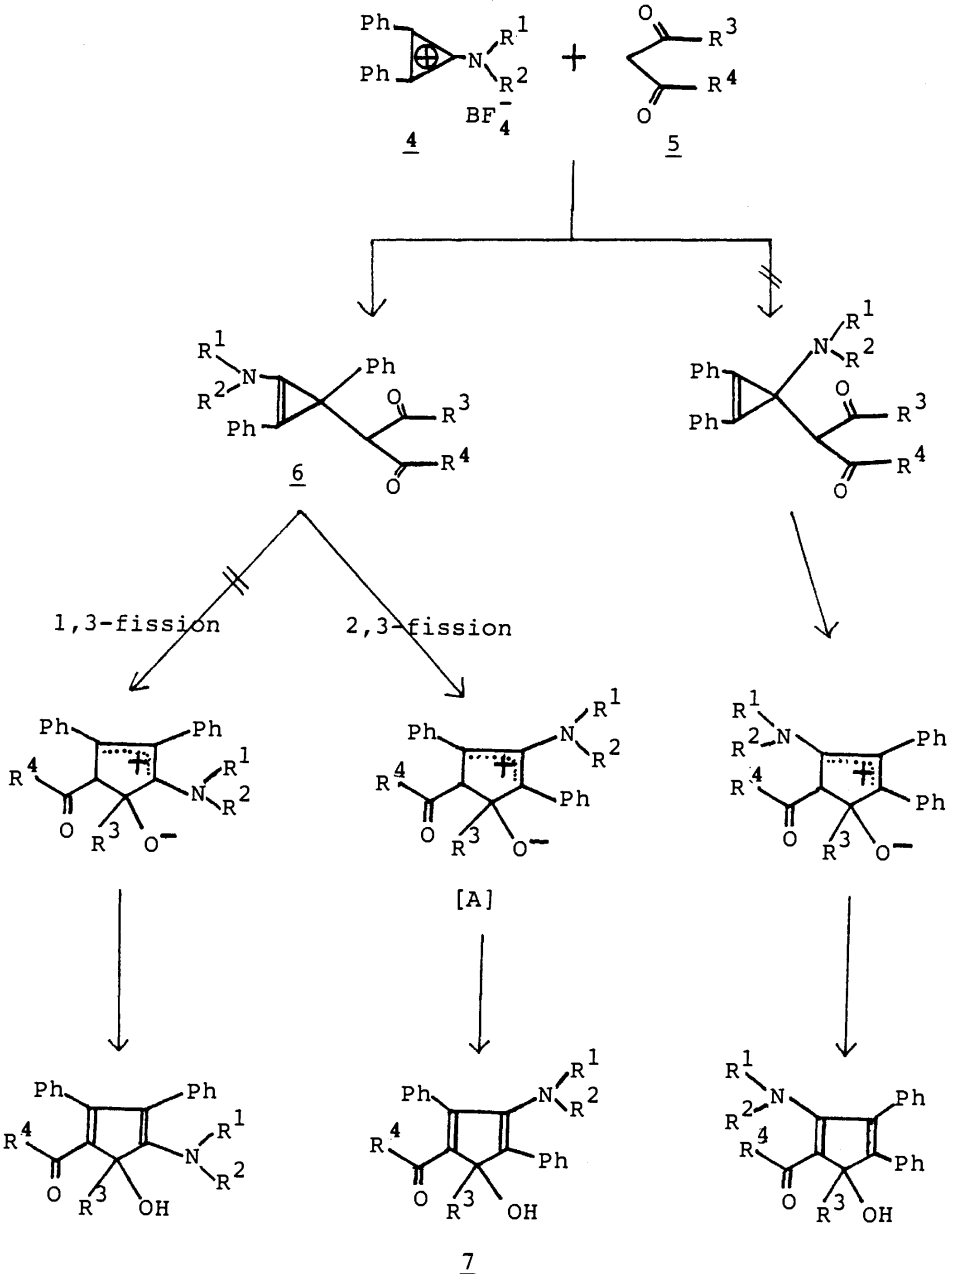
The results of the reaction of cyclopropenium ions possessing amino substituents **4a—4d** with acyclic and cyclic 1,3-diketones, -ketoesters, and diethyl malonates **5a—5j** are collected in Table 1. In certain cases, 1-aminocyclopropenes **6** were isolated, whose structure were elucidated on the basis of their IR (around 1840 cm^{-1}) and ^{13}C NMR (C_3, sp^3 carbon) spectroscopic studies. The cyclopropenes could be isolated when they were derived from either small enolizable[8-10] or bulky

diketones **5**, and/or bulky amines **4** (Table 1). The cyclopropenes **6** were converted to the corresponding cyclopentadienols **7** under the stronger conditions as listed in Table 2.

Six-membered cyclic ketones **5d** and **5e** showed high reactivities toward ions **4** yielding good crystalline products, whereas, a 5-membered ketone **5f** gave unstable mixtures from which no crystalline product could be isolated. The reaction of **4a** and **4b** with sterically hindered ketones **5c** afforded **6ac** and **7bc**, respectively, while **4d** gave no crystalline product with **5c**. Thus, the reactivities of the ions **4** seem to have been influenced by the basicities of the amines and bulkiness of the amino substituents. The pyrrolidinyl substituted **4c** reacted with diketones **5a**, **5c**, and **5d**, but gave unidentifiable tarry mixtures, probably because the enamine-type products would be hydrolyzed under the purification procedure.[11]

Finally, we propose a mechanism for the reaction of **4** with **5**, as illustrated in Scheme 4. The initial step involves a nucleophillic attack of the carbanion generated fron 1,3-diketones **5** on the C_2 or C_3 of **4** to yield 1-aminocyclopropene **6**, since the electron-releasing properties of the amino group would increase the electron density of C_1. Two routes are possible for the ring opening of the cyclopropenes. As we mentioned in an earlier paper,[3] 3-(1,2,3-triphenylcyclopropenyl)-2,4-pentadienone was stable at 100 °C in both the presence and absence of triethylamine. This observation indicates that the electron-attracting nature of the carbonyl



Scheme 4.

groups does not facilitate a ring opening of the cyclopropene. Considering the products obtained (**7**), a process involving a carbenium ion like **A** seems to be most stabilized by the adjacent amino group.

In the reaction of **1**, as shown in Scheme 1, acyclic and cyclic diketones gave two kinds of products, respectively (**2** and **3**). These results can be well-explained in terms of the electron-releasing and -accepting properties of the alkylthio group.[3] The electron-releasing nature of the amino substituent does not permit a formation of 2*H*-pyran derivatives (**3** analogues), yielding only cyclopropentadienol **7**(**2** analogues).

Experimental

General. Melting points were uncorrected. The ^{13}C NMR spectra were recorded either on a JEOL JMN FX-60 spectrometer (15.04 MHz) or JEOL JNM FX-90Q (22.49 MHz) and ^1H NMR spectra on a Hitachi R-24B (60 MHz). The IR spectra were recorded on a JASCO A-3 spectrometer.

Preparation of 1-Amino-2,3-diphenylcyclopropenium Tetrafluoroborates 4. The salts **4** were prepared by a known method.[5-7] Analytical and spectroscopic data for new derivatives are as follows. **4a** in 85% yield: mp 273—275 °C; IR(KBr) 1890 cm^{-1}; ^1H NMR ($CDCl_3$-CF_3CO_2H in 10:1) δ=4.04 (s, 8H, $2N(CH_2)_2O$) and 7.4—8.1 (m, 10H, 2Ph). Found: C, 62.53; H, 4.88; N, 3.69%. Calcd for $C_{19}H_{18}BF_4NO$: C, 62.84; H, 5.00; N, 3.86%. **4b** in 56% yield: mp 252—253 °C; IR(KBr) 1890 cm^{-1}; ^1H NMR ($CDCl_3$-CF_3CO_2H in 10:1) δ=1.88 (bs, 6H, $(CH_2)_3$), 3.8—4.2 (m, 4H, $N(CH_2)_2$), and 7.5—8.1 (m, 10H, 2Ph). Found: C, 66.62; H, 5.53; N, 3.99%. Calcd for $C_{20}H_{20}BF_4N$: C, 66.51; H, 5.58; N, 3.88%. **4c** in 15% yield: mp 275—278 °C; IR(KBr) 1900 cm^{-1}; ^1H NMR ($CDCl_3$-CF_3CO_2H in 10:1) δ=2.3—2.7 (m, 4H, $(CH_2)_2$), 4.0—4.4 (m, 4H, $N(CH_2)_2$), and 7.5—8.2 (m, 10H, 2Ph). Found: C, 65.47; H, 5.06; N, 4.12%. Calcd for $C_{19}H_{18}BF_4N$: C, 65.74; H, 5.23; N, 4.03%.

The Reaction of 4 with 1,3-Diketones 5. A general procedure. A mixture of **4** (1 mmol), **5** (1.1 mmol), and triethylamine (2 mmol) in 15 cm^3 of dry benzene was stirred at room temperature. After the reaction (no change of the precipitate and TLC of the reaction mixture) the solution was poured into cold water, and the organic layer was separated and dried over sodium carbonate. Recrystallization of the product from benzene-petroleum ether afforded faint-yellow crystals. Yields are listed in Table 1.

Thermal Reaction of 6. A solution of **6** (0.2 g) in an appropriate solvent (10 cm^3) was heated at reflux and the reaction was checked by TLC. After the reaction the mixture was condensed and the products which separated were recrystallized from benzene-petroleum ether (Table 2). The physical properties are as follows. **7aa:** mp 143—144 °C; IR(KBr) 3440 and 1620 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.41 (s, 3H, CH_3), 1.80 (s, 3H, $COCH_3$), 2.3—2.6 (m, 4H, $N(CH_2)_2$), 3.1—3.4 (m, 4H, $O(CH_2)_2$), 3.95 (s, 1H, OH), and 7.2—7.7 (m, 10H, 2Ph). ^{13}C NMR ($CDCl_3$) δ=25.4(q), 30.2(q), 50.9(t), 66.6(t), 83.4(s), 127.5(d), 128.6(d), 128.9(d), 130.2(d), 134.3(s), 134.4(s), 137.5(s), 144.1(s), 147.3(s), 153.5(s). and 196.1(s). Found: C, 76.57; H, 6.58; N, 3.83%; M^+, 375. Calcd for $C_{24}H_{25}NO_3$: C, 76.76; H, 6.72; N, 3.73%; M, 375. **7ab**: mp 164—165 °C; IR(KBr) 3350 and 1610 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.50 (s, 3H, CH_3), 2.2—2.5 (m, 4H, $N(CH_2)_2$), 3.1—3.4 (m, 4H, $O(CH_2)_2$), 3.57 (s, 1H, OH), and 6.8—7.8 (m, 15H, 3Ph). Found: C, 79.55; H, 6.21; H, 3.19%; M^+, 437. Calcd for $C_{29}H_{27}NO_3$: C, 79.61; H, 6.22; N, 3.20%; M, 437. **6ac**: mp 179—181 °C; IR (KBr) 1840, 1700, and 1670 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.66 (t, J=5Hz, 4H, $N(CH_2)_2$), 3.51 (t, J=5 Hz, 4H, $O(CH_2)_2$), 6.8—8.1 (m, 20H, 4Ph). ^{13}C NMR ($CDCl_3$) δ=51.0(t), 66.4(t), 87.5(s), 92.8(d), 124.7(s), 126.8(d), 127.2(d), 128.0(d), 128.2(d), 128.3(d), 128.6(d), 129.0(d), 129.6(d), 131.5(d), 132.2(d), 133.0(d), 133.9(d), 137.2(s), 139.7(s), 147.1(s), 150.8(s), 185.4(s), and 195.1(s). Synthesis and Acid-Catalyzed Ring Opening of 1-Alkenyl Cyclopropyl Ketones

Otohiko TSUGE,* Shuji KANEMASA, Tatsuya OTSUKA, and Toshiro SUZUKI

(Received February 26, 1988)

1-Alkenyl cyclopropyl ketones, when activated by cation-stabilizing substituents at the ring carbon or at the terminal carbon of the enone moiety, undergo polyphosphoric acid-catalyzed ring enlargement producing cyclopentanone or cyclohexenone derivatives. Similar acid-catalyzed ring opening of 1-alkenyl 2-phenoxycyclopropyl ketones offers a convenient and effective synthesis of 4-oxo-5-alkenals and their dioxolane-protected derivatives.

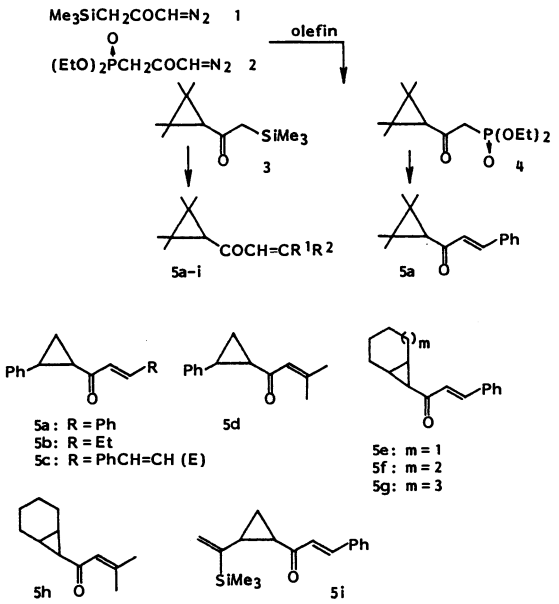
Our previous article described the simple synthesis of 1-alkenyl cyclopropyl ketones by a tandem cyclopropanation of 1-diazo-3-silyl-2-propanone and Peterson olefination sequence.[1] As a synthetic utilization and application of 1-alkenyl cyclopropyl ketones, homo-Nazarov type cyclization is expected since there are numerous examples known for ring opening reactions of cyclopropyl ketones[2] in the presence of acid catalysts such as protonic acids,[3] silylated acids,[4] Lewis acids,[5] and a pyridinium chloride.[6] Mostly the resulting carbonium ion intermediates are either quenched by nucleophiles present in the reaction mixture, e.g. conjugate bases arising from the acid catalysts or reaction solvents, or undergo β-elimination forming olefins.

To the best of our knowledge, no example of homo-Nazarov type ring enlargement of 1-alkenyl cyclopropyl ketones is known. Only a few examples for the related reactions have been reported previously. Aroyl cyclopropanes undergo acid-catalyzed ring enlargements to lead to tetralone derivatives,[7] or the cation intermediates involved in the acid-catalyzed ring opening were intramolecularly trapped by a separated aryl or olefin moiety.[8]

We wish to report here that 1-alkenyl cyclopropyl ketones undergo novel ring enlargements leading to cyclopentanones or cyclohexenones by action with polyphosphoric acid. Though the presence of an oxygen substituent on the cyclopropane ring of 1-alkenyl cyclopropyl ketones produces no ring-enlarged products, their ring openings are highly accelerated to furnish 4-oxo-5-alkenals or their dioxolane-protected derivatives.

Results and Discussion

1-Alkenyl cyclopropyl ketones **5a—h** used as substrates in the present work were previously prepared by a sequence of reactions including cyclopropanation of olefins with 1-diazo-3-trimethylsilyl-2-propanone (**1**), lithiation of the resulting cyclopropyl silylmethyl ketones **3**, and Peterson olefination using a variety of carbonyl compounds R^1COR^2 (Scheme 1).[1] Due to their susceptibility to moisture, silylmethyl ketones **3** were employed to the subsequent olefination without isolation and purification. As an additional example, the reaction of diazo ketone **1** with 2-(trimethylsilyl)-1,3-butadiene in the presence of a catalytic amount (1 mol%) of copper(II) acetylacetonate gave a mixture of two regioisomeric cyclopropanes. The mixture was then lithiated with lithium diisopropylamide (LDA) and allowed to react with benzaldehyde to afford **5i** and its regioisomer in 22% yield (2:1 by ^{1}H NMR, based on **1**).



Scheme 1.

It was expected that 1-diazo-3-[(diethoxyphosphoryl)-methyl]-2-propanone (**2**) could serve as a new synthetic equivalent of **1** and would lead to less moisture-sensitive cyclopropyl ketones such as **4**.[9] However cyclopropanations using diazo ketone **2** resulted in the formation of complex products. Only styrene furnished the corresponding cyclopropyl ketone **4** in a fair yield (44%).

Stable ketone **4** was converted into 1-alkenyl cyclopropyl ketone **5a** in 85% yield by the reaction with benzaldehyde in the presence of triethylamine and lithium bromide.[10]

With an expectation of acid-catalysis for the ring opening, the 1-alkenyl cyclopropyl ketone **5a** was treated with a variety of Lewis or protonic acids. In many cases **5a** was either recovered intact ($Zn(OTf)_2$ in CH_2Cl_2, rt, 48 h; $Zn(OTf)_2$ in MeCN, rt, 48 h; $AlMe_3$ in CH_2Cl_2, rt, 19 h; LiOTf in CH_2Cl_2, rt, 9 d; $BF_3 \cdot OEt_2$ in CH_2Cl_2, rt, 7 h; PPSE[11] in $MeNO_2$, rt, 30 min) or decomposed into complex mixture ($TiCl_4$ in $MeNO_2$, rt, 10 min; $SnCl_4$ in CH_2Cl_2, rt, 22 h; PPSE in $MeNO_2$, reflux, 2 d; CF_3SO_3H in CH_2Cl_2, rt, 1 h).

Treatment of **5a** with trifluoromethanesulfonic acid in trifluoroacetic acid (TFA) at room temperature gave the expected ring-opened product **6** (Table 1, Entry 1). In this reaction water served as a nucleophile (Nu) to trap the resulting carbonium ion **A** (Scheme 2). Use of benzene as a solvent caused electrophilic substitution of **A** on the benzene to provide **7** (Entry 2). Boron trifluoride etherate also works as an effective catalyst (E^+) in a polar solvent, nitromethane which accelerates the ring opening of **5a**. Thus by action of boron trifluoride etherate and acetic anhydride, **5a** or **4** was readily converted into diacetate **8** or **9**, respectively (Entries 3 and 4). Polyphosphoric acid (PPA) is also able to open **5h** to give hydroxy ketone **10** (Entry 5).

Both diacetates **8** and **9** were obtained as single isomers. *Z*-Geometry of **8** with respect to the newly formed enol acetate was confirmed on the basis of the NOE difference ^1H NMR spectrum in which notable signal enhancement was observed between β-H of the enol acetate and the two styryl protons. Equally *Z*-selective formation of **8** was achieved regardless of the cis-trans ratio of the starting cyclopropyl ketones **5a**.

The above *Z*-selectivity seems to be a kinetical result on the basis of the following discussion: In the acid-

Table 1. Acid-Catalyzed Ring Opening of Cyclopropyl Ketones **4** and **5**

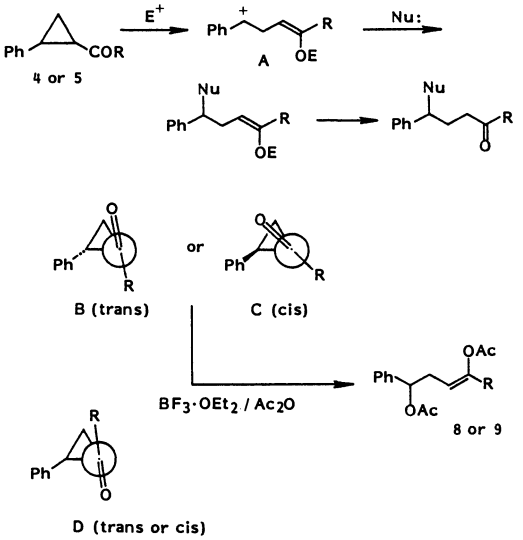
a) Yield of isolated products.

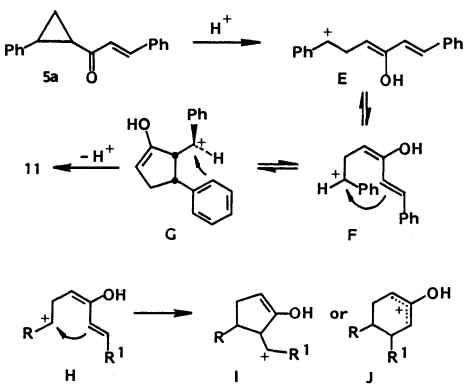
catalyzed ring opening of cyclopropyl ketones, the σ-bond to be cleaved must interact effectively with the carbonyl π-orbital.[12] So a concerted ring opening would occur in a stereospecific fashion if the bond to be cleaved is nearly perpendicular to the plane of the carbonyl. As the most stable conformations for *trans*-**5a** and for *cis*-**5a** are expected to bear the bulkier substituent R far from the unsubstituted methylene carbon (**B** for *trans*-**5a** and **C** for *cis*-**5a**),[13] their concerted ring opening would lead to *Z*-isomer **8**. This is the result actually observed. Conformation **D** may be less stable due to some serious steric hindrance between R and one of the ring methylene hydrogens.[14]



Scheme 2.

On treatment of cyclopropyl ketone **5a** with PPA under reflux in benzene in a two phase reaction, cyclopent[*a*]inden-1-one (**11**) was obtained in 71% yield as a single isomer (Table 1, Entry 6). The 3a,8a-cis-8,8a-trans stereochemistry was confirmed on the basis of the coupling constants ($J_{3a\text{-}8a}$=7.5 and $J_{8\text{-}8a}$=0.8 Hz).

