5,5-Dimethyl-8aα-methoxymethyl-3-(trimethylenedithio)-3,4,4aα,5,6,7,8,8a-octahydro-2(1*H*)-naphthalenone (16). A mixture of **15** (137 mg, 0.54 mmol), 1,3-propanedithiol ditosylate (225 mg, 0.54 mmol), potassium acetate (180 mg, 1.8 mmol), and methanol (5 ml) was gently refluxed for 15 h. The solvent was mostly removed under reduced pressure, and the residual oil was dissolved in CH_2Cl_2. The solution was washed successively with aqueous $NaHCO_3$, water and brine, and dried. The oily residue obtained on concentration was purified by TLC (1 : 1 ether-hexane) to provide **16** (152 mg, 85%) as colorless needles; mp 95—96 °C (from hexane-ether). IR (KBr) 1700, 1100, 620 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.95 and 1.13 (3H, s each, $C(CH_3)_2$), 1.1—2.6 (16H, m), 2.7—3.7 (1H, m), 3.03 and 3.53 (1H, d, J=10 Hz each, CH_2O), 3.30 (3H, OCH_3).

Found: C, 62.44; H, 8.45; S, 19.17%. Calcd for $C_{17}H_{28}O_2S_2$: C, 62.17; H, 8.59; S, 19.14%.

1α-(2,6-Dimethoxy-4-methylbenzyl)-5,5-dimethyl-8aα-methoxymethyl-3-(trimethylenedithio)-3,4,4aα,5,6,7,8,8a-octahydro-2(1*H*)-naphthalenone (18). A 50% sodium hydride dispersion in mineral oil (983 mg, 9.75 mmol) was washed with pentane, and DMSO (20 ml) was added. The mixture was warmed at 65 °C with stirring for 1.5 h and then cooled to 0 °C. To the resulting solution, a solution of **16** (3.20 g, 9.75 mmol) in THF (30 ml) was added dropwise, and the whole was stirred for an additional 30 min. Formaldehyde vapor generated by heating paraformaldehyde (ca. 3 g) at 160—170 °C was passed through the well-stirred, above mixture at −10 °C with the aid of a dry N_2 stream over 40 min. The reaction was then quenched with aqueous NH_4Cl, and the mixture was extracted with benzene. Concentration of the extract left a semisolid, which was chromatographed over 50 g of silica gel (1 : 3 hexane-ether) to give **17** (1.94 g, 58%) as colorless crystals; mp 80—82 °C (from hexane-ether). IR (KBr) 1680, 1595, 1100, 950 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.97 and 1.00 (6H in total, s, $C(CH_3)_2$), 1.1—2.75 (15H, m), 3.25 and 3.60 (1H, d, J=10 Hz each, CH_2-O), 3.30 (3H, OCH_3), 5.42 and 6.13 (1H, finely splitted s each, $=CH_2$). MS (70 eV) m/z 340 (M^+).

1.5 M butyllithium in hexane (5.1 ml, 7.63 mmol) was added to a stirred solution of orcinol dimethyl ether (1.48 g, 9.72 mmol) in THF (20 ml) at 0 °C and the resulting mixture was stirred at room temperature for an additional 30 min. The mixture was cooled at −40—−50 °C and a solution of **17** (1.18 g, 3.47 mmol) in THF (10 ml) was added dropwise. Stirring was continued for an additional 2 h, and the reaction was quenched with ice water. The product was extracted with ether, and the oily residue obtained by concentration of the extract was dissolved in $CHCl_3$ (30 ml). A $CHCl_3$ solution (0.1 ml) saturated with dry HCl was added to the above solution, and the mixture was stirred at room temperature for 30 min. Removal of the solvent under reduced pressure gave a semisolid, which was then chromatographed over 50 g of silica gel (1 : 3 ether-hexane) to give **18** (1.52 g, 89%) as colorless crystals; mp 148—149 °C (from ether). IR (KBr) 1710, 1610, 1580, 1110, 810, 580 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.93 and 1.03 (3H, s each, $C(CH_3)_2$), 1.1—4.0 (18H, m), 2.30 (3H, s, $ArCH_3$), 3.35 (3H, s, OCH_3), 3.43 (2H, s, CH_2O), 3.80 (6H, s, $ArOCH_3$), 6.28 (2H, s, ArH). MS (70 eV) m/z 492 (M^+).

Found: C, 65.63; H, 8.40; S, 12.74%. Calcd for $C_{27}H_{40}O_4S_2$: C, 65.83; H, 8.19; S, 13.00%.

1α-(2,6-Dimethoxy-4-methylbenzyl)-5,5-dimethyl-8aα-methoxymethyl-3,4,4aα,5,6,7,8,8a-octahydro-2(1*H*)-naphthalenone (19). A mixture of W-4 Raney-Ni (ca. 4 g) and a solution of **18** (320 mg, 0.64 mmol) in ethanol (10 ml) was gently refluxed for 2.5 h with stirring. After cooling to room temperature, precipitates were filtered and washed with ethanol. The combined filtrates were evaporated and the residue was dissolved in CH_2Cl_2. Concentration of the solution left a solid, which was purified by TLC (3 : 1 hexane-ether) to give **19** (230 mg, 91%) as colorless needles; mp 130—131 °C (from ether). IR (KBr) 1710, 1605, 1590, 810 cm^{-1} ^1H NMR ($CDCl_3$) δ=1.02 and 1.15 (3H, s each, $C(CH_3)_2$), 1.0—2.9 (14H, m), 2.28 (3H, s, $ArCH_3$), 3.28 (3H, s, OCH_3), 3.22 and 3.33 (1H, d, J=10 Hz each, CH_2O), 3.78 (6H, s, $ArOCH_3$), 6.30 (2H, s, ArH).

Found: C, 74.16; H, 9.40%. Calcd for $C_{24}H_{36}O_4$: C, 74.19; H, 9.34%.

1α-(2,6-Dimethoxy-4-methylbenzyl)-5,5-dimethyl-8aα-methoxymethyl-2-methylene-1,2,3,4,4aα,5,6,7,8,8a-decahydronaphthalene (20). A 50% sodium hydride dispersion in mineral oil (65 mg, 1.36 mmol) was washed with pentane, and DMSO (2 ml) was added. The resulting suspension was warmed at 60 °C for 1.5 h with stirring. A solution of methyltriphenylphosphonium bromide (480 mg, 1.36 mmol) in DMSO (1.5 ml) was added to the above solution at 0 °C, and stirring was continued at the same temperature for 30 min and then at room temperature for 30 min. A solution of **19** (250 mg, 0.64 mmol) in THF (1.5 ml) was added to the above ylide solution, and the mixture was stirred for an additional 15 h. The reaction was quenched with aqueous NH_4Cl, and the product was extracted with ether. Concentration of the extract gave an oil, which was purified by TLC (4 : 1 hexane-ether) to give **20** (199 mg, 80%) and recovered **19** (20 mg). **20**: colorless needles; mp 79—81 °C (from hexane-ether). IR (KBr) 1650, 1600, 1120, 980, 870, 820 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.97 and 1.05 (3H, s each, $C(CH_3)_2$), 1.1—2.3 (12H, m), 2.30 (3H, s, $ArCH_3$), 2.6—2.9 (2H, m), 3.28 (3H, s, OCH_3), 3.40—3.43 (2H, m, CH_2-O), 3.77 (6H, s, $ArOCH_3$), 4.26 and 4.45 (1H, br d, J=3 Hz each, $=CH_2$), 6.27 (2H, s, ArH).

Found: C, 77.60; H, 9.89%. Calcd for $C_{25}H_{38}O_3$: C, 77.67; H, 9.91%.

5,5-Dimethyl-1α-(2-hydroxy-6-methoxy-4-methylbenzyl)-8aα-methoxymethyl-2-methylene-1,2,3,4,4aα,5,6,7,8,8a-decahydronaphthalene (21). A mixture of **20** (120 mg, 0.31 mmol), sodium ethanethiolate (250 mg, 2.97 mmol) and DMF (3 ml) was gently refluxed for 1.5 h. After cooling to room temperature, water was added and the solution was extracted with ether. Concentration of the extract gave a semisolid, which was purified by TLC (3 : 1 hexane-ether) to afford **21** (95 mg, 82%) and recovered **20** (5 mg). **21:** mp 145—146 °C (from ether). IR (KBr) 3300, 1650, 1620, 1595, 1110, 925, 880, 820 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.91 and 1.07 (3H, s each, $C(CH_3)_2$), 1.1—2.6 (14H, m), 2.27 (3H, s, $ArCH_3$), ca. 3.5 (2H, m, CH_2O), 3.50 and 3.60 (3H, s each, OCH_3 and $ArOCH_3$), 4.0 and 4.45 (1H, finely splitted s each, $=CH_2$), 6.15 and 6.35 (1H s each, ArH), 7.63 (1H, s, ArOH). MS (70 eV) m/z 372 (M^+).

11-Methoxy-12bα-methoxymethyl-4,4,6aα,9-tetramethyl-1,2,3,4,4aα,5,6,6a,12aβ,12b-decahydro-12*H*-benzo[*a*]xanthene (9) and 11-Methoxy-12bα-methoxymethyl-4,4,6aβ,9-tetramethyl-1,2,3,4,4aα,5,6,6a,12aα,12b-decahydro-12*H*-benzo[*a*]-xanthene (22). a) A solution of **21** (46 mg, 0.12 mmol) and *p*-toluenesulfonic acid (2 mg) in benzene (2 ml) was gently refluxed for 2 h. After cooling to room temperature, the mixture was diluted with benzene and washed successively with aqueous $NaHCO_3$, water and brine, and then dried. The oily residue obtained by concentration was purified by TLC (14 : 1 hexane-ether) to provide **9** (25 mg, 54%) as crystals, mp 111—112 °C (from hexane-ether). IR (KBr) 1615, 1585, 1130, 1105, 810 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.98 and 1.10 (3H, s each, $C(CH_3)_2$), 1.2—2.8 (14H, m), 1.28 (3H, s, O-CCH_3), 2.25 (3H, s, $ArCH_3$), 3.27 (5H, s, CH_2OCH_3), 3.78 (3H, s, $ArOCH_3$), 6.20 (2H, br s, ArH); ^1H NMR (C_6D_6) δ= 0.97 and 1.09 (3H, s each, $C(CH_3)_2$), 1.2—3.0 (14H, m), 1.39 (3H, s, O-CCH_3), 2.28 (3H, s, $ArCH_3$), 3.09 (3H, s, OCH_3), 3.24 (2H, s, CH_2O), 3.53 (3H, s, $ArOCH_3$), 6.24 and 6.72 (1H, s each, ArH). MS (70 eV) m/z 372 (M^+), and **22** (12 mg, 26%) as crystals, mp 175—176 °C (from ether). IR (KBr) 1615, 1590, 1115, 810 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.98 and 1.10 (3H, s each, $C(CH_3)_2$), 1.20 (3H, s, O-CCH_3), 1.27—2.8 (14H, m), 2.23 (3H, s, $ArCH_3$), 2.63 and 3.50 (1H, d, J=10 Hz each, CH_2O), 2.92 (3H, s, OCH_3), 3.77 (3H, s, $ArOCH_3$), 6.17 and 6.20 (1H, br s each, ArH). MS (70 eV) m/z 372 (M^+).

Found for **9:** C, 77.16; H, 10.04%. Found for **22:** C, 76.94; H, 9.50%. Calcd for $C_{24}H_{36}O_3$: C, 77.37; H, 9.74%.

b) A solution of **13** (172 mg, 0.46 mmol) and *p*-toluenesulfonic acid (5 mg) in benzene (4 ml) was gently refluxed for 2 h. Workup and subsequent purification of the oily residue obtained by the same procodure as described in a) gave **9** (86 mg, 51%) and **22** (28 mg, 16%).

Siccanochromene E Methyl Ether (26). A solution of 640 mg (1.80 mmol) of siccanin methyl ether (**28**)[9] in acetic anhydride (4 ml) was treated with a catalytic amount of boron trifluoride etherate at 0 °C. After stirring for 10 min, the mixture was poured into ice water and extracted with ether. The extract was successively washed with aqueous $NaHCO_3$, water, and brine, and then dried. Concentration left a semisolid, which was chromatographed over 15 g of silica gel (1 : 4 ether-hexane) to provide **27** (135 mg, 19%), mp 137—138 °C (from hexane-ether). IR (KBr) 1735, 1625, 1610, 1580, 1240, 1140, 1050, 830 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.90 and 1.03 (3H, s, $C(CH_3)_2$), 1.35 (3H, s, O-CCH_3), 1.9—2.2 (11H, m), 2.02 (3H, s, CH_3C=O), 2.28 (3H, s, $ArCH_3$), 3.81 (3H, s, OCH_3), 3.87 and 4.10 (1H, d, J=10 Hz each, CH_2O), 6.24 and 6.28 (2H in total, s each, ArH), 6.62 (1H, s, =CH), and **24** (646 mg, 80%) as colorless needels, mp 208—209 °C (from ether). IR (KBr) 1735, 1620, 1600, 1500, 1250, 1120, 1050, 820 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.90 and 1.20 (3H, s each, $C(CH_3)_2$), 1.32 (3H, s, O-CCH_3), 1.0—1.9 (12H, m), 1.98 and 2.07 (6H in total, s each, CH_3C=O), 2.26 (3H, s, $ArCH_3$), 3.75 (3H, s, OCH_3), 4.57 (2H, s, CH_2O), 6.00 (1H, s, ArCH-O), 6.22 and 6.29 (2H in total, s each, ArH).

Found for **27**: C, 75.60; H, 8.69%. Calcd for $C_{25}H_{34}O_4$: C, 75.34; H, 8.60%. Found for **24:** C, 70.40; H, 8.53%. Calcd for $C_{27}H_{38}O_6$: C, 70.71; H, 8.35%.

A mixture of **27** (282 mg, 0.71 mmol) and lithium aluminium hydride (54 mg) in THF (4 ml) was stirred at room temperature for 10 h, and the reaction was quenched with wet ether. Precipitates were filtered and washed with ether. Concentration of the combined filtrates left a semisolid, which was filtered through a short silica-gel column with the aid of ether-hexane (1 : 1) to afford **26** (247 mg, 98%) as colorless needles. The IR and ^1H NMR spectra of the product was identical with those of an authentic sample.

12bα-Hydroxymethyl-11-methoxy-4,4,6aα,9-tetramethyl-1,2,3,4,4aα,5,6,6a,12aα,12b-decahydro-12*H*-benzo[*a*]xanthene (29) and 12bα-Hydroxymethyl-11-methoxy-4,4,6aα,9-tetramethyl-1,2,3,4,4aα,5,6,6a,12aβ,12b-decahydro-12*H*-benzo[*a*]-xanthene (33). A mixture of **26** (85 mg, 0.24 mmol), Pd-$SrCO_3$ (20 mg) and ethanol (5 ml) was stirred at room temperature for 20 h under hydrogen. The catalyst was filtered and washed with a small amount of ethanol, and the combined filtrates were concentrated under reduced pressure to give an oil. The oil was purified by TLC (1 : 1 ether-hexane) to provide **29** (R_f 0.57, 64 mg, 75%), **33** (R_f 0.5, 15 mg, 18%), and unchanged **26** (R_f 0.43, 5 mg). **29** (viscous oil): IR (neat) 3400, 1620, 1590, 1110, 1030, 810 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.0 and 1.22 (9H in total, s each, $C(CH_3)_2$ and

O-CCH$_3$), 1.1—2.1 (13H, m), 2.31 (3H, s, ArCH$_3$), 2.73 (2H, d, J=7 Hz, CH$_2$Ar), 3.83 (3H, s, ArOCH$_3$), 3.67 and 4.10 (1H, d, J=10 Hz each, CH$_2$O), 6.20 and 6.25 (2H in total, s each, ArH). MS (70 eV) m/z 358 (M$^+$). **33** (colorless crystals): mp 155—156 °C (from hexane-ether). IR (KBr) 3500, 1620, 1590, 1120, 1100, 810 cm^{-1}. ^{1}H NMR (CDCl$_3$) δ=1.04, 1.12, and 1.30 (9H in total, s each, C(CH$_3$)$_2$ and O-CCH$_3$), 1.0—2.9 (15H, m), 2.25 (3H, s, ArCH$_3$), 3.52 and 3.72 (1H, d, J=10 Hz each, CH$_2$O), 3.83 (3H, s, ArOCH$_3$), 6.25 and 6.29 (2H in total, s each, ArH). MS (70 eV) m/z 358 (M$^+$).

11-Methoxy-12bα-methoxymethyl-4,4,6aα,9-tetramethyl-1,2,3,4,4aα,5,6,6a,12aα,12b-decahydro-12*H*-benzo[*a*]xanthene (30). a) To a stirred mixture of 50% sodium hydride in mineral oil (14 mg, 0.3 mmol) and DME (0.5 ml) was added a solution of **29** (57 mg, 0.16 mmol) in DME (0.5 ml) at room temperature. After stirring for 20 min, a solution of methyl iodide (50 mg, 0.35 mmol) in DME (0.5 ml) was added and stirring was continued for an additional 10 h. Ether was added, and the oily residue obtained by workup the solution was purified by TLC (2 : 1 hexane-ether) to give **30** (45 mg, 77%) as colorless crystals; mp 157—158 °C (from hexane-ether). IR (KBr) 1620, 1590, 1115, 820 cm^{-1}. ^{1}H NMR (CDCl$_3$) δ=0.90 and 1.12 (3H, s each, C(CH$_3$)$_2$), 1,18 (3H, s, O-CCH$_3$), 1.1—2.1 (12H, m), 2.27 (3H, s, ArCH$_3$), 2.68 (2H, d, J=6 Hz, CH$_2$Ar), 3.30 and 3.72 (1H, d, J=10.5 Hz each, CH$_2$O), 3.29 (3H, s, OCH$_3$), 3.80 (3H, s, ArOCH$_3$), 6.2 and 6.24 (2H in total, s each, ArH); MS (70 eV) m/z 372 (M$^+$).

Found: C, 77.64; H, 9.62%. Calcd for $C_{24}H_{36}O_3$: C, 77.37; H, 9.74%.

b) To a stirred mixture of 50% sodium hydride in mineral oil (30 mg, 0.6 mmol) and DME (1 ml) was added a solution of **31**[9] (69 mg, 0.2 mmol) in DME (0.5 ml), and stirring was continued for 30 min at room temperature. A solution of methyl iodide (92 mg, 0.64 mmol) in DME (0.5 ml) was added, and the mixture was stirred for an additional 10 h. Workup and subsequent purification by the same procedure as described in a) gave **30** (59 mg, 80%).

Conversion of 33 to 9. A mixture of **33** (35 mg, 0.09 mmol), 50% sodium hydride in mineral oil (10 mg, 0.18 mmol), methyl iodide (29 mg, 0.18 mmol) and DME (1.5 ml) was stirred at room temperature for 12 h. Purification of the resulting oily residue, obtained by workup, by TLC (5 : 1 hexane-ether) gave crystals (31 mg, 86%), whose IR and ^{1}H NMR were identical with those of authentic **9** derived by acid-catalyzed cyclization of **13** or **21**.

Chromium Trioxide Oxidation of 30. To a stirred solution of **30** (25 mg, 67.1 mol) in acetic acid (0.4 ml) was added a 25% chromium trioxide solution in 80% aqueous acetic acid (92 µl) at 0 °C, and the mixture was stired at 0 °C for 15 h. After dilution with brine, the product was extracted with ether, and the extract was washed successively with aqueous NaHCO$_3$, water and brine, and dried. The oily residue obtained by evaporation was purified by TLC (10 : 1 hexane-ether) to afford, along with unreacted **30** (4 mg), **36** (10 mg, 40%) as pale yellow needles; mp 159—160 °C (from hexane-ether). IR (KBr) 1672, 1650, 1634, 1612, 1120, 980 cm^{-1}. ^{1}H NMR (CDCl$_3$) δ=1.00 and 1.08 (6H in total, s each, C(CH$_3$)$_2$), 1.2—2.3 (14H, m), 1.27 (3H, s, O-CCH$_3$), 2.03 (3H, d, J=1.4 Hz, CH=C-C<u>H</u>$_3$), 3.05 (3H, s, OCH$_3$), 3.1—3.3 (2H, m, OCH$_2$), 6.47 (1H, q, J=1.4 Hz, =CH). UV (EtOH) 262 (ε 11,400), 405 (ε 760) nm. MS (70 eV) m/z 372 (M$^+$).

11-Acetoxy-12bα-methoxymethyl-4,4,6aα,9-tetramethyl-1,2,3,4,4aα,5,6,6a,12aβ,12b-decahydro-12*H*-benzo[*a*]xanthene (34). A solution of **9** (39 mg, 0.10 mmol), sodium ethanethiolate (66 mg, 0.78 mmol) and DMF (2 ml) was gently refluxed for 6 h. After cooling to room temperature, water was added and the product was extracted with benzene. The oily residue obtained by concentration was purified by TLC (7 : 1 hexane-ether) to give **35** (31 mg, 83%) as a colorless oil. IR (neat) 3350, 1623, 1590, 1100, 1050, 820 cm^{-1}. ^{1}H NMR (CDCl$_3$) δ=0.97 and 1.10 (6H in total, s each, C(CH$_3$)$_2$), 1.27 (3H, s, O-CCH$_3$), 1.3—2.9 (14H, m), 2.18 (3H, s, ArCH$_3$), 3.28 (3H, s, OCH$_3$), 3.31 (2H, s, CH$_2$O), 4.98 (1H, s, OH), 6.17 and 6.20 (2H in total, br s each, ArH).

A solution of **35** (30 mg, 0.08 mmol), acetic anhydride (0.5 ml) and pyridine (0.5 ml) was stirred at room temperature for 5 h. The mixture was poured into ice water and extracted with ether. A semisolid obtained by concentration was purified by TLC to give **34** (24 mg, 72%) as colorless crystals; mp 160—162 °C (from hexane-ether). IR (KBr) 1760, 1625, 1585, 1205, 1100, 1050 cm^{-1}. ^{1}H NMR (CDCl$_3$) δ=0.97 and 1.08 (3H, s each, C(CH$_3$)$_2$), 1.27 (3H, s, O-CCH$_3$), 1.3—2.8 (14H, m), 2.23 and 2.28 (3H, s each, ArCH$_3$ and CH$_3$C=O), 3.29 (5H, m, CH$_2$OCH$_3$), 6.43 and 6.50 (2H in total, br s each, ArH).

Found: C, 74.81; H, 9.15%. Calcd for $C_{25}H_{36}O_4$: C, 74.96; H, 9.09%.

Attempted Oxidation of 34 with Chromium Trioxide. a) To a solution of **34** (24 mg, 0.06 mmol) in acetic acid (1 ml) was added a 25% chromium trioxide solution in 80% aqueous acetic acid (82 µl) at 0 °C, and the mixture was stirred at 0 °C for 20 h. After dilution with brine, the product was extracted with ether, and the extract was washed successively with aqueous NaHCO$_3$, water and brine, and dried. The oily residue obtained by concentration was purified by TLC (10 : 1 hexane-ether) to provide unchanged **34** (18 mg).

b) A 25% chromium trioxide solution in 80% aqueous acetic acid (90 µl) was added to a solution of **34** (25 mg, 0.06 mmol) in acetic acid (1 ml), and the mixture was stirred at room temperature for 20 h. Workup followed by purification in a similar manner provided unchanged **34** (4 mg) and unidentified polar oily products.

11-Acetoxy-12bα-methoxymethyl-4,4,6aα,9-tetramethyl-1,2,3,4,4aα,5,6,12aα,12b-decahydro-12*H*-benzo[*a*]xanthene (37). A mixture of **30** (116 mg, 0.31 mmol), sodium ethanethiolate (235 mg, 2.8 mmol) and DMF (3 ml) was heated at 110 °C for 7 h. After cooling to room temperature, water was added and the resulting solution was extracted with ether. Evaporation followed by purification of the oily residue by TLC (2 : 1 hexane-ether) provided phenol **32** (97 mg, 87%) as an amorphous powder. IR (KBr) 3500, 1630, 1595, 1110, 1080, 1060 cm^{-1}. ^{1}H NMR (CDCl$_3$) δ=0.90, 1.10 and 1.15 (3H, s each, C(CH$_3$)$_2$ and O-CCH$_3$), 1.1—2.0 (m, 12H), 2.20 (3H, s, ArCH$_3$), 2.68 (2H, d, J=6 Hz, CH$_2$Ar), 3.32 (3H, s, OCH$_3$), 3.35 and 3.70 (1H, d, J=10.0 Hz each, CH$_2$O), 5.0 (1H, s, OH), 6.15 and 6.20 (1H, s each, ArH).

A solution of **32** (66 mg, 0.18 mmol), acetic anhydride (0.5 ml), and pyridine (0.5 ml) was stirred at room temperatutre for 15 h. The mixture was poured into water and extracted with ether. Concentration of the extract afforded an oil, which was purified by TLC (2 : 1 hexane-ether) to give **37** (70 mg, 96%) as an amorphous powder. IR (KBr) 1760, 1630,

1580 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.90, 1.10 and 1.18 (3H, s each, $C(CH_3)_2$ and $O\text{-}CCH_3$), 1.0—2.2 (m, 12H), 2.25 (3H, s, $ArCH_3$), 2.32 (3H, s, $CH_3C{=}O$), 2.60 (2H, d, J=3.6 Hz, CH_2Ar), 3.18 and 3.68 (1H, d, J=10.0 Hz each, CH_2O), 3.30 (3H, s, OCH_3), 6.38 and 6.47 (1H, s each, ArH).

Found; C, 74.70; H, 9.03%. Calcd for $C_{25}H_{36}O_4$: C, 74.96; H, 9.06%.

Oxidation of 37. A 25% chromium trioxide solution in 80% aqueous acetic acid (0.3 ml) was added to a solution of **37** (88 mg, 0.23 mmol) in acetic acid (1 ml), and the mixture was stirred at 0 °C for 15 h. After dilution with water, the product was extracted with ether, and the combined extracts were washed successively with aqueous $NaHCO_3$, water, and brine, and dried. Removal of the solvent left an oil, which was purified by TLC (1 : 1 hexane-ether) to give **38** (19 mg, 23%) as a viscous oil. IR (neat) 1765, 1675, 1620, 1560 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.92, 1.13, and 1.22 (3H, s each, $C(CH_3)_2$ and $O\text{-}CCH_3$), 1.0—2.1 (m, 11H), 2.30 (3H, s, $ArCH_3$), 2.39 (3H, s, $CH_3C{=}O$), 2.54 (1H, s, $CHC{=}O$), 3.22 and 3.63 (1H, d, J=10.0 Hz each, CH_2O), 3.35 (3H, s, OCH_3), 6.40 and 6.61 (1H, s each, ArH). MS (70 eV) m/z 414 (M^+).

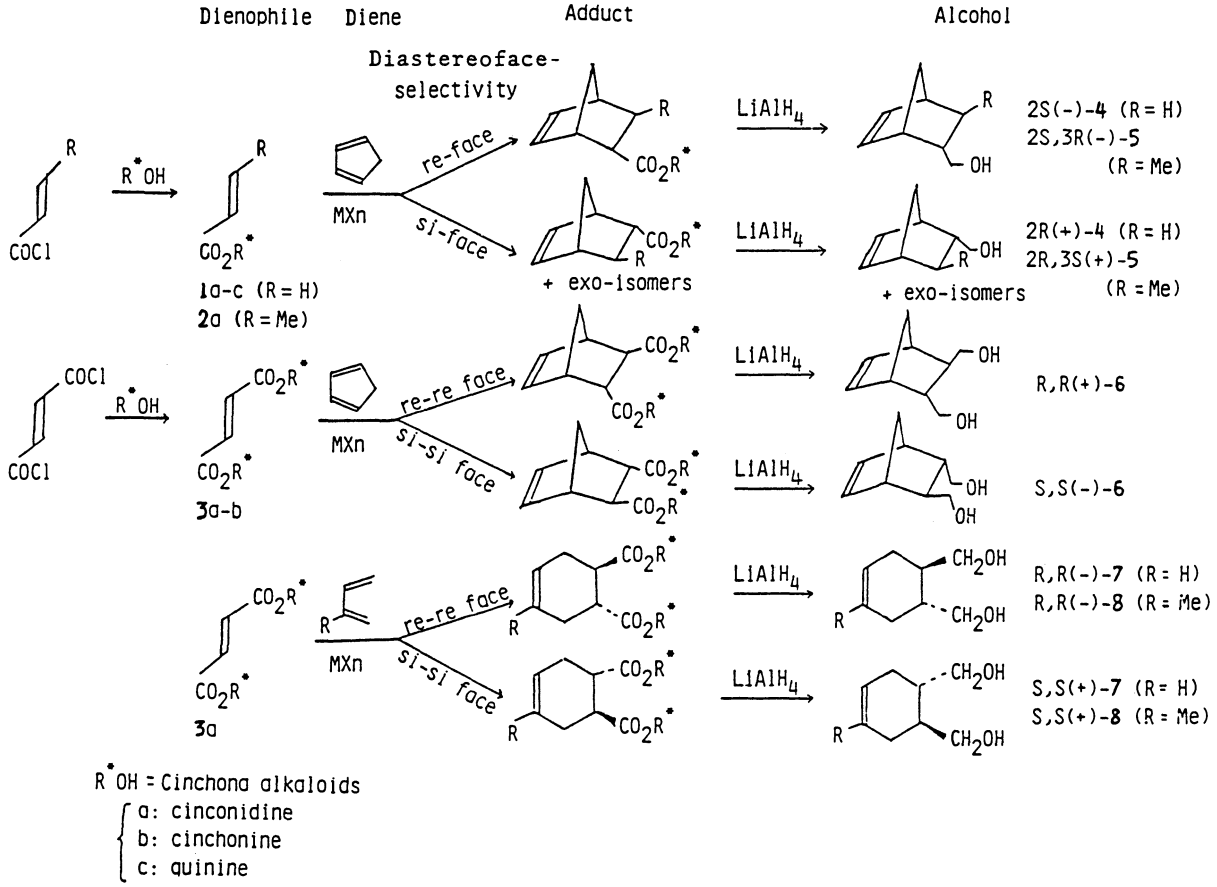
Acrylates, crotonate, and fumarates derived from cinchona alkaloids were easily prepared. The highly *re*-facial selective additions of the dienophiles derived from cinchonidine or quinine to some dienes were achieved in the presence of $SnCl_4$. Similarly, *si*-facial selective additions were also achieved by the use of cinchonine instead of cinchonidine or quinine as a chiral auxiliary alcohol with equal ease. The inverse diastereofacial selectivity was observed by the use of $TiCl_4$ instead of $SnCl_4$ as a Lewis acid in the case of the reaction of the acrylates cited above with cyclopentadiene. It was suggested by the infrared spectra of the dienophile-$SnCl_4$ complexes and by some circumstantial evidence that in the complexes, $SnCl_4$ coordinates with the oxygen atom of the C-O bond (not C=O bond) and probably also with the nitrogen atom of the quinuclidine framework to form a rigid five-membered ring structure.

The Diels-Alder reactions have been of considerable interest in organic syntheses. Recently, extensive efforts have been made concerning the asymmetric Diels-Alder reaction; cycloadducts with high stereoselectivity have been obtained by a variety of reactions.[1,2] Many kinds of auxiliary groups have been used.

Unfortunately, though, because of the limited availability of the auxiliary, only one of enantiomers of an auxiliary or one of the alternative topological counterparts has often been used as a chiral auxiliary, and only products enriched in one enantiomer have been synthesized. We aimed at the use of chiral auxiliary alcohols which 1) are readily available in both antipodal forms, 2) give their crystalline dienophiles, and 3) are removed easily from the final products without chromatography.

Thus, we made use of cinchona alkaloids as an auxiliary alcohol which seem to have the following merits: a) Several diastereomers are commercially available



Scheme 1.

in optically pure forms and can be directly treated with acids or acid chlorides to give the corresponding esters as dienophiles. b) The rigid structure containing the quinuclidine framework is capable of forming stable complexes with a suitable Lewis acid. In this paper we describe the highly diastereofacial selective Diels-Alder reactions of the dienophiles derived from cinchona alkaloids with some dienes.

Results and Discussion

The acrylic, crotonic, and fumarylic esters of cinchona alkaloids were prepared as dienophiles in high yields by reactions of the corresponding acid chlorides with cinchona alkaloids in THF followed by treatment with Et_3N in $CHCl_3$. The Diels-Alder reaction of the dienophiles with various dienes is shown in the Scheme 1 and Tables 1, 2. The reaction of cinchonidine acrylate (**1a**) with cyclopentadiene followed by a reduction of the adduct with $LiAlH_4$ (Table 1) was undertaken so as to determine the effects of the characteristics of the Lewis acid, solvents, and cinchona alkaloids used as auxiliary alcohol, as well as the reaction temperature on the chemical yield and the diastereofacial selectivity.

Lewis Acid. The extent and direction of the diastereoface-selection and the rate in the reaction of **1a** with cyclopentadiene varied greatly with the nature and quantity of the Lewis acid used. A low chemical yield and low diastereofacial selectivity were observed for a reaction using $BF_3 \cdot Et_2O$, $AlCl_3$, and $ZrCl_4$ as the Lewis acid, and upon a thermal reaction at −20 °C (entries 2 and 4—6). The use of $SnCl_4$ (entry 3) was found to greatly increase not only the chemical yield but also the diastereofacial selectivity, giving 2*S*(−)-2-hydroxymethyl bicyclo[2.2.1]hept-5-ene (**4**) with 93% *re*-facial selection of **1a** after a reduction of the adduct with $LiAlH_4$. The use of $TiCl_4$ or $BF_3 \cdot Et_2O$ (entries 6 and 7) instead of $SnCl_4$ caused a decrease in the endo as well as the diastereofacial selectivity to give **4**, which is unexpectedly enriched in the 2*R*(+)-enantiomer with *si*-facial selection, in low chemical yield. A reversal in the diastereoface-selection of dienophile by the different Lewis acids used is very unique in an asymmetric Diels-Alder reaction, and only one has been reported (T. Poll et al.[8] in 1984). A similar reversal was further observed in reactions using cinchonine acrylate (**1b**) and quinine acrylate (**1c**) as dienophiles (entries 18, 19, 21, and 22). The quantiy of $SnCl_4$ was found to strongly affect the diastereofacial selectivity. Generally, the selectivity was enhanced by increasing the mole equivalent of $SnCl_4$ toward **1a**; the highest value,

a) **3a**: cinchonidine fumarate; **3b**: cinchonine fumarate. b) GLC yields. c) HPLC analysis of the corresponding chiral Pirkle's carbamates.[3] d) Assigned by means of chiroptic measurements of alcohols (2,3-bis(hydroxymethyl)bicyclo[2.2.1]hept-5-ene (**6**)[6] for Entries 26—31, 1,2-bis(hydroxymethyl)-4-cyclohexene (**7**)[7] for Entries 32 and 33, and 1,2-bis(hydroxymethyl)-4-methyl-4-cyclohexene (**8**)[7] for Entries 34—36).

up to 93%, was recorded by carring out the reaction in the presence of 1.5 mol equiv of $SnCl_4$ (entry 3). On the other hand, in a reaction of cyclopentadiene with cinchonidine fumarate (**3a**), containing two pieces of the cinchonidine group, the highest value, up to 95% (entry 29 in Table 2), was recorded by carring out the reaction in the presence of 3 mol equiv of $SnCl_4$ toward **3a**. Thus, the use of 1.5 mol equiv mol of $SnCl_4$ toward per cinchona alkaloid group was found to be most efficient regarding asymmetric Diels-Alder reactions of the dienophile derived from cinchona alkaloids with diene.

Reaction Temperature. No evident temperature dependency in $SnCl_4$-promoted reactions (Tables 1 and 2), excluding the reaction of cinchonidine fumarate (**3a**) with cyclopentadiene, was observed between 0 and −45 °C, mainly because of its heterogeneity in the reaction media.

Solvent Effect. As can be seen in entries 14—16, increasing the density of π-electrons in the aromatic solvents (chlorobenzene, toluene, and xylene) caused a stepwise decrease, mainly in the chemical yield. This decrease may be attributable to the increased donating ability of these solvents to the acryloyl group in cinchonidine acrylate (**1a**) coordinated by $SnCl_4$.[9]

Cinchona Alkaloids as Chiral Auxiliary and the Diastereofacial Selectivities of Their Dienophiles. Three commercially available cinchona alkaloids (cinchonidine, cinchonine, and quinine) were selected as auxiliary alcohols. The dienophiles, **1a** and **1c**, derived from cinchonidine and quinine, respectively, containing the same configuration (8α ,9*R*), gave 2*S*(−)-**4** with a high *re*-facial selection upon reacting with cyclopentadiene in the presence of $SnCl_4$, followed by a reduction with $LiAlH_4$.

As expected, **1b** (antipode of **1a**) derived from cinchonine (8α, 9*S*) gave 2*R*(+)-**4** with a *si*-facial selection

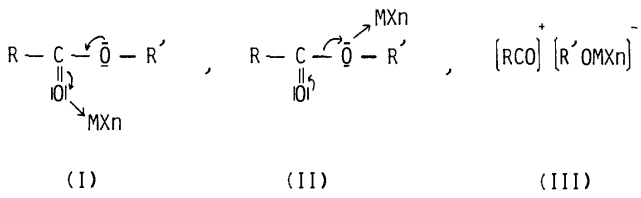

Fig. 1. Ester-Lewis acid complexes.

with equal ease (entry 18). Similarly, a highly *re-re* facial selective addition was achieved upon the reaction of cinchonidine fumarate (**3a**) with cyclopentadiene in the presence of $SnCl_4$ to yield 2*R*,3*R*(+)-2,3-bis(hydroxymethyl)bicyclo[2.2.1]hept-5-ene (**6**) followed by a reduction with $LiAlH_4$ (entry 29 in Table 2). A *si-si* facial selective addition was also achieved by the use of cinchonine fumarate (**3b**) instead of **3a** as a dienophile (entry 30 in Table 2). In the other reactions (entries 23—25 in Table 1 and 32—36 in Table 2), it was further confirmed that when cinchonidine was used as a chiral auxiliary alcohol, a high *re* (or *re-re*)-facial selection of the dienophiles used could be achieved in reactions with various dienes in the presence of $SnCl_4$.

Therefore, both diastereoface-differential Diels-Alder reactions were achieved by the use of the dienophiles derived from (8α, 9*R*) and (8α, 9*S*)-cinchona alkaloids in the presence of $SnCl_4$.

Structure of the Dienophile-$SnCl_4$ Complexes. Regarding the structures and infrared spectra of the ester-Lewis acid complexes, three structures (**I—III**) shown in Fig. 1 have been considered.[10]

A lengthening of the C=O bond (shift of the $\nu_{C=O}$ band to lower frequency), and a shortening of the C(O)-O bond (shift of the $\nu_{C(O)-O}$ band to higher frequency) are anticipated by a coordination of the Lewis acid with acyl-oxygen (structure **I**),[10] which has been

found in most cases of the ester-Lewis acid complexes.

On the other hand, the reverse is anticipated by a coordination with the alkyl-oxygen (structure **II**), which has been postulated in various reports.[11-13] However, it is apparently unprecedented in an identified form, with the exception of some cases that are somewhat different from structure **II** (i.e., the intramolecular hydrogen bonding to alkyl-oxygen in certain steroid hydroxy-esters,[14] the infrared spectra of which shows the $\nu_{C=O}$ band raised by 8—13 cm^{-1} and the $\nu_{C(O)-O}$ band lowered by 10—14 cm^{-1}, compared with the bands in esters with no hydrogen bonding to the alkyl-oxygen, were reported; also, the coordination of Cu with the nitrogen atom of amide in *N,N*-di(2-pyridylmethyl)amide-Cu(II) complexes,[15] the infrared spectrum of which shows the $\nu_{C=O}$ band raised by 26 cm^{-1} compared with that in free amide, was reported).

The acylinium ion in structure **III** would require the presence of the $\nu_{C\equiv O}$ band near 2190 cm^{-1}, which was observed in $[MeCO]^+[BF_4]^-$.[16]

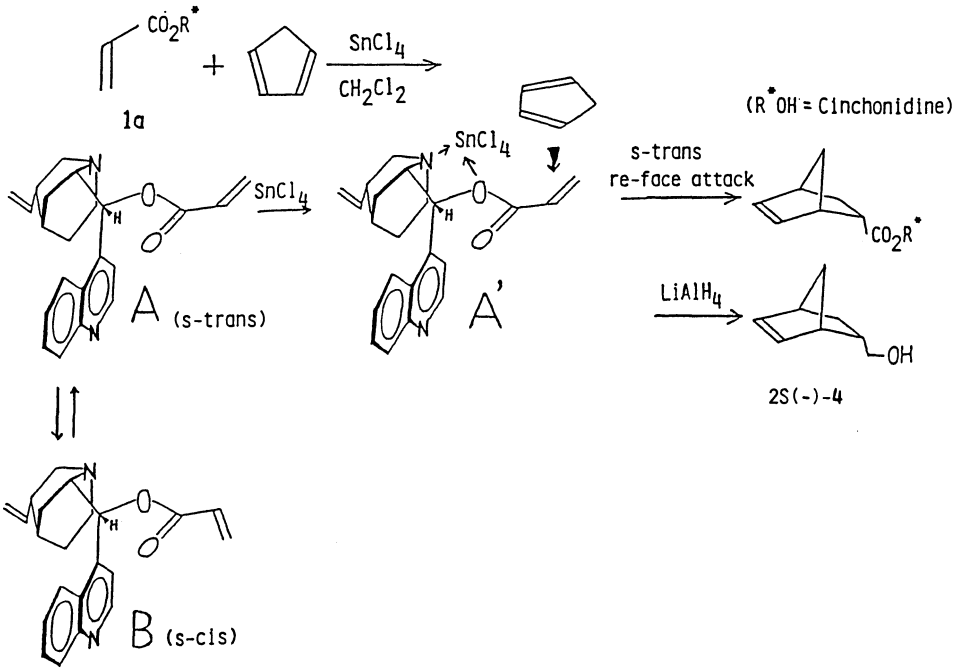
Now, the addition of $SnCl_4$ to **1a** in CH_2Cl_2 gave insoluble solids, the **1a**-$SnCl_4$ complex; the infrared spectrum (Nujol mulls) showed the $\nu_{C=O}$ band at 1738 cm^{-1}, raised by 20 cm^{-1}, and the $\nu_{C(O)-O}$ band at 1155 cm^{-1}, lowered by 25 cm^{-1}, compared with the bands in **1a**. The direction and extent of the shifts of these bands caused by adding $SnCl_4$ to **1a** agreed with that in the reports[14,15] cited regarding structure **II** (mentioned above), suggesting that $SnCl_4$ coordinates with the oxygen atom of the C-O bond (not C=O bond) in the **1a**-$SnCl_4$ complex.

On the other hand, the addition of $SnCl_4$ to a simple acrylate, methyl acrylate, in CH_2Cl_2 gave a homogeneous solution; the infrared spectrum showed the $\nu_{C=O}$ band at 1658 cm^{-1}, lowered by 67 cm^{-1}, and the $\nu_{C(O)-O}$ band at 1340 cm^{-1}, raised by 135 cm^{-1}, compared with the bands in free methyl acrylate, showing that $SnCl_4$ coordinates with the carbonyl-oxygen in the methyl acrylate-$SnCl_4$ complex.

The difference of the **1a**-$SnCl_4$ complex from the methyl acrylate-$SnCl_4$ complex in the infrared spectrum mentioned above may be caused by the presence of a quinuclidine framework in **1a**, suggesting that $SnCl_4$ coordinates not only with the oxygen atom in the C-O bond, but also with the nitrogen atom of the framework in the **1a**-$SnCl_4$ complex to form a rigid five-membered ring.

Assuming that $SnCl_4$ ordinarily coordinates with the carbonyl-oxygen and also with nitrogen atom, it is anticipated that a seven-membered ring structure is formed, resulting in the synthesis of **4** rich in the 2*R*(+)-enantiomer with a *si*-facial selection upon the reaction of **1a** with cyclopentadiene in the presence of $SnCl_4$ followed by reduction with $LiAlH_4$. However, our result (entry 3) showed a synthesis of 2*S*(−)-enantiomer with *re*-facial selection. Therefore, the coordination of $SnCl_4$ with the carbonyl-oxygen in the **1a**-$SnCl_4$ complex could be contradicted by the configuration of product **4**, and also the absence of the $\nu_{C=O}$ band near 1658 cm^{-1}, which was observed in the methyl acrylate-$SnCl_4$ complex mentioned above.

Similarly, the coordination of $SnCl_4$ with only the nitrogen atom in the **1a**-$SnCl_4$ complex could also be contradicted by the fact that $SnCl_4$ significantly promotes the rate in the reaction of **1a** with cyclopentadiene (entries 2 and 3), suggesting that $SnCl_4$ coordinates with the cabonyl-oxygen or the oxygen atom of the C-O bond.



Scheme 2.

Therefore, according to the infrared spectrum of the **1a**-$SnCl_4$ complex and the circumstantial evidence described above, it was suggested that $SnCl_4$ in the complex probably coordinates with the nitrogen atom of the quinuclidine framework and also with the oxygen atom, which is situated at the δ-position, counted from the nitrogen atom of the framework, of the C-O bond (not C=O bond), to form a rigid five-membered ring structure.

Reaction Models. For the purpose of illustrating the $SnCl_4$-promoted high diastereofacial selectivity descrived above, we referred to several models regarding the reaction of **1a** or **3a** with cyclopentadiene in the presence of $SnCl_4$.

Concerning the structures of the esters in solution or in solids, it has been widely accepted as a result of a spectral study[17] that the ester exists in solution as an equilibrium mixture of s-trans and s-cis conformations, in which the former is thermodynamically more stable, and by an X-ray analysis[18] that the ester exists in solids as s-trans conformation.

Now, cinchonidine acrylate (**1a**) dissolves in CH_2Cl_2 and seems to exists as an equilibrium mixture of the s-trans conformation **A** and the s-cis conformation **B** in Scheme 2, where the former is more stable (as mentioned above). Therefore, cyclopentadiene attacks **1a** more from the less-hindered *re*-face of conformation **A** than from the less-hindered *si*-face of conformation **B**, to yield **4** enriched in 2*S*(−)-enantiomer in the thermal reaction (entry 1), followed by reduction with $LiAlH_4$.

On the other hand, the addition of $SnCl_4$ to **1a** in CH_2Cl_2 gave solids that were insoluble in CH_2Cl_2. In solids composed of the **1a**-$SnCl_4$ complex, **1a** exists mainly as a s-trans conformation (as mentioned above) to yield conformation **A′**.

Therefore, cyclopentadiene selectively attacks **1a** in the presence of $SnCl_4$ from the less-hindered *re*-face of conformation **A′** to yield 2*S*(−)-**4** with a high diastereofacial selectivity, followed by a reduction with $LiAlH_4$.

Similarly, cyclopentadiene attacks cinchonidine fumarate (**3a**), in which two pieces of the cinchonidine group cover the *si-si* face by a cooperative blocking effect,[19] selectively from the less-hindered *re-re* face of conformation **C**, according to Scheme 3, to yield *R,R*(+)-**6** followed by a reduction with $LiAlH_4$.

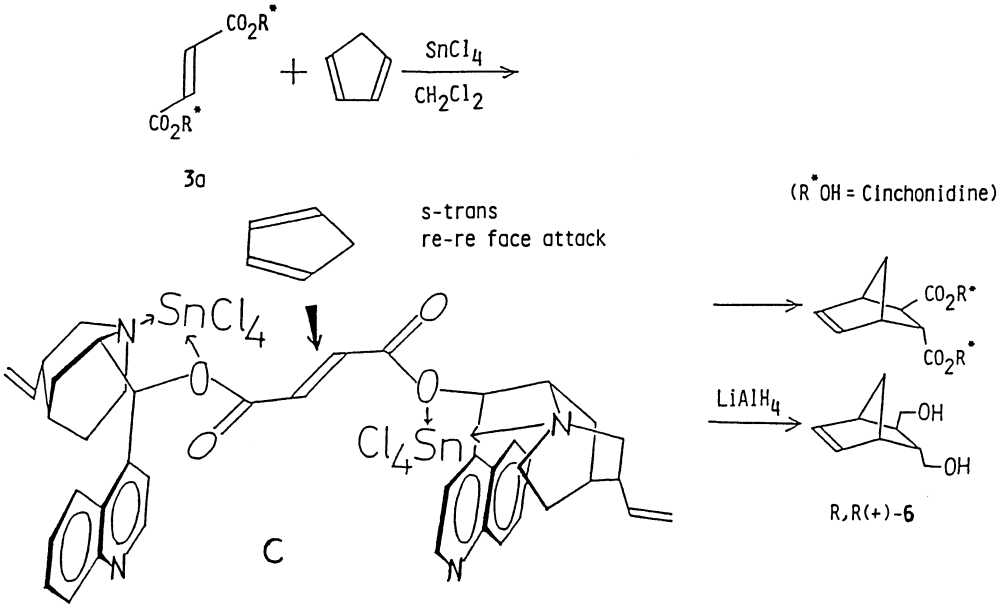
Experimental

General. The preparation of dienophiles, the Diels-Alder reaction and reduction of the adduct with $LiAlH_4$ were carried out under an atmosphere of argon.

Materials. Solvents and dienes were dried in the usual manner and distilled just before use. $SnCl_4$, $TiCl_4$, $BF_3 \cdot Et_2O$, acryloyl chloride, crotonyl chloride, and fumaroyl dichloride were also distilled under argon just before use. $AlCl_3$ and $ZrCl_4$ were purified by sublimation. Chiral 1-(1-naphthyl)ethyl isocyanate was obtained from the Aldrich Chemical Company and used without further purification.

Measurements. The melting point (uncorrected) were determined in a sealed tube with a Yamato melting-point apparatus. The IR spectra and the optical rotations were recorded with a Hitachi infrared spectrophotometer (EPI-G3) and a Union 101 polarimeter, respectively. The gas chromatographs were recorded with a Shimadzu gas chromatograph (GC-8A) using a column packed with 10% PEG-20M on Chromosorb W AW. The high-performance liquid chromatography (HPLC) was recorded with a Kyowa Seimitsu liquid chromatograph (column packed with SiO_2; eluents: hexane-ethyl acetate for entries 1—25 in Table 1 or hexane-ethanol for entries 26—36 in Table 2).

Dienophiles. Preparation of Cinchonidine Acrylate (1a) as a Typical Procedure. To a stirred solution of cinchonidine (25 g, 85 mmol) in THF (600 ml) was slowly added a solution of acryloyl chloride (5.8 ml, 71 mmol) in THF (50



Scheme 3.

ml) at 0 °C in the dark. The mixture was stirred for 24 h at 0 °C—r.t. in a dark room. After concentration under reduced pressure and a subsequent addition of $CHCl_3$ (50 ml) to the residual mass, Et_3N (19.8 ml, 142 mmol) was added dropwise under stirring at 0 °C. Stirring was continued for 2 h at r.t. and then acetone (500 ml) was added to the mixture. After cooling in a refrigerator overnight, precipitates composed of Et_3NHCl and excess cinchonidine were filtered off. The filtrate was evaporated and the pale-yellow residual mass was twice recrystallized from hexane-isopropyl alcohol to give white crystals **1a**; yield: 20 g (80%); mp 113—114 °C; $[\alpha]_D^{25}$ +10.5° (*c* 1.5, $CHCl_3$); IR(Nujol mulls); 1718 ($\nu_{C=O}$) and 1180 cm^{-1} ($\nu_{C(O)-O}$); Found: C, 75.64; H, 7.11; N, 7.98%. Calcd for $C_{22}H_{24}N_2O_2$: C, 75.86; H, 6.90; N, 8.05%. The other dienophiles: cinchonidine crotonate (**2a**); yield: 82%; mp 152—153 °C; $[\alpha]_D^{25}$ +38.0 (*c* 1.5, $CHCl_3$; IR(Nujol mulls) 1720 ($\nu_{C=O}$) and 1177 cm^{-1} ($\nu_{C(O)-O}$); Found: C, 75.91; H, 7.41; N, 7.53%. Calcd for $C_{23}H_{26}N_2O_2$: C, 76.21; H, 7.23; N, 7.73%. Cinchonidine fumarate (**3a**); yield: 78%; mp 221—223 °C; $[\alpha]_D^{25}$ +81.2° (*c* 1.5, $CHCl_3$); IR (Nujol mulls) 1718 ($\nu_{C=O}$) and 1167 cm^{-1} ($\nu_{C(O)-O}$); Found: C, 75.50; H, 6.70; N, 8.43%. Calcd for $C_{42}H_{44}N_4O_4$: C, 75.42; H, 6.63; N, 8.38%. Cinchonine fumarate (**3b**); yield: 86%; mp 104—107 °C; $[\alpha]_D^{25}$ +40.5° (*c* 1.5, $CHCl_3$); IR (Nujol mulls) 1720 ($\nu_{C=O}$) and 1164 cm^{-1} ($\nu_{C(O)-O}$); Found: C, 75.25; H, 7.10; N, 7.90%. Calcd for $C_{42}H_{44}N_4O_4$: C, 75.42; H, 6.63; N, 8.38%. Cinchonine acrylate[20] (**1b**); mp 63—64 °C; $[\alpha]_D^{25}$ +81.6° (*c* 1.5, $CHCl_3$), which was reported to be an oily material, $[\alpha]_D^{20}$ +80° (*c* 2, $CHCl_3$), and quinine acrylate[21] (**1c**) were also prepared by a similar procedure.

Asymmetric Diels-Alder Reaction. $SnCl_4$-Promoted Addition of 1a to Cyclopentadiene (Entry 3) as a Typical Procedure. To a stirred solution of **1a** (1.04 g, 3 mmol) in CH_2Cl_2 (18 ml) was added cyclopentadiene (1.2 ml, 15 mmol) at −70 °C. Subsequently, a solution of $SnCl_4$ (0.52 ml, 4.5 mmol) in CH_2Cl_2 (6 ml) was added dropwise to the mixture at −20 °C. The increase in the temperature of the mixture and the appearance of pale-yellow precipitates were noted as the addition of $SnCl_4$ proceeded.

After stirring for 5 h at −20 °C, Et_3N (2.5 ml, 18 mmol) and H_2O (1 ml) were added to the mixture. Excess cyclopentadiene was then removed in vacuo. To the resulting mass were added CH_2Cl_2 (200 ml), Et_3N (2.5 ml, 18 mmol), and saturated aq. NH_4Cl (20 ml), and stirred for 1 h. The two layers were separated and the aqueous layer was extracted with CH_2Cl_2. The combined organic phases were washed (H_2O), dried (Na_2SO_4), and evaporated to dryness. After the residue was treated with $LiAlH_4$ (1.5 g, 40 mmol) in ether for 20 h, the excess $LiAlH_4$ was decomposed by saturated aq. NH_4Cl, then acidified to pH 2—3. The two layers were separated and the aqueous layer was extracted with ether. The combined organic phases were washed (H_2O), dried (Na_2SO_4), concentrated, and distilled under reduced pressure to give the alcohol **4**, containing some of its exo isomer, as shown by GLC analysis. After removing the exo isomer by preparative GLC, the endo alcohol was treated with chiral 1-(1-naphthyl)ethyl isocyanate in benzene at 80 °C to give chiral carbamate for an HPLC analysis.[3] The other reactions were carried out in a similar way according to Scheme 1 and are shown in Tables 1 and 2 together with the results.

Dienophile-Lewis Acid Complexes. Preparation of 1a-$SnCl_4$ Complex as a Typical Procedure. To a stirred solution of **1a** (0.52 g, 1.5 mmol) in CH_2Cl_2 (10 ml) was added $SnCl_4$ (0.26 ml, 2.25 mmol). The mixture was stirred for 1 h at r.t. A cream-colored complex was filtered, washed (CH_2Cl_2), and dried in vacuo. Yield 1.03 g (93%); Decomp: 183 °C; IR(Nujol mulls) 1738 ($\nu_{C=O}$) and 1155 cm^{-1} ($\nu_{C(O)-O}$); Found: Cl, 28.6%. Calcd for $C_{44}H_{48}N_4O_4Cl_8Sn_3$ (**1a**-1.5 $SnCl_4$): Cl, 28.8%

The other complexes of some dienophiles with $SnCl_4$ or $TiCl_4$ were prepared in a similar way, and the infrared spectra showed similarly the $\nu_{C=O}$ band shifted to a higher frequency and the $\nu_{C(O)-O}$ band shifted to a lower frequency, compared with the bands in the corresponding free dienophiles.

Polymerization of Diene-Containing Lipids as Liposomes by Radical Initiators. 6:[1] Polymerization of 1,3-Bis(2,4-octadecadienoyl)-*rac*-glycero-2-phosphorylcholine

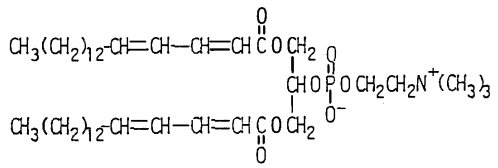
Shinji TAKEOKA, Etsuo HASEGAWA, Hiroyuki OHNO, and Eishun TSUCHIDA*
Department of Applied Chemistry, Waseda University, Tokyo 160
(Received September 26, 1987)

1,3-Bis(2,4-octadecadienoyl)-*rac*-glycero-2-phosphorylcholine (1,3-DPC), polymerizable lipid which contains diene groups in both 1- and 3-acyl chains, was polymerized as liposomes in an aqueous medium. Polymerization was initiated by water-insoluble azobis(isobutyronitrile) (AIBN) or water-soluble azobis(2-amidinopropane) dihydrochloride (AAPD). AIBN was mixed with the monomeric lipids and the mixture was dispersed in an aqueous medium by sonication to facilitate transfer of AIBN into monomeric lipid liposomes. On the other hand, AAPD was simply added to the liposome suspension. The 1,3-DPC liposomes were easily polymerized by the addition of either water-soluble AAPD or water-insoluble AIBN to give polymerization conversion of over 80% in both cases. No selective polymerization of diene groups in the different acyl chains was found in 1,3-DPC liposomes whereas the selective polymerization was clearly seen in 1,2-bis(2,4-octadecadienoyl)-*sn*-glycero-3-phosphorylcholine (DODPC). Polymerized 1,3-DPC liposomes were not soluble in organic solvent suggesting the formation of crosslinked bilayer structure. The obtained results suggested that the diene groups in both 1- and 3-acyl chains were almost equivalent and located in the interface between an aqueous phase and hydrophobic region. Polymerized liposomes thus prepared were stable against heating, detergent attack and even methanol washing. Copolymerization of mixed liposomes composed of 1,3-DPC and DODPC (5 : 1) revealed that the AIBN or AAPD initiated polymerization conversion of DODPC reached about 68%. 1,3-DPC is considered to be radical propagation transfer between diene groups in 1- and 2-acyl chains of DODPC during polymerization.

Liposomes and the lipid assemblies have attracted attention as one of potent candidates for the basic materials for the coming molecular devices. However, they are generally not so stable and usually cause aggregation and fusion.[2,3] Polymerizable amphiphiles have been synthesized as major components to construct stable bilayer membrane.[4-13] In our previous paper,[14] small unilamellar liposomes composed of 1,2-bis(2,4-octadecadienoyl)-*sn*-glycero-3-phosphorylcholine (DODPC), which contains one diene group in each acyl chain, were polymerized by radical initiators. It was revealed that the polymerization profile was significantly dependent on the characteristics of the applied radical initiators.[1] However this monomeric lipid had polymerizable groups in the same position (2,4-diene) in two acyl chains, polymerization of diene groups bound to the 1-acyl chains was selectively initiated by AIBN which was incorporated into a hydrophobic region of the bilayer membrane. On the contrary, the diene groups in the 2-acyl chains were polymerized by the addition of water-soluble radical initiators suggesting that the diene groups in 2-acyl chains faced an aqueous phase. Selective initiation of diene groups bound to 2-acyl chains by AAPD was clearly demonstrated by the model reaction using 1-palmitoyl-2-(2,4-octadecadienoyl)-*sn*-glycero-3-phosphorylcholine (POPC).[15] The polymerization of this POPC was initiated only by the addition of AAPD and no effect was found when AIBN was added to them.[15] We reported the unique method to evaluate the chemical environment of polymerizable groups in the lipid liposomes with their polymerization manner initiated by different radical initiators.[14,16] In the present paper, polymerizable lipid containing one diene group in 1- and 3-acyl chains was polymerized as liposomes by two different radical initiators to clarify the chemical environment of diene groups and the effects of the molecular packing of polymerizable lipids on the polymerization profile as liposomes.

Experimental

1,3-Bis(2,4-octadecadienoyl)-*rac*-glycero-2-phosphorylcholine (1,3-DPC) was synthesized according to the method as reported previously.[17] The purity was confirmed by thin layer chromatography (Merck, silica gel). TLC plates were developed with chloroform/methanol/water (65:35:5 by vol) to show a single spot with R_f value of 0.3.



1,3-DPC

Azobis(isobutyronitrile) (AIBN) and azobis(2-amidinopropane) dihydrochloride (AAPD) were purchased from Tokyo Kasei Co. AIBN and AAPD were purified twice by recrystallization from methanol and water, respectively. Triton X-100, polyethylene glycol mono-*p*-octylphenyl ether, was purchased from Tokyo Kasei Co. Ltd. and used without further purification. Fluorescent grade 5(6)-carboxyfluorescein (CF) was purchased from Kodak Co. and used

without further purification. Chloroform, methanol, and water were distilled twice before use.

Preparation of Liposomes. A total of 0.200 g of monomeric amphiphiles was dissolved in dehydrated chloroform and was slowly evaporated in a rotated sample tube to prepare thin lipid film on the inner surface of the tube.[14,18] Distilled water was then added to the tube to set the lipid concentration 1.0 wt%. Small unilamellar liposome suspension was prepared by sonication (Tip-type Tomy Seiko UR-200P) at 60 W for 20 min under nitrogen atmosphere. The freshly prepared liposomes were incubated in a refrigerator to prepare larger unilamellar liposomes with an average diameter of 75 nm. This process minimizes the structural defects and irregular molecular packing.[19]

Polymerization of Liposomes Initiated by Organic Free Radicals. Free radical initiated polymerization of 1,3-DPC was carried out by a similar manner as mentioned previously.[14] A total of 0.200 g of 1,3-DPC was dissolved with 2.1 mg of AIBN (5.0 mol% to the monomeric lipids) in chloroform and slowly evaporated in a rotated sample tube. Degassed distilled water (20.0 ml) was added to the tube. Liposome suspension was prepared by sonication method as mentioned above. These liposomes were polymerized at 60 °C under nitrogen atmosphere. The polymerization conversion was successively analyzed by the decrease in the absorption intensity at 243 nm for diene groups.

On the other hand, AAPD was added to the liposome suspension to avoid the decomposition of AAPD by sonication.[15] Liposomes were polymerized at 60 °C for several hours under nitrogen atmosphere. AAPD was added to the liposomes which had already been polymerized by AIBN. These were then re-polymerized to check the possibility of selective polymerization.[14]

UV Spectroscopic Analysis of the Polymerization. A small amount of the liposome suspension was periodically withdrawn with a pipette from the sample tube during polymerization. Accurately diluted sample solution was analyzed by UV spectrometry to quantitatively determine the polymerization conversion. Spectral change at 243 nm corresponding to the diene groups of 1,3-DPC as liposomes in an aqueous solution was analyzed to determine the polymerization conversion of 1,3-DPC.

Transmission Electron Microscopy. Polymerized liposome suspension was dropped on copper grids, and they were stained with uranyl acetate. The dried sample grids were analyzed to confirm their bilayer structure by TEM (JEOL-100CX).

Light-Scattering Measurement. A liposome suspension (concentration; 0.100 g/100 cm^3) was placed in a round cell of 10 mm diameter. Methanol was added to the suspension and the scattered-light intensities (90°) were subsequently recorded with apparatus (Union Giken LS-601) at 25 °C to evaluate stability of the polymerized liposomes upon addition of organic solvent. He-Ne laser with wavelength of 632.8 nm was used as the light source.

Fluorescein Leakage. 0.100 mol·l^{-1} of CF was incorporated into an inner aqueous phase of the polymerized liposomes at 60 °C for 100 h.[20] Then CF-containing liposome suspension was passed through gel permeation chromatography column (Sepharose CL-4B 30 mm ϕ, 600 mm h) to expel an excess CF dissolved in an outer aqueous phase. The leakage of CF was determined as the increase of fluorescence intensity at 520 nm by fluorescence spectrometer (JASCO FP-550) with excitation beam at 330 nm. A 100% CF leakage was carried out by the sonication of CF containing liposomes with the existence of Triton X-100.

Results and Discussion

Polymerization and Stability of 1,3-DPC Liposomes. 1,3-Bis(2,4-octadecadienoyl)-*rac*-glycero-2-phosphorylcholine (1,3-DPC) was dispersed in an aqueous medium, and small unilamellar liposomes were prepared by sonication under N_2 atmosphere. Preparation of closed small liposomes was confirmed by TEM and ^{1}H NMR measurements.[21] A DSC measurement revealed that the 1,3-DPC formed liposomes with gel-to-liquid crystalline phase transition temperature(T_c) of 28 °C. The T_c was also determined with ^{1}H NMR spectrometry. Proton signals attributed to hydrophobic methylene and terminal methyl groups appeared at temperatures higher than 28 °C, suggesting the formation of liposome structure. Figure 1 shows the ^{1}H NMR spectra for 1,3-DPC liposomes in deuterium oxide at 50 °C in the absence and presence of Eu^{3+}, a shift reagent. The proton signals attributed to hydrophilic choline methyl groups were split by the addition of 3.8 m mol·l^{-1} $Eu(NO_3)_3$. This is the proof of the closed liposome structure because Eu^{3+} interacted with polar head groups of lipids facing outer aqueous phase to shift its signal to higher magnetic field as shown in Fig. 1 (b). The ratio of the split signal intensities showed no change for over 60 min suggesting no Eu^{3+} leakage through the membrane. The average radius of the liposomes can be estimated from the intensity ratio of the split choline methyl proton signals.[20] The average radius of the liposomes analyzed in this experiment was calculated to be about

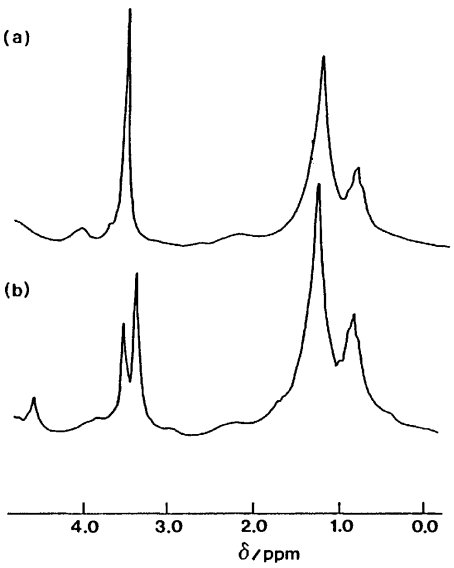


Fig. 1. ^{1}H NMR spectra of 1,3-DPC liposomes in D_2O at 50 °C in (a) absence or (b) presence of Eu^{3+}. [1,3-DPC]=10.0 g lipids dm^{-3} D_2O, [Eu^{3+}]=3.8 mmol·l^{-1}.

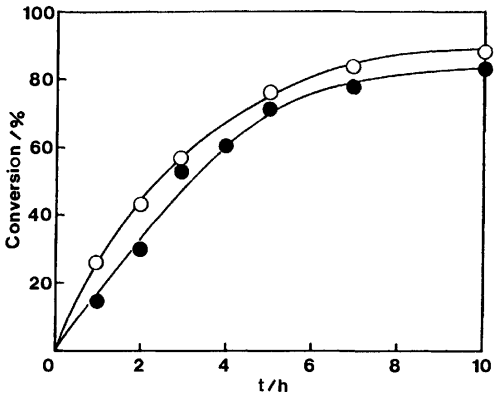

Fig. 2. Polymerization conversion of 1,3-DPC as liposomes at 60°C. 1,3-DPC liposomes (10.0 g lipids dm^{-3} H_2O) were polymerized by AIBN (●) or AAPD (○).

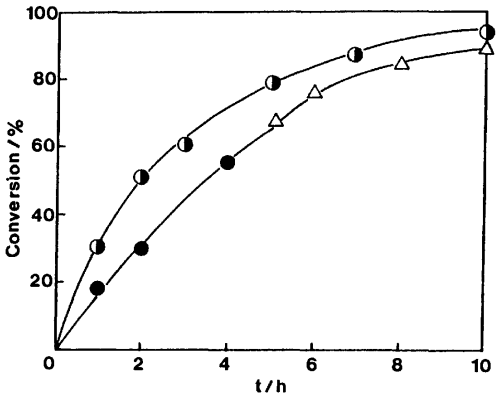

Fig. 3. Polymerization conversion of 1,3-DPC as liposomes. 1,3-DPC liposomes were polymerized by AIBN and AAPD simultaneously (◑), or by the addition of AAPD (△) to the DODPC liposomes which were pre-polymerized by AIBN (●) at 60°C for 5 h.

210 nm.

The AIBN and AAPD are potential azo compounds to initiate radical polymerization of lipids as liposomes.[9,10] AIBN and AAPD generate free radicals in hydrophobic region and aqueous region of lipid liposomes, respectively. It is known that polymerization profile reflects the acyl chain packing and chemical environment of diene group.[16] The 1,3-DPC liposomes were also polymerized by either one or both of these radical initiators to analyze chemical environment of diene groups. Figure 2 shows the results on the polymerization of 1,3-DPC as liposomes initiated by either AIBN or AAPD. Both AIBN and AAPD initiated radical polymerization of diene groups in 1,3-DPC liposomes and the polymerization conversion reached about 80% in both cases. It is previously reported that AIBN (5 mol% to the monomeric lipids) initiates radical polymerization of 1,2-bis(2,4-octadecadienoyl)-*sn*-glycero-3-phosphorylcholine (DODPC) for only 50%.[14,16] A simultaneous use of both AIBN and AAPD provided polymerization of DODPC in almost 100%. For DODPC liposomes, the diene groups bound in 1-acyl chains and those in 2-acyl chains were selectively polymerized by AIBN and AAPD radicals because of their non-equivalent chemical environment[16] Namely, diene groups in 2-acyl chains are considered to face the aqueous phase and they are polymerized by water-soluble radical initiators. And those in 1-acyl chains are located in the hydrophobic region and therefore polymerization should be initiated by the radical attack from hydrophobic region. 1,3-DPC however showed high polymerization conversion regardless the solubility of radical initiators, suggested that the chemical environment of diene groups in 1- and 3-acyl chains was almost equivalent. Furthermore they are located in the interface between the aqueous phase and hydrophobic region. One could also explain the result by assuming incomplete lipid packing which enabled the attack of radical initiators from both region. This was however denied by the ^1H NMR data as shown in Fig. 1, in which no leakage of Eu^{3+} was found.

We must note the following results for spectroscopic analysis of the polymerizable lipids as liposomes. Both 1,3-DPC and DODPC show the maximum UV absorbance at 265 nm attributed to diene groups in chloroform solution. The maximum UV absorbance of 1,3-DPC shifted to 243 nm when they formed liposomes in an aqueous phase. Against this, DODPC liposome suspension showed the maximum UV absorbance at 255 nm.[18] These different λ_{max} can be discussed in terms of different acyl chain packing. The maximum absorbance was found at 243 nm for both 1,3-DPC and DODPC below the phase transition temperature and it shifted to 255 nm beyond it. In the present work, polymerization conversion was carried out by UV spectrometry. The solution temperature for measurement was about 20°C and it was therefore lower than the T_c of 1,3-DPC. Anyway, spectral shift is strongly suggested to reflect the molecular packing of the polymerizable lipid as liposomes. Detailed results will be published elsewhere.

A simultaneous use of AIBN and AAPD did not improve the polymerization conversion of 1,3-DPC liposomes as shown in Fig. 3. There is little contribution of AAPD addition to the 1,3-DPC liposomes which has been previously initiated by AIBN radicals (Fig. 3 ●→△). This is considerably different from the polymerization profile for DODPC liposomes. These data also support equivalent chemical environment of the diene groups in 1- and 3-acyl chains for 1,3-DPC and their radical polymerization can be initiated by radical attack from both hydrophobic and hydrophilic phases. It can be concluded that 1,3-DPC packed more symmetrically than DODPC. No difference was found in the polymerization profile of 1,3-DPC with radical initiators employed in the present experiments. How-

ever, 1,3-DPC cannot be packed completely symmetrically but slight difference should be detected by other techniques such as small angle X-ray scattering.

The liposome structures of 1,3-DPC before and after polymerization were analyzed with TEM measurements. Figure 4 shows the TEM picture for the polymerized 1,3-DPC liposomes. Bilayer liposome structure is clearly seen in the micrographs for both monomeric and polymerized ones. The outlines of polymerized liposomes are more smooth than those of monomeric ones. It indicates that polymeric liposomes are more stable and maintain their spherical structures perfectly after dryness. This structure is found to be kept even after methanol washing. The effect of added methanol content on the scattered-light intensity from 1,3-DPC liposome suspension is depicted in Fig. 5. Monomeric liposomes showed decrease in the scattered light intensity, which may be attributed to the structural change such as destruction of liposomes structure with the addition of methanol. Nevertheless only a little intensity change was found for the polymerized one suggesting a stable membrane structure. Liposome structure was also observed with SEM even after washing large polymerized 1,3-DPC liposomes with pure methanol. In this experiment, giant 1,3-DPC liposomes were prepared by hydration method.[13] Polymerized 1,3-DPC liposomes with average diameter of about 1 μm were filtered on a Millipore membrane filter with average pore size of 0.05 μm. They were washed with pure methanol for several times, and their liposome structure was directly monitored with SEM after Au sputtering as shown in Fig. 6. Although they were aggregated, it was found that liposome structure was clearly maintained almost completely. This stable membrane structure was also confirmed by solubility test. The 1,3-DPC liposomes, polymerized with appropriate radical initiators, were insoluble in any organic solvents. This insolubility also supported the formation of crosslinking between

polymer chains, i.e., their polymerization underwent intermolecularly and no intramolecular polymerization occurred. In other words, diene group in 1-acyl chain does not form covalent bonding with that in 3-acyl chain of the same lipid monomer, but it may attack diene groups in not only 1-acyl chains but also 3-acyl chains of the neighboring lipid monomers. Related discussions on this polymerization manner will be mentioned later.

The leakage measurement of carboxyfluorescein (CF) was commonly used to evaluate the membrane structure or stability of the liposomes.[8,20] Figure 7 shows the leakage of CF from polymerized 1,3-DPC liposomes. Those from DODPC liposomes before and after polymerization were also plotted as references. Preparation of the polymerized liposomes containing CF molecules in their inner aqueous phase has already been mentioned elsewhere.[20] The CF leakage data for monomeric 1,3-DPC was not measured consistently because their liposomes were unstable and easily aggregated in solution under the conditions for this experiment. There was a certain temperature dependence of CF leakage from liposomes. No CF leakage was found from these polymerized liposomes at room temperature, and these measurements were therefore made at 50 °C to accelerate CF leakage. The CF leakage rate from an inner aqueous phase of the DODPC liposomes was considerably decreased by the polymerization, and almost the same CF leakage rate was found for the polymerized 1,3-DPC liposomes. It was demonstrated that radical polymerization of 1,3-DPC provided very stable membrane structure which was almost equivalent for that of polymerized DODPC liposomes.

Copolymerization of 1,3-DPC with DODPC in Mixed Liposomes. From the results obtained in the previous section, it was expected that the existence of 1,3-DPC might disturb selective polymerization manner and might induce further polymerization of DODPC as liposomes. Chloroform solution of 1,3-DPC was mixed with that of DODPC, and their mixed liposomes were prepared through the same procedure as mentioned above. Polymerization of the mixed liposomes was also analyzed by UV spectroscopy. Figure 8 shows the polymerization conversion for the DODPC/1,3-DPC (5/1 by mol) mixed liposomes initiated by AIBN (5.0 mol% to the total lipid monomers) at 60 °C. If 1,3-DPC and DODPC did not affect the polymerization manner with each other in the mixed liposome, theoretical polymerization conversion could be calculated from the results of their individual polymerization manner. For liposomes with average radius of 30 nm or more, AIBN initiated the polymerization of 1,3-DPC and DODPC liposomes to reach the polymerization conversion of about 80% (see Fig. 2) and 50%,[14] respectively at 60 °C for 12 h. Since we have collected kinetic data on the polymerization conversion of those lipid liposomes, the average polymerization conversion for the mixed liposome system can be calculated as a simple summation of the individual polymerization conversion at every stage of the polymerization. The calculated polymerization conversion was depicted in Fig. 8. The experimental data on the polymerization conversion (open circles in Fig. 8) was always higher than the calculated one. For example, the polymerization conversion reached 68% was actually found for the mixed liposomes after 12 h. heating at 60 °C in the presence of AIBN whereas the calculated value was only 55%. When the increase in the polymerization conversion was assumed to be due to the newly polymerized diene groups in 2-acyl chains of DODPC lipids, 31% of the diene groups in the 2-acyl chains of DODPC were calculated to be polymerized. The polymerized mixed liposomes obtained were stable against organic solvent washing and no channel or hole was formed by the skeletonization.[13] These results strongly suggest the following points: Firstly,

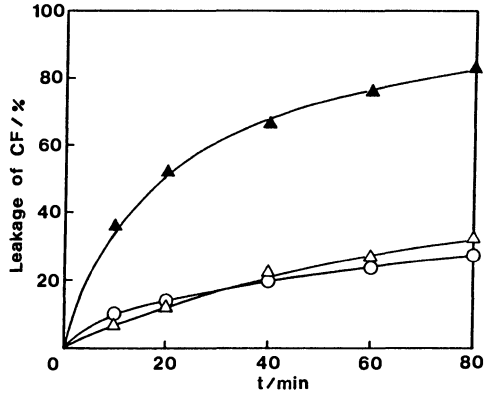

Fig. 7. Leakage of CF from inner aqueous phase of 1,3-DPC liposomes polymerized by both AIBN and AAPD simultaneously (○) at 50 °C. Monomeric (▲) and polymerized (△) DODPC liposomes were also analyzed under the same condition as references. No CF leakage was found at 30 °C.

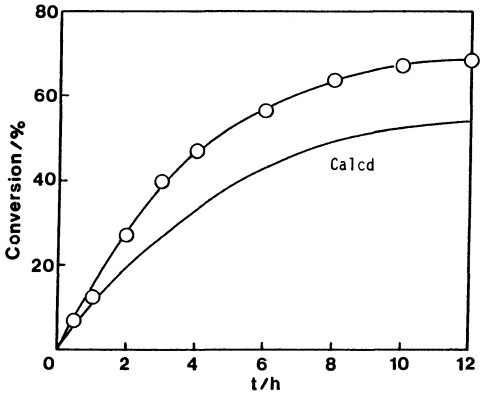

Fig. 8. Polymerization conversion of DODPC/1,3-DPC (5/1 by mol) mixed liposomes. Liposomes were polymerized by AIBN. Solid curve was obtained by calculation from polymerization conversions of DODPC[14] and 1,3-DPC liposomes.

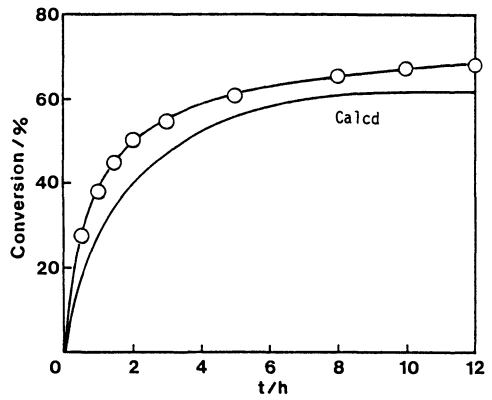

Fig. 9. Polymerization conversion of DODPC/1,3-DPC (5/1 by mol) mixed liposomes. Liposomes were polymerized by AAPD. Solid curve was obtained by calculation from polymerization conversions of DODPC[14] and 1,3-DPC liposomes.

1,3-DPC and DODPC were miscible with each other in the mixed liposomes and no phase-separated structure might be formed at 60 °C. Secondly, 1,3-DPC and DODPC lipids were copolymerized to form highly crosslinked ultrathin polymer membrane. And finally, terminal radicals on the 1,3-DPC in the copolymers might attack the diene groups in 2-acyl chains of DODPC which were never attacked by AIBN radicals in liposome systems.[14] Especially, the final point is very interesting and important. The diene groups in 2-acyl chains of DODPC lipids can be polymerized by the addition of AIBN in the presence of 1,3-DPC. The detailed study on the relationship between the improved polymerization conversion and composition of the mixed liposomes is now in progress.

It was previously reported that AAPD, a water-soluble radical initiator, was able to initiate radical polymerization of diene groups in 2-acyl chains of DODPC as liposomes.[14] The effect of 1,3-DPC on the polymerization of DODPC initiated by AAPD was also analyzed. A slight improvement was also found as shown in Fig. 9. About 16% of the diene groups in 1-acyl chains of DODPC were polymerized by AAPD under coexistence of 1,3-DPC. It is important that the polymerization conversion of 1,3-DPC/DODPC mixed liposomes reached a constant value, 68% regardless the employed radical initiators. This suggests that 1,3-DPC lipids certainly play a significant role to improve polymerization conversion as crosslinking agents.

Dichalcogen-Bridged Acenaphthenes as New Electron Donors

Yoshio Aso, Koji Yui, Takanori Miyoshi, Tetsuo Otsubo,
Fumio Ogura,* and Jiro Tanaka†

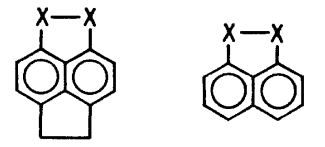
(Received October 7, 1987)

Three new electron donors, 5,6-dihydroacenaphtho[5,6-*cd*]-1,2-dithiole (**1a**), -diselenole (**1b**), and -ditellurole (**1c**) have been prepared with a view to developing new electron donors for low-dimensional molecular complexes. Their donor characters are markedly enhanced as compared with the corresponding dichalcogen-bridged naphthalenes. They formed charge-transfer complexes with tetracyanoquinodimethane (TCNQ). Their electrical conductivities increase in the order of polarizable chalcogen. The crystal structures of **1a**–TCNQ complex and neutral **1c** were determined by X-ray analyses. In the crystal, **1a** and TCNQ form a unique mixed stack, that is, a pair of donors and a pair of acceptors make an alternately stacking column. Neutral **1c** takes an almost planar conformation and molecules are connected to each other with strong Te–Te interactions.

Polycyclic aromatic compounds bearing peri-dichalcogen bridges, as represented by tetrathiotetracene (TTT), have been recognized as good electron donors for the formation of low-dimensional molecular complexes.[1] Although a number of tetrathiafulvalene (TTF) derivatives possessing alkyl or heteroatom substituents have been synthesized and have attracted much attention, there have been known few examples of chemical modifications of TTT-type donors. Meinwald et al. reported that even simple 1,8-dichalcogen-bridged naphthalenes **2a—c**, when the chalcogen was replaced by heavy element such as tellurium, could form a conducting charge-transfer (CT) complex with tetracyanoquinodimethane (TCNQ),[2] and they and we extended its study to acenaphthylene[3] and fluoranthene[4] system, respectively. In both cases, a donor character of peri-dichalcogenonaphthalene was rather reduced by the expansion of the π-system at another peri-position. We have recently reported the syntheses and some physical properties of 1,8:4,5-bis(dichalcogeno)-2,3,6,7-tetramethylnaphthalenes as the first example of alkyl-substituted TTT-type donors.[5] However, a marked enhancement of their donor characters, predicted by an electron-releasing effect of the methyl groups, was not observed for the sulfur nor selenium derivatives.[6] This is presumably a result of a lowering of the molecular planarity caused by steric repulsion.

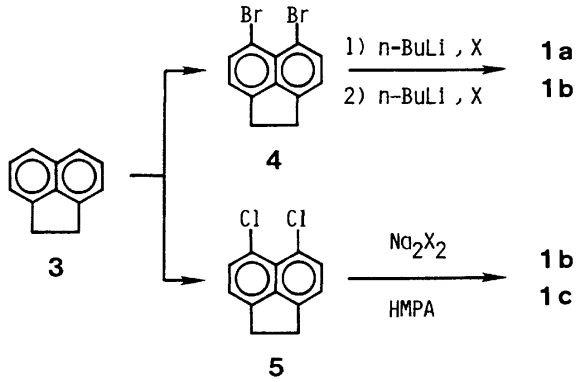
Now we wish to report the syntheses of 5,6-dichalcogen-bridged acenaphthenes **1a—c** and their properties as electron donors. The introduced methylene groups are not only located in opposite peri-positions of dichalcogen bridge but also bound together so as not to bring about steric repulsion, therefore being capable of increasing the donor character.



1a, X = S **2a**. X = S
1b, X = Se **2b**. X = Se
1c, X = Te **2c**. X = Te

Results and Discussion

Syntheses and Properties. 5,6-Dichalcogen-bridged acenaphthenes **1a—c** were synthesized starting from acenaphthene (**3**) (Scheme 1). 5,6-Dibromoacenaphthene (**4**) was prepared by bromination of **3** according to a reported method.[3] A reaction of 5,6-dilithioacenaphthene, generated from **4** and 2 equiv of butyllithium, with elemental chalcogen gave a complex mixture. However, the sequential reactions of **4** with 1 equiv of butyllithium, 1 equiv of elemental chalcogen, second 1 equiv of butyllithium, and 1 equiv of elemental chalcogen and subsequent air-oxidation resulted in the formation of **1a** (17%) or **1b** (6%). The tellurium analogue **1c** could not be obtained by the same series of reactions. On the other hand, 5,6-dichloroacenaphthene (**5**), prepared by the chlorination of **3** with sulfuryl chloride in the presence of aluminium chloride,[7] was submitted to a reaction with Na_2Te_2 in hexamethylphosphoric triamide (HMPA) to yield **1c** (5%). Furthermore, treatment of **5** with Na_2Se_2 gave **1b** in an improved yield (16%).



Scheme 1.

In the electronic spectra of compounds **1a—c**, marked bathochromic shifts of the longest wavelength absorptions, which were assigned to π-σ^* transition,[8] were observed in the order of polarizable chalcogens, indicating an increased electronic interaction between the naphthalene chromophore and the heavy chalcogen, λ_{max} in tetrahydrofuran (THF); **1a:** 422; **1b:** 550; **1c:** 691 nm. This phenomenon is common to the dichalcogen-bridged arenes.[4,5] More interestingly, the corresponding absorptions of naphthalene series, λ_{max} (THF); **2a:** concealed behind a strong shorter wavelength absorption at 368 nm; **2b:** 512; **2c:** 685 nm,[9] are shifted to longer wavelength by introduction of the ethylene bridge, reflecting an elevated π-HOMO level due to its electron-releasing effect. Its magnitude, however, decreases with increasing polarizability of chalcogen. In the wavelength region of π-π^* transition, the absorptions of **1b** are quite similar to those of **1a** except for slight bathochromic shifts whereas those of **1c** are considerably different in shape (cf. experimental section). This specificity of the tellurium derivative, also observed in naphthalene series, may be attributed to geometrical as well as electronic perturbation of very large and polarizable ditelluro bridge on the π-system of naphthalene.

The cyclic voltammograms of compounds **1a—c** exhibited one reversible wave corresponding to apparent one-electron oxidation,[8] and the second one was not observed in the measurable region. Their half-wave potentials $E_{1/2}$ are given in Table 1, together with those of peri-dichalcogenonaphthalenes **2a—c**. The donor strength of **1a—c** increases with introduction of the heavy chalcogen. Moreover, the ethylene bridges evidently exert an electron-donating perturbation on the π-system. These results are consistent with the electronic interactions stated above. Once again the effect of ethylene bridge decreases in the order of chalcogen triad and, in other words, is proportional to the oxidation potential of the naphthalene derivative. This is understandable as follows: The π-HOMO level of dichalcogen-bridged naphthalenes is raised in the order of polarizable chalcogen, and accordingly the interaction of the HOMO with ethylene bridge (hyperconjugation) decreases in the same order due to an increasing energy gap between the two interactive orbitals. It is worth noting that the oxidation potential of tellurium compound **1c** is the quite same as the first one of TTF (+0.33 V under the same conditions listed in Table 1) which forms a metallic complex with TCNQ.

Table 1. Half Wave Oxidation Potentials of **1** and **2** (V vs. Ag/AgCl)[a]

Compounds **1a** and **1b** readily formed black crystalline 1 : 1 CT complexes with TCNQ in THF. Tellurium compound **1c** was resistant to complexation with TCNQ (in THF or dichloromethane), and even if the complex was formed (in chloroform), its stoichiometry was rich in donor and lack of reproducibility. From chlorobenzene solution the 1 : 1 complex was eventually obtained under an atmosphere of nitrogen. Their physical properties are listed in Table 2. The difference between the half-wave potentials of donor and acceptor (TCNQ: +0.25 V under the same conditions listed in Table 1), ΔE, is known to be a measure to predict electrical properties of the complex.[10] From the ΔE value for each complex, therefore, it is predictable that **1a**-TCNQ and **1b**-TCNQ are non- or slightly ionic and **1c**-TCNQ is in incomplete CT state. Complexation with **1a** and **1b** caused slightly lower shifts in the nitrile stretching frequency of TCNQ, but with **1c** led to a great shift, supporting a large charge transfer in **1c**-TCNQ.[11] Electrical conductivities of **1a**-, **1b**-, and **1c**-TCNQ complexes increase in that order, reflecting the estimated degree of CT.

Crystal Structure. The crystal structures of **1a**-TCNQ complex and neutral **1c** were determined by X-ray analysis.

Complex 1a-TCNQ: The crystal composition is one donor and one acceptor, and both molecules take quite planar conformations. As shown in Fig. 1, they form unusual modified mixed stacking columns along [111] direction. A pair of donors and a pair of acceptors make an alternately stacking column.[12] A mixed stacking is often observed in low conductive CT complexes and, in such cases, the overlapping pattern is usually "direct" overlap or slightly "shifted" form so as to facilitate CT interaction.[13] As shown in Fig. 2, the donor and the acceptor overlapping of this complex is not of such type. The long molecular axis of TCNQ and **1a** are twisted to ca. 40°. The donors are overlapped head to tail, and there exist no short intrastack interactions of the S-S nor S-N type. On the other hand, there exist somewhat short interstack contacts; the shortest S-N distance of 3.39 Å is approximately equal to the van der Waals distance of S-N

(3.35 Å).[14] Applying the method of Kistenmacher et al.[15] to estimating the degree of CT based on TCNQ geometry, we calculated it at 0.12, a value which indicates a small CT.

Neutral 1c: In the crystal, **1c** maintains the almost planar molecular structure though substitution of very large and long (2.748 Å) ditelluro bridge considerably distorts bond length and angles of acenaphthene skeleton in its molecular plane, and this is consistent with the inference from the electronic spectrum. As shown in Fig. 3, the molecules are stacked along c axis, forming the tellurium columns, and also arranged side by side along a axis forming linear chains of tellurium atoms. Moreover, each column is arranged along b axis alternately with opposite orientation of ditelluro bridge, and hence there exist the tellurium layers in the ac plane. Intrastack Te-Te distances of 4.15 and 4.37 Å are somewhat longer than the sum of the corresponding van der Waals distance (4.12 Å).[14] A more interesting feature in the crystal is the strong interactions between adjacent columns caused by shorter Te-Te contacts; the shortest one goes down to 3.57 Å (Fig. 4). In adjacent columns along b axis, the positions of ditelluro bridges are shifted one another to c axis by one half of unit (Fig. 3, left). Therefore, each molecule is connected with other four molecules by strong Te-Te interactions (Fig. 4), that is, molecule A is connected with two molecules B and B′ by Te(2)-Te(2) (3.75 Å) and Te(2)-Te(1) (3.93 Å) interactions and also connected with two molecules C and C′ by Te(1)-Te(1) (3.57 Å) interaction. These situations result in the formation of a two-dimensional sheet-like tight network in the ac plane.

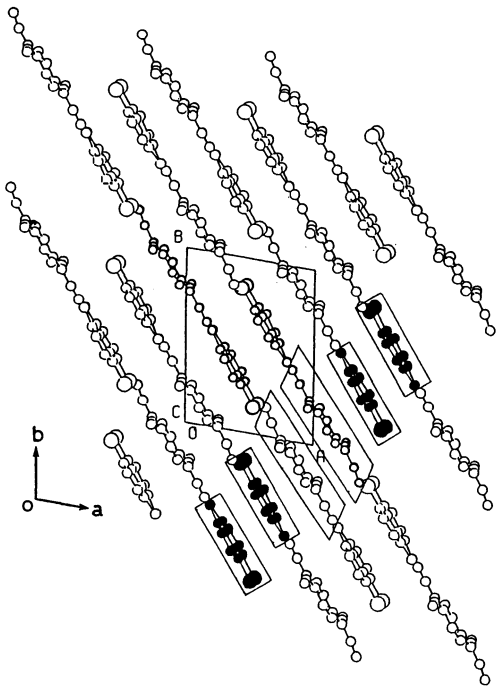

Fig. 1. Crystal structure of **1a**-TCNQ projected along c axis.

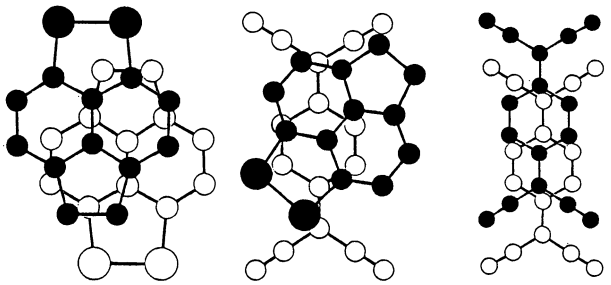

Fig. 2. Molecular overlapping patterns viewed perpendicular to the molecular plane.

Conclusion

The electron-donating character of dichalcogen-bridged naphthalene could be markedly enhanced by introduction of alkyl group without lowering the molecular planarity. Neither that of dithio- nor diseleno-bridged acenaphthene, however, was high enough to bring about an incomplete charge transfer in the TCNQ complex. Moreover, the result of X-ray analysis of **1a**-TCNQ indicated that the donor and the acceptor formed unusual mixed-staking columns probably due to the strong electronic and/or structural disorder of **1a**, and that this complex was characterized by a small CT, weak intrastack interactions, and tight interstack S-N interactions. The oxidation potential

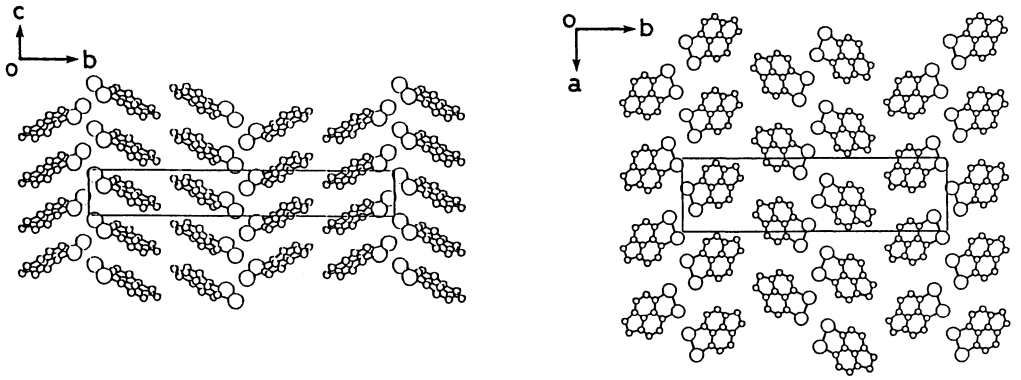

Fig. 3. Crystal structure of neutral **1c** projected along a axis (left) and c axis (right).

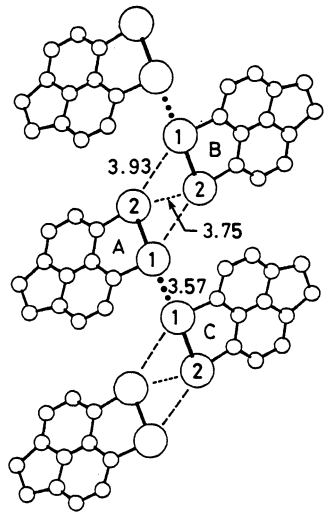

Fig. 4. The network of **1c** molecules projected along c axis. Close intermolecular Te-Te distances are illustrated. The symmetry operations are A (x,y,z), B ($-0.5-x,2.0-y,0.5+z$), B′ ($-0.5-x,2.0-y,-0.5+z$), C ($0.5-x,2.0-y,0.5+z$), and C′ ($0.5-x,2.0-y,-0.5+z$).

of **1c** was low enough, so that it formed a highly conducting TCNQ complex. In the crystal the molecules of **1c** associated to form densely packed tellurium layers resulting from the very strong Te-Te interactions. This marked tendency to aggregate seems to be reflected in low crystallinity of the CT complex and in its composition rich in donor. Such intermolecular strong interactions, however, are preferable for the enhancement of dimensionality of molecular complexes, especially for radical cation salts.[16] Finally, this study suggests that an enhancement of dimensionality of the CT complex as well as an increase in the donor strength may be achieved by the introduction of alkyl groups to a highly symmetrical doubly ditelluro-bridged arene without steric repulsion and a lowering of the symmetry. This is our target for future studies.

Experimental

General. All the melting points were uncorrected. Mass spectra were determined with a JEOL JMS-DX300 mass spectrometer. Proton NMR spectra were recorded with a JEOL JNM-PMX-60 spectrometer. Electronic spectra were measured with a JASCO UVIDEC-610A double beam spectrophotometer. Infrared spectra were recorded on a Hitachi infrared spectrophotometer, Model 260-30. The cyclic voltammetry was carried out at room temperature under nitrogen using a Hokuto Denko potentiostat/galvanostat HA-301 and a function generator HB-104. Gel-permeation liquid chromatography was carried out using a Japan Analytical Industry LC-08 liquid chromatograph, equipped with JAIGEL 1H and 2H columns, with chloroform as eluent.

Preparation of the Donors. 5,6-Dihydroacenaphtho[5,6-*cd*]-1,2-dithiole (1a): To a stirred solution of 5,6-dibromoacenaphthene (**4**)[3] (312 mg, 1.00 mmol) and *N,N,N′,N′*-tetramethylethylenediamine (232 mg, 2.00 mmol) in THF (30 cm^3) was slowly added a 1.6 mol dm^{-3} hexane solution of butyllithium (0.64 cm^3, 1.0 mmol) at −78 °C under argon. After the mixture was stirred for 15 min at −78 °C, sulfur (32 mg, 1.0 mmol) was added, and stirring was continued at −40—−30 °C for 2 h. After the mixture was cooled again to −78 °C, it was treated with butyllithium (0.64 cm^3, 1.0 mmol) and then sulfur (32 mg, 1.0 mmol) in the same way as described above. The mixture was quenched with acetic acid (0.2 cm^3), followed by exposure to air stream for oxidation. The resulting solution was concentrated under reduced pressure. After water was added, the mixture was extracted with dichloromethane. The extract was dried over anhydrous magnesium sulfate. After the solvent was removed under reduced pressure, the residue was purified by gel-permeation liquid chromatography and recrystallized from hexane to give 37 mg (17%) of **1a** as reddish brown prisms: mp 190.3 °C; MS (70 eV) m/z 216 (M^+); ^{1}H NMR (CCl_4) δ=3.25 (4H, s) and 6.90 (4H, s); UV (THF) 250 (ε 19600), 351 (11500), 369 (14000), and 422 nm (99.1); Anal. ($C_{12}H_8S_2$) C, H.

5,6-Dihydroacenaphtho[5,6-*cd*]-1,2-diselenole (1b): The title compound was prepared as described for **1a** (6%), and also as follows. To a solution of sodium diselenide, which was in situ prepared by heating sodium (308 mg, 13.4 mmol) and selenium (1.06 g, 13.4 mmol) at 120 °C for 2 h in HMPA (30 cm^3) under an argon atmosphere, was added a solution of 5,6-dichloroacenaphthene (**5**)[7] (1.00 g, 4.47 mmol) in HMPA (15 cm^3), and the mixture was stirred at 140 °C for 30 h. To the resulting solution were added brine (30 cm^3) and acetic acid (15 cm^3) with vigorous stirring. The resulting suspension was extracted with CS_2, and the extract was washed with water, dried over anhydrous magnesium sulfate, and then concentrated under reduced pressure. The residual solid was recrystallized from CS_2-hexane (3/1 volume ratio), purified with gel-permeation liquid chromatography, and again recrystallized from benzene to give 220 mg (16%) of **1b** as deep violet prisms: mp 208—213 °C; MS (70 eV) m/z 312 (M^+); ^{1}H NMR (CS_2) δ=3.22 (4H, s), 6.90 (2H, d, J=7 Hz), and 7.12 (2H, d, J=7 Hz); UV (THF) 259 (ε 10000), 379 (15000), and 550 nm (73.1); Anal. ($C_{12}H_8Se_2$) C, H.

5,6-Dihydroacenaphtho[5,6-*cd*]-1,2-ditellurole (1c): To a solution of sodium ditelluride, which was in situ prepared by heating sodium (154 mg, 6.71 mmol) and tellurium (856 mg, 6.71 mmol) at 125 °C in HMPA (20 cm^3) for 2 h under an argon atmosphere, was added a solution of **5** (500 mg, 2.24 mmol) in HMPA (15 cm^3), and the mixture was stirred at 150 °C for 31 h. The mixture was poured into water and extracted with CS_2. The extract was washed with water, dried over anhydrous magnesium sulfate, and then concentrated under reduced pressure. To the residual oil was added water, and the precipitated solid was filtered off, washed with acetone-water (1/1 volume ratio), and recrystallized from CS_2-hexane (3/1 volume ratio) to give 46 mg (5%) of **1c** as greenish black needles: mp 231 °C (decomp); MS (70 eV) m/z 408 (M^+); ^{1}H NMR (CS_2) δ=3.29 (4H, s), 6.92 (2H, d, J=7 Hz), and 7.15 (2H, d, J=7 Hz); UV (THF under argon) 223 (ε 3920), 258 (sh, 4830), 302 (1570), 404 (10400), 498 (2500), and 691 nm (134); Anal. ($C_{12}H_8Te_2$) C, H.

Preparation of Charge-Transfer Complexes. Both **1a**-TCNQ and **1b**-TCNQ complexes were prepared by mixing THF solutions of the donor and the acceptor in the same flask and standing for a few days. In the case of **1c**-TCNQ, hot chlorobenzene solutions of **1c** and TCNQ were mixed

under an atmosphere of nitrogen and stood at 0 °C for 15 min to give a black fine solid. The 1 : 1 stoichiometry of donor and acceptor was determined by elemental analyses which agreed with calculated values within ±0.3% for C, H, and N. Their properties are summarized in Table 2.

Crystal Structure Analysis. The X-ray diffraction data were collected by use of an automated four-circle diffractometer, Rigaku AFC-5, set on a rotating anode X-ray generator, Rigaku RU-200, with a graphite monochromated Cu radiation (Cu $K\alpha$=1.5418 Å). Crystallographic data are listed in Table 3. Crystal structures were solved by the Monte-Carlo direct method[17] using MULTAN 78 program system[18] and were refined on F^2 by the full-matrix least-squares program with the analytical absorption correction.[19] Atomic scattering factors were taken from International Tables for X-ray Crystallography.[20] Anisotropic temperature factors were used for the refinement of the non-H atoms. The hydrogen atoms of **1a**-TCNQ complex were located from difference Fourier maps and were refined with the isotropic temperature factors equivalent to that of the bonded carbon atoms. In the case of neutral **1c**, the H atoms were not included in the refinement. The atomic numbering scheme and the final atomic parameters are listed in Fig. 5 and Table 4, respectively. All estimated standard deviations for intermolecular atomic distances mentioned in the text were 0.00, and that for the Te-Te bond length of **1c** was 0.002. All computations were carried out at the Computation Center of Nagoya University using the library program of CRYSTAN system. Tables of structure factors, anisotropic thermal parameters, coordinates of hydrogen atoms, bond lengths, and bond angles are deposited as Document No. 8797 at the Office of the Editor of Bull. Chem. Soc. Jpn.

Synthesis of Naphthoquinone Derivatives. XIII. Reaction of 2,3-Dihydro-2-thioxo-1*H*-naphth[2,3-*d*]imidazole-4,9-dione with Dimethyl Acetylenedicarboxylate[1)]

Tateo NAKAMORI,* Toshiyuki SAITO, and Toshiyasu KASAI
Faculty of Engineering, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152
(Received October 14, 1987)

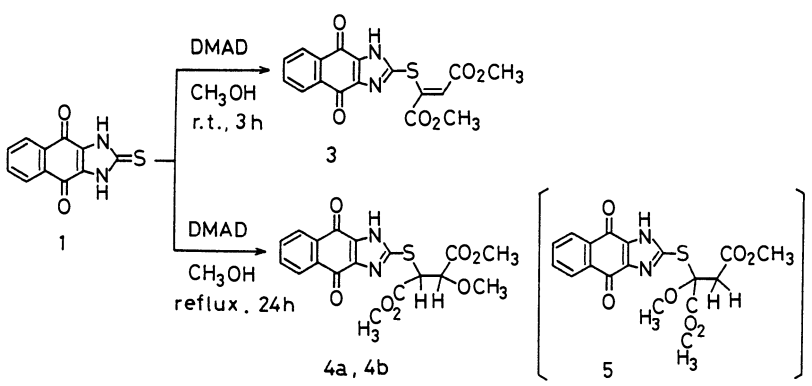
Tetracyclic compounds with a thiazolidinone or thiazinone ring fused to 1*H*-naphth[2,3-*d*]imidazole-4,9-dione were synthesized. Dimethyl 2-(4,9-dioxo-4,9-dihydronaphth[2,3-*d*]imidazol-2-ylthio)fumarate (**3**) was obtained by a reaction of 2,3-dihydro-2-thioxo-1*H*-naphth[2,3-*d*]imidazole-4,9-dione with dimethyl acetylenedicarboxylate in methanol. A ring-closure reaction of **3** in acetic anhydride was found to give selectively methyl (3,5,10-trioxo-2,3,5,10-tetrahydronaphth[2′,3′:4,5]imidazo[2,1-*b*]thiazol-2-ylidene)acetate, while, the cyclization of **3** in polyphosphoric acid afforded methyl 4,6,11-trioxo-6,11-dihydro-4*H*-naphth[2′,3′:4,5]imidazo[2,1-*b*]-thiazine-2-carboxylate.

1,4-Naphthoquinone derivatives fused with the azole ring have attracted much attention because of their physiological and coloring properties. However, a few reports[2)] have appeared in the literature which have described the synthesis of tetracyclic azole compounds. In our previous papers, we reported on the syntheses of imidazo[2,1-*b*]naphtho[2,3-*d*]thiazole-5,10-diones[3a)] and naphth[2′,3′:4,5]imidazo[2,1-*b*]thiazole-5,10-diones,[3b,c)] showing physiological activities. We then developed a convenient method for the synthesis of 2,3-dihydro-2-thioxo-1*H*-naphth[2,3-*d*]imidazole-4,9-dione (**1**). We were also interested in the syntheses of tetracyclic azole compounds, which may be easily available from compound **1**. This paper describes the preparation of tetracyclic azole compounds, fused thiazolidione or thiazinone ring from dimethyl 2-(4,9-dioxo-4,9-dihydronaphth[2,3-*d*]imidazol-2-ylthio)-fumarate (**3**), which was obtained by a Michael-type reaction of **1** with dimethyl acetylenedicarboxylate (DMAD). Furthermore, the effects of the quinone carbonyl groups on the cyclization reactions will be discussed.

Results and Discussion

A few reports[4)] concerning reactions of 2*H*-benzimidazole-2-thione (**2**) with DMAD have already appeared. A recent report by Wade[4a)] indicated that a reaction in methanol yields methyl 4-oxo-4*H*-[1,3]-thiazino[3,2-*a*]benzimidazole-2-carboxlate in one step. We first investigated the reaction of the thione **1** with DMAD by the method of Wade. When a solution of **1** with DMAD in methanol was stirred at room temperature for 3 h, the adduct **3** was isolated in 74% yield. A structural assignment for the product **3**, depending on the sulfur atom participates in the addition reaction, was accomplished through its ^{1}H NMR and IR spectra. The (*Z*)-geometry of **3**, which results from a trans addition, is assumed on the basis of the results of Hendrickson[5a)] and Truce[5b)] (Scheme 1). On the other hand, a reaction of **1** with DMAD at reflux temperature for 24 h gave yellow crystals **4a** (mp 171.0—172.0 °C, 11%) and **4b** (mp 131.0—132.0 °C, 15%). Also, compounds **4a** and **4b** were obtained from adduct **3** under the same conditions. The structures of diastereoisomers **4a** and **4b** formed by the addition of methanol to **3** were established on the basis of IR, ^{1}H NMR, and elemental analysis data. The structure of diastereoisomer **4b** was supported, rather than structure **5**, since there was little variation in the yield between **4a** and **4b**, and the proton coupling constant of **4a** and **4b** showed 3.5 and 5 Hz, respectively.

The reaction was carried out in the presence of sodium methoxide as a base in methanol, in order to



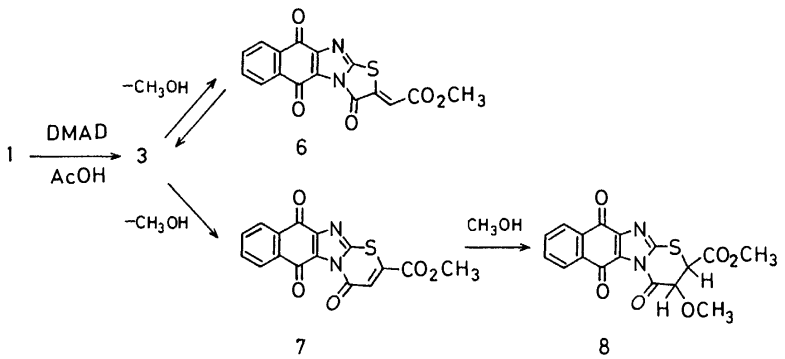
Scheme 1.

obtain cyclized compounds, i.e., methyl (3,5,10-trioxo-2,3,5,10-tetrahydronaphth[2′,3′ : 4,5]imidazo[2,1-*b*]thiazol-2-ylidene)acetate (**6**), methyl 4,6,11-trioxo-6,11-dihydro-4*H*-naphth[2′,3′ : 4,5]imidazo[2,1-*b*]thiazine-2-carboxylate (**7**). Compound **1** gave adduct **3** at room temperature for 30 min, but for prolonged reaction times compound **6** or **7** was not isolated but compound **1** formed by the methanolysis of **3** was recovered. These results could be explained in terms of the nucleophilicity of nitrogen in the imidazole ring being diminished by means of the electron-withdrawing character of the quinonoid moiety.

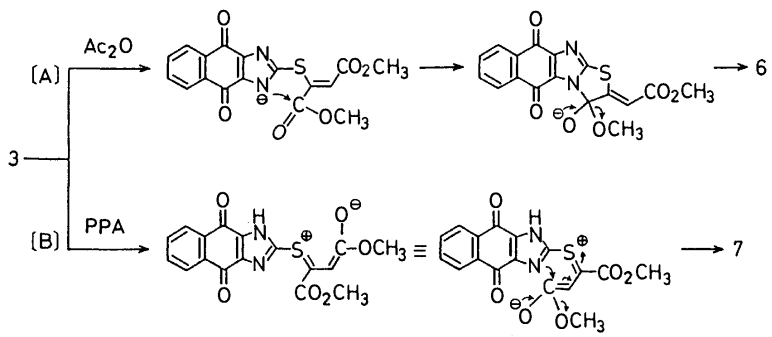
However, a mixture of **1** and DMAD in acetic acid was refluxed for 3 h to give the two isomers (**6** and **7**) in 22% yield, which could not be separated by column chromatography. The ^{1}H NMR analysis showed that **6** and **7** were produced in the ratio of 7 : 4. (Pure **6** and **7** were prepared from the adduct **3** individually as mentioned later.) In addition, when the reaction was carried out for 24 h, compound **8** (mp 209.0—210.0 °C) was unexpectedly obtained in 31% yield without the formation of **6** and **7**. The formation of **8** may involve the addition of methanol eliminated to the thiazinone ring of **7**. The position of the methoxyl group in compound **8** was determined by the ^{1}H NMR spectrum, which shows *vicinal* H_2 and H_3 protons at δ 5.98 and 5.07 ($J_{2,3}$=2 Hz), respectively. Furthermore, the H_7 proton of compound **8** appears at a lower field, compared with the other protons in the aromatic ring.[6] This downfield shift may be explained on the basis that the 4-oxo function is held in a rigid position, coplanar with and oriented toward the aromatic ring, thus exerting a deshielding effect on the H_7 proton. Secondly, the cyclization of adduct **3** using condensing agents[7,8] was investigated.

The solution of **3** in acetic anhydride was heated at 100 °C for 20 min to afford compound **6** in 42% yield. A prolonged reaction time did not show any increase in the yield of compound **6** nor in the formation of compound **7**. The formation of **6** might involve an attack of the nitrogen situated closely to the ester moiety (Scheme 3, route A). Under these conditions, using acetic anhydride acetylation on the nitrogen atom is postulated to be an initial reaction. It seems, however, that the acetylation does not occur because ethyl 3-(4,9-dioxo-4,9-dihydronaphth[2,3-*d*]imidazol-2-ylthio)acrylate (**9**) reacted unchanged in acetic anhydride, as will be mentioned later. On the other hand, the reaction of **3** in polyphosphoric acid (PPA) at 140—150 °C for 30 min gave compound **7** in 66% yield as the sole product. One possible mechanistic pathway to **7** is shown in route B of Scheme 3. Of particular interest is the selective formation into **6** and **7**. The structures of **6** and **7** were determined by the ^{1}H NMR spectra. In addition, to make this analysis more complete, we wanted to prepare a compound with a thiazinone ring like that of the structure of **7** by employing the alternative procedure shown in Scheme 4.

A suspension of **1** and ethyl propiolate in ethanol was refluxed for 5 h to afford a yellow compound **9a** (mp 260.5—262.0 °C) and an orange compound **9b** (mp 233.0—234.0 °C) in 29 and 48% yield, respectively. The



Scheme 2.



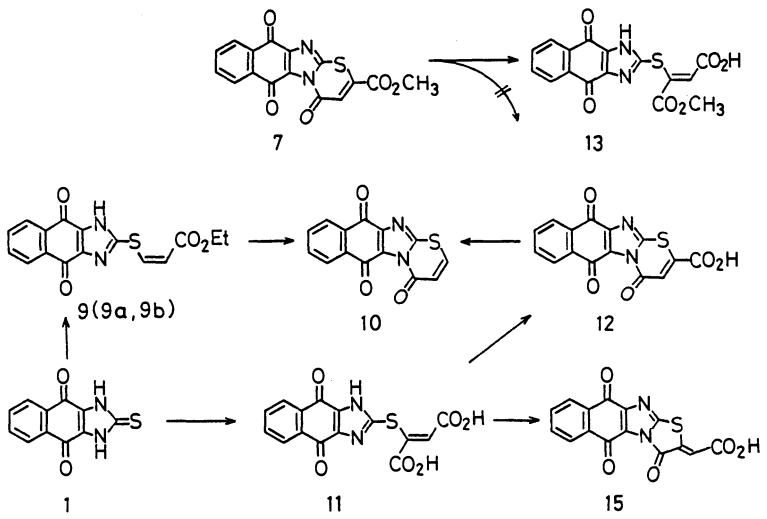
Scheme 3.

^{1}H NMR spectra of **9a** (*Z* form /trans addition product) and **9b** (*E* form /cis addition product) showed two doublets for the olefinic protons at δ 6.31 and 8.23 (J=10 Hz) and at 6.46 and 8.32 (J=16 Hz), respectively. The coupling constants were consistent with these geometorical assignments. The formation of the two isomers is of interest since the reaction of **1** with DMAD gave a single isomer (as mentioned above). No isomerization of **9a** to **9b** was observed under reflux in ethanol.

A cyclization of **9** is expected to produce compound **10** with a fused thiazinone ring. A suspension of **9a** or **9b** in PPA was heated to afford **10**: mp 265 °C (decomp); no reaction occurred in acetic anhydride. This result is in accord with the above-mentioned expectation. The synthesis of compound **10** via **12** from **7**, obtained by a reaction of **1** with DMAD, was tried. However, the hydrolysis of **7** with sodium hydroxide did not give compound **12** but, rather, compound **13** via a cleavage of the thiazinone ring; also, a reaction with hydrochloric acid or sulfuric acid did not give any isolable compound. The hydrolysis of **6**, as well as **7**, gave the monomethyl ester of fumaric acid (**14**). It is thus thought that the amide bond in the thiazolidinone or thiazinone ring was easily cleavaged since the quinone-carbonyl groups result in a decrease in the nucleophilicity of the nitrogen atom. Attempts to obtain compound **12** by the hydrolysis of **7** were unsucessful.

Compound **12** was finally obtained in PPA from adduct **11**, prepared by a reaction of **1** with acetylenedicarboxylic acid. A decarboxylation of **12** by thermolysis in biphenyl-diphenyl ether (1 : 3) at 250 °C afforded compound **10**, while the cyclization of **11** in acetic anhydride gave compound **15**. Furthermore, the $\nu_{C=O}$ of **12** and **15** were similar to those of **7** and **6**, respectively. These results suggest that compound **7** or **6** has a fused thiazinone or thiazolidinone ring, respectively.

The cyclization of the other related adducts in PPA and acetic anhydride are summarized in Table 1. It is of interest that the cyclization of **13** in acetic anhydride and of **14** in PPA gave the methyl esters, **6** and **7**, respectively, which might be formed via a further reac-



Scheme 4.

tion of **12** with methanol eliminated during the reaction.

In summary, tetracyclic azole compounds with a fused thiazolidinone or thiazinone ring were obtained from adduct **3**, prepared by the reaction of **1** with DMAD. It was found that the cyclization of **3** gave compound **6** or **7** by the use of acetic anhydride or PPA as an effective condensing agent, respectively.

Physiological evaluations of the synthesized compounds are currently under way and the results will be reported elesewhere.

Experimental

Measurements. The melting points were determined with a Yamato MP-1 apparatus and are uncorrected. IR spectra were taken on a JASCO IRA-1 spectrophotometer using KBr pressed discs. ^{1}H NMR spectra were recorded on a JEOL PS-100 (100MHz) spectrometer. Chemical shifts are given in ppm relative to tetramethylsilane as an internal standard. Mass specra were taken on a Hitachi RMU-7M mass spectrometer at an ion-source temperature of 200 °C and an ionizing potential of 75 eV.

Dimethyl 2-(4,9-Dioxo-4,9-dihydronaphth[2,3-*d*]imidazol-2-ylthio)fumarate (3). DMAD (0.65 g, 4.57 mmol) in 5 cm^3 of methanol was added dropwise with stirring to a suspension of the thione **1** (1.0 g, 4.35 mmol) in 15 cm^3 of methanol. After being stirred for 3 h at room temperature, the solid was collected by filtration, washed with ether, and dried to give 1.20 g (74%) of **3** (mp 204.0—206.0 °C). Recrystallization from ethyl acetate-hexane gave 0.74 g (46%) of pure **3** as yellow plates: mp 207.0—209.0 °C; IR 3215 (NH), 1715 and 1675 (C=O), 1600, 1418, 1337, 1275, 1220, 1065, and 980 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=3.57 (3H, s), 3.78 (3H, s), 6.86 (1H, s), 7.78—7.96 (2H, m), 7.98—8.18 (2H, m); MS *m/z* (rel intensity) 372 (M$^+$; 3), 342 (13), 341 (30), 340 (35), 283 (8), 282 (12), 281 (55), 260 (12), 259 (55), 258 (100), 255 (13), and 254 (50). Found: C, 54.91; H, 3.11; N, 7.58; S, 8.67%. Calcd for $C_{17}H_{12}N_2O_6S$: C, 54.84; H, 3.25; N, 7.52; S, 8.61%.

Methanol Addition to 3. A suspension of **3** (0.50 g, 1.34 mmol) in 20 cm^3 of methanol was heated at refluxing temperature for 24 h. After the mixture was allowed to stand overnight, the solid was collected by filtration, washed with ether, and dried to give 0.13 g of crude **4b** (mp 104.0—106.0 °C). Recrystallization from benzene gave 0.08 g (15%) of pure **4b** as a yellow powder: mp 131.0—132.0 °C; IR 3190 (NH), 2940 (CH), 1725 and 1670 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.52 (3H, s), 3.82 (3H, s), 3.85 (3H, s), 4.39 (1H, d, *J*=5 Hz), 4.85 (1H, d, *J*=5 Hz), 7.63—7.81 (2H, m), 8.05—8.30 (2H, m). Found: C, 53.60; H, 4.34; N, 6.41; S, 7.48%. Calcd for $C_{18}H_{16}N_2O_7S$: C, 53.47; H, 3.96; N, 6.93; S, 7.92%. To the mother liquor was added 100 cm^3 of water and was extracted with chloroform. The solution was evaporated under reduced pressure, giving 0.06 g (11%) of a yellow powder (mp 171.0—172.0 °C). Recrystallization from benzene-hexane gave 0.05 g of pure **4a**: mp 172.0—173.0 °C; IR 3300 (NH), 2920 (CH), 1740 and 1665 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.58 (3H, s), 3.80 (6H, s), 4.61 (1H, d, *J*=3.5 Hz), 5.02 (1H, d, *J*=3.5 Hz), 7.56—7.73 (2H, m), 8.00—8.18 (2H, m). Found: C, 53.49; H, 3.81; N, 6.93; S, 7.78%. Calcd for $C_{18}H_{16}N_2O_7S$: C, 53.47; H, 3.96; N, 6.93; S, 7.92%.

Methyl (3,5,10-Trioxo-2,3,5,10-tetrahydronaphth[2′,3′:4,5]-imidazo[2,1-*b*]thiazol-2-ylidene)acetate (6). A suspension of **3** (1.00 g, 2.69 mmol) in 20 cm^3 of acetic anhydride was heated at 100 °C for 20 min. After the mixture was allowed to come to room temperature, the solid was filtered off, washed with ether, and dried to give 0.38 g (42%) of **6** as yellowish green crystals. Recrystallization from chlorobenzene gave 0.23 g (25%) of pure **6**: mp 248.0 °C (decomp); IR 3050 (CH), 1770, 1725, 1680, and 1665 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.93 (3H, s), 7.32 (1H, s), 7.70—7.88 (2H, m), 8.12—8.32 (2H, m); MS *m/z* (rel intensity) 342 (M$^+$+2; 10), 341 (M$^+$+1; 9), 340 (M$^+$; 100), 312 (10), 309 (10), 283 (13), 282 (12), 281 (37), 258 (13), 255 (21), 254 (67). Found: C, 56.40; H, 2.34; N, 7.90; S, 9.24%. Calcd for $C_{16}H_8N_2O_5S$: C, 56.47; H, 2.35; N, 8.24; S, 9.42%.

Methyl 4,6,11-Trioxo-6,11-dihydro-4*H*-naphth[2′,3′:4,5]-imidazo[2,1-*b*]thiazine-2-carboxylate (7). A suspension of **3** (1.35 g, 3.63 mmol) in ca. 60 g of PPA was heated at 140—150 °C for 30 min. The reaction mixture was allowed to cool and then suspended in 300 cm^3 of water. The solid was collected by filtration, washed with acetone, and dried to yield 0.81 g (66%) of crude **7**: mp 245.0 °C (decomp). Recrystallization from 1-butanol gave 0.57 g (46%) of pure **7** as yellow needles: mp 255.0 °C (decomp); IR 3060 (CH), 1727, and 1680 cm^{-1} (C=O): ^{1}H NMR ($CDCl_3$) δ=4.06 (3H, s), 7.56 (1H, s), 7.68—7.84 (2H, m), 8.14—8.30 (2H, m); MS *m/z* (rel intensity) 342 (M$^+$+2; 30), 341 (M$^+$+1; 21), 340 (M$^+$; 100), 312 (10), 284 (16), 282 (10), 281 (20), 255 (12), 254 (24). Found: C, 56.26; H, 2.21; N, 8.21; S, 9.32%. Cacld for $C_{16}H_8N_2O_5S$: C, 56.47; H, 2.35; N, 8.24; S, 9.42%.

Methyl 3-Methoxy-4,6,11-trioxo-3,4,6,11-tetrahydro-2*H*-naphth[2′,3′:4,5]imidazo[2,1-*b*]thiazine-2-carboxylate (8). A suspension of DMAD (0.13 g, 0.91 mmol) in 3 cm^3 of acetic acid was added with stirring to a suspension of **1** (0.20 g, 0.87 mmol) in **2** cm^3 of acetic acid. After refluxing for 24 h, an insoluble solid was filtered off and the filtrate was left standing overnight in an ice box. The solid was collected by filtration, dried to give 0.18 g of yellow crystals and chromatographed on a Wakogel C-200 column using chloroform as an eluant. The evaporation residue from the second fraction gave 0.10 g (31%) of **8** as yellow needles: mp 209.0—211.0 °C; IR 2965 (CH), 1740, 1683, and 1660 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.86 (6H, s), 5.07 (1H, d, *J*=2 Hz), 5.98 (1H, d, *J*=2 Hz), 7.64—7.80 (2H, m), 8.04—8.17 (1H, m), 8.19—8.32 (1H, m). Found: C, 54.73; H, 3.10; N, 7.30; S, 8.13%. Calcd for $C_{17}H_{12}N_2O_6S$: C, 54.83; H, 3.25; N, 7.52; S, 8.61%.

Ethyl 3-(4,9-Dioxo-2-naphth[2,3-*d*]imidazolylthio)acrylate (9). Ethyl propiolate (0.24 g, 2.39 mmol) in 5 cm^3 of ethanol was added with stirring to a suspension of **1** (0.50 g, 2.17 mmol) in 10 cm^3 of ethanol and refluxed for 5 h. The solid was filtered off, washed with ether and dried to yield 0.68 g (95%) of **9**. Recrystallization from acetone gave 0.21 g (29%) of **9a** (*Z* form: mp 260.5—262.0 °C) as yellow needles. Crude **9a** was recrystallized from ethyl acetate-hexane to give pure **9a**: mp 263.0—264.0 °C; IR 3180 (NH), 3090, 3060, 2985 (CH), 1700, and 1680 cm^{-1} (C=O); ^{1}H NMR (DMSO-d_6) δ=1.24 (3H, t, *J*=7 Hz), 4.18 (2H, q, *J*=7 Hz), 6.31 (1H, d, *J*=10 Hz), 7.76—7.92 (2H, m), 8.01—8.15 (2H, m), 8.23 (1H, d, *J*=10 Hz); MS *m/z* (rel intensity) 329 (M$^+$+1, 1), 328 (M$^+$, 1), 285 (1), 284 (2), 283 (7), 282 (2), 267 (1), 258 (2), 257 (7), 256 (17), 255 (100), 254 (2), 231 (5), 230 (17). Found: C, 58.47; H, 3.55; N, 8.44; S, 9.82%. Calcd for $C_{16}H_{12}N_2O_4S$: C, 58.54; H, 3.66; N, 8.54; S, 9.77%. The filtrate of acetone recrystallization was evaporated and the residue was recrystallized from

chloroform and ethanol to give 0.34 g (48%) of **9b** (*E* form: mp 233.0—234.0 °C) as orange needles: IR 3125 (NH), 3085, 3035, 2985 (CH), 1695, 1685, and 1662 cm^{-1} (C=O); ^1H NMR (DMSO-d_6) δ=1.26 (3H, t, J=7 Hz), 4.24 (2H, q, J=7 Hz), 6.46 (1H, d, J=16 Hz), 7.84—8.05 (2H, m), 8.08—8.30 (2H, m), 8.32 (1H, d, J=16 Hz). Found: C, 59.32; H, 3.58; N, 8.58; S, 9.87%. Calcd for $C_{16}H_{12}N_2O_4S$: C, 58.54; H, 3.66; N, 8.54; S, 9.77%.

***4H*-Naphth[2′,3′:4,5]imidazo[2,1-*b*]thiazine-4,6,11-trione (10).** This compound as yellow needles: mp 265.0 °C (decomp) was obtained in 66% yield from **9a** using conditions similar to those described for **7**. IR 3030, 3000 (CH), 1715, and 1663 cm^{-1} (C=O); ^1H NMR (DMSO-d_6) δ=6.93 (1H, d, J=10 Hz), 7.81—7.95 (2H, m), 8.04—8.16 (2H, m), 8.35 (1H, d, J=10 Hz); MS m/z (rel intensity) 284 (M^++2, 12), 283 (M^++1, 21), 282 (M^+, 100), 255 (6), 254 (26), 238 (12), 230 (6). Found: C, 59.99; H, 1.98; N, 9.94; S, 11.34%. Calcd for $C_{14}H_6N_2O_3S$: C, 59.57; H, 2.13; N, 9.93; S, 11.35%.

2-(4,9-Dioxo-4,9-dihydronaphth[2,3-*d*]imidazol-2-ylthio)-fumaric Acid (11). Acetylenedicarboxylic acid (0.28 g, 2.45 mmol) in 5 cm^3 of acetonitrile was added to a suspension of **1** (0.50 g, 2.17 mmol) in 5 cm^3 of acetonitrile. After being stirred for 10 h at room temperature, the solid was collected by filtration, washed with ether, and dried to give 0.66 g (88%) of **11** as yellow crystals: mp 218.0 °C (decomp): IR 3300 (NH), 3050 (CH), and 1710—1670 cm^{-1} (C=O); ^1H NMR (DMSO-d_6) δ=6.90 (1H, s), 7.83—8.07 (2H, m), 8.08—8.27 (2H, m). Found: C, 52.56; H, 2.60; N, 7.61; S, 9.03%. Calcd for $C_{15}H_8N_2O_6S$: C, 52.33; H, 2.33; N, 8.14; S, 9.30%.

4,6,11-Trioxo-6,11-dihydro-4*H*-naphth[2′,3′:4,5]imidazo-[2,1-*b*]thiazine-2-carboxylic Acid (12). This compound as yellow plates: mp 252.0 °C (decomp) was obtained in 42% yield from **11** using conditions similar to those described for **7**. IR 3400 (OH), 1730 and 1673 cm^{-1} (C=O); MS m/z (rel intensity) 326 (M^+, 2), 285 (3), 284 (17), 283 (24), 282 (100), 256 (3), 255 (6), 254 (25), 239 (3), 238 (12), 232 (2), 231 (6), 230 (26). Found: C, 55.76; H, 1.61; N, 8.67; S, 10.12%. Calcd for $C_{15}H_6N_2O_5S$: C, 55.22; H, 1.84; N, 8.59; S, 9.82%.

(3,5,10-Trioxo-2,3,5,10-tetrahydronaphth[2′,3′:4,5]imidazo-[2,1-*b*]thiazol-2-ylidene)acetic Acid (15). A suspension of **11** (0.50 g, 1.45 mmol) in 5 cm^3 of acetic anhydride was heated at 100—110 °C for 10 min. The solid was collected by filtration, washed with ether, and dried to yield 0.36 g (76%) of **15** as yellow crystals: mp 255.0 °C (decomp): IR 3250—2800 (broad, OH), 1855, 1840, 1773, and 1670 cm^{-1} (C=O); MS m/z (rel intensity) 326 (M^+, 19), 284 (4), 283 (9), 282 (23), 256 (4), 255 (14), 254 (55), 238 (4), 232 (7), 231 (23), 230 (100).

Decarboxylation of 12. A suspension of **12** (0.10 g, 0.31 mmol) in 8.0 g of biphenyl-diphenyl ether (1 : 3) was heated at 250 °C for 10 min. The solid was collected by filtration, washed with hexane and ether, and dried to yield 0.07 g (80%) of **10**. This compound was identical as **10** on the basis of IR spectrum and mixed melting point.

(Received October 23, 1987)

Two endogenous γ-lactones, 3-hydroxy-4-butanolide (**1**) and 2-hydroxy-4-hydroxymethyl-4-butanolide (**2**) have been identified as substances that enhance, respectively, satiety and hunger by their effects on the feeding behavior and the central neurons of rats. To determine the stereochemistry of the physiologically active isomers, all the stereoisomers of these two lactones were synthesized and their effects on the feeding behavior and humoral factors were assessed by infusion into the rat third cerebroventricle. Among four isomers, (2*S*,4*S*)-2-hydroxy-4-hydroxymethyl-4-butanolide (**2a**) was most effective in elicitating the feeding and caused potent hypoglycemia with hyperinsulinemia. (*S*)-3-Hydroxy-4-butanolide (**1a**) suppressed the food intake more potently than the antipode and caused humoral responses reciprocal to those of **2a**. From these facts, it was concluded that **1a** and **2a** are physiologically active forms for conveying intrinsic signals of satiety and hunger to neurons in the hypothalamus.

Sufficient evidence has been accumulated to show that some endogenous blood factors such as glucose, free fatty acids, insulin, glucagon, and some peptides contribute to the induction of hunger and satiety.[1] In search of humoral factors that might be related to hunger and satiety, Oomura and coworkers analyzed human and rat blood serum, identified many organic acid derivatives in a gas chromatography-mass spectrometry system and investigated the effect of starvation on their blood serum levels.[2] From the observed patterns of changes of their serum levels at various stages of hunger, they postulated that two of them, structurally simple γ-lactones, 3-hydroxy-4-butanolide (**1**) and 2-hydroxy-4-hydroxymethyl-4-butanolide (**2**), might modulate food intake.[3] To confirm this assumption, they injected the synthesized lactones into the third cerebral ventricle of rats. Interestingly, the injection of 2.5 μmol of **1** suppressed both food intake and single neuron activity in the lateral hypothalamic area (LHA). The same treatment with **2** elicited feeding and increased LHA single neuron activity. From the high correlation between the feeding behavior and changes in LHA neuron activity, Oomura concluded that 3-hydroxy-4-butanolide (**1**) acts as an endogenous satiety substance and that 2-hydroxy-4-hydroxymethyl-4-butanolide (**2**) acts as a hunger substance.[4,5] The question arose as to which stereoisomers of the two possible isomers of **1** and the four isomers of **2** were really responsible for the suppression or elicitation of food intake. The question had been left unsolved since the materials used for the infusion tests were the racemate of **1** and the mixture of two pairs of diastereomers of **2**. Though the report that (*S*)-3,4-dihydroxybutanoic acid exists in human blood and urine suggests the possibility of (*S*)-3-hydroxy-4-butanolide (**1a**) to be the active isomer,[6] no report had been published about the natural occurrence of **2**.[7] It seemed to be impractical to isolate these two lactones from rat blood serum to decide their stereochemistry because of their paucity.[8] We decided to synthesize all the stereoisomers of these two lactones, **1a**, **b** and **2a**—**d**, in order to examine the effects on feeding activities and humoral factors of each isomer by direct infusion into rats. In this paper, we wish to report on the synthesis of these lactones and give a brief summary of the results of infusion test which led to the conclusion that (*S*)-3-hydroxy-4-butanolide (**1a**) and (2*S*,4*S*)-2-hydroxy-4-hydroxymethyl-4-butanolide (**2a**) are the physiologically active isomers.

Results and Discussion

Both optically active forms of **1** had been prepared by several methods.[9] Though a few reports had been published concerning the preparation of optically

† Present address: Takeda Chemical Industries, Ltd. 2-17-85 Jusohonmachi, Yodogawa-ku, Osaka 532.

active isomers of **2** from some sugars, these preparation methods did not necessarily seem to be suitable for obtaining all the stereoisomers.[10] We adopted a different approach. As common starting materials for the preparation of both lactones, we selected (*S*)-[11] and (*R*)-3,4-*O*-isopropylidene-3,4-dihydroxybutanal,[9b] (**3** and **3'**) which had been derived from (*S*)- and (*R*)-malic acid, respectively. For the preparation of **1a**, the method reported by Mori et al.[9b] was modified. (*S*)-

Aldehyde (**3**) was oxidized to a carboxylic acid (**4**) in 65% yield with $RuCl_3$ and $NaIO_4$ according to the method reported by Sharpless et al.[12] This made the very water-soluble product (**4**) isolation much easier compared with Mori's method which used Jones' reagent. Deprotection and lactonization with *p*-TsOH gave **1a** with $[\alpha]_D^{20}$ −75.7° in 94% yield. The same treatment of (*R*)-aldehyde (**3'**) gave **1b** with $[\alpha]_D^{20}$ +78.2°.

The preparation of **2a** and **2b** was carried out as follows. After some unsuccessful attempts to incorporate one carbon atom into (*S*)-aldehyde (**3**) by some reactions such as cyanosilylation,[13] vinylmagnesium bromide was treated with **3** to give a mixture consisting of two diastereomeric vinyl alcohols (**5**) in 95% yield. No essential diastereoselectivity was observed. No effort to increase the selectivity was carried out in this study. After benzoylation, the mixture (**6**) was subjected to double-bond cleavage with $RuCl_3$ and $NaIO_4$ by the method of Sharpless[12] to afford a mixture of two carboxylic acids (**7**) in high yield. All attempts to separate the two diastereomeric mixtures at stages **5**, **6**, and **7** were unsuccessful. However, the treatment of **7** with *p*-TsOH also gave a mixture of two diastereomeric benzoylated lactones in quantitative yield, which could be separated by preparative thin-layer chromatography (TLC) to obtain two benzoylated lactones, **8a** with $[\alpha]_D^{20}$ +21.1° and **8b** with $[\alpha]_D^{20}$ +41.9° in a ratio of 6 : 5. The hydrolysis and lactonization of **8a** and **8b** gave the desired optically active lactones, **2a** and **2b**, respectively, which showed $[\alpha]_D^{20}$ +23.2° and $[\alpha]_D^{20}$ +50.3°.

The stereochemistry of the benzoylated lactones, **8a** and **8b**, and the lactones, **2a** and **2b**, must be either (2*S*,4*S*) or (2*R*,4*S*), since the starting aldehyde (**3**) had the (*S*)-configuration. The nuclear magnetic resonance (NMR) signal of the proton at the 4-position of the benzoylated lactone, **8b**, appeared at 0.16 ppm down-field, compared with that of **8a**, while no significant difference of chemical shifts was observed between 4-positioned protons of **2a** and **2b**. This observation means that the 4-positioned proton of **8b** is apparently in the deshielding region of the benzoyloxyl group at the 2-position, and strongly suggests that the benzoyloxyl group and the proton at the 4-position locate at the same side of the lactone ring in **8b**. This means that **8b**, and then **2b**, have the (2*R*,4*S*)-configuration and that **8a** and **2a** have the (2*S*,4*S*)-configuration. This assignment was confirmed by reducing both lactones. As expected,[14] the lithium aluminum hydride reduction of **2a** gave an optically active tetrol (**9a**) with a (2*S*,4*S*)-configuration, which showed $[\alpha]_D^{20}$ −44.8° after benzoylation.[15] However, an optically inactive meso product (**9b**) was obtained by the reduction of **2b**, which did not show any essential optical rotation after benzoylation.[16] According to the same procedure started with (*R*)-aldehyde (**3'**), we obtained two lactones, **2d**, with a (2*R*,4*R*)-configuration and $[\alpha]_D^{20}$ −22.0° and **2c**, with a (2*S*,4*R*)-configuration and $[\alpha]_D^{20}$ −45.6°.

A preliminary comparison of 2-hydroxy-4-hydroxymethyl-4-butanolide in rat and human sera with the four lactone isomers of **2** was carried out after trimethylsilylation by gas chromatography. The retention time of the lactone from a natural source coincided with that of one pair of diastereomer, **2a** and **2d**, but no signal corresponding to that of **2b** and **2c** was observed in rat or human sera. This excluded the possibility of the stereochemistry of the natural lactone to be (2*R*,4*S*) or (2*S*,4*R*).

The effects of each isomer (**1a**, **1b**, **2a**, **2b**, **2c**, and **2d**) on feeding behavior and humoral factors were assessed by infusion into the rat third cerebroventricle in a laboratory of internal medicine I, faculty of medicine, Kyushu University. Details regarding the experiments and results are published elsewhere, but a brief summary of the results is given here. Adult male Wister King A rats were implanted with a cannula aimed at the third cerebroventricle[17] and used for tests after food and water intake, body weight and ambulatory activity returned to normal following surgery. Ten μl of a 0.25

Table 1. Ingestive and Ambulatory Behavior in a One-Hour Test Period Following Infusion of Each Stereoisomer of 2-Hydroxy-4-hydroxymethyl-4-butanolide (**2**) at Doses of 2.5 μmol or Phosphate Buffered Saline (PBS)

	2a	**2b**	**2c**	**2d**	PBS

Ambulation	+++	+			

a) $p<0.05$, compared to PBS.

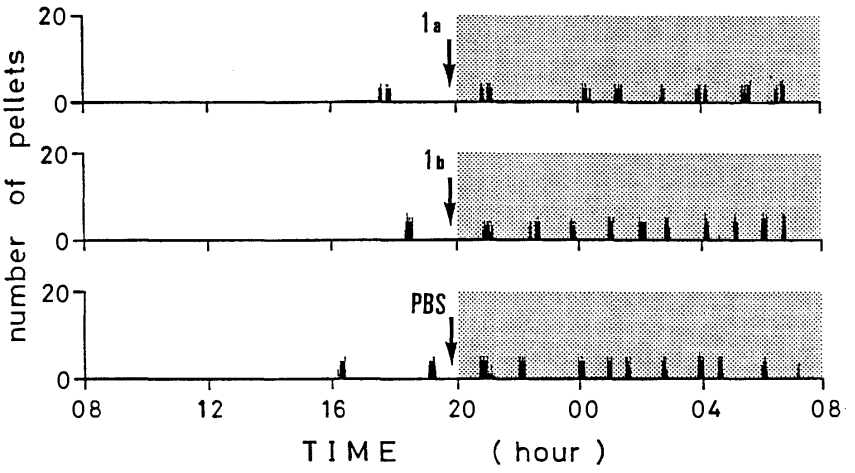

Fig. 1. Typical feeding patterns for rats after infusion of 2.5 μmol of **1a**, **1b**, and PBS solution into the third cerebro-ventricle. Shaded, dark time.

M solution (1 M=1 mol dm^{-3}) of each isomer in phosphate buffered saline (PBS. pH 7.3) was infused at a rate of 1 μl/1 min. The incidence and duration of eating and drinking, meal size, postprandial intermeal interval, and number of pellets and water-droplets ingested during meals[18,19] were recorded with a pellet-sensing eatometer and photoresistor drinkometer.[20] The ambulatory activity was measured by counting the crossings of 3×4 arrays of photobeams.[21] A statistical evaluation was carried out by either Fisher's exact probability test,[22] or by an analysis of the variance with replication. Typical feeding patterns after injection of **1a**, **1b**, and PBS are shown in Fig. 1. Compared with **1b** and PBS control groups which did not show any significant feeding suppression, the injection of **1a** potently suppressed food intake ($p<0.01$). In addition, **1a** prolonged the postprandial intermeal intervals and decreased the ambulatory bursts. The injection of **1a** raised the serum glucose level and decreased the serum insulin level over a 30-min testing period, while **1b** and PBS did not change these values.[23]

The injection of **2a** induced feeding more (75%) (Table 1), with a shorter latency to eat and a longer duration of meals than any other. Among the remaining isomers, **2b** elicited feeding (17%), but **2c**, **2d**, and PBS did not affect feeding. The intensity and frequency of ambulation were parallel to feeding. The effect to humoral factors was examined with **2a** and **2b**. In contrast to **1a**, injection of **2a** decreased the serum glucose level and raised the serum insulin level over a 30 min-testing period, but **2b** and PBS had no effect.[24]

From the facts described above, it seems quite reasonable to conclude that (*S*)-3-hydroxy-4-butanolide (**1a**) and (2*S*, 4*S*)-2-hydroxy-4-hydroxymethyl-4-butanolide (**2a**) are compounds that exist in human and rat sera and physiolosically active forms for conveying intrinsic signals to the LHA in feeding modulation.

Experimental

The ^{1}H NMR and ^{13}C NMR spectra were recorded at 90 and 25 MHz with a JEOL JNM-FX90Q spectrometer using Me_4Si as an internal standard. The IR spectra were taken with a Hitachi R-215 spectrometer. The MS spectra were taken with a JEOL-OISG-2 spectrometer. Optical rotations were measured on a Yanagimoto OR-50 polarimeter. Kieselgel F-254 (Merck) was used for column chromatography and glass plates precoated with silica gel 60F-254 (0.25 mm, Merck) were used for TLC and preparative TLC.

(*S*)-3-Hydroxy-4-butanolide (1a). A solution of $RuCl_3(H_2O)_n$ (4.8 mg) in water (0.5 ml) was added to a mixture of (*S*)-3,4-*O*-isopropylidene-3,4-dihydroxybutanal[11] (**3**, 150 mg, 1.04 mmol), $NaIO_4$ (912 mg, 4.27 mmol), CCl_4 (2 ml), CH_3CN (2 ml), and water (3 ml). The brown color of the solution changed to deep green immediately. The solution was stirred for 2 h at room temperature and the product was extracted with CH_2Cl_2. After drying and evaporation of the solvent, the residue was chromatographed on a short column of silica gel (AcOEt) to give a crude acid (**4**) as an oil (108 mg, 65%). This was used for the next step without further purification. *p*-TsOH (8.3 mg) was added to a solution of **4** (69.5 mg, 0.434 mmol) in CH_2Cl_2 (5 ml) and the solution was stirred at room temperature overnight. Triethylamine (7 μl) was added to the solution and the solvent was evaporated in vacuo. The residue was subjected to silica-gel chromatography (AcOEt) to give **1a** (42 mg, 94.8%). Colorless oil, $[\alpha]_D^{20}$ −75.7° (*c* 0.806, MeOH). (lit,[9d] $[\alpha]_D^9$ −85.9° (*c* 2.2, EtOH)). IR (neat) 3350, 1760, 1180, 1085, 1050, 992, and 965 cm^{-1}. ^{1}H NMR (CD_3OD) δ=2.45 and 2.68 (2H, H-2, and H-2′, dd and dd, $J_{2,2'}$=18 Hz, $J_{2,3}$=2.5 Hz, $J_{2',3}$=5.5 Hz), 4.2—4.8 (3H, H-3, H-4, and H-4′, m). ^{13}C NMR ($CDCl_3$) δ=37.45, 66.96, 76.14, and 177.03. Found: *m/z* 102.0311. Calcd for $C_4H_6O_3$: M, 102.0317. Found: C, 46.83; H, 6.01%. Calcd for $C_4H_6O_3$: C, 47.06; H, 5.92%.

(*R*)-3-Hydroxy-4-butanolide (1b) was prepared according to the same procedure starting with (*R*)-3,4-*O*-isopropylidene-3,4-dihydroxybutanal (**3′**).[9b] Colorless oil, $[\alpha]_D^{20}$ +78.2° (*c* 0.972, MeOH). (lit,[9b] $[\alpha]_D^{23}$ +77.3° (*c* 2.0, EtOH). Found: *m/z* 102.0317. Calcd for $C_4H_6O_3$: M, 102.0317. Found: C, 46.62;

H, 6.06%. Calcd for $C_4H_6O_3$: C, 47.06; H, 5.92%. The other spectroscopic properties are same as those of **1a**.

A Mixture of (3*S*,5*S*)- and (3*R*,5*S*)-5,6-*O*-Isopropylidene-1-hexene-3,5,6-triol (5). A solution of vinylmagnesium bromide which was prepared from vinyl bromide (1.11 ml, 15.8 mmol) and Mg (486 mg, 20 mmol) in THF (5 ml) was added dropwise to a cold solution (ice bath) of **3** (760 mg, 5.27 mmol) in THF (5 ml). The solution was stirred for 2 h at room temperature and quenched with an aqueous NH_4Cl solution. After extraction with ether and drying with $MgSO_4$, the evaporation of the solvent gave crude products. Purification by silica-gel chromatography (hexane : AcOEt =5 : 2) gave a mixture of (3*S*,5*S*)- and (3*R*,5*R*)-products (**5**, 865 mg, 95.3%). Colorless oil.[25] Found: C, 62.43; H, 9.11%. Calcd for $C_9H_{16}O_3$: C, 62.77; H, 9.36%.

A Mixture of (3*S*,5*S*)- and (3*R*,5*S*)-3-Benzoyloxy-5,6-*O*-isopropylidene-1-hexene-5,6-diol (6). Benzoyl chloride (507 μl, 4.35 mmol) was added to a solution of **5** (500 mg, 2.9 mmol) in pyridine (2.5 ml) at room temperature. After stirring overnight, the mixture was treated with an aqueous $NaHCO_3$ solution and the products were extracted with ether. After washing with an aqueous $NaHCO_3$ solution and water, the evaporation of the solvent gave a mixture of the benzoates (**6**) in a quantitative yield. The purification by silica-gel chromatography (CH_2Cl_2 : hexane=3 : 1) gave **6** as a colorless oil (788 mg, 98.2%).[25] Found: C, 69.72; H, 7.29%. Calcd for $C_{16}H_{20}O_4$: C, 69.55; H, 7.29%.

A Mixture of (2*S*,4*S*)- and (2*R*,4*S*)-2-Benzoyloxy-4-hydroxymethyl-4-butanolide (8a and 8b). A solution of $RuCl_3(H_2O)_n$ (3.1 mg) in water (1 ml) was added to a mixture of **6** (186 mg, 0.673 mmol), $NaIO_4$ (590 mg, 2.76 mmol), CCl_4 (2 ml), CH_3CN (2 ml), and water (2 ml). The solution was vigorously stirred at room temperature. The color of the solution changed to deep green immediately and to yellowish green after 2 h; the products were extracted with CH_2Cl_2. After drying with $MgSO_4$ and filtration through a short column of celite, evaporation of the solvent gave a mixture of acids (**7**, 187 mg, 95.4%). This was employed for the next step without further purification. *p*-TsOH (9.2 mg, 0.048 mmol) was added to a solution of **7** (141.8 mg, 0.482 mmol) in CH_2Cl_2 (3 ml) and stirred at room temperature overnight. After adding triethylamine (8 μl, 0.058 mmol), the solution was concentrated in vacuo and the residue was chromatographed on a short column of silica-gel (AcOEt) to give a mixture of lactones (120 mg, 75.5%). For the separation of **8a** and **8b**, the lactone mixture (400 mg) was subjected to preparative thin-layer chromatography (hexane : AcOEt=3 : 2). Since the difference of R_f-values was small (R_f-values, 0.1 and 0.15), development was repeated four times. From the lower zone, **8a** was obtained as colorless solids (120 mg). Mp 50—51 °C. $[\alpha]_D^{20}$ +21.1° (*c* 0.9, MeOH). IR (neat) 3490, 2950, 1790, 1721, 1278, 1200, 1130, and 718 cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.38 and 2.68 (2H, H-3, and H-3′, dt and ddd, $J_{3,3'}$=14.0 Hz, $J_{2,3}$=$J_{3,4}$=11.2 Hz, $J_{2,3'}$=9.8 Hz, $J_{3',4}$=6.8 Hz), 2.95 (1H, s, -OH), 3.72 and 3.96 (2H, H-5, and H-5′, ddd, $J_{5,5'}$=12.5 Hz, $J_{4,5}$=2.6 Hz, $J_{4,5'}$=4.8 Hz), 4.65 (1H, H-4, m), 5.78 (1H, H-2, dd, $J_{2,3}$=9.0 Hz, $J_{2,3'}$=10.5 Hz), 7.30—8.60 (5H, aromatic, m). Found: *m/z* 236.0819. Calcd for $C_{12}H_{12}O_5$: M, 236.0684. Found: C, 60.58; H, 5.22%. Calcd for $C_{12}H_{12}O_5$: C, 61.01; H, 5.12%. **8b** was obtained from the upper zone as colorless solids (100 mg). Mp 84—86 °C. $[\alpha]_D^{20}$ +41.9° (*c* 1.0, MeOH). IR (neat) 3450, 1785, 1765, 1610, 1460, 1390, 1365, 1292, 1235, 1000, 725, and 720 cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.48 and 2.78 (2H, H-3, and H-3′, dt and ddd, $J_{3,3'}$=14.0 Hz, $J_{2,3}$=$J_{3,4}$=8.9 Hz, $J_{2,3'}$=10.0 Hz, $J_{3',4}$=9.8 Hz), 2.90 (1H, s, -OH), 3.70 and 3.98 (2H, H-5 and H-5′, ddd, $J_{5,5'}$=12.5 Hz, $J_{4,5}$=2.9 Hz, $J_{4,5'}$=2.4 Hz), 4.81 (1H, H-4, m). Found: *m/z* 236.0717. Calcd for $C_{12}H_{12}O_5$: M, 236.0684. Found: C, 60.64; H, 5.21%. Calcd for $C_{12}H_{12}O_5$: C, 61.01; H, 5.12%.

(2*S*,4*R*)- and (2*R*,4*R*)-Isomers (8c and 8d) were prepared starting with (*R*)-aldehyde (**3′**) according to the same method described above. **8c**, Colorless solides. Mp 82—85 °C. $[\alpha]_D^{20}$ −42.1° (*c* 1.12, MeOH). Found: *m/z* 236.0647. Calcd for $C_{12}H_{12}O_5$: M, 236.0684. Found: C, 60.88; H, 5.22%. Calcd for $C_{12}H_{12}O_5$: C, 61.01, H, 5.12%. **8d**, colorless solids. Mp 49—50 °C. $[\alpha]_D^{20}$ −20.3° (*c* 0.87, MeOH). Found: *m/z* 236.0685. Calcd for $C_{12}H_{12}O_5$: M, 236.0685. Found: C, 60.91; H, 5.03%. Calcd for $C_{12}H_{12}O_5$: C, 61.01; H, 5.12%. The other spectroscopic properties of these lactones are same as those of **8b** and **8a**, respectively.

(2*S*,4*S*)-2-Hydroxy-4-hydroxymethyl-4-butanolide (2a). A mixture of **8a** (98.9 mg, 0.49 mmol), an aqueous NaOH solution (10%, 0.5 ml), and MeOH (0.5 ml) was stirred overnight at room temperature. The mixture was acidified with a diluted HCl solution and the solvents were evaporated in vacuo as much as possible. The product was extracted with AcOEt. After evaporation of the solvent, the residue was subjected to silica-gel chromatography (AcOEt) to give **2a** (40 mg, 72.2%) as a colorless oil. $[\alpha]_D^{20}$ +23.2° (*c* 3.61, MeOH). IR (neat) 3450, 2930, 1760, 1325, 1200, 1130, 995, 960, 900, and 803 cm^{-1}. ^1H NMR (CD_3OD) δ=1.93 and 2.53 (2H, H-3, and H-3′, dt and ddd, $J_{3,3'}$=12.3 Hz, $J_{2,3}$=$J_{3,4}$=10.6 Hz, $J_{2,3'}$=8.5 Hz, $J_{3',4}$=5.7 Hz), 3.59 and 3.81 (2H, H-5, and H-5′, ddd, $J_{5,5'}$=12.7 Hz, $J_{4,5}$=3.1 Hz, $J_{4,5'}$=4.8 Hz), 4.34—4.67 (2H, H-2, and H-4, m.). ^{13}C NMR (CD_3OD) δ=33.48, 63.76, 69.04, 78.48, and 178.59. Found: C, 44.92; H, 6.03%. Calcd for $C_5H_8O_4$: C, 45.46; H, 6.10%.[25]

(2*R*,4*S*)-, (2*S*,4*R*)-, and (2*R*,4*R*)-Isomers (2b, 2c, and 2d) were prepared by the same procedure described above from **8b**, **8c**, and **8d**, respectively. **2b**, colorless oil. $[\alpha]_D^{20}$ +50.3° (*c* 1.75, MeOH). IR (neat) 3400, 2950, 1775, 1640, 1460, 1357, 1205, 1115, 980, and 803 cm^{-1}. ^1H NMR (CD_3OD) δ=2.12 and 2.48 (2H, H-3, and H-3′, dt and ddd, $J_{3,3'}$=13.1 Hz, $J_{2,3}$=$J_{3,4}$=8.3 Hz, $J_{2,3'}$=8.5 Hz, $J_{3',4}$=3.2 Hz), 3.58 and 3.76 (2H, H-5, and H-5′, ddd, $J_{5,5'}$=13.1 Hz, $J_{4,5}$=2.6 Hz, $J_{4,5'}$=3.4 Hz), 4.47—4.73 (2H, H-2, and H-4, m). ^{13}C NMR (CD_3OD) δ=33.93, 64.35, 68.19, 79.59, and 179.17. Found: C, 45.56; H, 6.19%. Calcd for $C_5H_8O_4$: C, 45.46; H, 6.10%.[25] **2c**, colorless oil. $[\alpha]_D^{20}$ −45.6° (*c* 1.60, MeOH). Found: C, 44.99; H, 6.21%. Calcd for $C_5H_8O_4$: C, 45.46; H, 6.10%.[25] **2d**, colorless oil. $[\alpha]_D^{20}$ −22.2° (*c* 1.26, MeOH). Found: C, 44.96; H, 6.33%. Calcd for $C_5H_8O_4$: C, 45.46; H, 6.10%.[25] The other spectroscopic properties of **2c** and **2d** are the same as those of **2b** and **2a**, respectively.

(2*S*,4*S*)-1,2,4,5-Tetrakis(benzoyloxy)pentane (10a). A solution of **2a** (20 mg, 0.15 mmol) in THF (2 ml) was added to a solution of LAH (30 mg, 0.79 mmol) in THF (2 ml) and the mixture was stirred for 2 h at room temperature. The mixture was decomposed by the addition of a few drops of water and filtered and the residue was extracted thoroughly with a 2 : 1 mixture of THF and water. The concentration of the combined filtrate and extracts gave the residue which was dissolved in pyridine (1 ml) and treated with benzoyl chloride (120 mg, 0.85 mmol) overnight at room temperature. The mixture was treated with water, extracted with ether, and washed with diluted HCl and Na_2CO_3 solutions. After

drying over Na_2SO_4, removing the solvent gave a residue which was purified by silica-gel chromatography to give **10a** as a gum (59 mg, 76%). (lit,[26] a gum.) $[\alpha]_D^{20}$ −44.8° (*c* 1.12, AcOEt). ^{1}H NMR ($CDCl_3$) δ=2.39 (2H, H-3, and H-3′, dd, $J_{2,3}=J_{3,4}$=6.1 Hz, $J_{2,3'}=J_{3',4}$=7.0 Hz), 4.60 (4H, OCH_2×2, m), 5.70 (2H, H-2, and H-4, m), 7.20—8.10 (20H, aromatic).

***(meso)*-1,2,4,5-Tetrakis(benzoyloxy)pentane (10b)** was prepared according to the same procedure. Colorless solids. Mp 98—101 °C. (lit,[16] mp 104—105 °C). $[\alpha]_D^{20}$ ±0°. ^{1}H NMR ($CDCl_3$) δ=2.41 (2H, H-3, and H-3′, m), 4.60 (4H, OCH_2×2, m), 5.70 (2H, H-2, and H-4, m), 7.20—8.10 (20H, aromatic).

The authors wish to express their sincere thanks to Professor Yutaka Oomura, Faculty of Medicine, Kyushu University, for giving them the opportunity to carry out this study. We are indebted to Center of Advanced Instrumental Analysis Kyushu University for the measurement of mass spectroscopy.

(Received October 23, 1987)

The predominance of planar C-H/O=C approached conformations in methyl 3-formyl-2-, 2-formyl-3-, and 4-formyl-3-thiophenecarboxylates was shown experimentally by the chemical shifts of the formyl protons, the unusually large $^1J_{CH}$ values of the formyl groups, and their infrared C-H and C=O absorptions. The stability of the C-H/O=C approached conformation was attributed to the hydrogen-bond-like interaction between the two groups. The considerably large positive bond population between non-bonded H/O and the additional charge separation indicated by the MNDO calculations supported the presence of the intramolecular hydrogen bond.

In the course of our investigations of thiophene derivatives, we have synthesized a variety of thiophenecarbaldehydes and studied their NMR spectroscopic behaviors. The ^1H and ^{13}C chemical shifts, as well as the coupling constants ($^1J_{CH}$ and $^3J_{HH}$), of several series of substituted 2- and 3-thiophenecarboxylic[1,2] and β-(2- and 3-thienyl)acrylic esters[3,4] were measured and correlated with each other and with the substituent electronic parameters. Some formyl esters were included in these series of thiophene derivatives. As they are capable of taking a C-H/O=C approached conformation in which an intramolecular C-H/O hydrogen bond may be persistent, the possibility of such intramolecular interaction was further examined.

The existence of intramolecular CH/O hydrogen bonds has been suggested by several investigations. Pinchas insisted on the existence of intramolecular C-H/O hydrogen bonds in *o*-nitrobenzaldehyde and related compounds on the basis of their unusually high formyl C-H frequencies.[5] On the other hand, hydrogen bonds involving C-H groups have been studied theoretically[6] and the important role of the electrostatic factor has been pointed out.[7] The formyl group is expected to be a strong C-H donor because the hydrogen is linked to a very electronegative carbonyl carbon atom; therefore, the C-H bond is expected to have some ionic character. Thus, the possibility of an intramolecular hydrogen bonding of this sort in these and related formyl esters will be discussed in this paper on the basis of NMR and infrared spectroscopic evidence and also on the basis of the theoretical consequences from molecular orbital calculations.

Experimental

Spectral Measurements. The thiophenecarbaldehydes were prepared according to the methods reported previously.[1,2,8-12]

The NMR spectra were recorded on a JEOL FX-90Q spectrometer. The samples were dissolved in chloroform-*d*, the concentrations of the solutions being adjusted to approximately 0.6 mol dm^{-3}. The chemical shifts were measured from the internal TMS reference at the probe temperature. The ^{13}C spectra were collected by using a 30° pulse, 16k data points, and a 4.5 or 5.0 kHz sweep width. The ^{13}C-^1H coupling constants were obtained by measurements using a pulse sequence which allowed us to observe the non-decoupled spectra while maintaining a full NOE. (Pulse conditions: 45° pulse, 3 repetition rates, 16k data points, and 450 Hz sweep width.)

The infrared spectra were recorded on a Perkin-Elmer 257 spectophotometer in CCl_4.

MNDO Calculation.[13,14] The calculations were carried out by the use of the MOPAC program package[15] on a HITAC M-280H computer at the Computer Center of the University of Tokyo. A routine calculation gave the electronic energy, the density matrix (electron densities and bond orders), the eigen values and eigenvectors of MO's, and the other necessary quantities. The geometrical parameters of the stable conformations for MNDO calculations were cited from the Cambridge XDC Data Base whenever available. The s characters of the C-H bonds were computed from appropriate MO coefficients.

Results and Discussion

The ^{13}C NMR chemical shifts of substituted thiophenecarbaldehydes (**1a—4a**) were assigned on the basis of (i) the difference in the line intensities of the protonated and quarternary carbons, (ii) the substituent effect on the chemical shifts,[16,17] and (iii) the characteristics of the ^{13}C-^1H coupling constants, as reported previously.[18] The results are given in Tables 1—3.

A glance of the tables will show that the formyl $^1J_{CH}$ values of methyl *o*-formylthiophenecarboxylates are considerably larger than those of the other thiophenecarbaldehydes which have no neighboring methoxycarbonyl groups. Thus, the ^1J values of methyl 2-formyl-3-, 3-formyl-2-, and 4-formyl-3-thiophenecarboxylates (**1a**, **3a**, and **3b**) are 191.5, 188.9, and 187.5 Hz, respectively, larger than those of methyl 5-formyl-3-, 5-formyl-2-, and 4-formyl-2-thiophenecarboxylates (**1b**,

1c, and **3c**) by ca. 10 Hz. We compared the ring $^1J_{CH}$'s in order to examine the effects of substituents. All the other one-bond spin-coupling constants, $^1J_{C(2)\text{-}H(2)}$, $^1J_{C(3)\text{-}H(3)}$, $^1J_{C(4)\text{-}H(4)}$, and $^1J_{C(5)\text{-}H(5)}$, are affected by the position and the nature of ring substituents to a considerably less extent than in the cases of the formyl $^1J_{CH}$'s of the *o*-formylesters **1a**, **3a**, and **3b**. The very remarkable fact about the $^1J_{CH}$ values of other aldehydes is that the $^1J_{CH}$'s of vicinally methyl-substituted thiophenecarbaldehydes **2a**, **4a**, and **4b** have almost the same values as those of other methyl-substituted thiophenecarbaldehydes void of a vicinal methyl group in spite of the fact that the formyl C-H group is located in the proximity of the methyl group on the neighboring carbon atom and is susceptible to the effect of steric compression. After all, the $^1J_{CH}$ values larger than normal were observed only with formylthiophenecarboxylates carrying formyl and alkoxycarbonyl groups on adjacent carbon atoms. This fact apparently contradicts the hypothesis that the larger $^1J_{CH}$ value is

ascribable to the steric compression, though it may be relieved partly in the methylaldehydes (**2a**, **4a**, and **4b**) by taking the D conformer, in which the formyl hydrogen is located just in-between the two syn-clinal methyl hydrogens, in order to avoid the very large effect of steric hindrance; the reason for this anomaly might be found in the preferred C-H/O approached conformation of these aldehydes. Thus, an alternative interpretation which ascribes the larger $^1J_{CH}$ value to a specific interaction became necessary in order to account for the phenomenon. By analogy with the cases of other hydrogen atoms attached to electronegative carbon atoms such as those in chloroform and in hydrogen cyanide, a hydrogen-bond-like interaction is suspected to be operating in these circumstances where the C-H group is opposed to the carbonyl oxygen and is capable of forming a planar six-membered chelate ring by the interaction.

Thus, MNDO calculations were carried out on these aldehydes in order to gain some insight into the nature of the interaction involved and the bonds concerned and in order to reproduce the stability of the C-H/O=C approached conformations. The stable conformations and their populations, as estimated by means of MNDO calculations are given in Table 4 for a series of methoxycarbonyl- and methyl-substituted thiophenecarbaldehydes. The populations of the C-H/O approached conformers (A—C) were calcu' lated to be 96, 95, and 91% for **1a**, **3a**, and **3b**, respectively; they were expected to be privileged with the aldehydes carrying a vicinal methoxycarbonyl group.

In contrast, the calculated energies of all the possible planar conformers of the other methyl formylthiophenecarboxylates which have no formyl group in the neighborhood of the ester group were nearly equal at the ambient temperature (i.e., the variation was less than, or comparable to, the kinetic energy for thermal motion, kT, at that temperature). Thus, the aldehydes can be expected to exist as a mixture of several

conformers.

The percent s-character of the bonding orbital of the carbon atom which forms the formyl C-H bond (ρ_{CHO}) was estimated from the observed one-bond C-H coupling constants by the equation of Muller and Pritchard;[19] it is shown in Table 5, together with the values obtained from the MNDO calculations. The MNDO calculations gave a higher s-character of the carbon orbital for the C-H/O approached conformations of the *o*-formyl esters (**1a**, **3a**, and **3b**) than the others, accounting for the unusually large ^1J values observed with these aldehydes. Because of the high s-character of its bonding orbital, the formyl carbon becomes more electronegative, increasing the polarity of the formyl C-H bond. This should favor the attractive and hydrogen-bond-like interaction between the formyl C-H bond and carbonyl oxygen to a considerable extent. In turn, the attractive C-H/O interaction can be the driving force to force the *o*-formyl esters to take the C-H/O approached conformations (A—C).

The chemical shifts in Table 3 also suggest the predominance of the C-H/O approached conformations in the *o*-formyl esters. The ^{1}H chemical shifts of the formyl protons of **1a**, **3a**, and **3b** were observed at δ 10.65, 10.62, and 10.50, respectively.[1,2] These chemical shifts are about 0.7 ppm downfield from those of the non-adjacently functionalized formylthiophenecarboxylates. The downfield shift was observed also with the formyl ^{13}C chemical shifts of these aldehydes; it is ascribable to the strong magnetic anisotropy effect on the nucleus placed opposite to the robe of lone pair electrons of the carbonyl group.[20] In this way, the theoretically predicted predominance of the C-H···O approached conformers is supported experimentally by the unusually low ^{1}H NMR chemical shifts of the formyl protons of these aldehydes. The situation is very favorable to the hydrogen-bond-like interaction between the formyl C-H and the carbonyl groups. In fact, the downfield shifts are usually observed with both intra- and intermolecularly hydrogen-bonded

hydroxyl and amino protons and are used frequently as a criterion to prove the presence of hydrogen bonds.

Hydrogen bonds involving OH and NH groups as proton donors have been studied most frequently and most extensively by means of infrared spectroscopy.[21] Hvdrogen bond formation causes a significant low frequency shift of the OH or NH stretching absorption. The hydrogen bond shift of the X-H stretching band is very often accompanied with a considerable broadening and an increase in the intensity of the band, which can be another clue to detect the presence of a hydrogen bond.[22] Thus the infrared spectra of these formyl esters were measured with the aim of proving the presence of C-H/O hydrogen bonds.

Many aldehydes have been shown by the extensive study by Pozefsky and Coggeshall[23] to have two CH stretching absorption bands near 2720 and 2820 cm^{-1}. The doubling of the absorption band has been

ascribed to a Fermi resonance between the CH-stretching vibration and the first overtone of the CH-deformation vibration. The higher-frequency band has been shown to have the main CH-stretching character.[24] For this reason, our attention was focused on the CH bands above 2800 cm^{-1}. In contrast to the cases of the O-H/X and N-H/X hydrogen bonds, high frequency shifts of CH-stretching absorptions have been reported with some intramolecularly hydrogen bonded CH groups. For instance, the formyl CH group of *o*-nitrobenzaldehyde has been shown to absorb at 2860 cm^{-1}, about 50 cm^{-1} higher than unsubstituted benzaldehyde (2807 cm^{-1}).[5] Similar high-frequency shifts have been observed with the formyl esters **1a**, **3a**, and **3b**, which absorb at 2896, 2904, and 2891 cm^{-1}, respectively (Table 6). The frequencies are more than 50 cm^{-1} higher than those of the other aldehydes in Table 6.

The high-frequency shift is plausible if a C-H bond can interact attractively with an electronegative group (X) without weakening itself, i.e., without a decrease in its stretching force constant (k_{CH}), because the vibrational frequency of a linear (or, when the C-H···X angle is larger than 90°) C-H/X system can be expected to become higher than the isolated C-H bond when k_{CH} remains constant.[25] The effect of the steric compression of the CH bond may also operate. However, it cannot be very significant, since the steric crowdedness around the formyl hydrogen can easily be relaxed by tilting itself towards outside the plane of the thiophene ring. 3-Methyl-2-thiophenecarbaldehyde absorbs at 2819 cm^{-1}, and the effect of possible steric compression is not reflected significantly in the frequency of its formyl absorption band, even if the steric crowdedness of a same magnitude as in the formyl esters **1a**, **3a**, and **3b** can be expected from their molecular models.

The MNDO calculations[13-15] (Table 7) helped us to gain an insight into this apparently contradictory shift of the CH-stretching bands of the *o*-formyl esters. The nonbonded H···O bond populations in the C-H/O approached conformations of the formyl esters **1a**, **3a**, and **3b** range from 4.7×10^{-3} to 6.7×10^{-3}. These populations are comparable to the total CH_3···Ph bond population (4.79×10^{-3}) in the CH_3/pi interacted conformation of 1-phenyl-2-propanol and to about half of the OH···Ph bond population (1.62×10^{-2}) of the OH/π interacted conformation of the same molecule.[26] As both the OH/π and CH/π interactions have been well characterized and supported by experimental evidence, the hydrogen-bond-like C-H/O interaction in the *o*-formyl esters becomes more realistic.

The C-H and C=O bond populations of the formyl group seemed unperturbed by the C-H/O=C interaction. In the cases of all three *o*-formyl esters, the C-H bond populations tend to increase when compared with those of the corresponding next stable conformers. However, the increase is very slight and is assumed to be negligible when the reference is extended to all the formyl esters investigated. At any rate, there is no evidence for the decrease in the C-H bond population such as is often observed with the OH and NH bonds under similar circumstances. This gave a very clear explanation for the high frequency shift of the C-H stretching vibration in the C-H/O interacted system. On the other hand, the bond population of the hydrogen-accepting carbonyl group in the methoxycarbonyl moiety was shown to decrease considerably. The decrease was not very large, but it was meaningful when the populations were compared with those of other conformations and of other isomeric formyl esters. As to the hydrogen-accepting carbonyl group of the methoxycarbonyl moiety, the atomic populations of both carbon and oxygen vary in the direction of increasing their polarity, i.e., decreasing at the originally positive carbon atom and increasing at the negative oxygen atom in the C-H/O hydrogen-bonded conformer, when compared with the other less favorable conformer. In cooperation with the change in the charge distribution in the ester carbonyl group, the hydrogen-donating C-H bond becomes more polarized without perturbing the formyl carbonyl group appreciably. Thus, the attractive interaction was shown to originate both from the delocalizative contribution revealed as the positive bond population of nonbonded H···O and from the electrostatic contribution caused by the enhanced polarization of the originally dipolar C=O and C-H groups. Both the delocalizative and electrostatic stabilzations have been known as theoretical criteria for hydrogen bonding. In conclusion, the C-H/O attractive interaction involved have been shown to be hydrogen-bond-like in their nature both by the experimental evidence and by the theoretical consequences.

We wish to thank Mr. Hitoshi Shimazaki for his assistance in the MNDO calculations. Part of this work was supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science, and Culture, to which the authors are also grateful.

The 2- or 6-(α-Hydroxyalkyl- and α-Oxoalkyl)-5,8-dimethoxy-1,4-naphthoquinones from the Oxidative Demethylation of 2-(α-Hydroxyalkyl- and α-Oxoalkyl)-1,4,5,8-tetramethoxynaphthalenes with Cerium(IV) Ammonium Nitrate, and the Further Demethylations to Naphthazarins[1)]

Yasuhiro TANOUE and Akira TERADA*
Department of Chemistry, Kyushu Institute of Technology, Tobata, Kitakyushu, Fukuoka 804
(Received October 28, 1987)

Oxidative demethylation of 2-(α-hydroxyalkyl- and α-oxoalkyl)-1,4,5,8-tetramethoxynaphthalene with $(NH_4)_2Ce(NO_3)_6$ gave two isomeric dimethoxynaphthoquinones: 2-substituted and 6-substituted 5,8-dimethoxy-1,4-naphthoquinones. Further demethylations of the former isomers to the corresponding dihydroxynaphthoquinones required an AgO-40%HNO_3 reagent, while the latter isomers needed $AlCl_3$ as the demethylation reagent. Some comments regarding the mechanism of these oxidative demethylations with $(NH_4)_2Ce(NO_3)_6$ are given.

Naphthoquinones occur widely in nature among microorganisms and fungi,[2)] and have been studied regarding their colors and structures[3)] by many investigators. These days, many people are placing their hopes on such physiological activities[4)] as antitumor and antibiotic actions. Recently, Isayama et al.[5)] have applied for many patents for 5,8-dihydroxy-1,4-naphthoquinones as drugs for thrombosis, delayed hypersensitivity, and the healing of wounds.

Since our synthetic studies of naphthoquinone derivatives started, many problems have often occurred concerning the demethylation process of polymethoxynaphthalenes to hydroxynaphthoquinones. Therefore, the purpose of the present investigation was to search for a suitable reagent for a complete methoxyl cleavage of polymethoxynaphthalene intermediates. Although many reports[6)] have already appeared concerning demethylation, for example, on simple methyl ethers such as anisole, *p*-dimethoxybenzene, and monomethoxynaphthalene, no information in the literature has been found concerning the tetramethoxynaphthalenes, which we will report here.

It has been found by us that the demethylation of 1,4,5,8-tetramethoxynaphthalene with boron tribromide easily give naphthazarin.[7)] However, the treatment of the 2-substituted 1,4,5,8-tetramethoxynaphthalenes with boron tribromide or trimethylsilyl iodide gave no any desirable product, but, rather, only unidentified polymeric colored materials.

Demethylations of them with cerium(IV) ammonium nitrate[8)] (CAN) were successful and gave two isomeric dimethoxynaphthoquinones.

Further demethylation of them to the corresponding naphthazarins required AgO-40%HNO_3 or $AlCl_3$.

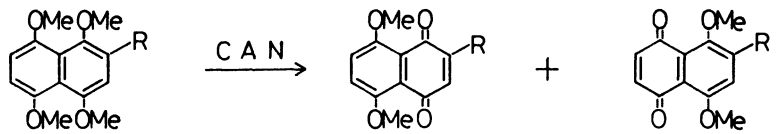
Fusarubin,[9)] Erythrostominone,[9)] Purpuromycin,[10)] and Fredericamycin A[11)] are new series of naphthazarin antibiotics.

Knowledge and information concerning demethylation, and the products obtained here, will generally be applicable for the synthesis of the above-mentioned naphthazarin antibiotics.[12)]

Results and Discussion

The demethylation of 2-substituted 1,4,5,8-tetramethoxynaphthalene (**1—9**) with 2.5 equiv of CAN usually gave two isomeric products, 2-substituted and 6-substituted 5,8-dimethoxy-1,4-naphthoquinones (former is named as type A and latter as type B) (Scheme 1, Table 1). The product mixture of A and B could be separated by silica gel or alumina column chromatography, and eluted by chloroform in the order of B and A.

Identifications of these naphthoquinone isomers were easy by ^1H NMR. The signals of their quinone ring protons were always observed more upfield than those of the benzene ring protons (Chart 1).[3a)] For example, in 5,8-dimethoxy-1,4-naphthoquinone (**1a**), the proton signals due to the quinone ring were observed at δ 6.77 (lit,[3a)] 6.75) and the benzene ring protons were at δ 7.32 (lit,[3a)] 7.31). A quinone ring proton of type A showed an allylic coupling with the



1 - 9 Type A 1a - 9a Type B 2b - 9b

Scheme 1.

protons at the α-positions of the side chain. For instance, the C_3-proton in 2-hydroxymethyl-5,8-dimethoxy-1,4-naphthoquinone (**2a**) showed a sharp triplet (J=1.6 Hz), clearly showing a coupling with two methylene protons of the hydroxymethyl side chain (Chart 2).

From Table 1, it can be seen that upon the demethylation of 2-substituted 1,4,5,8-tetramethoxynaphthalenes with CAN, substrates having electron-donating α-hydroxyalkyls gave, principally, type-A quinones; the minors were type-B. On the other hand, a substrate having electron-withdrawing an acetyl or a formyl group resulted in the formation of type-B, preferentially. These results suggested that CAN chose its target and attacked at the carbon atom having the highest electron density among the C_1, C_4, C_5, and C_8 (Table 2).

are shown in Table 2. In the compounds **2—7** of the electron-donating groups, the C_1s were shielded to an extent of about 5 ppm; inversely in **8** and **9** of the electron-withdrawing groups, the C_1s were deshielded to 1.8 and 5.5 ppm, respectively.

Our study on the correlation between Tables 1 and 2 resulted in the following conclusions. The carbon atom having the highest electron density among the C_1, C_4, C_5, and C_8 (namely, the carbon atom which was observed[13] at the most upfield), will receive the CAN-attack, and the para positional methoxyl group will immediately suffer the next oxidative demethylation to form dimethoxynaphthoquinones. The obtained dimethoxynaphthoquinones should not be affected by CAN any more because of their two carbonyls (as described later in this text). This conclusion will be supported by the fact that the demethylation of tetramethoxynaphthalene to dimethoxynaphthoquinone required 2 molar equiv of CAN (Table 3), and the use of any excess amount of CAN resulted only in the formation of dimethoxynaphthoquinone, with no other possible product such as mono-, tri-, and tetrahydroxylated naphthalenes.

Castagnoli et al.[8] studied the demethylation of 1,4-dimethoxy-2,3,5,6-tetramethylbenzene (**10**) with CAN in $H_2{}^{18}O$ and proved the fact that the product, quinone **12**, received two heavy oxygen atoms in their carbonyls from the heavy water medium. They proposed a demethylation mechanism (Scheme 2) in which a pathway through intermediate **11** is shown. However, they did not discuss the more detailed reaction mechanism.

Table 3. Demethylation of 2-Formyl-1,4,5,8-tetramethoxynaphthalene **9** with Various Amounts of CAN

1.5	68+16[a]
2.0	81
2.5	85
3.0	80
5.0	79
10.0	73

a) The recovery of **9**.

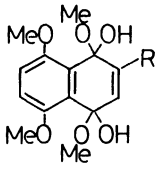
In our case, we also suppose two kinds of intermediates: one is **16** when the substituent R is electron-donating, and the other is **20** when R is electron-withdrawing (Chart 3).

The mechanism of the side-chain oxidation of alkylated aromatic hydrocarbons with CAN has been well established by Baciocchi et al.[14] There is no doubt that the first step of the reactions on toluene, for example, is a formation of the radical cation:

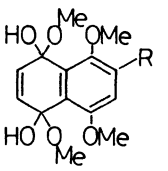
$$ArCH_3 + Ce^{IV}NO_3 \rightarrow ArCH_3^{\ddagger} + Ce^{III}NO_3$$

By analogy with their result, we supposed that the compounds **2—7** will form a radical cation intermediate **13**, which will be attacked by water to form the next radical **14**. Accordingly, as CAN in an aqueous solution is dissociated into $[Ce(NO_3)_6]^{2-}$ and $NH_4{}^+$ ions,[15] one-electron oxidation in the case of **2—7** with $[Ce(NO_3)_6]^{2-}$ gives a radical cation[16] **13** and an electron-donating group R will help in its formation and stabilization. Next, water attacks **13** to form radical **14** and the subsequent oxidation of the para positional methoxyl by another $[Ce(NO_3)_6]^{2-}$ ion affords **16** and the final products **2a—7a**, through **15**.

On the other hand, when R is an electron-withdrawing group, substrates **8** and **9** gave **8b** and **9b**,

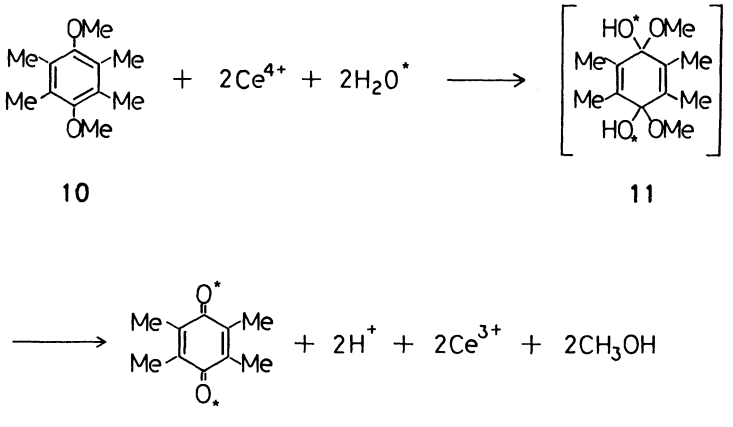


16



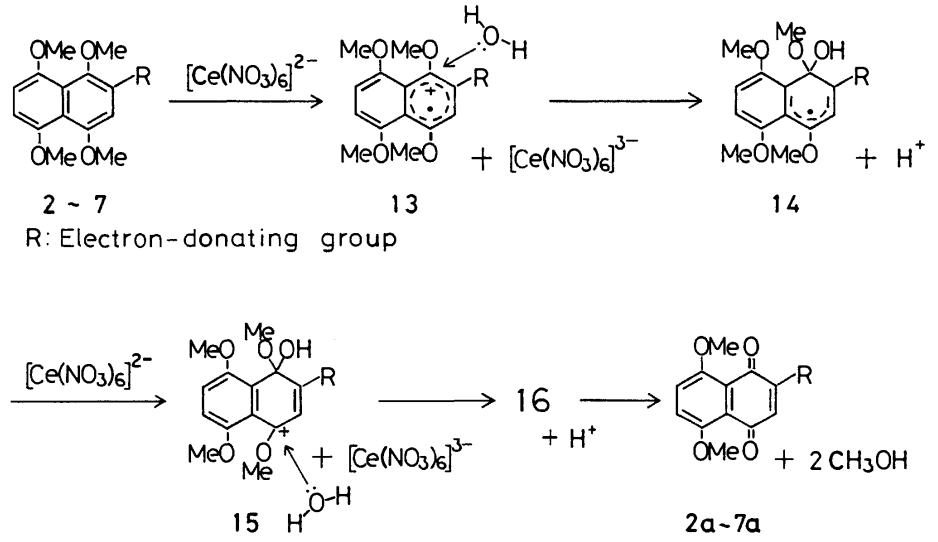
20

Chart 3.

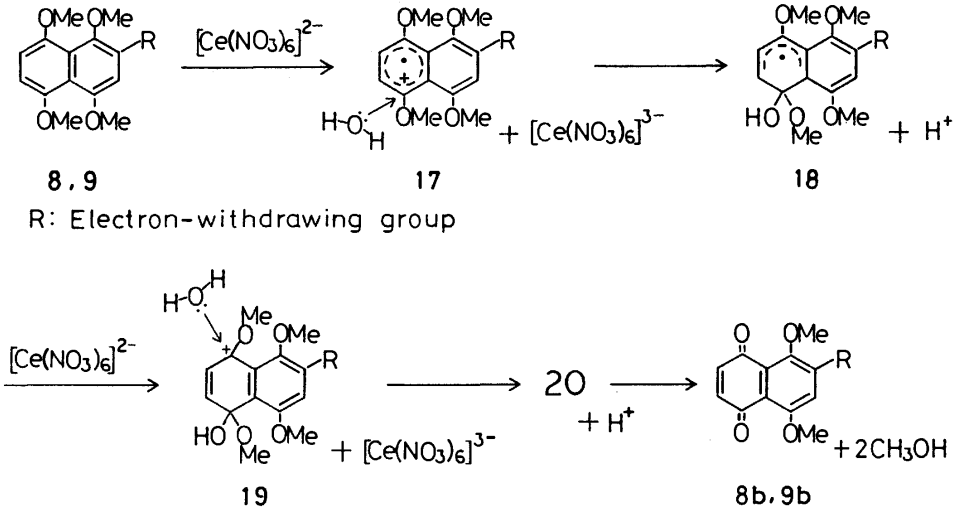


10 11 12

Scheme 2.



Scheme 3.



Scheme 4.

respectively, via intermediates **17**, **18**, **19**, and **20**.

A further treatment of these dimethoxynaphthoquinones **1a—6a**, **8a**, and **9b** with CAN resulted in no reaction; only the starting materials were recovered.

The ^{13}C chemical shifts of the ring carbon atoms of **1a**, **2a**, and **9b** are shown in Table 2, where the C_5 and C_8 carbons are more deshielded than those of **1**, **2**, and **9** within a range of 2—5 ppm. These downfield shifts are attributable to a decrease in the electron density of the carbon atoms (C_5 and C_8 of **1a**, **2a**, and **9b**) by near $C_{1,4}$-quinone-dicarbonyls. The decrease of the electron density at C_5 or C_8 prohibits a further CAN-attack either at C_5 or C_8.

Our subsequent studies concerning further demethylation of the 5,8-dimethoxy-1,4-naphthoquinones have yielded some other interesting results, as follows. The demethylation of the dimethoxynaphthoquinones (**1a—6a**) having electron-donating substituents with AgO-40% HNO_3[17] reagent gave 5,8-dihydroxy-1,4-naphthoquinones (**1c—6c**) (Table 4).

Table 4. Demethylation of 2-Substituted or 6-Substituted 5,8-Dimethoxy-1,4-naphthoquinone

Substrate	Product (%)
 AgO-40%HNO_3 	
R	
1a: H	**1c** (53)
2a: CH_2OH	**2c** (52)
3a: $CH(OH)CH_3$	**3c** (22)
4a: $CH(OH)(CH_2)_3CH_3$	**4c** (22)
5a: $CH(OH)(CH_2)_2CH(CH_3)_2$	**5c** (28)
6a: $CH(OH)(CH_2)_2C(OH)(CH_3)_2$	**6c** (27)
 $AlCl_3$ 	
8b: $COCH_3$	**8c** (71)
9b: CHO	**9c** (43)

However, the demethylation of the dimethoxynaphthoquinones **8b** and **9b**, having electron-withdrawing substitutents, required $AlCl_3$ instead of the above AgO-40%HNO_3 as the demethylation agent (Table 4). The AgO-40%HNO_3 system was quite unsuitable in these cases because of no reaction.

Experimental

^1H and ^{13}C NMR spectra were taken on a JEOL JNM-60 in $CDCl_3$ using Me_4Si and $CDCl_3$ as internal standards, respectively. Mass spectra and IR spectra were obtained with a JEOL DX-300 spectrometer, and a Hitachi 260-30 spectrometer, respectively. Column chromatography was carried out on silica gel (Wakogel C-200) or on alumina (Sumitomo, KCG-30) eluting with chloroform. Melting points were determined with a Yanagimoto micromelting point apparatus and were uncorrected.

2-Hydroxymethyl-1,4,5,8-tetramethoxynaphthalene (2). A sample of 2-formyl-1,4,5,8-tetramethoxynaphthalene (**9**)[7] (2.0 g, 7.24 mmol) in THF (40 ml) was reduced with $LiAlH_4$ (1.37 g, 36 mmol) under ice cooling. After stirring at room temperature for 3 h, the reaction mixture was decomposed by an addition of 1M HCl (1M=1 mol dm^{-3}), and extracted with chloroform (100 ml×3). The chloroform solution was washed with brine, dried over Na_2SO_4, and the solvent was evaporated. The crude product was chromatographed on silica gel to give 1.92 g (99%) of a sample of **2**, mp 99—100 °C. IR (KBr) 3520 (OH) and 1060 cm^{-1} (OCH_3, OH); ^1H NMR δ=2.42 (s, 1H, OH), 3.76, 3.88, 3.90, 3.92 (each s, 3H, OCH_3), 4.84 (s, 2H, CH_2), 6.80 (s, 2H, ArH), and 6.91 (s, 1H, ArH); MS, m/z 278 (M^+), 263, and 245. Calcd for $C_{15}H_{18}O_5$: C, 64.74; H, 6.52%. Found: C, 64.39; H, 6.57%.

2-(1-Hydroxyethyl)-1,4,5,8-tetramethoxynaphthalene (3). The aldehyde **9** (2.76 g, 10 mmol) in THF (40 ml) was added to methylmagnesium iodide (30 mmol) in ether (30 ml), and the mixture was stirred at room temperature for 1 h, decomposed with aq. NH_4Cl, and extracted with chloroform (100 ml×3). The usual work up and purification of the crude product by alumina chromatography gave 2.9 g (99%) of a sample of **3**. Recrystallization from hexane gave an analytical sample, mp 84—85 °C. IR (KBr) 3450 (OH), 1600, and 1070 cm^{-1}; ^1H NMR δ=1.50 (d, J=6.5 Hz, 3H, CH_3), 2.23 (broad, 1H, OH), 3.76, 3.89 (each s, 3H, OCH_3), 3.93 (s, 6H, OCH_3), 5.43 (q, J=6.5 Hz, 1H, CH), 6.81 (s, 2H, ArH), and 7.00 (s, 1H, ArH); MS, m/z 292 (M^+), 274 (M^+-H_2O), and 220. Calcd for $C_{16}H_{20}O_5$: C, 65.73; H, 6.91%. Found: C, 65.62; H, 7.00%.

2-(1-Hydroxypentyl)-1,4,5,8-tetramethoxynaphthalene (4). Treatment of the aldehyde **9** (1.66 g, 6 mmol) with butylmagnesium bromide (18 mmol) gave a crude product. Chromatographic purification on silica gel gave 1.99 g (99%) of a sample of **4** as an oil. IR (neat) 3450 (OH), 1600, and 1070 cm^{-1}; ^1H NMR δ=0.89 (t, J=6.6 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.42 (broad, 1H, OH), 3.74, 3.88 (each s, 3H, OCH_3), 3.92 (s, 6H, OCH_3), 5.22 (t, J=6.0 Hz, 1H, CH), 6.80 (s, 2H, ArH), and 6.97 (s, 1H, ArH); MS, m/z 334 (M^+), 316 (M^+-H_2O), 301, 270, 231, and 137; HRMS m/z Calcd for $C_{19}H_{26}O_5$ 334.1781. Found 334.1784.

2-Acetyl-1,4,5,8-tetramethoxynaphthalene (8). A mixture of the alcohol **3** (610 mg, 2.09 mmol) and an activated manganese dioxide[18] (6 g) in benzene (20 ml) was refluxed for 15 h. Filtration, concentration, and chromatography on silica gel gave 382 mg (63%) of a sample of **8**. Recrystallization from hexane gave yellow crystals, mp 68—68.5 °C. IR (KBr) 1665 (C=O), 1600, 1370, 1070, and 1050 cm^{-1}; ^1H NMR δ=2.77 (s, 1H, $COCH_3$), 3.79, 3.90, 3.96, 3.98 (each s, 3H, OCH_3), 6.92 (s, 2H, ArH), and 7.09 (s, 1H, ArH); MS, m/z 290 (M^+), 275 (M^+-CH_3), 260, 232, and 218. Calcd for $C_{16}H_{18}O_5$: C, 66.20; H, 6.25%. Found: C, 66.11; H, 6.30%.

General Procedure for Oxidative Demethylation of 2-Substituted 1,4,5,8-Tetramethoxynaphthalenes (1—9) with CAN. A solution of CAN (2.5—3 mmol, 2.5—3 equiv) in water (5 ml) was added dropwise to a solution of 2-substituted 1,4,5,8-tetramethoxynaphthalene (1 mmol) in acetonitrile (10 ml), or in a mixture of acetonitrile-chloroform (5 : 1 v/v), at room temperature for 30 min, the reaction mixture was diluted with water, extracted with chloroform, washed with brine, dried over Na_2SO_4, and concentrated. The residue was purified by chromatography on silica gel with chloroform as eluent and recrystallized.

1a: reddish-orange crystals from ligroine (bp 75—120 °C)-benzene; mp 160—161 °C (lit,[19] 157 °C); IR (KBr) 1650 (C=O), 1582, 1565, 1045, and 1020 cm^{-1}; ^1H NMR δ=3.96 (s, 6H, OCH_3), 6.77 (s, 2H, quinone ring H), and 7.32 (s, 2H, benzene ring H); MS, m/z 218 (M^+), 189, 172, 161, 131, and 76.

2a and 2b. 2b: the first fraction from silica gel chromatography; mp 135—136 °C; ^1H NMR δ=2.49 (t, J=6.1 Hz, 1H, OH), 3.83, 3.40 (each s, 3H, OCH_3), 4.87 (d, J=6.1 Hz, 2H, CH_2), 6.78 (s, 2H, quinone ring H), and 7.51 (s, 1H, benzene ring H). **2a:** the second fraction; orange crystals (from ethanol); mp 176—176.5 °C; IR (KBr) 3480, 3350, 1640 (C=O), 1585, 1565, 1075, 1045, and 965 cm^{-1}; ^1H NMR δ=2.41 (t, J=6.1 Hz, 1H, OH), 3.96 (s, 6H, OCH_3), 4.61 (dd, J=6.1 and 1.6 Hz, 2H, CH_2), 6.81 (t, 1H, J=1.6 Hz, quinone ring H), and 7.32 (s, 2H, benzene ring H); MS, m/z 248 (M^+), 233, 218, and 201. Calcd for $C_{13}H_{12}O_5$: C, 62.90; H, 4.87%. Found: C, 62.56; H, 4.88%.

3a and 3b. 3b: the first fraction from silica-gel chromatography; an orange semisolid; ^1H NMR δ=1.56 (d, J=6.5 Hz, 3H, CH_3), 2.2 (broad, 1H, OH), 3.83, 3.99 (each s, 3H, OCH_3), 5.30 (q, J=6.5 Hz, 1H, CH), 6.76 (s, 2H, quinone ring H), and 7.55 (s, 1H, benzene ring H). **3a:** the second fraction; orange crystals (from ligroine-benzene); mp 144—145 °C; IR (KBr) 3480 (OH), 1650 (C=O), 1050, and 1020 cm^{-1}; ^1H NMR δ=1.48 (J=6.6 Hz, 3H, CH_3), 2.70 (d, J=5.2 Hz, 1H, OH), 3.96, 3.97 (each s, 3H, OCH_3), 4.94 (m, 1H, CH), 6.78 (d, J=1.3 Hz, 1H, quinone ring H), and 7.32 (s, 2H, benzene ring H); MS, m/z 262 (M^+), 247 (M^+-CH_3), 231, 219, and 205. Calcd for $C_{14}H_{14}O_5$: C, 64.12; H, 5.38%. Found: C, 64.33; H, 5.43%.

4a and 4b. 4b: the first fraction from alumina chromatography; an orange oil; ^1H NMR δ=0.90 (t, J=6.0 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.55 (broad, 1H, OH), 3.83, 3.99 (each s, 3H, OCH_3), 5.12 (m, 1H, CH), 6.77 (s, 2H, quinone ring H), and 7.51 (s, 1H, benzene ring H). **4a:** the second fraction; an orange oil; IR (neat) 3480 (OH), 1655, 1590, 1570, and 1060 cm^{-1}; ^1H NMR δ=0.90 (t, J=6.0 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.55 (broad, 1H, OH), 3.96 (s, 6H, OCH_3), 4.74 (m, 1H, CH), 6.76 (d, J=1.4 Hz, 1H, quinone ring H), and 7.31 (s, 2H, benzene ring H); MS, m/z 304 (M^+), 289 (M^+-CH_3), and 247; HRMS, m/z Calcd for $C_{17}H_{20}O_5$ 304.1311. Found 304.1314.

7a and 7b. 7b: the first fraction from silica-gel chromatography; an orange oil; ^1H NMR δ=2.18 (s, 3H, $COCH_3$), 1.5—

2.9 (m, 5H, CH_2 and OH), 3.81, 3.94 (each s, 3H, OCH_3), 5.10 (m, 1H, CH), 6.77 (s, 2H, quinone ring H), and 7.55 (s, 1H, benzene ring H). **7a:** the second fraction; an orange oil; IR (KBr) 3470 (OH), 1710 (ketone C=O), 1655 (quinone C=O), 1590, 1570, and 1055 cm^{-1}; ^1H NMR δ=2.18 (s, 3H, $COCH_3$), 1.5—2.9 (m, 5H, CH_2 and OH), 3.94 (s, 6H, OCH_3), 4.78 (m, 1H, CH), 6.83 (s, 1H, quinone ring H), and 7.30 (s, 2H, benzene ring H); MS, *m/z* 318 (M^+), 300, and 247; HRMS, *m/z* Calcd for $C_{17}H_{18}O_6$ 318.1104. Found 318.1129.

8a and 8b. 8b: the first fraction from silica-gel chromatography; orange crystals (from ligroine-benzene); mp 155—155.5 °C; IR (KBr) 1685 (ketone C=O), 1655 (quinone C=O), 1620, 1580, and 1040 cm^{-1}; ^1H NMR δ=2.69 (s, 3H, $COCH_3$), 3.85, 4.00 (each s, 3H, OCH_3), 6.84 (s, 2H, quinone ring H), and 7.48 (s, 1H, benzene ring H); MS, *m/z* 260 (M^+), 245 (M^+-CH_3), 231, and 131. Calcd for $C_{14}H_{12}O_5$: C, 64.61; H, 4.65%. Found: C, 64.17; H, 4.72%. **8a:** the second fraction; an orange semisolid; ^1H NMR δ=2.60 (s, 3H, OCH_3), 3.85, 3.97 (each s, 3H, OCH_3), 6.98 (s, 1H, quinone ring H), and 7.35 (s, 2H, benzene ring H).

General Procedure for Oxidative Demethylation of 2-Substituted 5,8-Dimethoxy-1,4-naphthoquinones (1a—6a) with AgO-40%HNO_3. 40% HNO_3 (12 ml) was added dropwise to a mixture of AgO (10 mmol, 10 equiv), acetone (24 ml), and 2-substituted 5,8-dimethoxy-1,4-naphthoquinone (1 mmol) at 15—25 °C for 5 min. After stirring at room temperature for 30 min, the mixture was diluted with water, extracted with dichloromethane (50 ml×3) washed with brine, dried over Na_2SO_4, and concentrated. The residue was purified by silica-gel chromatography and recrystallized.

1c: reddish brown crystals; mp 202—205 °C (lit,[20] 201—202 °C); IR (KBr) 1610 (C=O), 1565, and 1225 cm^{-1}; ^1H NMR δ=7.14 (s, 4H, ArH) and 12.39 (s, 2H, ArOH); MS, *m/z* 190 (M^+), 136, 134, and 108.

2c: brown crystals (from hexane-ethanol); mp 180—183 °C; IR (KBr) 3430 (sharp, OH), 1610 (C=O), 1560, 1205, and 1080 cm^{-1}; ^1H NMR δ=2.11 (t, *J*=6.1 Hz, 1H, OH), 4.76 (dd, *J*=6.1 and 1.7 Hz, 2H, CH_2), 7.16 (t, *J*=1.5 Hz, 1H, quinone ring H), 7.21 (s, 2H, benzene ring H), 12.46 and 12.48 (each s, 1H, ArOH); MS, *m/z* 220 (M^+), 202 (M^+-H_2O), 191, 174, and 149. Calcd for $C_{11}H_8O_5$: C, 60.01; H, 3.66%. Found: C, 59.98; H, 3.77%.

3c: brown crystals (from hexane); mp 128—129.5 °C; IR (KBr) 3350 (broad, OH), 1610, 1570, 1200, 1105, and 1045 cm^{-1}; ^1H NMR δ=1.54 (d, *J*=6.6 Hz, 3H, CH_3), 1.96 (broad, 1H, OH), 5.08 (qd, *J*=6.6 and 1.3 Hz, 1H, CH), 7.17 (d, *J*=1.3 Hz, quinone ring H), 7.21 (s, 2H, benzene ring H), 12.46 and 12.58 (each s, 1H, ArOH); MS, *m/z* 234 (M^+), 216 (M^+-H_2O), 168, and 139. Calcd for $C_{12}H_{10}O_5$: C, 61.54; H, 4.30%. Found: C, 60.80; H, 4.30%.

4c: brown crystals (from hexane-ethanol); mp 95.5—96.5 °C; IR (KBr) 3250 (broad, 1H, OH), 1615, 1575, 1200, 1115, and 1060 cm^{-1}; ^1H NMR δ=0.92 (t, *J*=5 Hz, 3H, CH_3), 1.1—1.9 (m, 6H, CH_2), 2.20 (broad, 1H, OH), 4.89 (td, *J*=5.1 and 1.0 Hz, 1H, CH), 7.12 (d, *J*=1.0 Hz, 1H, quinone ring H), 7.19 (s, 2H, benzene ring H), 12.46 and 12.58 (each s, 1H, ArOH); MS, *m/z* 276 (M^+), 258 (M^+-H_2O), 229, 220, and 219. Calcd for $C_{15}H_{16}O_5$: C, 65.21; H, 5.84%. Found: C, 64.45; H, 5.91%.

General Procedure for Demethylation of 6-Substituted 5,8-Dimethoxy-1,4-naphthoquinones (8b and 9b) with $AlCl_3$. $AlCl_3$ (10 mmol, 10 equiv) was added to a solution of 6-substituted 5,8-dimethoxy-1,4-naphthoquinone (1 mmol) in dichloromethane (10 ml) cooled in an ice bath. After stirring at room temperature for 2 h, the reaction mixture was decomposed with 5 wt% aqueous oxalic acid (100 ml), extracted with chloroform, washed with brine, dried over Na_2SO_4, and concentrated. The residue was purified by silica-gel chromatography and recrystallized from hexane. **8c:** brown crystals; mp 120—121.5 °C; IR (KBr) 1678 (ketone C=O), 1610 (quinone C=O), 1550, and 1215 cm^{-1}; ^1H NMR δ=2.71 (s, 3H, CH_3), 7.11 (s, 2H, quinone ring H), 7.60 (s, 1H, benzene ring H), 12.13 and 13.08 (each s, 1H, ArOH); MS, *m/z* 232 (M^+), 217, 189, and 161. Calcd for $C_{12}H_8O_5$: C, 62.07; H, 3.47%. Found: C, 61.73; H, 3.51%.

9c: brown crystals; mp 172—174 °C (decomp); IR (KBr) 1690 (ketone C=O), 1610 (quinone C=O), 1555, and 1190 cm^{-1}; ^1H NMR δ=7.10 (s, 2H, quinone ring H), 7.79 (s, 1H, benzene ring H), 10.54 (s, 1H, CHO), 12.03 and 12.77 (each s, 1H, ArOH); MS, *m/z* 218 (M^+), 190 (M^+-CO), 172, and 134. Calcd for $C_{11}H_6O_5$: C, 60.56; H, 2.77%. Found: C, 60.42; H, 3.00%.

We are grateful to Professor Otohiko Tsuge of Kyushu University for valuable suggestions. We also thank Mr. Yoshiyuki Kitajima, Mr. Iwao Seto, Mr. Toshiyuki Tsuboi, and Mr. Takayuki Hayashida for their technical assistances, Mr. Yoshiharu Okada for the elemental analyses, Mrs. Eriko Furukawa for the NMR spectra, and Mrs. Keiko Yamaguchi for MS spectra.

(Received November 12, 1987)

ω-Hydroxy carboxylic acids (**3**, **5**, **6**, **7**, **10**, **12**, **14**, **17**, **18**, **20**, and **22**) bearing 2—6 ether oxygens and aromatic rings with or without a tetrahydrofuran ring and the ω-methoxy and ω-benzyloxy derivatives of **5** (**8** and **9**) were synthesized. These were employed as carriers for active and competitive transport of alkali metal ions through liquid membrane as well as for extraction of alkali metal ions to organic layers. Effect of hydrophobic group of aromatic and tetrahydrofuran rings, number of ether oxygens, and terminal hydroxyl group of the ionophores on the ion transport ability and selectivity were investigated. The hydrophobic groups increased total amount of transported ions as well as partition coefficients. The ionophore, **5**, which contains five ether oxygens, two aromatic rings, and *o*-toluic acid moiety transported K^+ selectively over Na^+ and Li^+ through 1,2-dichloroethane being consistent with the extraction experiments. The *m*- and *p*-substituted isomers, **6** and **7**, exhibited no transport ability through 1,2-dichloroethane. The ω-alkoxy derivatives of **5** (**8** and **9**) exhibited less selectivity for K^+ through 1,2-dichloroethane than **5** did. Through 1-hexanol, the ionophores, **5**—**9**, including linoleic acid with no ether linkage transported alkali metal ions. The ionophores (**3**, **12**, **20**, and **22**) containing 2—4 ether oxygens did not exhibit high transport ability.

Among naturally occurring compounds, there is a class of ionophores which form stable, lipophilic complexes with ions and are able to transport them across membranes.[2] The ionophores are classified based on their structures into two types. One is neutral ionophore which is cyclic and contains no ionizable functional group.[2a] Another is charged ionophore characterized by a carboxylic acid head group and a tail of a hydroxyl or an amino group capable of hydrogen-bonding interactions. The backbones are linear, containing heterocyclic rings with a variety of oxygen-containing functional groups. The carboxylic group is ionized at physiological pH and the complex with cation is neutral. Their complex formation and physiological activity have been investigated extensively.[3] A number of synthetic models for neutral ionophores, such as crown ethers, were reported in order to understand the mechanism of action of the naturally occurring ionophores as well as to dissolve reactive inorganic salts in organic solvents for organic synthesis.[4] However, synthetic analogues of natural carboxylic ionophores remain relatively unexplored.[5]

We have already reported transport of alkali metal ions across an organic liquid membrane mediated by synthetic carboxylic acid ionophores.[1] It was found that an ion was pumped against its concentration gradient by a coupled counterflow of proton and that formation of a pseudocyclic structure of the ionophore, with or without hydrogen bonding of the head and tail, was essential for lipophilization and transport of the cation similar to the case of natural ionophores.[1c,e]

We describe here synthetic procedures for new carboxylic acid ionophores together with already reported ones and systematic studies on transport of alkali metal ions by these ionophores.

Results and Discussion

Synthesis of Polyether Carboxylic Acids. As ionophore, eleven carboxylic acids containing 2—6 ether oxygens and one terminal hydroxyl group were synthesized. Aromatic and tetrahydrofuran rings were employed as hydrophobic groups and acetic or toluic acid moieties serving as the carboxyl group. Two derivatives with terminal ether groups were also prepared to clarify a role of head-to-tail hydrogen bonding. The synthetic procedures are based mainly on the Williamson ether synthesis.

2-(2-Hydroxyethoxy)phenol (**1**) was obtained by conventional means using the reaction of sodium catecholate with ethylene chlorohydrin.[6] A better yield was obtained using the previously reported reaction of phenol with ethylene carbonate.[7] Heating a mixture of catechol and ethylene carbonate at 160 °C in the presence of tetrabutylammonium iodide gave a 77% yield of **1**.

Coupling of ethylene glycol ditosylate with **1** gave the best result for synthesis of **4**.[8] Williamson coupling of **4** with methyl 2-(bromomethyl)benzoate and subsequent hydrolysis provided **5**. Similarly, *m*- and *p*-substituted isomers, **6** and **7** were afforded. ω-Alkoxy derivatives, **8** and **9**, were obtained by reaction of **5** with methyl iodide and benzyl chloride respectively and successive hydrolysis. Instead of methyl 2-(bromomethyl)benzoate, chloroacetic acid was employed for synthesis of **10**. Methyl 2-(bromomethyl)-benzoate was allowed to react with **1** directly followed

by hydrolysis to synthesize **3**. Treatment of **1** with tosyl chloride formed the ditosylate, **2**. Reaction of **2** with **1** and subsequent hydrolysis yielded **11**. Compound **12** was derived from **11**. Compound **14** was obtained similarly from **13** which was prepared by reaction of two equivalents of the sodium salt of **1** with bis(2-chloroethyl) ether. Coupling of tetrahydro-2,5-furandimethanol ditosylate (**15**)[9] with two equivalents of **1** afforded **16**. The reaction of **16** with methyl 2-(bromomethyl)benzoate formed **17**. The acetic acid derivative **18** was obtained from **16** and ethyl bromoacetate. Two equivalents of catechol and bis(2-hydroxyethyl) ether were employed to synthesize **19**[10] which was converted into **20** using methyl 2-(bromomethyl)benzoate. Compound **21**[11] obtained from catechol and two equivalents of ethylene chlorohydrin was allowed to react with methyl 2-(bromomethyl)benzoate to form lactone which was hydrolyzed to **22**.

These ionophores are classified by the number of ether oxygens in Table 1. Cavity sizes of the pseudocyclic conformers which are formed by head-to-tail hydrogen bonding between carboxyl and hydroxyl groups were measured in their CPK models. The cavity size increases as the number of ether oxygens increases. Hydrophobicity parameters (log *P*) are also shown in Table 1 where *P* is calculated value of partition coefficient to octanol obtained by the literature method.[12] Tetrahydrofuran compounds (**17**, **18**) have higher log *P* than the analogues containing oxyethylene residue (**5**, **10**) do. Toluic acid derivatives (**5**, **17**) are more hydrophobic than the corresponding acetic acid ones (**10**, **18**). Ionophores become more lipophilic by alkylation of terminal hydroxyl group (**5** to **8** or **9**). The cavity sizes and log *P*'s will be correlated with the

ion transport ability and ion selectivity.

Partition Coefficient of Alkali Metal Salts of Synthetic Ionophores. In order to investigate the hydrophobicity of alkali metal salts of synthetic carboxylic ionophores the salts in water were extracted with organic solvents. Partition coefficients of alkali metal salts of **5** to organic solvents (such as 1-hexanol, toluene, 1-hexanol-toluene, and 1,2-dichloroethane) together with dipole moment (μ) and dielectric constant (ε) are shown in Table 2. 1-Hexanol extracted more of the salts than 1,2-dichloroethane and none of the salts was extracted by toluene. With increased ratio of toluene in 1-hexanol-toluene (decrease in polarity), the amount of extracted salts decreased. The potassium salt was more extracted than the sodium salt. There was not much difference among the partition coefficients of the potassium, rubidium, and cesium salts.

Partition coefficients of alkali metal salts of synthetic ionophores **10**, **14**, **17** to organic solvents are shown in Table 3. The salts of **14** and **17** with toluic acid moiety as well as **5** (Table 2) have larger partition coefficients than that of **10** with acetic acid moiety. As can be seen in log *P*, the toluic acid derivatives are more hydrophobic, so that these salts are more soluble in organic solvents. K, Rb, and Cs salts of **14** and **17** were more extracted than that of the sodium salts in most cases.

Active Transport of Alkali Metal Ions by Ionophores Containing 5—6 Ether Oxygens. Competitive transport of Na^+ and K^+ through various liquid membranes was carried out by using **5** which was expected to exhibit high selectivity from partition coefficient experiments. The results are shown in Table 4. The ionophore exhibited high transport ability and K^+-selectivity through all the liquid membranes. 1,2-Dichloroethane gave the highest selectivity. Total transport was comparable at all ratios of 1-hexanol-toluene mixtures, and increase in toluene content enhanced K^+-selectivity. The ratio of 1/9 gave the highest selectivity comparable to that in 1,2-dichloroethane. Transport of Na^+ and K^+, by **5** exhibited preference for K^+ in all the liquid membranes consistent with the results of extraction experiments.

Competitive transport of alkali metal ions using **10**, **14**, **17**, and **18** as well as **5** was carried out. 1-Hexanol and 1,2-dichloroethane were employed as the liquid membrane and ion combinations of Na^+-K^+, Na^+-K^+-Cs^+, and K^+-Rb^+ were used. These results are shown in Tables 5 and 6.

Table 5 shows competitive ion transport through 1-hexanol. All the ionophores were K^+-selective in the transport of Na^+ and K^+. Although **17** and **18** with tetrahydrofuran ring have one more ether oxygen and the cavity sizes are larger than that of **5**, both had similar transport ability and selectivity to those of **5**. Results of competitive transport of Na^+, K^+, and Cs^+ by **5**. **10**, **14**, **17**, and **18** show that all the ionophores preferred K^+. The cavity size of **14** with six ether oxygens seems to fit diameter of Cs^+ better than that of K^+, whereas **14** had selectivity for K^+. No ionophore distinguished between K^+ and Rb^+ with similar diameter.

Table 6 shows the results of ion transport through 1,2-dichloroethane instead of 1-hexanol. In the transport of Na^+ and K^+, not only **5** but also **17** and **18** exhibited higher selectivity for K^+ than seen in 1-hexanol. Acetic acid derivative, **18** transported only 25% of the total salt. In the transport of Na^+, K^+, and Cs^+, the ionophores except for **10** displayed K^+-preference. Selective transport of Cs^+ was not achieved even by the compounds with six ether oxygens such as **14**, **17**, and **18**. Ionophores containing seven or more ether oxygens might fit for Cs^+. Poor transport ability of compounds bearing acetic acid moiety (**10** and **18**) is consistent with their partition coefficient experiments. Compounds **5** and **18** showed no preference between K^+ and Rb^+, but **17** exhibited a slight selectivity for Rb^+.

As mentioned above, it was found that the ionophores having five or six ether oxygens transported K^+ and Rb^+ in preference to the smaller Na^+ and the larger Cs^+. Since the cavity size of these ionophores in a pseudocyclic conformation formed by head-to-tail hydrogen bonding meets diameter of K^+ and Rb^+ rather than Na^+ and Cs^+, the hydrophobic conformations of the potassium and rubidium salts are more stable to diffuse into organic phase than those of the sodium and cesium salts resulting in the K^+- and Rb^+-preference.

Active Transport of Alkali Metal Ions by Derivatives of 5. Table 7 illustrates competitive active transport of alkali metal ions by **5** and its analogues including linoleic acid through 1,2-dichloroethane liquid membrane. Compound **5** and its methyl and benzyl ethers (**8** and **9**) were able to transport alkali metal ions whereas *m*- and *p*-substituted isomers of **9** (**6** and **7**) and linoleic acid had almost no transport ability. Compound **5** exhibited high specificity for K^+ over Na^+ and Li^+, but the methyl ether was less selective and the benzyl ether had no selectivity. Compounds **5** and **8** showed less selectivity for K^+ over Rb^+ and Cs^+ than over Na^+ and Li^+ in 1,2-dichloroethane.

All the compounds react with cations to form the salts at water/1,2-dichloroethane interface. In the case of **5** and its derivatives subsequent replacement of water molecules out of the hydration sphere by ether oxygens affords a lipophilic complex soluble in the liquid membrane. On the contrary, the ether oxygens of *m*- and *p*-isomers of **5** are too far away to interact with from hydrated metal ions and linoleic acid had no ether oxygen to coordinate metal ion, so the salts stayed at the interface. Ion selectivity of **5** could be accounted for in a similar manner to naturally occurring carboxylic ionophores.[2] A metal ion is entrapped in a hydrophilic cavity made by head-to-tail hydrogen bonding between carboxylato and hydroxyl groups of ionophore. The diameter of a potassium ion (2.66 Å) meets the cavity size of **5** (2.6 Å by CPK model) result-

a) Donor phase I contains an aqueous solution of 0.1 M Li^+ (1 M=1 mol dm^{-3}), 0.1 M Na^+, 0.1 M K^+, and 0.3 M OH^-. The other conditions are described in experimental section.

ing in the potassium selectivity. Since Na^+ and Li^+ are too small to fit in the cavity, these complexes are less stable than that of potassium salt of **5**. Smaller difference between the diameters of K^+ and Rb^+ (Cs^+) leads to less selectivity for K^+ over Rb^+ (Cs^+) by **5**. The methyl and benzyl ethers of **5**, **8**, and **9**, where the head-to-tail hydrogen bonding is impossible, could still adopt a pseudocyclic conformation fitting the size of K^+. However, the other conformations with smaller cavity sizes to meet Na^+ or Li^+ diameter would be also possible because of the enhanced hydrophobicities of **8** and **9**. This is responsible for less selectivity and increase in transported amount of Na^+ and Li^+. All the salts of the ionophores where cations are coordinated by all or some ether oxygens depending on the sizes of cations were hydrophobic enough to be extracted into organic membrane. There is not much difference between the stability of the complexes.

Behavior of these ionophores in 1-hexanol membrane is quite different from that in 1,2-dichloroethane as shown in Table 8. Not only *o*-substituted compounds **5**, **8**, and **9** but also *m*- and *p*-isomers **6** and **7** and linoleic acid served as a carrier. Compound **5** had still specificity for K^+ over Li^+ and Na^+, but Li^+ was more transported than Na^+. The other ionophores preferred Li^+. Any ionophore did not exhibit remarkable selectivity for K^+ over Rb^+ and Cs^+ regardless of the position of terminal carboxyl group or the structure of the other end.

Selectivity in the ion transport through 1-hexanol might be explained as follows: Water molecules of hydrated cations of linoleic acid salts formed at the interface were replaced by 1-hexanol molecules to solubilize in the organic membrane. The transport selectivity for Li^+ suggests that 1-hexanol can dehydrate more easily out of Li^+ with higher charge density. In the case of the synthetic ionophores containing ether oxygens, metal ions were coordinated by the ether oxygens of the ionophores and alcohol oxygens of the liquid membrane competitively. Compound **5** whose ether oxygens may be stronger ligands toward K^+ than 1-hexanol exhibited K^+ selectivity, but the complex coordinated by 1-hexanol oxygens was also produced resulting in lowering K^+-selectivity.

Active Transport of Alkali Metal Ions by Ionophores Containing 2—4 Ether Oxygens. The ionophores containing two to four ether oxygens were employed for ion transport as shown in Table 9. In 1-hexanol, the ionophores transported Li^+ more than Na^+ similar to the case of **5** and its derivatives as mentioned above. However, the total amount of transported ions was small. This could be accounted for by the small stability constant of the salt complexes solvated by 1-hexanol resulting from the low lipophilicity of these ionophores. Although the ionophores were expected to exhibit Li^+- or Na^+-selectivity through 1,2-dichloroethane from the cavity sizes, almost no ion was transported.[13]

Experimental

Methods. IR spectra were run with a Jasco IR-G spectrophotometer. ^1H NMR specta were recorded with a JEOL JNM-PMX 60 instrument using tetramethylsilane as internal standard. UV spectra were recorded on a Hitachi 124 spectrophotometer. Mass spectra were obtained on a Hitachi M-80 mass spectrometer operating at 30 eV. Elemental analyses were performed on a Yanaco Model MT-3. Flame spectrochemical analyses were performed with Hitachi 170-30 Atomic Absorption Spectrophotometer.

Materials. Unless stated otherwise reagent grade reactants and solvents were obtained from commercial suppliers and used without further purification. Dry ethanol and dry methanol were distilled in the presence of sodium alkoxides.

Dry *N*,*N*-dimethylformamide (DMF) and dry pyridine were distilled over NaH. Methyl 2-(bromomethyl)benzoate was prepared by photobromination of methyl 2-methylbenzoate with bromine according to the literature method[14] and the *m*- and *p*-isomers, methyl 3-(bromomethyl)benzoate and methyl 4-(bromomethyl)benzoate, were obtained similarly. Bis[2-(2-hydroxyphenoxy)ethyl] ether (**19**),[10] and 1,2-bis(2-hydroxyethoxy)benzene (**21**)[11] were prepared by Williamson synthesis from catechol and the appropriate halides according to the literatures. Ethylene glycol ditosylate[15] and tetrahydro-2,5-furandimethanol ditosylate (**15**)[9] were obtained according to the literature methods.

2-(2-Hydroxyethoxy)phenol (1). A mixture of catechol (22 g, 0.2 mol), ethylene carbonate (17.6 g, 0.2 mol), and tetrabutylammonium iodide (2.4 g, 6.5 mmol) was heated at 160 °C for about 1 h until evolution of CO_2 ceased. The mixture was distilled under reduced pressure (ca. 115 °C/0.1 mmHg(1 mmHg=133.322 Pa)) to get a solid. Recrystallization of this from water gave pure product (23.1 g, 77%). Mp 99—101 °C (lit,[6] mp 100—101 °C).

1,2-Bis[2-(2-hydroxyethoxy)phenoxy]ethane (4). A mixture of **1** (2 g, 13 mmol) and NaH (13 mmol) in dry DMF (8 ml) was stirred at room temperature for 30 min. To this was added dropwise ethylene glycol ditosylate[13] (2.4 g, 6.4 mmol) in dry DMF (25 ml) and the mixture was stirred at room temperature for 24 h. After removal of DMF in vacuo, water (40 ml) was added to the residue followed by reflux. After cooling, the precipitate was collected by suction. It was recrystallized from ethanol-water (1/1) to get **4** (1.71 g, 81%). Mp 88—89 °C (lit,[8] mp 99 °C). ^{1}H NMR ($CDCl_3$) δ=3.6—4.3 (8H, m, $OC\underline{H}_2C\underline{H}_2OH$), 4.3 (4H, s, $OC\underline{H}_2C\underline{H}_2$), 6.9 (8H, s, aromatic).

2,5-Bis[[2-(2-hydroxyethoxy)phenoxy]methyl]tetrahydrofuran (16). NaOH (2.1 g, 52 mmol) was dissolved in 1-butanol (100 ml) under reflux. After addition of **1** (8 g, 52 mmol) the mixture was refluxed for 1 h. To this was added dropwise a solution of **15**[14] (11 g, 25 mmol) in dry DMF (100 ml) and the mixture was heated under reflux for 16 h. After distillation of the solvents under reduced pressure the residue was dissolved in water (50 ml) with heating followed by acidification with 1 M HCl (1 M=1 mol dm^{-3}). The formed precipitate was collected by suction and was recrystallized from ethanol-water (1/1) to give **16** (4 g, 40%). Mp 99—101 °C. ^{1}H NMR (DMSO-d_6) δ=1.9 (4H, m, CH_2 of tetrahydrofuran), 3.1—4.7 (14H, m, OCH= and OCH_2), 6.9 (8H, s, aromatic). Found: C, 62.11; H, 7.31%. Calcd for $C_{22}H_{28}O_7 \cdot H_2O$: C, 62.54; H, 7.16%.

Bis[2-[2-(2-hydroxyethoxy)phenoxy]ethyl] Ether (13). From **1** (10 g), NaOH (2.6 g), and bis(2-chloroethyl) ether (4.65 g), **13** was synthesized similar to **4**. Yield (11 g, 90%). Mp 84—86 °C (50% ethanol). ^{1}H NMR ($CDCl_3$) δ=3.7—4.3 (16H, m, CH_2), 6.9 (8H, s, aromatic). Found: C, 57.72; H, 7.38%. Calcd for $C_{20}H_{26}O_7 \cdot 2H_2O$: C, 57.96; H, 7.30%.

2-(2-Hydroxyethoxy)phenol Ditosylate (2). To **1** (3.0 g, 20 mmol) in dry pyridine (20 ml) at 0 °C was added portionwise tosyl chloride (8.4 g, 44 mmol). The mixture was stirred at room temperature for 40 h and poured into ice water. The precipitate was filtered and washed with water. The solid dried in vacuo was recrystallized from ethanol-ethyl acetate to give white crystal of **2** (5.6 g, 61%); mp 125.5—126 °C. ^{1}H NMR ($CDCl_3$) δ=2.4 (6H, s, CH_3), 3.8—4.3 (4H, m, CH_2), 6.6—7.9 (12H, m, aromatic). Found: C, 57.23; H, 4.67; S, 13.96%. Calcd for $C_{22}H_{22}O_7S_2$: C, 57.13; H, 4.79; S, 13.87%.

2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]phenol (11). A mixture of **1** (1.5 g, 10 mmol) and NaH (10 mmol) in dry DMF (70 ml) was stirred at 80—90 °C to form alkoxide. To this was added dropwise **2** (4.6 g, 10 mmol) in dry DMF (40 ml) at room temperature and the mixture was stirred at 80—90 °C for 18 h. DMF was removed in vacuo and the residue dissolved in chloroform was washed with water. The organic layer dried over sodium sulfate was evaporated and chromatographed over silica gel (chloroform/methanol=100/5) to separate the monotosylate roughly. To this was added KOH (8.4 g), H_2O (14 ml), and ethanol (14 ml) followed by reflux for 1 h. This was acidified with HCl followed by extraction with chloroform. The organic layer dried over sodium sulfate was evaporated and applied to a silica-gel column (chloroform) to separate **11** (1.8 g, 62%). ^{1}H NMR ($CDCl_3$) δ=3.8—4.1 (4H, m, $OC\underline{H}_2C\underline{H}_2OH$), 4.2 (4H, s, $OC\underline{H}_2C\underline{H}_2$), 6.9 (8H, s, phenylene). Found: C, 66.16; H, 6.33%. Calcd for $C_{16}H_{18}O_5$: C, 66.20; H, 6.25%.

[2-[2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]phenoxy]-ethoxy]acetic Acid (10). To **4** (2.6 g, 7.4 mmol) dissolved in dry THF (80 ml) under gentle reflux was added portionwise small pieces of K (0.59 g, 15 mmol) and the mixture was stirred for 1 h to form precipitate of the alkoxide. Chloroacetic acid (0.7 g, 7.4 mmol) in dry DMF (20 ml) was added dropwise to the suspension and the mixture was refluxed for 9 h. After cooling, THF was removed in vacuo and to the residue was added appropriate amount of dil NaOH, then H_2O was removed in vacuo. The residual oil was washed with dioxane to remove the starting material of **4**. To the resulting solid was added 2 M HCl and chloroform and it was shaken. The organic layer was separated, dried over magnesium sulfate, and evaporated. The solid was recrystallized from 50% ethanol to give **10** (1.8 g, 60%). Mp 73—76 °C. IR (KBr) 1740 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.7—4.2 (10H, m, CH_2O), 4.3 (4H, s, OCH_2CH_2O), 6.9 (8H, s, aromatic). Found: C, 60.72; H, 6.34%. Calcd for $C_{20}H_{24}O_8$: C, 61.22; H, 6.17%.

2-[[2-[2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]phenoxy]-ethoxy]methyl]benzoic Acid (5). A mixture of **4** (3.34 g, 10 mmol) and NaH (10 mmol) in dry DMF (70 ml) was stirred at room temperature for 4 h. To the alkoxide was added dropwise methyl 2-(bromomethyl)benzoate (2.17 g, 10 mmol) in dry DMF (40 ml) and the mixture was stirred at room temperature for 4 h and at 80—90 °C for 24 h. DMF was removed in vacuo and to the residue was added 1 M NaOH followed by reflux for 2 h. It was acidified with dil HCl and the precipitate was collected by suction and washed with water thoroughly. To the solid dissolved in methanol was added anion-exchange resin (Amberlyst, OH^-, 5 g) and the mixture was stirred for 1 h. The resin was filtered, washed with methanol, and was poured into 1 M HCl. The resin was filtered off and washed with methanol. The combined filtrate and washing were evaporated in vacuo. The residue was recrystallized from 50% ethanol to give **5** (2.8 g, 59%). Mp 112—113 °C. IR (KBr) 1690 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.8—4.4 (8H, m, OCH_2), 4.4 (4H, s, OCH_2), 4.9 (2H, s, benzyl), 6.9 (8H, s, aromatic), 7.3—8.1 (4H, m, aromatic). Found: C, 66.03; H, 6.02%. Calcd for $C_{26}H_{28}O_8$: C, 66.66; H, 6.02%.

Compounds **18**, **14**, and **17** were prepared from **16** and ethyl bromoacetate, **13** and methyl 2-(bromomethyl)benzoate and **16** and methyl 2-(bromomethyl)benzoate respectively by

Williamson synthesis similar to that for **5**.

[2-[2-[[Tetrahydro-5-[[2-(2-hydroxyethoxy)phenoxy]methyl]-2-furanyl]methoxy]phenoxy]ethoxy]acetic Acid (18). Yield (0.9 g, 20%). Mp 115—118 °C (50% ethanol). IR (KBr) 1730 cm^{-1} (C=O); ^1H NMR (DMSO-d_6) δ=1.9—2.1 (4H, m, tetrahydrofuranyl CH_2), 3.5—4.5 (16H, m, all other CH_2 and tetrahydrofuranyl CH), 6.9 (8H, s, aromatic). Found: *m/z* 462.1901. Calcd for $C_{24}H_{30}O_9$: M, 462.1890.

2-[[2-[2-[2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]ethoxy]-phenoxy]ethoxy]methyl]benzoic Acid (14). Yield (0.51 g, 10%). Mp 82—84 °C (50% ethanol). IR (KBr) 1690 cm^{-1} (C=O); ^1H NMR (DMSO-d_6) δ=3.5—4.3 (16H, m, CH_2O), 4.85 (2H, s, benzyl), 6.9 (8H, s, phenylene), 7.3—7.9 (4H, m, aromatic of toluic acid). Found: *m/z* 512.2081. Calcd for $C_{28}H_{32}O_9$: M, 512.2046.

2-[[2-[2-[[Tetrahydro-5-[[2-(2-hydroxyethoxy)phenoxy]methyl]-2-furanyl]methoxy]phenoxy]ethoxy]methyl]benzoic Acid (17). Yield (1.35 g, 30%). The crystal from 50% ethanol became oil on drying under vacuum. IR (neat) 1710 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=1.9—2.2 (4H, m, tetrahydrofuranyl CH_2), 3.6—4.5 (14H, m, all other CH_2 and tetrahydrofuranyl CH), 6.9 (8H, s, aromatic), 7.3—8.1 (4H, m, aromatic of toluic acid). Found: *m/z* 538.2148. Calcd for $C_{30}H_{34}O_9$: M, 538.2203.

2-[[2-(2-Hydroxyethoxy)phenoxy]methyl]benzoic Acid (3). To sodium alkoxide prepared from **1** (0.87 g, 5.65 mmol) and NaH (5.68 mmol) in dry DMF (10 ml) was added dropwise methyl 2-(bromomethyl)benzoate (1.3 g, 5.68 mmol) in dry DMF (10 ml) and the reaction mixture was stirred at room temperature for 3 h and at 80 °C for 24 h. DMF was removed in vacuo and to the residue was added 1 M NaOH followed by reflux. It was acidified with 1 M HCl and extracted with chloroform. The organic layer was washed with water, dried over magnesium sulfate, and evaporated. The solid was recrystallized from CCl_4-$CHCl_3$-acetone (5/1/2) to give white crystals of **3** (0.42 g, 25%). Mp 138—139 °C. IR (KBr) 1690 cm^{-1} (C=O); ^1H NMR (acetone-d_6) δ=3.7—4.3 (4H, m, CH_2), 5.5 (2H, s, benzyl), 6.9 (4H, s, aromatic), 7.3—8.1 (4H, m, aromatic). Found: C, 66.08; H, 5.61%. Calcd for $C_{16}H_{16}O_5$: C, 66.66; H, 5.59%.

2-[[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]methyl]benzoic Acid (22). A mixture of **21**[11] (1.98 g, 10 mmol) and NaH (10 mmol) in dry DMF (30 ml) was stirred at 80—90 °C until evolution of hydrogen ceased. Methyl 2-(bromomethyl)benzoate (2.3 g, 10 mmol) in dry DMF (80 ml) was added dropwise and the mixture was stirred at 80—90 °C for 48 h. DMF was removed in vacuo and the residue dissolved in methanol was neutralized by addition of cation-exchange resin. The resin was filtered and the filtrate was evaporated. The residue was dissolved in hexane with heating and it was allowed to stand at room temperature to separate crystals of lactone (0.2 g, 6.4%). Mp 89—90 °C. IR (KBr) 1720 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=3.7—4.0 (2H, m, CH_2O), 4.0—4.3 (4H, m, CH_2O), 4.5—4.7 (2H, m, CH_2O), 5.1 (2H, s, benzyl), 6.8 (4H, s, phenylene), 7.0—7.8 (4H, m, aromatic of toluic acid). Found: C, 68.46; H, 5.88%. Calcd for $C_{18}H_{18}O_5$: C, 68.77; H, 5.77%. The lactone (0.13 g, 0.4 mmol) in 1 M NaOH (25 ml) was refluxed for 1 h. It was neutralized with 1 M HCl and extracted with $CHCl_3$. The organic layer dried over sodium sulfate was evaporated to give **22** (0.13 g, 98%). Mp 105—107 °C. IR (KBr) 1690 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=3.6—4.3 (8H, m, CH_2O), 4.9 (2H, s, benzyl), 6.8 (4H, s, phenylene), 7.0—7.9 (4H, m, aromatic of toluic acid). Found: C, 64.46; H, 6.26%. Calcd for $C_{18}H_{20}O_6$: C, 65.05; H, 6.07%.

2-[[2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]phenoxy]-methyl]benzoic Acid (12). A mixture of **11** (0.8 g, 2.8 mmol) and NaH (2.8 mmol) in dry DMF (30 ml) was stirred at room temperature to form alkoxide. To this was added dropwise methyl 2-(bromomethyl)benzoate (0.64 g, 2.8 mmol) in dry DMF (10 ml) and the mixture was stirred at room temperature for 18 h. DMF was removed in vacuo and to the residue was added 2 M NaOH followed by reflux for 2 h. It was acidified with 2 M HCl followed by extraction with chloroform. The organic layer dried over sodium sulfate was evaporated and applied to a silica-gel column (chloroform/methanol=100/1) to obtain **12** (0.34 g, 29%). IR (KBr) 1710 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=3.3—4.4 (8H, m, CH_2O), 5.4 (2H, s, benzyl), 6.9 (8H, s, phenylene), 7.2—8.0 (4H, m, aromatic of toluic acid). Found: *m/z* 424.1457. Calcd for $C_{24}H_{24}O_7$: M, 424.1522.

Compound **20** was synthesized from **19** and methyl 2-(bromomethyl)benzoate similar to synthesis of **12**.