Scheme 3 illustrates a possible mechanism for the stereoselective ring enlargement of 1-alkenyl cyclopropyl ketone **5a** leading to **11**. As discussed above (in Scheme 2), the acid-catalyzed ring opening of **5a** exclusively forms (*Z*)-enol cation intermediate **E** which can not undergo cyclization. Under the reaction conditions this enol **E** would equilibrate with (*E*)-enol cation **F** through a keto-enol tautomerization, presumably via a hydroxylated intermediate. Though olefin cyclization of **F** could lead to both cis benzyl cation intermediate **G** and its trans isomer, only **G** can undergo further cyclization. As a result, *cis*-selective cyclization into **G** takes place under equilibrating conditions. Intramolecular electrophilic substitution on the benzene ring as a substituent occurs again stereoselectively to give the isolated product **11**. As the cyclization of **G** should take place with the most stable

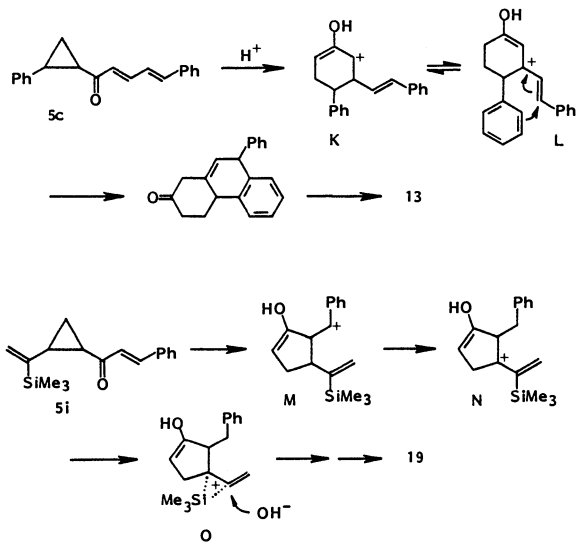


Scheme 3.

configuration where the bulkier phenyl group must be anti to the fused five-membered ring, it is now quite easy to understand the selective formation of **11**.

There are two possible cyclization patterns of intermediary cation **H** which is equivalent with the aforementioned intermediate **F**: One cyclization leads to five-membered ring **I** with an exo cation and the other six-membered ring **J** with an endo cation. It is expected that regiochemistry of the cyclization would depend upon the nature of cation stabilization by substituent R^1. Therefore some derivatives **5b—g** wearing a variety of substitution patterns were employed in PPA-catalyzed ring enlargement reactions.

Ketone **5d** bearing two methyl substituents on the β-carbon of enone showed a similar cyclization pattern, via intermediate **I**, to give **14** (Table 1, Entry 9). On the other hand, cyclizations of ketones **5b** and **5c** proceeded via six-membered intermediates **J** to furnish



Scheme 4.

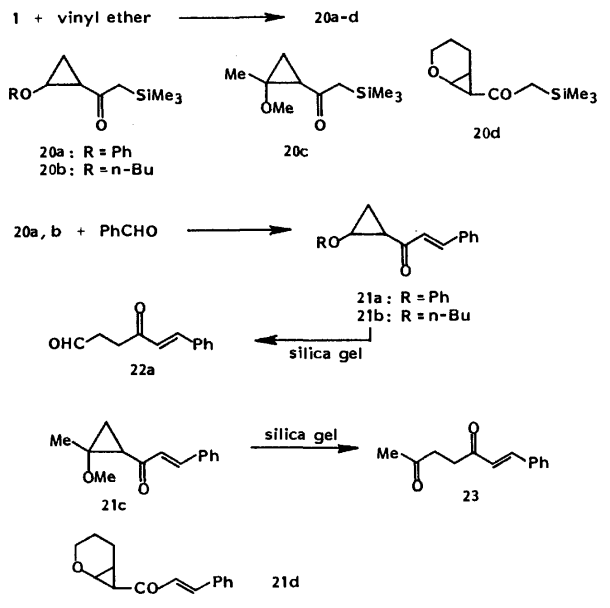
12 and **13** (Entries 7 and 8). Ring-fused cyclopropyl ketones **5e—g** are similarly isomerized into fused cyclohexenones **15—18** albeit in low yields (Entries 10—12).

In the isomerization of dienone **5c**, the direct cyclization of intermediate **K** is impossible due to the *E*-configuration of the styryl moiety (Scheme 4). This cation **K** can equilibrate with pentadienyl cation **L** through a deprotonation and reprotonation process, which is then transformed to the isolated product **13** via the step of making the second six-membered ring and the followed double-bond migration.

Ring enlargement of ketone **5i** bearing a 1-silylethenyl moiety on the cyclopropane ring occurred in a different way to produce desilylated cyclopentanone **19** as a single isomer. Structure of **19** was assigned to be *trans*-3-acetyl-2-benzylcyclopentanone mainly on the basis of the spectral data ($J_{2\text{-}3}$=9.7 Hz; ring CO: =210.03; MeCO: 1.88 and 200.70). This unusual reaction would involve the initial formation of intermediary benzyl cation **M** which then rearranges into equally stable tertiary 2-silyl-substituted allyl cation **N**. A 1,2-silyl migration[15] is followed by hydroxylation leading to the isolated product **19** after a spontaneous desilylation.

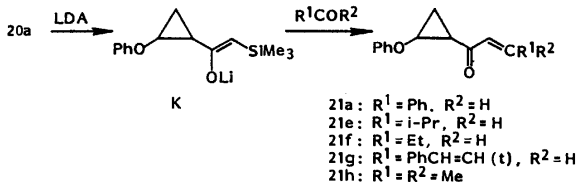
Though these PPA-catalyzed ring enlargements of 1-alkenyl cyclopropyl ketones are attractive as a new direct and stereoselective synthetic way to fused cyclopentanones and cyclohexenones, lack of the cation-stabilizing substituents in the substrates provides either only poor yields of ring-enlarged products or complex results.[16] An effective cation-stabilizing substituent is essential.

With an expectation that an alkoxy or aryloxy moiety would accelerate the ring enlargement, a variety of 1-alkenyl cyclopropyl ketones **21a—h** were prepared and their ring openings were studied.[17] Cyclopropanation of vinyl ethers with **1** in the presence of a catalytic amount (0.5—1 mol%) of copper(II) acetylacetonate or rhodium(II) acetate gives the corresponding cyclopropyl silylmethyl ketones **20a—d** in 46—79% yields (Scheme 5). As **20a—d** belong to moisture sensitive α-silyl ketones, vacuum distillation was the only practical separation method. Immediately after their separation **20a—d** were lithiated with LDA and then allowed to react with benzaldehyde to form 2-alkoxy enones **21a—d** in good yields (by ^{1}H NMR). Though in lower yields, these two steps of cyclopropanation and olefination can be performed in one flask (see Experimental).



Scheme 5.

Compared with the sufficient stability of the phenoxy derivative **21a** which can be separated and purified through column chromatography, the other three **21b—d** are all labile. Though their formation can be confirmed on the basis of ^{1}H and/or ^{13}C NMR spectra of the crude reaction mixtures, all attempts to isolate them by column chromatography resulted in their ring opening or decomposition. Thus crude **21b** and **21c** were chromatographed over silica gel to give 4-oxo-5-alkenal **22a** (60%) and 5-alkene-1,4-dione **23** (23% based on **1**), respectively, both as *E*-isomers (Scheme 5). The ring-fused enone **21d** decomposed to complex mixture by a similar procedure.



Scheme 6.

As the phenoxy-substituted enone **21a** proved to have higher stability, several derivatives **21e—h** were prepared from silylmethyl ketone **20a** by the same procedure applied for **21a** (Scheme 6). As a step-saving procedure, the following one-flask reactions can be employed: The reaction mixture containing crude **20a**, supplied from the cyclopropanation procedure using **1**, is immediately lithiated with LDA at −78 °C and then reacted with a variety of carbonyl compounds. The resulting mixtures are chromatographed over silica gel to give **21a** and **21e—h** in 20—40% total yields based upon **1**.

It was disappointing that treating **21a** with PPA under the same conditions applied in the conversion of **5a** into **11** gave no sign of formation of the expected cyclization product. However simple treatment of **5a** with TFA in aqueous tetrahydrofuran (THF) at room temperature gave (*E*)-4-oxo-6-phenyl-5-hexenal (**22a**) in 88% yield, which is identical with that obtained from **21b** (Scheme 7 and Table 2, Entry 1). Similarly a variety of 4-oxo-5-alkenals such as (*E*)-7-methyl-4-oxo-5-octenal (**22b**), (*E*)-4-oxo-5-octenal (**22c**), (*E*,*E*)-4-oxo-8-phenyl-5,7-octadienal (**22d**), and 6-methyl-4-oxo-5-heptenal (**22e**) were obtained in good yields (Entries 2—5). Although the ring opening of **21h** was so slug-

Table 2. Acid-Catalyzed Ring Opening of 1-Alkenyl 2-Phenyloxycyclopropyl Ketones **21a** and **21d—h**

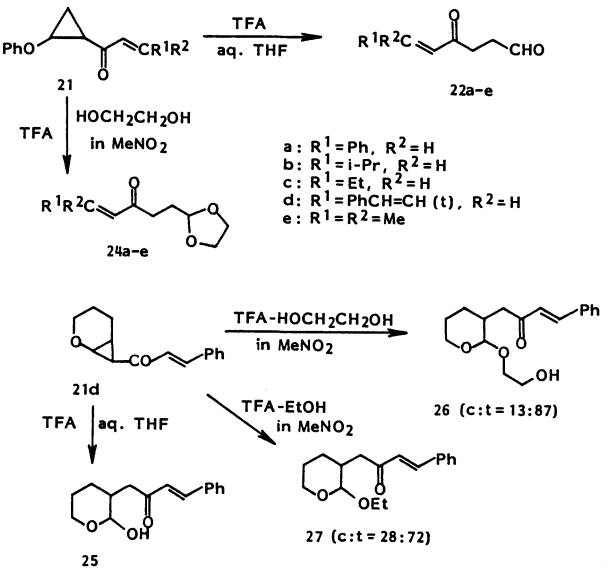
a) Yield of isolated products. b) Two equivalents of lithim chloride was used. c) Yield based on diazo ketone **1**. d) Inseparable mixture (NMR). e) Each isomer was isolated (cis : trans).



Scheme 7.

gish under these conditions that most of **21h** was recovered after a week at room temperature, the addition of lithium chloride accelerated this reaction to such an extent that the reaction was complete in 30 min to give 71% yield of **22e**.

When the ring opening reactions of **21** are carried out in the presence of 1,2-ethanediol in nitromethane, dioxolane-protected derivatives **24a—e** are directly obtained (Scheme 7 and Entries 6—10 in Table 2). The reactions proceed smoothly and are complete at 0 °C in less than 30 min.

The ring-fused cyclopropyl ketone **21d** is very susceptible to acid. Thus TFA in THF or nitromethane opens the cyclopropane ring of **21d** to give hemiacetals **25—27** through an addition of the nucleophiles employed (Scheme 7 and Entries 11—13 in Table 2).

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^1H NMR spectra were recorded on a Hitachi R-40 (90 MHz), a JEOL FX-100 (100 MHz), or a JEOL GSX-270 instrument (270 MHz), and ^{13}C NMR on a JEOL FX-100 (25.05 MHz) or a JEOL GSX-270 spectrometer (67.94 MHz). Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. High-resolution mass spectra were obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck). Visualization was made with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and silica gel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20×180 mm) packed with silica gel 60 (Merck, size: 0.04—0.063 mm). Preparative high-performance liquid chromatography (HPLC) was performed on a Kusano KHLC-201 apparatus with a UV-detector Uvilog-III using a column (22×300 mm) packed with silica gel (Wakogel LC-50H). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×50000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

Materials. 1-Diazo-3-trimethylsilyl-2-propanone (**1**),[1] 1-diazo-3-(diethoxyphosphoryl)-2-propanone (**2**),[9] (diethoxyphosphoryl)methyl 2-phenylcyclopropyl ketone,[9] 2-trimethylsilyl-1,3-butadiene,[18] phenyl vinyl ether[19] were prepared according to the reported methods. Butyl vinyl ether, 2-methoxypropene, and 3,4-dihydro-2*H*-pyran are all commercially available and used without further purification. Trifluoromethanesulfonic acid and polyphosphoric acid (PPA, H_3PO_4 content; 105%, Katayanma Kagaku Co., Ltd.) are also commercially available. 1-Alkenyl cyclopropyl ketones **5a—h** were previously prepared by one-pot proce-

dure for a sequence of cyclopropanation using diazo ketone **1** and Peterson olefination with a variety of carbonyl compounds.[1,9]

(*E*)-2-Phenylethenyl 2-[(1-Trimethylsilyl)ethenyl]cyclopropyl Ketone (5i): To the mixture of copper(II) acetylacetonate (3 mg, 0.01 mmol) and 2-trimethylsilyl-1,3-butadiene (1 g, 8 mmol) preheated at 75 °C was added slowly under nitrogen 1-diazo-3-trimethylsilyl-2-propanone (**1**, 0.156 g, 1 mmol) in a period of 0.5 h. After cooled to room temperature, the reaction mixture was diluted with dry THF (1 ml). This solution was added dropwise at −78 °C to lithium diisopropylamide (LDA, 1.61 mmol) freshly prepared in THF (1.5 ml). After 45 min at the same temperature, benzaldehyde (0.16 ml, 1.61 mmol) was added. The resulting mixture was stirred at −78 °C for 2 h and then at room temperature for 0.5 h. Saturated aqueous ammonium chloride was added and extraction procedure with dichloromethane (20 ml×2) was followed. The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane–ethyl acetate (20 : 1 v/v) to give **5i** (0.04 g, 15% based on **1**) and then (*E*)-2-phenylethenyl 2-trimethylsilyl-2-vinylcyclopropyl ketone (0.02 g, 7% based on **1**). **5i:** Colorless liquid; IR (neat) 1690, 1246, and 850 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.12 (9H, s, $SiMe_3$), 1.23 (1H, ddd, J=8.6, 8.0, and 3.8 Hz, ring CH_2), 1.55 (1H, ddd, J=8.6, 5.0, and 3.8 Hz, ring CH_2), 2.1—2.3 (2H, m, ring CH), 5.36 (1H, d, J=2.6 Hz, $=CH_2$), 5.49 (1H, dd, J=2.6 and 2.0 Hz, $=CH_2$), 6.88 (1H, d, J=16.1 Hz, =CH), 7.3—7.6 (5H, m, Ph), and 7.60 (1H, d, J=16.1 Hz, =CH); ^{13}C NMR ($CDCl_3$) δ=−1.71 ($SiMe_3$), 17.67 (ring CH_2), 29.43, 30.11 (ring CH), 121.97 ($=CH_2$), 126.55, 128.29, 128.91, 130.35, 134.35, 142.11, 150.97, and 198.45 (CO); MS m/z (rel intensity, %) 270 (M^+, 31), 139 (20), 131 (62), and 73 (base peak). HRMS Found: m/z 270.1444. Calcd for $C_{17}H_{23}OSi$: M, 270.1439.

(*E*)-6-Hydroxy-1,6-diphenyl-1-hexen-3-one (6). To a solution of **5a** (0.037 g, 0.15 mmol) in trifluoroacetic acid (TFA, 1 ml) was added trifluoromethanesulfonic acid (0.01 ml). After 3 h at room temperature, the mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with hexane–ethyl acetate (2 : 1 v/v) to provide **6** (0.026 g, 66%): Yellow liquid; IR (neat) 3430 and 1675 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.58 (1H, br s, OH), 2.14 (2H, dt, J=7.0 and 6.2 Hz, 5-H), 2.80 (2H, t, J=7.0 Hz, 4-H), 4.79 (1H, t, J=6.2 Hz, 6-H), 6.70 (1H, d, J=16.5 Hz, 2-H), 6.9—7.6 (10H, m, Ph), and 7.54 (1H, d, J=16.5 Hz, 1-H); ^{13}C NMR ($CDCl_3$) δ=33.36, 37.18 (each t, 4- and 5-C), 73.77 (d, 6-C), 126.13, 126.48, 127.83, 128.65, 128.83, 129.30, 130.89, 134.83, 143.24, 144.85, and 201.07 (s, CO); MS m/z (rel intensity, %) 266 (M^+, 15), 248 (82), 157 (22), 146 (44), 144 (20), 131 (base peak), 116 (33), 103 (58), 91 (24), and 77 (57). Found: C, 80.49; H, 6.81%. Calcd for $C_{18}H_{18}O_2$: C, 81.18; H, 6.81%.

(*E*)-1,6,6-Triphenyl-1-hexen-3-one (7). To a solution of **5a** (0.15 g, 0.6 mmol) in benzene (6 ml) was added trifluoromethanesulfonic acid (0.265 ml, 3 mmol). After stirred at room temperature for 1.5 h, the mixture was poured into aqueous sodium hydrogencarbonate and extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.197 g) was subjected to column chromatography over silica gel with hexane–ethyl acetate (9 : 1 v/v) to give **7** (0.165 g, 84%). Colorless needles; mp 124—125 °C (diethyl ether–hexane); IR (KBr) 1687 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.3—2.7 (4H, m, 4- and 5-H), 3.95 (1H, t, J=8.0 Hz, 6-H), 6.64 (1H, d, J=16.0 Hz, 2-H), 7.0—7.6 (15H, m, Ph), and 7.40 (1H, d, J=16.0 Hz, 1-H); ^{13}C NMR ($CDCl_3$) δ=29.77, 39.06 (each t, 4- and 5-C), 50.47 (d, 6-C), 126.42, 127.95, 128.30, 128.65, 128.95, 130.48, 134.54, 142.36, 144.54 (d, 1-C), and 199.89 (s, CO). Found: C, 88.43; H, 6.87%. Calcd for $C_{24}H_{22}O$: C, 88.31; H, 6.79%.

(*E*)-3,6-Diacetoxy-1,6-diphenyl-1,3-hexadiene (8). A mixture of **5a** (0.05 g, 0.2 mmol), boron trifluoride etherate (0.024 ml, 0.2 mmol), acetic anhydride (0.038 ml, 0.4 mmol), and nitromethane (1 ml) was stirred at room temperature for 10 min. Treatment with saturated aqueous sodium hydrogencarbonate was followed by extraction with dichloromethane (10 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.073 g) was subjected to column chromatography over silica gel by using hexane–ethyl acetate (4 : 1 v/v) to give **8** (0.042 g, 59%): Pale yellow liquid; IR (neat) 1760 and 1739 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.08, 2.30 (each 3H, s, COMe), 2.4—2.9 (2H, m, 5-H), 5.32 (1H, t, J=7.5 Hz, 4-H), 5.80 (1H, t, J=7.0 Hz, 6-H), 6.40 (1H, d, J=15.9 Hz, 2-H), 6.60 (1H, d, J=15.9 Hz, 1-H), and 7.2—7.4 (10H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=20.47, 21.18 (each q, COMe), 33.18 (t, 5-H), 74.59 (d, 6-C), 117.12 (d, 4-C), 123.07 (d, 4-C), 126.60, 126.83, 128.13, 128.36, 128.71 (each d), 136.36, 139.89 (each s), 148.01 (d, 1-C), 168.30, and 170.37 (each s, COMe); MS m/z (rel intensity, %) 350 (M^+, 1), 290 (34), 248 (36), 159 (87), 131 (51), 107 (39), 103 (26), 91 (24), 77 (31), and 43 (base peak). HRMS Found: m/z 350.1518. Calcd for $C_{22}H_{22}O_4$: M, 350.1517.

(*E*)-2,5-Diacetoxy-1-(diethoxyphosphoryl)-5-phenyl-2-pentene (9). To a solution of **4** (0.101 g, 0.34 mmol) in dry nitromethane (2 ml) were added at 0°C boron trifluoride etherate (0.041 ml, 0.34 mmol) and acetic anhydride (0.065 ml, 0.68 mmol). The mixture was stirred at room temperature under nitrogen for 18 h, poured into saturated aqueous sodium hydrogencarbonate, and extracted with dichloromethane (15 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.18 g) was subjected to column chromatography over silica gel with ethyl acetate to give **9** (0.105 g, 78%): Pale yellow liquid; IR (neat) 1753, 1240, 1051, and 1025 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.29 (6H, t, J=7.0 Hz, OEt), 2.06, 2.16 (each 3H, s, COMe), 2.4—2.7 (2H, m, 4-H), 2.84 (2H, d, $J_{H\text{-}P}$=21.5 Hz, PCH_2), 4.07 (4H, qd, J=8.4 and 7.0 Hz, OEt), 5.11 (1H, td, J=7.0 and $J_{H\text{-}P}$=4.5 Hz, 3-H), 5.74 (1H, t, J=7.0 Hz, 5-H), and 7.31 (5H, s, Ph); MS m/z (rel intensity, %) 398 (M^+, 0.5), 296 (50), 207 (67), 179 (24), 151 (24), and 43 (base peak). HRMS Found: m/z 398.1500. Calcd for $C_{19}H_{27}O_7P$: M, 398.1493.