2-[[2-[2-[2-(2-Hydroxyphenoxy)ethoxy]ethoxy]phenoxy]-methyl]benzoic Acid (20). Yield (0.5 g, 12%). Mp 111—114 °C. IR (KBr) 1710 cm^{-1} (C=O); ^1H NMR (acetone-d_6) δ=3.5—4.3 (8H, m, CH_2), 5.5 (2H, s, benzyl), 6.7—7.0 (8H, m, phenylene), 7.2—8.1 (4H, m, aromatic of toluic acid). Found: *m/z* 424.1438. Calcd for $C_{24}H_{24}O_7$: M, 424.1522.

4-[[2-[2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]phenoxy]-ethoxy]methyl]benzoic Acid (7). A mixture of **4** (3.3 g, 10 mmol) and NaH (10 mmol) in dry DMF (70 ml) was stirred at 80—90 °C to form alkoxide. To this was added dropwise methyl 4-(bromomethyl)benzoate (2.3 g, 10 mmol) in dry DMF (40 ml) and the mixture was stirred at 80—90 °C for 18 h. DMF was removed in vacuo and to the residue was added 2 M NaOH followed by reflux for 2 h. It was acidified with 2 M HCl followed by extraction with chloroform. The organic layer dried over sodium sulfate was evaporated and was applied to a silica-gel column (chloroform/methanol=100/1) to obtain **7** (0.70 g, 15%). IR (KBr) 1690 cm^{-1} (C=O); ^1H NMR (DMSO-d_6) δ=3.5—4.4 (12H, m, CH_2), 4.6 (2H, s, benzyl), 6.9 (8H, s, aromatic), 7.3—8.0 (4H, m, aromatic of toluic acid). Found: C, 66.18; H, 5.82%. Calcd for $C_{26}H_{28}O_8$: C, 66.02; H, 6.07%.

3-[[2-[2-[2-[2-(2-Hydroxyethoxy)phenoxy]ethoxy]phenoxy]-ethoxy]methyl]benzoic Acid (6). Compound **6** was synthesized by the same procedure as that for **7** using methyl 3-(bromomethyl)benzoate instead of *p*-isomer. Yield (1.2 g, 26 %). IR (KBr) 1690 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=3.6—4.4 (12H, m, CH_2), 4.6 (2H, s, benzyl), 7.0 (8H, s, aromatic), 7.4—8.1 (4H, m, aromatic of toluic acid). Found: C, 66.51; H, 5.96%. Calcd for $C_{26}H_{28}O_8$: C, 66.66; H, 6.02%.

2-[[2-[2-[2-[2-(2-Methoxyethoxy)phenoxy]ethoxy]phenoxy]-ethoxy]methyl]benzoic Acid (8). A mixture of **5** (0.5 g, 1.1 mmol) and NaH (4 mmol) in dry DMF (10 ml) was stirred at room temperature to form alkoxide. To this was added dropwise methyl iodide (0.71 g, 5 mmol) in dry DMF (5 ml) and the mixture was stirred at room temperature for 48 h. DMF was removed in vacuo and to the residue was added a mixture of KOH (0.84 g, 5 mmol), H_2O (5 ml), and ethanol (5 ml) followed by reflux for 2 h. It was acidified with HCl followed by extraction with chloroform. The organic layer dried over sodium sulfate was evaporated. The residue was applied to a silica-gel column (chloroform/methanol=100/1) to obtain **8** (0.38 g, 73%). IR (KBr) 1690 cm^{-1} (C=O);

^{1}H NMR ($CDCl_3$) δ=3.4 (3H, s, OCH_3), 3.6—4.4 (12H, m, CH_2O), 5.0 (2H, s, benzyl), 6.9 (8H, s, phenylene), 7.3—8.1 (4H, m, aromatic of toluic acid). Found: C, 67.28; H, 6.40%. Calcd for $C_{27}H_{30}O_8$: C, 67.21; H, 6.27%.

Compound **9** was prepared from **5** and benzyl chloride instead of methyl iodide by the same procedure as that for **8**.

2-[[2-[2-[2-[2-(2-Benzyloxyethoxy)phenoxy]ethoxy]phenoxy]ethoxy]methyl]benzoic Acid (9). Yield (0.54 g, 89%). IR (KBr) 1690 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=3.6—4.4 (12H, m, CH_2O), 4.6 (2H, s, benzyl), 4.9 (2H, s, toluic benzyl), 6.9 (8H, s, phenylene), 7.3 (5H, s, aromatic of benzyl), 7.3—8.1 (4H, m, aromatic of toluic acid). Found: C, 71.07; H, 6.29%. Calcd for $C_{33}H_{34}O_8$: C, 70.95; H, 6.14%.

Extraction of Alkali Metal Salts of Ionophores. Ionophore (10^{-4} mol) was dissolved in 0.1 M alkali metal hydroxide (10 ml) in 50 ml vial. To 10 ml was diluted 0.1 ml of the aqueous solution and the optical density of the diluted solution (OD_0) was measured at 273 nm. To the native aqueous solution was added an organic solvent (20 ml) and the mixture was vigorously shaken 60 times by hand. The vial was allowed to stand for 2 d to separate the aqueous layer from the organic layer. The aqueous solution (0.1 ml) was diluted to 10 ml and optical density of the diluted solution (OD_1) was measured at 273 nm. Partition coefficient of a salt of a carboxylic ionophore was calculated as follows: Partition coefficient=$(OD_0-OD_1)/2OD_1$.

Ion Transport Experiment. Ion transport was carried out in U-type or H-type cells[1b] at 35±1 °C for 5 d with stirring at 200 rpm. Donor phase I contains 10 ml aqueous solution of an alkali metal hydroxide (0.1 M) and other alkali metal chlorides (0.1 M). Acceptor phase II contains 10 ml aqueous solution of HCl (0.1 M) and all alkali metal cations with chloride anion (0.1 M). Organic phase III contains an organic solution of a 10^{-4} mol ionophore. An aqueous solution at acceptor phase was diluted to an appropriate volume. The concentration of alkali metal ions (10—100 ppm) was determined to be c_0 and c_1 before and after transport experiment by flame spectrochemical analysis. Transported ion (%) was calculated by $[(c_1-c_0)/c_0]\times100$.

Preparation of New Nitrogen-Bridged Heterocycles. 18.[1] Facile Formations of 3-Arylpyrazolo[1,5-*a*]pyridines and 1-Arylindolizines

Akikazu KAKEHI,* Suketaka ITO, Naosumi KINOSHITA, and Yukio ABAKA
Department of Industrial Chemistry, Faculty of Engineering, Shinshu University, Wakasato, Nagano 380
(Received November 14, 1987)

The alkaline treatment of 1-[(substituted benzylthio)methyleneamino]pyridinium and 1-[2-(substituted benzylthio)vinyl]pyridinium bromides possessing an electron-withdrawing substituent such as a nitro or cyano group in the presence or absence of a dehydrogenating agent afforded the corresponding 3-arylpyrazolo[1,5-*a*]-pyridines and 1-arylindolizines in moderate to good yields, while the reactions of the parent pyridinium salts and those having an electron-releasing group did not produce any significant products. The mode of the reaction, a ring contraction-desulfurization, is the same as that observed in related monocyclic species.

In a series of papers,[1,2] we have described convenient syntheses of various indolizines and pyrazolo[1,5-*a*]pyridines from the reactions of 1-[2-(substituted methylthio)vinyl]pyridinium and 1-[(substituted methylthio)methyleneamino]pyridinium halides with base in the presence or absence of a dehydrogenating agent. In addition, we stated that transient bicyclic intermediates such as **A** having a 12π system (see Fig. 1) are involved in these reactions and that their rearrangement and desulfurization aptitudes to give the corresponding heteroarmatics depend predominantly on the class of the substituent (R′). On the other hand, it is well-documented that the monocyclic 1,3,4-thiadiazinyl anion and related compounds such as **B** afforded only the desulfurized pyrazoles or pyrroles unless the substituent (R′) is hydrogen.[3] Since their substituents (R′) in both species **A** and **B** are not the same and there are some differences between their reactivities, however, it is still doubtful to conclude their mechanistic similarity. Therefore, it is worthwhile to introduce the same type of groups (R′=aryl group) in our bicyclic system **A** and to compare their reactivity with that of the monocyclic system **B**. In this paper we wish to report the generation of 4-arylpyrido[1,2-*d*]-1,3,4-thiadiazine and 1-arylpyrido[2,1-*c*]-1,4-thiazine intermediates and their transformations to desulfurized 3-arylpyrazolo[1,5-*a*]pyridines and 1-arylindolizines.

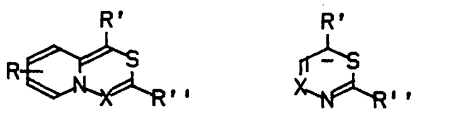

Fig. 1.

Results and Discussion

Preparations of 3-Arylpyrazolo[1,5-*a*]pyridines and 1-Arylindolizines. According to the procedure described in the syntheses of 3-cyano-, 3-ethoxycarbonyl-, and 3-aroylthiopyrazolo[1,5-*a*]pyridines,[2a,c,d] we examined first the reactions of 1-[(benzylthio)methyleneamino]pyridinium (**3a**) and 1-[(4-methylbenzylthio)-methyleneamino]pyridinium bromide (**3b**), readily obtainable from the *S*-alkylation of *N*-(1-pyridinio)-[(methylthio)thiocarbonyl]aminide (**1a**) with benzyl bromide (**2a**) and 4-methylbenzyl bromide (**2b**), in the presence of potassium carbonate in chloroform at room temperature. However, the expected heterocyclic products, 2-methylthio-3-phenyl- (**4a**) and 2-methylthio-3-(4-methylphenyl)pyrazolo[1,5-*a*]pyridine (**4b**), could not be detected. Similarly, the uses of other bases such as 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) or sodium hydride instead of potassium carbonate and of a dehydrogenating agent such as 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ), chloranil, or lead tetraacetate in these reactions afforded always intractable tarry materials and no significant product could be isolated from them.[4] Since the inaccessibility of these heterocycles **4a, b** was ascribed to the lack of the acidity of the benzyl proton, we focused our attention on the reactions of pyridinium salts possessing a benzyl group activated with an electron-withdrawing group. As expected, the treatment of 1-[(2-nitrobenzylthio)-methyleneamino]pyridinium bromides (**3c—h**) with DBU followed by the addition of chloranil or DDQ to the resulting reaction solutions at 0 °C gave the corresponding 3-(2-nitrophenyl)pyrazolo[1,5-*a*]pyridine derivatives (**4c—h**) in 46—89% yields, respectively. Similar reactions of 1-[(4-nitrobenzylthio)-(**3i—n**), 1-[(2-cyanobenzylthio)- (**3o—t**), and 1-[(4-cyanobenzylthio)-methyleneamino]pyridinium bromides (**3u—z**) in the presence or absence of a dehydrogenating agent afforded 3-arylpyrazolo[1,5-*a*]pyridines derivatives (**4i—z**) in considerable yields. In all cases, the possible alternatives, 3-(arylthio)pyrazolo[1,5-*a*]pyridines such as **6**, were not formed. In the reactions of the salts **3s**, y, *N*-(1-pyridinio)-[1-(2-cyanobenzylthio)-(**5s**) and 1-[1-(4-cyanobenzylthio)carbonyl]aminide (**5y**) were also formed in 14 and 24% yields together with pyrazolopyridines **4s** (34%) and **4y** (29%) (Scheme 1).

On the other hand, similar treatment of 1-[2-(benzylthio)-(**8a**) and 1-[2-(4-methylbenzylthio)vinyl]-pyridinium bromide (**8b**) prepared from 1-(1-pyridinio)-

Scheme 2.

[(methylthio)thiocarbonyl]methylide (**7a**) and benzyl bromides (**2a, b**) did not afford any products, but those of pyridinium salts **8c—v** obtained from methylides **7a—e** and bromides **2c—f** gave the corresponding 1-aryl-2-(methylthio)indolizine dervatives (**9c—v**) in moderate yields, respectively (Scheme 2).

The structures of 3-arylpyrazolo[1,5-*a*]pyridines (**4c—z**), and 1-arylindolizines (**9c—v**) were determined mainly by their elemental analyses and their IR and ^1H NMR spectral inspections. For example, the elemental analyses of pyrazolopyridines **4c—z** and indolizines **9c, e—m, o—v** were in good accord with the proposed compositions but not with their arylthio analogs such as **6**. The chemical shifts and signal

patterns of the pyridine moiety in the ^{1}H NMR spectra (see Tables 1 and 2) of compounds **4c—z** and **9c—v** were similar to those of various pyrazolo[1,5-*a*]pyridine and indolizine derivatives previously reported.[1,2,5] The IR spectra of products **4c—n** and **9c—l** showed two characteristic nitro absorption bands at near 1510 and 1340 cm^{-1} and compounds **4o—z** and **9m—v** exhibited a cyano absorption band at near 2220 cm^{-1}. The structures of *N*-(1-pyridinio) [1-(substituted benzylthio)carbonyl]aminides (**5s**, y) were established by their spectral inspection and their independent syntheses. In particular, the elemental analyses and the ^{1}H NMR spectra of **5s**, y clearly showed the absence of the ethoxy moiety in these molecules, and the thermolyses of pyridinium salts **3s**, y in chloroform at the reflux temperature gave the same *N*-ylides **5s**, y in 88 and 90% yields. From these results and our previous observation of the smooth dealkylation of 1-(2-alkoxyvinyl)pyridinium halides[2b] we concluded compounds **5s**, y are *N*-(1-pyridinio) aminides.

Reductions of the Nitro Group. Since the versatility of a nitro group to various functional groups is well-known, the transformations of some 4-nitrophenyl derivatives to 4-aminophenyl compounds were investigated. The hydrogenation of 2-methylthio-3-(4-nitrophenyl)pyrazolo[1,5-*a*]pyridines (**4i—k**) and ethyl 2-methylthio-1-(4-nitrophenyl)indolizine-3-carboxylates (**9h—j**) over palladium on charcoal (10%) in THF proceeded smoothly to give the corresponding 4-aminophenyl derivatives **10a—f** in good yields, respectively. These transformations complement our present method in which an aryl group having an electron-donating group can not be introduced to the corresponding heteroaromatics.

The structures of these compounds **10a—f** were determined mainly by the presence of the primary amino absorption bands appeared in the range of 3321—3620 cm^{-1} and by the absence of the nitro bands in their IR spectra.

Reaction Mechanism. A possible mechanism for these reactions is shown in Scheme 4. The corresponding 3-arylpyrazolo[1,5-*a*]pyridines (**4c—z**) and 1-aryl-

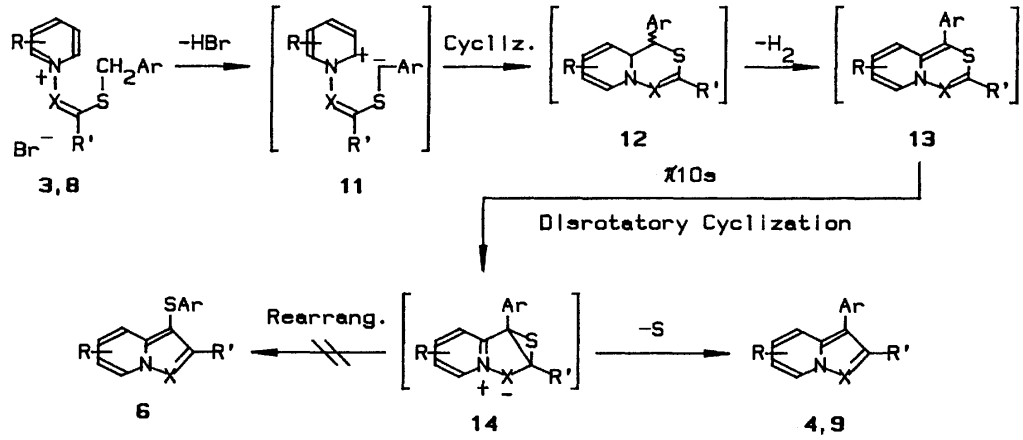
Scheme 3.



Scheme 4.

indolizines (**9c—v**) were formed only from pyridinium salts **3c—z** and **8c—v** having a benzyl substituent activated by an electron-withdrawing group but not from those **3a, b** and **8a, b** possessing a parent or methyl-substituted benzyl group; accordingly it can be presumed that the benzyl proton must be acidic for the generation of the zwitterionic intermediate **11**. Furthermore, it is noted that these reactions proceeded via the ring contraction-desulfurization of transient 1-arylpyrido[2,1-*c*]-1,4-thiazine and its 4-aza-analog such as **13** but not via their ring contraction-rearrangement leading to arylthio derivatives such as **6**. This behavior is the same as that in related monocyclic species, since Schmidt and Huth reported already the smooth transformations of monocyclic 2,6-diphenyl-1,3-thiazinyl and 6-phenyl-1,3,4-thiadiazinyl anions to the desulfurized 2,3-diphenylpyrrole and 4-phenylpyrazole.[3]

Our method for the preparation of 3-arylpyrazolopyridines and 1-arylindolizines, even if a parent phenyl and electron-rich aryl groups could not be introduced into them, has still a high value because of the cheapness and ready availability of the starting materials, and the wide versatility of the heterocycles formed.

Experimental

Melting points were measured with a Yanagimoto micro-melting point apparatus and are uncorrected. The microanalyses were carried out on a Perkin-Elmer elemental analyzer. The ^{1}H NMR spectra were determined with a Varian EM360A spectrometer in deuteriochloroform with tetramethylsilane as an internal standard; the chemical shifts are expressed in δ values. The IR spectra were taken with a Hitachi 260-10 infrared spectrophotometer.

Materials. *N*-(1-Pyridinio) aminides (**1a—f**) and 1-(1-pyridinio) methylides (**7a—e**) employed in the above reactions were prepared according to the procedures described in the literatures.[2,6]

Preparations of 3-Arylpyrazolo[1,5-*a*]pyridines and 1-Arylindolizines. General Method A. A solution of pyridinum *N*-ylide (2 mmol) and benzyl bromide (2.2 mmol) in chloroform (20 ml) was kept at room temperature until the spot of the *N*-ylide completely disappeared (1—4 d, by TLC monitoring). The resulting solution was concentrated under reduced pressure and the residue was washed three times with ether to remove unaltered benzyl bromide. To the chloroform solution (30 ml) of the pyridinium salt, DBU (0.38g, 2.5 mmol) was added dropwise and the resulting mixture was stirred at room temperature for 1 d. The solution was concentrated at reduced pressure, and the residual oil was separated by column chromatography (alumina) using chloroform as eluent. The removal of the solvent and recrystallization from chloroform-hexane gave the corresponding pyrazolo[1,5-*a*]pyridines.

Method B. To the chloroform solution of pyridinium bromide (2 mmol) prepared in Method A, DBU (0.38g, 2.5 mmol) was added dropwise in an ice bath. After 10 min, chloranil (0.49 g, 2 mmol) was added and the resulting mixture was allowed to react for a further 12 h at that temperature (0 °C). The solution was filtered to remove insoluble substances and the filtrate was concentrated under reduced pressure. The same work-up as described above afforded pyrazolo[1,5-*a*]pyridines.

Method C. In the procedure described in Method B, DDQ (0.45g, 2 mmol) instead of chloranil was used as a dehydrogenating agent.

Only 3-(4-nitrophenyl)pyrazolo[1,5-*a*]pyridine derivatives **4i—n** were formed without a dehydrogenating agent (Method A), but none of the other pyrazolo[1,5-*a*]pyridines **4c—h, o—z** and indolizines **9c—v** could be obtained by this method because 4,4a-dihydropyrido[1,2-*d*]-1,3,4-thiadiazine[2c] and 1,9a-dihydropyrido[2,1-*c*]-1,4-thiazine derivatives[2a,e] such as **12** generated in situ from the corresponding pyridinium salts **3c—h, o—z** were not oxidized under the conditions employed here.

The reactions of pyridinium salts such as **3a, b** and **8a, b**, prepared from pyridinium *N*-ylides **1a** and **7a** and benzyl bromide (**2a**), 4-methylbenzyl bromide (**2b**), 4-chlorobenzyl bromide, and 4-bromobenzyl bromide, were carried out under several reaction conditions, but no significant products could be isolated.

Compounds **4c, e, g, k, m, n** and **9c, g** were obtained as orange prisms, **4d** and **9e, j** as orange needles, **4f, l** and **9f, h, i, k, l, v** as yellow needles, **4h** as violet needles, **4i, j** and **9q** as

a) Starting materials. b) All of these yields were obtained by Method C. c) Satisfactory analytical data (within 0.3% for C, H, and N) were obtained for all new compounds except **9d**, **n**. d) Viscous oil. e) Neat. f) The preparation of a pure sample for analysis was unsuccessful.

yellow prisms, **4o—r**, **t**, **x** as colorless prisms, **4s**, **u—w** and **9m**, **p**, **s** as colorless needles, **4y**, **z** and **9o**, **r**, **t**, **u** as pale yellow needles, **9d** as orange viscous oil, and **9n** as yellow viscous oil.

These results together with some physical and analytical data are summarized in Tables 1—4.

Thermolyses of 1-[(2- or 4-Cyanobenzylthio)ethoxymethyleneanimo]pyridinium Bromides. General Method. Pyridinium bromide (**3s** or **3y**, 2 mmol) prepared as above was heated under reflux in chloroform (30 ml) on a water bath for 12 h. The usual work-up of the resulting solution and recrystallization from chloroform-ether gave *N*-(1-pyridinio)-[1-(2- or 4-cyanobenzylthio)carbonyl]aminides: **5s**, 88%, colorless needles, mp 119—121 °C, IR ν (KBr) 2218 (CN) and 1598 cm^{-1} (CO). ^{1}H NMR ($CDCl_3$) δ=4.33 (2H, s, SCH_2), 7.1—8.2 (7H, m, phenyl protons and 3-, 4-, and 5-protons), and 8.7—9.0 (2H, m, 2- and 6-protons). Anal. ($C_{14}H_{11}N_3OS$) C, H, N. **5y**, 90%, colorless needles, mp 135—136 °C, IR ν (KBr) 2221 (CN) and 1588 cm^{-1} (CO). ^{1}H NMR ($CDCl_3$) δ=4.14 (2H, s, SCH_2), 7.3—8.3 (7H, m, phenyl protons and 3-, 4-, and 5-protons), and 8.7—9.0 (2H, m, 2- and 6-protons). Anal. ($C_{14}H_{11}N_3OS$) C, H, N. These compounds **5s**, y were completely in accord with those obtained from the alkaline treatement of the salts **3s**, y.

Reduction of the Nitro Group. General Method. A mixture of 4-nitrophenyl derivatives (0.5 mmol), palladium on carbon (10%, 0.5 g), and THF (50 ml) was stirred at room temperature under hydrogen (1 atmosphere) for 1 d. The resulting mixture was filtered to remove the catalyst, and the filtrate was concentrated under reduced pressure. The residue was separated by column chromatography on alumina using chloroform as eluent. The removal of the solvent and the recrystallizations from chloroform-hexane afforded the corresponding 4-aminophenyl compounds **10c—f**. On the other hand, 3-(4-aminophenyl)-2-(methylthio)pyrazolo-[1,5-*a*]pyridines **10a**, **b** were converted to the *N*-acetyl derivatives by the action of acetic anhydride/pyridine because they were unstable and the preparation of pure samples for analyses was unsuccessful.

Some physical and analytical data of these 4-aminophenyl derivatives are shown below: **10a**, 96%, unstable colorless crystals, IR ν (KBr) 3330 and 3420 cm^{-1} (NH_2), ^{1}H NMR ($CDCl_3$) δ=2.62 (3H, s, SMe), 3.62 (2H, br s, NH_2), 6.5—7.7 (7H, m, 4-, 5-, 6-H, and phenyl protons), and 8.48 (1H, br d, J=7.0 Hz, 7-H). Its *N*-acetyl derivative, pale yellow prisms, mp 140—143 °C. Anal. ($C_{16}H_{15}N_3OS+H_2O$) C, H, N. **10b**, 86%, unstable colorless crystals, IR ν (KBr) 3321 and 3419 cm^{-1} (NH_2), ^{1}H NMR ($CDCl_3$) δ=2.62 (3H, s, SMe), 2.73 (3H, s, 7-Me), 3.61 (2H, br s, NH_2), 6.88 (1H, br d, 6-H), and 6.7—7.6 (6H, m, 4-, 5-H, and phenyl protons). Its *N*-acetyl derivatives, pale yellow prisms, mp 77—79 °C. Anal. ($C_{17}H_{17}N_3OS+H_2O$) C, H, N. **10c**, 92%, colorless prisms, mp 115—118 °C, IR ν (KBr) 3325 and 3392 cm^{-1} (NH_2), ^{1}H NMR ($CDCl_3$) δ=2.33 (3H, s, 5-Me), 2.61 (3H, s, SMe), 3.24 (2H, br s, NH_2), 6.50 (1H, dd, J=7.0 and 2.0 Hz, 6-H), 6.7—7.6 (5H, m, 4-H and phenyl protons), and 8.32 (1H, d, J=7.0 Hz, 7-H). Anal. ($C_{15}H_{15}N_3S$) C, H, N. **10d**, 99%, pale yellow prisms, mp 104—107 °C, IR ν (KBr) 1670 (CO), 3341 and 3420 cm^{-1} (NH_2), ^{1}H NMR ($CDCl_3$) δ=1.46 (3H, t, J=7.0 Hz, $OCH_2C\underline{H}_3$), 2.21 (3H, s, SMe), 3.33 (2H, br s, NH_2), 4.48 (2H, q, J=7.0 Hz, $OC\underline{H}_2CH_3$), 6.6—7.6 (7-H, m, 6-, 7-, 8-H, and phenyl protons), 9.47 (1H, br d, J=7.0 Hz, 5-H). Anal. ($C_{18}H_{18}N_2O_2S$) C, H, N. **10e**, 57%, pale yellow prisms, mp 144—146 °C, IR ν (KBr) 1665 (CO), 3377 and 3462 cm^{-1} (NH_2), ^{1}H NMR ($CDCl_3$) δ=1.45 (3H, t, J=7.0 Hz, $OCH_2C\underline{H}_3$), 2.19 (3H, s, SMe), 2.53 (3H, s, 5-Me), 3.51 (2H, br s, NH_2), 4.47 (2H, q, J=7.0 Hz, $OC\underline{H}_2CH_3$), 6.51 (1H, br d, J=7.0 Hz, 6-H), and 6.6—7.6 (6H, 7-, 8-H, and phenyl pro-

tons). Anal. ($C_{19}H_{20}N_2O_2S$) C, H, N. **10f**, 99%, pale yellow prisms, mp 164—167 °C, IR ν (KBr) 1650 (CO), 3370 and 3456 cm^{-1} (NH_2), ^1H NMR ($CDCl_3$) δ=1.45 (3H, t, J=7.0 Hz, $OCH_2\underline{CH_3}$), 2.19 (3H, s, SMe), 2.28 (3H, s, 7-Me), 3.41 (2H, br s, NH_2), 4.46 (2H, q, J=7.0 Hz, $OC\underline{H_2}CH_3$), 6.59 (1H, dd, J=7.0 and 2.0 Hz, 6-H), 6.6—7.4 (5H, m, 8-H and phenyl protons), and 9.35 (1H, d, J=7.0 Hz, 5-H). Anal. ($C_{19}H_{20}N_2O_2S$) C, H, N.

An Observation on Carboxylation of 4*H*-Cyclopenta[*def*]phenanthrene

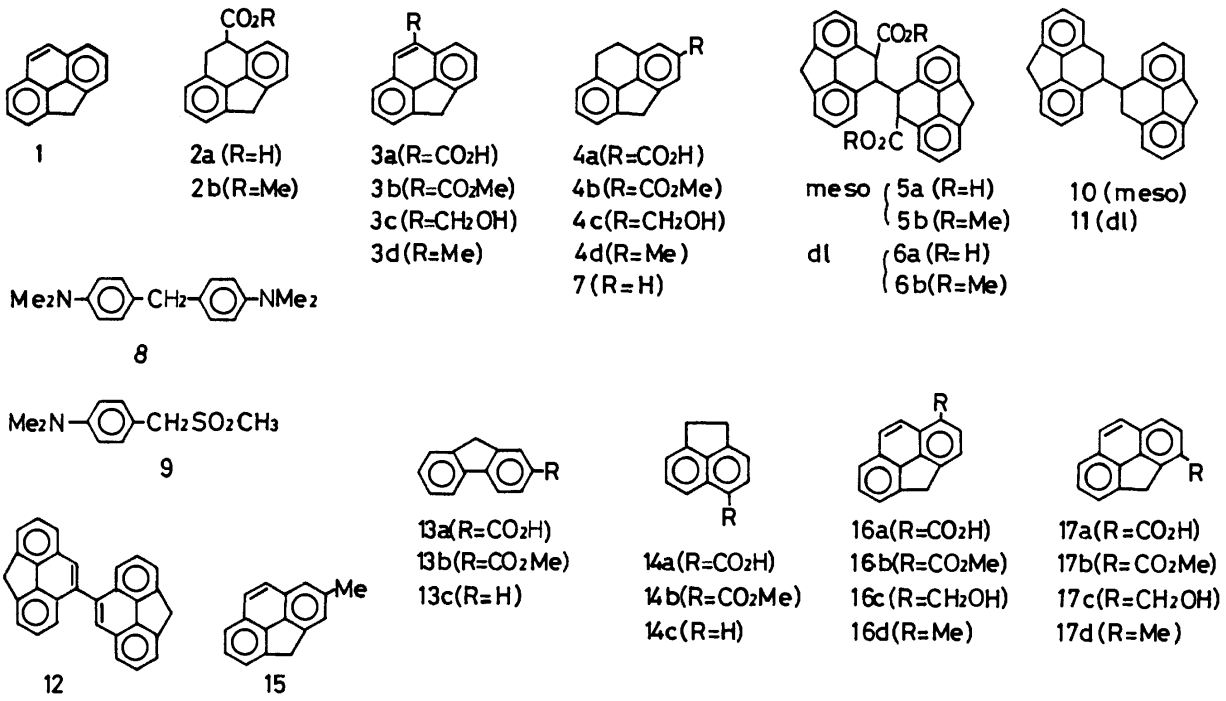
Masahiro MINABE,* Keisuke ISOZUMI, Ken-ichi KAWAI, and Masaaki YOSHIDA
Department of Industrial Chemistry, Faculty of Engineering, Utsunomiya University, Ishiicho, Utsunomiya 321
(Received November 18, 1987)

Photocarboxylation of 4*H*-cyclopenta[*def*]phenanthrene by carbon dioxide in the presence of *N*,*N*-dimethylaniline in dimethyl sulfoxide afforded 8,9-dihydro-4*H*-cyclopenta[*def*]phenanthrene-8- and 2-carboxylic acid, and 4*H*-cyclopenta[*def*]phenanthrene-8-carboxylic acid. These acids were derived into methyl-4*H*-cyclopenta[*def*]phenanthrenes.

The synthesis of arenecarboxylic acids was achieved by various methods, such as the hydrolysis of carboxylic acid derivatives, the oxidation of aralkyl reactants, the carbonylation of organometallic compounds, a direct carboxylation of arenes by carbonyl compounds, and a Kolbe-Schmidt reaction of phenols.[1] One recent advance in this field is the reductive carboxylation of arenes by photoirradiation in the presence of amine and carbon dioxide (CO_2), developed by Tazuke and colaboratorians: irradiation upon a mixture of phenanthrene and *N*,*N*-dimethylaniline (DMA) in dimethyl sulfoxide (DMSO) in the presence of CO_2 afforded 9,10-dihydro-9-phenanthrenecarboxylic acid.[2,3] Similar reactions have been applied to anthracene,[3] pyrene,[3] naphthalene,[2] and biphenyl,[2] giving the corresponding dihydro carboxylic acids.

During the course of studies on the reactivities of 4*H*-cyclopenta[*def*]phenanthrene (**1**),[4] 4*H*-cyclopenta[*def*]phenanthrene-8-carboxylic acid (**2a**)[5] has been required as a synthetic intermediate, in spite of the 8-derivatives being fairly hard to form by a direct acylation of **1**. The present paper deals with the photocarboxylation of **1** and with the conduction of carboxylic acid isomers of **1** to the corresponding methyl derivatives. This would suggest that the procedure has the possibility to promote a substitutional carboxylation of an aryl compound, in addition to reductive carboxylation.

Photoirradiation upon **1** and DMA in DMSO with bubbling of CO_2 afforded three kinds of monocarboxylic acid **2a**,[5] **3a**,[5] and **4a**, dimeric dibasic acid isomers **5a** and **6a**, and reductive hydrocarbon **7** as the derivatives of **1**, accompanied by bis(*p*-dimethylaminophenyl)methane (**8**)[6] and *p*-(dimethylamino)benzyl methyl sulfone (**9**) (Scheme 1).[7] The formations of **8** and **9** are ascribed to a reaction between DMA and DMSO under the conditions: *p*-(dimethylamino)benzyl methyl sulfoxide is temporarily assumed to be formed by the interaction of a radical cation of DMA with the carbanion of DMSO followed by the abstraction of



Scheme 1.

hydrogen. Reaction of the sulfoxide with the second radical cation should give **8** by elimination of methyl sulfoxide. Oxidation of *p*-(dimethylamino)benzyl methyl sulfoxide affords **9**.

The photoirradiation of **1** and DMA in DMSO was carried out under an atmosphere of nitrogen in order to clarify the effect of CO_2. The reaction gave *meso*- (**10**) and *dl*-8,8′-bi(8,9-dihydro-4*H*-cyclopenta[*def*]-phenanthrene) (**11**), **7**, and **9**. Dehydrogenations of **10** and **11** afforded 8,8′-bi(4*H*-cyclopenta[*def*]phenanthrene) (**12**): this supports that **10** and **11** are mutually steric isomers. These findings could be agreeably explained in a similar manner as the photoreaction of anthracene.[8]

One significant difference regarding the results with those of prior photocarboxylations[2,3] is the formation of **4a**: the reactions of phenanthrene, anthracene, and pyrene afforded the corresponding dihydro carboxylic acids by an interaction of the radical anion with CO_2 followed by a hydrogen transfer from the donor.[3] A part of **3a** can be regarded to be formed by the dehydrogenation of **2a** during the reaction. However, **4a** and the other part of **3a** should be assumed to be formed from **7** and **1**, respectively, as by-products by the substitutional sequence, different from reductive carboxylation.

In order to confirm the substitutional carboxylation, similar reactions of **7**, 9*H*-fluorene (**13c**), and acenaphthene (**14c**) were examined, giving **4a**, 9*H*-fluorene-2-carboxylic acid (**13a**),[9] and 5-acenaphthenecarboxylic acid (**14a**),[10] respectively. The isolated yields of these acids were very low due to the difficulty of the isolation procedure; only these acids were detected by gas-chromatographic analyses of the crude mixtures. The carboxylation could not proceed in the absence of light under similar conditions of DMA-DMSO. In the formations of **4a**, **13a**, and **14a**, therefore, it is postulated that the photoexcited hydrocarbons react with weak electrophile, CO_2, through an electrophilic sequence[11] under the conditions of DMA-DMSO with photoirradiation. In other words, there is a possibility that the system gives a reductive carboxylation product and an electrophilic-substituted product in the case of polycyclic aromatic hydrocarbons possessing a located double-bond character.

These carboxylic acids were isolated as the corresponding methyl esters. The esters, **3b** and **4b**, were converted into methanols, **3c** and **4c**; these were derived to the corresponding methyl derivatives, **3d** and **4d**. Dihydro compound, **4d**, was aromatized to give **15**. Isomeric 4*H*-cyclopenta[*def*]phenanthrene-1- (**16a**) and 3-carboxylic acid (**17a**)[12,13] were obtained by haloform reactions of the corresponding acetyl derivatives.[5] Compounds, **16a** and **17a**, gave 1-methyl- (**16d**)[14] and 3-methyl-4*H*-cyclopenta[*def*]phenanthrene (**17d**)[13] through the corresponding esters **16b** and **17b** and methanols **16c** and **17c**.

Experimental

All melting points are uncorrected. The NMR spectra were recorded on a Varian VXR-300 spectrometer in $CDCl_3$. The IR data (KBr-pellet) were obtained with a Jasco IR-G apparatus.

Photocarboxylation of 4*H*-Cyclopenta[*def*]phenanthrene (1). A mixture of **1** (2.85 g, 15 mmol) and DMA (18.2 g, 150 mmol) in DMSO (460 ml) was stirred at room temperature for 200 h with bubbling (ca. 12 l h^{-1}) of CO_2 under irradiation of a high-pressure mercury lamp (100 W) through a quartz tube. The reaction mixture was evaporated in vacuo and the residue was dissolved in dichloromethane (150 ml) and extracted with 5% HCl (3×50 ml).

The inorganic layer was neutralized with 5% aq. NaOH and extracted with PhH. The benzene layer was evaporated in vacuo to give a mixture of DMA and *N*-methylaniline (total 0.81 g). The residue was chromatographed on silica gel with PhH-AcOEt (3 : 1) to give **8** (70 mg, 0.4%, mp 88.0—88.5 °C) and **9** (40 mg, 0.1%). **9:** mp 156—157 °C; IR, 2940, 1618, 1533, 1300, and 1127 cm^{-1}; ^1H NMR, δ=2.72 (3H, s), 2.98 (6H, s), 4.16 (2H, s), 6.72 (2H, d, J=8.7 Hz), and 7.25 (2H, d, J=8.7 Hz); ^{13}C NMR, δ=38.53, 40.29, 60.95, 112.48, 114.99, 131.22, and 150.83; MS, m/z 213 (M^+) and 134.

The dichloromethane layer was extracted with 5% aq. NaOH (3×50 ml) and the organic layer was submitted to GLPC (5% sp-1000, 1 m, 200 °C); it (640 mg) contained **1** (347 mg, 12%) and **7** (64 mg, 2%). The residual part was chromatographed on silica gel with hexane to give **7** (20 mg, mp 139—141 °C) and **1** (231 mg).

The base extract was neutralized with aq HCl, extracted with dichloromethane, evaporated, and followed by esterification with MeOH (150 ml)-concd H_2SO_4 (0.5 ml) under refluxing for overnight. GLPC (sp-1000, 250 °C) data indicated the presence of **2b**[5] (1.15 g, 31%), **3b**[5] (0.94 g, 25%), and **4b** (0.11 g, 3%). Upon chromatography on SiO_2 with PhH, the residue gave **2b** (520 mg), **3b** (333 mg), **4b** (31 mg), **5b** (6 mg, 0.3%), and **6b** (7 mg, 0.4%). **2b:** mp 52.0—52.5 °C; ^1H NMR, δ=3.34 (1H, dd, J=16.8, 7.2 Hz), 3.54 (1H, dd, J=16.8, 7.2 Hz), 3.73 (3H, s), 3.91 (2H, s), 4.26 (1H, t, J=7.2 Hz), 7.16 (1H, d, J=7.5 Hz), 7.20—7.29 (3H, m), 7.36 (1H, d, J=7.5 Hz), and 7.41 (1H, d, J=7.5 Hz). **3b:** mp 82.0—82.5 °C; ^1H NMR, δ=4.08 (3H, s), 4.37 (2H, s), 7.66—7.81 (4H, s), 7.92 (1H, d, J=7.9 Hz), 8.71—8.74 (1H, m), and 8.78 (1H, s, H_9).

4b: mp 77.5—78.5 °C; IR, 1705 and 1300 cm^{-1}; ^1H NMR, δ=3.18 (4H, s), 3.93 (5H, s), 7.15 (1H, d, J=7.5 Hz, H_7), 7.26 (1H, t, J=7.5 Hz, H_6), 7.38 (1H, d, J=7.5 Hz, H_5), 7.87 (1H, s, H_1), and 8.06 (1H, s, H_3); ^{13}C NMR, δ=26.01, 26.03, 37.34, 52.01, 122.91 (C_5), 124.56 (C_3), 124.92 (C_7), 126.94 (C_1), 128.60 (C_6), 129.00, 130.00, 131.53, 138.35, 139.99, 141.68, 143.91, and 167.95. Found: C, 81.68; H, 5.67%. Calcd for $C_{17}H_{14}O_2$: C, 81.58; H, 5.64%.

4a: mp 273—274 °C; IR, 2930, 1688, and 1298 cm^{-1}; ^1H NMR ($CDCl_3$-DMSO-d_6, 60 MHz), δ=3.19 (4H, s), 3.93 (2H, s), 7.13—7.37 (3H, m), 7.87 (1H, s), and 8.06 (1H, s); MS (70 eV), m/z 236 (M^+), 219, and 189. Found: C, 81.16; H, 4.89%. Calcd for $C_{16}H_{12}O_2$: C, 81.34; H, 5.12%.

5b: mp 272.5—273.5 °C; IR, 2950, 1711, and 1185 cm^{-1}; ^1H NMR, δ=3.32 (6H, s), 3.58 (2H, bs), 3.97 (4H, bs), 4.36 (2H, bs), 6.56 (2H, d, J=7.5 Hz), 7.01 (2H, t, J=7.5 Hz), 7.29—7.37 (6H, m), and 7.44 (2H, dd, J=6.8, 0.9 Hz); ^{13}C NMR, δ=37.58, 44.42, 46.95, 52.03, 123.57, 123.80, 125.21,

125.58, 126.20, 127.49, 128.17, 129.76, 138.08, 139.05, 140.12, 140.37, and 173.58; MS, *m/z* 498 (M^+), 374, 250, and 190. Found: C, 81.73; H, 5.40%. Calcd for $C_{34}H_{26}O_4$: C, 81.91; H, 5.26%.

6b: mp 249.0—250.5 °C; IR, 2960, 1726, and 1150 cm^{-1}; ^1H NMR, δ=3.45 (6H, s), 3.72 (2H, s), 3.75 (2H, s), 3.88 (2H, s), 4.12 (2H, s), 6.59 (2H, d, J=7.5 Hz), 6.92—6.97 (4H, m), 7.12 (2H, t, J=7.5 Hz), 7.17 (2H, d, J=6.9 Hz), and 7.30 (2H, d, J=7.5 Hz); ^{13}C NMR, δ=37.36, 47.13, 47.22, 52.20, 123.45, 123.82, 125.30, 125.46, 126.20, 126.80, 127.30, 129.43, 138.87, 140.09, and 173.08; MS, *m/z* 498 (M^+), 377, 250, and 189. Found: C, 81.71; H, 5.18%.

Reaction of DMA in DMSO under Photoirradiation. A solution of DMA (13.4 g, 111 mmol) in DMSO (200 ml) was irradiated for 90 h with bubbling of CO_2. Upon evaporation of DMSO, the residue was chromatographed on Al_2O_3 with PhH giving 1.14 g (9%) of **8:** mp 88—89 °C (lit,[6] mp 88—89 °C); IR, 2920, 2820, 1613, 1522, and 1342 cm^{-1}; ^1H NMR, δ=2.90 (12H, s), 3.81 (2H, s), 6.69 (4H, d, J=8.7 Hz), and 7.06 (4H, d, J=8.7 Hz); ^{13}C NMR, δ=40.05, 41.12, 113.22, 129.58, 130.51, and 149.23; MS, *m/z* 254 (M^+), 210, 189, and 134.

Photoirradiation of 7 with CO_2. A mixture of **7** (960 mg, 5 mmol) and DMA (13.4 g, 111 mmol) in DMSO (200 ml) was stirred for 90 h with bubbling of CO_2 under irradiation of ultraviolet ray. Upon evaporation of solvent, 0.22 g (crude, ca. 19%) of **4a** and 0.43 g (45%) of **7** were isolated from the reaction mixture. The crude acid **4a** was treated with thionyl chloride (10 ml) in the presence of one drop of pyridine in ether (40 ml) with a gentle reflux, followed by refluxing of crude acid chloride in methanol (50 ml). Ester **4b** was given in a yield of 0.22 g (17%).

Reaction of 13c. A mixture of **13c** (1.66 g, 10 mmol) and DMA (13.4 g, 111 mmol) in DMSO (200 ml) was stirred for 90 h with bubbling of CO_2 under photoirradiation. Upon treatment similar to the above, 0.62 g (37%) of **13c** and 0.22 g (crude, ca. 10%, IR, 1688 cm^{-1}) of **13a** were obtained. Esterification of **13a** gave 110 mg (5%) of **13b**; mp 112—113 °C (lit,[9] mp 122 °C); ^1H NMR, δ=3.94 (5H, s), 7.36—7.41 (2H, m), 7.58 (1H, m), 7.81—7.85 (2H, m), 8.09 (1H, d, H_3), and 8.21 (1H, s, H_1); ^{13}C NMR, δ=36.81, 52.08, 119.53, 120.76, 125.21, 126.22, 126.99, 127.89, 128.25, 128.66, 140.56, 143.05, 144.32, 146.24, and 167.42.

Reaction of 14c. Hydrocarbon **14c** (1.54 g, 10 mmol) was treated by the similar procedure as the case of **13c**; 0.44 g (crude, ca. 22%, IR, 1662 cm^{-1}) of **14a**, 0.18 g (1.1%) of **8**, and 0.20 g (13%) of **14c** were obtained. Esterification of **14a** afforded 89 mg (4%) of **14b**; mp 71—73 °C (lit,[10] mp 73—74 °C); ^1H NMR, δ=3.41 (4H, s), 3.99 (3H, s), 7.29 (1H, d, J=7.2 Hz, H_3), 7.34 (1H, d, J=6.9 Hz, H_8), 7.58 (1H, t, J=6.9 Hz, H_7), 8.28 (1H, d, J=7.2 Hz, H_4), and 8.63 (1H, d, J=6.9 Hz, H_6); ^{13}C NMR, δ=30.32, 30.41, 51.77, 118.36, 119.92, 121.91, 122.01, 129.79, 130.16, 133.09, 139.54, 146.21, 152.92, and 167.85.

Photoirradiation of 1 in the Presence of DMA. A mixture of **1** (3.80 g, 20 mmol) and DMA (24 g, 0.2 mol) in DMSO (400 ml) was irradiated for 60 h at room temperature. After addition of PhH (200 ml), the reaction mixture was extracted with 5% aq HCl (300 ml), and the extract was neutralized with aq. $NaHCO_3$, extracted with PhH and distilled under reduced pressure to give 5.7 g of DMA. The residue was chromatographed on SiO_2 with cyclohexane-AcOEt (10 : 1) giving 43 mg (0.2%) of **9** (mp 156—157 °C).

The benzene solution was chromatographed on SiO_2 with cyclohexane. The first eluate afforded 981 mg (26%) of **7** (mp 138—140 °C). The second eluate was fractionally recrystallized from cyclohexane to yield **10** (186 mg, 5%) and **11** (706 mg, 19%). **10:** mp 189.5—191.5 °C; IR, 2930 and 1420 cm^{-1}; ^1H NMR, δ=3.13 (4H, d, J=5.4 Hz), 3.69 (2H, t, J=5.4 Hz), 3.83 (4H, s), 6.90 (2H, d, J=7.4 Hz), 6.95 (2H, d, J=7.4 Hz), 7.04 (2H, t, J=7.4 Hz), 7.14 (2H, t, J=7.4 Hz), 7.26 (2H, d, J=7.4 Hz), and 7.29 (2H, d, J=7.4 Hz); ^{13}C NMR, δ=30.75, 37.46, 42.26, 122.41, 122.94, 124.23, 125.35, 126.62, 127.23, 130.35, 132.08, 139.42, 140.01, and 140.42; MS, *m/z* 382 (M^+) and 191. Found: C, 94.27; H, 5.91%. Calcd for $C_{30}H_{22}$: C, 94.20; H, 5.80%.

11: mp 150.0—151.5 °C; IR, 2940 and 1455 cm^{-1}; ^1H NMR, δ=3.00 (4H, d, J=7.0 Hz), 3.95 (4H, s), 4.12 (2H, t, J=7.0 Hz), 6.80 (2H, d, J=7.4 Hz), 7.01—7.17 (2H, m), 7.25—7.33 (6H, m), and 7.41—7.45 (2H, m); ^{13}C NMR, δ=27.39, 37.57, 41.47, 122.46, 123.06, 123.78, 124.63, 127.30, 127.51, 130.26, 132.58, 139.08, 139.99, 140.32, and 140.53; MS, *m/z* 382 (M^+), 333, and 191. Found: C, 94.42; H, 5.74%. Calcd for $C_{30}H_{22}$: C, 94.20; H, 5.80%.

Dehydrogenations of 10 and 11. A mixture of **10** (19.1 mg, 0.05 mmol) and DDQ (42 mg, 0.18 mmol) in PhH (20 ml) was refluxed for 10 h, followed by chromatography on Al_2O_3 giving **12** (13.5 mg, 71%): mp 269—270 °C; IR, 1420 cm^{-1}; ^1H NMR, δ=4.67 (4H, s), 7.49—7.57 (4H, m), 7.69—7.79 (6H, m), 7.89 (2H, dd, J=7.6, 0.8 Hz), and 8.02 (2H, s); ^{13}C NMR, δ=37.70, 121.30, 121.42, 122.36, 122.69, 126.38, 127.19, 127.53, 127.84, 128.31, 137.09, 138.31, 138.51, 141.59, and 141.90; MS, *m/z* 378 (M^+), 189, and 187. Found: C, 95.17; H, 4.76%. Calcd for $C_{30}H_{18}$: C, 95.21; H, 4.79%.

The similar reaction of **11** (19.1 mg, 0.05 mmol) afforded 13.1 mg (69%) of **12**.

4*H*-Cyclopenta[*def*]phenanthrene-1-carboxylic Acid (16a). To a mixture of Br_2 (0.46 ml, 8.7 mmol) in aq. NaOH (1.44 g in H_2O, 6.5 ml) there was added 1-acetyl-4*H*-cyclopenta[*def*]-phenanthrene[5] (116 mg, 0.5 mmol) in dioxane (20 ml) at 0—5 °C. Upon refluxing for 30 min, the resulting mixture gave 71 mg (57%) of **16a**; mp>320 °C (decomp); IR, 3000, 1668, and 1265 cm^{-1}. The acid **16a** was converted into **16b** by refluxing in MeOH-H_2SO_4; yield 43%; mp 84—85 °C; IR, 1710 and 1242 cm^{-1}; ^1H NMR, δ=4.06 (3H, s), 4.39 (2H, s), 7.67—7.76 (3H, m), 7.88 (1H, d, J=7.6 Hz), 8.00 (1H, d, J=9.2 Hz, H_8), 8.46 (1H, d, δ=7.5 Hz, H_2), and 8.81 (1H, d, J=9.2 Hz, H_9); ^{13}C NMR, δ=37.53, 51.98, 120.65, 121.50, 122.74, 124.83, 125.91, 127.17, 127.43, 127.71, 127.82, 131.42, 137.85, 138.88, 141.36, 147.66, and 168.00. Found: C, 82.35; H, 4.91%. Calcd for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

17a;[12] yield 58%; mp>290 °C (lit,[12] mp 286—287 °C). **17b;**[12,13] yield 74%; mp 114—115 °C (lit,[12] mp 114—115 °C); ^1H NMR, δ=4.06 (3H, s), 4.67 (2H, s), 7.70 (1H, t, J=7.4 Hz), 7.78 (1H, d, J=6.4 Hz), 7.85—7.90 (3H, m), 7.97 (1H, d, J=8.5 Hz), and 8.28 (1H, d, J=8.5 Hz).

4*H*-Cyclopenta[*def*]phenanthrene-1-methanol (16c). A solution of **16b** (280 mg, 1.1 mmol) in ether (20 ml) was refluxed for 3 h with $LiAlH_4$ (209 mg, 5.5 mmol) to give 217 mg (87%) of **16c**; mp 105—106 °C; IR, 3350 and 1006 cm^{-1}; ^1H NMR, δ=1.75 (1H, t, J=5.1 Hz), 4.36 (2H, s), 5.23 (2H, d, J=5.1 Hz), 7.64—7.74 (4H, m), 7.86 (1H, d, J=7.6 Hz), 7.91 (1H, d, J=9.0 Hz), and 8.08 (1H, d, J=9.0 Hz). Found: C, 86.98; H, 5.60%. Calcd for $C_{16}H_{12}O$: C, 87.24; H, 5.49%.

17c;[13] yield 32%; mp 181—182 °C (lit,[13] mp 177—178.5 °C); ^1H NMR, δ=1.79 (1H, t, J=5.1 Hz), 4.40 (2H, s), 5.06 (2H, d, J=5.1 Hz), 7.63—7.74 (3H, m), and 7.83—7.87 (4H, m).

3c; yield 68%; mp 154—155 °C; IR, 3360, 1029, and 1000 cm^{-1}; ^1H NMR, δ=1.85 (1H, t, J=5.9 Hz), 4.38 (2H, s), 5.27 (2H, d, J=5.9 Hz), 7.65—7.74 (4H, m), 7.83 (1H, d, J=7.7 Hz), 7.88 (1H, s, H_9), and 8.02 (1H, d, J=7.7 Hz, H_7); MS, m/z 220 (M^+), 202, 191, and 189.

4c; yield 68%; mp 121—122 °C; IR, 3350 and 1010 cm^{-1}; ^1H NMR, δ=1.55 (1H, bs), 3.15 (4H, s), 3.89 (2H, s), 4.72 (2H, s), and 7.10—7.15 (2H, m), 7.20 (1H, t, J=7.4 Hz), and 7.33—7.38 (2H, m); MS, m/z 222 (M^+), 205, 193, 192, 191, and 189.

1-Methyl-4*H*-cyclopenta[*def*]phenanthrene (16d).[14] A solution of **16c** (206 mg, 1.0 mmol) in AcOH (10 ml) was added into a mixture of HI (57%, 1.0 ml) and red phosphorus (1.0 g) in AcOH (10 ml), and the resulting mixture was refluxed for 10 h to yield **16d** (138 mg, 72%); mp 80—81 °C (lit.[14] mp 83.5—84.5 °C); ^1H NMR, δ=2.76 (3H, s), 4.31 (2H, s), 7.45 (1H, dd, J=7.2, 0.9 Hz), 7.59 (1H, d, J=6.7 Hz), 7.63 (1H, t, J=7.2 Hz), 7.69 (1H, dd, J=7.2, 0.9 Hz), 7.82 (1H, d, J=6.7 Hz), 7.85 (1H, d, J=9.0 Hz), and 7.92 (1H, d, J=9.0 Hz).

17d;[13] yield 60%; mp 73—74 °C; ^1H NMR, δ=2.61 (3H, s), 4.21 (2H, s), 7.45 (1H, d, J=8.0 Hz), and 7.59—7.81 (6H, m).

3d; yield 57%; mp 83—84 °C; IR, 2960, 2900, and 1420 cm^{-1}; ^1H NMR, δ=2.79 (3H, s), 4.35 (2H, s), 7.58—7.75 (6H, m), and 7.88 (1H, d, J=7.5 Hz). Found: C, 93.86; H, 5.94%. Calcd for $C_{16}H_{12}$: C, 94.08; H, 5.92%.

4d; yield 44%; mp 78—79 °C; IR, 2950 and 1440 cm^{-1}; ^1H NMR, δ=2.41 (3H, s), 3.11 (4H, s), 3.84 (2H, s), 6.94 (1H, s, H_1), 7.08 (1H, d, J=7.3 Hz, H_7), 7.15 (1H, t, J=7.3 Hz, H_6), 7.16 (1H, s, H_3), and 7.31 (1H, d, J=7.3 Hz, H_5); MS, m/z 206 (M^+), 191, and 189.

15; obtained by aromatization of **4d** with DDQ in 75% yield; mp 90.0—90.5 °C; IR, 2940, 2850, and 1390 cm^{-1}; ^1H NMR, δ=2.66 (3H, s), 4.31 (2H, s), and 7.54—7.84 (7H, m); MS, m/z 204 (M^+) and 189.

We greatly thank Professor Takashi Toda, Utsunomiya University for his continuing interest.

Reinvestigation on Thermal Cycloaddition of 1-Aryl-2-(9-fluorenylidene)-1-haloethylenes[1)]

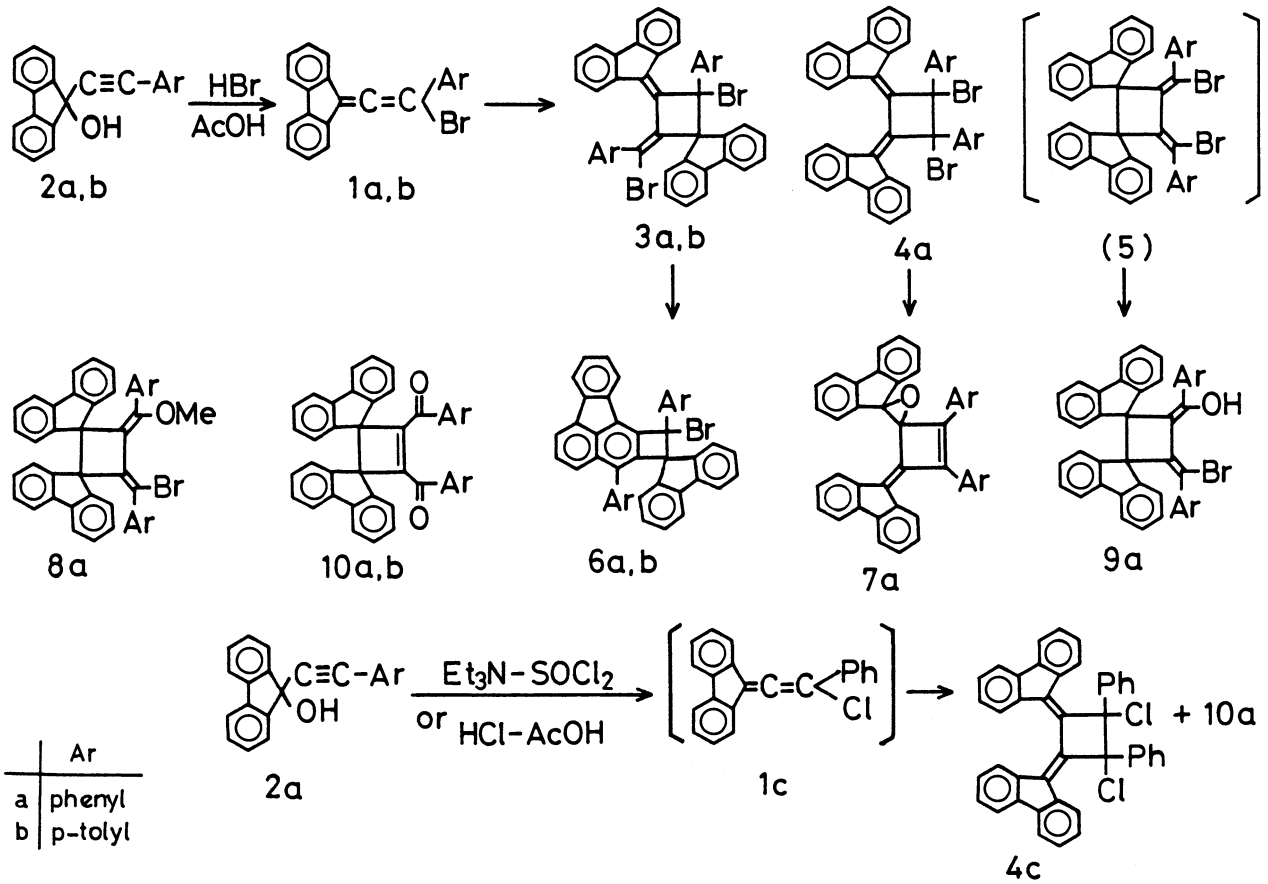
Masahiro MINABE, Masaaki YOSHIDA, Seiji SAITO, Keisuke TOBITA, and Takashi TODA*
Department of Industrial Chemistry, Faculty of Engineering, Utsunomiya University, Ishiicho, Utsunomiya 321
(Received December 10, 1987)

The thermal treatment of 1-bromo-2-(9-fluorenylidene)-1-phenylethylene afforded three different types of [2+2]cycloaddition products. The 1-tolyl homolog showed similar trends, but the chloro analog gave only two types. These results suggest that reactions of the rigid and bulky allenes take place through a 2,2′-biradical giving head-to-head, head-to-tail, and tail-to-tail adducts through the expected processes.

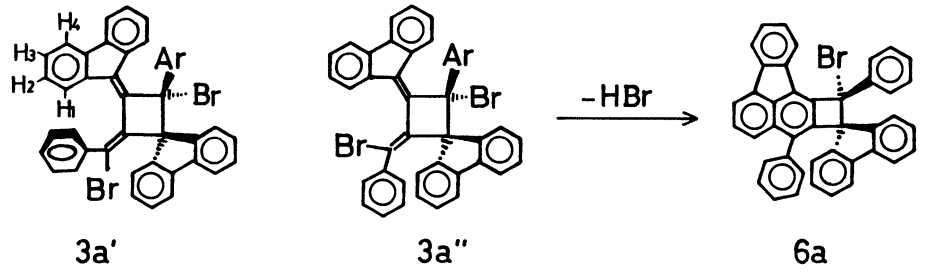
The chemistry of allenes has widely been investigated owing to the unique reactivities, important as synthetic intermediates, as well as the unique structures.[2)] The thermal [2+2]cycloaddition of haloallenes has suggested that it proceeds nonconcertedly via 2,2′-biradical and gives head-to-head and tail-to-tail adducts as the major products.[2,3)] The reaction of 1-chloro-2-(9-fluorenylidene)ethylene has been reported to yield a head-to-head dimer, 3,4-dichloro-1,2-bis(9-fluorenylidene)cyclobutane.[4,5)] However, a detailed study of the reaction showed that the above cycloaddition product was confirmed as a head-to-tail compound, 2-chloro-4-chloromethylene-3-(9-fluorenylidene)spiro[cyclobutane-1,9′-[9*H*]fluorene], with evidence of a similar product of bromo analog.[6,7)] The thermal treatment of 1-bromo-2-(9-fluorenylidene)-1-phenylethylene (**1a**),[5)] which was derived from 9-(phenylethynyl)-9-fluorenol (**2a**), also afforded a head-to-tail adduct **3a**[6,8)] (Scheme 1).

The present paper deals with a reinvestigation of the thermal cycloaddition of 1-bromo- and 1-chloroallenes **1**. This suggests that the reaction takes place to give all three possible dimers: head-to-head, head-to-tail, and tail-to-tail adducts.

By refluxing in benzene, **1a** afforded **3a** as the major product, accompanied by the formation of several other products: **4a**, **6a**, **7a**, **8a**, **9a**, and **10a** (Scheme 1). The reaction of 9-fluorenone with (*p*-tolylethynyl)-



Scheme 1.

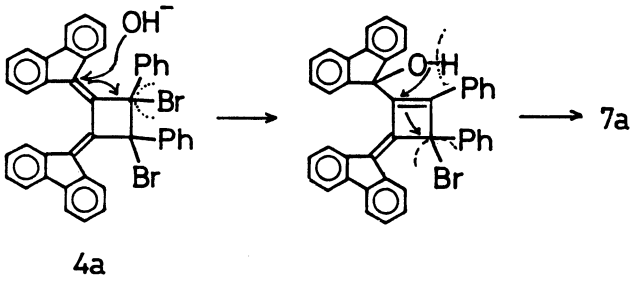


Scheme 2.

magnesium bromide, which was derived from *p*-tolylacetylene,[9] gave 9-(*p*-tolylethynyl)-9-fluorenol (**2b**); the alcohol was converted into another allene, **1b**. The reaction of **1b** gave **6b** as the major product and **3b** and **10b** as the minor products. Several attempts to obtain chloroallene **1c** failed as the result of reactions of **2a** with thionyl chloride in the presence of amine and with hydrochloric acid in acetic acid, though small amounts of **4c** and **10a** were isolated.

The orange needles, **3a**, were concluded to be the head-to-tail compound previously described in the literature[6,8] through a comparison with their UV data. The UV spectrum of **3b** is similar to that of **3a**. Characteristic peaks of the NMR spectra of **3a** and **3b** are high-field one-proton doublets, at δ 5.13 for **3a** and δ 5.18 for **3b**. The *J*-coupling and COSY data show that the doublets connect vicinally triplet at δ 6.29, successively triplet at δ 6.97, and doublet at δ 7.48 for **3a**, and triplet at δ 6.29, triplet at δ 6.97, and doublet at δ 7.53 for **3b**. These four-proton sets were reasonably assigned to H_1, H_2, H_3, and H_4, respectively, of the 9-fluorenylidene moiety, which is located in the same plane as the cyclobutane ring, as shown as **3a'** (Scheme 2). The high-field shift of H_1 is due to the ring current of the adjacent phenyl moiety of the arylbromomethylene group.

Compound **3a'** was stable under refluxing in cyclohexane. The geometrical isomer of **3a'** (**3a"**) should form by cycloaddition, but convert easily into a fluoranthene derivative **6a** by dehydrobromination during a reaction and/or separation. The UV spectra of **6a** and **6b** are very similar to that of fluoranthene, showing a red shift (about 40 nm). The molecular model of **6a** indicates that the aryl group attached to the fluoranthene moiety can rotate freely, but that the aryl group situated on the cyclobutane ring is restricted from free rotation. The two phenyl groups of **6a** are distinguishable by COSY spectra: the two-proton doublet at δ 5.95 is correlated to the two-proton triplet (δ 6.65), successively a one-proton triplet (δ 6.79); these were assigned to be attached to the free-rotating phenyl group connected to the fluoranthene. The other phenyl protons appear separately at δ 6.38 (d), 6.89 (t), 7.15 (t), 7.59 (t), and 7.36(d); this suggests that the ring is fixed sterically. The NMR spectra of **6b** show similar trends; the methyl-proton singlet (δ 1.96) and a



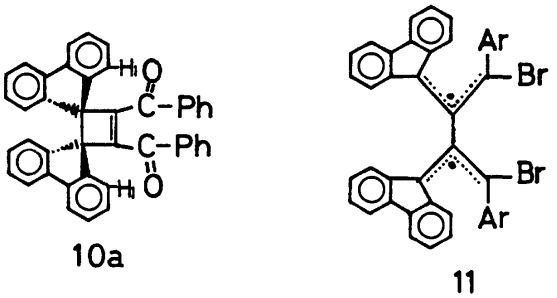
Scheme 3.

couple of two-proton doublets at δ 5.81 and 6.47 are due to the tolyl protons attached to the fluoranthene moiety. Also, the methyl protons (δ 2.02), the one-proton singlet (δ 6.16), and the one-proton doublet (δ 6.94) belong to the restricted-rotating tolyl group of the cyclobutane moiety.[10]

The absorption maxima (480—490 nm) of reddish **4a** and **4c** are similar to those of the head-to-head cycloadducts[7] obtained from 2,3-dibromo-1,4-bis(9-fluorenylidene)-1,3-butadiene. A molecular model of **4** shows that a part of the two 9-fluorenylidene plane accumulates each other. The NMR spectrum of **4c** is relatively simple and shows slightly broad signals, because of the symmetrical molecule and of the mutual interaction of the two fluorenylidene moieties.

The UV spectrum of **7a** is similar to that of **3a** and supports the conjugating system being 9-(4-phenyl-1,3-butadienyl)fluorene. However, **3a** may not be easy to give a compound having a molecular formula of $C_{42}H_{26}O$: **7a** is postulated to form by the hydrolysis of **4a** during the reaction and/or its separation, since **7a** does not show any carbonyl or hydroxyl absorption band in its IR spectrum (Scheme 3). The NMR signals of **7a** indicate an intramolecular mutual interaction that is similar to **4c**.

The UV spectra of the other cycloadducts, **8a**, **9a**, **10a**, and **10b**, significantly differ from those of head-to-tail and head-to-head addition products, and have absorption maxima between 300 and 310 nm. These compounds should be derived from tail-to-tail adduct **5**, which could not be isolated. The methoxy compound **8a** (OCH_3, ^1H NMR, δ=2.67) may be a tail-to-tail adduct formed from **1a**, **2a**, or **5a**. A small amount of methoxyallene could be formed from **2a** with contam-



Scheme 4.

inating methanol which was used for the recrystallization of **2a**; the methanol should be contained in **2a** since it is difficult to remove the methanol from **2a** due to the inclusion complex of **2a** with methanol, as in the case of 9-(1-propynyl)-9-fluorenol.[11]

The molecular formula ($C_{42}H_{27}OBr$) and the IR spectrum (3500 cm^{-1}) of **9a** indicate that one bromine of the primary product **5a** was hydrolyzed during the reaction and/or separation process.

Analytical data and strong absorptions (ca. 1650—1655 cm^{-1}) in the IR spectra of **10a** and **10b** suggest that **10a**, **b** possess two carbonyl groups which were formed by removing two halogen atoms of **5** by hydrolyses and a following oxidation. Phenyl protons of **10a** appear at δ 7.11 as a four-proton triplet, at δ 7.30 as a two-proton triplet, and at δ 7.74 as a four-proton doublet. The two-proton doublet at δ 8.36 is assigned to H_1 (Scheme 4, **10a**), which is sterically deshielded by the carbonyl group. Similarly, the tolyl groups of **10b** are a singlet at δ 2.22 and doublets at δ 6.90 and 7.62; the doublet at δ 8.35 is H_1.

The small amounts of these minor products did not allow for any further investigation. The [2+2]cycloaddition of **1** afforded mainly head-to-tail product **3** accompanied by the formation of head-to-head **4** and tail-to-tail **5**, in spite of the fact that the material balance of the reaction products was not good. These results could reasonably explained why the thermal [2+2]cycloaddition proceeds via 2,2′-biradical **11** from the 1-haloallene **1**, and **11** cyclizes by three possible ways, giving cyclobutanes.

Experimental

All melting points are uncorrected. The ^1H NMR spectra were measured on a Varian VXR 300 or (a part) a Jeol C-60 HL spectrometer in $CDCl_3$ (0.62 ml for 2—10 mg samples in 5 mm tube). The UV data were recorded using a Shimadzu UV-180 or a Hitachi U-3400 apparatus in CH_2Cl_2.

1-Bromo-2-(9-fluorenylidene)-1-phenylethylene (1a). According to the method described in literature,[6] to a cooled solution of **2a** (0.50 g, 1.77 mmol) in AcOH (15 ml) was added dropwise a solution of hydrobromic acid (47%, 1.5 g, 8.71 mmol) in H_2O (5 ml). Upon stirring for 1 h with cooling, the precipitate was filtered, washed with water in order to be neutralized, dried, and recrystallized from hexane giving yellow needles, **1a**: 0.546 g (89%); mp 117—119 °C (decomp); IR (KBr), 1936 cm^{-1} (C=C=C) (lit,[6] 1940 cm^{-1}); UV, λ_{max} 319 (log ε 4.28), 284 (4.27), 260 (4.74), and 253 nm (4.63); MS (70 eV), m/z 346, 344 (M^+), 265, and 187; ^1H NMR, δ=7.27—7.42 (7H, m), 7.61—7.67 (4H, m), and 7.72 (2H, dt, J=7.5, 0.9 Hz).

The allene **1a** (100 mg, 0.29 mmol) was percolated through silica-gel column (1 cm i.d. 10 cm) with benzene and 72 mg (72%) of **1a** was recovered. When alumina was used instead of silica, only 15 mg (18%) of 2-(9-fluorenylidene)-1-phenylethanone was isolated; mp 137—139 °C (lit,[12] 137 °C); IR (KBr), 1650 (C=O) and 1591 cm^{-1} (C=C).

9-(*p*-Tolylethynyl)-9-fluorenol (2b). To a ethylmagnesium bromide (obtained from ethyl bromide (13.10 g, 120 mmol) and magnesium (2.92 g, 120 mmol) in ether (100 ml) under an argon atmosphere) was added dropwise *p*-tolylacetylene (12.76 g, 110 mmol) with ice-cooling; the resulting mixture was refluxed for an additional 16 h. A solution of 9-fluorenone (18.0 g, 100 mmol) in benzene (150 ml) was added dropwise to the Grignard solution and the mixture was refluxed for an additional 26 h. Upon the usual treatment, 26.5 g (90%) of **1b** was isolated by means of column chromatography on silica gel: mp 44.5—46.5 °C; IR, 3530 cm^{-1} (OH); MS (70 eV), m/z 296 (M^+), 281, and 181; ^1H NMR (CCl_4), δ=2.24 (3H, s), 3.07 (1H, bs), and 6.88—7.77 (12H, m).

9-Methoxy-9-(*p*-tolylethynyl)fluorene was obtained as colorless oil by percolation of **2b** on silica gel with methanol: MS (70 eV), m/z 310 (M^+) and 279; ^1H NMR (CCl_4), δ=2.28 (3H, s), 3.01 (3H, s), and 6.78—7.68 (12H, m).

1-Bromo-2-(9-fluorenylidene)-1-(*p*-tolyl)ethylene (1b). The foregoing alcohol **2b** was treated in a manner similar to the case of **2a** to give **1b**: yield 84%; mp 125—127 °C (decomp); IR (KBr), 1920 cm^{-1} (C=C=C); UV, λ_{max} 321 (log ε 4.38), 285 (4.34), 261 (4.80), and 253 nm (4.68); MS (70 eV), m/z 360, 358 (M^+), and 279; ^1H NMR, δ=2.35 (3H, s), 7.14 (2H, d, J=8.1 Hz), 7.28 (2H, t, J=7.5 Hz), 7.38 (2H, t, J=7.5 Hz), 7.52 (2H, d, J=8.1 Hz), 7.61 (2H, d, J=7.5 Hz), and 7.71 (2H, d, J=7.5 Hz). Found: C, 74.09; H, 4.33%. Calcd for $C_{22}H_{15}Br$: C, 73.55; H, 4.21%.

Thermal Treatment of 1a. A solution of **1a** (1.99 g, 5.8 mmol) in benzene (40 ml) was refluxed in the dark under an atmosphere of argon for 4 h. Upon evaporation of the solvent, the residue was fractionally recrystallized from ethyl acetate to give **3a** (590 mg, 30%), **6a** (158 mg, 9%), and **4a** (75 mg, 3.8%). The separation of the mother liquor by silica-gel column chromatography with dichloromethane-cyclohexane (1 : 3) successively afforded **7a** (25 mg, 1.6%) and **8a** (65 mg, 3.5%). The eluent was exchanged into ethyl acetate and afforded **10a** (33 mg, 2%) and **9a** (54 mg, 3%). These compounds were recrystallized from dichloromethane-hexane. **3a**: mp 206—208 °C (decomp) (lit,[6] 203—204 °C), orange needles; UV, λ_{max} 412 (log ε 4.35), 276 (4.59), and 237 nm (4.75); MS (19 eV), m/z 692, 690, 688 (M^+), 611, 609, 529, 452, 365, and 265; ^1H NMR, δ=5.13 (1H, d, J=7.6 Hz), 6.29 (1H, dt, J=7.6, 1.0 Hz), 6.68 (2H, t, J=7.1 Hz), 6,78—6.88 (3H, m), 6.97 (1H, dt, J=7.6, 1.0 Hz), 7.03—7.10 (2H, m), 7.13—7.20 (1H, m), 7.22—7.47 (7H, m), 7.48 (1H, d, J=7.6 Hz), 7.57 (1H, d, J=7.8 Hz), and 7.63—7.83 (6H, m). Found: C, 72.53; H, 4.03%. Calcd for $C_{42}H_{26}Br_2$: C, 73.06; H, 3.80%.

4a: mp 169—171 °C (decomp), red needles; UV, λ_{max} 490 (log ε 5.30), 330 (4.97), 275 (5.58), and 244 nm (5.73); MS (70 eV), m/z 692, 690, 688 (M^+), 611, 609, 530, and 453.

6a: mp 317—319 °C (decomp), yellow crystals; UV, λ_{max} 398

(log ε 4.28), 378 (4.55), 359 (4.48), 343 (4.27), 307 (4.15), 295 (4.12), and 264 nm (4.96); MS (19 eV), *m/z* 610, 608 (M^+), 529, 452, 375, and 224; ^{1}H NMR, δ=5.95 (2H, d, *J*=7.5 Hz), 6.38 (1H, dd, *J*=7.5, 1.2 Hz), 6.65 (2H, t, *J*=7.5 Hz), 6.79 (1H, t, *J*=7.5 Hz), 6.89 (1H, dd, *J*=7.5, 1.2 Hz), 7.15 (1H, dt, *J*=7.5, 1.2 Hz), 7.22—7.26 (3H, m), 7.36 (1H, dd, *J*=7.5, 1.2 Hz), 7.40—7.45 (6H, m), 7.55 (2H, d, *J*=8.6 Hz), 7.59 (1H, dd, *J*=7.8, 1.3 Hz), 7.88 (2H, d, *J*=7.5 Hz), and 7.94 (2H, d, *J*=7.5 Hz). (Found: C, 81.68; H, 3.77%. Calcd for $C_{42}H_{25}Br$: C, 82.76; H, 4.13%.)

7a: mp 291—292 °C (decomp), orange-red needles; no halogen; IR (KBr), 1085 cm^{-1}; UV, λ_{max} 378 (log ε 4.55), 266 (4.61), and 246 nm (4.80); MS (20 eV), *m/z* 546 (M^+), 529, 453, 365, and 265; ^{1}H NMR, δ=6.76—6.90 (6H, m), 7.13 (2H, dt, *J*=7.4, 1.0 Hz), 7.23—7.39 (12H, m), 7.56 (2H, d, *J*=7.9 Hz), 7.69 (2H, d, *J*=7.0 Hz), and 7.75 (2H, d, *J*=7.3 Hz). Found: C, 92.07; H, 5.13%. Calcd for $C_{42}H_{26}O$: C, 92.28; H, 4.79%.

8a: mp 242—244 °C (decomp), colorless crystals; IR (KBr), 1085 cm^{-1} (C-O-C); UV, λ_{max} 309 (log ε 4.31) and 267 nm (4.50); MS (19 eV), *m/z* 642, 640 (M^+), 611, 609, 561, 529, 365, and 195; ^{1}H NMR, δ=2.67 (3H, s), 6.30 (2H, bs), 6.68 (2H, bs), 6.88—7.44 (16H, m), 7.58 (2H, d, *J*=6.6 Hz), 7.68 (2H, d, *J*=6.6 Hz), and 7.80 (2H, d, *J*=6.8 Hz). Found: C, 80.27; H, 4.55%. Calcd for $C_{43}H_{29}OBr$: C, 80.50; H, 4.56%.

9a: mp 214—216 °C (decomp), colorless crystals; IR (KBr), 3500 cm^{-1} (OH); UV, λ_{max} 311 (log ε 4.30) and 266 nm (4.52); MS (19 eV), *m/z* 628, 626 (M^+), 547, 546, 447, 445, and 181; ^{1}H NMR, δ=4.52 (1H, bs), 6.0—7.8 (24H, m), and 7.94 (2H, d, *J*=8.1 Hz). Found: C, 80.43; H, 4.44%. Calcd for $C_{42}H_{27}OBr$: C, 80.38; H, 4.34%.

10a: mp 290—292 °C (decomp), yellow crystals; IR (KBr), 1653 (C=O), 1593, and 1578 cm^{-1}; UV, λ_{max} 302 (log ε 4.24) and 264 nm (4.90); MS (20 eV), *m/z* 562 (M^+), 456, and 351; ^{1}H NMR, δ=6.96 (2H, dt, *J*=7.5, 1.2 Hz), 7.05 (2H, dt, *J*=7.5, 1.2 Hz), 7.11 (4H, t, *J*=7.6 Hz), 7.25—7.31 (8H, m), 7.63 (4H, dt, *J*=8.5, 1.0 Hz), 7.74 (4H, dd, *J*=7.6, 1.2 Hz), and 8.36 (2H, dd, *J*=7.8, 0.9 Hz). Found: C, 89.60; H, 4.57%. Calcd for $C_{42}H_{26}O_2$: C, 89.66; H, 4.66%.

Thermal Reaction of 1b. A solution of **1b** (1.436 g, 4 mmol) in benzene (50 ml) was refluxed for 5 h. Upon evaporation of the solvent, the residue was recrystallized from ether, yielding yellow needles, **6b** (244 mg, 19.2%). The mother solution was chromatographed on silica gel with hexane and **10b** (37 mg, 1.6%) was isolated as yellow crystals (from dichloromethane-hexane).

Another experiment using **1b** (718 mg, 2 mmol) in cyclohexane (7.5 ml) was carried out by refluxing for 4 h and concentrating into a small volume; yellow needles, **3b** was obtained in yield of 143 mg (19.9%). **3b**: mp 195.5—197.0 °C (decomp); UV, λ_{max} 413 (log ε 4.30), 277 (4.62), and 271 nm (s, 4.60); MS (70 eV), *m/z* 720, 718, 716 (M^+), 639, 637, and 558; ^{1}H NMR, δ=2.02 (3H, s), 2.34 (3H, s), 5.18 (1H, d, *J*=7.5 Hz), 6.29 (1H, dt, *J*=7.5, 1.2 Hz), 6.46 (2H, d, *J*=7.8 Hz), 6.66 (2H, d, *J*=8.4 Hz), 6.93 (1H, dt, *J*=8.1, 1.9 Hz), 6.97 (1H, dt, *J*=7.5, 1.2 Hz), 7.04—7.14 (2H, m), 7.19—7.50 (7H, m), 7.53 (1H, dd, *J*=7.5, 1.4 Hz), 7.55—7.64 (2H, m), and 7.69—7.82 (4H, m). Found: C, 73.47; H, 4.13%. Calcd for $C_{44}H_{30}Br_2$: C, 73.55; H, 4.21%.

6b: mp 314—316 °C (decomp); UV, λ_{max} 404 (log ε 4.37), 383 (4.57), 364 (4.50), 350 (s, 4.31), 306 (4.23), 295 (4.23), and 265 nm (4.70); MS (70 eV), *m/z* 638, 636 (M^+), 557, 449, and 277; ^{1}H NMR, δ=1.96 (3H, s), 2.02 (3H, s), 5.81 (2H, d, *J*=8.3 Hz), 6.16 (1H, s), 6.47 (2H, d, *J*=8.3 Hz), 6.94 (1H, d, *J*=8.0 Hz), 7.23—7.49 (11H, m), 7.54 (2H, d, *J*=8.0 Hz), 7.86 (2H, d, *J*=7.5 Hz), and 7.93 (2H, d, *J*=6.9 Hz). Found: C, 82.34; H, 4.73%. Calcd for $C_{44}H_{29}Br$: C, 82.88; H, 4.58%.

10b: mp 298.5—299.5 °C (decomp); IR (KBr), 1654 (C=O) and 1602 cm^{-1} (C=C); UV, λ_{max} 301 (log ε 4.38), 264 (4.86), and 258 nm (4.58); MS (70 eV), *m/z* 590 (M^+), 471, 352, and 119; ^{1}H NMR, δ=2.22 (6H, s), 6.90 (4H, d, *J*=7.8 Hz), 6.96 (2H, dt, *J*=7.8, 1.2 Hz), 7.03 (2H, dt, *J*=7.5, 1.5 Hz), 7.22—7.31 (6H, m), 7.60 (4H, d, *J*=7.5 Hz), 7.62 (4H, d, *J*=7.8 Hz), and 8.35 (2H, d, *J*=7.8 Hz). Found: C, 89.78; H, 4.95%. Calcd for $C_{44}H_{30}O_2$: C, 89.46; H, 5.12%.

Reaction of 2a with Thionyl Chloride. A cooled (0 °C) mixture of **2a** (282 mg, 1.0 mmol) and triethylamine (0.3 g, 3 mmol) in dry ether (5 ml) was added dropwise to thionyl chloride (0.3 g, 2.5 mmol). Upon stirring for 1 h, the reaction mixture was filtered; the filtrate was evaporated and chromatographed on silica gel with dichloromethane-cyclohexane (1 : 3) to yield **4c** (8 mg, 4%) and **10a** (2 mg, 1%, mp 290—292 °C, decomp). **4c**: mp 247.5—249.5 °C (decomp), red crystals; UV (EtOH), λ_{max} 481 (log ε 4.41), 330 (3.75), 272 (4.64), and 247 nm (4.75); MS (70 eV), *m/z* 604, 602, 600 (M^+), 567, 565, 530, 453, 365, and 265; ^{1}H NMR, δ=6.93 (2H, dt, *J*=7.7, 1.1 Hz), 6.98 (2H, dt, *J*=7.6, 1.1 Hz), 7.18 (2H, t, *J*=7.7 Hz), 7.23—7.30 (4H, m), 7.34—7.39 (4H, m), 7.45—7.49 (4H, m), 7.57—7.65 (6H, m), and 8.40 (2H, d). Found: C, 83.72; H, 4.51%. Calcd for $C_{42}H_{26}Cl_2$: C, 83.86; H, 4.36%.

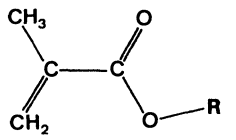
(Received November 21, 1987)

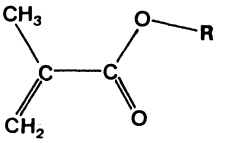
The molecular structures of α-methylbenzyl methacrylate, 1,2-diphenylethyl methacrylate, α-*t*-butylbenzyl methacrylate, 1,2,2,2-tetraphenylethyl methacrylate, diphenylmethyl methacrylate, and 1,1-diphenylethyl methacrylate in solution were investigated by means of IR spectroscopy and ^{1}H NMR spectroscopy using a lanthanoid-induced chemical shift (LIS) reagent [Eu(fod)$_3$] by reference to X-ray analysis data. The preferred conformation between the C=C double bond and the C=O group was estimated to be s-cis in solution. The conformation of ester groups of α-substituted benzyl methacrylates in toluene depended upon the α-substituent and the temperature. On the basis of structural data, the mechanism of the highly enantiomer-selective polymerization of racemic methacrylates with a (−)-sparteine-Grignard reagent complex is discussed.

(−)-Sparteine (Sp)-Grignard reagent complexes are effective initiators in the enantiomer-selective (asymmetric-selective or stereoelective) polymerization of racemic α-monosubstituted benzyl methacrylates such as α-methylbenzyl methacrylate (MBMA),[1,2] α-ethylbenzyl methacrylate (EBMA),[3] α-isopropylbenzyl methacrylate (iPrBMA),[3] 1,2-diphenylethyl methacrylate (DPEMA-1,2),[4] and α-*t*-butylbenzyl methacrylate (*t*-BBMA).[3] For example, in the polymerization of racemic MBMA with a cyclohexylmagnesium bromide (*c*-HexMgBr)-Sp complex in toluene at −78 °C, the polymer obtained in the early stage of the polymerization was rich in (*S*)-antipode whose optical purity was as high as 93%; the monomer recovered at about 65% conversion was almost optically pure.[2] (S)-Selective polymerization was also achieved for EBMA, iPrBMA, and DPEMA-1,2. However, for *t*-BBMA (*R*)-enantiomer was polymerized preferentially over (*S*)-enantiomer.[3] It has been pointed out that this reverse enantiomer selection of *t*-BBMA and other methacrylates may be caused by the difference in conformation of the monomers.[3] Recently, we also found that (*S*)-antipode of 1,2,2,2-tetraphenylethyl methacrylate (TrBMA) was polymerized preferentially with rather low enantiomer selectivity.[5] Among these monomers, DPEMA-1,2, *t*-BBMA, and TrBMA gave crystals suitable for X-ray diffraction study. The results of X-ray analyses have already been reported and the mechanism of the enantiomer-selective polymerization has been discussed on the basis of the determined molecular structures.[6] X-Ray structure analyses were also achieved on some achiral methacrylates, diphenylmethyl methacrylate (DPMMA),[7] 1,1-diphenylethyl methacrylate (DPEMA-1,1),[8] triphenylmethyl methacrylate (TrMA),[8] and diphenyl-2-pyridylmethyl methacrylate (D2PyMA)[9] which show interesting phenomena in the stereospecific polymerization with anionic and radical initiators.[10-12]

One of the problems concerning the molecular structures of methacrylates is the conformation between the C=C double bond and the C=O group: that is, whether it is s-trans or s-cis. This, especially on



s-trans



s-cis

methyl methacrylate (MMA), has been studied by several methods. However, the results obtained are not always consistent with one another. It has been found that the molecules of DPMMA, DPEMA-1,2, and D2PyMA have the s-trans form in crystal.[6,7,9] This is consistent with the results of an electron diffraction study,[13] molecular polarizability measurements[14] and an ab initio MO calculation of MMA.[15] On the other hand, DPEMA-1,1, TrMA, and TrBMA exist as the s-cis form in crystal.[6,8] This agrees with the results of the ^{1}H NMR study of molecular complexes of MMA and Lewis acids,[16] and the conformational analysis of MMA by a lanthanoid-induced chemical shift (LIS) reagent.[17]

The present work was undertaken in order to obtain more detailed information on the conformation of DPMMA, MBMA, DPEMA-1,2, DPEMA-1,1, TrMA, and TrBMA, in solution by IR spectroscopy and ^{1}H NMR spectroscopy with an LIS reagent. The results helped us to understand the mechanism of the

	R_1	R_2	R_3

enantiomer-selective polymerization of the racemic methacrylates with the (−)-Sp-Grignard reagent system in toluene.

Experimental

Materials. All methacrylates used in this study were synthesized and characterized according to our previous work.

An NMR shift reagent Eu(fod)$_3$ (Nakarai Chemical Co.) was used without further purification.

Measurements. IR spectra of the methacrylates were measured with a JASCO IR-810 spectrophotometer in KBr pellets and in CCl_4 or toluene with a 50-μm NaCl cell at room temperature. The wavenumbers were calibrated using a polystyrene film. The ^1H NMR spectra were recorded on a JNM MH-100 or JNM FX-100 (100 MHz) instrument in toluene-d_8; tetramethylsilane (TMS) was used as an internal standard.

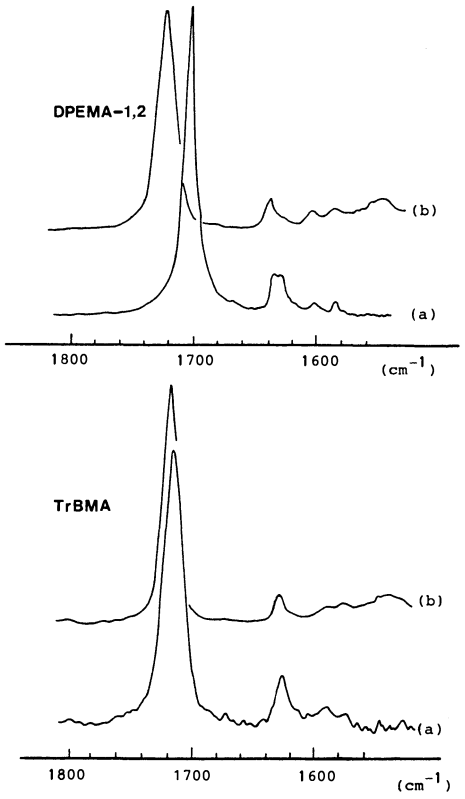

Fig. 1. IR spectra of C=O and C=C bands of DPEMA-1,2 and TrBMA in KBr (a) and in CCl_4 (b).

LIS Measurements. The lanthanoid-induced chemical shifts were measured with Eu(fod)$_3$ in toluene-d_8 at 35 and −40 °C. The concentration of the methacrylates was 0.5 mol l^{-1} and the molar ratio of [Eu(fod)$_3$]/[Methacrylate]([Ld]/[M]) was changed in a range of 0—0.30.

Results and Discussion

IR Spectra of Methacrylates. It has been well-known that IR spectroscopy differentiates the s-cis and s-trans conformations of α,β-unsaturated ketones and there exist some relatively simple rules in the relationship between the conformation (s-cis or s-trans) and the C=O and C=C bands of α,β-unsaturated ketones;[18,19] (1) there is a greater frequency separation between the C=O and C=C stretching bands of the s-cis form than the s-trans form, (2) the ratio of the band intensities of the C=O to the C=C stretching vibrations is considerably larger for the s-trans than the s-cis. However, so far, no such rules have been reported for α,β-unsaturated esters. The molecular structures of the methacrylates used in this study have already been determined by X-ray analysis. This promoted us to investigate the relationships between the conformation and the C=O and C=C bands of methacrylates in both crystal and solution by IR spectroscopy.

Figure 1 shows the IR spectra of DPEMA-1,2 and TrBMA in KBr pellets (a) and in CCl_4 solutions (b). The former methacrylate has the s-trans form and the latter the s-cis form in crystal according to X-ray diffraction studies. DPEMA-1,2 had a C=O band of 1702.5 cm^{-1} in KBr and its frequency moved by 20.2 cm^{-1} to 1722.7 cm^{-1} in a CCl_4 solution. TrBMA showed a C=O band at 1714.2 cm^{-1} in KBr and it only slightly shifted to 1719.0 cm^{-1} that was similar to the frequency of the C=O band of DPEMA-1,2 in a CCl_4 solution. The C=C bands appeared at ca. 1635 cm^{-1} in both KBr and CCl_4. These results strongly suggest that the conformation of DPEMA-1,2 changes from the s-trans in a crystalline solid to the s-cis in solution and TrBMA exists as the s-cis form both in a solid state and in a CCl_4 solution. Similar results were also obtained for other methacrylates (Table 1). The C=O band of

another s-trans methacrylate, DPMMA also shifted to a higher frequency in solution (from 1707.8 to 1722.8 cm^{-1}) but those of other s-cis methacrylates were little changed in a CCl_4 solution. The higher frequency shift of the C=O band of DPEMA-1,2 was also observed in a toluene solution (Table 1). These results are quite consistent with those of α,β-unsaturated ketones as mentioned above. However, the C=C band frequency and the ratio of the band intensities of the C=O to C=C stretching vibrations do not seem to be closely related to the conformation.

Conformational Analysis with LIS Reagent. The observed molar LISs were obtained from the line slopes of the plots of induced chemical shifts versus [Ld]/[M] ratios. The plots for DPEMA-1,2 is shown in Fig. 2 as an example. In all cases, good straight lines were obtained in the plots. The chemical shifts (δ) and molar LISs ($\Delta\delta$) are summarized in Table 2.

The molar LIS is the change in chemical shift caused by complexation with an equimolar lanthanoid shift reagent, being expressed by the McConnell and Robertson equation (Eq. 1):[20)]

$$\mathrm{LIS}(\Delta\delta) = K(3\cos^2 X - 1)/r^3, \quad (1)$$

where X is the O(2)-Ld-H internuclear angle (O(2) is the carbonyl oxygen in an ester group, see Fig. 3), r is the corresponding Ld-H distance and K is the pseudo-contact constant which refers to the magnitude of the induced magnetic dipole of a lanthanide ion. The most probable conformation of a methacrylate can be chosen by comparing the observed $\Delta\delta$ with the calculated molar LIS for a set of conformers.

The LIS simulation processes were worked-up according to the method reported by Montaudo et al.[21)] The structure of the complex of a methacrylate and $Eu(fod)_3$ in solution is shown in Fig. 3, where R is the Eu-O(2) distance (2.0—3.0 Å at 0.1 Å intervals), ϕ the Eu-O(2)-C(1) angle (120—180° at 5° intervals), ω the torsion angle of Eu-O(2)-C(1)-C(2) about the O(2)-C(1) bond (0—360° at 10° intervals) and θ the torsion angle of Hc-C(5)-O(1)-C(1) about the C(5)-O(1) (0—360° at 10° intervals). The conformation between the C=C and the C=O group was fixed to be

s-cis or s-trans. It has been confirmed that esters coordinate to a Eu ion at the carbonyl rather than the ether oxygen.[22] The structural data of a methacrylate are also shown in Fig. 3 which is depicted according to the molecular structures of methacrylates determined by X-ray analysis. However, two assumptions are involved; (1) methacrylate (CH_2=C(CH_3)-COOC) has a planar structure, (2) all bond angles in the methacryloyl group are 120°. These two assumptions seem reasonable for the LIS simulation process since the differences from the actual molecular structures determined by X-ray analysis are very little.

A computer simulation was performed according to the method reported by Montaudo et al.[21] The calculated LISs for a given set of R, ϕ, ω, θ values (i.e., for each Eu and Hc spatial location) were obtained. Evaluation of the difference between the observed and calculated LISs was carried out by using the agreement factor (AF) which is defined by the following equation (Eq. 2):[23]

$$AF = \sqrt{\frac{(LIS_{obsd} - LIS_{calcd})^2}{(LIS_{obsd})^2}} \qquad (2)$$

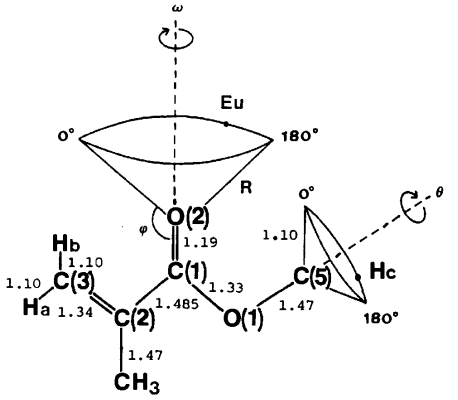

Fig. 3. Structure of the Eu(fod)$_3$-methacrylate complex.

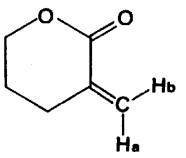
The conformer giving the minimum value of AF is assumed the most likely molecular geometry of a complex (Tables 2 and 3).

It has been pointed out that in the NMR of α,β-unsaturated ketones or esters, the C=O group causes the deshielding of β-methylene protons when the C=O and C=C are in s-cis position.[19,24] This deshielding effect of the C=O is considered to induce a significant difference of chemical shifts of the two methylene protons on β-carbon atom due to much closer position of one of methylene protons to the other (see Fig. 3). This effect is amplified by employing aromatic solvents. The differences of chemical shifts δ (Hb—Ha) observed for the β-methylene of all the methacrylates used in this study were in a range of 0.87—0.98 ppm at 35 °C and 1.00—1.06 ppm at −40 °C in toluene-d_8 (Table 2). These values are much greater than that of 0.19 ppm of s-trans alkyl vinyl ketone calculated by Naito et al.[25] and rather similar to 0.80 ppm for the s-cis form. The δ (Hb—Ha) value (0.83 ppm) of α-methylene-δ-valerolactone (MVL),[26] which exists only



MVL

in s-cis form, is nearly equal to those of the methacrylates. These results also indicate that the C=C and C=O groups of the methacrylates are likely to be in the s-cis position in toluene, although DPMMA and DPEMA-1,2 take the s-trans position in crystals.

The results of conformational analyses of the methacrylates by LIS are collected in Tables 2 and 3. The observed and calculated LISs at 35 and −40 °C are shown in Table 2, and the molecular geometry of the Eu(fod)$_3$ complexes giving the minimum AF values are listed in Table 3. The best agreement between experimental and calculated LISs i.e., the minimum agree-

Table 4. Molar Induced Shifts ($\Delta\delta$, ppm) of Two Groups (R and Ph) on the Asymmetric Carbon of Methacrylates[a]

	MBMA		DPEMA-1,2		*t*-BBMA	
	35 °C	−40 °C	35 °C	−40 °C	35 °C	−40 °C
R[b]	3.95	7.69	4.13	5.79	2.20	2.70
Ph[c]	2.91	4.99	1.88 3.55	2.20[d] 4.42[d]	3.98	4.80

a) In toluene-d_8, concentration of methacrylates=0.5 (mol l^{-1}). b) R are methyl, methylene, and *t*-butyl groups on the asymmetric carbon atoms of MBMA, DPEMA-1,2, and *t*-BBMA, respectively. c) Ortho proton of phenyl group. d) Two phenyl groups were observed separately.

ment factor, was always observed in the s-cis form. The s-trans form gave much greater agreement factors. The results in Tables 2 and 3 also indicates that the hydrogen atom (Hc) attached to the asymmetric carbon atom of the all methacrylates exists on the methacryloyl plane containing the C=C double bond and C=O group at 35 °C as shown in Fig. 4(A) and its position is rather similar to that determined by X-ray analysis. However, at −40 °C, the minimum agreement factor (AF) values for most methacrylates were obtained for the conformer in which Hc was at the gauche position to the methacryloyl plane as depicted in Fig. 4(B). DPMMA showed little conformational change at −40 °C, probably because of the symmetrical structure of the ester group.

We also presumed the positions of the other two groups attached to the asymmetric carbon atom by comparing the LISs at 35 and −40 °C (Table 4). In MBMA, the difference of LISs of the methyl group at two temperatures was larger than that of the ortho protons of the phenyl group. The same was true in DPEMA-1,2; the LIS change of the methylene group in benzyl group is also larger than those of the ortho protons of the phenyl groups, which seem to indicate that at −40 °C, the largest phenyl group attached to the asymmetric carbon atom occupy the position remote from the carbonyl group and the other groups are in staggered positions on either side of the ester carbonyl (see Fig. 5(a)). This was also supported by the fact that the Hc resonances of MBMA and DPEMA-1,2 did not shift downfield at −40 °C as large as Ha and Hb. On the other hand, in *t*-BBMA, the difference of LISs of the largest *t*-butyl group at 35 and −40 °C was nearly equal to that of the phenyl group and the LIS values of the *t*-butyl group were smaller than those of the ortho protons of the phenyl group. These results indicate that in *t*-BBMA the largest *t*-butyl group may occupy a position remote from the carbonyl group; the other groups, hydrogen and phenyl, may be in a staggered position as illustrated in Fig. 5(b). However, the deviation of Hc from the methacryloyl plane in *t*-BBMA at −40 °C seems to be smaller than that of MBMA and DPEMA-1,2, and the conformation may be analogous to that determined by X-ray analysis. It seemed to be difficult to estimate the positions of the two groups attached to the asymmetric carbon atom of TrBMA in a similar manner. Therefore, we assumed that the bulkyl triphenylmethyl group occupies a position remote from the carbonyl and other two, hydrogen and phenyl, groups were in a staggered position as in *t*-BBMA (Fig. 5(c)). This conformation has been observed in crystal although the deviation of Hc is smaller in crystal.

Mechanism of the Enantiomer-Selective Polymerization. Previously, we demonstrated that the enantiomer-selective polymerization of racemic methacrylates with Grignard reagent-Sp complexes in toluene at −78 °C proceeded in a coordination mechanism; that is, a monomer always coordinates to an active center before being incorporated into a polymer chain end.[2,3] The enantiomer selection may be controlled by two main interations. One is the interation between the ester group of a monomer and Sp, and the other is the interaction between the ester group of a monomer and the growing chain end. The hydrogen on the asymmetric carbon atom of the ester group is important in order to avoid any steric hindrance when the monomer, probably, its carbonyl group coordinates to the magnesium (Mg) counterion in the active center because the Sp-Grignard reagent complexes can not polymerize α,α-dimethylbenzyl methacrylate which has no hydrogen atom on the asymmetric carbon.[2] Figure 5 shows the schematical structures of active centers in the enantiomer-selective polymerization of MBMA (a), *t*-BBMA (b), and TrBMA (c) which have (*S*), (*R*), and (*S*) configurations, respectively. Their molecular structures are illustrated on the basis of the results obtained in this study.

In the case of (*S*)-MBMA, the large phenyl group occupies a position remote from the carbonyl group and other two smaller hydrogen and methyl group are in a staggered position. This conformation is analogous to those proposed for α-keto esters by Prelog.[27] The close position of the hydrogen on asymmetric carbon to (−)-sparteine makes it easy for the monomer to coordinate to Mg and to add to the growing end. However, in (*R*)-MBMA, the position of the hydrogen and methyl group is reversed, and the methyl group appears to hit (−)-sparteine moiety upon the coordination to Mg in the same way as shown in Fig. 5(a).

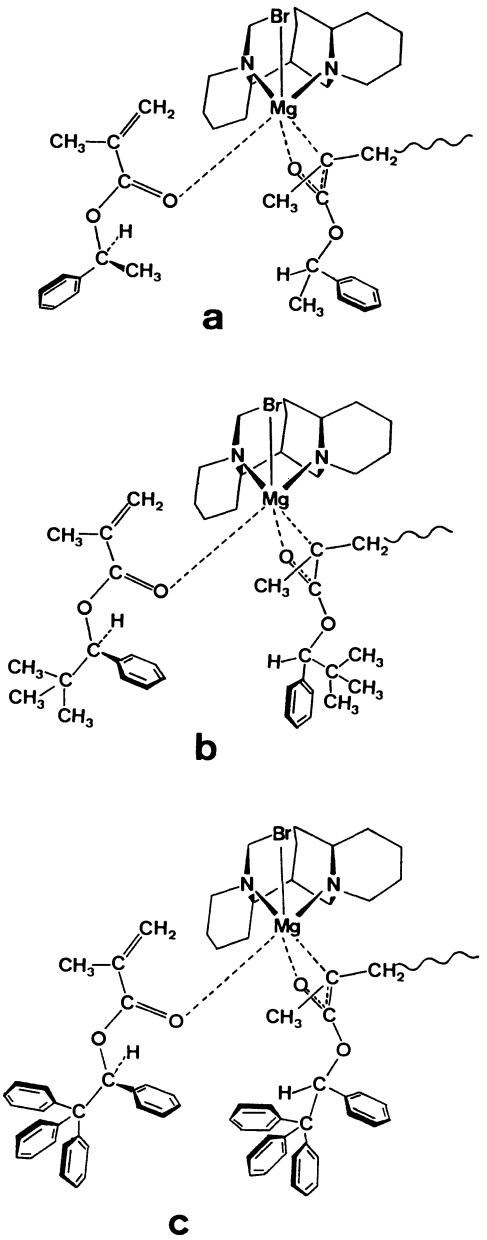

Fig. 5. Schematical structures of active centers in the enantiomer-selective polymerization of MBMA (a), *t*-BBMA (b), and TrBMA (c).

Hence, (*S*)-MBMA may be more reactive than (*R*)-MBMA. The structure of the active center, where the positions of the growing chain end and monomer are those in Fig. 5, may be favorable because the left-hand side of (−)-sparteine in Fig. 5 is more sterically hindered than the right-hand side of (−)-sparteine according to the molecular structure of Sp-ethylmagnesium bromide complex obtained by X-ray analysis, then the bulky growing chain end appears to occupy the right-hand side.[28]

In other monomers having smaller alkyl groups than phenyl on asymmetric carbon atom like EBMA, iPrBMA, and DPEMA-1,2, their conformation is probably similar to that as shown in Fig. 5(a) and (*S*) enantiomers are expected more reactive for the same reason discussed regarding MBMA.

However, when the alkyl group is larger than the phenyl group, like a *t*-butyl group, an enantiomer with the conformation shown in Fig. 5(b) must be preferable. Again, the hydrogen on the asymmetric carbon plays an important role to avoid any steric hindrance in the coordination process of the monomer to the Mg cation. Therefore, the reactive enantiomer must be the (*R*) isomer as observed in the polymerization of *t*-BBMA. In the case of TrBMA, we can also rationally explain that the preferable enantiomer is the (*S*) isomer, as shown in Fig. 5(c), where the phenyl group and hydrogen occupy staggered positions, as in *t*-BBMA and the bulky triphenylmethyl group exists at trans position to carbonyl group. Since the relative positions of the phenyl group to the triphenylmethyl group in the Cahn-Ingold-Prelog system is reversed to that of phenyl to the *t*-butyl group in *t*-BBMA, the (*S*)-isomer is favored for the enantiomer-selective polymerization of TrBMA.

The authors thank Mr. Kenji Wada for his help in the study using the LIS reagent.

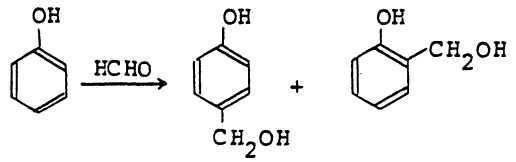
Determining Factors for the Product Para/Ortho Ratio and Reaction Rate in the Formation of (Hydroxymethyl)phenols from Phenol and Formaldehyde

Makoto KOMIYAMA
Institute of Materials Science, University of Tsukuba, Tsukuba, Ibaraki 305
(Received November 26, 1987)

Formations of 2- and 4-(hydroxymethyl)phenols from phenol and formaldehyde in aqueous alkaline solutions were kinetically investigated by the use of HPLC. The para/ortho ratio for the products sigmoidally increased with increasing concentration of sodium hydroxide, whereas the total yield of the (hydroxymethyl)-phenols showed a steep maximum at the charged molar ratio unity of sodium hydroxide to phenol. Use of lithium hydroxide and potassium hydroxide, in place of sodium hydroxide, as alkaline catalysts results in almost the same para/ortho ratios. The addition of potassium chloride and magnesium sulfate decreased both the para/ortho ratio and the yield. These results indicate that the reactions proceed via an electrophilic attack of formaldehyde, which is free from the adduct formation with hydroxide ion, at phenolate ion. Electrostatic interactions between the phenoxide oxygen atom of the phenol and the incoming hydroxymethyl residues in the transition state exhibit a predominant role in the determination of the para/ortho ratio.

Preparations of (hydroxymethyl)phenols by the reactions of phenol and formaldehyde in alkaline solutions (Eq. 1) are important in industry, since both of the products, 2- and 4-(hydroxymethyl)phenols, are valuable intermediates for the syntheses of various fine chemicals.



(1)

Previously, these reactions were kinetically examined by several authors.[1-7] However, the reported results are not necessarily consistent with each other. For example, the para/ortho ratios in the products for the sodium hydroxide-catalyzed reactions were 0.61, 1.0, and 1.4, according to Freeman,[1] Minami,[2] and Peer,[5] respectively. For all the reactions, the molar ratio of sodium hydroxide to phenol was unity. These discrepancies are, at least partly, associated with the fact that the reactions were followed by paper chromatography; thus, quantitative analyses were rather difficult. The reaction mechanism has not been sufficiently clarified yet.

Quite recently, the present author found that 4-(hydroxymethyl)phenol can be selectively prepared by the use of cyclodextrin as a catalyst for the reaction of Eq. 1.[8] This finding has prompted the author to study in more detail the effects of the reaction conditions on the selectivity and the rate for the reaction in the absence of cyclodextrin. The reactions have been precisely followed by HPLC.

This paper reports on the effects of kinds and concentrations of alkaline catalysts on the para/ortho ratio in the products and the rate for the formation of (hydroxymethyl)phenols from phenol and formaldehyde in water. Furthermore, results for the reactions in various organic solvents are described. Factors determining the para/ortho ratio and the reaction rate are shown.

Experimental

The reactions between phenol and formaldehyde were carried out at 30 °C under nitrogen. The product analyses were made by HPLC (JASCO $C_{18}S$ column, 10 cm; eluent, 2:1 water-ethanol mixture). All the reactions in the present study satisfactorily followed pseudo-first-order kinetics, and the reaction rates were expressed in terms of the yields with respect to the charged phenol in 1 h or 1 day. The formation of phenols having two or more hydroxymethyl groups was not detected.

Results

Effect of Concentration of Sodium Hydroxide on the Para/Ortho Ratio and the Reaction Rate. Figure 1 shows plots of the para/ortho ratio (4-(hydroxymeth-

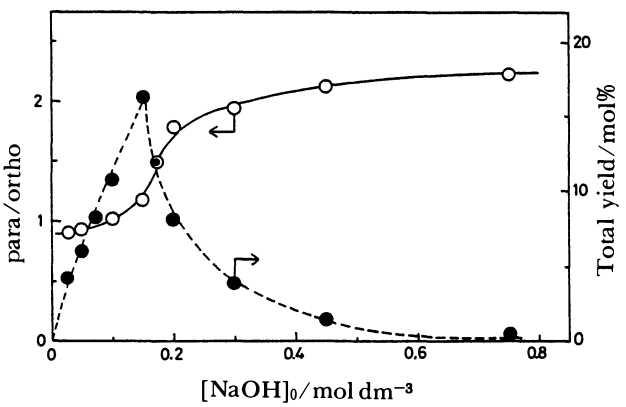


Fig. 1. Plots of the para/ortho ratio (○) and the total yield of 2- and 4-(hydroxymethyl)phenols (●) vs. the charged concentration of sodium hydroxide for the reactions of phenol and formaldehyde in water: $[phenol]_0=0.15$ and $[HCHO]_0=0.58\,mol\,dm^{-3}$; at 30 °C for 1 h.

yl)phenol/2-(hydroxymethyl)phenol) and the total yield of 2- and 4-(hydroxymethyl)phenols as functions of the charged concentration of sodium hydroxide for reactions in water. The initial concentrations of phenol and formaldehyde were kept constant at 0.15 and 0.58 mol dm^{-3}, respectively.

As shown by the open circles, the para/ortho ratio sigmoidally increases with an increase in the charged concentration of sodium hydroxide, showing a gradual saturation at large concentrations of sodium hydroxide.

The total yield (the closed circles) significantly increases with increasing concentration of sodium hydroxide up to the concentration 0.15 mol dm^{-3}, and then rapidly decreases. Thus, it shows a steep maximum at the charged molar ratio unity of sodium hydroxide to phenol.

Effects of Kinds of Alkaline Catalysts on the Para/Ortho Ratio and the Reaction Rate. Table 1 shows the para/ortho ratios and the yields for the reactions using various alkali metal hydroxides as catalysts. The concentrations of the catalysts are 0.75 mol dm^{-3}. The yields for the reaction with sodium hydroxide are larger than the values for the reactions with lithium hydroxide and potassium hydroxide. However, the para/ortho ratio is not significantly affected by the kinds of alkali metal hydroxide.

Table 1. Yields and Para/Ortho Ratios for the Reactions of Phenol and Formaldehyde Using Various Alkali Metal Hydroxides as Catalysts[a)]

Catalyst	Yield/mol%		para/ortho
	p	*o*	
LiOH	0.33	0.15	2.2
NaOH	0.44	0.20	2.2
KOH	0.24	0.11	2.2
NaOH+LiOH[b)]	0.35	0.15	2.3
NaOH+KOH[c)]	0.38	0.17	2.2

a) $[phenol]_0$=0.15 mol dm^{-3}; [alkali metal hydroxide]$_0$=0.75 mol dm^{-3}; $[HCHO]_0$=0.58 mol dm^{-3}; at 30 °C for 1 d. b) $[NaOH]_0$=0.15 and $[LiOH]_0$=0.60 mol dm^{-3}. c) $[NaOH]_0$=0.15 and $[KOH]_0$=0.60 mol dm^{-3}.

Table 2. Effects of Additive Salts on the Yields and the Para/Ortho Ratios for the Reactions of Phenol and Formaldehyde Using Sodium Hydroxide as Catalyst[a)]

Additive salt	Concentration of NaOH/mol dm^{-3}	Yield/mol%		para/ortho
		p	*o*	
KCl	0.75[b)]	0.23	0.12	1.9
KCl[c)]		0.22	0.13	1.7
None		0.44	0.20	2.2
KCl	0.15[b)]	5.0	4.4	1.1
$CaCl_2$		5.9	5.4	1.1
$MgSO_4$		5.0	5.3	0.94
None		8.8	7.7	1.1

a) $[phenol]_0$=0.15 mol dm^{-3}; $[HCHO]_0$=0.58 mol dm^{-3}; a) [Additive Salt]$_0$=0.6 mol dm^{-3} unless otherwise noted; at 30 °C. b) Reaction time, 1 d. c) $[KCl]_0$=2.0 mol dm^{-3}. d) Reaction time, 1 h.

The reaction involving mixture of sodium hydroxide and either lithium hydroxide or potassium hydroxide at the total concentration 0.75 mol dm^{-3} gives a similar para/ortho ratio.

Effects of Additive Salts. The effects of the addition of neutral salts on the para/ortho ratio and the yields for the formation of (hydroxymethyl)phenols are listed in Table 2. The charged concentration of phenol is 0.15 mol dm^{-3}.

When the charged concentration of sodium hydroxide is 0.75 mol dm^{-3}, the addition of potassium chloride exhibits a small but definite decrease in the para/ortho ratio. At a concentration 0.15 mol dm^{-3} of sodium hydroxide, magnesium sulfate also decreases the para/ortho ratio. However, potassium chloride and calcium chloride show no significant effects at concentration 0.6 mol dm^{-3}.

All the metal salts examined decreased the yields of both 2- and 4-(hydroxymethyl)phenols.

Reactions in Various Organic Solvents. The para/ortho ratios and the yields for the reactions in various organic solvents are presented in Table 3. The para/ortho ratio decreases in the following order:

ethanol > 2-propanol ≫ water ≈ methanol ≈ *N*,*N*-dimethylformamide ≫ 1,4-dioxane.

Discussion

Factors Determining the Reaction Rate. A plot of the yield vs. the concentration of sodium hydroxide (the closed circles in Fig. 1) satisfactorily fits the theoretical line (the dotted line) calculated in terms of the following scheme:

$$C_6H_5OH \underset{}{\overset{K_a}{\rightleftharpoons}} C_6H_5O^- + H^+ \quad (2)$$

$$HCHO + OH^- \overset{K}{\rightleftharpoons} H-\underset{\displaystyle OH}{\overset{\displaystyle O^-}{\underset{|}{\overset{|}{C}}}}-H \quad (3)$$

$$\text{Rate} = k[C_6H_5O^-]\,[HCHO_{free}] \quad (4)$$

Here, the activation of phenol for the reaction by deprotonation (Eq. 2) and the deactivation of formaldehyde by the addition of hydroxide ion (Eq. 3) are taken into consideration. The reaction rate is proportional to the product of the concentrations of phenolate ion and free formaldehyde, as shown by Eq. 4. The equilibrium constant K_a for Eq. 2 is taken as $10^{-9.998}$,[9)] and the value K for Eq. 3 has been determined as 13 mol^{-1} dm^3 by best-fitting method.

The concentration of phenolate ion significantly increases with an increase in the charged concentra-

tion of sodium hydroxide, when the charged molar ratio of sodium hydroxide to phenol is smaller than unity. Here, the concentration of free formaldehyde is almost identical with the charged concentration, since the equilibrium concentration of hydroxide ion is minimal. When the charged molar ratio of sodium hydroxide to phenol is larger than unity, however, the concentration of phenolate ion shows a gradual saturation, and the concentration of free formaldehyde decreases in a hyperbolic manner with increase in the equilibrium concentration of hydroxide ion. Thus the rate shows a steep maximum at a charged molar ratio unity of sodium hydroxide to phenol, as clearly shown in Fig. 1.

Similar kinetic analysis was attempted by Peer.[5] However, the analysis was qualitative due to insufficient accuracy of the data, especially at the large concentration of sodium hydroxide, as described by the author.

Factors Determining the Para/Ortho Ratio. The sigmoidal increase of the para/ortho ratio with increase in the charged concentration of sodium hydroxide, depicted by the open circles in Fig. 1, indicates that the electrostatic interactions between the incoming hydroxymethyl residues and the phenoxide oxygen atoms of phenol in the transition states predominantly determine the para/ortho ratio. In the highly alkaline media containing sufficient amounts of sodium hydroxide, the protonation of the hydroxymethyl groups prior to the transition state can not proceed efficiently; these groups are present mostly in anionic forms in the transition state. As a result, the electrophilic attack by formaldehyde at the ortho positions of phenolate is suppressed with respect to the reaction at the para position, since the magnitude of the electrostatic repulsion between the negative charge at the phenoxide oxygen atom and the negative charge at the hydroxymethyl residue is larger for the ortho-reaction.

On the other hand, the hydroxymethyl groups are effectively protonated to neutral species prior to the transition state, when the charged molar ratio of sodium hydroxide to phenol is smaller than unity and, thus, the media are less alkaline. The electrostatic repulsion is less important, and a reaction at the ortho positions takes place rather smoothly.

These arguments are definitely confirmed by the fact that the para/ortho ratio largely changes around the charged concentration 0.15 mol dm^{-3} of sodium hydroxide, where the equilibrium concentration of hydroxide ion significantly increases with increase in the charged concentration of sodium hydroxide (see Fig. 1). The charged concentration of phenol is 0.15 mol dm^{-3}.

The significance of the electrostatic interaction between the phenoxide oxygen atom and the incoming hydroxymethyl residues in the determination of the para/ortho ratio is further supported by the results for the reactions in organic solvents, shown in Table 3. The para/ortho ratios (2.1 and 1.7) for the reactions in ethanol and 2-propanol are larger than the values (1.1, 1.0, and 0.96) in water, methanol, and *N,N*-dimethylformamide, since the electrostatic interaction is stronger due to smaller dielectric constants (24.55 and 19.92); the dielectric constants for water, methanol, and *N,N*-dimethylformamide are 80.2, 32.7, and 36.71.[10] Quite a small para/ortho ratio (0.43) in 1,4-dioxane is ascribed to the fact that sodium phenoxide is present as an intimate ion pair, rather than as dissociated ions, in the solvent of small dielectric constant (2.209).[10]

Table 3. Yields and Para/Ortho Ratios for the Reactions of Phenol and Formaldehyde Using Sodium Hydroxide as Catalyst in Various Solvents[a]

Solvent	Yield/mol%		para/ortho
	p	*o*	
Ethanol	0.30	0.14	2.1
2-Propanol	1.4	0.81	1.7
Water	8.8	7.7	1.1
Methanol	0.05	0.05	1.0
N,N-Dimethylformamide	0.26	0.27	0.96
1,4-Dioxane	1.2	2.8	0.43

a) $[phenol]_0=[NaOH]_0=0.15$ mol dm^{-3}; $[HCHO]_0=0.58$ mol dm^{-3}; at 30 °C for 1 h.

A decrease of the para/ortho ratio upon the addition of potassium chloride (Table 2) is also consistent with the above arguments. The electrostatic repulsion is reduced by the increase in the ionic strength, promoting the ortho-reaction more than the para-reaction. The smaller effect of potassium chloride on the para/ortho ratio at the concentration 0.15 mol dm^{-3} of sodium hydroxide than that at the concentration 0.75 mol dm^{-3} is associated with the minor importance of the electrostatic repulsion here due to a smaller magnitude of the ionization of the hydroxymethyl residues.

The decrease in the para/ortho ratio by the addition of magnesium sulfate is consistent with the previous results[3,5] that the ratio for the magnesium hydroxide-catalyzed reaction is smaller than the value for the sodium hydroxide-catalyzed reaction.

Of the previously reported para/ortho ratios at the charged molar ratio unity of sodium hydroxide to phenol, Minami's value (1.0)[2] is close to the value (1.1) determined in the present study. Freeman's value (0.61)[1] is considerably smaller than the present one, whereas Peer's one (1.4)[5] is larger.

In conclusion, the present kinetic study shows that the rate of the formation of (hydroxymethyl)phenols from phenol and formaldehyde is governed by the concentration of hydroxide ion. The para/ortho ratio in the products is determined by factors affecting the magnitude of the electrostatic interaction between the phenoxide oxygen atom and the incoming hydrox-

ymethyl residue in the transition state.

Diastereomers of Methionine *S*-Oxide in the Hinge-Ligament Proteins of Molluscan Bivalve Species

Yasuo KIKUCHI,* Kiyoshi HIGASHI, and Nobuo TAMIYA
Department of Chemistry, Faculty of Science, Tohoku University, Aobayama, Sendai, Miyagi 980
(Received December 5, 1987)

The diastereomer ratio was analyzed on methionine *S*-oxide residues formed by in vivo posttranslational oxidation of methionine residues in a protein. The hinge-ligament protein of molluscan bivalves is distinct from usual proteins in containing a large amount of methionine *S*-oxide. The methionine *S*-oxide was released from the protein by proteolytic digestions and was found to be a mixture of approximately equall amounts of two diastereomers, (5*S*)- and (5*R*)-L-methionine *S*-oxide.

Molluscan bivalve species have ligaments at their hinges. The hinge-ligaments are elastic and function to open the shells: When the shells are closed by the contraction of adductor muscles, the hinge-ligaments are strained, and when the adductor muscles relax, the shells are opened by the elastic properties of the ligaments.

The hinge-ligaments are composed of proteins and aragonite crystals of calcium carbonate,[1,2] of which the protein may be primarily important for the elastic property. The hinge-ligament proteins contain cross-linking components, desmosine and isodesmosine,[3] and are insoluble unless hydrolyzed.[1] In the previous papers[1,4] we reported unusual amino acid compositions of hinge-ligament proteins from various bivalve species, such as surf clams (superfamily Mactracea), pearl oysters (superfamily Pteriacea) and a mussel (superfamily Mytilacea). They contain methionine (Met) at extremely high levels (20—40 mol% of the total amino acids) as compared to the Met contents of usual proteins, and almost all of the Met is found in an oxidized form, methionine *S*-oxide (MetO).[5] Since free MetO cannot be utilized as such in protein synthesis,[6] the MetO residues must have been derived from Met residues incorporated in the precursor form of the hinge-ligament proteins. It is known that the Met residues in proteins are oxidized slowly into MetO in various biochemical treatments. In the case of bivalves hinge-ligament proteins, however, the possibility of the artefactual oxidation is excluded by the observation that the intact hinge-ligaments are resistant to BrCN treatment[1] and by the non-destructive analyses of the hinge-ligament in solid-state ^{13}C NMR[7] and IR[2] spectrometries. The hinge-ligament protein is the first and the only instance of the MetO-containing proteins normally functioning in animals. The other instances of MetO-containing proteins are associated with some pathologically defective symptoms such as cataract[8] or rheumatoid arthritis.[9] Moreover, the in vitro oxidation of Met residues resulted in the loss of biological activities of various proteins.[10]

The conversion of Met into MetO introduces another asymmetric center into the amino acid molecule, namely *S*-oxide group of *S*- and *R*-configurations; they are designated as (5*S*)-MetO and (5*R*)-MetO, respectively.[5] Only one of the diastereomers can be expected when the Met-oxidation is catalyzed by enzymes, and even when the oxidation is non-enzymatic, the molecular size of the oxidant and the three-dimensional environments of the target Met residues may affect the stereochemical specificities in the Met oxidation. But the absolute configurations of MetO residues formed in vivo or in vitro have not been examined. The information on the composition of MetO diastereomers is essential for the understanding of the mechanism of Met-oxidation reaction and the roles of MetO residues in the elastic properties of hinge-ligaments. In the present paper we describe the analyses of MetO diastereomers released from the intact hinge-ligament proteins and those from the chemically reduced and reoxidized preparations.

Experimental

Bivalve Species and Their Hinge-Ligaments. Table 1 shows the bivalve species and their hinge-ligament layers subjected to the present study. The classification and the common names of the species are given according to Habe[11] and Abbott and Dance.[12] The hinge-ligaments of the species in superfamilies Mactracea and Limacea are a big rubber-like mass called 'resilium' (internal hinge-ligament). The ligaments of Veneracea species are composed of two histologically distinct layers, outer and inner layers. The ligaments of species in superfamilies Pteriacea and Ostracea are also composed of two layers, fibrous layer and lamellar layer. The resiliums, inner layers and fibrous layers were employed in the present study. They are ontogenetically homologous to one another.[13]

Methionine *S*-Oxide. An authentic MetO was prepared from Met (Wako Pure Chem. Ind. Co. Ltd., Osaka, Japan) and hydrogen peroxide as described by Toennies and Kolb.[14] Two diastereomers were resolved by fractional crystallization of the picrates as described by Lavine.[15] Their absolute configurations were determined by Christensen and Kjær.[16] Found (5*S*-diastereomer): C, 36.23; H, 6.89; N, 8.35%. Found (5*R*-diastereomer): C, 36.10; H, 6.91; N, 8.40%. Calcd for $C_5H_{11}NO_3S$: C, 36.35; H, 6.71; N, 8.48%.

Amino Acid Analyses. The amino acid compositions of the hinge-ligament proteins were determined on the HCl-hydrolysates prepared from ligament pieces (2—3 mg) in 6 M

Table 1. Bivalve Species and Their Hinge-Ligament Layers Subjected to the Present Work

Sample No.	Bivalve species	Ligament layer
	Mactracea species	
1	*Pseudocardium sachalinensis* (Sakhalin surf clam)[a]	Resilium
2	*Spisula (Hemimactra) solidissima* (Atlantic surf clam)[b]	Resilium
3	*Spisula solidia* (Solid mactra)[c]	Resilium
4	*Mactra chinensis* (Chinese mactra)[d]	Resilium
5	*Tresus keenae* (Keen's graper)[a]	Resilium
6	*Coecella chinensis* (Chinese anapella clam)[c]	Resilium
	Veneracea species	
7	*Saxidomus purpuratus* (Purplish Washington clam)[c]	Inner layer
	Pteriacea species	
8	*Malleus (Malleus) albus* (White hammer oyster)[c]	Fibrous layer
	Limacea species	
9	*Acesta (Acesta) goliath* (Giant lima)[d]	Resilium

(1 M=1 mol dm^{-3}) HCl (0.3 ml) at 105 °C for 24 h in vacuo. The amino acid analyses were carried out with JLC 200A amino acid analyzer (JEOL Co. Ltd., Tokyo, Japan). The contents of MetO, Met and homocysteic acid, the latter two of which were derived from MetO during the HCl-hydrolysis,[17,18] were combined and taken as Met content. The MetO contents were determined on NaOH-hydrolysates prepared from ligament pieces (2—3 mg) in 2.5 M NaOH (0.3 ml) at 105 °C for 15 h in vacuo. No correction was made for hydrolytic losses.

Decalcification of the Hing-Ligaments. The dried hinge-ligament pieces (about 50 mg) were swollen in H_2O (5 ml) at 4 °C for 18 h and powdered in an agate mortar with a pestle. The ligament powder was collected by centrifugation at 3000 *g* for 10 min and stirred in 2% (v/v) acetic acid (3 times, 2 ml each for 2, 4, and 18 h, at 4 °C). The decalcified ligament powder was washed with H_2O thoroughly and freeze-dried.

Proteolytic Solubilization of the Hinge-Ligament Protein. A suspension of decalcified ligament powder (4 mg) in 0.1 M sodium borate buffer solution (pH 8.8) (1 ml) and one drop of chloroform as preservative was added with 0.1 ml aliquots of crystalline bacterial alkaline protease (Katayama Chem. Ind. Co. Ltd., Osaka, Japan) (4 mg ml^{-1} in the same buffer solution) at the time intervals of 24 h and the mixture stirred at 25 °C for 120 h. The extent of the solubilization was monitored by the combined contents of Met, MetO and homocysteic acid in the HCl-hydrolysates of the supernatant aliquots (30 μl) taken out from the mixture at every 24 h.

Proteolytic Liberation of MetO. The above mixture was stirred at 25 °C and added with 0.1 ml aliquots of leucine amino peptidase (cytosole) (Sigma) (2 mg ml^{-1}) at the incubation times of 0, 27, 50, and 90 h. The contents of free MetO in the supernatant aliquots (30 μl) were determined with amino acid analyzer at the incubation times of 27, 50, 90, and 120 h.

Analyses of MetO Diastereomers. Two columns (0.8 cm×70 cm each) of sulfonated polystyrene resine (JLC-R-2, JEOL Co. Ltd. Tokyo, Japan) were tandemly connected and equipped on an amino acid analyzer, JLC 8AH (JEOL Co. Ltd.). The analysis was carried out at 54 °C with 0.067 M sodium citrate-NaCl buffer solution (pH 2.85, I[5]=0.2) at a flow rate of 0.5 ml min^{-1}. Under these conditions the diastereomers, (5*S*)- and (5*R*)-MetO, were equally sensitive to ninhydrin and eluted at 4.4 and 4.6 h, respectively. The peak areas were proportional to the amounts of materials up to 230 nmol and the routine analyses were carried out with 50—80 nmol each of the diastereomers.

Chemical Reduction of MetO Residues in the Hinge-Ligament Proteins. The decalcified ligament protein powder (about 150 mg) was stirred in 50% (w/v) aqueous *N*-methylmercaptoacetamide[19] (10 ml) at room temperature for 11 days. The protein powder was washed with H_2O by centrifugation and freeze-dried.

Chemical Reoxidation of Met Residues in the Reduced Hinge-Ligament Protein. Oxidation with Hydrogen Peroxide: A suspension of reduced ligament protein (8 mg) in H_2O (5 ml) was adjusted to pH 2 with 0.1 M HCl, added with 30% (w/v) hydrogen peroxide (0.5 ml) and stirred at room temperature for 18 h. The protein powder was washed thoroughly with H_2O and freeze-dried. The reduced ligament protein (8 mg) was also reoxidized in 0.1 M sodium borate (pH 8.8) (5 ml) in the same procedures as described above.

Oxidation with Chloramine T or *N*-Chlorosuccinimide: The Met residues in the reduced protein (12 mg) were oxidized with chloramine T or *N*-chlorosuccinimide (5 mol/mol of Met residues) in 0.033 M sodium citrate-NaCl buffer solution (pH 2.2, I=0.1) or 0.1 M Tris-HCl (pH 8.5) (40 ml) for 1 h at room temperature as described by Shechter et al.[20] The protein powder was washed with H_2O and freeze-dried.

Chemical Oxidation of Free Methionine. Oxidation with *N*-Chlorosuccinimide: A solution containing L-Met (75 mg) and *N*-chlorosuccinimide (80 mg) in 0.033 M sodium citrate-NaCl buffer solution (pH 2.2, I=0.1) (2 ml) was stirred for 1 h at room temperature, adjusted to pH 7 with 1-butylamine and added with methanol (4 ml) and acetone (40 ml). The precipitated amino acid was collected by centrifugation (3000 *g* for 10 min), washed with acetone (3 times, 30 ml each) and dried in vacuo (83 mg, 100%). The product agreed with the authentic MetO on TLC analysis using 0.1 mm precoated cellulose plates (Merck) and 1-butanol/water/acetic acid (5/2/1, by vol) as developing solvent.

Oxidation with Chloramine T: A solution containing L-Met (75 mg) and Chloramine T (170 mg) in 0.1 M Tris-HCl buffer solution (pH 8.5) (4 ml) was stirred for 1 h at room temperature and added with methanol (4 ml) and acetone (100 ml). The precipitated MetO was collected and characterized as described above (45 mg, 54%).

Results and Discussion

The compounds containing *S*-oxide moieties are

widely distributed in the natural products. Since their S-oxide groups are not racemic as reviewed by Kjær,[21] the enzymatic sulfide oxidation may be common in their biosynthetic pathways. On the other hand, the non-enzymatic mechanism was suggested for the in vivo oxidation of Met residues in the proteins from pathologically defective tissues, although the absolute configuration of the MetO residues was not analyzed.[22] In contrast to the above proteins, the ligament proteins are from non-defective and normally functioning hinge-ligaments of the bivalve species. They contain Met in extremely high contents and the extent of Met-oxidation in them is almost complete.

The amino acid compositions of the hinge-ligament proteins are shown in Fig. 1. The resilium proteins of the Mactracea species (1—6) are similar to one another in containing Gly and Met to the extents of 50 and 20 mol%, respectively, and almost all of their Met residues are present in the S-oxide form, MetO (Table 2, column 2). The ligament proteins from other species (7—10) also contain Met as predominant constituents and their Met residues are mostly in S-oxide form.

Since the hinge-ligament proteins are insoluble in usual protein solvents, they were solubilized by the proteolysis with crystalline bacterial alkaline protease (Fig. 2). The extents of solubilization were 80% or more in most cases examined. Amino acids were released from the solubilized peptides by the action of an exopeptidase, leucine amino peptidase (Fig. 3). About 80% of MetO was detected as a free amino acid in the digests of the ligament proteins from Sakhalin surf clam (*Ps. sachalinensis*) and Giant pacific oyster (*C. gigas*) (Fig. 3, A and E, respectively), but only 30—

Table 3. The Ratio of MetO Diastereomers Prepared by Chemical Oxidation of Met Residues in Reduced Resilium Protein of Sakhalin Surf Clam

Oxidant	(5*S*)-MetO/(5*R*)-MetO ratio	
	pH 2.2	pH 8.8
Hydrogen peroxide	1.1	1.1
N-Chlorosuccinimide	1.1	1.1
Chloramine T	n.d.[a)]	1.2

a) n.d.: not determined because of the low yield due to low solubility of the reagent in the buffer solution.

40% of MetO was liberated from the peptides in the other cases (Fig. 3, B, C, and D). The difference in the extent of the MetO liberation might be due to the difference in amino acid sequence of the protein.

The ratio of MetO diastereomers was determined by amino acid analysis. Figure 4 shows the results for the MetO from the resilium protein of Sakhalin surf clam (*Ps. sachalinensis*). The peaks at 4.4 and 4.6 h were assigned to (5*S*)- and (5*R*)-MetO, respectively. From their peak areas, the (5*S*)-MetO/(5*R*)-MetO ratio was determined as 1.1. Table 2 (column 3) shows the ratios of MetO diastereomers in the ligament proteins from various bivalve species. The values are 1.1—1.2 in most cases and 1.5 for the MetO from the resilium protein of Giant lima, *A. (A). goliath.* Since no interconversion was observed between the two diastereomers during the above proteolytic treatments (data not shown), the values show the ratios of MetO diastereomers in the ligament proteins. The results show that the two diastereomers are present in approximately equal amounts in the hinge-ligament proteins from bivalve species of a wide variety of the taxonomic classes.

The MetO residues in the resilium protein of Sakhalin surf clam (*Ps. sachalinensis*) were reduced into Met with *N*-methylmercaptoacetamide,[19] and the Met residues in the reduced protein were reoxidized with various reagents. The MetO/(Met+MetO) ratios were less than 0.03 in the reduced protein and more than 0.95 in the reoxidized preparations. The ratios of MetO diastereomers in the reoxidized preparations are shown in Table 3. The chemical reoxidations of Met residues with various reagents in either acidic or alkaline solutions resulted in the formation of the two MetO diastereomers in approximately equal amounts. The results may suggest that the in vivo Met oxidation is a nonenzymatic reaction, although the active oxidizing species, which is not identified yet, can be produced by some enzymes as suggested by Wong and Travis,[23] Fliss et al.[24] and Kühn et al.[25] The participation of enzymes in Met oxidation was examined as follows. The soft body of Sakhalin surf clam (*Ps. sachalinensis*) was dissected into eight tissues; adductor muscles, gills, mantle, labial palp, viceral mass, siphon, crystalline style and body wall (foot). The tissues were homogenized in phosphate buffer saline and the homogenates centrifuged at 15000 *g* for 30 min. The supernatant fractions were taken and incubated with reduced resilium protein of Sakhalin surf clam at 25 °C for 20 h. But no significant and reproducible increase in MetO/(Met+MetO) ratio was observed in any protein preparations incubated with the tissue extracts. Since the addition of D-glucose and L-leucine (50 mM each) into the medium did not affect the results, the possibilities of participation of glucose oxidase or amino acid oxidase, which would release hydrogen peroxide into the medium, were also

Table 4. The Ratio of MetO Diastereomers Prepared by Chemical Oxidation of Free L-Methionine

Oxidant	pH	(5S)-MetO/(5R)-MetO ratio
Hydrogen peroxide	2	1.4
N-Chlorosuccinimide	2.2	1.7
Chloramine T	8.5	1.6

excluded. When free Met was incubated with freshly prepared resilium powder, a small portion of it was converted into MetO. The results can, however, be explained by chemical exchange of oxygen atom between free Met and MetO residues in the protein.[26] Although these results indicate no enzyme participation in the in vivo oxidation of Met residues, the examination might be too preliminary to exclude the possibilities of enzymatic formation of active oxidizing species.

The chemical oxidation of free Met was not highly stereospecific: The (5S)-MetO/(5R)-MetO ratios were 1.4—1.7 in the MetO preparations obtained from free L-Met and various oxidizing reagents under conditions similar to those described above (Table 4). On the other hand, in the oxidation of Met residues in proteins, the stereospecificity of the reaction can be largely affected by the three-dimensional protein structures. Since the MetO in the hinge-ligament proteins was found to be a mixture of two diastereomers in approximately equal amounts, the conformation of the hinge-ligament proteins might be random and the two MetO diastereomers might be formed with equal probabilities. Alternatively, the protein conformation might determine the stereospecificities at every Met-oxidation sites in the protein to form the two MetO diastereomers in equal amounts.

As the MetO is a predominant constituent of the hinge-ligament proteins of some bivalve species, and as the conversion of Met into MetO is almost complete in these proteins, the MetO residues are supposed to play some essential roles in the properties of the hinge-ligaments. The MetO side chains make the protein highly hydrophilic and promote the swelling of the hinge-ligaments (Y. Kikuchi et al., unpublished data). The relationship between the MetO residues and the elastic properties of the ligaments will be discussed elsewhere.

The authors are grateful to professor Tadashige Habe (National Scientific Museum, Tokyo, Japan) for providing hinge-ligaments of some bivalve species, and to Mr. Hisaku Abe of this laboratory for amino acid analysis.

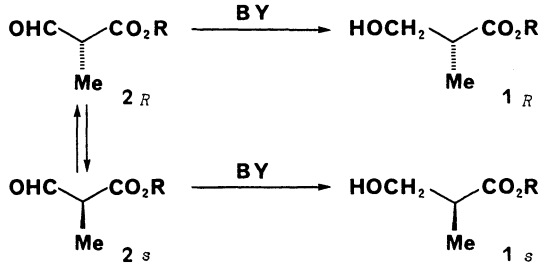
Enantioselective Reduction of 2-Methyl-3-oxopropionate by Bakers' Yeast[1)]

Kaoru NAKAMURA,* Takehiko MIYAI, Kazutoshi USHIO, Shinzaburo OKA, and Atsuyoshi OHNO
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611
(Received December 18, 1987)

Various esters of 2-methyl-3-oxopropionic acid were subjected to the reduction with bakers' yeast. Effects of size and bulkiness as well as hydrophobicity of alcohol moieties of the substrates on the enantioselectivity of the reduction were investigated. The substrates having bulky ester groups gave the (*R*)-hydroxy esters with high enantioselectivities. A mechanism to alter the stereoselectivity of the reduction is proposed.

Optically active 3-hydroxy-2-methylpropionic acid derivatives (**1**) have been used widely as versatile chiral building blocks.[2)] Although the use of a microbe in hydroxylation of isobutyric acid to obtain **1** of high optical purity has been reported,[3,4)] the handling of special microbes such as those reported is not so easy in laboratories of organic chemistry. However, bakers' yeast (BY), which is also a microbe, has advantages as a reagent in organic chemistry. BY is easily available and cheap. Special caution, such as sterilization or careful operation, is not necessary. Because of its simplicity of handling, BY has been used as a convenient pack of various enzymes to convert achiral organic compounds into chiral products.[5)] In this paper, we would like to report an enantioselective reduction of 2-methyl-3-oxopropionate (**2**) with BY to obtain chiral **1**. Although the reduction of **2** with BY was attempted by Seebach et al., the enantiomer excess (e.e.) observed was not satisfactory for practical use (54%).[6)] It should be noted that in the process of reduction, chirality is introduced at the position different from the reaction center. That is, the chirality arises on the C-2 position, whereas the reduction takes place at the C-3 position. Therefore, there is no doubt that the introduced chirality stems from difference in the rate of reduction of both enantiomers of the starting material (*R*-2 and *S*-2) by an enzyme or a set of enzymes that are operating simultaneously in bakers' yeast. In other words, the present reaction is a reductive resolution of racemic material. Since the starting material **2** is composed of a mixture of an aldehyde and its enol form, which was confirmed by ^{1}H NMR spectroscopy, interconversion between the two enantiomers (of the aldehyde form) is expected to be fast enough to keep the starting material as a racemic mixture during the whole reduction period even though one enantiomer is reduced faster than the other. Therefore, in principle, a particular enantiomer of the product can be obtained quantitatively, although the process itself is a kinetic resolution.



Scheme 1.

It seems that relatively low selectivity reported by Seebach et al. was due to a small difference in the reaction rates of both enantiomers of the aldehyde. One may therefore be able to obtain chiral **1** in high e.e. if one can modify the substrate so that the enantiomers exhibit a large difference in the reaction rate. According to the concept mentioned above, we investigated the reduction of **2** by BY.

Usually, the microbial reduction of a carbonyl compound does not necessarily afford the alcohol of desired configuration with satisfied e.e., and several methods to control the stereochemistry of reduction have been developed. Screening of microbes[7)] has been the method employed most widely but this is troublesome for organic chemists. Immobilization of microbes can also control the stereochemistry of the product.[8)] Modification of substrates has been used for stereochemical control.[9-11)] Since the latter two methods are familiar techniques for organic chemists, we have investigated the application of these two techniques for the reduction of **2**. The present report will discuss the results obtained from the modification of a substrate.

Results

In the ^{1}H NMR spectrum of **2a** ($CDCl_3$-TMS), the aldehydic proton appears at δ 9.77 and the olefinic proton appears at δ 6.98, which indicates that **2a** exists as a mixture of the aldehyde and its enol form.

Various esters of 2-methyl-3-oxopropionic acid were reduced with BY in water in the presence of glucose. Results are summarized in Table 1. The reduction of **2a** (ethyl ester) was resulted in low enantioselectivity (e.e.=45%). The e.e. of the reduction was slightly improved in the reduction of octyl ester (**2c**, e.e.=60%). Better results were obtained, however, in the reduction of substrates with bulky alcohol moieties such as 3-methylbutyl (**2f**, e.e.=84%), cyclohexylethyl (**2p**, e.e.=74%), and 2-(trimethylsilyl)ethyl (**2n**, e.e.=79%) groups.

Table 1. Reduction of **2** by Bakers' Yeast

Substrate	R	$[\alpha]_D^{20}$	e.e./%	Isolated yield/%
2a	$-C_2H_5$	−8.459	45	94
2b	$-(CH_2)_3CH_3$	−4.167	53	73
2c	$-(CH_2)_7CH_3$	−6.103	60	41
2d	$-CH(CH_3)_2$	−8.736	19	49
2e	$-CH_2CH(CH_3)_2$	−7.195	64	84
2f	$-(CH_2)_2CH(CH_3)_2$	−8.000	84	66
2g	$-(CH_2)_3CH(CH_3)_2$	−8.889	81	83
2h	$-CH_2CH(CH_2CH_3)_2$	−8.210	71	76
2i	$-CH_2CH{=}CH_2$	−8.587	48	58
2j	$-(CH_2)_2OCH_2CH_3$	−4.789	29	73
2k	$-(CH_2)_2OCH_3$	−10.047	47	59
2l	$-CH_2C(CH_3)_3$	−13.471	90	78
2m	$-(CH_2)_2C(CH_3)_3$	−9.923	81	66
2n	$-(CH_2)_2Si(CH_3)_3$	−6.344	79	70
2o	$-CH_2$-*c*-C_6H_{11}	−7.778	74	70
2p	$-(CH_2)_2$-*c*-C_6H_{11}	− 6.799	74	71

The substrate having the 2,2-dimethylpropyl group **2l** gave the highest value (e.e.=90%).

3-Hydroxy-2-methylpropionates thus obtained by the reduction with BY were converted into the corresponding ethyl ester and the absolute configuration of this ethyl ester was determined by comparing the sign of optical rotation with that reported.[6]

Discussion

Recently two reports described the effect of length in alcohol moeity on yeast reduction. The reduction of 3-oxo-6-heptenoic acid and its esters afforded (*R*)-3-hydroxy-6-heptenoic acid and its esters, respectively. The e.e. increased as the length in the alcohol moiety decreased and the best result was observed with the free acid.[9] The reduction of 4-chloro-3-oxobutanoate gave the corresponding (*R*)-hydroxy ester of higher e.e. with the substrate which had the alcohol moiety of longer alkyl chain.[10] Since the configuration of (*R*)-4-chloro-3-hydroxybutanoic acid is opposite to that of (*R*)-3-hydroxy-6-heptenoic acid,[11] these two reports show that the length of alkyl chain in alcohol moiety exerts the same stereochemical effect on different substrate.

We reported that the length of alkyl chain in the alcohol moiety affects the diastereoselectivity of reduction of 2-methyl-3-oxobutanoate (**3**), an analog of **2**.[12] Thus although methyl, ethyl, and other short alkyl esters did not give satisfactory results, the octyl ester yielded (2*R*, 3*S*)-3-hydroxy-2-methylbutanoate in excellent diastereoselectivity. Since 2-substituted 3-oxobutanoates are known to afford the (3*S*)-hydroxy esters in higher e.e. than the corresponding unsubstituted substrates,[13] the high diastereoselectivity in the reduction of **3** directly means that the reduction is highly enantioselective with respect to the 2-position, or the reduction affords only one stereoisomer almost exclusively out of four possible isomers (2*R*,3*S*: 2*R*, 3*R*: 2*S*,3*R*: 2*S*,3*S*=95 : < 1 : < 1 : 5).

Since **2** and **3** have quite similar molecular structures (aldehyde vs. ketone) each other, it is reasonably expected that the BY reduction of the octyl or higher alkyl esters of **2** might exert satisfactory enantioselectivity.

However, contrary to the expectation, the reduction of **2c** (the octyl ester) did not give the hydroxy ester in a high e.e. Thus, although the e.e. increased in the order; ethyl (45%), butyl (53%), and octyl (60%), the increase in the selectivity was not remarkable. It should be noted that the reduction of **2** is catalyzed by a primary alcohol dehydrogenase(s), but the secondary alcohol dehydrogenase(s) must be involved for the reduction of **3**. The same phenomenon was also observed in the BY reduction of 5-methoxy-3-oxopentanoate where the e.e. of the product increases from the ethyl (60%) to the butyl (82%) ester, then decreases in the hexyl ester (71%).[14] The substrate with a long alkyl chain in the ester part did not give the highest value. These results suggests that the structural similarity in substrates does not necessarily result in similar results in multi-enzyme systems. It is unfortunate that complex structure of microbe does not allow to predict a simple relationship between the structure of a substrate and the stereoselectivity of the reduction.

Since an attempt to control the stereochemistry in yeast reduction by changing the length of alkyl chain in the ester group appeared unsatisfactory, we intended to look for another method which affected stereochemical course of the reduction. In order to change the electronic property in the alcohol moiety, an oxygen function was introduced and the substrate was subjected to the BY reduction. It was expected that the difference in affinities to enzyme(s) along with changing a hydrocarbon unit to an oxygen might affect the stereochemistry of the reduction. However, this modification was found to shift the specificity toward the *S*-configuration, if any. Thus the e.e. of products from the 2-ethoxyethyl derivative was 29% and that of the 2-methoxyethyl derivative was 47%. Both of these substrates are not suitable in order to produce the (2*R*)-hydroxy esters in high enantioselectivities.

In order to achieve the third way of our challenge to increase the e.e. of yeast reduction, we focused attention on the bulkiness of the alcohol moiety of the substrate. In contrast to the length, the bulkiness of the alcohol moiety was found to play an important factor to change the e.e. of the products. That is, the substitution of a methyl group at the 3-position of the butyl ester resulted in the hydroxy ester in 81% e.e. whereas the e.e. of the corresponding butyl ester was 53%. Encouraged by these observations, we prepared several substrates from bulky alcohols. Neither 3,3-dimethylbutyl ester (81% e.e.) nor 2-(trimethylsilyl)ethylester (79% e.e.) improved the stereoselectivity. In other words, bulkiness of isopropyl group is enough as a single substituent at the 2-position of the ester to shift

the e.e. to an asymptotic value of about 80%. However, on the other hand, double substitution at the 2-position increases the e.e. value further; the reduction of the 2,2-dimethylpropyl ester proceeded with 90% e.e.

The reason why the bulkiness at the 2-position of the ester shifts the stereospecificity of the reaction toward the *R*-configuration is not clear at present. One plausible mechanism is that more than two dehydrogenases are involved in the reduction and each of them reduces a substrate in high e.e. but in opposite configuration. When both (*R*)- and (*S*)-hydroxy ester-producing enzymes contribute to the reduction in comparable extents, the e.e. of the product becomes low. On the contrary, if a bulky ester is not reduced by the (*S*)-hydroxy ester-producing enzyme, only the (*R*)-hydroxy ester-producing enzyme opperates and consequently the (*R*)-hydroxy ester will be produced exclusively. Although several dehydrogenases contribute to the reduction in the BY reduction of ethyl 4-chloro-3-oxobutanoate, it was pointed out that the octyl ester is reduced only by the (*R*)-hydroxy ester-producing enzyme and thus produced (*R*)-hydroxy ester has high e.e. We believe that the same recognition is operating here in the reduction of 2,2-dimethylpropyl 2-methyl-3-oxopropionate as that seen in the reduction of octyl 4-chloro-3-oxobutanoate. To confirm our suggestion, further investigation is necessary.

Experimental

^{1}H NMR spectra were recorded on a JEOL FX-100 (100 MHz), a Varian VXR-200 (200 MHz), and a JEOL GX-400 (400 MHz) spectrometer in $CDCl_3$ with Me_4Si as an internal reference. Gas chromatography was recorded on a Yanaco G-2800 gas chromatograph. HPLC was performed with a Hitachi 655 Liquid Chromatography (pump) and IRICA 852-III spectrophotometer, using a Cosmosil 5SL (4.6×250) column. IR spectra were recorded on a Hitachi EPI-S2 infrared spectrometer. Optical rotations were measured with a Perkin-Elmer 241 polarimeter.

Organic reagents were purchased from Nakarai Chemical Co., Tokyo Kasei Co., and Aldrich Chemical Co. unless otherwise indicated. Solvents and commercially available starting materials were generally used without additional purification unless otherwise indicated. Pyridine and benzene were refluxed on calcium hydride for 1 day and distilled before the use. Satisfactory results were obtained from elemental analyses of all of the products.

Preparation of Esters of 2-Methyl-3-oxopropionate. The corresponding ethyl ester was prepared according to the reference.[6] The other esters were prepared by transesterification with the ethyl ester. Two methods were used.

Method A. Ethyl 2-methyl-3-oxopropionate (10 mmol) and alcohol (50 mmol) were heated for an appropriate time and distilled under reduced pressure.

Method B. Ethyl 2-methyl-3-oxopropionate (10 mmol) was added to 15 mmol of alcohol in 20 ml of benzene and the solution was refluxed for an appropriate time, then distilled under reduced pressure, affording the desired ester.

Ethyl 2-Methyl-3-oxopropionate (2a): bp 60 °C/20 mmHg (1 mmHg=133.322 Pa); ^{1}H NMR ($CDCl_3$-TMS) δ=1.29 (aldehyde form, a), 1.32 (enol form, e) (3H, t, J=3.4 Hz (a), 3.4 Hz (e)), 1.34 (a), 1.66 (e) (3H, d, J=7.2Hz (a), 1.6Hz (e)), 3.37 (a), 6.98 (e) (1H, qd, J=7.2 Hz, 1.5Hz (a), dq, J=12.5Hz, 1.5Hz (e)), 4.23 (2H, q, J=7.3Hz (a,e)), 9.77 (a), 11.31 (e) (1H, d, J=1.5Hz (a), 12.5Hz (e)); IR (neat), 1727, 1673 cm^{-1}.

3-Methylbutyl 2-Methyl-3-oxopropionate (2f): Method A; bp 97—99 °C/20 mmHg; ^{1}H NMR ($CDCl_3$-TMS) δ=0.91 (a), 0.92 (e) (6H, d, J= 4.0 Hz (a), 4.9 Hz (e)), 1.12—1.78 (3H, m (a,e)), 1.36 (a), 1.68 (e) (3H, d, J=7.5 Hz (a), 1.0Hz (e)), 3.37 (a), 6.98 (e) (1H, qd, J=7.2 Hz, 1.5 Hz (a), dq, J=12.5 Hz, 1.0 Hz (e)), 4.05—4.33 (2H, m (a,e)), 9.78 (a), 11.31 (e) (1H, d, J=1.5 Hz (a), 12.5 Hz (e)); IR (neat), 1733, 1677 cm^{-1}.

4-Methylpentyl 2-Methyl-3-oxopropionate (2g): Method A; bp 119 °C/20 mmHg: ^{1}H NMR ($CDCl_3$-TMS) δ=0.88 (a), 0.89 (e) (6H, d, J=6.6 Hz (a), 6.6 Hz (e)), 1.15—1.77 (5H, m (a,e)), 1.34 (a), 1.67 (e) (3H, d, J=7.3 Hz (a), 1.1 Hz (e)), 3.38 (a), 6.98 (e) (1H, qd, J=7.3 Hz, 1.5 Hz (a), dq, J=12.5 Hz, 1.1 Hz (e)), 4.05—4.26 (2H, m (a,e)), 9.78 (a), 11.31 (e) (1H, d, J=1.5 Hz (a), 12.5 Hz (e)); IR (neat), 1728, 1672 cm^{-1}.

2-Ethylbutyl 2-Methyl-3-oxopropionate (2h): Method A; bp 115.5 °C/20 mmHg; ^{1}H NMR ($CDCl_3$-TMS) δ=0.85—0.94 (6H, m (a,e)), 1.12—1.58 (4H, m (a,e)) 1.36 (a), 1.67 (e) (3H, d, J=7.3 Hz (a), 1.3 Hz (e)) 3.37 (a), 6.98 (e) (1H, qd, J=7.2 Hz, 1.5 Hz (a), dq, J=12.4 Hz, 1.3 Hz (e)), 3.98—4.18 (1H, m (a,e)), 4.10 (2H, q, J=5.6 Hz (a,e)), 9.77 (a), 11.31(e) (1H, d, J=1.5 Hz (a), 12.4 Hz (e)); IR (neat), 1735, 1677 cm^{-1}.

Allyl 2-Methyl-3-oxopropionate (2i): Method A; bp 70 °C/15 mmHg; ^{1}H NMR ($CDCl_3$-TMS) δ=1.36 (a), 1.69 (e) (3H, d, J=7.2 Hz (a), 1.2 Hz (e)), 3.42 (a), 7.00 (e) (1H, qd, J=7.2 Hz, 1.4 Hz (a), dq, J=11.4 Hz, 1.2 Hz (e)), 4.56—4.70 (2H, m (a,e)), 5.26—5.39 (2H, m (a,e)), 5.83—6.05 (1H, m (a,e)), 9.78 (a), 11.22 (e) (1H, d, J=1.4 Hz (a), 11.4 Hz (e)); IR

(neat), 1727, 1674 cm^{-1}.

2-Ethoxyethyl 2-Methyl-3-oxopropionate (2j): Method A; bp 107—109 °C/15 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.15—1.24 (3H, m (a,e)), 1.35 (a), 1.69 (e) (3H, d, J=7.3 Hz (a), 1.0 Hz (e)), 3.43—3.73 (m, (a,e)), 6.99 (dq, J=12.6, 1.0 (e)) (5H), 4.24—4.41 (2H, m (a,e)), 9.79 (a), 11.18 (e) (1H, d, J=1.4 Hz (a), 12.6 Hz (e)); IR (neat), 1743, 1675 cm^{-1}.

2-Methoxyethyl 2-Methyl-3-oxopropionate (2k): Method A; bp 134 °C/20 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.34 (a), 1.68 (e) (3H, d, J=7.3 Hz (a), 1.0 Hz (e)), 3.36 (3H, d, J=1.5 Hz (a,e)), 3.52—3.76 (m (a,e)), 6.92 (dq, J=12.5, 1.0 (e)) (3H), 4.27—4.36 (2H, m (a,e)), 9.74 (a), 11.18 (e) (1H, d, J=1.5 Hz (a), 12.5 Hz (e)); IR (neat), 1729, 1673 cm^{-1}.

2,2-Dimethylpropyl 2-Methyl-3-oxopropionate (2l): Method A; bp 90 °C/20 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.95 (9H, d, J=4.1 Hz (a,e)), 1.36 (a), 1.70 (e) (3H, d, J=7.2 Hz (a), 1.2 Hz (e)), 3.42 (a), 7.05 (e) (1H, qd, J=7.2 Hz, 1.5 Hz (a), dq, J=12.6 Hz, 1.2 Hz (e)), 3.77—3.96 (2H, m (a,e)), 9.81 (a), 11.29 (e) (1H, d, J=1.5 Hz (a), 12.6 Hz (e)); IR (neat), 1732, 1678 cm^{-1}.

3,3-Dimethylbutyl 2-Methyl-3-oxopropionate (2m): Method B; Kugelrohr distillation; bp 75 °C/20 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.97 (9H, s (a,e)), 1.14—1.18 (2H, m (a,e)) 1.35 (a), 1.67 (e) (3H, d, J=7.3 Hz (a), 1.5 Hz (e)), 3.38 (a), 6.99 (e) (1H, qd, J=7.3 Hz, 1.5 Hz (a), dq, J=12.2 Hz, 1.5 Hz (e)), 4.25 (2H, t, J=7.3 Hz (a,e)), 9.78 (a), 11.33 (e) (1H, d, J=1.5 Hz (a), 12.2 Hz (e)); IR (neat), 1745, 1677 cm^{-1}.

2-(Trimethylsilyl)ethyl 2-Methyl-3-oxopropionate (2n): Method A; bp 113.5—114 °C/20 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.06 (9H, d, J=1.0 Hz (a,e)), 0.95—1.14 (2H, m (a,e)), 1.35 (a), 1.67 (e) (3H, d, J=7.3 Hz (a), 1.5 Hz (e)), 3.37 (a), 6.99 (e) (1H, qd, J=7.3 Hz, 1.5 Hz (a), dq, J=12.2 Hz, 1.5 Hz (e)), 4.29 (2H, m (a,e)), 9.78 (a), 11.37 (e) (1H, d, J=1.5 Hz (a), 12.2 Hz (e)); IR (neat) 1728, 1673 cm^{-1}.

Cyclohexylmethyl 2-Methyl-3-oxopropionate (2o): Method B; bp 139 °C/20 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.90—1.78 (11H, m (a,e)), 1.36 (a), 1.69 (e) (3H, d, J=7.3 Hz (a), 1.0 Hz (e)), 3.40 (a), 6.99 (e) (1H, qd, J=7.3 Hz, 1.5 Hz (a), dq, J=12.7 Hz, 1.0 Hz (e)), 3.99 (2H, d, J=6.3 Hz (a,e)), 9.80 (a), 11.31 (e) (1H, d, J=1.5 Hz (a), 12.7 Hz (e)); IR (neat), 1727, 1675 cm^{-1}.

2-Cyclohexylethyl 2-Methyl-3-oxopropionate (2p): Method B; bp 150 °C/20 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.97—1.77 (13H, m (a,e)), 1.36 (a), 1.68 (e) (3H, d, J=7.3 Hz (a), 1.0 Hz (e)), 3.39 (a), 6.99 (e) (1H, qd, J=7.2 Hz, 1.5Hz (a), dq, J=12.7 Hz, 1.0 Hz (e)), 4.22 (2H, t, J=6.6 Hz (a,e)), 9.79 (a), 11.33 (e) (1H, d, J=1.5 Hz (a), 12.7 Hz (e)); IR (neat) 1730, 1675 cm^{-1}.

Preparation of Racemic 3-Hydroxy-2-methylpropionate. Sodium borohydride (9.5 mg, 0.25 mmol) was added to a stirred and cooled solution of one mmol of 2-methyl-3-oxopropionate and 10 ml of ethanol in an ice bath. The resulted solution was stirred at room temperature for 1 h and the ethanol was removed under reduced pressure, then the residual solution was acidified with dilute hydrochloric acid. The organic portion was extracted with ether (30 ml), and the ether layer was washed with water, aqueous sodium hydrogencarbonate, and water (10 ml each) respectively. After dried over anhydrous sodium sulfate, the solvent was evaporated from the ether solution. Esters of 3-hydroxy-2-methylpropionate were obtained by Kugelrohr distillation.

Ethyl 2-Methyl-3-hydroxypropionate (1a): Kugelrohr distillation; bp 90 °C/21 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.26 (3H, t, J=7.1 Hz), 1.17 (3H, d, J=7.4 Hz), 2.41 (1H, m), 2.64 (1H, m), 4.15 (2H, q, J=7.1 Hz); IR (neat), 1739, 3470 cm^{-1}.

Butyl 2-Methyl-3-hydroxypropionate (1b): Kugelrohr distillation; bp 120 °C/21 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.93 (3H, t, J=7.2 Hz), 1.17 (3H, d, J=7.3 Hz), 1.29—1.70 (4H, m), 2.28—2.34 (1H, m), 2.57—2.74 (1H, m), 3.67—3.74 (2H, m), 4.11 (2H, t, J=6.6 Hz); IR (neat), 1737, 3480 cm^{-1}.

Octyl 2-Methyl-3-hydroxypropionate (1c): Kugelrohr distillation; bp 150 °C/21 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.88 (3H, t, J=5.9 Hz), 1.18 (3H, d, J=6.8 Hz), 1.28 (12H, m), 2.34 (1H, m), 2.70 (1H, m), 3.71 (2H, d, J=6.1 Hz), 4.11 (2H, t, J=6.8 Hz); IR (neat), 1738, 3460 cm^{-1}.

1-Methylethyl 2-Methyl-3-hydroxypropionate (1d): Kugelrohr distillation: bp 95 °C/24 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.24 (6H, m), 1.15 (3H, d, J=7.3 Hz), 2.37 (1H, m), 2.52—2.68 (1H, m), 3.64—3.72 (2H, m), 4.94—5.12 (1H, m); IR (neat), 1733, 3490 cm^{-1}.

2-Methylpropyl 2-Methyl-3-hydroxypropionate (1e): Kugelrohr distillation; bp 120 °C/25 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.93 (6H, d, J=6.7 Hz), 1.185 (3H, d, J=7.3 Hz), 1.65—2.05 (1H, m), 2.34 (1H, t, J=5.7 Hz), 2.58—2.75 (1H, m), 3.70 (2H, t, J=5.1 Hz), 3.89 (2H, m); IR (neat), 1737, 3480 cm^{-1}.

3-Methylbutyl 2-Methyl-3-hydroxypropionate (1f): Kugelrohr distillation; bp 130 °C/27 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.92 (6H, d, J=6.4 Hz), 1.17 (3H, d, J=7.3 Hz), 1.48—1.75 (3H, m), 2.28 (1H, m), 2.58—2.74 (1H, m), 3.65—3.77 (2H, m), 4.14 (2H, t, J=6.8 Hz); IR (neat), 1738, 3480 cm^{-1}.

4-Methylpentyl 2-Methyl-3-hydroxypropionate (1g): Kugelrohr distillation; bp 140 °C/27 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.88 (6H, d, J=6.6 Hz), 1.17 (3H, d, J=7.3 Hz), 1.22—1.28 (1H, m), 1.46—1.71 (4H, m), 2.31 (1H, m), 2.57—2.74 (1H, m), 4.09 (2H, t, J=6.8 Hz); IR (neat), 1738, 3490 cm^{-1}.

2-Ethylbutyl 2-Methyl-3-hydroxypropionate (1h): Kugelrohr distillation; bp 125 °C/22 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.89 (6H, t, J=7.6 Hz), 1.18 (3H, d, J=7.3 Hz), 1.28—1.43 (4H, m), 1.47—1.59 (1H, m), 2.32 (1H, m), 2.58—3.76 (1H, m), 3.68 (2H, m), 4.02—4.06 (2H, m); IR (neat), 1739, 3490 cm^{-1}.

Allyl 2-Methyl-3-hydroxypropionate (1i): Kugelrohr distillation; bp 105 °C/23 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.19 (3H, d, J=7.2 Hz), 2.27 (1H, m), 2.60—2.80 (1H, m), 3.70 (2H, m), 4.60 (2H, m), 5.20—5.40 (2H, m), 5.80—6.00 (1H, m); IR (neat), 1738, 3470 cm^{-1}.

2-Ethoxyethyl 2-Methyl-3-hydroxypropionate (1j): Kugelrohr distillation; bp 140 °C/23 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.18 (3H, d, J=7.3 Hz), 1.20 (3H, d, J=7.0 Hz), 2.35—2.55 (1H, m), 2.55—2.88 (1H, m), 3.53 (2H, q, J=7.0 Hz), 3.61—3.74 (4H, m), 4.25—4.33 (2H, m); IR (neat), 1738, 3480 cm^{-1}.

2-Methoxyethyl 2-Methyl-3-hydroxypropionate (1k): Kugelrohr distillation; bp 130 °C/26 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=1.58 (3H, d, J=7.2 Hz), 2.44 (1H, m), 3.38 (3H, s), 3.60 (2H, t, J=4.7 Hz), 3.71 (2H, m), 4.24—4.35 (2H, m); IR (neat), 1740, 3480 cm^{-1}.

2,2-Dimethylpropyl 2-Methyl-3-hydroxypropionate (1l): Kugelrohr distillation; bp 120 °C/25 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.95 (9H, d, J=4.1 Hz), 1.21 (3H, d, J=7.3 Hz), 2.36 (1H, m), 2.60—2.80 (1H, m), 3.73 (2H, m), 3.82 (2H,

d, J=1.5 Hz); IR (neat), 1737, 3490 cm^{-1}.

3,3-Dimethylbutyl 2-Methyl-3-hydroxypropionate (1m): Kugelrohr distillation; bp 130 °C/23 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.95 (9H, s), 1.17 (3H, d, J=7.3 Hz), 1.57 (2H, t, J=7.3 Hz), 2.33 (1H, m), 2.55—2.75 (1H, m), 3.71 (2H, m), 4.18 (2H, t, J=7.3 Hz); IR (neat) 1740, 3490 cm^{-1}.

2-(Trimethylsilyl)ethyl 2-Methyl-3-hydroxypropionate (1n): Kugelrohr distillation; bp 135 °C/24 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.05 (9H, s), 1.01 (2H, m), 1.17 (3H, d, J=7.3 Hz), 2.35 (1H, m), 2.54—2.74 (1H, m), 3.71 (2H, d, J=5.9Hz), 4.21 (2H, m); IR (neat), 1738, 3500 cm^{-1}.

Cyclohexylmethyl 2-Methyl-3-hydroxypropionate (1o): Kugelrohr distillation; bp 145 °C/22 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.70—1.90 (11H, m), 1.18 (3H, d, J=7.3 Hz), 2.40 (1H, t, J=6.1Hz), 2.58—2.77 (1H, m), 3.71 (2H, dd, J=5.4Hz, 6.4Hz), 3.93 (2H, d, J=6.4 Hz); IR (neat), 1739, 3480 cm^{-1}.

2-Cyclohexylethyl 2-Methyl-3-hydroxypropionate (1p): Kugelrohr distillation; bp 160 °C/23 mmHg; ^1H NMR ($CDCl_3$-TMS) δ=0.62—1.82 (13H, m), 1.18 (3H, d, J=7.3 Hz), 2.38 (1H, t, J=5.9 Hz), 2.56—2.76 (1H, m), 3.71 (2H, t, J=5.9 Hz), 4.15 (2H, t, J=6.8 Hz); IR (neat), 1736, 3480 cm^{-1}.

Reduction of 2 with Bakers' Yeast. One millimole of **2** was added to a suspension of 5 g of BY in 15 ml of water and the mixture was stirred at room temperature until no starting material was detected on gas chromatography (PEG, 1 m, 80 °C). Then Hiflo-Super-Cell (10 g) and ethyl acetate (30 ml) was added to the mixture and the resulted suspension was filtered. The organic portion was concentrated under reduced pressure and the residue was subjected to column chromatography (silica gel, eluent; hexane-ethyl acetate=9 : 1) to give the corresponding alcohol. The NMR and IR spectra were the same with the corresponding hydroxy ester obtained by sodium borohydride reduction. The optical rotational values, e.e.s, and chemical yields of each hydroxy ester are listed in the Table.

Reduction of 2a with Immobilized Bakers' Yeast. One millimole of **2a** in 50 ml of water was reacted for two days with immobilized BY prepared from 10 g of polyurethane prepolymer, 10 g of BY, and 10 g of water.[8] After filtration and extraction from the aqueous phase with ethyl acetate, **1a** was obtained in 45% chemical yield with 55% e.e. The e.e. was slightly improved from the reduction of **2a** by free BY (45% e.e.).

Determination of e.e. of the Reduced Product. The reduced product (**1a—p**) was converted into the corresponding (*R*)-(+)-α-methoxy-α-(trifluoromethyl)phenylacetic acid (MTPA) ester by the reaction of **1** and MTPA-chloride in the presence of pyridine in benzene. The e.e. was determined by HPLC analysis of the MTPA ester.

Determination of Absolute Configuration. The absolute configuration of the reduction product was determined by converting **1** into the corresponding ethyl ester and comparing its rotational value with that reported.

A mixture of 1 mmol of **1l**, ethanol (10 ml) and catalytic amount of *p*-toluenesulfonic acid was heated at reflux temperature for 4 days. Ethanol was distilled off under reduced pressure and the residue was subjected to column chromatography (silica gel, eluent; hexane-ethyl acetate=9 : 1), giving ethyl 3-hydroxy-2-methylpropionate. The hydroxy ester obtained from the yeast reduction of 2,2-dimethylpropyl 2-methyl-3-oxopropionate (**1l**) afforded the corresponding ethyl ester in 56% yield; $[\alpha]_D^{20}$ −20.26 (*c* 3.41, MeOH). Since the optical rotational value of (*R*)-ethyl 3-hydroxy-2-methylpropionate is −21.6, the absolute configuration of **1l** was determined to be *R*.

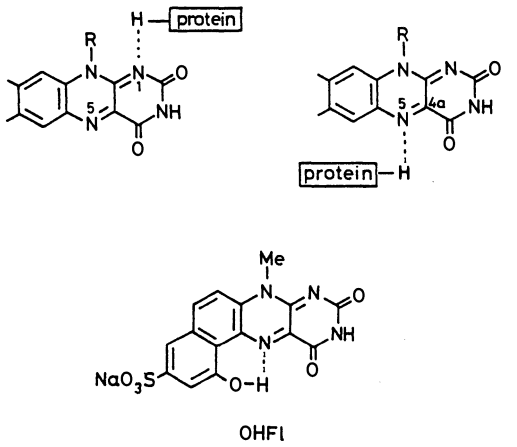
(Received December 19, 1987)

In order to assess the effect of intramolecular acid catalysis on the specific flavin reactivities, 3-methyl-10-(2-hydroxyphenyl)isoalloxazine (**1**(2OH)) and 3-methyl-10-(2-hydroxy-1-naphthyl)isoalloxazine (**2**(2OH)) were synthesized and the redox properties were compared with those of reference flavins such as 3-methyl-10-(2-methoxyphenyl)isoalloxazine (**1**(2OMe)) and 3-methyl-10-(2-methoxy-1-naphthyl)isoalloxazine (**2**(2OMe)). The pK_a values for **1**(2OH) and **2**(2OH) were determined to be 7.7 and 7.0, respectively, which were lower than that of 3-methyl-10-(4-hydroxyphenyl)isoalloxazine (**1**(4OH): pK_a 8.6). It is thus unlikely that 2′-OH and N(1) form a hydrogen bond at the initial state of the reaction (i.e., at the oxidized state). The X-ray crystallographic studies indicated that the phenyl ring makes an angle of 79.7° with the isoalloxazine ring and the 2′-OH group forms a hydrogen bond with methanol included in the crystal lattice. In acetonitrile at 30 °C 1-benzyl-1,4-dihydronicotinamide was not oxidized by **1**(2OMe), **1**(4OH), and **2**(2OMe). On the other hand, the oxidation took place with **1**(2OH) and **2**(2OH) which have an acidic OH group at the 2′-position of the 10-aryl substituent. The presence of the intramolecular acid catalysis suggests that 2′-OH and N(1) can interact at least at the transition state or at the final state of the reaction (i.e., at the reduced state). In general, the oxidized flavin adopts a "planar" structure which is sterically tense while the reduced flavin adopts a "bent" structure which is sterically relaxed. As the structure of the transition state is more or less similar to the reduced form, the hydrogen-bonding interaction could increase on going from the tense initial state to the relaxed transition state. This is a novel example for acid catalysis in flavin-mediated reactions.

Flavin coenzymes act as versatile redox catalysts in many biological systems, and it is now known that more than 100 proteins called flavoproteins require flavin coenzymes as their prosthetic groups.[1-3] In 1980, Massey and Hemmerich[4] proposed a stimulative hypothesis that a large number of flavoproteins may be classified into two groups from a viewpoint of their regiospecific reactivities: the first group is characterized by red semiquinone, high sulfite affinity, and bent structure of the reduced form, whereas the second group is characterized by blue semiquinone, low sulfite affinity, and almost planar structure of the reduced form. They explained that the most essential difference between these two groups is caused by regiospecific hydrogen bonding between flavin coenzymes and apoproteins:[4] that is, the first group has a hydrogen bond with N(1) leading to activation of the N(5) position while the second group has a hydrogen bond with the N(5) leading to activation of the C(4a) position. The situation reminds us of the role of 3-OH in pyridoxal coenzymes.

In order to obtain an insight into the latent capability of the hydrogen bond, we previously synthesized a flavin with hydrogen-bonded N(5) (OHFl: sodium 1-hydroxy-7-methyl-9,10-dioxo-7,9,10,11-tetrahydronaphtho-[1,2-g]pteridine-3-sulfonate).[5,6] We found that OHFl is "regioselectively" activated toward reactions involving 4a intermediates, for example, oxidation of thiols.[5,6] On the basis of several lines of evidence, the specific reactivity was ascribed to activation of the C(4a) position through hydrogen bonding with N(5).[5,6] Thus, the half of the hypothesis has been proved with OHFl, but the another half of the hypothesis (i.e., activation of the N(5) position through hydrogen bonding with N(1)) has been left equivocal. Based on our experience, it is extremely difficult to design a flavin derivative which involves hydrogen-bonded N(1).[7] Unlike OHFl, it is almost impossible to attach a fused aromatic ring to N(10) because of steric crowding. Also, $CH_2CH_2NH_3^+$ and CH_2COOH groups on N(10) were ineffective.[7] These examples of past failure suggest that the proximity effect plays a crucial role in the intramolecular acid catalysis.[5-7] Here, we wish to report the redox properties of 3-methyl-10-(2-hydrophenyl)isoalloxazine (**1**(2OH)) and 3-methyl-10-(2-hydroxy-1-naphthyl)isoalloxazine (**2**(2OH)). Examination of space-filling molecular models suggests that although it seems difficult for 2′-OH and N(1) to form a direct hydrogen bond at the oxidized state, the interaction is latently



OHFl

† Coenzyme Models 50.

possible at the sterically-relaxed reduced state. We have found that the acid catalysis arising from the hydrogen-bonding interaction (probably at the transition state) is observable in acetonitrile.

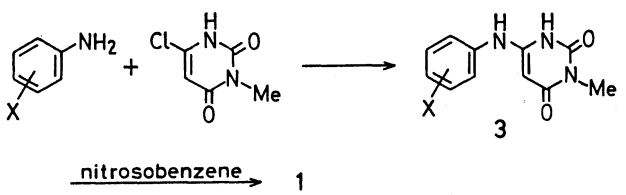
Experimental

Materials. Preparations of 3-methyl-10-phenylisoalloxazine (**1**(H)), 3-methyl-10-(1-naphthyl)isoalloxazine (**2**(H)), and 3-methyl-10-(2-methoxy-1-naphthyl)isoalloxazine (**2**(2OMe)) were described previously.[8]

3-Methyl-10-(2-hydroxy-1-naphthyl)isoalloxazine (2(2OH)). **2**(2OMe) (0.80 g; 2.08 mmol) was treated with 47% HBr (20 ml) at 130 °C. The progress of the reaction was followed by a TLC method. After 3 h the reaction mixture was diluted with water (100 ml) and neutralized by $NaHCO_3$. The precipitate was collected by filtration, washed with water, and then dried in vacuo. The yellow solid was recrystallized from acetic acid; mp >300 °C, yield 51%. Found: C, 63.90; H, 4.18; N, 12.99%. Calcd for $C_{21}H_{14}N_4O_3 \cdot CH_3CO_2H$: C, 64.18; H, 4.22; N, 13.02%. The elemental analysis indicates that the crystals contain one mol of acetic acid per one mol of **2**(2OH). We thus repeated recrystallization from ethanol; mp >300 °C, yield 49%. Found: C, 66.06; H, 4.76; N, 13.45%. Calcd for $C_{21}H_{14}N_4O_3 \cdot C_2H_5OH$: C, 66.33; H, 4.84; N, 13.46%. The result suggests that one mol of ethanol is included in the crystals. Toda et al.[9] demonstrated that molecules having crossed planes and the hydroxyl group(s) at the suitable position(s) easily form host-guest complexes in the solid state. Probably, **2**(2OH) satisfies this structural prerequisite to act as host molecules. Since the inclusion of acetic acid is very unfavorable for the titration experiments, we used the sample containing ethanol all through the present study.

Compounds **1** were synthesized according to the following scheme. The synthetic method was originally exploited by Yoneda et al.[10]



Scheme 1.

3-Methyl-6-(2-hydroxyanilino)uracil (3(2OH)). 3-Methyl-6-chlorouracil (1.00 g; 6.23 mmol) and *o*-aminophenol (2.71 g; 24.8 mmol) were stirred at 180—190 °C under a nitrogen stream. After 10 min the precipitate was formed from the melted reaction mixture. The product was well washed with 4 M[§] HCl; mp 273—275 °C, yield 68%; IR(KBr) ν_{OH}3400 cm^{-1} $\nu_{C=O}$ 1700, 1740 cm^{-1}. Found: C, 56.36; H, 4.76; N, 17.95%. Calcd for $C_{11}H_{11}N_3O_3$: C, 56.65; H, 4.75; N, 18.02%.

3-Methyl-6-(2-methoxyanilino)uracil (3(2OMe)). 3-Methyl-6-chlorouracil (1.00 g; 6.23 mmol) and *o*-methoxyaniline (3.06 g; 24.8 mmol) were stirred at 150—160 °C under a nitrogen stream. After 20 min the precipitate was formed from the melted reaction mixture. The product was well dispersed in ethanol and the precipitate was recovered by filtration. This operation was repeated once again; mp 261—263 °C, yield 85%; IR(KBr) ν_{NH} 3240 cm^{-1}, $\nu_{C=O}$ 1700, 1715 cm^{-1}. Found: C, 58.30; H, 5.18; N, 17.26%. Calcd for $C_{12}H_{13}N_3O_3$: C, 58.29; H, 5.30; N, 17.00%.

3(4OH) and **3**(4OMe) were prepared from *p*-aminophenol and *p*-methoxyaniline in manners similar to those described for **3**(2OH) and **3**(2OMe), respectively. We thus omit the detailed description of the experimental methods and recorded their analytical data.

3-Methyl-6-(4-hydroxyanilino)uracil (3(4OH)). Mp >300 °C, yield 82%; IR(KBr) ν_{OH} 3300 cm^{-1}, $\nu_{C=O}$ 1700, 1720 cm^{-1}. Found: C, 56.22; H, 4.77; N, 17.94%. Calcd for $C_{11}H_{11}N_3O_3$: C, 56.65; H, 4.75; N, 18.02%.

3-Methyl-6-(4-methoxyanilino)uracil (3(4OMe)). Mp 290—292 °C, yield 88%; IR(KBr) ν_{NH} 3250 cm^{-1}, $\nu_{C=O}$ 1720 cm^{-1}. Found: C, 58.26; H, 5.26; N, 17.17%. Calcd for $C_{12}H_{13}N_3O_3$: C, 58.29; H, 5.30; N, 17.00%.

3-Methyl-10-(2-hydroxyphenyl)isoalloxazine (1(2OH)). **3**(2OH) (1.90 g; 8.15 mmol) and nitrosobenzene (2.62 g; 24.5 mmol) were refluxed in 40 ml of acetic acid-acetic anhydride (1 : 4 v/v) under a nitrogen stream. The progress of the reaction was followed by a TLC method. After 30 min the reaction mixture was cooled and concentrated in vacuo. The residual oil was subjected to preparative TLC (silica gel, chloroform-methanol 30 : 1 v/v). There were two yellow spots on the TLC plate, which were identified to be **1**(2OH) (R_f=0.5) and 3-methyl-10-(2-acetoxyphenyl)isoalloxazine (R_f=0.7). We thus collected two isoalloxazines together and the mixture was refluxed for 1 h in 16 ml of 4 M HCl to hydrolyze the ester. The solution was neutralized by $NaHCO_3$ and the precipitate was recrystallized from acetic acid; mp >300 °C, yield 12%; IR(KBr) ν_{OH} 3350 cm^{-1}, $\nu_{C=O}$ 1660, 1710 cm^{-1}. ^1H NMR (Me_2SO-d_6): δ=3.27 (3H, NCH_3), 6.88 (1H, 9-H), 7.11 (1H, 5′-H), 7.16 (1H, 3′-H), 7.28 (1H, 6′-H), 7.49 (1H, 7-H), 7.65 (1H, 4′-H), 7.81 (1H, 8-H), 8.25 (1H, 6-H), 9.96 (1H, OH). Found: C, 63.90; H, 3.83; N, 17.38%. Calcd for $C_{17}H_{12}N_4O_3$: C, 63.75; H, 3.78; N, 17.49%.

3-Methyl-10-(4-hydroxyphenyl)isoalloxazine (1(4OH)). This compound was synthesized in a manner similar to that described for **1**(2OH). Mp >300 °C, yield 14%; IR (KBr) ν_{OH} 3370 cm^{-1}, $\nu_{C=O}$ 1660, 1720 cm^{-1}. Found: C, 63.59; H, 3.74; N, 17.30%. Calcd for $C_{17}H_{12}N_4O_3$: C, 63.75; H, 3.78; N, 17.49%.

3-Methyl-10-(4-methoxyphenyl)isoalloxazine (1(2OH)). This compound was synthesized from **3**(2OMe) (1.50 g; 6.07 mmol) and nitrosobenzene (1.95 g; 18.2 mmol) in 40 ml of acetic acid-acetic anhydride (1 : 1 v/v) at the reflux temperature under a nitrogen stream. After 30 min the reaction

§ 1 M=1 mol dm^{-3}.

mixture was cooled and concentrated in vacuo. The residual solid was recrystallized from acetic acid in the presence of activated charcoal: mp >300 °C, yield 47%; IR(KBr) $\nu_{C=O}$ 1660, 1710 cm^{-1}, ν_{C-O-C} 1270 cm^{-1}. Found: C, 64.52; H, 4.21; N, 16.67%. Calcd for $C_{18}H_{14}N_4O_3$: C, 64.66; H, 4.22; N, 16.76%.

3-Methyl-10-(4-methoxyphenyl)isoalloxazine (1(4OMe)). This compound was synthesized in a manner similar to that described for **1**(2OMe). Mp >300 °C, yield 45%: IR(KBr) $\nu_{C=O}$ 1655, 1710 cm^{-1}, ν_{C-O-C} 1270 cm^{-1}. Found: C, 64.66; H, 4.19; N, 16.64%. Calcd for $C_{18}H_{14}N_4O_3$: C, 64.66; H, 4.22; N, 16.76%.

Kinetic Measurements. The aqueous reaction with 1-benzyl-1,4-dihydronicotinamide was carried out aerobically at 30 °C and μ=0.1 with KCl. Under the aerobic conditions flavins are recycled automatically, so that the decrease in the absorption band of 1-benzyl-1,4-dihydronicotinamide (360 nm) satisfies the first-order equation. The medium pH was maintained by 0.01 M phosphate (pH<7.0), 0.01 M *N*-ethylmorpholine (7.0<pH<8.0), 0.01 M borate (8.0<pH<9.5), and 0.01 M carbonate (pH>9.5).

The reaction with 1-benzyl-1,4-dihydronicotinamide in acetonitrile was carried out anaerobically at 30 °C. The decrease in the absorption band of flavins (440 nm) satisfied the first-order equation in the presence of excess 1-benzyl-1,4-dihydronicotinamide (2.09×10^{-3} M; [flavin]=5.00×10^{-5} M). Since the pseudo-first-order rate constants (k_1') were first-order in 1-benzyl-1,4-dihydronicotinamide, the results were discussed with the second-order rate constants ($k_2=k_1'$/[1-benzyl-1,4-dihydronicotinamide]).

X-Ray Crystal Structure Analysis. Crystal data. $C_{17}H_{12}N_4O_3$, CH_3OH, *F.W.* 352.3, monoclinic, space group *C*2/*c*, *a*=23.853(3), *b*=10.342(1), *c*=13.894(1) Å, β=100.16(1)°, *V*=373.9(5) Å^3, D_c=1.387 g cm^{-3} for *Z*=8.

Orange colored, prismatic crystals were obtained by the recrystallization from a methanol-benzene mixed solvent. The crystal used had approximate dimensions of 0.45×0.23×0.18 mm.

Integrated intensities were collected on a Rigaku rotating anode, four-circle diffractometer using nickel-filtered Cu $K\alpha$ radiation(λ=1.5418 Å) by the θ-2θ scan technique up to 2θ=120°. The 2θ scan rate was 8° min^{-1}, and the scan width $\Delta2\theta=(2.4+0.3\tan\theta)°$. Backgrounds were counted for 4 s at both ends of a scan. Three standard reflections measured after every 100 reflections to monitor the stability and orientation of the crystal showed no significant decay through the experiment. Of the 2885 reflections measured, number of reflections observed was 2114 ($|F_o|>2\sigma(F_o)$, where σ is the standard deviation obtained from the counting statistics). Usual Lorentz and polarization corrections were applied but absorption correction was ignored [μ(Cu $K\alpha$)=8.50 cm^{-1}].

The structure was solved by the direct method (MULTAN 78).[11] All the non-hydrogen atoms could be located on successive Fourier syntheses. The hydrogen atoms except those of methanol, the crystalline solvent, were located on the calculated positions, which were confirmed on the difference Fourier map. The structure was refined by the block-diagonal least-squares procedure (HBLS V)[12] with anisotropic thermal parameters for nonhydrogen atoms and isotropic ones for hydrogen atoms. During the course of the refinement, the only remaining peak on the difference Fourier map was found to be assigned as the alternative position of the disordered methanol oxygen atom, O(5), which was included in the refinement with 20% occupancy. The final *R* value was 0.056. The weighting schemes used at the final cycle of the refinement were $w=(\sigma^2+0.01886|F_o|+0.00254|F_o|^2)^{-1}$ for $|F_o|>0$ and $w=0$ for $|F_o|=0$. The final atomic parameters are given in Table 1.[§§] Atomic scattering factors were taken from those of International Tables for X-Ray Crystallography, Vol. IV.[13] Computations were done on an ACOS S850 computer at the Crystallographic Research Center, Institute for Protein Research, Osaka University.

Results and Discussion

Crystal Structure of 1(2OH). The molecular struc-

§§ Tables of anisotropic thermal parameters of nonhydrogen atoms, coordinates of hydrogen atoms, and observed and calculated structure factors are kept at the Chemical Society of Japan, Document No. 8803.

ture is shown in Fig. 1.[14] The atom numbers in Fig. 1 are used only for the crystal structure. Selected bond lengths and bond angles are given in Table 2. The remarkable feature of the structure is that three six-membered hetero rings in the isoalloxazine ring is not coplanar: the dihedral angle between the rings I and II is 2.2(1)° and that between II and III also 2.2(1)°. The ring IV attached to the N(2) atom of the ring II makes an angle of 79.7° with the ring II. The *o*-hydroxyl group of the ring IV is, therefore, located too far from the N(4) atom of the ring III to form the hydrogen bond [O(3)···N(4)=3.265(3) and H(12)···N(4)=4.11(5) Å].

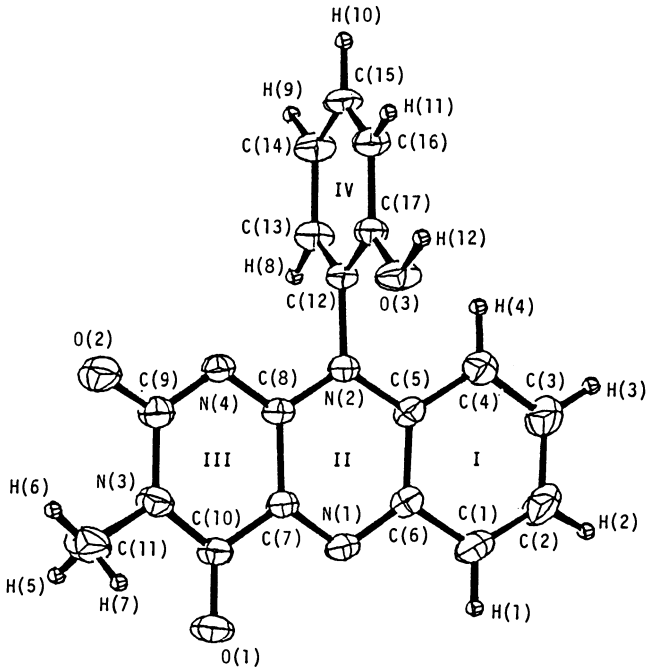

Fig. 1. A perspective view[14] of **1**(2OH). Nonhydrogen atoms are expressed as thermal ellipsoids with 20% probability level, and hydrogen atoms as spheres with B=1.0 Å^2.

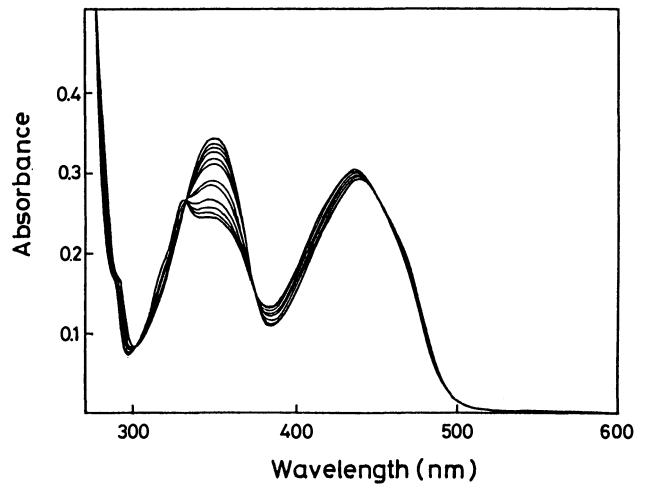

Fig. 2. pH Dependent spectral change in **2**(2OH) (4.00×10^{-5} M).

Instead, the hydroxyl group is bound by the hydrogen bond with the methanol molecule, the solvent of crystallization. However, the methanol showed a positional disorder: the major component, C(18)H_3O(4)H with 80% occupancy and the minor, C(18)H_3O(5)H with 20% occupancy [O(3)···O(4)=2.599(4), O(3)-H(12)=1.06(5), H(12)···O(4)=1.59(4) Å, and O(3)-H(12)-O(4)=158(4)°, and O(3)···O(5)=2.652(10), H(12)···O(5)=1.64(4) Å, and O(3)-H(12)-O(5)=159(4)°].

Phototitration of 1(2OH), 1(4OH), and 2(2OH). The pK_a values of the 2′-OH in three isoalloxazines were estimated by phototitration. As shown in Fig. 2, the absorption spectra of **2**(2OH) changed as a function of pH. This change is attributed to the dissociation of the 2′-OH because this group is the sole dissociable group in **2**(2OH) at pH 4—10. In Fig. 3 we

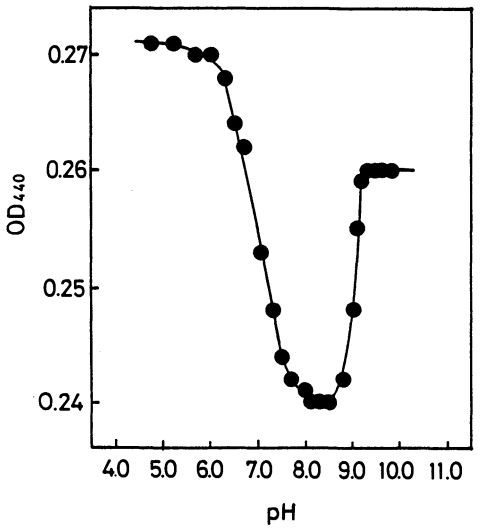

Fig. 4. Plot of OD_{440} vs. pH for **1**(2OH) (4.00×10^{-5} M).

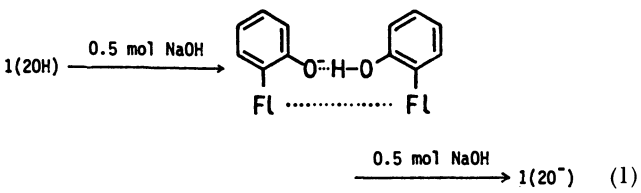
plotted OD_{350} against medium pH. The analysis of this plot by a titration equation afforded pK_a=7.0 for **2**(2OH). Similarly, the pK_a of the 2′-OH in **1**(4OH) was estimated to be 8.6. On the other hand, **1**(2OH) showed a spectral change different from others: with increasing medium pH the absorbance at 320—470 nm region first decreases with isosbestic points (314 and 478 nm) and then increases with different isosbestic points (275 and 490 nm). The plot of OD_{440} vs. pH gave a minimum absorbance at pH 8.3 (Fig. 4). We carefully examined the correlation between the spectral change and the consumed NaOH. It was found that 0.5 mol of NaOH is consumed per one mol of **1**(2OH) at pH 5.0—8.3 and another 0.5 mol of NaOH is consumed at pH 8.3—9.3. The finding supports that the biphasic spectral change is caused by the specific interaction between neutral **1**(2OH) and dissociated **1**($2O^-$). It is known that flavins easily form stacked aggregates in aqueous solution.[15,16] This is due to the poor solubility of flavins in water and also due to the large dipole moment across flavin molecules.[17] If this is the case in **1**(2OH), the flavin-flavin interaction would become maximum at the half-titrated pH, for example, owing to intermolecular hydrogen bonding between neutral **1**(2OH) and dissociated **1**($2O^-$) (Eq. 1). Anyway, we estimated the pK_a of **1**(2OH) to be the half-titrated pH 7.7.



(1)

It is not clear yet why such a biphasic spectral

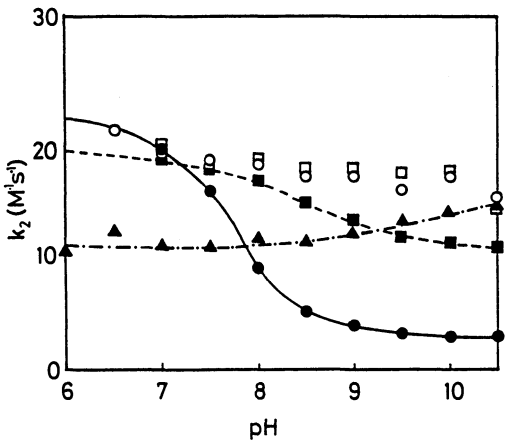


Fig. 5. pH Dependence of the k_2 for the reaction of **1**(2.75×10^{-5} M) and BNAH (7.91×10^{-5} M): ▲ **1**(H), ● **1**(2OH), ○ **1**(2OMe), ■ **1**(4OH), □ **1**(4OMe).

change is observed for **1**(2OH) but not for **2**(2OH). We have found that the rotation of the aryl group at the N(10) position of flavins is considerably restricted because of the steric effect and the rotation of the naphthyl group is much more difficult than the phenyl group.[8,18] Probably, the two isoalloxazines in **2**(2OH) cannot come closer enough to interact electronically because of steric hindrance arising from the 10-naphthyl group.

The pK_a values determined above are generally lower than those for analogous compounds (e.g., 9.71 for *o*-aminophenol and 10.30 for *p*-aminophenol).[19] Furthermore, **1**(2OH) has the pK_a lower than **1**(4OH). When the OH group forms the stable intramolecular hydrogen bond, the pK_a should be raised. Hence, these pK_a data suggest that **1**(2OH) and **2**(2OH) do not form the stable hydrogen bond at least at the initial state (i.e., oxidized state). The conclusion obtained in solution is in line with that obtained from the X-ray crys-

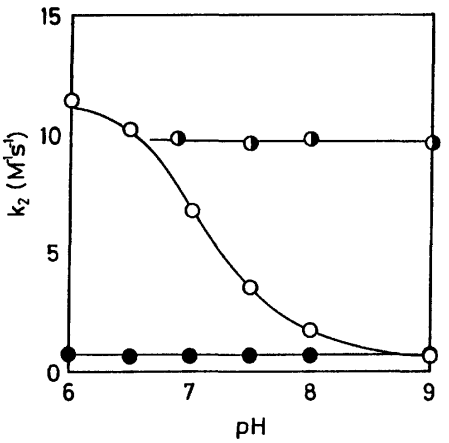

Fig. 6. pH Dependence of the k_2 for the reaction of **2**(2.75×10^{-5} M) and BNAH (7.91×10^{-5} M): ○ **2**(H), ○ **2**(2OH), ● **2**(2OMe).

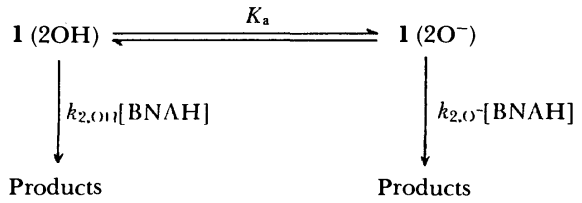
tallographic analysis.

pH Dependence for the Reaction with 1-Benzyl-1,4-dihydronicotinamide. The hydrogen-transfer reaction from 1-benzyl-1,4-dihydronicotinamide (BNAH) to five flavins was carried out at pH 7.0—10.4. As a prelude to kinetic studies, we confirmed that this reaction is not catalyzed by buffers (10^{-3}—10^{-1} M) in water. In Figs. 5 and 6 the second-order rate constants (k_2) are plotted against medium pH. It is seen from these figures that the k_2 values for **1**(H), **1**(2OMe), **1**(4OMe), **2**(H), and **2**(2OMe) which have no dissociable group at this pH range are almost constant. On the other hand, **1**(2OH), **1**(4OH), and **2**(2OH) gave the sigmoid curves which could be expressed by Scheme 2 (**1**(2OH) is taken as an example). Thus, the k_2 is expressed by Eq. 2 including the true second-order rate constants for each species, $k_{2,OH}$ and k_{2,O^-}.



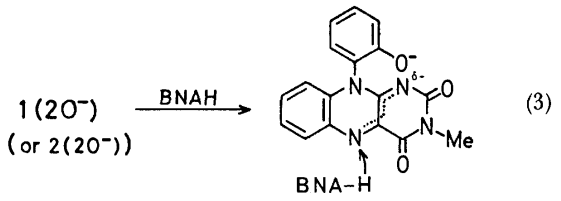
Scheme 2.

$$k_2 = \frac{k_{2,OH}[H^+] + k_{2,O^-}K_a}{[H^+] + K_a} \quad (2)$$

The $k_{2,OH}$ and k_{2,O^-} determined by computer-assisted curve-fitting with Eq. 2 are summarized in Table 3. Examination of Table 3 reveals that (i) in **1**(2OH) and **2**(2OH) the $k_{2,OH}$ values are greater by 8.1—27 fold than the k_{2,O^-} values but in **1**(4OH) the $k_{2,OH}$ is greater only by 1.8 fold than the k_{2,O^-} and (ii) the $k_{2,OH}$ for **2**(2OH) is greater by 2 fold than that for the 2′-methoxy counterpart but the $k_{2,OH}$ values for **1**(2OH) and **1**(4OH) are almost equal to those for the 2′-methoxy counterparts (less than 1.3). As described above, the aryl group at the N(10) position cannot enjoy the coplanarity with the isoalloxazine ring.[8,18] Therefore, the resonance effect of the 10-substituent should be relatively small. In fact, the dissociation of the 2′-OH group in **1**(4OH) decreased the rate constant only by a factor of 1.8. In contrast, the large rate decrease was observed for **1**(2OH) and **2**(2OH). The difference observed between the 2′-substituent and the 4′-substituent would be explained by the spatial electrostatic effect but not by the resonance effect: that is, reduction of these flavins develops an anionic charge on the N(1) position which is very close to the 2′-oxide anion (Eq. 3). Therefore, the progress of this reaction would induce an energetically-unfavorable electrostatic repulsion. Probably, this is why the large diffence was observed for **1**(2OH) and **2**(2OH).

Table 3. pK_a of the 2′-OH Group and the Second-Order Rate Constants (k_2) in an Aqueous System (30 °C)

Flavin	pK_a	$k_2/M^{-1}s^{-1}$	
		Neutral ($k_{2,OH}$)	Dissociated (k_{2,O^-})
1(H)	—	11.6	—
1(2OH)	7.7	22.0	2.70
1(2OMe)	—	16.6	—
1(4OH)	8.6	18.0	9.94
1(4OMe)	—	16.8	—
2(H)	—	9.71	—
2(2OH)	7.0	13.3	0.50
2(2OMe)	—	0.66	—



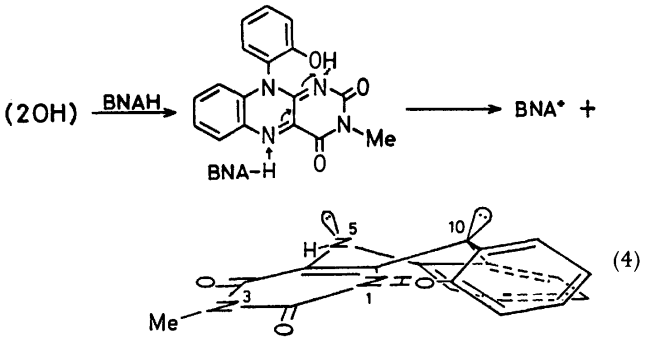
(3)

More important is the finding (ii). The rate difference between **2**(2OH) and **2**(2OMe) may be rationalized in terms of hydrogen bonding. On the other hand, the absence of the rate difference between **1**(2OH) and **1**(2OMe) may be due to the aggregate formation discovered through the phototitration. Subsequently, we carried out the reaction in acetonitrile where the effect of hydrogen bonding would be more strengthened.

Reaction with BNAH in Acetonitrile. It is known that the electrostatic and the hydrogen-bonding effect appear more clearly in organic solvents (especially, in aprotic solvents). For example, the influence of hydrogen bonding with trichloroacetic acid or trifluoroacetic acid on the absorption spectra of flavins was studied in detail in CCl_4.[20] Similarly, Sigman et al.[21,22] demonstrated that an anionic charge placed in the vicinity of N(1) in 1,4-dihydronicotinamide effectively

enhances the reducing ability in acetonitrile but not in an aqueous system. Yagi et al.[20] also found that the photoreduction of riboflavin tetrabutyrate by *N*-benzyl-*N*,*N*′-dimethylethylenediamine in CCl_4 is weakly catalyzed (1.2—1.4 fold) by strong proton acids such as trichloroacetic acid and trifluoroacetic acid. This suggests that the reduction of flavins may be general-acid-catalyzed in aprotic solvents such as CCl_4 although the position of the acid catalysis cannot be specified. We thus chose acetonitrile to obtain a further insight into the hydrogen bonding effect.

In the anaerobic reaction with BNAH (2.09×10^{-3} M) we found that only **1**(2OH) and **2**(2OH) (5.00×10^{-5} M) can oxidize BNAH with $k_2=2.06\times10^{-2}$ $M^{-1}s^{-1}$ and 7.31×10^{-2} $M^{-1}s^{-1}$, respecticely. The reaction with other six flavins was not detected at all ($k_2<10^{-5}$ $M^{-1}s^{-1}$). It is particularly worthy mentioning that **1**(2OH) is reactive but **1**(4OH) is totally unreactive in acetonitrile. The essential difference in the reactivity indicates that the reaction with **1**(2OH) (and also with **2**(2OH)) is acid catalyzed intramolecularly. It is known that oxidized flavins employ the planar structure with sp^2-hybridized N(5) and N(10) while reduced flavins employ the bent structure folded through sp^3-hybridized N(5) and N(10).[23-25] Thus, the steric crowding in oxidized flavins is significantly relaxed in folded reduced flavins.[8,18] Examination of Corey-Pauling-Koltun models suggests that it is not impossible to form a hydrogen bond in reduced **1**(2OH) (and also **2**(2OH)) (Eq. 4).



Presumably, intramolecular general-acid catalysis by the 2′-OH begins when the anionic charge is partially developed on N(1) and the isoalloxazine ring is partially folded. This implies that the transition state of this reaction lies more or less close to the final state.

We also found that the reaction with BNAH is general-acid-catalyzed by added acidic species in acetonitrile. As shown in Fig. 7, the k_2 increased linearly with increasing *p*-cyanophenol concentration: k_{ga} and 1.8×10^{-2} $M^{-2}s^{-1}$ for **2**(2OMe). If the acidity difference between 2′-OH and *p*-cyanophenol (pK_a 7.95)[19] is neglected, the effective concentration (k_2/k_{ga}) of the 2′-OH group in general-acid catalysis amounts to 0.71 M for **1**(2OH) and 4.1 M for **2**(2OH). These values are relatively small and are classified as a less effective contribution of general-acid catalysis.[26] It is concluded, therefore, that flavin activation through hydrogen bonding with N(1) does exist but is not so effective in these model compounds, **1**(2OH) and **2**(OH).

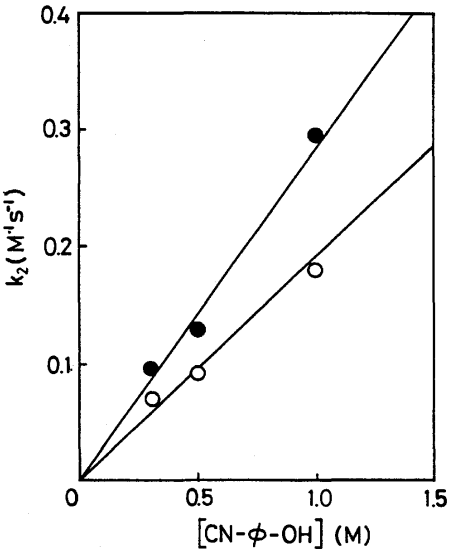


Fig. 7. General-acid catalysis by *p*-cyanophenol for the reaction of **1**(2OMe) (●) or **2**(2OMe) (○) (5.00×10^{-5} M) with BNAH (2.09×10^{-3} M) in acetonitrile.

We are currently devoting our research efforts on the development of more effective model systmes to prove the flavin activation through hydrogen bonding with N(1).

This research was supported by the Grant-in-Aid from the Ministry of Education, Science and Culture. We thank Professor Fumio Yoneda for helpful discussion.

The Reaction of Lupane and Friedo-Oleanane Type Triterpenes with *m*-Chloroperbenzoic Acid[1)]

Motoo Tori, Reiko Matsuda, Masakazu Sono, Yoshihiro Kohama, and Yoshinori Asakawa*
Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Yamashiro cho, Tokushima 770
(Received December 23, 1987)

Lupane-3β,28-diol, lupan-3β-ol, and friedelan-3β-ol were treated with *m*-chloroperbenzoic acid (*m*CPBA) in refluxing chloroform to afford corresponding lactones in one step, while lupane-3β,28-diyl diacetate, lupan-3β-yl acetate, and friedelan-3β-yl acetate to give hydroxylated or keto derivatives. Similar reaction of dendropanoxide with *m*CPBA yielded 6β-, 7β-, 21α-, and 22β-hydroxylated compounds.

Recently, we reported the reaction of natural products, monoterpenes,[2)] sesquiterpenes,[3)] triterpenes,[4)] and other class of compounds,[5)] with *m*CPBA in chloroform under reflux to afford hydroxylated or carbonyl compounds as a result of functionalization at unactivated carbon atoms. These reactions are very similar to dry ozonization[6)] of natural products. Takahashi et al., in 1977, reported dry ozonization of friedelane and friedelin to yield the corresponding 15, 16, 19, and 21-keto derivatives as well as the 18,19-epoxide.[7)] In these cases ozone attacked the rings D and E, which were protruding. We expect that the reactions of this class of compounds with *m*CPBA might occur at these positions. In order to compare dry ozonization with *m*CPBA oxidation, lupane-3β,28-diol (**1**), lupan-3β-ol (**2**), friedelan-3β-ol (**3**), lupane-3β,28-diyl diacetate (**4**), lupan-3β-yl acetate (**5**), friedelan-3β-yl acetate (**6**), and dendropanoxide (**7**) were allowed to react with *m*CPBA in chloroform under reflux. We now report the details of these reactions.

Triterpene Alcohols. Dihydrobetulin (**1**) was allowed to react with *m*CPBA (2.2 equiv) in chloroform for 6 h under reflux. After the removal of acidic fractions of the product by means of chromatography over Sephadex LH-20 ($CHCl_3$-MeOH=1 : 1), the product was subjected to silica-gel column chromatography (PhH-EtOAc, gradient) [work up procedure A] to afford 28-hydroxylupan-3-one (**8**, 50.2%), methyl 4,28-dihydroxy-3,4-seco-lupan-3-oate (**9**, 4.7%), and methyl 28-hydroxy-3,4-seco-lup-4(23)-en-3-oate (**10**, 7.9%). The structure of **8** was easily assigned by the spectral data [*m/z* 442; 3450 and 1700 cm^{-1}; δ 3.32 and 3.78 (each d, *J*=11 Hz, H-28)]. The MS and IR spectra of compound **9** showed the peaks at *m/z* 472 $(M-H_2O)^+$, 385, and 373 and the absorptions at 3450 and 1730 cm^{-1}, respectively. The ^1H NMR spectrum indicated the presence of a methoxycarbonyl group [δ 3.67 (3H, s)] and the protons at C-28 (δ 3.31 and 3.77, each d, *J*=11 Hz). As the signals of the two methyl groups shifted downfield (δ 1.23 and 1.28, each 3H, s), this compound was found to be a 4-hydroxy-3,4-seco derivative. Compound **10** showed similar spectral data to those of **9**, including the methoxycarbonyl group [1730 cm^{-1}, δ 3.66 (3H, s)] and the C-28 hydroxyl group [3450 cm^{-1}, δ 3.31 and 3.77 (each d, *J*=11 Hz)], except for the exo-methylene group (890 cm^{-1}, δ 4.65 and 4.85) and the vinyl methyl group (δ 1.73). Thus, this compound was found to be derived from compound **9** by dehydration. These two compounds, **9** and **10**, were presumably formed by methanolysis of the initially produced lactone **11** catalyzed by *m*-chlorobenzoic acid present in the reaction mixture during column chromatography over Sephadex LH-20 ($CHCl_3$-MeOH=1 : 1). Indeed, when lactone **11** was exposed to similar conditions (*m*-chlorobenzoic acid/$CHCl_3$-MeOH), **9** and **10** were formed. Therefore, the reaction of **1** with *m*CPBA was worked up by washing with aq Na_2SO_3, aq. $NaHCO_3$, and brine, successively [work up procedure B] to afford **8** (50.2%) and **11** (20%). These results were presumably explained as follows: **1** was oxidized to ketone **8** which underwent Baeyer-Villiger oxidation to give **11**, the lactone ring of which opened by methanolysis to afford the hydroxy methyl ester **9**. **9** underwent dehydration to give the unsaturated methyl ester **10** under the conditions employed.

worked up [procedure B] and purified by column chromatography over silica gel to give lupan-3-one (**12**, 33.5%),[8] and 3,4-seco-lupan-4,3-olide (**13**, 4.3%). The IR spectrum of lactone **13** showed the absorption at 1710 cm^{-1} and the molecular ion peak at m/z 442 was observed in its mass spectrum. The ^1H NMR spectrum was very similar to those of **11**. It showed the signals of two tertiary methyl groups (δ 1.40 and 1.47), two secondary methyl groups (δ 0.75 and 0.84) and four tertiary methyl groups (δ 0.76, 0.93, 1.08, and 1.09). These data clearly indicated that compound **13** is a lactone.

Similar treatment of friedelan-3β-ol (**3**) with *m*CPBA gave friedelin (**14**, 42.7%),[9] 4-epi-friedelin (**15**, 9.5%),[9] and 3,4-seco-friedelan-4,3-olide (**16**, 20.3%)[10] after work up procedure B. The structure of compound **15** was determined to be 4-epi-friedelin, since the base treatment (KOH/EtOH) of **15** yielded **14** very easily. Compound **16** was identical with that of the Baeyer-Villiger oxidation product of **14**. 4-Epi-friedelin was presumably derived from the 3α,4α-epoxide by acid-catalyzed opening under the conditions employed. The epoxide was formed through friedel-3-ene, which was derived from **3** by acid-catalyzed dehydration.

The hydroxyl groups at C-3 position of these triterpenes were susceptible to this oxidation to give ketones and/or followed by further oxidation to afford lactones, but the hydroxyl groups at C-28 of the lupane triterpenes were not attacked under these conditions presumably due to the steric hindrance.

Triterpene Acetates. Lupane-3β,28-diyl diacetate (**4**) was subjected to the reaction with *m*CPBA. In this case only one compound was produced (83.2%) and its spectral data were identical with those of 19β-hydroxylupane-3β,28-diyl diacetate (**17**) reported in the literature.[11] It is interesting to note that **17** was the sole product of both dry ozonization and *m*CPBA oxidation. It is probably owing to the assistance of the acetoxyl group located at C-28.

Lupan-3β-yl acetate (**5**) was next treated with *m*CPBA in $CHCl_3$ under reflux for 12 h to afford 13β-hydroxylupan-3β-yl acetate (**18**, 20.4%) and 16β-hydroxylupan-3β-yl acetate (**19**, 5.1%). Compound **18** showed molecular ion peak at m/z 486 and absorptions at 3500 and 1720 cm^{-1} in its MS and IR spectra, respectively, suggesting that a tertiary hydroxyl group was introduced in the skeleton. When **18** was subjected to dehydration with $POCl_3$ in pyridine, olefin **20** [δ 5.16, t, J=8 Hz; m/z 468 (M^+)] was formed. Since the MS spectrum of **20** indicated a fragment peak at m/z 218 due to retro-Diels-Alder fragmentation of the ring C, **20** must be formulated as lup-12-en-3β-yl acetate.[12] Hence, **18** was determined to be 13β-hydroxylupan-3β-yl acetate, providing that hydroxylation occurred with retention of configuration. The spectroscopic data of product **19** were identical with the literature data of 16β-hydroxylupan-3β-yl acetate.[12,13] The structure **19** was reconfirmed by Jones oxidation into known 16-oxolupan-3β-yl acetate (**21**)[13] and by measuring the solvent shift of the ^1H NMR data of **21**.

In the case of friedelan-3β-yl acetate (**6**), 15-oxofriedelan-3β-yl acetate (**22**, 12.9%) [m/z 484 (M^+), 1730 and 1695 cm^{-1}] was produced under similar conditions. The ^1H NMR spectrum of **22** showed the signals of two protons resonating at δ 2.16 and 2.50 (each d, J=18 Hz), suggesting the protons α to the carbonyl group. When compound **22** was hydrolyzed (KOH/EtOH) followed by Jones oxidation to afford diketone

23, it was found that the spectral data of **23** were identical with those of authentic friedelane-3,15-dione.[7] Hence, product **22** should be formulated to be 15-oxofriedelan-3β-yl acetate.

When the hydroxyl groups were protected as acetates, unactivated carbon atoms at relatively unhindered positions were attacked to give a hydroxylated and/or a carbonyl compound. In these cases, the reaction products are quite similar to those of dry ozonization.

Triterpene Ether. Dendropanoxide (**7**) is a hexacyclic triterpene oxide isolated from *Dendropanax trifidus*.[14] Dendropanoxide (**7**) was treated with *m*CPBA in $CHCl_3$ under reflux to afford four alcoholic products **24—27** and ketone **28** after purification by column chromatography, prep. TLC, and HPLC. The first product **24**, $C_{30}H_{50}O_2$ (by HRMS), showed a signal at δ 4.10 (dt, J=11.8 and 7 Hz) due to the proton attached to the carbon bearing the hydroxyl group (3400 cm^{-1}) as well as a signal at δ 3.77 (d, J=7 Hz) due to H-3. These data indicated that **24** is a secondary alcohol and that the position of the hydroxyl group is at either C-6 or C-7, because there were three protons in the neighbor of the hydroxyl group judging from the coupling pattern. Irradiation of the proton at δ 4.10 (H-6β) induced NOE's into two methyl groups (δ 1.09 and 1.10). Since the 24-Me (δ 1.10) was assigned by observing NOE between the H-3 and the 24-Me and NOE's between the 24-Me (δ 1.10) and H-6β, and the 25-Me (δ 1.09) and the H-6β were expected, **24** should be formulated to be 6α-hydroxydendropanoxide. The ^{1}H NMR spectrum of the second compound **25** showed pattern of signals (δ 4.20, brt, J=5 Hz) very similar to that of **24**, indicating the presence of a secondary hydroxyl group probably at C-7. As actually only one methyl (δ 1.19, 25-Me) was observed in the NOE difference spectrum, when the proton at δ 4.20 (H-7β) was irradiated, **25** was determined to be 7α-hydroxydendropanoxide. These structures were in good agreement with the assignment of the ^{13}C NMR data (vide infra).

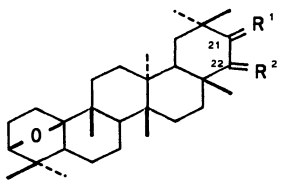
28



29 R^1=O, R^2=H_2
30 R^1=H_2, R^2=O

The spectral data of **26** (δ 3.70, dd, J=12 and 4 Hz) and **27** (δ 3.67, dd, J=12 and 5.6 Hz) only showed that these compounds had secondary hydroxyl groups having two protons in the neighbor. They would be located at C-11, 12, 15, 16, 21, or 22 position. It is difficult to assign by analysis of the ^{1}H NMR data or NOE experiments unless the ^{13}C NMR data of **7** are fully assigned. The ^{13}C NMR data of **7** were analyzed by the use of 2D NMR spectroscopy (COSY, ^{13}C-^{1}H correlation, long-range ^{13}C-^{1}H correlation, and H-H-C relayed correlation) and the results were shown in Table 1.[15] As the carbons of rings A—C of both compounds, **26** and **27**, have very similar chemical shifts to those of **7**, the positions of the hydroxyl groups are deduced to be at either C-21 or C-22. When **26** and **27** were subjected to Jones oxidation, they were converted to different ketones, namely, 21-oxodendropanoxide (**29**) and 22-oxodendropanoxide (**30**), respectively. Thus, **26** was determined to be 21α-hydroxydendropanoxide, because the irradiation of the proton at δ 3.70 (H-21β) induced NOE's into two methyl groups (28-Me and 29-Me). Only this position can give rise to

Table 2. Yields of the Products from **1**—**7**

Substrate	Work-up	Product (yield/%)[a]
1	A	**8** (50.2), **9** (4.7), **10** (7.9)
	B	**8** (50.2), **11** (20)
2	B	**12** (33.5),[8] **13** (4.3)
3	B	**14** (42.7),[9] **15** (9.5),[9] **16** (20.3)[10]
4	B	**17** (83.2)[11]
5	B	**18** (20.4), **19** (5.1)[12,13]
6	B	**22** (12.9)
7	B	**24** (1.6), **25** (1), **26** (0.4) **27** (0.2), **28** (0.3)

a) Yields shown indicate isolation yields based on consumed starting material.

NOE's into two methyl groups. However, the irradiation of the methine at δ 3.67 (H-22α) of **27** did not give any NOE into the methyl groups. If the hydroxyl group is located at 22α position, NOE into the 28-Me is expected upon irradiation of H-22β. Therefore, **27** was determined to be 22β-hydroxydendropanoxide.

The spectral data of **28** [1690 cm^{-1}; m/z 440 (M^+) and 221], which were not identical with those of **29** or **30**, showed the presence of the ketone instead of the alcohol. The protons which showed absorptions at δ 2.17 and 2.44 (each d, J=17 Hz) indicated the partial structure ■-CO-CH_2-■, in the molecule. The predominant fragment ion (m/z 221) shown by the wave line in the structure **28** suggests that the position of the carbonyl group is at C-15. This ion has been proved to possess the composition of $C_{15}H_{25}O$ by HRMS. The ^{13}C NMR data supported this result (Table 1). Thus, ketone **28** was determined to be 15-oxodendropanoxide. As a result, dendropanoxide was attacked at methylene carbons in rings B, D, and E, which were protruded and unhindered.

The results obtained in this work (Table 2) clearly show that when the compound has a hydroxyl group in the ring A, oxidation to the corresponding ketone predominates. Sometimes further oxidation, Baeyer-Villiger oxidation, occurs. While in the case of the acetate, oxidation by this method occurs at an unactivated carbon atom of the sterically unhindered position to afford a secondary or tertiary alcohol or a ketone. Dendropanoxide has been attacked in its rings B, D, and E, which are unhindered. Although the reaction site is not easy to predict, it is quite interesting to note that the sites of the reaction are similar to those of dry ozonization. These reactions would be convenient for introduction of the oxygen functions at unactivated carbon atoms of various bioactive natural products.

Experimental

General Procedures. See Ref. 4b.

Reaction of Lupane-3β,28-diol (1) with *m*CPBA. Method A: The diol **1** (600 mg) was dissolved in chloroform (36 ml) and *m*CPBA (800 mg, 2.3 equiv) was added. The mixture was refluxed for 6 h. After removal of the solvent, the residue was chromatographed over Sephadex LH-20 using $CHCl_3$-MeOH (1 : 1) for elution. The mixture was further purified by silica-gel column chromatography (PhH-AcOEt) to give 28-hydroxylupan-3-one (**8**, 200 mg), **9** (35 mg), **10** (20 mg), and **1** (200 mg).

28-Hydroxylupan-3-one (8): mp 210 °C; IR ($CHCl_3$): 3450, and 1700 cm^{-1}; ^1H NMR: δ=0.77 (3H, d, J=7 Hz), 0.84 (3H, d, J=7 Hz), 0.94, 0.97, 1.03, 1.07, 1.08 (each 3H, s), 2.55 (2H, m, H-2), 3.32 and 3.78 (each 1H, d, J=11 Hz, H-28); MS m/z: 442 (M^+), 411 (base), 205, and 191; HRMS, Found: m/z 442.3807, Calcd for $C_{30}H_{50}O_2$: M, 442.3811.

Methyl 3,28-Dihydroxy-3,4-seco-lupan-3-oate (9): mp 155—158 °C; IR ($CHCl_3$): 3450 and 1730 cm^{-1}; ^1H NMR: δ=0.77 (3H, d, J=7 Hz), 0.84 (3H, d, J=7 Hz), 0.95, 1.00, 1.05, 1.23, 1.28 (each 3H, s), 2.21 (1H, m, H-2), 2.45 (1H, m, H-2), 3.31 (1H, d, J=11 Hz, H-28), 3.67 (3H, s, -OMe), and 3.77 (1H, d, J=11 Hz, H-28); MS m/z: 472 ($M-H_2O$)$^+$, 441, 385, 373, 361, 191, and 109 (base); HRMS, Found: m/z 472.3902, Calcd for $C_{31}H_{52}O_2$: $M-H_2O$, 472.3916.

Methyl 28-Hydroxy-3,4-seco-lup-4(23)-en-3-oate (10): mp 122 °C (EtOAc); IR ($CHCl_3$): 3450, 1730, and 890 cm^{-1}; ^1H NMR: δ=0.77 (3H, d, J=7 Hz), 0.84 (3H, s), 0.87 (3H, d, J=7 Hz), 0.97 (3H, s), 1.07 (3H, s), 1.73 (3H, s, vinyl Me), 2.18 (1H, m, H-2), 2.33 (1H, m, H-2), 3.31 (1H, d, J=11 Hz, H-28), 3.66 (3H, s, -OMe), 3.77 (1H, d, J=11 Hz, H-28), and 4.65 and 4.85 (each 1H, s, C=CH_2); MS m/z: 472 (M^+), 441, 373, and 81 (base); HRMS, Found: m/z 472.3902, Calcd for $C_{31}H_{52}O_3$: M, 472.3916.

Method B: To a stirred solution of **1** (200 mg) in chloroform (12 ml) was added *m*CPBA (270 mg, 2.3 equiv). The mixture was refluxed for 6 h. More chloroform was added and the solution was washed successively with 5% Na_2SO_3 aq, 5% $NaHCO_3$ aq, and brine. The dried solution was evaporated in vacuo to give a residue (198 mg), which was separated by silica-gel column chromatography (PhH-EtOAc and PhH-Et_2O) to give **8** (60 mg), **1** (80 mg), and **11** (25 mg).

28-Hydroxy-3,4-seco-lupan-4,3-olide (11); mp 142 °C; IR ($CHCl_3$): 3450 and 1715 cm^{-1}; ^1H NMR: δ=0.77 (3H, d, J=7 Hz), 0.84 (3H, d, J=7 Hz), 0.96, 1.07, 1.08, 1.40, 1.48 (each 3H, s), 2.49 (1H, ddd, J=13, 6, and 3.5 Hz, H-2), 2.63 (1H, td, J=13 and 4 Hz, H-2), 3.32 and 3.77 (each 1H, d, J=11 Hz, H-28); MS m/z: 458 (M^+), 427, 369, 191, and 81 (base); HRMS, Found: m/z 458.3775, Calcd for $C_{30}H_{50}O_3$: M, 458.3760.

Methanolysis of Lactone 11. *m*-Chlorobenzoic acid (0.3 mg) was added to a solution of the lactone **11** (0.3 mg) in methanol (0.1 ml) and chloroform (2 drops) and the mixture stirred at rt for 1 h. TLC examination showed that there were three spots, one of which was **11**. Two new spots had the same R_f values (0.47 and 0.25: solvent system PhH-EtOAc (4:1)) as those of **10** and **9**, respectively.

Reaction of Lupan-3β-ol (2) with *m*CPBA. Lupan-3β-ol (**2**) (470 mg) was treated with *m*CPBA (250 mg, 2.2 equiv) in $CHCl_3$ (14 ml) under reflux for 6 h. After work up by method B, the solvent was evaporated to give a residue (253 mg), which was chromatographed over silica gel (EtOAc-PhH gradient as eluant) to give lupan-3-one **12** (30 mg),[8] **2** (110 mg) and **13** (4 mg). **3,4-Seco-lupan-4,3-olide (13);** mp 190 °C (EtOAc); IR: 1710 cm^{-1}; ^1H NMR: δ=0.75 (3H, d, J=7 Hz), 0.76 (3H, s), 0.84 (3H, d, J=7 Hz), 0.93, 1.08, 1.09, 1.40, 1.47 (each 3H, s), 2.49 (1H, ddd, J=14, 6.5, and 3.5 Hz, H-2),

2.63 (1H, td, J=14 and 4.5 Hz, H-2); MS m/z: 442 (M^+), 399, 369, 341, 291, 206, 191, and 81 (base); HRMS, Found: m/z 442.3792, Calcd for $C_{30}H_{50}O_2$: M, 442.3809.

Reaction of Friedelan-3β-ol (3) with *m*CPBA. Friedelan-3β-ol (**3**, 200 mg) was dissolved in $CHCl_3$ (20 ml) and *m*CPBA (260 mg, 2.2 equiv) was added. The mixture was refluxed for 12 h and worked up [procedure B] to give a residue (203 mg), which was chromatographed over silica gel using PhH-EtOAc and PhH-Et_2O solvent systems for elution to afford friedelin (**14**, 85 mg), 4-epi-friedelin (**15**, 8 mg), and lactone (**16**, 35 mg).

3,4-Seco-friedelan-4,3-olide (16); mp 273 °C (EtOAc); IR ($CHCl_3$): 1720 cm^{-1}; ^1H NMR: δ=0.83 (3H, s), 0.89 (3H, s), 0.95 (3H, s), 0.98 (3H, s), 0.99 (3H, s), 1.00 (3H, s), 1.17 (3H, s), 1.20 (3H, d, J=7 Hz), 2.52 (1H, t, J=13 Hz, H-2), 2.64 (1H, dd, J=13 and 6 Hz, H-2), and 4.21 (1H, q, J=7 Hz, H-4); MS m/z: 442 (M^+), 398, 205, and 95 (base); HRMS, Found: m/z 442.3815, Calcd for $C_{30}H_{50}O_2$: M, 442.3810.

Isomerization of 4-Epi-friedelin (15). 4-Epi-friedelin (**15**, 1.5 mg) was dissolved in 5% KOH-MeOH (5 ml) and the mixture was stirred at rt for 5 h. Work up as usual yielded friedelin (**14**, 1.0 mg).

Baeyer-Villiger Reaction of Friedelin (14). Friedelin (**14**, 50 mg) was treated with *m*CPBA (35 mg, 1.2 equiv) in $CHCl_3$ (60 ml) at rt for 2 days to afford the lactone **16** (40 mg) after chromatographic purification.

Acetylation of Diol 1. A solution of diol **1** (350 mg) in pyridine (15 ml) and acetic anhydride (2 ml) was stirred at 50° overnight. The mixture was worked up as usual to yield diacetate **4** (365 mg).

Reaction of Lupane-3β,28-diyl Diacetate (4) with *m*CPBA. *m*CPBA (168 mg, 1.2 equiv) was added to a solution of diacetate **4** (270 mg) in $CHCl_3$ (16 ml) in one portion and the mixture was refluxed for 6 h. The reaction mixture was worked up by method A to give a residue (273 mg). The mixture was purified by silica-gel column chromatography (PhH-Et_2O) to give **4** (235 mg) and 19β-hydroxylupane-3β,28-diyl diacetate (**17**) (30 mg).[11]

Reaction of Lupan-3β-yl Acetate (5) with *m*CPBA. Lupan-3β-yl acetate (**5**, 470 mg) was treated with *m*CPBA (280 mg, 1.2 equiv) in $CHCl_3$ (25 ml) under reflux for 12 h to afford a residue (490 mg) after work up by method A. The residue was subjected to column chromatography over silica gel. Elution with hexane-EtOAc solvent system afforded **5** (375 mg), **18** (20 mg), and **19** (5 mg).[12,13]

13β-Hydroxylupan-3β-yl Acetate (18); mp 250 °C; IR ($CHCl_3$): 3500 and 1720 cm^{-1}; ^1H NMR: δ=0.84 (3H, s), 0.85 (3H, s), 0.86 (3H, d, J=7 Hz), 0.87 (3H, s), 0.93 (3H, d, J=7 Hz), 0.96 (3H, s), 1.02 (3H, s), 1.07 (3H, s), 2.04 (3H, s, Ac), 4.48 (1H, dd, J=12 and 4.5 Hz, H-3α); ^{13}C NMR: δ=14.6 (q), 16.1 (q×2), 16.5 (q), 17.4 (q), 18.3 (t), 18.7 (q), 19.2 (q), 20.8 (t), 21.3 (q), 23.7 (t), 25.8 (t), 27.3 (t), 28.0 (q), 34.1 (t), 34.4 (t), 34.5 (d), 37.1 (t), 37.1 (d), 37.1 (s), 37.8 (s), 38.4 (t), 40.4 (t), 41.1 (s), 42.9 (s), 43.3 (s), 49.5 (d), 50.1 (d), 55.4 (d), 81.0 (d, H-3), 85.8 (s, H-13), and 171.0 (s, Ac); MS m/z: 486 (M^+), 426, 383, 365, 189, and 43 (base); HRMS, Found: m/z 486.4051, Calcd for $C_{32}H_{54}O_3$: M, 486.4073.

Dehydration of 18. The alcohol **18** (10 mg) was treated with $POCl_3$ (4 drops) in pyridine (3 ml) at 90 ° for 1 h. The usual work up and prep. TLC gave lup-12-en-3β-yl acetate (**20**, 6 mg).[12,13]

Oxidation of the Alcohol 19. To a stirred solution of **19** (3 mg) in acetone (1.5 ml) was added Jones reagent (3 drops) at rt. The mixture was stirred for 1 h and usual work up afforded 16-oxolupan-3β-yl acetate (**21**, 1.5 mg).[13]

Reaction of Friedelan-3β-yl Acetate (6) with *m*CPBA. Friedelan-3β-yl acetate (**6**, 100 mg) was treated with *m*CPBA (60 mg, 1.2 equiv) in $CHCl_3$ (10 ml) under reflux for 12 h. Work up by method B afforded a residue (104 mg), which was subjected to column chromatography over silica gel (hexane-Et_2O as eluant) and HPLC (μ-PORASIL, hexane-Et_2O 9:1, 2 ml min^{-1}) to give **6** (85 mg) and the ketone **22** (2 mg).

15-Oxofriedelan-3β-yl Acetate (22); mp 245 °C; IR ($CHCl_3$): 1730 and 1695 cm^{-1}; ^1H NMR: δ=0.82 (3H, d, J=7 Hz), 0.88, 0.89, 0.95, 1.01, 1.21, 1.32 (each 3H, s), 2.04 (3H, s, Ac), 2.16 and 2.50 (each 1H, d, J=18 Hz, H-16), and 4.89 (1H, m, H-3α).

Friedelane-3,15-dione (23). To a solution of 15-oxofriedelan-3β-yl acetate (**22**, 1 mg) in MeOH (0.5 ml) was added 5% KOH-MeOH (5 drops) and the mixture was stirred at 75 °C for 10 h. The reaction mixture was worked up as usual and chromatographed on silica gel (hexane-EtOAc) to give 3β-hydroxyfriedelan-15-one (0.5 mg). The alcohol in acetone (0.2 ml) was oxidized with Jones reagent (2 drops) at rt for 1 h to afford friedelane-3,15-dione (**23**, 0.3 mg).[7]

Reaction of Dendropanoxide (7) with *m*CPBA. To a stirred solution of dendropanoxide (**7**) (1.6 g) in chloroform (70 ml) was added *m*CPBA (0.98 g) and the mixture was refluxed for 12 h. More chloroform was added and the mixture was worked up by method B to give a residue (2.5 g), which was purified by silica-gel column chromatography (PhH-EtOAc, gradient), prep. TLC, and HPLC (Finepak SIL, hexane-EtOAc, gradient) to afford **24** (27 mg, 1.6%), **25** (17 mg, 1%), **26** (7 mg, 0.4%), **27** (3 mg, 0.2%), and **28** (4 mg, 0.3%) as well as **7**.

6α-Hydroxydendropanoxide (24); IR ($CHCl_3$): 3400 cm^{-1}; ^1H NMR: δ=0.95, 0.97, 0.99, 1.09, 1.10, 1.14, 1.14, and 1.17 (each 3H, s, Me), 3.76 (1H, d, J=5.8 Hz, H-3α), and 4.10 (1H, dt, J=11.8 and 7 Hz, H-6β); MS m/z: 442 (M^+), 427; HRMS, Found: m/z 442.3794, Calcd for $C_{30}H_{50}O_2$: M, 442.3811.

7α-Hydroxydendropanoxide (25); IR ($CHCl_3$): 3400 cm^{-1}; ^1H NMR: δ=0.90, 0.96, 0.96, 1.05, 1.05, 1.14, 1.19, and 1.19 (each 3H, s, Me), 3.77 (1H, d, J=5.6 Hz, H-3α), and 4.19 (1H, brt, J=5 Hz, H-7β); MS m/z: 442 (M^+), 427; HRMS, Found: m/z 442.3803, Calcd for $C_{30}H_{50}O_2$: M, 442.3811.

21α-Hydroxydendropanoxide (26); IR ($CHCl_3$): 3400 cm^{-1}; ^1H NMR: δ=0.90, 0.98, 1.01, 1.04, 1.04, 1.06, 1.15, and 1.19 (each 3H, s), 3.70 (1H, dd, J=12 and 4 Hz, H-21β), and 3.76 (1H, d, J=5.6 Hz, H-3α); MS m/z: 442 (M^+), 427; HRMS, Found: m/z 442.3794, Calcd for $C_{30}H_{50}O_2$: M, 442.3810.

22β-Hydroxydendropanoxide (27); IR ($CHCl_3$): 3400 cm^{-1}; ^1H NMR: δ= 0.90, 0.99, 1.01, 1.01, 1.03, 1.13, 1.18, and 1.21 (each 3H, s), 3.67 (1H, dd, J=12 and 5.6 Hz, H-22α), and 3.75 (1H, d, J=5.7 Hz, H-3α); MS m/z: 442 (M^+), 427; HRMS: Found: m/z 442.3816, Calcd for $C_{30}H_{50}O_2$: M, 442.3811.

15-Oxodendropanoxide (28); IR ($CHCl_3$): 1690 cm^{-1}; ^1H NMR: δ=0.86, 0.91, 0.96, 1.02, 1.02, 1.19, 1.31, and 1.38 (each 3H, s, Me), 2.17 and 2.44 (each 1H, d, J=17 Hz, H_2-16), and 3.76 (1H, d, J=5 Hz, H-3α); MS m/z 440 (M^+) and 221; HRMS, Found: m/z 440.3644, Calcd for $C_{30}H_{48}O_2$: M, 440.3655, Found: m/z 221.1893, Calcd for $C_{15}H_{25}O$: M, 221.1905.

Oxidation of 21α-Hydroxydendropanoxide (26). 21α-Hydroxydendropanoxide (**26**, 2 mg) was treated with Jones reagent (1 drop) in acetone (2 ml) at rt for 15 min. Work up as usual gave 21-oxodendropanoxide (**29**, 1.5 mg); ^1H NMR:

δ=3.77 (1H, d, J=5.6 Hz), 1.80 and 2.62 (each 1H, d, J=12.4 Hz); MS m/z: 440 (M^+); HRMS, Found: m/z 440.3649, Calcd for $C_{30}H_{48}O_2$: M, 440.3654.

Oxidation of 22β-Hydroxydendropanoxide (27). 22β-Hydroxydendropanoxide (**27**, 2 mg) was oxidized with Jones reagent (1 drop) in acetone (2 ml) at rt for 15 min. Work up as usual afforded 22-oxodendropanoxide (**30**, 1 mg); ^{1}H NMR: δ=3.75 (1H, d, J=5.4 Hz), 2.55 and 2.16 (each 1H, d, J=17 HZ); MS m/z: 440 (M^+); HRMS, Found: m/z 440.3659, Calcd for $C_{30}H_{48}O_2$: M, 440.3654.

We thank Professors Takeyoshi Takahashi and Takahiko Tsuyuki, The University of Tokyo, for their generous gift of betulin and friedelin used in this work and the spectra of authentic friedelane-3,15-dione. This work was supported in part by a Grant-in-Aid for Cancer Research from the Ministry of Health and Welfare.

A Novel Synthesis of 2-Acyl Cyclic Ethers and 3-Keto Cyclic Ethers Including Spiro Cyclic Ethers via Intramolecular Ring-Opening of α,β-Epoxy Sulfoxides with Hydroxyl Group[1)]

Tsuyoshi SATOH, Ken-ichi IWAMOTO, Atsushi SUGIMOTO, and Koji YAMAKAWA*
Faculty of Pharmaceutical Sciences, Science University of Tokyo, Ichigaya-funagawara-machi, Shinjuku-ku, Tokyo 162
(Received December 26, 1987)

The α,β-epoxy sulfoxides **1** and **2** bearing a ω-oxyalkyl group were synthesized from ω-oxyalkyl carbonyl compounds and 1-chloroalkyl phenyl sulfoxide. The intramolecular ring opening of the oxirane ring of these α,β-epoxy sulfoxides, through an attack of the terminal hydroxyl group, gave 2-acyl cyclic ethers or 3-keto cyclic ethers, including spiro-type cyclic ethers. This procedure is applicable to the preparation of five- and six-membered cyclic ethers.

The intramolecular ring opening of an oxirane ring[2)] with a hydroxyl group is a quite useful method for constructing cyclic ether systems which are found in many natural products having remarkable biological activity, e.g., polyether antibiotics.[3)] However, the compounds containing an epoxy group is usually synthesized from olefins by an epoxidation with several oxidizing agents. In other words, in the step of constructing epoxy groups, carbon-carbon bond formation reactions were rarely used.

Recently, we have reported a new synthetic method for the preparation of α-substituted carbonyl compounds from carbonyl compounds with carbon homologation through α,β-epoxy sulfoxides.[4)] In our papers we reported that the β-position of α,β-epoxy sulfoxides was quite reactive toward many kinds of nucleophiles, such as selenolate,[4a)] thiolates[4b)] and amines,[4c)] giving α-substituted carbonyl compounds in very good yields. With these results in hand, it was anticipated that the intramolecular version of this reaction would be quite promising for constructing heterocyclic compounds having a carbonyl group. In this paper, as a continuation of our studies on the development of new synthetic methods using α,β-epoxy sulfoxides, we report a novel method for the synthesis of 2-acyl cyclic ethers **3** and 3-keto cyclic ethers including spirocyclic 3-keto ethers **4**, both from carbonyl compounds and 1-chloroalkyl phenyl sulfoxides via α,β-epoxy sulfoxides. The whole sequence is shown in Scheme 1.

Results and Discussion

A Synthesis of 2-Acyl Cyclic Ethers. In a previous paper[4d)] we reported that the intermolecular reaction of the α,β-epoxy sulfoxides with alcohols did not work well; however, an intramolecular version of this reaction was thought to be possible since the rate of the intramolecular reaction was usually much faster than that of intermolecular reaction.

First, the α,β-epoxy sulfoxide **1d** was synthesized from 1-chloro-2-phenylethyl phenyl sulfoxide and aldehyde **6** (n=4)[6)] via chlorohydrins[4)] in over 85% yield. The treatment of **1d** with 0.2 equivalents of pyridinium p-toluenesulfonate (PPTS)[7)] in refluxing ethanol afforded deprotected alcohol within ten minutes; then an intramolecular ring opening of the epoxide group by the resulting alcohol took place slowly with a liberation of benzenesulfenic acid to give 2-acyltetrahydropyran **13** in 86% yield after heating for 6 h. The reaction time could be shortened to 2.5 h in refluxing 1-propanol. In this reaction PPTS was essential; upon heating the isolated intermediate alcohol in refluxing ethanol without PPTS, only a very

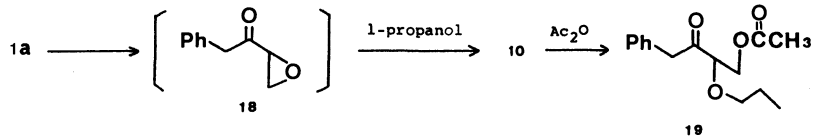
slow reaction was observed. Encouraged by this result, some kinds of α,β-epoxy sulfoxides **1** were allowed to react under the conditions described above. The results are summarized in Table 1. These α,β-epoxy sulfoxides **1** were synthesized from **7** or 1-chloro-1-cyclohexylmethyl phenyl sulfoxide and the aldehyde **6**. The α,β-epoxy sulfoxide **9** was conveniently synthesized from **1d** through the aldehyde **8**, as shown in



Scheme 3.

Scheme 4.

Scheme 2.

The product **10** of the reaction in entry 1 was thought to be produced from the expected cyclic ether **18** with 1-propanol. The structure of **10** was determined by the NMR spectrum of the corresponding acetate **19**. Entries 2—6 show that this method is quite promising for constructing five- and six-membered cyclic ethers. Even secondary alcohol **9** reacted well to afford cyclic ether **14**. Entries 7 and 8 show that the limitation of this procedure lies between the formation of six- and seven-membered cyclic ether. The α,β-epoxy sulfoxides **1f** and **1g** upon heating in refluxing 1-propanol with PPTS gave the products quite slowly; however, the products were not the desired cyclic ethers but, rather, alcohols **16** and **17**.[8] In these cases, **1f** and **1g** gave only deprotected alcohols and no trace of cyclic ethers, even though 2-butanol (the secondary alcohol having higher boiling point than 2-propanol) was used as the solvent.

A Synthesis of 3-Keto Cyclic Ethers. Next, endo-type ring opening of the oxirane ring of the α,β-epoxy sulfoxides **2** was investigated. First of all the α,β-epoxy sulfoxides **2c** and **2e** (see Table 2) were synthesized from 1-chloro-4-(tetrahydropyranyloxy)butyl phenyl sulfoxide[9] and benzaldehyde or cyclohexanone according to the procedure shown in Scheme 1. Heating of this α,β-epoxy sulfoxide **2c** in refluxing ethanol in the presence of 0.1 equivalents of PPTS quickly gave the deprotected alcohol; however, the cyclization was quite sluggish, giving the desired 3-oxo-2-phenyltetrahydropyran in 60% yield after 17 h. It is interesting to note that this endo-type reaction was much slower than that of exo-type (compare with entry 4 in Table 1). Another important characteristic of this reaction was that **2c** only gave a 6-endo-trigonal[10] type product **20** and no trace of the 5-exo-trigonal[10] type product **26**. This result is inconsistent with our finding that the β-position of α,β-epoxy sulfoxides is much more reactive than the α-position.

In contrast to this result, heating the α,β-epoxy sulfoxide **2e** in ethanol or 1-propanol with PPTS gave a complex mixture very quickly. Recently, we reported[11] that magnesium in primary alcohol was quite effective in promoting the ring opening of α,β-epoxy sulfoxides giving α-alkoxy ketones. The result was applied to this intramolecular ring opening of the epoxy group of **2e**. The tetrahydropyranyl group of **2e** was deprotected to afford the alcohol **2f**. Heating of **2f** in refluxing 2-propanol in the presence of one equivalent of magnesium chloride for 13 h gave the desired spirocyclic β-keto ether **22** in 74% yield. The results of this reaction are summarized in Table 2.

Entries 1 and 2 indicate that the 5-endo-trigonal ring closure is quite difficult, as reported by Baldwin.[10] The result in entry 4 is notable. The α,β-epoxy sulfoxide **2d** gave spirocyclic ether **21** in 77% yield in refluxing methanol for 1 h. This remarkable reactivity of **2d** may be attributable to the highly strained nature of the spiro-cyclic structure of **2d**. Entries 8 and 9 indicate that the limitation of this procedure again lies between the formation of six- and seven-membered cyclic ethers.

In conclusion, because of the total simplicity of the reaction this procedure contributes to the synthesis of five- and six-membered cyclic ethers having ketone group.

Experimental

All melting points are uncorrected. The IR spectra were measured directly on a NaCl plate or KBr disks with a Hitachi 215 spectrometer. ^{1}H NMR spectra were measured in a $CDCl_3$ solution with a JEOL FX-100 spectrometer or Hitachi R-24B spectrometer using Me_4Si as an internal standard. Electron-impact mass spectra (MS) were obtained on a Hitachi M-80 double-focusing spectrometer at 70 eV by direct insertion. Silica gel BW-127 ZH (Fuji-Devison) containing a 2% fluoresence reagent (254) and a quartz column were used for column chromatography; products showing ultraviolet (UV) absorption were detected by UV irradiation.

α,β-Epoxy Sulfoxides. All α,β-epoxy sulfoxides, **1** and **2**, except **8** and **9** used in this study were prepared from carbonyl compounds and 1-chloroalkyl phenyl sulfoxides through chlorohydrins in nearly quantitative yields, which were reported previously.[4]

α,β-Epoxy Sulfoxide 1a: *Z*-Isomer, colorless oil, IR (neat) 1090, 1050, 1035, and 1025 (SO) cm^{-1}; ^{1}H NMR δ=1.3—1.8 (6H, m), 2.61, 3.51 (each 1H, d, J=16 Hz), 2.91 (1H, dd, J=4, 5 Hz), 3.4—4.3 (4H, m), 4.61 (1H, bs), and 6.8—7.8 (10H, m). *E*-Isomer, colorless oil, IR (neat) 1090, 1080, 1060, and 1035 (SO) cm^{-1}; ^{1}H NMR δ=1.3—1.8 (6H, m), 3.0—4.1 (7H, m), 4.55 (1H, bs), and 7.0—7.7 (10H, m).

α,β-Epoxy Sulfoxide 1b: *E*-Isomer, colorless oil, IR (neat) 1095, 1080, 1060, and 1040 (SO) cm^{-1}; ^{1}H NMR δ=1.1—2.0 (10H, m), 3.07 (2H, s), 3.1—4.0 (5H, m), 4.50 (1H, bs), 7.18, and 7.53 (each 5H, m). *Z*-Isomer, colorless oil, IR (neat) 1090, 1055, 1040, and 1030 (SO) cm^{-1}; ^{1}H NMR δ=1.2—2.2 (10H, m), 2.54 (1H, d, J=15 Hz), 2.73 (1H, t, J=5 Hz), 3.1—4.1 (4H, m), 3.58 (1H, d, J=15 Hz), 4.56 (1H, bs), and 6.8—7.9 (10H, m).

α,β-Epoxy Sulfoxide 1c: Less polar isomer, colorless oil, IR (neat) 1090, 1055, 1040, and 1030 (SO) cm^{-1}; ^{1}H NMR δ=0.3—2.4 (21H, m), 3.2—4.0 (5H, m), 4.62 (1H, bs), and

7.3—7.8 (10H, m). More polar isomer, colorless oil, IR (neat) 1090, 1080, 1060, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=0.6—2.1 (21H, m), 3.2—4.0 (5H, m), 4.55 (1H, bs), and 7.4—7.8 (10H, m).

α,β-Epoxy Sulfoxide 1d: *E*-Isomer, colorless oil, IR (neat) 1095, 1080, 1060, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.1—2.0 (12H, m), 3.01, 3.05 (each 1H, d, J=16 Hz), 3.1—4.0 (5H, m), 4.52 (1H, bs), and 6.9—7.7 (10H, m). *Z*-Isomer, colorless oil, IR (neat) 1090, 1060, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.2—1.8 (10H, m), 2.01 (2H, m), 2.53, 3.54 (each 1H, d, J=15 Hz), 2.64 (1H, t, J=7 Hz), 3.2—4.0 (4H, m), 4.53 (1H, bs), and 6.8—7.8 (10H, m).

α,β-Epoxy Sulfoxide 9: A solution of 389 mg of **1d** (*E*-isomer) and PPTS (24 mg) in 20 ml of EtOH was heated at 50 °C for 4 h. The EtOH was evaporated to give a residue, which was dissolved in ether-benzene. The solution was washed once with half-saturated brine and dried over Na_2SO_4. The product was purified by silica-gel column chromatography to give 276 mg (90%) of deprotected alcohol as a colorless oil. IR (neat) 3430 (OH), 1095, and 1060 (SO) cm^{-1}; ^1H NMR δ=1.3—1.7 (6H, m), 3.01, 3.08 (each 1H, d, J=16 Hz), 3.4—3.8 (3H, m), and 6.9—7.7 (10H, m).

A solution of oxalyl dichloride (80 μl) in 3 ml of dry CH_2Cl_2 in a dry flask was cooled to −50 °C. DMSO (142 mg in 0.5 ml of CH_2Cl_2) was added to the solution dropwise with stirring and the mixture was stirred at −50 °C for 2 min. To this was added the alcohol (250 mg in 1 ml of CH_2Cl_2). The reaction mixture was stirred at −50 °C for 15 min; then, triethylamine (0.53 ml) was added. The reaction mixture was stirred and allowed to warm to 0 °C. The reaction was quenched by adding 10 ml of water and the whole was extracted with CH_2Cl_2. The product was purified by silica-gel column chromatography to afford 190 mg (77%) of the aldehyde **8** as a colorless oil. IR (neat) 2750 (CHO), 1730 (CO), 1095, and 1060 (SO) cm^{-1}; ^1H NMR δ=1.4—2.1 (4H, m), 2.2—2.6 (2H, m), 2.99, 3.08 (each 1H, d, J=16 Hz), 3.69 (1H, t, J=6 Hz), 7.0—7.8 (10H, m), and 9.66 (1H, t, J=1.5 Hz).

MeMgBr (1.1 equiv) was added dropwide to a solution of the aldehyde (**8**; 156 mg) in 7 ml of dry ether at −60 °C. The reaction mixture was stirred for 10 min; then, the reaction was quenched by satd. aq. NH_4Cl. The whole mixture was extracted with ether-benzene and the product was purified by silica-gel column chromatography to afford 142 mg (87%) of the alcohol **9** as a colorless oil. IR (neat) 3440 (OH), 1090, and 1060 (SO) cm^{-1}; ^1H NMR δ=1.14 (3H, d, J=6 Hz), 1.2—1.8 (6H, m), 2.97, 3.03 (each 1H, d, J=16 Hz), 3.4—3.9 (2H, m), and 6.9—7.7 (10H, m).

α,β-Epoxy Sulfoxide 1e: Less polar isomer, colorless oil, IR (neat) 1090, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=0.5—2.5 (23H, m), 3.26 (1H, t, J=6 Hz), 3.2—4.0 (4H, m), 4.57 (1H, bs), and 7.3—7.8 (5H, m). More polar isomer, colorless oil, IR (neat) 1090, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=0.6—2.0 (23H, m), 3.2—4.0 (5H, m), 4.54 (1H, bs), and 7.3—7.8 (5H, m).

α,β-Epoxy Sulfoxide 1f: *E*-Isomer, colorless oil, IR (neat) 1095, 1085, 1065, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.0—1.9 (14H, m), 3.00, 3.06 (each 1H, d, J=16 Hz), 3.1—4.0 (5H, m), 4.53 (1H, bs), and 7.0—7.7 (10H, m). *Z*-Isomer, colorless oil, IR (neat) 1090, 1060, 1045, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.1—2.1 (14H, m), 2.52 (1H, d, J=16 Hz), 2.63 (1H, t, J=6 Hz), 3.55 (1H, d, J=16 Hz), 3.2—4.0 (4H, m), 4.54 (1H, bs), and 6.8—7.8 (10H, m).

α,β-Epoxy Sulfoxide 1g: *E*-Isomer, colorless oil, IR (neat) 1090, 1080, 1055, 1045, and 1025 (SO) cm^{-1}; ^1H NMR δ=1.0—1.9 (26H, m), 3.00, 3.05 (each 1H, d, J=16 Hz), 3.1—4.0 (5H, m), 4.55 (1H, bs), and 6.9—7.7 (10H, m). *Z*-Isomer, colorless oil, IR (neat) 1090, 1085, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.0—2.1 (26H, m), 2.52 (1H, d, J=15 Hz), 2.61 (1H, t, J=6 Hz), 3.53 (1H, d, J=15 Hz), 3.2—4.0 (4H, m), 4.54 (1H, bs), and 6.8—7.8 (10H, m).

α,β-Epoxy Sulfoxide 2a: *E*-Isomer, colorless oil, IR (neat) 1090, 1060, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.2—2.1 (8H, m), 3.2—4.0 (4H, m), 4.54 (1H, bs), 4.97 (1H, s), and 7.0—7.9 (10H, m). *Z*-Isomer, colorless oil, IR (neat) 1090, 1080, 1055, and 1040 (SO) cm^{-1}; ^1H NMR δ=1.3—2.0 (7H, m), 2.4—2.9 (1H, m), 3.2—4.0 (4H, m), 4.64, 4.71 (each singlet), and 7.2—7.8 (10H, m).

α,β-Epoxy Sulfoxide 2b: Colorless crystals, mp 59—61 °C (AcOEt-hexane), IR (KBr) 3410 (OH), 1090, 1050, and 1035 (SO) cm^{-1}; ^1H NMR δ=1.3—2.4 (12H, m), 3.2—4.0 (3H, m), and 7.4—7.8 (5H, m); Found: C, 64.25; H, 7.29; S, 11.50%. Calcd for $C_{15}H_{20}O_3S$: C, 64.26; H, 7.19; S, 11.44%.

α,β-Epoxy Sulfoxide 2c: *E*-Isomer, colorless oil, IR (neat) 1095, 1085, 1065, 1045, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.1—1.9 (10H, m), 2.9—3.9 (5H, m), 4.39 (1H, bs), 4.81 (1H, s), and 7.0—7.9 (10H, m). *Z*-Isomer, colorless oil, IR (neat) 1095, 1080, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.1—2.0 (9H, m), 2.1—2.5 (1H, m), 3.0—3.9 (4H, m), 4.25 (1H, s), 4.28 (1H, bs), and 7.2—7.8 (10H, m).

α,β-Epoxy Sulfoxide 2d: Colorless oil, IR (neat) 1090, 1080, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=0.6—1.2 (1H, m), 1.2—2.2 (16H, m), 2.3—2.8 (1H, m), 2.9—3.24 (1H, m), 3.24—3.56 (2H, m), 3.56—3.90 (1H, m), 4.40 (1H, bs), and 7.3—7.8 (5H, m).

α,β-Epoxy Sulfoxide 2e: Colorless oil, IR (neat) 1095, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=0.5—1.1 (1H, m), 1.1—2.3 (19H, m), 2.8—4.0 (4H, m), 4.35 (1H, bs), and 7.3—7.9 (5H, m).

α,β-Epoxy Sulfoxide 2f: Colorless crystals, mp 90.5—92 °C (AcOEt-hexane), IR (KBr) 3460 (OH), 1090, 1050, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=0.7—1.2 (1H, m), 1.2—2.3 (13H, m), 3.37 (2H, t, J=6 Hz), and 7.3—7.8 (5H, m); Found: C, 65.20; H, 7.59; S, 11.08%. Calcd for $C_{16}H_{22}O_3S$: C, 65.27; H, 7.53; S, 10.89%.

α,β-Epoxy Sulfoxide 2g: Colorless crystals, mp 80.5—82.5 °C (AcOEt-hexane), IR (KBr) 3470 (OH), 1085, 1070, 1035, and 1025 (SO) cm^{-1}; ^1H NMR δ=1.0—2.1 (14H, m), 2.1—2.5 (2H, m), 3.35 (2H, t, J=6 Hz), and 7.3—7.8 (5H, m); Found: C, 66.11; H, 7.77; S, 10.48%. Calcd for $C_{17}H_{24}O_3S$: C, 66.20; H, 7.84; S, 10.40%.

α,β-Epoxy Sulfoxide 2h: *E*-Isomer, colorless oil, IR (neat) 1090, 1080, 1060, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.0—2.0 (11H, m), 2.1—2.7 (1H, m), 3.0—3.9 (4H, m), 4.44 (1H, bs), 4.78 (1H, s), and 7.0—7.8 (10H, m). *Z*-Isomer, colorless oil, IR (neat) 1090, 1080, 1055, 1040, and 1030 (SO) cm^{-1}; ^1H NMR δ=1.1—1.9 (11H, m), 2.0—2.5 (1H, m), 3.0—4.0 (4H, m), 4.44 (1H, s), 4.48 (1H, bs), and 7.2—7.8 (10H, m).

α,β-Epoxy Sulfoxide 2i: Colorless oil, IR (neat) 3450 (OH), 1085, and 1050 (SO) cm^{-1}; ^1H NMR δ=0.4—0.8 (1H, m), 1.0—2.3 (15H, m), 3.41 (2H, t, J=6 Hz), and 7.4—7.8 (5H, m).

General Procedure for the Preparation of 2-Acyl Cyclic Ethers and 3-Keto Cyclic Ethers from α,β-Epoxy Sulfoxides by PPTS-Induced Opening of the Oxiran Ring: The synthesis of 2-(1-oxo-2-phenylethyl)tetrahydrofuran (**11**) from

1b is described. To a solution of **1b** (96 mg) in 2 ml of EtOH was added PPTS (0.1 equiv) and the reaction mixture was stirred and heated at 50 °C for 30 min. The EtOH was evaporated under vacuum and the residue was dissolved in benzene. The solution was washed with satd. brine and dried over Na_2SO_4. The solvent was evaporated and the residue was purified by silica-gel column chromatography to afford 43 mg (90%) of **11** as a colorless oil. IR (neat) 1730 (CO) cm^{-1}; ^1H NMR δ=1.5—2.5 (4H, m), 3.83 (2H, s), 3.8—4.0 (2H, m), 4.20—4.45 (1H, m), and 7.0—7.4 (5H, m); MS *m/z* (%) 190 (M^+, 5), 136 ([M−C_4H_6]$^+$, 34), 91 ([M−$C_5H_7O_2$]$^+$, 100), and 71 ([M−C_8H_7O]$^+$, 42); Found: *m/z* 190.0985. Calcd for $C_{12}H_{14}O_2$: M, 190.0993.

4-Hydroxy-3-propoxy-1-phenyl-2-butanone (10) and Its Acetate (19). **10**: Colorless oil, IR (neat) 3450 (OH), 1730 (CO) cm^{-1}; ^1H NMR δ=0.93 (3H, t, *J*=6 Hz), 1.60 (2H, sextet, *J*=6 Hz), 2.12 (1H, t, *J*=6 Hz, OH), 3.38 (2H, t, *J*=6 Hz), 3.55—3.80 (2H, m), 3.80 (2H, s), and 7.12 (5H, bs). Acetate **19**: Colorless oil, IR (neat) 1740 (CO), 1250 (COC) cm^{-1}; ^1H NMR δ=0.95 (3H, t, *J*=7 Hz), 1.65 (2H, sextet, *J*=7 Hz), 2.02 (3H, s), 3.44 (2H, m), 3.91 (2H, s), 3.95 (1H, dd, *J*=5, 4 Hz), 4.32 (2H, dq, *J*=12, 4 Hz), and 7.24 (5H, m); MS *m/z* (%) 264 (M^+, 0.4), 204 ([M−$C_2H_4O_2$]$^+$, 0.3), 145 ([M−C_8H_7O]$^+$, 42), 103 (45), and 43 (100); Found: *m/z* 264.1374. Calcd for $C_{15}H_{20}O_4$: M, 264.1360.

2-(Cyclohexylcarbonyl)tetrahydrofuran (12). Colorless oil, IR (neat) 1720 (CO) cm^{-1}; ^1H NMR δ=0.6—2.4 (14H, m), 2.70 (1H, m), 3.90 (2H, m), and 4.41 (1H, m); MS *m/z* (%) 182 (M^+, 4), 111 ([M−C_4H_7O]$^+$, 7), and 71 (100).

2-(1-Oxo-2-phenylethyl)tetrahydropyran (13). Colorless oil, IR (neat) 1730 (CO) cm^{-1}; ^1H NMR δ=1.2—2.0 (6H, m), 3.28—3.60 (1H, m), 3.68—4.20 (2H, m), 3.86 (2H, s), and 7.21 (5H, m); MS *m/z* (%) 204 (M^+, 6), 136 ([M−C_5H_8]$^+$, 2), 91 ([M−$C_6H_9O_2$]$^+$, 25), and 85 ([M−C_8H_7O]$^+$, 100); Found: *m/z* 204.1128. Calcd for $C_{13}H_{16}O_2$: M, 204.1149.

2-Methyl-5-(1-oxo-2-phenylethyl)tetrahydropyran (14). Colorless oil, IR (neat) 1730 (CO) cm^{-1}; ^1H NMR δ=1.1—2.0 (6H, m), 1.26 (3H, d, *J*=6 Hz), 3.3—3.6 (1H, m), 3.76—3.95 (1H, m), 3.87, and 3.90 (each 1H, d, *J*=15 Hz); MS *m/z* (%) 218 (M^+, 9), and 99 ([M−C_8H_7O]$^+$, 100); Found: *m/z* 218.1320. Calcd for $C_{14}H_{18}O_2$: M, 218.1306.

2-(Cyclohexylcarbonyl)tetrahydropyran (15). Colorless oil, IR (neat) 1720 (CO) cm^{-1}; ^1H NMR δ=0.8—2.1 (16H, m), 2.80 (1H, m), 3.28—3.64 (1H, m), and 3.86—4.24 (2H, m); MS *m/z* (%) 196 (M^+, 2), and 85 ([M−$C_7H_{11}O$]$^+$, 100); Found: *m/z* 196.1463. Calcd for $C_{12}H_{20}O_2$: M, 196.1462.

8-Hydroxy-3-propoxy-1-phenyl-2-octanone (16). Colorlsss oil, IR (neat) 3400 (OH), 1730 (CO) cm^{-1}; ^1H NMR δ=0.93 (3H, t, *J*=7 Hz), 1.0—1.8 (10H, m), 3.32 (2H, m), 3.4—3.8 (3H, m), 3.82 (2H, s), and 7.23 (5H, m); MS *m/z* (%) 278 (M^+, 0.4), 218 ([M−C_3H_8O]$^+$, 1), 159 ([M−C_8H_7O]$^+$, 70), 99 (88), and 81 (100); Found: *m/z* 278.1876. Calcd for $C_{17}H_{26}O_3$: M, 278.1880.

14-Hydroxy-3-propoxy-1-phenyl-2-tetradecanone (17). Colorless oil, IR (neat) 3420 (OH), 1730 (CO) cm^{-1}; ^1H NMR δ=0.94 (3H, t, *J*=7 Hz), 1.0—1.9 (22H, m), 3.31 (2H, m), 3.5—3.8 (3H, m), 3.81 (2H, s), and 7.22 (5H, m); MS *m/z* (%) 362 (M^+, 0.3), 332 [M−CH_2O]$^+$, 0.3), 302 ([M−C_3H_8O]$^+$, 0.3), 243 ([M−C_8H_7O]$^+$, 88), and 43 (100); Found: *m/z* 362.2802. Calcd for $C_{23}H_{38}O_3$: M, 362.2818.

2-Phenyl-5,6-dihydro-2*H*-pyran-3(4*H*)-one (20). Colorless oil, IR (neat) 1730 (CO) cm^{-1}; ^1H NMR δ=1.96—2.32 (2H, m), 2.45—2.70 (2H, m), 3.68—4.22 (2H, m), 4.91 (1H, s), and 7.30 (5H, s); MS *m/z* (%) 176 (M^+, 25), 146 ([M−CO]$^+$, 84), 147 ([M−CHO]$^+$, 87), and 105 (100); Found: *m/z* 176.0823. Calcd for $C_{11}H_{12}O_2$: M, 176.0835.

6-Oxaspiro[4.5]decan-10-one (21). Colorless oil, IR (neat) 1710 (CO) cm^{-1}; ^1H NMR δ=1.4—2.2 (10H, m), 2.32 (2H, t, *J*=6 Hz), and 3.82 (2H, t, *J*=6 Hz).

2-Phenyl-3-oxepanone (24). Colorless oil, IR (neat) 1720 (CO) cm^{-1}; ^1H NMR δ=1.8—2.4 (4H, m), 2.4—2.6 (2H, m), 3.6—4.2 (2H, m), 4.87 (1H, s), and 7.35 (5H, s); MS *m/z* (%) 190 (M^+, 12), 162 ([M−CO]$^+$, 39), 161 ([M−CHO]$^+$, 45), and 105 ([M−C_5H_9O]$^+$, 100); Found: *m/z* 190.0994. Calcd for $C_{12}H_{14}O_2$: M, 190.0933.

General Procedure for the Preparation of Spirocyclic β-Keto Ethers from α,β-Epoxy Sulfoxides by $MgCl_2$-Induced Opening of the Oxirane Ring: The synthesis of 1-oxaspiro[5.5]undecan-5-one (**22**) from **2f** is described. $MgCl_2$ (33 mg; 0.34 mmol) was added to a solution of **2f** (100 mg; 0.34 mmol) in 7 ml of 2-propanol. The mixture was stirred and heated at reflux temperature under N_2 for 13 h. To the reaction mixture was added excess NH_4Cl and the 2-propanol was evaporated. The residue was extracted with benzene–ether and the organic layer was washed with satd. aq. NH_4Cl and dried over Na_2SO_4. The product was purified by silica-gel column chromatography to afford 45 mg (74%) of **22** as a colorless oil. IR (neat) 1720 (CO) cm^{-1}; ^1H NMR δ=0.8—2.0 (10H, m), 2.10 (2H, q, J=6 Hz), 2.49 (2H, t, *J*=6 Hz), and 3.84 (2H, t, *J*=6 Hz).

1-Oxaspiro[5.6]dodecan-5-one (23). Colorless oil, IR (neat) 1720 (CO) cm^{-1}; ^1H NMR δ=1.0—2.0 (12H, m), 2.10 (2H, q, *J*=6 Hz), 2.51 (2H, t, *J*=6 Hz), and 3.81 (2H, t, *J*=6 Hz); MS *m/z* (%) 182 (M^+, 16), 154 ([M−CO]$^+$, 28), and 112 (100); Found: *m/z* 182.1303. Calcd for $C_{11}H_{18}O_2$: M, 182.1305.

1-Chloro-1-(5-hydroxy-1-oxoheptyl)cyclohexane (25). Colorless oil, IR (neat) 3400 (OH), 1720 (CO) cm^{-1}; ^1H NMR δ=1.0—2.2 (14H, m), 2.77 (2H, t, *J*=6 Hz), and 3.64 (2H, t, *J*=6 Hz); MS *m/z* (%) 218 (M^+, 3), 157 (4), and 101 ([M−$C_6H_{10}Cl$]$^+$, 100).

The authors are grateful to Dr. Sei-ichi Saito, Tanabe Seiyaku Co., Ltd., for elemental analysis and Miss Noriko Sawabe and Miss Tomoko Fujimori of this laboratory for NMR and MS measurements.

Indirect Electrolytic Oxidation of Thioamides Using Organotellurium as a Mediator

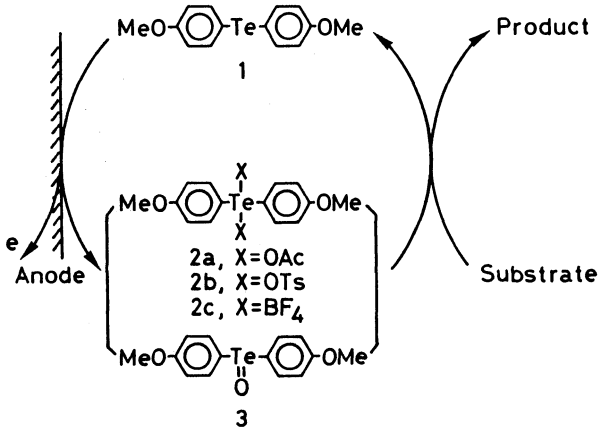
Toshiaki MATSUKI, Nan Xing HU, Yoshio ASO, Tetsuo OTSUBO, and Fumio OGURA*
Department of Applied Chemistry, Faculty of Engineering, Hiroshima University, Saijo, Higashi-Hiroshima 724
(Received December 26, 1987)

Bis(*p*-methoxyphenyl) telluride (**1**) electrochemically reacted with supporting electrolytes such as tetrabutylammonium acetate and tetraethylammonium tosylate under anhydrous conditions to give tellurium(IV) diacetate **2a** and ditosylate **2b**, respectively. On the other hand, **1** was electrolyzed in the presence of water to give telluroxide **3**. It has turned out that the tellurium compounds **2a** and **2b** like telluroxide **3** are mild oxidizing agents, but **2b** behaves differently in a reaction towards thioamide. Thus **2a** and **3** converted it into nitrile, while **2b** did it into 1,2,4-thiadiazole. An indirect electrolytic oxidation of thioamides with **1** as a mediator was examined under various conditions. As a result, nitriles or 1,2,4-thiadiazoles could be chemoselectively formed, depending on the intermediacy of **2a** or **3** as an active species for the former and **2b** for the latter.

There are few publications concerning the electrochemistry of organotellurium compounds. Recently Liftman and Albeck have reported that diaryl telluride electrochemically reacted with tetrabutylammonium perchlorate or lithium perchlorate as a supporting electrolyte under anhydrous conditions, giving diaryltellurium(IV) diperchlorate.[1] One might expect that the electrochemical oxidation of telluride in aqueous solution leads to the formation of telluroxide like the known conversion of sulfide into sulfoxide.[2] Diaryl telluroxide has been recently accepted as a versatile, mild oxidizing agent, which is reduced to the corresponding telluride in the oxidation reactions.[3,4] Taking into consideration that tellurium has the advantage of a lower oxidation potential than the other lighter chalcogens such as sulfur and selenium,[5] it looks promising to constitute a tellurium-mediated electrolytic oxidation. Such scope and limitation have been evaluated in this investigation. Here we like to report the electrochemical behavior of bis(*p*-methoxyphenyl) telluride (**1**) as well as an indirect electrolytic oxidation of thioamides using it as a mediator.

Results and Discussion

The electrochemical behavior of telluride **1** in the presence of tetrabutylammonium acetate or tetraethylammonium tosylate as an electrolyte is shown in Table 1. The electrolysis in water-free acetonitrile gave tellurium(IV) compound **2a** or **2b** (Scheme 1). On the other hand, the electrolysis in the presence of water gave a mixture of **2** and telluroxide **3**. Tellurium(IV) compound **2** is considered to be formed via a mechanism of a one-electron oxidation followed by a dispropotionation or a second one-electron oxidative reaction of the radical intermediate **4** as shown in Scheme 2.[1] The formation of telluroxide **3** must take a similar pathway (Scheme 3). From additional experiments, **2** and **3** have turned out to be in an equilibrium state



Scheme 1.

under electrolysis. These results suggest that it is possible to effect a chemoselective electrochemical reaction with **1** as a mediator, whose selectivity depends on the intermediacy of either **2** or **3** (Scheme 1).

An indirect electrolytic oxidation with 5 mol% of telluride **1** as a mediator was examined for thiobenzamide (**5**) as a model substrate, since thioamide resists a direct electrochemical oxidation,[6] but is more reactive to telluroxide **3**. The electrolysis resulted in the formation of benzonitrile (**6**) and 3,5-diphenyl-1,2,4-thiadiazole (**7**) (Scheme 4). The selectivity evidently depended on the adopted electrolytic conditions as

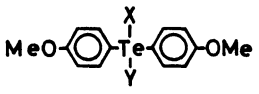
summarized in Table 2. In order to elucidate these results, the reactivities of bis(*p*-methoxyphenyl)tellurium diacetate (**2a**), tellurium ditosylate (**2b**), and telluroxide (**3**) towards thiobenzamide (**5**) were investigated in detail. Thiobenzamide was treated with one molar equivalent reagent **2** or **3** under conditions specified in Table 3. The reaction was monitored by HPLC analysis and followed good second-order kinetics with 1:1 stoichiometry, a typical example being demonstrated in Fig. 1. As shown in Table 3, the reaction with telluroxide proceeded very fast in water-free acetonitrile, giving benzonitrile (**6**) in an excellent yield. However, the rate dropped drastically in acetonitrile containing some water or in ethanol with water or not. This less reactivity may be rationalized as due to the fact that telluroxide **3** with water or ethanol forms tellurium(IV) adducts **8a** or **8b**.[7] Both tellurium(IV) diacetate **2a** and ditosylate **2b** were also not so reactive as telluroxide **3**, but the reactivities were little affected by the presence of water and, as a result, surpassed that of telluroxide **3** in the presence of water. Furthermore, it should be noted that the reaction with **2a** gave rise to benzonitrile (**6**) and with **2b** to thiadiazole (**7**) as the main product.



8a, X=Y=OH
8b, X=OH, Y=OEt

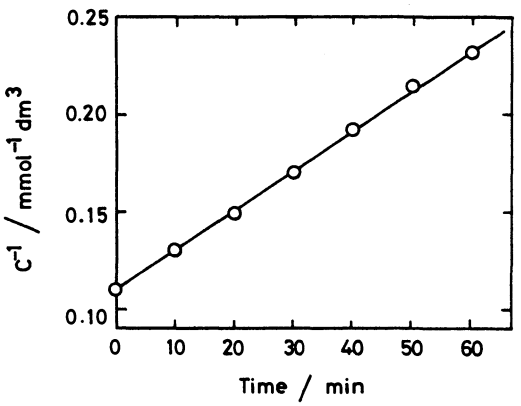


Fig. 1. Time dependence of the reciprocal of the concentration of **2b** in the equimolar reaction towards thiobenzamide in 10% aqueous acetonitrile at 25 °C.

As already indicated from Table 1, an active species in the electrolysis with tetrabutylammonium acetate as a supporting electrolyte is tellurium diacetate **2a** under water-free conditions and either **2a** or telluroxide **3** under water-containing conditions. Either species can give benzonitrile as the main product, being consistent with the indirect electrolyses of Table 2. On the other hand, the electrolysis with tetraethylammonium tosylate as electrolyte behaves differently. Tellurium ditosylate **2b** acted as an active species in anhydrous acetonitrile to give thiadiazole (**7**) in a high yield. The addition of a slight amount of water resulted in the formation of benzonitrile (**6**), indicating the intermediacy of telluroxide **3** as an active species. Further addition of water again gave thiadiazole (**7**). Telluroxide **3** with additional water can be understood to change to adduct **8a** which is less reactive than tellurium ditosylate **2b**. Such water dependence was not found in ethanol solution because the resulting telluroxide **3** with ethanol immediately forms a less reactive adduct **8b**. The electrolysis with tetrabutylammonium tetrafluoroborate as an electrolyte demonstrates a similar tendency. That is to say, tellurium bis(tetrafluo-

a) Method A: Current density 4mA cm^{-2}, Electricity 2.4 F mol^{-1}, Solvent 2% aq MeCN, Supporting electrolyte Bu_4NOAc. Method B: Current density 4 mA cm^{-2}, Electricity 2.4 F mol^{-1}, Solvent 2% aq EtOH, Supporting electrolyte Et_4NOTs.

roborate) **2c** is considered to be generated in the electrolysis and behaves like tellurium tosylate **2b** as an oxidizing agent, though it was not isolated.

Scheme 5 proposes a reasonable mechanism for the transformations of thioamide **5** into nitrile **6** and thiadiazole **7**.[4] A selection of both paths seems to depend on facility in eliminating an acid H-X in the initial common adduct **9**, in other words, basicity of the conjugated base X. Therefore, the elimination is favorable for X=OH and OAc, leading to nitrile **6**. On the other hand, it is hard for X=OTs and BF_4, so that the dimerization to **10** occurs, finally leading to thiadiazole **7**.

In conclusion, bis(*p*-methoxyphenyl) telluride (**1**) can be electrochemically oxidized to tellurium(IV) compound **2** or telluroxide **3**, enabling a chemoselective reaction using it as exemplified for the transformation of thiobenzamide to benzonitrile or diphenylthiadiazole. Table 4 demonstrates some other examples in which thioamides can be arbitarily transformed into either nitriles or thiadiazoles, depending on the two typical electrolytic conditions.

Experimental

Materials. Bis(*p*-methoxyphenyl) telluride (**1**)[8] and telluroxide (**3**)[3] were prepared according to the literatures.

Electrolytic Apparatus. A 20 ml of H-type glass cell with a fine frit diving the anolyte and catholyte compartments was used for electrolyses. It was equipped with platinum plates (1 cm^2) as the working and counter electrodes. All electrolyses with carefully purified reagent, solvent, and supporting electrolyte were conducted at room temperature in a nitrogen atmosphere.

General Procedure for Electrolyses of Bis(*p*-methoxyphenyl) Telluride (1). A solution of dry acetonitrile (10 ml) containing tetrabutylammonium acetate (360 mg) was placed in the electrolytic cell. Bis(*p*-methoxyphenyl) telluride (**1**) (100 mg, 0.3 mmol) was added in the anolyte compartment and electrolyzed under a constant current density of 8 mA cm^{-2}. After 2.2 F (1 F=96485 C) mol^{-1} of electricity had been passed, the mixture was thoroughly extracted with chloroform. The extract was washed with water, dried ($MgSO_4$), and concentrated in vacuo. Recrystallization of the residue from benzene gave colorless crystals of bis(*p*-methoxyphenyl)tellurium diacetate (**2a**); 131 mg (95%), mp 134.5—135.5 °C (lit,[9] mp 135—136 °C). ^1H NMR ($CDCl_3$) δ=7.69 (d, J=9 Hz, 4H, ArH), 6.90 (d, J=9 Hz, 4H, ArH), 3.77 (s, 6H, OMe), and 1.93 (s, 6H, OCOMe); IR (KBr) 1630 (C=O), 1585, 1490 (Ar ring), 1290, 1255, and 1175 (C-O) cm^{-1}. Found: C, 47.02; H, 4.39%. Calcd for $C_{18}H_{20}O_6Te$: C, 47.03; H, 4.39%.

When the electrolysis was carried out in aqueous acetonitrile, the isolated product was a mixture of **2a** and telluroxide **3** as shown in Table 1.

A similar electrolysis with tetraethylammonium tosylate electrolyte in dry acetonitrile deposited white crystals of bis(*p*-methoxyphenyl)tellurium ditosylate (**2b**) in the anolyte compartment, which was collected by filtration and washed with acetonitrile; 180 mg (93%), mp 257—260 °C. ^1H NMR ($CDCl_3$) δ=7.67 (d, J=9 Hz, 4H, ArH), 7.37 (d, J=8 Hz, 4H, ArH), 6.96 (d, J=8 Hz, 4H, ArH), 6.80 (d, J=9 Hz, 4H, ArH), 3.72 (s, 6H, OMe), and 2.30 (s, 6H, Me); IR (KBr) 1585, 1495 (Ar ring), 1295, 1250, 1220, 1180, 1130, and 1015 (SO_2O and C-O) cm^{-1}. Found: 49.09; H, 4.01%. Calcd for $C_{28}H_{28}O_8S_2Te$: C, 49.15; H, 4.12%.

General Procedure for Indirect Electrooxidations of Thioamides to Nitriles or Thiadiazoles. A mixture of thiobenzamide (**5**) (68.6 mg, 0.5 mmol) and bis(*p*-methoxyphenyl) telluride (**1**) (8.6 mg, 0.025 mmol) in 16 ml of dry acetonitrile containing tetrabutylammonium acetate (602 mg) was electrolyzed under a constant current density of 4 mA cm^{-2}. The reaction was monitored by HPLC (Microsorb C18 standard column, methanol eluent). After passage of 3.0 F mol^{-1} of electricity (10 h), the starting material **5** was consumed, forming benzonitrile (**6**) (89%) and 3,5-diphenyl-1,2,4-thiadiazole (**7**) (trace). Both products **6** and **7** were isolated as colorless oil and as colorless crystals with mp 89.5—90.5 °C (lit,[10] mp 89—90 °C), respectively, from column chromatography of the concentrate of the reaction mixture on silica gel with 1 : 1 benzene-hexane eluent. All the products from the electrolyses shown in Table 4 were similarly isolated as colorless crystals and characterized: *p*-methoxybenzonitrile, mp 56—57 °C (lit,[11] mp 59.5—60.5 °C); *p*-chlorobenzonitrile, mp 94—94.5 °C (lit,[12] mp 92 °C); diphenylcyanamide, mp 73.5—74 °C (lit,[13] mp 73 °C); 3,5-bis(*p*-methoxyphenyl)-1,2,4-thiadiazole, mp 137—138 °C (lit,[10] mp 139—140 °C); 3,5-bis(*p*-chlorophenyl)-1,2,4-thiadiazole, mp 161.5—162 °C (lit,[10] mp 161—162 °C; 3,5-bis(diphenylamino)-1,2,4-thiadiazole, mp 154—154.5 °C (lit,[10] mp 155 °C).

General Procedure for Reactions of Thiobenzamide (5) with Bis(*p*-methoxyphenyl)tellurium(IV) Compound 2 or Telluroxide 3. A 15 ml solution of thiobenzamide (**5**) (18.7 mg) was treated with one molar equivalent reagent **2** or **3** under conditions specified in Table 3. The reaction was monitored by HPLC analysis (Microsorb C18 standard column, methanol eluent). The rate constant k at 25 °C was evaluated by use of a second-order rate equation: $kt=(1/c)-(1/c_0)$ where c is the time-dependent concentration of thiobenzamide and c_0 is the initial one. A plot of $1/c$ against time is linear with less than 7.4% standard deviation.

Syntheses and Cytotoxicity of the AB-, C-, and BC-Ring Systems of Sesbanimides

Fuyuhiko MATSUDA, Masako OHSAKI, Kaoru YAMADA, and Shiro TERASHIMA*
Sagami Chemical Research Center, Nishi-Ohnuma, Sagamihara, Kanagawa 229
(Received December 26, 1987)

Preparation of some AB-ring systems **5** and **8** of sesbanimides **1** and **2**, potent antitumor alkaloids, were performed starting from the synthetic intermediates of our first total synthesis of **1** and **2**. The C-ring systems **14a—d** were synthesized by applying the previously explored novel Reformatsky reaction to various aldehydes. The optically active BC-ring systems **20** and **21** having the same absolute configurations as those of **1** and **2**, were derived from (−)-2,4-*O*-methylene-D-sorbitol (**15**) as the B-ring synthon. Since all of these compounds **5**, **8**, **14a—d**, **20**, and **21** and the previously synthesized AB-ring system **3** showed no significant in vitro cytotoxicity against P388 murine leukemia, its appeared evident that **1** and **2** exhibit their notable antitumor activity owing to cooperation of the A- and C-rings.

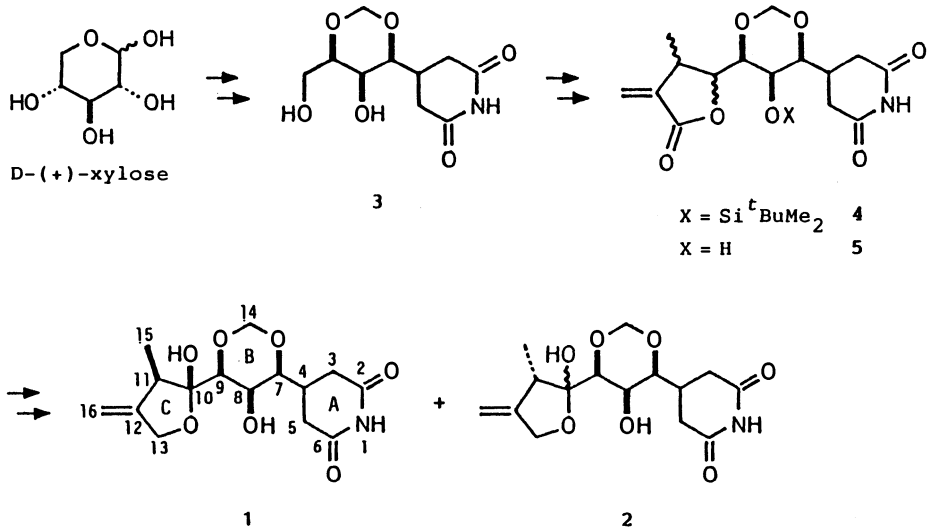
Sesbanimide A (**1**) and sesbanimide B (**2**), isolated as alkaloids from the seeds of the leguminous plants,[1,2] have been reported to exhibit notable cytotoxicity against KB cells in vitro and potent inhibitory activity against P388 murine leukemia in vivo. These compounds have unique tricyclic structures in which the three characteristic rings, glutarimide (A-ring), 1,3-dioxane (B-ring), and tetrahydrofuran (C-ring), are linked by two single bonds. Although the structure of **1** including its relative stereochemistry had been established by X-ray crystallographic analysis,[1a] its absolute configuration had not been determined.

Previously, we reported the first total synthesis of natural (+)-sesbanimide A (**1**) and (−)-sesbanimide B (**2**) from readily available D-(+)-xylose by way of the AB-ring system **3**.[3-5] Our total synthesis of these alkaloids obviously confirmed their absolute configurations.[3] With an aim to explore which parts of the structures of **1** and **2** are most responsible for their pronounced antitumor activity, the structure-activity relationships were next studied using various partial structures of **1** and **2**.

This report concerns with the syntheses of the AB-, C-, and BC-ring systems of sesbanimides achieved by employing the synthetic scheme explored in the course of our total synthesis,[3] and evaluation of cytotoxicity of these sesbanimide congeners produced in this and the previous studies.[3]

Results and Discussion

Syntheses and In Vitro Cytotoxicity of the Sesbanimide AB-Ring Systems. It was reported that **1** and **2** exhibits IC_{50} values of 7.7×10^{-3} μg ml^{-1} and 6.8×10^{-2} μg ml^{-1} against KB cells in vitro[1c] and T/C values of 140—181% in 8—12 μg kg^{-1}and 157—161% in 1.87—3.75 μg kg^{-1} dose levels against P388 murine leukemia in vivo,[1c] respectively. When the total synthesis of **1** and **2** were completed,[3] the synthetic samples of **1** and **2** were subjected to P388 murine leukemia in vitro cytotoxicity assay along with natural **1** provided by Powell. As shown in Table 1, synthetic and natural **1** were found to show the same magnitudes of cytotoxicity. Moreover, fairly intense cytotoxicity was also



Scheme 1.

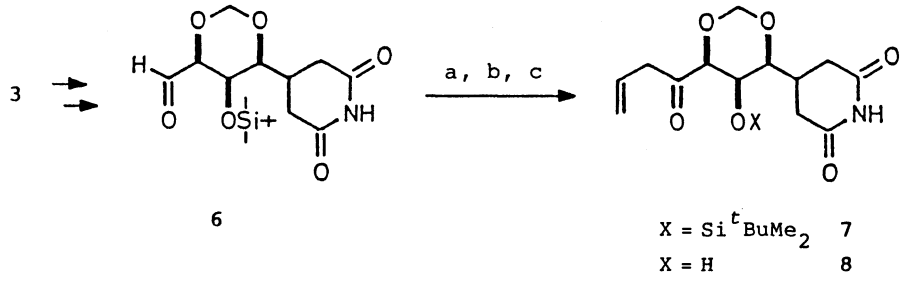
observed for synthetic **2**. These results were quite useful for identifying the synthetic samples with natural **1** and **2**, respectively.

With completion of the total synthesis of **1** and **2**, the sesbanimide congeners **3**, **5**, and **8** were first subjected to in vitro cytotoxicity assay to evaluate the roles of the AB-ring systems in prominent antitumor activity of **1** and **2**. The diol **3** had already been obtained during the course of our total synthesis. The *exo*-methylene-γ-lactone (**5**) was prepared from the synthetic intermediate **4** of **1** and **2** by simple deprotection. As shown in Scheme 2, the preparation of **8** was carried out by introducing an allyl group into the aldehyde **6** obtainable from **3**, followed by desilylation of the siloxy ketone **7**. The overall process proceeded in a moderate overall yield. Results summarized in Table 1 cleanly disclose that the AB-ring systems except for **5** carrying an *exo*-methylene-γ-lactone moiety which is well-known as a cytotoxic functionality, show no in vitro cytotoxicity against P388 murine leukemia. Although considerable in vitro cytotoxicity was recorded on **5**, it showed no significant antitumor activity against P388 murine leukemia in vivo (T/C 95% in 10 mg kg^{-1} dose level).

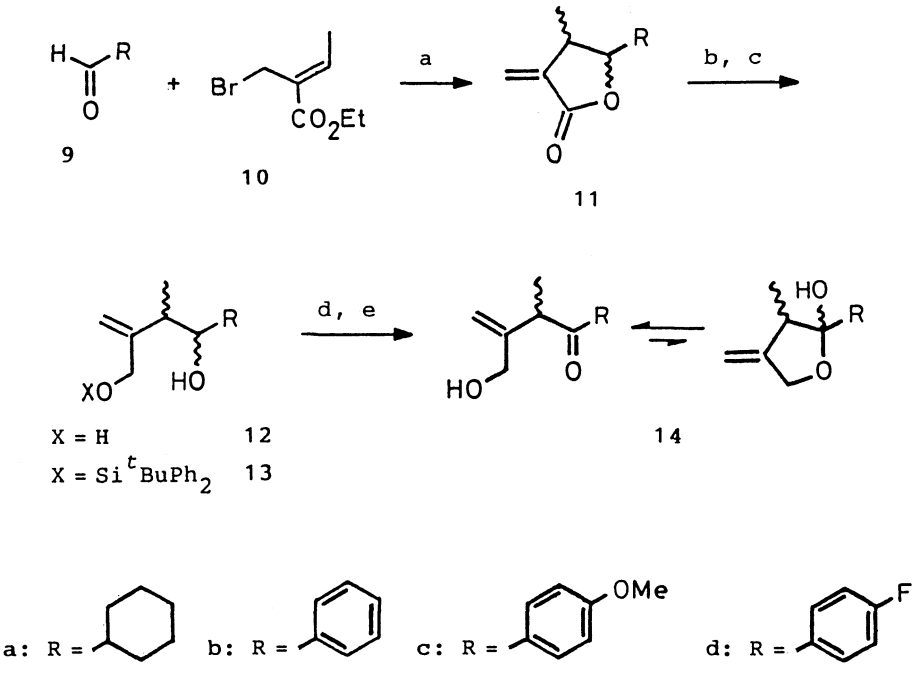
Table 1. In Vitro Cytotoxicity of Sesbanimides and Their AB-Ring Systems against P388 Murine Leukemia

Compound	$IC_{50}/\mu g\,ml^{-1}$ [a]
1	4.6×10^{-5} (3.3×10^{-5})[b]
2	3.1×10^{-2}
3	>25
5	9.0×10^{-3}
8	>30

a) Cell growth inhibition (percent) after incubation for 48 h at 37 °C. b) In vitro cytotoxicity observed on natural **1**.



Scheme 2. a) CH_2=$CHCH_2MgCl$, ether, −78 °C, 1 h. b) CrO_3·2Py, CH_2Cl_2, rt, 20 min, 42% (2 steps). c) AcOH, MeOH, rt, 5 min, 86%.



Scheme 3. a) Zn, THF, 0 °C, 2 h (for **9a**), reflux, 20 min (for **9b**), reflux, 8 min (for **9c**), reflux, 50 min (for **9d**). b) 1) ^{i}Bu$_2$AlH, CH_2Cl_2, 0 °C, 20 min; 2) $NaBH_4$, $CeCl_3$·7H_2O, MeOH, 0 °C, 30 min. c) ^{t}BuPh$_2$SiCl, imidazole, DMF, rt, 30 min, 65% (**13a**, 3 steps). d) CrO_3·2Py, CH_2Cl_2, rt, 10 min. e) Bu_4NF, THF, rt, 1 h, 49% (**14a**, 2 steps), 30% (**14b**, 5 steps), 39% (**14c**, 5 steps), 49% (**14d**, 5 steps).

Based on these results, it was anticipated that, in place of the AB-ring systems, the C-ring systems play an important role for **1** and **2** to exhibit their antitumor activity.

Syntheses and In Vitro Cytotoxicity of the C-Ring Systems. The compounds **14a—d** were selected as representative examples of the C-ring systems of **1** and **2**. Preparation of **14a—d** were examined employing the synthetic method explored in the course of the total synthesis, to cyclohexanecarbaldehyde (**9a**) and three sorts of the aromatic aldehydes **9b—d**. As shown in Scheme 3, the regioselective Reformatsky reaction[6] of **9a** with ethyl (*E*)-2-(bromomethyl)crotonate (**10**)[7] proceeded smoothly at 0 °C to afford the *exo*-methylene-γ-lactone (**11a**) as a 1 : 1.3 mixture of the two diastereomers. The Reformatsky reaction of **9b—d** carried out in refluxing tetrahydrofuran similarly gave **11b—d** as mixtures of the two diastereomers in good yields (the ratio of diastereomers: **11b**, 1 : 6; **11c**, 1 : 5; **11d**, 1 : 6). When **9a** was subjected to the Reformatsky reaction in refluxing tetrahydrofuran, extensive decomposition of **11a** was observed. The diastereomeric mixtures of **9a—d** were immediately used for the next step without separation of the isomers. Reduction of **11a—d** to the diol **12a—d** were attempted in a similar stepwise manner to that previously reported.[3] Thus, treatments of **11a—d** with diisobutylaluminum hydride yielded the corresponding lactols, which without isolation were further reduced with sodium borohydride in the presence of cerium(III) chloride,[8] giving **12a—d**. After selective protections of the primary hydroxyl groups of **12a—d** in forms of *t*-butyldiphenylsilyl ether, Collins oxidations of the remaining secondary hydroxyl groups of the siloxy alcohols **13a—d**, followed by removal of the silyl groups with tetrabutylammonium fluoride, afforded **14a—d** in fairly good overall yields (5 steps, 30—49%). The ^{1}H NMR spectra of **14a—d** revealed that these compounds consist of equilibrated mixtures of the ketonic and hemiacetal forms in which the formers predominate (**14a**, 4 : 1; **14b**, 3 : 1; **14c**, 10 : 1; **14d**, 3 : 1). It was uncovered by the ^{1}H NMR spectra that the hemiacetal forms of **14a—d** also involve the two epimeric isomers.

With completion of the synthesis, in vitro cytotoxicity assay was carried out on **14a—d** along with the corresponding *exo*-methylene-γ-lactones (**11a—d**). Disappointingly, **14a—d** showed no significant cytotoxicity despite slight activity was observed for **11a—d**. These results are summarized in Table 2. Accordingly, it appeared that the pronounced antitumor activity of **1** and **2** do not depend merely upon their C-ring systems.

Syntheses and In Vitro Cytotoxicity of the Sesbanimide BC-Ring Systems. Since it turned out obvious that both the AB- and C-ring systems are not the origin of antitumor activity of **1** and **2**, cytotoxicity of the BC-ring systems **20** and **21** was finally studied.

The synthetic route to optically active **20** and **21** in which (−)-2,4-*O*-methylene-D-sorbitol (**15**) is employed as the B-ring synthon, are shown in Scheme 4. Thus, after oxidative cleavage of the 1,2-glycol moiety of **15** prepared from D-(−)-sorbitol according to the reported method,[9] the resulting lactol was subjected to the Reformatsky reaction with **10**, affording the *exo*-methylene-γ-lactone (**16**) in a good overall yield. Similarly to the case of previous total synthesis of **1** and **2**,[3] **16** was found to consist of a mixture of the three diastereomers concerning the C-10 and C-11 positions (sesbanimide numbering). Determination of the stereostructures of these isomers was not attempted.

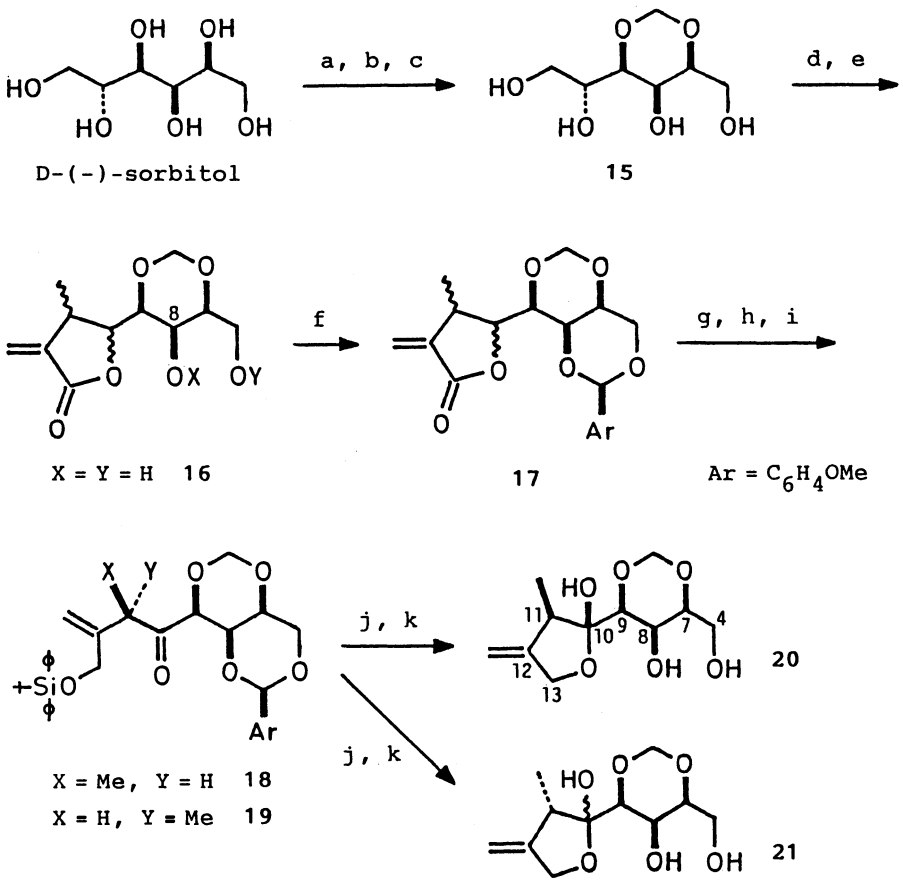
Table 2. In Vitro Cytotoxicity of the Sesbanimide C- and BC-Ring Systems and Their Corresponding *exo*-Methylene-γ-lactones against P388 Murine Leukemia

Sesbanimide C- and BC-ring system		*exo*-Methylene-γ-lactone	
Compound	IC_{50}/μg ml^{-1} [a]	Compound	IC_{50}/μg ml^{-1} [a]
14a	1.6	**11a**	0.39
14b	19	**11b**	2.6
14c	22	**11c**	1.1
14d	5.8	**11d**	0.49
20	>25	**16**	0.95
21	>25		

a) Cell growth inhibition (percent) after incubation for 48 h at 37 °C.

At the next stage, protection of the two hydroxyl groups of **16** was required for constructing the C-ring system according to the explored synthetic route.[3] After various protective groups were examined,[10] *p*-methoxybenzylidene group was found to be most suitable for this purpose. Benzylidenation of **16** under the usual conditions yielded the benzylidene γ-lactone (**17**) as a mixture of the three diastereomers. Separation of the mixture with column chromatography afforded a 1 : 1 mixture of the two isomers **17a** (66%) along with a small amount of the other isomer **17b** (6%). Each of the three diastereomers turned out to consist of a single isomer with regard to the benzylic position. Taking into account the difference of thermodynamic stability between the two possible isomers, the *p*-methoxyphenyl group was anticipated to take an equatorial position. Based on this speculation, stereochemistry of the benzylic position was tentatively assigned as shown in Scheme 4. Simply from practical reasons, only the main product **17a** was converted into the BC-ring systems **20** and **21**.

After reduction of the lactone part of **17a**, successive protection of the primary alcohol and Collins oxidation of the remaining secondary alcohol in a similar manner to that previously reported, gave the ketones as a mixture of the two diastereomers **18** and **19**. This mixture could be easily separated by TLC. Stepwise deprotections of the benzylidene and *t*-butyldiphenylsilyl groups transformed **18** and **19** into the optically active BC-ring systems of **1** and **2** (**20** and **21**), respec-



Scheme 4. a) 40% aq H_2CO–12M HCl, 60°C, 2 days, 52%. b) 18M H_2SO_4, AcOH–Ac_2O, 0°C, 10 min, 57%. c) NH_3 gas, MeOH, 0°C→rt, 5 h, 88%. d) $NaIO_4$, H_2O, rt, 5 min. e) **10**, Zn, THF–DMF, reflux, 1 h, 60% (2 steps). f) $MeOC_6H_4CHO$, *p*-TsOH·H_2O, PhH–CH_2Cl_2, reflux, 2 h, 66% (**17a**), 6% (**17b**). g) 1) $^iBu_2AlH$, CH_2Cl_2, −78°C, 1 h; 2) $NaBH_4$, $CeCl_3 \cdot 7H_2O$, MeOH, 0°C, 10 min, 89% (2 steps). h) $^tBuPh_2SiCl$, imidazole, DMF, rt, 5 min, 89%. i) CrO_3·2Py, CH_2Cl_2, rt, 10 min, 36% (**18**), 34% (**19**). j) 80% aq AcOH, rt, 1 h. k) Bu_4NF, THF, rt, 5 min, 70% (**20**, 2 steps), 68% (**21**, 2 steps).

tively. The 400 MHz ^1H NMR spectra of **20** and **21** showed that, similarly to **1** and **2**, these compounds completely adopt the hemiacetal structures. These phenomena may be rationalized by the formation of two intramolecular hydrogen bonds between the B- and C-rings which efficiently stabilized the hemiacetal structure.[11] Furthermore, **20** and **21** were found to consist of a single C-10 epimer and a 1 : 1.3 mixture of two equilibrated C-10 epimers, respectively. Detailed comparisons of coupling patterns of **20** and **21** with those of **1** and **2** revealed that the B- and C-rings of **20** and **21** take the same conformations as those of **1** and **2**, respectively. Based on these results, stereochemistries of the C-11 methyl groups of **18**—**21**, and that of the C-10 hydroxyl group of **20** were assigned as shown in Scheme 4.

In vitro cytotoxicity of **20** and **21** are shown in Table 2 along with that of **16**. Contrary to our expectation, no cytotoxicity was again observed for **20** and **21** although **16** showed marginal activity. These results are almost the same as those obtained for the C-ring systems **14a**—**d**. Accordingly, it became evident that the antitumor activity of **1** and **2** did not originate merely from their BC-ring systems.

Conclusion

Summing up the results accumulated by the structure-activity relationships, it appears evident that the marked antitumor activity of **1** and **2** does not originate solely from their AB-, C-, and BC-ring systems since these partial structures exhibited no significant cytotoxicity against P388 murine leukemia in vitro. Accordingly, it is anticipated that **1** and **2** show antitumor activity owing to delicate cooperation of their A- and C-rings probably including their B-rings.

Experimental

General. All melting points were determined with a Yamato MP-21 melting point apparatus and are uncorrected. Measurements of optical rotations were carried out using a Horiba SEPA-200 automatic digital polarimeter. IR

spectra measurements were performed with a JASCO A-200 IR spectrometer. ^{1}H NMR spectra were measured with a Hitachi R-90H spectrometer (90 MHz) and a Bruker AM-400 spectrometer (400 MHz). All signals are expressed as ppm down field from tetramethylsilane used as an internal standard (δ value). The following abbreviations are used: singlet (s), doublet (d), triplet (t), quartet (q), multiplet (m), broad (br). Assignments of signals are indicated according to the numbering of IUPAC nomenclature to avoid confusion. Mass spectra were taken with a Hitachi RMV-6MG mass spectrometer. Unless otherwise noted, all reactions were carried out using anhydrous solvents. Especially, tetrahydrofuran and ether freshly distilled from benzophenone ketyl were used. Wako Gel C-200 and Merck Silica Gel 60F$_{254}$ were used as an adsorbent for column chromatography and preparative thin-layer chromatography (PTLC), respectively. The following abbreviations are used for solvents and reagents: acetic acid (AcOH), chloroform ($CHCl_3$), dichloromethane (CH_2Cl_2), diisobutylaluminum hydride (DIBAL), *N*,*N*-dimethylformamide (DMF), ethanol (EtOH), ethyl acetate (AcOEt), methanol (MeOH), tetrabutylammonium fluoride (Bu_4NF), tetrahydrofuran (THF).

Syntheses of the AB-Ring Systems (5 and 8). 4-[(4*S*,5*R*,6*R*)-5-Hydroxy-6-(3-methyl-4-methylene-5-oxotetrahydrofuran-2-yl)-1,3-dioxan-4-yl]-2,6-piperidinedione (5). A solution of **4** (21 mg, 48 μmol)[3] and 10-camphorsulfonic acid (1.0 mg, 4.0 μmol) in wet CH_2Cl_2 (2.0 ml) was stirred at room temperature for 3 h. The mixture was diluted with AcOEt, washed successively with saturated aqueous $NaHCO_3$ and brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. The crude product was chromatographed (SiO_2, 50% AcOEt in $CHCl_3$) to give pure **5** (a mixture of the three diastereomers by NMR) as a colorless caramel (12 mg, 77%). ^{1}H NMR (90MHz, $CDCl_3$-D_2O) δ=1.13, 1.30, 1.32 (total 3H, each d, J=7 Hz, $C_{3''}$-Me), 2.1—3.2 (6H, m, C_3-H_2, C_4-H, C_5-H_2, $C_{3''}$-H), 3.2—4.0 (3H, m, $C_{4'}$-H, $C_{5'}$-H, $C_{6'}$-H), 4.1—4.5 (1H, m, $C_{2''}$-H), 4.74, 4.77 (total 1H, each d, J=6 Hz, $C_{2'\text{-ax}}$-H), 5.16, 5.18 (total 1H, each d, J=6 Hz, $C_{2'\text{-eq}}$-H), 5.69 (1H, m, olefinic proton), 6.32 (1H, m, olefinic proton); IR (film) 3490, 3250, 1770, 1705 cm^{-1}; MS *m*/*z* 326 (M^+H), 325 (M^+), 307 (M^+-H_2O); High-resolution MS, 325.1196, Calcd for $C_{15}H_{19}O_7N$: M, 325.1161.

(−)-4-[(4*S*,5*R*,6*R*)-6-(3-Butenoyl)-5-(*t*-butyldimethylsiloxy)-1,3-dioxan-4-yl]-2,6-piperidinedione (7). The aldehyde **6** (26 mg, 73 μmol) produced from the corresponding siloxy alcohol (30 mg, 84 μmol) in 87% yield by the same Collins oxidation as that reported,[3] was dissolved in ether (2.2 ml). Allylmagnesium chloride (1.0 ml, 0.8 M (1M=1 mol dm^{-3}) ethereal solution, 0.80 mmol) was added to the ethereal solution cooled at −78 °C under an argon atmosphere. After stirring for 1 h, the mixture was diluted with saturated aqueous $NaHCO_3$, allowed to warm up to room temperature, and extracted with AcOEt. The combined extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. The residue was dissolved in CH_2Cl_2 (3.0 ml). The dichloromethane solution was added to a stirred mixture of Collins reagent, prepared from anhydrous CrO_3 (0.26 g, 2.6 mmol) and pyridine (0.59 g, 7.5 mmol), and dry celite (0.52 g) in CH_2Cl_2 (3.8 ml) at room temperature under an argon atmosphere. After being stirred for 20 min, the mixture was diluted with ether and filtered through a pad of celite. The filtrate was concentrated in vacuo. The residue was dissolved in AcOEt, and the ethyl acetate solution was washed with brine, dried ($MgSO_4$), filtered, concentrated in vacuo. The residue was chromatographed (SiO_2, $CHCl_3$) to give pure **7** as a colorless caramel (12 mg, 42%), $[\alpha]_D^{20}$ −24.4° (*c* 0.50, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ=0.10 (3H, s, SiMe), 0.22 (3H, s, SiMe), 0.86 (9H, d, Si^{t}Bu), 1.73 (1H, dd, J=2.9 and 12.5 Hz, $C_{3\text{-ax}}$-H), 2.35 (1H, brd, J=18.6 Hz, $C_{5\text{-eq}}$-H), 2.40 (1H, ddt, J=3.6, 12.5, and 1.8 Hz, $C_{3\text{-eq}}$-H), 2.52 (1H, brdq, J=7.2 and 3.6 Hz, C_4-H), 2.67 (1H, dd, J=7.2 and 18.6 Hz, $C_{5\text{-ax}}$-H), 3.34 (1H, ddt, J=6.8, 18.2, and 1.5 Hz, $C_{2''}$-H), 3.48 (1H, ddt, J=6.8, 18.2, and 1.5 Hz, $C_{2''}$-H), 3.48 (1H, brs, $C_{4'}$-H), 4.06 (1H, brs, $C_{5'}$-H), 4.14 (1H, d, J=2.2 Hz, $C_{6'}$-H), 4.78 (1H, d, J=6.3 Hz, $C_{2'\text{-ax}}$-H), 5.12 (1H, dq, J=17.2 and 1.5 Hz, $C_{4''\text{-cis}}$-H), 5.20 (1H, dq, J=10.3 and 1.5 Hz, $C_{4''\text{-trans}}$-H), 5.23 (1H, d, J=6.3 Hz, $C_{2''\text{-eq}}$-H), 5.29 (1H, ddt, J=10.3, 17.2, and 6.8 Hz, $C_{3''}$-H), 6.01 (1H, brs, NH); IR (film) 3310, 3275, 1670 cm^{-1}; MS *m*/*z* 397 (M^+), 340 ($M^+-{}^t$Bu); High-resolution MS, Found: *m*/*z* 397.1910, Calcd for $C_{19}H_{31}O_6NSi$: M, 397.1921.

4-[(4*S*,5*R*,6*R*)-6-(3-Butenoyl)-5-hydroxyl-1,3-dioxan-4-yl]-2,6-piperidinedione (8). AcOH (1.0 ml) was added to a solution of **7** (12 mg, 30 μmol) in MeOH (1.0 ml) at room temperature. After stirring for 5 min, the mixture was concentrated in vacuo. The residue was chromatographed (SiO_2, 70% AcOEt in $CHCl_3$) to afford **8** as a colorless caramel (7.5 mg, 88%). ^{1}H NMR (90 MHz, $CDCl_3$-D_2O) δ=2.0—3.2 (5H, m, C_3-H_2, C_4-H, C_5-H_2), 3.42 (2H, dq, J=7 and 1 Hz, $C_{2''}$-H_2), 3.43 (1H, d, J=9 Hz, $C_{4'}$-H), 4.02 (1H, brs, $C_{5'}$-H), 4.11 (1H, d, J=1 Hz, $C_{6'}$-H), 4.80 (1H, d, J=6 Hz, $C_{2'\text{-ax}}$-H), 5.21 (1H, dq, J=17 and 1 Hz, $C_{4''\text{-cis}}$-H), 5.23 (1H, dq, J=10 and 1 Hz, $C_{4''\text{-trans}}$-H), 5.25 (1H, d, J=6 Hz, $C_{2'\text{-eq}}$-H), 5.95 (1H, ddt, J=10, 17, and 7 Hz, $C_{3''}$-H); IR (film) 3480, 3260, 1705 cm^{-1}; MS *m*/*z* 284 (M^+H), 214 ($M^+-COCH_2CH{=}CH_2$). This sample was found to readily undergo migration of the double bond on chromatographic purification. Since **8** was sufficiently pure (ca. 90% by NMR), it was directly subjected to in vitro cytotoxicity assay.

Syntheses of the C-Ring Systems 14a—d. Syntheses of the γ-Lactone 11a—d. Cyclohexanecarbaldehyde (**9a**) and three sorts of the aromatic aldehydes **9b—d** were found to show considerably different reactivity in the Reformatsky reaction. Therefore, typical experimental procedures are given for syntheses of the lactones **11a, b**. Other γ-lactones **11c, d** were prepared in a similar manner to that described for **11b**.

4-Cyclohexyl-3-methyl-2-methylene-4-butanolide (11a). A solution of **10** (0.11 g, 0.53 mmol)[7] in THF (1.5 ml) was added to a mixture of **9a** (39 mg, 0.35 mmol) and powdered Zn (0.23 g, 3.5 mmol) in THF (5.0 ml) cooled in an ice bath with stirring. After stirring for 2 h, water was added and the mixture was filtered through a pad of celite. The filtrate was extracted with ether and the combined extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. Column chromatography (SiO_2, 5% AcOEt in hexane) of the crude product afforded pure **11a** (a 1 : 1.3 mixture of the two diastereomers by NMR) as a colorless caramel (62 mg, 92%). ^{1}H NMR (90 MHz, $CDCl_3$) δ=0.6—2.1 (11H, m, C_6H_{11}), 1.16 (1.7H, d, J=7 Hz, C_3-Me, major isomer), 1.25 (1.3H, d, J=7 Hz, C_3-Me, minor isomer), 2.87 (0.43H, m, C_3-H, minor isomer), 3.14 (0.57H, m, C_3-H, major isomer), 3.85 (0.43H, t, J=5 Hz, C_4-H, minor isomer), 4.15 (0.57H, t, J=5 Hz, C_4-H, major isomer), 5.55 (0.57H, d, J=2 Hz, olefinic proton, major isomer), 5.58 (0.43H, J=3 Hz, olefinic proton, minor isomer), 6.17 (0.57H, d, J=2 Hz, olefinic

proton, major isomer), 6.26 (0.43H, d, J=3 Hz, olefinic proton, minor isomer); IR (film) 1770, 1670 cm^{-1} MS m/z 194 (M^+), 111 ($M^+-C_6H_{11}$); High-resolution MS, Found: m/z 194.1303, Calcd for $C_{12}H_{18}O_2$: M, 194.1307.

3-Methyl-2-methylene-4-phenyl-4-butanoilde (11b). A mixture of **9b** (0.14 g, 1.3 mmol), powdered Zn (0.88 g, 13 mmol), and **10** (0.42 g, 2.0 mmol)[7] in THF (10 ml) was heated at reflux for 20 min and cooled to room temperature. The same work-up as that described for **11a**, followed by purification with column chromatography (SiO_2, 50% $CHCl_3$ in hexane), gave pure **11b** (a 1 : 6 mixture of the two diastereomers by NMR) as a colorless caramel (0.20 g, 81%). ^1H NMR (90 MHz, $CDCl_3$) δ=0.87 (2.58H, d, J=7 Hz, C_3-Me, major isomer), 1.46 (0.42H, d, J=7 Hz, C_3-Me, minor isomer), 3.25 (0.14H, m, C_3-H, minor isomer), 3.80 (0.86H, m, C_3-H, major isomer), 5.43 (0.14H, d, J=8 Hz, C_4-H, minor isomer), 6.15 (0.86H, d, J=3 Hz, olefinic proton, major isomer), 6.17 (0.14H, d, J=3 Hz, olefinic proton, minor isomer), 6.21 (0.86H, d, J=9 Hz, C_4-H, major isomer), 6.96 (0.14H, d, J=3 Hz, olefinic proton, minor isomer), 6.98 (0.86H, d, J=3 Hz, olefinic proton, major isomer), 7.7—8.2 (5H, m, aromtic protons); IR (film) 1770, 1670, 1610, 1500 cm^{-1}; MS m/z 188 (M^+); High-resolution MS, Found: m/z 188.0812, Calcd for $C_{12}H_{12}O_2$: M, 188.0837.

4-(*p*-Methoxyphenyl)-3-methyl-2-methylene-4-butanolide (11c). The butanolide **11c** (a 1 : 6 mixture of the two diastereomers by NMR) was obtained as white crystals after purification with column chromatography. ^1H NMR (90 MHz, $CDCl_3$) δ=0.84 (2.58H, d, J=7 Hz, C_3-Me, major isomer), 1.30 (0.42H, d, J=7 Hz, C_3-Me, minor isomer), 2.29 (0.14H, m, C_3-H, minor isomer), 3.43 (0.86H, m, C_3-H, major isomer), 3.80 (3H, s, ArOMe), 4.87 (0.14H, d, J=8 Hz, C_4-H, minor isomer), 5.58 (0.86H, d, J=3 Hz, olefinic proton, major isomer), 5.60 (0.14H, J=3 Hz, olefinic proton, minor isomer), 5.61 (0.86H, J=9 Hz, C_4-H, major isomer), 6.31 (0.14H, d, J=3 Hz, olefinic proton, minor isomer), 6.33 (0.86H, d, J=3 Hz, olefinic proton, major isomer), 6.91 (2H, d, J=9 Hz, aromatic protons), 7.10 (2H, d, J=9 Hz, aromatic protons); IR (film) 1740, 1670, 1615, 1520 cm^{-1}; MS m/z 218 (M^+); High-resolution MS, Found: m/z 218.0939, Calcd for $C_{13}H_{14}O_3$: M, 218.0943.

4-(*p*-Fluorophenyl)-3-methyl-2-methylene-4-butanolide (11d). The butanolide **11d** (a 1 : 5 mixture of the two diastereomers by NMR) was obtained as a colorless caramel after purification with column chromatography. ^1H NMR (90 MHz, $CDCl_3$) δ=0.83 (2.5H, d, J=7 Hz, C_3-Me, major isomer), 1.34 (0.5H, d, J=7 Hz, C_3-Me, minor isomer), 2.98 (0.17H, m, C_3-H, minor isomer), 3.48 (0.83H, m, C_3-H, major isomer), 4.93 (0.17H, d, J=8 Hz, C_4-H, minor isomer), 5.64 (0.83H, d, J=3 Hz, olefinic proton, major isomer), 5.65 (0.83H, d, J=9 Hz, C_4-H, major isomer), 5.66 (0.17H, d, J=3 Hz, olefinic proton, minor isomer), 6.36 (0.17H, d, J=3 Hz, olefinic proton, minor isomer), 6.38 (0.83H, d, J=3 Hz, olefinic proton, major isomer), 6.9—7.5 (4H, m, aromatic protons); IR (film) 1770, 1670, 1610, 1510 cm^{-1}; MS m/z 206 (M^+); High-resolution MS, Found: m/z 206.0742, Calcd for $C_{12}H_{11}O_2F$: M, 206.0743.

Syntheses of the C-Ring Systems 14a—d from the γ-Lactones 11a—d. A typical experimental procedure is given for the synthesis of **14a**. Other C-ring systems were prepared according to the same procedure as that described for **14a**.

1-Cyclohexyl-4-hydroxy-2-methyl-3-methylene-1-butanone and 2-Cyclohexyl-2-hydroxy-3-methyl-4-methylenetetrahydrofuran (14a). DIBAL (0.56 ml, 1.0 M hexane solution, 0.56 mmol) was added to a stirred solution of **11a** (54 mg, 0.28 mmol) in CH_2Cl_2 (1.5 ml) cooled at 0 °C under an argon atmosphere. After stirring was continued for 20 min, MeOH (1.5 ml) was added, and the mixture was allowed to warm up to room temperature and concentrated in vacuo. The residue was dissolved in MeOH (3.5 ml) and the methanolic solution was cooled at 0°C. $CeCl_3 \cdot 7H_2O$ (0.11 g, 0.29 mmol) and $NaBH_4$ (11 mg, 0.29 mmol) was successively added, and the mixture was stirred for 30 min. After acidified to pH 3 with 1M HCl, the mixture was extracted with ether. The combined ethereal extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated in vacuo, to give crude **12a** as a colorless caramel. ^1H NMR (90 MHz, $CDCl_3$-D_2O) δ=0.9—2.0 (11H, m, C_6H_{11}), 1.05, 1.15 (total 3H, each d, J=7 Hz, C_2-Me), 2.3—2.8 (1H, m, C_2-H), 3.1—3.4 (1H, m, C_1-H), 4.11 (2H, brs, C_4-H_2), 5.00 (1H, brs, olefinic proton), 5.17 (1H, brs, olefinic proton). *t*-Butyldiphenylsilyl chloride (0.11 g, 0.40 mmol) was added to a stirred solution of **12a** and imidazole (59 mg, 0.87 mmol) in DMF (0.20 ml) at room temperature under an argon atmosphere. After stirred for 30 min, the mixture was diluted with AcOEt, washed with brine, and dried ($MgSO_4$). Filtration and concentration in vacuo, followed by separation with column chromatography (SiO_2, 10% AcOEt in hexane), afforded pure **13a** as a colorless caramel (79 mg, 65%). ^1H NMR (90 MHz, $CDCl_3$-D_2O) δ=0.9—1.8 (11H, m, C_6H_{11}), 0.98, 1.01 (total 3H, each d, J=7 Hz, C_2-Me), 1.07 (9H, s, Si^{t}Bu), 2.1—2.6 (1H, m, C_2-H), 3.0—3.3 (1H, m, C_1-H), 4.16 (2H, brs, C_4-H_2), 5.03, 5.10 (total 1H, each brs, olefinic proton), 5.32 (1H, brs, olefinic proton), 7.3—7.6 (6H, m, aromatic protons), 7.6—8.6 (4H, m, aromatic protons); IR (film) 3480, 1740, 1650, 1595 cm^{-1}; MS m/z 379 ($M^+-{}^t$Bu).

Pyridine (0.35 g, 4.4 mmol) was added to a stirred suspension of anhydrous CrO_3 (0.18 g, 1.8 mmol) in CH_2Cl_2 (4.5 ml) at room temperature under an argon atmosphere. After stirring was continued for 20 min, dry celite (0.36 g) and a solution of **13a** (79 mg, 0.18 mmol) in CH_2Cl_2 (1.0 ml) were successively added. After being stirred for 10 min, the mixture was diluted with ether and filtered through a pad of celite. The filtrate was washed successively with saturated aqueous $CuSO_4$ and brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. The residue was dissolved in THF (2.7 ml) and Bu_4NF (0.27 ml, 1.0 M THF solution, 0.27 mmol) was added at room temperature under an argon atmosphere. After stirring for 1 h, the mixture was diluted with ether. The ethereal solution was washed with brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. The residue was chromatographed (SiO_2, 10% AcOEt in hexane) to afford pure **14a** [a 4 : 1 mixture of the equilibrated ketonic and the hemiacetal (a 4 : 1 mixture of the two diastereomeric hemiacetals) forms by NMR] as a colorless caramel (17 mg, 48%). ^1H NMR (90 MHz, $CDCl_3$-D_2O) δ=1.0—2.9 (11H, m, C_6H_{11}), 1.05, 1.12 (total 0.6 H, each d, J=7 Hz, C_3-Me, hemiacetals), 1.22 (2.4H, d, J=7 Hz, C_2-Me, ketone), 3.52 (0.8H, q, J=7 Hz, C_2-H, ketone), 4.12 (1.6H, brs, C_4-H_2, ketone), 4.43 (0.4H, m, C_5-H_2, hemiacetals), 4.9—5.1 (0.4H, m, olefinic protons, hemiacetals), 5.00 (0.8H, brs, olefinic proton, ketone), 5.20 (0.8H, brs, olefinic proton, ketone); IR (film) 3480, 1710, 1650 cm^{-1}; MS m/z 196 (M^+), 129 ($M^+-C_3H_5O$); High-resolution MS, Found: m/z 196.1469, Calcd for $C_{12}H_{20}O_2$: M, 196.1463.

4-Hydroxy-2-methyl-3-methylene-1-phenyl-1-butanone and 2-Hydroxyl-3-methyl-4-methylene-2-phenyltetrahydrofuran (14b): Prepared as a colorless caramel [a 3 : 1 mixture of the equilibrated ketonic and the hemiacetal (a 4:1 mixture of the two diastereomeric hemiacetals) forms by NMR]. ^{1}H NMR (90 MHz, $CDCl_3$-D_2O) δ=0.61, 1.10 (total 0.75H, each d, J=7 Hz, C_3-Me, hemiacetals), 1.40 (2.25H, d, J=7 Hz, C_2-Me, ketone), 2.5—2.8 (0.25H, m, C_3-H, hemiacetals), 4.18 (1.5H, brs, C_4-H_2, ketone), 4.32 (0.75H, q, J=7Hz, C_2-H, ketone), 4.70 (0.5H, m, C_5-H_2, hemiacetals), 4.9—5.1 (0.5H, m, olefinic protons, hemiacetals), 5.06 (0.75H, brs, olefinic proton, ketone), 5.22 (0.75H, brs, olefinic proton, ketone), 7.3—8.1 (5H, m, aromatic protons); IR (film) 3450, 1680, 1600, 1580 cm^{-1}; MS m/z 190 (M^+), 123 ($M^+-C_3H_5O$); High-resolution MS, Found: m/z 190.0969, Calcd for $C_{12}H_{14}O_2$: M, 190.0994.

4-Hydroxy-1-(*p*-methoxyphenyl)-2-methyl-3-methylene-1-butanone and 2-Hydroxy-3-methyl-4-methylene-2-(*p*-methoxyphenyl)tetrahydrofuran (14c): Prepared as a colorless caramel (a 10 : 1 mixture of the equilibrated ketonic and hemiacetal forms by NMR). The ^{1}H NMR spectrum of the ketonic form is as follows. ^{1}H NMR (90 MHz, $CDCl_3$-D_2O) δ=1.40 (3H, d, J=7 Hz, C_2-Me), 3.89 (3H, s, ArOMe), 4.22 (2H, brs, C_4-H_2), 4.32 (1H, q, J=7 Hz, C_2-H), 5.06 (1H, brs, olefinic proton), 5.22 (1H, brs, olefinic proton), 7.66 (2H, d, J=9 Hz, aromatic protons), 8.02 (2H, d, J=9 Hz, aromtic protons); IR (film) 3460, 1675, 1600, 1575, 1510 cm^{-1}; MS m/z 220 (M^+), 153 ($M^+-C_3H_5O$); High-resolution MS, Found: m/z 220.1080, Calcd for $C_{13}H_{16}O_3$: M, 220.1099. The ratio of the two diasteromeric hemiacetals could not be determined.

1-(*p*-Fluorophenyl)-4-hydroxy-2-methyl-3-methylene-1-butanone and 2-(*p*-Fluorophenyl)-2-hydroxy-3-methyl-4-methylenetetrahydrofuran (14d): Prepared as a colorless caramel [a 3 : 1 mixture of the eqilibrated ketonic and the hemiacetal (a 1 : 4 mixture of the two diastereomeric hemiacetals) forms by NMR]. ^{1}H NMR (90 MHz, $CDCl_3$-D_2O) δ=0.67, 1.10 (total 0.75H, each d, J=7 Hz, C_3-Me, hemiacetals), 1.37 (2.25H, d, J=7 Hz, C_2-Me, ketone), 2.4—2.7 (0.25H, m, C_3-H, hemiacetals), 4.19 (1.5H, brs, C_4-H_2, ketone), 4.28 (0.75H, q, J=7 Hz, C_2-H, ketone), 4.66 (0.5H, m, C_5-H_2, hemiacetals), 4.9—5.1 (0.5H, m, olefinic protons, hemiacetals), 5.02 (0.75H, brs, olefinic proton, ketone), 5.22 (0.75H, brs, olefinic proton, ketone), 7.06 (0.5H, t, J=9 Hz, aromatic protons, hemiacetals), 7.13 (1.5H, t, J=9 Hz, aromatic protons, ketone), 7.61 (0.5H, dd, J=6 and 9 Hz, aromatic protons, hemiacetals), 8.05 (1.5H, dd, J=6 and 9 Hz, aromatic protons, ketone); IR (film) 1685, 1600, 1510 cm^{-1}; MS m/z 208 (M^+), 141 ($M^+-C_3H_5O$); High-resolution MS, Found: m/z 208.0885, Calcd for $C_{12}H_{13}O_2F$: M, 208.0899.

Syntheses of the BC-Ring Systems (20 and 21). (−)-2,4-*O*-Methylene-D-sorbitol (15). Methylene acetalization of D-(−)-sorbitol, mp 92—95°C $[\alpha]_D^{20}$ −2.2° (*c* 10.0, H_2O), with 40% aqueous formaldehyde and 12 M HCl (52%),[9] followed by sequential selective acetolysis with AcOH and Ac_2O (57%),[9] and deacetylation with NH_3 gas in MeOH (89%), afforded **15** via (−)-1,3 : 2,4 : 5,6-tri-*O*-methylene-D-sorbitol, mp 214—216°C (recrystallized from EtOH) [lit, 212—216°C (recrystallized from EtOH)[9]], $[\alpha]_D^{20}$ −31.3° (*c* 1.20, $CHCl_3$) [lit, $[\alpha]_D^{20}$ −30.8° (*c* 1.20, $CHCl_3$)[9]] and (+)-3,5-bis(*O*-acetoxymethyl)-1,6-di-*O*-acetyl-2,4-*O*-methylene-D-sorbitol, mp 110—112°C (recrystallized from EtOH) [lit, mp 111—112°C (recrystallized from EtOH)[9]], $[\alpha]_D^{20}$ +29.5° (*c* 1.20, $CHCl_3$) [lit, $[\alpha]_D^{20}$ +29.8° (*c* 1.20, $CHCl_3$)[9]]. The product **15** showed mp 165—166°C (recrystallized from EtOH) [lit, mp 163—164°C (recrystallized from EtOH)[9]] and $[\alpha]_D^{20}$ −9.8° (*c* 1.30, H_2O) [lit, $[\alpha]_D^{20}$ −9.8° (*c* 1.30, H_2O)[9]].

4-[(4*R*,5*R*,6*S*)-5-Hydroxy-6-hydroxymethyl-1,3-dioxan-4-yl]-3-methyl-2-methylene-4-butanolide (16). $NaIO_4$ (2.2 g, 10 mmol) was added to a solution of **15** (2.0 g, 10 mmol) in water (40 ml) at room temperature. After stirring for 5 min, the mixture was concentrated in vacuo. The residue was diluted with MeOH, and filtered through a pad of celite. The filtrate was concentrated in vacuo. A mixture of the residual oil, **10** (3.2 g, 15 mmol),[7] and powdered Zn (6.8 g, 0.10 mol) in a mixture of THF (80 ml) and DMF (5.0 ml) was heated at reflux for 1 h. After cooling to ambient temperature, the mixture was concentrated in vacuo. The residue was diluted with AcOEt, washed with brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. The residue was chromatographed (SiO_2, AcOEt) to give pure **16** (a mixture of the three diastereomers by NMR) as a colorless caramel (1.5 g, 60%). ^{1}H NMR (90 MHz, $CDCl_3$-D_2O) δ=1.13, 1.32, 1.38 (total 3H, each d, J=7 Hz, C_3-Me), 2.7—3.4 (1H, m, C_3-H), 3.5—4.1 (5H, m, $C_{4'}$-H, $C_{5'}$-H, $C_{6'}$-H, $C_{4'}$-CH_2OH), 4.2—4.8 (1H, m, C_4-H), 4.82, 4.83, 4.85 (total 1H, each d, J=6 Hz, $C_{2'\text{-ax}}$-H), 5.18, 5.20, 5.35 (total 1H, each d, J=6 Hz, $C_{2'\text{-eq}}$-H), 5.68 (1H, m, olefinic proton), 6.29 (1H, m, olefinic proton); IR (film) 3450, 1765, 1665 cm^{-1}; MS m/z 245 (M^+H), 244 (M^+); High-resolution MS, Found: m/z 244.0956, Calcd for $C_{11}H_{16}O_6$: M, 244.0947.

4-[(1*R*,2*R*,6*S*,9*R*)-9-(*p*-Methoxyphenyl)-3,5,8,10-tetraoxabicyclo[4.4.0]dec-2-yl]-3-methyl-2-methylene-4-butanolide (17). A solution of **16** (0.82 g, 3.4 mmol), *p*-anisaldehyde (2.3 g, 17 mmol), and *p*-toluenesulfonic acid monohydrate (0.20 g, 1.1 mmol) in a mixture of benzene (100 ml) and CH_2Cl_2 (20 ml) was heated at reflux for 3 h. After being cooled to room temperature, the mixture was concentrated in vacuo. The residue was diluted with AcOEt and the ethyl acetate solution was washed successively with saturated aqueous $NaHCO_3$ and brine, dried, filtered, and concentrated in vacuo. The crude product was separated with column chromatography (SiO_2, 30% AcOEt in hexane) to yield pure **17a** (a 1 : 1 mixture of the two diastereomers by NMR) as a colorless caramel (0.80 g, 66%) and pure **17b** as a colorless caramel (68 mg, 6%).

17a (the mixture of two less polar diastereomers): ^{1}H NMR (90 MHz, $CDCl_3$) δ=1.25 (1.5H, d, J=7 Hz, C_3-Me), 1.28 (1.5H, d, J=7 Hz, C_3-Me), 3.20 (1H, m, C_3-H), 3.63 (1H, brs, $C_{6'}$-H), 3.77 (1H, dd, J=2 and 9 Hz, $C_{2'}$-H), 3.82 (1.5H, s, ArOMe), 3.84 (1.5H, s, ArOMe), 4.11 (1H, brs, $C_{1'}$-H), 4.15 (1H, dd, J=2 and 12 Hz, $C_{7'}$-H), 4.35 (1H, dd, J=1 and 12 Hz, $C_{7'}$-H), 4.45 (0.5H, dd, J=5 and 9 Hz, C_4-H), 4.84 (0.5H, d, J=6 Hz, $C_{4'\text{-ax}}$-H), 4.85 (0.5H, d, J=6 Hz, $C_{4'\text{-ax}}$-H), 4.87 (0.5H, dd, J=7 and 9 Hz, C_4-H), 5.29 (1H, d, J=6 Hz, $C_{4'\text{-ax}}$-H), 5.65 (2H, m, $C_{9'}$-H, olefinic proton), 6.29 (0.5H, d, J=2 Hz, olefinic proton), 6.32 (0.5H, d, J=3 Hz, olefinic proton), 6.95 (2H, d, J=9 Hz, aromatic protons), 7.50 (2H, d, J=9 Hz, aromatic protons); IR (film) 1760, 1665, 1615, 1590, 1515 cm^{-1}; MS m/z 362 (M^+), 361 (M^+−H); High-resolution MS, Found: m/z 362.1359, Calcd for $C_{19}H_{22}O_7$: M, 362.1365.

17b (the more polar diastereomer): ^{1}H NMR (90 MHz, $CDCl_3$) δ=1.24 (3H, d, J=7 Hz, C_3-Me), 3.25 (1H, m, C_3-H), 3.60 (1H, brs, $C_{6'}$-H), 3.82 (3H, s, ArOMe), 3.88 (1H, dd, J=1 and 13 Hz, $C_{7'}$-H), 4.23 (1H, dd, J=1 and 13 Hz, $C_{7'}$-H), 4.48 (1H, dd, J=5 and 8 Hz, C_4-H), 4.85 (1H, d, J=6 Hz, $C_{4'\text{-ax}}$-H), 5.32 (1H, d, J=6 Hz, $C_{4'\text{-eq}}$-H), 5.48 (1H, d, J=3 Hz, olefinic proton), 5.50 (1H, s, C9′-H), 6.19 (1H, d, J=3 Hz, olefinic

proton), 6.90 (2H, d, J=9 Hz, aromatic protons), 7.40 (2H, d, J=9 Hz, aromatic protons); IR (film) 1770, 1670, 1615, 1590, 1515 cm^{-1}; MS m/z 362 (M^+), 361 (M^+−H); High-resolution MS, Found: m/z 362.1354, Calcd for $C_{19}H_{22}O_7$: M, 362.1365.

(−)-(2*R*)-4-(*t*-Butyldiphenylsiloxy)-1-[(1*R*,2*S*,6*R*,9*R*)-9-(*p*-methoxyphenyl)-3,5,8,10-tetraoxabicyclo[4.4.0]dec-2-yl]-2-methyl-3-methylene-1-butanone (18) and (−)-(2*S*)-4-(*t*-Butyldiphenylsiloxy)-1-[(1*R*,2*S*,6*R*,9*R*)-9-(*p*-methoxyphenyl)-3,5,8,10-tetraoxabicyclo[4.4.0]dec-2-yl]-2-methyl-3-methylene-1-butanone (19). DIBAL (6.7 ml, 1.0 M hexane solution, 6.7 mmol) was added to a solution of **17a** (0.78 g, 2.2 mmol) in CH_2Cl_2 (40 ml) cooled at −78°C under an argon atmosphere. After stirring for 1 h, the reaction was quenched by the addition of MeOH (40 ml). The mixture was allowed to warm up to room temperature, and concentrated in vacuo. The residue was diluted with MeOH. $CeCl_3 \cdot 7H_2O$ (2.0 g, 5.4 mmol) and $NaBH_4$ (90 mg, 2.4 mmol) were successively added to the methanolic solution cooled at 0°C. After stirring for 10 min, AcOH was added to the mixture to destroy excess $NaBH_4$. The mixture was concentrated in vacuo. The residue was diluted with AcOEt, washed with brine, dried ($MgSO_4$), and concentrated in vacuo. Purification of the residue with column chromatography (SiO_2, 10% AcOEt in $CHCl_3$) afforded the corresponding diol (a 1 : 1 mixture of the two diastereomers by NMR) as a colorless caramel (0.60 g, 86%). ^1H NMR (90 MHz, $CDCl_3$–D_2O) δ=1.11, 1.21 (total 3H, each d, J=7 Hz, $C_{2''}$-Me), 2.5—3.2 (1H, m, $C_{2'}$-H), 3.5—4.5 (6H, C_1-H, C_2-H, C_6-H, C_7-H_2, $C_{1'}$-H), 3.83 (3H, s, ArOMe), 4.15 (2H, brs, $C_{4'}$-H_2), 4.75, 4.83 (total 1H, each d, J=6 Hz, $C_{4\text{-ax}}$-H), 5.09 (1H, brs, olefinic proton), 5.20 (1H, brs, olefinic proton), 5.26, 5.29 (total 1H, each d, J=6 Hz, $C_{4\text{-eq}}$-H), 5.60 (1H, s, C_9-H), 6.94 (2H, d, J=9 Hz, aromatic protons), 7.51 (2H, d, J=9 Hz, aromatic protons).

t-Butyldiphenylsilyl chloride (1.6 g, 5.8 mmol) was added to a solution of the resulting diol (0.68 g, 1.9 mmol) and imidazole (0.89 g, 13 mmol) in DMF (1.5 ml) at room temperature under an argon atmosphere. After stirring for 5 min, the mixture was diluted with AcOEt. The ethyl acetate solution was washed successively with saturated aqueous $NaHCO_3$ and brine, dried ($MgSO_4$), filtered, and concentrated in vacuo. The crude product was chromatographed (SiO_2, 20% AcOEt in hexane) to give the siloxy alcohol (a 1 : 1 mixture of the two diastereomers by NMR) as a colorless caramel (1.0 g, 89%). ^1H NMR (90 MHz, $CDCl_3$–D_2O) δ=1.04, 1.08 (total 9H, each s, Si^{t}Bu), 1.09, 1.18 (total 3H, each d, J=7 Hz, $C_{2''}$-Me), 2.5—2.9 (1H, m, $C_{2'}$-H), 3.2—4.5 (8H, m, C_1-H, C_2-H, C_6-H, C_7-H_2, $C_{1'}$-H, $C_{4'}$-H_2), 4.50, 4.80 (total 1H, each d, J=6 Hz, $C_{4\text{-ax}}$-H), 5.0—5.2 (2H, m, olefinic protons), 5.25 (1H, d, J=6 Hz, $C_{4\text{-eq}}$-H), 5.58 (1H, s, C_9-H), 6.86, 6.90 (total 2H, each d, J=9 Hz, C_9-aromatic protons), 7.2—7.9 (12H, C_9-aromatic protons, $SiPh_2$).

Pyridine (2.5 g, 32 mmol) was added to a stirred suspension of anhydrous CrO_3 (1.1 g, 11 mmol) in CH_2Cl_2 (20 ml) at room temperature under an argon atmosphere. After stirring for 20 min, dry celite (4.4 g) and a solution of the obtained siloxy alcohol (0.21 g, 0.35 mmol) in CH_2Cl_2 (5.0 ml) were successively added, and the mixture was stirred for 10 min. The mixture was diluted with ether and filtered through a pad of celite. The filtrate was washed successively with water, saturated aqueous $CuSO_4$, and brine, and dried ($MgSO_4$). Filtration and concentration in vacuo followed by separation with PTLC (SiO_2, 20% AcOEt in hexane), yielded pure **18** as a colorless caramel (76 mg, 36%) and pure **19** as colorless solid (72 mg, 34%). The latter solid (**19**) was recrystallized from ether–hexane to give colorless crystals.

18 (the less polar diastereomer): $[\alpha]_D^{20}$ −104° (c 1.00, $CHCl_3$). ^1H NMR (90 MHz, $CDCl_3$) δ=1.07 (9H, s, Si^{t}Bu), 1.10 (3H, d, J=7 Hz, C_2-Me), 3.57 (1H, brs, $C_{6'}$-H), 3.62 (1H, q, J=7 Hz, C_2-H), 3.79 (3H, s, ArOMe), 4.06 (1H, dd, J=2 and 12 Hz, $C_{7'}$-H), 4.15 (1H, d, J=2 Hz, $C_{2'}$-H), 4.26 (3H, m, C_4-H_2, $C_{1'}$-H), 4.32 (1H, dd, J=1 and 12 Hz, $C_{7'}$-H), 4.63 (1H, d, J=6 Hz, $C_{4'\text{-ax}}$-H), 4.88 (1H, brs, olefinic proton), 5.05 (1H, d, J=6 Hz, $C_{4'\text{-eq}}$-H), 5.36 (1H, brs, olefinic proton), 5.50 (1H, s, $C_{9'}$-H), 6.85 (2H, d, J=9 Hz, $C_{9'}$-aromatic protons), 7.3—7.8 (10H, m, $SiPh_2$), 7.35 (2H, d, J=9 Hz, $C_{9'}$-aromatic protons); IR (film) 1725, 1650, 1620, 1590, 1520 cm^{-1}; MS m/z 545 (M^+−^{t}Bu). Found: C, 69.46; 7.14%. Calcd for $C_{35}H_{42}O_7Si$: C, 69.74; H, 7.02%.

19 (the more polar diastereomer): mp 210—211°C, $[\alpha]_D^{20}$ −5.4° (c 1.00, $CHCl_3$). ^1H NMR (90 MHz, $CDCl_3$) δ=1.06 (9H, s, Si^{t}Bu), 1.18 (3H, d, J=7 Hz, C_2-Me), 3.50 (1H, brs, $C_{6'}$-H), 3.60 (1H, q, J=7 Hz, C_2-H), 3.75 (3H, s, ArOMe), 4.00 (1H, dd, J=2 and 12 Hz, $C_{7'}$-H), 4.21 (2H, m, $C_{1'}$-H, $C_{2'}$-H), 4.26 (1H, dd, J=1 and 12 Hz, $C_{7'}$-H), 4.28 (2H, s, C_4-H_2), 4.72 (1H, d, J=6 Hz, $C_{4'\text{-ax}}$-H), 4.95 (1H, brs, olefinic proton), 5.24 (1H, d, J=6 Hz, $C_{4'\text{-eq}}$-H), 5.28 (1H, brs, olefinic proton), 5.52 (1H, s, $C_{9'}$-H), 6.80 (2H, d, J=9 Hz, $C_{9'}$-aromatic protons), 7.34 (2H, d, J=9 Hz, $C_{9'}$-aromatic protons), 7.3—7.8 (10H, m, $SiPh_2$); IR (Nujol) 1725, 1650, 1615, 1590, 1520 cm^{-1}; MS m/z 524 (M^+−^{t}Bu). Found: C, 69.73; H, 7.10%. Calcd for $C_{35}H_{42}O_7Si$: C, 69.74; H, 7.20%.

(+)-(4*S*,5*R*,6*S*)-5-Hydroxy-6-hydroxymethyl-4-[(2*R*,3*R*)-2-hydroxy-3-methyl-4-methylenetetrahydrofuran-2-yl]-1,3-dioxane (20). A solution of **18** (73 mg, 0.12 mmol) in 80% aqueous AcOH (6.0 ml) was stirred at room temperature for 1 h and concentrated in vacuo. Bu_4NF (0.25 ml, 1.0 M THF solution, 0.25 mmol) was added to a solution of the concentration residue in THF (1.5 ml) at room temperature under an argon atmosphere. After being stirred for 5 min, the mixture was concentrated in vacuo. The residue was diluted with AcOEt, washed with brine, dried ($MgSO_2$), and filtered. Concentration of the filtrate in vacuo followed by purification with column chromatography (SiO_2, 10% AcOEt in $CHCl_3$), gave pure **20** as a colorless caramel (21 mg, 70%), $[\alpha]_D^{20}$ +68.2° (c 1.00, $CHCl_3$). ^1H NMR (400 MHz, $CDCl_3$–D_2O) δ=1.22 (3H, d, J=6.8 Hz, $C_{3'}$-Me), 2.61 (1H, m, $C_{3'}$-H), 3.61 (1H, d, J=1.1 Hz, C_4-H), 3.70 (1H, ddd, 1.3, 4.4, and 5.7 Hz, C_6-H), 3.85 (1H, dd, J=4.4 and 12.0 Hz, C_6-C*H*OH), 3.91 (1H, dd, J=5.7 and 12.0 Hz, C_6-C*H*OH), 4.17 (1H, brs, C_5-H), 4.47 (1H, dq, J=13.0 and 2.2 Hz, $C_{5'}$-H), 4.57 (1H, dq, J=13.0 and 2.2 Hz, $C_{5'}$-H), 4.87 (1H, d, J=6.2 Hz, $C_{2\text{-ax}}$-H), 4.95 (1H, q, J=2.2 Hz, olefinic proton), 5.01 (1H, dt, J=3.0 and 2.2 Hz, olefinic proton), 5.27 (1H, d, J=6.2 Hz, $C_{2\text{-eq}}$-H); IR (film) 3420, 1720 cm^{-1}; MS m/z 246 (M^+), 228 (M^++H_2O); High-resolution MS, Found: m/z 246.1079, Calcd for $C_{11}H_{18}O_6$: M, 246.1103.

(−)-(4*R*,5*R*,6*S*)-5-Hydroxy-6-hydroxymethyl-4-[(3*S*)-2-hydroxy-3-methyl-4-methylenetetrahydrofuran-2-yl]-1,3-dioxane (21). The same sequential deprotections of **19** (72 mg, 0.12 mmol) as that described for **20**, followed by purification with column chromatography (SiO_2, 30% AcOEt in $CHCl_3$) yielded pure **21** (a 1 : 1.3 mixture of the two equilibrated epimers at the $C_{2'}$-position by NMR) as a colorless caramel (20 mg, 68%), $[\alpha]_D^{20}$ −21.2° (c 1.00, $CHCl_3$). ^1H NMR (400 MHz, $CDCl_3$–D_2O) δ=1.09 (1.3H, d, J=7.3 Hz, $C_{3'}$-Me, minor epimer), 1.17 (1.7H, d, J=6.8 Hz, $C_{3'}$-Me, major epi-

mer), 2.76 (0.43H, brq, J=7.3 Hz, $C_{3'}$-H, minor epimer), 2.92 (0.57H, m, $C_{3'}$-H, major epimer), 3.60 (0.43H, d, J=1.2 Hz, C_4-H, minor epimer), 3.66 (0.57H, d, J=1.2 Hz, C_4-H, major epimer), 3.69 (0.57H, ddd, J=1.2, 4.6, and 6.2 Hz, C_6-H, major epimer), 3.72 (0.43H, ddd, J=1.0, 4.4, and 5.4 Hz, C_6-H, minor epimer), 3.83 (0.57H, dd, 4.6 and 11.9 Hz, C_6-C*H*OH, major epimer), 3.87 (0.43H, dd, J=4.4 and 12.0 Hz, C_6-C*H*OH, minor epimer), 3.90 (0.43H, dd, J=5.4 and 12.0 Hz, C_6-C*H*OH, minor epimer), 3.95 (0.57H, dd, J=6.2 and 11.9 Hz, C_6-C*H*OH, major epimer), 4.05 (0.57H, brs, C_5-H, major epimer), 4.22 (0.43H, brs, C_5-H, minor epimer), 4.46 (0.43H, dq, J=12.9 and 2.2 Hz, $C_{5'}$-H, minor epimer), 4.52 (0.57H, dq, J=12.8 and 2.2 Hz, $C_{5'}$-H, major epimer), 4.56 (0.57H, dq, J=12.8 and 2.2 Hz, $C_{5'}$-H, major epimer), 4.59 (0.43H, ddt, J=1.2, 12.9, and 2.2 Hz, $C_{5'}$-H, minor epimer), 4.85 (0.43H, d, J=6.2 Hz, $C_{2'\text{-ax}}$-H, minor epimer), 4.87 (0.57H, d, J=6.2 Hz, $C_{2'\text{-ax}}$-H, major epimer), 4.96 (0.43H, q, J=2.2 Hz, olefinic proton, minor epimer), 5.00 (0.57H, q, J=2.2 Hz, olefinic proton, major epimer), 5.04 (0.43H, dt, J=1.5 and 2.2 Hz, olefinic proton, minor epimer), 5.07 (0.57H, dt, J=3.0 and 2.2 Hz, olefinic proton, major epimer), 5.24 (0.43H, J=6.2 Hz, $C_{2\text{-eq}}$-H, minor epimer), 5.26 (0.57H, J=6.2 Hz, $C_{2\text{-eq}}$-H, major epimer); IR (film) 3420, 1725 cm^{-1}; MS m/z 246 (M^+), 228 (M^+-H_2O); High-resolution MS, Found: m/z 246.1089, Calcd for $C_{11}H_{18}O_6$: M, 246.1103.

10) Initially, protection of **16** in a form of the bis(*t*-butyldimethylsilyl) ether was examined by treating with *t*-butyldimethylsilyl trifluoromethanesulfonate in the presence of 2,6-lutidine as a base. However, the C-8 silyl group (sesbanimide numbering) of the produced bissilyl ether (**16**: X=Y=Si^{t}BuMe$_2$) was found to be so labile that most of this silyl ether cleaved during purification with silica-gel column chromatography to give the monosilyl ether (**16**: X=H, Y=Si^{t}BuMe$_2$) as the main product. Comparisons of the ^{1}H NMR spectra of **16** and its bis- and monosilyl ethers made it clear that unexpected lability of the C-8 silyl group can be explained by remote distortion of the γ-lactone moiety brought about by the C-8 bulky silyl group. Thus, in the NMR spectrum of **16** (X=Y=Si^{t}BuMe$_2$), the signals of olefinic protons appeared at δ 5.07 and 5.33. In contrast, the olefinic protons of **16** (X=Y=H) and **16** (X=H, Y=Si^{t}BuMe$_2$) show the ordinary chemical shifts at δ 5.68 and 6.29 and δ 5.65 and 6.28, respectively. Similar remote distortion of the glutarimide ring by the C-8 bulky silyl group has been observed in the course of the total synthesis of **1** and **2**.[3)]

11) The similar two intramolecular hydrogen bonds may stabilize the structures of **1** and **2** which solely take the hemiacetal forms.

Synthesis of 2-(1-Phosphorylalkyl)- and 2-(1-Alkenyl)furans through Nitrile Oxide Cycloaddition Route

Otohiko TSUGE,* Shuji KANEMASA, and Hiroyuki SUGA

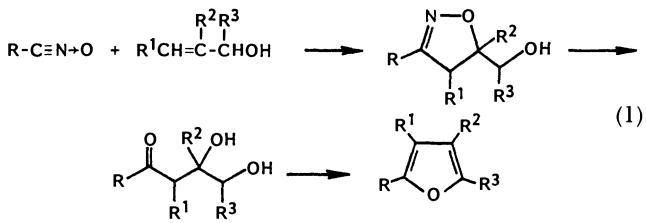
(Received January 11, 1988)

A new synthetic method of 2-(1-phosphorylalkyl)furans with a variety of substituents on the ring is presented. Cycloaddition of (diethoxyphosphoryl)acetonitrile oxide to *O*-protected allyl alcohols is followed by a simple sequential procedure including Raney Ni reduction and acid treatment to give 2-(1-phosphorylmethyl)-furans. The phosphorus-stabilized carbanions derived from the phosphorus-functionalized furans are applied to alkylation, oxidation with oxygen, or olefination to provide 2-(1-phosphorylalkyl)furans, 2-acylfurans, or 2-(1-alkenyl)furans, respectively. Some other synthetic applications are also described.

We have already reported some synthetic applications of a phosphorus-functionalized nitrile oxide, (diethoxyphosphoryl)acetonitrile oxide.[1] It undergoes regioselective 1,3-dipolar cycloadditions to olefins or acetylenes to furnish good yields of 2-isoxazolines[1a,b] or isoxazoles[1c] bearing a phosphorylmethyl moiety at the 3-position. Reductive N-O bond cleavage provides 4-hydroxy-2-oxo- or 2,4-dioxoalkylphosphonates which can be further converted into 1,4-alkadien-3-ones,[1b] 1-hydroxy-4-alken-3-ones,[1d] and 5-(1-alkenyl)-3(2*H*)-furanones.[1c]

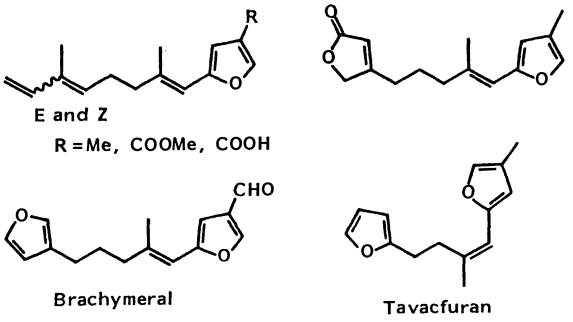
Regioselective cycloadditions of nitrile oxides to allyl alcohols will produce 2-isoxazoline-5-methanols. They are then hydrogenated leading to β,γ-dihydroxy ketones whose acid-catalyzed cyclization would give rise to furans (Eq. 1). Although the last cyclization step has not been well documented before,[2] similar acid-catalyzed furan syntheses from β,γ-epoxy ketones are known.[3] Substitution patterns of the furans depend upon those of the 2-isoxazolines, hence the nitrile oxides and allyl alcohols.



(1)

4-Substituted 2-(1-alkenyl)furan structures often occur in the important family of furanosesquiterpenoids, some of which are illustrated below.[4-8] As a phosphorylmethyl moiety may be introduced at the 2-position of furan rings by the cycloaddition route shown in Eq. 1 using a phosphorylacetonitrile oxide (RCNO, R=$(EtO)_2POCH_2$), this route will find useful synthetic applications in the construction of 2-(1-alkenyl) substituent of these furanosesquiterpenoids, especially the olefin substituent bearing *E*-configuration.

The present article describes a new synthesis of 2-(1-phosphorylmethyl)furans through cycloadditions of a phosphorus-functionalized nitrile oxide to *O*-protected allyl alcohols and a subsequent sequence of reductive N-O bond fission and acid treatment. These furans are further converted into 2-(1-phosphorylalkyl)furans, 2-(1-alkenyl)furans, 2-acylfurans, and 2,5-dioxoalkylphosphonates.



Results and Discussion

Cycloadditions of a Phosphorylacetonitrile Oxide to *O*-Protected Allyl Alcohols Leading to 2-Isoxazolines. The cycloaddition of (diethoxyphosphoryl)acetonitrile oxide (**2**) to allyl alcohol itself was first tried under the reaction conditions previously employed in the successful cycloadditions to olefins.[1a,b] Thus oxime **1** and 2-propen-1-ol (5 equiv) were treated with *N*-bromosuccinimide (NBS, 2 equiv) and triethylamine (1 equiv) in *N*,*N*-dimethylformamide (DMF)-diethyl ether (1 : 1 v/v) at room temperature for 18 h to give only 6% yield of the expected cycloadduct, 3-(diethoxyphosphoryl)methyl-2-isoxazoline-5-methanol, indicating the need of *O*-protection.

Therefore the tetrahydropyranyl (THP, **3a**) and trimethylsilyl ethers of 2-propen-1-ol were employed in the reaction with **2**. Under the same reaction conditions (5 equiv of the ether, rt, 18 h), the THP ether **3a** gave a better yield of cycloadduct **4a** (62%) than the trimethylsilyl ether (32%). When the former reaction was carried out under reflux in a mixed solvent, DMF-diethyl ether-hexane (1 : 1 : 1 v/v), the yield of **4a** was not improved (58%).[9]

Cycloadditions of **2** to a variety of allyl THP ethers

3a—f were performed at room temperature for 18 h by using excess amounts of the ethers **3** (5 equiv). Nitrile oxide **2** was generated in advance from *N*-[2-(diethoxyphosphoryl)ethylidene]hydroxylamine (**1**) according to the reported method (NBS in DMF, −20 °C, 1 h then 0 °C, 0.5 h, NEt_3 in diethyl ether).[1b]

Scheme 2.

Unsymmetrically mono- and disubstituted olefins provided satisfactory yields of regioselective cycloadducts **4a—d** (62—76% based on the oxime **1**), while a symmetrically disubstituted olefin and a trisubstituted olefin gave **4e** and **4f** only in fair yields (**4e**: 46%. **4f**: 29%. Scheme 1 and Table 1). These cycloadducts **4** were obtained all as mixtures of more than two diastereomers (^1H and ^{13}C NMR), however their separation was not attempted.

Conversion of 3-(1-Phosphorylalkyl)-2-isoxazolines into 2-(1-Phosphorylalkyl)furans. Conversion of the above cycloadducts, 3-(phosphorylmethyl)-2-isoxazolines **4**, into furans **5** was initially examined by using **4a** as an example (Scheme 2): Hydrogenation of **4a** on Raney Ni (W-2) in aq EtOH in the presence of $B(OH)_3$ gave β-hydroxy ketone **6** with the THP protecting group intact in 87% yield. Heating **6** with AcONa in AcOH at 100—110 °C for 3 h furnished the desired product, 2-[(diethoxyphosphoryl)methyl]furan (**5a**) in 77% yield. Since about a half of **6** is consumed by decomposition in a single operation on silica-gel chromatography, the purification step of **6** was omitted.

Thus the crude reaction mixtures separated in the Raney Ni reduction of isoxazolines **4a—f** were immediately treated with AcONa in AcOH at 90—100 °C for 0.5 h to give the expected furans **5a—f** in satisfactory yields (Scheme 2 and Table 1). As the isoxazoline **4e** affords a mixture of **5e**, its THP ether, and its *O*-acetate when cyclized in acetic acid, the cyclization was carried out in aq tetrahydrofuran (THF) in the presence of *p*-toluenesulfonic acid to give **5e** as a sole product. Yields of **5e** and **5f** are lower than the other cases.

An alkyl group can be introduced at the side chain of 2-isoxazolines **4c** and **4d** via the phosphorus-stabilized carbanions generated by the action of butyllithium to produce 3-(1-phosphorylalkyl)-2-isoxazolines **4g—j** in 59—65% yields. These alkylated 2-isoxazolines **4g—j** can be also converted into the corresponding furans **5g—j** through a sequence of reductive ring opening and acid-catalyzed cyclization (Scheme 2 and Table 2). The furans **5i** and **5j** bearing a methyl substituent at the 4-position were obtained only in fair yields. An alternative and more effective route leading to the furans **5i** and **5j** consists of alkylation after construction of the furan rings as shown in two examples of alkylation of **5d** (87—88%, Scheme 2 and Table 2).

Horner-Emmons Olefinations of 2-(1-Phosphorylalkyl)furans Leading to 2-(1-Alkenyl)furans. Two 2-[(diethoxyphosphoryl)methyl]furans **5b** and **5d** were employed in the Horner-Emmons olefinations using aldehydes: 4-Methylfuran **5d** was deprotonated with butyllithium in THF at −78 °C and then treated with benzaldehyde at room temperature to furnish 61% of (*E*)-4-methyl-2-(2-phenylethenyl)furan (**8b**). On the other hand, only 33% of (*E*)-5-methyl-2-(1-pentenyl)-furan (**8a**) and recovered **5b** (26%) were obtained from 5-methylfuran **5b** and butanal (2 equiv). In this case

Table 1. Cycloaddition of **2** to Allyl Ethers **3** and Subsequent Furan Synthesis

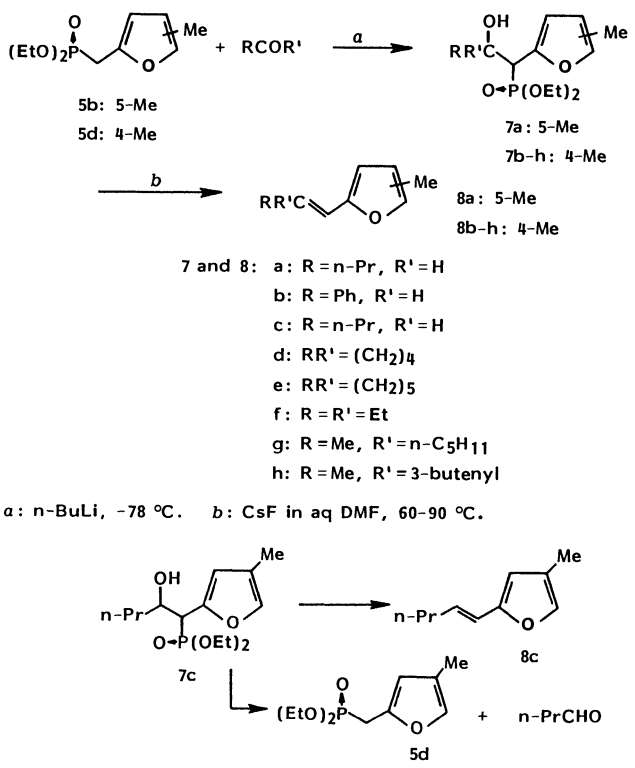
5d → n-$C_5H_{11}I$, 5 h, 88% → **5i**

5d → $PhCH_2Br$, 2.5 h, 87% → **5j**

a) Lithiation: *n*-BuLi, −78 °C, 1 h. Alkylation: −78 °C (1 h)→0 °C (1 h)→rt. b) Raney Ni, $B(OH)_3$ in aq EtOH, rt. c) AcONa in AcOH, 100 °C, 0.5 h. d) Recovered **4c**: 8%. e) −78 °C, 1 h. Alkylation: −78 °C.

condensation of butanal itself was the major reaction. Use of sodium hydride instead of butyllithium did not improve the yield of **8a** (29%).

It is known that, in olefination reactions between carbanions derived from alkylphosphonates and aldehydes, the addition step of aldehydes occurs rapidly in high yields but the rate-determining elimination step competes with the retro addition step, resulting in low yield formation of olefins.[10] Recently an example of the effective elimination of a phosphorus moiety from



Scheme 3.

carbonyl adducts has been reported.[11]

The reaction of the carbanion derived from 4-methylfuran **5d** and butyllithium with butanal at −78 °C for 30 min afforded an adduct **7c** as a mixture of two diastereomers (7:3) in 93% yield. The adduct **7c** was then subjected to an olefination by treatment with cesium fluoride and water (each 3.8 equiv) in DMF at 60 °C for 36 h to give 4-methyl-2-(1-pentenyl)furan (**8c**) (*E*:*Z*=96:4) in 64% yield together with the recovered **7c** (18%) and 4-methyl-2-(phosphorylmethyl)furan (**5d**) (4%) (Scheme 3). The latter compound **5d** corresponds to a retro-addition product of **7c**.

This two-step olefination procedure of 4-methyl-2-(phosphorylmethyl)furan **5d** was applied to some other carbonyl compounds. Like aldehydes, cyclic and acyclic ketones undergo smooth additions to furnish adducts **7d—h** whose elimination reactions are even cleaner than those of the aldehyde adducts **7b** and **7c** to produce 2-(1-alkenyl)-4-methylfurans **8d—h** (Scheme 3 and Table 3). Total yields of **8** are 49—71% based on **5** except for **8a** which was obtained by the one-pot procedure without isolation of **7a**. Compared to the almost exclusive formation of (*E*)-olefins (**8b** and **8c**) from the aldehyde adducts **7b** and **7c**, *E*-selectivities are only higher than 80% in olefinations from the adducts (**7g** and **7h**) to unsymmetrical ketones.

B: *n*-BuLi, −78 °C, 1 h; a carbonyl compound (1.5 equiv), −78 °C, 0.5 h. b) C: CsF (3.8 equiv) in aq DMF, 60 °C. c) Yield of isolated products. Yield with an asterisk: recovered **5** or **7**; two asterisks: retro aldol product **5**. d) Determined by GLC. e) Not isolated. f) Yield based on **5b**. g) Diastereomer ratio (^{1}H NMR).

Though the adduct **7b** was a 7:3 mixture of two diastereomers, *E*-selectivity in the olefination leading to **8b** is as high as 99% (Table 3). Under our elimination conditions (CsF in aqueous DMF at 60 °C), it is unlikely to happen that the anion of adduct **7b** is equilibrating with benzaldehyde and the anion of **5d**, a retro addition. Accordingly the high *E*-selectivity must be a kinetical result: Based on steric hindrance in the transition states, the major isomer **B** whose cis elimination leads to the *E*-isomer (*E*)-**8b** should undergo much more ready elimination than the other diastereomer **C** (Fig. 1, R=Ph). As a result, the retro addition product **5d** (20%) presumably arises mainly from the unreacted diastereomer **C** (R=Ph).

Similar kinetical resolution is observed in the olefination of **7c** (4:1) producing **8c** (64%, *E*:*Z*=96:4). In this case the unreacted **7c** recovered in 18% yield consists of almost pure diastereomer **C** (R=*n*-Pr), indicating the rapid olefin formation from the major diastereomer **B** (R=*n*-Pr).

Predominant formation of the diastereomers **B** over the other **C** in the addition reactions of lithiated **5d** with aldehydes can be well-interpreted with a six-membered chelation model (Fig. 1). The chair transition state **A** with two bulky substituents (4-methyl-2-furyl and R) at equatorial positions gives the major diastereomers **B**.

Two diastereomers of the adduct **7g** or **7h** to unsymmetrical ketones do not show such different reactivity in the elimination leading to **8g** or **8h**. Thus the isomer ratios between the two diastereomers of **7g** or **7h** (both 4:1) are nearly equal to those between the *E*- and *Z*-isomers of **8g** (80:20) or **8h** (82:18) (Table 3).

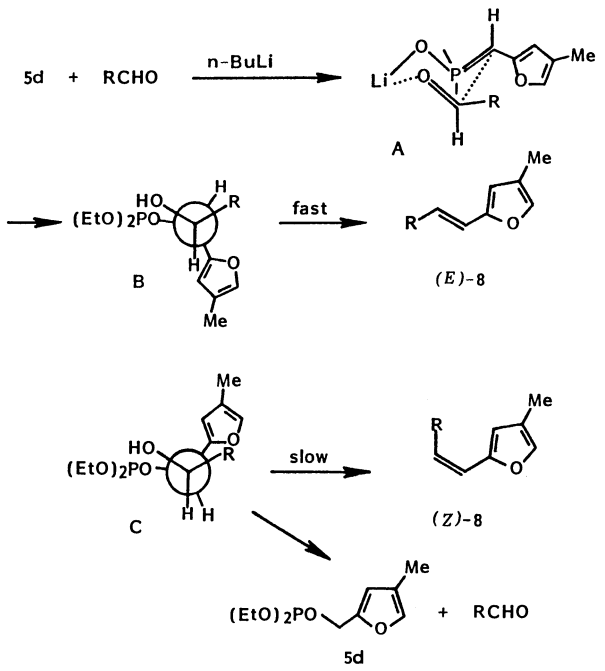

Fig. 1. Stereochemistry of Horner-Emmons olefinations of **5d** with aldehydes.

Conversion of 2-(1-Phosphorylalkyl)furans into 2-Acylfurans and 2,5-Dioxoalkylphosphonates. Air-oxidation of phosphorus-stabilized carbanions offers a simple preparation of ketones.[12] According to our previous procedure[1a,b] by which 3-acyl-2-isoxazolines have been prepared from 3-(1-phosphorylalkyl)-2-isoxazolines, the carbanion generated from 4-methyl-2-(1-phosphorylalkyl)furans **5i** and butyllithium was oxidized by dry oxygen at −78 °C to give 2-acylfuran **9a** in 30% yield (Scheme 4). Monitoring this reaction by thin-layer chromatography (TLC) showed the formation of complex mixture. Presumably the ketone **9a** as a product further reacted with the starting carbanion. So the carbanion of **5j** was oxidized at −100 °C in order to avoid the further condensation, but again only a low yield (20%) of **9b** was afforded.

On the other hand 5-substituted 2-(1-phosphorylalkyl)-furans **5** can be converted into 2,5-dioxoalkylphosphonates **10** through the usual hydrolysis method of furan rings.[13] Thus **5b**, **5c**, and **5g** were heated at 120 °C together with a catalytic amount of sulfuric acid in aqueous acetic acid to furnish moderate yields of 1,4-diketones **10a—c**, respectively, with the phosphoryl moiety intact (Scheme 4).

Though intramolecular cyclization of 1,4-diketones is one of the most important accesses to cyclopentenones, its regiochemical control has been a serious problem.[14] As the use of 2,5-dioxoalkylphosphonates will enable regioselective cyclization,[15] **10c** was treated with triethylamine (1.1 equiv) in the presence of lithium bromide (1.5 equiv) in refluxing THF to give 31% of 3-ethyl-2-octyl-2-cyclopenten-1-one (**11**) (Scheme 4).

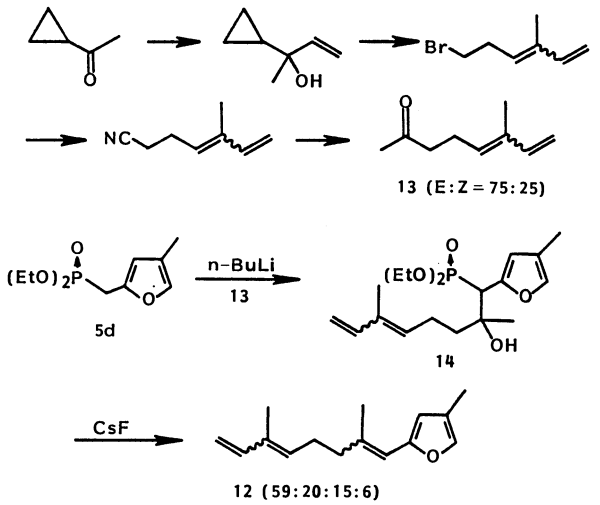

Scheme 5.

Synthesis of a Furanosesquiterpene. As briefly shown in the introduction, there are several furanosesquiterpenoids which bear a general structure of (*E*)-4-methyl-2-(2-methyl-1-alkenyl)furans. They would be readily accessible by the Horner-Emmons olefination of 4-methyl-2-[(diethoxyphosphoryl)methyl]furan (**5d**) with methyl ketones. Furanosesquiterpene **12**,[4] isolated from an Australian soft coral, also belongs to this family. And two isomers, (1'*E*, 5'*E*)-isomer **12a** and (1'*E*, 5'*Z*)-isomer **12b**, of 4-methyl-2-(2,6-dimethyl-1,5,7-octatrienyl)furan are naturally occurring. *E*-Geometry at the 1-position of the alkatrienyl substituent of **12** will be conveniently constructed by use of the Horner-Emmons olefination of **5d**.

6-Methyl-5,7-octadien-2-one (**13**) is the requisite ketone, and a mixture of *E*- and *Z*-isomers of **13** has been previously prepared.[16,17] A 75:25 inseparable mixture (GLC in a capillary column) of *E*- and *Z*-isomers of **13** was prepared according to this method (Scheme 5).

After 4-methyl-2-(phosphorylmethyl)furan **5d** was lithiated with butyllithium in THF, the resulting anion was allowed to react with the ketone **13** (1.5 equiv) at −78 °C for 30 min to give 79% of the adduct **14**. Though *E*:*Z* ratio of **14** was found to be 3:1 (by ^{1}H NMR), its diastereomer ratio could not be determined. The crude **14** was therefore treated with cesium fluoride (3.8 equiv) in aq DMF at 60 °C for 38 h to produce a mixture of four isomers of the desired furanosesquiterpene **12** in 60% yield.

The product **12** contains four isomers in a 59:20:15:6 isomer ratio (GLC in a capillary column). The two major products were identified to be (1'*E*, 5'*E*)-**12a** and (1'*E*, 5'*Z*)-isomer **12b** by comparison of the ^{1}H and ^{13}C NMR spectra with those of natural products.[4] The ratio **12a**/**12b** (59/20) is almost equal to the *E*/*Z* ratio (3/1) of the starting ketone **13**, confirming the 1'*E*, 5'*E* and 1'*E*, 5'*Z* structures of **12a** and **12b**. The remaining two minor products should have 1'*Z* geometry, and were determined to be (1'*Z*, 5'*E*)- **12c** and (1'*Z*, 5'*Z*)-isomer **12d** on the basis of the isomer ratio (15/6) as well as the NMR data, especially the ^{13}C NMR chemical shifts of 2'-Me, 3'-C, 5'-C, 6'-Me, and 8'-C (Table 4). *E*-Selectivity of the Horner-Emmons olefination is estimated to be 79:21 which is comparable to the selectivities obtained in similar olefinations using other methyl ketones (Table 3).

Separation of each isomer from the mixture was attempted by column chromatography on silica gel, thin-layer chromatography on silica gel containing 2% of silver nitrate, or high performance liquid chromatography (HPLC), but not even one of them could be isolated. Though gas-liquid chromatography (GLC) in a capillary column separates the four isomers, no separation was made on a preparative scale by GLC.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 MHz), a JEOL FX-100 (100 MHz), or a JEOL GSX-270

(270 MHz) instrument and ^{13}C NMR on a JEOL FX-100 (25.05 MHz) or a GSX-270 spectrometer (67.94 MHz). Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-OlSG-2 spectrometer at 70 eV of ionization energy. High-resolution mass spectra were obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck). Visualization was made with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. preparative high-performance liquid chromatography (HPLC) was performed on a Kusano KHLC-201 apparatus with a UV-detector Uvilog-III using a column (22×300 mm) packed with silica gel (Wakogel LC-50H). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×50000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

Materials. Tetrahydrofuran (THF) was distilled over lithium aluminum hydride in prior to its use. 2-(Diethoxyphosphoryl)acetaldehyde oxime (**1**) was prepared by the reaction with hydroxylamine hydrochloride according to the reported method.[1b] Allyl tetrahydropyranyl ethers **3a—f** were synthesized from the corresponding allyl alcohols and 3,4-dihydro-2*H*-pyran.[18] The boiling points and ^{1}H NMR spectra are given as follows: **3a**: Bp 80—83 °C/5187 Pa; ^{1}H NMR ($CDCl_3$) δ=1.4—2.0 (6H, m, THP), 3.3—4.4 (4H, m, CH_2OTHP and THP), 4.56 (1H, m, THP), 5.0—5.4 (2H, m, $=CH_2$), and 5.7—6.1 (1H, m, =CH). **3b**: Bp 87—90 °C/4522 Pa; ^{1}H NMR ($CDCl_3$) δ=1.4—2.0 (6H, m, THP), 1.72 (3H, s, Me), 3.3—4.3 (4H, m, CH_2OTHP and THP), 4.53 (1H, m, THP), and 4.7—5.0 (2H, m, $=CH_2$). **3c** (a mixture of two diastereomers): Bp 83—85 °C/4655 Pa; ^{1}H NMR ($CDCl_3$) δ=1.19, 1.27 (3H, each d, J=7.0 Hz, Me), 1.4—2.1 (6H, m, THP), 3.3—4.0 (2H, m, THP), 4.15, 4.23 (1H, each dq, CHOTHP), 4.60 (1H, m, THP), 4.9—5.3 (2H, m, $=CH_2$), and 5.4—6.1 (1H, m, =CH). **3d** (a mixture of two diastereomers): Bp 97—100 °C/4655 Pa; ^{1}H NMR ($CDCl_3$) δ=0.87, 0.93 (3H, each t, J=7.0 Hz, Et), 1.3—2.0 (8H, m, Et and THP), 3.3—4.1 (3H, m, CHOTHP and THP), 4.60 (1H, m, THP), 4.9—5.3 (2H, m, $=CH_2$), and 5.4—6.0 (1H, m, =CH). **3e**: Bp 125—127 °C/200 Pa; ^{1}H NMR ($CDCl_3$) δ=1.4—2.2 (12H, m, THP), 3.3—4.4 (8H, m, CH_2OTHP and THP), 4.55 (2H, m, THP), and 5.66 (2H, m, =CH). **3f**: Bp 150—155 °C/3325 Pa (bulb-to-bulb); ^{1}H NMR ($CDCl_3$) δ=1.1—2.1 (8H, m, THP and cyclopentenyl), 2.31 (4H, t, J=7.0 Hz, cyclopentenyl), 3.3—4.4 (4H, m, CH_2OTHP and THP), 4.59 (1H, m, THP), and 5.61 (1H, m, =CH). 6-Methyl-5,7-octadien-2-one (**13**) was prepared as a 75:25 mixture of *E*- and *Z*-isomers (GLC) from the commercially available 3-acetyltetrahydrofuran-2-one according to the known methods.[16,17]

Cycloadditions of Nitrile Oxide 2 to Allyl Ethers 3a—f Leading to 2-Isoxazolines 4a—f. As a standard procedure the reaction of **2** with **3a** is described below: To a solution of oxime **1** (0.39 g, 2 mmol) in DMF (4 ml) was added dropwise, at −20 °C in a period of 5 min, a solution of NBS (0.712 g, 4 mmol) in DMF (4 ml). The mixture was stirred at −20 °C for 1 h and then at 0 °C for 30 min. After cooled to −20 °C again, a solution of triethylamine (0.202 g, 0.28 ml, 2 mmol) in dry diethyl ether (4 ml) and then a solution of allyl ether **3a** (1.422 g, 10 mmol) in diethyl ether (4 ml) were added. The resulting mixture was stirred at room temperature for 18 h and then diluted with dichloromethane (250 ml). This solution was washed with water (200 ml×3), dried over magnesium sulfate, and evaporated in vacuo. The residue was chromatographed over silica gel by using ethyl acetate to give **4a** (0.419 g, 62%) as a mixture of two diastereomers. These 3-phosphorylmethyl-2-isoxazolines **4** except for **4e** are too hygroscopic to provide authentic samples for analyses. They were used in subsequent reactions without further purification.

4a: Pale yellow liquid; IR (neat) 1620, 1250, 1025, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.32 (6H, t, J=7.0 Hz, OEt), 1.4—1.9 (2H, m, THP), 2.93 (2H, d, $J_{H\text{-}P}$=22.0 Hz, CH_2P), 2.7—3.4 (2H, m, 4-H), 3.4—3.9 (4H, THP and CH_2OTHP), 4.12 (4H, dq, $J_{H\text{-}P}$=7.5 and J=7.0 Hz, OEt), 4.62 (1H, m, THP), and 4.77 (1H, m, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.18 (dq, $J_{C\text{-}P}$=5.9 Hz, OEt), 19.00, 19.12, 25.18 (each t, THP), 26.06 (dt, $J_{C\text{-}P}$=141.2 Hz, CH_2P), 30.24 (t, THP), 39.30, 39.59 (each t, 4-C), 61.89, 62.06 (each t, CH_2OTHP), 62.42 (dt, $J_{C\text{-}P}$=5.9 Hz, OEt), 67.71, 68.24 (each t, THP), 79.54 (d, 5-C), 98.83, 99.01 (each d, THP), and 151.27 (d, $J_{C\text{-}P}$=7.4 Hz, 3-C); MS *m/z* (rel intensity, %) 252 (5), 251 (16), 220 (M^+-CH_2THP, base peak), 164 (24), 153 (30), and 83 (73).

4b: A similar procedure using oxime **1** (0.39 g, 2 mmol), NBS (0.712 g, 4 mmol), triethylamine (0.202 g, 0.28 ml, 2 mmol), and allyl ether **3b** (1.562 g, 10 mmol) gave **4b** (0.533 g, 76%) as a mixture of four diastereomers after column chromatography over silica gel with ethyl acetate. Pale yellow liquid; IR (neat) 1620, 1255, 1025, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.15, 1.18 (3H, each d, J=6.5 Hz, Me), 1.32 (6H, t, J=7.0 Hz, OEt), 1.3—1.9 (6H, m, THP), 2.9—3.2 (2H, m, 4-H), 2.93 (2H, d, $J_{H\text{-}P}$=22.0 Hz, CH_2P), 3.3—4.1 (3H, m, THP and CHOTHP), 4.13 (4H, dq, $J_{H\text{-}P}$=7.5 and J=7.0 Hz, OEt), 4.50 (1H, m, 5-H), and 4.68 (1H, m, THP), ^{13}C NMR ($CDCl_3$) δ=13.88, 15.24, 17.00, 18.06 (each q, Me), 16.35 (dq, $J_{C\text{-}P}$=5.9 Hz, OEt), 19.35, 19.82, 25.47 (each t, THP), 26.24 (dt, $J_{C\text{-}P}$=141.2 Hz, CH_2P), 30.94 (t, THP), 37.65, 38.30, 39.18 (each t, 4-C), 62.59 (dt, $J_{C\text{-}P}$=5.9 Hz, OEt), 69.06, 71.42, 73.71, 74.12 (each d, CHOTHP), 82.95, 83.83, 84.06, 84.42 (each d, 5-C), 95.31, 96.42, 99.83, 100.24 (each d, THP), and 151.51 (d, $J_{C\text{-}P}$=7.4 Hz, 3-C); MS *m/z* (rel intensity, %) 304 (1), 220 (M^+−MeCHOTHP, 43), 193 (31), 178 (26), 164 (20), 153 (77), 125 (28), and 85 (base peak).

4c: A similar procedure using oxime **1** (0.39 g, 2 mmol), NBS (0.712 g, 4 mmol), triethylamine (0.202 g, 0.28 ml, 2 mmol), and allyl ether **3c** (1.682 g, 10 mmol) gave **4c** (0.529 g, 73%) as a mixture of three diastereomers after column chromatography over silica gel with ethyl acetate. Pale yellow liquid; IR (neat) 1620, 1255, 1025, and 810 cm^{-1}, ^{1}H NMR ($CDCl_3$) δ=0.92, 0.99 (3H, each t, J=6.5 Hz, Et), 1.32 (6H, t, J=7.0 Hz, OEt), 1.3—1.9 (6H, m, THP), 2.93 (2H, d, $J_{H\text{-}P}$=22.0 Hz, CH_2P), 2.9—3.3 (2H, m, 4-H), 3.3—4.0 (5H, m, THP, CHOTHP, and Et), 4.13 (4H, dq, $J_{H\text{-}P}$=7.0 Hz, OEt), and 4.4—4.9 (2H, m, 5-H and THP), ^{13}C NMR ($CDCl_3$) δ=9.06, 10.12 (each q, Et), 16.41 (dq, $J_{C\text{-}P}$=5.9 Hz, OEt),

19.71, 20.12 (each t, THP), 22.06, 23.30 (each t, Et), 25.53 (t, THP), 26.35 (dd, J_{C-P}=141.2 Hz, CH_2P), 31.06 (t, THP), 37.36 (t, 4-C), 38.41, 39.47 (each t, 4-C), 62.45 (dt, J_{C-P}=4.4 Hz, OEt), 62.59 (dt, J_{C-P}=2.9 Hz, OEt), 63.18, 63.36 (each t, THP), 77.65, 78.12 (each d, CHOTHP), 81.71, 82.01, 83.54 (each d, 5-C), 97.54, 99.65, 100.30 (each d, THP), and 151.75 (d, J_{C-P}=10.3 Hz, 3-C); MS *m/z* (rel intensity, %) 280 (1), 279 (1), 220 (M^+−EtCHOTHP, 37), 193 (37), 178 (27), 164 (25), 153 (78), 125 (26), and 85 (base peak).

4d: A similar procedure using oxime **1** (0.39 g, 2 mmol), NBS (0.712 g, 4 mmol), triethylamine (0.202 g, 0.28 ml, 2 mmol), and allyl ether **3d** (1.562 g, 10 mmol) gave **4d** (0.467 g, 67%) as a mixture of two diastereomers after column chromatography over silica gel with ethyl acetate. Pale yellow liquid; IR (neat) 1620, 1250, 1020, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (6H, t, J=7.0 Hz, OEt), 1.36 (3H, s, Me), 1.4—1.9 (6H, m, THP), 2.6—3.2 (2H, m, 4-H), 2.81 (2H, d, J_{H-P}=21.5 Hz, CH_2P), 3.3—3.9 (4H, m, THP and CH_2OTHP), 4.13 (4H, dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), and 4.63 (1H, m, THP); ^{13}C NMR ($CDCl_3$) δ=16.41 (dq, J_{C-P}=5.9 Hz, OEt), 19.18, 19.35 (each t, THP), 23.06, 23.18 (each q, Me), 26.59 (dt, J_{C-P}=141.2 Hz, CH_2P), 30.47 (t, THP), 45.00, 45.47 (each t, 4-C), 61.89, 62.18 (each t, THP), 62.53 (dt, J_{C-P}=5.9 Hz, OEt), 71.06, 71.36 (each t, CH_2OTHP), 86.18, 86.42 (each s, 5-C), 98.83, 99.18 (each d, THP), and 151.42 (d, J_{C-P}=8.8 Hz, 3-C); MS *m/z* (rel intensity, %) 234 (M^+−CH_2OTHP, base peak), 206 (24), 178 (58), 152 (35), and 85 (49).

4e: To a solution of oxime **1** (0.585 g, 3 mmol) in dry DMF (6 ml) was added NBS (1.068 g, 6 mmol) in DMF (6 ml) at −20 °C in a period of 5 min. The mixture was stirred at −20 °C for 1 h and then at 0 °C for 30 min. After diluted with dry diethyl ether (6 ml), triethylamine (0.304 g, 0.42 ml, 3 mmol) and then allyl ether **3e** (3.845 g, 15 mmol in diethyl ether (6 ml)) were added. The mixture was stirred at room temperature for 18 h and diluted with dichloromethane (200 ml). The dichloromethane was washed with water (200 ml×3), dried over magnesium sulfate, and finally evaporated in vacuo. The residue was chromatographed over silica gel by using ethyl acetate to give **4e** (0.618 g, 46%) as a mixture of four diastereomers. Colorless viscous liquid; IR (neat) 1620, 1250, 1025, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.2—2.0 (12H, m, THP), 1.32 (6H, t, J=7.0 Hz, OEt), 2.6—3.2 (2H, m, CH_2P), 3.3—4.0 (5H, m, THP and 4-H), 4.13 (4H, dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), and 4.32 (3H, m, THP and 5-H); ^{13}C NMR ($CDCl_3$) δ=16.41 (dq, J_{C-P}=5.9 Hz, OEt), 19.18, 19.41 (each t, THP), 25.44 (dt, J_{C-P}=145.6 Hz, CH_2P), 25.47, 30.53 (each t, THP), 50.36 (d, 4-C), 61.89, 62.30 (each t, CH_2OTHP), 65.30, 65.56 (each d, THP), 81.18, 81.36, 81.71, 81.95 (each d, 5-C), 98.99, 99.18 (each d, THP), 153.75 (d, J_{C-P}=10.3 Hz, 3-C), and 153.83 (d, J_{C-P}=5.9 Hz, 3-C); MS *m/z* (rel intensity, %) 366 (4), 281 (51), 264 (22), 251 (32), 250 (42), 234 (20), 233 (72), 232 (28), 220 (base peak), 178 (21), 152 (37), and 85 (92).

Found: C, 53.28; H, 8.14; N, 3.31%. Calcd for $C_{20}H_{36}O_8NP$: C, 53.44; H, 8.07; N, 3.12%.

4f: A similar procedure as employed for **4e** was applied to oxime **1** (0.39 g, 2 mmol), NBS (0.712 g, 4 mmol), triethylamine (0.202 g, 0.28 ml, 2 mmol), and allyl ether **3f** (1.823 g, 10 mmol) to give **4f** (0.2 g, 29%) as a mixture of two diastereomers. Yellow liquid; IR (neat) 1260, 1025, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (6H, t, J=7.0 Hz, OEt), 1.0—2.1 (12H, m, THP and CH_2), 2.5—3.2 (3H, CH_2P and 4-H), 3.3—3.8 (4H, m, THP and CH_2OTHP), 4.14 (4H, dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), and 4.65 (1H, m, THP); ^{13}C NMR ($CDCl_3$) J=16.43 (dq, J_{C-P}=6.1 Hz, OEt), 19.14, 19.34 (t, THP), 24.27 (t, 5-C), 25.12 (dt, J_{C-P}=140.4 Hz, CH_2P), 25.49, 30.47 (each t, THP), 37.21 (t, 4- and 6-C), 55.71, 56.05 (each d, 3a-C), 61.74, 62.43 (each dt, J_{C-P}=6.1 Hz, OEt), 62.74, 63.33 (each t, CH_2OTHP), 69.48, 69.68 (each t, THP), 97.31, 97.51 (each s, 6a-C), 98.78, 99.32 (each d, THP), and 153.17 (d, J_{C-P}=9.8 Hz, 3-C); MS *m/z* (rel intensity, %) 292 (10), 291 (18), 261 (16), 260 (base peak), 178 (45), 152 (34), 125 (30), 122 (26), and 85 (65).

Alkylation of 2-Isoxazolines 4c—d Leading to 4g—j. As a typical procedure the alkylation of **4c** with 1-iodooctane is presented as follows: To a solution of **4c** (0.321 g, 0.883 mmol) in dry THF (3 ml) was added at −78 °C butyllithium (15% in hexane, 0.55 ml, 0.883 mmol). After the mixture was stirred for 1 h at the same temperature, octyl iodide (0.424 g, 0.32 ml, 1.766 mmol) was added. The resulting mixture was stirred at 0 °C for 1 h and then at room temperature for 14 h. Saturated aqueous sodium chloride (30 ml) was added to the mixture and then extracted with dichloromethane (30 ml×3). The combined extracts were dried over magnesium sulfate and then chromatographed over silica gel by using hexane–ethyl acetate (1 : 1 v/v) to afford **4g** (0.267 g, 64%). The elution with ethyl acetate gave the starting **4c** (0.026 g, 8%).

4g (a mixture of four diastereomers): Colorless liquid; IR (neat) 1615, 1250, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.7—1.1 (6H, m, Et and n-C_8H_{17}), 1.1—2.0 (22H, m, Et, n-C_8H_{17}, and THP), 1.31 (6H, t, J=7.0 Hz, Et), 2.7—4.0 (6H, m, CH_2P, CHOTHP, THP, and 4-H), 4.11 (4H, dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), and 4.4—4.9 (2H, m, THP and 5-H), ^{13}C NMR ($CDCl_3$) δ=9.06, 10.06 (each q, Et), 14.12 (q, n-C_8H_{17}), 16.47 (dq, J_{C-P}=5.9 Hz, OEt), 20.18, 22.71, 23.64, 25.53, 26.46, 27.65, 28.18, 29.30, 31.06, 31.88 (each t, CH_2 and THP), 34.53, 35.88, 36.59, 38.00 (each t, 4-C), 37.80 (dd, J_{C-P}=139.7 Hz, CHP), 62.59 (t, OEt), 63.24, 63.83 (each t, THP), 76.89, 78.01 (each d, EtCHOTHP), 81.59, 82.89, 83.36 (each d, 5-C), 97.42, 99.83, 100.18, 100.65 (each d, THP), and 155.77 (s, 3-C); MS *m/z* (rel intensity, %) 475 (M^+, 3), 391 (83), 332 (23), 331 (base peak), 263 (77), 165 (31), 152 (39), and 85 (66). HRMS Found: *m/z* 475.3049. Calcd for $C_{24}H_{46}NO_6P$: M, 475.3060.

4h: A similar procedure using **4c** (0.396 g, 1.09 mmol), butyllithium (15% in hexane, 0.68 ml, 1.09 mmol), and pentyl iodide (0.432 g, 0.28 ml, 2.18 mmol) gave **4h** (0.307 g, 65%) after silica-gel chromatography with hexane–ethyl acetate (1:1 v/v) and the starting **4c** (0.049 g, 12%) from the elution with ethyl acetate. **4h** (a mixture of five diastereomers): Colorless liquid; IR (neat) 1610, 1250, 1025, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.7—1.2 (6H, m, OEt), 1.2—2.0 (16H, m, n-C_5H_{11}, Et, and THP), 1.31 (6H, t, J=7.0 Hz, OEt), 2.8—4.0 (6H, m, PCH, CHOTHP, THP, and 4-H), 4.11 (dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), and 4.4—4.9 (2H, m, THP and 5-H); ^{13}C NMR ($CDCl_3$) δ=9.03, 10.01, 10.16 (each q, Et), 13.96 (q, n-C_5H_{11}), 16.43 (qd, J_{C-P}=6.1 Hz, OEt), 19.72, 19.87, 20.12, 22.12, 22.41, 23.14, 23.63, 25.54, 26.46, 26.61, 27.29, 27.88, 31.02, 31.30 (each t, CH_2 and THP), 34.52, 36.57 (each t, 4-C), 37.79 (dt, J_{C-P}=139.2 Hz, CHP), 62.57 (dt, J_{C-P}=6.1 Hz, OEt), 63.04, 63.82 (each t, THP), 76.86, 77.68, 77.98 (each d, CHOTHP), 81.54, 83.15, 83.35 (each d, 5-C), 97.41, 97.51, 99.80, 100.14, 100.59 (each d, THP), and 155.46 (s, 3-C); MS *m/z* (rel intensity, %) 349 (4), 331 (7), 290 (24), 289 (base peak), 222 (85), 165 (42), and 85 (79).

Found: C, 57.90; H, 9.17; N, 3.27%. Calcd for $C_{21}H_{40}NO_6P$: C, 58.18; H, 9.39; N, 3.23%.

4i: A similar perocedure using **4d** (0.5 g, 1.43 mmol), butyllithium (15% in hexane, 0.89 ml, 1.43 mmol), and pentyl iodide (0.567 g, 0.37 ml, 2.862 mmol) afforded **4i** (0.352 g, 59%) after silica-gel column chromatography with hexane-ethyl acetate (1 : 1 v/v) together with the starting **4d** (0.054 g, 11%) from the fraction eluted with ethyl acetate. **4i** (a mixture of four diastereomers): Pale yellow viscous liquid; IR (neat) 1615, 1250, 1035, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (3H, t, J=6.0 Hz, n-C_5H_{11}), 1.0—2.0 (14H, m, THP and n-C_5H_{11}), 1.32 (6H, t, J=7.0 Hz, OEt), 1.37 (3H, s, 5-Me), 2.5—3.9 (7H, m, THP, CH_2OTHP, CHP), 4.12 (4H, dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), and 4.64 (1H, br s, THP); ^{13}C NMR ($CDCl_3$) δ=14.00 (q, n-C_5H_{11}), 16.47, (dq, J_{C-P}=5.9 Hz, OEt), 19.12, 19.35, 19.53, 22.41, 26.47, 27.24, 27.83 (each t, CH_2 and THP), 23.35 (q, 5-Me), 25.53, 30.36, 31.30 (each t, THP), 37.91 (dd, J_{C-P}=139.7 Hz, CHP), 42.36, 42.89, 43.24, 43.77 (each t, 4-C), 61.95 (dt, J_{C-P}=5.9 Hz, OEt), 62.45 (dt, J_{C-P}=7.4 Hz, OEt), 70.83, 71.24 (each t, CH_2OTHP), 85.77, 85.95, 86.06 (each s, 5-C), 98.60, 98.83, 99.12, 99.42 (each d, THP), and 155.12 (d, J_{C-P}=4.4 Hz, 3-C); MS m/z (rel intensity, %) 304 (M^+-CH_2OTHP, base peak) and 85 (21). Found: 56.97; H, 9.01; N, 3.36%. Calcd for $C_{20}H_{38}NO_6P$: C, 57.26; H, 9.13; N, 3.34%.

4j: A similar procedure using **4d** (0.5 g, 1.43 mmol), butyllithium (15% in hexane, 0.89 ml, 1.43 ml), and benzyl bromide (0.49 g, 0.34 ml, 2.86 mmol) gave **4j** (0.41 g, 65%) after silica-gel column chromatography with hexane-ethyl acetate (1 : 1 v/v) together with the starting **4d** (0.043 g, 9%) from the fraction eluted with ethyl acetate. As **4j** was hygroscopic, it was used for subsequent reactions without further purification. **4j** (a mixture of four diastereomers): Pale yellow viscous liquid; IR (neat) 1610, 1250, 1030, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.11, 1.16, 1.26, 1.29 (3H, each s, 5-Me), 1.32 (6H, t, J=7.0 Hz, OEt), 1.3—1.9 (6H, m, THP), 2.3—3.9 (6H, m, CHP, CH_2OTHP, THP, and 4-H), 4.13 (4H, dq, J_{H-P}=7.5 and J=7.0 Hz, OEt), 4.4—4.7 (1H, m, THP), and 7.29 (5H, br s, Ph); ^{13}C NMR ($CDCl_3$) δ=16.47 (dq, J_{C-P}=5.9 Hz, OEt), 19.30 (t, THP), 23.00 (q, 5-Me), 25.47, 30.41 (t, THP), 32.71 (t, CH_2Ph), 39.36 (dd, J_{C-P}=138.2 Hz, CHP), 43.18, 43.47, 43.94, 44.06 (each t, 4-C), 61.95 (t, THP), 62.68 (dt, J_{C-P}=7.4 Hz, OEt), 70.24, 70.48, 71.01 (each t, CH_2OTHP), 85.89, 86.12 (each s, 5-C), 98.95 (d, THP), 126.95, 128.72, 128.89 (each d), 137.89, 138.54 (each s), 154.51, and 154.80 (d, J_{C-P}=7.4 Hz, 3-C); MS m/z (rel intensity, %) 325 (15), 324 (M^+-CH_2OTHP, 87), 296 (22), 268 (30), 242 (21), 186 (25), 185 (21), 144 (31), 138 (24), 109 (26), 105 (21), 104 (40), 103 (35), 91 (base peak), 85 (98), 81 (36), and 77 (24).

Conversion of 2-Isoxazolines 4a—j to 2-(1-Phosphorylalkyl)-furans 5a—j. As a typical procedure the conversion of **4a** into **5a** is described: A mixture of 2-isoxazoline **4a** (0.173 g, 0.516 mmol), Raney Ni W-2 (suspension in ethanol, 0.5 ml), and boric acid (0.066 g, 1.06 mmol) in aqueous ethanol (17%, 3 ml) was stirred under hydrogen atmosphere at room temperature for 13.5 h. Insoluble material was filtered through Celite and washed with water and then dichloromethane. The combined filtrate and washings were extracted with dichloromethane (30 ml×3). The dichloromethane was dried over magnesium sulfate and evaporated in vacuo. The residue was heated with sodium acetate (0.179 g, 2.185 mmol) in acetic acid (1 ml) at 100 °C for 2 h. The reaction mixture was cooled to room temperature, diluted with dichloromethane (90 ml), washed with water (50 ml) and then saturated sodium hydrogencarbonate (50 ml), and finally dried over magnesium sulfate. The solvent was evaporated in vacuo and the residue was chromatographed over silica gel by using hexane-ethyl acetate (1 : 5 v/v) to give **5a** (0.067 g, 60%).

The same product **5a** was obtained in 77% yield (0.039 g) by a similar procedure (100 °C for 3 h) using purified **6** (0.079 g, 0.233 mmol), sodium acetate (0.095 g, 1.165 mmol), and acetic acid (0.5 ml). The preparation of **6** is described later.

5a: Pale yellow liquid; IR (neat) 3000, 1595, 1250, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.26 (6H, t, J=7.0 Hz, OEt), 3.21 (2H, d, J_{H-P}=21.5 Hz, CH_2P), 4.04 (4H, dq, J_{H-P}=8.0 and J=7.0 Hz, OEt), 6.1—6.4 (2H, m, 3- and 4-H), and 7.31 (1H, m, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.41 (dq J_{C-P}=4.9 Hz, OEt), 26.78 (dt, J_{C-P}=142.8 Hz, CH_2P), 62.45 (dt, J_{C-P}=7.3 Hz, OEt), 108.45 (dd, J_{C-P}=7.3 Hz, 3-C), 111.01 (dd, J_{C-P}=3.7 Hz, 4-C), 142.16 (dd, J_{C-P}=3.7 Hz, 5-C), and 145.95 (d, J_{C-P}=9.8 Hz, 2-C); MS m/z (rel intensity, %) 218 (M^+, 15), 162 (21), 109 (19), and 81 (base peak). HRMS Found: m/z 218.0704. Calcd for $C_9H_{15}O_4P$: M, 218.0707.

5b: A similar procedure using 1) **4b** (0.215 g, 0.615 mmol), Raney Ni W-2 in ethanol (0.6 ml), boric acid (0.078 g, 1.261 mmol), and aqueous ethanol (17%, 3.6 ml) at room temperature for 13 h, 2) sodium acetate (0.252 g, 3.075 mmol) and acetic acid (1.3 ml) at 100 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 3 v/v) gave **5b** (0.077 g, 54%): Pale yellow liquid; IR (neat) 3000, 1565, 1250, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.27 (6H, t, J=7.0 Hz, OEt), 2.24 (3H, d, J=1.7 Hz, 5-Me), 3.17 (2H, d, J_{H-P}=20.5 Hz, CH_2P), 4.06 (4H, dq, J_{H-P}=8.0 and J=7.0 Hz, OEt), 5.88 (1H, m, 4-H), and 6.08 (1H, t, J_{H-P}=J=3.4 Hz, 3-H), ^{13}C NMR ($CDCl_3$) δ=13.41 (q, 5-Me), 16.27 (dq, J_{C-P}=7.4 Hz, OEt), 26.65 (dt, J_{C-P}=144.1 Hz, CH_2P), 62.27 (dt, J_{C-P}=7.4 Hz, OEt), 106.71 (dd, J_{C-P}=2.9 Hz, 4-C), 109.01 (dd, J_{C-P}=8.8 Hz, 3-C), 143.66 (d, J_{C-P}=8.8 Hz, 2-C), and 151.54 (d, J_{C-P}=2.9 Hz, 5-C); MS m/z (rel intensity, %) 232 (M^+, 4) and 95 (base peak). HRMS Found: m/z 232.0887. Calcd for $C_{10}H_{17}O_4P$: M, 232.0863.

5c: A similar procedure using 1) **4c** (0.215 g, 0.615 mmol), Raney Ni W-2 in ethanol (0.6 ml), boric acid (0.075 g, 1.207 mmol), and aqueous ethanol (17%, 3.6 ml) at room temperature for 13 h, 2) sodium acetate (0.252 g, 2.945 mmol) and acetic acid (1.3 ml) at 100 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 3 v/v) gave **5c** (0.084 g, 60%): pale yellow liquid; IR (neat) 3000, 1560, 1250, 1025, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.18 (3H, t, J=8.0 Hz, Et), 1.27 (6H, t, J=7.0 Hz, OEt), 2.60 (2H, q, J=8.0 Hz, Et), 3.16 (2H, d, J_{H-P}=21.0 Hz, CH_2P), 4.05 (4H, dq, J_{C-P}=8.0 and 7.0 Hz, OEt), 5.88 (1H, d, J=3.5 Hz, 4-H), and 6.09 (1H, t, J_{H-P}=J= 3.5 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=12.24 (q, Et), 16.35 (dp, J_{C-P}=5.9 Hz, OEt), 21.35 (t, Et), 26.74 (dt, J_{C-P}=142.7 Hz, CH_2P), 62.33 (dt, J_{C-P}=7.4 Hz, OEt), 105.24 (dd, J_{C-P}=2.9 Hz, 4-C), 108.86 (dd, J_{C-P}=7.4 Hz, 3-C), 143.69 (d, J_{C-P}=10.3 Hz, 2-C), and 157.30 (s, 5-C); MS m/z (rel intensity, %), 246 (M^+, 4), 109 (base peak), 94 (12), and 81 (11). HRMS Found: m/z 246.1017. Calcd for $C_{11}H_{19}O_4P$: M, 246.1020.

5d: A similar procedure using 1) **4d** (2.48 g, 7.1 mmol), Raney Ni W-2 in ethanol (6 ml), boric acid (4.35 g, 71 mmol), and aqueous ethanol (17%, 41 ml) at room temperature for 13.5 h, 2) sodium acetate (2.91 g, 35.5 mmol) and acetic acid (16 ml) at 100 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 1 v/v) afforded **5d**

(1.16 g, 70%): Pale yellow liquid; IR (neat) 3000, 1620, 1240, 1020, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.27 (6H, t, J=7.0 Hz, OEt), 1.96 (3H, d, J=1.0 Hz, Me), 3.14 (2H, d, J_{H-P}=21.5 Hz, CH_2P), 4.05 (4H, dq, J_{H-P}=8.0 and J=7.0 Hz, OEt), 6.08 (1H, d, J_{H-P}=3.5 Hz, 3-H), and 7.06 (1H, m, 5-H); ^{13}C NMR ($CDCl_3$) δ=9.77 (q, Me), 16.41 (dq, J_{C-P}=5.9 Hz, OEt), 26.83 (dd, J_{C-P}=144.1 Hz, CH_2P), 62.42 (dt, J_{C-P}=5.9 Hz, OEt), 111.15 (dd, J_{C-P}=7.4 Hz, 3-C), 121.30 (d, J_{C-P}=2.9 Hz, 4-C), 138.78 (dd, J_{C-P}=2.9 Hz, 5-C), and 145.77 (d, J_{C-P}=8.8 Hz, 2-C); MS m/z (rel intensity, %) 232 (M^+, 10), 176 (10), 96 (12), 95 (base peak), and 80 (11). HRMS Found: m/z 232.0867. Calcd for $C_{10}H_{17}O_4P$: M, 232.0863.

5e: A similar procedure using **4e** (0.134 g, 0.298 mmol), Raney Ni W-2 in ethanol (0.3 ml), boric acid (0.038 g, 0.611 mmol), and aqueous ethanol (17%, 1.8 ml) at room temperature for 14 h gave a hydrogenated product (0.11 g). This crude product was added to aqueous THF (50%, 1 ml) containing *p*-toluenesulfonic acid (0.028 g, 0.149 mmol) and the mixture was heated at 70 °C for 6.5 h. After an additional *p*-toluenesulfonic acid (0.028 g, 0.149 mmol) was added, heating was continued at the same temperature for 1.5 h. To the cooled mixture was added saturated aqueous sodium hydrogencarbonate (20 ml), and extracted with ethyl acetate (30 ml×3). The combined extracts were similarly treated and chromatographed over silica gel with hexane-ethyl acetate (1 : 1 v/v) to give **5e** (0.03 g, 41%): Colorless liquid; IR (neat) 3400, 3000, 1510, 1240, 1025, 970, and 800 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.26 (6H, t, 7.0 Hz, OEt), 3.28 (2H, d, J_{H-P}=20.8 Hz, CH_2P), 4.00 (4H, dq, J_{H-P}=8.0 and J=7.0 Hz, OEt), 4.30 (1H, br s, OH), 4.44 (2H, s, CH_2OH), 6.38 (1H, d, J=1.8 Hz, 4-H), and 7.28 (1H, dd, J_{H-P}=3.5 and J=1.8 Hz, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.35 (dq, J_{C-P}=5.9 Hz, OEt), 25.62 (dt, J_{C-P}=142.7 Hz, CH_2P), 56.06 (t, CH_2OH), 62.95 (dt, J_{C-P}=5.9 Hz, OEt), 112.39 (dd, J_{C-P}=4.4 Hz, 4-C), 141.75 (dd, J_{C-P}= 4.4 Hz, 5-C), and 142.04 (d, J_{C-P}=10.3 Hz, 2-C); MS m/z (rel intensity, %) 248 (M^+, 6), 153 (21), 112 (52), 111 (52), 109 (75), 94 (34), 83 (69), 81 (70), 65 (25), and 56 (base peak). HRMS Found: m/z 248.0808. Calcd for $C_{10}H_{17}O_5P$: M, 248.0813.

5f: A procedure similar to that employed for **5a** using 1) **4f** (0.17 g, 0.494 mmol), Raney Ni W-2 in ethanol (0.5 ml), boric acid (0.063 g, 1.013 mmol), and aqueous ethanol (17%, 2.4 ml) at room temperature for 15 h, 2) sodium acetate (0.203 g, 2.47 mmol) and acetic acid (1 ml) at 90 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 3 v/v) gave **5f** (0.032 g, 25%): Pale yellow liquid; IR (neat) 2900, 1650, 1250, 1025, and 830 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.27 (6H, t, J=7.0 Hz, OEt), 2.1—2.7 (6H, m, CH_2), 3.14 (2H, d, J_{H-P}=20.5 Hz, CH_2P), 4.05 (4H, dq, J_{H-P}=8.0 and J=7.0 Hz, OEt), and 6.94 (1H, m, 5-H); MS m/z (rel intensity, %) 258 (M^+, 33), 121 (63), 120 (base peak), and 91 (25). HRMS Found: m/z 258.1019. Calcd for $C_{12}H_{19}O_4P$: M, 258.1020.

5g: A similar procedure using 1) **4g** (0.188 g, 0.395 mmol), Raney Ni W-2 in ethanol (0.4 ml), boric acid (0.05 g, 0.81 mmol), and aqueous ethanol (17%, 3 ml) at room temperature for 14 h, 2) sodium acetate (0.162 g, 1.975 mmol) and acetic acid (1 ml) at 100 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 5 v/v) gave **5g** (0.09 g, 64%): Pale yellow liquid; IR (neat) 2920, 1555, 1250, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.86 (3H, t, J=7.0 Hz, Et), 1.0—1.4 (21H, m, n-C_8H_{17} and OEt), 1.7—2.1 (2H, m, CH_2CHP), 2.60 (2H, q, Et), 3.11 (1H, ddd, J_{H-P}=23.0, J=9.0, and 6.0 Hz, CHP), 3.7—4.2 (4H, m, OEt), 5.88 (1H, d, J=3.2 Hz, 4-H), and 6.08 (1H, t, J_{H-P}=J=3.2 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=12.29 (q, Et), 14.06 (q, n-C_8H_{17}), 16.41 (dq, J_{C-P}=5.9 Hz, OEt), 21.47, 22.70, 27.53, 28.18, 28.53, 28.65, 29.24 (each t, n-C_8H_{17}), 31.88 (t, Et), 38.59 (dd, J_{C-P}=141.2 Hz, CHP), 62.45, 62.93 (each dt, J_{C-P}=7.4 Hz, OEt), 105.13 (dd, J_{C-P}=2.9 Hz, 4-C), 108.45 (dd, J_{C-P}=7.4 Hz, 3-C), 148.48 (d, J_{C-P}=8.8 Hz, 2-C), and 157.07 (d, J_{C-P}=2.9 Hz, 5-C); MS m/z (rel intensity, %) 358 (M^+, 34), 221 (base peak), 155 (66), 127 (41), 110 (41), 99 (57), 85 (28), and 81 (21). Found: m/z 358.2288. Calcd for $C_{19}H_{35}O_4P$: M, 358.2271.

5h: A similar procedure using 1) **4h** (0.198 g, 0.457 mmol), Raney Ni W-2 in ethanol (0.5 ml), boric acid (0.283 g, 4.57 mmol), and aqueous ethanol (17%, 2.4 ml) at room temperature for 20 h, 2) sodium acetate (0.187 g, 2.285 mmol) and acetic acid (1 ml) at 100 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 1 v/v) gave **5h** (0.092 g, 64%): Pale yellow liquid; IR (neat) 2940, 1555, 1250, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85 (3H, t, J=7.0 Hz, Et), 1.0—1.4 (15H, m, OEt and n-C_5H_{11}), 1.7—2.1 (2H, m, CH_2CHP), 2.60 (2H, q, J=7.0 Hz, Et), 3.11 (1H, ddd, J_{H-P}=23.0, J=9.0, and 6.0 Hz, CHP), 3.7—4.3 (4H, m, OEt), 5.89 (1H, d, J=3.2 Hz, 4-H), and 6.08 (1H, t, J_{H-P}=3.2 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=12.24 (q, Et), 13.94 (q, n-C_5H_{11}), 16.38 (dq, J_{C-P}=4.4 Hz, OEt), 21.41, 22.35 (each t, n-C_5H_{11}), 27.44 (dt, J_{C-P}=13.2 Hz, n-C_5H_{11}), 28.53 (dt, J_{C-P}=2.9 Hz, n-C_5H_{11}), 31.36 (t, Et), 38.53 (dd, J_{C-P}=141.2 Hz, CHP), 62.03 (dt, J_{C-P}=7.4 Hz, OEt), 62.36 (dt, J_{C-P}=8.8 Hz, OEt), 105.06 (dd, J_{C-P}=2.9 Hz, 4-C), 108.39 (dd, J_{C-P}=7.4 Hz, 3-C), 148.42 (d, J_{C-P}=8.8 Hz, 2-C), and 157.07 (d, J_{C-P}=2.9 Hz, 5-C); MS m/z (rel intensity, %) 316 (M^+, 13), 179 (base peak), and 110 (66). HRMS Found: m/z 316.1806. Calcd for $C_{16}H_{29}O_4P$: M, 316.1802.

5i: A similar procedure using 1) **4i** (0.33 g, 0.787 mmol), Raney Ni W-2 (0.8 ml), boric acid (0.1 g, 1.613 mmol), and aqueous ethanol (17%, 4.8 ml) at room temperature for 15 h, 2) sodium acetate (0.323 g, 3.935 mmol) and acetic acid (1.7 ml) at 100 °C for 0.3 h, and silica-gel column chromatography with hexane-ethyl acetate (1 : 1 v/v) afforded **5i** (0.062 g, 26%): Colorless liquid; IR (neat) 1610, 1250, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85 (3H, t, J=6.0 Hz, n-C_5H_{11}), 1.1—2.1 (8H, m, n-C_5H_{11}), 1.22, 1.28 (6H, m, OEt), 1.99 (3H, s, 4-Me), 2.10 (1H, ddd, J_{H-P}=23.0, J=9.0, and 6.0 Hz, CHP), 3.7—4.2 (4H, m, OEt), 6.09 (1H, d, J_{H-P}=4.0 Hz, 3-H), and 7.09 (1H, m, 5-H); ^{13}C NMR ($CDCl_3$) δ=9.82 (q, 4-Me), 14.00 (q, n-C_5H_{11}), 16.41 (dq, J_{C-P}=5.9 Hz, OEt), 22.41 (t, n-C_5H_{11}), 27.53 (dt, J_{C-P}=14.7 Hz, n-C_5H_{11}), 28.15 (dt, J_{C-P}=16.2 Hz, n-C_5H_{11}), 31.41 (t, n-C_5H_{11}), 38.68 (dd, J_{C-P}=139.7 Hz, CHP), 62.09 (dt, J_{C-P}=7.4 Hz, OEt), 62.50 (dt, J_{C-P}=7.4 Hz, n-C_5H_{11}), 110.74 (dd, J_{C-P}=7.4 Hz, 3-C), 121.19 (s, 4-C), 138.54 (dd, J_{C-P}=2.9 Hz, 5-C), and 150.48 (d, J_{C-P}=8.8 Hz, 2-C); MS m/z (rel intensity, %) 302 (M^+, 32), 232 (27), 165 (base peak), 164 (21), and 95 (92). HRMS Found: m/z 302.1656. Calcd for $C_{15}H_{27}O_4P$: M, 302.1645.

5j: A similar procedure using 1) **4j** (0.395 g, 0.899 mmol), Raney Ni W-2 (0.9 ml), boric acid (0.114 g, 1.843 mmol), and aqueous ethanol (17%, 5.4 ml) at room temperature for 15 h, 2) sodium acetate (0.369 g, 4.495 mmol) and acetic acid (2 ml) at 100 °C for 30 min, and silica-gel column chromatography with hexane-ethyl acetate (1 : 1 v/v) gave **5j** (0.045 g, 16%): Colorless liquid; IR (neat) 3000, 1610, 1250, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.22, 1.28 (6H, m,

OEt), 1.92 (3H, s, 4-Me), 3.0—3.6 (3H, m, $PhCH_2$ and CHP), 3.7—4.2 (4H, m, OEt), 6.01 (1H, d, J_{H-P}=3.5 Hz, 3-H), and 6.9—7.3 (6H, m, 5-H and Ph); ^{13}C NMR ($CDCl_3$) δ=9.29 (q, 4-Me), 15.94 (dq, J_{C-P}=5.9 Hz, OEt), 34.18 (t, CH_2), 40.24 (dd, J_{C-P}=141.2 Hz, CHP), 61.74 (dt, J_{C-P}=7.4 Hz, OEt), 111.15 (dd, J_{C-P}=7.4 Hz, 3-C), 120.57 (d, J_{C-P}=4.4 Hz, 4-C), 126.07, 127.95, 128.36 (each d), 138.24 (dd, J_{C-P}=2.9 Hz, 5-C), 139.07 (s), and 148.83 (d, J_{C-P}=8.8 Hz, 2-C); MS *m/z* (rel intensity, %) 322 (M^+, 50), 231 (96), 185 (60), 184 (99), 155 (21), 141 (34), 129 (25), 128 (23), 121 (47), 116 (23), 110 (46), 95 (74), 91 (base peak), and 81 (51). HRMS Found: *m/z* 322.1339. Calcd for $C_{17}H_{23}O_4P$: M, 322.1333.

Alkylation of 2-(Phosphorylmethyl)furan 5d Leading to 2-(1-Phosphorylalkyl)furans 5i, j. To a solution of **5d** (0.241 g, 1.033 mmol) in dry THF (3 ml) was added at −78 °C butyllithium (15% in hexane, 0.65 ml, 1.033 mmol). After 1 h at −78 °C under nitrogen, pentyl iodide (0.205 g, 0.13 ml, 1.033 mmol) was added and the mixture was stirred for 5 h at the same temperature. Aqueous THF (1 : 1 v/v, 50 ml) was added slowly and the product was extracted with dichloromethane (30 ml×3). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane–ethyl acetate (2 : 1 v/v) to give **5i** (0.274 g, 88%) and a later fraction afforded the starting **5d** (0.013 g, 5%). Spectral data of **5i** is presented above.

A similar procedure using **5d** (0.197 g, 0.848 mmol), butyllithium (15% in hexane, 0.53 ml, 0.848 mmol), and benzyl bromide (0.145 g, 0.1 ml, 0.848 mmol) in THF (3 ml) was followed by silica-gel column chromatography with hexane–ethyl acetate (1 : 1 v/v) to give **5j** (0.239 g, 87%).

Reductive Ring-Opening of 4a into 6. A mixture of **4a** (0.202 g, 0.614 mmol), Raney Ni W-2 (0.5 ml), and boric acid (0.078 g, 1.259 mmol) in aqueous ethanol (17%, 17.5 ml) was stirred under hydrogen atmosphere at room temperature for 19 h. After another portion of Raney Ni (0.5 ml) was added, stirring was continued also under hydrogen for additional 19.5 h. All the insoluble material was filtered through Celite and washed with water and then dichloromethane. The combined filtrate and washings were extracted with dichloromethane (50 ml×3). The extract was dried over magnesium sulfate and evaporated in vacuo. The residue (0.181 g, 87%) was chromatographed over silica gel by using ethyl acetate to give **6** (0.095 g) as a mixture of two diastereomers. Colorless liquid; IR (neat) 3400, 1710, 1250, 1025, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (6H, t, *J*=7.0 Hz, OEt), 1.4—1.96 (6H, m, THP), 2.80 (2H, d, *J*=6.5 Hz, 3-H), 3.14 (2H, d, J_{H-P}=22.5 Hz, CH_2P), 3.3—4.2 (6H, m, THP, CH_2OTHP, OH, and CHOH), 4.12 (4H, dq, J_{H-P}=8.0 and *J*=7.0 Hz, OEt), 4.54 (1H, m, THP), ^{13}C NMR ($CDCl_3$) δ=16.32 (dq, J_{C-P}=7.4 Hz, OEt), 19.82, 25.35, 30.65 (each t, THP), 43.12 (dt, J_{C-P}=126.5 Hz, CH_2P), 47.71, 47.94 (each t, 3-C), 60.83 (t, CH_2OTHP), 62.77 (dt, J_{C-P}=5.9 Hz, OEt), 67.01 (d, CHOH), 71.71, 72.01 (each t, THP), 99.89, 100.01 (each d, THP), and 201.71 (d, J_{C-P}=5.9 Hz, CO); MS *m/z* (rel intensity, %) 266 (1), 226 (12), 224 (39), 223 (M^+-CH_2OTHP, base peak), 219 (43), 195 (20), 152 (27), and 85 (42).

As this compound **6** is too hygroscopic to be submitted for analysis, it was converted into *O*-silyl derivative according to the following procedure: To a solution of **6** (0.16 g, 0.47 mmol) in dry DMF (1 ml) were added *t*-butyldimethylsilyl chloride (0.086 g, 0.568 mmol) and imidazole (0.081 g, 1.183 mmol). The mixture was stirred at room temperature for 15.5 h. Diethyl ether (100 ml) was added, the resulting mixture was washed with aqueous sodium chloride (50 ml×3), dried over magnesium sulfate, and then evaporated in vacuo. The residue was chromatographed over silica gel by using hexane–ethyl acetate (1 : 2 v/v) to give ethyl 4-(*t*-butyldimethylsilyloxy)-2-oxo-5-(2-tetrahydropyranyloxy)pentylphosphonate (0.171 g, 80%). Colorless liquid; IR (neat) 1720, 1250, 1030, 830, and 780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.09 (6H, s, Me_2Si), 0.84 (6H, s, *t*-BuSi), 1.33 (6H, t, *J*=7.0 Hz, OEt), 1.4—1.7 (6H, THP), 2.7—2.9 (2H, m, 3-H), 3.11 (2H, d, J_{H-P}=22.5 Hz, CH_2P), 3.6—3.9 (4H, m, THP and CH_2OTHP), 4.12 (4H, dq, J_{H-P}=8.0, and 7.0 Hz, OEt), 4.22 (1H, m, 4-H), and 4.55 (1H, m, THP); ^{13}C NMR ($CDCl_3$) δ=−4.59, −4.88 (each q, Me_2Si), 16.35 (dq, J_{C-P}=5.9 Hz, OEt), 18.06 (s, *t*-BuSi), 19.24, 19.41, 25.47 (each t, THP), 25.88 (q, *t*-BuSi), 30.53 (t, THP), 43.77 (dt, J_{C-P}=126.5 Hz CH_2P), 49.24 (t, 3-C), 62.06, 62.59 (each dt, J_{C-P}=5.9 Hz, OEt), 62.48, 62.71 (each t, CH_2OTHP), 68.18, 68.36 (each d, 4-C), 71.24 (t, THP), 98.83 (d, THP), 200.72, and 200.83 (each d, J_{C-P}=2.9 Hz, CO); MS *m/z* (rel intensity, %) 395 (M^+-t-Bu, 10), 337 (14), 311 (56), 220 (11), 219 (base peak), 191 (15), 163 (12), 84 (20), and 75 (13). Found: C, 53.11; H, 9.15%. Calcd for $C_{20}H_{41}O_7PSi$: C, 53.08; H, 9.13%.

Reactions of 2-(Phosphorylmethyl)furan with Carbonyl Compounds Leading to 7b—h. To a solution of **5d** (0.232 g, 1 mmol) in dry THF (3 ml) was added butyllithium (15% in hexane, 0.63 ml, 1 mmol) at −78 °C. The mixture was stirred at the same temperature under nitrogen for 1 h and a carbonyl compound (1 to 1.5 mmol) was added. After 30 min at −78 °C, saturated ammonium chloride (20 ml) was added and extraction with dichloromethane (30 ml×3) followed. The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with hexane–ethyl acetate (2 : 1 v/v) as an eluent to give **7**. Further elution with hexane–ethyl acetate (1 : 1 v/v) recovered the unreacted **5d**. Amounts of the carbonyl compounds are as follows: benzaldehyde (1.5 mmol), butanal (1 mmol), cyclopentanone (1.5 mmol), cyclohexanone (1.2 mmol, reaction time: 2 h), 3-pentanone (1.5 mmol), 2-heptanone (1.5 mmol), 5-hexen-2-one (1.5 mmol).

These adducts **7** are too hygroscopic to be submitted for analyses except for **7e** and **7g**. Accordingly they were used in the subsequent olefination without further purification.

7b: (a 7 : 3 mixture of two diastereomers): Pale yellow viscous liquid; ^1H NMR ($CDCl_3$) δ=1.0—1.4 (6H, m, OEt), 1.86 (7/10×3H, s, 4-Me), 1.95 (3/10×3H, s, 4-Me), 3.4—3.8 (1H, m, CHP), 3.8—4.3 (4H, m, OEt), 4.83 (1H, m, OH), 5.1—5.5 (1H, m, CHOH), 5.94 (7/10H, d, J_{H-P}=3.0 Hz, 3-H), 6.26 (3/10H, d, J_{H-P}=3.0 Hz, 3-H), 6.96 (1H, m, 5-H), and 7.20 (5H, s, Ph).

7c: (a 4 : 1 mixture of two diastereomers): Colorless viscous liquid; IR (neat) 3400, 2970, 1615, 1230, 1025, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (3H, m, *n*-Pr), 1.1—1.7 (10H, m, OEt and *n*-Pr), 2.02 (3H, s, 4-Me), 3.1—3.5 (1H, m, CHP), 3.8—4.4 (6H, m, OEt and CHOH), 6.14 (4/5H, d, *J*=3.0 Hz, 3-H), 6.34 (1H, d, *J*=3.0 Hz, 3-H), and 7.13 (1H, m, 5-H); MS *m/z* (rel intensity, %) 232 (M^+−PrCHO, base peak), 204 (22), 176 (33), and 95 (30).

7d: Colorless viscous liquid; IR (neat) 3440, 2980, 1610, 1225, 1025, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.16, 1.31 (each 3H, t, *J*=7.0 Hz, OEt), 1.4—2.1 (8H, m, CH_2), 1.90 (3H, s, 4-Me), 3.39 (1H, d, J_{H-P}=24.0 Hz, CHP), 3.6—4.3 (4H, m, OEt), 6.30 (1H, d, J_{H-P}=3.0 Hz, 3-H), and 7.10 (1H, br s,

5-H); MS *m/z* (rel intensity, %) 316 (M^+, 7), 232 (M^+−cyclopentanone, base peak), and 95 (23).

7e: Colorless viscous liquid; IR (neat) 3440, 2940, 1630, 1225, 1025, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.16, 1.29 (each 6H, t, J=7.0 Hz, OEt), 1.0—1.9 (10H, m, CH_2), 1.99 (3H, d, J=1.2 Hz, 4-Me), 3.40 (1H, d, J_{H-P}=24.0 Hz, CHP), 3.6—4.3 (5H, m, OEt), 6.27 (1H, d, J_{H-P}=3.0 Hz, 3-H), and 7.22 (1H, q, J=1.2 Hz, 5-H); MS *m/z* (rel intensity, %) 330 (M^+, 3), 232 (M^+−cyclohexanone), 159 (base peak), 129 (31), 126 (68), 117 (81), and 91 (73). HRMS Found: *m/z* 330.1592. Calcd for $C_{16}H_{27}O_5P$: M, 330.1595.

7f: Colorless viscous liquid; IR (neat) 3440, 2990, 1610, 1225, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.82, 0.90 (each 3H, t, J=7.5 Hz, Et), 1.14, 1.32 (each 3H, t, J=7.0 Hz, OEt), 1.5—1.9 (4H, m, Et), 2.00 (3H, s, 4-Me), 3.48 (1H, d, J_{H-P}=24.0 Hz, CHP), 3.6—4.3 (5H, m, OEt), 6.30 (1H, d, J_{H-P}=3.0 Hz, 3-H), and 7.12 (1H, m, 5-H); MS *m/z* (rel intensity, %) 318 (M^+, 1), 232 (M^+−3-pentanone, base peak), 176 (29), and 95 (32).

7g: (a 4 : 1 mixture of two diastereomers): Colorless viscous liquid; IR (neat) 3440, 2940, 1610, 1225, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (3H, t, J=7.0 Hz, *n*-C_5H_{11}), 1.0—1.7 (17H, m, OEt, Me, and *n*-C_5H_{11}), 2.02 (3H, s, 4-Me), 3.40 (1/5H, d, J_{H-P}=24.0 Hz, CHP), 3.45 (4/5H, J_{H-P}=24.0 Hz, CHP), 3.7—4.3 (4H, m, OEt), 4.38 (1H, s, OH), 6.23 (4/5H, d, J_{H-P}=3.0 /Hz, 3-H), 6.28 (1/5H, d, J_{H-P}=3.0 Hz, 3-H), and 7.12 (1H, m, 5-H); MS *m/z* (rel intensity, %) 346 (M^+, 0.1) and 232 (M^+−2-heptanone, base peak). Found: C, 58.70; H, 8.98%. Calcd for $C_{17}H_{31}O_5P$: C, 58.94; H, 9.02%.

7h: (a 4 : 1 mixture of two diastereomers): Colorless viscous liquid; IR (neat) 3430, 3000, 1640, 1610, 1225, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1—1.4 (9H, m, OEt and Me), 1.4—1.9 (2H, m, CH_2), 1.9—2.4 (2H, m, $CHCH_2$), 2.00 (3H, s, 4-Me), 3.42 (1/5×2H, d, J_{H-P}=24.0 Hz, CHP), 3.45 (4/5×2H, d, J_{H-P}=24.0 Hz, CHP), 3.7—4.3 (4H, m, OEt), 4.44 (1H, br s, OH), 4.8—5.1 (2H, m, $=CH_2$), 5.80 (1H, m, CH), 6.23 (4/5H, d, J_{H-P}=3.0 Hz 3-H), 6.28 (1/5H, d, J_{H-P}=3.0 Hz, 3-H), and 7.12 (1H, br s, 5-H); MS *m/z* (rel intensity, %) 232 (M^+−5-hexen-2-one, 15), 176 (25), 95 (26), 81 (20), 55 (22), and 43 (base peak).

Condensation of 5b with Butanal Leading to 8a. At −78 °C butyllithium (15% in hexane, 0.29 ml, 0.469 mmol) was added to a solution of **5b** (0.109 g, 0.469 mmol) in dry THF (3 ml). The mixture was stirred under nitrogen for 30 min. After butanal (0.068 g, 0.08 ml, 0.938 mmol) was added, the resulting mixture was stirred at −78 °C for 1 h, at −15 °C for 1 h, at 0 °C for 3 h, and at room temperature for 16 h. Saturated aqueous ammonium chloride (20 ml) was added and the extraction with diethyl ether (30 ml×3) followed. The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane to give **8a** (0.023 g, 33%). From the fraction with hexane-ethyl acetate (1 : 3 v/v) the unreacted **5b** (0.028 g, 26%) was recovered. **8a** (*E* : *Z*=98 : 2 by GLC): Colorless liquid; IR (neat) 2900, 1600, and 960 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.92 (3H, t, *n*-Pr), 1.2—1.7 (2H, m, *n*-Pr), 2.0—2.3 (2H, m, $=CHCH_2$), 2.25 (3H, s, 5-Me), and 5.8—6.3 (4H, m, 3-, 4-H, and CH=CH); MS *m/z* (rel intensity, %) 150 (M^+, 55), 122 (11), 121 (base peak), 91 (13), and 77 (14). Elemental analysis by HRMS was not attempted because of its easy polymerization.

Dehydration of Adducts 7b—h Leading to 8b—h. A mixture of adduct **7** (1 mmol) and cesium fluoride (0.578 g, 3.8 mmol) in wet DMF (2 ml containing water (0.07 ml)) was heated at 60 °C for 33—36 h. Diethyl ether (80 ml) was added, the ether solution was washed with water (50 ml×5), dried over magnesium sulfate, and evaporated in vacuo. The residue was chromatographed over silica gel with hexane to give **8** as rather unstable products. Further elution with the eluents shown below gave unreacted **7** and/or **5d** as a retro addition product.

8b: (*E* : *Z*=99 : 1 by GLC): Pale yellow prisms (hexane); mp 60—62 °C; IR (KBr) 1600 and 960 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.98 (3H, d, J=1.0 Hz, Me), 6.17 (1H, s, 3-H), 6.76 (1H, J=16.0 Hz, furylCH=), 6.91 (1H, s, 5-C), and 7.0—7.5 (6H, m, PhCH=); ^{13}C NMR ($CDCl_3$) δ=111.48 (d, 3-C), 116.89 (d, furylCH=), 122.13 (s, 4-C), 126.48, 127.01, 127.66, 128.83 (each d), 137.36 (s), 139.19 (d, 5-C), and 153.48 (s, 2-C); MS *m/z* (rel intensity, %) 184 (M^+, base peak), 155 (31), 141 (41), and 116 (25). Found: C, 84.18; H, 6.52%. Calcd for $C_{13}H_{12}O$: C, 84.75; H, 6.56%. The elution with hexane-ethyl acetate (1 : 2 v/v) afforded **5d** (20%).

8c: (*E* : *Z*=96:4 by GLC): Colorless liquid; IR (neat) 2940, 1600, and 960 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.92 (3H, t, J=7.0 Hz, *n*-Pr), 1.3—1.7 (2H, m, *n*-Pr), 1.96 (3H, s, 4-Me), 2.0—2.3 (2H, m, CH_2CH=), 6.06 (1H, d, J=15.5 Hz, furylCH=), 6.0—6.2 (1H, m, *n*-PrCH=), 6.10 (1H, s, 3-H), and 7.06 (1H, br s, 5-H); MS *m/z* (rel intensity, %) 150 (M^+, 19), 121 (28), 64 (21), 57 (29), 55 (27), and 43 (base peak). HRMS Found: *m/z* 150.1035. Calcd for $C_{10}H_{14}O$: M, 150.1044. The elution with hexane-ethyl acetate (1 : 2 v/v) gave a mixture of **7c** and **5d** (**7c**: 18%, **5d**: 4%).

8d: The reaction of **7d** (0.17 g, 0.537 mmol) with cesium fluoride (0.31 g, 2.041 mmol) in wet DMF (6.1 ml containing 0.04 ml of water) was heated at 60 °C for 30 h. Another portions of cesium fluoride (0.31 g, 2.041 mmol) and water (0.04 ml) were added and the heating was continued at 60 °C for 15 h and then at 80 °C for 5.5 h. A similar work-up gave **8d** (0.086 g, 78%). **8d**: Colorless liquid; IR (neat) 2960, 1660 and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.4—2.0 (4H, m, CH_2), 2.00 (3H, s, 4-Me), 2.3—2.6 (4H, m, CH_2), 5.99 (1H, s, 3-H), 6.18 (1H, tt, J=2.1 and 2.1 Hz, CH), and 7.08 (1H, s, 5-H); MS *m/z* (rel intensity, %) 162 (M^+, base peak), 121 (49), 105 (20), 91 (36), and 77 (20). HRMS Found: *m/z* 162.1048. Calcd for $C_{11}H_{14}O$: M, 162.1044. The fraction eluted with hexane-ethyl acetate (1 : 2 v/v) gave **7d** (0.005 g, 3%) and then **5d** (0.008 g, 6%).

8e: Colorless liquid; IR (neat) 2930, 1655, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.4—1.8 (6H, m, CH_2), 1.99 (3H, d, J=1.2 Hz, 4-Me), 2.22 (2H, m, CH_2CH=), 2.58 (2H, m, CH_2), 5.89 (1H, s, CH=), 6.02 (1H, s, 3-H), and 7.06 (1H, t, J=1.2 Hz, 5-H); MS *m/z* (rel intensity, %) 176 (M^+, base peak), 108 (55), and 95 (21). HRMS Found: *m/z* 176.1186. Calcd for $C_{12}H_{16}O$: M, 176.1200. The fraction eluted with hexane-ethyl acetate (2 : 1 v/v) gave **7e** (5%).

8f: Colorless liquid; IR (neat) 2960, 1655, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.06 (6H, t, J=7.0 Hz, Et), 2.00 (3H, s, 4-Me), 2.18, 2.40 (each 2H, q, J=7.0 Hz, Et), 5.94 (1H, s, CH=), 6.04 (1H, s, 3-H), and 7.09 (1H, m, 5-H); MS *m/z* (rel intensity, %) 164 (M^+, base peak), 149 (22), 135 (91), 107 (26), 93 (22), and 91 (28). HRMS Found: *m/z* 164.1209. Calcd for $C_{11}H_{16}O$: M, 164.1200. The fraction eluted with hexane-ethyl acetate (1 : 1 v/v) provided **7f** (3%) and with eluent of 1 : 2 v/v gave **5d** (8%).

8g: (*E* : *Z*=80 : 20 by GLC): Colorless liquid; IR (neat) 2940, 1655, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (3H, t, J=7.0

Hz, n-C_5H_{11}), 1.1—1.6 (6H, m, n-C_5H_{11}), 1.83 (20/100×3H, d, 1.0 Hz, =CMe, *Z*), 1.90 (80/100×3H, d, *J*=1.0 Hz, =CMe, *E*), 1.95 (3H, s, 4-Me), 2.0—2.5 (2H, m, =CCH_2), 5.98 (2H, s, 3-H and =CH), and 7.03 (s, 5-H); ^{13}C NMR ($CDCl_3$) δ=9.76 (q, 4-Me, *Z*), 9.81 (q, 4-Me, *E*), 14.07 (q, n-C_5H_{11}), 18.46 (q, =CMe, *E*), 22.63 (t, CH_2), 24.66 (q, =CMe, *Z*), 27.54 (t, CH_2, *Z*), 27.73 (t, CH_2, *E*), 31.53 (t, CH_2, *E*), 32.08 (t, CH_2, *Z*), 33.62 (t, =CCH_2, *Z*), 40.79 (t, =CCH_2, *E*), 109.76 (d, 3-C, *Z*), 110.10 (d, 3-C, *E*), 114.16 (d, =CH, *E*), 114.41 (d, =CH, *Z*), 121.18 (s, 4-C, *Z*), 121.29 (s, 4-C, *E*), 137.19 (d, 5-C, *Z*), 137.25 (d, 5-C, *E*), 138.66 (s, =C, *E*), 139.39 (s, =C, *Z*), 153.50 (s, 2-C, *Z*), and 153.85 (s, 2-C, *E*); MS *m/z* (rel intensity, %) 192 (M^+, 84), 135 (base peak), 122 (20), 107 (34), and 91 (38). HRMS Found: *m/z* 192.1528. Calcd for $C_{13}H_{20}O$: M, 192.1513. The fraction eluted with hexane-ethyl acetate (1 : 1 v/v) gave **7g** (0.019 g, 6%) and with eluent of 1 : 2 v/v afforded **5d** (0.01 g, 10%).

8h: (*E* : *Z*=82 : 18 by GLC): Colorless liquid; IR (neat) 2940, 1660, 1640, and 1600 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.87 (18/100×3H, d, *J*=1.2 Hz, =CMe), 1.94 (82/100×3H, d, *J*=1.2 Hz, =CMe), 2.00 (3H, *J*=1.2 Hz, 4-Me), 2.1—2.6 (4H, m, CH_2), 4.9—5.2 (2H, m, =CH_2), 5.6—6.0 (1H, m, CH=), 6.01 (1H, s, 3-H), and 7.08 (1H, t, *J*=1.2 Hz, 5-H); ^{13}C NMR ($CDCl_3$) δ=9.76 (q, 4-Me), 18.50 (q, =CMe, *E*), 24.62 (q, =CMe, *Z*), 31.98 (t, CH_2, *Z*), 32.32 (t, CH_2, *E*), 32.94 (t, =CCH_2, *Z*), 40.16 (t, =CCH_2, *E*), 109.96 (d, 3-C, *Z*), 110.29 (d, 3-C, *E*), 114.76 (t, =CH_2), 121.28 (s, 4-C), 137.32 (d, CH=), 137.49 (d, 5-C), 138.17 (s, =CMe, *E*), 138.51 (s, =CMe, *Z*), 153.26 (s, 2-C, *Z*), and 153.62 (s, 2-C, *E*); MS *m/z* (rel intensity, %) 176 (M^+, 38), 135 (base peak), 107 (46), 91 (49), and 79 (25). HRMS Found: *m/z* 176.1197. Calcd for $C_{12}H_{11}O$: M, 176.1200. The fraction eluted with hexane-ethyl acetate (1 : 1 v/v) gave **7h** (0.008 g, 4%) and with eluent of 1 : 2 v/v afforded **5d** (0.019 g, 12%).

4-Methyl-2-(1-oxohexyl)furan (9a): To a solution of **5i** (0.265 g, 0.876 mmol) in dry THF (4 ml) was added butyllithium (15% in hexane, 0.55 ml, 0.876 mmol) at −78 °C and stirred for 1 h. After dry oxygen gas was bubbled at −100 °C for 15 min, aqueous THF (50%, 20 ml) was slowly added. The products were extracted with diethyl ether (30 ml×3). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with hexane-ethyl acetate (10 : 1 v/v) to give **9a** (0.047 g, 30%): Colorless liquid; IR (neat) 2930, 1675, and 1600 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.90 (3H, t, *J*=6.0 Hz, n-C_5H_{11}), 1.2—2.0 (6H, m, n-C_5H_{11}), 2.08 (3H, s. 4-Me), 2.77 (2H, t, *J*=6.0 Hz, $COCH_2$), 7.03 (1H, s, 3-H), and 7.33 (1H, t, *J*=1.0 Hz, 2-H); MS *m/z* (rel intensity, %) 180 (M^+, 9), 124 (base peak), 110 (63), 53 (22), 43 (24), and 41 (30). Found: C, 73.38; H, 8.94%. Calcd for $C_{11}H_{16}O$: C, 73.30; H, 8.95%.

4-Methyl-2-(1-oxo-2-phenylethyl)furan (9b): Dry oxygen gas was bubbled at −78 °C for 1 h through the anion solution generated by a similar method using **5j** (0.21 g, 0.65 mmol) and butyllithium (15% in hexane, 0.45 ml, 0.65 mmol) in dry THF (3 m]). Usual hydrolytic work-up and silica-gel column chromatography with hexane-ethyl acetate (5 : 1 v/v) afforded **9b** (0.026 g, 20%): Colorless needles (hexane); mp 60.5—61 °C; IR (KBr) 3100, 1650, and 1600 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.04 (3H, dd, *J*=1.0 and 0.5 Hz, Me), 3.04 (2H, s, CH_2), 7.03 (1H, t, *J*=0.5 Hz, 3-H), 7.26 (5H, br s, Ph), and 7.32 (1H, t, *J*=1.0 Hz, 5-H); MS *m/z* (rel intensity, %) 200 (M^+, 9), 110 (base peak), 91 (55), and 65 (44). Found: C, 77.79; H, 5.86%. Calcd for $C_{13}H_{12}O_2$: C, 77.98; H, 6.04%.

Hydrolysis of 2-(1-Phosphorylalkyl)furans 5b, c and 5g Leading to 2,5-Dioxoalkylphosphonates 10a—c. A furan **5** (1 mmol) in aqueous acetic acid (67%, 2—3 ml) containing a catalytic amount of concd sulfuric acid was heated at 120 °C for 5 h. The reaction mixture was diluted with water (40 ml), neutralized with saturated aqueous sodium hydrogencarbonate, and then extracted with ethyl acetate (50 ml×3). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel to give **10** (**10a**: from ethyl acetate, 62%. **10b**: from ethyl acetate, 52%. **10c**: from hexane-ethyl acetate (3 : 2 v/v), 53%).

10a: Pale yellow liquid; IR (neat) 1710, 1250, 1020, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.33 (6H, t, *J*=7.0 Hz, OEt), 2.17 (3H, s, Me), 2.6—3.0 (4H, m, CH_2), 3.12 (2H, d, J_{H-P}=22.5 Hz, PCH_2), and 4.13 (4H, dq, J_{H-P}=7.8 and *J*=7.0 Hz, OEt); MS *m/z* (rel intensity, %) 250 (M^+, 7), 232 (34), 208 (31), 207 (70), 179 (98), 153 (56), 152 (76), 125 (53), 123 (52), 109 (42), 97 (28), 95 (51), 81 (34), and 43 (base peak). HRMS Found: *m/z* 250.0969. Calcd for $C_{10}H_{19}O_5P$: M, 250.0969.

10b: Pale yellow liquid; IR (neat) 1710, 1250, 1020, and 815 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.05 (3H, t, *J*=7.0 Hz, Et), 1.33 (6H, t, *J*=7.0 Hz, OEt), 2.47 (2H, q, *J*=7.0 Hz, Et), 2.6—3.0 (4H, m, CH_2), 3.12 (2H, d, J_{H-P}=22.5 Hz, PCH_2), and 4.13 (4H, dq, J_{H-P}=8.0 and *J*=7.0 Hz, OEt); ^{13}C NMR ($CDCl_3$) δ=7.77 (q, Et), 16.29 (dq, J_{C-P}=5.9 Hz, OEt), 35.77, 37.65 (each t, $COCH_2$), 42.50 (dt, J_{C-P}=128.0 Hz, PCH_2), 62.65 (dt, J_{C-P}=5.9 Hz, OEt), 201.01 (d, J_{C-P}=5.9 Hz, CO), and 209.72 (s, CO); MS *m/z* (rel intensity, %) 264 (M^+, 19), 246 (36), 235 (41), 208 (44), 207 (95), 179 (base peak), 153 (46), 152 (60), 125 (30), 123 (30), and 109 (32). HRMS Found: *m/z* 264.1116. Calcd for $C_{11}H_{21}O_5P$: M, 264.1125.

10c: Pale yellow liquid; IR (neat) 1710, 1250, 1025, and 790 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.87 (3H, t, *J*=6.0 Hz, n-C_8H_{17}), 1.05 (3H, t, *J*=7.0 Hz, Et), 1.1—1.4 (12H, m, n-C_8H_{17}), 1.32 (6H, t, *J*=7.0 Hz, OEt), 1.5—2.1 (2H, m, n-C_8H_{17}), 2.49 (2H, q, *J*=7.0 Hz, Et), 2.5—3.4 (5H, m, PCH and $COCH_2$), and 4.11 (4H, dq, J_{H-P}=8.0 and *J*=7.0 Hz, OEt); ^{13}C NMR ($CDCl_3$) δ=7.88 (q, Et), 14.12 (q, n-C_8H_{17}). 16.41 (dq, J_{C-P}=5.9 Hz, OEt), 22.71 (t, n-C_8H_{17}), 26.68 (dt, J_{C-P}=4.4 Hz, n-C_8H_{17}), 28.41 (dt, J_{C-P}=14.7 Hz, n-C_8H_{17}), 29.24, 29.41, 31.88 (each t, n-C_8H_{17}), 35.71, 35.94, 38.06 (each t, CH_2CO), 52.97 (dd, J_{C-P}=125.0 Hz, PCH), 62.56 (dt, J_{C-P}=4.4 Hz, OEt), 62.77 (dt, J_{C-P}=5.90 Hz, OEt), 205.04 (d, J_{C-P}=4.4 Hz, CO), and 209.71 (s, CO); MS *m/z* (rel intensity, %) 376 (M^+, 15), 347 (28), 319 (48), 291 (29), 264 (base peak), 263 (36), 221 (26), 207 (41), 179 (27), 165 (48), 153 (46), and 110 (26). HRMS Found: *m/z* 376.2365. Calcd for $C_{19}H_{37}O_5P$: M, 376.2377.

3-Ethyl-2-octyl-2-cyclopenten-1-one (11). A mixture of lithium bromide (0.029 g, 0.33 mmol) and **10c** (0.083 g, 0.22 mmol) in dry THF (3.5 ml) was stirred at room temperature for 10 min. After cooled to 0 °C triethylamine (0.027 g, 0.04 ml, 0.246 mmol) was added. The resulting mixture was stirred for 1.5 h at room temperature, heated under reflux for 24 h, diluted with water (20 ml), and then extracted with diethyl ether (30 ml×3). The combined extracts were dried (magnesium sulfate) and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane-ethyl acetate (3 : 1 v/v) as an eluent to give **11** (0.015 g, 31%). The starting **10c** (0.01 g, 12%) was recovered from a fraction eluted with hexane-ethyl acetate (1 : 1 v/v): Pale yellow liquid; IR (neat) 1700 and 1640 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.86 (3H, t, *J*=6.0 Hz, n-C_8H_{17}), 1.12 (3H, t, *J*=7.5 Hz, Et), 1.0—1.5 (12H, m, n-C_8H_{17}), and 2.0—2.6 (8H, m, CH_2C=, 4- and

5-H); MS *m/z* (rel intensity, %) 222 (M^+, 16), 193 (base peak), 124 (60), 123 (24), and 79 (23). HRMS Found: *m/z* 222.1982. Calcd for $C_{15}H_{26}O$: M, 222.1982.

Synthesis of Furanosesquiterpene 12. To a solution of **5d** (0.188 g, 0.81 mmol) in dry THF (2 ml) was added butyllithum (15% in hexane, 0.51 ml, 0.81 mmol) at −78 °C under nitrogen. After the mixture was stirred for 1 h, **13** (*E*:*Z*=75:25, 0.168 g, 1.215 mmol) was added and the stirring was continued for 30 min. The mixture was treated with saturated ammonium chloride solution (20 ml) and extracted with dichloromethane (30 ml×3). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with hexane-ethyl acetate (3:1 v/v) to give **14** (0.237 g, 79%). The fraction eluted with hexane-ethyl acetate (1:1 v/v) afforded the starting **5d** (0.022 g, 12%). **14** (a mixture of diastereomers, *E*:*Z*=3:1 by ^{1}H NMR): Colorless viscous liquid; IR (neat) 3440, 3000, 1640, 1610, 1225, and 1025 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.2—1.8 (14H, m, OEt, CH_2, MeC(OH), and MeCH=), 2.01 (3H, 4-Me), 2.1—2.3 (2H, m, CH_2CH), 3.41 (1/4H, d, J_{H-P}=23.8 Hz, PCH, *Z*), 3.47 (3/4H, d, J_{H-P}=23.5 Hz, PCH, *E*), 3.8—4.3 (4H, m, OEt), 4.46 (1H, s, OH), 4.9—5.4 (2H, m, CH_2), 6.23, 6.28 (1H, each d, J_{H-P}=3.3 Hz, 3-H), 6.33 (3/4H, dd, *J*=17.2 and 10.6 Hz, CH=, *E*), 6.7—6.8 (1/4H, m, CH=, *Z*), and 7.13 (1H, s, 5-H); MS *m/z* (rel intensity, %) 370 (M^+, 3), 232 (base peak), and 95 (23). HRMS Found: *m/z* 370.1906. Calcd for $C_{19}H_{31}O_5P$: M, 370.1907. A mixture of **14** (0.21 g, 0.567 mmol), cesium fluoride (0.327 g, 2.155 mmol), and water (0.04 ml, 2.155 mmol) in DMF (6.5 ml) was heated at 60 °C for 38 h. Diethyl ether (100 ml) was added to the mixture, the organic layer was washed with water (100 ml×4), dried over magnesium sulfate, and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane as an eluent to give **12** (0.074 g, 53%). The fraction eluted with hexane-ethyl acetate (1:2 v/v) gave **5d** (0.017 g, 13%). **12** (a 59:20:15:6-mixture of **12a**:**12b**:**12c**:**12d** by GLC): Colorless liquid; IR (neat) 2940, 1640, and 1610 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.56, 1.75, 1.81, 1.87, 1.96, 2.00, 2.02 (9H, each s, Me), 2.2—2.4 (4H, m, CH_2), 4.9—5.2 (2H, m, $=CH_2$), 5.4—5.6 (1H, m, 5′-H), 6.04 (2H, m, 3- and 1′-H), 6.36 (59/100H, dd, *J*=17.1 and 10.8 Hz, 7′-H of **12a**), 6.37 (15/100H, dd, *J*=17.1 and 10.8 Hz, 7′-H of **12c**), 6.78 (20/100H, dd, *J*=17.1 and 10.8 Hz, 7′-H of **12b**), 6.80 (6/100H, dd, *J*=17.1 and 10.8 Hz, 7′-H of **12d**), and 7.10 (1H, s, 5-H); ^{13}C NMR ($CDCl_3$) δ=9.76 (q, 4-Me), 11.63 (q, 6′-Me of **12c**), 11.68 (q, 6′-Me of **12a**), 18.52 (q, 2′-Me of **12a**), 19.74 (q, 2′-Me of **12b**, 6′-Me of **12b**, and 6′-Me of **12d**), 24.71 (q, 2′-Me of **12c**), 25.74 (q, 2′-Me of **12d**), 25.85 (t, 4′-C, **12d**), 26.00 (t, 4′-C of **12b**), 26.75 (t, 4′-C of **12c**), 26.91 (t, 4′-C of **12a**), 33.38 (t, 3′-C of **12c**), 33.78 (t, 3′-C of **12d**), 40.36 (t, 3′-C of **12a**), 40.75 (t, 3′-C of **12b**), 110.05 (d, 3-C of **12d**), 110.08 (d, 3-C of **12c**), 110.36 (d, 3-C of **12a** and 3-C of **12b**), 110.64 (t, 8′-C of **12a**), 110.87 (t, 8′-C of **12c**), 113.42 (t, 8′-C of **12d**), 113.57 (t, 8′-C of **12b**), 114.57 (d, 1′-C of **12a** and 1′-C of **12b**), 114.91 (d, 1′-C of **12d**), 115.09 (d, 1′-C of **12c**), 121.19 (s, 4-C of **12c** and 4-C of **12d**), 121.29 (s, 4-C of **12a** and 4-C of **12b**), 130.15 (d, 5′-C of **12b**), 130.58 (d, 5′-C of **12d**), 132.13 (d, 5′-C of **12a**), 132.65 (d, 5′-C of **12c**), 133.63 (6′- and 7′-C of **12b**), 133.74 (6′- and 7′-C of **12d**), 134.31 (s, 6′-C of **12c**), 134.38 (s, 6′-C of **12a**), 137.00, 137.46, 137.52, 137.85, 138.11, 141.49 (d, 7′-C of **12a**), 141.56 (d, 7′-C of **12c**), 153.26 (s, 2-C of **12c** and 2-C of **12d**), and 153.59 (s, 2-C of **12a** and 2-C of **12b**); MS *m/z* (rel intensity, %) 216 (M^+, 27), 135 (base peak), 107 (38), 91 (31), 78 (15), and 41 (12). HRMS Found: *m/z* 216.1515. Calcd for $C_{15}H_{20}O$: M, 216.1513.

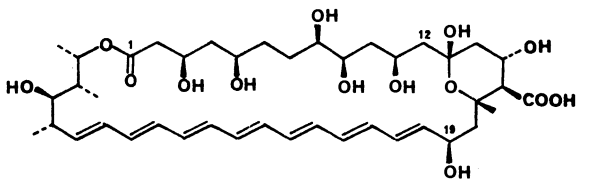
Synthetic Studies of Amphotericin B. III.[1] An Enantiospecific Synthesis of the C-1—C-19 Segment of the Amphotericin B Aglycon†

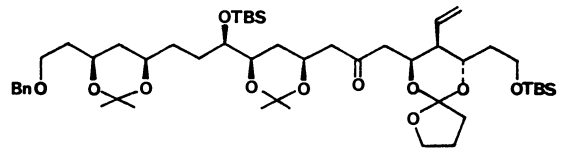
Mitsuhiro KINOSHITA,* Masato TANIGUCHI, Masahiko MORIOKA, Hitoshi TAKAMI, and Yasuhiro MIZUSAWA
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223
(Received January 14, 1988)

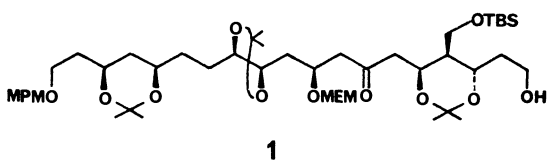
The title compound, (3*S*,4*S*,5*S*,9*S*,11*R*,12*R*,15*R*,17*S*)-4-[(*t*-butyldimethylsilyloxy)methyl]-1,3,5,9,11,12,15,17,19-nonahydroxy-3,5 : 11,12 : 15,17-tri-*O*-isopropylidene-19-*O*-(4-methoxybenzyl)-9-*O*-[(2-methoxyethoxy)methyl]-7-nonadecanone (**1**) was effectively synthesized through the coupling of (3*S*,5*R*,8*R*,9*R*,11*S*)-12-iodo-3,5 : 8,9-di-*O*-isopropylidene-1-*O*-(4-methoxybenzyl)-11-*O*-[(2-methoxyethoxy)methyl]-1,3,5,8,9,11-dodecanehexol (**2**) and (3*S*,4*R*,5*S*)-4-[(*t*-butyldimethylsilyloxy)methyl]-3,5-*O*-isopropylidene-1,1-bis(methylthio)-1-trimethylstannyl-6-heptene-3,5-diol (**36**). The C-13—C-19 segment **36** was enantiospecifically synthesized from 1,2 : 5,6-di-*O*-isopropylidene-α-D-*threo*-D-*glycero*-3-hexofuranosulose (**7**) via (2*S*,4*R*,5*S*)-5,6-epoxy-3-[(*t*-butyldimethylsilyloxy)-methyl]-1-hexen-3-ol (**6a**) in 11.6% overall yield.

Recently, the total syntheses of amphotericin B and its aglycon have been first achieved by Nicolaou et al.[2] The synthesis of key intermediate **A** corresponding to the C-1—C-19 portion of the aglycon has also been announced by Abiko et al.[3] In connection with our synthetic efforts[1] toward the aglycon of amphotericin B, we required access to the compound **1** which was considered to be practically useful as a C-1—C-19 synthetic segment for the construction of the aglycon. In this paper, we wish to describe an enantiospecific synthesis of **1**.

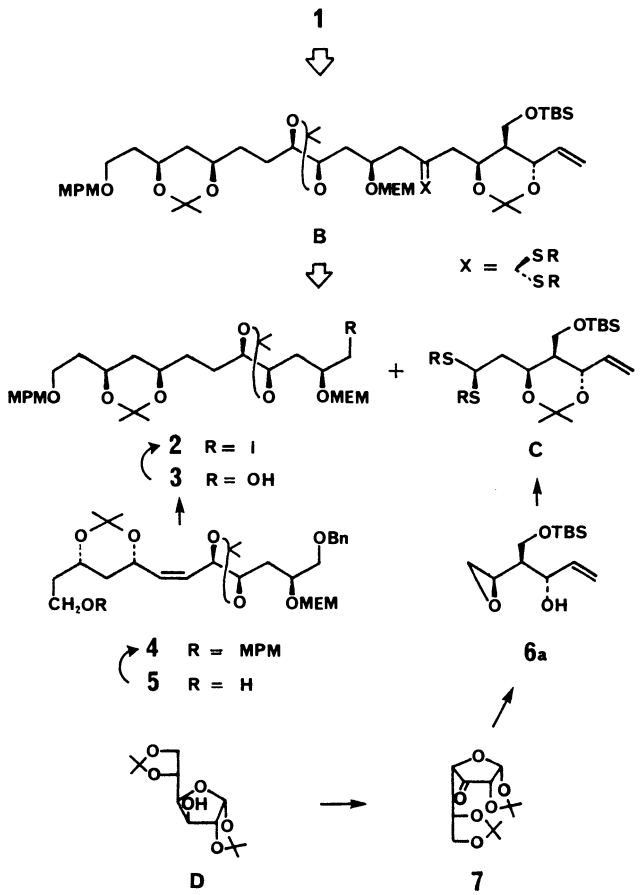
The synthetic plan is outlined in Scheme 1. The synthetic route to **1** through the intermediate **B** which is expected to be formed by the coupling of **2** and the dithioacetal compound **C** seems to be conventional and simple, whereas it may be rather interesting as a synthetic challenge because success of the coupling of **2** and **C** probably depends on the chemical stability of a lithiation derivative of **C**, which is now never precisely predictable (see Ref. 18). The C-1—C-12 segment **2** would be obtainable via **4** from **5**[1] which was previously prepared in our laboratory. The key intermediate **6a** useful for the preparation of various dithioacetal compounds **C** would be enantiospecifically synthesized via the compound **9** (see Scheme 2)







† A part of this paper was read at the 54th National Meeting of the Chemical Society of Japan, Tokyo, April 1987, Abstract papers No. 3III L 26.



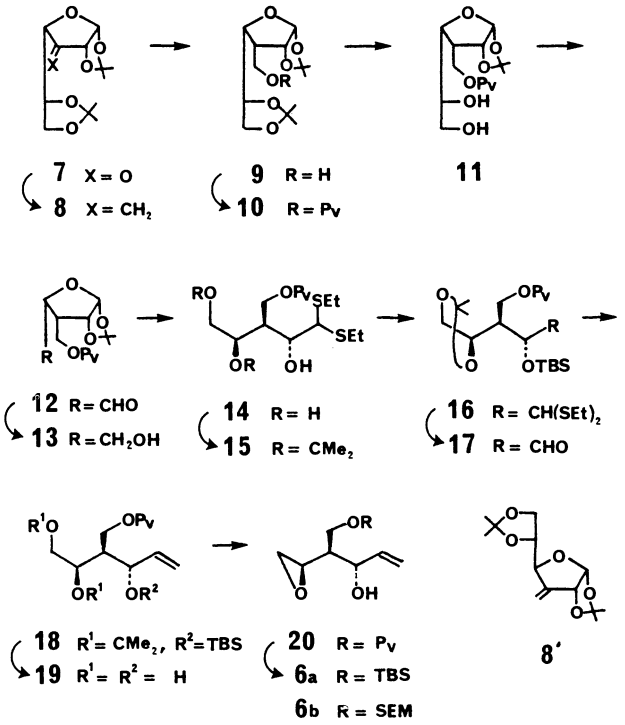
Scheme 1.

which will be stereoselectively prepared from the known compound **7**.[4] This plan was devised by considering that the absolute stereochemistry at C-2, C-3, and C-4 of **9** correlates to that of C-3, C-4, and C-5, respectively, of **6a**. The successful pursuit of the basic elements of this synthetic plan forms the topic of this report.

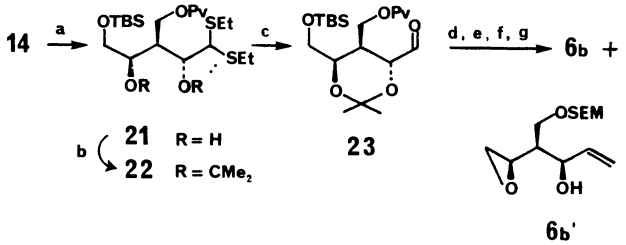
Preparation of 2. The alcohol **5**[1] was treated with 4-methoxybenzyl chloride (MPM-Cl) and NaH in THF to afford the O-MPM derivative **4** in 88% yield. Simultaneous catalytic reduction of the double bond and benzyloxy group in **4** proceeded effectively with Raney Ni W-4 (1 atm H_2, EtOH, 20 °C, 6 h) to give **3** in 86% yield. In this reduction, no cleavage of the O-MPM bond occurred.[5] In the last step, the iodination of the hydroxyl group at C-1 was carried out by treatment of **3** with triphenylphosphine, imidazole, and iodine in benzene to provide the segment **2** in 99% yield.

Synthesis of 6a. The synthesis of the key intermediate **6a** started with the known **7**[4] which was obtainable in 5 steps from commercially supplied 1,2:5,6-di-*O*-isopropylidene-α-D-glucofuranose (**D**). Wittig methylenation of **7** with methylenetriphenylphosphorane[7] in benzene at 25 °C afforded an 84% yield of **8** and a 7% yield of the α-D-erythro epimer 8'.[8] Hydroboration of **8** with dicyclohexylborane followed by oxidation with alkaline H_2O_2 gave the alcohol **9** in 94% yield, which was *O*-pivaloylated to afford **10** in quantitative yield. Partial hydrolysis of **10** with 75% aqueous acetic acid yielded **11** (67% yield) and unchanged **10** (31% yield). Periodate-oxidation of **11** followed by sodium borohydride reduction of the aldehyde **12** afforded the alcohol **13** in 85% yield. Dithioacetalization of **13** with ethanethiol and boron trifluoride etherate gave **14** in 74% yield from **11**. Regioselective 1,2-*O*-isopropylidenation of **14** with 2,2-dimethoxypropane (DMP) in acetone containing a catalytic amount of H_2SO_4 gave **15** in 95% yield. *t*-Butyldimethylsilylation (TBSOTf, 2,6-lutidine) of **15** followed by dedithioacetalization of the silyl ether **16** (83% yield) with 1:1 $HgCl_2$–HgO (red) in 80% aqueous acetone afforded the aldehyde **17** which was immediately methylenated with methylenetriphenylphosphorane[7] in ether at 23 °C to give **18** in 80% yield from **16**. Treatment of **18** with 75% aqueous acetic acid at 50 °C afforded the triol **19** in 95% yield, which was directly subjected to the one stage epoxidation[9] of vicinal diol with triphenylphosphine, diethyl azodicarboxylate (DEAD), and 3A Molecular Sieves in refluxed benzene to give the epoxide **20** in 72% yield. One step conversion of **20** into **6a** was well-achieved in 81% yield by the treatment of **20** in THF with *n*-BuLi (3.5 equiv) at −50 °C and then with TBS-Cl (2.5 equiv) at −8 °C for 12 h. The overall yield of **6a** from **7** in 14 steps was 11.6%.

The direct conversion of **20** to the *O*-[2-(trimethylsilylethoxy)methyl] (O-SEM) derivative **6b** using *n*-BuLi and SEM-Cl was not practicable (42% yield) because of low regioselectivity of SEM-Cl. However, **6b** was obtainable in 84% yield by the sequence of reactions involving *O*-*t*-butyldimethylsilylation, one-stage exchange of pivaloyl and SEM groups, and selective de-*O*-*t*-butyldimethylsilylation. It is noteworthy that a sample of **6b** which was prepared via **23** from **14** through the alternative reaction sequence as shown in Scheme 3 was revealed to be a ca. 3:1 4-epimeric mixture by the ^{1}H NMR (400 MHz) examination. The

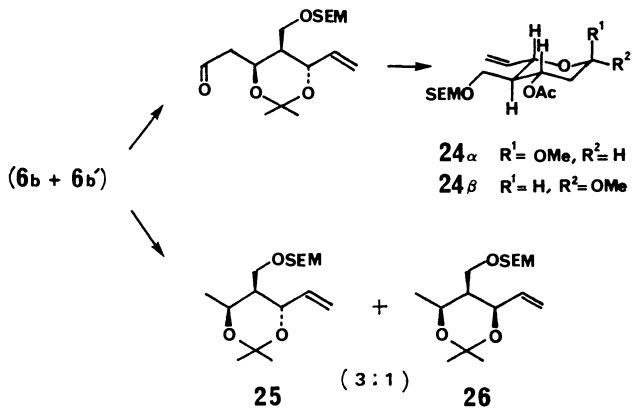


Scheme 2.



Scheme 3. (a) TBS-Cl, imidazole, DMF, 24°C; (b) DMP, Me_2CO, cat. H_2SO_4, 25°C; (c) $HgCl_2$, HgO, 80% Me_2CO–H_2O, 24°C; (d) $(Ph_3PCH_3)Br$, $NaCH_2SOMe$, Et_2O; (e) 75% AcOH–H_2O, 50°C; (f) Ph_3P, DEAD, PhH, MS 3A, 80°C; (g) 1. TBS-Cl, imidazole, DMF, 25°C, 3 h; 2. *n*-BuLi, THF (−60°C, 15 min); SEM-Cl, THF, 0°C, 16 h; 3. TBAF, THF, 0°C, 4 h.