2-(3-Methyl-1-oxo-2-butenyl)cyclohexanol (10). A mixture of **5h** (0.13 g, 0.73 mmol), polyphosphoric acid (PPA, P_2O_5 content, 75%, 1.3 g) in benzene (1 ml) was heated under reflux for 2.5 h. The mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was subjected to column chromatography over silica gel with hexane–ethyl acetate (20 : 1 v/v) to afford **10** (0.079 g, 55%) as a single isomer: Colorless liquid; IR (neat) 3440, 1680, and 1620 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.0—3.0 (11H, m,

CH_2 and CH), 1.84, 2.08 (each 3H, s, Me), 3.7—3.8 (1H, m, CHOH), and 6.00 (1H, s, =CH); ^{13}C NMR ($CDCl_3$) δ=20.82 (q and t, Me and CH_2), 24.65, 27.47 (each t), 27.76 (q, Me), 32.53 (t), 37.65 (d), 46.53 (t), 69.42 (d, CHOH), 124.48 (d, =CH), 155.83 (s, $=CMe_2$), and 201.95 (s, CO); MS *m/z* (rel intensity, %) 196 (M^+, 12), 178 (11), 99 (36), 98 (38), 83 (base peak), 82 (13), and 55 (49). HRMS Found: *m/z* 196.1462. Calcd for $C_{12}H_{20}O_2$: M, 196.1461.

3a,8a-*cis*-8,8a-*trans*-8-Phenyl-3,3a,8,8a-tetrahydrocyclopent[*a*]inden-1(2*H*)-one (11). A mixture of **5a** (0.15 g, 0.6 mmol) and PPA (P_2O_5 content, 75%, 1.5 g) in benzene (1.5 ml) was heated at 80—85 °C for 40 h during which time the reaction was monitored by GLC. The reaction mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane–ethyl acetate (50 : 1 v/v) to give **11** (0.106 g, 71%) as a single isomer: Colorless needles (ethyl acetate–hexane); mp 97—98 °C; IR (KBr) 1725, 1490, 1445, 1130, 795, 750 and 735 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.0—2.5 (4H, m, 2- and 3-H), 2.82 (1H, dd, *J*=7.5 and 0.8 Hz, 8a-H), 4.1—4.2 (1H, m, 3a-H), 4.75 (1H, d, *J*=0.8 Hz, 8-H), and 6.8—7.3 (9H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=26.26 (t, 2-C), 36.74 (t, 3-C), 46.00, 54.36, 61.06 (each d, 3a-, 8-, and 8a-C), 124.07, 125.66, 126.60, 127.48, 127.78, 127.90, 128.01, 128.78, and 221.31 (s, CO); MS *m/z* (rel intensity, %) 248 (M^+, 31), 220 (26), 204 (52), 192 (base peak), 191 (66), 189 (38), 165 (42), 115 (39), and 42 (21); Found: C, 87.27; H, 6.57%. Calcd for $C_{18}H_{16}O$: C, 87.06, 6.49%.

3-Ethyl-4-phenyl-2-cyclohexen-1-one (12). A similar procedure using **5b** (0.105 g, 0.53 mmol), PPA (P_2O_5 content, 75%, 1 g), and benzene (1 ml) under reflux for 30 h and subsequent chromatographic operation (silica gel, hexane–ethyl acetate (50 : 1 v/v)) gave **12** (0.066 g, 63%): Colorless liquid; IR (neat) 1660, 1445, 1245, 880, 760, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.02 (3H, t, *J*=6.5 Hz, Et), 1.1—2.4 (4H, m, CH_2), 2.09 (2H, q, *J*=6.5 Hz, Et), 3.60 (1H, t, *J*=4.0 Hz, 4-H), 6.0—6.1 (1H, m, 2-H), and 7.0—7.3 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=11.35 (q, Et), 29.36, 31.65, 34.00 (each t, CH_2), 45.47 (d, 4-C), 126.48, 127.24, 128.36, 129.01 (each d), 140.95 (s), 167.95 (s, 3-C), and 200.13 (s, CO); MS *m/z* (rel intensity, %) 200 (M^+, 63), 172 (53), 158 (38), 157 (42), 143 (39), 129 (base peak), 128 (41), 115 (51), 91 (25), and 43 (28). HRMS Found: *m/z* 200.2794. Calcd for $C_{14}H_{16}O$: M, 200.2794.

9-Phenyl-4,4a,9,10-tetrahydro-2(3*H*)-phenanthrenone (13). A similar procedure using **5c** (0.14 g, 0.5 mmol), PPA (P_2O_5 content, 75%, 1.4 g), and benzene (1 m) at 80—85 °C for 10 d and subsequent chromatographic separation (silica gel, hexane–ethyl acetate (30 : 1 v/v)) afforded **13** (0.06 g, 43%) as a single isomer: Colorless prisms (ethyl acetate–hexane); mp 114—115 °C; IR (KBr) 1670, 1430, 1370, 1290, 750, and 695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.0—3.2 (7H, m, CH_2 and CH), 4.2—4.4 (1H, m, 9-H), and 6.8—7.8 (10H, m, Ar and 1-H); ^{13}C NMR ($CDCl_3$) δ=23.35, 29.30, 31.00, 33.59 (each t, CH_2), 50.42 (d, 9-C), 126.48, 126.83, 128.13, 128.30, 128.60, 130.13, 130.48, (each d), 134.36 (d, 1-C), 141.42, 143.13, 145.71 (each s), 163.83 (s, 10a-C), and 209.72 (CO); MS *m/z* (rel intensity, %) 274 (M^+, base peak), 246 (53), 218 (71), 217 (42), 215 (28), 204 (20), and 202 (22). HRMS Found: *m/z* 274.1357. Calcd for $C_{20}H_{18}O$: M, 274.1368.

8,8-Dimethyl-3,3a,8,8a-tetrahydrocyclopent[*a*]inden-1(2*H*)-one (14). A similar procedure using **5d** (0.14 g, 0.62 mmol), PPA (P_2O_5 content, 75%, 1.4 g), and benzene (1.5 ml) at 80—85 °C for 47 h and subsequent chromatography (silica gel, hexane–ethyl acetate (50 : 1 v/v)) gave **14** (0.075 g, 89%): Colorless liquid; IR (neat) 1730, 1680, 1485, 1455, 1280, 1160, 805, and 765 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.27, 1.34 (each 3H, s, Me), 2.0—2.3 (4H, m, CH_2), 2.56 (1H, d, *J*=8.0 Hz, 8a-H), 3.9—4.1 (1H, m, 3a-H), and 7.0—7.2 (4H, m Ar); ^{13}C NMR ($CDCl_3$) δ=24.77 (q, Me), 27.07 (t, 3-C), 33.30 (q, Me), 38.71 (t, 2-C), 45.42 (d, 8a-C), 47.53 (s, 8-C), 61.95 (d, 3a-C), 122.18, 124.01, 127.54, 127.77 (each d), 143.36, 152.07 (each s), and 220.02 (s, CO); MS *m/z* (rel intensity, %) 200 (M^+, 17), 185 (56), 157 (39), 143 (52), 142 (23), 141 (28), 129 (base peak), 128 (87), 127 (30), and 115 (43). HRMS Found: *m/z* 200.1200. Calcd for $C_{14}H_{16}O$: M, 200.1213.

4-Phenyl-4a,5,6,7,8,8a-hexahydro-2(1*H*)-naphthalenone (15) and 4-Phenyl-4,4a,5,6,7,8-hexahydro-2(3*H*)-naphthalenone (16). A mixture of **5e** (0.14 g, 0.62 mmol), PPA (P_2O_5 content, 75%, 1.4 g), and benzene (1.5 ml) was heated at 80—85 °C for 55 h during which time the reaction was monitored by GLC. The mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with diethyl ether (15 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel; the elution with hexane–ethyl acetate (50 : 1 v/v) gave **15** (0.08 g, 57%) and with hexane–ethyl acetate (20 : 1 v/v) **16** (0.025 g, 18%), both as single isomers. **15**: Colorless viscous liquid; IR (neat) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1—3.0 (12H, m, CH_2 and CH), 6.24 (1H, s, 6-H), and 7.1—7.6 (5H, m Ph); ^{13}C NMR ($CDCl_3$) δ=20.47, 25.83, 27.17, 30.41 (each t, CH_2), 33.77 (d, 8a-C), 37.77 (t, 8-C), 39.71 (d, 4a-C), 124.95, 126.83, 129.01 (each d), 130.07, 138.18 (each s), 165.36 (s, 5-C), and 200.89 (s, CO); MS *m/z* (rel intensity, %) 226 (M^+, 26), 184 (33), 169 (26), 157 (23), 156 (29), 155 (26), 142 (34), 141 (76), 131 (30), 129 (59), 128 (87), 127 (37), 116 (25), 115 (base peak), 103 (33), 102 (42), 91 (41), and 77 (55). HRMS Found: *m/z* 226.1357. Calcd for $C_{16}H_{18}O$: M, 226.1363. **16**: Colorless prisms (ethyl acetate–hexane); mp 61—63 °C; IR (KBr) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1—3.1 (12H, m, CH_2 and CH), 5.90 (1H, s, 8-H), and 7.1—7.6 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=25.47, 26.59, 32.41, 35.71 (each t, CH_2), 44.06 (t, 2-C), 44.89, 47.77 (each d, 4a- and 5-C), 124.72, 127.13, 127.71, 128.89 (each d, Ph and 8-C), 142.83 (s, Ph), 166.30 (s, 8a-C), and 199.31 (s, CO); MS *m/z* (rel intensity, %) 226 (M^+, 16), 128 (24), 122 (base peak), 115 (41), 107 (21), 104 (60), 103 (34), 94 (65), 91 (65), 79 (63), 78 (59), and 77 (75). HRMS Found: *m/z* 226.1357. Calcd for $C_{16}H_{18}O$: M, 226.1351.

4-Phenyl-3,4,4a,5,6,7,8,9-octahydro-2*H*-benzocyclohepten-2-one (17). A similar procedure using **5f** (0.153 g, 0.64 mmol), PPA (P_2O_5 content, 75%, 0.85 g), and benzene (1.5 ml) at 80—85 °C for 40 h and subsequent chromatography over silica gel (hexane–ethyl acetate (50 : 1 v/v)) gave **17** (0.023 g, 15%) as a single isomer: Colorless viscous liquid; IR (neat) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.9—3.2 (14H, CH_2 and CH), 5.89 (1H, m, 4-H), and 7.0—7.4 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=26.18, 29.00, 29.18, 30.36, 37.06 (each t, CH_2), 44.42 (t, 2-C), 46.00, 47.53 (each d, CH), 127.07, 127.48, 127.71, 129.01 (each d), 143.42 (s), 171.07 (s, 4a-C), and 199.01 (s, CO); MS *m/z* (rel intensity, %) 240 (M^+, 31), 136 (base peak), 108 (52), 93 (24), 91 (34), 79 (37), 78 (21), 77 (35), 41 (25), and 39. HRMS Found: *m/z* 240.1513. Calcd for $C_{17}H_{20}O$: M, 240.1509.

4-Phenyl-3,4,4a,5,6,7,8,9,10-octahydrobenzocycloocten-2-(3*H*)-one (18). A similar procedure using **5g** (0.15 g, 0.6 mmol), PPA (P_2O_5 content, 75%, 1.5 g), and benzene (1.5 ml) at 80—85 °C for 65 h and subsequent chromatographic separation (silica gel, hexane–ethyl acetate (50:1 v/v)) gave **18** (0.039 g, 26%) as a single isomer: Colorless viscous liquid; IR (neat) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1—3.4 (16H, m, CH_2 and CH), 5.93 (1H, m, 4-H), and 6.9—7.3 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=24.35, 24.83, 25.06, 26.65, 31.94, 34.36 (each t, CH_2), 44.42 (t, 2-C), 44.77, 45.47 (each d, 1- and 10a-C), 127.07, 127.48, 129.01 (each d), 143.24 (s), 172.83 (s, 4a-C), and 198.48 (s, CO); MS *m/z* (rel intensity, %) 254 (M^+, 40), 150 (86), 122 (base peak), 91 (33), 77 (27), and 43 (20). Found: C, 84.99; H, 2.54%. Calcd for $C_{18}H_{22}O$: C, 85.12; H, 8.85%.

***trans*-3-Acetyl-2-benzylcyclopentanone (19).** A mixture of **5i** (0.026 g, 0.1 mmol) and PPA (P_2O_5 content, 75%, 0.3 g) in benzene (1 ml) was stirred at room temperature for 23 h during which time the reaction was monitored by GLC. The mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with diethyl ether (15 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with hexane–ethyl acetate (2:1 v/v) to give **19** as a single isomer: Yellow liquid; IR (neat) 1725 and 1715 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.88 (3H, s, COMe), 1.9—2.0 (1H, m, CH_2), 2.1—2.3 (1H, m, CH_2), 2.4—2.7 (4H, m, CH_2), 3.16 (1H, dt, *J*=9.7 and 3.8 Hz, CH), 3.27 (1H, dt, *J*=9.7 and 6.5 Hz, CH), and 7.2—7.4 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=28.11 (t, 4-C), 30.24 (q, COMe), 39.88 (t, 5-C), 46.41 (d, 3-C), 47.82 (t, $PhCH_2$), 55.35 (d, 2-C), 127.07, 127.32, 128.98 (each d, Ph), 141.81 (s, Ph), 200.70 (s, COMe), and 210.03 (s, CO); MS *m/z* (rel intensity, %) 216 (M^+, 48), 156 (28), 146 (22), 145 (20), 117 (27), 104 (27), 103 (21), 91 (48), 83 (28), 76 (23), 55 (24), and 43 (base peak). HRMS Found: *m/z* 216.1143. Calcd for $C_{14}H_{16}O_2$: M, 216.1149.

2-Phenoxycyclopropyl Trimethylsilylmethyl Ketone (20a). Under nitrogen, a mixture of phenyl vinyl ether (0.6 g, 5 mmol) and copper(II) acetylacetonate (0.006 g, 0.02 mmol) was heated at 75 °C. A solution of **1** (0.312 g, 2 mmol) in dry diethyl ether (0.5 ml) was added dropwise in a period of 1 h. The reaction mixture was subjected to micro vacuum distillation on a Kugelrohr distilling apparatus to provide **20a** (0.28 g, 46%): Pale yellow liquid; bp 130 °C/26 Pa (bulb-to-bulb); IR (neat) 1660, 1245, and 850 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.15 (9H, s, $SiMe_3$), 1.38 (1H, ddd, *J*=9.7, 5.4, and 3.8 Hz, ring CH_2), 1.54 (1H, dt, *J*=5.9 and 5.4 Hz, ring CH_2), 2.15 (1H, ddd, *J*=9.7, 5.4, and 2.2 Hz, ring CH), 2.37, 2.53 (each 1H, d, *J*=10.3 Hz, CH_2CO), 4.05 (1H, ddd, *J*=5.9, 3.8, and 2.2 Hz, ring CH), 6.9—7.1 (3H, m, Ph), and 7.2—7.4 (2H, m Ph); ^{13}C NMR ($CDCl_3$) δ=−0.07 ($SiMe_3$), 17.98 (ring CH_2), 30.17 (ring CH), 40.21 (CH_2CO), 59.23 (ring CH), 115.08, 121.63, 129.71, 158.26 (each Ph), and 206.55 (CO); MS *m/z* (rel intensity, %) 248 (M^+, 1), 155 (23), 153 (36), 94 (33), 82 (49), 81 (84), 76 (26), 72 (base peak), and 43(26). HRMS Found: *m/z* 248.1240. Calcd for $C_{14}H_{20}O_2Si$: M, 248.1231.

2-Butoxycyclopropyl Trimethylsilylmethyl Ketone (20b). Butyl vinyl ether (3 ml, 23 mmol) was heated at 75 °C under nitrogen together with copper(II) acetylacetonate (0.003 g, 0.01 mmol). Diazo ketone **1** (0.312 g, 2 mmol) was added dropwise in a period of 1 h. The reaction mixture was distilled under vacuum on a Kugelrohr distilling apparatus to give **20b** (0.29 g, 64%): Pale yellow liquid; bp 110 °C/106 Pa (bulb-to-bulb); IR (neat) 1670, 1250, and 850 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.15 (9H, s, $SiMe_3$), 0.91 (3H, t, *J*=7.3 Hz, *n*-Bu), 1.1—1.2 (1H, m, ring CH_2), 1.3—1.7 (4H, m, *n*-Bu), 1.9—2.0 (1H, m, ring CH_2), 2.2—2.5 (3H, m, ring CH and CH_2CO), and 3.3—3.6 (3H, m, *n*-Bu and ring CH); ^{13}C NMR ($CDCl_3$) δ=−0.83 (q, $SiMe_3$), 14.02 (q, *n*-Bu), 18.02 (t, ring CH_2), 19.46 (t, *n*-Bu), 30.41 (d, ring CH), 32.06 (t, *n*-Bu), 39.76 (t, CH_2CO), 63.29 (d, ring CH), 71.25 (t, *n*-Bu), and 206.97 (s, CO); MS *m/z* (rel intensity, %) 228 (M^+, 2), 80 (20), 73 (base peak), 57 (30), and 45 (25). HRMS Found: *m/z* 228.1542. Calcd for $C_{12}H_{24}O_2Si$: M, 228.1544.

2-Methoxy-2-methylcyclopropyl Trimethylsilylmethyl Ketone (20c). Under nitrogen, a mixture of 2-methoxypropene (2 ml, 20 mmol) and rhodium(II) acetate (0.002 g, 0.005 mmol) was heated at 75 °C. Diazo ketone **1** (0.312 g, 2 mmol) was added dropwise in a period of 1 h. The resulting mixture was distilled under vacuum on a Kugelrohr distilling apparatus to give **20c** (0.25 g, 63%) as a mixture of two stereoisomers: Colorless liquid; bp 80 °C/266 Pa (bulb-to-bulb); ^{13}C NMR ($CDCl_3$) δ=−1.28, −0.88 (each $SiMe_3$), 13.44, 18.39 (each ring CH_2), 22.54, 25.42 (each Me), 36.19 (ring CH), 40.45, 40.54 (each CH_2CO), 49.52, 54.22 (each MeO), 68.04 (ring CH), and 205.88 (CO). This mixture was directly used in the reaction with benzaldehyde leading to **21c**.

5-[(Trimethylsilyl)acetyl]perhydrocyclopropa[*b*]pyran (20d). A mixture of 3,4-dihydro-2*H*-pyran (3 ml, 33 mmol) and copper(II) acetylacetonate (0.003 g, 0.01 mmol) was heated under nitrogen at 75 °C. Diazo ketone **1** (0.312 g, 2 mmol) was added dropwise in a period of 1 h. The reaction mixture was distilled on a Kugelrohr distilling apparatus to give **20d** (0.335 g, 79%): Colorless liquid; bp 110 °C/80 Pa (bulb-to-bulb); IR (neat) 1665, 1250, and 850 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.08 (9H, s, $SiMe_3$), 1.3—1.5 (2H, m, 4-H), 1.7—2.0 (4H, m, 3-, 4a-, and 5-H), 2.28 (2H, s, CH_2CO), 3.2—3.4 (1H, m, 2-H), 3.5—3.6 (1H, m, 2-H), and 3.77 (1H, d, *J*=7.0 Hz, 5a-H); ^{13}C NMR ($CDCl_3$) δ=−0.90 (q, $SiMe_3$), 19.25 (t, 4-C), 22.17 (t, 3-C), 24.36 (d, 4a-C), 36.31 (t, 5-C), 40.01 (t, CH_2CO), 63.02 (d, 5a-C), 64.62 (t, 2-C), and 206.18 (s, CO); MS *m/z* (rel intensity, %) 212 (M^+, 42), 122 (47), 75 (38), and 73 (base peak). HRMS Found: *m/z* 212.1197. Calcd for $C_{11}H_{20}O_2Si$: M, 212.1231.

(*E*)-2-Phenoxycyclopropyl 2-Phenylethenyl Ketone (21a): Reaction of diazo ketone **1** (0.312 g, 2 mmol) with phenyl vinyl ether (1.2 g, 10 mmol) in the presence of a catalytic amount of copper(II) acetylacetonate (0.003 g, 0.01 mmol) was carried out according to the procedure mentioned above. The reaction mixture was diluted with dry THF (2 ml). This solution was added dropwise, at −78 °C under nitrogen, to LDA (1.8 mmol) freshly prepared in THF (2 ml). After 1 h, benzaldehyde (0.18 mmol) was added. The mixture was stirred at −78 °C for 1 h and at room temperature for 0.5 h. Quench with saturated aqueous ammonium chloride was followed by extraction with dichloromethane (15 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (1.02 g) was chromatographed over silica gel with hexane–ethyl acetate (50:1 v/v) to give **21a** (0.223 g, 42% based on **1**): Colorless needles (diethyl ether-hexane); mp 75—78 °C; IR (KBr) 1675, 1645, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.58 (1H, ddd, *J*=9.5, 5.5, and 4.4 Hz, ring CH_2), 1.76 (1H, ddd, *J*=6.6, 6.2, and 5.5 Hz, ring CH_2), 2.57 (1H, ddd, *J*=9.5, 6.2, and 2.2 Hz, ring CH), 4.12 (1H, ddd, *J*=6.6, 4.4, and 2.2 Hz, ring CH), 6.92 (1H, d, *J*=16.1 Hz, =CHCO), 6.9—7.6 (10H, m, Ph), and 7.65

(1H, d, J=16.1 Hz, =CH); ^{13}C NMR ($CDCl_3$) δ=17.98 (ring CH_2), 28.08 (ring CH), 60.13 (ring CH), 114.80, 121.65, 126.27, 128.40, 128.95, 129.57, 130.62, 134.39, 143.19, 157.99 (=CH), and 197.07 (CO); MS m/z (rel intensity, %) 171 (34), 170 (base peak), 143 (24), 141 (23), 131 (27), 128 (40), 115 (22), 103 (32), and 77 (55). Found: C, 81.86; H: 6.13%. Calcd for $C_{18}H_{16}O_2$: C, 81:80; H, 6.10%.