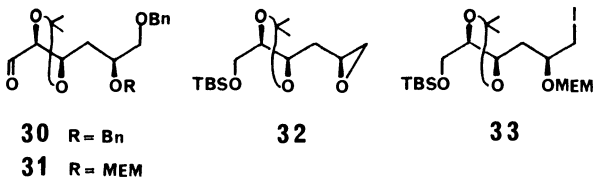
major and minor epimers proved to be **6b** and **6b'**, respectively, by the following fashions (Scheme 4): (a) The sample (**6b**+**6b'**) was converted into **24** (as an anomeric mixture) in 5 steps. The ^{1}H NMR spectrum of **24** showed signals in line with the depicted structure



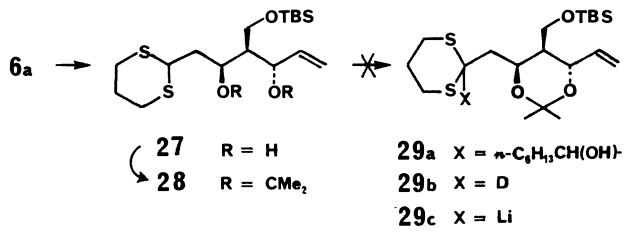
Scheme 4.

(see Experimental). (b) The sample (**6b**+**6b'**) was converted in two steps into a 3:1 mixture of **25** and **26**, whose structures were confirmed by ^{1}H NMR analysis (see Experimental). The formation of the epimer **6b'** in the route to **6b** via **23** from **14** may be ascribed to the epimerization that occurred at the C-4 carbon of the thermodynamically unstable 1,3-dioxane-4-carbaldehyde **23** during its Wittig methylenation using the ylide prepared from methyltriphenylphosphonium bromide by the Corey's method.[10]

Synthesis of C. For the construction of the target compound **1**, we first took account of the coupling of a dithiane derivative **28** (the segment **C**) with a model compound **32** or **33** which was obtained from the

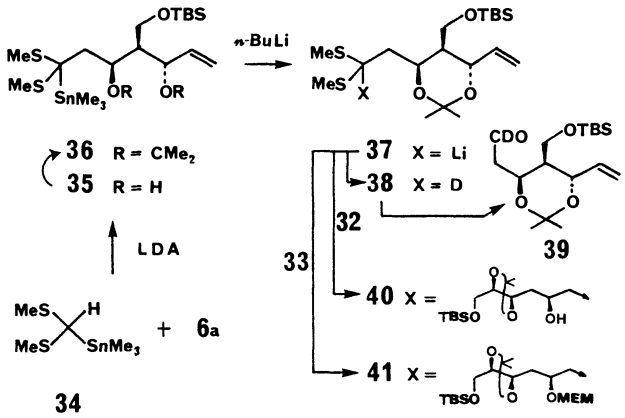


known **30** or **31**,[1] respectively. The treatment of the epoxide **6a** with 5 equivalents of 2-lithio-1,3-dithiane afforded the dithiane derivative **27** in 81% yield, which was subsequently isopropylidenated to give **28** in 92% yield. However, the attempted coupling of **28** with heptanal by the usual dithiane lithiation procedure[11] (*n*-BuLi, THF, −25 °C, 3 h) afforded no coupling product **29a**, recovering the reactants, **28** and heptanal. Even though the reaction mixture of lithiation was treated with D_2O instead of heptanal, no deuterio derivative **29b** could be detected. These facts suggested to us that the desired lithium derivative **29c** is very short-lived probably due to its unusually increased kinetic basicity[12] and it is practically impossible to generate **29c** from its conjugate acid **28**, which is far less acidic than 1,3-dithiane, by the lithiation using *n*-BuLi.[13] This suggestion prompted us to use the trimethylstannylated dimethyl dithioacetal compound **36** for the dithiane derivative **28**. The trimethylstannyl group in **36** would be instantaneously substituted by



Scheme 5.

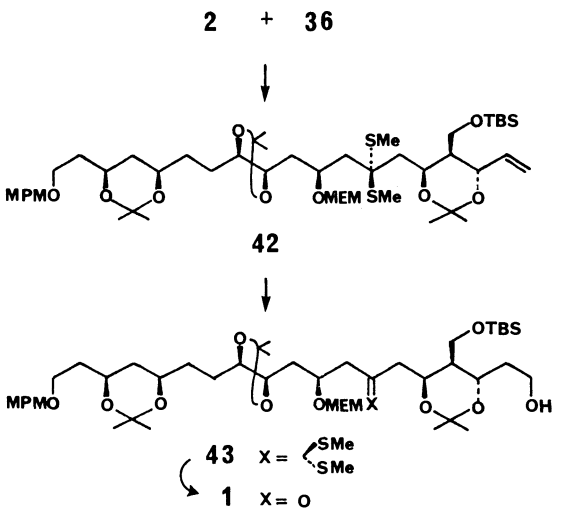
lithium on treatment with *n*-BuLi.[14] Moreover, it pleased us very much that in contrast to the H/Li-exchange, the Sn/Li-transmetallation should easily be detected by TLC. The validity of our choice was proved by the following sequence of reactions (Scheme 6). Lithiation of [bis(methylthio)methyl]trimethylstannane[15] (**34**) with lithium diisopropylamide (LDA)



Scheme 6.

in THF-HMPA followed by treatment with the epoxide **6a** afforded **35** in a ca. 70% yield, which was isopropylidenated with 2-methoxy-1-propene and pyridinium *p*-toluenesulfonate (PPTS) in dichloromethane to yield **36** in 62% yield from **6a**. Immediately the addition of *n*-BuLi (2 equiv) to a solution of **36** in THF-HMPA at −30 °C was complete, the reaction mixture was treated with D_2O to give the product **38** in 85% yield, which was carefully hydrolyzed to the deuterio aldehyde **39** in moderate yield (44%) by using *N*-bromosuccinimide (NBS) and $AgNO_3$ in 85% aqueous acetonitlile containing 2,4,6-trimethylpyridine.[16] Thus obtained sample of **39** showed a ca. 75—80% aldehydic deuterium content by ^{1}H NMR analysis. The reaction of the epoxide **32** with the lithium compound **37** generated from **36** (1.5 equiv) and *n*-BuLi (1.8 equiv) afforded a ca. 5:7 mixture of the coupling product **40** and the starting epoxide **32**. Whereas the iodo derivative **33** reacted more smoothly with **37** generated from **36** (1.43 equiv) and *n*-BuLi (1.71 equiv) to yield the coupling product **41** in 76% yield.

Synthesis of 1. In keeping with the successful results in the similar model coupling reactions using **36**, the coupling of the C-1—C-12 segment **2** with **36** was carried out to afford in 84% yield the desired prod-



Scheme 7.

uct **42** corresponding to the intermediate **B** (Scheme 7).[17] Hydroboration of **42** using dicyclohexylborane followed by treatment with alkaline H_2O_2 gave the alcohol **43** in 92% yield. Dedithioacetalization of **43** with 1 : 1 $HgCl_2$–HgO provided the target compound **1** in 82% yield.

Experimental

Melting points were determined on a micro hot stage Yanaco MP-S3 and were uncorrected. Optical rotations were measured on a JASCO DIP-360 photoelectric polarimeter in chloroform, and ^{1}H NMR spectra were recorded on a Varian EM-390 or a JEOL GX-400 spectrometer in $CDCl_3$ using TMS as internal standard unless stated otherwise. Mass spectra were measured on a Hitachi M-80 mass spectrometer. TLC was performed on Merck TLC plate (60F-254, 0.25 mm), and column chromatography on silica gel, Wakogel C-200 and Merck Kieselgel 60 (230—400 mesh) for "Flash Chromatography." In general, organic solvents were purified and dried by appropriate procedure, and evaporation and concentration were carried out under reduced pressure below 30°C, unless otherwise noted.

(2*S*,4*R*,5*R*,8*S*,10*S*)-(6*Z*)-1-*O*-Benzyl-4,5:8,10-di-*O*-isopropylidene-12-*O*-(4-methoxybenzyl)-2-*O*-[(2-methoxyethoxy)methyl]-6-dodecene-1,2,4,5,8,10,12-heptol (4). To an ice-cold solution of **5**[1] (321 mg, 0.597 mmol) in dry DMF (3.2 ml) was added 55% NaH suspension (65 mg, 1.49 mmol). After being stirred at 25 °C for 0.5 h, to this reaction mixture was added 4-methoxybenzyl chloride (130 µl, 0.90 mmol) at 0 °C. After being stirred at 25 °C for 15 h, the reaction mixture was poured into saturated aqueous $NaHCO_3$, which was extracted with benzene (3×5.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (20 g) with 2 : 1 hexane-ethyl acetate to afford **4** (346 mg, 88%) as a colorless syrup: R_f=0.74 (1 : 1 hexane-ethyl acetate); $[\alpha]_D^{32}$ −12.7° (*c* 1.32); ^{1}H NMR (90 MHz) δ=1.34, 1.40, 1.43 (6H, 3H, 3H, each s, 2×CMe_2), 1.17—2.20 (6H, m, 2×H-3, 2×H-9, 2×H-11), 3.33 (3H, s, OMe of MEM), 3.30—4.63 (13H, m, OCH_2-CH_2O, 2×H-1, H-2, 4, 5, 8, 10, 2×H-12), 3.80 (3H, s, OMe of MPM), 4.43 (2H, s, OCH_2(MPM)), 4.53 (2H, s, OCH_2(Bn)), 4.80 (2H, s, OCH_2O), 5.30—5.77 (2H, m, H-6,7), 6.80—7.00 (2H, m, MPM), and 7.20—7.50 (7H, m, MPM, Ph).

Found: C, 67.77; H, 8.26%. Calcd for $C_{37}H_{54}O_{10}$: C, 67.45; H, 8.26%.

(2*S*,4*R*,5*R*,8*S*,10*S*)-4,5:8,10-Di-*O*-isopropylidene-12-*O*-(4-methoxybenzyl)-2-*O*-[(2-methoxyethoxy)methyl]-1,2,4,5,8,10,12-dodecaneheptol (3). A solution of **4** (346 mg) in ethanol (6.9 ml) was stirred with a catalytic amount of Raney Ni W-4 under bubbling with H_2 gas at 20 °C for 6 h. The reaction mixture was filtered and concentrated to a syrup which was chromatographed on silica gel (15 g) with 1 : 2 benzene-ethyl acetate to afford **3** (257 mg, 86%): colorless syrup; R_f=0.20 (1 : 1 hexane-ethyl acetate); $[\alpha]_D^{32}$ +31.4° (*c* 1.02); ^{1}H NMR (90 MHz) δ=1.37, 1.43 (12H, each s, 2×CMe_2), 1.10—2.00 (10H, m, 2×H-3, 2×H-6, 2×H-7, 2×H-9, 2×H-11), 3.40 (3H, s, OMe (MEM)), 3.40—4.20 (10H, m, OH, 2×H-1, H-2, 4, 5, 8, 10, 2×H-12), 4.43 (2H, s, OCH_2(MPM)), 4.80 (2H, s, OCH_2O), 6.80—7.00 and 7.20—7.40 (each 2H, each m, MPM).

3-Deoxy-1,2:5,6-di-*O*-isopropylidene-3-*C*-methylene-α-D-*threo*-D-*glycero*-hexofuranose (8) and α-D-*erythro* Epimer (8′). To a suspension of freshly prepared methylenetriphenylphosphorane[7] (140 g, 507 mmol) in dry benzene (291 ml) was added a solution of **7**[4] (29.1 g, 113 mmol) in benzene (582 ml) dropwise at 25 °C in a 20-min period. After being stirred for 1.7 h, the reaction mixture was concentrated and diluted with ether (873 ml). The mixture was poured into cold water (800 ml), which was extracted with ether (3×700 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (1450 g) with 5 : 2 hexane-ethyl acetate to afford **8** (24.1 g, 84%) and **8′** (2.02 g, 7%). **8**: R_f=0.68 (1 : 1 hexane-ethyl acetate); mp 49 °C; $[\alpha]_D^{34}$ −0.32°, $[\alpha]_{365}^{34}$ +1.94° (*c* 1.23); ^{1}H NMR (90 MHz) δ=1.32, 1.38, 1.44, 1.56 (each 3H, each s, 2×CMe_2), 3.7—4.1, 4.3—4.6 (each 2H, each m, H-4,5, 2×H-6), 4.83 (1H, dd-like, H-2, $J_{2,1}$=4.2, $J_{2,C=CH_2}\fallingdotseq$1.0 Hz), 5.28 5.48 (each 1H,

each dd-like, C=C$\underline{H}_2$, J_{gem}≒1.5 Hz), 5.81 (1H, d, H-1).

Found: C, 60.88; H, 7.81%. Calcd for $C_{13}H_{20}O_5$: C, 60.93; H, 7.87%.

8′: Colorless syrup; R_f=0.89 (1 : 1 hexane-ethyl acetate); $[\alpha]_D^{30}$ +99° (*c* 1.30) [lit, $[\alpha]_D$ +75° (*c* 1.0);[8a]) $[\alpha]_D^{22}$ +104° (*c* 2)[8b]]; ^{1}H NMR (90 MHz) δ=1.38, 1.45, 1.52 (6H, 3H, 3H, each s, 2×CMe_2), 3.85—4.40 (4H, m, H-4,5, 2×H-6), 4.70—5.70 (1H, m, H-2), 5.40—5.60 (2H, m, C=C$\underline{H}_2$), 5.80 (1H, d, H-1, $J_{1,2}$=4.2 Hz).

3-Deoxy-3-*C*-hydroxymethyl-1,2:5,6-di-*O*-isopropylidne-α-D-gulofuranose (9). To a solution of dicyclohexylborane (55.2 mmol) in THF (50.0 ml) was added a solution of **8** (7.00 g, 27.3 mmol) in THF (21.0 ml) at 0 °C under Ar, and the mixture was stirred at 25 °C for 100 min. The reaction was quenched by addition of water (70.9 ml). To the mixture was added 3M†† aqueous NaOH (18.4 ml) and 30% H_2O_2 (16.6 ml) at 0 °C. After being stirred at 50 °C for 1 h, the reaction mixture was extracted with ethyl acetate (5×100 ml). The extracts were evaporated and the residue was chromatographed on silica gel (400 g) with 1 : 4 hexane-ethyl acetate to afford **9** (7.14 g, 94%) as colorless crystals. Recrystallization from hexane-ethyl acetate gave a pure sample of **9**: mp 145 °C; R_f=0.41 (1 : 4 hexane-ethyl acetate); $[\alpha]_D^{31}$ −20.4° (*c* 1.08); ^{1}H NMR (90 MHz) δ=1.34, 1.38, 1.46, 1.59 (each 3H, each s, 2×CMe_2), 2.5—2.7 (1H, m, H-3), 3.0—3.2 (1H, m, OH), 3.4—4.3 (5H, m, H-5, 2×H-6, $C\underline{H}_2OH$), 4.4—4.6 (1H, m, H-4), 4.76 (1H, dd, H-2, $J_{2,1}$=4.8, $J_{2,3}$=5.7 Hz), 5.82 (1H, d, H-1).

Found: C, 56.98; H, 8.01%. Calcd for $C_{13}H_{22}O_6$: C, 56.92; H, 8.08%.

3-Deoxy-1,2 : 5,6-di-*O*-isopropylidene-3-*C*-[(pivaloyloxy)methyl]-α-D-gulofuranose (10). To a solution of **9** (7.14 g, 26.0 mmol) in dry CH_2Cl_2 (71.4 ml) were added 4-(dimethylamino)pyridine (DMAP) (6.36 g, 52.1 mmol) and pivaloyl chloride (4.76 ml, 39.1 mmol) in sequence at 0 °C. The mixture was stirred at 25 °C for 40 min and then diluted with ethanol (7.14 ml). After being stirred at 25 °C for 0.5 h, the mixture was evaporated. The residue was dissolved in ethyl acetate and the solution was washed with water and saturated aqueous NaCl, dried, and evaporated to give a crude sample of **10** (9.3 g, 100%). Recrystallization from ethyl acetate-hexane afforded an analytical sample: mp 127°C, R_f=0.60 (1 : 2 hexane-ethyl acetate; IR (KBr) 1720 cm^{-1}; $[\alpha]_D^{31}$ −23.9° (*c* 1.08); ^{1}H NMR (90 MHz) δ=1.23 (9H, s, *t*-Bu), 1.31, 1.37, 1.46, 1.57 (each 3H, each s, 2×CMe_2), 2.5—2.9 (1H, m, H-3), 3.4—4.8 (7H, m, H-2, 4, 5, 2×H-6, PvOC$\underline{H}_2$), 5.83 (1H, d, H-1).

Found: C, 60.18; H, 8.15%. Calcd for $C_{18}H_{30}O_7$: C, 60.32; H, 8.44%.

3-Deoxy-1,2-*O*-isopropylidene-3-*C*-[(pivaloyloxy)methyl]-α-D-gulofuranose (11). A solution of **10** (7.63 g) in 75% aqueous acetic acid (76.3 ml) was stirred at 30 °C for 4.5 h. The mixture was evaporated at 40 °C in a 2-h period. The residue was then chromatographed on silica gel (350 g) with 2 : 1 hexane-ethyl acetate to afford unchanged **10** (2.34 g, 30.7%) and **11** (4.54 g, 67% from **9**) as colorless crystals. **11**: R_f=0.37 (1 : 1 hexane-ethyl acetate); mp 63 °C; $[\alpha]_D^{31}$ −14.8° (*c* 1.03), ^{1}H NMR (90 MHz) δ=1.20 (9H, s, *t*-Bu), 1.30, 1.55 (each 3H, each s, CMe_2), 2.4—3.3 (3H, m, H-3, 2×OH), 3.4—4.7 (6H, m, H-4,5, 2×H-6, PvOC$\underline{H}_2$), 4.65 (1H, dd, H-2, $J_{2,1}$=4.2, $J_{2,3}$=5.7 Hz), 5.83 (1H, d, H-1).

†† 1M=1 mol dm^{-3}.

3-Deoxy-1,2-*O*-isopropylidene-3-*C*-[(pivaloyloxy)methyl]-α-L-lyxofuranose (13). To a solution of **11** (11.5 g, 36.2 mmol) in 80% aqueous acetone (115 ml) was added a solution of $NaIO_4$ (11.6 g, 53.5 mmol) in water (116 ml) at 0 °C in a 15-min period. After being stirred at 25 °C for 35 min, the reaction mixture was evaporated. Ethyl acetate was added to the residue and the mixture was washed with water and saturated aqueous NaCl, dried, and evaporated to afford crystalline aldehyde **12** (11.6 g). To an ice cold solution of the aldehyde **12** (11.6 g) in methanol (116 ml) was added $NaBH_4$ (2.74 g, 72.4 mmol) and was stirred at 25 °C for 15 min. The reaction mixture was neutralized (pH=7) with CO_2 and evaporated. Ethyl acetate (550 ml) was added to the residue and the mixture was washed with water and saturated aqueous NaCl, dried, and evaporated to give crude **13** (8.92 g, 85% yield from **11**). An analytical sample was obtained after silica-gel column chromatography with 1 : 1 hexane-ethyl acetate: colorless crystals; R_f=0.54 (1 : 1 hexane-ethyl acetate); mp 81°C; $[\alpha]_D^{30}$ −14.1° (*c* 1.02); ^{1}H NMR (90 MHz) δ=1.21 (9H, s, *t*-Bu), 1.30, 1.55 (each 3H, each s, CMe_2), 2.42 (1H, br-s, OH), 2.5—2.9 (1H, m, H-3), 3.3—4.6 (5H, m, H-4, 2×H-5. PvOC$\underline{H}_2$), 4.68 (1H, dd, H-2, $J_{2,1}$=$J_{2,3}$=4.5 Hz), 5.84 (1H, d, H-1).

Found: C, 58.46; H, 8.28%. Calcd for $C_{14}H_{24}O_6$: C, 58.32; H, 8.39%.

(2*S*,3*R*,4*R*)-5,5-Bis(ethylthio)-3-[(pivaloyloxy)methyl]-1,2,4-heptanetriol (14). To a solution of the crude **13** (8.92 g, 30.9 mmol) in EtSH (268 ml) was added $BF_3 \cdot Et_2O$ (2.6 ml) at 0 °C. After being stirred at 25 °C for 0.5 h, the reaction mixture was neutralized with triethylamine (pH=7) at 0 °C, and was diluted with ethyl acetate (250 ml). The mixture was washed with water and saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (550 g) with 2 : 3 hexane-ethyl acetate to afford **14** (8.09 g, 74% from **11**). **14**: Colorless syrup; R_f=0.29 (1 : 1 hexane-ethyl acetate); $[\alpha]_D^{30}$ +64.5° (*c* 1.01); ^{1}H NMR (90 MHz) δ=1.21 (9H, s, *t*-Bu), 1.26, 1.29 (each 3H, each t, 2×$SCH_2\underline{Me}$), 2.2—2.9 (6H, m, 2×$SC\underline{H}_2$, H-3, OH), 3.4—4.6 (9H, m, H-1, 2,4, 2×H-5, PvOC$\underline{H}_2$, 2×OH).

Found: C, 50.68; H, 8.35%. Calcd for $C_{15}H_{30}O_5S_2$: C, 50.82; H, 8.53%.

(2*S*,3*R*,4*R*)-5,5-Bis(ethylthio)-1,2-*O*-isopropylidene-3-[(pivaloyloxy)methyl]-1,2,4-heptanetriol (15). To a solution of **14** (1.82 g, 5.14 mmol), 2,2-dimethoxypropane (DMP) (1.26 ml, 10.3 mmol) in dry acetone (36.4 ml) was added 1% H_2SO_4-acetone (0.188 ml) at 0 °C. After being kept at 25 °C for 25 min, the mixture was neutralized with $NaHCO_3$ (pH=7) under ice-cooling, and evaporated. The residue was partitioned between ethyl acetate and water. The organic layer was separated and washed with saturated aqueous NaCl, dried, and evaporated to afford an essentially pure sample of **15** (1.93 g, 95%) as colorless crystals. An analytical sample of **15** was obtained after silica-gel column chromatograpy with 8 : 1 hexane-ethyl acetate: R_f=0.24 (8 : 1 hexane-ethyl acetate; mp 65°C; $[\alpha]_D^{37}$ −0.47°, $[\alpha]_{365}^{37}$ +7.49° (*c* 1.28); ^{1}H NMR (90 MHz) δ=1.20 (9H, s, Pv), 1.15—1.50 (6H, m, 2×$SCH_2\underline{Me}$), 1.33, 1.39 (each 3H, each s, CMe_2), 2.30—2.65 (2H, m, H-3, OH), 2.62, 2.73 (4H, q, 2×$SC\underline{H}_2$, *J*=6.3 Hz), 3.70—4.50 (7H, m, 2×H-1, H-2, 4, 5, $C\underline{H}_2OPv$).

Found: C, 54.86; H, 8.56%. Calcd for $C_{18}H_{34}O_5S_2$: C, 54.79; H, 8.68%.

(2*S*,3*R*,4*R*)-4-*O*-(*t*-Butyldimethylsilyl)-1,2-*O*-isopropylidene-3-[(pivaloyloxy)methyl]-1,2,4-heptanetriol (16). To a solution of **15** (1.93 g, 4.88 mmol) in dry CH_2Cl_2 (4.88 ml) were added 2,6-lutidine (1.71 ml, 14.6 mmol), TBSOTf (2.24 ml, 9.76 mmol) at 0 °C. After being stirred at 0 °C for 70 min, the reaction mixture was poured into ice-water, which was extracted with ethyl acetate (3×20 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (250 g) with 12 : 1 hexane-ethyl acetate to afford **16** (2.06 g, 83%) as colorless syrup: R_f=0.54 (8 : 1 hexane-ethyl acetate); $[\alpha]_D^{35}$ −0.70°, $[\alpha]_{365}^{35}$ +7.72° (*c* 1.14); ^{1}H NMR (90 MHz) δ=0.90 (9H, s, *t*-BuSi), 1.20 (9H, s, Pv), 1.13—1.43 (12H, m, CMe_2, 2×$SCH_2\underline{Me}$), 2.1—2.48 (1H, m, H-3), 2.60, 2.68 (4H, 2×$SC\underline{H}_2$, *J*=4.5 Hz), 3.70—4.50 (7H, m, 2×H-1, H-2, 4, 5, $C\underline{H}_2OPv$).

Found: C, 56.89; H, 9.47%. Calcd for $C_{24}H_{28}O_5SiS_2$: C, 56.65; H, 9.51%.

(2*S*,3*R*,4*S*)-4-*O*-(*t*-Butyldimethylsilyl)-1,2-*O*-isopropylidene-3-[(pivaloyloxy)methyl]-5-hexene-1,2,4-triol (18). To a solution of **16** (2.06 g, 4.05 mmol) in 80% aqueous acetone (72.1 ml) were added in sequence HgO (3.86g, 17.8 mmol) and $HgCl_2$ (4.84 g, 17.8 mmol) at 25 °C with efficient stirring. After the addition, stirring was continued at 25 °C for 20 min. The reaction mixture was filtered through a Celite, and the filter cake was washed with acetone (5×5 ml). The filtrate and washings were evaporated, and to the residue was added chloroform. The mixture was washed with 10% aqueous KI and saturated aqueous NaCl, dried, and evaporated to give the aldehyde **17** (1.72 g). A solution of the crude aldehyde (1.72 g) in dry benzene (32.6 ml) was added to a solution of $Ph_3P{=}CH_2$ (5.03 g, 18.2 mmol) in dry benzene (16.3 ml) at 25 °C in a 5-min period. After being stirred at 25 °C for 20 min, the reaction mixture was evaporated. The residue was taken up in ether (40 ml) which was washed with water and then saturated aqueous NaCl, dried, and evaporated. The residual syrup was chromatographed on silica gel (130 g) with 15 : 1 hexane-ethyl acetate to afford **18** (1.30 g, 80% from **16**) as a colorless syrup: R_f=0.60 (8 : 1 hexane-ethyl acetate); $[\alpha]_D^{34}$ −1.20° $[\alpha]_{365}^{34}$ −11.3° (*c* 1.51); ^{1}H NMR (400 MHz, $CHCl_3$, δ=7.26) δ=0.02, 0.05 (each 3H, each s, $SiMe_2$), 0.89 (9H, s, *t*-BuSi), 1.19 (9H, s, Pv), 1.31 ,1.36 (each 3H, each s, CMe_2), 1.86 (1H, ddd, H-3), 3.70 (1H, dd, *J*=7.8, 7.8 Hz), 4.05 (1H, dd, *J*=5.9, 7.8 Hz), 4.13 (1H, dd, *J*=5.9, 11.2 Hz), 4.18—4.24 (2H, m), 4.26 (1H, dd, *J*=3.9, 11.2 Hz), 5.11 (1H, ddd, H-6, $J_{6,5}$=10.1 Hz), 5.15 (1H, ddd, H-6, $J_{6,5}$=17.3 Hz), 5.75 (1H, ddd, H-5, $J_{5,4}$=6.8 Hz).

(2*S*,4*R*,5*S*)-5,6-Epoxy-3-[(pivaloyloxy)methyl]-1-hexen-3-ol (20). A solution of **18** (2.92 g, 7.29 mmol) in 75% aqueous acetic acid (58.4 ml) was stirred at 50 °C for 5 h. The reaction mixture was concentrated to give a syrup, which was chromatographed on silica gel (50 g) with 1 : 2 hexane-ethyl acetate to afford **19** (1.72 g, 95%). A mixture of **19** (1.71 g, 6.95 mmol), triphenylphosphine (2.19 g, 8.34 mmol), Molecular Sieves 3A powder (17.1 g), and dry benzene (85.6 ml) was vigorously stirred at 80 °C for 10 min, and DEAD (1.29 ml, 8.34 mmol) was added dropwise to the mixture. After being stirred at 80 °C for 14 h, the cold reaction mixture was filtered through a Celite, and the filter cake was washed with benzene (5×40 ml). The filtrate and washings were evaporated, and the residue was chromatographed on silica gel (170 g) with 2 : 1 hexane-ethyl acetate to give **20** (1.15 g, 72%) as a colorless syrup: R_f=0.56 (1 : 1 hexane-ethyl acetate); $[\alpha]_D^{32}$ −11.2° (*c* 1.39); ^{1}H NMR (90 MHz) δ=1.23 (9H, s, *t*-Bu), 1.50—2.00 (1H, m, H-3), 2.57 (1H, d, OH, *J*=2.7 Hz), 2.67 (1H, dd, H-1, $J_{1,2}$=2.7, J_{gem}=4.5 Hz), 2.85 (1H, dd, H-1, $J_{1,2}$=4.5 Hz), 3.10 (1H, ddd, H-2, $J_{2,3}$=8.7 Hz), 4.1—4.5 (3H, m, H-4, PvO$C\underline{H}_2$), 5.40 (1H, ddd-like, H-6, $J_{6,5}$=10.5 Hz), 5.50 (1H, ddd-like, H-6, $J_{6,5}$=17.4 Hz), 5.95 (1H, ddd, H-5, $J_{5,4}$=6.6 Hz).

(2*S*,4*R*,5*S*)-5,6-Epoxy-3-[(*t*-butyldimethylsilyloxy)methyl]-1-hexen-3-ol (6a). To a cold (−50°C) solution of **20** (153 mg, 0.67 mmol) in dry THF (1.53 ml) was added a 1.64 M solution of *n*-BuLi in hexane (1.43 ml, 2.35 mmol) under stirring, and stirring was continued at −50 °C for 1 h. To this mixture was added a solution of TBS-Cl (252 mg, 1.68 mmol) in dry THF (0.504 ml). After being stirred at 8 °C for 12 h, the mixture was neutralized (pH=7) with 0.12 M HCl under ice-cooling, and then extracted with ethyl acetate (3× 4.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was flushchromatographed on silica gel (10 g) with 30:1 chloroform-acetone to afford **6a** (140.4 mg, 81%) as a colorless syrup: R_f=0.43 (15 : 1 chloroform-acetone); $[\alpha]_D^{31}$ −2.7°, $[\alpha]_{365}^{31}$ −12.5° (*c* 0.83); ^{1}H NMR (90 MHz) δ=0.83 (9H, s, *t*-Bu), 1.20—1.50 (1H, m, H-3), 2.53 (1H, dd, H-1, J_{gem}=4.8, $J_{1,2}$=2.7 Hz), 2.77 (1H, dd, H-1, $J_{1,2}$=4.8 Hz), 2.90—3.20 (1H, m, H-2), 3.37 (1H, d-like, OH, *J*=3.6 Hz), 3.80—4.29 (2H, m, $SiOCH_2$), 4.30—4.60 (1H, m, H-4), 5.18 (1H, ddd, H-6, $J_{6,5}$=10.5 Hz), 5.28 (1H, ddd, H-6, $J_{6,5}$=18.0 Hz), 5.93 (1H, ddd, H-5, $J_{5,4}$=4.8 Hz).

Preparation of (6b+6b′) via 23 from 22. By the procedure described in the preparation of **17**, the aldehyde **23** (6.86 g, 91.7% from **21**) was obtained from **22** (9.36 g, 18.5 mmol) after silica-gel chromatography with 6:1 hexane-ethyl acetate ($[\alpha]_D^{30}$ +21.8° (*c* 1.24)). A 4 M solution of methylsulfinylmethanide anion in DMSO (17.0 ml, 68.2 mmol) prepared from NaH and DMSO[10] was added to a stirred suspension of methyltriphenylphosphonium bromide (24.4 g, 68.2 mmol) in dry ether (274 ml) under Ar at 25 °C. The mixture was stirred at 25 °C for 15 min, and to the resulting yellow suspension of ylide, a solution of **23** (6.86 g, 17.0 mmol) in dry ether (137 ml) was added dropwise in a 20-min period. After being stirred at 25 °C for 20 min, the reaction mixture was poured into ice-water (500 ml), and the mixture was extracted with ether (3×500 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (340 g) with 12 : 1 hexane-ethyl acetate to afford the vinylic compound (5.51 g, 80.7%) as a colorless syrup which was treated with 75% aqueous acetic acid at 50 °C for 5 h to give a sample of **19** (3.39 g, 100%) after silica-gel chromatography with 1 : 2 hexane-ethyl acetate. By the procedure described in the preparation of **20**, the sample of **19** (349 mg) was epoxidated to afford a sample of **20** (230 mg, 71%) after silica-gel chromatography with 2 : 1 hexane-ethyl acetate. To a solution of the sample of **20** (42.7 mg, 0.187 mmol) in dry DMF (427 μl) were added imidazole (63.7 mg, 0.935 mmol) and TBS-Cl (113 mg, 0.748 mmol) at 0 °C. After being kept at 25 °C for 3 h, the reaction mixture was poured into ice-water which was extracted with ethyl acetate (3×1 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (3.2 g) with 6 : 1 hexane-ethyl acetate to give a colorless syrup (70.2 mg). To a solution of this syrup (64.1 mg, 0.187 mmol) in dry THF (641 μl) was added 1.07 M *n*-BuLi in hexane (437 μl, 0.468 mmol) at −60 °C. After being stirred at −60 °C for 15 min, a solution of SEM-Cl (99.3 μl, 0.561 mmol) in dry THF (497 μl) was added to the reaction mixture, which was stored at 0 °C for 16 h. Saturated aqueous NH_4Cl (2.0 ml) was added to the reaction mixture, and was extracted with ethyl acetate (3×2.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. A mixture of the residual syrup (104 mg), dry THF (727 μl), and *n*-Bu_4NF (374 μl, 0.374 mmol) was stored at 0 °C for 4 h. The reaction mixture was poured into ice-water which was extracted with ethyl acetate (3×2.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (1.5 g) with 5 : 2 hexane-ethyl acetate to afford an inseparable 3 : 1 mixture of **6b** and **6b′** (43.1 mg, 84% from **20**) as a colorless syrup: R_f=0.20 (3 : 1 hexane-ethyl acetate); ^1H NMR (400 MHz, $CHCl_3$, δ=7.26) δ=0.88—0.93 (2H, m, $SiCH_2$), 1.42—1.48 (0.25H, m, H-3), 1.53—1.61 (0,75H, m, H-3), 2.62 and 2.59—2.63 (1H, dd and m, H-1, $J_{1,2}$=3.0, J_{gem}=4.0 Hz), 2.81 (1H, dd, H-1, $J_{1,2}$=4.0 Hz), 2.87—2.94 and 2.97—3.02 (0.75H and 0.25H, br-s, OH), 3.05—3.39 (1H, m, H-2), 3.57—3.63 (2H, m, $SiCH_2C\underline{H}_2O$), 3.72 and 3.78 (1.5H, ABX , $SEMOC\underline{H}_2$, J_{AB}=9.6, J_{AX}=J_{BX}=4.5 Hz), 3.77 and 3.84 (0.5H, ABX, $SEMOC\underline{H}_2$, J_{AB}=9.6, J_{AX}=J_{BX}=4.5 Hz), 4.30—4.35 (0.25H, m, H-4), 4.37—4.42 (0.75H, m, H-4), 4.66 (2H, s, OCH_2O), 5.15—5.20 (1H, m, H-6), 5.28—5.35 (1H, m, H-6), 5.88 (0.25H, ddd, H-5, $J_{5,4}$=5.9, $J_{5,6}$=10.7, 16.6 Hz), 5.90 (0.75H, ddd, H-5, $J_{5,4}$=5.9, $J_{5,6}$=10.7, 16.6 Hz).

Conversion of (6b+6b′) into 24. To a solution of bis(methylthio)methane (173 μl, 1.73 mmol) in dry THF (1.73 ml) was added 1.53 M *n*-BuLi in hexane (1.13 ml, 1.73 mmol) at −40 °C. The mixture was stirred at −20 °C for 2 h, and a solution of (**6b+6b′**) (95.1 mg, 0.346 mmol) in dry THF (285 μl) was added to the mixture at −20 °C under stirring. After the mixture was stirred at −20 °C for 0.5 h, to this was added saturated aqueous NH_4Cl, and the mixture was extracted with ethyl acetate (3×4.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel with 3 : 1 hexane-ethyl acetate to give the dimethyl dithioacetal compound [122 mg, 93%, R_f=0.58 (2 : 1 hexane-ethyl acetate]. By the procedure described in the preparation of **36** from **35**, the dithioacetal (122 mg) was isopropylidenated to afford a sample of acetonide [123 mg, 91.4%, R_f=0.37 (10 : 1 hexane-ethyl acetate)] after chromatography. The acetonide (21.2 mg) was dedithioacetalized by the procedure described in the preparation of **39** from **36** to give a crude sample of aldehyde which was purified by silica-gel chromatography to afford pure aldehyde [7.2 mg, 42%, R_f=0.40 (5 : 1 hexane-ethyl acetate)] as a main product. A solution of the aldehyde (3.4 mg) in 0.02% methanolic HCl (60 μl, pH=4) was kept at 25 °C for 50 min. The mixture was neutralized (pH 7) with $NaHCO_3$ and filtered. The filtrate was evaporated and the residue was chromatographed on silica gel (0.5 g) with 2 : 1 hexane-ethyl acetate to give a cyclic methyl acetal derivative (2.6 mg, 83%) as a mixture of anomers [R_f=0.62, 0.56 (15 : 1 chloroform-methanol)]. Acetylation of this sample of acetal (2.6 mg) with Ac_2O (1.6 μl) and DMAP (3.0 mg) in CH_2Cl_2 (78 μl) at 25 °C for 17 min afforded the acetate **24** (2.9 mg) after chromatography (R_f=0.63, 8 : 1 benzene-acetone). This sample revealed to be a 6 : 4 mixture of **24α** and **24β** by its 400 MHz ^1H NMR spectrum ($CHCl_3$, δ=7.26): δ=0.017 (5.4H, s, Me_3Si of **24α**), 0.021 (3.6H, s, Me_3Si of **24β**), 0.86—0.94 (4H, m, $SiCH_2$), 1.45—1.68 (1.4H, m, H-4 and H-2 of **24β**), 0.66 (0.6H, dd, H-2 of **24α**, J_{gem}=12.8, $J_{2,1}$=3.4, $J_{2,3}$=11.5 Hz), 2.03 (1.8H, s, Ac of **24α**), 2.05 (1.2H, s, Ac of **24β**), 2.25 (0.6H, dd, H-2 of **24α**, $J_{2,1}$=ca. 1, $J_{2,3}$=4.8 Hz), 2.34 (0.4H, dd, H-2 of **24β**, $J_{2,1}$=2.0, $J_{2,3}$=5.8 Hz), 3.34 (1.8H, s, MeO of **24α**), 3.50 (1.2H, s, MeO of **24β**), 3.46—3.59 (4H, m, $SiCH_2$-$C\underline{H}_2OCH_2OC\underline{H}_2$), 3.98 (0.4H, dd, H-5 of **24β**, $J_{5,4}$=10.0, $J_{5,6}$=6.7 Hz), 4.28 (0.6H, dd, H-5 of **24α**, $J_{5,4}$=10.0, $J_{5,6}$=6.4 Hz), 4.43 (0.4H, H-1 of **24β**, $J_{1,2}$=10.0 Hz), 4.52 and 4.58 (0.8H, ABq, OCH_2O of **24β**, J_{gem}=6.4 Hz), 4.53 and 4.60 (1.2H, ABq, OCH_2O of **24α**, J_{gem}=6.4 Hz), 4.83 (0.6H, dd, H-1 of **24α**), 5.14 (0.4H, ddd, H-3 of **24β**, $J_{3,2}$=4.8, $J_{3,4}$=11.5 Hz), 5.28 (1H, ddd, H-7, $J_{7,6}$=9.6, J_{gem}=1.6, $J_{7,5}$=1.6 Hz), 5.35 (0.6H, ddd, H-3 of **24α**, $J_{3,4}$=11.5 Hz), 5.37 (1H, dd, H-7, $J_{7,6}$=17.9, $J_{7,5}$=0 Hz), 5.85 (0.4H, ddd, H-6 of **24β**, $J_{6,5}$=9.9 Hz), 5.88 (0.6H, ddd, H-6 of **24α**, $J_{6,5}$=9.9 Hz).

Conversion of (6b+6b′) into 25 and 26. To an ice-cooled solution of (**6b+6b′**) (140 mg, 0.51 mmol) in dry ether (4.2 ml) was added $LiAlH_4$ (29.1 mg, 0.765 mmol) and the mixture was stirred at 25 °C for 35 min. After water (0.1 ml), 3 M NaOH (0.1 ml), water (0.3 ml), and 3 M NaOH (0.3 ml) were added in sequence with vigorous stirring at 0 °C, the mixture was filtered through a Celite, and the filter cake was washed with ether (3×10 ml). The filtrate and washings were evapo-

rated and the residue was taken up in ethyl acetate (10 ml), which was washed with water and saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (7.0 g) with 2:1 hexane-ethyl acetate to afford the diol (109 mg, 78%); R_f=0.32 (2:1 hexane-ethyl acetate). By the procedure described in the preparation of **36** from **35**, the diol (83.4 mg) was isopropylidenated to give an inseparable 3:1 mixture of **25** and **26** (78.5 mg, 82%) after silica-gel chromatography with 10:1 hexane-ethyl acetate: colorless syrup; ^{1}H NMR (400 MHz, $CHCl_3$, δ=7.26) δ=0.02 (9H, s, Me_3Si), 0.90—0.97 (2H, m, $SiCH_2$), 1.21 (2.25H, d, H-1 of **25**, $J_{1,2}$=6.8 Hz), 1.24 (0.75H, d, H-1 of **26**, $J_{1,2}$=6.8 Hz), 1.38 (4.5H, s, CMe_2 of **25**), 1.39 and 1.46 (1.5H, each s, CMe_2 of **26**), 1.54—1.58 (0.25H, m, H-3 of **26**), 1.88—1.96 (0.75, m, H-3 of **25**), 3.49 and 3.58 (1.5H, ABX, SEMOC$\underline{H}_2$ of **25**, J_{AX}=J_{BX}=5.1, J_{AB}=9.3 Hz), 3.57—3.64 (1.5H, OC$\underline{H}_2$CH$_2$Si of **25**), 3.65—3.72 (0.5H, m, OC$\underline{H}_2$CH$_2$Si of **26**), 3.66 and 3.75 (0.5H, ABX, SEMOC$\underline{H}_2$ of **26**, J_{AX}=J_{BX}=5.1, J_{AB}=9.3 Hz), 4.03 (0.75H, dddd, H-4 of **25**, $J_{3,4}$=$J_{4,5}$=6.7 Hz), 4.17 (1H, dq, H-2, $J_{2,3}$=6.7 Hz), 4.48 (0.25H, dddd, H-4 of **26**, $J_{4,3}$=2.2, $J_{4,5}$=4.8 Hz), 4.59—4.67 (2H, m, OCH_2O), 5.16 (0.25H, ddd, H-6 of **26**, $J_{6,5}$=11.2, $J_{6,4}$=J_{gem}=ca. 0.8 Hz), 5.17 (0.75H, ddd, H-6 of **25**, $J_{6,5}$=11.2, $J_{6,4}$=J_{gem}=ca. 0.8 Hz), 5.26 (0.25 H, ddd, H-6 of **26**, $J_{6,5}$=17.6, $J_{6,4}$=ca. 0.8 Hz), 5.28 (0.75H, ddd, H-6 of **25**, $J_{6,5}$=17.6, $J_{6,4}$=ca. 0.8 Hz), 5.87 (0.75H, ddd, H-5 of **25**), 5.94 (0.25H, ddd, H-5 of **26**).

(2*S*,3*R*,4*S*)-3-[(*t*-Butyldimethylsilyloxy)methyl]-1-(1,3-dithian-2-yl)-2,4-*O*-isopropylidene-5-hexene-2,4-diol (28). To a solution of 1,3-dithiane (47.3 mg, 0.390 mmol) in dry THF (473 ml) was added 1.64 M *n*-BuLi in hexane (237 µl, 0.390 mmol) at −40 °C. After being stirred at −20 °C for 2 h, to this mixture was added a solution of **6a** (20.2 mg, 0.078 mmol) in dry THF (60.6 µl) at −40 °C. After being stirred at −20 °C for 0.5 h, the reaction mixture was poured into cold water which was extracted with ethyl acetate (3×1 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel 30:1 chloroform-acetone to give **27** (23.9 mg, 81%). A sample of **27** (22 mg) was isopropylidenated by the procedure described in the preparation of **15** from **14** to afford **28** (22.4 mg, 92%) after silica-gel chromatography with 10:1 hexane-ethyl acetate: R_f=0.75 (3:1 hexane-ethyl acetate), $[\alpha]_D^{32}$ −1.22°, $[\alpha]_{546}^{32}$ −1.71° (*c* 0.82); ^{1}H NMR (90 MHz) δ=0.86 (9H, s, *t*-Bu), 1.32 and 1.36 (each 3H, each s, CMe_2), 1.6—2.1 (5H, m, 2×H-1,3, $SCH_2C\underline{H}_2$), 2.6—2.9 (4H, m, 2×SCH_2), 3.57 and 3.69 (2H, ABX, TBSOC$\underline{H}_2$, J_{AX}=J_{BX}=6.6, J_{AB}=9.9 Hz), 3.8—4.4 (3H, m, S-C$\underline{H}$-S, H-2,4), 5.0—5.4 (2H, m, 2×H-6), 5.95 (1H, ddd, H-5, $J_{5,4}$=5.7, $J_{5,6}$=9.9, 17.4 Hz).

Found: C, 57.20; H, 8.79%. Calcd for $C_{20}H_{38}O_3Si$: C, 57.37; H, 9.15%.

(3*S*,4*R*,5*S*)-4-[(*t*-Butyldimethylsilyloxy)methyl]-3,5-*O*-isopropylidene-1-trimethylstannyl-1,1-bis(methylthio)-6-heptene-3,5-diol (36). To a solution of diisopropylamine (0.931 ml, 6.64 mmol) in a 4:1 mixture of THF-HMPA (16.5 ml) was added 1.64 M *n*-BuLi in hexane (4.05 ml, 6.64 mmol) at 0 °C. After being stirred at 0 °C for 15 min, to this mixture was added rapidly with stirring under Ar a solution of [bis(methylthio)methyl]trimethylstannane (1.64 g, 6.04 mmol) in dry THF (3.3 ml) at −65 °C and stirring was continued at −40 °C for 0.5 h. A solution of **6a** (130 mg, 0.503 mmol) in dry THF (390 µl) was then introduced and the mixture was stirred at −40 °C for 23 min. Then saturated aqueous NH_4Cl was added to the mixture which was extracted with ethyl acetate (3×20 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The oily residue was chromatographed on silica gel (40 g) with 8:1 hexane-ethyl acetate to afford **35** (190 mg, 71%) as a colorless syrup. To a solution of **35** (190 mg, 0.349 mmol) in dry CH_2Cl_2 (1.9 ml) was added 2-methoxy-1-propene (0.20 ml, 2.10 mmol) and PPTS (13.2 mg, 0.0524 mmol) at 0°C. After being stirred at 24 °C for 3 h, the reaction mixture was diluted with ethyl acetate (7.0 ml) and was washed with water and saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (18.5 g) with 15:1 hexane-ethyl acetate to give **36** (173 mg, 87%) as a colorless syrup: R_f=0.70 (10:1 hexane-ethyl acetate); $[\alpha]_D^{30}$ +8.8°, $[\alpha]_{435}^{30}$ +11.0° (*c* 0.82); ^{1}H NMR (400 MHz, δ ($CHCl_3$)=7.26) δ=0.055, 0.063 (each 3H, each s, $SiMe_2$), 0.24 (9H, s, Me_3Sn), 0.90 (9H, s, *t*-BuSi), 1.33, 1.46 (each 3H, each s, CMe_2), 1.80 (1H, dddd-like, H-4), 1.99, 2.03 (each 3H, each s, 2×SMe), 2.26 (1H, dd, H-2, $J_{2,3}$=2,4, J_{gem}=15.1 Hz), 2.39 (1H, dd, H-2, $J_{2,3}$=10.3 Hz), 3.62 and 3.78 (2H, ABX, C$\underline{H}_2$OTBS, J_{AX}=J_{BX}=5.4, J_{AB}=10.3 Hz), 4.10 (1H, dddd-like, H-5, $J_{5,4}$=$J_{5,6}$=6.4 Hz), 4.22 (1H, ddd, H-3, $J_{3,4}$=3.9 Hz), 5.16 (1H, ddd, H-7, J_{gem}≒$J_{7,5}$≒1.5, $J_{7,6}$=10.7Hz), 5.23 (1H, ddd, H-7, $J_{7,5}$≒1.0, $J_{7,6}$=17.6 Hz), 5.99 (1H, ddd, H-6).

Found: C, 46.64; H, 7.92%. Calcd for $C_{22}H_{46}O_3SiS_2Sn$: C, 46.40; H, 8.14%.

Preparation of Deuterio Product 38. To a solution of **36** (29.2 mg, 0.0495 mmol) in a 3:1 mixture of dry THF-HMPA (117 µl) were added a 1.5 M solution of *n*-BuLi in hexane (66.0 µl, 0.0991 mmol) and immediately D_2O (1.0 ml) at −20 °C. The reaction mixture was warmed up to room temperature and extracted with ethyl acetate (3×1 ml). The extracts were washed with saturated aqueous NaCl, dried and evaporated. The residue was chromatographed on silica gel (1.6 g) with 12:1 hexane-ethyl acetate to afford **38** (17.1 mg, 84.7%) as a colorless syrup: R_f=0.67 (5:1 hexane-ethyl acetate).

Preparation of Deuterio Aldehyde 39. To a mixture of NBS (40.6 mg, 0.228 mmol), $AgNO_3$ (40.8 mg, 0.240 mmol), 2,4,6-trimethylpyridine (60.3 µl, 0.456 mmol), and 85% aqueous acetonitrile (0.62 ml) was added a solution of **38** (15.5 mg, 0.380 mmol) in acetonitrile (46.5 µl) at room temperature. After being stirred at room temperature for 20 min, to the stirred mixture were added in sequence saturated aqueous Na_2SO_3 (0.11 ml), saturated aqueous $NaHCO_3$ (0.11 ml), and saturated aqueous NaCl (0.11 ml) in each 1-min period. Then, this mixture was filtered and the filter cake was washed with acetonitrile (3×2.0 ml). The filtrate and washings were extracted with ethyl acetate (3×2.0 ml), and the extracts were washed with water, saturated aqueous K_2SO_4, $NaHCO_3$, and NaCl, dried, and evaporated. The residue was chromatographed on silica gel (1.7 g) with 5:1 hexane-ethyl acetate to afford **39** (5.0 mg, 43.6%) as a colorless syrup.

Formation of 40 by Coupling of 36 and 32. To a solution of **36** (18.4 mg, 0.0312 mmol) in dry 3:1 THF-HMPA (98.8 µl) was added 1.5 M *n*-BuLi in hexane (25.0 µl, 0.0375 mmol) at −30 °C, and immediately a solution of **32** (6.3 mg, 0.0208 mmol) in dry THF (18.9 µl) was added. After being stirred at 0 °C for 5 h, saturated aqueous NH_4Cl (1.0 ml) was added to the reaction mixture which was extracted with ethyl acetate (3×1.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (1.5 g) with 8:1 hexane-ethyl acetate to afford a mixture of **40** and **32** (8.4 mg) as a colorless syrup

(R_f=0.44, 20 : 1 benzene-ethyl acetate). The ratio of **40** and **32** was determined to be 5 : 7 by ^{1}H NMR (90 MHz).

Preparation of 41 by Coupling of 36 and 33. To a solution of **36** (15.0 mg, 0.0254 mmol) in dry 3 : 1 THF-HMPA (60.0 μl) was added 1.5 M *n*-BuLi in hexane (20.3 μl, 0.0305 mmol) at −30 °C, and immediately a solution of **33** (9.2 mg, 0.0177 mmol) in dry THF (27.6 μl) was added. After being stirred at 25 °C for 40 min, saturated aqueous NH_4Cl (1.0 ml) was added to the reaction mixture which was extracted with ethyl acetate (3×1 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (1.4 g) with 10 : 1 hexane-ethyl acetate to afford **41** (10.1 mg, 76%) as colorless syrup: R_f=0.44 (5 : 1 hexane-ethyl acetate); ^{1}H NMR (90 MHz) δ=0.92 (18H, s-like, 2×*t*-Bu), 1.33, 1.38, and 1.47 (total 12H, each s, 2×CMe_2), 1.4—2.3 (7H, m, H-10, 2×H-8, 2×H-6, 2×H-4), 1.97 and 2.03 (each 3H, each s, 2×SMe), 3.38 (3H, s, OMe), 3.4—4.3 and 4.4—4.6 (total 13H, each m, H-2,3,5,9,11, 2×H-1, CH_2OTBS, OCH_2CH_2O), 4.74 and 4.88 (2H, ABq, OCH_2O, *J*=6.9 Hz), 5.0—5.4 (2H, m, 2×H-13), 5.8—6.3 (1H, m, H-12).

(3*S*,5*R*,8*R*,9*S*,11*S*,15*S*,16*R*,17*S*)-16-*O*-[(*t*-Butyldimethylsilyloxy)methyl]-3,5 : 8,9 : 15,17-tri-*O*-isopropylidene-1-*O*-(4-methoxybenzyl)-11-*O*-[(2-methoxyethoxy)methyl]-13,13-bis(methylthio)-18-nonadecene-1,3,5,8,9,11,15,17-octol (42). To a stirred solution of **36** (24.7 mg, 0.0434 mmol) in a 3 : 1 mixture of dry THF and HMPA (91.4 μl) was added rapidly 1.64 M *n*-BuLi in hexane (32.0 μl, 0.0521 mmol) at −29 °C. Immediately, to the resulting brown colored mixture was added a solution of **2** (20.6 mg, 0.0304 mmol) in dry THF (61.8 μl) rapidly. Then, saturated aqueous NH_4Cl was added to the yellow reaction mixture which was extracted with ethyl acetate (5×1.0 ml). The extracts were washed with saturated aqueous NaCl, dried, and evaporated to a syrup, which was chromatographed on silica gel (2.9 g) with 3 : 1 hexane-ethyl acetate to afford **42** (24.3 mg, 84%) as a colorless syrup: R_f=0.55 (3 : 1 hexane-thyl acetate); $[\alpha]_D^{32}$ +11.1° (*c* 0.90); ^{1}H NMR (400 MHz, δ($CHCl_3$)=7.26) δ=0.055, 0.061 (each 3H, each s, $SiMe_2$), 0.90 (9H, s, *t*-BuSi), 1.15 (1H, ddd, H-4, $J_{4,3}\fallingdotseq J_{4,5}\fallingdotseq J_{gem}\fallingdotseq$11.5 Hz), 1.32, 1.33, 1.347, 1.355, 1.40, 1.47 (each 3H, each s, 3×CMe_2), 1.97, 2.03 (each 3H, each s, 2×SMe), 1.25—2.15 (14H, m, 2×H-2, H-4, 2×H-6, 2×H-7, 2×H-10, 2×H-12, 2×H-14, H-16), 3.37 (3H, s, MeO of MEM), 3.45—3.67 (7H, m), 3.80 (3H, s, MeO of MPM), 3.73—3.88 (4H, m), 3.97—4.10 (3H, m), 4.41 and 4.43 (2H, ABq, OCH_2Ar, *J*=14.4 Hz), 4.45—4.51 (1H, m), 4.73 and 4.93 (2H, ABq, OCH_2O of OMEM, *J*=7.3 Hz), 5.16 (1H, ddd, H-19, $J_{19,18}$=10.7, $J_{gem}\fallingdotseq J_{19,17}\fallingdotseq$1.5 Hz), 5.25 (1H, ddd, H-19, $J_{19,18}$=17.6, $J_{19,17}\fallingdotseq$1.5 Hz), 5.97 (1H, ddd, H-18, $J_{18,17}$=5.9 Hz), 6.87, 7.25 (each 2H, each ddd-like, Ar).

Found: C, 61.26; H, 8.82%. Calcd for $C_{49}H_{86}O_{12}SiS_2$: C, 61.34; H, 9.03%.

(3*S*,4*S*,5*S*,9*S*,11*R*,12*R*,15*R*,17*S*)-4-[(*t*-Butyldimethylsilyloxy)methyl]-1,3,5,9,11,12,15,17,19-nonahydroxy-3,5 : 11,12 : 15,17-tri-*O*-isopropylidene-19-*O*-(4-methoxybenzyl)-9-*O*-[(2-methoxyethoxy)methyl]-7-nonadecanone (1). To a solution of dicyclohexylborane (0.406 mmol) in dry THF (0.228 ml) was added a solution of **42** (77.9 mg, 0.0812 mmol) in dry THF (0.234 ml) at 0 °C under Ar. After being stirred at 23 °C for 45 min, the reaction mixture was diluted with water (0.463 ml), and added in sequence 3 M aqueous NaOH (0.135 ml, 0.406 mmol) and 30% H_2O_2 (0.122 ml, 1.22 mmol) at 0 °C. After being stirred at 23 °C for 1 h, the reaction mixture was extracted with chloroform (3×1.0 ml). The extracts were washed with saturated aqueoud NaCl, dried, and evaporated. The residue was chromatographed on silica gel (7.9 g) with 2 : 1 hexane-ethyl acetate to afford **43** (73.2 mg, 92%) as a colorless syrup. To a solution of **43** (73.2 mg, 0.0749 mmol) in 80% aqueous acetone (2.6 ml) was added HgO (71.4 mg, 0.330 mmol) and $HgCl_2$ (89.5 mg, 0.330 mmol) at 23 °C. After being stirred at 23 °C for 25 min, the reaction mixture was filtered through a Celite and the filter cake was washed with acetone. The combined filtrate and washings were concentrated to remove acetone. The aqueous residue was extracted with chloroform (3×4.0 ml) and extracts were washed with aqueous 10% KI (2×5.0 ml), saturated aqueous NaCl, dried, and evaporated. The residue was chromatographed on silica gel (6.7 g) with 1 : 1 hexane-ethyl acetate to afford **1** (54.9 mg, 81.6%) as a colorless syrup: R_f=0.42 (1 : 1 hexane-ethyl acetate); $[\alpha]_D^{31}$ +6.5°, $[\alpha]_{435}^{31}$ +11.2° (*c* 0.68); IR($CHCl_3$) 1710 cm^{-1} (C=O); ^{1}H NMR 400 MHz, δ($CHCl_3$)=7.26) δ=0.05, 0.055 (each 3H, each s, $SiMe_2$), 0.89 (9H, s, *t*-Bu), 1.15 (1H, ddd, H-16, $J_{16,17}\fallingdotseq J_{16,15}\fallingdotseq J_{gem}\fallingdotseq$11.0 Hz), 1.318, 1.324, 1.33, 1.34, 1.35, 1.40 (each 3H, each s, 3×CMe_2), 1.42—1.95 (12H, m, 2×H-2, H-4, 2×H-10, 2×H-13, 2×H-14, H-16, 2×H-18), 2.53 (1H, br-t-like, OH), 2.54 (1H, dd, *J*=3.8, 16.8 Hz), 2.68 (1H, dd, *J*=9.6, 16.8 Hz), 2.72 and 2.80 (each 1H, each dd, *J*=6.4 and 16.8 Hz), 3.38 (3H, s, MeO of MEM), 3.46—3.87 (10H, m), 3.80 (3H, s, MeO of MPM), 3.97—4.05 (1H, m), 4.24—4.31 (1H, m), 4.41 and 4.44 (2H, ABq, OCH_2Ar, *J*=12.8 Hz), 4.43—4.49 (1H, m), 4.71 and 4.74 (2H, ABq, OCH_2O of MEM, *J*=6.4 Hz), 6.88 and 7.25 (each 2H, each ddd-like, Ar).

Found: C, 62.75; H, 8.79%. Calcd for $C_{47}H_{82}O_{14}Si$: C, 62.78; H, 9.19%.

We are grateful to the Institute of Microbial Chemistry for the generous support of our program. The present work was partially supported by a Grant-in Aid for Scientific Research No. 60470091 from the Ministry of Education, Science and Culture and by the Japan Antibiotics Research Association (Japan) Research Grant. We would like to thank Dr. Masaya Nakata for 400 MHz ^{1}H NMR spectral analyses, and Mr. Hisao Arita for elemental analyses.

12) The short-lived characteristic of **29c** was confirmed by the fact that a sample of the lithium derivative **37** generated in a moment from **36** with *n*-BuLi in THF (see text) changed rapidly at −25 °C into the protonated dithioacetal compound by the proton-abstraction probably from the solvent (THF). The unusually increased kinetic basicity as seen in the lithium compounds, **29c** and **37**, may be attributed to their extremely destabilized carbanion structures which may inherently exist in some complex polyoxygenated d^3-anions.[18,19]

13) The coupling of heptanal and **28** using *t*-BuLi instead of *n*-BuLi was also unsuccessful, affording only a complex mixture of side products formed by the reaction of **28** and *t*-BuLi.

17) Unfortunately, for the present, this procedure can not be adapted for large scale preparation of **42**. When the amount of **36** was greater than 25 mg, the yield of **42** sharply lowerd probably due to the short-lived characteristic of **37**.

Clay Montmorillonite: An Efficient, Heterogeneous Catalyst for Michael Reactions of Silyl Ketene Acetals and Silyl Enol Ethers with α,β-Unsaturated Carbonyl Compounds

Motomitsu KAWAI, Makoto ONAKA,* and Yusuke IZUMI*
Department of Synthetic Chemistry, Faculty of Engineering, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464
(Received December 28, 1987)

The Michael addition of silyl ketene acetals to α,β-unsaturated esters (enoates) is investigated. The reaction is catalyzed by clay montmorillonite (solid acid) most effectively among various, homogeneous and heterogeneous acid promoters. The montmorillonite-catalyzed reaction has several prominent features: (1) Not only α- or β-monosubstituted acrylates but also α,β- or β,β-disubstituted acrylates are applicable. (2) The highly regioselective 1,4-addition to a polyenoate is achievable. (3) The Michael adduct can be obtained in the form of a labile silyl ketene acetal owing to a simple work-up procedure. The Michael reaction of a silyl enol ether and silyl ketene acetals with α,β-unsaturated ketones (enones) is also described.

The Michael addition of an enolate to an α,β-unsaturated carbonyl system is one of the most important reactions for carbon-carbon bond formation.[1] However, its use in organic syntheses is occasionally restricted owing to a concurrent 1,2-addition reaction and polymerization of α,β-unsaturated carbonyl compounds. A new methodology to overcome these problems has been devised by the use of lithium enolates.[2,3] Another approach is to use silyl enol ethers and silyl ketene acetals as enolates. The Michael reaction of the silyl enol ethers with α,β-unsaturated ketones (enones) is generally performed with the aid of a stoichiometric amount of Lewis acid to afford 1,5-dicarbonyl compounds.[4,5] When the reaction is conducted thermally in acetonitrile,[6] under high pressure,[7] or by the use of $(Me_2N)_3S^+Me_3SiF_2^-$ [8] or $Ph_3C^+ClO_4^-$,[9] the intermediate adducts are isolable in the form of synthetically valuable silyl enol ethers.

Concerning the Michael reaction of a silyl enol ether with an α,β-unsaturated ester (enoate), the reaction with acrylate was the only example with the yield being not so high.[4] The reaction of fumarate or crotonate with a cyclic silyl enol ether gave a [2+2]cycloaddition product.[10] The single example of Michael reaction of a silyl ketene acetal with an enoate was reported in the study of "Group Transfer Polymerization (GTP)" by the use of $(Me_2N)_3S^+Me_3SiF_2^-$ [11] or Lewis acids.[12] One-to-one addition of a silyl ketene acetal to an enoate has not been reported.

Recently we have shown that clay montmorillonite (sheet silicate) is an efficient, heterogeneous acid catalyst for the aldol reaction of silyl enol ethers[13] or silyl ketene acetals[14] with aldehydes or acetals. We have also demonstrated that the Michael reaction of silyl ketene acetals with enoates can be effectively accomplished by the use of clay montmorillonite.[15,16] In this paper, we provide a detailed description of the Michael reaction catalyzed by montmorillonite, and show its scope and limitations.

Results and Discussion

In the presence of aluminium ion-exchanged montmorillonite (Al-Mont),[17] the reactions of silyl ketene acetals derived from propionates with croton-

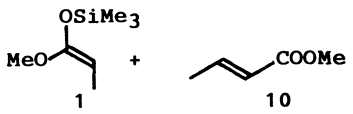
ate, cinnamate, sorbate, or fumarate were examined and the results are listed in Table 1. The reactions proceeded at low temperatures. After the reactions were complete, the solid catalyst of Al-Mont was easily removed through a Celite pad. Thereby the Michael products were isolated by simple distillation in the form of a trimethylsilyl ketene acetal. These products showed strong IR absorption around 1670 cm^{-1} ($\nu_{C=C}$), which is characteristic of the silyl ketene acetal structure.[18]

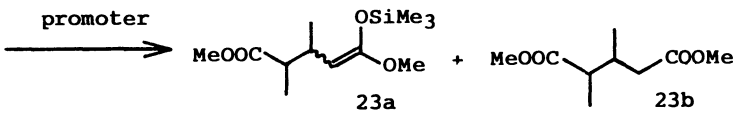
After the hydrolysis of the products with dilute HCl, the stereochemical assignment was made in comparison with authentic samples prepared via the conjugate addition of the corresponding lithium enolates.[3] Unfortunately the diastereoselectivities were low to moderate (1 : 1—3 : 1).

It is noteworthy that the present Michael addition to a polyenoate occurred regioselectively in the 1,4-fashion. In the case of methyl sorbate (Entry 4), the preferential 1,4-addition (98%) over 1,6-addition (2%) is notable because the addition of a lithium enolate gave a mixture (70 : 30) of 1,4- and 1,6-adducts in low yield (total yield 37%).[19]

For demonstrating the utility of the Al-Mont catalyst, representative, homogeneous acid promoters were employed for the same reaction (Table 2, Entries 2—6).[20] Compared with Al-Mont (Table 2, Entry 1), these promoters gave lower yield of the Michael product (**23a** or **23b**) due to deactivation during the reaction. For example, when Ph_3CClO_4 was added to the mixture of a silyl ketene acetal and an enoate in CH_2Cl_2, the yellow color of the trityl cation (Ph_3C^+) immediately disappeared at −78 °C, showing that Ph_3CClO_4 was destroyed.[21] In the case of CF_3SO_3H and $CF_3SO_3SiMe_3$, the Michael product was also isolable in the form of a silyl ketene acetal after the reaction mixture was

Table 2. The Michael Reaction of **1** with **10**[a]





Entry	Promoter (mol%)	Temp/°C (Time/h)	Product[b]	Yield/%	Syn : Anti
1	Al-Mont[c]	−78(0.5)	**23a**	84	27 : 73

a) **1** (1 mmol), **10** (1 mmol), CH_2Cl_2 (4 ml). b) Procedure for the isolation of products is described in the experimental section. c) Al-Mont (0.2 g) was used. d) The promoter was added in two portions.

quenched with organic amine (Entries 2 and 3).

In order to investigate the scope and limitations of the montmorillonite-catalyzed Michael reactions, we employed variously substituted silyl ketene acetals and enoates (Table 3). Concerning enoates, α- or β-monosubstituted and α,β- or β,β-disubstituted acrylates are applicable. Acrylate is the only case giving a Michael adduct in low yield and polymeric by-products (Entry 1). It should be noted that α,β- and β,β-disubstituted acrylates are reactive by the present method (Entries 3—5), while a lithium enolate of an ester is reported to have no reactivity to these disubstituted acrylates.[3a] In contrast to a silyl ketene acetal, a silyl enol ether is not reactive to enoates in the presence of Al-Mont (Entry 8).

Even though the Al-Mont catalyst was dried at 120 °C/0.5 Torr (1 Torr=133.322 Pa) prior to use,[22] a small amount of water remained in the interlayer of the catalyst. When the Michael reaction was carried out at low temperature, the product could be obtained in the form of a labile silyl ketene acetal without being hydrolyzed. However, in some cases of a sterically hindered substrate a higher reaction temperature was required, and the product was partly hydrolyzed with the water in Al-Mont (Table 3, Entries 4 and 6).

The tandem reaction[23] of the Michael addition of a silyl ketene acetal to an enoate followed by the aldol reaction with an aldehyde was also successful to give a corresponding product in good yield without isolation of an intermediate, the silyl ketene acetal (Scheme 1).

The Michael addition to enones was also achieved by the use of Al-Mont (Table 4). It is well-known that enones are more reactive than enoates in the 1,4-addition of alkylcopper reagents.[24] A similar trend was observed in the present Al-Mont-catalyzed reaction since enones reacted not only with silyl ketene acetals but also with a silyl enol ether in the 1,4-fashion.[25] The products were obtained in the form of a silyl enol ether. The behavior of diastereoselection of the reaction was similar to that of the reactions promoted by $TiCl_4$[5] and Ph_3CClO_4.[9b]

In conclusion, in spite of under heterogeneous con-

Table 3. The Michael Reactions of Enol Silanes with Enoates Catalyzed by Al-Mont[a]

Entry	Nucleophile	Acceptor	Temp/°C (Time/h)	Product	Yield/%

ditions, solid montmorillonite can facilitate the Michael additions of silyl ketene acetals and silyl enol ethers to enoates and enones. The montmorillonite proved to be an alternative to conventional, moisture-sensitive homogeneous acids which are frequently troublesome in manipulation and work-up.

Experimental

Measurement. ^1H NMR spectra were recorded in $CDCl_3$ with a Hitachi R-600 (60 MHz) spectrometer. ^{13}C NMR spectra were recorded in C_6D_6 with a JEOL JNM GX-500 (125 MHz) spectrometer. Infrared spectra were recorded in CCl_4 on a JASCO IRA-2 spectrometer. Analytical gas-liquid chromatography (GC) was done with a Shimadzu GC-8A instrument with a flame ionization detector and nitrogen carrier gas. The following capillary columns were used for analysis: OV-1 Bonded, 25 m×0.25 mm; PEG-HT Bonded, 25 m×0.25 mm. The flow rate of carrier gas was 2 ml min^{-1} (1.0 kg cm^{-2}). The following packed column was also used for monitoring the reaction: Silicone SE-30 on Uniport B, 1 m×3 mm.

Solvents and Reagents. Preparation of Aluminium ion-exchanged montmorillonite (Al-Mont) was previously described.[13)] Dichloromethane was distilled from P_2O_5 and stored over Molecular Sieves 3A. 1,2-Dimethoxyethane (DME) and diethyl ether were distilled from $LiAlH_4$ prior to use. $CF_3SO_3SiMe_3$ was distilled from CaH_2. $ZnBr_2$ was dried over flames at ca. 350 °C/0.5 Torr for 10 min. α,β-Unsaturated carbonyl compounds **10,13,15—18,21**, benzaldehyde, and CF_3SO_3H were purified by distillation. $BF_3 \cdot OEt_2$, **12**, and **22** were used without purification. Silyl enol ethers **7**,[26a)] **8** ($E:Z$=83 : 17)[26b)] and **9**[27)] were prepared according to the literatures. Enoates **11**[28a)] and **14,19,20**[28b)] were prepared by means of the known methods.

Silyl Ketene Acetals. These compounds should be free from amine for the present Michael reaction. They were prepared according to a minor modification of the standard procedure reported earlier.[18a,27)] The preparation of **3** is illustrative. To a stirred solution of 50 ml of hexane and 27

ml (0.19 mol) of diisopropylamine at 0 °C was added 100 ml (0.16 mol) of a 15% solution of butyllithium in hexane under nitrogen atmosphere. Hexane and excess amine were removed under reduced pressure at 0 °C. The flask was refilled with N_2 and residual white solids were redissolved in 50 ml of THF at 0 °C. The solution was cooled to −78 °C and a solution of 18 ml (0.16 mol) of ethyl propionate in 20 ml of THF was added over 10 min. After the mixture was stirred for 10 min, a solution of 20 ml (0.16 mol) of chlorotrimethylsilane in 20 ml of THF was added over 10 min. The reaction mixture was warmed to 0 °C over 1 h, diluted with 300 ml of cold pentane. The mixture was washed 15 times with 300 ml of ice-cold water and then with a 1 M (1 M=1 mol dm^{-3}) $Cu(OAc)_2$ solution until the aqueous layer became neutral. The organic layer was then washed with saturated brine and dried over Na_2SO_4. The solvent was removed with a rotary evaporator and the resulting crude product was purified by distillation to give 14 g (0.08 mol) of **3** (50%): bp 76—78 °C/55 Torr; *E*:*Z*=80:20 (isomeric ratio was determined by GC). **1** (*E*:*Z*=60:40) and **2** (*E*:*Z*=89:11) were similarly prepared. **4** (*E*:*Z*=32:68),[27] **5**,[18a] and **6**,[27] were prepared according to the known methods.

General Procedure for Al-Mont-Catalyzed Michael Additions of Silyl Ketene Acetals and Silyl Enol Ethers to α,β-Unsaturated Carbonyl Compounds. Al-Mont (0.2 g) in a 20 ml round-bottomed flask was dried at 120 °C and 0.5 Torr for 3 h in an oil bath, and cooled to −78 °C under nitrogen. A solution of an α,β-unsaturated carbonyl compound (1 mmol) in CH_2Cl_2 (4 ml) was added. After the mixture being stirred for 1 min, a solution of a silyl ketene acetal or a silyl enol ether (1 mmol) in CH_2Cl_2 (1 ml) was added at −78 °C. Then the mixture was stirred under the conditions listed in tables. The reaction was monitored by GC (SE-30, 1 m). As work-up, cold ether (−50 °C, 5 ml) was added, the montmorillonite was filtered off through a Celite pad and washed with ether. The organic layer was evaporated and distilled on a Kugelrohr apparatus to yield the Michael product.

If necessary, the Michael products in the form of silyl ketene acetals or silyl enol ethers were hydrolyzed as follows. One drop of 1 M HCl was added to a solution of the Michael product in methanol, ethanol, or THF at room temperature. The mixture was stirred for 0.5 h and quenched with aqueous $NaHCO_3$. Organic product was extracted with CH_2Cl_2. The extract was washed with brine, dried over Na_2SO_4, and the product was isolated by distillation in quantitative yield.

General Procedure for Homogeneous Acid Promoter-Mediated Reactions (Table 2, Entries 2—6). To a stirred solution of **1** (1 mmol) and **10** (1 mmol) in CH_2Cl_2 (4 ml) was added an appropriate amount of an acid promoter in CH_2Cl_2 (1 ml) under a nitrogen atmosphere at −78 °C. When the reaction was slow, the temperature was raised and/or the acid promoter was supplemented. The mixture was quenched with a few drops of triethylamine, diluted with ether, and poured into an aqueous $NaHCO_3$ solution. Organic products were extracted with ether. The extract was washed with water and with brine, and dried over Na_2SO_4. The products were purified by distillation.

Stereochemistry of Products. In comparison with the authentic samples (**23b**,[3b] **25b**,[3b] **26c**,[3b] **27b**,[3b] **36b**,[5] and **40b**,[9b]) prepared according to the known procedures, the relative configuration (syn or anti)[29] of the Michael products in the hydrolyzed form (1,5-dicarbonyl compounds) was assigned. Diastereomer ratios were determined by GC. The geometrical isomers (*E* or *Z*) of the Michael products in the form of a silyl ketene acetal or a silyl enol ether were not assigned.

Methyl 5-Methoxy-2,3-dimethyl-5-trimethylsiloxy-4-pentenoate (23a). Bp 110 °C (bath temp)/0.5 Torr; ^{1}H NMR ($CDCl_3$) δ=0.19 and 0.24 (two s, 3:7 ratio, 9H, CH_3Si), 0.96 (d, *J*=6.4 Hz, 3H, $C\underline{H}_3CHCH{=}C$), 1.10 (d, *J*=6.4 Hz, 3H, $C\underline{H}_3CHC{=}O$), 2.1—3.0 (m, 2H, $C\underline{H}C\underline{H}C{=}O$), 3.3—3.6 (m, 1H, CH=C), 3.51 (s, 3H, $CH_3OC{=}C$), and 3.68 (s, 3H, $CH_3OC{=}O$); IR (CCl_4) 1670 (C=C) and 1732 (C=O) cm^{-1}.

Dimethyl 2,3-Dimethylglutarate (23b). Obtained from **23a** by hydrolysis. A mixture of diastereomers (syn:anti=27:73): ^{1}H NMR ($CDCl_3$) δ=0.9—1.0 (m, 3H, $C\underline{H}_3CHCH_2$), 1.15 (d, *J*=6.4 Hz, 3H, $C\underline{H}_3CHC{=}O$), 2.2—2.6 (m, 4H, $C\underline{H}_2C\underline{H}C\underline{H}$), and 3.70 (s, 6H, CH_3O); IR (CCl_4) 1735 (C=O) cm^{-1}; GC (PEG-HT, 100 °C) t_R 10.8 min (anti), 11.3 min (syn).

Isopropyl 5-Isopropoxy-2,3-dimethyl-5-trimethylsiloxy-4-pentenoate (24a). Bp 130 °C (bath temp)/0.3 Torr; ^{1}H NMR ($CDCl_3$) δ=0.20 and 0.22 (two s, 9H, CH_3Si), 0.95 (d, *J*=6.4 Hz, 3H, $C\underline{H}_3CHCH{=}C$), 1.19 (d, *J*=6.0 Hz, 3H, $C\underline{H}_3CH{=}O$), 1.22 (d, *J*=6.0 Hz, 12H, $(C\underline{H}_3)_2CH$), 2.0—2.9 (m, 2H, $C\underline{H}C\underline{H}C{=}O$), 3.31, 3.44, 3.55, and 3.71 (four d, *J*=9.2, 9.3, 9.4, and 9.3 Hz, 1H, CH=C), 4.0—4.5 (m, 1H, $(CH_3)_2C\underline{H}OC{=}C$), and 4.98 (septet, *J*=6.0 Hz, 6H, $(CH_3)_2C\underline{H}OC{=}O$); IR ($CCl_4$) 1672 (C=C) and 1732 (C=O) cm^{-1}.

Diisopropyl 2,3-Dimethylglutarate (24b). Obtained from **24a** by hydrolysis. A mixture of diastereomers (syn:anti=55:45). ^{1}H NMR ($CDCl_3$) δ=0.9—1.1 (m, 6H, $C\underline{H}_3CH$), 1.23 (d, *J*=6.0 Hz, 12H, $(C\underline{H}_3)_2CH$), 2.1—2.6 (m, 4H, $C\underline{H}_2C\underline{H}C\underline{H}$), and 5.01 (septet, *J*=6.0 Hz, 2H, $(CH_3)_2C\underline{H}$); IR (CCl_4) 1732 (C=O) cm^{-1}. Diastereomer ratio was determined in the form of **23b** after transesterification.

Methyl 5-Methoxy-2-methyl-3-phenyl-5-trimethylsiloxy-4-pentenoate (25a). Bp 150 °C (bath temp)/0.5 Torr; ^{1}H NMR ($CDCl_3$) δ=0.10, 0.13, 0.20, and 0.22 (four s, 9H, CH_3Si), 0.98, 1.00, 1.17, and 1.19 (four d, *J*=7.0, 7.0, 7.0, and 7.0 Hz, 3H, $C\underline{H}_3CH$), 2.4—3.1 (m, 1H, $CH_3C\underline{H}$), 3.4—4.1 (m, 8H, $C\underline{H}C{=}C$, $PhC\underline{H}$, and $C\underline{H}_3O$), and 7.24 (s, 5H, C_6H_5); IR (CCl_4) 1670 (C=C) and 1732 (C=O) cm^{-1}.

Dimethyl 2-Methyl-3-phenylglutarate (25b). Obtained from **25a** by hydrolysis. A mixture of diastereomers (syn:anti=61:39). ^{1}H NMR ($CDCl_3$) δ=0.96 and 1.18 (two d, 3:2 ratio, *J*=6.4, 7.0 Hz, 3H, $C\underline{H}_3CH$), 2.6—3.1 (m, 3H, $C\underline{H}_2CHPhC\underline{H}$), 3.2—3.6 (m, 1H, $PhC\underline{H}$), 3.51, 3.56, and 3.72 (three s, 6H, CH_3O), and 7.26 (s, 5H, C_6H_5); IR (CCl_4) 1735 (C=O) cm^{-1}; GC (PEG-HT, 150 °C) t_R 24.0 min (syn), 24.5 min (anti).

Methyl 5-Methoxy-2-methyl-3-(1-propenyl)-5-trimethylsiloxy-4-pentenoate (26a). Bp 135 °C (bath temp)/0.8 Torr; ^{1}H NMR ($CDCl_3$) δ=0.19 (s, 9H, CH_3Si), 1.10 (d, *J*=6.6 Hz, 3H, $C\underline{H}_3CHC{=}O$), 1.66 (d, *J*=4.2 Hz, 3H, $C\underline{H}_3CH{=}CH$), 2.2—2.7 (m, 1H, $CHC{=}O$), 2.9—3.2 (m, 1H, $C\underline{H}CHC{=}O$), 3.2—3.7 (m, $CH{=}COSi$), 3.51 and 3.53 (two s, 3H, $CH_3OC{=}C$), 3.66 and 3.68 (two s, 3H, $CH_3OC{=}O$), and 5.3—5.5 (m, 2H, $C\underline{H}{=}C\underline{H}$); IR ($CCl_4$) 1670 (C=C) and 1730 (C=O) cm^{-1}.

Dimethyl 2-Methyl-3-(1-propenyl)glutarate (26b). Obtained from **26a** by hydrolysis. A mixture of diastereomers (syn:anti=39:61): ^{1}H NMR ($CDCl_3$) δ=1.11 and 1.13 (two d, *J*=6.6 and 6.6 Hz, 3H, $C\underline{H}_3CHC{=}O$), 1.66 (d, *J*=5.0 Hz, 3H, $C\underline{H}_3CH{=}CH$), 2.3—2.8 (m, 4H, $C\underline{H}_2C\underline{H}C\underline{H}C{=}O$), 3.68 and 3.70 (two s, 6H, CH_3O), and 5.3—5.7 (m, $C\underline{H}{=}C\underline{H}$, 2H); IR

(CCl_4) 1730 (C=O) cm^{-1}; GC (PEG HT, 120 °C) t_R 10.6 min (anti), 10.9 min (syn).

Dimethyl 2-Methyl-3-propylglutarate (26c). Obtained from **26** by hydrogenation on Pd/C in methanol. A mixture of diastereomers: ^1H NMR ($CDCl_3$) δ=0.90 (t, J=6.0 Hz, 3H, $C\underline{H}_3CH_2$), 1.10 and 1.13 (two d, 3:2 ratio, J=7.0 and 7.0 Hz, 3H, $C\underline{H}_3CH$), 1.3 (br, 4H, $CH_2C\underline{H}_2$), 2.2—2.9 (br, 4H, $CH_3C\underline{H}C\underline{H}C\underline{H}_2C$=O), and 3.69 (s, 6H, CH_3O); IR (CCl_4) 1735 (C=O) cm^{-1}.

The Michael Addition of Lithium Enolate of Methyl Propionate to 13.[3b] A solution of methyl propionate (2 mmol) in THF (5 ml) was added to a stirred solution of lithium diisopropylamide (2 mmol) in THF-HMPA (2 and 1 ml, respectively) at −78 °C. Then a solution of **13** (1.5 mmol) in THF (1.5 ml) was added and the mixture was stirred for 1 h at −78 °C. The reaction was quenched by adding saturated aqueous ammonium chloride. The organic layer was extracted with ether, washed with water and with brine, and dried over Na_2SO_4. The solvent was evaporated and the resulting crude product was distilled on a Kugelrohr apparatus to yield a mixture of 1,4-product **26b** (syn:anti=5:95) and 1,6-product **26d** in 37% yield (total yield). The ratio of **26b** to **26d** was 70:30 determined by GC. **26b** and **26d** were separated by column chromathography on silica gel using hexane-ether (4:1) as eluent.

Dimethyl 5,6-Dimethyl-3-heptenedioate (26d; 1,6-adduct). ^1H NMR ($CDCl_3$) δ=1.01 (d, J=7.0 Hz, 3H, $C\underline{H}_3CHCH$=C), 1.11 (d, J=7.0 Hz, 3H, $C\underline{H}_3CHC$=O), 2.2—2.6 (m, 2H, $CH_3C\underline{H}C\underline{H}CH_3$), 3.05 (d, J=5.6 Hz, 2H, CH_2C=O), 3.67 and 3.69 (two s, 6H, CH_3O), and 5.4—5.7 (m, 2H, $C\underline{H}$=$C\underline{H}$); IR (CCl_4) 1738 (C=O) cm^{-1}; GC (PEG-HT, 120 °C) t_R 16.5 and 17.1 min.

Diethyl 2-[2-Ethoxy-2-(trimethylsiloxy)ethenyl]-3-methylsuccinate (27a). Bp 145 °C (bath temp)/0.5 Torr; ^1H NMR ($CDCl_3$) δ=0.22 (s, 9H, CH_3Si), 1.17 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.23 (t, J=7.0 Hz, 9H, $C\underline{H}_3CH_2O$), 2.5—3.1 (m, 1H, $CH_3C\underline{H}$), 3.5—3.8 (m, 2H, $C\underline{H}C\underline{H}$=C), and 3.8—4.3 (m, 6H, $CH_3C\underline{H}_2O$); IR (CCl_4) 1668 (C=C) and 1725 (C=O) cm^{-1}.

Diethyl 3-Ethoxycarbonyl-2-methylglutarate (27b). Obtained from **27a** by hydrolysis. A mixture of diastereomers (syn:anti=42:58): ^1H NMR ($CDCl_3$) δ=1.19 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.27 (t, J=7.0 Hz, 9H, $C\underline{H}_3CH_2O$), 2.5—3.5 (m, 4H, $C\underline{H}C\underline{H}C\underline{H}_2$), and 4.18 (q, J=7.0 Hz, 6H, $CH_3C\underline{H}_2O$); IR (CCl_4) 1730 (C=O) cm^{-1}; GC (PEG-HT, 120 °C) t_R 14.2 min (syn), 14.9 min (anti).

Dimethyl 2-Methylglutarate (28b). Bp 105 °C (bath temp)/0.5 torr; ^1H NMR ($CDCl_3$) δ=1.17 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.8—2.1 (m, 2H, $C\underline{H}_2CHCH_3$), 2.3—2.7 (m, 3H, $CH_3C\underline{H}CH_2C\underline{H}_2$), and 3.67 (s, 6H, CH_3O); IR (CCl_4) 1742 (C=O) cm^{-1}.

Methyl 5-Methoxy-2,4-dimethyl-5-trimethylsiloxy-4-pentenoate (29a). Bp 115 °C (bath temp)/0.6 Torr; ^1H NMR ($CDCl_3$) δ=0.19 (s, 9H, CH_3Si), 1.10 (d, J=6.8 Hz, 3H, $C\underline{H}_3CH$), 1.49 and 1.53 (two s, 1:2 ratio, 3H, CH_3C=C), 2.1—2.7 (m, 3H, $C\underline{H}_2C\underline{H}$), 3.48 and 3.52 (two s, 1:2 ratio, 3H, CH_3OC=C), and 3.67 (s, 3H, CH_3OC=O); IR (CCl_4) 1690 (C=C) and 1732 (C=O) cm^{-1}; ^{13}C NMR (C_6D_6) δ=0.0, 0.1, 14.2, 15.0, 16.7, 35.4, 35.7, 38.4, 38.6, 51.0, 56.1, 56.8, 92.0, 92.3, 151.6, 152.3, and 176.5; GC (OV-1, 150 °C) t_R 4.0 and 4.6 min (67:33).

Dimethyl 2,4-Dimethylglutarate (29b). Obtained from **29a** by hydrolysis. ^1H NMR ($CDCl_3$) δ=1.15 and 1.17 (two d, J=6.7 and 6.7 Hz, 6H, $C\underline{H}_3CH$), 1.5—2.2 (m, 2H, CH_2), 2.2—2.8 (m, 2H, $CH_3C\underline{H}$), and 3.67 (s, 6H, CH_3O); IR (CCl_4) 1741 (C=O) cm^{-1}; GC (OV-1, 120 °C) t_R 3.8 and 4.2 min (42:58). Found: C, 57.18; H, 8.72%. Calcd for $C_9H_{16}O_4$: C, 57.43; H, 8.56%.

Methyl 5-Methoxy-2,3,4-trimethyl-5-trimethylsiloxy-4-pentenoate (30a). Bp 120 °C (bath temp)/0.4 Torr; ^1H NMR ($CDCl_3$) δ=0.19 and 0.21 (two s, 9H, CH_3Si), 0.9—1.2 (m, 6H, $C\underline{H}_3CH$), 1.38 and 1.43 (two s, 2:1 ratio, 3H, CH_3C=C), 2.3—2.9 (m, 2H, CH), 3.47, 3.49 and 3.61 (three s, 3H, CH_3OC=C), and 3.67 (s, 3H, CH_3OC=O); IR (CCl_4) 1682 (C=C) and 1732 (C=O) cm^{-1}.

Dimethyl 2,3,4-Trimethylglutarate (30b). Obtained from **31a** by hydrolysis. ^1H NMR ($CDCl_3$) δ=0.8—1.0 (m, 3H, $C\underline{H}_3CHCHC$=O), 1.18 (d, J=7.0 Hz, 6H, $C\underline{H}_3CHC$=O), 1.7—2.0 (m, 1H, $C\underline{H}CHC$=O), 2.2—2.9 (m, 2H, CHC=O), and 3.67 (s, 6H, CH_3O); IR (CCl_4) 1732 (C=O) cm^{-1}.

Diethyl 2,3,3-Trimethylglutarate (31b). Bp 115 °C (bath temp)/0.5 Torr; ^1H NMR ($CDCl_3$) δ=1.07 (s, 6H, $(CH_3)_2C$), 1.12 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.25 (t, J=7.0 Hz, 6H, $C\underline{H}_3CH_2$), 2.32 (s, 2H, CH_2C=O), 2.55 (q, J=7.0 Hz, 1H, $CH_3C\underline{H}$), and 4.12 (q, J=7.0 Hz, 4H, $CH_3C\underline{H}_2O$); IR (CCl_4) 1725 (C=O) cm^{-1}. Found: C, 62.29; H, 9.69%. Calcd for $C_{12}H_{22}O_4$: C, 62.58; H, 9.63%.

1-(1-Ethoxycarbonylethyl)-1-[2-ethoxy-2-(trimethylsiloxy)-ethenyl]cyclohexane (32a). Bp 150 °C (bath temp)/0.4 Torr; ^1H NMR ($CDCl_3$) δ=0.20 and 0.25 (two s, 5:1 ratio, 9H, CH_3Si), 1.07 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.25 (t, J=7.0 Hz, 3H, $C\underline{H}_3CH_2OC$=O), 1.28 (t, J=7.0 Hz, 3H, $C\underline{H}_3CH_2OC$=C), 1.2—1.8 (br, 10H, $(CH_2)_5$), 2.58 (q, J=7.0 Hz, 1H, $CH_3C\underline{H}$), 3.07 (s, 1H, CH=C), 3.74 (q, J=7.0 Hz, 2H, $CH_3C\underline{H}_2OC$=C), and 4.08 (q, J=7.0 Hz, 2H, $CH_3C\underline{H}_2OC$=O); IR (CCl_4) 1670 (C=C) and 1722 (C=O) cm^{-1}.

1-(1-Ethoxycarbonylethyl)-1-(ethoxycarbonylmethyl)cyclohexane (32b). Obtained from **32a** by hydrolysis. ^1H NMR ($CDCl_3$) δ=1.10 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.25 (t, J=7.0 Hz, 6H, $C\underline{H}_3CH_2O$), 1.5 (br, 10H, $(CH_2)_5$), 2.44 and 2.48 (two s, 2H, CH_2C=O), 2.85 (q, J=7.0 Hz, 1H, $CH_3C\underline{H}$), and 4.12 (q, J=7.0 Hz, 4H, $CH_3C\underline{H}_2O$); IR (CCl_4) 1735 (C=O) cm^{-1}. Found: C, 66.71; H, 9.77%. Calcd for $C_{15}H_{26}O_4$: C, 66.64; H, 9.77%.

Methyl 5-Methoxy-2,2,3-trimethyl-5-trimethylsiloxy-4-pentenoate (33a). Bp 120 °C (bath temp)/0.5 Torr; ^1H NMR ($CDCl_3$) δ=0.21 and 0.26 (two s, 5:1 ratio, 9H, CH_3Si), 0.89 (d, J=6.8 Hz, 3H, $C\underline{H}_3CH$), 1.09 and 1.14 (two s, 6H, $(CH_3)_2C$), 2.5—2.9 (m, 1H, $C\underline{H}CH_3$), 3.34 and 3.57 (two d, 5:1 ratio, J=10.0 and 10.0 Hz, CH=C), 3.51 (s, 3H, CH_3OC=C), and 3.67 (s, 3H, CH_3OC=O); IR (CCl_4) 1668 (C=C) and 1725 (C=O) cm^{-1}.

Dimethyl 2,2,3-Trimethylglutarate (33b). Obtained from **33a** by hydrolysis. ^1H NMR ($CDCl_3$) δ=0.91 (d, J=6.7 Hz, 3H, $C\underline{H}_3CH$), 1.13 (s, 6H, $(CH_3)_2C$), 1.7—2.1 (m, 1H, CH), 2.2—2.6 (m, 2H, CH_2), and 3.67 (s, 3H, CH_3O); IR (CCl_4) 1740 (C=O) cm^{-1}. Found: C, 57.18; H, 8.72%. Calcd for $C_9H_{16}O_4$: C, 57.43; H, 8.56%.

Methyl 5-(*t*-Butyldimethylsiloxy)-5-methoxy-3-methyl-4-pentenoate (34a). Bp 135 °C (bath temp)/0.8 Torr; ^1H NMR ($CDCl_3$) δ=0.16 (s, 6H, CH_3Si), 0.96 (s, 9H, $(CH_3)_3CSi$), 1.01 (d, J=6.0 Hz, 3H, $C\underline{H}_3CH$), 2.27 and 2.30 (two d, J=7.8 and 5.8 Hz, 2H, $CHC\underline{H}_2CO$), 2.7—3.2 (m, 1H, $C\underline{H}CH_3$), 3.38 and 3.63 (two d, J=8.6 and 8.6 Hz, CH=C), 3.48 (s, 3H, CH_3C=C), and 3.67 (s, 3H, CH_3C=O); ^{13}C NMR (C_6D_6) δ=−4.1, 22.0, 22.1, 25.1, 27.9, 42.8, 43.1, 50.7, 54.2, 54.6, 80.9, 86.9, 154.1, 156.9, and 172.4; IR (CCl_4) 1668 (C=C) and 1735 (C=O) cm^{-1}.

Found: C, 58.07; H, 9.94%. Calcd for $C_{14}H_{28}O_4Si$: C, 58.29; H, 9.78%.

Dimethyl 3-Methylglutarate (34b). Obtained from **34a** by hydrolysis. ^{1}H NMR ($CDCl_3$) δ=1.03 (d, J=6.0 Hz, 3H, $C\underline{H}_3CH$), 2.37 (br, 5H, $CH_2C\underline{H}C\underline{H}_2$), and 3.70 (s, 6H, CH_3O); IR (CCl_4) 1732 (C=O) cm^{-1}. Found: C, 54.88; H, 8.25%. Calcd for $C_8H_{14}O_4$: C, 55.16; H, 8.10%.

The Tandem Michael-Aldol Reaction of 1, 10, and Benzaldehyde. Al-Mont (0.2 g) in a 20 ml round-bottomed flask was dried at 120 °C and 0.5 Torr for 3 h in an oil bath, and cooled to −78 °C under nitrogen. A solution of **10** (1 mmol) in CH_2Cl_2 (4 ml) was added. After the mixture being stirred for 1 min, a solution of **1** (1 mmol) in CH_2Cl_2 (1 ml) was added at −78 °C. After stirring for 30 min, a solution of benzaldehyde (1 mmol) in CH_2Cl_2 (1 ml) was added at −78 °C. The temperature was raised to 0 °C, and the mixture was stirred for 1 h. After the addition of cold ether (−50 °C, 5 ml), the montmorillonite was filtered off through a Celite pad and washed with ether. The organic layer was evaporated and distilled on a Kugelrohr apparatus to yield the product of **35a** in 80% yield.

Dimethyl 2,3-Dimethyl-4-[α-(trimethylsiloxy)benzyl]-glutarate (35a). Bp 170 °C (bath temp)/0.5 Torr; ^{1}H NMR ($CDCl_3$) δ=−0.08 and −0.05 (two s, 9H, CH_3Si), 0.7—1.3 (m, 6H, $C\underline{H}_3CH$), 1.8—3.1 (m, 3H, $CH_3C\underline{H}C\underline{H}(CH_3)C\underline{H}C{=}O$), 3.3—3.8 (m, 6H, CH_3O), 4.8—5.1 (m, 1H, PhCH), and 7.30 and 7.33 (two s, 5H, C_6H_5); IR (CCl_4) 1732 (C=O) cm^{-1}.

Dimethyl 2,3-Dimethyl-4-(α-hydroxybenzyl)glutarate (35b). Obtained from **35a** by hydrolysis. ^{1}H NMR ($CDCl_3$) δ=0.8—1.5 (m, 6H, $C\underline{H}_3CH$), 1.8—3.2 (m, 4H, $CH_3C\underline{H}C\underline{H}$-$(CH_3)C\underline{H}C{=}O$ and OH), 3.45 and 3.68 (br s, 6H, CH_3O), 4.80—5.25 (m, 1H, PhC$\underline{H}$), and 7.35 (br s, 5H, C_6H_5); IR (CCl_4) 1740 (C=O) and 3520 (OH) cm^{-1}.

Ethyl 2-(3-Trimethylsiloxy-2-cyclohexenyl)propanoate (36a). Bp 135 °C (bath temp)/0.4 Torr; ^{1}H NMR ($CDCl_3$) δ=0.17 (s, 9H, CH_3Si), 1.09 (d, J=6.4 Hz, 3H, $C\underline{H}_3CH$), 1.24 (t, J=7.0 Hz, 3H, $C\underline{H}_3CH_2$), 1.5—2.6 (m, 8H, aliphatic CH), 4.15 (q, J=7.0 Hz, 2H, $CH_3C\underline{H}_2O$), and 4.71 and 4.85 (two br, 1:1 ratio, 1H, CH=C); IR (CCl_4) 1660 (C=C) and 1725 (C=O) cm^{-1}.

Ethyl 2-(3-Oxocyclohexyl)propanoate (36b). Obtained from **36a** by hydrolysis. A mixture of diastereomers (syn: anti=57:43): ^{1}H NMR ($CDCl_3$) δ=1.15 and 1.18 (two d, J=6.4 Hz and 6.4 Hz, 3H, $C\underline{H}_3CH$), 1.28 (t, J=7.0 Hz, 3H, $C\underline{H}_3CH_2$), 1.6—2.6 (m, 10H, aliphatic CH), and 4.16 (q, J=7.0 Hz, 3H, $CH_3C\underline{H}_2O$); IR (CCl_4) 1710 (C=O) and 1730 (C=O) cm^{-1}; GC (PEG-HT, 120 °C) t_R 14.2 min (syn), 14.9 min (anti). The authentic sample of **36b** was prepared by means of $TiCl_4$-mediated reaction[5] of **4** with **21** followed by transesterification.

Methyl 2-Methyl-2-(3-trimethylsiloxy-2-cyclohexenyl)propanoate (37a). Bp 130 °C (bath temp)/0.2 Torr; ^{1}H NMR ($CDCl_3$) δ=0.18 (s, 9H, CH_3Si), 1.11 (s, 6H, CH_3C), 1.4—2.8 (m, 7H, aliphatic CH), 3.68 (s, 3H, CH_3O), and 4.71 (br, 1H, CH=C); IR (CCl_4) 1658 (C=C) and 1725 (C=O) cm^{-1}.

Methyl 2-[3-(*t*-Butyldimethylsiloxy)-2-cyclohexenyl]acetate (38a). Bp 140°C (bath temp)/0.5 Torr); ^{1}H NMR ($CDCl_3$) δ=0.11 (s, 6H, CH_3Si), 0.91 (s, 9H, $(CH_3)_3CSi$), 1.5—2.1 (m, 6H, $C\underline{H}_2C\underline{H}_2C\underline{H}_2$); 2.27 and 2.29 (two d, J=7.8 and 6.2 Hz, 2H, $CH_2C{=}O$), 2.4—2.8 (m, 1H, C$\underline{H}$CH=C), 3.69 (s, 3H, CH_3O), and 4.80 (br, 1H, CH=C); IR (CCl_4) 1662 (C=C) and 1735 (C=O) cm^{-1}.

2-(3-Trimethylsiloxy-2-cyclohexenyl)-3-pentanone (39a). Bp 130 °C (bath temp)/0.2 Torr; ^{1}H NMR ($CDCl_3$) δ=0.16 and 0.18 (s, 9H, CH_3Si), 1.01 (d, J=6.3 Hz, 3H, $C\underline{H}_3CH$), 1.04 (t, J=7.0 Hz, 3H, $C\underline{H}_3CH_2$), 1.4—2.6 (m, 6H, aliphatic CH), 2.44 (q, J=7.0 Hz, 2H, CH_2CH_3), 2.5 (m, 2H, C$\underline{H}$C$\underline{H}$CO), and 4.60 and 4.79 (two br, 62:38 ratio, 1H, C=CH); IR (CCl_4) 1657 (C=C) and 1706 (C=O) cm^{-1}.

4-Methyl-5-phenyl-7-trimethylsiloxy-6-octen-3-one (40a) (Table 4, Entry 5). Bp 155 °C (bath temp)/0.6 Torr; ^{1}H NMR ($CDCl_3$) δ=0.11 and 0.13 (two s, 1:2 ratio, 9H, CH_3Si), 0.78 (t, J=7.3 Hz, 3H, $C\underline{H}_3CH_2$), 0.88 and 1.08 (two d, 1:2 ratio, J=6.7 and 6.7 Hz, 3H, $C\underline{H}_3CH$), 1.73 and 1.79 (two s, 1:2 ratio, 3H, $C\underline{H}_3C{=}CH$), 2.0—2.5 (m, 2H, $CH_3C\underline{H}_2$), 2.7—3.1 (m, 1H, $CH_3C\underline{H}$), 3.92 (t, J=9.3 Hz, 1H, PhCH), 4.55—4.80 (m ,1H, CH=C), and 7.17 (s, 5H, C_6H_5); IR (CCl_4) 1665 (C=C) and 1708 (C=O) cm^{-1}.

5-Methyl-4-phenyl-2,6-octanedione (40b). Obtained from **40a** by hydrolysis. A mixture of diastereomers (syn: anti=31:69). ^{1}H NMR ($CDCl_3$) δ=0.82 (t, J=7.0 Hz, 3H, $C\underline{H}_3CH_2$), 1.09 (d, J=7.0 Hz, 3H, $C\underline{H}_3CH$), 1.97 and 2.00 (two s, 1:2.2 ratio, 3H, CH_3CO), 2.1—2.4 (m, 2H, $CH_3C\underline{H}_2$), 2.4—3.1 (m, 3H, $C\underline{H}_2CHC\underline{H}CH_3$), 3.3—3.8 (m, 1H, PhC$\underline{H}$), and 7.20 (s, 5H, C_6H_5); IR (CCl_4) 1710 (C=O) cm^{-1}; GC (OV-1, 160 °C) t_R 9.1 min (syn), 9.6 min (anti). The authentic sample of **39b** was prepared by means of the $Ph_3C^+ClO_4^-$-mediated reaction of **9** with **22**.[9b]

19) As another example of selective 1,4-addition of a silicon-containing nucleophile, the $Bu_4N^+F^-$-mediated reaction of allyltrimethylsilane with ethyl sorbate was reported: G. Majetich, A. M. Casares, D. Chapman, and M. Behnke, *Tetrahedron Lett.*, **24**, 1909 (1983).

20) Entry 2 in Table 2 is the first example of the Michael reaction of a silyl ketene acetal with α,β-unsaturated carbonyl compounds by use of a protic strong acid such as CF_3SO_3H. We also showed that CF_3SO_3H catalyzed the aldol reactions such as silyl enol ethers with aldehydes or acetals.[13]

21) When the Michael reaction of an enone with a silyl enol ether was conducted by use of Ph_3CClO_4, the yellow color of the trityl cation remained during the reaction, and the Michael product was obtained in good yield.

22) The catalytic activity of Al-Mont is dependent on the drying conditions. On heat treatment at higher temperature, the structure of montmorillonite irreversibly changes and the cation-exchange capacity decreases: a) R. E. Grim, "Clay Mineralogy," ed by R. R. Shrock, McGraw-Hill, New York (1953), p. 139; b) A. C. Mathers, S. B. Weed, and N. T. Coleman, "Clays and Clay Minerals," ed by W. O. Milligan, Natl. Acad. Sci., Natl. Research Council, Washington, (1955), Publ. 395, p. 403.

23) A tandem Michael-aldol reaction of an enone was reported by the use of Ph_3CClO_4: S. Kobayashi and T. Mukaiyama, *Chem. Lett.*, **1986**, 221, 1805.

24) G. H. Posner, *Org. React.*, **19**, 1 (1972).

25) No 1,2-adduct was obtained in the reaction between an enone and silyl enol ethers or silyl ketene acetals.[4-9] On the contrary, a competitive 1,2-addition is a serious problem in the Michael reaction of enones with lithium enolates under basic conditions.[1,2]

The electrolytic conductance of $LiClO_4$ has been determined in *N,N*-dimethylformamide (DMF) and its binary mixtures with acetone (Ac) and ethyl methyl ketone (MEK) at 25 °C. Ion association constants (K_A) and limiting molar conductance (Λ_0) were calculated from these data using Fuoss equation with modifications. The K_A values of $LiClO_4$ in these binary mixtures are interpreted in terms of solvent separated ion pairs while in pure Ac and MEK almost contact ion pairs are expected. A comparison is made for Λ_0 and K_A values of this salt in Ac and Ac-DMF mixtures with those obtained by Gill et al. Further, a comparison is made between these results and spectroscopically derived results by others in analogous media. $LiClO_4$ has been found more associated in Ac-DMF solvent system than in the MEK-DMF mixed solvent system.

A large number of conductometric and spectroscopic studies of concentrated solutions of $LiClO_4$ have been carried out in an aprotic solvent systems in various laboratories.[1-4,14] But very few number of precise conductance measurements on dilute solution of this salt in acetone (Ac), *N,N*-dimethylformamide (DMF), and Ac-DMF mixed solvent system are available in literature.[5-7] No literature data have been found about conductance of $LiClO_4$ in ethyl methyl ketone (MEK) and its binary mixtures with DMF at 25 °C.

As a continuation of conductance measurements of electrolytes in dipolar aprotic solvent mixtures,[8] present paper reports conductance of $LiClO_4$ in Ac, MEK, DMF, Ac-DMF, and MEK-DMF binary mixtures in a concentration range 10^{-4}—10^{-2} mol dm^{-3} at 25 °C. The limiting molar conductance (Λ_0) and ion association constant (K_A) were evaluated from the conductance data using the Fuoss equation[10] with modifications. The Bjerrum ion association theory as modified by Fernandez-Prini and Pure[11,12] was also used for derivation of K_A (as K_A^{BFPP}) and ion pair distance parameter *a*. The derived parameters are compared with those obtained by Gill et al. for this salt in Ac-DMF binary mixtures. Further, results of spectroscopic studies of $LiClO_4$ in pure solvents (in Ac and DMF) which are available from literatures[4b,5,13] are discussed for comparison purpose with the present results.

Experimental

Chemicals. Acetone, DMF, and MEK were products of Merck (for synthesis). The procedure for purification of these solvents together with densities ρ, viscosities η, and dielectric constants ε are given in detail in previous papers.[8,9] All solution preparation was carried out in the presence of dry nitrogen gas. The purified solvents contained no more than 0.01% (w/w) water. The mixtures were prepared by weight and are given in Table 1. $LiClO_4$ and KCl were of analytical grade (pure p. a Fluka). They were twice recrystallized from conductivity water, dried in an oven at 170 °C for several days and then dried in vaccum at 70 °C over P_2O_5 and were kept in a desiccator over P_2O_5.

Conductance Measurements. Conductance measurements were carried out using ORION Research Conductivity Meter, Model 101 at 1 kHz. Two 1 dm^3 Kraus-type conductance cells were used, whose cell constants were 1.1538 and 0.1932 cm^{-1} calibrated with aqueous KCl solutions at 25±0.005 °C. The platinized Pt electrodes were used. Further procedure was the same as described earlier.[8] Measurements were carried out in a water bath at 25±0.005 °C and the reproducibility of the conductance measurement was better than ±0.01%. The conductance data are listed in Tables 2 and 3 and are presented in Figs. 1 and 2.

Results

The molar conductance of the salt solutions (listed in Tables 2 and 3) were corrected for the solvent conductances. The Fuoss conductance equation,[10] with modifications was used to evaluate the limiting molar conductance (Λ_0) and the conductometric association constant (K_A) from conductance data using his scan

program[10a] in which R (Gurney cosphere distance) was varied from 3 to 30 Å with increment of 0.2 Å.

K_A for ion pair formation of the type $M^+ + X^- = M^+X^-$ is given by

$$K_A = (1-\gamma)/C\gamma^2 f_{\pm}^2, \quad (1)$$

where $f_{\pm}$ was given by $\exp[-\tau/(1+kR)]$ with $\tau=\beta k/2$ where k^{-1} is the Debye distance, $\beta=e^2/\varepsilon RT$, and other symbols have their usual meanings. The scan program also evaluated σ (standard deviation expressed as a percentage of Λ_0). Plots of σ vs. R showed minima for each solvent mixtures and the derived values of Λ_0 and K_A along with σ and R are given in Tables 4 and 5.

The association constant K^{BFPP} from the Bjerrum ion association theory[11] as modified by Fernandez-Prini and Prue[12] was also evaluated from the following expression

$$K_A^{BFPP} = 4\pi NA \int_{r=a}^{q} \exp[-U(r)/K_BT]r^2 dr, \quad (2)$$

and

$$U(r) = \int_{\infty}^{r} e^2 \cdot dr/\varepsilon' r^2 = e^2 \int_{\infty}^{r_1} dr/\varepsilon r^2 + e^2 \int_{r_1}^{r} dr/\varepsilon' r^2, \quad (3)$$

where q is Bjerrum distance parameter.

In this modification, the association is corrected by introduction of a distance dependent dielectric coefficient ε' replacing the static dielectric constant (ε) of the medium. Booth[23] derived the following expression for the variation of ε' with intensity of electric field

$$\varepsilon' = (3/y)(\varepsilon - n^2)L(y) + n^2, \quad (4)$$

where $y=\beta' Ze/\varepsilon' r^2$, $L(y)$ is the Langevin function, $L(y) = \mathrm{Cot}\ h(y) - 1/y$, and $Ze/\varepsilon' r^2$ is the intensity of electric

field in the region r from the charge (Ze). The β' is given by the expression

$$\beta' = (n^2+2)\mu/2K_BT, \quad (5)$$

where n, μ are the refractive index and dipole moment of the medium respectively. The values of n and μ for pure solvents were taken from the literature[24] and for mixture it was supposed that $n_{mix.}=x_1n_1+x_2n_2$ and $\mu_{mix.}=(x_1\mu_1+x_2\mu_2)$ as found in case of other physical properties of these solvent mixtures.[9] Integrals Eqs. 2 and 3 were solved numerically and derived parameters are listed in Tables 6 and 7. In Eq. 2, a is the contact ion-pair distance. All the symbols in Eqs. 2 and 3 are described in detail in original papers.[12a] The values of K_A^{BFPP} were found almost the same as K_A. The values of $U(r)/K_BT$ and a derived from Eqs. 2 and 3 are given in Tables 6 and 7.

The thermodynamic ion pair association constant K_a for the reaction $M^+ + X^- \rightleftarrows M^+X^-$ was calculated from the K_A values using a relationship

$$K_a = (1000\,\rho/M)K_A, \quad (6)$$

where $M/1000\rho$ (dm^3 mol^{-1}) is the molecular volume of the solvent and M is its molecular weight.[10] The free energy of ion pair formation is related with K_a through a relationship

$$\Delta G = -RT \ln K_a. \quad (7)$$

The values of $-\Delta G/RT$ for $Li^+ClO_4^-$-ion-pair formation in the Ac, MEK, DMF, Ac-DMF, and MEK-DMF solvent systems are included in Tables 6 and 7.

Discussion

Limiting Molar Conductances. The Λ_0 ($LiClO_4$) values found for pure Ac, DMF, and MEK in the present work are 197.24, 77.24, and 178.86 $S \cdot cm^2 \cdot mol^{-1}$, respectively, in agreement with values reported in literature.[5-7] No values of Λ_0 for $LiClO_4$ in MEK were available in literature. Comparing with the values of Λ_0 for $LiClO_4$ in Ac and LiBr and LiI in MEK (154 and 147 $S \cdot cm^2 \cdot mol^{-1}$) respectively,[12b] the present value seems to be reasonable. This can be confirmed further by comparing viscosities of Ac and MEK which are 0.300 and 0.379 cp respectively. Addition of DMF either to Ac or to MEK decreased the values of Λ_0 for $LiClO_4$ in the Ac-DMF and MEK-DMF mixed solvent systems (Tables 4 and 5) due to the corresponding increase of viscosities of the mixtures.

The Association Constants. The association constants K_A and K_A^{BFPP} for $LiClO_4$ in Ac-DMF as well as in MEK-DMF showed no significant difference and consequently, only K_A are reported in Tables 4 and 5. These values for $LiClO_4$ in pure Ac, MEK, and DMF derived from conductance data in present work are

1.5×10^3, 7.9×10^2, and 9 mol^{-1} dm^3, respectively, in agreement with the literature.[5,7,18] But literature survey shows that $LiClO_4$ is almost dissociated in pure DMF. These results have been derived both from spectroscopic as well as conductimetric studies of $LiClO_4$ in DMF. Gill et al. have recently reported the value of K_A for $LiClO_4$ in Ac and DMF, but not reported K_A values in Ac-DMF binary mixtures.[7] Justice[18] has reported the K_A value of 8 mol^{-1} dm^3 for $LiClO_4$ in pure DMF, which is in good agreement with the value 9 ± 2 $mol^{-1}dm^3$ derived in the present work. Tables 4 and 5 show that, as the proportion of DMF increased, the corresponding association constant decreased in both Ac-DMF and MEK-DMF binary solvent systems. This is mainly due to the increase in dielectric constant of the medium with addition of DMF to Ac or MEK.

Comparing the K_A values for $LiClO_4$ in the Ac-DMF and MEK-DMF binary solvent system, it is observed that, despite higher dielectric constant values of the Ac-DMF binary mixtures, $LiClO_4$ is more associated in these mixtures than in the MEK-DMF binary mixtures. Thus, the isodielectric rule is again not valid in the present case. The present results also do not agree with the K_A values of $LiClO_4$ in MEK reported by Milaev.[15] Similar results were found in a previous study on LiCl in these mixed solvent systems.[8] Though MEK has lower dielectric constant, it has a greater polarizability volume than Ac. As pointed out by others[19] the solute-solvent interaction is specific. Both solute and solvent nature (shape, size, polarizability, dipole moment, and refractive index, etc.) are determinative factors for evaluation of the extent of association constant of electrolytes.

Further, the values of the contact ion-pair distance a for $Li^+ClO_4^-$ in pure Ac and DMF have been found to be 3 ± 0.2 and 5.33 ± 0.15 Å, respectively, which are in good agreement with values cited in literature.[5-7] The values of K_A and a in pure Ac, indicate that $LiClO_4$ exists as contact ion pairs; in MEK partial solvent-separated and in DMF almost solvent-separated ion pairs are expected (Tables 6 and 7). But small values of K_A and large values of a of $LiClO_4$ in the Ac-DMF binary solvent system clearly indicate that $LiClO_4$ is almost dissociated in these solvent systems. The value of K_a of $LiClO_4$ in MEK-DMF are smaller than those found in the Ac-DMF solvent system. Also, the values of a of $LiClO_4$ are larger in the MEK-DMF system than those found in the Ac-DMF solvent system. It shows that, the nature of the solvent is an important factor for determining an extent of ionic association. The order of preferential solvation of the Li^+ ion by these solvents is found to be DMF > MEK > Ac. Comparing the present results with those observed by others spectroscopically, in pure Ac[4b] and DMF,[13] an agreement with Popov's results of complete dissociation of $LiClO_4$ in DMF and disagreement with James et al.'s results—postulating no association of $LiClO_4$ in Ac upto 1 mol dm^{-3} concentration were found.

Free Energy Changes of Ion-Pair Formation and Potential Energy Function of Interionic Interaction. The values of ΔG, calculated from $\Delta G^\circ = -RT \ln K_a$

for ($Li^+ClO_4^-$) ion pair formation, become less negative as ε increases or the contents of DMF increase in Ac-DMF and MEK-DMF binary mixtures (Tables 6 and 7). This is because the enthalpic term ΔH in ΔG contains the work done in constituting a contact pair from free ions. The ΔH also contains a positive term due to replacement of nearest neighbor solvent molecule by the partner ion and hence causing a decrease in entropy. Tables 6 and 7 show that for $LiClO_4$—$|\Delta G(MEK)| < |\Delta G(Ac)|$, which is mainly due to larger polarizability volume of MEK than that of Ac and consequently major role of entropy term and decrease of ΔG value of ion-pair formation.

Tables 6 and 7 include the value of ε' —a parameter from dielectric saturation modification, and potential energy function ($U(r)/K_BT$) of interionic interactions. It is observed that the effect of dielectric saturation plays effective role in pure Ac, MEK and in mixtures of Ac-DMF; MEK-DMF, rich in Ac or MEK contents, respectively, for evaluation of K_A and a parameters for $LiClO_4$ in these solvent systems. As the contents of DMF increase in these two mixed solvent systems, the difference of (ε—ε') became less. The same trend is found for potential energy function (P.E.F) of Li^+ ion and ClO_4^- ion interactions. Both, ε' and P.E.F. are interionic distance dependent. Therefore, it can be postulated that Li^+ and ClO_4^- ions are separated by solvent molecules in Ac-DMF and MEK-DMF mixtures.

Gilkerson et al.[20] have recently studied conductimetrically some lithium salts in MEK and 2-proponal respectively. They have discussed their results in terms of the square-mound potential model[21] modification of Bjerrum's theory for ion association. Similarly, Salomon et al.[17] have also studied some lithium salts in dimethylsulfite (DMSI). They have discussed their results on the basis of Barthel's model[22] modification of the Bjerrum theory for ion association. In both above models, non-coulombic interaction term in P.E.F has been introduced. It has been found that in present case of Ac-$LiClO_4$-DMF and MEK-$LiClO_4$-DMF systems, all the three modifications of Bjerrum ion association theory, (i.e. those by Fernandez-Prini and Prue, Justice and Justice's squaremound potential model, and that of Barthel), give almost the same result which indicates that $LiClO_4$ ion pair is solvent-separated. Since it has been found previously a preferential solvation of Li^+ ion by DMF molecules,[7,8] it can be concluded that solvation of Li^+ ion by these solvents is of the order DMF > MEK > Ac.

Finally, it can be concluded that though Ac-DMF and MEK-DMF constitute almost ideal systems,[9,16] the binary mixtures do not act as a single solvent towards an electrolyte. The previous[8] as well as the present studies show that the ion association process depends upon both solvent and solute.

A comparison of above mentioned modifications of the Bjerrum ion association theory, for the systems Ac-LiCl-DMF, MEK-LiCl-DMF, Ac-$LiClO_4$-DMF, and MEK-$LiClO_4$-DMF will be published later on in a near future.

Author is thankful to Prof. O. Fischer of J. E. Purkyne University, BRNO for his useful discussion and guidance.

Ultrasonic Investigation on the Structure of Aqueous Solution of 2-Butanone

T. RAMANJAPPA* and E. RAJAGOPAL
Department of Physics, Sri Krishnadevaraya University, Anantapur-515003, India
(Received June 1, 1987)

The effect of 2-butanone on the temperature corresponding to adiabatic compressibility minimum (TACM), sound velocity maximum (TSVM) and specific acoustic impedance maximum (TSAIM) of pure water has been studied by experimentally determining the sound velocity and density of aqueous solution at different concentrations over a temperature range 34—70.5 °C. The structural contribution to the shift in TACM, TSVM, and TSAIM has been evaluated. The shift is positive throughout the concentration range studied and indicates that 2-butanone is hydrophobic in nature.

The hydrogen-bonded structure of water plays an important role in the nonideal thermodynamic behavior exhibited by aqueous nonelectrolytes. The solution structure of aqueous nonelectrolytes can be understood from the studies on the effect of these solutions on the anomalous behavior exhibited by water such as density maximum at 3.98 °C[1-3] adiabatic compressibility minimum at 64 °C,[4,5,16] sound velocity maximum at 74 °C[6,7,16] and impedance maximum[8] at 56.4 °C etc.

The physicochemical properties of water-2-butanone system has been studied extensively by various workers.[9-11] Roux et al.[9] have studied the concentration dependence of ϕ_C and ϕ_V for this system in the temperature range 4 to 40 °C. The studies on apparant molal volumes ϕ_V of various hydrophobic solutes indicate that ϕ_V decreases with concentration in the water rich region. In general, the more the hydrophobic nature of solute is the more negative would be the initial slope A_V. The apparant molal heat capacities ϕ_C decrease as a function of concentration and the decrease is more important for hydrophobic solutes. The apparant molal expansibilities ϕ_E are positive for such systems.

For water-2-butanone system, Roux et al.[9] observed a slight deviation from the typical behavior at 40 °C. Therefore an attempt has been made in the present investigation to study the temperature effect on the behavior of the solute.

The present paper deals with the studies carried out on the effect of 2-butanone on the temperature corresponding to adiabatic compressibility minimum (TACM), sound velocity maximum (TSVM), and specific impedance maximum (TSAIM) of water in order to see how the hydrophobic character of 2-butanone would change with temperature.

Experimental

Analar grade 2-butanone was used after necessary purification. The purity of the sample was checked by determining the density at 25 °C using a bicapillary pycnometer with an accuracy of 2 in 10^5. The density value, 800.44 kg m^{-3}, is in good agreement with the data available in the literature.[14] Ultrasonic velocity in pure liquid and aqueous solution was determined using a single crystal variable path interferometer working at 3 MHz with an accuracy of ±0.003%. The details of experimental technique were published elsewhere.[12] Ultrasonic velocities and densities were determined at an interval of ca. 2 °C over a temperature range of 34—70.5 °C.

Results and Discussion

The measurements of ultrasonic velocity in and density of aqueous 2-butanone solution as a function of temperature are presented in Table 1. Adiabatic compressibility ($\beta=1/u^2\rho$) and specific acoustic impedance ($z=u\rho$) are evaluated from the experimental data. The template method[12] has been employed to fix TACM, TSVM, and TSAIM with an accuracy of ±0.4 °C, ±0.2 °C, and ±0.3 °C respectively. The ultrasonic

velocity data have been corrected for diffraction effects.[13]

The adiabatic compressibility minimum (T_β) of the solution is given[5,12] by

$$T_\beta = \left[64 - \frac{\phi_2}{\phi_1}\frac{\alpha_\beta}{0.0032}\right]\left[1 + \frac{\phi_2}{\phi_1}\frac{\alpha_\beta^1}{0.0016}\right]^{-1} - \left[\frac{d\beta^E}{dt}\right]\left[1 + \frac{\phi_2}{\phi_1}\frac{\alpha_\beta^1}{0.0016}\right]^{-1}[\phi_1 \times 0.0032]^{-1}, \quad (1)$$

where ϕ_1 and ϕ_2 represent the volume fractions of pure water and organic solute respectively in the solution. α_β and α_β^1 are the constants of organic solute involved in adiabatic compressibility versus temperature relation given by

$$\beta_2 = \beta_2^\circ + \alpha_\beta t + \alpha_\beta^1 t^2. \quad (2)$$

The sound velocity maximum (T_u) of the solution is given[5,15] by

$$T_u = 74 - \left[\frac{\phi_2}{\phi_1}\right]^2 \frac{w_1}{w_2}\frac{\alpha_u}{0.049}\left[\frac{u_1}{u_2}\right]^3 - \frac{w_1}{\phi_1^2}\frac{u_1^3}{0.098}\left[\rho\frac{d\beta^E}{dt} + \beta^E\frac{d\rho}{dt}\right], \quad (3)$$

where w_1 and w_2 represent weight fractions of pure water and organic solute respectively in the solution. α_u is the temperature coefficient of sound velocity in the relation

$$u_2 = u_2^\circ - \alpha_u t. \quad (4)$$

The specific acoustic impedance maximum (T_z) of the solution is given[8] by

$$T_z = -\frac{\frac{7.5603\ w_1}{z_1^3} + \frac{2\alpha_z w_2}{z_2^3}}{\frac{-0.13404\ w_1}{z_1^3} + \frac{4\alpha_z^1 w_2}{z_2^3}} + \frac{\frac{1}{\rho}\left[\frac{d\beta^E}{dt} - \frac{\beta^E}{\rho}\frac{d\rho}{dt}\right]}{\frac{-0.13404\ w_1}{z_1^3} + \frac{4\alpha_z^1 w_2}{z_2^3}}, \quad (5)$$

where α_z and α_z^1 are the temperature coefficients of specific acoustic impedance in the relation

$$z_2 = z_2^\circ + \alpha_z t + \alpha_z^1 t^2 \quad (6)$$

The values of β_2°, α_β, α_β^1, u_2°, α_u, z_2°, α_z, and α_z^1 for 2-butanone are evaluated using the experimentally determined ultrasonic velocity and density data at different temperatures and the values are presented in Table 2.

In Eqs. 1, 3, and 5, first term ($T_{\beta\ \text{or u or z id}}$) represents the dilution effect and second term ($\Delta T_{\beta\ \text{or u or z str}}$) represents the structural contribution. ($\Delta T_{\beta\ \text{or u or z str}}$) can be evaluated experimentally from the relation

$$(\Delta T_{\beta\ \text{or u or z str}})_{\text{exp}} = T_{\beta\ \text{or u or z exp}} - T_{\beta\ \text{or u or z id}}. \quad (7)$$

The results of $(\Delta T_{\beta\ \text{str}})_{\text{exp}}$, $(\Delta T_{\text{u str}})_{\text{exp}}$, and $(\Delta T_{\text{z str}})_{\text{exp}}$ are presented in Table 3.

The variation of $[\Delta T_{\beta\ \text{str}}]_{\text{exp}}$ with mole fraction x_2 of 2-butanone is shown in Fig. 1. From this figure it is clear that the structural shifts are positive throughout the concentration range, indicating that the solute behaves as structure maker.

The concentration dependence of ϕ_C and ϕ_V of 2-butanone have been studied by Roux et al.[9] over a temperature range of 4 to 40 °C. The initial slopes are negative and become less negative as the temperature increases. The initial slopes exhibit a flat minimum around 40 °C. The slight change in the initial slopes

as a function of temperature still indicate the hydrophobic character of 2-butanone (the initial slope A_V at 40 °C is -0.11 cm^3 mol^{-2} kg).

$[\Delta T_{u\ str}]_{exp}$ (Fig. 2) is positive for 2-butanone and the magnitude is found to increase with increase in the concentration, indicating structural promoting nature of solution.

The variation of $[\Delta T_{z\ str}]_{exp}$ with mole fraction x_2 is shown in Fig. 3. $[\Delta T_{z\ str}]_{exp}$ is positive and increases with increase in concentration. This trend also confirms hydrophobic character of 2-butanone. From these studies, one can infer that 2-butanone is hydrophobic throughout the temperature range of the present study.

Electrophoresis of Progesterone Particles Dispersed in Aqueous Solutions of D-Glucose and Urea

M. L. SRIVASTAVA* and Bali RAM†
Department of Chemistry, University of Gorakhpur, Gorakhpur-273001, India
†Department of Chemistry, College of Basic Sciences and Humanities, G. B. Pant University of Agriculture and Technology, Pantanagar-263145, Nainital, India
(Received June 15, 1987)

Electrophoretic mobilities of progesterone particles dispersed in aqueous solutions of D-glucose and urea, in the concentration range 10^{-3}—10^{4} mol l^{-1} have been measured to investigate electrical properties of the interface. Zeta potentials have been determined for this purpose. The dependence of zeta potentials on concentration has also been examined. Theory of the electrical double layer has been used to explain the results.

Electrophoresis is a subject of interest in many branches of pure and applied science, playing an important role in matters as diverse as clinical diagnosis and study of colloid stability. It plays significant roles in clay technology, water purification, detergency, ore floatation, electrodeposition and is extensively used for the fractionation and analysis of proteins, nucleic acids, polysaccharides and other complex substances of biological interest and activity.[1-3] In our earlier papers[4-6] we have reported results on the electrophoresis of testosterone (a male sex hormone) particles dispersed in aqueous solutions of electrolytes (e.g. NaCl, KCl, and $MgCl_2$), nonelectrolyte (e.g. urea) and carbohydrate (e.g. D-glucose) to characterize the electrified testosterone-permeant interface. Such studies with other hormones are highly desirable. Progesterone, a female sex hormone, responsible for normal development of female sex organs and for the maintenance of secondary sex characteristics[7] has been chosen for this purpose. The characteristic biochemical and physiological effects of this hormone depends to a large extent on the properties of hormone/solution interface. A comprehensive physicochemical study with respect to progesterone interface in different type of nonelectrolytic solutions is thus needed for an understanding of the various facets of its functions.

Electroosmotic studies on progesterone-carbohydrate and progesterone-urea systems have been reported quite recently.[8] In order to supplement these studies, the electrophoresis of progesterone particles dispersed in aqueous solutions of D-glucose and urea which are of great metabolic relevane and medicinal utility[9] is being reported in the present communication

Experimental

(a) Materials and Suspensions. Progesterone obtained from Sigma Chemical Company (Saint Louis, U.S.A.) was used. AR grade samples of D-glucose and urea obtained from BDH (India) were employed as such without further purification.

Solutions of D-glucose and urea were prepared in doubly distilled water, redistilled over $KMnO_4$, having specific conductance of the order of 10^{-6} mho cm^{-1}. Suspensions were prepared by homogenizing finely grounded particles of progesterone in these solutions.

(b) Measurement of Electrophoretic Velocity. Measurements of electrophoretic velocities were made using an experimental cell shown in Fig. 1. Progesterone particles were pulverized and suspensions of these particles were prepared in the various solutions. Care was taken to obtain a fairly stable suspension. The experimental cell was fixed in a vertical position. The suspension was introduced into the experimental cell through K by opening the stopcock S, till half of the tube was filled. The stopcock S was then closed and the pure solvent/solution was gently filled in the remainder of the tube PQ so that a distinctly sharp boundary B, was formed. The diameter of the tube PQ was 0.35

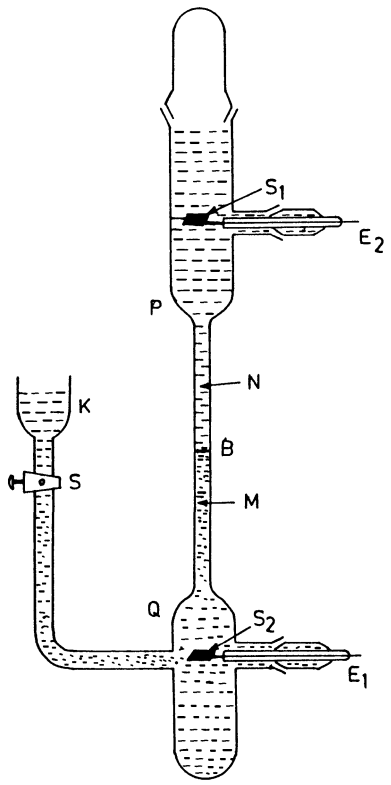

Fig. 1. Apparatus for measurement of electrophoretic velocity, S_1 and S_2 are silver plates coated with silver chloride; E_1 and E_2 are the silver wires attached with S_1 and S_2. S is the stopcock, B; boundary, K; wide mouth side tube for introducing the suspension. M; suspension, N; solvent/solution.

cm. Potential differences up to 50 volts were applied through silver-silver chloride electrodes E_1 and E_2, 15.1 cm apart, with an electronically operated power supply (HIL, India) in such a way that the movement of boundary occurred in the downward direction. The downward displacement of boundary was observed with a cathetometer reading up to ±0.001 cm. The position of boundary at various time intervals was noted and the rate of movement of boundary/electrophoretic velocity was thus determined. Corrections were made for downward movement due to the action of gravitational force. This was done by plotting the observed electrophoretic velocity against applied potential difference. The intercept on the ordinate gives the rate of suspended progesterone particles due to gravity alone. The movement of the boundary was found to occur from anode to cathode. All measurements were made in an air thermostat maintained at 25±0.5 °C.

Results and Discussion

The data on electrophoretic velocities, presented in Figs. 2 and 3, have been corrected by taking sedimentation velocities into account.

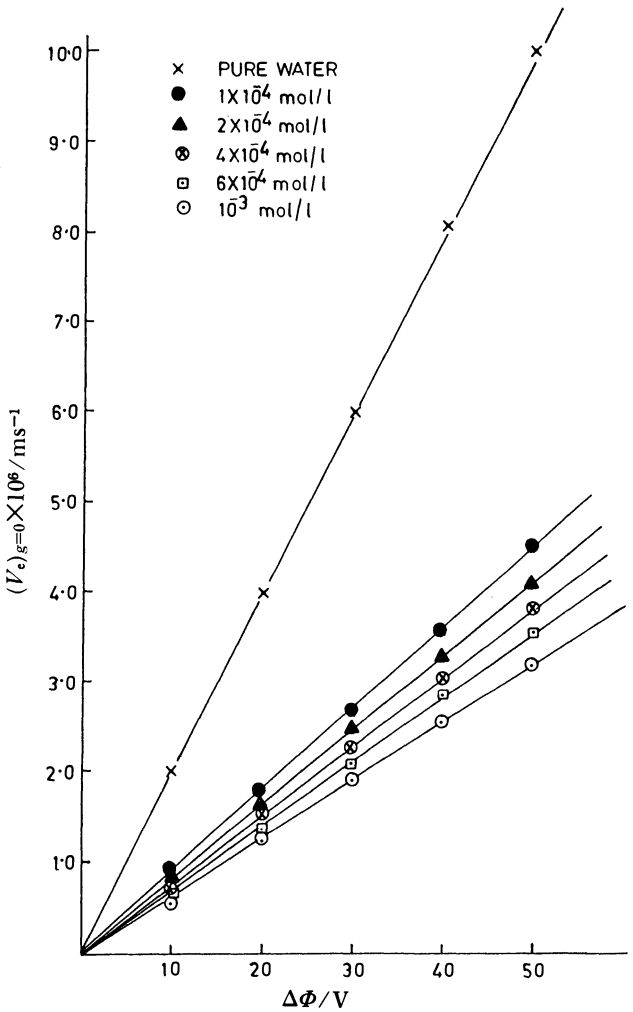

Fig. 2. Dependence of electrophoretic velocity $(V_e)_{g=0}$ on the applied potential difference, $\Delta\Phi$; for progesterone particles dispersed in aqueous solutions of D-glucose of different concentrations. (—×—) Pure water; (—●—) 1×10⁻⁴, (—▲—) 2×10⁻⁴, (—⊗—) 4×10⁻⁴, (—⊡—) 6×10⁻⁴, (—⊙—) 10⁻³ mol l⁻¹.

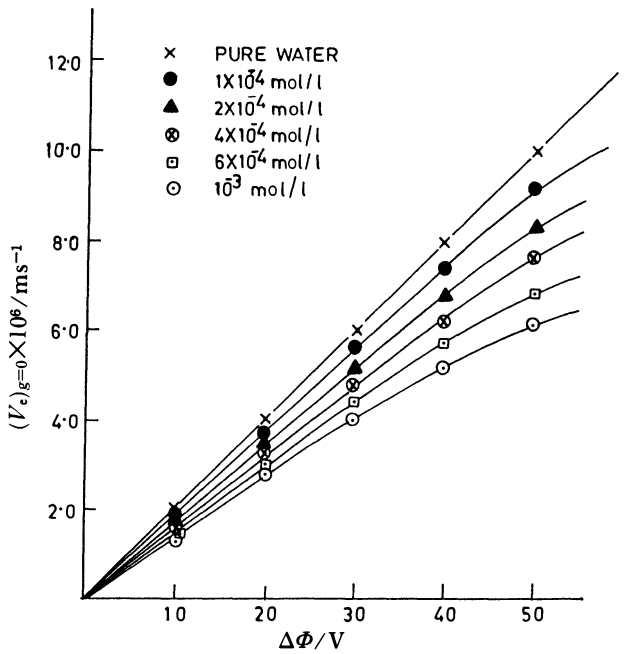

Fig. 3. Dependence of electrophoretic velocity $(V_e)_{g=0}$ on the applied potential difference, $\Delta\Phi$; for progesterone particles dispersed in aqueous solutions of urea at of different concentrations. (—×—) Pure water; (—●—) 1×10⁻⁴, (—▲—) 2×10⁻⁴, (—⊗—) 4×10⁻⁴, (—⊡—) 6×10⁻⁴, (—⊙—) 10⁻³ mol l⁻¹.

The following nonlinear second-order phenomenological equation has been found to satisfy the experimental data in case of progesterone-urea systems

$$(V_e)_{g=0} = L_{12}^* \left(\frac{\Delta\Phi}{T}\right) + \frac{1}{2} L_{122}^* \left(\frac{\Delta\Phi}{T}\right)^2, \quad (1)$$

However, in the case of progesterone-D-glucose systems, $(V_e)_{g=0}$ is found to be linearlity dependent on $\Delta\Phi$ (cf. Fig. 2) satisfying the euqation

$$(V_e)_{g=0} = L_{12}^* \quad (2)$$

with

$$\frac{L_{12}}{T} = \frac{\varepsilon\zeta_{e.p.}}{4\pi\eta l'} . \quad (3)$$

Here L_{12}^* and L_{122}^* are the first and second order electrophoretic transport coefficients respectively, ε is the dielectric constant of the medium, $\zeta_{e.p.}$ is the electrokinetic potential (or zeta potential), η is the coefficient of the viscosity of medium, and l' is the distance between the two electrodes in the electrophoretic cell.

According to Eq. 1 a plot of $(V_e/\Delta\Phi)$ against $\Delta\Phi$ yields a straight line as shown in Fig. 4.

The slope gives L_{122}^* and the intercept L_{12}^* for progesterone-urea systems. The value of L_{12}^* for progesterone-D-glucose system was obtained from the slope of linear plots of Eq. 2. The values of L_{12}^* and L_{122}^* evaluated in this way are recorded in Table 1.

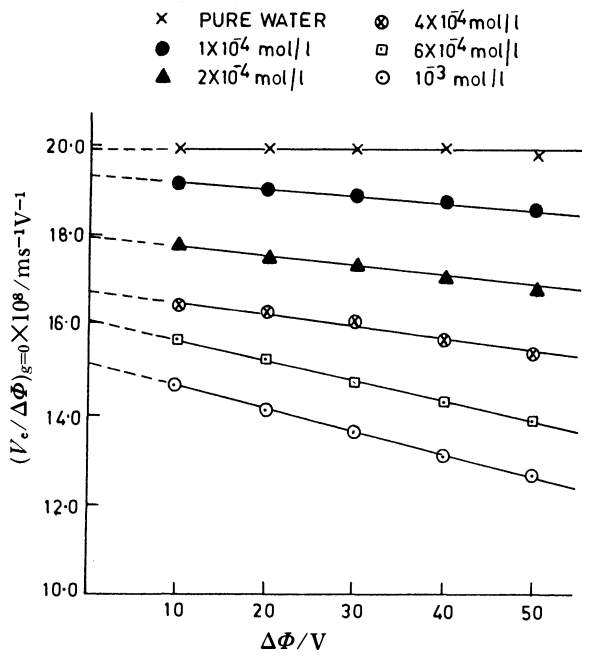

Fig. 4. Test of the applicability of the second order phenomenological equation (Eq. 1) for progesterone/aqueous urea solution systems.
(—×—) Pure water; (—●—) 1×10⁻⁴, (—▲—) 2×10⁻⁴, (—⊗—) 4×10⁻⁴, (—⊡—) 6×10⁻⁴, (—⊙—) 10⁻³ mol l⁻¹.

Evaluation of Zeta Potential. Electrophoresis, an electrokinetic phenomenon, is directly related to the nature of the mobile part of the electrical double layer, and may, therefore, only be interpreted in terms of zeta potential or the charge density at the surface of shear. Since no direct information is given about the charge density at the surface of the particles, only the zeta potential can give better information regarding the electrical nature of progesterone particles. Hence zeta potential was evaluated from the electrophoretic flux data by using the following equation.[5]

$$\zeta_{e.p.} = \frac{4\pi\eta l'}{\varepsilon} \times \left(\frac{L_{12}^*}{T}\right) \times 9 \times 10^4 \quad \text{volts} \qquad (4)$$

The occurrence of electrophoretic movement towards the cathode is an indication that an electrical double layer is formed at the surface of progesterone particles dispersed in these solutions due to adsorption of ions

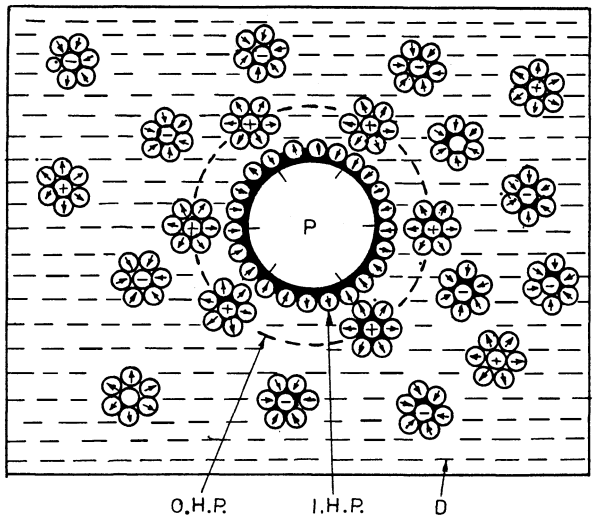

Fig. 5. Postulated picture of the electrical double layer at the progesterone/solution interface:
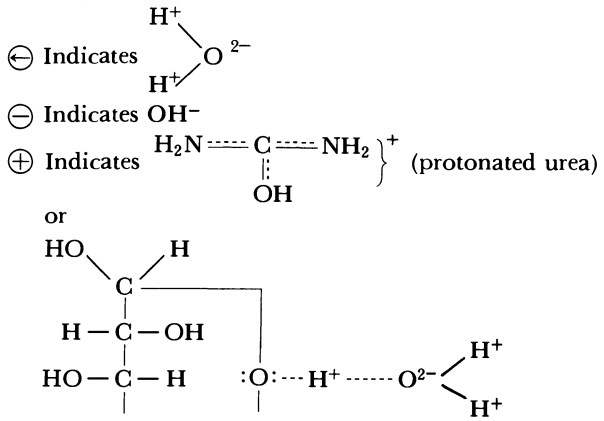
P=progesterone particle
D=diffused part of the electrical double layer



Glucose molecule surrounded with water molecules.

particularly cations (protonated urea and glucose) as shown in Fig. 5. From the schematic representation of the electrical double layer it is evident that all the progesterone particles bear a net positive charge facilitating their movement towards cathode when potential differences, $\Delta\Phi$, are imposed.

Origin of Nonlinearity. The nonlinear dependence of electrophoretic velocity, $(V_e)_{g=0}$ on applied electrical potential difference $\Delta\Phi$, for progesterone-urea system indicates that significant polarization of the electrical

double layer has occurred during electrophoresis, since water and urea both have permanent dipole moments (μ_{urea}=4.56D, μ_{H_2O}=1.85D). The polarizability α, may be represented as Ref. 10a

$$\alpha = \alpha_o + \alpha_\mu, \tag{5}$$

where α_o is the distortion polarizability and α_μ is the orientation-polarizability. The orientation-polarizability defined by[10b]

$$\alpha_\mu = \frac{\mu^2}{3kT}, \tag{6}$$

arises from the tendency of the permanent dipole moments to be oriented in the direction of the applied field.

Further, the polarizability α, is also dependent on the dipole moment that water and urea molecules acquire in an electric field $\Delta\Phi$, by the relation.[11]

$$\alpha = \frac{\mu}{\Delta\Phi} \tag{7}$$

Rastogi and Shabd[12] used Bockris[13] model of the electrical double layer for explaining the nonlinearity in electroosmotic measurements. According to them the zeta potential is regarded to be made up of two terms, $\Delta\psi$ the charge contribution potential and $\Delta\chi$, the dipolar contribution potential i.e.

$$\zeta = \Delta\psi + \Delta\chi_{eff} \tag{8}$$

with

$$\Delta\chi_{eff} = \Delta\chi_{H_2O} + \Delta\chi_{urea}. \tag{9}$$

The applied electrical potential may affect either of these contributions.

Similar considerations apply even in the case of electrophoresis. The electrical double layer around the particle is considered to be formed on account of —(i) uneven distribution of ions produced by the partial ionization of the dissociable groups of the particle itself, (ii) self dissociation of the solvent molecules, and (iii) preferential orientation of the adsorbed solvent dipoles at the particle surface.

However, the possibility of dissociation of progesterone particles under the influence of applied electrical potential does not exist.

Bockris, Devanathan, and Muller have taken into account the competition between the molecules of water and an organic substance for a site in the double layer and have emphasized the role of charge dependent orientation of water dipoles at the interface.[14] The charge on the particle will stimulate the water molecules to orient themselves (charge implies fields and dipoles tend to align with fields), resulting a water layer of oriented water dipoles at the surface. However, it must not be imagined that the water molecules are unaffected by the presence of their neighbors (urea molecule in this case). After all dipoles interact with dipoles; hence, the oriented water molecules experience lateral interaction — a phenomenon which

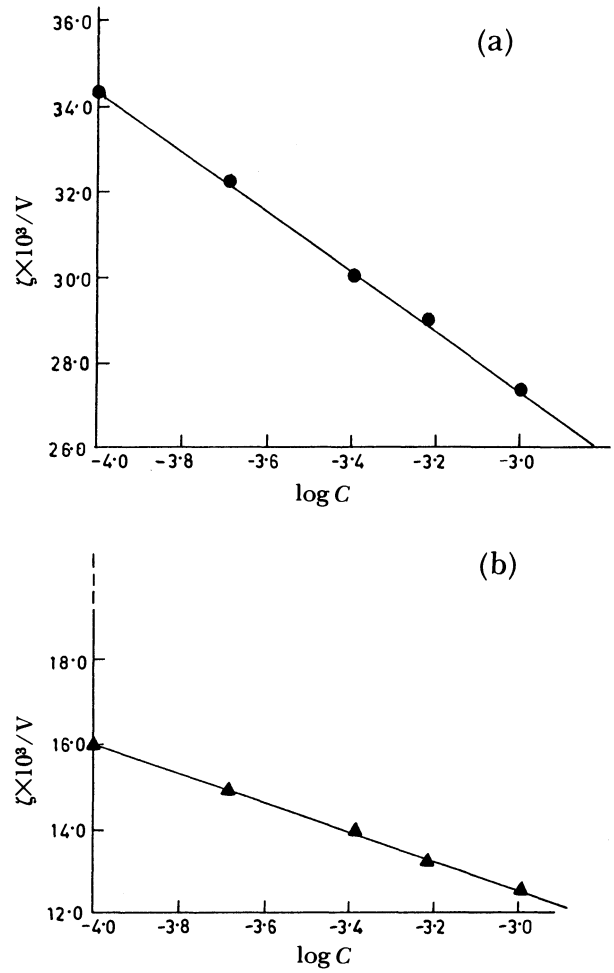

Fig. 6. Dependence of zeta potential (ζ) on log C for progesterone/aqueous solutions of urea (a); D-glucose (b).

affects the number of water molecules oriented in one direction and therefore the value of dipole potential $\Delta\chi$. Through, $\Delta\chi$, the potential difference across the interface and the structure of the interface will be affected. Thus the observed nonlinear variation of electrophoretic velocity and hence the ζ potential may be attributed to the enhanced dipolar contribution when $\Delta\Phi$ is varied. In addition, pronounced nonlinearity is observed at higher concentrations owing to strong interactions.

Zeta potential varies nonlinearly with concentration. However, the following linear equation[5,6] satisfies the dependence of zeta potential on log C.

$$\zeta = A - B \log C \tag{10}$$

where A may be taken as approximately constant for the conditions under which the charge on the membrance surface does not change sign and B is another constant which depends on topography of the surface. The results are shown in Fig. 6.

The authors are grateful to Prof. S. C. Tripathi, Head, Chemistry Department, University of Gorakhpur

for provoiding laboratory facilities, One of us (Bali Ram) is also grateful to CSIR, New-Delhi (India) for the award of a Senior Research Fellowship

Ion-Exchange Properties of Niobium(V) Materials. II. Synthesis and Characterization of Crystalline Niobium(V) Phosphate

Mohsin QURESHI,* Jai Prakash GUPTA,†† Hina KHAN, and Anees AHMAD†
Chemistry Section, Z. H. College of Engg. and Technology, Aligarh Muslim University, Aligarh 202002, India
†Analytical Laboratory, Chemistry Department, A.M.U. Aligarh 202002, India
(Received February 9, 1987)

An attempt has been made to synthesize and characterize the crystalline niobium(V) phosphate. The characterization was done on the basis of pH titration, X-ray, XPS, TGA, DSC, and IR studies. It is an ion exchange material which shows about 20% higher chemical stability over the amorphous niobium(V) phosphate. It was found to have a pseudocubical unit cell structure with a_0(H)=10.244 Å and a stiff three dimensional zeolytic structure. The empirical formula of the compound was obtained as $Nb_2O_5 \cdot 1.5\ P_2O_5 \cdot 7.5\ H_2O$. The proposed chemical formula is $(NbO)_2(HPO_4)_3 \cdot 6H_2O$ (d_{110}=7.23 Å). The exchanger is monofunctional in nature having the maximum exchange capacity of 4.6 meq g^{-1} for potassium ion at pH 8.5

During the last few years some niobium and tantalum based inorganic ion exchangers have been systhesized and their ion-exchange properties and analytical applications have been explored.[1-8] The exchangers were mostly amorphous or poorly crystalline. These studies suffer from the fact that the gels used were poorly characterized and/or the correct exchange capacity was not determined. In order to obtain thermodynamically meaningful results, the gel has to be well characterized.[9] Qureshi et al.[3] showed for the first time that when niobium antimonate is refluxed with mother liquor, its ion exchange behavior becomes more reproducible. Clearfield et al.[9] refluxed a precipitated gel of zirconium phosphate for 48 h in 0.5 M (M=mol dm^{-3}) phosphoric acid. These refluxed gels were more resistent to hydrolysis and their behavior was more reproducible than that of unrefluxed gels.

It is worthwhile to study the crystalline materials in detail as these materials show a more reproducible behavior and hence they can be used for the mechanistic studies. It is rather difficult to locate the exact exchange sites in amorphous materials and very little information exists regarding the structural aspects of amorphous inorganic ion exchangers. Further the amorphous materials show a greater tendency towards hydrolysis than the corresponding crystalline materials.

In this paper the results on the preparation and characterization of the crystalline niobium(V) phosphate are presented. Its structural properties have been elucidated on the basis of TGA, DSC, IR, XPS, and X-ray diffraction studies. An attempt has also been made to investigate the mechanism of ion exchange of alkali metal ions on this material and to locate the possible exchange sites.

Experimental

Reagents and Synthesis. Diniobium pentaoxide was obtained from BDH (Poole, England). All other reagents of analytical reagent grade were used.

Niobium solution (0.1M)[12] was prepared by dissolving calculated amount of Nb_2O_5 in concd H_2SO_4 in presence of sufficient amount of $(NH_4)_2SO_4$. The crystalline niobium(V) phosphate has been synthesized by mixing niobium solution (0.1M) and phosphoric acid (0.5M) in the volume ratio of 1:4. The pH of this mixture was adjusted to 1 with concentrated ammonia solution. The precipitate so obtained was left with mother liquor for 24 h. Then it was filtered and washed with dimineralized water until the filtrate was neutral to litmus and free from SO_4^{2-} ions. The gel was dried at 45 °C in an oven and then refluxed with 1M H_3PO_4 for 10 h. The exchanger was again washed and dried and stored over saturated solution of $BaCl_2$. It is partially in H^+-form and hence designated as C-NbPx. For ion-exchange studies, C-NbPx was converted completely into H^+-form by the batch method of Townsend[23] using 1M HNO_3. The sample will hereafter be referred to as C-NbP-H^+ in the H^+-form and C-NbP-M^+ (M^+=Li^+, Na^+, K^+ etc.) in the metal form.

Ion-Exchange Capacity. The breakthrough capacity measurements for Li^+, Na^+, Rb^+, and Cs^+ were done by the column elution method[13] using a column of 0.5 cm (i.d.). The feed (0.5 M) was passed until its pH became equal to that of the effluent collected. The hydrogen ions so eluted were titrated against standarized 0.1 M NaOH.

Composition and Chemical Stability. The exchanger was analyzed for the presence of niobium and phosphorus gravimetrically while its chemical stability in different solvents was checked spectrophotometrically using Bausch and Lomb Spectronic-710 spectrophotometer by the methods described earlier.[12]

Thermal Analysis. The TGA was performed by using 0.1 g sample. The heating was done in the atmosphere of air at the rate of 10 °C min^{-1}. The DSC was recorded in the atmosphere of helium at a flow rate of 200 ml min^{-1} and a heating rate of 10 °C min^{-1}. The results are given in Figs. 2(a) and 2(b). DuPont Thermal Analysers Model 950 and 900 were used for TGA and DSC studies respectively.

Water Absorption. The sample in H^+-form (0.5 g) was heated at 120 °C for 24 h in a covered silica crucible. It was then stored in a desiccator over a saturated solution of ammonium nitrate. The weight of the sample along with the crucible was recorded at different intervals.

pH Titration. The pH titrations were carried out by Topp and Pepper method.[10] Each sample of dry C-NbP-H^+ (200 mg) was equilibrated with 20 ml portions of

†† Present address: FOSROC Technology Ltd., Bourne Road, Aston, Birmingham, England.

0.1 M (MCl-MOH) solutions at 25±0.5 °C (M^+=Li^+, Na^+, K^+, and Cs^+). The molar ratio of MCl/MOH was varied to maintain a constant ionic strength (μ=0.1) of the equilibrating mixture. After 24 h the pH of the supernatant solutions were recorded and plotted against the milli equivalents of OH^- added per gram of dry exchanger (Fig. 1). Orion Research Microprocessor Ionalyzer/901 having combination glass electrode was used for the pH measurements.

X-Ray Diffraction and XPS Studies. Powder X-ray diffractograms of the exchanger in H^+, Li^+, Na^+, and K^+-forms were taken using nickel filtered Cu $K\alpha$ radiations. On the other hand only two samples of the exchanger, namely, C-NbPx and C-NbP-K^+ were used for XPS (or ESCA) studies (see Table 1).

IR Studies. The infrared spectra of niobium phosphate in H^+, Li^+, Na^+, and K^+-forms along with that of niobium hydroxide, synthesized in the laboratory, were taken using the KBr disc technique and recorded on a Perkin Elmer Spectrophotometer-621. The results are shown in Fig. 3.

Results and Discussion

The crystalline phase of niobium(V) phosphate, C-NbP, shows reproducibility in its ion-exchange capacity, composition and other characteristics. The chemical dissolution data of C-NbP-H^+ (Table 2) show an overall ca. 20% higher chemical stability over the amorphous niobium(V) phosphate[12] probably due to its crystalline nature. The trend of its stability, in different media, is similar to that of the amorphous material, i.e., HNO_3>HCl>CH_3COOH≫tartaric acid>H_2SO_4>NH_4OH>KOH. The same trend of stability of the two materials may be due to their similar chemical nature. They are less stable in sulfuric and tartaric acids due to the formation of sulfate and tartarate of niobium. On the other hand they are more soluble in ammonium and potassium hydroxides because of high pH.

The breakthrough capacities (meq g^{-1}) of C-NbP for the alkali metal ions decreas in the order K^+ (1.37)>Na^+(1.06) >Rb^+(0.86) >Cs^+(0.84) >Li^+ (0.70) showing a preferential uptake for potassium ions and the least uptake for lithium ions. The pH titration curves (Fig. 1) shows a similar trend. Furthermore, this order of uptake is only possible when the exchanger has an inelastic matrix. If the matrix were elastic, it would have resulted in a different order of exchange, probably parallel to the Hofmeister's lyotropic series i.e., Li^+<Na^+<$K^+$$Rb^+$<$Cs^+$. This adsorption sequence has been observed in zirconium phosphate and organic cation-exchange resins, which possess the elastic structure.[8] As we do not find this order of uptake in the crystalline niobium(V) phosphate, we can say that it may have a stiff three dimensional structure having a fixed pore size.

The results of X-ray diffraction (XRD) studies of C-NbP-H^+ show a large number of d-values of which the important $d(I/I_0)_{hkl}$ are 7.23 $(85)_{110}$, 4.55 $(41)_{210}$, 3.23 $(100)_{310}$, 2.28 $(43)_{420}$, and 1.42 $(29)_{551,711}$. The XRD of the different cationic forms (H^+, Li^+, Na^+, and K^+-forms) of the exchanger show that their d values are very close to each other and hence one can say that the exchanger possesses an appreciably stiff structure. The analysis of the X-ray data reveals its pseudocubical unit cell structure with $a_0(H^+)$=10.224 Å.

Since the exchanger is precipitated in presence of large amounts of SO_4^{2-} and NH_4^+ ions with the help of concentrated ammonia solution, it is reasonable to assume the possible contamination of the exchanger with these ions. XPS (or ESCA) studies were conducted to check this possibility. It is worth noting from Table 1 that only initially some NH_4^+ ions are present (as shown by a peak of nitrogen) in the exchanger which are later replaced by the potassium ions when the exchanger is converted into K^+-form. The XPS studies show no sign for the presence of sulfur and this rules out the possibility of sulfate contami-

Table 1. Binding Energies and Percent Atomic Compositions of Niobium(V) Phosphate Obtained by XPS

NbP3 = Amorphous niobium phosphate [12]

nation of the exchanger. Hence we can say that initially the exchanger (C-NbPx) contains some ammonium ions in exchanged form only and not due to entrapped ammonia/ammonium salt. The binding energies also confirm the presence of Nb and P in their pentavalent state. The ESCA of the sample shows surface contamination of niobium(V) phosphate due to carbon (Table 1). This contamination may be due to (i) rotary pump oil vapours adsorbed on the surface of the pellet during the pressing, (ii) the presence of niobium carbide as an impurity in Nb_2O_5, (iii) the adsorption of atmospheric CO_2 by the exchanger leading to the formation of carbonate on the surface of the material. Similar results were obtained by Alberti in the ESCA spectra of $ZrPO_4$.[10,11] The percent atomic composition of the surface obtained by XPS shows the Nb/P mole ratio between 1.42—1.54 (Table 1) which is very close to the 1.5 obtained by chemical analysis of the sample. This shows that the surface and the bulk composition is the same. On the basis of these findings one can assign the following formula to the H^+-form of C-NbP.

$$(NbO)_2(HPO_4)_3 \cdot nH_2O \quad (1)$$

The infrared spectra of C-NbP-H^+ (Fig. 3,b) shows a band between 3600—3100 cm^{-1} having two strong maxima at 3150 and 3450 cm^{-1}. They are characteristic of stretching vibrations of coordinated water molecules and this implies that hydrogen bonding exists between OH groups and water molecules surrounding them.[18] A sharp peak at 1630 cm^{-1} corresponds to the deformation vibration of interstitial water molecules and the hydroxyl group [$\delta(H_2O)$ and (OH)]. The sharp peak at 1400 cm^{-1} and a broad and strong peak at 1010 cm^{-1} may be assigned to the deformation vibration of P-OH groups [δ_2(P-OH)]. The peak at 690 cm^{-1} corresponds to the P-O stretching while those at 510 and 380 cm^{-1} may correspond to M-O interatomic vibrations [ν_1(Nb-O, P-O)]. The small peaks appearing between 260—200 cm^{-1} are due to the lattice vibrations.

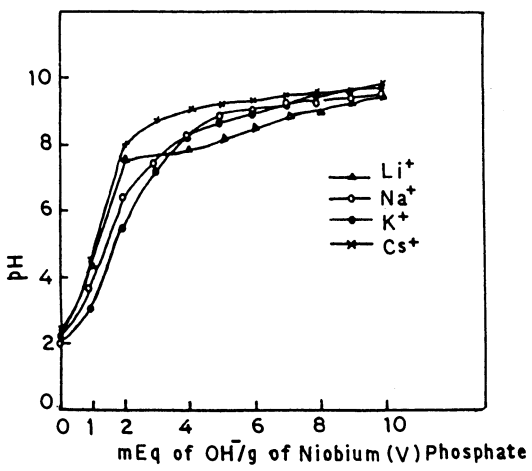

Fig. 1. pH-titration curves of Li^+, Na^+, K^+, and Cs^+, ions on the crystalline niobium(V) phosphate.

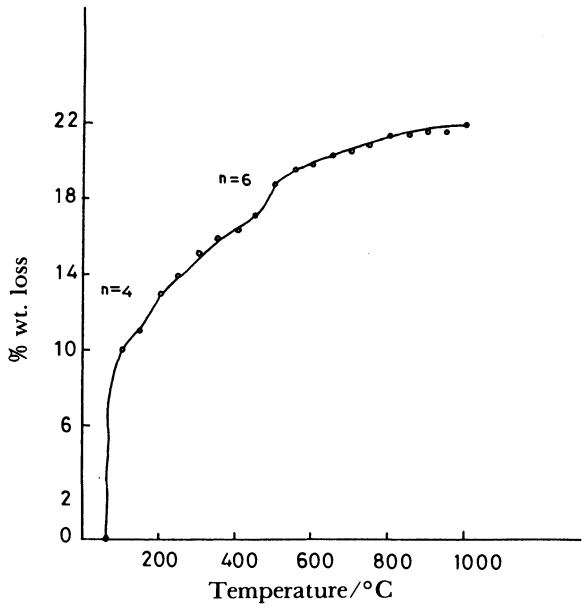

Fig. 2(a). TGA curve of crystalline niobium(V) phosphate(C-NbP-H^+).

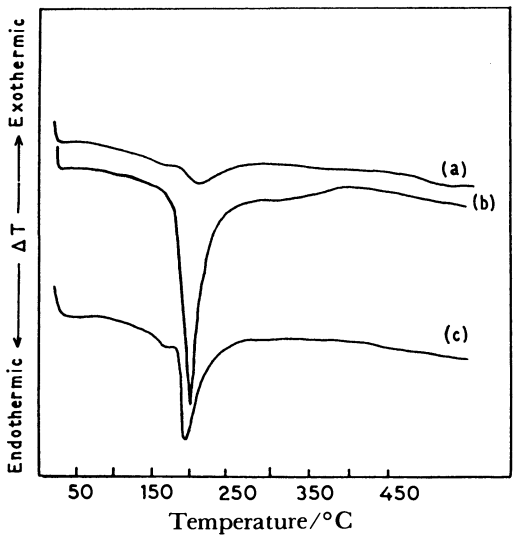

Fig. 2(b). DSC curves of crystalline niobium(V) phosphate; a=C-NbP-H^+, b=C-NbP-Na^+, c= C-NbP-K^+.

On comparing the IR spectroscopic behavior of niobium phosphate in the H^+-form with those in the Na^+ and K^+-forms (Fig. 3), it is found that all the three have a similar type of lattice structure. In the spectra of these three samples, bands relating to acidic HPO_4^{2-} groups (3150, 2320, 1400, and 510 cm^{-1}) are found.[18] If the alkali metal content approaches the total capacity value, these frequencies virtually disappear and only bands relating to water of crystallization are visible. Such a change suggests that the material was composed of strongly hydrogen bonded three dimensional aggregate,[19,20] having HPO_4^{2-} groups as the cation exchange sites. Here the proton of HPO_4^{2-} group is exchanged by M^+.

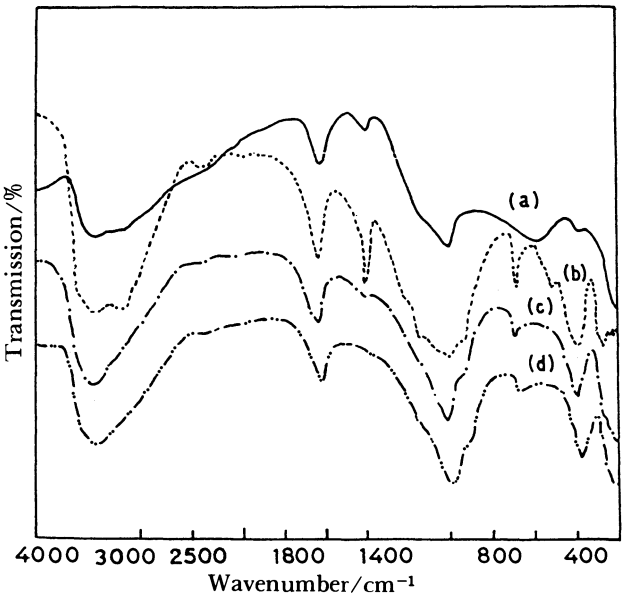

Fig. 3. IR spectra of niobium hydroxide and crystalline niobium(V) phosphate;
a=Nb-OH, b=C-NbP-H^+, c=C-NbP-Na^+, d=C-NbP-K^+.

$$HPO_4^{2-} + M^+ \rightleftarrows MPO_4^{2-} + H^+$$

Further the thermoanalytical investigations of C-NbP-H^+ indicate a weight loss of 22% up to 1000 °C (Fig. 2a). Assuming that at this temperature the composition of the sample is $Nb_2O_5 \cdot 1.5\ P_2O_5$, the number of moles of water lost per formula weight of the exchanger was calculated as 7.5.[21] It is the total number of moles of water present, a part of these are present as water of crystallization (6 mol) and the rest as water of constitution (1.5 mol). The later split up to form the OH species of the anionic part (HPO_4^{2-}) of which H^+ seems to give hydrogen exchange capacity in the H^+-form of the exchanger.[22] The DTA curves of the sample in H^+, Na^+, and K^+-forms are shown in Fig. 2b. It is evident that most of the water of crystallization is removed up to 200 °C after which there is a continuous energy consumption and loss in weight. It may be due to the removal of the remaining water of crystallization which are probably coordinated to niobium.

The weight loss at a higher temperature in C-NbP-H^+ may be owing to the condensation of HPO_4^{2-} species to $P_2O_7^{4-}$. This process of dehydration is an irreversible process above 200 °C and the water lost is not regained even after immersing the treated sample in water. But at 150 °C, 3.32 moles of water per formula weight are reversibly lost by the exchanger. The exchanger reabsorbs the lost water when left in atmosphere and results in the cracking of the former.

Further there is only one inflection point in the pH titration of C-NbP-H^+ corresponding to the monofunctional behavior of this material (see Fig. 1). Its ion-exchange capacity as determined by the titration curve, is 4.6 meq g^{-1} for K^+ at pH 8.5.

On the basis of these findings we can write the empirical formula as follows

$$(NbO)_2(HPO_4)_3 \cdot 6H_2O \quad (d_{110} = 7.231\ Å) \quad (2)$$
[Theoretical Exchange Capacity = 4.88 meq g^{-1}]

This formula agrees well with the experimental findings. The uptake of K^+ ions (46 meq g^{-1}) is very close to the theoretical exchange capacity of the proposed formula.

The CSIR (INDIA) is thanked for financial assistance.

Barium Ferrate Monohydrate $BaFeO_4 \cdot H_2O$, a Useful Oxidant for the Oxidation of Organic Compounds under Aprotic Conditions

Habib FIROUZABADI,* Daryoush MOHAJER, and Mohsen ENTEZARI-MOGHADAM
Chemistry Department, Shiraz University, Shiraz, Iran
(Received April 20, 1987)

Preparation of barium ferrate monohydrate with a slight modification is described. It is shown that this reagent is capable of oxidizing different organic compounds and could be used as a versatile reagent in organic synthesis. Primary and secondary alcohols are converted to their carbonyl compounds, α-hydroxy ketones to their diketones, and hydroquinones to their quinones. Aromatic amines are converted to their azo compounds, benzylamine to benzaldehyde, phenylhydrazones and oximes to their carbonyl compounds. Thiols are also converted to their disulfides in high yields. This reagent seems to be a non-toxic and a non-pollutant compound.

Oxidations of organic substrates have long been performed by manganese dioxide, potassium permanganate, chromium trioxide, and pottasium dichromate in organic synthesis.[1-3] The reaction conditions, special treatment for the activation of the reagent, and the lack of selectivity have restricted their use as oxidizing reagents in modern organic synthesis. Recently several chromium(VI) and manganese based oxidants have been prepared and reported in the literature,[4-35] in order to minimize the limitations encountered with mentioned reagents.

Reports are available which discuss manganese and chromium(VI) based oxidants and indicate that these reagents are toxic, pollutant, and are also corrosive and irritant to skin and mucous membrane.[26] Very recently it is reported that Cr(III), the product of the reduction of Cr(VI) is an animal carcinogen.[37]

Manganate, chromate, and ferrate anions are structurally similar species and as an oxidizing agent, organic chemists have long been familiar with potassium chromate. Recently attention has been paid to manganates as oxidizing agents and a few reports are also available in the literature.[30-32] Reports also exist which indicate that potassium ferrate has been used as an oxidizing reagent,[38-40] but the results reported are contradictory. Moreover, the reactions are performed in strongly basic aqueous media (pH 11.5—13.5) which limits drastically the use of this reagent as a versatile oxidizing agent in organic synthesis.

Ferrate anion decomposes in the presence of water according to the following equation;

$$2H_2O + 2FeO_4^{2-} \rightarrow Fe_2O_3 + 3/2O_2 + 4OH^-$$

The products obtained are unlikely to be toxic and pollutant. It is also reported that ferrate anion is a strong oxidant.[41] Unfortunately very little attention has been paid to these properties in preparative organic chemistry.

Very recently we have reported that silver ferrate[42] could be a good substitute for the potassium ferrate phase-transfer catalysis oxidation,[40] where a neutral, nonaqueous, and aprotic medium is of importance. However, silver ferrate is an expensive and a moderately stable reagent, therefore, these findings limit the use of this compound as a versatile agent.

The purpose of this investigation was to find a ferrate compound which would be stable and cheap, and could be used as a versatile oxidant in organic synthesis. The preparation of Co^{2+}, Pb^{2+}, Hg^{2+}, Fe^{3+}, and Zn^{2+} ferrate have been examined. Unfortunately it was found that all of these compounds were highly unstable and liberate their oxygen immediately after their formation in the reaction media.

Lately in a communication we introduced barium ferrate monohydrate[43] as an oxidizing agent for the oxidation of alcohols, and its advantages over potassium ferrate and manganese dioxide were indicated. Here we discuss with a slight modification, the preparation of pure barium ferrate monohydrate. We have extended our studies upon the oxidation of different classes of organic compounds with this reagent. Most of the results obtained are also extensively compared with barium manganate, a new and commercially available reagent.[31,32]

Results and Discussion

First sodium ferrate was prepared according to the procedure described by Thompson et al.[44]

In the previous report, barium ferrate monohydrate[45] has been prepared from potassium ferrate which in turn was made from sodium ferrate. In the present report we have used directly the solution of sodium ferrate as the precurser for the preparation of the barium salt, which improves drastically the yield of the desired product. By the addition of saturated solution of barium nitrate to the solution of sodium ferrate, barium ferrate monohydrate was precipitated immediately. In this preparation carbon dioxide-free distilled water was important, in order to avoid the formation of the corresponding carbonate. The precipitated barium ferrate monohydrate was washed with a weakly acidic solution (pH=5) until the filtrates pH reached 7, and was dried overnight in a vacuum desiccator under a dynamic vacuum.

Oxidation of organic substrates with barium ferrate monohydrate gives reproducible results and activation

of the reagent is not necessary. In contrast, oxidation with manganese dioxide usually does not give reproducible results.[20] Barium ferrate monohydrate is a very stable compound and could be stored for months without losing its oxidizing potential. This compound is a dark purple powder, which is very slightly soluble in water. Barium ferrate monohydrate does not irritate mucous membrane and skin, whereas barium manganate seriously does irritate mucous membrane. According to our findings, barium ferrate monohydrate is a good oxidizing reagent in organic synthesis and may replace toxic and pollutant reagents. This reagent is a good substitute for manganese dioxide in many respects; 1) it does not need special treatment for its activation, 2) the ratio of substrate to manganese dioxide can range from 1 : 5 to 1 : 50, this ratio for barium ferrate monohydrate in this study ranged from 1 : 1 to 1 : 10, which makes the isolation of the oxidation product from the reaction mixture easier and more practical, 3) the rate of the reaction and 4)

the yields are usually higher with barium ferrate monohydrate than those reported for active manganese dioxide (Table 1). The results obtained with this reagent are also very comparable with those obtained with barium manganate (Table 1). Barium ferrate monohydrate is a mild oxidizing agent and oxidizes different organic substrates in benzene, heptane, and toluene under reflux conditions.

Benzylic alcohols were converted to the corresponding carbonyl compounds in high yields. Cinnamyl alcohol was converted to cinnamaldehyde almost quantitatively. Saturated primary and secondary alcohols were also converted to their carbonyl compounds in good yields. α-Hydroxyketones, such as benzoin and furoin were converted to benzil and furil in excellent yields (Table 1).

The mildness of this reagent is demonstrated by the oxidation of different thiols to their corresponding disulfides in excellent yields (Table 2).

Coupling reaction of aromatic amines to their corresponding azo compounds were also investigated. 1-Naphthylamine and aromatic amines with nitro groups substituted on the aromatic ring gave low yields of their corresponding azo compounds. The same oxidations with manganese dioxide is reported to be quite unreactive.[46] Other amines such as benzylamine were converted to benzaldehyde quantitatively. Aniline, *m*- and *p*-chloroanilines, and *m*-toluidines were converted to their azo compounds in moderate yields (Table 3). Phenylhydrazine was converted to biphenyl in good yield. Oxidation of *p*-nitrophenylhydrazine and 2,4-dinitrophenylhydrazine produced nitrobenzene and *m*-dinitrobenzene respectively in good yields (Table 3). Oxidation of several oximes were also investigated. Benzophenone oxime, benzaldehyde oxime, and 2-naphthaldehyde oxime produced their corresponding carbonyl compounds from low to good yield. Anisaldehyde phenylhydrazone produced anisaldehyde in good yield. Benzophenone phenylhydrazone produced benzophenone in high yields and also biphenyl as a by-product (Table 3).

Catechol and hydroquinone were converted their

quinones in excellent yields. Alizarin was quite resistant towards oxidation with this oxidant (Table 1).

Experimental

General. All yields refer to isolated products. Products were characterized by comparison with authentic sample (IR spectrum, thin-layer and gas chromatography, melting point, and refractive index). Most reaction proceeded in dry benzene, unless otherwise indicated.

Preparation of Barium Ferrate Monohydrate. Sodium hydroxide (30 g) was dissolved in 75 ml of carbon dioxide-free distilled water and the solution was cooled to 20 °C. Chlorine gas was slowly bubbled through this solution, while being stirred vigorously, until a total weight gain of 20 g was achieved. The resulting hypochlorite solution was made strongly basic with the slow addition of 70 g of sodium hydroxide while the solution was being stirred vigorously and the temperature was permitted to rise to 30 °C. The resulting reaction mixture was cooled to 20 °C and the precipitated sodium chloride was removed by filtration. To the stirred solution of the resulting sodium hypochlorite at 25—30 °C, 25 g of iron(III) nitrate was added slowly, and this solution was saturated with sodium hydroxide at 30 °C with stirring. The reaction mixture was filtered with suction and to the resulting filtrate a sufficient amount of saturated solution of barium nitrate was added with stirring. The precipitated barium ferrate monohydrate was filtered rapidly and washed with a weakly acidic solution (pH=5) until the filtrates pH reached 7. The precipitate was dried overnight in a vacuum desiccator under a dynamic vacuum. The yield, based on sodium ferrate was almost quantitative. The analytical data were consistent with the proposed structure.

Oxidation of Benzhydrol to Benzophenone, Typical Procedure. To a solution of benzhydrol (194 mg, 0.001 mol) in dry benzene (30 ml), in a 100 ml round-bottomed flask, equipped with a condenser and magnetic stirrer, barium ferrate (1188 mg, 0.003 mol) was added and refluxed for 50 min. The reaction mixture was filtered with suction and the solid material was washed with benzene for several times. The filtrates were added together and evaporated. The resulting material was chromatographed on a silica-gel column eluted with benzene. Evaporation of the solvent afforded benzophenone (176 mg, 97%) (Table 1).

Oxidation of *p*-Chloroaniline to Its Corresponding Azo Compound, Typical Procedure. In a round-bottomed flask (100 ml), equipped with a condenser and a magnetic stirrer, *p*-chloroaniline (101 mg, 0.01 mol) in dry benzene (30 ml) was mixed with barium ferrate (1375 mg, 0.005 mol) and refluxed for 1.5 h. The reaction mixture was filtered with suction. The solid material was washed with acetone (15 ml). The filtrates were added together and evaporated. The resulting material was chromatographed on a silica-gel column eluted with benzene. Evaporation of the solvent afforded the desired azo compound (22.5 mg, 50% yield) (Table 3).

Conversion of Cyclohexanethiol to Dicyclohexyl Disulfide, Typical Procedure. To a solution of cyclohexanethiol (116 mg, 0.001 mol) in dry benzene (20 ml) in a 50 ml round-bottomed flask, equipped with a condenser and a magnetic stirrer, the oxidant (550 mg, 0.002 mol) was added. The resulting mixture was refluxed for 30 min. The reaction mixture was filtered, the solid material was washed with acetone (10 ml). The filtrates were added together and evaporated. The resulting material was chromatographed on a silica-gel column eluted with benzene. Evaporation of the solvent afforded the desired disulfide quantitatively (Table 2).

Conversion of Phenylhydrazine to Biphenyl, Typical Procedure. In a round-bottomed flask (50 ml), equipped with a condenser, and a magnetic stirrer, the oxidant (1375 mg, 0.005 mol) was added to a solution of phenylhydrazine (108 mg, 0.001 mol) in dry benzene (30 ml). The resulting mixture was refluxed for 6 min. The reaction mixture was filtered and the filter cake was washed with acetone (10 ml). The filtrates were added together and evaporated. The resulting material was chromatographed on a silica-gel column eluted with benzene. Evaporation of the solvent afforded biphenyl (54 mg, 70%) (Table 3).

Oxidation of Benzophenone Phenylhydrazone, Typical Procedure. In a round-bottomed flask (50 ml), equipped with a condenser and a magnetic stirrer, benzophenone phenylhydrazone (81 mg, 0.0003 mol) in dry benzene (30 ml) was mixed with the oxidant (495 mg, 0.00018 mol) and refluxed for 6 h. The reaction mixture was filtered with suction. The solid material was washed with acetone (10 ml). The filtrates were added together and evaporated. The resulting material was chromatographed on a silica-gel column eluted with benzene. Two fractions were isolated; benzophenone (47 mg, 85%) and biphenyl (4.5 mg, 10%) (Table 3).

Deoximation of Benzophenone Oxime, Typical Procedure. Barium ferrate monohydrate (171 mg, 0.0006 mol) was added to a solution of benzophenone oxime (24 mg, 0.00012 mol) in dry benzene (31 ml) in a round-bottomed flask (50 ml) equipped with a condenser and a magnetic stirrer. The resulting mixture was refluxed for 30 min. The reaction mixture was filtered and the filter-cake was washed with benzene (10 ml). The filtrates were added together and evaporated. The resulting material was chromatographed on a silica-gel column eluted with benzene. Evaporation of the solvent afforded benzophenone (20 mg, 91%) (Table 3).

(Received October 15, 1987)

Synopsis. 1,3,5,7-Tetramethyltetrahydro-1,3,5,7-tetrazocine-2,6-(1*H*,3*H*)-dione was prepared in a good yield, and its crystal structure was determined by means of X-ray analysis. The molecule is centrometric. It has practically a planar structure except for four methyl groups and two methylene linkages and a hole of 0.5—1.6 Å in the interior of the ring structure.

Many investigators[1-5] have reported on the condensation products of urea and urea derivatives with formaldehyde since Tollens.[6] Although most of these products are soluble crystalline compounds, however, no report on their crystal structures has been published.

1,3,5,7-Tetramethyltetrahydro-1,3,5,7-tetrazocine-2,6-(1*H*,3*H*)-dione (tetramethyldimethylenediurea: TMDMU) was prepared as needle crystals by Kadowaki in 1936.[7] *N,N'*-Dimethylurea was hydroxymethylated with formalin in the presence of barium hydroxide. Without the isolation of the hydroxymethylated products, they were methylenized in MeOH and concd HCl using the procedure of Kadowaki.[7] The yield of TMDMU from *N,N'*-dimethylurea was found to be 13%. It was supposed to have an eight-membered ring structure.

In order to confirm the cyclic nature of this compound and to elucidate its structural characteristics, TMDMU was prepared in a good yield and its crystal structure was determined by means of X-ray analysis.

Experimental

Preparation of TMDMU. Ten grams of *N,N'*-dimethylurea and 23.5 g of formalin were mixed, and the pH of the reaction solution was adjusted to 8.8 by the successive addition of a 0.1M NaOH solution (1 M=1 mol dm^{-3}). While its temperature was kept at 50 °C, the solution was stirred for 30 min. These hydroxymethylation conditions were milder than those adopted by Kadowaki.[7] The reaction mixture was then evaporated to dryness under reduced pressure at a low temperature. A large excess of MeOH was added to the desiccated products. Keeping the temperature of the solution at 0—5 °C by using an ice bath, the hydroxymethylated products were methoxymethylated in the presence of concd HCl. After 30 min, the reaction solution was neutralized with a 20% NaOH solution below −15 °C and then concentrated under reduced pressure. The resulting viscous solution was distilled at 1—2 Torr (1 Torr=133.322 Pa), and a distillate of 95—99 °C containing *N*-methoxymethyl-*N,N'*-dimethylurea was collected (71% yield). As an acid catalyst, 100 mg of *p*-toluenesulfonic acid was added to 5 g of *N*-methoxymethyl-*N,N'*-dimethylurea. The reaction mixture was heated in an oil bath at 110 °C for 30 min. On cooling, white crystals were deposited; they were subsequently recrystallized from EtOH. The yield of TMDMU from *N*-methoxymethyl-*N,N'*-dimethylurea was 86%. The overall yield of TMDMU from *N,N'*-dimethylurea was ca. 60%. Possibly this good yield is due to the mild hydroxymethylation and the use of isolated *N*-methoxymethyl-*N,N'*-dimethylurea and *p*-toluenesulfonic acid. The use of concd HCl or sulfonic acid slightly decreased the yield of TMDMU and increased the amount of bis(*N,N'*-dimethylureido)-methane. TMDMU was identified by means of elemental analysis, FD-MS, and ^{1}H NMR spectrometry. Mp 258 °C: Found: C, 47.98; H, 8.14; N, 27.99%: ^{1}H NMR (DMSO-d_6): δ=2.99 (12H, s, -C$\underline{H}_3$), 4.33 (4H, q, J_{ab}=15 Hz, -C$\underline{H}_2$-): MS (FD): m/z=200 (M^+).

X-Ray Analysis. A white crystal with dimensions of ca. 0.2×0.2×0.3 mm^3 was used. The intensity data were measured on a Rigaku AFC-6S automated four-circle X-ray diffractometer, with graphite-monochromated Mo $K\alpha$ radiation (λ=0.7107 Å), by means of the ω-2θ scan technique up to 2θ of 60° (scan speed=4° min^{-1}). The absence of systematic ($0k0$) reflections for $k=2n+1$ and ($h0l$) for $l=2n+1$ indicates that the space group is $P2_1/c$.

Crystal Data: $C_8H_{16}N_4O_2$, M.W.=200.24, monoclinic, space group $P2_1/c$: a=4.095(2), b=11.262(2), c=11.134(2) Å, β=103.68(4)°, V=498.9(5) Å^3, Z=2, D_c=1.33 g·cm^{-3}, μ(Mo $K\alpha$)=0.9 cm^{-1}. Among the 1462 reflections measured, 1119 reflections with $|F_o|>3\sigma(|F_o|)$ were used for the structure determinations. The measured intensities were corrected for the Lorentz-polarization factors, but no absorption correction was applied. All the calculations were carried out on a HITAC M-680H computer at the Computer Center of The University of Tokyo, using the local version of UNICS.[8] All the scattering factors were taken from the International Tables for X-Ray Crystallography.[9] The structure of TMDMU was solved by the direct method and refined by the block-diagonal least-squares procedure to a final R value of 0.047. The final atomic parameters are listed in Table 1. The complete table of observed and calculated structure factors is kept as Document No. 8800 at the Editor of the Bulletin of the Chemical Society of Japan.

Table 1. Final Atomic Parameters (Positional ×10^4, for H×10^3) and Thermal Parameters (B_{eq} for non H×10, B_{iso} for H×10), with Their Estimated Standard Deviations in Parentheses

Atom	x	y	z	B_{eq} (B_{iso})/Å^2

H_{43}	−308(6)	506(2)	165(2)	16(5)

Results and Discussion

A perspective drawing of the molecular structure of TMDMU is shown in Fig. 1. This figure is a view perpendicular to the plane which is composed of O, C_1, N_1, and N_2. The four atoms of O′, C_1', N_1', and N_2' are placed on practically the same plane. The structure agrees with that deduced from the spectroscopic data. The selected interatomic distances and angles are given in Table 2. The observed interatomic distance for the carbonyl group in TMDMU (1.216 Å(C_1-O)) is in fair agreement with 1.207 Å (C=O),[10] but differs from that of 1.262 Å in urea.[11] The C-N bonds of the ureido moiety in TMDMU (C_1-N_1: 1.377 and C_1-N_2: 1.378 Å) are longer than that of 1.335 Å in urea. These differences are correlated to the extent to which resonance occurs in TMDMU and urea. Furthermore, the difference in the C-O bond is probably due to the absence and presence of hydrogen bonds in TMDMU and urea respectively. All the hydrogen atoms of the two amino groups have been substituted in TMDMU, while four hydrogen atoms in urea form hydrogen bonds with oxygen atoms in the adjacent three molecules.[11]

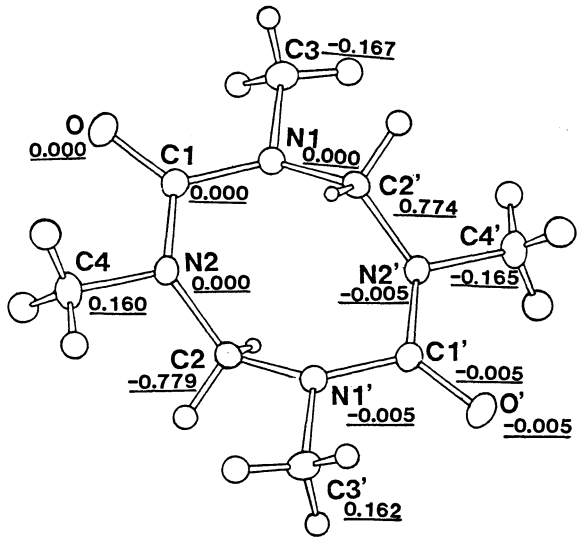

Fig. 1. The structure of 1,3,5,7-tetramethyltetrahydro-1,3,5,7-tetrazocine-2,6(1*H*,3*H*)-dione projected on the plane composed of O, C_1, N_1, and N_2. Underscored numbers are heights in Å of the atoms above or below the plane.

Table 2. Selected Interatomic Distances and Bond Angles for 1,3,5,7-Tetramethyltetrahydro-1,3,5,7-tetrazocine-2,6(1*H*,3*H*)-dione
N'_1 is the nitrogen atom opposite to N_1.

Bond distance	l/Å	Bond angle	ϕ/°
O-C_1	1.216(7)	C_1-N_1-C_3	116.2(7)
N_1-C_1	1.377(3)	C_1-N_2-C_2	119.0(11)
N_1-C_3	1.461(5)	C_1-N_2-C_4	116.1(4)
N_2-C_1	1.378(4)	C_2-N_2-C_4	117.5(12)
N_2-C_2	1.464(7)	O-C_1-N_1	122.7(6)
N_2-C_4	1.459(9)	O-C_1-N_2	122.7(10)
C_1-N_1'	1.458(9)	N_1-C_1-N_2	114.6(5)
		N_1-C_2-N_2	115.6(8)
		N_2-C_2-N_1	115.6(8)

In TMDMU, the interatomic distances between C_1-C_1', C_2-C_2', N_1-N_1', and N_2-N_2' are 4.09, 2.88, 3.38, and 3.76 Å respectively. The molecule has a hole which is surrounded by four electronegative nitrogen atoms, four hydrophobic methyl groups, and two methylene linkages. The size of the hole is estimated to be 0.5—1.6 Å by considering the radius of van der Waals. When the addition of TMDMU to the solution of phenol alkaline metal salts, the characteristic shoulder at 225 nm disappears and the absorption spectrum in UV region changes to that of phenol. This spectral change is observed in the solution of Li or Na salt, but not in that of K salt. The addition of *N,N′*-dimethylurea or *N*-methoxymethyl-*N,N′*-dimethylurea causes no spectral change in the solution of phenol alkaline metal salts. Although the details remain to be elucidated, these may be a specific interaction between TMDMU and Li^+ or Na^+.

The authors wish to express their hearty thanks to Prof. Hayao Kobayashi of Toho University for his kind support in the data collection on the Rigaku AFC-6S and the computation.

The Refractive Index of Molten $CaCl_2$-NaCl Mixtures

Kazuo IGARASHI* and Junichi MOCHINAGA
Department of Synthetic Chemistry, Faculty of Engineering, Chiba University, Chiba-shi, Chiba 260
(Received December 21, 1987)

Synopsis. The refractive indices of molten $CaCl_2$-NaCl mixtures were measured goniometrically with visible light at nine wavelengths and represented as a function of both the temperature and the wavelength using a modified Cauchy relation. Information on electronic polarization is also reported.

The knowledge of the refractive index of a melt is very useful for obtaining the hypersonic velocity which characterizes the high-temperature relaxation process.[1] Moreover the temperature derivatives of the indices are necessary for measuring the thermal conductivity of the liquids by means of wave-front shearing interferometry.[2] Furthermore the indices can be used to estimate the molar refractivity and the electronic polarizability in terms of the Lorentz-Lorenz equation and the Clausius-Mossotti equation, based on the evaluation of the effective local field around the species. We have measured the refractive indices for several binary chloride melts[3-7] and have evaluated the electronic polarizabilities of the ions in the mixture melts. The molten $CaCl_2$-NaCl mixture is of interest because the Ca^{2+} (0.100 nm) and Na^+ (0.102 nm) cations have nearly equal ionic radii.[8] For this molten system, we have already measured the molar volume[9] and the surface tension.[10] In the present study, the refractive indexes of this melt were measured, and the electronic polarizabilities of the ions were evaluated.

Experimental

A hollow prismatic cell made of fused silica was used for the goniometric measurement of the refractive index. The apparatus has been described in detail previously.[11] The angle of minimum deflection was read with a precision of 1 minute. The relation between the refractive index, n_λ, and the angle of minimum deflection, σ_λ is:

$$n_\lambda = \sin((\sigma_\lambda + A)/2)/\sin(A/2), \quad (1)$$

where A is the apex angle of the prismatic cell and the subscript λ refers to the wavelength. The apex angle A has been calibrated beforehand by the use of a reference material whose refractive index has been accurately measured by Gustafsson and Karawacki.[12] The temperature of the melt was automatically controlled and recorded with a precision of 0.1 °C using a sheathed chromel-alumel thermocouple inserted into the melt. The light of nine wavelengths, from 434.1 to 680 nm, was used. The chemicals, $CaCl_2$ and NaCl, are of an analytical reagent grade and were dried by means of a conventional technique.[7]

Results and Discussion

The refractive indices at 560 nm of the binary melts measured are shown in Fig. 1, together with those of molten pure $CaCl_2$ and NaCl reported previously.[3,7] They decreased linearly with the increase in the temperature at fixed wavelengths over the whole range of $CaCl_2$ composition. Such behavior is the same as that reported previously.[3-7] The accuracy attained for an aqueous electrolyte solution has usually been $\pm 1\times10^{-5}$ in the refractive index,[13] but for the molten $CaCl_2$-NaCl mixture $\pm 1\times10^{-4}$ was estimated because of the experimental difficulty at elevated temperatures.

The refractive indices decreased non-linearly with the increase in the wavelength at a given temperature, as is shown in Fig. 2. For the refractive index of molten salt with a normal dispersion, we have already proposed the following modification of Cauchy's equation:

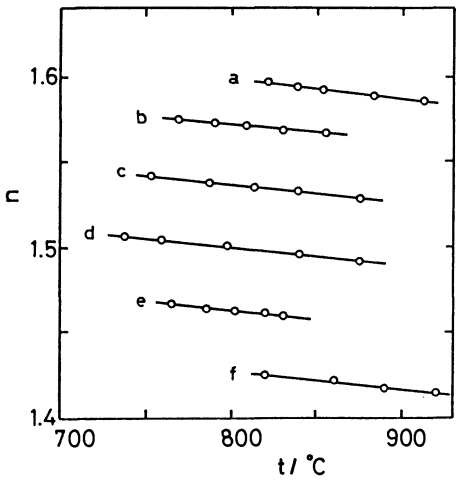

Fig. 1. Refractive indices of molten $CaCl_2$-NaCl at 560 nm. $CaCl_2$ mol%, a: 100.0, b: 79.2, c: 58.6, d: 39.1, e: 19.3, f: 0.0.

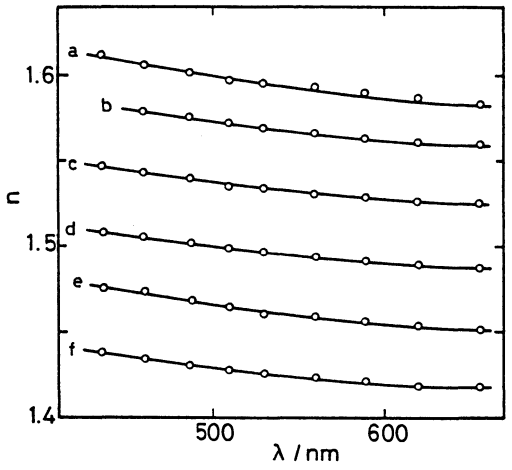

Fig. 2. Dispersions in refractive index of molten $CaCl_2$-NaCl at 850 °C. Symbols are the same as those in Fig. 1.

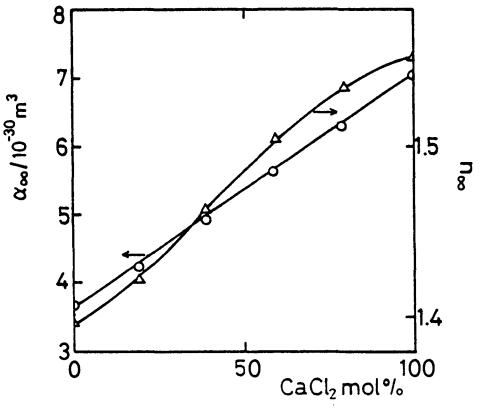

Fig. 3. Refractive index at infinite wavelength and electronic polarizability of molten $CaCl_2$-NaCl at 900 °C.

$$n(\lambda, t)=(\sum_{0}^{2} P_i\lambda^{-2i})+(\sum_{0}^{2} Q_i\lambda^{-2i})\,t, \qquad (2)$$

where t is the temperature in °C and λ is the wavelength in nm. The physical interpretation of the P_i and Q_i parameters was outlined previously.[6] The parameters determined by the least-squares fit are listed in Table 1, in which ε is the standard error of estimation.

The molar refractivity, R_λ, is one of the best parameters for the polarization phenomenon; it is calculated from the refractive index, n_λ, and the molar volume, V_m, by the use of the Lorentz-Lorenz equation:

$$R_\lambda=(n_\lambda^2-1)/(n_\lambda^2+2)V_m. \qquad (3)$$

It is generally known in binary systems that R_λ possesses a linear dependence on the composition. For the molten $CaCl_2$-NaCl mixture, a strong linear dependende was also observed. The molar volume used in the calculation was taken from a previous report.[9]

The polarizability discussed here is the electronic one,[14] which is reduced to a scalar in the case of a dense ionic melt. The electronic polarizability of a molecule is defined by the Clausius-Mossotti equation, in which an optical dielectric constant is substituted for the static one:

$$\alpha_\infty=(3/4\,\pi N_A)[(n_\infty^2-1)/(n_\infty^2+2)]V_m, \qquad (4)$$

where the subscript ∞ indicates an infinite wavelength and N_A is Avogadro's number. The electronic polarizabilities of the Ca^{2+}, Na^+, and Cl^- ions in the pure $CaCl_2$ and NaCl melts at 900 °C are known to 0.61, 0.43, and 3.24×10^{-30} m^3 respectively.[3,7] The isotherm of the electronic polarizability for the molten mixture is shown in Fig. 3, together with that of the refractive index at an infinite wavelength, as calculated from Eq. 2 by interpolating λ to ∞. The refractive indices at an infinite wavelength deviate from additivity, while the electronic polarizabilities increase linearly, with an increase in the mole fraction of $CaCl_2$, and their values seem to lie on the additive line. This indicates that the electronic polarizability is approximately inherent in the ion, even in the case of condensed systems such as molten salt.

The authors would like to express their gratitude to Mr. Junji Tominaga for assistance in measuring the refractive index.

Synopsis. Spectrophotometric studies have revealed that a green complex is formed by the reaction of a blue binuclear copper(II) complex of 2-hydroxy-1,4-butanediamine-*N,N,N',N'*-tetraacetic acid and H_2O_2, although analogous binuclear complexes of 2-hydroxy-1,3-propanediamine- and 3-hydroxy-1,5-pentanediamine-*N,N,N',N'*-tetraacetic acids are unreactive to H_2O_2.

New binuclear copper complexes which can interact with O_2 and related small compounds are of great interest as models for the active sites of Type III copper-containing proteins and as candidates for catalysts in oxidative synthetic reactions.[1,2] We recently reported the preparation of three analogous binuclear copper(II) complexes of amine-*N*-polycarboxylic acids with μ-alkoxide bridges at pH<6 as model complexes for Type III copper with respect to bridging ligands.[3] In this study, the reactivity of these three complexes with H_2O_2 has been investigated spectrophotometrically.

Experimental

Materials. The binucleating ligands used here are 2-hydroxy-1,3-propanediamine-, 2-hydroxy-1,4-butanediamine-, and 3-hydroxy-1,5-pentanediamine-*N,N,N',N'*-tetraacetic acids, which will be hereafter abbreviated as AC_3OH, AC_4OH, and AC_5OH, respectively. AC_3OH is commercially available. AC_4OH and AC_5OH were synthesized and purified by our own method which will be reported elsewhere in detail. The concentration of H_2O_2 in a commercial 30 wt% solution was determined precisely by redox titration with a standardized $KMnO_4$ solution. The sample solutions for spectral measurements were prepared by dissolving 2.5 mM AC_nOH (n=3, 4, or 5), 5.0 mM $Cu(ClO_4)_2$, 0.50 M $NaClO_4$, 0.05 M $Na_2B_4O_7$, and the desired amount of H_2O_2 in water and then by adjusting the solutions to pH 10.1 (1 M=1 mol dm^{-3}).

Measurements. UV and visible absorption spectra were recorded at 5.0±0.1 °C with a Shimadzu Model UV-240 spectrophotometer using 10 and 1-mm quartz cells.

Results and Discussion

In this study, it has been found that, when H_2O_2 is added to the blue aqueous solutions of the binuclear copper(II) complexes of AC_3OH, AC_4OH, and AC_5OH[3] at pH>7, only the solution of the second complex produces an intense green color. UV and visible absorption spectra for this complex system at varying H_2O_2 concentrations were measured at 5.0 °C in order to depress the formation of by-products as efficiently as possible (Fig. 1). In these spectra at $[H_2O_2]/[\text{the } Cu_2\text{-}AC_4OH \text{ complex}]<20$, there are two isosbestic points at 288 and 790 nm, indicating that there exists a reaction equilibrium. We analyzed these spectral changes at a constant pH of 10.1 on the assumption of the following equilibrium:

$$\text{Complex } \mathbf{1} + H_2O_2 \rightleftharpoons \text{Complex } \mathbf{2} + H^+ \quad (1)$$

where Complexes **1** and **2** are $[Cu_2(AC_4O)(OH)]^{2-}$ and $[Cu_2(AC_4O)(O_2)]^{3-}$ respectively and where K'=[Complex **2**][Complex **1**]$^{-1}$[H_2O_2]$^{-1}$. The analyses could be done at three wavelengths of 350, 600, and 650 nm, as exemplified by Fig. 2. The results thus analysed are summarized in Table 1.

Now, it seems probable that Complex **2** contains a peroxide ion, as shown in Eq. 1, because the absorption spectra of Fig. 1 have been satisfactorily analyzed

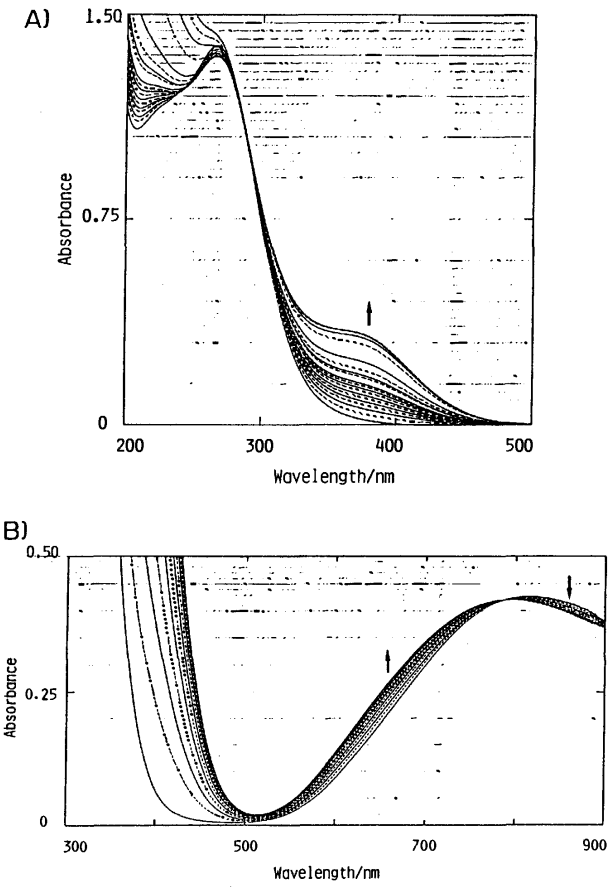

Fig. 1. UV (A) and visible (B) absorption spectra for the system of the Cu_2-AC_4OH complex (Complex **1**) and H_2O_2 in aqueous solutions at pH 10.1 at 5.0 °C (0.05 M $Na_2B_4O_7$ buffer; [$NaClO_4$]= 0.50 M; [$Cu(ClO_4)_2$]=5.114 mM; [AC_4OH]=2.557 mM; A), 1-mm quartz cells; B), 10-mm quartz cells). The spectra changed along the direction of arrows with increasing concentrations of H_2O_2, the concentrations being varied from 0 to 0.127 M for A and to 1.02 mM for B.

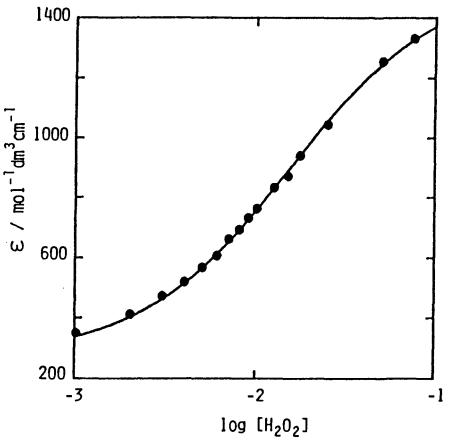

Fig. 2. Plots of molar extinction coefficients (ε) at 350 nm in Fig. 1(A) against the concentration of H_2O_2: darked circle, experimental; solid line, calculated with the parameter values listed in Table 1.

Table 1. Results[a] of Absorption Spectral Measurements for the Reaction System of Complex **1** and H_2O_2

Wavelength / nm	ε_1	ε_2	log K'
350	264.9	1533	1.84
600	35.35	88.8	1.83
650	75.83	140.6	1.84

a) ε_1 and ε_2 are the molar extinction coefficients (mol^{-1} dm^{-3} cm^{-1}) of Complexes **1** and **2**, respectively (see text as to Complexes **1** and **2** and K').

on the assumption of Eq. 1. Furthermore, it is obvious that Complex **2** shows two spectral pesks around 370 nm ($\varepsilon \approx 2000$) and 650 nm ($\varepsilon \approx 150$). Interestingly, this complex is quite similar to oxyhemocyanin and its analogues in the spectral band positions and in their intensity ratio.[4] However these bands of the present complex are too weak in intensity compared with those of oxyhemocyanin and its analogues. It is an interesting fact that H_2O_2 does not react with the binuclear copper(II) complexes of AC_3OH and AC_5OH, but only with that of AC_4OH, suggesting that the reactivity is severely dependent upon small structural variations of the binuclear complexes, for instance, the relative positions and asymmetrical environments of the two cupric ions. This study also shows that model complexes for the active sites of oxyhemocyanin and its analogues may be stably produced even in aqueous solutions at room temperature, contrary to the general belief that a hydrophobic environment is desirable for the dioxygen binding center in the biological systems and their model complexes.[1]

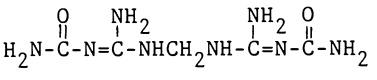
(Received August 6, 1987)

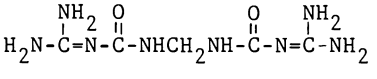
Synopsis. The condensation product in the reaction of *N''*-cyanoguanidine with paraformaldehyde under strongly acidic conditions was identified as *N,N'*-methylenebis[*N'*-(diaminomethylene)urea] by X-ray analysis. This structure agreed with that estimated from the ^{1}H NMR data.

The resinous products from *N''*-cyanoguanidine (CG) and formaldehyde are useful as modifiers for urea- and melamine-formaldehyde resins,[1] sticking agents for dyes,[2] and commercial flocculants.[3] The reaction of CG with formaldehyde is, however, complicated under acidic conditions because of the simultanious structural conversion of CG into diaminomethyleneaminourea (DU).[4]

Spiethoff[5] has prepared a condensate of CG with paraformaldehyde in the presence of 30% hydrochloric acid and identified it as bis(*N''*-carbamoylguanidino)-methane (**1**) on the basis of the infrared absorption bands at 1680 and 1740 cm^{-1}, which have been considered to be characteristic of the primary carbamoyl group:



(1)



(2)

The hydrochloride of the condensate was prepared according to the procedure of Spiethoff.[5] Elemental analysis: Found, C, 20.68; H, 4.92; N, 38.88; Cl, 24.22%: Calcd for $C_5H_{12}N_8O_2 \cdot 2HCl$, C, 20.77; H, 4.88; N, 38.76; Cl, 24.52%. It showed the same melting point (230—232 °C) as has previously reported. Its infrared spectrum in the KBr pellet exhibited the same absorption bands at 1680 and 1740 cm^{-1}. The ^{1}H NMR spectrum of the free base of the condensate was measured in a DMSO-d_6 solution, with TMS as the internal standard, at 90 MHz on a JEOL FX90Q instrument. In addition to the signal of methylene protons (δ=4.30, t, 2H), two signals (δ=6.57, s, 8H, -N<u>H</u>$_2$; 6.18, t, 2H, -N<u>H</u>-) were observed. This observation was conflict with Spiethoff's identification and suggested that the condensate was not **1** but *N,N'*-methylenebis[*N'*-(diaminomethylene)urea] (**2**).

X-Ray analysis was employed in order to confirm the structure of **2**. As crystals of dihydrochloride of **2** were twinned, a crystal of the free base was prepared by passing it through a Dowex SBR column, followed by extraction with acetone and the cooling of the acetone solution.

The unit-cell parameters and intensity data for a single crystal (ca. 0.1×0.2×0.2 mm^3) were measured on a Rigaku four-circle diffractometer AFC-6S with graphite-monochromatized Mo $K\alpha$ radiation (λ=0.7107 Å). Systematic absences led to the space group $P2_1/c$.

Crystal Data: $C_5H_{12}N_8O_2$, M.W.=216.21, monoclinic, space group $P2_1/c$, a=7.954(3), b=9.553(6), c=14.963(7) Å, β=123.76(3)°, V=945.2(9) Å^3, D_c=1.52 g·cm^{-3}, Z=4 and μ(Mo $K\alpha$)=1.1 cm^{-1}.

The intensity data were collected by the ω-2θ scan technique up to 2θ=60° with a scan rate of 4° min^{-1}. The intensity data were corrected to the F_o data in the usual manner. Absorption corrections were not applied. Reflections with $|F_o| > 3\sigma(|F_o|)$ were used for the structure determination. The structure was solved by the direct method and refined by a block-diagonal least-squares procedure. All the calculations were carried out on a HITAC M-680H computer at the Computer Center of The University of Tokyo, using the local version of UNICS III.[6] All the scattering factors were taken from the International Tables for X-Ray Crystallography.[7] The final residual values for 1862 reflections were R=0.068 and R_w=0.075.

The final atomic parameters are listed in Table 1. The equivalent isotropic temperature parameters were defined by Hamilton.[8] The coordinate and isotropic temperature factors of hydrogen atoms, the anisotropic thermal parameters of the non-hydrogen atoms, and

the F_o—F_c tables have been deposited as Document No. 8799 at the Office of the Editor of the Bulletin of the Chemical Society of Japan. Selected bond lengths and bond angles are listed in Table 2, while a perspective drawing of the molecular structure of the condensate is shown in Fig. 1. The structure agrees with that estimated from the ^{1}H NMR data. These results clearly show that the structure of the condensate is not **1** but **2**.

Although dihydrochloride of **2** has absorption bands at 1680 and 1740 cm^{-1} in the infrared region, these are not necessarily assigned to the primary carbamoyl group, but perhaps to the stretching of the C=N and C=O of **2**. Under strongly acidic conditions, CG can be expected to be converted into DU by the hydration of the cyano group, and the resulting DU can be estimated to be hydroxymethylated with formaldehyde selectively on the amino group in the carbamoyl group, but not on the amino group in the diaminomethyleneamino group probably because of the protonated amino group in the diaminomethyleneamino group is less active with the protonated formaldehyde ($^+CH_2OH$) than that in the carbamoyl group.

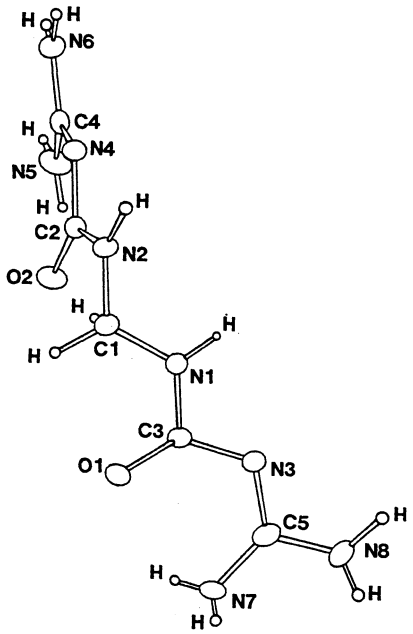

Fig. 1. A perspective drawing of the molecular structure of the condensate from *N*″-cyanoguanidine and paraformaldehyde projected on the plane at right angles to bc plane.

The authors wish to express their deep gratitude to Professor Hayao Kobayashi of Toho University for his kind support in the data collection and the computation.

A Convenient Synthesis of 3-Cyano-2-methylpyridines under Ultrasonic Irradiation

Katsuyoshi SHIBATA,* Katsuyoshi URANO, and Masaki MATSUI
Department of Chemistry, Faculty of Engineering, Gifu University, 1-1 Yanagido, Gifu 501-11
(Received September 18, 1987)

Synopsis. Ultrasonic irradiation of α,β-unsaturated carbonyl compounds **1a**—**i** with acetonitrile in the presence of potassium *t*-butoxide gave 3-cyano-2-methylpyridines **2a**—**i** in moderate to good yields. The pyridines are produced by a Michael reaction of 3-iminobutanonitrile, an acetonitrile dimer, to the substrates **1a**—**i**.

Ultrasonic irradiation has gained rapidly growing recognition as an effective method for increased reaction rates and yields in organic chemistry.[1-3] Meyer and Chatterjea have prepared 3-cyanopyridines from α,β-unsaturated carbonyl compounds and 3-aminocrotononitrile in low yields.[4,5] We report here a successful synthesis of 3-cyano-2-methylpyridines from α,β-unsaturated carbonyl compounds and acetonitrile in the presence of potassium *t*-butoxide under ultrasonic irradiation.

The results of ultrasonic irradiation of α,β-unsaturated carbonyl compounds are summarized in Table 1. In order to examine the effects of ultrasonic irradiation, a few experiments were conducted. Ultrasonic irradiation and mechanical agitation of **1a** with potassium *t*-butoxide in acetonitrile afforded **2a** in 70 and 30% yields, respectively (Runs 1 and 2). Reflux and ultrasonic irradiation of **1a** with 3-aminocrotononitrile in acetonitrile gave **2a** in 72 and 34% yields, respectively (Runs 3 and 4). The results clearly show that the advantages of ultrasonic irradiation include the shorter reaction time and the higher yield for the synthesis of 3-cyano-2-methylpyridines. Other pyridines **2b**—**i** were also obtained in moderate to good yields (Runs 5—12). In the case of **1f**, 4-cyano-1,2,3-triphenyl-1-butanone was produced by a Michael addition of acetonitrile to **1f** (Run 9). In the case of **1g**, 2-methyl-6-phenylbenzophenone was produced by a Michael reaction of 4-oxo-4-phenyl-2-buten-1-ide to **1g** followed by protonation, intramolecular aldol condensation, and aromatization (Run 10).

A reasonable mechanism in these pyridine formations is shown in Scheme 1. A key compound produced during the ultrasonic irradiation was identified as 3-aminocrotononitrile (**3**), the dimer of acetonitrile. No remarkable difference in the yield of **2a** was observed (Runs 1 and 3, in Table 1), suggesting that ultrasonic irradiation is effective for the formation of 3-aminocrotononitrile (**3**) in the solution. The nitrile exists as enamino and imino tautomers (**3** and **3'**, respectively) in the acetonitrile solution. On the basis of the ^{1}H NMR spectrum, the proportionality ratio of the imino isomer **3'** was calculated to be ca. 30% in acetonitrile. The imino isomer **3'** is easily converted into the carbanion **4** with potassium *t*-butoxide.

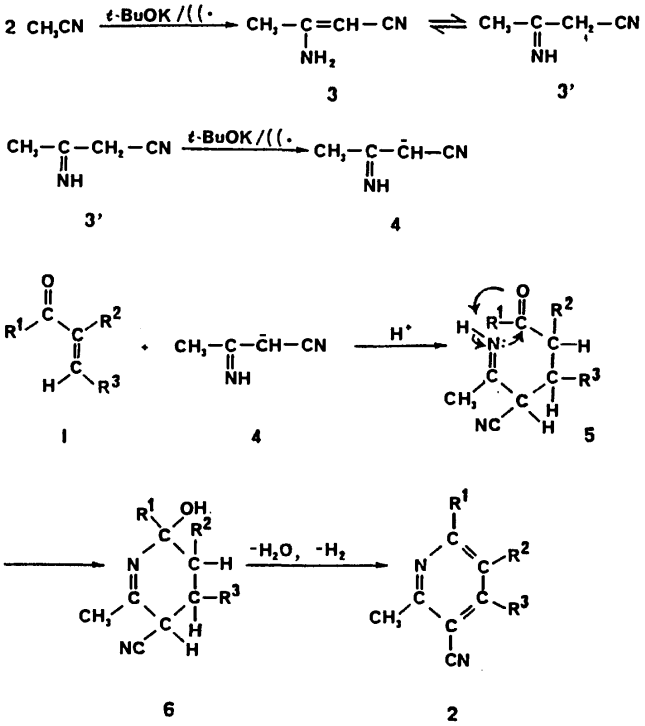
a) Isolated yield. b) Mechanical agitation at room temperature. c) **1a** was irradiated with 3-aminocrotononitrile (**3**, 0.04 mmol) in the presence of potassium *t*-butoxide in acetonitrile. d) Refluxed with 3-aminocrotononitrile (**3**, 0.04 mmol) in acetonitrile. e) Reference 2. f) 4-Cyano-1,2,3-triphenyl-1-butanone and *trans*-stilbene were obtained in 10 and 13% yields, respectively. g) 2-Methyl-6-phenylbenzophenone was also obtained in a 9% yield.



Scheme 1.

There are two possibilities for the formation of pyridines. One is the condensation reaction of the carbonyl group of **1** with the amino group of **3** followed by dehydrocyclization. Another is a Michael reaction of carbanion **4**. The ultrasonic irradiation of 4-oxo-2,4-diphenyl-2-butene did not give the corresponding pyridines, because of the steric hindrance of the methyl group at the β-position. This result suggests that a Michael addition of the imino isomer **3'** plays an important role in this reaction. α,β-Unsaturated carbonyl compounds react with the carbanion **4** followed by protonation to give the adduct **5**. Since the imino group is located close to the carbonyl group in the most stable conformation, the adduct **5** is easily cyclized to give the pyridine precursor **6**. Unfortunately, these compounds were not isolated. The precursor **6** is dehydrated, and dehydrogenated to give pyridine **2**.

Experimental

General. Melting points were measured with a Yanagimoto micro melting point apparatus and uncorrected. IR and NMR spectra were recorded with Jasco A302 and JEOL GX-270 spectrometers, respectively. Mass spectra were obtained with a Shimadzu GCMS 9020-DF spectrometer. Ultrasonic irradiation was carried out with a Branson ultrasonic laboratory cleaner (45 kHz, 100W).

Materials. α,β-Unsaturated carbonyl compounds **1e**, **1g**, and **1i** were available from Nakarai Chemicals Ltd. and used without further purification. The other compounds, **1a**, **1b**, **1c**, **1d**, **1f**, and **1h**, were prepared as described in the literature and their purity was checked by GLC. The melting or boiling points were as follows: **1a**: mp 114.5—115.0 °C (lit[6] 114.0—115.0 °C). **1b**: mp 56.0—57.0 °C (lit[7] 55.0—57.0 °C). **1c**: mp 106.5—108.0 (lit[8] 105—106 °C). **1d**: mp 42.0 °C (lit[9] 45.0 °C). **1f**: mp 99.0—100.0 °C (lit[10] 100 °C). **1h**: bp 180 °C (267 Pa) (lit[11] 167 °C (80 Pa)).

Preparation of 3-Cyano-2-methylpyridines. A dry acetonitrile suspension (50 cm^3) of potassium *t*-butoxide (100 mg) was irradiated on a water bath for 15 minutes at room temperature. α,β-Unsaturated carbonyl compounds (**1**, 0.48 mmol) was then added to the suspension, which was further irradiated. The end point of the reaction was checked by TLC. After the addition of water (50 cm^3) saturated with sodium chloride, the reaction mixture was extracted with ether (20 cm^3×2). The extract was dried over anhydrous sodium sulfate. The solvent was then evaporated under reduced pressure. In the cases of **1a—d**, the residue was recrystallized from ethanol. In the cases of **1e—i**, the residue was chromatographed on a silica-gel column (Wakogel C-200, hexane : chloroform=1 : 5). **2a**: Mp 178.0—178.5 °C (lit[5] 173 °C); IR (KBr) 2215 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.92 (3H, s) and 7.4—8.1 (10H, m). **2b**: Mp 121.5—122.5 °C (lit[5] 115—116 °C); IR (KBr) 2240 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.92 (3H, s) and 7.5—8.0 (11H, m). **2c**: Mp 138.5—139.0 °C; IR (KBr) 2220 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.89 (3H, s), 3.92 (3H, s), and 7.0—8.1 (10H, m). Found: *m/z* 300.1290. Calcd for $C_{20}H_{16}N_2O$: M, 300.1264. **2d**: Mp 89.0—90.5 °C; IR (KBr) 2220 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.38 (9H, s), 2.82 (3H, s), and 7.3—7.6 (6H, m). Found: *m/z* 250.1407. Calcd for $C_{17}H_{18}N_2$: M, 250.1471. **2e**: Mp 109.0—110.0 °C (lit[5] 105—106 °C); IR (KBr) 2220 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.63 (3H, s), 2.82 (3H, s), and 7.1—7.6 (6H, m). **2f**: Mp 180.0—181.5 °C; IR (KBr) 2220 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.93 (3H, s) and 6.8—7.3 (15H, m). Found: *m/z* 346.1550. Calcd for $C_{25}H_{18}N_2$: M, 346.1471. **2g**: Mp 74.0—76.5 °C; IR (KBr) 2220 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.53 (3H, s), 2.78 (3H, s), and 7.5—8.0 (10H, m). Found: *m/z* 208.1058. Calcd for $C_{14}H_{12}N_2$: M, 208.1002. **2h**: Mp 116.0—116.5 °C; IR (KBr) 2240 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.08 (3H, s), 2.83 (3H, s), and 7.2—7.8 (10H, m). Found: *m/z* 284.1296. Calcd for $C_{20}H_{16}N_2$: M, 284.1315. **2i**: Mp 98.5—99.5 °C; IR (KBr) 2240 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.87 (3H, s), 7.29 (1H, d, *J*=5.2 Hz), 7.5—8.6 (5H, m), and 8.68 (1H, d, *J*=5.2 Hz). Found: *m/z* 194.0825. Calcd for $C_{13}H_{10}N_2$: H, M, 194.0845.

The authors wish to express their thanks to Messrs. Katsuaki Shiratsuchi and Shozo Onishi of Shimadzu Corporation for the measurement of the mass spectra.

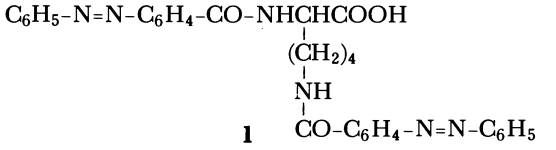
Photoresponsive Peptide and Polypeptide Systems. VI.[1] Reversible Solubility Change of Azo Aromatic Lysine

Hiroyuki YAMAMOTO* and Ayako NISHIDA
Institute of High Polymer Research, Faculty of Textile Science and Technology, Shinshu University, Ueda 386
(Received December 12, 1987)

Synopsis. The reversible solubility change of azo aromatic lysines due to the trans-cis photoconversion of azo moieties was studied. On irradiation at different wavelengths, azo aromatic lysines are soluble under ultraviolet light (cis) and precipitate under visible light (trans). The dipole moments of the solvents used are considered to play a role in the solubility change.

The two conformers of azobenzene are known to have two different dipole moments (μ); that is, the μ values are 0.5D for the trans conformer and 3.1D for the cis conformer.[2] Recently, Irie et al.[3-5] reported on the photostimulated reversible solubility change of aggregated polystyrene and poly(glutamic acid) containing azobenzene. Our group has previously investigated the photoresponsive systems using cationic peptides and polypeptides[1,6-9] because of their relevance to the molecular mechanism of photoregulation in biological materials and process. One difficulty in studying such photoresponsive systems is, however, the subject of their solubilities, since azo aromatic peptides with high azo moieties are sparingly soluble in common solvents. This series of studies raises the question of whether or not azo aromatic amino acids undergo a rapid change in their solubilities upon the irradiation of light.

In this note azo aromatic lysine (compound **1**) will be described in order to increase knowledge regarding the photoresponsive change in azo aromatic peptide systems, giving a clue to its improved solubility.



1

Experimental

Bis[*p*-(phenylazo)benzoyl]-L-lysine (BPAZ-L-Lys, **1**) was prepared according to the usual Schotten-Baumann procedure using L-lysine hydrochloride and *p*-(phenylazo)benzoyl chloride in a mixed NaOH-1,4-dioxane solvent; yield, 72%; mp 229 °C, $[\alpha]_D^{23}=-128°$ (*c* 0.25, 1,4-dioxane). Found: C, 68.45; H, 5.32; N, 14.94%. Calcd for $C_{32}H_{30}N_6O_4$: C, 68.31; H, 5.37; N, 14.94%. D-Antipode was prepared by the same procedure; yield, 64%; mp 229°C, $[\alpha]_D^{23}=132°$ (*c* 0.25, 1,4-dioxane). The absorbance spectra were measured with a Jasco UVIDEC-1 spectrometer. The critical solubilities of trans BPAZ-L-Lys at 25 °C are 3.8×10^{-4} mol dm^{-3} in a 1,4-dioxane-water mixture (1 : 1.1 v/v) and 2.3×10^{-4} mol dm^{-3} in acetonitrile, while those of the cis isomer are 1.6×10^{-3} mol dm^{-3} in a 1,4-dioxane-water mixture (1 : 1.1 v/v) and 9.8×10^{-4} mol dm^{-3} in acetonitrile. The cis isomer is 4.3 times more soluble in solvents than is its trans isomer. The turbid solutions were prepared by adding water to a clear trans BPAZ-L-Lys solution in 1,4-dioxane (ca. 1 : 1 v/v) until the precipitated solute could be observed or by using solvents with a poor solubility to BPAZ-L-Lys. The concentrations of BPAZ-L- and D-Lys in solutions were in the 4.8×10^{-4}—1.5×10^{-3} mol dm^{-3} range.

The irradiation of the sample solutions was carried out at 25 °C with a mercury lamp (400W) filtered with narrow-band interference filters from Toshiba, Ltd. The light intensities, as determined by chemical actinometry, were 1.8×10^{19} photon cm^{-2} s^{-1} at 360 nm and 1.3×10^{19} photons cm^{-2} s^{-1} at 460 nm.

Results and Discussion

Figure 1 shows the changes in the absorption spectra of BPAZ-L-Lys in 1,4-dioxane on irradiation. Before irradiation (trans, in the dark), the BPAZ-L-Lys exhibits its absorption bands at 217, 232, 258, 327, and 440 nm. The absorption bands exhibit photochromism when the trans conformer is converted to cis on irradiation at

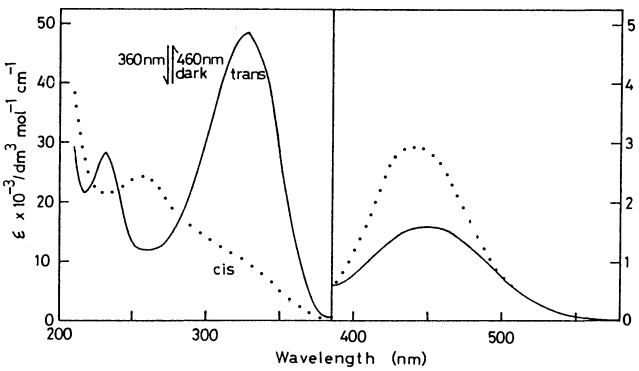


Fig. 1. Absorption spectra of BPAZ-L-Lys in 1,4-dioxane at 25 °C: —— trans, before irradiation and after reirradiation at 460 nm for 10 min; ····· cis, after irradiation at 360 nm for 10 min.

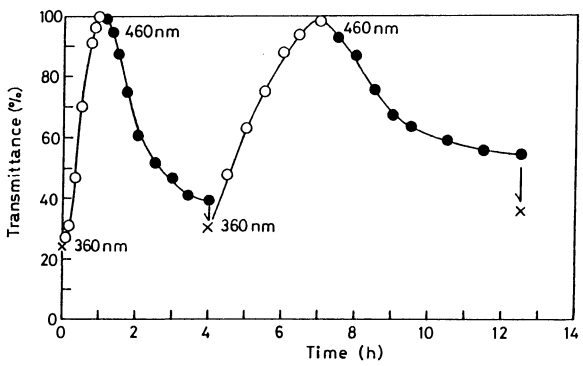

Fig. 2. Time dependence of the solubility change of BPAZ-L-Lys on irradiation at different wavelengths in 1,4-dioxane-water (1:1.1, v/v) at 25 °C: × dark adaptation. Transmittance at 650 nm; concentration 4.8×10^{-4} mol dm^{-3}.

360 nm (ultraviolet), whereas on the reirradiation of the irradiated solution at 460 nm (visible) the cis conformer returns to trans. The photoconversion from trans to cis on irradiation at ultraviolet and visible wavelengths is reversible.

Since the two conformers of azobenzene have the two different dipole moments of 0.5D (trans) and 3.1D (cis),[2] before irradiation we made turbid BPAZ-L-Lys solutions by mixing low- and high-dipole moment solvents or by cooling the heated solution to under the critical solubility. To a solution of trans BPAZ-L-Lys in 1 ml of 1,4-dioxane (μ, 0D), 1—1.1 ml of water (μ, 1.9D) was added to make it turbid. The turbid mixture becomes clear on irradiation at 360 nm for 1 h, accompanied by photoconversion to cis. On reirradiation at 460 nm, the clear solution becomes turbid again, as is shown in Fig. 2. Although this photoinduced solubility change due to the trans-cis isomerization of azo aromatic moieties is reversible, the time course to complete the first cycle (4 h) was much longer than is the case with the azo aromatic poly(glutamic acid) system.[5] Moreover, the second reversible cycle took 8 h, and bigger particles of the precipitated crystals were observed. Though not so marked, the dark adaptation (overnight) after irradiation at 460 nm further decreased the transmittance of the system. The reason for the rapid reversible change of the solubility on irradiation in the azo aromatic polymer system may be attributed to the solubilizing effect among azo aromatic moieties in the backbone chain, i.e., the polymeric effect.

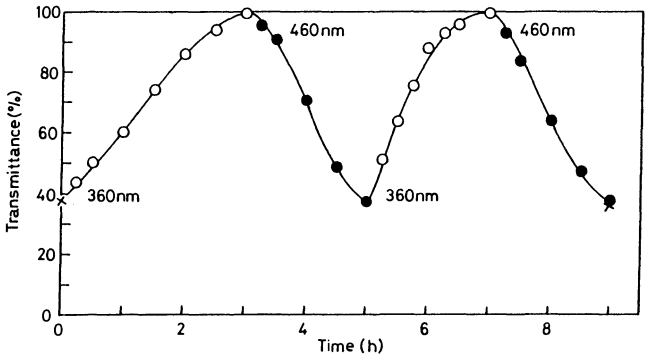

Fig. 3. Time dependence of the solubility change of BPAZ-L-Lys on irradiation at different wavelengths in acetonitrile at 25 °C: × dark adaptation. Transmittance at 650 nm; concentration 5×10^{-4} mol dm^{-3}.

Figure 3 shows the reversible solubility change of BPAZ-L-Lys in acetonitrile (μ, 3.8D). In the acetone (μ, 2.9D) and acetone-hexane (μ, 0.09D) mixed solvent the BPAZ-L-Lys photoresponded as in acetonitrile. D-Antipode, BPAZ-D-Lys, exhibited the same behavior as BPAZ-L-Lys. Thus, when their response times are improved, azo aromatic amino acids might be promising as physicochemical detective and sensory systems under controlled light conditions.

The present work was supported by a Grant-in-Aid for Scientific Research (No. 61490014) from the Ministry of Education, Science and Culture.

A New Synthetic Route to Aliphatic and Alicyclic Nitriles via Homolytic Desulfurization of α-(Dithiocarbamoylthio) Nitriles

Makoto YANAGAWA, Osamu MORIYA, Yoshihiko WATANABE, Yoshio UENO,† and Takeshi ENDO*
Research Laboratory of Resources Utilization, Tokyo Institute of Technology, Nagatsuta, Midori-ku, Yokohama 227
(Received December 26, 1987)

Synopsis. Chloroacetonitrile was transformed into aliphatic and alicyclic nitriles through (dimethyldithiocarbamoylthio)acetonitrile. The key steps in the synthetic route consisted of mono- and dialkylation via sulfur-stabilized carbanion and homolytic desulfurization using tributyltin hydride.

Recently, synthetic applications of homolytic processes by use of organotin hydrides have been intensively exploited in synthetic methodology.[1] One of the fundamental value of organotin hydrides lies in the selective reduction of carbon-sulfur bond via radical intermediates.[2] With regard to reductive desulfurization, several methods using reagents such as Raney nickel,[3] alkali metal in ammonia solution,[4] copper(II) chloride-zinc chloride-lithium aluminium hydride,[5] hydrazine,[6] and nickel boride[7] have been reported. Although these procedures are effective for the purpose of complete desulfurization, they lack the selectivity for the reduction of one carbon-sulful bond in polyfunctional-sulfur compounds.[8] In comparison with such procedures, the homolytic desulfurization using organotin hydrides enables an effective and a chemoselective reduction of sulfur containing moiety. On the other hand, the technique for carbon-carbon bond formation via sulfur-stabilized carbanion has been utilized for syntheses of various nitrile compounds, in which organosulfur derivatives are employed as the useful intermediates.[9] The combination of this technique and the homolytic desulfurization has the possibility to provide a convenient process for the preparation of nitriles. In this report, we wish to present a new synthetic route to aliphatic and alicyclic nitriles from chloroacetonitrile, which is derived from the strategy involving alkylation via sulfur-stabilized carbanion and reductive desulfurization via the homolytic process by use of tributyltin hydride (Bu_3SnH).

Results and Discussion

The choice of organosulfur intermediate was (dimethyldithiocarbamoylthio)acetonitrile (**1**), since the carbanion derived from **1** has been shown to possess suitable stability and reactivity towards electrophiles in the preceeding paper.[10] In addition, dithiocarbamoyl moiety is preferable to alkylthio one in view of facility of the desulfurization using organotin hydrides.[11]

The intermediate **1** was readily prepared by the reaction of chloroacetonitrile with sodium dimethyldithiocarbamate. The alkylation of **1** using alkyl halides with tetrabutylammonium iodide ($Bu_4N^+I^-$) in alkaline aqueous medium gave various α-cyano dithioesters **2** and **3**.[10] The reductive desulfurization using

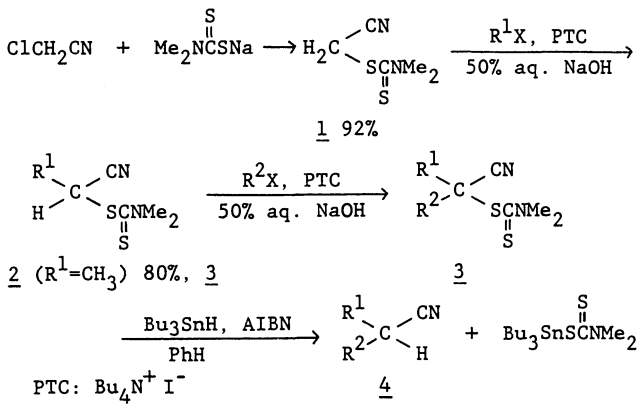

Table 1. Preparation of α-Cyano Dithioesters **3** and Nitriles **4**

Entry	α-Cyano dithioester **3**			Nitrile **4**, Yield/%	
	R^1	R^2	Yield/%

g	$-(CH_2)_4-$		81		85
h	$-(CH_2)_5-$		90		93

† Deceased February 27, 1985.

Bu_3SnH was performed under the usual conditions. Thus, a solution of **3**, Bu_3SnH, and a catalytic amount of azobisisobutyronitrile (AIBN) in dry benzene was refluxed under a nitrogen atmosphere for 5—6 h. The results of these reactions are listed in Table 1.

The process employing appropriate 1, ω-dibromoalkanes enabled the preparations of various carbocyclic cyanides such as cyclohexyl (**4f**), cyclopentyl (**4g**), and cyclobutyl cyanide (**4h**). The potential utility of the homolytic desulfurization was demonstrated by the preparations of functionalized nitriles **4b** and **4d**, which contained unsaturated carbon-carbon bond. Those results demonstrated that both primary and secondary cyanides could be prepared in high yields by the process starting from simple nitrile compound. The effectiveness of this procedure for desulfurization may be explained by the favorable influence of cyano group, which stabilizes the carbon-centered radical generated at the α-position.

Experimental

Preparation of α-Cyano Dithioesters 2 and 3. The α-cyano dithioesters **2**, **3a**, **3c**, and **3e—h** were prepared by the procedure reported before.[10] In the same manner, **3b** and **3d** were prepared as follows: 2-dimethyldithiocarbamoylthio-5-phenyl-4-pentenonitrile (**3b**). The mixture of (dimethyldithiocarbamoylthio)acetonitrile (**1**) (0.56 g, 3.5 mmol), cinnamyl bromide (0.45 g, 2.3 mmol) and tetrabutylammonium iodide (0.08 g) in benzene (5 ml) and 50% aqueous sodium hydroxide solution (10 ml) was stirred vigorously at room temperature. After 17 h, the mixture was diluted with water and extracted with ether. The ethereal extracts were dried over sodium sulfate and then evaporated. The residue was chromatographed on alumina with hexane and dichloromethane as eluant. The pure **3b** was obtained as viscous oil (0.30 g, 45%), IR (neat) 3040, 2920, 2240 (νC≡N), 1490, 1375, 1245 970, 745 cm^{-1}; ^1H NMR δ=2.86 (t, 1H, *J*=6.0 Hz), 3.28, 3.49 (ss, 6H), 5.23 (t, 1H, *J*=7.0 Hz), 5.99—6.86 (m, 2H), 7.35 (s, 5H). Found: C, 60.50; H, 5.73; N, 10.19; S, 23.39%. Calcd for $C_{14}H_{16}N_2S_2$: C, 60.84; H, 5.83; N, 10.19; S, 23.20%.

2-Methyl-2-dimethyldithiocarbamoylthio-5-phenyl-4-pentenonitrile (3d). Colorless prisms (methanol), mp 124—127 °C. IR (KBr) 3040, 2930, 2240 (νC≡N), 1490, 1380, 1250, 970, 750 cm^{-1}; ^1H NMR δ=1.87 (s, 3H), 2.75—3.62 (m, 8H), 5.85—6.85 (m, 2H), 7.38 (s, 5H). Found: C, 62.35; H, 6.19; N, 9.41; S, 21.8%. Calcd for $C_{15}H_{18}N_2S_2$: C, 62.04; H, 6.24; N, 9.64; S, 22.1%.

Reductive Desulfurization of α-Cyano Dithioesters (3). The solution of **3a** (0.76 g, 3.3 mmol), Bu_3SnH (0.96 g, 3.3 mmol), and AIBN (0.03 g, 5.5 mol%) in benzene (4 ml) was stirred at 80 °C for 5 h. The resulting solution was concentrated by a rotary evaporator and then distilled with a Kugelrohr apparatus to give hydrocinnamonitrile (**4a**) (0.18 g, 91%): bp 164—166 °C/6 mmHg (1 mmHg≈133.322Pa) (Kugelrohr). In the same manner, the nitriles **4b—h** were obtained in the yields shown in Table 1 and identified by comparison of spectral data with those of authentic samples.[12]

Radical Reactions of Alkenylstannanes with *S*-Benzoyl *Se*-Phenyl Selenosulfide

Takeshi Toru,* Yoshio Yamada, Eturô Maekawa, and Yoshio Ueno
Department of Applied Chemistry, Faculty of Engineering, Nagoya Institute of Technology, Gokiso, Showa-ku, Nagoya 466
(Received December 2, 1987)

Synopsis. Free radical reactions of allyltributylstannane or 2-butenyltributylstannane with *S*-benzoyl *Se*-phenyl selenosulfide (**1**) gave *S*-allyl benzenecarbothioate or a mixture of *S*-2-butenyl and *S*-1-methyl-2-propenyl benzenecarbothioates, respectively. The reaction of tributylvinylstannane with **1** gave an addition product, whereas the reaction of tributylstyrylstannane gave an addition-elimination product.

Alkyl radicals generated from alkyl halides or other radical precursors such as selenides or sulfides react with allylstannane in S_H2' manner to give allylated compounds.[1] The reaction of alkyl radicals with vinylstannanes affords addition-elimination products only when vinylstannanes bear an electron-withdrawing group.[2] Heteroatom-centered radicals such as seleno or thio radicals also react with allylstannane to give allyl selenide or sulfide.[3] Recently we have shown that *S*-benzoyl *Se*-phenyl selenosulfide [*SSe*-phenyl benzenecarbo(selenothioperoxoate)] (**1**) is a useful reagent for introducing both seleno and thioester groups by virtue of the free radical reaction with various olefins,[4] and is also useful for substitution of mercurials with a seleno group.[5] In order to extend the scope and limitations of reactions with selenosulfide **1** as a synthetic reagent we have examined the photo and thermal reactions of allylic and vinylic stannanes with **1**.

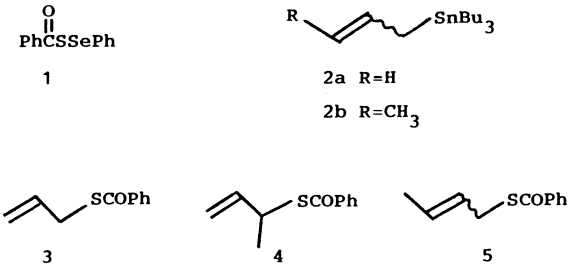

Table 1. Reaction of Alkenylstannanes with Selenosulfide **1**

Alkenyl-stannane	Method[a]	Reaction Time	Product (Yield,[b] %)
2a	A	2	**3** (86)

Results and Discussion

Ultraviolet irradiation of tributyl(2-propenyl)stannane[6] (**2a**) (referred to as allyltributylstannane) and 1.8 fold excess of selenosulfide **1** in benzene for 1.5 h resulted in the formation of *S*-2-propenyl benzenecarbothioate (**3**) in 84% yield. Thermal reaction of allylstannane **2** with selenosulfide **1** in benzene in the presence of AIBN (10 mol%) also afforded benzenecarbothioate **3** in high yield. These results together with others described below are summarized in Table 1. In the above reactions we encountered some difficulty in purifying **3** by silica-gel column chromatography because of contamination of tributyl(phenylseleno)-stannane formed during the reaction. Mercury(II) acetate was found to be most superior among several salts tested, including potassium fluoride that is effective to remove stannyl bromide,[7] to separate the stannane from benzenecarbothioate **3** in the reaction mixture. Thus, isolation of **3** could be achieved by addition of a small amount of mercury(II) acetate to the reaction mixture and subsequent filtration of the resultant precipitates followed by column chromatography.

The photo and thermal reactions of 2-butenyltributylstannane[6] (**2b**) (a 1:3 mixture of *Z*/*E* isomers) with selenosulfide **1** gave *S*-1-methyl-2-propenyl benzenecarbothioate[8] (**4**) and *S*-2-butenyl benzenecarbothioate[8] (**5**), the latter compound consisting of a mixture of the *Z*- and *E*-isomers whose ratio was 1:3 in the photostimulated reaction and 1:2 in the thermal reaction. The ratio of **4** to **5** was found to decrease as the reaction proceeded. In the photolysis monitored by the ^{1}H NMR spectroscopy it was shown that the first formed benzenecarbothioate **4** rearranged to **5** during the irradiation and reached to a mixture of **4** and **5** in the ratio 1:1 after about 80 min in carbon tetrachloride or in the ratio 2:1 after 110 min in deuterated benzene (see Table 2 in Experimental Section). This rearrangement was further verified by the irradiation of isolated benzenecarbothioate **4** which resulted in rapid and complete conversion to benzenecarbothioate **5** within 10 min. The complete conversion of **4** to **5** is probably due to the conditions without selenosulfide **1** or tributyl(phenylseleno)stannane in the reaction mixture. Similar facile rearrangement from 1-methyl-2-propenyl selenide to 2-butenyl selenide have been reported by Russell et al. in the reaction of 2-butenylstannane with diphenyl diselenide.[3] The above overall reactions can be rationalized by the S_H2' mechanism and subsequent interconversion of **4** to **5** as shown in Scheme 1, i.e., benzenecarbothioate **3** or **4** is

formed by β-elimination of the stannyl radical from the carbon radical generated at the vicinal position to the stannyl group by the reaction of stannane **2a** or **2b** with the thiyl radical and then resulting benzenecarbothioate **4** rearranges to benzenecarbothioate **5**.

Another example of facile β-elimination of the stannyl radical was encountered in the reaction of tributyl[(*E*)-styryl]stannane[9] (**6**) with selenosulfide **1**, affording *S*-styryl benzenecarbothioate (**7**) which is apparently formed via addition of the thiyl radical to the β-olefinic carbon and subsequent β-elimination of the stannyl radical. The photoinduced reaction proceeded much faster than the thermal reaction in this case (see Table 2).

On the other hand, tributylvinylstannane[10] (**8**) reacted with selenosulfide **1** to give the addition product **9** in moderate yield after 3 h in thermal reaction and 2.5 h on irradiation. Longer reaction time in both reactions did not improve the yield but caused the decomposition of the addition product **9**. The structure of **9** was assigned by the spectral data. The ^{13}C NMR spectrum showed the signals of butyl carbons at δ 12.77, 26.53 ($^3J_{Sn-C}$=58.5 Hz), 28.22 ($^2J_{Sn-C}$=19.5 Hz), 9.67 ($^1J_{Sn-C}$=312.7 and 327.7 Hz) assigned to the methyl carbon, γ-carbon, β-carbon, and α-carbon to the stannane, respectively, by their coupling constants between ^{13}C and $^{117,119}Sn$.[11] The methylene carbon appeared at δ 35.03 without any significant couplings, while the signal assigned to the methine carbon was observed at δ 22.70 with two sets of definitive couplings, J_{Sn-C}=217.6 and 227.8 Hz, and J_{Se-C}=90.8 Hz),[12] confirming the regiochemistry of the addition product **9**. The ^1H NMR spectrum showed three sets of a doublet of doublet at 3.28 (J=8.8 and 6.8 Hz), 3.47 (J=13.2 and 8.8 Hz), and 3.76 (J=13.2 and 6.8 Hz) ppm. The double resonance study of the ^{13}C NMR spectroscopy irradiated at δ 3.28, 3.47 and 3.76 confirmed the signal at δ 3.28 to correspond to the methine proton CH(Seph)$SnBu_3$ and the other two to the methylene protons attached to the thioester group. In addition, ^{77}Se appeared at δ 358 relative to dimethyl selenide. We have already shown that the thiyl radical generated from selenosulfide **1** adds selectively to the terminal carbon of monosubstituted olefins.[4] This high regioselectivity is derived from that the electron-deficient thiyl radical (PhCOS·) adds to the electron-rich terminal carbon.[13] It should be noted that alkyl radicals generated from alkyl halides does not react with unsubstituted and alkyl-substituted vinylstannanes.[2c] Vinylstannanes should be substituted with an electron-withdrawing group probably due to the nucleophilic nature of alkyl radicals. On the other hand, in our case the thiyl radical (PhCOS·) bearing an electron-withdrawing benzoyl group reacted readily with vinylstannane **8** as well as styrylstannane **6** because of its electrophilic nature.

The present reactions may serve a new synthetic method for the synthesis of thioates providing further scope of reactions with *S*-benzoyl *Se*-phenyl selenosulfide (**1**) as a synthetic reagent.[14]

Experimental

Apparatus. IR spectra were taken with a JASCO A-102 spectrometer. ^1H NMR spectra were recorded on a Varian XL-200 (200 MHz) or JEOL JNM-PMx60si (60 MHz) instruments. Chemical shifts are reported on the δ scale relative to Me_4Si as the internal standard. ^{13}C and ^{77}Se NMR spectra were obtained on a Varian XL-200 spectrometer for solutions in deuterochloroform. Microanalyses were performed by the Institute of Microanalyses, Kyoto University. All reactions were carried out under an argon atmosphere. Flash chromatography was performed using a Michael Miler column packed with Fuji Davison silica gel BW-200, equipped with FMI LAB Pump RP-G150 and FMI Pulse Damper PD-60LF, normally at a pressure of 1—2 kg cm^{-2}.

Reaction of Tributyl(2-propenyl)stannane (2a) with Selenosulfide 1. Thermal Reaction (Method A). A mixture of tributyl(2-propenyl)stannane (**2a**) (34 mg, 0.10 mmol), selenosulfide **1** (54 mg, 0.18 mmol) and AIBN (3 mg, 0.018 mmol) in degassed benzene (0.2 ml) was heated under reflux for 2 h. To the resulting yellow clear solution was added mercury(II) acetate (20 mg, 0.063 mmol) at room temperature and the mixture was stirred for 5 min when white precipitates appeared. The precipitates were filtered and the filtrate was concentrated in vacuo to leave an oil which was purified by flash column chromatography with hexane-benzene (98:2 to 8:2) to give 16 mg (86%) of *S*-2-propenyl benzenecarbothioate[8] (**3**): ^1H NMR (CCl_4) δ=3.73 (d, 2H, J=8 Hz), 5.00—5.40 (m, 2H), 5.50—6.10 (m, 1H), 7.26—8.00 (m, 5H); IR (film) 1660 cm^{-1}; MS (70 eV) m/z (rel intensity) 192 (M^+; 2), 137 (1), 105 (100), 77 (45), 56 (22), and 51 (30).

Photostimulated Reaction (Method B). A solution of tributyl(2-propenyl)stannane (**2a**) (36 mg, 0.11 mmol) and selenosulfide **1** (57 mg, 0.19 mmol) in degassed benzene (0.2 ml) was externally irradiated in a glass tube at a distance of 15 cm with an Toshiba H-400F high-pressure Hg lamp for 1.5 h. Similar treatment of the reaction mixture to Method A

and purification afforded 16 mg (84%) of *S*-2-propenyl benzenecarbothioate (**3**).

Reaction of 2-Butenyltributylstannane (2b) with Selenosulfide 1. Thermal reaction of 2-butenyltributylstannane (**2b**) (37 mg, 0.11 mmol) with selenosulfide **1** (66 mg, 0.23 mmol) in the presence of AIBN (4 mg) in benzene (0.2 ml) for 2 h and subsequent purification described above afforded a 79:14:7 mixture of **4**/(*E*)-**5**/(*Z*)-**5** (18 mg, 89%), whose ratio was determined by the ^{1}H NMR (200 MHz) spectrum.

Irradiation of a mixture of **2b** (32 mg, 0.093 mmol) and **1** (49 mg, 0.17 mmol) for 40 min afforded a 77:17:6 mixture of **4**/(*E*)-**5**/(*Z*)-**5** (14 mg, 79%).

The signals of the ^{1}H NMR spectrum were assigned as follows; for *S*-1-methyl-2-propenyl benzenecarbothioate[8] (**4**): δ=1.52 (d, 3H, J=8.0 Hz), 4.36 (ddq, 1H, J=5.0, 1.5, and 8.0 Hz), 5.08 (ddd, 1H, J=10.0, 1.5, and 1.5 Hz), 5.30 (ddd, 1H, J=17.0, 1.5, and 1.5 Hz), 5.94 (ddd, 1H, J=17.0, 10.0, and 1.5 Hz), 7.36—8.22 (m, 5H); for *S*-(*E*)-2-butenyl benzenecarbothioate[8] (*E*)-(**5**): δ=1.72 (d, 3H, J=7.2 Hz), 3.64 (d, 2H, J=5.0 Hz), 5.48 (dt, 1H, J=15.4 and 7.2 Hz), 5.70 (dq, 1H, J=15.4 and 5.0 Hz), and 7.40—8.20 (m, 5H); for *S*-(*Z*)-2-butenyl benzenecarbothioate[8] (*Z*)-(**5**): δ=1.78 (d, 3H, J=7.2 Hz), 3.71 (d, 2H, J=5.0 Hz), 5.40—5.80 (m, 2H), 7.40—8.20 (m, 5H).

Irradiation of 2-Butenyltributylstannane (2b) and 1 in a NMR Tube. The ^{1}H NMR signals (60 MHz) were monitored by the integration of a C-2 methine proton of *S*-1-methyl-2-propenyl benzenecarbothioate (**4**) at δ 4.00—4.63 and of a C-1 methylene proton of *S*-2-butenyl benzenecarbothioate (**5**) at δ 3.47—3.76. The results are shown in Table 2. The rearrangement in benzene proceeded slower than in CCl_4.

Irradiation of Benzenecarbothioate 4. The complete rearrangement of **4** to **5** in deuterated benzene was observed by the irradiation of **4**, obtained as a ca. 20:1 mixture of **4**/**5** by the short time thermal reaction, for 10 min as monitored by the ^{1}H NMR spectroscopy.

***S*-Styryl Benzenecarbothioate (7).** ^{1}H NMR (CCl_4) δ=6.67 (d, 1H, J=16 Hz), 7.10—8.10 (m, 11H); IR (KBr) 1665 cm^{-1}; MS (70 eV) m/z (rel intensity) 240 (M^+, 4), 105 (100). Found: C, 74.89; H, 5.10%. Calcd for $C_{15}H_{12}OS$: C, 74.97; H, 5.08%.

***S*-(2-Tributylstannyl-2-phenylselenoethyl) Benzenecarbothioate (9).** ^{1}H NMR (CCl_4) δ=0.80—1.70 (m, 27H), 3.28 (dd, 1H, J=8.8 and 6.8 Hz), 3.42 (dd, 1H, J=13.2 and 8.8 Hz), 3.76 (dd, 1H, J=13.2 and 6.8 Hz), 7.12—8.00 (m, 10H); ^{13}C NMR ($CDCl_3$) δ=9.67 (J_{Sn-C}=312.7 and 327.7 Hz, Sn$\underline{C}$H$_2$), 12.77 (SnCH$_2$CH$_2$CH$_2\underline{C}$H$_3$), 22.70 (J_{Sn-C}=217.6 and 227.8 Hz, J_{Se-C}=90.8 Hz, Sn-$\underline{C}$H-Se), 26.53 (J_{Sn-C}=58.5 Hz, SnCH$_2$CH$_2\underline{C}$H$_2$), 28.22 (J_{Sn-C}=19.7 Hz, SnCH$_2\underline{C}$H$_2$), 35.03 (PhCOS$\underline{C}$H$_2$), 125.91, 126.26, 127.33, 127.54, 128.06, 130.64, 131.65, 132.26, 136.21 (2Ph), 190.05 (C=O): ^{77}Se NMR ($CDCl_3$) δ=358 (m) (dimethyl selenide: ν=0 ($CDCl_3$)); IR (film) 1650 cm^{-1}; MS (20 eV) m/z (rel intensity) 473 (M^+—PhCOS, 6), 370 (100), 290 (14), 157 (5), 105 (50), 77 (13), 51 (3). Found: C, 53.34; H, 6.61%. Calcd for $C_{27}H_{40}OSSeSn$: C, 53.13; H, 6.62%.

The present work was partially supported by a Grant-in-Aid for Science Research No. 61470086 from the Ministry of Education, Science and Culture.

The Electronic Spectra of 6,6′-Diamino-2,2′-bipyridine

Masaki YAMADA, Koji ARAKI,* and Shinsaku SHIRAISHI*
Institute of Industrial Science, The University of Tokyo, 7-22-1 Roppongi, Minato-ku, Tokyo 106
(Received December 9, 1987)

Synopsis. The lowest-energy π–π^* band of 6,6′-diamino-2,2′-bipyridine (dabp) appeared at near-UV region, and was found to suffer a characteristic solvent effect. The results were discussed in terms of its electronic structure calculated by ab initio method using a STO-3G basis set.

Electronic structures of polyazabiphenyls and their derivatives, particularly 2,2′-bipyridine (bpy) and its derivatives, have been studied in relation to their physical, chemical, and physiological importances.[1,2] However, the effect of substituent(s), especially at 6,6′-positions, on the electronic structures and photochemical properties of bpy have not been so well understood though ligands of the bpy family are familiar in inorganic chemistry. We previously reported the synthesis, properties, and complexability of 6,6′-diamino-2,2′-bipyridine (dabp)[3] and its derivatives.[4] Introduction of the amino groups at 6,6′-positions of bpy causes a large red shift of the π–π^*-transition band, appearing in the near-UV region (320—340 nm) with a strong intensity ($\log\varepsilon>4$).[3] Furthermore, the absorption band has been found to suffer a characteristic solvent effect. In this report, a detailed study on the electronic spectra of dabp has been carried out, and the photometric and some related properties of dabp has been discussed in terms of the effect of amino substituents at 6,6′-positions.

Experimental

6,6′-Diamino-2,2′-bipyridine (dabp) was prepared and purified according to the method previously reported.[3] For spectral measurements, dabp was further purified by reprecipitation with a KOH–methanol/water system to remove a trace amount of acid salt and subsequent sublimation under reduced pressure. 2,2′-Bipyridine (bpy), 6,6′-dimethyl-2,2′-bipyridine (dmbp), and 2-aminopyridine (amp) were obtained from Wako Pure Chem. Ind., Ltd, and purified by usual procedures. 6,6′-Dibromo-2,2′-bipyridine (dbbp) were prepared according to the literature's method.[5] The electronic spectra were recorded on a JASCO UVIDEC-505 spectrophotometer at 20 °C. ^{13}C and ^{1}H NMR spectra were measured with a JEOL JNM-GX270 Spectrometer (67.8 and 270 MHz, respectively) at 27 °C.

Ab initio calculation with a STO-3G basis set was carried out at The Computer Center of The University of Tokyo, using GAUSSIAN 80 HITAC Version. To avoid prohibitive geometry optimizations, the reported geometries of the bpy ring having s-trans planar structure in the Ref. 6 and of the amino group of 2-aminopyridine (amp) in Ref. 7 were used in the calculation.

Results and Discussion

The measured absorption maxima at the longest wavelength of bpy and some of its 6,6′-disubstituted derivatives in methanol appear in the order of bpy (λ_{max}=281 nm, $\log\varepsilon$=4.13), dmbp (289 nm, 4.18), dbbp (303 nm, 4.19), and dabp (334 nm, 4.08). Dabp has a strong absorption band ($\log\varepsilon>4$) at around 330 nm, at much longer wavelength than other compounds. These absorption bands of bpy derivatives undergo a large red shift without decrease in the intensity upon protonation to the ring nitrogens in an acidic medium, i.e., the absorption maxima at the longest wavelength appear in the order of bpy (λ_{max}=302 nm, $\log\varepsilon$=4.21), dmbp (311 nm, 4.20), and dabp (358 nm, 4.19) in acidic methanol.[8] These results indicate that the bands are not due to a n–π^* but to a π–π^* transition band.[9,10]

Relatively few has been known as to the solvent effect on the electronic spectra of 6,6′-disubstituted bpy derivatives, and that of bpy has been reported to be little.[10,11] Those of dmbp and dbbp also suffered only a small solvent effect (Table 1). On the contrary, a larger and characteristic solvent effect was observed in the spectrum of dabp, i.e., an aprotic solvent of higher polarity caused a larger red shift to the π-π^* transition band of dabp, while water caused a blue shift. As the absorption maximum of this band suffered no change over the wide range of dabp concentration (10^{-4}—10^{-5} mol dm^{-3}) in any solvent, the solvent-dependent shifts were not due to a solute-solute interaction.[7] The imino-type tautomer of dabp is unlikely to contribute to the solvent-induced shifts, since the ^{13}C NMR spectra of dabp suffered only a small solvent effect in several different solvents (Table 2), indicating that dabp was presumably in the amino-form in these solvents.[3] The change in the conformation of two pyridine rings as a possible origin of the shifts[11] can be also ruled out from the ^{1}H NMR studies in several different solvents. The extent of the lower-field shift of the 3,3′-protons compared with the 5,5′-protons is known to be a good measure of the ring conformation of bpy moiety, and that of dabp was essentially the same as that of bpy in all solvents studied (Table 2),[11] confirming that dabp was in s-trans planar conformation.[3,4,12] Therefore, the solvent-induced shift of the absorption band may be attributed to the direct electronic effect of the amino substituents. Almost similar solvent-induced shift was observed for amp (Table 1).[7,13]

In order to understand the electronic structure of dabp, ab initio calculation with a STO-3G basis set was carried out. Bpy has six higher-lying occupied MO's, four π-MO's (π_3—π_6) and two n-MO's (n+ and n-), and four unoccupied π-MO's (π_1^*—π_4^*), which play essential role in the photochemical properties and complexability of bpy.[1,2,6] Dabp had also the same set of the corresponding MO's (Fig. 1). The MO levels of dabp were generally higher than the corresponding MO levels of bpy. In particular π_5 and π_6 levels of dabp were higher than the corresponding MO levels of bpy presumably due to an antibonding character between the amino-nitrogens and the 6,6′-carbons (Fig. 1, Table 3). However, the π_1^*-MO of dabp has small coefficients at the amino-nitrogens, affecting little to the energy level of this MO, thus lowering the energy gap between occupied π_5 or π_6-MO's and unoccupied π_1^*-MO (Fig. 1, Table 3). As the strong absorption band at the longest wavelengths are thought to have large weight on the allowed transition from the π_6 (B_g, HOMO) to the π_1^* (A_u, LUMO),[1,14] it is not surprising that the large red shift of this band was observed for dabp by introduction of amino substituents.

The solvent effect on the absorption band can be interpreted in terms of the calculated MO coefficients of π_6 (Fig. 1, Table 3). Hydrogen-bond formation by the amino-hydrogen of dabp to aprotic polar solvents may cause an increase in the electron density on the amino-nitrogens, raising the energy-level of π_6 and resulting in the red shift of the absorption band. While, the opposite effect may be resulted from hydrogen bonding of the amino-nitrogen of dabp with protons of the protic solvents (Fig. 2),[13] explaining the observed blue shift in water.

Introduction of amino substituents also affected the

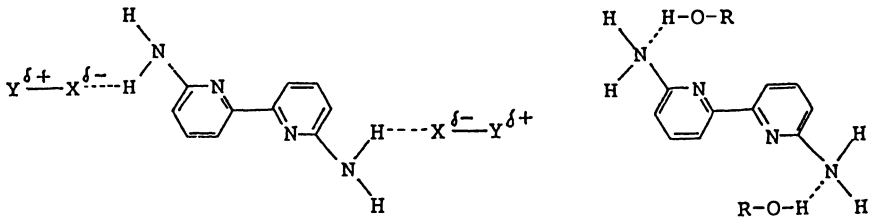

Fig. 2. The solute-solvent interactions of dabp.

basicities (proton affinities) of the nitrogen atoms of dabp, which were estimated from their ls-electron levels according to the method of Catalán et al.[15,16] The calculated proton affinities for dabp and bpy in this work[17] showed that the proton affinity of the ring-nitrogens of dabp (9.80×10^2 kJ mol^{-1}) were much higher than either those of bpy (9.22×10^2 kJ mol^{-1}) or the amino-nitrogens of dabp (8.67×10^2 kJ mol^{-1}), being in agreement with the results reported in Ref. 3.

Thus, the amino substituents at 6,6′-positions increased the σ-donating ability of the ring-nitrogens though they affected little to the lowest π^*-level (π_1^*). Since the σ-donor and π-acceptor capacities of the ligand interact synergistically in the transition-metal complexes,[18] the results described above explain the high stability of 1 : 1 complexes of dabp with divalent transition-metal ions.[3]

Band Structure of DEBP(TCNQ)$_4$

Martin R. WILLIS,† Takehiko MORI,* and Hiroo INOKUCHI
Institute for Molecular Science, Okazaki, 444
†Chemistry Department, Nottingham University, England
(Received January 21, 1988)

Synopsis. Band structure calculations are reported for the intermediate conducting complex salt, DEBP(TCNQ)$_4$ (DEBP: *N,N'*-diethyl-4,4'-bipyridinium, TCNQ: tetracyanoquinodimethane). They show that the array of TCNQs forms a two-dimensional band structure with conduction and valence band widths 0.1 and 0.03 eV respectively. Conduction in the third direction is likely to be by hopping or tunnelling. The results are consistent with the experimental observations of electrical conductivity, magnetic susceptibility and thermoelectric power.

TCNQ complex salts have been extensively studied to explore the relationship between structure and properties. The series of general formula R^{2+}-$(TCNQ)_n^{2-}$, where $2<n<5$ and R^{2+} is an organic dication, has been investigated in some detail and a wide range of electrical and magnetic behaviour reported.[1-4] The complex salt DEBP(TCNQ)$_4$ displays intermediate conductivity and is typical of this group of materials (Table 1). It is a semiconductor with a band gap of 0.5 eV, and the anisotropy of conductivity is qualitatively consistent with the crystal structure. Assuming the application of band theory, the mobilities of electrons and holes have been deduced from an analysis of thermoelectric power measurements.[2] Alternating current conductivity studies reveal a significant concentration of localized states resulting from crystal imperfections.[4] Magnetic measurements are consistent with a thermally accessible localized triplet state, and also indicate the presence of a significant concentration of imperfections.[3]

In this paper, band structure calculations are reported in an attempt to provide a more quantitative relationship between structure and properties.

Table 1. Summary of Electrical and Magnetic Properties

(A) Single crystal conductivity

Axis	Conductivity/ S cm^{-1}	E_A (260 K)/eV
a	1.2×10^{-4}	0.25
b	2.5×10^{-3}	0.28
c	3.2×10^{-3}	0.27

(B) Carrier mobility
Seebeck effect shows,
μ_e=10—25 cm^{2}V^{-1}s^{-1}, μ_h=4—8 cm^{2}V^{-1}s^{-1}
in intrinsic region, assuming 3-D band theory and $m^*=m$,

(C) E.S.R. intensity varies as

$$I \propto \frac{1}{T(3+\exp(J/k_BT))}$$

with J=0.075 eV.

(D) Indications of defect concentration
(i) Curie component of magnetic susceptivility gives
1.6×10^{22} spins per mole
(ii) Alternating current conductivity gives density of localized states at Fermi level as
1.3×10^{25} m^{-3}

Band Calculation

X-Ray crystallography shows that the TCNQ molecules are stacked plane to plane in groups of four along the b-axis (Fig. 1),[2] giving rise to a two-dimensional molecular lattice in the bc plane. The tetrad carries two negative charges which are evenly distributed over the four molecules. The dications lie between the conduction planes of the TCNQ molecules (Fig. 2).

The band structure calculation uses the tight-binding approximation based on the extended Hückel method and is similar to that of Whangbo and Hoffmann.[5] The programming details are described elsewhere.[6] Firstly the molecular wave functions for

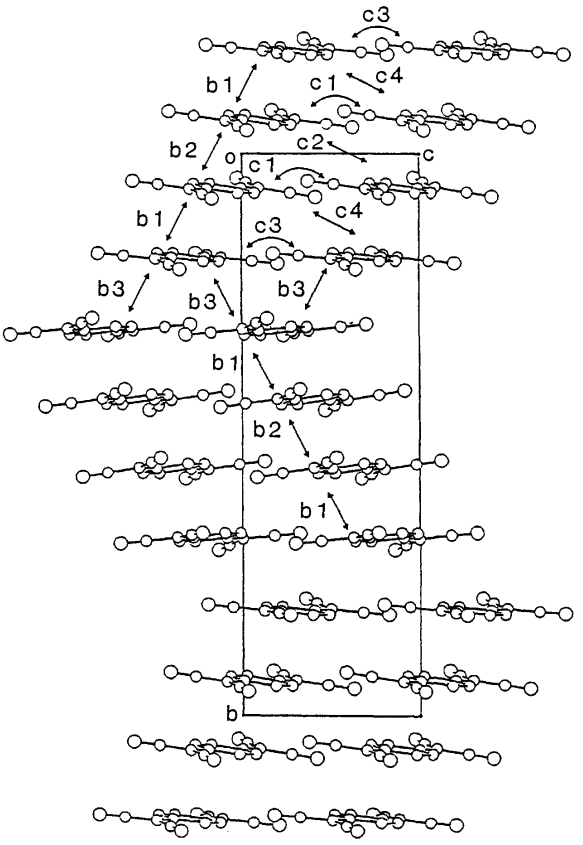

Fig. 1. The crystal structure of DEBP(TCNQ)$_4$ showing the interactions in the bc plane.

Table 2. Transfer Integrals t/eV

(a) Within the TCNQ sheet			
b1	0.176	c1	0.1×10^{-3}
b2	0.194	c2	1.4×10^{-3}
b3	0.038	c3	0.2×10^{-3}
		c4	1.4×10^{-3}
(b) Between cation and TCNQ sheet			
a1, a2, a3, a4	$<10^{-4}$		

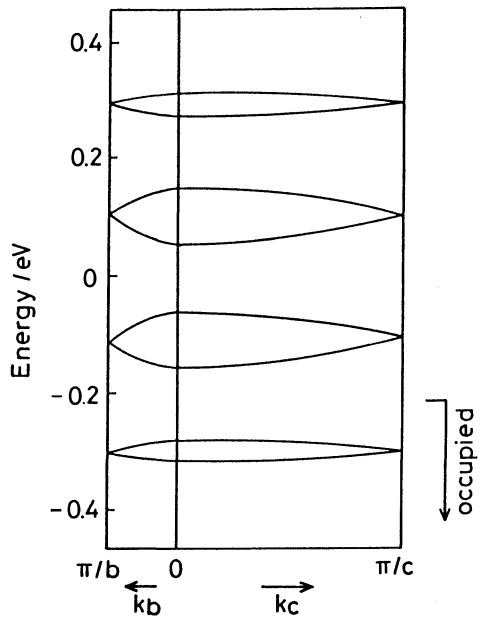

Fig. 3. The band structure of DEBP(TCNQ)$_4$.

the TCNQ molecules were calculated using the experimentally determined atomic positions. The various nearest neighbours overlap integrals (S) relevant to conduction, shown in Fig. 1 as b1, b2, b3, c1, c2, c3, and c4, were then calculated and the transfer integrals were obtained assuming proportionality to overlap integrals,

$$t = KS \tag{1}$$

where K is taken as -10 eV.[7]

Similarly, the molecular orbitals of the cation were calculated and the transfer integrals between cation and the nearest TCNQ molecules were estimated using second order perturbation theory because of the large energy difference.

The absolute values of the transfer integrals are listed in Table 2. Knowing the transfer integrals the band structure was calculated (Fig. 3). The interactions split the LUMO of TCNQ (or the HOMO of $TCNQ^-$) into four bands, the lowest of which is filled and the others empty at 0 K.

Results and Discussion

Dimensionality. From the values of the transfer integrals it is clear that interaction within the tetrad is nearly uniform (b1=b2), and that the most significant interaction between tetrads which determines the conduction path , is b3. By comparison, the transfer integrals between any of the TCNQ s in the tetrads and the cation (a1—a4) are negligible. The material can therefore be represented, to a good approximation, by a two-dimensional band structure. Furthermore, since the band width is determined by the transfer integral corresponding to b3, the conductivity in the b and c directions should be equivalent, which is in good agreement with the experimental observations (Table 1).

Band Conduction. The band calculation shows the material to be a semiconductor. The one-electron calculation gives a separation between the bands of 0.1 eV but allowance must be made for Coulomb interaction between the electrons to obtain the true band gap (E_g). It has been suggested that for a two-dimensional system,[3] the band gap is given by

$$2E_A = E_g = (U - 8t), \tag{2}$$

where t is identified with the average interaction. By taking U to be 1.5 eV, as proposed by Tanaka,[8] then E_g=0.5 eV, in good agreement with experiment.

The band widths calculated for the conduction band of 0.1 eV and for the valence band of 0.03 eV are well within the criterion for band conduction and since the band widths are both greater than k_BT (0.025 eV at room temperature), just satisfy the criterion for broad band conduction.[9] The greater width of the conduction band indicates that the electron has the higher mobility, in agreement with experiment (Table 1).

Conduction in the a Direction. Conduction in the direction normal to the two-dimensional array of TCNQs is clearly not band conduction, as the small

transfer integral would lead to far too narrow a band. A likely mechanism is hopping or tunnelling of the carriers via the cation. This is supported by the observation that the conductivity is lower in this direction by an order of magnitude, whilst the activation energy is isotropic within experimental error, indicating a low hopping barrier. When the carrier is an electron, the intermediate species formed is the resonance stabilized monocation, which corresponds to the violet species readily formed in solution.[10] In contrast, for methyltriphenylphosphonium$(TCNQ)_4$, which does not form such a stabilized intermediate, the anisotropy is two orders of magnitude greater.[11]

Thermoelectric Power. The band calculations give some insight into the validity of the assumptions made earlier in the analysis of the thermoelectric power measurements to derive electron and hole mobilities and their temperature dependencies.[2] The assumption of band conduction is clearly valid, but a two-dimensional density of states with allowance for the number of TCNQ sheets per unit cross section, might have been more appropriate. However, the significant concentration of imperfections tends to shift the density of states towards the three-dimensional value, so the error is likely to be small. No information was available on electron and hole effective masses so they were assumed to be approximately equal to the free electron mass. The calculated band widths enable the effective masses to be estimated from,[9]

$$m = \frac{\hbar}{Wa^2}, \tag{3}$$

where W is the band width and a the lattice constant. The value of m is clearly strongly dependent on the value of a which is not obvious for such a complex structure. If we regard the TCNQ tetrad, over which the electronic charges are fully delocalized, as the basic structural unit, then the repeat distance is 7—13 Å depending on the direction chosen. This gives m_e/m=0.5 to 1.6 and m_h/m=1.5 to 5, suggesting that equating the carrier masses with the free electron mass is a fair approximation.

Magnetic Properties. Since the intra-tetrad transfer integrals are much greater than those between tetrads, temperature dependent paramagnetism associated with the thermal population of a low lying triplet state is to be expected. The singlet triplet splitting is given by[8]

$$J = \frac{4t^2}{U}. \tag{4}$$

Taking the average transfer integral within the tetrad and U=1.5 eV, then J=0.088 eV, in reasonable agreement with the experimental value (Table 1).

Conclusion

The satisfactory agreement between theory and experiment provides strong support for the two-dimensional band model adopted for this group of compounds.

(Received November 27, 1987)

Synopsis. The crystal and molecular structures of the title complex has been determined by the single-crystal X-ray diffraction method. It is monoclinic, with the space group *Pn*, *Z*=2 (including 4 metal atoms), *a*=28.90(2), *b*=10.251(4), *c*=5.981(1) Å, and *β*=94.68(3)°. Both of the metal atoms, Sc(1) and Sc(2), have the hexa-coordinated octahedral geometry, being coordinated to four sulfonato oxygen atoms as well as to two water oxygen (Sc(1)) or to two hydroxide oxygen atoms (Sc(2)). Any pair of the neighboring metal atoms along the b-axis are bridged by two sulfonato ions, forming an infinite chain structure; however, the Sc(2)-O bond lengths (2.307(10)—2.556(19) Å; average, Sc(2)-O (sulfonate), 2.422; Sc(2)-O(OH^-), 2.394 Å) are much longer than the Sc(1)-O lengths (2.031(7)—2.150(8) Å; average, Sc(1)-O(sulfonate), 2.055; Sc(1)-O(H_2O), 2.122 Å).

Many scandium(III) salts are known to have a hexa-coordinated octahedral geometry around their metal atoms;[1-3] they are not in high coordination number like yttrium(III) or lanthanoid(III) complexes.[4,5] However, some scandium(III) salts, especially its carboxylates, have a chain structure like the other rare earth complexes.[6,7]

On the other hand, it was reported that arenesulfonate ions act as a unidentate in many rare earth(III) complexes;[8,9] moreover, alkyl sulfate ligands are not coordinated to the metal atoms in their salts,[10] although both of them are also oxo acidate anions.

Therefore, it is interesting to examine whether such sulfonate ligands can act as multidentates in some rare earth complexes, and whether or not the scandium(III) atom keeps the hexa-coordination geometry in such salts.

This time, since we could synthesize the title complex, its crystal and molecular structure was determined by the single-crystal X-ray diffraction technique.

Experimental

Synthesis of Deaquadihydroxotetrakis(*m*-nitrobenzenesulfonato)discandium(II) Scandium oxide (Sc_2O_3 0.14 g, including 2 mmol of Sc) was dissolved into hydrochloric acid (6 mol dm^{-3}, 20 cm^3), and the solution was evaporated off on a water bath. The residue was dissolved into 15 cm^3 of water together with sodium *m*-nitrobenzenesulfonate (1.36 g, 6.0 mmol). The solution was kept in a silica-gel desiccator until about one third of the solvent was evaporated off. The crystals deposited. Yield: 0.75 g (0.77 mmol (as a dimer), 77%). Found, C, 30.11; H, 2.48; N, 5.86%. Calcd for $Sc_2C_{24}H_{22}O_{24}N_4S_4$ (F.W., 968.62): C, 29.76; H, 2.29; N, 5.78%.

X-Ray Structure Analysis. The used crystal was colorless, approximately parallelepiped in shape (0.35×0.35×0.20 mm^3), monoclinic, space group *Pn*, *Z*=2 (including four Sc atoms in a unit cell), *a*=28.90(2), *b*=10.251(4), *c*=5.981(1) Å, *β*=94.68(3)°, *U*=1776(1) $Å^3$, D_m=1.79(3), D_x=1.82 g cm^{-3}, *μ*(Mo *Kα*)=7.25 cm^{-1}. The intensities were measured on a Rigaku AFC-6A automated 4-circle X-ray diffractometer with graphite monochromated Mo *Kα* radiation (*λ*=0.71073 A), an *ω*-scan technique being employed (the scanspeed was 4° min^{-1} (*θ*), scan width 1.03° (*θ*), and the scanned range was 3—65° (2*θ*)). Of the 6721 independent reflections measured, 4507 (reflections of $|F_o|>3\sigma(|F_o|)$) were used for a structure determination. The intensities were corrected for the Lorentz and polarization factors, but not for absorption and extinction. The structure was solved by the heavy-atom method. The positional and thermal parameters of the atoms were refined repeatedly by the block-diagonal least-squares method. At the final step, all non-hydrogen atoms were found and included in the refinement with the anisotropic temperature factors: all the hydrogen atoms were excluded from the structure factor calculations. The final *R* value was 0.074 (the *R* value for the structure assuming an inversed chirality was also 0.074).

All of the calculations were carried out on a HITAC M-682H computer at the Computer Center of the University of Tokyo using a local version of the UNICS program system.[11] The atomic scattering factors were taken from Ref. 12.

Results and Discussion

The selected bond lengths and bond angles are shown in Table 1. The perspective drawing of the complex, together with the numbering scheme of the atoms is shown in Fig. 1, and the projection of the unit cell to the ab-plane in Fig. 2.[13]

Both of the scandium(III) atoms, Sc(1) and Sc(2), are in an octahedral geometry, being coordinated with six oxygen atoms: in addition to four sulfonate oxygen atoms, two water oxygen (Sc(1)), or two hydroxide oxygen atoms (Sc(2)), are ligated to the respective metal atoms in a trans-configuration.

Each pair of the neighboring metal atoms along the b-axis are apparently bridged with two sulfonate ions,

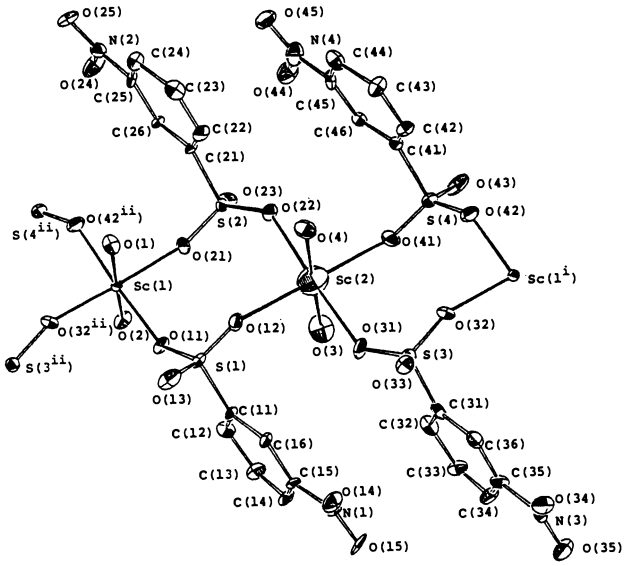

Fig. 1. A perspective drawing of the structure of the complex in a chain form, with the numbering scheme of the atoms. Key to the symmetry operations: i, x, $1+y$, z; ii, x, $-1+y$, z.

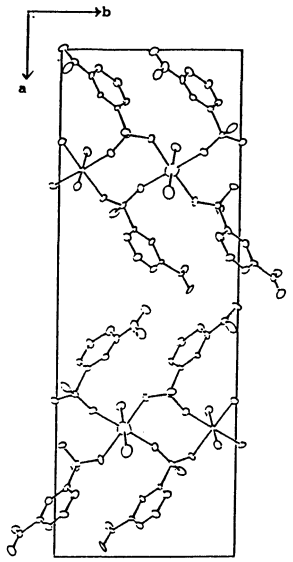

Fig. 2. A projection of the unit cell to the ab-plane.

where the anions act as a bidentate being coordinated to the both side metal atoms with their sulfonato oxygen atoms.

However, it is an interesting fact that the Sc-O bond lengths around the Sc(1) and Sc(2) atoms are much different from each other.

The Sc(1)-O(1,2) bond lengths (2.150(8) and 2.094(7) Å) are shorter than the Sc(2)-O(3,4) lengths (2.367(12) and 2.420(11) Å). From the spectrochemical study, it was proposed that a hydroxide ion is coordinated to a metal atom more weakly than a water molecule.[14] Therefore, the O(1) and O(2) atoms are assigned to be the water oxygen atoms, while the O(3) and O(4) atoms the hydroxide ones. This is also supported by the fact that, as shown in Table 1, the former two oxygen atoms have two hydrogen bondings to the sulfonate oxygen atoms of the neighboring complexes, while the latter two oxygen atoms have only one such hydrogen bonding, respectively.

Moreover, not only the Sc-O (H_2O, or OH^-) bond lengths, but also the Sc-O (sulfonato) bond lengths around the Sc(1) and Sc(2) atoms are different from each other: the average bond lengths around the Sc(1) atom is 2.055 Å (2.031(7)—2.095(8) Å), while that around the Sc(2) atom is 2.422 Å (2.307(10)—2.556(10) Å). The average of the all six Sc-O coordination bond lengths around the Sc(1) atom is 2.077 Å, while that around the Sc(2) atom is 2.412 Å: the former is approximately the same as the sum of the Shannon's ionic radii, 2.10 Å,[15] while the latter is much longer than the value.

Therefore, the circumstances around the Sc(1) and Sc(2) atoms are much different from each other. The Sc(1) atom is normally coordinated with the ligands, while the Sc(2) atoms is apparently only trapped in a cage of the negatively charged six oxygen atoms around it, because not only all the Sc(2)-O bond lengths are abnormally long, but also the thermal parameter of the latter metal atom is very large (B_{eq}=8.1$_9$ Å^2). Along the linear polymeric chain, which is formed parallel to the b-axis, these two types of the metal atoms are arranged alternately.

The inter-metal-atomic distances of Sc(1)$\cdots$Sc(2) and Sc(2)$\cdots$Sc(1^i) (key to the symmetry operation; i, x, $1+y$, z) are 5.102(6) and 5.149(6) A, respectively. Each linear complex chain along the b-axis is connected with the neighboring complex chains on both sides along the c-axis with some hydrogen bondings, but no such bondings are found in the a-axis direction. The nitro-group oxygen and nitrogen atoms are not ligated to any metal atoms.

Of the bridging ligands, the couples of the Sc-O-S angles on both sides of the S(1) and S(4) atoms are not much different from each other: the four angles are in the range of 140.7(5)—143.6(5)°. On the other hand, couples of the bond angles on both sides of the S(2) and S(3) atoms are much different from each other: 135.6(5)° and 164.2(5)° for the couple around the S(2), and 139.4(6)° and 160.5(5)° for those around the S(3) atoms, respectively. Therefore, the latter two bridgings are found to be deformed; however, no clear relation has yet been obtained between the angles and the corresponding Sc-O bond lengths.

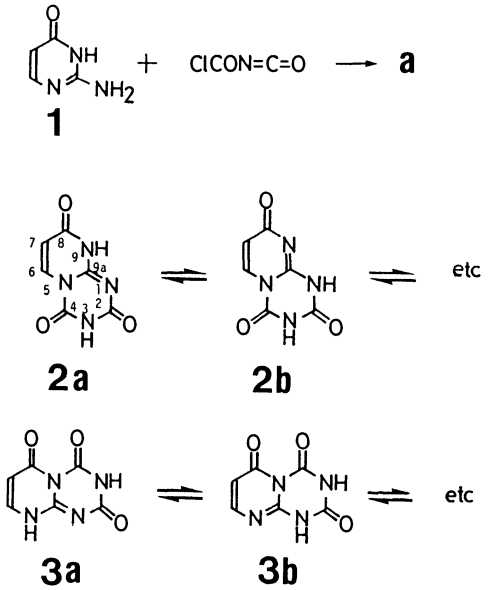
Synopsis. The reaction product **a** of 2-amino-4(3*H*)-pyrimidinone with chloroformyl isocyanate was methylated and the two resulting products were determined as **4** (for the major product) and **5** (for the minor one) by X-ray crystal structure analyses. In a DMSO solution of **a**, the **2a** tautomer was shown to be predominant by ^{13}C NMR analysis.

The reactions and reactivities of heterocyclic compounds have been extensively studied in view of synthetic, mechanistic, and biological interest.[1,2] We have reported on the formation of fused 1,3,5-triazine-2,4(1*H*,3*H*)-diones by a reaction of 4(1*H*)-pyridinone with alkyl isocyanates.[3,4]

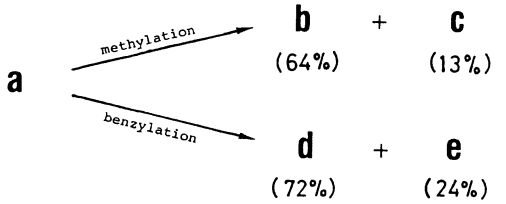
Recently, Kamal et al.[5] communicated the reaction of 2-aminopyrimidine with chloroformyl isocyanate (CFI)[6] to give 2*H*-pyrimido[1,2-*a*][1,3,5]triazine-2,4-(3*H*)-dione. As an extension of our synthetic studies using 4-pyridinone families,[3] we carried out a reaction of 2-amino-4(3*H*)-pyrimidinone (**1**) with CFI in acetonitrile under heterogeneous conditions. Here, we describe the structures of the reaction product and the dialkylated derivatives which have been determined by means of X-ray and ^{13}C NMR analyses.



Experimental

Materials. 2-Amino-4(3*H*)-pyrimidinone (mp 273—275 °C; 4.0 g; 36 mmol), which was synthesized by following the literature method,[7] was suspended in acetonitrile and triethylamine (4.0 g; 40 mmol). An acetonitrile solution (10 ml) of chloroformyl isocyanate (3.2 ml; 40 mmol) was added dropwise with cooling to the above solution under nitrogen atmosphere. The mixture was stirred overnight at room temperature. After removal of the solvent, water (40 ml) was added. The precipitated product was collected, washed twice with water (20 ml), and dried in vacuo (5.9 g; 91% yield, **a**); mp 279—281 °C (decomp); ^{1}H NMR (DMSO-d_6) δ=12.38 (1H, br, NH), 11.88 (1H, br, NH), 8.16 (1H, d, J=8.1 Hz, =CH-N), 6.05 (1H, d, J=8.1 Hz, =CH-CO); ^{13}C NMR (DMSO-d_6) δ=162.47 (C7), 152.55 and 151.24 (C2, C4), 146.35 (C8a), 134.25 (C5), 108.32 (C6); IR (Nujol) 1770, 1710, 1650 (CO) cm^{-1}; MS (70 eV) m/z 180 (M^+); pK_{a_1}=5.47±0.01, pK_{a_2}=9.71±0.03 (20 °C, H_2O); Anal. ($C_6H_4N_4O_3$) C, H, N.

Methylation of **a** was performed in DMF by excess methyl iodide in the presence of potassium carbonate. After the usual workup by medium-pressure column chromatography (silica gel), two kinds of dimethyl derivatives, **b** (mp 253—256 °C, 64% yield) and **c** (mp 218—219 °C, 13% yield) were obtained. Similarly, after benzylation of **a** by excess benzyl bromide, **d** (mp 122—123 °C, 72% yield) and **e** (mp 253—255 °C, 24% yield) were obtained(: for ^{13}C NMR data, see Table 2).



X-Ray Analysis. Colorless crystals of **b** and **c** were obtained by recrystallizations from ethanol and **d** from acetonitrile. Crystal data and analytical conditions are summarized in Table 1.[4a] Three dimensional intensity data were collected on a Rigaku AFC-5FOS automated four-circle diffractometer at room temperature. Mo$K\alpha$ (λ 0.710679 Å) radiation with a graphite crystal monochromator in the incident beam was used. Unit cell constants were determined by a least-squares fit of 15—25 reflections in the range of $15° < 2\theta < 35°$ for all cases. Intensity data were reduced to structure factors without any absorption corrections. Structures were reduced by MULTAN direct methods, refined by block-diagonal least-squares methods. Non-hydrogen atoms were assigned with anisotropic temperature factors. Hydrogen atoms were found from difference Fourier calculations and refined with isotropic thermal parameters. In the case of **c**, hydrogens were not included in the computation. The function minimized was $\sum\omega\,(|F_o|-|F_c|)^2$ with the same equation as described before.[4a]

Computations were carried out on a FACOM S3500 superminicomputer at Material Analysis Center, ISIR, Osaka Univ. or an ACOS-850 computer at Crystallographic Research Center, IPR, Osaka Univ.[8] In the former case, RASA and ANCHOR software were employed for structure analyses and a 3-dimensional graphic display, respectively.[9] From the results, it was determined that the structure of **b** is

Results and Discussion

By using elemental analysis, mass, ^{1}H, and ^{13}C NMR spectroscopic data of **a**, we could not identify one of four possible structures among **2a**, **2b**, **3a**, and **3b**. Since it was difficult to obtain a single crystal, **a** was converted into dimethyl (**b**,**c**) and dibenzyl derivatives (**d**, **e**). By X-ray crystal analyses, the structures of **b**, **c**, and **d** were confirmed to be **4**, **5**, and **8** (Fig. 1), respectively. Neither abnormal bond lengths nor bond angles were found in these structures.[4a)] These results suggest that the reaction of 2-amino-4(3*H*)-pyrimidinone with CFI gives 2*H*-pyrimido[1,2-*a*][1,3,5]-triazine-2,4,8(3*H*,9*H*)-trione in high yield.

^{13}C NMR data of alkyl-substituted derivatives of **2a** or **2b** are summarized in Table 2. There exist clear

differences in ^{13}C NMR chemical shifts. We can classify them into two types of derivatives: compounds with an alkyl substituent at the N-9 position and those at the N-1 position. For example, compared with N-1 substitutions (**5**, **9**, **11**), N-9 substitutions (**4**, **8**, **10**) show upfield-shifts in C8 (ca. 8 ppm), C7 (ca. 4 ppm), and downfield-shifts in C2, C4 (ca. 4 ppm), C9a (ca. 2 ppm): on the other hand, there are no clear differences in the ^1H NMR chemical shifts (C6-H, C7-H) between the two classes.

The ^{13}C NMR data of the parent compound (**2**) and the monobenzyl derivative at N-3 position (**12**)[2a] resemble each other. Furthermore, both compounds show a very similar ^{13}C NMR pattern to the former (N-9) substitution class. These observations indicate that the tautomer structure **2a** is much more favorable than **2b** in a DMSO solution.

The Synthesis of a Heavy-Atom Derivative of Gramicidin S (GS), [D-Phe(4-Br)$^{4,4'}$]-GS, by a Novel Method

Saburo AIMOTO
Institute for Protein Research, Osaka University, Yamadaoka, Suita, Osaka 565
(Received September 7, 1987)

Synopsis. A new approach for the preparation of cyclic peptides was successfully applied to the synthesis of *cyclo*(-Val-Orn-Leu-D-Phe(4-Br)-Pro-Val-Orn-Leu-D-Phe (4-Br)-Pro-) ([D-Phe(4-Br)$^{4,4'}$]-GS). [D-Phe(4-Br)$^{4,4'}$]-GS showing antibacterial activity was obtained as crystals.

Cyclic peptides show interesting functions, such as acting as ionophores or antibiotics, and also serve as good model compounds for the basic study of peptide and protein conformation. Thus, many cyclic peptides have been synthesized, but mostly by the solution method which takes much time and effort. To overcome these difficulties, a new, simple, and time-saving method was developed. The present paper describes how it was used to prepare [D-Phe(4-Br)$^{4,4'}$]-GS and also reports some characteristics of the compound.

Results and Discussion

Synthesis of [D-Phe(4-Br)$^{4,4'}$]-GS (7). [D-Phe(4-Br)$^{4,4'}$]-GS was synthesized according to the scheme shown in Fig. 1. The chain assembly of the peptide was carried out by the standard Merrifield solid-phase method[1] using Boc-amino acid derivatives of Val, Orn(Z), Leu, D-Phe(4-Br) and Pro for the chain elongation and Troc-Val for the introduction of N-terminal Troc-Val. The Troc group was used to block the α-amino group of the peptide because it is stable under acid-treatment conditions.[2-4] The weight increase in the protected-peptide resin **2** was 0.48 g, based on 1.54 g of Boc-Pro-$OCH_2C_6H_4$-resin (**1**). The HF treatment[5] of 1.05 g of Compound **2** gave 275 mg of a crude product **3**. This peptide was very soluble in aq acetonitrile and could be easily purified by reversed-phase high-performance liquid chromatography (HPLC), for it had no extra-protecting groups except for the Troc group. The purified Compound **3** (261 mg) was confirmed by fast-atom-bombardment (FAB) mass measurement. The Boc group was introduced to 200 mg of Compound **3** with the aid of *N*-(*t*-butoxycarbonyloxy)succinimide (Boc-ONSu) in the presence of triethylamine (TEA). The resultant material was purified by crystallization and gave 175 mg of Compound **4**. The Troc group on Compound **4** (84.5 mg) was cleaved by zinc-dust treatment in 90% aq acetic

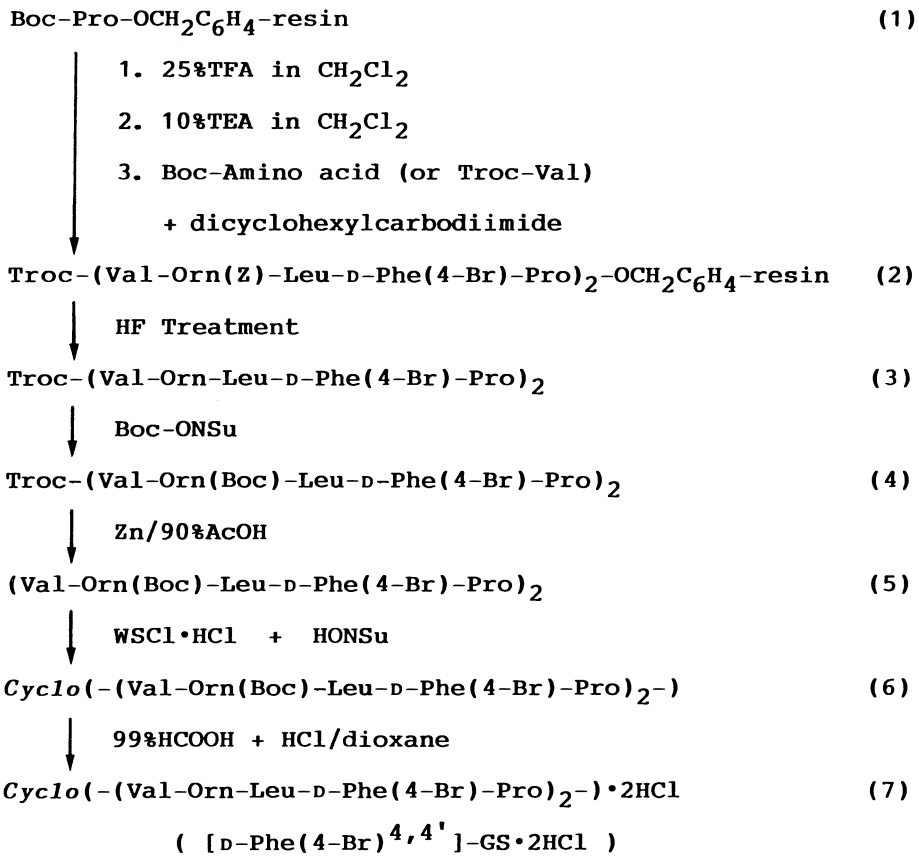

Fig. 1. Synthetic scheme of [D-Phe(4-Br)$^{4,4'}$]-GS.

acid.[2] After the removal of the zinc dust and zinc ions, the peptide solution was freeze-dried to a powder. Compound **5** (64.1 mg) was cyclized by adding about a twofold excess of 1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide hydrochloride (WSCI·HCl) and *N*-hydroxysuccinimide (HONSu) in a mixture of *N*,*N*-dimethylformamide (DMF)-CH_2Cl_2 at about 2.5 mM (1 M=1 mol dm^{-3}). One-pot cyclization proceeded, with a yield of about 80%, judging from the elution profile of the reaction mixture on HPLC. This yield was almost equal to those described by two other research groups.[6,7] No cyclic dimer was detected in the reaction mixture by FAB mass measurements. Compound **6** was purified by crystallization to give 36 mg of crystals in a 50% yield, based on Compound **4**. Compound **6** was treated with a mixture of 99% formic acid and HCl in dioxane to remove the Boc groups. After the separation of minor impurities from the main product by means of HPLC, the final product **7** was obtained in an 80% yield, based on Compound **6**. Each of the steps gave good yields, and the purities of the intermediates and the final products were satisfactory. This new approach was successfully applied to the synthesis of [D-Phe(4-Br)$^{4,4'}$]-GS. Starting from Boc-Pro-$OCH_2C_6H_4$-resin (**1**), the final product **7** was obtained as crystals in 2 weeks.

Biological Activity. The minimum concentration of [D-Phe(4-Br)$^{4,4'}$]-GS needed to completely inhibit the growth of several microorganisms was determined by a dilution method using nutrient agar. [D-Phe(4-Br)$^{4,4'}$]-GS showed antibacterial activity. The bromine atom on the phenyl group of D-Phe affected the biological activity of GS, but not seriously.

Crystallization. We attempted to prepare crystals of [D-Phe(4-Br)$^{4,4'}$]-GS under several conditions. The trifluoroacetate or hydrochloride gave fine needle crystals in aq EtOH, aq MeOH, or aq DMF. The perchlorate gave thick needle crystals in dimethyl sulfoxide. These crystals will be analyzed in a subsequent X-ray crystallographic study.

Experimental

The melting points were determined by the capillary method and are given as uncorrected values. The Pro, Val, Orn, and Leu used were of the L-configuration. High-performance liquid chromatography (HPLC) was carried out on a handmade column of the YMC-GEL ODS S5 100 Å Type (8×300 mm) (Yamamura Chemical Laboratory Co., Ltd., Kyoto, Japan), with the acetonitrile concentration increasing from 40 to 80% in 0.05% aq trifluoroacetic acid (TFA) at a flow rate of 2 ml min^{-1}.

Troc-Val-Orn-Leu-D-Phe(4-Br)-Pro-Val-Orn-Leu-D-Phe(4-Br)-Pro (3). The chain elongation of a peptide was carried out on a Beckman Model 990E synthesizer (Palo Alto, Ca, USA) according to the standard Merrifield solid-phase method. Boc-Pro-$OCH_2C_6H_4$-resin (**1**) (1.54 g), containing 0.4 mmol of Boc-Pro was used as the starting material. For the deprotection of the Boc group, the resin was treated twice with 25% TFA in CH_2Cl_2, for 1 min and then for 30 min. The resin was treated twice with 10% TEA in CH_2Cl_2, for 2 min and then for 5 min, to neutralize the resin. In each coupling reaction, 1.2 mmol of Boc-amino acid or Troc-Val was mixed with a peptide resin in the presence of dicyclohexylcarbodiimide (250 mg, 1.2 mmol) for 2 h. The Boc-amino acids used were Boc-Val, Boc-Orn(Z), Boc-Leu, Boc-D-Phe(4-Br), and Boc-Pro. Weight increase, 480 mg. The protected peptide resin **2** (1.05 g) was treated with anhydrous hydrogen fluoride (10 ml) containing anisole (1 ml) at 0 °C for 70 min. After the evaporation of the hydrogen fluoride, a peptide was extracted with 50% aq acetonitrile. The solution was passed through a column of Amberlite IR-45 (acetate form) (3.5×8 cm). All of the eluent was then collected and freeze-dried. The crude material was purified on HPLC. Lyophilization of the main fractions gave 261 mg of Compound **3**. Found: *m/z* 1489.2 $(M+H)^+$. Calcd for $C_{63}H_{94}O_{13}N_{12}Br_2Cl_3$: *m/z* 1489.5 $(M+H)^+$.

Troc-Val-Orn(Boc)-Leu-D-Phe(4-Br)-Pro-Val-Orn(Boc)-Leu-D-Phe(4-Br)-Pro (4). Compound **3** (200 mg, ca. 130 μmol) was dissolved in DMF (1.7 ml) containing 85 μl (ca. 600 μmol) of TEA. Boc-ONSu (110 mg, 512 μmol) was added to the solution, which was then stirred at room temperature for 1 h. The reaction mixture was poured into a dilute aqueous solution of citric acid. The precipitate thus formed was collected, dried over diphosphorus pentaoxide in vacuo, and crystallized from MeOH-EtOAc to give 175 mg of crystals **4** (ca. 79%): mp 228—229 °C, $[\alpha]_D^{24}$ −108° (*c* 0.5, EtOH). Found: *m/z* 1690.1 $(M+H)^+$. Calcd for $C_{73}H_{110}O_{17}N_{12}Br_2Cl_3$: *m/z* 1689.7 $(M+H)^+$. Found: C, 51.33; H, 6.56; N, 9.69; Br, 9.42; Cl, 6.27%. Calcd for $C_{73}H_{109}O_{17}N_{12}Br_2Cl_3 \cdot H_2O$: C, 51.24; H, 6.54; N, 9.82; Br, 9.34; Cl, 6.22%.

Val-Orn(Boc)-Leu-D-Phe(4-Br)-Pro-Val-Orn(Boc)-Leu-D-Phe(4-Br)-Pro (5). Compound **4** (84.5 mg, 49.4 μmol) in 90% acetic acid (5 ml) was treated with zinc dust (100 mg) while being stirred at room temperature for 5 h. After the removal of the remaining zinc dust and zinc ions, the peptide solution was freeze-dried to give 64.1 mg of Compound **5** (ca. 85%). Found: *m/z* 1515.4 $(M+H)^+$. Calcd for $C_{70}H_{109}O_{15}N_{12}Br_2$: *m/z* 1515.7 $(M+H)^+$.

***cyclo*(-Val-Orn(Boc)-Leu-D-Phe(4-Br)-Pro-Val-Orn (Boc)-Leu-D-Phe(4-Br)-Pro-) (6).** Compound **5** (64 mg, ca. 42 μmol) was dissolved in DMF (10 ml) containing 11.5 mg (100 μmol) of HONSu. Into the solution, 19.2 mg (100 μmol) of WSCI·HCl in CH_2Cl_2 (10 ml) was added at 0 °C. The solution was stirred at 0 °C for 1 h and at room temperature for 24 h. After the concentration of the reaction mixture in vacuo, the residual mass was solidified with water, collected by centrifugation, and dried over diphosphorus pentaoxide in vacuo. The solid material was crystallized from EtOAc-MeOH; yield, 36 mg (ca. 57%); mp 231—232 °C; $[\alpha]_D^{21}$ −277° (*c* 0.5, AcOEt). Found: *m/z* 1497.5 $(M+H)^+$. Calcd for $C_{70}H_{107}O_{14}N_{12}Br_2$: *m/z* 1497.7 $(M+H)^+$. Found: C, 54.70; H, 7.12; N, 10.91; Br, 10.46%. Crystallization of [D-Phe(4-Br)$^{4,4'}$]-GS Perchlorate. [D-Phe(4-Br)$^{4,4'}$]-GS trifluoroacetate or hydrochloride was dissolved in a small amount of methanol. To the solution, dilute perchloric acid was added until a precipitate formed. This precipitate was collected by centrifugation, washed with distilled water, and dried; then a minimum amount of dimethyl sulfoxide was added until the precipitate had dissolved completely. The solution in the uncovered test tube

was left standing. Crystals appeared after 3 d and were allowed to grow for one week. The crystal dimensions were 0.1×0.1×1.0 mm.

Microbiological Assays. The minimum inhibitory concentrations of [D-Phe(4-Br)$^{4,4'}$]-GS·2HCl·3H_2O for several microorganisms were determined by a dilution method using nutrient agar. The minimum inhibitory concentrations of the compound were 12.5 μg ml^{-1} on *Staphylococcus aureus* FDA 209P and *Staphylococcus aureus* 1840, 25 μg ml^{-1} on *Staphylococcus aureus* 308A-1, and 6.25 μg ml^{-1} on *Bacillus subtilis* PCI 219.

This paper is dedicated to the late Dr. Gopinath Kartha of the Roswell Park Memorial Institute, Buffalo, New York, who planned the synthesis of a heavy-atom derivative of GS. The author wishes thank Dr. Jake Bello of the Roswell Park Memorial Institute for his helpful discussions; he is also indebted to the members of the Analytical Laboratories of Takeda Chemical Industries, Ltd., for their assays of the activity and to Dr. Toshifumi Takao and Dr. Yasutsugu Shimonishi for the mass-spectral measurements.

Synopsis. The title compounds were synthesized from 2-[1-(1-imidazolyl)vinyl]phenol and their conformations were discussed on the basis of their ^{1}H and ^{13}C NMR spectra.

In recent decades, antifungal substaces have attracted considerable interests from pharmaceutical and agricultural points of view, and many investigations concerning their syntheses, structural elucidations, and biological activities have been reported.[2-4)] The present authors have also been studying a series of antifungal imidazole derivatives.[5,6)] One of our recent research includes the syntheses, NMR spectra, and antifungal activities of 4-(substituted aryl)-2-(1-imidazolyl, 1-pyrazolyl, and 1,2,4-triazol-1-yl)-1,3-dioxolanes.[7,8)]

In this connection, we synthesized several heterocyclic analogs of the above imidazole derivative and acyl derivatives of 2-[1-(1-imidazolyl)vinyl]phenol (**19**).[4)] Their syntheses, NMR spectroscopic studies, and antifungal activities are reported in this paper.

Experimental

The (imidazolylvinyl)phenol **19** was obtained by the reaction of *o*-hydroxyacetophenone and *N*,*N*′-sulfinyldiimidazole, prepared by adding thionyl chloride to a suspension of imidazole in dichloromethane.[4)] Then, acyl chloride (0.0176 mol) was added gradually to an ice-cooled pyridine solution (30 ml) of the phenol **19** (0.016 mol). The reaction mixture was kept standing for additional 10 min. The whole was poured into water and extracted with dichloromethane. Thus obtained crude products **1**—**14** were recrystallized or distilled in vacuo, and purified further by column chromatography on silica gel. Similarly ethers **15**—**18** were prepared by treating potassium phenolate of **19** with the corresponding arylmethyl chlorides in *N*,*N*-dimethylformamide.

^{1}H and ^{13}C NMR spectra were recorded on a JEOL FX-90Q spectrometer.

Results and Discussion

Various 1-[1-(2-aralkyloxy- and 2-acyloxyphenyl)-vinyl]-1*H*-imidazoles **1**—**18** were prepared starting form known 2-[1-(1-imidazolyl)vinyl]phenol (**19**). Most of them were prepared newly by the present authors and characterized by their physical properties, NMR spectra, and elemental analyses.

These *N*-(1-arylvinyl)imidazoles are structurally similar to cloconazole[4)] and potential antibacterial and antifungal agents.[7,8)] Since the biological activity is closely related with the shape of the active molecule, the conformations of the *N*-(1-arylvinyl)imidazoles **1**—**19** were elucidated by ^{1}H and ^{13}C NMR spectroscopy. The ^{13}C NMR chemical shifts are given in Table 1.

As the shapes of the *N*-(1-vinylaryl)imidazole molecules are expected to be altered most significantly by the conformational change caused by the rotations about the C-C bond connecting vinyl and *o*-R-oxyaryl groups, the C-N bond connecting vinyl and imidazolyl groups, and the C-O bond connecting the aryl and R-oxy groups, the substituent effect on the spectra of vinylidene groups were examined most carefully. Overviewing Tables 1 and 2, chemical shifts of vinyli-

dene carbons (C_α and C_β), as well as those of protons (H_a and H_b), were rather insensitive to the modifications in the acyl side chain.

The vinylidene ^{13}C chemical shifts were dependent on whether the side chain is acyloxyl or aralkyloxyl. The effect might be induced by a through-bond perturbation since the α-carbon connected directly to the aromatic carbon ortho to the RO group is affected more significantly. The through-bond effect of the RO group should be transmitted in an alternate manner causing high and low field shifts alternately and decaying gradually due to the pi-electron releasing mesomeric effect by RO group.[9,10] The observed ^{13}C chemical shifts are in accord with the above reasoning and can be rationalized if we assume that the original perturbation by an aralkyloxyl group is larger than that by an acyloxyl group.[11]

The vinylidene proton signals appeared as AX quartets. The signals at lower fields are assigned to the proton cis to the aryl group (hereafter designated as H_a) and the one at the higher fields to the proton cis to the imidazolyl group (hereafter designate as H_b) (Table 2). Geminal coupling constants J_{ab} are small, ranging from 1.0 to 1.2 Hz, and insensitive to the substituent and solvent effects. Modification of the side chain from aliphatic acyl group to aroyl causes a small but discernible high field shift of H_a signal in chloroform solutions. The shift might be ascribed to the anisotropy effect due to the aroyl aromatic ring. However the effect is obscured in other solvents.

As revealed by the chemical shifts of H_a and H_b in various solvents (in Table 2), their chemical shifts are susceptible to the solvent effect. Especially H_a is very sensitive to the nature of solvents and shows general tendency to shift considerably towards upfield in benzene-d_6 and, in contrast, to shift towards downfields in pyridine-d_5 and DMSO-d_6. With a very minor exception which shows the reversal of the order within an experimental error, the H_a signals are subjected to the solvent effect which aligns the chemical shifts in the order (from the high field); benzene>chloroform>pyridine>dimethyl sulfoxide. The upfield shifts in benzene is rather larger than the usual aromatic solvent induced shifts (ASIS) expected for this sort of proton. The larger shift might be caused by the acidic character of H_a, since ASIS is supposed to be originated from weak C-H···pi hydrogen bonding,[13] The acidity seems plausible if we consider the fact that the vinylidene protons occupy the positions vinylogous to acidic imidazole NH. As a large ASIS was not observed with the beta-protons of *o*-methoxy styrene (**20**), the importance of acidity in ASIS becomes more evident. Benzene induced shifts including the protons and carbons of other parts of the molecule were also examined with several of the *N*-(1-arylvinyl)imidazoles. Generally speaking, positively charged hydogen (and carbon) atoms orienting themselves toward outside the molecule showed the positive ASIS in accord with the reported trend of ASIS[12] and theoretical consequences. Besides those given in Table 2, the ^1H ASIS of arylmethoxyl CH_2 groups of **15—18** comes to be +0.75, +0.23, +0.55, and 0.57,

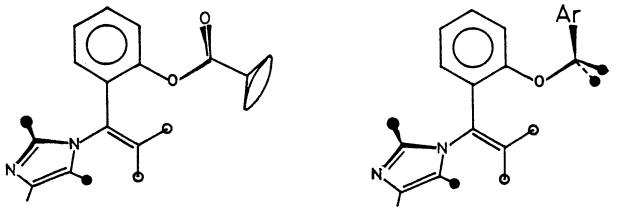
respectively, and that of the terminal methyl group of acyloxyl side chain in the series of compounds **1**—**5** is shown to decrease as the alkyl chain of the acyl group elongates (i. e., +0.39 for **1**, +0.20 for **2**, +0.17 for **3**, +0.13 for **4**, and +0.08 for **5**). As expected, relatively positive ^1H ASIS were observed with the CH_2 groups bonded to oxygen and the CH_3 in acetyl group of **1** which are expected to be considerably acidic owing to the inductive effect of adjacent electronegative groups.

In order to estimate the preferred conformation about the C_{vinyl}-C_{aryl} and C_{vinyl}-$N_{imidazoyl}$ bonds qualitatively, several NOE experiments were carried out. The irradiation of hetarylmethoxyl CH_2 protons in **15**—**17** enhanced the intensities of H_a in 4—10% (**15**, 5%; **16**, 4%; **17**, 10%; and **18**, 10%) in reference to other unirradiated protons. Similarly the irradiation of acetoxyl CH_3 protons in **1** caused the 3% enhancement of H_a signal. As the enhancement was rather small, the increase in intensity was ascertained by several repetitions of the measurements. The NOE experiments showed unambiguously that the acyloxyl or arylmethoxyl group is located syn to the vinylidene group with respect to the C_{vinyl}-C_{aryl} bond, taking a nearly coplanar conformation judging from the observed enhancement. In contrast, the imidazolyl ring should be nearly perpendicular to the plane of vinylidene moiety, keeping the 2′- and 5′-hydrogens farther than 3.4 Å away from both H_b and H_a of vinylidene moiety, since no enhancement of the H_a signal was observed by the irradiation of 2′-H and 5′-H. If we assume that the carbonyl group is exactly coplanar to the aryloxyl moiety, methyl group in **1** is located too far from H_a to observe NOE enhancement. However, the carbonyl group is expected to be twisted to a certain extent around $C_{carbonyl}$-$O_{aryoxyl}$ bond and pushed away from the aryloxyl plane in order to reduce the steric hindrance by 3-hydrogen atom on the benzene ring. In this conformation, methyl group should approach nearer to H_a, which enables us to observe the small enhancement. Judging from their chemical shifts of H_a higher than those of **1**—**5**, similar conformations in which H_a approaches from above the plane of aroyl aromatic ring might be realized. Analogously the pyridine and thiophene rings are assumed to occupy a position considerably deviated from the plane of vinylidenearyloxyl part of the molecule.

If the vinylidenearyloxyl moiety is nearly coplanar as stated above, one of the vinylidene hydrogen H_a should lie very close (as close as 1.63 Å, if completely coplanar) to the aryloxyl oxygen atom. When an acidic hydrogen is in the proximity of electronegative oxygen atom, C-H ··· O hydrogen bond is expected to be formed. T_1 measurements showed that the H_a has somewhat shorter T_1 than H_b and other hydrogens in the molecule. When the T_1 values were compared with those in *o*-methoxystyrene (**20**), T_1 values of H_a and H_b are generally short. The results imply the fact that the motion of H_a is significantly restricted in these molecules. Intramolecular C-H ··· O hydrogen bond may persist under such sterically favored circumstances, which, in turn, contributes to stabilize the planar vinylidenearyloxyl moiety.

In conclusion, following sketches for the steric structures of the title compound 1-(1-arylvinyl)-imidazoles can be drawn. This is in accord with the X-ray result recently reported by Ogata and coworkers,[14] and the solution structure was shown to be similar to that in crystal.



Antifungal and antibacterial activities of the 1-(1-arylvinyl)imidazoles are given in Table 3. The hetarylmethoxyl derivatives **15**—**18** are shown to have broad spectrum fungicidal and bacteriocidal activities, while the acyloxyl derivatives **1**—**14** are seldom active. The NMR spectroscopic studies showed that the difference in conformations between the hetarylmethoxyl derivatives and the acyloxyl derivatives is very slight in contrast to the remarkable difference in biological activities.

Since the acyloxyl derivatives are rather susceptible to hydrolysis and some of them are sensitive to atmospheric moisture, the instability might be the reason for the discrepancy. However, further investigation is necessary before ascribing the inactivity of the acyloxyl derivative to the hydrolytic degradation.

Regioselective Para Halogenation of Substituted Benzenes with Benzeneseleninyl Chloride and Aluminum Halide

Nobumasa KAMIGATA,* Takeshi SATOH, Masato YOSHIDA, Haruo MATSUYAMA, and Masayuki KAMEYAMA
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received September 26, 1987)

Synopsis. In the presence of aluminum halide, benzeneseleninyl chloride is an efficient regioselective halogenating reagent for activated aromatics such as toluene, phenol, anisole, phenetole, diphenyl ether, and *N,N*-dimethylaniline. Benzene and chlorobenzene are not halogenated under similar conditions.

Extensive studies on the halogenation of aromatic compounds have been reported.[1] Electron-donating substituents in a benzenoid compound generally give ortho- and para-substituted compounds, with the ortho-isomer frequently exceeding the para. Since the ortho- and para-isomers have similar physical properties, their separation is tedious. Many studies on the bromination of anilines and phenols have been reported in order to obtain a high para-regioselectivity.[2] However, these methods tend to give lower yields and also lead to di- or tri-substitution. The following three papers reportred recently are excellent methods for para-halogenation. Osa et al. found a high para-chlorination of anisole (para/ortho ratio= 25/1) by an electrochemical anodic reaction in the presence of α-CD.[3] Watson found a high para chlorination of phenols (para/ortho ratio=10.5/1) by use of sulfuryl chloride catalyzed by diphenyl disulfide and aluminum chloride.[4] Olah et al. found that phenols and anilines gave more than 97% para-halogenated products by a reaction with bromodimethylsulfonium bromide or chlorodimethylsulfonium chloride.[5]

Recently, we reported that benzeneseleninyl chloride in the presence of aluminum chloride or bromide is an excellent vinylic chlorinating or brominating reagent of olefins, respectively, in one step under mild reaction conditions, and the reaction mechanism involving positive halogen (chloronium or bromonium ion) intermediate is proposed.[6] If such a positive halogen intermediate is formed under the reaction conditions, the electrophilic halogenation of aromatic compounds would also be expected by this method. We have investigated the halogenation of aromatic compounds with benzeneseleninyl chloride (**1**) in the presence of aluminum halide and found that aromatic compounds possessing electron donating-group are halogenated regioselectively at para-position in high yield. We report herein the results of these novel para-halogenations of aromatic compounds.

Benzeneseleninyl chloride (**1**), prepared from benzeneselenenyl chloride treated with ozone in dichloromethane, was allowed to react with anisole in the presence of aluminum chloride. *p*-Chloroanisole (**2a**) was formed in quantitative yield, and no formation of *o*-chloroanisole was detected by gas chromatography. Similarly, compound **1** was allowed to react with phenetole, diphenyl ether, and *N,N*-dimethylaniline in the presence of aluminum chloride in dichloromethane at room temperature to give *p*-chlorophenetole (**2b**), *p*-chlorodiphenyl ether (**2c**), and *p*-chloro-*N,N*-dimethylaniline (**2d**), respectively, in quantitative yield; and no corresponding ortho-isomer was detected by gas chromatography. These observations show that the chlorination of activated aromatics with **1** cata-

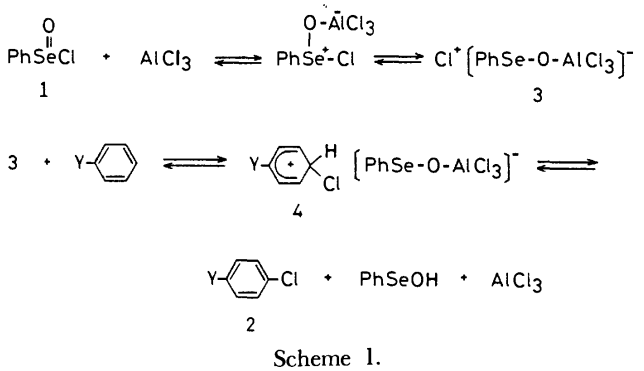
a) Determined by GLC using an internal standard. Isolated yields are given in parentheses.

lyzed by aluminum chloride is regiospecific, and that the method is quite efficient for the synthesis of para-chlorinated aromatic compounds.

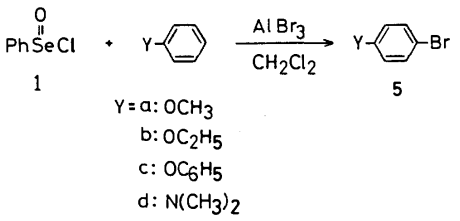
On the other hand, the reaction of **1** with phenol in the presence of aluminum chloride in dichloromethane at 40 °C gave a mixture of *o*- and *p*-chlorophenol (para/ortho ratio=64/36) in high yield. Similarly, the reaction of **1** with toluene under similar conditions afforded *o*- and *p*-chlorotoluene in 30 and 35% yield, respectively. The results show that both the yield and regioselectivity are lowered when the substituents on the benzene ring are OH or CH_3. Moreover, benzene and chlorobenzene were not chlorinated by **1** under similar reaction conditions. The results are summarized in the Table 1. These observations suggest that chlorination by this method is an electrophilic substitution on the activated aromatic nucleus.

The reaction mechanism is accounted for by Scheme 1, which involves a chloronium ion intermediate.[6] The aluminum chloride interacts with the oxygen atom of **1** to give chloronium trichloro(phenylselenooxy)aluminum intermediate (**3**). The following electrophilic reaction of the chloronium ion toward aromatic nucleus affords para-chlorinated products via carbocation intermediate (**4**). The observed high para-selectivity is a consequence of the transfer chlorinations going through a "late" arenium ion like transition state and of the bulky nature of the halogenating reagent (**3**).

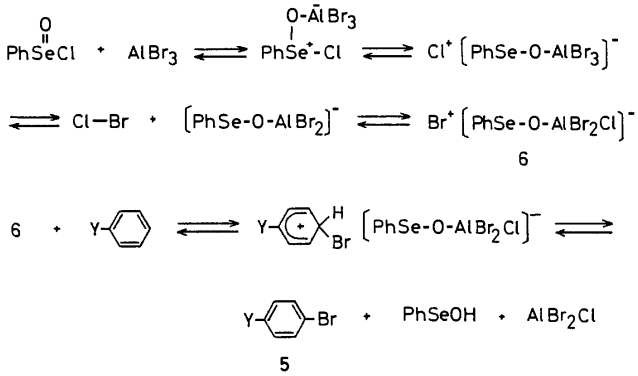


Scheme 1.

When a reaction of **1** with anisole was carried out in the presence of aluminum bromide instead of aluminum chloride in dichloromethane at room temperature, *p*-bromoanisole (**5a**) was obtained in 90% yield and no formation of the ortho-isomer was observed. Similarly, compound **1** was allowed to react with phenetole, diphenyl ether, and *N*,*N*-dimethylaniline in the presence of aluminum bromide to give *p*-bromophenetole (**5b**), *p*-bromodiphenyl ether (**5c**), and *p*-bromo-*N*,*N*-dimethylaniline (**5d**) in high yield, respectively. The results show that benzeneseleninyl chloride in the presence of aluminum bromide is a quite efficient para-brominating reagent of activated aromatics. The results indicate that a bromonium ion is involved in this reaction as a reactive intermediate, as shown in Scheme 2.



Y=a: OCH_3
b: OC_2H_5
c: OC_6H_5
d: $N(CH_3)_2$



Scheme 2.

In conclusion, benzeneseleninyl chloride in the presence of aluminum chloride and aluminum bromide is a versatile chlorinating and brominating reagent at the para-position of activated benzenes.

Experimental

Measurement. Gas chromatography was performed by using a Hitachi 163 and 263-10 gas chromatograph using SE 30 (10 %), 1 m column. Mass spectra were determined with a JEOL JMX-DX 300 mass spectrometer with JEOL JMA 5000 Mass Data System at an ionizing voltage of 20—70 eV.

Materials. Benzeneselenenyl chloride of Nakarai Chemicals was distilled prior to use; bp 82 °C/3 mmHg (120 °C/20 mmHg) (1 mmHg=133.322 Pa).[7] Benzeneseleninyl chloride (**1**) was prepared by ozonization of benzeneselenenyl chloride with stirring in dry dichloromethane at −70 °C until the orange-red color has faded to a light yellow[8] by introducing ozone prepared by a Nippon Ozone Model O-3-2 ozonizer. The benzeneseleninyl chloride prepared was used to the reaction with aromatic compounds in situ since the compound is extremely hygroscopic and care must be taken to avoid moisture. Toluene, chlorobenzene, phenol, anisole, phenetole, diphenyl ether, and *N*,*N*-dimethylaniline used were obtained from Tokyo Kasei Co.

General Procedure for the Reaction of Benzeneseleninyl Chloride (1) with Aromatic Compound. To a stirred solution of benzeneseleninyl chloride, prepared from benzeneselenenyl chloride (192 mg, 1 mmol) by ozonization at −70 °C in dichloromethane (20 cm^3), was added corresponding aromatic compound (1 mmol) and aluminum halide (1 mmol) under nitrogen-gas bubbling. The mixture was allowed to raise the temperature at 40 °C or room temperature and was stirred for an appropriate time (see Table 1). Water (30 cm^3) was added to the reaction mixture, which was then extracted with dichloromethane (20 cm^3×2). The combined organic extracts were washed with saturated solution of sodium carbonate (20 cm^3) and water (30 cm^3), and dried over magnesium sulfate. The halogenated aromatic products were analyzed by GLC and GC-MS comparing with their authentic samples, and the yields were determined by using acetophenone as the internal standard.

General Procedure for the Isolation of Para-Halogenated Benzenes. The halogenation of substituted benzene (30

mmol) by benzeneseleninyl chloride (10 mmol) in the presence of aluminum halide (10 mmol) in dichloromethane (300 cm^3) was carried out in a similar procedure shown above. The reaction mixture was quenched by water (50 cm^3); then dichloromethane was evaporated. The organic layer was extracted with ether (300 cm^3), dried over magnesium sulfate; the solvent was evaporated, and the residue was subjected to the silica-gel chromatography by using hexane as an eluent to give *p*-halogenated benzene. The product was further purified (if necessary) by gel-permeation chromatography on a JAI LC-08 liquid chromatograph with a JAIGEL-1m column (20ϕ×600 mm×2) using chloroform as an eluent.

(Received October 7, 1987)

Synopsis. A Eu^{III}/Eu^{II} photoredox system in alcohol induced an effective hydroxyalkylation at an α-position of a dialkyl malonate. The alcohol adduct was then converted to the lactone. A step-by-step hydroxyalkylation mechanism was suggested in which the Eu ion is used as a photocatalyst and also as a condensation catalyst for the reaction of dialkyl malonates and aldehydes.

We have investigated a series of photo-hydroxyalkylations of various unsaturated compounds induced by a Eu^{III}/Eu^{II} photoredox system in alcohols. The reaction of aromatic and aliphatic alkenes provided dihydrodimers and alcohol adducts as main products via a radical mechanism.[1,2] On the other hand, 1,3-dimethyluracil and its derivatives provided a hydroxyalkylation product at the C-6 position in a very high yield; a one-electron reduction mechanism has been suggested.[3,4] In this paper, we present an effective hydroxyalkylation and lactone formation of dialkyl malonates by the use of a Eu^{III}/Eu^{II} photoredox system in which the Eu ion is used as a photocatalyst and also catalyzes the condensation of dialkyl malonates and aldehydes.

Results and Discussion

A 180 mL methanol solution of dimethyl malonate (**1**: 85 mmol dm^{-3}) and $EuCl_3$ (2.2 mmol dm^{-3}) was saturated with Ar and irradiated in a Pyrex cell with a 350-W high-pressure mercury lamp at the temperature of running water. During the irradiation, the evolution of hydrogen gas was observed much as in substrate-free solution.[1,2] After a 22-h irradiation, all the substrate has been consumed; the reaction mixture was then worked up. The crude product was a mixture of a hydroxyethylated product **2** and its lactone **3**, which were confirmed by the NMR spectra. By distillation, **3** was isolated as a sole product in a yield of 76%. Without $EuCl_3$, no reaction was observed, and **1** was recovered. The absorption spectra suggested that $EuCl_3$ was the main light-absorbing agent. The reaction of diethyl malonate (**4**) in ethanol was carried out under similar reaction conditions, but the reaction rate was rather lower than that of **1** and the conversion was 77% at an 84-h irradiation.[5] In addition to a 1:2 alcohol adduct **5** (31%, based on conversion) and its lactone **6** (27%), a 1:1 adduct **7** (19%) and its dehydrated product **8** (8%) were obtained. They were presumed to be the primary products. The NMR spectra of **6** suggested the presence of two diastereomers **6a** and **6b**.[6].

The time course observation of the reaction of **4** was carried out to get an insight into the initial step of the reaction. The conversion of **4** and the product-formation were monitored by means of GLC(FID), so that **5** and **7** were determined to be **6** and **8** respectively. The reaction of dialkyl malonates needed a very long risetime compared with that of other olefinic substrates reported previously.[1,2] In the initial 20 h, hydrogen gas and acetaldehyde were obtained as the photolytic products of ethanol by means of a Eu^{III}/Eu^{II} photoredox stem.[1,2] After the 20-h irradiation, the products derived from **4** were barely observed. After a 75-h irradiation, **6** (and/or **5**) was determined in a yield of 24% (absolute yield). Furthermore, **8** (and/or **7**) which had been slightly observed during the irradiation, increased and became the main product (26%) upon standing for 45 h in the dark after a 75-h irradiation. These facts suggest that **8** might be a product of the dark reaction of **4** with acetaldehyde, which is a photolytic product of ethanol.[7] Indeed, the intentional addition of acetaldehyde (0.5 mol dm^{-3}) to this system obviously shortened the risetime of the photoproducts (**6** and/or **5**). In order to confirm this process, the reac-

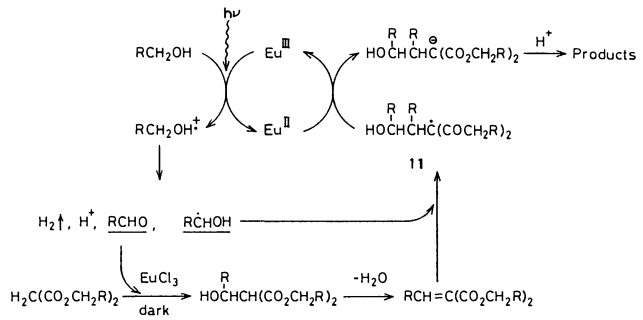
† Present address: Fuji Oil Co., Ltd., Izumisano, Osaka 598.

tion of dialkyl malonates with aldehydes were carried out in the dark.

The monitoring of reactions was carried out by means of GLC(FID). Thus, the alcohol adducts were determined to be the dehydrated esters. In the presence of $EuCl_3$, an ethanol solution of **4** and acetaldehyde provided an ethanol adduct **7** and/or **8** quantitatively, while no product was observed when there was no $EuCl_3$ (Table 1). In the reaction of **1** with formaldehyde, **1** disappeared. However, only oligomeric products were obtained instead of **9** (and/or **10**). This is consistent with the fact that **9** is easily dehydrated to provide **10**, which is very unstable and polymerizable under these conditions.[7] These observations suggest that the present reaction proceeds by the two steps shown in Scheme 1:

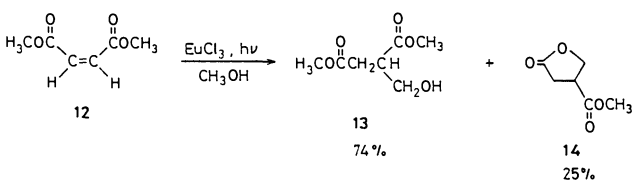


Scheme 1.

The first step is a reaction in the dark of dialkyl malonate with aldehyde, which is a primary photoproduct. This type of reaction, known as Knoevenagel reaction, was catalyzed by a Lewis acid, and the product was easily dehydrated to provide an unsaturated ester.[8] In this stem, $EuCl_3$ may act as a Lewis acid for the condensation. In the photoreaction of **1**, **9** may be supplied in a very low concentration; thus, the further reaction of **9** to produce **3** is preferred to the oligomerization.

The second step of the reaction, the photo-addition of alcohol to unsaturated esters **8** and **10**, is presumed to be induced by a hydroxyalkyl radical. The radical **11** produced by the addition of the hydroxyalkyl radical has two methoxycarbonyl group and is supposed to be easily reduced by Eu^{II}, thus generating the carbanion, which then, gives the product by protonation (Scheme 1).

Dimethyl maleate (**12**), another α,β-unsaturated ester, was irradiated in the presence of $EuCl_3$ in methanol. An alcohol adduct **13** and its lactone **14** were thus obtained in high yields. There, the Eu^{III}/Eu^{II} photoredox reaction is an efficient system for the hydroxyalkylation and successive lactone formation of unsaturated esters. The photo-reaction of dimethyl maleate in CH_3OD resulted in the incorporation of the D atom at the α-carbon of the product **13**,[9] which was consistent with the mechanism via a carbanion.



Experimental

The ^1H and ^{13}C NMR spectra were recorded on a Bruker WM-360 instrument using tetramethylsilane as the internal standard. The gas chromatography was carried out on a Shimadzu GC-7A apparatus with FID using OV-17 or Porapak Type QS. The mass spectra were recorded on a JEOL DX-300 apparatus with a JEOL JMA-3100 data processor.

Reaction of 1. A 180 mL methanol solution of **1** (2.0 g, 15.2 mmol) and $EuCl_3$ (150 mg, 0.4 mmol) was irradiated in a Pyrex cell with a high-pressure mercury lamp for 22 h under an Ar atmosphere. After the irradiation, the methanol was removed in vacuo. The residue was extracted with $CHCl_3$, after which, the solution was washed with water two times and dried with $MgSO_4$, and the $CHCl_3$ was removed in vacuo. The crude product, a colorless oil (1.96 g), was distilled (bath temp 80—100 °C/4 mmHg††) with a "One-Pot Still" after the NMR analyses. As the sole product, **3** was obtained (1.66 g).

2: Not isolated, but identified as a mixture with **3** by ^1H NMR and ^{13}C NMR; ^1H NMR ($CDCl_3$ δ=2.15 [d (J=6.1 Hz) and t (J=6.6 Hz), 2H], 3.17 (bs, 1H), 3.68 (t, J=6.1 Hz, 1H), and 3.75 (s, 6H). The 2H of -$C\underline{H}_2OH$ was not identified, because it was in the multiplet of 4.52—4.32 ; ^{13}C NMR ($CDCl_3$) δ=29.5, 48.1, 52.8, 63.4, and 174.3.

3: Colorless oil; ^1H NMR ($CDCl_3$) δ=2.54 (dddd, J=5.3, 7.5, 9.3, and 13.1 Hz, 1H), 2.68 (dddd, J=7.4, 7.9, 8.2, and 13.1 Hz, 1H), 3.59 (dd, J=7.9 and 8.9 Hz, 1H), 3.81 (s, 3H), 4.35 (ddd, J=7.4, 7.5, and 8.9 Hz, 1H), and 4.48 (ddd, J=5.3, 8.2, and 8.9 Hz, 1H); ^{13}C NMR ($CDCl_3$) δ=26.5 (t), 45.8 (d), 53.0 (q), 67.4 (t), 168.3 (s), and 172.3 (s); EIMS, m/z (relative intensity) 145 (M^++1, 2), 144 (4, M^+), 113 (29), 100 (32), 69 (100), 59 (22), 55 (39), and 41 (51); Found C, 49.74; H, 5.62%. Calcd for $C_6H_8O_4$: C, 50.00; H, 5.60%.

Reaction of 4. The crude product, which had been obtained much as in the photoreaction of **1**, was a colorless oil (22.29 g); and when it was separated by column chromatography on silica gel (eluent; a mixture of Et_2O and hexane, 2 : 1 v/v), and the three fractions were obtained: a mixture of **4** and **7**: 0.57 g; a mixture of **7** and **8**: 0.29 g; and a mixture of **5** and **6**: 0.91 g. The product yields were calculated by the use of the product ratio obtained by means of the ^1H NMR data.

5: Not isolated but identified by NMR analyses as a mixture with **6**; ^1H NMR ($CDCl_3$) δ=0.98 (d, J=7.0 Hz, 3H), 1.28 (t, J=7.1 Hz, 6H), 1.29 (d, J=6.4 Hz, 3H), 2.31 [d (J=2.5 Hz), t (J=7.0 Hz), and t (J=8.5 Hz), 1H], 2.47 (bs, 1H), 3.49 (d, J=8.5 Hz, 1H), 3.93 [d (J=2.5 Hz) and q (J=6.4 Hz), 1H], and 4.21 (q, J=7.1 Hz, 4H); ^{13}C NMR ($CDCl_3$) δ=10.7 (q), 14.1 (q), 20.7 (q), 39.5 (d), 55.7 (d), 61.5 (t), 68.3 (d), 169.1 (s), and 169.5 (s); m/z 204.

6a: Colorless oil. ^1H NMR ($CDCl_3$) δ=1.18 (d, J=6.6 Hz, 3H), 1.32 (t, J=7.1 Hz, 3H), 1.46 (d, J=6.2 Hz, 3H), 2.56 (m, 1H), 3.25 (d, J=11.6 Hz, 1H), 4.13 [d (J=9.4 Hz) and q (J=6.1 Hz), 1H], and 4.27 (q, J=7.1 Hz 2H); ^{13}C NMR ($CDCl_3$) δ=14.1 (q), 15.1 (q), 18.4 (q), 42.8 (d), 55.1 (d), 61.9 (t), 81.6 (d), 167.6 (s), and 171.1 (s).

6b: Colorless oil; ^1H NMR ($CDCl_3$) δ=1.11 (d, J=7.1 Hz, 3H), 1.29 (d, J=6.7 Hz, 3H), 1.32 (t, J=7.1 Hz, 3H), 3.00 (m, 1H), 3.26 (d, J=8.3 Hz, 1H), 4.26 (q, J=7.1 Hz, 2H), and 4.82 (quintet, J=6.7 Hz, 1H); ^{13}C NMR ($CDCl_3$) δ=13.3 (q), 14.1 (q), 15.5 (q), 38.0 (d), 53.6 (d), 61.9 (t), 78.7 (d), 167. 1 (s), and 171.5 (s); Found: m/z (mixture of **6a** and **6b**) 186.08935. Calcd

†† 1 mmHg=133.322 Pa.

for $C_9H_{14}O_4$: M, 186.08912.

7: Not isolated but identified by NMR analyses as a mixture with **8**; ^{1}H NMR ($CDCl_3$) δ=1.25 (d, J=7.0 Hz, 3H), 1.27 (t, J=7.0 Hz, 3H), 1.28 (t, J=7.0 Hz, 3H), 3.46 (d, J=9.2 Hz, 1H), 3.62 [d (J=9.1 Hz) and q (J=7.0 Hz), 1H], 4.19 (q, J=7.1 Hz, 2H), and 4.21 (q, J=7.1 Hz, 2H); ^{13}C NMR ($CDCl_3$) δ=14.1 (q), 18.0 (d), 59.0 (d), 61.4 (t), 73.9 (d), 167.3 (s), and 167.7 (s).

8: Colorless oil; ^{1}H NMR ($CDCl_3$) δ=1.29 (t, J=7.1 Hz, 3H), 1.34 (t, J=7.1 Hz, 3H), 1.96 (d, J=7.2 Hz, 3H), 4.25 (q, J=7.1 Hz, 2H), 4.31 (q, J=7.1 Hz 2H), and 7.09 (q, J=7.3 Hz, 1H); ^{13}C NMR ($CDCl_3$) δ=14.2 (q), 15.4 (q), 61.2 (t), 130.1 (s), 144.6 (d), 163.4 (s), 165.4 (s).

Reaction of 4 for the Quantitative Analysis. A 5-mL ethanol solution of **4** (100 mmol dm^{-3}) and $EuCl_3$ (5 mmol dm^{-3}) was saturated with Ar and irradiated in a Pyrex cell this with a 350-W high-pressure mercury lamp for 75 h. After this irradiation, the reaction mixture was left in the dark for 45 h. The reaction was followed by GLC every 5 h.

Reaction of 4 in the Dark. A 5-mL ethanol solution of **4** (800 mg, 5.0 mmol), $EuCl_3$ (180 mg, 0.5 mmol), and acetaldehyde (7 mL, 60 mmol) was stirred for the 72 h at room temperature in the dark, and then the EtOH was removed in vacuo. The mixture was extracted with $CHCl_3$, washed with water two times, and dried with $MgSO_4$; and $CHCl_3$ was then removed in vacuo. The products were distilled under reduced pressure (110 °C/4 mmHg). The NMR data were identical with those of photogenerated **10**.

Reaction of 12. A 180-mL methanol solution of **12** (123 mmol dm^{-3}) and $EuCl_3$ (2.2 mmol dm^{-3}) was saturated with Ar and irradiated in a Pyrex cell with a 350-W high-pressure mercury lamp for 24 h (conv. 100%). After the irradiation, the methanol was removed in vacuo, and the residue was extracted with a large amount of ether. The ether solution was filtered through Hyflosuper-cel to remove the $EuCl_3$; and a colorless oil was then obtained by removing the ether. The crude product was separated by column chromatography on silica gel (eluent: $CHCl_3$).

13: Colorless oil; ^{1}H NMR ($CDCl_3$) δ=2.63 (dd, J=6.2 Hz and 16.8 Hz, 1H), 2.78 (dd, J=7.5 Hz and 16.8 Hz, 1H), 2.87 (bs, 1H), 3.04 (dist. quintet, 1H), 3.70 (s, 3H), 3.73 (s, 3H), and 3.82 (d, J=5.4 Hz, 2H); ^{13}C NMR δ=32.7 (t), 44.1 (q), 50.3 (q), 52.0 (q), 62.6 (t), 172.7 (s), and 173.9 (s); Found: C, 47.77, H, 6.86%. Calcd for $C_7H_{12}O_5$: C, 47.72; H, 6.87%.

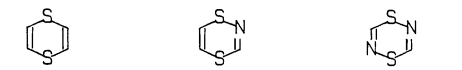
Formation of 1,4,2,5-Dithiadiazines as a Heterocyclic System by Reaction of 1,4,2-Dithiazolium Salts with Sulfenamides

Katsumi YONEMOTO,* Isao SHIBUYA,* and Kazumasa HONDA
National Chemical Laboratory for Industry, Tsukuba, Ibaraki 305
(Received December 5, 1987)

Synopsis. The first example of application of sulfenamides for ring expansion on nitrogen atom has been reported to give 1,4,2,5-dithiadiazines (**3**) from 1,4,2-dithiazolium salts (**1**). The structure of **3** was confirmed by X-ray crystallographic analysis. The similar ring expansion reaction occurred on 1,3-dithiolium salts (**5**) to afford 1,4,2-dithiazines (**6**).

The chemistry of 1,4-dithiins, an interesting 8π-electron ring system containing heteroatoms, has been extensively studied[1] and reviewed.[2] Their aza-analogues, 1,4,2-dithiazines, which were conveniently accessible by the reaction of 1,3-dithiolium salts with sodium azide,[3] have also been known and studied; much attention has been focused on their thermal decomposition reactions.[3,4] In contrast, the chemistry of 1,4,2,5-dithiadiazines, a higher aza-analogue, remains virtually unexplored, mainly because they were prepared for the first time only a few years ago by the reaction between thiobenzamide *S*-oxide and $Et_3O^+BF_4^-$.[5] Generally, 6-membered ring systems with four heteroatoms are much less known. As an extension of our studies on the reactivity of 1,4,2-dithiazolium salts (**1**) toward various kinds of amino compounds, we will report an alternative method for the preparation of unsymmetrically substituted 1,4,2,5-dithiadiazines (**3**) by the reaction of **1** with *S*-dimethylthiocarbamoyl-substituted sulfenamides (**2**).



Results and Discussion

1,4,2-Dithiazolium perchlorates **1** were allowed to react with 2 molar amount of sulfenamide **2a** in MeCN at room temperature to give 1,4,2,5-dithiadiazines **3** in good yields, whereupon tetramethylthiuram disulfide (**4**) and ammonium perchlorate were also formed.[6] The results are presented in Table 1. The products **3** were identified with spectral data and elemental analysis. However, we cannot unequivocally distinguish the spectral data between 1,4,2,5- and 1,4,2,6-dithiadiazine isomers; the structure, on the other hand, was determined by X-ray crystallographic analysis of **3f**. This analysis showed that the molecule is a 1,4,2,5-isomer and has a boat conformation similar to that of dithiins (Fig. 1).

In order to investigate the versatility of other sulfenamides for this reaction, the reaction of **1a** with sulfenamides **2b—g** was examined under the same conditions as used for **2a**. The results are presented in Table 2. The yield of **3a** was remarkably dependent on the kind of sulfenamides, ranging from 95 to 0%. From the present results, *S*-dimethylthiocarbamoyl-substituted

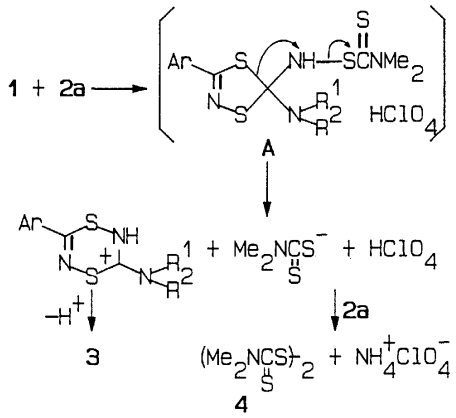
a)Isolated yield. b) No reaction. c) 5-Benzoylimino-3-phenyl-1,4,2-dithiazole **8** was formed; see Ref. 13.



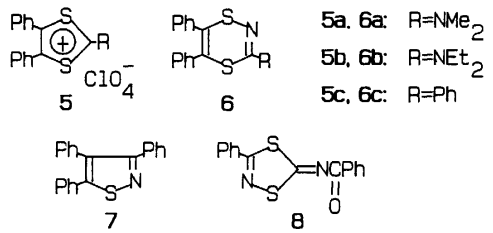
Scheme 1.

sulfenamides **2a**—**c** were most favorable for this reaction in terms of availability, stability, and high yields of **3**.

A mechanistic interpretation for the formation of **3** is shown in Scheme 1. Nucleophilic attack of the terminal amino group of sulfenamide **2a** on the C-5 carbon atom of dithiazolium cation leads to an intermediate **A** (Scheme 1), which is then converted into dithiadiazine **3** with liberation of dimethyldithiocarbamate followed by S-4 migration and deprotonation, although the exact timing of each step is indefinite. This mechanism is similar to that of the reaction of *N*-methylacridinium salts with hydroxylamine-*O*-sulfonic acid which gives 4-methyldibenzo-[*b*,*e*][1,4]-diazepine.[7] Furthermore, the observation in a separate experiment that disulfide **4** is formed by reaction of **2a** with sodium dimethyldithiocarbamate in the presence of *p*-toluenesulfonic acid is consistent with the proposed reaction mechanism.

Other attempts to convert **1b** into the target molecule **3b** by a ring expansion reaction using standard "*N*-expansion" reagents, such as sodium azide and *S*,*S*-diphenylsulfilimine ($Ph_2S{=}NH$), were unsuccessful. But 5-phenyl-1,2,3,4-tetrazole[8] and *N*-(dimethylthiocarbamoyl)-*S*,*S*-diphenylsulfilimine,[9] respectively, were obtained instead. It is therefore likely that the attack of nitrogen of these nucleophiles on the C-5 position in dithiazolium cation induces further ring cleavage in preference to the formation of nitrene.

In order to check the possibility of application of this reaction to other cation compounds, the reaction of 2-dialkylamino-4,5-diphenyl-1,3-dithiolium perchlorates (**5a**, **b**) with sulfenamide **2a** was carried out under the same conditions, from which 3-dialkylamino-5,6-diphenyl-1,4,2-dithiazines (**6a**, **b**) were obtained in good yields. On the other hand, treatment of **5a** with NaN_3 in refluxing toluene for 30 min did not give the expected **6a**. Furthermore, 2,4,5-triphenyl-1,3-dithiolium perchlorate (**5c**) was allowed to react with **2a** to give 3,5,6-triphenyl-1,4,2-dithiazine (**6c**) (20%) together with 3,4,5-triphenylisothiazole (**7**) (30%, mp 209 °C, lit,[3a] mp 211.5—212.5 °C), while Nakayama et al. reported that **5c** was subjected to react with NaN_3 in refluxing toluene to afford only a product **7**, which arose from **6c** by thermal elimination of sulfur.[3a]



In summary, we believe that this is the first example of the ring expansion on nitrogen atom with sulfenamides **2**. It belongs to important class of ring expansion reactions, especially because it can be smoothly carried out under mild conditions, i.e., at ambient temperature, without irradiation, and in the absence of a base. The application of this reaction to a wide range of cation compounds is currently under way.

Experimental

All the melting points were uncorrected. The ^1H NMR and ^{13}C NMR spectra were recorded on a Hitachi R-40 and a JEOL FX-90A spectrometers, respectively, in $CDCl_3$, using TMS as an internal standard. The IR spectra were measured on a JASCO A-302 spectrometer using KBr disks. The low-resolution mass spectra were taken on Hewlett Packard 5995A spectrometer by electron impact ionizing technique at 70 eV.

1,4,2-Dithiazolium salts **1** were readily prepared from disubstituted dithiocarbamate in three steps, utilizing our reported procedure.[10] 1,3-Dithiolium salts **5** were prepared from the reaction of dithiocarbamate (or dithiobenzoate) and 2-bromo-2-phenylacetophenone in a manner similar to that described in Ref. 11. Sulfenamides **2a**—**g** were prepared from the reaction of thiolates (RS^-) with hydroxylamine-*O*-sulfonic acid by the same method as described in literatures.[10,12]

Preparation of 1,4,2,5-Dithiadiazines 3a—f; General Procedure. 1,4,2-Dithiazolium perchlorate **1a—f** (1 mmol) was added to stirred solution (MeCN, 4 ml) of sulfenamide **2a** (2 mmol). The reaction mixture was stirred for a few days at room temperature, during which time disulfide **4** and/or ammonium perchlorate were crystallized out and filtered off.

The crude product was extracted with dichloromethane after addition of water. The residual solid was purified by column chromatography on silica gel and recrystallization from appropriate solvents (MeCN–ether, dichloromethane–hexane, etc.) to give **3a**—**f** as yellow powder.

MS m/z (rel intensity) 345 (M^+; 13), 313 (M^+−S; 10), 242 ($(PhCS)_2^+$; 29), 178 ($PhCCPh^+$; 50), 121 ($PhCS^+$; 100). **6c** tends to decompose slowly on standing in air, so elemental analysis of **6c** has been unsuccessful.

X-Ray Analysis of 3f. Crystal data: $C_{12}H_{12}ClN_3OS_2$; MW 313.83; orthorhombic; space group $Pca2_1$; a=15.408(4), b=4.064(2), and c=42.855(9) Å; U=2686(2) Å^3; D_c=1.55 g cm^{-3} for Z=8; μ(Cu $K\alpha$)=52.6 cm^{-1}. Intensity data were collected on a Rigaku AFC-4 four-circle diffractometer by using graphite monochromated Cu $K\alpha$ radiation (λ=1.5418 Å) in the 2θ–ω scan mode with a scan width of $\Delta\omega$=(1.0+0.5 tanθ) and a scan speed of 4.0° min^{-1} over the range of 2θ values of 3 to 120°. Intensities of 2240 reflections were measured and 1310 independent reflections ($|F_o|>3.0\sigma(|F_o|)$) were used for the analysis. The structure was solved by *MULTAN* 78 program. The structural parameters were refined by a full-matrix least-squares method to the final R value of 0.130 and the R_w=0.141 in conjunction with the weighting scheme of $w=(-0.002|F_o|^2+|F_o|-1)^{-1}$. The unit cell contains two crystallographically independent molecules and they have almost similar configurations. The difficulty in convergence may be attributable to some disorders and a pseudo symmetry of the crystal. All the computations were carried out on a FACOM M-380 computer using the *UNICS* III system.[14] Lists of the atomic coordinates and other structural parameters are deposited as Document No. 8801 at the Office of the Editor of Bull. Chem. Soc. Jpn.

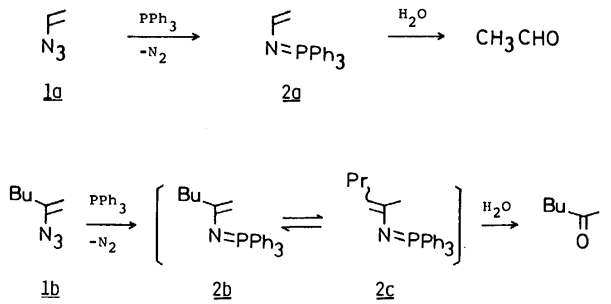
(Received December 11, 1987)

Synopsis. The novel *N*-vinyl- (**2a**) and a mixture of *N*-(1-butylvinyl)- (**2b**) and *N*-(1-methyl-1-pentenyl) iminotriphenylphosphoranes (**2c**) were prepared by the reaction of azidoethylene and 2-azido-1-hexene with triphenylphosphine, respectively. The thermal reaction of **2a**, **2b**, and **2c** with α,β-unsaturated ketones undergoes an enamine-type alkylation and the subsequent aza-Wittig reaction to give pyridine derivatives in modest yields.

Previously, we have accomplished the preparation of novel *N*-(1-phenylvinyl)iminophosphoranes by the Staudinger reaction[2)] of α-azidostyrene with trimethyl phosphite, triphenylphosphine, or tributylphosphine. These *N*-(1-phenylvinyl)iminophosphoranes seemed to provide convenient routes to 1,2-λ^5-azaphosphorines,[3)] 2-phenyl-1-azaazulenes,[4)] phenyl-substituted pyrroles,[1,5)] and phenyl-substituted pyridines.[1,6)] However, the potential value of *N*-vinyliminophosphorane bearing no substituent and alkyl substituent on vinyl groups remains unexplored. We describe here the first preparation of *N*-vinyliminotriphenylphosphorane (**2a**) and a mixture of *N*-(1-butylvinyl)- (**2b**) and *N*-(1-methyl-1-pentenyl) iminotriphenylphosphoranes (**2c**), and their reactions with α,β-unsaturated ketones to give pyridine derivatives.

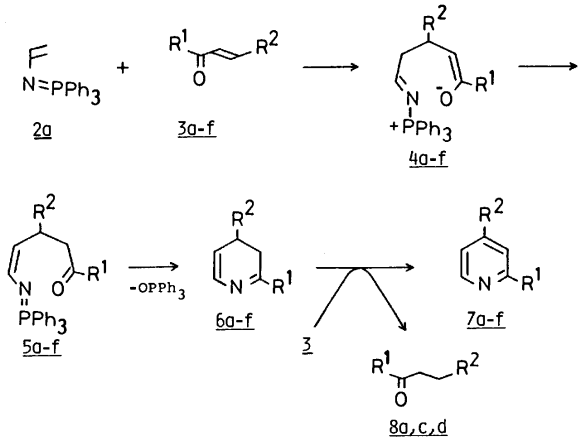
The reaction of azidoethylene (**1a**)[7)] with triphenylphosphine in anhydrous ether at 0 °C for 2 h gave crystalline *N*-vinyliminotriphenylphosphorane (**2a**) in 84% yield. The compound **2a** is unstable in moist solvent and hydrolyzed to acetaldehyde in quantitative yield (Scheme 1). Similarly, 2-azido-1-hexene (**1b**)[8)] was made to react with triphenylphosphine at room temperature for 2 h to give iminophosphoranes, which were inferred to be a mixture of *N*-(1-butylvinyl)-iminotriphenylphosphorane (**2b**) and *N*-(1-methyl-1-pentenyl)iminotriphenylphosphorane (**2c**) in a ratio of 1/2 (see Experimental). Since unstable **2b** and **2c** were not separable in pure form, no distinct physical data were obtained. However, the preparation of a mixture of **2b** and **2c** in CD_3CN and its ^1H NMR spectral study suggested several features of **2b** and **2c** (see Experimental). The initial ratio of **2b**/**2c** (1/2) changed to 1/4 after heating the mixture at 80 °C for 10 min. The ratio was fixed at 1/6 after 30 min or even after a prolonged heating at 80 °C. Thus, the thermal isomerization was suggested to occur, and the equilibrium between **2b** and **2c** is considered to lie on the side of **2c**. The tautomer **2b**, which is derived from **1b** directly, seems to be less stable than **2c**. Furthermore, the mixture of **2b** and **2c** (1/2) was hydrolyzed in moist benzene under refluxing for 10 h to give 2-hexanone in quantitative yield. Thus, the formation of **2b** and **2c** from **1b** and triphenylphosphine was assessed.



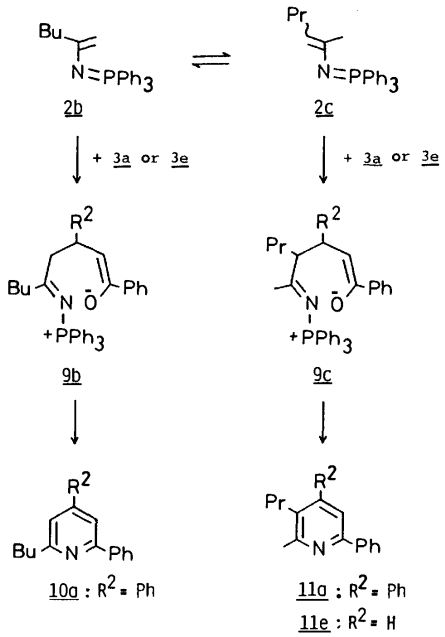
Scheme 1.

The reaction of **2a** with α,β-unsaturated ketones **3a—f** in anhydrous benzene was carried out under reflux to give pyridine derivatives **7a—f** in addition to **8a—d**. The reaction conditions and the yields of the products are summarized in Table 1. The structure of **7a—f** was unequivocally deduced from physical data (see Experimental). As previously reported,[1,6)] the results are very similar to those of *N*-(1-phenylvinyl)-iminophosphoranes with α,β-unsaturated ketones. The postulated reaction pathway for the present reaction is shown in Scheme 2. The enamine alkylation of **2a** to the β-carbon atom of **3a—f** initially occurs to give **4a—f**, followed by proton transfer to regenerate iminophosphoranes **5a—f**, which then undergo an intramolecular aza-Wittig reaction to give dihydropyridines **6a—f**. The compounds **6a—f** are dehydrogenated to give pyridines **7a—f** under the reaction conditions. The compounds **3a—d** seem also to act as a hydrogen acceptor of **6a—d** to result in the formation of **8a—d**.[6,9)]

Similarly, the reaction of a mixture of **2b** and **2c** with **3a** or **3e** in anhydrous benzene under refluxing, gave pyridines **10** and/or **11** in low yields (Scheme 3). When the reactions were carried out in toluene under refluxing, the yields of the pyridines were improved.



Scheme 2.



Scheme 3.

Table 1. Results Obtained in the Reaction of **2a** with **3a**—**f**[a]

3	R^1	R^2	Reaction time/h	Product yield/%		Recovery of 3/%
				7	**8**	
a	Ph	Ph	48	56	15	17

e	Ph	H	28	PhH	0	30	0
e			24	PhMe	0	52	0

The structural proofs for the pyridines were obtained from their physical data (see Experimental). The results are summarized in Table 2. In the case of **3a**, the addition of both **2b** and **2c** occurs on the β-carbon atom of **3a** to give **9b** and **9c**, and the following reaction sequences (cf. Scheme 2) give pyridines **10a** and **11a**, respectively.

In conclusion, the preparations of novel *N*-vinyl- (**2a**) and *N*-(1-butylvinyl)- (**2b**), and *N*-(1-methyl-1-pentenyl) iminotriphenylphosphorane (**2c**), and their reaction with α,β-unsaturated ketones were clarified. Although preparations, properties, and synthetic applications of pyridines have also been studied,[10,11] the present results will serve as a convenient method for preparating pyridine derivatives.

Experimental

The IR spectra were recorded on a Shimadzu IR-400 spectrometer. The ^1H NMR spectra and ^{13}C NMR spectra were recorded on a Hitachi R-24 and a R-90H spectrometer and the chemical shifts are given in ppm (δ) relative to the internal $SiMe_4$ standard. The mass spectral and high-resolution mass spectral studies were conducted using Shimadzu GCMS-QP1000 and JEOL DX-300 spectrometer. All of the melting points are uncorrected.

Preparation of *N*-Vinyliminotriphenylphosphorane (2a). A solution of azidoethylene (**1a**)[7] (480 mg, 7.0 mmol) and triphenylphosphine (1.31 g, 5.0 mmol) in dry ether (20 cm^3) was stirred for 2 h at 0 °C. The precipitated crystalline solids were filtered to give **2a** (1.27 g, 84%, based on triphenylphosphine used): mp 90 °C (decomp); ^1H NMR ($CDCl_3$) δ=3.97 (1H, ddd, J=7.4, 5.7, 1.4 Hz), 4.52 (1H, ddd, J=14.2, 1.4, 1.4 Hz), 6.69 (1H, ddd, J=14.2, 7.4, 23.2 Hz), 7.25—7.90 (15H, m); ^{13}C NMR ($CDCl_3$) δ=93.92, 129.98, 131.59, 132.43, 138.38, 142.36; IR ($CHCl_3$), 2985, 2916, 1591, 1487, 1437, 1405, 1311, 1106 cm^{-1}; HRMS Found: m/z 303.1194. Calcd for $C_{20}H_{18}NP$: M, 303.1178.

Reaction of 2a with Water. A solution of **2a** (91 mg, 0.3 mmol) in moist methanol (2 cm^3) was stirred at room temperature for 1 h. To this reaction mixture was added 2,4-dinitrophenylhydrazine (99 mg, 0.5 mmol) and a catalytic ammount of HCl, and the mixture was stirred for further 3 h. After the solvent was evaporated, the residue was separated by TLC on silica gel using benzene-AcOEt (1/1) as a developer to give 64 mg (95%) of acetaldehyde 2,4-dinitrophenylhydrazone, the structure of which was identical with that of the authentic specimen.

Preparation of *N*-(1-Butylvinyl)- (2b) and *N*-(1-Methyl-1-pentenyl)iminotriphenylphosphorane (2c). A solution of 2-azido-1-hexene (**1b**)[8] (63 mg, 0.5 mmol) and triphenylphosphine (131 mg, 0.5 mmol) in CD_3CN (0.2 cm^3) was made to react for 2 h. The ^1H NMR spectrum of the reaction mixture exhibited δ=0.7—2.4 (m), 3.39 (t, J=1.2 Hz), 3.67 (broad s), 4.08—4.54 (m), 7.1—7.8 (m). The signals at 3.39 and 3.67 are assigned to the vinyl protons of **2b**, and the signal at 4.08—4.54 is also assigned to the vinyl proton of **2c**. The ratio of **2b**/**2c** was estimated to be ca. 1/2 by the ^1H NMR spectrum. The ratio of **2b**/**2c** changed to 1/4 after heating the mixture at 80 °C for 10 min. Furthermore, by heating the mixture for 30 min, the ratio of **2b**/**2c** (1/4) changed to 1/6 and any further change was not observed after a prolonged heating.

Reaction of 2b and 2c with Water. A mixture of **2b** and **2c**, which were prepared by the reaction of **1b** (63 mg, 0.5 mmol) and triphenylphosphine (131 mg, 0.5 mmol) in benzene (2 cm^3), was made to react with water (30 mg) under refluxing for 10 h. To this reaction mixture was added 2,4-dinitrophenylhydrazine (119 mg, 0.6 mmol) in methanol (2 cm^3) containing a catalytic ammount of HCl and stirred for 5 h. The reaction mixture was then concentrated and separated by TLC on silica gel using AcOEt-hexane (1/1) as a developer to give 2-hexanone 2,4-dinitrophenylhydrazone (135 mg, 96%), which was identical with the authentic specimen.

General Procedure for the Reaction of 2a with 3a—f. A solution of **2a** (152 mg, 0.5 mmol) and **3** (0.5 mmol) in dry benzene (2 cm^3) was refluxed for a period indicated in Table 1 under nitrogen atmosphere. The reaction mixture was concentrated and the resulting residue was separated by TLC on silica gel using benzene-hexane (1/1) as a developer to give pyridine derivatives **7**, along with **3**, **8**, and triphenylphosphine oxide (60—90% based on **2a** used). The results are summarized in Table 1. The structural proofs for the pyridine derivatives **7a**—**f** were based on the following physical

data.

2,4-Diphenylpyridine (**7a**): mp 186—187 °C (from ethanol) (lit,[12] 190.5—192.5 °C); ^{1}H NMR (CCl_4) δ=7.20—7.90 (9H, m), 7.83 (1H, m), 7.95—8.20 (2H, m), 8.65 (1H, d, J=5.0 Hz).

2,4-Bis(4-chlorophenyl)pyridine (**7b**): mp 105—106 °C (from hexane); ^{1}H NMR ($CDCl_3$) δ=7.22—7.65 (7H, m), 7.75 (1H, broad s), 7.83 (2H, d, J=8.2 Hz), 8.66 (1H, d, J=4.8 Hz); IR ($CHCl_3$), 2977, 1603, 1545, 1497, 1469, 1382, 1093, 1015, 820 cm^{-1}; MS, m/z (rel intensity), 303 (M^+, 10), 301 (M^+, 69), 299 (M^+, 100). Found: C, 67.86; H, 3.77; N, 4.57%. Calcd for $C_{17}H_{11}NCl_2$: C, 68.02; H, 3.69; N, 4.67%.

2,4-Bis(4-methoxyphenyl)pyridine (**7c**): mp 152—153 °C (from benzene-hexane); ^{1}H NMR ($CDCl_3$) δ=3.81 (6H, s), 7.01 (2H, d, J=9.3 Hz), 7.02 (2H, d, J=10.7 Hz), 7.34 (1H, dd, J=5.2, 1.7 Hz), 7.63 (2H, d, J=9.3 Hz), 7.80—7.90 (1H, m), 8.05 (2H, d, J=10.7 Hz), 8.67 (1H, d, J=5.2 Hz); IR ($CHCl_3$), 2964, 2846, 1614, 1586, 1514, 1469, 1286, 1254, 1242, 1176, 1034, 824 cm^{-1}; MS, m/z (rel intensity), 293 (M^++2, 5), 292 (M^++1, 23), 291 (M^+, 100). Found: C, 78.69; H, 5.89; N, 4.78%. Calcd for $C_{19}H_{17}NO_2$: C, 78.33; H, 5.88; N, 4.81%.

4-Methyl-2-phenylpyridine (**7d**): mp 183—184 °C (picrate) (lit,[13] 185—187 °C); ^{1}H NMR (CCl_4) δ=1.41 (3H, s), 7.02 (1H, broad d, J=5.5 Hz), 7.33—7.60 (4H, m), 7.85—8.15 (2H, m), 8.55 (1H, d, J=5.5 Hz).

2-Phenylpyridine (**7e**): mp 174—175 °C (picrate) (lit,[14] 176—177 °C); ^{1}H NMR ($CDCl_3$) δ=7.03—7.30 (1H, m), 7.32—7.52 (3H, m), 7.60—7.72 (2H, m), 7.84—8.04 (2H, m), 8.67—8.70 (1H, m).

2-Methylpyridine (**7f**): 1,2-dimethylpyridinium iodide: mp 221—222 °C (from ethanol) (lit,[15] 229—231 °C). The hydrogenated compounds **8a**, **8b**, **8c**, and **8d** are known, and were confirmed by comparison of the physical data.

General Procedure for the Reaction of 2b and 2c with 3a,e. A solution of **2b** and **2c** was prepared in situ by the reaction of **1b** (75 mg, 0.6 mmol) and triphenylphosphine (131 mg, 0.5 mmol) at room temperature for 2 h. To this solution was added **3** (0.5 mmol), and the mixture was refluxed for a period indicated in Table 1 under nitrogen atmosphere. The reaction mixture was then concentrated and the resulting residue was separated by TLC on silica gel using benzene-hexane (1/1) as a developer to give pyridine derivatives and triphenylphosphine oxide (60—90%). The results are summarized in Table 2. The structural proof for the pyridine derivatives was based on the following physical data.

2-Butyl-4,6-diphenylpyridine (**10a**): mp 163—164 °C (picrate); ^{1}H NMR (CCl_4) δ=0.98 (3H, t, J=6.0 Hz), 1.17—2.17 (4H,m), 2.87 (2H, t, J=7.0 Hz), 7.12 (2H, s), 7.24—7.69 (8H, m), 7.90—8.15 (2H, m); IR ($CHCl_3$), 2963, 2938, 2868, 1596, 1584, 1549, 1496, 1452, 1402 cm^{-1}; MS, m/z (rel intensity) 287 (M^+, 1), 245 (100). HRMS Found: m/z 287.1657. Calcd for $C_{21}H_{21}N$: M, 287.1675.

2-Methyl-4,6-diphenyl-3-propylpyridine (**11a**): mp 145—146 °C (picrate); ^{1}H NMR (CCl_4) δ=0.80 (3H, t, J=6.4 Hz), 1.10—1.70 (2H, m), 2.40—2.70 (2H, m), 2.60 (3H, s), 7.10—7.45 (9H, m), 7.80—8.00 (2H, m); IR ($CHCl_3$), 2961, 2878, 1591, 1581, 1546, 1496, 1445, 1383 cm^{-1}; MS, m/z (rel intensity), 287 (M^+, 35), 258 (100). HRMS Found: m/z287.1657. Calcd for $C_{21}H_{21}N$: M, 287.1675.

2-Methyl-6-phenyl-3-propylpyridine (**11e**): mp 108—110 °C (picrate); ^{1}H NMR (CCl_4) δ=1.00 (3H, t, J=6.6 Hz), 1.23—1.87 (2H, m), 2.57 (2H, t, J=7.6 Hz), 2.57 (3H, s),7.25—7.50 (5H, m), 7.80—8.20 (2H, m); IR ($CHCl_3$), 2959, 2934, 2874, 1587, 1565, 1461, 1447, 1385 cm^{-1}; MS, m/z (rel intensity), 211 (M^+, 25), 182 (100). HRMS Found: m/z 211.1365. Calcd for $C_{15}H_{17}N$: M, 211.1362.

New and Convenient Synthesis of 2-Substituted 2,3-Dihydro-1*H*-benz[*de*]isoquinolin-1-ones

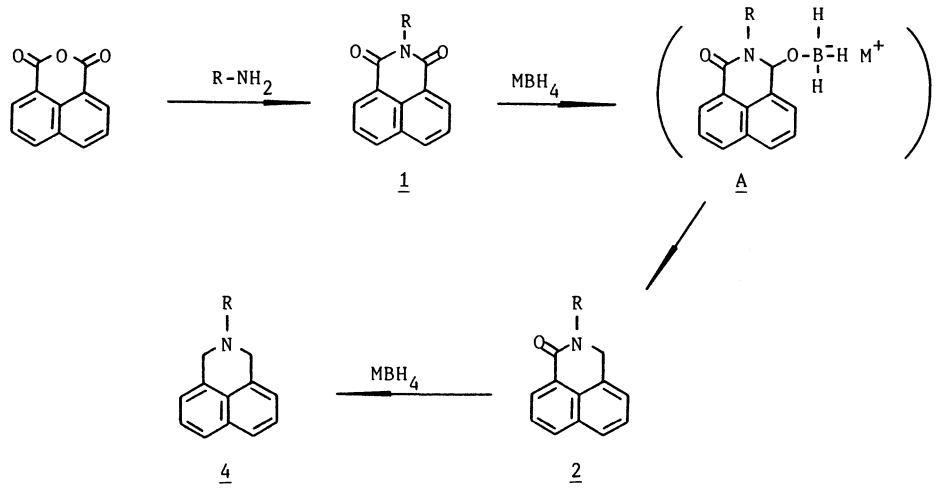
Ryu SATO,* Katsuyuki OIKAWA, Takehiko GOTO, and Minoru SAITO
Department of Resource Chemistry, Faculty of Engineering, Iwate University, Morioka 020
(Received December 24, 1987)

Synopsis. Various 2-substituted 2,3-dihydro-1*H*-benz[*de*]isoquinolin-1-ones were obtained in high yields by chemoselective reduction of 2-substituted 1*H*-benz[*de*]isoquinoline-1,3(2*H*)-diones with sodium or zinc borohydride at room temperature.

Although there have been many reports on the synthesis of isoindoles such as 2,3-dihydro-1*H*-isoindol-1-one,[1] the synthesis of 2,3-dihydro-1*H*-benz[*de*]isoquinolin-1-ones (**2**) have little been studied. Thus, only two papers have been reported on the troublesome synthesis of isoquinoline **2** by electrolytic[2] and catalytic[3] reduction of 2-substituted 1*H*-benz[*de*]isoquinoline-1,3(2*H*)-diones (**1**). In the course of our investigations on the chemistry of isoindoles,[4] we have been looking for new and convenient method for synthesis of isoquinolines **2**, which were novel heterocycles and considered to be versatile for synthesis of biologically active isoquinoline derivatives in connection with alkaloids.[5] It is well-known that carbonyl group of acid anhydride can be reduced to methylene group by sodium borohydride[6] but that of dicarboximides can not be reduced.[1] We could not find actually any example of such reduction in literatures. Therefore, our attempts to synthesize **2** were initially directed to the reactions of 1,8-naphthalenedicarbaldehydes with amines based on the previous results.[7] We could not, however, obtain 2-substituted isoquinolines **2** except for parent isoquinoline **2a**. Meanwhile, a successful example of the demethoxylation of 2,3-dihydro-3-methoxy-1*H*-benz[*de*]isoquinolin-1-one to **2a** with sodium borohydride by Warashawsky[8] was reported to stimulated us to examine selective reduction of 2-substituted 1*H*-benz[*de*]isoquinoline-1,3(2*H*)-diones (**1**), which were readily prepared by treating 1*H*,3*H*-naphtho[1,8-*cd*]pyran-1,3-dione with various amines,[9] to **2** using sodium or zinc borohydride.[10] In this paper, we wish to report a new and convenient chemoselective synthesis of **2** (Scheme 1).

As shown in Table 1, nine isoquinolines **2a—f** and **2o—q** having alkyl substituents were readily formed via intermediate **A** (Scheme 1) in high yields on treatment with sodium borohydride. When desired **2** could not be obtained from **1** with sodium borohydride, zinc borohydride was employed as a reductant to give **2** in moderate yields (Runs 7—11, 13, and 16) together with by-products, 2,3-dihydro-2-alkyl-1*H*-benz[*de*]isoquinoline (**4h—k**). It is noteworthy that the present reduction was compatible with hydroxyl, chloro, and carboxyl groups (Runs 13, 16, and 20—22). Interestingly, three new heterocycles **3l—n** were obtained by treating **1l—n** with sodium borohydride in moderate yields together with desired **2l—n**, as shown in Table 1. Moreover, an addition of magnesium perchlorate to the reaction system using sodium borohydride increased exceedingly the yields of cyclized products **3l—n** (Runs 14, 17, and 19). Although the role of magnesium ion is not necessarily obvious, **3l—n** seem to be formed by intramolecular migration of alkoxyl group of intermediate **B**, in which boron coordinated[11] with two oxygen atom of two hydroxyl groups, in basic conditions as shown in Scheme 2.

3n was obtained as a mixture of two diastereomers. The results of Table 1 show that a bulky substituent **1n** prevented the cyclization and **1o** having five methylene chains did not give the corresponding cyclic compounds (Runs 18 and 20). In the reactions of **1l** and **1m**, the use of zinc borohydride afforded desired **2l** and **2m** preferentially (Runs 13 and 16). Although various solvents such as methanol or tetrahydrofuran were



Scheme 1.

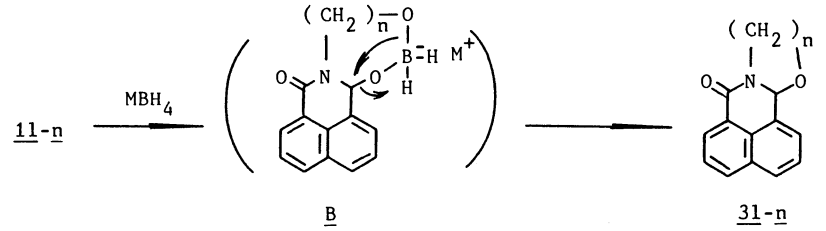
a) Reaction conditions: **1**, 0.5 mmol, $NaBH_4$, 5 mmol, $Zn(BH_4)_2$, 10 mmol, r.t. b) Isolated yields based on the substrate. c) $Mg(ClO_4)_2$(5 mmol) was added to the reaction system. d) A mixture of two diastereomer was obtained.



Scheme 2.

examined in all cases, only ethanol-water gave preferable results.

Experimental

Measurements. All the melting points were uncorrected. IR spectra were obtained on a Hitachi 295 spectrophotometer and ^1H NMR spectra were obtained on a Hitachi R-22 spectrometer using tetramethylsilane as an internal standard. Mass spectra were taken with a Hitachi RMU-6M mass spectrometer. Elemental analyses were performed with a Yanagimoto MT-3. All the reactions were carried out under a nitrogen atmosphere and monitered by TLC (Merck Kieselgel 60-GF).

Materials. All the reagents were obtained from Wako Pure Chemical Industries Ltd., Tokyo Kasei Co. Ltd., or Aldrich Chemical Co. The reagents used were further purified by usual methods such as recrystallization or distillation. Wako gel C-200 was used as a silica gel for column chromatography.

General Procedure. To a solution of sodium borohydride (5 mmol) in EtOH/H_2O (20 ml, v/v: 10/1) was added **1** (0.5 mmol) and then the mixture was stirred for 4 h at 25 °C. After quenching with aq. HCl, the reaction mixture was extracted with CH_2Cl_2 (20 ml×3). The combined organic layer was dried over $MgSO_4$ and evaporation of the solvent followed by chromatography on silica gel gave colorless crystals, 2-substituted 2,3-dihydro-1*H*-benz[*de*]isoquinolin-1-one (**2**). Elemental analyses for **2d**, **2e**, and **2f** were not available because of the lability and the difficulty of further purifications of these compounds.

2a,[8] **4h**,[12] **4i**,[13] **4j**,[12] and **4k**[12] was identified by comparison of the spectral and physical data with those of authentic sample.

2b: Mp 76 °C (from hexane-AcOEt); IR (KBr) 1610 and 1640 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.23 (s, 3H, CH_3), 4.93 (s, 2H, CH_2), and 7.20—8.36 (m, 6H, arom); MS (20 eV) *m/z* 195 (M^+). Found: C, 79.17; H, 5.67; N, 7.02%. Calcd for $C_{13}H_{11}NO$: C, 79.17; H, 5.62; N, 7.10%.

Conjugate Reduction of α,β-Unsaturated Ketones with Amphiphilic Reaction System

Katsumasa NONOSHITA, Keiji MARUOKA, and Hisashi YAMAMOTO*
Department of Applied Chemistry, Faculty of Engineering, Nagoya University, Chikusa, Nagoya 464
(Received January 16, 1988)

Synopsis. The conjugate reduction of α,β-unsaturated ketones has been effected with amphiphilic reaction system consisting of methylaluminum bis(2,6-di-*t*-butyl-4-alkylphenoxide) and certain complex aluminum hydride reagent.

Conjugate reduction of α,β-unsaturated carbonyl compounds is an important synthetic operation and a variety of promising approaches have been developed for this purpose.[1] Those include (1) catalytic hydrogenation of various noble metals;[2] (2) electrochemical reductions including dissolving metal reductions;[3] (3) biochemical reductions using microbioorganisms;[4] (4) reduction with several transition-metal hydride reagents including those produced in situ from transition-metal compounds and conventional reducing agents;[5] and (5) reduction with certain aluminum hydride and borohydride type reagents such as L-Selectride.[6] Here we wish to disclose a conceptually new approach to this transformation based on the amphiphilic reduction, i.e. nucleophilic reduction of electrophilically activated substrate by combining use of exceptionally bulky methylaluminum bis(2,6-di-*t*-

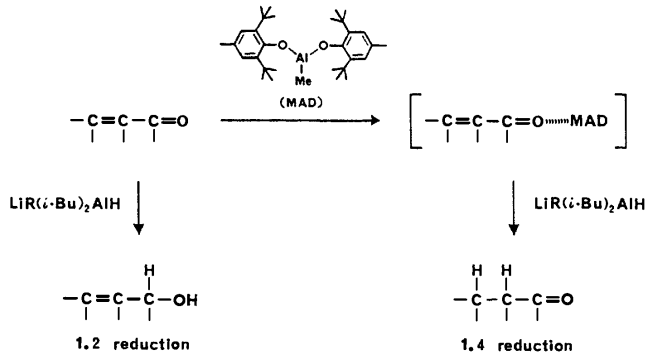
a) Unless otherwise noted, reduction was carried out at −78 °C by adding complex aluminum hydride reagent (2 equiv) in ether to the carbonyl compound (1 equiv)–MAD (2 equiv) complex in toluene. b) Reagent **A**: MAD/Li(*n*-Bu)(*i*-Bu)$_2$AlH; **B**: MAD/Li(*t*-Bu)(*i*-Bu)$_2$AlH; **C**: MAD/Li(Me)(*i*-Bu)$_2$AlH; **D**: MAD/$LiAlH_4$; **E**: MAT/Li(*n*-Bu)(*i*-Bu)$_2$AlH. c) Isolated yield. d) Use of a toluene solution of Li(*n*-Bu)(*i*-Bu)$_2$AlH. e) Use of a THF solution of Li(*n*-Bu)(*i*-Bu)$_2$AlH. f) Each 1 equiv of MAD and Li(*n*-Bu)(*i*-Bu)$_2$AlH was utilized.



Scheme 1.

butyl-4-alkylphenoxide) (as Lewis acid) and certain complex aluminum hydride reagent (as nucleophile) as illustrated in Scheme 1.[7]

Reaction of carvone with lithium butyl(diisobutyl)-aluminum hydride (Li(n-Bu)(i-Bu)$_2$AlH) was reported to give 1,2-reduction product solely.[8] However, initial complexation of carvone with methylaluminum bis(2,6-di-t-butyl-4-methylphenoxide) (abbreviated to MAD) in toluene and subsequent treatment with Li(n-Bu)(i-Bu)$_2$AlH in ether at −78 °C resulted in total reversal of selectivity, producing 1,4-reduction product almost exclusively in 93% yield. The initial hydride transfer from Li(n-Bu)(i-Bu)$_2$AlH to MAD followed by reduction of the resulting bulky hydride with the enone seems to be unlikely, since treatment of carvone with a pre-mixture of MAD and Li(n-Bu)(i-Bu)$_2$AlH at −78 °C gave result (88% of 1,2 adduct and 8% of 1,4 adduct) close to that in the sole addition of Li(n-Bu)(i-Bu)$_2$AlH. Some other examples are listed in Table 1, which revealed the following characteristic features. The α,β-unsaturated ketone possessing the sterically less demanding carbonyl moiety, even when combined with MAD, is readily susceptible toward the 1,2-hydride attack (Entries 3 and 10). The similar tendency was observed in the conjugate addition of RLi to the enone in the presence of MAD,[7d] although the present conjugate reduction exhibited better 1,4-selectivity. Among various nucleophilic aluminum hydride reagents examined, Li(n-Bu)(i-Bu)$_2$AlH would be most suitable in view of selectivity (Entries 11—14) and the ready availability.[3] The choice of solvents profoundly affects the selectivity. For example, in the MAD-mediated reduction of carvone, ether as solvent was found to be satisfactory, but use of toluene resulted in the predominant 1,2-reduction (Entry 5). Methylaluminum bis(2,4,6-tri-t-butylphenoxide) (MAT) lowered 1,4 selectivity (Entry 15).

Experimental

The IR spectra were determined on a Hitachi 260-10 spectrometer. The ^{1}H NMR spectra were recorded on a JNM-PMX 60 spectrometer, using TMS (tetramethylsilane) as an internal standard. Splitting patterns are indicated as s, singlet; d, doublet; m, multiplet; br, broad. The microanalyses were performed at the Institute of Applied Organic Chemistry, Faculty of Engineering, Nagoya University. Analytical gas-liquid phase chromatography (GLC) was performed on Gasukuro Kogyo Model 370 instruments with a flame-ionization detector and a capillary column of PEG-HT (0.25×25,000 mm) using nitrogen as carrier gas. Ether and tetrahydrofuran (THF) were distilled from benzophenone ketyl. Toluene was dried over sodium metal. Dichloromethane (CH_2Cl_2) was stored over 4-A Molecular Sieves. All experiments were carried out under an argon atmosphere. Purification of the product was carried out by column chromatography on silica gel Fuji-Davison BW-300.

Preparation of α,β-Unsaturated Ketones. 6-Methyl-2-cyclohexen-1-one and 4-t-butyl-2-cyclohexen-1-one were prepared by selenenylation-selenoxide elimination sequence according to Reich's method.[9] 5,5-Dimethyl-2-cyclohexen-1-one was prepared by reduction of enol ether of 5,5-dimethyl-1,3-cyclohexanedione with $LiAlH_4$ and subsequent acid hydrolysis. 5-(1-Dimethylphenylsiloxy-1-methylethyl)-2-cyclopenten-1-one was derived from aldol reaction of 2-cyclopenten-1-one lithium enolate (generated with LDA) with acetone followed by silylation with $Me_2PhSiCl$ and NEt_3. 1-(2-Methylphenyl)-3-phenyl-2-propen-1-one and 3-phenyl-1-(2,4,6-trimethylphenyl)-2-propen-1-one were prepared by aldol condensation according to the literature procedure.[10]

General Procedure. To a solution of 2,6-di-t-butyl-4-methylphenol (441 mg, 2 mmol) in toluene (5 ml) was added a 2 mol cm^{-3} hexane solution of Me_3Al (0.5 ml, 1 mmol) and the resulting colorless solution was stirred at room temperature for 1 h. After cooling to −78 °C, enone (0.5 mmol) was added at −78 °C, and after 5 min, Li(R)(i-Bu)$_2$AlH (1 mmol) in ether (2 ml) (prepared in another flask from DIBAH and RLi (R =n-Bu, t-Bu, and Me) at 0 °C for 10 min) was transferred to the enone-MAD complex by cannula. The mixture was stirred at −78 °C for 15 min, poured into 10% HCl, extracted with ether, and dried over Na_2SO_4. Evaporation of solvents and purification of the residue by column chromatography on silica gel (ether/hexane as eluant) gave the saturated ketone and/or the unsaturated alcohol depending on the enone substrates, hydride reagents, and reaction conditions.

2-Methylcyclohexanone: IR (neat) 2940, 2870, 1715, 1450 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.97 (d, J=7 Hz, 3H), 1.03—2.70 (m, 9H).

3,3-Dimethylcyclohexanone: IR (neat) 2950, 2875, 1705, 1450 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.96 (s, 6H), 1.17—2.40 (m, 6H), 2.05 (s, 2H).

4-t-Butyl-2-cyclohexen-1-ol: IR (neat) 3325, 3010, 2950, 2850, 1645, 1060, 735 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.87 (s, 9H), 1.01—2.20 (m, 5H), 3.16 (br s, 1H), 3.78—4.25 (m, 1H), 4.60 (s, 2H).

5-Isopropenyl-2-methylcyclohexanone: IR (neat) 3100, 2925, 2850, 1720, 1640, 1450, 890 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.92—2.85 (m, 11H), 0.97 (d, J=6 Hz, trans CHC$\underline{H}_3$), 1.02 (d, J=6 Hz, cis CHC$\underline{H}_3$), 1.75 (s, 3H, CH_3-C=C), 4.70 (s, 2H). GLC analysis showed the cis/trans ratio to be 14:86. t_R (trans)=14.2 min, t_R (cis)=15.2 min at 90 °C.

5-Isopropenyl-2-methyl-2-cyclohexen-1-ol: Bp 90—95 °C (Kugelrohr bath temp, 5 Torr (1 Torr≈133.322 Pa)); IR (neat) 3325, 3090, 2925, 1650, 1450, 1040, 895, 815 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.13—2.60 (m, 8H), 1.70 (s, 3H, CH_3-C=C), 2.94 (br s, 1H), 3.70—4.30 (m, 1H), 4.65 (s, 2H), 5.36 (br s, 1H). Anal. ($C_{10}H_{16}O$) C, H.

3,5-Dimethylcyclohexanone: IR (neat) 2965, 2885, 1720, 1455 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.66-2.50 (m, 8H), 1.03 (br d, 6H). GLC analysis indicated the cis/trans ratio to be 1:99. t_R (trans)=8.6 min, t_R (cis)=9.7 min at 70 °C.

3,5-Dimethyl-2-cyclohexen-1-ol: IR (neat) 3360, 2930, 1675, 1455, 1380, 1035 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.50—2.73 (m, 9H), 1.67 (s, 3H), 4.03 (br s, 1H), 5.16—5.73 (m, 1H).

2-(1-Dimethylphenylsiloxy-1-methylethyl)cyclopentanone:

IR (neat) 2970, 1715, 1635, 1445, 1415, 1370, 1265, 1190, 1005, 815 cm^{-1}; ^1H NMR (CCl_4) δ=0.28 (s, 6H), 1.25 (s, 6H), 1.48—2.41 (m, 7H), 6.98—7.61 (m, 5H). This product was spectroscopically identical with authentic sample which was prepared by aldol reaction of cyclopentanone lithium enolate (generated with LDA) with acetone followed by silylation with $Me_2PhSiCl$ and NEt_3.

(*E*)-4-Phenyl-3-buten-2-ol: IR (neat) 3325, 3020, 2975, 1650, 1490, 1455, 1060, 965, 745, 690 cm^{-1}; ^1H NMR (CCl_4) δ=1.27 (d, J=6 Hz, 3H), 3.53 (s, 1H), 4.33 (quintet, J=6 Hz, 1H), 5.86—6.66 (m, 2H), 7.13 (s, 5H).

1,3-Diphenyl-1-propanone: IR (neat) 3040, 2945, 1690, 1595, 1580, 1490, 1450, 1205, 750, 690 cm^{-1}; ^1H NMR (CCl_4) δ=2.54—3.55 (m, 4H), 6.83—8.04 (m, 5H), 7.11 (s, 5H).

(*E*)-1,3-Diphenyl-2-propen-1-ol: Bp 200—205 °C (Bath temp, 7 Torr); IR (neat) 3350, 3035, 2870, 1600, 1580, 1495, 1450, 1070, 1030, 965, 745, 695 cm^{-1}; ^1H NMR (CCl_4) δ=3.12 (br s, 1H), 5.11 (d, J=6 Hz, 1H), 5.87—6.68 (m, 2H), 6.94—7.72 (m, 10H). Anal. ($C_{15}H_{14}O$) C, H.

1-(2-Methylphenyl)-3-phenyl-1-propanone: Bp 170—175 °C (Bath temp, 4 Torr); IR (neat) 3060, 3025, 2930, 1685, 1600, 1575, 1490, 1450, 745, 695 cm^{-1}; ^1H NMR (CCl_4) δ=2.34 (d, J=7 Hz, 3H), 2.70—3.53 (m, 4H), 6.53—8.06 (m, 4H), 7.12 (s, 5H). Anal. ($C_{16}H_{16}O$) C, H.

(*E*)-1-(2-Methylphenyl)-3-phenyl-2-propen-1-ol: IR (neat) 3325, 3030, 2935, 2870, 1600, 1585, 1495, 1460, 1450, 1075, 1015, 970, 755, 695 cm^{-1}; ^1H NMR (CCl_4) δ=2.16 (s, 3H), 3.73 (br s, 1H), 5.25 (m, 1H), 5.86—6.70 (m, 2H), 6.83—7.60 (m, 9H).

3-Phenyl-1-(2,4,6-trimethylphenyl)-1-propanone: Bp 185—190 °C (Bath temp., 4 Torr); IR (neat) 3045, 2935, 1705, 1615, 1500, 1455, 1235, 855, 755, 700 cm^{-1}; ^1H NMR (CCl_4) δ=2.03 (s, 6H), 2.20 (s, 3H), 2.90 (s, 4H), 6.63 (s, 2H), 7.08 (s, 5H). Anal ($C_{18}H_{20}O$) C, H.

(Received January 16, 1988)

Synopsis. Organolithium reagents complexed with axially chiral biphenyl-substituted *N,N,N′,N′*-tetramethylethylenediamines (**1** and **2**) add to aldehydes in good enantioface selectivity. The pattern of the stereoselection, however, disagrees with that of the helical choice observed for the asymmetric polymerization of triphenylmethyl methacrylate with the same complexes.

Recently, Cram and co-workers[1,2] have been reported that *N,N,N′,N′*-tetramethylethylenediamine (TMEDA) derivatives having an atropisomeric 1,1′-binaphthyl unit (**3** and **4**) can be utilized as highly effective chirality-inducing ligands for organolithium compounds. They have successfully achieved the highly asymmetric alkylation of aldehydes by using the above complexes.[1] There is another interesting report, in which the asymmetric polymerization of methyl methacrylate (MMA) has been also studied with butyllithium (BuLi) complexed with **4**.[2] We almost concurrently presented reports that similar complexes between organolithiums and axially chiral biphenyl-substituted TMEDAs, such as **1** and **2**, serve as effective initiators in the asymmetric polymerization of related triphenylmethyl methacrylate (TrMA).[3,4] We directed our special attention to Cram's consideration:[2] a single stereoelectronic feature can explain consistently a variety of the ligand/product configurational correlations in the above two asymmetric reactions.

Herein, we report the asymmetric carbonyl addition of organolithium reagents to aldehydes assisted by **1** or **2**, and discuss the stereochemistry in connection with the mechanistic consideration on our asymmetric polymerization.

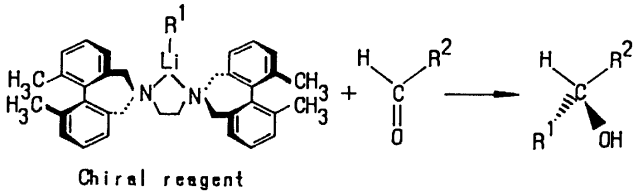
(S)-(3) (S,S)-(4)

Experimental

Materials. Optically pure diamines, **1** and **2**, were prepared from the resolved 6,6′-dimethylbiphenyl-2,2′-dicarboxylic acid,[5] according to the method reported previously.[3] (*R*)-**1**: Bp 140 °C (0.05 Torr (1 Torr=133.322 Pa)) $[\alpha]_D^{25}$ +43.0° (*c* 1.0, tetrahydrofuran); (*S*)-**1**: $[\alpha]_D^{25}$ −42.9°. (*R,R*)-**2**: Mp 156.5—158 °C (from hexane), $[\alpha]_D^{25}$ +115.1° (*c* 1.0, ethanol); (*S,S*)-**2**, mp 155—157 °C, $[\alpha]_D^{25}$ −114.0°. These diamines gave satisfactory analytical data and the expected ^{1}H NMR and mass spectra.



Chiral reagent

Asymmetric Carbonyl Additions. According to the procedure of Mazaleyrat and Cram,[1] a typical chiral organolithium (R^1Li) complex was prepared by mixing 4.6 cm^3 (3.0 mmol) of BuLi (0.65 mol l^{-1}) in hexane with a solution of (*S,S*)-**2** (1.56 g, 3.3 mmol) in 50 cm^3 of dry Et_2O under a nitrogen atmosphere at −50 °C. The solution was cooled to −78 °C, and a solution (1.0 cm^3; 1.2 mol l^{-1}) of benzaldehyde (1.2 mmol) in Et_2O was added. The homogeneous mixture was stirred for 3 h at −78 °C, and then rapidly quenched with 1 mol l^{-1} HCl. Extractive work-up gave an oil, which was purified by preparative TLC (silica gel, benzene) followed by bulb-to-bulb distillation to give (*S*)-(−)-1-phenyl-1-pentanol (0.17 g, 87%) pure by GLPC and ^{1}H NMR. Similarly, routine runs were carried out in various combinations among aldehydes, R^1Li, and the chiral diamines under different reaction conditions. The dominant configurations and enantiomeric excesses (ee's) of the produced alcohols were determined from their optical rotations based on the reported maximum values. The used bases were recovered in more than 90% yields without any noticeable loss in optical purity.

Results and Discussion

The results are summarized in Table 1. As can be seen from the ee's of produced alcohols, the both-side substituted TMEDA (**2**) exhibited a more preferable enantioface selectivity than **1** did. Both the temperature and the solvent of the reaction were important in order to achieve high optical yields. The highest ee. value of 99% was recorded in the reaction by using **2** in Et_2O at −120 °C. An addition way that R^2CHO was treated with an R^1Li reagent having a more bulky R^1 than R^2 resulted in a substantial decrease of the optical yield compared with that of the same product obtained in the reversed way. These results were quite analogous to those observed previously with similar chiral ligands of a 1,1′-binaphthyl analogue, **3** and **4** by Mazaleyrat and Cram.[1] Under the same reaction con-

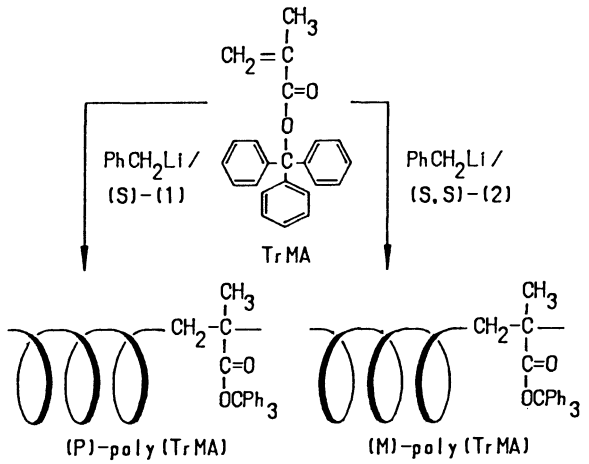
(*S,S*)-**2**	$PhCH_2$[e]	Ph	PhMe	48	0[f]	0

a) Reaction conditions: R^2CHO/R^1Li/diamine=1.2/3.0/3.3 mmol; solvent, 50 cm^3; reaction temperature, −78 °C; reaction time, 3 h. b) The optical rotations were taken in benzene solutions. c) Based on $[\alpha]_D$ 37.6° (*c* 3, benzene) (Refs. 1 and 5). d) Temperature, −120 °C, at which the reaction system became heterogeneous. e) When the BuLi complexes were prepared in toluene at room temperature, the anion was smoothly replaced by $PhCH_2Li$ (Ref. 6). f) In ethanol (Ref. 7).

ditions, **1** and **2** were found to provide almost equal levels of enantioface selection to those of **3** and **4**, respectively, as expected from the structural similarity of each couple of the ligands. The stereochemical consequences gained or reported in various combinations among the four axially chiral ligands, R^1Li, and R^2CHO can be predicted consistently in terms of the axial chirality of the biaryl substituents; that is, when the ligands have (*R*)-configuration, the chiral R^1Li complexes always prefer the *re*-facial approach onto aldehydes.

Previously, we reported that **1** and **2** recognized the helicity in high levels in the asymmetric polymerization of TrMA by using several organolithium complexes of these diamines in toluene at −78 °C.[3,4] The chiral catalysts generated successively asymmetric carbons of a single configuration through the polymerization in an isotactic manner, though after growing up, the polymer became pseudoasymmetric as the whole polymer chain. Okamoto et al. have reported that when poly(TrMA) is composed of the (*S*)-configurated monomer units in the initiating side, the polymer adopts (*P*)-helical conformation because of the isotactic sequence (more than 9-mer) of the bulky ester groups.[8] Accordingly, it was obvious that the chiral consequences of both the present carbonyl addition and the previous polymerization were dominated by carbon-carbon bond-forming processes.

Thus, we compared the ligand/product correlations in the two reactions. One of the most suitable anionic initiators was the benzyllithium (BzLi) complex of **1**.[4] On the contrary, no asymmetric induction occurred in the addition of this complex to benzaldehyde in toluene, which was the same solvent as that used for the polymerization. The result suggested that the initiation reaction between TrMA and the chiral complex took place with no or a very poor stereoselectivity. The stereoselection in the following addition steps might be considered to be primarily important to form the monomer sequence of single configuration, as pointed out by Okamoto et al.[8]



Most interestingly, even if **1** and **2** had the same configuration their BzLi complexes showed the opposed helical preferences in the asymmetric polymerization,[4] as shown in the scheme. The polymerization with (*S*)-**1** gave the (*P*)-helical polymer composed of the (*R*)-configurated monomeric units, while (*S,S*)-**2** induced (*S*)-configuration to the monomeric units leading to (*M*)-helicity. This pattern of the ligand/product stereochemical outcomes was contrary to that observed for the above asymmetric addition. It has been found that the BuLi complexes are not suitable initiators for the asymmetric polymerization.[9] This however does not mean a poor stereoselectivity toward the helical conformation, but does a problem on the poor solubility of the produced polymer in organic solvents because of its high molecular weight.[4] In the polymerization of TrMA by using the various complexes of **1** or **2**,[4] the pattern of the helical choice was not altered at all by changing organolithium compounds including BuLi. The disagreement in the stereoselection between the asymmetric carbonyl addition and the asymmetric polymerization of TrMA strongly suggests that different stereoelectronic interactions

operate in the chiral discrimination of the two reactions by using **1** or **2**.

On the other hand, Cram et al. have proposed an explanation that the stereochemistry of the asymmetric carbonyl addition of the BuLi/**4** complex may be applicable to that of the asymmetric polymerization of MMA with the same complex.[2] However this is contrary to our present results, although the monomers differ in the bulkiness of their ester groups. We may conclude at least that a transition state for the asymmetric polymerization of TrMA can't be compatibly depicted by Cram's model.

The asymmetric polymerization of less bulky MMA is very interesting for us and now under studying.

Vacuum Sublimation Behavior of Molybdenum(VI) and Tungsten(VI) Chelates with 8-Quinolinol

Takaharu HONJO* and Sumiko KAWASAKI
Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa 920
(Received September 3, 1987)

Synopsis. A vacuum sublimation apparatus with a continuous-temperature gradient (30—280 °C) along the glass tube (60—0 cm) at 10^{-2} and 10^{-1} Torr (1 Torr=133.322 Pa) was used. 8-Quinolinol (Oxine, ox) and its Mo^{6+} and W^{6+} chelates ($MoO_2(ox)_2$ and $WO_2(ox)_2$) in milligram amounts were sublimed without any thermal decomposition. The Mo^{6+} chelate (orange yellow) forms large, rectangular crystals in the crossed state, while the W^{6+} chelate (pale yellow) forms small, rectangular crystals in the scattered states after vacuum sublimation.

8-Quinolinol (Oxine, ox) forms extractable chelates with at least 50 metals.[1-3] Of these chelates, Al^{3+}, Fe^{3+}, $Co^{2+,3+}$, Ni^{2+}, Cu^{2+}, Zn^{2+}, and In^{3+} oxinates have been found to be useful for the purification and separation of metals by means of the vacuum sublimation method.[4] Now, the present authors have found that the Mo^{6+} and W^{6+} oxinates ($MoO_2(ox)_2$ and $WO_2(ox)_2$) in milligram amounts sublime without any thermal decomposition; their vacuum-sublimation behavior has been studied in detail with a continuous-temperature gradient under low pressure.

Experimental

Apparatus. A model PD-51 Yamato Vacuum Pump; a model PM-12 Shimadzu Pirani Gauge; a model CL Yamato Denki Mantle Heater; a model 105-A Tokyo Shibaura Electric Voltage Stabilizer; a model FPW-4 Hitachi Voltage Stabilizer; a model MP-S2 Yanagimoto Melting Point Measuring Apparatus; a model M-7II Hitachi-Horiba pH meter, and a model BH Olympus System Microscope were used.

Materials. The 8-quinolinol (Oxine, ox), purchased from the Wako Junyaku Kogyo Co., was a guaranteed-grade material. The metal oxinates were generally prepared by the addition of an acetic-acid solution of oxine to an aqueous solution of an excess of both metal salts, $Na_2MoO_4 \cdot 2H_2O$ and $Na_2WO_4 \cdot 2H_2O$, adjusted to pH 3—5 by adding 6M (1M=1 mol dm^{-3}) hydrochloric acid or 6M ammonia. After aging overnight on a water bath, the products were filtered off with a glass filter (1G4), washed with hot distilled water, and finally dried in a desiccator under low pressure or on heating at 100—120 °C.[2] The Mo^{6+} and W^{6+} oxinates ($MoO_2(ox)_2$ and $WO_2(ox)_2$) were decomposed at 291—295 °C and about

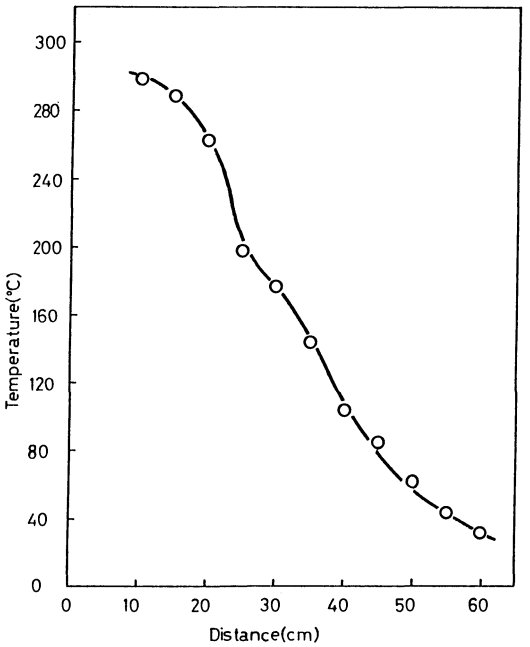

Fig. 1. Continuous temperature gradient along vacuum sublimator.

Table 1. Sublimation-Recrystallization-Zone Temperatures, Amounts Remaining, and Colors of Mo^{6+} and W^{6+} Oxinates after Sublimation at 10^{-2} and 10^{-1} Torr

Metal chelate	Sublimation pressure/Torr	Recrystallization-zone temperature /°C	Color	Chelate taken /mg	Metal compound remained[a]
Oxine(ox)	10^{-1}	<31	White	9.60	—
	10^{-2}	<31	White	9.60	—
$MoO_2(ox)_2$	10^{-1}	222—185	Orange yellow	6.18	A little
	10^{-2}	221—136	Orange yellow	6.30	A little
$WO_2(ox)_2$	10^{-1}	232—204	Pale yellow	3.43	Much
	10^{-2}	224—187	Pale yellow	3.85	Much

a) A little, 10—30%; much, <30%.
All the chelates taken were sublimed a few times without thermal decomposition. The examination of the metal compounds remaining in the sample tubes after every sublimation gave different values, depending on the state of their packing in the sample glass tube.

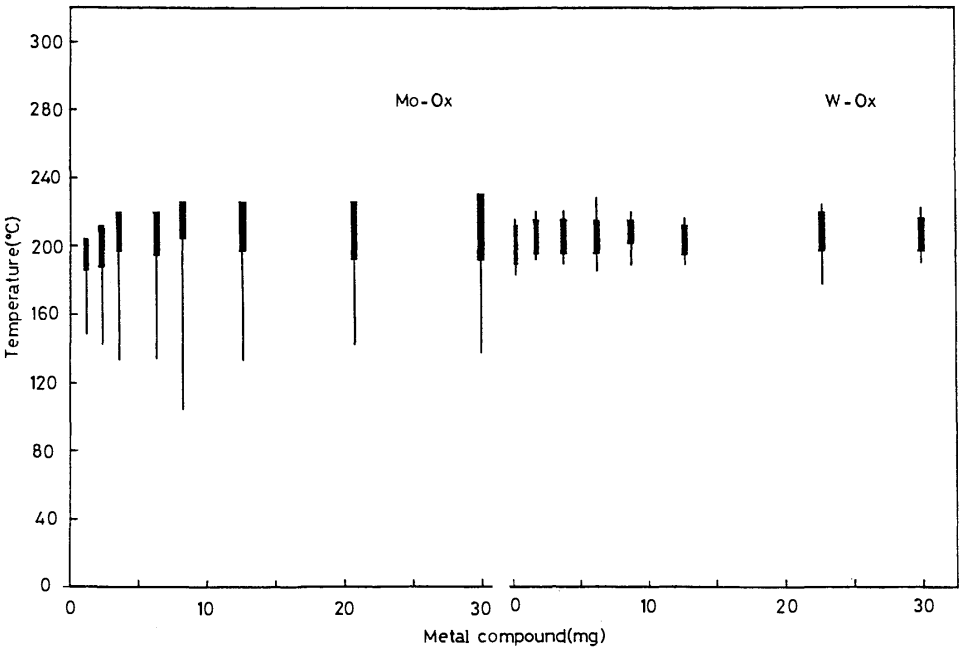

Fig. 2. Sublimation-recrystallization zone of Mo^{6+} and W^{6+} oxinates in various quantities.

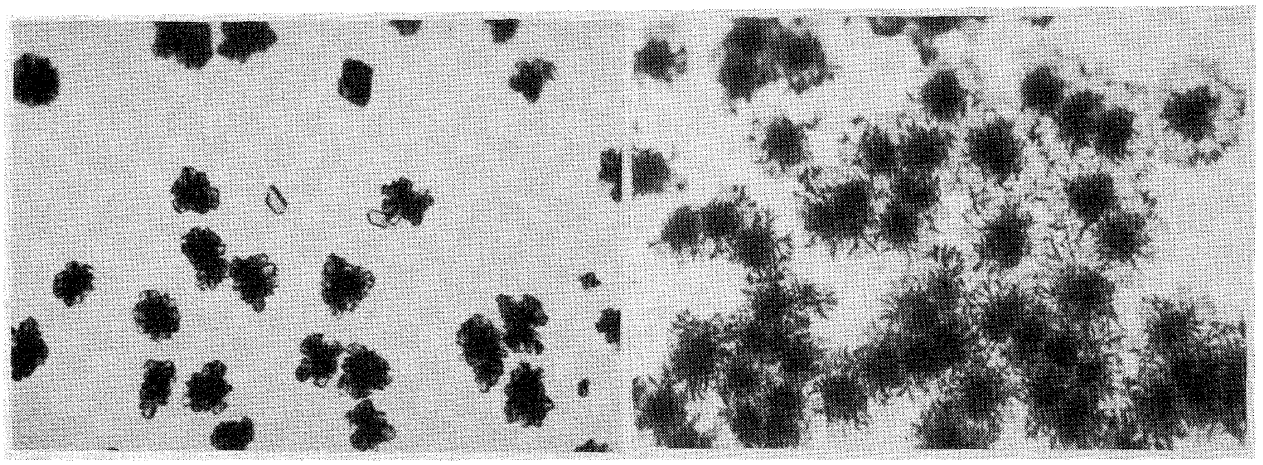

$MoO_2(ox)_2$ $WO_2(ox)_2$

Fig. 3. Microphotographs of metal chelates. Hox: Oxine, Magnification: ×32.

300 °C respectively under normal pressure; the materials were purified by vacuum sublimation before use, and were identified by means of spectrophotometry (λ_{max}=373 nm for $MoO_2(ox)_2$ and 367.5 nm for $WO_2(ox)_2$ in chloroform[2]).

Sublimation Procedure. A vacuum-sublimation apparatus which provided a continuous-temperature gradient (30—280 °C) along the tube (70—0 cm) at 10^{-2} and 10^{-1} Torr (1 Torr=133.322 Pa) was used, as has previously been described.[4-7] The temperature gradient along the sublimator, which consists of a Pyrex glass tube (3 cm in outer diameter; 100 cm in length) covered with a heating mantle, is shown in Fig. 1; it was obtained after the thermal equilibrium had been kept for 4 h. These patterns were obtained by supplying the following electric power through the heating mantle; 20, 10, and 4 V at 1.30 A. A small glass sample tube (0.6 cm in inner diameter; 5 cm in length) containing an individual chelate (0.5—30 mg) and an attached long glass tube (0.5 cm in outer diameter; 55 cm in length), wrapped tightly with Teflon tape, were inserted into the higher-temperature end of the sublimator. Metal chelates were placed inside of the apparatus for 5 h after the thermal equilibrium had been established. The sublimate zone along the sublimation tube was decided from the color of the chelate and its position. The thermal conditions of the sublimator were always checked from the sublimation zone of a definite amount of copper(II) acetylacetonate after sublimating it by the use of another sublimation tube with the metal chelates to be investigated, as has previously been described.[7] The sublimation-recrystallization-zone temperatures of copper(II) acetylacetonate (in 12 mg amounts) were about 89—60 °C at 10^{-2} Torr and 120—66 °C at 10^{-1} Torr (bluish rectangular crystal).

Results and Discussion

The temperature range of the deposited zones, the recovery, and the colors of the Mo^{6+} and W^{6+} oxinates

($MoO_2(ox)_2$ and $WO_2(ox)_2$) after sublimation at 10^{-2} and 10^{-1} Torr are summarized in Table 1. The Mo^{6+} chelate was almost sublimed without any thermal decomposition, while the W^{6+} chelate was thermally stable, but did not sublime completely. The sublimation-recrystallization temperatures of these chelates gave lower values under low pressures. This may have been caused by the rate of the sublimation of the chelate compounds, which depends upon the temperature established at the high-temperature end of the sublimator.[3-7] The sublimation-recrystallization zones for Mo^{6+} and W^{6+} oxinates in varying quantities (0.5—30 mg) at 10^{-2} Torr are graphically presented in Fig. 2. In general, the sublimation-recrystallization temperature of the Mo^{6+} chelate (0.5—6 mg) and the W^{6+} chelate (0.5—2 mg) gave higher values with an increase in the quantity of the chelates, while that of the Mo^{6+} chelate (6—30 mg) and the W^{6+} chelate (2—30 mg) gave almost invariable values. In cases where the recrystallization-zone pattern was not uniform, the deposition zones (where more than 90% of the chelates were found) are indicated by thicker lines.

Representative photomicrographs of metal oxinates deposited on the glass wall inside the sublimation tube are given in Fig. 3. The Mo^{6+} chelate forms large rectangular crystals in the crossed states, while the W^{6+} chelate forms small, rectangular crystals in the scattered states. Both of the metal chelates generally form large crystals under higher pressures. Therefore, it is evident that sublimation is useful for the purification of milligram amounts of both the Mo^{6+} and W^{6+} oxinates because of the sublimation of only mg amounts of metal compounds. The oxinates can be obtained as uniform and beautiful crystals by the use of the present experimental apparatus.

The authors wish to thank Professor Kikuo Terada of Kanazawa University for his helpful advice.

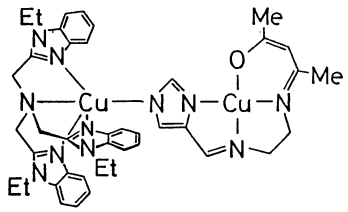
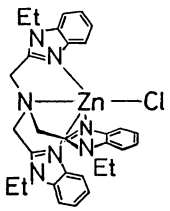
Synopsis. The crystal structure of the title complex has been determined by the single-crystal X-ray diffraction method. The zinc complex has approximately a trigonal bipyramidal coordination geometry, which is different from the copper(II) complex with the same tripod ligand.

The X-ray crystal structure of bovine erythrocyte superoxide dismutase(BESOD) has elucidated the specific binuclear structure of the active site, in which a zinc ion with a tetrahedral coordination sphere is linked to a cooper(II) ion with a square planar geometry through an imidazolate group.[1] In order to obtain the physical properties, the zinc ion has been substituted by copper(II) or cobalt(II) ion and the magnetic parameters have been obtained.[2,3] It is questionable whether the metal replaced compound has the same structure as the original complex. In a series of our studies on imidazolate-bridged binuclear complexes, we have shown an effective synthetic method which can mimic the structural characteristics of the active site of BESOD.[4-6] By applying the synthetic method, an imidazolate-bridged binuclear copper(II)-copper-(II) complex, **1**, has been prepared and its crystal structure has been determined.[4] In this study, we report on the crystal structure of the title zinc complex with the same tripod ligand, **2**.



1



2

Experimental

Synthesis. The tripod ligand tris[(1-ethyl-1*H*-benzimidazol-2-yl)methyl]amine (abbreviated as NTBEt) was prepared by a method described in the literature.[7]

[Zn(Cl⁻)(NTBEt)][BPh₄]·Acetone. To a solution of NTBEt (2 mmol) in 20 cm³ of acetone was added a solution of zinc(II) chloride (2 mmol) in 10 cm³ of methanol. The solution was warmed in a water bath for 10 min and then filtered. To the filtrate was added a solution of sodium tetraphenylborate (2 mmol) in 10 cm³ of methanol. After several hours, colorless prisms precipitated and were collected by suction filtration. Found: C, 70.34; H, 6.11; N, 10.04%. Calcd for $ZnClC_{54}H_{53}N_7B\cdot(CH_3)_2C{=}O$: C, 70.60; H, 6.13; N, 10.11%. Λ_M 144 S mol^{-1} cm^2 (in acetonitrile).

Physical Measurements. The elemental analysis was performed by Mr. Shinichi Miyazaki at The Technical Service Center of Kumamoto University. The molar electrical conductance was measured on a Denki Kagaku Keiki AOC-10 digital conductometer in 10^{-3} mol dm^{-3} solutions. The magnetic susceptibility was measured by the Faraday method at room temperature.

X-Ray Diffraction Study. Diffraction data were obtained on a Rigaku AFC-5 four-circle diffractometer at the Faculty of Science, Kyushu University, using graphite monochromatized Mo $K\alpha$ radiation at 20 °C. Information concerning conditions for crystallographic data collection and structure refinement is summarized below. [Zn(Cl⁻)(NTBEt)][BPh₄]·Acetone, Formula=$ZnClON_7C_{57}BH_{59}$ F.W.=969.7, triclinic, space group $P\bar{1}$, a=14.009(2) Å, b=17.372(2) Å, c=11.607(1) Å, α=95.52(1)°, β=113.08(1)°, γ=76.75(1)°, V=2529.4 Å^3, D_{calcd}=1.273 g cm^{-3} (Z=2), D_{obsd}=1.25 g cm^{-3} (by floatation method in aqueous KI solution), μ(Mo $K\alpha$)=5.94 cm^{-1}, crystal dimension 0.5×0.4×0.3 mm, scan mode θ-2θ, scan width (1.0+0.5tanθ), 2θ range 2.5°—48°, octant collected +h, ±k, ±l, no. of unique data used 5852.

The reflection data were corrected for Lorentz-polarization effects, but not for absorption. The structure was solved by a standard heavy-atom method and refined by a block-diagonal least-squares method. The final discrepancy indices, R and R_w, are 5.79 an 5.46%, where equal weight w=1 was adopted. The calculation was carried out by a FACOM M 386 computer at thc Computer Center of Kyushu University using the UNICS III computer program system.[8] The final positional parameters of non hydrogen atoms with their estimated standard deviations in parentheses are given in Table 1.[9]

Results and Discussion

The molar electrical conductance measured in acetonitrile is 144 S mol^{-1} cm^2, consistent with 1 : 1 electrolyte.[10] This indicates that the Cl⁻ ion is coordinated to the zinc ion. The complex is diamagnetism, being consistent with the d^{10} electronic configuration of Zn(II).

A perspective drawing of the cation [Zn(Cl⁻)-(NTBEt)]$^+$ with the atom numbering scheme is shown in Fig. 1. The zinc ion is coordinated by three imidazolyl nitrogen atoms of the tripod ligand NTBEt, forming a basal plane and a tertiary amine nitrogen atom N(7) and a Cl⁻ ion occupying two axial positions. The bond distances of Zn-axial ligand (Zn-Cl 2.236(1) and Zn-N(7) 2.274(4) Å) are elongated compared with those of Zn-basal plane ligand (Zn-N(1) 2.031(3), Zn-N(3) 2.056(4), and Zn-N(5) 2.046(4) Å). The geometry of the penta-coordinate metal complex can be analyzed and described by using an approach developed by Muetterties and Guggenberger.[11] In this method, the important dihedral angles (known as the shape determining angles (e_1, e_2, e_3)) can be calculated in order to describe the complex geometry. The two

possible limiting geometries for a penta-coordinate metal center are square-base pyramid(SP) and trigonal bipyramid(TBP) geometries. The shape-determining parameters are (e_1, e_2, e_3)=(75.7°, 75.7°, 0°) for an SP complex and (e_1, e_2, e_3)=(53.1°, 53.1°, 53.1°) for a TBP complex. As applied to the present complex **2**, the analysis yields parameters (44.9°, 46.9°, 54.9°), indicating that the coordination geometry is described as a trigonal bipyramid. On the other hand, the copper(II) sphere with the same tripod ligand NTBEt in the complex **1** has the shape determining parameters (72.0°, 63.7°, 18.5°),[4] indicating that the coordination geometry of the copper(II) sphere is an intermediate geometry between a square-base pyramid and a trigonal bipyramid. The structural difference between the zinc (II) and copper(II) sphere with the same ligand is probably attributable to their electronic configurations. The present result suggests that the molecular

structure of the metal-replaced compound of the hetero-metal polynuclear complex may be different from that the original complex.

A Simple and Convenient Synthesis of Aryl-Substituted Push-Pull Butadienes from 1,1-Diaryl-2-propyn-1-ols[1)]

Shin'ichi NAKATSUJI,* Kenichiro NAKASHIMA, Masahiko IYODA, † and Shuzo AKIYAMA*
Faculty of Pharmaceutical Sciences, Nagasaki University, 1-14 Bunkyo-machi, Nagasaki 852
†Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received December 14, 1987)

Synopsis. 1,1-Diaryl-2-propyn-1-ol derivatives reacted with several nucleophiles to afford novel 1,1-diarylbutadiene systems. An efficient one-step synthesis of aryl-substituted push-pull butadiene systems was achieved by this reaction.

Push-pull butadienes bearing an electron-donor on one end and an electron-acceptor on the other end of the molecule are one of the fundamental π-electron systems in merocyanine dyes.[2)] Recently, special interest regarding such π-electron systems is focused on their potential applicability to non-linear optics.[3)] Moreover, the systems are useful building blocks for the formation of cyclic systems by a Diels-Alder reaction.[4)]

In this paper, we wish to report on a new method for the synthesis of such butadienes, which have been found in the course of our studies on the new xanthenylium dye ethynologs **2**, possible near infrared dyes for the optical and laser data-storage technology.[5)]

Treatment of acetylenic alcohol **1** at room temperature with inorganic acids (e.g., $HClO_4$, HBF_4, etc.) or various organic acids (e.g., picric acid, *p*-TsOH, etc.) gave the mono-cationic salt **2**, as shown in Scheme 1.[5)] On the contrary, the reaction of **1** with thiobarbituric acid gave no cationic salt and resulted in the formation of reddish crystals (80%) with an absorption maximum at 588 nm (CH_2Cl_2). The spectroscopic investigations (IR, ^1H NMR, and MS), as well as elemental analyses, showed that the compound obtained was a new 1,3-butadiene derivative (**3b**).[6)] It was apparent from the result that the acidity of thiobarbituric acid was sufficiently strong to remove the hydroxyl group of **1** and the nucleophilicity of the conjugated base was sufficient to attack the terminal carbon (i.e., C_3) of the triple bond. Analogous reactions of **1** with barbituric acid, malononitrile, and 2,4-dinitrophenylhydrazine[7)]

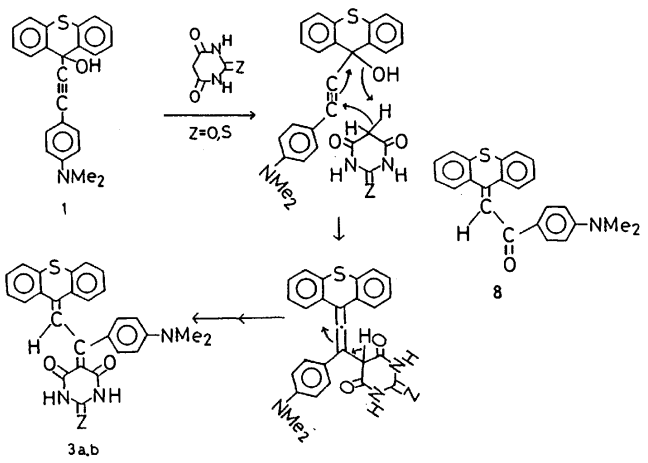

Scheme 3.

afforded **3a**, **3c**, and **3d** in 81, 62, and 79%, respectively (Scheme 1, Table 1).

As an extension of the reaction using acetylenic alcohol **1**, we have tried such reactions as shown in Scheme 2, using acetylenic alcohols **4a**, **4b** prepared by the ethynylation of the corresponding ketones.

The reaction with barbituric acid or thiobarbituric acid (**4**→**6**) could proceed readily, even at room temperature, in good yields. In the case of malononitrile (**4**→**5**), however, appropriate heating was necessary. The acid-catalyzed reaction with 2,4-dinitrophenylhydrazine (**4**→**7**) occurred readily in good yield.

A sort of acid-catalyzed propargylic rearrangement[8] would participate in the reactions and a plausible process of the formation of **3** is shown above (Scheme 3). No reaction of thiobarbituric acid with the ketone **8**[9] occurred under the same conditions and the starting materials were recovered. Therefore, the formation of the ketone as an intermediate in the reaction might be ruled out.

In conclusion, this simple, efficient method provides a new practical way to obtain push-pull type diene systems having potential applicability to dye chemistry and to synthetic chemistry as well.

Experimental

Melting points were uncorrected. IR spectra were obtained on Shimadzu IR 408 and JASCO IRA 810 spectrophotometers. ^{1}H NMR spectra were measured on a JEOL JNM-FX 90Q instrument and the chemical shifts are given in δ-values with respect to TMS used as an internal standard. UV spectra were obtained on a Hitachi 200-10 spectrophotometer. MS spectra were taken using a JEOL JMS-DX303 mass spectrometer.

The syntheses and some physical properties of acetylenic alcohol **1** and cationic salts **2** were partly reported in Ref. 5.

The Syntheses of Acetylenic Alcohol 4a and 4b: To a chilled solution (−10 °C) of 4-dimethylaminobenzophenone (2.0 g, 8.8 mmol) in abs. tetrahydrofuran (100 ml) was bubbled acetylene gas to be saturated. After 10 min, a lithium acetylide-ethylenediamine complex (6.1 g, 67 mmol) was added. The reaction mixture was stirred for 1.5 h at the same temperature and then for 1.5 h at ambient temperature, and poured into H_2O (100 ml). After separation and extraction of the water layer with benzene (100 ml, and then 50 ml), the combined organic layer was washed with brine (150 ml), dried over $MgSO_4$, and evaporated in vacuo. The crude solid obtained was recrystallized with ether to give 1.8 g (78%) of pure **4a** as colorless crystals: mp 121—122 °C; IR (Nujol) ca. 3300 (OH), 3270 (C≡CH), 2110 (C≡C), and 1610 cm^{-1} (C=C); ^{1}H NMR ($CDCl_3$) δ=2.75 (1H, s, OH), 2.82 (1H, s, C≡CH), 2.92 (6H, s, NMe_2), 6.62 (2H, d, J=9 Hz), 7.22—7.75 (5H, m, aromatic H); EI-MS m/z 251 (M^+). Found: C, 81.31; H, 6.77; N, 5.47%. Calcd for $C_{17}H_{17}NO$: C, 81.24; H, 6.82; N, 5.57%. By the same method as above, **4b** was prepared in 95% yield; mp 154—155 °C: IR (Nujol) ca. 3300 (OH), 3250 (C≡CH), 2110 (C≡C), and 1610 cm^{-1} (C=C); ^{1}H NMR ($CDCl_3$) δ=2.80 (1H, s, C≡CH), 2.93 (12H, s, NMe_2), 3.05 (1H, s, OH), 6.63 (4H, d, J=9 Hz, aromatic H), 7.40 (4H, d, J=9 Hz, aromatic H); EI-MS m/z 294 (M^+). Found: C, 77.18; H, 7.64; N, 9.41%. Calcd for $C_{19}H_{22}N_2O$: C, 77.52; H, 7.53; N, 9.52%.

Reactions of Acetylenic Alcohols 1, 4a, and 4b with Barbituric or Thiobarbituric Acid; General Procedure: Acetylenic alcohol **1** (80 mg, 0.22 mmol) in MeOH (20 ml) was mixed with thiobarbituric acid (32 mg, 0.22 mmol) in MeOH (20 ml) at room temperature. The color of the solution turned immediately from pale yellow to deep bluish-violet. After stirring for 1 h, the mixture was concentrated to give precipitates, which were filtered and then washed with ether. The resulting dark-red crystals (82 mg, 80%) were recrystallized with CH_2Cl_2-ether for an analytical sample: mp>300 °C; IR (Nujol) 3175 (NH), 1690, 1650 (C=O), and 1600 cm^{-1} (C=C); ^{1}H NMR (DMSO-d_6) δ=2.88 (6H, s, NMe_2), 6.29 (2H, J=9 Hz, aromatic H), 7.18 (2H, d, J=9 Hz, aromatic H), 7.14—7.42 (9H, m, aromatic and olefinic H), 11.83 (1H, s, NH); FAB-MS m/z 484 (M+1). By the same method as above **3a**, **6a**, **6b** were prepared from **1**, **4a** or **4b**; **3a**: dark-reddish violet crystals; IR (Nujol) 3200 (NH), 1720, 1690, 1665 (C=O), and 1600 cm^{-1} (C=C); ^{1}H NMR (DMSO-d_6) δ=2.88 (6H, s, NMe_2), 6.27 (2H, d, J=9 Hz, aromatic H), 7.12 (2H, d, J=9 Hz, aromatic H), 7.08—7.43 (9H, m, aromatic and olefinic H), 10.74 (1H, s, NH); FAB-MS m/z 468 (M+1). **6a**: yellowish green crystals; IR (Nujol) 3150 (NH), 1690, 1640 (C=O), and 1610 cm^{-1} (C=C); ^{1}H NMR (DMSO-d_6) δ=3.05 (6H, s, NMe_2), 6.77 (2H, d, J=9 Hz, aromatic H), 7.05—7.58 (7H, m, aromatic H), 7.65 (1H, d, J=13 Hz, olefinic H), 8.55 (1H, d, J=13 Hz, olefinic H), 12.02 (1H, s, NH); FAB-MS m/z 378 (M^+). **6b**: blue crystals; IR (Nujol) 3150 (NH), 1695, 1635 (C=O), and 1595 cm^{-1} (C=C); ^{1}H NMR (DMSO-d_6) δ=3.06 (12H, s, NMe_2), 6.79 (2H, d, J=9 Hz, aromatic H), 6.83 (2H, d, J=9 Hz, aromatic H), 7.13 (2H, d, J=9 Hz, aromatic H), 7.32 (2H, d, J=9 Hz, aromatic H), 7.82 (1H, d, J=13 Hz, olefinic H), 8.24 (1H, d, J=13 Hz, olefinic H), 11.32 (1H, s, NH), 11.93 (1H, s, NH); FAB-MS m/z 421 (M^+).

Reaction of 4b with Malononitrile: **4b** (0.11 g, 0.37 mmol) in EtOH (20 ml) was mixed with malononitrile (0.11 ml, 5 equiv) in EtOH (20 ml). The color of the solution gradually turned from pale yellow to slightly red. The solution was successively heated to reflux for 2 h. After cooling the solution to room temperature, the resulting wine-red solution was concentration in vacuo and the red residual oil obtained was purified by column chromatography (silica gel 10 g) using chroloform-ether as eluent to give **5a** as dark red crystals (0.11 g, 85%): mp 136—137 °C; IR (Nujol) 2240 (C≡N) and 1600 cm^{-1} (C=C); ^{1}H NMR ($CDCl_3$) δ=3.06 (6H, s, NMe_2), 3.07 (6H, s, NMe_2), 6.63 (2H, d, J=9 Hz, aromatic H), 6.71 (2H, d, J=9 Hz, aromatic H), 6.94 (1H, d, J=12 Hz, olefinic H), 7.10 (2H, d, J=9 Hz, aromatic H), 7.34 (2H, d, J=9 Hz, aromatic H), 7.47 (1H, d, J=12 Hz, olefinic H); EI-MS m/z 342 (M^+). By the similar manner **3c** and **5a** were prepared from **1** or **4a**; **3c**: dark red crystals; IR (Nujol) 2210 (C≡N) and 1605 cm^{-1} (C=C); ^{1}H NMR ($CDCl_3$) δ=2.97 (6H, s, NMe_2), 6.42 (2H, d, J=9 Hz, aromatic H), 6.78—7.55 (8H, m,

aromatic and olefinic H), 7.46 (2H, d, J=9 Hz, aromatic H), 7.55—7.88 (1H, m, aromatic H); EI-MS m/z 405 (M^+). **5a**: dark red crystals; IR (Nujol) 2220 (C≡N) and 1605 cm^{-1} (C=C); ^1H NMR ($CDCl_3$) δ=3.06 (6H, s, NMe_2), 6.62 (2H, d, J=9 Hz, aromatic H), 7.31 (2H, d, J=9 Hz, aromatic H), 7.06—7.51 (7H, m, aromatic and olefinic H); EI-MS m/z 299 (M^+).

Reaction of 1 with 2,4-Dinitrophenylhydrazine: **1** (80 mg, 0.22 mmol) and 2,4-dinitrophenylhydrazine (44 mg, 0.22 mmol) in EtOH (5 ml) containing 1 drop of concd HCl was warmed on a steam bath for 1 h. The resulting deep-red solution was concentrated to give precipitates, which were filtered and then washed with ether to give dark-red crystals (93 mg, 79%): mp ca. 231 °C (decomp); IR (Nujol) ca. 3500 (NH), 1605 (C=C and C=N), and 1585 cm^{-1} (NH); ^1H NMR ($CDCl_3$) δ=2.99 (6H, s, NMe_2), 5.46 (1H, d, J=9.5 Hz, aromatic H), 6.63 (2H, d, J=9 Hz, aromatic H), 7.51—7.79, 8.01—8.14 (12H, m, aromatic and olefinic H), 8.49 (1H, d, J=2.5 Hz, aromatic H); EI-MS m/z 537 (M^+). **7** was prepared by the similar manner: dark red crystals; IR (Nujol) ca. 3300 (NH), 1615 (C=C and C=N), and 1590 cm^{-1} (NH); ^1H NMR δ=3.00 (6H, s, NMe_2), 6.63 (2H, d, J=9 Hz, aromatic H), 6.88 (1H, d, J=10 Hz, olefinic H), 7.14—7.49 (7H, m, aromatic H), 7.63 (1H, d, J=9 Hz, aromatic H), 7.95 (1H, d, J=10 Hz, olefinic H), 8.27 (1H, dd, J=2, 9 Hz, aromatic H), 9.07 (1H, d, J=2 Hz, aromatic H), 10.97 (1H, s, NH); EI-MS m/z 430 (M^+).

The authors wish to thank Professor Emeritus Masazumi Nakagawa (Osaka University) for valuable discussions and Misses M. Kawakami and K. Takeshita for technical assistance. This work has been supported in part by a Grant-in-Aid for Scientific Research (No. 62470035) from the Ministry of Education, Science and Culture of Japan, which is gratefully acknowledged.

Regioselective Alkylation in the Course of Aldol Condensation under Phase-Transfer Catalytic Conditions

Xue-Ping GU, Isao IKEDA, and Mitsuo OKAHARA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka 2-1, Suita, Osaka 565
(Received December 18, 1987)

Synopsis. Regio- and stereoselective alkylation in the course of aldol condensation under liquid-solid phase-transfer catalytic conditions, affording conjugated dienyl ether (**5**) or α-substituted β,γ-olefinic aldehyde (**7**) depending on the starting halides, both in good yields, was disclosed. The reaction mechanism is also discussed.

Aldol condensation is a basic and useful reaction of aldehydes, and plays an important role in organic synthesis.[1-3] Recently, direct alkylation of aldehyde has also attracted attention. The aldehydes having one α-hydrogen atom[4] or an α,β-unsaturated group[5] have been directly alkylated to afford alkylated aldehydes such as α-,γ-, or *O*-alkyl products.

During the course of investigations regarding the reactivity of epichlorohydrin under phase transfer (PT) catalytic conditions, we have recently found a simple synthetic method for the preparation of oligoethylene glycol diglycidyl ethers in good yields,[6] and also the regioselective addition of organic chlorides to epoxides under mild conditions.[7] Now we wish to report a regio- and stereoselective alkylation of aliphatic aldehydes with epichlorohydrin or other organic halides during the course of aldol condensation in the presence of PT catalyst and solid sodium hydroxide.

The reaction of octanal with epichlorohydrin was carried out at 55 °C for 2 h in the presence of solid sodium hydroxide and tetrabutylammonium hydrogensulfate in dioxane. The reaction was very clean judging from inspection by GLC. Only two peaks were observed. The main peak was characterized as (5*Z*, 7*E*)-1,2-epoxy-6-hexyl-4-oxatetradeca-5,7-diene (**5**) by spectral analyses: absorptions due to conjugated carbon-carbon double bonds and an ether linkage were observed in the infrared spectra (1660, 1640, 1120 cm^{-1}). The presence of an epoxide ring and two kinds of olefinic moieties in *E* and *Z* forms respectively were deduced from chemical shift values and coupling constants in ^1H NMR. Especially H_h was characterized by Pascual's empirical equation[8] to support the structure of **5** (δ=2.52—2.70 (m, H_a), 2.70—2.90 (m, H_b), 3.04—3.28 (m, H_c), 3.40—4.08 (m, $H_{d,e}$), 5.30—5.70 (m, *J*=17.2 Hz, H_f), 5.70—5.95 (d, *J*=17.2 Hz, H_g), 6.10 (s, H_h)). A conspicuous component of short retention time was identified as *trans*-3-chloroallyl glycidyl ether, which was formed by the isomerization of epichlorohydrin under PT catalytic conditions followed by the condensation with another molecule of epichlorohydrin.[9]

In the absence of PT catalyst, the reaction mentioned above is different. The main product isolated is 2-hexyl-2-decenal (**8**) resulting from the aldol condensation. The alkylated product, **5**, formed only in a small amount in this case.

The stereospecific formation of product **5** under PT catalytic conditions can be explained reasonably by the postulation shown in Scheme 1: the intermediate **1** formed by aldol condensation of two aldehyde molecules rearranges to the intermediate **2**, which further changes to the enolate **3** forming a six-membered ring stabilized by the intramolecular hydrogen bonding. This structure of enolate **3** may cause the formation of a *Z* conformation at one of the two double bonds in **5**. Finally, the enolate **3** attacks epichlorohydrin to produce compound **4**, which is then dehydrated under alkaline conditions to form the conjugated dienyl glycidyl ether **5** with the thermodynamically stable *E*

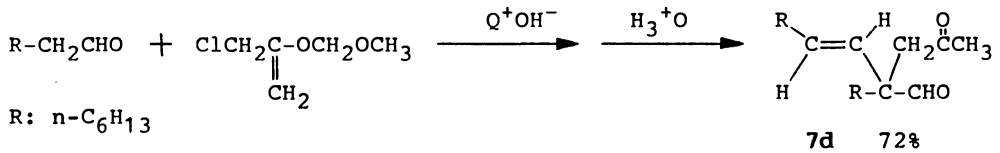

Scheme 3.

conformation.

However, the reaction of octanal with benzyl, methallyl, or octyl chlorides afforded different products even under the same PT catalytic conditions, as reported by Suyama and Shimizu.[10)] The sole product isolated was an α-substituted β,γ-olefinic aldehyde **7a—c** (Scheme 2). The distinguishing spectral feature of products **7** are the following: no infrared absorption due to conjugated carbon-carbon double bonds nor ether linkage appeared, while absorption due to isolated double bond and carbonyl group was observed in the IR spectra (1460, 1720 cm^{-1}, respectively). The signal of the aldehyde proton was clearly seen in the ^1H NMR spectra (δ 9.30). In these cases, the following reaction route is indicated. The intermediate **2** attacks organic chloride directly to afford compound **6** before rearrangement to the intermediate **3** (or even if **2** exists in equilibrium with **3**), **6** is then further dehydrated to **7a—c** (Scheme 2). Judging from the GLC, this reaction was also selective, and the yields of these products were 66, 68, and 31% for benzyl (**7a**), methallyl (**7b**), and octyl (**7c**) derivatives, respectively. Without PT catalyst, the main product in these cases was also an aldol condensation product **8** instead of **7**. The results of alkylation during the course of the aldol condensation are summarized in Table 1.

The reaction of octanal with 2-(chloromethyl)-3,5-dioxahex-1-ene, which was developed recently as an effective acetonylating reagent,[11] afforded γ-keto aldehyde **7d** in yield of 72% after hydrolysis in acidic medium (Scheme 3). It has been reported that γ-keto aldehydes are an important class of compounds especially as intermediates for the preparation of cyclopentenones.[12]

It is well-known that PT catalyst often modifies the mode of chemical reaction or changes the selectivity of the reaction.[13] The title alkylation during the course of aldol condensation under PT catalytic conditions provided additional highly selective examples. It is difficult properly to account for the different selectivities depending on the organic chloride observed in this study. The results of this alkylation reaction, however, agree with those for alkylation of ambident anions reported in the references.[4,14]

In the case of 2-octanone, the reaction with epichlorohydrin did not proceed under the same reaction conditions as those for octanal even at 80 °C for 2 h. The raw material, 2-octanone, was recovered almost quantitatively, except for the formation of a small amount of 3-chloroallyl glycidyl ether.

Experimental

^{1}H NMR spectra were recorded on a JEOL-PS-100 instrument in $CDCl_3$ with Me_4Si as an internal standard. Mass spectra were measured on a Hitachi RMU-6E spectrometer. HRMS were measured on a JMS-DX300 spectrometer. All the reagents were of reagent grade and were used without further purification. Evaporative distillation was performed from bulb to bulb distillation by a glass tube oven model GTO-250RS (Kugelrohr distillation).

Typical Procedure: Synthesis of (5*Z*, 7*E*)-1,2-Epoxy-6-hexyl-4-oxatetradeca-5,7-diene (5). A mixture of octanal (12.8 g, 0.1 mol), epichlorohydrin (9.2 g, 0.1 mol), sodium hydroxide (8 g, 0.2 mol, pellet), tetrabutylammonium hydrogensulfate (1.7 g, 0.005 mol) and dioxane (30 ml) was stirred with a magnetic stirrer at 55 °C for 2 h. After removing the solid materials by filtration through a short column filled with silica gel, and evaporating off the solvent, product **5** was obtained by Kugelrohr distillation under reduced pressure in 70% yield as a colorless oil; bp 130 °C/0.05 Torr (1 Torr≈133.322 Pa). ^{1}H NMR ($CDCl_3$) δ=0.72—1.10 (t, 6H), 1.30 (s, 16H), 1.90—2.36 (m, 4H), 2.52—2.70 (m, 1H), 2.70—2.90 (m, 1H), 3.04—3.28 (m, 1H), 3.40—4.08 (m, 2H), 5.30—5.70 (m, *J*=17.2 Hz, 1H), 5.70—5.95 (d, *J*=17.2 Hz, 1H), and 6.10 (s, 1H); MS *m/z* (relative intensity) 294 (M^+, 80), 223 (50), and 57 (100); IR (neat) 2950, 1660, 1480, 1640, 1180, 1120, 970, and 860 cm^{-1}; Found: *m/z* 294.2549. Calcd for $C_{19}H_{34}O_2$: M, 294.2557.

2-Benzyl-2-hexyl-3-decenal (7a). With the general procedure described above, **7a** was isolated as a colorless liquid in yield of 66%; bp 130 °C/0.02 Torr. ^{1}H NMR ($CDCl_3$) δ= 0.76—1.08 (t, 6H), 1.28 (s, 18H), 1.90—2.24 (m, 2H), 2.94 (s, 2H), 5.28—5.50 (m, *J*=17 Hz, 2H), 7.00—7.40 (m, 5H), and 9.45 (s, 1H); MS *m/z* (relative intensity) 328 (M^+), 237 (50), and 91 (100); IR (neat) 2950, 1735, 1460, 980, and 705 cm^{-1}; Found: *m/z* 328.2760. Calcd for $C_{23}H_{36}O$: M, 328.2764.

2-(2-Methylallyl)-2-hexyl-3-decenal (7b). With the general procedure described above, **7b** was obtained as a colorless oil in yield of 68%; bp 120 °C/0.02 Torr. ^{1}H NMR ($CDCl_3$) δ= 0.72—1.04 (t, 6H), 1.25 (s, 18H), 1.64 (s, 3H), 1.92—2.24 (m, 2H), 2.37 (s, 2H), 4.62—5.00 (d, 2H), 5.20—5.60 (m, *J*=17 Hz, 2H), and 9.34 (s, 1H); MS *m/z* (relative intensity) 292 (M^+), 237 (50), 179 (80), 55 (100), and 43 (90); IR (neat) 2950, 1720, 1460, 980, and 900 cm^{-1}. Found: C, 82.19; H, 12.70%. Calcd for $C_{20}H_{36}O$: C, 82.13; H, 12.41%.

2-Octyl-2-hexyl-3-decenal (7c). With the general procedure described above, **7c** was isolated in yield of 31% as a colorless liquid; bp 132 °C/0.02 Torr. ^{1}H NMR ($CDCl_3$) δ=0.76—1.04 (t, 9H), 1.10—1.80 (m, 32H), 1.96—2.25 (m, 2H), 5.20—5.60 (m, 2H), and 9.30 (s, 1H); MS *m/z* (relative intensity) 350 (M^+), 321 (83), 69 (100), 55 (100), and 43 (100); IR (neat) 2900, 1720, 1460, and 970 cm^{-1}; Found: *m/z* 350.3577. Calcd for $C_{24}H_{46}O$: M, 350.3546.

2-Acetonyl-2-hexyl-3-decenal (7d). A mixture of octanal (12.8 g, 0.1 mol), 2-(chloromethyl)-3,5-dioxahex-1-ene[11] (9.5 g, 0.075 mol), sodium hydroxide (8 g, 0.2 mol, pellet), tetrabutylammonium hydrogensulfate (1.7 g, 0.005 mol) and dioxane (30 ml) was stirred with a magnetic stirrer at 55 °C for 2 h. After removing the solid material by filtration through a short column filled with silica gel, the solvent was evaporated off. Then, 1% aqueous sulfuric acid 10 ml and dioxane 10 ml were added to the residue, and the mixture was stirred at 60 °C for 1 h. The organic components were extracted with ether and dried over anhydrous magnesium sulfate, then the solid material was removed by filtration and the solvent evaporated off. By Kugelrohr distillation of the resulting oil under reduced pressure, **7d** was isolated in yield of 72% (10.6 g) as a colorless liquid; bp 125 °C/0.05 Torr. ^{1}H NMR ($CDCl_3$) δ=0.76—1.00 (t, 6H), 1.24 (s, 20H), 1.90—2.20 (m, 5H), 2.84 (s, 2H), and 5.38—5.50 (m, 2H); MS *m/z* (relative intensity) 294 (M^+), 208 (25), and 43 (100); IR (neat) 2950, 1730, 1470, 1370, 1180, and 900 cm^{-1}; Found: *m/z* 294.2539. Calcd for $C_{19}H_{34}O_2$: M, 294.2557.

2-Hexyl-2-decenal (8): With the procedure similar to the preparation of **5** but in the absence of PT catalyst, **8** was obtained in yield of 30% as a colorless liquid; bp 115 °C/0.05 Torr. ^{1}H NMR ($CDCl_3$) δ=0.80—1.00 (t, 6H), 1.30 (s, 18H), 2.20—2.50 (m, 4H), 6.40—6.60 (t, 1H), and 9.40 (s, 1H); MS *m/z* (relative intensity) 238 (M^+), 55 (100), and 43 (100); IR (neat) 2950, 1700, and 1480 cm^{-1}.

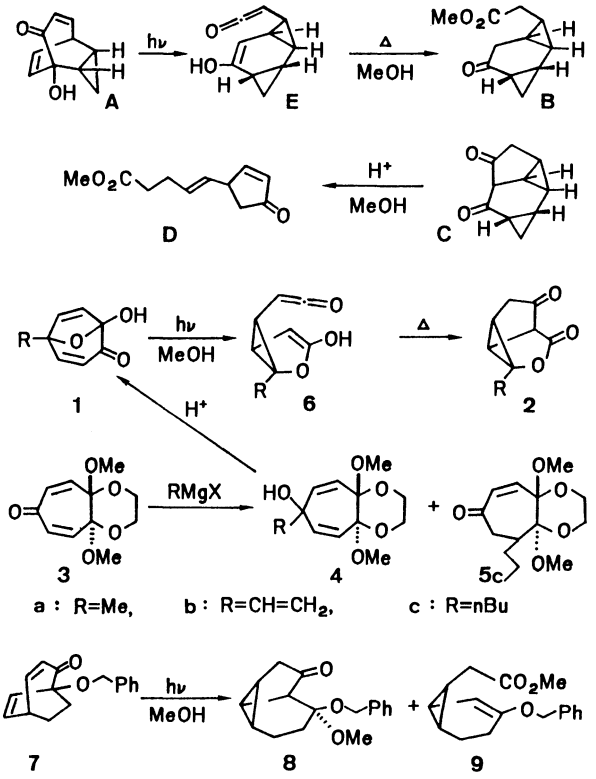
(Received December 21, 1987)

Synopsis. The irradiations of 5-alkyl-1-hydroxy-8-oxabicyclo[3.2.1]octa-3,6-dien-2-ones, either in benzene or methanol by means of a high-pressure mercury lamp produced 2-alkyl-3-oxatricyclo[3.3.0.0^{2,8}]octane-4,6-diones. Although the intermediate ketenes could be detected by low-temperature NMR, no adduct was formed in protic solvents.

In the late 1960s, Kende[2] and Chapman[3] respectively studied photorearrangements of bicyclic dienones and trienones via ketene intermediates, which were detected and characterized by low-temperature IR and ^{1}H NMR spectroscopies. Many related works have been reported. Among them particularly interesting was a facile formation of a potential precursor of prostanoids by photolysing 1-hydroxytricyclo[3.3.2.0^{2,4}]deca-6,9-dien-8-one (**A**) to a methoxycarbonyl derivative (**B**) in methanol and a tetracyclic β-diketone (**C**) and a cyclopentenone (**D**) in a mixed solution of methanol and acetic acid via a ketene (**E**).[4]

The photolysis of 5-alkyl-1-hydroxy-8-oxabicyclo-[3.2.1]octa-3,6-dien-2-ones (**1a**, R=CH_3; **1b**, R=CH=CH_2, and **1c**, R=C_4H_9) revealed a facile rearrangement to 2-alkyl-3-oxatricyclo[3.3.0.0^{2,8}]octa-4,6-diones (**2a**, **2b**, and **2c**), but no solvolysis occurred. The results will be briefly described herein.



Scheme 1.

The substrates, **1**, were prepared by Grignard reaction of *p*-tropoquinone bisacetal (**3**)[5] followed by an acid hydrolysis of alcohols (**4a**, **4b**, and **4c**) to spontaneously give bicyclic acetals, **1**. In a preparation of **4c**, a by-product, conjugate addition product **5c**, was isolated.

Structural evidence for **1** was obtained from the ^{1}H and ^{13}C NMR spectra; e.g., four vinylic proton signals appeared as two AB-type doublets with J=9.5 and J=5.5 Hz, respectively. Accordingly, **1** can only be explained as the 8-oxabicyclo[3.2.1]octadienone derivative.

When **1a** was irradiated with a 400-W high-pressure mercury lamp in benzene, a single product (**2a**, 57%) was obtained. Its NMR spectrum showed no C=C bond, and its IR spectrum [1790 and 1740 cm^{-1}] showed $\nu_{C=O}$ bands due to γ-lactone and cyclopentanone, but the former was ca. 20 cm^{-1} higher than those of ordinary γ-lactones, suggesting a partial enol lactone character by the π-like cyclopropyl linkage. These allowed us to assign the structure as shown in Scheme 1. In addition, the irradiation of **1a** in methanol only gave **2a** in 49% yield.

Similar irradiations of **1b** and **1c** derivatives in methanol formed corresponding γ-lactones (**2b**, 55%, and **2c**, 81%), but no methanol adduct.

Although adducts were undetectable, the intermediary of the ketene was certain: When the photoreaction of **1a** was carried out in methanol-d_4 at −80 °C, its low-temperature ^{1}H NMR revealed a formation of a new compound **6a** as showing an olefinic proton signal ascribable to a ketene. Warming up the solution to room temperature confirmed the formation of **2a**-d_1, whose yield from **1a** was 93% according to the NMR, which diminished the signal (δ=2.72) of *exo*-H-7 as shown in Fig. 1. Therefore, **6a** must be the ketene.

An apparent contrast to the photolysis of **A**, which gave **C** only in a mixed solution of methanol and acetic acid, is noteworthy. Since we obtained **2** by irradiating **1** in methanol without acetic acid, the Uyehara's proposal, an involvement of acetic acid to form **C**, should not be operative in **1** to **2**. In view of a facile formation of tricyclic compounds, **2**, reinvestigations of the bicyclo[3.2.n]dienones is desirable to understand the generality of the process.

Indeed, an irradiation of 1-benzyloxybicyclo[3.2.2]-nona-3,6-dien-2-one (**7**) in methanol gave 5-benzyloxy-5-methoxytricyclo[4.3.0.0^{2,9}]nonan-7-one (**8**), in 64% yield, together with methyl [3-benzyloxybicyclo[4.1.0]-hept-2-en-7-yl]acetate (**9**), in 9% yield.

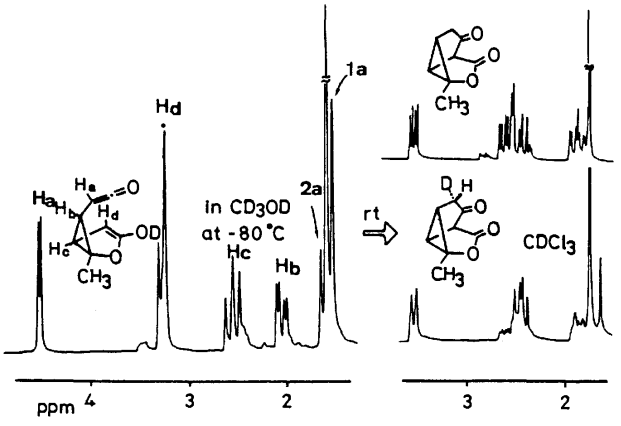


Fig. 1. Low-temperature NMR identification of ketene **6a**. A part of the doublet signal, Hd, overlapped with the solvent signal.

Nevertheless, a replacement of the carbon chain to the oxygen bridge in the vicinity of the hydroxyl group dramatically altered the course of the rearrangement to form cyclopropanes exclusively. The tricyclic derivatives, **2**, will be a good starting material for certain functionalized carbocycles since its rigid carbon skeleton will allow the introduction of various substituents via stereocontrolled reactions.

Experimental

Preparation of 4 (General Method). The starting materials, **4a**, **4b** and **4c**, were prepared from **3** by Grignard reaction. After the ordinary workup by hydrolysis and extraction with ether, the organic extracts were chromatographed on a silica-gel column to give **4** along with **5**.

4a [a colorless oil, 98%. Found: *m/z*, 242.1136. Calcd for $C_{12}H_{18}O_5$: M, 242.1152. ^{1}H NMR $\delta^{6)}$=1.37 (3H, s), 2.28 (1H, br s), 3.24 (3H, s), 3.28 (3H, s), 3.3—3.4 (4H, m), 5.40 (1H, d, J=12.5 Hz), 5.43 (1H, d, J=12.5 Hz), 5.73 (1H, dd, J=12.5, 2 Hz), and 5.83 (1H, dd, J=12.5, 2 Hz). ^{13}C NMR δ=28.5, 49.1, 49.2, 58.6 (2C), 71.5, 96.4, 97.1, 126.8, 127.2, 137.2, and 139.0. IR ν: 3550, 1450, 1400, 1215, 1150, 1090, 1065, and 1000 cm^{-1}].

4b [a pale yellow oil, 69%. Found: *m/z*, 254.1149. Calcd for $C_{13}H_{18}O_5$: M, 254.1151. ^{1}H NMR δ=2.40 (1H, br s), 3.18 (3H, s), 3.27 (3H, s), 3.4—4.2 (4H, m), 5.12 (1H, dd, J=10.2, 1.5 Hz), 5.36 (1H, dd, J=17, 1.5 Hz), 5.22 (1H, d, J=12.5 Hz), 5.47 (1H, d, J=12.5 Hz), 5.65 (1H, dd, J=12.5, 2 Hz), 5.73 (1H, dd, J=12.5, 2 Hz), and 5.83 (1H, dd, J=17, 10.2 Hz). ^{13}C NMR δ=49.1, 49.3, 58.5 (2C), 74.7, 97.4, 96.2, 113.8, 127.7, 127.9, 134.8, 136.7, and 139.8].

4c [a yellow oil, 48%. Found: C, 63.12; H, 8.46%. Calcd for $C_{15}H_{24}O_5$: C, 63.36; H, 8.51%. ^{1}H NMR δ=0.89 (3H, t, J=6 Hz), 1.1—1.5 (4H, m), 1.5—1.8 (2H, m), 2.18 (1H, br s), 3.22 (3H, s), 3.25 (3H, s), 3.3—4.2 (4H, m), 5.45 (1H, d, J=12.5 Hz), 5.47 (1H, d, J=12.5 Hz), 5.72 (1H, dd, J=12.5, 1.5 Hz), and 5.75 (1H, dd, J=12.5, 1.5 Hz). ^{13}C NMR δ=14.0, 23.1, 25.8 (2C), 42.2, 49.2, 58.7 (2C), 73.5, 96.8 (2C), 127.8, 128.9, 136.7, and 138.1. IR ν: 3450, 1450, 1400, 1210, 1145, 1100, 1060, and 1000 cm^{-1}].

5c [a pale yellow oil, 23%. Found: C, 63.30; H, 8.60%. Calcd for $C_{15}H_{24}O_5$: C, 63.36; H, 8.51%. ^{1}H NMR δ=0.90 (3H, t, J=6 Hz), 1.1—1.6 (4H, m), 1.7—2.0 (2H, m), 2.1 (1H, br m), 2.62 (2H, d, J=8 Hz), 3.15 (3H, s), 3.29 (3H, s), 3.4—4.2 (4H, m), and 6.07 (2H, s). ^{13}C NMR δ=14.2, 22.9, 30.9 (2C), 40.1, 45.3, 47.2, 49.2, 58.7, 59.1, 98.8, 100.4, 133.5, 141.2, and 202.7. IR ν: 1680, 1460, 1380, 1215, 1135, and 1090 cm^{-1}].

Hydrolysis of 4 to 1. An acetone solution containing 5% HCl (7 cm^3) of **4** (100 mg) was stirred at room temperature for 30 min. After evaporation of the volatile material in vacuo, the residue was diluted with water and extracted with $CHCl_3$. Silica-gel column chromatography of the extract gave **1**.

1a [a pale yellow oil, 59%. Found: *m/z*, 152.0479. Calcd for $C_8H_8O_3$: M, 152.0474. ^{1}H NMR δ=1.63 (3H, s), 4.49 (1H, br s), 5.61 (1H, d, J=9.6 Hz), 6.16 (1H, d, J=5.4 Hz), 6.74 (1H, d, J=5.4 Hz), and 7.19 (1H, d, J=9.6 Hz). ^{13}C NMR δ=21.4, 85.9, 107.4, 120.7, 133.7, 145.7, 158.1, and 193.2. IR ν: 3400, 1700, 1445, and 1305 cm^{-1}].

1b [a pale yellow oil, 20%. Found: *m/z*, 164.0468. Calcd for $C_9H_8O_3$: M, 164.0471. ^{1}H NMR δ=4.54 (1H, br s), 5.39 (1H, dd, J=10.5, 1 Hz), 5.50 (1H, dd, J=17.5, 1 Hz), 6.12 (1H, dd, J=17.5, 10.5 Hz), 5.64 (1H, d, J=9.6 Hz), 6.27 (1H, d, J=5.9 Hz), 6.76 (1H, d, J=5.9 Hz), and 7.26 (1H, d, J=9.6 Hz). IR ν: 3400, 1700, 1300, and 1180 cm^{-1}].

1c [a yellow oil, 82%. Found: *m/z*, 194.0939. Calcd for $C_{11}H_{14}O_3$: M, 194.0940. ^{1}H NMR δ=0.91 (3H, t, J=6 Hz), 2.1—2.7 (4H, m), 2.7—3.1 (2H, m), 4.65 (1H, br s), 5.60 (1H, d, J=9.5 Hz), 6.14 (1H, d, J=5.8 Hz), 6.70 (1H, d, J=5.8 Hz), and 7.19 (1H, d, J=9.5 Hz). ^{13}C NMR δ=13.9, 22.9, 26.1, 34.5, 89.1, 107.4, 121.0, 133.7, 145.0, 157.7, and 193.5. IR ν: 3400, 1700, 1460, and 1370 cm^{-1}. UV λ_{max}^{MeOH}: 224 nm (ε=2800), 267 (630), and 376 (70)].

Photorearrangement of 1a. a) A benzene solution (2 cm^3) of **1a** (65 mg) was irradiated with a high-pressure mercury lamp for 2 h under an N_2 atmosphere with cooling by water. After evaporation of the solvent, the residue was chromatographed on a silica-gel column to give **2a** [a colorless oil, 37.1 mg; 57%. Found: *m/z*, 152.0468. Calcd for $C_8H_8O_3$: M, 152.0471. ^{1}H NMR δ=1.72 (3H, s), 1.89 (1H, ddd, J=7.5, 6, 1.5 Hz), 2.40 (1H, dd, J=7.5, 5 Hz), 2.43 (1H, dd, J=19.5, 1.5 Hz), 2.72 (1H, ddd, J=19.5, 6, 2.5 Hz), and 3.54 (1H, dd, J=5, 2.5 Hz). ^{13}C NMR δ=18.4, 25.3, 26.6, 32.9, 58.7, 69.9, 172.1, and 206.5. IR ν: 1790, 1740, 1440, 1410, and 1330 cm^{-1}].

b) An MeOH solution (2 cm^3) of **1a** (44 mg) was irradiated under the similar conditions as above. Silica-gel column chromatography of the product gave **2a** [22 mg; 49%].

Photorearrangement of 1b. An MeOH solution (2 cm^3) of **1b** (36.7 mg) was similarly irradiated to give **2b** [a pale yellow oil, 20.1 mg; 55%. Found: *m/z*, 164.0476. Calcd for $C_9H_8O_3$: M, 164.0471. ^{1}H NMR δ=2.15 (1H, ddd, J=7, 6, 2 Hz), 2.34 (1H, dd, J=7, 5 Hz), 2.50 (1H, dd, J=19.5, 2 Hz), 2.78 (1H, ddd, J=19.5, 6, 2.5 Hz), 3.58 (1H, dd, J=5, 2.5 Hz), 6.25 (1H, dd, J=10.5, 1.5 Hz), 6.44 (1H, dd, J=17, 1.5 Hz), and 6.83 (1H, dd, J=17, 10.5 Hz). IR ν: 1800, 1750, 1410, and 1215 cm^{-1}].

Photorearrangement of 1c. Similarly, an MeOH solution (2 cm^3) of **1c** (36 mg) was irradiated to give **2c** [a pale yellow oil, 29.1 mg; 81%. Found: C, 67.75; H, 7.41%. Calcd for $C_{11}H_{14}O_3$: C, 68.02; H, 7.27%. ^{1}H NMR δ=0.92 (3H, t, J=6 Hz), 1.1—1.8 (4H, m), 1.8—2.1 (3H, m), 2.42 (1H, dd, J=19.5, 2 Hz), 2.43 (1H, dd, J=8, 5 Hz), 2.70 (1H, ddd, J=19.5, 6, 2.7 Hz), and 3.52 (1H, dd, J=5, 2.5 Hz). ^{13}C NMR δ=13.9, 22.4, 24.4, 25.6, 27.9, 32.2, 32.8, 58.4, 73.4, 172.2, and 206.4. IR ν: 1800, 1740, 1460, 1410, 1195, 1140, and 1075 cm^{-1}].

Photorearrangement of 1a in Methanol-*d*$_4$. A CD_3OD solution (0.3 cm^3) of **1a** (32 mg) was irradiated at −80 °C for 2 h to observe **6a** [^{1}H NMR (CD_3OD) at −80 °C δ=1.60 (3H, s), 2.05 (1H, dd, J=7.5, 3 Hz), 2.58 (1H, dd, J=7.5, 6.5 Hz), 3.30 (1H, d, J=6.5 Hz), and 4.56 (1H, d, J=3 Hz)]. An ordinary workup of the mixture via silica-gel column chromatography gave **2a**-d_1 [30 mg; 93%].

Diels-Alder Reaction of 2-Benzyloxytropone with Ethylene. A toluene solution (10 cm^3) of 2-benzyloxytropone (1.80 g) saturated with ethylene at 40 bar was placed in an autoclave and heated at 160 °C for 24 h. The mixture was chro-

matographed to give **7** [colorless crystals, mp 67—68 °C, 890 mg; 44%. Found: C, 80.40; H, 6.79%. Calcd for $C_{16}H_{16}O_2$: C, 79.97; H, 6.71%. ^{1}H NMR δ=1.6—2.3 (4H, m), 3.30 (1H, m), 4.75 (2H, s), 5.82 (1H, dd, J=11.5, 0.5 Hz), 6.06 (1H, d, J=9 Hz), 6.48 (1H, dd, J=9, 7 Hz), 7.01 (1H, dd, J=11.5, 8.5 Hz), and 7.2—7.5 (5H, m), ^{13}C NMR δ=24.4, 27.8, 36.5, 66.9, 87.4, 127.4, 127.7 (2C), 128.4 (2C), 128.7, 130.8, 136.7, 139.4, 152.2, and 195.9. IR ν: 1675, 1660, 1630, 1215, 995, and 740 cm^{-1}].

Photolysis of 7 to 8 and 9. An MeOH solution (5 cm^3) of **7** (370 mg) was irradiated with a high-pressure Hg lamp through a Pyrex-glass filter for 6 h. The mixture was then chromatographed on silica-gel column to give **8** [colorless crystals, mp 45—48 °C, 268 mg; 64%. Found: C, 74.74; H, 7.53%. Calcd for $C_{17}H_{20}O_3$: C, 74.97; H, 7.40%. ^{1}H NMR δ=0.7—2.2 (7H, m), 2.28 (1H, dd, J=20, 2 Hz), 2.60 (1H, ddd, J=20, 6, 2 Hz), 3.02 (1H, dt, J=7, 2 Hz), 3.29 (3H, s), 4.48 (2H, s), and 7.2—7.5 (5H, m). ^{13}C NMR δ=14.3, 14.9, 17.0, 18.1, 27.8, 37.7, 48.7, 49.8, 62.6, 65.4, 100.1, 127.6 (2C), 128.6 (2C), 138.8, and 217.9. IR ν: 1740 and 1110 cm^{-1}] and **9** [a colorless oil, 36.9 mg; 9%. Found: C, 74.94; H, 7.42%. ^{1}H NMR δ=1.0—2.4 (9H, m,), 3.64 (3H, s), 4.70 (1H, d, J=4 Hz), 4.73 (2H, s), and 7.29 (5H, m). ^{13}C NMR δ=12.2, 13.9, 18.6, 20.1, 26.3, 29.3, 51.6, 68.7, 91.2, 127.6 (2C), 127.8, 128.6 (2C), 137.6, 157.2, and 174.6. IR ν: 1730, 1710, 1419, and 1170 cm^{-1}].

The authors thank The Ministry of Education, Science, and Culture for a Grant-in-Aid for Scientific Research to H. T. (No. 61540401).

Volume of Mixing in the Liquid Bismuth-Lead System

Walid Ahmad BADAWI
Department of Chemistry, Faculty of Science, Al-Fateh University, Tripoli, Libya
(Received October 1, 1986)

Synopsis. The results obtained in determining the volume of mixing v^m in the liquid Bi-Pb system at 660 K using the pycnometer method indicate the compound Pb_3Bi_2 at the composition 0.6. The shifting of the slight positive v^m_{max} to the composition 0.4 is attributed to a nonlinear Wagner effect.

The behavior of liquid metallic systems has not yet been thoroughly explored. The theoretical relationships between the thermodynamic functions of metallic mixtures were derived for simple models e.g, the theory by Prigogine[1] which gives the relation of the volume of mixing to the enthalpy of mixing but could not illustrate the behavior of mixing in the liquid bismuth-lead system[2] or other of complicated behaviors.

In the present investigation we report the results obtained in determining the volume of mixing in the liquid Bi-Pb system at 660 K by using the pycnometer method since these results could shed light on the behavior of mixing in the Bi-Pb system and other related binary ones.

Experimental

The metal used were of extra purity grade (E. Merck Company). The experimental procedures adopted were similar to those used earlier.[3] The apparatus employed was a slightly modified version of the type used by Wittig and Huber.[3] Argon gas was used as a protector in order to avoid oxidation.

Theory and Procedure. The additional behavior y^{ad} is given by

$$y^{ad}=y_1^\circ+(y_2^\circ-y_1^\circ)x_2 \tag{1}$$

where y_1° and y_2° are the values of the molar quantities of the components 1 and 2, respectively and x_2 the mole fraction of the component 2. The form function of the excess function, X^y is given through the equation

$$X^y(x_2)=\frac{y^e}{x_2(1-x_2)} \tag{2}$$

y^e refers to the excess quantity. The excess volume and partial excess volumes can be expressed as polynomial functions:

$$v^e(x_2)=\sum_{k,l} a_{kl}\,x_2^k=\sum_{k,l} a_{kl}\,x_2^k(1-x_2)^l \tag{3}$$

$$v_1^e(x_2)=\sum_{k,l}(1-k)\,a_{kl}\,x_2^k \tag{4}$$

$$v_2^e(x_2)=\sum_{k,l}(1-k)\,a_{kl}\,x_2^k+\sum_{k,l} k\,a_{kl}\,x_2^{k-l}. \tag{5}$$

The density d has been computed at the temperature of measurement ϑ from the mass m and the volume of the pycnometer V_{py} as follows:

$$d=m/V^{22.9}\cdot[1+3a(\vartheta-22.9)], \tag{6}$$

where 22.9 °C is the calibration temperature of the pycnometer and a the thermal coefficient of silica glass which is given by

$$a_{SiO_2}=0.59\times10^{-6}\,K^{-1}. \tag{7}$$

Results and Discussion

Results of the density determinations are presented in Table 1. The results have been least squares fitted by the following polynomial expression:

$$d(x_2)=9.9297+0.5003\,x_2+0.2332\,x_2^2-0.0769\,x_3^3. \tag{8}$$

The standard deviation is 0.02% for a single measurement.