(*E*)-2-Butoxycyclopropyl 2-Phenylethenyl Ketone (21b). A solution of silylmethyl ketone **20b** (0.272 g, 1.19 mmol) in dry THF (1 ml) was added dropwise at −78 °C to LDA (1.43 mmol) freshly prepared in THF (1 ml). After 1 h, benzaldehyde (0.12 ml, 1.19 mmol) was added and the mixture was stirred at −78 °C for 1 h and then at room temperature for 1 h. Quench with saturated aqueous ammonium chloride was followed by extraction with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo to give **20b** which decomposed to **22a** (0.134 g, 60% based on **20b**) on column chromatography over silica gel (hexane-ethyl acetate (9 : 1 v/v)). **20b**: Yellow liquid; ^{13}C NMR ($CDCl_3$) δ=13.92 (*n*-Bu), 19.37 (*n*-Bu), 28.65 (ring CH_2), 31.60 (ring CH), 64.45 (*n*-Bu), 71.30 (*n*-Bu), 126.53, 128.41, 129.44, 130.51, 134.75, 142.43 (=CH), and 197.57 (CO). Purification of **21b** by chromatography over silica gel gave **22a**.

(*E*)-2-Methyl-2-methoxycyclopropyl 2-Phenylethenyl Ketone (21c). A similar one-flask procedure using **1** (0.156 g, 1 mmol in dry diethyl ether (1 ml)), rhodium(II) acetate (0.002 g, 0.005 mmol), and 2-methoxypropene (0.48 ml, 5 mmol) for cyclopropanation (80 °C, 1 h) and then LDA (1.61 mmol in THF (1.5 ml)) and benzaldehyde (0.16 ml, 1.61 mmol) for olefination (1 h at −78 °C and 0.5 h at room temperature) gave **21c** as unstable product. Column chromatography of **21c** gave **23** in 23% yield based on **1**.

(*E*)-5-(1-Oxo-3-phenyl-2-propenyl)perhydrocyclopropa[*b*]pyran (21d). To freshly prepared LDA (1.74 mmol) in dry THF (1 ml) was added at −78 °C a solution of silylmethyl ketone **20d** (0.307 g, 1.45 mmol). After 1 h at −78 °C under nitrogen, benzaldehyde (0.14 ml, 1.45 mmol) was added. Stirring was continued at the same temperature for 1.5 h and at room temperature for 0.5 h. The mixture was poured into saturated aqueous ammonium chloride and extracted with dichloromethane (15 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo to give **21d** as a labile product. This compound **21d** decomposed to complex mixture when chromatographed over silica gel. **21d**: ^{13}C NMR ($CDCl_3$) δ=19.19 (ring CH_2), 22.02 (ring CH_2), 25.72 (ring CH), 34.55 (ring CH), 64.09, 64.68 (ring CH_2 and CH), 126.75, 128.26, 128.91, 130.29, 134.74, 141.82 (=CH), and 196.95 (CO). Column chromatography of **21d** over silica gel led to complex mixture.

(*E*)-4-Methyl-1-oxo-2-pentenyl 2-Phenoxycyclopropyl Ketone (21e). A similar one-flask procedure using **1** (0.312 g, 2 mmol), copper(II) acetylacetonate (0.003 g, 0.01 mmol), and phenyl vinyl ether (1.2 g, 10 mmol) for cyclopropanation (1 h at 70 °C) and then LDA (3.2 mmol in THF (2 ml)) and 2-methylpropanal (0.3 g, 3.2 mmol) for olefination (1h at −78 °C and 0.5 h at room temperature) gave **21e** (0.179 g, 39% based on **1**) after column chromatography over silica gel with hexane-ethyl acetate (50 : 1 v/v). **21e**: Colorless liquid; IR (neat) 1677 and 1655 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.08 (6H, d, J=6.6 Hz, *i*-Pr), 1.46 (1H, ddd, J=9.5, 5.2, and 5.1 Hz, ring CH_2), 1.66 (1H, dt, J=6.2 and 5.2 Hz, ring CH_2), 2.4—2.6 (2H, m, ring CH and *i*-Pr), 4.02 (1H, ddd, J=6.2, 4.0, and 1.8 Hz, ring CH), 6.21 (1H, d, J=16.1 Hz, =CHCO), and 6.9—7.3 (6H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=17.66 (ring CH_2), 21.42, 21.45 (each *i*-Pr), 27.25 (ring CH), 31.40 (*i*-Pr), 59.96 (ring CH), 114.95, 121.73, 127.93, 129.64, 154.52, 158.16 (=CH), and 197.67 (CO); MS m/z (rel intensity, %) 137 (20), 136 (45), 121 (40), 105 (20), 97 (42), 95 (20), 94 (31), 93 (20), 91 (29), 81 (30), 79 (28), 77 (96), 75 (19), and 73 (base peak). Found: C, 77.67; H, 8.01%. Calcd for $C_{15}H_{18}O_2$: C, 78.23; H, 7.88%.

(*E*)-1-Oxo-2-pentenyl 2-Phenoxycyclopropyl Ketone (21f). A similar one-flask procedure using **1** (0.312 g, 2 mmol), copper(II) acetylacetonate (0.003 g, 0.01 mmol), and phenyl vinyl ether (1.2 g, 10 mmol) for cyclopropanation (1 h at 70 °C) and then LDA (2 mmol in THF (2 ml)) and propanal (0.22 ml, 2.4 mmol) for olefination (1 h at −78 °C and 0.5 h at room temperature) gave **21f** (0.128 g, 29% based on **1**) after column chromatography over silica gel with hexane-ethyl acetate (50 : 1 v/v). **21f**: Colorless liquid; IR (neat) 1677 and 1655 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.09 (3H, t, J=7.7 Hz, Et), 1.48 (1H, ddd, J=9.1, 6.2, and 4.0 Hz, ring CH_2), 1.67 (1H, dt, J=6.2 and 5.8 Hz, ring CH_2), 2.2—2.4 (2H, m, Et), 2.45 (1H, ddd, J=9.1, 5.8, and 2.2 Hz, ring CH), 4.03 (1H, ddd, J=6.2, 4.0, and 2.2 Hz, ring CH), 6.25 (1H, d, J=16.1 Hz, =CHCO), and 6.9—7.3 (6H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=12.45 (Et), 17.81 (ring CH_2), 25.27 (Et), 27.31 (ring CH), 60.01 (ring CH), 115.02, 121.81, 129.72, 149.93, 158.23 (=CH), and 197.60 (CO); MS m/z (rel intensity, %) 123 (38), 122 (base peak), 107 (36), 105 (19), 95 (46), 94 (18), 93 (15), 83 (40), 79 (27), and 77 (66). Found: C, 77.19; H, 7.48%. Calcd for $C_{14}H_{16}O_2$: C, 77.75; H, 7.46%.

(2*Z*,4*E*)-1-Oxo-5-phenyl-2,4-pentadienyl 2-Phenoxycyclopropyl Ketone ((*Z*,*E*)-21g) and (*E*,*E*)-1-Oxo-5-phenyl-2,4-pentadienyl 2-(Phenyloxy)cyclopropyl Ketone ((*E*,*E*)-21g). A similar one-flask procedure using **1** (0.312 g, 2 mmol), copper(II) acetylacetonate (0.003 g, 0.01 mmol), and phenyl vinyl ether (1.2 g, 10 mmol) for cyclopropanation (1 h at 70 °C) and then LDA (2 mmol in THF (2 ml)) and cinnamaldehyde (0.23 ml, 1.8 mmol) for olefination (1 h at −78 °C and 0.5 h at room temperature) gave (*Z*,*E*)-**21g** (0.051 g, 8% based on **1**) and then (*E*,*E*)-**21g** (0.288 g, 50% based on **1**) after column chromatography over silica gel with hexane-ethyl acetate (50 : 1 v/v). (*Z*,*E*)-**21g**: Yellow liquid; IR (neat) 1660, 1600, and 1580 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.52 (1H, ddd, J=8.6, 6.0, and 4.0 Hz, ring CH_2), 1.73 (1H, q, J=6.0 Hz, ring CH_2), 2.33 (1H, ddd, J=8.6, 6.0, and 2.0 Hz, ring CH), 4.07 (1H, ddd, J=6.0, 4.0, and 2.0 Hz, ring CH), 6.27 (1H, d, J=11.0 Hz, =CHCO), 6.66 (1H, t, J=11.0 Hz, =CH), 6.8—7.6 (11H, m, Ph and =CH), and 8.24 (1H, dd, J=15.8 and 12.5 Hz, =CH); MS m/z (rel intensity, %) 290 (M^+, 4), 225 (21), 205 (23), 94 (53), 76 (35), 75 (46), 73 (base peak), and 43 (27). (*E*,*E*)-**21g**: Colorless plates (hexane); mp 91—93 °C; IR (KBr) 1637 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.52 (1H, ddd, J=9.1, 5.1, and 4.0 Hz, ring CH_2), 1.72 (1H, dt, J=6.2 and 5.1 Hz, ring CH_2), 2.47 (1H, ddd, J=9.1, 6.2, and 2.2 Hz, ring CH), 4.08 (1H, ddd, J=6.2, 4.0, and 2.2 Hz, ring CH), 6.44 (1H, d, J=15.4 Hz, =CHCO), and 6.8—7.5 (13H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=17.85 (ring CH_2), 28.01 (ring CH), 60.06 (ring CH), 114.83, 121.64, 126.62, 127.31, 128.86, 129.31, 129.56, 135.96, 141.94, 143.18, 158.04, and 197.03 (CO); MS m/z (rel intensity, %) 290 (M^+, 14), 196 (36), 94 (29), and 32 (base peak); Found: C, 82.91; H, 6.30%. Calcd for $C_{20}H_{18}O_2$: C, 82.73; H, 6.25%.

3-Methyl-1-oxo-2-butenyl 2-Phenoxycyclopropyl Ketone

(**21h**). A similar one-flask procedure using **1** (0.312 g, 2 mmol), copper(II) acetylacetonate (0.003 g, 0.01 mmol), and phenyl vinyl ether (1.2 g, 10 mmol) for cyclopropanation (1 h at 70 °C) and then LDA (1.8 mmol in THF (2 ml)) and acetone (0.15 ml, 2 mmol) for olefination (2 h at −78 °C and 1 h at room temperature) gave **21h** (0.082 g, 19% based on **1**) after column chromatography over silica gel with hexane–ethyl acetate (50 : 1 v/v): Colorless liquid; IR (neat) 1670 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.42 (1H, ddd, J=9.5, 5.1, and 4.0 Hz, ring CH_2), 1.62 (1H, dt, J=6.2 and 5.5 Hz, ring CH_2), 1.92, 2.18 (each 3H, d, J=1.1 Hz, Me), 2.2—2.3 (1H, m, ring CH), 4.00 (1H, ddd, J=6.2, 4.0, and 2.2 Hz, ring CH), 6.28 (1H, dd, J=2.6 and 1.1 Hz, =CHCO), and 7.0—7.3 (5H, m Ph); ^{13}C NMR ($CDCl_3$) δ=17.45 (ring CH_2), 20.94 (Me), 27.72 (ring CH), 30.71 (Me), 59.72 (ring CH), 114.80, 121.51, 124.16, 156.01, 158.12 (=CH), and 197.46 (CO); MS m/z (rel intensity, %) 123 (33), 122 (base peak), 95 (63), 93 (21), and 82 (52). Found: C, 77.11; H, 7.56%. Calcd for $C_{14}H_{16}O_2$: C, 77.75; H, 7.46%.

(*E*)-**4-Oxo-6-phenyl-5-hexenal (22a).** A mixture of **21a** (0.223 g, 0.84 mmol), water (0.03 ml, 1.68 mmol), and trifluoroacetic acid (TFA, 0.064 ml, 0.84 mmol) in dry THF (2 ml) was stirred at room temperature for 20.5 h. The mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.195 g) was chromatographed over silica gel with hexane–ethyl acetate (9 : 1 v/v) to afford **22a** (0.139 g, 88%): Colorless liquid; IR (neat) 1715, 1680, 1653, and 1605 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.87 (2H, t, J=6.5 Hz, CH_2), 3.03 (2H, t, J=6.5 Hz, CH_2), 6.77 (1H, d, J=16.1 Hz, 5-H), 7.3—7.6 (5H, m, Ph), 7.60 (1H, d, J=16.1 Hz, 6-H), and 9.87 (1H, s, CHO); ^{13}C NMR ($CDCl_3$) δ=32.37, 37.58 (2- and 3-C), 125.74, 128.32, 128.97, 130.59 (each Ph), 135.17 (5-C), 143.06 (6-C), 197.45 (4-C), and 200.61 (CHO); MS m/z (rel intensity, %), 188 (M^+, 1), 160 (30), 131 (55), 103 (78), 102 (30), 91 (51), 76 (85), 51 (48), 42 (26), and 30 (base peak). HRMS Found: m/z 188.0838. Calcd for $C_{12}H_{12}O_2$: M, 188.0837.

(*E*)-**7-Methyl-4-oxo-5-octenal (22b).** A similar procedure using **21e** (0.044 g, 0.19 mmol), water (0.004 ml, 0.19 mmol), and TFA (0.015 ml, 0.19 mmol) in THF (0.5 ml) at room temperature for 24 h and subsequent silica-gel chromatography (hexane–ethyl acetate (9 : 1 v/v)) gave **22b** (0.029 g, 100%): Colorless liquid; IR (neat) 1720 and 1670 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.08 (6H, d, J=6.6 Hz, Me), 2.4—2.6 (1H, m, 7-H), 2.7—2.9 (4H, m, 2- and 3-H), 6.08 (1H, dd, J=16.1 and 1.5 Hz, 5-H), 6.86 (1H, dd, J=16.1 and 6.6 Hz, 6-H), and 9.84 (1H, s, CHO); MS m/z (rel intensity, %) 154 (M^+, 15), 126 (21), 97 (base peak), 84 (49), 82 (26), 69 (33), 41 (58), and 30 (22). HRMS Found: m/z 154.0990. Calcd for $C_9H_{14}O_2$: M, 154.0993.

(*E*)-**4-Oxo-5-octenal (22c).** A similar procedure employing **21f** (0.063 mg, 0.29 mmol), water (0.005 ml, 0.29 mmol), and TFA (0.022 ml, 0.29 mmol) in THF (1 ml) at room temperature for 22 h and subsequent column chromatography over silica gel with hexane–ethyl acetate (9 : 1 v/v) provided **22c** (0.029 g, 71%): Colorless liquid; IR (neat) 1725 and 1670 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.09 (3H, t, J=7.7 Hz, Et), 2.26 (2H, dq, J=7.7 and 1.4 Hz, 7-H), 2.79, 2.90 (each 2H, t, J=5.5 Hz, 2- and 3-H), 6.14 (1H, dt, J=16.1 and 1.4 Hz, 5-H), 6.95 (1H, dt, J=16.1 and 6.6 Hz, 6-H), and 9.83 (1H, s, CHO); MS m/z (rel intensity, %) 140 (M^+, 1), 82 (base peak), 55 (76), 41 (20), and 39 (38). HRMS Found: m/z 140.0794. Calcd for $C_8H_{12}O_2$: M, 140.0837.

(*E,E*)-**4-Oxo-8-phenyl-5,7-octadienal (22d).** A similar procedure using **21g** (0.045 g, 0.16 mmol), water (0.005 ml, 0.29 mmol), TFA (0.012 ml, 0.15 mmol) in THF (1 ml) at room temperature for 63 h and subsequent chromatography over silica gel with hexane–ethyl acetate (4 : 1 v/v)) gave **22d** (0.025 g, 73%): Colorless crystals; mp 71—73 °C; IR (KBr) 1718 and 1673 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.83, 2.96 (each 2H, t, J=6.6 Hz, 2- and 3-H), 6.31 (1H, d, J=15.4 Hz, 5-H), 6.8—7.0 (2H, m, 6- and 7-H), 7.3—7.5 (6H, m, Ph and 8-H), and 9.85 (1H, s, CHO); MS m/z (rel intensity, %) 214 (M^+, 31), 186 (20), 157 (41), 129 (25), 128 (35), and 32 (base peak). HRMS Found: m/z 214.0986. Calcd for $C_{14}H_{14}O_2$: M, 214.0993.

6-Methyl-4-oxo-5-heptenal (22e). To a mixture of **21h** (0.035 g, 0.16 mmol) and lithium chloride (0.013 g, 0.32 mmol) in THF (1 ml) were added water (0.006 ml, 0.32 mmol) and TFA (0.012 ml, 0.16 mmol). This mixture was stirred at room temperature for 30 min, poured into saturated aqueous sodium hydrogencarbonate, and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.039 g) was chromatographed over silica gel with hexane–ethyl acetate (9 : 1 v/v) to give **22e** (0.016 g, 71%): Colorless liquid; IR (neat) 1720 and 1687 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.90, 2.14 (each 3H, s, Me), 2.76 (4H, s, 2- and 3-H), 6.12 (1H, s, 5-H), and 9.83 (1H, s, CHO); MS m/z (rel intensity, %) 140 (M^+, 12), 83 (base peak), 55 (50), and 39 (21). HRMS Found: m/z 140.0838. Calcd for $C_8H_{12}O_2$: M, 140.0837.

(*E*)-**7-Phenyl-6-heptene-2,5-dione (23).** Crude **21c** prepared from **1** (0.156 g, 1 mmol) according to the above method was chromatographed twice over silica gel with hexane–ethyl acetate (9 : 1 v/v) to give **23** (0.046 g, 23%): Yellow liquid; IR (neat) 1715, 1690, and 1665 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.22 (3H, s, COMe), 2.81, 2.97 (each 2H, t, J=5.9 Hz, CH_2), 6.75 (1H, d, J=16.5 Hz, =CHCO), 7.3—7.5 (5H, m, Ph), and 7.58 (1H, d, J=16.5 Hz, =CH); ^{13}C NMR ($CDCl_3$) δ=30.00 (MeCO), 34.24, 37.06 (each CH_2), 126.00, 128.30, 128.94, 130.49, 134.47, 142.82 (=CH), 198.48 (CO), and 207.32 (COMe); MS m/z (rel intensity, %) 202 (M^+, 13), 144 (22), 131 (base peak), 108 (37), 107 (34), 103 (41), 83 (29), 78 (48), and 76 (51). HRMS Found: m/z 202.0990. Calcd for $C_{13}H_{14}O_2$: M, 202.0993.

(*E*)-**2-(3-Oxo-5-phenyl-4-pentenyl)-1,3-dioxolane (24a).** To a solution of **21a** (0.1 g, 0.37 mmol) and 1,2-ethanediol (0.05 ml, 0.82 mmol) in nitromethane (2.5 ml) was added TFA (0.03 ml, 0.39 mmol) at 0 °C. After stirring at the same temperature for 20 min, the mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.119 g) was chromatographed over silica gel with hexane–ethyl acetate (9 : 1 v/v) to give **24a** (0.078 g, 90%): Pale yellow liquid; IR (neat) 1685 and 1655 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.08 (2H, dt, J=7.3 and 4.4 Hz, CH_2), 2.82 (2H, t, J=7.3 Hz, CH_2), 3.8—4.0 (4H, m, OCH_2CH_2O), 4.97 (1H, t, J=4.4 Hz, CH), 6.74 (1H, d, J=16.1 Hz, =CHCO), and 7.3—7.6 (6H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=27.98, 34.56 (each CH_2), 64.89 (OCH_2CH_2O), 103.44 (CH), 126.20, 128.25, 128.94, 130.42 (each Ph), 134.54, 142.52 (each =CH), and 199.32 (CO); MS m/z (rel intensity, %) 232 (M^+, 14), 146 (35), 131 (74), 103 (74), 103 (56), 99 (47), 87 (59), 77 (40), 73 (base peak), and 44 (28). HRMS Found: m/z 232.1096. Calcd for $C_{14}H_{16}O_3$: M, 232.1099.

(*E*)-2-(6-Methyl-3-oxo-4-heptenyl)-1,3-dioxolane (24b). A similar procedure using **21e** (0.12 g, 0.52 mmol), 1,2-ethanediol (0.05 ml, 1.04 mmol), TFA (0.04 ml, 0.52 mmol) in nitromethane (2 ml) at 0 °C for 10 min and subsequent column chromatography over silica gel with hexane–ethyl acetate (9 : 1 v/v) gave **24b** (0.06 g, 58%): Colorless liquid; IR (neat) 1695, 1670, and 1630 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.06 (6H, d, J=6.6 Hz, *i*-Pr), 2.00 (2H, dt, J=7.7 and 4.4 Hz, CH_2), 2.46 (1H, dq, J=6.6 and 1.5 Hz, *i*-Pr), 2.70 (2H, t, J=7.7 Hz, CH_2), 3.8—4.0 (4H, m, OCH_2CH_2O), 4.94 (1H, t, J=4.4 Hz, CH), 6.05 (1H, dd, J=16.1 and 1.5 Hz, =CHCO), and 6.81 (1H, dd, J=16.1 and 6.6 Hz, =CH); ^{13}C NMR ($CDCl_3$) δ=21.32 (*i*-Pr), 27.90 (CH_2), 31.13 (*i*-Pr), 33.84 (CH_2), 64.97 (OCH_2CH_2O), 103.52 (CH), 127.48, 153.56 (each =CH), and 199.92 (CO); MS m/z (rel intensity, %) 198 (M^+, 3), 155 (25), 97 (25), 85 (22), and 73 (base peak). HRMS Found: m/z 198.1253. Calcd for $C_{11}H_{18}O_3$: M, 198.1255.

(*E*)-2-(3-Oxo-4-heptenyl)-1,3-dioxolane (24c). A similar procedure using **21f** (0.12 g, 0.56 mmol), 1,2-ethanediol (0.06 ml, 1.12 mmol), TFA (0.042 ml, 0.56 mmol) in nitromethane (2 ml) at 0 °C for 10 min and subsequent column chromatography over silica gel with hexane–ethyl acetate (9 : 1 v/v) gave **24c** (0.043 g, 42%): Colorless liquid; IR (neat) 1670 and 1630 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.08 (3H, t, J=7.3 Hz, Et), 2.00 (2H, dt, J=7.3 and 4.4 Hz, CH_2), 2.24 (2H, m, Et), 2.69 (2H, t, J=7.3 Hz, CH_2), 3.8—4.0 (4H, m, OCH_2CH_2O), 4.93 (1H, t, J=4.4 Hz, CH), 6.09 (1H, dt, J=16.2 and 1.5 Hz, =CHCO), and 6.90 (1H, dt, J=16.2 and 6.2 Hz, =CH); ^{13}C NMR ($CDCl_3$) δ=12.27 (Et), 25.54, (Et), 27.92, 33.81 (each CH_2), 64.98 (OCH_2CH_2O), 103.52 (CH), 129.37, 148.79 (each =CH), and 199.65 (CO); MS m/z (rel intensity, %) 184 (M^+, 11), 85 (23), 82 (32), and 73 (base peak). HRMS Found: m/z 184.1104. Calcd for $C_{10}H_{16}O_3$: M, 184.1099.

(*E,E*)-2-(3-Oxo-7-phenyl-4,6-heptadienyl)-1,3-dioxolane (24d). A similar procedure using **21g** (0.089 g, 0.31 mmol), 1,2-ethanediol (0.033 ml, 0.6 mmol), TFA (0.023 ml, 0.3 mmol) in nitromethane (1.5 ml) at 0 °C for 20 min and subsequent column chromatography over silica gel with hexane–ethyl acetate (9 : 1 v/v) gave **24d** (0.046 g, 58%): Colorless crystals; mp 66—70 °C; IR (KBr) 1654 and 1621 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.05 (2H, dt, J=7.3 and 4.4 Hz, CH_2), 2.74 (2H, t, J=7.3 Hz, CH_2), 3.8—4.1 (4H, m, OCH_2CH_2O), 4.95 (1H, t, J=4.4 Hz, CH), 6.28 (1H, d, J=15.7 Hz, =CHCO), and 6.8—7.5 (8H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=28.02, 34.41 (each CH_2), 64.97 (OCH_2CH_2O), 103.47 (CH), 126.72, 128.82, 129.14, 129.56, 136.02, 141.20, 142.52, and 199.33 (CO); MS m/z (rel intensity, %) 258 (M^+, 12) and 32 (base peak). HRMS Found: m/z 258.1254. Calcd for $C_{16}H_{18}O_3$: M, 258.1254.

2-(5-Methyl-3-oxo-4-hexenyl)-1,3-dioxolane (24e). A similar procedure employing **21h** (0.065 g, 0.3 mmol), 1,2-ethanediol (0.033 ml, 0.6 mmol), TFA (0.023 ml, 0.3 mmol) in nitromethane (1 ml) at 0 °C for 30 min and subsequent column chromatography over silica gel with hexane–ethyl acetate (9 : 1 v/v) provided **24e** (0.037 g, 67%): Colorless liquid; IR (neat) 1690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.88 (3H, d, J=1.1 Hz, Me), 1.97 (2H, dt, J=7.7 and 4.4 Hz, CH_2), 2.14 (3H, d, J=1.1 Hz, Me), 2.55 (2H, t, J=7.7 Hz, CH_2), 3.8—4.0 (4H, m, OCH_2CH_2O), 4.92 (1H, t, J=4.4 Hz, CH), and 6.08 (1H, t, J=1.1 Hz, =CH); ^{13}C NMR ($CDCl_3$) δ=20.71, 27.65 (each Me), 27.98, 38.07 (each CH_2), 64.97 (OCH_2CH_2O), 103.63 (CH), 123.70 (=CH), 155.03 (=CMe_2), and 199.76 (CO); MS m/z (rel intensity, %) 184 (M^+, 8), 86 (23), 82 (base peak), 73 (78), 55 (60), and 53 (20). HRMS Found: m/z 184.1097. Calcd for $C_{10}H_{16}O_3$: M, 184.1099.

(*E*)-3-(2-Oxo-4-phenyl-3-butenyl)-3,4,5,6-tetrahydro-2*H*-pyran-2-ol (25). To a solution of crude **21d** (0.257 g), which had been prepared from **20d** (0.184 g, 0.87 mmol) according to the method mentioned above, were added water (0.031 ml, 1.74 mmol) and TFA (0.066 ml, 0.87 mmol). After 20 min at room temperature, this mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.219 g) was subjected to column chromatography over silica gel with hexane–ethyl acetate (1 : 1 v/v) to provide **25** (0.095 g, 44% based on **20d**) as a 1 : 1 mixture of two inseparable stereoisomers: Colorless liquid; IR (neat) 3400 and 1675 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.3—1.9 (4H, m), 2.1—2.4 (1H m), 2.64 (1H, dd, J=17.8 and 6.5 Hz), 2.88 (1H, dd, J=17.3 and 6.5 Hz), 2.98 (1H, dd, J=17.3 and 6.5 Hz), 3.5—3.7 (1H, m), 3.9—4.1 (1H, m), 4.45 (0.5H, J=7.7 Hz), 5.11 (0.5H, d, J=2.6 Hz), 6.74 (1H, d, J=16.1 Hz), 6.75 (1H, d, J=16.1 Hz), and 7.2—7.6 (6H, m); ^{13}C NMR ($CDCl_3$) δ=24.42, 24.58, 24.97, 28.49 (each ring CH_2), 35.76, 38.44 (each ring CH), 41.93, 43.02 (each CH_2CO), 60.62, 65.84 (each ring CH_2), 93.77, 99.50 (each ring CH), 126.07, 126.56 (each =CHCO), 128.35, 128.39, 128.96, 130.55, 130.65, 134.35, 134.46, 143.02 (=CH), 143.28 (=CH), 200.06, and 200.12 (each CO); MS m/z (rel intensity, %) 246 (M^+, 23), 159 (28), 147 (41), 146 (20), 131 (base peak), 129 (21), 113 (31), 103 (61), 100 (32), 97 (27), 76 (41), 73 (74), and 43 (41). Found: C, 73.02; H, 7.45. Calcd for $C_{15}H_{18}O_3$: C, 73.15; H, 7.37%.

(*E*)-2-(2-Hydroxyethoxy)-3-(2-oxo-4-phenyl-3-butenyl)-3,4,5,6-tetrahydro-2*H*-pyran (26). A mixture of crude **21d**, which had been similarly prepared as above from **20d** (0.324 g, 1.52 mmol), 1,2-ethanediol (0.11 ml, 2.4 mmol), and TFA (0.09 ml, 1.2 mmol) in dry nitromethane (6 ml) was stirred at 0 °C for 1 h. This mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.334 g) was chromatographed over silica gel with hexane–ethyl acetate (1 : 1 v/v) to provide *cis*-**26** (0.028 g, 8% based on **20d**) and then *trans*-**26** (0.182 g, 52% based on **20d**). *cis*-**26**: Pale yellow liquid; IR (neat) 3450 and 1680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.5—1.8 (4H, m, ring CH_2), 2.3—2.4 (1H, m, ring CH), 2.58 (1H, dd, J=15.8 and 6.6 Hz, $COCH_2$), 2.79 (1H, dd, J=15.8 and 7.7 Hz, $COCH_2$), 2.89 (1H, br s, OH), 3.5—3.9 (6H, m, OCH_2), 4.71 (1H, d, J=3.3 Hz, ring CH), 6.75 (1H, d, J=16.5 Hz, =CHCO), and 7.3—7.6 (6H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=24.79, 24.94 (each ring CH_2), 36.20 (ring CH), 42.71 (CH_2CO), 60.32, 62.14 (OCH_2), 70.16 (ring CH_2), 99.29 (ring CH), 126.30 (=CHCO), 128.36, 128.98, 130.61, 134.42, 143.02 (=CHPh), and 199.65 (CO); MS m/z (rel intensity, %) 290 (M^+, 3), 144 (35), 131 (base peak), 103 (83), 77 (56), and 73 (22). HRMS Found: m/z 290.1525. Calcd for $C_{17}H_{22}O_4$: M, 290.1517. *trans*-**26**: Pale yellow liquid; IR (neat) 3450 and 1675 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.2—2.3 (5H, m, ring CH_2 and CH), 2.54 (1H, dt, J=15.8 and 6.6 Hz, $COCH_2$), 2.87 (1H, dd, J=15.8 and 7.0 Hz, $COCH_2$), 3.12 (1H, br s, OH), 3.5—4.1 (6H, m, OCH_2 and ring CH_2), 4.25 (1H, d, J=7.0 Hz, ring CH), 6.76 (1H, d, J=16.1 Hz, =CHCO), and 7.4—7.6 (6H, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=24.43, 27.80 (each ring CH_2), 37.52 (ring CH), 43.27 (CH_2CO), 62.11, 65.17 (CH_2O), 71.66 (ring CH_2), 104.85 (ring

CH), 126.06, 128.33, 128.95, 130.54, 134.44, 142.77 (=CH), and 199.49 (CO); MS *m/z* (rel intensity, %) 290 (M^+, 5), 157 (24), 144 (59), 131 (base peak), 103 (52), 101 (25), and 77 (28). HRMS Found: *m/z* 290.1520. Calcd for $C_{17}H_{22}O_4$: M, 290.1517.

(*E*)-2-Ethoxy-3-(2-oxo-4-phenyl-3-butenyl)-3,4,5,6-tetrahydro-2*H*-pyran (27). To a solution of crude **21d**, which had been prepared from **20d** (0.286 g, 1.35 mmol) according to the method mentioned above, and ethanol (0.08 ml, 1.36 mmol) in nitromethane (3 ml) was added TFA (0.052 ml, 0.68 mmol) at 0 °C. After stirring at the same temperature for 15 min, the reaction mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue (0.134 g) was chromatographed over silica gel with hexane–ethyl acetate (20:1 v/v) to give *cis*-**27** (0.026 g, 13% based on **20d**) and *trans*-**27** (0.06 g, 33% based on **20d**). *cis*-**27**: Pale yellow crystals; mp 67—71 °C; IR (KBr) 1691 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.20 (3H, t, J=7.0 Hz, OEt), 1.5—1.8 (5H, m, ring CH_2 and CH), 2.53 (1H, dd, J=16.5 and 7.0 Hz, CH_2CO), 2.79 (1H, dd, J=16.5 and 7.0 Hz, CH_2CO), 3.3—3.6 (2H, m, OEt), 3.7—3.8 (2H, m, ring CH_2), 4.68 (1H, d, J=2.9 Hz, ring CH), 6.73 (1H, d, J=16.1 Hz, =CHCO), and 7.3—7.6 (6H, m, Ph and =CH); MS *m/z* (rel intensity, %) 274 (M^+, 8), 131 (base peak), 128 (91), 103 (53), and 77 (26). HRMS Found: *m/z* 274.1566. Calcd for $C_{17}H_{22}O_3$: M, 274.1568. *trans*-**27**: Pale yellow liquid; IR (neat) 1690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.22 (3H, t, J=7.0 Hz, OEt), 1.2—2.2 (5H, m, ring CH_2 and CH), 2.48 (1H, dd, J=15.4 and 8.1 Hz, CH_2CO), 2.98 (1H, dd, J=15.4 and 5.5 Hz, CH_2CO), 3.4—3.6 (2H, m, OEt), 3.8—4.0 (2H, m, ring CH_2), 4.25 (1H, d, J=6.6 Hz, ring CH), 6.75 (1H, d, J=16.1 Hz, =CHCO), and 7.3—7.6 (6H, m, Ph and =CH); ^{13}C NMR ($CDCl_3$) δ=15.16 (OEt), 24.13, 27.03 (each ring CH_2), 36.89 (ring CH), 42.63 (CH_2CO), 63.86, 64.39 (each OCH_2), 103.35 (ring CH), 126.36 (=CHCO), 128.26, 128.92, 130.41, 134.57 (each Ph), 142.50 (=CH), and 199.22 (CO); MS *m/z* (rel intensity, %) 274 (M^+, 7), 141 (24), 131 (63), 128 (base peak), 103 (25), and 77 (25). HRMS Found: *m/z* 274.1564. Calcd for $C_{17}H_{22}O_3$: M, 274.1568.

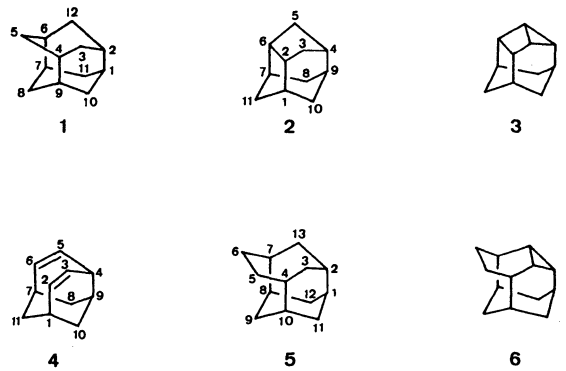
Homo-Diels-Alder reaction of tricyclo[5.3.1.$0^{4,9}$]undeca-2,5-diene with maleic anhydride proceeds very nicely in refluxed *o*-dichlorobenzene to give a single cycloadduct in 81% yield. The stereochemistry of the adduct is determined to be exo by leading to the *exo*-dimethyl ester and comparing it with the *endo*-dimethyl ester which is prepared by homo-Diels-Alder reaction of the above diene with dimethyl acetylenedicarboxylate followed by catalytic hydrogenation. Basic hydrolysis of the cycloadduct followed by oxidative decarboxylation with $Pb(OAc)_4$ in pyridine affords 3,13-dehydrohomoice-5-ene, catalytic hydrogenation of which gives 3,13-dehydrohomoiceane. Photoinduced intramolecular [$_\pi$2+$_\sigma$2] cycloaddition of 3,13-dehydrohomoice-5-ene produces the compound which contains two cyclopropane rings in its rigid structure. When this strained cage compound is treated with Pd-black under H_2, hydrogenolysis of the two cyclopropane rings takes place simultaneously to afford homoiceane.

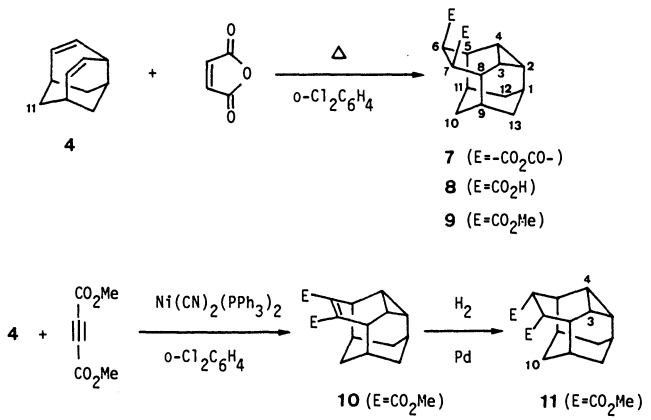
Iceane (**1**, tetracyclo[5.3.1.$1^{2,6}$.$0^{4,9}$]dodecane) is named after its geometrical similarity to one of the crystalline structure of water[2)] and possesses a unique rigid structure that consists of two chair and three boat cyclohexane rings.[3-5)] In the course of our works on synthesis and reactions of strained cage compounds related iceane,[6,7)] we previously reported synthesis of a nor-analogue of iceane, i.e. noriceane (**2**) as well as its 3,5-dehydro derivative, i.e. 3,5-dehydronoriceane (**3**).[6)] Recently we have found that tricyclo[5.3.1.$0^{4,9}$]undeca-2,5-diene (**4**) reacts with tetracyanoethene faster than norbornadiene to give the homo-Diels-Alder adduct, providing the first example of a 1,4-cyclooctadiene system participating as a diene partner in the homo-Diels-Alder reaction.[8)] In addition to its mechanistic interest, the resulting adduct consists of a skeleton of homoiceane (a homologue of iceane). We now wish to report here the first synthesis of homoiceane (**5**) and its 3,13-dehydro derivative **6** by using this highly efficient one-step framework construction.[9)]



Scheme 1.

Results and Discussion

When a 2:3 mixture of **4** and maleic anhydride in *o*-dichlorobenzene was heated under reflux for 12 h, the homo-Diels-Alder reaction proceeded very nicely to give the [2+2+2] adduct **7** as the single stereoisomer in 81% yield (Scheme 2). The ^{13}C NMR spectrum of **7** showed 9 peaks, supporting the C_s symmetry of **7**. Furthermore, the ^{13}C-H coupling constants of two higher field signals (δ=5.5 and 15.4) were 167 and 169 Hz, respectively, clearly indicating the presence of a cyclopropane ring. Thus, **4** demonstrated the remarkably high homo-Diels-Alder reactivity as a 1,4-cyclooctadiene derivative.[8)]

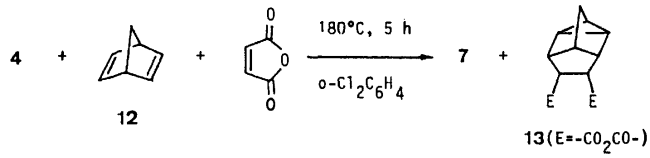


Scheme 2.

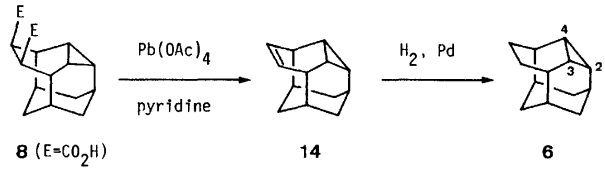
The stereochemistry of the adduct **7** was expected to be exo in consideration of the endo-selectivity of homo-Diels-Alder reaction and this expectation was further supported by the following experiments. Hydrolysis of **7** with potassium carbonate in H_2O gave the dicarboxylic acid **8**, which was esterified with diazomethane to afford the *exo*-dimethyl ester **9** in 86% yield (Scheme 2). On the other hand, the *endo*-dimethyl ester **11** was prepared as follows; cycloaddition of **4** with dimethyl acetylenedicarboxylate in the presence of catalytic amount of $Ni(CN)_2(PPh_3)_2$[10)] gave the cycloadduct **10** (45%), hydrogenation of which

over Pd-black took place from the exo-side, probably owing to steric hindrance by C^{10} methylene bridge, to give **11** (Scheme 2). The stereochemical assignments to **9** and **11** were compatible with a steric compression effect[11] observed in their ^{13}C NMR spectra: the signal due to C^3 (C^4) appears at higher field (δ=6.3) in **9** than in **11** (δ=10.6), whereas the signal due to C^{10} is at lower field (δ=32.2) in **9** than in **11** (δ=29.2). Thus, it is noteworthy that the present homo-Diels-Alder reaction proceeds exclusively in an endo-selective manner, since 67—79% endo-selectivity has been observed in the reaction of norbornadiene (**12**) with maleic anhydride.[12] The steric hindrance due to C^{11} methylene bridge of **4** may enhance the endo-selectivity in the present case.

In order to compare the homo-Diels-Alder reactivity of **4** with that of norbornadiene (**12**), we undertook a competitive reaction of **3** and **12** (Scheme 3). When a 1:1:1 mixture of **4**, **12**, and maleic anhydride in *o*-dichlorobenzene was heated at 180 °C in a sealed tube for 5 h, the cycloadducts, **7** and **13**,[13] were obtained in a ratio of 67:33 by ^1H NMR. This result suggested again the higher reactivity of **4** than that of **12**.[8]



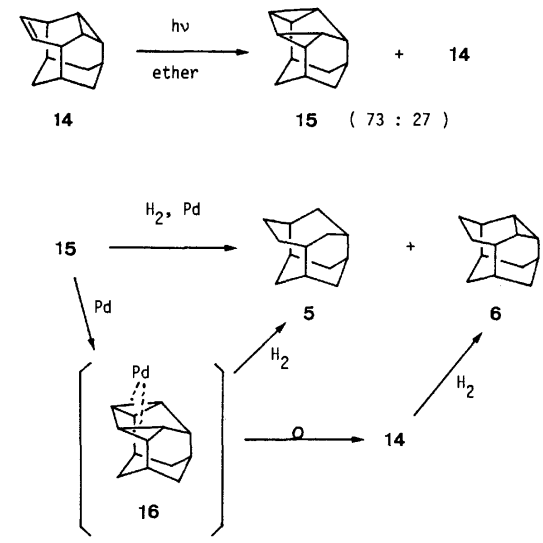
Scheme 3.



Scheme 4.

As the dehydrohomoiceane skeleton could be obtained in one step, we next examined transformation of **7** into **5** and **6**. Oxidative decarboxylation of **7** with lead tetraacetate in pyridine[14] gave the cage olefin **14** in 65% yield (Scheme 4). It should be noted that **14** contains a rigid chair bicyclo[4.1.0]hept-3-ene system, in which the π-σ interaction between the double bond and the cyclopropane ring has been of great interest.[15,16] Catalytic hydrogenation of **14** with Pd-black gave 3,13-dehydroiceane (**6**) in 97% yield.