In Table 2 are collected the values of the average molar volume of the mixture of Bi-Pb as found in the present study. The results have been least squares fitted by a polynomial expression with a standard deviation of 0.012% for a single measurement. The polynomial expression is given by

$$v(x_2)=21.0458-1.2445\,x_2-0.4103\,x_2^2+0.1805\,x_3^3 \tag{9}$$

Table 3 represents the values of the integral and partial molar volume of mixing as determined in the present study. The volume of mixing can be calculated according to the following equation:

$$v^m=v-v^{ad}=v-v_1^\circ+x_2(v_2^\circ-v_1^\circ) \tag{10}$$

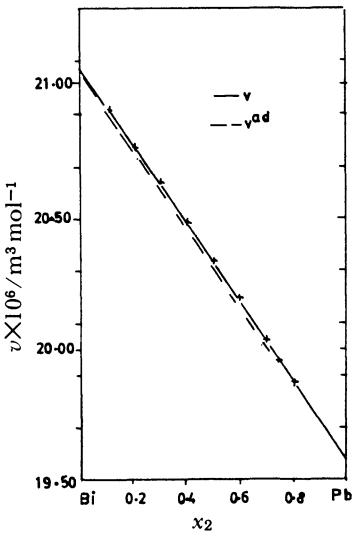

Fig. 1. Average molar volume, v, and additional volume, v^{ad}, for the mixture Bi-Pb.

where v_1° and v_2° are the molar volumes of the pure components 1 and 2, respectively. Figure 1 shows the average molar volume of the mixture, v and the additional volume v^{ad}. For the volume of mixing, the following polynomial expression is derived:

$$v^m = 0.2298\, x_2 - 0.4103\, x_2^2 + 0.1805\, x_2^3 \quad (11)$$

The partial molar volume of mixing of bismuth and lead are given through the following equations:

$$v_1^m = 0.04103\, x_2^2 - 0.3610\, x_2^3 \quad (12)$$

$$v_2^m = 0.2298 - 0.8206\, x_2 + 0.9518\, x_2^2 - 0.3610\, x_2^3 \quad (13)$$

As illustrated in Table 3, the estimated standard deviation (esd.) is not larger than expected from the pycnometer measurement uncertainties, 2.2×10^{-9}, 2.4×10^{-9} $m^3 mol^{-1}$. The plot of v^m versus the mole fraction x_2 is shown in Fig. 2. It is clearly observable that v^m takes slight positive values. The curve of v^m against x_2 and those of v_{Bi}^m and v_{Pb}^m point out to the existence of a compound. This was also recognized from the behavior of the enthalpy and free enthalpy in this system.[4]

According to the Wagner effect,[5] the compound will

be formed as follows: 3 Pb+2 Bi=Pb_3Bi_2. The composition of the compound and also that of the maximum of the volume of mixing, v_{max}^m, will be: 1−2/(2+3)=0.6. However, the Wagner effect requires sufficiently large difference in electronegativity between the acceptor (Bi) and the donor (Pb). In fact, the electronegativity difference between Bi and Pb (0.1—0.12) is not large enough. This could be a reason for the shifting of the maximum of the volume of mixing from the composition 0.6 to 0.4 (Fig. 2). This means that we have here to deal with a nonlinear Wagner effect as found in the systems Zn-Sb[7] and Cd-Bi.[8] A second possibility of the existence of a compound at the composition 0.4 (the composition of v_{max}^m) still remains under investigation.

In Table 4 are listed the values of the form function of the volume of mixing which is given by the follow-

ing linear function:

$$X^{v} = 0.2298 - 0.1805\, x_2 \qquad (14)$$

As given in Table 4, the esd. ranged from 2.0×10^{-9} to 2.6×10^{-9} $m^3\,mol^{-1}$.

One Pot Synthesis of Dinuclear Tungsten(V) Compounds Containing $[W_2XY(\mu\text{-}S)_2]^{2+}$ (X=O, S; Y=O, S) Cores by Thermally Induced Internal Electron-Transfer Processes

Mohammad A. ANSARI, Jayanthi CHANDRASEKARAN, and Sabyasachi SARKAR*
Department of Chemistry, Indian Institute of Technology, Kanpur 208016, India
(Received March 30, 1987)

Synopsis. New synthetic methods for the preparation of dimeric tungsten(V) complexes are described containing the core $[W_2XY(\mu\text{-}S)_2]^{2+}$ (X=O,S; Y=O,S). The synthesized complexes have been characterized by a variety of spectroscopic techniques. $[W_2OS(\mu\text{-}S)_2(S_2CNEt_2)_2]$ has been found to react with cyanide to give $[W_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$.

The tungsten-sulfur chemistry has received far less attention contrary to molybdenum-sulfur systems, partly due to the importance of molybdenum-sulfur systems in biology[1,2] and in catalysis[3,4] and partly due to the facile reactivity of molybdenum systems in terms of synthetic methodology. Recent observations place tungsten parallel to molybdenum in its biological aspects[5] as well as in its catalytic role.[6,7] Thus, there is a surge of new synthetic strategies to explore tungsten-sulfur chemistry.[8-10] But the synthesis of dinuclear tungsten(V)-sulfur complexes invariably involve multistep procedures.[8,10,11] Our present approach to form $[W_2O_2(\mu\text{-}S)_2]^{2+}$ core using externally induced, internal electron transfer reaction,[12] prompted us to search for a one-pot synthetic strategy for this type of complexes. In this paper we report the synthesis of a series of complexes containing $[W_2O_2(\mu\text{-}S)_2]^{2+}$, $[W_2OS(\mu\text{-}S)_2]^{2+}$ and $[W_2S_2(\mu\text{-}S)_2]^{2+}$ core with diethyl dithiocarbamate as ligand invoking intramolecular electron transfer.

Experimental

All the reactions were carried out under dry nitrogen atmosphere and in the absence of light unless otherwise specified. Solvents used were of analytical grade and were distilled before use but not degassed. Pyridine-d_5 (Aldrich) was used as received. Ammonium tetrathiotungstate, oxotrithiotungstate and dioxodithiotungstate were prepared by literature procedure.[13] Diethylammonium tetrathiotungstate and oxotrithiotungstate were prepared by our own method described below.

Infrared spectra were recorded on Perkin Elmer-580 spectrometer as KBr or CsI pressed pellets and referenced to polystyrene bands. Electronic spectra were recorded on Shimadzu UV-190 double beam spectrometer. NMR spectra were taken on Varian EM-390, 90 MHz spectrometer. XPS measurements were done on ESCALAB 510 photoelectron spectrometer using Al$K\alpha$ X-ray line (1486.6 eV) radiation. Binding energies were computed taking C ($1s_{1/2}$) binding energy (285.0 eV) as standard. Carbon, hydrogen, and nitrogen analyses were carried out at Microanalytical Laboratory, I.I.T, Kanpur (India) and sulfur was estimated as $BaSO_4$.

Synthesis of $(Et_2NH_2)_2WS_4$. Tungstic acid (5 g) was dissolved in a mixture of H_2O (10 ml) and Et_2NH (15 ml) by refluxing for 1 h. The solution was filtered and H_2S was passed rapidly for 4 h at 60 °C. The reaction mixture was cooled to obtain yellow crystals, which were washed with 2-propanol and ether. Found: C, 20.71; H, 5.42; N, 6.25%. Calcd for $C_8H_{24}N_2S_4W$: C, 20.86; H, 5.21; N, 6.08%. IR(KBr): ν(W-S) 460 cm^{-1}. Electronic spectrum: λ_{max} (in water) 387 (ε 7400 $dm^3\ mol^{-1}cm^{-1}$) and 277 nm (8100).[13] Yield: 7.36 g (80%).

Synthesis of $(Et_2NH_2)_2WOS_3$. Tungstic acid (5 g) was refluxed in a mixture of H_2O (10 ml) and Et_2NH (10 ml) for 1.5 h, filtered, into which H_2S was passed rapidly for 30 min. at 60 °C. The solution was cooled and to this 2-propanol (50 ml) and ether (20 ml) were added. The yellow orange oily mass obtained was recrystallized from methanol/ether. Found: C, 20.71; H, 5.32; N, 6.28%. Calcd for $C_8H_{24}N_2OS_3W$: C, 21.62; H 5.40; N, 6.30%. IR(KBr) ν(W=O) s, 880, ν(W-S) 450 cm^{-1}. Electronic spectrum λ_{max} (in water) 375 (ε 1400 $dm^3\ mol^{-1}cm^{-1}$), 332 (6150), and 270 nm (6200).[13] Yield: 6.48 g (73%).

Synthesis of $[W_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ (1): Method A. To a solution of $(Et_2NH_2)_2WOS_3$ (888 mg, 2 mmol) in DMF (10 ml), CS_2 (2 ml) was added and the mixture was refluxed for 4 h. Addition of 2-propanol (10 ml) and ether (100 ml) to the cold solution, precipitated a small amount of green brown product, which was filtered off and the filtrate was kept overnight at room temperature to yield **1** as yellow needle shaped crystals which were washed with water, ethanol and finally with ether. The compound was recrystallized from dichloromethane/petroleum ether. Found: C, 15.90; H, 2.81; N, 3.48; S, 25.31%. Calcd for $C_{10}H_{20}N_2O_2S_6W_2$: C, 15.78; H, 2.63; N, 3.68; S, 25.26%. IR(KBr): ν(C=N) 1550, ν(W=O) 985, 970, ν(WS_2W) 470, 338. Electronic spectrum: λ_{max} (in CH_2Cl_2) 415 (ε 200 $dm^3\ mol^{-1}cm^{-1}$), 332 (1500), and 296 nm (7600), ^1H NMR ($CDCl_3$): δ=3.54 (CH_2, q), 0.95 (CH_3, t). Yield: 290 mg (38%).

Method B. To a hot solution (130 °C) of $(NH_4)_2WO_2S_2$[13] (632 mg, 2 mmol) in DMF (10 ml), tetraethylthiuram disulfide (296 mg, 1 mmol) dissolved in DMF (5 ml) was added and the solution was cooled to 25 °C immediately. Addition of 2-propanol (20 ml) and ether (100 ml) yielded 340 mg (45%) of **1**, which was recrystallized as in method A.

Synthesis of $[W_2S_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ (2): Method A. A solution of $(Et_2NH_2)_2WS_4$ (920 mg, 2 mmol) in DMF (10 ml) and CS_2 (2 ml) was refluxed for 4 h under nitrogen atmosphere and in the absence of light. To the cold solution (ca. 25 °C), 2-propanol (10 ml) and ether (100 ml) were added. A small amount of dark brown product precipitated. This was filtered off and the filtrate was left at room temperature for 24 h to yield compound **2** as dark red needle shaped crystals, which were washed with water, ethanol, and ether. The crude product was recrystallized from dichloromethane/petroleum ether and further purified by chromatography.[14] Found: C, 15.43; H, 2.40; N, 3.68; S, 28.43%. Calcd for $C_{10}H_{20}N_2S_8W_2$: C, 15.15; H, 2.52; N, 3.53; S, 28.28%. IR (KBr): ν(C=N) 1545, ν(W=S) 535, 525, ν(WS_2W) 460, 332. Electronic spectrum: λ_{max} (in CH_2Cl_2) 420 (ε 2200 $dm^3\ mol^{-1}cm^{-1}$), 382 (6500), and 292 nm (30100), ^1H NMR ($CDCl_3$): δ=3.74 (CH_2, q), 1.08 (CH_3, t). Yield: 220 mg (ca. 28%).

Method B. Tetraethylthiuram disulfide (296 mg, 1 mmol) dissolved in DMF (5 ml) was added to a solution of $(NH_4)_2WS_4$ (696 mg; 2 mmol) in DMF (10 ml) at 130 °C under nitrogen atmosphere. The reaction mixture was cooled immediately to room temperature and 2-propanol (10 ml) and ether (250 ml) were added and kept in the refrigera-

Table 1. Binding Energy (eV) Observed by XPS

Compound	W($4f_{7/2}$)	W($4f_{5/2}$)	S(2p)	S($2s_{1/2}$)	W($4d_{5/2}$)	W($4d_{3/2}$)
$[W_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$	33.9	36.1	163.3	227.0	245.7	259.4
$[W_2S_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$	33.6	35.7	162.8	227.0	245.2	258.0

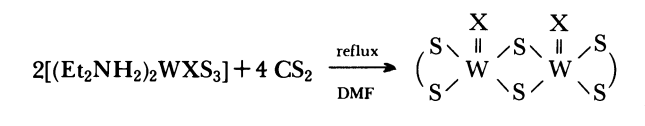
tor overnight. The crude product thus obtained was purified by chromatography as described in method A. The analytical results and spectral data are in agreement with those shown in method A. Yield: 96 mg (12%).

Synthesis of $[W_2OS(\mu\text{-}S)_2(S_2CNEt_2)_2]$ (3). The same procedure for the preparation of **2** (method A) was followed except that the reaction was carried out in the presence of air. The major product **3** (234 mg, 30%) was obtained after chromatographic purification.[15] However, if method B for synthesis of **2** is followed in the presence of air, **3** is obtained in low yield (90 mg, 12%).[16] Found: C, 15.78; H, 2.50; N, 3.72; S, 26.68%. Calcd for $C_{10}H_{20}N_2OS_3W_2$: C, 15.46; H, 2.57; N, 3.60; S, 26.80%. IR(KBr): ν(C=N) 1555, ν(W=O) 980, ν(W=S) 540, ν(WS_2W) 465, 335. Electronic spectrum: λ_{max} (in CH_2Cl_2) 418 (ε 700 $dm^3\ mol^{-1}\ cm^{-1}$), 352 (4400), and 294 nm (27400). ^1H NMR ($CDCl_3$): δ=3.62 (CH_2, q), 0.98 (CH_3, t). Yield: 90 mg (12%).

Reaction of 3 with KCN. A suspension of **3** (776 mg, 1 mmol); KCN (65 mg, 1 mmol) and Et_4NBr (210 mg, 1 mmol) in chloroform (50 ml), ethanol (15 ml) and water (5 ml) was refluxed for 96 h. The solvents were evaporated under vacuum and the residue was washed with water, methanol and diethyl ether. The bright yellow residue was dried in vacuo and recrystallized from dichloromethane/petroleum ether (yield: 544 mg, 73%). The compound showed identical results to that of **1** in elemental and spectral analysis. The washings gave positive test for thiocyanate.

Results and Discussion

Tungsten(V)-sulfur complexes have generally been prepared by multi-step synthesis.[8,10] Here we report new synthetic methods for their efficient one step preparation. Gradual heating of diethylammonium thiotungstates (WOS_3^{2-}, WS_4^{2-}) with excess CS_2 in DMF affords desired compounds with the overall reaction as shown in Eq. 1:



$$2[(Et_2NH_2)_2WXS_3] + 4\,CS_2 \xrightarrow[DMF]{reflux} \left(\begin{array}{ccc} S & X & S \\ \diagdown & \| & \diagup \\ & W & \\ \diagup & & \diagdown \\ S & X & S \end{array}\right) + (Et_2NCS_2)_2 + 4\,H_2S \quad (1)$$

X=O, S; $\left(\begin{array}{c} S \\ \\ S \end{array}\right)$ $= S_2CNEt_2^-$

The formation of H_2S and tetraethylthiuram disulfide (TLC comparison with an authentic sample) as by-products of the reaction suggests the above stoichiometry of the reaction.

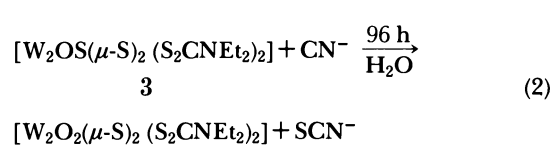
In the synthesis of $[W_2S_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ (**2**), $[W_2OS(\mu\text{-}S)_2(S_2CNEt_2)_2]$ (**3**) is formed as by-product of the reaction, probably as a result of **2** hydrolyzing with traces of moisture present in the reaction medium. The characterization of tetraethylthiuram disulfide as by-product shows that the reaction is a thermally induced redox reaction.

Spectral Studies. The IR, NMR, and electronic spectral studies of these complexes demonstrate the following important points. The strength of tungsten-oxygen bond is greater than that of molybdenum analogues[17] but the reverse has been observed for metal-sulfur bonds. Similar down field shifts of both methyl and methylene protons are observed by the replacement of oxygen by sulfur in the NMR studies. In the electronic spectral studies as expected, the intraligand transitions[18] and ligand to metal charge-transfer transitions[19] are observed. However the intensities of some of these transitions are not as high compared to similar tungsten(V) dimeric complexes.[10,11] Even using other substituted dithiocarbamates, the relative intensities of these transitions differ.[10,11] We do not have any explanations to offer for this discrepancy. The mixing of the orbitals especially between the metal and oxygen/sulfur might control the components of the electric dipolemoment. In the present case, especially with the oxo species probably there is not considerable charge redistribution during the transition for which the intensity of the band is weak.

XPS results have been tabulated in Table 1. In the spectra of $[W_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ and $[W_2S_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ a broad band around 163 eV is observed. In the first case, a resolution of the broad band (FWHM 2.87 eV) gives two sets of S(2p) binding energies at 163.1 and 163.5 eV. Thus a distinction can be made between the sulfur attached to two tungstens (163.5 eV) and the sulfur attached to one tungsten and one carbon atom (163.1 eV).[20] For the all sulfur compound **2**, S(2p) band is broader (FWHM 3.1 eV). This extra broadness for this compound compared to **1** suggests the presence of three different types of sulfur, S_{term}, S_{bri}, and S_{dtc}. For tungsten, the XPS shows considerable difference between the binding energies of W($4d_{5/2}$) as well as W($4d_{3/2}$) in $[W_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ and $[W_2S_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$. The former compound **1** shows more formal positive charge on the metal than the all sulfur compound **2**. This difference may be attributed to the difference in electron population across W=O and W=S bonds. The oxygen being more electronegative withdraws more electron from the metal compared to its sulfur analogue.

Comparison of X-ray powder diffractogram of **1** with its molybdenum analogue $[Mo_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2]$ suggests that both the compounds are isostructural.[21]

The treatment of **3** with one equivalent of cyanide results in the substitution of terminal sulfur with oxygen affording **1** in high yield, as shown in Eq. 2.



$$[W_2OS(\mu\text{-}S)_2(S_2CNEt_2)_2] + CN^- \xrightarrow[H_2O]{96\ h} [W_2O_2(\mu\text{-}S)_2(S_2CNEt_2)_2] + SCN^- \quad (2)$$

3 1

After extracting **1** from the reaction mixture, the residue was acidified and treated with iron(III) chloride solution. It gave red color, thus confirming the formation of SCN^-. Attempt to replace the bridging sulfur was not successful, by increasing the quantity of CN^- and the reaction time. This suggests that bridging sulfur atoms are more strongly bound with the metal centers than the terminal ones.

We are deeply indebted to Professor Achim Müller, University of Bielefeld, W. Germany for XPS measurements. This work has been supported by Department of Science and Technology, Government of India. M.A.A. thanks CSIR (India) for the award of a senior research fellowship.

Ion-Exchange Rate of Chromate and Dichromate Ions on Bis(triethylamine)zirconium

J. P. RAWAT* and CHITRA
Department of Chemistry, Aligarh Muslim University, Aligarh-202001, India
(Received May 6, 1987)

Synopsis. Kinetic studies of $K_2Cr_2O_7$ and K_2CrO_4 have been performed on an inorganic anion exchanger, bis(triethylamine)zirconium in Cl^- form. *F* values have been determined at four different temperatures 30, 40, 50, and 60 °C with ±1 °C variation and corresponding *Bt* values are evaluated and plotted as a function of temperature. The mechanism is found to be particle diffusion control. Various parameters viz. effective diffusion coefficient (D_i), diffusion coefficient (D_o), energy of activation (E_a), and entropy of activation (ΔS^*) have been evaluated.

Some studies on kinetics of ion exchange on inorganic ion exchangers have been reported.[1-9] The present report summarizes the kinetic studies for ion-exchange rate of chromate and dichromate ions on bis-(triethylamine)zirconium. Experimental and theoretical approaches have been used to show that the rate determining step is the diffusion through the particles. The energy of activation and other parameters are calculated.

Experimental

Synthesis of Ion-Exchange Material. Bis(triethylamine)-zirconium was prepared by mixing 0.1 M† zirconium dichloride oxide and 0.1 M triethylamine solution in the volume ratio of 1:2. After 24 h it was filtered, washed and dried in an incubator at 40±1 °C. The product was then broken down into small particles by immersing in water. Exchanger was kept in 1.0 M NaCl solution to convert it in chloride form. It was then washed and dried again at 40±1 °C.

Kinetic Measurements. Limited bath technique was applied to perform the kinetic measurements. The exchanger was finely ground and sieved into particles of different mesh sizes (30—50, 50—100, and 100—150) by using the U.S. standard mesh sieves. In all the cases studied, particles of 50—100 mesh were used, unless otherwise stated. In stoppered conical flasks 4 ml of standard anionic solutions of 0.02 M were shaken with exchanger (0.2 g) in a temperature controlled shaker (Sew India) at various temperatures at a frequency of 120 RPM. The pH of 0.02 M $K_2Cr_2O_7$ solution was 4.6 and that of K_2CrO_4, 8.2. After appropriate intervals of time, the solutions were filtered through Whatman No. 42 filter paper. The amount of $Cr_2O_7^{2-}$ and CrO_4^{2-} ions were determined iodometrically.[10] Kinetic experiments were performed at 30, 40, 50, and 60 °C with ±1 °C variation. Interruption test was performed in the similar way at 30 °C. After 20 min the solutions were separated from the exchanger and reimmersed after 10 min. The metal ion contents were determined at different intervals of time.

Results and Discussion

Interruption test for $Cr_2O_7^{2-}$ ion was used as an experimental test to decide whether the kinetics is controlled by film diffusion or particle diffusion. The results of interruption test (Fig. 1) show that rate of exchange increases after 10 min interruption. This indicates that mechanism should be particle diffusion. This is because the concentration gradients disappear in the particle during the interruption and are much greater than before at the surface.

Equations developed by Boyd et al.[11] and improved by Reichenberg[12] were used to obtain kinetic parameters. *F* values at different time intervals and temperatures were obtained for $Cr_2O_7^{2-}$-Cl^- exchange and plotted in Fig. 2. These results show that the rate of exchange increases with temperature. The uptake of ion is rapid initially but it decreases with the elapse of time. Similar behavior was shown by CrO_4^{2-} ion.

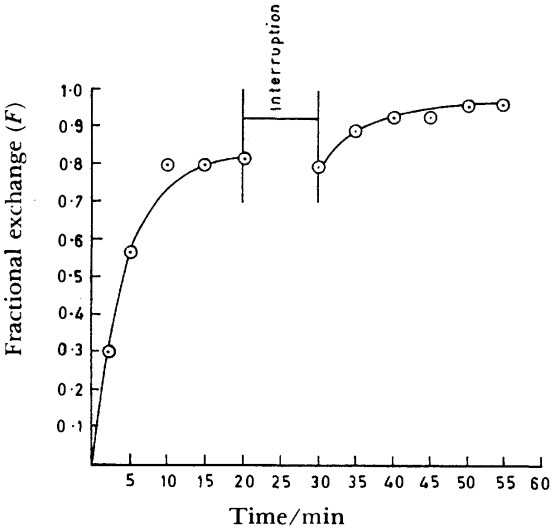

Fig. 1. Effect of an interruption test on the rate of $Cr_2O_7^{2-}$-Cl^- exchange on zirconium bis(triethylamine) at 30 °C.

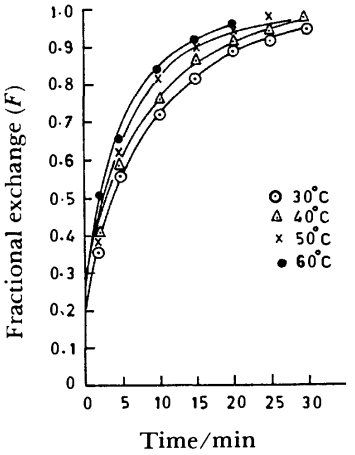

Fig. 2. Rate of exchange of $Cr_2O_7^{2-}$ at different temperatures on zirconium bis(triethylamine).

† 1M=1 mol dm^{-3}.

$$F = \frac{\text{amount of exchange after time } t}{\text{amount of exchange after infinite time (equil.)}}$$

For the limited bath technique the equations developed by Boyd et al.[11] can be used here

$$F = 1 - \frac{6}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \exp(-n^2 Bt), \quad (1)$$

where $$B = \frac{\pi^2 D_i}{\gamma^2}. \quad (2)$$

D_i is the effective diffusion coefficient, γ is the radius of the particle. Bt values were evaluated from the F values from the table of Reichenberg.[12] A typical Bt vs. t plot for $Cr_2O_7^{2-}$ ion (Fig. 3) at four different temperatures indicates that the plots are straight lines passing through the origin. The results confirm that the rate determining step is diffusion through the particle.

The particle size also has a marked influence on the rate of exchange which can be shown by the Bt vs. t plot for $Cr_2O_7^{2-}$ ion for three different particle radii at 40±1 °C (Fig. 4). The rate of exchange is inversely proportional to the square of the particle radius (Fig 5). The radius of the particles was calculated by the mesh size using the conversion table.[13] For this purpose the lower limit mesh corresponding to higher limit radius was taken instead of taking a mean radius. The higher limit radius was considered by keeping the view of slight swelling of the exchanger particles.

Equation 2 was used for the calculation of D_i. A linear relationship was obtained on plotting log D_o against T^{-1}/K (Fig. 6) assuming the Arrhenius equation

$$D_i = D_o \exp(-E_a/RT). \quad (3)$$

On extrapolating the plot of log D_i against T^{-1}/K, log

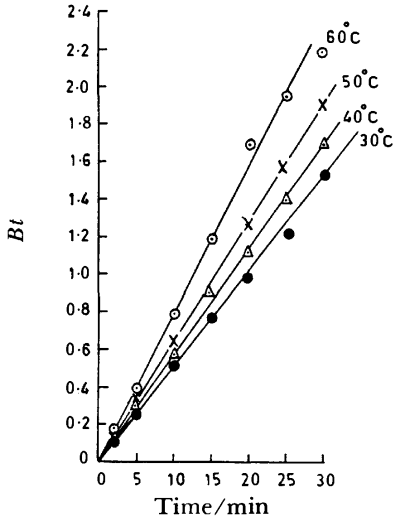

Fig. 3. Influence of temperature on the rate of exchange for $Cr_2O_7^{2-}$ ion using zirconium bis(triethylamine) r=0.015 cm.

Table 1. Diffusion Coefficient, D_o, Energy of Activation, E_a and Entropy of Activation, ΔS^*, of $Cr_2O_7^{2-}$ Ions on Bis(triethylamine)zirconium in Cl^- Form

Migrating ion	D_o	E_a	ΔS^*
	$m^2\,s^{-1}$	$kJ^{-1}mol^{-1}$	$JK^{-1}mol^{-1}$
$Cr_2O_7^{2-}$	5.01×10^{-7}	25.42	−25.72
CrO_4^{2-}	5.01×10^{-7}	23.89	−25.72

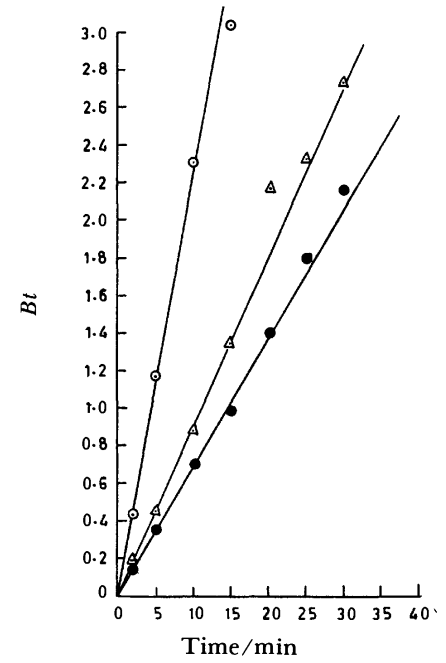

Fig. 4. Effect of particle size on the rate of exchange for $Cr_2O_7^{2-}$-Cl^- on zirconium bis(triethylamine). △ 0.015 cm, ● 0.030 cm, ⊙ 0.0075 cm.

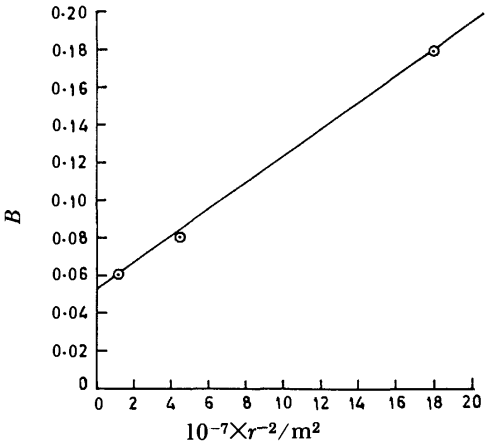

Fig. 5. Plots of B vs. r^{-2} for $Cr_2O_7^{2-}$ at 40 °C.

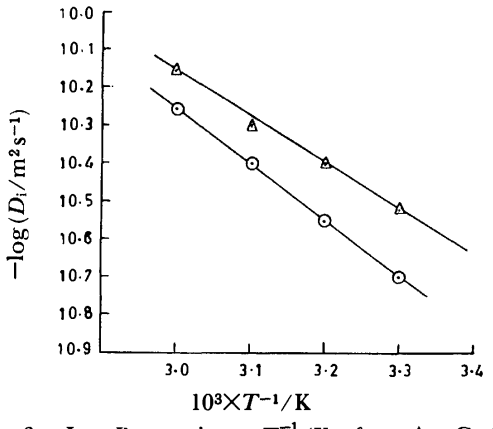

Fig. 6. Log D_i against T^{-1}/K for △ $Cr_2O_7^{2-}$, ⊙ CrO_4^{2-}.

D_o values are calculated. Substitution of these values in the following equation gives entropy of activation, ΔS^*

$$D_o = 2.72\, d^2\, KT/h \exp(\Delta S^*/R) \quad (4)$$

where d is the ionic jump distance assumed equal to 5×10^{-10} m (1), K the Boltzman constant, h Planck's constant, and R the gas constant. The values of E_a, D_o, and ΔS^* are given in Table 1.

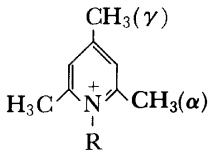
(Received June 9, 1987)

Synopsis. Carbon-13 chemical shifts of twelve *N*-substituted, 2,4,6-trimethylpyridinium (TMP) salts were determined. The data have been used to estimate the relative ring current (RRC) of the *N*-substituents on the pyridinium ring.

Verhoeven et al.[1-5] studying the UV spectra of some substituted pyridinium salts has pointed out that when R=phenyl, their UV spectra display a charge transfer band. Balaban et al.[6,7] utilized the proton NMR spectral data of some *N*-substituted TMP salts to estimate the relative ring current (RRC) of these systems.

Carbon-13 chemical shift, recieved little attention in this respect.[8,9] In this paper twelve new *N*-substituted TMP perchlorates (Scheme 1) were prepared[10] and their carbon-13 chemical shifts have been determined. Equation 2 is suggested for calculating RRC of the R group, using carbon-13 chemical shift of carbons 2 and 4.



Results and Discussion

Proton decoupled, as well as proton-coupled, carbon-13 spectra of the compounds **1—12** were recorded. Assignment of the chemical shift of these compounds (Tables 1 and 2) are based on; (i) the application of carbon-13 chemical shift of amines (RNH_2),[11] (ii) by applying the additivity rule, and substitution parameters, for the phenyl,[12,13] and the pyridinium rings,[14] and (iii) using off-resonance spectra of those compounds to determine the quaternary and protonated carbons.

Table 1 shows the trend of carbon-13 chemical shift of carbon 2,6, and the methyl carbons. It demonstrates the pronounced ring current effect of the N-aza aromatic ring on the chemical shift of those carbons.

It is accepted that analogous compounds are not coplanar.[15] Thus the α-methyl and carbons 2 and 6 are exposed to the ring current of the R substituent.

Equation 1[6] has been applied to calculate RRC using ^{1}H-chemical shift of compounds **6—12** (Table 3). The results are given in Table 3.

$$\mathrm{RRC} = 200\,(D + 0.25) - T \qquad (1)$$

where $T = 71.7\,x/(1+2.26\,x)$, x=the number of ortho substituents in R.

$$D = \delta_{(\gamma\text{-methyl})} - \delta_{(\alpha\text{-methyl})}$$

Furthermore Eq. 2 is suggested by us, as an extention, to calculate (RRC) using carbon-13 chemical shift of carbons 2 and 4.

Equation 1 was used as a basis to derive Eq. 2 which use carbon-13 chemical shift of carbon 2 and 4 for calculating the RRC. In Eq. 2 T have the same definition as in Eq. 1, and D is given as

$$\delta_{4,2} = D = \delta\,(\text{carbon 4}) - \delta\,(\text{carbon 2}). \qquad (1a)$$

When R=H, there is no ring current affecting carbons 2 and 4. The value of δ_4 and δ_2 in 2,4,6-trimethylpyridinium salt is 147.4 and 157.4 ppm,[16] therefore $\delta_{4,2}$ (−10 ppm) in this compound represents a correction factor for the D values in compounds **5—12**. Equation 1 could be modified as Eq. 1b by taking into account the above $\delta_{4,2}$ value.

$$\mathrm{RRC} = a\,(D + 10) - T. \qquad (1b)$$

Using compound **5** as a reference (compound) where RRC=100, and D=5.22 ppm (Table 2), applying those values to Eq. 1b, one obtain a value for a=6.57. Thus Eq. 2 could be written as

$$\mathrm{RRC} = 6.57\,(D + 10) - T. \qquad (2)$$

The calculated RRC values for compounds **6—12** are given in Table 3.

As it is expected $\delta_{C\text{-}2}$ and $\delta_{C\text{-}4}$ are affected by the nature of R. The difference between $\delta_{C\text{-}2}$ and $\delta_{C\text{-}4}$ increases in compounds **7—9** (Table 1). This increase might be due to a slight change in ring current of R, which shields C-2 in compounds **5—12** relative to compounds **1—4** (Table 1). These results are consistent with available data, emphasizing the leterature reports that the α-methyl, C-2 and C-6 are oriented in the shielding region of the aromatic ring.[17] It is obvious that the RRC effect decreases when there is one ortho substituent on R (compound **6**), or when there is a bulky substituent (compounds **10—12**, Table 1). This might suggest a change of the dihedral angle between the two rings relative to that in compound **5**. It seems that RRC calculated from carbon-13 chemical shift for compounds **6—12** is more realistic than that obtained from ^{1}H chemical shift because the steric crowdening will change the dihedral angle thus decrease the RRC. On this basis one expects that the RRC will have a maximum value when R=phenyl (Table 3). This may be explained on the basis that as ortho substituent on R ring increases, the methyl group, carbons 2 and 4 become less exposed to the ring current of R, thus RRC decreases for those compounds relative to compound **5**. A rather interesting case is that of compound **2** whose $\Delta\delta_{4,2}$=0.71 ppm. This value is appreciably different from those of compounds **1**, **3**, and **4** (Table 1). Such apparent inconsistency may be interpreted in terms of the deshielding

effect of the σ-ring current of the strained cyclopropyl ring on carbon 2.

Experimental

2,4,6-Trimethylpyrylium salts were prepared by reported procedures.[18,19] They were reacted with aliphatic primary amines to produce compounds **1—4**,[10] and with aromatic amines to yield compounds **5—12**. Carbon-13 spectra were recorded as 20 mol% solution in DMSO-d_6 in 5 mm NMR tubes. Optimum amount of TMS was added to the samples to act as internal reference. The proton-decoupled and proton-coupled carbon-13 NMR spectra were recorded on Varian FT 80 A operating at 20 MHz. The spectral width was 4 KHz, pulse width, 8 μs (θ=45°); aquisition time 1 s, pulse delay 2 s. Chemical shift were accurate to better than 0.06 ppm. The proton spectra were recorded for 5 mol% solution in $CDCl_3$ in 5 mm NMR tubes. TMS was added as internal reference. Varian FT 80 A operating at 80 MHz used to record the proton spectra.

Synthesis and Properties of Three Sulfur-Containing Porphyrins, One Water-Soluble

Nirmalendu DATTA-GUPTA,* Debasis MALAKAR, Celestine JENKINS, and Cynthia STRANGE
Department of Natural Sciences, South Carolina State College Orangeburg, South Carolina 29117, U.S.A.
(Received February 7, 1987)

Synopsis. Three new porphyrins with sulfur functional groups, one of which is water-soluble, have been prepared. Their UV-visible absorption, fluorescence emission, and ^{1}H NMR spectra as well as their copper(2+) insertion kinetics, pK_3 values and first and second reduction potentials determined. For the water soluble porphyrin, its binding with human serum albumin (HSA) determined.

In recent years several water-soluble synthetic porphyrins and metalloporphyrins have been studied as photosensitizers and radiation modifiers,[1-3] as DNA intercalators,[4-6] as binder with protein macromolecules,[7,8] and as tumor localizers.[9,10] Widely studied among these porphyrins are 5,10,15,20-tetrakis(4-sulfonatophenyl)porphyrin (4TSPP), 5,10,15,20-tetrakis(4-carboxyphenyl)porphyrin (4TCPP), 5,10,15,20-tetrakis(1-methyl-4-pyridinio)porphyrin (4TMPyP) and 5,10,15,20-tetrakis[4-(trimethylammonio)phenyl]porphyrin (4TAPP) and some of their metal complexes. The same porphyrins are also under study as sensitizers in photochemical systems for solar energy conversion.[11,12] In addition to the above, other water soluble porphyrins, namely, 5,10,15,20-tetrakis(2-carboxyphenyl)porphyrin (2TCPP), 5,10,15,20-tetrakis(3-carboxyphenyl)-porphyrin (3TCPP), 5,10,15,20-tetrakis(1-methyl-2-pyridinio)porphyrin (2TMPyP) and 5,10,15,20-tetrakis(1-methyl-3-pyridinio)porphyrin (3TMPyP) are known. Some of these are difficult to synthesize and purify. Besides, porphyrins with four negative charges usually remain as dimer in solution.[13] Therefore, it was felt that new water-soluble prophyrins with four positive charges should be prepared for studying the earlier mentioned important biological, biochemical, and photochemical properties. We report here the synthesis of three sulfur containing porphyrins and their physicochemical properties. They are 5,10,15,20-tetrakis[*p*-(methylthio)phenyl]porphyrin (**3**), 5,10,15,20-tetrakis[*p*-(methylsulfonyl)phenyl]-porphyrin (**4**), and 5,10,15,20-tetrakis[(*p*-ethylmethylsulfonio)phenyl]porphyrin perchlorate (**5**). Porphyrin **5** is water-soluble.

Experimental

The porphyrin **3** was obtained by refluxing equimolar amounts of pyrrole (**1**) and *p*-(methylthio)benzaldehyde (**2**). Upon reacting **3** with excess *m*-chloroperbenzoic acid in dichloromethane, porphyrin **4** was obtained. Porphyrin **5** was obtained by refluxing **3** with excess triethyloxonium tetrafluoroborate in DMF, followed by removal of DMF, dissolving the residue in water and saturating with solid $NaClO_4$.

UV-visible absorption and fluorescence emission spectra were measured on a SLM/AMINCO DW2C and SLM 4800S

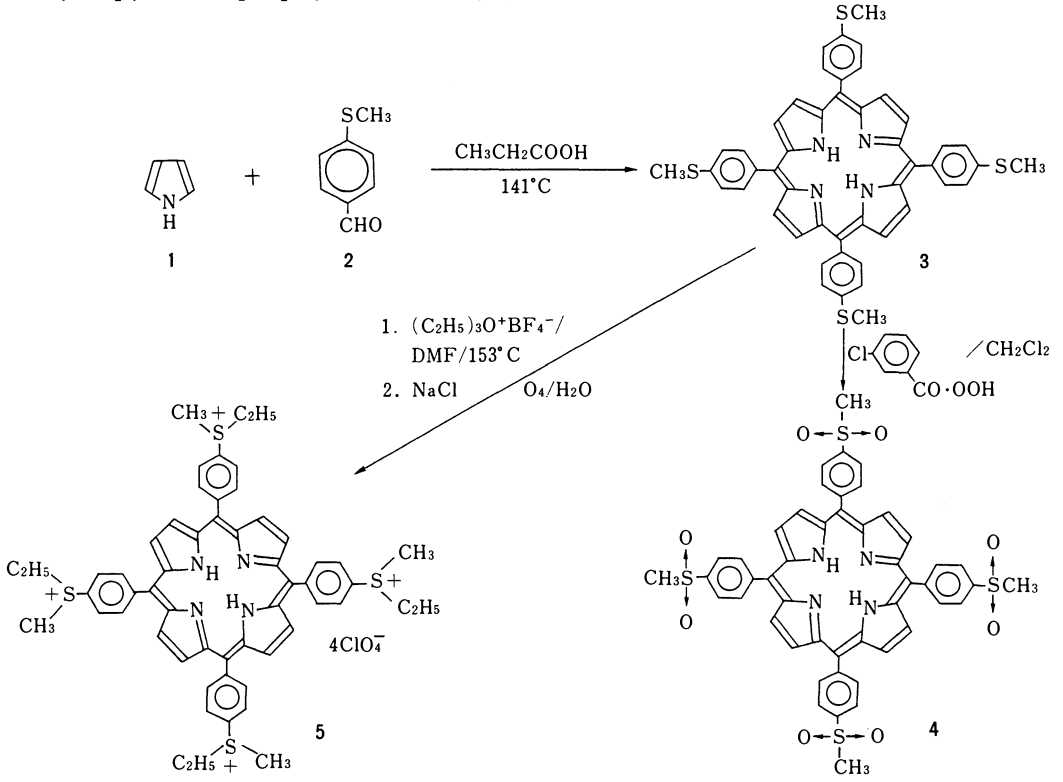

Table 1. UV-Visible Absorption Spectral Data in DMF

Porphyrin	λ_{max}/nm ($\varepsilon\times10^{-3}$)					
3	424(434)	490(9.9)	519(23)	556(18)	594(11)	631(12)
4	424(475)	484(14)	515(32)	549(20)	590(18)	646(13)
5	422(315)	—	516(25)	552(18)	591(16)	646(13)

recording spectrophotometers respectively. ^{1}H NMR spectra were recorded on a Bruker Spectrospin 250 MHz spectrometer. The pK_3[14] values and kinetics of Cu^{2+} insertion[15] are determined by methods described elsewhere. The first and second reduction potentials for the porphyrins were measured by square wave voltammetry (SWV), and verified by cyclic voltammetry. SWV were measured with an EG&G PARC Model 173 Potentiostat/Galvanostat attached to a Model 276 Interface and a Model 178 Electrometer connected to an ACC 178/41 Noise Filter. In addition, an Apple IIe computer with a monitor, an EPSON printer and a software, Model 276 Interface Demonstration Program, Volume II, were used. The Model 276 Interface allowed the potentiostat/galvanostat to be controlled by the Apple IIe computer which incorporates an IEEE-488 Interface. The cyclic voltammograms were measured with an EG&G Model 264A Polarographic Analyzer, an RE 0089 X-Y Recorder and a Model 303A SMDE. A glassy carbon electrode (EG&G PARC Part #G0197) was used as the working electrode throughout. A 10^{-4} M porphyrin solution (1 M=1 mol dm^{-3}) in DMF containing 0.1M TBAP was used for all electrochemical studies. As reference electrode, an aqueous saturated calomel electrode (SCE) was used. The SCE was placed in a bridge tube with vycor tip and was filled with 0.1 M TBAP in DMF. The tip of the bridge tube was placed in the porphyrin solution. A platinum wire was as a counter electrode. Deaeration of the porphyrin solution was achieved by bubbling oxygen-free-argon-saturated with DMF. The binding of porphyrin **5** with HSA was measured by fluorescence quenching of the single tryptophan residue in the protein as it was titrated with the porphyrin solution.[16]

Nitrobenzene and DMF were purified by standard methods and distilled under nitrogen before use. TBAP was recrystallized from ethanol and dried in vacuum at room temperature. All other chemicals were used as purchased.

5,10,15,20-Tetrakis[*p*-(methylthio)phenyl]porphyrin (3) was prepared by refluxing equimolar amounts of distilled pyrrole (**1**) and *p*-(methylthio)benzaldehyde (**2**) (0.1 mol each) in propionic acid, (500 ml), for 0.5 h; the solvent was removed under reduced pressure, the residue was dissolved in methanol, cooled and filtered to obtain the porphyrin. Yield: 8—10%. Found: C, 72.31; H, 5.00; N, 7.08%. Calcd for $C_{48}H_{38}N_4S_4$: C, 72.18; H, 4.76; N, 7.02%. ^{1}H NMR ($CDCl_3$): δ=−2.78 (s, 2H from NH), 2.75 (s, 12H from S-CH_3), 7.62 (d, 8H, phenyl protons ortho to porphyrin ring, J=8.23 Hz), 8.11 (d, 8H, phenyl protons meta to porphyrin ring, J=8.25 Hz), 8.85 (s, 8H, pyrrolic).

5,10,15,20-Tetrakis[*p*-(methylsulfonyl)phenyl]porphyrin (4) was prepared by refluxing **3**, (0.01 mol) in dichloromethane (500 ml) solution with *m*-chloroperbenzoic acid (0.16 mol) for 1 h. and subsequent removal of the solvent as well as excess *m*-chloroperbenzoic acid. Yield: 90%. Found: C, 61.80; H, 4.16; N, 5.77; S, 13.69%. Calcd for $C_{48}H_{38}N_4S_4O_8$: C, 62.00; H, 4.10; N, 6.04; S, 13.82%. ^{1}H NMR ($CDCl_3$) δ=2.85 (s, 2H from NH), 3.09 (s, 12H, S-CH_3), 8.09 (d, 8H phenyl protons ortho to porphyrin ring, J=7.26 Hz), 8.44 (d, 8H, phenyl protons meta to porphyrin ring, J=7.94 Hz), 8.85 (s, 8H, pyrrolic).

5,10,15,20-Tetrakis[*p*-(ethylmethylsulfonio)phenyl]porphyrin Perchlorate (5) was prepared by refluxing **3** (0.01 mol) in DMF (250 ml) with triethyloxonium tetrafluoroborate (0.08 mol) for 2 h. The solvent was removed under reduced pressure. The residue was dissolved in boiling water and solid $NaClO_4$ was added to obtain a precipitate of **5**. It was recrystallized from water and dried. Yield: 85%. Found: C, 51.47; H, 4.64; N, 4.32%. Calcd for $C_{56}H_{58}N_4O_{16}Cl_4S_4$: C, 51.22; H, 4.42; N, 4.27%. ^{1}H NMR (D_2O) δ=−2.79 (s, 2H, from NH), 1.72 (t, 12H, methyl protons of S-CH_2CH_3), 2.06 (q, 8H, methylene protons), 2.76 (S, 12H, S-CH_3), 7.64 (d, 8H, phenyl protons ortho to porphyrin ring, J=6.9 Hz), 8.12 (d, 8H, phenyl protons meta to porphyrin ring J=7.5 Hz), 8.83 (S, 8H, pyrrolic).

Table 2. Corrected Fluorescence Emission Spectral Data in DMF

Porphyrin	$\lambda_{ex\ max}$ /nm	$\lambda_{em\ max}$ /nm	Intensity ratio
3	423	663, 728	10:5.8
4	418	665, 719	10:9.9
5	421	659, 722	10:8.9
TPP[a]	420	655, 720	10:8.0

a) TPP is tetraphenylporphyrin. Included for comparison.

Results and Discussion

In the UV-visible absorption spectrum of porphyrin **5**, a shoulder at around 490 nm, observed in **3** and **4**, is missing (see Table 1). Compared to porphyrin **3**, porphyrin **4** and **5** show a blue shift in most of the absorption bands. In 0.05 M NaOH solution, **5** obeyed Beer's law over concentration range of 2×10^{-4} and 2×10^{-7} M. Therefore it does not dimerize or aggregate in aqueous solution, a property observed with 4TMPyP, 3TMPyP, and 2TMPyP. Unlike **3** and TPP, the two corrected emission maxima for porphyrins **4** and **5** are found to be almost equal in intensity (see Table 2). The pK_3 values (see Table 3) show that porphyrin **5** is more acidic than **3** and **4** as well as other water-soluble porphyrins. A good correlation between the rate of Cu^{2+} ion insertion in TPP and porphyrins **3**, **4**, and **5** is observed with their corresponding pK_3 values as well as their first and second reduction potentials (see Table 3). The lower the basicity and the negative first and second reduction potentials of the porphyrin, the

Table 3. pK_3 Values and Kinetics of Cu^{2+} Insertion, and Reduction Potentials

Porphyrin	pK_3±0.01	$\frac{10^{-3}\times k}{\text{min}^{-1}}$	$-E_{1/2}(1)$[b]	$-E_{1/2}(2)$[c]
TPP	3.99[a]	9.7	1.15	1.57
3	3.99[a]	9.4	1.06	1.54
4	3.20[a]	3.3	0.96	1.44
5	2.81[b]	1.2	0.80	1.13

a) In nitrobenzene, b) in water, c) in DMF, d) volts (±0.005) vs. SCE for the reaction (H_2 porphyrin)$^\circ$ $+e^- \rightarrow$ (H_2 porphyrin)$^-$, e) volts (±0.005) vs. SCE for the reaction (H_2 Porphyrin)$^-+e^- \rightarrow$ (H_2 porphyrin)$^{2-}$.

lower is the rate of Cu^{2+} insertion in it.

The binding of the water-soluble porphyrin **5** was studied with HSA in 0.1 M phosphate buffer, pH 7.2, and compared to the results obtained with other monomeric water soluble porphyrins,. Each of these porphyrins bound 1 : 1 with HSA. The dissociation constants for the porphyrin-HSA complex to HSA and the corresponding porphyrins, **5**, 4TMPyP, 3TMPyP, and 2TMPyP are found to 3.26, 2.20, 2.08, and 2.22 M respectively.

Synthesis of New Naturally Occurring 4-Phenyl-2*H*-1-benzopyran-2-ones

Virinder S. PARMAR,* Rajni JAIN, and Suddham SINGH
Department of Chemistry, University of Delhi, Delhi-110007, India
(Received February 9, 1987)

Synopsis. 5,7-Dimethoxy-4-(4-hydroxyphenyl)-2*H*-1-benzopyran-2-one and 5,7-dimethoxy-4-(4-methoxyphenyl)-2*H*-1-benzopyran-2-one, two new neoflavonoids occurring in *Courtarea hexandra* have been synthesized via Pechmann condensation. Attempts made to synthesize another 4-arylcoumarin, 5-hydroxy-7-methoxy-4-(2,5-dihydroxyphenyl)-2*H*-1-benzopyran-2-one, constituent of the same plant, led to the formation of the hitherto unknown 2-ethoxy-6-hydroxy-4*H*-1-benzopyran-4-one.

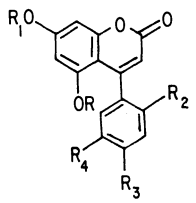
A few 4-phenylcoumarins having rare type of oxygenation pattern have recently been isolated[1,2] from the caulis of *Courtarea hexandra,* a folk medicinal plant used in Brazil as an antimalarial and antidiabetic agent. The structures to these compounds were assigned on the basis of their spectral data alone. In order to provide confirmation to the proposed structures of the natural products, we have attempted the syntheses of three of them (**1** and **2**,[1] and **3**[2]) and those of their dihydroxy analogues via Pechmann condensation of phloroglucinol and corresponding suitably substituted ethyl benzoylacetate.

Results and Discussion

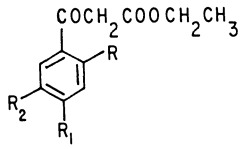
Ethyl 4-(benzyloxy)benzoylacetate (**4**) and ethyl 4-methoxybenzoylacetate (**6**) were prepared by treating 4-(benzyloxy)acetophenone[3] and 4-methoxyacetophenone,[4] respectively with diethyl carbonate in the presence of sodium hydride; **4** and **6** were fully characterized from their spectral data. Pechmann condensation of **4** with phloroglucine yielded 5,7-dihydroxy-4-(4-hydroxyphenyl)-2*H*-1-benzopyran-2-one (**5**), which on methylation with diazomethane yielded mainly the coumarin **1** along with a small amount of the coumarin **2**. The IR, UV, and ^{1}H NMR spectral data of **1** and **5** supported their structures. Similarly, the ester **6** on condensation with phloroglucine yielded the 4-phenylcoumarin **7**, which on methylation with dimethyl sulfate gave 5,7-dimethoxy-4-(4-methoxyphenyl)-2*H*-1-benzopyran-2-one (**2**); **2** and **7** were fully characterized from their spectral data. The mp behavior, and UV, IR, and ^{1}H NMR spectral data of our synthetic **1** and **2** were in agreement with those of the corresponding natural samples,[1] thus confirming the structures of the natural products occurring in *Courtarea hexandra.* However, a direct comparison of our synthetic samples with the natural samples could not be done because of the non-availability of the latter with us.

For the preparation of 5-hydroxy-7-methoxy-4-(2,5-dihydroxyphenyl)-2*H*-1-benzopyran-2-one (**3**),[2] ethyl 2,5-bis(benzyloxy)benzoylacetate (**8**), prepared by the reaction of 2,5-bis(benzyloxy)acetophenone[5] with diethyl carbonate in the presence of NaH was condensed with phloroglucine, as well as with mono-*O*-methylphloroglucine[6] under four different experimental conditions. The condensations in the presence of H_3PO_4, $POCl_3$, and concd H_2SO_4 led to the formation of only tarry materials, from which no crystalline substance could be isolated. Condensation in the presence of ethanolic HCl, in both the cases yielded the compound **9**, quite different from the required coumarin **3**; structure of **9** was established from a detailed study of its UV, IR, ^{1}H NMR, and mass spectra.

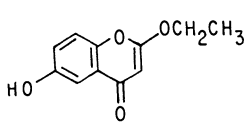
The UV absorption maxima of **9** at 202, 218, 258 (sh), 267, 280 (sh), and 326 nm suggested it to be a



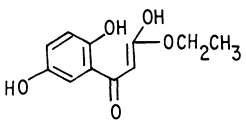
(1) $R=R_1=CH_3$, $R_2=R_4=H$, $R_3=OH$
(2) $R=R_1=CH_3$, $R_2=R_4=H$, $R_3=OCH_3$
(3) $R=R_3=H$, $R_1=CH_3$, $R_2=R_4=OH$
(5) $R=R_1=R_2=R_4=H$, $R_3=OH$
(7) $R=R_1=R_2=R_4=H$, $R_3=OCH_3$



(4) $R=R_2=H$, $R_1=OCH_2C_6H_5$
(6) $R=R_2=H$, $R_1=OCH_3$
(8) $R=R_2=OCH_2C_6H_5$, $R_1=H$



(9)



(10)

chromone; the IR spectra supported this and further indicated **9** to be an alkoxy- and hydroxy-substituted chromone as it exhibited strong absorptions at 3200, 1660, 1623, and 1280 cm^{-1}. A bathochromic shift of 38 nm in its λ_{max} in the presence of NaOMe and the presence of a D_2O exchangeable singlet (1H) at δ 9.80, a triplet (for 3H) at δ 1.40, and a quartet (for 2H) at δ 4.15 in its ^1H NMR spectrum confirmed **9** to be monohydroxy-monoethoxy-substituted. As there was no change in the λ_{max} of **9** on addition of NaOAc, the position of -OH group was indicated to be either C-6 or C-8; the location of -OH at C-6 was substantiated by the chemical shift values of the three protons in the aromatic ring in the ^1H NMR spectrum (a multiplet for 2H at δ 7.15 and an ortho-coupled doublet for 1H at δ 7.26). These data suggested **9** to be the hitherto unknown 2-ethoxy-6-hydroxy-4*H*-1-benzopyran-4-one; this structure was fully confirmed by its mass spectrum, which exhibited prominent peaks at *m/z* 207 $(M+1)^+$, 206 (M^+), 178 $(M-CO)^+$, 150 $(M-CO-C_2H_4)^+$, 137 (A_1+H), 136 $(A_1)^+$, 108 (A_1-CO) and 80 $(A_1-CO-CO)$. We believe that **9** is formed via the intermediate **10**, derived from the ester **8** under strongly acidic conditions of the experiment.

Experimental

All melting points were taken on a Nalge micro melting point apparatus and are uncorrected. Silica gel was used for all thin-layer and column chromatographic separations. UV spectra were recorded in methanol on a Perkin Elmer 554 spectrophotometer. IR spectra were recorded on Shimadzu model 535 spectrophotometer and ^1H NMR spectra on 90 MHz Perkin Elmer R-32 and 200 MHz Jeol JNM FX-200 FT NMR spectrometers using TMS as the internal standard. The mass spectra were recorded on a Varian Mat 311A instrument.

Ethyl 4-(Benzyloxy)benzoylacetate (4). To a vigorously stirred suspension of sodium hydride (4g) in dry ether (100 ml) containing diethyl carbonate (5.48 ml), a solution of 4-(benzyloxy)acetophenone[3] (5 g) in dry benzene (100 ml) was added dropwise during the course of 6 h. The mixture was then refluxed for 30 h, cooled, treated with ice and acidified with dilute hydrochloric acid; the organic layer that separated was washed with sodium hydrogen carbonate solution and dried. Residue obtained on removal of benzene and ether was macerated with petrol to remove unreacted diethyl carbonate; ethyl 4-(benzyloxy)benzoylacetate was obtained as an oil (**4**, 4 g); IR (Nujol) ν_{max}: 1735, 1660, 1260, 1105, 1030, and 830 cm^{-1}; UV λ_{max}: 210, 274 nm; ^1H NMR (90 MHz, $CDCl_3$): δ=1.25 (3H, t, *J*=7 Hz, $-COOCH_2C\underline{H}_3$), 3.90 (2H, s, $-COC\underline{H}_2COOC_2H_5$), 4.20 (2H, q, *J*=7 Hz, $-COOC\underline{H}_2CH_3$), 5.10 (2H, s, $-OC\underline{H}_2C_6H_5$), 7.00 (2H, d, *J*=8.5 Hz, H-3 and H-5), 7.35 (5H, s, $-OCH_2C_6\underline{H}_5$), and 7.85 (2H, d, *J*=8.5 Hz, H-2 and H-6). Found: C, 72.80; H, 6.40%; Calcd for $C_{18}H_{18}O_4$: C, 72.48; H, 6.04%.

5,7-Dihydroxy-4-(4-hydroxyphenyl)-2*H*-1-benzopyran-2-one (5). A cooled suspension of ethey 4-(benzyloxy)benzoylacetate (**4**, 1.5 g) and phloroglucine (0.71 g) in absolute ethanol (50 ml) was saturated with dry HCl gas (5.5 h). The reaction mixture was left at 28 °C for 2 d, water was added and the solution was concentrated in vacuo and cooled, when a yellowish-orange solid precipitated. It was filtered and crystallized from methanol as yellow crystals (**5**, 500 mg), mp 293—294 °C; IR (KBr) ν_{max}: 3530, 3235, 1660, 1550, 1480, 1360, 1020, and 830 cm^{-1}; UV λ_{max} (log ε): 260 (3.95), 322 (3.98); +NaOMe: 272, 304, 368 nm; ^1H NMR (90 MHz, CD_3COCD_3): δ=5.70 (1H, s, H-3), 6.25 (1H, s, H-6), 6.30 (1H, s, H-8), 6.80 (2H, d, *J*=8.5 Hz, H-3′ and H-5′), 7.23 (2H, d, *J*=8.5 Hz, H-2′ and H-6′), 8.50 (1H, s, -OH), 8.60 (1H, s, -OH).

5,7-Dimethoxy-4-(4-hydroxyphenyl)-2*H*-1-benzopyran-2-one (1). To a solution of (**5**, 100 mg) in methanol (8 ml), a saturated solution of diazomethane in ether (7 ml) was added under stirring. After 45 min, the reaction mixture was evaporated in vacuo and the residue was column-chromatographed using benzene–ethyl acetate (4 : 1) as eluent to give **1** (40 mg); mp 214—216 °C (mp of the natural product[1] 214—215 °C); IR (KBr) ν_{max}: 3300, 1706, 1612, 1159, 1048, 962, and 835 cm^{-1}; UV λ_{max} (log ε): 254 (4.09), 322 (4.05); +NaOMe: 254, 328, 372 nm; ^1H NMR (200 MHz, CD_3COCD_3): δ=3.56 (3H, s, C-5-OMe), 3.96 (3H, s, C-7-OMe), 5.84 (1H, s, H-3), 6.40 (1H, d, *J*=2.5 Hz, H-6), 6.56 (1H, d, *J*=2.5 Hz, H-8), 6.92 (2H, d, *J*=8.5 Hz, H-3′ and H-5′), 7.16 (2H, d, *J*=8.5 Hz, H-2′ and H-6′), 8.56 (1H, s, C-4′-OH). Fuund: C, 68.20; H, 5.00%; Calcd for $C_{17}H_{14}O_5$: C, 68.46; H, 4.70%.

Ethyl 4-Methoxybenzoylacetate (6). To a vigorously stirred suspension of sodium hydride (5.8 g) in dry ether (100 ml), diethyl carbonate (15 ml) was added in one lot and to this mixture, a solution of 4-methoxyacetophenone (9 g)[4] in dry ether (100 ml) was added dropwise during 6 h. The mixture was then refluxed for 30 h, cooled, treated with ice and acidified with dil HCl. The organic layer was separated, washed with sodium hydrogencarbonate solution, dried, concentrated and treated with dry hexane when **6** was obtained as an oil (8 g); IR (Nujol) ν_{max}: 1730, 1670, 1600, 1360, 1250, 1160, 1100, 1020, and 830 cm^{-1}; UV λ_{max}: 216, 276 nm; ^1H NMR (90 MHz, $CDCl_3$): δ=1.25 (3H, t, *J*=7 Hz, $-COOCH_2C\underline{H}_3$), 3.80 (3H, s, $-OCH_3$), 3.90 (2H, s, $-OC\underline{H}_2-COOCH_2CH_3$), 4.20 (2H, q, *J*=7 Hz, $-COOC\underline{H}_2CH_3$), 6.85 (2H, d, *J*=8.5 Hz, H-3 and H-5), and 7.85 (2H, d, *J*=8.5 Hz, H-2 and H-6). Found: C, 65.10%; H, 5.90%; Calcd for $C_{12}H_{14}O_4$: C, 64.86%; H, 6.31%.

5,7-Dihydroxy-4-(4-methoxyphenyl)-2*H*-1-benzopyran-2-one (7). Through a cooled solution of **6** (4 g) and phloroglucine (2.25 g) in absolute ethanol (100 ml), a stream of dry HCl gas was passed for 6 h and the reaction mixture was left at 30 °C for 3 d. Water was added and the solution was concentrated in vacuo. The solid obtained was filtered, washed with water and crystallized from methanol as yellowish brown solid (2.5 g); mp 256—258 °C; IR (Nujol) ν_{max}: 3300, 3190, 1688, 1620, 1595, 1510, 1170, 820, and 700 cm^{-1}; UV λ_{max} (log ε): 260 (4.07), 315 (4.05); +NaOMe: 262, 315, 380 nm; ^1H NMR (90 MHz, DMSO-d_6): δ=3.82 (3H, s, C-4′-OCH_3), 5.76 (1H, s, H-3), 6.28 (1H, d, *J*=2.5 Hz, H-6), 6.35 (1H, d, *J*=2.5 Hz, H-8), 6.93 (2H, d, *J*=8.5 Hz, H-3′ and H-5′), 7.32 (2H, d, *J*=8.5 Hz, H-2′ and H-6′), and 9.7 (1H, s, -OH). Found: C, 68.00; H, 4.60%; Calcd for $C_{16}H_{12}O_5$: C, 67.60; H, 4.23%.

5,7-Dimethoxy-4-(4-methoxyphenyl)-2*H*-1-benzopyran-2-one (2). A solution of **7** (0.5 g) in acetone (50 ml) was refluxed with potassium carbonate (1 g) and dimethyl sulfate (0.23 ml) for 3 h. Potassium salts were filtered off and washed with hot acetone. The combined filtrate and washings were concentrated and treated with ice. The solid obtained was filtered, washed with water and dried. It crystallized from methanol as yellowish-brown crystals **2** (0.4 g), mp 151—152 °C (mp of the natural product[1] 151—152 °C); IR (Nujol) ν_{max}: 1710, 1620, 1595, 1158, 1100, 1050, 940, 860, and 830 cm^{-1}; UV λ_{max} (log ε): 255 (4.04), 315 (4.00); ^1H NMR (90 MHz, $CDCl_3$): δ=3.50 (3H, s, C-5-OCH_3), 3.86 (6H, s, C-7 and C-4′-OCH_3), 5.96 (1H, s, H-3), 6.22 (1H, d, *J*=2.5 Hz, H-6), 6.50 (1H, d, *J*=2.5 Hz, H-8), 6.87 (2H, d, *J*=8.5 Hz, H-3′ and H-5′), and 7.20 (2H, d, *J*=8.5 Hz, H-2′ and H-6′).

Ethyl 2,5-Bis(benzyloxy)benzoylacetate (8). To a vigorously stirred suspension of NaH (10 g) in dry ether (100 ml) containing diethyl carbonate (6.2 ml), a solution of 2,5-bis(benzyloxy)acetophenone[5] (10 g) in dry benzene (100 ml)

was added dropwise during the course of 6 h. The mixture was refluxed for 36 h. Usual work-up gave the ester **8** as an oil (8 g); IR (KBr) ν_{max}: 2910, 2850, 1730, 1660, 1600, 1460, 1380, 1200, 1020, 810, and 740 cm^{-1}; UV λ_{max}: 210, 286, 334 nm; ^1H NMR (90 MHz, $CDCl_3$): δ=1.23 (t, J=7H, 3H, $-COOCH_2C\underline{H}_3$), 4.00 (s, 2H, $-COC\underline{H}_2COOCH_2CH_3$), 4.10 (q, J=7 Hz, 2H, $-COOC\underline{H}_2CH_3$), 5.03 (s, 2H, $-OC\underline{H}_2C_6H_5$), 5.11 (s, 2H, $-OC\underline{H}_2C_6H_5$), 7.05 (m, 2H, H-3, and H-4), 7.42 (m, 10H, $2\times-OCH_2C_6\underline{H}_5$), and 7.50 (d, 1H, J=2.5 Hz, H-6). Found: C, 73.90; H, 6.20%; Calcd for $C_{25}H_{24}O_5$: C, 74.26; H, 5.94%.

2-Ethoxy-6-hydroxy-4*H*-1-benzopyran-4-one (9). Through a cooled suspension of the ester **8** (2 g) and phloroglucine (0.75 g) in absolute ethanol (100 ml), a stream of dry HCl gas was passed for 6 h. The reaction mixture was left at 30 °C for 4 d. After usual work up, only one solid compound could be isolated which crystallized from methanol as yellow crystals **9** (100 mg), mp 228—230 °C; IR (Nujol) ν_{max}: 3200, 1660, 1623, 1615, 1560, 1500, 1460, 1410, 1380, 1280, 1230, 1190, 1082, 970, 830, 807, and 710 cm^{-1}; UV λ_{max} (log ε): 202 (4.25), 218 (4.29), 258 (sh) (3.85), 267 (3.89), 280 (sh) (3.76), 326 (3.57); +$AlCl_3$: 202, 218, 258 (sh), 267, 280 (sh), 326; +NaOAc: 205, 210, 258 (sh), 267, 280 (sh), 326; +NaOAc/Boric Acid: 210, 258 (sh), 267, 280 (sh), 326; +NaOMe: 202, 237, 274, 288, 364 nm; ^1H NMR (200 MHz, DMSO-d_6): δ=1.40 (t, J=7 Hz, 3H, $-OCH_2C\underline{H}_3$), 4.15 (q, J=7 Hz, 2H, $-OC\underline{H}_2CH_3$), 5.80 (s, 1H, H-3), 7.15 (m, 2H, H-5 and H-7), 7.26 (d, J=8 Hz, 1H, H-8), and 9.80 (s, 1H, -OH); EIMS m/z (%): 207 (9), 206 (M^+) (64), 178 $(M-CO)^+$ (10.5), 150 $(M-CO-C_2H_2)^+$ (5), 149 $(M-CO-C_2H_2-H)^+$ (3.5), 137 $(A_1+H)^+$ (12.8), 136 $(A_1)^+$ (100), 134 $(178-CH_2{=}CHOH)^+$ (10.5), 121 (149—CO) (3.5), 108 $(A_1-CO)^+$ (12.8), 80 $(A_1-CO-CO)$ (7). Found: C, 64.00; H, 4.50%; Calcd for $C_{11}H_{10}O_4$; C, 64.08; H, 4.85%.

The condensation of the ester **8** with monomethyl ether of phloroglucine[6] by the procedure given above yielded only **9**.

Two of us (RJ and SS) thank the CSIR, New Delhi for the award of Senior Research Fellowships.

Mixed Colloidal Dispersions of Silica and Hematite

Kunio ESUMI,* Hiroyuki IDOGAWA, and Kenjiro MEGURO
Department of Applied Chemistry, Institute of Colloid and Interface Science,
Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received November 4, 1987)

The colloidal behavior of mixed dispersions containing hematite (diameter=138.9 nm) and silica (diameter=7.0 nm) has been studied by measuring the stability ratio, zeta potential, and particle size. When various particle numbers of silica were added to a constant particle number of hematite, different colloidal behavior was observed, depending on the pH. In a pH region where the two solids were oppositely charged, hematite particles showed a dispersion-coagulation-redispersion process with increasing particle number of silica, resulting in a coating layer of silica particles on the hematite surface. On the other hand, in a region where both solids were negative, the addition of silica enhanced the stability of the hematite.

When an aqueous colloidal dispersion contains solid particles of more than one kind, it is expected that the various solids will have different surface charges in the solution and complicate interactions between their solids occur. Under these conditions, hetero coagulation due to the interaction of opposite charges can take place. The experimental testing of the theories of hetero coagulation proposed by Derjaguin,[1] Hogg et al.,[2] and Wiese and Healy[3] has been attempted by several workers.[4-6]

The phenomenon of hetero coagulation can be applied in the preparation of oxide supported metal catalysts. An oxide and an ultra fine particle of catalyst are mixed in aqueous solution. By adjusting the pH so that the oxide and the particle of catalyst are oppositely charged, it is possible to produce a well-spaced layer of catalyst particles on the oxide particle. However, many hetero coagulation studies have been limited to solid particles having similar particle size.

The aim of this work is to study the colloidal dispersion behavior of mixed silica and hematite spherical particles with narrow size distribution and a considerable difference in particle size. The mixed colloidal properties were characterized by measurement of the zeta potential, the stability ratio and the particle size.

Experimental

Materials. As solid particles, hematite, and silica were used.

Spherical hematite particles with a narrow size distribution were prepared by essentially the same procedure as Matijević and Scheiner[7] described. The 2×10^{-2} mol dm^{-3} of $FeCl_3$ aqueous solution was adjusted to pH 3.1 with HCl. The solution was then aged for 24 h at 100 °C. After cooling to room temperature, the collected particles were washed several times with aqueous $HClO_4$ solution (pH 3.1) to remove chloride and iron(III) ions. The particles were then redispersed in ion-exchanged water to be used as a stock sol. The final stock sol had a concentration of 3.20 mg cm^{-3}, as determined directly by dry-weight measurement. The particle diameter was determined to 138.9 nm by transmission electron microscopy.

Well monodispersed spherical silica was obtained from Japan Aerosil Co. The particle diameter was determined to 7.0 nm.

Procedure. Zeta potentials were measured using a Laser-Zee meter Model 500(Pen Kem Inc.).

The particle size of the mixed dispersion was measured using an Autosizer Model 700(Malvern Co., Ltd.).

Coagulation kinetics were followed using a standard turbidimetric technique,[8] in which the change of absorbance at 540 nm as a function of time was recorded continuously on a 220A Hitachi Spectrophotometer. As soon as the hematite sols had been mixed with the silica sols, the absorbance of the mixed dispersions was recorded and the initial slope of the absorbance vs. time curve was obtained. The stability ratio (W) was calculated from the ratio of the rapid-coagulation (k_0) to the slow-coagulation rate (k) of the sols:

$$W = k_0/k$$

The stability of the mixed dispersions was also evaluated from the magnitude of the absorbance after 12 h standing of the mixed dispersions, where the absorbance was also taken at 540 nm.

All measurements were carried out in 1×10^{-2} mol dm^{-3} sodium nitrate to keep the ionic strength constant. Nitric acid and sodium hydroxide were used to adjust the pH of these dispersions.

Results and Discussion

Figure 1 shows the zeta potentials of hematite and silica as a function of the pH and indicates that their isoelectric points are 7.9 for hematite and 3.1 for silica. To elucidate the behavior of colloidal mixed dispersions of hematite and silica, four different pH values were selected: pH 3.0, 4.0, 5.5, and 10.0. At pH 3.0, the zeta potential of the silica was almost zero, while that of the hematite was positive. At pH 4.0 and 5.5, the hematite and silica had opposite zeta potential values and at pH 10.0, they both showed negative zeta potentials. By using mixtures of these monodispersed particles with different isoelectric points, it is possible to study the interactions of dissimilar electrical double layers around spherical particles with different particle size.

The stability ratio (W) and absorbance of the mixed dispersions are shown in Fig. 2 in which the various

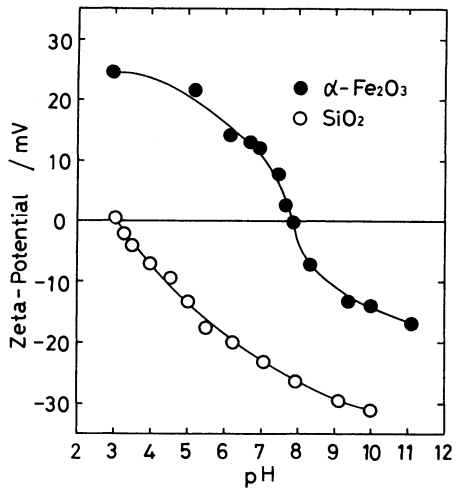

Fig. 1. Zeta potentials of hematite and silica as a function of pH.

particle numbers of silica are added to a constant particle number of hematite at four different pH. Here, the turbidity was mainly attributed to hematite particles because the particle size of the silica was too small to provide an appropriate turbidity value. Further, the silica particles were very stable over the entire pH region. In the case of hematite alone, the stability ratio was almost one at pH 3.0 and 10.0, whereas that at pH 4.0 and 5.5 was more than eight. When silica particles were added to the hematite dispersion system, the stability ratio varied, depending on the pH. At pH 3.0, the stability ratio was almost constant, i.e., one, against various particle numbers of silica. On the other hand, at pH 4.0 and 5.5, the stability ratio decreased upon addition of the silica particles. Further addition of silica considerably increased the stability ratio and a maximum stability ratio at pH 5.5 was greater than that at pH 4.0. At pH 10.0, the stability ratio upon addition of the silica increased gradually up to a certain amount of added silica (ca. 180). Thus, hematite particles exhibited the

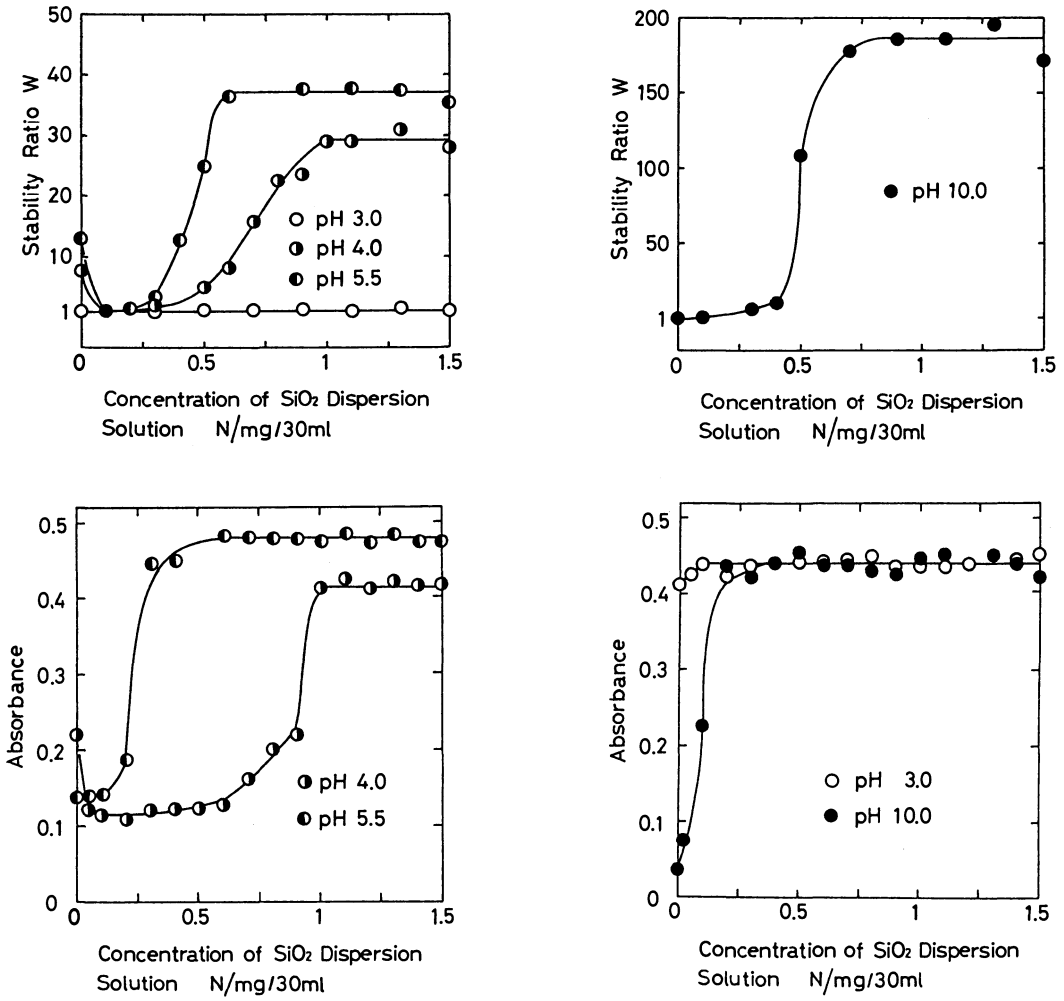

Fig. 2. Variations of stability ratio and optical density in mixed dispersion of hematite and silica with increasing amounts of silica: amount of hematite, 0.64 mg/30 ml.

dispersion–coagulation–redispersion process on addition of silica at pH 4.0 and 5.5. The optical density of the mixed dispersion after 12 h standing was also measured to evaluate the colloidal stability of mixed dispersion. The result is also shown in Fig. 2 which indicates that the behavior of the optical density upon addition of silica almost coincides with the stability ratio except at pH 3.0. At pH 3.0, the optical density of the mixed dispersions was high upon addition of silica although the stability ratio was almost unity. In order to clarify the relationship between the pH and the zeta potential in the mixed dispersion, the zeta potential of the mixed dispersion was plotted as a function of pH (Fig. 3). It can be seen that the zeta potential is significantly altered upon addition of silica at different pH. Further, it is noteworthy that the zeta potential values of the mixed dispersion upon addition of more than 0.5 mg/30 ml of silica at each pH coincide with that of silica alone at the corresponding pH. This implies that a coating layer of silica particles is formed on the hematite particle.

The change in mean particle size of the mixed dispersions is shown in Fig. 4. Here, the mean particle size is mainly considered to be due to hematite or silica coated hematite. At pH 4.0, 5.5, and 10.0, the behaviors in mean particle size of mixed dispersions are in fair agreement with the stability ratio and optical density. However, at pH 3.0, the mean particle size hardly changed upon addition of silica. This can be interpreted as follows: since the silica particles form a three-dimentional chain structure throughout the volume of the aqueous solution, this structure can generate a well dispersion state of hematite. The rate of structure formation will be remarkedly influenced by the time which the silica particles exist in aqueous solution. That is, during the measurement of the

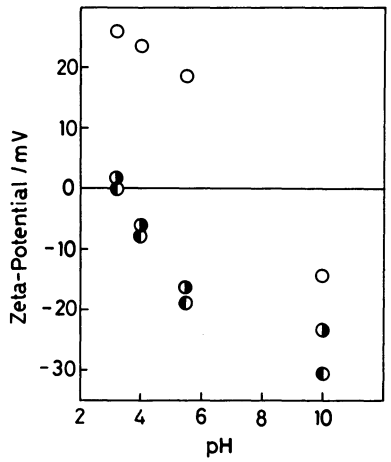

Fig. 3. Variation of zeta potential of mixed dispersion of hematite and silica with different additive amounts of silica at pH 3.0, 4.0, 5.5, and 10.0: concentration of silica; (○) 0, (◑) 0.1, (◐) 0.5 mg/30 ml.

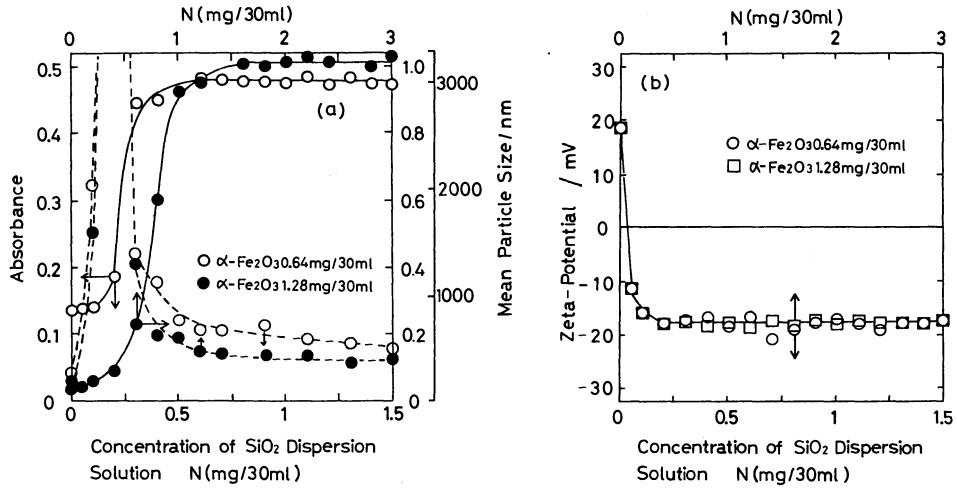

Fig. 5. Effect of amount of hematite on mixed dispersion of hematite and silica: (a) absorbance; solid line, mean particle size; dotted line (b) zeta potential.

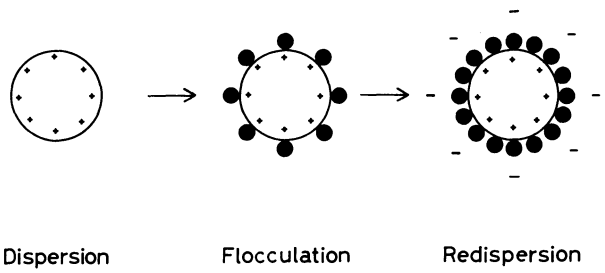

Fig. 6. A model for mechanism of coagulation and dispersion of mixed hematite and silica.

stability ratio, the structure formation is not fully established so that the stability ratio remains unity. On the other hand, during the measurement of the mean particle size and absorbance, sufficient time will be provided for the structure formation to stabilize the hematite particles.

Further, the amounts of hematite was varied and its effect on the mixed dispersion was studied. The result is shown at pH 5.5 in Fig. 5. Even using different amounts of hematite, the behavior in zeta potential, particle size and absorbance at pH 5.5 was similar to the result described before. Similar trends were observed for the other pH.

From the above results, the following mechanisms of mixed dispersions are proposed: at pH 4.0 and 5.5, silica particles are adsorbed on hematite particle due to electrical attraction forces since silica and hematite particles are oppositely charged. In the region where the zeta potential of the mixed dispersion becomes zero and the mean particle size becomes significantly large, the mixed dispersion leads to a coagulated state. On further addition of silica, a significant amount of silica particles are adsorbed on to the hematite particle and both the zeta potential and the mean particle size decrease appreciably, resulting in redispersion of the mixed coagulate. This model is presented in Fig. 6. Similar behavior was reported with latex and silica mixtures where the much smaller silica particles also adsorbed on the latex to form a monolayer and caused the latex to behave like a silica sol.[9]

In conclusion, when hematite and silica are oppositely charged, silica particles with a small particle size are adsorbed on hematite particles, resulting in coagulation of the hematite particles. Upon further addition of silica the coagulated hematite particles are redispersed due to considerable adsorption of silica particles on hematite. This mechanism is demonstrated by measurements of the stability ratio, the zeta potential and the particle size.

Liquid-Phase Dehydrogenation of Methanol with Homogeneous Ruthenium Complex Catalysts

Hiroaki ITAGAKI, Sumio SHINODA,† and Yasukazu SAITO*
Institute of Industrial Science, University of Tokyo,
22-1 Roppongi 7 Chome, Minato-ku, Tokyo 106
(Received November 17, 1987)

Catalytic dehydrogenation of methanol proceeded with homogeneous ruthenium(II) complexes, yielding formaldehyde and dihydrogen as primary products under refluxing conditions of the solution. The effects of additives on the initial reaction rate were examined for lithium chloride, lithium acetate, acetic acid and ethyldiphenylphosphine. A catalyst complex, $[Ru(OAc)Cl(PEtPh_2)_3]$, was deactivated gradually by the displacement of the bidentate OAc ligand with H and CO ligands during the reaction. These cis-disposed sites would be used for splitting the C-H bonds. A catalytic reaction cycle is proposed, in which such processes are included as solvolysis of the catalyst complex, β-H elimination from the OCH_3 ligand and attack of acetic acid on the hydride intermediate to generate dihydrogen.

Dehydrogenation of methanol, yielding formaldehyde and dihydrogen, is thermodynamically less favorable ($\Delta G°=64.0$ kJ mol^{-1}) than oxidative dehydrogenation ($\Delta G°=-173.2$ kJ mol^{-1}). The endothermic reaction ($\Delta H°=130.4$ kJ mol^{-1}) of Eq. 1 proceeds, however, in the liquid phase under very mild conditions, since most of the product dihydrogen is removed from the reaction medium owing to its limited solubility.[1]

$$CH_3OH \longrightarrow HCHO + H_2 \quad (1)$$

Homogeneous catalysts for alcohol dehydrogenation evolving dihydrogen have been extensively studied both thermally[2] and photochemically[3] except for methanol. Dobson and Robinson proposed a reaction mechanism for (trifluoroacetato)ruthenium(II) complexes, $[Ru(OAc_F)_2CO(PPh_3)_2]$,[2c] the catalytic activity of which was compared later among a series of (trifluoroacetato)ruthenium(II) complexes.[2e]

As for the methanol photocatalytic dehydrogenation was explored to give not only carbon monoxide[3d] but also ethylene glycol,[4a-c] dimethoxymethane,[4b,c] and products related to its reaction counterpart. Homogeneous catalytic dehydrogenation of methanol to yield organic products without photoirradiation has never been reported until some ruthenium(II) complexes were revealed to be active. Formaldehyde was formed under refluxing conditions (65 °C) with $[Ru_2(OAc)_4Cl]$ mixed with tertiary phosphine, or with $[Ru(OAc)Cl(PEtPh_2)_3]$.[5] Independently, the catalytic activity of $[RuCl_2(PPh_3)_3]$ was shown by Smith et al. to form methyl formate as the main product together with dimethoxymethane at 150 °C in good stoichiometric correlation with dihydrogen.[6]

In the present work, a reaction scheme is given for the acetato and phosphine-coordinated ruthenium(II) complexes based on the experimental details concerning the time course of the product distribution, the effect of additives on the initial rates and the structural change of a catalyst complex during deactivation.

Experimental

Procedure. All the operations of catalyst syntheses and dehydrogenation reactions were conducted under argon or nitrogen atmosphere. Degassing by repeated freeze-pump-thaw cycles was necessary for methanol, as the catalyst complexes were air sensitive in solution. The gas evolution reaction from the solution of $[Ru_2(OAc)_4Cl]$ (0.0474 g, 0.1 mmol) admixed with triphenylphosphine (0.1836 g, 0.7 mmol) (designated as 'composite-type' hereafter) or of $[Ru(OAc)Cl(PEtPh_2)_3]$ (0.1677 g, 0.2 mmol) in methanol (200 ml) was performed under refluxing conditions in a flask (500 ml) connected to a gas buret (50 ml) through a condenser. All the products, other than dihydrogen, were condensed by using an ethylene glycol/water mixture cooled to −15—−20 °C with a circulating cooler (Taiyo Kagaku Kogyo Ltd., Type CML-III). The volume increase due to the gas evolution was started to plot against the elapsed time after thermal equilibrium had been attained in the closed reaction system at atmospheric pressure. After the reaction, the solution was chilled with ice in order to perform GC analysis of the liquid components without loss by evaporation of dehydrogenated products.

Spectra. Infared spectra using pressed potassium bromide pellets were taken on a Hitachi 260-10 spectrophotometer from 650 to 4000 cm^{-1} with polystyrene reference. Proton, $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$NMR spectra were recorded on a Jeol JNM-FX60Q spectrometer operating in the FT mode at 59.80, 24.21, and 15.04 MHz, respectively. ^{31}P chemical shifts were referenced to an external standard of 85% H_3PO_4, with the downfield chemical shifts taken to be positive, whereas ^1H and ^{13}C NMR spectra were referenced internally to the CH_2Cl_2 solvent and converted to the TMS scale by using the CH_2Cl_2 chemical shifts of +5.3 and +54.2 ppm, respectively. GC analysis was performed on a Yanagimoto G-3800 gas chromatograph using GP-54 and active carbon culumns. The sensitivity of formaldehyde detection was enhanced by adopting a methane converter with the Ru/Al_2O_3 catalyst, which was added to a Porapak-T column in the Ohkura Rikagaku GC 103 gas chromatograph.

† Present address: Department of Industrial Chemistry, Faculty of Engineering, Seikei University, 3-1 Kichijyoji-Kitamachi 3 Chome, Musashino-Shi, Tokyo 180.

Syntheses. $[Ru_2(OAc)_4Cl]$ was prepared by the literature method.[7] Ruthenium(III) trichloride trihydrate and tertiary phosphine from commercial sources were used without further purification.

$[Ru(OAc)Cl(PPh_3)_3]$ was synthesized from $[Ru_2(OAc)_4Cl]$ and PPh_3. A methanol (500 ml) solution of $[Ru_2(OAc)_4Cl]$ (0.437 g, 1.00 mmol) and PPh_3 (1.836 g, 7.00 mmol) was refluxed for 1 h, after which part of the solvent methanol was removed by evacuation. When the solution was allowed to stand at −20 °C overnight, an orange crystal was precipitated. Its isolation was performed by decantation, washing with methanol, and drying in vacuo. Yield 0.81 g, 82%. Found: C, 70.61; H, 4.94; P, 9.20%. Calcd for $C_{56}H_{48}P_3O_2ClRu$: C, 68.46; H, 4.92; P, 9.46%. ^{31}P NMR: δ=43.8(2P) and 77.7(1P), J(PP) 27.3 Hz; ^{13}C(OAc): δ=182.2 and 24.3.

$[Ru(OAc)Cl(PEtPh_2)_3]$ was synthesized in a similar manner. Yield 0.58 g, 69%. Found: C, 63.03; H, 5.62; P, 10.81%. Calcd for $C_{44}H_{48}P_3O_2ClRu$: C, 63.04; H, 5.77; P, 10.84%. ^{31}P NMR: δ=40.0; ^{13}C(OAc): δ=187.1 and 25.8.

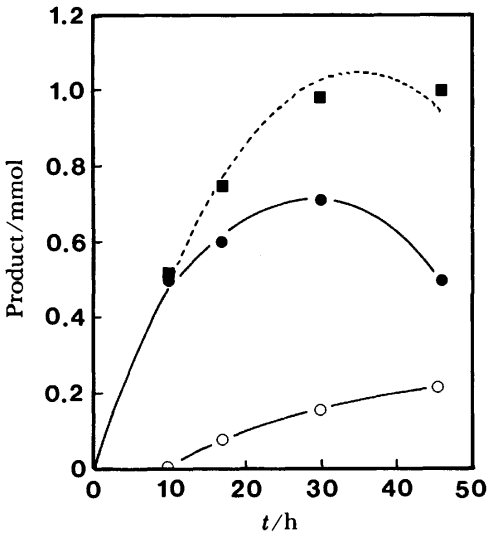

Fig. 1. Time-course plot of product distribution for methanol dehydrogenation with $[Ru_2(OAc)_4Cl]$/PPh_3 catalyst. $[Ru_2(OAc)_4Cl]$ 0.5 mmol dm^{-3}, $[PPh_3]$ 3.5 mmol dm^{-3}, methanol 200 ml, 65 °C (refluxing), (●) HCHO, (○) $HCOOCH_3$, (■) H_2. (------) amount of H_2 equivalence calculated from the dehydrogenated products ([HCHO]+[$HCOOCH_3$]×2).

Results and Discussion

Product Distribution. The change of product distribution in the composite-type ($[Ru_2(OAc)_4Cl]$-PPh_3; $[PPh_3]/[Ru_2]$=7.0) catalyst solution during the reaction was shown in Fig. 1. The reaction product in the initial 10 h period was only formaldehyde (5.2 turnovers), whereas methyl formate was formed as the secondary product, without accompanying dimethoxymethane in this catalyst solution. Neither carbon monoxide nor methane was detected in the evolved gas.

Excellent stoichiometry between dihydrogen and the sum of the dehydrogenated products was ascertained throughout the reaction.

Products during the 17 h reaction in the catalyst solutions of both the composite-type, $[Ru_2(OAc)_4Cl]$-PR_3(PR_3=PPh_3, $PEtPh_2$, and PEt_2Ph; $[PR_3]/[Ru_2]$= 7.0), and the mononuclear type, $[Ru(OAc)Cl(PEtPh_2)_3]$ are summarized in Table 1. Formaldehyde was found for all the catalysts. Methyl formate was found as the main product for the ruthenium complex coordinated with $PEtPh_2$ or PEt_2Ph. Some dimethoxymethane was detected in these catalyst solutions after the 17 h reaction.

Excellent stoichiometric coincidence of dihydrogen toward the sum of the dehydrogenated products was observed throughout the catalysts.

Initial Reaction Rate Dependence on Catalyst Concentration. The reaction rates at the refluxing temperature (65 °C) for the methanol solution of $[Ru(OAc)Cl(PEtPh_2)_3]$ were almost time-independent over a concentration range from 0.5 mmol dm^{-3} to 5.0 mmol dm^{-3} during the initial 17 h period (Fig. 2).

The dependence of the initial rate on catalyst concentration was linear below 0.5 mmol dm^{-3} and deviated to decrease from linearity at higher concentration (>1.0 mmol dm^{-3}). A similar rate dependence on the catalyst concentration was noted for the $[RuCl_2(PPh_3)_3]$ complex previously in the dehydrogenation of alcohol to evolve dihydrogen[8] and hydrogen transfer processes.[9]

Catalyst Deactivation Due to Structural Change. The catalytic activity of $[Ru(OAc)Cl(PEtPh_2)_3]$ for

a) $[Ru_2(OAc)_4Cl]$ 0.5 mmol dm^{-3}, PPh_3 3.5 mmol dm^{-3}. b) $[Ru_2(OAc)_4Cl]$ 2.5 mmol dm^{-3}, $PEtPh_2$ 17.5 mmol dm^{-3}. c) $[Ru(OAc)Cl(PEtPh_2)_3]$ 2.5 mmol dm^{-3}. d) $[Ru_2(OAc)_4Cl]$ 2.5 mmol dm^{-3}, PEt_2Ph 17.5 mmol dm^{-3}. Methanol 200 ml, reaction period 17 h, 65 °C (refluxing).

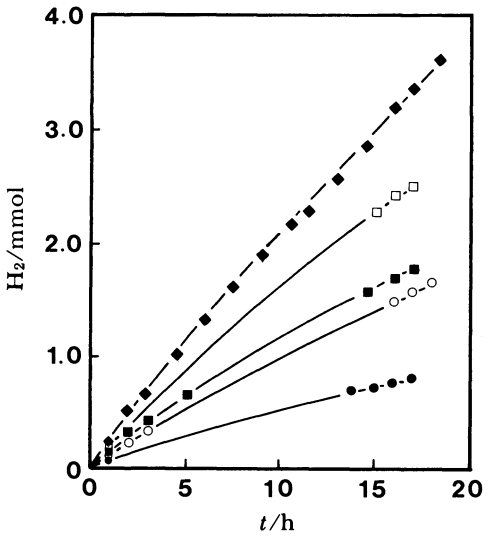

Fig. 2. Time-course plot of dihydrogen evolution from methanol with [Ru(OAc)Cl($PEtPh_2$)$_3$] catalyst. [Ru(OAc)Cl($PEtPh_2$)$_3$]: (●) 0.50 mmol dm^{-3}, (○) 1.0 mmol dm^{-3}, (■) 1.5 mmol dm^{-3}, (□) 2.5 mmol dm^{-3}, (◆) 5.0 mmol dm^{-3}. Methanol 200 ml, 65 °C (refluxing).

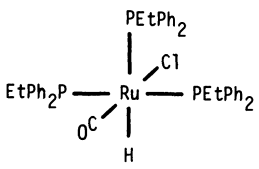
methanol dehydrogenation decreased gradually and disappeared finally (88 h). From the deactivated solution, a white complex was isolated and identified as [RuClH(CO)($PEtPh_2$)$_3$] on the basis of NMR, IR and elemental analyses. Found: C, 63.92; H, 5.79%. Calcd for $C_{43}H_{46}P_3OClRu$: C, 63.90; H, 5.74%. ^{31}P NMR: δ=36.9(2P) and 12.8(1P). ^2J(PP)=15.1 Hz, $^2J(PH)_{cis}$=22.9 Hz, and $^2J(PH)_{trans}$=103.9 Hz. ^{1}H NMR: δ=−7.1. IR (KBr): ν (CO) at 1924 (s), ν (RuH) at 1819 (w) cm^{-1}. Since one of the phosphine and hydride ligands are trans-disposed to each other ($^2J(PH)_{trans}$=103.9 Hz) and the other two and hydride are cis-disposed ($^2J(PH)_{cis}$=22.9 Hz), the remaining two ligands of Cl and CO are required to be coaxial. Based on these chemical analyses and spectroscopic characteristics, the coordination structure of the hydride carbonyl complex **1** in the solution is described as shown below.



1

After the 20 h reaction, the ^{31}P NMR spectrum of the catalyst solution (5.0 mmol dm^{-3}) consisted of only the hydride carbonyl complex **1** besides the original complex, suggesting its exclusive change into **1** during the reaction. The addition of paraformaldehyde accelerated the rate decrease, supporting the view that the product formaldehyde supplied the H and CO ligands of this deactivated complex **1**. Provided that these ligands replaced the bidentate OAc ligand of the original complex, these cis-disposed sites were usable for splitting the methoxyl C–H bond to give a hydride complex.[10]

Table 2. Effect of Additives on the Initial Rate of Dihydrogen Evolution from Methanol with [Ru(OAc)Cl($PEtPh_2$)$_3$] Catalyst[a]

Additive	Amount/mmol dm^{-3}	H_2/mmol
None	—	0.54
LiCl	1.0	0.58
$LiOAc\cdot 2H_2O$	1.0	0.55
$PEtPh_2$	3.0	0.55

a) [Ru(OAc)Cl($PEtPh_2$)$_3$] 1.0 mmol dm^{-3}, methanol 200 ml, reaction period 5 h, 65 °C (refluxing).

Table 3. Effect of Added CH_3COOH on the Rate of Dihydrogen Evolution from Methanol with [Ru(OAc)Cl($PEtPh_2$)$_3$] Catalyst[a]

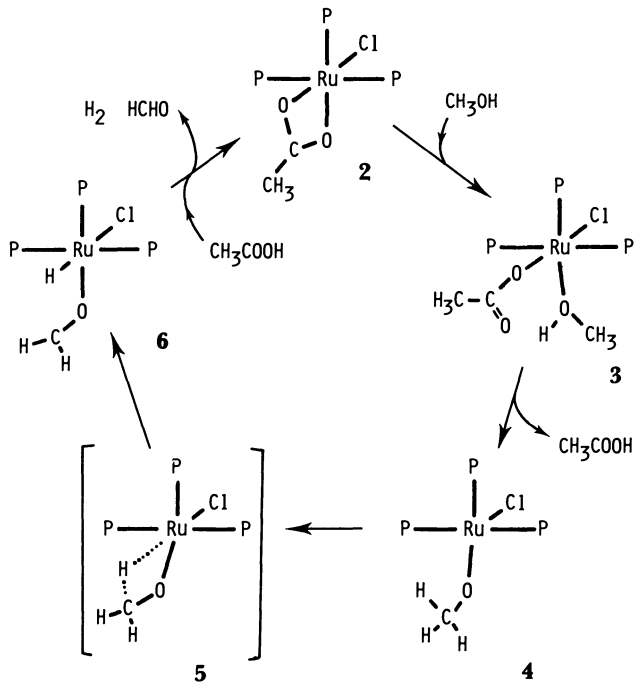
[CH_3COOH]/[Ru] ratio	Turnover number 17 h	42 h
0.0	10.20	18.59
0.5	14.11	21.81
1.0	16.15	24.52
2.0	16.32	26.87
5.1	15.30	26.97
20.0	14.28	29.67

a) [Ru(OAc)Cl($PEtPh_2$)$_3$] 0.25 mmol dm^{-3}, methanol 400 ml, 65 °C (refluxing).

Effect of Additives on Reaction Rate. As shown in Table 2, initial reaction rate of the [Ru(OAc)Cl($PEtPh_2$)$_3$] complex was unchanged by adding either an equimolar amount of lithium acetate or lithium chloride. Even at a three-fold excess, free $PEtPh_2$ gave a negligible effect. Consequently, spontaneous dissociation of the acetato, chlorido and phosphine ligands would be unlikely in the methanol solution.

Rate enhancement was observed, however, on the addition of acetic acid (Table 3). During the initial reaction period (17 h), the rate increased up to an optimum ratio of catalyst to acid of 2.0 mol mol^{-1}, accompanied by progressive inhibition at higher concentrations. Monotonous rate enhancement was observed after the reaction period of 42 h. As is well-known, some kinds of hydride complexes react with protonic compounds, yielding dihydrogen.[11] It is therefore reasonable that acetic acid accelerates the dihydrogen evolution, as far as a hydride complex is incorporated as the reaction intermediate in the catalytic dehydrogenation cycle. In the presence of excess free acid, this accelerating effect would be depressed by another reaction process such as solvolysis of the catalyst.[2c]

Postulated Reaction Scheme for Dehydrogenation of Methanol. A reaction mechanism of alcohol de-



Scheme 1. Reaction scheme postulated for methanol dehydrogenation.

hydrogenation was proposed previously by Dobson and Robinson. This consisted of three essential processes: (1) substitution of a bidentate carboxylato ligand (Ac_FO) with alcohol (ROH) to generate free acid (Ac_FOH), an alkoxyl ligand (RO) and a vacant site, (2) splitting of the C–H bond at the β position of the alkoxyl ligand to give an intermediate coordinated with a hydride ligand, leaving the dehydrogenated product, and (3) dihydrogen evolution by protonating this hydride ligand with free acid (Ac_FOH) to regenerate the carboxylato ligand (Ac_FO).[2c] On the basis of this reaction mechanism in addition to our experimental results concerning the structure of deactivated complex **1** and the effect of additives on the initial reaction rate, the following reaction scheme is postulated for the catalytic methanol dehydrogenation with $[Ru(OAc)Cl(PEtPh_2)_3]$ (Scheme 1).

The bidentate acetato ligand of the original complex **2** is changed into a monodentate one by methanol coordination **3**. By a proton transfer from the coordinated methanol to the monodentate acetato ligand, acetic acid is liberated from the complex, leaving a vacant site cis-disposed to the methoxyl ligand **4**. The C–H splitting at the β-position of the methoxyl ligand would be facilitated by an agostic interaction[12,13] between the ruthenium and hydrogen atoms **5**.[10] The hydride intermediate complex **6** thus formed is attacked by free acetic acid to yield the products H_2 and HCHO, regenerating the original complex **2**.

Characterization of Active Sites in Sulfided Molybdenum/Alumina Hydrodesulfurization Catalysts

Akinori MAEZAWA, Masaru KITAMURA, Yasuaki OKAMOTO,* and Toshinobu IMANAKA
Department of Chemical Engineering, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received December 4, 1987)

The site configuration of Al_2O_3-supported molybdenum sulfides catalytically active for hydrodesulfurization (HDS) of thiophene has been investigated as a function of pretreatment conditions (H_2S/H_2=0—0.2) by using X-ray photoelectron, laser Raman and IR spectroscopies and temperature-programmed desorption of adsorbed NO. It has been found that when MoO_3/Al_2O_3 catalysts are presulfided with H_2S/H_2, MoS_2-like species are formed, whereas when prereduced and subsequently sulfided during the HDS reaction, molybdenum oxide sulfides or highly dispersed amorphous molybdenum sulfides are initially produced. The turnover frequency of the HDS reaction calculated on the basis of the NO adsorption was shown to increase with decreasing dispersion degree of sulfided molybdenum. It is proposed that two kinds of NO adsorption sites are present; triply and doubly coordinatively unsaturated (cus) molybdenum sites. It is considered that both sites are catalytically active, possibly, the triply cus species being more active. It is concluded that the HDS activity of sulfided MoO_3/Al_2O_3 catalysts is determined by the structure, dispersion and coordinative unsaturation of sulfided molybdenum.

Supported molybdenum catalysts are widely used in industry for hydrodesulfurization (HDS). Cobalt and/or nickel are employed to promote the molybdenum catalysts. The synergic effects of the promoters have been studied by many workers[1-6] and reviewed by several authors.[7-12] Recently, Topsøe et al. have shown by using Mössbauer emission spectroscopy that a Co-Mo-S phase on promoted sulfide catalysts is responsible for HDS reactions.[12-15] In this model, it is considered that molybdenum is described as a MoS_2-like structure. EXAFS studies indicated the presence of such structures on sulfided Mo/Al_2O_3 and $Co\text{-}Mo/Al_2O_3$ catalysts.[16-18] However, the configurations of active sites on these dispersed molybdenum sulfides have not been unveiled yet. They are functions of the degree of the molybdenum sulfidation[19] and support.[20]

In order to characterize the catalytically active Mo-sites, several molecules are used as a probe; NO,[21-27] O_2,[14,28-35] CO,[36,37] H_2S,[38,39] and pyridine.[19,40,41] The amount of NO,[15,42] O_2,[43] or H_2S[38] chemisorption is relatively well correlated to HDS activities. However, it has not been established yet which is the most appropriate probe molecule. Nitric oxide is considered to be one of the most convenient molecule for the IR studies due to its high extinction coefficient and for differentiating adsorption sites.[21-27] In addition, it is well-established that NO adsorbs on multiply cus (coordinatively unsaturated) molybdenum sites as a dinitrosyl[21] or dimeric[23] complex. Valyon and Hall[22] have suggested that cus Mo-sites in reduced catalysts are Mo^{2+} from the IR study of the coadsorption of NO and O_2.

In order to reveal the configuration of the active sites on molybdenum sulfides responsible for the thiophene HDS reaction, an NO adsorption study was carried out herein for MoO_3/Al_2O_3 catalysts sulfided under various conditions, coupled with X-ray photoelectron (XPS), laser Raman (LRS) and IR spectroscopies and temperature-programmed desorption techniques.

Experimental

γ-Al_2O_3 was supplied by the Catalysis Society of Japan as a reference catalyst (JRC-ALO-4).[39] The B.E.T. surface area of the support was 163 m^2g^{-1}.

Supported molybdenum catalysts were prepared by an incipient impregnation method.[39] The loading level of MoO_3 was adjusted to be 2.5—30 wt% with respect to the support. An aqueous solution of the appropriate concentration of ammonium heptamolybdate (Nakarai Chemicals) was added to the Al_2O_3 (1.2 $cm^3g\text{-}(Al_2O_3)^{-1}$) and kneaded for 10 min at room temperature. Subsequently, the catalyst slurry was dried at 383 K for 18 h, followed by calcination in air at 823 K for 5 h.

The presulfidation of the catalyst was carried out at 673 K for 1.5 h in a stream of an atmospheric pressure of H_2S/H_2 (H_2S/H_2; 0—0.20, 500 mL STP min^{-1}). Subsequently, the HDS reaction of thiophene was carried out at the same temperature in an atmospheric pressure of a thiophene/H_2 stream (1.6% thiophene, 1 L STP min^{-1}), followed by measurements of catalytic activity at the reaction time of 1—1.5 h. The reaction gas was analyzed by GLC. The catalyst was, then, treated with an atmospheric pressure of a deoxygenated and dehydrated H_2-stream at 673 K for 1 h and evacuated for 1 h at the same temperature. After being cooled to room temperature under a dynamic vacuum, the amount of NO chemisorption was measured at room temperature (exposed to NO for 0.5 h and evacuated for 1 h, accompanied by NO physisorption experiments). After that, the XP spectra of the catalyst was measured without exposing the catalyst to air. The XPS measurements were made on a Hitachi 507 photoelectron spectrometer using Al $K\alpha_{1,2}$ radiation (1486.6 eV). The anode was operated at 9 kV and 50 mA. Assuming linear backgrounds, the intensity ratios were determined by using the integrated

areas of the Mo3d, S2p, S2s, and A12p levels. The binding energies were referenced to the A12p level at 74.5 eV.

The measurements of IR, temperature-programmed desorption (TPD) of NO and LR spectra were made in situ for the activated catalyst samples. The samples were exposed to NO and/or H_2S at room temperature for the IR and TPD studies. The IR spectra of the catalyst were recorded in a transmittance mode at room temperature on a Hitachi EPl-G double beam spectrophotometer by employing self-supporting wafers. The TPD study of NO adsorbed on the sulfided catalyst was conducted in a dynamic vacuum at a rate of 1.8 K min^{-1} from room temperature to ca. 570 K and evolved gases were continuously and repeatedly analyzed by a mass filter (ULVAC, MSQ-150A). The LR spectra were obtained by using an in situ cell at room temperature with a JASCO R-800 spectrometer equipped with a double monochromater. The 514.5 nm line of a NEC GLS-3200 Ar^+ laser was used for excitation at the intensity of 150—200 mW at the source. A spectral resolution was 5 cm^{-1}.

Results and Discussion

The HDS activities of the MoO_3/Al_2O_3 catalysts for thiophene are shown in Fig. 1 as a function of the H_2S/H_2 ratio in the presulfidation and the loading level of MoO_3. It is apparent that when the catalyst (5–30 wt% MoO_3) is presulfided at an increasing H_2S/H_2 ratio, the activity decreases steeply at a low H_2S/H_2 ratio (< 0.02) and then diminishes gradually at a futher increase in the ratio. At $H_2S/H_2=0$, the MoO_3/Al_2O_3 catalyst was reduced with H_2 and then sulfided with thiophene and/or resultant H_2S during the HDS reaction. At 2.5 wt% MoO_3 content, on the other hand, the HDS activity increases as the H_2S/H_2 ratio increases. It has been previously found that the activation mode of the catalyst affects the activity of the sulfided catalyst.[19]

In addition, the duration of the sulfiding treatment is an important factor determing the HDS activity when the H_2S/H_2 ratio is very low. On the sulfidation by thiophene/H_2 ($H_2S/H_2=0$ in Fig. 1), the catalytic activity of the 15 wt% MoO_3/Al_2O_3 catalyst decreased gradually to a conversion of 35% after a 12 h-treatment. During this treatment, the H_2S/H_2 ratio caused by the conversion of thiophene was calculated to be ca. 0.008. Therefore, the H_2S/H_2 ratio is considered to determine the rate of the sulfidation of molybdena under our experimental conditions. A direct sulfidation of the catalyst without the prereduction has been found to provide a sulfided catalyst similar to the one obtained at $H_2S/H_2=0$.[19] Accordingly, it is considered that the dependence of the HDS activity on both the sulfidation conditions and the loading level of MoO_3 is correlated to the differences in the structure (including a transient one) and dispersion degree of molybdenum sulfides formed on the catalyst surface.

As shown in Fig. 1 the HDS activity increases up to a loading level of 15 wt% MoO_3 and becomes independent of the MoO_3 loading level regardless of the sulfidation conditions. This is attributable to a formation of well-dispersed molybdenum species up to 15 wt% MoO_3 and in accord with the XRD and XPS results; no detection of crystalline MoS_2 by XRD and a linear correlation between the Mo3d/A12p XPS intensity ratio and the surface concentration of molybdenum at <15 wt% MoO_3 as observed previously.[19] No significant change in the Mo3d/A12p ratio was observed on the sulfidation of the catalyst with H_2S/H_2. The previous observations[19] of a considerable variation in the XPS intensity ratio on sulfidation may be attributed to the use of CS_2/H_2 for sulfiding instead of H_2S/H_2 and/or to different levels of impurities on Al_2O_3 surfaces which greatly modify the surface properties of Al_2O_3 as shown previously for the H_2S adsorption.[39]

The degree of sulfidation of molybdenum, S/Mo atomic ratio, is depicted in Fig. 2 as a function of the

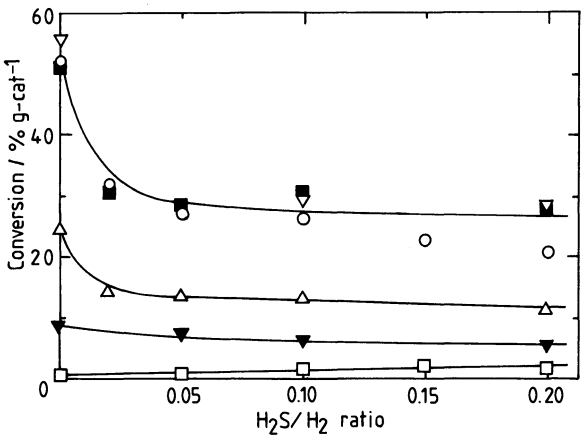

Fig. 1. Dependence of the thiophene HDS activity of sulfided MoO_3/Al_2O_3 catalyst on the H_2S/H_2 ratio in sulfiding.

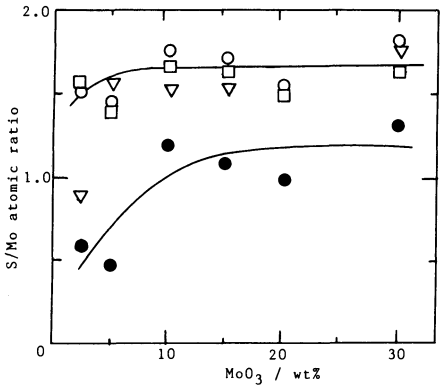

Fig. 2. S/Mo atomic ratio as a function of the MoO_3 content for the sulfided catalyst after the HDS of thiophene at 673 K.
●, $H_2S/H_2=0$; ▽, 0.05; ○, 0.1; □, 0.2.

MoO_3 content. The S/Mo ratio was calculated from the S2p/Mo3d XPS intensity ratio.[19] Apparently, the S/Mo ratio is increased by the H_2S/H_2-presulfidation and almost independent of the H_2S/H_2 ratio at>0.05. The S/Mo ratio gradually increases with the MoO_3 content up to 10 wt% (except a considerably low S/Mo ratio for the 2.5 wt% MoO_3 catalyst activated at 0.05) and becomes constant (S/Mo=1.6—1.7). It is evident that the S/Mo ratio is lower than two, this suggesting an incomplete transformation of supported molybdenum to MoS_2. As shown in Fig. 2, under the conditions of H_2S/H_2=0, however, the S/Mo atomic ratio increases with increasing the MoO_3 content up to 15 wt% and levels off at a lower S/Mo ratio (1.0—1.2) compared with that attained when presulfided. This suggests that the structures of sulfided molybdenum species formed on the catalyst surface are significantly different between the presulfidation and prereduction conditions. It is noted that the molybdenum sulfide species produced at a very low H_2S/H_2 ratio are gradually transformed to the stable molybdenum sulfide species produced at H_2S/H_2> 0.1 (vide infra).

These findings suggest that a considerable portion of molybdenum species which resists sulfiding exists in the low MoO_3 content catalysts, especially, at 2.5 wt% MoO_3. Zingg et al.[44] have reported with MoO_3/Al_2O_3 catalysts that the molybdenum occupies mainly tetrahedral sites at a low MoO_3 content and that two types of tetrahedral molybdenum species are present on the oxidic catalyst. These are monomeric and dimeric species. The monomeric species resists sulfiding, while the dimeric species are easily sulfided to MoS_2. Our results are in line with their model.

It is well-established that NO adsorbs on cus Mo-sites in a pair.[21] The amount of NO adsorption is relatively well correlated to the HDS activity.[15,42] Therefore, the dispersion degree of molybdenum was assessed by the amount of NO chemisorption. The fraction of cus Mo-sites thus obtained is shown in Fig. 3 against the MoO_3 content. The fraction varied with the H_2S/H_2 ratio, too. At H_2S/H_2 ratio of >0.1, the proportion of the adsorption site decreases as the MoO_3 content increases. As for the 2.5 wt% MoO_3 catalyst, 25–30% of molybdenum adsorb two NO molecules when properly activated. While, at the low H_2S/H_2 ratios, the fraction of NO-adsorption sites shows a maximum (at 10 and 20 wt% MoO_3 for H_2S/H_2=0.05 and 0, respectively). The proportion of cus Mo-sites in the low MoO_3 content catalysts (2.5 and 5 wt%) increases with increasing H_2S/H_2 ratio, while the fraction decreases for the catalysts containing 10—30 wt% MoO_3.

The turnover frequency (TOF) of the thiophene HDS reaction on the sulfided molybdenum catalyst was obtained on the basis of the amount of NO chemisorption. The TOF is shown in Fig. 4 as a function of the MoO_3 content. When the catalyst was presulfided with H_2S/H_2, the TOF increased with the MoO_3 content almost irrespective of the sulfidation conditions. At H_2S/H_2=0, however, a plateau is seen above 15 wt% MoO_3. It is considered that the dependence of TOF on the MoO_3 content results from the changes of the structure and dispersion of active molybdenum species.

In an analogy with the estimation of the dispersion degree of metal by using CO or H_2 adsorption for supported metal catalysts,it is proposed that the extent of dispersion of molybdenum sulfides (D_{Mo-S}) is evaluated from the amount of NO adsorption and the degree of sulfidation of molybdenum as in Eq. 1.

$$D_{Mo-S} = \text{(Fraction of Mo which adsorbs } (NO)_2\text{)/ (Fraction of molybdenum sulfides)} \quad (1)$$

On the basis of the XPS results of Li and Hercules,[45] it is assumed here that the stoichiometry of sulfided

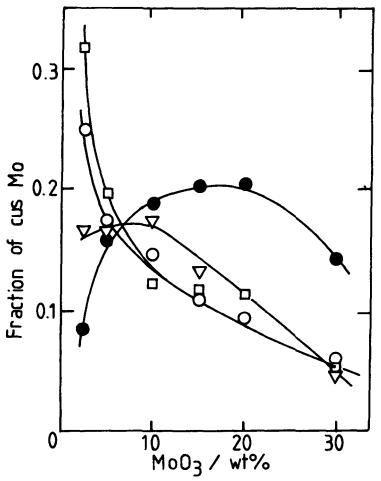

Fig. 3. Fraction of cus Mo (a half of the NO/Mo molecular ratio) vs. MoO_3 content measured after the HDS of thiophene at 673 K.

molybdenum species is two. The incomplete sulfiding of Mo in Fig. 2 indicates a partial transformation of Mo oxides to the sulfide species. The TOF of the thiophene HDS reaction is depicted in Fig. 5 against the dispersion degree of molybdenum sulfides. When the catalyst was presulfided ($H_2S/H_2 > 0$),the TOF is evidently correlated to the dispersion degree of molybdenum sulfides; the TOF increases, as the degree of MoS_2 dispersion decreases. The decreased dispersion degree is considered to correspond to an increased size of molybdenum sulfides, although no crystalline MoS_2 was detected by XRD except the catalyst with the lowest dispersion (30 wt% MoO_3). However, the TOF at $H_2S/H_2=0$ is higher than that for the presulfided catalysts and seems independent of the dispersion degree of molybdenum sulfides. It is suggested that the structure of sulfided molybdenum species formed at $H_2S/H_2=0$ are different from those produced by presulfiding with H_2S/H_2.

In order to characterize the molybdenum sulfides, in situ LRS techniques were used. Typical spectra are shown in Fig. 6. Regardless of the H_2S/H_2 ratio and loading levels, the peak at ca. 960 cm^{-1} in the oxidic state, which is characteristic of well-dispersed polymolybdate phases,[46-48] completely disappeared after sulfidation. The LR spectra indicated that molybdenum oxides with Mo=O bonds were completely sulfided by H_2S/H_2 or the thiophene HDS reaction. When the catalyst was presulfided, a strong peak at 405 cm^{-1} accompanied by broad peaks at ca. 450 and 380 cm^{-1} was observed. These pair peaks are assigned to a MoS_2 phase.[49] The above findings indicate that the molybdenum sulfides formed on sulfided catalyst have a MoS_2-like structure. Clausen et al.[16,17] and Huntly et al.[18] recently observed the presence of microcrystalline MoS_2 in sulfided catalysts by using EXAFS. On the other hand, when the catalyst was prereduced and subsequently sulfided during the

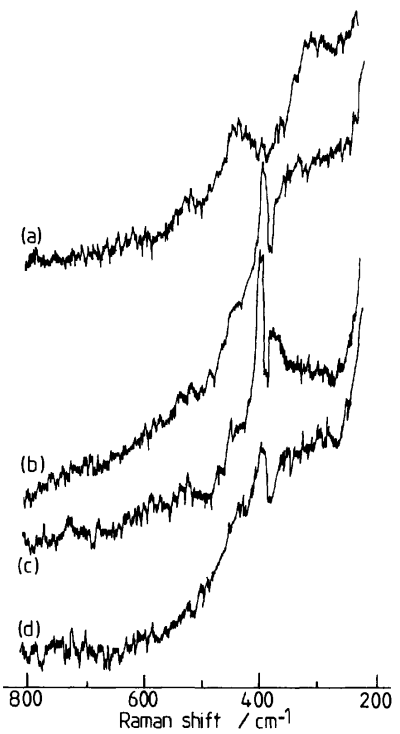

Fig. 6. In situ laser Raman spectra for MoO_3/Al_2O_3 catalysts sulfided at 673 K in an atmospheric H_2S/H_2 stream, followed by the HDS of thiophene at the same temperature.

reaction, the peaks at 380 and 405 cm^{-1} were not observed and only broadened peaks at 450 and 350 cm^{-1} due to a Mo-S stretching bands[49] were detected as shown in Fig. 6. It is considered that the structure of the active molybdenum species is not a MoS_2-like structure, suggesting the formation of molybdenum oxide sulfides or highly dispersed amorphous molybdenum sulfides. However, after a prolonged sulfiding by the thiophene/H_2(12 h), the LR spectra showed a transformation of the above sulfides to MoS_2-like species. This is consistent with the variation in the catalytic activity.

The IR spectra of NO adsorbed on the sulfided catalysts are illustrated in Fig. 7. Irrespective of the pretreatment conditions, the spectra consist of two adsorption peaks at 1795 and 1715—1690 cm^{-1}. They are assigned to symmetric and asymmetric stretching bands of dinitrosyl species, respectively.[50] The band positions indicate that two NO molecules adsorb on sulfided Mo-sites.[22,25] It is considered that even under the pretreatment conditions of $H_2S/H_2=0$, cus Mo-sites are actually sulfided during the HDS reaction of thiophene. However, the spectroscopic features at $H_2S/H_2=0$ and those at 0.1 are significantly different; the symmetric/asymmetric intensity ratios are 1.02 and 1.36 at $H_2S/H_2=0$ and 0.1, respectively. The ON-Mo-NO angle (θ) is suggested to be different in

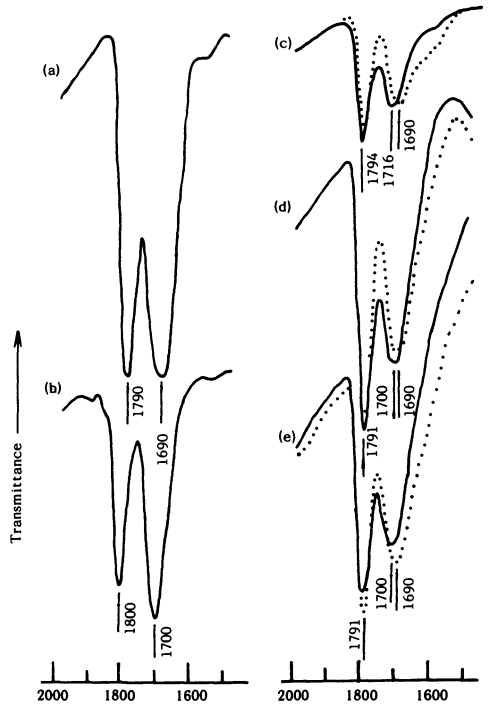

Fig. 7. IR spectra of NO adsorbed on the MoO_3/Al_2O_3 catalysts reduced or sulfided at 673 K in an atmospheric H_2 or H_2S/H_2 stream, followed by the HDS of thiophene at the same temperature.
(a) 10 wt%, only reduced; (b) 10 wt%, $H_2S/H_2=0$; (c) 2.5 wt%, 0.1; (d) 10 wt%, 0.1; (e) 20 wt%, 0.1. The dotted line shows the change of the IR spectrum of preadsorbed NO when the sample was exposed to H_2S (5.3 kPa) and evacuated at room temperature for 30 min.

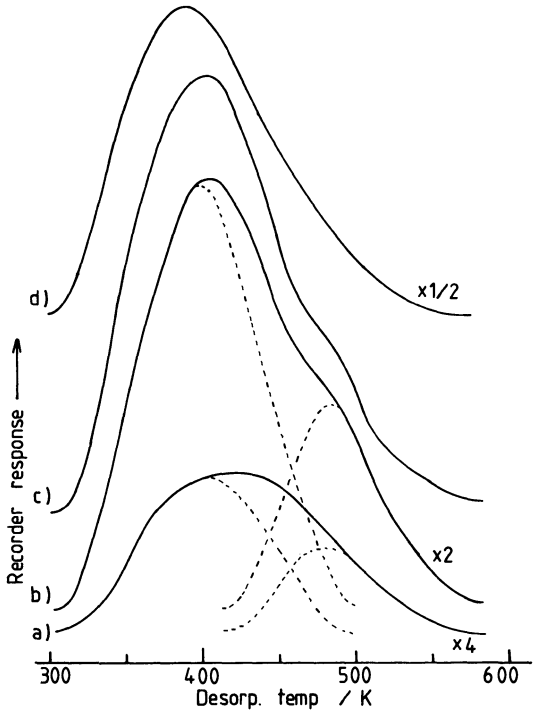

Fig. 8. TPD profiles ($m/z=30$) of NO adsorbed on the sulfided MoO_3/Al_2O_3 catalyst ($H_2S/H_2=0.1$).
(a) 2.5 wt%, (b) 5 wt%, (c) 10 wt%, (d) 20 wt%. The broken lines show the resolved peaks.

these two sulfides and calculated to be 90 and 81°, when prereduced and presulfided, respectively, on the basis of a theoretical equation;[50] $I_{sym}/I_{asym}=\cot^2(\theta/2)$. In conjunction with the results of LRS measurements, the IR spectrum observed at $H_2S/H_2=0.1$ is assigned to NO molecules adsorb on a MoS_2-like structure, whereas the spectrum at $H_2S/H_2=0$ to dinitrosyls adsorbed on molybdenum oxide sulfides or highly dispersed amorphous molybdenum sulfides. The IR spectroscopic features for NO adsorbed on the catalyst at $H_2S/H_2=0$ is very close to those for NO held on a reduced MoO_3/Al_2O_3 catalyst as shown in Fig. 7. This suggests that the structure of the sulfides formed under mild sulfidation conditions is similar to the structure of molybdenum oxide precursor phase. Taking into consideration the observations[51] that part of polymolybdate species are reduced at a relatively low temperature such as 673 K employed here, it is considered that initial sulfidations occur with polymolybdate species irrespective of the prereduction and keep these original structures almost intact to produce molybdenum oxide sulfides or amorphous molybdenum sulfides. A formation of oxide sulfides from polymolybdates has been proposed by Schrader and Chang using LRS.[49]

The dependence of the TOF of thiophene HDS reaction on the dispersion degree of sulfided molybdenum in Fig. 5 suggests the presence of several kinds of molybdenum sites. In order to characterize further the NO adsorption sites, the TPD study of NO adsorbed on sulfided catalyst was conducted. The TPD profiles of NO ($m/z=30$) are shown in Fig. 8. The main peak is observed at a desorption temperature of ca. 400 K, accompanying a weak shoulder at a higher temperature side (ca. 480 K). It seems that the relative intensity of the main peak at ca. 400 K increases with increasing MoO_3 content in the catalyst. It is revealed that two kinds of NO adsorption sites are differentiated by the TPD techniques. According to the IR measurements in Fig. 7, the TPD peaks are likely to be attributed to the signals due to distinct sulfided Mo-sites but not to composite peaks of sulfided and reduced Mo-sites. The presence of two desorption peaks in the TPD study was confirmed for molybdenum sulfides supported on TiO_2 in a more conclusive manner.[52] Segawa et al.[53] reported two NO desorption peaks for reduced MoO_3/TiO_2 systems. The thermal desorption of NO accompanied a production of N_2O; the desorption temperature of N_2O was ca. 400 K and the peak area intensity ratio of N_2O/NO did not vary significantly with MoO_3 content.

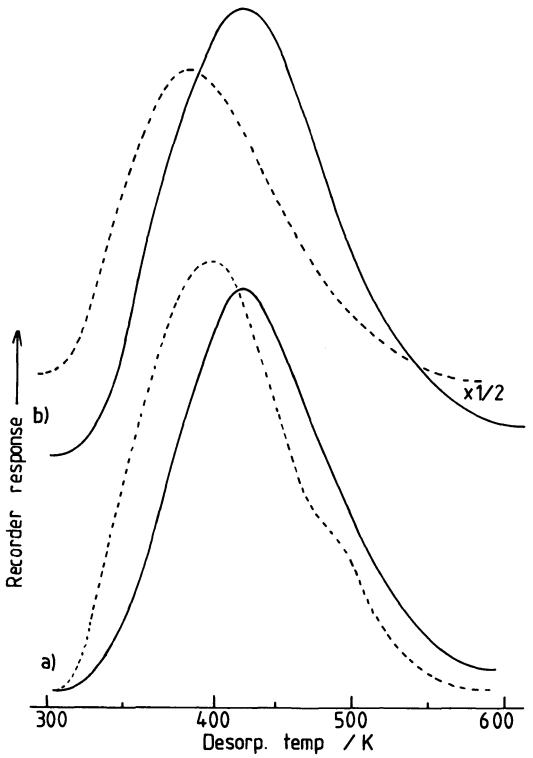

Fig. 9. TPD profiles (m/z=30) of NO on the sulfied MoO_3/Al_2O_3 catalyst (H_2S/H_2=0.1) coadsorbed with H_2S.
(a) 10 wt%, (b) 20 wt%. The broken lines show the TPD profile of adsorbed NO alone.

In order to determine the configuration of the sulfided Mo-sites, a coadsorption of NO and H_2S was examined. Figure 7 shows the changes in the IR spectra of NO when H_2S was introduced. No NO molecules were desorbed by the exposure of the sample to H_2S and by a subsequent evacuation at room temperature. On a contact of the NO-adsorption system with H_2S, the symmetric and asymmetric bands became considerably well separated, since the wavenumber of the latter peak was red-shifted by ca. 10 cm^{-1}. A pre-adsorption of H_2S considerably reduced the IR intensity of adsorbed NO. However, a similar red-shift of the lower-wavenumber peak of NO band was also observed. Accordingly, the spectral changes are considered to result from the interactions between adsorbed NO and H_2S molecules.

The TPD profiles of NO coadsorbed with H_2S are shown in Fig. 9. The desorption peak of H_2S (m/z=34) was observed at ca. 360 K. This is attributed to α-H_2S adsorbed on bare Al_2O_3 surface.[39] Hydrogen sulfide adsorbed on sulfided molybdenum sites is expected to desorb at higher temperature than 600 K.[39] It is noteworthy that the temperature of NO desorption at ca. 400 K is increased by 30 K on the exposure of the sample to H_2S. The peak area intensity ratio of N_2O/NO significantly decreased by the H_2S adsorption. These findings also suggest the presence of direct interactions between adsorbed NO and H_2S molecules. On the basis of the IR and TPD results, we propose here that sulfided Mo-sites for NO adsorption consist of triply and doubly cus molybdenum species and that NO molecules adsorbed on the triply cus sites desorb at ca. 400 K, while those on the doubly cus sites at ca. 480 K. Both NO species adsorb to form dinitrosyl or dimeric complex. Hydrogen sulfide molecule adsorbs on the triply cus Mo-sites preadsorbed with two NO molecules, affecting the IR and TPD of NO. The TPD peak at 430 K is assigned to the desorption of NO adsorbed on the triply cus Mo-sites coadsorbed with H_2S or SH. With increasing MoO_3 content in the MoO_3/Al_2O_3 catalyst, the size of MoS_2 particles increases as deduced from the decrease in the NO/Mo ratio, accompanying an increase in the fraction of the triply cus Mo-sites. This may be rationalized by a stabilization of multiply cus Mo-sites by electronically compensating properties of bulky semiconducting MoS_2 phases.

Combining the results on the TOF of sulfided MoO_3/Al_2O_3 catalysts for the HDS reaction with the configuration of the NO adsorption sites, it is suggested that both the triply and doubly cus molybdenum species are active for the HDS of thiophene, probably the triply cus Mo-sites showing higher activity. The activity of the sulfided MoO_3/Al_2O_3 catalyst is determined by two adverse factors; the number of active sites (NO adsorption sites) and the relative proportion of the triply and doubly cus Mo-sites. These adverse factors are considered to cause a volcano type correlation between the intrinsic activity (activity/unit weight of Mo) and sulfidation degree of molybdenum (S/Mo) as observed previously.[19]

Conclusion

On the basis of the results of XPS, LRS, and IR of NO absorbed on the catalyst, it is revealed that the structure of molybdenum sulfides formed on MoO_3/Al_2O_3 catalysts varies with the H_2S/H_2 ratio in the presulfiding atmosphere. It is demonstrated that MoS_2-like structure is formed when presulfided (H_2S/H_2>0.02), while molybdenum oxide sulfides or highly dispersed amorphous molybdenum sulfides are initially formed when prereduced (H_2S/H_2=0). The difference in the structure causes the difference in the thiophene HDS activity.

From the results of IR and TPD of NO adsorbed on sulfided catalysts, it is suggested that the NO adsorption sites consist of multiply cus molybdenum species, triply and doubly cus Mo-sites. The fraction of the triply cus Mo-sites increases with increasing molybdenum content or with increasing size of

molybdenum sulfide clusters. Taking into account the thiophene HDS activity, it is considered that both sites are active for the reaction, the triply cus sulfided molybdenum species being more active than the doubly cus sulfided molybdenum species.

Synthesis, Crystal Structure, and Physical Properties of the Charge-Transfer Complex Bis[benzo[1,2-*c*:3,4-*c'*:5,6-*c''*]trithiophene]-tetrafluorotetracyanoquinodimethan, $(BTT)_2(TCNQF_4)$

(Received December 11, 1987)

The semiconductive 2:1 charge-transfer complex between benzo[1,2-*c*:3,4-*c'*:5,6-*c''*]trithiophene and 2,2'-(2,3,5,6-tetrafluoro-2,5-cyclohexadiene-1,4-diylidene)bis[propanedinitrile], $(BTT)_2(TCNQF_4)$, crystallizes in the monoclinic system, space group $P2_1/c$, with the following cell constants: a=8.893(2) Å, b=10.589(2) Å, c=18.528(4) Å, β=114.52(1)°, V=1587.5(10) Å^3, D_x=1.61 g cm^{-3}, and Z=2. The crystal structure of $(BTT)_2(TCNQF_4)$ consists of stacking columns of alternating donor dyads and acceptor monads (DAD units) along the crystallographic b axis. Side-by-side sulfur-sulfur contacts shorter than the sum of the van der Waals radii were found along the axis between BTT molecules on the neighboring columns. Polarized reflectance spectra were measured with the single crystal of $(BTT)_2(TCNQF_4)$ at room temperature, showing a charge-transfer band polarized parallel to the stacking direction. The degree of charge transfer was estimated to be 0.21 from the oscillator strength and the transition energy of the charge-transfer band. From this, as well as the electric and magnetic properties of the complexes and the atomic distances for $TCNQF_4$, it was concluded that $(BTT)_2(TCNQF_4)$ is a weakly ionized charge-transfer complex.

Benzo[1,2-*c*:3,4-*c'*:5,6-*c''*]trithiophene (BTT) is one of aromatic molecules with heteroatoms at the periphery, which may act to increase transverse interchain interactions in the solid consisting of molecular stacking columns. BTT was first synthesized by Hart and Sasaoka[1] as a model chalcogen-bridged hexaradiarene, a molecule of considerable theoretical interest. However it was also shown by them that BTT forms air- and moisture-stable crystalline 1:1 charge-transfer (CT) complexes with the electron acceptors TCNE, TCNQ, DDQ, and chloranil.[1,2]

Recently, bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF), which is an electron-donating aromatic molecule with heteroatoms at the periphery, was found to form side-by-side contacts shorter than the sum of the van der Waals radii between the heteroatoms.[3] This fact prompts us to investigate CT complexes based on BTT in order to find another electron donor which could form side-by-side contacts between molecules, since BTT gives CT complexes with some electron acceptors. 2,2'-(2,3,5,6-tetrafluoro-2,5-cyclohexadiene-1,4-diylidene)bis[propanedinitrile] (commonly abbreviated to tetrafluorotetracyanoquinodimethan $TCNQF_4$) is an electron acceptor having a redox potential higher than that of chloranil, TCNE, TNCQ, and DDQ. $TCNQF_4$ was therefore chosen as an electron acceptor to find ionic CT complexes, which might exhibit interesting electric and magnetic properties.

The present paper describes the synthesis and crystal structure of 2:1 CT complex of BTT with $TCNQF_4$, $(BTT)_2(TCNQF_4)$.[4] The polarized reflectance spectra observed for $(BTT)_2(TCNQF_4)$ are discussed on the basis of the crystal structure. The degree of charge transfer in $(BTT)_2(TCNQF_4)$ is estimated from the molecular geometry of $TCNQF_4$ and also from the oscillator strength and the transition energy of the CT band observed in the reflectance spectra. The electric and magnetic properties are discussed in relation to the degree of charge transfer.

Experimental

BTT was prepared according to the procedures described by Hart and Sasaoka.[1] $TCNQF_4$ was kindly provided by Professor Gunzi Saito of the Institute for Solid State Physics. $(BTT)_2(TCNQF_4)$ was obtained by the following way: 41.8 mg (0.170 mmol) of BTT and 46.0 mg (0.166 mmol) of $TCNQF_4$ were dissolved into a hot acetonitrile solution under an argon atmosphere and then the solution was allowed to stand until it cooled to room temperature. The precipitate was filtered off and washed with small amount of acetonitrile to give 47.4 mg (73%) of dark-green long-needle crystals of $(BTT)_2(TCNQF_4)$. Found: C, 56.22; H, 1.51; N, 7.08%; Calcd for $(C_{12}H_6S_3)_2C_{12}N_4F_4$: C, 56.24; H, 1.57; N, 7.29%. A 1:2 mixture of chlorobenzene and acetonitrile was also used as the solvent.[5] The crystals of the same composition with larger width were obtained from the mixture.

X-Ray diffraction intensities were measured at room temperature with the θ–2θ scan technique on a Rigaku automated four-circle diffractometer employing Mo $K\alpha$ radiation ($2\theta \leqq 60°$) and were corrected for Lorentz and polarization effects, but not for the absorption. The dimensions of the crystal used were 0.10×0.25×0.40 mm.

§ Present address: Matsushita Electric Industrial Co., Ltd., Kadoma, Osaka 571.

The structure was solved by the direct method and refined by the block-diagonal least-squares procedure to an R value of 0.063 with unit weight, using 2581 independent reflections ($|F_o|>3\sigma(|F_o|)$). Anisotropic thermal parameters were adopted for all non-hydrogen atoms, and the hydrogen atoms were refined isotropically. Atomic scattering factors and anomalous scattering corrections were taken from International Tables for X-ray Crystallography.[6] Observed and calculated structure factors, anisotropic thermal factors, and positional parameters for H atoms are deposited as Document No. 8809 at the Office of the Chemical Society of Japan. Calculations were carried out on a FACOM-U1300 computer at Toho University and a HITAC M680H computer at the Computer Centre of the University of Tokyo with a local version of UNICS.[7]

The polarized reflectance spectra at normal incidence on the ab and ac planes were measured at room temperature over the spectral range from 8000 to 28000 cm^{-1} using a microspectrophotometer described briefly in a previous paper.[8]

The dc conductivity along the needle (crystallographic b) axis of the single crystal was measured in the temperature range between 240 and 300 K by means of the two probe method.

The static magnetic susceptibility for 37 mg of the tiny crystals oriented randomly was measured with a Faraday-type susceptometer over the temperature range from 2 to 300 K at 3 T. The details of the apparatus were described previously.[9]

Crystal Structure

$(BTT)_2(TCNQF_4)$ crystallizes in the monoclinic system, space group $P2_1/c$, with the following cell constants: a=8.893(2) Å, b=10.589(2) Å, c=18.528(4) Å, β=114.52(1)°, V=1587.5(10) Å^3, Z=2, D_x=1.61 g cm^{-3}, and μ(Mo $K\alpha$)=47.1 mm^{-1}. The positional parameters for the atoms are given in Table 1. The atomic numbering schemes and the molecular geometries within the BTT donor and the $TCNQF_4$ acceptor are shown in Fig. 1. The $TCNQF_4$ molecule is located on a center of symmetry. The BTT and $TCNQF_4$ molecules are nearly planar with maximum diviations from their least-squares planes by 0.06 Å [S(1)] and 0.13 Å [F(2)], respectively. No anomalous bond distances and angles are found for both molecules.

The crystal structure of $(BTT)_2(TCNQF_4)$, as illustrated in Fig. 2, consists of stacks of alternating donor dyads and acceptor monads, extending along the crystallographic b axis. Within these stacking columns, the interplanar separations between two donors and between donor and acceptor are 3.42 Å and 3.29 Å respectively. The latter separation is an average value because of the slightly unparallel overlap with the dihedral angle of 5.5° between the planes. Crystallographic symmetry requires that the components

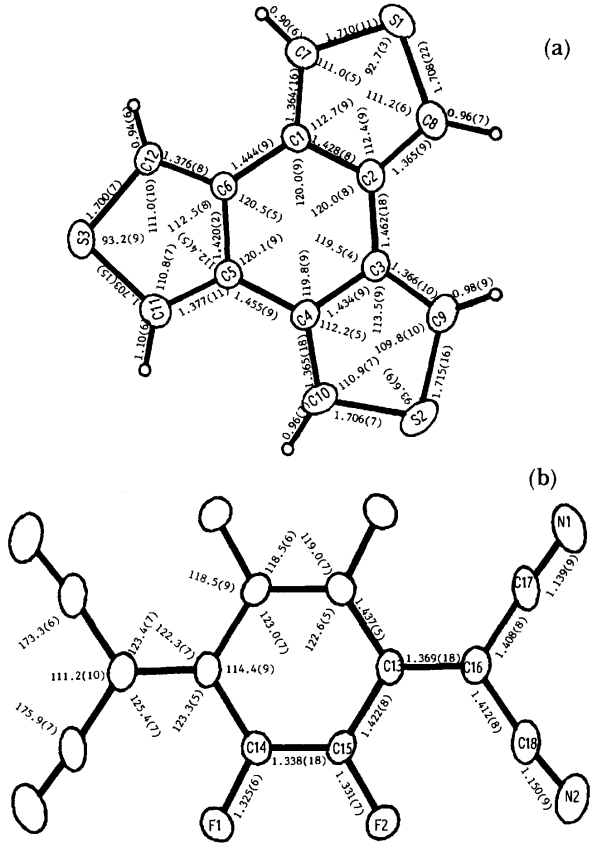

Fig. 1. Atomic numbering schemes and molecular geometries of the BTT donor (a) and the $TCNQF_4$ acceptor (b).

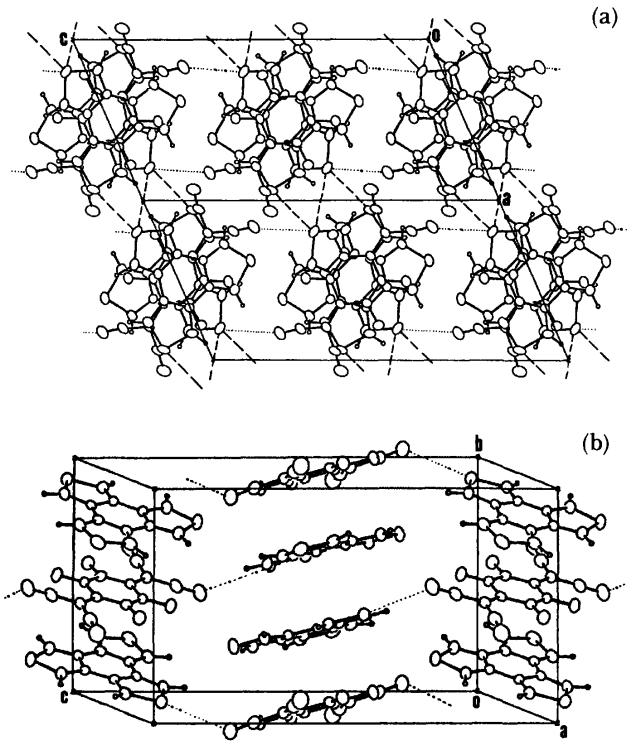

Fig. 2. Projection of the structure on the ac (a) and bc (b) planes. Broken lines represent S–S contacts shorter than the sum of vdW radii 3.70 Å between BTT molecules. Dotted lines represent S–N contacts between BTT and $TCNQF_4$ molecules.

of the donor dyads be parallel. The donor-acceptor interplanar separation is unusually short for a sulfur containing donor and rather close to that observed in the TCNQ complexes with donors containing no sulfur atoms, (perylene)$_3$(TCNQ) (3.37 Å)[10] and (benzidine)(TCNQ) (3.24 Å)[11] which exhibit a strong CT band.[12,13]

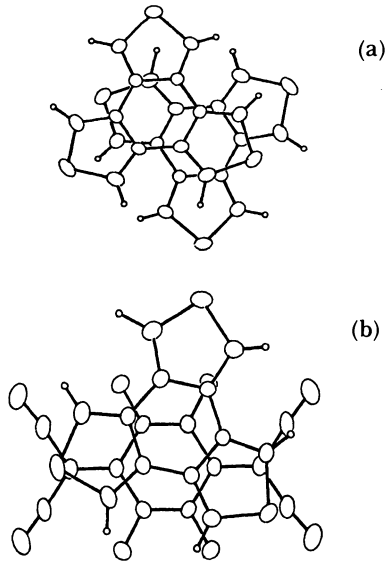

Fig. 3. Molecular overlapping modes of the donor-donor (a) and donor-acceptor (b) pairs.

The donor-donor and donor-acceptor molecular overlapping modes are shown in Fig. 3. Within the donor dyad the BTT molecule is rotated by approximately 60° with respect to the neighboring molecule so that the sulfur atoms at the periphery of the neighboring molecules keep away from each other. The central benzene rings of BTT are stacked in a ring-over-bond motif found commonly in planar aromatic hydrocarbons. One of the in-plane twofold rotation axes of BTT is rotated by 18° with respect to the molecular long-axis of $TCNQF_4$.

A significant feature of the crystal structure of $(BTT)_2(TCNQF_4)$ is that the interchain side-by-side sulfur-sulfur contacts shorter than the sum of the van der Waals radii (vdW) are found along the a axis. Short contacts between S(2)-S(3^i) at 3.572(4) Å and S(3)-S(3^i) at 3.567(2) Å (2×vdW(S)=3.70 Å), where i represents the key to symmetry code $1+x$, y, z, are indicated by the broken lines in Fig. 2(a). No sulfur-sulfur contacts shorter than the sum of vdW is found along the c axis. However close contact between S(3) and N(2^{ii}) at 3.41(6) Å (vdW(S)+vdW(N)=3.35 Å; ii represents the key to symmetry code $1-x$, $1/2+y$, $1/2-z$) is found along the c axis as shown in Fig. 2(b). The S-N contacts along the c axis are restricted within a DAD unit, whereas the S-S contacts along the a axis extend over an infinite chain. These findings demonstrate that BTT is capable of forming multi-dimensional molecular networks as expected from its molecular structure.

Polarized Reflectance Spectra

Figure 4 shows the reflectance spectra of $(BTT)_2(TCNQF_4)$ for light polarizations parallel to the crystallographic a, b, and c axes. Figure 5 shows the frequency dependent conductivity $\sigma(\tilde{\nu})$ of $(BTT)_2(TCNQF_4)$ calculated from the reflectance spectra

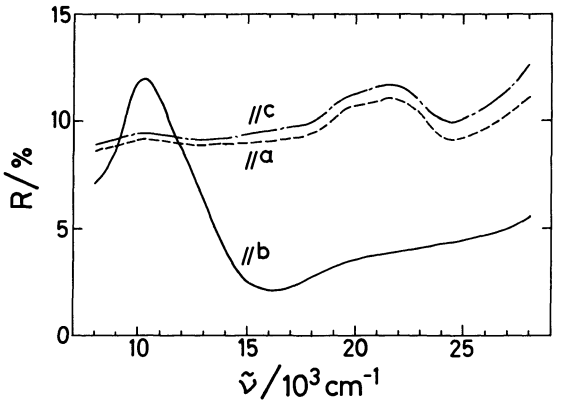

Fig. 4. Reflectance spectra of $(BTT)_2(TCNQF_4)$ with the polarization parallel to the crystallographic a, b, and c axes.

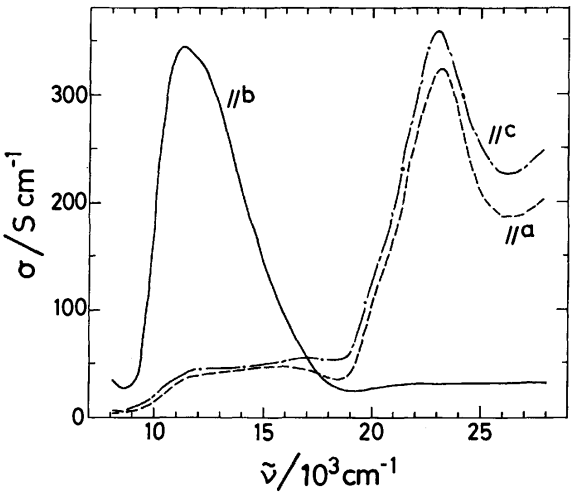

Fig. 5. Frequency dependent conductivity $\sigma(\tilde{\nu})$ of $(BTT)_2(TCNQF_4)$ with the polarizations parallel to the a, b, and c axes obtained by a Kramers-Kronig analysis of the reflectance spectra.

using the modified Kramers-Kronig transformation technique.[14] A conductivity peak appears in the near infrared region of the //b spectrum, whereas another peak appears in the visible region of the //a and //c spectra.

The conductivity peak located at 11200 cm^{-1} is almost completely polarized in the b axis which is parallel to the stacking direction and nearly perpendicular to the molecular planes of BTT and $TCNQF_4$. Since the lowest intramolecular excitations in BTT, $TCNQF_4$, and $TCNQF_4^-$ are expected to be polarized parallel to the planes, this peak would not be attributable to such intramolecular excitations, even if the low-lying excitation in $TCNQF_4^-$ appears in the region between 11000 and 15000 cm^{-1}.[15] The polarization direction of excitation corresponding to the conductivity peak is approximately parallel to the direction passing through the molecular centers of the donor and the acceptor. Therefore the conductivity peak at 11200 cm^{-1} can safely be attributed to the CT excitation between BTT and $TCNQF_4$,. The CT excitation band is asymmetric and tails to the high frequency side. A possible interpretation of the asymmetric band shape is superimposing of the progressional vibronic bands, since a more clear superimposed shoulder is sometimes observed for the CT band of the mixed-stack CT complexes such as $(perylene)_3(TCNQ)$.[12]

The conductivity peak appearing at 23100 cm^{-1} in the //a and //c spectra would be attributed to the intramolecular excitation in $TCNQF_4$. Absorption spectrum of $TCNQF_4$ exhibits an intense peak at 22900 cm^{-1} in a solid and at 26000 cm^{-1} in a solution,[16] while BTT shows absorption peaks at positions higher than 30000 cm^{-1}.[1] Thus it is unlikely to attribute the conductivity peak to the intramolecular excitation in BTT. It is clear from the //a, //b, and //c spectra that the conductivity peak is almost polarized along the ac plane in which the molecular planes of $TCNQF_4$ lie. The conductivity peak located at 23100 cm^{-1} is therefore most likely assigned to the low-lying intramolecular excitation in $TCNQF_4$.

Degree of Charge Transfer

It is of great importance to know the degree of charge transfer from the donor to the acceptor in order to discuss the physical properties of $(BTT)_2(TCNQF_4)$. The value of the degree of CT ρ from donor D to acceptor A may be related to the oscillator strength f by[17]

$$f = \frac{4\pi mc}{\hbar}\tilde{\nu}_{CT}|R_{DA}|^2\rho = 3.254\times10^{-5}\tilde{\nu}_{CT}|R_{DA}|^2\rho, \quad (1)$$

where R_{DA} is the distance (Å) between the molecular centers of D and A and $\tilde{\nu}_{CT}$ is the excitation energy of CT band in the cm^{-1} scale. The oscillator strength is given by[18]

$$f = \frac{4mc}{Ne^2}\int_{\tilde{\nu}_1}^{\tilde{\nu}_2}\sigma(\tilde{\nu})d\tilde{\nu}\cos^2\theta, \quad (2)$$

where N is the number of D-A pair per unit volume and θ is the angle between the light polarization and the transition dipole moment. By a numerical integration of the CT band in the conductivity spectrum, f is found to be 0.89. Thus ρ is estimated to be 0.21 from f using $\tilde{\nu}_{CT}$=11200 cm^{-1} and R_{DA}=3.43 Å.

The degree of CT obtained is 0.21. This value strongly suggests that $(BTT)_2(TCNQF_4)$ is not an ionic CT complex but a non-ionic (weakly ionized) CT complex. This finding is further checked by the comparison of bond distances of $TCNQF_4$ in $(BTT)_2(TCNQF_4)$ with those of neutral $TCNQF_4$[19] and ionic complexes of $TCNQF_4$[20-22] summarized in Table 2. The bond distance c is most sensitive to the ionicity of $TCNQF_4$. As seen in Table 2, c of $(BTT)_2(TCNQF_4)$ is close to that of neutral $TCNQF_4$. In general, however, bond distances are influenced by the molecular packing even if the molecule has the same ionicity. Kistenmacher et al.[23] proposed a way to determine the degree of CT for the crystal of TCNQ derivatives that consists of mixed stacks of alternating donors and the acceptors. The degree of CT ρ may be related to the ratio $\alpha=c/(b+d)$ by

$$\rho = \frac{\alpha_x - \alpha_0}{\alpha_1 - \alpha_0}, \quad (3)$$

where α_0, α_1, and α_x are the ratios for $TCNQ^0$, $TCNQ^-$, and $TCNQ^{x-}$ ($0<x<1$), respectively. We applied the relation to the $TCNQF_4$ complexes to estimate the degree of CT because the ratios obtained for $TCNQF_4$ and TCNQ are very close to each other (0.477 for $TCNQF_4^0$ and 0.476 for $TCNQ^0$; 0.498 for

Table 2. Comparison of Specific Bond Distances (Å) for the $TCNQF_4$ Molecules

$TCNQF_4^-$ and 0.500 for $TCNQ^-$). By using Eq.3 and the ratio 0.482 obtained for $(BTT)_2(TCNQF_4)$, ρ is found to be 0.24. This value agrees reasonably with that estimated from the conductivity spectra.

Electric and Magnetic Properties

Although BTT and $TCNQF_4$ molecules are essentially in non-ionic states as shown in the preceding section, charge transport may occur passing through the crystal. We examined the temperature dependence of electrical conductivity of the single crystal. The conductivity at room temperature along the stacking direction is found to be 1.0×10^{-8} S cm^{-1} and the activation energy 0.27 eV (1 eV=1.602×10^{-19} J). The conductivity is smaller than that (6×10^{-8} S cm^{-1}) reported for the 1:1 complex by Cowan et al., for which the degree of CT is estimated to be 0.60 from the CN stretching frequency.[4]

The activation energy is small for non-ionic CT complexes. The energy gap E_g (i.e., the energy required for the intrinsic carrier formation) for a CT complex can be estimated by the following relation;

$$E_g = I(D) - A(A) - \{P(D^+) + P(A^-)\} \quad (4)$$

where I(D) is the ionization potential of the donor D and A(A) is the electron affinity of the acceptor A. $P(D^+)$ and $P(A^-)$ are the polarization energies associated with the formations of D^+ and A^- ions in the crystal, respectively. The ionization potential of BTT in the solid state is determined experimentally to be 4.9 eV.[24] This value corresponds to $I(D)-P(D^+)$. At present, the electron affinity and the polarization energy of $TCNQF_4$ have not been experimentally determined. The electron affinity A(A) of TCNQ is, however, estimated to be 2.8 eV.[25] $P(A^-)$ of TCNQ could reasonably be assumed to be 1.5—2 eV. If we put these figures into Eq.4, the energy gap is estimated to be in the range of 0.1—0.6 eV, into which the twice the activation energy (i.e., energy gap) actually observed for $(BTT)_2(TCNQF_4)$ falls. The agreement between estimated and observed values would be further improved by using the parameters proper to $TCNQF_4$. It is therefore suggested that the observed conductivity in $(BTT)_2(TCNQF_4)$ is due to the intrinsic carrier formation.

The suggestion mentioned above is further supported by the results of static magnetic susceptibility measurements. The paramagnetic susceptibility was evaluated by subtracting the diamagnetic contribution $\chi_d=-418\times10^{-6}$ emu mol^{-1} (1 emu mol^{-1}=4π cm^3 mol^{-1}) which is the sum of the diamagnetic susceptibilities of the components $\chi_d=-134\times10^{-6}$ emu mol^{-1} for $TCNQF_4$ and -142×10^{-6} emu mol^{-1} for BTT). The paramagnetic susceptibility follows the Curie-Weiss law over the entire temperature range with a small Weiss constant -2.9 K. The Curie constant 4.7×10^{-4} emu K mol^{-1} is very small and corresponds to only 0.05% of unpaired electrons per formula unit. Therefore, there are essentially no unpaired electrons carrying charges and spins in the ground state, while the degree of CT is estimated to be 0.21—0.24. Thus the charge carriers are produced intrinsically by the excitation across the energy gap.

Conclusion

Benzo[1,2-*c*:3,4-*c'*:5,6-*c''*]trithiophene (BTT) gives a weakly ionized 2:1 charge-transfer (CT) complex with tetrafluorotetracyanoquinodimethan ($TCNQF_4$). The crystal structure of $(BTT)_2(TCNQF_4)$ consists of stacking columns of alternating donor dyads and acceptor monads, extending along the b axis. The degree of CT from BTT to $TCNQF_4$ is estimated to be 0.21 from the conductivity spectra and 0.24 from the molecular geometry of $TCNQF_4$. Semiconducting charge transport passing through the crystal occurs with intrinsic carrier formation due to the CT interaction between BTT and $TCNQF_4$. Side-by-side sulfur-sulfur contacts shorter than the sum of the van der Waals radii are found between the BTT molecules as expected from its molecular structure. However, the effects of the contacts on the physical properties of the crystal remains unclear because of the non-ionic ground state. It is therefore of interest to search ionic complexes and salts of BTT in order to elucidate the

transverse interchain interaction through the side-by-side contacts provided by the sulfur atoms at the periphery of the BTT molecule.

Prebiotic Synthesis Obeys the Rule of Topological Charge Stabilization

Jun-ichi AIHARA
Department of Chemistry, Faculty of Science, Shizuoka University,
Oya, Shizuoka 422
(Received December 18, 1987)

Most organic molecules synthesized in primitive-Earth-simulation experiments conform to the rule of topological charge stabilization. Heteroatoms in these molecules are all located at the best sites to stabilize the conjugated systems. The situation must be the same for organic molecules formed under prebiotic conditions on primitive Earth.

Chemical evolution may be defined as prebiotic chemical processes leading to the origin of life on Earth.[1-7] It must have occurred in the presence of water and minerals, utilizing the components of the primitive atmosphere, such as carbon dioxide, carbon monoxide, methane, and hydrogen.[1-7] Small amounts of ammonia, hydrogen cyanide (HCN), and hydrogen sulfide were presumably dissolved in the primitive lakes and oceans. Chemical processes must have been driven principally by solar energy in the form of light, lightning, and heat. Some thermal energy was provided by volcanoes, meteoritic impact and radioactive decay.

Many laboratory experiments have been designed to model the prebiotic formation of amino acids, nucleoside bases, and many other biologically important molecules.[1-7] A variety of organic molecules can indeed be synthesized in primitive-Earth-simulation (PES) experiments. Most organic molecules synthesized in PES experiments have one or more heteroatoms in their π-electron systems. It might be a very important matter to seek for the reason why these molecules are produced under prebiotic conditions. Of course, it is never easy to answer this question. Even a partial answer will mark an important progress in the study of chemical evolution and the origin of life.

In 1983 Gimarc pointed out that the pattern of charge densities in a molecule is determined primarily by the connectivity or the topology of the molecule.[8-11] Many examples indicate that nature prefers to place heteroatoms of great electronegativity in those positions where the isostructural, iso-π-eleccronic hydrocarbon has large charge densities. Gimarc called the effect the rule of topological charge stabilization or the TCS rule.[8] This paper aims at explaining the stability of organic molecules formed in PES experiments in terms of Gimarc's TCS rule. We will show below that all these molecules are thermodynamically stable owing to the heteroatoms located at the right sites.

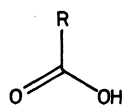
Theory

Charge densities calculated for a molecule containing heteroatoms depend on the choice of semiempirical parameters, but in the isostructural, iso-π-electronic hydrocarbon charge densities are determined only by the topology of the molecule and the number of π electrons. Gimarc referred to the isostructural, iso-π-electronic hydrocarbon as the uniform reference frame (URF).[8-10] The URF is nothing other than a conjugated hydrocarbon obtained by replacing all heteroatoms in a given molecule by sp^2 carbons and then by donating the same number of π electrons to the resulting system. The TCS rule utilizes such URF's to estimate the stability of organic molecules of abiotic origin. First-order perturbation theory has given a justification for the rule.[8]

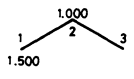
All charge densities given below will be those calculated for the π-electron systems of the URF's. We used the Hückel molecular orbital (HMO) model in its simplest form. The HMO model is best suited for the present purpose which requires only a qualitative pattern of charge distributions.[8,11] All alkyl substituents will be disregarded for simplicity because they are scarcely conjugated with the parent π-electron framework.

Results and Discussion

Amino acids are crucial building blocks of life. Since the Miller-Urey experiment reported in 1953,[12] a great number of amino acid syntheses have been accomplished using a variety of gas mixtures subjcted to different energy sources.[1-4,7] Various amino acids can also be obtained by heating solutions of hydrogen cyanide.[1-6] All amino acids have one or more isolated carboxylic π-electron systems. A general formula for amino acids is shown in **1**. Here and hereafter, R, R_1, and R_2 represent the substituents not conjugated with a π-electron system in question. Not only amino acids but also carboxylic acids have been detected in many PES experiments.[1,4,6] Carboxylic acids can also be



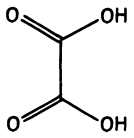
1



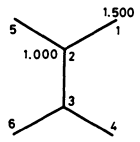
2

expressed as **1**.

The allyl anion $C_3H_5^-$ (**2**, four π electrons) represents the URF of a carboxyl group **1** not conjugated with the remainder of the molecule (R in **1**). The calculated charge densities in the URF are greater at the edge carbons than at the central carbon. Topological charge stabilization says that electronegative heteroatoms prefer to occupy the sites where electron density is already very great in the iso-π-electronic URF.[8-11] Oxygen is much more electronegative than carbon.[13] Stability of amino acids and carboxylic acids is attributable to the two constituent oxygens. These atoms occupy the two sites of greatest charge density in the URF. Oxalic acid (**3**) has also been formed in some PES experiments.[6] This acid again conforms to the TCS rule. Four oxygens in oxalic acid or oxalates occupy the sites of high charge density in the URF (**4**).

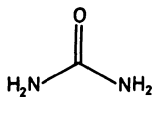


3

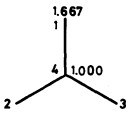


4

Urea (**5**) was produced in many PES experiments.[1-4,6] The trimethylenemethane dianion (**6**, six π electrons) constitutes the URF of urea. The calculated charge densities are greater at the peripheral carbons than at the central carbon. Nature puts electronegative atoms, oxygen and nitrogen, in the peripheral positions of the URF.[8] A molecule which is iso-π-electronic with **6** has been referred to as a Y-aromatic species, i.e., an exceptionally Y-shaped aromatic molecule, since it is of great stability.[14] Urea is a stable aromatic species in this sense, conforming to the TCS rule.

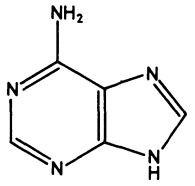


5

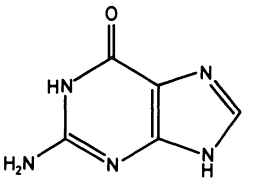


6

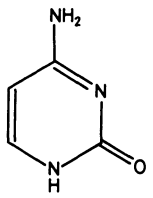
The purine and pyrimidine bases are key components of nucleic acids. Adenime (**7**), guanine (**8**) cytosine (**9**), thymine (**10**), and uracil (**11**) are formed under various prebiotic conditions.[1-7] These bases can be synthesized all at once in the electric-discharge experiment with methane-nitrogen-water mixtures.[15] Senarios can be developed for the prebiotic synthesis of aino acids, purines, and pyrimidines, using HCN as the sole source of carbon.[6] The occurrence of HCN on primitive Earth is supported by its facile formation under a variety of conditions.[6] HCN oligomerizes easily in laboratory experiments. HCN oligomers then hydrolyze to amino acids, purines, and pyrimidines. This synthetic scheme is very attractive, in that all three types may have been produced at the same time and place on primitive Earth.[6]



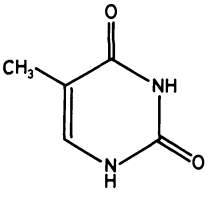
7



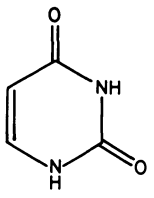
8



9

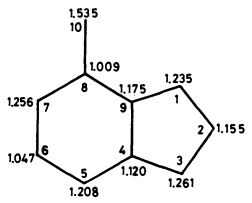


10

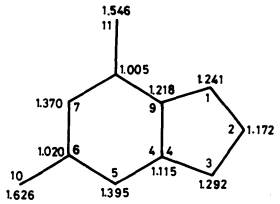


11

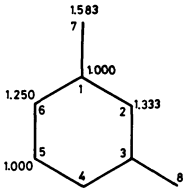
The URF's of two purine bases **7** and **8** are shown in **12** and **13**, respectively. Heteroatoms in these bases, without exception, are situated at the sites of large charge density in their respective URF's. All positions of high charge density in the URF's are occupied by heteroatoms in the corresponding purine bases. Three pyrimdine bases **9**, **10**, and **11** happen to have the same URF (**14**) with ten π electrons. Heteroatoms in these bases occupy the sites of high charge density in their common URF. Thus, nucleoside bases are not only stable but also easy to form on primordial Earth.



12



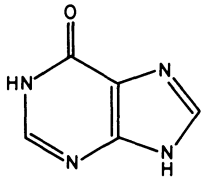
13



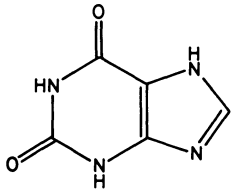
14

Similar PES experiments yield some more molecules which have either a purine or pyrimidine nucleus.[5,6] Among them are hypoxanthine (**15**),

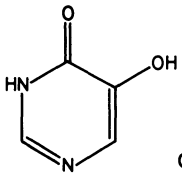
xanthine (**16**), 4,5-dihydroxypyrimidine (**17**), 5-hydroxyuracil (**18**), and orotic acid (**19**). The URF's of hypoxanthine and xanthine are the same as those of adenine (**12**) and guanine (**13**), respectively. The URF's of 4,5-dihydroxypyrimidine, 5-hydroxyuracil, and orotic acid are shown in **20**, **21**, and **22**, respectively. All these molecules conform to the TCS rule.



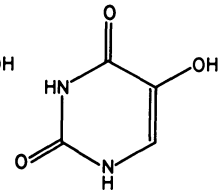
15



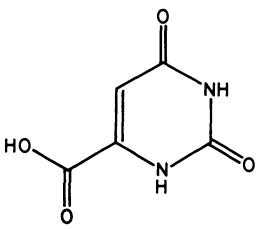
16



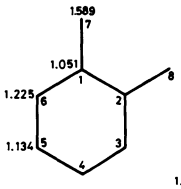
17



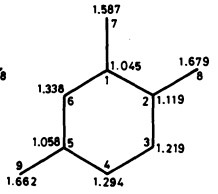
18



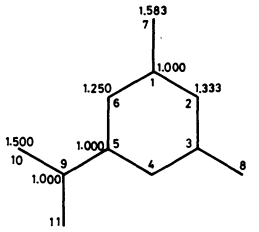
19



20



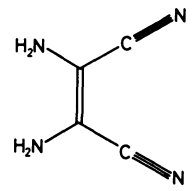
21



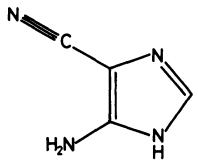
22

According to the original TCS rule,[8] one does not need to place heteroatoms at all sites of high charge density in the URF to construct a stable molecule. Position 6 in the URF of pyrimidine bases (**14**) has high charge density, but these bases has no heteroatom there. In contrast, heteroatoms in **2**, **3**, **5**, **7**, **8**, **15**, and **16** occupy all sites of high charge density in their respective URF's. We might say that these molecules are extremely faithful to the TCS rule.

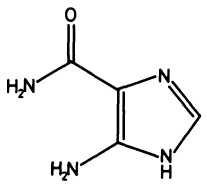
The tetramerization of HCN to form diaminomaleonitrile (DAMN, **23**) is a key step for the synthesis of nucleoside bases from HCN.[2-6] 5-Amino-4-imidazolecarbonitrile (AICN, **24**), 5-amino-4-imidazolecarboxamide (AICA, **25**), and 5-amino-4-imidazolecarboxamidine (AICAI, **26**) are formed during the origomerization of HCN. These molecules are plausibly prebiotic since they are produced by the reaction of DAMN with some appropriate simple molecules.[2-6] Then, purine bases are synthesized from AICA and AICAI. Therefore, it is instructive to



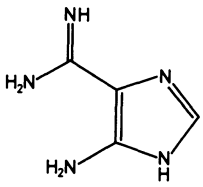
23



24

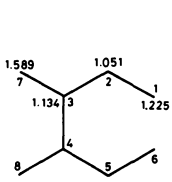


25

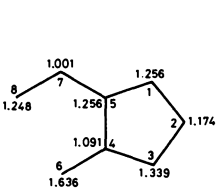


26

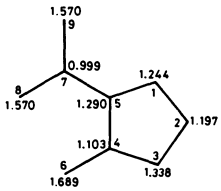
see if these three molecules conform to the TCS rule. The URF's of **23**, **24**, and **25** are shown in **27**, **28**, and **29**, respectively. The URF of **26** is identical with that of **25**. It is clear from these URF's that **23**–**26** obey the TCS rule. This implies that the TCS rule operates in almost every step of prebiotic chemistry.



27

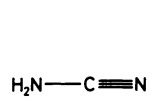


28

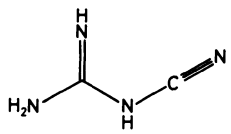


29

Cyanamide (**30**) can be formed under prebiotic conditions from ammonium cyanide by a photochemical reaction.[1,2,6] This molecule undergoes self-addition to form a dimer, cyanoguanidine (**31**).[2,6]

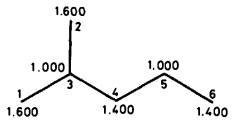


30

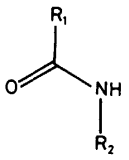


31

These two compounds may funtion as condensing agents in phosphorylation and peptide formation. The URF of cyanamide is identical with that of carboxylic acid **2**. The URF of cyanoguanidine is shown in **32**, which may be regarded as a cyano derivative of a Y-aromatic compound (guanidine). Heteroatoms in both molecules are placed at the sites of high charge density in the URF's. Individual peptide bonds **33** in polypeptide are iso-π-electronic with the allyl anion **1**. Peptide bonds also confrom to the TCS rule.



32



33

Concluding Remarks

Gimarc pointed out that the TCS rule has potential value as a guide for synthetic efforts to be made by organic chemists.[8] We have shown above that many candidates for prebiotic organic molecules conform to the TCS rule. All heteroatoms in every molecule investigated are placed at the sites of large charge density in its URF. Amino acids, nucleoside bases, and related molecules are fully consistent with the TCS rule. This may imply that a chemical reaction with simple molecules, driven by a primitive energy source, yields molecules conforming to the TCS rule.

It seems very likely that real prebiotic chemical evolution[1,2] occurred in harmony with the TCS rule on primitive Earth. Then, nature presumably picked up these molecules to construct living organisms. Some of the molecules must have exerted important functions incidentally in cellular systems. Conversely, nature has been so skillful as to choose biologically important molecules from the products of chemical evolution on primitive Earth.

As noted by Gimarc,[8] a molecule conforming to the TCS rule is relatively stable in a thermodynamic sense. In general, a stable molecule is associated with low activation energy of formation.[16] Thus, nature has utilized energetically very accessible ways of organic synthesis. Living organisms must have chosen useful molecules from organic molecules readily available on primitive Earth. These molecules necessarily conform to the TCS rule. Thus, topological charge stabilization[8,11] serves as a unifying principle for the systematization of chemical evolution.

We thank Prof. Kensei Kobayashi (Yokohama National University) for familializing us with the concept of chemical evolution.

Characterization of Monomeric and Polymeric (Octacyanophthalocyaninato)metals in Thin Films

Hisao YANAGI, Yasukiyo UEDA, and Michio ASHIDA*
Department of Industrial Chemistry, Faculty of Engineering, Kobe University, Rokkodai, Nada-ku, Kobe 657
(Received January 5, 1988)

Thin films were prepared by the reaction of 1,2,4,5-tetracyanobenzene with Ni, Co, Fe, Zn films at various temperatures. The films were characterized by infrared, UV/visible and photoelectron spectroscopy and analytical electron microscopy in comparison with films prepared on substrates of a KCl single crystal and a Cu film. The films produced on the metal films below 400 °C were composed of tentacle-like crystals growing from the surface and an amorphous layer condensed over the metal substrate. The tentacle-like crystals were soluble in concentrated sulfuric acid and were identified as intercalation compounds of (octacyanophthalocyaninato)metal with the respective metal atoms. The amorphous layers contained polymerization products with a polynitrile structure, which were insoluble in concentrated sulfuric acid. The films produced on the metal films at 450 °C were composed of a thick layer and had a very limited solubility in concentrated sulfuric acid. They were ascribed to metal complexes of polyphthalocyanines(poly-M(Pc)) and cross-linked polymers with structure elements such as polynitrile and triazine.

(Phthalocyaninato)metals(M(Pc))[1-7] (**1**) and their polymeric derivatives[8-11] have recently attracted a good deal of attention as new functional materials because of their interesting electronic and optical properties. According to Wöhrle et al.[12,13] phthalocyanine polymers were synthesized by a reaction of 1,2,4,5-tetracyanobenzene(TCNB) (**2**) with metal salts or metals, and (octacyanophthalocyaninato)metals (M[Pc(CN)$_8$]) (**3**) were produced as precursors of polymeric (phthalocyaninato)metals (poly-M(Pc)). The structure of polymeric phthalocyanines has been considered that phthalocyanine units link each other by the peripheral benzene ring to form either a ribbon or a sheet of parquet pattern (**4**).

In order to prepare thin films of these phthalocyanine derivertives, the synthesis has been proceeded by a reaction of TCNB vapor with substrates such as a KCl crystal and a Cu plate in an evacuated tube.[14] The films produced on these substrates at temperatures between 250 and 400 °C were composed of tentacle-like crystals which were characterized as M[Pc(CN)$_8$] (M=K$_2$,Cu). The films included extra metals, more than would be required for coordination in phthalocyanine rings; the metals were distributed uniformly in the film. High-resolution electron microscopic observation of the thin crystal produced on KCl[15] has elucidated that the film is composed of an intercalation compound of K$_2$[Pc(CN)$_8$] with potassium atoms coordinated to the peripheral cyano groups of the Pc molecules. The reaction of TCNB with KCl or a Cu plate above 450 °C produced amorphous and continuous films of poly-M(Pc) (M=K$_2$, Cu). The ratio of polymeric phthalocyanine to monomeric one increased with elevating reaction temperature. However, their structure and molecular weights have not been examined in detail, owing to the poor solubility of the polymers. Wöhrle et al.[13] has pointed out that the structure of polymer is affected by the condition of the reaction and polymeric phthalocyanines with uniform structure are obtained only in a reaction with specific metals.

4 : poly-M(Pc)

In the present work, thin films were prepared by the reaction of TCNB vapor with various metal substrates of Ni, Co, Fe, and Zn films as well as KCl and a Cu film. The products were characterized by infrared(IR) and UV/visible(UV/VIS) spectroscopy and morphologies of the films were observed by scanning electron microscopy(SEM). The compositions of the films produced on the substrates were examined by photoelectron spectroscopy and X-ray microanalysis. The structures of the products are discussed in comparison with those of films produced on KCl and Cu.

Experimental

Synthesis. TCNB was synthesized from pyromellitic dianhydride by the method of Bailey et al.[16] The crude TCNB was purified by recrystallization from acetic acid. The substrate materials used were a cleavage surface of a KCl single crystal and metallic films. As metallic films, Cu, Ni, Co, Fe, and Zn were evaporated on a cleavage surface of KCl which had been preheated at 150 °C and then kept at room temperature in a vacuum of 1×10^{-4} Pa. Thickness of the metallic films was estimated to be about 100 nm by a quarts crystal microbalance. The refined TCNB and the substrate material were sealed in an evacuated Pyrex glass tube at 10 Pa after flushing with argon gas. The tube was heated at temperatures between 250 and 450 °C for 10 h in a hot air oven. After the reaction the tube was opened in air at room temperature.

IR and UV/VIS Spectra. IR spectra were recorded on a Shimazu 20 DXB spectrometer. The produced films were milled and pressed together with the substrates and examined by the KCl tablet method. The films were dissolved in concentrated sulfuric acid and UV/VIS spectra of the solutions were recorded by a Shimadzu UV-240 spectrometer.

Photoelectron Spectroscopy. X-Ray photoelectron spectra (XPS) were taken on a KRATOS EXAM800, using Mg $K\alpha$ radiation ($h\nu$=1254 eV). A produced film on a substrate was directly attached to a sample holder. All measurements were performed at a pressure of 1×10^{-7} Pa in the analyzing chamber. Surface cleanliness was checked by scanning through the region of binding energy from 0 to 1150 eV. The binding energy was calibrated by a thin gold film vacuum-deposited on the sample, taking the Au($4f_{7/2}$) peak as a reference at 83.8 eV. The C(1s) spectra were deconvoluted with Gaussian curves after subtraction of the background. The spectra of the films were compared with those of metal-free octacyanophthalocyanine (H_2[Pc(CN)$_8$]) synthesized by Wöhrle et al.[12] and copper phthalocyanine (Cu(Pc)) evaporated on a cleavage surface of KCl. The sample of powdered H_2[Pc(CN)$_8$] was examined on an indium plate.

Scanning Electron Microscopy and X-Ray Microanalysis. The morphology of the films produced on substrates was observed by the SEM mode of a JEM-200CX electron microscope. The metal distribution in the films was analyzed by a Kevex-7000 energy dispersive X-ray spectrometer(EDS).

Results and Discussion

UV/VIS Spectra. Films with green or dark blue color were formed on the substrates of Ni, Co, Fe, and Zn films by reaction of TCNB at temperatures between 250 and 400 °C. The films produced below 300 °C were completely soluble in concentrated sulfuric acid. Figure 1 shows the UV/VIS absorption spectra of solutions of the films produced at 300 °C. The films produced on Ni, Co, Fe, and Zn films showed identical absorption bands as those of M[Pc(CN)$_8$] reported by Wöhrle and Hündorf.[12] The intense bands in the 600—750 and 200—400 nm regions are assigned,

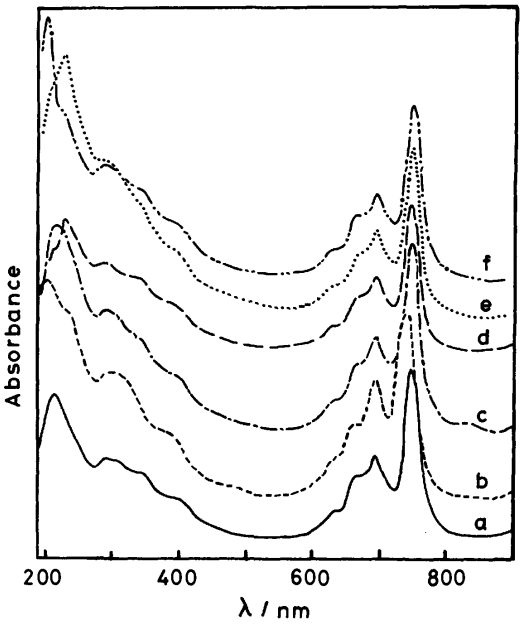

Fig. 1. UV/VIS spectra (in concd sulfuric acid) of films produced on KCl(a), Cu(b), Ni(c), Co(d), Fe(e), and Zn(f) at 300°C.

respectively, as the Q-band and the Soret band caused by π-π^* transitions in phthalocyanine macrocycles. The maximum peaks in the Q-band of those products appear at a shorter wavelength than those of M(Pc).[17] This shift of the Q-band peaks is caused by an electron-withdrawing effect of the peripheral cyano groups in M[Pc(CN)$_8$] molecules. Because the electronegative cyano groups attract a certain amount of electrons from the conjugated π electron system of the Pc macrocycle, the ground state of the π electrons becomes a lower energy level, giving rise to an increase in the π-π^* transition energy. Therefore, the Q-band peaks of M[Pc(CN)$_8$] shift to shorter wavelengths. The films became less soluble in concentrated sulfuric acid upon elevating the reaction temperature. The films produced at 350 °C contained a small amount of insoluble portion in concentrated sulfuric acid, and those at 400 °C contained a considerable amount of the insoluble one. The soluble portions of the films produced on the substrates at 350 and 400 °C, except the film produced on Zn at 400 °C, showed the same spectra as those produced at 300 °C. The films produced on the substrates at 450 °C were gray and black color with a metallic gloss and had a very limited solubility in concentrated sulfuric acid. Figure 2 shows the UV/VIS absorption spectra of the soluble portions of the films produced at 450 °C. The film produced on Zn at 400 °C showed the same spectrum as that at 450 °C. The absorption bands became broader and the maximum peaks in the Q-band shifted to shorter wavelengths by 15 to 21 nm than those of the films produced at 300 °C . The blue shifts of the Q-bands have been observed for associated

porphyrins[18)] and Pc's,[19,20)] dimeric Pc's,[21,22)] and cofacially polymerized Pc's.[9)] These shifts have been discussed in terms of exciton coupling,[23)] which is based on the interaction between the excited states of Pc molecules. On the other hand, Wörhle et al.[13)] have found a red shift of the maximum peak in Q-band for polymerized M(Pc), and concluded that the red shift was caused by an intramolecular π electron delocalization in the Pc polymer. In the present case, it is considered that the soluble portion of the films produced at 450°C is associated or oligomeric $M[Pc(CN)_8]$ and that the insoluble portion of the films produced above 350°C is polymerization products of TCNB.

Infrared Spectra. The IR absorption spectra of the films produced on metal substrates at 350°C are listed in Table 1. The spectra of the films produced on Ni, Co, Fe, and Zn showed similar absorption bands to those of $K_2[Pc(CN)_8]$ and $Cu[Pc(CN)_8]$,[14)] though slight changes in the wave number occurred. The absorption bands in a range from 1000 to 1600 cm^{-1} are characteristic ones of Pc's, which are assigned to C-C and C-N stretching in a Pc skeleton. The absorption bands with high intensity at 2220—2240 cm^{-1} are ascribed to a C≡N stretching of peripheral cyano groups of $M[Pc(CN)_8]$ molecules. In the case of $M[Pc(CN)_8]$ the band appears at 2220 cm^{-1} being independent of metals.[13)] In the present case, however, the bands are of higher wave number than 2220 cm^{-1}, depending on the kinds of metal. In a previous study,[15)] we found that the product formed on KCl could be identified as an intercalation compound of $K_2[Pc(CN)_8]$ with potassium atoms coordinated to the peripheral cyano groups of the Pc molecules. It is assumed that a certain amount of charge is transferred from the potassium atom to the cyano groups by this coordination. The band of C≡N may be affected by this charge transfer, which depends on the electronic configuration of metal atoms. Therefore, the shift suggests that the films produced on the metal substrates form similar complexes between the cyano groups and the respective metals. The formations of these complexes have been confirmed by direct imaging of the thin films with high-resolution electron microscopy.[24)] The ratio of the absorption intensity of the cyano group at 2220—2240 cm^{-1} to the characteristic band of M(Pc) at 1095—1105 cm^{-1}, listed in Table 1, reveals the quantitative value of the cyano groups per Pc unit.[25)] Those ratios of the films

produced on Ni, Co, Fe, and Zn are larger than those of $K_2[Pc(CN)_8]$ and $Cu[Pc(CN)_8]$.[14] This suggests that Pc skeletons are less produced and other products having cyano groups, such as polynitrile, are yielded in reactions with Ni, Co, Fe, and Zn, in comparison with the reaction with KCl and Cu. It is also noted that the films on Ni, Co, Fe, and Zn show absorption bands at 1610—1620cm^{-1} which are stronger than those of the films on KCl and Cu. Lin et al.[26] have observed this band for polymeric Cu(Pc) and Wöhrle et al.[13] have reported that this absorption band is attributed to a -C=N-C=N- linkage in the polynitrile structure **5** produced by the polymerization of the cyano groups. Therefore, it is considered that the films produced on Ni, Co, Fe, Zn contain a certain amount of polynitrile, and the products on these substrates are not so structurally uniform in comparison with those on KCl and Cu. Figure 3 shows the IR spectra of the films produced on Ni at various reaction temperatures. The films produced at 300 and 350 °C showed almost same absorption bands. The spectrum of the film produced at 400 °C showed some signs of structural change. The absorption of C≡N stretching at 2225 cm^{-1} decreased significantly and other absorption bands became broader than those of the fimls produced below 350 °C. The spectrum of the film produced at 450 °C showed a very weak absorption at 2225 cm^{-1} and a broad band without fine structure between 1600 and 1000 cm^{-1}. The ratio, I_{2225}/I_{1100}, decreases with elevating reaction temperature. The films produced on Co, Fe, and Zn showed a similar spectral change upon elevating the reaction temperature. It seems that Pc units polymelize by their residual peripheral cyano groups to form poly-M(Pc) and polynitriles, and that extensive reaction causes a cross linkage such as triazine structure[13] **6** at high temperature. These polymeric products are considered to correspond to the insoluble portions of the films in concentrated sulfuric acid, as mentiond in the previous section.

lines; the data are summarized in Table 2. The spectrum of Cu(Pc) consists of two C(1s) bands with an intensity ratio of 1:3. The band with high energy is attributed to eight carbon atoms bonding with two meso-position nitrogens, and the band with low energy is attributed to 24 carbon atoms in benzene rings of a Cu(Pc) molecule.[27,28] The spectrum of $H_2[Pc(CN)_8]$ shows three C(1s) bands in relative intensity of about 1:2:6. The lowest-energy band is attributed to the carbons of the benzene rings and the intermediate band to the carbons bonding with the two meso-position nitrogen atoms. The third band with a FWHM of 2.5 eV is observed at 288.6 eV. It is well known that a satellite band accompanied with the C(1s) band is observed at about 288 eV for $H_2(Pc)$ and M(Pc).[28,29] However, the third band indicates a considerably strong intensity and a large FWHM for $H_2[Pc(CN)_8]$, as compared with that of the satellite band. Chemical shifts in the photoelectron spectrum of the core electrons are caused by a variation of the valence electron state. Cyano groups polarize to draw the valence electrons from the carbon atom to the nitrogen atom, and the core electrons in the carbon atom are attracted to the nucleus more tightly than those in an isolated carbon atom. Therefore, the binding energy of the C(1s) electron in the cyano groups is higher than that of the normal carbon atoms. Thus, the third band of $H_2[Pc(CN)_8]$ may be assigned to the carbon of the peripheral cyano groups. However, the intensity ratio of the cyano group is smaller than that estimated from the molecular structure of $H_2[Pc(CN)_8]$, which would give an intensity ratio of 1:1:3. This finding suggests that a sample of $H_2[Pc(CN)_8]$ would include a certain amount of polymeric products, such as poly-M(Pc) and triazine structure, since the contents of the cyano groups in these compounds are lower than that of $H_2[Pc(CN)_8]$. The C(1s) spectrum of the film produced on KCl showed two bands with an intensity ratio of 2:3; however, the third band, ascribed to the cyano groups, was not observed in the spectrum and the intensity of high energy band was twice of that of Cu(Pc). The film produced on KCl is composed of an intercalation compound of $K_2[Pc(CN)_8]$ with potassium atoms, in which half of cyano groups coordinate to the intercalated potassium atom and other ones overlap in antiparallel between the adjacent $K_2[Pc(CN)_8]$ molecules, owing to counterbalance of the opposite polarity of $-\overset{\delta+}{C}\equiv\overset{\delta-}{N}$.[30] Because the polarization in -C≡N is relaxed by the coordination and antiparallel overlap, the C(1s) spectrum from cyano groups in the complex crystal would shift to an energy lower than that of the cyano groups in $H_2[Pc(CN)_8]$. Consequently, the band of high energy in the film produced on KCl is ascribed to eight carbons in the cyano groups and eight carbons bonding with meso-position nitrogen atoms in a Pc ring, and the band of low energy to 24 carbons in the benzene rings of a $K_2[Pc(CN)_8]$ molecule. The C(1s) spectrum of the film produced on Cu showed two bands similar to that of the film produced on KCl and did not show the third band ascribed to isolated cyano groups. It suggests that the film on Cu is composed of an intercalation compound of $Cu[Pc(CN)_8]$ with copper atoms isomorphous to that of $K_2[Pc(CN)_8]$ with potassium atoms.

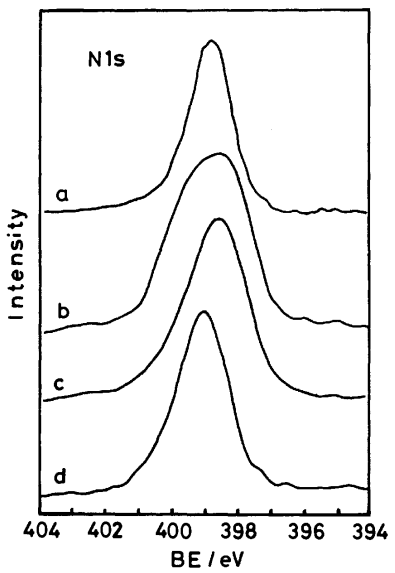

Fig. 5. Nitrogen 1s photoelectron spectra of Cu(Pc)(a), $H_2[Pc(CN)_8]$(b), and films produced on KCl(c) and Cu(d) at 350°C.

Figure 5 shows the N(1s) spectra of Cu(Pc), $H_2[Pc(CN)_8]$, and the films produced on KCl and Cu at 350 °C. The N(1s) band of $H_2[Pc(CN)_8]$ is broad because a $H_2[Pc(CN)_8]$ molecule has four kinds of nitrogen atoms, that is, four pyrrole nitrogens(two -NH- and two -N=), four meso-position nitrogens, and eight nitrogens of the peripheral cyano groups. On the other hand, the N(1s) spectrum of Cu(Pc) showed a narrow band, since the energy separation between the four equivalent pyrrole-ring nitrogens and the four meso-position nitrogens is estimated to be small.[29] The N(1s) spectra of the films produced on KCl and Cu also showed relatively narrow bands. The nitrogen atoms of the peripheral cyano groups seem to have a binding energy close to those of the other nitrogens in $K_2[Pc(CN)_8]$ and $Cu[Pc(CN)_8]$ molecules, owing to formation of the complex crystals. The films produced on Ni, Co, Fe, and Zn at 350 °C showed similar N(1s) spectra to those of films produced on KCl and Cu.

Figure 6 shows C(1s) and K(2p) spectra of the films produced on KCl at various temperatures. The film produced at 300°C shows one broad C(1s) band, which can not be separated into two bands by deconvolution. This suggests that $M[Pc(CN)_8]$ is not completely

formed at 300 °C, and that the films contain a certain amount of products with low molecular weights. In a film produced at 400 °C, the high-energy band of the C(1s) spectrum shows a large intensity and the K(2p) spectrum emerges clearly. The film produced at 450 °C shows a C(1s) shoulder of low energy at about 283 eV. Such a low-energy C(1s) band is well-known for graphite, which consists of a planar conjugated system of π electrons. It seems that the film produced at 450 °C is composed of poly-M(Pc) and cross-linked planar polymers with structure elements such as polynitrile and triazine. The intensity of the K(2p) band increased with elevating the reaction temperature. This indicates that more potassium atoms diffuse from the substrate to the surface of the produced film as temperature increases.

Figure 7 shows the valence band spectra of the films produced on various substrates at 350 °C. The spectrum of a film produced on KCl is in good agreement in binding energy from 8 to 30 eV with that of phthalocyanines reported by Höchst et al.[28] The valence band spectra in this region of M(Pc) could be explained as the spectra of benzene and pyrrole; the spectra were not interfered with by the bond between the central metals and the Pc ligands.[28,29] The spectrum of the film produced on Cu shows similar bands to those of the film produced on KCl, although their relative intensities are different. The spectral features of the films produced on Ni, Co, Fe, and Zn deviate from that of the film produced on KCl and the relative intensities in their spectra are different from that of M(Pc). It seems that the spectral deviation is ascribed to a smaller yield of M[Pc(CN)$_8$] in these films, as compared with the films produced on KCl and Cu.

Scanning Electron Microscopy and X-Ray Microanalysis. Figure 8 shows scanning electron micro-

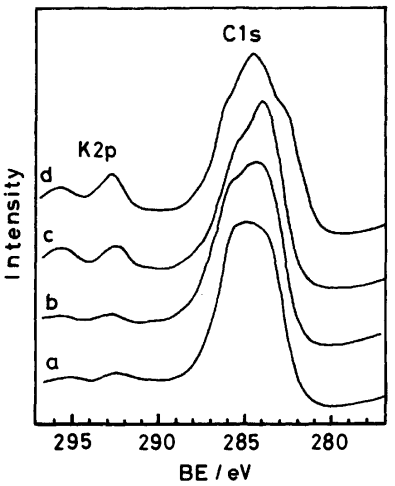

Fig. 6. Carbon 1s and potassium 2p photoelectron spectra of films produced on KCl at 300°C(a), 350°C(b), 400°C(c), and 450°C(d).

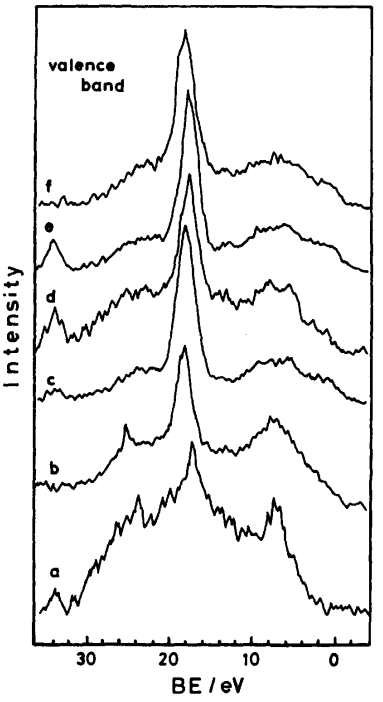

Fig. 7. Valence-band photoelectron spectra of films produced on KCl(a), Cu(b), Ni(c), Co(d), Fe(e), and Zn(f) at 350°C.

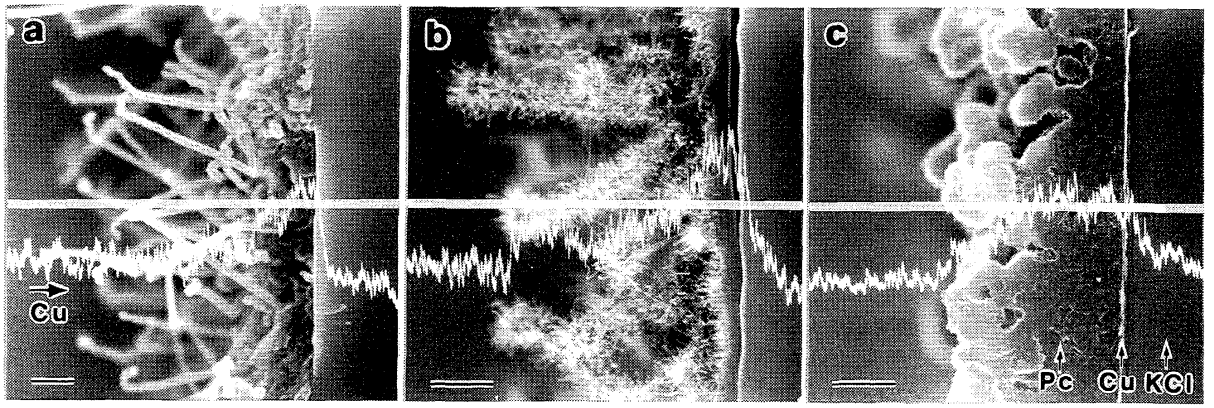

Fig. 8. Scanning electron micrographs and X-ray microanalyses of copper in the films produced on Cu at 250°C(a), 350°C(b), and 450°C(c). Bar=5 μm.

graphs of sections of the films produced on Cu at various temperatures and the distribution of Cu measured by EDS in which the electron beam was scanned from the surface to the bottom of the film along the center line of the figure. The film produced at 250 °C is composed of long and slender crystals of the intercalation compound of Cu[Pc(CN)$_8$] with Cu atoms. At 350 °C, the crystals grow thin and are a fine tentacle-like type which branch from each thick crystal. The EDS signal shows that Cu atoms are distributed from the bottom to the surface of the film and that the tentacle-like crystals contain Cu atoms. At 450 °C, the film is composed of an amorphous thick layer with bulb-like crystals on the surface. The thick layer is considered to be highly polymerized products of poly-M(Pc) and cross-linked polymers with structure elements, such as polynitrile and triazine, which are insoluble in concentrated sulfuric acid.

Figure 9 shows the morphology of films produced on various substrates at 350 °C and the distribution of the respective metal atoms. The film on KCl is composed of long tentacle-like crystals of the intercalation compound of K_2[Pc(CN)$_8$] with potassium atoms, as observed previously.[14] These crystals grow directly on the surface of the KCl substrate. On the other hand, the films on Ni, Co, Fe, and Zn consist of three layers: that is, a thin metal layer evaporated on KCl, a thick amorphous layer, and tentacle-like crystals in the top layer. The EDS signals show that the respective metals are distributed from the substrates to the surfaces of the films. The tentacle-like crystals are considered to be intercalation compound of M[Pc(CN)$_8$] (M=Ni, Co, Fe, and Zn) with the respective metal atoms, because their morphology resembles that of the K_2[Pc(CN)$_8$] complex. It seems that the amorphous layer contains polynitriles which condense among the tentacle-like crystals. Furthermore, this layer may correspond to the insoluble portion in concentrated sulfuric acid, because the film on Cu (Fig. 8(b)) which has only a thin amorphous layer shows a higher solubility than the others.

In conclusion, the products in the films are summarized in Table 3. The films produced on Cu, Ni, Co, Fe, and Zn below 400 °C contained M[Pc(CN)$_8$] (M=Cu, Ni, Co, Fe, and Zn) and polymerized products such as polynitrile. The M[Pc(CN)$_8$] molecules formed tentacle-like crystals of the intercalation compound with the respective metals and were soluble in concentrated sulfuric acid. The intercalation compounds were produced less in these films compared with that in a film produced on KCl. The polymerized products formed amorphous layers, which were insoluble in concentrated sulfuric acid. These polymerized products increased in the films

a) Products; 3:M[Pc(CN)$_8$] (M=K$_2$, Cu, Ni, Co, Fe, Zn), 3': intercalation compounds of M[Pc(CN)$_8$], 3'': associated or oligomeric M[Pc(CN)$_8$], 4: poly-M(Pc) containing structure elements of 5 and 6, 5: polynitrile, 6: triazine. b) K$_2$[Pc(CN)$_8$] is not completely formed and a certain amount of products with low molecular weight is contained.

with elevating reaction temperature. The film produced at 450 °C contained highly polymerized products of poly-M(Pc) and cross-linked polymers with such structural elements as polynitrile and triazine. A small amount of the soluble portion in concentrated sulfuric acid was identified as associated or oligomeric M[Pc(CN)$_8$].

The authors are grateful to Professor Dieter Wöhrle of Bremen University for supplying the sample of H$_2$[Pc(CN)$_8$] and helpful discussions. Thanks are also due to Mr. Satoru Nishiyama for access to the photoelectron spectroscopy and for his helpful advice.

Photoinduced Extraction and Active Transport of Anions by a Triphenyl Methane Derivative

Hiroshi SASAKI, Akihiko UENO, and Tetsuo OSA*
Pharmaceutical Institute, Tohoku University, Aobayama, Sendai 980
(Received January 26, 1988)

Triphenylmethane derivative leukobase (**1**) was converted to its cation form **2** by UV irradiation. This lipophilic cation form was stable in dichloromethane with green color (λ_{max}=634 nm), and returns to the original colorless form of **1** when shaked with an alkaline solution. Compound **2** exhibited excellent anion extraction ability (from aqueous solution into dichloromethane) under the conditions of appropriate pH, but **1** has no anion extraction ability. Photoinduced active transport of anions across a liquid (dichloromethane) membrane was achieved by using the difference in the extraction ability between **1** and **2** together with the difference in pH between the source and receiving phases.

Many photoresponsive systems are widely studied for the purposes of developing excellent photosensors, photomemories, and molecular devices for efficient energy conversion. Among many chromophores, which can be used as photoswitches of these systems,[1,2] azobenzene and spirobenzopyran have most frequently been employed. We have already shown that photoinduced changes of ion permeability[3,4] and of membrane potential,[5-15] can be attained with poly(vinyl chloride) (PVC) membranes containing azobenzene or spirobenzopyran derivatives. The photoresponsiveness of triphenylmethane derivatives is very different from that of azobenzene and spirobenzopyran since it is dissociated into two species, one is an organic cation and another is a hydroxide anion, and consequently triphenylmethane derivatives have been used to change solution properties[16-18] or ionic features of materials[19,20] by light. The present study deals with the use of a triphenylmethane derivative leukobase (**1**) as a photocontrollable anion carrier, and the active transport performed here may be compared with the similar phenomena achieved in the systems where spirobenzopyran[21] and azobenzene[22] derivatives act as photoresponsive carrier.

Experimental

Materials. Sodium picrate was prepared according to the Fuoss method.[23] Methyl Orange purchased as extra pure reagent grade was purified by recrystallization. The pH values of the aqueous solutions used in liquid-liquid extraction and active transport experiments were adjusted by using NaOH and HCl solutions. Dichloromethane was of spectral grade.

Bis[4-(dibutylamino)phenyl]phenylmethanol (1). *N,N*-Dibutylaniline (6 g, 29.2 mmol) and benzaldehyde (1 g, 9.4 mmol) were dissolved in a mixture of ethanol (8 ml) and 35% HCl (3 ml). The mixture was refluxed for 48 h, and cooled and alkalized with 2 mol dm^{-3} NaOH. The solution was extracted with dichloromethane, and the organic layer was dried over K_2CO_3 and evaporated. Purification by silica-gel column chromatography (eluted by hexane until *N,N*-dibutylaniline was completely removed and subsequently by a mixed solvent of hexane and ether (50:1 by volume)) afforded 3 g (62%) of **1** as pale yellow oil. Found: C, 81.83; H, 10.01; N, 5.15%. Calcd for $C_{35}H_{50}N_2O$: C, 81.66; H, 9.79; N, 5.44%. ^{1}H NMR ($CDCl_3$) δ=0.7—1.7 (28H, m, $N(CH_2C_3\underline{H}_7)_2$), 3.1—3.6 (8H, m, $N(C\underline{H}_2C_3H_7)_2$), 5.3 (1H, s, OH), 6.4—7.4 (13H, m, aromatic ring).

Liquid-Liquid Extraction. At 25 °C, a 2 ml of aqueous solution containing sodium picrate or Methyl Orange (1.0×10^{-5} mol dm^{-3}) and sodium hydroxide (various concentrations) was vigorously shaken with an equal volume of dichloromethane solution containing **1** or **2** (1.0×10^{-5} mol dm^{-3}). After sufficient agitation, the picrate concentration in aqueous layer was determined by absorbance change at 354 nm. The Methyl Orange concentration was also determined in a similar manner at 462 nm.

Method of Anion Transport across a Liquid Membrane. All measurements were carried out at 25 °C with a cylindrical U-tube (diameter: 17 mm) having a plain area (2.0 cm^2) in the center of the tube, which allows effective UV irradiation. The composition of the system is as follows: phase A: Methyl Orange (1.0×10^{-5} mol dm^{-3}) solution (5 ml of water); phase B: dichloromethane solution (20 ml) containing 5.0×10^{-6} mol dm^{-3} of **1**; phase C: Methyl Orange (1.0×10^{-5} mol dm^{-3}) solution containing various concentrations of NaOH (5 ml of water). During transport experiments the phase B (liquid membrane) was stirred gently.

Photoirradiation Conditions. Photoirradiation was performed with a 500 W xenon lamp (Ushio Electric Inc.) using a Toshiba cut-off filter UV D-35 for isolating UV light (320 nm$<\lambda<$400 nm).

Results and Discussion

Photochemical and pH-Dependent Interconversion between 1 and 2. Absorption spectra of **1** before and after UV irradiation in dichloromethane are shown in Fig. 1. Compound **1** before UV irradiation showed an absorption band at 270 nm (ε=35000) and the solution was colorless. After UV irradiation (ca. 6 min), the absorption band at 270 nm was decreased and a new absorption band was observed at 634 nm (ε=55000), the color of the solution being green. This spectral change indicates that **1** was converted to **2**.[16] The time course of the reaction monitored by the absorbance change at 634 nm is shown in Fig. 2. The reaction was completed within 6 min. The cation form **2** was very stable as shown by no change in the

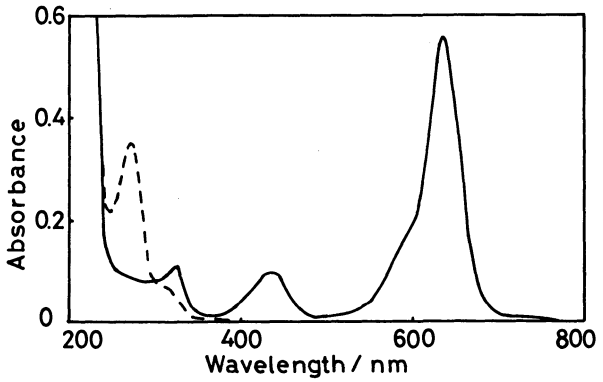

Fig. 1. Absorption spectra of **1** in dichloromethane (1.0×10^{-5} mol dm^{-3}) before (---) and after (——) UV irradiation.

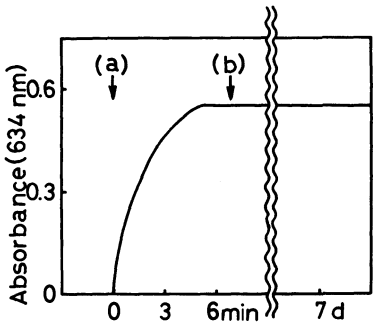

Fig. 2. The change of the absorbance at 634 nm of **1** (1.0×10^{-5} mol dm^{-3}) in dichloromethane induced by UV irradiation.

absorbance at 634 nm even after 7 d. The extent of the reversal of **2** to **1** was examined at 25 °C by shaking a 2 ml of dichloromethane solution of **2** (1.0×10^{-5} mol dm^{-3}) with the equal volume of the aqueous solutions of different pHs. The concentration of **2** depended upon the pH of the aqueous solutions (line (a) in Fig. 3); the cation form **2** was transformed into the original form of **1** by the addition reaction of hydroxide ions to the tertiary carbon in **2** when shaked with alkaline solutions. On the contrary, **2** was not transformed to **1** when shaked with acidic solutions of pH>1.

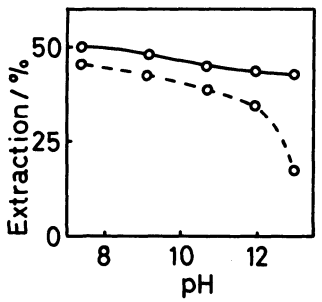

Fig. 4. Effect of pH on extraction by **2**.
——; Sodium picrate. ---; Methyl Orange. The conditions are same as those in Fig. 3.

Liquid-Liquid Extraction. The results of liquid-liquid extraction with **1** and **2** are shown in Fig. 4. The extraction ability of **2** decreased with increasing pH value. In the case of Methyl Orange, an abrupt drop of the extraction ability was observed around pH 12. The absorbances of the dichloromethane solutions measured after the extraction are shown as lines (b) and (c) in Fig. 3. The results indicate that electrostatic interaction of **2** with picrate or Methyl Orange enables **2** to be hardly affected by hydroxide ion. This effect has not been seen with benzoate anion or 1- or 2-naphthaleneacetate anion, the pH profiles being the same as shown in Fig. 3-(a). It is interesting that there are significant differences between picrate and Methyl Orange anions in extraction facility and in the ability of stabilizing the cation form **2** against the attack of hydroxide ion. These results also imply that various anions may be selectively extracted by **2** under appropriate conditions (the selectivity for the picrate anion is most remarkable around pH 13 in this study).

Photoinduced Active Transport. Based on the anion extraction ability of **2**, photoinduced active transport has been attempted. Figure 5 illustrates time response of the concentration of Methyl Orange in phases A and C. The pHs of phases A (without

NaOH) and C (containing 0.10 mol dm^{-3} of NaOH) were initially set to be 7.3 and 13.0, respectively. In the dark the concentration changes of Methyl Orange in both phases A and C were negligible. After UV irradiation for 10 min onto phase B,[24] the concentration of Methyl Orange began to decrease in phase A, and increase in phase C with time. After 10 h, the concentrations of Methyl Orange in phases A and C became ca. 30% and ca. 150%, respectively, of the initial concentration.[25] After 72 h, the concentrations in phases A and C became ca. 1% and ca. 196%, respectively, and at this point 90% of compound **2** was found to be changed to **1**. The result also indicates that the system can be used for transporting various organic salts against the gradient of hydroxide ion. When the pH of phase C is 11.9, active transport still proceeds, but the rate of the Methyl Orange transportation is smaller than the case of pH 13.0. When the pH in phase C was 10.6, active transport was not attained, the concentration of Methyl Orange in phase C decreasing as in phase A (Fig. 6). When the pH in phase C was 8.8, the rate of Methyl Orange diminution in phase C was almost equal to in phase A. Table 1 lists the concentrations of Methyl Orange in phases A and C, at the time of 8 and 72 h after UV irradiation in the above mentioned pH runs. In any case the concentration in phase A decreases with time. On the contrary, the profile of concentration change of Methyl Orange in phase C is affected by the pH in the phase.

The mechanism of the active transport is shown in

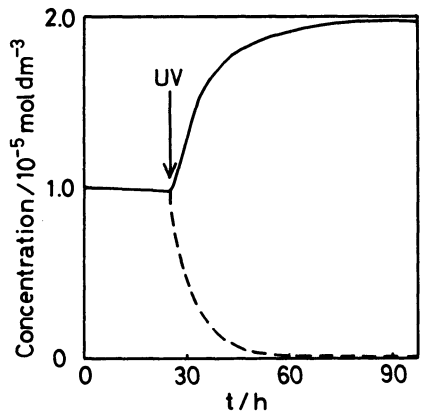

Fig. 5. Time response of the concentration of Methyl Orange in phases A (---) and C (——).
pH values in phases A and C were 7.3 and 13.0, respectively. The concentration of **1** in phases A and C was 1.0×10^{-5} mol dm^{-3}. UV means UV irradiation for 10 min.

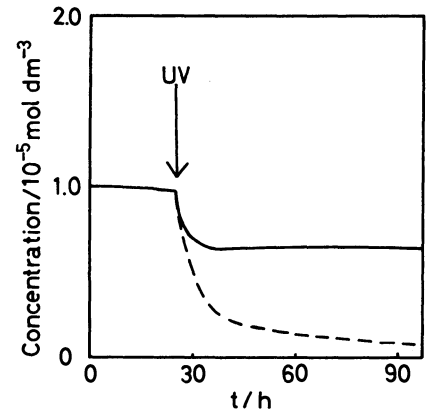

Fig. 6. Time response of the concentration of Methyl Orange in phases A (---) and C (——).
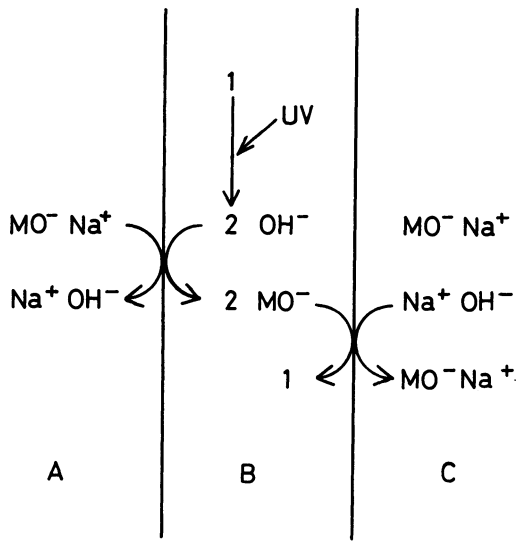
pH values in phases A and C were 7.3 and 10.6, respectively. The concentration of **1** in phases A and C was 1.0×10^{-5} mol dm^{-3}. UV means UV irradiation for 10 min.

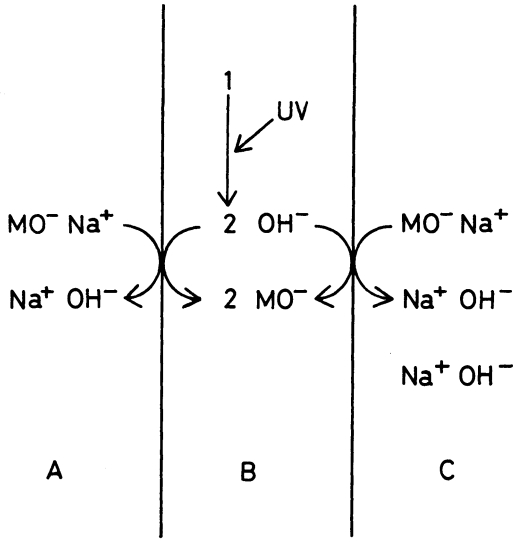


Scheme 1. Schematic sketch of the photoinduced active transport mechanism (the pH in phase C was higher than 11). MO$^-$; Methyl Orange anion.

Table 1. Methyl Orange Concentrations in Phases A and C after UV Irradiation for 10 min

pH in phase C	Methyl Orange concentration/10^{-5} mol dm^{-3}			
	a)		b)	
	Phase A	Phase C	Phase A	Phase C
13.0	0.39	1.40	0.01	1.96
11.9	0.39	1.29	0.04	1.49
10.6	0.36	0.65	0.08	0.64
8.8	0.56	0.55	0.53	0.59

pH in phase A was 7.3. Initial concentration of Methyl Orange in phases A and C was 1.0×10^{-5} mol dm^{-3}. a) 8 h after UV irradiation. b) 72 h after UV irradiation.



Scheme 2. Schematic sketch of the photoinduced transport mechanism (the pH in phase C was lower than 11). MO^-; Methyl Orange anion.

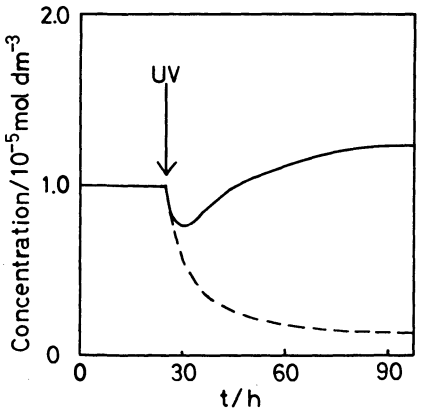


Fig. 7. Time response of the concentration of sodium picrate in phases A (---) and C (——).
pH values in phases A and C were 7.0 and 12.9, respectively. The concentration of **1** in phases A and C was 1.0×10^{-5} mol dm^{-3}. UV means UV irradiation for 10 min.

Scheme 1. At first compound **1** is converted to **2** by UV irradiation, and then **2** binds Methyl Orange at the interface between A and B, releasing hydroxide ion toward phase A. The complex of Methyl Orange anion and **2** is attacked by excess hydroxide ion at the interface between phases B and C, and **2** is converted to **1** releasing Methyl Orange anion toward phase C. When the pH in phase C was less than 11, the concentration of Methyl Orange in phase C decreased as in phase A. The proposed mechanism of the phenomenon is shown in Scheme 2. In this case, the conversion from **2** to **1** does not occur and Methyl Orange is extracted into phase B from both phases of A and C.

We also examined active transport of sodium picrate. The result is shown in Fig. 7. According to the extraction data (Figs. 3 and 4), the anion binding ability of **2** for sodium picrate was stronger than for Methyl Orange, and the ability for sodium picrate was depended upon the pH value to a lesser extent than for Methyl Orange. Therefore, the concentration in phase C (cf. Fig. 5) decreased at an early stage of UV irradiation as in phase A. After 72 h the concentration in phase C slightly increased as the subsequent phenomenon of efficient extraction of picrate anion from phase A to phase B.

Conclusion

The results of extraction data indicate that compound **2** has excellent anion binding ability which depends upon pH value and anion species. Photoinduced active transport of anions through a liquid membrane was achieved on this basis. This photochromic compound works without host–guest complexation and may be regarded as a new system for photoregulated transportation.

This work was supported by a Grant-in-Aid for Encouragement of Young Scientist (No. 61790179) from the Ministry of Education, Science and Culture.

(Received January 30, 1988)

The heat capacities of *p*-terphenyl and *p*-terphenyl-d_{14} were measured by adiabatic calorimetry between 3 and 300 K. The phase transition associated with a molecular conformation change was observed as a λ-shaped anomaly at (193.5±0.1) K and at (180.3±0.1) K. The enthalpies of transition are (304±20) J mol^{-1} and (288±20) J mol^{-1} and the entropies of transition are (1.63±0.10) J K^{-1} mol^{-1} and (1.63±0.10) J K^{-1} mol^{-1}, respectively. The anisotropy of the intermolecular interaction is discussed and the anomalous portion of the heat capacities in the transition region was compared favorably with a two-dimensional Ising model.

The molecule of *p*-terphenyl (1,1′:4′,1″-terphenyl) is twisted in the gaseous and in the liquid states.[1-4] However, it is seemingly planar in the crystal at room temperature.[5-8] The crystal belongs to the space group $P2_1/a$ and the molecule occupies the center of inversion. On cooling, however, the crystal undergoes a phase transition at about 194 K, below which the molecule is twisted though it still occupies the inversion center.[9] The space group of the low temperature phase is $P\bar{1}$. Similar phase transitions (twist transitions) have been observed in the related substances, so-called poly(*p*-phenylene)s, i.e. in biphenyl[10-17] at 40.4 K[18-20] and in *p*-quaterphenyl[21,22] at 233.0 K.[23]

Many experimental works which made use of optical[24-31] and other techniques[32-40] have revealed that the transition of *p*-terphenyl is continuous or very-nearly continuous under the normal pressure. Under high pressures ($\gtrsim 10^8$ Pa), the transition has been reported discontinuous.[19,31] Critical exponents for some physical properties under the normal pressure have been reported as β=0.15[41] and ν=0.12.[42] These values can be related to a two-dimensional Ising model. The two-dimensionality of the interaction has been supported by neutron[43,44] and NMR[45] experiments.

Baudour et al.[7] refined the crystal structure at room temperature on the assumption that the room temperature phase was a disordered one. They have obtained a doubly peaked electron density diagram for the central phenyl ring, which strongly suggests an order-disorder nature of the transition and is consistent with the failure in search for soft-modes.[25,26] Dynamical aspects of the transition have been investigated by using neutron scattering[41,43,44,46,47] and NMR,[45,48-51] and thereby the critical phenomenon, the critical slowing down of the order parameter fluctuation, was found, which also implied an order-disorder nature of the transition.

It is interesting to note that the pressure dependence of the transition temperature is negative,[29,31] which fact also suggests that the transition is related to a subtle balance between intra- and intermolecular interactions because the intermolecular interaction, which prefers a planar conformation, is more affected by compression than the intramolecular interaction.

A theoretical work by Ramdas and Thomas[52] predicted the existence of another unknown phase on the basis of calculation of static lattice energies. Raich and Bernstein[53] theoretically confirmed an order-disorder nature of the transition through calculation of generalized susceptibility of twisting motion within one-particle scheme.

Although extensive investigations have been carried out on the twist transitions of poly(*p*-phenylene)s and many interesting features were revealed, no systematic study had been reported on thermodynamics of the transitions when we began thermodynamic investigations on biphenyl and related substances[18-20,23,54-60] in an attempt toward a unified understanding of the twist transitions of poly(*p*-phenylene)s. After completion of the study presented here, the results of precision heat capacity measurements on nonlabelled *p*-terphenyl were reported by Chang.[40] Because we measured also on *p*-terphenyl-d_{14} for which there had been no precision thermodynamic data reported, we thought it deserves publication. To provide a consistent set of data from the same calorimeter, we will record the heat capacity values of nonlabelled *p*-terphenyl as well as those of *p*-terphenyl-d_{14}.

Experimental

p-Terphenyl was purchased from Nakarai Chemicals, Ltd. and purified by the method of fractional sublimation in vacuum at about 400 K. The purity of the sublimed specimen was better than 99.9 moles per cent as confirmed by gas chromatography. A part of the sublimed specimen

† Contribution No. 143 from Chemical Thermodynamics Laboratory, Faculty of Science, Osaka University.

was used for adiabatic calorimetry without any further treatment; it weighed 21.0701 g (0.091488 mol) in vacuum. The rest of the sublimed specimen was melted under a helium atmosphere (10^5 Pa), gradually cooled down to room temperature for recrystallization, and pulverized gently. The heat capacity of the melt-pulverized sample was also measured; its mass was 15.2290 g (0.066124 mol). Each sample was loaded into a gold-plated copper calorimeter vessel, which was sealed after adding some helium gas (7 kPa at room temperature) to aid thermal uniformity of the vessel. The contribution of the helium gas was negligibly small in comparison with both the sample and the total heat capacities. The as-sublimed sample contributed 64 per cent at 10 K to the total heat capacity including that of the calorimeter vessel; the contribution decreased to 40 per cent at 100 K and then increased to 54 per cent at 300 K as temperature rose.

p-Terphenyl-d_{14} (nominal isotope purity of 98 per cent, Merck Sharp & Dohme Canada, Ltd.) was purified by fractional sublimation in vacuum at about 400 K. The sublimed specimen was melted under a helium atmosphere (10^5 Pa) and cooled gradually down to room temperature for recrystallization. The specimen was then pulverized gently for the ease of loading it into the calorimeter vessel. The chemical and the isotope purities of the specimen were better than 99.9 moles per cent as confirmed by gas chromatography and 98 per cent by high-resolution NMR, respectively. The powdered specimen (8.7131 g, 0.035652 mol) was loaded into the same calorimeter vessel and treated in the same way as for *p*-terphenyl. The contribution of the sample to the total heat capacity was 51 per cent at 10 K, 27 per cent at 100 K and 42 per cent at 300 K.

The working thermometers attached to the calorimeter vessel were a platinum (model 8164, Leeds & Northrup Co.) and a germanium (model CR-1000, CryoCal Inc.) resistance thermometers. Their temperature scales are based on the IPTS-68, helium gas thermometry and the 1958 ^{4}He vapor pressure scale. The apparatus and the operation of the adiabatic calorimetry were the same as described elsewhere.[58]

Results and Discussion

Heat Capacities and Thermodynamic Functions.

The heat capacity measurements were made between 3 and 300 K. The primary data are tabulated in Table 1 for *p*-terphenyl and Table 2 for *p*-terphenyl-d_{14} in chronological sequence and both are plotted in Fig. 1, where data of the *p*-terphenyl specimen that was sublimed and melted are not included. Curvature corrections were not made. After each energy input was over, thermal equilibrium within the calorimeter vessel was attained in 2 min below 20 K. As temperature rose, the time needed for equilibration gradually increased to 10 min at 80 K and 20 min just below the transition temperature, and it abruptly decreased to 10 min above the transition.

As the difference in sample preparation might cause differences in thermodynamic properties especially at the phase transition, the heat capacities of the as-sublimed *p*-terphenyl sample was compared with

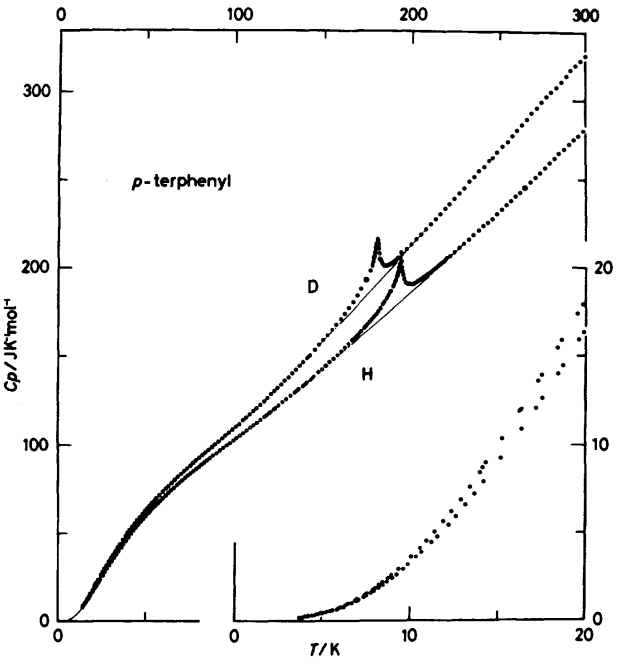

Fig. 1. Measured molar heat capacities of *p*-terphenyl (○) and *p*-terphenyl-d_{14} (●).

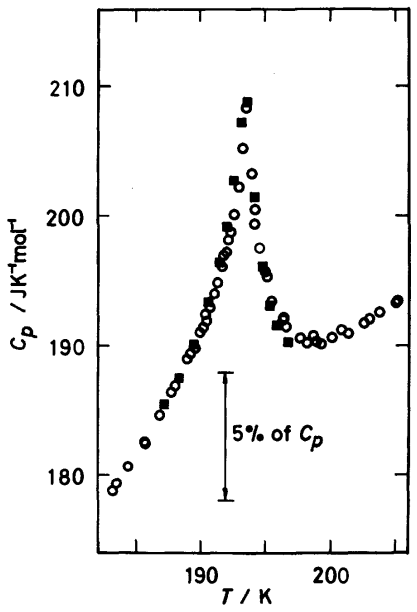

Fig. 2. Comparison of the anomalies due to the twist transition of the as-sublimed (○) and the sublimed-melted (■) *p*-terphenyl samples.

those of the melt-pulverized sample as shown in Fig. 2. The fact that there is no apparent difference rules out any possibilities of the formation of metastable phases and/or difference in crystallinity.

Figure 3 shows deviations of the present and Chang's[40] data from the smooth heat capacities determined from the present *p*-terphenyl results. The present results are systematically smaller by ca. 0.2 per cent than Chang's data in other than the transition region above 20 K.

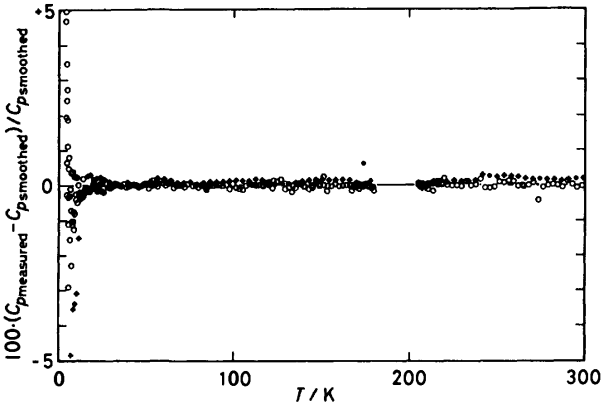

Fig. 3. Deviations of the measured values from the smooth curve determined from the present data for p-terphenyl; O, present work; ◆, Chang.[40]

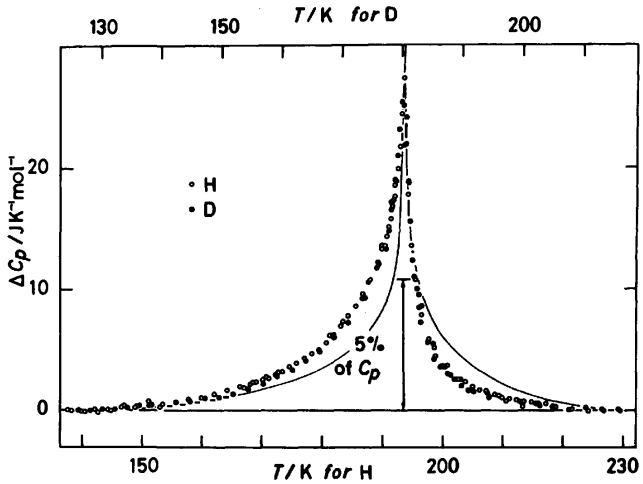

Fig. 4. Excess heat capacities due to the twist transition of p-terphenyl (O) and p-terphnyl-d_{14} (●).

Some thermodynamic quantities calculated from the present results are given at rounded temperatures in Tables 3 and 4, where small contributions below 4 K were estimated by extrapolating the heat capacity curve from the high temperature side smoothly.

Anomaly Due to Phase Transition. As clearly seen in Fig. 1, the twist transition is observed as a λ-shaped anomaly with a maximum at (193.5±0.1) K for p-terphenyl and (180.3±0.1) K for p-terphenyl-d_{14}. The transition temperature of the H compound reported by Chang[40] (193.55 K) agrees well with our result. The general shape of the anomaly is also in good agreement. The C_p maximum determined by Cailleau and Dworkin[39] occurred at 193.33 K, whereas they gave 191.0 K from DSC experiment. Cailleau and Dworkin also reported the transition temperature of the D compound as 178.8 K from DSC. In spite of sharp rise in heat capacity, no latent heat was detected in agreement with the results reported by Cailleau and Dworkin,[39] and Chang.[40] By assuming the normal portions of heat capacity as shown by the solid lines in Fig. 1, the excess parts were separated. This can be seen in Fig. 4 and the anomaly ranges from 145 K to 225 K (p-terphenyl) and 130 K to 210 K (p-terphenyl-d_{14}). The values of the enthalpies and the entropies of transition obtained by graphical integration are given in Table 5 and compared with the literature values.[39,40] Small differences between ours and those reported by Chang[40] are mainly due to the difference in estimation of the normal portion of heat capacity. As the estimation of the excess parts is more or less artificial in cases of structural phase transitions, it is considered that these values are in reasonable agreement. Thus, the entropy of transition of p-terphenyl is much larger than that of biphenyl (0.129 J·K^{-1}·mol^{-1})[18-20] which undergoes a displacive type of transition. This fact is consistent with an order-disorder nature of the transition of p-terphenyl. The detailed comparison of the properties of the twist transitions of biphenyl, p-terphenyl, and p-quaterphenyl was given in a previous paper.[23]

The critical exponent α for heat capacity was determined by plotting the excess heat capacities

$$\Delta C_p^{\infty} |T - T_c|^{-\alpha}$$

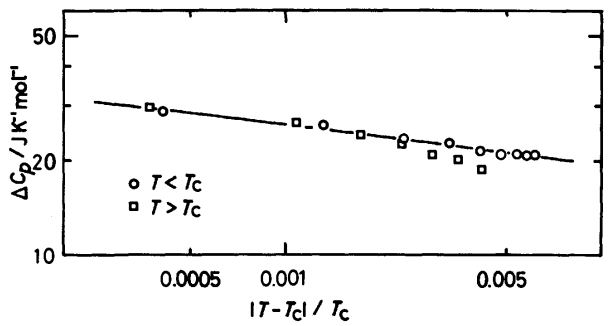

Fig. 5. Determination of the critical exponent α.

measured in series 26 in Table 1 as shown in Fig. 5. The temperature interval between adjacent points is about 0.1 K. The same value, $\alpha=0.13$, was obtained below and above the transition. This value is more like that of three-dimensional Ising model, and the positive sign of the exponent should result in an infinite heat capacity at the transition point. However, the measured heat capacity is finite at the transition point. Chang[40] reported an apparent rounding of the anomaly using a smaller temperature increment (0.025 K). He gave a larger α of 0.55 below the phase transition from a very detailed study close to the C_p maximum. It was not possible to obtain α for *p*-terphenyl-d_{14} because scatter of the measured points was larger.

Now, we will compare thermodynamic properties of the twist transitions in crystalline *p*-terphenyl and *p*-terphenyl-d_{14}. The shapes of the anomalies and the values of the entropies of transition indicate that the two compounds undergo the transition of the same mechanism and therefore the same model should apply. On the other hand, the transition temperature lowers on deuteration by about 13 K. The lowering of the transition temperature on deuteration also occurs in biphenyl.[18-20,58] Since the inter- and the intramolecular interactions are expected almost the same in the crystals of hydrogenated and deuterated compounds, these isotope effects reflect the roles of the molecular mass and/or moment of inertia in the twist transition though Raich and Bernstein[53] ruled out such a dynamical origin of the isotope effect. It is noteworthy that *p*-terphenyl-2,2″,3,3″,4,4″,5,5″,6,6″-d_{10} (C_6D_5-C_6H_4-C_6D_5) shows the twist transition at an intermediate temperature, 185.3 K.[47] Relative importance of the moment of inertia and the molecular mass in the mechanism of the transition will be experimentally demonstrated if one performs a study on

a) Read from Fig. 1 of Ref. 39. b) Determined by DSC.

p-terphenyl-4,4″-d_2.

Although Chen et al.[38] suggested that there is another phase transition at about 8 K based from their EPR experiments, any anomalous behavior was not observed in the present experiments.

Anisotropy of Interaction The examination of crystal structures of poly(*p*-phenylene)s makes us suspect that the interaction within the ab plane (a, b, and c refer, hereafter, to the crystal axes of the room temperature phase) is much stronger than in the direction of the c axis because the nearest neighbor distance is much shorter in the ab plane than that along the c axis. Furthermore, in view of the order-disorder mechanism, it is also expected that inter-"spin" interaction, i.e. a part of the intermolecular interaction which depends on molecular twisting is much stronger within the ab plane than along the c axis since the interatomic distance between two neighboring molecules in the c direction changes little upon twisting of one of them. Indeed, two-dimensionality of interaction has been reported experimentally.[43–45]

In order to see the anisotropic interaction, we now examine the low temperature ordered structure.[9] The

structure viewed along the c axis is schematically shown in Fig. 6, where Roman numerals distinguish translationally inequivalent molecules. The solid line represents the triclinic unit cell of the low-temperature phase and the broken line the monoclinic unit cell of the room-temperature phase. All of the molecules shown there lie at the same height. Since the "spin" in this case corresponds to twisting of the central phenyl ring with respect to the outer rings, the atomic position of "wrong" molecules were determined from those of "right" molecules which are known by experiment.[9] The intermolecular interactions were then calculated assuming that it may be expressed by the sum of interatomic potentials of Buckingham type.[60] Summation was made over all the atom pairs between the two adjacent molecules under consideration.