On the other hand, transformation into homoiceane (**5**) was not so straightforward as above, because hydrogenolysis of the cyclopropane ring of **6** gave a unsymmetrical product which might be formed by hydrogenolysis of the side C-C bond (C^2-C^3 or C^2-C^4) of the cyclopropane ring: treatment of **6** with PtO_2 under H_2 in AcOH at 50 °C gave a compound, the ^{13}C NMR spectrum of which showed a lack of symmetry. In order to accomplish a regioselective cleavage of the central C-C bond (C^3-C^4), we have noticed an intramolecular [π2+σ2] cycloaddition[16] between the olefin and the cyclopropane moieties in **14**. Thus, irradiation of **14** in ether by a medium-pressure mercury lamp through a quartz filter afforded a 73:27 mixture of the [π2+σ2] cycloadduct **15** and unchanged **14** in 83% yield (Scheme 5). The ^1H NMR spectrum of **15** showed no olefinic protons and its ^{13}C NMR spectrum showed 8 peaks, suggesting C_s symmetry. The ratio of **15** to **14** was not changed after prolonged irradiation, suggesting a photostationary state between **14** and **15**.[17]



Scheme 5.

Since **15** contains two cyclopropane rings in its rigid cage structure, **15** is expected to be reactive toward transition metals.[18] When **15** was treated with Pd-black under H_2, hydrogenolysis of the two cyclopropane rings took place simultaneously to afford a 1:1 mixture of homoiceane (**5**) and **6**, along with a small amount of an unidentified compound (Scheme 5). The ^{13}C NMR spectrum of **5** clearly indicated C_s symmetry. The successful simultaneous hydrogenolysis of the two cyclopropane rings and the formation of **6** could be rationalized as follows (Scheme 5). The reaction would be probably initiated through complexation of Pd to the two cyclopropane rings, such as **16**. When **16** would undergo a valence isomerization to **14**, **6** would be produced after hydrogenation of the olefinic group. On the other hand, reaction of **16** with H_2 *before the isomerization* could afford **5**.

Experimental

All the temperatures were uncorrected. The IR spectra were obtained on a Hitachi 215 spectrometer. The mass spectra were taken by using a Hitachi RMS-4 mass spectrometer. The ^1H and ^{13}C NMR spectra were obtained on Varian EM-390 and CFT-20 or a JEOL FX-90Q spectrometer, Me_4Si being chosen as an internal standard. Analytical

GLC were carried out on a Shimadzu GC-4C gas chromatography with 10% SE-30 and 10% PEG-20M on Chromsorb W columns. Preparative GLC were performed on a Varian 920 gas chromatography with a 10% PEG-20M on Chromsorb W column. The microanalyses were carried out by Kyoto University Elemental Analysis Center.

Pentacyclo[7.3.1.$0^{2,4}$.$0^{2,8}$.$0^{5,11}$]tridecane-*exo,exo*-dicarboxylic Anhydride (7). A mixture of tricyclo[5.3.1.$0^{4,9}$]undeca-2,5-diene (146 mg, 1.0 mmol), maleic anhydride (147 mg, 1.5 mmol), and a small amount of hydroquinone in *o*-dichlorobenzene (15 mL) was heated at reflux under Ar for 12 h. The reaction mixture was chromatographed on silica gel. Elution by hexane and, then, a mixture of hexane and CH_2Cl_2 (1 : 1) gave **7** (198 mg, 81%): mp 153—155 °C; MS *m/z* (%) 244 (M^+, 100); IR (Nujol): 1845, 1780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.09 (s, 2H), 2.80—3.05 (m, 2H), 1.84—2.30 (m, 3H), 1.10—1.73 (m, 7H), 0.67—1.04 (m, 2H); ^{13}C NMR ($CDCl_3$) δ=174.7 (s), 44.1 (d), 32.6 (t), 31.9 (t), 31.0 (d), 28.4 (d), 18.4 (d), 15.4 (d, $^1J_{C\text{-}H}$=169 Hz), 5.5 (d, $^1J_{C\text{-}H}$=167 Hz). Found: C, 73.60; H, 6.60%. Calcd for $C_{15}H_{16}O_3$: C, 73.75; H, 6.60%.

***Dimethyl* Pentacyclo[7.3.1.$0^{2,4}$.$0^{3,8}$.$0^{5,11}$]tridecane-*exo,exo*-6,7-dicarboxylate (9).** A mixture of **7** (305 mg, 1.3 mmol) in 5% aqueous K_2CO_3 (10 mL) was heated at reflux for 2 h. The reaction mixture was acidified by 10% aqueous HCl and extracted with AcOEt. The organic solution was washed with H_2O and dried (Na_2SO_4). Evaporation of the solvent gave pentacyclo[7.3.1.$0^{2,4}$.$0^{3,8}$.$0^{5,11}$]tridecane-*exo*-,*exo*-6,7-dicarboxylic acid (**8**, 317 mg, 97%). A solution of **8** (123 mg, 0.5 mmol) in diethyl ether (30 mL) was treated with CH_2N_2 generated from $C_7H_7SO_2N(NO)CH_3$ and KOH. Usual work-up and chromatography on silica gel gave **9** (117 mg, 86%): mp 98—101 °C; MS *m/z* (%) 290 (M^+, 30), 258 (100); IR (Nujol): 1760, 1740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.61 (s, 6H), 2.94 (s, 2H), 2.53—2.80 (m, 2H), 1.57—2.20 (m, 4H), 0.93—1.53 (m, 7H); ^{13}C NMR ($CDCl_3$) δ=174.8 (s), 51.4 (q), 44.1 (d), 32.8 (t), 32.2 (t), 31.9 (d), 30.7 (d), 18.8 (d), 16.3 (d), 6.3 (d). Found: C, 70.07; H, 7.57%. Calcd for $C_{17}H_{22}O_4$: C, 70.32; H, 7.64%.

Dimethyl Pentacyclo[7.3.1.$0^{2,4}$.$0^{3,8}$.$0^{5,11}$]tridec-6-ene-6,7-dicarboxylate (10). A mixture of **4** (146 mg, 1.0 mmol), dimethyl acetylenedicarboxylate (710 mg, 5.0 mmol), $Ni(CN)_2(PPh_3)_2$ (12 mg, 0.02 mmol), and a small amount of hydroquinone in *o*-dichlorobenzene (5 mL) was heated at reflux under Ar for 4 h. The reaction mixture was chromatographed on silica gel. Elution by hexane, hexane-CH_2Cl_2 (1 : 1), and CH_2Cl_2 gave a mixture of **10** and some by-products, which was distilled (Kugelrohr, 130 °C/53 Pa) to give **10** (131 mg, 45%, 95% pure by ^1H NMR). Further purification by using a Lobar column (10% AcOEt-hexane) gave pure **10**: mp 63—4 °C; MS *m/z* (%) 288 (M^+, 28), 256 (83), 228 (100); IR (Nujol): 1720 cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.77 (s, 6H), 3.07—3.33 (m, 2H), 2.00—2.33 (m, 1H), 1.43—1.97 (m, 3H), 0.73—1.37 (m, 8H); ^{13}C NMR ($CDCl_3$) δ=168.6 (s), 143.5 (s), 51.9 (q), 34.2 (d), 31.5 (t), 30.2 (t), 24.3 (d), 23.8 (d), 18.5 (d), 15.6 (d). Found: C, 70.86; H, 6.80%. Calcd for $C_{17}H_{20}O_4$: C, 70.81; H, 6.99%.

Dimethyl Pentacyclo[7.3.1.$0^{2,4}$.$0^{3,8}$.$0^{5,11}$]tridecane-*endo-endo*-6,7-dicarboxylate (11). A mixture of **10** (68 mg, 0.3 mmol) and Pd-black (27 mg) in MeOH (5 mL) was stirred under H_2 for 48 h and, after addition of Pd-black (20 mg), for 48 h. Pd-black was filtered off through Celite and the solvent was evaporated. The residue was chromatographed on silica gel and elution by CH_2Cl_2 gave **11** (35 mg, 51%): mp 80—82 °C; MS *m/z* 290 (M^+, 22), 258 (100); IR (Nujol): 1730 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.64 (s, 6H), 3.08 (br s, 2H), 2.45—2.83 (m, 2H), 1.57—2.27 (m, 4H), 0.63—1.53 (m, 8H); ^{13}C NMR ($CDCl_3$) δ=174.1 (s), 51.3 (q), 44.5 (d), 32.9 (t), 32.0 (d), 29.2 (t), 27.8 (d), 19.4 (d), 18.3 (d), 10.6 (d). Found: C, 69.93; H, 7.69%. Calcd for $C_{17}H_{22}O_4$: C, 70.32; H, 7.64%.

Competitive Reaction of 4 and Norbornadiene (12) with Maleic Anhydride. A mixture of **4** (73 mg, 0.5 mmol), **12** (46 mg, 0.5 mmol), maleic anhydride (49 mg, 0.5 mmol), and a small amount of hydroquinone in *o*-dichlorobenzene (3 mL) was heated at 180 °C in a sealed tube for 5 h. The similar work-up to the above gave a mixture of **7** and **13** (46 mg) in a ratio of 67 : 33 (by ^1H NMR). The endo : exo ratio of **13** was determined to be 67 : 33 by ^1H NMR.

Pentacyclo[7.3.1.$0^{2,4}$.$0^{3,8}$.$0^{5,11}$]tridec-6-ene (14). To dry pyridine (11 mL) saturated with O_2 was added **8** (733 mg, 2.8 mmol) and $Pb(OAc)_4$ (1880 mg, 4.2 mmol). The mixture was heated at 65—70 °C in a preheated oil bath for 3 min and immediately cooled to room temperature in an ice bath. The reaction mixture was poured into 10% aqueous HNO_3 and extracted with diethyl ether. The ether solution was washed with saturated $NaHCO_3$ and brine, and dried (Na_2SO_4). The solvent was evaporated and the residue was chromatographed on silica gel. Elution by pentane gave **14** (322 mg, 67%) and further elution by CH_2Cl_2 gave **7** (66 mg, 10%). **14**: mp 205 °C (decomp); MS *m/z* (%) 172 (M^+, 70), 129 (72), 91 (100); IR (Nujol): 1465 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.17 (dd, 2H, *J*=2, 5 Hz), 2.57—2.90 (m, 2H), 1.97—2.27 (m, 1H), 1.06—1.77 (m, 8H), 0.63—1.03 (m, 3H); ^{13}C NMR ($CDCl_3$) δ=135.4 (d), 32.8 (t), 31.5 (d), 30.9 (t), 24.3 (d), 23.7 (d), 19.2 (d), 15.8 (d). Found: C, 90.62; H, 9.51%. Calcd for $C_{13}H_{16}$: C, 90.64; H, 9.36%.

Pentacyclo[7.3.1.$0^{2,4}$.$0^{3,8}$.$0^{5,11}$]tridecane (6). A mixture of **14** (76 mg, 0.44 mmol) and Pd-black (7.6 mg) in MeOH (4 mL) was stirred under H_2 for 2h. The catalysts were removed by filtration through Celite and the solvent was evaporated. The residue was chromatographed on silica gel and elution by pentane gave **6** (75 mg, 97%): mp 207 °C (decomp); MS *m/z* (%) 174 (M^+, 100); ^1H NMR ($CDCl_3$) δ=0.50—2.50 (m, 18H); ^{13}C NMR ($CDCl_3$) δ=33.5 (t), 31.9 (t), 30.4 (d), 27.5 (d), 24.1 (t), 19.8 (d), 14.9 (d), 8.8 (d). Found: C, 89.30; H, 10.64%. Calcd for $C_{13}H_{18}$: C, 89.59; H, 10.41%.

Hexacyclo[7.3.1.$0^{2,7}$.$0^{3,5}$.$0^{4,11}$.$0^{6,8}$]tridecane (15). A solution of **14** (228 mg, 1.3 mmol) in diethyl ether (15 mL) was irradiated through quartz filter under Ar by medium-pressure mercury lamp for 12h. The solvent was evaporated and the residue was chromatographed on silica gel. Elution by pentane gave a mixture of **15** and **14** (198 mg) in a ratio of 73 : 27 (by GLC). Pure **15** was isolated by preparative GLC. **15**: mp 199 °C (decomp); MS *m/z* 172 (M^+, 29), 91 (100); ^1H NMR ($CDCl_3$) δ=0.60—3.00 (m, 16H); ^{13}C NMR ($CDCl_3$) δ=35.6 (d), 35.5 (t), 33.8 (d), 33.3 (d), 32.4 (t), 27.1 (d), 26.7 (d), 22.5 (d). Found: C, 90.47; H, 9.50%. Calcd for $C_{13}H_{16}$: C, 90.64; H, 9.36%.

Tetracyclo[6.3.1.$1^{2,7}$.$0^{4,10}$]tridecane (5). A mixture of **15** (70 mg, 0.41 mmol) and Pd-black (7 mg) in MeOH (5 mL) was stirred under H_2 for 6 h. The catalysts were removed by filtration through Celite and the residue was chromatographed on silica gel. Elution by pentane gave a mixture of **5**, **6**, and an additional product (57 mg) in a ratio of 2 : 2 : 1 (by GLC). Pure **5** was isolated by preparative GLC. **5**: mp 176 °C; MS *m/z* (%) 176 (M^+, 100); ^1H NMR ($CDCl_3$)

δ=0.65—2.70 (m, 20H); ^{13}C NMR ($CDCl_3$) δ=35.0 (t), 34.2 (t and d), 32.8 (t), 31.7 (d), 30.7 (t), 30.2 (d), 26.4 (d). Found: C, 88.72; H, 11.72%. Calcd for $C_{13}H_{20}$: C, 88.57; H, 11.43%.

We thank Dr. E. Ōsawa for valuable discussions. This work was partially supported by a Grant-in-Aid for Scientific Research from Ministry of Education, Science and Culture (Nos. 58470073 and 62303004).

Novel Syntheses of Arylcarbamic Esters from Carbon Dioxide and Aromatic Amine via a Zinc Carbamate

Yasuhiko YOSHIDA,* Shigeru ISHII, Akinori KAWATO, Tadataka YAMASHITA, Masahiro YANO,† and Shohei INOUE†

(Received March 12, 1988)

Arylcarbamic esters were synthesized directly from carbon dioxide and an aromatic amine via a zinc carbamate. The alkylation of the reaction mixture of carbon dioxide, an aromatic amine, and diethylzinc with dialkyl sulfate formed alkyl arylcarbamate in a high yield. Also, 2-hydroxycyclohexyl diphenylcarbamate was obtained selectively in a good yield by the reaction of carbon dioxide, epoxycyclohexane, and ethylzinc diphenylamide. Other arylcarbamates of 1,2-cyclohexanediol were obtained by the reactions of carbon dioxide, an aromatic amine, diethylzinc, and epoxycyclohexane.

The carbamic esters are used industrially as plasticizers for rubbers and melamine alkyd resins, fuel additives, and agricultural chemicals such as insecticide and herbicide. The process to synthesize carbamic esters uses isocyanate, carbamoyl chloride, or chloroformate, which are obtained by the reaction using phosgene as a starting material.[1] Since phosgene is toxic and corrosive, and its use produces a large quantity of HCl, it is of interest to develop the novel synthetic methods of carbamic ester without phosgene.

The interest in the fixation of carbon dioxide has led us to investigate the direct synthetic reaction of carbamic ester from carbon dioxide as a starting material.[2-6] Alkylcarbamic esters of 1,2-diol or hemiacetal can be synthesized directly by the reaction of carbon dioxide, primary or secondary aliphatic amines, and epoxides or vinyl ethers, respectively. An analogous reaction by using aromatic amines did not occur, since their basicities are evidently lower.

On the other hand, it is well-known that carbon dioxide inserts to the nitrogen-metal bond to form the salt of carbamic acid.[7-25]

$$R_2N\text{-}M + CO_2 \rightarrow R_2NCOO\text{-}M \quad (1)$$
(M: Ti,Zr,V,Nb,Ta,W,Sn,Si,Ge,P,As,Sb,Zn,Al)

Hydrolysis of the salt, however, forms metal hydroxide and releases amine with evolution of carbon dioxide. Since carbamic acid is unstable, the fixation of carbon dioxide may not be accomplished by this reaction only.

We reported that the reactions of carbon dioxide, epoxycyclohexane, and metal dimethylamides, such as $Ti(NMe_2)_4$, $TiCp_2(NMe_2)_2$, or $W(NMe_2)_6$+$W_2(NMe_2)_6$, proceeded to afford dimethylcarbamate of 1,2-cyclohexanediol in high yields.[5,6] Similar reaction using metal arylamide, however, has not been reported. This paper reports a novel synthesis of arylcarbamic esters by the reaction of carbon dioxide with zinc arylamides followed by alkylation with dialkyl sulfates or an epoxide.

Results and Discussion

Synthesis of Arylcarbamic Esters by the Reaction of Zinc Carbamate with Dialkyl Sulfate. The reaction of *N*-methylaniline, diethylzinc, and carbon dioxide at 120 °C for 5 h was confirmed to give the corresponding ethylzinc carbamate quantitatively, as observed by the NMR spectral analysis of the reaction mixture.

$$PhMeNH + Et_2Zn + CO_2 \rightarrow PhMeNCOO\text{-}Zn\text{-}Et \quad (2)$$

When the reaction of *N*-methylaniline, diethylzinc, and carbon dioxide was followed by the alkylation of the product with diethyl sulfate at 140—160 °C for 20 h, ethyl methylphenylcarbamate was obtained in 93—96% yield (Eq. 3).

$$PhMeNCOO\text{-}Zn\text{-}Et + Et_2SO_4 \rightarrow PhMeNCOOEt \quad (3)$$

Attempted alkylation of zinc carbamate with diethyl sulfate at a temperature below 100°C hardly occurred (Table 1, Runs 1—5). The results of the synthesis of carbamic esters using various aromatic amines are shown in Table 1. By this method, aromatic amines gave the corresponding alkyl arylcarbamates in good yields.

Synthesis of Arylcarbamic Esters by the Reaction of Zinc Carbamate with Epoxycyclohexane. 2-Hydroxycyclohexyl arylcarbamates were found to be obtained selectively in good yields by the reaction of epoxycyclohexane with zinc arylcarbamates.

Carbon dioxide (50 atm) was reacted with an equimolar mixture of epoxycyclohexane and ethylzinc diphenylamide ($EtZnNPh_2$) in benzene solution at 80 °C for 120 h, to give selectively *trans*-2-hydroxycyclohexyl diphenylcarbamate in 48% yield (Table 2, Run 10).

a) Aromatic amine; 50 mmol, $ZnEt_2$; 50 mmol, CO_2; 50 atm, benzene; 30 ml, 120 °C, 5 h. b) R_2SO_4; 110 mmol, 20 h. c) 2-Naphthylphenylamine. d) *N*-Ethyl-*p*-toluidine. e) The yields of carbamates were based on amine. f) Yield by GLC of the reaction mixture of Et_2SO_4 and zinc carbamate for 15 h. g) Isolated yield by recrystallization from 1-pentanol. h) Isolated yield by distillation.

Table 2. The Reaction of Aromatic Amine, Et_2Zn, CO_2, and Epoxycyclohexane[a]

Run	Aromatic amine	Time h	Temp °C	Product Arylcarbamate/%[b]
1	Ph_2NH	16	40	0
2	Ph_2NH	16	60	15
3	Ph_2NH	16	80	32
4	Fh_2NH	16	100	40
5	Ph_2NH	2	80	21
6	Ph_2NH	4	80	23
7	Ph_2NH	8	80	29
8	Ph_2NH	32	80	37
9	Ph_2NH	44	80	44
10	Ph_2NH	120	80	48
11	PhMeNH	68	80	65
12	PhEtNH	48	80	34
13	PhNpNH	72	80	27

a) Aromatic amine; 40 mmol, $ZnEt_2$; 40 mmol, CO_2; 50 atm, epoxycyclohexane; 40 mmol, benzene; 40 ml. For Runs 1—10, ethylzinc diphenylamide prepared from Ph_2NH and $ZnEt_2$, was reacted with CO_2 and epoxycyclohexane. b) The isolated yields of arylcarbamates based on amine.

Although arylcarbamic ester was not formed in the reaction for 16 h at 40 °C, the yields of arylcarbamic ester increased to 40% at a high temperature such as 100°C (Table 2, Runs 1—4). No side products, such as polyether (homopolymer of epoxide), polycarbonate (copolymer of carbon dioxide and epoxide), or cyclic carbonate (the equimolar reaction product of epoxide and carbon dioxide), could be detected even in the reaction at 100 °C.

The reactions of epoxycyclohexane with carbon dioxide, diethylzinc, and an aromatic amine, without isolation of the zinc aromatic amide, were found to give the corresponding 2-hydroxycyclohexyl arylcarbamate, as shown in Table 2. In the case of secondary aromatic amines (PhMeNH, PhEtNH, and PhNpNH), arylcarbamic esters were obtained in good yields (Table 2, Runs 11—13), but the yields of arylcarbamic ester from primary aromatic amines were low.

A similar reaction of carbon dioxide, epoxycyclohexane, and diethylaluminum diphenylamide (Et_2AlNPh_2)[26] instead of $EtZnNPh_2$ also gave diphenylcarbamic ester in a low yield (9%), and simultaneously yielded polycarbonate.

Experimental

General. Commercially available aromatic amines, epoxycyclohexane, benzene, diethylzinc, and triethylaluminium were purified by recrystallization or distillation, and stored in a nitrogen atmosphere. Dialkyl sulfates were used without further purification. Commercial high-purity carbon dioxide gas was introduced into an autoclave directly from a gas cylinder without further purification.