The calculated intermolecular and inter-"spin" interactions are summarized in Table 6, where the inter-"spin" interaction energy J is defined by

$$J=\frac{1}{2}(E_{r-r}+E_{w-w})-\frac{1}{2}(E_{r-w}+E_{w-r}).$$

It is evident that interactions within the ab plane are much stronger than those along the c axis. Thus, a two-dimensional Ising model will apply to the twist transition of *p*-terphenyl at least in the first approximation. Indeed, the experimental excess heat capacity is well reproduced with a two-dimensional Ising mdel as shown in Fig. 4.

It is well-known that the heat capacity of any two dimensional Ising model diverges as $\ln|T-T_c|$ at T_c and shows the critical exponent $\alpha=0$. However, the experimental value determined in this study is not 0 but 0.13. However, the discrepancy is not crucial because the exact formula of the heat capacity gives a slope of about 0.1 at $|T-T_c|/T_c\simeq 0.001$, where the experiments were done.

Figure 7 shows the calculated heat capacity of, for

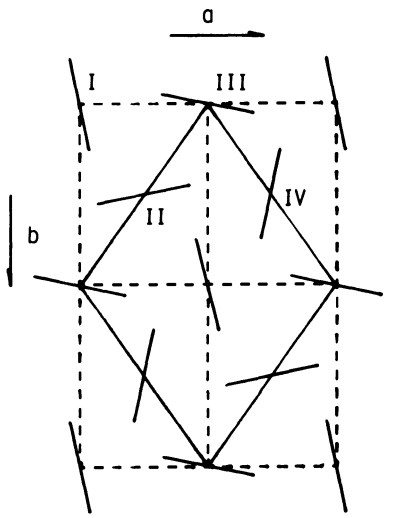

Fig. 6. Crystal structure of the low temperature phase viewed along the c axis (schematic). Broken line represents the unit cell of the room temperature phase.

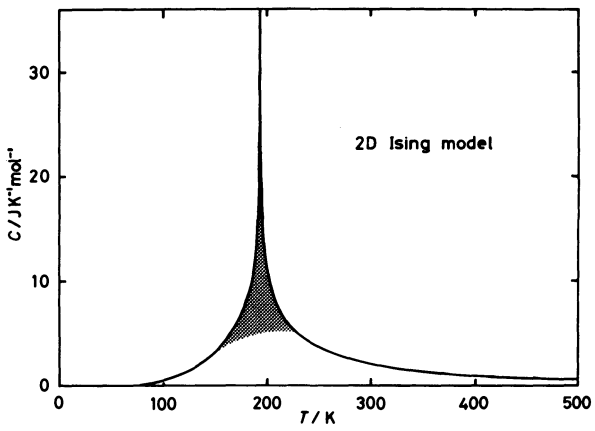

Fig. 7. Calculated heat capacity of the two-dimensional square lattice of Ising model with a critical temperature of 193.5 K.

simplicity, the two-dimensional square lattice of Ising model[61] with the critical temperature of 193.5 K (J=709 J·mol^{-1}). There exist large tails on both the lower and the higher temperature sides of the transition. Remember that the experimental excess heat capacity was separated by drawing the smooth interpolating curve. For the sake of consistent comparison, therefore, the theoretical "excess" heat capacity should be separated also in the same manner as the experimental. This was done in the transition region determined experimentally (145 K to 225 K). The "excess part" is shaded in Fig. 7 and compared with the experimental one in Fig. 4. While the general agreement between the calculated and experimental curves in Fig. 4 shows that the transition may be approximated by a two-dimensional order-disorder model, discrepancies at the tail parts indicates that there is room for improvement in the model; extending the range of interaction beyond the nearest neighbors and/or introducing a small contribution of the third dimension.

It is noted that the ideal value of entropy of transition, Rln2, is obtained only when one integrates C/T between zero and high-temperature limits. This will be one of the reasons why the entropy of transition is smaller than Rln2.

Finally, a comment is in order about the change in the nature of the twist transitions of poly(*p*-phenylene)s from a displacive phase transition in crystalline biphenyl to order-disorder transitions in *p*-terphenyl and in *p*-quaterphenyl. In the case of biphenyl, the substitution of *p* and *p'* hydrogens with fluorine atoms[56,59] or hydroxyl groups[57] mainly modifies the intramolecular potential for the twisting motion and the twist transition disappears owing to the stabilization of the planar conformation that favors greater π-conjugation. This suggests that the twist transition of *p*-terphenyl may change its nature from an order-disorder type to a displacive type upon such substitutions. Thus, it is interesting to investigate the properties of suitably substituted *p*-terphenyls in order to elucidate the nature of displacive and order-disorder types of phase transitions.

(Received February 2, 1988)

The conformation and molecular packing of ditetradecyldimethylammonium bromide monohydrate ($2C_{14}N^+2C_1Br^-\cdot H_2O$), $C_{30}H_{62}NBr\cdot H_2O$, has been determined by the X-ray diffraction method. The crystals are triclinic with the space group $P\bar{1}$, $Z=2$, $a=2.9827(9)$, $b=0.7847(3)$, $c=0.7480(3)$ nm, $\alpha=104.69(4)$, $\beta=90.64(7)$, and $\gamma=90.84(6)°$. The structure was determined by direct methods and refined by the least-squares procedure: $R=0.07$ ($R_w=0.07$) for 3335 observed reflections. Two amphiphile molecules of the unit cell are related by centrosymmetry and pack tail to tail in a bilayer structure. The hydrocarbon chains tilt about 45° with respect to the bilayer normal. There are statistically four water molecules with half occupancies in a unit cell. Water molecules and bromide anions make hydrogen-bonding networks along the c-axis in the hydrophilic layer. The above molecular and crystal structure of $2C_{14}N^+2C_1Br^-\cdot H_2O$ was quite similar to those of $2C_{18}N^+2C_1Br^-\cdot H_2O$.

The fundamental organization of biomembrane is based on the bilayer structure of lipid molecules. Although lipid molecules in biomembranes are in the form of liquid crystal, the bilayer structures of this form are closely related to those of the gel (crystal) form. For better understanding of the bilayer structure and its properties, it is essential to accumulate detailed knowledge about preferred molecular and crystal structures of various types of bilayer-forming amphiphiles. It has, however, been difficult to get single crystals of amphipathic molecules suitable for X-ray structure analyses which could provide the most detailed and accurate information about molecular and crystal structures.

Since one of the authors (T. Kunitake) succeeded in formation of the biomembrane-like bilayer structure from totally synthetic amphiphiles,[1,2] a large number of other long-chain mono-, di-, and trialkyl amphiphiles were shown to form bilayer structures. These synthetic bilayer membranes, especially dialkylammonium membranes, has been intensively investigated their structures and physicochemical properties by means of electronmicroscopy, X-ray diffraction, differential scanning calorimetry, and so on.[3,4] Recently, we succeeded in growing single crystals of dialkyldimethylammonium bromides[5] and the detailed crystal structure of dioctadecyldimehylammonium bromide has been determined.[6] According to the structure of this compound, two amphiphile molecules pack tail to tail in a bilayer structure with tilting hydrocarbon chains by about 45° to the bilayer surface. In the hydrophilic layer bromide anions make hydrogen-bonding networks along the c-axis with water molecules contained statistically in a unit cell.

In this paper we discuss detailed structure of ditetradecyldimethylammonium bromide, $2C_{14}N^+2C_1Br^-$, which has the shortest alkyl chains among the homologs crystallized so far. Because of the short alkyl chains, the crystal liquid-crystal transition temperature, T_c, is rather low, 16 °C in dilute aqueous solution.

Experimental and Structure Determination

Ditetradecyldimethylammonium bromide, $2C_{14}N^+2C_1Br^-$, was prepared by step-wise alkylation of dimethylamine. Detailed procedures have been reported elsewhere.[1] $2C_{14}N^+2C_1Br^-$ (50 mg) was dissolved in 1 ml of dichloromethane. After complete dissolution, 4 ml of hexane was added. Transparent, plate-like crystals formed by keeping the solution for several days at about 8 °C. The size of the crystal used for the intensity measurement was about 0.8 mm×0.5 mm×0.01 mm.

Lattice parameters and diffraction intensities were measured on a Rigaku four-circle diffractometer with Ni-filtered Cu $K\alpha$ radiation ($\lambda=0.1542$ nm). The lattice parameters were refined by the least-squares fit using 24 reflections in the 2θ range of 11°—35°. By using the ω-scan mode at a scan rate of 6° min^{-1}, intensities of 5037 reflections were measured up to 120° in 2θ. The scan width was $\Delta\omega=(1.8+0.15\tan\theta)°$. Three reference reflections monitored every 53 reflections showed no significant intensity deterioration during the data collection. Corrections were made for the Lorentz and polarization factors, but not for absorption and extinction effects. A total of 3344 reflections greater than $3\sigma(F_o)$ were used in the following analysis.

Density was measured by flotation method using aqueous solution of sodium chloride. Since the specimen dissolved a little during the measurement, the value of the obtained density was not accurate and reliable. However, we could not find out more stable solution than aqueous sodium chloride for this compound. On the basis of the measured density and a unit cell volume, the unit cell contains two $2C_{14}N^+2C_1Br^-$ molecules. In the process of X-ray structure analysis, the monohydrated structure was revealed as shown

in the following section.

Crystal Data: $C_{30}H_{64}NBr \cdot H_2O$, F.W.=534, triclinic, space group $P\bar{1}$, Z=2, a=2.9827(9), b=0.7847(3), c=0.7480(3) nm, α=104.69(4), β=90.64(7), γ=90.84(6)°, V=1.693(1) nm^3, D_x=0.91, D_m=1.01 g cm^{-3}, μ(Cu $K\alpha$)=18.5 cm^{-1}.

Determination and Refinement of the Structure

The direct method with the MULTAN 78 program[7] was applied for $P1$ and $P\bar{1}$, space groups. For the both space groups, two planar zigzag alkyl chains could be readily discerned. In the former space group, the revealed structure consisted of two amphiphile molecules related by a centrosymmetry, which supported $P\bar{1}$ space group for the $2C_{14}N^+2C_1Br^- \cdot H_2O$ crystal. After several cycles of block-diagonal least-squares refinement starting from the coordinates of all the non-hydrogen atoms of the amphiphile obtained by the direct method, difference Fourier syntheses revealed two peaks, which were assumed to be oxygen atoms of water molecules. After another several cycles including these newly found water positions, a full-matrix least-squares calculation was performed to investigate occupancies of two water oxygen atoms, since the short distances between these oxygens (OW1···OW2, 0.18 nm and OW2···OW2, 0.22 nm) made it impossible to accomodate both of them simultaneously in the same unit cell. It was found from this calculation that two water molecules with half occupancies were most preferable and they were accomodated statistically in an asymmetric unit.

At this stage, all the magnitudes of the observed structure factors for the (h00) reflections with $h \leqq 9$ were consistently smaller than those of the calculated ones. This systematic disagreement was attributable to the absorption effect originated from the plate-like crystal shape and its long lattice constant a directed normal to the plate surface, and fairly large absorption coefficient of this compound. Therefore, these 9 reflections were excluded from the reflection data set during the following calculations. After an anisotropic refinement of non-hydrogen atoms, hydrogen atoms located on their calculated positions with isotropic temperature factors were included in the refinement. The quantity minimized was $\sum w$

$B_{eq}=4\times(B_1\times a^2+B_2\times b^2+B_3\times c^2)/3$, where B_1, B_2, and B_3 are diagonal components of the anisotropic thermal parameters.

$(|F_o|-|F_c|)^2$ with $w=1.0$ for all reflections. After several cycles some hydrogen atoms with unacceptable geometry were excluded from further calculations. The final R value was 0.070 (R_w=0.067) for all non-hydrogen atoms and 61 hydrogen atoms. The final fractional coordinates and equivalent thermal parameters of the non-hydrogen atoms are given in Table 1.[8]

The atomic scattering factors were taken from International Tables for X-Ray Crystallography, Vol.IV.[9] Computations were done on an ACOS 700 S computer at the Crystallographic Research Center, Institute for Protein Research, Osaka University and on a HITAC M-280 H computer at the Computer Center, University of Tokyo with the help of the programs in UNICS III.[10]

Results and Discussion

Molecular Conformation of $2C_{14}N^+2C_1Br^-$. Figure 1 shows the molecular structure of $2C_{14}N^+2C_1$ viewed parallel (a and b) and perpendicular (c) to the zigzag plane. It also shows bond lengths, bond angles and dihedral angles together with the atom numbering following that of $2C_{18}N^+2C_1Br^-$.[6] The average C-C bond distance and C-C-C bond angle in the molecule

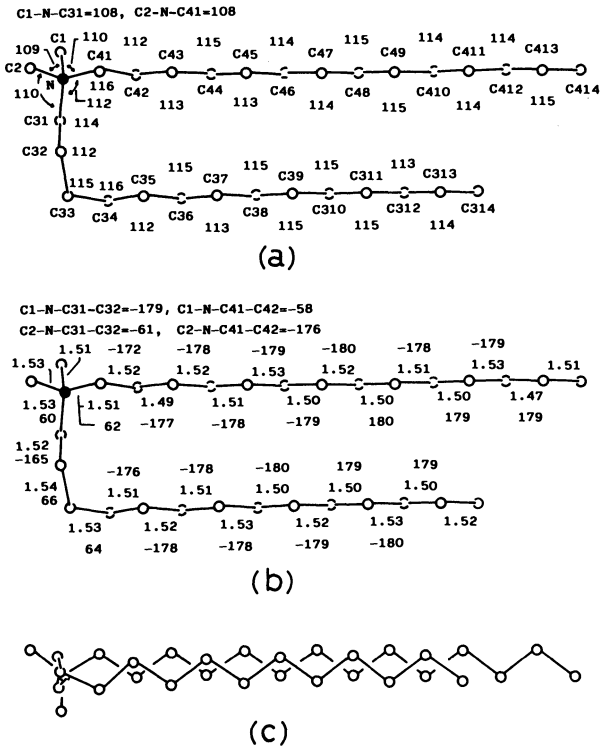

Fig. 1. (a) Atomic labelling and bond angles (/°), and (b) bond lengths (1×10/nm) and dihedral angles (/°) in $2C_{14}N^+2C_1Br^-$. Maximum estimated standard deviations for bond lengths, bond angles and dihedral angles are 0.002 nm, 1° and 1°, respectively. (c) Molecular conformation viewed from the direction normal to the zigzag plane.

are 0.151(1) nm and 114(1)°, respectively. The average bond distance is shorter by 0.002 nm and the average bond angle is wider by 2° than the corresponding values of $2C_{18}N^+2C_1Br^-$. These are still in good agreement with those previously reported for the long hydrocarbon chains of the amphiphilic compounds.[11,12] All the dihedral angles are within the range of 180°±2°, with exception in the connection parts between the head portion (N, C(31), C(32), C(33)) and the zigzag plane, C(33)-C(34)-C(35)-C(36) (−176°) and N-C(41)-C(42)-C(43) (−172°). One of the hydrocarbon chains (C(31), C(32), C(33), ···, C(314)) is bent at the C(33) atom at almost right angles. Since the quaternary nitrogen atom can be regarded as a carbon atom in the geometrical point of view, the molecular structure may be taken as one hydrocarbon chain from C(414) to C(314) folding at the bilayer surface just like polyethylene folding at the surface of the single crystal. Short atomic interactions between two chains in the same molecule are 0.405 (C(35)···C(42)), 0.407 (C(37)···C(44)), 0.407 (C(39)··· C(46)), 0.409 (C(311)··· C(48)), and 0.413 nm (C(313)···C(410)). The values of equivalent isotropic temperature factors (B_{eq}) of the chain carbon atoms gradually increase along the hydrocarbon chains. This kind of disorder was commonly observed in the bimolecular structures built up with amphiphilic molecules.[6,11,12] The detailed molecular structure of $2C_{14}N^+2C_1$ is quite similar to that of $2C_{18}N^+2C_1$, including the folding pattern (G, G, T, G, G) in the head portion.

Crystal Structure of $2C_{14}N^+2C_1Br^-$. The packing arrangement of $2C_{14}N^+2C_1Br^-$ viewed along the c-axis is shown in Fig. 2 together with short interatomic distances between neighbouring hydrocarbon chains and those between a bromide anion and the head portion of the amphiphile. There are two amphiphile molecules in a unit cell, arranged tail to tail fashion in a bilayer structure with tilting long hydrocarbon chains by about 45° to the layer surface. The molecules of the two opposite bilayer halves are related by centrosymmetry. The short intermolecular contacts between carbon atoms at the tail portions are 0.378 (C(413)···C(413)), 0.401 (C(314)···C(414)), and 0.427 nm (C(413···C(313)). While in the hydrophilic region, the bromide anion is in contact with many atoms with fairly short distances, 0.382 (C(41)), 0.391 (C(42)), 0.394 (C(31)), 0.409 and 0.388 (C(1)), 0.411 (C(2)), 0.401 (C(32)), 0.399 (C(33)), 0.345 (OW2), and 0.342 and 0.322nm (OW1). Though the direction of a-axis is slightly different from each other, the above detailed packing structure of $2C_{14}N^+2C_1Br^-$ is quite similar to that of $2C_{18}N^+2C_1Br^-$,[6] including hydrogen bonding networks between the bromide anions and water oxygens, mentioned below.

There are statistically four water oxygen atoms with half occupancies in a unit cell. Because of the short atomic contacts of OW1···OW2 (0.177 nm) or OW2···

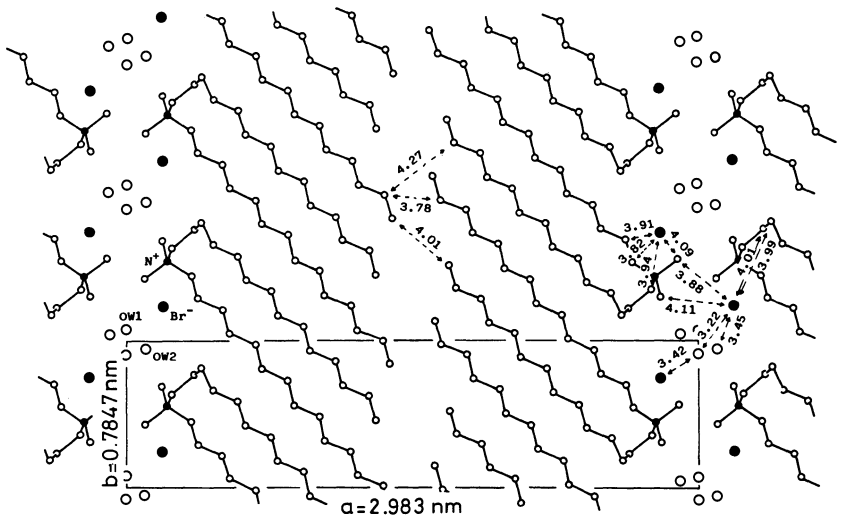

Fig. 2. Packing of $2C_{14}N^{+}2C_1Br^{-}\cdot H_2O$ projected onto the *ab*-plane (ORTEP[14] drawing). Four water oxygen atoms, OW1 and OW2 and their centrosymmetrical mates, are located on their positions in the unit cell. Distances (1×10/nm) between arrowed atoms are indicated short contacts in the structure.

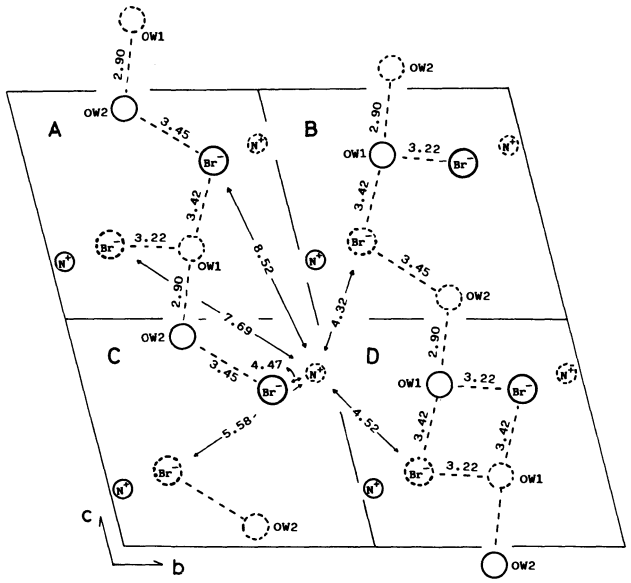

Fig. 3. Schematic illustration of hydrophillic layer of $2C_{14}N^{+}2C_1Br^{-}\cdot H_2O$ projected onto the *bc*-plane. Two water oxygen atoms are accomodated in a unit cell. Each unit cell, A, B, C, and D, has a different pair of water oxygens and hydrogen bonding scheme. Hydrogen bonds between bromide anions and water oxygen atoms are indicated by broken lines together with their bond lengths (1×10/nm). Solid and broken circles represent atoms on the upper and lower side of the hydrophillic layer, respectively. The unit cell is shifted by 0.5 along the *b*-axis for the comparison with that of $2C_{18}N^{+}2C_1Br^{-}$.

OW2 (the centrosymmetric mates at the origin) (0.219 nm), only four types of arrangement for water molecules are possible (Fig. 3). To make a comparison between $2C_{14}N^{+}2C_1Br^{-}$ and $2C_{18}N^{+}2C_1Br^{-}$, the unit cell in Fig. 3 was translated by 0.5 along the *b*-axis. Type A and B contain two water oxygen atoms, OW1 and OW2, with full occupancies. While type C or D contains a pair of centrosymmetrically related OW2 or OW1, respectively. In these arrangement, the water oxygen OW1 links to two Br^{-} and OW2 by hydrogen bonds with bond length of 0.342 and 0.322, and 0.290 nm, respectively. While the other water OW2 links to a bromide anion and OW1 by hydrogen bonds with 0.345 and 0.290 nm, respectively. Depending on the combination of the unit cell type, hydrogen-bonding networks are continuous (AA, BB, BD, DA) along the *c*-direction.

Both ammonium cations and bromide anions make a plane parallel to the bilayer surface (Fig. 2 and Table 1). There are two such planes in a hydrophilic layer. An ammonium cation is surrounded by three bromide anions, two in the same plane (0.432 and 0.452 nm) and one in the other plane (0.447 nm) (Fig. 3). Since distances to the other bromide anions are larger than 0.55 nm, the plus charge on an ammonium cation seems to be exclusively cancelled by these bromide anions.

From the analyses of $2C_nN^{+}2C_1Br^{-}$ (n=18,14) single crystal, it was found that the bilayer structure of $2C_nN^{+}2C_1Br^{-}$ is stabilized by the hydrogen bonding networks between water molecules and bromide anions, the electrostatic fources between bromide anions and ammonium cations, and the hydrophobi c interactions between long alkyl chains. It is suggested that single crystals of $2C_nN^{+}2C_1Br^{-}$ could be obtained by the above stabilizing fources.

Structural Study of Lithium, Magnesium, and Barium Vanadate Glasses by Means of Mössbauer Spectroscopy

Tetsuaki NISHIDA,* Setsuko SARUWATARI, and Yoshimasa TAKASHIMA
Department of Chemistry, Faculty of Science, Kyushu University 33,
Hakozaki, Higashiku, Fukuoka 812
(Received August 1, 1987)

All the isomer shifts for Li_2O–, MgO–, and BaO–V_2O_5 glasses containing 10 mol% Fe_2O_3 are in a range of 0.39—0.37 mm s^{-1}, indicating that iron is present as tetrahedral Fe^{3+} ions. This suggests that all the Fe^{3+} ions are present at the substitutional sites of tetrahedral V^{5+} or V^{4+} ions constituting the skeleton of each glass matrix. Distinct decreases in the quadrupole splitting and the glass transition temperatures are observed when Li_2O is incorporated into V_2O_5 matrix, suggesting a gradual change of the glass matrix from the layer structure originally composed of VO_5 tetragonal pyramids to a chain structure composed of VO_4 tetrahedra. This structural change is essentially the same as that of Na_2O– and K_2O–V_2O_5 glasses. On the other hand, simultaneous increases in the quadrupole splitting and the glass transition temperatures are observed with increasing MgO or BaO content in the case of MgO– and BaO–V_2O_5 glasses. This suggests a gradual change of the glass matrix from the original layer structure to a highly complicated three-dimensional network structure composed of VO_4 tetrahedra, similarly to the case of P_2O_5–V_2O_5 glasses.

It is well known that V_2O_5 has a layer structure composed of distorted VO_5 tetragonal pyramids, which can also be viewed as distorted trigonal bipyramids.[1,2] Each V^{5+} (or V^{4+}) ion is known to be present at the center of the tetragonal pyramids, surrounded by five oxygen atoms. An IR study of several vanadate (V_2O_5-based) glasses performed by Dimitriev et al.[3] revealed that introduction of alkali or alkaline earth oxides into the V_2O_5 matrix results in a destruction of the layer structure followed by a formation of tetrahedral VO_4 units. Furthermore, Dimitriev et al.[3] elucidated that only VO_4 units are present in the skeleton of metavanadate glasses having alkali or alkaline earth oxide to V_2O_5 ratio equal to unity. The same conclusion was obtained by Segel and Creel[4] in an NMR study of KVO_3 glass. Considering that alkali metavanadate crystals (e.g. KVO_3 crystal) have a one-dimensional chain structure composed of VO_4 tetrahedra,[5] it is not surprising that alkali metavanadate glasses have a chain structure composed of VO_4 tetrahedra. These results are consistent with the recent Mössbauer results of alkali vanadate (K_2O–V_2O_5[6] and Na_2O–V_2O_5[7]) glasses containing 10 mol% Fe_2O_3, obtained by the present authors. In the K_2O– and Na_2O–V_2O_5 glasses,[6,7] all the Fe^{3+} ions proved to be present at the substitutional sites of the V^{5+} or V^{4+} ions constituting VO_4 tetrahedra. In the recent Mössbauer study of phosphorus vanadate (P_2O_5–V_2O_5) glasses,[8] it was concluded that introduction of P_2O_5 into the V_2O_5 matrix results in a structural change of the glass matrix from the layer structure originally composed of VO_5 tetragonal pyramids to a three-dimensional network structure composed of VO_4 tetrahedra. In contrast to these results, a neutron diffraction study performed by Wright et al.[9] showed that V^{5+} or V^{4+} ion is surrounded by five oxygen atoms in P_2O_5–V_2O_5, BaO–V_2O_5, and PbO–V_2O_5 glasses and that the vanadate glasses are composed of interconnected and distorted VO_5 tetragonal pyramids. A similar conclusion was obtained in EXAFS and XANES[10] and NMR and ESR[11] studies of P_2O_5–V_2O_5 glasses.

The present Mössbauer study was performed in order to elucidate the structural change of lithium, magnesium, and barium vanadate glasses, brought about by incorporating Li_2O, MgO, and BaO into V_2O_5 matrix. DTA measurements were performed in order to examine the structural change, such as a change in the coordination number of V^{5+} or V^{4+} ions and a formation of nonbridging oxygen atoms, through the composition dependency of the glass transition temperatures (T_g).

Experimental

Lithium, magnesium, and barium vanadate glasses containing 10 mol% Fe_2O_3 were prepared by melting the individual mixtures (1 g) of commercially available Li_2CO_3, $MgCO_3$, $BaCO_3$, V_2O_5, and Fe_2O_3, of guaranteed reagent grade. Each of the mixture was melted at 950—1000 °C for 1 h in an electric muffle furnace under the ambient atmosphere. Ten mol% Fe_2O_3 was incorporated into the individual mixture as a Mössbauer probe. After the fusion, each melt in a platinum crucible was quenched with ice-cold water. All the vanadate glasses prepared in the present study are almost black in color, having a metallic luster. Mössbauer and DTA measurements were performed on the pulverized glasses, according to the procedures reported in the previous papers.[6,8] A piece of metallic iron foil enriched with ^{57}Fe was used as a reference for the isomer shift. Powder of Al_2O_3 was used as a standard material in the DTA measurements.

Results and Discussion

A Mössbauer spectrum of Li_2O–V_2O_5 glass measured at room temperature is shown in Fig. 1, which indicates only the presence of paramagnetic Fe^{3+} ions of high spin state.[12,13] No absorption peak due to Fe^{2+} ions nor magnetic species is observed in any of

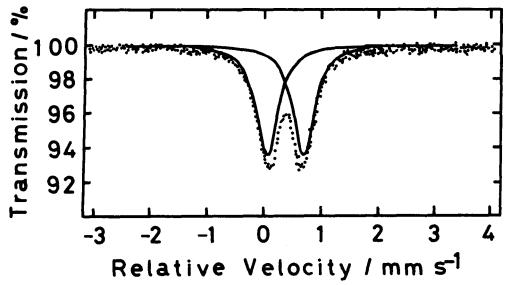

Fig. 1. Mössbauer spectrum of $30Li_2O \cdot 60V_2O_5 \cdot 10Fe_2O_3$ glass measured at room temperature.

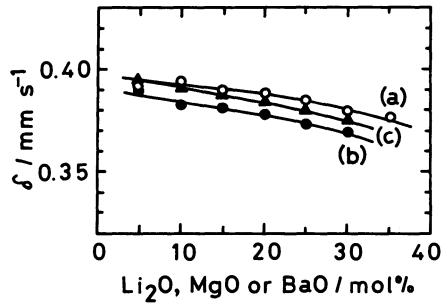

Fig. 2. Composition dependencies of the isomer shift (δ) of Fe^{3+} ions in (a) Li_2O–, (b) MgO–, and (c) $BaO-V_2O_5$ glasses containing 10 mol% Fe_2O_3.

the Mössbauer spectra. The linewidth (FWHM) is characteristic of the absorption peak due to iron in glasses, being in a range of 0.59—0.46 mm s^{-1}. All the isomer shifts of Fe^{3+} ions are located in a small range of 0.39—0.37 mm s^{-1} with respect to metallic iron, as is shown in Fig. 2. Earlier Mössbauer studies of several glasses[14–16] have shown that Fe^{3+} ions are present at tetrahedral environments in borate and silicate glasses. This is the case for the recent Mössbauer results on borate[17–20] and borosilicate[20–22] glasses obtained by the present authors' group. In these glasses,[17–22] all the isomer shift values are located in a range of 0.38—0.22 mm s^{-1} with respect to metallic iron. The experimental error for the isomer shift is usually estimated to be ± 0.01 mm s^{-1}. Judging from the experimental results shown in these reviews and papers,[14–22] it is concluded that all the Fe^{3+} ions are present at tetrahedral environments in the Li_2O–, MgO–, and $BaO-V_2O_5$ glasses, forming FeO_4 tetrahedra. This conclusion indicates the presence of tetrahedral VO_4 units, because Fe^{3+} ions should be present either at the substitutional sites of the V^{5+} (or V^{4+}) ions constituting the skeleton of the glass matrix or at the interstitial sites in the glass matrix. (The presence of V^{4+} ions has already been confirmed by ESR measurements of several vanadate glasses, e.g., $P_2O_5-V_2O_5$ glasses.[8]) It is considered that coordination number of metal ions present at interstitial sites is usually larger than that of the metal ions at substitutional sites. The same conclusion on the presence of VO_4 tetrahedra has been obtained in the

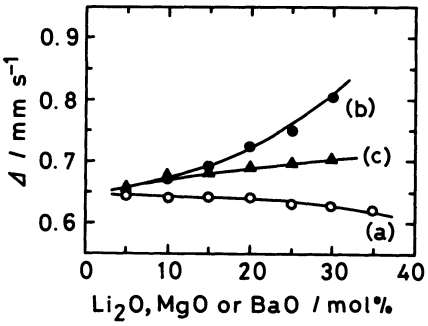

Fig. 3. Composition dependencies of the quadrupole splitting (Δ) of Fe^{3+} ions in (a) Li_2O–, (b) MgO–, and (c) $BaO-V_2O_5$ glasses containing 10 mol% Fe_2O_3.

recent Mössbauer studies of K_2O–, Na_2O–, and $P_2O_5-V_2O_5$ glasses containing 10 or 5 mol % Fe_2O_3.[6–8] The isomer shift values show a distinct decrease with increasing Li_2O, MgO, or BaO content (Fig. 2). Similar composition dependency of isomer shift observed in $K_2O-V_2O_5$[6] and $Na_2O-V_2O_5$[7] glasses was ascribed to a formation of nonbridging oxygen atoms in VO_4 tetrahedra, because a simultaneous decrease in the isomer shift and the quadrupole splitting of Fe^{3+} ions was observed with increasing K_2O or Na_2O content. This is true in the case of $Li_2O-V_2O_5$ glasses studied in the present paper, where a simultaneous decrease in the isomer shift (Fig. 2) and the quadrupole splitting (Fig. 3) is observed with increasing Li_2O content. The experimental error for the quadrupole splitting is estimated to be ± 0.02 mm s^{-1}. The decrease in the quadrupole splitting of Fe^{3+} ions is well ascribed to an increased symmetry of the iron-oxygen tetrahedra, because high-spin Fe^{3+} ions have a symmetric electron configuration of $3d^5$ in the outermost orbital and the electric field gradient brought about by the neighboring atoms or ions should primarily cause the nuclear quadrupole interaction. The simultaneous decrease in the isomer shift (Fig. 2) and the quadrupole splitting (Fig. 3) observed in $Li_2O-V_2O_5$ glasses is therefore ascribed to a formation of nonbridging oxygen atoms in VO_4 tetrahedra. Also, it is considered that a structural change of the glass matrix occurs from the two-dimensional layer structure originally composed of VO_5 tetragonal pyramids to a chain structure composed of VO_4 tetrahedra, similarly to the case of $K_2O-V_2O_5$[6] and $Na_2O-V_2O_5$[7] glasses.

On the other hand, increases in the quadrupole splitting are observed in the case of MgO– and $BaO-V_2O_5$ glasses (Fig. 3). A similar phenomenon was observed in $P_2O_5-V_2O_5$ glasses containing 5 mol% Fe_2O_3,[8] where an increase in the quadrupole splitting of Fe^{3+} ions, indicating a decreased symmetry of the FeO_4 (and VO_4) tetrahedra, was ascribed to a gradual change of the glass matrix from the layer structure originally composed of VO_5 tetragonal pyramids to

the three-dimensional network structure composed of VO_4 tetrahedra. The same conclusion was drawn from the similar composition dependency of the glass transition temperatures of the P_2O_5-V_2O_5 glasses.[8] The increase in the quadrupole splitting of Fe^{3+} ions, observed in the case of MgO- and BaO-V_2O_5 glasses (Fig. 3), is therefore ascribed to a gradual change of the glass matrix from the two-dimensional network structure composed of VO_5 tetragonal pyramids to a highly complicated three-dimensional network structure composed of VO_4 tetrahedra. In contrast to Li_2O-V_2O_5 glasses, it is considered that nonbridging oxygen atoms are rarely formed in the VO_4 tetrahedra constituting the skeleton of MgO- and BaO-V_2O_5 glasses, because the quadrupole splitting values show a continuous increase with increasing MgO or BaO content. It is therefore concluded that fraction of nonbridging oxygen atoms decreases with increasing MgO or BaO content in the MgO- and BaO-V_2O_5 glasses. It can be seen from Fig. 3 that the quadrupole splitting of Fe^{3+} ions in the MgO-V_2O_5 glasses shows a more distinct composition dependency than that of the Fe^{3+} ions in the BaO-V_2O_5 glasses. This will be due to a large ionic potential of Mg^{2+} ion. (The ionic potential is generally denoted by Z/r, where Z is the charge of cation and r is the ionic radius.) It is speculated that cations having large ionic potential will bring about an increased chemical bond strength between the cations and neighboring oxygen atoms. As a result, the resultant structure will become more complicated.

Regarding the short-range (local) structure of vanadate glasses, all the recent[6-8] and present Mössbauer results are consistent with the IR results obtained by Dimitriev et al.[3] and also with the NMR results obtained by Segel and Creel.[4] (In these studies,[3,4] it was reported that all the vanadate glasses are composed of VO_4 tetrahedra.) Regarding the middle- or long-range structure, it is concluded that structure of the glass matrix (skeleton) strongly depends on the type of so-called "network modifier," and that the glass matrix of alkaline earth vanadate glasses has highly complicated three-dimensional network structure. This structural change is similar to that of P_2O_5-V_2O_5 glasses.[8] It is interesting to compare the present results on MgO- and BaO-V_2O_5 glasses with the previous results obtained by different methods, such as a neutron diffraction[9] result on P_2O_5- and BaO-V_2O_5 glasses, an EXAFS and XANES[10] result on P_2O_5-V_2O_5 glasses, and an NMR and ESR[11] result on P_2O_5-V_2O_5 glasses. In these studies,[9-11] coordination number of V^{5+} or V^{4+} ions was reported to be always 5 irrespective of the composition. It seems that apparently higher coordination number (5) was obtained in those studies[9-11] owing to a highly complicated three-dimensional network structure of the glass matrix.

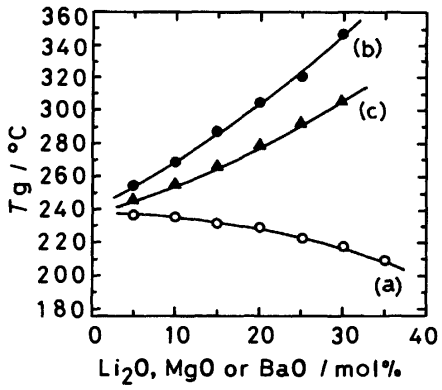

Fig. 4. Composition dependencies of the glass transition temperature (T_g) of (a) Li_2O-, (b) MgO-, and (c) BaO-V_2O_5 glasses containing 10 mol% Fe_2O_3.

Each DTA curve of the Li_2O-, MgO-, and BaO-V_2O_5 glasses containing 10 mol% Fe_2O_3 consists of an endothermic peak due to glass transition and one or a few exothermic peak(s) due to crytallization, similarly to the case of several vanadate glasses studied recently.[6-8] All the glass transition temperatures (T_g) are plotted in Fig. 4 against Li_2O, MgO, or BaO content. Previous Mössbauer and DTA studies of K_2O-V_2O_5[6] and Na_2O-V_2O_5[7] glasses revealed that T_g shows a distinct decrease when coordination number of V^{5+} or V^{4+} ions decreases from 5 to 4 and when nonbridging oxygen atoms are formed in the VO_4 tetrahedra. This is the case for the Li_2O-V_2O_5 glasses studied in the present paper, where the T_g shows a continuous decrease from 236 to 209 °C with increasing Li_2O content (Fig. 4). Considering the NMR result on KVO_3 glass[4] described above, i.e. the glass has a chain structure composed of VO_4 tetrahedra, the present Mössbauer and DTA results on the Li_2O-V_2O_5 glasses lead to the conclusion that a gradual structural change occurs from the two-dimensional layer structure originally composed of VO_5 tetragonal pyramids to the one-dimensional chain structure composed of VO_4 tetrahedra. (This corresponds to the decrease in the coordination number of V^{5+} and V^{4+} ions from 5 to 4.) It can be seen from Fig. 4 that a formation of nonbridging oxygen atoms in the VO_4 and FeO_4 tetrahedra is also reflected as a continuous decrease in T_g of the Li_2O-V_2O_5 glasses. On the other hand, an increase in T_g is observed with increasing MgO or BaO content in the MgO- and BaO-V_2O_5 glasses (Fig. 4). This is in good agreement with the Mössbauer results described above, i.e., a gradual change of the glass matrix occurs from the original layer structure composed of VO_5 tetragonal pyramids to the three-dimensional network structure composed of VO_4 tetrahedra. It should be noted that the T_g shows a distinct increase in spite of the decreased coordination number of V^{5+}or V^{4+} ions

from 5 to 4, as described above. Similar results were obtained in the DTA measurements of P_2O_5–V_2O_5 glasses[8] having a three-dimensional network structure. The difference in the structural change between alkali and alkaline earth vanadate glasses will be caused by the different positive charges of alkali (+1) and alkaline earth (+2) metal ions present at the interstitial sites. It is also considered that higher ionic potential of alkaline earth metal ions (e.g. Mg^{2+} ions) causes the formation of highly complicated three-dimensional network structure.

It is concluded that all the Fe^{3+} ions are tetrahedrally coordinated with oxygen atoms and are present at the substitutional sites of V^{5+} or V^{4+} ions, which constitute the skeleton of vanadate glasses in the form of VO_4 tetrahedra. It is also concluded that introduction of Li_2O into V_2O_5 matrix results in a gradual change of the glass matrix from the original layer structure composed of VO_5 tetragonal pyramids (or trigonal bipyramids) to the chain structure composed of VO_4 tetrahedra. It is considered that VO_4 tetrahedra have some nonbridging oxygen atoms and that the structural change of Li_2O–V_2O_5 glasses is essentially the same as that of Na_2O- and K_2O–V_2O_5 glasses. On the other hand, it is concluded that introduction of MgO or BaO into the V_2O_5 matrix results in a gradual change of the glass matrix from the original layer structure composed of VO_5 tetragonal pyramids to the highly complicated three-dimensional network structure composed of VO_4 tetrahedra, similarly to the structural change of P_2O_5–V_2O_5 glasses.

Structural Study of Potassium Gallate Glasses by Mössbauer Spectroscopy and Differential Thermal Analysis

Tetsuaki NISHIDA,* Setsuko SARUWATARI, and Yoshimasa TAKASHIMA
Department of Chemistry, Faculty of Science, Kyushu University 33,
Hakozaki, Higashiku, Fukuoka 812
(Received December 4, 1987)

Mössbauer spectra of a series of potassium gallate (Ga_2O_3-based) glasses, containing 10 mol% Fe_2O_3 as a Mössbauer probe, consist of two types of quadrupole doublet peaks due to tetrahedral Fe^{3+} ions bonded with nonbridging and bridging oxygen atoms and those bonded only with bridging oxygen atoms. This indicates that all the Fe^{3+} ions are present at the substitutional sites of the tetrahedral Ga^{3+} ions constituting the skeleton of network structure. An increase in the K_2O content results in an increased fraction of the FeO_4 (and GaO_4) tetrahedra bonded with nonbridging oxygen atom(s). A Mössbauer spectrum of $70K_2O \cdot 20Ga_2O_3 \cdot 10Fe_2O_3$ glass consists of only one quadrupole doublet peak due to the FeO_4 tetrahedra having nonbridging oxygen atom(s). This suggests that each of the Fe^{3+} (and also Ga^{3+}) ions is tetrahedrally bonded with at least one nonbridging oxygen atom. Structural information obtained from the Mössbauer measurements is confirmed by DTA measurements of the gallate glasses, T_g of which shows a drastic decrease from 647 to 555 °C when the K_2O content is changed from 35 to 70 mol%.

Recently, Dumbaugh and Tyndell[1,2] and Kokubo et al.[3–5] revealed that ternary gallate glasses are easily prepared by the conventional crucible-melting technique when alkali or alkaline earth oxides are incorporated into the Ga_2O_3 matrix with so-called middle oxides such as Nb_2O_5, Ta_2O_5, and TiO_2. It was also revealed that gallate glasses have an excellent optical transparency ranging from UV to IR (about 7 or 8 μm).[1–5] Structural study of gallate glasses was performed using IR[3–5] and Raman scattering,[6,7] where most of the Ga^{3+} ions were reported to be tetrahedrally coordinated with oxygen atoms. In addition to the tetrahedral GaO_4 units, it was considered that a small amount of GaO_6 octahedra might be present in gallate glasses when the alkali or alkaline earth oxides content is low.[3–7] In the IR[3–5] and Raman[6,7] studies it was discussed that so-called three-fold coordinated oxygen atoms will be present in gallate glasses. Besides the IR and Raman spectroscopies, often used for the structural study of glasses, ^{57}Fe-Mössbauer spectroscopy has been utilized for the structural study of several kinds of glasses, such as borate,[8,10] borosilicate,[11–12] and vanadate[13–15] glasses. As a result, some useful information on the short-range (local) structure has been obtained, concerned with the coordination number of network-forming atoms and a formation of nonbridging oxygen atoms in BO_4, SiO_4, and VO_4 tetrahedra.[8–15]

The present Mössbauer study was carried out in order to elucidate the short-range structure of potassium gallate glasses and a structural change caused by K_2O molecules incorporated into the Ga_2O_3 matrix. Potassium gallate glasses were chosen as one of the representative example of alkali gallate glasses. Differential Thermal Analysis (DTA) measurements were performed in order to examine the structural change in the gallate glasses, e.g., a change in the coordination number of Ga^{3+} ions and a formation of nonbridging oxygen atom(s).

Experimental

Potassium gallate glasses denoted by $xK_2O \cdot (90-x)Ga_2O_3 \cdot 10Fe_2O_3$ were prepared by fusing the individual mixtures (2g) of commercially available K_2CO_3, Ga_2O_3, and Fe_2O_3, of a guaranteed reagent grade, in an electric muffle furnace. Each mixture in a platinum crucible was fused in the ambient atmosphere at 1400 °C for 2.5 — 8.5 h, depending on the K_2O content. During the fusion, each of the platinum crucibles was covered with a piece of platinum foil to prevent the mixture from evaporating. The x value was changed from 30 to 75 at 5 intervals. Ten mol% Fe_2O_3 was incorporated into the individual mixture as a Mössbauer probe. After the fusion, each melt in a platinum crucible was quickly quenched by immersing the crucible into ice-cold water. As a result, homogeneous glass samples were prepared in the compositional region $35 \leqq x \leqq 70$. (Only glass-ceramics were obtained when x was 30 and 75.) All the gallate glasses obtained in this way are transparent and dark brown in color, being hygroscopic. Mössbauer measurements were performed on the pulverized glasses under a dry nitrogen atmosphere, according to the procedures shown in the previous papers.[8–15] In the Mössbauer measurement, a piece of metallic iron foil enriched with ^{57}Fe was used as a reference of the isomer shift and for calibrating the velocity of the spectrometer. DTA measurements were performed under a nitrogen atmosphere, using Al_2O_3 powder as a standard material. Glass transition temperatures (T_g) were obtained from the DTA measurements performed in the range of room temperature to 800 °C. Each of the glass samples was heated with a heating rate of 5 °C min^{-1}.

Results and Discussion

Most of the Mössbauer spectra observed in the present study consist of two types of quadrupole doublet peaks, as indicated with broken lines in Fig. 1. No magnetic absorption peak is observed in the potassium gallate glasses, similarly to the case of several iron-containing oxide glasses so far studied by the present authors.[8–15] In the case of potassium gallate glasses containing 10 mol% Fe_2O_3, it is

expected that all the iron (Fe^{3+} ions) should be present either at the substitutional sites of the Ga^{3+} ions constituting the skeleton of network structure or at the interstitial sites in the network structure. All the Mössbauer parameters obtained for the $xK_2O \cdot (90-x)Ga_2O_3 \cdot 10Fe_2O_3$ glasses are summarized in Table 1. It can be seen from Table 1 that the linewidth (FWHM), ranging from 0.40 to 0.68 mm s^{-1}, is characteristic of the absorption peak due to iron in glasses. This means that all the Fe^{3+} ions are homogeneously distributed in the glass matrix and are not forming a precipitate or aggregate which shows a magnetic hyperfine interaction. It is generally known that isomer shift indicates whether the Mössbauer nuclei (^{57}Fe in the present study) are present at the tetrahedral or octahedral environments.[8-18] All the isomer shift values obtained for one or two types of quadrupole doublets are shown in Fig. 2. Figure 2 and Table 1 indicate that all the isomer shifts obtained for the $xK_2O \cdot (90-x)Ga_2O_3 \cdot 10Fe_2O_3$ glasses are much smaller than 0.39 or 0.40 mm s^{-1} which is the boundary of isomer shift between octahedral and tetrahedral Fe^{3+} ions.[8-18] The experimental error of isomer shift is usually estimated to be ± 0.01 mm s^{-1}. Experimental results shown in Fig. 2 and Table 1 suggest that all the Fe^{3+} ions are present at the tetrahedral environments. This means that all the Fe^{3+} ions are present at the substitutional sites of the tetrahedral Ga^{3+} ions in the skeleton of network structure. When the isomer shift indicates the presence of octahedral Fe^{3+} ions, we can conclude that such Fe^{3+} ions are present at the interstitial sites of network structure composed of several GaO_4 tetrahedra. It is easily understood from Fig. 2 that the skeleton of network structure of gallate glasses, other than $70K_2O \cdot 20Ga_2O_3 \cdot 10Fe_2O_3$ glass, is composed of two types of FeO_4 (and GaO_4) tetrahedra having the isomer shifts of about 0.32 (inner doublet) and 0.23 mm s^{-1} (outer doublet). Figure 2 demonstrates that isomer shift values of inner (a) and outer

(b) doublets are constant irrespective of the K_2O content. Recently, Fukunaga et al.[6,7] revealed that several nonbridging oxygen atoms are present in the GaO_4 tetrahedra and each of the GaO_4 tetrahedra has at least one nonbridging oxygen atom when CaO content exceeds about 67 mol%, which corresponds to a composition $2CaO \cdot Ga_2O_3$. Taking into account the Raman results,[6,7] we can conclude that two types of the quadrupole doublets having different isomer shift values are concerned with the FeO_4 (and GaO_4) tetrahedra with and without nonbridging oxygen atoms.

This conclusion is consistent with the structural information obtained from composition dependencies of the quadrupole splitting (Fig. 3). The quadrupole splitting of outer doublets (b) shows a distinct decrease with increasing K_2O content. On the other hand, the quadrupole splitting of inner doublets (a) shows a less distinct decrease with increasing K_2O content. The experimental error of the quadrupole splitting is usually estimated to be ± 0.02 mm s^{-1}. Decrease in the quadrupole splitting of Fe^{3+} ions is ascribed to an increase in the symmetry of FeO_4 tetrahedra, because high-spin Fe^{3+} ion has a symmetric electron configuration of $3d^5$ in the outermost orbital. In such a case, the electric field gradient brought about by the neighboring oxygen atoms will primarily cause the quadrupole interaction (splitting).[8–15] It is generally considered that symmetry of the FeO_4 tetrahedra having nonbridging oxygen atom(s) is much higher than that of the FeO_4 tetrahedra bonded only with bridging oxygen atoms, because nonbridging oxygen atoms have higher degree of freedom. In the recent Mössbauer studies, the formation of nonbridging oxygen was observed as a decrease in the quadrupole splitting of Fe^{3+} ions.[8–15] The experimental results indicate that nonbridging oxygen atom(s) are present at less distorted sites than bridging oxygen. On the contrary, the quadrupole splitting of outer doublets (Fig. 3b) concerned with the nonbridging oxygen atom(s) is much greater than that of inner doublets (Fig. 3a) concerned only with bridging oxygen atoms. The large quadrupole splitting values observed for the outer doublets (Fig. 3b) may be concerned with so-called three-fold coordinated oxygen atoms proposed in IR[3–5] and Raman[6,7] studies. Three-fold coordinated oxygen atoms, if present, will greatly decrease the symmetry of the FeO_4 and GaO_4 tetrahedra because of higher distortion and lower degree of freedom. The FeO_4 and GaO_4 tetrahedra bonded with three-fold coordinated oxygen atom(s) will be present in more distorted (and highly energetic) states than those bonded with ordinary two-fold coordinated oxygen atoms. Therefore, it is concluded that large quadrupole splitting values of Fe^{3+} ions (Fig. 3b) are observed because the Fe^{3+} (and Ga^{3+}) ions are simultaneously bonded with so-called three-fold coordinated oxygen and nonbridging oxygen atoms. Further investigation will clarify the presence and role of the unfamiliar three-fold coordinated oxygen atoms. The continuous decrease in the quadrupole splitting of outer doublets (Fig. 3b) is concluded to be due to an increased fraction of nonbridging oxygen atoms in the FeO_4 (and GaO_4) tetrahedra. Small isomer shift values of the Fe^{3+} ions bonded with nonbridging oxygen atom(s) are ascribed to a decreased interatomic distance and therefore increased covalency between the Fe^{3+} ion and nonbridging oxygen atom. The peak assignment of the FeO_4 (and GaO_4) tetrahedra described above is confirmative when we see the distinct composition dependency of the relative absorption intensity of the Fe^{3+} ions bonded with nonbridging oxygen atom(s). This is shown in Fig. 4, where the relative absorption intensity (area) of the FeO_4 (and GaO_4) tetrahedra having nonbridging oxygen atom(s) (outer doublet) is increased with increasing K_2O content, and becomes 100% when the K_2O content is close to 70 mol%. A Mössbauer spectrum of $70K_2O \cdot 20Ga_2O_3 \cdot 10Fe_2O_3$

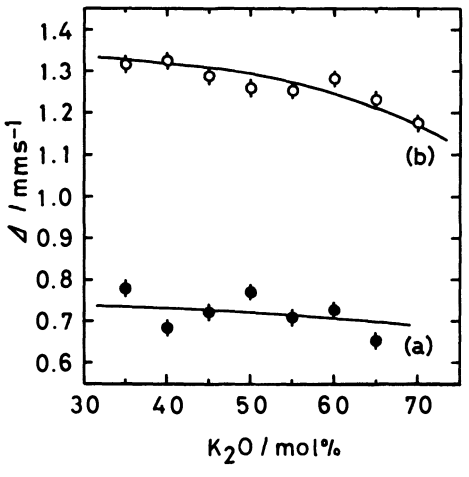

Fig. 3. Composition dependencies of the quadrupole splitting (Δ) of (a) inner and (b) outer doublet peaks shown in Fig. 1.

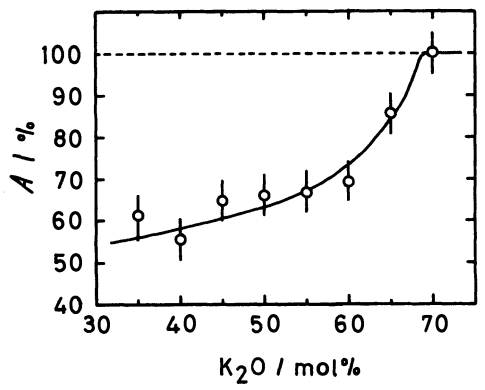

Fig. 4. Composition dependency of the relative absorption intensity of the outer doublets shown in Fig. 1.

glass is composed of only one quadrupole doublet corresponding to the outer doublet (Fig. 1). The experimental results on the formation and fraction of nonbridging oxygen atoms in the FeO_4 and GaO_4 tetrahedra are consistent with the Raman results recently obtained by Fukunaga et al.[6,7] In the Raman[6,7] and IR[3-5] studies, it was suggested that small amounts of octahedral GaO_6 units are present in the alkali or alkaline earth gallate glasses. In the present Mössbauer study, however, no absorption peak due to FeO_6 (and GaO_6) octahedra has been observed even in the low K_2O-content glasses. This is also in contrast to the ^{71}Ga-NMR results obtained by Zhong and Bray[19] recently, who elucidated that a large number of GaO_6 octahedra are present in caesium gallate glasses when the Cs/Ga ratio is smaller than unity. From the unambiguous NMR-spectral change of the caesium gallate glasses, Zhong and Bray[19] suggested that a gradual change of local structure from GaO_6 octahedra to GaO_4 tetrahedra was caused by caesium oxide molecules introduced into the Ga_2O_3 matrix. The NMR-spectral change is somewhat similar to the gradual change of Mössbauer spectra (Fig. 1), ascribed to the formation of nonbridging oxygen atoms in the FeO_4 and GaO_4 tetrahedra. If the NMR result of caesium gallate glasses[19] is taken into account, the absence of Mössbauer absorption peak due to FeO_6 (and GaO_6) octahedra in the present study may be responsible for the chemical property of iron in alkali gallate glasses. Fe^{3+} ions may be preferentially substituted for tetrahedral Ga^{3+} ions than octahedral Ga^{3+} ions. In such a case, a Mössbauer spectrum will be obtained only due to the tetrahedral FeO_4 (and also GaO_4) units. On the other hand, if Fe^{3+} ions are equivalently substituted for octahedral and tetrahedral Ga^{3+} ions, we can conclude that the fraction of GaO_6 octahedra in alkali (potassium) gallate glasses is too small to be detected by Mössbauer spectroscopy. Considering the precision of Mössbauer spectroscopy, we can estimate that the fraction of GaO_6 octahedra is less than several percent and that the skeleton of the $xK_2O\cdot(90-x)Ga_2O_3\cdot 10Fe_2O_3$ glasses is composed of only GaO_4 (and FeO_4) tetrahedra.

Each DTA curve of the potassium gallate glasses containing 10 mol% Fe_2O_3 consists of a weak endothermic peak due to glass transition and an exothermic peak due to crystallization. All the glass transition temperatures (T_g) of the $xK_2O\cdot(90-x)Ga_2O_3\cdot 10Fe_2O_3$ glasses are shown in Fig. 5, where the T_g shows a drastic decrease with increasing K_2O content. Similar composition dependency of T_g has recently been observed in K_2O-V_2O_5,[13] Na_2O-V_2O_5,[14] and Li_2O-V_2O_5[15] glasses containing 10 mol% Fe_2O_3. It should be noted that the decrease in T_g of potassium gallate glasses (Fig. 5) is much greater than that of alkali vanadate glasses.[13-15] In alkali vanadate

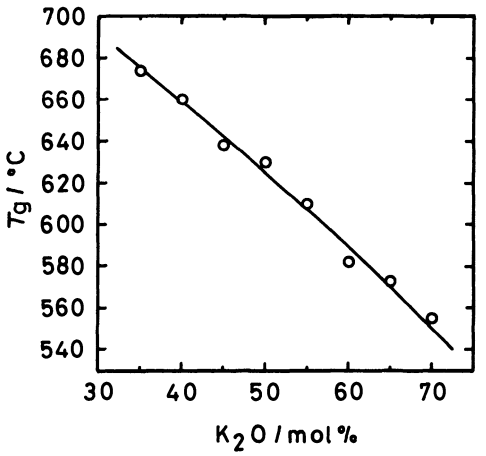

Fig. 5. Composition dependency of the glass transition temperature (T_g) of $xK_2O\cdot(90-x)Ga_2O_3\cdot 10Fe_2O_3$ glasses.

glasses,[13-15] the decrease in T_g was ascribed to a formation of nonbridging oxygen atoms in VO_4 and FeO_4 tetrahedra, followed by a gradual change of the glass matrix from the two-dimensional layer structure, originally composed of VO_5 tetragonal pyramids, to the one-dimensional chain structure composed of VO_4 tetrahedra. Mössbauer and DTA results obtained for alkali vanadate glasses[13-15] suggest that the pronounced decrease in T_g of potassium gallate glasses (Fig. 5) is closely correlated with a formation of nonbridging oxygen atoms in GaO_4 (and FeO_4) tetrahedra. In alkali vanadate glasses,[13-15] a continuous decrease in T_g amounting to about 30—60 °C was observed when the alkali oxide content was changed from 0 to 35 mol%. On the other hand, a drastic decrease in T_g amounting to more than 120 °C is observed in the potassium gallate glasses when K_2O content is changed from 35 to 70 mol% (Fig. 5). This suggests that fraction of nonbridging oxygen atoms in the GaO_4 tetrahedra constituting alkali gallate glasses is much greater than that in the VO_4 tetrahedra constituting alkali vanadate glasses. In Fig. 5, the increasing fraction of nonbridging oxygen atoms in the GaO_4 and FeO_4 tetrahedra is observed as a drastic and apparently linear decrease of T_g. The formation of nonbridging oxygen atoms is considered to be equivalent to a depolymerization of the glass matrix. Regarding the relationship between the structure and physical properties of gallate glasses, it is speculated that high optical transparency of gallate glasses ranging from UV to IR[1-5] may be concerned with the extraordinarily high fraction of nonbridging oxygen atoms in the GaO_4 tetrahedra constituting the skeleton of network structure.

The Spectrofluorometric Determination of Anthraquinone with Hydroxylamine in the Dimethyl Sulfoxide Medium Containing Sodium Methoxide and Methanol

Masaki TACHIBANA* and Motohisa FURUSAWA
Faculty of Engineering, Yamanashi University, Takeda, Kofu 400
(Received December 15, 1987)

Anthraquinone reacts with hydroxylamine in the dimethyl sulfoxide (DMSO) medium containing sodium methoxide and methanol. Since the reaction product is fluorescent in the medium, this reaction can be used for the fluorometric determination of anthraquinone. A DMSO solution of a sample was mixed with a DMSO solution of hydroxylamine hydrochloride and a methanolic solution of sodium methoxide. The mixture was then allowed to stand for 20 min at 60 °C in a volumetric flask with a tightly fitting stopper. After cooling and dilution to the mark with DMSO, the fluorescence intensity of the solution was measured at 597 nm, with excitation at 494 nm. The intensity was stable for at least 2 h in the tightly stoppered flask. The determination limit of anthraquinone was 100 ng. By the application of this spectrofluorimetry, anthraquinone in 9,10-phenanthrenequinone could be successfully determined over the content range from 0.2 to 4%.

Anthraquinone, which is known as an oxidation product of anthracene, is of great value as a starting material for the manufacture of vat dyes. It is also utilized in the pulp industry as a catalyst for delignification. On the other hand, trace amounts of anthraquinone may be contained as an impurity in chemicals made from coal tar because anthracene is one of the main components of tar. As a result, there is great interest in monitoring the level of the anthraquinone content in such industrial products, intermediates, and wastes. A sensitive method for the determination of anthraquinone is, therefore, of importance. Several methods for determination have been developed, including gas chromatography,[1,2] liquid chromatography,[3-5] polarography,[6,7] and spectrophotometry.[8-10] The method using spectrofluorimetry has, however, been little discussed in the literature.

In the present paper, the reaction conditions of anthraquinone with hydroxylamine are investigated for the spectrofluorometric determination. This reaction proceeded advantageously in the dimethyl sulfoxide (DMSO) medium containing sodium methoxide and methanol. Anthraquinone could be determined by measuring the fluorescence intensity of the reaction product at 597 nm, with excitation at 494 nm. The product, however, could not be identified in the present research because of difficulties in isolating it from the reaction system. As a result of the application of this fluorimetry, anthraquinone in 9,10-phenanthrenequinone could be successfully determined.

Experimental

Reagents. DMSO was cooled to a temperature below the freezing point (18.5 °C). When about 90% of the DMSO had been frozen, the liquid remaining without solidification was removed. After the solid thus obtained had been completely melted, the same process was repeated 3 times. The DMSO finally obtained was stored in a tightly stoppered vessel because of its hygroscopicity. Anthraquinone and 9,10-phenanthrenequinone were purified by zone melting. Hydroxylamine hydrochloride was of a guaranteed reagent grade purchased from Tokyo Kasei Kogyo Co., Ltd. A methanolic solution of sodium methoxide was prepared by the dilution of a commercial chemical (sodium methoxide, about 28% in methanol, purchased from Wako Pure Chemical Industries, Ltd.) with proper amounts of methanol. The exact concentration of the commercial sodium methoxide solution was determined by titration.

Apparatus. All the fluorometric measurements were carried out using a Hitachi 650-40 fluorescence spectrophotometer. A 150-W Xenon lamp was used as the exciting source.

Procedure. Five milliliters of a sample solution containing less than about 2 μg of anthraquinone in 5 ml of DMSO was transferred into a 10-ml volumetric flask. Then, 2 ml of a 0.1 M (1 M=1 mol dm^{-3}) solution of hydroxylamine hydrochloride dissolved in DMSO was added to the flask. After stirring, 0.7 ml of a 3.5 M methanolic solution of sodium methoxide was added. The mixture was allowed to stand for 20 min at 60 °C in the tightly stoppered flask, with occasional stirring, and then it was diluted to the mark with DMSO after cooling in tap water. The anthraquinone was determined by measuring the fluorescence intensity of the resultant solution at 597 nm, with excitation at 494 nm. A DMSO solution containing 2.00 μg of anthraquinone per 5 ml was treated under the same conditions and at the same time; the fluorescence was used as the standard.

Results and Discussion

Fluorescence Spectra. The fluorescence spectra of the reaction product of anthraquinone with hydroxylamine are shown in Fig. 1. The excitation spectrum has maxima at 396, 471, and 494 nm. The emission spectrum exhibits a maximum at 597 nm. In order to minimize the interferences of diverse substances, 494 nm was selected as the excitation wavelength for the determination. The fluorescence intensity of the reagent blank was negligibly small. At the present stage, little is known about the structure of the fluorescent product. By a comparison of the

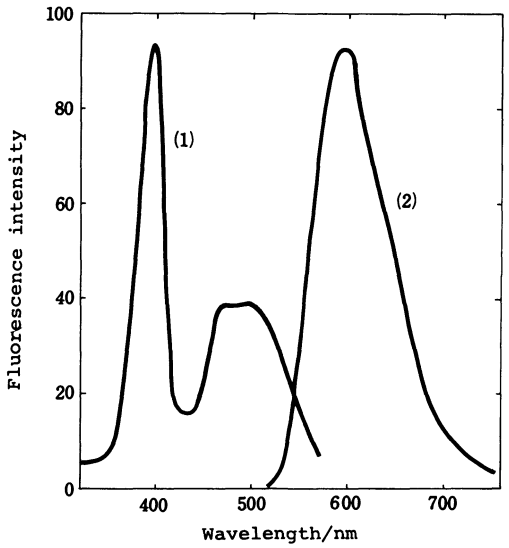

Fig. 1. Fluorescence spectra of the reaction product of anthraquinone.
(1): Excitation spectrum; (2): emission spectrum; uncorrected.

absorption and fluorescence spectra, however, the product was found not to be anthraquinone oxime, the formation of which is commonly predictable from a reaction with hydroxylamine.

Effects of Sodium Methoxide and Methanol. The reaction of anthraquinone with hydroxylamine proceeded well in DMSO containing sodium methoxide and methanol. Sodium methoxide was employed in order to make the DMSO medium strongly basic and methanol in order to increase the solubility of the sodium methoxide in the medium. The concentrations of these reagents had a relatively large influence on the fluorescence intensity of the reaction product. To study the effects of these reagents, various amounts of sodium methoxide (0.5—4.7 mmol) were added to 7 ml of a DMSO solution containing anthraquinone (2 μg) and hydroxylamine hydrochloride (0.2 mmol), together with 0.5, 0.7, and 1.0 ml of methanol. The fluorescence intensities were measured after the mixtures had stood for 20 min at 60 °C and had then been diluted to 10 ml with DMSO. The results of these experiments are shown in Fig. 2. Figure 2 indicates that an increase in the amount of methanol results in a decrease in the fluorescence intensity, and further that the increase requires more amounts of sodium methoxide for the maximum intensity to be reached. Therefore, it is necessary to take into account the simultaneous effects of these two reagents on the determination of anthraquinone. The maximum intensity observed in the presence of 0.7 ml of methanol is not so weak compared with that of 0.5 ml, and it is approximately constant over the broad range of 2—3 mmol of sodium methoxide. It is recommended, therefore, that a mixture of 0.7 ml of methanol and approximately 2.5 mmol of sodium

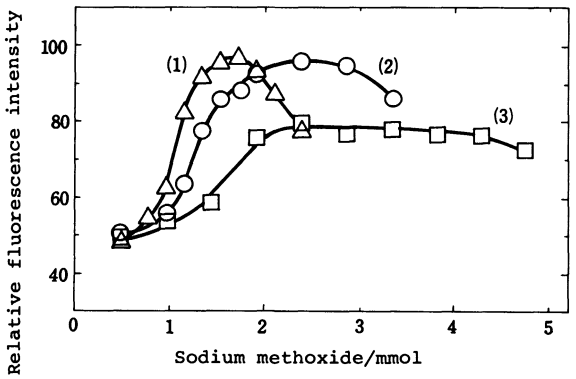

Fig. 2. Effects of the amounts of sodium methoxide and methanol.

methoxide be used for the determination. In the determination procedure, 0.7 ml of a 3.5 M methanolic solution of sodium methoxide was added to a sample solution.

Effect of Hydroxylamine. Hydrochloride of hydroxylamine was used as the reaction reagent because of facility in handling. The effect of hydroxylamine was measured by varying the amount over the wide range from 20 μmol to 1 mmol in the presence of 2 μg of anthraquinone (approximately 10 nmol) and 2.5 mmol of sodium methoxide. These experiments showed that a large excess of hydroxylamine caused the fluorescence intensities to decrease. A milky turbidity appeared when more than 0.5 mmol of hydroxylamine hydrochloride had been added. In the region less than about 0.1 mmol, on the other hand, the fluorescence spectra were distinct from those

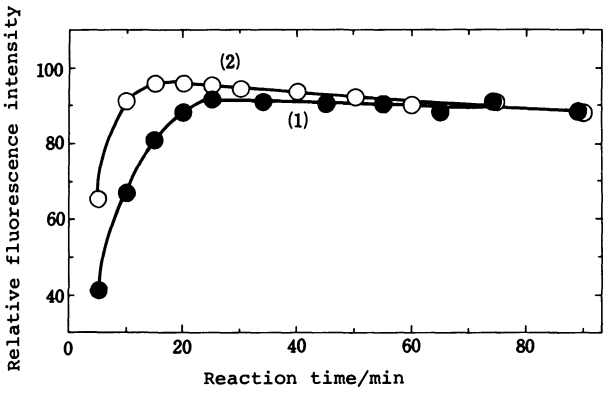

Fig. 4. Effects of reaction time and temperature. Standard: the intensity of the solution of Rhodamine B (20 ng ml^{-1}) was taken as 90.0 div.; anthraquinone: 2.00 mg/10 ml; (1): reacted at 50 °C; (2): 60 °C.

shown in Fig. 1. The fluorescence intensities of the reaction product, as measured over the range of hydroxylamine hydrochloride up to 0.6 mmol, are illustrated in Fig. 3. The maximum fluorescence intensity was obtained when approximately 0.2 mmol of the hydrochloride was added. Another unique peak is further observed at the approximate amount of 0.04 mmol in Fig. 3. Judging from the spectra, it seems likely that the peak was due to the formation of the mono-reacted species. The species, however, was unstable under these conditions, and the intensity decreased rapidly. Therefore, 2 ml of a 0.1 M DMSO solution of hydroxylamine hydrochloride was used in the determination procedure.

Effects of Reaction Temperature and Time. The reaction temperature and the time are important variables for the determination. The effects of these variables on the fluorescence intensity of the product were studied under various conditions. Figure 4 illustrates the results obtained by varying the standing time from 5 to 90 min at the reaction temperatures of 50 and 60 °C. All the measurements were carried out in a 10-ml volumetric flask with a tightly fitting stopper. As is shown in Fig. 4, the reaction of anthraquinone with hydroxylamine at temperatures of 50 and 60 °C is completed by letting it stand for approximately 25 and 15 min respectively. If the flask was left open, however, the fluorescence intensity was unstable and in some cases increased with the increase in the standing time without arriving at a constant value until at least 2 h. Therefore, this reaction was performed by letting the mixture stand for 20 min at 60 °C in the tightly stoppered flask.

Stability of the Fluorescence. In order to investigate the stability of fluorescence of the reaction product, 5 ml of a DMSO solution containing 2 μg of anthraquinone was allowed to react according to the determination procedure. The solution was cooled in tap water, diluted to the mark with DMSO, and then allowed to stand at room temperature. The fluorescence intensity of this solution was measured at adequate time intervals. The intensity was consequently constant for at least 2 h in the tightly stoppered flask. When the stopper was opened, however, the intensity became relatively unstable. This unstability may be attributable to atmospheric oxygen, carbon dioxide, and/or moisture, but no obvious conclusion could be drawn even from additional experiments.

Calibration Curve and Reproducibility. A calibration curve for the determination of anthraquinone was prepared from its DMSO solutions containing 0—2.00 μg per 5 ml according to the determination procedure. The solution with the highest concentration was used as the standard. The calibration curve thus prepared was linear between the fluorescence intensity and the concentration of anthraquinone. According to this curve, 0.1—2 μg of anthraquinone could be determined. The reproducibility of this method was measured by using 2.00 μg of anthraquinone. The relative standard deviation was 1.7% on 20 measurements over a several-day period. In these experiments, an ethanolic solution of Rhodamine B was used as the standard.

Behavior of Other Quinones and Polynuclear Aromatic Carbonyl Compounds. Since it seemed reasonable to assume that this reaction is applicable to other quinones, additional research was undertaken. Several aromatic compounds which have carbonyl groups were selected in order to investigate their reactivities with hydroxylamine. The spectral data of the resulting fluorescent products of these compounds are shown in Table 1. In this research, approximately 10—20 μg of each compound was treated under the same conditions as anthraquinone. *p*-Benzoquinone and 9-fluorenone were indistinct where the fluorescent substances were produced under the present conditions. Table 1 indicates that most of the quinones react with hydroxylamine much like anthraquinone, even though the conditions are not the optimum ones. Therefore, there is a good possibility that such nonfluorescent compounds can be determined by fluorimetry using hydroxylamine as the reaction reagent.

Effects of Diverse Substances. The effects of 16 different substances were studied for the determination of anthraquinone. Table 2 summarizes the effects on the fluorescence intensity of the reaction product of anthraquinone. The measurements of the intensity are not interfered with by the presence of even 100-fold amounts of biphenyl, naphthalene, acenaphthene, phenanthrene, dibenzofuran, dibenzothiophene, and carbazole. Pyrene and fluoranthene give negative errors, and fluorene, a positive one. Since anthracene changes in part to anthraquinone by oxidation during the determination process, the presence of large

Table 1. Fluorescence Excitation and Emission Maxima of the Reaction Products of a Variety of Quinones and Polynuclear Aromatic Carbonyl Compounds

Substances	Excitation maxima	Emission maxima
	nm	nm

a) The fluorescence intensity of a solution of the reaction product (2.00 μg anthraquinone per 10 ml) was taken as 100 div.

amounts of anthracene gives a positive error. Quinones and the other carbonyl compounds have an observable effect on the determination of anthraquinone, for these substances also react with hydroxylamine. Acridine has a relatively large influence, much as do fluoranthene, fluorene, and the quinones. Anthrone is the most influential of all these substances.

Determination in 9,10-Phenanthrenequinone. The fluorometric method was applied to the determination of anthraquinone in 9,10-phenanthrenequinone (9,10-PQ). The influence of 9,10-PQ on the determination was first studied. A DMSO solution containing 2.00 μg of anthraquinone per 5 ml was treated, according to the determination procedure, in the presence of 0—110 μg of 9,10-PQ. Blank experiments were also carried out in the presence of 9,10-PQ at the same time. The results of these experiments are

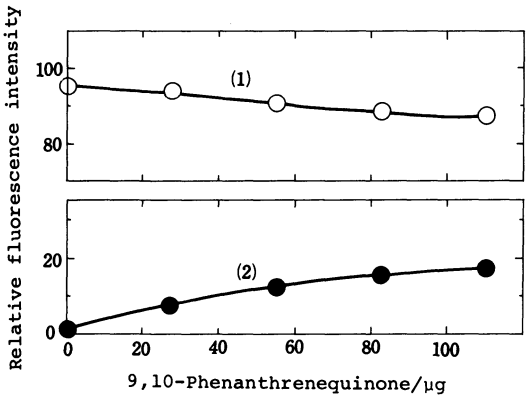

Fig. 5. Effect of the amount of 9,10-phenanthrenequinone.
Standard: the intensity of the solution of Rhodamine B (20 ng ml^{-1}) was taken as 90.0 div.; (1): 9,10-phenanthrenequinone solution containing anthraquinone (2.00 mg/10 ml); (2): 9,10-phenanthrenequinone alone.

Table 3. Analytical Results for Anthraquinone in Synthetic Mixtures of 9,10-Phenanthrenequinone

Content %	Relative fluorescence intensity[a)]	Found %

a) The fluorescence intensity of the product (2.00 μg anthraquinone per 10 ml) was taken as 95.0 div.

shown in Fig. 5. Figure 5 indicates that the fluorescence intensity of the reaction product of anthraquinone decreases with an increase in the amount of 9,10-PQ, but that the intensity of the blank solution increases. This apparently conflicting influence of 9,10-PQ is because the negative interference is greater than the positive one, which is based on the fluorescence of the reaction product of 9,10-PQ with hydroxylamine. For the determination of anthraquinone it is necessary to reduce such interference due to 9,10-PQ. In case it is present in small amounts, however, the effect can be corrected by the use of a calibration curve prepared in the presence of 9,10-PQ. Therefore, a calibration curve for anthraquinone (0—2 μg) was prepared in the presence of 50 μg of 9,10-PQ according to the procedure. The solution obtained by treating 2.00 μg of anthraquinone was used as the standard. The curve thus obtained was linear between the fluorescence intensity and the concentration of anthraquinone. However, the curve did not intersect at the point of origin, and its gradient was smaller than that for anthraquinone alone because of the influence of 9,10-PQ. The analytical results for anthraquinone in synthetic mixtures of 9,10-PQ are shown in Table 3. Each synthetic mixture contains 2% of phenanthrene, carbazole, and 9-fluorenone, as well as 0.2% of 1,4-naphthoquinone, acenaphthenequinone, dibenzofuran, dibenzothiophene, acridine, biphenyl, naphthalene, acenaphthene, anthracene, fluoranthene, and pyrene. Table 3 indicates that the anthraquinone in 9,10-PQ can be determined over the range from 0.2 to 4%. In addition, anthraquinone in 3 different chemicals of 9,10-PQ was determined; the resulting contents were 0.4, 4.0, and below 0.2%. The emission spectrum of the solution used for the determination agreed well with that of the solution prepared in the presence of 9,10-PQ. From the results of these experiments, the present fluorimetry can be applied to the determination of small amounts of anthraquinone in 9,10-PQ.

The authors are grateful to the Eisai Company, Ltd., for its gift of vitamin K_2.

(Received February 3, 1988)

The crystal structure of $(-)^{CD}_{500}$-*mer*-[Co(edma)(dien)]$Br_2 \cdot 2/3CH_3OH \cdot 2/3H_2O$ was determined by the X-ray diffraction method. The crystal is triclinic, space group $P\bar{1}$, a=13.824(8), b=13.814(8), c=8.055(3) Å, α=101.18(6), β=101.17(6), γ=116.32(5)°, and Z=3. All of the crystallographically independent complex cations, in which the terdentate ligands coordinate meridionally, have a δ spiral configuration, and the asymmetric nitrogen donor atoms of the edma ligands take an *S* configuration. The racemization reactions due to the inversion at the secondary amine nitrogen atom of the edma ligand in $(-)^{CD}_{500}$-*mer*-[Co(edma)(dien)]$^{2+}$ and $(-)^{CD}_{514}$-*mer*-[Co(edma)(mdien)]$^{2+}$ were studied at 20—35 °C in the pH range of 6.10—7.24. The rate law for both complexes was described as $R=k$[OH^-][complex]. The activation parameters at 30.0 °C were ΔH^* of 94.9 kJ mol^{-1} and ΔS^* of 126 J K^{-1} mol^{-1} for the dien complex and ΔH^* of 73.8 kJ mol^{-1} and ΔS^* of 62.0 J K^{-1} mol^{-1} for the mdien complex.

Four possible geometrical isomers for each of [Co(edma)(dien)]$^{2+}$ and [Co(edma)(mdien)]$^{2+}$ (edma, dien, and mdien denote ethylendiamine-*N*-acetate, 3-azapentane-1,5-diamine, and 3-methyl-3-azapentane-1,5-diamine, respectively) have been separated and resolved into their optically active isomers.[1] Two pairs of enantiomers are possible for *mer*-[Co(edma)(dien)]$^{2+}$ and *mer*-[Co(edma)(mdien)]$^{2+}$ as shown in Fig. 1, where the enantiomers are designated by the combination of the *R* or *S* configuration due to the asymmetric nitrogen atom of the edma ligand and the δ or λ spiral configuration due to the arrangement of the two trans N-H groups in *mer*-[Co(edma)(dien)]$^{2+}$ or due to the arrangement of the trans N-H and N-CH_3 groups in *mer*-[Co(edma)(mdien)]$^{2+}$. However, it is difficult to determine spectrochemically their absolute configurations, and then we determined the crystal structure of $(-)^{CD}_{500}$-*mer*-[Co(edma)(dien)]$Br_2 \cdot 2/3CH_3OH \cdot 2/3H_2O$ by the X-ray diffraction method. A preliminary report has been presented.[2]

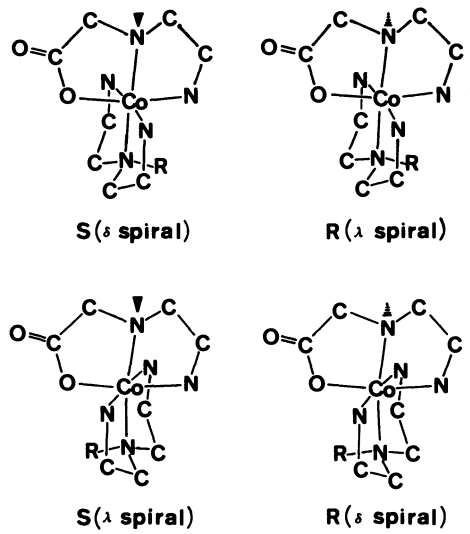

Fig. 1. Two pairs of enantiomeric isomers in *mer*-[Co(edma)(dien)]$^{2+}$ (R=H) and *mer*-[Co(edma)(mdien)]$^{2+}$ ($R=CH_3$).

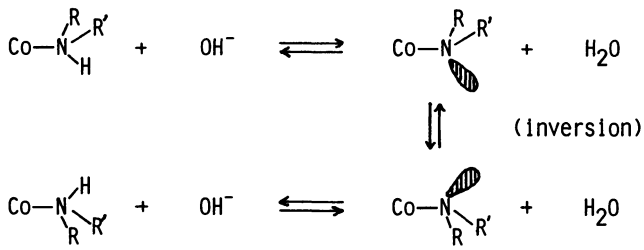
Similar cases have been reported for *mer*-[Co(aepn)(dien)]$^{3+}$ (aepn; 3-azahexane-1,6-diamine) and *mer*-[$Co(dien)_2$]$^{3+}$. Two pairs of enantiomers are possible for *mer*-[Co(aepn)(dien)]$^{3+}$ and the absolute configuration of the $(-)^{CD}_{474}$ isomer has been determined by Ishii et al.[3] On the other hand, a pair of enantiomers are possible for mer-[$Co(dien)_2$]$^{3+}$ and designated as δ and λ spiral configurations. Their absolute configurations have been determined by Okiyama et al.[4] The kinetics of racemization due to δ spiral$\rightleftarrows\lambda$ spiral change for *mer*-[$Co(dien)_2$]$^{3+}$ has been studied by Searle and Keene.[5] The bis(dien) complex racemizes with inversion[6] at one of the two secondary amine nitrogen (sec-N) centers. The racemization process was described by a rate law of $R=k$[OH^-][complex], and a mechanism of Scheme 1 has been proposed.

In the case of *mer*-[Co(edma)(dien)]$^{2+}$, the inversion at the sec-N center in the coordinating edma results in $S(\delta$ spiral$)\rightleftarrows R(\lambda$ spiral) or $S(\lambda$ spiral$)\rightleftarrows R(\delta$ spiral) change (racemization) (Fig. 1). While, the inversion at the sec-N center in the coordinating dien results in $S(\delta$ spiral$)\rightleftarrows S(\lambda$ spiral) or $R(\delta$ spiral$)\rightleftarrows R(\lambda$ spiral) change (epimerization); the vicinal CD contribution due to the asymmetric sec-N of the coordinating edma



Scheme 1.

remains. These configurational changes must involve the dissociation of the N-H bonds.[5] Therefore, in the case of *mer*-[Co(edma)(mdien)]$^{2+}$ only inversion at the sec-N center in the coordinating edma is possible; racemization occurs. The present paper is concerned with the structure and racemization of the two mer edma complexes.

Experimental

Complexes. The complexes used in the present work were prepared and resolved according to the methods described in our previous paper:[1] $(-)^{CD}_{500}$-*mer*-[Co(edma)(dien)]Br·2/3CH_3OH·2/3H_2O ($\Delta\varepsilon_{500}$=−0.437, $\Delta\varepsilon_{450}$=+0.705), $(-)^{CD}_{514}$-*mer*-[Co(edma)(mdien)]Cl_2·H_2O ($\Delta\varepsilon_{514}$=−0.490, $\Delta\varepsilon_{460}$=+0.730).

Racemization. The racemization reactions were followed spectropolarimetrically with a JASCO J-22 spectropolarimeter. A reaction vessel with a jacket and a water-jacket cell mounted in the cell compartment of the spectropolarimeter were thermostated at a constant temperature (±0.1 °C) with circulating water from a constant-temperature bath. During the kinetic runs, the temperature and the pH of the reaction solution were checked with a thermistor-type thermometer (Takara D-221) and a pH meter (Toa TSC-10A), respectively. The reaction was started by dissolving the complex in 20 cm^3 of a buffered solution in the reaction vessel. About 3 cm^3 of this solution was quickly transferred into the cell in order to record the decrease of the CD intensity at a suitable wavelength (450 nm for *mer*-[Co(edma)(dien)]$^{2+}$ and 460 nm for *mer*-[Co(edma)(mdien)]$^{2+}$). The following conditions were set: pH 6.0—7.0 (Na_2HPO_4-KH_2PO_4 and collidine-HNO_3 buffers), complex concentration 1.8×10^{-3} M (M=mol dm^{-3}), ionic strength 1.0 M ($NaNO_3$), and temperature 19.9—40.0 °C. The ionic product of water at the appropriate temperature was obtained from the literature[7] and the appropriate activity coefficient corrections for ionic strength were made using the data from the same source. The hydroxide concentration could then be calculated.

For the racemization processes of both *mer*-[Co(edma)(dien)]$^{2+}$ and *mer*-[Co(edma)(mdien)]$^{2+}$, plots of $\ln[(L_0-L_{eq})/(L_t-L_{eq})]$ vs. time, where L represents the CD intensity at the subscripted time, gave straight lines over three half-lives, from which the pseudo-first-order rate constant k_{obsd}(s^{-1}) were obtained. Analyses of the kinetic data were carried out on an NEC PC-9801F computer using the least-squares method. In each of the kinetic data analysis, the value of the standard error was within ±1% of the rate constant.

X-Ray Data Collection. Unit cell parameters and intensity data for the single crystal (ca. 0.30×0.32×0.63 mm^3) were measured on a Rigaku-denki four-circle diffractometer (AFC-5) with graphite-monochromatized Mo Kα radiation. The unit cell parameters were determined by a least-squares refinement based on 49 reflections (24 reflections; 8.7°<2θ<11.7° and 25 ones; 20°<2θ<25°). Systematic absences led to the space group $P1$. Crystal data: $C_8H_{22}N_5O_2Br_2Co$·2/3CH_4O·2/3H_2O, M.W.=472.4, triclinic, space group $P1$, a=13.824(8), b=13.814(8), c=8.055(3) Å,

a) $B_{eq}=8\pi^2(U_{11}+U_{22}+U_{33})/3$. b) Isotropic temperature factor.

α=101.18(6), β=101.17(6), γ=116.32(5)°, V=1282(2) Å^3, D_x= 1.835 g cm^{-3}, D_m=1.82 g cm^{-3}, Z=3, and μ(Mo $K\alpha$)=60.08 cm^{-1}.

The intensity data were collected by the ω-2θ scan technique up to 2θ=60° with scan rate of 3° min^{-1}. The intensity data were converted to the F_o data in the usual manner. Absorption corrections were not applied. A total of 5001 independent reflections with $|F_o|>3\sigma(|F_o|)$ of the measured 8064 reflections were considered as "observed" and used for the structure analysis.

Determination of the Crystal Structure. The X-ray analysis calculations were carried out on a FACOM M-382 computer at University of Tsukuba. The positions of three cobalt and six bromide atoms were determined by the direct method (program MULTAN[8]) was used). The difference-Fourier maps based on the three cobalt and six bromide positions revealed the other all non-hydrogen atoms. The structure was refined by a full-matrix least-squares refinement using the positional parameters, the anisotropic thermal parameters of the non-hydrogen atoms of the complex ions, and the isotropic thermal parameters of the non-hydrogen atoms of the water molecules (program RFINE by Finger[9]) was used). The atomic scattering factors for all the non-hydrogen atoms were taken from the literature.[10] The final residual values were R=0.049 and R_w=0.058, respectively. We attempted to determine the absolute configuration of the complex ions by an anomalous-scattering technique. When the refinements were carried out by use of a set of the atomic parameters containing the δ spiral configuration of the complex cations, the residual values converged to R=0.047 and R_w=0.056, respectively. On the contrary, the refinements in the enantiomeric atomic parameters (the λ spiral configuration) resulted in the residual values of R=0.054 and R_w=0.062, respectively. These facts suggest that the former is probably the correct choice, namely, the complex cation takes the δ spiral configuration. A similar relationship was observed for the determination of the absolute configration for the cobalt(III) complexes.[11,12]

The final positional parameters are listed in Table 1. A list of structure factors (Table A) and anisotropic thermal parameters of non-hydrogen atoms (Table B) are kept at the Chemical Society of Japan as Document No. 8810.

Results and Discussion

Description of the Structure. A perspective drawing of the [Co(edma)(dien)]$^{2+}$ cation (CoA species) is shown in Fig. 2, together with the numbering scheme. The bond distances and angles (with standard deviations) are summarized in Table 2. There are three crystallographically independent complex cations in an asymmetric unit, though their shapes and sizes remarkably resemble one another. The cobalt atom is octahedrally surrounded by an oxygen atom and five nitrogen atoms. The ethylenediamine-*N*-acetate and 3-azapentane-1,5-diamine coordinate meridionally to

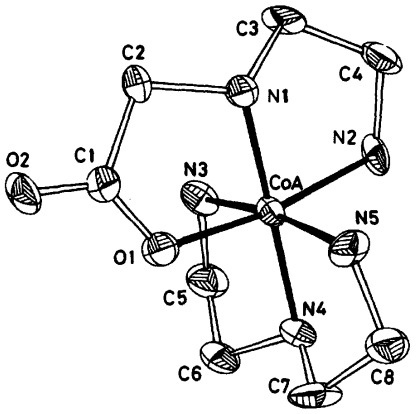

Fig. 2. Perspective view of $(-)^{CD}_{500}$-*mer*-[Co(edma)(dien)]$^{2+}$ ion.

the cobalt atom as terdentate ligands. For the *mer*-[Co(edma)(dien)]$^{2+}$ isomers, two pairs of enantiomers are possible, where the enantiomers are designated by the combination of the *R* or *S* configuration due to the asymmetric nitrogen donor atom of the edma ligand and the δ or λ spiral configuration due to the arrangement of the two trans N-H groups as in the case of *mer*-[Co(ida)(dien)]$^{+}$ (ida; iminodiacetate).[11] The absolute configuration of the asymmetric nitrogen donor atom in the present complex cation, which has the δ spiral configuration, was determined to be *S* (Fig. 2). This seems to indicate that one of two pairs of enantiomers, *S*(δ spiral) and *R*(λ spiral) isomers, were selectively formed in the crystalline state, because both of the *R*(δ spiral) and *S*(λ spiral) isomers have a significantly intramolecular steric interaction between the amino group in the edma ligand and the two methylene groups in the dien ligand.

The bond distances and angles for the coordinating dien in the three crystallographically independent complex cations are quite similar to those for *mer*-[Co(mida)(dien)]$^{+}$[11] and *mer*-[Co(dien)$_2$]$^{3+}$.[4] The bond distances and angles for the N1-O1 chelate moiety in the edma ligand also resemble to those for the cobalt(III) complexes with amino carboxylates,[11-13] although the Co-O1 distance (av. 1.91(1) Å) is somewhat longer and the Co-N1 one is somewhat shorter (av. 1.93(1) Å) than those of the corresponding distances. The conformations of the edma and dien ligands in the three complex cations resemble one another. The N1-O1 chelate ring in the edma ligand takes an envelope form with λ conformation as in the case of the cobalt(III) complexes with amino carboxylates,[11-13] and the diamine chelate ring N1-N2 takes an asymmetric skew form with δ conformation. Two coupled chelate rings in the dien ligand take asymmetric skew forms with δ and λ conformations, respectively, which somewhat differ from *mer*-[Co(mida)(dien)]$^{+}$[11] and *mer*-[Co(dien)$_2$]$^{3+}$.[4]

CD Spectra. Figure 3 shows the absorption and CD spectra of optically active *mer*-[Co(edma)(dien)]$^{2+}$ and *mer*-[Co(edma)(mdien)]$^{2+}$ measured in 0.1 M HCl at room temperature. These optically active isomers were stable in acidic solution and exhibited no measurable absorption and CD spectral changes. However, these isomers easily racemized in neutral or basic solution. Similar behavior was observed for the optically active isomers of complexes such as [Co(sar)(NH$_3$)$_4$]$^{2+}$ (sar; sarcosinate anion)[14] and *mer*-[Co(dien)$_2$]$^{3+}$.[5] The CD curves of $(+)^{CD}_{500}$ and $(-)^{CD}_{500}$ isomers of *mer*-[Co(edma)(dien)]$^{2+}$ are exactly symmetrical each other, indicating that these isomers are in an enantiomeric relation; the configuration of the $(+)^{CD}_{500}$ isomer is assigned to *R*(λ spiral).

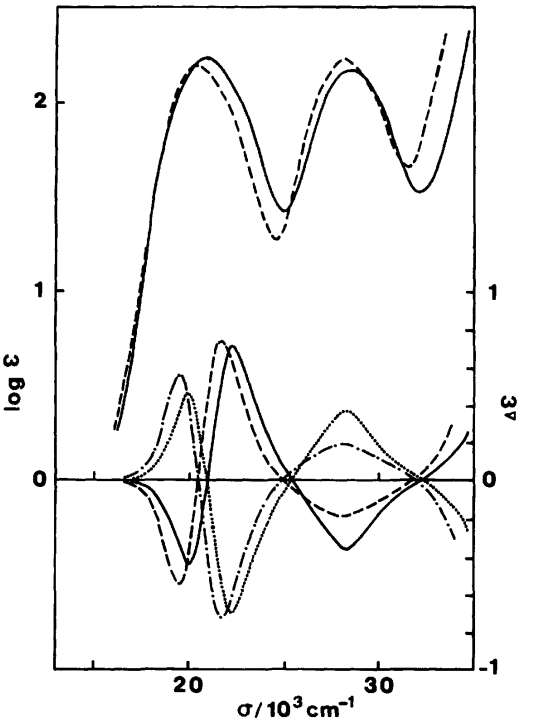

Fig. 3. Absorption (AB) and CD spectra: $(-)^{CD}_{500}$ (——) and $(+)^{CD}_{500}$ (·····) isomers of *mer*-[Co(edma)(dien)]$^{2+}$ and $(-)^{CD}_{514}$ (– – –) and $(+)^{CD}_{514}$ (– – – –) isomers of *mer*-[Co(edma)(mdien)]$^{2+}$. Solvent: water for AB measurements and 0.1 M HCl for CD measurements.

$(-)^{CD}_{514}$- and $(+)^{CD}_{514}$-[Co(edma)(mdien)]$^{2+}$ show very similar CD spectra to those for $(-)^{CD}_{500}$ and $(+)^{CD}_{500}$ dien analogues, respectively (Fig. 3). Accordingly, *S*(δ spiral) is assigned to the $(-)^{CD}_{514}$ isomer of *mer*-[Co(edma)(mdien)]$^{2+}$ and *R*(λ spiral) to the $(+)^{CD}_{514}$ one.

Both *mer*-[Co(edma)(dien)]$^{2+}$ and *mer*-[Co(edma)(mdien)]$^{2+}$ have two CD contributions, one from the spiral configuration and the other from the so-called vicinal effect due to the asymmetric sec-N in the edma ligand. The CD intensities in the first band region for these complexes are stronger than those for *mer*-[Co(dien)$_2$]$^{3+}$[5] and *mer*-[Co(ida)(dien)]$^{+}$[11] having only the CD contribution from the spiral configuration.

Racemization. Figure 4 shows CD spectral change

with time of $(-)^{CD}_{500}$-*mer*-[Co(edma)(dien)]$^{2+}$ in phosphate buffered solution at 39.9 °C. The initial CD curve almost coincided with the CD curve measured in 0.1 M HCl. The isocircular dichroism points lay on the base line and the values of CD intensities at various wavelengths decreased in the same ratio. The CD spectrum almost disappeared after 2 h. The absorption spectrum changed little during the CD measurement, indicating that no isomerization and/or decomposition occurred. In the $(-)^{CD}_{500}$-*S*(δ spiral) isomer of *mer*-[Co(edma)(dien)]$^{2+}$, the inversion at the sec-N in the dien ligand brings about the *S*(δ spiral)$\rightleftarrows$*S*(λ spiral) change (epimerization). In this case, however, the vicinal CD contribution due to the asymmetric sec-N of the edma ligand is expected to remain. On the other hand, the inversion at the sec-N center of the edma ligand leads to the *S*(δ spiral)$\rightleftarrows$*R*(λ spiral) change (racemization). The CD decrease in Fig. 4 conforms to the *S*(δ spiral)$\rightleftarrows$*R*(λ spiral) change, that is, the inversion at the sec-N of edma. This result, therefore, means that (1) the *S*(δ spiral)$\rightarrow$*S*(λ spiral) change is very slow compared with the *S*(δ spiral)$\rightarrow$*R*-(λ spiral) change or (2) the *S*(δ spiral)$\rightleftarrows$*S*(λ spiral) equilibrium extremely lies to the *S*(δ spiral) side if the rate of the *S*(δ spiral)$\rightarrow$*S*(λ spiral) change is comparable to that of the *S*(δ spiral)$\rightarrow$*R*(λ spiral) change. In $(-)^{CD}_{514}$-*mer*-[Co(edma)(mdien)]$^{2+}$, only the inversion at the sec-N center of the edma ligand is expected to occur. In fact, this complex showed the decrease of the CD intensity in the same pattern as $(-)^{CD}_{500}$-[Co(edma)(dien)]$^{2+}$ did.

The progress of the racemization was followed by monitoring the decrease of the CD intensity at 450 nm for *mer*-[Co(edma)(dien)]$^{2+}$ and at 460 nm for *mer*-[Co(edma)(mdien)]$^{2+}$. Kinetic data are summarized in Table 3. The values of the racemization rate constant $k(=k_{obsd}/[OH^-])$ for *mer*-[Co(edma)(dien)]$^{2+}$ at 39.9 °C are essentially constant, so the rate law is described as $R=k[OH^-][complex]$. Activation energies E_a were computed by least-squares analysis of the Arrhenius plots of *k*. The activation parameters calculated for the two complexes are given in Table 4. The close similarity in the activation parameters between the *mer*-[Co(edma)(dien)]$^{2+}$ and *mer*-[Co(dien)$_2$]$^{3+}$ complexes, as compared in Table 4, strongly suggests that a common mechanism takes place (Scheme 1). The racemization rate of *mer*-[Co(edma)(dien)]$^{2+}$ is about twice faster than that of *mer*-[Co(dien)$_2$]$^{3+}$. The difference in the rates of racemization might be explained by the electronic and conformational properties of the chelates. The electronegative carboxyl group decreases the electron density on the sec-N center. Consequently, the pre-equilibrium of Scheme 1 displaces to the deprotonated form and the rate of racemization increases. The glycinate chelate ring in *mer*-[Co(edma)(dien)]$^{2+}$ has a little conformational deformation out of the N-Co-O plane, whereas the ethylenediamine chelate rings in *mer*-[Co(dien)$_2$]$^{3+}$ is markedly puckered; therefore, the conformational interchange may be easier in the edma ring than in the dien ring for *mer*-[Co(edma)(dien)]$^{2+}$.

The racemization rate of *mer*-[Co(edma)(mdien)]$^{2+}$ is about one order faster than that of *mer*-[Co(edma)(dien)]$^{2+}$ (Table 3), and the activation enthalpy of the former is smaller than that of the latter (Table 4). It seems likely that the electron donative

CH_3 group exerts a trans effect in *mer*-$[Co(edma)(mdien)]^{2+}$, enhancing the racemization rate.

The racemization of optically active $[Co(sar)(NH_3)]^{2+}$ has been studied in a number of buffers.[14] The rate was about twice slower in phosphate buffer rather than in collidine buffer, and this feature was rationalized on the basis of ion pairing; the complex reacts with the phosphate anion (HPO_4^{2-} or $H_2PO_4^-$) to give an ion pair which no longer reacts with OH^- at a rate comparable to that of the original complex, so that the racemization rate would be consequently diminished. In the case of $[Co(dien)_2]^{3+}$, the racemization rate in phosphate buffer was also slower than that in collidine buffer, but the difference between their rates was slight. However, in the present complex, the reverse tendency is observed (Table 3), so that the proposal given in the case of the racemization reaction of $[Co(sar)(NH_3)_4]^{2+}$ is inapplicable to the racemization reaction of the present complex. The reason is unknown at present. The studies for the factors such as the orientation of the complex ion in the ion pairing and the catalytic ability of phosphate anion may be required.

Asymmetric Grignard Cross-Coupling Reaction Using Chiral Ligands Derived from Carbohydrates

Akihito IIDA and Mitsuji YAMASHITA*
Department of Applied Chemistry, Faculty of Engineering, Shizuoka University, Hamamatsu 432
(Received September 18, 1987)

Chiral diphenylphosphine and diphenylphosphinite derivatives of carbohydrates such as D-glucose, D-galactose, and L-rhamnose were used as the ligand of metal catalysts for asymmetric Grignard cross-coupling reaction. Coupling of *s*-butylmagnesium bromide with bromobenzene was carried out in the presence of nickel or palladium chloride with the chiral ligand. The highest optical yield was observed when D-galactose ligand was used.

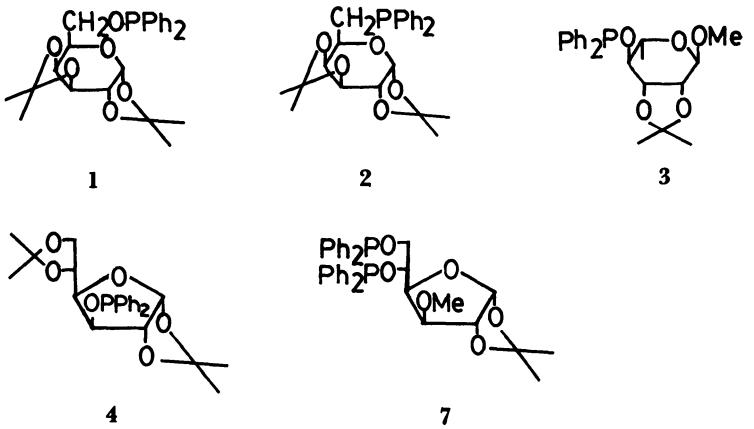
Investigation of good chiral ligands is very important field in catalytic asymmetric reactions such as asymmetric hydrogenations and asymmetric coupling reactions.[1] A wide variety of ligands were used for asymmetric hydrogenations, where many monodentate and bidentate chiral phosphines such as CAMP, DIOP, and Norphos afforded chiral products in excellent optical yields.[2] For asymmetric Grignard cross-coupling reactions the ligands gave the product in poor to fair optical yields.[3] Chiral carbohydrate ligands, which can be easily prepared from readily available carbohydrates without optical resolution, are not so well investigated.[1),4] Some of the ligands showed potential ability for asymmetric induction in prochiral olefins.[4] To spread the application of carbohydrate ligands in the field for asymmetric synthesis we now tried to use them for cross-coupling reactions.

Coupling reactions of 1-phenylethylmagnesium halides with vinyl halides were successful using ferrocene[5] and amino acid derivatives[6] as the chiral ligand. But couplings of *s*-butylmagnesium halides with halobenzenes were unsuccessful so far. The coupling reactions, where phenyl groups in the Grignard reagents are absent, are competed with isomerization and elimination reactions.[7,8] This paper deals with asymmetric Grignard cross-coupling reaction using carbohydrate ligands of catalysts.

Carbohydrates exist widely in nature and they have some advantages for asymmetric synthesis in such properties as ready availability, rigidity of the structure, and chirality of the framework. Some ligands derived from carbohydrates were used for asymmetrical catalytic hydrogenations,[2,4,9,10] however, they were scarcely applied to asymmetric coupling reactions.[3] It is suggested that diphenylphosphinite derivatives afford higher optical yields than corresponding diphenylphosphine derivatives do, and that diphenylphosphinite derivatives can easily be synthesized through a shorter pathway than corresponding diphenylphosphine derivatives by at least two steps from starting carbohydrates having free hydroxyl groups.

Results and Discussion

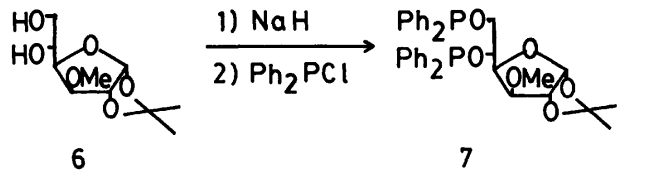
Synthesis of Chiral Phosphino Ligands from Carbohydrates. Compounds **1**, **2**; **3**; and **4**, **7** were prepared from D-galactose; L-rhamnose; and D-glucose, respectively by known methods.[10] Reaction of glucose **6** with diphenylphosphinous chloride in the presence of sodium hydride in dry ether afforded not only diphosphino compound **7**, but also monophosphino compound **5** (Eq. 1). These ligands were immediately used for coupling reaction without isolation.



1 2 3

4 7

Scheme 1.



6 7

monophosphino deriv. 5 (1)

Asymmetric Grignard Cross-Coupling Reaction. Nickel- or palladium-catalyzed cross-coupling reaction of *s*-butylmagnesium bromide **8** with bromobenzene **9** using chiral ligands was carried out (Eq. 2). The reaction conditions and results are summarized in Table 1.

$$\underset{\mathbf{8}}{s\text{-BuMgBr}} + \underset{\mathbf{9}}{\text{PhBr}} \longrightarrow \underset{\mathbf{10}}{s\text{-BuPh}} + \underset{\mathbf{11}}{n\text{-BuPh}} \quad (2)$$

Table 1 shows that non-isomerized product **10** was obtained in higher yield than isomerized product **11**. The ratio of **10** to **11** obtained is higher than that reported using monodentate triphenylphosphine ligand.[11] This reason may be attributable to the property of the ligand having P-O-C bond, where electron density of phosphorus atom is lower than that of P-C bond.[7] Indeed the diphenylphosphinite ligand used in Entries 1 and 2 afforded less isomerized product than the corresponding diphenylphosphine ligand did in Entries 3 and 4. In asymmetric induction, the carbohydrate ligand having phosphorus atom out of the hemiacetal ring induced higher optical yield than the ligand having phosphorus atom in the hemiacetal ring did. Especially, D-galactose ligands **1** and **2** afforded the highest optical yields (Entries 2 and 3). These results confirmed that carbohydrate ligands are accessible for asymmetric cross-coupling reaction as chiral sources.

Experimental

Measurements. ^{1}H NMR spectra were measured on a Hitachi R-24B (60 MHz) spectrometer with tetramethylsilane as an internal standard, and IR spectra on a Japan Spectroscopic Co., Ltd., A-3 infrared spectrometer. Optical rotations were measured on a Japan Spectroscopic Co., Ltd., DIP-4 digital polarimeter. Isolation of coupling products was performed by a Yanaco Gas Chromatograph G 1800, equipped with a 1.5 m stainless steel column packed with silicone gum SE30 (30% on chromosorb W) at 100 °C (column) and 175 °C (injection).

Preparation of 6-*O*-(Diphenylphosphino)-1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose (1). To a solution of 1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose 0.39 g (1.50 mmol) in dry ether was added 72 mg (1.8 mmol) of sodium hydride, and the mixture was stirred for 12 h at room temperature under argon atmosphere. Diphenylphosphinous chloride (1.5 equiv) was added to the reaction mixture through a septum cap. After 24 h the mixture was filtered and the filtrate was successively washed with water and brine. The solution was dried over sodium sulfate and evaporated in vacuo. Crude product **1** (0.50 g) was obtained

a) Reaction condition: ratio of **8** to **9** was 2:1 except for Entry 2 (**8** to **9** was 1.05:1 for Entry 2); and ratio of **9** to MCl_2 was 50:1. Reactions were carried out for about 40 h at 35 °C under argon atmosphere. b) Conversion was calculated on a basis of **9** recovered. c) Yield was calculated on a basis of **9** reacted. d) Benzene was used as the solvent. Less than 7% concentration dependence of $[\alpha]_D$ value was observed. e) Optical yield was calculated based on the specific rotation of (*S*)-2-phenylbutane: $[\alpha]_D^{25}$=+29.26° (neat).[8]

in 74% yield. The purity was checked by TLC on silica gel (eluent: ethyl acetate; R_f=0.74). IR ν_{max}^{neat} (cm^{-1}), 1442 (P-Ph), 1080 (P-O-C). ^1H NMR ($CDCl_3$) δ=1.32, 1.42, 1.46, (3s, 12H, $2CMe_2$), 3.7—4.8 (m, 6H, $C_{2-6,6'}$-H), 5.56 (d, 1H, $J_{H_1H_2}$=5.0 Hz, C_1-H), and 7.2—7.7 (m, 10H, PPh_2).[10b]

Preparation of Other Diphenylphosphinite Ligands. Methyl 4-*O*-(diphenylphosphino)-2,3-*O*-isopropylidene-α-L-rhamnopyranoside (**3**), 3-*O*-(diphenylphosphino)-1,2:5,6-di-*O*-isopropylidene-α-D-glucofuranose (**4**), and 5,6-di-*O*-(diphenylphosphino)-1,2-*O*-isopropylidene-3-*O*-methyl-α-D-glucofuranose (**7**) were prepared almost in pure form except **7** by the same procedure as above from the corresponding precursors. Crude product **7** showed two spots of TLC on silica gel (R_f; 0.88 and 0.71 (ethyl acetate)). They were monophosphino and diphosphino derivatives, respectively, and were used for the coupling reaction without isolation. Spectral data for **7**: ^1H NMR ($CDCl_3$) δ=1.20, 1.31 (2s, 6H, CMe_2), 3.30 (s, 3H, OMe), 3.5—4.4 (m, 5H, $C_{3-6,6'}$-H), 4.42 (d, 1H, $J_{H_1H_2}$= 3.5 Hz, C_2-H), 5.75 (d, 1H, $J_{H_1H_2}$=3.5 Hz, C_1-H), 7.0—8.0 (m, 20H, $2PPh_2$); IR ν_{max}^{neat} (cm^{-1}), 1442 (P-Ph), 1030 (P-O-C); MS *m/z*, 602 (M^+).

Preparation of 6-*C*-(Diphenylphosphino)-1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose (2). Through a septum cap a solution of 0.248 g (0.60 mmol) of the 6-*O*-*p*-toluenesulfonyl derivative in dry THF was added to refluxing THF solution of lithium diphenylphosphinide prepared by the treatment of 0.157 g (0.60 mmol) of triphenylphosphine with lithium under argon atmosphere.[11] The mixture was further refluxed for 4 h and cooled to room temperature. The product was extracted with ether and washed with water and brine. The solution was dried with sodium sulfate and evaporated in vacuo to give 0.257 g (quantitative yield) of crude **2**, which was contaminated with the tosylate, used without further purification. IR ν_{max}^{neat} (cm^{-1}), 1440 (P-Ph), 722 (C-P). ^1H NMR ($CDCl_3$) δ=1.30, 1.35, 1.46, 1.50 (4s, 12H, $2CMe_2$), 1.7—2.2 (m, 2H, $C_{6,6'}$-H), 3.6—4.7 (m, 4H, C_{2-5}-H), 5.45 (d, 1H, $J_{H_1H_2}$=5.0 Hz, C_1-H), 7.2—8.2 (m, 10H, PPh_2).

General Procedure for Coupling Reactions. In a 50 ml two-necked flask equipped with a stirring bar, a septum cap, and a stopcock was placed 13.0 mg of nickel chloride (0.1 mmol=2.0 mol%) or 17.7 mg of palladium chloride. The reaction vessel was filled with argon after evacuation and a solution of 0.2 mmol of ligand **1**, **2**, **3**, or **4**, or of 0.1 mmol of ligand **7** in freshly distilled 2—3 ml of THF was added via syringe through the ceptum cap. The reaction mass was refluxed for 1 h and cooled to 0 °C. To the solution were added 0.52 ml (5.0 mmol) of bromobenzene and solution of *s*-butylmagnesium bromide (prepared from 10 mmol of *s*-butyl bromide and magnesium in 10 ml of dry ether under nitrogen atmosphere) via a syringe through the septum cap. The reaction mixture was again refluxed for about 40 h and hydrolyzed with 8 ml of 10% hydrochloric acid. Extraction of the product with ether (6 ml×3) followed by successive washing the organic layer with aq. sodium hydrogencarbonate (4 ml×2) and water (5 ml), drying over anhydrous sodium sulfate, and removal of low boiling materials (bp<120 °C) afforded crude analytical sample. Unreacted bromobenzene and *s*- and *n*-butylbenzenes were isolated from the sample by gas chromatography. The structures of all the products were confirmed by ^1H NMR.

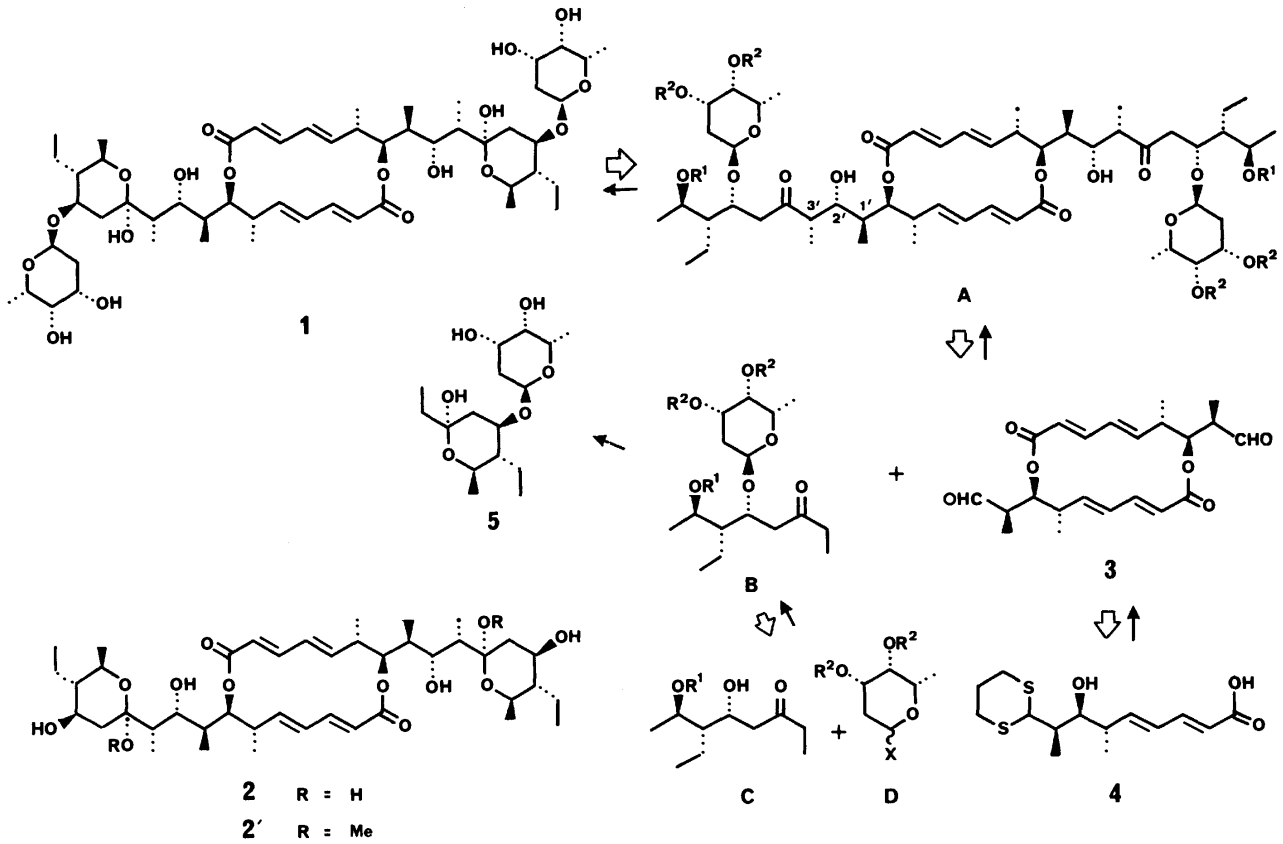
Total Synthesis of Elaiophylin (Azalomycin B)

Kazunobu TOSHIMA, Kuniaki TATSUTA, and Mitsuhiro KINOSHITA*
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223
(Received November 4, 1987)

Antibiotic elaiophylin (**1**) has been first synthesized by a convergent route involving aldol coupling of (5*R*,6*R*,7*R*)-5-*O*-[2-deoxy-3,4-bis-*O*-(isopropyldimethylsilyl)-α-L-fucopyranosyl]-6-ethyl-7-*O*-(diethylisopropylsilyl)-5,7-dihydroxy-3-octanone (**25f**) and (7*S*,8*S*,15*S*,16*S*:3*E*,5*E*,11*E*,13*E*)-8,16-bis[(1*R*)-1-formylethyl]-7,15-dimethyl-1,9-dioxa-3,5,11,13-cyclohexadecatetraene-2,10-dione (**3**), followed by desilylation. The appropriately O-protected segment **25f** and the macrocyclic dialdehyde **3** were synthesized from D-glucose and 2-deoxy-L-fucose.

The anti-Gram-positive bacterial antibiotic elaiophylin (**1**) was first isolated in 1959 by Arcamone et al.[1] and then isolated as azalomycin B in 1960 by Arai.[2] The chemical structure was elucidated partially by Takahashi et al.[3–5] and fully by Kaiser and Keller-Schierlein,[6] and the absolute configuration was established by X-ray crystallography.[7,8] Elaiophylin (**1**) belongs to a group of C_2-symmetrical 16-membered macrodiolides.[9] Of this class of natural products, the molecule of **1** has the most complex side chain with a glycosidated β-hydroxy hemiacetal structure. The similar side chain structure has also been found in other class of macrolide antibiotics such as concanamycins.[10] The isolation of the cyclic methyl acetal aglycon derivative **2′** from the methanolysis products of **1** and the total synthesis of **2′** from chiral carbon sources other than carbohydrate have been reported in 1985 by Seebach et al.[11,12] Other synthetic efforts toward **1** have been made by Wakamatsu et al.[13] As a synthetic challenge, we have been interested in **1** which is so sensitive to acid and base that its free aglycon **2** has never been isolated.[4–6,12] Herein we wish to describe, in full,[14] the total synthesis of elaiophylin (**1**) (azalomycin B), which makes use of carbohydrates as chiral source.

The retrosynthetic analysis of **1** is shown in Scheme 1 along with our synthesis plan. The synthesis of **1** through the glycosidation of free aglycon **2** would be impossible because of the extraordinary instability of **2**,[12] whereas it would be possible to synthesize an



Scheme 1.

appropriately protected segment **B** from a more stable β-hydroxy ketone **C** and a sugar derivative **D**. The aldol coupling of **B** with the macrocyclic dialdehyde **3** which is obtainable through the dimerization of **4** would give a key intermediate **A**. The target compound **1** then will be obtainable, if the deprotection of **A** followed by the hemiacetalization produced smoothly without any decomposition of **1** formed. In this case, **B** (a synthetic segment of **A**) should have appositely chosen protecting groups (R^1 and R^2) to afford effectively the hemiacetal compound **5** by its deprotection under conditions in which **1** is stable. The conversion of **A** into **1** is presumably achieved under almost the same conditions as used in the deprotection of **B**. Thus it would be required to find the ideal protective groups for the segment **B** to make a success of the elaiophylin synthesis by our plan. Furthermore, it would be a formidable[15] but challenging task to realize the highly stereocontrolled aldol coupling of **B** and **3** in the penultimate step to the aforesaid deprotection.

Preparation of the Segment B. The starting material **6**[16] was obtainable in large scale by the reaction of methyl 2,3-anhydro-4,5-*O*-benzylidene-α-D-mannopyranoside[17] and ethylmagnesium chloride in ether. The reaction product was once recrystallized from ethyl acetate–hexane to afford a 7:1 mixture of **6** and the by-product **6′**.[16] The yields of **6** and **6′** from the starting 2,3-anhydro sugar derivative were assumed to be ca. 64 and 9%, respectively. The complete isolation of **6** from **6′** by further recrystallization or column chromatography was impracticable at this stage. The facile one-step conversion of the crude **6** into the furanose derivative **7** was well-achieved by the direct treatment of **6** with a catalytic amount of boron trifluoride etherate in acetone; an 80% yield of the pure **7** was obtained after chromatography. Selective 5,6-de-*O*-isopropylidenation of **7** with 75% aqueous acetic acid afforded **8** in 85% yield. The periodate oxidation of **8** followed by sodium borohydride reduction of the resulting aldehyde **9** gave **10** in 97% yield. The alcohol **10** was converted into the mesylate **11** by the usual way, which was immediatelly reduced with lithium aluminium hydride (LAH) in ether to afford **12** in 72.5% yield from **10**. Hydrolysis of **12** with 50% aqueous acetic acid gave the free sugar **13** in 82% yield, which was treated with LAH in THF to afford **14** in 95% yield. The triol **14** was directly subjected to the one-step epoxidation[18] of vicinal diol with triphenylphosphine, diethyl azodicarboxylate (DEAD), and 3A Molecular Sieves in refluxed benzene to yield **15**. The crude sample of **15** isolated through a short silica-gel column was contaminated with a considerable amount of *N,N*-bis(ethoxycarbonyl)hydrazine. Since further chromatographic purification of this sample was not practicable, the crude **15** was *t*-butyldimethylsilylated to obtain the pure sample of **16a** in 57% overall yield from **14**. The reaction of **16a** with 5 equivalents of 2-ethyl-2-lithio-1,3-dithiane in THF afforded a 90% yield of essentially pure **17a**. The dithioacetal group of **17a** was cleaved with a 1:1 mixture of $HgCl_2$ and HgO to generate the ethyl ketone **18a** in 93% yield.

We have now in our hand the segment **C** in which R^1 is *t*-butyldimethylsilyl (TBS), a most useful silyl protective group. In our preliminary deprotection experiments for the TBS group of **18a**, it was found that **18a** was smoothly deprotected by tetrabutylammonium fluoride[19] (TBAF) in THF to give the hemiacetal **19**, but the tetrahydropyranyl (THP) derivative **20**, which was prepared from **18a** by the usual way, afforded under the similar desilylation conditions the unsaturated ketone **21** in 48% yield instead of the expected **22**. It was also observed that the mild acidic hydrolysis (3:1:3 AcOH–H_2O–THF,[20] 0 °C, 3 h or 22 °C, 2.5 h) of **20** yielded **19** (20%), **22** (16%), and considerable amounts of **18a** and **21**. These results suggested that the 5-*O*-glycosidation of **18a** may lead to a β-eliminated desilylation product under the basic conditions (TBAF in THF), furthermore, under the acidic conditions (3:1:3 AcOH–H_2O–

20 **21**

THF), the rate of hydrolytic cleavage of the TBS ether linkage may be rather slower than that of the cleavage of the glycosidic linkage with the 2-deoxysugar moiety. In this respect, it was noteworthy that azalomycin B[21] (**1**) was immediately decomposed by TBAF in THF even at lower temperature, but it was hardly affected by 3:1:3 AcOH–H_2O–THF, recovering the unchanged **1** after evaporation of the resulting mixture and subsequent silica-gel column chromatography. Although the TBS group thus seemed to be not apposite as the protective group (R^1) of the segment **C**, we first pursued the 5-*O*-glycosidation of **18a** with a 3,4-di-*O*-protected 2-deoxy-L-fucose derivative. Treatment of 2-deoxy-D-fucose with di-2-pyridyl disulfide and tributylphosphine[22] followed by silylation[23] with TBS triflate and 2,6-lutidine in DMF afforded the α-thioglycoside **23** along with the minor β-anomer. 2-Propanol reacted with **23** in acetonitrile in the presence of *N*-bromosuccinimide (NBS) and 4A Molecular Sieves[24] to give only the α-glycoside **24a** in 55% yield. However, the reaction of **18a** and **23** provided no glycoside **25a** under the similar conditions or with $Pb(ClO_4)_2$ in acetonitrile, recovering **18a** in 71% yield. Desilylation of **24a** in an acidic conditions (6.9% aqueous 46% HF in acetonitrile,[25] 20 °C, 16 h) failed, resulting in only the cleavage of glycosidic bond of **24a**. We next pursued the glycosidation of **18a** with the glycal derivative **26a** which was obtained by the silylation[23] of L-fucal[26] in 52% yield. The glycosidation of **18a** with **26a** was first accomplished by the method[27] which was previously developed in our laboratories. The reaction of **18a** and **26a** in the presence of NBS afforded a ca. 3:1 mixture of α- and β-anomeric bromo derivative, which was chromatographed on silica gel to separate the desired α-anomer **27a** in 65% yield. Debromination of **27a** with tributylstannane and α,α'-azobisisobutyronitrile (AIBN) in benzene afforded **25a** in 73% yield (47.5% overall yield from **18a**). The synthetic route to segment **B** (R^1=R^2=TBS) was thus confirmed. However, as had been predicted by the desilylation experiment for **20** and **24a**, **25a** was decomposed with TBAF in THF at 20 °C to give no deprotected hemiacetal **5** (Scheme 1), while **25a** was hardly affected with 3:1:3 AcOH–H_2O–THF at 25 °C for 7 h.

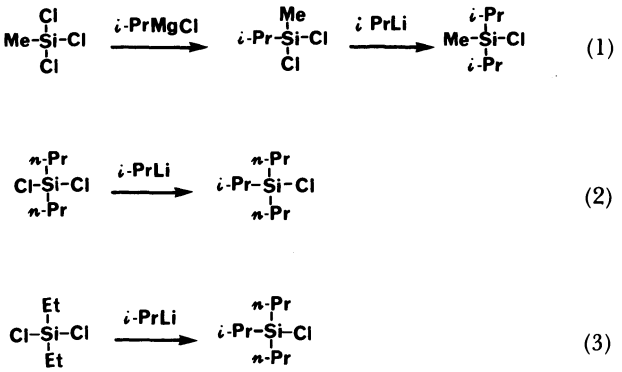
Our selection of the ideal silyl protective group for the segment **B** was aided by the classical reasoning that the rate of acidic hydrolysis of alkylsilyl ether should be subtly influenced by steric effects of alkylsilyl ligands on silicon.[28] We examined the alkylsilyl groups less hindered than TBS, such as triethylsilyl (TES), isopropyldimethylsilyl (IPDMS), diisopropylmethylsilyl (DIPMS), isopropyldipropylsilyl (IPDPS), and diethylisopropylsilyl (DEIPS). The silylating agents, DIPMS-Cl[29] and unknown reagents, IPDPS-Cl and DEIPS-Cl, were prepared from the appropriate chlorosilanes according to the reactions (1,2,3) shown in Scheme 2, respectively. The silylation of the crude **15** using TES-Cl, IPDMS-Cl,[30] IPDPS-Cl, DIPMS-Cl, and DEIPS-Cl with imidazole in dichloromethane afforded **16b**, **16c**, **16d**, **16e**, and **16f**, respectively, which were converted into the corresponding dithiane derivatives, **17b**, **17c**, **17d**, **17e**, and **17f** in good yields. Among them **17d**, **17e**, and **17f** were smoothly dedithioacetalized with $HgCl_2$–H_2O to give **18d**, **18e**, and **18f** in 91, 80, and 79% yields, respectively, whereas **17b** and **17c** afforded **18b** (58%) and **18c** (44%) together with hemiacetal **19** (30 and 46%), respectively. From a preparative point of view, the silyl derivatives, **18d**, **18e**, and **18f**, were more suitable for the segment **C**.

The glycal derivatives, **26b**, **26c**, and **26d**, were prepared by treatment of L-fucal with the corresponding silylating agents and imidazole in DMF. The model glycosides (**24b**, **24c**, **24d**) were then prepared



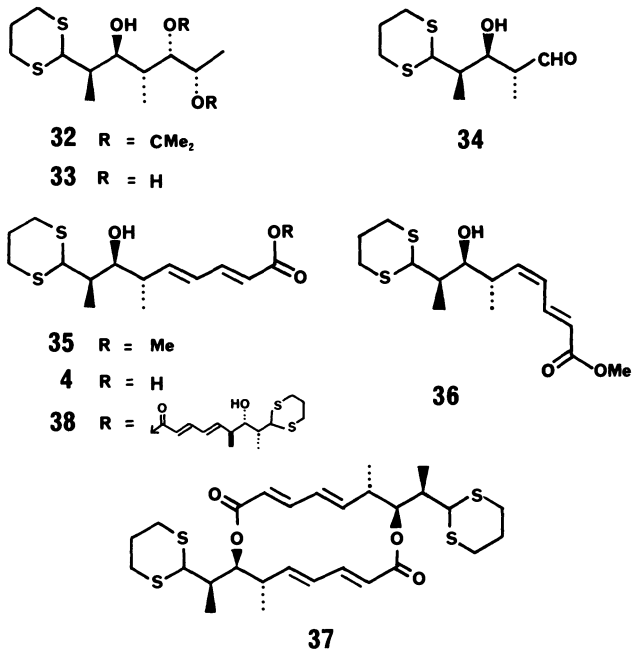
Scheme 2.

from the corresponding glycals and 2-propanol by the procedure described in the preparation of **25a**. Based on the facilities in the formation of the desilylation products **28** from **24b**, **24c**, and **24d** under the acidic conditions (8:1:8 AcOH-H_2O-THF, 30 °C, 24 h),[31] the most apposite protective group for the sugar moiety of **B** was assumed to be IPDMS, therefore **26c** became the most promising glycal derivative.

Each of the selected ketone derivatives, **18d**, **18e**, and **18f**, were subjected to glycosidation with **26c** followed by debromination to afford the glycosides, **25d** (24% via **27d**), **25e** (38% via **27e**), and **25f** (30% via **27f**), respectively. The glycosidation of **18f** with fluoride **30** did not proceed because the thioglycoside **29**, a precursor of **30**, was completely deprotected under the conditions of its fluoridation with (dimethylamino)-sulfur trifluoride (DAST) and NBS.[24,32] However, we found that the treatment of **18f** (1 equiv) with the glycal **26c** (3.5 equiv) and *dl*-10-camphorsulfonic acid (CSA) (0.36 equiv) in dichloromethane containing 4A Molecular Sieves[33] by modification of the Wakamatsu's methods[13a] afforded **25f** as a sole anomer in 80% yield.

Finally, thus obtained **25d**, **25e**, and **25f** were subjected to a deprotection test to determine the most favorable compound for the segment **B**. Exposure of **25d** to 2:1:2 AcOH-H_2O-THF (28 °C, 6 h) or 2:1:2 AcOH-aq 0.46% HF-THF (28 °C, 4 h) afforded mainly **5** accompanied by a small amount of partially deprotected product and 2-deoxy-L-fucose, which were detectable on TLC. Treatment of **25e** with 3:1:3 AcOH-H_2O-THF (25 °C, 20 h) or 2:1:2 AcOH-aq 0.46% HF-THF (26 °C, 6 h) gave mainly **5** and the same Kind of by-products. Exposure of **25e** to 8:1:8 AcOH-H_2O-THF (26 °C, 11 h) yielded mainly **31** in 45% yield. Treatment of **25f** with 2:1:2 AcOH-H_2O-THF (24—26 °C, 12—18 h) also afforded **5** as major product. In view of the minimal formation of by-products observed in the deprotection test, **25f** was considered to be the most promising segment **B**. In fact, **25f** provided a 64% yield of **5** on treatment with 3:1:4 AcOH-aq 1% HF·KF-THF (30 °C, 14 h). Under this conditions, natural azalomycin **B** was confirmed to be stable. The synthesis of the segment **B** was accomplished.

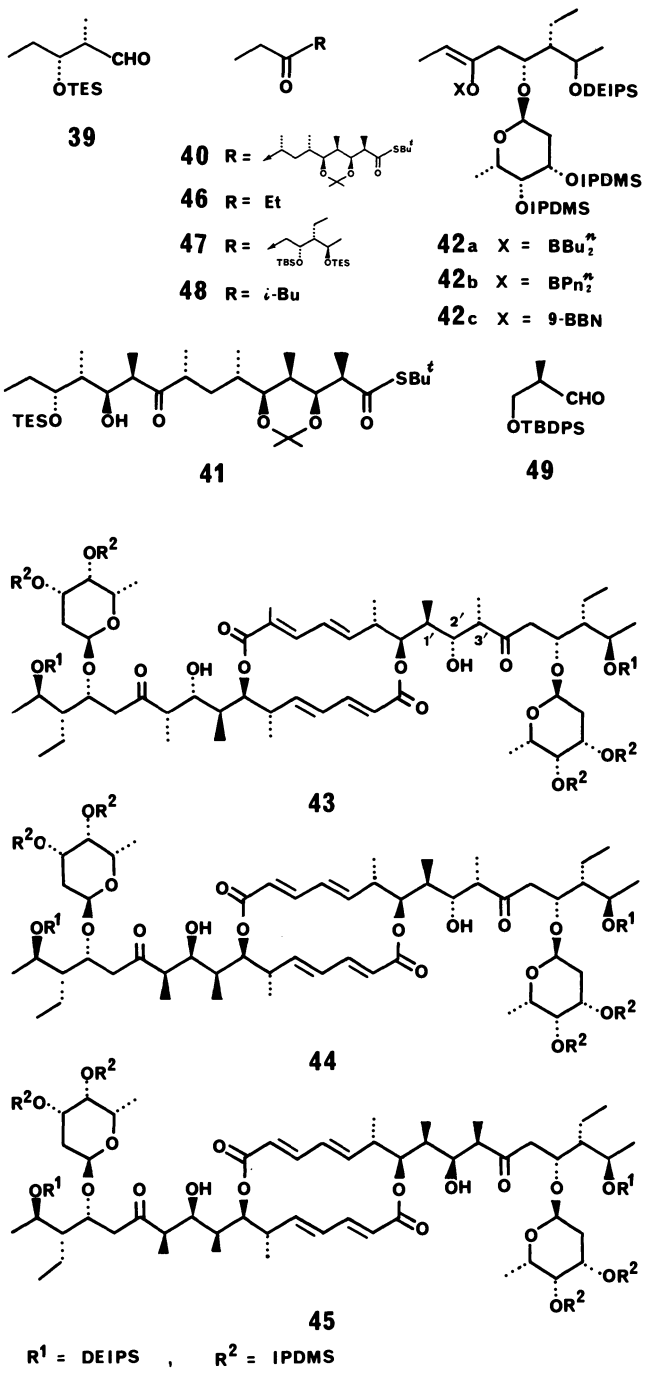
Preparation of the Segment 3. The synthesis of the second segment **3**[11,12] started from **32** which was previously prepared from D-glucose in our laboratories.[34] Deisopropylidenation of **32** with 50% aqueous acetic acid afforded the crystalline triol **33** in 90% yield. Treatment of **33** with lead tetraacetate[35] gave the aldehyde **34** (ca. 95% yield) which was allowed to react with [(2*E*)-3-methoxycarbonyl-2-propenyliden]triphenylphosphorane[36] in toluene at 80 °C to yield (2*E*,4*E*)-dienoic ester **35** and its (4*Z*)-isomer **36** in 51 and 21% overall yields from **33**, respectively, after chromatographic separation. The (4*Z*)→(4*E*) isomerization of **36** proceeded in benzene



37

with a catalytic amount of iodine[37] at 25 °C for 1 m to afford **35** and **36** in 37.4 and 27% isolated yields, respectively. Saponification of **35** with lithium hydroxide gave the hydroxy dienoic acid **4** in quantitative yield. The dimerization of **4** was best effected by the Yamaguchi's method[38,39] to afford the crystalline diolide **37** in 31% yield. It was found that the reaction of **4** with 1-chloro-2-methylpyridinium iodide and triethylamine according to the Mukaiyama's method[40] gave the anhydride **38** in 85.5% yield, which was treated with 4-(dimethylamino)pyridine (DMAP) in acetonitrile to afford the diolide **37** in 9.4% overall yield from **4**. Dedithioacetalization of **37** with 1:1 $HgCl_2$-HgO (red) was carried out with irradiation in the water bath of an ultrasound laboratory cleaner to give the crystalline dialdehyde **3** in 70% yield.

Aldol Coupling of 25f and 3, and Synthesis of Elaiophylin. In the synthesis of 6-deoxyerythronolide B, Masamune et al.[41] have found that the aldol coupling of chiral aldehyde **39** and (*Z*)-lithium enolate prepared from ethyl ketone **40** with lithium bis-(trimethylsilyl)amide (LBTMSA) give the anti-Cram-syn aldol **41** in 88% yield and 94% diastereomeric purity. The aldol coupling of **25f** and **3** was first pursued according to this procedure. The lithium enolate was prepared by treatment of **25f** (2.4 equiv) with LBTMSA (2.4 equiv) in THF at −78 °C for 0.5 h. This was added slowly to a THF solution of **3** (1 equiv) at −78 °C and the resulting colorless mixture was stirred at −78 °C for 2 h. By careful chromatographic purification of the reaction products, three diastereomeric aldols, **43** (5.2%), **44** (8.9%), and **45** (6.3%), could be obtained in low yields. The minor aldol **43** proved to be the desired precursor **A** to elaiophylin **1** as will be described in the next paragraph. When inversely was added the aldehyde **3**

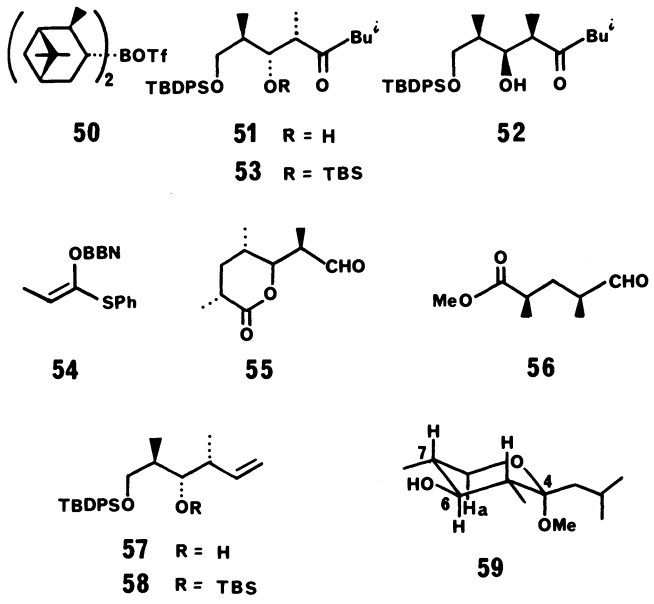


to the lithium enolate solution at −78 °C, the resulted red-colored reaction mixture afforded only poor yields of the aldol products. It was revealed that **3** was very sensitive to the strong base such as lithium enolate.

It has also been known that dibutylboryl triflate[42] reacts with ethyl ketones such as **46** and **47**[11,12] in the presence of weak base *i*-Pr2NEt to give with high stereoselectivity the (*Z*)-boron enolates[43] which add to aldehydes to provide syn aldols.[12,42-44] The coupling of **25f** and **3** was next carried out by this procedure using dialkylboryl triflates. The (*Z*)-boron enolate **42a** was prepared under the standard conditions[43] (*n*-Bu2BOTf, *i*-Pr2NEt, ether, −78 °C, 0.5 h). The reaction was performed by addition of an etherial solution of **42a** (4 equiv) to an etherial solution of **3** (1 equiv) at −78 °C under argon. It was allowed to warm to −10 °C and stirred for 2 h. Quenching with a phosphate buffer (pH 7) (25 °C, 3 min)[45] followed by chromatographic isolation afforded the three aldols, **43**, **44**, and **45** in 13, 24, and 26% yields, respectively. The ^{1}H NMR examination of these products revealed that **43** and **45** were C_2 symmetric, while **44** was unsymmetric (see Experimental). Upon treatments of these products with 3:1:3 AcOH–1% aqueous HF·KF–THF at 30 °C for 18 h, only **43** gave a 22% yields of **1**. The TLC behavior of **1** was coincidental with azalomycin B, and after two recrystallizations from ethyl acetate there was obtained colorless needles, mp 179—182 °C, $[\alpha]_D$ −53° which compared well with natural material. Comparison of ^{1}H NMR spectra at 400 MHz showed both materials to be identical. Unexpectedly, we could not obtain the diastereomers[46] of **1** from the aldol diastereomers **44** and **45** under the same deprotection conditions. Having thus assigned **43** as the bis(1′,2′-anti-2′,3′-syn)-product, **45** and **44** were assumed to be the bis(1′,2′-syn-2′3′-syn)- and (1′,2′-anti-2′,3′-syn:1″,2″-syn-2″,3″-syn)-products, respectively.

The reaction of **3** with other (*Z*)-boron enolates **42b** and **42c** which were prepared from **25f** and the corresponding boryl triflates were carried out by the procedure described above to afford **43** (12 and 5%), **44** (25.5 and 16.5%), and **45** (19 and 39%), respectively. The reaction of **3** with **42a** in the presence of $ZnCl_2$ in THF gave **43** (14%), **44** (31%), and **45** (21%). Moreover, the Mukaiyama's aldol reaction of **3** with **25f** via divalent tin enolate[47] gave **43** (6.5%), **44** (21%), and **45** (28%).

With the goal of obtaining the desired anti-Cram (1′,2′-anti) product **43** in high yield, we also examined the aldol reaction with the boron enolate of **25f** with chiral ligands attached to boron. A model coupling reaction of **48** and **49** using the chiral boryl triflate **50**[48,49] was carried out under the Paterson's conditions[49] (*i*-Pr2NEt, ether, 0 °C) to afford a 2:1 mixture of **51** (anti-Cram product[51]) and **52** (Cram product[51]) in 30% yield. While the coupling using achiral boryl triflates, *n*-Bu2BOTf and 9-BBNOTf, gave 2.3:1 and 1.2:1 mixture of **51** and **52** in 59 and 93% yields, respectively. The (−)-diisopinocampheylboron enolate of **48** showed to be of little help for enhancement of the expected *si*-face selectivity[50] in direction of the inherent 1,2-asymmetric induction on addition of achiral boron enolates to the α-chiral aldehyde **49**. Furthermore, on the reaction of **49** and **25f** using **50**, there could not be obtained any aldol products. The enolization of the large ethyl ketone **25f** with the bulky boryl triflate **50** seemed to be quite difficult. An extensive study by Masamune[52] revealed that Cram/anti-Cram selectivity in the coupling of boron enolate



50 51 R = H 52

53 R = TBS

54 55 56

57 R = H

58 R = TBS

59

54 with chiral aldehydes depended on the aldehydes employed: the reaction of **54** with lactone aldehyde **55** afforded the Cram product in a 1.9—2.5:1 selectivity, whereas the reaction with linear aldehyde **39** or **56** gave the anti-Cram product in a 1.5:1 or 55:45 selectivity, respectively. The Cram selectivity observed in the coupling of **3** with **42c** and the anti-Cram selectivity in the reaction of **49** with 9-BBN enolate of **48** appeared to be in line with the Masamune's observation. The rationalization for these results is now not available.

Although the closing stages of this total synthesis of **1** were sullied by the minor preponderance of the unwanted Cram (1′2′-syn) product **45** over the anti-Cram (1′2′-anti) product **43** in the aldol reaction step, the synthesis of elaiophylin (**1**) which was sensitive to acid and base was first achieved via **43** by using the appropriate O-protecting groups such as DEIPS and DMIPS.

Experimental

Melting points were determined on a micro hot-stage Yanaco MP-S3 and were uncrrected. Optical rotations were measured with a Carl Zeiss photoelectric polarimeter or a JAS.CO DIP-360 photoelectric polarimeter in chloroform unless otherwise stated. IR spectra were recorded on a Hitachi Perkin-Elmer 225 spectrometer, UV spectra on a JAS.CO UVIDEC-1 spectrometer, and ^{1}H NMR spectra on a Varian EM-390, a Bruker WM 250, or a JEOL GX-400 spectrometer in $CDCl_3$ using TMS as internal standard unless otherwise stated. Mass spectra were measured with a Hitachi M-80 mass spectrometer or a Hitachi RMU-6M mass spectrometer. TLC was carried out on Merck TLC plates (60F-254, 0.25 mm). Column chromatography was performed on silica gel, Wakogel C-200 and Merck Kiesel gel 60 (230—400 mesh) for "Flash Chromatography". In general, organic solvents were purified and dried by the appropriate procedure, and evaporation and concentration were carried out under reduced pressure below 35 °C, unless otherwise noted.

3-Deoxy-3-*C*-ethyl-1,2:5,6-di-*O*-isopropylidene-β-D-altrofranose (7). To a solution of the crude sample of **6** (32.2 g) containing ca. 12.5% of **6′** in dry acetone (1.29 l) was added $BF_3 \cdot Et_2O$ (6.04 ml, 65.4 mmol) under ice-cooling. After being kept at room temperature for 15 h, the reaction mixture was neutralized with Et_3N under ice-cooling and then concentrated to afford a yellow syrup, which was chromatographed on silica gel (2 kg) with 6:1 toluene–ethyl acetate to give **7** (21.3 g, 80% based on **6**) as colorless needles. R_f=0.41 (9:1 toluene–ethyl acetate); mp 63—64 °C; $[\alpha]_D^{22}$ +16° (*c* 1.07); ^{1}H NMR (90 MHz) δ=1.00 (3H, t, 3-$CH_2C\underline{H}_3$, *J*=6.6 Hz), 1.30, 1.35, 1.40, and 1.53 (each 3H, each s, CMe_2×2), 1.2—1.8 (2H, m, 3-$C\underline{H}_2CH_3$), 2.37 (1H, dt, H-3, *J*=2.4, 7.5 Hz), 3.6—4.4 (4H, m, H-4, 5, 6, 6′), 4.43 (1H, d, H-2, *J*=4.5 Hz), and 5.77 (1H, d, H-1, *J*=4.5 Hz).

Found: C, 61.74; H, 8.88%. Calcd for $C_{14}H_{24}O_5$: C, 61.63; H, 8.71%.

3-Deoxy-3-*C*-ethyl-1,2-*O*-isopropylidene-β-D-altrofuranose (8). A solution of **7** (671 mg, 2.46 mmol) in aqueous 75% acetic acid (13.4 ml) was stirred at 30 °C for 4 h and then concentrated to give a crude syrup (684 mg) which was chromatographed on silica gel (21 g) with 1:1 toluene–ethyl acetate to afford **8** (487 mg, 85%) as a colorless surup: R_f=0.12 (3:2 toluene–ethyl acetate); $[\alpha]_D^{28}$ +13° (*c* 1.18); ^{1}H NMR (90 MHz) δ=1.00 (3H, t, 3-$CH_2C\underline{H}_3$, *J*=6.3 Hz), 1.30 and 1.53 (each 3H, each s, CM_2), 1.2—1.8 (2H, m, 3-$C\underline{H}_2CH_3$), 2.25—2.7 (2H, m, H-3 and OH), 2.87 (1H, d like, OH), 3.65—4.15 (4H, m, H-4.5, 6, 6′), 4.43 (1H, d, H-2, *J*=3.9 Hz), and 5.80 (1H, d, H-1, *J*=3.9 Hz).

Found: C, 56.71; H, 8.32%. Calcd for $C_{11}H_{20}O_5$: C, 56.88; H, 8.68%.

3-Deoxy-3-*C*-ethyl-1,2-*O*-isopropylidene-β-D-arabinofuranose (10). To an ice-cooled solution of **8** (4.55 g, 19.5 mmol) in acetone (45.5 ml) was slowly added a solution of $NaIO_4$ (8.35 g, 39.1 mmol) in water (83.5 ml). After being stirred at room temperature for 30 min, the mixture was concentrated to remove the acetone. The residue was diluted with water (100 ml), extracted with ethyl acetate (50 ml×3), and the extracts were washed with saturated aqueous NaCl (50 ml), dried and concentrated to afford a crude sample of **9** (4.35 g) as pale yellow needles, which was used without further purification. Powdered $NaBH_4$ (1.64 g, 43.5 mmol) was slowly added to a stirred ice-cooled solution of the crude sample of **9** (4.35 g) in methanol (43.5 ml), and then the mixture was stirred at room temperature for 10 min. The reaction mixture was neutralized with CO_2 (solid) and concentrated. The residue was triturated with chloroform, and the chloroform solutions were evaporated to give a pale yellow syrup, which was chromatographed on silica gel (110 g) with 1:1 toluene–ethyl acetate to afford **10** (3.83 g, 97% from **8**) as a colorless syrup. R_f=0.46 (1:1 toluene–ethyl acetate); $[\alpha]_D^{27}$ +11° (*c* 0.90); ^{1}H NMR (90 MHz) δ=1.00 (3H, t, 3-$CH_2C\underline{H}_3$, *J*=6.6 Hz), 1.30 and 1.53 (each 3H, each s, CMe_2), 1.25—1.55 (2H, m, 3-$C\underline{H}_2CH_3$), 1.9—2.2 (1H, m, H-3), 2.2—2.45 (1H, br, OH), 3.55—4.1 (3H, m, H-4,5,5′), 4.42 (1H, dd, H-2, *J*=1.5, 4.5 Hz), and 5.81 (1H, d, H-1, *J*=4.5 Hz).

Found: C, 59.71; H, 8.88%. Calcd for $C_{10}H_{18}O_4$: C, 59.39; H, 8.97%.

3-Deoxy-3-*C*-ethyl-1,2-*O*-isopropylidene-5-*O*-methylsulfonyl-β-D-arabinofuranose (11). To a solution of **10** (4.50 g, 22.2 mmol) in dry pyridine (45.0 ml) was added methanesulfonyl chloride (2.07 ml, 26.7 mmol) under ice-cooling. After being stirred at room temperature for 0.5 h, the reaction mixture was poured into cold water (50 ml), extracted with ethyl acetate (20 ml×3), washed with saturated aqueous NaCl (30 ml), dried, and concentrated to afford a crude sample of **11** (6.40 g) as yellow needles which was suitable for the next synthesis. Analytical sample was obtained after silica-gel column chromatography with 3:1 benzene-ethyl acetate. R_f=0.40 (3:1 toluene-ethyl acetate); mp 69.5—70 °C (ethyl acetate-hexane); $[\alpha]_D^{33}$ +25° (*c* 0.88); ^{1}H NMR (90 MHz) δ=1.00 (3H, t, 3-$CH_2C\underline{H}_3$, *J*=6.6 Hz), 1.30 and 1.58 (each 3H, each s, CMe_2), 1.25—1.7 (2H, m, 3-$C\underline{H}_2CH_3$), 2.10 (1H, dt, H-3, *J*=3.0, 1.5 Hz), 3.10 (3H, s, OMs), 4.0—4.75 (4H, m, H-2,4,5,5′), and 5.83 (1H, d, H-1, *J*=3.3 Hz).

Found: C, 46.92; H, 7.00%. Calcd for $C_{11}H_{20}O_6S$: C, 47.13; H, 7.19%.

3,5-Dideoxy-3-*C*-ethyl-1,2-*O*-isopropylidene-β-D-arabinofuranose (12). To an ice-cooled solution of the crude sample of **11** (6.40 g) in dry ether (96.0 ml) was slowly added powdered $LiAlH_4$ (2.60 g, 68.5 mmol) under stirring. The stirring was continued at room temperature for 5 h and to the reaction mixture were successively added dropwise water (2.60 ml), aqueous 15% NaOH (2.60 ml) and water (7.80 ml) under ice-cooling. The resulting mixture was then filtered, and the filter cake was washed with chloroform. The filtlate and washings were combined, and concentrated (10 °C, 40 mmHg; 1 mmHg≈133.322 Pa) to give a syrup (15.8 g) which was chromatographed on silica gel (790 g) with 10:1 hexane-acetone to afford **15** (3.00 g, 72.5% from **10**) as a colorless syrup. Analytical sample was obtained by distillation [bp_5 78—80 °C (bath temp)]. R_f=0.63 (5:1 toluene-ethyl acetate); $[\alpha]_D^{25}$ 0°, $[\alpha]_{365}$ +4.2° (*c* 1.19); ^{1}H NMR (90 MHz) δ=1.00 (3H, t, 3-$CH_2C\underline{H}_3$, *J*=6.6 Hz), 1.25—1.55 (2H, m, 3-$C\underline{H}_2CH_3$), 1.30 and 1.53 (each 3H, each s, CMe_2), 1.37 (3H, d, 4-Me, *J*=7.5 Hz), 1.75—2.1 (1H, m, H-3), 3.87 (1H, dq, H-4, *J*=7.5, 1.5 Hz), 4.37 (1H, dd, H-2, *J*=4.5, 1.5 Hz), and 5.72 (1H, d, H-1, *J*=4.5 Hz).

2-[(2*R*,3*R*,4*R*)-4-*O*-(*t*-Butyldimethylsilyl)-3-ethyl-2,4-dihydroxypentyl]-2-ethyl-1,3-dithiane (17a). A solution of 2-ethyl-1,3-dithiane (997 mg, 6.73 mmol) in dry THF (9.97 ml) was cooled to −40 °C under argon. A solution of 1.42 M butyllithium (1 M=1 mol dm^{-3}) in hexane (4.74 ml, 6.73 mmol) was added to the solution dropwise under stirring. After being stirred for an additional 2 h at −20 °C, the mixture was again cooled to −50 °C. A solution of **16a** (329 mg, 1.35 mmol) in dry THF (0.99 ml) was then added dropwise to this solution, and stirring was continued at −50 °C→−20 °C for 4 h. The reaction mixture was poured into cold water (20 ml) and extracted with chloroform

(10 ml×3). The extracts were washed with saturated aqueous NaCl (10 ml), dried, and concentrated. The residual syrup (1.40 g) was chromatographed on silica gel (210 g) with benzene to afford **17a** (474 mg, 90%) as a colorless syrup. R_f=0.43 (benzene); ^{1}H NMR (90 MHz) δ=0.87 (9H, s, *t*-Bu), 0.88 (3H, t, 2-$CH_2C\underline{H}_3$, J=7.2 Hz), 1.07 (3H, t, 3′-$CH_2C\underline{H}_3$, J=7.5 Hz), 1.30 (3H, d, H-5′, J=6.0 Hz), 1.15—1.35 (1H, m, H-3′), 1.4—1.8 (2H, m, 3′-$C\underline{H}_2CH_3$), 1.75—2.35 (6H, m, 2-$CH_2C\underline{H}_3$, H-1′, $SCH_2C\underline{H}_2$), 2.75—2.95 (4H, m, $SC\underline{H}_2CH_2C\underline{H}_2S$), 3.47 (1H, s, OH), 4.10 (1H, dq, H-4′, J=7.5, 3.0 Hz), and 4.3—4.7 (1H, m, H-3′).

(5*R*,6*R*,7*R*)-7-*O*-(*t*-Butyldimethylsilyl)-6-ethyl-5,7-dihydroxy-3-octanone (18a). To a mixture of **17a** (23.4 mg, 0.0596 mmol), mercury(II) oxide (56.8 mg, 0.262 mmol) and 80% aqueous acetone (1.64 ml) was added mercury(II) chloride (71.2 mg, 0.262 mmol) under ice-cooling with efficient stirring. The reaction mixture was stirred under ice-cooling for 0.5 h and filtered through a Celite. The filter cake was washed with acetone, and then the filtrate and the washings were combined. After removal of the acetone under reduced pressure (0 °C), to the aqueous residue was added aqueous 10% KI until orange color was disappeared. The mixture was then extracted with chloroform (7 ml×3) and the extracts were washed with saturated aqueous NaCl (10 ml), dried, and concentrated to give a crude syrup (22.6 mg) which was chromatographed on silica gel (2 g) with 8:1 hexane–ethyl acetate to afford a pure sample of **18a** (16.7 mg, 93%) as a colorless syrup. R_f=0.30 (benzene); $[\alpha]_D^{29}$ −2.9° (*c* 1.18); IR ($CHCl_3$) 1710 cm^{-1}; ^{1}H NMR (90 MHz) δ=0.89 (9H, s, *t*-Bu), 0.93 (3H, t, H-1, J=6.0 Hz), 1.03 (3H, t, 6-$CH_2C\underline{H}_3$, J=7.2 Hz), 1.30 (3H, d, H-8, J=6.0 Hz), 1.40 (2H, q, 6-$C\underline{H}_2CH_3$, J=7.2 Hz), 1.2—1.4 (1H, m, H-6), 2.2—2.95 (4H, m, H-2,2′,4,4′), 3.63 (1H, br s, OH), 4.17 (1H, dq, H-7, J=3.0, 6.0 Hz), and 4.5—4.85 (1H, m, H-5).

Found: C, 63.75; H, 11.10%. Calcd for $C_{16}H_{34}O_3Si$: C, 63.52; H, 11.33%.

2-Pyridinyl 3,4-Bis-*O*-(*t*-butyldimethylsilyl)-2-deoxy-1-thio-α-L-fucoside (23) and β-Anomer (23-β). To a solution of 2-deoxy-L-fucose[26] (35.2 mg, 0.238 mmol) in dry THF (0.70 ml) was added *n*-Bu_3P (88.8 µl, 0.357 mmol) dropwise and PySSPy (38.5 mg, 0.357 mmol) under ice-cooling. After being stirred under ice-cooling for 2 h, *n*-Bu_3P (29.6 µl, 0.119 mmol) and PySSPy (26.2 mg, 0.119 mmol) was added to the reaction mixture and stirred at room temperature (25 °C) for 1 h. The resulting mixture was concentrated to a crude syrup (0.3 g) which was chromatographed on silica gel (27 g) with 2:1 chloroform–acetone to afford a pale yellow syrup (39 mg). To an ice-cold solution of this sample (0.495 g, 2.15 mmol) in dry CH_2Cl_2 (4.95 ml) was added successively 2,6-lutidine (1.57 ml, 8.20 mmol) and TBDMSOTf (1.27 ml, 10.9 mmol) and the mixture was stirred under ice-cooling for 0.5 h. The reaction mixture was dilluted with ethyl acetate (20 ml) and water (10 ml) and extracted with saturated aqueous NaCl (20 ml), dried, and concentrated to give a crude syrup (1.6 g) which was chromatographed on silica gel (80 g) with 10:1 hexane–acetone to afford **23** (0.773 g, 80%) and **23-β** (0.173 g, 18%) as pale yellow syrup.

23: R_f=0.54 (10:1 hexane–acetone); ^{1}H NMR (90 MHz) δ=0.93 and 0.97 (each 9H, each s, *t*-Bu×2), 1.17 (3H, d, 5-Me, J=6.2 Hz), 1.82 (1H, ddd, H-2_{eq}, J=13.0, 4.5, 1.5 Hz), 2.58 (1H, ddd, H-2_{ax}, J=15.0, 13.0, 6.0 Hz), 3.63 (1H, br, H-4), 3.85—4.30 (2H, m, H-3,5), 6.27 (1H, dd, H-1, J=6.0, 1.5 Hz), 6.9—7.15 (1H, m), 7.2—7.7 (2H, m), and 8.4—8.7 (1H, m).

23-β: R_f=0.54 (10:1 hexane–acetone); ^{1}H NMR (90 MHz) δ=0.93 and 0.97 (each 9H, each s, *t*-Bu×2), 1.28 (3H, d, 5-Me, J=6.2 Hz), 1.7—1.95 (1H, m, H-2_{eq}), 2.05—2.25 (1H, m, H-2_{ax}), 3.55—4.15 (3H, m, H-3,4,5), 5.35 (1H, dd, H-1, J=12.6, 2.3 Hz), 6.6—6.9 (1H, m), 7.0—7.35 (1H, m), 7.35—7.75 (1H, m), and 7.95—8.15 (1H, m).

3,4-Bis-*O*-(*t*-butyldimethylsilyl)-L-fucal (26a). To a solution of L-fucal (48.4 mg, 0.372 mmol) and 2,6-lutidine (0.173 ml, 1.49 mmol) in dry CH_2Cl_2 (0.484 ml) was added TBDMSOTf (0.216 ml, 1.12 mmol) under ice-cooling. The resulting suspension was stirred at the same temperature for 20 min, and then the reaction mixture was poured into cold water (5 ml) and extracted with ethyl acetate (5 ml×3). The extracts were washed with saturated aqueous NaCl (10 ml), dried, and concentrated to a crude syrup (200 mg). The syrup was chromatographed on silica gel (10 g) with 70:1 hexane–ethyl acetate to afford **26a** (68.8 mg, 51.6%) as a colorless syrup. R_f=0.65 (50:1 hexane–ethyl acetate); $[\alpha]_D^{25}$ +31° (*c* 1.00); ^{1}H NMR (90 MHz) δ=0.90 (18H, s, *t*-Bu×2), 1.30 (3H, d, 5-CH_3, J=6.0 Hz), 3.75—3.9 (1H, m, H-4), 4.07 (1H, dq, H-5, J=6.0, 1.5 Hz), 4.25—4.35 (1H, m, H-3), 4.57 (1H, dd, H-2, $J_{1,2}$=6.3, $J_{2,3}$=2.0 Hz), and 6.20 (1H, dd, H-1, $J_{1,2}$=6.3, $J_{1,3}$=1.5 Hz).

(5*R*,6*R*,7*R*)-5-*O*-[2-*C*-Bromo-3,4-bis-*O*-(*t*-butyldimethylsilyl)-2-deoxy-α-L-fucosyl]-7-*O*-(*t*-butyldimethylsilyl)-6-ethyl-5,7-dihydroxy-3-octanone (27a). To a mixture of **18a** (46.0 mg, 0.156 mmol) and **26a** (273 mg, 0.760 mmol) in dry CH_3CN (0.273 ml) was added NBS (135 mg, 0.760 mmol) under ice-cooling. The reaction mixture was stirred under ice-cooling for 0.5 h and then stirred at room temperature (25 °C) for 2 h. The solution was poured into cold saturated aqueous $NaHCO_3$ (5 ml) and extracted with ethyl acetate (5 ml×3). The extracts were washed with saturated aqueous NaCl (7 ml), dried, and concentrated to give a syrup (509 mg) which was chromatographed on silica gel (80 g) with 12:1 hexane–ethyl acetate to afford **27a** (72.9 mg, 65%) and **27a-β** (23.0 mg, 16%) as a colorless syrup, respectively.

27a: R_f=0.53 (10:1 hexane–ethyl acetate); ^{1}H NMR (90 MHz) δ=0.87 and 0.97 (30H, m, *t*-Bu×3, 6-$CH_2C\underline{H}_3$), 1.01, 1.15, and 1.24 (each, 3H, each d, H-1,8, 5′-Me, each J=6.0 Hz), 1.0—1.65 (3H, m, H-6, 6-$C\underline{H}_2CH_3$), 2.3—3.15 (4H, m, H-2,4), 3.35—3.4 (1H, m, H-4′), 3.8—4.15 (3H, m, H-2′,3′,5′), 4.15—4.55 (2H, m, H-5,7), and 5.02 (1H, d, H-1′, J=2.8 Hz).

27a-β: R_f=0.42 (10:1 hexane–ethyl acetate); ^{1}H NMR (90 MHz) δ=0.8—1.7 (42H, m, *t*-Bu×3, H-1,8,6, 5-CH_2CH_3), 2.3—3.2 (4H, m, H-2,2′,4,4′), and 3.3—4.7 (7H, m, H-5,7,1′,2′,3′,4′,5′).

(5*R*,6*R*,7*R*)-5-*O*-(*t*-Butyldimethylsilyl)-[3,4-bis-*O*-(*t*-butyldimethylsilyl)-2-deoxy-α-L-fucosyl]-6-ethyl-5,7-dihydroxy-3-octanone (25a). To a solution of **27a** (53.4 mg, 0.0722 mmol) in dry benzene (0.379 ml) was added *n*-Bu_3SnH (46.5 µl, 0.173 mmol) and AIBN (1.42 mg, 0.00866 mmol) and then stirred at 60 °C for 1 h under argon. The solution was cooled and concentrated to give a syrup which was chromatographed on silica gel (16 g) with 12:1:0.6 hexane–ethyl acetate–chloroform to afford **25a** (34.9 mg, 73% from **18a**) as a colorless syrup. R_f=0.30 (12:1:0.6 hexane–ethyl acetate–chloroform); $[\alpha]_D^{20}$ −46° (*c* 1.36); IR ($CHCl_3$) 1710 cm^{-1}; ^{1}H NMR (90 MHz) δ=0.75—1.7 (42H,

m, *t*-BuX3, H-1,6,8,6-CH_2CH_3, 5'-Me), 1.7—3.0 (6H, m, H-2,4,2'), 3.2—3.25 (1H, m, H-4'), 3.6—4.6 (4H, m, H-5,7,3',5'), and 4.97 (1H, m, H-1').

Preparation of DEIPS-Cl. To a solution of Li (1.90 g) in petroleum ether (130 ml) was added slowly a solution of *i*-PrCl (11.9 ml, 130 mmol) in dry petroleum ether (38 ml). The mixture was irradiated in the sonicator (65 W, 48 kHz) at 30—50 °C for 45 min to afford about 0.53 M *i*-PrLi–petroleum ether. To this 0.53 M *i*-PrLi–petroleum ether (120 ml) was added Et_2SiCl_2 (9.91 ml, 63.1 mmol) and stirred at 50 °C for 1 h. The reaction mixture was cooled to room temperature and LiCl was filtered off under argon. The filtrate was distilled at atmospheric pressure to remove solvent and then the residue distilled to give DEIPS-Cl (8.14 g, 92%) as a colorless liquid. Bp_{32} 73—74.5 °C.

Preparation of DPIPS-Cl. This experiment was carried out under the conditions described in the preparation DEIPS-Cl. DPIPS-Cl (3.12 g, 75%) was obtained as a colorless liquid from *n*-Pr_2SiCl_2 (4.14 ml). Bp_{26} 96.5—97.0 °C.

Preparation of DIPMS-Cl. To a suspension of Mg (3.97 g, 0.164 mmol) in dry THF (127 ml) was added dropwise $MeSiCl_3$ (30.0 ml, 0.256 mol) and *i*-PrCl (11.6 ml,

0.128 mol) and the reaction mixture was then refluxed for 14 h. The mixture was cooled to room temperature and the solvent was removed by distillation under atmospheric pressure. To the residue was added dry ether (150 ml), and $MgCl_2$ was filtered off under argon. The filtrate was distilled to give *i*-Pr(Me)$SiCl_2$ (5.17 g, bp 88—90 °C) as a colorless liquid. Next experiment to introduce the *i*-Pr group to this sample was carried out under the conditions described in the preparation DEIPS-Cl. DIPMS-Cl (2.99 g, 11%) was given as a colorless liquid. Bp 141—143 °C.

(2*R*,3*R*,4*S*,5*S*,6*R*)-4-Methyl-6-(1,3-dithian-2-yl)-2,3,5-heptanetriol (33). A solution of **32** (416 mg, 1.30 mmol) in aqueous 50% acetic acid (8.31 ml) was stirred at 50 °C for 1 h and then concentrated to give a syrup which was chromatographed on silica gel (20 g) with 10:1 chloroform–methanol to afford **33** (327 mg, 90%) as colorless needles. R_f=0.43 (10:1 chloroform–methanol); mp 134.9—135.2 °C (acetone–hexane); $[\alpha]_D^{21}$ 0°, $[\alpha]_{405}$ +1.9°, $[\alpha]_{315}$ +3.7°, (*c* 0.67); ^{1}H NMR (90 MHz, CD_3OD) δ=0.83 and 1.03 (each 3H, each d, Me×2, each *J*=7.2 Hz), 1.05—1.2 (3H, m, Me), 1.45—2.35 (4H, m, H-4,6, $SCH_2C\underline{H}_2$), 2.65—3.0 (4H, m, $SC\underline{H}_2CH_2C\underline{H}_2S$), 3.55—4.1 (3H, m, H-2,3,5), and 4.17 (1H, d, H-2′, *J*=8.4 Hz).

Methyl (6*S*,7*S*,8*R*)-(2*E*,4*E*)-7-Hydroxy-6-methyl-8-(1,3-dithian-2-yl)-2,4-nonadienoate (35) and (4*Z*)-Isomer (36). To a suspension of **33** (263 mg, 9.38 mmol) and potassium acetate (463 mg, 4.69 mmol) in dry CH_3CN (21.8 ml) was added lead tetraacetate (462 mg, 0.938 mmol) at −25 °C and then stirred for 3 min. The resulting mixture was chromatographed on Florisil (10 g) with ether to afford a crude sample of **34** (208 mg) which was suitable for the next synthesis. A mixture of the crude sample of **34** (319 mg) and [(2*E*)-3-methoxycarbonyl-2-propenylidene]triphenylphosphorane (980 mg, 2.72 mmol) in dry toluene (15.9 ml) was stirred at 80 °C for 0.5 h. The reaction mixture was concentrated and the residue (1.42 g) was chromatographed on silica gel (210 g) with 9:1 dichloromethane–ethyl acetate to afford **35** (232 mg, 51% from **33**) and **36** (93.4 mg, 21% from **33**) as colorless syrups.

35: R_f=0.51 (8:1 dichloromethane–ethyl acetate); $[\alpha]_D^{22}$ −22° (*c* 1.06); IR ($CHCl_3$) 1705 cm^{-1}; UV (EtOH) λ_{max} nm (log ε) 261 (4.39); ^{1}H NMR (90 MHz) δ=1.03 and 1.13 (each 3H, each d, Me×2, each *J*=7.2 Hz), 1.85—2.25 (4H, m, H-8, $SCH_2C\underline{H}_2$, OH), 2.30—2.65 (1H, m, H-6), 2.7—3.05 (4H, m, $SC\underline{H}_2CH_2C\underline{H}_2S$), 3.65—3.95 (1H, m, H-7), 3.77 (3H, s, COOMe), 4.17 (1H, d, H-2′, *J*=7.5 Hz), 5.83 (1H, d, H-2, *J*=15.3 Hz), 6.1—6.35 (2H, m, H-4,5), and 7.15—7.50 (1H, m, H-3).

Found: C, 56.71; H, 7.55; S, 20.08%. Calcd for $C_{15}H_{24}O_3S_2$: C, 56.93; H, 7.64; S, 20.26%.

36: R_f=0.56 (8:1 dichloromethane–ethyl acetate); ^{1}H NMR (90 MHz) δ=1.02 and 1.17 (each 3H, each d, Me×2, each *J*=7.2 Hz), 1.7—2.65 (5H, m, H-6,8, $SCH_2C\underline{H}_2$, OH), 2.7—3.05 (4H, m, $SC\underline{H}_2CH_2C\underline{H}_2S$), 3.75 (3H, s, COOMe), 4.05—4.3 (2H, m, H-8,2′), 5.7—6.45 (2H, m, H-4,5), 5.91 (1H, d, H-2, *J*=15.3 Hz), and 7.65 (1H, dd, H-3, $J_{2,3}$=15.3 and $J_{3,4}$=12.0 Hz).

Isomerisation of 36 to 35. A solution of **36** (2.11 g, 6.67 mmol) and iodine (8.4 mg) in dry benzene (51.3 ml) was stirred at room temperature (25 °C) in daylight for about a month. The reaction mixture was then washed with a saturated aqueous sodium thiosulfate solution (50 ml) and extracted with ethyl acetate (30 ml×3). The extracts were washed with saturated aqueous NaCl (40 ml), dried, and then concentrated to a crude syrup which was chromatographed on silica gel (300 g) with 9:1 dichloromethane–ethyl acetate to afford the (*E*,*E*)-diene **35** (790 mg, 37.4%) and the starting diene **36** (570 mg, 27%).

(6*S*,7*S*,8*R*)-7-Hydroxy-6-methyl-8-(1,3-dithian-2-yl)-2,4-nonadienoic Acid (4). To a solution of the methyl ester **35** (232 mg, 0.733 mmol) in 50% THF–H_2O (8.81 ml) was added 0.2 M LiOH/50% THF–H_2O (6.41 ml, 1.28 mmol) and the mixture was kept at 24 °C for 7 h. The solution was then neutralized with CG-50 resin (H^+ type) under ice-cooling, and filtered. The filterate and methanolic washings were combined and concentrated to give a crude syrup (0.5 g) which was chromatographed on silica gel (20 g) with 10:1:0.2 chloroform–acetone–acetic acid to afford **4** (220 mg, 100%) as a white form. R_f=0.26 (10:1:0.1 chloroform–acetone–acetic acid); $[\alpha]_D^{20}$ −31° (*c* 1.04); IR ($CHCl_3$) 1640 and 1685 cm^{-1}; UV (EtOH) λ_{max} nm (log ε) 254 (4.28); ^{1}H NMR (90 MHz) δ=1.03 and 1.12 (each 3H, each d, Me×2, each *J*=7.2 Hz), 1.75—2.2 (3H, m, H-8, $SCH_2C\underline{H}_2$), 2.3—2.65 (1H, m, H-6), 2.7—3.0 (4H, m, $SC\underline{H}_2CH_2C\underline{H}_2S$), 3.87 (1H, dd, H-7, *J*=8.4, 2.8 Hz), 4.18 (1H, d, H-2′, *J*=7.5 Hz), 5.85 (1H, d, H-2, *J*=15.3 Hz), 6.1—6.4 (2H, m, H-4,5), 6.4—6.95 (2H, br, OH, COOH), and 7.15—7.55 (1H, m, H-3).

Found: C, 55.86; H, 7.23; S, 20.96%. Calcd for $C_{14}H_{22}O_3S_2$: C, 55.60; H, 7.33; S, 21.20%.

(7*S*,8*S*,15*S*,16*S*:3*E*,5*E*,11*E*,13*E*)-7,15-Dimethyl-8,16-bis-[(1*R*)-1-(1,3-dithian-2-yl)ethyl]-1,9-dioxa-3,5,11,13-cyclohexadecatetraene-2,10-dione (37). Method A: A solution of **4** (208 mg, 0.688 mmol) in THF (2.98 ml) was treated with triethylamine (115 μl, 0.826 mmol) and 2,4,6-trichlorobenzoyl chloride (185 mg, 0.757 mmol) and the mixture was then stirred at room temperature for 2 h. The triethylamine hydrochloride was then filtered off and the filtrate diluted with dry toluene (344 ml). This solution was then added at 35 °C over a period of 2 h to a solution of 4-(dimethylamino)pyridine (505 mg, 4.13 mmol) in dry toluene (68.8 ml). After the addition had completed, the mixture was stirred at 35 °C for an additional 2.5 h, and then diluted with ether (300 ml). The mixture was washed with saturated aqueous citric acid (300 ml), saturated aqueous $NaHCO_3$ (300 ml), and finally saturated aqueous NaCl (300 ml). The organic layer was dried and concentrated to a syrup (290 mg) which was chromatographed on silica gel (43 g) with 5:1 dichloromethane–ethyl acetate to afford a pure sample of **37** (57.9 mg, 31%) as colorless crystals. R_f=0.44 (2:1 hexane–acetone); mp 262.0—263.5 °C (dichloromethane–hexane); $[\alpha]_D^{30}$ +75° (*c* 1.16); IR (KBr) 1640 and 1710 cm^{-1}; ^{1}H NMR (250 MHz) δ=1.07 and 1.19 (each 3H×2, each d, 7-Me, 15-Me, 1′-Me×2, each *J*=7.2 Hz), 1.86 (1H×2, ddq, H-1′×2, $J_{1',Me}=J_{1',2'}$=7.2 and $J_{1',8\text{or}16}$=10.6 Hz), 2.0—2.3 (2H×2, m, $SCH_2C\underline{H}_2$×2), 2.44 (1H×2, ddq, H-7,15, *J*=7.2, 1.1, 11.4 Hz), 2.75—2.95 (4H×2, m, $SC\underline{H}_2CH_2C\underline{H}_2SC\underline{H}_2S$×2), 4.02 (1H×2, d, H-2″×2, *J*=7.2 Hz), 5.18 (1H×2, dd, H-8,16, *J*=10.6, 1.1 Hz), 5.60 (1H×2, d, H-3,11, *J*=15.2 Hz), 5.62 (1H×2, dd, H-6,14, *J*=9.5, 15.0 Hz), 6.00 (1H×2, dd, H-5,13, *J*=15.0, 11.4 Hz), and 6.98 (1H×2, dd, H-4,12, *J*=11.4, 15.2 Hz); MS *m/z* 568 (M^+).

Method B: To a solution of **4** (48.2 mg, 0.159 mmol) in dry CH_3CN (12.7 ml) was added triethylamine (0.176 ml, 1.28 mmol) and the mixture was added to a solution of 2-chloro-1-methylpyridinium iodide (163 mg, 0.638 mmol) in dry CH_3CN (16 ml) for 15 min. After being stirred at 25 °C, the reaction mixture was concentrated to give a syrup which was subsequently chromatographed on silica gel (20 g) with 2:1 hexane-acetone to afford **38** (40.0 mg, 85.5%) as a colorless syrup. R_f=0.30 (2:1 hexane-acetone); IR (CH_3Cl_3) 1710 and 1765 cm^{-1}; To a solution of **38** (9.60 mg, 0.0164 mmol) in dry CH_3CN (0.192 ml) was added 4-(dimethylamino)pyridine (5.20 mg, 0.00425 mmol) and the reaction mixture was stirred at room temperature (26 °C) for 30 min. Then the mixture was poured into cold water (1 ml) and extracted with ethyl acetate (0.5 ml×3) and the combined extracts were washed with saturated aqueous NaCl (1 ml), dried, and concentrated. The residue was chromatographed on silica gel (1 g) with 3:1 hexane-acetone to afford **37** (0.5 mg, 11% from **38**).

(7*S*,9*S*,15*S*,16*S*:3*E*,5*E*,11*E*,13*E*)-8,16-Bis[(1*R*)-1-formylethyl]-7,15-dimethyl-1,9-dioxa-3,5,11,13-cyclohexadecatetraene-2,10-dione (3). To a mixture of **37** (30.6 mg, 0.159 mmol) and mercury(II) oxide (51.7 mg, 2.39 mmol) in 4:7 CH_2Cl_2–80% aqueous acetone was added mercury(II) chloride (64.9 mg, 2.39 mmol) at room temperature. The mixture was ultrasonificated in the sonicator (65 W, 48 kHz) at 30—50 °C for 8 h, cooled, and filtered through a Celite. The filter cake was washed with acetone, and the filtrate and the washing were combined. After the subsequent removal of the acetone by concentration, to the aqueous residue was added aqueous 10% KI until orange color disappeared and extracted with chloroform (30 ml×3). The extracts were washed with saturated aqueous NaCl (20 ml), dried, and concentrated to give crude crystals which was chromatographed on silica gel (10 g) with 5:1 chloroform-ethyl acetate to afford the pure sample of **3** (43.1 mg, 70%) as colorless crystals. R_f=0.19 (10:1 chloroform-ethyl acetate); mp 152—156 °C (dichloromethane-hexane); $[\alpha]_D^{25}$ +46.8° (*c* 0.35, MeOH after 45 min); IR (KBr) 1710 cm^{-1}; UV (EtOH) λ_{max} nm (log ε) 253 (4.74); ^{1}H NMR (90 MHz) δ=1.10 and 1.19 (each 3H×2, each d, 7-Me, 15-Me, 2′-Me×2, each *J*=7.2 Hz), 2.3—2.9 (2H×2, m, H-7,15,2′×2), 5.39 (1H×2, dd, H-8, 16, *J*=10.8, 2.8 Hz), 5.56 (1H×2, d, H-3,11, *J*=15.6 Hz), 6.07 (1H×2, dd, H-5,13, *J*=15.0, 10.8 Hz), 6.98 (1H×2, dd, H-4,12, *J*=15.6, 10.8 Hz), and 9.69 (1H×2, s, CHO×2).

In the case of the aldol coupling of **25f** and **3** in the presence of $ZnCl_2$, 4 molar equivalents of $ZnCl_2$ was first added to the THF solution of **3** and then to this mixture was added the ethereal boron enolate mixture prepared from **25f** with *n*-Bu_2BOTf by the aforesaid procedure.

(B) With Sn(OTf)$_2$: To a suspension of $Sn(OTf)_2$ (25.8 mg, 0.0618 mmol) and 1-ethylpiperidine (0.0093 ml, 0.060 mmol) in dry CH_2Cl_2 (0.124 ml) was added dropwise **25f** (39.6 mg, 0.0618 mmol) in CH_2Cl_2 (0.124 ml) at −78 °C under argon with stirring. After the mixture was stirred for 30 min, the solution was added dropwise to a solution of **3** (6.0 mg, 0.0155 mmol) in dry CH_2Cl_2 (0.060 ml) at −78 °C and then stirred at −78 °C for 30 min and at −78 °C→−10 °C for 2.5 h. To the reaction mixture was added pH 7 posphate buffer (0.5 ml) at −10 °C and then stirred at room temperature for 3 min, and extracted with CH_2Cl_2 (0.5 ml×3). The extracts were washed with saturated aqueous NaCl (1 ml), dried, and concentrated to give a crude syrup which was purified by flash chromatography on silica gel (10 g) with 6:1 benzene-ethyl acetate and 3.5:1 benzene-ethyl acetate to afford **43** (1.7 mg, 6.5%), **44** (5.4 mg, 20.8%), and **45** (7.2 mg, 27.7%) and recoverd **25f** (17.6 mg, 44.4%).

(C) With LiN(TMS)$_2$: To a solution of **25f** (24.6 mg, 0.0383 mmol) in dry THF (0.0766 ml) was added dropwise 1 M LiN(TMS)$_2$-THF (0.0383 ml, 0.0383 mmol) at −78 °C under argon with stirring. After the mixture was stirred for 30 min, the solution was added dropwise to a solution of **3** (6.2 mg, 0.0160 mmol) in dry THF (0.124 ml) at −78 °C and then stirred for 2 h at the same temperature. To the reaction mixture was added saturated aqueous NH_4Cl (0.4 ml), warmed to room temperature and extracted with ether (0.5 ml×3). The extracts were washed with saturated aqueous NaCl (1 ml), dried, and concentrated to give a crude syrup (30 mg) which was chromatographed on silica gel (10 g) with 4:1 benzene-ethyl acetate to afford fraction A (**25f**, **44**, **45**, 12.4 mg), fraction B (**43**, **3**, 2.0 mg), and **3** (1.7 mg, 6.3%). Further, fraction A was purified by flash chromatography on silica gel (2.5 g) with benzene-ethyl acetate to afford **25f** (8.3 mg, 33.7%), **45** (2.4 mg, 8.9%), and **44** (1.7 mg, 6.3%). Fraction B was purified by flash chromatography on silica gel (1 g) with 3:1 benzene-ethyl acetate to afford **43** (1.4 mg, 5.2%).

Elaiophylin (1). A solution of **43** (9.5 mg, 0.00565 mmol) in 3:1:3 acetic acid-aqueous 1% HF·KF-THF (0.380 ml) was stirred at 30 °C for 18 h. To the reaction mixture was added water (0.5 ml) and chloroform (0.5 ml) and then extracted with chloroform (0.5 ml×3). The extracts were washed with saturated aqueous NaCl (1 ml), dried, and concentrated to crude crystals (10.0 mg) which were purified by flash chlomatography on silica gel (2.5 g) with 6:1 chloroform-methanol to afford **1** (1.3 mg, 22.4%) as colorless crystals. R_f=0.31 (6:1 chloroform-methanol); $[\alpha]_D^{20}$ −53° (*c* 0.26, MeOH); mp 179—182 °C (AcOEt); mixture mp 179—182 °C; The ^{1}H NMR spectra (400 MHz, 5:1 $CDCl_3$-CD_3OD) was identical with that of the authentic sample of azalomycin B.

We are grateful to Prof. Sumio Umezawa, Institute of Bioorganic Chemistry, and the late Prof. Hamao Umesawa, Institute of Microbial Chemistry for their generous support of our program. The present work was partially supported by a Grant-in-Aid for Scientific Research No. 60470091 from the Ministry of Education, Science and Culture, the Japan Antibiotics Research Association Research Grant, and Sankyo Foundation of Life Science. We are indebted to Dr. Hiroshi Naganawa, Institute of Microbial Chimistry for 400 MHz ^{1}H NMR spectral analyses. We also thank Mr. Saburo Nakada and Mr. Hisao Arita of Keio University for elemental analyses and Messrs. Ken Ishiyama and Mutsumi Horikoshi for their technical assistance.

(Received November 6, 1987)

Selective monoesterification of a dicarboxylic acid with longer carbon chains by diazomethane in a mixture of dicarboxylic acids, [dodecanedioic acid (C_{12}) plus glutaric acid (C_5), adipic acid (C_6), pimelic acid (C_7), suberic acid (C_8), or sebacic acid (C_{10})] was achieved by adsorbing and aligning the acids on alumina. The larger the difference in the number of carbon atoms, the higher the selectivity. In the case of the combination of C_{12} and C_5 the highest selectivity was observed and the preferential 89% formation of the monomethyl ester of C_{12} was obtained in contrast to the 9% formation for the monomethyl ester of C_5. Selective reactions were also observed in the case of the combination of C_{10} and C_4, and that of C_{12} and *trans*-1,4-cyclohexanedicarboxylic acid.

The use of solid adsorbents such as alumina and silica gel as a reaction medium is becoming increasingly widespread in organic synthesis.[1-6] Usually it is the reagents that are supported. Reagent-doped adsorbents can be used to achieve some very mild and consequently selective organic transformations. Recent examples are given for the use of solid adsorbents as substrate support. Solid adsorbents are used deliberately as the reaction field for substrates to achieve highly selective reaction, in which the substrate molecules orient and/or are captured with suppression of translational movement on the surface of the solid adsorbents. This gives rise to the chance for highly selective reactions, for example ozonolysis of aliphatic ester,[7] terminal (ω) chlorination of octanoic acid,[8] enone photocycloaddition,[9] selective synthesis of crown ether,[10] *O*-methylation of alcohol[11] and monomethyl esterification of dicarboxylic acid.[12]

Fatty acids in general, when adsorbed on air–water interfaces, occupy an area of 0.205 nm^2 per molecule independent of chain length or molecular weight.[13] The molecules are aligned with their axis perpendicular to the interface in a close-packed, rigid array. We could develop a method for selective synthesis of the monomethyl esters of dicarboxylic acids with the aid of this phenomenon.[12] Aliphatic dicarboxylic acids were considered to be adsorbed as a monomolecular layer on alumina and to form a stable membranelike structure with the aid of van der Waals interactions between the methylene groups as in Fig. 1a.

If two kinds of dicarboxylic acids are adsorbed as in Fig. 1b, a facile reaction of the non-adsorbed carboxyl group of the longer chain dicarboxylic acid is easily recognized, while the shorter one would be expected to be hardly reactive. We reported briefly this new type of selective reaction proceeding on an aluminum surface on which the monomethyl esterification of dodecanedioic acid (C_{12}) proceeded preferentially in the presence of other shorter chain acids.[14] This paper presents details of this reaction and application of this adsorption-reaction procedure to other dicarboxylic acids.

Results and Discussion

Effect of Surface Coverage (θ) on Monomethyl Esterification of Suberic Acid (C_8). Figure 2 shows the formation of monomethyl ester of C_8 under the various θ values of C_8 on alumina. The value of θ is estimated as follows; θ=adsorption amount of C_8/

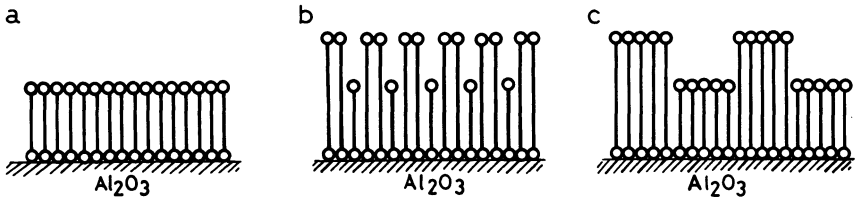

Fig. 1. Models for the aggregation of aliphatic dicarboxylic acids adsorbed on alumina, open circle represents carboxyl group and thick line represents aliphatic carbon chain: a) monomolecular layer of the acid; b) well-mixed aggregation of the mixture of two kinds of the acids; c) mosaic aggregation of the mixture of two kinds of the acids.

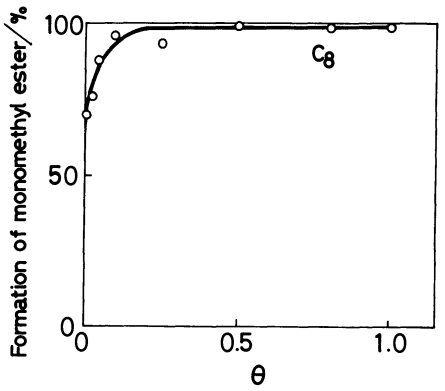

Fig. 2. Dependence of surface coverage (θ) on monomethyl ester formation for suberic acid (C_8): θ= adsorption amount of C_8/saturation amount (4.0×10^{-4}mol g-$Al_2O_3^{-1}$). The adsorption sample was suspended in cyclohexane. About 6 molar equivalents of diazomethane was added at room temperature.

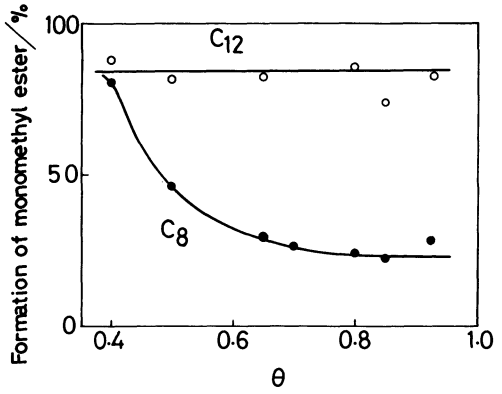

Fig. 3. Dependence of surface coverage (θ) on preferential monomethyl esterification of dodecanedioic acid (C_{12}) (○) in a mixture of C_{12} and suberic acid (C_8) (●): θ=adsorption amount (C_{12}+C_8)/saturation amount (4.0×10^{-4} mol g-$Al_2O_3^{-1}$). The adsorbed sample contained C_{12} and C_8 in a molar ratio of 2 to 1. Cyclohexane was used as a suspending agent. About 6 molar equivalents of diazomethane was added at room temperature.

saturation amount (4.0×10^{-4} mol g-$Al_2O_3^{-1}$).[12] The monomethyl ester was formed quantitatively in the range where the θ value exceeds 0.4 while the monomethyl ester was not formed quantitatively in the range where the value is less than 0.4. Quantitative formation of the monomethyl ester in the higher range of the θ value suggests that the adsorbed molecules would form the monomolecular layer in which one of the two carboxyl groups is chemisorbed on alumina with the rest of the carboxyl group in a position remote from the surface as shown in Fig. 1a.

Effect of θ on Selective Reaction. Selective monomethyl esterification of one of the dicarboxylic acids in a mixed system was attempted, and the effect of the surface coverage was examined by use of C_{12} and C_8 in a 2:1 molar ratio. As shown in Fig. 3, the difference

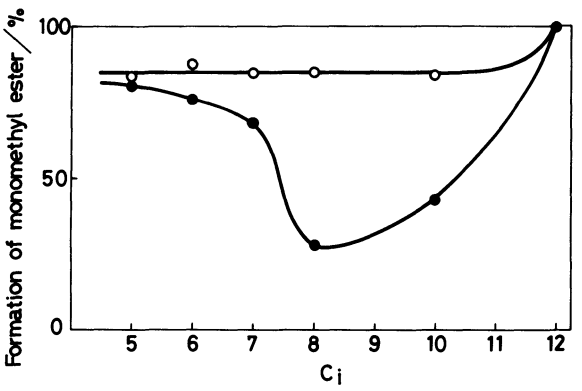

Fig. 4. Monomethyl ester formation for dodecanedioic acid (C_{12}) (○) and shorter chain acid (C_i) (●) adsorbed in the molar ratio of 2 to 1 where C_i means the aliphatic dicarboxylic acid having i carbons. The adsorbed sample consisted of a total of 0.32 mmol of the acids per gram of alumina (θ=0.8). About 6 molar equivalents of diazomethane was added at room temperature.

in reactivities of C_{12} and C_8 developed with increase in θ value. The formation of the monomethyl ester of C_8 decreased with increase in the θ value, and the formation for the monomethyl ester of C_{12} and that of C_8 became constant where the θ value exceeded about 0.8. The value of 0.8 was an adequate value for a sufficiently selective reaction, in which preferential 89% formation for the monomethyl ester of C_{12} was obtained in contrast to the 28% formation for the monomethyl ester of C_8 besides 1% formation for the dimethyl ester of C_{12}, 10% intact C_{12} and 72% intact C_8.

The same reactivity of the carboxyl groups of C_{12} and C_8 was confirmed in the following way. In a homogeneous reaction in a 1% DMF solution, the reactivities of C_{12} and C_8 were the same yielding the monomethyl esters in about 50% maximum yield at the same conversion.

Effect of Carbon Chain Length for the Selectivity at Low Ratio of C_{12}/Shorter Chain Dicarboxylic Acid (C_i). Various kinds of dicarboxylic acids were tested by combining with C_{12} for the selective monomethyl esterification of C_{12}. Figure 4 shows that the combination of C_{12} and C_8 was most effective for selective monomethyl esterification, 89% formation for the monomethyl ester of C_{12} and 28% formation for that of C_8, when the adsorption sample containing C_{12} and C_i in 2/1 molar ratio was used. From the alternative model as shown in Fig. 1b, the shorter chain dicarboxylic acids would be expected to be hardly reactive. But actually in the case of glutaric acid (C_5), adipic acid (C_6), and pimelic acid (C_7), the shorter the carbon chain of the dicarboxylic acids, the lower the selectivity became. Nonselective reaction occurred in the case of the combination of C_{12} and C_5.

Nonselective reaction was also observed even in a case of the combination of C_{12} and C_8 when the same

quantity of C_{12} and C_8 was used, and equal amounts of their monomethly esters were obtained quantitatively. The determining factor for the selective reaction appears to be the state of aggregation of the components acids. Selective reaction occurs when the two kinds of acids are adsorbed as in Fig. 1b. Based on the measurement of the surface pressures of mixed monolayers of pentadecanoic acid with acetates of its near neighbors in chain length, Matuo et al. found the interaction between the two components in a mixed monolayer decreased with an increase in the difference in chain length between the two components.[15] The formation of the aggregate as shown in Fig. 1b seems to be acceptable in the case of the combination of C_{12} and C_{10}, but in the case of the combination of the C_{12} and the much shorter carbon chain acids the formation of the aggregate seems to be difficult. Probably each acid might aggregate independently. The low selectivities in the combination of C_{12} and the much shorter carbon chain acids are considered to be due to the formation of "island"[16] aggregates of each kind of acids as shown in Fig. 1c.

Selective Monomethyl Esters Formation of C_{12} and C_i in Various Molar Ratios of Acids. As mentioned above, the selectivity decreased when the same quantity of C_{12} and C_8 was used. The effect of the molar ratio of C_{12} to C_i was examined. Figure 5 shows the selective monomethyl esterification of C_{12} with the increase in the molar ratio. The amount of the monomethyl ester of C_{12} formed was held preferentially high and constant regardless of the ratios, while that of the shorter carbon chain acids drastically changed. In the case of the combination of C_{12} and C_5 the higher ratio ($\geqslant 6$, more than six) of C_{12}/C_5 led to a decrease of monomethyl ester of C_5 formed, though the formation of the monomethyl ester could not be suppressed at a lower ratio (less than 4). In the case of the combination of C_{12}/C_8 the formation of the monomethyl ester of C_8 was sufficiently suppressed even at the lower ratio. In a region higher than 6/1 the formation for the monomethyl esters of both of the shorter carbon chain acids sufficiently decreased, and their values became constant; 28% for C_8, 9% for C_5. Two kinds of acids in both of the combinations at the higher molar ratio might be adsorbed on alumina as in Fig. 1b, in which shorter carboxylic acid molecules are surrounded with the longer on alumina surface. It is considered that in the combination of C_{12} and C_5 the state of aggregation of the acid mixture changed from the aggregate as shown in Fig. 1c to that of Fig. 1b with increase in the ratio, and the selective reaction then occurred.

Effect of Chain Length of Acid on the Selective Formation of Monomethyl Eater of C_{12} at High Ratio of C_{12}/C_i. A molar ratio of 6/1 for C_{12} to shorter chains was a large enough ratio to ensure an adequate protection of the shorter chain acids. Accordingly we tried the selective monomethyl esterification using this ratio. The results shown in Fig. 6 illustrate the selective preferential monomethyl esterification of C_{12}. Figure 6 presents a great contrast from Fig. 4 in that differences in the chain length of the shorter chain acids affected their reactivities. On the other hand, most of C_{12} reacted in every case. The larger the difference in the number of carbon atoms, the higher the selectivity obtained. The combination of C_{12} and C_5 was most effective for selective monomethyl esterification. An 89% yield of the monomethyl ester of C_{12} was obtained in contrast to a 9% yield for the monomethyl ester of C_5.

This method was applied to the other combination of acids. The formation of each monomethyl ester under the same reaction conditions described in this paragraph was as follows; C_{10}/C_6=81%/21% and C_{12}/*trans*-cyclohexanedicarboxylic acid=88%/45%.

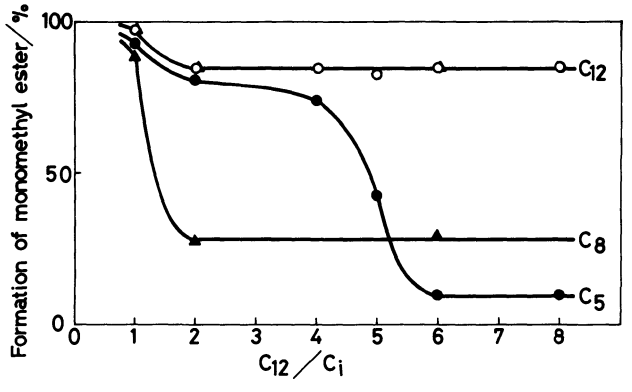

Fig. 5. Effect of the molar ratio of C_{12} to C_i on the formations of monomethyl esters: samples containing C_{12} (○) and C_5 (●); samples containing C_{12} (△) and C_8 (▲), respectively. The adsorbed sample consisted of a total of 0.32 mmol of the acids per gram of alumina (θ=0.8). About 6 molar equivalents of diazomethane was added at room temperature.

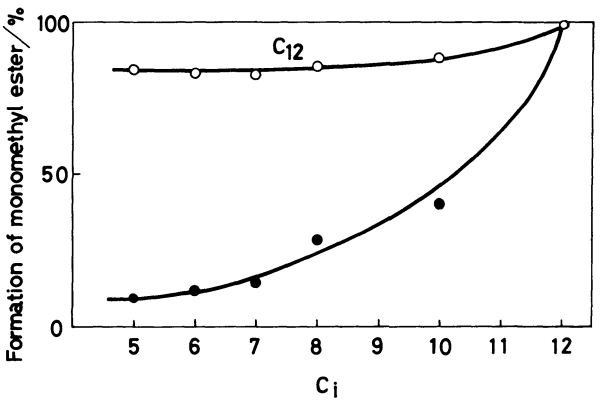

Fig. 6. Selective monomethyl ester formation for dodecanedioic acid (C_{12}) (○) and C_i (i=5—8,10) (●) adsorbed in the molar ratio 6:1 and a total of 0.32 mmol of the acids per gram of alumina (θ=0.8) where C_i is the aliphatic acid having i carbon atoms. About 6 molar equivalents of diazomethane was added at room temperature.

Interestingly, in the former case (the combination of C_{10} and C_6) 60% for the difference between the formation of each monomethyl ester was observed as in the case of C_{12}/C_8. These two values for the two systems are similar, and the difference in carbon number (the number 4) between two components acids is the same in both systems. This agreement demonstrates the adequate protection of shorter chain acids in which the differences in chain length of the shorter chain acids affects the reactivity of the shorter chain. No selective monomethyl esterification was observed in the case of the combination of C_{12}/terephthalic acid and C_{12}/isophthalic acid.

Experimental

Materials. Diazomethane was prepared from *N*-methyl-*N*-nitroso-*p*-toluenesulfonamide[17] without ether and was carried in a stream of nitrogen through a dry tube containing potassium hydroxide pellets and then into the reaction vessel. Alumina {the reference catalyst of the Catalysis Society of Japan (JRC-ALO-5);γ-type, 60—200 mesh, modal pore diameter 5.5 nm, Na_2O content 0.02%, adsorption capacity of 4.0×10^{-4} mol g^{-1} [12] of aliphatic dicarboxylic acid} was dried at 110 °C for a day and stored in a desiccator. Other materials were commercially available and used without further purification.

Preparation of Adsorption Samples. One gram of alumina powder was added to a 10 mL of *N,N*-dimethylformamide (**DMF**) solution containing 0.32 mmol of total amounts of two different carboxylic acids, dodecanedioic acid (C_{12}) plus glutaric acid (C_5), adipic acid (C_6), pimelic acid (C_7), suberic acid (C_8), sebacic acid (C_{10}), *trans*-1,4-cyclohexanedicarboxylic acid, terephthalic acid, or isophthalic acid to produce 80% surface saturation. The mixture was allowed to stand for 8 h at 30 °C with occasional shaking. The DMF was then slowly removed under reduced pressure.

Reaction Procedure. About 6 molar equivalents of diazomethane was introduced in a stream of dry nitrogen into a vigorously agitated reaction vessel containing 500 mg of the adsorbed sample and about 5 g of cyclohexane at room temperature. After all the diazomethane had been consumed or passed through the reaction vessel (about 45 min), the alumina was transferred to a glass column and eluted with **DMF**. After the eluate had been concentrated under reduced pressure, the products were analyzed by GSC with a Chromosorb 101 column, and/or HPLC with a ODS column. No reaction other than esterification was observed. Any other information about experimental section was described in the previous work.[12]

(Received November 11, 1987)

2a-Substituted dichlorodihydrocyclobuta[c]quinolin-3(4*H*)-one (**3**) and trichlorovinyl-2-quinolone (**4**) were obtained from the cross photocycloadduct of 2-quinolone and tetrachloroethylene. The position of the substituent on **3** was determined from the NOE volumes in the NOESY spectrum in comparison with the AM1 geometries. The reaction of the photoadduct (**1**) with a base or nucleophile, yielding **3** and/or **4**, was interpreted to proceed via a cyclobutene intermediate formation followed by an S_N2' displacement or [2+2] cycloreversion.

The reactivity of a heterocyclic ring, such as a coumarin ring, shows enhanced reactivity when a cyclobutane ring is fused to that ring by photochemical cyclobutanation. We have reported high reactivities of coumarin dimers and their lactone-opened derivatives.[2,3)] In previous papers,[4)] we showed unique reaction behaviors of the photocycloadduct of coumarin with tetrachloroethylene, such as (a) ring contraction from a [4,6,6]- to a [4,5,6]-fused ring system through a lactone-opening, (b) cyclobutene formation, followed by an intramolecular S_N2' displacement, and (c) a [2+2] cycloreversion at the cyclobutene intermediate, yielding trichlorovinylcoumarin. These behaviors were ascribed to the strain in lactone ring induced by the adjacent cyclobutane ring.

As a part of a continuing study of compounds having a [4,6,6]-fused ring system, we investigated the reaction of 1,1,2,2-tetrachloro-2,2aα,4α,8bα-tetrahydrocyclobuta[c]quinolin-3(1*H*)-one (**1**), a cyclobutane-fused quinolone derivative. Contrary to our expectation, based on the reaction behavior of the cycloadduct from coumarin with tetrachloroethylene,[4)] **1** gave a new cyclobutene compound and trichlorovinyl-2-quinolone, but gave no ring-contracted product.

We report here the reaction of **1** with nucleophiles or bases, the structure of the product, and molecular orbital (MO) geometry calculations.

Experimental

Measurements. All melting points were measured on a MELTEMP micro melting point apparatus and are uncorrected. IR spectra were recorded on a JASCO IR-810 spectrophotometer. NMR spectra were observed on a JEOL GX-400 spectrometer at 400 MHz. The chemical shifts for ^1H and ^{13}C NMR spectra are given in ppm in reference to the internal tetramethylsilane (TMS) signal.

2D (COSY and NOESY) spectra were recorded with a 3.1 s recycle time, 8 transitions correlated for each t_1 value, and accumulations of 512 spectra each consisting of 2048 data points.

Theoretical Calculations. Semiempirical AM1[5)] and MNDO[6)] calculations were performed on a HITAC M-680 or M-682 with the MOPAC package, version 3.1, of J. J. P. Stewart[7)] with complete geometry optimization.

Reactions. All the reagents and solvents were purified by methods described in the literature.[8)]

Photoirradiation was performed with an Eiko-sha EHB-WI(F)-500 high-pressure mercury lamp (500 W).

Unless specified otherwise, the reactions were carried out under an argon atmosphere. The extracts were washed with saturated aqueous sodium chloride and dried overnight over an appropriate deciccant. The deciccant was removed by filtration and the solvents were stripped off on a flash evaporator at a temperature below 10 °C. The conversions were determined from the ^1H NMR spectra of the reaction products dissolved in $CDCl_3$. Separations of the products were carried out by column chromatography using silica gel (Wako-gel C-200, 100—200 mesh).

1,1,2,2-Tetrachloro-2,2aα,4α,8bα-tetrahydrocyclobuta[c]-quinolin-3(1*H*)-one (1): 2-Quinolone (5.81 g, 40.0 mmol) and benzophenone (1.24 g, 6.8 mmol) were dissolved in a mixture of 1327.9 g (8.0 mol) of tetrachloroethylene and 1000 ml of dichloromethane. The solution was irradiated by a 500-W high-pressure mercury lamp through a Pyrex filter for 87 h. The reaction mixture was concentrated under reduced pressure and then passed through a silica-gel column (Wako C-200) with benzene as an eluent. Recrystallization from dichloromethane gave 5.64 g (43.9%) of pure **1**: Mp 285.0 °C (decomp).

1,2-Dichloro-2aα-methoxy-2aα,8bα-dihydrocyclobuta[c]-quinolin-3(4*H*)-one (3a): To a stirred methanol solution (20 ml) of **1** (31.0 mg, 0.10 mmol), 1 M NaCl (1.0 ml) (1 M =1 mol dm^{-3}) was added at room temperature. After stirring for 16 h at room temperature, the reaction mixture was poured into 1 M HCl (20 ml). The resultant solution was concentrated until the methanol was removed; then, the products were extracted three times with $CHCl_3$ (20 ml each). All extracts were combined, dried ($MgSO_4$), and concentrated under reduced pressure to leave a white solid. The residue was dissolved in $CDCl_3$. Based on the integrated intensities of the ^1H NMR lines of the residues, the content of **3a** was calculated to be 89% and that of **4** to be 11%.

† Present address: Advanced Technology Research Center, Nippon Kokan K.K.

Evaporation of $CDCl_3$ followed by recrystallization from CH_2Cl_2–hexane gave **3a** as white needles (15.1 mg, 56%): Mp 183 °C (decomp); IR (KBr) 1680, 1640, 1100, and 780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.51 (3H, s, methoxyl protons), 4.21 (1H, s, cyclobutene ring proton), 7.00—7.14 (2H, m, aromatic protons), 7.23—7.32 (2H, m, aromatic protons), and 9.51 (1H, s, NH proton); ^{13}C NMR ($CDCl_3$) δ=53.2 (d), 54.3 (q), 80.7 (s), 116.6 (d), 118.3 (s), 123.9 (d), 126.2 (s), 128.5 (d), 129.3 (d), 131.9 (s), 135.3 (s), and 166.0 (s). Found: C, 53.24; H, 3.39; N, 5.18%. Calcd for $C_{12}H_9Cl_2NO_2$: C, 53.36; H, 3.36; N, 5.19%.

1,2-Dichloro-2aα-ethoxy-2aα,8bα-dihydrocyclobuta[*c*]-quinolin-3(4*H*)-one (3b): To a stirred ethanol solution (60 ml) of **1** (31.0 mg, 0.10 mmol), 1 M NaOH (1.0 ml) was added at room temperature. After stirring for 16 h at room temperature, the reaction mixture was poured into 1 M HCl (20 ml). The solution was concentrated until the ethanol was removed; then, the products were extracted three times with CH_2Cl_2 (20 ml each). The extracts were combined, dried ($MgSO_4$), and concentrated under reduced pressure. The residue was recrystallized from $CHCl_3$ to give white needles of **3b** (49.6 mg, 35%):Mp 190 °C (decomp); ^1H NMR ($CDCl_3$) δ=1.30 (3H, t, ethoxyl methyl protons), 3.70 (2H, m, ethoxyl methylene protons), 4.01 (1H, s, cyclobutene ring proton), 6.80—7.30 (4H, m, aromatic protons), and 9.72 (1H, s, NH proton); ^{13}C NMR ($CDCl_3$) δ=15.3 (q), 54.2 (d), 63.0 (t), 80.0 (s), 116.8 (d), 118.4 (s), 123.8 (d), 126.5 (s), 128.4 (d), 129.2 (d), 131.6 (s), 135.4 (s), and 166.7 (s). Found: *m/z* 283.0161. Calcd for $C_{13}H_{11}Cl_2NO_2$:M, 283.0167, (rel intensity, M:M+2:M+4=8.8:5.7:1.0).

1,2-Dichloro-2aα-butylamino-2aα,8bα-dihydrocyclobuta[*c*]-quinolin-3(4*H*)-one (3c): To a stirred acetone solution (50 ml) of **1** (155.0 mg, 0.50 mmol), butylamine (365.7 mg, 5 mmol) was added at room temperature. After stirring for 7 h at room temperature, the solution was concentrated to give a black solid. The residue was washed by hexane (50 ml), dissolved in 1 M NaOH (30 ml). The products were extracted three times with CH_2Cl_2 (50 ml each). The extracts were combined, dried ($MgSO_4$), and concentrated to leave colorless glass, which was washed with hexane to give **3c** (140.2 mg, 90%): Glass; ^1H NMR ($CDCl_3$) δ=0.90 (3H, t, *J*=7.5 Hz, $CH_2CH_2CH_2\underline{CH_3}$), 1.32—1.43 (2H, m, $CH_2CH_2\underline{CH_2}$-CH_3), 1.49—1.57 (2H, m, $CH_2\underline{CH_2}CH_2CH_3$), 2.58—2.66 (2H, m, $\underline{CH_2}CH_2CH_2CH_3$), 4.20 (1H, s, cyclobutene ring proton), 6.68 (1H, br s, amine proton), 6.89—7.18 (2H, m, aromatic protons), 7.20—7.29 (2H, m, aromatic protons), and 9.12 (1H, s, amide proton). Found: *m/z* 310.0638. Calcd for $C_{15}H_{16}Cl_2NO_2$:M, 310.0640, (rel intensity, M:M+2:M+4=9.0:6.2:1.0).

3-(Trichlorovinyl)-2-quinolone (4): Triethylamine (4.5 g, 45.0 mmol) was added to a stirred benzene solution (300 ml) of **1** (311.0 mg, 1.0 mmol) at room temperature. After stirring at room temperature for 15 min, the reaction mixture was poured into water (50 ml). The products were extracted three times with $CHCl_3$ (50 ml each). The extracts were combined, dried ($MgSO_4$), and concentrated under reduced pressure to leave a white solid. Recrystallization from acetone gave **4** as parallelepiped: Mp 276—278 °C; IR (KBr) 1660, 1570, and 1430 cm^{-1}; ^1H NMR (DMSO-d_6) δ=7.21—7.37 (2H, m, aromatic protons), 7.55—7.76 (2H, m, aromatic protons), and 8.27 (1H, s, olefinic proton). Found: C, 47.92; H, 2.20; N, 5.09%. Calcd for $C_{11}H_6Cl_3NO$: C, 48.13; H, 2.20; N, 5.10%.

Results and Discussion

Reaction of 1 with a Nucleophile and/or a Base. Cross adduct **1** was obtained from 2-quinolone and tetrachloroethylene under irradiation with a 500-W high-pressure mercury lamp. The yield of **1** based on 2-quinolone was 43.9%. Our procedure gives a higher yield than the method described by Evanega and Fabiny.[9]

Upon treatment of **1** with a nucleophile and/or a base, we obtained two products, a cyclobutene compound **3** and trichlorovinyl-2-quinolone (**4**), in place of the expected compound having a [4,5,6]-fused ring system.[4] The ratio of **3** to **4** in the products was influenced by the nucleophile used. The results of the reaction are summarized in Table 1. For the reaction of **1** with NaOH in methanol, the yields of **3** and **4** based on **1** were 70 and 7%, respectively. When NaOMe was used as a nucleophile, the conversion and yield were almost the same as those for the reaction of **1** with NaOH in methanol. Using NaH or Et_3N as a base in aprotic solvent benzene we obtained **4** exclusively, which is similar to the results of the reaction of the coumarin-tetrachloroethylene photoadduct with a non-nucleophilic base.[4] From the reaction of **1** with NaOH in aqueous acetone, **4** was also formed quantitatively. When butylamine was used in aprotic solvent acetone, **3** was obtained

Table 1. Reactions of **1** with Various Bases (See Experimental Section for Detailed Reaction Conditions)

Base	Equiv. to **1**	Solvent	Time/h	Conv. (Yield)/%[a]	
				3	**4**
NaOH	10	MeOH	16	89(70)	11(7)
NaOMe	900	MeOH	14	86(70)	14(5)
$NaHCO_3$	23	MeOH	23	40(32)	60(50)
NaOH	10	EtOH	7	40(35)	60(51)
NaOH	1900	Acetone (aq.)	16	0	100(85)
NaH	15	Benzene	5	0	100(90)
NEt_3	45	Benzene	7	0	100(92)
$BuNH_2$	10	Acetone	7	100(97)	0

a) Based on **1**.

exclusively. Thus the fraction of the cyclobutene compound **3** in the products was different, depending on the nucleophile employed. The highest ratio and yield of **3** in the products was observed for butylamine nucleophile. When methoxide and ethoxide anions were used, the ratio of **3** was lower than that observed for butylamine. Methoxide anion gave a higher ratio of **3** than the ethoxide anion. No product attacked by an OH^- anion at the carbon α to the carbonyl carbon, nor at β, was obtained when **1** was treated with an alkaline solution in alcohols.

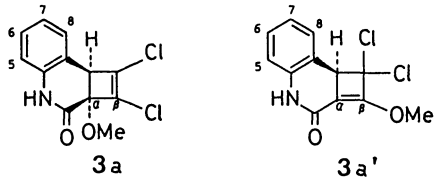

Fig 1. The candidate structures, **3a** and **3a'**, for the cyclobutene product **3** (Nu = OMe).

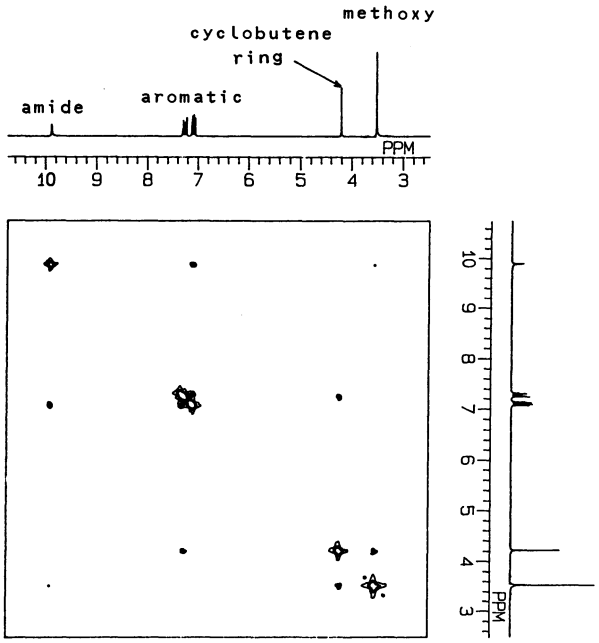

Fig 2. 400 MHz proton NOESY NMR spectrum of **3** in $CDCl_3$ at 27 °C. Data matrix by 1024 points with a frequency range of 5000 Hz in both dimensions was zero-filled to 2048.

Structure of the Cyclobutene Compound. For the cyclobutene compound **3** (Nu=OMe) two possible structures can be considered (Fig. 1). One is compound **3a** having a methoxyl group on the α carbon with respect to the carbonyl carbon formed as a result of the S_N2' replacement reaction. The other is **3a'**, where the chlorine atom at the β position to the carbonyl carbon is substituted by the methoxyl group via a 1,4-addition reaction. To determine which is the structure of the cyclobutene product, **3a** or **3a'**, we studied the Nuclear Overhauser Effect (NOE) by 2D NMR spectroscopy[10] and compared the results with the fully optimized geometries predicted by the AM1[5] and MNDO[6] MO calculations. Under the condition that the NMR T_1 values of the compared nuclei are almost the same, the NOE value becomes approximately proportional to $1/R^6$ for the correlated nuclei couple separated by a distance R.[11] The relative values of NOE can be determined from the volume of the cross-peak in the NOESY spectrum and, hence, candidate geometries predicted by MO calculations can be checked by the observed cross-peak volumes.

The NOESY contour plot observed for compound **3** ($Nu=OCH_3$) is shown in Fig. 2. In the COSY spectrum, no off-diagonal peak due to proton-proton J coupling was observed, except for those among aromatic protons. Thus, the correlation between the peaks at 3.5 ppm (methoxyl protons) and 4.2 ppm (cyclobutene ring proton) in the NOESY spectrum indicates that the geometrical distance between these protons is very short (less than 4 Å). The cross peak between 4.2 ppm (cyclobutene ring proton) and 7.2 ppm (one of the aromatic protons) indicates that these protons are also closely located. Furthermore, a correlation was observed between one of the aromatic protons and the amide proton (9.93 ppm). NOE values for these three correlations were determined from the cross-peak volumes in the NOESY spectrum and are given in Table 2, where the volumes of the cross peaks are given in relative to those between the cyclobutene proton and one of the aromatic protons (a proton at C8 in Fig. 1). Since the aromatic protons

Table 2. Observed Relative NOE Volumes of the Product **3** (Nu = OCH_3), and Expected Distance R and Relative $1/R^6$ for **3a** and **3a'**

Proton pair	Relative NOE volume	Relative $1/R^6$ (Distance/Å)[a] **3a**	**3a'**
H(cyclobutene)-H(Aro)[b]	1.0	1.0 (2.589)[c]	1.0 (2.979)[c]
H(cyclobutene)-H(OMe)	2.0	1.9 (2.418 / 3.936 / 3.461)	0.3 (4.967 / 6.626 / 5.532)
H(NH)-H(Aro)[b]	1.3	1.6 (2.392)[d]	3.6 (2.411)[d]

a) Calculated for the AM1 optimized geometries. b) Aro stands for one of the aromatic protons. c) Aromatic proton is assumed on the C8 in the phenyl ring (Fig. 1). d) Aromatic proton is assumed on the C5 in the phenyl ring (Fig. 1).

give a complex multiplet structure, as shown in the one-dimensional spectrum, the cross-peak volumes involving aromatic protons were determined after the line assignments as an ABCD 4-spin system had been performed with the aid of the LAOCN3 program.[12] Table 2 also shows the relative values of $1/R^6$, together with the proton-proton distance R, calculated for the geometries predicted from AM1 MO calculations. A good correlation between each NOE volume and the corresponding relative $1/R^6$ value is found for the candidate structure **3a**. It follows that the methoxyl group is situated at the α position with respect to the carbonyl carbon. Product **3** is, therefore, confirmed to be 1,2-dichloro-2aα-methoxy-2aα,8bα-dihydrocyclobuta-[*c*]quinolin-3(4*H*)-one (**3a**) (Fig. 3).

Reaction Mechanism. In the case of the [4,6,6] lactone-fused ring system studied before,[4] the first step of the reaction with a nucleophile is the lactone-ring-opening reaction. The second and third steps are a dehydrochlorination and an intramolecular S_N2' displacement to form the [4,5,6] fused ring system.[4] On the contrary, a lactam-ring-opening at **1** dose not occur under the mild conditions employed in this study, since the amide linkage in the lactam ring is known to be far stronger than the ester linkage in the corresponding lactone ring. Thus, the first step should be dehydrochlorination to yield the unstable intermediate **2**, although we did not try to isolate **2**.

For a reaction from **2** to the cyclobutene product **3** (i.e. **3a** or **3a'**), we calculated the heats of formation of these two candidates by the MNDO and AM1 MO methods. The heat of formation of **3a** (−0.6 kcal mol^{-1} from AM1, and −23.3 kcal mol^{-1} from MNDO) was slightly higher than that of 1,4-adduct **3a'**

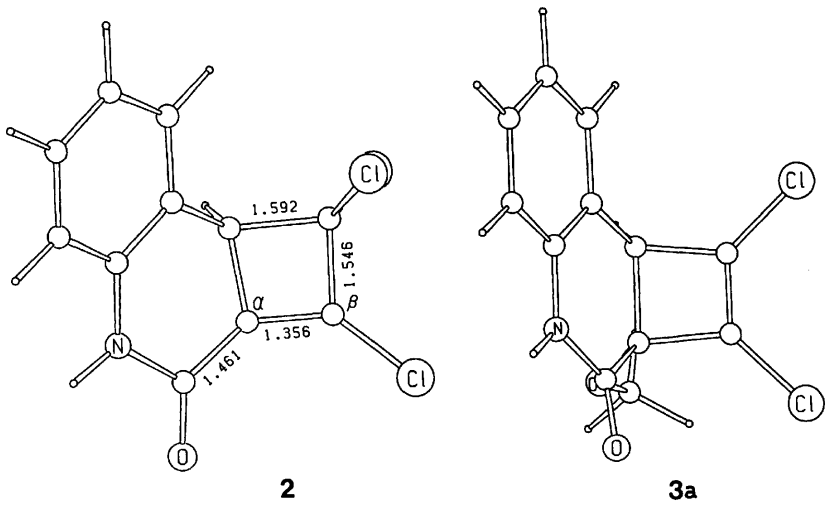

Fig 3. ORTEP[13] perspective view of **2** and **3a**, determined by the AM1 MO calculations.

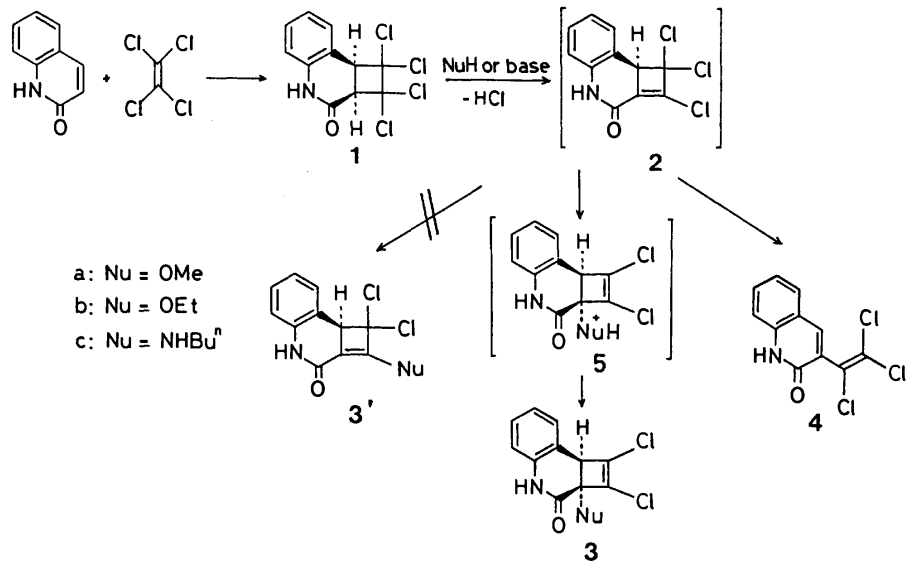

Scheme 1.

(-3.4 kcal mol^{-1} from AM1, and -26.9 kcal mol^{-1} from MNDO), suggesting that **3a** was thermodynamically less stable than **3a'**. Since **3a'** was not detected experimentally, as discussed in the previous section, the reaction of **2** with a nucleophile is not a thermodynamically equilibrium reaction. The lactam ring of **2** at the AM1 geometry (Fig. 3) is folded in against the cyclobutene ring by 51 ° while the benzene ring is on the same plane with the lactam ring. All these geometrical features indicate that the carbonyl group and the cyclobutene double bond are not well conjugated, which is also suggested from the calculated π-π overlap population. In these situations, a 1,4-addition of the attacking methoxide anion to the β position with respect to the carbonyl carbon should be improbable. Thus, molecular orbital calculations again support the conclusion from the NOE measurements described in the previous section that the cyclobutene product is **3a**.

Based on the information given above, the following reaction mechanism can be drawn (Scheme 1). In the first step of the reaction from **1**, dehydrochlorination leading to **2**, i.e. cyclobutene formation, takes place. In the second step, two possible routes can be considered. One is an S_N2' displacement by an attack of a nucleophile at the α carbon with respect to the carbonyl carbon in the cyclobutene intermediate **2**, resulting in another cyclobutene compound **3** by way of the assumed intermediate **5**. The other is the [2+2] cycloreversion of **2**, yielding trichlorovinyl-2-quinolone **4**. Since **2** should be very unstable due to the high steric strain expected for the AM1 geometry, the succeeding competitive reactions, i.e. a nucleophilic substitution reaction or the cycloreversion of the cyclobutene ring, may take place immediately when **2** is produced.

We wish to thank Mr. Hiroshi Tsuchiya, Mr. Mikio Kaihara, and Dr. Hiroaki Mametsuka (Advanced Technology Research Center, Nippon Kokan K. K) for the measurement of high mass spectra.

Novel Preparation of 1- and 3-Substituted Bicyclo[3.2.2]nona-3,6,8-trien-2-ones from Tropones and 2,3-Bis(methoxycarbonyl)-7-oxabicyclo-[2.2.1]heptadiene by High-Pressure Cycloaddition-Thermal Cycloreversion Procedure

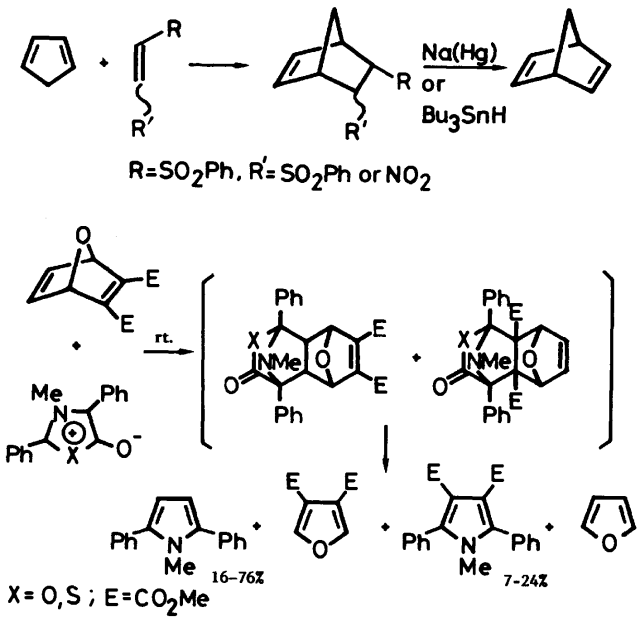
Guan Rong TIAN,† Shigeru SUGIYAMA, Akira MORI, and Hitoshi TAKESHITA*
Institute of Advanced Material Study, 86, Kyushu University,
Kasuga-koen, Kasuga, Fukuoka 816
(Received November 12, 1987)

The Diels-Alder adduct of tropone with 2,3-bis(methoxycarbonyl)-7-oxabicyclo[2.2.1]hepta-2,5-diene formed homobarrelenone on heating at 130 °C. Similarly prepared were 1-hydroxy-, 3-methoxy-, 1-chloro-, and 3-chlorohomobarrelenones. High-pressure cycloaddition improved the yields of the Diels-Alder adducts. In reactions of 2-methoxy- and 2-chlorotropones with the 7-oxanorbornadiene derivative, the endo-isomers were predominantly produced together with the exo-isomers.

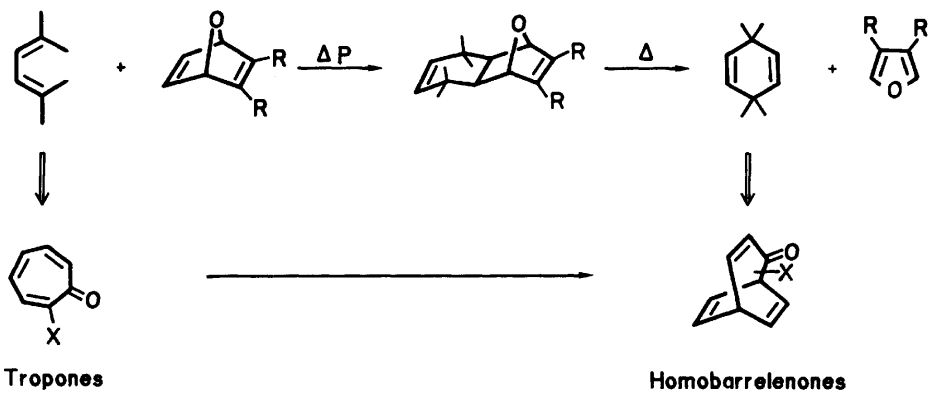
There have been a number of Diels-Alder[1] and retro-Diels-Alder[2] reactions applied to organic syntheses. However, particularly important is the development of a synthon equivalent to acetylene for the cycloaddition reactions, since there seems to still be no versatile procedure; oxidative decarboxylations of Diels-Alder adducts from maleic acid were successful only in limited instances,[3] or reductive eliminations of halogens from dihaloethene adducts sometimes have limitations, depending on the other functional groups in the molecule.[4] A recently developed two-step sequence, Diels-Alder reaction of dienes to 1,2-bis(phenylsulfonyl)ethene[5] and β-nitrosulfonylethene[6] and subsequent reductive elimination with sodium amalgam or tributyltin hydride, usually gave good results; however, the use of mercury would be undesirable from environmental points of view.

Since it is well-known that cycloadducts of furans have a tendency to cyclorevert,[7] 7-oxabicyclo[2.2.1]-heptadiene, which corresponds to the Diels-Alder adduct of furan and acetylene,[8] should serve as a substitute for acetylene.

In fact, the 1,3-dipole additions of 7-oxabicyclo-[2.2.1]heptadiene derivatives and 1,3-dipoles have given five-membered heteroaromatic compounds via



Scheme 1.



Scheme 2.

the cycloaddition-fragmentation reactions.[9] We herein describe the synthesis of homobarrelenones **3a**,[10] **3b**, **3d**, **4c**, and **4d** by the thermolyzing the Diels-Alder adducts obtained from 2,3-bis(methoxycarbonyl)-7-oxabicyclo[2.2.1]heptadiene (**1**)[11] and tropones **2a—d** under high-pressure conditions. To date, only a few derivatives of **3** have been prepared,[12-14] including the 6,7-bis(methoxycarbonyl) derivative by the Diels-Alder addition of **2a** with dimethyl butynedioate.[14,15] Since the derivatives of **3** were recently utilized in natural product syntheses,[12] a versatile synthesis of **3** must be worthwhile.

Results and Discussion

Thermal Reaction of 1 and Tropone. In 1972, Sasaki et al.[16] described the Diels-Alder reaction of tropone **2a** with **1** to form a 1:1-adduct **5a**. However, we have found, through a repeated experiment, a formation of three other products **3a**, **6**, and **7a** together with the expected adduct **5a** even under the Diels-Alder conditions. The ^{1}H NMR data of **3a** were in accord with those reported,[10] and the structures of **6** and **7a** were deduced to be 3,4-bis(methoxycarbonyl)-furan and 1-indanone, respectively, from their NMR data. The reaction also gave better results under high-pressure conditions; at a pressure of 3000 bar, the yield of the Diels-Alder adduct was improved to 88%. Therefore, a retro-Diels-Alder fragmentation of **5a** to **3a** and **6** might be quite facile and the process can be used for the synthesis of derivatives of **3**.

Thermal Reaction of 1 and Tropolone. The reaction of tropolone **2b** with **1** at 130 °C under 1 bar similarly gave, together with the adduct **5b**[16] in 50% yield, fragmentation products 1-hydroxyhomobarrelenone (**3b**), 7-hydroxy-1-indanone (**7b**), and **6**. Again, a reaction under 3000 bar afforded **5b** in 67% yield. The structure of **3b** was confirmed by the NMR data and that of **7b** was identified by a comparison with the authentic sample.[17]

Thermal Reactions of 1 and 2-Methoxy- and 2-Chlorotropones. This high-pressure reaction could be further extended to 2-methoxytropone (**2c**) and 2-chlorotropone (**2d**) with **1**; in both cases, three adducts **5c**, **8c**, and **9c** from **2c** and **5d**, **8d**, and **9d** from **2d** formed under 3000 bar. On the other hand, the reactions at 1 bar with **2c** and **2d** were rather complicated; new types of Diels-Alder adducts **10c** and **10d** were isolated together with the cycloreversed homobarrelenones **3d**, **4c**, and **4d** and indanones **7c** and **7d**. Table 1 summarized the results of Diels-Alder reactions.

The structures of Diels-Alder adducts from **2c** and **2d** were established by the ^{1}H and ^{13}C NMR spectroscopies. The chemical shifts and the coupling constants are summarized in Tables 2 and 3. Since the NMR spectra of the main product **5c** resembled those of **5a** and **5b**, the structure of **5c** was determined to be an endo-exo [4+2]π-adduct[18] with a substituent on the bridge-head carbon.

From the splitting patterns of H_2 and H_7 ($J_{1,2}$=0 Hz and $J_{7,8}$=1.5 Hz) and those of H_3 and H_6 ($J_{2,3}$=$J_{6,7}$=0 Hz), the structure of **8c** was deduced to be another endo-exo [4+2]π-adduct with a chlorine substituent at C-10.

While **9c** also had a substituent on C-10 and the signals of H_3 and H_6 appeared as two singlets, the coupling constants of $J_{1,2}$ (5.5 Hz) and $J_{7,8}$ (5.5 Hz) suggested that H_2 and H_7 had an endo configuration in bicyclo[3.2.2] framework. Therefore, **9c** was the exo-exo [4+2]π-adduct.

The structure of **10c** was the exo-exo [4+2] π-adduct

—: Not observed. ×: Not existed.

from the presence of four olefinic protons and the value of the coupling constant ($J_{1,2}$=5.9 Hz, $J_{2,3}$=$J_{6,7}$= 1.1 Hz). Similarly, the structures of four 1:1-adducts **5d**, **8d**, **9d**, and **10d** from **1** and **2d** were confirmed from the NMR data, as shown in Scheme 3.

In addition, the structures of homobarrelenones **3d**, **4c**, and **4d** were also clarified by their NMR analysis. All ^{13}C NMR displayed seven lines. Since the ^{1}H NMR spectrum of **3d** showed six olefinic protons, **3d** was deduced to be 1-chlorohomobarrelenone. In **4c** and **4d**, the appearance of five olefinic and two methine protons determined the structures to be 3-methoxy- and 3-chlorohomobarrelenones, respectively.

The indanone **7c** was identified to be 7-methoxy-1-indanone by a direct comparison with the authentic sample.[17]

Pressure Effect on the Cycloaddition Reaction. Table 1 shows the pressure effect on the endo/exo ratio and the site selectivity [(**5**+**10**):(**8**+**9**)] in the reactions between **1** and **2c** or **2d**. In both cases, the pressure did not affect to the site selectivity under 3000 bar, but the endo/exo ratio was larger as roughly twice than that under 1 bar. When the time-course of the cycloreversion of the endo-adduct **5d** and exo-adduct **10d** in toluene-d_8 was monitored by ^{1}H NMR spectroscopy, the formation of **6** was observed in ca. 40% conversion from **5d** and in less than 1% conversion from **10d** after heating at 130 °C for 24 h. Therefore, an endo/exo ratio under 1 bar could be estimated to be larger than the observed value (5.8 for **2c** and 3.7 for **2d**). If all of **6** was formed by the cycloreversion of endo-adducts and the yields of **6** were added to the yields of endo-adducts, the endo/exo ratios became 8.5 and 6.9 in the reactions between **1** and **2c** or **2d**, respectively. This means that the change of the endo/exo ratio was insignificant within the present pressure range.