Measurements. IR spectra were recorded on a Hitachi EPI-G3 apparatus, and NMR spectra were measured by using Hitachi 24B spectrometer operating at 60 MHz and JEOL FX90Q at 90 MHz, using hexamethyldisiloxane (HMDS) as internal standard. GC-MS spectra were measured by using a Shimadzu QP-1000 GC-MS spectrometer, and gas liquid chromatogram (GLC) were recorded on a Shimadzu GC-4C apparatus with a thermal conductor.

Reaction of Carbon Dioxide with the Reaction Mixture of Diethylzinc and *N*-Methylaniline. A 100 cm^3 stainless autoclave was swept free of air by displacement with nitrogen. Into the autoclave was added a solution of Et_2Zn (10 cm^3, 100 mmol) and *N*-methylaniline (10.8 cm^3, 100 mmol) in 30 cm^3 of benzene, and CO_2 gas was introduced directly from gas cylinder until the pressure reached 50 atm (5.1×10^6 Pa). After the autoclave was allowed to stand in an oil bath controlled at 120 °C for 5 h, the excess of CO_2 gas was released, and IR and ^1H NMR of the reaction mixture was measured. The IR spectrum of the reaction mixture showed a new absorption at 1565 cm^{-1} to suggest the presence of carboxylate group. ^1H NMR spectrum of the reaction mixture in $CDCl_3$ showed signals at δ 0.2 (2H, q), 1.4 (3H, t), 3.1 (3H, s, $NC\underline{H}_3$), and 7.0 (5H, $C_6\underline{H}_5N$), while ethyl group bonded to zinc such as ethylzinc diethylamide is known to show signals at δ 0.4 (2H, q, $CH_3C\underline{H}_2Zn$) 1.4 (3H, t, $C\underline{H}_3CH_2Zn$).[27]

Synthesis of Arylcarbamate. Reaction of Et_2Zn, aromatic amine, and CO_2, followed by the reaction of the product with dialkyl sulfate: A typical example for the synthesis of

ethyl ethyl(4-methylphenyl)carbamate is as follows.

A 100 cm^3 stainless autoclave was swept free of air by displacement with nitrogen. Into the autoclave was added a solution of Et_2Zn (5.1 cm^3, 50 mmol) and *N*-ethyl-*p*-toluidine (7.2 cm^3, 50 mmol) in 30 cm^3 of benzene, and CO_2 gas was introduced directly from gas cylinder until the pressure reached 50 atm. After the autoclave was allowed to stand in an oil bath controlled at 120 °C for 5 h, the excess of CO_2 gas was released, and diethyl sulfate (14.4 cm^3, 110 mmol) was added into the reaction mixture in the autoclave. After the reaction mixture was heated at 140 °C for 20 h, the contents of the reaction mixture was washed with diluted hydrochloric acid, then with water, and subjected to distillation under a reduced pressure to give the product, ethyl ethyl(4-methylphenyl)carbamate, 100 °C/1.5 mmHg (1 mmHg=133.322 Pa), 8.15 g (79%).

Preparations of other alkyl arylcarbamates were carried out by a similar procedure.

Synthesis of 2-Hydroxycyclohexyl Arylcarbamate: A typical example for the synthesis of 2-hydroxycyclohexyl diphenylcarbamate is as follows.

A 100 cm^3 stainless autoclave was swept free of air by displacement with nitrogen. Into the autoclave was added a solution of $EtZnNPh_2$[24] (10 g, 40 mmol) and epoxycyclohexane (4.0 cm^3, 40 mmol) in 40 cm^3 of benzene, and CO_2 gas was introduced directly from gas cylinder until the pressure reached 50 atm. After the autoclave was allowed to stand in an oil bath controlled at 80 °C for 16 h, the excess of CO_2 gas was released and the contents of the reaction mixture was washed with diluted hydrochloric acid, then with water, and subjected to freeze drying to give a white powder. The white powder was recrystallized from hexane to yield 3.8 g (32%) of 2-hydroxycyclohexyl diphenylcarbamate, mp 133 °C. This carbamate was confirmed to be of trans form, since *trans*-1,2-cyclohexanediol was obtained quantitatively by the hydrolysis of the carbamic ester with methanolic sodium hydroxide.

Preparations of other 2-hydroxycyclohexyl arylcarbamates were carried out by using Et_2Zn and an aromatic amine instead of $EtZnNPh_2$.

Reaction of Et_2AlNPh_2, CO_2, and Epoxycyclohexane: Diethylaluminum diphenylamide (Et_2AlNPh_2)[26] (11 g) in benzene solution (40 cm^3) was heated with epoxycyclohexane (3.9 g) at 80 °C for 87 h under a carbon dioxide pressure (50 atm) in a 100 cm^3 stainless autoclave. The reaction mixture was washed with diluted hydrochloric acid, then with water, and poured to methanol (500 cm^3) to give a white powdery precipitate (polycarbonate; 1.4 g). Evaporation of the solvent from the filtrate left a white residue, which was recrystallized from hexane to give 1.1 g (9%) of 2-hydroxycyclohexyl diphenylcarbamate.

Identification of the Products. Ethyl Methylphenylcarbamate: Bp 79—80 °C/0.45 mmHg (lit,[28,29] 79—80 °C/1 mmHg); IR(neat) 1700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.15 (3H, t, $OCH_2C\underline{H}_3$), 3.2 (3H, s, $NC\underline{H}_3$), 4.1 (2H, q, $OC\underline{H}_2CH_3$), 7.2 (5H, $NC_6\underline{H}_5$); MS (70 eV) m/z=179 (M^+).

Ethyl Diphenylcarbamate: Mp 69—70 °C (lit,[29] mp 72—73 °C); IR (KBr pellet) 1695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1 (3H, t, $OCH_2C\underline{H}_3$), 4.1 (2H, q, $OC\underline{H}_2CH_3$), 7.1 (10H, s, N($C_6\underline{H}_5$)$_2$); MS (70 eV) m/z=241 (M^+).

Ethyl (2-Naphthyl)phenylcarbamate: Mp 87—89 °C (lit,[30] mp 93 °C); IR (KBr pellet) 1708 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.4 (3H, t, $OCH_2C\underline{H}_3$), 4.1 (2H, q, $OC\underline{H}_2CH_3$), 7.2 (5H, s, $NC_6\underline{H}_5$), 7.1—7.8 (7H, m, naphthyl group); MS (70 eV) m/z=291 (M^+).

Ethyl Ethyl(4-methylphenyl)carbamate: Bp 100 °C/1.5 mmHg; IR (neat) 1710 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.9—1.2 (6H, methyl groups of NC_2H_5 and OC_2H_5), 2.1 (3H, s, CH_3 of 4-methylphenyl group), 3.6 (2H, q, $NC\underline{H}_2CH_3$), 4.0 (2H, q, $OC\underline{H}_2CH_3$), 7.0 (4H, aromatic ring); MS (70 eV) m/z=207 (M^+); EA,Found: C, 69.54; H, 8.26; N, 6.76%. Calcd for $C_{12}H_{17}NO_2$: C, 69.69; H, 8.34; N, 6.73%.

Methyl Ethyl(4-methylphenyl)carbamate: Bp 83.3—83.4 °C/0.5 mmHg; IR (neat) 1695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.0 (3H, t, $NCH_2C\underline{H}_3$), 2.2 (3H, s, CH_3 of 4-methylphenyl group), 3.5 (3H, s, $OC\underline{H}_3$), 3.6 (2H, q, $NC\underline{H}_2CH_3$), 7.0 (4H, aromatic ring); MS (70 eV) m/z=193 (M^+); EA,Found: C, 68.37; H, 7.82; N, 7.25%. Calcd for $C_{11}H_{15}NO_2$: C, 68.35; H, 7.81; N, 7.21%.

2-Hydroxycyclohexyl Diphenylcarbamate: Mp 133 °C (recrystallized from hexane); IR (KBr pellet) 3500 and 1695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.0—2.1 (8H, methylenes of cyclohexane ring), 2.6 (1H, O$\underline{H}$), 3.4 (1H, C$\underline{H}$-OH), 4.4 (1H, C$\underline{H}$-O(C=O)), 7.2 (10H, N($C_6\underline{H}_5$)$_2$); EA, Found: C, 72.93; H, 6.89; N, 4.48%. Calcd for $C_{19}H_{21}NO_3$: C, 73.29; H, 6.80; N, 4.50%.

2-Hydroxycyclohexyl Methylphenylcarbamate: Mp 100 °C (recrystallized from hexane); IR (KBr pellet) 3500 and 1695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.0—2.1 (8H, methylenes of cyclohexane ring), 3.2 (4H, $NC\underline{H}_3$ and O$\underline{H}$), 3.5 (1H, C$\underline{H}$-OH), 4.4 (1H, C$\underline{H}$-O(C=O)), 7.2 (5H, $NC_6\underline{H}_5$); EA, Found: C, 67.35; H, 7.90; N, 5.61%. Calcd for $C_{14}H_{19}NO_3$: C, 67.45; H, 7.68; N, 5.62%.

2-Hydroxycyclohexyl Ethylphenylcarbamate: Bp 66 °C/7 mmHg; IR (neat) 3500 and 1695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.9—2.1 (8H, methylenes of cyclohexane ring), 1.0 (3H, t, $NCH_2C\underline{H}_3$), 3.1—3.6 (2H, C$\underline{H}$-C$\underline{H}$), 3.6 (2H, q, $NC\underline{H}_2CH_3$), 4.4 (1H, m, C$\underline{H}$-O(C=O)), 7.2 (5H, $NC_6\underline{H}_5$); EA,Found: C, 68.19; H, 8.37; N, 5.15%. Calcd for $C_{15}H_{21}NO_3$: C, 68.41; H, 8.03; N, 5.31%.

2-Hydroxycyclohexyl (2-Naphthyl)phenylcarbamate: Mp 175 °C (recrystallized from hexane); IR(KBr pellet) 3500 and 1695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.0—2.1 (8H, methylenes of cyclohexane ring), 2.6 (1H, O$\underline{H}$), 3.4 (1H, C$\underline{H}$-OH), 4.6 (1H, C$\underline{H}$-O(C=O)), 6.8—7.9 (12H, phenyl and 2-naphthyl groups); EA,Found: C, 76.61; H, 6.39; N, 3.91%. Calcd for $C_{23}H_{23}NO_3$: C, 76.43; H, 6.41; N, 3.87%.

Retentive Solvolysis. 15. Salt Effect on the Retentive Phenolyses of 1-(*p*-Substituted phenyl)ethyl *p*-Nitrobenzoates. The Pattern of Salt Effect and the Number of Ion-Pair Intermediates in the S_N1 Solvolysis

Tomomi KINOSHITA,* Koichi SHIBAYAMA, Keizo IKAI, and Kunio OKAMOTO†
Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Kyoto 606
(Received March 14, 1988)

The salt effect of sodium phenoxide on the polarimetric (k_p) and titrimetric rate constants (k_t) has exhibited pattern B for the phenolysis of optically active 1-(*p*-methylphenyl)ethyl *p*-nitrobenzoate (ROPNB; (**1**)) in pure phenol. The other patterns A, C, and D were previously observed for the phenolyses of 1-phenylethyl *p*-nitrobenzoates with *p*-MeO- (**2**), *p*-H- (**3**), and *p*-NO_2-substituents (**4**), respectively. Thus, the k_p–k_t pattern changes in the order A → B → C → D as the stability of the intermediate decreases in the order of **2**>**1**>**3**>**4**. All the k_p–k_t patterns can be correlated with the ion-pair stage for product formation, i.e., the pattern A with the second ion-pair intermediate and the patterns B, C, and D with the first one. The pattern of salt effect on the product distribution (% of ROPh, *o*- and *p*-RC_6H_4OH, and *p*-$MeC_6H_4CH{=}CH_2$) for **1** is also compatible with the k_p–k_t pattern B.

The structure of ion-pair intermediates in the S_N1 solvolysis[2] should be discussed after confirmation of the ion-pair stage of nucleophilic attack, e.g., the first ion-pair intermediate (Int-**1**) or the second one (Int-**2**). For such confirmation, the pattern of salt effect of an added salt on the polarimetric and titrimetric rate constants (k_p and k_t, respectively) can serve as a useful tool.[2e,2i,3-8] The possible k_p–k_t diagrams in the S_N1 solvolysis can be generally classified into four patterns, A, B, C, and D,[8,9] provided no normal salt effect[10] was observed (Fig. 1).

On the basis of a stability-selectivity relationship for solvolysis intermediate,[11] it was anticipated that the k_p–k_t pattern should change in the order A → B → C → D with a decrease in the stability of ion-pair intermediate.[9] The retentive phenolyses of 1-(*p*-substituted phenyl)ethyl *p*-nitrobenzoates exhibited the patterns A, C, and D for the *p*-methoxy (**2**), *p*-H (**3**), and *p*-nitro derivatives (**4**), respectively, in the presence of sodium phenoxide.[7] However, the pattern B has not been known for any of 1-phenylethyl systems.

In this paper, we report that the k_p–k_t profile for the phenolysis of 1-(*p*-methylphenyl)ethyl *p*-nitrobenzoate (**1**) exhibited the pattern B, filling up the sequence and, as a consequence, we have confirmed a clear-cut correlation between the stability of phenolysis intermediates (*p*-MeO>*p*-Me>H>*p*-NO_2) and the k_p–k_t pattern, A → B → C → D.

2: Y = CH_3O
3: Y = H
4: Y = NO_2

Results and Discussion

Phenolysis Rates and Stability of the Ion-Pair Intermediate. Racemic **1** was solvolyzed in pure phenol in the presence of NaOPh (0.106 M) (1M=1 mol dm^{-3}) at 125 °C. The phenolysis rate was determined by the titrimetric method. The k_t value is shown along with those for **2**, **3**, and **4**, which had been previously reported,[7] in Table 1.

The k_t value decreases in the sequence **2**>**1**>**3**>**4** (relative rate 220 : 14.1 : 1.00 : 0.0430 at 125 °C). The k_p value ($k_p/k_t < 1.32$) also decreases in the sequence **3**>**4** (relative rate 1.00 : 0.034). Thus, each of the phenolysis intermediates should become less stable in the order of the rate sequence.

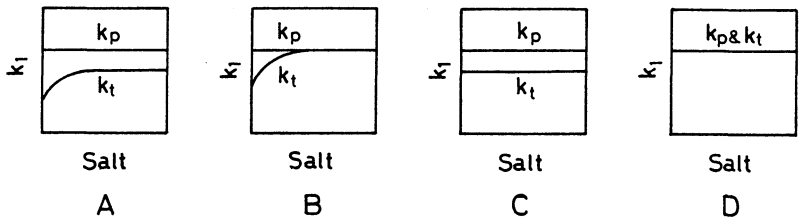

Fig. 1. Four patterns of salt effect on k_p and k_t in the S_N1 solvolysis (in the absence of normal salt effect; cited from Refs. 8 and 9).

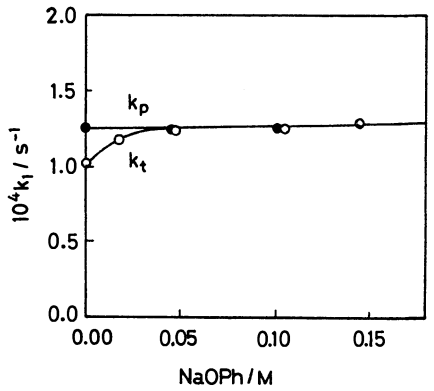

Fig. 2. Effect of added NaOPh concentration on the first-order rate constants (k_p and k_t) for the phenolysis of 1-(*p*-methylphenyl)ethyl *p*-nitrobenzoate in phenol at 75 °C.

Solvolysis rate constants for several aralkyl systems, including 1-phenylethyl acetates in aqueous ethanol,[12] are reported to be well correlated by the Brown-Okamoto equation.[13] In contrast, the σ^+ plot of log k_t shows definitely a curved line for the phenolyses of **1**—**4**, similarly to those of 2,2-dimethyl-1-phenylpropyl *p*-nitrobenzoates,[8] the hydrolyses of 1-phenylethyl chlorides,[14,15] and many other solvolyses.[16] However, a linear plot is given by the use of Yukawa-Tsuno equation,[16] $\log(k/k_0)=\rho[\sigma^0+r(\sigma^+-\sigma^0)]$ with $\rho=-1.78$ and $r=1.88$ (correlation coefficient 0.9939) for the phenolyses of **1**—**4**. Such a *r* value is comparable with that (2.05)[8] for the phenolyses of 2,2-dimethyl-1-phenylpropyl system and is larger than those (1.25 and 0.28) for the hydrolyses of 1-phenylethyl chlorides[14,15] and those (0.542—1.350) for the other solvolysis systems,[16] which may be attributed to the larger resonance effect for the phenolysis system than those for the other systems. Although the *r* value might be a parameter characteristic of the structure of the possible transition state model as well as a parameter measuring the availability of the transition state resonance, it could hardly describe the number and the detailed structure of ion-pair intermediate.

The phenolyses of **1**—**4** exhibit a reactivity parallel with that of the corresponding chlorides in aqueous ethanol[14] and in aqueous acetone;[15] there is a linear free-energy relationship (correlation coefficient 0.991 and 0.988) between the phenolysis and the hydrolysis rates, reflecting approximately similar transition states to each other.

Salt Effect on the Phenolysis Rates. The k_p and k_t for the optically active and racemic substrates **1** were measured in the presence of sodium phenoxide in phenol at 75 °C. Satisfactory first-order kinetic behavior, as expected for the S_N1 solvolysis, was observed at variable concentrations (0—0.145 M) of added sodium phenoxide. The k_p and k_t are summarized in Table 2, and are plotted against the salt concentrations (Fig. 2).

The salt effect of NaOPh on the k_p-k_t diagram for the phenolysis of **1** exhibits a pattern which belongs to the pattern B (Fig. 1) where the discrepancy between k_p and k_t virtually disappears, owing to the special salt effect[3,4,17] on k_t, at higher salt concentrations. We can characterize such salt effect using the parameters proposed by Winstein and his coworkers,[17a] i.e., $k^0_{t,ext}/k^0_t=k^0_p/k^0_t=1.21$ and $[salt]_{1/2}=0.012$ M and also using Winstein's equation[17a] $k_t=k^0_{t,ext}(1+0.0275\cdot[salt])$, where $k^0_{t,ext}$ is k_t value extrapolated at zero salt concentration from its linear part at higher salt concentrations, k^0_t and k^0_p are the k_t and k_p values at zero salt concentration, and $[salt]_{1/2}$ is the salt concentration corresponding to 1/2 $(k^0_{t,ext}+k^0_t)$.

Such k_p-k_t pattern indicates that the phenoxide ion attacks the first ion-pair intermediate (Int-**1**), not the second one (Int-**2**), to produce all the products and to result in neither ion-pair return nor racemization of the intermediate itself at higher NaOPh concentrations.[6,9]

Table 3. The Relative Rates and the Features[a] of Four k_p–k_t Patterns for the Phenolyses of 1-(*p*-Substituted phenyl)ethyl *p*-Nitrobenzoates (RX) **1**—**4** in the Presence of Sodium Phenoxide in Phenol

RX	$k_{t,rel.}$[b] (125 °C)	k_p–k_t pattern[c]	No. of intermediate	Nucleophile[d]	Ion-pair return	Ion-pair intermediate		
						Stability (Reactivity)	Life	Racemization
2	220	A	2	NaOPh	exists	higher (lower)	longer	more
1	14.1	B	1	NaOPh	exists[e]	↑	↑	less[f]
3	1.00	C	1	PhOH	exists	↓	↓	less
4	0.0430	D	1	PhOH	not exist	lower (higher)	shorter	no

a) Cited from Ref. 9. b) Cited from Table 1. c) See Fig. 1 for each profile. d) Reacting with ion-pair intermediate at higher salt concentrations. e) Does not exist at higher salt concentrations. f) No racemization at higher salt concentrations.

The other examples of this pattern have been observed for the phenolyses of 2,2-dimethyl-1-phenylpropyl *p*-nitrobenzoate,[8,9] 2,2-dimethyl-1-(*p*-methoxyphenyl)propyl trifluoroacetate,[8] 1,5-dimethyl-1-ethylhexyl chloride[8] and *p*-nitrobenzoate,[6] and 1-methylheptyl tosylate,[6] the acetolysis of 2-(*p*-methoxyphenyl)propyl tosylate,††[4] and the trifluoroacetolysis of 1-methylpropyl tosylate.[18]

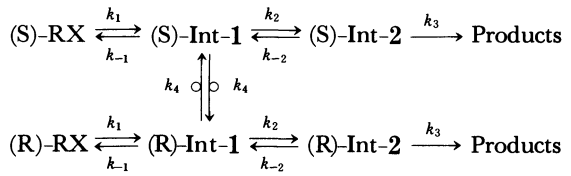
Features of the k_p–k_t profiles for **1**—**4** are summarized in Table 3. These results distinctly show that the k_p–k_t pattern does change in the sequence A → B → C → D as the stability of phenolysis intermediate decreases.

Thus, by means of each of the four k_p–k_t patterns, we can unambiguously determine (i) the number of ion-pair intermediate, in other words, the ion-pair stage of product formation, in addition, (ii) the species of nucleophile reacting with the ion-pair intermediate, and (iii) the existence or absence of ion-pair return.

The kinetic features of each k_p–k_t pattern (Table 3) can be expressed by the following reaction Schemes 1 and 2 for the patterns A and B-D, respectively.

According to such schemes, the total rate expressions for k_p and k_t can be derived as the following equations (Eqs. 1—4).