Thermal Cycloreversion of Adducts. To obtain homobarreleones, the adducts were thermolyzed at 130 °C for a prolonged period; e.g., **5a** gave **3a**, **7a**, and **6** in 26, 22, and 48% yields, respectively. The results are summarized in Table 4. The isolated yields for **3** and **4** were relatively low. This was due to their volatility and a facile isomerization to indanone derivatives. Therefore, in order to avoid any further transformation of **3** to **7**, we thermolyzed **5** in a flow system and could improve the yield of **3a** to 64% without indanone formation. This was applicable to preparing other homobarrelenones **3b** and **3d**.

Table 4. Pyrolysis of Adducts

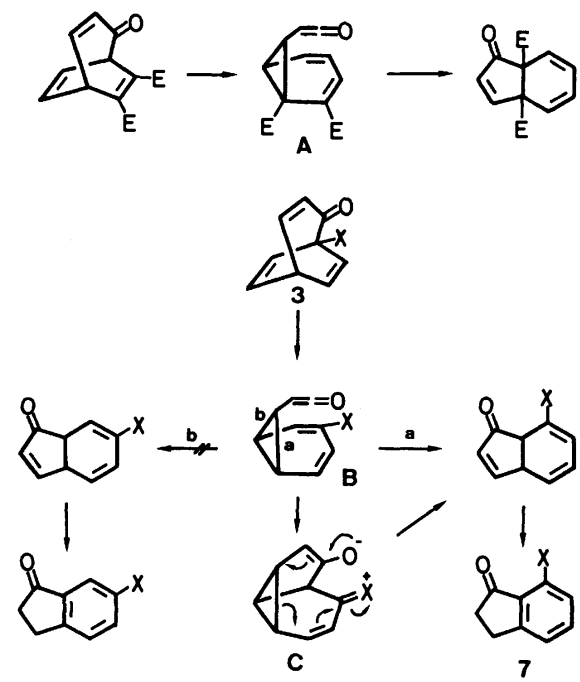
Adducts	Condition		Product (Yield/%)[a]		
5a	130 °C,	15 h	**3a** (26)	**7a** (22)	**6** (48)
5b	120 °C,	6 d	**3b** (39)	**7b** (36)	**6** (81)
5c	120 °C,	7 d		**7c** (95)	**6** (100)
8c+**9c**	130 °C,	7 d	**4c** (50)		**6** (50)
5d	130 °C,	12 h	**3d** (17)	**7d** (17)	**6** (62)
8d+**9d**	130 °C,	6 d	**4d** (86)		**6** (88)

a) Yield was based on comsumed adduct.

An attempted fragmentation of **5c**, the major product from **2c**, resulted only the formation of **7c**; however **5d**, the major adduct from **2d**, produced **3d** and 7-chloro-1-indanone (**7d**).[19] Thus, the electron-releasing group on the bridge-head carbon facilitates the indanone formation.

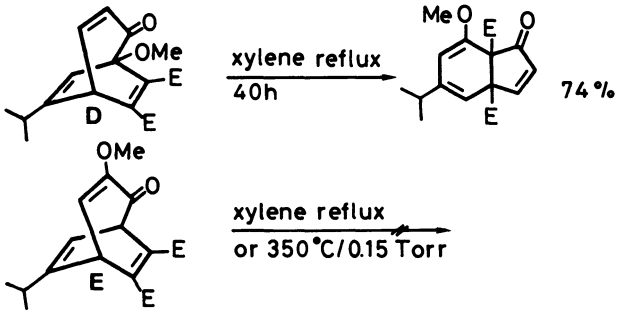
Mechanism of Thermal Rearrangement. The mechanism of thermal isomerization, homobarrelenones to dihydroindenones, has already been proposed;[15] a [3,3] sigmatropic shift of a homobarrelenone to the 7-*syn*-norcaradienylketene intermediate (**A**) followed by a [3,5] sigmatropic shift (antarafacial or Möbius) to a dihydroindenone. If an intermediate (**B**) like **A** was involved, there should be two routes (a and b) to indanones. However, an exclusive formation of 7-substituted indanones is consistent only with path a from **B**, as illustrated in Scheme 4. The methoxyl group of 1-methoxyhomobarrelenone would assist the formation of the tricyclic intermediate (**C**) and the bond a cleavage to 7-methoxyindanone. Such an intermediate **C** has been noticed in the photochemical isomerization of 5-hydroxytricyclo[3.3.2.0^{2,4}]deca-7,9-dien-6-one[20] and 5-alkyl-1-hydroxy-8-oxabicyclo[3.2.1]-octa-3,6-dien-2-ones.[21]

The by-products **8c** and **9c** from **2c** and **8d** and **9d** from **2d** were, respectively, converted to **4c** and **4d** by cycloreversion. However, **4c** and **4d** gave no indanones, unlike 1-substituted homobarrelenones. A simi-

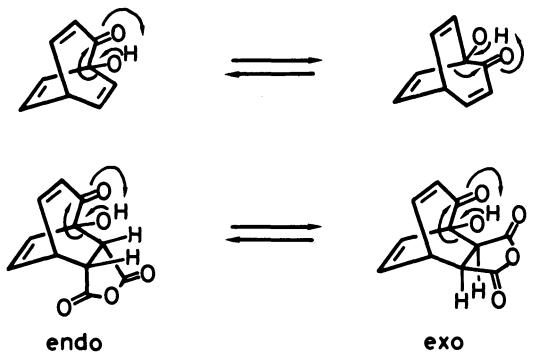


Scheme 4.

lar result has been observed in the pyrolysis of 9-isopropyl-1-methoxy-6,7-bis(methoxycarbonyl)bicyclo-[3.2.2]hepta-3,6,8-trien-2-one (**D**) and 9-isopropyl-3-methoxy-6,7-bis(methoxycarbonyl)bicyclo[3.2.2]hepta-3,6,8-trien-2-one (**E**); **D** gave a dihydroindenone derivative in 74% yield, while **E** did not give any products.[13] Probably, the electron-releasing methoxyl group at the α-position rather increased the electron density of the α,β-unsaturated ketone moiety. No occurrence of an indanone from **4d** could also be explained by the mesomeric effect of the chlorine atom on the α-position of the enone.



Scheme 5.



Scheme 6.

It is interesting that 1-hydroxyhomobarrelenone (**3b**) could be isolated after the thermal reactions, as shown in Table 1; probably, this would be attributable to a suppression of the rearrangement to indanone due to an alternative rearrangement, thermal acyloin rearrangement, which has been detected in the Diels–Alder adducts of maleic anhydride with tropolones.[22]

The NMR Spectral Analysis of Homobarrelenones. The ^1H and ^{13}C NMR chemical shifts of homobarrelenones prepared were systematically analyzed. As compiled in Table 5, the ^{13}C NMR chemical shifts of C-7(8) in **3b** and **3d** were at lower fields by ca. 6 ppm than the corresponding carbon in **3a**. Similar low-field shifts were observed for C-13 in 1:1-adducts summarized in Table 2. The chemical shift of the carbonyl carbon in **3a** was 189.7 ppm and the hydroxyl group at C-1 and the methoxyl group at C-3 did not affect the chemical shift of the carbonyl carbons, while the chlorine atom at C-1 and C-3 made the chemical shift of the carbonyl carbon higher by 6—8 ppm. These high field shifts can be explained in terms of the supressed polarization of the carbonyl group due to the polar substituent, the chlorine atom, at the α-position. Similar high field shifts were also observed in other 1:1-adducts (Table 2).

In the ^1H NMR spectra, protons H_3 in **3b** and **3d** and H_1 in **4c** and **4d** appeared at lower fields by ca. 0.3—0.4 ppm than those in **3a**. Protons H_8 and H_{10} in **8** and **5** behaved similarly. Thus, the substituent, being across the carbonyl group, caused a considerable change in the proton chemical shift.

Conclusion

As mentioned above, the Diels–Alder and the retro-Diels–Alder reactions provided a versatile two-step synthesis of structurally interesting bicyclic ketones, homobarrelenones. Substituted homobarrelenones at

a) Figures shown in the parentheses were chemical shift differences with unsubstituted **3a**.

the bridge-head carbon tended to rearrange to the indanones, while 3-isomers did not.

This procedure, high-pressure cycloaddition and thermal fragmentation, may be widely applicable, and **1** will conveniently serve as a substitute for acetylene.

Experimental

The elemental analyses were performed by Miss S. Hirashima of Institute of Advanced Material Study, Kyushu University. NMR spectra were measured using a JEOL 100 and 270H spectrometer in $CDCl_3$ solution (unless otherwise specified); chemical shifts are expressed in the unit δ. Mass spectra were measured with a JEOL OlSG-2 spectrometer. IR spectra were taken as a $CHCl_3$ solution using a Jasco IR-A 102 spectrometer. UV spectra were measured by a Hitachi U-3200 spectrophotometer.

Preparation of 1 under 3000 bar. An ether solution (12 cm^3) of furan (13.1 g) and dimethyl butynedioate (5.80 g) was kept at room temperature under 3000 bar for 20 h. The solvent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **1** [colorless oil, 5.53 g, 66%] together with two 1:1-adducts [4.31 g, 34%] between **1** and furan.

Thermal Reaction of 2a and 1. a) A chlorobenzene (CB) solution (1.5 cm^3) of **2a** (109 mg) and **1** (267 mg) was heated at 100 °C under 3000 bar for 11 h. The solvent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **5a** [colorless crystals, mp 100—102 °C, (lit,[16] 100—102 °C), 271 mg, 88%. ^{1}H NMR δ=2.50 (1H, d, J=8 Hz), 2.70 (1H, d, J=8 Hz), 3.44 (1H, tm,J=8 Hz), 3.68 (1H, d, J=8 Hz), 3.78 (3H, s), 3.80 (3H, s), 4.92 (1H, d, J=1 Hz), 5.01 (1H, d, J=1 Hz), 5.70 (1H, dd, J=11, 2 Hz), 6.10 (1H, t, J=8 Hz), 6.24 (1H, t, J=8 Hz), and 7.18 (1H, dd, J=11, 8 Hz)] and recovered **1** [61.4 mg].

b) A CB solution (3 cm^3) of **2a** (303 mg) and **1**(611 mg) was heated at 130°C for 12 h. The solvent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **3a** [colorless needles, mp 45 °C (lit,[10] 44 °C), 44.6 mg, 11%. ^{1}H NMR δ=3.85 (1H, m), 4.15 (1H, tq, J=6.5, 1.5 Hz), 5.04 (1H, ddd, J=11, 2, 1 Hz), 6.33 (2H, ddd, J=8, 6.5, 1.5 Hz), 6.67 (2H, ddd, J=8, 6.5, 1.5 Hz), and 7.02 (1H, dd, J=11, 8 Hz)], **5a** [582 mg, 64%], **6** [110 mg, 21%], and **7a** [a colorless oil, 21 mg, 5%. ^{1}H NMR δ=2.6—2.8 (2H, m), 3.0—3.2 (2H, m), and 7.3—7.8 (4H, m)].

Thermal Reaction of 2b and 1. a) A CB solution (2 cm^3) of **2b** (244 mg) and **1** (426 mg) was heated at 120 °C under 3000 bar for 12 h. The mixture gave **5b** [mp 114—115 °C, (lit,[16] 114—115 °C), 394 mg, 67%], recovered **2b** [28 mg], and **1** [22.4 mg].

b) A CB solution (1 cm^3) of **2b** (122 mg) and **1** (210 mg) was heated at 130 °C for 12 h. The mixture gave **3b** [a colorless oil, 14.3 mg, 11%. Found: m/z, 148.0523 (M^+). Calcd for $C_9H_8O_2$: 148.0523. IR ν: 3450 and 1670 cm^{-1}. UV λ_{max}^{MeOH}: 202 nm (ε=11700), 229 (3500), and 282 (540)], **5b** [165 mg, 50%], **6** [25.4 mg, 14%], and **7b** [colorless crystals, mp 111—112 °C (lit,[17] 111 °C), 3 mg, 2%. ^{1}H NMR δ=2.7—2.8 (2H, m), 3.0—3.2 (2H, m), 6.71 (1H, d, J=7.5 Hz), 6.89 (1H, d, J=7.5 Hz), 7.43 (1H, t, J=7.5 Hz), and 9.02 (1H, s). UV λ_{max}^{MeOH}: 221 nm (ε=21750), 255 (10600), and 314 (3400)].

Thermal Reaction of 2c and 1. a) A CB solution (2 cm^3) of **2c** (358 mg) and **1** (680 mg) was heated at 120 °C under 3000 bar for 12 h. The mixture gave **5c** [colorless crystals, mp 102—103 °C, 306 mg, 34%. Found: C, 62.20; H, 5.23%. Calcd for $C_{18}H_{18}O_7$: C, 62.42; H, 5.24%. IR ν: 1720 cm^{-1}. UV λ_{max}^{MeOH}: 221 nm (ε=12100)], **8c** [colorless crystals, mp 129—131 °C, 99 mg, 12%. Found: C, 62.29; H, 5.21%. Calcd for $C_{18}H_{18}O_7$: C, 62.42; H, 5.24%. IR ν: 1730, 1710, and 1675 cm^{-1}. UV λ_{max}^{MeOH}: 234 nm (ε=9000) and 287 (2700)], and **9c** [colorless crystals, mp 176.5—178 °C, 33 mg, 4%. Found: C, 62.39; H, 5.22%. Calcd for $C_{18}H_{18}O_7$: C; 62.42; H, 5.24%. IR ν: 1775 cm^{-1}. UV λ_{max}^{MeOH}: 232 nm (ε=6600) and 292 (2050)].

b) A CB solution (1 cm^3) of **2c** (126 mg) and **1** (214 mg) was heated at 130 °C for 12 h to give **4c** [a colorless oil, 4.1 mg, 3%. Found: m/z, 162.0682 (M^+). Calcd for $C_{10}H_{10}O_2$: 162.0681. IR ν: 1720, 1680, 1640, 1605, and 1120 cm^{-1}. UV λ_{max}^{MeOH}: 201 nm (ε=9150), 239 (2600), and 305 (990)], **5c** [76.6 mg, 24%], **6** [27.3 mg, 16%], **7c** [colorless plates, mp 98.5—100°C (lit,[17] 102—103 °C), 6 mg, 4%. ^{1}H NMR δ=2.6—2.75 (2H, m), 3.0—3.15 (2H, m), 4.90 (3H, s), 6.76 (1H, d, J=7.5 Hz), 6.96 (1H, d, J=7.5 Hz), and 7.50 (1H, t, J=7.5 Hz)], **8c** [36 mg, 11%], **9c** [11 mg, 3.4%], and **10c** [colorless crystals, mp 142—143 °C, 9.1 mg, 2.4%. Found: C, 62.37; H, 5.21%. Calcd for $C_{18}H_{18}O_7$: C, 62.42: H, 5.24%. IR ν: 1725, 1675, and 1230 cm^{-1}. UV λ_{max}^{MeOH}: 220 nm (ε=9500) and 289 (1250)].

c) A CB solution (2 cm^3) of **2c** (273 mg) and **1** (448 mg) was heated at 130 °C for 20 h to give **4c** [54.8 mg, 17%], **6** [96 mg, 26%], **5c** [170 mg, 25%], and **7c** [34 mg, 10%].

Thermal Reaction of 2d and 1. a) A CB solution (2 cm^3) of **2d** (281 mg) and **1** (420 mg) was heated at 120 °C under 3000 bar for 12 h. The mixture gave **5d** [colorless needles, mp 146—147 °C, 231 mg, 44%. Found: C, 58.10; H, 4.32%. Calcd for $C_{17}H_{15}O_6Cl$: C, 58.21; H, 4.31%. IR ν: 1740, 1720, 1685, 1640, and 1225 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=11000)], **8d** [colorless needles, mp 122—123 °C, 106.5 mg, 20%. Found: C, 58.23; H, 4.31%. Calcd for $C_{17}H_{15}O_6Cl$: C, 58.21; H, 4.31%. IR ν: 1730, 1715, and 1680 cm^{-1}. UV λ_{max}^{MeOH}: 234 nm (ε=9700)], **9d** [colorless needles, mp 157—159 °C, 37.3 mg, 7%. Found: C, 58.10; H, 4.33%. Calcd for $C_{17}H_{15}O_6Cl$: C, 58.21; H, 4.31%. IR ν: 1720 and 1670 cm^{-1}. UV λ_{max}^{MeOH}: 224 nm (ε=7800) and 268 (3400)], **6** [38.8 mg, 14%], and unreacted **2d** [70.3 mg].

b) A CB solution (5 cm^3) of **2d** (234 mg) and **1** (350 mg) was heated for 130 °C for 12 h to give **3d** [colorless needles, mp 67—69 °C, 14 mg, 6%. Found: m/z, 166.0160 and 168.0154 (M^+). Calcd for C_9H_7OCl: 166.0183 and 168.0154. IR ν: 1680 cm^{-1}. UV λ_{max}^{MeOH}: 203 nm (ε=12800), 227 (3250), and 283 (700)], **4d** [colorless needles, mp 85.5—87 °C, 23.5 mg, 11%. Found: m/z, 166.0179 and 168.0146 (M^+). Calcd for C_9H_7OCl: 166.0183 and 168.0154. IR ν: 1680 and 1630 cm^{-1}. UV λ_{max}^{MeOH}: 203 nm (ε=9800), 241 (3600), and 295 (900)], **5d** [128.5 mg, 28%], **8d** [61 mg, 13%], **9d** [24 mg, 5%], **10d** [colorless needles, mp 152—153 °C, 27.5 mg, 6%. Found: C, 58.32; H, 4.27%. Calcd for $C_{17}H_{15}O_6Cl$: C, 58.21; H, 4.31%. IR ν: 1730 cm^{-1}. UV λ_{max}^{MeOH}: 224 nm (ε=7600)], **6** [84 mg, 35%], **7d** [colorless needles, mp 92—93.5 °C (lit,[19] 95 °C), 17.3 mg, 8%. ^{1}H NMR δ=2.6—2.9 (2H, m), 3.0—3.3 (2H, m), and 7.2—7.5 (3H, m)], and unreacted **2d** [52 mg].

Thermal Reaction of 5a. a) A CB solution (1.5 cm^3) of **5a** (254 mg) was heated at 130 °C for 15 h. The solvent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **3a** [5 mg, 25%], **6** [13 mg, 48%], **7a** [4.3 mg, 22%], and **5a** [208 mg].

b) Crystalline **5a** (130 mg) was placed in a tube equipped with a dry-ice cold finger and thermolyzed at 160—170 °C for 2 h under 50 mmHg (1 mmHg=133.322 Pa). The thermolysate deposited on a wall was washed with ether and chromatographed on a PTLC to give **3a** [28.9 mg, 64%] and **6** [45.2 mg, 70%]. 21 mg of **5a** was remained in a tube.

Thermal Reaction of 5b. a) A CB solution (1 cm^3) of **5b** (175.5 mg) was heated at 120 °C for 6 d to give **3b** [17.4 mg, 39%], **6** [45 mg, 81%], **7b** [16 mg, 36%], and **5b** [75.5 mg].

b) Crystalline **5b** (160 mg) was thermolyzed at 180—185 °C for 2 h under 50 mmHg to give **3b** [42 mg, 59%], **6** [60 mg, 68%], and **7b** [18 mg, 25%].

Thermal Reaction of 5c. A CB solution (1 cm^3) of **5c** (132 mg) was heated at 120 °C for 7 d to give **7c** [40 mg, 95%], **6** [48 mg, 100%], and **5c** [42 mg].

Thermal Reaction of a Mixture of 8c and 9c. A xylene (XL) solution (1 cm^3) of a 3:1-mixture of **8c** and **9c** (105 mg) was heated at 130 °C for 7 d to give **4c** [14.7 mg, 50%], **6** [18.4 mg, 50%], and a mixture of **8c** and **9c** [35 mg].

Thermal Reaction of 5d. a) A XL solution (1 cm^3) of **5d** (141 mg) was heated at 130 °C for 12 h. The solvent was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **3d** [6 mg, 17%], **6** [24.8 mg, 62%], **7d** [6 mg, 17%], and **5d** [65.5 mg].

b) Crystalline **5d** (108 mg) was heated at 180—190 °C for 1.5 h under 50 mmHg to gvie **3d** [21.3 mg, 44%], **6** [37 mg, 62%], and **7d** [17.5 mg, 36%].

Thermal Reaction of a Mixture of 8d and 9d. A XL solution (1 cm^3) of a 2.6:1-mixture of **8d** and **9d** (98 mg) was heated at 130 °C for 6 d to give **4d** [31 mg, 86%], **6** [35 mg, 88%], and unreacted **8d** and **9d** [22 mg].

A New Method of Synthesizing 7-(2-Hydroxy-5-oxo-1-cyclopentenyl)heptanoic Acid and Related Compounds

Hirokazu NAORA,* Takashi OHNUKI, and Asao NAKAMURA
Applied Research Dept., Central Laboratories, Ajinomoto Co., Inc.,
1-1, Suzuki-cho, Kawasaki, Kanagawa 210
(Received December 1, 1987)

A useful prostanoid synthon, 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoic acid (**3**), was prepared from commercially available cyclooctanone in two steps. Nine other related cyclopentanoids which are also valuable synthons for prostaglandins were obtained from **3** in reasonable yields via several steps. The procedure is capable of generating these useful synthons on a laboratory scale.

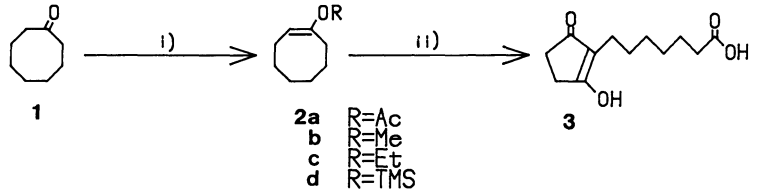
New methods of constructing of cyclopentane derivatives **3**—**7** are highly desirable, since these compounds have served as useful precursors in the synthesis of the naturally occurring prostaglandins and their congeners. In a preliminary report,[1] we described a synthesis of the 15-dehydroPGB$_1$ methyl ester from 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**4a**) and 1-octen-3-one. Furthermore, some prostaglandin derivatives have been prepared from methyl 7-(2-bromo-3-hydroxy-5-oxo-1-cyclopentenyl)-heptanoate (**5b**) in our laboratory.[2] PGB$_1$ was obtained[3] from 7-(2-hydroxy-5-oxo-1-cyclopentenyl)-heptanoic acid (**3**) and ω-chain moieties via a Grignard reaction as a key step. PGE$_1$, PGF$_1$ and their analogues were prepared from methyl 7-(3-hydroxy-5-oxo-1-cyclopentenyl)heptanoate (**6b**)[4] by means of a Michael-type reaction with several ω-chain moieties, and 11-deoxyPGE$_1$, 11-deoxyPGF$_1$, and their derivatives were derived from methyl 7-(5-oxo-1-cyclopentenyl)heptanoate (**7**).[5]

Recently, we reported[6] the use of the Cleisen condensation of dimethyl 4-oxo-1,12-undecanedioate in preparing methyl 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoate (**3'**). Novák et al.[7] converted **3'** to **4c** by phosphorus trichloride in a 70% yield, and dechlorinated **4c** with a silver–zinc couple to give **7** in a 62% yield. Compound **6b** was prepared via several steps from methyl 7-(2-oxocyclopentyl)heptanoate by Alvarez et al.[8] In this report, we will describe in detail an entirely novel method for the preparation of **3** and the derivation of other prostanoid synthons **4**—**7**.

The precursors **2** were prepared[9] from commercially available starting substances. The yields and conditions are shown in Scheme 1. 1-Cyclooctenyl acetate (**2a**) was allowed to react with succinic anhydride to afford 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoic acid (**3**). The reaction was achieved in 1,2-dichloroethane mediated by aluminium trichloride. The yield, via two steps from cyclooctanone (**1**), was 23%. Compound **3** was obtained from **2b**—**2d** under almost the same conditions (Table 1). The reaction may include Friedel–Crafts-type C–C bond-formations and acid-catalyzed hydrolysis with a C–C bond-cleavage.[10]

Succinyl dichloride instead of succinic anhydride could be available, but the yield of the product was lower. Aluminium tribromide could also mediate the reaction. As for the reaction solvents, the reaction occurred in 1,1,2-trichloroethane, 1,1,2,2-tetrachloroethane, nitromethane, and nitrobenzene. When chlorotrimethylsilane was added to the reaction system, an improvement in its yield was observed.

Compound **3** was converted to **4a** in one pot by bromination with dibromotriphenylphosphorane and subsequent esterification with absolute methanol. 7-(2-Bromo-5-oxo-1-cyclopentenyl)heptanoic acid (**4b**) was obtained by a similar method without methanol. After the removal of the triphenylphosphine oxide by silica-gel chromatography, pure **4a** or **4b** was obtained in a 68 or 67% yield respectively. Methyl 7-(2-chloro-5-oxo-1-cyclopentenyl)heptanoate (**4c**) was obtained from **3** in a 55% yield by chlorination with phosphorus trichloride and by subsequent esterification. Methyl 7-(2-iodo-5-oxo-1-cyclopentenyl)-



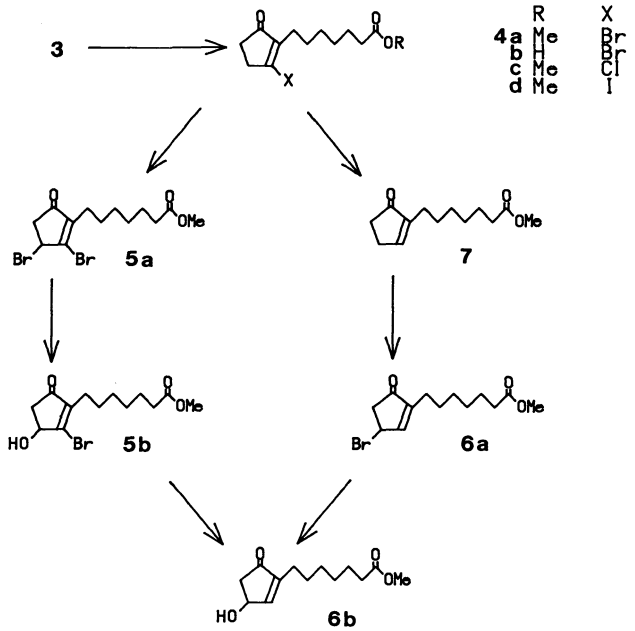
i) a) Isopropenyl acetate, p-TsOH, 115 °C, 95%; b) $HC(OMe)_3$, p-TsOH, r.t., 75%;
c) $HC(OEt)_3$, p-TsOH, r.t., 45%; d) TMSCl, Et_3N, DMF, reflux, 80%.
ii) Succinic anhydride, $AlCl_3$, 1,2-dichloroethane, 80 °C.

Scheme 1.

Table 1. Synthesis of **3** from **2**

	Starting material	Condition[a]				Yield/%	
		Catalyst	Solvent	Time/h	Temp/°C	Crude	Recrystal.
1	**2a** (R=Ac)	$AlCl_3$	A	28	80	20	18
2	**2a** (R=Ac)	$AlCl_3$	A	92	80	42	22
3[b]	**2a** (R=Ac)	$AlCl_3$	A	28	80	47	24
4	**2a** (R=Ac)	$AlCl_3$	B	24	110	31	16
5	**2a** (R=Ac)	$AlCl_3$	C	24	110	27	12
6	**2a** (R=Ac)	$AlCl_3$	D	3	100	16	10
7	**2a** (R=Ac)	$AlCl_3$	E	3	100	19	13
8	**2a** (R=Ac)	$AlBr_3$	A	28	80	20	18
9	**2b** (R=Me)	$AlCl_3$	A	63	80	27	17
10	**2c** (R=Et)	$AlCl_3$	A	92	80	16	10
11	**2d** (R=TMS)	$AlCl_3$	A	28	80	29	13

a) Catalyst: 1.95 equiv to **2**. Solvent: A: 1,2-dichloroethane; B: 1,1,2-trichloroethane; C: 1,1,2,2-tetrachloroethane; D: nitromethane; E: nitrobenzene. b) TMSCl was added (2.3 equiv to **2a**).



Scheme 2.

heptanoate (**4d**) was derived from methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**4a**) with sodium iodide quantitatively.

Methyl 7-(2,3-dibromo-5-oxo-1-cyclopentenyl)-heptanoate (**5a**) was obtained in a 51% yield from **4a** by allyl bromination with *N*-bromosuccinimide in tetrachloromethane. The substitution of the 3-bromo group of **5a** to the 3-hydroxyl group was achieved by the treatment of silver perchlorate, giving methyl 7-(2-bromo-3-hydroxy-5-oxo-1-cyclopentenyl)heptanoate (**5b**) in an 86% yield. Compound **5b** could be converted to methyl 7-(3-hydroxy-5-oxo-1-cyclopentenyl)heptanoate (**6b**) in a 90% yield by debromination with a silver-zinc couple.

Methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**4a**) was debrominated by a method similar to that described above to give a known prostaglandin intermediate **7** in a 96% yield. Methyl 7-(3-bromo-5-oxo-1-cyclopentenyl)heptanoate (**6a**) was obtained from **7** with *N*-bromosuccinimide in a 43% yield and converted to **6b** in a 92% yield with silver perchlorate.

The outlined synthesis represents a short and facile route to prostaglandin synthons **3**—**7**, because the starting materials are easily accessible and the operations of the reactions and purifications are suitable for the preparation of a sample.

Experimental

The ^1H NMR spectra were measured with a Varian EM-390 (90 MHz) spectrometer. The chemical shifts are expressed in parts per million (ppm) (δ) downfield from tetramethylsilane. The infrared spectra were obtained using a JASCO IR-810 Spectrometer. The low-resolution mass spectra (MS) and high-resolution mass spectra (HRMS) were determined on a JEOL G-300 Mass Spectrometer. The melting points and boiling points are uncorrected.

7-(2-Hydroxy-5-oxo-1-cyclopentenyl)heptanoic Acid (3).[3] Succinic anhydride (1.00 g: 10.0 mmol) was added to a suspension of 2.60 g (19.5 mmol) of aluminium trichloride in 1,2-dichloroethane, and the mixture was stirred for 1.5 h at room temperature. At 0 °C, to the resultant mixture were added dropwise 1.70 g (10.0 mmol) of 1-cyclooctenyl acetate (**2a**) and 2.50 g of chlorotrimethylsilane successively. The reaction mixture was then stirred at room temperature for 24 h, heated at 80 °C for 28 h, and then poured into 1.5 M (1 M=1 mol dm^{-3}) HCl with ice, and extracted with 40 ml of ethyl acetate five times. The combined organic layer was washed with 20 ml of water and extracted with 80 ml of aq. sat. $NaHCO_3$ and 20 ml of water. The resultant inorganic layer was adjusted to pH 1.5 and extracted with 40 ml of ethyl acetate four times. After washing with 30 ml of brine, the solvents were removed to give 1.06 g of a solid (47%). Recrystallization from water gave 0.54 g (24%) of **3**; mp 154.5—156 °C (lit,[3] mp 156—157 °C). ^1H NMR (acetone-d_6) δ=4.2—2.5 (br, 2H), 2.37 (s, 4H), 2.36—2.00 (m, 4H), and 1.8—1.2 (m, 8H); (methanol-d_4) δ=2.43 (s, 4H), 2.4—1.9 (m, 4H), and 1.8—1.2 (m, 8H); IR (KBr) 3400, 2900, 2830, 1690, 1550, and 1360 cm^{-1}.

Methyl 7-(2-Bromo-5-oxo-1-cyclopentenyl)heptanoate (4a). At 0 °C, to a stirred solution of 28.8 g (0.11 mol) of triphenylphosphine in 700 ml of benzene was added 110 ml of a 1 M bromine-benzene solution drop by drop, over a

15-min period. To the resultant mixture were then added 10 ml of triethylamine and 11.3 g of **3**. The reaction mixture was stirred at room temperature for 17 h, and then 10 ml of absolute methanol was added. After stirring for 15 min, the reaction mixture was poured into 300 ml of water. After ethereal extraction, the removal of the solvents gave crude **4a**. Silica-gel column chromatography (Merck Kieselgel 60 No. 7734: 300 g; hexane:ethyl acetate=2:1) gave 10.3 g (68%) of pure **4a**; bp 122 °C/0.15 mmHg (1 mmHg=133.322 Pa). ^{1}H NMR (chloroform-d_1) δ=3.56 (s, 3H), 2.95—2.7 (m, 2H), 2.65—2.4 (m, 2H), 2.4—2.15 (m, 4H), and 1.8—1.2 (m, 8H); IR (film) 2930, 2850, 1735, 1705, and 1630 cm^{-1}; Found: C, 51.41; H, 6.35; Br, 26.48%. Calcd for $C_{13}H_{19}O_3Br$ (Mw=303.2): C, 51.50; H, 6,32; Br, 26.35%. MS *m/z* 304, 302 (M^+), 273, 271 (M−MeO), and 223 (M−Br).

7-(2-Bromo-5-oxo-1-cyclopentenyl)heptanoic Acid (4b). To a solution of 288 mg of triphenylphosphine in 10 ml of benzene was added 1.1 ml of a 1 M bromine-benzene solution, drop by drop, at 0 °C. After the mixture had then been stirred for 15 min at room temperature, 0.15 ml of triethylamine and 113 mg of **3** were added at 0 °C. The reaction mixture was then stirred for 24 h at room temperature and poured into 20 ml of ice water. The mixture was extracted with 20 ml of ether three times. The organic layer was washed with equal volumes of water and brine, and then dried. After the evaporation of the solvent, the residue was purified on silica-gel chromatography (benzene:acetone=1:1) to give 97 mg (67%) of **4b**; ^{1}H NMR (chloroform-d_1) δ=3.0—2.8 (m, 2H), 2.60—2.43 (m, 2H), 2.30 (t, J=7 Hz, 2H), 2.20 (t, J=6 Hz, 2H), and 1.9—1.25 (m, 8H); IR (film) 3100 (br), 2920, 2840, 1730, 1700, and 1620 cm^{-1}.

To a solution of 50 mg of **4b** in 5 ml of methanol was added an excess of an ethereal diazomethane solution. An ordinary work-up and purification by means of silica-gel column chromatography (LiChroprep Si 60) gave 39 mg (78%) of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**4a**); The ^{1}H NMR and IR spectra of this agreed with those of an authentic sample.

Methyl 7-(2-Chloro-5-oxo-1-cyclopentenyl)heptanoate (4c).[7] At 0 °C, to a stirred suspension of 2.24 g of 7-(2-hydroxy-5-oxo-1-cyclopentenyl)heptanoic acid (**3**) in 10 ml of benzene (dried with zeolite A-4) were added 2 ml of phosphorus trichloride and 2.02 g of triethylamine successively. The reaction mixture was then stirred for 30 min at room temperature and heated under reflux for 2 h. Methanol (1 ml) and then 10 ml of water were stirred in, drop by drop, at 0 °C. The reaction mixture was extracted with 10 ml of ether three times. A combined organic layer was washed with equal volumes of water, 0.1 M $NaHCO_3$ (twice), water, and brine successively, and then dried. Silica-gel column chromatography (LiChroprep Si 60, hexane:ethyl acetate=2:1) gave 1.42 g (55%) of **4c**; ^{1}H NMR (chloroform-d_1) δ=3.60 (s, 3H), 2.85—2.67 (m, 2H), 2.60—2.40 (m, 2H), 2,35 (t, J=6.6 Hz, 2H), 2.22 (t, J=6.6 Hz, 2H), and 1.8—1.1 (m, 8H); IR (film) 2920, 2850, 1735, 1705, and 1630 cm^{-1}; MS *m/z* 260, 258 (M^+), 229, 227 (M−MeO), 223 (M−Cl), and 191 (M−Cl−MeOH).

Methyl 7-(2-Iodo-5-oxo-1-cyclopentenyl)heptanoate (4d). Sodium iodide (0.5 g) which had been dried at 100 °C under 1 mmHg for 3 h and 0.05 g of *p*-toluenesulfonic acid were added to a solution of 100 mg of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**4a**) in acetone dried by zeolite A-4. The reaction mixture was then stirred at room temperature for 21 h. The resultant mixture was filtered, and the precipitate was washed with 20 ml of ether. The combined solution was concentrated under reduced pressure. Ether and water (10 ml and 5 ml respectively) were added to the residue. After vigorous shaking, the separated inorganic layer was extracted with 5 ml of ether twice. The combined ethereal layer was washed with equal volumes of water four times and with brine twice, and then dried. The removal of the solvents gave 116 mg (100%) of **4d**; bp 143 °C/0.3 mmHg; ^{1}H NMR (chloroform-d_1) δ=3.60 (s, 3H), 2.95 (m, 2H), 2.43 (m, 2H), 2.27 (t, J=6 Hz, 2H), 2.23 (t, J=6 Hz, 2H), and 1.8—1.2 (m, 8H); IR (film) 2920, 2840, 1730, 1700, and 1605 cm^{-1}; Found: C, 44.61; H, 5.48; I, 35.24%. Calcd for $C_{13}H_{19}O_3I$ (Mw=350.2): C, 44.59; H, 5.47; I, 35.60%.

Methyl 7-(2,3-Dibromo-5-oxo-1-cyclopentenyl)heptanoate (5a). *N*-Bromosuccinimide (0.8 g) and 0.03 g of benzoyl peroxide were added to a solution of 1.21 g of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)heptanoate (**4a**) in 20 ml of tetrachloromethane (distilled from P_2O_5), and the resultant mixture was heated under reflux for 3 h. Furthermore, 0.4 g of *N*-bromosuccinimide and 0.01 g of benzoyl peroxide were added at room temperature, and the mixture was heated under reflux for 1.5 h. The reaction mixture was then filtered, and the precipitates were washed with 10 ml of tetrachloromethane. After the subsequent removal of the solvents, silica-gel column chromatography (LiChroporep Si 60; hexane:ethyl acetate=2:1) gave 0.78 g (51%) of the oily title compound **5a**; bp 85 °C/0.18 mmHg. ^{1}H NMR (chloroform-d_1) δ=4.98 (dd, J=6, 3 Hz, 1H), 3.60 (s, 3H), 3.13 (dd, J=6, 18 Hz, 1H), 2.93 (dd, J=18, 3 Hz, 1H), 2.27 (t-like, J=7.5 Hz, 4H), and 1.8—1.2 (m, 8H); IR (film) 2940, 2860, 1740, 1720, and 1620 cm^{-1}; MS *m/z* 353, 351, 349 (M−MeO), 303, 301 (M−Br), and 271, 269 (M−Br−MeOH); (HRMS) Found: *m/z* 352.9392, 350.9452, 348.9471. Calcd for $C_{12}H_{15}O_2Br_2$: (M−MeO): 352.9398, 350.9441, 348.9940; Found: C, 40.73; H, 4.87; Br, 42.22%. Calcd for $C_{13}H_{18}O_3Br_2$ (Mw=382.1):C, 40.87; H, 4.75; Br, 41.82%.

Methyl 7-(2-Bromo-3-hydroxy-5-oxo-1-cyclopentenyl)-heptanoate (5b). To a solution of 0.76 g of methyl 7-(2,3-dibromo-5-oxo-1-cyclopentenyl)heptanoate (**5a**) in 21 ml of aq. acetone (acetone:water=20:1) was added 1 g of silver perchlorate at room temperature under argon. The reaction mixture was stirred at room temperature for the first 50 min and at 50 °C for the next hour. To the mixture was then added 0.5 g of $NaHCO_3$ at room temperature, after which the mixture was stirred for 3 min. The reaction mixture was filtered, and the filtrate, with 70 ml of ether added, was washed with an equal volume of aq.sat.$NaHCO_3$, water and brine, and dried. The subsequent removal of the solvents gave 0.55 g (86%) of the oily title compound **5d**; ^{1}H NMR (chloroform-d_1) δ=4.77 (m, 1H), 3.58 (s, 3H), 2.87 (dd, J=18, 6 Hz, 1H), 2.6—2.1 (m, 5H), and 1.9—1.2 (m, 8H); IR (film) 3450 (br), 2940, 2860, 1740, 1720, and 1630 cm^{-1}; MS *m/z* 240 (M+H−Br), 222 (M+H−Br−H_2O), 208 (M+H−Br−MeOH), and 190 (M+H−Br−MeOH−H_2O); (HRMS) Found: *m/z* 240.1373. Calcd for $C_{13}H_{20}O_4$: (M+H−Br), 240.1362.

Methyl 7-(3-Hydroxy-5-oxo-1-cyclopentenyl)heptanoate (6b).[5] To a solution of 48 mg of silver acetate in 1 ml of glacial acetic acid at 100 °C was added 107 mg of zinc powder which had been activated by 10% HCl. The reaction

mixture was then stirred at 100 °C for 30 min. The supernatant liquid was removed by decantation at room temperature, after which the precipitate was washed with 1 ml of acetic acid twice and with 2 ml of ether five times. To the resultant precipitate was added a solution of 100 mg of methyl 7-(2-bromo-3-hydroxy-5-oxo-1-cyclopentenyl)-heptanoate (**5b**) in 2 ml of methanol, and the mixture was heated under reflux while being vigorously stirred for 2 h. The reaction mixture was filtered through a sintered-glass filter (G-4). The precipitate was then washed with methanol, and the washing was combined with the mother liquid. The resultant solution was concentrated under reduced pressure to dryness, and 5 ml of ether was added. The precipitate was separated, dissolved in 5 ml of 1 M HCl, and extracted three times by the use of 5 ml of ether. The ethereal layers thus obtained were washed with water and brine, and dried. The removal of the solvents from the combined ethereal layer gave 61 mg (90%) of **6b**. The ^{1}H NMR and IR spectra of this substance agreed with those in the literature.[5]

Methyl 7-(5-Oxo-1-cyclopentenyl)heptanoate (7).[7] To a solution of 49 mg of silver acetate in 5 ml of glacial acetic acid at 100 °C was added 1 g of zinc powder which had been activated by 10% HCl. The reaction mixture was then stirred at 100 °C for 7 min. The supernatant liquid was removed by decantation at room temperature. The precipitate was washed with 5 ml of acetic acid once and with 5 ml of ether five times. To the resultant precipitate was added a solution of 700 mg of methyl 7-(2-bromo-5-oxo-1-cyclopentenyl)-heptanoate (**4a**) in 5 ml of methanol. The reaction mixture was then stirred at 60 °C for 24 h and filtered through a sintered-glass filter (G-4). The precipitate was washed with methanol, and the washing was combined with the mother liquid. The resultant solution was concentrated under reduced pressure to dryness, and 10 ml of ether was added. The precipitate was dissolved in 10 ml of 1 M HCl and extracted with 10 ml of ether three times. The extracts thus obtained were washed with water and brine, and then dried. The subsequent removal of the solvents gave 496 mg (96%) of **7**. The ^{1}H NMR and IR spectra of this substance agreed with those in the literature.[7]

Methyl 7-(3-Bromo-5-oxo-1-cyclopentenyl)heptanoate (6a).[11] A solution of 780 mg of methyl 7-(5-oxo-1-cyclopentenyl)heptanoate (**7**), 682 mg of *N*-bromosuccinimide, and 24 mg of benzoyl peroxide in 35 ml of anhydrous tetrachloromethane was heated under reflux for 2.5 h under argon. The reaction mixture was then filtered, and the precipitate was washed with 50 ml of tetrachloromethane. After the removal of the solvents from the combined mother liquid and washing, purification by silica-gel column chromatography (LiChroprep Si 60; hexane:ethyl acetate=2:1) gave 450 mg (43%) of the oily title compound. The ^{1}H NMR and IR spectra of this substance agreed with those in the literature.[11]

Conversion to 6b from 6a. To a solution of 450 mg of methyl 7-(3-bromo-5-oxo-1-cyclopentenyl)heptanoate (**6a**) in 18 ml of aq. acetone (acetone:water=15:3) at 0 °C was added 306 mg of silver perchlorate under argon, after which the reaction mixture was stirred for 1 h. To the reaction mixture was then added 175 mg of $NaHCO_3$, and the mixture was stirred for 5 min. After the filtration of the AgBr, the filtrate was extracted with 20 ml of ether. The ethereal extracts were washed with equal volumes of aq. sat.$NaHCO_3$, water, and brine successively, and then dried. After the subsequent removal of the solvents, 326 mg (92%) of the title compound was obtained. The ^{1}H NMR and IR spectra of this substance agreed with those in the literature.[5]

The Synthesis of Methyl (15*S*)-16-Hydroxydehydroabietate and Its (15*R*)-Epimer

Takashi MATSUMOTO,* Sachihiko IMAI, and Noriaki HAYASHI
Department of Chemistry, Faculty of Science, Hiroshima University,
Higashisenda-machi, Naka-ku, Hiroshima 730
(Received December 5, 1987)

In order to elucidate the absolute configuration of C-15 in natural 16-hydroxydehydroabietic acid, a metabolite of (+)-dehydroabietic acid in rabbits, methyl (+)-dehydroabietate was transformed into methyl (15*S*)-16-hydroxy-8,11,13-abietatrien-18-oate (**3a**) and its (15*R*)-epimer (**3b**). The synthetic **3a** was identical with a methyl ester derived from the natural acid. Thus, the absolute configuration of C-15 in natural 16-hydroxydehydroabietic acid was conclusively assigned as an *S*-configuration.

16-Hydroxydehydroabietic acid (**1**), a biotransformation product of (+)-dehydroabietic acid (**2**), has been isolated independently as its methyl ester (**3**) by three groups, Ekman and Sjöholm,[1] Asakawa et al.,[2] and Nakashima et al.[3] However the absolute configuraion of C-15 in the biotransformation product has remained unsettled. In order to elucidate the unknown stereochemistry at C-15, we have now attempted the syntheses of methyl (15*S*)-16-hydroxy-8,11,13-abietatrien-18-oate (**3a**) and its (15*R*)-epimer (**3b**) starting from methyl (+)-dehydroabietate (**4**).

Dehydrogenation of **4** with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone in refluxing 1,4-dioxane afforded the corresponding isopropenyl compound (**5**) which was immediately submitted to hydroboration-oxidation to give a mixture of the desired C-15 epimeric methyl 16-hydroxy-8,11,13-abietatrien-18-oates (**3**) in 39% yield from **4**. Compound **3** was then transformed into a mixture of the corresponding benzoates (**6**) by heating with benzoyl chloride in pyridine in a quantitative yield. Since a separation of the C-15 epimers in the mixture of **3** or **6** was unsuccessful, the benzoate **6** was converted into a C-15 epimeric mixture (ca. 1:1 ratio) of 12-acetyl compounds **7a,b** by Friedel–Crafts acylation using acetyl chloride and anhydrous aluminum chloride in dichloromethane in 86% yield. This mixture of **7a,b** was carefully separated by repeated column chromatography on silica gel and recrystallization to afford a pure crystalline methyl 12-acetyl-16-benzoyloxy-8,11,13-abietatrien-18-oate (**7a**), mp 113—114 °C, and its C-15 epimer (**7b**), mp 140—141.5 °C. The absolute configuration of C-15 in these diastereomers **7a** and **7b** were determined by the following chemical correlation. The Baeyer–Villiger oxidation of **7a** and **7b** with *m*-chloroperbenzoic acid and *p*-toluenesulfonic acid in refluxing 1,2-dichloroethane, followed by hydrolysis of the resulting acetates, **8a** (91%) and **8b** (85%), with aqueous sodium hydroxide in refluxing methanol, afforded the C-15 epimeric methyl 12,16-dihydroxy-8,11,13-abietatrien-18-oates **9a** (98%) and **9b** (92%), respectively. For the protection of the hydroxyl groups, the 12,16-diol **9a** was treated with a mixture of chloromethyl methyl ether, potassium iodide, and anhydrous potassium carbonate in refluxing ethyl methyl ketone to give a 12,16-methylenedioxy compound **10a** (55%) together with a 12,16-bis(methoxymethyl) ether **11a** (4%) and a 16-methoxymethyl ether **12a** (18%). The hydrolysis of **12a** with dilute hydrochloric acid in refluxing tetrahydrofuran produced **9a** and **10a** in 62 and 27% yields, respectively. A reduction of **10a** with lithium aluminum hydride in ether followed by tosylation of the resulting alcohol with *p*-toluenesulfonyl chloride in pyridine afforded the tosylate **13a** (95%). This was further treated with sodium iodide and zinc powder in *N,N*-dimethylformamide at 120—125 °C to give a 4,4-dimethyl compound **14a** (64%). The hydrolysis of **14a** with dilute hydrochloric acid in refluxing ethanol produced the known (15*S*)-16-hydroxyferruginol(**15a**)[4,5] in 78% yield. Thus, the absolute configurations of C-15 in **7a** and its derivatives **8a—14a** were assigned as the same *S*-configuration.

Similarly, the 12,16-diol **9b** was also converted into the known (15*R*)-16-hydroxyferruginol (**15b**).[4,5] Thus, the absolute configurations of C-15 in **7b** and its

derivatives **8b**—**14b** were also assigned as the same *R*-configuration.

Subsequently, syntheses of methyl (15*S*)-16-hydroxy-8,11,13-abietatrien-18-oate (**3a**) and its (15*R*)-epimer (**3b**) were carried out as follows. Partial hydrolysis of methyl (15*S*)-12-acetoxy-16-benzoyloxy-8,11,13-abietatrien-18-oate (**8a**) with dilute hydrochloric acid in refluxing methanol afforded methyl (15*S*)-16-benzoyloxy-12-hydroxy-8,11,13-abietatrien-18-oate (**16a**) in 87% yield. In order to remove the C-12 hydroxyl group, the phenolic compound **16a** was converted into the corresponding 1-phenyl-5-tetrazolyl ether **17a** (91%) by refluxing with 5-chloro-1-phenyl-1*H*-tetrazole and anhydrous potassium carbonate in ethyl methyl ketone. However, an attempt to hydrogenolyze this ether **17a** over 10% Pd–C in ethanol at room temperature gave no deoxygenation product and only the starting **17a** was recovered. Therefore, the 12,16-diol **9a** was treated with 5-chloro-1-phenyl-1*H*-tetrazole under the same conditions to produce methyl (15*S*)-16-hydroxy-12-(1-phenyl-1*H*-tetrazol-5-yloxy)-8,11,13-abietatrien-18-oate (**18a**: 48%) together with a dihydrobenzofuran derivative **19a** (37%) which was identical with authentic methyl (15*S*)-12,16-epoxy-8,11,13-abietatrien-18-oate.[6] Catalytic hydrogenolysis of **18a** over 10% Pd–C in ethanol at room temperature under an atmosphere of hydrogen afforded the desired methyl (15*S*)-16-hydroxy-8,11,13-abietatrien-18-oate (**3a**: 39%[7]), which gave a 4-nitrobenzoate (**20a**), mp 116—117 °C.

Similarly, methyl (15*R*)-12-acetoxy-16-benzoyloxy-8,11,13-abietatrien-18-oate (**8b**) was also transformed into methyl (15*R*)-16-hydroxy-8,11,13-abietatrien-18-oate (**3b**), which gave a 4-nitrobenzoate (**20b**), mp 133—134 °C. The methyl ester of the metabolite of (+)-dehydroabietic acid (**2**) in rabbits[2] and its 4-nitrobenzoate (mp 116—117 °C) were identical with the synthetic **3a** and **20a**, respectively.

Experimental

All melting points are uncorrected. The IR spectra and optical rotations were measured in chloroform, and the ^1H NMR spectra in carbon tetrachloride at 60 MHz, with tetramethylsilane as an internal standard, unless otherwise stated; s: singlet, bs: broad singlet, d: doublet, bd: broad doublet, dd: double doublet, m: multiplet. The column chromatography was performed using Merck silica gel (0.063 mm).

Methyl 8,11,13,15-Abietatetraen-18-oate (5). A mixture of methyl (+)-dehydroabietate (**4**) (21.07 g) and 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (96%: 19.01 g) in 1,4-dioxane (210 ml) was refluxed for 4 h. The mixture was passed through an alumina (Merck Act. II—III, 200 g) column and the column was washed with benzene (600 ml). The eluate was evaporated in vacuo to give a crude **5** (16.88 g) as an oil, which was used, without purification, in the next reaction. IR 1715 and 1625 cm^{-1}, ^1H NMR δ=1.19 (3H, s, $C_{10}-CH_3$), 1.22 (3H, s, C_4-CH_3), 2.08 (3H, bs, $C_{15}-CH_3$), 3.61 (3H, s,

$-CO_2CH_3$), 4.88 (1H, bs) and 5.17 (1H, bs) ($-C(CH_3)=C\underline{H}_2$), 6.93 (1H, s) and 7.05 (2H, s) (aromatic protons).

Methyl 16-Hydroxy-8,11,13-abietatrien-18-oate (3). A solution of borane-tetrahydrofuran complex (1 mol dm^{-3}: 27.0 ml) was added to a stirred solution of the crude **5** (16.88 g) in dry tetrahydrofuran (170 ml) at −15—−10 °C for 20 min under a stream of nitrogen. After the mixture had been stirred at −10—0 °C for 10 min and at 0—5 °C for 3 h, there were added successively aqueous tetrahydrofuran (50%: 11.8 ml), aqueous sodium hydroxide (12%: 11.8 ml), and hydrogen peroxide (30%: 11.8 ml) at −15—−5 °C. The mixture was stirred at −5—0 °C for 30 min and then at room temperature for 1 h, diluted with brine, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated in vacuo. The residue was chromatographed on silica gel (0.063—0.200 mm, 200 g), using ether-benzene (3:97) as an eluent, to give mainly methyl dehydroabietate (**4**) (6.97 g). Further elution with ether-benzene (3:97 and then 6:94) afforded a mixture of C-15 epimers **3** (8.64 g: 39.0% from **4**) as an oil which, after standing at room temperature, was solidified. IR 3580, 3450, and 1720 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.19 (3H, s, C_{10}-CH_3), 1.23 (3H, d, J=7 Hz, C_{15}-CH_3), 1.27 (3H, s, C_4-CH_3), 3.67 (2H, d, J=7 Hz, $-C\underline{H}_2OH$), 3.67 (3H, s, $-CO_2CH_3$), 6.86 (1H, bs, C_{14}-H), 6.96 (1H, dd, J=9 and 2 Hz, C_{12}-H), 7.18 (1H, d, J=9 Hz, C_{11}-H). Found: C, 76.14; H, 9.38%. Calcd for $C_{21}H_{30}O_3$: C, 76.32; H, 9.15%.

Methyl 16-Benzoyloxy-8,11,13-abietatrien-18-oate (6). A mixture of **3** (7.992 g) and benzoyl chloride (4.18 ml) in pyridine (15.0 ml) was heated at 75—80 °C for 1.5 h. The mixture was cooled, poured into ice-dilute hydrochloric acid, and extracted with ether. The ether extract was washed successively with dilute hydrochloric acid, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (0.063—0.200 mm, 200 g), using hexane-benzene (2:8) as an eluent, to give an oily mixture of C-15 epimeric benzoates **6** (10.337 g: 98.4%). IR 1720 cm^{-1},^1H NMR (90 MHz, $CDCl_3$) δ=1.19 (3H, s, C_{10}-CH_3), 1.26 (3H, s, C_4-CH_3), 1.36 (3H, d, J=7 Hz, C_{15}-CH_3), 3.14 (1H, m, C_{15}-H), 3.65 (3H, s, $-CO_2CH_3$), 4.27 (1H, dd, J=11 and 7 Hz) and 4.41 (1H, dd, J=11 and 7 Hz) (C_{15}-CH_2O-), 6.92 (1H, bs, C_{14}-H), 7.00 (1H, dd, J=9 and 2 Hz, C_{12}-H), 7.18 (1H, d, J=9 Hz, C_{11}-H), 7.25—7.6 (3H, m) and 7.98 (2H, dd, J=8 and 2 Hz) ($-OCOC_6H_5$). Found: C, 77.54; H, 8.19%. Calcd for $C_{28}H_{34}O_4$: C, 77.39; H, 7.89%.

Methyl (15S)-12-Acetyl-16-benzoyloxy-8,11,13-abietatrien-18-oate (7a) and Its (15R)-Epimer (7b). Anhydrous aluminum chloride (1.70 g) was added at −10 °C to a stirred solution of **6** (1.387 g) and acetyl chloride (0.91 ml) in dichloromethane (15 ml). The mixture was stirred at this temperature for 15 min and then at room temperature for 64 h, poured into ice-dilute hydrochloric acid, and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (50 g), using hexane-chloroform (2:8) as an eluent, to give a C-15 epimeric mixture (ca. 1:1 ratio) of methyl 12-acetyl-16-benzoyloxy-8,11,13-abietatrien-18-oate (**7a,b**) (1.314 g: 86.4%). The mixture (**7a,b**) was separated into the pure **7a**, mp 113—114 °C (from methanol), $[\alpha]_D$ +49.2° (*c* 2.32), IR 1718 and 1680 cm^{-1}, and **7b**, mp 140—141.5 °C (from methanol), $[\alpha]_D$ +49.1° (*c* 3.95), IR 1718 and 1680 cm^{-1}, by repeated column chromatography on silica gel and recrystallization. ^1H NMR of **7a** (90 MHz) δ=1.19 (3H, s, C_{10}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.31 (3H, d, J=7 Hz, C_{15}-CH_3), 2.47 (3H, s, C_{12}-$COCH_3$), 3.62 (3H, s, $-CO_2CH_3$), 3.87 (1H, m, C_{15}-H), 4.33 (2H,d, J=7 Hz, C_{15}-CH_2O-), 7.03 (1H, s, C_{14}-H), 7.39 (1H, s, C_{11}-H), 7.2—7.45 (3H, m) and 7.92 (2H, dd, J=8 and 2 Hz) ($-OCOC_6H_5$). Anal. of **7a**; Found: C, 75.72; H, 7.89%. Calcd for $C_{30}H_{36}O_5$: C, 75.60; H, 7.61%. ^1H NMR of **7b** (90 MHz) δ=1.19 (3H, s, C_{10}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.32 (3H, d, J=7 Hz, C_{15}-CH_3), 2.47 (3H, s, C_{12}-$COCH_3$), 3.62 (3H, s, $-CO_2CH_3$), 3.88 (1H, m, C_{15}-H), 4.30 (2H, d, J=7 Hz, C_{15}-CH_2O-), 7.02 (1H, s, C_{14}-H), 7.39 (1H, s, C_{11}-H), 7.2—7.45 (3H, m) and 7.92 (2H, dd, J=8 and 2 Hz) ($-OCOC_6H_5$). Anal. of **7b**; Found: C, 75.42; H, 7.91%. Calcd for $C_{30}H_{36}O_5$: C, 75.60; H, 7.61%.

Methyl (15S)-12-Acetoxy-16-benzoyloxy-8,11,13-abietatrien-18-oate (8a) and Its (15R)-Epimer (8b). a): A mixture of **7a** (1.655 g), *m*-chloroperbenzoic acid (80%: 1.498 g), and *p*-toluenesulfonic acid (30 mg) in 1,2-dichloroethane (15 ml) was refluxed for 3 h. The mixture was cooled, diluted with ether, and the ether solution was washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (18 g), using ether-benzene (3:97) as an eluent, to give **8a** (1.552 g: 90.8%) which was recrystallized from methanol, mp 126—128 °C, $[\alpha]_D$ +33.5° (*c* 3.17), IR 1755 and 1718 cm^{-1}, ^1H NMR δ=1.23 (6H, s, C_4-CH_3 and C_{10}-CH_3), 1.28 (3H, d, J=7 Hz, C_{15}-CH_3), 2.25 (3H, s, C_{12}-$OCOCH_3$), 3.25 (1H, m, C_{15}-H), 3.62 (3H, s, $-CO_2CH_3$), 3.75—4.5 (2H, m, C_{15}-CH_2O-), 6.77 (1H, s) and 6.90 (1H, s) (C_{11}-H and C_{14}-H), 7.27—7.54 (3H, m) and 7.95 (2H, dd, J=8 and 2 Hz) ($-OCOC_6H_5$). Found: C, 72.83; H, 7.50%. Calcd for $C_{30}H_{36}O_6$: C, 73.14; H, 7.37%.

b): A mixture of **7b** (1.804 g), *m*-chloroperbenzoic acid (80%: 1.470 g), and *p*-toluenesulfonic acid (30 mg) in 1,2-dichloroethane (20 ml) was refluxed for 3.5 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (40 g), using ether-benzene (3:97) as an eluent, to give the recovered **7b** (152 mg) and an oily **8b** (1.585 g: 85.1%) $[\alpha]_D$ +66.8° (*c* 5.79), IR 1753 and 1718cm^{-1} , ^1H NMR δ=1.20 (3H, s) and 1.24 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 1.29 (3H, d, J=7 Hz, C_{15}-CH_3), 2.25 (3H, s, C_{12}-$OCOCH_3$), 3.27 (1H, m, C_{15}-H), 3.60 (3H, s, $-CO_2CH_3$), 3.9—4.5 (2H, m, C_{15}-CH_2O-), 6.78 (1H, s) and 6.90 (1H, s) (C_{11}-H and C_{14}-H), 7.25—7.6 (3H, m) and 7.97 (2H, dd, J=8 and 2 Hz) ($-OCOC_6H_5$). Found: C, 73.35; H, 7.45%. Calcd for $C_{30}H_{36}O_6$: C, 73.14; H, 7.37%.

Methyl (15S)-12,16-Dihydroxy-8,11,13-abietatrien-18-oate (9a) and Its (15R)-Epimer (9b). a): A mixture of **8a** (544 mg) and aqueous sodium hydroxide (20%: 1.5 ml) in methanol (6.0 ml) was refluxed for 1 h. The mixture was cooled, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (10 g), using ether-benzene (1:9) as an eluent, to give **9a** (375 mg: 98.0%) which was recrystallized from ether-hexane, mp 105—107 °C, $[\alpha]_D$ +50.0° (*c* 3.20), IR 3600, 3325, and 1720 cm^{-1}; ^1H NMR (90 MHz) δ=1.13 (3H, s, C_{10}-CH_3), 1.19 (3H, d, J=7 Hz,

C_{15}-CH_3), 1.20 (3H, s, C_4-CH_3), 3.02 (1H, m, C_{15}-H), ca. 3.6 (2H, m, overlap, C_{15}-CH_2OH), 3.61 (3H, s, -CO_2CH_3), 6.57 (2H, s, C_{11}-H and C_{14}-H). Found: C, 72.63; H, 8.86%. Calcd for $C_{21}H_{30}O_4$: C, 72.80; H, 8.73%.

b): A mixture of **8b** (1.207 g) and aqueous sodium hydroxide (20%: 3.0 ml) in methanol (10 ml) was refluxed for 1 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (16 g), using ether–benzene (1:9) as an eluent, to give an oily **9b** (662 mg: 91.9%), $[\alpha]_D$ +65.5° (*c* 8.11), IR 3600, 3325, and 1720 cm^{-1}; ^1H NMR (90 MHz) δ=1.11 (3H, s, C_{10}-CH_3), 1.17 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.19 (3H, s, C_4-CH_3), 3.02 (1H, m, C_{15}-H), ca. 3.6 (2H, m, overlap, C_{15}-CH_2OH), 3.60 (3H, s, -CO_2CH_3), 6.57 (2H, s, C_{11}-H and C_{14}-H). Found: C, 72.78; H, 8.85%. Calcd for $C_{21}H_{30}O_4$: C, 72.80; H, 8.73%.

Reactions of 9a and 9b with Chloromethyl Methyl Ether. a): A stirred mixture of **9a** (584.0 mg), chloromethyl methyl ether (0.89 ml), potassium iodide (2.34 g), and anhydrous potassium carbonate (2.34 g) in ethyl methyl ketone (10 ml) was refluxed for 5 h. The mixture was cooled, diluted with water, and extracted with ether. The ether extract was washed successively with aqueous sodium thiosulfate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (20 g), using ether–benzene (1:99) as an eluent, to give methyl (15*S*)-12,16-methylenedioxy-8,11,13-abietatrien-18-oate (**10a**) (332.0 mg: 54.8%) which was recrystallized from methanol, mp 154—155 °C, $[\alpha]_D$ +27.2° (*c* 1.62), IR 1715 cm^{-1}, ^1H NMR (90 MHz) δ=1.19 (3H, s) and 1.21 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 1.28 (3H, d, *J*=7 Hz, C_{15}-CH_3), 2.6—3.0 (3H, m, C_7-H_2 and C_{15}-H), 3.53 (1H, dd, *J*=12 and 2 Hz) and 3.82 (1H, dd, *J*=12 and 4 Hz) (C_{15}-CH_2O-), 3.61 (3H, s, -CO_2CH_3), 4.52 (1H, d, *J*=7 Hz) and 5.16 (1H, d, *J*=7 Hz) (-OCH_2O-), 6.65 (1H, s, C_{14}-H), 6.72 (1H, s, C_{11}-H). Found: C, 73.59; H, 8.63%. Calcd for $C_{22}H_{30}O_4$: C, 73.71; H, 8.44%.

Subsequent elution with ether–benzene (2:98) gave methyl (15*S*)-12,16-bis(methoxymethoxy)-8,11,13-abietatrien-18-oate (**11a**) as an oil (29.0 mg: 4.0%), $[\alpha]_D$ +52.7° (*c* 0.74), IR 1720 cm^{-1}, ^1H NMR δ=1.19, (3H, s, C_{10}-CH_3), 1.20 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.23 (3H, s, C_4-CH_3), 3.20 (3H, s, C_{16}-OCH_2OCH_3), 3.42 (3H, s, C_{12}-OCH_2OCH_3), 3.60 (3H, s, -CO_2CH_3), 4.46 (2H, s, C_{16}-OCH_2OCH_3), 5.03 (2H, s, C_{12}-OCH_2OCH_3), 6.67 (1H, s) and 6.78 (1H, s) (C_{11}-H and C_{14}-H). Found: C, 69.28; H, 9.06%. Calcd for $C_{25}H_{38}O_6$: C, 69.09; H, 8.81%.

Further elution with ether–benzene (5:95) afforded methyl (15*S*)-12-hydroxy-16-methoxymethoxy-8,11,13-abietatrien-18-oate (**12a**) (119.5 mg: 18.2%) which was recrystallized from acetone–hexane, mp 81.5—82.5 °C, $[\alpha]_D$ +50.3° (*c* 1.53), IR 3325 and 1720 cm^{-1}, ^1H NMR δ=1.17 (3H, s, C_{10}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.26 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.23 (3H, s, C_{16}-OCH_2OCH_3), 3.60 (3H, s, -CO_2CH_3), 4.54 (2H, s, C_{16}-OCH_2OCH_3), 6.57 (2H, bs, C_{11}-H and C_{14}-H), 6.69 (1H, s, C_{12}-OH). Found: C, 70.98; H, 8.97%. Calcd for $C_{23}H_{34}O_5$: C, 70.74; H, 8.78%.

b): A stirred mixture of **9b** (572.0 mg), chloromethyl methyl ether (0.87 ml), potassium iodide (2.28 g), and anhydrous potassium carbonate (2.28 g) in ethyl methyl ketone (10 ml) was refluxed for 5 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (16 g), using ether–benzene (2:98) as an eluent, to give methyl (15*R*)-12,16-methylenedioxy-8,11,13-abietatrien-18-oate (**10b**) (213.0 mg: 36.0%) which was recrystallized from methanol, mp 134—135 °C, $[\alpha]_D$ +93.3° (*c* 2.53), IR 1718 cm^{-1}, ^1H NMR (90 MHz) δ=1.16 (3H, s, C_{10}-CH_3), 1.20 (3H, s, C_4-CH_3), 1.24 (3H, d, *J*=7 Hz, C_{15}-CH_3), 2.65—3.0 (3H, m, C_7-H_2 and C_{15}-H), 3.56 (1H, dd, *J*=12 and 2 Hz) and 3.78 (1H, dd, *J*=12 and 4 Hz) (C_{15}-CH_2O-), 3.61 (3H, s, -CO_2CH_3), 4.57 (1H, d, *J*=7 Hz) and 5.12 (1H, d, *J*=7 Hz) (-OCH_2O-), 6.63 (1H, s, C_{14}-H), 6.71 (1H, s, C_{11}-H). Found: C, 73.62; H, 8.74%. Calcd for $C_{22}H_{30}O_4$: C, 73.71; H, 8.44%.

Subsequent elution gave methyl (15*R*)-12,16-bis(methoxymethoxy)-8,11,13-abietatrien-18-oate (**11b**) as an oil (72.2 mg: 10.1%), $[\alpha]_D$ +54.2° (*c* 2.59), IR 1720 cm^{-1}, ^1H NMR δ=1.18 (3H, s, C_{10}-CH_3), 1.18 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.21 (3H, s, C_4-CH_3), 3.21 (3H,s, C_{16}-OCH_2OCH_3), 3.42 (3H, s, C_{12}-OCH_2OCH_3), 3.59 (3H, s, -CO_2CH_3), 4.43 (2H, s, C_{16}-OCH_2OCH_3), 5.03 (2H, s, C_{12}-OCH_2OCH_3), 6.67 (1H, s) and 6.79 (1H, s) (C_{11}-H and C_{14}-H). Found: C, 68.89; H, 8.95%. Calcd for $C_{25}H_{38}O_6$: C, 69.09; H, 8.81%.

Further elution with ether–benzene (5:95) afforded methyl (15*R*)-12-hydroxy-16-methoxymethoxy-8,11,13-abietatrien-18-oate (**12b**) (162.9 mg: 25.3%) which was recrystallized from acetone–hexane, mp 118—119 °C, $[\alpha]_D$ +61.2° (*c* 2.06), IR 3330 and 1720 cm^{-1}, ^1H NMR δ=1.15 (3H, s, C_{10}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.26 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.26 (3H, s, C_{16}-OCH_2OCH_3), 3.60 (3H, s, -CO_2CH_3), 4.54 (2H, s, C_{16}-OCH_2OCH_3), 6.57 (2H, bs, C_{11}-H and C_{14}-H), 6.77 (1H, s, C_{12}-OH). Found: C, 70.79; H, 9.04%. Calcd for $C_{23}H_{34}O_5$: C, 70.74; H, 8.78%.

Hydrolyses of 11b, 12a, and 12b. a): A mixture of **11b** (20.0 mg) and dilute hydrochloric acid (15%: 0.15 ml) in tetrahydrofuran (1.5 ml) was refluxed for 2.5 h. The mixture was cooled, diluted with ether, and the ether solution was washed with brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (6 g), using ether–benzene (1:9) as an eluent, to give a 12,16-diol (12.8 mg: 80.3%), the IR and ^1H NMR spectra of which were identical with those of the authentic **9b**.

b): A mixture of **12a** (68.0 mg) and dilute hydrochloric acid (15%: 0.3 ml) in tetrahydrofuran (3.0 ml) was refluxed for 2.5 h. After the work-up (as described in **a**)) the crude product was chromatographed on silica gel (10 g), using ether–benzene (3:97) as an eluent, to give a 12,16-methylenedioxy compound (16.6 mg: 26.6%), the IR and ^1H NMR spectra of which were identical with those of the authentic **10a**. Further elution with ether–benzene (1:9) afforded a 12,16-diol (37.4 mg: 62.0%), the IR and ^1H NMR spectra of which were identical with those of the authentic **9a**.

c): A mixture of **12b** (111.0 mg) and dilute hydrochloric acid (15%: 0.4 ml) in tetrahydrofuran (4.0 ml) was refluxed for 2.5 h. After the work-up (as described in **a**)) the crude product was chromatographed on silica gel (8 g), using ether–benzene (3:97) as an eluent, to give a 12,16-methylenedioxy compound (22.9 mg: 22.5%), the IR and ^1H NMR spectra of which were identical with those of the authentic **10b**. Further elution with ether–benzene (1:9) afforded a 12,16-diol (67.4 mg: 68.4%), the IR and ^1H NMR spectra of which were identical with those of the authentic **9b**.

(15*S*)-12,16-Methylenedioxy-18-tosyloxy-8,11,13-abietatriene (13a) and Its (15*R*)-Epimer (13b). a): A mixture of

10a (146 mg) and lithium aluminum hydride (20 mg) in dry ether (4.0 ml) was stirred at room temperature for 1 h. The mixture was poured into ice-dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give a crude alcohol (134 mg) as an oil, IR 3630 and 3475 cm^{-1}.

A mixture of the above crude alcohol (134 mg) and *p*-toluenesulfonyl chloride (93 mg) in pyridine (1.5 ml) was heated at 80—85 °C for 4 h. The mixture was cooled, poured into ice-dilute hydrochloric acid, and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (8 g), using ether-benzene (2:98) as an eluent, to give **13a** (188 mg: 95.3%) which was recrystallized from methanol, mp 113—114 °C, $[\alpha]_D$ +16.1 ° (*c* 2.36), IR 1360 and 1178 cm^{-1}, ^1H NMR δ=0.88 (3H, s, C_4-CH_3), 1.17 (3H, s, C_{10}-CH_3), 1.28 (3H, d, *J*=7 Hz, C_{15}-CH_3), 2.44 (3H, s, -$C_6H_4CH_3$), 3.3—4.0 (4H, m, C_4-CH_2OTs and C_{15}-CH_2O-), 4.51 (1H, d, *J*=7 Hz) and 5.15 (1H, d, *J*=7 Hz) (-OCH_2O-), 6.66 (1H, s, C_{14}-H), 6.72 (1H, s, C_{11}-H), 7.28 (2H, d, *J*=9 Hz) and 7.74 (2H, d, *J*=9 Hz) (-$C_6H_4CH_3$). Found: C, 69.60; H, 7.75%. Calcd for $C_{28}H_{36}O_5S$: C, 69.40; H, 7.48%.

b): A mixture of **10b** (182 mg) and lithium aluminum hydride (25 mg) in dry ether (5.0 ml) was stirred at room temperature for 1 h to give a crude alcohol (170 mg) as an oil, IR 3625 and 3460 cm^{-1}

The above crude alcohol (170 mg) was tosylated with *p*-toluenesulfonyl chloride (116 mg) in pyridine (2.0 ml) at 80—85 °C for 4 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (8 g), using ether-benzene (1:99) as an eluent, to give **13b** (220 mg: 89.4%) which was recrystallized from methanol, mp 155—156 °C, $[\alpha]_D$ +70.7 ° (*c* 2.05), IR 1358 and 1174 cm^{-1}, ^1H NMR δ=0.87 (3H, s, C_4-CH_3), 1.13 (3H, s, C_{10}-CH_3), 1.24 (3H, d, *J*=7 Hz, C_{15}-CH_3), 2.43 (3H, s, -$C_6H_4CH_3$), 3.3—4.0 (4H, m, C_4-CH_2OTs and C_{15}-CH_2O-), 4.51 (1H, d, *J*=7 Hz) and 5.08 (1H, d, *J*=7 Hz) (-OCH_2O-), 6.61 (1H, s, C_{14}-H), 6.69 (1H, s, C_{11}-H), 7.24 (2H, d, *J*=9 Hz) and 7.68 (2H, d, *J*=9 Hz) (-$C_6H_4CH_3$). Found: C, 69.55; H, 7.68%. Calcd for $C_{28}H_{36}O_5S$: C, 69.40; H, 7.48%.

(15*S*)-12,16-Methylenedioxy-8,11,13-abietatriene (14a) and Its (15*R*)-Epimer (14b). a): A stirred mixture of **13a** (163.0 mg), sodium iodide (252 mg), and zinc powder (220 mg) in *N*,*N*-dimethylformamide (3.0 ml) was heated at 120—125 °C for 6 h. The mixture was cooled, diluted with ether, and then filtered. The filtrate was poured into dilute hydrochloric acid and extracted with ether. The ether extract was washed successively with aqueous sodium thiosulfate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (7 g), using benzene as an eluent, to give an oily **14a** (68.0 mg: 64.4%), $[\alpha]_D$ +33.9 ° (*c* 3.30), ^1H NMR δ=0.94 (6H, s, -$C(CH_3)_2$), 1.16 (3H, s, C_{10}-CH_3), 1.28 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.35—3.95 (2H, m, C_{15}-CH_2O-), 4.50 (1H, d, *J*=7 Hz) and 5.13 (1H, d, *J*=7 Hz) (-OCH_2O-), 6.62 (1H, s, C_{14}-H), 6.71 (1H, s, C_{11}-H). Found: C, 80.48; H, 9.53%. Calcd for $C_{21}H_{30}O_2$: C, 80.21; H, 9.62%. Further elution with ether-benzene (6:94) afforded the recovered **13a** (24.9 mg: 15.3%).

b): A stirred mixture of **13b** (150.0 mg), sodium iodide (232 mg), and zinc powder (202 mg) in *N*,*N*-dimethylformamide (4.0 ml) was heated at 120—125 °C for 6 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (8 g), using benzene as an eluent, to give an oily **14b** (59.2 mg: 60.8%), $[\alpha]_D$ +101 ° (*c* 1.91), ^1H NMR δ=0.94 (6H, s, -$C(CH_3)_2$), 1.14 (3H, s, C_{10}-CH_3), 1.26 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.35—3.95 (2H, m, C_{15}-CH_2O-), 4.54 (1H, d, *J*=7 Hz) and 5.13 (1H,d, *J*=7 Hz) (-OCH_2O-), 6.63 (1H, s, C_{14}-H), 6.72 (1H, s, C_{11}-H). Found: C, 80.15; H, 9.55%. Calcd for $C_{21}H_{30}O_2$: C, 80.21; H, 9.62%.

Further elution with ether-benzene (6:94) afforded the recovered **13b** (32.1 mg: 21.4%) and (15*R*)-12,16-methylenedioxy-8,11,13-abietatrien-18-ol (9.9 mg: 9.7%).

(15*S*)-16-Hydroxyferruginol (15a) and Its (15*R*)-Epimer (15b). a): A mixture of **14a** (63.0 mg) and dilute hydrochloric acid (15%: 0.2 ml) in ethanol (2.0 ml) was refluxed for 6 h. The mixture was cooled and diluted with ether. The ether solution was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (7 g), using ether-benzene (1:9) as an eluent, to give **15a** (47.4 mg: 78.4%) which was recrystallized from acetone-hexane, mp 177—178 °C, $[\alpha]_D$ +45.5 ° (*c* 0.51), IR (KBr) 3555 and 3275 cm^{-1}, ^1H NMR (90 MHz, $CDCl_3$) δ=0.91 (6H, s, -$C(CH_3)_2$), 1.16 (3H, s, C_{10}-CH_3), 1.26 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.15 (1H, m, C_{15}-H), 3.64 (1H, dd, *J*=10 and 7 Hz) and 3.88 (1H, dd, *J*=10 and 4 Hz) (C_{15}-CH_2OH), 6.74 (2H, s, C_{11}-H and C_{14}-H). Found: C, 79.31; H, 10.18%. Calcd for $C_{20}H_{30}O_2$: C, 79.42; H, 10.00%. The physical and spectral data of **15a** were identical with those of the authentic (15*S*)-16-hydroxyferruginol.[4,5]

b): A mixture of **14b** (50.2 mg) and dilute hydrochloric acid (15%: 0.2 ml) in ethanol (2.0 ml) was refluxed for 5.5 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (6 g), using ether-benzene (1:9) as an eluent, to give **15b** (38.1 mg: 78.9%) which was recrystallized from ether-hexane, mp 139—140 °C, $[\alpha]_D$ +65.7° (*c* 0.34), IR (KBr) 3520 and 3300 cm^{-1}, ^1H NMR (90 MHz, $CDCl_3$) δ=0.89 (3H, s) and 0.91 (3H, s) (-$C(CH_3)_2$), 1.13 (3H, s, C_{10}-CH_3), 1.24 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.15 (1H, m, C_{15}-H), 3.64 (1H, dd, *J*=10 and 7 Hz) and 3.88 (1H, dd, *J*=10 and 4 Hz) (C_{15}-CH_2OH), 6.72 (2H, s, C_{11}-H and C_{14}-H). Found: C, 79.24; H, 10.28%. Calcd for $C_{20}H_{30}O_2$: C, 79.42; H, 10.00%. The physical and spectral data of **15b** were identical with those of the authentic (15*R*)-16-hydroxyferruginol.[4,5]

Methyl (15*S*)-16-Benzoyloxy-12-hydroxy-8,11,13-abietatrien-18-oate (16a) and Its (15*R*)-Epimer (16b). a): A mixture of **8a** (1.412 g) and dilute hydrochloric acid (15%: 2.0 ml) in methanol (20 ml) was refluxed for 1 h. After removal of the methanol in vacuo, the residue was dissolved in ether and washed successively with brine, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (23 g), using ether-benzene (2:98) as an eluent, to give **16a** (1.123 g: 87.0%) as an oil, $[\alpha]_D$ +25.8° (*c* 3.96), IR 3600, 3400, and 1718 cm^{-1}; ^1H NMR δ=1.12 (3H, s, C_{10}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.34 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.63 (3H, s, -CO_2CH_3), 3.9—4.7 (2H, m, C_{15}-CH_2O-), 6.62 (1H, s, overlap, C_{12}-OH), 6.62 (1H, s) and 6.71 (1H, s) (C_{11}-H and C_{14}-H), 7.2—7.6 (3H, m) and 7.99 (2H, dd, *J*=7 and 2 Hz) (-$OCOC_6H_5$). Found: C, 74.53; H, 7.67%. Calcd for $C_{28}H_{34}O_5$: C, 74.64; H, 7.61%.

b): A mixture of **8b** (308 mg) and dilute hydrochloric

acid (15%: 0.4 ml) in methanol (4.0 ml) was refluxed for 1 h. After the work-up (as described in **a**)) the crude product was chromatographed on silica gel (8 g), using ether-benzene (1:99) as an eluent, to give **16b** (279 mg: 98.9%) which was recrystallized from acetone-hexane, mp 75—78 °C, $[\alpha]_D$ +78.6° (*c* 2.10), IR 3600, 3400, and 1715 cm^{-1}, ^1H NMR δ=1.14 (3H, s, C_{10}-CH_3), 1.21 (3H, s, C_4-CH_3), 1.35 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.62 (3H, s, -CO_2CH_3), 3.8—4.7 (2H, m, C_{15}-CH_2O-), 6.20 (1H, s, C_{12}-OH), 6.59 (1H, s) and 6.69 (1H, s) (C_{11}-H and C_{14}-H), 7.2—7.6 (3H, m) and 8.03 (2H, dd, *J*=7 and 2 Hz) (-$OCOC_6H_5$). Found: C, 74.58; H, 7.83%. Calcd for $C_{28}H_{34}O_5$: C, 74.64; H, 7.61%.

Methyl (15*S*)-16-Benzoyloxy-12-(1-phenyl-1*H*-tetrazol-5-yloxy)-8,11,13-abietatrien-18-oate (17a) and Its (15*R*)-Epimer (17b). a): A stirred mixture of **16a** (980 mg), 5-chloro-1-phenyl-1*H*-tetrazole (97%: 810 mg), and anhydrous potassium carbonate (3.013 g) in ethyl methyl ketone (15 ml) was refluxed for 10 h. The mixture was cooled, diluted with water, and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (20 g), using hexane-benzene (1:3) and ether-benzene (5:95) as eluents, to give an oily **17a** (1.179 g: 91.1%), $[\alpha]_D$ +61.1° (*c* 2.96), IR 1720 cm^{-1}, ^1H NMR ($CDCl_3$) δ=1.21 (3H, s) and 1.28 (3H, s) (C_4-CH_3 and C_{10} -CH_3), 1.33 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.39 (1H, m, C_{15}-H), 3.67 (3H, s, -CO_2CH_3), 4.31 (2H, d, *J*=7 Hz, C_{15}-CH_2O-), 7.02 (1H, s, C_{14}-H), 7.22 (1H, s, C_{11}-H), 7.3—8.1 (10H, m, 2 -C_6H_5). Found: C, 70.98; H, 6.59; N, 9.42%. Calcd for $C_{35}H_{38}O_5N_4$: C, 70.68; H, 6.44; N, 9.42%.

b): A stirred mixture of **16b** (582 mg), 5-chloro-1-phenyl-1*H*-tetrazole (97%: 480 mg), and anhydrous potassium carbonate (1.785 g) in ethyl methyl ketone (10 ml) was refluxed for 10 h. After the work-up (as described in **a**)) the crude product was purified by column chromatography on silica gel (10 g), using benzene and ether-benzene (1:9) as eluents, to give an oily **17b** (726 mg: 94.6%), $[\alpha]_D$ +45.4° (*c* 3.46), IR 1720 cm^{-1}, ^1H NMR ($CDCl_3$) δ=1.23 (3H, s) and 1.29 (3H, s) (C_4-CH_3 and C_{10}-CH_3), 1.33 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.39 (1H, m, C_{15}-H), 3.67 (3H, s, -CO_2CH_3), 4.31 (2H, d, *J*=7 Hz, C_{15}-CH_2O-), 7.04 (1H, s, C_{14}-H), 7.24 (1H, s, C_{11}-H), 7.3—8.1 (10H, m, 2 -C_6H_5). Found: C, 70.87; H, 6.38; N, 9.40%. Calcd for $C_{35}H_{38}O_5N_4$: C, 70.68; H, 6.44; N, 9.42%.

Hydrolyses of 17a and 17b. a): A mixture of **17a** (1.090 g), sodium carbonate (291 mg), water (4.0 ml), and methanol (40 ml) was stirred at room temperature for 2.5 h. The mixture was acidified with dilute hydrochloric acid and then evaporated in vacuo to remove most of the methanol. The residue was extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (30 g), using ether-benzene (8:92) as an eluent, to give the recovered **17a** (507 mg: 46.5%). Subsequent elution with ether-benzene (1:9) gave a 12,16-diol (74 mg: 11.7%, 21.8%[7]), the IR and ^1H NMR spectra of which were identical with those of the authentic **9a**. Further elution with ether-benzene (1:9 and then 3:7) afforded methyl (15*S*)-16-hydroxy-12-(1-phenyl-1*H*-tetrazol-5-yloxy)-8,11,13-abietatrien-18-oate (**18a**) as an oil (366 mg: 40.7%, 76.1%[7]), $[\alpha]_D$ +34.0° (*c* 2.62), IR 3425 and 1720 cm^{-1}, ^1H NMR (90 MHz, $CDCl_3$) δ=1.18 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.19 (3H, s, C_{10}-CH_3), 1.25 (3H, s, C_4-CH_3), 3.11 (1H, m, C_{15}-H), 3.64 (2H, d, *J*=7 Hz, C_{15}-CH_2OH), 3.66 (3H, s, -CO_2CH_3), 7.00 (1H, s, C_{14}-H), 7.16 (1H, s, C_{11}-H), 7.45—7.9 (5H, m, -C_6H_5). Found: C, 68.75; H, 7.26; N, 11.17%. Calcd for $C_{28}H_{34}O_4N_4$: C, 68.55; H, 6.99; N, 11.42%.

b): A mixture of **17b** (620 mg), sodium carbonate (166 mg), water (3.0 ml), and methanol (30 ml) was stirred at room temperature for 2 h. After the work-up (as described in **a**)) the crude product was chromatographed on silica gel (20 g), using ether-benzene (1:9) as an eluent, to give the recovered **17b** (306 mg: 49.4%) and a 12,16-diol (35 mg: 9.7%, 19.1%[7]), the IR and ^1H NMR spectra of which were identical with those of the authentic **9b**. Further elution with ether-benzene (1:9 and then 3:7) afforded methyl (15*R*)-16-hydroxy-12-(1-phenyl-1*H*-tetrazol-5-yloxy)-8,11,13-abietatrien-18-oate (**18b**) (200 mg: 39.1%, 77.2%[7]) which was recrystallized from acetone-hexane, mp 169—170 °C, $[\alpha]_D$ +74.7° (*c* 1.78), IR 3425 and 1720 cm^{-1}, ^1H NMR (90 MHz, $CDCl_3$) δ=1.19 (3H, s, C_{10}-CH_3), 1.20 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.25 (3H, s, C_4-CH_3), 3.12 (1H, m, C_{15}-H), 3.64 (2H, d, *J*=7 Hz, C_{15}-CH_2OH), 3.66 (3H, s. -CO_2CH_3), 7.00 (1H, s, C_{14}-H), 7.16 (1H, s, C_{11}-H), 7.45—7.9 (5H, m, -C_6H_5). Found: C, 68.36; H, 7.18; N, 11.44%. Calcd for $C_{28}H_{34}O_4N_4$: C, 68.55; H, 6.99; N, 11.42%.

Reactions of 9a and 9b with 5-Chloro-1-phenyl-1*H*-tetrazole. a): A stirred mixture of **9a** (145 mg), 5-chloro-1-phenyl-1*H*-tetrazole (97%: 156 mg), and anhydrous potassium carbonate (579 mg) in ethyl methyl ketone (5.0 ml) was refluxed for 10 h. After the work-up (as described above) the crude product was chromatographed on silica gel (8 g), using hexane-benzene (2:3) as an eluent, to give a dihydrobenzofuran derivative (51.3 mg: 37.3%) which was identical with authentic methyl (15*S*)-12,16-epoxy-8,11,13-abietatrien-18-oate (**19a**).[6] ^1H NMR (90 MHz, $CDCl_3$) δ=1.18 (3H, s, C_{10}-CH_3), 1.25 (3H, s, C_4-CH_3), 1.28 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.47 (1H, m, C_{15}-H), 3.66 (3H, s, -CO_2CH_3), 3.99 (1H, dd, *J*=8 and 7 Hz) and 4.62 (1H, t, *J*=8 Hz) (C_{15}-CH_2O-), 6.67 (1H, s, C_{11}-H), 6.78 (1H, s, C_{14}-H). Further elution with ether-benzene (15:85) afforded **18a** (98.5 mg: 48.0%), the IR and ^1H NMR spectra of which were identical with those of the authentic sample.

b): A stirred mixture of **9b** (67.8 mg), 5-chloro-1-phenyl-1*H*-tetrazole (97%: 70.8 mg), and anhydrous potassium carbonate (271 mg) in ethyl methyl ketone (3.0 ml) was refluxed for 10 h. After the work-up (as described above) the crude product was chromatographed on silica gel (12 g), using hexane-benzene (1:3) as an eluent, to give a dihydrobenzofuran derivative (24.2 mg: 37.6%) which was identical with authentic methyl (15*R*)-12,16-epoxy-8,11,13-abietatrien-18-oate (**19b**).[6] ^1H NMR (90 MHz, $CDCl_3$) δ=1.18 (3H, s, C_{10}-CH_3), 1.25 (3H, s, C_4-CH_3), 1.27 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.47 (1H, m, C_{15}-H), 3.66 (3H, s, -CO_2CH_3), 4.00 (1H, dd, *J*=8 and 7 Hz) and 4.62 (1H, t, *J*=8 Hz) (C_{15}-CH_2O-), 6.68 (1H, s, C_{11}-H), 6.80 (1H, s, C_{14}-H). Further elution with ether-benzene (1:4) afforded **18b** (28.5 mg: 29.6%), mp 169—170 °C (from acetone-hexane), the IR and ^1H NMR spectra of which were identical with those of the authentic sample.

Methyl (15*S*)-16-Hydroxy-8,11,13-abietatrien-18-oate (3a) and Its (15*R*)-Epimer (3b). a): A mixture of **18a** (219.0 mg) and 10% Pd-C (300 mg) in ethanol (15 ml) was hydrogenated at room temperature under an atmosphere of

hydrogen for 85 h. After the usual work-up, the crude product was chromatographed on silica gel (10 g), using ether–benzene (5:95) as an eluent, to give an oily **3a** (37.6 mg: 25.5%, 39.3%[7]) which was allowed to stand at room temperature to give a solid, mp 51—53.5 °C, $[\alpha]_D$ +44.7° (*c* 1.37). IR 3590, 3475, and 1718 cm^{-1}; ^1H NMR (90 MHz) δ=1.16 (3H, s, C_{10}-CH_3), 1.17 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.39 (1H, s, C_{16}-OH), 3.50 (2H, d, *J*=7 Hz, C_{15}-CH_2OH), 3.60 (3H, s, -CO_2CH_3), 6.77 (1H, bs, C_{14}-H), 6.84 (1H, dd, *J*=8 and 2 Hz, C_{12}-H), 7.07 (1H, d, *J*=8 Hz, C_{11}-H). Found: C, 76.18; H, 9.03%. Calcd for $C_{21}H_{30}O_3$: C, 76.32; H, 9.15%. Further elution with ether–benzene (1:9) afforded a 12,16-diol **9a** (21.6 mg: 14.0%, 21.6%[7]), and the recovered **18a** (77.1 mg: 35.2%).

b): A mixture of **18b** (105.0 mg) and 10% Pd-C (110 mg) in ethanol (7.0 ml) was hydrogenated at room temperature under an atmosphere of hydrogen for 64 h. After the usual work-up, the crude product was chromatographed on silica gel (8 g), using ether–benzene (1:9) as an eluent, to give **3b** (64.6 mg: 91.4%) which was recrystallized from hexane, mp 71.5—73 °C, $[\alpha]_D$ +65.8° (*c* 1.57), IR 3590, 3475, and 1718 cm^{-1}; ^1H NMR (90 MHz) δ=1.16 (3H, s, C_{10}-CH_3), 1.17 (3H, d, *J*=7 Hz, C_{15}-CH_3), 1.22 (3H, s, C_4-CH_3), 1.32 (1H, s, C_{16}-OH), 3.50 (2H, d, *J*=7 Hz, C_{15}-CH_2OH), 3.60 (3H, s, -CO_2CH_3), 6.77 (1H, bs, C_{14}-H), 6.84 (1H, dd, *J*=8 and 2 Hz, C_{12}-H), 7.07 (1H, d, *J*=8 Hz, C_{11}-H). Found: C, 76.21; H, 9.33%. Calcd for $C_{21}H_{30}O_3$: C, 76.32; H, 9.15%.

Methyl (15*S*)-16-(4-Nitrobenzoyloxy)-8,11,13-abietatrien-18-oate (20a) and Its (15*R*)-Epimer (20b). a): A mixture of **3a** (25.0 mg) and 4-nitrobenzoyl chloride (28.1 mg) in pyridine (1.0 ml) was heated at 70—80 °C for 2.5 h. After the usual work-up, the crude product was chromatographed on silica gel (8 g), using benzene as an eluent, to give **20a** (35.0 mg: 96.5%) which was recrystallized from hexane, mp 116—117 °C, $[\alpha]_D$ +9.2° (*c* 2.95), IR 1720, 1530, and 1350 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.18 (3H, s, C_{10}-CH_3), 1.26 (3H, s, C_4-CH_3), 1.35 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.18 (1H, m, C_{15}-H), 3.67 (3H, s, -CO_2CH_3), 4.41 (2H, d, *J*=7 Hz, C_{15}-CH_2O-), 6.90 (1H, bs, C_{14}-H), 7.01 (1H, dd, *J*=8 and 2 Hz, C_{12}-H), 7.20 (1H, d, *J*=8 Hz, C_{11}-H), 8.10 (2H, d, *J*=8 Hz) and 8.28 (2H, d, *J*=8 Hz) (-$C_6H_4NO_2$). Found: C, 70.34; H, 7.17; N, 2.62%. Calcd for $C_{28}H_{33}O_6N$: C, 70.12; H, 6.94; N, 2.92%.

b): A mixture of **3b** (38.0 mg) and 4-nitrobenzoyl chloride (42.7 mg) in pyridine (1.5 ml) was heated at 70—80°C for 2.5 h. After the usual work-up, the crude product was chromatographed on silica gel (6 g), using benzene as an eluent, to give **20b** (53.3 mg: 96.7%) which was recrystallized from hexane, mp 133—134 °C, $[\alpha]_D$ +66.4° (*c* 2.23), IR 1720, 1530, and 1350 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.18 (3H, s, C_{10}-CH_3), 1.26 (3H, s, C_4-CH_3), 1.36 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.18 (1H, m, C_{15}-H), 3.67 (3H, s, -CO_2CH_3), 4.41 (2H. d, *J*=7 Hz, C_{15}-CH_2O-), 6.90 (1H, bs, C_{14}-H), 7.01 (1H, dd, *J*=8 and 2 Hz, C_{12}-H), 7.20 (1H, d, *J*=8 Hz, C_{11}-H), 8.10 (2H, d, *J*=8 Hz) and 8.28 (2H, d, *J*=8 Hz) (-$C_6H_4NO_2$). Found: C, 70.38; H, 7.14; N, 2.93%. Calcd for $C_{28}H_{33}O_6N$: C, 70.12; H, 6.94; N, 2.92%.

c): Methyl (+)-16-hydroxydehydroabietate[2] (20.0 mg) ($[\alpha]_D$ +48.6° (*c* 1.11)[8]), a methyl ester of a metabolite of (+)-dehydroabietic acid (**2**) in rabbits, was treated with 4-nitrobenzoyl chloride (23.0 mg) in pyridine (1.5 ml) at 70—80°C for 2.5 h. After the usual work-up, the crude product was chromatographed on silica gel (7 g), using benzene as an eluent, to give a 4-nitrobenzoate (28.7 mg: 99.0%) which was recrystallized from hexane, mp 116—117°C, $[\alpha]_D$ +9.5° (*c* 1.16), IR 1720, 1530, and 1350 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.18 (3H, s, C_{10}-CH_3), 1.26 (3H, s, C_4-CH_3), 1.35 (3H, d, *J*=7 Hz, C_{15}-CH_3), 3.18 (1H, m, C_{15}-H), 3.67 (3H, s, -CO_2CH_3), 4.41 (2H, d, *J*=7 Hz, C_{15}-CH_2O-), 6.90 (1H, bs, C_{14}-H), 7.01 (1H, dd, *J*=8 and 2 Hz, C_{12}-H), 7.20 (1H, d, *J*=8 Hz, C_{11}-H), 8.10 (2H, d, *J*=8 Hz) and 8.28 (2H, d, *J*=8 Hz) (-$C_6H_4NO_2$). Found: C, 70.37; H, 7.15; N, 2.76%. Calcd for $C_{28}H_{33}O_6N$: C, 70.12; H, 6.94; N, 2.92%.

The physical and spectral data of the natural 4-nitrobenzoate were identical with those of the synthetic (15*S*)-isomer **20a.**

The authors are grateful to Dr. Takashi Ishida, The Hiroshima Institute of Technology, for a generous gift of natural methyl (+)-16-hydroxydehydroabietate.

(Received December 9, 1987)

1,10-Disubstituted 1,4,7,10,13,16-hexaazacyclooctadecanes (hexaaza-18-crowns) having lipophilic groups were synthesized from 1,2-ethanediamine as a starting material. Cyclization of 3,6-ditosyl-3,6-diazaoctanedioyl dichloride and 3,6-ditosyl-3,6-diazaoctane-1,8-diamine under the high dilution conditions, followed by diborane reduction of the amide carbonyl, gave the macrocyclic precursor. A series of reactions, i.e., acylation, diborane reduction, and detosylation, afforded 1,10-disubstituted hexaaza-18-crowns. Their extractability for metal cations was examined by spectrophotometric analysis. They showed relatively high extractability for Ag^{+}, Zn^{2+}, and Cd^{2+}.

An understanding of the underlying factors for metal ion recognition by organic substrates is important in wide-ranging ramifications, especially in the areas of chemistry and biochemistry. Cyclic ligands can be further "tuned" by adjusting the macrocyclic hole-size until an optimum fit is achieved for a metal ion of interest. Such macrocyclic hole-size variation is considerably interest, and many studies of this type are directed to cyclic polyether ligands and typical metal ions.[1] Recently, similar studies directed to transition metal ions have received attention.[2] Further, by introducing additional ligating groups into a macrocycle its properties can be modified, so that its specificity in metal ion binding increases and/or its solubility changes.[3]

Macrocyclic polyamines have been synthesized and their binding properties toward metal cations are described; most of the works concern tetraaza-12(or 14)-membered ring systems.[4] For example, 12-membered **1** gives stable alkali and alkaline earth metal ion complexes[5] whereas the unsubstituted ligand binds only transition metal ions. Macrocycle **2**, of which a long lipophilic side chain makes the ligand and its metal ion complex soluble in organic solvents, can be used in extraction of metal ions from an aqueous solution to an organic phase.[6]

Tetraazamacrocyclic ligands containing a single pendant-arm have been synthesized based on template methods.[7] Macrobicyclic polyamines are also synthesized by a sequential two-step pathway[8] or by direct macrobicyclization via tripode-tripode coupling reaction.[9] But, there is no report on the selective introduction of two lipophilic groups in 1,4,7,10,13,16-hexaazacyclooctadecane (hexaaza-18-crown) at the symmetrical, e.g., 1,10-positions. Here we report the synthesis and extractability of macrocyclic polyamines, which are characterized by the parent azacrown ring and "arms".

Results and Discussion

Synthesis of 1,10-Disubstituted Hexaaza-18-crowns. According to the literature,[10] 3,6-ditosyl-3,6-diazaoctanedioyl dichloride (**6**) was prepared from 1,2-ethanediamine via 1,2-bis(tosylamino)ethane (**3**), dimethyl 3,6-ditosyl-3,6-diazaoctanedioate (**4**) and then 3,6-ditosyl-3,6-diazaoctanedioic acid (**5**). The melting point of **6** was lower than that in the literature[10b] by 100 °C, but the structure of **6** was confirmed by IR and ^{1}H NMR spectra, and elemental analysis.

Diacid dichloride **6** was treated with excess liquid ammonia in dichloromethane to give the corresponding diamide **7** in 77% yield, which was converted into 3,6-ditosyl-3,6-diazaoctane-1,8-diamine (**8**) by the reduction with diborane (64% yield). Cyclization of **6** and **8** in dichloromethane under the high dilution conditions in the presence of triethylamine as a condensing agent gave cyclic diamide, 4,7,13,16-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane-2,9-dione (**9**) in 50% yield. The macrocyclic precursor, 1,4,10,13-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane (**10**) was obtained by reduction of **9** with diborane in 56% yield. 1,10-Dialkyl-4,7,13,16-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecanes (**12a, b**) were synthesized by acylation with benzoyl chloride and octanoyl chloride, respectively, in the presence of triethylamine in dichloromethane, followed by the reduction with diborane.

Hydrolysis with hydrogen bromide in acetic acid in the presence of phenol and reductive elimination with lithium aluminium hydride are known to be effective for detosylation of *N*-tosylated amine derivatives. But, detosylation of **12** by these reagents gave

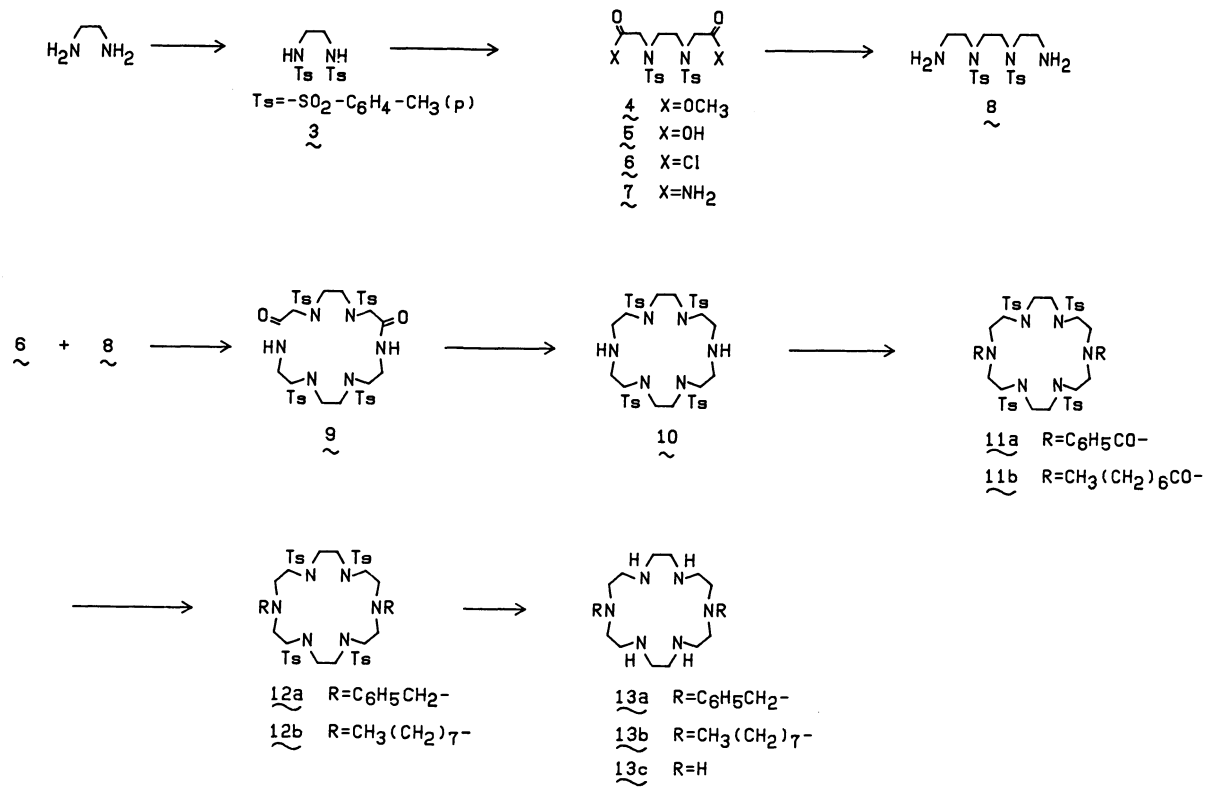

Table 1. Extractability of Hexaaza-18-crowns for Metal Cations

R%[a]	Li^+	Na^+	K^+	Ca^{2+}	Ba^{2+}

Conditions: a) [crown]=5×10^{-5} M (1 M=1 mol dm^{-3}), [MOH]=5×10^{-5} M, [$M(OH)_2$]=2.5×10^{-5} M, [picric acid]=5×10^{-5} M. b) [crown]=5×10^{-5} M, [MCl]=5×10^{-5} M, [MCl_2]=2.5×10^{-5} M, [MCl_3]=1.7×10^{-5} M, except for Ag^+~[$AgNO_3$]=5×10^{-5} M and Mg^{2+}~[$MgSO_4$]=2.5×10^{-5} M, [NaOH]=5×10^{-5} M, [picric acid]=5×10^{-5} M.

only complex mixtures. Finally, hydrolysis with concd. sulfuric acid at about 100 °C was found to be effective, giving 1,10-dialkyl-1,4,7,10,13,16-hexaazacyclooctadecane (1,10-disubstituted hexaaza-18-crown) (**13a, b**) in moderate yields.

Extractability. Metal cation-binding property of 1,10-disubstituted hexaaza-18-crowns **13a, b** and unsubstituted **13c** was investigated by equilibrating a dichloromethane solution of **13** with an aqueous solution of metal picrate, which was chosen as a metal cation source, at 25 °C. The results on the extraction of metal picrates with **13** are summarized in Table 1.

Metal picrates could not be extracted into a dichloromethane phase in the absence of **13**. Then, metal picrates may be extracted by the interaction with **13**, and the degree of extraction into a dichloromethane phase would reflect the cation-binding ability of **13**.

As shown in Table 1, **13a** and **13b** exhibited enhanced extraction efficiency compared with **13c**.

For alkali metal and alkaline earth metal cations the orders of the extractability of **13a** and **13b** were $Rb^+>K^+>Cs^+\geqq Na^+\simeq Li^+$ and $Ba^{2+}>Ca^{2+}>Mg^{2+}$, while unsubstituted **13c** exhibited metal cation selectivity in the orders of $Li^+\simeq Na^+\simeq K^+>Cs^+\simeq Rb^+$ and $Ca^{2+}>Ba^{2+}>Mg^{2+}$. On the other hand, the size of hexaaza-18-crown ring was found to be almost equal to that of 1,4,7,10,13,16-hexaoxacyclooctadecane (18-crown-6) on the basis of the structural analysis using CPK molecular models. The cation selectivities of 18-crown-6 are $Ba^{2+}>Ca^{2+}>Mg^{2+}$ and $K^+>Na^+$ and are well explained on the basis of the cation size vs. the cavity size correlation.[11] Then, the difference in extractability between **13a**, **b** and **13c**, which have the same binding site structure, and between **13** and 18-crown-6, which have similar ring size to each other, indicates that both of the side arms and the heteroatoms in the macrocycle play an important role in the incorporation of cations into the cavity of **13** and in the extraction to the organic phase.

The extractability of **13a** and **13b** for transition metal cations was higher than that for typical metal cations. The similar tendency was obtained for **13c**. This phenomenon can be explained by hard soft acid base principle; rather soft nitrogen atom has stronger affinity toward soft transition metal cations than hard typical metal cations. It is noticeable that **13** shows relatively high extractability for Ag^+, Zn^{2+}, and Cd^{2+}.

In most cases, the extractability of dioctylated hexaaza-18-crown **13b** for metal cations was a little higher than that of dibenzylated hexaaza-18-crown **13a**. Octyl group is probably more flexible and lipophilic than benzyl group. Then, **13b** would be liable to incorporate metal cations and its metal cation complexes would be more soluble in the organic phase in comparison with **13a**. The distinct reverse tendency in Ag^+ would result from π-interaction of Ag^+ with phenyl group in **13a**.

These 1,10-disubstituted hexaaza-18-crowns would wrap around the guest cations in such a way that the arms provide axial capping of the guest cations coordinated with the parent hexaaza-18-crown ring. The mobility of the arms attached to hexaaza-18-crown ring may permit dynamic complexation and decomplexation.

Experimental

Measurement. All melting points were measured on a Laboratory Devices MEL-TEMP apparatus and are uncorrected. IR spectra were recorded on a JASCO IR-810 spectrometer. ^1H NMR spectra were recorded on a Hitachi R-40 spectrometer in $CDCl_3$ or DMSO-d_6 using TMS as an internal standard. UV spectra were measured on a Shimadzu UV-260 spectrometer.

Materials. 3,6-Ditosyl-3,6-diazaoctanedioic acid (**5**) was prepared from 1,2-ethanediamine by the method in the literature.[10]

1,4,7,10,13,16-Hexaazacyclooctadecene (hexacyclen) (**13c**) was prepared from commercially available hexacyclen trisulfate (Aldrich Chem. Co.) by the method in the literature.[12]

Solvents were purified and dried by the standard procedures.

3,6-Ditosyl-3,6-diazaoctanedioyl Dichloride (6). 3,6-Ditosyl-3,6-diazaoctanedioic acid (**5**) (8.00 g, 16.5 mmol) was heated with thionyl chloride (100 ml) under reflux until the solution became clear. The excess thionyl chloride was evaporated at 60 °C. The remaining brownish crystals were repeatedly recrystallized from benzene to give **6** (7.30 g, 85% yield) as white crystals: mp 143—144 °C; IR (KBr) 2920, 2850, 1720, 1600, 1450, 1400, 1360, 1160, 1090, 1060, 960, 910, 805, 790, 750, 720 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.40 (6H, s), 3.26 (4H, s), 3.97 (4H, s), 7.50 (4H, d, J=7.5 Hz), and 7.59 (4H, d, J=7.5 Hz). Found: C, 46.26; H, 4.06; N, 5.31%. Calcd for $C_{20}H_{22}N_2O_6S_2Cl_2$: C, 46.07; H, 4.25; N, 5.37%.

3,6-Ditosyl-3,6-diazaoctanediamide (7). To a solution of **6** (72.2 g, 0.13 mol) in 700 ml of dichloromethane was introduced gaseous ammonia for 2 h at −78 °C to give white precipitates. After the excess ammonia was removed, the precipitates were collected by filtration, washed with water until the washing was no longer alkaline, and dried in vacuo. The precipitates were recrystallized from 2-methoxyethanol to give **7** as white crystals (48.6 g, 77%): mp 243.5—244.5 °C; IR (KBr) 3400, 3180, 2950, 2920, 1670, 1600,1500, 1460, 1420, 1360, 1310, 1290, 1250, 1190, 1160, 1120, 1090, 1050, 1020, 940, 900, 820, 790, 730 cm^{-1}; ^1H NMR (DMSO-d_6) δ=2.36 (6H, s), 3.26 (4H, s), 3.72 (4H, s), 6.97 (4H, brs), 7.42 (4H, d, J=7.5 Hz), and 7.51 (4H, d, J=7.5 Hz). Found: C, 49.99; H, 5.64; N, 11.33%. Calcd for $C_{20}H_{26}N_4O_6S_2$: C, 49.78; H, 5.43; N, 11.61%.

3,6-Ditosyl-3,6-diazaoctane-1,8-diamine (8). To a well-stirred suspension of 8.20 g (0.22 mol) of pulverized sodium borohydride in 300 ml of tetrahydrofuran (THF) containing 38.6 g (0.08 mmol) of **7** was added 55 ml (0.44 mol) of boron trifluoride etherate in 55 ml of dry THF in a period of 2 h at 0 °C under nitrogen atmosphere, then the mixture was refluxed for 12 h. After cooling at room temperature, the excess hydride was decomposed with water (60 ml), and 80 ml of 6 mol·dm^{-3} HCl solution was added. The solution was concentrated under reduced pressure. The residue was basified about pH 10 with 5 mol·dm^{-3} NaOH solution and extracted with dichloromethane (100 ml×3). Removal of the solvent gave solid mass. The crude product was recrystallized from methanol to afford white needles (23.2 g, 64%): mp 139—140 °C; IR (KBr) 3400, 2920, 2850, 1620, 1590, 1490, 1450, 1340, 1310, 1290, 1160, 1090, 1010, 960, 860, 810, 760, 720, 700 cm^{-1}; ^1H NMR (DMSO-d_6) δ=1.70 (4H, brs), 2.40 (6H, s), 2.65 (4H, t, J=7 Hz), 3.07 (4H, t, J=7 Hz), 3.22 (4H, s), 7.50 (4H, d, J=7.5 Hz), and 7.59 (4H, d, J=7.5 Hz). Found: C, 53.07; H, 6.68; N, 12.12%. Calcd for $C_{20}H_{30}N_4O_4S_2$: C, 52.84; H, 6.65; N, 12.32%.

4,7,13,16-Tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane-2,9-dione (9). A solution of **6** (7.30 g, 14 mmol) in dichlomethane (280 ml) and a solution of **8** (6.36 g, 14 mmol) and triethylamine (7.8 ml, 56 mmol) in dichloromethane (280 ml) were simultaneously added to a vigorously stirred dichloromethane (1700 ml) in a period of 12 h at the same dropping rate at 0 °C. Stirring was continued at 0 °C for additional 2 h. The solution was then washed with

water, dried with magnesium sulfate, and concentrated under reduced pressure to give the crude product. Purification by alumina column chromatography (the eluent: CH_2Cl_2) gave **9** as a white solid mass (6.33 g, 50%): IR (KBr) 3420, 2950, 2920, 1670, 1600, 1530, 1490, 1450, 1340, 1310, 1290, 1160, 1100, 1040, 1020, 1000, 930, 870, 820, 760, 720, 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.40 (12H, s), 3.31 (16H, brs), 3.72 (4H, s), 7.36 (8H, d, J=7.5 Hz), 7.45 (8H, d, J=7.5 Hz), and 8.11 (2H, brs). For the preparation of **10** the chromatographed **9** was used without further purification.

1,4,10,13-Tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane (10). To a well-stirred suspension of 1.14 g (30 mmol) of sodium borohydride in 120 ml of THF containing 4.15 g (5 mmol) of **9** was added 10 ml of boron trifluoride etherate (11.2 g, 80 mmol) in 40 ml of THF in a period of 1 h under nitrogen atmosphere at 0 °C, and the reaction mixture was refluxed for 24 h. After cooling at room temperature, the mixture was treated with water (25 ml) to decompose the excess hydride. The solution was concentrated under reduced pressure and extracted with dichloromethane (50 ml×5). The dichloromethane was evaporated, and 30 ml of 6 mol·dm^{-3} HCl solution was added to the residue. The acidic solution was heated at 80 °C for 1 h. After removal of excess HCl, saturated Na_2CO_3 solution was added until the evolution of gas ceased, and the product was extracted with dichloromethane (50 ml×3). The extracts were combined, dried, concentrated, and purified by alumina column chromatography (the eluent: CH_2Cl_2) to give **10** in 81%. The product was recrystallized from acetonitrile to give **10** (2.43 g, 56%): mp 208—212 °C; IR (KBr) 3420, 2940, 2860, 1590, 1500, 1450, 1340, 1310, 1290, 1190, 1160, 1120, 1090, 1040, 1010, 980, 920, 810, 760, 720 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.57 (2H, brs), 2.40 (12H, s), 2.73 (8H, t, J=5.0 Hz), 3.13 (8H, t, J=5 Hz), 3.31 (8H, s), 7.36 (8H, d, J=7.5 Hz), and 7.45 (8H, d, J=7.5 Hz). Found: C, 55.14; H, 6.31; N, 9.58%. Calcd for $C_{40}H_{54}N_6O_8S_4$: C, 54.90; H, 6.22; N, 9.60%.

1,10-Dibenzoyl-4,7,13,16-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane (11a). To a stirred solution of **10** (0.60 g, 0.68 mmol) and triethylamine (0.40 ml, 2.8 mmol) in dichloromethane (30 ml) was added a solution of benzoyl chloride (0.38 ml, 2.8 mmol) in dichloromethane (5 ml) at 0 °C. After stirring for 8 h at room temperature, the reaction mixture was washed with water, dried, and concentrated under reduced pressure. The product was purified by silica-gel column chromatography (the eluent: CH_2Cl_2) to give **11a** (0.61 g, 83%): IR (KBr) 3070, 3040, 2940, 2870, 1720, 1640, 1600, 1500, 1450, 1420, 1350, 1310, 1160, 1120, 1100, 1040, 1020, 980, 910, 820, 740, 720, 700, 660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.30 (12H, s), 3.0—3.9 (16H, m), 3.54 (8H, t, J=5 Hz), 7.37 (2H, dd, J=2 Hz, J'=9.5 Hz), 7.42 (4H, dd, J=7 Hz, J'=9.5 Hz), 7.43 (8H, d, J=7.5 Hz), 7.51 (8H, d, J=7.5 Hz), and 8.08 (4H, dd, J=2 Hz, J'=7 Hz).

1,10-Dioctanoyl-4,7,13,16-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane (11b). The synthesis of **11b** was carried out in a similar manner to that of **11a**. Silica-gel chromatographic purification (the eluent: CH_2Cl_2) afforded **11b** in 94% yield: IR (KBr) 2930, 2850, 1720, 1640, 1600, 1460, 1420, 1350, 1310, 1160, 1090, 1040, 1020, 980, 910, 820, 740, 720, 700, 600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (6H, t, J=5 Hz), 1.27 (16H, brs), 1.63 (4H, t, J=5 Hz), 2.40 (12H, s), 3.08—3.81 (16H, m), 3.54 (8H, t, J=5 Hz), 7.43 (8H, d, J=7.5 Hz) and 7.51 (8H, d, J=7.5 Hz).

1,10-Dibenzyl-4,7,13,16-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane (12a). To a solution of 0.70 g (0.64 mmol) of **11a** in 6 ml of THF was slowly added a solution of 11 ml of 1 mol·dm^{-3} diborane in THF (Aldrich Chem. Co.) at 0 °C under nitrogen atmosphere. The solution was then refluxed for 24 h. After cooling to room temperature, 10 ml of water was added to the solution, and the THF was evaporated. To the remaining residue was added 2 ml of 6 mol·dm^{-3} HCl solution, and the mixture was heated at 80 °C for 30 min. After concentration of the solution, the residue was basified with 10% LiOH solution (5 ml) and extracted with dichloromethane (30 ml×5). The extracts were concentrated under reduced pressure to give the crude product. Crystallization from benzene gave pure **12a** (0.49 g, 72%): mp 185—189 °C (decomp.); IR (KBr) 3060, 3030, 2930, 2860, 1630, 1600, 1500, 1460, 1400, 1340, 1310, 1160, 1100, 980, 920, 820, 740, 720, 700, 660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.40 (12H, s), 2.65 (8H, t, J=7 Hz), 3.14 (8H, t, J=7 Hz), 3.24 (8H, s), 3.62 (4H, s), 7.35 (10H, s), 7.43 (8H, d, J=7.5 Hz), and 7.51 (8H, d, J=7.5 Hz). Found: C, 64.86; H, 6.41; N, 6.88%. Calcd for $C_{54}H_{66}N_6O_8S_4 \cdot 3/2C_6H_6$: C, 64.53; H, 6.45; N, 7.17%.

1,10-Dioctyl-4,7,13,16-tetratosyl-1,4,7,10,13,16-hexaazacyclooctadecane (12b). In a similar manner mentioned above, **12b** was synthesized. Recrystallization from acetonitrile gave pure **12b** in 81% yield: mp 160—163 °C (decomp); IR (KBr) 2930, 2850, 1630, 1600, 1500, 1460, 1350, 1310, 1160, 1100, 980, 820, 750, 710, 660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (6H, t, J=5 Hz), 1.25 (24 H, brs), 2.41 (12 H, s), 2.65 (12H, t, J=7 Hz), 3.14 (8H, t, J=7 Hz), 3.24 (8H, s), 7.43 (8H, d, J=7.5 Hz), and 7.51 (8H, d, J=7.5 Hz). Found: C, 61.32; H, 8.02; N, 7.94%. Calcd for $C_{56}H_{86}N_6O_8S_4$: C, 61.17; H, 7.88; N, 7.64%.

1,10-Dibenzyl-1,4,7,10,13,16-hexaazacyclooctadecane (13a). A solution of **12a** (106 mg, 0.1 mmol) in 0.7 ml of concd. H_2SO_4 was heated at 100 °C for 10 h. The solution was poured into an ice-cold water and basified with 10 mol·dm^{-3} NaOH solution, followed by extraction with dichloromethane (20 ml×5). The extracts were combined, dried, and concentrated under reduced pressure. The residue was chromatographed on an alumina column (the eluent: CH_2Cl_2) to give **13a** (30 mg, 69%): IR (neat) 3320, 3050, 2950, 2830, 1660, 1600, 1500, 1460, 1280, 1120, 1030, 910, 740, 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.50—2.95 (16H, m), 2.75 (8H, s), 3.62 (4H, s), 4.33 (4H, brs), and 7.25 (10H, s).

1,10-Dioctyl-1,4,7,10,13,16-hexaazacyclooctadecane (13b). In a similar manner, **13b** was prepared from **12b** in 60% yield: IR (neat) 3320, 2930, 2850, 1660, 1460, 1280, 1110, 910, 800, 740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (6H, t, J=5 Hz), 1.25 (24H, brs), 2.39—2.92 (16H, m), 2.82 (8H, s), and 3.98 (4H, brs).

Extraction Procedure. Extractability of unsubstituted and 1,10-disubstituted hexaaza-18-crowns for metal cations was examined in a similar manner to the method described in the literature.[13] A dichloromethane solution (5 ml) of hexaaza-18-crown (5×10^{-5} mol·dm^{-3}) and an aqueous solution (5 ml) containing equivalents of metal hydroxide (or metal chloride+sodium hydroxide) and picric acid were agitated at 25 °C for 1 h. An aliquot of the upper aqueous solution was withdraw, and UV spectrum was recorded. A similar extraction was performed without hexaaza-18-crown. The extractability was determined on the basis of the absorbance of picrate ion in the aqueous solutions by means

of the following equation:

$$\text{extractability } (\%) = [(A_0 - A)/A_0] \times 100$$

where A_0 is the absorbance in the absence of hexaaza-18-crown and A is the absorbance in the presence of hexaaza-18-crown.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 61226004 from the Ministry of Education, Science and Culture.

(Received December 23, 1987)

Symmetrical tetraazapentalene derivatives **5** and **6** were synthesized by a convenient one-pot reaction using lithium thioureide/phenacyl chloride/alkyl (or allyl) isothiocyanate system. Unsymmetrical tetraazapentalene derivatives **8** were prepared by the reaction of various isothiocyanates with thiadiazolopyrimidine derivatives **7** which were derived from symmetrical tetraazapentalene derivatives. The structure of **5c** was determined by a single crystal X-ray diffraction.

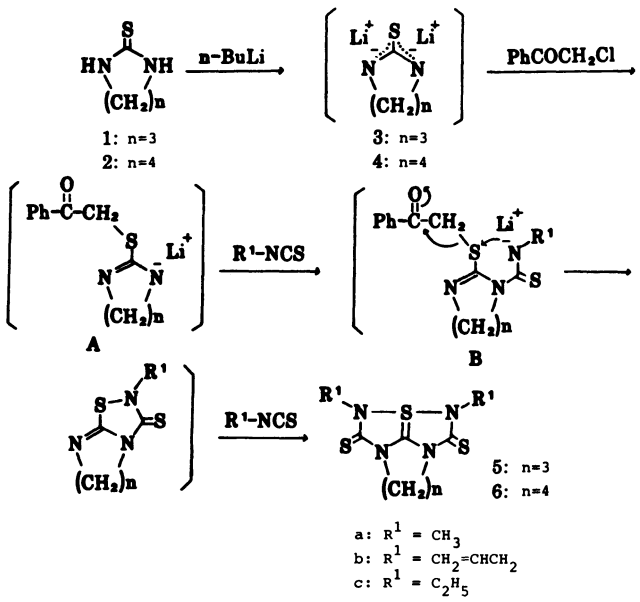
Chemistry of π-hypervalent heterocyclic systems related to 6a-thia(S^{IV})pentalene has been of considerable current interest, and several systems containing S–S^{IV}–S, S–S^{IV}–O, or N–S^{IV}–N bond and 10π-electrons in the framework were synthesized.[1] We have recently reported that the dianion **3** of 3,4,5,6,-tetrahydro-2(1*H*)-pyrimidinethione (**1**) reacted with methyl isothiocyanate to give 6,7-dihydro-2,3-dimethyl-5*H*-2a-thia(*2a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4-(2*H*,3*H*)-dithione (**5a**)[2] in low yield. Compounds of this type[3] containing π-hypervalent sulfur and 12π-electrons in the framework are of interest, because the structure, stability, and reactivity should be different from those of the other 6a-thia(S^{IV})pentalene analogs mentioned above. Recently, we have established general preparation of the symmetrical and unsymmetrical tetraazapentalene derivatives reported as preliminary communications.[4] In this paper, we describe the detail of preparation of symmetrical tetraazapentalene derivatives **5** and **6**, the first example of the X-ray crystallographic structure of a new heteropentalene, 6,7-dihydro-2,3-diethyl-5*H*-2a-thia-(*2a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*, 3*H*)-dithione (**5c**), and the smooth conversion of the symmetrical tetraazapentalene derivatives to the unsymmetrical ones **8** via selective elimination of alkyl (or allyl) isothiocyanate followed by 1,3-dipolar cycloaddition.

Results and Discussion

Synthesis of Symmetrical Tetraazapentalene Derivatives. Cyclic thioureas **1** and **2** were treated with two molar equivalents of butyllithium in tetrahydrofuran (THF) at 0 °C under argon. When the resulting dianions **3** and **4** were reacted with a molar equivalent of phenacyl chloride to give intermediate **A**, followed by addition of isothiocyanate (three molar equivalents), the tetraazapentalene derivatives **5** and **6** were obtained as colorless solids in good yields. These compounds are stable under the atmosphere.

The yields of products are shown in Table 1. The structures of **5** and **6** were determined by IR, ^{1}H NMR, ^{13}C NMR, mass spectra, and elemental analyses.

Scheme 1 shows a possible reaction mechanism for the formation of tetraazapentalenes, **5** and **6**. In this reaction, the formation of acetophenone was recognized. The yields of products depended on the ring size of cyclic thiourea and on the bulkiness of the alkyl group of alkyl isothiocyanate. When phenyl or *t*-butyl isothiocyanate was used in this reaction, no tetraazapentalene derivative was produced. The dianion **3**



Scheme 1.

Table 1. Preparation of Tetraazapentalene Derivatives[a]

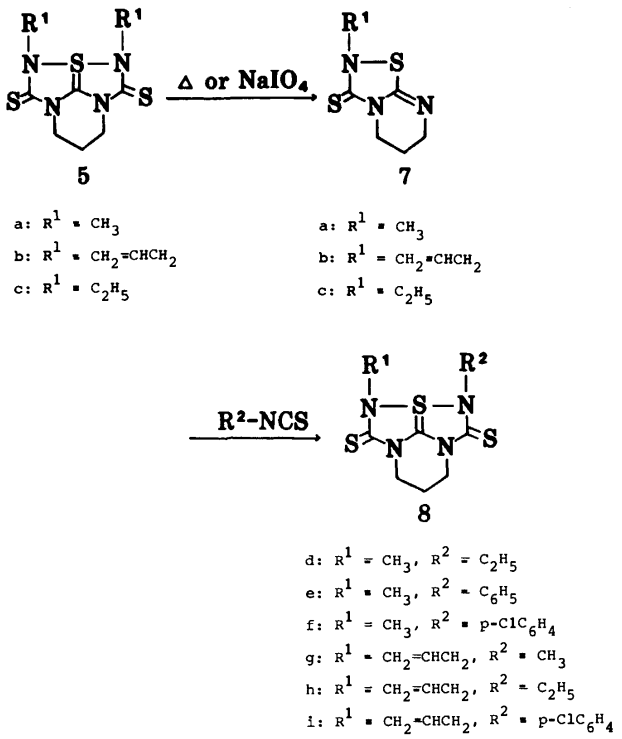
Entry	Dianion	R in R-NCS	Product	Yield/%[b]
1	**3**	CH_3	**5a**	74
2	**3**	CH_2=$CHCH_2$	**5b**	65
3	**3**	C_2H_5	**5c**	64
4	**4**	CH_3	**6a**	27
5	**4**	CH_2=$CHCH_2$	**6b**	9
6	**4**	C_2H_5	**6c**	14

a) The reactions were carried out in tetrahydrofuran at room temperature for 24 h under argon. b) Isolated yield.

derived from the 6-membered ring thiourea **1** gave tetraazapentalene derivatives more effectively than the dianion **4** derived from the 7-membered ring thiourea **2**. On the other hand, when a dianion derived from the 5-membered ring thiourea, 2-imidazolidinethione, was used in this reaction, tetraazapentalene derivative was not obtained. The intermediate derived from the 2-imidazolidinethione could not have favorable conformation for the attack of the nitrogen atom to the sulfur atom.

Synthesis of Unsymmetrical Tetraazapentalene Derivatives. The thermolysis or oxidation reaction of 6,7-dihydro-2,3-dimethyl-5*H*-2a-thia(2*a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (**5a**) gave easily 6,7-dihydro-2-methyl-5*H*-1,2,4-thiadiazolo[4,5-*a*]pyrimidine-3(2*H*)-thione (**7a**). Furthermore, **7a** was found to undergo a 1,3-dipolar cycloaddition with various isothiocyanates to give unsymmetrical tetraazapentalene derivatives having different groups at 3,4-positions (Scheme 2).

When the compounds **5** were heated at 170 °C under reduced pressure (2 mmHg, 1 mmHg≈133.322 Pa) or treated at room temperature with sodium periodate in methanol, the products **7** were obtained in moderate yields. The yields are shown in Table 2.



Scheme 2.

The thermolysis under reduced pressure (method A) is preferable to the oxidation reaction using $NaIO_4$ (method B) for the preparation of **7**. The structure of **7** was determined by IR, ^{1}H NMR, mass spectra, and elemental analyses. The compound **7** reacted smoothly with the isothiocyanates to give the unsymmetrical tetraazapentalene derivatives **8**. When the reaction of various isothiocyanates (1.5 times molar quantity of **7**) with **7** were carried out in refluxing chloroform for 3 h, the unsymmetrical tetraazapentalene derivatives **8** were obtained in good yields. The yields are shown in Table 3. All compounds were characterized by IR, ^{1}H NMR, ^{13}C NMR, UV, mass spectra, and elemental analyses.

Structure of Tetraazapentalene Derivatives. In order to establish the structure of the tetraazapentalene derivatives, a single crystal X-ray diffraction of **5c** was performed. The crystal of **5c** was most suitable for an X-ray diffraction among those of **5**, **6**, and **8**. Figure 1 shows the molecular structure of **5c**. Selected bond lengths and angles are listed in Table 4.

Figure 2 shows the molecular structure of **5c** viewed along the S(2)-C(1) bond and Table 5 shows the distance to the plane from the atoms in the molecule. The X-ray crystallographic analysis provides the following structural characteristics: (i) The S(1)-C(2) bond length [1.705 Å] is fairly shorter than the usual S(6a)-C(3) bond length [1.75 Å][5] of 6a-thia(S^{IV})pentalene analogs; (ii) the S(1)-N(1) [1.927 Å] and S(1)-N(2) [1.891 Å] bond lengths differ from each

Table 2. Preparation of Thiadiazolopyrimidine Derivatives **7**

	R^1	Method	Product	Yield/%

a) The reactions were carried out in refluxing chloroform for 3 h. b) Isolated yield.

other, and it means that **5** has an unsymmetrical structure; (iii) the S–N bond length [1.91 Å, average] is 9% longer than the usual S–N single bond length [1.74 Å];[6] the external C=S double bond length [1.68 Å, average] is 4% longer than the usual C=S double bond length [1.61 Å];[6] and (v) the tetraazapentalene framework can be regarded as planar, because the maximum distance between the framework atoms and the plane is only 0.013 Å as seen in Table 5. Figure 3 shows the drawing of the molecular packing.

In spite that the tetraazapentalene **5c** formally has four tertiary nitrogen atoms, the framework was elucidated to be planar by X-ray crystallographic analysis. This fact indicates much contribution from polar resonance contributors to the electronic structure of **5** as illustrated in Scheme 3. The extension of the external C=S double bond length is due to such polar resonance contributors. In accord with the planarity of the framework, the four nitrogen atoms may have nature of the sp^2 configuration. In the conjugated π-system, twelve π-electrons are well delocalized on the tetraazapentalene framework.

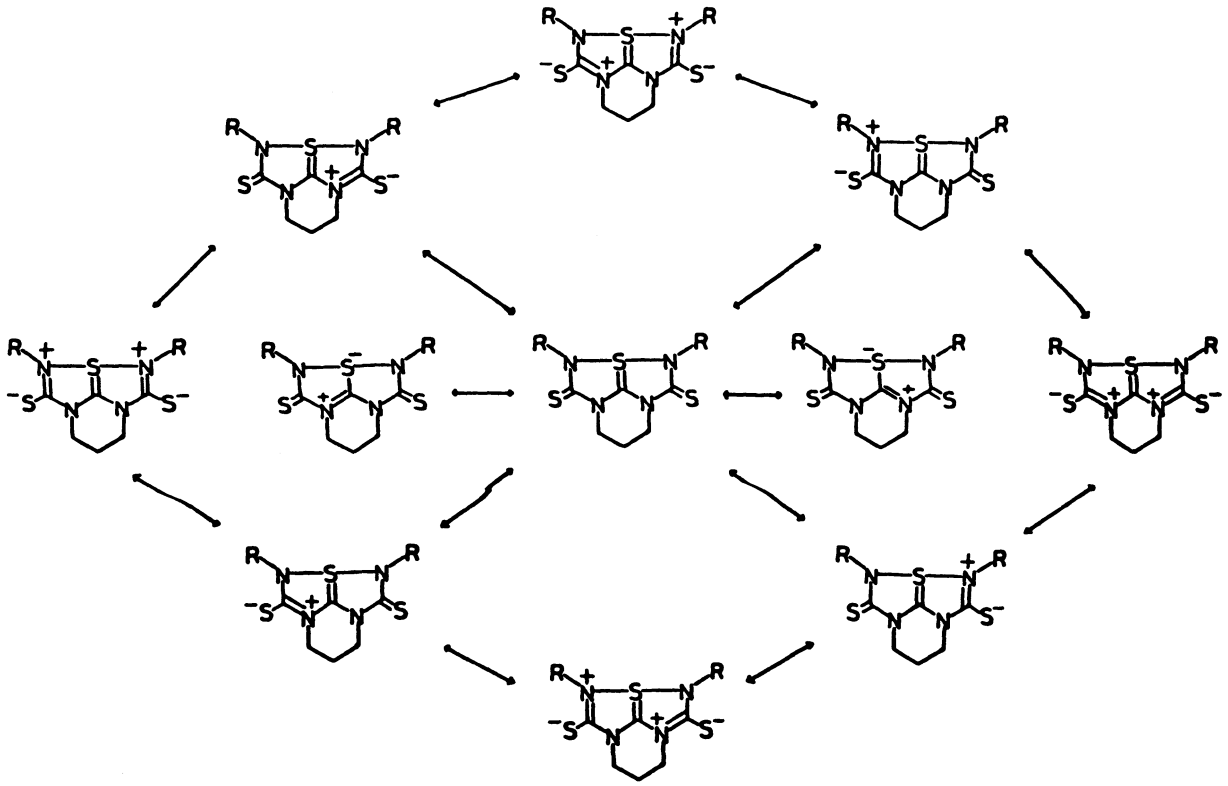

Scheme 3.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and were uncorrected. Proton magnetic resonance (^{1}H NMR) spectra were obtained using a Hitachi Perkin-Elmer R-24 spectrometer (60 MHz), JEOL FX-90Q (90 MHz), and JEOL JNM-GX270 (270 MHz). ^{13}C NMR spectra were obtained using a JEOL FX-90Q and JEOL JNM-GX270. Chemical shifts are reported in ppm from TMS as an internal standard and are given in δ units. The IR and UV spectra were determined on a Hitachi 215 Grating infrared spectrometer and Hitachi 124 spectrometer, respectively. Mass spectra were obtained with a SHIMADZU-LKB 9000 instrument equipped with a solid injector; the ionizing voltage was 70 eV. Purifications of products were conducted by column chromatography on silica gel (Wakogel C-300) or by preparative TLC on silica gel (Merck Kieselgel 60 GF_{254}).

General Procedure for the Preparation of Symmetrical Tetraazapentalene Derivatives 5 and 6. To a cooled THF solution (0 °C, 25 ml) of cyclic thiourea **1** or **2** (2.0 mmol) was added a hexane solution of butyllithium (4.4 mmol) with stirring at 0 °C under argon, and the mixture was stirred for 1 h under the same conditions. To the resulting dianion **3** or **4** was added dropwise a THF solution (5 ml) of phenacyl chloride (2.0 mmol). The solution immediately became wine red, and the reaction mixture was refluxed for 1 h under argon. After cooling to room temperature, the 5 ml of solution of alkyl isothiocyanate (6.0 mmol) in THF was added, and the reaction mixture was stirred at room temperature for 20 h under argon. After THF was evaporated, the residue was poured into an aqueous ammonium chloride. The solution was extracted with chloroform, and the extract was washed with water, dried over anhydrous Na_2SO_4, and condensed under reduced pressure. The residue was chromatographed on a silica-gel column or preparative TLC using dichloromethane as an eluent to give tetraazapentalene derivatives **5** or **6**. All tetraazapentalene derivatives were recrystallized from hexane–chloroform.

Spectroscopic data of 6,7-dihydro-2,3-dimethyl-5*H*-2a-thia(*2a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (**5a**) and 6,7-dihydro-2,3-diethyl-5*H*-2a-thia-(2a-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (**5c**) coincided with previously reported data.[2]

6,7-Dihydro-2,3-diallyl-5*H*-2a-thia(*2a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (5b). Mp 177—180 °C (decomp); IR (KBr) 2960, 1580, 1530, 1470, 1180, and 1160 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.37 (m, 2H, $NCH_2\underline{CH_2}CH_2N$), 4.36 (t of d, 4H, J=1.5 and 6.0 Hz, $2\times CH_2$=$CH\underline{CH_2}N$), 4.37 (t, 4H, J=6.0 Hz, $N\underline{CH_2}CH_2\underline{CH_2}N$), 5.20—5.28 (m, 4H, $2\times\underline{CH_2}$=$CHCH_2N$), and 5.88—6.02 (m, 2H, $2\times CH_2$=$\underline{CH}$-CH_2N); ^{13}C NMR ($CDCl_3$) δ=19.99, 44.84, 47.79, 118.10, 132.20, 156.66, and 169.57; UV (CH_3CN) 260 (log ε 4.52) nm; MS *m/z* (rel intensity) 213 (M^+-CH_2=$CHCH_2NCS$; 30), 99 (83), 72 (39), and 41 (100). Found: C, 46.02; H, 5.11; N, 17.91%. Calcd for $C_{12}H_{16}N_4S_3$: C, 46.12; H, 5.16; N, 17.93%.

5,6,7,8-Tetrahydro-2,3-dimethyl-2a-thia(*2a*-S^{IV})-2,3,4a,8a-tetraazacyclopent[*cd*]azulene-1,4(2*H*,3*H*)-dithione (6a). Mp 187—190 °C (decomp); IR (KBr) 2910, 1550, 1530, 1500, 1190, 1120, 1090 and 970 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.20 (m, 4H, $NCH_2\underline{CH_2}\underline{CH_2}CH_2N$), 3.15 (s, 6H, $2\times CH_3$), and 4.95 (m, 4H, $N\underline{CH_2}CH_2CH_2\underline{CH_2}N$); ^{13}C NMR ($CDCl_3$) δ=24.01, 31.49, 48.33, 161.49, and 170.78; UV (CH_3CN) 264 (log ε 4.56) nm; MS *m/z* (rel intensity) 201 (M^+-CH_3NCS; 91), 168 (32), 73 (100), 72 (81), and 69 (58). Found: C, 39.73; H, 5.19; N,

20.02%. Calcd for $C_9H_{14}N_4S_3$: C, 39.42; H, 5.15; N, 20.43%.

5,6,7,8-Tetrahydro-2,3-diallyl-2a-thia(2*a*-S^{IV})-2,3,4a,8a-tetraazacyclopent[*cd*]azulene-1,4(2*H*,3*H*)-dithione (6b). Mp 145—148 °C (decomp); IR (KBr) 2930, 2880, 1530, 1480, 1405, 1175, 1130, 1090, and 970 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.25 (m, 4H, $NCH_2C\underline{H}_2C\underline{H}_2CH_2N$), 4.33 (t of d, 4H, J=6.0 and 1.5 Hz, $2\times CH_2$=$CHC\underline{H}_2N$), 5.00 (m, 4H, $NC\underline{H}_2CH_2CH_2C\underline{H}_2N$), 5.20—5.27 (m, 4H, $2\times C\underline{H}_2$=$CHCH_2N$), and 5.87—6.02 (m, 2H, $2\times CH_2$=$C\underline{H}CH_2N$); ^{13}C NMR ($CDCl_3$) δ=23.96, 48.22, 48.38, 118.19, 132.01, 162.25, and 170.80; MS *m/z* (rel intensity) 227 (M^+-CH_2=$CHCH_2NCS$; 48), 194 (28), 114 (39), 99 (100), 72 (90), and 55 (50). Found: C, 47.30; H, 5.58; N, 17.01%. Calcd for $C_{13}H_{18}N_4S_3$: C, 47.82; H, 5.56; N, 17.16%.

5,6,7,8-Tetrahydro-2,3-diethyl-2a-thia(2*a*-S^{IV})-2,3,4a,8a-tetraazacyclopent[*cd*]azulene-1,4(2*H*,3*H*)-dithione (6c). Mp 159—162 °C (decomp); IR (KBr) 2960, 2920, 1550, 1530, 1430, 1190, 1080, and 980 cm^{-1}; ^1H NMR($CDCl_3$) δ=1.32 (t, 6H, J=7.3 Hz, $2\times CH_2C\underline{H}_3$), 2.24 (m, 4H, $NCH_2C\underline{H}_2C\underline{H}_2CH_2N$), 3.75 (q, 4H, J=7.3 Hz, $2\times C\underline{H}_2CH_3$), and 5.00 (m, 4H, J=5.6 Hz, $NC\underline{H}_2CH_2CH_2C\underline{H}_2N$); ^{13}C NMR ($CDCl_3$) δ=13.68, 24.01, 40.30, 48.08, 161.72, and 169.81; UV (CH_3CN) 264 (log ε 4.54) nm; MS *m/z* (rel intensity) 215 ($M^+-CH_3CH_2$-NCS; 65), 182 (17), 114 (25), 87 (100), 72 (62), 59 (61), and 55 (54). Found: C, 43.73; H, 6.30; N, 18.20%. Calcd for $C_{11}H_{18}N_4S_3$: C, 43.68; H, 6.00; N, 18.52%.

General Procedure for the Preparation of Thiadiazolopyrimidine Derivatives 7. Method A (Thermolysis of **5**): Thermolysis of **5** (200 mg) using sublimation apparatus was carried out at 170 °C for 5 h under reduced pressure (2 mmHg). Then the sublimation products were collected with chloroform and chromatographed on a preparative TLC (dichloromethane:ethyl acetate=4:1 as an eluent) to give **7** as a colorless solid. Method B (Oxidation of **5** with $NaIO_4$): To a methanol solution (50 ml) of **5** (0.23 mmol) was added a sodium periodate (0.33 mmol) with stirring at room temperature under argon. After the stirring was continued for 5 h, methanol was removed in vacuo. To the residual mixture was added chloroform (50 ml), stirred for 1 min, and the resulting suspension was filtered. After the filtrate was condensed under reduced pressure, the residue was chromatographed on a preparative TLC (dichloromethane:ethyl acetate=4:1 as an eluent) to give **7** as a colorless solid.

6,7-Dihydro-2-methyl-5*H*-1,2,4-thiadiazolo[4,5-*a*]pyrimidine-3(2*H*)-thione (7a). Mp 119—122 °C (decomp); IR(KBr) 2925, 2850, 1640, 1480, 1350, 1290, 1110, 945, and 750 cm^{-1}; ^1H NMR($CDCl_3$) δ=1.90 (m, 2H, $NCH_2C\underline{H}_2CH_2N$), 2.35 (s, 3H, CH_3), 3.55 (t, 2H, J=6.0 Hz, C=NCH_2), and 3.90 (t, 2H, J=6.0 Hz, NCH_2); MS *m/z* (rel intensity) 187 (M^+; 100), 154 (23), 72 (33), 69 (38), and 41 (26).

Picrate of 7a. Mp 196—200°C (decomp); Found: C, 34.60; H, 2.85; N, 20.12%. Calcd for $C_{12}H_{12}N_6O_7S_2$: C, 34.61; H, 2.90; N, 20.18%.

6,7-Dihydro-2-allyl-5*H*-1,2,4-thiadiazolo[4,5-*a*]pyrimidine-3(2*H*)-thione (7b). Mp 92—95 °C (decomp); IR (KBr) 2920, 2840, 1645, 1415, 1360, 1215, 1120, 855, and 835 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.10 (m, 2H, $NCH_2C\underline{H}_2CH_2N$), 3.65 (m, 2H, C=$NCH_2$), 4.00 (m, 2H, NCH_2), 4.55 (m, 2H, $NC\underline{H}_2CH$=CH_2), 5.20—5.65 (m, 2H, NCH_2CH=$C\underline{H}_2$), and 5.75—6.35 (m, 1H, $NCH_2C\underline{H}$=CH_2); MS *m/z* (rel intensity) 213 (M^+; 65), 180 (27), 128 (28), 100 (28), 99 (29), 72 (44), and 41 (100).

Picrate of 7b. Mp 171—174 °C (decomp); Found: C, 37.94; H, 3.02; N, 19.02%. Calcd for $C_{14}H_{14}N_6O_7S_2$: C, 38.01; H, 3.20; N, 18.99%.

6,7-Dihydro-2-ethyl-5*H*-1,2,4-thiadiazolo[4,5-*a*]pyrimidine-3(2*H*)-thione (7c). Mp 86—88 °C (decomp); IR (KBr) 2920, 2850, 1640, 1480, 1295, 1215, 1120, and 855 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30 (t, 3H, J=7.0 Hz, $CH_2C\underline{H}_3$), 2.05 (m, 2H, $NCH_2C\underline{H}_2CH_2N$), 3.55 (t, 2H, J=6.0 Hz, C=NCH_2), 3.95 (q, 2H, J=7.0 Hz, $C\underline{H}_2CH_3$), and 4.35 (t, 2H, J=6.0 Hz, NCH_2); MS *m/z* (rel intensity) 201 (M^+; 100), 83 (43), 72 (50), 55 (39), and 41 (42).

Picrate of 7c. Mp 207—209 °C (decomp); Found: C, 36.24; H, 3.17; N, 19.16%. Calcd for $C_{13}H_{14}N_6O_7S_2$: C, 36.28; H, 3.28; N, 19.52%.

General Procedure for the Preparation of Unsymmetrical Tetraazapentalene Derivatives 8. A mixture of **7** (0.3 mmol) and isothiocyanate (0.45 mmol, 1.5 times molar quantity of **7**) in chloroform (30 ml) was refluxed for 3 h. After the solvent was removed, the residue was chromatographed on a preparative TLC (dichloromethane as an eluent) to give **8**. Recrystallization from hexane-chloroform gave a pure sample as a colorless solid.

6,7-Dihydro-2-methyl-3-ethyl-5*H*-2a-thia(2*a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (8d). Mp 200—202 °C (decomp); IR (KBr) 2960, 2920, 1575, 1540, 1495, 1310, 1240, 1185, and 1120 cm^{-1}; ^1H NMR($CDCl_3$) δ=1.32 (t, 3H, J=7.2 Hz, $CH_2C\underline{H}_3$), 2.36 (m, 2H, $NCH_2C\underline{H}_2CH_2N$), 3.22 (s, 3H, CH_3), 3.78 (q, 2H, J=7.2 Hz, $C\underline{H}_2CH_3$), and 4.41 (t, 4H, J=6.0 Hz, $NC\underline{H}_2CH_2C\underline{H}_2N$); ^{13}C NMR($CDCl_3$) δ=13.86, 20.04, 31.15, 39.89, 44.67, 44.85, 156.00, 168.72, and 169.52; UV (CH_3CN) 259 (log ε 4.53) nm; MS *m/z* (rel intensity) 201 (M^+-CH_3NCS; 17), 187 ($M^+-CH_3CH_2NCS$; 25), 116 (22), 87 (100), 73 (89), 72 (45), 69 (22), and 59 (43). Found: C, 39.59; H, 5.31; N, 19.93%. Calcd for $C_9H_{14}N_4S_3$: C, 39.42; H, 5.15; N, 20.43%.

6,7-Dihydro-2-methyl-3-phenyl-5*H*-2a-thia(2*a*-S^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (8e). Mp 179—182 °C (decomp); IR (KBr) 2920, 1570, 1530, 1450, 1320, 1245, 1165, 1130, 955, and 785 cm^{-1}; ^1H NMR($CDCl_3$) δ=2.35 (m, 2H, $NCH_2C\underline{H}_2CH_2N$), 3.20 (s, 3H, CH_3), 4.40 (m, 4H, $NC\underline{H}_2CH_2C\underline{H}_2N$), and 7.30 (s, 5H, aromatic); UV (CH_3CN) 257 (log ε 4.49) nm; MS *m/z* (rel intensity) 249 (M^+-CH_3NCS; 2), 187 ($M^+-C_6H_5NCS$; 58), 154 (16), 135 (100), 77 (62), 72 (26), and 69 (29). X-Ray Crystallographic Analysis of 5c.[7] A colorless crystal of **5c** was grown from hexane–chloroform solution. The crystal shape was a hexagonal prism. A single crystal of dimensions 0.52×0.24×0.17 mm was selected for X-ray investigations. Data were collected on a Rigaku AFC-5 diffractometer using Mo $K\alpha$ radiation. Reflections in the range $2\theta \leq 55°$ were measured by the ω/θ–2θ scan technique with a scan width of $1.4°+0.5°\tan\theta$. The structure was solved by the direct method with MULTAN 78[8] and refined by block-diagonal least-squares to final R value of 0.043 for 1315 absorption corrected[9] independent reflection [$|F_o|>3\sigma(F_o)$]. The weighting scheme $w=[\sigma^2_{count}+(0.03|F_o|)^2]^{-1}$ was employed. Crystal data for **5c** are as follows: $C_{10}H_{16}N_4S_3$, M=288.433, monoclinic, space group $P2_1$, a=13.060(5) Å, b=9.988(3) Å, c=5.211(2) Å, β=98.31(3)°, U=672.6(4) Å^3, Z=2, D_c=1.42 g cm^{-3}, $F(000)$=304, μ(Mo $K\alpha$)=5.19 cm^{-1}.

Pharmaceuticals Research Center, Kanebo, Ltd., Tomobuchi-cho, Miyakojima-ku, Osaka 534
(Received January 5, 1988)

The reaction of rifamycin S and the quinonic 3-(hydrazonomethyl)rifamycin derivatives with sodium sulfinates under neutral conditions were found to afford the hydroquinone-type 4-*O*-sulfonyl derivatives of rifamycin. 3-Amino-4-deoxo-4-iminorifamycin S also gave rise to the hydroquinone-type 4-deoxy-4-sulfonylamino derivatives of rifamycin when treated with sodium sulfinates. Under acidic conditions, rifamycin S and 3-bromorifamycin S produced the hydroquinone- and quinone-type 3-sulfonyl derivatives of rifamycin, respectively, by reactions with sodium sulfinates. Some of sodium salts of 4-*O*-sulfonylrifamycin SV derivatives afforded rifamycin S and sodium sulfinates and/or sodium sulfonates when heated in AcOEt.

We have recently reported on the reaction of rifamycin S (**1A**) with sodium sulfite.[2)] In connection with this work, we investigated the reaction of **1A** with sodium *p*-toluenesulfinate (**2a**), which is anticipated to formally resemble sodium sulfite, and found the unusual formation of sulfonic ester sodium salt **4Aa** under neutral conditions. This paper describes the reaction of **1A** with **2a** under various conditions (alkaline, neutral, or acidic), the formation of sulfonic ester sodium salts **4**, sulfonic esters **5** and sulfonamides **9**, and the decomposition of some of **4A** in AcOEt.

Results and Discussion

Reaction of 1A with 2a. We have reported that the reaction of **1A** with sodium sulfite under mild alkaline conditions gives the 3-substituted product, sodium rifamycin SV-3-sulfonate.[2)] In connection with this

observation, **1A** was allowed to react with **2a** in an aq $NaHCO_3$–DMSO mixture (mild alkaline conditions). As a result, no products formed. However, in the absence of $NaHCO_3$ (neutral conditions) the reaction proceeded smoothly and almost quantitatively to produce a compound which fluoresced an orange color on a silica-gel TLC plate under an UV lamp (365 nm).[3] The reaction solution was poured into aq NaCl, and the extraction with AcOEt gave the sulfonic ester sodium salt **4Aa** in 85% yield. Sodium salt **4Aa** was converted to the corresponding acid form **5Aa** by acidification. The 4-*O*-sulfonyl structure of **5Aa** was deduced as follows. The UV spectrum (Table 2, footnote d) of **5Aa** resembling that[4] of rifamycin SV (**6A**), confirmed the 1,4-naphthalenediol derivative structure for **5Aa**; the NMR spectrum ($CDCl_3$) showed the signal at δ 7.42, which unfortunately overlapped with the signals of the *p*-tolyl group, but was attributed to the proton at the 3-position; the IR spectrum (KBr) showed the characteristic band of sulfonic ester at 1176 cm^{-1} ($\nu_s SO_2$). These spectral data suggested the 4-*O*-sulfonyl structure for **5Aa**, but the 1-*O*-sulfonyl structure is also possible. In order to distinguish these two possible structures, the 25-*O*-deacetyl derivative of **5Aa** was prepared from 25-*O*-deacetylrifamycin S[5] and **2a**. The IR spectrum ($CDCl_3$) of the 25-*O*-deacetyl derivative of **5Aa** clearly showed the furanone νC(11)=O band at 1709 cm^{-1} without disturbance of the 25-*O*-acetyl νC=O band.[6] This observation confirms the 4-*O*-sulfonyl structure for **5Aa**, because if **5Aa** takes the 1-*O*-sulfonyl structure the furanone νC(11)=O band should appear at ca. 1650 cm^{-1} due to the intramolecular hydrogen-bonding between the furanone C(11)=O group and the 4-OH group.[7] The furanone νC(11)=O band of the 25-*O*-deacetyl derivative of sodium salt **4Aa** in $CDCl_3$ appeared at 1675 cm^{-1}. A decrease of νC(11)=O in the salt form should be accounted for by the contribution of structure **7Aa**.

The formation mechanism of sulfonic ester is not clear, but the oxidation potential of **1A** seems to play an important role, because rifamycinol[5] (the 11-deoxo-11-hydroxy derivative of **1A**) did not react with **2a** under the same conditions as that described above.[8]

The reaction of **1A** with **2a** in aq AcOH (acidic conditions) produced 3-(*p*-tolylsulfonyl)rifamycin SV (**6F**) as a main product (9% yield) along with many complex products in which a trace amount of **5Aa** could be detected (analytical TLC). The IR spectrum ($CDCl_3$) of **6F** showed the characteristic bands of sulfone at 1292 ($\nu_{as}SO_2$) and 1137 cm^{-1} ($\nu_s SO_2$), and the singlet at δ 7.82 due to the proton at the 3-position of **1A** was absent in the NMR spectrum ($CDCl_3$).

Formation of Sulfonic Ester Sodium Salts 4A and Their Acid Form 5A, and Decomposition of Some of 4A in AcOEt. Similarly to **2a**, various sodium sulfinates were also found to react with **1A** under neutral conditions to afford sulfonic ester sodium salts **4A**, which upon acidification produced **5A**. The results are summarized in Tables 1 and 2. All sulfonic esters, except for **5Ac** and **5Ag**, fluoresced similarly to

5Aa. The formations of **4A** proceeded very cleanly, but **4A** and **5A** were proved to decompose during work up. Accordingly, the decomposition of some of **4A** in AcOEt, which was used as an extraction solvent, was next investigated. The sodium salts **4Aa**, **4Ac**, **4Ad**, and **4Af** were heated at 70 °C in a solution of AcOEt for several hours. As a result, each salt decomposed to afford **1A** as a main product and many complex compounds along with the formation of precipitates. The precipitate from **4Ac** was found to be sodium *p*-acetylbenzenesulfinate (**2c**) by a comparison of the NMR spectra (D_2O) with that of the authentic sample. The identification was also confirmed by the reaction of **1A** with the precipitate to afford the compound identical with **4Ac** (analytical TLC). The IR spectra (KBr) of the precipitates from **4Aa** and **4Af** showed the sulfonate $\nu_s SO_2$ bands at 1200 and 1190 cm^{-1}, respectively; these precipitates were confirmed to be sodium *p*-toluenesulfonate (**3a**) and sodium *p*-methoxybenzenesulfonate (**3f**), respectively, by comparing the NMR spectra (D_2O) with those of the authentic samples. The IR spectrum (KBr) of the precipitate from **4Ad** showed the sulfonate $\nu_s SO_2$ band at 1200 cm^{-1}, while its NMR spectrum (D_2O) showed that it consisted of two sorts of the compounds, sodium *p*-chlorobenzenesulfinate (**2d**) and sodium *p*-chlorobenzenesulfonate (**3d**) (molar ratio, 1:ca. 2). The results are summarized in Table 3. It is of interest that the decomposition reactions of sodium salts **4Aa**, **4Ac**, **4Ad**, and **4Af** in AcOEt commonly afforded **1A**, while the oxidation states of the precipitates were different depending upon the nature of the substituent involved in the phenylsulfonyl group. The mechanism of decomposition is not clear. Heating of **5Aa** in AcOEt at 70 °C for 4 h resulted in the decomposition of **5Aa** into many complex compounds in which **1A** could not be detected (analytical TLC).

Formation of Sulfones 6G and 6H. Sodium benzenesulfinate (**2b**) was allowed to react with **1A** in aq AcOH to afford 3-(phenylsulfonyl)rifamycin SV (**6G**) in 5% yield. On the other hand, it was observed by TLC analysis that the 1,4-naphthoquinone derivative **1G** could be produced in good yield by the reaction of 3-bromorifamycin S[9] (**1B**) with **2b** in aq AcOH. Indeed, 3-(methylsulfonyl)rifamycin SV (**6H**) was obtained in 63% yield by the reaction of **1B** with sodium methanesulfinate (**2i**) in aq AcOH followed by reduction with L-ascorbic acid.

Formation of Sulfonic Esters 5C—E. The reactions of the 3-(hydrazonomethyl)rifamycin derivatives **1C—E** with some of **2** under neutral conditions followed by acidification, afforded the corresponding sulfonic esters **5C—E**. The sulfonic ester structures of **5C—E** were supported by the characteristic $\nu_s SO_2$ bands of the sulfonic esters. The results are summarized in Table 4.

Formation of Sulfonamides 9. When 3-amino-4-deoxo-4-iminorifamycin S[10] (**8**) were treated with some of **2** under neutral conditions, the reaction proceeded almost quantitatively to afford sulfona-

Table 3. Decomposition of Sulfonic Ester Sodium Salts **4Aa**, **4Ac**, **4Ad**, and **4Af** in AcOEt at 70°C

Compound	Time/h	Isolation yield/% of **1A**	Identification of the precipitate (Yield/%)
4Aa	5.75	46	**3a** (ca. 71)
4Ac	4.75	70	**2c** (ca. 80)

mides **9** after acidification. The sulfonamide structures of **9** were supported by the characteristic $\nu_s SO_2$ bands of the sulfonamides. The results are summarized in Table 5. All sulfonamides in Table 5, except for **9g**, fluoresced similarly to **5Aa**.

Conclusion

Quinone- and quinone imine-type derivatives of rifamycin were found to react with sodium sulfinates under neutral conditions, giving the sulfonic esters and the sulfonamides, respectively. To our knowledge, only limited numbers of reports are concerned with the formation of sulfonic esters and sulfonamides in the reactions of quinonic or quinoniminic compounds with sulfinic acids or their salts.[11] Novel examples of such reactions are provided as described above.

Experimental

Analytical TLC was performed on Silica gel 60 F_{254} pre-coated plates (0.25 mm, Merck), using $CHCl_3$–CH_3OH (10:1 or 4:1) as a developing solvent. Preparative TLC was performed on Silica gel 60 F_{254} pre-coated plates (2 mm, Merck). IR spectra were measured on a JASCO IRA-1, a Shimadzu IR-440 spectrometer, or a Hitachi 270-50 infrared spectrometer. UV spectra were taken with a Shimadzu UV-210 spectrometer. Measurements of NMR spectra were carried out using a JEOL PS-100, a Hitachi R-24A spectrometer, or a Hitachi R-24B spectrometer. Tetramethylsilane was used as an internal reference for a solution of $CDCl_3$. NMR spectra of sodium sulfinates or sodium sulfonates were recorded in a solution of D_2O without an internal reference. Elemental analyses were performed with a Yanagimoto CHN-CORDER MT-3 or at the Elemental Analysis Center of Kyoto University.

Rifamycin Derivatives 1C—E. These compounds were prepared by oxidation of compounds[12] **6C—E** in $CHCl_3$ with MnO_2 (70%, Wako Pure Chemical Ind., Ltd.) followed by washing with dil H_2SO_4.

Sodium Sulfinates 2a—n and Sodium Sulfonates 3a, 3d, and 3f. Compounds **2a**, **2b**, **3a**, and **3d** were purchased. Compounds **2d**,[13a] **2g**,[13b] **2i**,[14b] **2j**,[14b] and **2k—n**[15] were prepared by the methods reported. Compounds **2c** and **2f** were prepared as **2d** from the corresponding sulfonyl chloride.[14a,16] Compound **2e** was prepared as **2g** from *p*-hydroxybenzenesulfonyl chloride.[17] Compound **2h** was prepared[18] from the corresponding sulfonyl chloride.[13c,d] Compound **3f** was prepared by hydrolysis of *p*-methoxybenzenesulfonyl chloride with $NaHCO_3$

Preparation of Sulfonic Ester Sodium Salts in Table 1 and the 25-*O*-Deacetyl Derivative of 4Aa. General Procedure: A solution of an excess amount of **2** in H_2O was added to a solution of **1A** in DMSO. After being stirred for several hours, the reaction mixture was poured into aq NaCl, and extracted with AcOEt. The combined extracts were washed with aq NaCl, dried over Na_2SO_4, then evaporated in vacuo. The resulting residue was precipitated from AcOEt–hexane, AcOEt–benzene, or AcOEt–benzene–hexane to afford **4A**, tabulated in Table 1. As a typical run, the preparation of **4Aa** is described below.

A solution of **2a** (2.16 g, 12 mmol) in H_2O (10 ml) was added to a solution of **1A** (2.00 g, 2.9 mmol) in DMSO (50 ml). After being stirred at r.t. for 3 h, the reaction mixture was treated according to the general procedure to afford 2.24 g (85% yield) of **4Aa** as a dark yellow powder after precipitation from AcOEt–benzene–hexane.

The 25-*O*-deacetyl derivative of **4Aa** was obtained from 25-*O*-deacetylrifamycin S[5] and **2a** in 82% yield. The 25-*O*-deacetyl derivative of **4Aa**: IR (KBr) 1175 cm^{-1} ($\nu_s SO_2$). IR ($CDCl_3$) 1675 cm^{-1} (νC(11)=O). Anal. ($C_{42}H_{50}NNaO_{13}S \cdot 1/2H_2O$) C, H, N.

Preparation of Sulfonic Esters 5Aa, 5Ac, 5Af, 5Ag, 5Aj and the 25-*O*-Deacetyl Derivative of 5Aa (Procedure A). General Procedure: A sodium salt **4A** was dissolved in AcOEt, then aq NaCl acidified with H_2SO_4 (acidic aq NaCl) was added to the solution. The mixture was shaken, and the organic layer was separated, washed with aq NaCl, dried over Na_2SO_4 or $MgSO_4$, and evaporated in vacuo. The resulting residue was precipitated from AcOEt–hexane or AcOEt–benzene–hexane to afford the title compounds. As a typical run, the preparation of **5Aa** is described below.

A solution of 1.13 g of **4Aa** in 80 ml of AcOEt was treated according to the general procedure, and the resulting residue was precipitated from AcOEt–hexane to afford 0.91 g (85% yield) of **5Aa** as a yellow powder. **5Aa:** ^1H NMR ($CDCl_3$) δ=2.33 (3H, s, the methyl protons of the *p*-tolylsulfonyl group), 7.04 (2H, d, the aromatic protons of the *p*-tolylsulfonyl group), 7.34—7.52 (3H, signals due to the aromatic protons of the *p*-tolylsulfonyl group and the proton at the 3-position).

The 25-*O*-deacetyl derivative of **5Aa** was obtained from the 25-*O*-deacetyl derivative of **4Aa** in 83% yield. The 25-*O*-deacetyl derivative of **5Aa**: IR (KBr) 1176 cm^{-1} ($\nu_s SO_2$). IR ($CDCl_3$) 1709 cm^{-1} (νC(11)=O). Anal. ($C_{42}H_{51}NO_{13}S \cdot H_2O$) C, H, N.

Preparation of Sulfonic Ester 5Ab (Procedure B). A solution of **2b** (0.19 g, 1.2 mmol) in H_2O (1 ml) was added to

a solution of **1A** (0.20 g, 0.29 mmol) in DMSO (8 ml). After being stirred overnight at r.t., the reaction mixture was poured into acidic aq NaCl. The resulting precipitate was collected, washed with acidic aq NaCl, and dissolved in AcOEt. The ethyl acetate solution was washed with aq NaCl, dried over $MgSO_4$, then evaporated in vacuo. The resulting residue was precipitated from AcOEt–benzene–hexane to afford 0.08 g (32% yield) of **5Ab** as a dark yellow powder.

Preparation of Sulfonic Esters 5Ad and 5Ae (Procedure C). As a typical run, the preparation of **5Ad** is described below.

A solution of **2d** (0.27 g, 1.4 mmol) in H_2O (1.5 ml) was added to a solution of **1A** (0.20 g, 0.29 mmol) in DMSO (7 ml). After being stirred overnight at r.t., the reaction mixture was treated by the same procedure as that described for **5Ab.** The resulting residue was separated on preparative TLC plates (4:1 $CHCl_3$–CH_3OH). The yellow band was collected and extracted with CH_3OH. AcOEt was added to the methanolic extract. The ethyl acetate solution was washed successively with acidic aq NaCl and aq NaCl, dried over $MgSO_4$, and evaporated in vacuo. The resulting residue was precipitated from AcOEt–hexane to afford 0.08 g (31% yield) of **5Ad** as a pale-yellow powder.

Compound **5Ae** was obtained from **1A** and **2e** in 16% yield.

Preparation of 3-Sulfonylrifamycin Derivatives 6F and 6G. As a typical run, the preparation of **6F** is described below.

A solution of **2a** (2.5 g, 14 mmol) in H_2O (20 ml) was added to a solution of **1A** (0.70 g, 1.0 mmol) in AcOH (30 ml). After being stirred at r.t. for 12 h, the reaction mixture was poured into H_2O. The resulting precipitate was collected, washed with H_2O, and dissolved in AcOEt. The ethyl acetate solution was washed with aq NaCl, dried over Na_2SO_4, and evaporated in vacuo. The resulting residue was separated on preparative TLC plates (two developments with 200:20:1 $CHCl_3$–EtOH–AcOH). The orange band was collected and extracted with CH_3OH. The methanolic solution was diluted with AcOEt, and the organic mixture was washed successively with acidic aq NaCl and aq NaCl, dried over Na_2SO_4, and evaporated in vacuo. The resulting residue was recrystallized from acetone to afford 0.08 g (9% yield) of **6F** as orange crystals. Mp ca. 180 °C (decomp). IR ($CDCl_3$) 1292 ($\nu_{as}SO_2$) and 1137 cm^{-1} (ν_sSO_2). ^1H NMR ($CDCl_3$) δ=2.41 (3H, s, the methyl protons of the *p*-tolylsulfonyl group), 7.28 (2H, d, the aromatic protons of the *p*-tolylsulfonyl group), 7.88 (2H, d, the aromatic protons of the *p*-tolylsulfonyl group). Anal. ($C_{44}H_{53}NO_{14}S \cdot 1/2H_2O$) C, H, N.

Physical data of **6G** are as follows. Mp ca. 174 °C (decomp). IR ($CDCl_3$) 1295 ($\nu_{as}SO_2$) and 1140 cm^{-1} (ν_sSO_2). ^1H NMR ($CDCl_3$) δ=7.3—7.7 (3H, m, the aromatic protons of the phenylsulfonyl group), 7.9—8.1 (2H, d, the aromatic protons of the phenylsulfonyl group). Anal. ($C_{43}H_{51}NO_{14}S \cdot H_2O$) C, H, N.

Preparation of 3-(Methylsulfonyl)rifamycin SV (6H). A solution of **2i** (0.47 g, 4.6 mmol) in H_2O (1 ml) was added to a solution of 3-bromorifamycin S[9] (**1B**) (0.50 g, 0.65 mmol) in AcOH (6 ml). After being stirred at r.t. for 40 min, the reaction mixture was poured into H_2O. The resulting precipitate was collected, washed with H_2O, and dissolved in AcOEt. The ethyl acetate solution was added to a solution of 2.5 g of L-ascorbic acid in aq CH_3OH. The mixture was shaken for several min, washed with aq NaCl, dried over $MgSO_4$, and evaporated in vacuo. The resulting residue was purified by preparative TLC in a similar manner to that described for **6F**, affording 0.32 g (63% yield) of **6H** as an orange powder after precipitation from AcOEt–ligroine. Mp ca. 204 °C (decomp). IR ($CDCl_3$) 1290 ($\nu_{as}SO_2$) and 1125 cm^{-1} (ν_sSO_2). ^1H NMR ($CDCl_3$) δ=3.50 (3H, s, the methyl protons of the methylsulfonyl group). Anal. ($C_{38}H_{49}NO_{14}S$) C, H, N.

Decomposition of Sulfonic Ester Sodium Salts 4Aa, 4Ac, 4Ad, and 4Af in AcOEt. As a typical run, the decomposition of **4Aa** is described below.

A 300 mg of **4Aa** was dissolved in 20 ml of AcOEt. After being stirred at 70 °C for 5.75 h, the resulting precipitate was collected by filtration and washed with AcOEt, affording 46 mg of a brownish powder. IR (KBr) 1200 cm^{-1}. The NMR spectrum in D_2O was identical with that of the authentic sample of **3a**. The filtrate and the washings were combined and evaporated in vacuo. The resulting residue was separated by a preparative TLC plate (10:1 $CHCl_3$–CH_3OH). The yellow band was collected and extracted with CH_3OH. The methanolic solution was diluted with AcOEt, and the organic mixture was washed successively with a mixture of a pH 4 buffer and aq NaCl and aq NaCl, dried over $MgSO_4$, and evaporated in vacuo. The resulting residue was crystallized from *i*-C_3H_7OH to afford 116 mg of yellow crystals. The IR spectrum in $CHCl_3$ was identical with that of **1A**.

Preparation of Sulfonic Esters in Table 4. These compounds were prepared from 3-(hydrazonomethyl)rifamycin derivatives **1C—E** and **2** by a similar procedure to that described for **5Ad**. As developing solvents for preparative TLC, AcOEt–CH_3OH (60:1—20:1) or $CHCl_3$–CH_3OH (10:1) was used. AcOEt–hexane or AcOEt–ligroine was used as a crystallizing solvent.

Preparation of Sulfonamides in Table 5. General Procedure: A solution of an excess amount of **2** in H_2O was added to a solution of 3-amino-4-deoxo-4-iminorifamycin S[10] (**8**) in DMSO. After being stirred at r.t. for several min, the reaction mixture was poured into aq NaCl and extracted with $CHCl_3$. The chloroform extracts were combined and reextracted with H_2O. The aqueous layers were extracted again with $CHCl_3$ under acidic conditions which were made by addition of dil H_2SO_4. The combined extracts were washed with aq NaCl, dried over Na_2SO_4, and evaporated in vacuo. The resulting residue was precipitated from $CHCl_3$–hexane to afford a sulfonamide **9** in Table 5. As a typical run, the preparation of **9h** is described below.

A solution of **2h** (0.13 g, 0.59 mmol) in H_2O (0.4 ml) was added to a solution of **8** (0.14 g, 0.20 mmol) in DMSO (2.4 ml). After being stirred at r.t. for 5 min, the reaction mixture was treated according to the general procedure, affording 0.13 g (70% yield) of sulfonamide **9h** as a yellow powder.

Reaction of Rifamycin S with Hexahydro-1,3,5-triazines Prepared from Formaldehyde and Primary Aliphatic Amines

Masahiro TAGUCHI,* Norio AIKAWA, and Goro TSUKAMOTO
Pharmaceuticals Research Center, Kanebo, Ltd., Tomobuchi-cho, Miyakojima-ku, Osaka 534
(Received January 5, 1988)

Rifamycin S (**1**) and 25-*O*-deacetylrifamycin S reacted with 1,3,5-tri-*t*-butylhexahydro-1,3,5-triazine to give deep-blue compounds. The structures of the deep-blue compounds are discussed based on ^{13}C NMR data, and it is concluded that the earlier structures[1] should be partly re-revised. The mechanism of formation of the deep-blue compounds and the reaction of **1** with several hexahydro-1,3,5-triazines, which were prepared from formaldehyde and primary aliphatic amines, are also described.

We previously reported[1] that rifamycin S (**1**) was allowed to react with 1,3,5-tri-*t*-butylhexahydro-1,3,5-triazine (**2c**) to afford a characteristic deep-blue colored compound, which was identical with the compound prepared according to the method of Marsili and Pasqualucci,[2] who proposed that the structure of the deep-blue compound was **3c**. We suggested[1] that the deep-blue compound did not consist of an oxazinium ring but, rather, a dihydropyrimidinium ring. We partly revised the earlier structure, **4c**, suggested by Maggi et al.,[3-5] in which the 4-hydroxyl group was dissociated, to the enolized structure, **5c**, based on the IR spectral data and the interpretation[3] of Maggi et al. on a polarographic oxidation wave.[1] Here, we report that the structure of the deep-blue compound should be re-revised based on the ^{13}C NMR data to **6c** in which the 8-hydroxyl group is dissociated. Moreover, the mechanism of formation of the deep-blue compound and the reaction of **1** with several hexahydro-1,3,5-triazines **2** prepared from formaldehyde and aliphatic primary amines are reported.

Results and Discussion

The Structure of the Deep-Blue Compound Obtained in the Reaction of 1 with 2c. We previously suggested that the deep-blue compound, **A**, which was obtained in the reaction of **1** with **2c**, had the enolized structure **5c**.[1] The suggestion was based on the IR spectral data of **A** and its 25-*O*-deacetyl derivative **B** (no furanone νC(11)=O band was observed at ca. 1740 cm^{-1}; the amide νC(15)=O band was observed at ca. 1660 cm^{-1}) and the interpretation of Maggi et al.[3] on a polarographic oxidation wave. Later, we prepared *N*-methylrifamycin S (**8**),[6] 25-*O*-deacetyl-4-*O*-(*p*-tolylsulfonyl)rifamycin SV (**9**) and its sodium salt (**10**),[7] and from their IR spectral data ($CDCl_3$) we knew that the amide νC(15)=O band might appear at rather low frequency, owing to a structural factor of the amide group (**8**, tertiary amide, 1659 cm^{-1}) and that the furanone νC(11)=O band also might appear at rather low frequency, owing to a dissociation of the 8-hydroxyl group (**9**, 1709cm^{-1}; **10**, 1675 cm^{-1}). Moreover, it has been known that the occurrence of a polarographic two-step oxidation wave can be interpreted as being due to the presence of a stable intermediate radical,[8] but not due to the nonequivalence of the hydroquinone hydroxyls, the interpretation of Maggi et al.[3] This information brought us another possible structure, **6c**, in which the 8-hydroxyl group was dissociated, to the chromophores of **A** and **B**. The structure **6c** can be used to interpret the IR

spectral data of **A** and **B**, as well as their characteristic ^{1}H NMR spectral data, which showed two singlets due to the phenolic hydroxyl protons in the very low field (**A**, δ 16.57 and 14.87; **B**, δ 16.44 and 14.74). Namely, the amide νC(15)=O band appears at a rather low frequency (ca. 1660 cm^{-1}), owing to the structural factor of the amide group (tertiary amide), not owing to an intramolecular hydrogen bonding between the amide C(15)=O and the 1-hydroxyl group. The furanone νC(11)=O band appears at low frequency, perhaps at ca. 1590 cm^{-1} owing to dissociation of the 8-hydroxyl group and an intramolecular hydrogen bonding between the furanone C(11)=O and 4-hydroxyl group. The large chemical shift values of the two phenolic hydroxyl protons are due to strong intramolecular hydrogen bonding between the ionized 8-hydroxyl group and the 1-hydroxyl group and between the furanone C(11)=O and the 4-hydroxyl group (the oxygen atom of the furanone C(11)=O is considered to be charged much negatively due to contribution of a limiting structure **7c**). The possible structure of **6c** was substantiated by ^{13}C NMR data. Chemical shifts and assignments in ^{1}H and ^{13}C NMR spectra of **A** (**6c**) and **B** (25-OH-**6c**) in $CDCl_3$ are summarized in Tables 1—3. Assignments for protons and carbon atoms, except for two phenolic hydroxyl protons and all quaternary carbon atoms, were made based on H–H and C–H correlation spectroscopy. For assignments of quaternary carbon atoms, proton nondecoupling spectra were recorded, and assignments were performed with reference to the chemical shifts and the multiplicities of the quaternary carbon atoms of rifampicin (**11**) and 3-[(dimethylhydrazono)methyl]rifamycin SV.[9] The assignments for the

two phenolic hydroxyl protons were carried out by long-range selective proton decoupling (LSPD) experiments. The results of LSPD experiments for **B** (25-OH-**6c**) are summarized in Table 4.[10] The LSPD of the δ 14.59 proton affected the signals at 118.92 and 107.58, which were attributed to C-10 and C-3, respectively; hence, the δ 14.59 proton are assigned to the 4-hydroxyl proton. This implies that the 4-hydroxyl proton is not dissociated. The LSPD of the δ 16.44 proton affected the signals at 147.11 and 121.67, which were attributed to C-1 and C-2, respectively; hence, the 1-hydroxyl proton is also not dissociated. Therefore, the remaining 8-hydroxyl proton must be dissociated. The signals due to C-8 of **A** (**6c**) and **B** (25-OH-**6c**) are shifted downfield compared with that of **11** for 14 ppm (**A**, 183.29; **B**, 183.39; **11**, 169.19). This phenomenon is interpreted in terms of the contribution of a limiting structure **7c**,[11] and supports the structure of **6c**, in which the 8-hydroxyl group is completely dissociated. Thus, the structures of the deep-blue compounds, which have been reported by Marsili and Pasqualucci,[2] Maggi et al.,[3-5] and the authors,[1,12,13] should be revised to structures comprising a dihydropyrimidinium ring in which the 8-hydroxyl group is dissociated.

Mechanism of the Formation of Compound 6c. The process of the reaction of **1** with **2c** in pyridine at 63 °C was investigated by analytical silica-gel TLC. In the early stages of the reaction (after ca. 30 min from beginning) an intermediate product **C**, **6c** and the remaining starting material **1** were detected. At the end of the reaction (after ca. 1.5 h from beginning) **C** and **1** disappeared, while 3-[(*t*-butylamino)methylene]rifamycin (**12c**)[14] and rifamycin SV (**14**) as well as **6c** were detected. From this reaction mixture, **6c** was isolated in 38% yield. The intermediate product **C** was detected more clearly when the reaction was carried out at r.t., and it was considered that **C** was an intermediate for **6c**, because two-dimensional TLC showed that **C** gradually transformed on TLC plates into several compounds in which **6c** was included. Attempts to isolate **C** were not successful, due to its instability. However, it was observed by TLC that L-ascorbic acid reduced **C**, while the resulting reduction product **D** reverted to **C** upon treatment with MnO_2. The reduction product **D** was also observed by TLC to be the same compound which was formed by reduction of **6c** with $NaBH_4$ in EtOH. Additionally, it was observed by TLC that 3-[(*t*-butylamino)methyl]rifamycin S (**13c**), which was prepared by oxidation of 3-[(*t*-butylamino)methyl]rifamycin SV (**15c**) with MnO_2, transformed immediately and completely into **C** by treatment with **2c** in pyridine at r.t., and after warming at 62 °C for 1 h **6c** was obtained in 41% yield.[15] These facts imply that the structure of the intermediate product **C** can be assigned to **17c**, and it is concluded that in the reaction of **1** with **2c** the Mannich derivative **13c** is formed at first, then **17c**, and finally **6c** is formed by isomerization of **17c**. The formation of **17c** from **13c** is very fast, and this is the reason for the failure of the detection of **13c** by TLC. It is described above that **12c** and **14** were also detected at the end of the reaction of **1** with **2c**. This is interpreted as meaning that **6c** partly underwent aminolysis into **16c** by the action of *t*-butylamine, which was released during the course of the reaction; then, the redox reaction between the resulting **16c** and the remaining **1** proceeded to afford **12c** and **14**. In fact, it was observed by TLC that **12c** and **14** were formed by treating **6c** with *t*-butylamine

in the presence of **1** in pyridine at 65 °C.

Reaction of 1 with Other Hexahydro-1,3,5-triazines 2. Hexahydro-1,3,5-triazine **2d** reacted with **1** exactly like **2c**, and at the end of the reaction **6d**, **12d** and **14** were detected by TLC. The isolation yield of **6d** was 48%. Hexahydro-1,3,5-triazines **2a**, **2b**, or **2e** also reacted with **1**, but the results of the reaction were very different from the results described for **2c** and **2d**. The yields of compounds **6a**, **6b**, or **6e** were very low and the major products were observed by TLC to be the hydroquinone-type derivatives **18a**, **18b**, or **18e** and **14**. The formations of **12a**, **12b**, or **12e** were not observed. These different results from that of a reaction of **1** with **2c** or **2d** are attributed to the reducing power of hexahydro-1,3,5-triazines **2a**, **2b**, and **2e**.[12] As a representative example the result of the reaction of **1** with **2a** is interpreted as follows. At first, compound **17a** is formed via **13a**, then isomerizes into **6a**; however, the iminium bond of **6a** is reduced with the remaining **2a**, and **18a** is formed. The redox reaction between **18a** and the remaining **1** results in the formation of **17a** and **14**. Thus, the transformation of **1** into **18a** and **14** continues until **1** disappears; at the end of the reaction, **18a** and **14** are formed as major

a) Pyridine was used as a solvent. b) The 25-O-deacetyl derivative of **1** was used.

products, while **6a** is obtained in very low yield. The results are summarized in Table 5.

Experimental

Analytical TLC was performed on silica gel 60 F_{254} pre-coated plates (layer thickness 0.25 mm, Merck), using $CHCl_3$–CH_3OH (10:1) as a developing solvent. Preparative TLC was performed on silica gel 60 F_{254} pre-coated plates (layer thickness 0.5 mm, Merck). ^1H NMR spectra were recorded on a JEOL PS-100 spectrometer or a Bruker AM-300 spectrometer and TMS was used as an internal reference. ^{13}C NMR spectra were recorded on a Bruker AM-300 spectrometer and TMS was used as an internal reference. IR spectra were obtained with a Hitachi Perkin-Elmer model 225 spectrometer. UV spectra were obtained with a Shimadzu UV-210A spectrometer. Melting points were measured with a Yanagimoto micro melting-point apparatus and are uncorrected. Elemental analyses were performed with a Yanagimoto CHN-CORDER MT-3 or at the Elemental Analysis Center of Kyoto University.

Preparation of Hexahydro-1,3,5-triazines 2a—e. A similar method to that described by Smolin and Rapoport[16] was employed. Under cooling with ice-cold water, formalin was gradually added to an equimolar amount of amine. Isolation procedures were as follows.

2a, 2b, and 2d: A powder of K_2CO_3 was added to the reaction solution, and the products were extracted with $CHCl_3$. The extract was dried over K_2CO_3, evaporated in vacuo, and the residue was distilled. **2a**: Bp 40—42 °C/15 mmHg.** **2b**: Bp 63 °C/7 mmHg. In the case of **2d**, *N*-methylene-*t*-pentylamine (bp 92—93 °C) was obtained by distillation; however, this *N*-methyleneamine trimerized spontaneously into **2d** on standing.

2c: Pellets of NaOH were added to the reaction solution, and the resulting organic layer was separated, dried over KOH, and distilled in the presence of *d*-10-camphorsulfonic acid to afford *N*-methylene-*t*-butylamine (bp 67—68 °C); however, this *N*-methyleneamine trimerized spontaneously into **2c** on standing.

2e: The reaction products were extracted with ether, then the extract was dried over NaOH, evaporated in vacuo, and the residue was recrystallized from hexane. Mp 72—73 °C.

Reaction of 1 with Hexahydro-1,3,5-triazines 2a—e. As a typical run, the reaction of **1** with **2c** is described below.

To a solution of 300 mg of **1** in 3 ml of pyridine was added 76 mg of **2c**. After being stirred at 63 °C for 1.5 h, the reaction solution was poured into 10% AcOH, and the products were extracted with AcOEt. The extract was washed with 10% AcOH, brine, dried over Na_2SO_4, and evaporated in vacuo, then preparative TLC was carried out using $CHCl_3$–CH_3OH (20:1) as a developing solvent. The deep blue band was collected, and extracted with $CHCl_3$–CH_3OH (10:1). The extract was evaporated in vacuo, and the residue was further purified by column chromatography (Wakogel C-200, 10 g, Wako Pure Chemical Ind., Ltd.) using $CHCl_3$–CH_3OH (100:1, then 50:1) as an eluent. The deep-blue eluate was collected, and evaporated in vacuo to afford 133 mg (yield, 38%) of **6c** as a deep-blue powder. The reaction conditions and yields of **6a—e** are summarized in Table 5. The 25-*O*-deacetyl derivative of **6c** was prepared from 25-*O*-deacetylrifamycin S[17] and **2c**. Compounds **6a,b**, and **6e** were identical with authentic samples.[12] ^1H and ^{13}C NMR data of **6c** and its 25-*O*-deacetyl derivative are summarized in Tables 1—4. Other physical data of **6c** and its 25-*O*-deacetyl derivative have already been reported.[1] **6d**: UV λ_{max} (CH_3OH) 225 (log ε 4.58), 276 (4.35), 314 (sh, 4.17), 360 (4.28), and 600 nm (4.03); IR ($CHCl_3$) 3440, 1720, 1655 and 1580 cm^{-1}; ^1H NMR ($CDCl_3$) δ=9.00 (1H, s, iminium proton), 15.02 (1H, s, 4-OH), and 16.52 (1H, s, 1-OH). Found: C, 61.66; H, 6.95; N, 3.12%. Calcd for $C_{44}H_{58}N_2O_{12}\cdot 3H_2O$: C, 61.38; H, 7.14; N, 3.25%.

Preparation of 15c. To a solution of 8.0 g of 3-formylrifamycin SV[18–20] in 50 ml of pyridine was added 4.0 g of *t*-butylamine. The mixture was stirred at r.t. for 10 min; then 0.5 g of $NaBH_4$ was added to the mixture at 0 °C. After being stirred at 0 °C for 10 min, the reaction mixture was added to 1 l of cold 10% H_2SO_4. The products were extracted with AcOEt, and the extract was washed with H_2O, dried over Na_2SO_4, and evaporated in vacuo. The residue was dissolved in $CHCl_3$–AcOEt (1:1), and the solution was concentrated in vacuo to afford 2.0 g (yield, 22%) of **15c** as orange crystals. ^1H NMR ($CDCl_3$, after treatment with D_2O) δ=1.51 (9H, s, *t*-butyl), 3.76 (1H, d, *J*=11 Hz, $C\underline{H}_2NH$), and 4.15 (1H, d, *J*=11 Hz, $C\underline{H}_2NH$). Found: C, 62.08; H, 7.35; N, 3.62%. Calcd for $C_{42}H_{58}N_2O_{12}\cdot 3/2H_2O$: C, 62.28; H, 7.59; N, 3.45%.

Reaction of 13c with 2c. To a solution of 200 mg of **15c** in 20 ml of $CHCl_3$ was added 2.0 g of MnO_2 (70%, Wako Pure Chemical Ind., Ltd.). After being stirred at r.t. for 15 min, the mixture was filtered, and the filtrate was evaporated in vacuo. The residue, in which **13c** and **12c** were included,[15] was dissolved in 4 ml of pyridine, and to the solution 23 mg of **2c** was added. After being stirred at 62 °C for 1 h, the reaction mixture was extracted with AcOEt under acidic conditions (10% AcOH). The extract was washed with brine, dried over Na_2SO_4, and evaporated in

** (1 mmHg≈133.33 Pa.)

vacuo; then, preparative TLC was carried out using $CHCl_3$–CH_3OH (10:1) as a developing solvent. From the orange band 40 mg (yield, 20%) of **12c** was obtained (AcOEt was used as an eluent). From the deep-blue band 85 mg (yield, 41%) of **6c** was obtained (10:1 $CHCl_3$–CH_3OH was used as an eluent).

The authors wish to express their thanks to Mr. Yukinobu Yamane, Development Research Laboratories, Kanebo, Ltd., for obtaining the NMR spectra and his helpful discussions.

The Synthesis of *C*-Methyl Branched-Chain Deoxy Sugar Nucleosides by the Deoxygenative Methylation of *O*-Tosylated Adenosines with Grignard Reagents[1)]

Masajiro KAWANA,* Kikuko TAKEUCHI, Takayo OHBA, and Hiroyoshi KUZUHARA
RIKEN (The Institure of Physical and Chemical Research),
Wako, Saitama 351-01
(Received January 7, 1988)

The reaction of appropriately protected 2′-*O*-tosyladenosines with methylmagnesium bromide (or iodide) gave 9-(2-deoxy-3-*C*-methyl-β-D-*threo*-pentofuranosyl)adenine after deprotection. The same reaction on 3′-*O*-tosyladenosine derivatives afforded an epimeric pair of 2′-*C*-methyl-3′-deoxy sugar nucleosides. The modified structures of the sugar moieties were determined unambiguously.

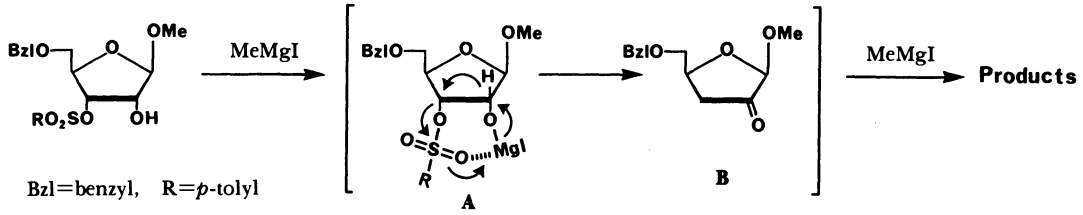
There has been considerable interest during the past decade in the synthesis and chemistry of branched-chain sugar nucleosides,[2)] because modification of the sugar moieties has produced compounds with biologically interesting properties. Walton et al.[3)] reported that 2′-*C*- and 3′-*C*-methyladenosines were resistant to adenosine deaminase (adenosine aminohydrolase; EC 3.5.4.4) and that they exhibited inhibitory activity against KB cells in a culture. These findings prompted us to develop a convenient method for synthesizing a new type of adenosine analogue, branched-chain deoxy sugar nucleosides.

Previously we have described that methyl 5-*O*-benzyl-2-*O*- or -3-*O*-tosyl-β-D-ribofuranosides reacted with methylmagnesium iodide (MeMgI) to produce the corresponding 2-deoxy-3-*C*- or 3-deoxy-2-*C*-methyl branched-chain sugar furanosides in an efficient one-pot procedure.[4)] These reactions involved a [1,2]-hydride shift and a concerted elimination of a sulfonyloxy group, as is depicted in **A** (Scheme 1).[5)] The resulting α-deoxygenated keto sugar **B** was converted into products in the presence of an excess of MeMgI.[6)] We have now extended the scope of this reaction to the preparation of adenosine analogues. (A preliminary report on this work has been published.)[7)] During the course of this work, a report on the preparation of 1-(2-deoxy-3-*C*-methyl-5-*O*-trityl-β-D-*erythro*-pentofuranosyl)uracil by using 2′-*O*-tosyl-5′-*O*-trityluridine and MeMgI appeared.[8)]

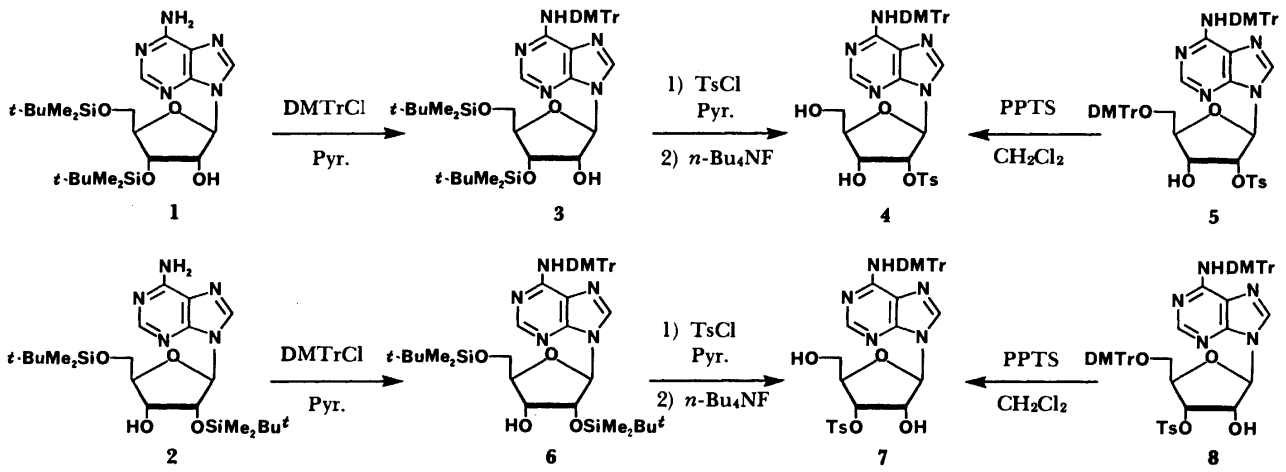
Results and Discussion

Appropriately protected 2′-*O*- and 3′-*O*-tosyladenosines were prepared from adenosine by the operations outlined in Scheme 2. Thus, the silylation of adenosine with *t*-butyldimethylsilyl chloride according to the method of Ogilvie et al.[9)] gave a mixture of 3′,5′-di-*O*- and 2′,5′-di-*O*-sililated adenosines (**1** and **2**), along with a 2′,3′,5′-tri-*O*-protected derivative; the compounds were isolated in a ratio of 51:41:8 by silica-gel column chromatography. The protection of an NH_2 group in **1** with 4,4′-dimethoxytrityl chloride (DMTrCl) afforded the corresponding N^6-(4,4′-dimethoxytrityl) derivative **3** in a good yield. A similar reaction conducted with **2** and DMTrCl gave the N^6-protected compound **6**. The conventional tosylation of **3**, followed by deprotection with tetrabutylammonium fluoride,[9b)] gave N^6-(4,4′-dimethoxytrityl)-2′-*O*-tosyladenosine (**4**). Alternatively, **4** was prepared from N^6,$O^{5'}$-bis(4,4′-dimethoxytrityl)-2′-*O*-tosyladenosine[6i)] (**5**) by the selective detritylation of **5** with pyridinium *p*-toluenesulfonate (PPTS).[10)] Similarly, N^6-(4,4′-dimethoxytrityl)-3′-*O*-tosyladenosine (**7**) was obtained from **6** or N^6,$O^{5'}$-bis(4,4′-dimethoxytrityl)-3′-*O*-tosyladenosine (**8**).[6i)] The conventional tritylation of 2′-*O*-tosyladenosine provided the corresponding 5′-*O*-trityl derivative **9**.[6c,11)]

The deoxygenative methylations of **4**, **5**, and **7**—**9** were carried out in dry benzene with methylmagnesium bromide (MeMgBr; in tetrahydrofuran) or MeMgI (in diethyl ether) at room or an elevated temperature (Scheme 3). The products were not purified but were directly deblocked with 80% acetic acid or zinc bromide ($ZnBr_2$);[12)] in the former case, a depurination from 2′-deoxy nucleosides took place to some extent during the reaction and work-up. The

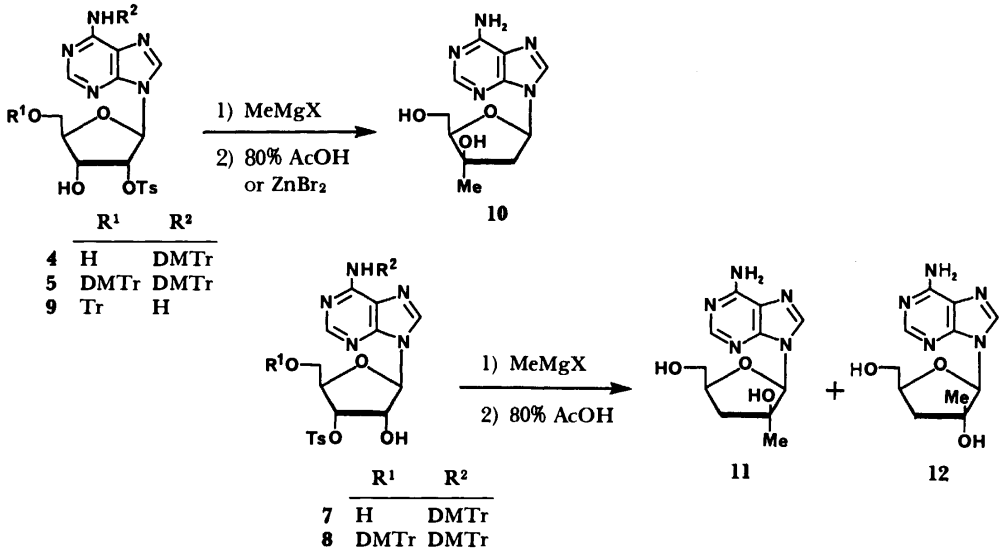


Scheme 1.



DMTr=4,4-dimethoxytrityl; PPTS=pyridinium *p*-toluenesulfonate; Ts=tosyl.

Scheme 2.



Tr=trityl; X=Br or I.

Scheme 3.

deprotection of the 5′-trityl group in the product derived from **9** was achieved with $ZnBr_2$ at 65 °C without the depurination. The resulting free nucleosides were isolated by means of ion-exchange [Dowex-1 (OH^- form)] column chromatography. In these operations, **4**, **5**, and **9** were successfully converted into 9-(2-deoxy-3-*C*-methyl-β-D-*threo*-pentofuranosyl)adenine (**10**). The results are summarized in Table 1.

The structure of the modified sugar moiety in **10** was established on the basis of its elemental analyses, the UV and ^1H NMR spectral data, and the fact that the methanolysis of **10** gave isomeric mixtures of methyl pentosides, whose ^1H NMR spectrum was identical with those of specimens prepared from the known methyl 2-deoxy-3-*C*-methyl-β-D-*threo*-pentofuranoside[4] except for the intensity of the signals. No erythro isomer with the 3′-"up"-methyl group could be detected in the deoxygenative methylation of **4**, **5**, and **9**. In the case of the uridine derivative,[8] however, the erythro (3′-"up"-methyl group) derivative was the main product. The steric course of the methyl group in these reactions was strongly influenced by the nature of the base moiety attached to the anomeric position,[13] but the reason for this is not clear at this time. On the other hand, the reactions of **7** and **8** with MeMgBr or MeMgI proceeded at elevated temperatures to produce a pair of isomers, 9-(3-deoxy-2-*C*-methyl-β-D-*threo*- and -*erythro*-pentofuranosyl)adenine (**11** and **12**), after the deprotection (Table 1). Satisfactorily elemental analyses and spectral data were obtained for these products. The structure of the sugar moiety in **11** was correlated with that for the known methyl 3-deoxy-2-*C*-methyl-β-D-*threo*-pento-

a) Some of the reaction conditions are described in the Experimental Section. b) rt=room temperature.

furanoside[4] by the methanolysis. In addition, the ^{1}H NMR spectrum (in DMSO-d_6) of **12** showed that the signal due to the methyl protons shifted upfield by 0.45 ppm relative to that for the corresponding protons in **11**, while the H-8 signal shifted downfield by 0.25 ppm. Similar shifts were observed in the ^{1}H NMR spectrum measured in MeOH-d_4. These facts indicated that, in **12**, the methyl group and the imidazole ring in a base moiety were located close to each other; the erythro structure of **12** was thus established.

Very recently Koole et al.[14] have reported the synthesis of **11** by the stereoselective addition of MeMgI to a protected 3′-deoxy-2′-keto nucleoside, followed by deprotection: the keto nucleoside was prepared from 5′-*O*-(4-methoxytrityl)-9-(3-deoxy-β-D-*erythro*-pentofuranosyl)adenine. The ^{1}H NMR (in MeOH-d_4) spectral data of **11** prepared by our method were almost identical with those previously reported.[14]

The reactions of 2′- or 3′-*O*-tosyladenosine derivatives with Grignard reagents other than MeMgI or MeMgBr gave various products, depending on the structure of the organic residues in the reagents; the preliminary results have been previously published.[7]

Experimental

General. The melting points were determined in capillary tubes with a Yamato micro melting-point apparatus and are uncorrected. The optical rotations were measured with a Perkin-Elmer Model 241MC polarimeter in a 1-dm cell. The UV spectra were measured with a Varian Cary 2200 apparatus using a 1-cm cell. The ^{1}H NMR spectra were recorded with a JEOL JNM-GX 400 spectrometer, using tetramethylsilane as the internal standard. The coupling constants were measured directly from the spectra or were calculated from the peak listing. The TLC was performed on precoated plates (0.25 mm) of Silica Gel 60 F_{254} (Merck). Detection was done by means of UV (254 nm) or by spraying the plates with a solution of methanol–sulfuric acid–*p*-anisaldehyde (85:15:5, v/v), followed in the latter case by heating at above 200 °C. The column chromatography was effected on Silica Gel 60 (Merck 70—230 mesh, ASTM). The elemental analyses were performed by the Microanalytical Laboratory of this Institute. The solvent extracts were dried with anhydrous magnesium sulfate, and the solutions were evaporated under diminished pressure at 40—45 °C. The analytical samples were dried at 60 °C for 4 h in vacuo over diphosphorus pentaoxide. The Grignard reagents were purchased from the Tokyo Chemical Industry Co., Ltd.

3′,5′-Bis-*O*-(*t*-butyldimethylsilyl)adenosine (1) and Its 2′,5′-Isomer (2). The method of Ogilvie et al.[9] was slightly modified.

To a stirred solution of adenosine (2.67 g, 10 mmol) in a mixture of dry pyridine (4 ml) and DMF (10 ml), we added silver nitrate (3.40 g, 20 mmol), after which the mixture was stirred at room temperature for 2 h. After cooling with iced water, THF (20 ml), and *t*-butyldimethylsilyl chloride (3.02 g, 20 mmol) were added and the mixture was stirred at room temperature for 1 h. The undissolved materials were removed by filtration through a Celite pad and washed with THF. The combined filtrate and washings were diluted with ether containing a small amount of chloroform. The mixture was then washed successively with aq. sodium hydrogencarbonate and water (three times), dried, and concentrated. The pyridine was removed by repeated co-evaporation with toluene. The residue was chromatographed on a silica-gel column with benzene–ethyl acetate (7:3). The compound emerging first was 2′,3′,5′-tris-*O*-(*t*-butyldimethylsilyl)adenosine (427 mg, 7%). The second product eluted with the same solvent system (1:1) was **2** (1.74 g, 35%). The elution of **1** (2.18 g, 44%) was effected with benzene–ethyl acetate–methanol (25:25:1).

1: ^{1}H NMR ($CDCl_3$) δ=0.07 and 0.09 (3H, each s, 3′-SiMe), 0.17 (6H, s, 2×5′-SiMe), 0.90 (9H, s, 3′-SiBu^t), and 0.95 (9H, s, 5′-SiBu^t), 3.43 (1H, br d, OH), 3.77 (1H, dd,

J=2.9 and 11.4 Hz, H-5′), 3.93 (1H, dd, J=3.5 and 11.4 Hz, H-5″), 4.13 (2H, br s, H-2′ and H-3′), 5.94 (2H, br s, NH_2), 6.04 (1H, d, J=4.3 Hz, H-1′), 8.10 (1H, s, H-2), and 8.34 (1H, s, H-8).

2: ^{1}H NMR ($CDCl_3$) δ=−0.12 and −0.05 (3H, each s, 2′-SiMe), 0.14 and 0.15 (3H, each s, 5′-SiMe), 0.84 (9H, s, 2′-*t*-Bu), 0.96 (9H, s, 5′-SiBu^t), 2.85 (1H, d, J=4.3 Hz, OH), 3.86 (1H, dd, J=2.4 and 11.5 Hz, H-5′), 4.02 (1H, dd, J=2.4 and 11.5 Hz, H-5″), 4.22 (1H, m, H-4′), 4.29 (1H, m, H-3′), 4.64 (1H, t, J=5.0 Hz, H-2′), 5.92 (2H, br s, NH_2), 6.12 (1H, d, J=5.2 Hz, H-1′), 8.23 (1H, s, H-2), and 8.35 (1H, s, H-8).

3′,5′-Bis-*O*-(*t*-butyldimethylsilyl)-N^6-(4,4′-dimethoxytrityl)adenosine (3). Compound **1** (3.14 g, 6.33 mmol) was dried by co-evaporation with dry pyridine-toluene. This product was then dissolved in dry pyridine (30 ml), and 4,4′-dimethoxytrityl chloride (2.79 g, 8.2 mmol) was added. The mixture was then stirred at room temperature for 17 h. After cooling, 50% aq. pyridine was added; the products were extracted with ether. The extracts were washed with water, dried, and concentrated. The residual pyridine was removed by co-evaporation with chloroform–toluene, and the residue was chromatographed on a silica-gel column with toluene–ethyl acetate–triethylamine (9:1:0.1) to give **3** (4.34 g, 86%) as a foam. A portion of the product was dissolved in a small amount of dichloromethane and precipitated by the addition of the dichloromethane solution to an excess of pentane under vigorous stirring. The resulting precipitates were collected and dried to afford an analytical sample: amorphous powders: $[\alpha]_D^{22}$ −23.1° (*c* 0.49, $CHCl_3$); UV λ_{max}^{MeOH} 275 nm (ε 20200); ^{1}H NMR ($CDCl_3$) δ=0.03 and 0.07 (3H, each s, 3′-SiMe), 0.16 (6H, s, 2×5′-SiMe), 0.88 (9H, s, 3′-SiBu^t), 0.94 (9H, s, 5′-SiBu^t), 3.29 (1H, d, J=6.4 Hz, OH), 3.78 (6H, s, 2×OMe), 3.75 (1H, dd, J=2.9 and 11.2 Hz, H-5′), 3.89 (1H, dd, J=3.8 and 11.2 Hz, H-5″), 4.10 (1H, m, H-4′), 4.58 (2H, m, H-2′ and H-3′), 5.97 (1H, d, J=4.6 Hz, H-1′), 6.76—7.43 (14H, m, Arom. and NH), and 8.00 and 8.05 (1H, each s, H-2 and H-8). Found: C, 64.77; H, 7.43; N, 8.70; Si, 7.04%. Calcd for $C_{43}H_{59}N_5O_6Si_2$: C, 64.71, H, 7.45; N, 8.77; Si, 7.04%.

N^6-(4,4′-Dimethoxytrityl)-2′-*O*-tosyladenosine (4). From **3.** Compound **3** (2.85 g, 3.6 mmol) was dried by co-evaporation with dry pyridine–toluene. This was then dissolved in dry pyridine (32 ml), and tosyl chloride (2.75 g, 14.3 mmol) was added. The mixture was stirred at room temperature for 5 d and then quenched with 50% aq. pyridine. The products were extracted with diethyl ether containing a small amount of chloroform. The extracts were washed successively with water, aq. sodium hydrogencarbonate, and water, and then dried. The solvents were evaporated, and the residual pyridine was removed by repeated co-evaporation with toluene. The residue was dissolved in THF (30 ml), and tetrabutylammonium fluoride (1 mol dm^{-3} solution in THF; 7.2 ml) was added. The mixture was then stirred at room temperature for 30 min. After cooling, it was diluted with diethyl ether and a small amount of chloroform. The solution was washed three times with water, dried, and concentrated. The residue was chromatographed on a silica-gel column with chloroform–ethyl acetate (9:1), followed with chloroform–ethyl acetate–methanol (9:1:0.1), to give amorphous **4** (2.12 g, 82%). Precipitation from dichloromethane–pentane gave an analytical sample: amorphous powders: $[\alpha]_D^{23}$ −13.9° (*c* 0.49, $CHCl_3$); UV λ_{max}^{MeOH} 275 nm (ε 22700); ^{1}H NMR ($CDCl_3$) δ=2.24 (3H, s, CMe), 3.28—3.37 (1H, br s, 5′-OH), 3.78 (6H, s, OMe), 3.63 (1H, br t, J=12 Hz, H-5′), 3.81 (1H, br d, J=11 Hz, H-5″), 4.21 (1H, br s, H-4′), 4.63 (1H, dd, J=1.7 and 4.4 Hz, H-3′), 5.47 (1H, dd, J=4.4 and 7.8 Hz, H-2′), 5.93 (1H, d, J=7.8 Hz, H-1′), 6.37 (1H, dd, J=2.0 and 12.0 Hz, 3′-OH), 6.78—7.44 (18H, Arom. and NH), 7.68 (1H, s, H-2), and 7.84 (1H, s, H-8). Found: C, 63.06; H, 5.25; N, 9.40; S, 4.38%. Calcd for $C_{38}H_{37}N_5O_8S$: C, 63.06; H, 5.15; N, 9.68; S, 4.43%.

From **5.** A solution of PPTS (450 mg, 1.8 mmol) in dichloromethane (8 ml) was added to a solution of **5** (4.56 g, 4.4 mmol) in dichloromethane (40 ml). The mixture was stirred at room temperature for 3 h and then diluted with dichloromethane. The solution was washed successively with aq. sodium carbonate and water, dried, and concentrated. The residue was chromatographed on a silica-gel column with chloroform–ethyl acetate (9:1), followed with chloroform–ethyl acetate–methanol (9:1:0.1), to give **4** (2.56 g, 80%).

2′,5′-Bis-*O*-(*t*-butyldimethylsilyl)-N^6-(4,4′-dimethoxytrityl)-adenosine (6). Compound **2** (2.94 g, 5.9 mmol) was treated under conditions similar to those used in the preparation of **3.** The usual work-up and purification by silica-gel column chromatography [toluene–ethyl acetate–triethylamine (9:1:0.1)] gave **6** as crystals: mp 186 °C (sintered), 193.5—194.5 °C (benzene–hexane); $[\alpha]_D^{22}$ −29.7° (*c* 0.52, $CHCl_3$); UV λ_{max}^{MeOH} 275 nm (ε 24700); ^{1}H NMR ($CHCl_3$) δ=−0.17 and −0.07 (3H, each s, 2′-SiMe), 0.12 and 0.14 (3H, each s, 5′-SiMe), 0.80 (9H, s, 2′-SiBu^t), 0.95 (9H, s, 5′-SiBu^t), 2.71 (1H, d, J=3.9 Hz, OH), 3.78 (6H, s, 2×OMe), 3.84 (1H, dd, J=2.5 and 11.3 Hz, H-5′), 4.00 (1H, dd, J=2.8 and 11.3 Hz, H-5″), 4.19 (1H, m, H-4′), 4.26 (1H, m, H-3′), 4.65 (1H, t, J=5.1 Hz, H-2′), 6.05 (1H, J=5.1 Hz, H-1′), 6.76—7.34 (14H, m, Arom. and NH), 8.04 (1H, s, H-2), and 8.11 (1H, s, H-8). Found: C, 64.62; H, 7.41; N, 8.66; Si, 6.84%. Calcd for $C_{43}H_{59}N_5O_6Si_2$: C, 64.71; H, 7.45; N, 8.77; Si, 7.04%.

N^6-(4,4′-Dimethoxytrityl)-3′-*O*-tosyladenosine (7). From **6.** Compound **6** (1.78 g, 2.2 mmol) was treated under condition similar to those described for the synthesis of **4** from **3**, giving **7** (1.37 g, 85%): amorphous powders; $[\alpha]_D^{21}$ −29.6° (*c* 0.64, $CHCl_3$); UV λ_{max}^{MeOH} 275 nm (ε 21100); ^{1}H NMR ($CDCl_3$) δ=2.46 (3H, s, CMe), 3.05—3.2 (1H, br s, OH), 3.76 and 3.77 (6H, s, 2×OMe), 3.55 (1H, br t, J=13 Hz, H-5′), 3.82 (1H, d, J=13.7 Hz, H-5″), 4.37 (1H, m, H-4′), 5.11 (2H, m, H-2′ and H-3′), 5.76 (1H, d, J=7.1 Hz, H-1′), 6.72—7.34 (15H, m, Arom., NH, and OH), 7.39 (2H, d, J=8.6 Hz, Arom.), 7.85 (2H, d, J=8.5 Hz, Arom.), 7.76 (1H, s, H-2), 7.95 (1H, s, H-8). Found: C, 62.92; H, 5.14; N, 9.57; S, 4.33%. Calcd for $C_{38}H_{37}N_5O_8S$: C, 63.06; H, 5.15; N, 9.68; S, 4.43%.

From **8.** A solution of PPTS (270 mg, 1.08 mmol) in dichloromethane (5 ml) was added to a solution of **8** (2.77 g, 2.7 mmol), and the mixture was stirred at room temperature for 8 h. The resulting fine crystals of 3′-*O*-tosyladenosine tosylate salt[6i] were filtered off, and the filtrate was diluted with dichloromethane. The solution was washed successively with aq. sodium carbonate and water, dried, and concentrated. The residue was chromatographed on a silica-gel column with chloroform–ethyl acetate (9:1), followed by chromatography with chloroform–ethyl acetate–methanol (9:1:0.4), to afford **7** (1.33 g, 68%).

9-(2-Deoxy-3-*C*-methyl-β-D-*threo*-pentofuranosyl)adenine

(10). Some of the reaction conditions and the results are summarized in Table 1.

To a stirred mixture of MeMgI (2 mol dm^{-3} solution in diethyl ether) or MeMgBr (1 mol dm^{-3} solution in THF) and dry benzene (3 ml), we added a solution of **4**, **5**, or **9** (ca.0.5 mmol) in dry benzene (3 ml) at room temperature, after which the mixture was stirred at the given temperature for the given reaction time. After cooling, aq. ammonium chloride was added, and the products were extracted with diethyl ether containing a small amount of chloroform. The extracts were then washed with water, dried, and concentrated. The residue was dissolved in chloroform (2.5 ml), and the solution was added to a solution of $ZnBr_2$ (450 mg, 2 mmol) in a mixture of methanol (0.54 ml) and chloroform (2.2 ml).[12] After the mixture had been stirred at the given temperature for the given reaction time, it was diluted with methanol and then concentrated to a few ml at room temperature in vacuo. The residue was chromatographed on a silica-gel column with chloroform–methanol (9:1 → 8:2). The combined eluates containing the product were concentrated to about 10 ml, and then the concentrate was diluted with methanol. This solution was then concentrated to a few ml and placed in an ion-exchange column (Dowex 1X-2, OH^-, 100—200 mesh) made up with water. Elution with the same solvent gave **10**: mp 166—167 °C (from MeOH–diisopropyl ether); $[\alpha]_D^{25}$ +4.7° (*c* 0.44, H_2O); UV λ_{max}^{MeOH} 259 nm (ε 15100); ^1H NMR (DMSO-d_6) δ=1.34 (3H, s, Me), 2.36 (1H, dd, *J*=2.7 and 14.4 Hz, H-2′), 2.65 (1H, dd, *J*=8.8 and 14.4 Hz, H-2″), 3.55—3.73 (3H, m, H-4′ and H-5′, 5″), 4.67 (1H, t, *J*=5.5 Hz, 5′-OH), 6.06 (1H, s, 3′-OH), 6.20 (1H, dd, *J*=2.8 and 8.7 Hz, H-1′), 7.36 (2H, br s, NH_2), 8.14 (1H, s, H-2), and 8.35 (1H, s, H-8). Found: C, 49.00; H, 5.70; N, 26.32%. Calcd for $C_{11}H_{15}N_5O_3 \cdot 0.2H_2O$: C, 49.14; H, 5.77; N, 26.05%.

9-(3-Deoxy-2-*C*-methyl-β-D-*threo*-pentofuranosyl)adenine (11) and Its Erythro Isomer (12). Some of the reaction conditions and the results are listed in Table 1.

Compound **7** or **8** (ca. 0.5 mmol), was subjected to a Grignard reaction under conditions similar to those used in the synthesis of **10**. After the reaction mixture had been worked up, the residue was dissolved in 80% acetic acid (10 ml) and the solution was stirred at room temperature for the given reaction time. The acetic acid was removed by repeated co-evaporation with ethanol–toluene, the residue was partitioned between chloroform and water. The water solution was washed with chloroform and then concentrated. The residue was chromatographed on a column of ion-exchange resin (Dowex 1X-2, OH^- form, 100—200 mesh) packed with water. Elution with the same solvent gave **12**, and then **11**.

11: Mp 218—219 °C (from MeOH–diisopropyl ether); $[\alpha]_D^{27}$ +34.9° (*c* 0.45, H_2O); UV λ_{max}^{MeOH} 259 nm (ε 16200); ^1H NMR (DMSO-d_6) δ=1.30 (3H, s, Me), 2.17 (2H, m, H-3′,3″), 3.55—3.70 (2H, m, H-5′,5″), 4.16 (1H, m, H-4′), 5.34 (1H,s, 2′-OH), 5.36 (1H, t, *J*=4.9 Hz, 5′-OH), 5.88 (1H, s, H-1′), 7.24 (2H, br s, NH_2), 8.13 (1H, s, H-2), and 8.28 (1H, s, H-8); (MeOH-d_4) δ=1.38 (3H, s, Me), 2.26 (1H, dd, *J*=5.5 and 13.4 Hz, H-3′), 2.37 (1H, dd, *J*=8.5 and 13.4 Hz, H-3″), 3.72 (1H, dd, *J*=3.7 and 11.9 Hz, H-5′), 3.87 (1H, dd, *J*=2.8 and 11.9 Hz, H-5″), 4.33 (1H, m, H-4′), 6.01 (1H, s, H-1′), 8.19 (1H, s, H-2), and 8.43 (1H, s, H-8). Found: C, 48.72; H, 5.65; N, 26.12%. Calcd for $C_{11}H_{15}N_5O_3 \cdot 0.3H_2O$: C, 48.81; H, 5.81; N, 26.12%.

12: Mp 233—234 °C (from EtOH); $[\alpha]_D^{22}$ −32.3° (*c* 0.54, H_2O); UV λ_{max}^{MeOH} 259 nm (ε 14900); ^1H NMR (DMSO-d_6) δ=0.85 (3H, s, Me), 1.84 (1H, dd, *J*=4.9 and 13 Hz, H-3′), 1.87 (1H, br t, *J*=12 Hz, H-3″), 3.63 (1H, m, H-5′), 3.84 (1H, m, H-5″), 4.40 (1H, m, H-4′), 5.22 (1H, t, *J*=5.1 Hz, 5′-OH), 5.55 (1H, s, 2′-OH), 5.92 (1H, s, H-1′), 7.29 (2H, br s, NH_2), 8.14 (1H, s, H-2), and 8.53 (1H, s, H-8); (MeOH-d_4) δ=0.97 (3H, s, Me), 1.95 (1H, dd, *J*=5.0 and 13.3 Hz, H-3′), 2.32 (1H, dd, *J*=11.3 and 13.1 Hz, H-3″), 3.77 (1H, dd, *J*=2.9 and 12.4 Hz, H-5′), 4.04 (1H, dd, *J*=2.6 and 12.4 Hz, H-5″), 4.55 (1H, m, H-4′), 6.06 (1H, s, H-1′), 8.20 (1H, s, H-2), and 8.64 (1H, s, H-8). Found: C, 49.19; H, 5.70; N, 26.51%. Calcd for $C_{11}H_{15}N_5O_3 \cdot 0.1H_2O$: C, 49.47; H, 5.74; N, 26.22%.

Methanolysis of Methyl 2-Deoxy-3-*C*-methyl-β-D-*threo*-pentofuranoside and 10. A mixture of methyl 2-deoxy-3-*C*-methyl-β-D-*threo*-pentofuranoside[4] (15 mg, 0.09 mmol) and Dowex 50W-X8 (125 mg, H^+ form, 100—200 mesh) in methanol (1.5 ml) was stirred at room temperature for 6 h. The resin was then removed by filtration through a Celite pad and washed with methanol. The combined filtrate and washings were concentrated to give methyl 2-deoxy-3-*C*-methyl-α- and -β-D-*threo*-pentosides (14 mg, 93%): ^1H NMR ($CDCl_3$) δ=1.23 (0.6H, s, CMe), 1.36 (1.1H, s, CMe), 1.39 (0.3H, s, CMe), 1.43 (1.0H, s, CMe), 3.39, 3.40, 3.446, and 3.448 (each s, OMe), 4.62 (0.4H, dd, *J*=3.4 and 6.6 Hz, H-1), 4.81 (0.2H, br d, *J*=3.2 Hz, H-1), 5.02 (0.1H, dd, *J*=2.1 and 3.5 Hz, H-1), and 5.16 (0.3H, dd, *J*=3.2 and 5.9 Hz, H-1).

The methanolysis of **10** (32 mg, 0.012 mmol) with Dowex 50W-X8 (127 mg, H^+ form, 100—200 mesh) in methanol (1.5 ml) was carried out at room temperature for 2.3 h. A work-up similar to that described above gave methyl pentosides (17 mg, 89%), whose thin-layer chromatographic behavior and ^1H NMR spectrum were identical with those for the pentosides prepared by the methanolysis of methyl 2-deoxy-3-*C*-methyl-β-D-*threo*-pentofuranoside.

Methanolysis of Methyl 3-Deoxy-2-*C*-methyl-β-D-*threo*-pentofuranoside and 11. A mixture of methyl 3-deoxy-2-*C*-methyl-β-D-*threo*-pentofuranoside[4] (15 mg, 0.09 mmol) and Dowex 50W-X8 (126 mg, H^+ form, 100—200 mesh) in methanol (1 ml) was stirred first at room temperature for 1.5 h and then at 50 °C for 5.5 h. The resin was removed by filtration and washed with methanol. The combined filtrate and washings were concentrated to give methyl 3-deoxy-2-*C*-methyl-α- and -β-D-*threo*-pentosides (13 mg, 89%): ^1H NMR ($CDCl_3$) δ=1.34 (s, CMe), 1.35 (s, CMe), 1.86 (0.74H, dd, *J*=2.7 and 13.4 Hz, H-3a,b), 1.94 (0.52H, d, *J*=7.6 Hz, H-3a,b), 2.25 (0.74H, dd, *J*=10.0 and 13.4 Hz, H-3a,b), 3.36 (s, OMe), 3.50 (s, OMe), 3.57 (0.74H, dd, *J*=1.7 and 11.7 Hz, H-5a,b), 3.71 (0.26H, dd, *J*=2.7 and 11.7 Hz, H-5a,b), 3.91 (0.74H, dd, *J*=2.1 and 11.6 Hz), 4.40 (0.25H, s, H-1), and 4.59 (0.75H, s, H-1).

A similar methanolysis of **11** (41 mg, 0.15 mmol) with Dowex 50W-X8 (H^+ form, 130 mg) in methanol (2 ml) afforded the pentosides (22 mg, 92%), whose thin-layer chromatographic behavior and ^1H NMR spectrum were identical with those for the pentosides prepared from methyl 3-deoxy-2-*C*-methyl-β-D-*threo*-pentofuranoside.

We wish to thank Dr. Jun Uzawa and Mrs. Tamiko Chijimatsu for the measurement of the ^1H NMR spectra, and Dr. Hiroshi Yamazaki and his staff for the

elemental analyses. This work was supported, in part, by a Research Grant for Life Science granted by this Institute.

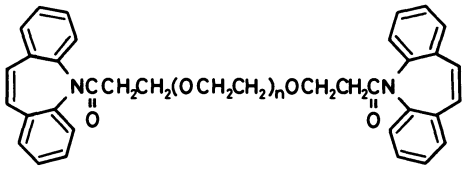
Yoshida, Sakyo-ku, Kyoto 606
(Received January 8, 1988)

The triplet-sensitized photochemical reaction using a series of poly(oxyethylene) chains with a pair of photoactive terminal groups, dibenz[*b,f*]azepine (DBA) chromophores (DBA-$COCH_2CH_2(OCH_2CH_2)_nOCH_2$-$CH_2CO$-DBA, n=0—10) was examined. The photoirradiation of bichromophoric compounds caused either intra- or intermolecular reactions. These reactions were kinetically analyzed by two different methods: the measurement of deactivation processes of the reaction intermediates (excited triplet state of DBA) by nanosecond laser photolysis and the quantitative analysis of the reaction products by GPC. The intramolecular deactivation rate constant, k^{intra}, showed a remarkable chain-length dependence; the maximum k^{intra} value appeared at n=5 and it was found to be 5.9×10^4 s^{-1}. On the other hand, the intramolecular cyclization rate also depends on the chain length; the maximum quantum yield, ϕ_d^{intra}, was given at n=7 (ϕ_d^{intra}=0.51). The chain length for the maximum cyclization yield shifted slightly to the longer region than that for the maximum k^{intra} value due to the restriction of the terminal structure (anti-configuration). The results obtained for this reaction system are compared with those obtained for the previously reported polymethylene system and the effect of chain flexibility on the intramolecular ring-closure reaction is discussed.

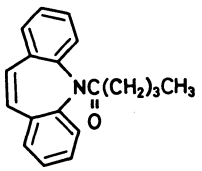
Previously, we reported on the intra- and intermolecular end-to-end photochemical reactions of a pair of terminal dibenz[*b,f*]azepine (DBA) chromophores linked by polymethylene chains.[1,2] The probing DBA chromophore undergoes photodimerization via an excited triplet intermediate under the sensitized conditions and gives an anti-cyclobutane dimer as a unique reaction product.[3,4] In contrast with other intramolecular ring-closure reactions reported in the past,[5–15] these characteristics of DBA chromophore give the following features to this reaction system: (1) The reaction intermediate, the triplet state of DBA chromophore, has a long lifetime, 17 μs, so a wide range of chain lengths can be pursued for the cyclization reaction. (2) Ring-closure probability of specific chain conformation can be obtained, since two terminal DBA groups must approach each other from an opposite side for the cycloaddition reaction to make the anti-cyclobutane ring.

Our previous results, obtained for the polymethylene system, demonstrated that the intramolecular cyclization rate is pronouncedly controlled by the chain length connecting a pair of terminal DBA groups and that the terminal direction of a molecular chain exerts a great influence upon the chain-length dependence of the intramolecular ring-closure reaction.[1] That is, we concluded in the previous work that the intramolecular reaction yield is determined by the equilibrium ring-closure probability of a molecular chain. Generally, the cyclization reaction is considered to be affected not only by the chain length, but also by the chain nature. Sisido et al. carried out intrachain reactions of a pair of reactive groups attached to both ends of the polysarcosine chain,[16] and poly(oxyethylene) chain[17] and the intrachain reactivities were compared among the polymer chains. They showed that the intrachain reaction of the polysarcosine chain proceeds more effectively than that of the poly(oxyethylene) chain and that the intrachain reaction of the polysarcosine chain is more efficient than that of the polymethylene chain by two or three times. The flexibility of a molecular chain is expected to be one of the most important nature in determining the reaction yield of the cyclization; that is, a flexible molecular chain will show a higher cyclization yield than a rigid one.

In the present work, we investigated the intra- and intermolecular end-to-end reaction of bichromophoric poly(oxyethylene) compounds, as shown in Fig. 1. These compounds are denoted as DE-n (n=0—10, l=3n+5). Hereafter, "n" represents the number of



DE-n (n=0~10, l=3n+5)



5-Valeryl-DBA

Fig. 1. A series of poly(oxyethylene) compounds having a pair of DBA groups as the terminal reactants, DE-n (n=0—10). Monomeric compound, 5-valeryl-DBA, is also shown.

oxyethylene units, and "l" the number of atoms in the poly(oxyethylene) chain. The experimental results obtained for this system were compared with those obtained for the polymethylene system and the effect of chain nature on the intramolecular cyclization was examined.

Experimental

Materials. Bichromophoric Compounds: A series of poly(oxyethylene) compounds having a pair of dibenz[*b,f*]-azepine (DBA) as the terminal groups were synthesized according to the procedure reported by Kricka et al.,[18] i.e., by an acylation reaction of the corresponding poly(oxyethylene)dicarboxylic acid dichloride with 5*H*-DBA. For example, 5,5′-(4,7,10,13,16,19-hexaoxadocosanedioyl)bisdibenz[*b,f*]azepine (DE-5) was prepared as follows. Hexaoxadocosanedicarboxylic acid dichloride (1.1 g) in dry benzene was added dropwise to a stirred benzene solution of 5*H*-DBA (1.0 g, Aldrich) at room temperature. The reaction mixture was refluxed for 5 h, then cooled and washed with water. A solution of the reaction mixture was dried with calcium chloride, and evaporation of the solvent afforded a yellow oily product. The product was purified by column chromatography on neutral alumina eluted with the mixture of dichloromethane and methanol (500:3). A series of other bichromophoric compounds, except for DE-0, were prepared by the same procedure as DE-5. DE-0 was obtained by an acylation reaction of 5*H*-DBA with 3,3′-oxybis-(propanoyl chloride). All obtained compounds were identified by IR, UV, and NMR spectra. The spectra for the obtained bichromophoric compounds showed the same characteristic spectra. The data were as follows: IR (KBr); 3100, 2850, 1660, 1600, 1490, 1370, 1100, 800, and 760 cm^{-1}, UV (CH_2Cl_2); λ_{max}=287 nm, ^1H NMR (CD_2Cl_2); δ=1.8—2.8 (m, $-COCH_2CH_2-$), 3.2—3.8 (m, $-OCH_2CH_2O-$), 6.9 (s, $-CH=CH-$), 7.2—7.5 (m, aromatic). The reaction yields of all obtained compounds were about 60%. The purity of the compounds was confirmed by TLC (one spot, on neutral alumina).

Poly(oxyethylene)dicarboxylic Acid Dichlorides: Each poly(oxyethylene)dicarboxylic acid dichloride was prepared from the corresponding poly(oxyethylene)dicarboxylic acid by a reaction with thionyl chloride; e.g., 3,6,9,12,15,18-hexaoxaeicosanedicarboxylic acid dichloride was obtained as follows. 3,6,9,12,15,18-Hexaoxaeicosanedicarboxylic acid dissolved in thionyl chloride was heated at 50°C for 1 h under stirring. When the evolution of hydrogen chloride stopped, the excess thionyl chloride was removed by distillation and an acid chloride was obtained. A series of other acid chlorides were obtained by the same procedure as 3,6,9,12,15,18-hexaoxaeicosanedicarboxylic acid dichloride.

Poly(oxyethylene)dicarboxylic Acids: Each poly(oxyethylene)dicarboxylic acid was prepared by the hydrolysis of the corresponding poly(oxyethylene)dicarbonitrile with hydrochloric acid; e.g., 3,6,9,12,15,18-hexaoxaeicosanedicarboxylic acid was obtained as follows. 3,6,9,12,15,18-Hexaoxaeicosanedinitrile was dissolved in hydrochloric acid (12 M (1 M=1 mol dm^{-3})) and was refluxed for 5 min; then the water was removed by distillation. The residue was extracted by dichloromethane and the evaporation of dichloromethane afforded 3,6,9,12,15,18-hexaoxaeicosanedicarboxylic acid. A series of acids were obtained by the same procedure as 3,6,9,12,15,18-hexaoxaeicosanedicarboxylic acid.

Poly(oxyethylene)dicarbonitriles: Each poly(oxyethylene)-dicarbonitrile was prepared by an addition reaction of acrylonitrile to poly(ethylene glycol); e.g., 3,6,9,12,15,18-hexaoxaeicosanedinitrile was prepared as follows. Acrylonitrile in benzene was added dropwise to the benzene solution of pentaethylene glycol under stirring in the presence of potassium hydroxide as a catalyst. The reaction mixture was stirred for 1 h at room temperature. After the insoluble substance was filtered off, benzene was evaporated to yield 3,6,9,12,15,18-hexaoxaeicosanedinitrile. A series of other nitriles were obtained by the same procedure as 3,6,9,12,15,18-hexaoxaeicosanedinitrile.

Polyethylene Glycols: Commercial polyethylene glycols (Tokyo Kasei) were used for the shorter chains than tetraethylene glycol. A series of polyethylene glycols longer than tetraethylene glycol were prepared according to the procedure of Pedersen,[19] i.e., by the Williamson method. For example, pentaethylene glycol was prepared as follows. Potassium hydroxide was dissolved in excess ethylene glycol (Wako) under stirring. 1,2-Bis(2-chloroethoxy)ethane (Tokyo Kasei) was added to the solution and heated at 80 °C for 48 h. The reaction mixture was cooled to room temperature and potassium chloride was filtered off. After unreacted ethylene glycol was removed by distillation under reduced pressure, pentaethylene glycol was obtained by fractional distillation under highly reduced pressure. Other polyethylene glycols were obtained by a similar procedure.

Benzophenone (BP, Wako) used as the triplet sensitizer was purified by recrystallization from ligroin several times and dried in vacuo.

Dichloromethane used as the solvent was purified as follows. Dichloromethane was washed with sulfuric acid and water, and then washed with 10% sodium hydroxide aqueous solution and with water till it became neutral. Dried 1,2-dichloroethane with calcium chloride was distilled twice over calcium hydride.