For the pattern A:



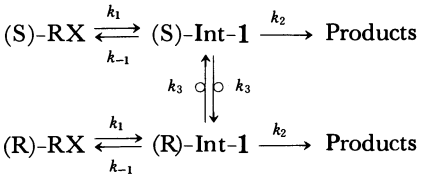
Scheme 1.

$$k_p = \frac{k_1}{1 + \dfrac{k_{-1}}{[k_2 k_3/(k_3 + k_{-2})] + 2k_4}} \quad (1)$$

$$k_t = \frac{k_1}{1 + \dfrac{k_{-1}}{k_2 k_3/(k_3 + k_{-2})}} \quad (2)$$

$$k_3 = k_3' + k_3''[\mathrm{PhOH}] + k_3'''[\mathrm{NaOPh}]$$

For the patterns B, C, and D:



Scheme 2.

$$k_p = \frac{k_1}{1 + [k_{-1}/(k_2 + 2k_3)]} \quad (3)$$

$$k_t = \frac{k_1}{1 + k_{-1}/k_2} \quad (4)$$

$$k_2 = k_2' + k_2''[\mathrm{PhOH}] + k_2'''[\mathrm{NaOPh}]$$

where $k_2''' = 0$ for the pattern C
$k_2''' = 0$, and $k_3 = 0$ and/or $k_{-1} = 0$ for the pattern D

All solvolysis systems are summarized in Table 4, which have been unequivocally proved to proceed via multiple, e.g., two, and a single ion-pair intermediate on the basis of the k_p–k_t pattern. Table 4 suggests that, although S_N1 solvolysis has been generally recognized to proceed through multiple ion-pair intermediates,[2a-h] such a solvolysis system is rather exceptional and, in major ones, the first ion-pair intermediate (Int-1) is the product source.

Salt Effect on the Product Distribution. The product distribution was analyzed by the use of GLPC for the phenolysis of **1** (ROPNB) under identical conditions with those employed for the rate study. The

†† Although the pattern A was previously reported for this system,[4] reexamination of the pattern of salt effect has clarified that it does not follow pattern A, but B.[9]

phenolysis produces a major amount of ROPh and small amounts of *o*- and *p*-RC_6H_4OH, and *p*-methylstyrene. Plots of the distribution (%) against the salt concentration exhibit patterns similar to the salt effect on k_t; the yield (%) of aralkyl phenyl ether decreases and those of *o*- and *p*-aralkylphenol and *p*-methylstyrene increase (Fig. 3). Analogous patterns of the salt effect on product distributions were observed for the phenolyses of 1-aryl-2,2-dimethylpropyl systems.[9] The constancy of the product distribution at higher salt concentrations gives an indication that all the products come from the reaction of the ion-pair intermediate (Int-**1**) with added NaOPh, not with the solvent phenol molecule, at higher salt concentrations. The product distribution, which is extrapolated at zero base concentration from curves for respective products, suggests ROPh as the single product (Fig. 3). In contrast to such extrapolated product distribution, the phenolysis actually gave no ROPh but *o*- and *p*-RC_6H_4OH in the absence of NaOPh. This is most probably due to the slow rearrangement of ROPh to RC_6H_4OH by the liberated acid.[19]

In conclusion, it has been clearly confirmed that we can determine the number of ion-pair intermediate, namely, the ion-pair stage of nucleophilic attack by means of each of the four k_p–k_t patterns.

The structure of ion-pair intermediate will be discussed in the following paper on the basis of the stereochemical outcomes for *O*- and *C*-alkylations in the phenolysis of **1**.

Experimental

^{13}C and ^{1}H NMR spectra were taken with a JEOL model JNM FX-90Q 22.5 MHz (FT) and a Hitachi R-24 60 MHz instruments, respectively. IR spectra were recorded with a Hitachi model 215 spectrophotometer. Optical rotations were measured with a JASCO model DIP-SL polarimeter. GLPC was performed with Hitachi model 163 and model 023-6003 instruments. MPLC was done with a chromatograph system composed of a FMI model RP-SY-2 pump and a Merck silica gel 60 column. Melting points were measured on a Yamato model MP-21 apparatus. Microanalyses were performed by the Elemental Analytical Center, Kyoto University.

Materials. Sodium phenoxide was synthesized in the usual way.[7] Racemic[14] and optically active ROH's[20] were synthesized by the literature method. Other organic reagents were of analytical grade, dried, and fractionated prior to use.

Synthesis of 1-(*p*-Methylphenyl)ethyl *p*-Nitrobenzoate. According to the usual method,[7] optically active ROPNB was synthesized. A solution of (*R*)-(+)-ROH (10.017 g, 0.0735 mol, $[\alpha]_D^{26.0}$ +20.5±0.03° (*c* 10.90, ethanol)) and *p*-nitrobenzoyl chloride (15.66 g, 0.08440 mol) in pyridine (40 ml) was stirred at room temperature for 3 h. After usual work-up,[21] (*R*)-(−)-ROPNB (12.29 g, 58.60% yield; mp 69.8—70.5 °C (uncorr.); $[\alpha]_D^{23.4}$ −8.27±0.05° (*c* 3.784, benzene) was obtained. Racemic ROPNB was obtained in a similar manner. The physical constants and spectral data for ROPNB are shown along with those for the phenolysis products in Tables 5 and 6.

Rate Measurements. The usual aliquot technique was employed for measurements of k_p and k_t as previously described.[21] In each run, the reaction was followed to at least 80% conversion; smooth first-order linear relationships were obtained (the correlation coefficients ≥ 0.999). The rate data against the added NaOPh concentration are shown in Tables 1 and 2 and Fig. 1.

Table 6. ^{13}C NMR Spectral Data for 1-(*p*-Methylphenyl)-ethyl Derivatives (RX) Relevant to the Phenolysis[a]

RX	CH_3	-CH-	Ar
ROPNB	21.01 (q) 21.95 (q)	73.97 (d)	123.29 (d) 135.79 (s) 125.99 (d) 137.85 (s) 129.16 (d) 150.29 (s) 130.51 (d) 163.68 (s)

p-RC_6H_4OH	20.83 (q) 22.00 (q)	43.41 (d)	115.15 (d) 135.24 (s) 127.29 (d) 138.87 (s) 128.56 (d) 143.68 (s) 128.93 (d) 153.21 (s)

a) δ; in $CDCl_3$. b) Corresponding to four carbon atoms.

Product Distribution Analysis. Each phenolysis of racemic **1** was carried out in the presence of diphenyl ether as an internal standard under the conditions identical with those adopted for the rate study. After usual work-up[22] with ether, each ethereal solution was concentrated by a distillation using a short column. Then product distributions were analyzed by GLPC in a manner similar to those reported earlier.[22] They are plotted against the added NaOPh concentration in Fig. 3.

Isolation of the Phenolysis Products. Residues of the reaction solutions used for the rate measurements were combined. After the usual work-up as described previously,[21] products were separated by MPLC, distilled in vacuo, and identified on the basis of their IR, ^{13}C and ^{1}H NMR spectral data, chromatographic data, and the elemental compositions. They are summarized along with those for ROPNB in Tables 5 and 6.

The authors thank the Ministry of Education, Science and Culture for a Grant-in-Aid for Scientific Research.

Radical Transport Reaction. Concurrent Transfer of Electron and Proton

Junji ICHIKAWA, Takaaki SONODA, and Hiroshi KOBAYASHI*
Institute of Advanced Material Study, Kyushu University, Kasuga, Fukuoka 816
(Received March 14, 1988)

Concurrent transport of electron and proton on the same molecule; formal hydrogen-transfer reaction, is successfully realized in aprotic media by using 1-butyl-4,4′-bipyridinium cation radical ($BuPPH^{+\cdot}$), which is prepared from 1-butyl-4-(4-pyridyl)pyridinium ion. Hydrogen reduction with $BuPPH^{+\cdot}$ was discriminated from electron reduction with octylviologen cation radical by the chemoselective reduction preferring enedione to *vic*-dibromide in aprotic media.

Alkylviologens (1,1′-dialkyl-4,4′-bipyridinium, RV^{2+}) are well-known to undergo one-electron reduction to give the resonance-stabilized cation radicals ($RV^{+\cdot}$), which in turn easily release an electron to regenerate RV^{2+}. On the merits of their reversible redox reactions with large negative potentials, they have been widely used as effective electron carriers in a variety of studies in photochemistry,[1] solar energy conversion and storage,[2] and organic synthesis,[3,4] In all cases, however, alkylviologen served as an electron-transfer agent, and the overall reactions were most frequently completed with protons which were supplied from a large excess of surrounding protic media.

Our interests had been focused on the functions of alkylviologens as a catalytic electron mediator across a liquid membrane and a cation transporter coupled therewith, which led us to explore the potentialities of viologen analogues to transport concurrently both an electron and a cationic species, formally equivalent to a radical species. In the first place, we examined the hydrogen-transfer reduction as the simplest example of this scheme. On the basis of the structure of alkylviologens, one of the two *N*-alkyl groups was replaced with a protic hydrogen, which was expected to be transferred along with an electron (Scheme 1). In this article, we report that 1-butyl-4,4′-bipyridinium cation radical ($BuPPH^{+\cdot}$) functions efficiently as a formal hydrogen-transfer agent in aprotic media, and the scheme is exemplified by the selective reduction preferring enedione to *vic*-dibromide.

Results and Discussion

1-Butyl-4-(4-pyridyl)pyridinium ion ($BuPP^+$) showed the lowest redox potential, −0.48 V vs. NHE, in a pH<3 region,[5] where it is in the form of 1-butyl-4,4′-bipyridinium ($BuPPH^{2+}$). The formation of $BuPPH^{+\cdot}$ X^-, where X denotes halogen, was effected by the reduction of $BuPP^+Br^-$[6] with zinc under acid conditions (Scheme 1), and was characterized by a strong sharp band at 400 nm and a weak broad one at 610 nm, resembling those of alkylviologen cation radicals (e.g. that of octylviologen, $C_8V^{+\cdot}$). The blue coloration lasted long enough stably under unaerobic conditions.

When prepared in the two-phase system of aqueous buffer and dichloromethane, $BuPPH^{+\cdot}$ X^- was partitioned only in the aqueous phase, but it could be incorporated into the dichloromethane phase by anion-exchanging the halide for highly lipophilic tetrakis-[3,5-bis(trifluoromethyl)phenyl]borate ($TFPB^-$)[7] (Eq. 1). $BuPPH^{+\cdot}$ was also prepared under anhydrous conditions by using anhydrous TsOH in DMF (Eq. 2). For comparison, other radical analogues having no protic hydrogens within each molecule were prepared according to Eqs. 3—5. In every case, an excess of zinc was filtered off before use.

In order to prove the efficacy of $BuPPH^{+\cdot}$ as a hydrogen-transfer agent, two types of model substrates were selected to be reduced. One is (*E*)-1,4-diphenyl-2-

Table 1. Reduction of Enedione **1** and *vic*-Dibromide **3**

Entry	Reductant	Additive	Yield/%[a]	
			2 in (A)	**4** in (B)
1	$BuPPH^{+\cdot}TFPB^-$[b] /CH_2Cl_2		97[c]	38
2	$BuPPH^{+\cdot}TsO^-$/DMF		99	97
3	$BuPP^{\cdot}$/DMF		7[d]	84[c]
4	$C_8V^{+\cdot}X^-$[e]/CH_2Cl_2		Trace[d]	Quant.

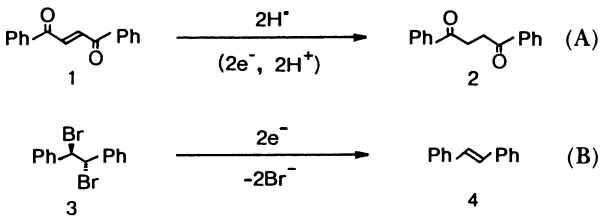
butene-1,4-dione (**1**), whose reduction to 1,4-diketone **2** requires proton source for its completion (System (A)), and the other is *meso*-1,2-dibromo-1,2-diphenylethane (**3**), which can be debrominated to olefin **4** by accepting electrons alone (System (B)). The reducing efficiencies of BuPPH‡ are summarized in Table 1, in comparisons with those of BuPP· and C$_8$V‡ in the two reaction systems (A) and (B).



As shown in Table 1, BuPPH‡ worked dually as a hydrogen-reducing agent in the system (A),[8] as well as an electron-reducing agent in the system (B) both in dichloromethane and DMF (Entries 1 and 2), though seemed more favorable to the former system (A). By contrast, C$_8$V‡ served only as an electron-reducing agent in such aprotic media to afford the debrominated product in the system (B), and when applied to the system (A), afforded only a trace amount of the hydrogenated product (Entries 4 and 5). In the same reaction systems, BuPP· which had no protic hydrogens in the molecule showed similar chemoselectivities to those of C$_8$V‡ (Entry 3 vs. Entry 5). The highly efficient reduction of the system (A) in the presence of protic hydrogens may be explained as follows: Enedione **1** initially accepts an electron to give the anion radical **5**, which is difficult to accept an additional electron to the dianion **6**. However, if the anion radical **5** is protonated in situ to the radical **7**, then it is easily reduced further to yield the expected product **2** (Scheme 2). Therefore, when the separate proton source such as TsOH or pyridinium tosylate (PyH$^+$ TsO$^-$) was added, the reduction of the system (A) proceeded even with C$_8$V‡, though did to much less extent than the reaction with BuPPH. (Entries 6 and 7 vs. Entry 2). These results indicate that the protic hydrogen which is carried concurrently with an electron on the same molecule promoted the hydrogenation of the system (A) more efficiently than that carried separately from the electron, thus, the concurrent transport of an electron and a proton; formal hydrogen transfer, was successfully attained by BuPPH‡.

These observations forced us to examine the effica-

Table 2. Reduction of α,β-Unsaturated Ketones with $BuPPH^+$ in DMF

Substrate	Product	Temp	Time/h	Yield/%
p-Benzoquinone	Hydroquinone	r.t.	20	60
Diphenyl diketone	Benzoin	r.t.	10	83
Chalcone	1,3-Diphenyl-1-propanone	r.t.	4	11

cies of hydrogen and electron transfer in terms of chemoselectivities in the reduction of enedione **1** and *vic*-dibromide **3**. When the equimolar mixture of **1** and **3** was treated with $BuPPH^+$ or C_8V^+ in dichloromethane, the reduction of **1** or **3** proceeded selectively without affecting the other substrate which could be recovered in each case (Scheme 3). In these reactions it is noted that $BuPPH^+$ favors exclusively the hydrogen reduction and the chemoselective reduction between **1** and **3** can be achieved simply by the selection of the present two types of bipyridinium salts. $BuPPH^+$ could hydrogenate some analogous substrates, as shown in Table 2, though in the last line rather poor yield resulted.

This reagent would be also useful as hydrogen-transporting agent through a hydrophobic liquid membrane, combined with the photosensitized formation of 4,4′-bipyridinium cation radicals.[3b,4a)]

Experimental

Materials. $BuPP^+Br^-$ was prepared from the reaction of 4,4′-bipyridine with butyl bromide in acetonitrile according to the literature.[6,9)] When $BuPP^+Br^-$ was stirred with powdered zinc in DMF under an argon atmosphere, the blue coloration was rapidly developed due to the formation of $BuPP^{\cdot}$; VIS 736.2 (relative absorbance 0.05), 665 (sh, 0.16), 607.6 (0.31), 400.8 (1.00), 390 (0.67), and 375 nm (0.43). The absorption maxima of its protonated form, $BuPPH^+$, developed in the presence of an equimolar amount of TsOH were almost unchanged; VIS 736.4 (0.08), 666 (sh, 0.20), 609.6 (0.39), 400.4 (1.00), 388.6 (0.85), and 374.6 nm (0.72). These values corresponded to those of C_8V^+ in DMF; VIS 736.0 (relative absorbance 0.06), 660 (sh, 0.16), 608.8 (0.33), 400.8 (1.00), 390 (0.62), and 373 nm (0.37).

Procedures. Reductions of **1** or **3** with viologen analogues were carried out at room temperature, where the viologen analogue was used by 2.2 times molar amounts to the substrate, unless otherwise described, and reduced with powdered zinc to its radical form. The excess of zinc was removed before use by filtration through a disposable Teflon membrane filter (pore size of 0.5 μm) attached to the nozzle of a syringe. The product was isolated by column chromatography on silica gel, eluted with 9:1 mixture of hexane and ether.

Typical procedures of the reduction reaction were as follows:

Reduction of 1 with $BuPPH^+$ $TFPB^-$ in Dichloromethane: Into a two-phase mixture of dichloromethane (20 cm^3) and aqueous HCl-KCl buffer (pH 2.0, 20 cm^3) were added $BuPP^+Br^-$ (97 mg, 0.33 mmol) and Na^+TFPB^- $2.5H_2O$ (308 mg, 0.33 mmol). The mixture was stirred under argon atmosphere, and was added powdered zinc (106 mg, 16.2 mmol). Blue coloration of $BuPPH^+TFPB^-$ rapidly developed in the organic phase. After stirred for 1 min at room temperature, the organic phase was filtered. The filtrate was added to **1** (24 mg, 0.10 mmol) and the reaction mixture was stirred at room temperature for 20 h. After usual work-up, 1,4-diphenyl-1,4-butanedione (**2**) (23 mg, 97% yield) was isolated.

Reduction of 1 with $BuPPH^+TsO^-$ in DMF: To a DMF solution (4 cm^3) of $BuPP^+Br^-$ (78 mg, 0.27 mmol) and anhydrous TsOH (46 mg, 0.27 mmol) was added powdered zinc (183 mg, 2.8 mmol) under an argon atmosphere. After stirred for 1 min at room temperature, the mixture was filtered. To the filtrate, **1** (29 mg, 0.12 mmol) in DMF (1 cm^3) was added dropwise and the reaction mixture was stirred at room temperature for 11 h. After usual work-up, 1,4-diphenyl-1,4-butanedione (**2**) (29 mg, 99% yield) was isolated.

Reduction of 1 with $C_8V^+Br^-$ in the Presence of TsOH: $C_8V^+Br^-$ in DMF was prepared from $C_8V^{2+}2Br^-$ (106 mg, 0.20 mmol) and zinc (126 mg, 1.9 mmol). Anhydrous TsOH (34 mg, 0.20 mmol) was added to the filtrate before the addition of **1**. After usual work-up, **2** (5.6 mg, 27% yield) was isolated.

Reduction of 3 with $C_8V^+Br^-$ in the Presence of TsOH: $C_8V^+Br^-$ in DMF was prepared in a similar manner as above. The addition of the filtrate to a mixture of anhy-

drous TsOH and **3** resulted in **4** (8.8 mg, 64% yield).

Reduction of a Mixture of 1 and 3 with $BuPPH^+TFPB^-$ in Dichloromethane: $BuPPH^+TFPB^-$ was prepared in a two-phase mixture of dichloromethane and aqueous HCl-KCl buffer (pH 2) from $BuPP^+Br^-$ (38 mg, 0.13 mmol), $Na^+TFPB^- 2.5H_2O$ (133 mg, 0.14 mmol) and zinc (444 mg, 6.79 mmol) in a similar manner as above. $BuPPH^+TFPB^-$ in dichloromethane was added to a mixture of **1** (14 mg, 0.059 mmol) and **3** (20 mg, 0.059 mmol). After usual work-up, **2** (13 mg, 92% yield) and **3** (19 mg, 95% recovery) were isolated.

Reduction of a Mixture of 1 and 3 with $C_8V^+X^-$ in Dichloromethane: $C_8V^+X^-$ was prepared in dichloromethane from $C_8V^{2+}2Br^-$ (58 mg, 0.11 mmol) and zinc (350 mg, 5.35 mmol). The filtered solution of $C_8V^+X^-$ was added to a mixture of **1** (21 mg, 0.089 mmol) and **3** (30 mg, 0.089 mmol). After usual work-up, **4** (16 mg, quantitative yield) and **1** (21 mg, quantitative recovery) were isolated.

Synthesis and Properties of Dinitromethylated Arenes. Reinvestigation of the Ponzio Reaction[1)]

Hitomi SUZUKI,* Hiroshi TAKAOKA, Hidetoshi YAMAMOTO, and Takuji OGAWA
Department of Chemistry, Faculty of Science, Ehime University, Bunkyo-cho, Matsuyama 790
(Received March 22, 1988)

Several title compounds have been prepared by the modified Ponzio procedure and their IR, ^{1}H and ^{13}C NMR data are presented. In some cases trinitromethylated arenes were obtained as a by-product. Oxidative cleavage to parent aldehydes and oxidation to carboxylic acids were the major competing reactions. 9-Anthracenecarbaldehyde oxime and 10-methyl-9-anthracenecarbaldehyde oxime reacted with nitrogen dioxide in an unexpected way, giving 10-nitro-9-anthracenecarbonitrile oxide and 10-methyl-10-nitro-9-anthrone as the respective main products. Nitration of (dinitromethyl)benzene has also been examined under various conditions.

In a previous paper,[2)] we reported that the action of concentrated nitric acid on 9-methyl-9-nitro-10-nitromethylene-9,10-dihydroanthracene led to 9-methyl-10-trinitromethylanthracene as one of the main products. Contrary to our expectation, 9-dinitromethyl-10-methylanthracene could not be detected in the product mixture. This unexpected result made us necessary to investigate the behavior of dinitromethylated arenes toward nitric acid. Search for relevant literature revealed that there are only several scattered papers which describe the preparation and properties of (dinitromethyl)arenes.[3-9)] The sole general method for the direct preparation of this type of compounds is that first reported by Ponzio, who converted benzaldehyde oxime (**1a**) into (dinitromethyl)benzene (**2a**) by the action of nitrogen dioxide in ether.[3,4)]
